Epac1-mediated RE/mitochondria interactions promotes mitochondrial Ca2+ overload and cell death during ischemia/reperfusion injury

L Fazal[1]; M Laudette[1]; S Paula-Gomes[1]; J Fauconnier[2]; J Mialet-Perez[1]; F Lezoualc'h[1]
[1]Institute of Cardiovascular and Metabolic Diseases, Toulouse, France; *[2]University of Montpellier, Montpellier, France*

Introduction: It is well accepted that ischemia/reperfusion (I/R) injury is accompanied by an increase in mitochondrial Ca2+ that triggers the opening of mitochondrial permeability transition pore (MPTP), the subsequent depolarization of the mitochondrial membrane potential ($\Delta\Psi m$), leading to cardiomyocyte death. However, the mechanisms that control mitochondrial Ca2+ entry in that context are far to be understood. Having shown that the cAMP binding protein Epac1 contributes to I/R injury, we therefore addressed whether Epac1 would play a role in such a process.
Purpose: To investigate the role of mitochondrial exchange protein directly activated by cAMP 1 (Epac1) in ischemia/reperfusion injury.
Methods: Isolated adult cardiomyocytes from Epac1 knock-out (KO) and wild-type (WT) littermates were exposed to hypoxia (HX) for 4h followed by a 2h of reoxygenation period (HX+R). Cell death was determined by Trypan blue staining and LDH release. MPTP opening was monitored by the calcein loading CoCl(2)-quenching technique. Mitochondrial Ca2+ uptake was measured with Rhod-2-AM fluorescent dye.
Results: Our data showed that HX+R induced a decrease in calcein fluorescence corresponding to MPTP opening in WT cardiomyocytes. Genetic deletion of Epac1 prevented MPTP opening in HX+R conditions. In addition we found that Epac1 was expressed in mitochondria and its activation induced a robust increase in mitochondrial Ca2+ accumulation in WT cardiomyocytes but not in those of Epac1-/- cardiomyocytes. Furthermore, treatment of Epac1-/- cardiomyocytes with 50 μM Ca2+ induced much less mitochondrial Ca2+ overload compared to WT suggesting that Epac1 regulates Ca2+ entry into the mitochondria. During ischemia, Epac1 favors Ca2+ exchange between the endoplasmic reticulum (ER) and the mitochondrion, by increasing interaction with VDAC1/GRP75/IP3R1 protein complex leading to mitochondrial Ca2+ overload and opening of the MPTP.
Conclusion: Epac1 regulates different aspects of mitochondrial function such as Ca2+ uptake and MPTP opening. Our findings suggest Epac1 as a promising target for the treatment of ischemia- induced myocardial damage.

Background: Intracoronary and intramyocardial autologous or allogeneic mesenchymal stem cell (MSC) therapy for treatment of acute and chronic ischemic heart disease has shown promising results in preclinical and early clinical trials mainly via the rich paracrine effects of MSCs, in spite of low cell retention rate. Hypoxia-inducible factor-1α (HIF1α) is one of the most powerful anti-ischemic factor, modulating over hundreds of angiogenic and regenerative substances.
Purpose: In order to enhance the paracrine anti-ischemic and anti-remodelling efficacy of the cell therapy, porcine allogeneic MSCs were transfected with virus-free minicircle plasmid driving HIF1α transgene (MSC-MiCi-HIF1α).
Methods: Domestic male pigs (n=16) underwent closed-chest reperfused acute myocardial infarction (MI) via balloon-occlusion of the mid-LAD for 90 minutes, followed by reperfusion. One month later (chronic ischemic left ventricular remodelling), the animals were randomized to receive either MSCs alone (n=6) or MSC-MiCi-HIF1α (n=10) (15 ± 3 x10^6 cells). Cells were injected into the border zone of infarction by using the 3D guided NOGA electro-anatomical mapping system (9 ± 1 locations). One animal at 3, 12, 24 hr, and 1 week of the MSC-MiCi-HIF1α group was harvested to prove the HIF1α expression and early angiogenesis in the heart. Magnetic resonance imaging with late enhancement was performed in the surviving 6 animals of each group. Angiogenesis proteome profiling were performed and RT-PCR quantified mRNA (Angiopoietin-2, VEGF-A, CD31) and miRNA (miR-1, miR-24, miR132) expressions. Immunohistology sections were stained with anti-caspase-3 antibody and apoptosis rate was quantified.
Results: Success of transfection procedure was confirmed by Western blots of the cell culture medium, showing HIF1α expression. Proteome profiling of the short-term follow-up hearts revealed upregulation of angiogenesis-related protein expressions (angiopoietin, endoglin, VEGF-A and TGF-alpha) up to 12 hr post-delivery, while the angiogenetic apelin expression increased after 12 hr. Anti-hypertrophic miR-1, pro-angiogenic miR-132, and anti-fibrotic miR-24 levels were increased in response to MSC-MiCi-HIF1α treatment (fold-changes vs control: 7.51 ± 0.61 miR1, 23.01 ± 4.87 miR132, and 6.50 ± 2.95 miR24) between 12 and 24 hr post-transfected cell injections. MSC-MiCi-HIF1α delivery resulted in moderate improvement of LV ejection fraction, and reduced infarct size and LV end-diastolic volume (111 ± 17 vs 133 ± 16 mL, $p<0.05$) at 1 month post treatment. Apoptosis in infarct border zone also decreased after MSC-MiCi-HIF1α delivery (fold-change vs control: 0.75 ± 0.07).
Conclusions: In a pre-clinical translational model of chronic post-infarction heart failure, therapy combining MSCs transfected with minicircle plasmid expressing HIF1α significantly decreases infarct size and improves adverse remodelling via modulation of angiogenic and antifibrotic processes of the heart.

Background: Doxorubicin (DOX) is a widely used chemotheraputic agent with well recognised cardiotoxic side effects. High doses of DOX are frequently used to induce cardiomyopathy in experimental animal models of heart failure (HF). However, less data are available regarding the cardiotoxicity of therapeutic doses of DOX, analogous with human oncotherapy.
Purpose: Our aim was to establish a rodent model of cardiomyopathy demonstrating early myocardial injury induced by repeated iv. DOX injections, with concentrations (ccs) extrapolated from consecutive cycles of DOX chemotherapy applied in cancer patients. In addition, we tested prophylactic and delayed combined HF therapies in order to prevent DOX induced adverse myocardial changes.
Methods: We used 12-week-old male Wistar rats in our study and divided them into 4 subgroups. Blood pressures (BP) and heart rate (HR) were monitored during the

study by the tail-cuff method. DOX ccs were calculated from human doses of existing chemotherapy protocols and were corrected to the body surface of rats. Effective DOX doses were validated by in vitro electron microscopic measurements. Following baseline echocardiography, animals in the prophylactic group received a daily combination of oral bisoprolol (2.5 mg/kg), perindopril (2 mg/kg) and eplerenone (6.25 mg/kg) before (PRE), while those in the post-exposure group 1 month after DOX treatment (POST). Drugs were applied in a mucous vehicle by oral gavage. Positive controls received both DOX treatment and drug-free vehicle (D-CON), while negative controls received drug-free vehicle only (CON). DOX exposure was carried out by administering 1.5 mg/kg iv. DOX into the tail veins of the animals on 6 occasions. Follow-up echocardiography was carried out 1 and 2 months after the DOX treatment.

Results: Systolic and diastolic BP, as well as HR were significantly lower in the PRE group, compared to all other groups. Follow-up echocardiography revealed a gradually reducing ejection fraction (EF) in the D-CON and POST animals over the 2-month-period compared to CON (64.3 ± 3.5 and 67.4 ± 4.7% vs. 72.4 ± 3.2%, respectively, $p = 0.0001$), while the prophylactic treatment prevented any significant drop in the EF in the PRE group (79.2 ± 6.4%). At 2 months, a restrictive filling pattern was observed in the D-CON and POST groups but not in the CON and PRE animals. DOX induced a significant increase in the isovolumetric relaxation time, which could not be attenuated by either the PRE or POST treatment.

Conclusions: We successfully established a rodent model to examine the cardiotoxic side effects of DOX chemotherapy. Prophylactic, but not post-exposure supportive treatment was capable of attenuating the DOX induced systolic and diastolic dysfunction. This model seems eligible for future investigations to further elucidate cardiotoxic side effects of DOX, as well as for the development of early drug intervention protocols to eliminate myocardial injury induced by DOX chemotherapy.

32

NPA7, an innovative multivalent designer natriuretic peptide: Co-therapy with Furosemide to mediate renoprotection in experimental ADHF

LMG Meems[1]; Y Chen[1]; GJ Harty[1]; GE Harders[1]; BK Huntley[1]; SR Iyer[1]; DM Heublein[1]; JC Burnett Jr[1]
[1]*Mayo Clinic, Cardiovascular Disease, Rochester, United States of America*

Acute decompensated heart failure (ADHF) is a heart failure syndrome with high morbidity and mortality. Current initial therapy focuses on relief of signs and symptoms using diuretics, such as Furosemide (FURO). Diuretic therapy however may induce Cardiorenal Syndrome, which itself is a predictor of mortality and worse outcome. This warrants novel therapeutic strategies to protect the heart and kidney. We have previously reported the engineering of a highly novel multivalent cardiorenoprotective designer peptide that we call NPA7. In this study we test the renoprotective properties of NPA7 in a large animal model of ADHF compared with FURO. We furthermore investigate the actions of NPA7 and FURO co-therapy including the importance of NPA7 pre- or post-therapy, and hypothesized that the timing of NPA7 treatment is an important factor in obtaining maximal renoprotection. Ten male mongrel canines were paced at 240 beats per minute for 10 days. On day 11, canines randomly received 45 minutes infusion of NPA7 (8.66 pmol/L) or FURO (1mg/kg), followed by NPA7 + FURO or FURO + NPA7 co-therapy respectively. Hemodynamic parameters were monitored and continuous urines were collected. Results are presented as mean baseline changes ± standard deviation.

In canines with ADHF, NPA7 decreased systemic vascular resistance (SVR) (-9.6 ± 1 mmHg/L/min, $p < 0.001$) and reduced pulmonary capillary wedge pressure (-3.5 ± 0.1 mmHg, $p < 0.05$) while increasing renal blood flow (RBF) (+25 ± 3 mL/min, $p < 0.05$). Secondly, NPA7 increased urinary flow (UV) (+0.08 ± 0.02 mL/min, $p < 0.01$) and urinary sodium excretion (UNaV) (+24 ± 17 μEq/min, $p < 0.05$), albeit it to a lesser extent than FURO (NPA7 vs. FURO UV: +0.3 ± 0.2 vs +2.5 ± 0.8 mL/min,$p < 0.05$; UNaV: 26 ± 60 vs 246 ± 90 μEq/min, $p < 0.05$). In contrast to NPA7, FURO lacked vasodilatory actions (NPA7 vs. FURO SVR: -2.0 ± 1.0 vs. +2.0 ± 1.1 mmHg/L/min, $p < 0.05$), impaired kidney function (NPA7 vs. FURO estimated glomerular filtration rate (eGFR): 18 ± 5.0 vs. -2.1 ± 5.3 mL/min, $p < 0.05$) and activated the renin-angiotensin-aldosterone system (RAAS) (NPA7 vs FURO plasma Angiotensin II: -56 ± 22 vs. +85 ± 48, $p < 0.05$ pg/mL; plasma Aldosterone: -13 ± 3.4 vs 1.2 ± 3.6 ng/dL, $p < 0.05$). Importantly, NPA7 + FURO co-therapy had synergistic natriuretic and diuretic efficacy while preserving RBF and eGFR, which was not observed with FURO followed by NPA7 infusion.

In conclusion, in experimental ADHF, NPA7 is a vasodilatory therapeutic with cardiac unloading, diuretic and natriuretic actions. FURO is more diuretic, but is associated with significant renal impairment, vasoconstriction and RAAS-activation. In addition, pre-treatment with NPA7 enhances natriuresis and diuresis while preserving kidney function. Priming with NPA7 may therefore represent a novel renoprotective strategy for treatment of ADHF. Importantly, this study underscores the need for future studies assessing the impact of timing of diuretics on treatment effects of novel therapies in patients with ADHF.

Background: Eosinophils contain preformed IL-4 within their cytoplasmic granules, a cytokine which can mediate alternative activation of macrophages and promote tissue repair. Patients develop peripheral blood eosinopenia within 24 hours of the onset of myocardial infarction (MI) symptoms, but whether eosinophils are recruited to the infarct and have a role in regulating infarct repair is currently unknown.

Purpose: This study sought to investigate the role of eosinophils, a source of the Th2 cytokine IL-4, in infarct healing.

Methods: MI was induced by permanent coronary artery ligation in 12-15 week-old male wild-type (WT) BALB/c mice and ΔdblGATA mice that are deficient in eosinophils (BALB/c background). Cardiac function was assessed 7 days later by high-resolution ultrasound, and flow cytometry was performed on single cell digests of infarct zone tissue.

Results: Histochemical staining (Siglec F) and single cell digestion of infarcted WT BALB/c hearts revealed significant recruitment of (CD11b+ F4/80- SiglecF+) eosinophils to the infarcted heart. Genetic eosinophil deficiency in ΔdblGATA mice led to greater left ventricular dilatation relative to WT mice (End-Systolic Area: 29 ± 2 cm vs 22 ± 2 cm; $p = 0.02$) and worse cardiac function (Ejection Fraction: 22 ± 4% vs. 34 ± 4; $p = 0.04$) at Day 7 post-MI, despite comparable plasma troponin I (Infarcted BALB/c WT; 26 ± 4 ng/l vs. Infarcted ΔdblGATA; 25 ± 5 ng/l, $p = 0.74$), indicative of similar injury, at 24 hours after coronary artery ligation. Expression of CD206, a surface marker for pro-repair alternatively activated macrophages, was reduced on infarct zone CD11b+F4/80+Ly6G- macrophages from ΔdblGATA mice. Eosinophil replenishment of ΔdblGATA mice restored expression of CD206 on infarct zone macrophages after coronary artery ligation (Mean Fluorescence Intensity [MFI] for CD206: 2134 ± 536 a.u. in eosinophil replenished ΔdblGATA mice vs. 277 ± 134 a.u. in PBS treat ΔdblGATA mice; $p = 0.04$). Furthermore, treatment with IL-4 complexes was able to rescue the adverse cardiac remodelling of eosinophil deficient ΔdblGATA mice (ejection fraction: 32 ± 2% vs. 23 ± 2% in IL-4 complex and PBS treated ΔdblGATA mice, respectively, $p = 0.02$, $n = 8$-15 per group).

Conclusions: This study provides the first evidence for an essential role of eosinophils in modulating the inflammatory response and cardiac remodelling following MI, likely through provision of IL-4. Peripheral blood eosinopenia is a common feature of heart failure patients. Correcting a deficiency for eosinophils or specifically IL-4 therapy may offer a novel immune-modulatory intervention in the setting of heart failure.

Background: Reactive oxygen species (ROS) production contributes to both adaptive and maladaptive remodelling pathways in the heart and is involved in the pathophysiology of cardiac hypertrophy and failure. NADPH oxidase-4 (Nox4), a specialised ROS-generating enzyme has beneficial effects by promoting adaptive remodelling during pressure-overload cardiac hypertrophy.

Purpose: To understand how Nox4, a ROS-generating enzyme promotes adaptive cardiac remodelling to achieve beneficial effects in the chronically stressed heart.

Methods and Results: An unbiased global overview of putative Nox4-mediated changes, from cardiac-specific Nox4 transgenic (TG) and wild-type (WT) mouse hearts was first characterised through a 2D-DIGE proteomics approach. The proteome of TG hearts demonstrated a significant over-representation of changes in protein levels of enzymes involved in glucose and fatty acid utilisation. Targeted LC-MS approaches identified a differential accumulation of glycolytic intermediates in the proximal part of glycolysis both in unstressed and pressure-overloaded TG hearts. To specifically quantify glucose uptake, glycolysis, glucose oxidation and fatty acid oxidation rates, ex vivo working heart studies were conducted. TG hearts had a marked increase cf. WT in palmitate oxidation rate in the unstressed

as well as pressure-overloaded heart (3.6 fold increase; n = 6/group; p = 0.01). Glucose uptake was unaltered but glycolysis and oxidation rates were decreased, suggesting diversion of glucose away from oxidation. Importantly, an increase in palmitate oxidation was not detrimental either for in vivo cardiac energetics (31P-NMR) or contractile function during pressure-overload hypertrophy. We found that activity of the hexosamine biosynthesis pathway (HBP), an alternative route for glucose metabolism, was increased in TG hearts as assessed by the O-GlcNAc post-translational modification of cardiac proteins by N-acetylglucosamine, the end-product of HBP. O-GlcNAc levels were 2.4 fold higher in TG cf. WT (n = 4/group; p = 0.02). In cultured cardiomyocytes, endogenous Nox4 induced similar changes in HBP and palmitate oxidation (extracellular flux analysis), and it was found that changes in O-GlcNAcylation regulated fatty acid oxidation. Mechanistically, the rate-limiting enzyme of HBP - Gfat1 was specifically upregulated by Nox4 and we could also demonstrate that the O-GlcNAcylation of Cd36 (the main fatty acid uptake protein in the heart) was dependent on Nox4, providing a potential reason for increased FAO.

Conclusion: These results show that Nox4 reprograms substrate utilisation in the heart by directing glucose towards the HBP and inducing a linked increase in fatty acid oxidation. These data identify a novel redox mechanism that drives beneficial metabolic reprogramming in the heart. In particular the results suggest that increasing fatty acid oxidation in the chronically stressed heart may be a beneficial therapeutic tratégy.

35

Galectin-3 and dilated cardiomyopathy: distinct effect of pharmacological and genetic interventions

MN Nguyen[1]; H Kiriazis[1]; Z Thomas[1]; Y Su[1]; XM Gao[1]; JR Mcmullen[1]; J Sadoshima[2]; X-J Xiao-Jun Du[1]
[1]*Baker IDI Heart and Diabetes Institute, Experimental Cardiology, Melbourne, Australia*; [2]*New Jersey Medical School, Department of Cell Biology and Molecular Medicine Rutgers, New Jersey, United States of America*

On behalf of: Experimental Cardiology, Baker IDI Institute
Funding Acknowledgements: NHMRC of Australia

Background: Galectin-3 (Gal-3) is regarded as a potential biomarker of heart failure. Pre-clinical studies in models including hypertensive heart disease consistently reported 2˜5 fold increase in cardiac expression of Gal-3 and beneficial effects by treatment with Gal-3 inhibitors, such as modified citrus pectin (MCP). However, Gal-3 expression level and effects of anti-Gal-3 interventions in dilated cardiomyopathy (DCM) have not been investigated.
Purpose: Cardiac-restricted transgenic (TG) overexpression of mammalian sterile 20-like kinase 1 (Mst1) leads to typical DCM. We determined Gal-3 expression in TG hearts and studied effects of pharmacological (MCP) and genetic interventions on DCM phenotypes.
Methods: Mst1 TG and wild-type (NTG) littermates were used in MCP treatment study. MCP therapy was for a period of 4 months (2 to 6 months of age) at 200 mg/kg/day for 2 months and then 500 mg/kg/day for a further 2 months. Gal-3 gene deletion was achieved by cross-breeding TG mice with Gal-3 knockout (KO) mice and TG and TG/Gal3-KO mice as well as mice with relevant control genotypes. Echocardiography was performed using Vevo2100 system. RT-PCR was applied for gene expression and Gal-3 protein level was detected by ELISA kit. Collagen content was determined by hydroxyproline assay.
Results: Relative to NTG control (n = 13˜16/group), TG mice had atrial dilatation (by 3-fold), increase in weights of atria, lungs, liver and spleen duet to congestion, suppressed left ventricular (LV) ejection fraction (EF, 27% vs 55%) and cardiac output (CO, 10 vs 15 mL/min), higher myocardial collagen content (by 3-fold), and upregulated fibrotic genes (by 4-8 fold). These phenotypes were stable over 2-6 months of age. Gal-3 expression increased in TG than NTG hearts by 35-40-fold at mRNA and protein levels. Immunohistochemistry revealed lack of accumulation of neutrophils (CD45) or macrophages (CD68) in TG hearts, indicating that Gal-3 was derived from cardiac cells. A 4-month treatment with MCP failed to alleviate DCM phenotype nor to attenuate the level of collagen, Gal-3 or fibrotic genes. In contrast, Gal-3 depletion in Mst1-TG mice by cross-breeding lowered cardiac fibrosis (by 17%), suppressed expression of fibrotic genes (by 40-70%), and normalized pulmonary and left atrial weights. Echocardiography revealed reduced LV volume at end-diastole (51 ± 2 vs 70 ± 7 μL) and end-systole (32 ± 2 vs 51 ± 5 μL), and improved LV EF (37 ± 3 vs 27 ± 2%, all P < 0.01).
Conclusions: Gal-3 expression is markedly increased in Mst1 TG heart exhibiting overt DCM. Whereas MCP therapy showed no beneficial effect, partial or complete Gal-3 gene deletion effectively suppressed cardiac fibrosis and LV dilatation, and improved contractile function. Thus, suppression of Gal-3 expression forms a new therapeutic approach in DCM.

36

Metformin prevents cardiac fibrosis by attenuating mitochondrial NADPH oxidase 4/PKC-alpha/Gal-3 signaling pathway in myocardial infarction

MC Asensio-Lopez[1]; AM Lax[1]; MJ Fernandez Del Palacio[2]; MC Sanchez-Perez[1]; Y Sassi[3]; R Hajjar[3]; DA Pascual-Figal[4]
[1]*Biosanitary Research Institute of Murcia (IMIB-Arrixaca)., Cardiology, Murcia, Spain*; [2]*Department of Animal Medicine and Surgery, Murcia, Spain*; [3]*Icahn School of Medicine at Mount Sinai, Cardiology, New York, United States of America*; [4]*University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain*

Background: The antifibrotic mechanism of metformin (MET) is incompletely understood. We have determined the role of MET in cardiac fibrosis following myocardial infarction and characterized the molecular mechanism.
Methods: Eight-week-old male rats (Sprague-Dawley) were subjected to left ventricular systolic dysfunction by permanent ligation of the anterior coronary artery. Rats received MET (250 mg/kg/day) or normal saline for 4 weeks. An experimental model of biomechanical strain and a coculture, to allow cross talk between primary cultures of cardiomyocytes and cardiac fibroblasts (all obtained from C57BL6J mice using a Langendorff system), were established to characterize the underlying molecular mechanisms involved in the MET antifibrotic actions. The role of AMPK was determined via siRNA-mediated knockdown while those of the NADPH oxidase 4 (mitoNox) and PKCα were determined using the inhibitors GKT137831 and Chelerythrine, respectively. The mRNA and protein expression of different markers were measured by quantitative RT-PCR and Western blot, respectively. The enzymatic activities of mitoNox and PKCα were also assessed using spectrofluorimetry.
Results: MET treatment following MI, was associated with a reduction of myocardial fibrosis, Gal-3 mRNA and protein levels, as well as macrophages infiltration. MET also increased AMPK α1/α2 levels (p < 0.001) and blocked the mRNA expression of both mitoNox and PKCα as their enzymatic activities (p < 0.001, in all cases). Following MI, the increase in expression and activity of both enzymes was associated with an increase in the accumulation of the superoxide anion (p < 0.001) which positively correlated with mitoNox and PKCα activities (rs = 0.362, p = 0.018), as well as an increase in the lipid peroxidation (p < 0.001) and the activation of the apoptotic death program characterized by the activation of initiatory procaspase 9 (p < 0.001) and effectory procaspase 3 (p < 0.001). MET therapy was associated with lower superoxide accumulation (p < 0.001), lipid peroxidation (p < 0.001) and caspases activation (p < 0.001) after 4 weeks of treatment. These findings were replicated using a biomechanical strain model. The silencing of AMPK expression with siRNA blocked the ability of MET to protect adult cardiomyocytes from biomechanical strain, in terms of mitoNox and PKCα activities, Gal-3 levels, percentage of viability and proliferation and levels of reactive oxygen species (p < 0.001, in all cases). The use of the inhibitors GKT137831 or Chelerythrine supported that PKCα is downstream of mitoNox, and the activation of this pathway results in Gal-3 up-regulation. The Gal-3 secreted by cardiomyocytes has a paracrine effect on cardiac fibroblasts, inducing their activation.
Conclusions: MET-induced AMPK increase significantly improves cardiac remodeling post-MI, and this effect is related to the inhibition of mitoNox/ PKCα/Gal-3 pathway. Cardiomyocytes under biomechanical stress activate the fibroblasts in a paracrine manner.

Effects of acute intravenous infusion of nitroxyl donor BMS-986231 on left ventricular function and cardiac rhythm in anaesthetised dogs with intracoronary microembolisation-induced heart failure

HN Sabbah[1]; JC Hartman[2]; J Reardon[3]
[1]*Henry Ford Hospital, Detroit, Michigan, United States of America*; [2]*Pharmaceutical R&D Consulting, LLC, Loveland, Colorado, United States of America*; [3]*HemoShear Therapeutics, LLC, Charlottesville, Virginia, United States of America*

Funding Acknowledgements: Financial support for this work was provided by Bristol-Myers Squibb

Background: BMS-986231 is a novel nitroxyl donor in development for the treatment of acute decompensated heart failure (HF).
Purpose: Assess the effects of BMS-986231 on left ventricular (LV) function and induction of arrhythmias in dogs with HF.
Methods: Chronic LV failure was produced in dogs via sequential embolisations until an LV ejection fraction of ˜30% was achieved. In Study A, seven isoflurane-anaesthetised animals each received continuous intravenous (IV) infusions of three different doses of BMS-986231 (0.7, 2 and 7 μg/kg/min) as well as vehicle for 4 hours; haemodynamic, angiographic and echocardiographic measurements were obtained. Animals were monitored for 1 hour post-infusion. In Study

B, another seven animals with induced HF received BMS-986231 (7 μg/kg/min) and vehicle over 2 hours, before undergoing programmed ventricular stimulation (PVS). PVS was terminated when it provoked ventricular fibrillation (VF) or a sustained monomorphic ventricular tachycardia (SVT) lasting >30 seconds. Threshold data for SVT or VF were quantified in which progressively increasing scores were indicative of higher magnitudes of required stimulation.
Results: With vehicle, all measured/calculated variables were stable from baseline through 4 hours. At 4 hours, BMS-986231 resulted in significant ($p < 0.05$) increases in early-to-late diastolic velocity-time integral ratio (mean Δ from baseline across doses: 1.6 to 2.7) and deceleration time of early mitral valve inflow velocity (Δ10.4 to 12.4 msec), and significant decreases in LV end-diastolic wall stress (Δ-9.3 to -13.4 gm/cm) versus baseline, all suggesting positive lusitropy. BMS-986231 also led to significant increases in LV ejection fraction (Δ5.6 to 8.8%), LV fractional area shortening (Δ6.1 to 11.3%), stroke volume (Δ3.7 to 5.9 ml) and cardiac output (Δ0.24 to 0.47 l/min), suggesting positive inotropy. Systemic vascular resistance was significantly decreased with all doses (Δ-457 to -704 dynes.sec.cm5), suggesting a vasodilatory effect. BMS-986231 had little effect on heart rate (Δ-0.6 to -1.6 bpm, p = NS) and no de novo arrhythmias were detected during infusion. Myocardial oxygen consumption was significantly reduced below baseline with the high dose (Δ-73.1 μmols/min). During PVS, BMS-986231 increased the mean threshold score for SVT or VF twofold versus vehicle (18.0 vs. 9.0) and had no impact on subsequent cardioversion to restore sinus rhythm.
Conclusions: BMS-986231 was associated with outcomes suggestive of inotropic, lusitropic and vasodilatory effects without an impact on heart rate, and with a reduction in myocardial oxygen consumption. BMS-986231 did not induce ventricular arrhythmias and significantly increased the threshold for triggering such episodes with PVS. Based on these findings, BMS-986231 may be a suitable candidate for further development in acute decompensated HF.

38

Activation of the innate immune receptor toll-like receptor 4 (tlr4) by fibronectin fragments negatively regulates cardiac myofibroblast differentiation.

R J Richard Heads[1]; M Khan[1]; Y Chuluunbaatar[1]; V Budhram-Mahadeo[2]
[1]King's College London, Cardiovascular Division, London, United Kingdom; *[2]University College London, Medical Molecular Biology Unit, London, United Kingdom*

Activation of the innate immune system receptors such as Toll-like receptors (in particular TLR4) during post-MI myocardial remodelling and progression to heart failure is generally regarded as pro-inflammatory and pro-injury, leading to adverse remodelling, increased fibrosis and decreased cardiac function. However, these adverse effects are primarily driven by activation of TLR4 on professional innate immune cells such as monocytes and macrophages in the inflammatory infiltrate which secrete pro-inflammatory cytokines. Our work on isolated, cultured resident cardiac fibroblasts/endothelial cells has shown that activation of TLR4 actually inhibits myofibroblast differentiation, inhibits endothelial to mesenchymal transition (EndMT) in response to TGFb and reduces the expression of pro-fibrotic markers. Fibroblast TLR4 activation upregulates the expression of an anti-fibrotic, positive wound healing phenotype. This phenotypic switching is mediated by signal integration between the Ca2+ -dependent protein phosphatase calcineurin (CN) and protein kinase C epsilon (PKC) and controls the transcription of genes involved in cardioprotection and wound healing. This signalling occurs following activation of TLR4 by fragments of extra cellular matrix (ECM) proteins including specific type III repeats of fibronectin (FN), such as FN-EDA and FN-III1-c. This results in CN and PKC-dependent activation of the transcription factors (TFs) Nuclear Factor of Activated T-cells (NFAT) and Activator Protein-1 (AP-1) and synergistic induction of Cyclooxygenase-2 (COX-2), Lipocalin-2 (LCN2), interleukin-6 (IL-6) and Tissue Inhibitor of MetalloProteinase-1 (TIMP-1). At the same time TLR4 activation inhibits the expression of pro-fibrotic genes including Connective Tissue Growth Factor (CTGF), several collagen isoforms and fibronectin itself. Whereas the activation of CN alone is pro-fibrotic, the co-activation of PKCe converts this signal into an anti-fibrotic response. Interestingly, knockdown of PKCe using siRNA or ectopic expression of DN-PKCe causes a compensatory upregulation of PKCd which is pro-fibrotic. Furthermore, we have shown that the POU IV class POU domain TF POU4f1 (Brn3a) is expressed in cardiac fibroblasts and is upregulated in the border zone 24 hours after MI. Brn3a controls myofibroblast differentiation and regulates collagen expression via consensus TF binding sites in the Col1A1 promoter. TLR4 activation inhibits the expression and activity of Brn3a and downregulates collagen expression. Therefore, TLR4 activation by specific FN type III repeats leads to the switching of myofibroblast phenotype from a pro-fibrotic ECM secreting phenotype to a reparative wound healing phenotype and thus promotes beneficial myocardial remodelling.

Objective: MicroRNA-21 (miR-21) has been shown to inhibit apoptosis of cardiomyocytes and promote cardiac fibrosis. However, the role of miR-21 in post-ischemic inflammation remains obscure. Our aim is to determine whether miR-21 regulates DAMPs-triggered inflammation after MI in mice and investigate the underlying signal mechanism.
Methods: We engineered miR-21 knockout (KO) mice. For in vivo experiment, miR-21 KO mice or WT mice subjected with myocardial infarction which induced by left coronary ligation. The inflammatory cytokines in peri-infarct heart tissues were evaluated by Q-PCR, ELISA, IHC and double immunofluorescence staining. The LVEF, LVFS, LVESD and LVEDD were detected by echocardiography 14 days after MI induction and the myocardial infarct size was analyzed by Masson trichrome and TTC staining. The expression of inflammatory cytokines and the activation of MAPK and NF-B signal in macrophage triggered by DAMPs were determined, respectively. In mechanism, we analyzed the targeting gene using TargetScan7.1and verify the interaction between miR-21 and targeting gene with luciferase reporter assay. With silence of target gene by specific siRNA in mouse macrophagesQ-PCR and Western blot analysis were respectively use to detect the DAMPs-induced production of inflammatory cytokines and the activation of MAPK and NF-B signal.
Results: In peri-infarct heart tissues of miR-21 KO mice, the expression of IL-1β, IL-6 and TNF-α were higher than that in WT mice. LVEF and LVFS were significantly decreased, and LVESD, LVEDD and myocardial infarct size were apparently increased in miR-21 KO mice compared with WT mice. Macrophages from miR-21 KO mice have an increased production of IL-1β, IL-6 and TNF-α stimulated with rmHSP60 and rmHMGB1. The phosphorylated levels of P38, IKK-α/β and P65 were significantly increased in stimulated macrophages from miR-21 KO mice. Furthermore, we found that miR-21 mimic markedly decreased the luciferase activity of wild type KBTBD7 luciferase (KBTBD7-Luc) and the expression of KBTBD7 was found to be increased in miR-21 KO mice macrophage. Moreover, the production of IL-1β, IL-6 and TNF-α and the phosphorylated levels of P38, IKK-α/β and P65 were significantly reduced in siRNA silence of KBTBD7 macrophages stimulated with rmHSP60 and rmHMGB1 compared to that with control siRNA. In addition, KBTBD7 could interact with MKK3 and MKK6 which were the upstream regulator of P38 and NF-B in mouse macrophages.
Conclusions: These data show that miR-21 down-regulates inflammatory response after MI by alleviating the activation of P38 and NF-B signalling pathway. MiR-21 inhibits the protein and mRNA expression levels of the KBTBD7 in mouse macrophages, these data indicate that miR-21 attenuate MI-induced inflammatory response by regulating the target gene KBTBD7.

40

Hypoxia induces gene-specific epigenetic modifications in human cardiac fibroblasts which are associated with the development of myocardial fibrosis and aberrant post-ischemic cardiac remodelling

N Glezeva[1]; S Das[1]; B Moran[1]; M Ledwidge[2]; K Mcdonald[2]; C Watson[3]
[1]University College Dublin, Conway Institute of Biomolecular and Biomedical Research, Dublin, Ireland; *[2]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland*; *[3]Queen's University of Belfast, Wellcome-Wolfson Institute for Experimental Medicine, Belfast, United Kingdom*

Introduction: Ischemia caused by coronary artery disease and myocardial infarction leads to aberrant ventricular remodelling and cardiac fibrosis. This occurs partly through accumulation of gene expression changes in resident fibroblasts, resulting in an overactive fibrotic phenotype. Long-term adaptation to a hypoxic insult is likely to require significant modification of chromatin structure. We have recently shown that human myocardial tissue hypoxia is associated with an enhanced pro-fibrotic gene profile in the tissue and, more significantly, that hypoxia-induced pro-fibrotic changes in cardiac fibroblasts are associated with global DNA hypermethylation. Based on this epigenetics data, we have conducted a gene-specific methylation study to investigate methylation changes that occur in hypoxic fibroblasts and to gain novel insights into pathways and mechanisms that may contribute to post-ischemic cardiac remodelling.
Methods: Human ventricular cardiac fibroblasts were exposed to 1% oxygen for up to 8 days. Global methylation changes were assessed using anti-5-methylcytosine (5MeC) staining, flow cytometry, QPCR, and western blot. Gene-specific methylation changes associated with hypoxia and an increased fibrotic state were determined by 5MeC immunoprecipitation and GeneChip human promoter arrays (Affymetrix),

and validated by bisulphite genomic sequencing (BGS). Gene functional classification and pathway analysis were performed (DAVID, FUNRICH).
Results: Hypoxia-induced pro-fibrotic changes in cardiac fibroblasts included increased cell proliferation and increased alpha smooth muscle actin (αSMA), collagen 1, DNA methyltransferase 1 (DNMT1) and DNMT3B expression which associated with global DNA hypermethylation. In specific, 32 gene-specific hypermethylation changes and 101 hypomethylation changes occurred in hypoxia. Fifteen pathophysiologically relevant genes (5 hypermethylated, 10 hypomethylated) were identified by functional classification and pathway analysis to have a role in cardiac fibrosis, extracellular matrix remodelling, transforming growth factor beta (TGF) signalling, cell proliferation and fate, wound repair, ischemia, hypertension, hypertrophy, and heart failure. These were validated using BGS.
Conclusion: Epigenetic modifications and changes in the epigenetic machinery identified in cardiac fibroblasts during prolonged hypoxia may contribute to the pro-fibrotic nature of the ischemic milieu in the heart during disease. The potential use of epigenetic modifiers, such as DNA methylation modifiers, as a treatment option for cardiac pathologies associated with fibrosis, ischemia, and hypertrophy may provide therapeutic benefit.

Studying beta-adrenergic signalling in a patient-specific induced pluripotent stem cell model for Takotsubo syndrome

D Huebscher[1]; T Borchert[1]; D Lam[1]; Cl Guessoum[1]; C Templin[2]; G Hasenfuss[1]; K Katrin Streckfuss-Boemeke[1]
[1]Heartcenter, Dept. of Cardiology und Pneumology, Georg-August-University of Gttingen, Gttingen, Germany; *[2]University Heart Center, Clinic for Cardiology, Zurich, Switzerland*

Funding Acknowledgements: DZHK, Heidenreich von Siebold, IRTG1816, SFB1002

Purpose and Aim: Takotsubo syndrome (TTS) is characterized by acute transient left ventricular dysfunction in the absence of responsible obstructive coronary lesions. The pathogenic mechanism leading to TTS is still unknown. However an adrenergic overstimulation seems to play an important role in TTS. The aims of the study were to use an in vitro induced pluripotent stem cell (iPSC)-TTS model to prove the hypothesis of an altered β-adrenergic signaling under high catecholamine stress in patient specific TTS iPSC-cardiomycytes (ps-iPSC-CMs), and to gain a comprehensive understanding into the pathophysiology of TTS.
Methods and Results: Human somatic TTS cells and controls were reprogrammed to ps-iPSCs and high-quality iPSC clones were directly differentiated into pure functional cardiomyocytes (CMs). 3-month-old iPSC-CMs were treated with catecholamines to mimick a TTS-specific phenotype and analyzed regarding β-adrenergic signaling and cardiac function. To study cAMP dynamics in these cells, we transduced iPSC-CMs with an adenoviral construct expressing a Frster Resonance Energy Transfer (FRET)-based cAMP sensor Epac1-camps. TTS-iPSC-CMs show a higher cAMP response to increasing β-adrenergic receptor (β-AR) agonist Iso levels, which was shown by a significant increase of the FRET ratio at high Iso (1mmol/L) concentration. In comparison, control iPSC-CMs reacted to low Iso concentration (100nM) with a clear cAMP response but without any further increase at higher Iso.
We analyzed the -adrenergic signalling on a molecular level and found an increase of 1-AR expression in TTS and control iPSC-CMs after Iso stimulation, whereas 2-AR-expression was decreased under the same conditions. In accordance to an increased -AR signaling, the Iso-dependent activation of the PKA and specific hyperphosphorylation of its cellular targets including RYR2-S2808 and phospholamban-S16 is enhanced in TTS-iPSC-CMs.To analyze the different beta-AR classes, we pretreated the iPSC-CMs with selective β1- and β2-AR inhibitors before Iso stimulation. Control-iPSC-CMs show a Iso- and β2-dependent response. In contrast, we found a similar subtype-specific signaling of β2-AR and β1-AR in TTS-iPSC-CMs. In addition, in TTS-iPSC-CMs β1-AR and β2-AR cAMP responses are significantly inducible by increasing Iso concentrations of 1μmol/L, which was not found in control cells.
Conclusion: Our data show an induction of stressful events and an altered functionality in response to Iso in iPSC-CMs of TTC patients including the -adrenergic signaling. The FRET measurements pointed to an increasable cAMP response by rising catecholamine levels and argue for higher receptor sensitivity towards high catecholamines under intensive stress conditions in TTS patients. Our study highlights that iPSC-CMs can be used to study the disease mechanism of TTC to provide a versatile tool for evaluating new treatment options for TTC.

42

Crosstalk between FGF23 and angiotensin II-mediated calcium handling in cardiac hypertrophy.

K Mhatre[1]; P Wakula[1]; S Menzel[1]; E Bisping[2]; B Pieske[1]; F Heinzel[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Experimental Cardiology, Berlin, Germany; *[2]Medical University of Graz, Cardiology, Graz, Austria*

The hormone fibroblast growth factor 23 (FGF23) is strongly linked to heart failure-related cardiovascular mortality. It is a mediator of left ventricular hypertrophy which may involve calcium-regulated transcriptional pathways. High circulating levels of FGF23 are associated with an altered systemic renin-angiotensinaldosterone system (RAAS) response. Our aim was to compare and study FGF23 and angiotensin II (ATII)-mediated calcium-dependent signaling in ventricular cardiomyocytes.
Neonatal rat ventricular cardiomyocytes (NRVMs) were isolated and cultured for 5 days. ATII (1μM) or FGF23 (25ng/ml) were used as hypertrophy stimuli. Cell surface area was studied by immunostaining with NRVM specific desmin antibody. Time-dependent changes in gene expression (1-24h) were accessed by qPCR. Calcium transient (CaT) amplitude (F/F0peak at 1Hz; Fluo-4 AM) and integral were quantified in cytosol and nucleus. Phospholipase C (PLC-) phosphorylation levels were detected by Western blot.
Both FGF23 and ATII treatment induced hypertrophy in NRVM as reflected by cell area and pro-hypertrophic gene expression. Cell area was increased by 46.8% with ATII and by 37.4% with FGF23 after 48h ($p < 0.001$). ATII showed peak increase at 1h in ACTA-1 (1.98fold $p = 0.08$) and RCAN-1 (1.91fold $p < 0.05$) gene expression. For FGF23, peak increase was observed at 6h for ACTA-1 (5.2fold) and RCAN-1 (2.4fold) ($p < 0.05$).
NRVMs treated (15 mins-1h) with ATII or FGF23 showed similar early changes in CaT. Both the treatment elicited increase in F/F0peak (1.5fold) and integral (2-2.8fold) in cytosol ($p < 0.01$). However, there was more pronounced rise in integral for ATII (2.9fold) and FGF23 (3.7fold) in the nucleus ($p < 0.001$) than in cytosol, suggesting augmented calcium release into the nucleus with both thehormones. Further, this effect of ATII and FGF-23 on nuclear CaT integral was decreased with inositol trisphosphate receptor (InsP3R) inhibitor 2-APB (5-10μM), implyinginvolvement of InsP3R in the nuclear calcium release.
Further, we used ATII receptor antagonist, losartan (1μM) on the FGF23 treated NRVMs to decipher the overlap between FGF23 and ATII signaling. Losartan inhibited FGF23-induced increase in cell surface area after 48h ($p < 0.001$) and completely attenuated the FGF23-mediated alterations in CaT. These outcomes indicate an involvement of intracellular ATII in FGF23-mediated signaling. On the other hand, FGFR4-PLC--Calcineurin pathway is known to mediate FGF23 induced cardiomyocyte hypertrophy.Losartan inhibited PLC- phosphorylation in presence of FGF23 ($p < 0.005$) suggesting a possible mechanism by which it obstructs the effects of FGF23 treatment.
In conclusion, the response of cardiomyocytes to FGF23 and ATII were comparable at multiple levels (cell hypertrophy, increased cellular and nuclear CaT integral, effect of InsP3R inhibitor). Overall, our results suggest a crosstalk between FGF23 and ATII mediated calcium-dependent hypertrophic signaling in cardiomyocytes.

Cardiotrophin-1 is associated with perivascular fibrosis, increased collagen cross-linking and diastolic dysfunction in Dahl salt-sensitive hypertensive rats with heart failure with preserved ejection

A Gonzalez Miqueo[1]; C Brugnolaro[1]; B Lopez Salazar[1]; S Ravassa Albeniz[1]; MU Moreno Zulategui[1]; J Beaumont Ezcurra[1]; G San Jose Eneriz[1]; J Diez Martinez[1]

Funding Acknowledgements: Instituto de Salud Carlos III (CIBERCV CB16/11/00483; FIS PI15/01909); European Commission FP7-FIBRO-TARGETS.

Background: Myocardial interstitial fibrosis, characterized by increased deposition and stiffness (i.e. collagen cross-linking or CCL) of collagen fibres, is a common feature in patients with heart failure with preserved ejection fraction (HFPEF). On the other hand, cardiotrophin-1 (CT-1) has been shown to be associated with myocardial fibrosis in experimental models but its role has been poorly analysed in HFPEF.
Purpose: This study was designed to analyse the expression of CT-1 in a rodent model of hypertension and HFPEF and to evaluate its association with myocardial fibrosis and left ventricular (LV) morphology and function.
Methods: Dahl salt-sensitive male rats started receiving a high salt diet at 7 weeks of age (HSD; n = 18) until sacrifice (at 23 weeks). A control group (n = 8) was fed with a normal diet all along the study. Blood pressure was evaluated in a subgroup of animals (n = 3 per group) by telemetry. LV mass, morphology, systolic and diastolic

function were evaluated by echocardiography. Total, interstitial and perivascular myocardial fibrosis was measured in picrosirius red- stained sections using an image analysis software (Cell^D). CCL was evaluated by colorimetric and enzymatic techniques. CT-1 mRNA and protein levels were analysed by real time RT-PCR and western blotting, respectively. Lysyl oxidase (LOX) protein levels were analysed by western blotting.

Results: Compared to control rats, HSD animals showed increased ($P < 0.05$) mean arterial pressure, LV hypertrophy (increased left ventricular mass [$P < 0.001$] and relative wall thickness [$P < 0.05$]), and diastolic dysfunction (decreased E/A [$P < 0.05$] and increased isovolumetric relaxation time [$P < 0.05$]) with similar ejection fraction. These rats presented higher LV fibrosis ($P < 0.01$) with an increase both in interstitial ($P < 0.05$) and perivascular ($P < 0.001$) fibrosis. They also showed increased CCL ($P < 0.01$) and increased expression of LOX ($P < 0.05$), the main enzyme responsible for CCL. The myocardial expression of CT-1 was higher in HSD rats than in control rats both at mRNA ($P < 0.05$) and protein ($P < 0.05$) level. CT-1 protein was directly correlated with total ($r = 0.438$; $P < 0.05$) and perivascular ($r = 0.481$; $P < 0.05$) LV fibrosis, with CCL ($r = 0.493$; $P < 0.05$) and with LOX ($r = 0.721$; $P < 0.001$) in all animals. Moreover, it was inversely correlated with the E/A ratio ($r = -0.457$; $P < 0.05$) in all rats.

Conclusions: CT-1 is increased in the myocardium of hypertensive HSD rats with HFPEF and is associated with LV perivascular fibrosis and increased CCL, as well as with diastolic dysfunction. These results suggest that CT-1 facilitates the development of myocardial fibrosis and stiffening which may contribute to the development of LV diastolic dysfunction and the progression to HFPEF in this experimental model.

MODERATED POSTER SESSION 1 - PROGNOSIS

Daytime periodic breathing patterns and risk of appropriate cardioveter defibrillator therapies in heart failure patients

M T La Rovere[1]; R Maestri[2]; E Robbi[1]; M Lovagnini[1]; D Rossi[1]; E Traversi[1]; GD Pinna[2]
[1]Istituti Clinici Scientifici Maugeri, IRCCS Montescano, Department of Cardiology, Montescano (Pavia), Italy; *[2]Istituti Clinici Scientifici Maugeri, IRCCS Montescano, Department of Biomedical Engineering, Montescano (Pavia), Italy*

Background: Although Central Sleep Apnea (CSA) is a recognized risk factor for life-threatening arrhythmias (T Bitter and coll, Eur Heart J 2011), the occurrence of arrhythmic events does not show an increased nighttime frequency (T Bitter and coll, Int J Cardiol 2014). Abnormal breathing patterns in the form of periodic breathing (PB) - are frequently observed during daytime in patients with heart failure (HF) but their contribution to an increased malignant arrhythmia susceptibility is not known.
Methods: We analysed data from 378 patients with clinically stable, optimally treated moderate-to-severe HF (age 59 ± 9 years, NYHA class 2.7 ± 0.5, LVEF 31 ± 9%) who had a cardioverter defibrillator implanted according to current guidelines. All patients were submitted to a 10-minute daytime supine respiratory recording. PB was defined as an oscillation of tidal volume with regularly recurring hyperventilation and apnea or hypopnoea, with a greater than 25% variation in peak to trough values of tidal volume occurring in more than 75% of the 10 min record. Cox regression models were used to assess the association between PB and appropriate ICD discharge.
Results: PB was observed in 158/378 (42%) patients. Patients with PB were older (60 ± 9 vs 57 ± 9 years, p = 0.002), with a lower ejection fraction (29 ± 8 vs 31 ± 9%, p = 0.04) and a higher NT-proBNP (2611 ± 3747 vs 1988 ± 2390, p = 0.008) and creatinine value (1.5 ± 0.6 vs 1.4 ± 0.5, p = 0.03). During a median of 33.5 months, 71 patients had an appropriate ICD discharge. No significant differences were observed in clinical predictors between patients who did or did not receive appropriate ICD discharge. At univariate analysis PB was a significant predictor of ICD discharge (Relative Risk 1.72, 95% CI 1.08-2.77, p = 0.02). The presence of PB remained significant (p = 0.033) in a multivariable model including LVEF, creatinine, NT-ProBNP, serum potassium level, NYHA cl, and six-minute walking test.
Conclusions: The presence of PB has a relevant impact on the occurrence of malignant ventricular arrhythmias requiring ICD discharge in patients with heart failure.

46

Global longitudinal strain (GLS) by speckle-tracking echocardiography (STE) predicts appropriate defibrillator therapy in patients with dilated cardiomyopathy (DCM)

H Hazem Omran[1]; D Hering[1]; N Bogunovic[1]; D Horstkotte[1]; L Faber[1]
[1]Herz- und Diabeteszentrum NRW, Ruhr-Universitt Bochum, Clinic for Cardiology, Bad Oeynhausen, Germany

Background: Patients (pat) with DCM have an increased risk for sudden cardiac death (SCD) which may be prevented by an implantable cardioverter-defibrillator (ICD). Current guidelines link the indication to implant an ICD in DCM pat to a left ventricular ejection fraction (LV-EF) of 35%. LV GLS as assessed by STE, directly measuring myocardial deformation in the longitudinal dimension, is a new method to characterize global LV function.
Aim: The aim of this study was to assess whether GLS measurements predict the rate of appropriate ICD therapies in DCM-pat.
Methods: Pat with DCM who underwent primary prophylactic ICD implantation from 2011-2016, who had baseline echocardiographies adequate for STE analysis, and a follow-up duration of >6 months were included. ICD interrogation data were retrieved from our electronic records. Pat with secondary preventive ICD indication were excluded.
Results: 115 pat were included (26% females, age: 61.3 ± 12.4 years, LV-EF 27.9 ± 5.4%, NYHA functional class 2.7 ± 0,5). During a follow-up time of 35.2 ± 12.3 months 30 pat had at least one appropriate ICD therapy (25 pat had anti-tachycardia pacing (ATP), 8 pat had ICD-shocks). Mean GLS in pat with ICD therapy was significantly worse than in those without ICD therapy (-6.4% vs. -7.8%, p = 0.018). Multivariate logistic regression analysis showed that GLS (odds ratio 1.31, 95% confidence interval: 1.07-1.60, p = 0.01) and FU duration (OR 1.05, 95% CI 1.02-1.07, p = 0.001) but not LV-EF (OR 0.001, p = 0.17) were the only independent predictors of appropriate ICD therapy.
Conclusion: Our findings indicate that LV GLS is a useful marker to risk stratify pat with DCM, outperforming the current standard LV-EF.

47

Remote ischemic conditioning in ST elevation myocardial infarction as adjuvant to primary angioplasty: one-year results of a randomized clinical trial

A Gaspar[1]; A Lourenco[1]; P Azevedo[2]; M Pereira[2]; J Marques[2]; A Leite-Moreira[1]
[1]Faculty of Medicine University of Porto, Department of Physiology and Cardiothoracic Surgery, Cardiovascular R&D Unit, Porto, Portugal; *[2]Hospital de Braga, Cardiology, Braga, Portugal*

Funding Acknowledgements: Portuguese Foundation for Science and Technology; European Commission Grant FP7-Health-2010; Jos de Mello Sade.

Background: Despite a significant improvement in STEMI care, mortality and morbidity remain high. One of the possible reasons is that reperfusion itself may paradoxically cause additional myocardial injury, through the so-called ischemia-reperfusion injury (IRI). Remote cardiac ischemic conditioning (RCIC) has shown encouraging results in reducing IRI.
Purpose: To evaluate the clinical impact of RCIC as an adjuvant to primary angioplasty in STEMI.
Methods: We conducted a randomized clinical trial to evaluate RCIC versus no intervention in patients with STEMI with < 12 h of symptom evolution (exclusion criteria: shock, post-cardiorespiratory arrest status or indication for surgical revascularization rather than angioplasty). RCIC consisted of intermitent left thigh ischemia through three cycles of 5-min inflation followed by 5-min deflation of a blood-pressure cuff. The primary endpoint was a combined endpoint of cardiac death or hospitalization for heart failure (including device implantation: implantable cardioverter defibrillator, cardiac resynchronization, or left ventricular assist device). We report an interim evaluation at one-year follow-up.
Results: 516 patients were randomized, of which 448 were retained for analysis (231 in the RCIC group and 217 in the no-intervention group). There were no differences in baseline characteristics between the 2 groups. Patients without RCIC evolved more frequently with heart failure during the initial hospitalization (24.4% vs. 16.9%, p = 0,06). There were also more in-hospital deaths of cardiac cause among patients not submitted to RCIC (1.8% vs. 0%, p = 0.05). At follow-up, patients not submitted to RCIC had more frequently an EF < 40% (18.8% vs. 10.1%, p = 0.03). At one-year follow-up, the combined endpoint was more frequent in nonconditioned patients (8.2% vs. 2.3%, p = 0.007).
Conclusion: In this randomized study, RCIC as an adjuvant to primary angioplasty was associated with a better prognosis.

48

Importance of structural heart disease and diastolic dysfunction in heart failure with preserved ejection fraction assessed according to the ESC guidelines

D Matan[1]; H Persson[1]; E Donal[2]; L H Lund[3]; E Oger[2]; C Hage[3]; J-C Daubert[2]; C Linde[3]
[1]Danderyd University Hospital, Cardiology, Stockholm, Sweden; *[2]University Hospital of Rennes, Cardiology, Rennes, France*; *[3]Karolinska University Hospital, Cardiology, Stockholm, Sweden*

On behalf of: To be presented by Dmitri Matan on behalf of KaRen Investigator group

Background/Introduction: Forty to 50% of the patients with heart failure (HF) have preserved left ventricular (LV) ejection fraction (EF), named HFpEF. Both morbidity and mortality in HFpEF are similar to those in HF with reduced LVEF, but there is no established treatment.
Purpose: To study prevalence and prognostic importance of presence and severity of diastolic or structural dysfunction in patients with suspected HFpEF in the prospective KaRen registry.
Methods: Following an acute HF-presentation, using Framingham criteria, BNP >100 ng/L or NT-pro-BNP >300 ng/L, and LVEF >45%, echocardiography was repeated after 4-8 weeks and analysed at a core laboratory. Eight diagnostic

echocardiographic criteria for HFpEF were used according to the 2016 ESC HF guidelines. A total of 539 patients were included, complete echocardiography and ECG at 4-8 weeks were available in 356 patients. The primary study endpoint was time to death from all causes or first hospitalisation for HF.

Results: Signs of structural dysfunction (LAVI ≥ 34 ml/m2 or LVMI ≥ 95/115 g/m2) were found in 92% (n = 328) and diastolic dysfunction (DD) (E/e ≥ 13, or < 9 cm/s, or TR ≥ 2.8 m/s) in 82% (n = 290). At least one criterion for HFpEF was found in 98% (n = 351) and 94% (n = 333) had ≥2 criteria. Grading was possible in 352 (99%): 107 patients (30%) had mild DD, 97 patients (27%) had moderate DD and 124 patients (35%) had severe DD. Normal diastolic LV function was found in 24 patients (7%) and 4 (1%) were non-classifiable. After multivariate analyses with adjustment for age, gender, LVEF and natriuretic peptides we found two independent predictors of worse prognosis for event-free survival: moderate to severe diastolic dysfunction (p = 0.0037) or a high number (≥4) of abnormal echocardiographic parameters (p = 0.0033).

Conclusion(s): A vast majority of patients presenting with acute suspect HFpEF met objective echocardiographic criteria for HFpEF according to ESC guidelines. Our findings support the use of ESC guidelines for diagnosis and risk prediction in HFpEF.

Table

Number of pathological diastolic parameters	Hazard ratio	95% CI L	95% CI Up	
4-8 vs 1-3 pathological parameters	0.51	0.32	0.79	0.0033
-	-	-	-	-
Grade of diastolic dysfunction (DD)				
Moderate/severe DD vs none/mild DD	0.56	0.37	0.83	0.0037

Multivariate analysis of 1) the nr of diastolic parameters and 2) grade of diastolic dysfunction, with adjustment for age, gender, EF and BNP/NTpro-BNP. CI L / CI U = lower/ upper control limit of 95% confidence interval.

Background: Asia has the largest proportion of the worlds population, and has the highest global burden of hypertension and diabetes, both known risk factors for heart failure with preserved ejection fraction (HFpEF). However, little is known about the clinical characteristics of HFpEF across different parts of Asia.

Purpose: To compare the clinical characteristics and outcomes of HFpEF across Asia

Methods: The baseline clinical characteristics and outcomes of 1203 patients with HFpEF (LVEF ≥ 50%) from 11 Asian countries, grouped as East Asia (Hong Kong, Taiwan, China, Japan and Korea, n = 543); South Asia (India, n = 252); and Southeast Asia (Malaysia, Thailand, Singapore, Indonesia, Philippines, n = 408) were analyzed. Outcomes were independently adjudicated.

Results: The mean age was 68 ± 12 years (37% were < 65 y), 50% were women, body mass index was 27 ± 6 kg/m2 and 80% were in NYHA Class II/III. South Asian patients (63 ± 13 years) were the youngest, and East Asians the oldest (72 ± 12 years). Comorbidities were highly prevalent albeit varying by region (Figure): 70% of patients had 2 or more comorbidities, with hypertension (71%) being the most common, followed by anemia (57%), chronic kidney disease (50%), diabetes (45%), coronary artery disease (29%), atrial fibrillation (AF; 29% by history; 24% by ECG) and chronic lung disease (9%). Notably, Southeast Asian patients had the highest prevalence of all comorbidities except AF. South Asians had the lowest prevalence of all comorbidities except anemia. These regional differences in the burden of comorbidity were associated with differences in echocardiographic characteristics and outcomes. Concentric remodeling and hypertrophy were most prominent among South and Southeast Asians respectively, whereas East Asians had the most eccentric remodeling (Figure; p < 0.001). Among 883 patients who completed 6 months follow-up, 69 (7.8%) patients died or were hospitalized for HF, with the highest number of events in Southeast Asians (14.1%).

Conclusion: These first prospective multinational data from Asia show that Asian patients with HFpEF carry a high burden of co-morbidities despite relative youth, with approximately a third of patients being under the age of 65 years. There is striking diversity of HFpEF in Asia, with the highest rates of comorbidities, concentric hypertrophy and adverse outcomes observed in Southeast Asia. These findings have important implications for public health measures and global HFpEF trials.

Do patients with acute heart failure and preserved ejection fraction have heart failure at follow-up, impact of framingham criteria

C Camilla Hage[1]; U Lofstrom[1]; E Donal[2]; E Oger[3]; J-C Daubert[2]; C Linde[1]; LH Lund[1]
[1]*Karolinska Institutet, Department of Medicine, Cardiology unit, Stockholm, Sweden*; [2]*Dpartement de Cardiologie & CIC-IT U 804, Centre Hospitalier Universitaire de Rennes, , Rennes, France*; [3]*Clinical Investigation Centre of Rennes, INSERM CIC-1414, CHU, Rennes, France*

On behalf of: KaRen group

Purpose: Heart failure with preserved ejection fraction (HFpEF) is heterogeneous and poorly defined. We assessed prevalence and consistency of Framingham signs and symptoms in acute vs. stable HFpEF.
Methods: In the multi-center Karolinska-Rennes HFpEF study, patients with acute HF according to Framingham criteria, EF ≥45% and elevated brain natriuretic peptides (NPs; NT-proBNP >300 ng/L; BNP >100 ng/L) were assessed again in stable condition 4-8 weeks after hospitalization. Logistic regression was used to assess association between baseline characteristics and types and number of Framingham criteria in acute HFpEF, and the presence of HF at follow-up defined according to four models based on Framingham, the ESC and the PARAGON trial echo criteria (TABLE 1).
Results: In 398 patients, all met Framingham criteria for HF in acute HFpEF and the number of Framingham "points" (2 for major criterion; 1 for minor) were in median 8 (Interquartile range 6-10) in acute HFpEF and 2 (1-4) at stable follow-up ($p < 0.01$). The most common criteria in acute HFpEF were dyspnoea at exertion (90%) and pulmonary rales (71%), which were present in 70% and 13% respectively at follow-up. At follow-up HF was present according to the four models in 27%, 22%, 22% and 22% respectively. Associations between acute characteristics and presence of HF at follow-up are shown in TABLE.
Conclusions: Among patients with acute HFpEF, only a quarter meet the HF definition at stable follow-up according to different contemporary criteria. Characteristics of acute HFpEF that predict persistent HF at stable follow-up were higher age and JVD but not severity of HF. Pleural effusion and tachycardia may yield "false positive" HFpEF diagnoses. This has implications for HFpEF trial design and patient screening.

Table 1

Variable at baseline	Framingham criteria only	Framingham criteria + NP criteria	Framingham criteria + NP criteria + ESC ECHO HFpEF criteria	Framingham criteria + NP + Paragon ECHO structural heart disease criteria
	n=107 (27%)	n=82 (22%)	n=61(22%)	n=69 (22%)

Capnography in spontaneously breathing chronic heart failure patients: resting partial pressure of end-tidal carbon dioxide a new non-invasive factor on heart failure.

ACGB Alexandra Lima[1]; FMF Silva[1]; FMT Teixeira[1]; ML Silva[1]; AA Missias[1]; R Furtado[1]; SHR Ramalho[1]; F Staufer[1]; G Cipriano[1]
[1]*University of Brasilia, Health Sciences and Technologies, Brasilia, Brazil*

Introduction: Given the elevated risk of adverse events in patients with heart failure (HF), identifying clinical variables with prognostic value that are also easily obtainable and cost-efficient is a high priority. The partial pressure of end-tidal CO2 (PetCO2) measured by cardiopulmonary exercise testing (CPX) at rest and during exercise has been shown to accurately reflect disease severity and cardiac function in HF patients. The partial pressure of end-tidal CO2 (PetCO2) measured by capnography was introduced by Fletcher during the early 1980s and most clinical applications concerning intubated and ventilated patients. The use of capnography in spontaneously breathing patients resulted however in additional technical and clinical challenges.
Purpose: The purpose of the current study was to evaluate the pattern of behavior of resting PetCO2 measured by LifeSense Tabletop Capnography in spontaneously breathing HF patients, compare to PetCO2 measured in resting and exercise by CPX (rest PetCO2CPX and peak PetCO2CPX) and evaluate the correlation with important prognostic parameters in HF (peak Oxygen consumption peak VO2 and the minute ventilation–carbon dioxide production relationship VE/VCO2 Slope).
Methods: A total of 155 patients with reduced left ventricle ejection fraction (LVEF < 50%) in current standard medical therapy were included in this analysis. All patients collected the resting PetCO2CAP after one, two and three minutes of rest, followed by a symptom limited CPX in bicycle for the measured of resting PETCO2CPX, peak PETCO2CPX, peak VO2 and VE/VCO2 slope). The data were analyzed in SPSS 21 and significance was considered as $p < 0.05$. The strength of reproducibility between three measures of resting PETCO2Cap was evaluated by the intra-class coefficient (ICC) of correlation. The association between PetCO2CAP, PetCO2CPX and VE/VCO2 slope was made by the Pearson correlation test.
Results: One hundred fifty-five HF patients (gender = 60.0% male; age = 56.3 ± 12.9 years; 35.5% isquemic HF, 39.4% NYHA class III, peak VO2 = 13.6 ± 5.5 ml.kg-1.min-1, VE/VCO2 Slope = 35.9 ± 12.5, LVEF = 38.0 ± 5.1%) were evaluated. The ICC between the three measures of resting PetCO2CAP demonstrate concordance among observations (ICC = 0.983 (0.978-0.987), $p < 0.001$). There was positive correlation between mean resting PETCO2CAP and peak VO2 ($r = 0.352$, $p < 0.001$), resting PETCO2CPX ($r = 0.373$, $p < 0.001$) and peak PETCO2CPX ($r = 0.431$, $p < 0.001$) and inverse correlation between resting PETCO2CAP and VE/VCO2 Slope ($r = -0.481$, $p < 0.001$).
Conclusion: Data supporting the potential clinical utility of capnography in spontaneously breathing chronic HF patients. The results of our study support the correlation between resting PETCO2 by capnography and measured during CPX and the VE/VCO2 slope). We are describing a new non-invise parameter that could be a useful prognostic marker in HF patients resting PETCO2 by capnography.

52

The left ventricular noncompaction syndrome in fifty adults: clinical variants, follow-up and outcomes

O V Blagova[1]; AV Nedostup[1]; EV Pavlenko[1]; VP Sedov[1]; NV Varionchik[1]; NV Gagarina[1]; EA Mershina[2]; VE Sinitsyn[2]; VA Sulimov[1]
[1]*I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation*; [2]*Roszdrav Medical Rehabilitation Center, Moscow, Russian Federation*

Purpose: to study clinical variants, follow-up and outcomes of the left ventricular noncompaction (LVN) syndrome in adult patients.
Methods: The diagnosis of LVN was established in 50 adults (22 females, 18-76 years, on the average 42.8 ± 14.9) on the basis of visual criteria, in 12 patients using three methods (Echo-CG, MRI, CT), in 32 patients using any two methods. Were also performed myocardial biopsy and autopsy (n = 10/4) with viral DNA detection (real-time PCR), anti-heart antibody measurement. The mean follow-up was 12 [5.5; 25.5] months.
Results: there was a high frequency of the association of LVN syndrome and other heart disease by adults: 7 patients (14%) had congenital heart disease (atrial and ventricular septal defects, pulmonary artery stenosis, bicuspid aortic valve, vascular malformations), 3 (6%) hypertrophic cardiomyopathy, 2 (4%) arrhythmogenic right ventricular dysplasia, 1 (2%) systemic myodystrophy, 1 (2%) restrictive cardiomyopathy, 1 (2%) Danon disease. Only one patient with LVN syndrome had no symptoms, but signs of dilated cardiomyopathy (DCM). In 9 patients (18%) LVN had "idiopathic" arrhythmias mask, in 15 patients (30%) mask of DCM, in 7 patients (14%) LVN was first identified at the same time with acute myocarditis. In 6 cases (12%) LVN was associated with coronary atherosclerosis, but in 2 patients (4%) the initial diagnosis "ischemic heart disease" was false. The associated myocarditis was in 29 patients (58%) detected, incl. 12 patients by morphologic study of myocardium and one patient with sarcoidosis. The virus was found in 6 patients in the myocardium (parvovirus B19 in 5, human herpes virus type 6 in 2, herpes simplex virus type 1, 2 in 1 and Epstein-Barr virus in 1) and in 12 patients in the blood.
Heart failure was in 86% of patients and angina pectoris in 32% diagnosed; 7 patients had a typical signs of the myocardium infarction. The incidence of atrial fibrillation was 30%, stable and unstable ventricular tachycardia 78%. The average LV diastolic size was 6.1 ± 0.8 cm, LV ejection fraction 34.6 ± 14.0%. Eleven patients (22%) without anticoagulants had intracardiac thrombi; 10 of them had LV ejection fraction less than 40%. Six patients (12%) had embolism (renal,

pulmonary, myocardium infarct, stroke). The devices were in 23 patients (46%) implanted: CRT/D in 1/4, ICD in 14, pacemakers in 4 patients. In three patients was cardiac transplantation performed. The mortality was 10.0% (5 patients) due to myocardial infarction, arrhythmias, heart failure. Conclusions. LVN syndrome in adults is vary polymorphic and often associated with other cardiomyopathy (18%) and myocarditis (58%). The frequency of complications (incl. stable ventricular tachycardia, embolism) is high, that requires development of differential approaches to the treatment.

53

Causes and consequences of longitudinal left atrial dysfunction assessed by 2d-strain echocardiography in patients with cardiac amyloidosis

D Diane Bodez[1]; A Guellich[1]; U Vergeylen[1]; E Alonso[1]; S Guendouz[1]; A Galat[1]; AS Cottereau[2]; V Plante-Bordeneuve[3]; JL Dubois-Rande[1]; L Hittinger[1]; JF Deux[4]; D Mohty[5]; T Damy[1]

[1]*University Hospital Henri Mondor, Department of Cardiology, Creteil, France*; [2]*University Hospital Henri Mondor, Department of Nuclear Medicine , Creteil, France*; [3]*University Hospital Henri Mondor, Department of Neurology, Creteil, France*; [4]*University Hospital Henri Mondor, Department of Radiology, Creteil, France*; [5]*University Hospital of Limoges, AL Amyloidosis referral center, Limoges, France*

Background: In cardiac amyloidosis (CA), left atria (LA) enlargement, dysfunction (LASD) and intra atria thrombi have been described mostly in systemic light chain CA (AL). The prevalence and physiopathological causes and consequences of these alterations are unclear.

Purpose: Demonstrate that LA 2D strain echocardiography (2D-SE), a new tool, is useful to anlayse LA systolic dysfunction and to explore its causes, consequences and association with thromboembolic events in different types of CA.

Methods: CA patients in sinus rhythm were included. At baseline, history of thromboembolic event, clinical and biological characteristics and echocardiography were recorded. Global and regional LA longitudinal strain (LS) by 2D speckle-tracking echocardiography (2D-SE) were measured. Patients were followed-up to identify independent predictors of mortality.

Results: Seventy-six CA, of whom 21 had AL, 42 hereditary transthyretin (m-TTR) and 13 wild-type (wt-TTR) were included. Peak atrial longitudinal strain (PALS-4C) was negatively correlated to NT-proBNP ($r = -0.6$, $p < 0.0001$) and to LA end-diastolic volume ($r = -0.48$, $p = ou < ? 0.0001$). LA volume was higher and PALS-4C more altered in wt-TTR compared to the AL and m-TTR. The 19 patients who presented a history of thromboembolic event at baseline, had a significantly lower PALS-4C compared to those without ($p = 0.003$). No association of PALS-4C and LA infiltration estimate by Cardiac MRI and by bone scintigraphy was observed. Multivariate analysis identified PALS-4C as the only left atrial echocardiographic independent factor of mortality with an optimal cutoff value of 9.5% (AUC 0.75, IC95% 0.60-0.89). Therefore including all the variables, only NTproBNP was an independent marker of prognosis.

Conclusions: Atrial function estimated by strain is useful to identify patients at risk of death and might be helpful to select patients that may benefit from preventive anticoagulant treatment.

Clinical Case Corner 1 - HoT heart: inflammation and infections in heart failure

54

Eosinophilic myocarditis due to vasculitis

P Prithwish Banerjee[1]; V Dhakshinamurthy[1]
[1]*University Hospital, Coventry, United Kingdom*

Acute heart failure with eosinophilia is not a common presentation but may signal an underlying reversible myocarditic process if recognised early. Making a diagnosis of the aetiology of the heart failure in this situation involves investigating the several causes of eosinophilia. We present such a patient who presented many learning points to the heart failure team looking after him.

A 65 year old lady with a previous history of asthma and skin rashes presented with a clinical picture of a respiratory tract infection with marked oesinophilia of 9.06 x 109 /L but no pneumonia. She later developed signs of acute heart failure with a higher eosinophil count of 22.94 x 109 /L and a large Troponin T rise of 3153 ng/L with a normal ECG and severe left ventricular systolic dysfunction on echocardiography. Myocarditis was suspected and confirmed on cardiac MRI which showed patchy late gadolinium enhancement with myocardial oedema and a LVEF of 28%. Coronary angiography was normal and the vasculitis screen showed an indeterminate pattern anti-neutrophil cytoplasmic antibodies (ANCA) and raised IgE. Other causes of eosinophilia such as parasitic and other infections, haematological malignancies (including bone marrow biopsy, trefine and cytogenetic studies) and drugs were excluded but peripheral neuropathy was diagnosed on neurophysiology investigations. The differential diagnosis at this point was between hyperoesinophilic syndome and Eosinophilic Granulomatosis with Polyangitis (EGPA). An endomyocardial biopsy was undertaken which showed eosinophilic myocarditis. Finally, EGPA was felt to be the most likely diagnosis.

She was successfully treated with high dose steroids and azathioprine along with standard heart failure medications resulting in significant improvement in LV systolic function. Eosinophilic myocarditis should be strongly considered in patients with acute heart failure and peripheral oesinophilia.

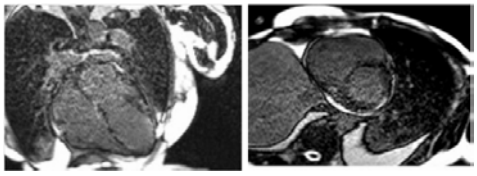

Figure 1. Delayed enhancement on MRI

55

Acute reactivation of chagas disease in post cardiac transplant patient under immunosuppression with cutaneous lesions manifestation

SL Sarah Leandro Da Silva Souza[1]; FS Fabricio Da Silva[1]; RSC Rafael Silva Cortes[1]; MB Marcelo Botelho Ulhoa Junior[1]; VSB Vitor Salvatore Barzilai[1]; FAA Fernando Antibas Atik[1]; RBC Renato Bueno Chaves[1]
[1]*Instituto de Cardiologia do Distrito Federal, Brasilia, Brazil*

Introduction: Chagas disease is a parasitary infection caused by Trypanosoma cruzi, transmitted by a triatomine insect, popularly known as "barbeiro" or "kissing bug". Epidemiologically, this disease was already diagnosed in the whole American continent, since the south of United States of America till Argentina. The patient, once infected, presents both forms acute and chronic, and, in some occasions, the reactivated chronic form. This one, at first, occurring in immunosuppressed patients, whether by hematological diseases, HIV or post transplant patients in use of immunosuppressant drugs aiming to inhibit the graft rejection. In the presence of the acute chronic form, its necessary the early diagnostic with the intention to stop the damages to the organism and, when it comes to a post transplant patient, to the graft. The goal, in this case, is to attempt to the clinical signs of reactivation like fever, acute myocarditis signs and cutaneous lesions for the treatment to be soon implemented.

Case report: S.O.A, female, 39 years old, with chagasic myocardiopathy and cardiac transplant in October 2013. The patient was under immunosuppresion with tacrolimus, mycophenolate mofetil and predinisone, undergoing outpatient follow-up. Routine ecocardiography, in July 2015, showed significant loss of left ventricule with ejection fraction of 25%. In despite of no symptomes, the patient was hospitalized for investigation. During hospitalization, the patient presented characteristic face, upper and lower limbs cutaneous rash, soon interpreted as Chagas disease reactivation. With this evidence, the patient was submitted to oral treatment with benznidazole for eight weeks. After thirty days of the treatment beggining, it was noticed an increase of the left ventricule function, with a left ventricule ejection fraction of 40% and full remission of the cutaneous lesions. After the end of the treatment, there was a ventricular function recovery. The patient was discharged asymptomatic and, till the send date of this case, there werent new episodes of the disease reactivation and the graft function remains preserved.

Conclusion: The patient with Chagas disease, after cardiac transplant, must me submitted to immunosuppressant therapy aiming to avoid the graft rejection. Therefore, he becomes susceptible to the disease reactivation. The focus, in this case, is the early diagnosis, once further damages must be avoided, between them, the loss of cardiac function. Thus, a classical sign as the presence of cutaneous lesions, easily seen to the ectoscopy, cant become unnoticed, for the treatment to be soon begun and the reactivation reversed.

Lesion

Acute myocarditis and myositis after immune checkpoint inhibition

D Witham[1]; S Knauss[1]; A Marek[1]; H Dreger[1]; L Harms[1]; K Joehrens[1]; W Stenzel[1]; G Baldenhofer[1]; V Stangl[1]; K Stangl[1]
[1]*Charite - Campus Mitte (CCM), Berlin, Germany*

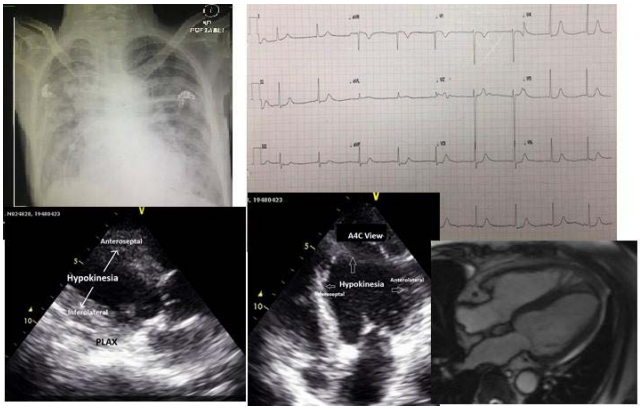
A 74 year old man with metastatic malignant melanoma presented to the emergency department with exertional dyspnea, fever, diplopic images, and muscle weakness nineteen days after intravenous infusion of nivolumab and ipilimumab. There were no abnormalities in the examination of heart and lung. Edema and signs of a deep venous thrombosis were absent. Neurological examination revealed bulbar deviation and ptosis on the left side. An ECG showed sinus rhythm tachycardia (110/minute), new atrioventricular block I, complete right bundle branch block, and left anterior hemiblock. The blood work revealed ten-fold elevated troponin T and creatinkinase levels. Initial transthoracic echocardiography showed septal dyskinesia. Suspected non-ST-segment elevation myocardial infarction was immediately ruled out by invasive coronary angiography. As D-dimers were not elevated, pulmonary embolism was unlikely. Neurological symptoms gave rise to perform a cerebral MRI scan, which did not show any abnormalities. Further analyses revealed strongly elevated anti-myolemmal, anti-sarcolemmal, anti-titin, and anti-voltage gated calcium-channel-(VGCC, N-Type) antibodies. Cardiovascular MRI showed a slight, but insignificant myocardial gadolinium uptake. The findings led us to suspect autoimmune related adverse events after administration of nivolumab and ipilimumab. Thus, oral glucocorticoid therapy was initiated. Septal dyskinesia, atrioventricular, and right bundle branch block disappeared. During short term follow up, the patient reported amelioration of dyspnea, but still suffered from diplopic pictures. An intravenous immunoglobuline therapy was performed over five days, but the patient still was compromised and creatinkinase and troponin levels did not decrease. Finally, skeletal and endomyocardial biopsy were performed.
The diagnosis of myositis and myocarditis was confirmed and most likely attributed to the past therapy with nivolumab and ipilimumab. PCR for typical cardiotropic viruses was negative. Both, the myocardium and skeletal muscle showed interstitial fibrosis and inflammatory cell infiltration dominated by lymphocytes. Immunohistochemical staining revealed that about 80% of the cells were CD3+ T-lymphocytes and accounted in equal parts to the CD4+ and CD8+ subgroup. Myophagocytosis was seen in areas where CD68+ macrophages were infiltrating skeletal muscle and myocardium. Interestingly, there was a significant membranous expression of Programmed Cell Death Protein 1 (PD1) ligand on cardiomyocytes and myocytes whereas about 50% of the infiltrating lymphocytes were positive for PD1 receptor.
Nivolumab blocks the PD1 receptor on T-lymphocytes, thereby inhibiting immunosuppressive signaling throughout cancer cells overexpressing PD1 ligand in order to evade the hosts immune system. Accordingly, PD1 receptor blockade on lymphocytes with nivolumab might not only have lead to an intensified immune attack against cancer cells, but also to an intensified autoimmune attack against the patients self tissues including striated muscle cells with the result of a cytotoxic and humoral immune reaction.
Immune checkpoint inhibitors actually belong to the most promising therapy options for patients with end stage melanoma and probably many other cancer entities. Accordingly, the absolute number of irAE might increase in the future challenging inpatient and outpatient physicians.

57

Managing acute heart failure (AHF) in severe dengue-leptospirosis co-infection - Walking a tightrope

TIAU Wei Jyung Patrick[1]; SG Shatishkumar Govindaraju[1]; TS Tan[2]; SHAWAL Mohd Shawal Faizal Mohamad[1]; CK Choor[1]; HH Hamat Hamdi Che Hassan[1]; OM Oteh Maskon[1]
[1]*University Kebangsaan Malaysia (UKM), Cardiology, Kuala Lumpur, Malaysia*;
[2]*University Kebangsaan Malaysia (UKM), Kuala Lumpur, Malaysia*

Introduction: Acute myocarditis often caused by a viral infection, and less commonly non-viral pathogens. It is usually mild and self-limiting, but may rarely manifests as a severe fulminant form, resulting in cardiogenic shock with a high mortality.
Case: We present a 68 year-old man complaining of fever and lethargy for 5 days. He was febrile, dehydrated and hypotensive. Fluid resuscitation was given but he developed acute pulmonary oedema shortly after. ECG showed diffuse ST depressions over leads V3-V6. An echo showed global LV hypokinesia EF 35%, elevated LV filling pressure (elevated E/e 15, ePWCP of 17mmHg). Cardiac troponins were markedly raised. He denied chest pain and there were no symptoms of heart failure prior to this. Investigations showed severe thrombocytopaenia and lactate acidosis. He was reviewed by cardiologist and ID team, and was diagnosed with fulminant myocarditis secondary to severe dengue-leptospirosis co-infection, based on positive serology for the two disease.
His condition remained critical, required BiPAP respiratory support. Antibiotic was started. He was in the critical phase of an acute dengue infection with potential plasma leakage, hence, the use of diuretic would risk of further depleting the intravascular volume and causing distributary shock. Cardiac output was maintained with inotrope infusion (noradrenaline,dobutamine) and continuous hemodynamic (CO,CI,SVRI,SVR) monitoring were used to guide fluids/diuretic therapy during the critical phase.
His condition started to improve after 48 hours. Serial echo showed good LV function recovery (EF 52%). He did not agree for angiogram and was discharged after one week. CMR which was done 3 weeks later showed no LGE in the myocardium.
Discussion: In this patient who presented with acute febrile illness and thrombocytopaenia; dengue hemorrhagic virus and zoonotic-leptospirosis infection need to be considered as it is highly prevalent in the South East Asia, and acute myocarditis has been reported in both conditions, resulting in AHF. Differentiate acute myocarditis from an acute myocardial infarction(MI) can be challenging, and to perform a diagnostic procedure such as endomyocardial biopsy or angiogram here would certainly carry a high risk of bleeding and complications. Therefore, diagnosis of fulminant myocarditis here could only be made clinically, and the absence of chest pain would make the diagnosis of Type 1 spontaneous MI less likely.
Dengue shock syndrome has a high mortality and it is often due to plasma leakage during the critical phase, causing hypovolaemic shock which would require fluids resuscitation. However, in this patient who also complicated with severe LV dysfunction and cardiogenic shock, excessive fluids had resulted in acute pulmonary oedema. Therefore, managing this patient was extremely challenging, as on one hand it was essential to maintain adequate cardiac output and perfusion, but on the other hand, overzealous fluid replacement could lead to worsening pulmonary congestion. The use of continuous hemodynamic assessment (CO,CI,SVRI) here has become invaluable in determining the inotropic/fluids/diuretic therapy.
Fulminant myocarditis is associated with a higher mortality, but following the acute phase, LV function usually recover. Mechanical circulatory support with VAD as a bridge to recovery has been successfully used in intractable HF.
Conclusion: In summary, identifying the underlying aetiology of AHF is crucial, in order to tailor the individualise treatment for AHF. In this case, a multidisciplinary care is important, and resulted in a favourable clinical outcome.



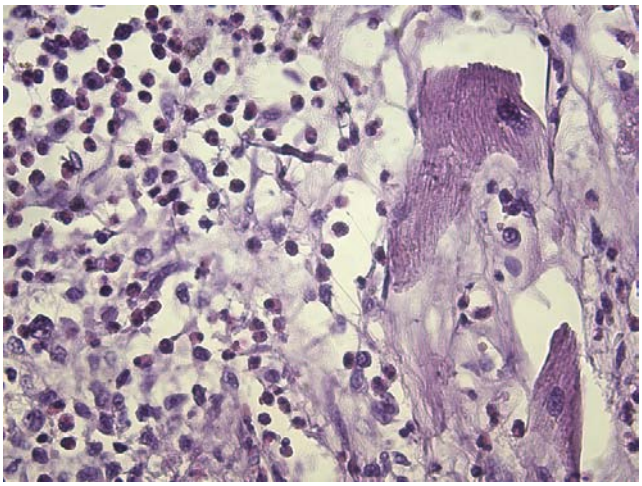
58

Endomyocarditis as a rare complication of toxocariasis

M KH Lepshokova[1]; NV Kijvatova[1]; OM Mesheryakova[1]; O N Ponkina[1]; HD Kosmachova[1]; IA Shelestova[1]; A M Namitokov[1]
[1]*Krasnodar Regional Clinical Hospital No1, Krasnodar, Russian Federation*

We present a case of a patient with rare and life-threatening cardiac complication of toxocariasis.
A 53-year-old man was admitted to neurological department of hospital for recent motor weakness, ataxia, pruritus and increased body temperature to 37.5. He had a previous history of asthma, but did not take any medications. The vital signs were blood pressure 110/70 mmHg, heart rate 110/min, respiratory rate 19/min, body temperature 37.5. Initial laboratory investigations showed leukocytosis (29,800/μL) with hypereosinophilia (8.84/μL), elevated CK-MB (55.2/μL); troponin I was 29.73 ng/μL. Serum total IgE level was 401 IU/mL, C-reactive protein was 158.59 mg/L. Chest x-rays was unremarkable. An electrocardiogram showed sinus tachycardia and nonspecific T wave and ST depsession on inferior and posterolateral leads. Computer tomography of the brain did not revealed pathology and computer tomography of the chest and abdomen showed a splenomegaly and an increased number of normal-sized mediastinal and retroperitoneal lymph nodes. Echocardiogram revealed increased left ventricule (LV) wall thickness (12

mm) with decreased LV systolic function (EF 48%) and a mass 14 mm in diameter from lateral wall of LV, that reduced mobility of mitral valve posterior leaflet. Peripheral blood eosinophilia, elevated level of cardiac enzymes, previous history of asthma, LV wall thickness, decreased LV systolic function are the important clues for early suspicion of eosinophilic myocarditis. While all this symptoms may be a parts of paraneoplastic syndrome of heart malignancy, our aim was to differential diagnosis between this diseases. We performed screening for helminthiasis using an in-house enzyme-linked immunosorbent assay. The next step we planned to performe endomyocardial biopsy, but about 6 hours after arrival patient had ventricular fibrillation and unsuccessful resuscitation. Screening for helminthiasis revealed a positive titer for Toxocara spp of 6.2 optical density ([OD] normal, <0.5 OD). Autopsy and histological examination showed myocardial disarray, interstitial oedema with diffuse eosinophilic inflammatory infiltrate and myocardial necrosis, nonbacterial thrombotic endocarditis with in mitral valve.
Thus, patient had Toxocariasis-associated endomyocarditis. Eosinophilic myocarditis is one of the most fatal and rare complications of hypereosinophilia. One of the reasons of hypereosinophilia is parasite infection. In case of heart injury accompanied by fever and eosinophilia with allergic skin rashes, tissue infestation by parasites should be considered.



Endomyocardial biopsy

59

A case of myopericarditis in a patient with crohn's disease who responded promptly to selenium supplementation

H Altay[1]; F Ozkalayci[1]; B Yasar[2]
[1]Baskent University Istanbul Hospital , Cardiology, Istanbul, Turkey; *[2]Baskent University Istanbul Hospital , gastroenterology, Istanbul, Turkey*

Introduction and case report description: A 44-year-old woman was evaluated for progressive, severe dyspnea and tachycardia while she had been hospitalized for crohns disease with multiple intestinal fistules and perianal abscess in the gastroenterology department. Physical examination revealed an under-nourished cachectic and ortopneic woman. She had a blood pressure of 100/60 mmHg and a persistent sinus tachycardia at a rate of 140 beats per minute, repiratory rate of 23 breaths per minute and an oxygen saturation of 90% despite continuous oxygen therapy given at a rate of 4 liter per minute. She had an elevated jugular venous pressure and third heart sound heard at apex but no pericardial friction rub. Fine crackles and decreased breath sounds were heard at bilateral bases of her lungs, left greater than right. Laboratory studies revealed a hematocrit level of 32,4%, a white blood cell count of 11,3 X 103 and a normal platelet count. Her high-sensitivity troponin and NT- proBNP levels were elevated, at 78,1 ng/ml (normal range $<$ 15 ng/ml) and 35,000 pg/ml,respectively. The eritrocyte sedimentation rate was 22 mm/h, C-reactive protein concentration 192 mg/L and the albumin level 2,8 g/dL. Serum selenium level was 3,62 microgram per liter (normal range 46-143). The electrocardiogram showed sinus tachycardia with non specific ST-T wave changes. A chest radiograph revealed interstitial pulmonary edema and left-sided pleural effusion. Transthoracic echocardiography (TTE) revealed global hypokinesis of left ventricular (LV) walls, severe LV systolic dysfunction with an ejection fraction of 30% and a mild- to moderate-sized pericardial effusion without evidence of tamponade physiology (Figure 1). Angiography showed normal coronary arteries. Description of the problem This patient had decompensated heart failure most probable due to subacute myopericarditis. She also had selenium deficiency due to malnourishment. Answers and discussion: Myocarditis in this patient could be related to enhanced systemic inflammatory immune response which is a well known condition in crohns disease. Myocarditis and cardiomyopathy could also be due to selenium deficiency which is usually described in crohns disease. She was treated with ramipril, karvedilol, spirinalactone and furosemide. After that, dyspnea diminished and she was discharged with selenium supplementation. After one month of discharge, she was seen in the outpatient clinic. Echocardiographic measurements were within the normal limits as well as the serum selenium level Conclusions and Implication for clinical practice: The case was unique in the way she responded to treatment with selenium supplementation for subacute myopericarditis and selenium deficiency in crohns disease with a rapid recovery of cardiac function in a matter of weeks. The possibility of selenium deficiency should be considered in all malnourished patients with myocarditis and crohns disease.

Autoinmune acute myocarditis induced by pembrolizumab

C Anaya-Quesada[1]; D Rangel Sousa[1]; A Campos-Pareja[1]; E Jimenez-Baena[1]; MP Gotarredona-Serrano[2]; MP Villa Gil-Ortega[3]; JM Sobrino-Marquez[1]; E Lage-Galle[1]
[1]University Hospital of Virgen del Rocio, Heart Failure and Heart Transplantation Unit. Service of Cardiology, Seville, Spain; *[2]University Hospital of Virgen del Rocio, Cardiothoracic Image Unit, Seville, Spain*; *[3]University Hospital of Virgen del Rocio, Haemodynamic and Interventional Cardiology Unit, Seville, Spain*

Introduction: Immune checkpoint inhibitors (ICI) have improved clinical outcomes associated with numerous cancers, but high-grade, immune-related adverse events can occur, particularly with combination immunotherapy. Pembrolizmab (PEM) is an ICI, an antiprogrammed death-1 (PD-1) antibody that have individually improved survival in patients with melanoma. Case-report:53 years old caucasian man with personal history of arterial hypertension, light alcohol comsumption up to 2014 and no previous heart disease known. Diagnosed of advanced melanoma (debut in 2007 with right foot skin lesion) stage IV BRAF wild-type enrolled in a clinical trial reciving PEM 200 mg iv QW3 plus Epacadostat 300 mg BID for the two previous months. Admitted to Emergency Room complaining sudden paroxysmal nocturnal dyspnea and oedema in lower limbs wihout chest pain. No flu-like symptoms the previous days. A 3-millimeter ST elevation was detected throughout the precordial series in ECG with evidence of myocardical necrosis (Troponin T us 5341 ng/L, CPK 981 mU/mle) and myocardial wall stress (NT-ProBNP 8452 pg/ml) biomarkers elevation. Red and white blood cells count and platelets were normal. Urgent coronary angiography was performed without evidence of epicardial coronary artery obstructive lesions neither vasospasm. A transthoracic echocardiogram was carried out showing a dilated left ventricle with global hypokinesis and severely depressed LVEF(29%) with mild functional central mitral regurgitation, and dilated right ventricle with severe systolic dysfunction along with severe tricuspid insufficiency due to tricuspid ring dilatation. Acute pulmonary tromboembolism (APE) was ruled out with angio-CT. Cardiac magnetic resonance showed biventricular enlargement with systolic disfunction (22% RVEF and 30% LVEF) with signs of acute inflammation (edema) and necrosis (pathological late gadolinium enhancement -LGE-) with a patchy non-coronary intra myocardium LGE pattern) with main RV involvement compatible with toxic myocarditis by drug (Fig.1). Evolution with medical treatment including steroids was adequate and the patient could be discharged. Discussion: Acute myocarditis diagnosis is sometimes a challenge. Acute coronary syndromes, APE, stress cardiomyopathy, e.g. should be ruled out. Clinical data along with image techniques as CMR improves accuracy of diagnosis. A toxic aetiology of myocarditis always should be considered as the patient is enrolled in a clinical trial. Conclusion: The development of myocarditis from ICI does have biologic plausibility. In studies in mice, PD-1 plays a role in myocardial

immune responses and protects against inflammation and myocyte damage in models of T-cellmediated myocarditis. Genetic deletion of PD-1 in mice leads to cardiomyopathy that is caused by autoantibodies against cardiac troponin I. As nivolumab, another antiprogrammed death-1 (PD-1) antibody, PEM can be related to toxic myocarditis due an autoinmune mechanism.

A new phenotype of immune related cardiac adverse events induced by immune checkpoint inhibitors

Y Yuki Fujii[1]; M Takei[1]; R Onoguchi[1]; A Endo[1]; N Hirata[1]; K Suzuki[1]; T Hasegawa[1]; T Takahashi[1]; S Nakagawa[1]
[1]*Saiseikai Central Hospital, Cardiology, Tokyo, Japan*

Introduction: Anti PD-1 antibody, nivolumab, is a new anti-cancer drug which works as an immune checkpoint inhibitor. Despite the impressive benefits of this drug, its use can cause serious immune related adverse events (irAEs), characterized by abnormal invasion of immune cells into normal tissues. Some cases of myocarditis with infiltration of CD8+ immune cells into cardiac tissue have already been reported as the cardiac manifestation of irAEs. We report cases of two patients who developed cardiomyopathies during treatment with nivolumab. Interestingly, clinical courses and histopathological analyses of hearts were different from those of previously reported. Case reports: Patient 1; A 56-year-old woman with lung adenocarcinoma was admitted to our hospital due to acute decompensated heart failure two months after the initiation of the treatment with nivolumab. Her chest X-ray showed bilateral pleural effusions and cardiac dilatation. The plasma BNP level increased to 1600 pg/ml, and the echocardiogram revealed diffuse left ventricular hypokinesis with an ejection fraction of 32%. CT coronary angiogram showed no stenosis in her coronary arteries. Biopsy samples from her heart showed mild myocardial hypertrophy without any evidence of inflammation nor fibrosis. Cardiac MRI showed no apparent late gadolinium enhancement and T2 high spots. Cardiomyopathy caused by nivolumab was suspected, thus the interruption of the drug and the initiation of βblocker and ACE inhibitor were undertaken. 2 months later, her left ventricular systolic function improved to normal range. Patient 2; A 71-year-old man with lung adenocarcinoma was admitted to our hospital with anorexia after receiving the treatment with nivolumab for a month. His ECG showed ST segment elevation in leads V2-V6. The high sensitive troponin I level increased to 400 pg/ml, and the echocardiograms showed preserved left ventricular systolic function. No significant stenosis was found with coronary angiography. Biopsy samples from his heart revealed myocardial hypertrophy and subtle replacement of myocardium with fibrotic tissue. He was treated with hydrocortisone for 5 days and his symptom was gradually improved. ST segment elevation was resolved and he was discharged to home after two weeks of hospital stay. Discussion: Some cases of myocarditis during treatment with immune checkpoint inhibitors were already reported. Most of them resulted in death in spite of treatment with high-dose steroid. Furthermore, in those cases, histopathological analyses of hearts demonstrated lymphocytic infiltration with a predominance of CD8+ T cells. In our two cases, however, the patients were recovered and histopathological analyses of their hearts did not show lymphocytic infiltration. These two cases suggest the existence of new phenotypes of cardiac adverse events induced by immune checkpoint inhibitors, distinguished from previously reported lymphocytic myocarditis with histopathological findings.

62

A case of reversible dilated cardiomyopathy caused by Takayasu arteritis

S-H Sung-Hee Shin[1]; JH Jang[1]; SW Kwon[1]; SD Park[1]; SI Woo[1]; DH Kim[1]; J Kwan[1]
[1]*Inha University Hospital, Incheon, Korea Republic of*

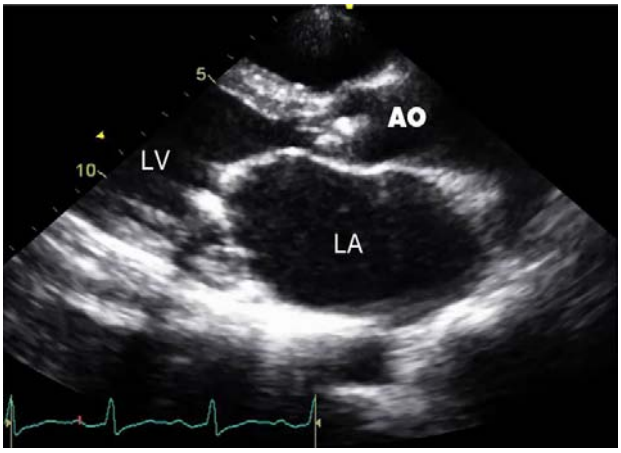
27-year-old female was consulted to the cardiology because of cardiomegaly on chest X ray. She had been treated with a suspicion of bronchial asthma at local clinics. She had no history of hypertension or diabetes and suffered from exertional dyspnea from 6 months ago. Transthoracic echocardiography showed dilated left atrium and left ventricle (LV) with severely depressed LV systolic function. The aortic valve was mildly thickened with moderate regurgitation. On subcostal view, abdominal aorta was diffusely narrowed. Abdomen CT was done and it revealed diffuse wall thickening of lower thoracic and abdominal aorta with segmental narrowing from celiac axis to inferior portion of renal vein, which was compatible with aortits. Coronary angiography showed no significant stenosis of coronary artery. Brain MRA demonstrated severe stenosis of bilateral common carotid artery and proximal subclavian artery. Cardiac MRI showed delayed hyperenhancement at the mid wall of mid to basal antero- and infero- lateral wall. Takayasus arteritis was finally diagnosed. Immunosuppressive treatment was started with traditional heart failure management. After 3 months, follow-up echocardiography showed that LV function markedly improved with decreased LV size.

63

Acute heart failure in patient with zoonotic endocarditis

O Pachirat[1]; D Kaewkes[1]; K Anutarapongpan[1]
[1]*Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand*

Introduction: Infective endocarditis (IE) is a life-threatening disease. Zoonotic pathogen can cause blood-culture negative endocarditis(BCNE). The study aimed to diagnose IE caused by zoonotic agents, Bartonella spp., Coxiella burnetii in BCNE by non-culture assays to enhance the standard diagnostic evaluation.
Case: A 45 year-old male with underlying rheumatic heart disease who was referred to our center because of shortness of breath, orthopnea and weight loss for 3 months. On admission he had clinical evidence of congestive heart failure, heart murmur consistent with severe aortic regurgitation, mitral stenosis and regurgitation. A transthoracic echocardiogram showed mobile vegetations on the aortic with perforation of right coronary cusp with severe aortic regurgitation and on the mitral valve (Figure 1). Intravenous ampicillin and gentamicin were begun on admission. The patient underwent urgent aortic and mitral valve replacement due to intractable heart failure. Histopathological examination of the heart valve tissue showed subacute, active endocarditis. Three sets of routine blood cultures were negative but B. henselae was demonstrated in the excised heart valve tissue by serology, PCR and immunohistochemical staining. The patient' s overall clinical condition improved soon after surgery and was discharged from the hospital within three weeks. One year follow-up, the patient remained clinically stable. Discussion: Bartonella is a zoonotic, fastidius, gram-negative pathogen that causes a wide spectrum of clinical infections from asymptomatic to IE. Zoonotic pathogens are important cause of BCNE and should be included in the differential diagnosis. Increase awareness of this agent in patient who has previous valvular heart disease with BCNE should be consider. Conclusion and implication: The targeted therapy and prompt surgical intervention are important to treat Bartonella endocarditis with good outcome.



RAPID FIRE 3 - ACUTE HEART FAILURE - FROM DIAGNOSIS TO PROGNOSIS

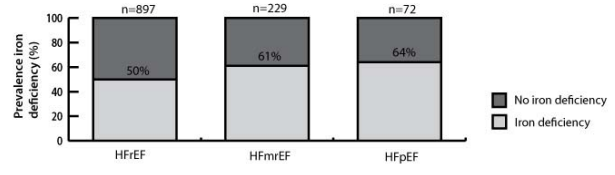
[1]*Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium*

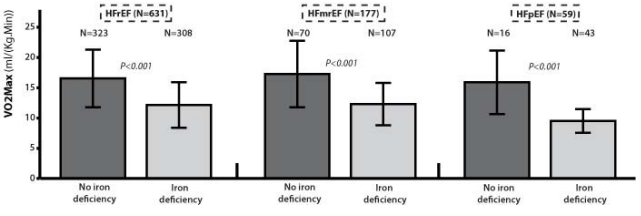
Funding Acknowledgements: Pieter Martens is supported by a doctoral fellowship by the Research Foundation Flanders (FWO, grant-number: 1127917N

Background: Both iron deficiency and anemia are prevalent in heart failure with reduced ejection fraction (HFrEF) and affect clinical outcome. Little information is available about the prevalence, impact on excercise capacity and outcome of iron deficiency in Heart failure with mid-range (HFmrEF) and preserved (HFpEF) ejection fraction in comparison to HFrEF. Furthermore, no data is available about the progression of iron deficiency in patients without baseline anemia.
Methods: We evaluated baseline iron and hemoglobin (Hb) status in a single center, prospective heart failure database. Baseline functional status including New York Heart Association (NYHA) class, VO2max, echocardiography data and clinical outcome defined as all-cause mortality and heart failure admission were evaluated. Iron deficiency was defined according to established criteria (a ferritin below 100 μg/L or a ferritin between 100 - 300 μg/L with a transferrin saturation below 20%). Anemia was defined according to WHO-criteria (Hb < 12g/dl in females and Hb < 13 g/dl in males). LVEF was used to categorize patients in HFrEF (< 40%), HFmrEF (40-50%) and HFpEF(>50%).
Results:A total of 1197 patients (71% male) were evaluated (HFrEF;n = 897, HFmrEF;n = 229, HFpEF;n = 72). The overall prevalence of iron deficiency was 53% (panel A depicts prevalence for HFrEF, HFmrEF and HFpEF) and 36% for anemia. Iron deficiency was associated with a lower VO2max in patients with HFrEF, HFmrEF and HFpEF (panel B). Iron status more closely related to a poor VO2max than anemia status (p < 0.001). Furthermore, poor clinical-outcome was more strongly associated with iron status than anemia status. Iron deficiency without anemia associates with an adjusted HR = 3.24 (2.31-4.56;p < 0.001) and iron deficiency with anemia associates with an adjusted HR = 4.93 (3.47-7.00;p < 0.001) for heart failure admission and all-cause mortality. While patients with anemia in the absence of iron deficiency had an adjusted HR = 1.74 (1.09-2.78;p = 0.020) for the same combined endpoint. Exposing 8 patients without anemia to iron deficiency for 39 months resulted in one patient developing new-onset anemia (defined as progression of iron deficiency). Patients with progression of iron deficiency exhibited a significant higher risk of heart failure hospitalization and all-cause mortality (HR = 1.4; CI = 1.01-1.94; p = 0.046) than patients without progression.
Conclusions: Iron deficiency is common in patients with HFrEF, HFmrEF, and HFpEF and negatively affects VO2max and clinical-outcome. Progression of iron deficiency parallels an increased risk for worsening of heart failure.

Panel A: prevalence of iron deficiency in HFrEF, HFmrEF and HFpEF.



Panel B: impact of iron deficiency on excercise capacity.



89

Phase 2 open-label extension (OLE) study of patisiran for the treatment of hereditary ATTR (hATTR) amyloidosis: 24-month safety and efficacy in subgroup of patients with cardiac involvement

D Adams[1]; T Coelho[2]; I Conceicao[3]; M Waddington Cruz[4]; H Schmidt[5]; J Buades[6]; J Campistol[7]; J Pouget[8]; JL Berk[9]; N Ziyadeh[10]; AM Partisano[10]; M Sweetser[10]; J Chen[10]; J Gollob[10]; OB Suhr[11]

Funding Acknowledgements: Study supported by Alnylam Pharmaceuticals

Intro: Hereditary ATTR (hATTR) amyloidosis is a rapidly progressive, life-threatening disease caused by a mutation in the transthyretin (TTR) gene, resulting in misfolded TTR proteins accumulating as amyloid fibrils in multiple organs, including the nerves, heart, and gastrointestinal tract. hATTR is a heterogeneous disease and includes sensory, motor/autonomic neuropathies, and cardiac dysfunction. Patisiran, an investigational RNAi therapeutic, targets mutant and wild-type TTR. Data from the patisiran Phase 2 OLE study showed a >80% sustained mean reduction of serum TTR, that it was generally well tolerated in patients (pts) with hATTR and resulted in stabilization or improvement of neuropathy.
Purpose: To highlight the 24 month (mos) safety/efficacy data in the cardiac subgroup from the patisiran Ph 2 OLE study in hATTR.
Methods: In this study (NCT01961921), pts with hATTR received patisiran (0.3mg/kg IV) q3W x 24 mos and a corticosteroid-containing premedication prior to each dose. Primary objective: safety/tolerability of patisiran; secondary objectives: change in mNIS + 7 (composite measure of neurologic impairment).A subgroup of pts with cardiac involvement (cardiac subgroup) included pts with LV wall thickness of ≥13 mm on baseline echocardiogram (echo) and no history of uncontrolled hypertension or aortic valve disease. Patients in this subgroup had additional assessments, including serial quantification of cardiac biomarkers. Results: 27 pts were enrolled, 11 of whom met criteria for the cardiac subgroup. In this subgroup, baseline characteristics included: median age 69 yrs (range: 58-75); V30M TTR mutation 73%; FAP stage 1 82%; mean mNIS + 7: 66.2 (range: 30-122.4); NYHA Class I 45%, Class II 55%; mean LV wall thickness 16mm (range: 13-19); mean NT-proBNP 809.8 ng/L (range: 105-2070); mean Troponin 0.14 ng/mL (range: 0.03-0.69); mean ejection fraction (EF) 62% (range: 41-76); and mean 10-meter walk test (10MWT) speed: 0.95 m/s (range: 0.4-1.5). Safety profile of patisiran in the cardiac subgroup was consistent with that observed in the overall study population. 3 pts in cardiac subgroup had SAEs unrelated to study drug (including one death [MI]); AEs reported in ≥20% of pts included flushing (36%); cataract, infusion site extravasation, pyrexia, UTI, wound, and insomnia (27% each); 1 pt (9%) had a mild infusion related reaction. Following 24 mos of patisiran, pts in the cardiac subgroup had a mean 10.0-point decrease (improvement) in mNIS + 7 (range: -34.6-3.9); echo (including LV wall thickness, EF), circulating cardiac biomarkers (NT-proBNP, troponin) and 10MWT were stable. Additional clinical activity and cardiac parameters data to be presented. Conclusions: Following 24 mos of dosing, patisiran was generally well-tolerated in pts with cardiac involvement. The decrease in mNIS + 7 and stability of cardiac measures among these pts suggest that patisiran can potentially reduce progression of disease in this heterogeneous condition.

Heart failure and inflammation-related biomarkers as predictors of new onset diabetes in the general population

N Suthahar[1]; W C Meijers[1]; F P Brouwers[1]; H J Lambers Heerspink[1]; R T Gansevoort[1]; S J L Bakker[1]; R A De Boer[1]
[1]*University Medical Center Groningen, Cardiology, Groningen, Netherlands*

Funding Acknowledgements: CVON-DOSIS, grant 2014-40, to Dr. de Boer (Netherlands Heart Foundation); NWO VIDI, grant 917.13.350 to Dr. de Boer (IRIS program of NOSR)

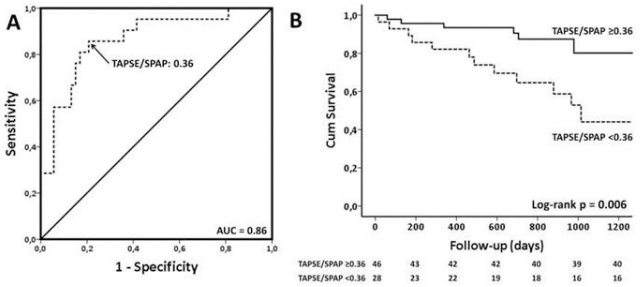
Background : There is a strong reciprocal relationship between Heart Failure (HF) and Diabetes Mellitus (DM). Shared pathophysiological mechanisms might be a possible explanation. Therefore, we hypothesized that biomarkers that have been linked to new onset HF might also predict new onset DM in the general population.
Methods: The study cohort consisted of 6087 participants of the Prevention of Vascular and Renal End-stage Disease (PREVEND) study that were free of DM and HF at baseline. To study the relationship between HF and DM, we evaluated the incidence of new onset DM in subjects who developed new onset HF and vice-versa. Multiple HF-related, inflammation-related and renal function-related biomarkers were evaluated regarding their predictive value for new onset DM. These biomarkers included: N-terminal-pro B-type natriuretic peptide (NT-proBNP), MR-pro-atrial natriuretic peptide (MR-proANP), Mid-regional pro-Adrenomedullin (MR-proADM), c-terminal pro Endothelin-1 (CT-pro-ET-1), Plasminogen activator inhibitor-1 (PAI-1), high sensitivity Troponin-T (hs-TnT), Galectin-3, Copeptin, Procalcitonin (PCT), hs-C-Reactive Protein (hs-CRP), Cystatin-C, Urinary Albumin Excretion (UAE), Renin and Aldosterone.
Results : The study populations mean age was 48 (SD 12) years and 54% were female. 318 (5.2%) were diagnosed with new-onset DM and 207 (3.4%) were diagnosed with new-onset HF over a mean follow up of 11 (±3) years. Total incidence over time of DM in patients who first developed HF was 11.6% versus 5.0% in those who had not developed HF ($p < 0.001$). Incidence of HF in patients who first developed DM was 7.5% versus 3.2% in those who had not developed DM ($p < 0.001$). Out of the 14 biomarkers that we examined, the classical HF biomarkers NT-proBNP and hs-TnT were not associated with increased risk for new onset DM. However, the inflammatory biomarkers hs-CRP [HR 1.12 (95% 1.04-1.21 CI)], procalcitonin [HR 1.20 (95% 1.00-1.44 CI)] and PAI-1 [HR 1.46 (95% 1.32-1.61 CI)] were predictive for new onset DM. This association remained significant after multivariable adjustment of established predictors of DM (age, sex, smoking, hypertension, waist circumference and family history of DM).
Conclusions : We validate the intimate relation between HF andDM. Further, we observed that several biomarkers of inflammation were associated with new onset DM. Although HF and DM have been described to have a very strong correlation with each other, systemic biomarkers that predict new onset HF do not predict new onset DM, suggesting that other, indirect, pathophysiological mechanisms may explain their strong relation.

91

Right ventricular-vascular coupling in heart failure with preserved ejection fraction and pre- versus post-capillary pulmonary hypertension.

T M Thomas Gorter[1]; DJ Van Veldhuisen[1]; AA Voors[1]; YM Hummel[1]; CSP Lam[2]; RMF Berger[3]; JP Van Melle[1]; ES Hoendermis[1]
[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands; *[2]National Heart Centre Singapore, Cardiology, Singapore, Singapore*; *[3]University Medical Center Groningen, Paediatric Cardiology, Groningen, Netherlands*

Background: Many patients with heart failure with preserved ejection fraction (HFpEF) develop post-capillary pulmonary hypertension (PH) due to increased left-sided filling pressures. However, a subset of patients develops combined post- and pre-capillary PH.
Purpose: We studied the characteristics and non-invasive identification of pre- versus post-capillary PH in HFpEF, using invasive hemodynamics as gold standard.
Methods: Consecutive HFpEF patients with simultaneous right heart catheterization and echocardiography were identified. Patients were divided into: no PH, isolated post-capillary PH and post-/pre-capillary PH based on right heart catheterization. Systolic pulmonary arterial pressure (SPAP), tricuspid valve annular plane systolic excursion (TAPSE) and right ventricular-vascular coupling (TAPSE/SPAP) were measured on echocardiography. VO2-max was assessed as well. The primary endpoint was defined as all-cause mortality.
Results: A total of 97 patients were included: 22% no PH, 47% isolated post-capillary PH and 31% post-/pre-capillary PH. Patients with post-/pre-capillary PH had more often diabetes mellitus (47 vs. 24%, $p = 0.04$), had more heart failure hospitalizations (57 vs. 26%, $p = 0.007$) and lower VO2-max (10 vs. 13 ml/min/kg, $p = 0.008$), compared to those with isolated post-capillary PH. Patients with post-/pre-capillary PH also had more reduced TAPSE (17 vs. 21 mm, $p = 0.001$) and TAPSE/SPAP ratio (0.3 vs. 0.5, $p < 0.001$). TAPSE/SPAP ratio <0.36 had a good accuracy of identifying patients with additional pre-capillary PH (C-statistic 0.86, sensitivity 86% and specificity 79%). TAPSE/SPAP ratio was independently associated with increased mortality (HR 2.16 [95% CI 1.16-4.01], $p = 0.02$).
Conclusion: Abnormal right ventricular-vascular coupling (i.e. low TAPSE/SPAP ratio) reliably identifies patients with additional pre-capillary PH and predicts poor outcome in HFpEF.



TAPSE/SPAP ratio in HFpEF

92

Definition of iron deficiency based on the gold standard of bone marrow iron staining and treatment effect of ferric carboxymaltose in heart failure patients

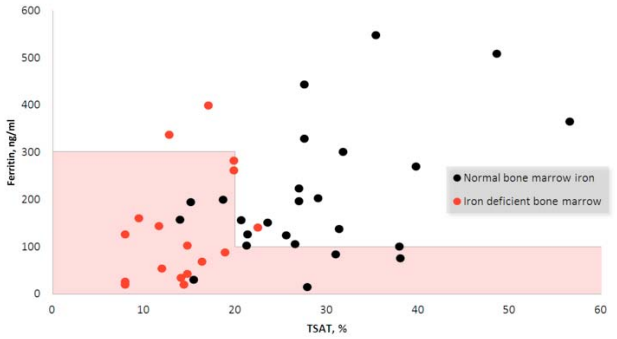
N Niels Grote Beverborg[1]; P Van Der Meer[1]
[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands

On behalf of: the DEFINE-HF study group

Background: The most commonly used definition of iron deficiency (ID) (ferritin < 100ng/ml or ferritin 100-300ng/ml and transferrin saturation [TSAT] < 20%) has not been validated in patients with heart failure (HF).
Purpose: We aimed to validate and possibly optimize the biomarker-based definition of ID in HF, using bone marrow iron staining as the gold standard. Second, we aimed to apply this optimized definition to the treatment response to ferric carboxymaltose in patients with HF.
Methods: Bone marrow aspiration with iron staining was performed in 42 patients with HF and a reduced ejection fraction (LVEF45%) undergoing median sternotomy for coronary artery bypass grafting. Subsequently, an individual patient data meta-analysis of clinical trials (N=837) on the effects of intravenous ferric carboxymaltose in patients with HF was used to test if the optimal definition of ID identified treatment responders from non-responders on cardiovascular morbidity and mortality.
Results: Patients in the bone marrow study were mostly male (76%), mean age was 68±10 years, median NTproBNP 914ng/L [IQR:454-1755]. Bone marrow ID was found in 17 (40%) of the HF patients. The most commonly used definition of ID (ferritin < 100ng/ml or ferritin 100-300ng/ml and TSAT < 20%), had a sensitivity of 82% and a specificity of 72%. A definition solely based on TSAT (optimal cut-off 19.8%) had a sensitivity and specificity of 94% and 84% ($p < 0.05$ compared to the former definition). In the meta-analysis, TSAT19.8%, and not ferritin, distinguished responders from non-responders to intravenous ferric carboxymaltose (interaction $p = 0.009$; rate ratio for cardiovascular morbidity and mortality [RR] (95%CI): 0.45 (0.290.71) for patients with TSAT19.8% and RR (95% CI): 1.55 (0.693.47) for patients with TSAT>19.8%).
Conclusions: The conventional definition of ID performs reasonably in diagnosing ID. However, a single value (TSAT19.8%) alone performs at least as good in selecting patients with true ID and identifies responders to ferric carboxymaltose.

Diagnostic characteristics for ID		
	Ferritin < 100ng/ml or ferritin 100-300ng/ml and TSAT < 20%	TSAT≤19.8%
Sensitivity, %	82.4	94.1
Specificity, %	72.0	84.0
ROC-AUC	0.772	0.891
Positive Predictive Value, %	66.7	80.0
Negative Predictive Value, %	85.7	95.5

The diagnostic characteristics for the diagnosis of iron deficiency of the conventional definition and TSAT19.8% ID=iron deficiency; TSAT=transferrin saturation; ROC=receiver operating characteristics; AUC=area under the curve.



Legend. Each dot represents one patient with the black dots reflecting normal bone marrow iron status and the red dots iron deficient patients. The red coloured area represents the most commonly used definition (ferritin <100 ng/ml or ferritin 100-300 ng/ml with a TSAT <20%). TSAT=transferrin saturation.

Biomarkers vs. bone marrow iron status

Background: LMNA-related familial dilated cardiomyopathy (fDCM) is caused by mutation in the LMNA gene and is characterized by left ventricular enlargement and reduced systolic function. LMNA-related DCM is an aggressive disease often leading to heart transplantation and sudden cardiac death. Currently, there are not circulating biomarkers that could be used to monitor cardiac abnormalities in LMNA-related DCM. Circulating microRNAs (miRNAs) are mediators of intercellular communication with great potential as cardiovascular biomarkers. However, no previous study has evaluated the clinical association between fDCM and circulating miRNAs.
Purpose: We aimed to identify novel diagnostic biomarkers of LMNA-related fDCM.
Methods: An initial screening study was performed in 8 patients with fDCM carrying the mutation in the LMNA gene and 8 age-matched healthy subjects without the LMNA mutation. Validation study was performed in three study groups: i) 20 fDCM patients with a LMNA pathogenic variant; ii) 20 idiopathic DCM (iDCM) patients without LMNA pathogenic variant; iii) 20 age-matched healthy subjects. Detailed clinical and echocardiographic information was obtained from each subject. The plasma miRNA signature was analysed using RT-qPCR as previously described by our group. Bioinformatic analysis was performed to explore the potential molecular pathways related to the miRNA profile observed in plasma.
Results: From the panel of 179 miRNAs evaluated in the screening study, a total of 111 miRNAs were specifically deregulated in patients with fDCM compared to healthy controls, even after adjusting for multiple comparisons. The expression level of 20-candidate miRNAs was then assessed in the validation study. Following post-hoc analysis, thirteen miRNAs were significantly upregulated in both DCM groups, fDCM and iDCM, compared with healthy group. Five miRNAs were significantly increased in fDCM group compared to healthy and iDCM control groups (let-7a-5p, miR-125a-5p, miR-142-3p, miR-145-5p and miR-454-3p). Two miRNAs (miR-191-5p and miR-222-3p) were different expressed between all study groups. Differences remain statistically significant even after adjusting for potential confounders. These miRNAs signatures were associated with molecular pathways potentially implicated in the disease pathology. The levels of the established clinical parameter NT-proBNP differed between healthy and DCM groups; however, similar levels were observed between fDCM and iDCM groups.
Conclusions: We have identified, for the first time, a specific circulating miRNA profile which is differentially expressed in patients with fDCM. Interestingly, the miRNA signature of fDCM was different from that observed in a similar clinical entity such as iDCM. This circulating miRNA signature could serve as novel non-invasive biomarker for risk stratification in this challenging population and provide clinical information about the physiopathology of LMNA-related DCM.

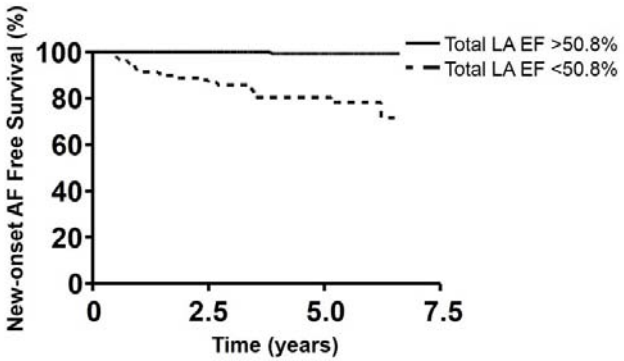
Total left atrial emptying fraction determined by real time 3-dimensional echocardiography is an independent predictor of new-onset atrial fibrillation in patients with Chagas disease

CAS Nascimento[1]; NP Pacheco[2]; GF Alves[2]; FS Madeira[2]; AR Costa[2]; AS Sousa[2]; MT Holanda[2]; LHC Sangenis[2]; FSNS Mendes[2]; HH Veloso[2]; GMS Silva[2]; MF Mediano[2]; SS Xavier[2]; RM Saraiva[2]

[1]National Institute of Cardiology, Rio de Janeiro, Brazil; *[2]Oswaldo Cruz Foundation, Evandro Chagas National Institute of Infectious Disease, Rio de Janeiro, Brazil*

Background: Changes in LA function are common in heart failure and Chagas disease. LA function parameters predict risk of atrial fibrillation (AF) in several conditions. Therefore, LA function analysis can yield new prognostic indicators in Chagas disease.
Purpose: Evaluate if LA function indexes derived from new echocardiographic techniques, including real time three-dimensional echocardiography (RT3DE) and strain () analysis, can predict new-onset AF in patients with Chagas disease.
Methods: This is a prospective longitudinal study including adult patients with indeterminate and cardiac forms of Chagas disease. All patients underwent echocardiographic evaluation including 2-dimensional echocardiography, evaluation of left ventricular (LV) diastolic function (mitral inflow, pulmonary vein flow, color M-mode echocardiography, and tissue Doppler analysis), and LA function by RT3DE and strain analysis. New echocardiographic indexes studied included LA maximal, minimal and pre-A volumes, total, passive and active LA emptying fractions, and LA total, positive and negative . A multivariate Cox proportional-hazards regression analysis was performed to identify independent predictors of new-onset AF. ROC (receiver operating characteristic) curves were generated to determine the optimal cut-offs, with corresponding sensitivities and specificities, to preview new-onset AF. Cumulative survival curves were constructed using the KaplanMeier method in combination with log rank test. P values of 0.05 or less were considered significant.
Results: A total of 391 patients with Chagas disease (age 53 ± 11 years old; 40% male) were included and followed prospectively for the occurrence of new-onset AF during 3.9 ± 1.9 years. From those, 145 patients presented the indeterminate form and 246 presented the cardiac form of Chagas disease. A total of 24 events occurred during the study period. Cox proportional-hazards regression revealed that total LA emptying fraction (HR 0.93, 95% CI 0.91 to 0.96, P < 0.0001) and age (HR 1.06, 95% CI 1.00 to 1.12, P=0.03) were independent predictors of new-onset AF. The optimal cut-off value of total LA emptying fraction to predict new-onset AF prediction was 50.8% according to ROC curve analysis (area under curve 0.83, sensitivity 95.4%, specificity 69.2%, P < 0.0001). According to Kaplan-Meier analysis of survival, patients with total LA emptying fraction under 50.8% had a worse prognosis (HR=49.8, 95% CI 8.9 to 52.7, P < 0.0001).
Conclusions: In this series of patients with Chagas disease, a low total LA emptying fraction, determined by RT3DE, was an independent predictor of new-onset AF. This new echocardiographic index may add prognostic power to traditional parameters to predict new-onset AF in Chagas disease.



Survival curve free of new-onset AF

95

High prevalence of subclinical right ventricle cardiomyopathy among patients infected with human immunodeficiency virus on highly active antiretroviral therapy

MN Montoro Lopez[1]; CI Soto[2]; R Florez Gomez[1]; A Alonso Ladreda[1]; I Ponz De Antonio[1]; E Refoyo Salicio[1]; M Moreno[1]; JI Bernardino[2]; JJ Rios Blanco[2]; G Guzman Martinez[3]
[1]University Hospital La Paz, Department of Cardiology, Madrid, Spain; *[2]University Hospital La Paz, Internal Medicine, Madrid, Spain*; *[3]National Centre for Cardiovascular Research (CNIC), Madrid, Spain*

Background. The development of highly active antiretroviral therapy (HAART) has entailed a significant decrease in AIDS-related complications and mortality. However, cardiovascular disease has become the main cause of mortality among HIV + patients on HAART. Most of the published has been focus on LV pathology but there is scarce data about the existence of right ventricle (RV) abnormalities. Because of its known relation to pulmonary hypertension (PH) and hepatitis virus co-infection (HCV) hypothesized that there might be a significant prevalence of subclinical RV abnormalities in ambulatory HIV patients.
Methods: We conducted an analytic, observational, cross-sectional study in a tertiary hospital (Spain). We included HIV infected patients under routine follow-up in the specialized Internal Medicine clinic of our institution. All of them provided written informed consent. and underwent a comprehensive transthoracic echocardiogram at the Imaging Unit of the Cardiology department.
Results: A total of 100 HIV infected patients were included. Sixty-two showed some cardiac abnormality. RV heart disease was more frequent than LV disease (48 vs. 30 patients). Biventricular abnormalities were found in 15 patients. The most common abnormal finding was RV hypertrophy (RVH, 26 patients), although only 3 patients showed signs of PH. Abnormal RV fractional area change was observed in 17% while only 2% showed impaired LV ejection fraction(figure). Patients with RVH, were more prevalent among those with positive viral load, history of intravenous drug use and HCV co-infection(table).
Conclusion: In HIV-infected patients on HAART, subclinical RV abnormalities were common and even more prevalent than LV disease. RVH seems to be related not only to the presence of PH but also to positive viral load, history of IDU or HCV co-infection.

Factors linked to RVH

	RVH (total n=26)			RVH (without PH n=23)		
Variables	OR	95% CI	p	OR	95% CI	p
VL	4.14	1.14-14.99	0.02	3.61	0.94-13.86	0.05
IDU	3.78	1.47-9.72	0.006	3.75	1.39-10.13	0.007
HCV	2.79	1.08-7.23	0.03	2.71	1.00-7.42	0.05

RVH: right ventricle hypertrophy, VL: viral load, IDU: intravenous drug user, HCV: hepatitis C virus. PH: pulmonary hypertension Figure legend. LVH: left ventricle hypertrophy, LVD: LV dilation, LVSD: LV systolic dysfunction measured by Simpson biplane, LVDD: LV diastolic dysfunction, LAD: Left atrial dilation, RVH: right ventricle hypertrophy, RVSDg: RV systolic dysfunction measured by RV fractional area change, RVSDr*: RVSD measured by Pulsed Doppler S wave, RVSDr**: RVSD measured by TAPSE

Safety of metformin use in hospitalized acute heart failure patients with diabetes mellitus

J J Jin Joo Park[1]; JH Ohn[1]; CH Yoon[1]; DG Park[2]; IH Chae[1]; DJ Choi[1]
[1]Seoul National University Bundang Hospital, Division of Cardiology,, Seongnam, Korea Republic of; *[2]Hangang Sacred Hospital, Division of Cardiology, Seoul, Korea Republic of*

Funding Acknowledgements: This work was supported by Research of Korea Centers for Disease Control and Prevention [2010-E63003-00, 2011-E63002-00, 2012-E63005-00, 2013-E63003-0

Background: Diabetes mellitus is a common comorbidity in heart failure patients. Metformin is the drug of choice in diabetic patients; however, in contrast to chronic stable heart failure patients, there exists concern about lactic acidosis associated with metformin use in acute heart failure requiring hospital admission.
Methods: In Korea acute heart failure registry, a total of 5,620 patients with confirmed diagnosis of acute heart failure patients were consecutively enrolled at 10 university hospitals. In this analysis we included only patients with diabetes mellitus. The primary outcome was the composite of in-hospital all-cause mortality or heart transplantation. Secondary outcomes included admission to intensive care unit, the use of mechanical circulatory support, mechanical ventilation, and renal replacement therapy.
Results: Overall, 1,998 patients (35.5%) had diabetes mellitus. At hospital admission the prescription rate of anti-diabetic medication was 46.4%, 35.3%, 35.2%, 1.8%, 8.3%, and 11.9% for insulin, sulfonylurea, metformin, thiazolidinedione, acarbose, and DPP-4 inhibitor, respectively.
Patients with metformin use had lower all cause in-hospital death or urgent heart transplantation than those without metformin use (2.1% vs. 7.4%, $P < 0.001$). The rate of ICU admission, cardiopulmonary resuscitation, intravenous inotropes and vasopressor use did not differ between the patients with and without metformin use. Interestingly, the use of mechanical ventilation and renal replacement therapy, a potential outcome variable for lactic acidosis, was lower in patients with metformin use. After adjustment for significant covariates, metformin use was associated with reduced risk for in-hospital death and heart transplantation (OR, 0.37; 95% CI, 0.17-0.82).
Conclusions: Metformin use at admission for acute heart failure was not associated with an excess risk of in-hospital death or heart transplantation, suggesting that its use may be safe in heart failure patients.

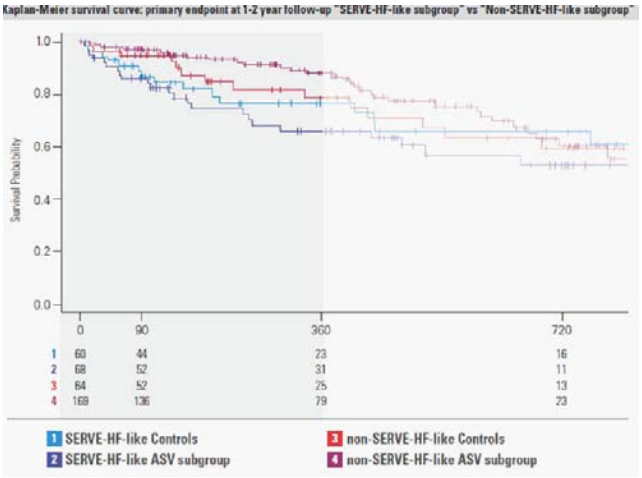
Morbidity and mortality of chronic heart failure (CHF) patients with central sleep apnoea (CSA) treated by adaptive servoventilation (ASV): Interim results of FACE cohort study

T Damy[1]; R Tamisier[2]; JL Pepin[2]; P Levy[2]; L Morin[3]; MP D'ortho[4]; JM Davy[5]
[1]University Hospital Henri Mondor, Heart Failure and Amyloidosis , Creteil, France; *[2]University Hospital of Grenoble, Physiology, sleep and Exercise, Grenoble, France*; *[3]ResMed Science Center, Martinsried, Germany*; *[4]University Hospital Bichat-Claude Bernard, Physiology and Functional Explorations, Paris, France*; *[5]University Hospital Arnaud de Villeneuve, Cardiology, Montpellier, France*

On behalf of: FACE Investigators
Funding Acknowledgements: ResMed

Background: Central Sleep Apnea (CSA) is associated with a worse prognosis of CHF. However SERVE-HF randomized control trial showed an increase of mortality risk in CHF with Reduced (CHF-REF) Left Ventricular Ejection Fraction (LVEF) with predominant CSA treated with ASV therapy.
Purpose: The multicentre cohort study FACE is collecting long-term real world clinical data of CHF-REF or CHF with Preserved LVEF (CHF-PEF) with CSA and eligible for ASV therapy.
Methods: Morbidity and mortality, changes in cardiac function, respiratory/sleep data, quality of life (using Minnesota Living with Heart Failure questionnaire) are assessed over a period of 2 years. The control group included patients who refused or was not compliant with ASV therapy. Combined primary outcome is time for all-cause death or unplanned hospitalization for worsening HF. Secondary outcomes are time for all-cause or cardiovascular-related death, all-cause unplanned hospitalization or unplanned hospitalization for worsening HF. Event-free survival will be estimated by Kaplan-Meier method and compared using log-rank test. Interim 1-2 year follow-up (FU) data are presented here.
Results: 361 CHF pts with CSA were included in the ITT analysis. Median FU for analysis was 11 months. Baseline characteristics were: age 70.7 ± 11.0 y, 88% male, body mass index 28.1 ± 5.1 kg/m2. LVEF was reduced or preserved in 65% and 35% of patients, respectively. 71% had predominantly CSA, and 29% had coexisting CSA and obstructive apnoea (CSA-OSA). Mean apnoea-hypopnoea index (AHI) was 43 ± 18/h and 76% of pts had severe sleep apnoea (AHI >30/h). ESS



score was 7.6 ± 5.2 (75% had no excessive sleepiness). Major comorbidities were arterial hypertension (72%), dyslipidemia (60%), moderate to severe Chronic Kidney Disease (54%), atrial fibrillation (42%), diabetes (37%), obesity (34%), cerebrovascular event (25%) or Chronic Obstructive Pulmonary disease (12%). Drug treatment included -blockers (77%), ACE inhibitors or angiotensin II receptor blockers (81%), diuretics (72%), and aldosterone antagonists (28%); non-drug therapy was a cardiac resynchronization device (12%) or implantable cardioverter defibrillator (17%). 66% of patients were compliant to ASV therapy (≥3h/night). Globally, adjusted multivariate analysis did not confirm any benefit or deleterious effect of ASV. However, CHF-REF with predominant CSA seemed to have poorer prognosis under ASV therapy compared to untreated patients. Conversely, other CHF populations (CHF-PEF or CHF with CSA-OSA) treated with ASV may have better survival.

Conclusion: CHF patients eligible for ASV therapy have severe CSA and multiple cardiac and metabolic comorbidities. These results are consistent with those of SERVE-HF trial. Furthermore, the FACE cohort study may be a useful tool to better understand the impact of ASV therapy in other CHF populations with CSA, especially in CHF-PEF or CHF with CSA-OSA. Long-term FU is expected for additional analysis of the FACE study.

HOT INSIGHTS IN METABOLIC INTERVENTIONS

Funding Acknowledgements: AFM

Background Myocardial metabolic impairment is a major feature in chronic heart failure (HF). The major drugs used in the clinic to treat HF do not directly address this problem. As a major coenzyme in fuel oxidation and oxidative phosphorylation metabolism and a co-substrate molecule for enzymes signaling energy stress and oxidative stress response (e.g. SIRT1, PARP1), NAD+ is emerging as a metabolic target in a number of diseases including HF. However, little is known on mechanisms regulating homeostasis of NAD+ in the failing heart and the interest of stimulating NAD+ biosynthetic pathways for HF therapy.
Methods: To explore possible alterations of NAD+ homeostasis in the failing heart, we quantified the myocardial levels of NAD+ and the expression of NAD+ signaling and biosynthetic enzymes in the heart of a mouse model of dilated cardiomyopathy and in human failing heart and studied the impact of NAD+ precursor supplementation on cardiac functions.
Results: We observed a 30% loss in levels of NAD+ in the murine failing heart that was accompanied by a shift in the expression level of enzymes involved in NAD+ synthesis. The expression of the NAMPT enzyme that recycles the nicotinamide (NAM) precursor is depressed whereas the NMRK2 kinase that phosphorylates the nicotinamide riboside (NR) precursor is strongly increased. This shift was also observed in human failing heart biopsies compared to non-failing controls. We show that the Nmrk2 gene is an AMPK and PPARalpha responsive gene that is activated by energy stress and NAD+ depletion and that NR efficiently contributes to NAD+ synthesis in isolated neonate and adult rat cardiomyocytes. Accordingly, NR supplementation in food stabilizes myocardial NAD+ levels in the murine failing heart while raising the levels of methyl-NAM and N1-Methyl-4-pyridone-5-carboxamide, which are terminal products of NAD+ metabolism inducing NRF2 antioxidant responses. NR supplementation also preserves citrate synthase activity and raises the acetylation level of FoxO1 transcription factor. Conclusions The data show that nicotinamide riboside could be useful for treatment of HF notably in the context of dilated cardiomyopathy, a disease with few therapeutic options.

Introduction: Recent evidence demonstrates that polyphenol-enriched alcoholic beverages can be beneficial for several chronic diseases. The purpose of this study was to investigate if consumption of a polyphenol-enriched beer could modulate the pathophysiology of pulmonary arterial hypertension (PAH).
Methods: Male Wistar rats (180-200g) were divided in two groups: Monocrotaline (MCT, sc, 60 mg/kg) and Control (sc, 0.9% saline solution). Animals were randomly divided accordingly to beverage intake: 5% ethanol (Control + ETOH, MCT + ETOH) and xanthohumol (XN)-fortified beer (Control + XN, MCT + XN). After 25 days of MCT, animals were submitted to cardiac stress test. At the end of the protocol (D28) the animals were submitted to hemodynamic evaluation, followed by sample collection of cardiac and pulmonary samples for histology and molecular biology.
Results: After 4 weeks of MCT, MCT + ETOH group presented a significant increase in the pulmonary arteries medial thickness (38%, $p < 0.0001$ vs. Control + ETOH). This remodelling was prevented in the MCT + XN groups through a decrease in the expression of proteins responsible for proliferation such as ERK1/2 (-50%, $p < 0.01$ vs. MCT + ETOH) and for cell viability such as AKT (-58%, $p < 0.05$ vs. MCT + ETOH). Additionally, the intake of XN-fortified beer resulted in the inhibition of the anti-apoptotic protein BCL-XL (-64%, $p < 0.05$ vs. MCT + ETOH). At cardiac level, MCT + ETOH rats presented an elevation of RV systolic pressure (128%, $p < 0.01$ vs. Control + ETOH). This increase was correlated with a rise in RV mass ($r = 0.71$, $p < 0.05$), fibrosis ($r = 0.87$, $p < 0.05$) and cardiomyocyte cross sectional area ($r = 0.24$, $p < 0.05$). Moreover, the cardiac remodelling observed in the MCT + ETOH animals was also associated with an increase in the VEGF-R2 expression (147%, $p < 0.05$ vs. MCT + ETOH). The ingestion of XN-fortified beer resulted in a significant attenuation of all these alterations in the MCT + XN group ($p < 0.05$ vs. MCT + ETOH). Lastly, the cardiopulmonary improvements observed in the MCT + XN animals contributed to the increase in the VO2max (30%, $p < 0.05$ vs. MCT + ETOH), exercise tolerance (73%, $p < 0.05$ vs. MCT + ETOH) and survival rate (40%, $p < 0.05$ vs. MCT + ETOH) of these.
Conclusion: This study demonstrates that regular consumption of polyphenol-enriched beer can interfere with proliferation and apoptosis signalling pathways associated with PAH, contributing to ameliorate some features in experimental PAH.

The role of endothelin-1 in mediating myocardial steatosis in diabetes cardiomyopathy

B Bambang Widyantoro[1]; N Hersunarti[1]; AU Rahajoe[1]; M Kasim[1]; N Emoto[2]; AM Soesanto[1]
[1]Dept of Cardiology and Vascular Medicine, Universitas Indonesia-NCVC Harapan Kita Hospital, Jakarta, Indonesia; *[2]Kobe University, Cardiovascular Medicine, Kobe, Japan*

Diabetes may cause endothelial dysfunction and remodelling of cardiac structure and function, independent to atherosclerosis and hypertension. Considering the increased risk of heart failure in diabetic cardiomyopathy, investigation of etiology and mechanism is important. Pre-clinical studies have shown association of endothelin-1 (ET-1) with cardiac fibrosis, and we have reported the involvement of endothelial cells-derived ET-1 in mediating cardiac fibrosis through endothelial-to-mesenchymal transition (EndMT). However, litle is known about mechanism of cardiac accumulation of triglycerides (cardiac steatosis/fatty heart). This present study combined experimental and clinical works to investigate the role of ET-1 in development of fatty heart in diabetes animal model and patients.
For animal study, we used mice with conditional knockout of ET-1 in vascular endothelial cells (VEETKO mice) and develop streptozotocin-induced diabetes model. VEETKO mice have less accumulation of triglycerides (TG) in myocardium as compared to its wild-type littermates, as shown by quantification of lipid droplets from electron microscopy and myocardial TG content by radioimmunoassay. The mechanism is under investigation, with oxidative stress and glucose transporter enzyme regulation being focused.
In addition, 41 diabetes and non diabetes subject with no history of myocardial infarct were recruited. PlasmaET-1 level were measured with radioimmunoassay, diastolic function by doppler echocardiography and myocardial TG content by MRI spectroscopy.
Plasma ET-1 level is higher in diabetes group (1.48 + 0.50 vs. 1.08 + 0.22 pg/ml, $p < 0.05$). All diabetes subjects develop diastolic dysfunction with higher grade as compared to non diabetes. Subject with severe diastolic dysfunction has higher ET-1 as compare to normal one (1.78 + 0.50 vs. 1.09 + 0.19 pg/ml). Diabetes subject with high plasma ET-1 level had higher myocardial TG content reflecting cardiac steatosis (0.77 + 0.04 vs. 0.60 + 0.03).
In conclusion, our animal study revealed prevention of cardiac steatosis in mice with lack of ET-1 and higher plasma ET-1 level is associated with accumulation of TG in diabetic human.

An intriguing case of cardiogenic shock: 2 pathologies and 2 modes of mechanical support

T A Tarique Al Musa[1]; D Neil[1]; H S Lim[1]
[1]*University Hospital Birmingham NHS Foundation Trust, Transplant Cardiology, Birmingham, United Kingdom*

A fit and well 54-year-old man presented acutely with an anterior ST elevation myocardial infarction. Primary percutaneous coronary intervention to the culprit LAD was attempted (Figure A) but revascularisation was unsuccessful. Cardiac MRI revealed an EF of 10%, transmural infarction with 12 non-viable segments, and anterior wall and septal microvascular obstruction. Catheter study showed RA pressure 4mmHg, PA systolic/diastolic/mean pressure 34/15/23, PA wedge pressure 20, cardiac index 1.7 L/min/m2 dependent upon on Intra-Aortic Balloon Pump. High sensitivity troponin remained persistently >10,000 over one week into admission. He underwent LVAD implantation with successful LV unloading and good RV systolic function. Post-operatively there was notable left-sided weakness and CT confirmed extensive infarction within the right MCA territory (Figure B). Stroke team evaluation deemed he was likely to be wheel-chair bound with preservation of right sided function and speech. On day 6, he developed recurrent episodes of haemodynamically significant VT and VF despite amiodarone, lignocaine and beta-blocker, requiring in excess of 60 external defibrillations. This precipitated a significant deterioration in RV function. We proceeded with temporary percutaneous RVAD support after extensive discussions with the family, in accordance with the patients perceived wishes for full treatment. A percutaneous dual lumen cannula was positioned in the PA via the right internal jugular vein (Figure C) and connected to a centrifugal pump. With biventricular support, he was treated with intravenous flecainide, which resulted in cessation of ventricular arrhythmias. By day 12, he developed profound hypoxemia despite oxygenator support with radiographic changes consistent with ARDS. Treatment was withdrawn on the basis of his large stroke, worsening ARDS and multi-organ dysfunction following discussions with his family. Examination of the ventricular core from LVAD implant revealed extensive necrosis, infiltrates and multinucleate giant cells diagnostic of Giant Cell Myocarditis (GCM) (Figure D, *).

Problems: 1) The survival benefit of an LVAD is balanced by the recognised potential for stroke and prognostication in this context is challenging 2). Malignant arrhythmias can compromise RV function and requires both anti-arrhythmic therapy and RV support. 3) GCM is a rare cause of malignant arrhythmias.

Discussion: 1). Stroke following LVAD mandates a multidisciplinary approach to decision making 2). Persistently high troponins and ventricular arrhythmias may well have been manifestations of an unexpected coexistent GCM. 3). The use of a percutaneous RVAD avoided re-sternotomy and facilitated control of ventricular arrhythmias.

Conclusions: Stroke, ventricular arrhythmias and RV failure post LVAD are clinically challenging. The histology of the ventricular core from LVAD implant should be examined routinely.

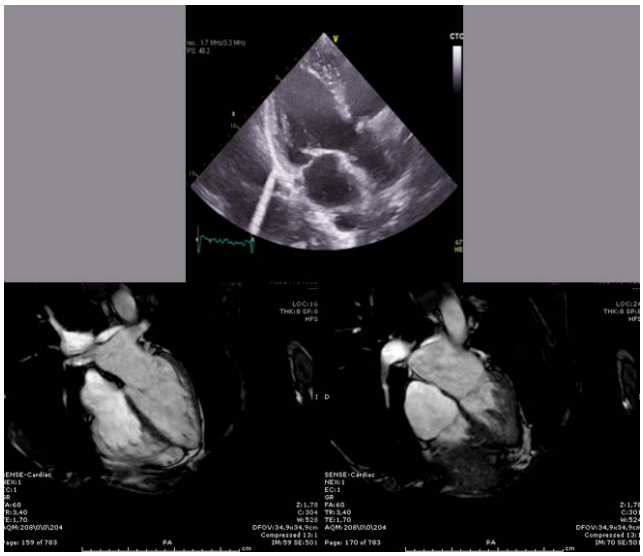
The starving myocardium

P Pastor[1]; F Dronda[2]; D Del Val[1]; GL Alonso[1]; M Valverde[1]; A Marco Del Castillo[1]; S Fernandez-Santos[1]; M Castillo[1]; E Gonzalez-Ferrer[1]; JL Zamorano[1]
[1]*University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain*; [2]*University Hospital Ramon y Cajal de Madrid, Infectious Disease Unit, Madrid, Spain*

Case description: A 51 year old man with previous diagnosis of HIV infection and heroin consumption presented in the emergency room because of breathlessness and orthopnea. He had a previously normal functional capacity and no heart disease was known. During the 5 weeks prior to admission, he had suffered progressive dyspnea with orthopnea and bilateral ankle swelling. He denied chest pain, syncope and palpitations. Besides, he had suffered severe dysphagia during the last three months due to oesophageal candidiasis. Physical exam at admission revealed cachectic appearence (body mass index: 16), audible third heart sound, bilateral pulmonary crackles, elevated yugular pressure and bilateral leg oedema. Arterial pressure was 121/68 and heart rate 102 bpm. Arterial oxygen saturation was 89% and respiratory rate was 19 breaths per minute. Chest x-ray showed an enlarged cardiac silhouette and bilateral pulmonary rales. ECG was unremarkable and BNP was elevated (2670 pg/mL). He was admitted with the diagnosis of normotensive acute heart failure and managed with intravenous diuretic therapy. A transthoracic echocardiography showed an enlarged left ventricle with global hypokinesis and moderately depressed systolic function (LVEF 38% by Simpson-biplane mode), as well as moderate functional mitral regurgitation secondary to annular dilation. Diastolic function showed a pseudonormal pattern and pulmonary artery pressure was mildly elevated. Right ventricle had a normal size function. Coronary angiography showed normal coronary arteries and elevated left ventricular telediastolic pressure. Because of the HIV-infection, subacute dysphagia and physical appearance, a complete nutritional evaluation was performed.



Pre-post nutritional supportive therapy

Possible differential diagnosis: In this scenario (HIV patient with poor nutritional status) two main possibilities need to be differentiated: HIV-related cardiomyopathy and malnutrition cardiomyopathy. The first nutrition-focused blood analysis showed low levels of total proteins (5.6 g/dL, normal values 6.4-8.3), serum albumin concentration (3.0 g/dL, normal values 3.5-5 g/dL), phosphorus (1.3 mg/dL, normal values 2.7-4.5 mg/dL), cholesterol (HDL 31 mg/dL, LDL 60 mg/dL), retinol binding protein (2.58 mg/dL, normal values 3.0-6.0 mg/dL), pre-albumin (10.9 mg/dL, normal values 20-40 mg/dL), vitamine A (22.2 ug/dL, normal values 30-60ug/dL) and L-carnitine (6uM/l, normal values 33-50 uM/l). Hemoglobin and platelet levels were within normal limits. Severe lymphopenia was present (470/μL), with 9.8% CD4 cells.

Oral nutritional supplements were initiated following current malnutrition guidelines. Diuretic intravenous treatment was continued for 4 days, and after congestive symptoms decreased oral enalapril and bisoprolol were initiated. The patients clinical situation improved quickly and he was discharged 16 days after admission in a good nutritional status, with all previously reported parameters within normal limits and a body mass index of 21. A cardiac magnetic resonance was performed in his last day of hospitalization, showing a normal-sized left ventricle without alterations in contractility and an LVEF of 52%, mild functional mitral regurgitation and no late-gadolinium enhancement. At discharge, he was included in an occupational integration programme and followed by social services, and his clinical situation one year later is good, without signs and symptoms of heart failure and controlled HIV status.

Conclusion: This case illustrates an infrecuent and reversible cause of heart failure (malnutrition-related cardiomyopathy) that might be underdiagnosed in clinical practice (especially in patients with chronic comorbidities) and emphasizes the importance of a multidisciplinary management of heart failure.

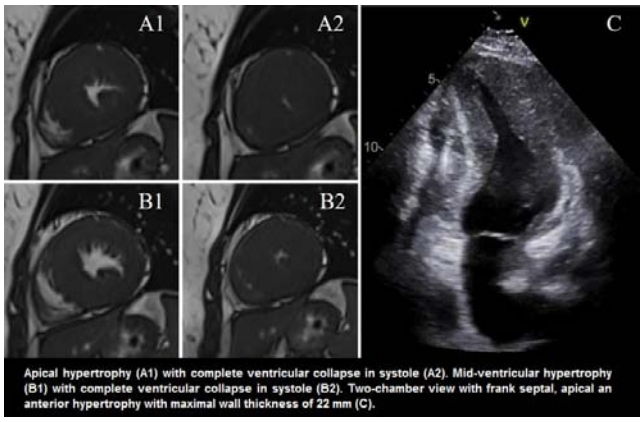
178

Recurrence of hypertrophic cardiomyopathy in a 25-year-old woman post heart transplant

J Jacinthe Boulet[1]; E Carelli[1]; N Giannetti[1]
[1]*McGill University Health Centre, Internal Medicine, Montreal, Canada*

This is a 25-year-old woman who was diagnosed at the age of 13 with autosomal dominant hypertrophic cardiomyopathy (HCM). She underwent an uncomplicated heart transplant 10 years ago. No genetic testing was done at the time of diagnosis but she had a strongly positive family history. The pathology of her native heart showed marked myocardial hypertrophy with focal interstitial fibrosis and no significant disarray or inflammation. The initial transthoracic echocardiogram (TTE) post transplant revealed an unremarkable heart. One year later, there was evidence of hyperdynamic left ventricular (LV) function. Four years post transplant, the cardiac apex appeared to be hypertrophied with obliteration of the distal LV cavity. A cardiac magnetic resonance imaging (CMR) showed LV apical hypertrophy suggestive of apical HCM. Significant progression of disease was observed on CMR 4 years later (July 2016) with maximum wall thickness of 22 mm at the apex, marked increase in LV mass (201g and LV mass index 112g/m2), and large areas of patchy subendocardial and mid wall scarring affecting the hypertrophied segments of the mid ventricle and apex (representing approximately 38% of the myocardial mass).

The differential diagnosis for apical HCM includes cardiac variant of Fabry disease, transthyretin-related hereditary amyloidosis, iatrogenic causes such as Tacrolimus-induced hypertrophy, and coronary artery disease. Undiagnosed pathologies in the donor heart include apical variant of HCM, isolated ventricular non-compaction, and neoplasm. At that time, Tacrolimus was stopped and changed for Cyclosporine. A Holter, requested in the context of palpitations, was remarkable only for intraventricular conduction delay. The patient underwent a PM/ICD insertion in November 2016 given her family history of sudden cardiac death. In December, she was treated for acute cellular rejection with Alemtuzumab and Prednisone. Repeat biopsies showed no evidence of rejection.



Apical hypertrophy (A1) with complete ventricular collapse in systole (A2). Mid-ventricular hypertrophy (B1) with complete ventricular collapse in systole (B2). Two-chamber view with frank septal, apical an anterior hypertrophy with maximal wall thickness of 22 mm (C).

Apical hypertrophy of transplanted heart

In January 2017, genetic analysis demonstrated that the allograft was heterozygous in the TTN gene for a sequence variant that has not previously been described in the primary literature. All biopsies and imaging to date have been inconclusive for the differential diagnoses elaborated upon above. Tacrolimus-induced apical variant of HCM remains a diagnosis of exclusion. At this time, the transplant team has decided to proceed with retransplantation.

Despite the significant advances of genetic testing for HCM, this case illustrates the limitations of detection of disease-causing mutations in patients with a phenotype of HCM. This may be relevant given the presence of HCM mimickers, such as Fabry disease which could have different implications for prognosis and management. On the other hand, management of true HCM is not influenced by the substantial heterogeneity described in pathogenic gene mutations.

179

Familial amyloidotic polyneuropathy and chylous ascites: The heart of the problem

M Maria Trepa[1]; I Silveira[1]; R Baggen Santos[1]; MF Oliveira[1]; L Caiado[1]; VA Dias[1]; S Torres[1]
[1]*Hospital Center of Porto, Cardiology, Porto, Portugal*

Hereditary transthyretin amyloidosis (ATTR) is the most frequent form of familial systemic amyloidosis. It remains a challenging diagnosis due to great phenotypic variability ranging between the most common and well known neurological involvement to strictly cardiac presentation.

We report the case of a 70 years old patient with late-onset familiar amyloid polyneuropathy (diagnosed late at 60yo with V30M mutation). We was the index case in his family and presented with peripheral polyneuropathy. His previous history was also remarkable for pacemaker implantation in 2010 due to 2 degree AV block and syncope, stage 2 (by MDRD) chronic kidney disease and class II NYHA heart failure with no previous decompensations.

He was transferred from his local hospital to our cardiology ward due to decompensated heart failure and acute on chronic kidney injury. In the two months preceding hospital admission, he developed generalized edema unresponsive to up-titration of oral diuretics, rapidly worsening dyspnea and orthopnea, and multiple episodes of symptomatic orthostatic hypotension. At hospital admission he was in anasarca with tension ascites and need for diagnostic and therapeutic paracentesis. Breath sounds were abolished at the base of both lungs and X-Ray had severe pulmonary congestion and pleural effusion with heart silhouette enlargement. There was no respiratory insufficiency. EKG was in ventricular pacemaker rhythm. The analysis of the peritoneal liquid showed an unsual high value for triglycerides (444 mg/dL) meeting criteria for chylous ascites. Transthoracic echocardiogram revealed severe biventricular hypertrophy (LV mass index 244g/m2) with moderate impairment of left ventricular ejection fraction. Right heart function was compromised with signs of pulmonary hypertension (PSAP 50 mmHg) and dilated inferior vena cava. There was diastolic dysfunction (E/e': 22) and pericadial thickening with small effusion.

Given the discrepancy between the relatively acute onset of HF symptoms andthe grade of myocardial hypertrophy combined with a surprising finding of chylous ascites we sought to rule out any other contributing causes for the clinical picture. Serum immunoelectrophoresis revealed a polyclonal band corresponding to a immunoglobulin G of uncertain significance. Tc-DPD scintigraphyshowed significantly enhanced DPD uptake (visual score 3) in the myocardium, compatible with transthyretin amyloid deposition. Extensive laboratory work up and a thoracic-abdominal-pelvic computed tomography ruled out neoplasic, obstructive or lymphatic causes for chylous ascites. After reviewing the literature for similar cases, we assumed the diagnosis of chylous ascites due to right heart failure and associated portal hypertension.

The patient slowly improved clinically and was discharged after 3 weeks although fluid management was challenging. Due to the preferential depletion of intravascular volume by loop diuretics, moderate increases in their dose lead to various episodes of symptomatic hypotension. Balance was achieved by careful dosing of furosemide, metolazone and spironolactone combined with scheduled paracentesis combined and fluid intake restrictions.

This case is remarkable because of three distinct important messages:

The late onset and the exuberant cardiac infiltration is quiteuncommon for patients with Portuguese type V30M mutation who usually have mainly a neurological phenothype.

Heart failure is a rare cause of chylous ascites and its usually an exclusion diagnosis. Severely impaired cardiac compliance creates challenges to achieve optimal diuretic dosing that permits sufficient removal of third space fluid without major intravascular depletion.

180

An 85-year-old man with progressive dyspnea after eating fish

H Park[1]; J Y Jae Yeong Cho[1]; KH Kim[1]; HJ Yoon[1]; JC Park[1]; DY Hyun[1]; JM Won[1]
[1]*Chonnam National University Hospital, Cardiology, Gwangju, Korea Republic of*

An 85-year-old male patient presented to emergency room with a complaint of progressive dyspnea started 2 days ago. He complained of al little bit of abdominal

discomfort also. On chest auscultation, inspiratory crackles were noted on both lung field suggesting pulmonary edema. His electrocardiogram showed mild left ventricular hypertrophy and widespread T-wave inversions in precordial leads. His chest x-ray revealed a haziness in both lung field suggesting pulmonary congestion. In the laboratory findings, leukocytosis (11,100 /mm3), mildly elevated liver function tests, elevated serum creatinine (1.4 mg/dL) and hyperkalemia (6.0 mEq/L) were noted. However, cardiac troponin was not elevated on admission.

His echocardiography showed decreased basal wall motion and relatively preserved mid to apical contraction with a left ventricular ejection fraction of 28%. A coronary angiogram was performed to rule out acute coronary syndrome and showed patency on the left and the right coronary arteries. A ventriculogram also displayed good mid to apical left ventricular wall motion with an akinesia in the basal wall.

The management of heart failure was performed with diuretics and an angiotensin-converting enzyme inhibitor. The peak cardiac troponin- I level was increased up to 10.8 ng/ml.

By the way, we looked at the chest x-ray again and discovered some kind of inverted-J-shaped material in the midline within the trachea. It was obviously silhouette of a fish hook. The fish that he ate 2 days ago must have been caught with the hook by a fisherman. The final diagnosis was made as a stress-induced cardiomyopathy associated with a foreign body in the esophagus and a surgical removal of a 2cm-sized fish hook from his esophagus was performed to prevent mediastinitis with rupture. The procedure was successful and the cardiac troponin-I level started to decrease after the surgery. On hospital day 14 just before discharge, his ECG showed normal sinus rhythm and T-wave inversion in multiple precordial leads has been resolved. Follow-up echocardiography showed no regional wall motion abnormality and the ejection fraction of 68%. He was discharged without any further problem.

Stress-induced cardiomyopathy is usually caused by emotional or physical stress. However, the actual causes are unknown in up to 30% of cases. In the present case, we discovered a fish hook a little bit late because the old man strangely did not complain of throat or chest pain at first. Physicians should not overlook chest X-ray and food history in acute heart failure without any coronary lesion.

A fish hook from the patient's esophagus

Making the case for complex cardiogenic shock: from profile to recovery

A Hernandez-Montfort[1]; E Lau[1]; M Slawsky[1]; A Islam[1]; G Valania[1]; J Chou[1]
[1]*Baystate Medical Center, Heart and Vascular Center, Springfield, United States of America*

Introduction: Cardiogenic shock remains a complex and heterogeneous clinical disorder associated with high mortality challenging cardiovascular programs across the world. We present a profiled case of cardiogenic shock in which staged interventional and pharmacological therapies to treat complex coronary and stenotic aortic disease where performed with the aid of two separate temporary mechanical circulatory support devices.pgtaghb**Description:** 71 year old gentleman (BMI 26) with hypertension, dyslipidemia, CAD s/p CABG 2006 (LIMA-LAD, SVG-OM1 and SVG-R PDA), severe calcific aortic stenosis, HFrEF NYHA II ACC D due to ischemic cardiomyopathy presented with de novo ACS related acute heart failure syndrome with pulmonary edema clinical profile associated with new onset atrial fibrillation with rapid ventricular response/aberrant conduction which required mechanical ventilation followed by PAC insertion which showed: RA 20 mmHg, PA 80/50 mmHG, PCWP 30 w/V waves 40 mmHg and CI by Fick 2.0. ECHO estimated AVA 0.8 cm2, LVEF 20% akinesis of anterolateral/apical/inferior wall with moderate functional MR and reduced right heart function. Intra-aortic balloon pump was placed with angiography revealing patent LIMA-LAD and SVG-R PDA but 100% occluded SVG-OM1 graft with severe LM disease (80%) and mid LAD (80%) and critical osteal LCX (90%) this latter vessel supplying territory of the previously occluded vein graft to OM1. The IABP + dobutamine under PAC guided therapy was then transitioned to Impella CP in which BAV and PCI with balloon angioplasty of LAD and rotational atherectomy with DES of LCX. The patient had a favorable clinical response and Impella CP was weaned and removed following our standard daily echo/hemodynamic protocol in 72 hrs and was extubated off inotropes 3 days after. He was discharged on low dose diuretics with no residual end organ function damage. Patient returned from home 6 weeks after and underwent succesful TAVR with #26 Edward-Sapiens bioprosthesis and has remained 1-2 months after with adequate functional capacity and quality of life, while tolerating neurohormonal therapy with a low range proBNP.pgtaghb**Question:** Does adequate profiling in complex CS treated with early temporary MCS allows the possibility of treating potentially reversible rhythm, valvular and coronary abnormalities with the aim of transition to myocardial recovery?

Conclusion: Further research studies in CS are needed and should focus on profiling with adequate clinical, echocardiographic and hemodynamic data in addition to best practices in transitions from acute MCS to durable solutions that are focused on myocardial recovery rather than LVAD or HTx.

THE VERY BEST FROM CLINICAL CASES - 1

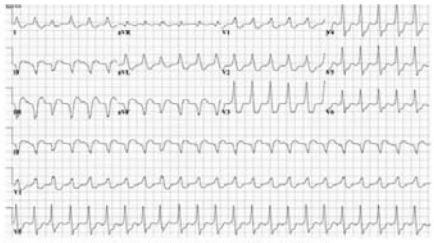
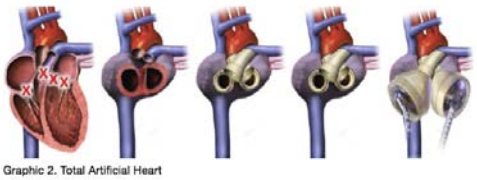
Acute heart failure exacerbation of idiopathic cardiomyopathy in the setting of electrical storm secondary to ventricular tachycardia: Total artificial heart or left ventricle assist device?

J S Juan Rico Mesa[1]; C Hoyos[1]; R Correa[2]; M Prasad[3]; S Kapa[3]
[1]University CES, Antioquia, Medellin, Colombia; *[2]Cardiovascular Clinic Santa Maria, Medellin, Colombia*; *[3]Mayo Clinic, Rochester, United States of America*

Introduction and Background: Acute Heart Failure (AHF) may have multiple etiologies. Ventricular Tachycardia (VT) electrical storm is a life threatening-condition that can cause AHF., In patients with VT electrical storm and reduced Left Ventricular Ejection Fraction (LVEF), who are refractory to medical management, salvage therapies with mechanical heart assist devices as a bridge to Orthotopic Heart Transplantation (OHT) may be useful.
Case report description: A 64-year-old male presented with AHF secondary to VT electrical storm. He had a history of idiopathic dilated cardiomyopathy with reduced LVEF (16%) and had a dual-chamber Intracardiac Defibrillator (ICD) for secondary prevention of sudden cardiac death. After admission, he failed medical management with Amiodarone, Lidocaine and Sotalol, requiring multiple electrical cardioversions despite dose optimization. Subsequently, endocardial and epicardial VT ablations were attempted followed by stellate ganglion block, without rhythm control. Unfortunately, he had worsening LVEF, evident signs of low cardiac output despite inotropes and multiple cardiac arrests in the context of recurrent episodes of sustained VT.



Graphic 1. Electrical storm secondary to ventricular tahycardia



Graphic 2. Total Artificial Heart

VT electrical storm and TAH

Description of the problem, procedures and clinical decision-making: A discussion involving the Heart Failure (HF) team and Electrophysiology (EP) staff suggested that his cardiovascular condition would benefit from OHT in the long-term. To achieve this, bridge therapy was considered for AHF compensation. Veno-arterial Extra Corporeal Membrane Oxygenation (ECMO) was utilized in the acute setting for hemodynamic stabilization, but given that its use was only possible for a limited period of time, long-term therapies were the main objective. Thus, further artificial therapies with a Left Ventricle Assist Device (LVAD) or Total Artificial Heart (TAH) were considered as a bridge to transplant. LVAD would have provided left ventricular support but given the severe right ventricular dysfunction and recurrent arrhtymias, this was not thought to be a good option. Total Artificial Transplant instead, guaranteed superior hemodynamic stability and eliminated the need for medical right ventricular support or rhythm control. Acute heart failure compensation was achieved after he successfully responded to TAH implantation. Long-term support with TAH was continued and he is currently on a waiting list for OHT with ventricular biopsy results pending.

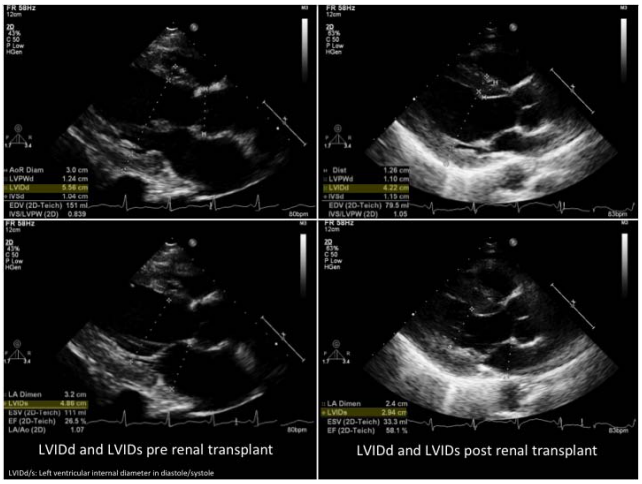
Conclusions and implications for clinical practice: This case exemplifies the importance of a multidisciplinary heart team decision on AHF management. Clinicians should carefully evaluate the benefits of TAH over LVAD as an alternative therapy for those patients with biventricular AHF in the setting of refractory VT and end-stage heart failure. These patients often present with right ventricular dysfunction, making TAH a suitable option. Further studies are needed to define specific indications for TAH implantation on clinical practice.

210

Two for the price of one: improvement in left ventricular systolic function in a patient with end stage renal disease following successful kidney transplantation.

M Webber[1]; P Dupont[2]; P Jeetley[1]
[1]Royal Free Hospital , Cardiology, London, United Kingdom; *[2]Royal Free Hospital , Acute Kidney Unit, London, United Kingdom*

Introduction: Left ventricular systolic dysfunction (LVSD) is prevalent amongst patients with end stage renal disease (ESRD) on dialysis and can disadvantage patients considered for renal transplantation. The best treatment strategies for these patients remain unclear and poorly understood.



LV dimensions pre and post transplant

Case: A 37-year-old female with a background of ESRD on haemodialysis secondary to renovascular disease presented to our department for routine assessment prior to renal transplantation. A transthoracic echocardiogram (TTE) revealed a dilated left ventricular (LV) cavity size with LV internal dimensions of 5.56cm in diastole and 4.86cm in systole. Her ejection fraction (EF) by Simpsons method was 25-30% indicating severe LV dysfunction. Following discussion in the cardio-renal MDT, she underwent exercise stress echocardiography to assess her LV response to exercise and to exclude underlying ischaemia. She had a reasonable effort tolerance achieving stage 3 of the Bruce protocol. Post stress echocardiography demonstrated contractile reserve with an improvement in LV function and no ischaemia. Coronary angiography confirmed the absence of significant coronary artery disease. She subsequently underwent an uncomplicated live donor related renal transplant. Two months later she reported an improvement in her exercise tolerance to NYHA class I. Her post-transplant TTE showed normalisation of her LVSD with an estimated EF of 55% and an improvement in her LV cavity dimensions to 4.22cm in diastole and 2.84cm in systole.pgtaghb**Problems:** Improvement in LVSD in ESRD patients post renal transplant has been described but the reason for this phenomenon is not

well understood. The optimal management for these patients is unclear, in particular whether recommendations for conventional treatment for LVSD can be extrapolated from the general population. These patients may be turned down for transplant on the basis of increased perioperative morbidity and mortality.
Discussion: It is thought that a prolonged exposure to uremic toxins, particularly "middle molecules", in dialysis patients may lead directly to cardiac myocyte dysfunction and LV impairment. Dialysis induced variations in blood volume and haemodynamics can also significantly affect systolic function. We have seen an improvement in EF in the post-transplant period in a number of our patients with non-ischaemic cardiomyopathy. We therefore postulate that in addition to conventional medical therapy for LV dysfunction, treatment regimes should also include optimising fluid management and early consideration for renal transplantation.
Conclusions: We have successfully demonstrated that renal transplantation can be safely performed in selected patients with LVSD and results in the improvement of EF, LV systolic dimensions and symptoms of heart failure. These patients, traditionally considered high risk for surgery, may benefit from early renal transplantation and demonstrate reversibility of their LV dysfunction.

A patient with human immunodeficiency virus infection and acute decompensated heart failure; never forget the pericardium

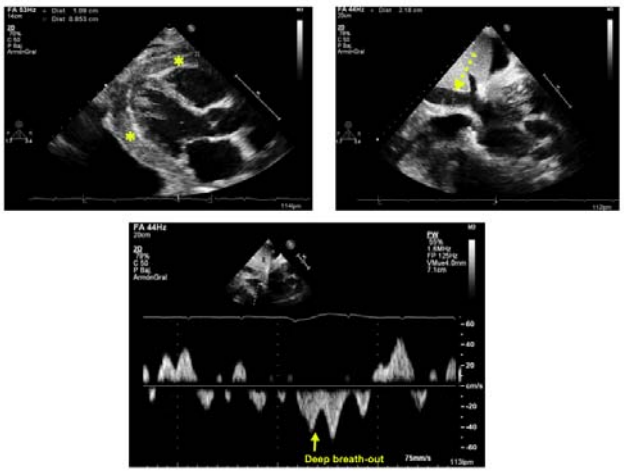
AF Miranda-Arboleda[1]; JP Florez-Munoz[2]; JA Gandara-Ricardo[2]; E Arevalo-Guerrero[2]; E Munoz-Ortiz[2]
[1]Universidad de Antioquia, Cardiologa , Medellin, Colombia; [2]Hospital Universitario San Vicente Fundacin, Servicio de Cardiologa, Medellin, Colombia

A 35-year-old male patient with past medical history of Human Immunodeficiency Virus (HIV) infection non-compliant to antiretroviral therapy (ARV) presented complaining of 2 moths of dyspnoea on exertion, fever, night chills and weight loss. M. tuberculosis was found from cultures and genome detection through protein chain reaction (PCR) in bronchial samples, pericardial fluid and pericardium samples obtained from a pericardial window. Disseminated tuberculosis infection was diagnosed and therapy was started.
He was readmitted due to dyspnoea, ortopnea, paroxysmal nocturnal dyspnoea, abdominal pain and anasarca. Exploration revealed bilateral jugular vein dissension, hepatojugular reflux, reduced breath sounds reduced, hepatomegaly, ascites and bilateral lower leg pitting edema. Electrocardiogram showed generalized low voltage, echocardiography proved pericardial thickening up to 13 mm, mild pericardial effusion, restrictive diastolic dysfunction, bilateral atrium enlargement, interventricular interdependence with inspiration, inversion of the flow diastolic in suprahepatic veins in exhalation, reduction of left ventricular inflow (E wave) >25% with inspiration and IVC dilation. Left and right ventricle systolic function were preserved.

Microbiological test.	
Adenosine deaminase in pericardial fluid	86 U/L (Reference: 0 to 10)
M. tuberculosis culture in pericardium biopsy	Positive
M. tuberculosis culture in pericardial fluid	Positive
M. tuberculosisprotein chain reaction in pericardial fluid	Positive
Pericardium biopsy	Granuloma formation with multinucleate cells and caveating necrosis.
M. tuberculosis culture in bronchoalveolar lavage	Positive
M. tuberculosis protein chain reaction in bronchoalveolar lavage	Positive
CD4 positive lymphocytes	294/ul
HIV Viral load	6595 copies/ml

HIV: human immunodeficiency virus

Questions, problems or possible differential diagnosis: What is the most probable diagnosis of this patient? What would be the acute initial management? What would be the best option for the long-term management?
Answers and discussion: Final diagnosis was tuberculous constrictive pericarditis in an HIV positive patient. Tuberculosis is the main cause of pericarditis and pericardial effusion in patients living in endemic countries and in patients with HIV infection it responds for more than 90% of cases. The mortality after pericardial tuberculosis can be as high a 40% six months after diagnosis.
Acute management was based on support intervention and symptomatic relief. Long-term management of this patient was made by the cardiovascular staff. The patient had poor prognosis predictors such as cachexia and limitation to give treatment for the primary diagnosis due to patient persistent refusal to take ARV medications. Taking this into account and the high mortality and morbidity associated with pericardiectomy, the patient was discharged with follow-up
Conclusions and implications for clinical practice: Tuberculosis and HIV infection are still a dangerous combination affecting patients living in developing countries. Pericardial involvement during M. tuberculosis infection can be disastrous during acute episodes generating the necessity of invasive procedures or extensive work-up increasing risk of complications. The decision-making process is not easy and must be individualized to each patient because medical therapy and surgical interventions also have the potential risks.



Echocardiographic findings

First report of heart failure due to zika myocarditis

I Mendoza[1]; K Karina Gonzalez Carta[2]; I Mendoza Britto[3]; I Morr[1]; T Allison[2]; F Misticchio[1]; Y Meza[1]; V Finizola[4]
[1]Central University of Venezuela (UCV), Instituto de Medicina Tropical, Caracas, Venezuela; [2]Mayo Clinic, Cardiovascular Diseases, Rochester, United States of America; [3]Jackson Memorial Hospital, Cardiac Electrophysiology, Miami, United States of America; [4]Lisandro Alvarado University , ASCARDIO, Barquisimeto, Venezuela

Introduction. Zika virus infection (ZIKV), is a mosquito-borne disease that has become a global health hazard. There are no reports of cardiovascular manifestations, heart failure (HF) or arrhythmias associated with ZIKV disease. Case report: A 51 year-old man from Venezuela, previously asymptomatic and with a history of well-controlled arterial hypertension and type 2 diabetes mellitus that in a recent medical evaluation had a normal electrocardiogram (ECG) and echocardiogram (TTE) with a left ventricular ejection fraction (EF) of 68 %. On May 2016, he developed low-grade fever, polyarthralgia, widespread pruritic maculopapular rash, conjunctivitis and myalgia. These clinical manifestations were resolved in 2 days. Five days after the onset of this acute episode, however, he was admitted to the hospital with rapid progressive dyspnea, rated according to the New York Heart Association (NYHA) as class IV. The ECG, five days after onset, showed a new left-bundle branch block and on the TTE a severely reduced EF of 16%. A coronary angiogram was performed which was normal. A holter recording showed frequent atrial and ventricular premature beats. A cardiac MRI (cMRI) exhibited severe impaired left ventricular systolic function (EF 16%), hiperintensive inferior wall signal on T2-weighted and lateral subepicardial enhancement in late gadolinium sequence. ZIKV-induced myocarditis was diagnosed based on the following criteria: i) ZIKV RNA was detected in serum with the use of reverse-transcriptase polymerase chain reaction (RT-PCR) and Zika virus-specific IgM antibody; ii) Potential simultaneous infection including Dengue, Chikungunya, HIV, and other virus or parasitic infections such as Chagas were ruled out; iii) Clinical, TTE, ECG and cMRI evidence of myocarditis was detected; iv) Normal coronary arteries on angiogram. The patient was initially treated with intravenous furosemide and oral digoxin for a period of one month, along with enalapril, carvedilol and eplerenone and his condition improved to NYHA Class II-III and then, after discontinuing enalapril and administering sacubutril/valsartan titrated

up to 200 mg twice daily, improved further to NYHA Class I. Discussion. Zika virus infection is usually mild with non-specific symptoms. Cardiovascular complications might be underdiagnosed in clinical practice. Therefore the importance of cardiovascular screening in suspected cases. Further research is needed to determine the pathophysiology of Zika myocarditis and would help to develop a pharmacological target and treatments for countering progression of the disease.
Conclusion: This is the first report of cardiac involvement with congestive heart failure in a patient with Zika. This case is unique since the patient developed rapidly progressive left ventricular dysfunction and new ECG changes, previously known to have normal cardiac function. Future research is needed to determine the incidence of cardiovascular involvement of Zika virus infection.

Zika myocarditis

	NYHA	EF (%)	ECG	Treatment

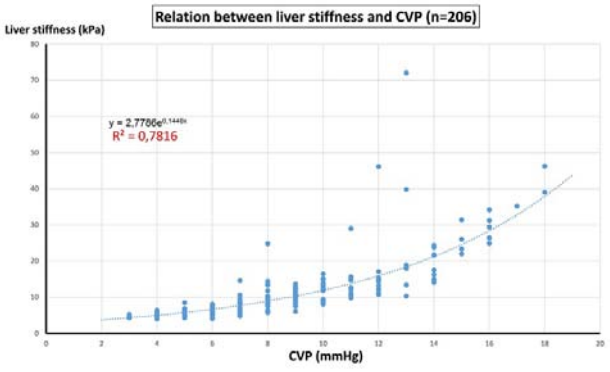
POSTER SESSION 1

ACUTE HEART FAILURE

P213
Towards non-invasive assessment of central venous pressure variations using real time and quantitative liver stiffness estimation

O Villemain[1]; F Sitefane[1]; M Pernot[2]; S Malekzadeh-Milani[1]; M Tanter[2]; D Bonnet[1]; Y Boudjemline[1]
[1]M3C Necker, Pediatric and Congenital Cardiology, Paris, France; *[2]Waves and Acoustics Laboratory Institute Langevin, Paris, France*

Objectives: The main purpose of this study was to assess the correlation between the liver stiffness (LS) estimated by shear wave elastography (SWE) and the central venous pressure (CVP) during hemodynamic variations in a cohort of children with heart disease.
Background: SWE has been shown and used as a non-invasive, quantitative and reproducible approach to assess LS. LS has been reported to be associated with fibrosis but there is also a potential dependence of LS with the CVP.
Methods: 103 children (6.8 ± 5.5 years) referred to our institution for diagnostic or interventional right heart catheterization (RHC) were prospectively enrolled. CVP and LS were measured simultaneously at baseline and after 15 ml/kg of volume loading. Inferior vena cava (IVC) diameter and pulsed-Doppler profile of hepatic veins were also evaluated. Plasma level of NT-pro-BNP was assayed during the RHC.
Results: At baseline RHC, the mean CVP was 7.4 ± 2.9 mm Hg [range 3–16] and the mean LS was 9.0 ± 5.8 kPa [4–46.1]. After volume loading, the mean CVP increased significantly to 10 ± 3.3 mm Hg [3-18] ($p < 10\text{-}4$) and the mean LS increased significantly to 14.4 ± 9.1 kPa [4.3-72] ($p < 10\text{-}4$). LS strongly correlated with CVP, pre-loading ($r=0.86$, $p < 10\text{-}4$) and post-loading ($r=0.87$, $p < 10\text{-}4$)]. Optimal cut-off value of LS for detection of CVP > 10 mmHg was 10.8 kPa (Se=89.3%, Sp = 86.0%), with an area under the curve of 0.946 (95% CI 0.920 to 0.971; $p = 0.01$). Beyond this correlation, LS is sufficient to provide an indirect and reliable measurement of quantitative CVP variations ($p < 10\text{-}4$, multivariate model). IVC diameter, pulsed-Doppler profile of hepatic veins and NT-pro-BNP were less robust than LS to estimate CVP.
Conclusions: Here, we show that LS measurement using SWE is a reliable surrogate of quantitative estimation of the CVP. It can also be used to measure CVP changes in real time. LS could potentially be a useful non-invasive tool for evaluation and follow-up of acute and chronic right heart failure.



Relation between liver stiffness and CVP

P214
Heart failure with mid-range ejection fraction: who are these patients?

L Reis[1]; A Fernandes[1]; C Lourenco[1]; R Teixeira[1]; M Marta[1]; P Dinis[1]; J Ribeiro[1]; L Puga[1]; I Almeida[1]; J Nascimento[1]; L Goncalves[1]
[1]University Hospitals of Coimbra, Coimbra, Portugal

Introduction: Classification in heart failure (HF) is based on the left ventricular ejection fraction (LVEF). The most recent European guidelines created a new group of patients with a LVEF - 40-49% (mid-range LVEF). However, few data are available regarding these patients (P).
Objectives: To evaluate P with HF with mid-range LVEF in demographic, clinical, treatment and prognostic terms.
Methods: Retrospective and single-center study involving 263 P consecutively admitted into a cardiac intensive care unit during 6 years. Three groups were created according to the LVEF: reduced LVEF (G1: LVEF < 40%, N=182), mid-range LVEF (G2: LVEF 40-49%, N=34) and preserved LVEF G3: FEVE≥50%, N=47). Demographic, laboratory, echocardiographic, therapeutic and prognostic data were compared. Clinical follow-up (5 years) was performed targeting for readmission with AHF and mortality.
Results: The population mean age was 70 ± 13 years old with a majority of male patients (78%). Readmission for HF occurred in 40% of the cases. In-hospital mortality was 15% and during the follow-up 42%.
During admission the groups presented similar clinical and analytical characteristics: congestive HF (G1 100% vs G2 91% vs G3 100%), NT-proBNP values (G1 17590 ± 23014 pg/nL vs G2 29137 ± 57308 pg/nL vs G3 13895 ± 16897 pg/nL) and creatinine (G1 151 ± 81 ug/dL vs G2 168 ± 137 μg/dL vs G3 157 ± 148 ug/dL). The etiology was ischemic in 28% of the P in G1, 4.1% in G2 and 22% in G3. Regarding treatment, no statistically significant differences were found in terms of intravenous diuretics were given in the majority (G1 72% vs G2 62% vs G3 63%); noradrenaline/dobutamine (G1 24% vs G2 14% vs G3 16%) and noninvasive ventilation (G1 52% vs G2 41% vs G3 56%).
When comparing the P of G1 and G2 we found that they had similar in-hospital mortality (93% vs 7.4%, $p = 0.204$) however P of G1 had higher mortality during follow-up (92% vs 8.0%, $p = 0.009$) and a higher rate of readmisson for HF (88% vs 12%, $p = 0.002$).
When comparing the P of G2 and G3, we found that P with mid-range LVEF had higher in-hospital mortality (85% vs 15%, $p = 0.034$) and during follow-up (77% vs 23%, $p = 0.009$), however, readmission rates for HF were similar (52% vs 48%, $P = 0.502$).
At discharge, there were no statistically significant differences among groups in terms of angiotensin-converting enzyme inhibitors, beta-blockers and diuretics treatment.
Conclusions: In our population, we concluded that P with mid-range LVEF presented a similar clinical profile to P with reduced and preserved LVEF. However, they present a higher in-hospital mortality and during follow-up as compared to P with preserved FEVE and similar in-hospital mortality as compared to P with reduced FEVE.

P215
HFmrEF in elderly patients: the pathogenetic role of ischemia. Real world data from the ATHENA registry.

F Orso[1]; A Pratesi[1]; S Parlapiano[1]; A Herbst[1]; F Bacci[2]; G Ciuti[2]; A Berni[2]; AC Baroncini[1]; G Baglioni[1]; N Marchionni[3]; L Gabbani[1]; L Poggesi[2]; A Moggi Pignone[2]; C Nozzoli[2]; S Baldasseroni[1]
[1]Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy; *[2]Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; *[3]Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: ATHENA study group

Background: Heart failure (HF) classification based on the presence of preserved or reduced left ventricular systolic function, which identifies two main categories of patients, those with HFpEF and those with HFrEF, has become important from an epidemiological, clinical, therapeutical and prognostic point of view. Recently, the European Society of Cardiology has recognized the presence of a "gray area" of patients with ejection fraction (EF) between 40 and 49% defined as "mid-range" (HFmrEF). Purpose: to better characterize patients with HFmrEF from an etiopathogenetic point of view in a real world setting of elderly patients hospitalised for acute HF.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (≥ 65 years) admitted with diagnosis of AHF (worsening or de novo) to the Emergency department (ED) of a tertiary University teaching-hospital in the period 01.12.2014-01.12.2015. The present analysis included patients with complete echocardiographic data.
Results: 246 patients were included in the present study: patients with HFmrEF were 19.5%, 30.5% had HFrEF and 50.0% had HFpEF. Patients with HFmrEF and HFpEF shared similar demographic characteristics: higher mean age 83.8, 84.5 and 79.9 years, $p < 0.001$; higher prevalence of females 41.7%, 67.5% and 32.0% for HFmrEF, HFpEF and HFrEF respectively, $p < 0.001$. Ischemia seemed to be a common denominator for HFmrEF and HFrEF patients. History of coronary artery disease (CAD), was more frequent in patients with HFmrEF (41.7%) and HFrEF (36.0%) than patients with HFpEF (19.5%), $p = 0.004$, as well as the prevalence of previous percutaneous coronary intervention that was 27.1%, 25.3% and 11.5% for HFmrEF, HFrEF and HFpEF respectively, $p = 0.014$. Furthermore, ischemic aetiology of HF was typically present in patients with HFmrEF (47.9%) and HFrEF (40.0%), differently from those with HFpEF in which it was present only in the 28.5% of cases, $p = 0.038$. To further support the importance of ischemia, acute coronary syndromes represented, in patients with HFmrEF, the most frequent precipitating cause of acute HF (11.6%) and coronary angiography was the procedure most frequently performed during hospitalisation in elderly with HFmrEF (12.5%) and in those with HFrEF (22.7%) with percentage values higher than those reported for patients with HFpEF (6.5%), $p = 0.004$.
Conclusions: These data suggest that ischemia plays an important role in the pathogenesis of HFmrEF. We could therefore hypothesize that patients with HFmrEF are a heterogeneous group consisting of a subgroup of patients with HFpEF that, following an acute event, could have experienced a reduction of ejection fraction (EF) and of a subgroup of patients with HFrEF that, due to the positive effect of therapeutic strategies, could have improved at least part of the left ventricle EF: this group has also been recently been classified as HFrecEF (Heart Failure with Recovered Ejection Fraction).

P216

HFmrEF in elderly patients hospitalised for acute heart failure: data from the ATHENA registry.

S Parlapiano[1]; S Baldasseroni[1]; A Herbst[1]; A Pratesi[1]; F Bacci[2]; C Tozzetti[2]; C Ghiara[1]; G Ciuti[2]; G Baglioni[1]; L Poggesi[2]; C Nozzoli[2]; A Moggi Pignone[2]; L Gabbani[1]; N Marchionni[3]; F Orso[1]
[1]Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy; *[2]Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; *[3]Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: ATHENA study group

Background: Heart failure (HF) is a pathological condition that involves 65 million of people worldwide and has a high prevalence in the elderly. Recently, the European Society of Cardiology (ESC) has recognized the presence of a "gray area" of patients with ejection fraction (EF) between 40 and 49% defined "mid-range" (HFmrEF) and has redefined the specific cut off values for HF with preserved EF (> 50%, HFpEF) and HF with Reduced EF(< 40%, HFrEF).
Purpose: to better characterize patients with HFmrEF and compare them to those with HFpEF and HFrEF in a real world setting of elderly patients hospitalised for acute HF.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (≥ 65 years) admitted with diagnosis of AHF (worsening or de novo) to the Emergency department (ED) of a tertiary University teaching-hospital and transferred to cardiology, internal medicine and geriatric wards in the period 01.12.2014-01.12.2015.
Results: 246 patients with complete echocardiographic data composed the study population: patients with HFmrEF were 19.5%, 30.5% had HFrEF and 50.0% had HFpEF. HFmrEF and HFpEF had similar demographic characteristics, compared to patients with HFrEF: mean age of three group of patients was respectively 83.8, 84.5 and 79.9 years, $p < 0.001$; the prevalence of females was 41.7%, 67.5% and 32.0% for HFmrEF, HFpEF and HFrEF respectively, $p < 0.001$. With regard to cardiovascular risk factors: hypertension was more frequent in patients with HFmrEF (82.2%) than patients with HFrEF (79.5%) and diabetes was more frequent in patients with HFmrEF (41.3%) than patients with HFrEF (39.2%) and HFpEF (35.0 %). Furthermore with HFmrEF many of the most important comorbidities, such as chronic obstructive pulmonary disease, chronic kidney disease, atrial fibrillation, cognitive impairment or depression, were present with values more similar to those of patients with HFpEF. No significant differences were found in the setting of care for HFmrEF patients who were equally distributed among cardiology, internal medicine and geriatric wards ($p = 0.2$). In-hospital mortality was not significantly different in the three groups of HF patients ($p = 0.977$): HFmrEF (6.3%), HFpEF (5.7%) and HFpEF (5.3%). Patients with HFmrEF, however, had an increased, even if not statistically significant, hospital length of stay: 11.7 days, 9.4 days and 10.1 days for HFmrEF, HFpEF and HFrEF respectively ($p = 0.18$).
Conclusions: Our study shows that patients with HFmrEF represent a significant portion of patients with HF. These patients appear to have clinical and demographic characteristics similar to patients with HFpEF. Hospital length of stay and in-hospital mortality of patients with HFmrEF do not differ significantly to those with HFpEF and HFrEF. Studies are needed to confirm whether patients with HFmrEF can get the same benefits from the treatments that have proved to be effective for patients with HFrEF.

P217

Modified shock index at admission as predictor of in-hospital adverse events in patients with myocardial infarction

RA Rui Azevedo Guerreiro[1]; J Pais[1]; D Bras[1]; K Congo[1]; J Carvalho[1]; M Carrington[1]; D Neves[1]; AR Santos[1]; B Picarra[1]; A Caeiro[1]; J Aguiar[1]
[1]Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal

Introduction: Myocardial infarction (MI) presents even today a considerable in-hospital morbimortality. There are several risk scores to stratify patients with MI – TIMI, GRACE – but its sophisticated calculus does not help its utilization on a daily basis. Modified shock index (MSI), defined by the ratio of cardiac frequency / mean blood pressure at admission, due to its easy calculation, can be an advantage in the risk stratification of patients with MI.
Purpose: Authors pretend to validate MSI as predictor of in-hospital adverse events in patients with myocardial infarction and to calculate the best cut-off point that maximizes sensibility and specificity.
Methods: Observational retrospective study, with a sample of consecutive patients admitted for MI. MSI at admission was calculated for all patients. As in-hospital adverse events were considered death by any cause, aborted sudden cardiac death, cardiogenic shock, acute pulmonary oedema and re-infarction during hospitalization. The value with the highest Youden-index of ROC curve was defined as the cut-off point and its sensibility and specificity was calculated. MSI with values above the cut-off point were considered positive. Uni and multivariate analysis were performed to access the association between positive MSI and in-hospital adverse events.
Results: 692 patients were included, with mean age 67.56 ± 13.79 years, 503 (72.69%) men, of which 135 (19.51%) patients had an in-hospital adverse event. Patients with positive MSI were older (69.33 vs 66.78 years, $p = 0.025$), less men (65.6% vs 75.8%, $p = 0.005$), with higher prevalence of diabetes (42.7% vs 31.7%, $p = 0.005$), less prevalence of smoking (21.1% vs 30.3%, $p = 0.013$) and without statistically significant difference in the prevalence of arterial hypertension (78.7% vs 76.3%, p = NS), hyperlipidaemia (57.5% vs 54.7%, p = NS) and family history of coronary artery disease (7% vs 6.7%, p = NS). Patients with positive MSI had similar distribution of types of MI ($p = 0.057$; with ST-segment elevation: 43.4% vs 42.7%), similar severity of coronary artery disease ($p = 0.115$) but with more frequent occlusion of left anterior descending coronary artery (25.7% vs 18.7%, $p = 0.018$) and less frequent reperfusion therapy (73.3% vs 86.1%, $p = 0.009$). Area under the curve ROC for MSI as predictor of in-hospital adverse events in patients was 0.664 and the best cut-off point was 0.9, with 51% sensibility and 77% specificity. In univariate analysis, positive MSI was predictor of in-hospital adverse events (OR 3.03, 95% CI 2.05 – 4.46, $p < 0.001$). In multivariate analysis, controlling for age, sex, diabetes and smoking, positive MSI was still predictor of in-hospital adverse events (OR 2.69, 95% CI 1.77 – 4.09, $p < 0.001$).
Conclusion: MSI at admission was predictor of in-hospital adverse events in patients with myocardial infarction. Patients with MSI above 0.9 have 169% more risk of having in-hospital adverse events, with 51% sensibility and 77% specificity.

P218

CHA2DS2VASc score an useful tool to predict heart failure in patients admitted with STEMI

G Abreu[1]; P Azevedo[1]; C Rodrigues[1]; I Campos[1]; C Braga[1]; J Martins[1]; C Arantes[1]; S Rocha[1]; A Gaspar[1]; M Alvares Pereira[1]; J Marques[1]
[1]Hospital de Braga, Cardiology, Braga, Portugal

Background: The CHA2DS2VASc score is used clinically for stroke risk stratification in atrial fibrillation (AF). Many of the individual risk factors included in this score are also risk factors for heart failure.
Aim: To examine the CHA2DS2-VASc score performance in predicting acute heart failure in subjects admitted with ST segment elevation myocardial infarction.

Methods: We analysed 851 patients admitted consecutively in our coronary care unit with a diagnosis of ST segment elevation myocardial infarction in a five-year period. Patients with previous atrial fibrillation (n = 36) or in cardiogenic shock (n = 30) were excluded. CHA2DS2-VASc score was calculated for each patient. The cohort was divided in three groups according to the value obtained: CHA2DS2VASc 0-1 (n = 243, 31%); CHA2DS2VASc 2-3 (n = 334, 42.5%); and CHA2DS2VASc ≥4 (n = 208, 20.5%). For each group we compared clinical and laboratory features, treatment and adverse events. Primary endpoint was the occurrence of acute heart failure after a STEMI.
Results: Patients from CHA2DS2VASc ≥4 group were older (76 ± 9 vs 64 ± 11 vs 55 ± 9 years; $p < 0.001$). Conventional risk factors were more represented in the higher CHA2DS2VASc score groups: diabetes (51.0% vs 31.1% vs 7.4%; $p < 0.001$), hypertension (90.9% vs 75.7% vs 37.9%; $p < 0.001$) and dyslipidaemia (59.6% vs 59.9% vs 42.6%; $p < 0.001$); except for smoking (8.2% vs 33.2% vs 56.8%; $p < 0.001$). On admission patients with CHA2DS2VASc ≥4 had more often anaemia (40.1% vs 20.1% vs 12.3%; $p < 0.001$), renal insufficiency (eGFR < 60 ml/min) (54.6% vs 19.5% vs 3.7%; $p < 0.001$) and three vessels disease (21.2% vs 17.5% vs 9.1%; $p = 0.005$). Left systolic ventricular dysfunction was more prevalent (59.1% vs 39.8% vs 34.6%; $p < 0.001$) in that group. During hospital-stay, patients with CHA2DS2VASc ≥4 developed more frequently heart failure (52.4% vs 24.9% vs 16.9%; $p < 0.001$), new-onset atrial fibrillation (19.2% vs 11.1% vs 4.1%; $p < 0.001$); ischemic stroke (2.9% vs 0% vs 0.4%; $p = 0.002$) and respiratory tract infection (11.1% vs 3.0 vs 5.3%; $p < 0.001$). In-hospital (8.7% vs 2.4% vs 0.4%; $p < 0.001$) and 6-month overall mortality (16.7% vs 6.4% vs 2.5%; $p < 0.001$) were higher in patients with higher CHA2DS2VASc score. In multivariate analysis and after adjusting for different baseline characteristic CHA2DS2VASc score revealed to be an independent predictor of development of heart failure (0.041). Patients with CHA2DS2VASc ≥4 were associated with higher risk of development heart failure [OR 2.88, 95% CI (1.27 - 6.54), $p = 0.012$] compared to those with CHA2DS2VASc 0-1.
Conclusion: CHA2DS2VASc score revealed to be a strong predictor of acute heart failure among STEMI patients.

Endocan - Novel biomarker in patients with acute heart failure?

I Potocnjak[1]; M Trbusic[2]; S Dokoza Teresak[1]; G Pregartner[3]; S Frank[4]; V Degoricija[2]
[1]University Hospital Centre Sisters of Charity, Zagreb, Croatia; *[2]University of Zagreb School of Medicine, Zagreb, Croatia*; *[3]Medical University of Graz, Institute for Medical Informatics, Statistics und Documentation, Graz, Austria*; *[4]Medical University of Graz, Institute of Molecular Biology and Biochemistry, Center of Molecular Medicine, Graz, Austria*

On behalf of: AHF study group

Background: Endocan is known as an endothelial cell-specific molecule 1 (ESM-1), exhibiting anti-inflammatory properties. It is a proteoglycan with a chondroitin/dermatan sulfate chain. Its elevated level is connected with endothelial activation, inflammation and carcinogenesis. According to the manufacturer, the normal range is 0.3-3ng/mL. To our knowledge, endocan has not been previously investigated in Acute heart failure (AHF) patients (pts).
Purpose: The aim of this study was to investigate the impact of sex, age, ejection fraction (EF), NYHA classification, CRP and blood pressure (BP) on endocan values in AHF pts.
Methods: The study was performed as a prospective, non-interventional, single-center observational study from November 2013 to February 2015 in the University hospital centre, Croatia. There were 80 pts with AHF included. Complete analysis was performed for 75 pts since five of them had high endocan values (≥20ng/ml), which were considered unmeasurable. For analysis, ELISA kit was used to detect and quantify human Endocan/ESM-1 in serum. Pts were grouped according to demographic and laboratory parameters, with cut-off values of 5mg/L for CRP, ≤40%, 41-49%, and ≥50 for EF, and 140/90mmHg for BP. Pts were classified and treated according to ESC guidelines. The study was conform to the principles of the Declaration of Helsinki of the World Medical Association. Differences between the groups were determined by the non-parametric Mann-Whitney U or Kruskal-Wallis test. Results will be shown as median and minimum and maximum. The analyses were conducted using R version 3.3.1.
Results: The median endocan concentration was 4.8ng/ml (1.3-15.2). Endocan was not significantly different between the sexes [4.8ng/ml (1.3-15.2) for men, 4.4ng/ml (1.5-14.7) for women; $p = 0.848$]. Pts ≤75 years of age had a median value of 3.2ng/ml (1.6-14.7) and pts >75 had 5.2ng/ml (1.3-15.2) ($p = 0.054$). The median endocan value in NYHA classification groups 2 or 3 was 4.8ng/ml (1.3-15.2) and 4.6ng/ml (1.5-14.7) in group 4 ($p = 0.630$). In pts with normal CRP (≤5), median endocan was 4.3ng/ml (1.6-14.7) and with elevated CRP (>5) was 5.2 ng/ml (1.3-15.2) ($p = 0.610$). According to EF, the median endocan value for pts with decreased EF ≤40% was 5.0ng/ml (1.5-14.7), with an EF 41-49% was 4.8ng/ml (1.3-14.3) and with EF ≥50 was 4.4ng/ml (1.6-15.2) ($p = 0.625$). Pts with a systolic BP of < 140mmHg had a median endocan value of 5.5ng/ml (1.3-15.2) whereas with ≥140mmHg had 4.2ng/ml (1.6-14.7) ($p = 0.148$). For diastolic BP, pts with < 90mmHg had a median endocan value of 4.8ng/ml (1.3-15.2) whereas with ≥90mmHg had 4.4ng/ml (1.6-14.7) ($p = 0.595$).
Conclusion: To our knowledge this was the first research of endocan in AHF pts. According to the results of this study on 75 pts, endocan was higher in our AHF pts compared to previously measured values in healthy volunteer, but did not differ significantly between groups according to sex, age, EF, NYHA classification, CRP and BP.

P220

Impact of an advanced heart failure program on the characteristics and care of patients admitted with worsening heart failure in a developing country

F Bader[1]; M Al-Sarie[2]; G Gabra[1]; M Soliman[1]; B Bassam Atallah[3]; M Khalil[1]
[1]Cleveland Clinic Abu Dhabi, Cardiovascular Medicine, Abu Dhabi, United Arab Emirates; *[2]University of Toledo Medical Center, Toledo, United States of America*; *[3]Cleveland Clinic Abu Dhabi, Pharmacy Services, Abnu Dhabi, United Arab Emirates*

Background: Heart failure (HF) is a leading cause of global morbidity and mortality. Management of HF patients requires comprehensive multidisciplinary clinical care, best provided through the establishment of advanced HF programs. Such programs have become increasingly important in developing countries, where healthcare systems face educational and socioeconomic challenges. Our aim is to highlight the impact of advanced HF program establishment on the characteristics and care of acutely decompensated heart failure (ADHF) patients.
Methods: We conducted a retrospective chart review to identify patients admitted with ADHF before and after the establishment of an advanced HF program. One-hundred and forty ADHF admissions within the 24 months period prior to the establishment of the program (Group 1) were compared with 54 ADHF admissions that took place 6 months after program establishment (Group 2). Demographic, clinical, hemodynamic, and laboratory characteristics were evaluated at the time of admission and hospital discharge.
Results: At hospital admission, patients in group 1 tended to be more symptomatic, had higher mean arterial pressure (MAP) and higher heart rate (HR) than patients in group 2 (Figure, 1 panel A). At discharge, patients in group 2 had lost more weight and had lower MAP. Duration of hospital admission was not significantly different between the two groups (Figure, panel B). HF medications were used more in group 2, both at hospital admission and at discharge (Figure 1, panels A and B).
Conclusion: After the establishment of an advanced HF program, patients admitted with ADHF were more optimally managed before and during their admission, with more evidence- based therapies and better hemodynamics. Although the duration of hospital stay was the same, more effective diuresis took place when patients were followed by the HF program. Longer follow up is needed to assess differences in readmission rate.

The PARASAIL study Patient reported outcomes from the Canadian real world experience use of sacubitril/valsartan in patients with heart failure and reduced ejection fraction

H Haddad[1]; S Bergeron[2]; A Ignaszewski[3]; G Searles[4]; N Bastien[5]
[1]University of Saskatchewan, Saskatoon, Canada; *[2]Centre de Recherche de l'Institut Universitaire de Cardiologie et de Pneumologie de Quebec, Quebec, Canada*; *[3]University of British Columbia, Vancouver, Canada*; *[4]Saint John Regional Hospital, Saint John, Canada*; *[5]Novartis Pharmaceuticals Canada Inc, Dorval, Canada*

Background/Introduction: Following the completion of the PARADIGM-HF trial, there is an opportunity to further explore the drug knowledge in a broader patient population through real world experience. PARASAIL, a Canadian prospective, multicenter, open-label, study aims at characterizing the effectiveness and safety of Sacubitril/Valsartan (Sac/Val) in 300 Canadian patients with heart failure with reduced ejection fraction (HFrEF) followed for 12 months.
Methods: The exploratory objectives from this study focus on validated quality of life questionnaires recorded by patients (Minnesota living with HF questionnaire (MLHFQ), EQ-5D questionnaire and patient global assessment (PGA)who have been converted to Sac/Val at 4, 12 and 24 weeks. Participants who were considered to be eligible were adult HFrEF outpatients with an ejection fraction of < 40%, NYHA class II or III and on stable doses of ACEI or ARB recruited in 32 centers across Canada. The suggested starting dose of Sac/Val was 24 mg/26 mg bid replacing ACEI or ARB. Up-titration to 49 mg/51 mg bid then to 97 mg/103 mg bid can occur every 2-4 weeks as per clinical judgement. Symptomatic hypotension and/or SBP below 100 mmHg, estimated GFR below 30mL/min/1.73m2, angioedema or necessity to use ACEI or ARB concomitantly, were amongst the exclusion criteria. The results presented here are those from the initial 54 patients who completed 24 weeks of treatment.
Results: Mean patient age was 66 years old, 82% male, 89% Caucasian, and BMI of 31.3 kg/m2, mostly NYHA Class II (91%), with baseline blood pressure of 123/73 mmHg. Baseline standard HF therapy was commonly used in most patients: 63% on ACEI or 26% ARB before Sac/Val initiation, 89% on beta-blockers, 46 % on MRA and 52% on diuretics. Drug initiation and titration started at the 24/26 mg dose of Sac/Val for most patients (87%) and up-titration to maximum dose of Sac/Val was achieved for the majority (70%) at 12 weeks. For both PGA and MLHFQ, there were improvement in the QoL: 45% of patients experienced an improvement of their scores (slightly, moderately and markedly) with PGA at week 4 and 56% at week 12, and there was a significant improvement in the MLHFQ at both weeks 4 and 12 with 18% and 26% decrease in the score compared to baseline respectively (P= 0.0096 and P= 0.0020 respectively). For the EQ-5D questionnaire, there were no changes in the VAS score at week 4 and week 12, and no changes in the 5 individual domains either. The treatment was safe and well tolerated and no patient discontinued it within the initial 12 weeks of follow-up.
Conclusion: The PARASAIL trial is designed to evaluate real-life effectiveness and safety of Sac/Val in HFrEF patients. Initial results of QoL questionnaires detected early signs of improvement in 2 of the 3 validated questionnaires. While placebo effect cannot be ruled out, further analysis of the total cohort of the patients will provide more insights about this possibility.

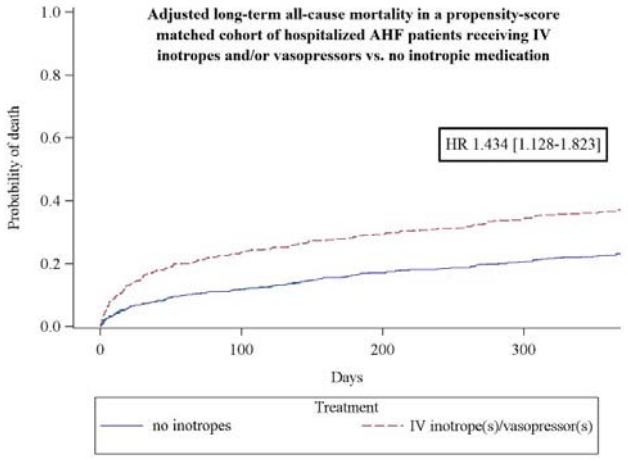
P222

Long term safety of inotropes and/or vasopressors in acute heart failure: results from ESC-HF-LT registry

A Mebazaa[1]; J Motiejunaite[2]; E Gayat[1]; E Akiyama[2]; MG Crespo-Leiro[3]; LH Lund[4]; AP Maggioni[5]; O Chioncel[6]; F Ruschitzka[7]; G Filippatos[8]
[1]Hospital Lariboisiere, Department of Anesthesiology and Critical Care, Paris, France; *[2]Inserm UMR-S 942, Paris, France*; *[3]Complexo Hospitalario Universitario A Coruna, CHUAC, Unidad de Insuficiencia Cardiaca Avanzada y Trasplante Cardiaco, La Coruna, Spain*; *[4]Karolinska University Hospital, Department of Cardiology, Stockholm, Sweden*; *[5]ANMCO Foundation For Your Heart, Florence, Italy*; *[6]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*; *[7]University Heart Center, Department of Cardiology, Heart Failure Clinic and Transplantation, Zurich, Switzerland*; *[8]Attikon University Hospital, Athens, Greece*

On behalf of: on behalf of ESC-HF-LT registry investigators

Introduction: Increasing short term safety concerns have been reported concerning the use of inotropes and/or vasopressors in the initial management of acute heart failure (AHF). However, data on long-term safety of these agents is scarce. We therefore sought to assess safety, especially long term mortality, of intravenous inotropes and/or vasopressors in AHF by a post-hoc analysis of a large AHF registry.
Methods: The European Society of Cardiology Heart Failure Long – Term Registry (ESC-HF-LT) was a multicenter prospective observational registry conducted in 21 countries between 2011 and 2013. Median follow-up duration was 381 [363; 457] days. For present analysis we selected patients (pts) with unscheduled hospitalizations for AHF, for whom intravenous (IV) therapy was needed (n = 6900), including 833 (12%) pts who received one or more inotropes and/or vasopressors. A further analysis of 1212 pts was derived using propensity score matching (606 pts in each treatment group) in which 35 baseline variables were balanced as assessed by standardized mean differences. Primary endpoint was long-term all-cause mortality. Secondary endpoints were in-hospital mortality, all-cause post-discharge mortality and post-discharge rehospitalization.
Results: Long-term all-cause mortality was greater in pts receiving IV inotrope and/or vasopressor compared to those who did not, both in the whole (43.7 % vs. 23.2 %) and the matched cohorts (39.8 % vs. 29.4 %). Adjusted hazard ratio (HR) for the association between the use of IV inotrope and/or vasopressor and long-term all-cause mortality was 1.720 [1.498 – 1.975] in the whole cohort and 1.434 [1.128-1.823] in the matched cohort. Adjusted HR for associations between the use of IV inotrope and/or vasopressor and in-hospital mortality were 3.138 [2.432-4.048] in the whole and 1.873 [1.151 – 3.048) in the matched cohorts. Adjusted HR for long-term all-cause mortality in patients discharged alive were 1.249 [1.059-1.474] in the whole and 1.078 [0.769-1.512] in the matched cohorts. No association was found between the use of IV inotropeand/or vasopressor and post-discharge rehospitalization, neither in the whole nor in the matched cohorts (HR 1.101 [0.924-1.311] and 1.117 [0.788-1.582] respectively).
Conclusions: The use of inotropes and/ or vasopressors in AHF was associated with increased long-term risk of all-cause death.



P223

The bleeding risk in thrombolysed patients with intermediary-high risk pulmonary embolism

A Alexandru Ion[1]; C Andrei[1]; M Raducan[2]; C Sinescu[1]
[1]University of Bucharest Carol Davila, Bagdasar Arseni Emergency Hospital, Cardiology Department, Bucharest, Romania; *[2]Bagdasar-Arseni Emergency Hospital, Cardiology, Bucharest, Romania*

Background: The intermediary-high risk pulmonary embolism (PE) is associated with an early mortality risk which shows the need for upgrading medical therapy. The main purpose in using thrombolytics in patients with intermediary-high risk PE is to obtain an improvement in the clinical status and the mortality risk, without increasing the bleeding risk
Purpose: The purpose of this study is to assess the bleeding risk in patients with intermediary-high risk PE thrombolysed with t-PA compared to patients treated with unfractionated heparin (UFH). The main purpose is to identify the group of patients which has the lowest bleeding risk with thrombolytic therapy, in order to reduce the main side effect.
Material and methods: We included 65 patients with intermediary-high risk PE. The inclusion criteria were: 1. First symptomatic acute PE (in the last 2 weeks). The exclusion criteria were: 1. Age > 80 y.o.; 2. Severe anemic syndrome (Hb < 8 g/dl); 3. Pre-existing pulmonary hypertension; 4. Dilative cardiomyopathy with severe LV dysfunction (EF < 30%); 5. Aortic or mitral valvulopathies which may produce pulmonary hypertension. The subjects were divided in two groups : 1. study group - received t-PA (10mg bolus and 90 mg in 2 hours) and UFH -; 2. control group was treated with UFH alone, with therapeutic aPTT. In the control group were included patients with contraindications for thrombolysis, with BMI > 30

or BMI < 18.5, or with end stage renal failure, as these factors were associated with an increased thrombolytic bleeding risk. The patients were assessed regarding the bleeding risk by major and minor bleeding events and the severity of the bleeding event was calculated by the Hb decrease compared to inclusion status. There were no differences regarding the sex distribution in the two groups but there was a significant difference between the medium age (68.48 +/- 12.3 y.o. in control group vs 63.32 +/- 17.4 y.o. in study group (p 0.05)). This difference can be explained by the inclusion and exclusion criterias.
Results : Regarding the major bleedings there was only one major bleeding in the study group (intracerebral hematoma) and no major bleedings in the control group. Meanwhile the minor bleeding rate was 1:7 in the study group vs 1: 9.25 (p 0.075). The medium Hb value on admision in the study group was 13.32 +/- 1.1 g/dl vs 12.91 +/- 1.24 g/dl in the control group, with no statistical difference. Comparing the Hb value between the two groups in the fifth day we noticed a decrease of 6.08% in the study group vs 3.87% in control group(p 0.04).
Conclusion: These data prove the safety use of thrombolytics in selected patients with intermediary-high risk PE, these leading to an optimal risk/benefit ratio which may identify the best patient profile for receiving this therapy.

P224

Clinical profile of heart failure admissions in a tertiary hospital. Implications for multidisciplinary management

L Vicent[1]; A Ayesta[1]; MT Vidan[1]; JM De Miguel-Yanes[1]; J Garcia[1]; V Gomez-Carrillo[1]; S Veliz[1]; M Tamargo[1]; H Gonzalez-Saldivar[1]; F Fernandez-Aviles[1]; M Martinez-Selles[1]
[1]*University Hospital Gregorio Maranon, Cardiology, Madrid, Spain*

Introduction. Population aging has produced notable changes in heart failure admissions.
Purpose: Our aim was to analyse the characteristics, comorbidity, management, and outcomes of these patients in three departments.
Methods: Prospective registry during 45 days. All patients admitted for heart failure in Internal Medicine, Cardiology and Geriatrics were included.
Results: From 235 patients, 124 patients (52.7%) were admitted in Internal Medicine, 83 (35.3%) in Cardiology, and 28 (11.9%) in Geriatrics. Mean age was 77.0 ± 20.2 years (Cardiology 71.5 ± 13.5; Internal Medicine 79.2 ± 21.1; Geriatrics 89.9 ± 5.1; p < 0.001). Preserved ejection fraction was found in 121 patients (51.5%) and this rate was higher in Internal Medicine (62.5%) and Geriatrics (70.0%) than in Cardiology (31.3%), p < 0.001. Comorbidity was frequent, especially atrial fibrillation (126; 53.6%) renal disease (89; 37.8%), and chronic obstructive pulmonary disease (65; 27.6%). Infections were the most common decompensating trigger in Internal Medicine (56; 45.2%) and frequently there was no trigger in Cardiology (45; 54.2%) and Geriatrics (14; 50.0%), p < 0.0001. Treatment administered is resumed in the table. During 45 days follow-up 23 patients (9.9%) were readmitted, this was more frequent in Internal Medicine than in Cardiology (odds ratio 3.0 [95% confidence interval: 1.1 - 8.6], p = 0.03), without other significant comparisons.
Conclusions: Patients admitted for decompensated heart failure are elderly and present frequent comorbidity. There are major differences between services with respect to age and clinical profile.

Treatment in patients with LVEF<40%

	Total (n = 70, 31.5%)	Cardiology (n = 44, 53.0%)	Internal Medicine (n = 23, 18.5%)	p
Pre admission				
Renin-angiotensin system inhibitors	45 (64.3%)	30 (68.2%)	14 (60.9%)	0.32
Betablockers	42 (60.0%)	24 (54.5%)	16 (69.6%)	0.07
Spironolactone	29 (41.4%)	24 (54.5%)	4 (17.3%)	0.001
At discharge				
Renin-angiotensin system inhibitors	52 (74.3%)	35 (79.5%)	13 (56.5%)	0.001
Betablockers	45 (64.3%)	29 (65.9%)	12 (52.1%)	0.003
Spironolactone	46 (65.7%)	39 (88.6%)	6 (26.1%)	< 0.0001

Treatment in patients with left ventricular ejection fraction <40% according to the department of admission. Geriatrics data are not presented since only 3 patients of this department had ventricular dysfunction, and at discharge all were treated with beta-blockers and ACE inhibitors (angiotensin converting enzyme inhibitors/angiotensin-2 receptor blockers).

P225

Current use and impact on 30-day mortality of pulmonary artery catheter in cardiogenic shock patients: results from the CardShock Study.

M Rivas Lasarte[1]; J Sans-Rosello[1]; M Vila[1]; H Tolppanen[2]; J Lassus[2]; M Lindholm[3]; A Mebazaa[4]; V-P Harjola[2]; A Sionis[1]
[1]*Hospital de la Santa Creu i Sant Pau, Cardiology Department, Barcelona, Spain*; [2]*Helsinki University Central Hospital, Cardiology department, Helsinki, Finland*; [3]*Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*; [4]*Inserm UMR-S 942, Paris, France*

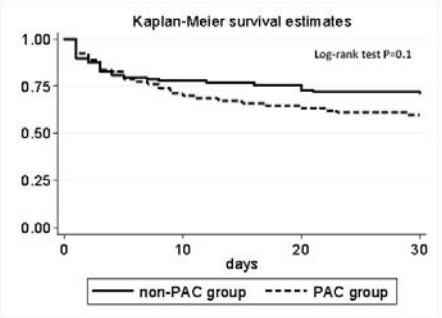
On behalf of: CardShock Investigators

Background: Cardiogenic Shock (CS) is the most life-threatening manifestation of heart failure (HF). Its complexity and high mortality, would justify the need for invasive monitoring with a pulmonary artery catheter (PAC) that may allow the clinician to establish an accurate diagnosis at all times and to guide treatment. Randomized clinical trials have failed to demonstrate clinical benefit of PAC use in critically ill patients, but CS patients were grossly underrepresented.
Purpose: This study aims to describe the real-world use of PAC in a contemporary cohort of patients with CS and to evaluate its prognostic impact on 30-day mortality.
Methods: This is a sub-study of the previous published CardShock study an observational, prospective, multicenter cohort of patients with CS. The use of PAC was within the discretion of the physician in charge.
Results: The CardShock study included 219 patients; PAC was used in 82 patients (37.4%). The management was more aggressive in those with PAC (table). Overall 30-day mortality was 38.6%, with no differences between PAC and non-PAC patients (figure).PAC use did not affect mortality [OR: 1.24 (95% CI 0.60-2.56) p = 0.56], in a multivariate analysis adjusted by a propensity score (including the history of prior myocardial infarction, inotropic use at admission, etiology of shock, mechanical ventilation, and assist device use).
Conclusions: This study revealed that PAC is used in 1/3 of CS patients. They are characterized by a prior poorer prognosis and by more aggressive management. PAC use was not associated with 30-day mortality.

Characteristics of the study population

	PAC group (82 patients, 37.4%)	Non-PAC group (137 patients, 62.6%)	P value
SBP at admission, mean (SD)	79.61 (1.75)	76.47 (1.05)	0.10
Inotrope use at admission*, n (%)	41 (50.00)	36 (26.28)	0.000
Confusion at admission, n (%)	63 (77.78)	85 (62.96)	0.02
Baseline LVEF, mean (SD)	31.43 (1.73)	33.94 (1.20)	0.22
IABP, n (%)	56 (76.71)	57 (46.34)	0.000
ECMO and LVAD, n (%)	6 (7.41)	5 (3.73)	0.23
Mechanical ventilation, n (%)	73 (89.02)	64(47.06)	0.000
30-day mortality, n (%)	35 (42.68)	49 (35.77)	0.31

PAC: pulmonary artery catheter; SD: standard deviation; SBP: systolic blood pressure; HR: heart rate; ACS: acute coronary syndrome, LVEF: left ventricular ejection fraction, IABP: intra-aortic balloon pump; ECMO: extracorporeal membrane oxygenation; LVAD: left ventricular assist device, CRR: continuous renal replacement. *Inotrope use refers to dobutamine, adrenaline, levosimendan or milrinone use.



Kaplan-Meier curves for 30-day survival

Intravenous beta-blocker therapy in st-segment elevation myocardial infarction

E Elmir Omerovic[1]; O Angeras[1]; I Haraldsson[1]; C Dworeck[1]; J Odenstedt[1]; D Ioanes[1]; P Petursson[1]; S Volz[1]; P Albertsson[1]; B Redfors[1]
[1]*Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: Beta-blockade is recommend in all stable patients with ST-elevation myocardial infarction (STEMI) within 24 hours. However, the role of intravenous (IV) beta-blockade is less clear in the modern era of reperfusion therapy.
Aims: To investigate the impact of intravenous (IV) beta-blockade therapy on short-term mortality and risk of development of cardiogenic shock in patients with STEMI.
Methods: We used data from the nationwide Swedish Web-system for Enhancement and Development of Evidence-based care in Heart disease Evaluated According to Recommended Therapies (SWEDEHEART) registry for patients in Västra Götaland County. All patients with STEMI undergoing PCI between 2006 and 2014 were included. The primary endpoint was mortality within 30 days and the secondary endpoints was in-hospital cardiogenic shock. We used multilevel modeling based on complete-case mixed-effects logistic regression to adjust for clustering of observations in a hierarchical database and for differences in patient characteristics.
Results: In total, 5,869 patients were included in the study of which 1,131 (19.3%) were treated with IV beta-blockade. At 30 days, there were 688 (11.7%) deaths and 426 (7.3%) cases of cardiogenic shock. IV beta-blockade was not associated with higher risk of death (OR 1.01, 95% CI 0.80-0.1.28, P=0.91) nor with higher risk of in hospital cardiogenic shock (OR: 1.18, 95% CI 0.90-1.54).
Conclusion: In our study, the use of IV beta-blockade in patients with STEMI was not associated with higher risk of short-term mortality and in-hospital cardiogenic shock.

Relationship between improvements in long term outcomes and baseline systolic blood pressure in acute heart failure patients treated with TRV027: an exploratory subgroup analysis of BLAST-AHF

G Gadi Cotter[1]; PP Pang[2]
[1]*Momentum Research Inc., Durham, United States of America*; [2]*Indiana University School of Medicine & Regenstrief Institute , Indianapolis, United States of America*

On behalf of: BLAST-AHF Executive Committee and Investigators

TRV027 is a novel 'biased' ligand of the angiotensin II type 1 receptor (AT1R). In a large phase 2b acute heart failure (AHF) trial (BLAST-AHF), TRV027 did not affect a composite clinical outcome at 30 days.
Methods: Post-hoc analyses from BLAST-AHF (n = 618) were performed to examine the effects of TRV027 according to baseline systolic blood pressure (SBP) on changes in: post-baseline SBP, renal function, and 180-day outcomes. Patients were treated with one of four TRV027 dosing regimens, 1, 5 or 25 mg/hr, or matching placebo for up to 96 hours. Interactions between baseline SBP and the selected endpoints were identified using subpopulation treatment effect pattern plots (STEPP) analysis, grouping patients by SBP tertile: < 127 mmHg, ≥ 127 mmHg and < 140 mmHg, and ≥ 140 mmHg
Results: TRV027 did not affect SBP in patients with lower baseline SBP but was associated with a trend towards SBP increase in patients in the highest two SBP tertiles. TRV027 induced a trend towards increased creatinine over the first 3 days in patients with lower baseline SBP. In patients in the higher two SBP tertiles, TRV027, specifically the 1 mg/hr dose, tended to reduce creatinine at days 5 and 30. Beneficial effects on 180-day outcomes, especially all-cause mortality and cardiovascular (CV) death or readmission, were observed in patients with higher baseline SBP (≥ 127 mmHg) in the TRV027 1mg/hr dose group (all-cause mortality HR 0.39, 95% CI 0.14 - 1.06, p = 0.056; CV death or HF/RF rehospitalization HR 0.53, p = 0.049), while more adverse outcomes were observed in patients with baseline SBP in the lower tertile.
Conclusions: In this post-hoc analysis from the BLAST-AHF trial, patients with baseline SBP ≥ 127 mmHg treated with TRV027 experienced improved 180-day outcomes.

P228

feasibility of integrating multiple remote monitoring technologies as a single heart failure decision support tool

E Berry[1]; A Silvera[1]; W Downer[1]; D Agar[1]; S Beske Radford[1]; N Chiromeras[1]; M Bogart[1]; N Bonnet[1]
[1]*Morristown Medical Center, The Heart Success Program, Morristown, United States of America*

Funding Acknowledgements: Verizon

Background: Acute heart failure (AHF) is the leading cause of hospitalizations in patients aged 65 and older, and one of the leading diagnoses associated with 30-day readmissions. Preventing hospital admissions and reducing short-term readmissions is a critically important unmet need for patients, caregivers, and hospitals due to its high morbidity and cost. Non-invasive remote monitoring provides capabilities that enable patient self-care management, thereby leading to a greater patient engagement, empowerment, satisfaction and efficiencies.
Purpose: The purpose was to evaluate the feasibility of merging two disparate remote monitoring and management systems into an enhanced singular decision support tool that enabled timely and impactful interventions by a mature heart failure (HF) disease management program. The rate of hospital readmissions or ED visits 30 days post discharge was evaluated.
Methods: This is a prospective, interventional, nonrandomized study of AHF patients. Patients hospitalized for AHF were identified. Patients discharged to home were supplied with cutaneous wearable sensors and connected to a telehealth system. Patients discharged to a skilled nursing facility were given cutaneous wearable sensors and connected to a separate mobile monitoring application. Patients were monitored by these technologies for 30 days post discharge. Clinicians were alerted using variables from the remote monitoring systems to evaluate and guide further assessment and intervention.
Results: A total of 31 patients were enrolled during the 13 month study period. The mean age of participants was 78.5 years, 58% being 80 years old or older. 42% percent were male and 58% female. Of the participants, seven withdrew within 30 days. The readmission rate of patients that did not withdraw from the program was 20.8%. Thirteen patients had atrial fibrillation detected remotely.
Conclusion: The combination of these two disparate systems were successfully integrated within an established HF management program to provide decision support for HF interventions. The readmission rate of 20.8% suggests improved outcomes; however requires further investigation.

P229

Tolvaptan reduces readmission rates in acute heart failure patients with hypervolemic hyponatremia

L Lynne Wagoner[1]; CE Walton[2]; EK Walton[3]; R Cassidy[1]; DL Dietrich[1]
[1]*Mercy Fairfield Hospital, Mercy Heart Institute, Cincinnati, United States of America*; [2]*Summit Country Day School, Cincinnati, United States of America*; [3]*Wake Forest University, Winston Salem, United States of America*

Background: A significant portion of health care dollars is spent in the hospitalization and management of acute heart failure (AHF) patients (pts). Tolvaptan, an oral vasopressin receptor antagonist, is approved for treatment of pts with AHF and hypervolemic hyponatremia. In the EVEREST trial, no difference was observed in mortality or readmissions in pts admitted with AHF (not necessarily with hyponatremia) treated with tolvaptan vs placebo. We used tolvaptan to assist in the management of pts admitted with AHF with hyponatremia (defined as sodium < 135 mmol/L).
Methods: We reviewed charts of admitted pts at 5 community hospitals owned by Mercy Health in Cincinnati, Ohio between 2012 and 2016. Charts of our treatment group were reviewed for pts who had received tolvaptan for treatment of hyponatremia and AHF. A control group included pts with AHF and hyponatremia that did not receive tolvaptan. Charts were reviewed at admission and discharge for sodium (Na) levels, BUN, creatinine, weight loss, length of stay, cost per case, number of readmissions within 6 mos., and death.
Results: Our pertinent findings are listed in the table below. For the calculated cost per pt: # of readmits is multiplied by Cost/admission.
Conclusion: In clinical practice, pts with hypervolemic hyponatremia and AHF treated with tolvaptan demonstrated a greater improvement of sodium levels and a reduction in the number of readmissions in the next 6 mos. Furthermore, the 6 month calculated cost per patient is significantly lower for the patients treated with tolvaptan. Although the LOS and cost/case did not reach statistical signficance in the pts treated with tolvaptan, the cost of readmissions alone is important in reducing health care costs. Thus, tolvaptan can be a cost effective therapy when used in the management of hyponatremic AHF pts.

Tolvaptan vs Control

	Tolvaptan (n = 172)	Control (n = 71)	p value
Change in Sodium (mmol/L)	+ 7.9 ± 0.4	+ 4.8 ± 0.7	< 0.0001
# of Readmits in 6 months	1.01 ± 0.10	1.48 ± 0.2	0.038
Length of Stay (days)	8.7 ± 0.5	9.2 ± 0.7	NS
Cost/Admission (U.S. dollars)	16,525 ± 1,576	18,202 ± 2,533	NS
Calculated cost per pt in 6 months (U.S. dollars)	22,145 ± 6,565	35,125 ± 2,118	0.032

P230

Clinical experience with eplerenone in patients with heart failure nyha iii-iv functional class and midrange ejection fraction

T Tatqna Chakalova- Yancheva[1]; K Gospodinov[1]; Y Mladenova[1]; N Stancheva[1]; P Tonchev[1]; S Tisheva[1]
[1]*Medical University Pleven, Pleven, Bulgaria*

Objective: Clinical evaluation of the effect and safety of the addition of eplerenone to standard diuretic therapy in patients with heart failure III-IV NYHA functional class compared with that of the spironolactone.
Material and methods: A total of 78 patients with symptoms of decompensated heart failure III-IV functional class NYHA, where treated in University Hospital "G. Stransky"- Pleven, Bulgaria, between 1.01.2015-31.06.2015. The patients included were with left ventricular ejection fraction (LVEF) 40 to 49% - 'HF with midrange EF" in the absence of renal failure with creatinine clearance < 30 mL/min 1.73/ m2.The treatment was initiated with high-dose loop diuretic furosemide 120 mg per 24 hours. Co-medication with spironolactone was used in 42 patients (Group1) and with eplerenone in 36 (Group 2). The included patients were treated and closely monitored in the intensive care unit of the clinic of cardiology.
The treatment effect was assessed by clinical improvement of the patient expressed in mastering the congestion, reduction of subjective complaints, weight and diuretic response. The potassium levels were monitored during hospitalization in both groups.
Statistical methods: Chi-square test, Student test, IBM SPSS 21 were used for statistical analysis.
Results: The groups did not differ significantly by gender, age and severity of HF by NYHA. Diuretic response> 3000m / 24h. Was considered as good. Good diuretic response was demonstrated in 24 patients (78%) from the eplerenone group vs. 23(55%) in the spironolactone group (Chi Squared = 4.537, p = 0,03317 < 0,05)
Hypokalemia (K < 3,5) was observed in 29 patients (69%) treated with spironolactone vs. 11 patients (31%), treated with eplerenone. (Chi Squared = 11,496, p = 0,000697 < 0.05,).
Conclusion: The efficiency regarding additive diuretic effect of eplerenone to standard therapy with a loop diuretic in the study group is greater than that of spironolactone in patients with decompensated heart failure III-IV NYHA class and moderately reduced ejection fraction. Greater safety of eplerenone use is demonstrated in reduction the risk of potentially dangerous hypokalemia.

P231

Short course oral digoxin treatment in acute heart failure: a case control study

I Imen Trabelsi-Bchir[1]; TN Tounsi[1]; BK Beltaief[1]; MMA Msolli[1]; EM Echeikh[1]; SA Sekma[1]; BN Bziouich[1]; FN Fredj[1]; ZZ Zina[1]; GMH Grissa[1]; BH Boubaker[1]; BR Boukef[1]; BW Bouida[1]; NS Nouira[1]
[1]*university of Monastir, monastir, Tunisia*

Heart failure (HF) is a major worldwide health problem and one of the most important causes of hospitalization and readmission in older adults. Digoxin is one of the oldest and least expensive modulator for the management of HF. We conducted a matched case control study including 42 patients consulting the emergency department (ED) for acute HF (AHF), treated with short course digoxin, and 162 control patientsadmitted to the ED for AHF during the same period and did not receive digoxin. In these patients, hospital death and 30-day readmission rates were considered as main outcome. Secondary outcome was the effect of digoxin on left ventricular ejection fraction (LVEF), cardiac output (CO), and systolic time intervals including pre-ejection periode (PEP) and left ventricular ejection time (LVET) 72 hours after ED admission. Results showed that digoxin treatment was associated with reduction in mortality (12.3% vs 7.1%, p = 0.027) and all cause hospital readmission (16.05% vs 9.5%,p = 0.012). Compared to control group, LVEF and cardiac output increased in digoxin group (p = 0.003, p = 0.155,respectively). Simultaneously, digoxin decreased PEP (p = 0.018) and increased LVET (p = 0.013). NT proBNP decreased but not significantly in digoxin group (p = 0.06). We conclude that digoxin has a beneficial clinical and physiological effect in patients admitted to the ED for AHF.

HFrEF, HFmrEF and HFpEF: which is the treatment of choice at discharge? Real world data from the ATHENA registry.

A Pratesi[1]; S Baldasseroni[1]; A Herbst[1]; S Parlapiano[1]; A Berni[2]; F Bacci[2]; G Ciuti[2]; C Tozzetti[2]; A Cortese[2]; C Nozzoli[2]; L Gabbani[1]; L Poggesi[2]; A Moggi Pignone[2]; N Marchionni[3]; F Orso[1]
[1]*Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy*; [2]*Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; [3]*Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: ATHENA study group

Background: Heart failure (HF) is a highly prevalent condition particularly in the elderly. Prognosis has improved in HFrEF due to the availability of evidence based treatments. Currently, no treatments have proven efficacy in HFpEF patients and also in HFmrEF, the new category of HF, recently introduced by the Heart Failure Association of the European Society of Cardiology.
Purpose: to evaluate treatments at discharge in a real world setting of elderly patients after an episode of acute HF in the three different groups of HF: HFpEF, HFrEF and HFmrEF.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (≥ 65 years) admitted with diagnosis of AHF to a tertiary University teaching-hospital in the period 01.12.2014-01.12.2015.
Results: study population was composed by 246 patients: 19.5% with HFmrEF, 30.5% with HFrEF and 50.0% with HFpEF. Mean age of three group of patients was respectively 83.8, 84.5 and 79.9 years, p < 0.001. Pharmacological treatments at discharge in the three HF groups are shown in the attached table. BBs and MRAs were the only two classes of drugs that had a statistically different prescription rate across the three HF groups: patients with HFmrEF received BBs in similar percentage to patients with HFrEF. MRAs prescription rate in HFmrEF was intermediate compared to the other two groups. Furthermore, the average number of drugs taken by patients at the time of discharge was 11.8 with no differences across the groups.
Conclusion: at present, in the absence of specifical evidences from randomised clinical trials, patients with HFmrEF are treated similarly to those with HFrEF. Also, a high percentage of patients with HFpEF receive treatments that only have been to improve prognosis in HFrEF patients. Randomised clinical trials evidences are needed to appropriately treat HFmrEF patients.

Treatments	Tot n=246	HFrEF n=75	HFmrEF n=48	HFpEF n=123	P Value

Frequency and prognostic impact of heart failure type following an episode of cardiac decompensation

S Brenner[1]; M Breunig[1]; C Morbach[1]; G Ertl[1]; CE Angermann[1]; S Stork[1]; G Guder[1]
[1]*University of Würzburg, Department of Internal Medicine I / Comprehensive Heart Failure Center , Würzburg, Germany*

On behalf of: INH-study group

Aim: The current European Society of Cardiology heart failure (HF) guidelines define three stages of left ventricular ejection fraction (LVEF): HF with reduced LVEF (< 40%, HFrEF), HF with mid-range LVEF (40-49%, HFmrEF) and HF with preserved LVEF (≥50%, HFpEF). We evaluated the progressive change of LVEF and its subsequent effect on LVEF staging and prognosis in patients initially presenting with HFrEF.
Methods: We studied patients from the Randomized INH Trial leaving the hospital with a LV ejection fraction ≤40% after an episode of decompensated HF. Six months after discharge, LVEF was re-evaluated by echocardiography and patients were grouped as defined above into HFrEF, HFmrEF, HFpEF. Events on cause-specific death and re-hospitalisation were subsequently collected for another follow-up period of 12 months.
Results: We report on 679 patients, 75% male, mean age 66 ± 12years, i.e. about 70% of the original cohort (n = 1032) surviving at least 6 months after discharge from index hospitalisation and providing echocardiography data. Six months after discharge, HFrEF, HFmrEF and HFpEF was found in 267 (39%), 225 (33%) and 187 (28%) of all patients, respectively. During the subsequent 12 month follow-up period, 52 patients (7.7%) died, 32 of those (5.0%) from cardiac causes. Further, 270 patients (39.8%) experienced re-hospitalization, of which 154 (22.7%) happened for cardiac reasons. In univariable Cox regression, HFrEF but not HFmrEF was associated with an increased risk of all-cause and cardiac death in comparison to the referent stage HFpEF (hazard ratio with 95% confidence interval); for all-cause death: 3.9 (1.6-9.4; p = 0.002) vs 2.0 (0.8-5.1; p = 0.164); for cardiac death: 3.1 (1.2-8.2; p = 0.023) vs 1.0 (0.3-3.3; p = 0.98), respectively. However, both, HFrEF

and HFmrEF were associated with increased risk for all-cause rehospitalisation and re-hospitalisation for cardiac reasons; for all-cause rehosp: 1.9 (1.4-2.6; p < 0.001) and 1.4 (1.0-2.0; p = 0.030); for cardiac reshosp: 4.4 (2.6-7.4; p < 0.001) and 2.5 (1.4-4.3; p = 0.001), respectively.
Conclusions: In patients leaving the hospital after an episode of cardiac decompensation with the phenotype of HFrEF, LVEF remains very dynamic. Six months later, prevalence of HFmrEF and HFpEF is about 30% each in survivors. LVEF recovery is a very important feature in these patients as both HFrEF and HFmrEF indicate worse prognosis compared to HFpEF.

Prediction of in-hospital mortality in acute heart failure: comparing risk scores

J G Julio Gil Goncalves Pereira[1]; H Antunes[1]; L Abreu[1]; L Goncalves[1]; B Marmelo[1]; I Pires[1]; I Cunha[1]; R Silverio[2]; LF Santos[1]; J Costa Cabral[1]

Introduction: Risk stratification of patients with Heart Failure (HF) could improve clinical outcome and allocation of resources. Multiple risks scores (RS) have been created for the prediction of in-hospital mortality, such as OPTIMIZE-HF (1) by Abraham, the Peterson et al study GWTG-HF (2) and the work formulated by O´Connor. PROTECT (3).
Purposes and Methods: A retrospective study was performed on patients admitted for HF. Clinical, analytical, and echocardiographic parameters were evaluated. Calculation of the OPTIMIZE-HF, GWTG-HF and PROTECT RS were determined and compared. The risk score better at predicting in-hospital mortality was determined.
Results: A total sample of 952 patients were evaluated, 50.8% male, with a mean age of 77 ± 10 years old. Regarding in-hospital mortality, the ROC curve detailed in the image was ascertained.
The following table shows the mean values of each RS in alive vs deceased patients and the AUC of the ROC curve and the corresponding statistical significance.
Conclusion: In this population, only the GWTG-HF RS performed moderately well at predicting in-hospital mortality. Both the PROTECT and OPTIMIZE-HF RS underperformed, although the latter RS achieved better predictive power. Since HF represents such a heterogeneous group, creating risk scores is especially difficult in this population.

Background: Growth differentiation factor (GDF) -15 mirrors inflammation and oxidative stress in cardiovascular diseases. Brain Natriuretic peptide (BNP) is associated with cardiomyocyte stretch in heart failure (HF). We aimed to evaluate the correlation between these biomarkers and to study the it´s prognostic impact acute HF.
Methods: We studied a group of patients prospectively recruited as part of an acute HF registry. Patients admitted with the diagnosis of acute HF were elegible. Patients were treated at the discretion of the attending physician. A venous blood sample was drawn at discharge. Patients were followed up to 2 years and the endpoint was all-cause mortality. A spearman correlation coefficient was used to study correlation between GDF 15 and BNP, age, creatinine, C-reactive protein (CRP) and hemoglobin. Patients with discharge GDF 15 below and above the median value were compared. Cox-regression multivariate models were built to study the association of GDF 15 (continuous and dichotomized according to the mean) and mortality. Patients were further cross-classified according to discharge GDF 15 (mean) and discharge BNP (mean) and independent association with mortality was studied. RESULTS: We studied 158 patients. Seventy (50%) male, mean age 75 years, 87 (55.1) had left ventricular ejection fraction <40%; mean discharge BNP was 1000.2pg/mL and mean discharge GDF 15 was 3013.3ng/mL. During the 2-year follow-up 71 patients (44.9%) died. Patients with higher GDF 15 (≥3000ng/mL) were significantly older and had higher BNP, higher creatinine and CRP and lower hemoglobin. No differences were observed concerning sex, etiology of HF and left ventricular function. GDF 15 correlated positively with age (Rho=0.27), BNP (Rho=0.36), creatinine (Rho=0.51) and CRP (Rho=0.28) and negatively with hemoglobin (Rho=-0.305). BNP and GDF 15 (analyzed as continuous or as categorical variables) associated with 2-year mortality. Patients with discharge BNP≥1000pg/mL had an age-, gender-, creatinine-, CRP-, hemoglobin- and GDF 15-) independent risk of 2-year mortality of 2.10 (95% CI: 1.22-3.61) and the age-, gender-, creatinine, CRP-, hemoglobin- and BNP- adjusted risk for GDF15≥ 3000ng/mL was 1.70 (95% CI:1.01-2.87). Patients discharged with both BNP and GDF 15 above the mean had a multivariate adjusted HR of 2-year death of 3.64 (1.80-7.34) p < 0.001 when compared with the reference category (both BNP and GDF 15 below the mean). Patients with only one of the variables above the mean had an HR of 2-year mortality of 1.66 (0.94-2.92), p = 0.08 CONCLUSIONS: Higher GDF15 associated with worse prognosis in acute HF independently of BNP. When both biomarkers GDF 15 and BNP were elevated at discharge, the 2-year mortality risk increased over 3-fold. Biomarkers related to different pathophisyologic pathways can provide incremental prognostic information in acute HF. We reinforce the concept of a multimarker approach in the prognostic assessment of acute HF

On behalf of: KorAHF registry
Funding Acknowledgements: Korea Centers for Disease Control and Prevention

Background: Assessment of risk at time of admission could be a useful tool for guiding management of acute decompensated heart failure (ADHF). The aim of this study was to develop a novel and simple assessment tools for better hospital discharge risk stratification.
Methods: A total of 5,625 cohort patients enrolled in Korean acute heart failure registry (KorAHF). Clinically relevant variables were collected in all the patients (Table 1).

The entire study population had complete 1-year follow-up data. Multivariate analysis by step-wise Cox regression models tested variables that were significant at a p value < 0.2 in univariate analysis.
Results: During 1-year follow-up, all-cause death occurred in 970 out of 5,625 patients (17.2%) in the development cohorts. By multivariate Cox regression analysis, the 11 independent factors that increased the risk of 1-year mortality were described in Table 1. The score was calculated by sum of one point for each variable. A new risk score (KorAHF score) for ADHF showed a strong graded relation to 1-year mortality (2.4% to 53.2%; Figure 1).
Conclusion: The KorAHF score for Korean patients with ADHF is a simple and relevant risk scoring system in prediction of 1-year all-cause mortality. Validation of the risk scoring system in a larger cohort would be needed.

Variables in the risk score system

	BetaCoefficient	P value	Multivariate Hazard Ratio(95% CI)
Age >75 years	0.642	< 0.0001	1.90 (1.66-2.17)
NYHA Fc IV	0.183	0.006	1.20 (1.06-1.37)
SBP < 100 mmHg	0.397	< 0.0001	1.49 (1.26-1.75)
GFR < 60 ml/min	0.350	< 0.0001	1.42 (1.23-1.63)
LVEF < 30%	0.185	0.008	1.20 (1.05-1.38)
Na+ < 135 mEq/L	0.386	< 0.0001	1.47 (1.29-1.68)
Hemoglobin < 10 g/dL	0.373	< 0.0001	1.45 (1.25-1.69)
Nutritional risk index < 89	0.539	< 0.0001	1.71 (1.50-1.97)
Uric acid >7.5 mg/dL	0.138	0.048	1.15 (1.00-1.32)
BNP>1000 pg/ml or NT-proBNP >5000 pg/ml	0.398	< 0.0001	1.49 (1.30-1.71)
No use of RAAS or Beta-blocker	0.328	< 0.0001	1.39 (1.21-1.59)

NYHA Fc = New York Heart Association functional class; SBP = systolic blood pressure; GFR = glomerular filtration rate; LVEF = left ventricular ejection fraction; BNP = brain natriuretic peptide; NT-proBNP = N-terminal pro B type natriuretic peptide; RAAS = renin-angiotensin-aldosterone system; NRI = (1.519 x serum albumin[g/dl]) + (41.7 x weight [kg]/ideal body weight [kg])

Precipitating factors leading to hospitalization and subsequent clinical outcomes in acute decompensated heart failure

J-H Ju-Hee Lee[1]; DH Bae[1]; KK Hwang[1]; MC Cho[1]
[1]*Chungbuk National University Hospital, Cardiology, Cheongju, Korea Republic of*

On behalf of: KorAHF investigators

Background: There are few data examining the factors identified as contributing to heart failure (HF) hospitalization. We evaluated the frequency of clinical factors leading to admission for heart failure and the association between precipitating factors and subsequent outcomes.
Method: We evaluated acute decompensated HF patients hospitalized in ten regionally-representative tertiary university hospitals who registered in the Korean Acute Heart Failure (KorAHF) Registry from March 2011 to February 2014. Precipitating factors were identified at admission and included acute coronary syndrome/ischemia, severe hypertension, atrial or ventricular tachyarrhythmia, bradyarrhythmia, infection, pulmonary embolism, renal failure, anemia or bleeding, medications which can aggravate HF, noncompliance, excessive alcohol or illicit drug use, endocrine abnormalities, recent addition of negative inotropic drugs. In-hospital mortality and 1-year mortality were assessed.
Results: Mean age was 68.5 ± 14.5 and 2,993 patients (53.2%) were male. Among the 5,625 patients who were registered at KorAHF Registry, 4,874 patients (86.7%) had 1 or more precipitating factors identified, with acute coronary syndrome/ischemia (26.3%), atrial or ventricular tachyarrhythmia (20.5%), and infection (19.6%) being most frequent. Acute coronary syndrome/ischemia was most common precipitating factor in HFrEF whereas atrial or ventricular tachyarrhythmia was most common in HFpEF. Acute coronary syndrome/ischemia (8.2% vs 3.5%, P < 0.001) and renal failure (7.6% vs 4.6%, P=0.018) were associated with higher in-hospital mortality, and infection (19.4% vs 11.8%, P=0.038), renal failure (29.5% vs 16.6%, P < 0.001) and anemia or bleeding (26.8% vs 17.0%, P < 0.001) were associated with higher 1-year mortality. But in multivariate analysis adjustment for 14 risk variables, only acute coronary syndrome/ischemia was independently associated with higher in-hospital mortality (odds ratio 2.00, 95% CI 1.44-2.78, P < 0.001) and anemia or bleeding was independently associated with higher 1-year mortality independently (hazard ratio 1.45, 95% CI 1.04-2.03, P=0.031) in all HF patients. In HFrEF patients, acute coronary syndrome/ischemia was also associated with higher in-hospital mortality (odds ratio 1.81, 95% CI 1.26-2.58, P=0.001), whereas renal failure and medications which can aggravate HF were associated with higher 1year mortality (hazard ratio 1.38, 95% CI 1.04-2.03, P=0.046; hazard ratio 1.62, 95% CI 1.04-2.03, P=0.012). In HFpEF patients, infection is associated with higher in-hospital mortality (odds ratio 2.11, 95% CI 1.03-4.33, P=0.041) whereas no precipitating factor can predict 1-year mortality.
Conclusion: Precipitating factors are frequently identified in patients hospitalized for HF and are associated with clinical outcomes independent of other predictive variables. Increased attention to these factors, many of which are avoidable, is important in optimizing the management of HF.

P238
Prognostic role of severe renal impairment in patients with HFrEF or HFpEF hospitalised for acute heart failure: data from the IN-HF Outcome Italian Registry

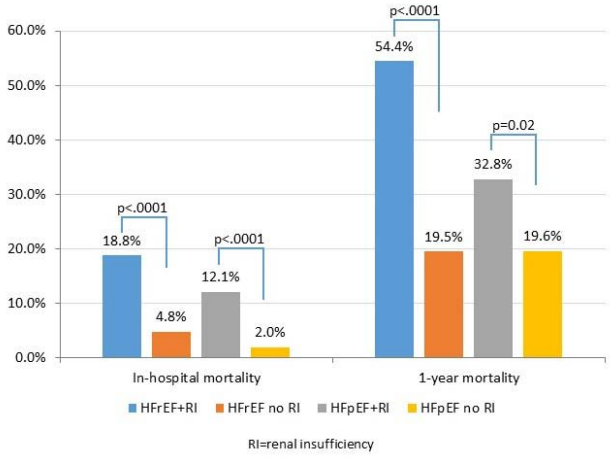
Health Science Foundation, Cotignola, Italy*

On behalf of: IN-HF Outcome Investigators
Funding Acknowledgements: The study was partially supported by an unrestricted grant by Novartis, Abbott, and Medtronic, Italy

Background: Renal insufficiency (RI) frequently coexists with heart failure (HF) and worsens outcomes by adding a negative prognostic effect per se and by limiting the use of HFrEF life-saving treatments such as ACE-Inhibitors (ACE-I) and mineralcorticoid receptor antagonists (MRAs). Prognostic impact of RI in patients with HFpEF is less defined.
Aims: To evaluate the prognostic role of RI in patients with HFrEF or HFpEF hospitalised for HF.
Methods: We analysed patients hospitalised for acute heart failure (AHF) included in the IN-HF Outcome Italian registry with available data regarding left ventricular ejection fraction (LVEF) and estimated glomerular filtration rate (eGFR) data on admission. We than compared the prognostic role of severe RI (< 30 ml/min/1.73m2) in patients with HFrEF (LVEF < 45%) and in patients with HFpEF (LVEF≥45%).
Results: The study population was composed by 1643 patients: 1131 patients had HFrEF and among these patients the prevalence of severe RI was 13.2%. Compared to those with more preserved renal function, HFrEF patients with severe RI were older (75 ± 10 vs 70 ± 12 years, p < 0.0001), with a higher prevalence of females (40.9% vs 30.4%, p = 0.010) and had a higher prevalence of ischemic aetiology of HF (62.4% vs 47.2%, p < 0.001). Analysing treatments in the week prior to admission, HFrEF patients with severe RI received a lower prescription rate of ACE-I or angiotensin receptor blockers (46.3% vs 59.2%, p = 0.003) and of digoxin (7.4% vs 15.4%, p = 0.009), while prescription rates of betablockers and MRAs were similar. HFrEF patients with severe RI had higher in-hospital and one-year all-cause mortality (see Figure). Patients with HFpEF were 512 and 11.2% of these had severe RI. Compared to those with more preserved RI, HFpEF patients with

severe RI had a similar percentage of females (55.2% vs 56.67%, p = 0.84) and similar age (77 ± 9 vs 74 ± 10 years, p = 0.07) and a higher prevalence of ischemic aetiology of HF (39.7% vs 29.2%, p = 0.03). The in-hospital and 1-year mortality rates of HFpEF patients with or without severe RI are reported in Figure.
CONCLUSIONS. In patients with AHF, severe RI is significantly associated with a worse in-hospital and one-year all-cause mortality not only in patients with HFrEF but also in those with HFpEF.



P239

Clinical characteristics and outcome of acute heart failure patients with mid-range ejection fraction

E Edoardo Sciatti[1]; V Carubelli[1]; A Ravera[1]; D Tomasoni[1]; E Vizzardi[1]; I Bonadei[1]; CM Lombardi[1]; M Metra[1]
[1]University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy

Background: Heart failure (HF) with mid-range ejection fraction (HFmrEF) is a new entity defined by the recent ESC heart failure guidelines.
Purpose: To investigate the medium-term prognosis of HFmrEF after hospitalization for acute heart failure (AHF).
Methods: In a retrospective, single center study we included patients hospitalized for AHF at our Institute. Left ventricular ejection fraction (LVEF) was assessed with echocardiography during the hospitalization in all patients. For the purposes of this analysis patients were divided according LVEF in HFrEF (LVEF < 40%), HFmrEF (LVEF 40-49%), and HFpEF (LVEF ≥ 50%). Primary outcomes were cardiovascular (CV) death and CV death and HF hospitalization at day 180.
Results: A total of 948 patients were included in this analysis, 625 (65.9%) HFrEF, 117 (12.4%) HFmrEF, and 206 (21.7%) HFpEF. HFmrEF patients showed intermediate characteristics between HFrEF and HFpEF as regards age, sex, cardiac and extracardiac comorbidities. At baseline systolic blood pressure differed significantly in the three groups (HFrEF 125 ± 27 vs HFmrEF 138 ± 32 vs HFpEF 138 ± 31 mmHg; p < 0.001) as well as values of Nt-proBNP (6665 [IQR 4369-13753] ng/mL vs 4826 [IQR 2847-6915] ng/mL vs 3264 [IQR 1976-4766] ng/mL; p < 0.001). Treatment with ACEi/ARBs and beta blockers was highly implemented in both HFrEF and HFmrEF patients at discharge (HFrEF 69.8% baseline to 77.6% discharge vs HFmrEF 67.5% baseline to 74.4% discharge for ACEi/ARB; HFrEF 65.1% baseline to 83.5% discharge vs HFmrEF 62.4% baseline to 82.1% discharge, for beta blockers). At Cox regression analysis, the risk of CV mortality to day 180 did not differ across groups (HFrEF HR 1.576, 95% CI 0.983-2.527; p = 0.059 vs HFmrEF HR 0.580, 95% CI 0.268-1.254; p = 0.166 vs HFpEF HR 0.746, 95% CI 0.435-1.279; p = 0.286). Similarly the risk of CV death and HF hospitalization was comparable between groups (HFrEF HR 1.180, 95% CI 0.919-1.515; p = 0.195 vs HFmrEF HR 0.956, 95% CI 0.669-1.368; p = 0.807 vs HFpEF HR 0.824, 95% CI 0.614-1.106, p = 0.198) (Figure 1a and b).
Conclusion: AHF patients with mid-range LVEF seem to show intermediate clinical characteristics and similar outcomes of patients with HFrEF and HFpEF. This study confirms the limited prognostic power of LVEF in predicting post discharge events in AHF setting.

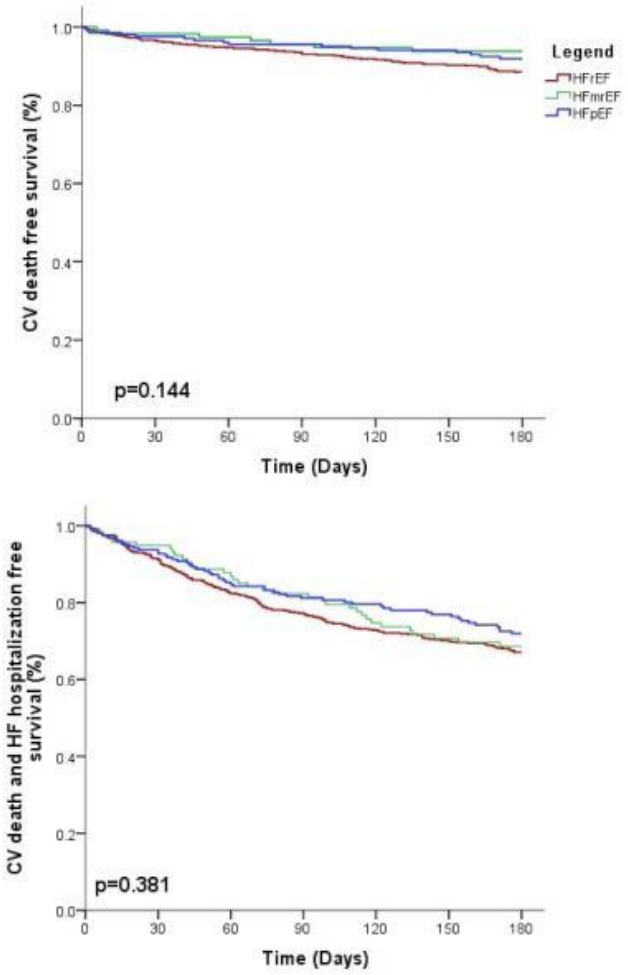


Figure 1

P240

Contemporary assessment of lung ultrasound, bnp and echocardiography predicts outcome in patients with acute heart failure independently to systolic dysfunction

A Palazzuoli[1]; G Ruocco[1]; M Beltrami[1]; R Nuti[1]; JG Cleland[2]
[1]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy; *[2]Imperial College London, National Heart & Lung Institute and National Institute of Health Research Cardiovascular Biomedical , London, United Kingdom*

Background: Pulmonary and systemic congestion at hospital discharge predict an adverse prognosis in patients with heart failure. Lung ultrasound (LUS) may be a simple, accurate, fast and economic tool to assess pulmonary congestion by imaging 'comets' or B-lines.
Purpose: 1) To investigate the relationships of B-lines to B-type natriuretic peptide (BNP), left ventricular ejection fraction (LVEF) and LV filling pressure at admission. 2) To evaluate their relationship to prognosis at six months and the added value of repeat measurements before discharge. 3) To explore potential differences in patients with HFpEF and HFrEF.
Methods: Patients admitted for worsening heart failure were assessed within 12h of admission. B-lines and BNP values were also evaluated at discharge. The primary composite outcome was re-hospitalization for heart failure or death at 6 months. Continuous variables are shown as median and inter-quartile range (IQR). Categorical variables are shown in percentage (%) or count.
Results: Of 162 patients enrolled, 95 had HFrEF and 67 had HFpEF; median age was 80 [77-85] years and 85 (52%) were women. The median number of B-lines at admission was 31 [27-36] and median plasma BNP was 1007 [768-1540]ng/L. Patients with HFrEF were slightly older, more likely to be men and less likely to have a history of hypertension. At admission, B-lines correlated with BNP (r=0,43;p < 0,001), clinical congestion (r=0,25; p = 0,001) and PAP (r=0,42; p < 0,001). Failure to reduce

B-lines during hospitalization was strongly associated with worse outcome (AUC 0,91 [0,85-0,96]; p < 0,001); a B-line reduction of <40% from admission to discharge had a sensitivity 90%, specificity 70% and correctly predicted outcome at 180 days in 76% of cases (p < 0,001). In univariate Cox regression analysis, the number of B-lines at discharge (HR 1.12 [1.09-1.16]; p < 0,001) and change in B-lines during admission (HR 0.95 [0.94-0.96]; p < 0,001) were related to poor outcome. Multivariable analysis confirmed the association with change in B-lines.
Conclusions: LUS appears a useful method to assess the severity and monitor the resolution of lung congestion. Measurement of lung congestion at discharge provides prognostic information for patients with either HFpEF or HFrEF.

Funding Acknowledgements: ISCIII/PIE13/00024/Cofinanciado FEDER

Objective: Heart failure (HF) is a complex cardiometabolic disorder resulting from the combination of genetic and environmental factors. Recent advances in genomics offer a smart option for predicting future risk of disease early in life and prognosis. The objective of this study was to examine the prognostic value of a series of single nucleotide polymorphisms (SNP) previously related with metabolic disorders and obesity.
Methods: A selection of 199 SNP found to be related with obesity, BMI, circulating lipids, HF, and cerebral infarction were genotyped in 227 patients with HF diagnosis following the current European guidelines of clinical practice. Anthropometrical and clinical variables were collected for each patient and a follow-up period was stablished for registry of death and re-hospitalization by HF as the primary endpoint. An additive genetic model was assumed, and the genotypes were analysed by Cox regression to study the association with HF prognosis.
Results: A total of 63 events (defined by the combination of death and re-hospitalization for HF) were registered. From the total of SNP, rs2107595, rs6882076, and rs737337 variants were independently associated with HF prognosis during a follow-up period of 438 (263-1077) days [median (IQR)]. Results were further adjusted for baseline characteristics (age, sex, body mass index (BMI), diabetes mellitus, hypertension, hyperlipidaemia, and blood lipid concentrations). Age and diabetes mellitus were also bad prognostic variables whereas higher total cholesterol was related with better prognosis, as expected in HF patients. Only rs737337 was related with BMI values, being the protective variant more present in normal weight (BMI $<$ 25) and obesity type I (30 $<$ BMI $\leq$ 35). A combined score of the three genomic variants was highly predictive of bad prognosis, in combination with diabetes mellitus and low levels of total cholesterol concentration.
Conclusions: Three SNP were identified as important predictors of major clinical outcomes in patients with HF, independently to age, diabetes mellitus and blood lipid concentrations. A combined score with these genomic variants could be a good independent predictor of bad prognosis in this clinical context.

Worsening renal function in patients hospitalized for acute decompensated heart failure

E J Zaidel[1]; MI Sosa Liprandi[1]; JM Picco[1]; CN Pignataro[1]; R Villarreal[1]; HG Cestari[1]; EF Mele[1]; A Sosa Liprandi[1]
[1]Sanatorio Guemes, Cardiology, Buenos Aires, Argentina

On behalf of: Heart Failure Division, Sanatorio Güemes, Argentina

Background: It is usual to see an increase in creatinine levels in patients admitted for acute decompensated heart failure (ADHF), and renal dysfunction is a marker of adverse events in short and long term. Several pathophysiologic mechanisms have been proposed. However, there is lack of information about the rate and clinical predictors of worsening renal function (WRF).
Purpose: The aim of this study was to describe the rate of WRF in patients admitted for ADHF, and search for predictors of WRF.
Methods: A prospective registry of ADHF patients admitted to a University Hospital in the city of Buenos Aires was developed during two consecutive years (June 2013-June 2015). Baseline characteristics and daily creatinine and urea levels were registered. WRF was defined as a raise of creatinine levels ≥0.3 mg/dL or an increase of 1.5 times from baseline levels (Acute Kidney Injury Network definition). Conventional descriptive and comparative analyses were performed. The correlation between days and mean level of creatinine was evaluated with R2. Predictors of WRF were evaluated with univariate and multivariate models.
Results: 353 consecutive patients were recruited, with a median age of 75 years [IQR 67-85], and 54% were male. The most frequent etiologies were ischemic (30%), hypertensive (29%), and valvular (21%). Half of the patients had HF with preserved ejection fraction. After excluding patients on dialysis and patients included in randomized clinical trials with drugs that could potentially modify renal function (ularitide, serelaxin), 315 patients remained for the analysis. Among them, 111 (35.7%) had WRF.
Mean daily creatinine levels were 1.19, 1.22, 1.27, 1.30, and 1.35 mg/dL, respectively (R2=0.98). Mean baseline creatinine clearance was 66 ml/min/1.73 m2 (±24) (MDRD). The median hospitalization days was 9 [6-17], in WRF patients vs 7 [5-11] (p = 0.032) in non WRF, and in-hospital mortality of WRF patients was 23.4% vs 7.8% respectively (OR= 3.59; CI 95%: 1.83-7.01, p = 0.01). Five factors were related to WRF in the univariate analysis: age (75 vs 72 years), ischemic etiology (34% vs 25%), prior use of ACE inhibitors (44% vs 36%), and HF with preserved ejection fraction
(20% vs 25%), while prior use of angiotensin receptor blockers was related with a lower rate of WRF (20% vs 25%). All those factors were included in the multiple logistic regression model, and the ischemic etiology was the only independent predictor of WRF (OR=1.74; CI 95%: 1.03-3.0, p = 0.042).
Conclusions: One third of ADHF patients develop WRF, and the ischemic etiology of heart failure was the only independent predictor found. Further investigations are needed about differential mechanisms of renal dysfunction in ischemic patients.

P243
Different impact and prevalence of hyperuricemia in patients with acute heart failure with preserved ejection fraction respect to reduced ejection fraction

A Palazzuoli[1]; G Ruocco[1]; O De Vivo[1]; R Nuti[1]; PA Mccullough[2]
[1]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy; *[2]Baylor University Medical Center, Baylor Jack and Jane Hamilton Heart and Vascular Hospital, Dallas, United States of America*

Background: The association between elevated uric acid levels and cardiovascular diseases has been known for almost half a century. Although the relationship between uric acid and chronic heart failure has also been demonstrated, the clinical and prognostic role in acute settings remains controversial and still poorly examined. Therefore, this study aims to evaluate the significance of uric acid in acute heart failure (AHF) and verify any different impact in heart failure with reduced ejection fraction (HFrEF) compared to heart failure with preserved ejection fraction (HFpEF).
Methods: This was a retrospective analysis which included consecutively 324 subjects, screened from interventional Diur-HF Trial (NCT01441245) from January 2011 to February 2016. Patients were eligible if they were admitted with a primary diagnosis of AHF. Enrolled subjects were categorized based on ejection fraction (EF): HFrEF [EF <50%], HFpEF [FE≥50%]. Blinded physicians assigned a standardized congestion score at the time of enrollment. We defined as hyperuricaemia as serum uric acid (UA) ≥ 7 mg/dL in men and ≥ 6 mg/dL in women. Patients were followed for six months after discharge with clinical visits or telephone contacts. The primary outcome was the composite of death or rehospitalization for AHF.
Results: 173 HFrEF and 151 HFpEF patients were followed and hyperuricemia was found in 160 subjects with greater proportions in HFpEF compared to HFrEF

(57% vs 43%; p = 0,01). It was significantly more prevalent in women (74% vs 60%; p = 0.008), those with diabetes (39% vs 19%; p <0.001), hypertension (62% vs 43%; p = 0.001) and atrial fibrillation (48% vs. 34%; p = 0.01). In HFrEF patients, univariate analysis showed that hyperuricemia [HR 1,48 (1,02-2,15); p = 0.04] and congestion score ≥ 3 [HR 2,83 (1,52-5,28); p < 0.001] were related to the primary outcome; after adjustment, multivariable analysis demonstrated that only congestion score ≥ 3 [HR 2,08 (1,06-4,10); p = 0.03] was independently associated with the primary outcome. On the contrary, in HFpEF patients, the only significant predictor of poor prognosis was hyperuricemia, both in univariate [HR 2,25 (1,44-3,50); p < 0.001] and multivariable [HR 2,38 (1,32-4,28); p = 0.004] analysis.
Conclusions: In Acute Heart Failure hyperuricemia is common among those with HFrEF and HFpEF. In the HFpEF subgroup, hyperuricemia was independently associated with an increased risk of death or hospitalization.

P244

Acid-base balance disorders are associated with increased 1-month and 3-month mortality in patients with acute heart failure

G Gabrielius Jakutis[1]; M Balciunas[2]; A Montvilaite[3]; R Norvilaite[3]; A Mebazaa[4]; A Kavoliuniene[5]; J Celutkiene[2]

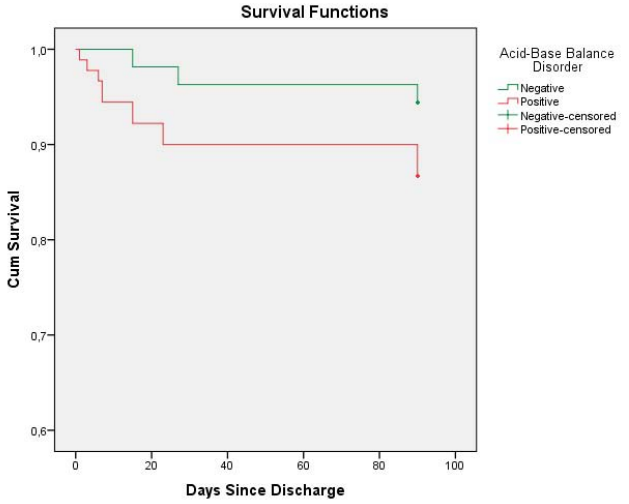
Background/Introduction: Arterial blood gas (ABG) analysis is one of the main tests for decision-making in patients with severe dyspnea. However, the significance of ABG analysis on the prognosis for the acute heart failure (AHF) patients remains unclear.
Purpose: The study evaluated whether acid-base balance disorders at the time of admission are associated with 1- and 3-month rehospitalisation and mortality rates of AHF patients.
Methods: A prospective observational cohort study enrolled consecutive patients with acute dyspnea from March, 2015 till August, 2016. The exclusion criterion was a suspected acute coronary syndrome. Data of 144 study patients with adjudicated diagnosis of AHF, available ABG and biochemical blood analyses at admission and completed 3-months follow up were included in the analysis. Outcomes were evaluated with Kaplan-Meier curves and Cox proportional hazard model to estimate survival rates, hazard ratios (HR) and 95% confidence intervals (CI). Data were analysed using SPSS v23 statistical package.
Results: 71 (49.3%) patients were male and 73 (50.7%) female. Acid-base balance disorders were found in 90 (62.5%) patients: 25 (17.3%) patients had acidosis (15 [10.4%] metabolic, 10 [6.9%] respiratory), 58 patients (40.3%) had alkalosis (7 [4.9%] metabolic, 51 [35.4%] respiratory), 7 (4.9%) patients had a mixed A-B disorder. Both respiratory and metabolic acidosis (HR=4.65, 95% CI: 1.42; 15.25, P=0.011) and mixed A-B disorders (HR=4.66, 95% CI: 1.05; 21.58, P=0.049) at admission were significantly associated with 1-month mortality (total number of deaths – 8). Metabolic acidosis (HR=7.63, 95% CI: 2.46; 23.67, P < 0.001) and mixed A-B disorders (HR=5.52, 95% CI: 1.55; 19.57, P=0.008) also displayed a significant effect on 3-month mortality (total 12 deaths). On-admission A-B disorders had no impact on 1- and 3-month rehospitalisation rates. The cumulative 90-day survival was 85% for patients with A-B disorders and 93% for individuals with normal A-B balance (p = 0.135). Patients with on-admission A-B balance disorders had a higher count of leukocytes (mean 9140/mm3 vs. 7360/mm3, p = 0.049), increased CRP (mean 29.95 mg/L vs. 12.25 mg/L, p = 0.028), glucose (mean 7.55 mmol/L vs. 6.22 mmol/L, p = 0.014), urea (mean 11.61 mmol/L vs. 7.86 mmol/L, p = 0.022) as well as high sensitivity (hs) troponin I serum concentration (mean 70.65 ng/mL vs. 45.31 ng/mL, p = 0.024) compared to patients without A-B balance disorders. No significant difference was observed in admission serum BNP concentration (mean 1554.45 pg/mL vs. 829.73 pg/mL, p = 0.065) in patients with and without A-B balance disorders.
Conclusions: On-admission acid-base balance disorders demonstrate a significant impact on 1- and 3-month mortality rates of patients with AHF. Patients with acid-base balance disorders have a distinct biochemical profile in terms of inflammatory and necrosis biomarkers. These patients require careful monitoring during first three months after the discharge.



Survival of AHF patients

P245

Short-term outcomes in heart failure patients with chronic obstructive pulmonary disease in the community

I Elhaddad[1]; K Kharbouche[1]; L Azouzi[1]; R Habbal[1]
[1]chu ibn rochd, cardiology, casablanca, Morocco

Aims: Heart failure (HF) and chronic obstructive pulmonary disease (COPD) are common co-morbidities. The combination presents diagnostic challenges and has been linked with worse prognosis in patients admitted to hospital. There is hardly any prognostic data in patients with both co-morbidities in the community.
Methods: And Results: We evaluated 783 patients (27.2%) with left ventricular systolic dysfunction under the care of a regional nurse-led community heart failure team between June 2007 - June 2010. 101 patients (12.9%) also had a diagnosis of COPD. 94% of patients were on loop diuretics; 83% on ACE Inhibitors, 74% on b-blockers; 9.6% were on bronchodilators and 42% on aldosterone antagonists. Mean age of the patients was 77.9 + 5.7 years; 42% were females and mean NYHA
class was 2.1 + 0.6. Mean follow-up was 28.2 + 2.9 months. b-blocker utilization was markedly lower in in patients receiving bronchodilators compared to those without (overall 24.4% vs 81%; P , 0.0001). 24 month survival was 93% in patients with HF alone and 89% in those with both co-morbidities (P=NS). The presence of COPD was associated with increased HF hospitalizations [HR 1.56 (1.4-2.1); P ,0.001] and major adverse cardiovascular events [1.23 (1.03 - 1.75); P , 0.001].
Conclusions: COPD is a common co-morbidity in ambulatory HF patients in the community and is a powerful predictor of worsening HF. It does not however appear to affect short-term mortality in ambulatory HF patients.

P246

Clinical characteristics and outcomes of patients with acute heart failure and 'mid-range' ejection fraction: data from the IN-HF Outcome Italian Registry

F Orso[1]; A P Aldo Pietro Maggioni[2]; G Fabbri[2]; D Lucci[2]; SA Ciricugno[3]; E Giagnoni[4]; L Moretti[5]; S Valente[6]; L Tavazzi[7]

Health Science Foundation, Cotignola, Italy*

On behalf of: IN-HF Outcome Investigators
Funding Acknowledgements: The study was partially supported by an unrestricted grant by Novartis, Abbott, and Medtronic, Italy

Background. Recent guidelines of the European Society of Cardiology recognized as a "gray area" the patients with heart failure (HF) and an ejection fraction (EF) between 40 and 49%, defined "mid-range" (HFmrEF), and confirmed the cut-off values for HF with preserved EF (≥50%, HFpEF) and HF with reduced EF (< 40%, HFrEF).

Aims: To compare in patients hospitalised for acute heart failure (AHF) demographic and clinical characteristics as well as outcomes of HFmrEF patients with those of HFpEF or HFrEF.
Methods: Data are from the prospective nationwide Italian Network on Heart Failure (IN-HF) Outcome Registry which collects information on in-hospital and outpatients with HF.
Results: We studied 1669 patients hospitalised for AHF and with EF assessed during hospitalization: patients with HFmrEF were 19.0%, 58.4% had HFrEF and 22.6% HFpEF. HFmrEF had intermediate demographic characteristics: mean age was 73 ± 10 vs 70 ± 12 years in HFrEF and 75 ± 10 in HFpEF ($p < 0.001$), prevalence of females in HFmrEF was 43.9% compared to 30.3% and 60.0% in HFrEF and HFpEF respectively ($p < 0.001$). Ischemic etiology was more frequent in HFrEF (48.9%) and HFmrEF (47.6%) than in HFpEF patients (20.7%), $p < 0.001$, which had a higher rate of hypertensive etiology. Compared to those with HFrEF and HFpEF, patients HFmrEF had a higher prevalence of diabetes (48.0% vs 38.8% and 39.0%, $p = 0.01$), dyslipidaemia (26.2% vs 24.0% and 16.7%, $p = 0.005$) and chronic kidney disease (36.9% vs 33.0% and 25.2%, $p = 0.003$). At entry mean systolic blood pressure was significantly higher ($p < 0.0001$) in HFpEF (147 ± 34mmHg) vs HFmrEF (143 ± 33 mmHg) vs HFrEF (127 ± 30 mmHg) patients. Acute pulmonary edema was more frequent in HFmrEF (47.0%) compared to HFrEF (34.5%) and HFpEF (33.2%), $p < 0.0001$. No differences were found in the use of IV diuretics, while use of inotropes (dopamine, dobutamine, levosimendan) was higher in HFrEF (25.6%) with respect to HFmrEF (10.7%) and HFpEF (8.0%), $p < 0.0001$. In hospital mortality was higher in HFrEF patients (7.3%) compared to HFmrEF (4.1%) and HFpEF (2.9%), $p = 0.003$, but this difference was not significant at 1 year (24.6%, 23.7% and 19.6% respectively, $p = 0.16$).
Conclusions: Patients with HFmrEF represent a significant portion of patients with HF and appear to have intermediate clinical characteristics. In-hospital mortality rate was lower than that observed in HFrEF and higher than that found in HFpEF. However, this difference becomes non-statistically significant at 12 months follow-up.

P247
Evaluation of prognostic indicators of in-hospital evolution and re-hospitalization of patients admitted to the coronary unit with acute heart failure

MA Mariano Agustin Maydana Martn[1]; DE Echazarreta[1]; F Amendola[1]; LM Ortiz[1]
[1]*Hospital San Juan de Dios, Heart Failure and Pulmonary Hypertension Section, La Plata, Argentina*

Background: The term "acute heart failure" refers to the beginning of heart failure signs and symptoms, or a sudden and unexpected worsening of them. Being a life-threatening clinical condition, it demands urgent evaluation and treatment, as it often results in most of the patients having to be admitted to critical care units. In a recent research carried out in Argentina among a group of patients experiencing this situation, it was found out that 25% of them were diabetic, 20% had chronic obstructive pulmonary severe disease, and almost 10% had renal failure. The part of the population that suffers heart failure "de novo", had a tendency towards atrial fibrillation. The appropriate diagnosis of the type of acute heart failure the patient is having and the recommended treatment (e.g. reducing fluid overload and improving load conditions with diuretics, vasodilators, and even with inotropic agents to achieve better tissular perfusion), will determinate the in-hospital evolution, and/or the early re-admission at discharge; that happen in almost 25% of the patients, 30 days after being discharged, which is associated with risk of cardiovascular death. Therefore we must be meticulous and recognize variables related with in-hospital worsening, and at 30 days after discharge evolution, to prevent events in that patients.
Purpose: Identify predictors of in-hospital death from cardiovascular cause, and 30 days after discharge. Identify predictors of readmission.
Methods: We recruited fifty patients admitted to the Coronary Unit of the Hospital with diagnosis of acute heart failure since july 2016 to november 2016. We checked at admission, at discharge and 30 days the following information: filiation dates, portable x ray, cardiovascular risk factors, lab variables including biomarkers, vital signs, clinical presentation, echocardiographic variables, anthropometry, electrocardiographic findings, medications, and semiological findings.
Results: The final analysis included 50 patients with acute descompensated heart failure. The average age was 65 (SD 13), 32 p (64%) was male. 52% of patients had hypertension, and the most frequent clinical presentation was descompensated chronic heart failure. The mortality rate was 10%. Exploratory analysis indicated that hiponatremia was associated with an increased in the risk of cardiovascular mortality with a significant difference (RR=12,8 95% confidence interval 2,9-54,9 $p = 0,00002$). The creatinine clereance < 30ml/min/m2 and the serum concentration of NT-porBNP >800pg/ml was associated with an increased risk of cardiovascular death, but with no significant difference (RR=3,5 CI 0,69-17,7 $p = 0,12$ // RR=0,17 CI 0,02-0,36 $p = 0,12$ respectively).
Conclusions: In our poblation study the mortality rate was very high, and hiponatremia was a valious predictor of in-hospital and 30 day after discharge mortlity. There was not predictors associated with an increased readmission.

P248
Predictors of one year mortality in chronic systolic heart failure newly diagnosed

H M Hadj Mohammed Ali Lahmar[1]; N Laredj[1]; F Boukerche[1]; L Hammou[1]
[1]*Universitary Hospital Center of Oran, department of medecine, Oran, Algeria*

Introduction and problematic:heart failure is a common pathology, with a heavy morbidity and mortality. Its prevalence in the world varies between 1 and 2% of the adult population and reaches 10% after 70 years. It represents the ultimate evolution of many cardiovascular diseases, especially ischemic and hypertensive. Heart failure is associated with high morbidity and mortality. A lot of progress where new techniques have emerged and made possible functional improvement and, especially a better survival, to certain category of patients. Therefore, the prognostic evaluation becomes a crucial step in the management of heart failure, to guide treatment decisions based on individual risk.
Objective : identifying and measuring predictors of one-year mortality in newly diagnosed chronic systolic heart failure
Methods: we conducted a longitudinal prospective analytical bi –centric study, with one year follow-up.
Results: : 206 patients were enrolled with a mean age of $54,9 \pm 1.8$ years, a sex ratio of 1,9. The prevalence of diabetes mellitus was 39,8%, hypertension 30,1%. Coronary artery disease was present in 50,5%, dilated cardiomyopathy in 30,1% and toxic cardiomyopathy in 1,9%. The mortality rate was 12,7% (11,7% in men vs 14,2% in women, p not significant) and re-admission rate was 17,6% (23,1 % for men vs 6,6% in women, $p = 0.004$). Most clinical, echographic, biological and functional parameters cited in the literature have demonstrated prognostic predictive value with different rates of sensitivity and specificity. In multivariate analysis, pulmonary vascular resistance (new highly sensitive and specific parameter , RR 47), BNP , TAPSE , dP / dt, the distance travelled in six-minutes' walk test and serum sodium level were predictors of mortality in heart failure. The median survival by Kaplan- Meier was 24 months, with no gender difference. All parameters influencing mortality had an impact on survival. Improving the quality of life as measured by the six minutes' walk test and the questionnaire was significantly improved in patients remained alive. Finally, the evaluation of drug prescriptions trends, according to new international guidelines, is quite reassuring in that the new molecules that allowed a significant reduction in morbidity and mortality in heart failure are widely prescribed in our patients.

P249
Incidence, risk predictors and prognosis of left ventricular systolic dysfunction after acute coronary syndrome

L Luis Santos[1]; F Montenegro Sa[1]; C Ruivo[1]; S Pernencar[1]; F Soares[1]; F Saraiva[1]; A Antunes[1]; J Correia[1]; J Guardado[1]; N Carvalho[1]; P Gomes[1]; J Morais[1]
[1]*Hospital Santo Andre, Cardiology, Leiria, Portugal*

Introduction: Left ventricular systolic dysfunction (LVSD) is a strong marker of worse prognosis in acute coronary syndrome (ACS) and information is lacking about independent predictors of LVSD after ACS. Thus, it is relevant to search for those determinants in order to better manage ACS patients, prevent heart failure (HF) development and improve prognosis.
Purpose: To identify predictors of LVSD after ACS and to evaluate how it influences prognosis.
Methods: Retrospective analysis of 327 patients with ACS consecutively admitted for coronariography in a non-tertiary hospital between January 2014 and December 2015. All patients underwent a routine invasive strategy and were evaluated by echocardiography, with left ventricular ejection fraction (EF) measure, before hospital discharge. Patients were divided into 2 groups according to their EF: A – EF $\geq$ 40% (n = 287; 87.8%); B – EF < 40% (n = 40; 12.2%) which defines LVSD. A one year follow-up was performed. Logistic regression analysis was used to assess independent predictors of LVSD after ACS.
Results: Overall, 141 cases (43.1%) presented with ACS without ST elevation, the mean age was 65.6 ± 13.2 years, with 97 (29.7%) being female. Patients presenting with ST elevation ACS ($p = 0.033$), heart rate >100 bpm ($p = 0.003$), and signs of heart failure (Killip-Kimball $\geq$ 2) at admission ($p = 0.001$), and those with prior history of HF ($p = 0.003$) or taking oral anticoagulants ($p = 0.038$) were significantly prone to show LVSD. Similarly, these patients showed higher levels of myocardial markers of necrosis ($p = 0.004$) and natriuretic peptides (BNP) over hospitalization ($p = 0.001$). They underwent coronariography by femoral artery access more often ($p = 0.016$), with higher rates of coronary bypass surgery referral ($p = 0.004$). One year mortality was also higher in group B ($p = 0.008$). Logistic regression showed strong association between Killip-Kimball $\geq$ 2 at admission (15.0% vs 37.5%; OR 2.6; IC95% 1.2-5.6, $p = 0.016$), maximum BNP levels $\geq$ 200 pg/mL (59.9% vs 89.2%; OR 3.9; IC95% 1.3-11.8) and LVSD.
Conclusion: Based on this unicentric data survey, LSVD after SCA, which had an incidence of 12.2%, can be predicted by assessment of HF signs at admission

and maximum BNP levels above 200 pg/mL during hospitalization. This feature was associated with higher mortality. Therefore, this patients should be early identified and subjected to a more diligent management.

P250

Relationship between hypoalbuminemia on admission and long-term mortality in hospitalized patients following acute decompensated heart failure.

S Yatsu[1]; T Kasai[2]; H Matsumoto[2]; A Murata[1]; T Kato[1]; S Suda[2]; M Hiki[1]; A Takagi[1]; H Daida[1]
[1]*Juntendo University School of Medicine, Department of Cardiology, Tokyo, Japan*; [2]*Juntendo University Graduate School of Medicine, Cardiovascular Respiratory Sleep Medicine, Tokyo, Japan*

Background: Despite advances in specific treatments, heart failure is still recognized as one of the major public health concerns such as poor clinical outcomes. Among such HF patient population, several studies showed that HF patients with hypoalbuminemia has poorer clinical outcomes compared those without. However, in patients with acute decompensated HF (ADHF), conflicting results were reported regarding the relationship between serum albumin level and clinical outcomes. Indeed, it remains controversial whether hypoalbuminemia on admission is associated with worse prognosis in ADHF patient population. Thus, in the present study, we investigate the relationship between hypoalbuminemia on admission and long-term mortality in hospitalized patients following ADHF.
Purpose: We aimed to investigate the relationship between hypoalbuminemia on admission and long-term mortality in hospitalized patients following ADHF.
Methods: We targeted a cohort of 1684 consecutive patients who admitted to the cardiac intensive-care unit from 2007 to 2011. Among them, patients with ADHF were divided into 2 groups according to the presence or absence of hypoalbuminemia on admission defined as a serum albumin <3.4 g/dl. Relationship between admission albumin level and mortality was analyzed by univariable and multivariable Cox proportional analyses. Multivariable analysis included variables which showed <0.1 in univariable analyses.
Results: Out of the 551 patients, 311 (56%) were classified as hypoalbuminemia on admission. There were 152 deaths (27.5%) during a median follow-up of 1.9 years. Kaplan-Meier survival plots in patients with and without hypoalbuminemia are shown in the Figure. Hypoalbuminemia on admission tended to be associated with increased mortality in univariable Cox proportional hazard regression analysis (hazard ratio [HR], 1.32; P=0.098). In the multivariable Cox proportional hazard regression analysis, there was no relationship between hypoalbuminemia on admission and mortality (HR, 1.01; P=0.959). Even when we treated serum albumin levels as a continuous variable, no association between admission albumin level and mortality was observed.
Conclusion: Either hypoalbuminemia or serum albumin levels on admission was not associated with long-term mortality in patients with ADHF. These data suggest that hypoalbuminemia or serum albumin levels on admission may not be a predictor for worse long-term clinical outcomes in patients with ADHF in our patient population. Considering results of previous studies, hypoalbuminemia or serum albumin level at discharge and changes in albumin levels from admission to discharge may play some roles in relationship between albumin status in HF patients and long-term clinical outcomes.

The prognostic value of carbohydrate antigen 125 level in patients with acute decompensated heart failure: correlation with echocardiographic parameters

JJ Sir[1]; SA Lee[1]; SM Choi[1]; SB Joo[1]
[1]*National Medical Center, Seoul, Korea Republic of*

Funding Acknowledgements: The authors wish to acknowledge financial support from National Medical Center located in Seoul, South Korea (No. NMC2012-MS-18)

Background: Recently, serum CA-125 has emerged as a potential biomarker in patients with ADHF.
Purpose: The aim of this study is to investigate the prognostic value of CA-125 and to assess the association between CA-125 and clinical, biochemical and echocardiographic parameters in a population of Korean patients admitted for ADHF.
Methods: We enrolled 110 patients [59 men; median age of 72 year] admitted for ADHF. Serum CA-125, pro-BNP and other biochemical parameters were measured and all patients underwent transthoracic echocardiographic examination on admission. The MACE, defined as stroke, ACS, new-onset AF, re-hospitalization for ADHF and cardiac death were recorded during follow-up.
Results: We found that CA-125 increased accordingly as cardiac function declined from the NYHA Fc II to class III and further from class III to IV [(13.0(9.1-28.7) vs. 47.6(15.1-156.9) vs. 58.0(22.5-192.5) U/ml;$p=0.001$)]. Furthermore, the CA-125 significantly correlated LVEF($r=-0.38$,$p<0.05$), LVEDD($r=0.25$,$p<0.05$), deceleration time($r=0.41$,P=0.001), LAVI($r=-0.26$,$p<0.05$), RVSP($r=0.40$,$p<0.001$), T3($r=-0.39$,$p<0.05$), fT4($r=0.23$,$p<0.05$) and proBNP($r=0.51$,$p<0.05$). MACE developed in 34 patients during 170 ± 90 days of follow-up. The patients with MACE showed significantly elevated serum CA-125 than those without MACE [53.2(16.6-175.1)vs.28.2(11.2-91.0) U/ml,$p<0.05$]. Receiver operating characteristic curve analysis identified CA-125 for increased risk of adverse cardiac events (AUC=0.66;$p=0.01$;cut-off value:64.4 U/ml).
Conclusion: In ADHF patients, CA-125 could reflex the severity of HF and serve as prognostic biomarker for cardiovascular death and HF hospitalization, although the pathophysiology remains to be established.

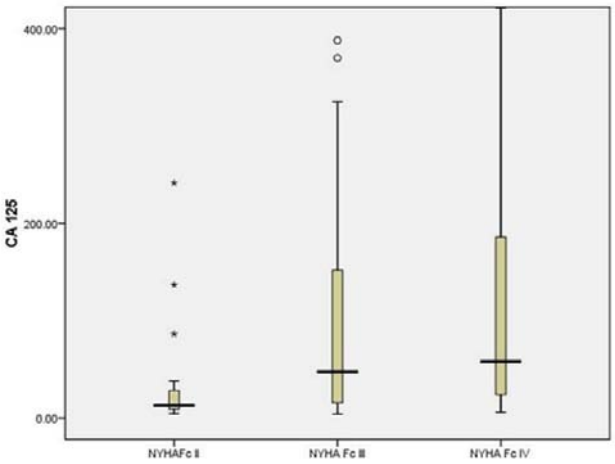

Figure 1.

P252

The prognostic value of echocardiography in early evaluation of patients with non acute coronary syndrome pulmonary edema

V Enache[1]; AC Nechita[1]; I Iordache[1]; SC Stamate[1]
[1]*University of Medicine and Pharmacy Carol Davila, Emergency Hospital St. Pantelimon, Bucharest, Romania*

Introduction: Identifying echocardiographical parameters with a prognostical value for in hospital mortality(IHM) in Acute Pulmonary Edema outside of an acute coronary syndrome (non ACS APE) of diversified ethiologies.
Methods: 92 patients with non ACS APE consecutively hospitalized in Cardiology Clinic St. Pantelimon, between 01.01-31.12.2013, distributed and analyzed according to three etiologies, based on anamnesis, clinical and paraclinical data: ischemic (ischemic coronary disease(ICD) clinically and/or imagistically documented), primary valvular (at least moderate hemodinamic valvular lessions, no ICD) and hypertensive (with preserved LVEF, without significant valvular or documented coronary artery

disease). An echocardiography was performed on admission.The IHM was analized according to echo parameters (LVEF, EDLVd, LAd, TAPSE, PAAT, DTE wave, E/E′ ratio) and ethiology.
Rezults: The following parameters have significantly corellated with IHM in our group: LVd($p = 0.006$), the cut off value 54mm at ROC curve analysis with 90 sensibility, specificity 60, 95%CI 0.58 -0.78, under the curve area 0.69, $p = 0.0003$) TAPSE ($p = 0.0002$, cut off value 17mm, sens 100, spec 48.48, 95%CI 0.66- 0.85, area 0.76, $p < 0.0001$), PAAT($p = 0.0001$, cut off value 102 ms, sens100,spec 65.71, 95%CI 0.68 -0.86, $p < 0.0001$, area 0.78), DTE($p = 0.003$, cut off value 196 ms,sens 81.82, spec 60, 95%CI 0.601 – 0.79, area 0.70, $p = 0.0002$.), E/E' ratio($p = 0.009$). The significance differs according to ethiology. Statistically significant remain: for valvular - LVd($p = 0.003$), for ischemic- TAPSE and PAAT ($p = 0.01$; $p = 0.005$) and for hypertensive - TAPSE ($p = 0.001$), PAAT ($p = 0.009$), DTE($p = 0.008$) and E/E' ($p = 0.01$).
Conclusions: A series of echocardiographical parameters, easily obtained in the first hours of admission have proven a positive predictive and independent value in our analysis for IHM. Their prognosis value changes when assessed according to ethiology, a result that gives echocardiography an important role in evaluating non ACS APE in the emergency room for identifying the ethiology, risk stratification and prognosis purpose.

P253
Echocardiography in acute heart failure: an incremental value for patient prognosis

S Pierre[1]; O Huttin[2]; S Coiro[1]; C Suty-Selton[2]; N Sadoul[2]; F Zannad[1]; N Girerd[1]
[1]*Clinical Investigation Centre Pierre Drouin (CIC-P), Cardiologie, Nancy, France*; [2]*University Hospital of Brabois , Cardiology, Nancy, France*

Introduction: Echocardiography is currently indicated in some, but not at all patients with suspected acute heart failure (AHF), mainly to identify cardiac abnormalities and refine the diagnosis of the hospitalization trigger. We intended to identify the most predictive echocardiography variables of outcome at AHF admission.
Methods: We studied a prospective cohort study of 182 patients (72 ± 14 years, 55.5% men, 31% ischemic HF), admitted for AHF between 2010 and 2013, from the ICALOR database. Each patient had benefit of a complete echocardiography at bedside within first days after admission. Clinical and biological data, with BNP value, at admission were also collected. The end-point was readmission for HF and all-cause mortality after discharge.
Results: During a mean follow-up of 9 months after discharge: 41 patients died (22.5%) and 71 (39%) were readmitted for AHF. In univariable analysis, a RV dysfunction with a TAPSE < 15mm (HR=1.69,(1.00-2.87), $p = 0.048$) and elevated PAPs (HR=3.29,(1.58-6.84),$p = 0.001$) are associated with poor outcome. After adjusting for potential confounders, high BNP value (HR=1.86,(1.17-2.97), $p = 0.009$) and PASP (HR=1.04,(1.01-1.08),$p = 0.012$) are associated with mortality whereas mitral regurgitation (HR=3.33,(1.37-8.06),$p = 0.007$) and A mitral wave velocity (HR=0.22,(0.06-0.79),$p = 0.02$) were independent predictors of readmissions for AHF. Survival was not significantly different across subgroups of ejection fraction and left filling pressures.
Conclusion: Limited sets of echo variable (PASP, mitral regurgitation and mitral A wave amplitude) quantified within first days of AHF admission were associated with mid-term outcome. These results suggest that echocardiography, mainly through congestion quantification, could help risk stratification in patients with AHF.

P254
Is arrival on the weekend associated with increased short term mortality of patients with acute dyspnea?

D Dovydas Verikas[1]; D Kuscenko[2]; D Aniulyte[1]; A Kukulskis[1]; S Damalakas[1]; K Stasaitis[1]; J Motiejunaite[1]; V Juknevicius[2]; A Mebazaa[3]; A Kavoliuniene[4]; J Celutkiene[5]

On behalf of: GREAT network
Funding Acknowledgements: The work was supported by the Research Council of Lithuania, grant Nr. MIP-049/2015 and approved by Lithuanian Bioethics Committee, No. L-15-01.

Introduction: Arrival to the emergency department during the weekends might be associated with poorer care and subsequent longer hospitalisation and worse outcomes. So far few data have been published on the frequency and impact of the admission on the weekend.
Purpose: To evaluate the association of referral to the emergency department on the weekend with the short-term mortality and length of hospital stay (LOS) in patients presenting with acute dyspnea.
Methods: The prospective observational cohort study conducted in two partner institutions enrolled consecutive patients admitted to the emergency department with acute dyspnea due to acute decompensated heart failure, exacerbation of chronic obstructive pulmonary disease, pneumonia, pulmonary embolism and other causes. Data of 678 patients were included in the analysis. The death rate due to all causes was assessed after 1-month and 3-month follow-up period using Cox Regression analysis.
Results: Mean age in analysed cohort was 69.3 ± 19.9 years, 393 pts (58.0%) were male. The study revealed that 122 (18%) patients sought medical care during the weekends. During 3-month follow-up, in total 73 (10.8%) patients died, 56 of them died during the first month (8.3%). The 3-month mortality of those who came on the weekends did not differ significantly from those who came on the weekdays: 8.2% vs 11.3%, respectively, $p = 0.319$. Furthermore, 360 patients (53.1%) were hospitalised with mean LOS found to be 13.02 ± 15.06 days and 3-month death rate 7.2%.
CONCLUSION: High 1- and 3-month all-cause mortality was revealed in the prospective acute dyspnea cohort with the substantial frequency of the referral on the weekends. No impact of arrival at the weekends on the short-term mortality was found in this patient population.

P255
Survival after cardiopulmonary resuscitation by first detected electrical rhythm in patients hospitalized for acute heart failure

CI Radulescu[1]; L Antohi[1]; M Chivulescu[1]; I Cosei[1]; A Covaliov[1]; R Radu[1]; A Ambrosy[2]; C Macarie[1]; M Gheorghiade[3]; O Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania*; [2]*Duke University Medical Center, Cardiology, Durham, United States of America*; [3]*Northwestern University, Cardiology, Chicago, United States of America*

Purpose: In patients hospitalized with acute heart failure (AHF), prognosis after in-hospital cardiac arrest is determined by prompt application of cardiopulmonary resuscitation (CPR) and by severity of cardiac structural abnormality. CPR algorhythms depend on initial electrical rhythm before CPR. Limited data exists regarding the outcome of CPR by first detected electrical rhythm (FDER), in patients hospitalized for AHF.
Methods: The Romanian AHFS (RO-AHFS) registry enrolled 3224 consecutive patients hospitalized for AHFS over a 12-month period. CPR has been considered as event on course of hospitalization and FDER before CPR was recorded in all patients. Successful resuscitation was defined as restoration of spontaneous circulation.
Results: CPR was attempted in 274 patients (8.5% of cohort) during hospitalization. FDER before CPR was recorded as VF/VT, Asystole, and PEA, respectively, for 18.7%, 28.1%, and 53.2% of attempts. Baseline characteristics at admission for CPR patients by FDER are depicted in Table 1. The proportion of patients with restoration of spontaneous circulation was 37% for VF/VT, 14.2% for asystole, and 24.3% for PEA. Only 14% of patients requiring CPR survived to discharge. The rate of survival to discharge for VF/VT, Asystole, and PEA, were, respectively, 29.6%, 7.7%, and 11.6%. Conclusions: Initial pulseless electrical rhythm reflects electromechanical and biohumoral severity of HF and may influence the success of CPR and short-term survival.

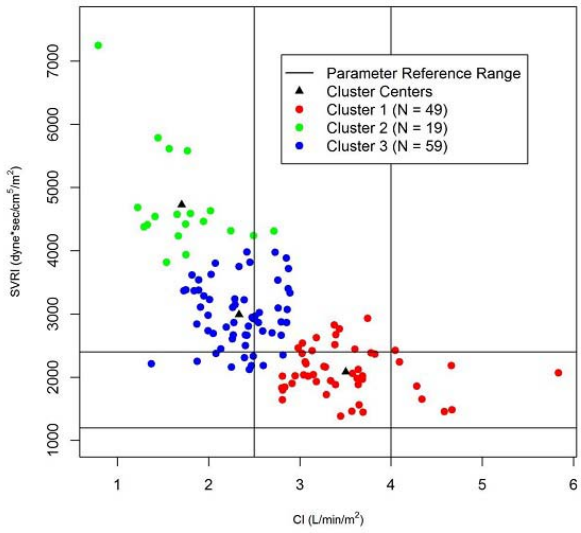
P256
What are the differences between HFrEF, HFmrEF and HFpEF patients admitted for acute heart failure?

E Goncalvesova[1]; P Lesny[1]; M Luknar[1]; M Dankova[1]; V Simovicova[1]; M Kovacova[1]
[1]*The National Institute of Cardiovascular Diseases, Department of Heart Failure and Heart Transplant, Bratislava, Slovak Republic*

On behalf of: on behalf of SLOVASeZ investigators

Backgroud: HF Guidelines 2016 proposed new classification of heart failure based on ejection fraction – HFrEF, HFmrEF and HFpEF.
Aim of the study was to evaluate and compare the three groups of patients according LVEF admitted due to acute heart failure.**Methods:** Data from nationwide multicenter AHF surveys (SLOVASeZ I and II) with 1452 consecutive patients enrolled in 14 hospitals throughout Slovakia were analysed. Ejection fraction was measured during indexed hospitalization in 71,4% of patients and these patients were included to the further evaluation. Mean age of the patients was 72,2 ± 11,7 years, 52% of them were men. Majority of patients were admitted with decompensated heart failure (71,3%), AHF de novo was diagnosed in 28,6% of patients. We identified 41,6% patients with HFrEF, 22,2% patients with HFmrEF and 36,2% patients with HFpEF. Nineteen characteristics of these patients were selected to the statistical analysis. Patients with HFrEF were younger (mean 67,3 v.s. 73,9 years, p = 0,02), with higher proportion of men (69,7% v.s. 36,6%, p = 0,0001). Women were represented more often in HFpEF. Patients with HFrEF were admitted mostly for decompensated chronic heart failure (74,1%, p = 0,02). Coronary heart disease was considered as primary etiology in all group of patients, but the most present in HFmEF (72,3%, p = 0,001), followed by HFrEF (58,6%) and HFpEF (49,7%). Systolic blood pressure at admission was lower in HFrEF (p = 0,01) compared to other groups, with no difference in heart rate between groups. We also did not find difference in the sodium and creatinine levels. Hypertension was reffered as the most frequent comorbidity in HFmrEF and HFpEF compared to HFrEF (p = 0,001). Atrial fibrillation (p = 0,01) and anemia (p = 0,05) were more often in HFpEF. There was no difference in the incidence of diabetes mellitus and chronic kidney disease between groups. There was strong trend to higher in-hospital letalityin HFrEF, but did not reach statistical significance. **Conclusions:** The most significant differences were between HFrEF and HFpEF. Patients with HFmrEF are very close to those with HFpEF but have more CHD as dominant HF etiology.



AHF clusters using the CI and SVRI

Presenting emergency department hemodynamic phenotypes of acute heart failure patients

RM Nowak[1]; S Disomma[2]; P Nanayakkara[3]; B Reed[4]; M Moyer[1]; S Millis[4]; P Levy[5]
[1]Henry Ford Health System, Emergency Medicine, Detroit, United States of America; *[2]Sapienza University of Rome, Department of Medical-Surgical Sciences and Translational Medicine, Rome, Italy*; *[3]VU University Medical Center, Internal Medicine, Amsterdam, Netherlands*; *[4]Wayne State University, Biostatistics, Detroit, United States of America*; *[5]Wayne State University, Emergency Medicine and Physiology and Cardiovasculaer Reserach Institute, Detroit, United States of America*

Funding Acknowledgements: Partially funded by an unrestricted research grant from BMEYE, Edwards LifeSciences, Irvine, California, USA

Purpose: There is little known about the baseline hemodynamic (HD) profiles (beyond pulse/blood pressure) of patients presenting to the Emergency department (ED) with acute heart failure (AHF). Assessing these baseline parameters could help differentiate underlying HD phenotypes which could be used to develop specific phenotypic specific approaches to patient care.
Methods: Patients with suspected AHF were enrolled in the PREMIUM (Prognostic Hemodynamic Profiling in the Acutely Ill Emergency Department Patient) multinational registry and continuous HD monitoring was initiated on ED presentation using noninvasive finger cuff technology (Nexfin, BMEYE, Edwards LifeSciences, Irvine, California). Individuals with clinically suspected and later confirmed AHF were included in this analysis and initial 15 minute averages for available HD parameters were calculated. K-means clustering was performed to identify out of 23 HD variables a set that provided the greatest level of inter-cluster discrimination and intra-cluster cohesions.
Results: A total of 127 patients had confirmed AHF. The final model, using mean normalized patient baseline HD values was able to differentiate these individuals into 3 distinct phenotypes. Cluster 1: normal cardiac index (CI) and systemic vascular resistance index (SVRI); cluster 2: very low CI and markedly increased SVRI: and cluster 3: low CI and an elevated SVRI. These clusters were not differentiated using clinically available ED information.
Conclusions: Three distinct clusters were defined using novel noninvasive presenting HD monitoring technology in this cohort of ED AHF patients. Further studies are needed to determine whether phenotypic specific therapies based on these clusters can improve outcomes.

Background: Heart failure represents a burden to the health-care system and it is one of the most important public health problem. Population-based studies in other countries report a reduction in recent years, but in Spain we lack data about the profile and temporal evolution in a well-defined population framework.
Purpose: To evaluate temporal trends in heart failure hospitalization in the Region of Murcia in the period comprised between 2003 and 2013.
Methods: Study based on the minimum basic hospital discharge data from all hospitals in the Region of Murcia between 2003-2013. We obtained the healthcare episodes by individual health card. For each year, were studied: crude and standardized attendance by age/ sex, ratio of feminization, length of stay, mortality, demographic and clinical variables. Results: 27 158 episodes were obtained in the period. The hospital discharges increased by 76.7%, from 1.28 ° to 2.26 ° (crude) and 1.06 ° to 1.77 ° (standardized). People ≥75 years doubled their attendance, up 19.9 ° in 75-84 years and 32.5 ° in ≥85 years, while in <74 years did not change. Arrhythmias, ischemic heart disease and valvular heart disease were the most prevalent causative disorders.The ratio of feminization was 1.34, but after standardization was matched and did not change. Length of stay was 9.4 days and in-hospital mortality was 9.2%, both of them were unchanged. Conclusions: Between 2003-2013 there is an increase in hospital discharges for HF, which affects the population >74 years, independent of population increasing. They are necessary strategies targeting this population.

Acute heart failure in patients with stress cardiomiopathy

A Shilova[1]; M Gilyarov[1]; A Nesterov[1]; D Shchekochikhin[1]; A Svet[1]
[1]Moscow City Hospital named after N. Pirogov, coronary care unit, Moscow, Russian Federation

Background: Stress cardiomyopathy is known to be a disorder with reversible left ventricular dysfunction, regressing within few weeks. Although, prognosis of Takotsubo syndrome was initially thought to be favorable compared to myocardial infarction, recent studies show that in-hospital and long-term mortality are both consistent to STEMI. The incidence of acute heart failure in stress cardiomyopathy patients varies a lot in different regions.
Methods: We have analyzed respectively 24 cases of takotsubo (stress) cardiomyopathy according to Mayo clinical criteria, hospitalized in a City Hospital in year 2016. 20 (83,6%) of patients were hospitalized as suspected STEMI, representing 2,64% of all cases of MI in the hospital during year 2016.
Results: Of 24 patients with stress cardiomyopathy, 22 (91,7%) were women (mean age 68,54 ± 4,34). Mean EF on presentation was 41,6%. Physical triggers were more common, than emotional (50% vs 35%, $p < 0,05$), in 15% no evident triggers were found. In 36% of patients with Takotsubo syndrome psychiatric abnormalities (severe dementia, delirium or schizophrenia) were found, 3 (12,5%) patients were alcohol abused and represented with delirium tremens. In 16 (66,7%) of cases angiography showed intact coronary arteries, when in 8 (33,3%) cases multivessel atherosclerosis was found with no signs of obstructive coronary lesions. In 12 (50%) patients, takotsubo cardyomopathy caused acute heart failure (AHF). 3 (12,5%) patients developed cardiogenic shock and 5 (20,8%) patients suffered from lung edema. All alcohol abused patients suffered from severe AHF. In 5 (20,8%) of cases dobutamine administration was required, with mean duration of dobutamine infusion 7,2 days. Vasopressors (norepineprine) had to be administrated in 3 (12,5%) cases. LVOT obstruction developed in 1 case during dobutamine treatment. Mortality rate was no significantly higher, than from STEMI in our department, 2 (9,1%) vs 31 (8,4%).
Conclusions: The incidence of AHF, requiring intensive therapy is significantly high. Treatment with dobutamine seems to be safe. It seems like alcohol abused patients have worse prognosis when suffering from stress cardiomiopathy. Treatment approaches are to be further investigated.

P261

ExtraHF survey: the european survey on implementation of exercise training in heart failure patients: regional differences in training modalities

A Verde[1]; SM Binno[1]; U Corra'[2]; P Seferovic[3]; GQ Villani[1]; G Filippatos[4]; PP Ponikowski[5]; MF Piepoli[1]
[1]Guglielmo da Saliceto Hospital, Heart Failure Unit, Department of Cardiology, Piacenza, Italy; [2]Fondazione Maugeri, Department of Cardiology, IRCCS Scientific Institute of Veruno, Veruno, Italy; [3]University Belgrade Medical School, Department of Cardiology, Clinical Center of Serbia, Belgrade, Serbia; [4]Attikon University Hospital, Heart Failure Unit at the Department of Cardiology, Athens, Greece; [5]Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland

On behalf of: Committee on Exercise Physiology & Training of the Heart Failure Association of the ESC

Background: In heart failure (HF), exercise training programmes [ETP] are well-recognised intervention to improve symptoms, but still poorly implemented. The Heart Failure Association promoted a survey to investigate whether and how cardiac centres in Europe are using ETP in their HF patients. Aim of this study is to investigate the presence of geographical difference in ETP availabilities, and modalities of implementation
Methods: The study was designed as a web-based survey of cardiac units in countries affiliated to the ESC. The data collected were subsequently divided in five areas, according to the UNO division of the countries involved: Northern, Southern, Eastern and Western Europe, and extra-EU.
Results: 173 centers replied to the survey, in charge of 78,514 patients: Northern 52 centers (15040 patients), Southern 48 centers (27127 patients), Western Europe 34 centers (11769 patients), Eastern Europe 24 centers (12748 patients), ESC countries extra-Europe 14 centers (11830 patients).
Overall aerobic continuous exercise was the most common modality of training programme in all regions, (58-62%) with the exception of the northern region where this modality was implemented in only 42% of the cases, and in contrast interval low-intensity training was mostly used (85% of the cases). High intensity exercise training was implemented in around 25% of the cases, but in eastern and extra European countries this modality was employed in less than 10% of the cases. Bicycle training was used in most cases (>70%) except in the extra European countries where treadmill modality was mostly employed (60%). Other mode of aerobic endurance training with other cardio fitness facilities (e.g. elliptical trainer) was implemented in around 10% with the exception of the northern region where this modality was implemented in 30% of the cases
Conclusions: Differences in training modality implementation are evident among different European regions. Further studies should investigate ETP outcomes based on different modality of training implementation in order to identify the most effective program

Severe acute heart failure complicating ST-elevation myocardial infarction. Results from the BIHOTZEZ-Gipuzkoa registry.

C Goena Vives[1]; M Telleria Arrieta[2]; L Quintas Ovejero[1]; R Garcia Martin[1]; I Lluis Serret[1]; P Morrondo Valdeolmillos[3]; JJ Artaetxeberria Zuazo[3]; K Ibarguren Olalde[4]
[1]Mendaro´s Hospital, Cardiology, Mendaro, Spain; [2]Donostia Universitary Hospital, Hemodynamic Department, Donostia, Spain; [3]Donostia University Hospital, Intensive Care Unit, Donostia, Spain; [4]Osakidetza, Emergency department, Donostia, Spain

On behalf of: BIHOTZEZ-Gipuzkoa

Introduction: Acute heart failure (AHF) complicating ST-segment elevation myocardial infarction (STEMI) is recognized as an ominous complication and studies assess the prognosis of AHF according to its timing. Purpose:We aimed to evaluate incidence and impact of severe AHF in a multicenter STEMI network patients (BIHOTZEZ) treated by primary percutaneous coronary intervention (pPCI) and also evaluate if the timing meets the recommended delays.
Methods: 254 patients included during 2015 in a prospective multicenter registry were analyzed.Patients with severe AHF (Killip III-IV) were compared to those with Killip I-II.In-hospital and 30 days mortality were the primary endpoints.Results:age, gender and anterior wall infarction did not differ between the two groups.12 patients (4.8%) presented with severe AHF.It was associated with increased in-hospital mortality rate (66.67%vs.4.6%,$p < 0.005$) and 30 days mortality rate (66.67%vs.5.9%,$p < 0.005$)(see table 1).Severe AHF patients displayed the highest mortality rate and it was the strongest predictor of in-hospital and 30-days

mortality.The Killip III-IV group had further delays due to the time required to stabilize before the transfer to hospital.This difference was no statistically significant and it is not related to mortality in our series.Conclusion:Severe AHF remains a dreadful complication of STEMI in our population and delays to achieve hemodynamic stability do not increase short-term mortality.

P263

Clinical profile and inhospital outcomes according ejection fraction in patients admitted with acute decompensated heart failure

M L Talavera[1]; A Acosta[1]; A Benavidez[1]; J Otero[1]; M Diez[1]
[1]*Cardiovascular Institute of Buenos Aires (ICBA), Heart Failure , Buenos Aires, Argentina*

Background: The current evidence suggests that patients (pts) with heart failure (HF) and preserved systolic function (PSF) differ from those with left ventricular systolic dysfunction (LVSD) in their clinical characteristics and outcomes, but there is still a controversy about phenotypes and prognosis in both populations.
Aim: To evaluate baseline characteristics, treatments and in-hospital outcomes of pts admitted for acute decompensated heart failure (ADHF) according to left ventricle ejection fraction.
Methods: 223 consecutive pts admitted with ADHF between October-2015 and October-2016 were selected; Patients' characteristic and blood exam results were analyzed; LVSD and PSF were defined as left ventricle ejection fraction ≤45% or > 45%, respectively. Complex therapy was defined as the requirement of any of the following: inotropics, intra-aortic balloon pump, mechanical ventilation, coronary revascularization or aortic percutaneous valvuloplasty. Chi2 and Fisher tests were used to evaluate categorical variables. $p < 0.05$ was considered statistically significant.
Results: Of the total cohort, 120 (53,8%) pts had LVSD and 103 (46,2%) had PSF; pts with LVSD were more likely to be younger (74 +/-12 vs 77 +/-10, p = 0.0021), male (74% vs 53%, p = 0,001) and had a significantly higher incidence of coronary disease (47% vs 17%, p < 0,0001) than those with PSF; valvular disease was more prevalent in PSF (55% vs 22, p < 0,0001). At admission, the absence of a precipitating factor was more frequent in LVSD (44% vs 28%, p = 0,01) while uncontrolled hypertension was more prevalent in pts with SPF (22% vs 13%, p = 0,05), LVSD pts had more prevalence of low cardiac output (17% vs 2%, p = 0,0001), with higher creatinine values (1.34 IQR25-75: 1,18-1,85 vs 129 IQR25-75 1,01-1,52 mg/dl, p = 0,007) than those with PSF. During hospitalization, LVSD pts had more renal function impairment than PSF (1,7 IQR 1.34-22 vs 1,45 IQR 1.21-1,82, p = 0,003) and required more complex therapies (18% vs 2%, p = 0,01). There were no significant differences in length of stay (7 IQR25-75 4-12 vs 6 IRQ 25-75 4.12 days, p = NS) but in-hospital death or heart transplantation were more frequent in LVSD pts (14% vs 3%, p = 0,003). At discharge, LVSD pts were on of beta-bloquers: 63%, ACEi: 84% and aldosterone receptor antagonists: 43%; low cadiac output was associated to non-use of beta-bloquers (p < 0,0001) and renal impairment with non-use of aldosterone receptor antagonists (p = 0,02).
Conclusions: In this population, LVSD was associated with a more severe clinical profile at admission, a higher use of complex therapies and worse in-hospital outcomes. Nevertheless, there were no differences in length of stay, this may be related with no measurable factors in pts with SPF like fragility or complications related to invasive procedures. At discharge, LVSD pts, despite being a greater risk population, received lower rates of pharmacological treatment according to clinical practice guidelines.

P264

The safety of intermittent sequential pneumatic compression sleeves in patients with severely reduced ejection fraction.

G Gassan Moady[1]; M Khader[1]; A Shturman[1]; S Atar[1]
[1]*Galilee Medical Center, Cardiology, Nahariya, Israel*

Background: Intermittent sequential pneumatic compression sleeves (ISPC-S) are often used in bedridden patients and during laparoscopic surgery. This technique is associated with several hemodynamic changes, and its safety in patients with severely reduced left ventricular function (LVF), and its effect on Brain Natriuretic Peptide (BNP) levels have not been clearly defined yet.
Purpose: To investigate the safety of ISPC-S in patients with severely reduced LVF by measuring hemodynamic parameters and BNP levels before, during and after the use of the pneumatic sleeves.
Methods: Fourteen patients with severely reduced LVF (< 40%) who were admitted to intensive cardiac care unit in our hospital with exacerbation of heart failure symptoms were Studied. All the participants were in NYHA functional classes II-III. The ISPC-S was operated in two cycles every one minute for 1 hour by compressing sleeves which contains 10 air cells in each side. Left ventricular ejection function (LVEF), hemodynamic parameters and BNP levels were studied in each patient before, during and after the ISPC-S operation. We used the Wilcoxon signed –rank test in the statistical analysis.
Results: 11 (78.6%) of the patients were male, the median age was 65.1 ± 8.4 years, of them 11 were of ischemic etiology. The average LVEF on baseline was 31.2% with no significant change shortly after the use of ISPC-S (31.2% ± 10 vs 33.1% ± 9 p = 0.673). After using the ISPC-S system there was no significant difference in systolic blood pressure (122 ± 23 vs 118 ± 18, p = 0.158), diastolic pressure (64 ± 10 vs 66 ± 9, p = 0.567) nor in the pulse measurements (78 ± 11 vs 76 ± 11, p = 0.594). Central venous pressure measurements were 8.9 ± 3.8, 10.4, 8.7 ± 4.7 before, during and after the ISPC-S use (P=0.649). There was also no change in oxygen saturation before and after (93.9% ± 7.2 vs 93.4% ± 7.1, p = 0.683). The BNP levels were 985.3, 836.6, 762 pg/ml before, during and after the ISPC-S use, respectively (p = 0.074). There was no arrhythmic or ischemic events during or after the use of ISPC-S in any participant.
Conclusion: The use of ISPC-S in patients with severely reduced LVEF seems to be safe with no detrimental effects on hemodynamic parameters or BNP levels.

Diastolic dysfunction is also related with the formation of left ventricular apical thrombus in patients with acute anterior ST elevation myocardial infarction

UL Choi[1]; JH Jae-Hyeong Park[1]; BJ Sun[1]; JK Oh[1]; SW Seong[1]; JH Lee[1]; SW Choi[1]; JO Jeong[1]; IW Seong[1]
[1]*Chungnam National University Hospital, Daejeon, Korea Republic of*

Background: Left ventricular (LV) apical thrombus is a clinically important complication which can cause systemic embolization in patients with acute

anterior myocardial infarction (AMI). Systolic dysfunction has been a risk factor for developing LV apical thrombus in AMI patients. However, the importance of diastolic dysfunction in the development of LV apical thrombus has been poorly proved in these patients.
Purpose: We performed to evaluate whether diastolic dysfunction can influence the development of LV apical thrombus.
Methods: We retrospectively analyzed all consecutive anterior AMI patients with available echocardiographic images within 1 month from January 2005 to April 2016. After gathering clinical characteristics from their medical records, systolic and diastolic functions were analyzed from the digitally stored images.
Results: We included total 1140 patients (813 males, 64 ± 12 years old) with anterior AMI, and 540 were diagnosed as STEMI. The incidence of LV apical thrombus was 3.2% (37/1140), and they had larger LV diastolic dimension (40 ± 9 vs 34 ± 8mm, $p < 0.01$), larger LV diastolic volume (71 ± 35 vs 105 ± 38mm, $p < 0.01$), larger LV systolic volume (105 ± 38 vs 89 ± 32mm, $p < 0.01$), and lower LVEF (34 ± 10 vs 48 ± 11mm, $p < 0.01$). Also, LV apical thrombus group showed higher mitral E velocity over mitral annular E′ velocity ratio, an indicator of LV end-diastolic pressure, (17.0 ± 9.6 vs 12.3 ± 5.6, $p < 0.01$).
After propensity score matching with age, gender and LVEF, we selected total 56 patients without LV apical thrombus as a reference group. In the LV apical thrombus group, pseudonormal (35.1 vs 19.6%,) and restrictive filling pattern (27.0 vs 5.4%) were more prevalent ($p < 0.01$). The presence of more than grade 2 diastolic dysfunction was significantly associated with the presence of LV apical thrombus (OR=2.53, 95% CI=1.28˜5.01, $p < 0.01$). Conclusions: Along with LV systolic function, LV diastolic function was also related with the presence of LV apical thrombus in patients with anterior AMI.

P266
Infective endocarditis complicated by heart failure: Prognosis and predictive factors of mortality

M Hassine[1]; M Boussada[1]; M Tahar[1]; M Mahjoub[1]; M Ben Massoud[1]; Z Dridi[1]; F Betbout[1]; H Gamra[1]
[1]*Cardiology A Department – Fattouma Bourguiba University Hospital, monastir, Tunisia*

Background: Although the progress of antibiotic prophylactic field, infective endocarditis remains a frequent pathology. Heart failure represents his main complication.
The aim of the study: was to determine the various characteristics of patients suffering from heart failure complicated by infective endocarditis and to define its impact on the mortality.
Patients and methods: From the infective endocarditis register of our service comparing 241 patients and responding to criteria of the University which collected retrospectively, we included patients with heart failure on admission, namely dyspnea greater or equal to NYHA stage II. A total of 85 patients were enrolled in the heart failure (35.2% of register).
Results: Heart failure complicating infective endocarditis of native valve had occurred in 66 cases (77.6%). The microbiological investigation was positive in 43.5 % of cases with a predominance of staphylococcus. The using of surgery was necessary in 65.8 % of cases. Hemodynamic instability was the main indication.
The total mortality in our registry was 19.5%, but higher in the group with heart failure (28.2% vs 14.7%; $p = 0.006$). In the multivariate analysis we found, as predictive factors for mortality of infective endocarditis complicated by heart failure group, the significant influence of anemia (OR= 5.2 ; IC 95% [1.6-24]; $p = 0.02$), infection by staphylococcus aureus (OR= 5.7 ; IC 95% [0.8-29.8]; $p = 0.03$) and surgery delay (OR=3.1 ; IC 95% [1.1- 14.7]; $p = 0.01$).
Conclusion: Heart failure is the most frequent complication of infectious endocarditis, and its first cause of death.

CHRONIC HEART FAILURE

P267
Semiotics of coronary vessels in patients with chronic heart failure of ischemic etiology with type 2 diabetes

AM Karimov[1]; HG Fozilov[1]; TA Abdullaev[1]; I A Igor Tsoy[1]
[1]*Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan*

Introduction (goals / objectives): Objective: To study the semiotics of angiographic coronary arteries in coronary heart disease with low ejection fraction in patients with type 2 diabetes.
Material and Methods: The study involved 60 patients with a diagnosis of chronic heart failure of ischemic etiology (CHF) between the ages of 40 to 80 years, including 39 men and 21 women, mean LVEF by Simpson 37,2 ± 4,6%. The patients were divided into 2 groups: 1 c. - 30 people who have had diabetes 2tipa place collateral. And 2 c. - 30 patients without diabetes 2tipa. The average duration of diabetes type 2 in one group was 6,2 ± 2,4 (5 to 8) years, while the duration HSN- 2,8 ± 2,3 (1 to 3 years). In the 2nd c., Ie, in individuals without type 2 diabetes, the average duration amounted to CHF 2,1 ± 1,8 (1.5 to 3) years.
Results: According to the CAG it found that the most common atherosclerotic lesions were located in the basin of the left anterior descending branch (LAD), amounting to - 23 (38%) cases. The second highest frequency of occurrence proved pool right coronary artery (RCA) - 12 (20%) patients. Frequency of atherosclerotic lesions of the circumflex artery (OA) and the obtuse marginal branch of OA was 11 (18.3%) and 5 (8.3%) cases, respectively. Atherosclerotic lesion in the posterior interventricular branch of the basin (ZMZHV) was observed in 3 (5%) patients. In the intermediate zone of the artery (PA), posterior-lateral branch (ZBV) and the left coronary artery (LCA) - 2 (3.33%) cases.
By the number of affected arteries revealed the following: 1 vessel disease was observed in 17 (28.3%) patients; of these patients 1g. 7 (11.6%)., Patients 2g. 10 (16.6%). ; Sosudistoe- 2s in 21 (35%) patients; 1g. 6 (10%) patients. 2 c. 15 (25%). ; and 3h- and more vascular porazhenie- in 22 (36.6%) patients; 1 of them c. 17 (28.3%) patients, 2 c. 5 (8.3%) patients.
Conclusion: CHD patients with reduced LVEF with concomitant type 2 diabetes characterized by 2s and multivessel disease compared with patients with the absence of type 2 diabetes.

P268
The membrane-modifying effect of hyperbaric oxygen therapy in chronic heart failure

V Victor Ruzov[1]; EN Altynbaeva[1]; MN Goryachaya[1]; BB Kostishko[1]; AM Vorobev[1]; M Mulenga[1]
[1]*Ulyanovsk state University, medicine, Ulyanovsk, Russian Federation*

Chronic heart failure (CHF) which complicates the course of cardiovascular diseases is accompanied by severe hypoxia, organ ischemia and platelet hemostatic disorders. The use of hyperbaric oxygen therapy for their correction is pathogenetically justified.
Purpose of the study: To study the effect of hyperbaric oxygenation on platelet membrane with different functional activity in patients with chronic heart failure of ischemic etiology.
Materials and methods: The study involved 24 patients with CHF I-III functional class (FC) of ischemic etiology.
The average age of the patients was 52,91 ± 11,54 years, mostly men (70%).
All patients for 5 days were on standard CHF medical therapy and were administered hyperbaric oxygen therapy (pressure chamber 303MK, Russia) with a duration of 30 min per session at 1.2 ATA.
Platelet aggregation was evaluated with an aggregometer “Biola 230LT” (Russia), evaluating the elastic properties of platelet membranes was done using a scanning probe of an atomic force microscope - Solver P47-PRO (Nt-MDT, Russia) in contact mode. To determine the platelet membrane elasticity, Young’s modulus was used based on the Hertz model.
Results: Prior to hyperbaric oxygen therapy (HBO) in patients with CHF, disruption of platelet aggregation in the form hyper-aggregation was found in 33.3%, hypo-aggregation - 25% and normal aggregation in 41.7%
Platelet membrane elasticity was 0.84 ± 0.19, 0.74 ± 0.22, 0.71 ± 0.20 MPa respectively.
After 5 sessions of HBO we found/revealed opposite changes the elastic properties of the membrane, depending on the functional activity of platelets
Increased platelet membrane elasticity was observed during platelet hyper-aggregation in comparison to the normal and hypo-aggregation.
The use of HBO in these patients was accompanied by a decrease in elastic modulus with 0,84 ± 0,19 to 0,42 ± 0,16 ($p = 0.04$), which indicates an increase in the elasticity of the membrane and decrease the degree of platelet aggregation activity.
Conclusion: Hyperbaric oxygen therapy in patients with CHF FC I-III is accompanied by membrane-modifying effect in the form of increasing the elasticity of the membrane with platelet hyperactivity.

P269
Assessment of the lipidic exchange at patients with chronic heart failure depending on the functional condition of kidneys

UK Kamilova[1]; ZD Rasulova[1]; DR Tagaeva[1]; VH Juraeva[1]; DR Masharipova[1]
[1]*Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Cardiology, Tashkent, Uzbekistan*

Purpose: To study indicators of the body weight index (BWI) and condition of lipidic exchange at patients with chronic heart failure (CHF) taking into account functional condition of kidneys.

Methods: In total 120 patients with the coronary heart disease with I (37), II (43) and the III functional class (FC) (40 patients) of CHF have been inspected. The FC of CHF was estimated according to recommendations of the NYHA by means of the test of 6-minute walking. As reliable indicator of condition of food calculated the BWI on formula: BWI = weight (kg)/height2 (sq.m). Results interpreted as follows: normal BWI - 20,0-24,9 kg/sq.m, the excess body weight (preobesity) - 25,0-29,9 kg/sq.m, obesity - 30,0 kg/sq.m and above, subnutrition - is lower than 19,9 kg/sq.m. Indicators of lipidic exchange (the general cholesterol, cholesterol of lipoproteids: of the high density (LPHD) and low density (LPLD), triglycerides (TG)). To all patients determined the level of serumal creatinine (Kr), glomerular filtration rate (GFR) by formula MDRD (Modification of Diet in Renal Disease Study) in ml/min/1,732.
Results: Results of research have shown that among the inspected patients with CHF - normal BWI is revealed in 29% of cases, raised - in 62% (from them 58,5% fall to the share of obesity), lowered - in 9%. In the analysis of the BWI at patients CHF taking into account FC it is revealed that at the I FC CHF 77% investigated have the increased body weight; at the II FC CHF - 67,5%; at the III FC CHF - 46,5%. Normal BWI is available 23% of patients from the I FC CHF, for 24% - II FC CHF, for 28% - III FC CHF. Reduced BWI is available 8,5% of patients from the II FC CHF, for 25,5% of patients with the III FC CHF, at the I FC CHF such patients were absent ($p = 0,05$). At 67% (78 patients) of the inspected patients had GFRMDRD≥60 ml/min/1,732. In the analysis BWI at patients CHF taking into account GFRMDRD it is revealed that at GFRMDRD≥60 ml/min/1,732 reduced BWI had 17,9% (14 patients) of the investigated; normal BWI - 44,9% (35); the raised BWI - 37,2% (29); at GFRMDRD < 60 ml/min/1,732 (42) reduced BWI had 35,7% (15); normal BWI - 47,6% (20); the raised BWI - 16,7% (7 patients) of the investigated.
Conclusion: Among patients CHF the syndrome of dislipidemiya (DL) meets more often: the hypercholesterolemia (HHL) is noted in 45,9% of cases ($p < 0,05$ in comparison with control), hypertriglitseridemiya (HTG) - in 23% ($p = 0,03$), increase of LPLD - in 62% ($p = 0,02$), decrease in LPHD - in 15,3% of cases ($p < 0,05$). The HHL and HTG are more characteristic for patients with the II FC CHF - 62,5 and 43,6% respectively, with the III FC CHF the share of patients with this type of DL authentically decreases to 34,5 and 27,3% according to ($p < 0,05$). Specific weight of the patients having the increased LPLD level and reduced LPHD in blood tends to increase in process of increase of FC ($p < 0,05$). In our research more than a half of patients had the raised BWI (obesity and preobesity).

Introduction: Chagas' disease (CD), caused by the hemoflagellate protozoan, Trypanosoma cruzi, is endemic in most countries of South and Central America, where it continues to be a major source of social, health, and financial burden. Cardiac involvement is the most frequent and serious manifestation of chronic CD, and typically leads to heart failure (HF), arrhythmias, thromboembolism, and sudden death.
Purpose: HF is often a late manifestation of chronic CD, and is associated with high morbidity and mortality. Early identification of patients with CD, therefore, would be desirable as early intervention may help improve prognosis. Inflammatory biomarkers can play a vital role in early diagnosis, as inflammation mediated by cytokines plays an important role in pathogenesis and progression of CD, and may be present even in the absence of HF.
Methods: Keeping in view the inflammatory nature of CD, this study investigated the possible role of 21 different inflammatory cytokines as biomarkers for prediction and prognosis of CD. The plasma concentration of each of these cytokines was measured in a group of patients with CD, and then compared with those measured in patients with dilated cardiomyopathy (DCM) from idiopathic causes, and with control subjects.
Results: To the best of our knowledge, this is the first study to investigate cytokines such as monokine induced by interferon gamma (MIG) and stem cell growth factor beta (SCGF beta) in CD and idiopathic DCM patients. Using mono-variate analysis, plasma levels of cytokines such as SCGF beta, hepatocyte growth factor (HGF), MIG, and macrophage inhibitory factor (MIF) were significantly increased in CD patients with advanced HF, but they were unable to show any predictive or prognostic potency in CD. Further, multi-variate analysis was able to prognosticate a large proportion of CD and DCM patients, but it could not discriminate CD from idiopathic DCM.
Conclusion: It is possible that some of the cytokines that were studied here are only regulated in HF due to specific etiologies such as ischemic HF. Also, cytokines other than the ones that were investigated may play a role in causing severe inflammation and fibrosis seen in CD. Studies in future, therefore, should focus on identifying further inflammatory biomarkers that could be used as tools for early prediction and prognosis of CD. Identifying patients at an early stage of the disease may help in providing effective treatment and prevent the development of HF and thus early death.

Role of obstructive sleep apnea syndrome in development of left ventricular diastolic dysfunction

A Alexey Kuchmin[1]; IV Makarova[1]; AA Kazachenko[1]; KB Evsukov[1]; AA Shevelev[1]
[1]*The Kirov Military Academy, St-Petersburg, Russian Federation*

Background: The purpose of this study was to determine the role of obstructive sleep apnea syndrome (OSAS) as a risk factor for the development of left ventricular diastolic dysfunction in middle-aged OSAS men.
Methods: We examined 38 newly diagnosed middle-aged OSAS men without conditions, affecting left ventricular diastolic function. All subjects underwent sleep study, 24-hour ambulatory blood pressure monitoring (ABPM), and an echocardiogram. Inclusion criteria for OSAS patients were: apnea-hypopnea index (AHI) ≥10 h−1 and excessive daytime sleepiness. In OSAS patients, relationships between sleep parameters, diastolic echocardiographic parameters and blood pressure recordings were also analyzed.
Results: An abnormal left ventricular filling pattern was present in 23 (60,5%) of the 38 OSAS patients. Impaired relaxation was by far the most common abnormal pattern in this group (18 (47,4%) patients), whereas a pseudonormal pattern was present only in 5 (13,2%) patients with OSAS. We analyzed separately OSAS patients with normal filling pattern and those with impaired relaxation of left ventricle. Patients with impaired relaxation had higher AHIs than those with normal pattern. LV mass, and LV mass index were also higher in OSAS patients with impaired relaxation. The study showed a significant correlation between AHI and E/A ratio ($r=-0.39$, $P < 0,01$), DT ($r=0.33$, $P < 0,05$), and IVRT ($r=0.39$, $P < 0,05$). In the model of logistic regression diastolic dysfunction was predicted only by AHI and patients age.
Conclusions: In middle-aged men OSAS can affect left ventricular diastolic function independently of other possible factors. It may be an early response to cardiac overload caused by OSAS.

P272

What is the incidence of elevated pulmonary artery pressure amongst patients presenting to the incident heart failure clinic?

A Abdallah Al-Mohammad[1]; L Allcock[1]; D Rogers[1]; N Lewis[1]; A Charalampopoulos[1]; D Robson[1]
[1]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*

Purpose: Pulmonary hypertension (PH), defined as a systolic pulmonary artery pressure above 40mmHg is associated with increased morbidity and mortality. We investigated the frequency of pulmonary hypertension as derived by transthoracic echocardiography (TTE) amongst patients referred to our incident heart failure (HF) clinic.
Methods: Patients suspected of having new onset HF are referred to the incident HF clinic if their NTproBNP is > 400 ng/l. The clinic serves a city populated by 550,000 inhabitants. All patients undergo detailed echocardiography and are assessed by a HF consultant cardiologist. We collected data on the patients seen between April 2012 and December 2016.
Results: A total of 3939 patients were seen in this period. 779 patients (20%) had an estimated systolic pulmonary artery pressure over 40mmHg. Of this cohort, PH was the only problem identified on TTE in 188 patients (24% of those with PH). PH was found in association with HF with preserved left ventricular ejection fraction (HFPEF) in 282 patients (36% of those with PH). PH was diagnosed in association with HF with reduced left ventricular ejection fraction (HFREF) in 263 patients (34% of the patients with PH) and finally PH was detected in those with associated valvular disease in 46 patients (6%). Table 1.
Conclusions: Pulmonary hypertension is present in 1 in 5 of the patients presenting to the diagnostic HF clinic. In 76% of these patients it is found in combination with other types of heart failure, but in 24% it is the only abnormality detected on echocardiography.

Table 1

Diagnosis	2012	2013	2014	2015	2016	Total
HF PH	23	43	68	30	24	188
HF PH HFPEF	21	41	97	81	42	224
HF PH HFREF	42	77	108	22	14	263
HF PH Valve	5	17	14	8	2	46

Incidence of HF PH in 5 years

Pulmonary and cardiac characteristics of heart failure patients comparing three groups based on left-ventricular ejection fraction

W Robaeys[1]; S Bektas[1]; JJ Boyne[1]; V Van Empel[1]; N Uszko-Lencer[1]; C Knackstedt[1]; HP Brunner-La Rocca[1]
[1]*Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands*

Funding Acknowledgements: GlaxoSmithKline Pharma

Background: Patients with heart failure (HF) are vulnerable to chronic obstructive pulmonary disease (COPD) and gas exchange disturbances. Vice versa patients with COPD might experience structural changes in the right heart depending on the development of pulmonary hypertension. The frequency of cardiopulmonary abnormalities is not yet investigated sufficiently in HF patients divided in the recently defined three groups based on left-ventricular ejection fraction (LVEF); i.e. HF with reduced (HFrEF), HF with mid-range (HFmrEF) and HF with preserved LVEF (HFpEF). Moreover, the influence of lung function abnormalities on the right heart is insufficiently understood.
Purpose: Therefore, the present study investigated the frequency of lung and right ventricular (RV) functions in the three HF groups. Furthermore, relations of HF and COPD were explored.
Methods: Overall, 186 consecutive stable HF patients seen in our outpatient clinic were divided into HFrEF (n = 70), HFmrEF (n = 55), and HFpEF (n = 61). Airflow limitation and gas exchange disturbance were measured by spirometry (forced exhaled volume in the first second / forced vital capacity (FEV1/FVC) (%)) and DLCO (diffusion capacity of the lungs for carbon monoxide). Standard echocardiography was performed to measure RV structure (RV diameter) and function (tricuspid annular plane systolic excursion/pulmonary artery systolic pressure (TAPSE/PASP)). Correlations were used to assess possible relations between COPD and measures of the RV.
Results: None of the investigated pulmonary parameters differed significantly between the three groups (all p>0.1); FEV1/FVC was 70 ± 12%, 70 ± 13%, and 74 ± 10% in patients with HFrEF, HFmrEF, and HFpEF (P=0.12) and DLCO was 5.7 ± 1.6, 5.7 ± 1.8, and 5.6 ± 1.6 mmol/min/kPa, respectively (P=0.95). RV structure and function did not differ either (TAPSE/PASP 0.58, 0.60 and 0.57, respectively (P=0.84)). There was only a weak correlation of DLCO (r=0.34, $p < 0.001$), and even less of AL (r=0.19, $p < 0.03$) with RV function.
Conclusion: In this outpatient clinic population pulmonary function abnormalities were comparable in the three HF groups as was RV functional impairment. Thus, identifying lung function abnormalities in stable HF is important irrespectively as to LVEF. The influence of pulmonary function abnormalities on the RV seems to be limited and not clinically meaningful.

P274

Comparing mildly-reduced with preserved ejection fraction heart failure patients: two flips of the same coin?

B Neves[1]; N Hammoudi[1]; F Pousset[1]; P Balagny[1]; L Legrand[1]; M Komajda[1]; R Isnard[1]
[1]*Hospital Pitie-Salpetriere, Cardiology Department, Paris, France*

Introduction: Patients with preserved ejection fraction Heart Failure (HF) are a heterogeneous group whose clinical trials have been negative so far. Heterogeneity of this population has been attributed to this systematic failure and efforts have been made to try to identify different subgroups inside this population. The most recent European Heart Failure guidelines subdivide the previously called preserved ejection fraction group into mildly reduced (MrEF) with 40-49% and preserved (PEF) with ≥50% ejection fraction. Our aim was to characterize a group of patients admitted with heart failure decompensation and left ventricular ejection fraction (LVEF) ≥40% in terms of clinical, laboratory and echocardiographic characteristics.
Methods: A cohort of patients admitted for HF decompensation between June 2015 and June 2016 on a tertiary HF center was analysed. Electronic medical records and echocardiograms were sourced for data introduction. HF was defined as current ESC criteria guidelines. Patients with HF diagnosis and EF ≥40% were included. Exclusion criteria included history of previously reduced EF, moderate valvular heart disease, constrictive pericarditis, congenital heart disease and previous cardiac transplantation.
Results: 717 patients were admitted during the study period, from what 303 fulfilled inclusion criteria. After exclusion criteria, 225 were enrolled and 211 had complete echocardiographic data for analysis. 69 (30,7%) patients had MrEF. There were no differences between groups in terms of age (p = 0,57), gender (p = 0,45) or biometrics. Coronary artery disease (CAD) and prior coronary revascularization was more frequent in MrEF (p = 0,004, p = 0,009 respectively). CAD was correlated with lower LVEF (OR 2.46 (1.36-4.51, CI 95%). Remaining comorbidities were equally present on both groups. End-diastolic and end-systolic left ventricular volumes, left ventricular end-diastolic diameter were significatively higher in MrEF patients ($p < 0,001$). Left ventricular mass showed a trend to be higher in MrEF (p = 0.052). Relative-wall-tickness was significatively higher in PEF patients ($p < 0,001$). TAPSE and tricuspid annular S′ showed a trend to lower values in MrEF patients (p = 0,07).
Conclusions: In this cohort of patients lower EF tends to be more associated with CAD and LV dilation which is consistent with a transition group between truly preserved EF and reduced EF. Further prospective studies should confirm these results and may eventually analyse CAD separately among populations with HFpEF.

P275

The role of sympathetic co-transmitter galanin on autonomic control in heart failure : An active player or a bystander in sympathovagal crosstalk

D Ozkaramanli[1]; M Sagbas[2]; A Akyuz[1]; S Guzel[3]; S Alpsoy[1]; N Guler[1]

Funding Acknowledgements: Namζk Kemal University Scientific Research Projects FundNKUBAP.02.YL.16.046

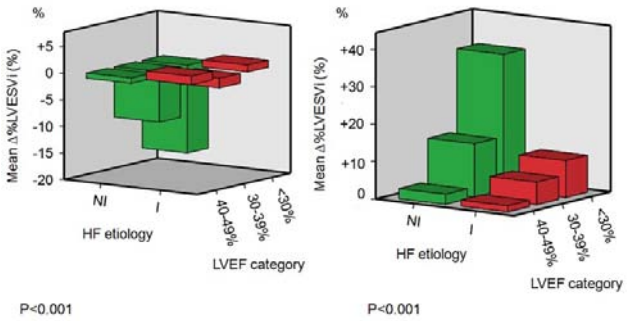
Background: Autonomic imbalance in favor of sympathetic nervous system is an important clinical feature of heart failure (HF). Sympathetic cotransmitters neuropeptide Y(NPY) and galanin, located in the adjacent vesicles to the main transmitter norepinephrine, attenuate the vagal tonus after burst sympathetic activity by a mechanism called 'sympathovagal crosstalk'. On the basis of preliminary data from animal studies suggesting increased levels of galanin in HF models and improvement in cardiac function subsequent to treatment with galanin antagonists, we examined the levels of galanin and NPY, the two main cotransmitters of sympathovagal crosstalk in chronic heart failure patients.
Purpose: We evaluated whether the levels of galanin correlated with the levels of NPY, the humoral activity expressed by Pro BNP and copeptin concentrations; and myocardial performance estimated by echocardiography in patients with HF. To our knowledge, this is the first study to document plasma concentrations of galanin in chronic HF patients.
Methods: The study population consisted of 57 patients with chronic systolic HF and 30 control subjects. Of HF patients, 68.4%(n:39) had ischemic and 31.6%(n:18) had dilated cardiomyopathy. All subjects underwent detailed transthoracic echocardiography, had their demographic characteristics recorded and blood collected for proBNP, copeptin, galanin and NPY analysis.
Results : The ProBNP, copeptin and NPY were significantly elevated in HF group.(2128.9 ± 1104.5 vs 212.6 ± 96.4 pg/mL, $p < 0.0001$; 872.3 ± 280.7 vs 640.7 ± 279 pg/mL, $p < 0.0001$; 139.8 ± 65.5 vs 79.8 ± 35.9 pg/mL, $p < 0.0001$ respectively). Galanin, on the other hand, was not statistically different between HF or control groups.(32.5 ± 19.06 vs 31.9 ± 18.4 pg/mL, p = 0.9). The correlation analysis revealed that NPY was correlated with the echocardiographic parameters of HF severity(r:-0.22, p = 0.03 for EF; r=0.3, p = 0.05 for left atrial volume index; r=0.3, p = 0.005 for Tei index of right ventricle; r=-0.23, p = 0.03 for tricuspid annular plane excursion; r=0.24, p = 0.024 for E/e′) and with proBNP(r:0.22, p = 0.047); while galanin was correlated only with humoral biomarkers ProBNP and copeptin (r=0.39, $p < 0.0001$ and 0.41, $p < 0.0001$ respectively). The NPY levels were also strongly associated with beta blocker(BB) use, in which BB significantly decreased the levels of NPY(1048.8 ± 245.1 with BB to 834.7 ± 275.6 without BB, p = 0.032). The multivariate linear regression analysis revealed that among variables like copeptin, proBNP, BMI, smoking status and beta blocker use, which were proved to be associated with galanin in univariate comparisons, only proBNP was the significant predictor of galanin levels in HF patients.(b=0.534,CI 95% 0.005-0.014, $p < 0.0001$)
Conclusions : Our findings confirmed the direct role of NPY on autonomic balance in HF and suggest that, until further evidence emerges, galanin seems not to be an active player in sympathovagal crosstalk in the failing human heart.

P276

Reverse remodeling in systolic heart failure: the relevance of aetiology and baseline function

A Alberto Aimo[1]; G Vergaro[2]; V Castiglione[1]; A Barison[2]; A Giannoni[2]; V Chubuchny[2]; L Zyw[2]; C Passino[1]; M Emdin[1]
[1]Sant'Anna School of Advanced Studies, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*

Background: Reverse remodeling (RR) refers to the complete or partial recovery of left ventricular (LV) geometry and function following guideline-recommended treatment for heart failure (HF). At present, diagnostic criteria for RR do not take into account HF aetiology or baseline function, and standardized criteria are lacking.
Purpose: To assess how aetiology and baseline function impact on RR, and to search for RR criteria with prognostic relevance in a population of patients with systolic HF.
Methods: Patients with stable systolic HF (left ventricular ejection fraction - LVEF < 50% at baseline) undergoing two transthoracic (TTE) examinations within 12 ± 4 months, were selected. The follow-up started with the second TTE. The endpoint was cardiovascular death or heart transplantation.
Results: In our population of 927 patients (age 68 ± 12 years, LVEF 34 ± 9%, ischaemic aetiology in 53%), baseline LVEF categories < 30%, 30-39% and 40-49% were similarly represented (n = 287 [31%], 324 [35%] and 316 [34%], respectively). Over the 33-month [interquartile range - IQR 15-59] follow-up, the endpoint occurred in 126 patients (14%).
Patients with non-ischaemic aetiology experienced significantly greater variations (%) in LVEF, LV end-systolic volume index (LVESVi) and LV end-diastolic volume index (all P < 0.001). %LVEF and LVESVi were significantly different across LVEF categories (P < 0.001 and 0.028, respectively), with the greatest improvement in patients with LVEF < 30%. When stratifying patients according to both aetiology and baseline LVEF category, the greatest recovery in LVESVi and LVEF was observed in patients with LVEF < 30% and non-ischaemic HF, followed by LVEF 30-39% and non-ischaemic HF, while decreasing sharply in patients with LVEF 40-49% and non-ischaemic HF. The improvements in LVESVi and LVEF were much less prominent in patients with ischaemic aetiology; LVEF recovery was greater in patients with LVEF < 30% (Figure).
When searching for RR criteria with prognostic relevance, in patients with non-ischaemic HF the highest area under the curve (AUC) values were obtained for %LVESVi, the best cut-points being -11% for LVEF < 30% (AUC 0.584), -10% for LVEF 30-39% (AUC 0.632), and -2% for LVEF 40-49% (AUC 0.680). In the ischaemic subgroup, the highest AUC values were obtained for %LVEF, the best cut-points being + 10% for LVEF < 30% (AUC 0.595), + 8% for LVEF 30-39% (AUC 0.613), and + 2% for LVEF 40-49% (AUC 0.615).
Conclusions: In stable systolic HF, the potential for recovery is greater in patients with non-ischaemic aetiology or lower baseline LVEF category. When taking into account both information and patient prognosis, the following criteria for RR were defined: -11%, -10% and -2% %LVESVi (for LVEF < 30%, 30-39% and 40-49%, respectively) in patients with non-ischaemic HF; + 10%, + 8% and + 2% %LVEF (for LVEF < 30%, 30-39% and 40-49%, respectively) in patients with ischaemic HF.



Abbreviations: HF, heart failure; I: ischemic; LVEF, left ventricular ejection fraction; LVESVi, left ventricular end-systolic volume indexed; NI, non-ischemic.

Role of aetiology and baseline function

P277

Do we treat heart failure differently according to gender?

I Irene Rilo Miranda[1]; JR Beramendi Calero[1]; S Garcia Gutierrez[2]; A Anton Ladislao[2]; L Quintas Ovejero[3]; C Goena Vives[3]; M Morillas Bueno[2]; F De La Cuesta Arzamendi[1]
[1]Hospital Donostia, San Sebastian, Spain; *[2]Hospital Galdakao-Usansolo, Bilbao, Spain*; *[3]Hospital Comarcal de Mendaro, Cardiology, Mendaro, Spain*

Introduction: This study aims to determine the differential characteristics between the treatment among men and women with acute heart failure admitted to the Emergency Services 3 hospitals in our network between 2011 and 2013.
Methods: Observational prospective cohort study including 1824 patients presenting to the emergency room of our hospital for acute decompensated heart failure.
Results: The sample included 1824 patients. 48% (886) were male and 51% (938) female.
The use of antialdosteronic treatment was significantly higher in males (19% vs 13 % p = 0.0007) and it was higher too the use of antiagregants (36 % in males vs 30 % in women p = 0,0041) probably because of the higher rate of ischemic cardiomyopathy in males ((40 % vs 25 % p < 0.0001) and anticoagulant drugs (52 % in males vs 45,1 % in women p = 0,0021) although the rates of atrial fibrillation were similar in both groups (54 % vs 52 % p = 0.45)
Among men the use of betablockers was significantly higher (40 % vs 35 % p-0,05) and in the other hand, women presented a higher rate of calcium channel blockers (25 % in females vs 22 % in men p = 0.03).
Despite the higher prevalence of heart failure with preserved systolic function among females (62 % vs 38 % p < 0,0001) the use of loop diuretics was similar in both groups (63 % in women vs 61 % in men p = 0,2855).
Conclusions: 1. The use of antiagregants was higher in males probably because of the higher rate of ischemic cardiomyopathy among then.
2. The use of anticoagulant drugs was higher in men although the rates of atrial fibrillation were similar in both groups
3. Among men the use of betablockers was significantly higher and in the other hand, women presented a higher rate of calcium channel blockers probably because of the higher prevalence of heart failure with preserved ejection fraction in women
4. Despite the higher prevalence of heart failure with preserved systolic function among females the use of loop diuretics was similar in both groups

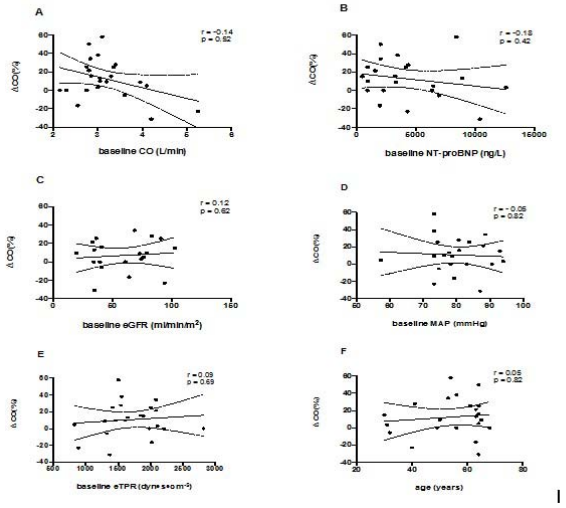
Hemodynamic effects of levosimendan in advanced but stable chronic heart failure

E Emil Najjar[1]; M Stalhberg[1]; C Hage[1]; E Ottenblad[1]; A Manouras[1]; IH Lofman[1]; LH Lund[1]
[1]Karolinska University Hospital, Department of Cardiology, Stockholm, Sweden

Funding Acknowledgements: OrionPharma Inc., the Swedish Research Council, the Swedish Heart Lung Foundation and the Stockholm County council

Background: Levosimendan improves hemodynamics in acute decompensated heart failure (HF). However, it is increasingly used for repetitive or intermittent infusions in advanced but stable chronic HF; without clear indication, selection criteria or effect.
Purpose: To test the hypotheses that (1) levosimendan improves hemodynamics in stable chronic HF and (2) that the response is dependent on baseline clinical and hemodynamic factors.
Methods: Twenty-three patients (median age 56 [49-64] years, 4 [17%] women) with stable New York Heart Association (NYHA) III-IV HF received a single 24-hour levosimendan infusion. Noninvasive hemodynamics (inert gas re-breathing technique), estimated glomerular filtration rate (eGFR) and N-terminal pro-brain natriuretic peptide (NT-proBNP) were assessed before and after infusion.
Results: Levosimendan had the following effects (median change): a significant increase in cardiac output (CO) (+ 9.8 ± 21.6%; p = 0.026) and decrease in NT-proBNP (-28.1 ± 16.3%, p < 0.001), estimated total peripheral resistance (eTPR) (-16.9 ± 18.3%, p = 0.005) and mean arterial pressure (MAP) (-5.9 ± 8.2%, p = 0.007) but no change in eGFR (+ 0.89 ± 14.0%, p = 0.955). There were no significant associations between baseline clinical and/or hemodynamic factors and the levosimendan effect on CO.
Conclusions: Levosimendan was associated with improved hemodynamics in patients with stable chronic HF but we could not identify any predictors of the magnitude of hemodynamic response.

Figure 3. Correlations between baseline cardiac output (A), NT-proBNP (B), eGFR (C), MAP (D), eTPR (E) and age (F) and change in cardiac output in response to levosimendan



Correlations

Prevention of left ventricular diastolic dysfunction with long-term CPAP treatment in OSAS patients.

A Alexey Kuchmin[1]; IV Makarova[1]; KB Evsukov[1]; AA Kazachenko[1]; AA Shevelev[1]; AN Kulikov[1]
[1]*The Kirov Military Academy, St-Petersburg, Russian Federation*

Background: The purpose of this study was to determine the effect of hronic CPAP application on diastolic left ventricular filling in middle-aged OSAS men with diastolic dysfunction.
Methods: The study included 18 otherwise-healthy patients who had confirmed impaired relaxation of left ventricle and moderate to severe obstructive sleep apnea seen at the sleep laboratory at a single clinic. A battery of cardiac assessments, including 2D and 3D echocardiography, was done on them at baseline and after treatment with CPAP for 8 weeks. Complete measurements were available in 17 patients. ne patient failed to complete the trial.
Results: - There were no differences in blood pressure recordings, heart rate or weight at baseline and after CPAP in OSAS patients. After 8 weeks on effective CPAP, left ventricular filling pattern were not modified, but a significant increase in E/A ratio (0.69 ± 0.17 and 0.90 ± 0.13, $P < 0,01$) and reduction in DT (296.6 ± 41.3 ms and 263 ± 37.8 ms, $P < 0,05$) and IVRT (112.3 ± 8.7 ms and 101.2 ± 9.3 ms, $P < 0,01$) values were induced. Left atrial volume index also improved on both 2D and 3D echo ($P < 0.01$).
Conclusions: Chronic CPAP application can modify diastolic left ventricular filling and avoids the progression of diastolic abnormalities, and indeed, it might reverse these alterations, at least in the initial stages before severe ventricular structural changes develop. The mechanism for diastolic improvements needs further study but it may be correction in blood pressure, hypoxia, and sympathetic system activity.

P280

Effect of potassium/magnesium enriched salt on functional capacity and quality of life in symptomatic patients with chronic heart failure

I Iryna Voloshyna[1]; VA Vizir[1]; MA Voloshyn[1]; VI Krivenko[1]; VI Ponomarenko[2]
[1]*Zaporozhye State Medical University, Zaporozhye, Ukraine*; [2]*Institute of Ecology, Melitopol, Ukraine*

Background: Nowadays the clinical studies highlight the contradicting results regarding sodium restriction impact on outcomes in patients with chronic heart failure (CHF). Plasma magnesium and potassium concentrations are often reduced in CHF patients causing increased risk of hospitalizations and mortality.
Purpose: The present study aimed to evaluate whether potassium/magnesium enriched salt consumption could improve exercise capacity and quality of life in symptomatic patients with CHF.
Methods: A total of 64 symptomatic patients aged 66-80 years with CHF and preserved left ventricle ejection fraction were recruited. All patients were randomly assigned to 2 groups: first – with moderate (less than 5-6 g/day) salt-restricted diet ($n = 32$), second group of participants received recommendations to use potassium/magnesium enriched salt contained 30% of potassium and 5% of magnesium in their daily intake no more than 5-6 g/day. All enrolled participants were on stable treatment with 3 more drugs and initially had serum potassium level 3.9-4.7 mmol/L. Six-minute walk distance as physical function assessment, quality of life, health status, and daily activity using Minnesota Living With Heart Failure Questionnaire (MLWHFQ) were measured at baseline and at 8 weeks.
Results: There was a significant difference in change for the six-minute walk distance at 8 weeks in moderate salt-restricted diet group ($+10.5$ m; 95% CI, $+2.5$ to 26.8 m; $p = 0.02$) whereas in patients used potassium/magnesium enriched salt a slightly improved dynamic of exercise capacity had been noticed ($+17.2$ m; 95% CI, $+3.1$ to 37.2 m; $p = 0.03$) although the intergroup distinction was insignificant ($p = 0.07$). Moderate sodium salt-restricted interventions were not notably associated with quality of life enhancement. The MLWHQ overall score decreased on 15% ($p = 0.06$) mainly due to diminishing of physical subscore (-26%; $p = 0.04$). In group with potassium/magnesium enriched salt intake the greater changes of quality of life parameters had been revealed. The MLWHQ overall score reduced on 29% ($p = 0.04$), physical subscore fell on 36% ($p = 0.03$), psychosocial/symptomatology subscore decreased on 19% ($p = 0.04$). Thus, the significant correlation was found between potassium/magnesium enriched salt consumption and physical subscore of MLWHQ ($r = -0.28$; $p = 0.02$).
Conclusions: Dietary interventions concerning moderate sodium restriction either with potassium/magnesium salt enrichment lead to enhancement of exercise capacity in patients with CHF and preserved ejection fraction. Daily use of potassium/magnesium enriched salt could be a promising non-pharmacological treatment option for managing impaired quality of heart failure patient's life.

P281

Characteristics of newly diagnosed patients with heart failure managed in the primary care and cardiology settings in France

S Eisenring[1]; C C Proenca[2]; B Balas[3]; F Calado[3]; C Thonnelier[4]; S Bruce Wirta[5]
[1]*QuintilesIMS Switzerland, Basel, Switzerland*; [2]*Wellmera AG, Basel, Switzerland*; [3]*Novartis Pharma AG, Basel, Switzerland*; [4]*Novartis Pharma SAS, Rueil Malmaison, France*; [5]*Novartis Sweden AB, Stockholm, Sweden*

Background and purpose: This study aimed to describe and compare characteristics of newly diagnosed patients with heart failure (HF) in the primary care and cardiology settings in France.
Methods: Electronic medical records from two French databases (a general practitioner [GP] panel and a cardiologist panel) were used to identify patients. All patients (aged $\geq$18 years) who were newly diagnosed with HF from 1 January 2009 to 30 September 2013 were included. Patient histories available in the databases, from January 1994 (GP panel) or January 1998 (cardiologists) to December 2008, were used to exclude patients with a previous diagnosis of HF. Patients who were not prescribed a new treatment after diagnosis were also excluded.
Results: The study population comprised 6566 patients with newly diagnosed HF (GP panel 4940; cardiologist panel 1626). The mean $\pm$ SD age of the overall population at diagnosis was 75.0 ± 12.4 years. Patients diagnosed by cardiologists were similar in age to those diagnosed by GPs. A smaller proportion of patients diagnosed by GPs were male (54.2% vs 60.3%). Mean $\pm$ SD systolic and diastolic blood pressures of the overall population were 133.0 ± 17.5 mmHg and 75.7 ± 9.7 mmHg, respectively. Mean heart rate was higher in patients diagnosed by the GP panel than the cardiologist panel (97.5 bpm vs 82.5 bpm). At diagnosis, New York Heart Association (NYHA) functional classification was recorded for 61% of patients diagnosed by a GP and 52% of those diagnosed by a cardiologist. Overall, the majority of patients were classified as NYHA class II (56.6%), followed by class III (21.4%), class I (18.5%) and class IV (3.5%); the proportions were similar for the two panels. Insufficient data on ejection fraction were available to allow this parameter to be evaluated. In the 6-month period before diagnosis, diuretics were the most commonly prescribed cardiovascular drug by both GPs and cardiologists (54.0% and 34.4%, respectively), followed by β-blockers (44.4% and 33.7%), angiotensin-converting enzyme inhibitors (37.4% and 23.8%) and angiotensin II receptor blockers (31.7% and 19.5%). Clinical characteristics were more frequently reported at diagnosis by GPs than cardiologists: body mass index (64.0% vs 48.8%), systolic and diastolic blood pressure (77.3% vs 24.5%), potassium level (45.7% vs 18.5%), estimated glomerular filtration rate (23.9% vs 8.9%) and heart rate (78.9% vs 46.0%). N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels and haemoglobin levels were rarely recorded (NT-proBNP: GP panel 6.8%, cardiologist panel 6.0%; haemoglobin: GP panel 1.1%, cardiologist panel 0.1%).
Conclusions: The age and NYHA class distributions in patients diagnosed by a GP and those diagnosed by a cardiologist were very similar. Clinical characteristics at

diagnosis were more frequently recorded by GPs than by cardiologists; however, an absence of data on ejection fraction was common to both groups.

P282

Comparison of office heart rate and mean 24-hours ambulatory heart rate in chronic heart failure patients

V Habenicht[1]; E Kolesnik[1]; J Schmid[1]; K Brandner[1]; A Tomaschitz[1]; S Pilz[1]; F Fruhwald[1]; D Von Lewinski[1]; K Ablasser[1]; N Verheyen[1]
[1]*Medical University of Graz, Graz, Austria*

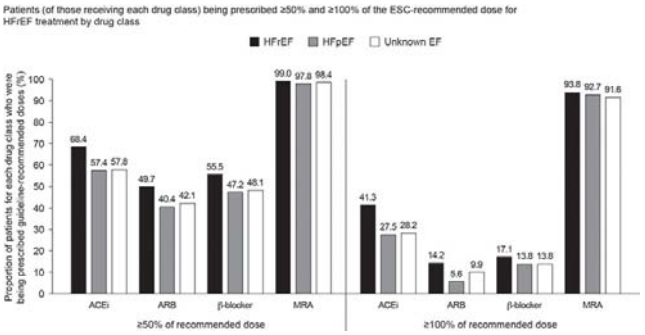
Objective: Heart rate (HR) control in heart failure patients is commonly based on single office measurements at rest. However, 24-hours ambulatory heart rate measurement may yield a more accurate surrogate parameter of individual HR than single measurements. In a pilot study, we investigated the association between measures of office HR and mean 24-hours ambulatory heart rate in chronic patients with heart failure.
Methods: Patients with stable chronic heart-failure and a left ventricular ejection fraction (EF) < 50 % were prospectively enrolled in the outpatient clinic of a tertiary care hospital. Office HR was measured after 5 minutes rest both in the sitting and in supine position, mean ambulatory HR was determined using a certified ambulatory blood pressure monitoring device (Mobil-O-Graph, I.E.M. GmbH, Stolberg, Germany) and was calculated as the mean of all successful HR measurements during 24 hours. HR >= 70 beats per minute (bpm) was considered elevated.
Results: We enrolled 28 subjects with mean age of 62.6 +/- 10.3 years (35% females) and mean EF of 34 +/- 9 %. Mean sitting HR was 69.5 +/-15.6 bpm and mean supine HR was 71.5 +/- 15.3 bpm, mean 24-hours ambulatory HR was 67.6 +/- 10.6 bpm. Ambulatory HR was correlated with sitting HR (Pearson's r = 0.620, P = 0.001) and supine HR (r = 0.398 , P = 0.044) HR was elevated in 9 subjects (33.3%) in sitting position, in 13 subjects (46.4%) in supine position, and in 13 subjects (48.1%) in ambulatory read-outs.
Among those with a normal supine HR (n = 14), 3 (21.4%) had an elevated ambulatory HR. Vice versa, 3 individuals (23.1%) of those with elevated supine HR revealed a normal ambulatory HR.
Comparing sitting HR with ambulatory HR, 5 (29.4%) had an elevated ambulatory HR, although presenting with a normal sitting HR, while 2 (22.2%) of those with elevated sitting HR had a normal amulatory HR.
Conclusion: Office HR measurements and ambulatory HR show only moderate correlation in subjects with chronic heart failure. Office HR measurements tend to be higher than ambulatory measurements. Approximately one in five patients with normal office HR has elevated ambulatory HR, while a similar proportion of subjects with elevated office HR have normal ambulatory HR. After confirmation in larger cohorts, the clinical relevance of this divergence and the usefulness of 24-hours ambulatory HR beyond office HR as target parameter in heart failure treatment should be investigated in future studies.

P283

Suboptimal dosing of common heart failure treatments in newly diagnosed patients with heart failure: a retrospective population-based cohort study in Sweden

G Wikstrom[1]; K Boman[2]; M Olofsson[2]; J Stalhammar[3]; G J Bergman[4]; M Tornblom[4]; V Wintzell[4]; B Balas[5]; S Corda[5]; K Lindmark[6]
[1]*Uppsala University, Institute for Medical Sciences, Uppsala, Sweden*; [2]*Umea University, Research Unit, Medicine, Skellefteå, Department of Public Health and Clinical Medicine, Umea, Sweden*; [3]*Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden*; [4]*QuintilesIMS, Solna, Sweden*; [5]*Novartis Pharma AG, Basel, Switzerland*; [6]*Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden*

Background: Studies in real-world settings have shown that patients with heart failure (HF) often do not receive medication at doses recommended by the European Society of Cardiology (ESC). By studying dosing patterns of HF treatments in newly diagnosed patients, healthcare professionals can evaluate how well treatment guidelines are being implemented in the real world.
Purpose: To assess treatment dosing in newly diagnosed patients with HF with reduced (HFrEF), preserved (HFpEF) and unknown ejection fraction (EF) according to the ESC 2012 guidelines for HFrEF (ESC does not make recommendations for HFpEF or unknown EF), using data from the Swedish counties of Uppsala and Västerbotten.
Methods: Patients with HF were identified via electronic medical records from primary and/or secondary care in Uppsala and Västerbotten, linked via unique identifiers to the National Patient Register and Swedish Prescribed Drug Register. Local echocardiography data identified HFrEF (< 50%) and HFpEF (≥50%). Patients aged ≥18 years with ≥2 diagnoses of HF between 01/01/2010 and 31/03/2015 and an ICD-10 diagnostic code of I50 (inclusive of all granular codes), I42.0, I42.6, I42.7, I42.9, I110, I130 or I132 in any position were included. The date of the first diagnosis was the index date. A 10-year look-back period was used to exclude prevalent HF cases. For each drug class commonly used in HF (angiotensin-converting enzyme inhibitors [ACEis], angiotensin II receptor blocker [ARBs], β-blockers and mineralocorticoid receptor antagonist [MRAs]), this study assessed the proportion of patients who were prescribed a median maintenance treatment dose (defined as volume of drug dispensed [mg]/duration of dispensation [days]), of ≥50% and ≥100% of the recommended target dose of individual treatments within the class. Maintenance treatment was assumed to start ≤90 days after treatment initiation, and the duration of each dispensation during maintenance was 90 days.
Results: In total, 8702 patients with HF were identified (HFrEF, 23.5%; HFpEF, 12.9%; unknown EF, 63.6%; mean ± SD age, 76.6 ± 12.6 years; 46.0% female). More patients with HFrEF than those with HFpEF or unknown EF received a common HF treatment (ACEi: HFrEF, 56.3%; HFpEF, 43.8%; unknown EF, 44.1%; ARB: HFrEF, 31.6%; HFpEF, 27.0%; unknown EF, 26.9%; β-blocker: HFrEF, 80.6%; HFpEF, 64.6%; unknown EF, 63.4%; MRA: HFrEF, 48.9%; HFpEF, 32.9%, unknown EF, 26.0%). Patients with HFrEF were more likely to be prescribed maintenance treatment doses of ≥50% and ≥100% of the recommended dose than those with HFpEF and unknown EF (Figure).
Conclusions: Prescription of ESC-recommended doses of HF treatment is low. With the exception of MRAs, most patients receiving treatment were not prescribed ESC-recommended doses, highlighting suboptimal treatment of HF in Sweden. This study did not consider underlying causes of the low doses prescribed, which may be influenced by tolerability.



P284

Management of patients with heart failure with preserved versus reduced ejection fraction: a retrospective population-based cohort study in Sweden

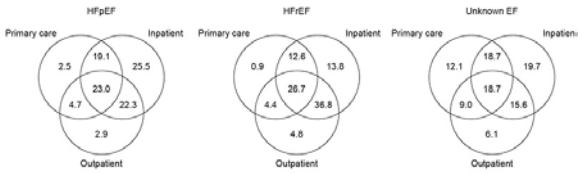
J Stalhammar[1]; K Boman[2]; M Olofsson[2]; G Wikstrom[3]; G J Bergman[4]; M Tornblom[4]; V Wintzell[4]; S Bruce Wirta[5]; C C Proenca[6]; R Schlienger[7]; K Lindmark[8]
[1]*Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden*; [2]*Umea University, Research Unit, Medicine, Skellefteå, Department of Public Health and Clinical Medicine, Umea, Sweden*; [3]*Uppsala University, Institute for Medical Sciences, Uppsala, Sweden*; [4]*QuintilesIMS, Solna, Sweden*; [5]*Novartis Sweden AB, Stockholm, Sweden*; [6]*Wellmera AG, Basel, Switzerland*; [7]*Novartis Pharma AG, Basel, Switzerland*; [8]*Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden*

Background and purpose: Little is known about how patients with heart failure (HF) with preserved (HFpEF), reduced (HFrEF) or unknown ejection fraction (EF) are managed in clinical practice in Sweden. In an effort to gain a better understanding of the management of these patients, we evaluated the different care settings in which they received cardiovascular disease (CVD)-related care in the first year after diagnosis.
Methods: Patients with HF were identified via electronic medical records from primary and/or secondary care in Uppsala and Västerbotten, linked via unique identifiers to the National Patient Register. Local echocardiography data identified HFpEF (≥ 50%) and HFrEF (< 50%). Patients aged ≥ 18 years with ≥ 2 diagnoses of HF between 01/01/2010 and 31/03/2015 and an ICD-10 diagnostic code of I50 (inclusive of all granular codes), I42.0, I42.6, I42.7, I42.9, I110, I130 or I132 in any position were included. The date of the first diagnosis was defined as the index date. Unadjusted proportions of patients treated in primary care (provided in an outpatient, office-based setting) and secondary care (provided in an inpatient or outpatient hospital setting) were assessed in the first year post-index.
Results: In total, 8702 patients with HF were identified. HF phenotype could be defined for 36.4% of patients (HFpEF, 35.4% [mean age ± SD, 74.2 ± 12.6 years; 48.8% male]; HFrEF, 64.6% [69.9 ± 13.7 years; 67.4% male]); EF was unknown for 63.6% of patients (79.5 ± 11.0 years; 50.0% male). Smaller proportions of patients with known EF than with unknown EF were treated in only a primary care setting (HFpEF, 2.5%; HFrEF, 0.9%; unknown EF, 12.1%). Small proportions of patients were seen in only an outpatient setting (HFpEF, 2.9%; HFrEF, 4.8%; unknown EF, 6.1%), while larger proportions were seen in only an inpatient setting (HFpEF,

25.5%; HFrEF, 13.8%; unknown EF, 19.7%). Most patients received CVD-related care in multiple settings, most commonly inpatient + outpatient (HFpEF, 22.3%; HFrEF, 36.8%; unknown EF, 15.6%) and primary care + inpatient + outpatient (HFpEF, 23.0%; HFrEF, 26.7%; unknown EF, 18.7%) settings. Patients with HFrEF were less commonly seen in only one setting than those with HFpEF or unknown EF (Figure). In secondary care, internal medicine wards were the most common settings for visits by patients with HFpEF (outpatient, 17.0%; inpatient, 30.7%), while cardiology clinics were the most common settings for visits by patients with HFrEF (outpatient, 26.6%; inpatient, 37.9%).

Conclusions: Patients with HFpEF, HFrEF and unknown EF are managed differently in terms of the healthcare settings in which they receive care. Patients with HFrEF are more commonly managed in an inpatient setting than those with HFpEF and unknown EF, possibly reflecting more frequent hospitalization of these patients.

Figure. Proportions of patients treated in primary care, and inpatient and outpatient settings.



EF, ejection fraction; HFpEF, heart failure with preserved ejection fraction; HFrEF, heart failure with reduced ejection fraction.

P285

Long-term effects of patiromer for hyperkalaemia treatment in patients with HFrEF and diabetic nephropathy on RAASi

B Pitt[1]; D Garza[2]; R Zawadzki[3]; A Romero[4]; A Conrad[4]; M Lainscak[5]
[1]University of Michigan, Ann Arbor, United States of America; *[2]Relypsa, Inc., Clinical Development, Redwood City, United States of America*; *[3]Relypsa, Inc., Biometrics, Redwood City, United States of America*; *[4]Relypsa, Inc., Medical Affairs, Redwood City, United States of America*; *[5]General Hospital Murska Sobota, Murska Sobota, Slovenia*

Purpose: Renin angiotensin aldosterone system inhibitors (RAASi) are indicated in patients (pts) with heart failure with reduced ejection fraction (HFrEF). RAASi increase the risk of hyperkalaemia (HK), particularly in pts with chronic kidney disease (CKD) and/or diabetes, and are often discontinued in HFrEF pts. Patiromer, a nonabsorbed, sodium-free potassium (K+)-binder, was previously shown in the AMETHYST-DN study to lower serum K+ (s-K+) through 52 weeks in pts with HK and diabetic nephropathy on RAASi. In this post-hoc analysis we examined the effects of patiromer on s-K+ in HK patients with HFrEF.

Methods: Patients with type-2 diabetes, CKD, and HK (baseline s-K+ >5.0– <6.0 mmol/L) were randomized to patiromer starting doses of 8.4–33.6 g/day, divided twice daily. All pts were receiving RAASi during study treatment. Changes in mean s-K+ from baseline through Week 52 were evaluated in the subgroup with HFrEF (EF ≤40%). Results: Of 306 randomized pts, 26 had HFrEF (100% Caucasian, 62% male, 69% ≥65 yr of age, mean [SD] EF: 37 [3]%, mean [SD] eGFR: 43.6 [17.7] mL/min/1.73m2. Mean s-K+ was reduced to <5.0 mmol/L at the first post-baseline visit (day 3, 48 hr after first patiromer dose) through Week 52 and stopping patiromer led to a rise in s-K+ (Table). No pts discontinued due to high s-K+. Patiromer was generally well tolerated, with 17 (65%) pts reporting ≥1 adverse event (AE) during the study. Mild or moderate gastrointestinal AEs were the most common class (occurring in 2 pts) of patiromer-related AEs, with abdominal discomfort, nausea and vomiting each occurring in 1 pt. No pts had s-K+ <3.5 mmol/L, 1 pt had serum magnesium <1.4 mg/dL (<0.57 mmol/L), and there were no reports of edema. From a baseline mean (SE) of 151.1 (2.0)/90.8 (2.1) mmHg, systolic/diastolic BP decreased by 17.0 (2.2)/ 16.2 (2.3) mmHg at Week 52. Conclusions: Patiromer decreased s-K+ through 52 weeks in HFrEF pts with HK and diabetic nephropathy. These post-hoc results, suggesting that patiromer allows continuous management of HK in HFrEF pts on RAASi, require further prospective evaluation.

Serum K+ Over 52 Weeks in HFrEF Patients	
Baseline (n=26)	5.23 (0.5)
Day 3 (n=26) Δ from baseline	4.82 (0.07) −0.41 (0.07)
Week 4 Δ from baseline	4.60 (0.08) −0.58 (0.09)
Week 24 (n=19)Δ from baseline	4.62 (0.06)−0.55 (0.09)
Week 52 (n=19) Δ from baseline	4.57 (0.08) −0.61 (0.07)
End of treatment (EOT) (n=20)	4.57 (0.10)
Follow-up Day +28 (n=17) Δ from EOT	4.97 (0.10)+0.49 (0.08)

Drug treatment patterns in patients newly diagnosed with heart failure: a retrospective population-based cohort study in Sweden

G Wikstrom[1]; K Lindmark[2]; M Olofsson[3]; J Stalhammar[4]; G J Bergman[5]; M Tornblom[5]; V Wintzell[5]; S Bruce Wirta[6]; B Balas[6]; K Boman[3]
[1]Uppsala University, Institute for Medical Sciences, Uppsala, Sweden; *[2]Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden*; *[3]Umea University, Research Unit, Medicine, Skellefteå, Department of Public Health and Clinical Medicine, Umea, Sweden*; *[4]Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden*; *[5]QuintilesIMS, Solna, Sweden*; *[6]Novartis Pharma AG, Basel, Switzerland*

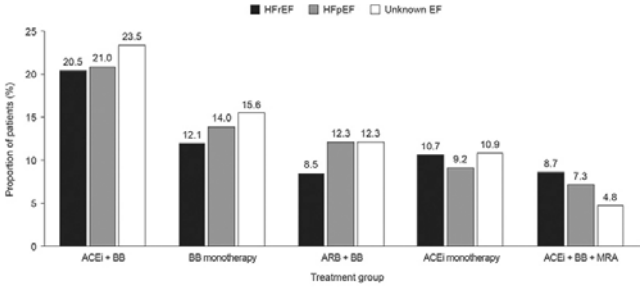
Background and purpose: Limited data are available on longitudinal drug treatment patterns in newly diagnosed patients with heart failure (HF) with preserved (HFpEF), reduced (HFrEF) and unknown ejection fraction (EF) in Sweden. We evaluated drug treatment patterns in these patients based on ESC 2012 guidelines, which recommend treatment with angiotensin-converting enzyme inhibitors (ACEis), angiotensin II receptor blockers (ARBs), β-blockers (BBs) and mineralocorticoid receptor antagonists (MRAs) for HFrEF (ESC does not make recommendations for HFpEF or unknown EF).

Methods: Patients were identified via electronic medical records from primary and/or secondary care in Västerbotten, linked via unique identifiers to the National Patient Register and Swedish Prescribed Drug Register. Local echocardiography data identified HFrEF (<50%) and HFpEF (≥50%). Patients aged ≥18 years with ≥2 diagnoses of HF between 01/01/2010 and 31/03/2015 and an ICD-10 diagnostic code of I50 (inclusive of all granular codes), I42.0, I42.6, I42.7, I42.9, I110, I130 or I132 in any position were included. The date of the first diagnosis was defined as the index date. A 10-year look-back period was used to exclude prevalent HF cases. ATC codes were identified from drug prescriptions. Patients with a 4-year look-back and 2 years of follow-up were included.

Results: Overall, 4357 patients were included (mean ± SD age, 76.6 ± 12.6 years; 27.7% aged ≥85 years; HFrEF, 24.6%; HFpEF, 12.9%; unknown EF, 62.5%). At the index date, 63.0% of patients were treated with an ACEi or an ARB, 62.3% with a BB and 16.0% with an MRA; 18.5% were not receiving treatment. The most common treatment groups (monotherapy or combinations) were: ACEi + BB (HFrEF, 20.5%; HFpEF, 21.0%; unknown EF, 23.5%); BB monotherapy (HFrEF, 12.1%; HFpEF, 14.0%; unknown EF, 15.6%); and ARB + BB (HFrEF, 8.5%; HFpEF, 12.3%; unknown EF, 12.3%) (Figure). The majority of patients receiving an ACEi or ARB at the index date continued to do so for the following 2 years (ACEi, 63.6%; ARB, 60.9%); most of these were receiving doses lower than those recommended by the ESC (70.8% and 88.9%, respectively). A small proportion of patients receiving an ACEi at the index date switched to an ARB over the 2-year period (4.1%) and vice versa (2.6%). Most patients were not receiving the recommended ESC dose before switching (ACEi, 81.8%; ARB, 77.8%). Similarly, most patients who discontinued an ACEi (37.3%) or ARB (39.1%) were not receiving the recommended dose before discontinuation (ACEi, 64.8%; ARB, 87.4%).

Conclusions: A large proportion of patients with HF in Sweden do not receive drug combinations recommended by the ESC. Furthermore, few patients are prescribed ESC-recommended doses of HF drugs and few undergo up-titration of treatment before switching. These findings are remarkable for HFrEF, for which guidelines are established. These findings may be partly reflective of the high proportion of elderly patients studied.

Figure. Most common treatment groups (monotherapy or combinations) received by patients with HF at index.



ACEi, angiotensin-converting enzyme inhibitor; ARB, angiotensin II receptor blocker; BB, β-blocker; MRA, mineralocorticoid receptor antagonist.

Degree of dyspnoea at admission and discharge in patients with heart failure and respiratory diseases

L Vicent[1]; JM Nunez Olarte[1]; L Puente-Maestu[1]; A Oliva[1]; JC Lopez[1]; R Luna[1]; A Postigo[1]; I Martin[1]; F Fernandez-Aviles[1]; M Martinez-Selles[1]
[1]University Hospital Gregorio Maranon, Cardiology, Madrid, Spain

Background: Dyspnoea is a disabling symptom in patients admitted with heart failure (HF) and respiratory diseases (RD).
Aims: The main aim of this study is to evaluate its intensity at admission and discharge and the relation with quality of life. We also describe its management, intensity, and evolution in HF and RD.
Methods: We included prospectively all patients admitted with decompensated HF and chronic obstructive pulmonary disease (COPD)/pulmonary fibrosis during 4 months. Surveys quantifying dyspnoea (Numerical Rating Scale 1-10) and quality of life (EuroQoL 5d) were administered.
Results: A total of 258 patients were included: 190 (73.6%) with HF and 68 (26.4%) with RD (62 COPD and 6 pulmonary fibrosis). Mean age was 74.0 ± 1.2 years, and 157 (60.6%) were men. Dyspnoea before admission was 7.5 ± 0.1. Patients with RD showed greater dyspnoea than those with HF both before admission (8.1 ± 0.2 vs. 7.3 ± 0.2, p = 0.01) and at discharge (3.2 ± 0.3 vs. 2.0 ± 0.2, p = 0.0001). They also presented a higher rate of severe dyspnoea (≥5) at discharge (23 [34.3%] vs. 36 [19.2%], p = 0.02). Opioids were used in 36 (15.5%), mean dose 10.3 ± 1.8 mg Morphine Equivalent Daily Dose. HF patients had worse EuroQoL 5d punctuation than those with RD, due to mobility problems (118 [62.1%] vs. 28[41.8%], p = 0.004), and lower punctuation in Visual Analogue Scale (57.9 ± 1.6 vs. 65.6 ± 1.0, p = 0.006). Progression of dyspnea and pain during hospital admission by Numerical Rating Scale are resumed in the figure. The independent predictors of severe dyspnea at hospital discharge are depicted in the table.
Conclusions: About a quarter of patients admitted with HF or RD persist with severe dyspnoea at discharge. Opioids are probably underused. HF patients have less dyspnoea than patients with RD but present worse quality of life.

Predictors of severe dyspnea

Variable	OR (95% CI)	P
Age	1.1 (1.02-1.2)	0.004

The role of IGFBP7, mimecan and osteopontin in the management of heart failure with preserved and reduced ejection fraction.

N G H M Nick Marcks[1]; S Sanders-Van Wijk[2]; HP Brunner-La Rocca[2]
[1]Cardiovascular Research Institute Maastricht (CARIM), Cardiology, Maastricht, Netherlands; *[2]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands*

On behalf of: TIME-CHF

Background/Objectives: Biomarkers are increasingly used in the management of heart failure (HF), where different pathophysiological pathways are involved. Thus, it is not surprising that the value is not uniform and new biomarkers are sought to better determine the underlying pathophysiology and to predict outcome. Therefore, we investigated three newly discovered biomarkers that were found to be linked with HF in a well described population to determine levels, progression and prognostic value of these biomarkers in comparison to the best established biomarker in HF, i.e. NT-proBNP.
Methods: We performed a retrospective analysis of the TIME-CHF trial, including a total of 622 patients with symptomatic HF (NYHA ≥ II), aged 60 years or older, who either received NT-proBNP or symptom-guided therapy. 462 blood samples were available at baseline (BL) for analysis. Echocardiography was performed at baseline to objectify left ventricular ejection fraction (LVEF), dividing the population in 366 patients with reduced (HFrEF, i.e. ≤45%) and 96 with preserved LVEF (HFpEF, i.e. >45%). Osteopontin (OPN), Mimecan and insulin-like growth factor binding protein 7 (IGFBP7) together with NT-proBNP were measured at baseline and after 1, 3, 6, 12 and 18 months. Follow-up (FU) was up to 5½ years.
Results: At baseline, NT-proBNP and OPN differed significantly between HFrEF and HFpEF, whereas IGFBP7 and Mimecan did not. In HFrEF patients, IGFBP7 levels showed a non-significant fluctuation between FU visits. OPN levels also showed a fluctuating progression, with a non-significant decrease after the 1-month visit and a non-significant increase after the 12-month visit. No significant differences were found between BL and month 18 for IGFBP7 and OPN. Mimecan levels showed a non-significant increase between each individual FU visit, but with an overall significant increase from BL to month 18. Secondly in HFpEF, IGFBP7 levels however did show significant fluctuations over time, with a significant change between BL and month 18. OPN levels showed a significant decrease between the 1 and 3-month visit, but no significant differences between the other individual visits. Like in HFrEF, no significant differences were found between BL and the 18-month visit. Mimecan levels did not significantly in HFpEF change during individual FU visits or the 18-month FU. OPN turned out to be the strongest predictor for overall survival without deaths due to cancer in HFrEF, shortly followed by IGFBP7, NT-proBNP, and Mimecan. In HFpEF, no of the biomarkers reached statistical significance in predicting overall survival without deaths due to cancer.
Conclusion: The three new biomarkers showed a pattern different to that of NT-proBNP despite comparable prognostic values. This supports a different underlying pathophysiological mechanism and suggests that they may be helpful in addition to NT-proBNP and stratifying new therapeutic targets, which needs to be further investigated in future studies.

Coenzyme Q-10 in treatment of patients with heart failure: Results Russian multicenter double blind placebo controlled study

V Y Mareev[1]; Y V Minina[2]; Y V Mareev[3]
[1]Medical Scientific Educational Center of M V Lomonosov Moscow State University, Moscow, Russian Federation; *[2]Russian Society of Heart Failure Specialists , Moscow, Russian Federation*; *[3]Royal Brompton & Harefield Hospitals, Imperial College, London, United Kingdom*

Background: Q-10 was showed the ability to reduce mortality in HF patients in several clinical studies; however, the drug is still is not in ESC guidelines this why additional information about it effects and safety is needed to find its role in HF treatment.
Aim: To estimate clinical effects and safety of water soluble Q-10 in the form of nasal drops (90 mg/day = equivalent 225 mg/day for liposoluble tablets) in patients with heart failure.
Materials: patients with NYHA I-IV and LVEF < 45% who was on optimal medical therapy. Patients were randomized on Q-10 and placebo group. It was multicenter, randomized (ratio 2:1), placebo-controlled, double-blinded study. The Duration of study was 24 weeks. The primary endpoints were: dynamics of NYHA, and scale for HF to Optimize Clinical Status (SHOCS), distance of 6 minutes walking test.
Results: 148 patients were enrolled into the study: 101 in the Q10 group and 47 in the placebo group. There was no statistically significant difference in clinical characteristics and therapy of patients in Q10 and placebo groups. Patients in the Q10 group had greater positive dynamics of NYHA during the study (- 0.16 vs. – 0.08, =0,002), SHOCS (-1.06 vs -0.53, p = 0.036) and 6 minute walk distance (+ 32m vs + 13m, p = 0.044). Also, there were greater positive dynamics of LVEF in Q10 group (+3.1% in Q10 vs + 1.3 placebo, p = 0.038). Patients in the Q10 group have a reduction of BNP level during the study and there was an increase in BNP levels in placebo group (- 34 pg/ml vs + 34 pg/ml, p = 0.032). Safety analysis showed a similar rate of adverse reaction in Q-10 and placebo groups.
Conclusion: Results of our study support, that Q 10 showed clinical, functional, and hemodynamic improvement in clinical relevant CHF. These results can explain mechanisms by which this treatment can improve prognosis in CHF

Effects of angiotensin receptor blocker at discharge in patients with heart failure with reduced ejection fraction

KH Ki Hong Choi[1]; GY Lee[1]; JO Choi[1]; YJ Lee[1]; ES Ju[1]; ES Jeon[1]
[1]Samsung Medical Center, Divison of Cardiology, Seoul, Korea Republic of

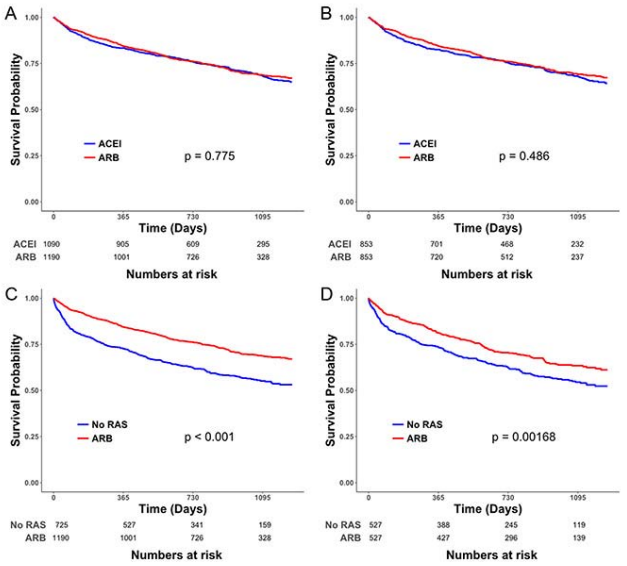
On behalf of: KorAHF investigators
Funding Acknowledgements: This research was supported by Research of Korea Centers for Disease Control and Prevention [2013-E63003-00].

Introduction: There are limited data on comparison between the effects of angiotensin converting enzyme (ACE) inhibitors and angiotensin receptor blocker (ARB) in patients with heart failure with reduced ejection fraction (HFrEF) after introduction of up-titration strategy.
Purpose: To investigate the association between treatment with angiotensin receptor blocker (ARB) at discharge and clinical outcomes in patients with HFrEF compared with treatment with angiotensin converting enzyme (ACE) inhibitors or no RAS blockade.
Methods: The Korean Acute Heart Failure registry is a prospective multicenter cohort and included patients who were hospitalized for acute heart failure (AHF) from 10 hospitals between March 2011 and February 2014. We studied 3,005 patients with HFrEF (<40%), representing 53.4% of the total study population. Our Study population was divided into an ARB (n=1,190), an ACE inhibitor (n=1,090), and a no RAS blockade (n=725) groups. Propensity score matching was performed to reduce confounding factors.
Results: All-cause death during follow-up occurred in 346 patients (29.1%) in the ARB group, 315 patients (28.9%) in the ACE inhibitor group, and 305 (42.1%) in the no RAS blockade group. After propensity score matching analysis (ARB vs. ACE inhibitor, 853 pairs), there was no significant difference between the two groups in the rate of all-cause death (hazard ratio [HR] 0.94, 95% confidence interval [CI] 0.79 to 1.12, p=0.49). The rate of all-cause death was significantly lower in the ARB group than in the no RAS blockade group in the matched population (ARB vs. no RAS blockade, 527 pairs, HR 0.73, 95% CI 0.6 to 0.89, p=0.002). The ARB group had a significantly lower discontinuation rate within 1 year than the ACE inhibitor group in the overall population (ARB vs. ACE inhibitor, 20.8% vs. 33.6%, p<0.001) and the propensity-matched population (18.5% vs. 34.0%, p<0.001).
Conclusions: For the treatment of AHF with reduced EF after hospitalization, ARB at discharge shows a mortality benefit comparable to that of ACE inhibitors. In addition, tolerability of medication was greater for ARB than for ACE inhibitor.

Outcomes according to RAS blockade use

	ARB	Comparison group	HR (95% CI)	P value
Propensity matched population				
Comparison with. ACEi (n=1706)	246 (28.8)	252 (29.5)	0.94 (0.79 to 1.12)	0.49
Comparison with no RAS (n=1054)	183 (34.7)	303 (57.5)	0.73 (0.6 to 0.89)	0.002

ACEi=angiotensin converting enzyme inhibitor; ARB=angiotensin receptor blocker; CI=confidence interval; HR=hazard ratio; RAS=renin-angiotensin system



Survival curve per use of RAS blockade

Beta blockers and chronic heart failure: prognostic impact of a dose targeted therapy vs. heart rate targeted strategy

A Corletto[1]; H Froehlich[1]; T Taeger[1]; M Hochadel[2]; R Zahn[3]; C Kilkofski[3]; R Winkler[3]; H A Katus[1]; J Senges[2]; L Frankenstein[1]
[1]University Hospital of Heidelberg, Cardiology and Pneumology, Innere Medizin III, Heidelberg, Germany; [2]Stiftung Institut für Herzinfarktforschung, Ludwigshafen, Germany; [3]Hear Center Ludwigshafen, Ludwigshafen, Germany

Background/Introduction: Beta blockers improve survival in patients with chronic heart failure (CHF). Whether physicians should aim for target dose or target heart rate (HR), however, is still under debate.
Purpose: Our purpose was trying to understand the different impact on survival of beta blockers on a target-dose vs. target heart-rate regimen.
Methods: We identified 1,669 patients with systolic CHF due to ischemic heart disease or idiopathic dilated cardiomyopathy from the University Hospital and the Clinic, Germany. All patients were treated with an angiotensin converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) and had a history of CHF known for at least 6 months. Target dose was defined as treatment with ≥95% of the respective published guideline-recommended dose. Target HR was defined as 51-69 bpm. All-cause mortality was analysed with respect to beta blocker dosing and resting HR.
Results: 201 (12%) patients met the dose target, 285 (17.1%) the HR target, 627 (37.6%) no target and 556 (33.3%) did not receive beta blockers. During a median follow-up of 42.8 months, 733 (43.9%) patients died, 42 (20.9%), 81 (28.4%), 261 (41.6%), and 349 (62.8%) in each group (p < 0.001). The prognostic impact of being on target dose was comparable to that being on target HR. Prognosis was best in patients who met both the dose and the HR target.
Conclusions: Aiming to the guidelines recommended beta blocker dose or to HR control has a similar positive impact on survival. When on target dose, a supplemental HR control additionally improves survival.

The impact of digoxin on mortality in patients with chronic systolic heart failure

M May Khateeb[1]; R Odeh[1]; A Ahmed[1]; S Saker[1]; R Elshawi[1]; B Bdier[1]; M Almallah[1]
[1]*King Abdulaziz Medical City, Riyadh, Saudi Arabia*

Background / Aim: Prior Studies showed mixed results in association of digoxin use with allcause mortality (ACM). The aim of this analysis is to identify the impact of digoxin use on ACM in a contemporary heart failure (HF) cohort treated with guideline based

Methods: We included 2,298 consecutive patients seen in a HF clinic between 2000 and 2015. Patients were considered to be a digoxin user if he/she received digoxin at any point during the enrollment period in the HF clinic. Patients were matched based on digoxin utility using propensity matching in 2-3:1 fashion. The primary outcome was ACM.

Results: Of 2,298 patients, 325 digoxin users were matched with 750 non-digoxin users. Matched cohort did not have differences among demographics and clinical variables except for worse HF symptomatology and increased prevalence of AF. Overall, the prevalence of the use of guideline suggested therapies was 96%. After a median followup duration of 4 years (IQR 2 - 6 years), digoxin use was associated with increased ACM (21.8% versus 12.9%, unadjusted HR 1.81; 95 CI 1.33 to 2.45; p = 0.001). This association remained significant after adjusting for the propensity score, atrial fibrillation, ejection fraction and New York HF Class (HR 1.74; 95% CI 1.20 to 2.38; P < 0.0001).

Conclusions: In this analysis of well treated HF patients, digoxin was associated with increased ACM. Further randomized controlled trials are needed to determine whether digoxin therapy should be used in well treated HF patients. Until then, routine use of digoxin in clinical practice should be discouraged

P293

Comparison of outcome in systolic heart failure patients using ivabradine, digoxin or neither of them: a real life study

On behalf of: TREAT-HF Investigators

Background and Purpose: Ivabradine is considered with a class IIa recommendation as a fourth-line therapy to reduce heart failure (HF) hospitalization and cardiovascular death in symptomatic chronic HFrEF patients with LVEF ≤35%, in sinus rhythm and a resting heart rate ≥70 bpm despite receiving maximally tolerated optimal medical therapy. Digoxin has received a class IIb recommendation to reduce the risk of hospitalization for these patients. A real-life comparison between both agents is lacking. The aim of this study was to compare their effects on cardiovascular (CV) mortality and rehospitalization in a cohort of chronic stable HFrEF patients.

Methods: The Turkish research team-HF (TREAT-HF) is a network undertaking multicenter, observational cohort studies in HF. This study is a subgroup analysis of TREAT-HF outpatient cohorts who fulfilled following criteria: (1) symptomatic HFrEF patients, (2) in sinus rhythm, and (3) using either ivabradine or digoxin on top of maximally tolerated medical therapy or (4) patients meeting ivabradine recommendation criteria but not using any of the study drugs. A total of 297 patients with available follow-up data for CV death and recurrent HF hospitalization were included in the study.

Results: A total of 61 (20.5%) patients were using ivabradine, 83 (27.9%) patients were under digoxin, and 153 (51.5%) were not using any of them despite being in sinus rhythm, and having LVEF ≤35% and a resting heart rate ≥70 bpm. During a mean follow-up of 15 ± 6 months, 59 (19.9%) patients developed CV death and 225 (76%) patients had at least one HF rehospitalization. Rate of CV death was similar among patients using ivabradine and digoxin, but higher in patients not using these agents [CV death: 8 (13.1%) in ivabradine, 13 (15.7%) in digoxin and 38 (24.8%) in neither drug users; p = 0.080]. Patients using digoxin had slightly less rehospitalization [61 (73.5%)] compared to other groups [ivabradine 47 (77%) and neither drug users [117 (77%)] but the difference between the three groups was not statistically significant (p = 0.818). Mean number of HF rehospitalization was also not different (1.5 ± 1.3 in ivabradine, 1.5 ± 1.3 in digoxin, 1.6 ± 1.4 in neither drug users; P = 0.835). In Kaplan-Meier analysis, ivabradine and digoxin had comparable effects on CV death (P = 0.087), rate of rehospitalization (P = 0.823) and combination of these endpoints (P = 0.801).

Conclusion: In this real life registry, ivabradine and digoxin had comparable effects on CV mortality and rate of rehospitalization in chronic HFrEF patients.

P294

NTproBNP in primary care: initial experience.

JL Bonilla Palomas[1]; AL Gamez Lopez[1]; M Moreno Conde[1]; MC Lopez Ibanez[1]; CJ Raez Ruiz[1]; M Cruz Ruiz[1]; E Jimenez Medina[1]; JM Abad Ortega[1]; J Leal Helmling[1]; A Villar Raez[1]
[1]*Hospital San Juan de la Cruz, Úbeda, Spain*

Introduction: The plasma concentration of brain natriuretic peptides (BNP or NTproBNP) can be used as an initial diagnostic test in patients with dyspnea or suspected heart failure (HF). Patients with normal BNP/NTproBNP concentrations are unlikely to have HF. In the other hand, elevated BNP/NTproBNP help establish an initial working diagnosis, identifying those who require further cardiac investigation. However, in Spain, the use of natriuretic peptides in primary care is not widespread.

Purpose: To describe the initial experience in our health area (a population of 150000 inhabitants) of NTproBNP use in primary care as initial diagnostic test in patients with dyspnea or suspected HF.

Methods: From april 2016 NTproBNP is available for the diagnostic evaluation of symptomatic primary care patients, specially with the goal to exclude HF using a cut-point of 300 ng/L. We evaluated the management of these patients according to the test result.

Results: During 8 months a total of 77 simptomatic primary care patients were avaluated with NTproBNP. NTproBNP was <300 ng/l in 45 patients and >300 ng/L in 32 patients. Among patients with NTproBNP<300, only 4 (9%) patients were referred to the cardiologist (No one presented abnormalities in the echocardiography study), 1 patient (2%) was referred to the pulmonologist, and 40 patients (89%) remained in

primary care, as established. Among patients with NTproBNP>300 ng/L, 15 (47%) patients were referred to the cardiologist and 17 (53%) remained in primary care. The last group of patiens presented lower NTproBNP levels than those who were referred to the cardiologist (median 960 ng/L, intercuartile range 434-1399 ng/L vs 2814 ng/L, interquartile range 967-6020 ng/L, respectively, p = 0,01).
Conclusion: In our experience, NTproBNP use among symptomatic primary care patients is particularly appropiate and useful for exclusion of the diagnosis of HF. In addition, NTproBNP use in primary care has reduced the demands of cardiac referrals and has propiciated that a significant number of patients remain managed in primary care.

P295
Ivabradine reduces rehospitalization in patients with chronic systolic heart failure: single country data from OPTIMIZE- HF program

H Sisakian[1]; H Hayrapetyan[2]; L Sahakyan[1]; M Hovhanisyan[1]; H Petrosyan[2]
[1]Yerevan State Medical University Hospital 1: University Cardiology Clinic, Department of General and Invasive Cardiology, Yerevan, Armenia; *[2]Erebouni Medical Center, Cardiovascular Center, Yerevan, Armenia*

Funding Acknowledgements: Servier

Despite advances of heart failure (HF) current therapy HF related rehospitalizations remain a challenging problem. OPTIMIZE HF program was open prospective study aiming to investigate ivabradine associated heart rate reduction influence on recurrent hospitalizations and mortality. Patients with chronic systolic heart failure who had been hospitalized for HF were randomized to ivabradine or regular recommended HF therapy (including maximized beta-blockade). In one country substudy totally 177 patients from two sites included with 12 month follow up period. The mean NYHA , EF and guideline based therapy were comparable in both groups. 58 patients were prescribed to ivabradine according to guideline based recommendations. Ivabradine was associated with fewer all cause and HF hospitalizations: 7(12 %) vs. 33 (28 %) in controls.; incidence rate ratio 0.75, 95 % confidence interval, 0,65-0,72, p = 0.001). In ivabradine treated group 3 deaths (5,2 %) vs 12 deaths (10 %) in controls were observed during 12 month period.
Conclusion: : in patients with chronic systolic heart failure treatment with ivabradine on a background of guideline based HF therapy is associated with a substantial reduction of rehospitalizations during 1 year follow up period. These effects may contribute to the quality of life and survival with reduction of health care costs.

P296
An audit exploring the effectiveness in medical data recording on implementation of an inpatient heart failure proforma

K Lattey[1]; H Bethell[1]; JS Shah[1]
[1]North West London Hospitals NHS Trust, London, United Kingdom

Background: Heart failure is an increasingly complex condition with the aging population and associated co-morbidities. Documentation in healthcare is of paramount importance for the communication of patient care. However, documentation of heart failure is complex, with multiple parameters requiring regular review on wards that may not have continuity of medical staff.
Purpose: The purpose of our project was to assess the safety and feasibility of the introduction of specific heart failure ward round proformas to standardise medical documentation in this patient group.
Methods: Based on national heart failure and ward round clinical guidelines an audit tool was developed to assess the minimum information required for a heart failure patient. The minimum data (each piece of information = 1 point) required for a new admission summary (NAS) (total score 39 points) and for a daily ward round (DWR) (total score 32 points) were collected on patients in a specialised eight-bedded heart failure unit of a cardiology ward in a busy district general hospital. The case notes of 24 patients, over a period of 15 days, before the introduction of the proformas (15 NAS and 99 DWR) and 21 case notes, over a similar period (6 NAS and 98 DWR) after the introduction of the proformas were reviewed by an independent reviewer. Scores were assigned to NAS and DWR data sets. Additionally, qualitative data was collected from members of the multi-disciplinary team using a five point likert scale questionnaire.
Results: 97% of entries included the date, patient's name, hospital number and doctor's name and 93% included documentation of a clear management plan. However, many of the clinically relevant aspects of documentation were poor, for example less than 28% of entries included the patient's past medical history and 16% included the reason for admission. The proformas resulted in a mean increase in 7 points (95% CI = 1.8,12.3; p = 0.01) for the NAS and a mean increase of 10.6 points (95% CI = 9.1, 12.1; p < 0.001) for the DWR (figure 1). Questionnaire results (n = 10) qualitatively demonstrated perceptions from the multi-disciplinary team that the proforma increased documentation. Staff on the ward previously felt that 66.5% of key outcomes were documented "always" or "most of the time", whereas this increased to 92.7% after implementing the proforma.
Conclusion: This audit demonstrates that the ward round proforma improves and standardises medical documentation in the notes for patients with heart failure. This is supported by a qualitative improvement in the medical documentation as assessed by a multi-disciplinary team. Further work is needed to determine if this kind of documentation impacts on patient outcomes.

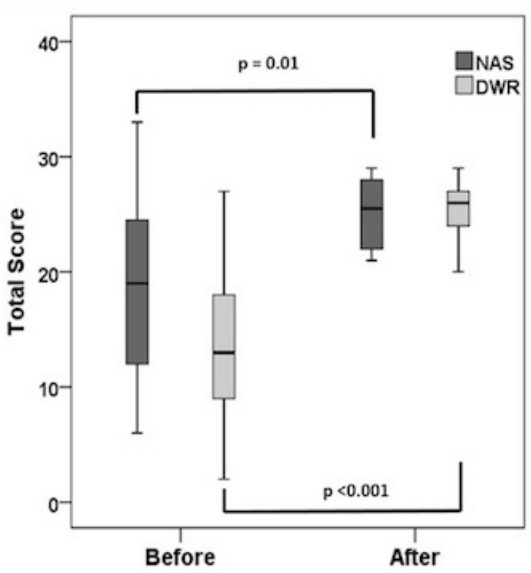

Figure 1

P297
Factors affecting medication adherence trajectories for elderly outpatients with chronic heart failure

VN Larina[1]; II Chukaeva[1]; DG Karpenko[1]; AS Bayramova[1]
[1]The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation

Objectives: To study the factors that determine adherence to threatment of elderly outpatients with chronic heart failure (HF).
Methods: In an open comparative study were included 42 outpatients aged 60 years and older (71,1 ± 9,8 yrs) with chronic heart failure NYHA II-IV class, due to coronary heart disease and/or hypertension. Patients were performed general clinical examination, ECG, EcoCG; Dual-energy X-ray absorptiometry (DEXA). Mental status was assessed using the Mini-mental State Examination scale (MMSE). Adherence to treatment was assessed by scale of complience Morisky – Green. Frailty was defined as three or more of the following: unintentional weight loss, low physical activity, frequent falls, chair stand up test >10 sec, disorders of psychological and emotional status. Results: 64,3% of patients were taking ACE inhibitors, 71,4% - beta-blockers, 9,5% - mineralocorticoid receptor antagonists. The group 1 included 25 patients (59,5%) with treatment adherence, the group 2– 17 patients (40,5%). Patients in the Group 1 were younger (68,6 ± 10 yrs) than patients in the Group 2 (74,8 ± 8,4 yrs). 56% patients of the Group 1 were with the higher education, and in the Group 1 - 64,7% patients were with the higher education. 21 patients (84%) of the Group 1 and 13 patients (76,5%) of the Group 2 were living with the family. 18 (72%) patients of the Group 1 and 8 (47%) of the Group 2 were physically active. 52% patients of the Group 1 and 64,7% patients of the Group 2 had III-IV FC NYHA. Patients of the Group 1 were taking 4,3 ± 1,5, of the Group 2 - 5,8 ± 1,7 medications. 48% and 41% of patients of two groups respectively were taking 5 or more medications. LVEF in patients of the Group 1 were 53,1 ± 13,1% and in patients of the Group 2 - 55,7 ± 13,9%. Comorbidities (anemia, diabetes, atrial fibrillation, COPD, osteoporosis on DEXA) were recorded more frequently in the nonadherence group. Frailty was found in 20% patients of Group 1 and in 35,2% patients of Group 2 and correlated with age (p = 0,003, r=0,45) and high HF FC (p = 0,003, r=0,447), that can be considered frailty as a marker of HF severity. MMSE mean score was 26,7 ± 2,4 points in patients group 1 and 25,1 ± 2,4 points – group 2 (=0,019). Severe cognitive

impairment was detected less frequently in patients of group 1 (8%), than in patients of group 2 (29,4%). Adherence to treatment correlated with impaired cognitive status (p = 0,017, r=0,36). Conclusions: Adherence to treatment of elderly outpatients was 59,5%. Patients with nonadherence to treatment were older, more often they were lonely, less physically active, and they were taking more medications. Also in this patients comorbidities and geriatric syndromes were more frequently detected, and the clinical condition was more severe than that in patients with adherence to treatment. Along with polymorbidity and polypharmacy, frailty had a significant impact in reducing the adherence to treatment, which, in turn, was associated with the frailty.

P298

Ceiling dose of valsartan improves better ventricular-vascular coupling index than usual dose in severe heart failure

W-J Wook-Jin Chung[1]; H Choi[1]; J Moon[1]; M-S Shin[1]
[1]*Gachon University, Cardiology, Gachon Cardiovascular Research Institute, Incheon, Korea Republic of*

On behalf of: VAD trial
Funding Acknowledgements: Norvatis

Background: Effects of Valsartan on LV Diastolic Function in heart failure(VaD) trial was designed as a multi-institutional, prospective and open-labeled trial in patients with stable HF who are intolerable to ACE inhibitors.
Objectives: To compare the effects of non-ceiling dose(80mg bid, NCD) vs. ceiling dose(160mg bid, CD) of valsartan in HF on surrogate markers of functional capacity, LV diastolic and systolic function.
Methods: One hundred thirty eight patients(59.3 ± 12.4 years old; 66% male; LVEF; 29.9 ± 5.9%) were forced-titrated to 160 mg of valsartan, bid for 24 weeks. Echocardiography, treadmill test, Korean activity scale index(KASI) and biochemical studies including NT-proBNP were measured at baseline and after 24-weeks therapy.
Results: Clinical examination and blinded echocardiogram showed significant improvement in NT-proBNP, LVEF, E/E′ ratio, total exercise time and KASI in all, CD(n = 72) and NCD(n = 56), respectively ($p < 0.05$). Interestingly, a significant improvement in the ventricular-vascular coupling index (VVI) was observed in CD with LVEF < 40% (2.4 ± 0.6 → 1.8 ± 0.5, $p < 0.01$). Also, CD showed improvement of symptoms as well as LV mass index compared with NCD($p < 0.05$). Conclusions: As we expected, valsartan led to a notable improvement in LV systolic and diastolic function and exercise capacity in patients with HF. The CD of valsartan showed better improvement of VVI meaning net cardiac performance in the LVEF < 40% and LV mass index, compared with NCD.

On behalf of: CONTEM Study
Funding Acknowledgements: Servier Laboratories Mexico

Background: We don't have a reliable Heart Failure (HF) Registry in Mexico.
Objective: To describe the clinical profile and impact of early treatment optimization after an Acute Decompensated Heart Failure (ADHF) hospitalization.
Methods: We conducted a prospective observational study in patients after an ADHF episode. All the patients were followed at 7, 30, 60 and 90 days after the hospitalization.
Results: We included 41 patients (30 men and 11 women), The mean age was 67.6 ± 12.0 years. The Left Ventricle Ejection Fraction (LVEF) was 28.5 ± 6.6%. The principal etiology was ischemic heart disease 41.5%), followed by cardiomyopathies (29.3%). Functional Class according with NYHA Classification was III (63.4%), II (19.5%) and IV (17.1%). Heart Rate at discharge was 79.2 ± 15.9 BPM, Systolic Blood Pressure 116 ± 21.1 mmHg. , The commonest comorbidities were Diabetes mellitus (29.3%), atrial fibrillation (29.3%) and renal dysfunction (29.3%). Table I show the treatment at hospital discharge.
Conclusions: The clinical profile of HF Mexican patients is similar with another countries. We discover a gap between the recommendations of HF Guidelines and its application in "Real world" scenario, especially with the use of life threatening medications. This represent an urgent call to action. The results of this study will lead us to generate national policies in terms to improve the assessment and care of HF patients in México.

Treatment after discharge

Treatment	Number (%) (N= 41)
ACEIs	15 (36.6%)
ARBs	7 (17.1%)
Beta blockers	26 /63.4%)
Aldosterone antagonists	16 (39%)
Ivabradine	11 (26.8%)
Diuretics	33 (80%)
Digoxin	15 (36%)
Nitrates	2 (4.9%)

P301

The effect of ivabradine on reduction of heart rate and improvement of the quality of life in patients with angina or heart failure in morocco.

A Bennis[1]; A Kifani[1]; N Chemaou[2]; K Adnan[1]
[1]*Private Cardiology practice, casablanca, Morocco*; [2]*Private Cardiology Practice, Tanger, Morocco*

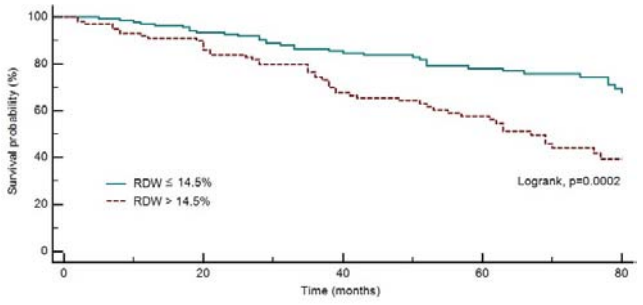
Introduction: A selective reduction of heart rate (HR) has an anti-ischemic and antianginal properties and has demonstrated beneficial effects on cardiovascular events, particularly in heart failure.
Purpose: The ESSENTIEL study aims to observe the effectiveness of exclusive heart rate reduction with Ivabradine on clinical status, LV function and quality of life in patients with angina or heart failure treated over a 4 months.
Methods: Non-interventional, observational conducted on an open cohort in Morocco, in patients with angina or heart failure. Heart rate, a current cardiovascular treatments, an Ejection Fraction, a functional classification of NYHA as well as the SEATTLE self-assessment quality of life questionnaire for angina patients, were documented after 1 and 4 months. The results were analyzed using descriptive statistical methods, by the STATA version 13.
Results: Six hundred and thirteen patients were included, their mean age was 65.77 ± 10.51 years and 60.20% of them were men. 88.11% were receiving a beta-blockers, 42.66% of which was carvedilol. Other concomitant medications included angiotensin-converting enzyme inhibitors (81.06%), long-acting nitrates (32.59%) and calcium channel blockers (37.75%). At baseline, the mean HR of patients was 90.17 ± 14.43 bpm, 14.09% of the patients were in the HR < 75 bpm, 14.96% at the 7580bpm. 37.78% and 40.34% of patients were classified as NYHA II and III, respectively. The mean value of the five SAQ domains of coronary artery disease was: physical limitation 27.91 ± 19.67, stabilization of angina 54.99 ± 29.63, angina frequency 64.25 ± 30.76, treatment assessment 42.75 ± 26.30, and perception of disease 33.96 ± 29.02. After 1 and 4 months of Ivabradine treatment the mean HR was reduced to 70.73 ± 10.65 bpm and 62.40 ± 7.60 bpm, respectively. A 4.83% improvement in mean LVEF was observed after one month of treatment and 8.27% at 4 months, accompanied by a shift in NYHA classification towards better functional class 55.85% in the V1 and 80.98% in the V2. The mean value of the five SAQ domains at 1 month and 4 months was 43.27 ± 21.09 and 55.11 ± 20.28 for the physical limitation of 77.66 ± 21.79 and 90.18 ± 14.17 for the stabilization of angina, 81.46 ± 22.15 and 91.65 ± 13.54 for the frequency of angina 69.44 ± 20.41 and 82.9 ± 17.19 for the evaluation of the treatment, 62.34 ± 26.33 and 78.37 ± 21.49 for the perception of the disease. The rate of adverse events was 1.14%.
Conclusion: over 4 months of treatment, using Ivabradine is associated with a significant reduction in HR, an improvement in the symptoms of heart failure and stable angina, these benefits were accompanied by improved QoL and good general tolerability.
Key words: heart rate, angina, Ivabradine, NYHA, Quality of life, heart failure.

P302

Red cell distribution width: an easily available parameter and an independent predictor of mortality in chronic heart failure

A R Ana Rita Marinheiro[1]; P Amador[1]; L Parreira[1]; C Sa[1]; T Duarte[1]; M Fonseca[1]; S Goncalves[1]; R Rodrigues[1]; R Caria[1]
[1]*Hospital Center of Setubal, Setubal, Portugal*

Background: Red Cell Distribution Width (RDW), a measure of the variability in the size of circulating erythrocytes, is an easily available parameter in clinical practice. In some studies a higher RDW has been described as a marker of poor prognosis in patients with heart failure (HF). However, it is unknown whether the upper limit of reference range or another cut-off value should be used in this setting.
Purpose: To evaluate the prognostic significance of RDW and to determine a cut-off value associated with an increased risk of mortality in patients with chronic HF.
Methods: We evaluate all consecutive patients admitted in a single-center HF clinic between January 2008 and December 2013. Patient baseline characteristics, laboratory values, echocardiographic evaluation and current medication were obtained in the first visit. The primary endpoint was all-cause mortality.
Results: Two-hundred and thirty-four (234) patients (mean age 65 ± 11 years, 73% male) were studied. During a mean follow-up of 57 ± 27 months, 72 patients (31%) died. The multivariate Cox regression model selected RDW (HR 1.20, p = 0.0017), creatinine level (HR 1.46, p = 0.0001) and age (HR 1.04, p = 0.0014) as independent predictors of mortality while the use of angiotensin-converting enzyme (ACE) inhibitors (HR 0.35, p = 0.0005) and angiotensin II receptor antagonists (ARAII) (HR 0.38, p = 0.0148) were independently associated with lower mortality. The optimal cut-off value for RDW by receiver operating characteristic (ROC) curve was 14.5% (AUC 0.590, p = 0.02), which corresponds to the upper limit of reference range. The Kaplan-Meier analysis demonstrated that a RDW above this value was associated with an increased long-term mortality (p [logrank] = 0.0002) (figure).
Conclusion: In this population of chronic HF patients, RDW was an independent preditor of mortality and a value greater than 14.5% was associated with an increased risk of long-term mortality.



Kaplan-Meier survival curve

P303

Prognostic significance of asymptomatic hyperuricemia and allopurinol therapy in chronic systolic HF outpatients

R Rossella Bani[1]; L Caldini[2]; A Paoletti Perini[1]; M Nesti[1]; P Pieragnoli[1]; G Ricciardi[1]; M Beltrami[1]; L Padeletti[1]
[1]Careggi University Hospital (AOUC), Arrhythmic Unit, Florence, Italy; [2]Italian College of General Practitioners, Florence, Italy

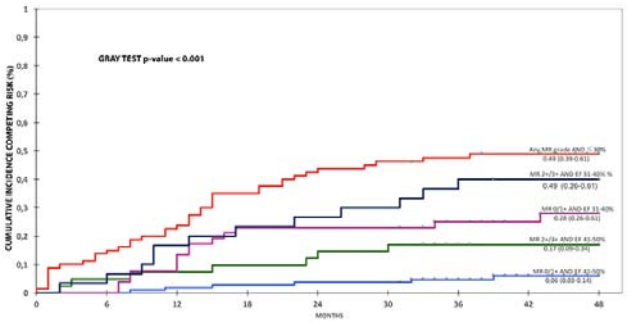
Background: Heart failure (HF) is a disease of epidemic proportions, with relevant social impact and increasing hospitalization and mortality rates. Hyperuricemia has been identified as a potential risk factor for HF development and progression. However, guidelines concerning asymptomatic hyperuricaemia (AHU) have not yet been published and specific literature is lacking. Association between high serum uric acid (SUA) levels and cardiovascular (CV) disease such as hypertension, ischemic stroke and HF has been demonstrated. Some authors underlined that xanthine oxidase inhibitors improves outcome in patients with elevated SUA. However recent findings reported opposite results.
Purpose: To evaluate the impact of AHU and of Allopurinol therapy on CV events, including hospitalizations and death, in chronic systolic HF outpatients.
Methods: We retrospectively evaluated 239 consecutive systolic HF outpatients undergoing complete clinical and instrumental cardiac examination between 2003 and 2010 at a single Cardiologic Unit. All patients were followed up to 5 years. Hyperuricemia was defined for SUA levels > 8 mg/dL and > 6 mg/dL for men and women respectively, as previously suggested. To avoid the confounding effect of treatment, the study population was divided into 2 subgroups: Group T included patients treated with Allopurinol, Group NT those not treated. The study endpoint was the combination of CV hospitalization and death. Cumulative event rates for CV events were estimated by the Kaplan-Meier method. Multivariable Cox analysis was performed to evaluate the endpoint related risk, according to SUA levels, after correction for gender and estimated glomerular filtration rate (eGFR) as covariates.
Results: Among 239 patients, (mean age 70 ± 9 years), 96 (40%) had hyperuricemia; 50 (21%) received Allopurinol therapy (Group T), whereas 189 (79%) did not (Group NT). In Group T hyperuricemic patients were 46 (40%), in Group NT 20 (24%). Baseline clinical characteristics were comparable, except for eGFR (NT: 66 ± 23 ml/min, vs T: 56 ± 20 ml/min; p = 0,004). Over a mean follow-up of 46 ± 13 months, 143 (60%) CV events occurred; 111 (78%) in Group NT, 32 (22%) in Group T. Hyperuricemic patients in Group NT showed a higher rate of CV events when compared to normouricemic patients [34 (74%) vs 77 (54%); p = 0,016)] and AUS was an independent predictor of CV events (HR:1,108; 95%CI:1,005-1,221; p = 0,039). By contrast, in Group T, CV events rate was similar between normouricemic patients (responder to Allopurinol treatment) and hyperuricemic patients (non-responder to Allopurinol treatment) [19 (59%) vs 13 (41%); p = 0.904], and CV events risk did not differ between responder and non-responder to treatment (HR:0,884; 95% CI:0,436-1,791; p = 0,733).
Conclusions: In chronic systolic HF outpatients, SUA level proved an independent predictor of major CV events. However, Allopurinol therapy is not able to improve prognosis in such patients.

P304

Clinical, humoral and echocardiographic profile of patients with heart failure can predict long-term quality of life.

M Michele Di Mauro[1]; R Petroni[1]; D Clemente[1]; A Calafiore[1]; S Romano[1]; M Penco[1]
[1]University of L'Aquila, Department of Cardiology, L'Aquila, Italy

Background. The aim of this retrospective study is to identify clinical, humoral and echocardiographic variables predicting poor QoL.
Methods. From 2009 to 2012, 310 patients were admitted forf HF with reduced ejection fraction (HFrEF). Median age was 78 years (72-84), males and females were 165 and 145. All the patients were followed by phone, calling the patients or the referring GP. The number of re-hospitalization was collected from Outpatients clinic or Hospital Administration Database. The Minnesota Living with Heart Failure Questionnaire (MLHFQ) was used as the instrument to evaluate QoL. MLHFQ < 24 is a good QoL, 24-45 is moderate QoL and >45 is poor QoL, as reported in the literature. The primary event was poor QoL at 4 year (Median follow up was 40 months), defined MLHFQ >45 and/or re-hospitalization. To avoid competing risk, Cumulative Incidence (CI) was used for univariate analysis. Multivariable analysis was performed with Cox Hazard Proportional Regression. MLHFQ was administered to all survivors. Results. Seventy-nine patients died at median time of 21months (6-35); 4-year cumulative mortality was 25 ± 2%. Re-hospitalization was recorded in 60 (19%) with a mean number of re-hospitalization of 2.6. Among 231 survivors, MLHFQ score was good in 99 (42%), moderate in 50 (21%) and poor in 88 (37%). Cumulative incidence of poor QoL was 26 ± 3% at 4 years. Univariate analysis identified following risk variables: mitral regurgitation grade stratified by EF class (Fig. 1), NT-proBNP at admission and discharge, ischemic disease and diabetes, severe tricuspid regurgitation, atrial fibrillation in presence of dilated left atrium, hypercholesterolemia, chronic pulmonary disease, age classes, left ventricular diastolic diameter, renal impairment. The multivariable analysis identified following variables: Hypercholesterolemia (HR 2.5, 1.3-4.9), chronic pulmonary disease (1.9, 1.1-3.3), ischemic heart disease and diabetes (2.1, 1.3-3,5), NT-proBNP (1.02, 1.01-1.03), severe tricuspid regurgitation (2.3, 1.3-3.9), atrial fibrillation with dilated left atrium (1.1, 1.01-1.2) and mitral regurgitation (MR) by EF: MR 2+/3+ & EF 41-50% (4.7, 1.5-15), MR 0/1+ & EF 31-40% (5.0, 2.0-12.-6), MR 2+/3+ & EF 31-40% (5.3, 2.7-10.3) and any MR grade with EF ≤30%. C-statistics of the final model was 0.78. Conclusions. Clinical, humoral and echocardiographic profile is crucial to predict long-term quality of life of patients admitted for heart failure.



Impact of MR by EF on quality of life

P305

The role of simple clinical indicators in the assessment of prognosis in patients with stable systolic heart failure

LV Prokopova[1]; MY Sitnikova[1]; EV Shlyakhto[1]
[1]*Federal Almazov Medical Research Centre, Heart failure, Saint Petersburg, Russian Federation*

Today, patients with systolic heart failure developed high-tech treatments that can improve the prognosis. Prediction of the course of the disease helps the doctor in the selection of patients for high-tech methods of treatment: the implantation of a cardioverter-defibrillator, heart transplantation, implantation of mechanical circulatory support. Objective: In a sample of patients with stable systolic heart failure reveal the routine clinical and laboratory parameters associated with the risk of an adverse outcome for 1 year.
Materials and Methods: The study included 212 patients, observed a cardiologist, a specialist in heart failure. Inclusion criteria: patients with heart failure II-IV functional class,ejection fraction of left ventricular (Simpson) less than 35% between the ages of 18 to 70 years, signed a voluntary consent to participate in the study. After 1 year, analyzed the predictive value of 200 parameters.
Results: 83% (n = 176) examined patients were men, 17% - women (n = 36). At the time of enrollment age was 49,7 ± 11,5 years. Left ventricular ejection fraction was 24,8 ± 7,4%. After 1 year, 64% of patients survived (n = 135), at 2% (n = 5) system implanted mechanical circulatory support, in 24% (n = 51) recorded fatal. In deceased patients revealed the following parameters are unfavorable outcome: speeded respiratory rate and heart rate, low blood pressure; hyponatremia, low hemoglobin, erythrocytes, lymphocytes, total cholesterol and high levels of c-reactive protein, urea, total bilirubin and erythrocyte distribution width in the serum volume; hepatomegaly, the presence of an aneurysm of the left ventricle; Statin therapy, anticoagulants (warfarin), desagregants, inotropic support. On the basis of these parameters regression analysis was performed. A model of one-prediction systolic heart failure, including heart rate (p = 0,005), systolic blood pressure orthostasis at 5 minutes (p = 0,001), respiratory rate (p = 0,001), the width of erythrocyte volume distribution (p = 0,036).
Conclusions: The model prediction of systolic heart failure consists of simple indicators. This model is available for outpatient and inpatient care.

P306

Phase angle by bioelectrical impedance vector analysis as predictor of prolonged hospital stay

L Verdeja-Vendrell[1]; D Gonzalez-Islas[2]; A Orea-Tejeda[2]; A Navarrete-Penaloza[2]; R Sanchez-Santillan[2]; A Jimenez-Cepeda[2]; G Perez-Cortes[2]; V Pelaez-Hernandez[2]; A Figueroa-Herrera[2]; S Torres-Montiel[2]; B Robles-Uribe[2]
[1]*Autonomous University of Puebla, Puebla, Mexico*; [2]*Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Distress Clinic , Mexico City, Mexico*

Background: The phase angle (PA) is an indicator of malnutrition, functionality and integrity of cell membranes, as well as a predictor of prolonged hospital stay in patients with sepsis, cancer and cirrhosis, adverse outcomes after cardiac surgery and mortality in patients with heart failure (HF). However, in patients with HF and respiratory failure (RF) the relationship between PA and prolonged hospital stay has not been explored. Objective: To determine if PA is a predictor for prolonged hospital stay in patients with HF and RF.
Methods: A cross-sectional study was performed including hospitalized patients aged 18 years or older with a diagnosis of HF and RF. Prolonged hospital stay was defined as ≥ 7 days, while the cut-off point for the PA was 4.5°. A logistic regression was performed to determine the risk of prolonged hospital stay associated with a low phase angle. Results: 43 patients (26.3%) were men (mean age 54.02 ± 21.76 years). Patients with prolonged hospital stay had a higher prevalence of COPD (52.6% vs 10.2%, p = 0.005) and HF (42.1% vs. 10.5 %, p = 0.027), and had lower PA (4.63° ± 1.38 vs 5.78° ± 1.56, p = 0.022) compared to patients with short hospital stay. No differences were found between the groups in total body water, extracellular water or other comorbidities such as hypertension, diabetes mellitus, obesity and kidney disease. Patients with a PA < 4.5° had 7 times more risk of having a prolonged hospital stay (OR 7.65, CI 95%, 1.37 - 42.71, p = 0.020). Conclusions: A PA less than 4.5° is associated with a longer hospital stay in patients with HF and RF.

P307

The association between left ventricular ejection fraction, previous chronic heart failure and mortality in patients with acute coronary syndrome (data of Russian RECORD-3 registry)

AD Erlikh[1]
[1]*City hospital 29, Cardiac Care Unit, Moscow, Russian Federation*

On behalf of: Participants of RECORD-3 registry

Background and Purpose: As well known the low left ventricular ejection fraction (LVEF) and previous chronic heart failure (CHF) in patients with acute coronary syndrome (ACS) have association with bad prognosis. The aim of analysis was estimate of association the combination of low LVEF and previous CHF with short-term and medium-term prognosis in patients included in independent Russian ACS registry RECORD-3.
Methods: All consecutive patients with ACS symptoms hospitalized in 47 participant hospitals within 1 month (Mar-Apr 2015) were included in RECORD-3 registry. The CHF was defined as the presence of exercise dispnoe or documented CHF before ACS onset. Low LVEF (< 40%) as defined as local hospital rules. As adverse events were estimated in-hospital death and any causes death during 6 month after discharge from the hospitals.
Results: Among 2370 patients included in registry previous CHF was in 47.6%, and low LVEF – in 11.2%. 6-month follow-up was performed in 1433 patients. Among patients with previous CHF the rate of in-hospital death was 1.3% in patients with normal LVEF and 9.3% in patients with low LVEF (relative risk [RR] 7.34; 95% confidential interval [95CI] 3.36-16.08; p < 0.0001). Among patients without with previous CHF the rate of in-hospital death was 2.0% in patients with normal LVEF and 3.6% in patients with low LVEF (RR 1.81; 95CI 0.54-6.01; p = 0.23). Among patients with previous CHF the rate of 6-month post-discharge death was 4.1% in patients with normal LVEF and 13.5% in patients with low LVEF (RR 3.32; 95CI 1.72-6.39; p = 0.0006). Among patients without with previous CHF the rate of 6-month post-discharge death was 3.1% in patients with normal LVEF and 6.8% in patients with low LVEF (RR 1.81; 95CI 0.67-7.08; p = 0.38).
Conclusion: The data of Russian registry ACS RECORD-3 showed that statistically significant association of low LVEF with high in-hospital and 6-month post-discharge death was revealed only for patients with previous CHF. For patients without previous CHF this association there is only as trend.

P308

Prognostic markers in heart failure patients with mid-range ejection fraction

EE Yakubovskaya[1]; IYU Giverts[1]; MG Poltavskaya[1]; VP Sedov[1]; MV Serova[1]; MD Kuklina[1]; AA Doletsky[1]; AL Syrkin[1]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Objectives: heart failure (HF) with left ventricular ejection fraction (LVEF) in a range of 40-49% has been recently defined by 2016 European guidelines as HF with mid-range EF (HFmrEF). The data concerning prognosis and prognostic predictors in this specific type of patients is scarce. The aim of the study was to identify significant predictors of adverse outcomes among various clinical and laboratory parameters in patients with HFmrEF.
Methods: we retrospectively analyzed the subgroup of 35 patients with HFmrEF, NYHA classes II-III (26 male, mean age 59.9 ± 12,6 years, mean EF=44,3 ± 3,4%) previously included in the prospective observational study. All patients were on optimal medical treatment. At baseline the patients underwent comprehensive investigation including standard clinical examination, echocardiography, 6-minute walk test (6-mwt) and cardiopulmonary exercise testing. Average follow-up amounted 35,9 ± 22,5months. Composite end-point of cardiovascular death and hospitalization for HF was considered a primary analysis variable.
Results: Composite end-point was observed in 51,4% of patients (n = 18). Numerous clinical and laboratory variables were analyzed with respect to their prognostic value. ROC-analysis demonstrated the significant independent predictive value of left atrial volume (AUC=0,798; 95% CI 0,619 ± 0,918; p = 0,0002), E/e' AUC=0,741; 95% CI 0,533 ± 0,891; p = 0,016) and 6mwt distance (AUC=0,746; 95% CI 0,558 ± 0,884; p = 0,01).
Conclusions: In a subgroup of patients with HFmrEF left atrial volume, E/e' ratio and 6-minute walk test distance appear to be strong predictors of cardiovascular death or heart failure hospitalization similarly to HF patients with reduced or preserved EF. Further investigations are necessary to confirm this data.

P309

Can thyroid function be a predictor of poor prognosis in heart failure?

CS Catarina Sofia Soares De Sa[1]; T Duarte[1]; S Goncalves[1]; R Marinheiro[1]; MARTA Fonseca[1]; R Rodrigues[1]; D Ferreira[1]; S Correia[1]; A Lourenco[1]; F Seixo[1]; R Caria[1]
[1]*Hospital Center of Setubal, Cardiology, Setubal, Portugal*

Introduction: Thyroid hormones exert important effects on cardiac structure and function. Both hypo and hyperthyroidism could induce heart failure. However, data regarding the clinical significance in patients with heart failure are sparse.
Purpose: Evaluate the relationship between values of TSH and T4 and death/rehospitalization in a population of patients with heart failure (HF)
Methods: Retrospective study of a population of patients admitted in our heart failure clinic with mean ejection fraction of left ventriculum of 32%. Values of TSH

and T4 were divided into quartiles and the characteristics between them were compared. The occurrence of events (rehospitalization/death/combined endpoint) was determined and compared.

Results: Our population included 150 patients, aged 67 ± 11 years and mostly men (72%). Mean TSH values were 1,75 ± 0.96nmol/L and mean T4 values were 1,06 ± 0,18ng/dl. Of the patients evaluated none had abnormal values of thyroid function and 3 were treated with levothyroxine. During the follow up of these patients 8 died (5,3%) and 50 were re-admitted (33%) for decompensated HF.

We compared the quartiles of T4 and verified higher prevalence of hypertension in higher values of T4 e higher prevalence of anemia in lower values of T4. There was no difference in sex, age, ejection fraction, NYHA class or HF etiology between the quartiles.

A higher prevalence of mortality was demonstrated in patients with T4 values in the upper quartiles (1,10 a 1,22; >1,23).

There was no association between TSH values and rehospitalization, death or combined endpoint.

Conclusion: In our population we fail to verify a significative association between valued of THS and T4 and the endpoints of death and rehospitalization. Probably , a larger population will be necessary to verify a predictive association between thyroid hormones and the endpoint studied

Table I

	T4	p			
	0,99	1-1,1	1,11-1,22	>1,23

P310

Left ventricular remodeling and inflammation features as predicting factors of sudden cardiac death after myocardial infarction

I A Leonova[1]; S Boldueva[1]; E Bykova[1]
[1]*North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation*

The sudden death (SD) after myocardial infarction (MI) is an important issue, so this study was dedicate to comparison of patients survived and died suddenly after MI. 667 patients with MI were included. In addition to standard methods marker of apoptosis of CD 95 lymphocytes and monocytes CD 14, interleukin 1β, 2, 6, and TNF α were investigated. The patient's follow-up period was 1 - 7 years. During this period, 61 people died suddenly.

When comparing the SD and survived patients no significant differences in age, smoking, hypertension, diabetes were found. Number of male was higher (90.2% vs 74.3% p = 0.006) among SD patients, and these patients had more frequent history of repeated MI (55.7% vs 24.3% p = 0.001) and circular MI (8.2% vs. 2.8% p = 0.01). Acute and chronic heart failure, left ventricular aneurysm, ventricular extrasystole were detected significantly more frequently among SD patients compared with survived (23% and 6.3% 4*10-6; 34.4% and 8.9%3*10-9; 41% vs 19.3% 8*10-5; 48.9% vs 21.4% 8*10-5 respectively). SD patients had greater decrease in left ventricular ejection fraction (LVEF) (47,1% ± 13,6% against 56,5% ± 10,7%, p = 1*10-8), larger values of end-diastolic size (57,6 ± 8,6mm ± 6,6mm against 52,3 p = 2*10-7), end-diastolic volume (180 ± 125,8 ± 60,7ml against 38,4ml p = 2*10-5), end-systolic size (43,3 ± 12mm against 35.3 ± 7,8mm, p = 9*10-8), end-systolic volume of the left ventricle (93,9 ± 43,3ml vs. 53.1 ± 22 ml, p = 1*10-7) and left atrium (42.8 ± 4,7mm against 40.4 ± 5.3mm, p = 0.002) and more frequently recorded LV hypertrophy (3.9 % versus 57.6%, p = 0.03). Among suddenly died restrictive type of diastolic dysfunction was detected more frequently (27.3% vs. 10.8% p = 0.004). The level of lymphocyte in the first day of MI was significantly lower among SD patients than in survivors (1,3 ± 0,5 109 / l vs. 1,8 ± 0,7 10 left ventricular akinesia / L; p = 0.03). On other parameters (IL 1β, IL-2, IL-6 and TNF-α, expression of CD95 and CD14 on lymphocytes, monocytes) statistically significant differences were not found. In order to determinate the independent factors for the risk of development of SD stepwise multivariate Cox analysis was conducted. For SD development such risk factors were the most important: acute left ventricular failure III-IV class Killip (β = 1,09; OR = 2.99; 95% CI = 1,44-6,18; p = 0.003) LV end-diastolic dimension (β = 0,05; OR = 2.46; 95% CI = 1,07-2,68; p = 0.02), LVEF (β = -0,03; OR = 1.63; 95% CI = 0,40-1,75; p = 0.05) and a left ventricular akinesia (β = -0,88; OR = 2.42; 95% CI = 1,30-5 41; p = 0.006). The most important and independent factors for predicting of SD in patients after MI are the end-diastolic dimension, LVEF, LV akinesia, LV failure III-IV by Killip. Leukocytes and their classes, pro-inflammatory cytokines (IL-1.beta, IL-2, IL-6 and TNF-α), and the expression of CD95 on lymphocytes and CD14 monocytes do not have independent prognostic value in acute MI.

P311

Echocardiography parameters in heart failure patients with moderate functional mitral regurgitation and correlation with six months outcome

DR Vakilian Aghouee[1]; DR Ghaderi[1]; MR Sheikhandalibi[1]; MS Bijari[1]; MS Sahranavard[1]
[1]*Mashad University of Medical Sciences, Cardiology Department, Mashad, Iran (Islamic Republic of)*

Introduction: Heart failure is a growing problem with different etiologies. Left Ventricular Ejection Fraction (LV EF) and functional Mitral regurgitation (FMR) are important prognostic factors. This study planned to evaluate echocardiography as an available tool in differentiating etiologies of FMR and correlation with 6 months outcome.

Methods: and material: In this prospective cross-sectional study 62 HFreduced EF:less than 40%) patients with moderate FMR (40 ICM and 22 NICM) were enrolled. Patients were followed for 6 months. Primary end-points were death, re admission and NYHA class. Logistic regression and multivariate analysis was done.

Results: Mean age was 62.6 ± 11.7 and 47.4 ± 19.2 in ischemic and non-ischemic groups respectively.LV sphericity index, posterior tenting angle (PTA) and time to pick inferior S was significantly different within groups (p < 0.01). The best cut point for LV sphericity index was 1.46 and for PTA ≥40 degrees.Time to pick inferior S ≥ 140 msec and anterior Sm-velocity < 4 m/s indicate ischemic etiology(table 1). Primary end-point (readmission or death) was observed in 35.2% (17.5% and 9.1% in ischemic and non-ischemic groups, respectively). Age, diabetes, smoking, time to pick inferior Sm≥ 140 msec and ischemic etiology of FMR was associated with re admission and higher mortality(HR=3.2).

Conclusion: PTA> 40 degrees and time to peak inferior Sm>140 msec are independent predictors of MR etiology, readmission and mortality.

table 1

Parameters of Mitral valve deformity				
Anterior tenting angle (degrees)	35.2 ± 9.8	34.3 ± 11.7	34.9 ± 10.4	0.671 [b]
Posterior tenting angle (degrees)	50.7 ± 12.2	40.1 ± 11.4	43.7 ± 12.6	0.002* [a]
Medio lateral MVAD (cm)	2.8 ± 0.5	2.9 ± 0.8	2.9 ± 0.6	0.099 [b]
Antero posterior MVAD (cm)	2.8 ± 0.5	3.0 ± 0.5	2.9 ± 0.5	0.205 [a]
Tenting area (cm2)	2.2 ± 0.8	2.3 ± 0.9	2.2 ± 0.8	0.691 [b]

On behalf of: optimize Colombia project
Funding Acknowledgements: Servier sponsored the study

Multidisciplinary Heart failure programs (MHFP) , that included a specialized staff with a cardiology and a nurse, with a training in this field are a cost effective strategy to reduce mortality, new hospitalization and to improve quality of life, however this programs are not widely available in our country and they are just focused in some hospitals. The prevalence of heart failure is increasing so it is necessary to have a strategy to improve the care of patients in hospitals with less resources.
Objective: To describe the impact of the implementation of OPTIMIZE program in the composite outcome of decompensation + hospitalizations after 30 days from hospital discharge. The OPTIMIZE program was a simple strategy implemented at hospital discharge and included: education in the hospital, a material to enhance adherence to treatment , up titration of medications in the hospital and early initiation of ivabradine to obtain a goal heart rate of 60 – 70 bpm. The outcomes were analyzed by the hospital status: with and without MHFP.
Results: 436 patients were included, 44% (N= 192) from hospitals with MHFP and 56% (n= 244) without MHFPs. 68% were male and 32% were females, the mean age was 66 years with a mean ejection fraction of 32%. 20.3% of the patients from MHFP were treated with Ivabradine vs 59.83% in hospitals without MHFP. Only 61.4% of the patients were followed in an outpatient service. After 30 days from the hospital discharge, the percentage of composite outcome of decompensations + hospitalizations was 2.2% vs 3.3 % (p = 0.530), in hospital with and without MHFP respectively.
Conclusion: The implementation of optimize program in hospitals without a MHFP improves the results of the short term prognosis of patients, with a rate of composite outcome of decompensations + hospitalizations at 30 days similar than the observed in MHFP.I,.The implementation of this program and the use of ivabradine early in the vulnerable phase, from the hospital discharge, is a good strategy to standardize the health care in all type of hospitals as a part of a quality-improvement initiative.

P313

Prognostic impact of the combined presence of anemia and chronic kidney disease on long-term mortality in patients with reduced and preserved ejection fraction following myocardial infarction

L Savic[1]; I Mrdovic[1]; M Asanin[1]; G Krljanac[1]; D Matic[1]; R Lasica[1]; D Rajic[1]
[1]*Clinical Center of Serbia, Institute for Cardiovascular Disease, Emergency Hospital, Belgrade, Serbia*

Purpose: Anemia and chronic kidney disease (CKD) are common and frequently coexist in patients with acute coronary syndrome. The aim of this study was to analyse the prognostic impact of anemia and CKD on long-term mortality in patients with reduced and preserved ejection fraction (EF) following ST-elevation myocardial infarction (STEMI).
Method: we included 2157 consecutive STEMI patients who were treated with primary percutaneous coronary intervention (pPCI). Anemia was defined as baseline hemoglobin level < 12g/dl in women and < 130g/dl in men. CKD was defined as baseline creatinine clearance < 60ml/min/m2. Reduced EF was defined as ≤ 40%. Echocardiographic examination was performed before disharge. Patients presenting with cardiogenic shock and patients on hemodyalisis were excluded.
Results: Among analysed patients 573 (26%) patients had reduced and 1496 patients (74%) had preserved EF; anemia was present in 98 (4.5%) patients, CKD in 273 (12.6%) patients and combined presence of anemia and CKD in 70 (3.2%) patients. Five year mortality rate was 21.1% and 2.9% in patients with reduced and preserved EF respectively. Estimated five year survival probability in patients with reduced and preserved EF according to the pesence of anemia, CKD and CKD + anemia is shown in the Figure 1. After multivariable adjustement in Cox regression model CKD, anemia and the combined presence of CKD and anemia were independent predictors of 5-year mortality in patients with reduced ejection fraction: CKD HR 1.89 (95%CI 1.1-3.54), p = 0.047; Anemia HR 1.83 (95%CI 1.3-4.5), p = 0.048; CKD + Anemia HR 2.4 (95%CI 1.3-4.5), p = 0.006. Other independent predictors of 5-year mortality in patients with reduced EF were older age, Killip class >1 at admission and postprocedural flow TIMI < 3. In patients with preserved EF there was no association of anemia and/or CKD with 5-year mortality and independent predictors of 5-year mortality in patients with preserved EF were only older age and Killip class >1 at admission.
Conclusion: The combined presence of anemia and chronic kidney disease is a strong independent predictor of five year mortality in patients with reduced EF following STEMI. In STEMI patients with preserved ejection fraction anemia and chronic kidney disease are not risk factors for long-term mortality.

Gender difference of obesity paradox in systolic heart failure

BS Byungsu Yoo[1]; JW Son[1]; JY Kim[1]; MS Ahn[1]; SH Lee[1]; JH Yoon[1]
[1]*Wonju College of Medicine, Yonsei University, Division of Cardiology, Department of Internal Medicin, Wonju, Korea Republic of*

Background: Obesity is often associated with better clinical outcomes in heart failure. This so called 'obesity paradox' still remains controversial. The aim of present study was to investigate the prognostic value of the obesity in patients hospitalized with systolic heart failure.
Method: We performed a pooled analysis of data from the three multi-center, observational heart failure studies, Survey of Guideline Adherence for Treatment of systolic Heart Failure in Real World; COAST, Clinical Outcomes in Relation with Serum Sodium Level in Asian Patients Hospitalized for Systolic Heart Failure]. Patients (> 18 years old) who were hospitalized with systolic heart failure (EF≤45%) were eligible for present study. We divided the subjects into 2 groups, Normal BMI group (BMI < 25) and High BMI group (BMI ≥ 25). Study endpoints included all cause mortality and any re-hospitalization within 1 year. All analysis was performed separately by gender.
Results: Total 3145 patients (male 1824, female 1321) were enrolled. In men, high BMI group (n = 563) presented more hypertension (52.9% vs. 47.9, p = 0.048). The high BMI was significantly associated with lower 1 year mortality rate (OR 0.543, 95% CI 0.355-0.833) after adjusting for age, hypertension, diabetes, ischemic heart failure, previous myocardial infarction, serum creatinine, anemia (Hb < 10g/dL) and ejection fraction. In women, patients with high BMI (n = 404) more presented hypertension (61.4% vs. 54.1%, p = 0.016), diabetes (45.2% vs. 35.2%, p < 0.001), and chronic kidney disease (12.9% vs. 8.1%, p = 0.005). After adjustment for clinical characteristics, high BMI was not significantly associated with 1 year mortality (OR 0.739, 95% CI 0.450-1.216) or 1 year rehospitalization (OR 0.958, 95% CI 0.696 - 1.319).
Conclusions: In pooled analysis from 3 Korean heart failure registries, there was a gender difference of obesity paradox. The high BMI was independently associated with lower 1 year mortality rate in systolic heart failure, especially in men.

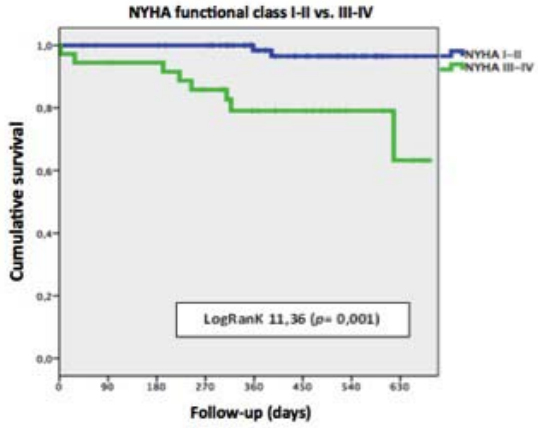
P315

Clinical predictors of mortality in patients with severe aortic stenosis undergoing surgical and percutaneous aortic valve intervention

I S S Ines Goncalves[1]; JR Agostinho[1]; IA Ricardo[1]; J Rigueira[1]; ARF Francisco[1]; T Guimaraes[1]; GL Silva[1]; R Santos[1]; A Ferreira[1]; AG Almeida[1]; F Pinto[1]
[1]*Hospital Universitário de Santa Maria/CHLN, CAML, CCUL,Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*

Introduction: Symptomatic severe aortic stenosis (AS) presents high mortality, and the only prognosis modifiable therapy is aortic valvular intervention (AVi). There are some factors identified as predictors of mortality in patients (pts) undergoing

AVi, such as the presence of ventricular dysfunction and coronary artery disease; however, it's not known which co-morbidities and factors associated with the clinical presentation influence the prognosis most directly.
Purpose: To determine the clinical predictors of mortality in the pts diagnosed with AS submitted to AVi.
Methods: A retrospective unicentric study was made, with inclusion of consecutive pts with AS (excluding low flow low gradiente and and paradoxal aortic stenosis), diagnosed during 2015 in a tertiary center, who underwent AVi until the end of the follow-up period. Clinical data were collected and their relationship with mortality was analyzed using the Cox regression statistical method and Kaplan-Meier survival analysis.
Results: A total of 278 pts (54% women and 46% men, mean age 74 ± 9 years) were included, with a mean follow-up of 389 ± 186 days, of which 192 were submitted to intervention (51.8% women, mean age 75 ± 8.8 years; 87% underwent aortic valve replacement surgery and 13% underwent percutaneous implantation). Mortality in this subgroup was 9.7% (vs. 50% in the subgroup not submitted to AVi). The mean time from the diagnosis of AS to AVi was 59 days. In patients undergoing AVi, NYHA functional class ($p = 0.007$) and NTproBNP ($p = 0.002$) were identified as clinical predictors of mortality at diagnosis, using univariate Cox analysis. None of the cardiovascular comorbidities analyzed (hypertension, diabetes, obesity, coronary artery disease, cerebrovascular disease and chronic kidney disease) showed a significant relationship with mortality in this group. Using multivariate analysis by Cox regression, only the NYHA functional class was an independent predictor of mortality: patients in class > 2 had a 12 times higher risk of death (hazard ratio = 11.7, 95% CI, 1.37-100, P = 0.025); (P = 0.001).
Conclusions: In this group of pts with AS, the NYHA functional class was the only clinical predictor of mortality. This reflects the importance of early intervention in the course of the disease, as soon as the first symptoms appear, avoiding the delay of the intervention only for more advanced functional classes, regardless of the comorbidities or the age of the patient.



P316

Significance of NT-proBNP, TnT and soluble ST2-receptor concentrations in risk stratification in patients with acute decompensated heart failure

V N Protasov[1]; AA Skvortsov[1]; OY Narusov[1]; D E Protasova[2]; GA Tkachev[1]; VP Masenko[1]; SN Tereshchenko[1]
[1]*Russian Cardiology Research and Production Complex, Moscow, Russian Federation*; [2]*National Research Center for Preventive Medicine, Moscow, Russian Federation*

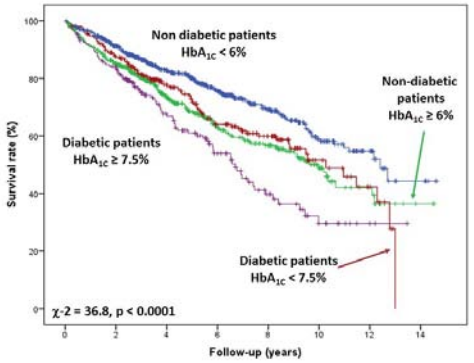
Background: sST2 and NT-proBNP are more strong predictors of adverse long-term prognosis in pts with ADHF compared TnT. Purpose: to evaluate the significance of sST2, TnT and NT-proBNP in risk stratification pts with ADHF.
Methods: In the study were included 159 pts with ADHF. Blood samples to determine NT-proBNP, sST2, hsTn-T concentrations were collected at the admission and at discharge from the hospital. The primary end point was total cardiovascular events that included cardiovascular (CV) death and hospitalization due to HF. Results: At admission all pts had elevated concentrations of NT-proBNP, hsTnT and sST2. During the period of hospitalization there was a reduction of biomarker concentrations, $p < 0,01$. During 1-year follow-up 56 pts (35,2%) had CV events. At the admission biomarker concentrations in low risk pts (without CV events) were significantly lower compared with high risk pts (with CV evnts): NT-proBNP 2819 (1233;4912,7)pg/ml vs 5215,5 (3010;8768,5)pg/ml; hsTnT 28,2 (18,85;41) pg/ml vs 41,1 (25,3;69,1) pg/ml; sST2 53,64 (37,04; 72,35) ng/ml vs 72,07 (59,27;117,75) ng/ml, $p < 0,0001$ for all. The similar trend was observed and at discharge: NT-proBNP 1439 (753,3; 2604,5)pg/ml, vs 3358 (1623,7;5432,7) pg/ml, hsTnT 24,49 (19,8;36,6) pg/ml vs 33,9 (23,2;59,2)pg/ml; sST2 31,28 (21,68;48,00) ng/ml vs 60,19 (37,25;98,35) ng/ml, $p < 0,0001$ for all.The positive predictive value was found for all tested markers. TnT concentration had the most predictive capacity in the short-term period (90 days): at the admission AUC 0,811 (0,707-0,916) and at the discharge (AUC 0,756 (0,612-0,892). In the long-term period there was a decrease of predictive capacity of TnT concentration at the admission(6 month: AUC 0,715 (0,614-0,817), 12 month: AUC 0,663 (0,567-0,758). At the discharge NT-proBNP and sST2 concentrations had the most predictive capacity relatively the primary end point during 1-year follow-up: AUC=0,726 (95% CI 0,637-0,816), AUC=0,768 (95% CI 0,682-0,854), respectively. The model with combined determination of the concentrations of the two markers at the discharge (sST2 and NT-proBNP) had the most predictive value in the medium-term (180 days), and long-term (365 days) prognosis: AUC 0,821 (0,74-0,901), R 3,33 (1,726-6,434) < 0.0001 and AUC 0,802 (0,72-0,884), OR 3,54 (2,078-6,035), < 0.0001, respectively. Including of sST2 and NT-proBNP concentrations at the discharge in the clinical and biochemical model was accompanied by increase of AUC from 0,812 (0,72-0,905); R 2,43 (1,66-3,56), < 0.0001 to 0,883 (0,816-951); R 2,86 (2,12-3,85), < 0.0001 for 6 month and from 0,747 (0,653-0,84); R 2,37 (1,657-3,389), < 0.0001 to 0,85 (0,774-0,927); OR 2,91 (2,166-3,916), < 0.0001 for 12 month. Conclusion: The TnT has a relationship with a adverse prognosis in the short -term period. NT-proBNP and sST2 at the discharge reflect the adverse prognosis in pts with ADHF in the medium-term and long-term follow-up period.

P317

Prognostic impact of glycated hemoglobin in patients with systolic heart failure

E Hebbar[1]; C Le Goffic[1]; T Mercier[1]; V Cousin[1]; H Riddon[1]; A Duva Pentiah[1]; M Fertin[1]; N Lamblin[1]; C Bauters[1]; P De Groote[1]
[1]*Lille University Hospital, Institut Coeur-Poumon, Lille, France*

Background: There are conflicting results concerning the prognostic impact of glycated hemoglobin (HbA1C) in patients with systolic heart failure.
Objectives: To analyze the prognostic impact of HbA1C in stable patients with chronic systolic heart failure.
Methods: All the patients were ambulatory, stable with optimal medical therapy at the time of inclusion. All the patients performed an echocardiography, a cardiopulmonary exercise test and a radionuclide angiography. Blood samples were drawn at rest.
Results: 1583 patients were included, of whom 436 were diabetics. Mean age was 55 ± 12 years old, left ventricular ejection fraction (LVEF) was 37 ± 12%, ischemic cardiopathy was more frequent in diabetic patients (59% vs 39%, $p < 0.0001$). During a follow-up period of 4.2 years [2.42 – 7.09], there were 508 deaths, of whom 391 were cardio-vascular related deaths, 74 non-urgent cardiac transplantations, 28 UNOS1 transplantations, 24 LVAD implantations and 11 patients were lost of follow-up. Cut-off values for HbA1C were determined by ROC curves analyses in diabetic and in non-diabetic patients. As shown in the Figure, non-diabetic patients with a HbA1C ≥ 6% had the same survival than diabetic patients with a HbA1C < 7.5% (chi-2 = 15.8, $p < 0.0001$ between the 2 subgroups of non-diabetic patients and chi-2 = 7.96, $p = 0.005$ in diabetic patients). HbA1C ≥ 7.5% in diabetic patients was an independent predictor of survival even after multiple adjustments (clinical data, LVEF, VO2 and BNP) (HR = 1.56 [1.09-2.24], $p = 0.02$). However, in non-diabetic patients, HbA1C ≥ 6% was not an independent predictor of survival.
In conclusion, HbA1C is a predictor of survival in a population of stable patients with systolic heart failure, particularly in diabetic patients.



Survival curves in different subgroups

P318

Prognostic importance of inclusion serum cystatin C level for eGFR calculation by CKD-EPI equation in patients with first decompensation of HFPEF

TV Nikiforova[1]; D Shchekochihin[1]; AS Shilova[1]; HE El Manaa[1]; AA Lomonosova[1]; PH Y Kopylov[1]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Background: HFPEF in a common phenotype of HF with substantial increase in incidence and prevalence. There is no direct prognostic estimator for these patients to the date. Decreased renal function is a well-known independent negative prognostic factor in heart failure patients populations. Several formulas are accepted for eGFR. The best formula for eGFR estimating in HFPEF patients regarding prognostic information remains unknown. The aim of the study is to compare prognostic significance of decreased eGFR derived by CKD-EPI equation based on serum creatinine and serum cystatin C versus CKD-EPI equation based on serum creatinine only in patients with first decompensation of HFPEF.
Materials and methods: 117 patients with first decompensation of HFPEF (average age 71,6 ± 9,1 years; 65,8% - women) were included in prospective study. 85,5% of the patients had atrial fibrillation with persistent form in 38,5%.25,6% had diabetes mellitus.32,5% had ischemic origin of HF. HFPEF was diagnosed according to ECS guidelines. All patients signed informed consent. The study was approved by ethical committee. Blood samples for biomarkers estimation erre derived during index hospitalization. The patients were mentored by phone monthly during first six months and every three months until 24 month period. Mortality, HF hospitalization and combined end point were used. Kaplan-Mayer curves with Log-rank test were used for survival analysis. P value of 0,05 or less was considered to be significant.
Results: Average eGFR at inclusion was 50,2 ± 16,9 ml/min/1.73 sq.m by serum creatinine formula and 46,4 ± 16,1 ml/min/1.73 sq.m by combined formula ($p < 0,05$). Addition of cystatin C to equation regrouped the patients by CKD classification with more numbers for 3B stage (41,0% vs 35,9%; $p < 0,05$). During follow-up 45,3% of the patients reached combine end-point, mortality was 11,9%,hospitalization due to HF was necessary in 33,3% of the patients. Study population was divided for two groups, with eGFR> 45 ml/min/1.73 sq.m or eGFR <45 ml/min/1.73 sq.m by both formulas. The groups divided by serum creatinine formula did not differ significantly in mortality, morbidity and combined end-point achievement during survival analysis ($p = 0,07$; $p = 0,7$ and $p = 0,2$). However, if the patients were divided by combined creatinine and serum cystatine C formula, the patients with eGFR <45 ml/min/1.73 sq.m demonstrated significantly increased achievement of combined end-point ($p = 0,03$) and increased mortality ($p = 0,03$).
Conclusions: Decreased baseline eGFR by CKD-EPI equation based on serum creatinine and cystatine C levels is a negative prognostic factor in patients with first decompensation of HFPEF. However decreased eGFR by CKD-EPI equation based on serum creatinine only does not. Significance of serum cystatine C level in HFPEF can be attributed to more accurate renal function measurement or GFR-independent estimation of alerted collagen turnover.

P319

A simplified bedside prognostic tool for heart failure: the proSCANNED score

K Kamila Solecki[1]; CM Duflos[2]; B Mandoorah[1]; F Huet[1]; S Cade[1]; F Cransac[1]; A Agullo[1]; P Battistella[1]; G Mercier[2]; F Roubille[2]
[1]*University Hospital Arnaud de Villeneuve, cardiology, Montpellier, France*; [2]*University Hospital of Montpellier, economic evaluation unit, Montpellier, France*

Background: Heart failure (HF) represents a major cause of death and hospitalisation. Evaluation of the prognosis remains challenging. Various prognostic risk models have been already developed. The MAGGIC model is promising but is in reality difficult to apply in practice. Similarly to the CHADS implemented in the daily management of patients with atrial fibrillation, there is a need for a very simple tool to assess the prognosis of HF very quickly.
Purpose: To define a simplified bedside prognostic tool for HF.
Methods: All patients with stable HF were prospectively included in cardiology outpatient clinic. Based on the original mortality model of MAGGIC, some of its complicated and with poor additional-value variables were excluded and natriuretic peptides were added. The primary outcome was to predict one-year mortality.
Results: 182 patients were included. 65 (38%) patients died during a median follow-up of 42 months. 8 independent predictor variables were identified to built the integer score including: natriuretic peptides Nt-proBNP>5000 pg/mL, current smoker, chronic obstructive pulmonary disease, age ≥ 75 years-old, no betablockers, dyspnea graduated at III or IV of New York Heart Association scale, left ventricular ejection fraction ≤ 35%, diabetes. This score is able to predict 1-year survival, with an area under the curve of 0.79 (95%CI : 0.7-0.89).
Conclusion: The proSCANNED score appears as a new tool, easy to integrate in daily practice in HF patients. The power of this score has to be validated especially on larger population.

Selected variables for the integer score

	Rate ratio	95 % CI	Log Rate Ratio	p-value
Age ≥ 75 years	3.01	(1.61-5.63)	1.10	0.0006
NYHA III-IV	2.28	(1.12-4.65)	0.83	0.0228
LVEF ≤ 35 %	2.61	(1.31-5.17)	0.96	0.0061
Nt-proBNP >5000 pg/mL	3.22	(1.64-6.33)	1.17	0.0007
No betablockers	3.55	(1.70-7.42)	1.27	0.0007
Diabetes	3.32	(1.74-6.34)	1.20	0.0003
COPD	1.79	(0.84-3.82)	0.58	0.1340
Current smoker	1.83	(0.92-3.64)	0.61	0.0844

CI, confidence interval; COPD, chronic obstructive pulmonary disease; LVEF, left-ventricular ejection fraction; Nt-proBNP, Nt-pro brain natriuretic peptide; NYHA, New York Heart Association.

Heart rate response to exercise in heart failure patients: the prognostic role of metabolic-chronotropic relation and heart rate recovery

J Jan Benes[1]; P Hajdusek[1]; M Kotrc[1]; E Benesova[2]; J Kautzner[1]; P Jarolim[3]; V Melenovsky[1]
[1]*IKEM, Prague, Czech Republic*; [2]*First Faculty of Medicine and General Teaching Hospital, Institute for History of Medicine, Prague, Czech Republic*; [3]*Brigham and Women's Hospital, Department of Pathology and TIMI-group, Boston, United States of America*

Funding Acknowledgements: GACR 15-14200S, AZV 15-27682A, AZV 16-27496A, Institutional support IKEM: 00023001

Background: The dynamics of the sinus node response to exercise is linked to functional capacity and outcome in heart failure (HF). The goal of the work was to analyze determinants and impacts of cardio-acceleration, described by the concept of metabolic-chronotropic relation (MCR) and of cardio-deceleration, described by heart rate recovery (HRR).
Methods: A cohort of 25 healthy controls and 78 patients with advanced systolic HF and optimized medical and/or device therapy (97% receiving beta-blockers, 54% ICD) underwent maximal cardiopulmonary exercise test and were prospectively followed.
Results: HF patients had impaired exercise performance compared with controls (pVO2 15 ± 4 vs. 29 ± 7 ml.kg-1.min-1, $p < 0.0001$) and lower both MCR slope (0.54 ± 0.24 vs. 0.90 ± 0.15, $p < 0.0001$) and HRR (14.7 ± 7.9 vs. 18.3 ± 4.2 min-1, $p = 0.03$), representive MCR slope of a control subject and HF patients are in Fig. 1. In HF patients, MCR slope was inversely associated with beta-blocker dose (r=-0.24), NYHA class (r=-0.28) and HF duration (r=-0.25), whereas HRR with estimated glomerular filtration rate (eGFR, r= 0.39), age (r= -0.28) and BMI (r= -0.30, all $p < 0.05$). During a follow-up of 1269 ± 933 days, 64% patients experienced an adverse outcome (death, urgent transplantation, left ventricular assist device implantation). Those patients had higher NT-proBNP ($p = 0.02$), worse left ventricular

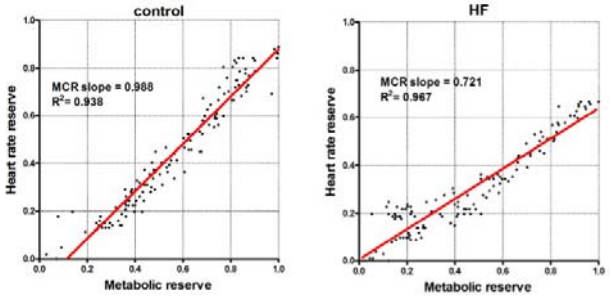
systolic function (LVEF, p = 0.03) and lower MCR slope (p = 0.02) but not HRR (p = 0.19). MCR slope (but not HRR) was a significant outcome predictor (p = 0.02 for Cox unadjusted model) even after adjustment for LVEF, serum natrium, systolic blood pressure, eGFR and NT-proBNP (p = 0.039), Table 1.

Conclusion: MCR slope is associated with different clinical variables than HRR. Compared to HRR, MCR slope provides significant prognostic information in HF patients.

Predictive power of MCR slope

	Hazard ratio	95% confidence interval	p
Model 1	0.25	0.075- 0.82	0.022
Model 2	0.19	0.036- 0.95	0.04
Model 3	0.23	0.054- 0.93	0.039

Cox proportional hazard model. Model 1. MCR slope alone; Model 2: MCR slope adjusted to left ventricle ejection fraction, serum natrium, systolic blood pressure, estimated glomerular filtration rate; Model 3: Model 2 + NT-proBNP



MCR slope in a control and HF patient

P321

A re-examination of the beta-blocker evaluation of survival trial (BEST) using composite outcomes including emergency department visits

L Shen[1]; PS Jhund[1]; UM Mogensen[2]; L Koeber[2]; JJV Mcmurray[1]
[1]University of Glasgow, the British Heart Foundation Cardiovascular Research Centre, Glasgow, United Kingdom; [2]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark

Background: We examined the influence of choice of endpoint on trial size, duration and interpretation of results in patients with heart failure enrolled in the Beta-blocker Evaluation of Survival Trial (BEST).

Methods: We used BEST to examine the effect of bucindolol on the now standard composite of cardiovascular death or heart failure hospitalization (CVD/HFH), compared with the original primary endpoint of all-cause death, expansion of this composite to include emergency department (ED) visits and the consequences for trial size and duration. We also undertook an analysis of recurrent events in addition to conventional time-to-first event analysis. The effect of treatment on death, the CVD/HFH composite, and on the expanded composite outcome (CVD/HFH/ED visit) and its components was examined using Cox regression analysis. Recurrent events were analysed using the Lin, Wei, Ying and Yang (LWYY) method.

Results: 448 placebo patients (33%) and 411 bucindolol patients (30%) died (HR 0.90; 95% CI 0.78-1.02; p = 0.11); CV deaths were 388 (29%) and 342 (25%), respectively (0.86; 0.75-1.00; p = 0.045). 730 patients (54%) experienced CVD/HFH on placebo and 624 (46%) on bucindolol (0.80; 0.72-0.89; p < 0.001). Adding ED visits increased these numbers to 768 (57%) and 668 (49%), respectively (0.81; 0.73-0.90; p < 0.001). 568 placebo patients (42%) experienced HFH compared with 476 (35%) bucindolol patients (0.78; 0.69-0.89; p < 0.001) with a total of 1333 and 1124 admissions, respectively. With the same statistical assumptions, using the composite endpoint (or expanded composite) instead of all-cause death would reduce trial size by 40% and duration of follow-up by 69%. Using the LWYY method, the rate ratio for recurrent events (CVD/HFH) was 0.83 (0.73-0.94), p = 0.003.

Conclusion: Choice of endpoint has major implications for trial size and duration, as well as interpretation of results. Use of a broader composite endpoint and inclusion of recurrent events showed a consistent benefit of bucindolol.

P322

Hospitalization for heart failure following cardiac resynchronization therapy: Impact in mortality

M Maria Trepa[1]; R Baggen Santos[1]; I Silveira[1]; B Brochado[1]; MF Oliveira[1]; C Gomes[1]; VA Dias[1]; C Roque[1]; PV Vieira[1]; H Reis[1]; S Torres[1]
[1]Hospital Center of Porto, Cardiology, Porto, Portugal

Introduction: Cardiac resynchronization therapy (CRT) in advanced heart failure (HF) is not always accompanied by improvement. Some patients fail to respond to CRT and their evolution is complicated by hospitalization for HF and decreased survival rates. We aimed to study the impact in mortality of hospitalization for HF after CRT implantation.

Methods: Single-center retrospective observational study including 303 patients who underwent cardiac resynchronization therapy (CRT). The median follow-up time was of 34.1 ± 21.1 months. Cox hazard models were adjusted for variables who proved significant (p < 0.1) in univariate regression analysis: clinical response (improvement in at least 1 NYHA class 6-12 months after CRT), echocardiographic response [improvement of > 5% in left ventricular ejection fraction (LVEF) 6-12 months after CRT], etiology (ischemic vs non-ischemic), chronic kidney disease [(CKD) defined as a creatinine clearance ≤ 60 ml/m2 determined by MDRD], diabetes and impaired right heart function after CRT. Kaplan-Meier survival curves were determined for analysis of the association between hospitalization for HF and all-cause mortality at 5 years.

Results: The study population (n = 303) had a mean age of 69 ± 10 and previous to CRT implantation, most patients (77%) were in NYHA class III. The mean LVEF was 27.5 ± 6.1% and mean QRS duration was 160 ± 24ms.

During follow-up 19% of patients (n = 57) were hospitalized for HF. In univariate analysis, they were more likely to be ischemic (p = 0.02) diabetic (p = 0.05) and have CKD (p < 0.01). Age, gender, pre-implantation LVEF, QRS duration and pattern were not statistically different between the groups. Patients who presented worst clinical and echocardiographic response to CRT were at increased risk for hospitalization (p < 0.01 in both cases), as were those with impaired right heart function after CRT (p = 0.02). In multivariate analysis absence of echocardiographic response (OR 4.58; p = 0.07) and CKD (OR 4.09; p = 0.01) proved to be independent predictors of HF hospitalization.

The primary outcome of all-cause mortality at 5 years occurred in 60% of patients with HF hospitalizations and in 22% of the control group (log rank p < 0.01). After adjusting for confounding factors by cox regression HF hospitalizations was an independent predictor of mortality (HR 5.9; 95% CI 1.6- 21.2)

Conclusions: Hospitalization for HF after CRT implantation is independently associated with mortality. Absence of echocardiographic response and CKD identified a subgroup of CRT patients who are at significantly increased risk for adverse outcomes.

P323

Long-term prognostic information of BNP levels in patients with stable systolic heart failure

T Mercier[1]; E Hebbar[1]; P Pigny[2]; M Fertin[1]; A Duva Pentiah[1]; N Lamblin[1]; P De Groote[1]
[1]Lille University Hospital, Institut Coeur-Poumon, Lille, France; [2]Lille University Hospital, Biological Department, Lille, France

BNP is a powerful prognostic parameter in pts with systolic heart failure (SHF). Few studies have analyzed the long-term prognostic power of a single determination of BNP.

Methods: BNP was measured with the Shionoria BNP RI kit. Survival analyses were performed in all the pts and in subgroups with the exclusion of deceased pts during the first yrs of follow-up (FU).

Results: We included 459 ambulatory pts: 56 ± 12 yrs, NYHA class III: 25%, ischemic:46%; LVEF:33 ± 12%, left atrial diameter:44.6 ± 8 mm, peak VO2:15.4 ± 5.1 ml/min/kg, (59.3 ± 17.3 %). BNP: 110 [41-322] pg/ml. During a FU of 7.78 yrs [0.26 - 14], there were 311 deaths (68%) of whom 245 (53%) were cardiac related, 5 pts were lost to FU, 45 had cardiac transplantation. In univariate analyses, BNP was a predictor of survival even after the exclusion of deceased pts during the 7 first years of FU. In Cox analyses, BNP was an independent predictor of survival during the 3 first yrs of FU (Table). In contrast, peak VO2 remained an independent predictor of long-term survival (at least 7 yrs).

In conclusion, in stable pts with SHF, despite the variability of its measurement, BNP was an independent predictor of survival 3 years after its determination.

Independent predictors of survival		
Variables	HR	p
All pts

Prevalence and prognostic impact of co-morbidities in heart failure: data from the Slovenian national heart failure registry

M Pusnik Vrckovnik[1]; B Jug[2]; A Marolt[1]; D Kosuta[3]; LM Hodoscek[4]; M Mulej[5]; T Ravnikar[3]; CS Pusnik[1]; M Valentincic[6]; T Vizintin Cuderman[2]; M Lainscak[7]
[1]General Hospital Slovenj Gradec, Slovenj Gradec, Slovenia; *[2]University Medical Centre of Ljubljana, Department of vascular diseases, Ljubljana, Slovenia*; *[3]Izola General Hospital, Izola, Slovenia*; *[4]General Hospital Murska Sobota, Murska Sobota, Slovenia*; *[5]General Hospital Jesenice, Jesenice, Slovenia*; *[6]General Hospital Nova Gorica, Nova Gorica, Slovenia*; *[7]General Hopsital Celje, Celje, Slovenia*

Background: Heart failure (HF) is a condition of elderly and polymorbid patients thus management is challenging.
Purpose: To prospectively assess the prevalence and prognostic impact of co-morbidities in a nation-wide population of patients with HF.
Methods: Data from the prospective registry of heart failure (started in 2014 by the national cardiology society and including a nation-wide network of general and university hospitals) were analysed. Patients with HF enrolled by June 2015 were included, and HF-related events (HF-related mortality, hospitalisations and emergency department visits) were recorded. Anaemia, atrial fibrillation (AF), depression, diabetes mellitus, coronary artery disease (CAD), chronic kidney disease (CKD) and chronic pulmonary obstructive disease (COPD) was assessed, and their respective prognostic impact was analysed using Cox multivariable model.
Results: A total of 693 patients were included (54% female, median age 78 years, interquartile range 71-83) and 46% had HF with preserved ejection fraction. CKD was the most prevalent co-morbidity (42%), followed by diabetes mellitus (35%), CAD (31%), anaemia (23%), depression (21%), and COPD (11%). During a median follow-up of 180 (interquartile range 104-264) days, 129 (19%) patients experienced a HF-related event. On multivariate analysis, anaemia (adjusted odds ratio [OR] 2.30; 95% confidence interval [CI] 1.27-4.12, p = 0.006), COPD (OR 1.95, 95% CI 1.22-3.13, p = 0.005) and CAD (OR 1.81, 95% CI 1.25-2.63) independently predicted HF-related events, while AFib and CKD showed a significant trend towards predicting unfavourable prognosis (OR 1,44, 95% CI 0.997-2.08, p = 0.052 and OR 1,45, 95% CI 0.995-2.12, p = 0.053, respectively).
Conclusion: In real-life clinical practice of unselected HF patients, co-morbidities are highly prevalent and confer unfavourable prognosis.

P325

Patient phenotypes and outcome in heart failure: a national hospitalization database cluster analysis

D Daniel Omersa[1]; J Farkas[2]; I Erzen[1]; M Lainscak[2]
[1]National Institute of Public Health, Ljubljana, Slovenia; *[2]General Hospital Murska Sobota, Department of Research and Education, Murska Sobota, Slovenia*

Introduction: Patient phenotype (e.g. sex, age, comorbidities) in heart failure (HF) varies substantially and simple descriptive analysis is often insufficient to identify patients at risk of adverse outcome.
Purpose: To identify phenotypes associated with higher risk of all cause mortality following first HF hospitalization.
Methods: We recorded all first HF hospitalizations from the Slovenian national hospital discharge registry and linked it with national death registry. Patient general characteristics and comorbidities were retrieved and all patients were followed until death or the end of year 2013. Hierarchical cluster analysis was performed using Gower's distance dissimilarity matrix that included age, sex and comorbidities. Differences between clusters were analysed using ANOVA, chi square, and Kaplan-Maier with log rank test. All statistical analyses were conducted in R 3.2.2 (R Core Development team).
Results: We identified 8248 patients (45.5% men, mean age 75.4 ± 11.1 years) that were followed for 23808 patient-years. Using the dissimilarity matrix, three clusters of patients were identified: men (cluster 1, N = 2736), women (cluster 2, N = 2693), and men and women with cancer, chronic kidney disease (CKD), and chronic obstructive pulmonary disease (COPD) (cluster 3, N = 2819). Besides sex, cluster 1 and 2 differed mostly in age (71.6 vs. 78.0 years) and prevalence of diabetes mellitus (19.6% vs. 31.2%) – P < 0.0001 for both. Cluster 3, compared to cluster 1 and 2, had higher number of comorbidities (5.5 vs 4.5 and 4.7), higher prevalence of cancer (19.2% vs. 4.3% and 0.8%), CKD (15.7% vs. 8.6% and 10.1%), and COPD (14.2% vs. 4.1% and 3.1%) - P < 0.0001 for all. During follow-up, 3727 (45.2%) deaths were recorded. Cluster 3 had the lowest survival during follow-up (P < 0.0001) - figure.
Conclusion: We identified three distinctive phenotypes and a specific combination of non-cardiovascular comorbidity (cancer, CKD and COPD), irrespective of sex, was associated with poorest survival.

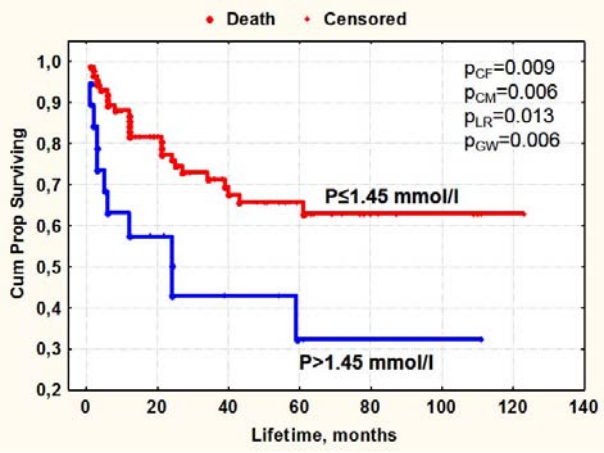
Hyperphosphatemia is a predictor of poor prognosis in patients with chronic heart failure

EV Resnik[1]; GE Gendlin[1]; IG Nikitin[1]
[1]Russian National Research Medical University, Internal Disease 2 Department, Moscow, Russian Federation

Purpose: Recent studies show that elevated serum phosphorus is associated with risk of heart failure in general population and mortality in patients with and without chronic kidney disease. Our aim was to study clinical and prognostic value of hyperphosphatemia in chronic heart failure (CHF) patients.
Methods: We evaluated serum inorganic phosphorus (P), intact parathyroid hormone (PTH), 25-OH-vitamin D, estimated glomerular filtration rate (eGFR, CKD-EPI), urinary albumin excretion (UAE), bone mineral density (dual-energy X-ray absorptiometry), Fracture Risk Assessment Tool (FRAX model) in prospective study of 212 CHF I-IV NYHA class patients with left ventricular ejection fraction (LV EF) < 45% without primary renal, endocrine, oncological and bone diseases on contemporary optimal treatment [median (interquartile range) of age – 64.0 (56.0;70.0) years; LV EF – 30.5 (25.3;36.9) %, eGFR – 61.3 (48.7;77.7) ml/min/1.73m2, UAE – 47.2 (33.0-70.0) mg/24h]. We observed the patients over 10 years. The follow-up time for death or the end of the study was 26 (12; 60) months. Survival was analysed by Kaplan-Meier method, Cox's F (CF), Cox-Mantel (CM), Log-Rank (LR) and Gehan's Wilcoxon (GW) Tests.

Results: Serum phosphorus was 1,23 (1,08; 1,41) mmol/l in CHF patients. Hyperphosphatemia (P>1.45 mmol/l) was in 23.03%. Hyperphosphatemic patients had more severe NYHA class, higher blood pressure in anamnesis, higher urinary albumin excretion, lower eGFR ($p < 0.05$). Osteoporosis (-score = or < -2.5SD) was found in 32.4(95%CI 14.7-51.9) %, osteopenia (T scores between -1.0 and -2.5SD) – in 40.5 (95%CI 22.0-59.0) % of CHF patients. PTH was 77.6 (38.2;136.0) pg/ml. 25–vitamin D was 47.3 (38.8;54.6) nmol/l. 67.8% of CHF patients died during follow-up. Survival of patients with hyperphosphatemia was significantly lower than in patients without it (Picture). In Cox regression model, it was found that serum phosphorus was one of the strongest predictors of survival and was comparable with the value of LV EF and eGFR (Table). Also there was a trend to increase the 10-year risk of any fracture in FRAX model in patients with hyperphosphatemia.
Conclusions: Hyperphosphatemia is a predictor of poor prognosis in patients with chronic heart failure. Further work is required to determine whether lowering serum phosphate levels may improve the prognosis in CHF.

Cox's regression model for CHF, =0.007			
Parameter	β	Standart error	
LV EF, %	-0.04	0.019	0.030
Serum phosphorus,mmol/l	1.02	0.54	0.046
eGFRCKD-EPI, ml/min/1,73m2	-0.016	0.009	0.050



Hyperphosphatemia and surviving in CHF

P327
Prevalence and determinant of cognitive impairment in elderly patients with heart failure - A pilot study in a geriatric hospital

S Shutaro Futami[1]; J Ishikawa[1]; C Jubishi[1]; A Suzuki[1]; A Morozumi[1]; Y Saito[1]; K Nemoto[1]; T Okawa[1]; J Tanaka[1]; T Ishiyama[1]; Y Tsuboko[1]; K Takeda[1]; H Fujimoto[1]; K Harada[1]
[1]*Tokyo Metropolitan Geriatric Hospital, Cardiology, Tokyo, Japan*

Backgrounds: In elderly patients who admitted to a hospital due to heart failure often have cognitive impairment; however, mechanisms causing cognitive impairment are unclear.
Methods: We enrolled 43 patients who admitted to a geriatric hospital because of heart failure. We excluded patients who had pre-diagnosed dementia and those who were unable to walk. We evaluated echocardiography, blood test, Mini Mental State Examination (MMSE) score and body composition using bioelectrical impedance analysis (Inbody S10) just before discharge.
Results: Mean age was 85.1 ± 8.0 (range 60-99) years (male 44.2 %). The ejection fraction was 46.9 ± 16.2 % and stroke volume was 36.5 ± 12.4 ml; median B-type natriuretic peptide was 269.1 pg/dl. The Mini Mental State Examination (MMSE) score was 20.5 ± 5.4 and there were 66.7 % of patients with cognitive impairment (MMSE < 23). MMSE score was significantly related to Age (r=-0.344, P=0.032), Regular alcohol drinking habit (r=0.437, P=0.007), uric acid (r=0.413, P=0.010), and extracelluar water per total body water (ECW/TBW) ratio (r=-0.437, P=0.007). In stepwise regression analysis that included these covariates, MMSE score was significantly associated to ECW/TBW ratio (beta=0.443, P=0.009) (i.e. body water distribution). However, when echocardiographic parameters of end-diastolic left ventricular volume (EDV) (r=0.327, P=0.048), left atrial volume index (LAVI) (r=-0.411, P=0.012), and A wave of transmitral flow (r=-0.625, P=0.001)) were included to the model, MMSE score was related to A wave of transmitral flow (P=0.001) and LAVI (P=0.015) (measures of diastolic function).
Conclusion: Cognitive function in elderly patients with heart failure might be affected by distribution of body water and cardiac diastolic function.

P328
Optimizing atrial fibrillation management in primary care by utilizing an electronic medical record dashboard for population health management

JH Michael Qiu[1]; D Ngui[2]; F Lo[3]

Funding Acknowledgements: Thanks to Pfizer for their unrestricted educational grant

Background: Systematically applying evidence based guidelines for Atrial Fibrillation (A. Fib) management in family practice can be challenging. Some physicians may benefit from automated and sustainable methods to improve patient care and outcomes leveraging the use of EMRs.
Purpose: By piloting an A. fib Electronic Medical Record (EMR) dashboard in a multi-physician family practice, our
objectives were to determine the EMR dashboard's ability to identify care gaps in Atrial Fibrillation. We also want to assess our ability to address these care gaps with 1:1 physician reviews and team based pharmacist medication reviews with patients within the practice.
Methods: We reviewed the medical literature regarding ideal design characteristics and review articles (needs reference) on utilization of EMR dashboards in health care. Also, we reviewed relevant A. fib clinical guidelines (needs reference) and developed a prototype A. Fib tool through an interactive process with feedback from physicians.
From a period of x to y, we used this dashboard to review one physicians patient roster. We recalled patients with care gaps identified by the EMR dashboard for management reassessment by a physician or alternatively, eligible patients were also seen by clinical pharmacists to review their medications. The results were tracked in real-time by the dashboard and allowed us to generate a report at the end of our intervention.
Results: A review of the dashboard for one physician resulted in identifying 15 patients who were recalled for review and we achieved the following tasks divided up into themes.
1. Patient panel/roster clean up: correctly revised atrial fibrillation in 5 patients. We had an overall increase in clinic patients identified with A. fib through improved ability to review cases.
2. Improved identification of investigation and lab monitoring care gaps: the number of A. fib patients without eGFR in 12 months decreased and the number of A. fib patients without ECHO on file decreased.
3. Improved identification of medication care gaps: the number of A. fib patients without anticoagulation agent decreased.
4. Increased referrals for shared care with team members to improve patient education
5. Improved ability to generate meaningful data for clinical audit and monitoring effect of interventions:
Conclusion: Our A. Fib EMR Dashboard allowed us to manage our A. fib patients more systematically, efficiently and effectively. This tool improved our recalls and ability to generate physician alerts increase referrals to clinic team members. The concept of utilizing the A. fib dashboard is applicable to any EMR and is a needed paradigm shift to promote the use of technology to target care gaps. This holds promise to improve the management of A. Fib in primary care, but requires further investigation.

P329
Demographic, clinical, and biological characteristics of outpatient heart failure patients in oman

M Matlooba Alzadjali[1]
[1]*Royal Hospital, Cardiology , Muscat, Oman*

Introduction: The clinical profile, and outcome of HF in western population is well demonstrated, little systematic data exist regarding the clinical profile and management of HF patients in Oman. Hence, the heart failure registry established after development of heart failure clinic to provide systematic report of the characteristics of HF patients.

Aim: To describe the demographic, clinical, and biological characteristics of outpatient heart failure patient in Oman.
Method: Outpatient heart failure registry is a prospective registry aimed to describe the clinical characteristics, management, and outcomes of consecutive patients who attended in heart failure clinic in National Heart Center in Oman since Jan 2016 until October 2016.
Results: A total of 275 patients, with mean age 57 years, were enrolled. Forty one percent females and 59% were males. With average of LVSEF 32% and pulse rate 72%. It had been noted that the average of QRSD duration among these patients were approximately 106 MS. Furthermore, serum creatinine was increased among those with LVS EF < 15-30% mean 164 mmol/l, most of the patients were on evidence based medications for heart failure treatment.
Conclusion: From this registry it's very obvious that heart failure it is burden in Oman, data on the clinical profile, management, and outcome of HF in Oman is scarce, accordingly it is highly important to evaluate the magnitude of the problem and to guide management and future plans.

P330

Probability of cardiovascular events in chronic heart failure patients with preserved and mid-range ejection fraction depending on different phenotypes of peripheral arterial system

AA Anastasia Shchendrygina[1]; YN Belenkov[1]; EV Privalova[1]; EA Zheleznykh[1]; YA Danilogorskaya[1]; VY Kaplunova[1]; MV Kozhevnikona[1]; GA Shakar'iants[1]; IS Chekneva[1]; AO Yusupova[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Purpose: to describe phenotypes of peripheral arterial system in heart failure (HF) patients with preserved and mid-range ejection fraction (EF) and assess their prognostic significance.
Methods: We conducted a prospective cohort study of 50 patients (pts.) with heart failure and preserved EF (HFpEF) (n = 25;male:16; mean age:65 (58;68)) or mid-range ejection fraction (HFmrEF) (n = 25;male:19; mean age:67 (61;73)) NYHA class II-III. 30 healthy controls (male:17; mean age: 57 (51;63)) were enrolled. We performed transthorocal echocardiography to estimate LVEF, E/A,Left Ventricle Mass Index (LVMI), Left Atrial Volume Index (LAVI). To determine arterial damage in different level, digital photoplethysmography and nailfold computer videocapillaroscopy during vinous occlusion were performed. Endothelial function of small (occlusion index, IO) and large vessels (phase shear, PS, ms) were estimated. Vascular remodeling of aorta (stiffness index, SI,m/s) and skin capillaries (capillary densities after vines occlusion, CDvo, cap/mm2) were determine. Followed cardiovascular events was monitoring once a year during 5 years. The study complied with the Declaration of the Helsinki regarding investigation in humans.
Results: Endothelial dysfunction and remodeling of large and small vessels were found in HF pts. IO,PS,SI was significantly higher than in controls ($p < 0.05$). The measures of remodeling of large and small vessels did not correlate (SI, CDvo (rs= - 0,15, p >0,05) as well as PS and IO (rs= -0,18, p>0,05). Individual arterial phenotype was determined by assessment of macro- and microcirculation damage associations. It was described 4 phenotypes: Type 1- functional changes of large or small vessels; Type 2-structural and functional changes of large vessels; Type 3- structural and functional changes of small vessels, Type 4 -disturbance of both small and large vessels.We found that in CHF group was 24 % pts. (n = 12) with Type1. Type2 had 8 % (n = 4). Type 3 had 2% (n = 1) and 62 % (n = 31) had Type4. There was no significant difference in types between HFpEF and HFmrEF groups. In controls only 13% (n = 4) had no changes. Type 1 had 53 % (n = 16). Type 2 was found in 7% (n = 2). Type 3 had 17% (n = 5). Type 4 was determined in 10 % (n = 3) of participants. Type 4 HF patients have significantly higher BMI, LVMI in comparison with those who has Types 1-3 (LVMI Type4 - 101 (85;125) vs. LVMI Type1-3 - 132 (106;158), p = 0,001).Cardiovascular events had 28 patients. Kaplan-Meier analysis demonstrated a significantly higher probability of cardiovascular events in HF pts. with Type 4 than those with Types 1-3 (mean follow-up: 838 days; log-rank test: $p < 0.02$).
Conclusion: It was described 4 phenotypes of arterial damage in HF pts. All the types was found in similar proportion in HFpEF and HFmrEF groups. Those who had disturbance of both small and large vessels was obese and had severe LV remodeling. Moreover, Type 4 correlated with future cardiovascular events in HF patients.

P331

Influence and management of diabetes mellitus in patients with heart failure with reduced ejection fraction followed in a non-tertiary hospital heart failure unit.

V Martinez Mateo[1]; L Cejudo Del Campo[1]; MJ Fernandez Anguita[1]; E Martin Barrios[1]; AJ Paule Sanchez[1]
[1]Hospital Mancha Centro, Cardiology, Alcázar De San Juan, Ciudad Real, Spain, Spain

Background/Introduction: Cardiovascular safety of oral antidiabetic drugs in patients with diabetes mellitus (DM) and heart failure (HF) with reduced left ventricular systolic function (LVSF) has not been established yet.
Purpose/Methods: We analyzed characteristics and treatment patterns in diabetic patients with symptomatic HF followed prospectively in the Heart Failure Unit (HFU) of a non-tertiary hospital.
Results: Since the begin of Unit in 2010 until 2016, 367 patients have been followed (median 44 months, 76.1% men, mean age 69.7 +/- 12.5 years [median 73]). The majority of patients presented severe LV systolic dysfunction (67.6%), functional class II (50.8%) and ischemic origin of cardiomyopathy (47.5%). Rate of treatment with beta blockers, angiotensin converting enzyme inhibitors/angiotensin receptor blockers and aldosterone antagonists were 86.1%, 95.8% and 62.9% respectively without significant differences between diabetic or no diabetic patients. The prevalence of DM was 32.9%, mainly type 2 (96%). Oral antidiabetics alone were the main scheme of hypoglycemic treatment (61.5%), being metformin the main drug used (73.3%) both in monotherapy and in combination, followed of dipeptidyl peptidase IV inhibitors (40.0%). Treatment with insulin was utilized in 38.3% diabetic patients, mainly with bolus-basal regimen (52.7%). The percentage of well-controlled patients was 48.1% (according with therapeutics goals established in guidelines) with a rate of micro and macrovascular complications of 51.6% and 67.2% respectively. Regarding the prognosis, the overall accumulated survival at 65 months was 62.6%. Diabetic patients did not present a higher mortality although the subgroup of diabetic patients with worse metabolic control, those treated with insulin and those with a higher renal failure rate did present a higher mortality compared to the rest of the patients. The use of antidiabetic drugs was not associated with a worse prognosis or a higher incidence of decompensation with any of the pharmacological groups.
Conclusion: Incidence and evolution of DM in patients with symptomatic HF due to LV systolic dysfunction followed in a HFU of a non-tertiary hospital is similar to that described by other groups. Mortality was higher in those patients with worse metabolic control and impaired renal function. The use of different oral antiadiabetic drugs were safe and not associated to worse prognosis or a higher rate of decompensation.

On behalf of: FRESH group

New ESC guidelines pointed out the need to specify what are heart failure (HF) patients with mid-range left ventricular ejection fraction (mrLVEF) – defined by LVEF 40 to 49%- as compared to patients with preserved LVEF (pLVEF) and reduced LVEF (rLVEF). By using French Survey on Heart Failure (FRESH), we aim to compare characteristics of these 3 subgroups in chronic HF.
Methods: FRESH is an on-going multicenter survey collecting exhaustive data in both acute and chronic HF (NCT01956539). Comparisons were performed using chi^2 or Fisher test for categorial variables and ANOVA or non-parametric Kruskal Wallis test for continuous variables. Multinomial logistic regression was performed.
Results: Among 1093 chronic HF patients, 56% had rLVEF, 22% had mrLEVF and 22% had pLVEF.
There were significant differences across LVEF subgroups in age as well as gender, underlying cardiac disease, atrial fibrillation, comorbidities, BMI, blood pressure, NYHA class, haemoglobin, natremia, BUN, creatininemia, natriuretic peptides and use of medications. The table shows significant results of the multivariate analysis.
Conclusion: Chronic HF patients with mrLVEF exhibit some significant differences with both HF-rEF and HF-pEF regarding clinical and biological characteristics, which deserves further investigations.

	Odd ratio	95%CI	p

Iron and infection in patients admitted for heart failure in an internal medicine ward

J Azevedo Duarte[1]; J Almeida[1]; R Ribeiro[1]; C Henriques[1]; J Delgado Alves[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Internal Medicine 4, Amadora, Portugal*

Background: Iron deficiency (ID) is an important comorbidity in patients with chronic heart failure (CHF). Either absolute or functional, ID is an independent predictor of outcomes, even in the absence of anemia. Functional iron deficiency (FID) is defined as an inadequate iron supply when iron stores are replenished and it is present whenever the ferritin level is between 100-299mg/L and transferrin saturation is lower than 20%. Iron supplementation in patients with FID improves clinical symptoms and reduces the risk of hospitalization due to decompensated CHF. Several studies have shown that iron deficiency is associated with an impaired humoral and cell mediated immunity, thereby contributing to an increased risk of infections. Despite this, iron deficiency is still overlooked in daily clinical practice and guidelines are frequently not followed in the "real world".
Methods: Retrospective analysis of patients with heart failure admitted to an Internal Medicine ward in the period of one year (August 2015 - August 2016).
Purpose: To determine if there is any relationship between iron deficiency, iron supplementation and infection susceptibility in patients with CHF.
Results: 225 patients were included in the analysis. 201 (89%) were admitted due to decompensated cardiac insufficiency, and of these 133 (59%) had iron deficiency (ID), which in turn was functional in 43% (n = 57) of cases and absolute in 57% (n = 76). In patients with FID, the average ferritin value was 176,7mg/L, with an average transferrin saturation of 14,3%; iron therapy was administered in only 33% (n = 19) of cases. Time of admission for both cohorts was 16,2 days in patients with FID and 14,9 days in the ones with absolute ID; there was no significant difference between the two groups.
Regarding the incidence of infections, 71% (n = 49) of the patients with FID had at least one infection, whereas only 67% (n = 62) of the patients without FID were infected. Respiratory infections were the most common (46%), followed by urinary tract infections (28%); in 20% of patients more than one infection occurred during hospitalization.
Patients with decompensated HF had a significantly higher prevalence of FID (n = 55, 27%) in comparison with patients without decompensated HF (n = 2, 8%). However, there was no significant relationship between overall iron deficiency and the incidence of infection, X2 (2, N=225) = 4,313, p = 0,116. Additionally, in patients with FID there was no relationship between those who did iron therapy and the occurrence of infection, p = 0,401, two-tailed Fisher's exact test, Cramer's V=0,111.
Conclusion: Patients with CHF have a high incidence of functional iron deficiency. Whether the infection susceptibility is mainly due to the CHF itself or to the FID is difficult to differentiate, as FID cannot be seen as an independent factor from CHF. Iron deficiency might not be a relevant factor for infections in admitted patients due to the short period of time that is considered.

Funding Acknowledgements: The work was supported by the Research Council of Lithuania, grant Nr. MIP-049/2015 and approved by Lithuanian Bioethics Committee, Nr. L-15-01.

Introduction: Cardiac arrhythmias are important co-morbidities in heart failure (HF) patients associated with worse prognosis. Given the new classification of HF presented in 2016 ESC guidelines, the prevalence of arrhythmias in particular HF types requires re-evaluation. Aim. To evaluate the prevalence of rhythm and conduction disorders in three different HF types in the population of acutely decompensated chronic heart failure (ADHF).
Methods: Prospective observational two-centre cohort study enrolled consecutive patients admitted to the emergency department with acute dyspnea. Patients with final ADHF diagnosis and available left ventricular ejection fraction (LVEF) were included in the analysis (n = 329, median of age 70 [26;96] years). Presence of atrial fibrillation (AF), left and right bundle branch block (LBBB and RBBB), combined intraventricular conduction defect and AV block were collected at admission electrocardiogram. Analysis was done by SPSS v20 statistical package using Chi Square test. The significance level was $p < 0.05$. Results. Atrial fibrillation was found in 167 (50.8%) participants, remaining 162 (49.2%) patients were in sinus rhythm, 35 patients (10.6%) had pacemakers. Intaventricular conduction disorders were detected in 76 (23.1%) patients: LBBB, RBBB and combined defects in 54 (16.4%), 11 (3.4%) and 11 (3.4%) patients, respectively. AV block was detected in 15 (4.5%) patients. Combination of cardiac rhythm and conduction abnormalities was found in 37 (11.2%) of patients. The distribution of rhythm and conduction disorders in HFrEF, HFmrEF and HFpEF are presented in the Table1. The highest prevalence of AF (54.9%) was found in HFmrEF group (n = 51), however, without significant difference. Intraventricular conduction disorders and combined abnormalities were significantly less frequent in HFmrEF group compared to HFrEF, and though not significantly different, were observed more frequently in HFmrEF compared to HFpEF. Conclusions. Even half of the patients with acutely decompensated chronic heart failure present with atrial fibrillation, which is found to be similarly frequent in different HF types. Heart failure with mid range ejection fraction demonstrates different profile in terms of rhythm and conduction disorders compared to other two types of HF.

Table1

Cardiac rhythm and conduction disorders	HFrEF(< 40%) N=156 (47.4%)	HFmrEF (40-49%) N=51 (15.5%)	HFpEF (≥50%) N=122 (37.1%)
Atrial fibrillation	80 (51.3%)	28 (54.9%)	59 (48.4%)
Intraventricular conduction abnormalities	50 (32.3%)	9 (17.6%)*	17 (13.9%)
Combined abnormalities	24 (30.4%)	4 (15.3%)*	9 (14.3%)

*p < 0.05 HFmrEF vs HFrEF

P335

The relationship between the buckberg index and functional capacity in stable chronic heart failure patients.

T Mannion[1]; S Fall[1]; M Carey[1]; L Devaney[1]; A Jago[1]; S Fay[1]; R Pharithi[1]; V Maher[1]
[1]*Adelaide & Meath Hospital, Dublin, Ireland*

Background: The Buckberg index, a diastolic to systolic pressure-time integral ratio, is a resting measure of myocardial oxygen supply and demand. It compares the delivery of oxygen to the heart muscle during diastole to the cardiac workload during systole. A suboptimal Buckberg index creates a supply–demand imbalance which may limit cardiac performance and functional capacity in patients with chronic stable heart failure.
Purpose: This study was conducted to assess the association between Buckberg index and functional capacity in chronic stable HF patients.
Methods: 156 clinically stable HF patients, whose weight, condition and medications had not changed in the previous 3 months, participated. Buckberg Index was completed using SphygmoCor system. Systolic-to-diastolic pressure shifts were assessed by the systolic and diastolic pressure-time integrals and expressed as a percentage. Patients were then categorised as follows; Group 1= Buckberg index

Table 1. P337

Abbreviations: 6MWD, 6-minute walk distance; EF, ejection fraction; CO, cardiac output; CI, cardiac index; SV, systolic volume; ICON, myocardial contractility; TFC, thoracic fluid content; k-thoracic impedance

≤ 150% Group 2= Buckberg index 151 - 200% Group 3= Buckberg index ≥ 201% Functional capacity was evaluated via 6 Minute Walk testing, NYHA Class, 3 day accelerometer measuring daily step count (FitBit) and Kansas City Cardiomyopathy Questionnaire (KCCQ).
Results: Univariate analysis demonstrated statistically significant correlations between Buckberg index and 6MWT distance (Pearsons r=0.23, p = 0.004), NYHA Class (r= - 0.18, p = 0.022), and the KCCQ, but not with daily step count (Fitbit). ANOVA revealed statistically significant differences among patients grouped (1-3) by Buckberg indexes in relation to 6MWT ((F (2, 155)= 8.737, p = 0.001)), NYHA Class ((F (2, 156)= 3.407, p = 0.036)), KCCQ Overall summary score ((F (2, 149)=7.516, p = 0.001) and KCCQ Clinical Summary Score ((F (2,146)=11.308, p = 0.001))
Conclusion: Buckberg index is associated with functional capacity in chronic stable HF patients. We recommend that HF patients are best managed if the Buckberg ratio is driven as high as possible.

Understanding heart failure with middle range ejection fraction: results from a Colombian population

C I Clara Ines Saldarriaga[1]; GA Ortega Ramirez[2]; GE Ortega Ramirez[3]; C Gallego[1]; LA Fajardo[1]; AM Agudelo[1]; E Canas[2]
[1]Cardiovascular Clinic Santa Maria, Universityof Antioquia cardiology department, Medellin, Colombia; *[2]Universidad Pontificia Bolivariana, Cardiology, medellin, Colombia*; *[3]Industrial University of Santander, medicine, Bucaramanga, Colombia*

Funding Acknowledgements: this study was funding by universidad Pontificia bolivariana and clinica CardioVID

Middle range ejection fraction (HFmrEF) is a group of patients with different features and prognosis. There is no data about this population in Latin America, despite epidemiology that differs from the rest of the world.
Objective: To identify the clinical characteristics, treatment and prognosis of the HFmrEF patients in a Colombian heart failure (HF) program.
Methods: observational, retrospective study.
Results: In a population of 994 patients from a HF program, 147 patients had HFmrEF. The mean age was 67.4 +/- 13.5 years, and 44.2% were women. The mean EF was 42.8% +/- 2.7 %. Ischemic heart disease was the cause of HF (46.3%), followed by idiopathic (22.4%), and valvular disease (10.2%). The comorbidities are described in table 1. The functional class was as follows: NYHA I: 42.9%, NYHA II 36.7%, NYHA III 17%, and NYHA IV 3.4%. The total mortality was 4.8%, and cardiovascular death occurred in 85.4% of the cases. 32.7% were hospitalized at least once per year, 10.2% twice, and 3.4% three or more times. The treatment prescribed was ACE inhibitors in 50.3%, ARB in 44.9%, beta blockers 95.2%, MRA 57.1% and diuretics in 70.7%.
Conclusion: in our heart failure program, HFmrEF represents a group of mostly male patients with ischemic cardiomyopathy with a majority in NYHA I – II. They have many comorbidities, plus a rate of hospitalizations and mortality, that requires a close follow up.

TABLE 1: comorbidities

Comorbidities	Percentage
Atrial fibrillation	30.6%
Coronary disease	51.7%
Hypertension	73.5%
Diabetes	27.9%
Chronic kidney disease	27.2%

comorbidities

Non-invasive cardiac output monitoring after cardiopulmonary exercise testing in patients with heart failure

E Emilia Sawicka[1]; M Marcinkiewicz-Siemion[1]; K Ptaszynska- Kopczynska[1]; M Lapinska[2]; M Szpakowicz[2]; J Skawronska[2]; W J Musial[1]; K A Kaminski[3]
[1]Medical University of Bialystok, Department of Cardiology, Bialystok, Poland; *[2]Medical University of Bialystok, Department of Community Medicine and Civilization Disease Prevention, Bialystok, Poland*; *[3]Medical University of Bialystok, Department of Cardiology, Department of Community Medicine and Civilization Disease Prevention, Bialystok, Poland*

Funding Acknowledgements: The study was found by statutory grants and funds from National Scientific Leading Center of Medical University of Bialystok.

Introduction: Heart failure with reduced ejection fraction (HF-REF) is one of the most severe outcomes of cardiovascular diseases. Reliable non-invasive evaluation of hemodynamic parameters in rest and exercise may improve patient assessment and care. Some valuable hemodynamic variables may be obtained by continuous non-invasive cardiac output monitor (ICON) that relies on impedance cardiography. However, this metod was not tested after exercise.
Purpose: To evaluate the hemodynamic parameters obtained by ICON in HF-REF patients before and after exercise in relation to the measurements obtained in cardiopulmonary exercise testing (CPET).
Methods: The study included 24 stable, optimally treated patients (median 60.5 IQR 54.5-64 years, 4 females) with HF-REF in NYHA II, who were assessed with ICON before and after CPET. The latter hemodynamic measurement was performed within 90 seconds after the end of the exercise. Because of muscular movements during physical exercise it was not possible to make measurements during the CPET. The control group included 20 patients without history of HF-REF (median 62 IQR 57.5–65.5 years, 4 females).
Results: The study did not reveal significant differences between hemodynamic parameters measured using ICON at rest between HF-REF and controls. After CPET, however, HF-REF patients were characterized by lower cardiac output (CO) (p = 0.037) and systolic volume (SV) (p = 0.012) than controls, despite significant increase in CO (p < 0.001), SV (p = 0.006), myocardial contractility (ICON) (p = 0.001) and decrease in thoracic fluid content (TFC) (p = 0.008) after CPET in comparison to rest (Table 1).
Although CO after exercise correlated with 6-minute walk distance (R=0.5,p = 0.017), it was not significantly associated with any CPET variables. Only TFC correlated with VO2 ml/kg/min at anaerobic treshold (R=-0.42, p = 0.043).
Conclusions: Hemodynamic paramaters obtained in impedance cardiography reflected changes after physical excercise, however they did not present association with the well-established parameters in CPET. The usefulness of ICON monitor after exercise, remains to be further investigated.

P338

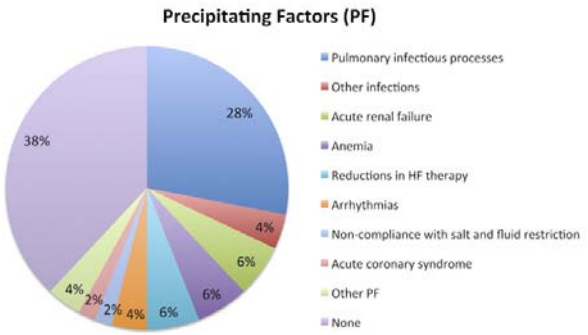
Change in the precipitating factors of heart failure admission in patients included in a heart failure unit

Z Blazquez Bermejo[1]; D Iglesias Del Valle[1]; E Garcia[1]; J De Juan[1]; E De La Cruz[1]; R Cadenas[1]; V Martinez[1]; C Casanova[1]; A Garcia[1]; A Martin[1]; E Prieto[1]; R Cano[1]; I Plaza[1]
[1]University Hospital Infanta Sofia, Cardiology, Madrid, Spain

Background: Avoidable precipitating factors (PF), such as non-compliance with pharmacologic therapy for heart failure (HF) or with salt and fluid restriction, have been identified in 32-54% of HF admissions. Moreover, multidisciplinary programs that focus on enhancing patient self-care activities reduce HF hospitalizations.
Purpose: The aim of this study was to review the different PF of decompensated HF admissions in patients that are closely monitored in a HF unit.
Methods: 112 patients with HF diagnosis were prospectively included in the HF unit at our institution between May 2014 and December 2016. Self-care education and a telephone contact were provided. Patients were systematically followed-up in the

HF outpatient clinic. All changes in clinical status, admissions and deaths were documented.
Results: Baseline characteristics and HF therapy are summarized in the table. A total of 50 episodes of decompensated HF in 25 different patients were attended during a median follow-up of 13 ± 8.4 months. 70% required hospitalization and 30% were discharged from the emergency department. The PF of the episodes are shown in the figure. Pulmonary infectious process was the most common known PF (28%) and only 8% of the 50 episodes were considered avoidable.
Conclusions: Avoidable PF of HF admissions are low in the context of multidisciplinary management programs. A better self-care education and closer follow-up may explain the reduction of HF hospitalizations in these programs.

Baseline characteristics and HF therapy	
Age (years)	64.3±13.2
Male sex	70.5%
Arterial hypertension	66.1%
Diabetes mellitus	36.6%
Significant coronary artery disease	37.5%
GFR < 60mL/min/1.73m^2	35.7%
COPD	17.0%
Anemia	27.7%
LVEF < 40%	83.0%
Beta-blockers	91.1%
ACE-I or ARB or ARNI	87.5%
MR antagonist	73.2%
ICD	19.6%
CRT	17.0%

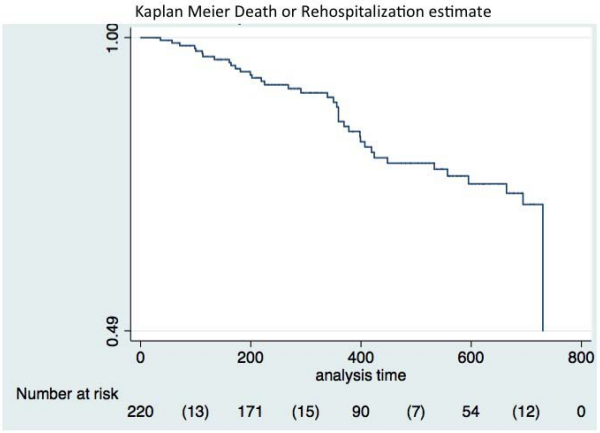


Precipitating factors of HF admission

P339
Optimize Brazil - Analysis of a multidisciplinary approach in a multicenter brazilian cohort to optimize heart failure treatment

P Schwartzmann[1]; HT Moreira[1]; R Mourilhe-Rocha[2]; H Villacorta[3]; JD Souza-Neto[4]; T Sickler-Cruz[5]; D Albuquerque[2]; MV Simoes[1]
[1]Medical School of Ribeirao Preto, University of Sao Paulo, Internal Medicine, Ribeirao Preto, Brazil; *[2]State University of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil*; *[3]Universidade Federal Fluminense - RJ, rio de janeiro, Brazil*; *[4]Hospital de Messejana Dr Carlos Alberto Studart Gomes, Fortaleza, Brazil*; *[5]Santa Helena Saúde, São Paulo, Brazil*

Introduction: Heart Failure (HF) is a major health problem worldwide, with elevated proportion of deaths, hospitalizations and morbidity. In Brazil, a national prospective registry demonstrated an even higher rate of death and re-hospitalizations. The treatment is challenging and requires a multidisciplinary initiative to improve pharmacological and non-pharmacological treatment in this population. This comprehensive multidisciplinary approach is the main goal of the Optimize Program and is focused beyond the pharmacological treatment in educating patients and their families about the disease and providing information for self-monitoring.
Purpose: We aimed at assessing the clinical effect of Optimize-HF Program in a retrospective multicenter Brazilian cohort of heart failure patients.
Methods: We retrospectively included a total of 219 patients (124 males, 59.9 ± 13.5 y.o.) with heart failure and reduced left ventricular ejection fraction (LVEF) mainly with non-ischemic etiology (151 patients – 68.9%). Patients were followed in HF clinics of five Brazilian HF centers and received the multidisciplinary orientations contained in the Optimize program.
Results: The baseline characteristics were: LVEF = 29.8 ± 0,09%, systolic arterial pressure = 111 ± 21 mmHg, heart rate = 72,2 ± 14 bpm, 38.3% of the patients were in NYHA functional class II and 48% of the patients were in NYHA functional class III, NT-ProBNP 2973 ± 3216 pg/mL, 7% had implantable cardioverter defibrillator or cardiac resynchronization therapy. Patients were treated following the recommendations of the guidelines: 84% were using betablockers, 78% ACE inhibitors or ARBs, 15.9% ivabradine. The follow-up time was 414 ± 223 days, with 5% of mortality and 21.3% of the combined outcome of death or rehospitalization. The low mean LVEF, the worse functional class (more than a half of patients were from NYHA III-IV) and the high mean NT-ProBNP level suggest that this is a high risk HF population. The outcome rate of death and a combined outcome of death or rehospitalization were markedly lower in comparison to the Brazilian National Registry of HF, which showed more than 50% of mortality and rehospitalization over a year.
Conclusion: The optimization of HF treatment using a multidisciplinary program in this multicenter Brazilian cohort presented a lower rate of death and death or rehospitalization. These results suggest the potential benefit of this multidisciplinary strategy to improve prognosis of patients with heart failure and reduced LVEF.



P340
Stroke prevention with combination of ivabradine with low dose of carvedilol versus optimized dose of carvedilol alone in chronic heart failure patients.

NARESH Sen[1]; SONAL Tanwar[2]; ASHOK Jain[3]
[1]NARAYANA HRUDAYALAYA INSTITUTE OF MEDICAL SCIENCE, BANGALORE, India; *[2]Rajasthan University of Health Sciences, Cardiology, Jaipur, India*; *[3]Fortis Escorts Heart Institute, Jaipur, India*

Background: According to proved cardiac physiology high heart rate in patients with chronic heart failure (CHF) is linked to adverse cardiovascular events like arrythemia or stroke and worsening of dyspnea. Carvedilol and Ivabradine both are recommended in CHF for heart rate reduction. However, Carvedilol also role in reduction of blood pressure which compromises cerebral perfusion pressure and may risk for stroke events.
Purpose: Our aim is to access stroke evidence in chronic heart failure patients with comparison between Ivabradine with Low dose of Carvedilol and optimized dose of Carvedilol alone.
Method: 3 years randomized observational study performed at three different cardiac centres. We have divided two groups : group A(n = 1084) treated with low dose 3.125 to 6.25 mg Carvedilol with Ivabradine 5 to 7.5 mg twice daily and group B (n = 890) treated with Carvedilol 12.5 to 25 mg twice daily. We observed stroke events rate and exercise test for functional capacity.
Result: In our study, 1974 patients of chronic heart failure were enrolled. Age of patients - 39 to 71 yrs, Systolic Blood pressure -128 to 168 mmHg , Diastolic Blood pressure - 78 to 108 mmHg, Heart Rate - 92 to 138 beat/min. Heart rate was reduced in both groups, but a greater reduction of blood pressure in group B optimized dose of Carvedilol was observed. There was significant reduction in stroke rate in group A(n = 21) versus group B (n = 48) (1.9% vs 5.4% , p < 0.004). The distance walked on

the 6-min walking test and the exercise time on MVO(2) test significantly improved in combination group A ($P < 0.02$).
Conclusion: Ivabradine with low dose of Carvedilol has better results in stroke rate reduction in chronic heart failure patients as compared to optimized dose of carvedielol alone.

P341
Outcome of a transitional care clinic to reduce heart failure readmission in high-risk inner city population

J Justin Lee[1]; F Reyes[1]; M Ramirez[1]; M Rahman[1]
[1]*SUNY Downstate Medical Center, Internal Medicine, Brooklyn, United States of America*

Background: Heart failure (HF) is a worldwide problem with an astronomical amount of burden on healthcare expenditure that is only projected to increase in the future. Previous studies have shown that black population with low socioeconomic status has significantly higher rates of HF than other ethnicities. Population at our institution consists of 80% black ethnicity, with 31% living below poverty level. Managing our patients with chronic medical conditions is particularly challenging as many of them do not fully understand the complexity of their illness and the importance of adherence with medical treatment plan. Reasons for hospital admissions for HF exacerbation include not only medication non-compliance, but also failure to follow up with primary care appointments and inappropriate use of the emergency room as the medium for immediate aid during crisis.
Our institution has established a transitional care clinic (TCC) in May 2015, with aims to aid patients with chronic medical conditions by providing early post-discharge follow up regardless of patient's financial or insurance status.
Methods: Retrospective review was conducted for patients who were scheduled for TCC with a diagnosis of HF, from May 2015 to October 2016. Our TCC model includes, follow-up appointment within 7 days post-discharge and reminders via phone calls a day before TCC appointment, post clinic follow up phone calls and additional TCC clinic visits as needed to bridge patient over to his or her primary care clinic. A 30-day readmission rate was calculated and compared between patients who followed up with their TCC and who did not, by using Fisher's exact test. Also, readmission rates were compared for patients who followed at TCC vs. cardiology clinic.
Results: Total of 204 admissions for HF were identified in the study period. Majority of patients were black (91%) with a mean age of 65 years and median length of stay of 5 days. Out of 137 patients who did not follow up with our TCC, 44 were readmitted (32.12%) within 30 days of discharge. From the 67 patients who followed with our TCC, 7 were readmitted (10.45%). Forty percent of patients who did not show up to neither TCC nor cardiology clinic were readmitted, compared to 8% who showed up to either TCC or cardiology and 6% who followed up with both.
Conclusions: Our transitional care clinic model demonstrates early success with 22% decrease in 30-day all-cause HF readmission in patients who were followed up at the clinics. Rate of readmission did not differ significantly on patients who were followed at TCC, compared to those who were followed by their cardiologists. Future study design can be directed towards cost analysis, comparison to historical data from other inner-city population and interventions focused on ways to increase compliance with TCC appointment, including more frequent reminders using emails, text messages, etc.

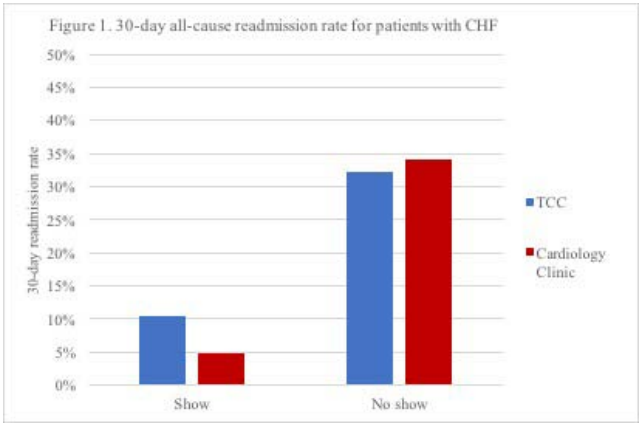


Figure 1.

P342
NO metabolism in patients of elderly age with chronic heart failure.

I Ime Etukudo[1]; L Abugu[2]
[1]*Kharkov National University of V.N. Karazina, Internal Medicine , Kharkov, Ukraine*; [2]*Kharkov National Medical University, Internal Medicine , Kharkov, Ukraine*

Important role in pathogenesis of chronic heart failure (CHF) is the disturbance of vasodilatory function of endothelium, determined by level of synthesis and metabolism of nitric oxide (NO). S-nitrosothiol – complex: made as a result of introducing NO into dinitrozol complexes of iron with thiol ligands forming a physiological oxidation that reflects the intensity of its synthesis.
Aim of investigation: determination of peculiarities of NO metabolism in patients of elderly age with CHF.
Matherial and methods: 68 patients with ischemic heart disease of age from 60 to 92 were examined. CHF of II functional class (FC) was determinated in 44 (64%), CHF of III FC–in 24 (35%) patients (NYHA). 29% had hypertensive disease (HD), 19% patients diabetes mellitus (DM). Nitrates and nitrites were determinated in serum by method of Griss' diasoreaction with determination of nitric junction. S-nitrosothiol was determinated by fluorometric method.
Results: there was a significant decrease of S-nitrosotiol levels comparing to control group. Comparing level of S-nitrosothiol in groups 60-75 and >75 years, in men and women, depending on presence of HD and DM in anamnesis meanings of this metabolite had no difference. Nitrate levels in patient with II and III FC of CHF was significantly less of those in control ($< 0{,}05$; $< 0{,}05$). Nitrites level in patients with CHF II FC was lower ($< 0{,}05$), in CHF III FC – had no difference from normal one. Level of nitrates and nitrites in CHF III FC was significantly higher CHF II FC($< 0{,}01$; $< 0{,}05$). At the age of > 75 years, level of nitrates and nitrites were significantly lower than at the age of 60-75 years ($< 0{,}05$; $< 0{,}05$). Indices of NO were significantly higher in patients with HD and DM comparing to patients without HD and DM in anamnesis ($< 0{,}05$).
Conclusion: Depression of NO metabolites formation testify about decreasing of intensity of NO metabolism and reflects physiological and pathological processes caused by CHF, endothelial dysfunction. In CHF III FC, HD and DM in anamnesis, they were significantly higher rates of nitrites and nitrates. This fact can be related to induction of iNOS with increasing formation of NO that due to CHF can be caused by growing ischemia, due to HD – increased endothelial dysfynction and high blood pressure, due to DM – metabolic disturbances, which connected to unbalance of pressors and depressors acting of insulin. In such way, changes of vasodilatory function in patients of elderly age depend on severity of CHF, age of the patient and presence of polymorbide background.

P343
State of the thromboxane-prostacykline system in patients with chronic heart failure

V Valery Vishnevsky[1]
[1]*Medical Institute of Orel State University, Departament of Internal Diseases, Orel, Russian Federation*

Background: In recent years in the study of the pathogenesis of several diseases of the cardiovascular system, and chronic heart failure (CHF) in particular, careful attention is drawn to the prostanoids, because keeping active physiological balance between thromboxane and prostacyclin is one of the main conditions for maintaining optimal blood flow in the myocardium.
Aim: To study thromboxane-prostacyclines system (TPS) in patients with coronary heart disease (CHD) complicated by the CHF.
Methods: The status TPS was analyzed among 82 patients with CHD and CHF at the age of 42-60 years. Investigated in blood plasma the stable metabolites of prostacyclin – 6-keto-prostaglandin F1a (6-keto-PGF1a), prostaglandin E – PGE1, thromboxane A2 – TxB2 immunoenzyme method sets of reactants of company IBL. Depending on the functional class (FC) of the CHF patients were divided into 3 groups: 1 gr. – with the CHF FC I (34 patients), 2 gr. – with the CHF FC II (27 patients), 3 gr. – with the CHF FC III-IV (21 patients).
Results: In the control group content of TxB2 in blood plasma amounted to $147{,}2 \pm 2{,}9$ ng/ml, 6-keto-PGF1a – $87{,}3 \pm 2{,}8$ ng/ml, PGE1 – of $0{,}62 \pm 0{,}07$ ng/ml, the ratio of TxB2/6-keto-PGF1a – $1{,}65 \pm 0{,}26$. With progression of CHF biosynthesis prostacyclin was significantly decreasing, level of TxB2 and the ratio of TxB2/6-keto-PGF1a in patients of 2 gr. and 3 gr. was significantly higher compared to the control group and 1 gr. Thus, in patients of 2 gr. and 3 gr. the content of prostacyclin amounted to $70{,}2 \pm 5{,}6$ ng/ml and $64{,}6 \pm 4{,}9$ ng/ml, respectively ($p < 0{,}05$, $p < 0{,}01$). Level of TxB2 in 2 gr. was $183{,}4 \pm 8{,}1$ ng/ml, 3 gr. – $226{,}4 \pm 9{,}3$ ng/ml ($p < 0{,}01$); the ratio of TxB2/6-keto-PGF1a in 2 gr. and 3 gr. – $2{,}61 \pm 0{,}29$ and $3{,}43 \pm 0{,}36$, respectively ($p < 0{,}01$).
Indicators of PGE1 in patients of 1 gr. were higher than in the control group, but in patients of 2 gr. and 3 gr. the level of PGE1 was declining, however, it exceeded targets. Reduction of the level of 6-keto-PGF1a, increase of TxB2 in plasma with

increasing FC CHF indicates their involvement in the mechanism of progression of heart failure and breach response the TPS as the exacerbation of the pathological process. Comment: The decrease of prostacyclin level in blood plasma, increased thromboxane and their ratio in patients with coronary heart disease probably reflects not only the severity of coronary insufficiency, but also chronic heart failure.

P345

Impact of ejection fraction on the clinical features in heart failure patients with concominant chronic obstructive pulmonary disease

VM Violetta Gazizianova[1]; OV Bulashova[1]; EV Khazova[1]
[1]*Kazan State Medical University, Kazan, Russian Federation*

The problem of management heart failure (HF) patients with concominant chronic obstructive pulmonary disease (COPD) is relevant and understudied. The research continues for clinical markers for aggravating both diseases, as well as criteria for their unfavorable course and prognosis. It is proved that the state of left ventricular systolic function, determined by the size of the ejection fraction, largely affects the survival of patients with heart failure. It is expected that adherence to heart failure, COPD significantly change clinical phenotype.

Purpose: To investigate the clinical features of heart failure in association with chronic obstructive pulmonary disease, depending on the value of left ventricular ejection fraction.

Methods: We enrolled 105 HF patients in association with COPD (average age – 68,4 ± 9,4 years, left ventricular ejection fraction – 53,8 ± 11,4%, I-II FC – 43,9%, III-IV –56,1%). Duration of heart failure did not exceed 6 years. In the study we used Questionnaire Minnesota living with heart failure for assessment quality of life, walk test, clinical assessment scale.

Results: All patients, depending on the value of left ventricular ejection fraction (LVEF), were divided into 3 groups according to recommendations of the European Society of Cardiology (2016.): 1. preserved left ventricular ejection fraction –81 patients (77,1%), 2. midrange –12 (11,45%), reduced left ventricular ejection fraction – 12 (11,45%). The frequency of severe course COPD was higher in the second group than in the others – 62,5%. The most unfavorable cohort was a group with a reduced left ventricular ejection fraction, which was confirmed by the worst results of the test distance (190,6 ± 96,1 m) and clinical assessment test (6,9 ± 2,1 points), worse quality of life (62,3 ± 20,9 points). The direct correlation of moderate intensity was determined between LVEF and Tiffno index ($r = 0,354$, $p < 0,05$), functional vital capacity of the lungs (FVC) – $r = 0,322$, $p < 0,05$, and also between heart failure functional class (FC) and clinical features of COPD, measured by clinical assessment test (CAT) and MRC ($r = 0,444$, $p = 0,01$ and $r = 0,344$, $p < 0,05$).

Conclusions: The results of this study indicate mutual influence on the clinical characteristics of both heart failure and bronchial obstructive disease on the formation of the clinical phenotype of the patient. The study showed that LVEF in patients significantly affects on the course of both diseases. At the same time, the clinical criteria for COPD have an impact on the course of both diseases, evidenced by a correlation between CCQ and clinical assessment scale ($p < 0,05$, $r = 0,473$), CCQ and CHF FC ($p < 0,05$, $r = 0,344$). The positive correlation between the results of COPD Assessment Test – CAT, reflecting the clinical condition of the patient at the time of the study, and CHF FC ($p < 0,05$, $r = 0,346$), clinical assessment scale ($p < 0,05$, $r = 0,410$), quality of life ($p < 0,05$, $r = 0,49$) was founded.

P346

The effectiveness of tolvaptan does not correlate with the severity of hyponatremia

R Rissa Setiani[1]; R Soerarso[1]; N Hersunarti[1]; BB Siswanto[1]
[1]*Harapan Kita Hospital, Jakarta, Indonesia*

Background: Heart failure is a disease associated with high morbidity and mortality rates, as well as increasing costs. Patients with heart failure often develop hyponatremia due to the changes in neurohormonal system. Hyponatremia has been associated with longer hospital stay, increased complications, larger costs, as well as increased rate of hospitalization. Tolvaptan is a selective, competitive vasopressin receptor 2 antagonist used to treat hyponatremia associated with congestive heart failure.

Purpose: This study aims to assess the effects of tolvaptan in heart failure patients with various severity of hyponatremia.

Methods: Prospective cohort study design was used. Patient recruitment was done in our Cardiovascular Center from 2015 to 2016, resulting in 31 in-hospital subjects. Inclusion criteria was adult patients who had heart failure and received tolvaptan. Data was collected through interview, physical examination, medical record, and laboratory examinations. The outcome of tolvaptan administration was assessed from the decrease in body weight and edema, as well as 24-hour urine volume. Data analysis was done using SPSS 20.0. The severity of hyponatremia is classified into below or above 120 mEq/L.

Results: Thirty-one subjects were included in this study. Seventy-one percent of the subjects were male, with average age of 51.2 ± 2.3 years old. NYHA classes of the population were as following: II (6.4%), III (61.3%), IV (32.3%). The median baseline sodium level was 131 (103-138) and median LVEF was 29% (14%-71%). All of the participants were prescribed furosemide (median dose 332 [40-840] mg) and 38.7% were prescribed spironolactone (median dose 25 [12.5-50] mg). Thirty percent of the participants had comorbid conditions. Tolvaptan effects on participants with hyponatremia below ($n = 6$) or above ($n = 25$) 120 mEq/L are not significantly different ($p > 0.05$), with average diuresis of 3021 (SD 1279) cc/day.

Conclusion: Tolvaptan can effectively improve diuretic effects of furosemide in heart failure patients despite various severity of hyponatremia.

ADVANCED HEART FAILURE

P347

Influence of a continuous veno-venous hemofiltration on the long-term prognosis in patients with an advanced heart failure and an acute coronary syndrome

Introduction: Heart failure (HF) is one of the most common and challenging therapeutic problems. Coronary artery disease (CAD) can lead to HF and coronary angiography followed by PCI are utilized for its diagnosis and treatment. The use of contrast media could impair renal function while prophylactic fluid infusion is a standard of care. An adequate hydration in overloaded HF patients with urgent indications for intervention in acute coronary syndrome (ACS) setting is challenging. Periprocedural use of continuous veno-venous hemofiltration (CVVH) in such patients could be a valuable option.

Purpose: To analyze the long-term prognosis of patients with an advanced HF, undergoing PCI with periprocedural CVVH use.

To assess safety of CVVH and identify patients at increased risk for complications.

Methods: We performed prospective interventional study, which included 52 patients with chronic HF (NYHA II-IV), reduced ejection function (EF < 45%) and chronic kidney disease (stages III-IV), referred for coronary angiography/PCI due to ACS.

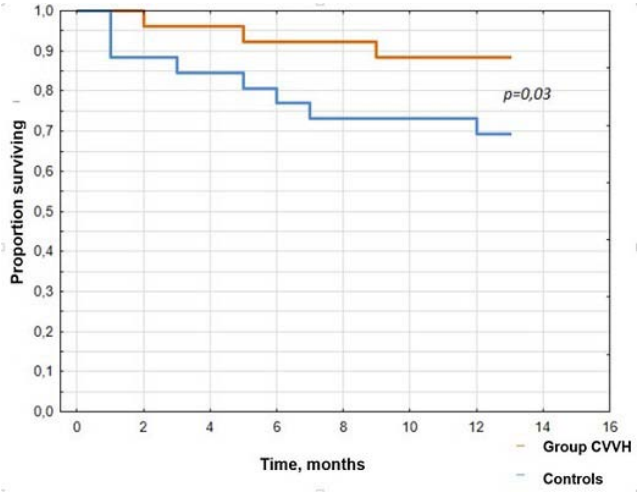
In 26 patients CVVH was used during the PCI procedure and 24h afterwards as an addition to a standard care. Another 26 patients received only standard treatment.

We measured serum creatinine levels at 24, 48 and 72h post PCI in both groups as well as NT-proBNP levels at 24 and 48h in CVVH group. In 3,5 years follow-up we assessed the risk of cardiovascular death and mortality from any cause.

Results: Patients in CVVH group were more often diabetic (73,1% vs. 38,5%, $p = 0,025$), active smokers (38,5% vs. 7,7%, $p = 0,02$), had history of previous PCI (57,7 vs. 23,1%, $p = 0,023$), were in significantly higher NYHA class ($p = 0,03$) and had pulmonary edema at admission (46,1% vs 11,5%, $p = 0,01$). Both groups were similar in routine laboratory measurements, except for higher initial creatinine ($p = 0,017$) and potassium levels ($p = 0,018$) in CVVH group. In CVVH group creatinine level significantly declined at 24h after the PCI (161,87 ± 63,4 vs. 124,71 ± 39,8 μmol/l, $p = 0,003$) with subsequent nonsignificant rise at 48 and 72h. In controls, the lowest observed creatinine level at admission (129,9 ± 38,1 μmol/l) significantly increased at 24h (136,4 ± 43,6, $p = 0,049$ μmol/l). NT-proBNP levels significantly decreased at 24 and 48h after the CVVH ($p = 0,015$). In CVVH group we observed a trend toward higher bleeding rate and need for transfusion (19,2 vs. 7,7%, $p = 0,42$). All bleeding events were related to vascular access site and occurred exclusively in female patients (100%, $p = 0,004$).

We observed significantly higher probability of survival at one year in CVVH group patients (88,5 vs. 73,1%, for CVVH and control groups respectively, $p = 0,03$), but this difference lost statistical significance at 3,5 years follow up.

Conclusions: Use of CVVH in patients with an advanced HF might result in a decrease of 1-year mortality with no such effect at a longer follow up. The use CVVH in women could increase the risk of bleeding complications.



survival probability in 1-year follow-up

P348

Beta-blockers uptitration between infusions predicts event-free survival in advanced heart failure treated with repeated cures of low-dose levosimendan

N Barras[1]; J Regamey[1]; P Vogt[1]; R Hullin[1]; PO Yerly[1]
[1]*University Hospital (CHUV), Department of cardiology, Lausanne, Switzerland*

Background: Prognosis of Advanced heart failure (AHF) is very poor. Because of low blood pressure (BP) and fluid overload, uptitration of Angiotensin converting enzyme inhibitors (ACEi), Angiotensin receptor antagonists (ARA), beta-blockers (BB) and mineralocorcticoid receptor antagonists (MRA) is not tolerated. Intermittent levosimendan (levo) infusions may then be a of value to alleviate symptoms and possibly improve outcome.
Purpose: The goal of this study was to find out factors predictive of 1 year event-free survival in 42 AHF patients (LVEF < 40%, NYHA 3-4 despite optimal therapy>3 months) treated with repeated low dose Levo (0.05 µg/kg/min during 24h every 4 wks) (4.37 + /-1.9 infusions/ pat).
Methods: Medical files were reviewed for the composite endpoint of mortality, re-hospitalization or LVAD implantation during 1 year after first infusion. Patients' baseline characteristics and status at inclusion and after 3 infusions were compared between the 14 who reached the endpoint (33%) and the 28 event-free survivors.
Results: Nor patients' characteristics (age 61.4 + 8.9y vs 59.7 + 7 y, P=0.62; female 17.85% vs 7.14%, P=0.64; IHD 50% vs 64.3%, P=0.51; LVEF 0.21 + 0.05 vs. 0.22 + 0.06) nor patients' baseline status predicted outcome (Table). Only BB therapy, percent of BB target dose and heart rate after 3 infusions predicted endpoint occurrence (Table). After adjustement for HR and BB, only BB dose >35% target dose remained significant (OR=0.64; 95%CI 0.07-0.87).
Conclusion: repeated levo infusions offer the opportunity tu uptitrate HF background therapy, particularly BB, which in turn may predict mid-term outcome.

P349

Utility of cTnT-hs and sAXL for prognosis evaluation after heart transplantation

S Sonia Mirabet Perez[1]; J Ordonez Llanos[1]; P Garcia Frutos[2]; V Brossa Loidi[1]; L Lopez Lopez[1]; M Tauron[1]; E Sole[1]; A Ferrero[1]; E Roig Minguell[1]
[1]*Hospital de Sant Pau, Barcelona, Spain*; [2]*Department of Cell Death and Proliferation, IIBB-CSIC, IDIBAPS , Barcelona, Spain*

Cardiac allograft vasculopathy (CAV) is one of the main limiting factors for long-term survival after heart transplantation (HTx). Once CAV is established it is associated with worse outcomes, but the progression of the disease is very variable and the prediction of cardiovascular events sometimes is uncertain. Some patients with CAV have a rapid deterioration while others remain stable for long periods of time despite being diagnosed with CAV. The aim of this study was to evaluate the usefulness of sAXL, Lp-PLA2, GDF-15 and cTnT-hs to assess prognosis in HTx recipients.
Methods: This is an observational single center study that include HTx patients who had undergone routine CAV assessment, by coronary angiography or by coronary multi-slice computed tomography (MSCT) between January 2012 and April 2015. CAV was classified according the recomendations of the ISHLT. Blood samples were collected at the time that angiography or MSCT was done. sAxl (protein involved in vascular remodeling) , Lp-PLA2 (marker of atherosclerosis), cTnT-hs (marker for myocardial necrosis) and GDF 15 (marker associated with cardiovascular events) were assessed and were correlated with the development of cardiovascular events during the follow-up (until December 2016). Cardiovascular events (CV) were defined as a combined endpoint that included cardiovascular death, acute myocardial infarction or angina, heart failure or EF < 50% not due to rejection.
Results: A total of 96 HTx patients were included. Mean time after HTx was 9 ± 7 years. CAV was diagnosed in 49 patients (CAV1 in 26, CAV2 in 6, and CAV3 in 17 patients). During the follow up nineteen patients (20%) presented cardiovascular events. Five patients died, 6 had angina or AMI, and the remaining 8 had heart failure or EF < 50%. All the patients that presented cardiovascular events had CAV (13 were CAV3, 2 CAV2 and 4 CAV1). There were significant differences in cTnT-hs values between patients with and without cardiovascular events (50 ± 41 vs 19 ± 19 ng/L; p < 0.01) and sAXL values (104 ± 67 vs 69 ± 27 ng/L; p < 0.04). cTnT-hs ≥21 ng/L predicted the development of cardiovascular events with a specificity of 78%, sensitivity of 68%, positive predictive value of 43%, and negative predictive value of 91%. In the multivariate analysis cTnT-hs and sAXL were independent predictors of increased risk for cardiovascular events after HTx. Survival without cardiovascular events in HTx patients with cTnT-hs >21 ng/L was 47% compared with 70% in patients with cTnT-hs < 21 ng/L (p < 0.01) (Figure 1). Lp-PLA2 and GDF15 had no correlation with cardiovascular events.
Conclusions: sAXL and cTnT- hs could be useful biomarkers to assess the prognosis of Heart transplantation recipients. In our study, values of cTnT-hs ≥ 21 ng/L have a high negative predictive value for cardiovascular events in patients with CAV. Therefore, the routine assessment of cTnT-hs after HTx may help to improve the management of chronic HTx patients.

table P348

	Baseline			After 3 infusions		
Variable	No endpoint (n = 28)	Endpoint (n = 14)	P	No endpoint (n = 28)	Endpoint (n = 14)	P

Predictors of mortality at six months after in advanced heart failure patients attended in primary care

JM Verdu-Rotellar[1]; MA Munoz[1]; E Calero[1]; N Farre[2]; R Abellana[1]; C Checa[1]
[1]Primary Care Research Institute (IDIAP), Barcelona, Spain; *[2]Hospital del Mar, Cardiology, Barcelona, Spain*

On behalf of: GRECAP Study group
Funding Acknowledgements: IDIAP Jordi Gol

Background: To know the predictors of survival in patients with advanced heart failure is crucial to decide end-of-life options.
Purpose: to determine the factors related to the six months mortality of heart failure patients at functional status New York Heart Association (NYHA) IV attended in primary care.
Methods: Retrospective cohort study including 726 heart failure patients at NYHA IV functional status in Catalunya (Spain) was carried out. Demographic and clinical data, laboratory tests, treatments, comorbidity and vital status were drawn from primary care electronic medical records.
Logistic regression models and multiple imputations were performed.
Results: Mean age was 83.2 years (SD 7.8) and 62.9% were women, 43,0% were diabetic, 32.8% had coronary heart disease, 15.6% had history of stroke, atrial fibrillation was present in 49.7%, and 19.1% of patients had cancer.
Adjusted multivariate analysis found that: age (OR 1.04, 95% CI 1.01-1.06), low systolic blood pressure (OR 3.75, 95% CI 1.68-8.33),low body mass index (OR 4.62 95% CI 2.19-9.76), heart rate > 100/min (OR 2.14, 95% CI 1.05-4.35), renal impairment (OR 1.80, 95% CI 1.11-2.93), limitations in daily living activities (OR 1.68, 95% CI 1.02-2.75) and furosemide dosis (mg/day) (OR 1.007, 95% CI 1.003-1.02) were related to a higher mortality.
Conclusion: : A small number of variables easily obtained from primary care can predict which kind of patients are more probably going to be death in the six months after reaching the NYHA IV functional status.

P351

Low dose of basiliximab for induction immunosuppresion therapy for heart transplant results in favourable outcomes

V Veraprapas Kittipibul[1]; P Tantrachoti[1]; P Ongcharit[1]; A Ariyachaipanich[1]; S Siwamogsatham[1]; T Chaemchoi[2]; S Sritangsirikul[2]; S Puwanant[1]
[1]Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand; *[2]King Chulalongkorn Memorial Hospital, Bangkok, Thailand*

Background: Basiliximab 20 mg IV on Day 0 and Day 4 has been used as induction immunosuppression therapy for heart transplant. This simplified two-dose regimen was adopted from the studies in renal transplant. Little is known about the efficacy and safety of a low-dose regimen of Basiliximab (10 mg IV on Day 0 and Day 4) for induction immunosuppression therapy for heart transplant.
Methods: We studied safety and efficacy outcomes of Basiliximab 10 mg IV on Day 0 and Day 4 for induction immunosuppression therapy in 17 consecutive adult heart transplant recipients. All patients received cyclosporine or tacrolimus, mycophenolic acid, and prednisolone.
Results: Of 17 recipients (age 42 ± 14 years, 82% male, weight 54 ± 10 kg, height 166 ± 7 cm, body surface area 1.6 ± 0.2 m2, 100% CMV of D+/R+, ischaemic time 228 ± 78 minutes) receiving Basiliximab 10 mg IV on Day 0 and 4 for induction immunosuppression therapy, no rejection or mortality reported within 2 weeks post-operation. The efficacy and safety were shown in Table 1.
One death was attributed to Acinetobacter Baumanii infection occurring at 3 months post-transplant. No CMV disease, malignancy, or Post-transplant lymphoproliferative disorder detected at 1-year follow-up. None of 17 patients had adverse reactions (flushing, hypotension, serum sickness, or anaphylaxis). Mean serum creatinine at 6 months was 1.27 ± 0.41 mg/dl. Compared with previous studies using Basiliximab of 20 mg, the rejection, mortality, and infection rates were comparable.
Conclusions: Low dose of Basiliximab (10 mg IV on Day 0 and Day 4) for induction immunosuppression therapy for heart transplant results in no rejection or mortality within 2 weeks post operation in all patients. At 6 months post-transplant, moderate acute cellular rejection (ISHLT grade ≥ 2R) event-free rate was 86%. One-year survival was 90%. Further study comparing two induction regimens of Basiliximab (20 mg vs. 10 mg) on Day 0 and Day 4 along with CD25 and pharmacodynamic/kinetic profiles in heart transplant recipients is needed.

Table 1: Efficacy and safety outcomes

Post-HTx duration	Survival	≥2R ACR event-free rate	Graft failure event-free rate	CMV infection even-free rate	Treated infection event-free rate
2 weeks	100%	100%	100%	100%	94%
1 month	100%	88%	100%	83%	94%
3 months	94%	88%	100%	65%	75%
6 months	93%	86%	100%	57%	71%
12 months	90%	70%	100%	40%	50%

Intermitent treatment with levosimendan in outpatients with chronic advanced heart failure: our experience.

DJ Daniel Jose Elena Aldana[1]; MLG Miguel Antonio Lopez Garrido[1]; PCC Maria Del Pilar Cardila Cruz[1]; LJM Laura Jordan Martinez[1]; VBM Victor Manuel Becerra Munoz[1]; NAM Nasiba Abdeselam Mohamed[1]; AGC Ana Guijarro Contreras[1]; ARM Ainhoa Robles Mezcua[1]; RJA Rafael Jimenez Arjona[1]; RCA Rafael Campos Arjona[1]; AMR Ana Molina Ramos[1]; VGR Maria Victoria Garcia Ruiz[1]; LMH Luis Morcillo Hidalgo[1]; JMGP Jose Manuel Garcia Pinilla[1]
[1]University Hospital Virgen de la Victoria, Cardiology, Malaga, Spain

Introduction: Intermitent treatment with levosimendan might be a alternative for patients with chronic advanced heart failure, since there is not enough cientific evidence according to this. The aim of this study was to reach the clinical evolution of the patients undergo this therapy in our hospital.
Methods: We studied all the outpatients with chronic advanced heart failure treated with intermitent levosimendan therapy, recording clinical features, analytical values and events during the follow-up.
Results: From the 23 patients we have studied (65 years, 35% women), 11 (47,8%) of these had an isquemic ethiology. The mean of LVEF was 28% and the mean of Charlson Comorbidity Index was 5,5. 14 patients (60.9%) were admitted due to heart failure episode in the previous year before starting the therapy, and 9 (39,1%) had descompensated heart failure episodes. The mean of NT-proBNP pre-therapy was 3798 pg/ml, decreasing in 56,5% of the patients in the next 3 months and getting better in the 21.7% in the next 6 and 12 months. The median follow up duration was 11 months (IQR 5-18), recording at the 12th month an improvement of functional class in 10 patients (43,5%), 3 (13%) descompensated heart failure, 4 (17.4%) readmitted at hospital, 7 (30.4%) deaths and 3 (13%) heart transplantation. Patients with anemia had more descompensated heart failure episodes (37.5%vs0%, p = 0.032).
Conclusions: -NT-proBNP levels decreased in a high percentage of patients at the third month and less at the sixth and twelfth month of the follow-up.
-The prevalence of readmission and descompensated heart failure after intermitent therapy with levosimendan decreased according to the previous year pre-treatment.

P353

The safety and the efficacy of opioid agents for palliative care in patients with advanced heart failure

Y Nishihata[1]; H Mochizuki[1]; M Ono[1]; I Komatsu[1]; T Fukuda[1]; M Mizuno[1]; N Nakaoka[1]; Y Kijima[1]; Y Shiina[1]; N Komiyama[1]
[1]*St. Luke's International Hospital, Department of Cardiology, Tokyo, Japan*

Background: Palliative care for patients with advanced heart failure is recommended in the guidelines for the acute and chronic heart failure and it has been the focus of attention in this pandemic of heart failure. Because cardiologists are not familiar with opioids, there might be the underuse of those drugs for fear of those negative effects.
Purpose: To investigate the safety and the efficacy of opioid agents for palliative care in patients with advanced heart failure.
Methods: We investigated 4640 patients admitted to our cardiovascular center from January 2013 to September 2016, and extracted 28 patients with advanced heart failure treated with opioid agents to palliate their dyspnea. We examined patient´s background, starting dosage and maintenance dosage of opioids, concomitant drugs and clinical responses.
Results: About all 28 patients, their mean age was 79.4 years-old and 13 (46.4%) were male. Of those patients, 25 (89.3%) had renal dysfunction defined as estimated glomerular filtration rate (eGFR) of under 60 ml/min and 20 (71.4%) had severe renal dysfunction defined as eGFR of under 30 ml/min. Morphine hydrochloride, fentanyl and oxycodone were administered for 22, 3, and 3 patients respectively. The mean starting dosage of morphine, fentanyl and oxycodone were 5.8 ± 3.2, 0.71 ± 0.50, and 4.7 ± 0.58 mg/day, and the maintenance dosage were 8.7 ± 7.6, 0.77 ± 0.40, and 14.7 ± 13.6 mg/day, respectively. Inotropic agents, diuretics, and sedative medication were administered in combination with opioids in 89.3%, 17.9%, and 25.0%. Systolic and diastolic blood pressure did not change significantly after administration of opioids (97 ± 22.1 to 98.1 ± 20.2 mmHg and 49.9 ± 13.6 to 52.3 ± 14.1 mmHg). Heart rate and respiratory rate were significantly reduced by opioids (87.8 ± 25.2 to 83.8 ± 24.3 bpm, $p < 0.01$, and 27.3 ± 7.9 to 22.0 ± 6.5 bpm, $p < 0.01$) but nobody experienced significant respiratory depression nor symptomatic bradycardia. Their dyspnea score assessed by 'Face Scale' was significantly improved by opioids (2.9 ± 1.0 to 1.5 ± 0.9, $p < 0.01$).
Conclusions: Low dose opioids were relatively safe and effective for palliative care in patients with advanced heart failure and renal dysfunction.

P354

End of life care and symptom control in the final year preceding mortality from end-stage heart failure - Observations from a heart failure disease management programme.

V Voon[1]; S Chew[1]; C Craig[2]; D White[1]; E Wong[1]; C Cahill[1]; B Meany[1]; F Twomey[1]; T Kiernan[1]
[1]*University Hospital Limerick, Limerick, Ireland*; [2]*University of Limerick, Iimerick, Ireland*

Background: End of life care (EOLC) preceding end-stage heart failure (ESHF) death is poorly described, even within the context of a HF disease management programme (HF-DMP). It is thought that extending this period of recognition may provide greater opportunity for better care, particularly specialist palliative care (SPC). Therefore, we aimed to characterize EOLC, especially symptom control, during the final year preceding ESHF deaths.
Methods: All patient deaths (n = 53) within University Hospital HF-DMP in 2014-2015, were identified and categorized as ESHF and non-ESHF deaths. We retrospectively compared medical record data between both groups for demographics, HF clinic visits, hospitalizations and SPC referral during 12 months preceding death. Missing data was excluded. Data were expressed as mean ± SD or %.
Results: All ESHF deaths had at least NYHA III dyspnea prior to last hospitalization/HF clinic visit. None were eligible for heart transplant. No significant differences were observed between ESHF (n = 21) vs Non-ESHF (n = 20) deaths in terms of age, gender or nursing home admission within last year of life. Left ventricular ejection fraction in all patients was 30 ± 13% with approximately a third of patients in both groups with implantable cardiac defibrillators (ICD). Within last 12 months of life, ESHF deaths had more HF clinic visits for HF symptom control with diuretics, versus non-ESHF deaths (1.2 ± 2.0 vs 0.3 ± 0.4, p = 0.04). However, there were no significant between-group differences in HF and non-cardiovascular hospitalizations. In both groups, less than a quarter of patients had documented ICD deactivation discussions and less than a third of patients had documented SPC referrals, which were only initiated within the last 3 months of life. During this period, reported symptoms for control in ESHF deaths were dyspnea (86%), pain (19%), fatigue (57%) and oedema (67%), and were not significantly different to comparator group.
Conclusion: A low incidence of documented SPC referral for symptom control and ICD deactivation discussions was observed during EOLC of ESHF deaths. This is despite greater HF symptom burden during final 12 months of life within the ESHF deaths group. More work is required to explore these observations, including the use of structured assessment to document such parameters.

Prolonged P-wave duration is associated with atrial fibrillation recurrence after radiofrequency catheter ablation

Y-S Wang[1]; G-Y Chen[2]; X-H Li[2]; X Zhou[2]; Y-G Li[1]
[1]*Xinhua Hospital of Shanghai Jiao Tong University School of Medicine, Department of Cardiology, Shanghai, China People's Republic of*; [2]*Xinhua Hospital of Shanghai Jiao Tong University School of Medicine, Clinical Research Unit, Shanghai, China People's Republic of*

Funding Acknowledgements: National Natural Science Foundation of China (NSFC), No. 81500188

Background/Objectives: A change in the P-wave duration (PWD) was approved in patients with atrial fibrillation recurrence (AFR) after radiofrequency catheter ablation (RFCA). The correlation between the PWD and AFR and the potential utilization of a prolonged PWD in the prediction of AFR after RFCA remains unclear.
Methods: A meta-analysis of clinical studies that investigated the relationship between PWD and AFR after RFCA was performed. Studies regarded PWD in patients with or without AFR after RFCA, and also studies concerned with the predictive effect of prolonged PWD on AFR after RFCA, were included and summarized. Outcome measures are reported as absolute risk differences with 95% confidence intervals. A receiver operating characteristic (ROC) curve was used to evaluate the potential cut-off value of PWD for AFR. Summary receiver operating characteristic curve (SROC) analysis was performed to show the overall predictive efficiency of PWD for AFR.
Results: Nine studies were included in the meta-analysis. An overall effect test based on 8 studies that contained a total cohort of 1,010 patients showed a highly significant association between prolonged PWD and AFR after RFCA ($Z = 14.20$, $P < 0.000$). A statistic summary included 4 studies that included a total of 593 patients indicated an obviously higher risk of AFR among patients with prolonged PWD ($Z = 5.86$, $P < 0.000$). ROC curve analysis indicated 149.5 ms as the potential cut-off value of PWD for AFR after RFCA. SROC analysis suggested an acceptable predictive efficiency of PWD for AFR (AUC = 0.66)
Conclusions: The risk of AFR after RFCA is strongly related to a prolonged PWD. PWD is one potential low-cost and feasible predictor for AFR after RFCA.

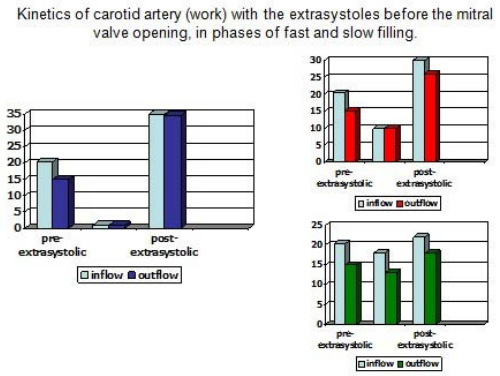
P356

Extrasystoles from the point of view of its functional importance

O A Olga Germanova[1]; NN Kryukov[1]; AV Germanov[1]
[1]*Samara State Medical University, Samara, Russian Federation*

Atrial fibrillation is considered to be a risk factor of thromboembolic events because of the high probability of mural thrombus in auricles with ability of its further fragmentation. The majority of researches acknowledge the kardioembolic nature of stroke. However it's not paid attention to the role of elastic and muscle-elastic arteries on the background of multifocal arterial atherosclerosis with extrasystoles and atrial fibrillation in tromboembolic danger.
Aim: To determine the influence of intra-arterial hemodynamic and kinetic disorders of main arteries on the probability of thromboembolic events in the patients with different types of extrasystoles and atrial fibrillation.
Methods: We examined 186 patients with the permanent form of atrial fibrillation and supraventricular and ventricular extrasystoles. We used extrasystoles classification in accordance to the moment of their appearance in cardio cycle. We have identified:
Extrasysoles before the mitral valve opening.
Extrasystoles in rapid ventricular filling phase before the transmitral blood flow peak. Extrasystoles in rapid ventricular filling phase after the transmitral blood flow peak. Extrasystoles in slow ventricular filling phase.
We registered sphygmograms and doppler -ultrasound of carotid, radial, ulnaris, posterior tibia, arch of foot arteries. We analyzed the peak speed direct blood flow, blood flow volume. To know the moment of extrasystoles appearance in cardio cycle and ectopic center localization we used apex-cardiography and electrocardiography. The volume of cardiac output and transmitral blood flow were measured by echocardiography. We determined the parameters of heart biomechanics and main arteries kinetics, which characterized speed, acceleration, capacity and work in each phase of heart cycle in systole and diastole, and also the periods of dominance of outflow over inflow. We valued the contribute to the circulation of the premature contraction and first post-extrasystolic contraction.

Conclusion: The main importance to the hemodynamics changes has the moment of extrasystole appearance in cardio cycle and the ability of the first post-extrasystolic contruction to reestablish an adequate resulting blood flow. On the background of multifocal lesions of main arteries the main importance has the first post-extrasystolic contraction. It is accompanied by the sharp increase of hemodynamic and kinetic parameters of arteries and the increased deformation of vascular wall. The maximums of these parameters are revealed in first post-extrasystolic contruction in case of extrasystoles before the mitral valve opening and before the transmitral peak flow. In atrial fibrillation the main danger are the first ventricular contractions after the maximum time pauses. It causes the significant increase of cardiac output, arteries diameter as well as non-stability of atheromas and mural thrombus fragmentation with high embolism probability.



P357

Ventricular tachycardia and atrial fibrillation complicating the clinical course of takotsubo cardiomyopathy

B Schneider[1]; A Athanasiadis[2]; J Schwab[3]; U Gottwald[4]; W Toepel[5]; R Schoeller[6]; U Sechtem[2]
[1]Sana Kliniken, Luebeck, Germany; *[2]Robert-Bosch-Krankenhaus, Stuttgart, Germany*; *[3]Klinikum Nuernberg, Nuernberg, Germany*; *[4]Allgemeines Krankenhaus, Celle, Germany*; *[5]Klinikum Idar-Oberstein, Idar-Oberstein, Germany*; *[6]DRK Kliniken Berlin | Westend, Berlin, Germany*

Background: Takotsubo cardiomyopathy (TTC) has increasingly been recognized over the past years. Most studies, however, are fairly small. A German TTC registry has been initiated to further characterize this syndrome in a larger patient population.
This study evaluated the incidence and clinical relevance of ventricular arrhythmias (VA) and atrial fibrillation (AF) as a complication of TTC.
Methods: From 37 heart centres, 324 pts (296 f, 28 m, age 68 ± 12) were included according to the following criteria: 1) acute chest symptoms, 2) ischemic ECG changes, 3) reversible LV akinesia not corresponding to a single coronary artery territory, 4) absence of coronary artery stenoses. During hospitalisation, 7/324 pts (2.2%) died (cardiogenic shock n=4; myocardial rupture, stroke and asystole n=1 each).
Results: During the first 48 hours, 209 pts were continuously monitored and had daily ECG recordings. Ventricular tachycardia and/ or ventricular fibrillation was documented in 17 pts (8%) and newly diagnosed AF in 32 pts (15%). TTC pts with and without arrhythmias were compared.
In pts with VA, time from symptom onset to hospital admission was shorter (3.8 ± 3.2 vs 8.7 ± 7.3 hours, $p < 0.001$). Pulmonary oedema (29% vs 12%, $p < 0.05$), need for intraaortic balloon pumping (6% vs 0.5%, $p < 0.05$) or resuscitation (18% vs 3%, $p < 0.002$) and left ventricular thrombi (12% vs 3%, $p = 0.05$) were seen more frequently. The QTc interval was only slightly more prolonged (476 ± 45 vs 470 ± 55 ms day 1, 521 ± 80 vs 510 ± 57 ms day 2, 533 ± 93 vs 508 ± 60 ms day 3, all p = ns). Heart rate and other ECG parameters (ST- segment elevation, T- wave inversion, Q waves) were similar. Regarding age, sex, symptoms, trigger events, cardiac markers, ejection fraction, ballooning pattern, pre- and acute medication and mortality there was no significant difference among pts with and without VA.
Pts with AF frequently were on a pre-medication with diuretics (50% vs 12%, $p < 0.005$), had a lower ejection fraction (45 ± 14% vs 52 ± 15%, $p < 0.02$) und presented more frequently with pulmonary oedema (25% vs 11%, $p < 0.05$) and cardiogenic shock (16% vs 5%, $p < 0.05$). Age, sex, symptoms, trigger events, cardiac markers, ECG changes, ballooning pattern, pre- and acute medication other than diuretics, and mortality were not significantly different among pts with and without newly diagnosed AF.
Conclusion: During the acute phase of TTC, ventricular arrhythmias are observed in 8% and atrial fibrillation in 15%. Patients with arrhythmias have a more complicated clinical course, however, mortality is not increased.

P358

Life threatening ventricular arrhythmias in patients hospitalized for acute heart failure

Cl Radulescu[1]; L Antohi[1]; M Chivulescu[1]; I Cosei[1]; R Radu[1]; A Covaliov[1]; A Ambrosy[2]; C Macarie[1]; M Gheorghiade[3]; O Chioncel[1]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; *[2]Duke University Medical Center, Cardiology, Durham, United States of America*; *[3]Northwestern University, Cardiology, Chicago, United States of America*

Background: During hospitalization for acute heart failure (AHF), some patients may experience life-threatening ventricular arrhythmias, including sustained ventricular tachycardia (sVT) and ventricular fibrillation (VFib), placing them at high risk of in-hospital mortality.
Aim: To identify clinical variables independently associated to incidence of sVT/VFib during hospitalization for AHF.
Methods: The Romanian AHFS (RO-AHFS) registry prospectively enrolled 3224 consecutive patients admitted for AHF in 5 academic and 8 community hospitals, over a 12-month period. A multivariate logistic regression model was developed to identify baseline clinical variables predictive of incident sVT/VFib.
Results: During hospitalization for AHF, the incidence of sVT and VFib was 3.6% and 3%, respectively. Patients who experienced sVT/VFib had higher in-hospital mortality compared to patients who did not (24.8% vs 5.7%; $p < 0.001$). The incident sVT/VFib was associated to in-hospital mortality in the whole cohort (HR=3.82;95%CI=1.59-5.21) and this association has been maintained event after adjustment by 18 baseline clinical variables (HR=2.60; 95%CI= 1.03-6.75). Patients who experienced sVT/VFib in a ICU/ICCU setting had a lower mortality compared to patients who had arrhythmias on regular ward (21.5% vs 26.7%; $p = 0.03$). Using a multivariate logistic regression model, creatinine at admission (HR=1.06;95%CI= 1.03-1.11), diabetes (HR=1.20;95%CI= 1.09-1.35), EF < 40% (HR=1.64;95%CI= 1.53-1.72), without beta-blocker at admission (HR=1.79;95%CI= 1.63-1.85), history of previous revascularization (HR=1.91;95%CI= 1.82-2.05) , need of inotropic agents (HR=2.70;95%CI= 1.93-3.65) were found to be independent risk factors for incident sVT/VFib during hospitalization.
Conclusions: Clinical variables commonly measured at the time of admission may help to identify at-risk patients for VT/VFib during hospitalization. Early disposition decision-making, as well as intense monitoring may help to prevent mortality in this group of patients.

P359

Left atrial remodeling and ventricular-arterial coupling in patients with recurrent atrial fibrillation: effects of amiodarone and sotalol

A Shavarov[1]; EV Kokhan[2]; GK Kiyakbaev[1]; VS Moiseev[1]
[1]RUDN University, Moscow, Russian Federation; *[2]Lomonosov Moscow State University, Moscow, Russian Federation*

Background: Impaired left ventricular-arterial coupling (VAC) might lead to diastolic dysfunction (DD) and therefore structural and functional changes of the left atrium (LA) that are substrate for atrial fibrillation (AF). The effects of amiodarone and sotalol on LA remodeling and VAC parameters remain unclear.
Purpose: To compare the effects of amiodarone and sotalol on LA remodeling and VAC parameters in patients with recurrent AF and preserved left ventricular systolic function.
Methods: The study included 60 hypertensive patients [45% male, median age 65 (61; 72) years] with paroxysmal and persistent AF and preserved left ventricular systolic function. The patients were treated with amiodarone (A) 200 mg + metoprolol 50 mg daily (n = 30) or sotalol (S) 160 mg daily (n = 30). All the patients underwent echocardiography and speckle tracking analysis before and 3 months after treatment. Global peak LA longitudinal strain (PALS) and strain rate (PALSR) in the reservoir (r) and contractile (c) phases were assessed using 6 segments in the 4-chamber and 2-chamber views. To estimate VAC arterial elastance index (Eal), left ventricular end-systolic elastance index (Eesl), Ea/Ees, systemic vascular resistance index (SVRI) and total arterial compliance (TAC) were calculated.
Results: A and S had comparable favorable effect on most clinical and echocardiographic parameters. Both A and S significantly reduced Eesl (from 1.41 to 1.25 and from 1.7 to 1.6 mm Hg/ml/m^2, respectively, p for all < 0.001) and increased TAC (from 1.15 to 1.35 and from 1.11 to 1.40 ml/mm Hg, respectively, p for all < 0.001). There were no significant changes in Eal and SVRI in A and S groups. The reduction of LA size was significantly greater in A group compared to S group (: -2.0 vs

-1.1 mm, p = 0.02). Both A and S similarly improved PALSRc (: -0.23 vs -0.28 1/s, p = 0.35) that was independently associated with the efficacy of antiarrhythmic therapy.
Conclusion: A comparable change in VAC parameters was observed in both groups. Amiodarone and sotalol had comparable antiarrhythmic effect due to similar influence on PALSRc. The effect of amiodarone on LA reverse remodeling was, however, more favorable.

ATRIAL FIBRILLATION

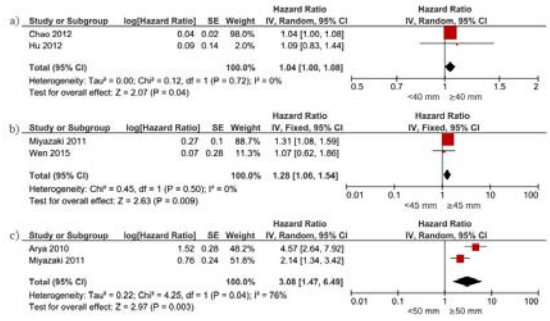
Left atrial size as predictor of recurrences after catheter ablation in paroxysmal atrial fibrillation: a systematic review and meta-analysis

I Ibadete Bytyci[1]; G Bajraktari[1]; MY Henein[2]
[1]University Clinical Centre of Kosova, Clinic of Cardiology, Pristina, Kosovo Republic of; *[2]Umea University, Department of Public Health and Clinical Medicine, Umea, Sweden*

Background and Aim: Left atrial (LA) enlargement is associated with paroxysmal atrial fibrillation (PAF) incidence and outcome. The predictive role of the LA size in AF treatment with catheter ablation is still controversial. The aim of this meta-analysis was to analyze the potential association between LA diameter in patients with PAF undergoing ablation and AF recurrence after ablation.
Methods: We systematically searched PubMed-Medline, EMBASE, Scopus, Google Scholar and the Cochrane Central Registry, up to December 2016 in order to select clinical trial and observational studies, which assessed the predictive role of LA diameter in AF recurrence after catheter-ablation. 2962 patients from 16 studies with paroxysmal AF (PAF) were included.
Results: The pooled analysis showed that after a follow-up period of 19. 66 ± 8.31 months, patients with AF recurrence had larger LA size compared with those without AF recurrence, with a weighted mean difference (WMD) 2.31 ([95% CI 1.27 to 3.34], P < 0.0001).
LA diameter ≥40 mm predicted AF recurrence HR:1.04 [95% CI 1.00 to 1.08], P=0.04), but the best cut-off value, in all included patients, was ≥50mm HR:3.08 [95% CI 1.47 to 6.49], P=0.003).
Conclusions: Enlarged left atrium in patients with PAF undergoing catheter ablation predicts recurrences. The diameter more than 50 mm is the best cut-off of the recurrences of AF, but diameter of 40 mm also can predict recurrences in these patients.



Multivariate HR (Hazard ratio) of AF rec

P361
Step by step treatment of patients with congestive heart failure and long-standing persistent atrial fibrillation using combining of crt and catheter ablation

E Zhelyakov[1]; A Ardashev[1]; A Kocharyan[1]; Y Belenkov[1]
[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation

Aim: to assess clinical results of combining CRT-D and catheter ablation in long-standing persistent atrial fibrillation (AF) pts with congestive heart failure (HF) and reduced ejection fraction (EF).
Material and methods: We studied 8 consecutive patients (2 women, 51.4 ± 13.6 years of age) with long-standing persistent AF, congestive HF who underwent CRT-D placement as the first step of treatment. After CRT-D placement biventricular pacing mode (VVI from 70 to 85) was activated and rate control drugs dose was titrated. As the second step all patients underwent catheter ablation (RFA) for AF 3 mos. later. The ablation performed using 3D mapping system and included antral isolation of the PVs with additional left atrial linear ablation of the roof, mitral isthmus and substrate modification of the left atrium posterior wall. Switch of mode pacing from biventricular VVI to DDD was performed at the end of procedure after sinus rhythm restoration. Follow up included repeat echocardiography, device interrogation with percent of pacing and ventricular events checks, NYHA HF functional class (FC) evaluation at baseline and at months 3, 6, and 12.
Results: At the first step there were no complications associated with CRT-D implantation. At the 3 month of follow up the NYHA FC improved from 3.1 ± 0.4 to 2.3 ± 0.6, percent of biventricular pacing ranged from 72 to 99 (mean 88 ± 7%). Echocardiography showed a mean LV EF of 32.9 ± 7.5%, an increase from a baseline of 29.2 ± 7.8%. There were no complications associated with RFA of AF. At 6 months of follow up 6 of 8 pts were free from AF. Two pts had 3 episodes of AF which required external cardioversion performing. NYHA FC improved from 2.3 ± 0.6 to 1.9 ± 0.6, a mean LV EF increased from 32.9 ± 7.5% to 42.1 ± 4.8%. At 12 months of follow up 5 of 8 pts were free from AF. Three pts had 7 episodes of AF which required external cardioversion performing (3 pts) and redo ablation of AF (2 pts). NYHA FC improved from 1.9 ± 0.6 to 1.6 ± 0.6 to, a mean LV EF increased from 42.1 ± 4.8% 45.6 ± 5.2%. Device interrogation showed 5 episodes of nonsustained ventricular arrhythmias (1 episodes of ventricular fibrillation and 4 episodes of ventricular tachycardia) without therapy in 2 pts during all period of follow up.
Conclusion: Combining CRT-D and catheter ablation in patients with congestive HF and long-standing AF may be reasonable approach, although there is little data supporting its use.

P362
Maze III procedure in patients with heart failure, atrial fibrillation and valve disease.

AA Kulikov[1]
[1]Cardiology Research and Production Center, Moscow, Russian Federation

Research objective: To estimate effectiveness of Maze III procedure combined with a mitral valve operation in patients with heart failure and long-standing atrial fibrillation.
Methods: In the study were included 100 adult patients (48 men) with heart failure, persistent and longstanding persistent forms of AF and valvular pathologies. Average age of patients was 59 years. Average AF duration was 4 years.
Functional class of heart failure on NYHA 2,7 ± 0,75. The size of the left atrium 5,1 ± 1,5 cm, average left ventricular ejection fraction 61 ± 8,6%.
Antiarrhythmic therapy was tried to all patients, however it was inefficient.
All patients had mitral valve pathology. Also 80% of patients had the tricuspid valve insufficiency.
To all patients the electric cardioversion was made. After restoration of a sinus rhythm, the EP was executed. Then, on the first or second day after EP, correction of valve pathologies combined with "Maze III" procedure was carried out.
Results: Following the results of Maze III procedure combined with correction of valve disease, disposal of AF was observed in 95% of patients. 46% of patients had stable sinus rhythm to the moment of discharge from the hospital. 24% of patients had atrial rhythm with the maximum heart rate of 80-110 bpm (according to results of 24-hour Holter monitoring). For 25% of patients, it was necessary to implant a pacemaker. According to results of EP study, 13% of these patients suffered from sick sinus syndrome before operation. For 9% of the remaining 12% of patients, the indications for pacemaker implantation were atrioventricular nodal rhythm with low heart rate and pauses more than 3 sec long. For 1% of patients the indication was second degree AV block (type 2) and second degree SA block (type 2); for 1% the indication was complete heart block, and for 1% it was atrial rhythm and pauses more than 3 sec long.
13% of patients with an atrial rhythm and normal heart rate developed typical atrial flutter (AFL) in the early postoperative period. For all of them the RF catheter ablation with linear ablation of the right atrial isthmus and creation of isthmus block was effective, and further recurrence of AFL was not observed.
Conclusions: In the early postoperative period Maze III procedure combined with a mitral valve operation proved to be an effective surgical technique of treatment of persistent and long-standing persistent forms of AF in patients with heart failure. NYHA class II heart failure was not an obstacle for surgical treatment of AF.

P363

A new predictor of atrial fibrillation after coronary artery bypass graft surgery: HATCH score

M Mithat Selvi[1]; H Gungor[1]; C Zencir[1]; S Gulasti[1]; M Akpek[1]; U Eryilmaz[1]; C Akgullu[1]
[1]*Adnan Menderes University, Cardiology, Aydin, Turkey*

Background: The aim of this study was to investigate the association between HATCH score and atrial fibrillation (AF) after coronary artery bypass graft (CABG) surgery.
Methods: 369 patients (103 patients with AF and 266 patients without AF) undergoing isolated CABG surgery were analyzed. Complete medical records were retrospectively collected to investigate HATCH score.
Results: The median age of patients with AF was significantly higher than the median age of sinus rhythm group (60.8 ± 10.0 years vs. 67.8 ± 9.5 years, p < 0.001). HATCH score was significantly higher in patients who developed AF after CABG surgery than the sinus rhythm group (p = 0.017). Multivariate logistic analysis showed that, HATCH score [odds ratio (OR): 1.334; 95% confidence interval (CI), 1.022-1.741, p = 0.034] was independent predictor of AF after CABG surgery (Table 1). Receiver operating characteristic curve analysis showed that the cut-off point of HATCH score related to predict AF was 1, with a sensitivity of 42% and specificity of 70%.
Conclusion: Patients with elevated preoperative HATCH score may have higher risk for AF after CABG surgery.

1

Variables	Adjusted OR*	95% CI*	p value

Results from a comparison of cryoballoon vs radiofrequency ablation using carto 3 system for paroxysmal atrial fibrillation, (the first algerian experience af ablation with

DR Bouame[1]; DR Tebache[1]
[1]*Central Hospital of the Army, Algiers, Algeria*

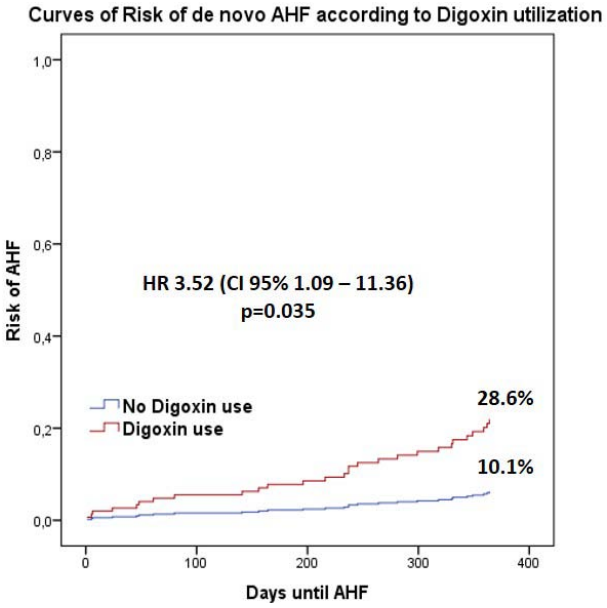
Introduction: Cryoballoon ablation has emerged as a new alternative for the treatment of symptomatic drug-refractory atrial fibrillation (AF) , comparative data of early recurrence rates of atrial fibrillation (ERAF) following second-generation cryoballoon (CB-G2) and radiofrequency current (RFC, using the carto 3 system with smartouch) ablation for pulmonary vein isolation (PVI) in paroxysmal AF (PAF) are rare. We randomized PAF patients into either PVI with CB-G2 (group 1) or PVI with a combined RFC-approach applying contact force (CF, smartouch) with the endpoint of unexcitability (group 2) to investigate ERAF (for a duration of six months).
Methods: In group 1 (n = 19), CB-G2-PVI was performed. After CF-PVI in group 2 (n = 15), bipolar pacing on the ablation line and additional ablation until unexcitability was conducted. Follow-up included 72 h of in-hospital monitoring followed by 15-day Holter ECGs (24h) 3, and 6 months, , post ablation to evaluate ERAF.
Results: Acute PVI was reached in 98% of group 2 and in 97% of group 1. Shorter procedure durations (114.5 ± 13.9 vs. 167.3 ± 18.7 min, P < 0.05) but extended fluoroscopy times (22.5 ± 11,5min vs. 17.5 ± 10.3 min, P < 0.05) were found in the CB-G2 group. Six non-severe complications occurred (4 vs 2 in group 1 and 2, P = 0.73). In group 2, three patients suffered from ERAF vs. three patients in group 1 (P = 0.67). The time until the occurrence of ERAF was shorter in group 2 when compared with group 1 (P = 0.025).
Conclusion: ERAF rates were equal among groups at six months; however, they occurred earlier in the initial phase (the first month) after RFC ablation when compared with CB-G2 (the third month). PVI utilizing cryoablation is associated with shorter procedure durations but extended fluoroscopy time while being similarly secure.
We acknowledge an absence of superiority in the efficiency and safety of one technique compared to another.

P365

Chronic digoxin utilization in patients with atrial fibrillation is associated with hospitalization for de novo acute heart failure

J B Augusto[1]; M Borges Dos Santos[1]; D Roque[1]; D Faria[1]; H Ferreira[1]; J Urzal[1]; C Santos[2]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal*; [2]*Hospital Santo Andre, Leiria, Portugal*

Background: The treatment of atrial fibrillation (AF) is complex. There are conflicting data regarding the effects of digoxin used for rate control in these patients.
Purpose: We aimed to evaluate the incidence of hospitalization for de novo acute heart failure (AHF) at 12-month follow-up in patients with atrial fibrillation who were under digoxin therapy.
Methods: We included retrospectively 2181 consecutive patients with AF who were evaluated in our Emergency Department (ED) in a 12 month period. Among them, 423 patients were admitted for in-hospital management. Patients who had previous known heart failure (n = 101) were excluded. We determined the proportion of digoxin prescription at discharge. Primary outcome was the incidence of hospitalization for de novo AHF 12 months after discharge.
Results: We included 253 AF patients who were successfully discharged and followed for 12 months (mean age of 70.7 ± 12.6 years, 37.5% males). A total of 5.9% (n = 15) had digoxin prescribed at discharge. Kaplan-Meier analysis (Figure) showed that patients with AF who were taking digoxin had a higher incidence of de novo AHF 12 months after discharge (28.6 vs. 10.1%; log-rank p = 0.027). Multivariable Cox regression analysis controlled for age, gender, systemic hypertension, diabetes mellitus, pattern of AF (paroxysmal or non-paroxysmal), successful cardioversion at discharge, CHA2DS2VASc score, chronic kidney disease and glomerular filtration rate at discharge showed that digoxin therapy was an independent predictor of de novo AHF (HR 3.52; CI 95% 1.09 – 11.36; p = 0.035). There was a trend towards a higher mortality rate 12 months after discharge in AF patients taking digoxin (26.7 vs. 10.5%; p = 0.079).
Conclusions: Digoxin may be harmful in AF patients, as it is associated with hospitalization for de novo AHF, as well as a tendency towards higher mortality. This finding could have an impact on the management of patients with AF who are at risk of developing heart failure.



Risk of de novo AHF

P366

Why don't beta-blockers work in patients with heart failure and atrial fibrillation? Pauses?

Y Mareev[1]; AR Lyon[1]; R Lane[2]; P Rogers[2]; C Butcher[1]; R Smith[2]; J Cleland[1]
[1]*Royal Brompton & Harefield Hospitals, Imperial College, London, United Kingdom*; [2]*Royal Brompton & Harefield NHS Foundation Trust, London, United Kingdom*

Funding Acknowledgements: Dr Mareev received ESC HFA research fellowship grant

Background: Recent analyses suggest that patients with heart failure and a reduced left ventricular ejection fraction (HFrEF) who are in atrial fibrillation (AF) do not benefit from beta-blockers. This might be because the benefits of beta-blockers are offset by induction of arrhythmias, particularly pauses.
Aim: To quantify, in patients with heart failure who are either in sinus rhythm (SR) or AF, the burden of brady- and tachy-arrhythmias and provide insights into the relationship between them and heart rate measured at clinic.
Methods: Ambulatory patients with symptomatic chronic heart failure treated with loop diuretics but with no implanted device were invited to wear a patch to record

their ECG for up to 14 days. Baseline differences between those with AF and SR were made using Mann–Whitney U or Fisher's exact tests. The primary endpoint was a composite; bradycardia ≤30bpm for ≥ one minute; high-degree atrioventricular (AV) block; pauses ≥3 seconds; average of >1,000 ventricular ectopics beats per day; ventricular tachycardia (VT) with ≥100 bpm for ≥5 beats.
Results: Patients were predominantly in NYHA class II with a median LVEF of 37%; 30 were in AF and 47 in SR. Patients with AF were older (77 vs. 68 years), had higher heart rate (73 vs. 64 bpm) and were less likely to receive beta-blockers (53% vs. 87%) and ACEi/ARA (70% vs.96%) and more likely to receive digoxin (43% vs. 4%). The median duration of monitoring was similar between groups (331 hours). Of patients in AF, 23 (77%) met the primary endpoint compared to 22 (47%) in SR ($p = 0.02$). Compared to patients in SR, more patients in AF had pauses (20% vs. 2%, $p = 0.01$) or heart rate <30bpm (6% v 0%). The median clinic heart rate for those with AF and pauses was 70bpm (IQR: 67-76) bpm. The rate of brady-related VT was similar in AF and SR (6.6% vs. 8.5%; $P = 1.0$). One patient in SR developed an idio-ventricular rhythm at 40bpm during recording, then symptomatic VT and ventricular fibrillation from which they were resuscitated.
Conclusions: Although patients with heart failure and AF have higher clinic heart rates than those in SR, they have a high incidence of brady-arrhythmias, some of which are followed by episodes of VT. Whether this accounts for the failure of beta-blockers to improve prognosis in patients with HFrEF requires further research.

Pregnancy in women with hypertrophic cardiomyopathy: data from the European Society of Cardiology initiated Registry of Pregnancy and Cardiac disease (ROPAC)

S Sorel Goland[1]; IM Van Hagen[2]; G Elbaz-Greener[3]; U Elkayam[4]; A Shotan[5]; WM Merz[6]; SC Enar[7]; IR Gaisin[8]; PG Pieper[9]; MR Johnson[10]; R Hall[11]; A Blatt[3]; JW Roos-Hesselink[2]
[1]Kaplan Medical Center, Rehovot, Israel; *[2]Erasmus MC, Rotterdam, Netherlands*; *[3]Assaf Harofeh Medical Center, Zerifin, Israel*; *[4]University of Southern California, Los Angeles, California, United States of America*; *[5]Hillel Yaffe Medical Center, Hadera, Israel*; *[6]University Bonn Medical School, Bonn, Germany*; *[7]Turkiye Hospital, Istanbul, Turkey*; *[8]Izhevsk State Medical Academy, Izhevsk, Russian Federation*; *[9]University Medical Center Groningen, Groningen, Netherlands*; *[10]Imperial College School of Medicine, Chelsea and Westminster Hospital,, London, United Kingdom*; *[11]Norwich Medical school, University of East Anglia, Norwich, London, United Kingdom*

Aims: We report the maternal and fetal outcomes at birth and after 6 months in a cohort of pregnant women with hypertrophic cardiomyopathy (HCM).
Background: Although most women with HCM tolerate pregnancy well, there is an increased risk of obstetric and cardiovascular complications.
Methods: All pregnant women with HCM entered into the prospective worldwide Registry of Pregnancy and Cardiac disease (ROPAC) were included in this analysis. The primary endpoint was a major adverse cardiovascular event (MACE), which included death, heart failure (HF), thromboembolic event and arrhythmia. Baseline and outcome data were analysed and compared for patients with MACE versus without MACE and for patients with obstructive HCM versus non-obstructive HCM.
Results: Sixty pregnant women (mean age 30.4 ± 6.0 years) with HCM (41.7% obstructive) were included. No maternal mortality occurred in this cohort. In 14 (23%) patients at least one MACE occurred: 9 (15.0%) HF and 7 (12%) an arrhythmia (6 ventricular and 1 atrial fibrillation). MACE occurred most commonly during the 3rd trimester and postpartum period. In total, 3 (5.0%) women experienced fetal loss. Women with MACE had a higher rate of emergency Caesarean delivery for cardiac reasons (21.4% vs. 0%, $p = 0.01$). No significant differences in pregnancy outcome were found between women with obstructive and non-obstructive HCM. NYHA functional class of ≥ II and signs of HF before pregnancy, were associated with MACE.
Conclusions: Although most women with HCM tolerated pregnancy well, cardiovascular complications were not uncommon and predicted by pre-pregnancy status facilitating pre-pregnancy counselling and targeted antenatal care.

P368
Serum NT-probrain natriuretic peptide and high-sensitivity cardiac troponin I levels in carriers of myosin-binding protein C founder mutation

G Gunnar Thor Gunnarsson[1]; B Adalsteinsdottir[1]; CY Ho[2]; BJ Maron[3]; MA Burke[4]; R Danielsen[5]; JG Seidman[4]; CE Seidman[4]
[1]University of Iceland, Faculty of Medicine, Akureyri, Iceland; *[2]Brigham and Women's Hospital, Department of cardiology, Boston, United States of America*; *[3]Minneapolis Heart Institute Foundation, The Hypertrophic Cardiomyopathy Centre, Minneapolis, United States of America*; *[4]Harvard Medical School, Department of Genetics, Boston, United States of America*; *[5]Landspitali University Hospital, Reykjavik, Iceland*

On behalf of: The Icelandic HCM project

Background: Increased levels of serum NT-probrain natriuretic peptide (NT-proBNP) and cardiac troponins have been observed in patients with overt hypertrophic cardiomyopathy (HCM) and are associated with various clinical features such as severity of left ventricular hypertrophy (LVH), symptoms of heart failure and degree of fibrosis. Additionally NT-proBNP concentration predicts overall prognosis and survival in HCM. However, limited data exists on the role of cardiac biomarkers in sarcomere mutation carriers with normal left ventricular (LV) wall thickness.
Purpose: The aim of this study was to determine if serum NT-proBNP and high-sensitivity cardiac troponin I (hsTNI) may play a role as markers of LV remodeling in MYBPC3 mutation carriers before the development of LVH.
Methods: In total of 290 genotyped individuals were studied from Icelandic families with the MYBPC3 c.927-2A>G founder mutation. Subject were divided into 3 groups based on genotype status and the presence or absence of LVH (≥12mm). NT-proBNP and hsTNI levels were compared between 60 genotype-positive individuals without LVH (G+/LVH-; age 33 ± 17), 108 genotype-positive with LVH (G+/LVH+; age 52 ± 17), and 122 healthy control relatives (G-/LVH-; age 41 ± 18).
Results: A stepwise increase in mean NT-proBNP levels was observed between groups; 37.5 ± 1.09 pg/mL in controls, 65.3 ± 1.1 pg/mL in G+/LVH- subjects and 179 ± 1.14 in G+/LVH+ (values expressed as means + SE, adusted for age and gender; $p < 0.0001$ between each group). However, there was a substantial overlap in NT-proBNP levels between the G+/LVH– and control groups. In G+/LVH+ subjects, hsTNI was significantly higher (5.46 ± 1.12 pg/mL) compared to the other groups. There was not a significant difference in hsTNI levels between G+/LVH- subjects (1.71 ± 1.24 pg/mL) and controls (1.26 ± 1.11 pg/mL; $p = 0.113$).
Conclusions: Higher concentration of NT-proBNP in G+/LVH- subjects compared to controls may reflect early LV remodeling process in HCM. A follow-up study is needed to determine if serum concentrations of NT-proBNP in genotype-positive individuals can predict the risk of developing LVH.

P369
Echocardiographically estimated pulmonary artery systolic pressure predicts progressive heart failure and systemic embolic events in patients with hypertrophic cardiomyopathy

K Kanbayashi[1]; S Shintaro Haruki[1]; Y Minami[1]; R Maeda[1]; K Haruki[1]; R Itani[1]; A Suzuki[1]; T Suzuki[1]; K Ashihara[1]; T Shiga[1]; N Hagiwara[1]
[1]Tokyo Women's Medical University, Cardiology, Tokyo, Japan

Background: Echocardiographically estimated pulmonary artery systolic pressure (PASP) is a non-invasive widely available method that is used to estimate pulmonary arterial pressure. Although elevated PASP predicts mortality in patients with hypertrophic cardiomyopathy (HCM), the details of adverse events is not available. This study aimed to determine whether elevated PASP is predictive of progressive heart failure and systemic embolic events in a tertiary referral HCM cohort.
Methods: This study included 374 clinically diagnosed patients with HCM. PASP was estimated from tricuspid regurgitant jet velocity using the modified Bernoulli equation at the initial evaluation.
Results: The median (interquartile range) PASP was 33 (28–37) mm Hg, and elevated PASP (>40 mm Hg) was observed in 66 (17.6%) patients. Patients with elevated PASP had a higher proportion of female sex, were more likely to have atrial fibrillation, and had a larger left atrial dimension than those without elevated PASP (≤40 mm Hg). Twenty of the 66 (30.3%) patients with elevated PASP and 30 of the 308 (9.7%) patients without elevated PASP experienced episodes of progressive heart failure with an increase to ≥3 New York Heart Association functional class ($P < 0.001$). In addition, 17 of the 66 (25.8%) patients with elevated PASP and 24 of the 308 (7.8%) patients without elevated PASP experienced stroke and systemic embolic events during the 10.3 ± 7.4 years of follow-up ($P < 0.001$; Figure). Multivariable analysis showed that PASP >40 mm Hg was independently associated with progressive heart failure (adjusted odds ratio, 2.08; P=0.049) and embolic events (adjusted hazard ratio, 2.66; P=0.008).
Conclusions: PASP estimated by Doppler echocardiography could help risk stratification for progressive heart failure and embolic event in patients with HCM.

Characterization of circulating miRNA21 in young and elderly patients with symptomatic hypertrophic cardiomyopathy

VG Victoria Davydova[1]; TG Bezhanishvili[2]; EN Semernin[1]; AA Poliakova[1]; S Pyko[3]; EV Kiseleva[2]; AA Zakharenco[2]; MI Zaraiskii[2]; AY Gudkova[2]
[1]Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation; *[2]Saint Petersburg Pavlov State Medical University, Saint Petersburg, Russian Federation*; *[3]Saint Petersburg Electrotechnical University "LETI", Saint Petersburg, Russian Federation*

Background: The level and function of circulating miRNA21 in genetic cardiac diseases have been studied not enough.
Aim: Our aim was to study the level of circulating miRNA21 in patients with familial hypertrophic cardiomyopathy (HCM) in different age groups.
Methods: 72 individuals were examined. The study group included 27 probands with HCM at the age 19 - 70 years (45,67 ± 3,23 years). The diagnosis of HCM was established according to the guideline of the European society of cardiology on the diagnosis and treatment of HCM, 2014. The control group included 45 healthy donors without cardiovascular diseases and other severe pathologies, matched by age and sex with the studied group. Total RNA was extracted from plasma of patients. miRNA21 and reference RNA U6 cDNA was prepared based on StemLoop-technology. Expression was examined using semiquantitative RT-PCR protocol. Calculation of the relative gene expression level of miRNA21 was done according to the standard procedure 2-ΔCt.
Results: The level of the miRNA21 in the group of patients with HCM compared to control group ranged from 0.66 to 337,79 (37,73 ± 13,51) versus from 0.01 to 9,85 (1,84 ± 0,40), p < 0.001, respectively. 16 patients had symptomatic HCM and in 11 cases there was diagnosed asymptomatic HCM. In patients with symptomatic HCM the level of miRNA21 compared to asymptomatic HCM ranged from 1.87 to 337,79 (57,87 ± 21,46) versus from 0.66 to 45,25 (8,45 ± 3,85), respectively. Elevated levels of circulating miRNA21 were found in patients with symptomatic HCM (p < 0,004). Patients with symptomatic HCM were divided into 2 subgroups: 1 — young patients at the age from 19 to 43 (30,56 ± 3,09); 2 - elderly patients at the age from 51 to 68 (63,14 ± 2,38). The main symptoms in young patients were dizziness, syncope, ventricular arrhythmia (III-V class according to Lown classification). The risk of sudden death corresponded to the intermediate and high risks according to the 5-year risk of SCD using the HCM Risk-SCD model (a Web-based calculator is provided with the Guidelines, 2014).
The leading syndrome in older patients was heart failure NYHA II-III. In both groups the majority of patients had an adverse cardiac remodeling. In young patients with symptomatic hypertrophic cardiomyopathy the level of miRNA21 ranged from 7 ,46 to 337,79 (83,64 ± 34,61) and it was higher (p < 0.042) than in the group of patients with symptomatic HCM older than 45 years, in which the level of miRNA21 ranged from 1.87 to 119.43 (24,73 ± 15,92).
Conclusion: The significant increase of the level of miRNA21 was found in young patients with HCM with a high risk of sudden cardiac death and adverse cardiac remodeling. Age is an important determinant of the clinical course of the HCM.

P371

Can plasma proteomic profiling differentiate patients with hypertrophic cardiomyopathy from other cardiovascular patients?

R Radek Pudil[1]; S Stulik[2]; H Rehulkova[2]; P Rehulka[2]; A Fucikova[2]; L Horakova[1]
[1]Charles University Prague, Faculty of Medicine in Hradec Kralove, 1st Department of Medicine, Hradec Kralove, Czech Republic; *[2]Faculty of Military Health Sciences, University of Defence, Department of Molecular Pathology and Biology, Hradec Kralove, Czech Republic*

Introduction: Hypertrophic cardiomyopathy (HCM) is a hereditary cardiovascular disease with a prevalence of 1:500. Even if numerous genetic mutations were described and many diagnostic methods are used, some method that could help with early diagnosis would be beneficial. Proteome discovery analysis represents a promising outlook in an effort of identification novel disease specific markers of different cardiovascular diseases.
Purpose: The aim of this study was to compare plasma profiles of patient cohort suffering from non-obstructive HCM and group of healthy donors and also other cohorts of selected cardiovascular diseases: dilated cardiomyopathy (DCM), aortic valve stenosis (AS), chronic stable coronary artery disease (CAD) and stable arterial hypertension (AH). The next aim was to identify disease-unique protein markers that could be potentially used in early diagnosis of HCM.
Methods: In this study were analyzed pooled plasma samples of patient individuals. All these samples were depleted from fourteen most abundant proteins in human plasma. Proteomic labeling with isobaric tags for relative and absolute quantitation (iTRAQ) was applied to all of these samples. Firstly, plasma reduction, alkylation and trypsin digestion was done according the manufacturer's protocol. Secondly, all samples were labeled with iTRAQ reagents and mixed. Sample mixtures were purified and fractionated using reverse phase chromatography with mobile phase buffered at pH = 10. Acidified, evaporated and reconstituted fractions were further submitted to LC-MS/MS analysis using Q-Exactive mass spectrometer.
Results: Out of the high number of identified proteins, 293 proteins showed significant up- or down- regulation at least in one cardiovascular cohort in comparison to control group of healthy donors. We have focused only on 128 disease-uniquely shifted proteins in plasma concentration. More than sixty disease-unique proteins were identified in DCM cohort and almost fifty proteins in AS cohort., and only seven disease-unique markers were detected in HCM group, whereas all of them are related to this disease as was confirmed by the search in the published literature. Both principal component analysis and hierarchical clustering analysis identically divided the disease groups into two main clusters: first involving HCM, AH and control group of healthy donors; second cluster containing DCM, AS and CAD.
Conclusion: The aim of this study was a plasma profiles comparison of selected cardiovascular diseases. Many proteins with significant differences and also proteins with disease-unique plasma profile differences were identified. These proteins are intended to be consequently validated via targeted proteomic analysis and some of these proteins (in case of successful verification) could later serve as potential markers of HCM or other studied cardiovascular diseases.

P372

Heart fatty acid binding protein and glycogen phosphorylase bb are associated with the morphologic and functional parameters in patients with non-obstructive hypertrophic cardiomyopathy

R Radek Pudil[1]; M Vasatova[2]; L Horakova[1]; P Rehulka[3]; H Rehulkova[3]; J Stulik[3]; V Palicka[2]
[1]Charles University Prague, Faculty of Medicine in Hradec Kralove, 1st Department of Medicine, Hradec Kralove, Czech Republic; *[2]University Hospital Hradec Kralove, Institute of Clinical Biochemistry and Diagnostics, Hradec Kralove, Czech Republic*; *[3]Faculty of Military Health Sciences, University of Defence, Department of Molecular Pathology and Biology, Hradec Kralove, Czech Republic*

Background: Hypertrophic cardiomyopathy (HCM) is mostly autosomal dominant disease of the myocardium, which is characterized by myocardial hypertrophy. The association of increased myocardial structural markers and the severity of left ventricle outflow tract obstruction are very well know.
Purpose: The aim of study was to analyze the clinical significance of these markers in structural and functional changes in patient with non-obstructive type of HCM.
Methods: In the group of 47 patients (58.4 ± 12.4 years, 12 females) with non-obstructive HCM, we assessed plasma concentrations of glycogen phosphorylase BB (GPBB), cardiac troponin T (hsTnT) and heart type of fatty acid binding protein (hFABP) and analyzed its association with morphological and functional parameters.
Results: Left ventricle mass was 344.8 ± 129.9 g, and it exceeded reference values for two-dimensional method in all patients. Left ventricle mass index was 171.4 ± 60.2g.m-2, and it exceeded reference values in all patients. The mean of the left ventricle ejection fraction was 67.1 ± 9.9%, and, only in 2 (4%) patients, the LV ejection fraction was below the reference values. Left ventricle fractional shortening was 33.7 ± 8.7, and it exceeded the reference values in 3 (6%) patients. None of the patients had left ventricle outflow tract obstruction. Compared to healthy controls, plasma levels of structural markers were increased [hsTnT: median: 9ng/L (IQR: 5 - 16 ng/L), vs. 7 (5 - 9) ng/L, p 0.03; hFABP: 1.8 (1.4 - 3.3) μg/L vs. 1.6 (1.3 - 2.1) μg/L, p 0.05; GPBB: 3.9 (2.5 - 6.3) μg/L vs. 2.3 (1.9 - 4.2) μg/L, p 0.001]. We found significant association of plasma cardiac markers levels and left ventricle mass index (hFABP: r 0.41, 95% CI: 0.07-0.66, p 0.01; GPBB: r 0.21, 95% CI: 0.12-0.51, p

0.05; hsTnT: r = 0.39, 95%CI: 0.12 - 0.62, p 0.008) and LV ejection fraction (hFABP: r -0.31, 95% CI: -0.57 - -0.02, p 0.05; GPBB: r -0.46, 95% CI: -0.68 - -0.14, p 0.004).
Conclusions: Increased hFABP, GPBB and hsTnT levels are associated with structural and functional parameters in patients with HCM and could serve as a potential tool for diagnostic process of these patients.

P373
Clinical risk factors of new onset atrial fibrillation in patient with hypertrophic cardiomyopathy.

J-H Jung-Hyun Choi[1]; BW Kim[1]; SH Lee[1]
[1]*Busan National University Hospital, Busan, Korea Republic of*

Backgrounds: Atrial fibrillation(AF) is common clinical manifestation of HCMP patients. Prevalence of AF in HCMP patients is known to approximately 20%. There are limited data available to predictive factor of AF in patient of HCMP. The aim of this study is to investigate of clinical risk factor of AF in HCMP patients.
Methods: This study is retrospective observational study. We investigated the HCMP patients who performed echocardiography and had sinus rhythm at presentation (n = 40) from 2011 to 2015 at our national university hospital. We divided into two groups according to newly developed AF during follow up period (AF group: n=40) and maintained sinus rhythm (Sinus group: n=360). AF was defined by electrocardiogram and Holter monitoring at index visit. We compared clinical characteristics and conventional echocardiographic parameter and atrial electromechanical delays. AEMD was defined as the time interval between the onset of ECG P wave and the initial(AEMDi) or peak a' wave(AEMDp) on the medial mitral annular tissue Doppler velocity curve(TDI) or PW Doppler at the mitral valve inflow level.
Results: Compared to sinus rhythm group, new onset AF group had more complained dyspnea. Compared to sinus group, new onset AF group has higher conventional echocardiographic parameter including RVSP(36.58 ± 14.89 vs 31.00 ± 7.99, p = 0.001, LAVI(59.01 ± 24.09 vs 43.58 ± 16.37, p < 0.001, Mitral E velocity(77.03 ± 27.78 vs 61.74 ± 17.56, p < 0.001) and AEMDi (72.07 ± 15.90 vs 63.08 ± 15.43, p = 0.004), AEMDp(152.41 ± 27.59 vs 141.98 ± 15.43. p = 0.022) by PW Doppler. After using multivariate logistic regression, we found that LAVI(OR=1.028[1.006-1.051], p = 0.012), AEMDi by PW Doppler (1.029[1.000-1.059], p = 0.049) are independent predictive factors of new onset AF in HCMP patients.
Conclusion: This observational study shows AEMDi by PW Doppler may have an additional predictive value to LAVI of new onset AF in HCMP patients.

P374
The course of dilated cardiomyopathy, depending on the availability of ECG changes

NA Kurbanov[1]; TA Abdullaev[1]; I A Igor Tsoy[1]
[1]*Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan*

Objective: The study of the clinical and functional status of pts with dilated cardiomyopathy (DCM) with and without pathological changes on ECG.
Methods: The study included 274 pts with DC at the age of 17 to 61 years (mean age 42,9 ± 1,1 years). In addition to the clinical examination all pts underwent ECG, Holter ECG monitoring (HMECG), echocardiogram, 6MWT. All pts were divided into 4 grs. Gr 1 included 47 pts in whom the ECG recorded blockade of the left leg bundle branch block (LBBB). Pts of the 2 gr (44) in the ECG were detected pseudo-Q wave. The 3 gr consisted of 124 pts, which were characterized on the ECG by decreasing of R wave amplitude, a deep S wave in the right leads, and high R wave in the left precordial leads. 4 gr of pts on the ECG were found complete blockade of right bundle branch block (n = 16) or a bundle branch block (44 pts), which were excluded from the study of this fragment.
Results: Source FC HF in the I and II gr was significantly higher than in gr III. (3,5 ± 0,1 and 3,3 ± 0,1 versus 3,1 ± 0,1; p < 0.01). the clinical status of pts found that in gr III. 6MWT parameters were significantly higher (232 ± 9m) than in grs I and II, respectively (196 ± 12 m and 202 ± 11m p < 0.01). A number of indicators, indicating the presence of right ventricular heart failure, such as ascites, peripheral edema were significantly more frequent in the gr with LBBB pseudo Q-wave and ECG changes. Analysis of the parameters of intracardiac hemodynamics revealed an increase in the linear dimensions of the left heart of pts I and II: improving performance of EDD - on 9.2% and 3.2% (both p < 0.01), ESD - on 12.5%, and 5,1% (p < 0.01), while LVEF was lower on 12.1% and 16% (both p < 0.01) in gr I and II, respectively. Analysis of conduction disorders according HMEKG showed that I st. AV block significantly more common in the I and II grs (32% and 39% vs. 12%; p < 0.01), respectively. It should be noted that the progression of heart failure in the 15 pts with AV- blockade of I degree in 4 cases, the AV-conduction violation worsened up to the III degree, requiring pacemaker implantation in the future, in the absence of this kind of dynamics in the other grs. Analysis of the frequency of occurrence of heart rhythm disorders has shown that high grade ventricular arrhythmias were significantly more frequent in gr I and II, amounting to 68% and 77% versus 28.9% (p < 0.01). However, it noted the prevalence of the number of pts with atrial fibrillation in gr III (p> 0.05).
Thus, in pts with dilated cardiomyopathy and LBBB with the presence of the ECG pseudo-Q-wave observed more pronounced destructive changes in the myocardium, as evidenced by the low contractility function, the prevalence of the presence of high grade ventricular arrhythmias and conduction atrioventricular violation and also a high incidence of registration signs of right heart failure compared with pts without the presence of these changes.

P375
Genetic meta-analysis in idiopathic diated cardiomyopathy: can gene expression repositories offer a new insight?

C T Cormac O'connor[1]; M E O'callaghan[2]; D O'hare[1]; T Kiernan[1]
[1]*University Hospital Limerick, Cardiology Department, Limerick, Ireland*; [2]*University of Limerick, Research Department, limerick, Ireland*

Introduction: Despite advances in genetic analysis and the increasing availability of analytical technologies, the genetics of Idiopathic (non-familial) Dilated Cardiomyopathy (DCM) is poorly understood. Microarray analysis allows the simultaneous analysis of up to 40,000 gene products. Public gene expression repositories (PGER) house microarray expression data from over 50,000 individual experiments.
Purpose: To utilise PGERs to identify genetic differences between normal and cardiomyopathic hearts, and use this data to identify dysregulated intracellular pathways.
Methods: Search was conducted differentiating hearts with idiopathic DCM and normal controls. Nine experiments were considered suitable for analysis. Raw genetic expression data was extracted and analysed using R statistical software. Genes that were dysregulated from controls were compared across all nine experiments using de novo visual basic script (VBS) code. Enrichment analysis was conducted using Ingenuity pathway software.
Results: A total of 23,967 genes were dysregulated across all experiments (table 1). Frequency analysis identified genes occuring most commonly across experiments. Enrichment analysis allowed the identification of specific pathways which were observed to become up- and down-regulated in at least 66% (6 out of nine experiments). Pathways which were seen to be up-regulated in DCM have been associated with: 1) Immune cell infiltration effects seen in rheumatoid arthritis, 2) c-AMP signalling, 3) Cardiac B-Adrenergic signalling and , 4) HGF signalling (Figure 1). Pathways down-regulated were 1) PTEN signalling, 2) Protein Kinase A signalling, and 3) the STAT3 Pathway.
Conclusions: PGERs successfully established a genetic consensus in identifying intracellular pathways which have become dysregulated in idiopathic DCM. This novel type of meta-analytical technique shows promise in establishing intracellular aetiology in systemic pathology.

Genes most frequency of dysregulated

Gene	Number of Experiments gene was dysregulated (out of Nine experiments).	Up or down -regulated	Known Intracellular function
LAMB1	9	UP	Laminin B1, extracellular matrix protein
CD14	8	DOWN	Innate immune protein involved with bacterial surveillance
PDE4DIP	8	DOWN	C-AMP mediated immunomodulation
DSC2	8	UP	Cell-cell adhesion protein previously associated with with arrhythmogenicright ventricular dysplasia
HEY1	8	UP	Associated with embryonic cardiovascular development
INSIG1	8	UP	Mediates feedback control of cholesterol synthesis in cells.
KCNAB1	8	UP	Voltage-gated Potassuim channel, shaker-related subfamily.
NAP1L1	8	UP	Nucleosome assembly protein (NAP) family, involved in cell proliferation

Genes most frequency of dysregulated

Clinical significance of excessive myocardial trabeculation in dilated cardiomyopathy patients

A Sousa[1]; T Pinho[2]; O Azevedo[3]; L Lopes[4]; M Campelo[2]; B Moura[5]; A Madureira[2]; F Rocha Goncalves[1]; J Silva Cardoso[1]; E Martins[1]
[1]Faculty of Medicine University of Porto, Porto, Portugal; [2]H. São João, Porto, Portugal; [3]Guimares Hospital, Guimaraes, Portugal; [4]Garcia de Orta Hospital, Lisbon, Portugal; [5]Regional Military Hospital nº1, Porto, Porto, Portugal

On behalf of: FATIMA investigators
Funding Acknowledgements: PTDC/BIM-MEC/0650/2012

Introduction: Left ventricular noncompaction (LVNC) is characterized by extreme morphologic variability and considerable overlap with other cardiomyopathies. Whether LVNC is a distinct pathological entity or a merely an anatomical phenotype shared by different cardiomyopathies remains a matter of debate.
Purpose: The goal of this study is to evaluate the clinical relevance of excessive myocardial trabeculations in dilated cardiomyopathy (DCM) patients.
Methods: We included 80 consecutive idiopathic and familial DCM patients, followed at 5 national referral centers, that underwent a comprehensive CMR study as part of their diagnostic work-up. Ventricular volumes, ejection fraction and mass were measured using dedicated software. Late gadolinium enhancement (LGE) presence, pattern and location were assessed. We compared clinical, electrocardiographic, imagiological and molecular data and outcomes between patients with or without noncompaction criteria at CMR.
Results: Nine patients (11%) fulfilled noncompaction criteria. They presented similar age (47 ± 13 vs 46 ± 12, p = 0.829; at diagnosis 42 ± 8 vs 38 ± 14, p = 0.652), gender (56% males vs 52%, p = 1.000) and identical clinical profile (symptoms at presentation, cardiovascular risk factors, previous hospitalizations, NYHA class, congestion, heart-failure medical therapy, devices, heart transplant and family history of DCM, heart transplant, sudden death or heart failure death – p NS for all comparisons). Mean left ventricular ejection fraction was 32 ± 11% vs 34 ± 11% (p = 0.514) and end-diastolic volume 129 ± 29 mL/m2 vs 127 ± 37 mL/m2 (p = 0.889). LGE was present in similar proportion of patients, although in patients with LVNC, LGE was preferentially located in apical-lateral and apical-anterior segments. There was no difference in any electrocardiographic parameters. At least one genetic variant was found in 44% pts with LVNC vs 19% of those without, although the difference was not statistically significant. At a median follow-up of 32 months (IQR 16), nine patients experienced an adverse event, but the presence of LVNC was not a predictor of those (OR 2.86, 95%CI [0.48-17.0], p = 0.248).
Conclusion: In our series of patients the presence of excessive trabeculations was neither associated with major differences in clinical presentation, molecular profile, functional parameters, nor it was a predictor of worse prognosis. This argues against LVNC being a distinct form of cardiomyopathy or being associated with a more severe form of DCM.

P377

Clinical markers of LMNA-associated DCM and prognostic predictors of life-threatening ventricular tachyarrhythmias

T G Vaikhanskaya[1]; N G Danilenko[2]; L N Sivitskaya[2]; O G Davydenko[2]
[1]Republican Scientific and Practical Center "Cardiology", Minsk, Belarus; [2]Institute of Genetics and Cytology, National Academy of Science, Minsk, Belarus

Lamin-related phenotype of DCM associated with a high risk of sudden cardiac death (SCD) even in the absence of significant dilatation and left ventricular contractile dysfunction.
Purpose: The aim of this study was to evaluate clinical predictors of the LMNA-associated DCM phenotype and non-invasive prognostic markers of life-threatening ventricular tachyarrhythmic events.
Methods and results. The study included 165 patients with DCM who had a heart rhythm disorder and conduction disturbance (aged 49,2 ± 11,5 years; 135/81,8% male; NYHA 2,67 ± 0,45; LVEF 27,6 ± 10,1 %; follow-up 39,7 ± 12,4 months). All patients underwent clinical studies, screening of lamine A/C (LMNA) gene, CPK and NT-proBNP levels definition, neuromuscular investigation. LMNA mutations were detected in 45 (27,3%) patients. As a result of ROC analysis only ECG predictors (PR ≥ 215 ms: AUC 0.987, 95% CI 0.973 - 0.999, p = 0.0001, sensitivity 95 %, specificity 95 %; pathological mTWA test ≥ 25 % : AUC 0.775, 95% CI 0.701 - 0.848, p = 0.0001; QRS ≥ 122 ms: AUC 0.773, 95% CI 0.689 – 0.857, p = 0.0001) were demonstrated a priority predictive significance to assess LMNA-positive phenotype compared to laboratory tests (serum CPK level ≥ 118 u/l: AUC 0.671, 95% CI 0.548 - 0.793, p = 0.009; sensitivity 65%, specificity 69%; NT-proBNP: AUC 0.538, 95 % CI 0.275 - 0.802, = 0.75) and echocardiography parameters (LV GLS: AUC 0.645, 95% CI 0,548 - 0.793, p = 0.092; LVEF: AUC 0.473, p = 0.75). Events of sustained ventricular tachycardia (sVT) and/or ventricular fibrillation (VF), and documented SCD were accepted as a primary endpoints to the multivariate Cox regression model. By analysis independent predictors of life-threatening tachyarrhythmias were revealed such as nsVT episodes (beats ≥5, bpm ≥ 150: HR 2.23; 95% CI 1.03-4.96; p = 0.033) and changes in LMNA gene (missense mutations and/or rs4641, s.1698C>T: HR 1.87; 95% CI, 1.09 - 3. 01; p = 0.02).
Conclusions: Our findings support an important position of genetic research LMNA mutations in DCM patients for an early prediction of adverse clinical outcomes. According to the Cox regression analysis were detected an independent predictors (cumulative effect of the combination identified predictors such as nsVT events and LMNA-positivity: HR 5.23; 95% CI 1.45-16.9, p = 0.013) that should be used to improve the risk-stratification of SCD and optimization of the general management for DCM.

Implantable cardioverter/defibrillators for primary prevention in dilated cardiomyopathy post-DANISH: an updated meta-analysis and systematic review of randomized controlled trials

A Karathanos[1]; G Wolff[1]; Y Lin[1]; M Brockmeyer[1]; S Wolters[1]; B Nowak[2]; A Fuernkranz[1]; H Makimoto[1]; M Kelm[1]; V Schulze[1]
[1]University Hospital Dusseldorf, Department of Cardiology, Pneumology and Angiology, Dusseldorf, Germany; [2]Cardiology Centre Bethanien (CCB), Frankfurt am Main, Germany

Background: Sudden cardiac death (SCD) is frequent in patients with heart failure due to dilated cardiomyopathy (DCM). Implantable cardioverter/defibrillator (ICD) device therapy is currently used for primary prevention. However, publication of the DANISH trial has recently given reason for doubt, showing no significant improvement in all-cause mortality in comparison to contemporary medical therapy.
Methods: We performed a meta-analysis of all randomized controlled trials comparing ICD therapy to medical therapy (MT) for primary prevention in DCM. The primary outcome was all-cause mortality; secondary analyses were performed on sudden cardiac death, cardiovascular death and non-cardiac death.
Results: Five trials including a total of 2,992 patients were included in the pooled analysis. Compared to contemporary medical treatment there was a significant mortality reduction with ICD device therapy (odds ratio (OR) 0.77, confidence interval (CI) 0.64-0.93; p = 0.006). SCD was decreased significantly (OR 0.43, CI 0.27-0.69; p = 0.0004), while cardiovascular death and non-cardiac death showed no differences. Sensitivity analyses showed no influence of amiodarone therapy on overall results. Analysis of MT details revealed the DANISH population to adhere best to current guideline recommendations.. Furthermore, it was the only study including a substantial amount of CRT devices (56%).
Conclusions: Our meta-analysis of all available randomized evidence shows a survival benefit of ICD therapy for primary prevention in DCM. DANISH results suggest an attenuation of this ICD advantage when compared to contemporary medical and cardiac resynchronization therapy. ICD therapy should remain the recommendation for primary prevention of SCD in DCM according to current literature.

P379

Arrhythmogenic phenotype of dilated cardiomyopathy: predictors of life-threatening ventricular tachyarrhythmias

T G Vaikhanskaya[1]; L N Sivitskaya[2]; N G Danilenko[2]; T V Kurushka[1]; O G Davydenko[2]
[1]Republican Scientific and Practical Center "Cardiology", Minsk, Belarus; [2]Institute of Genetics and Cytology, National Academy of Science, Minsk, Belarus

Patients (pts) with dilated cardiomyopathy (DCM) are developing a life-threatening ventricular tachyarrhythmias (VTAs) sometimes in the early stages even in the absence of symptoms of severe heart failure and a free linked with systolic dysfunction. This clinical phenotype is arrhythmogenic and associated with an increased risk of sudden cardiac death (SCD)

The aim of this study was to evaluate a clinical prevalence of arrhythmogenic DCM and identify a non-invasive prognostic predictors of life-threatening ventricular tachyarrhythmic events.

Methods and results. One hundred sixty patients with a recent diagnosis of DCM (aged 47,3 ± 11,4; 132\82,5% male; NYHA 2,35 ± 0,49; LV EF 29,6 ± 9,13%) were comprehensively evaluated and followed for 47,9 ± 12,4 months. Arrhythmogenic DCM phenotype was dened by Holter 24h monitoring ECG (or CRT-D/ICD device interrogation) as at presence ≥1 of the following signs: non-sustained or sustained ventricular tachycardias (nsVT\sVT), ≥1500 premature ventricular contractions/24 hours, and ≥50 ventricular couplets/24 hours. Of the 160 patients, 92 (57,5%) pts demonstrated these criteria. In 45 (28,1%) pts with DCM were identified changes in Lamin A\C gene (LMNA). As a primary end points to the multivariate Cox analysis were accepted a successful resuscitation, ICD-shock, documented SCD, sustained ventricular tachycardia (sVT) or ventricular brillation (VF). By the Cox regression multivariable model analysis criteria as a nsVT (5 beats with HR≥150 bpm: HR 2.24; 95% CI 1.02-5,49; p = 0.029) and LMNA missense mutations (≥ 1 nucleotide changes: HR 1.99; 95% CI, 1.09 - 3.97; p = 0.032) were identified as independent and cumulative predictors (HR 5.63; 95% CI 1.63-17.5, p = 0.011) of life-threatening VTAs.

Conclusions: Thus, more half of DCM patients developed an arrhythmogenic phenotype associated with increased risk of VTAs during follow-up. Independent predictors (a fast nsVT and LMNA missense mutations) predicts a poor prognosis and an increased risk of SCD and therefore to improvement of risk-stratification should be used purposely to select of potential candidates for preventive ICD therapy.

Introduction: Idiopathic dilated cardiomyopathy (IDCM) is a frequent cause of heart transplantation. Potentially valuable blood markers are being sought and low-density lipoprotein receptor-related protein 1 (LRP1) has been linked to the underlying molecular basis of the disease.

Purpose: This study compared circulating levels of soluble LRP1 (sLRP1) in IDCM patients and healthy controls, and elucidated whether sLRP1 is exported out of the myocardium through extracellular vesicles (EVs) to gain a better understanding of the pathogenesis of the disease.

Methods: LRP1 α chain expression was analyzed in samples collected from the left ventricles of explanted hearts using immunohistochemistry. sLRP1 concentrations were determined in platelet-free plasma by enzyme-linked immunosorbent assay. Plasma-derived EVs were extracted by size-exclusion chromatography (SEC) and characterized by nanoparticle tracking analysis and cryo-transmission electron microscopy. The distributions of vesicular (CD9, CD81) and myocardial (caveolin-3) proteins and LRP1 α chain were assessed in SEC fractions by flow cytometry.

Results: LRP1 α chain was preferably localized to blood vessels in IDCM compared to control myocardium. Circulating sLRP1 was increased in IDCM patients. CD9- and CD81-positive fractions enriched with membrane vesicles with the expected size and morphology were isolated from both groups. The LRP1 α chain was not present in these SEC fractions, which were also positive for caveolin-3.

Conclusions: The increase in circulating sLRP1 in IDCM patients may be clinically valuable. Although EVs do not contribute to higher sLRP1 levels in IDCM, a comprehensive analysis of EV content would provide further insights into the search for novel blood markers for these patients.

Association between bisphenol A exposure and dilated cardiomyopathy

M Moustafa Kamal Saad[1]; K Elkhashab[1]; N Elsherbiny[2]; H Ebeid[1]
[1]Fayoum University, cardiology, Fayoum, Egypt; *[2]Fayoum University, community medicine and public health department, Fayoum, Egypt*

Background: Bisphenol A (BPA) has become a common environmental chemical released into food or beverage over time, especially under heat and acidic solutions. BPA exposure also occurs in human through inhalation. Studies have suggested potential links between BPA exposure and diseases including cancer, obesity, diabetes, reproductive disorders, neuroendocrine, immune systems and Cardio-Vascular system disorders. BPA exposure may be a risk factor for a range of CVS abnormalities as cardiomyopathies and cardiac arrhythmias. Aims: This study aimed to determine serum (BPA) concentrations in patients with dilated cardiomyopathy (DCM) as well as the serum level of estradiol and testosterone compared with a healthy control group.

Materials and Methods: Fifty DCM patients and thirty healthy controls subjects were included. A thorough physical examination, ECG and a complete echocardiographic assessment was performed. Serum BPA levels, estradiol and testosterone were measured by using corresponding ELISA Kits. RESULTS: BPA was significantly more detected in the DCM groups than in the normal group (P value = 0.048). Patients with DCM and detected BPA had more significant right side chambers affection (in terms of dimensions and function) and left atrial dilation (P value=0.0001 and 0.05 respectively). Atrial fibrillation was significantly detected in the DCM patients than in the normal group (P value = 0.004). Estradiol level was significantly higher in the DCM patients' than in the normal group. CONCLUSION: Our findings demonstrated that BPA exposure increased in DCM patients compared with healthy controls, which raise the possibility that BPA exposure might be responsible for some of the cases of dilated cardiomyopathy.

prevelance of BPA in the study groups

Variables	Cases(N=50)	Control(N=30)	P-value
BPA (bisphenol A)	N (%)	N (%)	
Detected(found but level not incorporated into the comparison)	12 (24 %)	2 (6.7%)	0.048
Not detected	38 (76 %)	28 (93.3%)

Risk stratification of life-threatening ventricular tachyarrhythmias in patients with dilated cardiomyopathy

T G Vaikhanskaya[1]; O P Melnikova[1]; A V Frolov[1]
[1]Republican Scientific and Practical Center "Cardiology", Minsk, Belarus

The study of prognostic factors of life-threatening ventricular tachyarrhythmias with tightly related sudden cardiac death (SCD) remains the cornerstone issue still.

Purpose: Design of prognostic model to define personalized risk of life-threatening ventricular tachyarrhythmias in patients with dilated cardiomyopathy (DCM) was the aim of this study.

Material and methods. The study enrolled and followed up 53,1 ± 12,6 months 268 pts with DCM (74,6% male, aged 47,2 ± 11,7 years, LVEF 28,7 ± 10,1%; NYHA class 2,7 ± 0,4). We analyzed age, gender, NYHA, 6-MWT, peak VO2, EchoCG, Holter ECG (PVEs, sVT, nsVT, VF), QRS width, device interrogation and high definition ECG (Intecard-7) with assessment of HRT, mTWA, JTd, and QTd. For multivariate ROC analysis and binary logit-regression model as a primary endpoints were accepted SCD documented, successful resuscitation, sustained VT, and CRT-D\ICD appropriated discharges.

Results: Predictors and their cut-off parameters defined as a result of ROC analysis were included in the binary logit regression model (table). As a result binary logit regression analysis of independent risk factors (PVES, sVT, mTWA, HRT, JTd and LV GLS mean) predictive model was constructed (F=31,2; χ2=143,2; p = 0,0001) eventually:

P = 1/(1 + e^(-(7,25-0,38×LV GLS-0,76×PVEs-4,35×nsVT-1,46×JTd-4,28×HRT-5,03 ×mTWA)))

The range of probability of P was divided into the risk level quintiles: 0.5 to 0.6 for low risk; 0.61 to more than 0.91 high risk. Risk grading is presented in Figure 1.The classification matrix demonstrated a high prognostic significance of discriminant function (F=31.2; χ2=143,2; p < 0.0001; sensitivity of 80.8 %; specificity 99.1 %).

Conclusion: The proposed risk stratification allows to classify correctly to 93.9% DCM pts. Non-invasive and an individualized method enable to stratify patients with higher risk of life-threatening VTA by standard clinical investigations (ECG, Echo, Holter ECG) that allows to select of potential candidates for preventive ICD therapy.

Women vs. men in takotsubo cardiomyopathy

M Margarida Oliveira[1]; D Bento[2]; R Santos[3]; MJ Vieira[4]; H Antunes[5]; L Reis[6]; C Ruivo[7]; R Faria[8]; A Marreiros[9]; AR Almeida[10]
[1]Alto Ave Hospital Center, Guimaraes, Portugal; *[2]Faro Hospital, Faro, Portugal*; *[3]Hospital Centre do Tamega e Sousa, Penafiel, Portugal*; *[4]Hospital of Santarem, Santarem, Portugal*; *[5]Hospital Sao Teotonio, Viseu, Portugal*; *[6]University Hospitals of Coimbra, Coimbra, Portugal*; *[7]Hospital Santo Andre, Leiria, Portugal*; *[8]Centro Hospitalar do Médio Ave E.P.E, Vila Nova de Famalicao, Portugal*; *[9]Universidade do Algarve, Ciências Biomédicas e de Medicina, Faro, Portugal*; *[10]Hospital Garcia de Orta, Almada, Portugal*

On behalf of: SUNSHINE

Introduction: Takotsubo cardiomyopathy (TCM) is a cardiac syndrome characterized by transient left ventricular dysfunction in the absence of coronary artery disease. It usually affects postmenopausal women but it can also affect men. Differences between genders regarding TCM are still not clearly defined.
Aim: To determine the differences between men and women regarding clinical presentation, evolution and complications in TCM.
Methods: We performed a multicentre study involving 12 Portuguese hospitals including every patient diagnosed with TCM in the last 12 years. Clinical, electrocardiographic and echocardiographic data were collected and analysed in order to establish the differences between genders. SPSS 23.0 was used for statistical analysis.
Results: We included 234 patients, 24 men and 210 women (168 were postmenopausal). Physical stressor was mainly observed in men (54.2% vs 14.3%, $p < 0.001$) and emotional stressor in women (50% vs 16.7%, $p = 0.002$). Symptoms at presentation were also different between genders, being chest pain more prevalent in females (90.5% vs. 58.3%, $p < 0.001$) and syncope in males (25% vs. 3.3%, $p < 0.001$). Mean follow-up was 33 ± 33months. Mortality was significantly higher in men (20,8% vs 4,8%, $p = 0,002$) and due to cardiac causes in all men and non-cardiac in women ($p = 0,002$).
Conclusion: This study showed significant differences between men and women regarding type of precipitating factor, clinical presentation and prognosis of TCM. Men, compared to women, have more commonly a physical stressor, present more often with syncope and less frequently with chest pain and have higher mortality from cardiac causes.

P384

Development of tachycardia is not related to ejection fraction in patients on clozapine with suspected cardiotoxicity

G George Joy[1]; M Bolstridge[2]; A Porras-Segovia[3]; E Whiskey[2]; S Shergill[2]; C Plymen[4]
[1]King's College Hospital, London, United Kingdom; *[2]South London and Maudsley NHS Foundation Trust, London, United Kingdom*; *[3]University of Granada, Granada, Spain*; *[4]Imperial College Healthcare NHS Trust, London, United Kingdom*

Introduction: Clozapine is the most effective management for treatment-resistant schizophrenia however, its use is limited due to side effects. Tachycardia is a common side effect, although considered relatively benign but, clozapine-associated myocarditis & cardiomyopathy are associated with significant mortality. Patients on clozapine who develop tachycardia are often referred due to concern of cardiotoxicty. In such patients we assessed the relationship between heart rate (HR) & ejection fraction (LVEF).
Method: Retrospective study of 27 patients on clozapine referred to a cardiology tertiary unit with suspected cardiotoxicity. Echo, ECG & demographic data were analysed by students t test & linear regression analysis.
Results: There was no significant correlation between HR & LVEF; in fact, a higher LVEF was associated with a marginally higher HR ($r=0.148$ $p = 0.058$;Fig 1).
There was no significant difference in age, gender, length of time on clozapine, QRS or QTc durations between these two groups (Table 1). Clozapine was frequently discontinued in both groups, but earlier in those with reduced LVEF, see table1. During a follow-up period of 6.1 ± 5 years no patient suffered cardiac mortality.
Discussion: We find that clozapine associated tachycardia is associated with a normal LVEF. We isolated two distinct manifestations of cardiotoxicity related to clozapine: those with tachycardia had normal LVEF & those with reduced LVEF did not exhibit significant tachycardia.
This confirms that the development of tachycardia is not sensitive for cardiomyopathic process but might infer a benign cardiac course to treatment. We suggest that management of these patients should be interdisciplinary with close liaison between cardiologists & psychiatrists to prevent unnecessary cessation of an effective psychiatric medication.

Cardiological evaluation of patients with Becker muscular dystrophy

A Markman[1]; M Markman[1]; B Markman[2]; A Miranda[3]; A Lordsleem[2]; M Vianna[4]; V Van Der Linden[3]
[1]Agamenon Magalhães Hospital, Cardiology, Recife, Brazil; *[2]Federal University of Pernambuco, Cardiology, Recife, Brazil*; *[3]AACD - Disabled Child Care Association, Recife, Brazil*; *[4]University of Pernambuco, Recife, Brazil*

Background: Becker muscular dystrophy (BMD) is a genetic disease linked to X and is associated with a defect in the gene encoding a protein, dystrophin. Progressive weakness of the skeletal muscles, cardiomyopathy and respiratory failure are the most prominent features, with heart disease being the main cause of morbidity and mortality.
Objectives: our aim is to present the cardiological characteristics of a series of cases of patients with BMD in a specialized center in Brazil.
Methods: between May 2013 and November 2016 were attended 14 men with BMD. They underwent rest electrocardiogram (ECG), 24-hour Holter monitoring and two-dimensional transthoracic echocardiography (2D TTE) during follow up.
Results: the mean age was 23.2 years. Six patients (42.8%) reported heart disease as antecedent, nine (64.2%) were asymptomatic. Symptoms of palpitation and dyspnea were present in 42% and 60%, respectively, in the symptomatic ones. Twelve patients (85.7%) presented abnormal ECG, from which right bundle conduction disorder (33.3%), sinus tachycardia (16.6%) and left ventricular hypertrophy (16.3%) were the most frequent pathologic changes. Nine patients underwent echocardiography and systolic dysfunction was present in five (55.5%) with mean ventricular ejection fraction of 39.5%, diastolic dysfunction in one (11%) and left ventricular hypertrophy in one (11%). Holter monitoring were done in 28.5% of the patients and one (25%) showed nonsustained ventricular tachycardia.
Conclusion: the majority of patients in this group had resting ECG changes and more than half of them appeared to have myocardial dysfunction. We conclude that an early cardiologic evaluation is necessary in patients with BMD.

P386

Clinical characteristics and outcome of patients admitted by alcoholic cardiomyopathy to a university hospital from western spain

C Carbonell Munoz[1]; C Herrera Flores[2]; R Antunez Conde[2]; C Santos Jimenez[2]; R Casin Bricio[2]; P Segovia Alonso[1]; FJ Laso Guzman[1]; M Marcos Martin[1]

Funding Acknowledgements: Partially funded by the ISCIII, Spain, RTA-RETICS, RD12/0028/0008 and FEDER funds

Background: Alcoholic cardiomyopathy is a form of heart disease caused by chronic alcohol abuse. There is a paucity of data regarding clinical and epidemiological characteristics of this disease.
Purpose: The aim of this study was to analyse clinical and echocardiographic characteristics as well as long-term follow-up of patients admitted by alcoholic cardiomyopathy at a tertiary university center.
Methods: Retrospective study of a case series of patients admitted during a thirteen year period to a tertiary universitary center with alcoholic cardiomyopathy as main diagnosis (International Classification of Diseases, 9th revision code: I42.9). Data were obtained from the Admission Department and from medical records. For patients with several admissions, the first episode was considered.
Results: We identified 30 patients with alcoholic cardiomyopathy as main diagnosis during the study period. Mean age was 55.83 years (standard deviation [SD] = 10.20), and 29 patients (96.7%) were men. Twenty-three patients (76.67%) were admitted in the Cardiology Department and six (20.0%) in the Internal Medicine Department. Reason for admission was to perform cardiac procedures (11 patients, 36.70%), followed by heart failure (10 patients, 33.33%). Mean hospital stay was 9.27 (SD = 7.69) days. During a median follow-up of 44.80 months, five patients died (16.67%) and twenty patients were readmitted for a total of 47 hospital readmissions.
ECG showed signs of ventricular hypertrophy in 8 patients (26.67%) and atrial fibrillation in 8 cases (26.67%). Ischemic heart disease was present in 5 patients (16.67%) and alteration of liver function tests in 10 patients (33.33%). Echocardiogram showed left ventricular dysfunction in 27 patients (93.10%), with a mean left ventricular ejection fraction of 38.90% (SD=14.56%); left ventricular dilatation was found in 23 patients (79.31%), with an average end-diastolic volume of 167.65 (SD = 83.35) mL.
Alcohol consumption before admission was quantified in 19 patients, with a mean consumption of 565.3 grams per week [SD = 333.2]). Alcohol consumption was qualitatively recorded in 9 patients and was not recorded in one patient. Only 16 discharge reports (53.33%) recommended patients not drink alcohol.
Conclusion(s): The clinical characteristics of our patients are similar to those found in the medical literature. The lack of quantification of alcohol consumption and the percentage of discharge reports not recommending abstinence may suggest a low awareness towards alcohol-induced cardiac damage. Quantitative recording of alcohol intake and promoting abstinence should be promoted among patients with alcoholic cardiomyopathy.

P387

Meta-analysis on the diagnosis of inflammatory cardiomyopathy in endomyocardial biopsies - Comparison of immunohistology with histology and cardiac magnetic resonance

M Noutsias[1]; J Katzmann[1]; P Schlattmann[2]; E Noutsias[3]; C Konstas[1]; JG Westphal[1]; P Aftanski[1]; B Bigalke[4]; C Tschoepe[5]; PC Schulze[1]

Funding Acknowledgements: DFG SFB TR 19 “DCMi” and UKGM 10/2009 “T cell functionality in DCMi”

Background: Diverse immunohistological (IHC) concepts have been elaborated for the sensitive detection of inflammatory cardiomyopathy (DCMi) in endomyocardial biopsies (EMB).
Purpose: Meta-analysis on the immunohistologic diagnosis of DCMi in EMB.
Results: We included n=61 investigations, with 10,491 patients (mean age: 47.1 years; men: 66%) who underwent EMB obtainment and IHC-diagnostics for infiltrate density and/or endothelial cell adhesion molecule (CAM) expression. In these studies, n=460 control patients were devoid of IHC-proof of DCMi. The mean IHC-detection rate of DCMi was 50.8% (95% CI: 47.7–53.8%; range: 18.4–91.7%). A substantial publication bias was excluded (Funnel Plot: $p = 0.4264$). This IHC-detection rate was significantly ($p < 0.0001$) higher compared to the mean detection rate of myocarditis according to the histological Dallas criteria (mean: 8.04%; 95%-CI: 5.08–12.5%; subset of n=3,274 patients in n=30 publications). However, 13 different criteria were described in the various publications, with various thresholds of diverse phenotypes of infiltrates, and expression of diverse CAM, quantified either visually or by digital image analysis (DIA). The comparison of IHC and cardiac magnetic resonance (CMR) data available in a subset of n=13 publications with 1,185 patients revealed a sensitivity of 69% (95%-CI: 58-79%), a specificity of 73% (95%-CI: 59-84%), and a ROC-AUC of 0.77 (95%-CI: 0.73-0.81) (Figure 1).
Conclusions: The results of this meta-analysis encompassing 10,491 patients confirm that the IHC-detection of DCMi has significantly higher sensitivity compared to the histological Dallas criteria, and cannot be fully substituted by CMR. However, standardization of the different IHC-diagnostic protocols seems pertinent.

Using longitudinal strain to identify wild type transthyretin amyloidosis in patients with aortic stenosis

G Robin[1]; T Cognet[1]; M Galinier[1]; D Carrie[1]; M Elbaz[1]; I Berry[2]; G Victor[2]; O Lairez[3]
[1]*Toulouse Rangueil University Hospital (CHU), Cardiology, Toulouse, France*; [2]*Toulouse Rangueil University Hospital (CHU), Nuclear Medicine, Toulouse, France*; [3]*Toulouse Rangueil University Hospital (CHU), Cardiology and Nuclear Medicine, Toulouse, France*

Introduction: Wild-type transthyretin amyloidosis (ATTRwt) and degenerative severe aortic stenosis (sAS) are both age-related pathologies with influence on prognosis. Diagnostic of cardiac amyloidosis may be confusing with the consequences of sAS on the left ventricle. Our aim was to describe a specific echocardiographic pattern for a better screening of cardiac amyloidosis in patients with severe aortic stenosis (sAS).
Methods: Echocardiography with speckle tracking analysis of 65 sAS without ATTRwt was compared to 15 ATTRwt with AS (moderate/severe = 8/7) and 31 ATTRwt with no AS.
All patients received 740 MBq of 99mTc-DPD intravenously. Genetic test with transthyretin gene sequencing was indicated in all patients with positive 99mTc-DPD scintigraphy to distinguish hereditary from ATTRwt.
Results: Specific echocardiographic pattern in patients with combined ATTRwt and AS was defined by more pronounced left ventricular hypertrophy (LVH) ($p < 0.001$), lower global longitudinal strain (GLS) ($p < 0.001$) and higher proportion of patients with longitudinal apical sparing (LAS) with a ratio > 0.93 (100% in sAS and 88% in moderate AS), as a consequence of severe decrease in basal ($p < 0.001$) and mid ($p < 0.001$) longitudinal strain. Low-gradient sAS despite preserved left ventricular function was observed in 43% of sAS with ATTRwt versus 9% in sAS without ATTRwt ($p < 0.05$).
Conclusion: ATTRwt in sAS may be suspected in patients with specific echocardiographic pattern combining lower GLS with exacerbated LAS, in presence of LVH and low-flow, low-gradient profile.

Remodeling of vascular walls in different levels of arterial system in patients with progressive course of hypertrophic cardiomyopathy

VYU Kaplunova[1]; GA Shakaryants[1]; MV Kozhevnikova[1]; EO Korobkova[1]; MA Kiryupina[1]; AI Malakhov[1]; EV Privalova[1]; YUN Belenkov[1]
[1]*I.M. Sechenov First Moscow Medical State Universityul. Trubetckay , 8, str. 2, 119992 Moscow, Russia, therapy, Moscow, Russian Federation*

Purpose: to assess the relationship between remodeling of large and small vessels and markers of endothelium dysfunction and growth factors in patients with progressive course of hypertrophic cardiomyopathy (HCM) by photoplethysmography, nail fold computer videocapillaroscopy and applantation tonometry.
Methods: 54 patients with progressive course of HCM were included in the study. All of them had heart failure with preserved ejection fraction. Group 1 included HCM patients (n-30; male: 12, mean age 47,96 + 16,97) and group 2 – HCM patients with metabolic syndrome (MS) (n-24; male: 18, mean 50,18 + 18,56). Digital photoplethysmography and nail fold computer videocapillaroscopy at baseline and with arterial and venous occlusion tests were performed. We estimated endothelial function of large vessels (phase shear (PS, ms) and microcirculation (occlusion index (IO)). Remodeling of large vessels (stiffness index (aSI, in/s) and skin capillaries (capillary densities (CD, cap/mm2) were evaluated. The levels of biological markers (TGF-α, IGF-1, von Willebrand factor and NT-proBNP, TIMP-1, endothelin) were estimated. Rheocardiography was performed on RheoCardioMonitor system. To asses aortic stiffness the applantation tonometry were performed.
Results: Central aortic systolic pressure (CASP) was above normal level in both groups (group1 - 125,00 + 3,86; group2- 128,00 + 3,55; norm 80-120 mmHg) by applantation tonometry was founded in both groups. Capillary densities was decreased in HCM patients 29.37 cap/mm2 (26.87;31.87). Significant reduction of system vascular resistance (SVR) measured by rheocardiography (9,14 + 6,82; $p < 0.05$) was found in HCM patients.A positive correlation between TIMP-1 level and RI (r=0,517; $p < 0,05$), and negative correlation between TIMP-1 level and CD (r=-0,413; $p < 0,05$) in group 1 was determined. IFR level associated with RI (r=0,517; $p < 0,05$). A positive correlation between VEGF-A level and SI (r=0,699; $p < 0,05$) in group 2 was identified. CASP correlated with TGF level (r=-0,401; $p < 0,05$).
Conclusion: 1. The tendency for enlargement of large vessels vascular stiffness and capillary remodeling was found in patients with progressive course of HCM. 2. Remodeling of small and large vessels correlates with growth factors.

P390

Coronary calcium scoring in patients with takotsubo syndrome - Is takotsubo protective against coronary atherosclerosis?

E Elmir Omerovic[1]; J Lundgren[1]; A Ali[1]; Y Shao[1]; B Redfors[1]
[1]*Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: Takotsubo syndrome is an increasingly recognised clinical entity with signs and symptoms similar to acute myocardial infarction and acute heart failure. Coronary artery calcium (CAC) score reflects the severity of coronary artery disease and is a predictor of future coronary events. The aim of this study was to evaluate CAC score in patients with takotsubo syndrome.
Methods: We included 73 patients diagnosed with takotsubo syndrome at Sahlgrenska university hospital (Gothenburg, Sweden) between 2005 and 2013. All patients underwent CT examination on a multi-slice CT scanner (Siemens Definition Flash). In addition to calcium scoring, we also performed contrast CT angiography (Omnipaque 350 mg/ml, 325 mg iodine/kg) in 43 patients without contraindications. The CT scans were performed during a breath hold and with ECG-gating. Each coronary vessel was identified with a multiplanar reconstruction technique. Calculation of total CAC score was done according to the standard scoring system. The area (mm2) of each calcified lesion was multiplied by a density factor depending on the maximum computed number Hounsfield units (HU) in the lesion; 1= 130-199 HU, 2= 200-299 HU, 3= 300-399 HU and 4= ≥ 400 HU. The total CAC score was determined by calculating the sum of all calcifications in each patient.
Results: The mean age was 65.7 years and 9 (12%) were male. The distribution of the traditional risk factors for coronary artery disease was similar to age and gender matched population. Successful CT examination was achieved in 72 (99%) patients. Of these, 35 patients (49%) had no calcifications in coronary arteries. The median total calcium score was 1.5 . This value is lower than median calcium score (˜8) reported previously in healthy volunteers in Sweden. Only 5 patients (7%) had a total CAC score of >400. We found significant stenosis (>50%) in two (4.6%) patients.
Conclusions: Patients with takotsubo syndrome have low total CAC score. The takotsubo phenotype may confer protection against progression of atherosclerosis in coronary arteries.

P391

Severe heart failure due to development of cardiac sarcoidosis in the patient with familial sarcomeric cardiomyopathy

O V Olga Blagova[1]; AV Nedostup[1]; VP Sedov[1]; SA Alexandrova[2]; MV Yakovleva[3]; ME Polyak[3]; EV Zaklyasminskaya[3]
[1]*I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation*; [2]*Bakoulev Center for Cardiovascular Surgery RAMS, Moscow, Russian Federation*; [3]*B.V. Petrovsky Russian Scientific Center of Surgery of the Russian Academy of Medical Sciences, Moscow, Russian Federation*

Purpose: to evaluate diagnosis stages and treatment of severe heart failure in a patient with familial form of cardiomyopathy and associated sarcoidosis.
Methods: male patient, 64 y.o., suffers dyspnea and paroxysmal atrial fibrillation from age 61 years. One year later, the patient first noted appearance of cough. X-ray revealed intrathoracic lymphadenopathy. A month ago, the patient significantly increased dyspnea, also appears edema of the lower limbs. Patient's daughter 35 y.o. and son 39 y.o. has been established the diagnosis of non-obstructive hypertrophic cardiomyopathy. Echocardiography (Echo-CG), Holter ECG monitoring, computer tomography (CT), cardiac magnetic resonance imaging (MRI), and DNA diagnostic were performed in the father.
Results: The examination revealed mild jaundice, symmetrical edema of the lower limbs, increased respiratory rate (24 per minute) and a little crepitation, irregular heart rhythm with a heart rate of 40-50 per minute, blood pressure 110/70 mm Hg, a slight increase in liver size. ECG showed sinus bradycardia (42 beats per minute), ventricular premature beats (PVBs), decreased amplitude of R wave. Holter monitoring showed signs of sick sinus syndrome, episodes of atrial fibrillation, PVBs

and nonsustained ventricular tachycardia. Echocardiography revealed signs of a noncompact myocardium, restrictive cardiomyopathy with reduced ejection fraction (36%), and also mitral regurgitation grade 2, tricuspid regurgitation grade 3. Systolic pulmonary artery pressure was 45 mm Hg, the thickness of the left ventricular myocardium 13 mm. The level of anti-heart antibodies was increased by 2-3 times. MRI showed definite signs of noncompact myocardium (22% of myocardial mass), intramyocardial gadolinium enhancement in the early and late phase in the interventricular septum, right ventricle, anterolateral wall of the left ventricle and papillary muscles; volume of fibrosis was 26%. During electrophysiological study induced ventricular fibrillation (VF), cardioverter defibrillator (ICD) was implanted. CT scan has shown the lymphadenopathy without pulmonary lesions, the diagnosis of sarcoidosis confirmed using thoracoscopic biopsy. In the patient and his two children was identified MYBPC3-p.Q1233* mutation. The patient receives a steroid and cardiotropic therapy for 2.5 years, symptoms of heart failure reduced. After ICD shock due to VF sotalol was replaced on amiodarone.
Conclusions: One mutation in the gene sarcomeric proteins (myosin binding protein C) has a different phenotype in the same family: myocardial noncompaction in the father and similar non-obstructive hypertrophic cardiomyopathy in two children. The development of sarcoidosis in the father led to a worsening of myocardial dysfunction. The cardiac sarcoidosis is confirmed by the presence of restrictive cardiomyopathy, specific pattern of gadolinium enchancement by MRI, high titers of ant-heart antibodies, and the positive effect of steroid therapy.

P392
Predictors of outcome in takotsubo cardiomyopathy, a multicenter study

A L Ana Calvo[1]; O Azevedo[1]; J Bispo[2]; I Cruz[3]; RP Santos[4]; MJ Vieira[5]; B Marmelo[6]; L Reis[7]; C Ruivo[8]; A Marreiro[2]; R Faria[9]
[1]Alto Ave Hospital Center, Cardiology, Guimaraes, Portugal; *[2]U.Algarve, Algarve Biomedical Center, Algarve, Portugal*; *[3]Hospital Garcia de Orta, Almada, Portugal*; *[4]Hospital Centre do Tamega e Sousa, cardiology, Penafiel, Portugal*; *[5]Hospital of Santarem, Cardiology, Santarem, Portugal*; *[6]Hospital Sao Teotonio, Viseu, Portugal*; *[7]University Hospitals of Coimbra, Coimbra, Portugal*; *[8]Hospital Santo Andre, Leiria, Portugal*; *[9]Centro Hospitalar Medio Ave, Cardiology, Famalicao, Portugal*

Introduction: Takotsubo cardiomyopathy (TC) is characterized by a transient left ventricular (LV) dysfunction in the absence of significant coronary artery disease. The predictors of prognosis of TC are not yet fully established.
Purpose: To identify predictors of outcome in patients (P) diagnosed with TC.
Methods: Multicenter study involving 13 hospital centers that included all patients diagnosed with TC in the last 12 years. We assessed demographic data, precipitating factors and clinical presentation, trying to establish the predictors of after discharge outcomes. We define the occurrence of an outcome in the follow-up of TC patients as a variable that combine the occurrence of death, stroke/TIA, acute myocardial infraction (AMI) and TC recurrence.
Results: We included 234 P diagnosed with TC predominantly female (89.7%). During hospitalization occurred complications: heart failure (24.4%), cardiogenic shock (6.8%), atrial fibrillation (9.0%), complete atrioventricular block (2.1%), acute pulmonary edema (4.3%), stroke / TIA (1.7%), LV thrombus (1.3%) and death (2.2%). Over a follow-up of 33 ± 33 months, there were: TC recurrence (4.3%), stroke / TIA (3.0%), AMI (0.4%) and death (6.4%). An outcome in the follow-up occurred in 12.4% of patients.
The following variables were identified by the CHAID technic as predictors of complications at follow-up: (i) Presentation without an emotional stress factor (p = 0,019); (ii) Presentation with dyspnea (p = 0.049).
Conclusion: TC has a relatively low rate of complications in the follow-up. Presentation without an emotional stress factor or dyspnea are independent predictors of complications in the follow-up of TC patients.

P393
Will patients with a history of psychiatric disease be different from the rest of the patients with takotsubo cardiomiopathy?

On behalf of: SUNSHINE

Introduction: Takotsubo Cardiomyopathy (TCM) is increasingly been described as a "stress" cardiomyopathy that can be triggered by physical and emotional factors. A higher prevalence of neuropsychiatric disease has been described in these patients but little is known about their characteristics.
Objectives: To evaluate and characterize a population of patients with TCM and history of psychiatric disease.
Methods: Multicenter retrospective study including 234 patients hospitalized with TCM. Two groups were formed: Group A, with a history of psychiatric disease (n = 17, 7.3%), and Group B, without psychiatric history disease (n = 217, 92.7%). The groups were compared in terms of their demographic characteristics, comorbidities, precipitating factors, clinical presentation, electrocardiographic, echocardiographic changes and in-hospital evolution. Statistical analysis was performed using SPSS version 23.0.
Results: Patients with a history of psychiatric disorder did not present significant differences in gender, comorbidities or postmenopausal status compared to the rest.
These patients do not present more frequently a precipitating factor (47.1% vs 60.4%, p 0.282), nor factors associated with emotional stress (35.3% vs 47.5%, p 0.333).
The clinical presentation of the patients did not differ between the two groups, with chest pain being the main complaint at presentation (100% vs 86.2%, p 0.139). Also the characteristics of ECG and echocardiogram did not differ significantly between the 2 groups, including the type of TCM.
During hospitalization, patients with psychiatric conditions did not present a significant difference in the new event rate compared to the rest.
Conclusions: In our study, patients with Takotsubo Cardiomyopathy with a psychiatric history did not present significantly different characteristics when compared with the remaining TCM patients.
The in-hospital prognosis of patients with psychiatric conditions seems to be similar to that of the remaining TCM patients.

P394
Will patients with a history of neurological disease be different from the other patients with takotsubo cardiomyopathy?

On behalf of: SUNSHINE

Introduction: Takotsubo Cardiomyopathy (TCM) is a clinical entity associated with changes in the brain-heart connection, culminating in transient, sometimes fatal, left ventricular dysfunction. It appears to be triggered by physical and emotional factors and a higher prevalence of neuropsychiatric disease has been described in these patients.
Objectives: To determine if patients with TCM and a history of neurological pathology have different in-hospital clinical features and prognosis.
Methods: A multicenter retrospective study including 234 hospitalized patients with the diagnosis of TCM. Two groups were formed: a Neuro group, including patients with a history of neurological disease (n = 10; 4.3%); A non-Neuro group without history of neurological disease (n = 224, 95.7%). The groups were compared in terms of their demographic characteristics, comorbidities, precipitating factors, clinical presentation, electrocardiographic, echocardiographic alterations and evolution in hospitalization. Statistical analysis was performed using SPSS 23.0.
Results: Patients with a history of neurological disease did not present significant gender or age differences.
With regard to comorbidities, patients in the Neuro group were more often smokers than those in the non-Neuro group (40% vs 12.9% p 0.037). There were no differences regarding the remaining comorbidities.
No significant differences were found between the groups regarding the existence of precipitating factors. Patients in the Neuro group presented more frequently with syncope (20% vs 4.9%, p 0.042). There were no differences in the other modes of presentation. Regarding the ECG and echocardiogram characteristics, the Neuro group presented less frequently atrial fibrillation (AF) at the initial ECG (10% vs 45.1%, p 0.046).There were no differences between the two groups regarding the in-hospital evolution.
Conclusions: Patients with Takotsubo Cardiomyopathy with known neurological disease were more often smokers, more frequently presented syncope at

admission and less frequently atrial fibrillation at the initial ECG AF. No differences were found regarding the in-hospital prognosis of TCM patients.

P395
Clinical features and prognosis of amyloidosis cardiac

J Joffrey Eduardo Lujan Valencia[1]; L Madrona Jimenez[1]; M Chaparro Munoz[1]; B Prado Gotor[1]; A Recio Mayoral[1]
[1]*Virgen Macarena University Hospital, Sevilla, Sevilla, Spain*

Introduction: The amyloidosis cardiac is an entity of great clinical relevance, often underdiagnosed with potentially curable medical treatment, its diagnosis requires a high clinical suspicion and a compatible anatomopathological sample. Our objective is to describe the etiology of the disease, presentation form, diagnostic methods, therapeutic strategy and follow-up.
Methods: Retrospective analysis of a series of patients at our center between 2007-2015.
Results: We analyzed 10 patients with a mean age of 64 (38-95) years, 5 (50%) were women. The etiology responds in 8 (80%) to primary amyloidosis (LA), 1 (10%) senile, 1 (10%) secondary. The main symptoms were dyspnea in 11 (91.7%), edema in 9 (75%), cachexia in 4 (33.3%), hepatomegaly in 3 (25%), splenomegaly in 2 (16.7%), pleural effusion in 6 %) And cardiomegaly in 4 (33.3%). NYHA at diagnosis was III-IV in 8 (66.6%) and I-II in 4 (33.3%). Renal insufficiency was found in stage I in 2 (16.7%), stage II in 8 (66.7%), stage III-IV in 2 (16.7%). Cardiac MRI was performed in 8 (66.7%) patients, of whom they presented subendocardial late enhancement 6 (50%). Other diagnostic procedures included bone marrow biopsy in 7 (58.3%), abdominal fat in 10 (83.3%), cardiac biopsy in 1 (8.3%) and rectum in 1 (8.3%). Protein electrophoresis was also performed, which was diagnosed in 6 patients (50%). Regarding the treatment, 7 (58.3%) were treated with Inhibitors of the angiotensin-converting enzyme, being interrupted in one of them (8.3%) for symptomatic hypotension; Moreover they also received beta-blockers 4 (33.3%), loop diuretics 11 (91.7%), antialdosteronic 4 (33.3%) and thiazide 1 (8.3%). Oral anticoagulant therapy was performed 4 (33.3%). The chemotherapist was, melphalan in 1 patient (8.3%), cyclophosphamide in 2 (16.7%) and therapy with immunomodulatory drugs in 3 (25%). Dexamethasone was associated in 3 patients (25%), other types of corticoid in 4 (33.3%). Bone marrow transplantation was performed in 3 patient (25%) and cardiac transplantation was performed in 1 patient (8.3%). The NYHA at the end of follow-up was I-II in 4 (33.3%) and III-IV in 5 (4.7%). During the follow-up, 4 (33.3%) patients died, with an average survival of 18.67 months.
Conclusions: The prognosis of cardiac amyloidosis remains uncertain, presenting a significant deterioration of the functional class at follow-up and a high mortality rate. Further studies with recent immunomodulatory drugs may improve outcomes.

P396
Mortality predictors in patients with takotsubo cardiomyopathy

B Bebiana Faria[1]; B Marmelo[2]; P Azevedo[3]; C Ruivo[4]; R Santos[5]; A Gomes[6]; M Vieira[7]; L Teles[8]; A Marreiros[9]; A Almeida[6]; L Calvo[1]; J Portugues[1]
[1]*Hospital Guimaraes, Guimaraes, Portugal*; [2]*Hospital Sao Teotonio, Viseu, Portugal*; [3]*Faro Hospital, Cardiology, Faro, Portugal*; [4]*Hospital Santo Andre, Cardiology, Leiria, Portugal*; [5]*Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*; [6]*Hospital Garcia de Orta, Almada, Portugal*; [7]*Hospital of Santarem, Cardiology, Santarem, Portugal*; [8]*University Hospitals of Coimbra, Coimbra, Portugal*; [9]*Algarve University, Cardiology, Faro, Portugal*

On behalf of: SUNSHINE

Introduction: Takotsubo cardiomyopathy (TC) is characterized by transient left ventricular dysfunction in the absence of artery coronary disease. The prognosis is generally favorable but there are cases of death. TC is a rare disease with a low number of events and because of that, there are few studies that describe mortality predictors.
Objective: Identify mortality predictors in Takotsubo cardiomyopathy.
Methods: Retrospective study, including all patients (P) with diagnosis of Takotsubo Cardiomyopathy in 12 portuguese hospitals in the last 12 years. Demographic, clinical, electrocardiographic (ECG) and echocardiographic data were collected to identify mortality predictors during follow-up.
Results: The sample consisted in 234 P, composed mainly by women (89.7%). In 59% of cases it was possible identify the precipitating factor, in 18.4% was physical stress and 47% refers an emotional stress. The most frequent clinical presentation was chest pain in 87% of the P and 89% had elevation of troponin at admission. About 24% developed heart failure (HF) during hospitalization, and 6.8% of P presented in Killip IV class. The average follow-up was 33 ± 33 months and overall mortality rate was 6.4%.
The factors that were significantly associated with death during follow-up were male gender ($p = 0.002$), angina history ($p = 0.024$), presence of chronic renal failure ($p = 0.26$), presence of precipitating factor ($P = 0.08$), namely emotional stress ($p = 0.001$), dyspnea at presentation ($p = 0.002$), atrial fibrillation at admission ECG ($p = 0.016$), Killip class at admission ($p = 0.004$), as well as the development of HF during hospitalization ($p < 0.001$). After multivariate analysis, the only independent mortality predictor was the development of HF during hospitalization ($p < 0.001$).
Conclusion: These results allowed to confirm the low mortality rate associated with Takotsubo cardiomyopathy. The results suggest the existence of a strong association between the development of HF during hospitalization and mortality in Takotsubo cardiomyopathy.

P397
Cardiac function and endothelial progenitor cells recruitment in recovered patients with takotsubo cardiomyopathy

L Liaz Zilberman[1]; A Zalik[1]; I Fugenfirov[1]; G Gandelman[1]; S Shimoni[1]; J George[1]; S Goland[1]
[1]*Kaplan Medical Center, heart institute, Rehovot, Israel*

Background: Takotsubo Cardiomyopathy (TCM) is a transient cardiomyopathy and endothelial dysfunction has been proposed as the main potential mechanism involved in the pathogenesis. Post-recovery cardiac function and endothelial function including endothelial progenitor cells (EPCs) were not evaluated in TCM yet.
Aim: To evaluate the measures of endothelial function, inflammatory markers and to assess cardiac function using comprehensive echocardiographic techniques such as Tissue Doppler Imaging (TDI) and 2-dimentional strain (2DS) imaging in post-TCM patients.
Methods: Twenty five post-TCM patients were included in this study. All patients underwent echocardiographic evaluation including left ventricle (LV) and right ventricle (RV) function assessment using standard echocardiography, TDI, and 2DS techniques. The number of EPCs: CD34+ cells, CD34+KDR cells, vascular endothelial growth factor (VEGF) levels and inflammatory markers: hsCRP, IL6 and Ox-LDL antibodies were quantified in 12 patients. All echocardiographic and laboratory measures were compared to age-matched controls.
Results: All patients recovered from TCM and were evaluated at mean follow-up of 3.7 ± 1.8 months from the acute event. The mean age was 60 ± 13 years, 24 women, and the mean LV ejection fraction (EF) at follow-up was 58.1 ± 11.5%. Although there was no difference in LVEF between the two groups ($p = 0.13$), patients with post-TCM had significantly lower early velocities E' septal (6.3 ± 1.7 versus. 8.8 ± 2.4 cm/s, $p = 0.003$) and systolic velocity S' septal (6.4 ± 1.7 versus 7.5 ± 1.5 cm/s, $p = 0.02$) by TDI. Lower LV global longitudinal strain (-18.8 ± 3.9 versus -21.1 ± 3.1%, $p = 0.03$), RV global strain (-20.9 ± 4.2 versus -23.3 ± 3.3%, $p = 0.07$) and significantly lower early diastolic strain rate (1.0 ± 0.3 versus 1.28 ± 0.4 1/s, p0.001) were obtained in post-TCM patients. Compared to controls, post-TCM patients had higher concentration of circulating CD34+KDR levels (0.18 ± 0.05 versus 0.07 ± 0.04, $p = 0.01$), with no difference in VEGF, hsCRP, IL6 and Ox-LDL between the groups.
Conclusions: In this pilot study comprehensive echocardiographic techniques such as TDI and 2DS were able to identify altered cardiac function in recovered patients with TCM. Enhanced recruitment of EPCs, cells that have been implicated to improve endothelial regeneration after initial vascular injury was evident even after LV recovery in patients with takotsubo cardiomyopathy.

P398
Diastolic function in Crohn patients _a study of strain analysis by speckle_tracking

M Oliveira[1]; MR Lourenco[1]; O Azevedo[1]; T Curdia Goncalves[1]; MJ Moreira[1]; F Castro[1]; L Calvo[1]; B Faria[1]; P Von Hafe[1]; J Portugues[1]; J Cotter[1]; A Lourenco[1]
[1]*Hospital Guimaraes, Guimaraes, Portugal*

Introduction: Crohn's disease (CD) is a chronic inflammatory bowel disease that affect the gastrointestinal tract but has also extraintestinal manifestations. Cardiac involvement is considered rare and limited to sporadic cases of myocarditis, endocarditis and pericardial effusion. Myocardial deformation imaging is the most sensitive technique to evaluate left ventricular function. E/SRe ratio has been considered to be a better index of left ventricular filling pressures and a prognostic predictor in many pathologies. There are no studies in literature evaluating diastolic function in CD by myocardial deformation imaging.
Objective: The aim of this study was to evaluate left ventricular diastolic function in CD patients using conventional 2D echocardiography, tissue Doppler imaging and strain analysis by speckle tracking.
Methods: Cross-sectional study including 40 patients with CD, followed in hospital consultation of Gastroenterology, and no other causes of left ventricular dysfunction. We collected clinical and demographic data. We performed 2D transthoracic echocardiogram including conventional echocardiography and tissue Doppler imaging. We performed 2D strain analysis by speckle-tracking and determined early diastolic strain rate (SRe) and E/SRe ratio.

Results: Patients were mainly female (57%), with mean age of 34,4 ± 10,3 years and mean disease duration of 8,2 ± 6,4years. Harvey-Bradshaw activity index showed that 30 patients were in remission, 8 patients had mild disease activity and 2 patients had moderate disease activity. 32,5% patients had already been submitted to surgery because of CD complications.
CD patients had significantly lower ejection fraction than controls (58,18 ± 0,66 vs. 65,58 ± 0,82 %, p < 0.001). Regarding diastolic function parameters: E/A ratio (1,49 ± 0,07 vs. 1,49 ± 0,08; p = 0,982), lateral E' velocities (16,65 ± 0,65 vs. 16,76 ± 0,66 cm/s; p = 0,908), septal E' velocities (13,34 ± 0,42 vs. 14,55 ± 0,64 cm/s; p = 0.111) and mean E/E′ ratio (6,08 ± 0,23 vs. 6,09 ± .0,22, p = 0,993) were normal for age without diferences between CD patients and controls.
Indexed left atrial volume was significantly higher in CD patients (23,3 ± 0,7 vs. 19,8 ± 1,1 ml/m2, p = 0.007) although within normal range.
E/SRe ratio was significantly higher in CD patients than controls (48,0 ± 7,5 vs. 42,4 ± 7,4cm, p = 0.005). This difference neither correlates with disease activity (p = 0.790) or disease duration (p = 0.990) nor was associated with past complications (p = 0.224), previous surgery (p = 0.106) or medication (p = 0.870).
Conclusion: This is the first study evaluating left ventricular diastolic function in CD by myocardial deformation imaging. Our study showed that CD, like other systemic inflammatory diseases, results in subclinical left ventricular diastolic dysfunction.

P399

Prognostic Value of Echocardiography in Peripartum Cardiomyopathy - Speckle tracking study

K Hristova[1]; R Marinov[1]; G Stamenov[2]; K Chacheva[2]; M Michova[2]; S Persenska[2]; N Dimova[2]; A Racheva[2]
[1]National Heart Hospital, Sofia, Bulgaria; *[2]Nadezhda Women's Health Hospital , Sofia, Bulgaria*

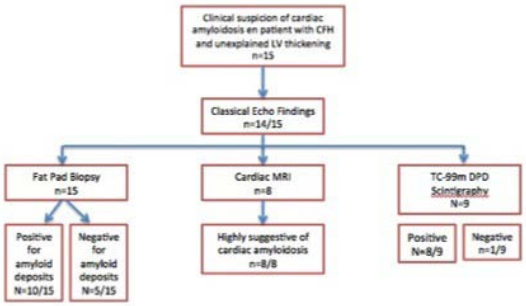
Normal pregnancy is associated with reversible changes in both systolic and diastolic mechanics, consistent with an increase in preload and decrease in afterload and systemic vascular resistance. The aim of the study is to evaluate left ventricular cardiac mechanics via speckle tracking echocardiography in a population of pregnant women with per partum cardiomyopathy and preeclampsia(PE) after invitro fertilization (IVF) during different stages of pregnancy.
The study population included 42 pregnant women with PE, after IVF, 10 of them with multiple pregnancy (46.5 ± 3 years) and 20 healthy nonpregnant women (33 ± 4years).Apical and basal short axis and apical view for three, two and four chamber for 2D images were acquired (65 ± 7 frames/s) during the first, second and third trimester of the pregnancy, as well as up to two months post partum. The curves of longitudinal(GLS), circumferential(GCS), radial strain(GRS) and LVT /LVUR were extracted using a commercial software.
Results: Peak LVT and LVUR increased significantly in the 3rd trimester in both pregnancy groups (13.48 ± 2.90°,13.12 ± 3.30°,16.83 ± 3.61°,P < 0.001; and -111.52 ± 23.54°/sec,-107.40 ± 26.58°/sec,-144.30 ± 45.14°/sec, P < 0.001; in the 1st, 2nd, and 3rd trimester, respectively.The pregnants with twins have the highest value for LVT and LVUR compare with other pregnants (p < 0.01), but in the last trimester, the time to peak LVUR is prolonged. An independent correlation was found between the change in LVT and LV end-systolic volume in 1st and 3rd trimester (r = 0,56). Peak LVUR at the 3rd trimester correlated significantly with LV end-diastolic volume. Multiple regression analysis indicates that only systolic blood pressure (r = 0.394, P = 0.005) was an independent predictor for increased LV torsion. Arterial hypertension (AH) and prevalence of preeclampsia (PE) are more often in IVF group. Longitudinal strain decreased significantly (p < 0.001) during 3th trimester in women with AH and PE. Global longitudinal strain measures of the LV were non-significantly different between the different groups in first and second trimester (GLS-20.6 ± 3,14 vs.-19,29 ± 2,17).There are not found significant differences for GCS and GRS during pregnancy. Conclusions: During pregnancy LV twist and peak untwisting rate increase in the 3rd trimester and correlate with end-systolic and end-diastolic volume, respectively. Blood pressure and condition of multiple pregnancy are independently associated with increased torsion during pregnancy and may predict the new onset heart failure and perinatal cardiomyopathy. Global longitudinal strain is the main predictor of new onset peripartum cardiomyopathy

P400

Multimodality non-invasive imaging diagnosis of cardiac amyloidosis

M Groba-Marco[1]; A Cardenes-Leon[1]; A Garcia-Quintana[1]; M Blanco-Nuez[1]; I Menduina-Gallego[1]; H Mendoza-Lemes[1]; J Hernandez-Ramirez[1]; R Sakhrani-Gobind[1]; V Quevedo-Nelson[1]; JD Marin-Esmenota[1]; J Garcia-Salvador[1]; D Valeron-Hernandez-Abad[1]; E Caballero-Dorta[1]
[1]University Hospital Dr Negrin, Cardiology, Las Palmas De Gran Canaria, Spain

Background: Cardiac amyloidosis (CA) is a common underdiagnosed cause of restrictive cardiomyopathy and heart failure. Two major types of CA are cardiac amyloid light-chain (AL) and transthyretin-related cardiac amyloidosis (ATTR, mutant and wild types). An early diagnose determines prognosis and therapeutic options.
Purpose: To determine the role of different non-invasive imaging techniques in the diagnosis of CA and its ability to differentiate between subtypes.
Methods: We analysed the use of a 2D- echocardiography, a cardiac MRI and a 99m-Tc-DPD-cardiac-scintigraphy in patients with unexplained left-ventricle thickening that resulted on the diagnosis of CA. The cohort included 15 patients admitted at the University Hospital between March 2011 and June 2016, 9 (60%) had ATTR wt, 5 had AL (33%), and 1 (6%) was confirmed but untyped. Mean age was of 81.3 ± 3.4 and 66.8 ± 6.3 years of age in the group with ATTR wt and AL respectively (p < 0,001).
Results: A 12-lead ECG and 2D-transthoracic echocardiography were done firstly. Significant low voltage and poor R-wave progression with significant LV thickening was observed in 47% of the patients (n = 7/15), and 93% (n = 14/15) had classical echocardiographic signs of infiltrative cardiomyopathy.
In 8 patients a Cardiac-MRI was performed, all highly suggestive of CA with diffuse late gadolinium enhancement, without significant difference of the pattern observed in both subtypes (ATTR n=4, AL n= 3, untyped n=1). In 4 patients the MRI was not done due to having a cardiac pacemaker (n = 1, AL), significant renal failure (n = 2, 1 AL and 1 ATTR) or both (n = 1, ATTR), and in 1 patient it had to be postponed until further clinical improvement due to supine position intolerance (n = 1, ATTR). In 4 of these 5 patients, the cardiac scintigraphy was done, presenting positive myocardial uptake of Tc-99m-DPD in 3 (75%, all ATTR).
Fat pad biopsy was taken in all of the patients, observing amyloid deposits in 10 studies (67%, n=15). In the other 5 patients with negative results, 3 patients (all ATTR) had both MRI and scintigraphy suggestive signs of CA, 1 patient (AL) only a suggestive cardiac MRI, and 1 patient (ATTR) only a positive cardiac-scintigraphy.
Conclusions: Although endomyocardial biopsy with immunostaining is considered the gold standard, multimodality non-invasive imaging techniques provide an attractive alternative for the detection of CA. Cardiac-scintigraphy, especially in ATTR, is an effective and safe technique to be used in patients with significant renal failure and cardiac pacemaker. No significant differences were observed in these modalities to distinguish between ATTR and AL cardiac affectation, but the age of the patient should be taken into consideration for a diagnostic approximation. We advocate for a multimodality imaging approach for the diagnosis of an underdiagnosed CA.



P401

Meta-analysis for the value of colchicine for the therapy and prevention of pericarditis and postpericardiotomy syndrome

JG Westphal[1]; P Schlattmann[2]; LL Lutschinger[1]; C Konstas[1]; P Aftanski[1]; T Bekfani[1]; PC Schulze[1]; M Noutsias[1]
[1]University Hospital of Jena, Department of Internal Medicine I, Division of Cardiology, Pneumology, and Intensive Medical Care, Jena, Germany; *[2]University Hospital of Jena, Institute of Medical Statistics, Informatics and Documentation (IMSID), Jena, Germany*

Introduction: Colchicine inhibits mitotic processes via interference with formation of microtubule, which eventually also inhibits the activation of immunocompetent cells. Colchicine has been used for the treatment and secondary prevention of pericarditis (PC) and of postpericardiotomy syndrome (PPS).
Aim: Meta-analysis of investigations on the clinical effects of colchicine for the treatment and secondary prevention of PC and PPS.
Methods and Results: By systematic literature search pathways, we identified n=10 relevant prospective trials, with 1,981 patients (mean age: 57.8 + 7.3 years; men: 62.5%; mean follow-up: 13.6 + 91 months). Two studies with n=981 patients (mean age: 57.6 + 6.7 years) used an open label design, in which the patients were randomized to the respective study group. The remaining eight trials were randomized controlled trials (RCT). The n=1.000 control patients (mean age: 57.9 + 8.0 years) had a conventional therapy. In the colchicine treated study patients, the daily dose of colchicine was 0.5-1.0 g (depending on tolerance) in n=7 trials, 1.0 g daily in n=2 trials, and 1.0 g daily in one further trial. Colchicine treatment was associated with a significant reduction of a recurrence of pericarditis (OR: 0.33; 95%-CI: 0.25-0.44), and of rehospitalization both for PC and PPS (OR: 0.25; 95%-CI: 0.13-0.49). The rate of gastrointestinal adverse effects was significantly higher in the colchicine treated patients (OR: 2.6; 95%-CI: 1.82-3.72).

Conclusions: the results of this meta-analysis based on 1,981 patients confirm the efficacy of colchicine for the treatment and secondary prevention of pericarditis (PC) and of postpericardiotomy syndrome (PPS).

P402

Chronic heart failure as a specific form of the arrhythmogenic right ventricle dysplasia/cardiomyopathy and a consequence of associated myocarditis.

Y A Yulia Alexandrovna Lutokhina[1]; O V Blagova[1]; A V Nedostup[1]; S A Alexandrova[2]; E A Mershina[3]; A G Shestak[4]; EV Zaklyazminskaya[4]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; *[2]Bakoulev Center for Cardiovascular Surgery RAMS, Moscow, Russian Federation*; *[3]Roszdrav Medical Rehabilitation Center, Moscow, Russian Federation*; *[4]Russian Research Center of Surgery, Petrovsky, Moscow, Russian Federation*

Background: Arrhythmogenic right ventricle dysplasia/cardiomyopathy (ARVD) was described in 1977, however, generally accepted clinical classification of the disease is still missing. Frequency and factors of the development of chronic heart failure (CHF) in various forms of ARVD are not determined.
Purpose: To evaluate the frequency and factors of the development of CHF in three main clinical forms of ARVD and to relate CHF with the presence of associated myocarditis.
Methods: forty seven patients (mean age 38,8 ± 15,8 y 40.4% males) with ARVD according to Revised Task Force Criteria 2010 (TFC) were evaluated (22 patients with definite, 13-with borderline and 12 with possible diagnosis). All patients underwent ECG, 24h-Holter monitoring, echocardiography, blood tests for detection of anti-heart antibodies and DNA of cardiotropic viruses. Mutations were identified by Sanger sequencing. Also were performed magnetic resonance imaging (MRI, n=40), signal-averaged ECG (n = 15), morphological study of the myocardium (endomyocardial biopsy, n=2, and autopsy, n=2).
Results: According to the features of clinical course of ARVD, we identified three clinical forms of the disease. I. Latent arrhythmic form - characterized by frequent premature ventricular contractions and/or nonsustained ventricular tachycardia (VT) in the absence of sustained VT (SVT) and syncope. II. Manifested arrhythmic form – SVT/ventricular fibrillation. III. ARVD with progressive CHF (as the main manifestation of the disease). These forms were diagnosed in 24, 10, and 13 patients respectively. These three groups were compared by 4 main parameters: 1) confidence of diagnosis; 2) structural-functional characteristics; 3) presence/absence of myocarditis; 4) the results of the DNA-diagnostics. Patients with the III form (severe CHF) differed from others patients with higher confidence of diagnosis, significantly larger size of the right ventricle, lower ejection fraction of both ventricles, low voltage ECG but with a lower incidence of SVT. Significant differences in the frequency of detection of mutations have not been detected, however, in patients with the III form are dominated by mutations in DSP gene, which are associated with CHF and left ventricle involvement. The frequency of associated myocarditis in patients with III form was not significantly higher than in patients with manifested arrhythmic form (61.5% and 30.0%). Probably, in patients with CHF the presence of myocarditis facilitated the realization of abnormal genetic program, which resulted in more severe clinical course: congestive CHF, greater requirement in implantable cardioverter defibrillator (53.8 v 11.8%), presence of lethal outcomes (15.4 v 0%).
Conclusions: It is reasonable to allocate the patients with ARVD with CHF in a separate clinical form, characterized by the presence of mutations, associated with CHF, that in combination with associated myocarditis result in the severe clinical course and worse prognosis.

P403

Electrocardiographic changes in takosubo cardiomyopathy: differences between apical and mid-ventricular involvement

B Schneider[1]; K Peters[1]; U Desch[1]; J Stein[1]
[1]Sana Kliniken, Luebeck, Germany

Background: Besides the typical presentation of apical ballooning (AB), a variant form of takotsubo cardiomyopathy (TTC) with mid-ventricular ballooning (MB) has been recognized. This study assessed if there are electrocardiographic differences between these two TTC variants.
Methods: Over a 9-year period, we observed 76 TTC patients (69 f, 7m; 70 ± 12 years). By angiography, 45 patients (59%) had AB and 31 (41%) MB. ECG on admission, at the time of maximal T-wave inversion, before discharge and the daily QTc-interval were compared.
Results: Time from symptom onset to first ECG (8.8 ± 7.7 vs 7.9 ± 9.9 hours, p = ns) and heart rate (88 ± 21 vs 90 ± 25/min, p = ns) were not different in patients with AB and MB. At presentation, most patients had ST elevation (AB 96%, MB 84%, p = ns). In AB there was a trend towards a higher number of leads with ST elevation (4.3 ± 2.1 vs 3.4 ± 2.5 leads) and a greater magnitude of ST elevation (0.65 ± 0.41 mV vs 0.47 ± 0.4 mV, both p = ns). The number of patients with ST-elevation in V2 (87% vs 68%, p < 0.05), V3 (93% vs 65%, p < 0.002) and V4 (73% vs 32%, p < 0.001) was greater in AB whereas ST-elevation in aVL occurred more frequently in MB (11% vs 29%, p < 0.05). The occurrence of a Q wave was similar in both groups (AB 33%, MB 29%, p = ns) but the number of leads with a Q wave was higher in AB (2.3 ± 0.7 vs 1.6 ± 0.7, p < 0.02). Reciprocal ST segment depression was similar (AB 24%, MB 29%, p = ns).
During follow-up, AB patients showed more leads with T-wave inversion (8.2 ± 1.17 vs 6.1 ± 2.7 leads, p < 0.001), and the magnitude of T-wave inversion (3.3 ± 1.5 vs 1.6 ± 1.0 mV, p < 0.001) was larger. The presence of T-wave inversion was similar in lead I, aVR, aVL and V2 but AB patients developed more wide spread T-wave inversion in lead II (80% vs 45%, p < 0.002), aVF (AB 58%, MB 32%, p < 0.05), V3 (AB 97%, MB 71%, p < 0.001), V4 (AB 98%, MB 58%, p < 0.001), V5 (AB 98%, MB 61%, p < 0.001) and V6 (AB 93%, MB 52%, p < 0.001). The QTc interval on day 2 was longer in AB (538 ± 66 vs 508 ± 52 ms, p < 0.05). Ventricular arrhythmias (AB 7%, MB 13%) and atrial fibrillation (AB 22%, MB 13%, both p = ns) were similar. Time to ECG normalization was significantly longer in AB (86 ± 98 vs 45 ± 30 days, p < 0.04).
Conclusion: In patients with TTC, ECG changes are much more pronounced in AB than in MB. At presentation, ST-segment elevation in lead V2–V4 and the number of leads with abnormal Q waves are higher in AB. During follow-up, the QTc interval on day 2 and the extent of T-wave inversion is greater in AB than in MB, and time to complete ECG normalization is longer in AB.

P404

Incidence and clinical relevance of left ventricular thrombus in patients with takotsubo cardiomyopathy

B Schneider[1]; A Athanasiadis[2]; J Schwab[3]; U Gottwald[4]; W Toepel[5]; R Schoeller[6]; U Sechtem[2]
[1]Sana Kliniken, Luebeck, Germany; *[2]Robert-Bosch-Krankenhaus, Stuttgart, Germany*; *[3]Klinikum Nuernberg, Nuernberg, Germany*; *[4]Allgemeines Krankenhaus, Celle, Germany*; *[5]Klinikum Idar-Oberstein, Idar-Oberstein, Germany*; *[6]DRK Kliniken Berlin | Westend, Berlin, Germany*

Background: Takotsubo cardiomyopathy (TTC) is increasingly recognized all over the world. Left ventricular thrombi (LVT) complicating TTC have been reported only sporadically. This study evaluated the incidence and clinical relevance of LVT in patients (pts) of a large TTC registry.
Methods: From 37 hospitals, 324 pts (296 f, 28 m, age 68 ± 12) were included according to the following criteria: 1) acute chest symptoms, 2) ischemic ECG changes, 3) reversible LV akinesia not corresponding to a single coronary artery territory, 4) absence of coronary artery stenoses.
Results: Within the first week of symptom onset, 301 pts were studied by echocardiography (echo, n=276) and/or cardiac MRI (n = 147). In 8 female pts (incidence 2.7%), LVT was diagnosed between day 1 and day 5. Apical ballooning was present in 7 pts and mid- ventricular ballooning in 1 pt. Multiple mobile thrombi were seen in 3 pts, and in 1 pt spontaneous echo contrast was present within the dyskinetic apex. In 3 of 4 pts studied by both echo and CMRI, LVT were detected only by CMRI. No pt had right ventricular thrombus.
Pts with LVT were significantly older (76 ± 12 vs 67 ± 12 years, p < 0.05). Symptoms, triggering events, time from symptom onset to hospital admission and cardiac markers were not different among both groups. The admission ECG in pts with LVT more frequently displayed negative T-waves (100% vs 66%, p < 0.05); heart rate, ST-segment elevation and Q waves were similar.
The QTc was longer (491 ± 67 vs 465 ± 52 ms day 1, 539 ± 87 vs 500 ± 64 ms day 3) and ventricular tachycardia (29% vs 8%, p = 0.05) occurred more frequently in pts with LVT, whereas atrial fibrillation was similar (14% vs 15%).
LV ejection fraction (48 ± 21% vs 49 ± 14%) was not different, but right ventricular involvement (50% vs 17%, p < 0.02) and the need for an intraaortic balloon pump (12.5% vs 0.7%, p < 0.001) were significantly more frequent in pts with LVT. Acute medication (ASS, clopidogrel, heparin, beta-blocker, ACE-inhibitor, catecholamines) was similar in both groups. In 2 of 8 pts (25%) LVT were progressing despite therapeutic doses of heparin, aspirin and clopidogrel. Both suffered a large stroke, 1 pt died.
One additional pt had a stroke on day 2 after TTC onset; echo did not show LVT. CMRI, however, had not been performed.
Conclusion: LV thrombi occur in 2.7% of pts with TTC and a severe clinical course. CMRI is the imaging method of choice as echo underestimates the incidence of LVT. Despite therapeutic anticoagulation, LVT may grow and embolize, resulting in disabling stroke.

Funding Acknowledgements: None

Background: Cardiac Amyloidosis (CA) is a rare disease. Therefore, cardiac involvement in systemic light-chain (AL) amyloidosis is more frequent than expected and carries poor prognosis. Chemotherapy combining (at the same time) cyclophosphamide, bortezomib and dexamethasone (CyBorD) is widely used in CA and improves long-term outcome in mild CA. However, chemotherapy might destabilize severe cardiac amyloidosis (CA) particularly during the early phase of administration leading to death. Indeed, 26 of the 67 patients with CA who were treated in our center between 2010 and 2014, 11 died within the first month all in the score III of the Mayo Staging. These disappointing results led to a change in the protocol i.e., escalation-sequential treatment regimen with the hypothesis that the combination of the drugs might increased the cardiac toxicity: Dexamethasone is known induced fluid retention, bortezomib is suspected of direct cardiac toxicity and both three drugs might induced an acute release of free light chain that might increase the amyloid burden.
Methods and Findings: In an attempt to understand the underlying mechanisms, the first nine patients with the new protocol were closely followed. The first cycle of this protocol consisted of three sequences, with weekly successive introduction of low-dose dexamethasone, cyclophosphamide and bortezomib. Serum cardiac biomarkers including NT-proBNP and troponin HS as well as free light chains were quantified at time 0, 4h and 24h for each sequence. Kinetic of Serum Bortezomid concentration was also measured at 0, 4h and 24h after administration of this drug. Interestingly, NT-proBNP serum concentrations increased 2-folds at 24h for each of the three sequences following Dexamethasone. No significant variation was observed for troponin, light chains and bortezomib concentration and no patient died during the first month.
Conclusions : Corticoids may destabilize the frail heart function of patients with CA most likely through fluid retention. Strategies that limit abrupt exposition to corticoid during the first cycles may be preferred in CA. Larger studies are needed to define the best sequence and dose of chemotherapy in these patients.

Detection of cardiac dysfunction in asymptomatic cancer survivors with exercise strain echocardiography

K Kaitlyn Lam[1]; F Lee[2]; T Long[3]; L Naylor[3]
[1]Fiona Stanley Hospital, Advanced Heart Failure and Cardiac Transplant Service, Perth, Australia; *[2]Fiona Stanley Hospital, Cardiology, Perth, Australia*; *[3]The University of Western Australia, Perth, Australia*

Background: Cardiac dysfunction can have a latency period when patients are asymptomatic for several years after the completion of cancer therapy. Abnormalities may not be detected until the process is advanced & costly therapy is required.
Purpose: The purpose of this study was to use stress echo to detect pre-clinical stages of cardiac disease in young adult survivors of childhood cancer.
Method: 15 asymptomatic survivors of ALL had exercise Vo2 /stress echocardiography. Echo images obtained assessed chamber size & biventricular function by 2D, 3D imaging, 2D speckled strain analysis & Doppler assessment.
Results: 10 Males, 5 Females with mean age 18.8± 3 years. The mean VO2ml/kg.min was 40.72± 12.42. The stress echoes showed significant reductions in cardiac strain at peak exercise & recovery. When compared to baseline values, global longitudinal strain reduced by 21.8% & 7.6%, global circumferential strain by 16.5% & 10.5% at peak exercise& recovery respectively.
Conclusion: Exercise stress strain echocardiography can detect early cardiotoxicity in asymptomatic cancer patients.

Echocardiography parameters as predictors of left ventricular ejection fraction reduction in cancer patients

M Laufer Perl[1]; A Milwidsky[1]; B Sadeh[1]; D Ravid[1]; N Amrami[1]; G Keren[1]; Y Topilsky[1]; Y Arbel[1]
[1]Tel Aviv Sourasky Medical Center, Cardiology, Tel Aviv, Israel

Background: Advances in treatment have led to improved survival of cancer patients, but with the price of increased morbidity and mortality, mainly due to cardiac causes. Echocardiography is the method of choice for the detection of myocardial dysfunction during and after cancer therapy. Early identification of Left Ventricular (LV) Dysfunction may prevent the development of Heart Failure. Currently, diastolic parameters are known to be common among cancer patients, but have not been found to be prognostic for Left Ventricular Ejection Fraction (LVEF) reduction.
Objectives: To evaluate Echocardiography parameters as predictors of LVEF reduction (defined as EF reduction ≥5%) in cancer patients with normal baseline LV function.
Methods: A retrospective, single-center observational study that included 82 consecutive patients evaluated in the Cardio-oncology clinic from January 2015

to September 2016. Clinical and echocardiographic variables were evaluated for all patients. All patients performed at least two echocardiography exams and excluded were patients with reduced LV function (Ejection Fraction < 60%) at baseline.
Results: Among 82 consecutive patients, 18 patients (22%) developed LVEF reduction. Several echocardiography parameters were found to be a significantly predictors of LVEF reduction, including larger LV end diastolic diameter (LVEDD) (49 ± 5mm vs 46 ± 5mm, p = 0.002), lower e' septal (6.1 ± 2.2cm/s vs 7.7 ± 2.4 cm/s, p = 0.019), lower e' lateral (8 ± 2.5 cm/s vs 10.1 ± 2.7 cm/s, p = 0.015), higher E/e' septal (13.8 ± 6.6 cm/s vs 11 ± 5.3 cm/s, p = 0.046). However, E/A and deceleration time were not predictive of deterioration in EF (p = 0.520, 0.627).
Conclusions: Early identification of cardiac dysfunction is essential for the prevention of symptomatic heart failure. Our study demonstrates that parameters associated with depressed diastolic function, and larger LV size may identify early cardiac dysfunction which may lead for early cardio protective treatment and prevention of irreversible LVEF reduction and heart failure.

Characterization of the clinical and echocardiographic profile of a population of women with breast cancer.

J Joao Pais[1]; B Picarra[1]; RA Guerreiro[1]; A Bernardo[2]; C Tata[2]; D Bras[1]; J Carvalho[1]; K Congo[1]; AR Santos[1]; R Matos[1]; C Cruz[1]; J Aguiar[1]
[1]*Hospital Espirito Santo de Evora, Departement of Cardiology, Evora, Portugal*; [2]*Hospital Espirito Santo de Evora, Evora, Portugal*

Introduction: Cancer patients are treated with several therapies with potential harmful cardiotoxic effects. Carrying out appropriate cardiovascular therapy to the clinical profile of these patients may minimize the risk of such cardiotoxicity.
Purpose: To characterize the clinical and echocardiographic profile of a population of women with breast cancer.
Methods: In a 2-year period, all women with breast cancer who underwent an echocardiogram in our echocardiography laboratory were evaluated. All women had started some type of oncologic therapy (chemotherapy or radiotratherapy). Cardiovascular risk factors, echocardiographic data and type of chemotherapy and / or radiotherapy were recorded.
Results: The study included 116 women, with a mean age of 60.5 ± 13.0 years. 99% of these women underwent chemotherapy and 70% were submited to radiotherapy. The prevalence of cardiovascular risk factors was hypertension - 34.7%, Diabetes Mellitus - 20.8%, dyslipidaemia 30.7%, smoking - 7.9%, smoking habits in the past - 5, 0%, and coronary disease - 3.0%. The echocardiographic evaluation revealed that the great majority of the women had good left ventricular function (93.3%) and that only 1.9% had moderate or severe left ventricular function depression. In 58.7% of the women, minor valve disease were reported, but in only 8.2% of these patients the disease were moderate or severe. The presence of pericardial effusion was found in 4.8% of the women, and in all cases the effusion was slight.
Conclusions: In our population of women with breast cancer there was a low prevalence of cardiovascular risk factors. Most of these patients have good left ventricular function, with no significant valve disease.

P409
Basal renal function and its evolution in patients admitted for decompensated heart failure.

L Secco[1]; SM Mettini[1]; F Jaliff[1]; J Zubiri[1]; DA Fernandez[1]; L Lapadula[1]; C Cejas[1]; G Sumay[1]; MG Masuelli[1]; SM Pereiro Gonzalez[1]
[1]*Hospital Center Churruca-Visca, Buenos Aires, Argentina*

Background: The worsening of renal function (RF) is very common in patients hospitalized because of decompensated heart failure, it is associated with high prevalence of events on the follow up..
Methods: It is a prospective analysis of 474 patients (p) admitted for decompensated of heart failure, consecutively, in our Cardiology Department, from June 2012 to November 2016, with a median follow up of 26 months (Q1 13 - Q3 33). We divided two groups (G): G1 with basal normal RF (n 236) and G2 (n 226) with basal abnormal RF. We defined normal RF those with serum creatinine levels < 1.3 mg/dl and creatinine clearance >60 ml/min/1.73m2; those which lower clearance and/or higher creatinine serum levels were classified as abnormal basal RF. We also classified as worsening renal function, those with increased serum creatinine greater than 0.3 mg/dl and/or decrease in creatinine clearance > 10 ml/min/1,73 m2. Quantitative variables with normal distribution were expressed with medium and with standard deviation (analyzed by test Fisher's Test); those with not normal distribution, were expressed with median (m) and quartiles (analyzed by Mann Whitney's Test). Dichotomous variables were analyzed by Chi^2.
Results: We observed that G1 had more worsening RF that G2, with differences statistically significant (DSS) (p = 0.0000, G1 57.2% vs G2 36.7%-table 1), we analyzed the median of maximum furosemide dose and it was 80 mg/day, for both, without DSS. Hospital mortality was higher for those in G2 with DSS (p = 0.0421, G1 3% vs G2 7.1%) as the amount of p older than 75 years old (p = 0.00005, G1 46.2% vs G2 62.4%). There were no differences in the rehospitalization, follow-up mortality, combination of both, or if they had ejection fraction higher than 50%.
Conclusions: The cardiorenal syndrome was present in the older patients and had more hospital mortality (DSS). There were no differences between groups in rehospitalizations or mortality in the follow-up. Nevertheless, we observed, that those with better renal function worsen it, despite not having differences in the doses of furosemide. Our next step is analyze it.

Table 1

Basal RF	% (n)	Worsening	
Normal	51,1 % (236)	57,2 %	p = 0,0000OR 0,43IC 95% 0,29-0,63
Abnormal	48,9 % (226)	36,7 %	

P410
Prevalence and prognostic value of comorbidities in patients with decompensated heart failure and acute kidney injury

A Klimenko[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: Patients admitted with acute decompensated heart failure (ADHF) often have multiple concomitant diseases that complicate management and may adversely affect outcomes. Up to 70% of ADHF patients had at least 1 noncardiac comorbidity (CoM), of which the most common are chronic kidney disease (CKD), anemia, diabetes mellitus (DM) and chronic obstructive pulmonary disease (COPD).
Purpose: The aim of the study was to determine the prevalence of CoM in ADHF patients depending on the presence of acute kidney injury (AKI) and to evaluate the impact on short-term (30-days mortality) and long-term (6 months rate of ADHF rehospitalizations) outcomes.
Methods: in 183 patients admitted with ADHF (125 male, 69 ± 9 years (M ± SD), arterial hypertension 87%, ischemic heart disease 56%, myocardial infarction 53%, atrial fibrillation 51%, DM 36%, known CKD 40%, COPD 29%, anemia 20%, ejection fraction 44 ± 15%) the prevalence of AKI and main CoM was assessed. AKI was defined using 2012 KDIGO Guidelines. Mann-Whitney and multiple logistic regression analysis were performed. P < 0.05 was considered statistically significant.
Results: Patients with AKI versus patients without AKI had higher rates of DM (40 vs 26%, < 0.05) and anemia (33 vs 11%, p < 0.001). 41% of patients developed AKI and 79% of them had at least 1 CoM and 5% pts all 4 of them. AKI in patients with COPD versus without COPD was transient (76 vs 48%, p < 0.05), had higher rate of long-term outcomes (71 vs 41%, p < 0.05) and there was tendence to more frequent community-acquired (presenting on admission) AKI (76 vs 50%, p>0.05). There was not found any difference in prognosis between anemic and non-anemic pts. AKI in DM patients versus AKI without DM was persistent (87 vs 18%, p < 0.001), had higher risk of 30-days mortality (30 vs 9%, p < 0.05) and tendence to higher 6 months rate of ADHF rehospitalizations (53 vs 44%, p>0.05). Development of AKI in the presence of CKD versus AKI de novo less often was transient (45 vs 71%, p < 0.01), had lower risk of 30-days mortality (11 vs 29%, p < 0.05) and higher 6 months rate of ADHF rehospitalizations (60 vs 29%, p < 0.01). Evaluation the impact of CoM on outcomes demonstrated the increasing risk of long-term outcomes in parallel with the increasing number of CoM (1CoM-44%, 2- 50%, 3- 76%, 4- 100%, p < 0.05).
Conclusions: 79% of ADHF patients with AKI had at least 1 main comorbidity. The presence of comorbidities is the independent risk factor for adverse short- and long-term outcomes in ADHF patients with AKI.

P411
Prognostic impact of renal dysfunction in the patients with acute heart failure

E Mezhonov[1]; Y Vyalkina[2]; S Shalaev[1]
[1]*GBUZ TO "Regional clinical hospital", Tyumen, Russian Federation*; [2]*Tyumen State Medical University, Tyumen, Russian Federation*

Background: Renal disease as a target organ is often found in patients with cardiovascular disease patients. The question of influence on the state of renal function during acute heart failure (AHF), as well as the extent to which these disorders

determine the prognosis of patients becomes urgent. Purpose. To estimate the prevalence of renal dysfunction and its prognostic value in patients with AHF.
Materials and methods. The study included 141 patients (mean age 57.4 ± 9.86 years, 75.2% men), admitted to the hospital due to the development of symptoms of AHF, left ventricular ejection fraction of 15% to 80% (mean 37.8 ± 14.19%). Indicators of renal function were divided into 6 categories according to the estimated glomerular filtration rate (GFR) using a calculation formula CKD-EPI. Acute kidney injury (AKI) diagnosed according to the KDIGO recommendations (2012). The primary endpoint was defined as rehospitalization due to symptoms of AHF or death from cardiovascular causes. Result. Analyzed the frequency of occurrence of the endpoint, depending on the level of GFR and microalbuminuria (MA). With the decline of GFR levels increased in direct proportion to the frequency of rehospitalization due to AHF, so if GFR greater than 90 ml/min it amounted to 37.5%, 60-89 ml/min – 33.9%, while the GFR 45-59 ml/min – 48.9%, 15-44 ml/min – 78.6%, less than 15 ml/min - 100% (p = 0.027). Reduced GFR of less than 45 ml/min was associated with an increase in death from cardiovascular causes - 43.8%, while in patients with GFR over 45 ml/min death from cardiovascular causes registered with 12,8% (p = 0.005). Increased MA to levels of over 300 mg/l was associated with a poor prognosis, the endpoint and death from cardiovascular causes was reported in 81.8% and 36.4% of patients, and in patients without MA – 39.8% and 12.0% respectively (p = 0.012 and p = 0.036). Analyzed OR of the primary endpoint of the depending on the level of GFR and MA. GFR of less than 60 ml/min increases the risk of an endpoint of 2.5 times (OR 95% 2.541 (1.284-5.028), p = 0.007), and GFR less than 45 ml/min - 10 times (OR 95% 10.157 (2.213-46.622), p = 0.003). GFR of less than 45 ml/min increases the risk of death from cardiovascular causes of 5 times (OR 95% 5.299 (1.732-16.214), p = 0.003). The presence of MA over 300 mg/l increases the risk of the primary endpoint in 6 times (OR 95% 5.946 (1.236-28.611), p = 0.026). Development AKI associated with an increase of the frequency of the primary endpoint as compared to patients without AKI, 85.7% and 41.7% respectively (p = 0.003). The frequency of death in patients with AKI also increased to 57.1%, whereas in patients without AKI – 11.8% (p < 0.001). The AKI increases the risk of the primary endpoint in 8 times (OR 95% 8.377 (1.8-38.996), p = 0.007) and the risk of death from cardiovascular causes of 10 times (OR 95% 9.956 (3.035-32.652), p < 0.001). Conclusion. Reduced GFR and MA is important predictors of cardiovascular morbidity and mortality in patients with AHF.

P412
The interaction between heart failure and renal failure

AN Anass Inchaouh[1]; A Hadadi[1]; R Habbal[1]
[1]*Ibn Rochd University Hospital, Casablanca, Morocco*

Introduction: Heart failure (HF) is an important public health problem whose incidence and prevalence are progressively increasing. Multiple comorbid conditions are common in patients with HF. Renal failure (RF) is one of the important comorbid condition that shares common cardiovascular risk factors with HF. The interaction between HF and RF has been suggested to cause a deterioration of each of these conditions. Moreover, the interaction between these conditions has been suggested to form a vicious cycle, termed cardio-renal syndrome, which increases mortality.
Aim: Our aim was to investigate the prevalence, the clinical characteristics of HF patients with different deg rees of renal dysfunction
Methods: This is a retrospective study of all HF patients registered in the therapeutic Unit of Chronic Heart failure in the cardiology department over a period of 2 years. Renal function was determined from the estimated glomerular filtration rate (GFR), and patients were divided into 4 stages : GFR 60-89(Mildly reduced kidney function), GFR 30-59 (Moderately reduced kidney function), GFR 15-29 (Severely reduced kidney function) and GFR < 15 mL/min per 1.73 m^2 or on dialysis (endstage kidney failure).
Results: The study was conducted in 1280 patients with a mean age of 68.6 years and male predominance (60,1%). RF was found in 62% of the patients. Patients with moderate RF were characterized by the higher prevalence of strokes, myocardial infarction and the lowest ejection fraction. Patients with severe RF had the worst cardiovascular risk profile : older age, higher prevalence of cardiovascular risk factors, diabetes, hypertension, dyslipidemia, the lowest walking parameter of the 6-minute walk test and the most prescription of diuretics. Patients with endstage RF had more anemia and less prescription of angiotensin-converting enzyme (ACE) inhibitors.
Conclusion: RF seem to be highly prevalent in HF patients with a worse risk profile. The presence of cardio-renal syndrome highlights the necessity of early treating these comorbidities.

P413
Cardiohepatic syndrome is driven by congestion rather than hypoperfusion in decompensated heart failure

A Soloveva[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Department of Internal Disease Propaedeutics, Moscow, Russian Federation*

Objective: Abnormal liver function tests (LFT) are associated with specific clinical, biological and prognostic features in decompensated heart failure (DHF) and defined as cardiohepatic syndrome (CHS), but their predictors are still unknown. The aim of this study was to assess the prevalence and predictors of CHS in DHF.
Methods: In 322 patients with ADHF (190 male, 69.5 ± 10.6 years (M ± SD), arterial hypertension 87%, myocardial infarction 57%, atrial fibrillation (AF) 65%, diabetes mellitus 42%, known chronic kidney disease 39%, chronic anemia 29%, left ventricular ejection fraction (EF) 37.6 ± 12.6%, EF<35% 39.1%) alanine transaminase (ALT), aspartate transaminase (AST), direct and total bilirubin (DB and TB), alkaline phosphatase (AP), gamma-glutamyl transpeptidase (GGT) were measured on admission. CHS was considered when at least one LFT level exceeded upper normal limit. Multivariate logistic regression analysis was performed. p < 0.05 was considered statistically significant.
Results: CHS occurred in 274 (85.1%) of patients with DHF. Increase of ALT was detected in 50 (15.5%), AST in 46 (14.3%), DB in 262 (81.4%), TB in 192 (59.6%), AP in 90 (27.9%) and GGT in 102 (31.7%) of patients with DHF. Most of LFT elevations were moderate (≤ 3UNL) - ALT in 38 (76%), AST in 42 (91.3%), DB in 150 (57.3%), TB in 186 (96.9%), AP in 86 (96.7%), GGT in 74 (72.5%) of alterations cases. The independent predictors of CHS were severe tricuspid regurgitation (odds ratio (OR) 32.3, 95% confidential interval (CI) 7.7-135.7, p < 0.001), right ventricular end diastolic volume >31 mm (OR 11.7, CI 5.2-26.2, p < 0.05), heart rate on admission >115 per minute (OR 10.9, CI 2.6-45.9, p < 0.05), EF<31% (OR 6.7, CI 2.4-19.3, p = 0.02), chronic AF (OR 5.7, CI 2.7-11.8, p < 0.05), hydrothorax (OR 4.3, CI 1.9-9.4, p < 0.05) and ascites (OR 2.7, CI 1.3-5.7, p < 0.05).
Conclusions: severe tricuspid regurgitation and right ventricular dilation were more powerful predictors of cardiohepatic syndrome in DHF than heart rate on admission >115 per minute and EF<31%.

P414
Nonalcoholic fatty liver disease and increased risk of 1-year all-cause and cardiac hospital readmissions in elderly patients admitted for acute heart failure

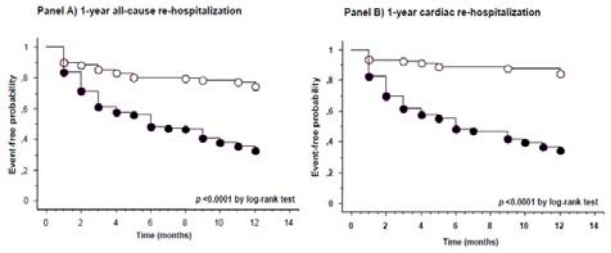
F Filippo Valbusa[1]; D Agnoletti[1]; S Bonapace[2]; L Scala[1]; C Grillo[1]; P Arduini[3]; E Turcato[3]; G Targher[4]; G Arcaro[1]
[1]*Sacro Cuore - Don Calabria Hospital, Internal Medicine, Negrar-Verona, Italy*; [2]*Sacro Cuore - Don Calabria Hospital, Division of Cardiology, Negrar-Verona, Italy*; [3]*Sacro Cuore - Don Calabria Hospital, Division of Geriatry, Negrar-Verona, Italy*; [4]*University and Azienda Ospedaliera Universitaria Integrata of Verona, Section of Endocrinology, Diabetes and Metabolism, Verona, Italy*

Background: Nonalcoholic fatty liver disease (NAFLD) is an emerging risk factor for heart failure (HF). The rates of hospital readmissions and the related costs continue to rise dramatically. The aim of this study was to investigate whether NAFLD diagnosed at hospital admission was independently associated with 1-year all-cause and cardiac re-hospitalizations in patients admitted for acute HF (AHF).
Methods: We studied 212 elderly patients who were consecutively admitted with AHF to our hospital over a 1-year period. NAFLD was diagnosed by ultrasonography. Patients with known acute myocardial infarction, severe valvular heart diseases, endstage renal disease, cancer, known liver diseases or decompensated cirrhosis were excluded. Cox regression was used to estimate hazard ratios (HR) for the associations between NAFLD and the outcomes of interest.
Results: The cumulative rate of 1-year all-cause re-hospitalizations was 46.7% (n = 99). Patients with NAFLD (n = 109; 51.4%) had remarkably higher 1-year all-cause and cardiac re-hospitalization rates compared with their counterparts without NAFLD. NAFLD was associated with an approximately 5-fold increased risk of 1-year all-cause re-hospitalization (adjusted-HR 5.26, 95% CI 3.03-9.08, p < 0.0001) after adjustment for established risk factors and potential confounders. Similar results were found for 1-year cardiac re-hospitalization (adjusted-HR 8.33, 95% CI 3.98-16.7, p < 0.0001).
Conclusions: NAFLD was independently associated with increased risk of 1-year all-cause and cardiac re-hospitalization in elderly patients admitted with AHF.

Table 1

Cox regression analyses - Association between NAFLD and risk of 1-year all-cause or cardiac re-hospitalization rates in hospitalized patients with AHF at baseline			
CoxHazard Models	Hazard ratio(s)	95% CI	p value
1-year all-cause re-hospitalization: NAFLD (yes vs. no) (n: 212)			
Unadjusted model	3.50	2.23-5.49	< 0.0001
Adjusted model	5.26	3.03-9.09	< 0.0001
1-year cardiac re-hospitalization: NAFLD (yes vs. no) (n: 187)			
Unadjusted model	5.86	3.27-10.4	< 0.0001
Adjusted model	8.33	3.98-16.7	< 0.0001

Data are expressed as hazard ratios ± 95% confidence intervals (CI) as assessed by either univariable (unadjusted) or multivariable Cox hazard models. Covariates included in multivariable regression models, with NAFLD, were: age, sex, hospital ward, pre-existing diabetes, CHD, LV-ejection fraction, eGFR and NT-proBNP, serum sodium and GGT levels.



P415

Mixed phenotype of cardiohepatic syndrome is common and associated with worse prognosis in patients with decompensated heart failure

A Soloveva[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Department of Internal Disease Propaedeutics, Moscow, Russian Federation*

Objective: Over the last several years different mechanisms of cardiohepatic syndrome (CHS) in decompensated heart failure (DHF) have been discussed. The purpose of the study was to assess the prevalence and associations of different phenotypes of CHS in patients with DHF.
Methods: In 322 patients with DHF (190 male, 69.5 ± 10.7 years (M ± SD), arterial hypertension 87%, myocardial infarction 57%, atrial fibrillation 66%, diabetes mellitus 42%, known chronic kidney disease 39%, chronic anaemia 29%, ejection fraction (EF) 38 ± 13%, EF<35% 39%) liver function tests (LFT) - alanine transaminase (ALT), aspartate transaminase (AST), direct and total bilirubin (DB and TB), alkaline phosphatase (AP), gamma-glutamyl transpeptidase (GGT) were measured on admission.
LFT were considered abnormal when levels exceeded local upper normal limit (UNL). Only ALT and/or AST increase was considered as hepatocellular CHS. Isolated increase of GGT, AP, DB and TB (with DB increase) – as cholestatic CHS. The simultaneous increase of markers of cytolysis and cholestasis was considered as mixed CHS. Mann-Whitney test was performed, $p < 0.05$ was considered statistically significant.
Results: Abnormal LFT occurred in 274 (85.1%) of patients. Hepatocellular, cholestatic and mixed CHS were detected in 0.4, 32.8 and 66.8% of patients with DHF and CHS. Patients with mixed vs cholestatic CHS had higher levels of AST (median 32 (interquartile range 23;49) vs 21 (18;27) U/l,), ALT (30 (15;53) vs 17 (12;25) U/l), DB (12 (7;17) vs 6 (4;9) μmol/l,) and TB (33 (25;41) vs 19 (15;22) μmol/l), $p < 0.001$ for all comparisons. Patients with mixed vs cholestatic CHS had higher cholestatic markers increase incidence (DB (97 vs 93%, $p < 0.05$), TB (90 vs 31%, $p < 0.001$), GGT (44 vs 24%, $p < 0.01$) and AP (39 vs 20%, $p < 0.01$)) and severity: incidence of increase >2UNL of DB (82 vs 40.5%, $p < 0.01$), TB (24.4 vs 0%, $p < 0.01$), GGT (60 vs 54.6%, p>.05) and AP (18 vs 11%, $p < 0.01$). Patients with mixed vs cholestatic CHS had higher NT-proBNP level (9200 ± 7985 vs 7122 ± 6572 pg/ml, $p < 0.05$), incidence of EF<35% (47 vs 36%, $p < 0.05$), severe mitral regurgitation (51 vs 31%, $p < 0.01$), vasopressor therapy (11 and 4%, $p < 0.05$), lower systolic blood pressure (SBP) (132 ± 17 vs 144 ± 21 mmHg, $p < 0.001$) and pulse BP (51 ± 14 vs 60 ± 15 mmHg, $p < 0.001$) on admission. No significant differences in signs of congestion were observed between groups. Mixed CHS was associated with higher all-cause death in 6 months (30 vs 23%, $p < 0.05$).
Conclusions: The prevalence of mixed CHS in patients with DHF was 66.8%. Patients with mixed vs cholestatic CHS had higher LFT and NT-proBNP levels, incidence of LFT increase, severe mitral regurgitation, EF<35%, vasopressor therapy, lower SBP and pulse BP on admission and had worse prognosis.

P416

In-hospital changes of liver stiffness and biomarkers of liver fibrosis in patients with acute decompensated heart failure

AA Balashova[1]; PV Lazarev[1]; IV Garmash[1]; VS Moiseev[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Purpose: To assess the dynamic changes in liver stiffness measurements (LSM) and direct fibrosis markers in patients hospitalized with acute decompensated heart failure (ADHF) receiving standard heart failure therapy according to the international guidelines.
Methods: 35 patients [8 female, median age 58 (IQR 47-68) years, NYHA III class n=16 (46%), NYHA IV class n=19 (54%)] were included. Transient elastometry measurements (FibroScan®) and direct markers of fibrosis were analyzed at baseline and discharge from hospital. The median duration of hospitalization was 14 days. Serum concentration of direct markers of fibrosis [matrix metalloproteinase-9 (MMP-9), N-Terminal Propeptide of Type III Collagen (PIIINP), laminin] was determined by means of immunosorbent assay.
Results: Heart failure therapy resulted in the reduction of signs of congestion [weight loss 5.5 (4.0-7.0) kg]. There was a significant decrease in LSM (26,3 [19-48] vs. 16.6 [11-21.8] kPa; $p < 0.01$) from baseline to end of hospitalization, although they remained elevated (grade 4 METAVIR score). A decline in LSM significantly correlated with weight loss (rho 0.4, < 0.05) and reduction of leg circumference (rho 0.3, < 0.05). On admission direct markers of fibrosis were elevated above reference values [MMP-9 850 (525.0-1390.0) ng/ml, PIIINP 33.4 (24.4-55.2) ng/ml, laminin 218 (167.0-248.5) ng/ml], and no significant changes occurred during hospitalization [ΔMMP-9 50 (-420 - 260) ng/ml, ΔPIIINP 5 (-0.7 - 13.7) ng/ml, Δlaminin 12 (-33 - 50) ng/ml, p>0.05 for all comparisons].
Conclusion: Increased LSM in patients with ADHF is not explained by fibrosis alone, and tends to be overestimated due to the presence of congestion This is confirmed by the absence of dynamic changes in fibrosis markers. Therefore, the application of transient elastometry for assessment of fibrosis in patients with ADHF is limited.

P417

Improvement of heart failure symptoms through novel implantable remede central sleep apnea treatment device: first long-term experience

H Fox[1]; T Bitter[1]; D Horstkotte[1]; O Oldenburg[1]
[1]*Herz- und Diabeteszentrum NRW, Ruhr-Universität Bochum, Clinic for Cardiology, Bad Oeynhausen, Germany*

Background: Sleep-disordered breathing (SDB) and Cheyne-Stokes respiration (CSR) are associated with shorter survival periods in patients with heart failure (HF). A novel treatment method for this patient group is unilateral phrenic nerve stimulation by the remedē system, a transvenously implantable neurostimulation device, which has recently been studied in a short-term randomized, controlled trial. Previous literature has shown the efficacy and safety of the treatment with this first-generation device, but hardly any data is available on long-term clinical parameters in HF patients.
Methods: We performed remedē® device replacement in the first three consecutive HF patients for battery depletion and documented observations on clinical parameters, longevity, operation procedure, complications and difficulties with this novel device therapy.
Results: All patients were on permanent neurostimulation treatment by phrenic nerve neurostimulation when device replacement became necessary. Apnoea-hypopnoea index (AHI from 45 ± 4/h to 9 ± 4/h), oxygen-desaturation index (ODI from 35 ± 7/h to 7 ± 6/h) and time spent with oxygen saturation of < 90% (T < 90% from 5 ± 7 to 0 ± 0%) were improved and improvements remained constant throughout the four-year follow-up. Mean battery life was 4.2 ± 0.2 years, mean replacement procedure time was 25 ± 5.1 minutes. Using conventional X-ray

stable lead positions in a long-term setting were documented and no major complications occurred. In addition, clinical exercise capacity and sleepiness symptoms improved.
Conclusions: The novel remedē® device shows a sustained therapy efficacy and safety in terms of stable lead positions over four years. Long-term phrenic nerve neurostimulation therapy for central SDB/CSR in HF appears feasible in a clinical routine setting to improve HF symptoms.

P418
Sleep disorders and quality of life in patients with heart failure

I Uchmanowicz[1]; J Orzepowska[2]; M Wleklik[1]; MH Magdalena Hanna Lisiak[1]
[1]Wroclaw Medical University, Department of Clinical Nursing , Wroclaw, Poland; *[2]Wroclaw Medical University, Cardiology Department, Wroclaw, Poland*

Introduction: Population aging dynamics contribute to increasing numbers of elderly individuals, including heart failure (HF) patients. Age is a risk factor for a multitude of diseases, including cardiovascular disorders, as well as a factor affecting sleep quality and quantity. Patients with HF commonly experience poor sleep quality, which reduces both total sleep quantity and sleep effectiveness, and increases sleep and awakening latencies, compared to individuals without HF. The sleep disorders seen in HF patients significantly affect their quality of life and self-care capabilities.
Purpose: To analyze correlations between sleep disorders and quality of life in HF. To analyze the impact of socio-demographic and clinical factors on sleep disorders in HF.
Material and methods: The study included 100 patients (40 female and 60 male, mean age: 68.69 ± 14.27 years) hospitalized in a Cardiology Ward. Material was collected using a socio-demographic questionnaire, the patients' clinical data, and standardized research instruments: the Epworth Sleepiness Scale, the Minnesota Living with Heart Failure (MLHF) questionnaire specifically evaluating quality of life in HF, and the general WHO Quality of Life (WHOQoL) questionnaire. Correlations and differences at $p < 0.05$ were considered statistically significant.
Results: Patients with sleep disorders were shown to have a lower quality of life than those without sleep problems, both in the MLHF ($p < 0.001$) and in the WHOQoL (r=1.36, $p = 0.002$) scales. Sleep disorders indicated by the Epworth scale were correlated with NYHA functional class (r=3.917, $p = 0.003$), left ventricular ejection fraction – LVEF (r=-0.056, $p = 0.029$), the use of diuretics (r=1.208, $p = 0.034$), and the use of digoxin (r=1.854, $p = 0.015$).
Conclusions: 1. Sleep disorders adversely affect quality of life in heart failure patients. 2. Increased use of diuretics and digoxin contributes to sleep disorders in HF patients. 3. Sleep disorders in HF patients are correlated with higher NYHA class, lower LVEF, and higher proBNP levels.

P419
Sleep apnea in peri-partum cardiomyopathy patients admitted in acute heart failure: a longitudinal study in Mozambique

M Machava[1]; I Mbanze[1]; P Deyoung[2]; J Orr[2]; A Malhotra[2]; E Calua[1]; R Banze[1]; C Muianga[1]; V Govo[1]; N Jessen[1]; A Fabula[1]; A Oliveira[1]; A Damasceno[1]
[1]Eduardo Mondlane University, Maputo, Mozambique; *[2]UCSD, S. Diego, United States of America*

Funding Acknowledgements: Resmed grant

Background: There are very few studies on sleep apnoea in Sub Saharan Africa and much lees in peripartum cardiomyopathy. We reported previously that sleep apnoea was common in patients admitted with acute heart failure in a cardiac service in Mozambique despite being younger and leaner than the ones usually studied in other series. Moreover, longitudinal follow-up also show that sleep apnoea improved in some treated and compensated patients but not in all.
Purpose: Peripartum cardiomyopathy is common in Sub Saharan Africa and occurs in young patients. Furthermore, Cheyne-Stokes respiration is uncommon in women. Therefore, we sought to examine the prevalence and outcomes of sleep apnoea in peripartum cardiomyopathy patients admitted with decompensated acute heart failure recently diagnosed.
Methods: Subjects were recruited from an acute care cardiology unit in Mozambique. Consenting acute decompensated heart failure subjects admitted to our service underwent type III portable sleep testing (ApneaLink, Resmed) and echocardiography at both baseline and at 6 month follow up. Follow up evaluation was performed after heart failure treatment according to local practice. Sleep studies were scored by a RPSGT using a modified Chicago criteria (3% desaturation).
Results: To date, 153 subjects have undergone baseline evaluation. Mean age was 41 ± 16 years, 60% were female, 26% known HIV positive and BMI was 23.7 ± 7 kg/m2. Of these, 13% of subjects had peripartum cardiomyopathy. Peripartum patients were younger (28 ± 6 versus 43 ± 17 years; $p < 0.001$), with similar BMI, but lower LVEF (26 ± 3% versus 36 ± 2%; $p = 0.02$) and smaller left atrial size (44 ± 1 versus 53 ± 1 cm3; $p = 0.001$). Baseline AHI was not significantly different between those with peripartum and non-peripartum aetiology (17.8 ± 2.6/hr versus 19.3 ± 1.7/hr; $p = 0.403$). Similarly, there was no difference in OAI, CAI, hypopnea index, %CSR, baseline or nadir Sp02, or %time SpO2 < 90%.
Follow up data at 6 months were available for 77 subjects, including 16 subjects that had died. Using fixed effect modelling, the AHI decreased by a mean of 6.2 ± 3.0/hr ($p = 0.037$). There was no significant difference in this change in the peripartum group ($p = 0.736$) as well as in change in AHI from baseline to 6 months between the peripartum and non-peripartum groups. LVEF improved non-significantly by a mean of 4.7 ± 3.0% with no significant difference between the two groups.
Conclusion: Sleep apnoea is similarly severe in acutely decompensated heart failure patients with peripartum cardiomyopathy compared to other aetiologies, despite younger age, female gender, and differences in echocardiographic measures. Although the sample size is small, we found no differences in the improvement of sleep apnoea in peripartum patients compared with the whole group.

P420
Identification of cognitive impairment and delirium in patients with decompensated heart dailure

S Mitchell[1]; K Jones[2]; J Taylor[2]; T Quinn[2]
[1]University of Glasgow, Glasgow, United Kingdom; *[2]Glasgow Royal Infirmary, Glasgow, United Kingdom*

Background: Delirium is common in older hospitalized patients and associated with morbidity and mortality. The majority of patients admitted with acute decompensated heart failure (ADHF) are older but there has been limited study of delirium in this group. The local target is to perform cognitive screening in all older unscheduled admissions and implement delirium prevention/management in all at risk.
Purpose:We aimed to benchmark cognitive screening of in-patients with ADHF and identify patients with delirium.
Methods: Patients admitted to a cardiology ward with ADHF were screened over 5 weeks. The ward admits unselected adults with cardiovascular pathologies not requiring level 2 care. Cases were identified by case-note review. Preferred cognitive screens in our centre are the 4 point Abbreviated Mental Test (AMT) and 4AT for delirium. The Think, Investigate, Manage, Explore (TIME) bundle is used to initiate delirium prevention/management. We recorded any completed cognitive assessment. We then assessed ADHF patients using the 4AT, 10 point AMT and an informant questionnaire for cognitive impairment (AD8).
Results:We identified 43 patients, mean age 78.7 years (range 52-95). Two patients refused to participate, 1 was terminally ill. Of 40 patients assessed, AMT4 and 4AT were completed by ward staff in 85% and 45% respectively. The TIME bundle was initiated in 42.5% of patients, none fully completed. Four patients had an established diagnosis of cognitive impairment. Following our assessment, a further 11 patients were identified as having cognitive impairment, 8 of these had not been identified by the treating team. Eight patients (20%) screened positive for delirium of whom 5 were assessed as also having likely underlying cognitive impairment.
Conclusions: Cognitive impairment, in particular delirium, is common in patients hospitalized with ADHF, but recommended screening and management bundles are infrequently completed. This has important implications for the training of healthcare professionals around recognition and management of these conditions.

P421
Heart failure and cardiogenic shock are predisposing factors for nosocomial infections in an intensive cardiac care unit.

M Carrington[1]; J Pais[1]; B Bruno Cordeiro Picarra[1]; AR Santos[1]; R Guerreiro[1]; J Carvalho[1]; K Congo[1]; D Bras[1]; J Aguiar[1]
[1]Hospital do Espírito Santo, Évora, Portugal

Introduction: Patients with heart failure (HF) usually had multiple comorbidities and could be more susceptible to nosocomial infections. Currently, there is a lack of information regarding its prevalence and prognostic impact of nosocomial infections in patients admitted to an Intensive Cardiac Care Unit (ICCU).
Purpose: To determine the prevalence of nosocomial infections in patients hospitalized in an ICCU and to identify possible predictors of their appearance.
Methods: Prospective study, which included all patients consecutively admitted to the ICCU within 4 years. We considered 2 groups: Group 1 - patients who developed nosocomial infections and Group 2 - patients who did not develop nosocomial infections. We registered demographic data, patient's provenience (emergency department (ED), other general intensive care units (ICU), outpatient clinic or other hospitals), diagnosis of admission, duration of hospitalization and destination of the patient (cardiology ward, ambulatory or death).
Results: From a total of 1633 patients admitted to the ICCU, 150 patients (9,1%) developed nosocomial infections, of these 40,0% were respiratory, 26,7% urinary, 16,0% had fever without an identified infectious focus, 14,0% were severe sepsis

and septic shock, and 3,3% had infection of another etiology. These patients were older (72,4 ± 11,8 vs 67,7 ± 14,2 years, p = 0,001), with no differences between genders. The main diagnosis of admission was acute coronary syndrome in both groups (Group 1: 53,3% vs 52,8%, p = ns); however, Group 1 patients were more frequently admitted for decompensated heart failure (16,7% vs 6,4%, p = 0,001) and cardiogenic shock (6,0% vs 0,6%, p = 0.001), with no differences in the nosological groups of arrhythmias, valvular heart disease or disease of the myocardium or pericardium. The majority of patients in both groups were admitted from the ED (Group 1: 56,0% vs 57,9%, p = ns); however, Group 1 patients were more frequently admitted from general ICU (17,3% vs 8,8%, p = 0,002), and less frequently from the outpatient clinic (2,7% vs 9,7%, p = 0,014), p = 0,006). Patients with nosocomial infection had longer hospitalizations (6,8 ± 5,2 vs 3,0 ± 2,0 days, p = 0,001), higher mortality (9,3% vs 3,1%, p = 0,001), and lower direct ambulatory discharges (4,7% vs 15,8%, p = 0,001).
Conclusions: Nosocomial infections are frequent, being presented 9,1% of patients hospitalized in our ICCU and were associated with a 2,3-fold increase in days of hospitalization and 3-fold increase in mortality. Heart failure and cardiogenic shock seems to be predisposing factors for its appearance.

P422
The relationship between employment status and depressive symptoms and minnesota living with heart failure questionnaire

G Guliz Kozdag[1]; K Hebert[2]; D Ural[3]; I Gogichaishvili[4]; L Arcement[5]; O Argan[6]
[1]Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey; *[2]General Electric, Wakasha Wisconsin, United States of America*; *[3]Koc University, Cardiology, Istanbul, Turkey*; *[4]Cleveland Clinic, Cleveland, Ohio, United States of America*; *[5]Chabert medical center, Houma Louisiana, United States of America*; *[6]Kocaeli Government Hospital, Cardiology, Kocaeli, Turkey*

Background: The association between unemployment and depression is explained by both causation and selection. The aims of this study were to identify the relationship between employment status and depressive symptoms and to determine the effects of work status on the score of Minnesota living with heart failure questionnaire (MLHFQ).
Patient Health Questionnaire (PHQ-9) does not establish a diagnosis of depression, but screens patients who are at risk. Scores between 0 and 4 identified patients at no risk for depression, scores between 5 and 9 represented patients who screened positive for mild depressive symptoms, and patients who scored 10 were tentatively diagnosed with moderate depression. For the purposes of this study, the PHQ-9 score was dichotomized to a ''non-depressed'' (PHQ-9: 0–9) and a ''depressed'' cohort (PHQ-9: ≥ 10).
Methods: and Results: This is a prospective, nonrandomized, cohort study of outpatients with heart failure (HF) and ejection fraction 40% by echocardiography. Patients in this study were enlisted in the country of Georgia from a hospital-affiliated outpatient HFDMP for systolic HF located at Central University Hospital, Tbilisi, Georgia. 377 patients (109 female, 268 male, mean age: 64 ± 13 years, mean ejection fraction: 32% ± 6) were enrolled between in August 2007 and July 2008. 15% of patients' PHQ-9 score were ≥ 10. 22% of unemployed patients had depressive symptoms, 19% of currently employed patients had depressive symptoms and 9% of previously employed patients had depressive symptoms. The difference was statistically significant between unemployed patients and previously employed patients (p = 0.004). Unemployed patients' MLHFQ score was 66 ± 16, currently employed patients' MLHFQ score was 62 ± 13 and previously employed' patients MLHFQ score was 56 ± 12. There was a statistical difference between currently employed patients' MLHFQ score and previously employed patients' score (p = 0.005). It was determined a statistical difference between previously employed patients' MLHFQ score and unemployed patients' MLHFQ score (p < 0.001).
Conclusion: Unemployed patients' group had the highest MLHFQ score and the highest ratio of depressive symptoms in this cohort.

P423
Comparison of sleep quality disturbances between patients with chronic heart failure and cancer patients

V Bistola[1]; E Keka[1]; E Danousi[1]; G Bakosis[1]; J Parissis[1]; J Lekakis[1]; G Filippatos[1]
[1]Attikon University Hospital, Heart Failure Unit, Cardiology Department, Athens, Greece

Background: Severe chronic diseases including heart failure (HF) and cancer are frequently associated with sleep quality disturbances. However, differences in the severity and individual components of such disturbances between different diseases are not known.
Aim: To compare severity and individual components of sleep quality disturbances between patients with HF and cancer.
Methods: One hundred patients hospitalized for HF (assessed at pre-discharge) and 100 cancer patients were included in the study. Sleep quality was assessed by Athens Insomnia Scale (AIS), a self-administered questionnaire that includes 8 items, 5 of which assess night sleep features and 3 assess daytime functional impairment due to insomnia. Each item has 4 possible answers, graded 0-3, higher rating denoting worse sleep quality.
Results: HF patients were 80% males, of age (mean ± SD) 72 ± 12 years, while cancer patients were 32% males, aged 61 ± 11 years. HF patients had higher scores in all individual components of night sleep quality and associated daytime functioning compared to cancer patients, including (mean ± SD): sleep induction (2.91 ± 1.02 vs 2 ± 0.98, p < 0.001), awakenings during the night (3.26 ± 0.836 vs 2.52 ± 0.904, p< 0.001), final awakening (2.20 ± 1.27 vs 1.63 ± 1.04, p = 0.001), total sleep duration (2.61 ± 1.12 vs 1.71 ± 0.945, p < 0.001), sleep quality (2.67 ± 1.11 vs 1.80 ± 0.921, p < 0.001), and well-being (2.73 ± 0.851 vs 1.95 ± 0.833, p < 0.001), functioning capacity (2.73 ± 0.862 vs 1.95 ± 0.821, p < 0.001) and sleepiness during the day (2.50 ± 0.969 vs 1.92 ± 0.917, p < 0.001).
Conclusion: Nighttime sleep quality and associated daytime functioning is worse in patients with HF as compared to cancer patients.

P424
Impact of chronic obstructive pulmonary disease on left ventricular geometry

A Milovancev[1]; M Kojicic[1]; S Puskar[1]; A Stojsic Milosavljevic[2]; M Stefanovic[2]; A Ilic[2]; S Tadic[2]; I Srdanovic[2]
[1]Institut of Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia; *[2]Institute of Cardiovascular Diseases of Vojvodina, Sremska Kamenica, Serbia*

Background: Left ventricular hypertrophy (LVH) represents significant risk factor for cardiovascular mortality. LVH impairs myocardial relaxation and causes diastolic dysfunction which may lead to heart failure (HF). The prevalence of HF especially HF with preserved ejection fraction (HFpEF) in chronic obstructive pulmonary disease (COPD) patients is high but often underdiagnosed and undertreated. The aim of our study was to assess left ventricular geometry in COPD patients with no previous history of cardiovascular (CVD) diseases.
Methods: We performed a prospective cohort study of 120 male patients with stable previously diagnosed COPD. All patients underwent spirometry and transthoracic echocardiography. LVH was defined as left ventricular mass index (LVMI) of >115 g/m2. Exclusion criteria were formerly diagnosed CVD including arterial hypertension.
Results: The mean value of forced expiratory volume in one second (FEV1) was 54.7 ± 27, 94% of the predicted value. The mean LVM index (LVMI) was 103. 4 ± 27.3 g/m2. The prevalence of LVH was 37. 2 % in COPD patients, 25. 2% had concentric LVH and 12% had eccentric LVH. There was a positive linear correlation between left atrial volume (LAV) and LVMI (r=0.32, p = 0.0004). The overall prevalence of HFpEF was 23, 3 % in COPD patients.
Conclusion: The frequency of LVH as an early sign of left ventricular remodeling is high in COPD patients with no history of CVD and HFpEF is present in majority of those patients.

P425
Outcome predictors for short and long-term evolution in patients with prosthetic valve endocarditis and prior heart failure with initial conservative intention to treat

MM Baluta[1]; E Panaitescu[2]; MM Vintila[3]
[1]Carol Davila University of Medicine-St Pantelimon Clinical Emergency Hospital-Cardiology Department, bucharest, Romania; *[2]Carol Davila University of Medicine and Pharmacy , Medical Informatics and Biostatistics, Marketing, Medical Technology , Bucharest, Romania*; *[3]St. Pantelimon Emergency Hospital, Cardiology, Bucharest, Romania*

Introduction: Short and long-term mortality in prosthesic valve endocarditis (PVE) remains high and strongly dependent on patients characteristics, disease course and on initial therapeutic strategy.
Purpose: The aim of our work was to identify common factors for short-term and long-term outcome in patients with PVE and initial conservative intention to treat, managed in infection disease departments.
Methods: We analyzed retrospectively 56 PVE patients (age 54.64 ± 11.34, 20 women and 36 men), diagnosed with modified Duke criteria along 5 consecutive years (2000-2004). They had either early PVE (n = 29) or late PVE (n = 27). Initial follow up was performed at the end of antibiotic treatment (EoAT). Long-term follow up (LTFU) was performed after 12.87 ± 0.97 years (15 years maximum). Final vital status was verified in National Insurance Database. Variables analyzed: demography, comorbidities, etiology, clinical, biochemical, echocardiography data and outcome. Ten patients were lost to LTFU (6 from early and 4 from late PVE group) and excluded from our analysis.
Results: Conservative therapy was successful in 71% of patients admitted in infectious diseases departments, with only one case of in-hospital death.

21.4% patients were transferred for early surgery due to conventional antibiotic treatment failure. The perioperative death rate was 33%. At the end of antibiotic cure of all studied patients, survival was 90.4% with a total duration of antibiotic therapy (AT) of 33.55± 12.8 days. Early valve surgery was determined by perivalvular extension of infection (p < 0.001), prostheses dysfunction (p = 0.00009), embolism (p = 0.007), persistent fever (p = 0.03). Factors strongly related to mortality overall at EoAT were age (p = 0.04), diabetes (p = 0.016), coexistence of ischemic heart disease (p = 0.07), prior heart failure (p = 0.07), ischemic left ventricular (LV) systolic dysfunction (p = 0.0002), hemodynamic instability (p = 0.04), persistent fever (p = 0.06), anemia (p = 0.001). We found at long-term follow up a reduced survival in remaining patient, only 44% (52.4% early PVE, 35% late PVE). Factors related to long-term mortality: advanced age (p = 0.0009), diabetes (p = 0.038), mid range LV ejection fraction 40% ≤EF < 50% (p = 0.038) and staphylococcus infection (p = 0.053). NYHA class at baseline does not influenced outcome statistically significant. Conclusions: We observed a very high long-term mortality in patients admitted in infectious diseases departments with an initial conservative intention to treat. Common outcome factors determined for both short-term and long-term survival in PVE patients were diabetes and advanced age. Short-term only poor prognosis factors were nonresponsive infection with valve dysfunction, embolism, prior heart failure, and anemia. Long-term only prognosis factors were staphylococcus infection, ischemic left ventricular systolic dysfunction, and mid range LVEF at baseline.

P426

Osteoporosis, frailty and non-adherence to the treatment in patients with chronic heart failure

VN Larina[1]; Il Chukaeva[1]; DG Karpenko[1]; AS Bayramova[1]; AV Pozdnyakova[2]
[1]*The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation*; [2]*M.V. Lomonosov Moscow State University, Faculty of Fundamental Medicine, Moscow, Russian Federation*

Non-adherence to guidelines is prevalent among elderly CHF patients, despite guideline-adherent treatment being independently associated with lower risk of all-cause and CV deaths. Efforts to improve adherence would lead to better outcomes for elderly HF patients. According to the World Health Organization, the adherence to the CHF treatment is the extent to which a patient's medication taking coincides with the prescribed treatment. The objective to determine the factors related to non-adherence to the treatment in elderly outpatients with CHF.
Methods: 40 female and 13 male, aged 60-88 yrs, suffering from NYHA FC II-III CHF entered the study. All patients had clinical, laboratories evaluation, Echo CG. The participants were identified as frail according to the frailty criteria of Fried. Frailty was diagnosed in patients with a score 3 or greater: unintentional weight loss (more than 10 pounds within the past year), self-reported exhaustion, slow walking speed, MMSE < 24 points, weakness. Validated questionnaire Morisky Medication Adherence Scale (MMAS-4) is being used to evaluate treatment adherence. Bone mineral density (BMD) in the lumbar spine (LI-LIV) and femoral neck (FN) were examined using dual-energy X-ray absorptiometry. Results. Osteoporosis (OP), T-score < -2.4 SD, was present in 62,3% (group 1), absent- in 37,7% patients (group 2). Patients of 2 groups did not differ with respect to the age, education, family presence, working status, NYHA FC, systolic/diastolic BP, AF cases or 6 min WT. Diabetes was found in 45% patients with OP and in 18,2%-without OP, =0,036. HbA1 was higher among patients without OP compared with those with OP (6,3 ± 0,7% vs 5,9 ± 1,3%, =0,047). N-proBNP was 1418 ± 170 pg/ml in patients with OP, 229 ± 180 pg/ml – without OP, =0,001. Patients with OP had higher rates of past bone fractures compared to those without OP, < 0,001. Treatment adherence was 42,4% in patients with OP and 45% - without OP. MMAS mean score was 3,3 ± 0,9 in patients with OP and 3,25 ± 0,8- without OP. There was correlations between high adherence and severity of CHF symptoms (=0,027, r=0,42), MMSE (=0,017, r=0,36), systolic BP (< 0,001, r=-0,44), low density cholesterol (=0,044, r=-0,33), diastolic BP (=0,04, r=-0,27) and past OP bone fractures (p = 0,039, r=0,46). Frailty associated with NYHA FC (=0,003, r=0,45), CHF hospitalization (=0,009, r=0,40), LVEF (=0,025, r=-0,37), OP (p = 0,019, OR 4,5, 95%CI 1,3-15,8) and past MI (p = 0,001, OR 6,8, 95%CI 2,2-20,8). Conclusion. These findings indicate that non-adherence was similar in two groups of patients and correlated with disease severity and past OP bone fractures. Due to fact that frailty in this population significantly associated with OP, we can suppose that the frailty influences on elderly patient's adherence. Our finding raises the fact that OP fractures and frailty could be a mere marker of HF severity and should become a routine additional assessment of HF outpatients' adherence to treatment.

P427

Prevalence and risk factors of venous thromboembolism in acute heart failure patients

T Titaya Sukhupanyarak[1]; T Yingchoncharoen[1]; P Sritara[1]; P Vathesatogkit[1]; S Yamwong[1]; P Angchaisuksiri[1]; T Panpikoon[1]
[1]*Mahidol University, medicine cardiology, Bangkok, Thailand*

Background: Venous thromboembolism is one of the consequences of heart failure and also impacts mortality and quality of life. However, the previous studies of VTE in heart failure in Thailand were small and the data was limited.
Objective: To evaluate the prevalence of VTE and risk factors in acute heart failure patients in Thailand.
Method: The prospective cohort study was conducted from December 2015 to July 2016 in Ramathibodi hospital, Mahidol university, Thailand. The patients who were hospitalized due to acute heart failure were enrolled and screened for deep vein thrombosis (DVT) by Doppler ultrasonography beyond 5 days and computed tomography angiography (CTA) if clinical suspected pulmonary embolism. Multiple logistic regression was performed to identify risk factors of VTE.
Results: 80 patients were enrolled in the study, 41 were male (51.3%), mean age was 73 years old, mean BMI was 22.4 kg/m2, primary etiology of heart failure were ischemic (37.5%) and hypertensive cardiomyopathy (25%), mean NT pro-BNP was 6637 pg/mL, mean D-dimer was 1139 ng/mL, mean EF was 50 %. Among 80 patients, 36 patients (45%) had history of prior heart failure, 4 patients (5%) had history of prior VTE and 7 patients (8.8%) had history of cancer. The prevalence of VTE was 10% (8 patients). Multiple logistic regression showed history of prior VTE as an independent risk of VTE in our population (OR 71.795 (95% CI 4.161-1238.679, P value 0.003).
Conclusion: In Thailand, the prevalence of VTE in hospitalized heart failure patients is 10%. The history of prior VTE increases risk factor of VTE in hospitalized heart failure.

multivariable analysis

Patient characteristics	Odd ratio	95% CI	P-value
History of cardiovascular condition: Venous thromboembolism	71.795	4.161-1238.679	0.003
History of non cardiovascular condition: anemia	5.579	0.850-36.634	0.073
ICU admission	6.567	0.645-66.819	0.112

P428

Intensive statin therapy has no impact on cognition in high cardiovascular risk patients

M Vorobyeva[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Objective: The recent cholesterol guidelines recommend aggressive statin therapy in patients at high cardiovascular (CV) risk. Rates of cognitive impairment are relatively high in populations with CV diseases and risk factors. The relationship between statins and cognition remains unclear. The aim of the study was to investigate the cognitive dysfunction (CD) and effects of intensive statin therapy on cognition in patients at high CV risk.
Methods: In 187 patients with history of clinically evident CV disease and fasting low-density lipoprotein cholesterol (LDL-C)>1.8 mmol/l or non-high-density lipoprotein cholesterol (non-HDL-C)>2.6 mmol/l (64% male, 60.8 ± 8.6 (M ± SD) years, >65 years 37.4%, current smoking 42%, abdominal obesity 65%, arterial hypertension 90%, myocardial infarction 73%, percutaneous coronary intervention 58%, coronary artery bypass surgery 13%, non-hemorrhagic stroke 30%, diabetes mellitus 22%, symptomatic peripheral arterial disease 8%, 42%, previous statin therapy 74%), the cognitive impairment and effects of intensive statin therapy (atorvastatin 80 mg/day) was assessed. Cognitive functions were evaluated by using the Montreal Cognitive Assessment (MoCA) scale before and 6 months after start of aggressive statin therapy. Wilcoxon test and multivariate logistic were performed. P < 0.05 was considered significant.
Results: Atorvastatin 80 mg decreased lipids significantly: total cholesterol from 5.4 ± 1.5 to 4.0 ± 0.8 mmol/l; LDL-C from 3.3 ± 1.3 to 2.2 ± 0.6 mmol/l; non-HDL-C from 4.3 ± 1.4 to 2.9 ± 0.7 mmol/l; triglycerides from 2.1 ± 1.3 to 1.5 ± 0.9 mmol/l, (p < 0.05 for all). Changes of HDL-C were insignificant. Mean MoCA performance was 24.3 ± 2.6. 118 (63%) patients had CD (MoCA score < 26). Patients with vs without stroke (22.4 ± 3.1 vs 24.7 ± 2.7 scores by MoCA, p < 0.05) and older vs less 65 years (21.1 ± 3.3 vs 25.6 ± 1.8 scores by MoCA, p < 0.05) had more severe CD. 87.5% of patients with stroke and 72.9% of patients >65 years had CD. After 6 months of intensive statin therapy mean total MoCA performance was 23.9 ± 3.1. Changes of cognitive function were unsignificant (p = 0.4). In patients with stroke and patients with baseline MoCA score < 26 we observe a trend to decline of cognitive functions: from 21.1 ± 3.3 to 21.6 ± 3.9 (p = 0.08) and from 21.3 ± 3.8 to 20.4 ± 3.8 (p = 0.09), respectively. Severity of CD and changes of MoCA scores were not associated with lipid levels and their dynamics.
Conclusions: 63% of high CV risk patients have CD according to MoCA scale. Patients with stroke and patients ≥65 years had higher prevalence and more

severe CD. No significant association between statin use and cognition was found. Changes of cognitive status were not associated with lipid levels and their dynamics.

P429

Depressive disorders and peculiarities of cardiohemodynamics in patients with chronic heart failure and comorbidity

G Ganna Tytova[1]; O Liepieieva[2]; N Ryndina[1]; M B Teclebrhan[1]
[1]Kharkiv National Medical University, Kharkiv, Ukraine; *[2]City clinical hospital #27, CCU, Kharkov, Ukraine*

Anemia and kidney dysfunction are considered to be predictors of unfavorable course of chronic heart failure. Numerous studies proved that depressive disorders are a risk factor for re-hospitalization and death in patients with CHF.
Purpose: Study of morpho-functional myocardial changes and estimation of depressive disorders in anemic patients with chronic heart failure and chronic kidney disease.
Material and methods: 145 patients (age 71,42 ± 8,66y.) with CHF II- IVFC as a result of IHD. Main group consisted of 87 patients with anemia and CKD II-III st. on a background of CHF. The comparison group consisted of 58 pts with CHF without anemia and CKD. FC of CHF was estimated by NYHA classification. CKD was defined by USA NKF classification K/DOQ. Anemia – by ICST, 1989 classification. Thus mild anemia was found in 50 pts (Igr), moderate – in 25 pts (II gr) and severe in 12 pts (III gr) of the main group. In order to study the structural and functional myocardium echocardiography was used. Beck depression inventory was used to study depressive disorders.
Results: There was no significant difference in LVESD and LVEDD in mild anemic patients with CHF and CKD. Patients of II gr had tendency for increasing LVESD and LVEDD, pts of III gr had significally increased (p≤ 0,05) comparing to group of pts without anemia and CKD. Patients of the I gr. had significally decreased LVPWd, IVS, EF and increased sizes of RA and RV comparing to group of comparison. Comparing these parameters in pts of I and II groups with comparison group there were no significant differences (p≥ 0,05). There was significant increasing of LVESD, LVEDD, LVESV, LVEDV, sizes of LA and RV, and decreasing of LVPWd, EF in pts of III gr comparing to pts of I and II gr. Due to Beck scale symptoms of depression grew in proportion to severity of anemia with maximum in pts of the III gr. Patients of the Igr mostly had cognitive-affective disorders. Patients of II and III gr, mostly had cognitive-affective disorders as well as somatic manifestation of depression.
Conclusion: : Negative influence of anemic syndrome on myocardium was seen in formation of anemic cardiomyopathy with dilation of heart chambers and decreased EF and also in emotional sphere as development of depressive disorders, which worsen not just a course of CHF but also decrease life quality ruining social and family functioning and behavior in general, aimed at overcoming the disease.

P430

High prevalence of masked arterial hypertension in patients with rheumatoid arthritis

E Troitskaya[1]; S Velmakin[1]; S Villevalde[1]; Z Kobalava[1]
[1]RUDN University, Moscow, Russian Federation

Background: Patients with rheumatoid arthritis (RA) have increased cardiovascular risk. Arterial hypertension (AH) is highly prevalent, and seems to be under-diagnosed and under-treated among patients with RA. Data on ABPM profile in patients with rheumatoid arthritis are lacking.
The aim of the study was to evaluate ABPM parameters and characterize phenotypes of blood pressure (BP) in patients with RA.
Materials and Methods: 58 patients with RA (EULAR 2010) without known cardio-vascular disease were examined (76% females, age 55,9 ± 15,8 (M ± SD) years, 10% smokers, 56% with AH, 34% with dyslipidemia). Median duration of RA was 8,5 years (IQR 3-16). Seropositive RA was diagnosed in 69% of patients. All patients received disease-modifying antirheumatic drugs (DMARDs), 22 (38%) - biological treatment. Median duration of AH was 4,0 years (IQR 0-12 years). All patients with AH received antihypertensive treatment. 24-h peripheral and central BP monitoring was performed (BPLab Vasotens, 'Petr Telegin'). P < 0.05 was considered significant.
Results: Mean office BP was 126 ± 19/78 ± 11 mmHg (peripheral) and 118 ± 20/80 ± 11 mmHg (central). 10 (17%) patients had elevated office BP (>140/90 mmHg). Mean BP values for peripheral and central BP were as follows: 125 ± 13/73 ± 9 and 116 ± 13/75 ± 9 mmHg for 24-h BP; 127 ± 14/74 ± 9 and 117 ± 13/77 ± 9 mmHg for daytime BP; 119 ± 13/69 ± 10 and 112 ± 14/71 ± 10 mmHg for nighttime BP. AH according to daytime BP was found in 14 (24,1%) pts, nighttime BP – in 28 (48,3%) pts, 24-h BP - in 9 (31,0%) pts. Phenotypes of BP were as follows: sustained normotension – in 36 (62,1%), masked hypertension in 12 (20,7%), sustained AH – in 8 (13,8%), white-coat hypertension in 2 (3,4%) patients. Isolated nocturnal AH was observed in 12 (20,7%) pts. 10 (17%) patients had isolated elevated central BP. 20 (34,5%) pts had elevated central SBP according to individual reference values; all patients with high office BP had elevated central BP.
Conclusions: High prevalence of AH is observed in patients with RA free of CVD and most of patients have satisfactory control of office BP. Relatively high prevalence of masked and isolated nocturnal hypertension despite antihypertensive treatment are observed in this population. These findings may help to optimize hypertension treatment in patients with RA.

P431

Arterial stiffness elevation is associated with high inflammatory activity in patients with rheumatoid arthritis

VSV Sergey Velmakin[1]
[1]RUDN University, internal disease, Moscow, Russian Federation

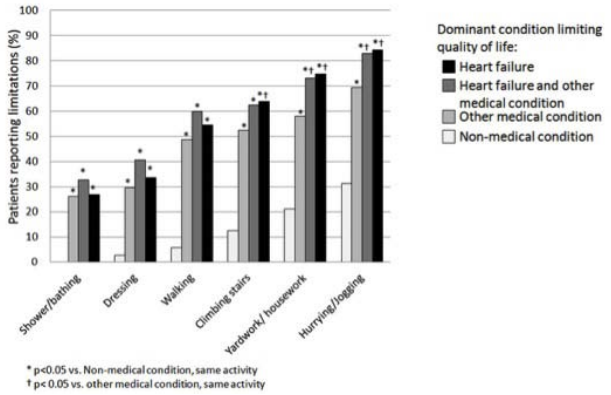
Background: Patients with rheumatoid arthritis (RA) are at higher risk of cardiovascular morbidity and mortality. Aortic stiffness is a predictor of CVD. Chronic inflammation plays a role in the development of atherosclerosis in RA. Relationships between inflammation and arterial stiffness in patients with RA are not well understood. The aim of the study was to evaluate parameters of arterial stiffness and their associations with inflammation activity in patients with RA.
Materials and methods: 42 patients with RA (EULAR 2010) were examined (67%female, age 59.7 ± 15.2 years, 14% smokers, 60% with AH, 47% with dyslipidemia. Median duration of RA was 9 years (interquartile range (IQR)3-17). Seropositive RA was diagnosed in 42% of patients. All patients received disease-modifying antirheumatic drugs (DMARDs),20% - biological treatment. hs-CRP and RF were assessed in all patients. Arterial stiffness was measured by applanation tonometry (SphygmoCor, AtCor) and cardio-ankle vascular index (CAVI) was assessed (VaSera1500).p < 0.05 was considered significant.
Results: Median CRP was 13 mg/dl (IQR 3-24mg/dl), median RF was 32 IU/ml (IQR8-165 IU/ml). Median PWV was 9.4 m/s (IQR7-11m/s). PWV increase>10m/s was observed in 16(37.8%) patients. Patients with PWV>10m/s were older (72.0 ± 8.5vs53.3 ± 14.9 years), had higher BMI (30.5 ± 5.9vs24.9 ± 4.5kg/m2) and longer duration of AH (median 14 years [IQR 7.5-18] vs 0 years [IQR 0-4.5]) and higher BP levels (143 ± 21/84 ± 9vs124 ± 13/78 ± 9 mmHg). They also had higher levels of LDL-C (3.0 ± 1.0vs4.1 ± 0.8 mmol/l), plasma glucose (5.6 ± 0.9vs4.9 ± 0.8 mmol/l), hs-CRP (median 9[IQR 2-17.1] vs 22[IQR 13-56.6] mg/dl) and CAVI (9.2 ± 0.5vs7.2 ± 1.2), p < 0.05 for trend. Spearmen analysis revealed positive correlations of PWV with age (r=0.65), BMI (r=0.53), SBP (r=0.62), DBP (r=0.41), LDL-C (r=0.60), glucose (r=0.38), AH duration (r=0.69) and hs-CRP (0.28), < 0.05 for trend. Multiple regression analysis confirmed that age (β=0.3, =0.0012), AH duration (β=0.4, =0.0001), SBP (β=0.42, < 0.0001) and hs-CRP-level (β=0.26, =0.0004) were independent predictors of arterial stiffness increase.
Conclusion: Inflammatory activity as well as other traditional risk factors is a predictor of arterial stiffness increase in patients with RA receiving DMARDs

P432

Variable contribution of heart failure to patient-reported limitation of daily activities

R R T Castro[1]; EF Lewis[1]; SR Motiwala[1]; M Bargash[1]; A Nohria[1]; E Joyce[2]; G Stewart[1]; A Desai[1]; LW Stevenson[1]
[1]Brigham and Women's Hospital, Boston, United States of America; *[2]Cleveland Clinic Foundation, Cleveland, United States of America*

Background: While therapy for heart failure (HF) has reduced hospitalization and death, patient-reported outcomes remain a target for further intervention. It is not known how often ambulatory pts report limitation to specific daily activities and how they perceive the effect of HF on their quality of life (QOL).
Objectives: To assess limitation during daily activities as reported by pts, and their perception of the role of HF to decrease their QOL.
Methods: During routine HF clinic visits, 736 ambulatory pts NYHA Class I-III rated limitations during six specific tasks and ascribed the major limitation to their QOL as due to heart failure, or due equally to HF and other medical conditions, more to other medical conditions, or most to non-medical issues.
Results: Limitation was described by 25% of all pts for bathing and 62% for yardwork/housework (Figure). QOL impairment was attributed mostly to HF by 48% of pts, whose limitations were similar to the 19% of pts who perceived equal impairment from HF and other medical conditions, but 33% of pts reported other medical or non-medical conditions to be more important.
Conclusion: Ambulatory pts without Class IV symptoms nonetheless reported substantial limitations to daily activity. However, half of HF patients perceived other medical or non-medical conditions to be equally or more limiting than HF to their QOL. While patient-reported outcomes offer a broad target in the ambulatory population, non-HF conditions may confound the ability to detect the impact of therapy.



Limitations reported by HF patients

P433

Prevention of contrast-induced acute kidney injury by furosemide with matched hydration in patients undergoing interventional procedures. a systematic review and Meta-Analysis of randomized trials

M Martina Boscolo Berto[1]; A Putzu[1]; A Belletti[2]; E Pasotti[1]; T Cassina[1]; T Moccetti[1]; G Pedrazzini[1]

[1]Cardiocentro Ticino, Cardiology, Lugano, Switzerland; *[2]San Raffaele Hospital of Milan (IRCCS), Intensive care, Milan, Italy*

The objective of this meta-analysis of randomized trials was to evaluate if the administration of furosemide with matched hydration using the RenalGuard System reduces contrast-induced acute kidney injury (CI-AKI) in hight risk patients, undergoing interventional procedures- CI-AKI is a serious complication following angiographic procedures and a powerful predictor of unfavorable early and long-term outcomes.The primary outcome was the incidence of CI-AKI, and the secondary outcomes were need for renal replacement therapy, mortality, stroke, and adverse events. Four trials (698 patients) published between 2011 and 2016 were included in the analysis and included patients undergoing percutaneous coronary procedures and transcatheter aortic valve replacement. RenalGuard therapy was associated with a lower incidence of CI-AKI compared with control treatment (27 of 348 [7.76%] vs. 75 of 350 [21.43%] patients; odds ratio: 0.31; 95% confidence interval: 0.19 to 0.50; I2=4%, $p < 0.00001$) and with a lower need for renal replacement therapy (2 of 346 [0.58%] vs. 12 of 348 [3.45%] patients; odds ratio: 0.19; 95% confidence interval: 0.05 to 0.76; I2=0%, $p = 0.02$). No major adverse events occurred in patients undergoing RenalGuard therapy. The main finding of this meta-analysis is that furosemide with matched hydration by the RenalGuard System may reduce the incidence of CI-AKI in high-risk patients undergoing percutaneous coronary intervention or transcatheter aortic valve replacement. However, further independent high-quality randomized trials should elucidate the effectiveness and safety of this prophylactic intervention in interventional cardiology.

P434

Predictors and implications of the left atrium volume index in an outpatient clinic.

W Robaeys[1]; HP Brunner-La Rocca[1]

[1]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands

Background: An increased left atrium (LA) is caused by multiple aetiologies and is known to be a risk factor for the development of a cerebrovascular accident and mortality. The LA size has been previously investigated mainly in specific populations (e.g. only hypertension, heart failure (HF), diabetes mellitus, or hypertrophic cardiomyopathy) and/or by inferior echocardiographic techniques (e.g. LA diameter) compared to LA volume index (LAVI), which is the most accurate technique to estimate LA size.
Purpose: Therefore, the objective of the present study was to investigate the predictors and implications of increased LAVI in unselected patients referred by general practitioners for cardiac consultation.
Methods: Investigating an outpatient clinic population of 3441 patients, this study analysed demographics (e.g. medical history), ECG (heart frequency and conduction times), laboratory (e.g. urea and NT pro-BNP), and echocardiography (e.g. E/A and mitral valve regurgitation (MR)) in all patients with a measurement of LAVI during their visit (n = 570). These patients were divided into two groups according to LAVI (LAVI $\geq$ 34 ml/m2, i.e. enlarged LA: n=254; LAVI $<$ 34 ml/m2: n=316). Logistic regression was used to qualify possible predictors and implications of enlarged LAVI.
Results: The present study established increased NT Pro-BNP (enlarged LAVI: 20 (8%), normal LAVI: 3 (1%), odds ratio [OR]:8.9, 95% confidence interval [CI]: 2.6-30.4, $P < 0.001$), prolonged QTc time (enlarged QTc time: 30 (12%), normal LAVI: 9 (3%), OR: 4.6, CI: 2.1-9.8, $P < 0.001$), hyperuricemia (enlarged LAVI: 25 (10%), normal LAVI: 8 (3%), OR: 4.2, CI: 1.9-9.4, $P < 0.001$), history of paroxysmal AFib (atrial fibrillation) (enlarged LAVI: 54 (21%), normal LAVI: 24 (8%), OR: 3.3, CI: 2.0-5.5, $P < 0.001$) and HF (enlarged LAVI: 20 (6%), normal LAVI: 6 (2%), OR: 4.4, CI: 1.7-11.2, P=0.001), history of intake of antiarrhythmics (enlarged LAVI: 55 (22%), normal LAVI: 17 (5%), OR: 4.9, CI: 2.7-8.6, $P < 0.001$), and bradycardia (enlarged LAVI: 59 (23%), normal LAVI: 31 (10%), OR: 2.8, CI: 1.7-4.5, $P < 0.001$) as the most important predictors for increased LAVI in this outpatient clinic. In multivariable analysis, patients with intake of antiarrhythmics are at risk for an enlarged LAVI (OR: 4.9, CI: 2.7-8.6, $P < 0.001$). Implications of enlarged LAVI were newly developed AFib (enlarged LAVI: 20 (8%), normal LAVI: 10 (3%), OR: 2.6, CI: 1.2-5.7, P=0.01) and increased risk for mortality (enlarged LAVI: 48 (19%), normal LAVI: 22 (7%), OR: 3.1, CI: 1.8-5.3, $P < 0.001$).
Conclusion: There are multiple risk factors for an increased LAVI in this low-risk population. Of those antiarrhythmic treatment seems to be the most important one. Patients with an enlarged LAVI are at increased risk to develop AFib or to decease.

VALVULAR HEART DISEASE (DIAGNOSIS, MANAGEMENT AND INTERVENTIONAL THERAPIES)

P435

Hospital and one year mortality in patients who underwent redo-MVR operation: a 11-year single center experience

A Artan Bajraktari[1]; I Bytyci[2]; E Prifti[1]

[1]University Hospital Center Mother Theresa, Division of Cardiac Surgery, Tirana, Albania; *[2]University Clinical Centre of Kosovo (UCC), Clinic of Cardiology, Pristina, Kosovo Republic of*

Background and Aim: Major advances in mitral valve (MV) surgery, and MV replacement (MVR), improved the survival in these patients, which has inevitably meant that more patients will require redo-MVR during the follow-up. Redo surgery may be associated with significant risk, which must be balanced against the benefits of patients. The aim of this study was to investigate the hospital and one year mortality of patients who underwent the redo-MVR in patients who underwent redo-MVR with previous mitral valve procedures.
Methods: We included in this study 116 patients with age 49 ± 11 years (20-76 years), who underwent redo-MVR operations between 2004 and 2014. We described clinical, pre and postoperative data of the study patients. The hospital and one year follow-up for death were registered for all study patients.
Results: Of study patients, 84% were female, 86% in NYHA III and 12% in NYHA IV class. Re-interventions were done for the first time in 89%, for the second time in 7.8 % and for the third time in 3.5 % of the patients. Mean time of the re-intervention was 11 ± 7.5 years from the previous intervention. Planned operation was done in 68%, whereas in 32% of patients it was an emergency. Previous MVR had 44% of patients, 40% were patients after commisurotomy, 2% after mitral valve reparation and 15% of them had concomitant interventions. Indications for in redo-MVR were: valvular structural degeneration (40%), thrombosis of MV prosthesis (17%), residual MV stenosis (14%), paravalvular fistulas and mitral valve regurgitation (11%, for both). Mechanical MV prosthesis was implanted in 77%, whereas biological MV prosthesis in 12% of patients. Concomitant heart intervention was performed in 40% of operated patients and the duration of hospitalization was 22 ± 13 days.
Patients that underwent redo-MVR had one year overall mortality of 13.7% (13 of116 study patients). The hospital mortality was 8.3%, whereas the mortality at one year follow-up was 5.4%.
Conclusions: Redo mitral valve replacement is safe and can be performed with an acceptable mortality.

P436

Beneficial effects of percutaneous mitral valve repair (MitraClip): a multiparametric evaluation

C Carlo Vignati[1]; G Damiani[1]; L Fusini[2]; P Gripari[2]; G Tamborini[2]; M Muratori[1]; S Ghulam Ali[2]; M Pepi[2]; P Agostoni[1]

[1]Cardiology Center Monzino IRCCS, Heart Failure Unit, Milan, Italy; *[2]Cardiology Center Monzino IRCCS, Department of Cardiovascular Imaging, Milan, Italy*

Background: MitraClip (MC) therapy is as a secure, feasible treatment option for patients with severe mitral regurgitation (MR) and a high surgical risk. The role of the gold standard surgical repair in patients with functional mitral regurgitation (FMR) is currently under much debate.
Purpose: to evaluate the efficacy of MC therapy in terms of new functional outcomes, comparing data related to degenerative MR and FMR.
Methods: 72 patients with +3 to +4 MR and not eligible for surgical mitral valve repair were enrolled. All patients were assessed before MC implant and after 6 months using echocardiogram, BNP assay, non-invasive measurement of cardiac output (CO) with inert gas rebreathing technique, and cardiopulmonary exercise test (CPET).
Results: MC implant rate was 95%. Immediate success with reduction of MR to ≤2+ was observed in 86.7% of cases. In FMR and DMR, a significant reduction of MR from baseline with was observed ($p < 0.001$). NYHA functional class showed a significant improvement in the functional group (NYHA III-IV from 75% to 34.6% of patients, $p = 0.002$). Significant LV remodeling was observed in both groups (LV End-diastolic Volume in FMR was 211 ± 62 ml at baseline, 190 ± 77 ml at 6 months, $p = 0.003$; in DMR was 123 ± 33 ml at baseline, 103 ± 35 ml at 6 months, $p < 0.001$). LV End-systolic volume (LVESV) also showed a significant reduction at 1 month only in the functional group (LVESV in FMR was 135 ± 55 ml at baseline, 123 ± 67 ml at 1 month, $p = 0.027$). Systolic pulmonary pressure (PAPs) values were significantly reduced from baseline in the population with the functional disease (46 ± 11 mmHg at baseline, 38 ± 8 mmHg at 6 months, $p = 0.005$); in the degenerative group, PAPs showed small variations (42 ± 11 mmHg at baseline and 39 ± 9 mmHg at 6 months, p>.05). CO and cardiac index (CI) increased significantly at rest (3 ± 0.7 l/min at baseline, 3.6 ± 0.9 l/min at 6 months; 1.64 ± 0.42 l/min/m^2 at baseline, 2 ± 0.4 l/min/m^2 at 6 months, respectively, both $p = 0.01$) and at peak of exercise (CO 4.9 ± 1.7 l/min at baseline, 6.3 ± 1.5 l/min at 6 months; CI 2.71 ± 0.98 l/min/m^2, 3.44 ± 0.90 l/min/m^2, both $p = 0.023$) in the functional group. On the other hand, the population with DMR did not present any improvement. Oxygen consumption, anaerobic threshold, and other functional parameters were measured during CPET and showed an improving trend. Heart rate and arteriovenous oxygen difference did not show significant changes both at rest and during exercise.
Conclusions: MC device reduced MR and produced a significant left ventricular reverse remodeling over 6 months in both the populations treated. Functional outcomes, as the implement of CO and CI at rest and during CPET, proved the efficacy of the percutaneous mitral valve repair in patients with FMR. Observing the concurrent absence of significant variation of heart rate and arteriovenous oxygen difference, the improvement of CO could be attributed only to an increase in stroke volume (SV).

P437

Factors associated with the presence of chronic mitral regurgitation in patients with stable coronary artery disease

A N Alexey Sumin[1]; EV Korok[1]; T YU Sergeeva[1]; LS Barbarash[1]
[1]RAMS Scientific-Research Institute for Complex Studying of Cardiovascular Diseases, Kemerovo, Russian Federation

Background: Mitral regurgitation (MR) of ischemic genesis is an unfavorable prognostic sign. The mechanism of MR development can be various, the cause of its development can be the disorders of regional contractility, left ventricular remodeling and its dyssynchrony. The optimal treatment strategy of ischemic MR (medication, invasive interventions, surgery) depends on the prevailing mechanism of its occurrence.
Purpose: To study the factors, associated with the presence of chronic MR in patients with stable coronary artery disease (CAD).
Material and methods: The study included 874 patients with CAD, who were examined and treated before the planned surgical interventions on coronary arteries, carotid arterial system, abdominal aorta and the arteries of lower limbs. Depending on the presence and severity of MR all the patients were divided into here groups: group 1 – patients without MR (n = 448), group 2– with MR grade I (n = 378), group 3– with MR grade II-IV (n = 48).
Results: It was noted that a clinical presentation of angina pectoris ant the signs of chronic heart failure (CHF) of grade I were observed more often among the patients without MR and with MR grade I (=0.006 and $p < 0.001$). At this the presence of MI history and rhythm disturbances prevailed in the groups of patients with MR grade II-IV (83.3% 29.2%; $p = 0.055$ and $p = 0.059$). According to the results of echocardiography the dimensions and the volumes of left ventricle (LV) cavity, left atrium in the group of patients with MR grade II-IV were significantly higher than the same parameters in other groups, and LV ejection fraction (EF) was the lowest (< 0.001). In this group the presence of chronic LV aneurysm was registered more often (=0.020). The analysis of prevalence and localization of coronary atherosclerosis didn't show any reliable intergroup differences except for the prevalence of significant stenoses of circumflex artery in the group of patients with MR grade I and MR grade II-IV (42.9% and 43.8%; =0.047). Concurrently the risk of perioperative complications by EuroSCORE scale was lower among the patients without MR (< 0.001). According to the results of multivariate analysis the independent predictors of MR grade II-IV detection were: the history of MI (=0.044), LV aneurysm (=0.004), the increase in LV end-systolic volume (ESV) (< 0.001), the increase in risk by EuroSCORE scale (=0.004), as well as the female gender, the presence of the symptoms of CHF and angina pectoris.
Conclusion: When performing the examination of patients with stable CAD a mild ischemic dysfunction of mitral valve was revealed in 43.2% of cases, moderate and severe dysfunction – in 5.5% of patients. The independent factors associated with the presence of moderate and severe MR were the presence of MI history, LV aneurysms, increased LV ESV, symptoms of CHF and angina pectoris, female gender, herewith no connection with the localization of coronary stenoses was noted.

P438

Right ventricular strain increases early after percutaneous mitral valve repair in patients suffering from severe mitral regurgitation

J Jonas Georg Neuser[1]; HJ Buck[1]; M Hallbaum[1]; F Zauner[1]; JT Sieweke[1]; T Reinke[1]; M Akin[1]; U Bavendiek[1]; J Bauersachs[1]; JD Widder[1]; D Berliner[1]
[1]Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany

Introduction: Mitral regurgitation (MR) is the second most common valvular heart disease within the western world. Percutaneous mitral edge-to-edge procedure (PMVR) using the MitraClip system (Abbot Vascular, Santa Clara, CA) is an established therapy for severe MR in patients judged inoperable or at high surgical risk. However, despite of improvement in functional capacity, a notable amount of patients die or are re-hospitalized for heart failure within the first year after PMVR. Right ventricular (RV) function determines exercise capacity, but also has prognostic value in heart failure, as well as after cardiac surgery. We therefore investigated the impact of PMVR on early changes in RV function in patients with severe MR.
Methods: and Results: We analyzed 27 consecutive patients (mean age 79 ± 5y) suffering from severe MR undergoing PMVR using the MitraClip system at our department. Transthoracic echocardiography was performed before and early (2-12d) after PMVR using PHILIPS EPIQ7 ultrasound machines. RV and left ventricular (LV) global longitudinal strain (GLS) as well as 3D determined LV ejection fraction (EF) were assessed using PHILIPS QLAB.
Symptoms of heart failure were apparent in all patients (NYHA class II: 18.5%, III: 77.8%, IV: 3.7%). Most patients (88.9%) presented with reduced LV systolic function (LVEF 36.7 ± 9.8%), caused by ischemic cardiomyopathy in almost half of the study population (44.4%). Acute heart failure had occurred in 44% of all cases. Comorbidities encompassed hypertension (85%), diabetes mellitus (37%), COPD (22%), and atrial fibrillation (85%). Etiology of MR was primary in 34.6% and secondary in 30.8%, while definite discrimination was not possible or combined etiology was apparent in 34.6% of all cases. On average, PMVR significantly improved MR severity (≥2 grades in 22 patients). LVEF did not show any early significant changes ($p = 0.81$) and LV GLS even decreased significantly in patients suffering from ischemic cardiomyopathy (-2.14 ± 2,34%, $p = 0.04$ vs. non-ischemic cardiomyopathy: -0.25 ± 0.30%, $p = 0,75$). However, a significant increase in RV GLS (-1.82 ± 2.42%, $p < 0.01$) and RV free wall longitudinal strain (-0.32 ± 8.31%, $p = 0.02$) early after PMVR was detected.
Conclusion: Our data indicate an early improvement of RV function after PMVR. Further follow-up will show, whether RV function at baseline or an improvement after PMVR is associated with favorable changes in patients' functional capacity, re-hospitalization and survival.

P439

Effects of atrial fibrillation on mitral valve repair with the mitraclip system in patients with reduced left ventricular ejection fraction.

A M Anna Maria Caggegi[1]; S Scandura[1]; S Mangiafico[1]; G Castania[1]; G Ronsivalle[1]; M Chiaranda'[1]; S Giaquinta[1]; S Farruggio[1]; F Felici[1]; T Salerno[1]; M E Di Salvo[1]; C Grasso[1]; P Capranzano[1]; D Capodanno[1]; C Tamburino[1]
[1]Ferrarotto Hospital - Institute for Cardiology, Department of Cardiovascular, Catania, Italy

Background: Atrial fibrillation (AF) is common in patients with mitral regurgitation (MR) referred for therapy, being often associated with more advanced valvular disease, heart failure and non cardiac comorbidities. However, specific data relating to the impact of this condition on the outcomes after percutaneous mitral valve repair are limited.
Purpose: The aim of this prospective, observational study was to characterize one-year outcomes of MitraClip therapy in high surgical risk patients with moderate-to-severe or severe MR and reduced left ventricular ejection fraction (LV EF) with or without AF.

Methods: Patients enrolled in the prospective Getting Reduction of Mitral Insufficiency by Percutaneous Clip Implantation (GRASP) with LVEF < 40% who were eligible at one-year follow-up were included in the present analysis. The primary efficacy endpoint was the composite of death, surgery for mitral valve dysfunction and grade 3+/ 4+ MR at one-year follow-up. Secondary endpoints were the components of the primary endpoint, re-hospitalization rates and functional NYHA class. Also echocardiographic parameters at baseline and one-year follow-up were assessed.
Results: A total of 178 patients were included: 106 (59.6%) without AF and 72 (40.4%) with AF. Comparable clinical and echocardiographic baseline characteristics were observed between the two groups except for age, STS score, pace-maker implantation and left atrial (LA) volume (higher in the AF group) and for previous myocardial infarction and percutaneous revascularization (more frequent in the no AF group). A total of 171 (96.4%) patients had a post-procedural residual MR≤2+. At one-year follow-up, no significant differences were reported in terms of primary end-point (21.3% in patients with AF versus 15.9% in patients without AF, p = 0.748). Secondary endpoints rates concerning the two groups are reported in Table 1. At one-year follow-up, a significant reduction in LV volumes was observed regardless of AF; no relevant changes were reported in LA volumes.
Conclusions: The MitraClip procedure was associated with low rates of adverse events in patients with AF and reduced LV EF, reporting one-year outcomes comparable to patients without AF.

Table 1

	no AF	AF	p
Death	15.9%	19.7%	0.522
Surgery for mitral valve	-	-	-
MR grade ≥3+	15.6%	6.6%	0.134
Re-hospitalization	15.6%	22.9%	0.226
NYHA class ≤2	85.1%	79.5%	0.388

Moderate/severe aortic regurgitation after TAVI with corevalve - anatomically or procedurally determined

S Sara Moura Ferreira[1]; J Almeida[2]; P Fonseca[2]; T Dias[2]; C Guerreiro[2]; R Barbosa[2]; P Teixeira[2]; N Pelicano[1]; N Ferreira[2]; R Faria[2]; P Braga[2]; V Gama[2]
[1]Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal; *[2]Hospital Center of Vila Nova de Gaia/Espinho, Cardiology, Vila Nova de Gaia, Portugal*

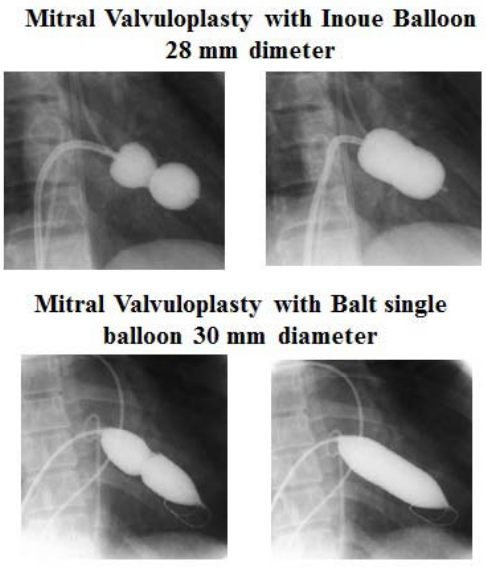
AIM: To investigate the determinants of moderate/severe aortic regurgitation (AR) occurring after transcatheter aortic valve implantation (TAVI) with CoreValve.
Methods: Retrospective, observational study including all patients with severe aortic stenosis and submitted to TAVI with CoreValve prosthesis between August 2007 and October 2016. TAVI with CoreValve was performed in 112 patients with severe aortic stenosis (50% male, mean age 79.4 ± 8.8 years old, mean EuroSCOREII 6.3 ± 69) between August 2007 and October 2016. Contrast-enhanced electrocardiogram (ECG)-gated multidetector computed tomography (MDCT) was performed before and after TAVI. Indexed aortic valve (AV), left ventricular outflow tract (LVOT) and device landing zone (DLZ) calcification was quantified by a standard Agatston methodology for all available pre-procedure contrast-enhanced MCDT, with a threshold for calcium detection set at 850 Hounsfield Units. Annular diameter, indexed annular perimeter and area, ellipticity index and transcatheter heart valve (THV) oversizing were determined using post-procedure contrast-enhanced MCDT data, during late systolic phase. Procedure and pre-discharge echocardiographic data were also collected.
Results: TAVI with CoreValve was performed in 112 patients in our centre (50% male, mean age 79.4 ± 8.8 years old, mean EuroSCOREII 6.4 ± 6.8). The incidence of moderate/severe AR after TAVI was 15.1%. Balloon post-dilation was performed in 21.8% of patients. Indexed AV, LVOT and DLZ calcification; annular diameter and indexed annular perimeter and area were significantly different between patients with moderate/severe post-procedure AR and those with milder degrees of AR. The were no significant differences in THV oversizing and ellipticity index between the two groups. After multivariate analysis was performed, only indexed DLZ calcification and indexed annular area remained independent predictors of moderate/severe post-procedure AR.
Conclusion: In the present study, only anatomic parameters assessed by ECG-gated contrast-enhanced MDCT (indexed DLZ calcification and indexed annular area) were independently associated with the development of moderate/severe AR occurring after TAVI with CoreValve. The intraprocedural parameters assessed did not independently predict of the outcome.

P441

Percutaneous mitral valvuloplasty with inoue versus balt single balloon in mitral stenosis. Survival and event free survival in long-term follow-up

I P Ivana Picone Borges[1]; ECS Peixoto[1]; RTS Peixoto[1]; RTS Peixoto[2]; AAB Aragao[1]; ILPB Anjos[3]
[1]Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil; *[2]State Institute of Cardiology Aloysio de Castro, Rio de Janeiro, Brazil*; *[3]Severino Sombra University, School of Medicine, Rio de Janeiro, Brazil*

Background: The single balloon (SB) is the less expensive technique to perform mitral balloon valvuloplasty (MBV) for mitral stenosis.
Objective: This study aimed to demonstrate that mitral balloon valvuloplasty (MBV) with the Balt single balloon (BSB) has similar outcome and long-term follow-up (FU) than MBV performed with the Inoue worldwire accepted technique.
Methods: From 1987 to 12/31/2013 a total of 526 procedures were performed, being 313 with a FU, 57 (18.8%) with Inoue balloon (IB), the IB group (IBG) and 256 (82.1%) SB Balt group (SBG). The mean FU in IBG was 33 ± 27 (2 to 118) months and in SBG 55 ± 33 (1 to 198) months (p < 0.0001). Univariate analysis and multivariate Cox analysis were utilized to determine independent predict of survival variables and event free survival (EFS) in both technique groups being major events (ME): death, cardiac surgery and new MBV.
Results: In IBG and SBG there were: female 43 (75.4%) and 222 (86.7%) procedures, (p = 0.0276), mean age 37.3 ± 10.0 (19 to 63) and 38.0 ± 12.6 (13 to 83) years (p = 0.7138), sinus rhythm 51 (91.1%) and 215 (84.0%), (p = 0.1754), echo score (ES) 7.6 ± 1.3 (5 to 10) and 7.2 ± 1.5 (4 to 14) points (p = 0.0528), echo mitral valve area (MVA) pre-MBV 0.96 ± 0.18 and 0.93 ± 0.21 cm2 (p = 0.2265). Post-MBV mean MVA (Gorlin) were 2.00 ± 0.52 and 2.02 ± 0.37 cm2 (p = 0.9550) and at the end of the FU: echo MVA 1.71 ± 0.41 and 1.54 ± 0.51 cm2 (p = 0.0552), new severe mitral regurgitation in 5 (8.9%) and 17 (6.6%) patients (p = 0.5633), new MBV in 1 (1.8%) and 13 (5,1%), (p = 0.4779), mitral valve surgery in 3 (5.4%) and 27 (10.4%), (p = 0.3456), deaths 2 (3.6%) and 11 (4.3%) deaths, (p = 1.000), cardiac deaths 1 (1.8%) and 9 (3.5%), (p = 1.0000), ME 5 (8.9%) and 46 (18.0%), (p = 0.1449). In univariate analysis and in multivariate Cox analysis the SB or IB do not predict survival or event free survival and independent risk factors to survival in multivariate Cox analysis with 2 models with 5 and 6 variables were: age < 50 years (p = 0.016, HR=0.233, CI 95% 0.071-0,764), ES ≤8 (p < 0.001, HR=0.105, CI 95% 0.34-0.327), MBV dilatation area (p < 0.001, HR=16.838, CI 95% 3.353- 84.580) and no mitral valve surgery in the FU (p = 0.001, HR=0.152, CI 95% 0.050-0.459) and to event free survival: no prior commissurotomy (p = 0.012, HR=0.390, CI 95% 0.187-0.813) and post-MBV MVA ≥1.50 cm2 (p < 0.001, HR=7.969, CI 95% 3.413-18.608).
Conclusions: SB and IB MBV had similar survival and event free survival in the FU. Independent predictors of survival were: age, ES, MBV dilatation area and no mitral valve surgery in the FU and event free survival: no prior commissurotomy and post-MBV MVA.



P442

Thrombocytopenia as a predictive marker of heart failure in patients with infective endocarditis

MA Sorokina[1]; NM Povalyaev[1]; AS Pisaruk[2]; EO Kotova[2]
[1]*M.V. Lomonosov Moscow State University, Basic Medicine, Moscow, Russian Federation*; [2]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Purpose: To study the features of thrombocytopenia in patients with infective endocarditis (IE).
Materials and Methods: 156 patients (97 men) with IE (Duke 2015) were included, of which 55 (35%) patients have IE with thrombocytopenia (group 1) and 101 (65%) have IE without thrombocytopenia (group 2). We evaluated the anamnesis, echocardiogram, heart failure (NYHA rates and NT-pro-BNP), inflammation markers (CRP, RF, procalcitonin, presepsin), microbiology tests, CBC (PLT, WBC, HB), embolic complications (EC) and mortality rates. Thrombocytopenia was characterized by total platelet count lower than 180*10^9/l. EC was defined as any embolism at the moment of hospital admission or developed during hospitalization. All EC were verified by instrumental methods of diagnostics (US, CT, MRI). Micro EC as Osler nodes, Janeway lesions, Lukin and Roth spots were not included in this study.
Results: The median age in the group 1 was 42 [34; 66.5], in group 2 60 [36; 72] years, $p > 0.05$. Groups did not differ by gender and comorbidity. cute IE prevailed in both groups [37 (67.3%) in group 1 vs. 53 (52.5%) in group 2, $p > 0.05$], left ventricular EF was mainly preserved [57% (54; 61) vs. 58% (50; 60), respectively, $p > 0.05$]. Mean platelet count in group 1 was 97*10^9/l [71; 152], in group 2 264*10^9/l [214;336], $p < 0.001$. EC (N=68) were found in 29 patients in group 1 (52.7%), in 39 patients in group 2 (38.6%), $p = 0.048$. Also an increase in CRP value of 146.3 mg/l [83.4; 210.5] for group 1 and of 108.9 mg/l [41.8; 190.0] in group 2, $p < 0.001$, was revealed and associated with the severity of thrombocytopenia ($p = 0.011$). Thrombocytopenia in patients with IE is associated with more severe course of heart failure, $p = 0.038$. 55 patients (100%) in group 1 and in 43 patients in group 2 (42.6%), $p < 0.001$ had clinical symptoms of lass III-IV heart failure. Significantly higher incidence of spleen- and hepatomegaly ($p = 0.025$ and $p = 0.004$ respectively) was found in the thrompocytopenia group (1). ongested spleen, in its turn, may be one of the causes of the low platelet count due to the increased platelet uptake. Overall mortality was higher in patients with low total platelet count: in group 1 N = 20 (36.4%), in group 2 N=19 (18,8%), $p = 0.0014$.
Conclusion: IE complicated by thrombocytopenia more frequently occur in younger adults and is associated with more severe course of heart failure and higher activity of the infectious process. Mortality rate, as well as frequency of EC in such patients is also significantly higher.

P443

Indexed device landing zone calcium volume predicts the need for balloon post-dilation in tavi procedures with self-expandable prosthesis

S Sara Moura Ferreira[1]; J Almeida[2]; P Fonseca[2]; T Dias[2]; C Guerreiro[2]; A Barbosa[2]; P Teixeira[2]; N Pelicano[1]; N Ferreira[2]; R Faria[2]; P Braga[2]; V Gama[2]
[1]*Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal*; [2]*Hospital Center of Vila Nova de Gaia/Espinho, Cardiology, Vila Nova de Gaia, Portugal*

Introduction: Calcification of the device landing zone (DVL) is associated with the need of balloon pos-dilation (BPD) in thranscatheter aortic valve implantation (TAVI) procedures. This study sought to evaluate the relationship of DLZ calcium volume with the need for BPD during TAVI with 1st and 2nd generation self-expandable prosthesis.
Methods and Results: Retrospective, observational study including all patients with severe aortic stenosis and submitted to TAVI with self-expandable prosthesis between August 2007 and October 2016. Calcification of the DLZ was quantified for all available contrast scans, using a dedicated software (3mensioValvesTM), with a threshold for calcium detection set at 850 Hounsfield Units. TAVI with self-expandable prosthesis was performed in 180 patients in our centre (47,8% male, mean age 79.7 ± 7.8 years old). Most of the devices implanted were 1st Generation Self-Expandable Prosthesis (n = 112, 62.2%). BPD was performed in 40 TAVI procedures (22.5%). Body surface area (BSA) indexed DLZ calcium volume was significantly different between patients with and without need for BPD during TAVI procedures: $259{,}1 \pm 45{,}1$ vs. $126{,}6 \pm 9{,}5$ ($p < 0.01$). Area under the curve (AUC) for BSA indexed DLZ calcium volume was 0.70 (95% CI 0.60–0.79 $p < 0{,}01$).
We considered the best cut off point for BSA indexed DLZ calcium volume to be 93.3 (sensitivity 84.2%, specificity 49.6%). In a binary logistic regression model, an BSA indexed DLZ calcium volume equal or above 93.3 was associated with 3 times increase in the probability BPD need during TAVI procedures with self-expandable prosthesis. There were no significant differences in the incidence of moderate/severe AR after TAVI with self-expandable prosthesis, regarding device generation (X2 (1)=007, $p = 0.85$).
Conclusion: Calcification of the DLZ predicts the need for BPD in TAVI Procedures with Self-Expandable Prosthesis, both in 1st and 2nd generation devices.

Comparison of electrophysiological and surgical methods of treatment in patients with heart failure complicated with atrial fibrillation

T Tatyana Troyanova[1]; A Kurlianskaya[1]; D Goncharik[1]; A Chasnoyt[1]; A Kovsh[1]; Y Ostrovsky[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Background: Cardiac resynchronization therapy (CRT) is an effective method of treatment in patients with severe heart failure, complicated with atrial fibrillation. 100% biventricular pacing is needed to achieve maximum clinical effect, what can be reached by ablation of atrioventricular node (AV-ablation). Valvular surgery with MAZE procedure is also an effective method of treatment.
Purpose: to explore and compare the effectiveness of electrophysiological and surgical methods of treatment in patients with chronic heart failure with NYHA functional class III or IV (III-IV FC CHF), ejection fraction (EF) $< 35\%$, QRS duration ≥ 120 ms and permanent atrial fibrillation (PAF).
Methods: The study involved 30 patients who underwent CRT with AV-ablation (group 1) and 30 patients underwent valvular surgery with MAZE procedure (group 2). Examination was carried out at baseline, in 6 and 12 months after surgery, and included general clinical tests, 24-Hour Holter Monitoring, determination of the level natriuretic peptide (NT-proBNP), myocardial dyssynchrony, transthoracic echocardiography and 6-minute walk test.
Results: After 6 months the improvement in intracardiac hemodynamics was revealed in both groups (table 1, $M \pm SD$, $p<0.05$). However, after 12 months the worsening of global left ventricular contractility was noted in group 1. The effectiveness of surgical treatment was maintained during the year of monitoring in group 2 (table 1, $p<0.05$).
Conclusions: The choice of electrophysiological methods or methods of cardiac surgery in treatment of patients with severe heart failure and atrial fibrillation should be differentiated based on etiology of cardiomyopathy. Electrophysiological methods of treatment are preferably carried out in patients with tachycardia-induced cardiomyopathy. Patients with atrial fibrillation and a heart rate less than 90 beats per minute should be preferably undergone valvular surgery with MAZE procedure.

Endocardial left ventricle lead implantation for cardiac resynchronisation therapy: an australian experience.

C Caitlin Cheshire[1]; J Alison[1]; S Healy[1]; S Lockwood[1]; J D Cameron[2]; E Kotschet[1]
[1]*Monash Health , Monash Heart , Melbourne, Australia*; [2]*Monash University, Monash Cardiovascular Research Centre , Melbourne, Australia*

Introduction: Cardiac resynchronisation therapy (CRT) is an established therapy for symptomatic patients with advanced heart failure. However, traditional left ventricular lead placement may not always be technically feasible via the coronary sinus approach. Left ventricular (LV) endocardial lead implantation via a transseptal atrial approach may be a potential alternative.
Purpose: We sought to review the feasibility and clinical outcomes in patients undergoing LV lead implantations in a single-centre, tertiary, Australian institution. Endpoints included: technical success, peri-procedural complication rates, percent LV pacing load, change in New York Heart Association (NYHA) class and change in LV ejection fraction (LVEF).
Methods: and Results: Between August 2015 and December 2016, four patients underwent endocardial LV lead implantation (3 males, mean age 71 +/-5 years). All patients had previously failed LV lead placement via the coronary sinus. Mean pre-procedural LVEF was 24 +/-8%, mean QRS duration 161+/- 19ms and baseline NYHA was III (n = 3) and IV (n = 1). All patients had existing indications for therapeutic anticoagulation and were anticoagulated with warfarin (3 for atrial fibrillation, 1 for mechanical aortic valve). Warfarin was withheld for 3 days prior to the procedure. Mean international normalized ratio (INR) at the time of the procedure was 1.6+/-0.3. LV access was via an inferior approach, using femoral transseptal access, with a snare from superior subclavian venous access providing access to the left atrium. The lead was then inserted via the deflectable guiding sheath into the lateral LV endocardial wall. Successful implantation was achieved in all patients. One patient had a thromboembolic complication (non disabling stroke) post procedure, despite an INR of 2.1 at the time. That patient subsequently died from progressive heart failure within a month of the procedure. The 3 remaining patients have a mean follow up of 10 +/-7 months. The mean biventricular pacing volume was 93 +/-5%. %. All 3 patients had an improvement by at least one NYHA class. In the two

•p<0.05

patients followed up for more than one year, there was a marked improvement in LVEF (mean 35 + /-7%).
Conclusion: Endocardial LV lead implantation via a transseptal atrial approach is a feasible alternative for CRT in patients with failed lead placement via traditional coronary sinus approach. Thromboembolic complications despite therapeutic anti-coagulation remain the major risk.

P446
Super-response to cardiac resynchronisation therapy

AM Anna Soldatova[1]; VA Kuznetsov[1]; DV Krinochkin[1]; TN Enina[1]
[1]*Tyumen Cardiology Center, Tyumen, Russian Federation*

Background: Data from multicenter studies suggest that left bundle brunch block (LBBB) and wide QRS complex are associated with good response to cardiac resynchronisation therapy (CRT). Other studies evaluated echocardiographic parameters of mechanical dyssynchrony for patient selection to CRT. However, in real clinical practice the usage of these criteria is still debated.
The aim: To evaluate potential clinical, electrocardiographic and echocardiographic parameters related to super-response after CRT.
Methods: 51 CRT patients (mean age 55.6 ± 9.5 years; 72.5% men) with congestive heart failure (CHF) II-IV NYHA functional class were enrolled. At baseline, 1 month, 3 months and each 6 months after implantation clinical, electrocardiographic and echocardiographic parameters were evaluated. Criteria for LBBB were: QRS duration ≥ 130 ms in women or ≤ 140 ms in men, rS or QS morphology in lead V1, mid QRS notching/slurring in at least two of the leads V1, V2, V5, V6, I, aVL (by Strauss). According to the best decrease of left ventricular end-systolic volume (LVESV) (mean follow-up period 29.8 ± 15.4 months) patients were classified as super-responders (SR) (n = 27; reduction in LVESV of ≥30%) and non-SR (n = 24; reduction in LVESV of < 30%).
Results: SR had wider QRS complex (180.3 ± 24.8ms in SR vs 153.9 ± 23.7 ms in non-SR; p < 0,001) and higher incidence of mechanical dyssynchrony (p = 0.032). Percentage of LBBB was equal between groups (96.2% in SR vs 79.2% in non-SR; p = 0.071).
The survival rates in SR and and non-SR were 100% and 79.2% respectively (log-rank test P=0.002). Multiple logistic regression analysis showed that female sex (HR 5.773; 95% CI 1.149–28.998; P = 0.033) and width of QRS complex (HR 1.047; 95% CI 1.017–1.078; P=0.002) were independent predictors for CRT super-response. ROC curve analysis demonstrated sensitivity 75% and specificity 81.5% (AUC=0,824; p < 0.001) of this model in prediction of super-response to CRT in patients with CHF. Conclusion: Super-response to CRT is associated with better survival in long term period. LBBB defined according to Strauss criteria was not associated with CRT super-response. Female sex and width of QRS complex can be used as independent predictors of super-response.

P447
Typical left bundle branch block is associated with more favorable response to cardiac resynchronization therapy in heart failure patients

J Jaewon Oh[1]; JS Uhm[1]; IC Kim[1]; TH Kim[1]; HN Pak[1]; MH Lee[1]; B Joung[1]; SM Kang[1]
[1]*Yonsei University College of Medicine, Cardiology Division, Seoul, Korea Republic of*

Introduction: Left bundle branch block (LBBB) is a well-known predictor for good response to cardiac resynchronization therapy (CRT). Recently, the presence of typical LBBB was reported to be associated with improved long-term clinical outcomes after CRT.
Methods: We retrospectively analyzed 51 LBBB patients with CRT implantation with follow-up (median 555 days). CRT responders were defined as decreased LV end systolic volume >15%. Typical LBBB was defined as 1) QRS duration of ≥140 ms in men or ≥ 130 ms in women & 2) QS or rS in leads V1 and V2 & 3) mid-QRS complex slowing or notching in ≥ 2 contiguous leads of V1, V2, V5, V6, I, and aVL.
Results: There were 45 (88.2%) typical LBBB patients including notching in V1-2 (5.9%), V5-6 (51.0%), I & aVL (68.6%) leads. The CRT response rate in typical LBBB group was significantly higher (60.0% vs. 0%, p = 0.017) compared to non-typical LBBB group. Especially, mid-QRS notching in V5-6 was significantly related to CRT response (odd ratio: 10.23, 95% confidence interval: 1.91-54.96, p = 0.007) after adjusting other confounders. The LBBB patients with typical LBBB had significantly lower mortality rate (8.9% vs. 66.7%, p = 0.004) and tended to readmit less for HF aggravation (15.6% vs. 33.3%, p = 0.284).
Conclusion: Typical LBBB, especially mid-QRS notching in V5-6 was related to more favorable CRT response and clinical outcomes.

P448
Low EF as a predictor of poor CRT response

R El-Sherif[1]; N Awadh[2]; A Hussein[1]; H El-Aassar[1]
[1]*Cairo University Hospitals, Cairo, Egypt*; [2]*Saudi German Hospitals, Critical Care, Sanaa, Yemen*

Cardiac Resynchronization Therapy (CRT) is a treatment of choice in patients with systolic heart failure and reduced left ventricular ejection fraction (LVEF%) despite optimal medical therapy according to the latest guidelines. Despite the impressive results of CRT, 30% of patients remain non-responders.
Purpose: To assess clinical and echocardiographic response to CRT and to determine whether a low baseline LVEF% (<30%) could be a cause of poor CRT response.
Methods: 25 patients eligible for CRT implantation were included. All patients underwent full history, complete clinical examination, NYHA class, 6MHW distance and echocardiography with measurement of left ventricular end-diastolic and end-systolic diameters and calculation of LVEF%. Echocardiography, NYHA class and 6 MHW were reassessed 6 months after CRT implantation.
Clinical responder was defined as improvement of at least one NYHA class, while echocardiographic responder was defined as absolute increase of LVEF% by ≥ 5% 6 months after CRT
Results: 25 patients (88% males) with mean age of 53 ± 11.7 yrs. 15 patients (60%) had ischemia as a cause of heart failure. Hypertension was present in 48%, diabetes in 44% and chronic pulmonary disease in 20%. The mean 6MHW distance at baseline was 32.1 ± 10.8 m, reaching 37.5 ± 11.9 after 6 months with p 0.001. At baseline, 12% of patients were in NYHA class II, 52% in class III and 36% in class IV.
Thirteen patients (52%) were clinical responders and 9 pts (37%) were echocardiographic responders.
According to the baseline LVEF%, 11 patients had LVEF% ≥30% (all were males with mean age of 52 ± 14 yrs and ischemia as a cause of HF in 73%) and 14 patients had LVEF% <30% (79% males with mean age of 54 ± 9.5 yrs and ischemia as a cause of HF in 50%) When LVEF% was ≥30%, clinical responders were 82% and echocardiographic responders were 55%. The mean 6MHW distance was 41 ± 6 m and reached 47.5 ± 4.9 after CRT. When LVEF% was <30%, clinical responders were 29%, and echocardiographic responders were 22%. The mean 6MHW distance was 24.7 ± 7.4 m and reached 28.8 ± 8.9 after CRT.
Conclusions: Clinical and echocardiographic response to CRT were achieved with a higher incidence in patients with an LVEF% ≥ 30% than those with lower LVEF%. A very low LVEF% is probably a cause for inappropriate CRT response.

P449
Value of cardiac work estimation in the prediction of response to cardiac resynchronization therapy

E Galli[1]; C Leclercq[1]; A Hubert[1]; O Smiseth[2]; A Bernard[3]; E Samset[2]; A Hernandez[4]

[1]University Hospital of Rennes, Cardiology, Rennes, France; [2]University of Oslo, Oslo, Norway; [3]University Hospital of Tours, Tours, France; [4]Laboratory Signal Processing and Image, Rennes, France

Background: Cardiac resynchronization therapy (CRT) in heart failure is limited by still too many non-responders.
Purpose: to evaluate if the estimation of cardiac performance by pressure-strain loops (PSLs) analysis is useful for the selection of CRT candidates.
Methods: 97 patients undergoing CRT (ejection fraction: 27 ± 6%, QRS duration: 164 ± 18 ms) according to current guidelines were studied before and after a median 6-month follow-up (FU). Conventional dyssynchrony parameter were evaluated, and left ventricular (LV) global longitudinal strain (GLS) was used to estimate LV positive work (PosW) and negative work (NegW) by PSLs. Results: At FU, positive response to CRT (CRT+) was defined as ≥15% reduction in LV end-systolic volume and was observed in 63 (65%) patients.
In a multivariate regression model (Basal model, χ^2=27.9) including clinical, electrocardiographic, echocardiographic data and classic dyssynchrony parameters, non-ischemic etiology (OR 3.16, p = 0.036), septal flash (OR 4.20, p = 0.009) and LV end-systolic diameter (OR 0.92, p = 0.016) emerged as significant predictor of CRT+. The addition of both PosW and NegW at the Basal model caused a significant increment in model power (χ^2=47.5, p < 0.0001). After addition of PosW and NegW, SF (OR 8.16, p = 0.002), PosW>1057 mmHg/% (OR 7.9, p = 0.003) and NegW >384 (OR 13.89, p = 0.006) remained the only predictors of CRT+. The combination of PosW >1057 mmHg/% and NegW >384 mmHg/% showed an excellent specificity (100%), positive predictive value (100%) and accuracy (89%) for the identification of CRT +.
Conclusions: the estimation of cardiac work by PSL curves appears to be a novel and very promising tool to identify CRT responders, even when compared with more traditional indexes of cardiac dyssynchrony. Further studies on larger series should be designed to confirm these results.

P450
CRT response, complication-rate and prognosis in elderly patients

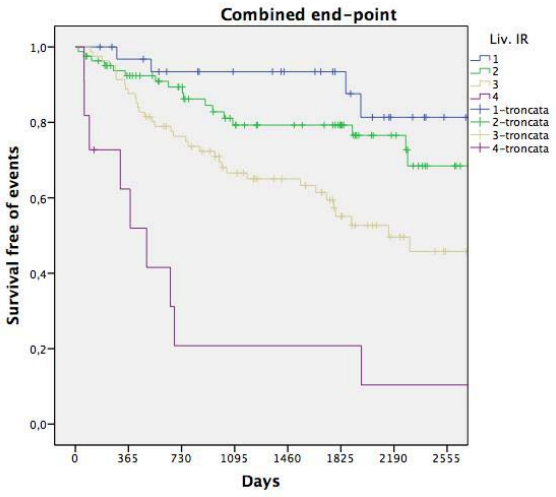
R Baggen Santos[1]; M Trepa[1]; I Silveira[1]; MJ Sousa[1]; C Roque[1]; A Pinheiro Vieira[1]; H Reis[1]; A Albuquerque[1]; S Torres[1]
[1]Hospital Center of Porto, Cardiology, Porto, Portugal

Introduction: The prevalence of congestive heart failure (CHF) increases with advancing age, affecting 10-20% of the elderly population. As such, many patients who receive cardiac resynchronization therapy (CRT) in clinical practice are in fact older than those included in clinical trials. The aim of this study was to evaluate CRT response, complication-rate and prognosis in elderly patients.
Methods: Single-center, retrospective analysis of 316 patients who underwent biventricular device placement, with or without a defibrillator (CRT-P or CRT-D, respectively), between January 2002 and March 2016. Patients were divided into two groups according to age (<75 and ≥75 years old). Baseline characteristics, echocardiographic and clinical response, all cause-mortality and hospitalizations for heart failure were determined. Echocardiographic (echo) responders were defined as those with a ≥5% improvement in left ventricular ejection fraction (LVEF) 6-12 months after CRT. Clinical responders were defined as those with an improvement of at least 1 NYHA functional class 6-12 months after CRT assessed by chart review. Patients were considered global responders if they had both echo and clinical response.
Results: In this study, 34% of patients were ≥ 75 years old (n = 108). These patients had a higher percentage of CRT-P implanted than younger patients (70% vs 33%, p < 0,001).There were no significant differences concerning gender or cardiomyopathy etiology. Surprisingly, cardiovascular comorbidities (hypertension, diabetes, dyslipidemia, tobacco exposure) weren´t significantly different between groups. LVEF before implantation was comparable (28% in older group vs 27% in the younger group; p = 0,6), but older patients had higher NYHA class (90% vs 79% in class III/IV, p = 0,018). As expected, total mortality was higher for the older group (44% vs 27%, p = 0,003), but there was no significant difference between five year survival rates (27% vs 21%, p = 0,3). Hospitalization and complication rates were also not significantly different between older and younger patients (16% vs 19%, p = 0,4 and 14% vs 18%, p = 0,4, respectively). In regard to CRT-response, echo and global response rates were similar for the older and younger groups (58% vs 55%, p = 0,8 and 56% vs 45%, p = 0,1). Clinical response was even considered significantly better for ≥75 year olds (80% vs 68%, p = 0,026). In multivariate analysis (including age, gender, sinus rhythm, QRS length and left bundle branch block), age was not an independent predictor of global response.
Conclusion: In the studied population, patients ≥ 75 years old responded at least as well as younger patients to CRT, without a higher complication rate, confirming the benefit of this therapy to the older group.

P451
Renal function at the moment of cardiac resynchronization therapy (CRT) is a powerful predictor of events during the follow-up.

G Giosue Mascioli[1]; G Coppola[2]; E Lucca[1]; F Michelotti[1]; L Tarantino[1]; A Mignano[2]; R Russo[1]
[1]Cliniche Humanitas Gavazzeni, Bergamo, Italy; [2]University Hospital Paolo Giaccone, Palermo, Italy

Background: Chronic kidney disease (CKD) is significantly related to prognosis in patients affected with heart failure (HF), but data on different stages of CKD in patients treated with CRT are limited.
Aim of the study: Aim of our retrospective study was to analyze the impact of renal function on clinical outcome of patients implanted with a CRT device.
Material and methods: All patients implanted with a CRT device at our Centres were inserted in a custom made database and – for the purpose of this study – data related to CKD stage (eGRF was calculated with CKD-EPI formula) were used to divide pts in four group according to CKD stage (stage 1: eGRF> 90 ml/min/1.73m2; 2: 60 – 90; 3: 30 – 60; 4: 15 – 30; 5: < 15). The end-point was a combined end-point of first hospitalization for acute HF or death: data were evaluated with the log-rank test.
Population: 207 pts (163 men, mean age 70 ± 8 yrs, mean LVEF 28 ± 5%, mean QRS duration 173 ± 27 ms, 108 ischemic, 166 CRT-D) were included in this study. Gr. 1 is constituted by 33 pts, Gr. 2 by 82, Gr. 3 by 81 and Gr. 4 by 11; no pts had a stage 5 CKD. There were no differences between the 4 groups as far as gender, kind of cardiopathy, LVEF and QRS duration, but pts in gr. 3 and 4 were older than pts with in the other 2 groups (gr. 1 66 ± 12 yrs, gr. 2 68 ± 10 yrs, gr. 3 74 ± 6 yrs and gr. 4 72 ± 8 yrs, p < 0.001). There were no significant differences in use of B-blockers and ACE-inhibitors, but less pts with higher stages of CKD were on antialdosteronic drugs and in gr. 3 and 4 the doses of furosemide were higher.
Results: Survival free of events at 1, 3, 5 and 7 yrs were the following: Gr. 1 97%, 93%, 93%, 81%; Gr. 2: 92%, 79%, 79%, 68%; Gr. 3: 87%, 67%, 55%, 46%; Gr. 4: 62%, 10%, 10%, 10% (see Figure). At 7 yrs 88% of Gr. 1 were still alive vs. 81% in Gr. 2, 66% in Gr. 3 and 32% in Gr. 4. Conclusions: Level of renal function at the moment of CRT implant is a powerful predictor of events in the follow-up. Pts with stage 4 CKD have a very negative prognosis both in term of recurrences of acute HF and survival and the use of CRT-D in this group of pts has probably a limited usefulness.



Survival free of combined end-point

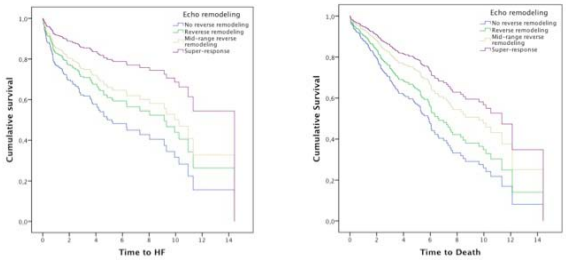
Introduction: Reverse remodeling response in HF patiens after CRT was defined as ≥5% increased in LVEF, and super-responders have been considered if LVEF ≥50%. We aimed to evaluate the long-term benefit of CRT according the new terminology of HF.

Methods: We investigate the long term outcomes according to ventricular remodeling 1 year after CRT as follows: no reverse remodeling (reduced EF or increased <5%), reverse remodeling (Increase ≥ 5% of LVEF with LVEF <40%), mid-range reverse remodeling (increase ≥ 5% of LVEF with LVEF 40-49%) and super-responders (LVEF ≥ 50%). CRT was implanted in 328 patients between 2002 and 2015 in a single terciary center. Mean follow-up was 4.2 ± 2.9 years.

Results: No echocardiographic response was observed in 110 (33.5%) patients, Reverse remodeling in 71 (21.6%), mid-range reverse remodeling in 79 (24.1%) and super-response in 68 (20.7%). Baseline characteristics were shown in Table1. Mid-range reverse remodeling were not associated with an increased risk of mortality (HR 1.31, IC 95(0.72-2.38), p0.378) or HF (HR 1.83, IC 95% 0.93-3.61, p0.079) than Super-responders. But relative risk was increased when no reverse remodeling (HR 2.34, IC 95% 1.42-4.00, p 0.001 for mortality; and HR 3.06, IC 95% 1.66-5.64, p 0.000 for HF) and with reverse remoding (HR 1.86, IC95% 1.06-3.26, p 0.030 for mortality, HR 1.83, IC 95%0.93-3.61, p 0.079) (Figure 1).

Conclusion: Mild range reverse remodeling has been shown similar outcomes in HF/death events than superresponders. This classification of the echocardiographic response at 1 year of CRT may help best predict long-term prognosis.



Adjusted mortality and Heart Failure

Optimal medical treatment and cardiac resynchronization therapy? Prognostic implications. HF-CardioCHUS Registry

B Alvarez[1]; FJ Garcia Seara[1]; RA Abellas Sequeiros[1]; D Dieguez Alvarez[1]; M Rodriguez Manero[1]; L Gonzalez Melchor[1]; RA Agra Bermejo[1]; MI Gomez Otero[1]; A Varela Roman[1]; XA Fernandez Lopez[1]; A Martinez Monzonis[1]; JL Martinez Sande[1]; JR Gonzalez Juanatey[1]

[1]University Hospital of Santiago de Compostela, Cardiology - CIBERCV, Santiago de Compostela, Spain

Background: Cardiac resynchronization therapy (CRT) is indicated in symptomatic heart failure (HF) patients after achieving optimal medical therapy (OMT). However, many patients may not be under OMT when the CRT device was implanted. We aimed to evaluate the long-term benefit of CRT in symptomatic HF patients according OMT before or after CRT.

Methods: We investigated the effect of being or not under OMT on the clinical outcomes HF/mortality, in 328 consecutive patiens implanted with a CRT device between 2001 and 2015 in a single terciary center. We categorize the patients into three groups: no-basal OMT, OMT at basal and OMT at 1 year follow-up. Multivariate Cox proportional hazards models were used to determinate the effect of OMT on the clinical outcomes.

Results: Patients on basal OMT were 122(37.2%). Baseline characteristics are shown in Table 1. The absence of OMT at baseline was not associated with an increased risk of mortality/HF (HR0.72; 95%CI 0.50-1.02;p0.067) compared with no OMT at basal. 84(40.8%) patients without basal OMT could achieve OMT at 1 year follow-up. Patients without OMT had more risk of mortality or HF than OMT in follow-up (HR1.94, 95%CI 1.25-3.01;p0.003), and the risk of patients with basal OMT and OMT in follow-up was similar (HR0.95, 95%CI 0.59-1.53, p0.826) (Figure)

Conclusion: Basal OMT before CRT implant could not be associated with better outcomes. OMT achieved at 1 year-follow-up was associated with a reduced risk of HF/mortality. Our results suggest that efforts should be made for medical treatment optimization after CRT.

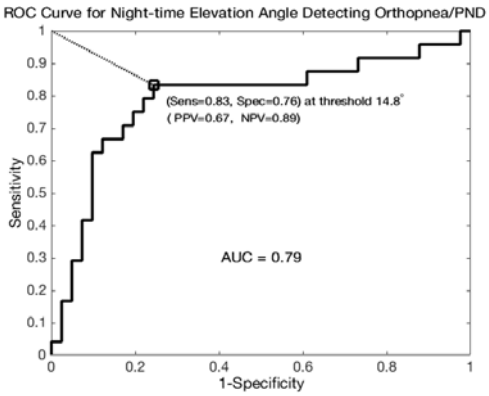
Night-time elevation angle in heart failure patients indicates orthopnea and paroxysmal nocturnal dyspnea

S J Rials[1]; J D Hatlestad[2]; A Smith[3]; D Pubbi[4]; D Slotwiner[5]; J P Boehmer[6]
[1]Grant Medical Center, OhioHealth, Columbus, United States of America; *[2]Boston Scientific CRM, Saint Paul, United States of America*; *[3]Emory University Hospital, Atlanta, United States of America*; *[4]First Coast Heart And Vascular, Jacksonville, United States of America*; *[5]Long Island Jewish Medical Center, New Hyde Park, United States of America*; *[6]Penn State Milton S. Hershey Medical Center, Hershey, United States of America*

Funding Acknowledgements: Boston Scientific Corporation

Background: Orthopnea and paroxysmal nocturnal dyspnea (O-PND) are cardinal signs of worsening heart failure (HF). Guidelines for HF patient management recommend routine assessment of O-PND. These postural symptoms are typically assessed by asking about patients' sleep angle in terms of number of pillows. We evaluated the use of automated posture sensing in assessing O-PND in HF patients.
Methods: 46 HF patients (35 male, 45-83 years of age, NYHA class I-III) in the MultiSENSE study wore an external posture monitoring device for a few days (0.9-14) at a time. At each patient visit, O-PND symptoms were assessed. We compared the device-determined night-time elevation angle (NTEA) for patient visits with & without reported O-PND symptoms.
Results: Patient visits associated with O-PND (n = 24) had an average NTEA of 23.2 ± 2.8 (mean ± standard error), compared to an average NTEA of 10.7 ± 1.7 for those patient visits not associated with O-PND (n = 41, p = 0.0001 using non-paired t-test). A receiver operating characteristic (ROC) curve analysis (see figure) yielded an area under the curve of 0.79 for NTEA detecting O-PND. Selecting an NTEA threshold of 14.8 yielded a sensitivity of 83% and specificity of 76%.
Conclusion: Orthopnea & PND are key symptoms of HF. Night-time elevation angle is indicative of these symptoms, presumably reflecting the tendency of patients to sleep partially elevated to avoid dyspnea. Monitoring posture in future devices may provide valuable insight for the remote management of HF patients.



P455

Acceptance of home telemonitoring in patients with heart failure: the ecare client impact survey in the european funded project smartcare

D Radini[1]; GM Apuzzo[1]; K Stellato[1]; G Sola[1]; N Delli Quadri[2]; E Fragiacomo[2]; A Di Lenarda[1]
[1]Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy; *[2]Ospedale Cattinara, Trieste, Italy*

Objectives: The main goal of this work was to analyze the impact of telemonitoring (TLM) in elderly patients with chronic or post-acute heart failure (HF), and the presence of ≥1 social needs, requiring intensive home monitoring.
Methods: The SmartCare Project was developed as a cohort, prospective, randomized, controlled trial that enrolled from November, 2014 to February, 2016, 201 pts in home care (>50 years, at least 1 severe chronic diseases - HF, COPD or diabetes - and ≥1 missing BADL) to intervention arm (INT - automatic BP monitoring, weight, FC, SO2, ECG: n = 100) or usual care (UC; n = 101). At the end of the program, a culturally adjusted eCare Client Impact Survey (eCCIS) was collected in pts randomized to INT.
Results: General data collected: the patients enrolled were elderly (81 years, 54% males) and with multimorbidities (44% Charlson Index ≥5; 58% ≥7 drugs/day). HF was present in 79% of pts, COPD in 38%, diabetes in 68%. Most pts showed a low level of education (primary school in 58% of end users); 38% were living alone, and 42% were reliant on care. Data eCare Client Impact survey was collected in 45 subjects out of 88 INT users. Reasons for non-responding were: death, hospital admission, not directly involved in self-monitoring activities. Out of a total of 45 respondents, 26 end users experienced a positive increase in motivation; 35 experienced a better emotional wellbeing; 30 experienced a greater ability to perform daily physical activities; 30 had a reduction in anxiety; 29 felt less lonely; 19 experienced an improvement in their relationship with their family carer; 29 experienced an improvement in their relationship with their professionals; 35 felt a general improvement in their ability to manage their health condition; 39 expressed satisfaction with the service, and 39 felt the service was well worth the effort and would continue to use it.
Conclusion: While considering that the questionnaire involved about 50% of patients in the intervention group, the data collected showed good acceptance of TLM system with improved self-care and relationships with relatives and health workers, reduction of anxiety and loneliness. Patients have also expressed a positive opinion about the service and wish to continue with TLM.

P456

How do cardiologists and nurses think about telemonitoring in patients with heart failure? A survey in Lithuania and Norway

E Lycholip[1]; IT Aamodt[2]; I Lie[2]; J Celutkiene[1]; A Stromberg[3]; T Jaarsma[4]
[1]Vilnius University, Clinic of Cardiac and Vascular diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania; *[2]University of Oslo, Oslo University Hospital, Department of Cardiothoracic surgery, Oslo, Norway*; *[3]Linkoping University, Department of Medical and Health Sciences, Linkoping, Sweden*; *[4]Linkoping University, Department of Social- and Welfare studies, Norrkoping, Linkoping, Sweden*

Background: Currently there is still lack of evidence that telemonitoring in heart failure (HF) patients is an effective way to early notice and react to the patient's deterioration when at home, to reduce the frequency of hospitalisations. Meanwhile these systems are implemented in several parts of Europe. Little is known about the opinion of cardiologists and cardiac nurses regarding the suitability and relevance of telemonitrong in Norway and Lithuania.
Purpose: To describe health care professionals' (HCP) perceptions of the feasibility and relevance of telemonitoring in patients with HF in Lithuania and Norway.
Methods: The survey was performed nationwide in two Nordic Baltic countries enrolling cardiologists and cardiac nurses working with HF patients in 47 hospitals in Lithuania and 60 hospitals in Norway. Validated translations from English to Lithuanian and Norwegian of a previously developed validated questionnaire were used. Data were collected between September and December 2016.
Results: Responses from 541 HCP (n = 315 in Lithuania [135 cardiologists, 173 nurses] and n=226 in Norway [62 cardiologists, 157 nurses]) were analysed. Educational degree of respondents included 12% and 9% doctoral, 36% and 11% master and 21% and 67% bachelor in Lithuania and Norway, respectively.
Almost all participants use e-mail and Internet, while 72% and 93% in Lithuania and Norway, respectively, use e-mail in their mobile phones. More than one fifth of respondents in both countries were familiar with TM.
The majority of the cardiologists and nurses in both Nordic Baltic countries consider the outpatient clinic and home visits most often as good ways to follow-up patients after discharge. In total 49% and 58% of the participants in Lithuania and Norway answered that internet-based monitoring was a good way of follow up. Substantial proportion of respondents reported telemonitoring as a relevant (55 and 58%) or very relevant measure (14 and 20%) and frequently named daily feedback to the patient as feasible (22 and 47%).

Conclusion: Modern digital technologies are widely used by health care professionals in Lithuania and Norway. A substantial proportion of cardiologists and nurses are familiar with telemonitoring and believe that daily feedback to the patients is feasible. However, the majority of HC providers in both Lithuania and Norway see a large role for outpatient clinics, GP's and home visits by nurse.

P457

Telemonitoring of vital signs has a minor impact on clinical decision making but well-being improves in patients with chronic heart failure.

FWG Wenzelburger[1]; B Zippel-Schultz[2]; T Luiz[3]; R Erchinger[1]; B Fischer[1]; D Lommel[1]; S Kuerwitz[1]; T Helms[2]; B Schumacher[1]
[1]Westpfalz Klinikum Kaiserslautern, Cardiology, Kaiserslautern, Germany; *[2]Deutsche Stiftung für Chronisch Kranke, Berlin, Germany*; *[3]Fraunhofer Institut - IESE, Kaiserslautern, Germany*

Funding Acknowledgements: Grant of Regional Government of Rhineland Palatinate/Germany

Background: Providing health care for heart failure (HF) patients becomes increasingly difficult because of adverse demographic changes: the number of patients is increasing while the number of physicians, particularly in rural areas, decreases. Telemonitoring (TM) might reduce the symptoms of HF patients and improve their overall well-being. However, how the improvement is achieved remains controversial.
Purpose: The aim of this study was to evaluate the impact of TM of vital signs and weight in a telemedicine program for HF patients.
Method: 68 patients (63.3 ± 11.7 years; 57 male, 11 female) living in a rural area with stable systolic HF (EF < 35%, NYHA II-IV) were included and monitored for 6 months. Patients were equipped with TM systems which sent daily semi-automatically updated data on blood pressure, heart rate, and weight into an integrated electronic health record. An alarm was issued by the software whenever data exceeded a range that was individually defined for each patient. HF nurses of the TM service centre decided whether to wait for a control measurement or to call the patient immediately. During the telephone calls with the patients they discussed symptoms and offered advice regarding further treatment. Every alarm, the following action and a thorough content overview of the telephone calls were documented. Routine telephone calls including questions about the health status and educational elements were performed (every week during the first month, monthly starting from the second month). Symptoms and a depression score (PHQ-9) were evaluated at the inclusion and after 6 months.
Results: During the 6 months 2069 alarms were issued. Every patient had at least one alarm (minimum 3, maximum 132, median 18.5). Most alarms were issued due to blood pressure measurements (86,5%). 10.9% of alarms were sent due to heart rate irregularities, and 2.6% due to an increase in weight. An extra of 116 alarms was registered due to missing transmission of data. 63.1% of blood pressure alarms and 75.1% of heart rate alarms were classified as neglectable within the context of the patient's individual history. After 36.9% of blood pressure alarms and 24.9% of heart rate alarms patients were called and were stable with no further action. 3.6% of all alarms were followed by a clinical decision and a change in therapy or the recommendation to see a physician in due course. The depression score decreased from 8.4 ± 0.8 to 5.5 ± 0.6 ($p < 0.001$). Symptoms improved substantially. This did not correlate with the number of alarms or the number of telephone calls due to alarms.
Conclusion: TM of vital signs and weight had minor impact on clinical decision making in HF patients. However, well being and health related quality of life improved. This may be achieved by the educational effects of taking part in the project and routine telephone calls. Further investigations into the working process of TM are needed to focus on the pivotal techniques in the future.

P458

Heart failure virtual consult: utilising technology to improve heart failure care in the community

SI James[1]; J Gallagher[2]; C Keane[2]; A Fitzgerald[1]; B Travers[1]; M Ledwidge[2]; K Mc Donald[1]
[1]St Vincent's University Hospital, Cardiology, Dublin, Ireland; *[2]Heart Beat Trust, Dublin, Ireland*

Background: One hospital in Ireland had been providing heart failure virtual consult (HFVC) service for primary care physicians (PCPs). HFVC utilises teleconferencing technology to mentor PCPs on management of heart failure (HF). We report on the experience and outcome of HFVC.
Methods: Consecutive 132 consultations from May 2014 till November 2016 were included. The natures of the consultations were categorised as new diagnostic (possible new HF), emerging deterioration (HF with worsening symptoms), or therapeutic (drug therapies query) cases. The demography, comorbidity and medications were recorded. Outcome were measured as final diagnoses in the new diagnostic cases and metric of patient convenience.
Results: In 31 months, there were 73 new diagnostic (49.3% male; median age 78 [72 : 82] years), 35 emerging deterioration (60% male; median age 81.5 [76 : 86] years) and 24 therapeutic (54.2% male; median age 82 [71 : 86] years) cases. High prevalence of hypertension (46.6%; 42.9%; 33.3%) and atrial fibrillation (34.2%; 34.3%; 33.3%). High incidence of IHD in emerging deterioration (42.9%) and therapeutic (45.8%) cases. DM, lipid disorder and CKD were important comorbidity noted. There were high use of ACE-I/ARBs, B-blockers, diuretics and statins. In new diagnostic cases, 34.2% were confirmed HF, 37.0% were confirmed not HF, and 28.8% were still indeterminate HF. The metric of patient convenience is describe in Table 1.
Conclusions: HFVC service is a feasible model in providing specialist care for heart failure patients in the community. This single center early experience proved that HFVC could save time and travel distance for heart failure patients by receiving treatment by their PCPs.

Metric of patient convenience

	New diagnostic case	Emerging deterioration case	Therapeutic case

Post-transplant outcomes in patients bridged with temporary mechanical support.

G Caixal[1]; M Hernandez[1]; E Flores[1]; R San Antonio[1]; G Jimenez[1]; A Garcia[1]; M Farrero[1]; MA Castel[1]; D Pereda[1]; M Castella[1]; R Cartanya[1]; E Santiago[1]; P Sanchez[1]; G Caldentey[1]; F Perez-Villa[1]
[1]Barcelona Clinic Hospital, Barcelona, Spain

Introduction: Heart transplantation is the treatment of choice in several patients with advanced heart failure not responding to medical therapy and cardiac resynchronization. The use of short and mid-term ventricular assist devices (VAD) is increasingly used as a bridge to heart transplantation due the lack of donors.
Objective: To describe our center outcomes in heart transplant patients bridged with ventricular temporary mechanical support.
Methods: We retrospectively reviewed heart transplant patients bridged with temporary VAD from April 2010 to May 2016. We excluded patients died before transplant. We analysed basal characteristics, complications and survival.
Results:A total of 91 patients were transplanted during this period. From them, 18 (19.8%) received VAD as a bridge. Mean age was 53.7 (17-66) years and 67% were male. Pre-existing heart conditions were as follows: ischemic cardiomyopathy 55% (n = 10), dilated non-ischemic cardiomyopathy 33% (n = 6), and postcardiotomy shock 11% (n = 2). Devices used were ECMO in 9 patients, Left Levitronix in 7 (two after ECMO) and biventricular Levitronix in 2. Mean time of support was 11.9 ± 10.9 days. In-hospital complications were infectious with secondary hemodynamic inestability (mediastinis or pneumonia) 61% (n = 11), need of renal replacement therapy (RRT) 50% (n = 9), neurological (ictus or cerebral anoxia) 17% (n = 3), hemorrhage with need of re-intervention 17% (n = 3) and peripheral vascular ischemia 11% (n = 2). Severe right ventricle dysfunction evidenced by echocardiography appeared in 28% (n = 5) and in 4 of them RRT was needed. Only in one case ventricular mechanical support was implanted. Four patients died (4 of 18, 22%) in the immediately post-transplant period, without no new deaths in 1-year follow-up. Mortality was higher in patients with right ventricular dysfunction (3 of 5, 60%). Also, the need of RRT is more frequent among this patients (4 of 5, 80%).
Conclusion: VAD is an effective treatment of terminal heart failure. Post transplant mortality in our series was the same as reported previously. The need of RRT and right ventricular dysfunction were related to a higher mortality.

P460

Improvement in liver and renal biochemistry following left ventricular assist device therapy in advanced heart failure

T A Tarique Al Musa[1]; C D Chue[1]; H S Lim[1]
[1]*University Hospital Birmingham NHS Foundation Trust, Transplant Cardiology, Birmingham, United Kingdom*

Background: Liver and kidney dysfunction are associated with adverse prognosis in patients with advanced heart failure. LVAD therapy effectively bridges patients to heart transplantation but there is little data on the specific effects upon liver and kidney biochemistry.
Purpose: To assess changes in renal and liver biochemistry (and consequent Model in End-stage Liver Disease eXcluding INR, MELD-XI score) at 30 days and 6 months following LVAD.
Methods: A single-centre study of 61 consecutive patients with HeartMate II or III LVADs (bridge to transplant) between January 2011 and October 2016. Renal and liver biochemistry and eGFR were assessed before LVAD, at 30 days and at 6 months. CKD was defined by the Kidney Disease Outcomes Quality Initiative. The MELD-XI score was calculated from bilirubin and creatinine. Data are presented as mean ± standard deviation or median (IQR).
Results: 61 patients (age 53.0 ± 11.1 years, 87% male, 11% diabetic, 84% INTERMACS Profile ≤3, CI 1.78 ± 0.54 L/min/m2) were studied. 6-month follow-up data were available in 42. Baseline urinary albumin: creatinine ratio (UACR) was available in 36 (2.1 (0.0 – 8.9) mg/mmol). No patients required dialysis.
Urea, creatinine and CKD stage improved at 30 days. The improvement in eGFR from baseline persisted at 6 months.15 patients had baseline albuminuria (UACR>3.0) and renal function did not change in these patients. There were significant improvements in serum bilirubin, ALT and albumin, all of which remained normal at 6 months. The MELD-XI score had improved from baseline at 30 days (25.8 ± 5.7 vs. 20.9 ± 5.2, $p < 0.001$) and remained so at 6 months (25.8 ± 5.7 vs. 21.4 ± 4.1, $p < 0.001$).
Conclusions: LVAD therapy is associated with early improvements in liver and renal function which are sustained at 6-month follow-up.

Renal and Hepatic changes post LVAD

	Baseline (n = 61)	30 days (n = 61)	p Value	6 months (n = 42)	p Value (vs. baseline)

Is the implantation of mechanical circulatory support device a risk factor for immunisation of patients with terminal heart failure ?

I Malek[1]; T Gazdic[2]; M Hegarova[1]; L Hoskova[1]; I Netuka[2]; A Slavcev[3]; L Voska[4]; J Pirk[2]
[1]*Institute for Clinical and Experimental Medicine, Cardiology, Prague, Czech Republic*; [2]*Institute for Clinical and Experimental Medicine, Cardiovascular surgery, Prague, Czech Republic*; [3]*Institute for Clinical and Experimantal Medicine, Laboratory methods, Prague, Czech Republic*; [4]*Institute for Clinical and Experimental Medicine (IKEM), Pathology, Prague, Czech Republic*

Introduction: Program of mechanical circulatory support (MCS) contributed significantly to the treatment of terminal heart failure. As a bridge to transplant MCS led to decreased mortality on waiting lists, in some cases even enables successful cardiac transplantation (CTX). One of possible risks of MCS is the immunisation of patients (pts). This complication was frequent in the era of extracorporal pulsatile systems, in contemporary used implantable non pulsatile systems the data are not consistent.
Aim of the study: To find out whether implantation of contemporary used MCS devices would be a risk factor for anti HLA antibody (HLAabs) development before and during the 1st year after CTX.
Patients and methods. Between 1/2011 and 7/2013 CTX was performed in 119 pts. We studied the group of 91 pts (age 21-73 years,75 men,) who survived at least 12 months after CTX and had complete clinical and immunological data. MCS (Heart-Mate II fi. Thoratec) before CTX was implanted in 31 pts. Follow up was 36-67 months. HLAabs were investigated by single antigen beads (SAB, Luminex) method, cellular rejection (ACR) and antibody mediated rejection (AMR) were assessed from endomyocardial biopsy samples, graft dysfunction (GD) was defined as a decrease of left ventricular ejection fraction below 40 % on echocardiography, coronary vasculopathy (CAV) was evaluated by selective coronary angiography. Examination of HLAabs was performed before and 1, 3, 6 and 12 months after CTX. Clinical end points (EPs) were: treated ACR, AMR, GD, CAV and death from cardiovascular cause. We compared the development of HLAabs and EPs between groups transplanted on / without MCS (chi-square test).
Results: HLAabs developed in 37 (41 %) of pts. EP was reached in 21 (23 %) of pts, in 35 % who developed HLAabs and 11 % without HLA abs ($p = 0.006$). HLAabs developed in 12 from 31 pts (39 %) on MCS and 25 from 60 pts (42 %), without MCS ($p = 0.786$). EP was detected in 8 from 31 pts (26 %) on MCS and 13 from 60 pts (22 %) without MCS ($p = 0.657$).
Conclusion: Non-pulsatile implantable devices for long term circulatory support Heart-Mate II are not a risk factor for HLAabs development before and during the 1st year after CTX as well as for the occurence of immunological complications during middle-term follow up.

P462

Dual antiplatelet therapy use in continuous flow left ventricular assist device patients: a comparison of bleeding and thrombosis outcomes in a single centre

F Njue[1]; K Lam[1]; L Naylor[1]
[1]*Fiona Stanley Hospital, Advanced Heart Failure and Transplant Unit, Perth, Australia*

Background: Left ventricular Assist Device (LVAD) pump thrombosis is a significant complication associated with poor survival. Current guidelines include the use of warfarin and antiplatelet therapy for long-term management. Previous studies found that the highest risk of bleeding was related to higher International Normalised Ratio (INR) levels; consequently, INR of 1.5 to 2.5 is the recommended target range. We implemented dual antiplatelet (aspirin & clopidogrel) with warfarin strategy due to detected "white" thrombus in our LVAD dysfunction cases. We performed minimum weekly INR monitoring on all patients. There is minimal data regarding the risk benefit ratio of this strategy.
Purpose: To assess impact of dual antiplatelet therapy (DAPT) on bleeding or thrombotic events in LVAD patients.
Methods: This is a retrospective observational study of all patients (n = 50) implanted with Heartware and Heartmate II LVADs in Western Australia between 2006 -2016. Data on antiplatelet use, INR level and bleeding/thrombotic events were analysed monthly upto 13 months post implant. Patients were grouped into DAPT + warfarin or Other (nil/warfarin/aspirin/single antiplatelet& warfarin).
Results: 448 months of therapy reviewed. Bleeding occurred in 77 months (17%) and thrombosis in 24 months (5%). INR was within 1.8 to 3.0 in 342 months (76%). DAPT received in 274 months (61%). 21 (42%) patients were on DAPT + warfarin within first month post implant. 34(68%) patients had a bleeding event. Bleeding rates were similar between the groups with 15/24 patients on DAPT + warfarin experiencing a bleed (P=0.31). Time to first bleed was longer in this group compared

to Other (96 vs 43 days, P <0.05) despite similar age and INR levels. 14 patients had a thrombosis event. Of note, 50% of thrombotic events occurred in patients on DAPT + warfarin, despite an average INR >2.

Conclusion: Patients on DAPT plus warfarin therapy receiving regular INR monitoring do not have significantly increased risk of bleeding or thrombotic events whilst on LVAD support. The DAPT plus warfarin strategy at our center is associated with a lower incidence of device thrombosis and comparable bleeding rates to those reported in the literature.

On behalf of: Ege Heart Failure Team

Introduction: Left ventricular assist devices have become standart theraphy for advanced heart failure patients. Aim of this study to investigate in hospital mortality predictors after HVAD (HeartWare International, Framingham, MA) implantation.

Method: From August 2010 to December 2016, 228 patients underwent HVAD implantation. The analysis was performed using a prospectively maintained institutional patient database. The variables evaluated included baseline characteristics, preoperative laboratory, baseline hemodynamics characteristics, echocardiographic data, preoperative clinical data, intraoperative data, and postoperative variables.

Results: Total 228 advanced heart failure patients (mean age: 50.7 ± 12.7, 86% male and 14% female) underwent HVAD implantation. The cause of heart failure was ischemic cardiomyopathy 52.1% (n = 113), dilated cardiomyopathy 44.7% (n = 97) and valvular cardiomyopathy 3.2% (n = 7). In hospital mortality was 17.5% (n = 38)

Subgroup analysis demonstrated preoperative cardiac surgery that was an independent risk factor for hospital mortality. Fifty two (24.1%) patients operated for any cardiac etiology before HVAD implantation who was operated before any cardiac etiology 39.5% (n = 15) died after HVAD implantation (p = 0.014).

The preoperative laboratory parameters were comparable beetween two groups. NT-proBNP was higher in hospital mortality subgroup (6884 ± 8223 vs 16652 ± 17969 pg/ml p = 0.049). In addition to this, higher preoperative blood urea nitrogen was independent predictor hospital mortality (45.4 ± 27.5 vs 68.8 ± 41.0 mg/dl p = 0.002). Moreover serum albumin level was independent predictor hospital mortality (3.92 ± 0.53 vs 3.56 ± 0.58 p = 0.002)

Postoperative major cause of death was early right sided heart failure (RHF), after HVAD implantation 30 patients (13.9%) had diagnosis of RHF and 14 patients (36.8%) died in consequence of RHF. Post operative central venous pressure which reveals RHF was higher in hospital mortality group (14.1 ± 3.2 vs 15.71 ± 3.9 p = 0.024)

Conclusion: Preoperative cardiac surgery and laboratory parameters NT-proBNP, BUN and albumin are predictors of hospital mortality. Post operative major cause of death was RHF and post operative CVP was independent predictor of hospital mortality.

Combining echocardiography with cardiopulmonary exercise stress testing to evaluate recovery of systolic function in patients with left ventricular assist devices

JW Christle[1]; KJ Moneghetti[2]; R Ha[3]; F Haddad[2]; D Banerjee[1]; MT Wheeler[1]
[1]*School of Medicine, Program in Mechanical Circulatory Support, Division of Cardiovascular Medicine, Stanford, United States of America*; [2]*School of Medicine, Biomarker and Phenotypic Core, Cardiovascular Institute, Stanford, United States of America*; [3]*School of Medicine, Department of Cardiothoracic Surgery, Stanford, United States of America*

Background/Introduction: Left ventricular assist devices (LVAD) are increasingly being used for patients with end stage heart failure as a bridge to cardiac transplantation or destination therapy. Some patients with LVAD recover native LV function and exercise capacity, and are considered for explant (bridge to recovery). Pre-explant evaluation involves separate cardiopulmonary exercise testing (CPX) and echocardiographic (echo) examination on full and minimal LVAD support, but CPX with simultaneous echo has not been well studied.

Purpose: We combined CPX with echo to assess native LV and cardiopulmonary function with and without LVAD support in patients being considered for explant.

Methods: Patients with an LVAD of any type and with any indication were recruited for this study. Patients were included if they had CPX to volitional exhaustion within the last six months, were clinically stable and had an INR > 2.0 on the day of examination. Patients were examined on two separate occasions (within 14 days): (a) LVAD at the patient's baseline speed; and (b) LVAD at the lowest speed safely allowed by the device. CPX was performed on upright cycle ergometers with echocardiography performed during rest, exercise, and recovery.

Results: Patients were between 29 and 75 years and 40% female. There were no adverse events during or following testing and adequate image quality was obtained. LVAD speeds were 8400 (Heartmate II) and 2400 (HVAD) rpm at baseline, and 6000 rpm and 1800 rpm on minimal support. Average RER was 1.14 ± 0.09, RPE was 17 ± 1 and resting LVEF was 40%. VO2peak and peak MET were 1.2 ml/kg/min and 1 MET higher for CPX with minimal LVAD support than with full support. Peak LVEDD, SV and SV reserve (% change in SV from resting to peak) were 2 mm, 7.1 ml and 12% higher with minimal LVAD support (see table 1). One patient did not complete a turn-down test due to evidence of ischemia on initial CPX confirmed as a significant coronary artery stenosis. Sixty percent have been successfully explanted.

Conclusion(s): Combining CPX and echo is feasible and effective as part of LVAD pre-explant evaluation. The comprehensive assessment of cardiopulmonary and ventricular function may result in improved clinical decision making for LVAD explantation candidacy.

Selected CPX and Echo parameters

LVAD speed	VO2peak (ml/kg/m)	METs	VE/VCO2 slope	peak LVEDD (mm)	peak SV (ml)	SV Reserve (%)	PA diameter (mm)
High	17.2 ± 4.8	9 ± 3	38.7 ± 11.9	52.5 ± 4.0	61.4 ± 10.4	14	2.13 ± 0.08
Low	18.4± 5.5	10 ± 4	2.4 ±4.5	54.5 ± 7.5	68.5 ± 15.9	26	2.20 ± 0.14

The role of BNP longitudinal monitoring as a biomarker of continuous flow pump (Heart Mate II) thrombosis

M Marketa Hegarova[1]; Z Dorazilova[1]; I Malek[1]; T Gazdic[2]; V Melenovsky[1]; J Kautzner[1]; T Marek[2]; J Maly[2]; I Netuka[2]
[1]*Institute for Clinical and Experimental Medicine (IKEM), Department of Cardiology, Prague, Czech Republic*; [2]*Institute for Clinical and Experimental Medicine, Department of cardiovascular surgery, Prague, Czech Republic*

Background: Continuous flow pump malfunction due to the thrombosis in pts with end-stage HF represents life threatening complication. The clot entrapped or developed in the inflow and outflow cannulas or within the rotor entails diminished blood flow with consequent low cardiac output syndrome or thromboembolism. Timely diagnosis of this complication is critical for effectual therapeutic interventions - pump exchange or urgent OHTx in case of a suitable donor.

Purpose: The aim of our study was a retrospective evaluation of BNP dynamics in patients diagnosed with pump thrombosis.

Methods: Longitudinal laboratory measures (BNP levels, Lactate dehydrogenase (LDH) levels , plasma free Hemoglobin (pfHb), echocardiographic parameters alongiside with post pump explant inspection analysis outcomes were correlated.

Results: Between 1.1.2014 till 31.12.2016 4 pump exchanges and 2 urgent OHTx due to pump thrombosis were performed in our institution representing 6 % from 99pts implanted from 18.12.2013. The table 1 depicts laboratory findings in this patient subset. All pts presented with dyspnoea and BNP elevation at a time of

diagnosis. BNP levels ("BNP pump dysf.") increased significantly in contrast to stable status ("BNP on pump") and almost uniformely reached the levels prior to HM II implant (Tab. No. 1). Consequently,LDH levels in 5 pts LDH reached level greater than 3 times upper normal limit and 4 pfHb greater then 40g/l. We have revealed pathological "ramp" test in 5 pts. In 1 patient with restrictive cardiomyopathy, even reappearance of severe pulmonary hypertension has occured. Notably, after the pump exchange, BNP levels decreased to original levels in all patients. All patients but one are still alive and well, the only non-survivor one succumbed 7 months after the pump exchange due to intracerebral haemorrhage.

Conclusion: Abrupt substantial elevation of BNP levels may serve as early and cost-efficient noninvasive tool in suspected pump thrombosis diagnostic algorithm and should prompt further investigations, namely serial recording of LV unloading by means of stepwise pump speed "ramp" test.

Table No.1

Pt. No.	BNP before (ng/l)	BNP on pump (ng/l)	BNP pump dysf. (ng/l)	% BNP pump dysf./ before	BNP after pump exchange (ng/l)	LDH (μkat/l)	free Hb (g/l)

On behalf of: Heart Failure and Transplant Unit. Cardiology Department. La Fe

Introduction and Objetive: In recent years, the percentage of urgent transplantations has increased and short/medium-term mechanical assist devices have been widely used. This study aims at assessing hospital mortality and and primary graft dysfunction in urgent heart transplantation according to the type and duration of circulatory/ventricular mechanical assistance.

Methods: All patients who underwent an urgent heart transplantation with extracorporeal membrane oxygenation (ECMO) and with centrifugal pump were retrospectively and consecutively recruited, from the 21st October 2007 to the 20th December 2016. The sample was divided in 5 groups: group 1 (ECMO assistance for less than 5 days), group 2 (ECMO assistance for 5-10 days), group 3 (ECMO assistance for more than 10 days), group 4 (ECMO assistance and, afterwards, centrifugal pump) and group 5 (centrifugal pump).

Results: 72 patients were included in the study, 52 men (72%) and 20 women (28%), average age 51 ± 13 years. Ischemic dilated cardiomyopathy was the most frequent primary etiology (28 patients, 39%), followed by idiopathic dilated cardiomyopathy (25 patients, 35%). Table I describes the indication, days of stay in the critical care unit, hospital mortality and incidence of primary graft dysfunction in every group. The higher percentage of patients with mechanic ventilation corresponded to those with ECMO assistance up to 10 days (94% in group 1; 100% in group 5; $p < 0.001$). Global hospital mortality of urgent transplantation with circulatory/ventricular assistance was 25% (18 of 72 patients) while it was higher in those with ECMO for more than 10 days (9 patients, 35%), probably related to a higher incidence of primary graft dysfunction in this group (14 patients, 54%, $p < 0.01$).

Conclusions: Hospital mortality is high in urgent heart transplantation with prolonged circulatory/ventricular mechanical assistance, especially at the expense of a higher incidence of a primary graft dysfunction in these patients. The direct implantation of a centrifugal pump as a bridge to urgent trasplantation could identify a subgroup with a better prognosis.

Table I

Group	Number of patients	Primary etiology	Days in the critical care unit	Mechanic ventilation (n, %)	Hospital mortality (n, %)	Primary graft dysfunction

Successful myocardial recovery of patients with heart failure on long-term left ventricular assist device HeartMate II in IKEM between 12/2006 to 10/2016

Z Dorazilova[1]; M Hegarova[1]; I Netuka[2]; Z Tucanova[2]; J Pirk[2]

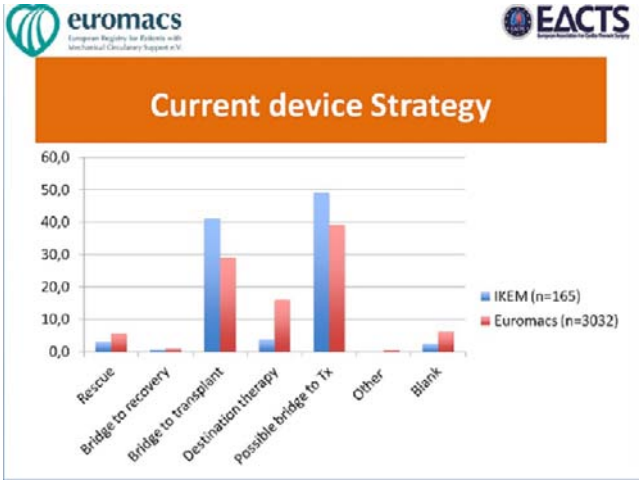
[1]Institute for Clinical and Experimental Medicine (IKEM), Department of cardiology, Prague, Czech Republic; *[2]Institute for Clinical and Experimental Medicine (IKEM), Department of Cardiac surgery, Prague, Czech Republic*

Introduction: LVAD is used in treatment of end-stage heart failure (HF) to assist or completely replace function of failing left ventricle (LV) remain patients alive until heart transplantation. Mechanical circulatory support (MCS) leads in addition to positive effects in the failing heart at the cellular and structural levels. Drug therapy treatment of terminal HF may also contribute with max. titrated doses of drugs (ACEi, BB, spironolactone, AT1-B) known to enhance reverse remodeling of LV. But rarely myocardial recovery allows LVAD explantation, in INTERMACS registry is 1% incidence within a year of support implantation.

File characteristics: Among 208 pts with implantation LVAD HM II between 2006 and 2016 were 40(19%) men and women under 40 years old, with a short history of HF and diagnosis of non-ischemic cardiomyopathy, listed as bridge to transplant (BTT). The unloading of LV in the first year of out-patients follow-up leads to a predictable parameters affecting LV, i. e. regression of end-diastolic diameter (EDD), in isolated cases we also detected increasing of LV ejection fraction (EF), by echocardiographic exam., to value meeting one of the Harfield´s criteria for LVAD explantation.

Results: Six pts(5M) in our cohort of patients with implanted LVAD (2,4%), the average age was 34,8 years, 2 pts with the diagnosis of congenital heart disease, i. e. bicuspidal aortic valve with significant aortic insufficiency and 4 pts with dilated cardiomyopathy, during ambulatory monitoring are observed significant changes not only regression the average LV EDD from 70 ± 8 mm to 51 ± 6 mm, but also to improve the average LV EF from 22 ± 6% to 50 ± 4%. Given the persistence satisfactory parameters despite max. reduction in pump speed, i. e. 8000 RPM for several weeks, some of them testing max. oxygen consumption with exercise (VO2 max) > 18ml/kg/min and improvement of 6 MWDT > 450m (75% predicted value), was approached to explantation system by 2 ways. After 30 min of pump off on the operating room with unchanged echocardiographic measurements were first pts explanted classical technique of total MCS explantation with a patch on the apex of LV, the second way by the minimally invasive technique with an occluder or last time with a special plug on the opening after inflow cannula. The overall mechanical support time was 302 days (between 113 and 755). 5 pts(83%) were successfully discharged from our hospital for ambulatory monitoring, follow-up 7 to 60 months, one patient died one year after explantation due to IE (infection endocarditis) biological aortic valve replacement. One year after explantation the average LV EF was 40 ± 4%, the average LV EDD 54 ± 3 mm.

Conclusion: The results of our single center are consistent with published studies from abroad and international registries, confirmed possibility of reversal end-stage HF secondary to non ischemic cardiomyopathy in a group of young patients using LVAD and special drug therapy.



Strategy of LVAD implantation

Introduction: The REDUCE LAP-HF study showed that an interatrial shunt device (IASD) placed in patients with heart failure with preserved or mid-range ejection fraction improved symptoms and exercise (EX) hemodynamics through 6 months (6M) of treatment.
Purpose: We assessed sustainability of IASD effects in patients who underwent repeat EX hemodynamic tests at 12 months (12M).
Methods: 64 patients with heart failure and LV ejection fraction (EF) ≥ 40%, NYHA class II-IV, PCWP ≥15 mmHg at rest or ≥25 during symptom-limited supine bike EX and CVP < 15 mmHg at rest, were implanted with an IASD. All patients were followed for symptoms and EX hemodynamics at 6M. A subset of 18 patients underwent a second, optional repeat EX test at 12M.
Results (Table): Patients averaged 70 ± 8 yrs old with EF 45 ± 6. At baseline Ex markedly increased PCWP, CVP and PCWP-CVP. IASD yielded a shunt with Qp:Qs ˜1.3. Improvements in EX duration, EX intensity and peak cardiac output (CO) were observed at 6M. Following IASD implant, CVP increased, PCWP decreased and the PCWP-CVP gradient was lower at peak EX. Workload-normalized PCWP (PCWP/W/kg) decreased significantly. No changes in pulmonary artery mean pressure (mPAP) or pulmonary vascular resistance (PVR) were noted. All effects noted at 6M were sustained at 12M.
Conclusion: The Corvia IASD remains patent through 12M, with stable inter-atrial shunting. IASD increased exercised duration and reduced PCWP so that PCWP/W/kg decresaed; lower PCWP/W/kg values have been correleated with better outcomes. A randomized, blinded study is underway to further quantify the effects of this IASD. Funding: The study was supported by Corvia Medical.

Propensity matched comparison of two different continuous-flow left ventricular assist devices. A matter of device?

J Jonida Bejko[1]; T Bottio[1]; M Carrozzini[1]; M Comisso[1]; F Toto[1]; V Tarzia[1]; C Lombardi[2]; D Gregori[1]; M Metra[2]; G Gerosa[1]
[1]University Hospital of Padova, Padua, Italy; *[2]Civil Hospital of Brescia, Brescia, Italy*

BACKGROUND: Few comparisons of continuous-flow Left ventricular assist devices (LVADs) have been done. We compared two LVADs implanted at our center: Jarvik-2000 and Heartware-HVAD for early outcomes and further follow-up.
Materials and Methods: Between December 2008 and December 2015, 93 patients were implanted with the Jarvik-2000 (n = 52) or the Heartware-HVAD (n = 41). Outcomes were compared by propensity matching the patients.
Results: After propensity matching, two groups of 73 individuals, were similar for most of the preoperative covariates. The results are presented for original-data (OD) and propensity-adjusted-data (PAD). Similar survival of almost 60% at 2,5 years on Kaplan Meier estimation was recorded (p = 0.088 in OD and p = 0.99 in PAD). Driveline infection incidence was comparable in both groups (p = 0.97 in OD and 1 in PAD). Jarvik-2000 group presented significantly higher incidence of chronic Right-Ventricle-Failure (RVF) (OD p = 0.008; PAD p < 0.001). Higher incidence of VAD-thrombosis (OD p = 0.004, PAD p < 0.001), mortality due to gastrointestinal hemorrhage and hemorrhagic stroke (OD p = 0.2, PAD p = 0.001 and OD p = 0.2, PAD p = 0.001, respectively) was evidenced in HVAD group. The impact of devices on the major outcomes in multivariate analyses is described in Table 1. Different management and accuracy was recorded for the drivelines and the anticoagulation therapy, with much more attention by the HVAD patients and their caregivers. A predictive score for chronic RVF was constructed.
CONCLUSIONS: We believe that due to differences on efforts required for driveline management, antithrombotic therapy, and organ-function-recovery after LVAD implantation, HVAD results more appropriate for BTT support, while Jarvik-2000 for DT.

Impact of device on major outcomes.

Outcome	Original data OR (95% C.I.)	Propensity score adjusted OR (95% C.I.)
Chronic RVF	4.49 (1.37-14.66)	13.19 (2.43-70.71)
Driveline Infections total	0.98 (0.34-2.76)	1.00 (0.23-4.19)
Driveline infections over 6 months	3.03 (0.59-15.46)	2.04 (0.21-19.11)
Driveline infections within 6 months	0.44 (0.09-1.96)	0.47 (0.08-2.60)
Gastrointestinal Complications	1.97 (0.47-8.14)	0.71 (0.12-4.10)
Fatal Cerebral Events	0.37 (0.10-1.38)	0.05 (0.008-0.39)
30-days Mortality	0.67 (0.20-2.17)	0.44 (0.07-2.60)
90-days Mortality	9.21 (1.04-80.94)	5.14 (0.51-51.84)

Estimates are presented both unadjusted and adjusted by propensity score analysis. OR refers on Jarvik-2000 vs HVAD. The table shows Odds ratios and 95% CI. Abbreviations: RVF – right ventricle failure.

P470

Optimising implantable cardiac device prescriptions at the time of generator change

DC Thompson[1]; H Bolam[1]; J Waller[1]; N Andrews[1]; S Kirubakaran[1]; P Kalra[1]; G Morton[1]
[1]*Portsmouth Hospitals NHS Trust, Cardiology Department, Portsmouth, United Kingdom*

Introduction: Implantation of permanent pacemakers (PPM), implantable cardioverter defibrillators (ICD), cardiac resynchronisation therapy with (CRT-D) or without (CRT-P) defibrillators is increasingly common. Follow up, including arranging generator changes, is routinely carried out by cardiac physiologists with minimal physician input. However, many patients' clinical status will change during the lifetime of the device and a planned generator change presents an opportunity to review the original device prescription.
Purpose: To assess the impact of introducing screening pathways to identify patients who may need a change in their device prescription at the time of a generator change.
Methods: Single centre study evaluating the first 11 months after two pathways were implemented in October 2015. A cardiac physiologist led pathway for patients due PPM generator change used a short proforma assessing symptoms, QRS duration and percent of right ventricular (RV) pacing. Those with symptoms suggestive of heart failure, in particular breathlessness, and a prolonged native QRS or >40% RV pacing had an echocardiogram and multidisciplinary team (MDT) discussion within 2 weeks. If device upgrade was indicated the patient was reviewed in clinic to assess suitability. The second pathway aimed to ensure that all patients due an ICD/CRT-D generator change were discussed at MDT. Those with a change in clinical status that may affect the appropriateness of on-going defibrillator therapy were reviewed in clinic.
Results: 189 consecutive patients (145 PPM, 20 CRT-P and 24 CRT-D/ICD), mean age 77 yrs, were included. The pathways resulted in a change in the type of device therapy in 8 patients; 6/145 (4%) of those due PPM and 2/24 (8%) due CRT-D/ICD generator change. All PPM patients were proforma screened. 139/145 PPM patients (96%) went ahead with PPM generator change. 17 patients identified as potential candidates for upgrade to CRT had an echocardiogram. 5 of these had severe LV impairment and MDT/physician review. 4 patients were ultimately upgraded to CRT devices and for 1 patient the upgrade was deemed inappropriate. In 2 patients ongoing device therapy of any kind was felt to be inappropriate and no procedure was undertaken. 10/24 (42%) patients due a CRT-D/ICD generator change were reviewed at MDT. Of these 2 patients went on to have their devices downgraded from CRT-D to CRT-P after discussion.
Conclusions: Physiologist-led follow up can be enhanced with robust and quick screening to ensure that patients get the most appropriate device at the time of generator change. Excellent rates of PPM screening were achieved whereas ICD/CRT-D screening rates need to be improved. Around 1 in 20 of all patients had device prescription changed as a result of these pathways. With the significant morbidity associated with receiving an inappropriate device prescription, implementation of a simple screening process seems to be clinically justifiable.

P471

Hydrostatic pressure gradient implantable ultrafiltration device: a novel approach for extracellular fluids removal

Y Feld[1]
[1]*Sunnybrook Health Sciences Centre, Cardiology, Toronto, Canada*

Funding Acknowledgements: Paragate Medical LTD, Rambam Health Care Campus

Introduction: Diuretic therapies aiming to enhance fluid removal in chronic heart failure are limited due to diuretic resistance in about 30% of the patients. Intravenous diuretics, Dialysis and ultrafiltration as an alternative are associated with side effects, multiple visits of the patient in dedicated centers, and high cost.
Purpose: We suggest a novel approach, in which a permeable absorption chamber is implanted intraperitoneally. A negative hydrostatic pressure is induced in the absorption chamber by a pump, prompting fluids ultrafiltration through the peritoneal membranes into the chamber. The accumulated extracellular fluids are drained to the urinary system. In this work the feasibility of this novel concept is presented and compared to common peritoneal catheters.
Methods: A PTFE disk shaped absorption chamber with 15mm diameter one sided orifice was covered by semi-permeable membrane. The absorption chamber was implanted in the peritoneum cavity of six rats. A micro-catheter that drains the fluids from the chamber was routed to percutaneous port. Drainage and sampling of fluids were conducted for 4 weeks.
Results: Extracellular fluids were drained from the chambers at an average rate of 2.8 ± 0.4 cc/kg/hour during intermittent hydrostatic vacuum induction. The fluids electrolytes and proteins were comparable to the serum content. The average drainage rate remained stable throughout 4 weeks of follow up, ranging between 2 to 3.3 cc/kg/hr. Unlike designated chambers, catheter based designs drained only 0.4 ± 0.2 cc/min per square centimeter, 25 folds less than the membrane based devices.
Conclusions: Implantable absorption chamber enables systemic extracellular fluids removal through the peritoneal membranes, probably due to the direct interface between peritoneal and device's membranes. More broadly, this study suggests that an implantable absorption chamber may be used in fluids overload clinical conditions, providing future novel heart failure therapy.

Baroreflex activation therapy in congestive heart failure: an additional therapeutic option for many of our patients?

H Hazem Omran[1]; KJ Gutleben[1]; D Horstkotte[1]; G Noelker[1]
[1]*Herz- und Diabeteszentrum NRW, Ruhr-Universität Bochum, Clinic for Cardiology, Bad Oeynhausen, Germany*

Background: Baroreflex activation therapy (BAT) is a new promising treatment option for patients (pts) suffering from heart failure with reduced left ventricular ejection fraction (HFrEF) to improve functional status and quality of life. Yet it is unknown how many pts are suitable for this therapy. We aimed to evaluate these pts in a large heart center for eligibility.
Methods: A cross-sectional analysis was performed on all adult pts suffering from cardiomyopathy treated in different departments of our center between April 1st 2015 and March 31th 2016. Pts suffering from hypertrophic cardiomyopathy (HCM) or congenital heart disease (CHD) were excluded from analysis. To evaluate eligibility for BAT, pts were stratified according to the inclusion and exclusion criteria applied in the largest randomized controlled trial of BAT in HFrEF (HOPE4HF). Inclusion criteria mainly consisted of symptomatic HFrEF with New York Heart Association (NYHA) functional class III and left ventricular ejection fraction (LVEF) <35% on stable guideline-directed medical therapy. Pts who recently received ICDs (within 3 months) or CRTs (within 6 months) were excluded.
Results: Screening revealed a total of 1576 pts, after exclusion for HCM or CHD 1504 pts were included in the analysis. Of these, 107 pts (7.1 %) met the above

mentioned criteria and were eligible for BAT. Of those 78.5 % were male, 68 % had an ischemic etiology of HFrEF, and 64.5% had CRT. Other pts characteristics were (mean ± standard deviation) 63.3 ± 10.7 years of age, LVEF 27.6 ± 5%, systolic blood pressure 119.9 ± 15.6 mmHg. Main reasons for exclusion were NYHA < III in 762 pts (50.7%) and LVEF > 35% in 677 pts (45%). In particular, 107 of482 pts in NYHA class III with an LVEF < 35% were eligible for BAT (22.2%).
Conclusion: According to our single center analysis, up to 7.1% of all pts suffering from non-HCM/CHD-cardiomyopathy are suitable for additional device-based BAT. In particular, a high proportion of symptomatic pts with severely impaired LVEF seems to be eligible.

P473

Possibility of renal denervation in patients with chronic heart failure and reduced ejection fraction

A Kurlianskaya[1]; D Goncharik[1]; T Troyanova[1]; T Denisevich[1]; O Zotova[1]; T Osmolovskaya[1]; L Rachok[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Background. The problem of the search of new approaches in treatment of chronic heart failure (CHF) still remains relevant because of its high incidence and severity. Catheter denervation of renal arteries (CDRA) is a promising direction in the treatment of patients with CHF and reduced ejection fraction.
Purpose: to explore an effectiveness of CDRA in patients with NYHA functional class III or IV (III-IV FC CHF), ejection fraction (EF) < 40% and sinus rhythm.
Methods: The study involved 30 patients. 15 patients with CHF, EF < 40%, QRS duration < 130ms underwent CDRA (group 1). 15 patients with CHF, EF < 40%, QRS duration ≥130ms underwent cardiac resynchronization therapy (CRT) (group 2). The examination of patients carried out at baseline and at 6 months after surgery; it included transthoracic echocardiography according to a standard methodology, determination of the level natriuretic peptide, 6 minutes walk test and assessment of quality of life using the Minnesota living with heart failure questionnaire.
Results: The study showed a decrease of end systolic and diastolic dimensions (ESD, EDD), end systolic and diastolic volumes (ESV, EDV), an increase in ejection fraction (EF) in both groups (table 1, Me (LQ; UQ)).
We also found an improvement in 6 minute walk test in both groups: from 245 (190-300) meters to 300 (210-380) meters in group 1 ($p < 0.05$) and from 243 (195-290) meters to 317 (215-420) meters in group 2 ($p < 0.05$). A decrease in the severity of CHF FC III to II NYHA was noted in 7 patients after CDRA (46,7%). A significant improvement of quality of life was revealed after surgical treatment in both groups that was confirmed by the median absolute value of the indicator of quality of life. In group 1 this parameter declined by 33%, in the group 2 - 42 %.
Conclusions: Effectiveness of CDRA is comparable to that after CRT in patients with III-IV FC CHF (NYHA), EF < 40% and sinus rhythm. Preliminary results of the study showed the positive dynamics of echocardiographic parameters that was accompanied by improved quality of life. CDRA is might to be considered as a method of treatment in patients with chronic heart failure, reduced ejection fraction and QRS duration < 130ms.

Dynamics of echocardiographic parameters

Parameters	At baseline (group 1)	After 6 months (group 1)	At baseline (group 2)	After 6 months (group 2)

First steps and experience in cardiac contractility modulation in patients with heart failure with reduced ejection fraction: looking into the near future.

M Trukshina[1]; EA Lyasnikova[1]; VL Galenko[1]; MY Sitnikova[1]; TA Lelyavina[1]; IE Titova[1]; SV Urina[1]; VM Tishkova[1]; ML Abramov[1]; EN Mihaylov[1]; EI Zubarev[1]; MA Vander[1]; DS Lebedev[1]; K Simonova[1]; EV Shlyakhto[1]
[1]*Federal Almazov Medical Research Center , Heart failure, St.Petersburg, Russian Federation*

Purpose: Cardiac contractility modulation (CCM) presented a new promising treatment option in patients with heart failure with reduced ejection fraction (HFrEF) and narrow QRS complex.
Methods: 50 patients were screened and met the inclusion criteria: age > 18 yo, HFrEF, II-III fc NYHA, on OMT, sinus rhythm, QRS<120 ms, signed informed consent. 50 CCM devices (Optimizer IVs) were successfully implanted in the period from 20 Oct 2016 till 22Dec 2016, devices were programmed, patients were educated in device charging, discharged alive and were followed-up (FU) in outpatient HF clinic.
Results: Group of first 20 patients after the operation was analyzed, 15 of them were male, 50 ± 9,7 y.o., CAD- 14, DCM - 6, CHF-2,0 ± 0,5 fc, LV EF 25,0 ± 4,9 (17- 34%), QRS 100 ± 5,3ms (90-110), 6-MWT 375,0 ± 110,2m (92-550), cardiopulmonary exercise test Vo2- 16,7 ± 5,3 m/kg/min (9,1-32,8), NT-proBNP - 1159,0 ± 783,3 pg/ml (241-3453). Among early postoperative complications- 1 patient with device pocket infection lead to device deimplantation, 1 case of unstable angina and hospitalization in FU period, treated conservatively. All patients had 1 month FU with device programming, all patients were stable, no hospitalizations with HF decompensation occurred. HF fc remained unchanged in most patients, decrease in 2 patients, ECG on FU showed no QRS prolongation, arrhythmias or any conduction abnormalities, patients didn't feel uncomfortable during the time periods of stimulation, had good compliance in device charging at home.
Conclusions: Cardiac contractility modulation is newly recommended method of treatment in patients with HFrEF and narrow QRS complex with perspective of improving clinical status and heart contractility. Our first experience in patients with implanted CCM devices confirmed positive trend obtained even after short-time period of follow-up with good patients tolerance of stimulation, absence of arrhythmias and conduction abnormalities on ECG, compliance in therapy and technical aspects of regular device charging.

Efficacy of adipose graft transposition procedure (agtp) in patients with a myocardial scar: rationale and design of the AGTP II trial.

P Paloma Gastelurrutia[1]; C Galvez-Monton[1]; J Nunez[2]; A Bayes-Genis[3]
[1]*Germans Trias i Pujol Health Sciences Research Institute, Badalona, Spain*; [2]*University Hospital Clinic of Valencia, Valencia, Spain*; [3]*Germans Trias i Pujol University Hospital, Badalona, Spain*

Funding Acknowledgements: SAF2014-59892-R, JCI-2012-14025, La MARATÓ TV3, RD16/0011/0006, CB16/11/00403, FIS PI14/01682, FEDER, La Caixa, AdvanceCat 2014-2020.

Background: Cardiac adipose tissue is a source of progenitor cells with regenerative capacity. Studies in rodent models have shown that the intramyocardial delivery of cells derived from this tissue improves cardiac function after myocardial infarct (MI). Thus, we have developed a new reparative approach for the damaged myocardium that integrates the regenerative properties of cardiac adipose tissue with tissue engineering. In brief, in our Adipose Graft Transposition Procedure (AGTP) we dissect a vascularized flap of autologous pericardial adipose tissue and position this over the myocardium scarred area. Following encouraging results for the AGTP in both an acute and chronic MI porcine model, we performed the AGTP-I clinical trial (NCT01473433, AdiFLAP Trial) to evaluate safety in patients with chronic MI undergoing coronary artery bypass grafting. There were no differences in safety, and trends in efficacy were detected. This favorable safety profile warranted progression to a larger trial, that we now describe.
Design: The AGTP-II Trial (NCT02798276) is an investigator-initiated, prospective, randomized, controlled, multi-center study to assess the efficacy of AGTP in patients with a non-revascularizable MI. The primary endpoint is change in necrotic mass ratio, with secondary endpoints that include changes in functional parameters and safety outcomes.
Implications: The trial is expected to provide a novel, effective, and technically simple technique for patients that have a non-revascularizable MI with no other therapeutic options.

Preoperative levosimendan is associated with lower mortality in high-risk cardiac surgery patients with systolic left ventricular dysfunction - results of a single-centre retrospective study

M Mihai Stefan[1]; M Luchian[1]; I Marinica[1]; A Paunescu[1]; S Marin[1]; D Filipescu[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Anaesthesia and Intensive Care II, Bucharest, Romania*

Background: Levosimendan was shown to improve cardiac function in various settings. Furthermore, perioperatively, via its pleiotropic effects, it offers a conceptual framework to improving outcomes.
Purpose: We assessed the effects of preoperative administration of levosimendan in patients with left ventricular (LV) dysfunction, scheduled for coronary artery bypass grafting (CABG) and mitral valve repair/replacement (MVR).
Methods: We performed a retrospective analysis of our practice. Patients undergoing elective CABG plus MVR, with LV dysfunction (LV ejection fraction < 50%), between January 2011 and December 2013, were reviewed. Part of the anaesthesia team adhered to preoperative administration of levosimendan in high-risk cases. These patients were admitted in the ICU before surgery and infused levosimendan at a dose of 0.1 μg/kg/min, for 8-12 hours prior to surgical incision. The others received conventional therapy. Retrospective data were collected using written and electronic registries.
Results: Forty-two patients with LV dysfunction underwent elective CABG plus MVR in the two year period. Of these, 2 were excluded due to severe bleeding, 17 received levosimendan and 23 received conventional therapy. Patients treated with levosimendan had a lower in-hospital mortality, despite a pre-operative lower median LVEF (Table 1). The ICU length of stay (LOS), duration of mechanical ventilation, acute kidney injury and new-onset atrial fibrillation rates were not different between the two groups.. A trend toward less need for intra-aortic balloon pump assistance was noted.
Conclusions: Levosimendan shows promise when administered preoperatively in high-risk cardiac surgery. Further research is warranted for establishing whether this translates into better outcomes.

Incidence and risk factors for cytomegalovirus infection after heart transplantation

E Elizabet Mendez Eirin[1]; E Barge- Caballero[1]; MJ Paniagua-Martin[1]; R Marzoa-Rivas[1]; D Couto-Mallon[1]; G Barge-Caballero[1]; A Canizares[1]; JM Vazquez-Rodriguez[1]; MG Crespo-Leiro[1]
[1]*University Hospital A Coruna, Cardiology, Corunna, Spain*

Background: Cytomegalovirus (CMV) remains the most common viral pathogen in heart transplant (HT) recipients. The prevalence of asymptomatic CMV infection and disease is variable among centers, partially related to immunosuppressive protocols and therapeutic strategies to treat CMV.
Purpose: The purpose of this study was to analyze the incidence of CMV infection and disease during the first year after HT and to identify potential risk factors for CMV infection.
Methods: A retrospective, single-centre study analyzed 222 HT recipients (mean age 54 ± 12 years, 80 % men) who underwent transplantation between February 2001 and December 2011. All patients received universal prophylaxis and were prospectively monitored for CMV infection during the first year after HT. Preemptive treatment was applied to patients with asymptomatic CMV infection. Risk factors for CMV infection were investigated using Cox regression analysis.
Results: The asymptomatic CMV infection incidence rate in the first year post-transplant was 71.9 [95% confidence interval (95% CI), 61.1-84.0] per 100 person-years and the CMV disease incidence rate was 9.6 [95% CI, 5.9-14.7] per 100 person-years. Multivariate analysis showed that donor-recipient CMV discordant serostatus (donor positive and recipient negative [D+/R−]), recipient age, diabetes mellitus, pre-transplant circulatory support and the use of tacrolimus, were independently associated with increased risk of CMV infection (table 1).
Conclusions: In our series, the CMV infection rate was similar to that seen in previous studies, but the progression to overt CMV disease was very low. The donor and recipient CMV serological status, recipient age, diabetes mellitus, pre-transplant circulatory support and the use of tacrolimus, were indentified as independent risk factors for developing CMV infection.

Multivariate Analysis for Risk Factors

Risk factor	HR	CI 95%	p
Recipient age	1.021	1.00-1.039	0.020
Diabetes mellitus	1.862	1.135-3.053	0.014
Risk serology group	1.922	1.196-3.088	0.007
Pre-transplant circulatory support	1.586	1.059-2.376	0.025
Tacrolimus	1.635	1.133-2.360	0.009

Surgical ventricular reconstruction: an alternative therapy in heart failure and coronary artery disease

N Nicolas Lalor[1]; A Acosta[1]; M Vrancic[1]; F Piccinini[1]; M Camporrotondo[1]; L Rodriguez[1]; M Diez[1]; D Navia[1]
[1]*Cardiovascular Institute of Buenos Aires (ICBA), Buenos Aires, Argentina*

Surgical ventricular reconstruction is a specific procedure for the management of heart failure with left ventricular remodeling caused by coronary artery disease. Heart transplant is an option when nothing else is appropriate. However, limited donors, waiting list may be long, presence of comorbidities or advanced age, restrict this therapy for few patients. In this scenario surgical ventricular reconstruction with CABG is an alternative treatment for patients with coronary anatomy suitable for such surgery, left ventricular ejection fraction of 35% or less, ventricular volumes increase and extended akinesia or dyskinesia.

Objetives: Evaluate hospital mortality, changes in ventricular volumes, ejection fraction and long term follow up of quality of life and survival in those patients who underwent CABG with surgical ventricular reconstruction.

Methods: Between 2001 and 2015, 4503 patients were undergo CABG. Of these patients, 251 had severe left ventricular systolic dysfunction, 45 (1%) underwent CABG with surgical ventricular reconstruction, selecting those with left ventricular ejection fraction of 35% or less, ventricular enlargement (defined by LVESV > 55 ml/m2) and symptoms in NYHA heart failure class III-IV. The follow-up continued through December 31, 2016. The median follow-up for all surviving patients was 60 months. The median age was 58 years, and 43 of the 45 patients were men, 33% diabetic, with body mass index of 27 and 15% had chronic renal insufficiency. The median left ventricular ejection fraction was 25%. The median end-systolic volume index was 92 ml per square meter of body-surface area. Multivessel coronary artery disease was present in all patients.

Results: Perioperative mortality occurred in 5 patients (11%). During the follow up for 5 years, 13 patients died (5 of sudden death and 8 due to non cardiovascular causes). Today out of living 27 patients, 21 have a good and 6 regular quality of life as measured by Duke Index. One patient underwent heart transplant. Table 2 showed changes in ventricular volumes and ejection fraction. The surgical ventricular reconstruction showed an acceptable perioperative mortality with good survival and adequate quality of life in the long run. This strategy should be considered as a potential treatment in heart failure.

	Preoperative	Posoperative	P value
LVESV (ml)	180(146/200)	110 (87/133)	< 0.001
LVEDV (ml)	240(220/290)	150(133/197)	< 0.001
LVESV/m2	92 (76/102)	59 (44/68)	< 0.001

Metoprolol and carvedilol in heart failure - different mechanisms, similar effect?

AD Farcas[1]; AF Cocoi[2]; FP Anton[1]; MA Stoia[1]; CM Goidescu[1]; IL Gavrila[2]; LA Vida-Simiti[1]
[1]*University of Medicine and Pharmacy, Cardiology Department of County Clinical Emergency Hospital, Cluj Napoca, Romania*; [2]*Cardiology Department of County Clinical Emergency Hospital, Cluj Napoca, Romania*

Background: N-terminal pro-brain natriuretic peptide (NT-proBNP), some specific types of white blood cells (WBC) and neutrophil/lymphocyte ratio (NLR) are well-known independent predictors of the worse outcome of HF patients. Plasma cathecolamines induce redistribution of the leukocitary formula [by the activation of lymphocytic β2-adrenoreceptors (AR) and neutrophilic α-AR]. By inhibiting AR (α, β1, β2), beta-blockers (BB) reverse this effect improving the outcome of HF patients.

Purpose: Our goal was to evaluate if BB specificity for different types of AR influences the positive effect on the WBC differential formula (WBC-DF) redistribution in HF patients.

Methods: Our study enrolled 278 patients with HF, NYHA class II-IV (62.7 ± 15.2 yrs), 51.8% male and 48.2% female. After signing an informed consent, all patients were clinically evaluated and blood was drawn to measure: NT-proBNP, total WBC, WBC- differential formula and NLR. The study methodology was approved by the Ethical Committee. Statistical data processing was performed with SPSS.

Results: There were no significant differences regarding gender and age between groups with and without BB treatment. On admission, 61.16% of patients had a BB in their chronic therapy: 44.13% - metoprolol and 26.25% - carvedilol. There was no significant difference in the number of lymphocytes ($p = 0.074$) and granulocytes ($p = 0.910$); our results show that NLR (7.58 ± 13.30 vs 4.58 ± 3.74, $p = 0.045$) and NT- proBNP (2669.01 ± 5923.49 vs 865.82 ± 2476, $p = 0.004$) were significantly higher in patients without BB therapy compared with those with BB at admission. The BB dose on admission was negatively correlated with NT-proBNP plasma level. NT proBNP levels (1079.14 ± 283.48 vs 2328.56 ± 1439.29, $p = 0.005$) were significantly lower in patients treated with metoprolol compared with those treated with carvedilol. In fact, the type and dose of BB used is responsible for 6.1% and 5.9% of the variability in the number of lymphocytes and neutrophiles, respectively. The patients that received treatment with at least 100 mg metoprolol/day had a higher number of lymphocytes (1.74 ± 01.44 vs 1.13 ± 0.63, $p = 0.029$), but not of granulocytes ($p = 0.06$) compared with those treated with lower doses, with a smaller reduction in the values of NLR (4.55 ± 4.77 vs 3.77 ± 2.03, $p = 0.049$). Patients treated with at least 25 mg carvedilol, had a smaller number of lymphocytes (0.73 ± 0.59 vs 0.92 ± 0.76, $p = 0.029$) and a greater number of granulocytes (4.6 ± 3.94 vs 2.29 ± 2.10, $p = 0.026$) respectively, compared with those treated with lower doses, with an increase in the value of NLR (7.10 ± 4.41 vs 2.46 ± 1.09, $p = 0.01$). Although both BB have the same rehospitalisations rate during the 12 months follow-up.

Conclusion: Although their influence on NT-proBNP plasma levels and the NLR was found to be different, both BB improves the outcome of HF patients.

Beta-blockers in chronic heart failure registry FAR NHL and one year follow up

K Karel Labr[1]; J Spinar[2]; J Parenica[2]; L Spinarova[1]; F Malek[3]; M Spinarova[1]; O Ludka[2]; J Jarkovsky[4]; K Benesova[4]; R Labrova[2]
[1]*St. Ann university hospital and Masaryk university, Brno, Czech Republic*; [2]*University hospital Brno and Masaryk university, Brno, Czech Republic*; [3]*Na Homolce Hospital, Prague, Czech Republic*; [4]*Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic*

Funding Acknowledgements: This study was supported by Specific University Research Grant MUNI/A/1270/2015.

Background: Beta-blockers (BB) decrease morbidity and mortality and are part of the first line treatment of heart failure with reduced ejection fraction (HFrEF).

Purpose: We aimed to compare influence of beta-blocker doses and other factors on hospitalization and mortality in heart failure patients with systolic dysfunction.

Methods: The data come from the FARmacology and NeuroHumoraL activation multicenter registry (FAR NHL). Patients with left ventricle ejection fraction (EF LK) under 50 % who were at least one month stable were included.

Results: 1100 patients were included, mean age 65 years, 80.8 % were male. From those receiving beta blockers 20 % received low dose (LD), 57 % medium dose (MD) and 17 % high dose (HD). 6.2 % of patients were not treated by BB at all (O). The higher the blood pressure (BP; LD 124/77; MD 129/80; HD 132/82 mm Hg, $p < 0.001$), EF LK (LD 29.5; MD 30.5; HD 32.0 %, $p = 0.003$), creatinine clearance rate (CrCl; LD 78.7; MD 87.8; HD 91.1 ml/min, $p = 0.001$) or patients weight (LD 83.2; MD

88.7; HD 93.5 kg, p < 0.001) was, the higher dose of BB they received. The lower NT-proBNP was, the higher dose of BB they got (LD 767; MD 456; HD 314 pg/ml, p < 0.001). At one year follow up 83 patients (7.5 %) died and 436 were hospitalized (39.6 %). The higher was beta-blocker dose, the lower was number of death (O 13.2; LD 10.7; MD 6.3; HD 5.9 %) and hospitalized patients (O 45.6; LD 43.8; MD 38.0; HD 38.0 %). 17 patients underwent orthotopic heart transplant.
Conclusions: According to FAR NHL registry, nearly 94 % of HFrEF patients received BB. But only 17 % received the high dose of BB. The more severe illness was, defined by lower BP, CrCl, EF LK, body weight, or higher NT-proBNP, the lower dose of BB patients got and tolerated. The higher was BB dose the lower was all-cause mortality and hospitalization number.

P481
The reasons of no-prescription of beta blockers in patients with chronic heart failure

K Kaoutar Kharbouche[1]; I Elhaddad[1]; K Kharbouche[1]; L Azouzi[1]; R Habbal[1]
[1]*chu ibn rochd, cardiology, casablanca, Morocco*

Background: Beta-blockers are the cornerstone in the treatment of chronic heart failure (HF), and are actually recommended as first line therapy for systolic HF. However, betablockers (BB) have a low prescription rate comparatively to ACEI and several surveys have documented that many patients are not offered treatment or are not titrated to target doses.
The aim of our study is to analyzed different reasons for no-prescription of b-blockers in CHF and we propose an approach to improve their level of prescription.
Methods: and results: 1600 patients with chronic heart failure and left ventricular dysfunction (mean age: 74 + 11 years) were included into the study between 2009 and December 2014 in our heart failure therapeutics unit, 81 % of patients were being treated with BB. 31% of patients were at the target dose,52% were at ≥50% target dose and 19 % don't received BB, bradycardia and cardiac decompensation were the principal reason of non prescription in 25,6% and 42,1% respectively, then hypotension in 23,8%, and chronic obstructive pulmonary disease in 8,4%.
Conclusion: Given the effectiveness and the potential benefit of beta blockers in terms of mortality, 19% of no-prescription remains high, we need to broaden their prescriptions through some precautions; we propose an approach to improve the level of prescription.

P482
Beta-blockers and lipid profile in heart failure - statins as a dealmakers. Results from CIBIS ELD study.

D Dragana Stanojevic[1]; S Apostolovic[1]; D Kutlesic Kurtovic[1]; R Jankovic-Tomasevic[1]; S Salinger-Martinovic[1]; T Kostic[1]; D Djordjevic-Radojkovic[1]; M Damjanovic[1]; V Mitic[1]; V Atanaskovic[1]; S Dakic[1]; E Tahirovic[2]; HD Dungen[2]
[1]*Clinic for Cardiovascular Diseases, Nis, Serbia*; [2]*Charite - Campus Virchow-Klinikum, Department of Internal Medicine-Cardiology, Berlin, Germany*

On behalf of: CIBIS ELD

Background: Beta-blockers (BB), which decrease sympathetic nervous system activation via β-adrenergic receptor antagonism, are effective in reducing cardiovascular morbidity and mortality in heart failure (HF). Despite these clinical benefits, many physicians are still reluctant to prescribe BB because of perceived negative metabolic effects including dyslipidemia. Numerous studies have established that vasodilating β-blockers (as carvedilol) are associated with more favorable effects on glucose and lipid profiles than nonvasodilating β-blockers (as bisoprolol).
Purpose: The aim of our study was to investigate the influence of BB dosage increase during 12 weeks on lipid profile [total cholesterol (HOL), high-density lipoprotein (HDL), low-density lipoprotein (LDL) and triglycerides (TG)].
Methods: In CIBIS ELD study 876 patients with HF were enrolled. The average age was 72.88 ± 5.49 years, 62.4% men. Prior to randomization participants had to be clinically stable and to be BB naive or on ≤25% of the guideline-recommended target or equivalent dose. We up-titrated BB (bisoprolol or carvedilol) up to maximum tolerated dose, over three months.
Results: At the beginning of the study 62.7% of patients had dyslipidemia, however, 52.8% of them had statin in their therapy and 2% fibrates or ezetimibe. We found significant difference in lipid profile before and after increase of BB blocker dose (HOL: 5.35 vs. 5.25 mmol/L, p < 0.01; HDL: 1.32 vs. 1.29 mmol/L, p = n.s.; LDL: 3.32 vs. 4.36 mmol/L, p < 0.05, TG: 1.83 vs. 4.12 mmol/L, p < 0.01). In patients on bisoprolol, there were no significant differences before and after BB titration in HOL, HLD, LDL, TG values (5.27 vs. 5.18 mmol/L; 1.29 vs. 1.27 mmol/L; 3.22 vs. 3.88 mmol/L; 1.85 vs.4.35 mmol/L).
In patients on carvedilol, however, difference was found in HOL, HDL, LDL, TG values (5.43 vs. 5.31 mmol/L, p = 0.02; 1.35 vs. 1.32 mmol/L, p = n.s.; 3.42 vs. 4.82 mmol/L, p = n.s; 1.80 vs. 3.91 mmol/L, p = 0.014).
Conclusions: Our study patients on carvedilol (which has a mild alpha activity that has been shown to exert a beneficial effect on a patient's lipid profile) had significant increase in TG and significant decrease in HOL levels, partially due to fall in HDL fraction, at the end of study. In patients on bisoprolol similar changes were detected in lipid profile, however they were statistically insignificant. Interestingly, only half of our HF patients with dyslipidemia were treated with lipid lowering agents. Although BB interfere with lipoprotein metabolism they should not be withheld/sub-dosed in HF patients. Use of statins and other lipid lowering agents should be also encouraged in HF patients with dyslipidemia.

P483
Acute coronary syndromes without ST-segment elevation and beta-blocker therapy: benefit for preserved or mid-range ejection fraction?

L Reis[1]; A Fernandes[1]; C Lourenco[1]; R Teixeira[1]; M Madeira[1]; P Dinis[1]; J Ribeiro[1]; L Puga[1]; I Almeida[1]; M Costa[1]; J Nascimento[1]; L Goncalves[1]
[1]*University Hospitals of Coimbra, Coimbra, Portugal*

Introduction: According to the guidelines of the European Society of Cardiology, it's suggested to prescribe beta-blockers (BB) after an acute coronary syndrome (ACS) without ST-segment elevation (NSTEMI) in patients (P) with reduced left ventricular ejection fraction (LVEF) to reduce mortality, recurrence of infarction and hospitalization for heart failure (HF). However, there is limited evidence of the role of BB after an NSTEMI ACS with preserved (LVEF≥50%) or mid-range LVEF (40-49%).
Objectives: To evaluate the prognostic impact of BB in P with preserved or mid-range LVEF after an NSTEMI ACS.
Methods: Retrospective and single center study of 533 P (69 ± 13 years, 67% male) admitted to a cardiac intensive care unit over 4 years. All patients underwent transthoracic echocardiography with LVEF assessment and were categorized into 2 groups: Group 1 (G1: LVEF 40-49%, N=131) and Group 2 (G2: LVEF≥50%, N=402). In each group we stratified the P who received BB on discharge and we compared them with P that were discharged without BB in relation to the primary objective (reinfarction and cardiovascular mortality) and secondary objectives (reinfarction, readmission of HF, and total mortality).
Results: The P from G1 and G2 who received BB on discharge were similar to P who were discharged without BB were similar in terms of baseline characteristics, such as demographics, cardiovascular risk factors, history of coronary disease and chronic kidney disease. They also showed similar Killip class, creatinine, troponin I, NT-proBNP and Grace Scores on admission. There were no differences in coronary angiography (acute occlusion, number of lesions or PCI) and in-hospital medical treatment.
We found that P of the G1 treated with BB didn't present statistically significant differences in relation to the primary composite objective (55% vs 56.2%, p = 0.93), re- infarction (17.2% vs 14.3%, p = 0.78) and mortality (36% vs 25%, p = 0.39) compared to those not treated with BB. However, we observed that they had a lower percentage of re-admisson for HF (12.9% vs 35.7%, p = 0.030). In multivariate analysis, BB prescription was an independent predictor for reduced readmission due to HF (OR 0.26, p = 0.035).
With respect to the P of the G2, we observed that the P under BB didn't present significant differences regarding the primary composite objective (77% vs 23%, p = 0.97) and secondary objectives [re-infarction (67% vs 33%, p = 0.089), readmission for HF (89% vs 11%, p = 0.083) and mortality (74% vs 25%, p = 0.63)].
Conclusions: The use of BB in NSTEMI ACS P with preserved LVEF did not show to have a prognostic impact. However, in NSTEMI ACS P with mid-range LVEF, the use of BB was shown to be associated with a reduction in readmission for HF.

METABOLISM – DIABETES MELLITUS – OBESITY

P484
Relationship between cardiac autonomic neuropathy and heart rate variability in young patients with type 1 diabetes mellitus

D Denis Medvedev[1]; VP Efimova[2]; YK Mahamat[1]; AF Safarova[1]; ZHD Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*; [2]*City Clinical Hospital No 64, City Clinical Hospital 64, Moscow, Russian Federation*

Background: Type 1 diabetes mellitus (T1DM) is an independent risk factor for the development of various cardiovascular disorders, such as dysrhythmias, sometimes leading to fatal outcomes. Cardiac autonomic neuropathy (CAN) is considered to be the main mechanism responsible for the onset of rhythm disturbances. Assessment of heart rate variability (HRV) is one of the methods applied to determine the predictors of CAN development.
Purpose: To study HRV parameters in young T1DM patients without coronary artery disease (CAD) and history of dysrhythmias.
Material and methods: The study included 71 patients with T1DM [mean age 28.7

years, 41 (57%) male, mean glycated hemoglobin 9,9% (84 mmol/mol), mean body mass index 23,4 kg/m2, mean diabetes duration 6,84 (0,5; 24) years, mean NT-proBNP 62,62 pg/ml, mean EF (modified Simpson method) 61,7%]. All patients underwent stress treadmill testing, 24-hour Holter ECG monitoring (Shiller). We calculated time domain HRV parameters (SDNN, SDNNi, rMSDD, pNN50, circadian index - CI).
Results: Time domain HRV measurements in all studied patients deviated from the lower limit of age-specific reference values (SDNN — 368.82 ± 29.82 ms, SDNNi — 108.51 ± 10.35 ms, rMSDD — 182.17 ± 47.52 ms, and pNN50 — 12.34 ± 10.20 %). Mean 24-hour heart rate was 97.60 beats/min [58; 147]. Time domain HRV parameters were significantly higher in women: SDNN (420.71 ± 85.31 vs 127.40 ± 38.83), SDNNi (139.42 ± 23.49 vs 62.4 ± 22.14), rMSDD (275.43 ± 62.4 vs 51.60 ± 23,11), p < 0,001 for all comparisons. Men had higher pNN50 values than women (15.16 ± 10.08 vs 10.01 ± 38.00, p < 0.05). Mean CI was 1.15 ± 0.94. CI was rigid (< 1.2) in 59.15%, normal (1.24 – 1.42) – in 18.31%, and mildly decreased (1.20-1.23) in 22.53% cases. All participants were in sinus rhythm. Paroxysmal supraventricular tachycardia was detected in 2.8%, incidental ventricular tachycardia in 1.4%, supraventricular premature beats in 22.5%, ventricular premature beats in 8.5%, wandering atrial pacemaker in 11.3%, and second-degree sinoatrial block in 2.8% of patients.
Conclusion: The identified abnormalities in time domain HRV measures and impairment of CI rigidity in young T1DM patients without CAD and history of dysrhythmias indicate the development of CAN.

P486

The relationship between glycemic control and preclinical diastolic dysfunction in patients with type 2 diabetes mellitus or prediabetes

A Albana Doko Banushi[1]; I Refatllari[1]; V Paparisto[1]; N Kuka[2]; S Qirko[1]; A Goda[1]
[1]*University Hospital Center Mother Theresa, Tirana, Albania*; [2]*Polytechnic University, Tirana, Albania*

Background: Type 2 diabetes mellitus (T2DM) is associated with an increased risk of micro and macrovascular complications. The relationship between heart failure and glycemic control is not well established.
Purpose: The aim of this study was to assess relationship between diastolic dysfunction (DD) and glycemic control (HbA1c) in patients (pts) with T2DM or prediabetes (PD) with preserved systolic function (left ventricular ejection fraction ≥ 55%), asymptomatic for heart failure and without overt heart disease.
Methods: 170 diabetics or prediabetic pts (57.8 ± 8.3 years, 52% male) without evident heart disease, and 43 age and sex–matched control subjects were enrolled. Conventional echocardiography, tissue Doppler parameters and HbA1c were measured for all pts.
Results: In pts with good glycemic control (HbA1c 7-7.9%) the risk of DD was 3.6 fold higher (95% CI, 1.03-12.5; p = 0.044) compared to those with tight glycemic control (HbA1c < 7%), in pts with poor glycemic control (HbA1c 8-8.9%) the risk of DD was 5.9 fold higher (95% CI, 1.79-19.57; p = 0.004), and in pts with HbA1c ≥9% this risk was 8.2 fold higher (95% CI, 2.70-25.25; p < 0.001). A logistic regression analysis showed glycemic control as an independent predictor of DD (OR= 1.36; 95% CI, 1.17-1.59; p <0.001).
Conclusion: Our findings support the idea that glycemic control is strongly related with preclinical DD in patients with T2DM or PD.

P487

Weight gain was associated with better prognosis after hospital discharge in patients admitted with heart failure

RM Rosa Maria Agra Bermejo[1]; S Eiras[1]; A Varela Roman[1]; R Gonzalez Ferreiro[1]; I Gomez Otero[1]; A Castro[2]; F F Casanueva[2]; JR Gonzalez Juanatey[1]
[1]*UNIVERSITY CLINICAL HOSPITAL OF SANTIAGO DE COMPOSTELA, DEPARTMENT OF CARDIOLOGY, SANTIAGO DE COMPOSTELA, Spain*; [2]*University Hospital of Santiago de Compostela, Endocrinology, Santiago de Compostela, Spain*

Background: Obesity and overweight were defined as factors associated with higher survival in heart failure (HF) patients. However, the prognostic value of weight gain after hospital discharge in patients admitted with HF is unknown.
Purpose: The aim of our study was to know the consequence of BMI changes in patients after being hospitalized for HF.
Methods: We selected 86 patients consecutively admitted in our hospital for acute HF. Body Mass Index (BMI) was calculated as the weight in kilograms divided by the square of the height in meters. BMI was determined during the admission and 6 months after. The mean of follow up was 416 ± 256 days. Cox regression analyses were employed to calculate the estimated hazard ratio (HR) of death or readmission with 95% confidence interval (CI).
Results: During the follow-up 46 patients gained weight, 26 loosed weight and 14 maintained weight. Patients who had gained weight were represented by those with more frequently non-ischemic HF (54.2%). The Kaplan Meir curve showed that patients who gained weight have lower mortality and readmissions during the follow-up compared with the other two groups (p < 0.05). The Cox regression analyses showed that weight gain proved to be a protective factor against death and/or readmission (HR=0.377; CI 95% 0.168-0.847, p = 0.048).
Conclusions: Weight gain after hospital discharge in patients admitted for HF determines a better outcome in terms of death and/or readmission.

P488

Rosuvastatin dose-dependently improves flow-mediated dilation, but reduces adiponectin levels and insulin sensitivity in hypercholesterolemic patients

K Kwang Koh[1]
[1]*Gachon University, Incheon, Korea Republic of*

Background: Increased risk of type 2 diabetes noted with statins is at least partially explained by HMG-coenzyme A reductase inhibition. We investigated vascular and metabolic phenotypes of different dosages of rosuvastatin in hypercholesterolemic patients.
Methods: This was a randomized, single-blind, placebo-controlled, parallel study. Age, sex, and BMI were matched among groups. Forty-eight patients were given placebo, and 47, 48, and 47 patients given rosuvastatin 5,10, and 20 mg, respectively daily during a 2 month treatment period.
Results: Rosuvastatin 5,10, and 20 mg dose-dependently and significantly improved flow-mediated dilation (34, 40, and 46%) after 2 months therapy when compared with baseline (P < 0.001 by paired t-test) or when compared with placebo (P < 0.001 by ANOVA), and increased insulin (median % changes; 16, 20, and 20%, respectively) and glycated hemoglobin levels (mean % changes; 2, 2, and 3%, respectively), and decreased adiponectin levels (mean % changes; 3, 9, and 14%, respectively) and insulin sensitivity (mean % changes; 2, 3, and 4%, respectively) after 2 months therapy when compared with either baseline (all P < 0.05 by paired t-test), or when compared with placebo (P=0.006 for insulin, P=0.012 for glycated hemoglobin, P=0.007 for adiponectin, and P=0.002 for insulin sensitivity by ANOVA).
Conclusions: Rosuvastatin treatment dose-dependently and significantly resulted in decreasing insulin sensitivity and increasing ambient glycemia by reducing adiponectin levels and increasing insulin levels in hypercholesterolemic patients.

P489

Significance of speckle-tracking in identifying subclinical myocardial injury of young patients with Type1 Diabetes mellitus without cardiovascular disease.

Y Makhamat[1]; VP Efimova[1]; DM Medvedev[1]; AF Safarova[1]; ZHD Kobalava[1]
[1]*RUDN University, propaedeutics of internal diseases, Moskow, Russian Federation*

The Aim: to study the importance of speckle-tracking to identify the presence of subclinical myocardial injury of young patients with Type1 Diabetes mellitus without cardiovascular disease and determine the impact of Type1 Diabetes mellitus (DM) on systolic and diastolic function of left ventricle of young patients without clinical of cardiovascular disease.
Methods: Young patients with Type1 DM (N=71) and without cardiovascular disease admitted to the therapy department of Moscow city clinical hospital 64 in the period 2015 till 2016 years were included in the study. Treadmill test was conducted to all patients in order to exclude coronary disease, and also NT-proBNP, glomerul filtration rate (GFR), urine albumin-to-creatinine ratio (uACR). EchoCG examination including analyses of LV EF (modified Simpson method) and global longitudinal systolic deformation (GLS) by speckle-tracking (VIVD 7 Dimencion, GE).
The Results: Mean age was 28,7 years, 57% men, mean glycated hemoglobin 9,9% (84 mmol/mol), mean body mass index 23,4 kg/m2, and mean diabetes duration 6,84 [0,5; 24], mean NT-proBNP 62,62 pg / ml, mean LV EF 61,7%. Subclinical systolic disfunction, that is defined as GLS < 20%, was observed in 63,3%(45/71) cases. Left ventricular mass, left ventricular end-systolic volume and left ventricular end-systolic diameter were higher in patients with GLS < 20% than in patients with GLS>20% (p < 0,05). Furthermore EF, MAPSE; APSE were considerably lower in patients with GLS < 20% than in patients with GLS>20% (p < 0,05). Left atrium volume index(LAVI) was higher in patients with GLS < 20%, but the difference was statistically insignificant(p < 0,01). Left ventricular diastolic disfunction with slow relaxation(grade1) was observed in 5,6 (4/45) patients with insulin-dependent diabetes (Type1) and GLS < 20% as opposed to patients with GLS>20%,who the diastolic disfunction wasn't found. While making the multivariate and regressive analysis it was identified that albuminuria is an independent determining factor of /' (β = 0,22, < 0,001) with the age (β = 0,36, < 0,001) and female(β = 0,24, < 0,004), and also GFR correlate closely with GLS (= 0,28, < 0,006). The strong correlation was found for GFR and GLS (χ2 12,9, < 0,05, r=0,62), and delicate correlation for index albumin/creatinine (χ2 2,47, < 0,05, r=0,26). At the same time the relative risk of GLS decreasing with GFR < 90ml/min/1,73m2 increased in 2,8 (OR 2,8; 95% CI:

1,4;3,2;p < 0,001), with GFR < 60ml/min/1,73m2 increased in 3,4 (OR 3,4; 95% CI: 2,3 ;4,6 ;p < 0,001).
Conclusions: 1) Global longitudinal systolic LV myocardial deformation, identified by speckle-tracking is a sensitive marker of subclinical myocardial injury of young patients with Type1 DM without cardiovascular disease.
2) The correlation was identified: GFR < 90ml/min/1,73m2 with the decreasing global longitudinal systolic LV myocardial deformation (GLS < 20%)

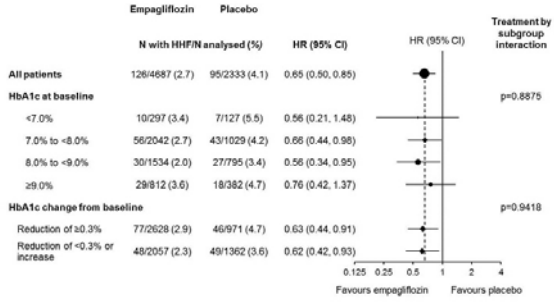
P490

Reduction in hospitalisation for heart failure with empagliflozin is consistent across categories of baseline HbA1c and change in HbA1c: results from the EMPA-REG OUTCOME trial

D Fitchett[1]; SE Inzucchi[2]; C Wanner[3]; M Mattheus[4]; JG George[5]; HJ Woerle[4]; B Zinman[6]
[1]St. Michael's Hospital, Division of Cardiology, University of Toronto, Toronto, Canada; *[2]Section of Endocrinology, Yale University School of Medicine, New Haven, United States of America*; *[3]Department of Medicine, Würzburg University Clinic, Würzburg, Germany*; *[4]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany*; *[5]Boehringer Ingelheim Ltd, Bracknell, Berkshire, United Kingdom*; *[6]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, and Division of Endocrinology, University of Toronto, Toronto, Canada*

Funding Acknowledgements: The EMPA-REG OUTCOME® trial was funded by the Boehringer Ingelheim & Eli Lilly and Company Diabetes Alliance.

Background: In the EMPA-REG OUTCOME trial, EMPA given in addition to standard of care significantly reduced the risk of hospitalisation for heart failure (HHF) vs placebo (PBO) (HR 0.65; 95% CI 0.50, 0.85) in patients with type 2 diabetes (T2DM) and established CV disease. We investigated whether baseline HbA1c or change in HbA1c influenced the effect of EMPA on HHF.
Methods: Patients were randomised to receive EMPA 10 mg, EMPA 25 mg, or PBO. Background glucose-lowering therapy was to remain unchanged for 12 weeks and then be adjusted to achieve glycemic control according to local guidelines. HHF was analysed in the pooled EMPA group vs PBO by categories of (1) baseline HbA1c (< 7.0%; 7.0 to < 8.0%; 8.0 to < 9.0%; ≥9.0%) and (2) change in HbA1c from baseline to the last value in the trial (reduction of ≥0.3%; reduction of < 0.3%). Differences in risk between treatment groups were assessed using a Cox proportional hazards model.
Results: A total of 7020 patients were treated. Median observation time was 3.1 years. The benefit of EMPA vs PBO on HHF was consistent irrespective of baseline HbA1c or change in HbA1c from baseline to the last value before HHF (for patients with HHF) or the last value in the trial (for patients without HHF) (Figure).
Conclusion: In patients with T2DM and established CV disease, the reduction in the risk of HHF with EMPA vs PBO was largely independent of baseline HbA1c and the change in HbA1c from baseline to the last value before HHF or the last value in the trial.



P491

Sacubitril/valsartan and metformin, enemies in the metabolic control of diabetic patients with heart failure?

CN Perez Garcia[1]; D Enriquez[1]; TS Luque[1]; A Travieso[1]; C Olmos[1]; I Vilacosta[1]; D Vivas[1]; J Higueras[1]; M Perez[1]; C Macaya[1]; R Bover[1]; A Esteban[1]
[1]Hospital Clinic San Carlos, Instituto Cardiovascular Clínico San Carlos, Madrid, Spain

Introduction: The combination of sacubitril/valsartan (SV) is a new therapeutic step in patients with heart failure (HF) and reduced ejection fraction, after showing an improvement in functional class, reduced hospital admission due to HF and lower cardiovascular mortality. The increasing commercialization of this drug in the context of a patient with multiple comorbidities and chronically polymedicated, favors the interaction among commonly used drugs, with the possible clinical repercussion that this implies. This phenomenom has already been objectified in pharmacokinetic and pharmacodynamics studies in relation to certain drugs such as omeprazole, ethinylestradiol and metformin.
We report the clinical case of a type 2 diabetic patient on oral treatment with metformin, with introduction of SV in the previous 6 months.
Objective: Through a case report, it is hypothesized that the clinical interaction between metformin and SV has clinical repercussions in terms of a worse metabolic control as well as the role of oral antidiabetic titration in this situation.
Material and Method: We report the case of a type 2 diabetic patient treated with metformin and followed by the HF Unit of a Spanish tertiary hospital for non-ischemic dilated cardiomyopathy since 2013. Because of a LVEF of 32% and persistence of symptoms despite optimized medical treatment with beta-blockers, ARB and eplerenone, SV is introduced at doses of 24/26 mg b.d. In a periodic review at 3 months, the patient reports worse control of capillary glycemia levels after starting the new drug. Pre- and postprandial capillary glycemias are recorded and compared to the previous records in by a non-parametric test (Wilcoxon test for paired data), as well as comparison of glycated haemoglobin (HbA1c) figures. In addition, titration of metformin and new control in 3 months of HbA1c is carried out.
Results: At the moment the patient referred the poor glycemic control, capillary glycemia data were recorded for breakfast, lunch and dinner weekly. So that the preprandial glycemias in breakfast, lunch and dinner before SV were 128.3 ± 4.41, 106.2 ± 13.99 and 122 ± 10.04 mg/dL, respectively. After the onset of SV, these values corresponded to values of 178 ± 14.3, 160 ± 19.4 and 168 ± 19.7 mg/dL with p value < 0.05 in all cases.
As regards postprandial glycemias before SV: 127.8 ± 5.5, 122 ± 8.99 and 116.5 ± 9.7 mg/dL, which increased significantly after SV (193 ± 27.8, 163 ± 20.1 and 161 ± 27 mg/dL, with p < 0.05). Likewise, of a HbA1c of 7% prior to SV, it rises at the third month to 7.9%.
Metformin is tritated (from 850 mg b.d. to 850 mg t.d) reaching three months later a HbA1c of 7.2%.
Conclusions: SV could contribute by pharmacokinetic interaction with metformin to poorer metabolic control of diabetic patients with HF. Metformin dose titration is a suitable option to balance the long term effects of an irregular metabolic control in this subset of patients.

Gender-specific association between metabolic parameters and arterial stiffness in young healthy subjects

E Ekaterina Starostina[1]; I Strazhesko[1]; YA Orlova[1]
[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation

Early vascular aging (increased arterial stiffness) is associated with cardiovascular diseases, mainly with heart failure. There are some studies demonstrated the association between arterial stiffness, measured as increased pulse wave velocity (PWV), increased central blood pressure (BPao), and metabolic disturbances. Several observational studies suggest that the metabolic syndrome increases the cardiovascular morbidity in women to a greater extent than in men. There are no enough data about gender-specific differences in relationship between increased arterial stiffness and metabolic status.
The objective of this study was to determine the sex-specific association between the metabolic parameters and arterial stiffness in young adults.
Material and methods: We investigated 258 healthy young adults, mean age 18,8 ± 1,6 years, 47% male. PWV and BPao were measured with ambulatory blood pressure monitoring device BPLab Vasotens (BPLab, Russia). Waist circumference (WC), body mass index (BMI), fasting plasma glucose (FG), insulin resistance (HOMA-IR) and lipid profile were measured using routine methods.
Results: Only in women PWV was significantly related to BMI (r=0.34; P < 0.001), WC (r=0.39; P < 0.001), high-density lipoprotein level (r=-0.13; P < 0.01). In both genders PWV was significantly associated with triglycerides, FG, HOMA-IR. All measured metabolic parameters were significantly related to systolic and diastolic BPao in men and women. In women unlike men fasting plasma glucose, HOMA-IR were independent predictors of PWV in a multiple stepwise regression model.
Conclusions: The metabolic parameters are associated with arterial stiffness more severely in women than in men. More importance to women with metabolic disturbances should be given.

Risk of hospitalization for decompensated heart failure in patients with BMI <25 and reduced ejection.

DR Fernando Manzur Jattin[1]; DR Hugo Corrales Santander[1]; DR Rafael Herrera[1]
[1]Centro de Investigaciones Biomédicas - Universidad de Cartagena, Facultad de Medicina, Cartagena, Colombia

Funding Acknowledgements: Beca - Pasantía Joven Investigador 2015 - COLCIENCIAS

Introduction: obesity is a risk factor for the development of heart failure (HF), however, recet evidence has shown that there is more frequency negative outcomes in hospitalized patients with normal or low body mass index (BMI) than in patient with overweight or obesity, when both groups have decompensated heart failure, a phenomenon called "obesity paradox in HF" (1, 2).
Aim: To estimate the association of BMI in patients with heart failure reduced with ejection fraction (HFrEF) and its impact on hospitalization due to decompensation in a health institution in Colombia.
Methodology: A prospective cohort study was conducted between April 2014 and April 2015, in patients with HFrEF, collected at the outpatient department of Cardiology of a hospital in the city of Cartagena. Patients with BMI <25 kg / m2 and unexposed BMI> 25 kg / m2, without renal impairment, were considered as exposed cohorts. Quarterly follow-up was done by external consultation and telephone follow-up for variables of interest.
Results: 52 patients were included in the present study. 65.4% were male, average age 65.4 ± 13.8. 51.9% (27/52) of patients had BMI greater than or equal to 25kg/m2 and 48.1% (25/52) with BMI <25kg/m2. Of these, 18.5% (5/27) and 20% (5/25) had a smoking habit, 7.4% (2/27) and 4.0% (1/25) alcoholism, 77.7% (21/27) and 92% (23/25) hypertension, 14.8% (4/27) and 24% (6/25) diabetes, 14.8% (4/27) coronary heart disease, 85.1% (23/27) and 68% (17/25) had class Functional NYHA I and II, 14.8% (4/27) and 32.0% (8/25) class III and IV. The incidence rate of hospitalization in exposed patients was 43 x 1,000 person-years and 30.8 x1,000 person years for the non-exposed. The risk of hospitalization for decompensated heart failure in patients with BMI <25 was RR: 1.4 [95% CI 0.7-2.6], and attributable risk was 15%.
Conclusion: Having normal or low weight increased 1.4 [95% CI 0.7-2.6] times the risk of hospitalization for decompensated heart failure. It is suggested to carry out analytical studies with larger sample size.

HEART FAILURE IMAGING

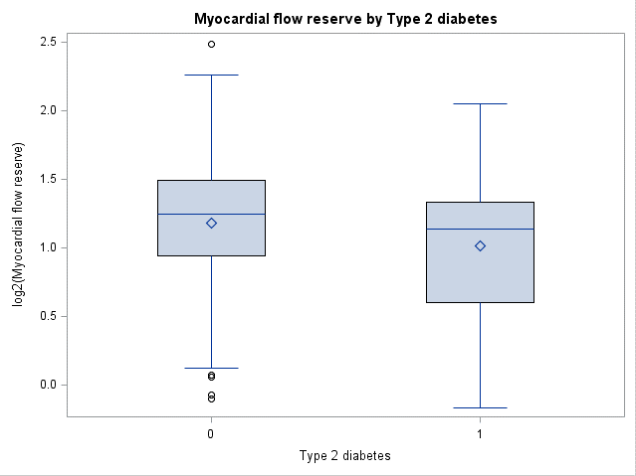
Myocardial perfusion is reduced in patients with type 2 diabetes as comorbidity to non-ischemic systolic heart failure

C Byrne[1]; P Hasbak[2]; A Kjaer[2]; JJ Thune[3]; L Koeber[1]
[1]Rigshospitalet - Copenhagen University Hospital, Heart Centre, Department of Cardiology, Copenhagen, Denmark; [2]Rigshospitalet - Copenhagen University Hospital, Department of Clinical Physiology, Nuclear Medicine & PET, Diagnostic Centre, Copenhagen, Denmark; [3]Bispebjerg University Hospital, Department of Cardiology, Copenhagen, Denmark

Funding Acknowledgements: The Danish Heart Foundation

Introduction: Patients with non-ischemic systolic heart failure (HF) often have reduced myocardial blood flow without significant coronary atherosclerosis. However, the mechanism is unknown. Similarly, patients with type 2 diabetes (T2DM) have reduced myocardial perfusion compared with control persons. To our knowledge, no one has previously compared myocardial perfusion in patients with non-ischemic systolic HF with and without T2DM.
Purpose: To investigate whether changes in myocardial perfusion are associated with T2DM in patients with non-ischemic systolic HF.
Methods: In a prospective cross-sectional study, we scanned patients with non-ischemic systolic HF with and without T2DM with 82-Rubidium positron emission tomography (PET)/computed tomography (CT) at rest and adenosine-induced stress, thereby obtaining the myocardial flow reserve (MFR=stress flow/rest flow); 28 patients with T2DM and 123 without T2DM were included. We used a general linear model (GLM) procedure for multiple regression analysis of explanatory variables.
Results: Patients with T2DM had a median age of 68 years (range 60-75 years) and 21.4% were women. The patients without T2DM had a median age of 68 years (range 62-72 years) and 33.3% were women. Patients with T2DM had higher body mass index (BMI) than patients without (29.9 vs. 26.5 kg/m2; P=0.02). Blood glucose measured right before the scan was higher among patients with T2DM (6.2 vs. 5.7 mmol/L; P=0.03) and hypertension was more common in this group (50.0 vs. 26.8%; P=0.02). Also more patients with T2DM were treated with cholesterol lowering medication (60.7 vs. 35.0% P=0.02). Apart from these variables, the two groups were similar. In a multivariable analysis, including sex, age, BMI, T2DM, atrial fibrillation during scan, left bundle branch block, hypertension, N-terminal pro-brain natriuretic peptide and left ventricular mass, MFR was 16 % lower in patients with T2DM compared with patients without (Estimate 0.84; 95% confidence interval [CI] 0.71 to 0.996; P=0.04). In addition MFR was significantly lower in patients with atrial fibrillation during scan (Estimate 0.69; 95% CI 0.57 to 0.82; P < 0.001) and MFR increased with increasing BMI (Estimate 1.02; 95% CI 1.00 to 1.04; P=0.01).
Conclusion: Patients with T2DM and systolic HF had lower myocardial flow reserve compared with HF patients without diabetes. This indicates that T2DM is an independent impairing factor to the coronary microvascular function in patients with non-ischemic systolic HF.



Myocardial flow reserve by diabetes

On behalf of: FATIMA investigators
Funding Acknowledgements: PTDC/BIM-MEC/0650/2012

Introduction: Right ventricular (RV) function assessed by echocardiography has found to have prognostic value in ischemic and idiopathic dilated cardiomyopathy (DCM).
Purpose: We aimed to analyze RV function and volumes, assessed with cardiac magnetic resonance imaging (CMR) in a cohort of patients with genetically characterized DCM and to evaluate their clinical relevance.
Methods: National multicentric study of consecutive patients with idiopathic and familial DCM that underwent a comprehensive CMR study as part of their diagnostic work-up. Ventricular volumes and ejection fraction (EF) were measured using dedicated software. Patients underwent extensive clinical evaluation, ECG, 24h-Holter, echocardiogram and molecular analysis (using next-generation sequencing combined with Sanger sequencing).
Results: 80 patients were included, 52% men, mean age at diagnosis 38 ± 14 years, with 55% of familial cases (44 patients corresponding to 38 families). At least one genetic variant was found in 21%. Mean left ventricular (LV) end-diastolic volume was 127 ± 36 mL/m2 and LVEF 34 ± 12%. Most patients were in NYHA class I (52%). In median follow-up of 41 (IQR 64) months a composite of death/heart transplant/aborted sudden cardiac death was documented in 12% of them.
Mean RVEF, RV end-diastolic and RV end-systolic volumes were 52 ± 11%, 78 ± 22 mL/m2 and 39 ± 21 mL/m2, respectively. Reduced RVEF was found in 45% of patients and enlarged RV end-diastolic and RV end-systolic volumes in 9% and 32%, respectively.
There were no differences in RV parameters between patients with familial or idiopathic DCM or between patients with or without a genetic variant.

Patients with previous hospitalizations presented lower RVEF (48 ± 12% vs 55 ± 10%; p = 0.014) and patients with non-sustained ventricular tachycardia and right bundle brunch block presented higher RV end-diastolic (85 ± 21 mL/m2 vs 72 ± 16 mL/m2, p = 0.015; 112 ± 34 mL/m2 vs 76 ± 21 mL/m2, p = 0.002) and RV end systolic volumes (44 ± 17 mL/m2 vs 33 ± 12 mL/m2, p = 0.014; 68 ± 37 mL/m2 vs 37 ± 19 mL/m2, p = 0.004).
A moderate positive correlation was found between RVEF with LVEF (r=0. 452, p < 0.001) and RV end-systolic volume with left atrium diameter (r=0.414, p = 0.001). There were no differences in RV parameters according to the presence of late gadolinium enhancement or noncompaction criteria.
In univariate analysis RVEF was predictor of the composite outcome (OR 1.066, 95%CI [1.004-1.132], p = 0.036).
Conclusions: RV dysfunction was frequent in DCM patients and was associated with some features of worse clinical outcome. RV functional profile didn't vary between idiopathic or familial DCM or according to molecular results.

Funding Acknowledgements: Instituto de Salud Carlos III (CIBERCV); Fundación Caja Navarra; European Commission FP7-FIBRO-TARGETS.

Background: The assessment of alterations in the extracellular matrix (ECM) by cardiac magnetic resonance (CMR) has shown promising results in different cardiomyopathies, mostly in stage of clinical heart failure (HF). However, little is known about its value in patients at earlier stages of the syndrome.
Purpose: To assess alterations of the myocardial ECM by CMR in patients with arterial hypertension with (stage C) or without (stage B) clinical HF and to analyse their associations with parameters of left ventricular (LV) function.
Methods: The study included 37 hypertensive patients without coronary artery disease or suspected cardiac amyloidosis. Eighteen of them presented LV hypertrophy and/or diastolic dysfunction with no clinical symptoms of HF (stage B) and the remaining 19 presented clinically overt HF (stage C). A group of 10 healthy subjects was included as a control group for CMR parameters. In the CMR study the extracellular volume (ECV) was calculated after T1 mapping to assess the presence of diffuse interstitial fibrosis, and the late gadolinium enhancement (LGE) positive mass was quantified using a signal intensity threshold of 5 standard deviations (SD) above the mean remote myocardium to assess the presence of microscars.
Results: ECV was increased in both stage B (24.40 ± 0.47%; P < 0.05) and stage C (28.84 ± 0.68%; P < 0.001) patients compared with control subjects (21.42 ± 0.54%), being higher (P < 0.001) in stage C patients than in stage B patients. LGE was also increased in both groups of patients compared to control subjects (control: 1.18 ± 0.19 g; Stage B: 3.98 ± 0.72 g; stage C: 6.78 ± 1.51 g; P < 0.01 and P < 0.001, respectively), but there were no significant changes between the two groups of patients. Whereas ECV was correlated with the E:E′ ratio (r=0.447; P < 0.05), LGE was correlated with the LV end-diastolic volume (r=0.449; P < 0.05) and LV ejection fraction (r=-0.455; P < 0.05) in all patients. Both ECV (r=0.458; P < 0.05) and LGE (r=0.511; P < 0.01) were correlated with NT-proBNP in all patients. All these associations were independent of age and gender. Conclusions: CMR-assessed alterations in the myocardial ECM of hypertensive patients are present before overt HF develops and are associated differently with LV function (i.e., the increase in ECV is associated with diastolic dysfunction and the increase in LGE is associated with LV remodelling and systolic dysfunction). Therefore, it is suggested that the involvement of myocardial ECM in the pathophysiology of hypertensive HF is variable and depends on the type of alteration considered (i.e., diffuse interstitial fibrosis or microscars).

P497

Late gadolinium enhancement, reverse remodeling and prognosis in patients with non-ischaemic dilated cardiomyopathy and moderate-to-severe systolic dysfunction

A Alberto Aimo[1]; A Barison[2]; A Ortalda[3]; V Castiglione[1]; C Passino[1]; M Emdin[1]
[1]Sant'Anna School of Advanced Studies, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*; *[3]San Raffaele Hospital of Milan (IRCCS), Milan, Italy*

Background: Reverse remodeling (RR) is defined as the recovery from left ventricular (LV) dilation and systolic dysfunction following guideline-recommended medical treatment for heart failure (HF). The absence of late gadolinium enhancement (LGE) at cardiac magnetic resonance (CMR) has been reported to predict the occurrence of RR in patients with idiopathic dilated cardiomyopathy (DCM).
Purpose: In the broader setting of non-ischaemic DCM (NIDCM), and among patients with moderate-to-severe systolic dysfunction, we explored the relationship among LGE (visually assessed or automatically quantified), RR, and prognosis.
Methods: The inclusion criteria were: diagnoses of NIDCM and stable, chronic HF; two CMR examinations within a maximum interval of 5 years; left ventricular ejection fraction (LVEF) < 45% at baseline CMR. The exclusion criteria were coronary artery disease, recent myocarditis (< 6 months), severe primary valvular disease, untreated hypertension, cardiac amyloidosis, estimated glomerular filtration rate < 30mL/min. RR was defined as a ≥15% reduction of LV end-systolic volume index across the two CMR examinations. The follow-up started at the second CMR examination. The endpoint was a composite of all-cause death, hospitalization for either HF or ventricular arrhythmias, appropriate implantable cardiac defibrillator discharge, ventricular assist device implantation or heart transplant.
Results: Seventy-one patients were enrolled (age 57 ± 14 years, 43 males [61%], LVEF 35% [interquartile range - IQR 27-41%]). NIDCM was idiopathic in 45 patients (63%). Median previous disease duration was 3 month [IQR 1-7 months]. LGE was found in 42 patients (59%). LGE mass was 9 g [IQR 5-18 g], and LGE% was 7% [IQR 3-12%].
Thirty-eight patients (54%) developed RR. The absence of LGE at baseline was univariate predictor of RR (OR 0.338 [95% CI 0.125-0.914]; P=0.033). LGE extent (percentage of LV mass) was significantly lower in the RR subgroup, and emerged as univariate predictor of RR (OR 1.112 [95% CI 1.022-1.210]; P=0.013). At ROC analysis, the best LGE cut-off for RR prediction was 7% (area under the curve - AUC 0.657, sensitivity 65%, specificity 62%).
Over a 42-month [IQR 15-73] follow-up, the endpoint occurred in 36 patients (51%). LGE presence was univariate predictor of the primary endpoint (OR 3.087 [95% CI 1.151-8.284]; P=0.025). Also LGE extent predicted this endpoint (OR 1.109 [95% CI 1.018-1.208]; P=0.018). The optimal LGE cut-off was again 7% (AUC 0.676, sensitivity 65%, specificity 66%). Kaplan-Meier analysis confirmed that patients with LGE < 7% had a significantly better prognosis (Figure).
Conclusions: In patients with NIDCM and moderate-to-severe systolic dysfunction, the absence of LGE at baseline predicts subsequent RR. Among patients with LGE, LGE extent < 7% is a predictor of RR, as well as of better prognosis.

Echocardiographic assessments of left atrial mechanic as potentially predictors of worse prognosis during six months follow up in STEMI patients

G Krljanac[1]; D Trifunovic[1]; M Asanin[1]; L Savic[1]; D Matovic[2]; L Jovanovic[2]; G Stankovic[1]; V Vukcevic[1]; I Mrdovic[1]
[1]Clinical Centre of Serbia, Cardiology Clinic, Medical Faculty, Belgrade, Serbia; *[2]Clinical center of Serbia, Cardiology Clinic, Belgrade, Serbia*

Parameters of left atrial mechanic could be substrate of worse prognosis and incidence of major cardiac events (MACE) defined as death, re-infarction, emergency revascularization, ventricular arrhythmias (VT and/or VF) and heart failure which need emergency re-hospitalization in STEMI patients (pts) treated with primary percutaneous interventions (PPCI). Aim: To determine left atrial mechanic parameters as

predictors of MACE during 6 month follow up (FU). We studded conventional echo parameters and parameters of left atrial mechanics: strain (S LA) and strain rate (Sr LA). Method: 99 consecutive STEMI pts treated with PPCI were prospectively included. Echo examination performed on day 4 ± 2 (VIVID 9GE, Echo PAC Ver 113). Results: 12/99 (12.1%) of all pts had MACE during 6 month FU. Parameters of left atrial mechanic: first positive peak (S LAs) and second positive peak (S LAa) LA longitudinal strain, strain rate parameters during systole (Sr LAs), and late diastole (Sr LAa) were significant predictors as well as conventional echo parameters. (table 1). The largest area under the ROC had LA vol index (area 0.724, p = 0.009, 95% CI 0.662-0.938) for cut off 18.43ml/m2, Sn 78%, Sp 60%. LVEF had lower area under the ROC (0.256, p = 0.035, 95% CI 0.088-0.423) and lower Sn 65% and similar Sp 64% for cut off LVEF 46.5%. S LAs (ROC 0.271; p = 0.048, 95% CI 0.066-0.477) had significant Sn 71%, and Sp 72% for cut off 16.45%. Sr LAs (ROC 0.247; p = 0.029, 95% CI 0.073-0.420) had low Sn 57%, but higher Sp 86% for cut off -0.755 s-1. Sr LAa (ROC 0.772, p = 0.019, 95% CI 0.593-0.952), for cut off -1.085 had the better Sn 71% and Sp 80%. Conclusion: During first months after PPCI period the left atrial mechanic parameters could be important to predict of MACE. Still, larger studies are needed to define the best left atrial mechanic parameter of myocardial deformation as predictor of worse prognosis.

Table 1

	Pts without MACE (n = 87)	Pts with MACE (n = 12)	p
LVEF (%)	49.7±10.6	38.4±11.3	0.003
LA vol index (ml/m^2)	18.65±6.21	23.32±6.48	0.039
S LAs (%)	20.54±7.99	14.61±6.57	0.035
S LAa (%)	11.50±6.00	7.82±4.22	0.036

Subclinical lv dysfunction detection in hypertensive patients with preserved lv ejection fraction: role of speckle tracking echocardiography

KARIMA Taamallah[1]; IMEN Hamdi[1]; CHADIA Chourabi[1]; HAJER Malek[1]; HOEIDA Mahfoudhi[1]; WAFA Fehri[1]; HABIB Haouala[1]
[1]*Military Hospital of Tunis, cardiology, military hospital, Tunis, Tunisia*

Introduction: Hypertension is a well-recognized risk factor for cardiovascular diseases and causes left ventricular (LV) pressure overload, which results in various geometric changes that progress to diastolic heart failure and/or heart failure, with LV systolic dysfunction. Early detection of subclinical left ventricular (LV) systolic dysfunction in hypertensive patients is important for the prevention of progression of hypertensive heart disease.
The aim of the present study was to detect subclinical LV dysfunction in hypertensive patients with apparently normal LV systolic function, using speckle tracking echocardiography (longitudinal strain pattern).
Patients and methods: Prospective case-control study was carried out on 112 hypertensive patients (61 male/51 female) and 40 age- and sex-matched healthy subjects as a control group. Conventional echocardiographic Doppler study, tissue Doppler imaging, and 2D speckle tracking imaging were performed using Vivid 9 (General Electric Healthcare). Longitudinal strain imaging by 2D-speckle tracking echocardiography (2D-STE) was done with high-quality images from the apical four-chamber, two-chamber, and three-chamber views. The strain values for all the segments were recorded and averaged to obtain the GLS.
Results: In hypertensive patients, The mean age was 60,5 ± 10,53 years. The left ventricular mass index(LVMI) was significantly higher in the hypertensive group. There was no significant difference in the global LV ejection fraction (LVEF) and the tele-diastolic diameter of LV between the two groups. The size of the interventricular septum was higher in the hypertensive group (P < 0.001). E/A ratio and é velocities were significantly lower in the hypertensive patients (p < 0.001). left atrium volume is significantly higher in the hypertensive group (p < 0.001). In comparison with normal controls, GLS was significantly attenuated in patients with systemic hypertension (-22,5 ± 3,19 in the control group vs -17,69 ± 4,06 in the hypertensive group, p < 0.001). this decrease was more marked In the hypertensive group with left ventricular hypertrophy (LVH) (SLG : 13,57 ± 2,045) (p < 0,001).
Conclusion: In hypertensive patients, LV systolic function is commonly considered normal if the global EF and fractional shortening (FS) are normal. However, the EF and FS reflect only the global cardiac contractile function and do not take regional systolic abnormalities into consideration. Our results show that 2D speckle tracking is able to detect subclinical myocardial dysfunction in hypertensive patients, despite normal global systolic parameters by conventional 2D echocardiography. This suggests that earlier intervention in these patients may be beneficial.

P500

Left ventricular diastolic dyssynchrony in patients with in patients with treatment-naive hypertension and the effects of antihypertensive therapy

BJ Kwon[1]
[1]*Hyosung Medical Center, Department of Cardiology, Cheong-ju, Korea Republic of*

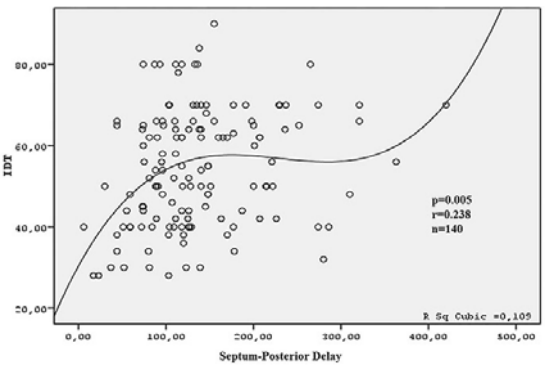
Background: Diastolic dyssynchrony (DD) is an important manifestation in heart failure. We tried to investigate (1) DD in patients with hypertension (2) determinants of DD; (3) the effects of 6-month medical therapy; and (4) the predictors associated with change of DD by performing comprehensive studies.
Methods: and results-DD was more prevalent (15.4% vs. 7.0%, P=0.007) in 325 treatment-naïve hypertensive patients, compared with 172 normal controls. Male (odds ratio [OR], 7.60, 1.69-34.30), magnesium levels (OR per 1 SD, 4.18, 1.54-11.30), nighttime heart rate (HR) (OR per 1 SD, 2.79, 1.19-6.53), and mitral E/A (OR per 1 SD, 0.11, 0.03-0.41) were independent determinants for the DD in hypertensive patients. A follow-up echocardiography was performed in 74 of 275 patients without DD (group 1) and 26 of 50 patients with DD (group 2) at 6 months. Severity and prevalence of DD (Δ=-8.3 ms, -14.6 to -2.1 and 57.7%, P=0.001) improved in group 2 after medical therapy, while those did not in group 1. Baseline daytime HR (P=0.008) and magnesium levels (P=0.029) and changes of the mitral E/A (P=0.003), mean annulus Ea (P = 0.003), mean annulus Ea/Aa (P = 0.020), and mitral peak E (P = 0.042) were independent predictors for changes of DD.
Conclusions: DD is not uncommon in patients with treatment-naïve hypertension. Male, magnesium levels, nighttime HR, and mitral E/A are independent determinants for the DD. Medical therapy reduces the DD, particularly in patients with DD. Moreover, daytime HR, magnesium levels, and indicative of diastolic dysfunction are independent predictors for changes of DD.

P501

Intrinsicoid deflection time predicts ventricular dyssynchrony better than QRS width in patients with indication to cardiac resynchronization therapy

M Koc[1]; O Kaypakli[1]; G Gozubuyuk[1]; DY Sahin[1]
[1]*Adana Numune Training and Research Hospital, Adana, Turkey*

Aim: CRT was shown to improve HF prognosis. But many patients do not benefit from CRT. Patients with LBBB are more likely to benefit from CRT. One of the criteria of LBBB is prolonged time to peak R wave (intrinsicoid deflection) > 60 ms in V5 and V6. In this study, we aimed to investigate the relationship between echocardiographic intraventricular and interventricular dyssynchrony and IDT (Intrinsicoid deflection time).
Methods: We prospectively included 140 patients with HF, QRS≥120 ms, LBBB, NYHA II-IV, LVEF < 35% and scheduled for CRT (84 male, 56 female; mean age 64.9 ± 10.8). Septal-posterior >130 ms delay in M-mode, septal-lateral >60 ms delay for the beginning and >65 ms delay for the peak of systolic velocity in TDI was accepted as intraventricular dyssynchrony. A delay in aortic PSEP > 40 ms was taken as interventricular dyssynchrony. IDT was measured as the time from the beginning of the QRS complex to the peak of the R wave in V5 and V6.
Results: Septum-posterior delay was associated with LDL, LVEF, IDT and QRS width in bivariate analysis. In logistic regression analysis, IDT was only independent parameter for predicting septum-posterior delay (OR= 1.037, p = 0.025). IDT was also associated with septal-lateral delay for beginning, septal-lateral delay for peak of systolic velocity, pulmonary-aortic PSEP delay in bivariate correlations and ROC curve (p < 0.05 for all).
Conclusion: IDT is closely associated with all echocardiographic intraventricular and interventricular dyssynchrony parameters and has a better predictive value than QRS width to detect ventricular dyssynchrony in patients with indication to CRT.



IDT-septum-posterior delay- Scatter plot

Assessment of right and left ventricle function in HIV-infected patients

A Destounis[1]; C Tountas[1]; P Zachos[1]; N Kasinos[1]; C Ioannidis[1]; K Kipourou[1]; M Vassaki[1]; A Theodosis-Georgilas[1]; D Beldekos[1]; G Chrysos[1]; S Foussas[1]
[1]*Tzanio General Hospital, Department of Cardiology, Piraeus, Greece*

Introduction: HIV-infected individuals are at increased risk for pulmonary hypertensionand cardiomyopathy, portending a poor prognosis. Right ventricular (RV) and Left ventricular (LV) diastolic dysfunction isassociated with worse outcomes in these conditions. Therefore early identification of these entities in course disease is crucial for further treatment of these patients.
Purpose: In this study we assessed in relatively newly diagnosed HIV young patients several indices of RV and LV function.
Methods: Echocardiograms were evaluated in 15 HIV-infected adults. Measurements included several indices of LV diastolic function from pulsed Doppler transmitral flow (E, A, DT) and Tissue Doppler Imaging measurements (S, Ea, Aa from the lateral wall and intraventricular septum). In addition, we analyzed indices of RV function such as tricuspid annular plane systolic excursion (TAPSE), RV longitudinal regional and global myocardial strain (RV LMS) and RV fractional area change (RVFAC).
Results: Data from fifteen HIV-infected patients were analyzed (mean age 41,6 ± 11 years, 13 males, body mass index 1,95 ± 0,2 kg/m^2, mean HIV infection 75,1 ± 68).In HIV- infected patients duration of HIV insult was negatively correlated with FAC (r=-0,527, p = 0,053) and had positive correlation with RV systolic area (r=0,56, p < 0,05). Additionally, HIV load was negatively correlated with transmitral E (r=-0,577, p < 0,05). We could not find any correlation with global or regional longitudinal strain of RV and either HIV virus load, duration of infection and CD4 count at time of measurement.
Conclusions: These data suggests that duration of HIV infection affects negatively the RV systolic function. In addition the HIV viral load is also associated with diastolic dysfunction independently of age and duration of HIV infection. In patients of high HIV virulence and increased duration of HIV infection thorough assessment of possible RV and LV diastolic dysfunction should be done.

P503

Epidemiological and ultrasound characteristics of intracardiac thrombosis

B Bassem Rekik[1]; R Hammami[1]; D Abid[1]; L Abid[1]; M Hentati[1]; S Kammoun[1]
[1]*Hedi Chaker University Hospital, Cardiologie department , Sfax, Tunisia*

Introduction: Our objective is to describe the epidemiological clinical and ultrasound characteristics of intracardiac thrombosis, to underline the interest of the early diagnosis, and the efficiency of the treatment in this pathology.
Methods: It is a descriptive study including cases of patients with intracardiac thrombosis revealed by the echocardiographic examination, during the period from January 01st, 2010 till January 31th, 2013, in our Cardiology department.
Results: Among 13290 echocardiography examinations performed, we diagnosed 43 patients with intracardiac thrombus (0.32%). The sex ratio was 1.3 and the average age was 57.4 years. Topographically we find 20 left ventricule thrombosis (60.5%), 9 left atria thrombosis (20.9%), 6 right atria thrombosis and 2 right ventricles thrombosis.
The mean diameter of thrombus was 19.9 mm and there were 2 cases of multiples thrombi.
The most frequently underlying heart disease were ischemic cardiomyopathy(51.2%), secondary atria fibrillation (18.6%), primitive dilated cardiomyopathy(11.6%) and valvular diseases (one aortic stenosis ,4 mitral stenosis and 4 mitral regurgitation). The thrombus disappeared with only medical treatment (anticoagulant and antiplatelet) in 31 patients after a mean of 3 months, and was treated by surgery in 10 patients. Only 4 patients showed systemic embolization.
Conclusion: Our results suggests that cardiac thrombosis is most frequently localized in the left ventricle and especially in ischemic heart disease , we should ensure an echocardiographic monitoring for these patients so that we can avoid the systemic embolization.

P504

Two dimensional speckle-tracking echocardiography in comparison to contrast enhanced cardiac magnetic resonance for analysis of myocardial fibrosis in patients with idiopathic dilated cardiomyopathy

L Lupi[1]; E Chiari[1]; A Ravera[1]; D Farina[1]; E Gavazzi[1]; R Maroldi[1]; M Metra[1]; S Nodari[1]
[1]*University of Brescia, Brescia, Italy*

Background: Myocardial deformation analysis by speckle-tracking echocardiography (STE) has been used for analysis of fibrosis, especially in patients with myocardial infarction with preserved left ventricular ejection fraction (LVEF). However there is no data on the use of this method for the identification of regional myocardial fibrosis in patients with idiopathic dilated cardiomyopathy (IDCM) with left ventricular systolic dysfunction.
Purpose: the aim of our study was to evaluate the association between myocardial fibrosis detected by late gadolinium enhancement (LGE) cardiac magnetic resonance (CMR) and 2-dimensional (2D) STE.
Methods: We enrolled retrospectively patients suffering from IDCM with LVEF ≤45% followed at our Heart Failure Department from January 2012 to February 2016 underwent CMR with paramagnetic contrast agent administration and STE echocardiography (time range < 90 days between the two tests). LGE CMR was performed to identify the presence of fibrosis in every myocardial segment; the amount of fibrosis was calculated by manual planimetry at each short axis section. Peak systolic longitudinal strains were determined for analysis of regional function (regional longitudinal - RL2D - strain for eachone of the 17 myocardial segments) and global function (global longitudinal - GL2D - strain).
Results: We enrolled 72 patients (76% male, mean age 56 ± 15 years). LGE (found in 60 patients) had midwall and subepicardial distribution in 82% and 8% of patients respectively. There was a positive correlation between the amount of myocardial fibrosis determined by LGE CMR and peak systolic longitudinal strain for the entire left ventricle (rho 0.523, p < 0.0001), basal segments (rho 0.606, p < 0.0001) and midventricular segments (rho 0.497, p < 0.0001), but not for apical segments. A cut-off value of RL2D strain of -7.5% by receiver-operating characteristic (ROC) curves identified LGE segments (sensitivity 91%, sensibility 81%) and a cut-off value of GL2D strain of -10,2% by ROC curves identified LGE presence in left ventricle (sensitivity 76%, specificity 72%).
Conclusions: There is an association between the amount of myocardial fibrosis detected by LGE CMR and myocardial deformation by 2D STE. RL2D and GL2D strain could be helpful for detecting and localizing myocardial fibrosis, especially in patients who cannot perform LGE CMR, and might have a role in prognostication.

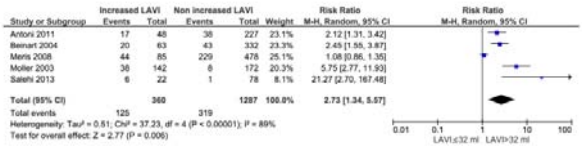
P505

Left atrial volume index as a predictor of outcome in patients with acute myocardial infarction: a systematic review and meta-analysis

I Ibadete Bytyci[1]; G Bajraktari[1]
[1]*University Clinical Centre of Kosova, Clinic of Cardiology, Pristina, Kosovo Republic of*

Introduction: Increased left atrial volume is a marker of diastolic dysfunction and longstanding elevated left ventricle (LV) pressure. The aim of this study was to assess the role of increased baseline left atrial volume in outcome of patients with acute myocardial infarction (AMI).
Methods: We systematically searched PubMed-Medline, EMBASE, Scopus, Google Scholar and the Cochrane Central Registry, up to December 2016 in order to select clinical trials and observational studies, which assessed the predictive role of left atrial volume indexed (LAVI) in outcome in patients with AMI.
We compared clinical outcomes of enlargement LAVI (>32ml/m2) vs. non-enlargement LAVI (≤32ml/m2). Primary end-points were cardiovascular (CV) events: major adverse cardiac events (MACE), and all-cause mortality.
Results: A total of 1647 patients from 5 observational studies with a mean follow-up 25 ± 12 months, were included in the meta-analysis. The increased LAVI correlated with increased risk for MACE (relative risk [RR]=2.73, 95% confidence interval [CI], 1.34 to 5.37, p = 0.006), and all-cause mortality (RR=3.21, 95%CI: 1.48 to 6.97, p = 0.003) in patients with AMI.

In conclusion: Increased LAVI is an independent predictor of outcome in patients with AMI. The assessment of this LA index in these patients in daily practice is important for better risk stratification.



Risk estimates of major adverse cardiac

P506

Correlation between electrocardiography and stress echocardiographic abnormalities and cardiovascular events

P Pedro Von Hafe Leite[1]; T Lopes[1]; F Castro[1]; M Oliveira[1]; B Faria[1]; P Azevedo[1]; M Lourenco[1]; J Portugues[1]; L Calvo[1]; O Azevedo[1]; A Lourenco[1]
[1]Alto Ave Hospital Center, Cardiology, Guimaraes, Portugal

Background: Pharmacological Stress Ecocardiography (SE) has prognostic value in patients with known or suspected coronary artery disease. SE positive for myocardial ischemia and the wall motion score index (WMSI) are associated with a worse outcome. However, the literature is ambiguous regarding the prognostic value of ECG changes during pharmacological SE.
Purpose: To correlate the severity of electrocardiographic and echocardiographic changes during pharmacological SE with the occurrence of cardiovascular (CV) events at follow up.
Methods: Unicentric, retrospective study with 789 patients who underwent pharmacological SE between 2010 and 2015. Demographic, clinical, electrocardiographic and echocardiographic data were collected. CV events were defined as death of cardiac cause, occurrence of AMI and need for revascularization. Statistical analysis to assess whether stress ECG changes and peak WMSI during SE relate to the occurrence of CV events at follow up.
Results: The sample of this study has a higher prevalence of male patients (65%) with a mean age of 64 ± 11 years. From the sample, 55% of the subjects had SE due to suspected ischemic coronary disease (ICD) and 43.9% had SE for the evaluation of already known ICD. SE was performed with dobutamine in 70.6% and dipyridamole in 29.4% of the cases, being positive in 13.6% of the cases. Of the patients studied 13.3% had CV events during the follow up.
ST segment changes during stress ECG were associated with SE positivity ($p < 0.001$) and occurrence of CV events ($p < 0.001$). The value of peak WMSI was statistically different between patients with and without ST elevation during SE (1.67 ± 0.30 vs. 1.2 ± 0.30, $p < 0.001$). There was also a correlation between the dimension of ST-segment elevation and the peak WMSI value ($P = 0.049$). These findings did not occur for patients with ST depression.
Value of peak WMSI was statistically different between patients with and without unsustained ventricular tachycardia during SE (1.55 ± 0.43 vs. 1.2 ± 0.40; $p = 0.002$).
There was a statistically significant difference in peak WMSI between patients with and without CV events (1.58 ± 0.40 vs. 1.27 ± 0.39, $p < 0.001$), a difference that was observed when univariate logistic regression was applied ($p < 0.001$).
Conclusion: Study demonstrated an association between the presence of ST-segment changes in stress ECG and the occurrence of CV events. There was also a statistically significant relationship between the size of ST elevation in SE and peak WMSI, which in turn was associated with the development of CV events.

C-type natriuretic peptide in human blood of adolescent with different degree of endothelial dysfunction: a different trend for plasma levels and mRNA expression.

M Cabiati[1]; V Bianchi[2]; C Caselli[1]; B Marchi[2]; S Marchetti[2]; E Randazzo[2]; G Federico[2]; S Del Ry[1]
[1]Institute of Clinical Physiology of CNR, Pisa, Italy; [2]University of Pisa, Unit of Pediatric Endocrinology and Diabetes, Pisa, Italy

Background: C-type natriuretic peptide (CNP) is a member of natriuretic peptides system and it performs its major functions in an autocrine or paracrine manner through specific binding to the membrane guanylyl cyclase natriuretic peptide receptor B (NPR-B). Recent studies indicated that CNP is an important natural regulator of adipogenesis, possibly involved in obesity pathophysiology, especially in pediatric age. Unfortunately, while CNP plasmatic levels are known in pediatric subjects, no data are available on CNP/NPR-B mRNA expression.
Purpose: Aim of the study was to evaluate both CNP plasma levels and expression of CNP/NPR-B mRNAs in normal-weight (N, n=21) and obese (O, n=15) adolescents (age:13.5 ± 0.4, years).
Methods: Subjects without cardiac dysfunction, referred as outpatients to the Unit of Pediatric Endocrinology and Diabetes, Department of Clinical and Experimental Medicine, Italy, were enrolled. CNP plasma levels were measured with a specific RIA in plasma samples, while expression of CNP and NPR-B mRNAs was assessed in human whole blood samples by Real-Time PCR. Endothelial function was assessed by measuring reactive hyperemia index (RHI)
Results: CNP plasma levels resulted significantly lower in O (6.1 ± 0.8 pg/mL) than in N (15.2 ± 1.3 pg/mL; $p < 0.0001$), while CNP and NPR-B mRNA expression resulted similar in N (4.1 ± 1.7; 5.0 ± 1.6, respectively) and O (4.3 ± 1.6; 3.5 ± 1.1 respectively). Plasma PCR values were significantly ($p < 0.0001$) higher in O (0.3 ± 0.01 mg/dL) than in N (0.01 ± 0.002 mg/dL), while RHI resulted significantly ($p < 0.0001$) lower in O (1.4 ± 0.08) than in N (2.1 ± 0.04) subjects. Surprisingly, dividing all subjects by RHI median (Group 1>1.9, n=18, Group 2 < 1.9, n=18) CNP plasma levels resulted significantly ($p = 0.017$) lower in Group 1 (14.3 ± 1.7) than in Group 2 (8.9 ± 1.2) showing a significant correlation between CNP and RHI (r=0.47, $p = 0.0026$), while CNP mRNA expression was significantly ($p = 0.05$) higher in Group 2 (6.3 ± 2.1) than in Group 1 (1.8 ± 0.4). NPR-B mRNA resulted similar in Group 1 (4.7 ± 1.8) and Group 2 (4.2 ± 1.0). Our data suggest a different trend in CNP plasma levels and in CNP mRNA expression, that were detected for the first time in human peripheral blood mononucleated cells. This discrepancy could reflect changes occurring at CNP transcriptional level in activated leucocytes, due to inflammation, and in blood levels, having CNP paracrine/autocrine activities.
Conclusion: The regulation of CNP/NPR-B transcription constitutes a fruitful area for investigating new therapies targeting CNP/NPR-B production, useful to treat diseases characterized by endothelial dysfunction, such as obesity.

Funding Acknowledgements: This study was granted by Roche Diagnostics

Introduction: Since the introduction of routine assay for Natriuretic Peptides (NP), their number of clinical applications has grown. Numerous studies have defined their analytical characteristics in patients presenting with acute or chronic dyspnea. Since the prevalence of chronic heart failure (CHF) increases with age averaging 7.5–10% in patients over the age of 75 years, measurements of NP should increase in a similar way. Plasma concentrations of (NT-pro)BNP are known to be more elevated in women and rise with advancing age in apparently healthy adults almost doubling each age decade. The same age-dependent pattern is also seen in patients with CHF. Our aim was to report the age-distribution of NP measurements and concentrations in a very large population.
Methods: We examined all biological tests performed in two districts from the west part of France, "the French Brittany", covering 13.653km2 and corresponding to a population of 1.723.653 persons. From February 2010 to august 2015, 22 laboratories (including 6 Hospital/clinic laboratories and16 non hospital/clinics laboratories) performed 3.606.432 analysis prescriptions in 3.606.432 adult patients>20y. All laboratories are equipped with Roche diagnostics platform and measure NT-proBNP as the NP.
Results: During the study period, 56.653 (1.6%) measurements of NT-proBNP were performed in 27.527 distinct patients, including 10.1% of measurements in dedicated emergency labs.
NT-proBNP was more often measured in men versus women up to 80 years ($p < 10\text{-}5$), was more frequent in women >80y with overall 28.345 measurements in women and 28.303 in men. NT-proBNP measurements gradually increased by 10y-age categories up 80-90y; 39.828 (70.3%) of measurements have been done in elderly patients ≥ 75y, 31523 (55.6%) in patients ≥ 80y and 7.605 (13.4%) in patients ≥ 90y.
In all 10y-age categories, the number of measurements gradually increased over time ($p < 10\text{-}5$ in all).

As expected, NT-proBNP concentrations increased with advanced age ($p < 10\text{-}5$), with respective mean ± SD and median (IQR) concentrations of 3564 ± 6440 ng/L and 1453 ng/L (468-3778) in patients ≥ 75y and 3642 ± 6730 ng/L and 1825 ng/L (543-4133) in patients ≥ 80y. Opposite to expectations, NT-proBNP concentrations were more elevated in men versus women ($p < 10\text{-}5$).

Conclusion: Among a very large cohort, we report a gradual increase of NP measurements with advances age, averaging 70% of total measurements in patients≥ 75years. NP concentrations also increased with advanced age but unlike expected were overall more elevated in men versus women. Our report suggests that references values should be clearly defined in elderly patients and possibly stratified by sex. Big data analysis may offer a unique opportunity to improve our knowledge in current practices.

P509

Potential prognostic and clinical role of early measurement of N-terminal pro brain natriuretic peptide (NT-proBNP) in patients of acute coronary syndrome

M Maka Gegenava[1]; T Gegenava[1]

[1]*Tbilisi State Medical Unversity, Tbilisi, Georgia Republic of*

Introduction: The clinical and prognostic role of cardiac natriuretic peptides (NTP) in patients with heart failure is well known; recently, several studies have evaluated the possibility of using N-terminal pro brain natriuretic peptide (NT-proBNP) to evaluate their potential prognostic role in patients with acute coronary syndromes (ACS). Aim of our study was to evaluate the sprognostic value of the early measurement of NT-proBNP in patients with acute coronary syndrome-ACS and compare it' significance with other parameters of systolic dysfunction, for example ejection fraction-EF

Methods: We enrolled n=50 patients admitted to our coronary care units with the diagnose of acute coronary syndrome- ACS. We used diagnostic methods, such as: Resting ECG, determination of cardiacTroponin I level (cTnI), measurements of NT-proBNP, we also measured CK-MB and performed echocardiography measurement of EF. NT-proBNP and echocardiography measurement we performed also during follow up: 1-3 months later after the hospital discharge. Results: According our results totally NT-proBNP was elevated in 36% (n = 18) of hispitalized patients who had not symptoms of heart failure and were hospitalized because of ACS (STEMI and NSTEMI). EF < 54% was seen just in n=8 patients who had elevated level of NT-proBNP. All these patients were investigated after 1-3 months from hospital discharge. In our study group we had not no one case of patient death. From the group with elevated level of NT-proBNP seven patients (38,8%) had recurrent ischemic events (2 subsequent MI, 5 recurrent angina), and 11 (61%) had ymptoms of heart failure (NYHA II-III). We couldn't find correlation between NT-proBNP and decreased EF during hospitalization, but correlation revealed between NT-proBNP elevated level and decreased EF(ejection fraction) $p < 0.005$ in STEMI group during follow up. Such kind of correlation wasn't found in NSTEMI group $p < 0.007$, but during follow up we revealed direct correlation between recurrent episode of ischemia, heart failure symptoms, elevetated NT-Pro BNP level and decreased EF.

Conclusions: Our results suggest that NT-proBNP levels, measured at admission can have much more predictive value for complications, especially for short-term development of heart failure symptoms in patients with ACS, than EF itself in both subgroups-STEMI and NSTEMI. Measurement of this marker at early stage of hospitalization is easy and simple way to predict short-term complications and avoid them

P510

Patterns and prognostic Role of N-terminal pro-B-type natriuretic peptide in heart failure with mid-range vs. preserved vs. reduced ejection fraction

G Savarese[1]; N Orsini[2]; C Hage[1]; U Dahlstrom[3]; GMC Rosano[4]; LH Lund[1]

[1]*Karolinska Institute, Division of Cardiology; Department of Medicine, Stockholm, Sweden*; [2]*Karolinska Institute, Department of Public Health Sciences, Stockholm, Sweden*; [3]*Linkoping University, Department of Cardiology and Department of Medical and Health Sciences, Linkoping, Sweden*; [4]*St George's University of London, Cardiovascular and Cell Sciences Research Institute, London, United Kingdom*

Funding Acknowledgements: The County Council of Stockholm, The Swedish Heart and Lung Foundation and The Swedish Research Council.

Background: Evidences about the role of N-terminal pro-B-type natriuretic peptide (NT-proBNP) in heart failure (HF) with mid-range ejection fraction (HFmrEF) are still limited. NT-proBNP levels are influenced by demographic and clinical characteristics that may differ in HFmrEF vs. HF with preserved (HFpEF) and reduced (HFrEF) EF.

Purpose: To determine the different determinants and compare the prognostic role and discriminatory power of NT-proBNP levels in HFmrEF vs. HFpEF vs. HFrEF.

Methods: 9,847 out-patients with HFpEF (EF>50%; n=1,811) or HFmrEF (EF 40-49%; n=2,122) or HFrEF (EF < 40%; n=5,914) enrolled in the Swedish Heart Failure Registry were studied. High vs. low NT-proBNP levels were defined according to the median value of peptides. Logistic and linear regression analyses were performed to identify the different predictors of high NT-proBNP levels in HFmrEF vs. HFpEF vs. HFrEF. Survival models were performed to compare high vs. low NT-proBNP levels for prognosis (overall mortality and the composite of mortality and HF hospitalization) across the HF subtypes. ROC curves were fitted to assess the different predictive power of NT-proBNP for each outcome in HFmrEF vs. HFpEF vs. HFrEF.

Results: Median NT-proBNP levels in HFmrEF (1540 pg/ml, IQR: 652-3317) were intermediate between HFpEF (1428 pg/ml, IQR: 623-3000) and HFrEF (2288 pg/ml, IQR: 1022-4835; $p < 0.001$). Among 30 variables analyzed (demographic, clinical, medication use), body mass index (BMI), hypertension, diabetes, dilated cardiomyopathy, atrial fibrillation/flutter (AF), use of angiotensin receptor blockers (ARBs), nitrates, oral anticoagulants and digoxin differently predicted high NT-proBNP levels in HFmrEF vs. HFpEF vs. HFrEF. In particular, in HFmrEF the impact of high BMI (>30 kg/m2) and AF on NT-proBNP was intermediate between that in HFpEF and HFrEF, whereas hypertension, diabetes and use of ARBs and oral anticoagulants were associated with higher NT-proBNP levels in HFmrEF. Digoxin use was associated with higher NT-proBNP in HFmrEF and HFpEF vs. HFrEF, whereas reduced estimated glomerular filtration rate was associated with higher NT-proBNP levels in HFrEF (Fig A). All-cause mortality risk in patients with high NT-proBNP levels vs. those with low values was similarly increased in HFpEF (HR: 2.2), HFmrEF (HR: 1.9) and HFrEF (HR: 1.8), but the risk of the composite outcome was significantly more increased in HFpEF (HR: 2.0) and HFmrEF (HR: 1.9) vs. HFrEF (HR: 1.5)(Fig B). ROC curves showed NT-proBNP having a higher predictive power in HFmrEF vs. HFpEF vs. HFrEF (Fig C). When only the subgroup of patients with AF was analyzed, NT-proBNP predictive power was equivalent across HF subtypes.

Conclusions: HFmrEF, HFpEF and HFrEF show different predictors of high NT-proBNP levels. High NT-proBNP, as compared with lower levels, was associated with higher risk of events in HFpEF and HFmrEF vs. HFrEF NT-proBNP levels had higher predictive power in HFmrEF vs. HFpEF and HFrEF.

Combined hs-cTnT and NT-proBNP plasma levels identify patients with high risk stable coronary artery disease and early LV dysfunction.

C Caselli[1]; C Prontera[2]; V Lorenzoni[3]; R Ragusa[3]; S Del Ry[1]; A Clerico[2]; M Emdin[4]; J Knuuti[5]; SR Underwood[6]; D Neglia[4]
[1]Institute of Clinical Physiology of CNR, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*; *[3]Scuola Superiore Sant'Anna, Pisa, Italy*; *[4]Gabriele Monasterio Foundation, Scuola Superiore Sant'Anna, Pisa, Italy, Pisa, Italy*; *[5]Turku University Hospital, Turku, Finland*; *[6]Imperial College London, London, United Kingdom*

On behalf of: EVINCI

Background: It has been demonstrated that plasma levels of high sensitive-cardiac Troponin T (hs-cTnT) and N terminal-pro brain natriuretic peptide (NT-proBNP) are related with long term prognosis in patients with coronary artery disease (CAD) and heart failure (HF). It is not known whether combined measurements of hs-cTnT and NT-proBNP plasma levels may identify higher risk individuals among patients with stable angina without HF.
Purpose: To correlate plasma levels of hs-cTnT and NT-proBNP with the severity of CAD, the presence of unrecognized myocardial dysfunction and prognosis in patients with stable angina and without HF.
Methods: Clinical, biohumoral and imaging data were collected in 390 patients (237 males, mean age 61 ± 9 years) with stable angina and without known CAD or HF enrolled in the Evaluation of INtegrated Cardiac Imaging (EVINCI) study. All patients underwent baseline echocardiography, circulating hs-cTnT and NT-proBNP measurements, coronary computed tomography angiography (CCTA) to assess the presence of obstructive CAD (>50% stenosis of a major coronary vessel) and stress imaging to detect high risk myocardial ischemia (>10% of LV myocardium). Adverse cardiovascular events (death, hospital admission for non fatal myocardial infarction, heart failure or late >90 days revascularization) were registered in a long term follow-up (average 4.5 yrs).
Results: LVEF was 60 ± 8% (mean ± SD). Circulating hs-cTnT was 7.9 ± 6.2 ng/L and NT-proBNP was 133 ± 217 ng/L. Patients with combined values of hs-cTnT and NT-proBNP above the median values (N=109) had higher prevalence of obstructive CAD at CCTA (44% vs. 23%, $p < 0.001$), of high risk stress induced ischemia (32% vs 14%, $p < 0.001$), of lower systolic function (LVEF<55%) (42% vs. 22%, $p < 0.001$), and of adverse cardiovascular events at follow-up (18% vs. 11%, $p < 0.05$). At multivariate logistic analysis, after correction for age, sex and cardiovascular risk factors, the two combined biomarkers were independent predictors of obstructive CAD (OR 1.72 [1.02-2.91], $p < 0.05$), high risk ischemia (OR: 2.91 [1.62-5.22], $p < 0.001$) and lower LVEF (Coefficient: 2.53 [1.51-4.24], P< 0.001).
Conclusions: Combined hs-cTnT and NT-proBNP levels identify stable angina patients with more severe CAD and early LV dysfunction predisposing to worse prognosis.

P512

Brain natriuretic peptide: a potential modifier of the pharmacodynamic response to antiplatelet agents in acute heart failure

L Malinova[1]; N Furman[1]; P Dolotovskaya[1]; N Puchinyan[1]; T Denisova[2]
[1]Saratov State Medical University, Research institute of cardiology, Saratov, Russian Federation; *[2]Saratov State Medical University, Saratov, Russian Federation*

Expression of natriuretic peptides (NP) receptors in vascular wall and blood cells (including platelets) suggests possibilities of NP involvement in hemostatic balance regulation.
The purpose of the study was to characterize on-treatment platelet aggregation dynamics and to assess influence of brain natriuretic peptide on platelet functions in acute heart failure.
Methods: 80 male patients (54 (47; 60) years old) admitted with STEMI were recruited into the study. According to clinical presentation and baseline level of BNP (cut off level – 100 pg/mL) patients were divided into acute heart failure (AHF) and control groups. Antiplatelet medication consisted of acetylsalicylic acid and ticagrelor in standard doses. Platelet functional testing was performed at admission and on the 7th day. Additionally platelet aggregation was assessed in practically healthy male volunteers (PHV, n = 7) and male patients with AHF (n = 11) with preincubation (37C, 1200 rpm) with BNP solution (37C, 1200 rpm, 1, 3, 5 min, 0 … 1000 pg/mL). Follow-up period was 30 days after admission.
Results: All recruited patients report no previous history of coronary heart disease, prior acute coronary event or heart failure. No one was on antiplatelet therapy before admission. On treatment ADP induced platelet aggregation at base line was significantly higher in patents with BNP level < 100 hg/mL: 2 (1; 8) Ohm vs 0 (0; 2) Ohm, p level 0.019, as well as aggregation slope 2.0 (2.0; 4.0) vs 0.5 (0.0; 1.0), p level 0.013. Patients with AHF showed no significant dynamics of ADP induced platelet aggregation, whereas in patients of control group all studied parameters of platelets aggregation (maximal amplitude, slope and Lag time) decreased (down to 0s) at 7th day of admission (p levels –0.041). Preincubation of blood samples with BNP solution (500 pg/mL and 1000 pg/mL) leaded to significant decrease of both maximal amplitude and slope of aggregation curve in both PHV ($p = 0.041$, 0.036) and patients with AHF ($p = 0.045$, 0.041). Dense granules secretion was not changing in patients with AHF and control group, as well as during preincubation with BNP of blood samples from PHV and AHF patients. Neither bleeding events, nor deaths were observed in recruited patients during 30 days of follow-up period. Early adverse cardiovascular events (stent thrombosis, reinfarction, life-threatening arrhythmias) were observed in 27 patients (33.7%), and these patients had significantly higher level of BNP at 7th day of admittance ($p = 0.040$).
Conclusion: Received data demonstrate potential modifying effect of BNP on pharmacodynamic response to dual antiplatelet therapy in acute heart failure. Dual antiplatelet therapy seems to be more effective in patients with BNP level < 100 pg/mL, whereas further investigation should be performed to assess risk of bleeding events in this group and to increase the statistical power of the study.

Cardiac CD68 and stabilin-1 positive macrophages in wound healing following myocardial infarction

A Aleksandra Gombozhapova[1]; Y Rogovskaya[1]; M Rebenkova[2]; J Kzhyshkowska[3]; V Ryabov[4]
[1]Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, Russian Federation; *[2]National Research Tomsk State University , Tomsk, Russian Federation*; *[3]University of Heidelberg, Heidelberg, Germany*; *[4]Siberian State Medical University, Tomsk, Russian Federation*

Introduction: Myocardial infarction (MI) and following heart failure remain the leading cause of mortality and morbidity around the world. The need for better prevention and treatment of heart failure resulted in exploration of new therapeutic strategies to repair the infarct heart. Myocardial regeneration has become one of the most ambitious goals in prevention of adverse cardiac remodeling. Macrophages are key innate immune cells that play a significant role in transition from inflammatory to regenerative phase during wound healing following MI. Scavenger receptor stabilin-1 is proposed as one of the biomarkers for ex vivo diagnostics of M2 macrophages.
Purpose: The purpose of the study is translation of the basic research findings on cardiac macrophage subsets into clinical knowledge in patients with MI.
Methods and Results. The study included 41 patients with fatal MI type 1. All patients were divided into 4 groups depending on the timeline of MI histopathology. Macrophages infiltration was assessed by immunohistochemistry. We used CD68 as a marker for the cells of the macrophage lineage and stabilin-1 as M2 macrophages biomarker. The numbers of CD68+ and stabilin-1+ macrophages in the infarct area increased and peaked in regenerative phase and was not decreased in the late stage. In the peri-infarct area the number of CD68+ macrophages increased in the inflammatory phase, peaked during reparative phase and was not decreased in the late phase. The quantity of stabilin-1+ cells increased in the regenerative phase and further remained unchanged. Numbers of CD68+ and stabilin-1+ macrophages depended on MI phase. The numbers of CD68+ cells correlated with time of MI: strong positive correlation was found in infarct area ($R=0.67$, $p = 0.001$) and moderate positive correlation was found in peri-infarct area ($R=0.55$, $p < 0.001$). Similar relationship was found for stabilin-1+ cells (infarct area: $R=0.6$, $p < 0.001$; peri-infarct area: $R=0.42$, $p = 0.007$). In according to regression analysis, we suggest models which displayed the correlation between macrophage infiltration and clinical scenario of MI. There was relationship between frequency of recurrent MI and following independent variables ($R=0.73$, $p = 0.00013$): day of MI (b=0.46); presence of extensive MI (b=-0.03), chronic kidney disease (b=0.22), postinfarction angina (b=0.42); and quantity of stabilin-1+ macrophages in infarct area (b=-0.36).
Conclusions: Our study translates animal data regarding macrophage subpopulations into human knowledge in clinical settings. There was observed biphasic cardiac macrophage response following MI reminded a murine model. We have noted the increase of stabilin-1+ macrophage infiltration in myocardium during the regenerative phase and strong positive correlation between the number of stabilin-1+ macrophages and timeline of MI. We have supposed the opportunity of usage stabilin-1 as a diagnostic and prognostic M2 macrophage biomarker in wound healing following MI.

Galectin-3 is related to cardiac and vascular function in patients with acute heart failure and preserved left ventricular ejection fraction

A Bechlioulis[1]; S Giannitsi[2]; M Bougiakli[2]; G Chasiotis[3]; K Kontodimou[3]; A Kotsia[1]; I Gkirdis[4]; E Bairaktari[3]; LK Michalis[1]; KK Naka[1]
[1]University of Ioannina, 2nd Department of Cardiology and Michaelidion Cardiac Center, Ioannina, Greece; *[2]University of Ioannina, Michaelidion Cardiac Center, Ioannina, Greece*; *[3]University Hospital of Ioannina, Laboratory of Biochemistry, Ioannina, Greece*; *[4]University of Ioannina, 2nd Department of Cardiology, Ioannina, Greece*

Background: Acute heart failure (AHF) syndromes are related to increased morbidity and mortality. Galectin-3 is released by macrophages in response to inflammation and has been considered to be a marker of myocardial fibrosis but also an independent predictor of cardiovascular and total mortality in heart failure patients. The aim of the study was to investigate the role of Galectin-3 in hospitalized patients with AHF and its association with clinical and biochemical parameters.
Methods: We enrolled 76 consecutive patients admitted in a tertiary cardiology department with a diagnosis of AHF (mean age 71 years, 82% males). All participants were evaluated after clinical stabilization 1-2 days prior to discharge. A complete evaluation of all patients was performed including echocardiogram, vascular function (arterial stiffness) and functional status (6 minute walking test – 6MWT). All patients were followed for 6 months and the occurrence of cardiovascular events (fatal, non-fatal or HF rehospitalization) was investigated.
Results: Galectin-3 levels were positively associated with age (r=0.272, p = 0.018), female gender (r=0.225, p = 0.052), NTproBNP levels (r=0.224, p = 0.053), and inversely with creatinine clearance levels (CrCL) (r=-0.244, p = 0.035) in the total population. In patients with left ventricular ejection fraction (LVEF)>40% (n = 30), increased Galectin-3 was associated with female gender, reduced CrCL, increased aortic pulse wave velocity, E/E′ ratio and systolic pulmonary artery pressures (p < 0.05 for all). In patients with LVEF >45% (n = 13), there was a strong association of Galectin-3 with LVEF (r=-0.575, p = 0.040) and NTproBNP (r=0.768, p = 0.002), while the presence of LVEF >45% was associated with higher Galectin-3 levels (r=0.262, p = 0.025). No relations between Galectin-3 levels and 6MWT or future events were observed . No significant association between Galectin-3 and other parameters was seen in patients with reduced LVEF (i.e. LVEF < 40-45%).
Conclusions: In patients hospitalized with an AHF syndrome, Galectin-3 was shown to differentially relate to clinical and biochemical parameters according to the HF phenotype. In patients with preserved LVEF, Galectin-3 was associated with natriuretic peptides levels, arterial stiffness and echocardiographic indices of heart congestion. No relation of Galectin-3 with cardiovascular events was observed at 6 month follow-up.

P515
Biological markers for the diagnosis of heart failure with preserved left ventricular ejection fraction

E Ekaterina Bazaeva[1]; SA Boytsov[1]; RP Myasnikov[1]
[1]National Research Center for Preventive Medicine, Clinical Cardiology and Molecular Genetics, Moscow, Russian Federation

Purpose: the possibility of using biological markers of myocardial stress and inflammation for the diagnosis of chronic heart failure (CHF) with preserved (over 50%) left ventricle (LV) ejection fraction (EF).
Methods: included 105 patients with stable CHF (65% men) aged 24-84 (mean 58 ± 14) years. Duration CHF ranged from 2 to 96 (mean 24 ± 18) months. The etiology of CHF was as follows: ischemic heart disease - 35 (33%) patients, arterial hypertension - 70 (67%). Distribution of patients with CHF by functional classes according to the NYHA classification was: I - 72%, II - 28%. All CHF patients received drug treatment: ACE inhibitors - 76%, beta-blockers - 72%, diuretics and aspirin - 100%, statins - 80%. The control group consisted of 35 healthy. All subjects identified NT-proBNP, ANP, adiponectin, galectin, pentraxins-3 and growth differentiation factor-15 (GDF-15) by enzyme immunoassay (ELISA) using procedures recommended by the manufacturers of the reagents. Also, all we surveyed performed echocardiography. Results are expressed as median (interquartile range).
Results: The content in NT-proBNP, ANP, galectin, Pentraxin-3 and GDF-15 in patients with CHF was significantly higher than in the control group (p < 0.001 in all cases). In contrast, the level of adiponectin was significantly higher than in healthy individuals - 11.90 (11.39; 12.65) vs 7.73 (3.58; 8.86) ng/ml in patients with chronic heart failure (p < 0.001). The value of LVEF in CHF patients ranged from 30% to 55% and amounted to 45 (38; 51)%. In 35 (33%) of patients with CHF LVEF greater than 50%. Correlation analysis Spearman found significant strong correlation (p < 0.001 for all markers) between the value of LVEF and the content of all biomarkers, in this case between LVEF and the level of adiponectin found a direct correlation (r = 0,862), and between LVEF and the other biomarkers - reverse (from -0.858 to -0.901). Multivariate linear regression analysis found the strongest correlation with the value of LVEF at pentraxins-3 and adiponectin. ROC-analysis confirmed the diagnostic value of adiponectin in patients with CHF with preserved LVEF. Adiponectin values greater than 8.3 ng/ml predicted the presence of CHF in patients with LVEF> 50% with a sensitivity of 94.3% and a specificity of 92.9% (area under the curve 0.977; 95% confidence interval of 0,954-0,999, p < 0.001).
Conclusions: 6 among the studied biological markers of myocardial stress and inflammation only adiponectin has diagnostic significance in patients with CHF with preserved LVEF.

P516
The role of st2 in patients with st segment elevation myocardial infarction

IR Vishnevskaya[1]; OV Petyunina[1]; MP Kopytsya[1]; YV Hilova[1]; LL Peteneva[1]
[1]Government institution'L.T. Malaya Therapy National institute of the National academy of medical sci, Kharkiv, Ukraine

The biomarker ST2 is a member of interleukin family, which is expressed by cardiomyocytes in two forms – membrane — bound (ST2L) and soluble isoform (sST2). sST2 is a "decoy-receptor" for interleukin 33, its level tells us about the left ventricular (LV) remodeling grade and the heart failure's stage.
Purpose: to investigate the role of sST2 in patients with ST segment elevation myocardial infarction (STEMI).
Methods: 65 patients with STEMI were enrolled to the study. Among them are 83,1% male and 16,9% female. Mean age was 57 ± 2,3 years. All patients underwent a baseline investigation which includes: standard electrocardiography, echocardiography, angiography with stenting of the infarct-related artery. In addition, the level of sST2 was determined during the first day of the disease via ELISA test.
Results: Correlation analysis of the studied parameters showed significant negative correlation between the level of sST2 and the ejection fraction of LV (r=-0,5; p = 0,0001), also the rank of correlation coefficient was identified between sST2 and the end diastolic diameter of LV (r=0,31; p = 0,03), and the end systolic diameter of LV (r=0,4; p = 0,007) which is consistent with the role of sST2 in the progression of ventricular remodeling. The level of sST2 was significantly higher in females compared to males, 98,41 ± 36,64 ng/ml and 73,54 ± 29,35 ng/ml, respectively. After comparing the levels of sST2 accordingly to presence or absence of a stable angina before index hospitalization, the patients with a history of stable angina had a significantly lower level of sST2 (p = 0,01). Patients with anterior STEMI had higher concentration of sST2 (88,84 ± 33,66 ng/ml) than those with inferior STEMI - 69,38 ± 23,81 ng/ml, p = 0,003. For patients with two-vessel coronary artery disease (CAD) sST2 level was 118,26 ± 57,67 ng/ml, for those with three-vessel CAD - 61,79 ± 31,98 ng/ml (p = 0,002).
Conclusions: Females are more vulnerable for an early postinfarction remodeling. Higher level of sST2 in patients with anterior STEMI is related to increased infarct zone. Low level of sST2 verifies the patients with a good developing coronary collateral circulation with a history of stable angina. The number of injured coronary artery influences on the heart remodeling – two-vessel injury associated with more expressed remodeling compared with multi-vessel in patients with STEMI.

P517
Biomarkers in long-term prognosis of chronic heart failure formation in patients with acute coronary syndrome

IR Vyshnevska[1]; MP Kopytsya[1]; OV Petyunina[1]; NV Titarenko[1]; YV Hilova[1]
[1]Government institution'L.T. Malaya Therapy National institute of the National academy of medical sci, Kharkiv, Ukraine

The progression of chronic heart failure (CHF) after acute coronary syndrome (ACS) significantly worsens the prognosis for this group of patients. Risk stratification of high risk patient of heart failure formation is very important. In order to diagnose this condition in time the search for biomarkers is going. One of them is the Growth differentiation factor 15 (GDF 15).
Purpose: to estimate the role of GDF 15 in the formation of CHF during the first year after ACS.
Methods: 73 patients were screened with different forms of ACS (55 male and 18 female), mean age was 61, 8 ± 1, 3 years. Among them, 54% patients with Q-wave myocardial infarction, 20% - with non-Q-wave myocardial infarction, 26% - unstable angina. All patients underwent a baseline investigation. In addition, the levels of GDF 15, N terminal-pro B-type natriuretic peptide (NT-pro BNP) were determined during the first day of hospitalization. The follow-up period was 1 year. The 6-minute walk test (6MWT) was performed for all patients after 1 year for exercise tolerance estimation. All patients were divided into four groups accordingly to the New York Heart Association (NYHA) guidelines (stages I-IV).
Results: the effect of various variables of clinical, instrumental and laboratory status were assessed on CHF progression. For identification of the main risk factors for adverse outcome, we have used logistic regression (LR) method: NT-pro BNP (area under curve (AUC) 0.54; p < 0.8; 95% confidence interval (CI): 0.31 – 0.72), level of serum creatinine (AUC 0.76; p < 0.0002; 95% CI: 0.62 – 0.90), GDF 15 (AUC 0.87; p < 0.0001; 95% CI: 0.79 – 0.96). NT- pro BNP had no predictive significance. During the statistical analysis the predictive value for estimated parameters was calculated: GDF 15 > 2508 pg/ml (specificity (Spe) 95%, sensitivity (Se) 68%), serum creatinine >118 μmol/l (Spe 86,6 %, Se 56 %). We have developed a LR model (p < 0.0001, X2=14,75) with 88% of Se and 98% of Spe that can predict HF formation in patients during the first year after ACS.

Conclusion: the model can be used for risk stratification in development of CHF in patients after ACS in 1 year prognosis.

P518

PlGF: a putative biomarker in heart failure?

AM Matos[1]; AG Gil[1]; APS Da Silva[1]; T Sequeira[1]; IP Pinheiro[2]; MB Bicho[1]; L F Luiz Filipe De Menezes Falcao[2]; LMF Menezes Falcao[2]
[1]Faculty of Medicine, University of Lisbon, Laboratory of Genetics and Institute of Environmental Health, Lisbon, Portugal; [2]University of Lisbon, Faculty of Medicine, Lisbon, Portugal

Background/Introduction: Placental growth factor (PlGF) was recently associated to heart failure, contributing to atherosclerosis and vascular remodeling. This putative biomarker might modulate clinical parameters, such as haemolytic parameters involved in HF subjects.
Purpose: To determine PlGF levels in patients with HF, as well as its relation with disease severity, cardiac biomarkers and genetic variability.
Methods: In patients with HF and preserved or decreased EF (EF < 40%) were evaluated some possible cardiac biomarkers, PlGF (pg/mL), NT-proBNP (pg/mL), Galectin-3 (ng/mL) and EPO (mIU/ml) determined by ELISA. The genetic polymorphisms of ACE1 and NOS3 were determined by PCR. The sample consisted in 94 patients with HF, aged 78.95 ± 11.9, 52 women (55.3%) and 42 men (44.7%). Statistical methods were the Mann-Whitney test and Spearman´s correlations. Statistical significance were considered for $P < 0.05$.
Results: In HF subjects, PlGF medians were 6.09 (0.2-34.3) and EPO medians were 9.45 (1.1-94.1). In our population PlGF were not associated with severity (EF < 40%), but EPO levels were (P=0.001). Despite the circulating levels of PlGF and EPO were not correlated between them; we found that PlGF levels and Galectin-3 were inversely correlated with hemoglobin (r=-0.287, P=0.041) and EPO levels directly correlated with neutrophils (%) (r=0.300, P=0.022). Relatively to genetic variability, we found that HF subjects with allele A of NOS3 polymorphism (AA + AB genotypes) presented a trend for higher levels of PlGF in relation to subjects with BB genotypes (median: 7.39, IQR: 5.47 vs. median: 5.92, IQR: 6.44; P=0.085).
Conclusions: Although we didn't confirm the role of PlGF in HF, we hypothesized it may be related to inhibition by fms-like tyrosine kinase 1 (Flt-1). Furthermore, the association of higher levels of PlGF to allele A of NOS3 polymorphism (lower activity of endothelial nitric oxide) may reflect a hypoxia status in HF subjects and an increased inflammatory process.

P519

Panel of serum markers of fibrosis does not contribute to prognosis in dilated cardiomyopathy

P Pawel Rubis[1]; S Wisniowska-Smialek[1]; E Dziewiecka[1]; L Khachatryan[1]; P Matusik[1]; A Karabinowska[1]; A Kozanecki[1]; E Wypasek[1]; P Podolec[1]
[1]Department of Cardiac and Vascular Disease, John Paul II Hospital, Institute of Cardiology, Krakow, Poland

Funding Acknowledgements: Grant from the Poland National Centre of Science (no. 2013/09/D/NZ5/00252)

Background: Serum markers of fibrosis are easily accessible parameters that non-invasively provide insight into the dynamics of fibrosis process in heart failure (HF) and dilated cardiomyopathy (DCM). However, their role as predictors of cardiovascular (CV) events in DCM is less clearly defined.
Methods: Since July 2014 till October 2015 we included 70 DCM patients (pts) (48 ± 12.1 years, EF 24.4 ± 7.4). All pts underwent right ventricular endomyocardial biopsy to study the presence and degree of fibrosis. Markers of collagen type I and III synthesis – procollagen type I and III carboxy- and amino-terminal peptides (PICP, PIIICP, PINP, and PIIINP), fibrosis controlling factors – tumor growth factor (TGF1-β) and connective tissue growth factor (CTGF) were measured in serum. Primary outcome of the study was combined with CV death and urgent HF hospitalization. Results: During 12 month of observation, 6 CV deaths and 19 HF hospitalization occurred. Based on logistic regression models, we verified whether serum markers of fibrosis are associated with the primary outcome. Two predictive models were analyzed: unadjusted model and model with the adjustments to the age, disease duration, ejection fraction, collagen volume fraction, and NT-proBNP. None of the analyzed parameters predicted the occurrence of the primary outcome, either in an unadjusted or adjusted model. Conclusions: Serum markers of fibrosis were found not to be useful in predicting cardiovascular events in DCM during 12 months of observation.

P520

Soluble st2 and galectin 3 as potential biomarkers for cardiac fibrosis in peripartum cardiomyopathy

F Feriel Azibani[1]; V Dowling[1]; J Baard[1]; O Briton[1]; T Adam[1]; S Kraus[1]; J Anthony[2]; K Sliwa[1]
[1]University of Cape Town, Medicine, Cape Town, South Africa; [2]University of Cape Town, Obstetrics & Gynaecology , Cape Town, South Africa

Background and objective: Peripartum cardiomyopathy (PPCM) is characterized by new onset of heart failure in late pregnancy and up to the first five months postpartum. The implication of cardiac fibrosis remains controversial in PPCM patients despite clear evidences from animal models. Galectin 3 is a β-galactoside-binding lectin protein that is required for transforming growth factor (TGF)-β pathway-mediated myofibroblast activation leading to cardiac fibrosis. Soluble ST2 (sST2), a truncated soluble receptor of the IL-1 receptor superfamily is highly induced and positively correlated with markers of fibrosis. MicroRNA-21 is implicated in the control of myocardial fibrosis. Galectin-3, sST2 and microRNA-21 were described as prognostic biomarkers in heart failure patients. We aimed to determine the expression levels of these factors and whether they are associated with poor outcome in PPCM patients.
Methods: and results: We recently performed a subgroup biomarker study on 40 consecutive patients with PPCM and 10 age-matched healthy subjects. All patients received ACE inhibitors and beta-adrenergic blocking agents. Plasma NT-proBNP, Galectin 3, microRNA-21 and serum sST2 levels were measured at baseline. Echocardiograms were performed at baseline and six months postpartum. Poor outcome in PPCM patients was defined by NYHA ≥3 or death at 6 month.
At baseline, PPCM patients had significantly higher NT-proBNP, sST2, Galectin 3 and microRNA-21 levels than healthy controls ($p = 0.0005$, $p = 0.0038$, $p = 0.0064$ and $p = 0.01$, respectively). Six months postpartum, three patients did not improve their cardiac function (EF, 26.7 ± 7.4%) and eight died. Baseline NT-proBNP (3973.1 ± 955 vs. 1835.2 ± 268 pmol/l, $p = 0.02$), sST2 (67.01 ± 14.2 vs. 28.5 ± 4.3 ng/ml, $p = 0.011$) and Galectin 3 (15.37 ± 2.8 vs. 8.55 ± 0.66 ng/ml, $p = 0.01$) levels were significantly higher in patients with poor outcome compared to patients that improved their cardiac function (EF, 45.7 ± 11.3%). sST2 and Galectin 3 expression levels were not correlated with baseline ejection fraction. Circulating microRNA-21 levels were not different between recovered and poor outcome patients.
Conclusion: These preliminary results are very promising as for the first time we demonstrated that sST2, Galectin 3 and microRNA-21 are upregulated in PPCM. Galectin 3 and sST2 may be clinically useful biomarkers that identify a subset of PPCM patients at highest risk of myocardial dysfunction due to fibrosis. These findings should be confirmed in a larger cohort.

P521

HYCHeF: A risk score to predict Congestive Heart Failure Incidence in HYpertension. Based on 18795 individual patient data.

H-H Hai-Ha Le[1]; H Ottomani[1]; G Sitruck[1]; F Subtil[1]; F Gueyffier[1]
[1]University Claude Bernard of Lyon, Evaluation and Modeling of Therapeutic Effects, UMR5558, Lyon, France

Funding Acknowledgements: HHL is currently receiving the scholarship of the French Ministry of Higher Education & Research

Objectives: Patients with hypertension present risk of heart failure development. We aimed to build here a risk score to predict congestive heart failure (CHF) incidence in these patients using data from well-done randomized controlled trials (RCTs) of anti-hypertensive agents.
Method: Data of 18795 hypertensive patients was collected from four trials of INDANA database (Coope, SHEP, STOP and SYST-EUR. The whole population was randomly divided in two subsets: derivation set for model construction and the remaining for model validation with the ratio 2:1 and with similar patient characteristics. We used the Cox proportional hazards model to test the association of each covariable to CHF incidence separately (univariable analysis) and altogether (multivariable analysis) until obtaining the final model where all covariables were significant.
Results: Thirty baseline factors were examined for risk of CHF incidence using a multivariable Cox model, adjusted on trials. Treatment was associated with a significant reduction of 50% of CHF incidence and had no interaction observed with trial or any other covariable. A risk score of CHF incidence in five years was built with 10 significant risk factors: treatment (HR 0.50, CI 95%, 0.36 - 0.69), age (HR 1.52, 1.3 - 1.78 by 5-year increase), serum total cholesterol (HR 0.83, 0.73 - 0.96), cigarette smoking (HR 1.74, 1.10 - 2.75), renal function (HR 0.93, 0.87 - 1.00 by 5 mL/min/1.73 m2 increase of glomerular filtration rate), body mass index (HR 1.05, 1.01 - 1.09 by 1 kg/m2 increase), history of myocardial infarction (HR 3.07,

1.76 - 5.34), history of stroke (HR 3.03, 1.47 - 6.25), diabetes baseline (HR 1.63, 1.01 - 2.63) and ratio of systolic/diastolic blood pressure (HR 1.36, 1.17 - 1.58). This model was then transformed to an integer system, with points added for each factor according to its association with CHF incidence risk.

Conclusion: Our work provides a simple risk scoring system for CHF incidence prediction in hypertension, using individual data from well-established RCTs of antihypertensive treatments. We confirmed the same classical risk factors of CHF development found by other studies on other populations of cardiovascular risk.

Table 1. Final model to predict congestive heart failure incidence in hypertension

Covariables	Hazard Ratio (95% CI)	p-value
Antihypertensive treatment	0.50 (0.36 - 0.69)	<0.0001
Age (by 5 year increase)	1.52 (1.30 - 1.78)	<0.00001
Glomerular filtration rate (by 5 mL/min/1.73 m2 increase)	0.93 (0.87 - 1.00)	0.04
Smoker	1.74 (1.10 - 2.75)	0.018
Body mass index (by 1 kg/m2 increase)	1.05 (1.01 - 1.09)	0.014
Serum total cholesterol (mmol/l increase)	0.83 (0.73 - 0.96)	0.011
History of myocardial infarction	3.07 (1.76 - 5.34)	<0.0001
History of stroke	3.03 (1.47 - 6.25)	0.003
Diabetes baseline	1.63 (1.01 - 2.63)	0.044
Ratio of systolic/diastolic blood pressure	1.36 (1.17 - 1.58)	<0.0001

Multivariable analysis adjusted on trials and performed on the training set.

Exploring risk markers for incident heart failure using a targeted proteomics chip

J Molvin[1]; M Pareek[2]; O Melander[3]; L Rastam[3]; U Lindblad[4]; B Daka[4]; M Leosdottir[1]; PM Nilsson[3]; MH Hecht Olsen[2]; M Magnusson[1]
[1]Lund University, Department of Cardiology, Skåne University Hospital , Malmoe, Sweden; *[2]Odense University Hospital, Department of Endocrinology, Centre for Individualized Medicine in Arterial Diseases (CIMA), Odense, Denmark*; *[3]Department of Clinical Sciences, Lund University, Skåne University Hospital, Malmö, Sweden*; *[4]University of Gothenburg, Institute of Medicine, Department of Public Health and Community Medicine, Sahlgrenska Academy, Gothenburg, Sweden*

Background: The evolving use of multiplex proteomic platforms provides excellent tools for investigating associations between multiple proteins and risk of incident cardiovascular disease (CVD). In this study, we evaluated the impact of 92 proteins, included in a multiplex panel, on incident heart failure (HF).

Methods: All 92 proteins from the OLINK CVD III panel were analyzed in 1,734 participants from a subsample of the population-based Malmö Preventive Project. Only one protein was below detectable limits in >15% samples, i.e., N-terminal pro-brain natriuretic peptide (Nt-proBNP). Therefore, Nt-proBNP was analyzed separately using a competitive enzyme immunosorbent assay. Exclusion of subjects with prevalent HF and missing covariates at baseline examination rendered a final study population of 1,705 subjects. Standardized hazard ratios (HR) for logarithmic values of protein concentrations were reported. A two-sided Bonferroni corrected P-value of 0.05/92=5.4x10-4 was considered statistically significant.

Results: Mean age was 67 years, 29% were women, and 28% had prevalent diabetes. During a mean follow-up time of 8.9 ± 1.5 years, 91 incident HF cases were detected. In age- and sex-adjusted analyses, four proteins were associated with incident HF: Nt-proBNP (hazard ratio (HR): 2.55, 95% CI, 2.07-3.15; P=3.4x10-18), Galectin-4 (GAL-4) (HR 1.60, 1.26-2.01; P=8.4x10-5), Azurocidin (AZU-1) (HR 1.43, 1.17-1.74; P=4.0x10-4) and Growth-differentiation factor 15 (GDF-15) (HR 1.58, 1.27-1.97; 3.8x10-5). When adjusting for traditional risk factors (age, sex, height, systolic blood pressure, anti-hypertensive medication use, diabetes mellitus, prevalent atrial fibrillation and previous myocardial infarction), only Nt-proBNP (HR 2.1, 1.53-2.85; P=4.0x10-6) and GDF-15 (HR 1.37, 1.01-1.84; P=0.042) remained significantly associated with incident HF.

Conclusion: In a community sample of 1,705 elderly individuals without HF, we used an immunoassay designed to analyze 92 proteins with proposed involvement in immunity/inflammation, CVD, and metabolism to explore potential biomarkers for incident HF, and found Nt-proBNP and GDF-15 to be independently associated with future HF development.

Kaplan-Meier curves for cumulative all-heart failure incidence from re-examination (2002-2006) to the end of follow up (31st dec 2014) among 1,705 participants in MPP stratified according to quartiles of log Nt-proBNP.

Morphological alterations of the cardiomyocyte nuclear envelope may preclude the potential for reverse remodelling in patients with non-ischemic cardiomyopathy.

T Katsimichas[1]; T Ohtani[1]; Y Asano[1]; M Kanzaki[1]; Y Tsukamoto[1]; H Kioka[1]; O Yamaguchi[1]; Y Sakata[1]
[1]Osaka University Graduate School of Medicine, Department of Cardiovascular Medicine, Osaka, Japan

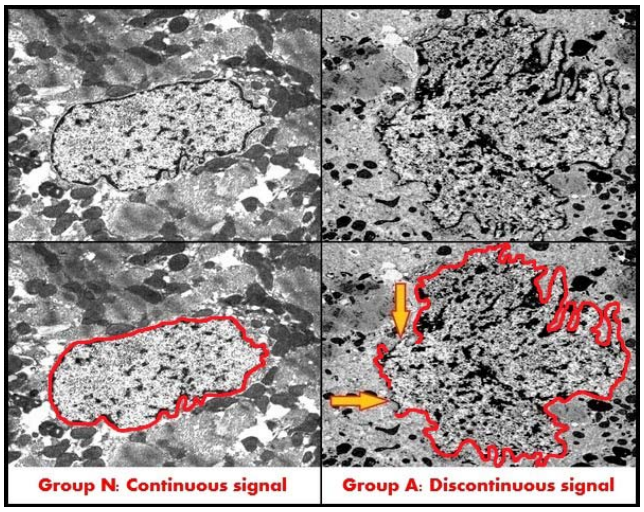
Background: We have previously shown that certain morphological alterations of cardiomyocyte nuclei observed by electron microscopy are associated with worse outcomes in non-ischemic cardiomyopathy (NICM) patients. However, it is unknown whether such characteristics may also preclude a better prognosis, as represented by the process of reverse remodelling (RR). Since no definitive prognostic markers of RR currently exist, research in this field may yield important insights that will improve treatment planning.

Purpose: The purpose of this work was to investigate whether certain alterations of the cardiomyocyte nuclear envelope may preclude reverse remodelling in patients with NICM.

Methods: We conducted a retrospective study of 132 NICM patients with severe heart failure [ejection fraction (EF) < 30%], who were admitted for treatment in our hospital between 2009 and 2015. RR was defined as an increase of EF>10 percentage points, leading to a post-EF>35% after one year, without any occurrence of cardiac events – namely death or left ventricular assist device implantation. Electron microscopy images of all the cardiomyocyte nuclei of samples taken during diagnostic myocardial biopsies were evaluated by a customized computer software. This software measures a signal that corresponds to the thickness and intactness of the nuclear envelope; alterations of the signal, represented by gaps in signal continuity, indicate thinning or breaching of the nuclear envelope. Based on the evaluation, patients were categorized into either Group A (thin or breached nuclear envelope) or Group N (normal nuclear envelope) (Figure).

Results: No group A patients (n = 13) underwent RR (0%), while 45 of 119 group N patients (38%) did (p < 0.01). This difference was significant even after adjustment for age, brain natriuretic peptide, EF, or left ventricular end-diastolic diameter. The EF at baseline was not significantly different between the two groups (20.6 ± 7.7% vs. 20.8 ± 5.3%), and neither was β-blocker dosage.

Conclusion: Our results show that morphological alterations of the cardiomyocyte nuclear envelope in NICM patients might predict the lack of potential for RR. If confirmed in future prospective studies, they may help establish an important prognostic process, accelerating decisions for drastic intervention in patients with NICM.



Group N and Group A nuclei

Plasma glycoproteomics reveals gender-specific activation of distinct pathways linked to heart failure development following myocardial infarction

Y Deleon-Pennell[1]; OK Ero[1]; ER Flynn[1]; I Espinoza[1]; SK Musani[1]; RS Vasan[2]; ME Hall[1]; ER Fox[1]; ML Lindsey[1]
[1]The University of Mississippi Medical Center, Jackson, United States of America; *[2]Boston University, School of Medicine, Boston, United States of America*

Funding Acknowledgements: NIH HHSN268201300046C and HHSN268201-300047C; T32HL105324 (OKE); HL075360, HL129823, and GM114833 (MLL), HL051971 and GM104357; VA 5I01BX000505 (MLL)

Background and Introduction: Identifying early plasma protein biomarkers that predict the development of heart failure (HF) following myocardial infarction (MI) will help to stratify at risk subjects and provide insight into more effective therapeutic strategies.
Purpose: The goal of this study was to catalogue early post-MI plasma proteins that linked to the development of HF by targeting extracellular proteins using a glycoproteomic approach.
Methods: Plasma samples collected at visit 2 from 60 African American participants in the Jackson Heart Study were analyzed. All participants were diagnosed with MI (but without prevalent HF) prior to collection. The participants were divided into subjects who later presented with adjudicated incident HF after visit 2 (MI + HF; n=15; 3 men/ 12 women) and those who had remained stable through 2012 (MI; n=45; 24 men/ 21 women). N-linked plasma glycopeptides were quantified by solid-phase extraction coupled to mass spectrometry and identified using RefSeq and SwissProt. Proteins were mapped for biological processes and functional pathways using Ingenuity Pathway Analysis (IPA).
Results: A total of 379 glycopeptides corresponding to 88 proteins were identified. Of these, 18 glycopeptides were significantly different between the MI only and MI + HF groups and corresponded to 6 proteins: apolipoprotein F, transthyretin, apolipoprotein C-IV, prostaglandin-D2 synthase, complement C9, and CD59 (p0.05 for all). With the exception of CD59, all other proteins were significantly elevated in MI + HF group. IPA analysis identified 4 canonical pathways enriched in the MI + HF group. Activation of the acute phase response, liver X receptor/retinoid X receptor (LXR/RXR) pathway, and macrophage reactive oxygen species generation were significantly upregulated in the MI + HF group (p0.05 for all). The coagulation pathway was significantly downregulated in the MI + HF group (p0.05). Interestingly, the percentage of women who developed HF after MI was higher (80%) compared to men (47%; p0.05). In the MI group, partial least squares discriminant analysis showed overlapping protein distributions, indicating a lack of gender effect. When comparing patients who developed heart failure post-MI, there was a distinct separation between men and women. By IPA analysis, men who developed HF had upregulation of acute phase response and LXR/RXR pathways, whereas women who developed HF had downregulation of the coagulation pathway. This suggests there are gender-specific pathways responsible for post-MI outcomes.
Conclusion: Our investigation identifies early plasma glycoprotein changes that link to later MI patient outcomes and provides insight into unexplored mechanisms that may explain sex differences in the pathogenesis of post-MI development of HF. Additional studies are warranted to replicate these hypothesis-generating findings in larger samples.

P525

Association of brain natriuretic peptide and adrenomedullin plasma levels with left ventricular filling pressures in end-stage renal disease patients

E Tzatzaki[1]; V Kamperidis[2]; D Konstantinou[2]; G Giannakoulas[2]; P Sarafidis[2]; H Karvounis[2]
[1]Onassis Cardiac Surgery Center, Athens, Greece; *[2]First Cardiology Department, AHEPA Hospital, Aristotle University , thessaloniki, Greece*

Funding Acknowledgements: Hellenic Cardiological Society

Backgrounds: Adrenomedullin (ADM) and brain natriuretic peptide (BNP) are known to be associated with elevated left ventricular filling pressures. However, little is known about this association in end-stage renal disease (ESRD) patients with preserved left ventricular ejection fraction.
Purpose: The association between E/e′ ratio and plasma levels of BNP and ADM in ESRD patients with preserved left ventricular ejection fraction undergoing chronic hemodialysis.
Methods: The study group enrolled 62 ESRD patients treated with hemodialysis three times weekly. BNP and ADM plasma concentration measurements and echocardiographic investigation were performed 30 minutes after hemodialysis. E/eratio, evaluated by tissue Doppler imaging, measured at the basal septum was used as a surrogate marker for assessing left ventricular filling pressures.
Results: The mean age of patients was 62 ± 25 years, 57% male. The mean BNP and ADM values after hemodialysis were 0.40 ± 6.73pg/ml and 0.06 ± 2.12pg/ml, respectively. Patients of older age, being on hemodialysis for a longer period, with hypertrophied left ventricles and larger left atria displayed higher E/e values. BNP (r=0.324. p = 0.018) and ADM (r=0.319, p = 0.042) plasma levels were positively and significantly associated with E/e. Multivariate regression analysis including BNP, ADM, age, hemodialysis duration, left ventricular end-systolic volume index, ejection fraction, left ventricular mass index and left atrium volume index, revealed that ADM (p value 0,025) but not BNP levels, were independently associated with E/e′ ratio.
Conclusions: ADM, but not BNP, was independently associated with septal E/e in ESRD patients with preserved left ventricular ejection fraction. ADM plasma levels may be helpful to evaluate left ventricular filling pressures in ESRD patients.

Correlation of ceruloplasmin, an acute phase protein, with NT-proBNP and liver function tests in stable HFrEF

F Filip Malek[1]; T Andreasova[2]; D Vondrakova[2]; L Sedlackova[3]; J Dvorak[4]; L Taborsky[3]; P Neuzil[2]
[1]Charles University Prague, 3rd Faculty of Medicine, 1st Clinical Dept of Internal Medicine, Prague, Czech Republic; *[2]Na Homolce Hospital, Department of Cardiology, Prague, Czech Republic*; *[3]Na Homolce Hospital, Clinical biochemistry, hematologa and immunology, Prague, Czech Republic*; *[4]National Institute of Public Health, Prague, Czech Republic*

Funding Acknowledgements: Supported by Ministry of Health, Czech Republic – conceptual development of research organization (Nemocnice Na Homolce – NNH,00023884), IG160502

Background: ceruloplasmin (Cp) is an acute phase protein produced by liver cells, production is stimulated by circulating cytokines. Liver function test are usualy impaired in CHF patients, mainly increased bilirubin and decreased albumin identify depressed metabolic and synthetic liver function.
Study objective: to assess association of Cp with liver function tests and prognostic parameters in patients with stable HFrEF
Patients and methods: serum Cp, NT-proBNP and liver function tests including total bilirubin, ALT, AST, GMT, ALP and albumin were analyzed in 164 consecutive stable HFrEF patients, mean LV EF was 32 %.
Results: mean Cp level was 0.23 g/l and NT-proBNP 218 pmol/l (1850 pg/ml). Cp correlated significantly with NT-proBNP (r = 0.323, p < 0.001), total bilirubin (r = 0.213, p = 0.0067) and with albumin (inverse correlation r = - 0.273, p = 0.0005), correlation with other liver function tests was not significant. Cp level correlated with NYHA (r = 0.230, p = 0.0034) and LV EF (inverse correlation – 0.237, p = 0.0025) too.
Conclusion: Cp in stable HFrEF correlates with NT-proBNP, total bilirubin and albumin (inverse correlation). Cp might be new potential biomarker reflecting severity of heart failure and hepatic impairment.

P527

Role of uric acid in progression of heart remodeling in patients after myocardial infarction: liaison between metabolic profile and subclinical inflammation

S Sofiya Lypovetska[1]
[1]*Ternopil State Medical University, Ternopil, Ukraine*

Aim: to investigate the potential impact of SUA levels on metabolic profile, subclinical inflammation and heart remodeling in patients after myocardial infarction.
Methods: 147 patients (59,2 ± 0,8 years old) in 6 months after myocardial infarction were included in cross-sectional study. The subjects were divided in two groups with high (0,59 ± 0,06 mmol/l, n=82) and normal (0,32 ± 0,05 mmol/l, n=65) serum uric acid (SUA) levels. Lipid profile and inflammatory biomarkers (high-sensitivity C-reactive protein (hc-CRP), Interleukin -1 (IL-1), tumor necrosis factor (TNF)) identification, echocardiograph assessment were performed.
Results: patients with high SUA had STEMI (61,3% vs 17,1%), mostly anterior (53,8% vs 28,6%), while patients with normal SUA – NSTEMI (82.9% vs. 38.7%). Congestive heart failure often manifested in patients with high SUA (24,5 % vs 4,9 %). Left ventricle aneurysm was formed only in 7 patients with hyperuricemia. Metabolic syndrome was more often found in patients with high SUA than with normal (60.5% vs 7.3%).
Lipid profile of patients with hyperuricemia was characterized by significant increased levels of total cholesterol - 20,9%, triglyceride - by 38,1%, LDL cholesterol - by 31,8% and lower HDL cholesterol - by 32,8% ($p < 0,01$) compared with patients with normouricemia. Combined dyslipidemia (67.9% vs 2.4%) and hypertriglyceridemia (6.6% vs 2.4%) were prevailed in case of hyperuricemia. In patients with high SUA inflammatory biomarkers were increased significantly, including hc-CRP - by 71,4 %, IL-1 - 49,9%, TNF - to 76,2% ($p < 0,01$) compared with patients with normal SUA. The correlation between elevated levels of hc-CRP and SUA ($r = 0,7$, $p < 0,01$), TNF ($r = 0,8$, $p < 0,01$), IL-1 ($r = 0,7$, $p < 0,01$) was found, confirming the direct role of SUA in inflammation.
Patients with high SUA, compared to those with low SUA, had higher left ventricular mass index (220,9 ± 6,9 vs 147,4 ± 8,3, $p < 0,01$) and left atrial dimension (4,0 ± 0,5 vs 3,5 ± 0,8, $p < 0,01$), while did not differ in ejection fraction. Concentric and eccentric hypertrophy were observed in 56,6 % and 40,6 % patients with hyperuricemia, 26,8 % and 31,7% - with normouricemia. Diastolic dysfunction was more frequently investigated in patients with high SUA than with normal (85,8 % vs 36,6 %, $p < 0,01$). SUA levels correlated significantly with mitral A wave velocity ($r=0,61$, $p < 0,01$), E wave decelaration time ($r=0,26$, $p < 0,01$), E/A ratio ($r=0,21$, $p < 0,05$).
Conclusion: Elevated SUA level is associated with heart remodeling progression after myocardial infarction as well as significant inflammatory activation and lipid disorders, reflecting increased cardiovascular risk.

P528

Association of endothelial dysfunction with biomarkers of myocardial fibrosis and left ventricle strain in patients with heart failure

G Gerasimos Siasos[1]; E Dimitropoulos[1]; E Oikonomou[1]; E Kokkou[1]; C Chrysohoou[1]; K Mourouzis[1]; G Vogiatzi[1]; A Antonopoulos[1]; S Tsalamandris[1]; M Vavuranakis[1]; C Stefanadis[1]; D Tousoulis[1]
[1]*National & Kapodistrian University of Athens, Department of Cardiology, Athens, Greece*

Background: Adrenomedullin (ADM) is involved in vascular homeostasis and endothelial function. Atrial natriuretic peptide (ANP) has potent diuretic, and vasodilating actions. Mid-regional epitopes of these peptides (MRproANP and MRproADM) present increased plasma stability. Soluble suppression of tumorigenicity 2 (sST2) has emerged as a novel biomarker for HF, and has been identified as a novel biomarker of cardiac stress, fibrosis and remodeling. We hypothesized that endothelial dysfunction in patients with is associated with markers of myocardial strain and fibrosis.
Methods: In this cohort study we enrolled 75 consecutive patients with stable chronic systolic HF in NYHA class II to IV and 80 matched for age and sex control subjects. Endothelial function was evaluated by flow mediated dilatation (FMD). Serum levels of MRproANP, MR-proADM and sST2 were measured with ELISA. Several other clinical and demographic characteristics were also collected.
Results: There was no difference in age (64 ± 10y vs 65 ± 11y, $p = 0.67$) and male gender (64% vs. 67%, $p = 0.78$) between HF and control subjects. Subjects with HF had significantly impaired FMD compared to control subjects (4.95 ± 2.28% vs. 6.12 ± 3.12%, $p = 0.04$). In HF patients FMD was inversely associated with sST2 levels (rho=0.57, $p < 0.001$) and with MRproADM levels (rho=0.26, $p = 0.02$) while there was no association of MRproANP with FMD (rho=0.09, $p = 0.94$). In HF patients FMD was significantly associated with age ($r=19$, $p = 0.04$), while there was no association of FMD with ejection fraction ($r=0.037$, $p = 0.65$), with NYHA status ($r=0.04$, $p = 0.70$) and with creatinine levels ($r=0.06$, $p = 0.34$). Interestingly, after adjustment for multiple established confounders (age, ejection fraction, NYHA status, smoking status, gender and the use of mineralocorticoid receptor antagonists, angiotensin receptor blockers or angiotensin converting enzyme inhibitors) sST2 was independently associated with FMD in patients with HF [b=0.17 95%CI (0.22, 0.05), $p < 0.05$].
Conclusions: These findings confirm the complex interrelationship between left ventricle strain, myocardial fibrosis and endothelial dysfunction in patients with heart failure.

P529

Creatinine or cystatin-C? Differences in renal function estimates and relation to cardiac parameters in patients with neuromuscular disorders

WC Meijers[1]; J Kootstra[2]; J Doorn[2]; J Nieuwenhuis[3]; HE Meulenbelt[4]; RA De Boer[1]
[1]*University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands*; [2]*University Medical Center Groningen, Clinical chemistry, Groningen, Netherlands*; [3]*University Medical Center Groningen, Pulmonary Disease, Groningen, Netherlands*; [4]*University Medical Center Groningen, Rehabilitation medicine, Groningen, Netherlands*

Background: Commonly used formulas use creatinine plasma levels to predict kidney function. However, in patients with neuromuscular disorders estimation of kidney function is severely limited due to very low creatinine levels and muscle turnover. Cystatin-C, an emerging marker of kidney function is not influenced by skeletal muscle degradation, and might be of clinical value in these patients. Therefore we studied the association of the CKD-EPI formula using either the cystatin C or creatinine plasma levels with both renal and cardiac function.
Methods: In a tertiary referral academic hospital, we consecutively enrolled 39 patients with neuromuscular disorders that were screened for possible cardiac involvement. In all these patients we measured the plasma levels of creatinine, cystatin-C, NT-proBNP, high sensitivity troponin-T and galectin-3. We performed echocardiography to assess left ventricular function. To directly compare the performance of creatinine and cystatin-C, we used the CKD-EPI formula using either creatinine or cystatin-C.
Results: Mean age of the study patients was 31 (SD ± 11), 82% of the patients were male and 59% were diagnosed with either Duchenne or Becker muscular dystrophy. Median creatinine value was 10 µmol/L (IQR 7-23), and for cystatin-C it was 0.81 mg/L (0.71-0.92). Creatinine and cystatin-C in these patients were not correlated with each other. We calculated creatinine based and cystatin-C based CKD-EPI, and they were markedly different: 252 mL/min per 1.73 m2 and 113 mL/min per 1.73 m2, respectively. NT-proBNP levels were strongly associated with left ventricular ejection fraction (LVEF) (β -0.78 $P < 0.001$). Cystatin-C based eGFR (CKD-EPI) was associated with age and galectin-3 levels (β -0.63 $P < 0.001$; β -0.43 P=0.008), which have established relation to renal function, while creatinine based eGFR (CKD-EPI) was only weakly associated with troponin-T and NT-proBNP (β 0.36 P=0.026; β 0.32 P=0.045).
Conclusions: These data indicate that estimation of renal function cannot reliably be achieved with creatinine, while cystatin-C appears a reasonable alternative. Since the majority of patients with neuromuscular dystrophies develop heart failure, and at some point require heart failure medication, adequate monitoring of renal function is warranted.

P530

Profile of biomarkers of extracellular matrix, inflammation and apoptosis in left ventricular reverse remodeling

S M R Amorim[1]; I Falcao-Pires[2]; M Oliveira[2]; J Rodrigues[1]; M Campelo[1]; B Moura[3]; F Macedo[1]; A Leite-Moreira[2]; J Silva-Cardoso[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Cardiology, Porto, Portugal*; [2]*Faculty of Medicine University of Porto, Cardio-Toracic Surgery, Porto, Portugal*; [3]*Military Hospital, Porto, Portugal*

Introduction: Limited data exists regarding the usefulness and validation of novel biomarkers to predict left ventricular (LV) reverse remodeling (LVRR) in dilated cardiomyopathy (DCM). We aim to evaluate the potential of emerging biomarkers in LVRR, in a cohort of DCM patients, after optimal pharmacological or resynchronization therapy.
Methods: We prospectively included 35 DCM patients with reduced LV ejection fraction (LVEF < 40%, 59.1 ± 9 years-old, 51.4% males) who were referred to our heart failure (HF) outpatient clinic. Clinical and echocardiographic data as well as blood samples were collected before (baseline) and 41.2 ± 23.4 months after to assess LVRR (defined as an increase of LVEF> 10 units) and correlate these parameters to levels of circulatory markers of extracellular matrix (MMP-3, TIMP-2, ST2, Galectin-3) and HF (BNP, GDF-15, sTNF RI, CA 125).

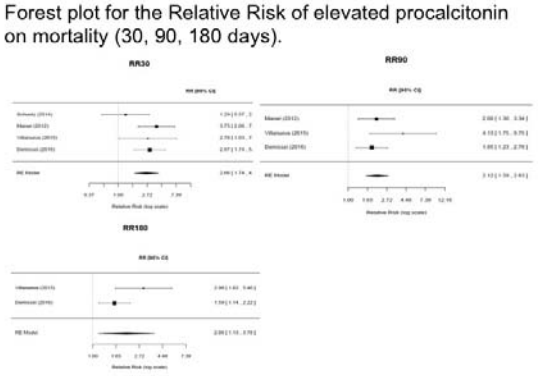
Results: LVRR occurred in 45.7% of patients within 22.6 ± 5.28 months after optimal pharmacological or resynchronization therapy. In this group, LVEF increase 24.6 ± 9.3% and a LV diastolic diameter (LVDD) decrease of 8.8 ± 7.8 mm compared to baseline values (follow-up LVEF of 47.8 ± 7.5% and follow-up LVDD of 53.9 ± 6.9 mm). Concerning the progression of biomarkers plasma levels in the overall population, there was a significant decrease in BNP (35.3 ± 82.2 vs 120.9 ± 266.5 pg/ml, p = 0.01) as well as an increase in GDF-15 (1161.2 ± 826.4vs 935.0 ± 512.6 pg/ml; p = 0.04), MMP-3 (10.1 ± 6.0 vs 6.1 ± 3.0 ng/ml; p < 0.01) at the end of follow-up. A subgroup analysis revealed that BNP and MMP-3 changes occurred both in patients with or without LVRR. GDF-15 increased (marginally) in patients that recovered LVEF (1140.01 ± 928.45 vs 808.35 ± 416.66 pg/ml; p = 0.07). Additionally, patients with pharmacological LVRR had lower baseline values of galectin-3 (5.61 ± 2.98 vs 8.68 ± 4.35ng/ml, p = 0.03).
BNP correlated with LVDDi (r=0.63, p < 0.01), LVDVi (r=0.53, p < 0.01), LVEF (r=-0.43, p < 0.01), LMMi (r=0.42,p < 0.01), LAVi (r=0.36, p = 0.01), E/e´ (r=0.33, p = 0.01). CA 125 correlated with LAVi (r=0.48, p = 0.01), PASP (r=0.62, p < 0.01) and LVDD (r=0.51, p = 0.01). GDF-15 correlated with E/e′ (r=0.32, p = 0.01); TIMP-2 correlated with LVDVi (r=0.31, p = 0.01), LAVi (r=0.28, p = 0.02) and sphericity index (r=-0.29, p = 0.02). MMP-3 had a positive correlation with LVEF (r=0.35, p = 0.01).
Conclusions: Lower baseline values of galectin-3 were associated with LVRR. GDF-15 and MMP-3 increased during follow-up showing important significant correlations between their circulatory levels and echocardiographic parameters of LV remodeling, suggesting there is a multidirectional pathway of activation in HF that involves cytokines, ECM activation and apoptosis. Considering the role that these markers hold at the level of myocardial fibrosis, our data clearly demonstrate the changes at the ECM have an impact on myocardial function and structure recovery in DCM patients.

P531

Diagnostic and prognostic value of elevated serum concentrations of procalcitonin in patients with suspected heart failure and infection - A systematic review and meta-analysis

L Aissou[1]; E Sorbets[1]; E Lallmahomed[1]; FX Goudot[1]; N Pop[1]; L Benouda[1]; C Meune[1]
[1]*Hospital Avicenne of Bobigny, Cardiology, Bobigny, France*

Purpose: The serum concentration of procalcitonin (PCT), a diagnostic tool of bacterial infection, is higher in patients presenting with heart failure (HF) and concomitant infections than in patients with HF alone, and in patients with infection alone. However, its prognostic significance remains uncertain in patients with HF. We reviewed and performed a meta-analysis of studies that measured PCT in patients with acute or chronic HF and suspected infection in order to evaluate the diagnostic robustness and the prognostic impact of PCT concentration in this population.
Methods: Out of 73 published studies, we identify 7 that were eligible for our analysis, including a total of 5,810 patients. We estimate PCT concentration in patients with or without HF and/or infection. We also compared the short-term mortality of patients with versus without elevated serum PCT concentrations. Risk ratios (RR) and confidence intervals (CI) were calculated.
Results: The mean age of the study samples ranged for 58 to 81 years and the proportion of men ranged to 47 to 66%. The analyzed follow-up ranged from 22 to 180 days and the cutoff PCT concentrations ranged from 0.1 to 0.25 ng/l. Patients with HF and concomitant infection tended to have a higher PCT concentration than those with HF alone (respectively 0.26 ng/l [0.06, 0.46] vs 0.10 ng/l [0.08, 0.12]; p = 0.059%).
The mortality rates of patients with elevated PCT concentrations was significantly higher that of patients with PCT concentrations in the normal range at 30, 90 and 180 days (respectively RR 30 days 2.66 [1.74 , 4.05]; RR 90 days 2.12 [1.59 , 2.83]; RR 180 days 2.06 [1.13 , 3.78]).
Conclusions: This review and meta-analysis contribute to strengthen the conclusions of several recent studies of the prognostic role of PCT in patients suffering from HF. The measurements of PCT concentrations enabled their short-term risk stratification. Further studies may investigate outcomes with risk-stratification driven by procalcitonin levels in patients presenting with suspected or confirmed HF.



mortality rates

P532

A novel risk score for prediction of new onset heart failure in patients undergoing coronary or peripheral angiography: Results from the CASABLANCA study

N Ibrahim[1]; A Lyass[2]; HK Gaggin[1]; Y Liu[2]; RRJ Vankimmenade[3]; SR Motiwala[4]; NP Kelly[5]; PU Gandhi[6]; ML Simon[1]; AM Belcher[1]; JE Harisades[1]; JM Massaro[2]; RB D'agostino[2]; JL Januzzi[1]
[1]*Massachusetts General Hospital, Cardiology , Boston, United States of America*; [2]*Baim Institute for Clinical Research, Boston, United States of America*; [3]*Radboud University Medical Centre, Cardiology, Nijmegen, Netherlands*; [4]*Beth Israel Deaconess Medical Center, Cardiology, Boston, United States of America*; [5]*Brigham and Women's Hospital, Boston, United States of America*; [6]*Yale University, New Haven, United States of America*

Background: Heart failure (HF) is a major public health concern with increasing prevalence in the general population. Methods to identify patients at risk for new-onset HF would be welcome as such patients might benefit from earlier interventions. However, clinical risk factors alone are insufficient to identify risk; adding biomarker results to clinical risk factors may improve accuracy. Using the resources of the Catheter Sampled Blood Archive in Cardiovascular Diseases study, we sought to identify clinical and biomarker predictors of the development of new-onset HF in a population undergoing coronary and/or peripheral angiography for various indications as this may have implications on future management.
Methods: The CASABLANCA study is a prospective single-center observational trial of 1251 patients who underwent coronary and peripheral procedures with or without intervention for various indications. Multiple cardiac and renal biomarkers were obtained immediately before the procedure in order to assess their value in predicting short- and long-term events; median follow-up was 3.8 years. Our sample consisted of 991 patients free of prevalent HF at baseline. We used stepwise Cox Proportional Hazard models (using alpha level of 0.05 for both entry and retain) to develop a score to predict an adjudicated diagnosis of new-onset HF using a list of pre-selected covariates. Model discrimination and reclassification (categorical net reclassification and integrated discrimination improvement, NRI/IDI) with and without biomarkers was evaluated.
Results: During follow up, 177 (18%) developed new-onset HF. Patients with incident HF were more likely to be older, and to have history of numerous risk factors for HF such as arrhythmia, hypertension, coronary artery disease, diabetes mellitus or chronic kidney disease; numerous prognostic biomarkers were abnormal in those suffering new-onset HF, including higher concentrations of highly sensitive troponin I, amino-terminal pro-B type natriuretic peptide (NT-proBNP), cystatin C, myeloperoxidase and ST2. Independent predictors of new-onset HF were identified and a scoring system was developed consisting of 5 clinical variables (age, male sex, heart rate, history of atrial fibrillation/flutter, and history of hypertension) and 2 biomarkers (NT-proBNP and ST2). Age and sex were forced into the model. The c-statistic for the model without biomarkers was 0.69; including biomarkers substantially increased the c-statistic to 0.76 (p < 0.0001). Biomarkers also significantly reclassified risk for new-onset HF beyond clinical variables (NRI 0.26; IDI 0.10; both p < 0.0001). When the HF risk score was divided into quintiles, patients in the highest quintile had the highest incidence of development of new-onset HF compared to those with scores in lower quintiles (Figure 1).
Conclusions: We describe an accurate clinical and biomarker score for predicting new-onset HF in an at-risk population.

The relationship between physical activity and appetite in heart failure - A cross sectional study

C Andreae[1]; K Arestedt[1]; L Evangelista[2]; A Stromberg[1]
[1]*Linkoping University, Department of Medical and Health Sciences, Division of Nursing Science, Linkoping, Sweden*; [2]*University of California at Irvine, Program in Nursing Science, Irvine, United States of America*

Background: Physical activity and appetite are important for maintaining physical health. Yet, sedentary lifestyle and poor appetite are frequently observed in the heart failure (HF) population. However, the relationships between these phenomena are not yet clearly understood.
Purpose: To investigate the relationship between physical activity and appetite in patients with stable HF.
Methods: In this cross sectional study, a consecutive sample of 186 patients with confirmed HF with NYHA class II-IV (median age 72y, 70% men, NYHA class II 61%) participated in the study. Patients were recruited from three HF outpatient clinics in central Sweden. Physical activity measures included total energy expenditure (TEE), active energy expenditure (AEE) above 3 METs, average daily METs and number of steps per day during four days using a validated multi-sensor wearable armband (SenseWear®, Body Monitoring System). Patients also self-reported their physical activity on a ten point numeric rating scale, from extremely low (1) to extremely high (10). Self-reported appetite was measured by Council on Nutrition Appetite Questionnaire (CNAQ), an 8-item instrument (score range 8-40) where CNAQ $\leq$28 indicate poor appetite. Associations between physical activity and appetite were analyzed by Spearman correlation while differences in physical activity between poor vs good appetite were analyzed using Mann Whitney U test.
Results: There was a significant positive relationship between physical activity and appetite assessed by TEE (rs=.184, p = .012), AEE of moderate intensity >3 METs (rs=.262, p = .000), number of steps (rs=.292, p = .000), average METs intensity (rs=.249, p = .001), and self- reported physical activity (rs=.191, p = .009). Levels of physical activity in the low appetite group differed significantly from the group with better appetite, this was seen in all physical dimensions, TEE (U=3225, z=-2.26, p = .024), AEE (U=2902, z=-3.178, p = .001), number of steps (U=2706, z=-3.734, p = .000), average METs intensity (U=3128, z=-2.541, p = .011), levels of self-reported physical activity (U=3185, z=-2.47, p = .013).
Conclusion: This study shows that physical activity is associated with appetite and that levels of physical activity differs between patients with poor and good appetite. These findings has implications for both research and practice and underlines the importance in monitoring both physical activity and appetite. Further research is needed to determine whether interventions targeting physical activity also improve appetite and vice versa in the HF population.

P534

Gender differences in patients-partner dyads affected by heart failure

A Anna Stromberg[1]; M Liljeroos[2]; S Agren[2]; T Jaarsma[3]
[1]*Linkoping University Hospital, Linkoping, Sweden*; [2]*Linkoping University, Department of Medical and Health Sciences, Division of Nursing Science, Linkoping, Sweden*; [3]*Linkoping University, Department of Social and Welfare Studies, Linkoping, Sweden*

Background: It is known that women often experience poorer quality of life and more symptoms of depression, both among patients with heart failure and in the norm population. Further it is also known that female caregivers experience more burden and stress in relation to caregiving compared to men.
Aim: The aim of this study was to explore gender differences with regard to quality of life, symptoms of depression, perceived control, emotional support and caregiver burden in patients-partner dyads affected by heart failure.
Method: The study is a secondary analysis of baseline data from a RCT targeting patients with heart failure and their caregiving partners. A total of 155 patient-partner dyads where included. Data were collected using SF-36 , Beck Depression Inventory, Control Attitude Scale, a single item to measure emotional support and the Caregiver Burden Inventory.
Results: There were no significant difference in age, educational level, lifestyle or comorbidities between the genders in either the patient or caregiver group. Mean age of female patients (n = 38) was 70 and male patients (n = 117) 72 years, female caregivers 68 and male caregivers 70 years. Most patients and caregivers stated that they had someone to confine in. Male patients experienced this to a significantly higher extent than female patients (p = 0.01). There were no significant gender differences between the caregivers in perceived emotional support or caregiver burden. There were several gender differences in the eight domains of health-related quality of life measured by SF-36 among the patients. Male patients had significantly better physical function (48 $\pm$ 27 versus 36 $\pm$ 24), social function (67 $\pm$ 28 versus 52 $\pm$ 27) and mental health (70 $\pm$ 22 versus 61 $\pm$ 17). A similar picture was seen among caregiving partners with male partners having significantly better physical function (81 $\pm$ 21 versus 72 $\pm$ 23), less bodily pain (82 $\pm$ 20 versus 67 $\pm$ 2), and better mental health (75 $\pm$ 15 versus 68 $\pm$ 22). Female patients had more symptoms of depression than males (p = 0.048) with 50% of the females having depressive symptoms and 30% of the males. However, there was no gender difference with regard to depressive symptoms in caregivers. No significant gender differences in perceived control over the heart disease neither among the patients, nor among their caregiving partners were found.
Conclusion
In patient and caregiver groups that were equal with regard to age, educational level and comorbidities we found differences between male and female caregivers with regard to health-related quality of life, but no differences in emotional support, perceived control over the heart failure condition, depressive symptoms or caregiver burden. Female patients were found to be more vulnerable than males with poorer quality of life, less emotional support and more depressive symptoms. Interventions targeting to support female patients are warranted, Support programs for caregivers should include both men and women.

P535

Adherence to low sodium diet in heart failure patient-caregiver dyads

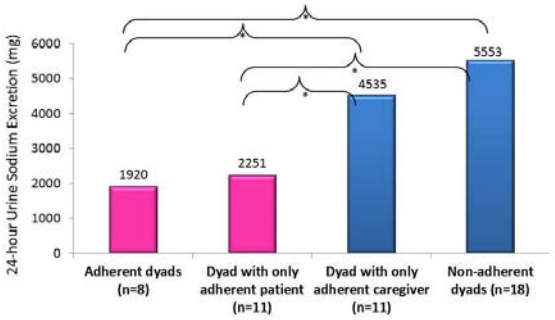
ML Misook Chung[1]; DK Moser[1]; TA Lennie[1]
[1]*University of Kentucky, College of Nursing, Lexington, United States of America*

Funding Acknowledgements: NIH/ National Institute of Nursing Research, USA

Background: Despite the importance of following a low sodium diet (LSD) in improving outcomes of patients with heart failure (HF), adherence to LSD remains. Poor support from family members was identified as a major barrier for patients. However, there is limited knowledge about whether patients increase their adherence to LSD when family caregivers also follow a LSD.
Purpose: To examine the association of adherence to LSD between patients with HF and their family caregivers.
Methods: This was a cross-sectional study in which patients with HF and their primary family caregivers were recruited from a HF clinic in the southern United States. Patients and their caregivers completed 24-hour urine collection for sodium excretion as a measure of sodium intake. Paired t-test was used to compare LSD adherence between patients and caregivers dyad members. One-way ANOVA was used to compare sodium intake among 4-dyad groups stratified by adherence using a cut point of urinary sodium excretion (UNa) less than 3000mg: adherent dyads, non-adherent dyads, dyads with only adherent caregiver, dyads with only adherent patient).
Results: A total of 48 patients (60% male, mean age 59) and 48 caregivers (65% female, mean age 53) provided 24-hour urine samples. The estimated sodium intake of patients was 3957mg ($\pm$2308) which was similar to family caregivers (3621mg $\pm$ 1556, p = .38). There was no difference in adherence rate (UNa < 3000mg) between patients and caregivers (40% vs 40%, p>.05). Half of dyads (54%) had members that were either both adherent (17%) or both non-adherent (38%), and remainder of dyads had only one adherent member. Among 4 dyad groups, patients who were in the non-adherent dyads had highest sodium intake (5553mg), averaging 3300mg higher than those of patients in the adherent dyads (p < .05, Figure 1).
Conclusion: Family support is pivotal in patients' adherence to LSD. In this study, patients and their family caregivers consumed similar amounts of sodium. Sodium

intake was highest in patients whose caregiver also consumed a high sodium diet. These results suggest that interventions aimed at improving LSD adherence should target both patients and family members together.

Figure 1. Comparisons of patients' 24-hours Urinary Sodium Excretion among dyads classified by adherence



ANOVA $P < .001$; * post-hoc test, $p<.05$

Health Care Professionals' compassion rounds

I Ioanna Lakatamitou[1]; E Lambrinou[2]; J Rilley[3]; P Andreou[2]; N Middleton[2]; J Pepper[3]

[1]American Heart Institute, American Heart Institute/American Medical Center, Nicosia, Cyprus; *[2]Cyprus University of Technology, Limassol, Cyprus*; *[3]Imperial College London, London, United Kingdom*

Funding Acknowledgements: HFA nurse training fellowship

Background: "Heath Care Professionals' (HCPs') compassion" rounds are a multidisciplinary forum aiming to help HCPs improve emotional expression, teamwork and communication. The main aim of our study was to explore the views of HCPs about the rounds and assess the impact of these rounds on teamwork and job satisfaction.
Method: A quasi experimental study was conducted in a cardiology/cardiosurgery hospital. Three rounds were established in which a patient case was described and then discussed by a multidisciplinary group. Twenty-five HCPs participated in the study and completed TeamSTEPPS and Minnesota Satisfaction Questionnaires validated in Greek, before and after the rounds. After the rounds, 10 participants were selected (via purposive sampling) to participate to focus groups. Quantitative and qualitative data were analyzed using t-test and content analysis, respectively.
Results: An upward trend on teamwork and job satisfaction was observed after the rounds, with no statistical significance ($p=0.10$, $p=0.18$). Four main themes extracted: exposing emotions; personal impact; inequality of topics; frontiers. Overall, participants reported benefited on sharing concerns and identifying needs in their work environment, teamwork and the management that could be improved.
Conclusions: Findings suggest that "HCPs' compassion rounds'' may contribute to more positive feelings about teamwork, better collaboration and job satisfaction.

POPULATION STUDIES – EPIDEMIOLOGY

The potential use of ivabradine among ambulatory patients with heart failure with reduced ejection fraction in the real world scenario

Zl Zaza Iakobishvili[1]; D Murninkas[2]; A Porter[1]; H Jino[2]; S Birkenfeld[2]; D Hasdai[1]

[1]Rabin Medical Center, Petah Tikva, Israel; *[2]Heart Failure Unit, Clalit Health Services, Tel Aviv, Israel*

Background: Ivabradine, an inhibitor of the If channel, is a relatively new addition to the pharmacological therapeutic regimen for heart failure with reduced ejection fraction (HFrEF). In particular, it is indicated for HFrEF patients in sinus rhythm, NYHA class ≥2, ejection fraction (EF) ≤35%, and heart rate ≥75/min.
Aim: We sought to evaluate the potential use of ivabradine in a large cohort of real-world, ambulatory HFrEF patients.
Methods: We analyzed the electronic records of all 115739 patients 18 years old and insured by our Health Services in the Holon/Bat-Yam District. We identified 550 patients with EF≤40% and age under 85 years. We then further sought the patients who met the criteria for use of ivabradine, as described above.
Results: Of the 550 patients (123 women), with a mean age of 71.4 ± 9.8 years and mean EF of 32.1% + 6.7, 432 patients were in sinus rhythm, 451 patients were in NYHA class≥2, 401 patients had EF≤35%, and 362 patients had heart rate ≥75/min (some patients had more than one exclusion criterion). Altogether, only 154 patients (28.0%) were apparently suitable for consideration of treatment of ivabradine, of whom 138 patients (89.6%) were under treatment with beta blockers (mean 38.6% + 21.6 of maximal dose, and only 2.7% of patients receiving maximal beta blocker dose).
Conclusions: In a large cohort of real-world, ambulatory HFrEF patients, approximately only a quarter of the patients were apparently suitable for consideration of ivabradine treatment. Some patients were not under beta blocker treatment, and the vast majority was receiving submaximal doses. Thus, it seems that there is substantial room for improvement in beta blocker therapy before initiating treatment with ivabradine.

P538

The characteristics of heart failure ambulatory patients with reduced ejection fraction who attend a specialized heart failure clinic compared to those who decline such follow-up

Zl Zaza Iakobishvili[1]; D Murninkas[2]; A Porter[1]; H Jino[2]; S Birkenfeld[2]; D Hasdai[1]

[1]Rabin Medical Center, Petah Tikva, Israel; *[2]Heart Failure Unit, Clalit Health Services, Tel Aviv, Israel*

Background: Specialized heart failure (HF) clinics have been established to ameliorate management. The proportion of HF patients who choose to attend such clinics and their demographic and clinical characteristics remain unknown.
Methods: We analyzed the electronic records of all 115739 patients 18 years old and insured by our Health Services in the Holon/Bat-Yam District. We identified 550 patients with EF≤40% and age under 85 years. In collaboration with the general practitioners in the district and under the auspices of the district management, all suitable patients were actively solicited by a dedicated nurse to attend a specialized HF clinic within their community.The demographic and clinical characteristics of the patients who elected to attend the clinic were compared with those who declined.
Results: Of the patients who were actively solicited, of whom 22.4% were women, 210 (38.1%) elected to attend the clinic, 173 men and 37 women. Men were more likely to attend the clinic (40.5% of men in the cohort vs 30.0% of women, p0.05). Of interest, patients who attended the clinic were less likely to be in NYHA class 1-2 (39.0% vs 65.6% among patients who did not attend, p0.01) and tended to be more likely to have diabetes mellitus (60.4% vs 52.1% among patients who did not attend, $p=0.06$). There were no other differences in baseline characteristics, including the proportion of patients receiving evidence-based medications.
Conclusions: Although a specialized HF clinic was readily available, in our cohort of ambulatory HF patients with reduced election fraction only 38.1% elected to attend. Efforts should be made to to make this service attractive and accessible.

P539

Acute heart failure in the elderly and very old.

L Luis Abreu[1]; H Antunes[1]; L Goncalves[1]; J Gil[1]; I Cunha[1]; B Marmelo[1]; MI Pires[1]; I Almeida[1]; E Correia[1]; C Cabral[1]

[1]Hospital Sao Teotonio, Cardiologia, Viseu, Portugal

Introduction: Heart Failure (HF) is a syndrome with increasing incidence with population aging. However, the guidelines are based on studies in younger populations, and it is not always possible to apply all therapies measures due to comorbidities ande interactions.
Objectives: To evaluate the impact of advanced and very advanced age on comorbidities, therapy and outcomes in a population admitted with HF.
Methods: All consecutive HF admissions in a cardiology department were evaluated for a 6 years (Y) period. Only the first episode of each patient was included. Patients were divided into groups (G) according to age (GA: ≤ 75Y, GB: 76-85Y, GC: ≥86Y). The remaining demographic data, previous co-morbidities, previous medication and the date of discharge, and in-hospital mortality were evaluated. Results: A total of 1006 hospitalizations were performed, corresponding to the same number of patients, with a mean age of 77.5 ± 10.1Y, 50.8% of males. 336 patients were included in GA (36.4%), 417 in GB (41.5%) and 223 in GC (22.2%). The inter-groups comparison is presented in table. In-hospital mortality was 3.8% in GA, 8.4% in GB, and 9.0% in GC ($p=0.041$).
Conclusion: In this population it is evident the negative impact of age on intrainternational mortality. Its also evident a higher prevalence of females and patients with HF with preserved EF (HFpEF) with advancing age, which are underrepresented in clinical studies. Somewhat unexpectedly, there is a lower prevalence of AF, coronary artery disease (CAD) and diabetes mellitus (DM) in the older patient group, which can be explained by the greater pervalence of HFpEF. As expected, its also evident that medical therapies are underused in the elderly.

Group comparison				
	GA (≤ 75Y)	GB (76-85Y)	GC (≥86Y)	
Male	63,7%	45,6%	39,5%	P=0,000
Hipertension	66,8%	68,1%	65,9%	P=n.s.
DM	42,2%	34,1%	27,8%	P=0,000
CAD	19,7%	12,2%	10,3%	P=0,002
Atrial Fibrilation	52,6%	55,9%	48,9%	P=n.s.
Cronic Kidney Desease	20,2%	19,6%	38%	P=0,012
HFpEF	36,7%	49,0%	57,3%	P=0,000
BNP at admission	763±857	880±947	974±1151	P=n.s.
Beta-Blockers at discharge	57,6%	38,0%	33,5%	P=n.s.
ACE inibitor at discharge	76,5%	74,2%	69,3%	P=n.s.
Aldosterone Antagonists	52,1%	39,6%	46,0%	P=0,003

P541

Is there a significant gender bias in treatment among ambulatory patients with heart failure with reduced ejection fraction in the real world scenario?

ZI Zaza Iakobishvili[1]; A Porter[1]; D Murninkas[2]; H Jino[2]; S Birkenfeld[2]; D Hasdai[1]
[1]Rabin Medical Center, Petah Tikva, Israel; *[2]Heart Failure Unit, Clalit Health Services, Tel Aviv, Israel*

Background: Heart failure (HF), in particular with reduced ejection fraction (HFrEF), is associated with considerable morbidity and mortality in both genders. Frequently, women are less likely to receive evidence-based treatments than men, despite similar management recommendations.
Aim: We sought to investigate gender differences in treatment for HFrEF in a large cohort of ambulatory patients.
Methods: We analyzed the electronic records of all 115739 patients 18 years old and insured by our Health Services in the Holon/Bat-Yam District. We identified 550 patients with EF≤40% and age under 85 years.
Results: Women comprised a small minority of the cohort (n = 123, 22.4%), tended to be slightly older (72.7 + 10.2 vs 70.9 + 9.6 years, p = 0.08), and had slightly higher EF values (33.2% + 6.9 vs 31.7% + 6.6 ,p = 0.02), yet were similarly likely to be in NYHA class 1-2 (53.5% vs. 46.6%, p = 0.55). Women had lower eGFR (61.1 + 22.6 vs 66.5 + 24.3 ml/min/1.73m2, p = 0.03) and hemoglobin levels (12.0 + 1.8 vs 13.1 + 1.7 gr/dl, p0.01), and were less likely to have diabetes mellitus (47.9% vs. 57.3%, p = 0.08). Nevertheless, evidence-based treatments were comparable among genders (Table), including the proportion of patients receiving the maximal recommended dosage.
Conclusions: Although there is a strong male preponderance among ambulatory HFrEF patients and subtle differences in demographic and clinical characteristics, we did not identify a gender bias in pharmacological treatment in our cohort.

P542

Characteristics of a group of patients admitted for heart failure presenting intermediate FE

JR Beramendi Calero[1]; I Irene Rilo Miranda[1]; S Garcia Gutierrez[2]; A Anton Ladislao[2]; L Quintas Ovejero[3]; C Goena Vives[3]; M Morillas Bueno[2]; F De La Cuesta Arzamendi[1]
[1]Hospital Donostia, San Sebastian, Spain; *[2]Hospital Galdakao-Usansolo, Bilbao, Spain*; *[3]Hospital Comarcal de Mendaro, Cardiology, Mendaro, Spain*

Objective: Study the characteristics of a group of patients admitted for heart failure who presented FE (49%) and depressed FE (FE < 40%) compared to patients with preserved EF
Methods: A prospective observational cohort study involving a total of 582 patients who come to our hospital for acute decompensated heart failure (acute heart failure and decompensated chronic heart failure).
The following variables were collected: sociodemographic, CV risk factors, comorbidities, history of heart disease (ischemic, cardiomyopathy, valvular, arrhythmia) and analytical and echocardiographic data of the emergency department and hospital admission.
We compared the characteristics of patients with intermediate EF in relation to the patients with preserved EF and depressed EF of 582 patients with a diagnosis of heart failure admitted to 3 hospitals of the Basque Health Service between 2011 and 2013. 188 patients had EF < 40 (Group A), 101 patients FE between 40 - 49% (Group B) and 193 patients FE> 49% (Group C)
Results: 29.26% of patients in group A, 48.51% in Group B and 59.73% in Group C were women (p < 0.0001). The mean age of group A was 73.58 + 12.13, group B 78.33 + 10.73 and group C 80.14 + 9.01 years (p < 0.0001). 77.59% of Group A, 79.17% of Group B and 89.47% of Group C were hypertensive (p 0.0013). 34.57% of patients in group A, 32.67% in Group B and 33.45% in Group C were diabetic (p 0.94). 42.55% of Group A, 31.68% of Group B and 25.94% of Group C had ischemic heart disease (p 0.0007). 43.62% of Group A, 55.00% of Group B and 59.66% of Group C presented atrial fibrillation (p 0.0026). 6.38% of Group A, 2.97% of Group B and 4.78% of Group C had renal failure (p 0.43).
Conclusions: 1. Patients with intermediate EF are older than patients with depressed EF, with no significant difference from the preserved EF group. The presence of women in the intermediate EF group is greater than in the group with depressed EF and lower than in the group with preserved EF.
2. The presence of hypertension in the intermediate EF group is lower than in the group with preserved EF and similar to the group with depressed EF.
3. There is no difference between the intermediate EF group and the other groups regarding the presence of ischemic heart disease and atrial fibrillation, although there is a difference between the group of preserved EF and depressed EF.
3. There are no significant differences regarding the presence of diabetes mellitus and renal failure among the 3 groups.

P543

Clinical characteristics in patients with chronic heart failure who are living in high altitude

S Bolivar[1]; J Lopez[1]; R Lasso[1]; J Torres[1]; L Jumbo[1]; C Segarra[1]; E Izaguirre[1]; J Valiente[1]; J Jativa[1]; E Aguilar[1]; P Segovia[1]; C Saenz[1]
[1]Military Hospital, Cardiology, Quito, Ecuador

Background: Hypoxemia is an adverse atmospheric condition that patients with heart failure (HF) have to face when living in high altitude (HA). It is known that acute ascents generate adverse pathophysiological changes, however little is known about the adaptation of these patients when they are living in HA chronically. Actually, all guidelines have been developed at sea level (SL) and it is not known if these guidelines would be applicable to them.
Methods: We studied 42 patients with compensated HF in the city of Quito that is at 2800 meters and compared to 36 patients living in Guayaquil that is at SL. In both groups patients had to live for at least one year under these conditions. Its clinical characteristics were observed; a six-minute walk test was performed in both groups and they were observed for one year. Mortality, emergencies and hospitalizations were determined in both groups.
Results: The average age was lower in HA (6 8.1 vrs. 77.8 years p 0,0002). The mean left ventricular ejection fraction ih HA was higher (51.1 vrs. 37.7 % p 0.0006). Ischemic disease etiology was more common in SL, while hypertension was mor common in HA. There was a better performence in six minute walk test in patients who are living in HA (370.9 vrs 277.5 meters p 0.004). There were no differences between mortality (20.5% vrs 17.3% p 0.5), hospitalizations (24,3% vrs 34% p 0.7) and cardiac emergencies (29.7% vrs 39.1% p 0.31) in both groups.
Conclusion: In spite of chronic hypoxemia, patients living at high altitude had no significant clinical differences with patients who are living at sea level. Guidelines could be applied to them without significant changes.

P544

Epidemiological, clinical, and etiological study of heart failure on a ten years period (2005 - 2014), in cardiology department of an Hospital

F Fouad Belamri[1]; K Oumokrane[1]; S Lehachi[1]; M Krim[1]
[1]Beni-Messous Hospital, Cardiology, algiers, Algeria

Introduction and problematic: Heart failure is a common pathology, with a heavy morbidity and mortality.Its prevalence in the world varies between 1 and 2% of the adult population and reaches 10% after 70 years. It represents the ultimate evolution of many cardiovascular diseases, especially ischemic and hypertensive.
Heart failure is associated with high morbidity and mortality.
The 5 year survival is 35% in men and 53% in women, significantly lower than the survival of certain cancers. It represents a major public health problem with the highest care cost among all cardiovascular disease. Knowledge about the pathophysiology of heart failure have evolved considerably in recent years ; therefore, its management has also seen a lot of progress where new techniques have emerged and made possible functional improvement and, especially a better survival, to certain category of patients.
Aim: Describe the epidemiological, clinical , etiological and therapeutic characteristics of acute heart failure in patients hospitalized in the cardiology department of the hospital during the period 2005- 2014.
Methods: This descriptive study analyzed retrospectively the records of patients hospitalized for acute heart failure between 2005 and 2014 in the cardiology department.
Results: 550 patients of which 64% are men. The average age was 63 years. The most frequent antecedents were ischemic heart disease (42.36%) hypertensive heart disease (40.36%) and valvular heart disease (27.27%).

Hypertension, diabetes mellitus, and tobacco were the most frequent risk factors.The left heart failure was the most common table.73.45% of patients were in their first acute decompensation.
Regarding the trigger bronchial infection (29.45%) and dietary change (22.72%) were the most common factors.62.91% had impaired FE. The average hospital stay was 17 days.
The mortality rate during hospitalization was 22.36%, with the main cause cardiogenic shock. Finally, the evaluation of drug prescriptions patterns, according to new international recommendations, is quite reassuring to the extent that the new molecules that enabled a significant reduction in morbidity and mortality in heart failure are widely prescribed in our patients.
Conclusion: The results of our study were comparable to data from the literature in particular as regards the epidemiological profile of heart failure patients with a relatively high average age, male predominance, and ischemic etiology that is the main cause of failure heart.

P545

High rates of left ventricular systolic dysfunction in patients with diabetes in Malawi, Africa

CJ Watson[1]; M Chisale[2]; H Lee[3]; J Wu[3]; J O'donoghue[4]; A Cheung[1]; M Ledwidge[5]; K Mcdonald[6]; J Chipolombwe[2]; J Gallagher[5]
[1]Queen's University of Belfast, Belfast, United Kingdom; *[2]Mzuzu Central Hospital, Mzuzu, Malawi*; *[3]Luke International Norway, Mzuzu, Malawi*; *[4]Imperial College London, London, United Kingdom*; *[5]University College Dublin, Dublin, Ireland*; *[6]Heart Failure Unit, St Vincent's University Hospital, Dublin, Ireland*

Background: It is estimated that 415 million people worldwide suffer from diabetes with more than 80% living in low and middle-income countries (LMIC). Sub-Saharan Africa (SSA) will see an 81% rise in incidence of diabetes by 2030, with a predicted 68% increase in hypertension over a similar period. Ventricular dysfunction and heart failure are major complications of diabetes and is involved in the pathogenesis and prognosis of the disease. Limited data is available on heart failure and diabetes in SSA populations. The aim of this project was to investigate the prevalence of left ventricular systolic dysfunction in a cohort of people with diabetes attending a hospital clinic in Malawi, Africa.
Methods: Ninety-five consecutive consenting patients attending a Diabetes Outpatient Clinic were recruited to the MTIMA pilot study. Anthropometric and medication data was collected. Point of care testing for blood glucose, glycated HbA1c, and lipids were conducted. All patients underwent echocardiography.
Results: Echocardiography analysis revealed a high rate of left ventricular systolic dysfunction in patients with diabetes in Malawi, with 35% having an ejection fraction less than 50%. The mean age of the study population was 58 years (range 35-85), and 38% were male. The mean time since initial diagnosis was 6 years (range 0-45 years). Mean BMI was 27, with 24% of the cohort having a BMI >30. Mean HbA1c was 68mmol/mol (range 28-129mmol/mol), with 59% of the patients above IDF HbA1c target for limited care in LMIC. Mean reported lipid data for this cohort was; total cholesterol (4.48mmol/l), LDL (2.71 mmol/l), HDL (0.98 mmol/l), triglycerides (1.79 mmol/l). Blood pressure control was sub-optimal, mean SBP/DBP 147mmHg (96-216) / 86mmHg (54-124), with 79% patients above the IDF blood pressure target for limited care in LMIC.
Discussion: Patient recruitment into this observational study is ongoing with the aim to report of additional heart failure related features in patients with diabetes in Malawi, including profiling of cardiac biomarkers.

P546

Elder heart registry- focus on heart failure: clinical profile and outcome of elderly patients aged above eighty years admitted to a tertiary care center in a developing country.

K Kiran Jacob[1]; S Ahmad[1]; A Bahekar[1]; K Venugopal[1]
[1]Pushpagiri Medical College, Cardiology, Thiruvalla, India

Introduction - Heart failure represents a major public health problem in the elderly. Limited clinical and prognostic data is available in India for development of appropriate prevention and treatment strategies in this subgroup
PURPOSE: - To know the demographics, co morbidities, clinical profile, treatment and outcomes in the 'oldest old'.
Methods: The registry enrolled consecutive admissions of patients with age ≥ 80 yrs in the cardiac care unit from Jan 1st 2014 to Dec 31st 2015. Clinical characteristics at presentation, co morbidities, treatment pattern and in hospital outcomes were collected.A telephonic follow up was done [follow up duration varying from 6 months to 2 years].
Results: - A total of 4199 patients were admitted to CCU in the study period, of which 406 patients were enrolled which constituted 9.67% of the total admissions. The mean age was 84.24(±3.67) years.
The percentage of patients with heart failure was 36.45%. Main etiology for heart failure was ischemia (54.72%). HFpEF was seen in 51.74% of patients. 22.29 % patients had AF. Inhospital mortality among the patients with heart failure was 9.45%.Rehospitalisation rate was 18.9% while mortality on follow up was 8.1%. Among the patients with HFpEF and HFrEF, there was no significant difference in inhospital mortality, rehospitalisation and mortality on follow up.
Conclusion: : The high rates of ACS, HFpEF and AF among the elderly are highlighted, along with the high inhospital mortality, particularly in those who presented with severe LV systolic dysfunction.

Profile of Heart Failure among elderly

	HFpEF(%)	HFrEF(%)	P value
Mean age	84.1	85.27	0.095
Male:female	0.93	1.23	-
Diabetes	58.3	60.34	0.851
Hypertension	63.34	56.89	0.455
Ischemic heart disease	56.67	74.13	0.055
Chronic kidney disease	16.67	22.41	0.490
AF	20	18.96	0.910
Complete heart block	6.67	1.72	0.365
Coronary angiogram	11.66	3.44	0.071
Percutaneous coronary intervention	3.34	1.72	0.420
In hospital mortality	10	12.06	0.775
Rehospitalisation	20	15.52	0.814
Mortality on follow up	8.34	8.62	0.972

P547

Heart failure as the cause of more than 40% of dyspneas in an orthopedic surgery unit

P Losada Mora[1]; A M Alfonso Miguel Garrido Castro[1]; JL Carrillo Linares[1]; M Jimenez[1]; L Morcillo[1]; J M Garcia Pinilla[1]
[1]University Hospital Virgen de la Victoria, Cardiology, Internal Medicine, Malaga, Spain

Introduction: Consultations are a widely used resource between different units in a hospital. In particular, those from Orthopedic Surgery and Traumatology (OST) Unit are some of the most frequent.
Objectives: To analyze the most frequent consultations patients admitted to OST unit asked to a specific team of Cardiology and Internal Medicine physicians, and identify how many of them can be attributed to heart failure.
Material and methods: Descriptive analysis of the reasons for consultation on patients admitted to the OST Service who suffered some kind of medical decompensation that needed to be notified to Cardiology or Internal Medicine.
Results: From June 2008 to November 2014, 1486 consultations were sent from the OST Service to a team assigned to the control of medical pathologies, formed by professionals of Cardiology and Internal Medicine. The most common reason for consultation was "dyspnea" in 371 cases (25%), followed by "pluripathology control" in 163 (11%), "diabetes control" and "blood pressure", both with 124 (8.3% %) and 123 (8.3%) queries. The digestive pathology occupied 10.5% of the consultations, but these were specified according to the disease (diarrhea, nausea-vomiting or abdominal pain). 4% of the consultations were sent because of "analytic alterations". It was remarkable the absence of "fever" as a reason for consultation, which is frequent in other surgical units analyzed; this is because fever is valued in OST by the Infectious Diseases Service.
The team analyzed the meaning of the main reason for consultation, "dyspnea", as a term that was considered too nonspecific. The result was that 46.7% of the dyspneas were of respiratory origin, with the most frequent pneumonia (32%, of which 56% were nosocomial), noncondensing respiratory infection (26%), exacerbation of COPD (18%) and bronchospasm (16%).
41% of dyspnea corresponded to heart failure; 66% of the cases, the main factor inducing dyspnea was not clearly identified (most of the patients presented mixed respiratory and cardiologic episodes), while 13.6% of those with dyspnea presented excessive intravenous fluid therapy, 11.3% anemia secondary to the intervention, and another 11.3% was due to uncontrolled atrial fibrillation. The rest of dyspneas were mainly due to anxiety (4.7%) and pulmonary thromboembolism (2%). In 3,7% of the cases no dyspnea was observed.
Conclusions: One-fourth of the consultations for medical decompensation in patients admitted to OST correspond to dyspnea. Almost half of them correspond to heart failure, induced in a very high percentage by potentially preventable situations such as excessive intravenous therapy or anemia after the surgery. Besides, high

blood pressure and diabetes are cardiovascular risk factors frequently decompensated. We suggest that an early examination of diabetes, blood pressure and factors that could induce to heart failure, performed before the surgery, could be benefitial in terms of morbidity.

P548

Mortality and re-hospitalization in patients with new onset acute heart failure in a region of northern italy

D Pavan[1]; E Clagnan[1]; F Valent[1]; G Lardieri[1]; V Moretti[1]; L Massa[1]; C Fresco[1]; A Di Chiara[1]; P Pierluigi Lesizza[1]; L Zanier[1]; A Di Lenarda[1]
[1]Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy

Background: Our Regional Social and Health Information System (SISSR) provides reliable information on epidemiology, health care pathways and prognosis of cardiovascular diseases (CV). The objective of our analysis was to analyze the survival and the likelihood of short- and medium-term rehospitalization for heart failure (HF) among residents in our region in 2009-10.
Methods: The analyses were made by querying the SISSR using SAS Enterprise Guide 7.1. The new cases of HF in 2009-2010 were identified from the Hospital Discharge Diagnosis Codes of the residents in our region with first ICD-9-CM codes 398.91, 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13, 404.91, 404.93, 428.0-4 , 428.9. For the survival analysis SISSR was linked with regional Registry of Deaths. The follow-up ended 31/12/2015.
Results: In 2009-2010 there were 5963 admissions for HF (average rate of 2.41 per 1000 patient-years; range in the 5 Regional Health Authorities from 2.14 to 2.72). Hospital admission involved in 86% subjects ≥70 years. 82% of the pts were discharged from Medicine, 11% from Cardiology. Of 5963 pts hospitalized in 2009-10, 506 (8.5%) died during hospitalization. The 5457 discharged alive, 1970 (33%) were re-hospitalized (25% within 76 days from the first admission, 50% within 299 days, 75% within 805 days). At the end of 2015, of 5963 patients from the 2009-10 cohort, 1835 (31%, range 29% -34%) were still alive (25.4% among patients aged ≥ 70 years, 64% of those age <70 years). In the 5 regional Health Authorities survival was similar in pts ≥70 years, while there was a significant difference in pts <70 years. The survival curve of females (significantly older) was significantly worse than males. Conclusions:Our regional data warehouse provides useful information to plan educational activities and improvement of quality of care and clinical pathways. The trend of new admissions for HF is highly variable in the 5 regional Health Authorities, as well as it is clear a lot of room for improvement of post-discharge pathways. Also for this reason re-admissions and mortality are still high especially in older females.

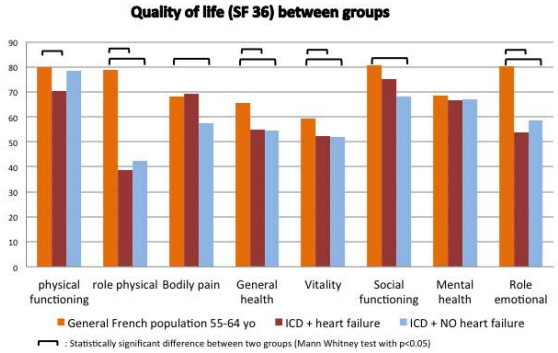
Impact of the implantation of a cardioverter defibrillator on quality of life in heart failure patients: preliminary results of the EDUC-DAI study

CM Maupain[1]; FP Pousset[1]; AHS Abid Saidi[1]; SS Staraci[2]; NB Badenco[1]; XW Waintraub[1]; GD Duthoit[1]; TC Chastre[1]; CH Himbert[1]; YDH Dagher-Hayek[1]; JF Fedida[1]; FHL Hidden-Lucet[1]; EG Gandjbakhch[1]
[1]AP-HP - Hospital Pitie-Salpetriere - Institute of Cardiology, Rhythmology Department, Paris, France; *[2]Centre de référence des maladies cardiaques héréditaires, Paris, France*

Funding Acknowledgements: Fédération Française de Cardiologie

Background: : The implantation of a cardioverter defibrillator (ICD) is associated with an impairment of quality of life. Quality of life in heart failure patients with an ICD is not well documented.
Objectives: To assess quality of life in heart failure patients implanted with ICD (with or without a cardiac resynchronization therapy) in a French tertiary center and involved in our educational therapeutic program.
Materials and Methods: Every patient receiving an ICD from September 2015 to July 2016 at Pitié Salpêtrière university hospital were included. This cohort comes from the EDUC-DAI study which evaluates the impact of an educational therapeutic program for ICD patients. Quality of life was assessed through the Short Form (SF 36) health status questionnaire completed 1 month after ICD implantation and before the first session of the program. Quality of life of ICD heart failure patient was compared to those without heart failure. It was then compared to the general French population aged from 55 to 64 years old.
Results: : Between September 2015 and July 2016, 80 patients completed the SF36 questionnaire. 46/80 (61%) had a clinical heart failure. The mean age of the heart failure patients was 63,4 +/- 10,1 years old. Mean left ventricular ejection fraction in the heart failure group was 29 +/- 8% and 34/46 (74%) benefited from a cardiac resynchronization therapy. Quality of life was significantly impaired in both groups compared to the general French population aged from 55 to 64 years old. Quality of life wasn't different between the heart failure group and the non heart failure group for the 8 domains of the SF 36 (Figure 1).
Conclusion: : In this cohort, ICD recipients have an impaired quality of life compared to the general French population whether or not they experience heart failure. This suggests that ICD implantation has a real impact in quality of life for all patients. Therapeutic education of patients can help them to develop coping skills.



Quality of life between groups

Short term health perception and psychological functioning in heart failure patients undergoing surgical left ventricle restoration and cardiac rehabilitation

E Callus[1]; E Quadri[1]; S Pagliuca[1]; E G Bertoldo[1]; G Frigerio[1]; V Milani[2]; L Maresca[3]; B Girardi[3]; C Tardio[3]; S Lucibello[3]; S Castelvecchio[4]; L Menicanti[4]; R Tramarin[3]
[1]IRCCS, Policlinico San Donato, Clinical Psychology Service , San Donato Milanese, Italy; *[2]IRCCS, Policlinico San Donato, Biostatistics Unit, San Donato Milanese, Italy*; *[3]IRCCS, Policlinico San Donato, Perioperative and Cardiac Rehabilitation Dept. , San Donato Milanese, Italy*; *[4]IRCCS, Policlinico San Donato, Adult Cardiac Surgery Dept., San Donato Milanese, Italy*

Background: Surgical left ventricular restoration (SVR) is a valuable therapeutic option for heart failure (HF) pts with ischemic cardiomyopathy (IC). For these pts health perception, psychological functioning and quality of life (QoL) are relevant outcome indicators.
Purpose: The aims of this study are to evaluate the short-term impact of SVR on health perception, anxiety, depression and QoL and to identify variables that could affect them.
Methods: SF-36 questionnaire and EuroQol for health perception, the Hospital Anxiety and Depression Scale (HADS) and the Minnesota Living with Heart Failure for quality of life, together with biographical data and information about lifestyle were administered to 100 consecutive HF pts with IC (78 males, mean age 65.5 ± 11) who underwent SVR in the last 3 yrs, followed by a comprehensive inpatient cardiac rehabilitation (CR) programme. All questionnaires were administered preoperatively (t0), and the EuroQol and HADS were administered also during admittance (t1) and discharge (t2) from cardiac rehabilitation. The average duration of hospitalization in cardiac surgery is 5-7 days, and 21 days in cardiac rehabilitation. Descriptive data are expressed as means (±1SD) for all continuous variables. Repeated-measures analysis is used to assess trend over time (T0 preoperatively, T1 admission in cardiac rehabilitation and T2 discharge from rehabilitation). Univariate linear regression analysis was performed to identify the variables associated with the variation defined as change from preoperative status to discharge from CR (n = 37) or as change from postoperative status to discharge from CR (n = 85) of the anxiety and depression scales. The analyses included continuous variables (preoperative EuroQol, preoperative NT-proBNP, ejection fraction, age) and categorical variables (sex and NYHA class).
Results: Analyses indicate significant changes in time in health perception and QoL ($p < 0.001$). There is an indication of improvement at discharge from CR in health perception (EuroQol) (Preop mean score 63.2 ± 23.1 and at discharge 81.3 ± 18.9). There is also a significantly decrease in the mean scores of anxiety after discharge from CR (mean score of anxiety 5.1 ± 4.4 to 2.4 ± 3.3 at discharge) ($p < 0.001$). The mean scores of depression was in the normal range at all times. At univariate analysis the variation of the levels of anxiety and depression, during hospitalization in cardiac surgery (t0 to t1) and cardiac rehabilitation (t1 to t2) were not associated to the medical variables and health perception.

Conclusions: These preliminary analyses indicate that HF pts undergoing SVR perceive an improvement in their health status following the SVR procedure. Interestingly, neither the medical variables, nor subjective health perception, were found to be correlated with levels of anxiety and depression. Qualitative data gathered from psychological sessions were used in order to make further inferences.

P551

Comparison of quality of life and perceived self-efficacy between caregivers of heart failure patients and caregivers of heart failure and chronic obstructive pulmonary disease patients.

SC Torres-Montiel[1]; V Pelaez-Hernandez[2]; A Orea-Tejeda[2]; B Robles-Uribe[2]; F Figueroa-Herrera[2]; D Gonzalez-Islas[2]; A Jimenez-Cepeda[2]; A Navarrete-Penaloza[2]; L Verdeja-Vendrell[2]; R Sanchez-Santillan[2]; GK Perez-Cortes[2]
[1]National Autonomous University of Mexico, Mexico City, Mexico; *[2]Instituto Nacional de Enfermedades Resporatorias Ismael Cosio Villegas, Heart Failure and Distress Respiratory Clinic, Mexico City, Mexico*

Introduction: Being a caregiver (CG) of a heart failure (HF) patient affects health negatively. It is thought that this impairment mainly depends on the CGs' characteristics and not on the patients'. However, HF patients often have comorbidities such as chronic obstructive pulmonary disease (COPD), and there are no studies that describe if the CGs' health characteristics differ between CGs of HF patients and CGs of HF + COPD patients. Purpose. To compare the health-related quality of life and the perceived self-efficacy of CGs of HF patients and CGs of HF + COPD patients.
Methods: This study included 18 CGs of HF patients (G1) and 18 CGs of HF + COPD patients (G2), which completed the SF-12 questionnaire and the Perceived Self-efficacy in Caregivers of Chronically Ill Scale. The first includes 8 dimensions: Physical functioning, Social functioning, Role-physical, Role-emotional, Mental health, Energy/vitality, Pain and General health perception. The second classifies perceived self-efficacy as low, moderated and high. Comparisons between groups were made by unpaired Mann-Whitney U test since the data did not have a normal distribution. Results. There were no significant differences in age and sex between the two groups (G1: 55.50 ± 12.22 years, 77.8% women; G2: 55.83 ± 12.90 years, 77.8% women). There were significant differences in the General health perception (XG1=66.39 ± 21.20, XG2=50 ± 27.11; U=96, $p < 0.05$) and Mental health (XG1=77.03 ± 21.62, XG2=64.81 ± 16.41; U=99, $p < 0.05$) SF-12 dimensions, and also in the total score of perceived self-efficacy (XG1=100.44 ± 8.64, XG2=80.39 ± 28.32; U=85, $p < 0.05$). For both tests, a lower score indicates more impairment. Conclusions. CGs of HF + COPD patients have higher impairment in their general and mental health, and they perceive themselves less efficient. For this reason, treatment that offer them caregiving and solving problems skills should be priority, as it could improve their health and self-efficacy.

P552

Comparison of anxiety, depression and psychological stress between heart failure and chronic obstructive pulmonary disease patients with better and poorer performance of the six-minute walk test

SC Torres-Montiel[1]; A Orea-Tejeda[2]; V Pelaez-Hernandez[2]; F Figueroa-Herrera[2]; B Robles-Uribe[2]; D Gonzalez-Islas[2]; GK Perez-Cortes[2]; L Verdeja-Vendrell[2]; A Navarrete-Penaloza[2]; A Jimenez-Cepeda[2]; R Sanchez-Santillan[2]
[1]National Autonomous University of Mexico, Mexico City, Mexico; *[2]Instituto Nacional de Enfermedades Resporatorias Ismael Cosio Villegas, Heart Failure and Distress Respiratory Clinic, Mexico City, Mexico*

Introduction: Psychosocial factors such as anxiety, depression and psychological stress affect the prognosis of patients with heart failure and chronic obstructive pulmonary disease (HF + COPD). Performance of the Six-Minute Walk Test (6MWT) has been used for estimating this prognosis. Literature states that patients who walk less than 300 meters have a worse prognosis. Purpose. To compare the anxiety, depression and psychological stress scores of those patients with HF + COPD who walked less or more than 300 m in the 6MWT.
Methods: This study included 31 patients with HF + COPD, which completed the Hospital Anxiety and Depression Scale (HADS) and the Perceived Stress Scale. The HADS questionnaire is a reliable self-rating scale that classifies anxiety and depression into three ranges: normal, mild-moderate and severe. The Perceived Stress Scale measures the frequency of exposure to stressful situations during the past month. Comparisons between groups were made by unpaired Mann-Whitney U test since the data did not have a normal distribution. Results. The sample was divided into two groups based on the walking distance of the 6MWT: Group 1 (G1) walked less than 300 m (163.19 ± 82.99 m) and Group 2 (G2), more than 300 m (414.13 ± 91.77 m), 51.6% of the patients walked less than 300 m (G1: n=16, G2: n=15). There were no significant differences in age and sex between the two groups (G1: 69.38 ± 14.52 years, 68.8% women; G2: 65.07 ± 13.57 years, 53.3% men). There were significant differences in anxiety scores (XG1=6.19 ± 4.05, XG2=2.53 ± 2.66; U=52, $p < 0.01$). Although there were no significant differences in depression and psychological stress, G1 had higher depression (XG1=6.19 ± 3.97, XG2=4 ± 3.25) and perceived stress scores (XG1=24.75 ± 5.13, XG2=21 ± 5.60).
Conclusions: In this sample, patients that walk less than 300 m in the 6MWT have higher scores of anxiety. For this reason, treating anxiety symptoms is essential, as it could improve the patients' prognosis and quality of life. Although these are preliminary results from a small sample, we will continue working on it.

P553

Factors associated with self-care behaviours in heart failure: a systematic review of european heart failure self-care behaviour scale (EHFScBS) studies

N Natasa Sedlar[1]; M Lainscak[2]; J Martensson[3]; A Stromberg[4]; T Jaarsma[5]; J Farkas[2]
[1]National Institute of Public Health, Ljubljana, Slovenia; *[2]General Hospital Murska Sobota, Department of Internal Medicine, Murska Sobota, Slovenia*; *[3]Jönköping University, School of Health and Welfare, Department of Nursing, Jönköping, Sweden*; *[4]Linköping University, Department of Medical and Health Sciences, Linköping, Sweden*; *[5]Linköping University, Faculty of Health Science, Department of Social and Welfare Studies, Linköping, Sweden*

Funding Acknowledgements: Heart failure epidemiology in Slovenia: prevalence, hospitalizations and mortality (J3-7405) financially supported by the Slovenian Research Agency.

Background: Due to the important role of self-care in the comprehensive management of patients with heart failure (HF), The European Heart Failure Self-care Behaviour Scale (EHFScBS) was developed and tested to measure behaviours that HF patients perform to maintain daily life activities, healthy functioning, and wellbeing. Available evidence shows individual differences in patients' engagement in HF self-care behaviours, but the findings regarding the influence of personal and environmental factors on HF self-care remain inconclusive.
Aims: We reviewed literature to evaluate importance of factors associated with HF self-care behaviours as measured by the EHFScBS.
Methods: Following PRISMA guidelines, PubMed, Scopus and ScienceDirect were searched for studies using EHFScBS. Associating factors of HF self-care, obtained in observational studies were qualitatively synthesised to explore association levels of most commonly addressed factors.
Results: From total of 1357 potentially eligible abstracts screened 74 full-text papers were retrieved and reviewed to include 30 studies in the qualitative synthesis. A diverse range of personal and environmental factors associated with self-care behaviours in HF patients was identified (71 different factors in 18 sub-categories and 6 categories). Association levels between the EHFScBS score and seven factors: age (reported in 11 studies), health-related quality of life (8), gender, education, NYHA class (7), depressive symptoms (6) and LVEF (5), were most often reported, generally indicating negligible or low associations. However, consistent significant association ($p < 0.05$, demonstrated in ≥ 75 % of studies) between HF self-care behaviours and depression was found, while NYHA class and health-related quality of life showed non-significant associations with HF self-care behaviours in most of the studies.
Conclusion: Many factors were analysed for potential associations but only depression was consistently associated with EHFScBS score.

EXERCICE TESTING AND TRAINING

Physical activity of STEMI patients after cardiac rehabilitation.

S Borodzicz[1]; P Balsam[1]; M Peller[1]; R Glowczynska[1]; L Koltowski[1]; P Lodzinski[1]; KJ Filipiak[1]; M Grabowski[1]; G Opolski[1]
[1]Medical University of Warsaw, 1st Chair and Department of Cardiology, Warsaw, Poland

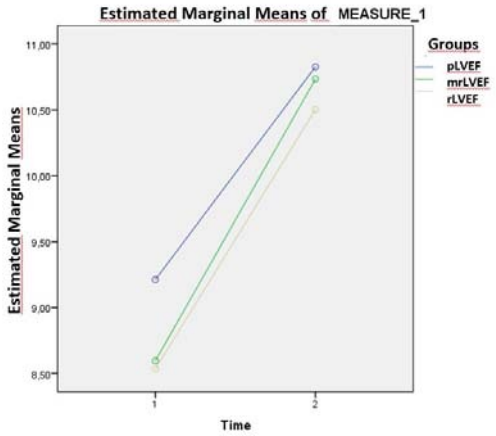
Introduction: While there is a common agreement regarding the efficiency of cardiac rehabilitation (CR) in improving the prognosis of patients after ST-elevated myocardial infarction (STEMI), improving physical activity (PA) after CR is another important goal in STEMI patients.
Purpose: The aim of our study was to estimate the levels of PA in STEMI patients after CR, also known as the third stage of CR and to analyse possible association of both early and late factors of CR and levels of PA in the future.
Methods: It was a retrospective analysis of STEMI patients who underwent invasive coronary angiography and percutaneous coronary intervention (PCI) after STEMI followed by CR in years 2007-2013. The group consisted of 141 patients; the average time of follow-up was 30 ± 14 months (max. 96 months). Information on patients' current activity was assessed with validated International Physical Activity Questionnaire (IPAQ), which takes into consideration time per day and week spent on vigorous (e.g. lifting heavy weights, aerobics) and moderate (riding bike, playing volleyball) activity, walking and sitting. The analysed factors of further physical activity were: gender, age, body mass index (BMI), hypertension, diabetes mellitus

type 2, atrial fibrillation, history of previous MI or stroke, ejection fraction, type of infarction related artery, localization of MI, peak levels of troponin I (TnI), creatine kinase-MB (CK-MB) mass, initial metabolic equivalent of task score (METs), METs after CR, improvement of METs, number of training sessions (12 or 24).
Results: In the analysed group of patients 97.89% of them maintained any form of physical activity. The percentages of patients classified to the high, moderate and low/absent level of activity groups were 20.57% (n = 29), 59.57% (n = 84) and 19.86% (n = 28), respectively. No statistically significant relation between the factors and physical activity was observed.
Conclusions: The physical activity long after CR is maintained by the majority of patients. Most commonly patients maintain the moderate PA.

P555
Response to cardiac rehabilitation: does left ventricle ejection fraction matter?

M Marta Braga[1]; A Rocha[1]; H Nascimento[1]; M Tavares-Silva[1]; R Pinto[1]; G Pestana[1]; P Araujo[1]; A Nunes[1]; V Araujo[1]; F Parada-Pereira[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Introduction: Development of left ventricular systolic dysfunction (LVSD) in acute coronary syndrome (ACS) patients significantly worsens their prognosis. In addition, LVSD is associated with diminished functional capacity (FC). Even though CRP is an essential tool for secondary prevention, some argue against an early cardiac rehabilitation program (CRP) referral of patients with LVSD.
Purpose: The aim of this study was to evaluate baseline clinical characteristics and compare the response to CRP of patients according to left ventricle ejection fraction (LVEF).
Methods: We performed a retrospective analysis of prospectively collected data on a cohort of patients referred to CRP after an ACS. Patients were divided into three groups: Preserved LVEF (pLVEF): LVEF≥50%, mid-range LVEF (mrLVEF): LVEF 40-49% and reduced LVEF (rLVEF): LVEF < 40%. FC was assessed using metabolic equivalents (METs) achieved at a standard exercise test using Bruce protocol before and after CRP. We used ANOVA analysis and a mixed between-within analysis of variance.
Results: Of a total 586 patients, 370 (63.1%) had pLVEF, 115 (19.6%) had mrLVEF and 101 (17.3%) had rLVEF. Mean age was no different between groups (pLVEF: 53.9 ± 10.0, mrLVEF: 53.8 ± 9.6, rLVEF: 54.9 ± 10.5, p = 0.601) and most patients were males in all groups. Prevalence of diabetes, hypertension, active smoking, and dyslipidaemia were no different between groups. The main diagnosis in pLVEF patients was acute myocardial infarction (AMI) without ST elevation (51.4%) while in mrLVEF and rLVEF patients was AMI with ST elevation (73.0% and 76.2%, respectively). Coronarography showed obstructive disease of one coronary artery in majority of patients in all groups and percutaneous coronary intervention was the treatment of choice in pLVEF, mrLVEF and rLVEF groups. Baseline FC was better in pLVEF patients (9.2 ± 2.3 METs), followed by mrLVEF (8.6 ± 2.3 METs) and rLVEF patients (8.5 ± 2.3 METs). After CRP, all groups significantly improved their FC (pLVEF: 10.8 ± 2.1 METs, mrLVEF: 10.7 ± 2.0 METs, rLVEF: 10.5 ± 2.1 METs, within-groups partial Eta square 0.28, p < 0.001). Comparing between-groups, improvement of FC was associated with LVEF, being mrLVEF patients the group that showed the best response to CRP (p = 0.041).
Conclusion: FC ameliorated after CRP in all groups of patients despite different LVEF. Patients with mrLVEF were those who presented a better responder to CRP. Other studies are needed to further confirm this data in order to reinforce the referral of patients to CRP in spite of LVEF.



Response to CRP according to LVEF

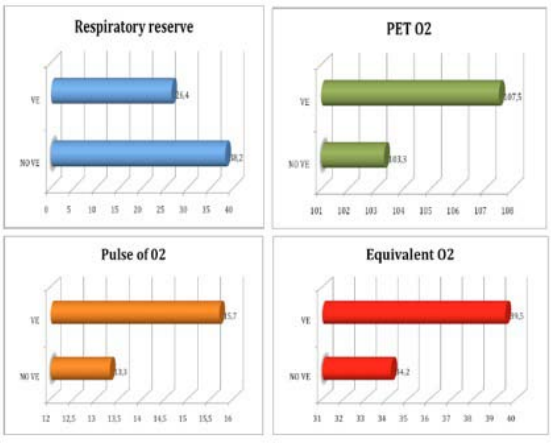
Determinants of frequent ventricular extrasistole during ergometry with oxygen consumption in patients with coronary disease

N G Uribe Heredia[1]; J Balaguer Recena[2]; H Alvaro Fernandez[1]; L Gil Fraguas[1]; LG Piccone Saponara[3]; R Arroyo Espliguero[2]; S Moreno Reviriego[2]; E Novo Garcia[2]; S Garcia Ortego[2]; E Diaz Carballo[2]; I Rodriguez Guinea[2]; JL Garcia Gonzalez[2]; ME Jimenez Martinez[2]; B Tarancon Zubimendi[2]; MA San Martin Gomez[2]
[1]*Guadalajara University Hospital, Cardiac Rehabilitation Unit, Guadalajara, Spain*; [2]*Guadalajara University General Hospital, Cardiology Department, Guadalajara, Spain*; [3]*Hospital General de Ciudad Real, Nefrology, Ciudad Real, Spain*

Introduction: In patients with coronary artery disease, ventricular arrhythmias during exercise may indicate a two to eightfold increase in the probability of cardiac death. However, factors related to ventricular extrasystoles (VE) other than ischemia are not known.
Material and Methods: Cross-sectional study. 63 patients undergoing ergometry with oxygen consumption, with ischemic heart disease who were discharged from an acute coronary event who underwent cardiac catheterization and coronary revascularization between 2 and 3 months before the test were included, being excluded those with a positive result for myocardial ischemia. Frequent VE were considered in those that were at rest not observed in the VE and during any stage of the exercise test (based on previous work by Schweikert RA). manifested a frequency of seven or more VE/minute, isolated, in pairs, bigeminism or ventricular trigeminism. Demographic variables, blood analysis, characteristics coronary and angioplasty, electrocardiographic, echocardiographic, cardiovascular risk factors and other comorbidities were evaluated. Statistical analysis SPSS 20. Qualitative variables were evaluated by X^2. The quantitative are expressed as means +/-SD, evaluated with student T and the non-parametric with U Mann-W. Statistical significance p < 0.05.
Results: 63 patients analyzed; 14(22.2%) presented exercise-induced VE. Mean age 57.8years; 90.5%men, 6.3%bronchopathy moderate, 49.2%hypertension, 20.6%diabetics, 63.5%dyslipemic, 50.8%smokers, mean ejection fraction 56.3%. There were significant differences between the two groups; In the thickness of the interventricular septum, a mean 10.4mm in the group that did not present VE (group1) and 12mm in the patients Induced the VE (group2), p = 0.01. Maximum heart rate reached during the exercise test, group1 a mean 133.3bpm, while in group2 120.4bpm, p = 0.03. Pulse of oxygen was lower in group1 a mean 13.3ml/beat was obtained and in group2 15.7ml/beat, p = 0.03. RER achieved, group1 reached an RER 1.04, while group2 1.1, p = 0.03. The respiratory reserve, being higher in group1 with an average 38.2% and in group2 26.4%, p < 0.01. The pressure of O2 at maximum load is lower in group1 with a mean 103.3mmHg and in group2 107.5mmHg, p = 0.02. The equivalent O2 is lower in group1 with a mean 34.2mmHg and in group2 39.5mmHg, p < 0.01. HDL cholesterol, in group1 38.7mg/dl and in group2 32.4mg/dl, P=0.02. The creatinine levels were lower in group1 with 0.96mg/dl and in group2 1.1mg/dl, p = 0,02.
Conclusions: In our study, the group of patients who had frequent VE induced during the exercise test had interventricular Septum thickness, reached a lower cardiac frequency at maximum load, a lower maximum pulse O2 rate, RER on higher maximal load, higher respiratory reserve consumption, higher oxygen pressure at maximal load, higher oxygen equivalent, lower HDL cholesterol levels and higher creatinine levels than the group of patients who did not present VE during the exercise test.

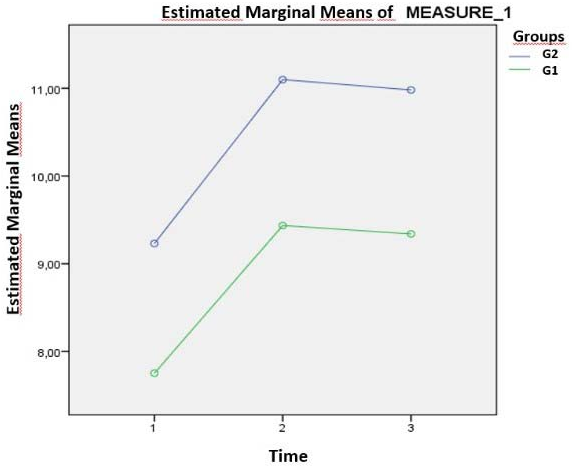


P557

Cardiac rehabilitation in older patients: long-term effects

M Marta Braga[1]; A Rocha[1]; H Nascimento[1]; R Pinto[1]; G Pestana[1]; M Tavares-Silva[1]; P Araujo[1]; A Nunes[1]; V Araujo[1]; F Parada-Pereira[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Introduction: It has been acknowledged that elderly may also benefit from cardiac rehabilitation programmes (CRP). However, the long-term impact of controlled exercise training in older patients is not completely clear.
Purpose: To compare patients aged ≥65 years with those < 65 years concerning baseline clinical profile, functional capacity (FC) and the long-term response to CRP.
Methods: We performed a retrospective analysis of prospectively collected data on a cohort of patients referred to CRP after an acute coronary syndrome (ACS). Patients were divided into two groups, G1: age≥65 years and G2: age < 65years. FC was assessed using metabolic equivalents (METs) achieved in standard exercise test performed in 3 moments, T1: baseline; T2: at the end of CRP; T3: after 12 months of follow-up. A mixed between-within analysis of variance was used to allow comparison between groups and at different time periods.
Results: Of a total 469 patients, 73 patients were aged ≥65 years. Mean age was 69.1 ± 3.9 years in G1 and 51.3 ± 7.9 years in G2. In both groups, most patients were male. Diabetes was more prevalent in G1 (37.3% vs 13.5%, p < 0.001) while active smoking was more frequent in G2 (58.0% vs 29.3%, p < 0.001). Mean LDL-cholesterol was higher in G2 (125.0 ± 37.7 mg/dl vs 105 ± 32.8 mg/dl, p < 0.001). The main diagnosis in G1 was acute myocardial infarction (AMI) without ST elevation (50.9%) and in G2 was AMI with ST elevation. In both G1 e G2, obstructive disease of one coronary artery was the most prevalent finding at coronarography and percutaneous coronary intervention was the treatment of choice. Patients from the 2 groups improved their FC between T1 and T2, and showed a nonsignificant decrease between T2 and T3 (T1: G1: 7.8 ± 1.9 METs vs G2: 9.2 ± 2.2 METs; T2: G1 9.4 ± 1.8 METs vs. G2: 11.1 ± 2.0 METs; T3: G1: 9.3 ± 1.8 METs vs G2 11.0 ± 2.2 METs, within-groups partial Eta square 0.28, p < 0.001). Comparing between-groups, FC of G2 was better than G1 at all 3 moments (partial Eta square 0.09, p < 0.001).
Conclusion: Although FC of older patients was inferior to younger patients, we demonstrated that the benefit of CRP in elderly is sustained one year after ACS. This data reinforces the need for more referral of this group of patients for a structured CRP.



Response to CRP in older patients

P558

Exercised-based cardiac rehabilitation in heart failure patients with mid-range ejection fraction after myocardial infarction

I Burazor[1]; P Seferovic[2]; S Dodic[3]; Y Adler[4]; Z Cosic[5]; R Babic[6]; M Moraca[5]; A Kovacevic[5]; B Milovanovic[5]
[1]*Institute for rehabilitation, Medical Faculty, Cardiology, Belgrade, Serbia*; [2]*Medical Faculty, University of Belgrade, Clinical Center of Serbia, Belgrade, Serbia*; [3]*Institute of Cardiovascular Diseases of Vojvodina, Sremska Kamenica, Serbia*; [4]*Sheba Medical Center, Tel Aviv, Israel*; [5]*Institute for rehabilitation, Belgrade, Serbia*; [6]*Institute for Cardiovascular Diseases Dedinje, Belgrade, Serbia*

Heart failure is a major cause of morbidity, mortality and re- hospitalizations and is highly prevalent in myocardial infarction survivors. Cardiac rehabilitation based on exercise training and heart failure self-care counseling have each been shown to improve clinical status and clinical outcomes. We aimed to evaluate the usefulness of exercise based in house cardiac rehabilitation in patients with heart failure with mid-range ejection fraction (HFmrEF) after myocardial infarction.
Patients and methods: Out of 1654 patients who were admitted to our three weeks in- hospital secondary prevention program – exercised based cardiac rehabilitation, we analyze a total of 89 patients who were admitted early after coronary revascularization (percutaneus coronary interventions or coronary bypass surgery) with HFmrEF. The majority of patients were males (66%).We noted risk factors and co morbidities. Patients were selected for exercise training after six minute walking testor exercise stress test (cardiopulmonary dominantly to evaluate unexpected exertional dyspnea). After 3 weeks in hospital cardiac rehabilitation the patients were re-tested.
Results: The major comorbidities in our patient population were as follows: hypertension, diabetes and dyslipidemia. Six minutes walking test was performed and the total distance walked ranged from 120 to 440 meters and the beginning of the program. Patient had 7 -days a week training program. After the 3 weeks in hospital exercise rehabilitation the improvement in the test was ˜39%. Cardiopulmonary test showed also improvement of functional capacity.We noted several rhythm disturbance complications by telemetry (VT, VES, SVES, and new on set of AF). Also we noted silent ischemia in 2% after CABG with ST segment depression detected by telemetry. None had acutisation of heart failure (with peripheral edema and congestion). All patients fulfilled cardiac rehabilitation program.
Conclusions: Supervised multidisciplinary cardiac rehabilitation program, including an individualized exercise component is safe and can improve functional status and exercise tolerance in patient with HFmrEF after myocardial infarction.

P559

Linear correlation between cardiac output and oxygen uptake at peak exercise at different heart failure stages.

A Del Torto[1]; N Corrieri[1]; P Gentile[2]; C Vignati[3]; G Cattadori[4]; S Paolillo[3]; P Agostoni[3]
[1]*University of Milan, Milan, Italy*; [2]*University of Trieste, Trieste, Italy*; [3]*Cardiology Center Monzino IRCCS, Milan, Italy*; [4]*IRCCS Multimedica of Milan, Milan, Italy*

Introduction: In heart failure (HF) patients, alterations in central haemodynamics, peripheral vasodilatory capacity, intrinsic skeletal muscle changes, pulmonary factors, iron deficiency, anaemia and overall conditioning status can all impair effective oxygen delivery and utilization. A reduced cardiac output (CO) response during exercise is an early and major limiting factor to exercise performance in HF patients. According to Fick's law, CO is directly proportional to oxygen consumption (VO2) and inversely proportional to arteriovenous oxygen difference (Δ(a-v)O2). However in HF patients Δ(a-v)O2 shows a relevant interpatient variability and the role of the different peripheral mechanisms in determining exercise performance may vary at different stages of the disease.
Purpose: To analyze the correlation between peak exercise VO2, CO and Δ(a-v)O2 at different stages of HF.
Methods: We retrospectively analyzed data of 278 consecutive stable ambulatory HF patients (NYHA II-III) who performed a maximal cardiopulmonary exercise test with simultaneous CO measurement by inert gas rebreathing technique. We evaluated resting hemoglobin of all patients and in a subset of them also biomarkers of iron metabolism. Iron deficiency was defined as serum ferritin concentration < 100 μg/L or between 100 and 300 μg/L with transferrin saturation < 20%.
Results: A linear regression model demonstrated the following equation: CO = 5.3 x VO2 + 1.13 (r^2=0.705, p < 0.001). We analyzed the correlations between peak CO and peak VO2 grouping patients according to exercise limitation (% achieved of predicted peak exercise VO2): Group 1 consisted of 101 patients with peak VO2 < 50% of predicted; Group 2 of 89 patients with peak VO2 ≥50% < 65% of predicted peak VO2; Group 3 of 88 patients with peak VO2 ≥65% of predicted. Group 1 patients had the lowest peak exercise CO and Δ(a-v)O2. Group 2 patients achieved a significantly lower peak exercise CO when compared to Group 3. We observed a linear relationship between VO2 and CO at peak exercise in Group 1 (r^2=0.381, p < 0.001), the strongest in Group 2 (r^2=0.756, p < 0.001) and Group 3 (r^2=0.744, p < 0.001). Several reasons may be responsible for the lower Δ(a-v)O2 observed in Group 1. Hemoglobin was on the average lower in Group 1 than in Group 2 and 3, but, it cannot be considered the only cause; in a small subset of patients, we finally observed a non-statistically significant trend (p = 0.059) toward a greater prevalence of iron deficiency in Group 1 (86%) compared to Group 2 (57%) and Group 3 (53%). Other reasons could be impaired peripheral vasodilatory capacity and intrinsic skeletal muscle changes.
Conclusions: The peripheral component of peak VO2 seems to be multifactorial and more determinant in patients with more severe HF, while the haemodynamic

component seems to be the major determinant of peak VO2 in patients with less severe HF.

Effect of pedometer-based walking intervention on functional capacity and neurohumoral modulation in patients with chronic heart failure: study protocol for a multicentre randomized controlled trial

M Michal Siranec[1]; T Vetrovsky[2]; V Bunc[2]; A Linhart[1]; J Belohlavek[1]
[1]First Faculty of Medicine and General Teaching Hospital, Second Internal Clinic – Clinic of Cardiology and Angiology, Prague, Czech Republic; *[2]Charles University of Prague , Faculty of Physical Education and Sport, Prague, Czech Republic*

Background: Regular physical activity is recommended in patients with chronic heart failure to improve their functional capacity. Walking is a popular, effective and safe form of physical activity and pedometers have shown potential to increase walking across a range of chronic diseases. It is not known whether a pedometer-based intervention improves functional capacity and neurohumoral modulation in heart failure patients.
Methods: The project is designed as a multicentre randomized controlled trial, with follow-up at 6 and 12 months. Physically inactive participants (n = 200) with chronic heart failure (with both reduced and preserved ejection fraction) will be randomly assigned to intervention or control arms.
The six-month intervention will consist of an individualized pedometer-based walking program with weekly step goals, monthly face-to-face sessions with the physician, and monthly telephone calls with the research nurse. The intervention will be based on effective behavioural principles (goal setting, self-monitoring, personalized feedback).
The primary outcome is the change in a 6-minute walk distance at 6 months. The secondary outcomes include changes in serum biomarker levels, pulmonary congestion assessed by lung ultrasound, average daily step count measured by accelerometry, anthropometric measures, depression symptoms, health-related quality of life, self-efficacy, and MAGGIC Risk Score.
Discussion: To our knowledge, this is the first study to evaluate a pedometer-based walking intervention in patients with chronic heart failure. The study will contribute to a better understanding of physical activity promotion in heart failure patients as well as to informing future physical activity recommendations and heart failure guidelines.

Influence of a physical exercise program over functional capacity of patients with artificial pacemakers

LEONARDO Lopes Do Nascimento[1]; TSV Jardim[1]; LAB Sa[1]; IPM Garcia[2]; AS Oliveira[3]; AMC Lima[4]; PCBV Jardim[1]
[1]Federal University of Goias, Hypertension League, Goiania, Brazil; *[2]State University of Goias, Physical Therapy, Goiania, Brazil*; *[3]Salgado de Oliveira University , Physical Therapy, Goiania, Brazil*; *[4]Santa Casa Hospital, Goiania, Brazil*

Patients with pacemakers are prone to functional capacity limitations despite the disease that lead to the device implantation. Cardiac Rehabilitation programs addressed to improve functional capacity of this group are rare. The aim of the present study was assess functional capacity of subjects with pacemakers after 12 weeks of physical exercise program. The sample included patients with pacemakers that were divided in two groups with 10 subjects each: control group (CG) and exercise group (EG). The patients performed an exercise test (ET) to plan the exercises and a six-minute walk test (6MWT) to evaluate initial and final functional capacity. The EG program frequency was 3 times a week and included: 5′ warming up, 40′ conditioning in treadmill (moderate intensity) and 5′ of cooling down; the CG remained in its usual activities. The CG sample was mainly female (70%), with mean age of 62,7 (±8,32) years while the EG was predominantly male (70%), mean age 64,20 (± 6,25). The groups were similar in the beginning regarding to functional capacity (table 1). The covered distance in the 6MWT (D6MWT) from the CG was 506,90m ± 67,08 in the first evaluation and 532,80m ± 89,89 in the second (p = 0,14). The D6MWT from the EG was 536,10m ± 100,54 e 590,40m ± 67,97, respectively (p = 0,007). The EG increased the covered distance in 54,30m ± 49,14. During the training period no complications prevented the protocol completion. In conclusion a supervised exercise program is safe and promotes improvements in the D6MWT performance and functional capacity in patients with cardiac pacemakers.

Comparison between the D6MWT			
Variables	1ª Evaluation	2ª Evaluation	p*
Control	506,90 ± 67,08	532,80 ± 89,89	0,14
Exercise	536,10 ± 100,54	590,40 ± 67,97	0,007
p**	0,35	0,09

Real-time monitoring of hemodynamic response during resistance exercise in cardiac surgery patient

J-H Jung-Hyun Choi[1]; B-J Lee[1]; M-J Shin[1]
[1]Busan National University Hospital, Busan, Korea Republic of

Object: Coronary artery bypass grafting (CABG) is a surgery that improves blood flow to the heart for the patient who have severe coronary artery disease. After that surgery, the patient should be treated in intensive care unit (ICU). During that period, physical functioning will be impaired. Physical therapy interventions delivered in the ICU can reduce these impairments, but the safety is not still established especially to the patient who received CABG. We monitored the patients using a software during exercise and this is the first attempt in Korea.
Method: 4 patients who received CABG, were extubated, had hemodynamic stability and proper awareness to cooperate were enrolled to exercise. A low-intensity resistance exercise was comprise of 3 sets of isokinetic knee extension, 10 times per each set, with 2-Kg sandbag at the patient's ankle. We use the software named Datex-Ohmeda S/5 Collect to collect records of vital signs from B650 monitoring system. (Fig 1)
Result: All four patients had the low intensity resistance exercise safely in ICU at post-operative day 3. In the patient 1, vital signs during exercise were as follow: at the resting period, blood pressure (BP) was 137.93 ± 1.02/84.98 ± 0.62 mmHg (mean BP : 103.39 ± 0.75 mmHg). At the 1st, 2nd and 3rd exercise period, BP were slightly increased to 142.35 ± 0.67/87.96 ± 0.30 mmHg, 142.42 ± 0.91/88.76 ± 0.33 mmHg, 144.73 ± 0.90/82.29 ± 0.56 mmHg, respectively. The BP was decreased to 140.15 ± 0.77/85.21 ± 0.44 mmHg at recovery period. Baseline heart rate (HR) was 78.83 ± 0.55 beats/minute, increased to 80.38 ± 1.15 beats/minute at exercise period and decreased to 77.15 ± 0.63 beats/minute at recovery. The blood oxygen saturation level (SpO2) was maintained, between 97.95 ± 0.13% and 98.51 ± 0.02%. The patient did not complained of chest pain, dyspnea, excessive fatigue, and other symptoms during the entire period.
Discussion: Exercise for critically ill patients in ICU is important and necessary, but physicians were passive to prescribe exercise because of safety issue by this time. But using this type of monitoring system, we can monitor real-time vital signs during interventions. In future, well-designed randomized study involving more participants may be necessary to confirm the safety and effectiveness of exercise during ICU hospitalization and early post-operative days.

P563

Cardiac rehabilitation after sudden cardiac arrest in patients with left ventricular systolic dysfunction

V Veronica Angela Rial Baston[1]; R Dalmau Gonzalez-Gallarza[1]; FJ Irazusta Cordoba[1]; P Meras Colunga[1]; O Gonzalez Fernandez[1]; SO Rosillo Rodriguez[1]; AM Iniesta Manjavacas[1]; RA Mori Junco[1]; CA Alvarez Ortega[1]; L Rodriguez Sotelo[1]; JM Garcia De Veas[1]; A Rivas Perez[1]; A Velez Salas[1]; A Castro Conde[1]; JL Lopez Sendon[1]
[1]University Hospital La Paz, Cardiology, Madrid, Spain

Background and objectives: Patients (P.) with left ventricular systolic dysfunction (LVSD) benefit from close monitoring, which can be provided in cardiac rehabilitation programs (CRP). However, information is still missing regarding its effectiveness and safety in special features such as sudden cardiac arrest (SCA). We aimed to describe the impact of CRP on these patients (P.).
Methods: We studied 29 P. with low ejection fraction (EF) (defined as EF<51 %) who were resuscitated from cardiac arrest and then referred to a CRP between May 2006 and October 2014. An echocardiogram and a treadmill test were performed at the beginning and at the end of the program (Pr.) to evaluate respectively the EF and the exercise capacity (EC). The Pr. included supervised exercise training and comprehensive disease-related self-care counseling. Results: 86.2% were male with a mean age of 53.9 ± 11.3 years. The most frequent reason for their inclusion in the CRP was an ST-elevation acute myocardial infarction (AMI) in 24 P. (88.9%), followed by non-ST elevation AMI in 2 P. (7.4%) and chronic ischaemic heart disease in 1 P. (3.7%). 10.3% needed inotropes or an intra-aortic balloon pump during

hospitalization and 3 P. were implanted with an ICD before starting the Pr. The initial mean EF was 39.5% and EC measured in METs was 7.0 ± 2.7. There were no complications in any of the P. and only one of them left the Pr. prematurely. Eighteen P. (75%) experienced an improvement in functional capacity of at least 2 METS (mean EC increase in absolute terms: 2.7 ± 1.1 METs), 2 P. (11.1%) normalized their ventricular function and the percentage of P. with severe LVSD was reduced from 13.8% to 5.6% (p = 0.02). The results of the Pr. are shown in table 1.
Conclusion: Cardiac rehabilitation can be safely implemented in P. with LVSD after SCA. Therefore, we should not be hesitant to refer these P. to a CRP as they can benefit from exercise capacity improvement and lifestyle correction, which in turn will help to improve their cardiovascular outcomes.

Results of the program

	At the beginning of the Pr.	At the end of the Pr.	p
Smoking	22 patients (75.9%)	3 patients (14.3%)	p = 0.05
HbA1c	8.1	7.3	p = 0.3

Background: The favorable effects of a combined exercise program (CEP) in patients with heart failure (HF) are established in the literature. There are controversies if these beneficial effects are due to the improvement in left ventricle diastolic function (LVDF) with the exercise. The aim of this study was to evaluate the effect of CEP on LVDF assessed by echocardiogram and verifies if the LVDF is associated with improvement in the quality of life (QOL) and functional capacity (FC) of these patients.
Methods: Randomized clinical trial that included 42 patients with HF and reduced ejection fraction (< 50%), older than 18 years divided into two groups matched for age and sex: Control group n = 20: not subjected to the practice of EFC. Intervention group n = 22: underwent supervised CEP, composed of aerobic exercise supplemented by resistance exercise 3 times a week for 12 weeks. The two groups underwent initially and after 12 weeks for clinical evaluation, 12-minute walk test to assess the FC, transthoracic echocardiography and assessment of QOL by the SF-36 questionnaire. The diastolic function was assessed by mitral annulus velocities on tissue Doppler, mitral inflow patterns and indexed atrium volume in the absence of significant mitral reflow. Statistical analysis was performed using test "t" of the results of the differences between the pre and post moments of the protocol comparing the two groups, or Mann Whitney test for data with non-normal distribution. Correlation test was used for variable associations of the same group. Results: There was no difference in diastolic function variables between the groups and no correlation with QOL and CF. The Intervention Group, compared to Control Group, showed significant improvement at the end of research in the dyspnea (p = 0.01) and chest pain (p = 0.02) symptoms, improvement in the FC (p < 0.001) and in four of the eight dimensions of QOL questionnaire: functional capacity (p < 0.001), physical limitation (p = < 0.001), general health (p < 0.001) and vitality (p < 0.001).
Conclusion: Supervised CEP of 12 weeks was able to promote favorable impact on symptoms, CF and QOL in patients with HF and reduced ejection fraction. These effects did not depend on LVDF.

CPET-based "rule out" tool for pulmonary vascular resistance > 3 WU

V Vera Marinho[1]; J Ferreira[1]; P Alves[1]; C Domingues[1]; M Santos[1]; R Baptista[1]; S Costa[1]; M Ferreira[1]; F Franco[1]; F Goncalves[1]; M Pego[1]
[1]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal

Aims: We aimed to elucidate potential relationships between cardiopulmonary exercise test (CPET) variables and invasive measures of right ventricular afterload and translate those findings into a clinical "rule out tool" for pulmonary vascular resistance (PVR) > 3 WU, in end stage heart failure patients awaiting cardiac transplantation.
Methods: Retrospective study that included stable end-stage heart failure patients who underwent a scheduled in-hospital evaluation for heart transplantation and performed CPET and invasive hemodynamic assessment ≤ 7 days apart.
Results: 52 patients were included. PVR was positively correlated with VE/VCO2 slope (r=0,41, p = 0,013) and negatively correlated with PETCO2 at AT and peak O2 pulse (r=-0,42, p = 0,013 and r=-0,38, p = 0,005, respectively). Pulmonary arterial compliance was negatively correlated with VE/VCO2 slope (r=-0,34, p = 0,046) positively correlated with PETCO2 at AT and O2 pulse at AT (r=0,47, p = 0,005 and r=0,46, p = 0,007, respectively). A "rule out" tool for PVR>3 WU including peak O2 pulse and VE/VCO2 slope showed a sensitivity of 91%, specificity of 48%, positive likelihood ratio of 1,75 and negative likelihood ratio of 0,19, being particularly useful in the identification of low risk patients for high PVR. For an estimated pre-test prevalence of 42%, a low risk classification decreases the probability of high PVR to 12%. Conclusion: CPET predicts invasive measures of right ventricular afterload in end stage HF patients. A low risk CPET reduces the probability of PVR>3 WU from 42% to 12%. A potential clinical application of these findings is the periodicity guidance of invasive hemodynamic assessment in patients listed for cardiac transplantation

PULMONARY HYPERTENSION

P566
Platelet reactivity in advanced chronic left heart failure with secondary pulmonary artery hypertension - A hidden potential tool in patient management?

M Pasalic[1]; J Samardzic[1]; B Skoric[1]; H Jurin[1]; J Ljubas Macek[1]; M Cikes[1]; D Milicic[1]
[1]University Hospital Centre Zagreb, Department of Cardiovascular Diseases, Zagreb, Croatia

Background: Pulmonary artery hypertension (PAH) caused by chronic heart failure (HF) has a large impact on patient outcomes. Both systolic and diastolic HF cause an increased left atrial filling pressure and a postcapillary PAH which, if left untreated, eventually induces irreversible structural changes in pulmonary arteries. Pathogenetic pathway leading towards elevated pulmonary vascular resistance (PVR) in idiopathic PAH is based on vasoconstriction, inflammation, thrombosis and vascular proliferation. Platelets are known mediators in each of these processes and have been shown to have an important role in the development of idiopathic PAH. However, the extent to which platelets are involved in the pathogenesis of secondary PAH, especially due to HF, remains unclear and insufficiently explored.
Purpose: We investigated whether platelet reactivity (PR) correlates to the level of PAH and/or the reversibility of pulmonary artery haemodynamics in patients with advanced HF.
Methods: Platelet reactivity was tested using Multiplate function analyzer (ASPI, ADP, COL, TRAP tests) in patients with advanced chronic HF undergoing diagnostic evaluation at our department. Blood samples were taken directly from Swan-Ganz catheter during the right heart catheterization before and immediately after PVR reversibility tests was performed using intravenous prostaglandins.

Results: Herein, we report analyzed data collected on 75 patients (84% male, mean age 57.1 ± 11.5 y), most of which suffer from either dilated or ischemic cardiomyopathy. Arachidonic acid mediated PR (ASPI test) showed statistically significant correlation with changes in transpulmonary pressure gradient during reversibility test (R=-0.348, P=0.037), while changes in ASPI, ADP and COL tests correlated significantly to changes in PAPm (R=0.589, P=0.000; R=0.406, P=0.021; R=0.607, P=0.004, respectively).
Conclusion: Although the present sample size is insufficient to confirm our hypotheses, current results suggest that PR has a significant role in pulmonary vasculature changes in patients with PAH (WHO II). Results warrant further research to determine whether platelet function testing might have a potential role in routine management of these patients.

P567

Exercise pulmonary artery pressure change as a prognostic parameter in heart failure

I Sari[1]; R Darvishova[1]; M Sunbul[1]; N Sayar[1]; K Tigen[1]; B Ozben[1]; Y Basaran[1]
[1]*Marmara University, Faculty of Medicine, Department of Cardiology, Istanbul, Turkey*

Background: Although increased resting systolic pulmonary artery pressure (sPAP) is associated with adverse outcome in patients with heart failure and previous myocardial infarction, the significance of exercise sPAP is less clear. Furthermore, pulmonary artery pressure normally increases with exercise but clinical significance of change in sPAP from rest to peak exercise (ΔsPAP) is not known.
Purpose: We aimed to investigate the role of resting and peak exercise sPAP and ΔsPAP to predict cardiovascular (CV) outcome.
Methods: A total of 50 patients (mean age 61.6 ± 11.3 years, 40 % female) with heart failure and a history of myocardial infarction were included into the study. Demographic, laboratory and resting echocardiographic parameters of the patients were collected. Additionally all patients underwent bicycle stress echocardiograph and resting sPAP, peak exercise sPAP and ΔsPAP were recorded. Primary end point was development of any CV event (hospitalization for a cardiovascular event including heart failure, recurrent acute myocardial infarction, coronary revascularization or CV death).
Results: During median follow-up of 12 months CV events occurred in 26 of 50 patients (52%). The incidence of CV events was higher in females (p: 0.01) when compared with males. In addition those who experienced CV events were older (64.7 ± 12.2 years vs 58.3 ± 9.6 years, p:0.042), had lower 6 minutes walking distance (321.9 ± 111.5 m vs 411.4 ± 84.5 m, p:0.002), higher log-NT-proBNP level (3.19 ± 0.6 vs 2.6 ± 0.6, p: 0.001), worse NYHA class (2.3 ± 0.6 vs 1.6 ± 0.5, p: 0.001), higher peak exercise sPAP (57.5 ± 13.6 mmHg vs 47.6 ± 10.7 mmHg, p:0.006) and higher ΔsPAP (18.1 ± 9.4 mmHg vs 11.1 ± 6.1 mmHg, p < 0.001). In univariate analyses peak exercise sPAP, ΔsPAP, log-NT-proBNP level, 6 minutes walking distance, gender and NYHA class were among predictors of CV event development. In multivariate analyses, only female gender (p: 0.038, odds ratio: 5.316, 95 % confidence interval: 1.100 - 25.683) and ΔsPAP (p: 0.022, odds ratio: 1.125, 95% confidence interval: 1.017 - 1.243) were independent predictors of CV event development. In Receiver-Operating Curves analysis a ΔsPAP of 15 mmHg or higher predicted CV event development with a sensitivity of 73 % and specificity of 75 % (area under curve: 0.747) (Figure 1). Sensitivity was 69% and specificity 71% for peak exercise sPAP (area under curve: 0.730) and sensitivity and specificity were both 50% for rest sPAP (area under curve: 0.599).
Conclusions: Our study is the first to investigate and demonstrate the clinical significance of ΔsPAP. According to our findings ΔsPAP has a potential to be used in diagnosis, classification, staging and management of various disease states which needs and warrants to be tested with large scale prospective studies.

Early diagnosis of severe right ventricular dysfunction in pulmonary arterial hypertension through clinical evaluation. Insights from Argentine RECOPILAR Registry

E R Eduardo Perna[1]; A Lescano[2]; A Echazarreta[3]; G Cursack[4]; M Coronel[1]; L Lema[5]; S Pereiro[6]; J Caneva[7]; L Favaloro[7]; D Echazarreta[3]; M Diez[8]
[1]*J.F. Cabral Cardiology Institute, Corrientes, Argentina*; [2]*Finochietto Clinic, Buenos Aires, Argentina*; [3]*Hospital San Juan de Dios, La Plata, Argentina*; [4]*Sanatorio Esperanza, Esperanza, Argentina*; [5]*Model Institute of Cardiology, Cordoba, Argentina*; [6]*Hospital Argerich, Buenos Aires, Argentina*; [7]*Favaloro Foundation University Hospital, Buenos Aires, Argentina*; [8]*Cardiovascular Institute of Buenos Aires (ICBA), Buenos Aires, Argentina*

On behalf of: RECOPILAR Investigators

Severe right ventricular dysfunction (SRVD) is commonly diagnosed by echocardiogram (ECHO) and it is considered an important marker of poor prognosis in patients with pulmonary arterial hypertension (PAH). We sought to evaluate the prevalence of SRVD in PAH in Argentinean RECOPILAR Registry, and to identify simple clinical and biochemical variables associated with the diagnosis of SRVD.
Material and methods: From Jul-14 to Jul-15, 144 incident and prevalent patients with PAH were prospectively included by 60 investigators from 20 provinces of Argentina. The inclusion criteria were: 1-patients over three months of age; 2 -mean pulmonary arterial pressure (mPAP) at rest ≥ 25 mmHg by right heart catheterization and 3 - clinical stability in the absence of hospitalization in last month. SRVD was defined by tricuspid annular plane systolic excursion (TAPSE) < 16 mm.
Results: Mean age was 49 ± 19 years (SD) and 74% were females. SRVD was identified in 54 cases (35,5%). Patients with and without SRVD were different in terms of history of heart failure (HF) (37 vs 15.6%, p = 0.007), Dressler sign (48 vs 30%, p = 0.045), hepatomegaly (HEP) (45.7 vs 16.3%, p = < 0.01), positive hepatojugular reflux (RHY)(28 vs 10%, p = 0.008), right third sound (S3), peripheral edema ≥ 2 + (29.6 vs 13.3%, p = 0.017), elevated jugular venous pressure ≥ 2/3 (JVP) (50 vs 23.3%, p = 0.001), systolic blood pressure < 115 mmHg (lowSBP) (76 vs 49%, p = 0.003), urea > 30 mg/dl (79,2 vs 61,1%, p = 0.037), and creatinine > 0.90 mg/dl (68 vs 48%, p = 0.027). Classification and regression tree (CART) analysis was carried out to categorize the best predictors of SRVD (Figure 1). Three group of risk were identified: High (22%) (HEP + JVP + urea > 30 mg/dl; or absence of HEP + HF + lowSBP), intermediate (15,3%)(HEP + no JVP; or absence of HEP + HF + no lowSBP) and low (62,7%)(all the others), with an incidence of SRVD of 76.9, 44.4 and 21.6%, respectively (p < 0.0001).
Conclusions: One out of three patients with PAH had SRVD. Simple and widely available clinical variables allow the early diagnosis of this condition, thus helping in decision making for early initiation of specific treatment

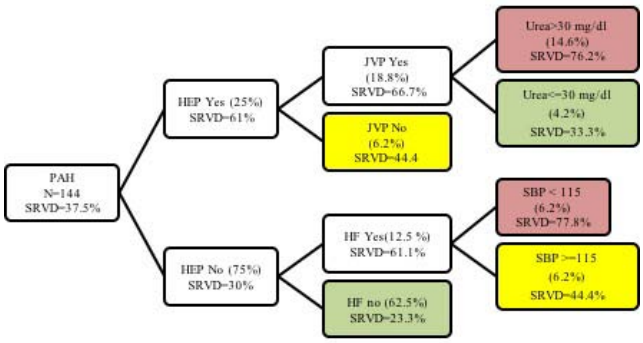

Figure 1

P569

Gender differences in functional capacity, quality of life, anxiety, depression and common symptoms in pulmonary arterial hypertension patients

M S Serdar Kucukoglu[1]; R Demir[1]; R Ceylan[1]; Ü Y Sinan[1]
[1]*Istanbul University Institute of Cardiology, Department of Cardiology, Istanbul, Turkey*

Pulmonary Arterial Hypertension (PAH) negatively affects patients' exercise capacity, quality of life (QOL), psychological mood. Although PAH is known to be more common in women, little is known about the effect of gender on symptoms and

functional capacity (FC). We aimed to investigate the difference between men and women in terms of FC, QoL, anxiety (A), depression (D) and common symptoms in PAH.
Methods: Data were retrieved from 41 (10 males, mean age 35.5 and 30 females mean age 42.4) stable PAH patients in NYHA classes I- III. All patients were assessed by measurement of dyspnea levels with UCSD-Shortness Of Breath Questionnaire, Baseline Dyspnea Index, Modified Medical Research Council, Oxygen-Cost Diagram and Modified Borg Dyspnea scale, fatigue levels with Fatigue Severity Scale, Modified Borg Fatigue scale, sleep quality with Pittsburg Sleep Quality Index and PAHSS-Sleep Disturbance Subscale, QoL with Nottingham Health Profile and SF-36 questionnaires,A-D levels with Hospital A and D Scale and functional capacity with six-minute walk test.
Results: None of the parameters were significantly different between men and women).
Conclusion: There was no difference between men and women in terms of FC, QoL, anxiety, depression and common symptoms in patients with PAH.

P570

Morbidity and mortality in patients with pulmonary hypertension treated with iloprost

L C Liz Carolina Casafuz Martinez[1]; FNG Fernandez Chamorro[1]
[1]*Social Security Institute , Cardiology, Asuncion, Paraguay*

Introduction: Pulmonary hypertension (PH), has a difficult diagnosis and poor prognosis, can be primary or secondary and has a high mortality rate.
Objective: To determine the morbidity and mortality in PH in patients under treatment with Iloprost during the period of August, 2013 to August, 2016.
Methods: Observational, cross-sectional, retrospective study in patients with PH treated with iloprost in functional class III or IV of the World Health Organization (WHO) upon admission.
Results: Study population 33 patients. Deaths from August 2013 to August 2016: 8/33 (24%), mortality was as follows: first year 4/33 (9%), second year 6/33 (18%) and third year 8/33 (24%). Distribution by sex: female 26/33 (79%). Deaths by sex: female 4/26 (15%), male 4/7 (57%). Mean age 51± 13 years. Labor occupation: teacher 30%, administrative 27%, household chores 24%. High-risk PH factors that were associated with increased hospitalization: 6-minute walk test (PC6min) <300m (79%), time of onset of symptoms> 1 year (79%), Pro-BNP> 300pg/ml (39%), right ventricular failure (30%). Reasons for hospitalization: Acquired community pneumonia 21%, Congestive Heart Failure (13%), Arrhythmias (12%), Haemorrhages (12%). Connective tissue diseases (CTE) (39%) were the most frequent and the highest percentage of deaths were: 6 of 8 deaths (75%), 4 with Scleroderma and 2 with lupus. The most frequent cardiovascular risk factors (CVRF) were: Hypertension (45%), obesity (24%), overweight (21%).
Conclusion: A mortality rate was observed according to the international literature. The female-male sex ratio was 3.7 / 1. There was a higher mortality rate among men. The high risk factor for PH that was related to a higher percentage of hospitalization was PC6min <300m. The reason for major hospitalization in these patients was Acquired community pneumonia. Patients with CTE predominated, with a high mortality rate. The most frequent CVRF was Hypertesion.

P571

Right ventricular 18F-FDG uptake in PET/MRI hybrid and hemodynamics in patients with pulmonary arterial hypertension.

K Karol Kaminski[1]; R Kazimierczyk[1]; M Jasiewicz[2]; P Blaszczak[3]; L Malek[4]; B Milosz-Wieczorek[5]; J Misko[5]; P Szumowski[6]; D Jurgilewicz[7]; M Hladunski[7]; B Sobkowicz[2]; R Grzywna[3]; J Mysliwiec[6]; WJ Musial[2]
[1]*Medical University of Bialystok, Bialystok, Poland*; [2]*Medical University of Bialystok, Department of Cardiology, Bialystok, Poland*; [3]*Cardinal Wyszynski Hospital, Cardiology, Lublin, Poland*; [4]*Collegium Masoviense, Zyrardow, Poland*; [5]*Institute of Cardiology, Cardiac Magnetic Resonance Unit, Warsaw, Poland*; [6]*Medical University of Bialystok, Department of Nuclear Medicine, Bialystok, Poland*; [7]*Medical University of Bialystok, Laboratory of Molecular Imaging, Bialystok, Poland*

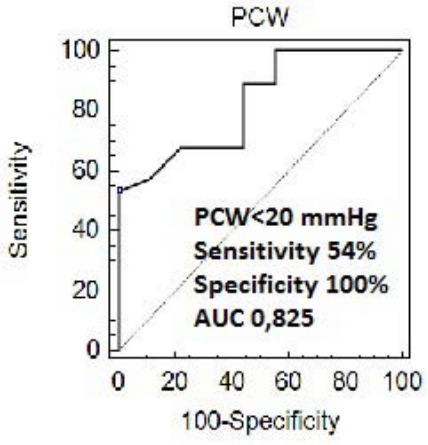
Right ventricular (RV) function is a major determinant of survival in patients with pulmonary arterial hypertension (PAH). RV 18F-fluoro-2-deoxyglucose (FDG) accumulation in positron emission tomography (PET) was recently connected with progressive RV dysfunction in PAH patients. In our pilot study we compared hemodynamic parameters obtained during right heart catheterization (RHC) and RV function assessed in magnetic resonance imaging (MRI) with PET-derived glucose uptake values.
Methods: Twenty stable PAH patients (mean age 50.1 ± 16.5 years, diagnosis confirmed in RHC according to current ESC criteria, I-III WHO class, all prevalent cases, treated with specific PAH therapies) had cardiac PET/MRI scans with FDG as a tracer. FDG uptake was presented as a standardized uptake value (SUV) of both left (LV) and right ventricle. A ratio of SUVRV/SUVLV was then calculated. RVEF was assessed in MRI scans performed simultaneously with PET, whereas hemodynamic measurements were obtained from right heart catheterisation performed within two months from the PET/MRI scanning.
Results: Subjects presented wide range of pulmonary vascular resistance (PVR) (2.1 to 18.9 WU), mean pulmonary artery pressure (mPAP) (24 to 90 mmHg) and RV ejection fraction (RVEF) (27% to 58%). SUVRV directly correlated with mPAP (r=0.85, $p < 0.0001$), PVR (r=0.76, $p < 0.0001$), right atrial pressure (RAP) (r=0.48, $p = 0.03$) and inversely with RVEF (r=-0.52, $p = 0.04$). Mean SUVRV/SUVLV ratio was 0.97 ± 0.63. SUVRV/SUVLV ratio also correlated with mPAP (r=0.84, $p < 0.0001$), PVR (r=0.75, $p < 0.0001$) and RVEF (r=-0.7, $p = 0.02$). Patients with mPAP higher than 40 mmHg presented abnormally high SUVRV/SUVLV ratio (1.28 vs 0.38, $p < 0.0001$).
Conclusions: Increased glucose uptake in RV myocytes as assessed by FDG PET is associated with worse hemodynamics indicating more advanced PAH. Similarly, worse RV function evaluated in MRI was associated with increased FDG uptake in RV. PET/MRI hybrid could provide insights into right ventricle function and metabolism in PAH patients, however its usefulness in diagnostic process requires further investigations.

P572

Predictors of irreversible pulmonary hypertension reduction with Sildenafil therapy in heart transplant candidates

A Agata Duszanska[1]; M Zakliczynski[1]; M Zembala[1]
[1]*Medical University of Silesia, Silesian Centre for Heart Diseases, Zabrze, Poland*

Objective: Increased transpulmonary gradient (TPG) and pulmonary vascular resistance (PVR) without reversibility with vasodilators(irreversible pulmonary hypertension-IPHT), are considered as contraindications to orthotropic heart transplantation (OHT) in advanced heart failure (HF) patients. We sought to determine predictors of reduction of IPHT secondary to Sildenafil therapy in patients with advanced HF disqualified from OHT due to increased TPG and PVR.
Methods: 50 patients (46 M, mean age 54,3 ± 8,9 years, NYHA 3 ± 0,4, ischaemic etiology n=19) with indications for OHT based on clinical assessment, N-terminal pro-brain natriuretic peptide (NT-proBNP), ECG, echocardiography, cardiopulmonary test (VO2) were disqualified from OHT following right heart catheterization with nitropruside (NPS) study confirming IPHT (TPG>12 mmHg, PVR>2,5 Wood units). In all patients Sildenafil was introduced and uptitrated to a maximal tolerated dose following optimal medical therapy according to ESC guidelines. Patients were assessed at 3-month intervals. Results: During 10,9 ± 4,2 months observation reduction of TPG(16 ± 5,9 to 9 ± 3, with NPS: 11,5 ± 4,5 to 7,7 ± 3,3 mmHg) and PVR (4,2 ± 1,3 to 2,2 ± 1,0, with NPS:2,8 ± 1,1 to 1,6 ± 0,8 W) enabling qualification for OHT was observed in 37 pts. On univariate analysis pulmonary capillary wedge pressure (PCW) [[OR 0,79; 95% CI (0,67-0,94) $p = 0.008$], mean pulmonary arterial pressure (mPAP) [OR 0.79, 95% CI (0.67-0,93) $p = 0.005$]; PVR at baseline [OR 0,55, 95% CI (0,31-0,99) $p = 0.05$] were defined as markers of IPHT reduction with Sildenafil. On multivariate analysis PCW ($p = 0.03$) was identified as an independent predictor of of successful reduction of TPG and PVR with Sildenafil enabling patient qualification for OHT (PCW < 20 mmHg, sensivity 54%, specificity 100%). Conclusions: Sildenafil can support pulmonary hypertension reduction in advanced heart failure patients ineligible for orthotropic heart transplantation due to increased transpulmonary gradient and pulmonary vascular resistance. Pulmonary capillary wedge pressure prior to Sildenafil therapy was identified as an independent predictor of successful reversibility of pulmonary hypertension.



Independent predictor of IPHT reduction

P573

Physiological insights of exercise hyperventilation in pulmonary hypertension

N Bruno[1]; S Farina[1]; C Agalbato[1]; M Contini[1]; S Harari[2]; P Agostoni[1]
[1]Cardiology Center Monzino IRCCS, cardiology , Milan, Italy; *[2]San Giuseppe Hospital, Pneumology , Milan, Italy*

Background: Pulmonary hypertension (PH) patients show, during exercise, an excessive increase in pulmonary ventilation (VE) compared to carbon dioxide output (VCO2), determining a high VE/VCO2 slope. There are several possible causes, including an elevated dead space ventilation (VEDS), VE/perfusion (Q) mismatch and/or an enhanced peripheral or central chemoreceptor activity. We evaluated the causes of exercise hyperventilation in PH patients.
Methods: Eighteen class I and IV PH patients underwent cardiopulmonary exercise test with hemogasanalysis at every minute. VE, alveolar ventilation (VEALV) and VEDS vs. VCO2 relationship were calculated. Resting chemoreceptor sensitivity was analyzed through hypoxia/hypercapnia tests.
Results: PeakVO2 and VE/VCO2 slopes were 1.06 ± 0.24L/min and 39.1 ± 9.0, respectively. Throughout the exercise, 30% of VE was due to VEDS. VE/VCO2 slope significantly correlated with VEDS/VCO2 slope (r=0.82, $p < 0.001$) but not with VEALV/VCO2 slope (r=0.3, p=ns). Peak exercise end-tidal CO2 (PetCO2) correlated with VEDS/VCO2 slope (r=-0.79, $p < 0.001$) and VE/VCO2 slope (r=-0.91, $p < 0.001$). DS/tidal volume and P(arterial-et)CO2 were elevated without arterial hypoxemia suggesting an high VE/Q mismatch. Peripheral responses to hypoxia and hypercapnia were 0.416 ± 0.402 L/min/O2Sat and 0.076 ± 0.047 L/min/mmHg, respectively; central hypercapnic chemosensitivity was 4.475 ± 3.99 L/min/mmHg. Chemoreceptor peripheral response was unrelated with exercise. Vice versa, a positive correlation was found between central CO2 response and VEALV/VCO2 slope (r=0.65, $p = 0.013$).
Conclusions: Increased DS and VE/Q mismatch are among the main mechanisms involved in exercise hyperventilation in PH. Central CO2 chemoreceptor seems to play a role, since it positively correlates with VEALV.

P574

Simple parameters predict combined post- and pre-capillary pulmonary hypertension in patients with severe heart failure

P Peter Lesny[1]; M Luknar[1]; V Simovicova[1]; M Kovacova[1]; M Dankova[1]; S Wimmerova[2]; E Goncalvesova[1]
[1]National Institute for Cardiovascular Diseases, Bratislava, Slovak Republic; *[2]Slovak Medical University, Bratislava, Slovak Republic*

Background: Pulmonary hypertension (PH) is a negative prognostic factor in patients (pts) with left-sided heart failure (HF). Particularly, pts with combined post-capillary and pre-capillary PH are at risk.
Purpose: To determine simple predictors of combined PH (defined as mean pulmonary arterial pressure (mPAP) ≥ 25 mmHg, pulmonary arterial wedge pressure > 15 mmHg, pulmonary vascular resistance > 3 W.U. and/or diastolic pressure gradient ≥ 7 mmHg) in pts with severe HF.
Patients and methods: Three hundred and eighty five heart transplant candidates were retrospectively evaluated. Mean age was 48.3 ± 10.1 years, left ventricular ejection fraction 23.9 ± 7.9 %. Eighty nine % of pts were in NYHA classes III or IV. Main etiologies of HF were dilated cardiomyopathy in 53% and coronary artery disease in 32% of pts. Right heart catheterization using Swan-Ganz catheter was performed. Presence and type of PH, as well as one-year mortality for each PH type were determined. Twenty simply available clinical and laboratory parameters were included in multivariate stepwise logistic regression analysis to determine independent predictors of combined PH.
Results: Prevalence of pts without PH, with isolated post-capillary PH and with combined post- and pre-capillary PH was 21%, 38% and 41%, respectively. One-year mortality was 13.5%, 18.1% and 27.2% in pts without PH, isolated post-capillary PH, and combined PH, respectively ($p < 0.05$, for combined PH group vs two other groups of pts). Right ventricular diameter >35 mm, and daily furosemide dose > 160 mg were identified as only independent predictors of combined post- and pre-capillary PH.
Conclusion: Right ventricular dilation and high daily furosemide dose are independent predictors of combined post-capillary and pre-capillary PH in pts with severe HF. Due to their worse prognosis, these pts should be referred to an HF center earlier.

P575

Clinical efficiency of macitentan in patients with pulmonary hypertension. our experience in argentina

H Gomez Santa Maria[1]; A Ferro[1]; G Bortman[2]; V Gregorietti[3]; N Atamanuk[4]; N Carusso[2]; A Adrian Lescano[1]
[1]Finochietto Clinic, Buenos Aires, Argentina; *[2]Sanatorium Mitre, Buenos Aires, Argentina*; *[3]Hospital El Cruce, Florencio Varela, Buenos Aires, Argentina*; *[4]Hospital Fernandez, Buenos Aires, Argentina*

Introduction: Pulmonary Hypertension (PH) is a disease characterized by an increase in pulmonary resistances that leads to right heart disfunction, heart failure and death. There are multiple associated pathophysiological mechanisms that are used as therapeutic targets. Macitentan (M) is a non-selective inhibitor of endothelin receptors, which has demonstrated clinical benefits in morbidity and mortality in a Phase III study. (Macitentan and Morbidity and Mortality in Pulmonary Arterial Hypertension SERAPHIN trial).
Objective: To describe the clinical efficacy in our population of Macitentan in PH patients.
Material and methods: A prospective, consecutive, open, phase IV registry of patients with PH who started treatment with M (Opsumit MR) in Argentina, from March 2015 to November 16, was performed. We included those p who received M for at least 6 months or presented an event. Baseline characteristics, functional class (FC), 6-minute gait test (TM6M), adverse effects and survival were determined according to the recommendations of the national and international guidelines, at baseline and at 6 month. Clinical efficacy was determined by the improvement in FC from III-IV (advanced) to FC I-II (not advanced), and improvement in 6MWT> 15%. The data was loaded into an Excel database and evaluated with the Bioestat 5.0 program. The normality of the sample was analyzed by the D'Agostino-Pearson test. In relation to the distribution, the t test was used for quantitative variables, Chi^2 for qualitative and McNemar test for paired variables. A p value of < 0.05 was defined as a significant difference between baseline and 6 months.
Results: We included 151 p, 74% women, the average of age was 46 years (28-63) and 98.4% had HP group 1. 98.6% received M 10 mg and 1.4% 5 mg. At baseline, functional class evaluation presented the following distribution: FC I 2.4%, II 19.4%, III 65.3% and IV 12.9% (advanced FC 78.2%). The mean baseline TM6M was 321 m (250-400). At 6 months FC I was 13.5%, II 62.2% and III 24.3% (advanced FC 24.3%), with significant statistical benefit ($p < 0.001$). The mean TC6M reached 397.2 m (320-467), an increase of 24%, with a significant difference ($p < 0.0001$, 95% IC-533-51.6).
Conclusion: In our PH registry, administration of Macitentan was associated with a significant benefit in achieving the objectives of functional class improvement and the distance reached in the 6MWT (76 meters), at 6 months. These data are in agreement with those obtained in the randomized study SERAPHIN.

RIGHT VENTRICULAR FUNCTION

P576

Right ventricular dilatation in coronary artery disease patients without myocardial infarction

El Yaroslavskaya[1]; VA Kuznetsov[1]; DV Krinochkin[1]; GS Pushkarev[1]; EA Gorbatenko[1]
[1]Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Tyumen, Russian Federation

Background: Detection of right ventricular (RV) dilatation in patients with coronary artery disease (CAD) is very important to identify subjects at high risk for adverse cardiovascular events. Data about factors associated with RV dilatation in CAD patients without myocardial infarction (MI) are insufficient.
Purpose: To reveal factors associated with RV dilatation in CAD patients without MI.
Methods: Out of 16.839 patients from coronary angiography database we selected patients without acute or prior MI, congenital or acquired valvular heart disease with stenosis ≥75% of at least one coronary artery: 1.134 patients without RV dilatation (end-diastolic RV outflow tract diameter measured by echocardiography ≤26 mm) and 75 patients with RV dilatation (RV outflow tract diameter ≥30 mm). Patients with RV diameter >26 mm and < 30 mm were not included to have higher discrimination between groups.
Results: There were more male patients in the group with RV dilatation (92.0% vs 80.2%, $p = 0.012$). Mean body mass index (BMI) was higher in this group (31.7 ± 5.2 kg/m2 vs 30.1 ± 4.7 kg/m2, $p = 0.010$). Patients with RV dilatation more often had a higher NYHA functional class (III – 22.2% vs 12.5%, $p = 0.002$), arrhythmias (45.5% vs 17.8%, $p < 0.001$), reduced LV systolic function (LV ejection fraction < 50% - 24.3% vs 2.9%, $p < 0.001$) and significant mitral regurgitation (MR) (29.4 % vs 4.0 %, $p < 0.001$). There were no differences in lipid profile and coronary angiographic parameters between the groups. The prevalence of high CCS angina class (III/IV) was lower in the group with RV dilatation (30.3% vs 52.8%, $p = 0.007$). According to the multivariate analysis, RV dilatation was independently associated with reduced LV systolic function (OR 4.22; 95% CI 1.73-10.30; $p = 0.002$), male gender (OR 4.03; 95% CI 1.47-11.04; $p = 0.007$), arrhythmias (OR 2.98; 95% CI 1.62-5.49; $p < 0.001$), significant MR (OR 2.34; 95% CI 1.44-3.81; $p = 0.001$), higher NYHA functional class (OR 1.87; 95% CI 1.05-3.32; $p = 0.034$), higher BMI (OR 1.08; 95% CI 1.02-1.15; $p = 0.010$), and lower CCS angina class (OR 0.42; 95% CI 0.25-0.71; $p = 0.001$).
Conclusions: RV dilatation in patients without MI was predominantly associated with male gender, parameters describing severity of LV dysfunction and higher BMI.

P577

Right ventricular systolic dysfunction in patients with coronary artery disease: gender-related differences

A N Alexey Sumin[1]; EV Korok[1]; OG Arhipov[2]
[1]*RAMS Scientific-Research Institute for Complex Studying of Cardiovascular Diseases, Kemerovo, Russian Federation*; [2]*Sanatorium Topaz, Mysky, Russian Federation*

Background: Right ventricular (RV) dysfunction is one of the most significant independent predictors of prognosis in patients with coronary artery disease (CAD) who were presented with myocardial infarction (MI) and without it. However, gender-related differences in RV function of CAD patients are still poorly understood.
Aim: To evaluate gender-related differences in echocardiographic parameters of the right chambers of the heart in CAD patients.
Material and Methods: 719 patients with coronary artery disease undergoing medical examination on an outpatient basis in the Federal Budgetary Institution Rehabilitation Center "Topaz" of the RF Social Insurance Fund were included in the study. All patients were assigned to two groups according to the gender: Group 1 – men (n = 432, 61 [55; 67] years), Group 2 - women (n = 287, 62 [56; 67] years).
Results: The analysis of the structure and systolic function of the RV showed that RV and right atrium (RA) end-diastolic dimension, diastolic RV wall thickness, and RA area were significantly higher in men than in women ($p < 0.001$). Thus, the prevalence of RV systolic dysfunction (SD) was similar in both groups of patients: 17.6% in men and 15% in women ($p = 0.356$). The independent predictors of LV SD in both groups were as follows: prior coronary artery bypass grafting (CABG), decreased early mitral flow propagation velocity ($p < 0.05$). However, reduced left ventricular ejection fraction (LVEF; $p < 0.001$) was found only in men.
Conclusion: The prevalence rate of right ventricular systolic dysfunction in patients with coronary artery disease was similar in both men and women. Men demonstrated lower values of systolic and diastolic LV function. The factors associated with RV systolic dysfunction in both groups were as follows: prior CABG and diastolic LV dysfunction. Reduced LVEF was found only in men. The results of this study should be used to assess gender-related differences in RV dysfunction in CAD patients.

P578

echocardiographic predictors of acute right ventricular dysfunction in postoperative state of congenital heart surgery

LA Cota Apodaca[1]; E Garcia Cruz[1]; F Baranda Tovar[1]; C Salgado Solorio[1]; E Bucio Reta[1]; N Garcia Cruz[1]
[1]*National Institute of Cardiology Ignacio Chavez, Cardiac Intensive Care Unit, Mexico City, Mexico*

Background: Congenital cardiac diseases have become more prevalent in adult population.. We can now say that in most of the western civilization it is possible for the 85% of the new born with congenital cardiac disease to survive to adult age. Congenital defects are classified as simple and complex, in the study we now present we included complex congenital cardiopathies and patients with two or more common defects.
Purpose: This study suggests that the patient who will present chronic heart failure tends to show less acute heart failure signs during the immediate post surgical time, because of a preconditioning effect.
Methods: We analyzed the files of the intensive care unit from January 2015 to December 2016. Inclussion criteria: complex congenital heart disease who went through a surgical correction of their defect, age greater than 18 years, cardiothoracic post surgical status. We excluded patients with: unique ventricle, incompletepatient's file, one congenital common defect. To determine if the patient with right heart hypertrophy or chronic right heart failure shows a minor probability of acute heart failure, all of the variables were obtained from the echocardiographic evaluation: chronic right heart failure was define as decreases in fractional area shortening, tricuspid annular plane systolic excursion (TAPSE), Doppler S′ velocity or increases in the right heart dimensions. Acute right heart failure was define as an decrease in the fractional area shortening less than 25% or paradoxical septal movement plus inotropic administration for more than 24 hours. We determined the echocardiographic variables before and after the surgical event.
Results: 16 patients met the inclusion criteria: 9 with right ventricular hypertrophy (right free wall thickening >5 mm), 6 met chronic right heart failure criteria, 8 patients showed acute right heart failure, and 8 did not. We did a bivariate analysis obtaining an OR 0.3, Fisher's test 0.34. Right free wall hypertrophy in relation to acute heart failure, obtaining an OR of 0.2 , Fisher's test of 0. 15. In the same way, the right ventricular free wall strain was analyzed and severe dysfunction was defined as less than -6%.This latter parameter was related to acute right heart failure with an OR 1.3, Fisher's test of 0.68.
Conclusions: The free wall strain was only calculated after cardiac surgery, obtaining an OR of 1.3, and it showed relation to acute right ventricular dysfunction. Free wall thickening measure reflects preconditioning that can bear greater intracavitary pressure and this can be a protection factor against acute heart failure during the postsurgical process and also chronic right heart failure. Nevertheless the exact Fisher's test for both parameters showed no statistical significance maybe restricted by the amount of the sample, which was one of the most important limitations of our study.

P579

Acute adaptation of the right ventricle to pressure and volume overload. Preliminary analysis in human model

Background/Introduction: Acute overload of the RV produce a remodeling that, if it is not reversible, can condition an adverse prognosis. Thus we did a comparative and descriptive analysis of the response of the RV to acute overload, including volume and pressure overload, and its short-term evolution. PURPOSE. To assess structural and functional changes of RV when there is acute pressure and volume overload, and its potential reversibility.
Methods: Prospective study including 30 consecutive patients recruited between June 2014 and June 2016. Severe pulmonary embolism (PE) was the selected model for the study of acute pressure overload, whilst implantation of a transjugular intrahepatic portosystemic shunt (TIPS) was selected for the acute volume overload. Electrocardiogram (ECG), determination of biomarkers and echocardiographic study were serially performed to all patients.

Table I P579

	Pressure overload, n 13 Basal	Pressure overload, n 13 Early (4 h)	Pressure overload, n 13 3 m	p	Volume overload, n 17 Basal	Volume overload, n 17 Early (48 h)	Volume overload, n 17 3 m	p

S′	9±2,5	13±2,6	15±3	0,02	15±2	14±3,50	15±2	0,60

ABBREVIATIONS: hs-cTnT: Ultrasensitive Troponin t; RV: Right ventricle; PASP: Pulmonary artery systolic pressure, estimated by transthoracic echocardiography; TAPSE: Tricuspid annular plane systolic excursion (mm); S´: Systolic velocity of the tricuspid ring (cm/seg); m: Months

Results: 13 patients with acute pressure overload were evaluated. Table I shows the main analytical and echocardiographic results, both basal and evolutive. At baseline, 10 patients (77%) had a depressed function of the RV and 11 (85%) presented RV dilatation. At 3 months all patients normalized the function of the RV. 17 patients with acute volume overload were assessed, 14 men (84%), average age 57 ± 8 years. At the first moment after overload, no patient presented RV dysfunction; however, 6 patients (35%) presented a slight RV dilatation which did not implied related clinical events. At 3 months, 2 patients had a slight RV dilatation without dysfunction.
Conclusions: Ventricular dilatation and dysfunction with short-term reversibility is frequent in RV acute pressure overload. Dilatation without dysfunction is produced in the RV acute volume overload, but dilatation tends to persist.

Funding Acknowledgements: The GIPS-III trial was supported by grant 95103007 from the Netherlands Organization for Health Research and Development

Background: Pathologic cardiac remodeling as a result of acute myocardial infaction (AMI) can deteriorate systolic and/or diastolic function and ultimately cause heart failure. Previous research in the post-AMI setting has mainly focused on systolic function. This one-sided focus has left gaps in our knowledge on how remodeling affects diastolic function.
Purpose: We aimed to determine the risk factors associated with diastolic function and diastolic remodeling after AMI.
Methods: This is a sub-study of the GIPS-IIII trial, a single center, randomized, double blind, placebo-controlled study. Non-diabetic ST-elevated myocardial infarction (STEMI) patients were randomized to metformin or placebo initiated directly after PCI.The primary endpoint was left ventricular ejection fraction at 4 months measured by MRI. Trans-thoracic echocardiography was performed during hospitalization and after 4 months to evaluate diastolic function as a predetermined secondary endpoint. As previously reported, both endpoints were unaffected by metformin treatment. The ratio of E/e′, signifying cardiac filling pressure, was used as a marker of diastolic functioning status for the current study.
Results: 267 (70%) patients from the GIPS-III cohort had E/e' available at both time points. Mean age was 58.0 (± 11.3) years and 23.2% were females. Linear regression analyses of the baseline variables found a multivariabel model with age, gender, hypertension, multi vessel disease, glucose, and peak CK-total be predictive for E/e′ (R^2:0.20). After correction for E/e' during hospitalization female gender (β: 0.26), multi vessel disease (β: 0.26), and higher glucose (β: 0.26) were found to be associated with adverse diastolic function.
Conclusions: Age, female gender, history of hypertension, multi vessel disease, glucose and peak CK-total are independently associated with worse diastolic function at 4 months after STEMI. Furthermore, female gender, multi vessel disease and higher glucose are independently associated with adverse diastolic remodeling.

Table: Multivariate prediction models

Mid-range ejection fraction as a continuum of poor prognosis - a national STEMI patients analysis

C Catarina Ruivo[1]; F Montenegro Sa[1]; L Graca Santos[1]; J Correia[1]; J Morais[1]
[1]*Hospital Santo Andre, Cardiology, Leiria, Portugal*

On behalf of: Portuguese National Registry of Acute Coronary Syndromes

Background: Heart failure with mid-range ejection fraction (mrEF – ejection fraction 40-49%) is a newly defined entity that certainly will be considered in future ST segment elevation myocardial infarction (STEMI) patients approaches. We aim to characterize these patients and analyze in-hospital adverse events according to their EF.
Methods: A retrospective analysis of data from consecutive STEMI patients enrolled in a multicenter national registry from October 2010 to September 2016 was conducted among 3914 patients. Patients without echocardiographic (Echo) EF evaluation or without reperfusion strategies were excluded. The clinical characteristics and coronary angiographic findings were evaluated and compared between patients with EF>50% (n = 2236, 57.1%), EF 40-49% (n = 929, 23.7%) and EF < 40% (n = 749, 19.1%) on Echo. Different components of delay were considered and compared: time from symptom onset (SO) to first medical contact (FMC) (SO-FMC), from SO to reperfusion therapy [(SO-RT) both fibrinolysis and percutaneous coronary intervention] and FMC to RT (FMC-RT). In-hospital adverse events (death, sustained arrhythmias or mechanical complications) were considered as endpoints.
Results: Comparative analyses between patients with EF>50%, EF 40-49% and EF < 40% found a continuum in: increase age (61 ± 13 vs. 63 ± 14 vs. 64 ± 14, p = 0.008), longer delays [SO-FMC: median time of 110 (interquartile range: 60-205) minutes vs. 120 (66-128) vs. 123 (60-247), p = 0.02; SO-RT: 227 (162-360) vs. 255 (174-414) vs. 275 (183-455), p < 0.001; FMC-RT: 105 (65-165) vs. 115 (70-178) vs. 125 (83-200), p < 0.001], more severe acute event [Killip-Kimball class > I (6.0% vs. 12.1% vs. 29.0, p < 0.001)] and multivessel coronary artery disease in an increase proportion of patients (40.6% vs. 41.0% vs. 45.4%, p = 0.08). Analyzing the endpoints, we observed increasing in-hospital mortality rates (0.7% vs. 2.4% vs. 9.2%, p < 0.001), sustained arrhythmias (1.3% vs. 3.0% vs. 6.3%, p < 0.001) or mechanical complications (0.5% vs. 1.1% vs. 2.3%, p < 0.001). Conclusion: Patients with mrEF are particularly important stratum of patients to identify because they have significant rates of in-hospital adverse events. They represent a continuum of higher baseline risk profile and higher hemodynamic instability, in whom the tendency to delay their treatment can lead to higher myocardial damage, with reduction of EF.

P582
Very long-term LVEF dynamics and prognosis in HFrEF and HFmrEF

M De Antonio[1]; J Lupon[1]; J Lopez-Ayerbe[1]; P Moliner[1]; M Domingo[1]; E Ferrer[1]; E Zamora[1]; N Vallejo[1]; F Gual[1]; A Teis[1]; G Junca[1]; MI Troya[1]; M Rodriguez[1]; B Gonzalez[1]; A Bayes-Genis[1]
[1]*Germans Trias i Pujol University Hospital, Badalona, Spain*

Background: Advances in heart failure (HF) treatment are responsible for systolic function improvement in patients with reduced (HFrEF) and mid-range (HFmrEF) ejection fraction. Left ventricular ejection fraction (LVEF) dynamics and associated survival is not completely elucidated.
Purpose: To prospectively assess very long-term (up to 13 years) LVEF dynamics and prognosis in consecutive HFrEF and HFmrEF patients.
Methods: Ambulatory patients admitted to a multidisciplinary HF Unit were prospectively evaluated by 2D-echocardiography at baseline and at 1,3,5,7,9,11, and 13 years of follow-up. Out of 1912 patients, 1097 patients with LVEF < 50% and at least 2 determinations of LVEF were included in the study. Patients with CRT previous two the second echocardiography were excluded. Two patients were censored at the moment of heart transplantation and 59 at the moment of CRT.
Results: LVEF measurements were obtained from 1097, 995, 610, 393, 239, 148, 112, and 62 patients at the predefined time-points, accounting for 100%, 91%, 72%, 65%, 61%, 57%, 64%, and 63% of the alive patients at every time. Mean number of echocardiography measurements performed were 3.3 ± 1.6 per patient. Mean LVEF at each study time-points were: 30% ± 9, 38% ± 12, 40% ± 12, 41% ± 12, 42% ± 13, 42% ± 11, 42% ± 12, and 41% ± 11. Paired data comparisons showed statistical significance between baseline and 1 year (p < 0.001) and between 1 and 3 years (p < 0.001). HFmrEF patients showed significantly lower improvement than HFrEF at 1 year (3 ± 9 vs. 9 ± 12 points respectively, p < 0.001) but maintained better LVEF than HFrEF patients up to 7 years (p = 0.01). At the end of follow-up survivors of both groups has similar LVEF. LVEF at each study time-points in HFmrEF: 43% ± 3, 46% ± 9, 46% ± 11, 45% ± 10, 46% ± 12, 44% ± 10, 43% ± 12, and 41% ± 11. LVEF at each study time-points in HFrEF: 28% ± 7, 37% ± 12, 39% ± 12, 40% ± 13, 41% ± 13, 41% ± 12, 41% ± 12, and 41% ± 11. Non-ischemic patients, despite slightly lower baseline LVEF, showed higher numbers during follow-up vs. ischemic HF patients (around 7-10 points, all p < 0.01). Remarkably, patients who

died in the following period after each of the predefined time-points of follow-up, had always lower previous LVEF (figure). Also during the first 5 years patients who died had significantly worse LVEF dynamics in the precedent period.
Conclusions: LVEF in patients with depressed systolic function significantly improves up to 3 years, and remains steady afterwards. HFrEF showed higher LVEF rise during follow-up relative to HFmrEF, yet at the end of follow-up survivors of both groups had similar LVEF. Non-ischemic aetiologies showed higher improvement and maintain higher LVEF values along follow-up. Decedents always had lower LVEF and also tended to have worse dynamics in the precedent study period.

Development and validation of sex-specific diagnostic models to detect diastolic dysfunction in primary care

A Aisha Gohar[1]; H Den Ruijter[1]; R Kievet[2]; A Hoes[2]; G Pasterkamp[1]; M Bots[2]; F Rutten[2]
[1]*University Medical Center Utrecht, Experimental Cardiology, Utrecht, Netherlands*; [2]*Julius Health Center - Julius Gezondheidscentra, Utrecht, Netherlands*

Funding Acknowledgements: Dutch Heart Foundation: 2013/T084

Background: The prevalence of undetected left ventricular diastolic dysfunction (DD) is high in the general population particularly in the elderly population. This is mainly due to the asymptomatic nature of the disorder making it difficult to diagnose in primary care. Identifying people at high risk of DD is important as DD is a prognostic indicator of heart failure and future cardiovascular and all-cause mortality.
Purpose: The purpose of this study was to develop diagnostic models that can be implemented in primary care to assess who is at risk of DD and therefore requires referral for echocardiography. Given that diastolic dysfunction impacts men and women differently, sex-specific models were developed.
Methods: Individual patient data from four primary care HF-screening studies were analysed (1477 participants, 732 men). 11 candidate predictors were entered into sex-specific logistic regression models to predict the presence of DD. Internal-external cross-validation was performed to develop, validate and calibrate the models by omitting a different cohort each time for use as the validation cohort.
Only age and pulse pressure remained as clinical predictors in women. In men, the model consisted of age, body mass index, pulse pressure, AF and use of beta-blockers. The model performed poorly in women with the c-statistic ranging from 0.55 to 0.65. The model performed better in men with a c-statistic ranging from 0.59 to 0.75
Conclusions: Clinical predictors of DD differ between men and women highlighting importing sex differences in the underlying mechanisms of DD. We present a diagnostic model for DD that performs better in men than for women indicating the need to investigate DD in a sex-specific manner.

Heart failure with mid-range ejection fraction: prognostic impact of left bundle branch block

H Hugo Antunes[1]; L Abreu[1]; J Pereira[1]; ML Goncalves[1]; B Marmelo[1]; I Pires[1]; D Moreira[1]; I Almeida[1]; M Correia[1]; C Cabral[1]
[1]*Hospital Sao Teotonio, Cardiology, Viseu, Portugal*

Introduction: Left Bundle Branch Block (LBBB) is associated with poorer prognosis in patients (P) with heart failure (HF) with reduced ejection fraction (rEF). In the new classification of HF, a new group of P with mid-range ejection fraction (mrEF) appears. Clinical characteristics and therapeutic approach still remain uncertain in this group of P.
Objectives: To evaluate the prognostic impact of LBBB in P with HF and mrEF.
Methods: We identified all patients admitted for HF in a single center between 01/01/2009 and 31/12/2014. Only the first episode of each patient was included. Only the P with mrEF (40-49%) were selected. We considered 2 groups: group with presence of LBBB (gLBBB) and a control group without LBBB (gCONTR). We compared in-hospital mortality (IHM), the combined endpoint (death / hospitalization for HF) at 6 and 18 months (M) and the survival curves of each group.
Results: Of a total of 1006 P admitted, 191 cases were included: 59.7% male and mean age 75.72 ± 10.33 years. IHM was 2.6%. The combined endpoint at 6M was 29.7% and 52.2% at 18M. gLBBB represents 17.8% of the P. In this group, there was predominance of females (64.7% vs 35.0%, $p < 0.001$) and of P diabetics (50.0% vs 29.5% $p = 0.021$) compared to gCONTR. There were no differences in age, other cardiovascular risk factors, history of ischemic heart disease, chronic kidney disease or atrial fibrillation.
Analytically, there was no difference in hemoglobin, creatinine or BNP on admission. gLBBB evolved more frequently with acute renal injury (32.4% vs 16.2%, $p = 0.031$). There were no statistically significant differences in IHM (gLBBB 2.9% vs 2.5%). There was a greater number of events (combined end-point) at 6M and 18M in gLBBB (45.5% vs 26.3%, $p = 0.029$ and 68.8% vs 48.6%, $p = 0.039$). Survival curves showed that the gLBBB has a worse outcome at 6M and at 18M ($p = 0.036$ and $p = 0.034$ respectively - Figure 1).
Conclusion: In this study, the LBBB showed to have a prognostic impact on P with mrEF heart failure compared to P without LBBB and was associated with a greater number of events in the medium and long term follow-up. These results may have an impact on future research, particularly with regard to the benefit of early cardiac resynchronization therapy.

Prevalence and correlates of left ventricular diastolic dysfunction in hypertensive community residents with preserved ejection fraction. Insights from survey-SEPHAR III

A Scafa Udriste[1]; OF Tautu[1]; RO Darobant[1]; D Dimulescu[1]; D Pitic[2]; G Tamasescu[2]; M Stoian[2]; S Onciul[2]; M Dorobantu[1]
[1]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*; [2]*Emergency Hospital Bucharest, Bucharest, Romania*

Introduction: Left ventricular diastolic dysfunction (LVDD) is present in half of patients with hypertension and has been associated with increased cardiovascular morbidity, as well as the development of heart failure with preserved ejection fraction (HFpEF). Without proper medical treatment the progression continue tword systolic LV disfunction an clinical overt heart failure
Purpose: We aimed to evaluate the presence and predictors of distolic dusfunction in hypertensive adults from an national representative survey SEPHAR III survey.
Methods: Adult subjects enrolled in SEPHAR III survey were evaluated throughout two study visits by: anthropometric measurements, 3 sitting BP measurements per visit according to ESC-ESH guidelines, arterial stiffness measurements (with an oscillometric device), laboratory workup (lipids, fasting plasma glucose, HbA1c) and standard echocardiography. Normotensive state was defined as BP below 140/90 mmHg and lack of HT history or treatment. LVH was defined as indexed left ventricular mass (ILVM) > 95g/m2 in females and > 115 g/m2 in males. HT prevalence and control was defined by current ESC-ESH Guidelines. Diastolic dysfunction was defined by E/A < 1 or ≥2 on Doppler mitral inflow.
Results: From the total 889 adult hypertensive subjects identifies in SEPHAR III survey (mean age 55.79 ± 15.68, 51% males, 72,2% treated hypertensives out of which 30.8% with controlled BP values), diastolic dysfunction was recorded in 46.9%. Diastolic dysfunction was similar in treated vs. non-treated hypertensive (46.3% vs. 48.6%), and significantly less frequent among controlled vs. uncontrolled hypertensives (39.9% vs. 48.9%). Adjusting for MAP, treatment and treatment controll, regression analysis confirmed as predictors of diastolic dysfunction: PWVao (OR 1.11; 95% CI for OR: 1.01-1.12), LVH (OR 1.04; 95% CI for OR: 1.03-1.05), AF (OR 1.76; 95% CI for OR: 1.72-1.81), BP control (OR 0.85; 95% CI for OR: 0.82-0.89), antihypertensive treatment with RAAS blockers (OR 0.74; 95% CI for OR: 0.71-0.76), aortic SBP (OR 1.10; 95% CI for OR: 1.01-1.25).
Conclusions: Our study reveals that beyond well recognized determinants of diastolic dysfunction (LV, AF, BP values, RASS blockade), parameters of arterial stiffness and central BP values independently contributes to diastolic dysfunction adult hypertensive subjects, stressing the need specific treatment strategies, preventing the progression to overt heart failure.

P586

Hemodynamic correlates of right ventricular dilation in pulmonary hypertension due to HFpEF

E Berthelot[1]; MT Bailly[1]; S El Hatimi[1]; I Robard[1]; D Montani[2]; D Chemla[3]; P Assayag[3]
[1]*Hopital Bicetre, AP-HP - Service de Cardiologie, Université Paris-Sud, Le Kremlin-Bicetre, France*; [2]*Hopital Bicetre, AP-HP - Service de Pneumologie et Soins Intensifs, Université Paris-Sud, Le Kremlin-Bicetre, France*; [3]*AP-HP - Hospital Bicetre, University Paris Sud 11, Le Kremlin-Bicetre, France*

Background: Right ventricular (RV) remodelling and pulmonary hypertension (PH) are increasingly recognized in heart failure with preserved ejection fraction (HFpEF), with high prevalence and poor outcome. Factors leading to RV dilation in PH-HFpEF patients are unknown.
Purpose: We thought to determine the hemodynamic correlates of RV dilation (indexed end- diastolic right ventricular area EDRVA) in HFpEF patients with PH.
Methods: Right heart catheterization and echocardiography were performed in 93 PH-HFpEF patients (60 women) enrolled prospectively in our center. PH-HFpEF was defined by a resting mean pulmonary artery pressure (mPAP) ≥25 mmHg and a resting pulmonary artery wedge pressure (PAWP) >15 mmHg.
Results: Mean age (± SD) was 69 ± 12 years, mPAP was 40 ± 10 mmHg, PAWP was 21 ± 4 mmHg. 30 PH-HFpEF patients (31%) had RV dilation. The Pearson correlation coefficient between EDRVA (9.6 ± 3.1 cm^2/m^2) and hemodynamic variables was 0.39 for right atrial pressure (RAP) and 0.36 for the diastolic pressure gradient (each $p < 0.001$), and 0.27 for mPAP ($p = 0.01$). There was no correlation between EDRVA and PAWP, pulmonary vascular resistance or pulmonary arterial stiffness.
Conclusion: In PH-HFpEF patients, we documented a significant relationship between RV remodeling and RAP, mPAP and the diastolic pressure gradient. The classic variables quantifying pulmonary arterial load (resistance, stiffness) did not contribute.

P587

Left ventricular diastolic dysfunction and cardiovascular mortality in dialysis patients with preserved ejection fraction.

M Cafka[1]; M Rroji[2]; J Djamandi[3]; J Seiti[1]; G Burazeri[4]; A Goda[1]
[1]*University Hospital Center Mother Theresa, Department of Cardiology & Cardiac Surgery, Tirana, Albania*; [2]*University Hospital Center, Nefrology-Dialysis-Transplant Department, Tirana, Albania*; [3]*Hygeia Hospital, cardiology department, Tirana, Albania*; [4]*Institute of Public Health, Tirana, Albania*

Introduction: Cardiovascular disease is the major cause of death in dialysis patients. Diastolic dysfunction (DD) is common among dialysis patients. The aim of the study was to evaluate diastolic dysfunction, using TDI, in hemodialysis (HD) or peritoneal dialysis (PD) with preserved ejection fraction, and to identify its correlation with cardiovascular mortality.
Methods: A case control study was conducted, enrolling all patients on chronic dialysis (HD and PD) older than 18 years, who had more than 3 months in therapy. The echocardiography was performed 2-24 h after the dialysis session. LV diastolic dysfunction was defined as E/E′average (septal and lateral wall) ≥ 14. All patients had been followed up for 2 years. The end point was cardiovascular mortality.
Results: :Our population consisted in 122 pts, 78 pts (61%) on hemodialysis, mean age 53.4 ± 14.5 years, mean time on therapy 40.4 ± 14.4 months, 56% of patients were male, 27.8% with diabetes melitus,31.8% with hypertension; EF 0.60 ± 0.07. 30% of the patients have E/E′averaged >14. Cardiovascular mortality during follow up was 15.5% (19 events). The main causes of CV death were sudden deaths (31.5%), deaths from ischemic heart disease and stroke with 26.4% respectively ; 19.7 % in the group of patients with E/E′averaged >14) vs 10.1% in the group with E/E′averaged <14 ($p = 0.023$). Binary logistic regression analysis showed that E/E′averaged >14 [OR= 1.06 (1.01-1.21) $p = 0.011$], was independent risk factor for cardiovascular mortality
IN CONCLUSION: Diastolic dysfunction is independent predictor of cardiovascular mortality in dialysis patients with preserved ejection fraction.

P588

Left atrial volume index progresses significantly over time in diabetic and non-diabetic at risk populations

G O' Carroll[1]; E Tallon[1]; S Zhou[1]; C Watson[1]; M Ledwidge[1]; J Gallagher[1]; V Harkins[1]; K Mc Donald[1]
[1]*St Vincent's University Hospital, Dublin, Ireland*

Purpose: Left atrial volume index (LAVI) elevation is a significant predictor of cardiovascular disease. Progression of LAVI has also been shown to predict cardiovascular outcomes in the general population but little data exists in the diabetic population. LAVI progression may contribute to heightened cardiovascular risk in diabetic patients. The aim of this study is to describe LAVI progression in a community diabetic population compared with a non diabetic at risk cohort.
Methods: Patients attending the STOP-HF service between January 2011 and December 2013 were included in this study. Using transthoracic echocardiography, we measured LAVI in all participants in addition to standard Doppler-echocardiographic parameters. Echocardiography was performed at baseline and at a predefined follow up visit (2 – 5 years post baseline). Based on previous reported observations from our unit, significant change in LAVI ('LAVI progression') was defined as a change in baseline LAVI > 3.5 ml/m2.
Results: There were 1253 patients enrolled in the service. Four hundred and fifty four (36.2%) of these were diabetic (median age 65.3, 57.7% male). There was no difference in baseline cardiovascular risk factor between the groups except hypertension which was higher in the diabetic population (74% vs 66.8% p = 0.01). LAVI progression was seen in almost one third of patients (44.3% male, median age 67.9) (Table one).
Diabetics with LAVI progression were more often male (60.3% vs 34.8%, p < 0.001) with hyperlipidaemia (86% vs 71.6% p = 0.05). Both groups had similar rates of hypertension (78.5% vs 72.1% p = 0.24) There was no significant difference between the progressor groups in left ventricular ejection fraction (baseline median 67% vs 67%, follow up median 66.2% vs 66%, p = 0.97), left ventricular mass index (baseline median 91.1g/m2 vs 98.9g/m2, follow up median 93.6g/m2 vs 97g/m2, p = 0.004) or E/E′ (baseline median 8.4 vs 8.9, follow up median 8.5 vs 9.2, p = 0.02). Use of RAAS modifying therapy was similar in both progressor groups (48.1% vs 48.7% p = 0.25).
Conclusion: LAVI progression was similar in the diabetic and non diabetic groups, occurring in almost one third of patients. These at risk groups need further attention given the increased cardiovascular risk associated with diastolic dysfunction.

comparison of LAVI progression

	DM group	Non DM group	p value
Mean baseline LAVI	26.1 ml/m2	26.8 ml/m2	0.0766
Mean change in LAVI at follow up	2.18 ml/m2	2.20 ml/m2	0.54
LAVI change > 3.5 ml/m2	121 (30.9%)	204 (28.7%)	0.49

P589

Heart rate variability in heart failure patients with mid-range versus preserved ejection fraction and premature ventricular complexes

G Gheorghe[1]; A Ciobanu[2]; I Hartan[2]; ACD Gheorghe[2]; G Stanciu[2]; IT Nanea[2]
[1]University of Bucharest Carol Davila, cardiology, Bucharest, Romania; *[2]"Th. Burghele" Hospital, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania*

Background: Heart failure (HF) with reduced left ventricular ejection fraction (LVEF) has a high ventricular arrhythmic risk but there is few information about the arrhythmic risk in patients (pts) with heart failure and mid-range LVEF (HFmrEF) or preserved LVEF (HFpEF).
Purpose: To evaluate the heart rate variability (HRV) in the time and frequency domains as marker of myocardial electrical instability in sinus rhythm pts with HFmrEF versus pts with HFpEF.
Method: We included consecutive pts in sinus rhythm with HFmrEF (EF 40-49%) and HFpEF (EF≥50%) and premature ventricular complexes (PVC) during 24 hours ECG Holter monitoring. Pts with HF and reduced LVEF, atrial fibrillation or autonomic neuropathy were excluded. Demographic data, NYHA class and medical history were noted. The severity of PVC was evaluated according to the Lown classification. HRV was determined in the time domain (standard deviation of normal to normal (NN) R-R intervals - SDNN; standard deviation of the average NN intervals calculated over 5 minutes periods - SDANN; mean of the 5-min standard deviation of the NN interval calculated over 24 h - SDNN index; root mean square of successive differences - rMMSD; proportion of pairs of successive NNs that differ by more than 50 ms divided by total number of NNs - pNN50) and in the frequency domains (total power - TP; very low frequency – VLF; low frequency – LF; high frequency – HF, LF/HF ratio). Statistical analysis was performed with Epi Info 8.
Results: 70 pts were included, 73 ± 9 years old, 57.1% men. 88.6% pts had hypertension, 65.7% coronary artery disease, 40% old myocardial infarction, 8.6 % peripheral artery disease, 40% diabetes, 40% chronic kidney disease. 48.6% pts had HFpEF and 51.4% HFmrEF. 62.9% pts were in NYHA class II, 28.6% in NYHA class III and 8.6% in NYHA class IV. There were statistical significant more Lown IV PVC (couplets and ventricular tachycardia) in HFmrEF than in HFpEF pts (94.4% vs 52.9%, p < 0.001). There were no statistical differences between the two groups regarding SDNN, SDANN, SDNNI, rMMSD, pNN50. LF/HF ratio was augmented in HFmrEF comparing to HFpEF (p = 0.08).
Conclusions: The majority of HFmrEF pts had Lown IV PVC, with a statistical significant greater prevalence than in HFpEF pts. HRV parameters were similar in HFmrEF and HFpEF pts except LF/HF which was augmented in HFmrEF compared to HFpEF, reflecting a more important sympathetic nervous stimulation

P590

Does RAAS modifying therapy attenuate the cardiomyopathic effect of diabetes?

G O' Carroll[1]; E Tallon[1]; S Zhou[1]; C Watson[1]; M Ledwidge[1]; K Mc Donald[1]
[1]St Vincent's University Hospital, Dublin, Ireland

Purpose: In the general population, the presence of left ventricular diastolic dysfunction (LVDD) is an independent risk factor for cardiovascular disease including heart failure. We hypothesise that LVDD is more prevalent in diabetic populations than in a general at risk cohort resulting in worse cardiovascular outcomes. The aim of this study is to describe the prevalence of diastolic dysfunction in a community diabetic population and an at risk nondiabetic population and to characterise those with diastolic dysfunction.
Methods: Patients enrolled in the STOP-HF service between January 2011 and December 2013 were included in this study. Using transthoracic echocardiography, we measured LAVI in addition to standard Doppler- echocardiographic parameters. (LAVI < 28ml/m2 = normal, 28 – 32ml/m2 = indeterminate and > 32 ml/m2 = increased). Echocardiography was performed at baseline and at a predefined follow up visit (2 – 5 years post baseline).
Results: There were 1253 patients in this cohort. Four hundred and fifty four (36.2%) of these were diabetic (median age 65.3, 57.7% male). Baseline cardiovascular conditions were similar in both groups except hypertension which was higher in the diabetic population (74% vs 66.8% p = 0.01). The median BNP level at baseline was lower in the diabetic group (15.9 pg/ml vs 21.9 pg/ml, p < 0.001). The mean LAVI was 26.1 ml/m2 in the diabetic group and 26.8 ml/m2 in the non diabetic group (p = 0.0766). E/E′ was similar in both groups (baseline median 8.8 vs 8.1 p = 0.0669). Use of RAAS modifying therapy was higher in the diabetic group (59.7% vs 44%, p < 0.001).
Conclusion: Despite the higher rate of hypertension in the diabetic group, prevalence of LVDD was similar in both groups. This may reflect the fact that both groups are managed in a heart failure prevention service where emphasis on RAAS modifying therapies and other cardioprotective medications is standard.

comparison of diastolic parameters

	DM Population Baseline	Non DM Population Baseline
LAVI < 28 ml/m2	288 (63.4%)	492 (61.5%)
LAVI 28 - 32 ml/m2	50 (11%)	112 (14%)
LAVI > 32 ml/m2	67 (14.7%)	120 (15%)
E/E' < 8	197 (43.3%)	403 (50.4%)
E/E' 8 - 15	224 (49.3%)	340 (42.5%)
E/E' > 15	16 (0.2%)	33 (4.1%)

Significant diastolic dysfunction is associated with cardioembolic stroke independent of history

I Indranill Basu Ray[1]; G Schwing[2]; T Middour[2]; D Monlezun[2]; K Katikitala[1]; K Korrane[1]; S Martin - Schild[3]; W Lam[1]; H Afsar[1]; I Giorgberidze[4]; J Cheng[1]; M Saeed[1]
[1]Texas Heart Institute, Cardiac Electrophysiology, Houston, United States of America; *[2]Tulane University, Cardiology , New Orleans, United States of America*; *[3]Tulane University, neurology , New Orleans, United States of America*; *[4]Michael E. DeBakey VA Medical Center , Cardiac electrophysiology , houston, United States of America*

Hypothesis: Diastolic dysfunction (DD) is an independent risk factor for Cardioembolic Stroke (CES) in patients both with and without atrial fibrillation (AF).
Background: DD may be associated with a thrombotic milieu, even in the absence of AF. Present guidelines are ambiguous whether risk stratification for AF should include DD. It is also unknown if DD is a risk factor for stroke without AF.
Methods: All patients admitted with diastolic dysfunction grade <4 and recorded stroke based on TOAST classification between 6/2008-5/2014 were identified.

Transthoracic echocardiogram was used to diagnose and grade DD. Multivariable logistic regression was used to investigate the possible independent association between stroke type and DD, adjusting for age, race, sex, and history of CHF, HTN, DM, stroke, mitral regurgitation (MR) >1 and AF. (Table)
Results: 388 patients met study criteria, 97(25.00 %) had DD grade > 1, the mean (SD) age was 62.46 (11.67), 154 (39.79%) were female, 17 (4.44%) had AF, and 77 (27.80%) had CES. In fully adjusted multivariable regression, DD grade >1 significantly increased the odds of CES (OR 3.96; 95%CI 1.02-15.36; p = 0.047).
Conclusion: DD (grade > 1) is an independent risk factor for patients with CES irrespective of AF. Larger studies are essential to delineate the complex relationship of DD and CES, both with and without AF, to determine appropriate anticoagulation strategy. This is particularly so as DD itself has been incriminated in the pathogenesis of AF.

Multivariable analysis of DD and Stroke

Covariate	OR(95% CI ; p - value)
DD grade> 1	3.95(95% CI1.02-15.36; p = 0.047)
Age	1.02(95% CI0.97-1.07; p = 0.461)
Black	0.50(95% CI0.15-1.62; p = 0.245)
Female	0.39(95% CI0.13-1.21; p = 0.102)
CHF History	2.56(95% CI0.63-10.50; p = 0.191)
Hypertension History	0.39(95% CI0.07-2.30; p = 0.300)
Diabetes History	0.41(95% CI0.13-1.30; p = 0.130)
Atrial Fibrillation History	3.01(95% CI0.17-54.83; p = 0.456)

P592
A single blind, randomised, cross over trial of short term oxygen use during cycle ergometry in ambulatory patients with heart failure with normal ejection fraction

P Shah[1]; P Pellicori[1]; S Rimer[1]; A Bennett[1]; A Clark[1]
[1]*Castle Hill Hospital, Academic Cardiology, Hull, United Kingdom*

Introduction: Diuretics are the only treatment that improves exercise tolerance in patients with heart failure with normal ejection fraction (HFnEF). We investigated whether increased concentrations of inspired oxygen (FiO2) affects exercise tolerance in patients with HFnEF.
Methods: This is a single centre, randomised, single blind, crossover trial. HFnEF was defined as signs and symptoms of heart failure requiring treatment with diuretics, with a left ventricular ejection fraction of more than 45% and N-terminal pro brain natriuretic peptide (NTproBNP) >220 ng/l. 30 patients with HFnEF undertook three maximal incremental exercise tests with different FiO2 (room air, 28% and 40%) in random order. Patient blinding was maintained by using the same Venturi mask for all visits and FiO2 was controlled by investigator.
Results: Mean age was 74 years (73% male) and median NTproBNP of 1289 (IQR: 566-2243) ng/l. The results of the outcome variables measured are shown in the table:
Conclusion: Increasing FiO2 during exertion does not improve exercise capacity in patients with HFnEF.

P593
Diagnostic score for the detection of cardiac amyloidosis in patients with left ventricular hypertrophy

E Eve Cariou[1]; GM Galinier[1]; CD Carrie[1]; RJ Roncalli[1]; FP Fournier[1]; RD Ribes[1]; LO Lairez[1]
[1]*Toulouse Rangueil University Hospital (CHU), Toulouse, France*

Background: Cardiac amyloidosis (CA) is a disease with poor prognosis. Early non-invasive identification is of growing clinical importance. The objective of our study was to integrate clinical, electrocardiographic and echocardiographic parameters to build a diagnostic score in patients with left ventricular hypertrophy (LVH).
Methods and Results: 114 patients with LVH underwent a cardiac magnetic resonance and a 99mTc-3,3-diphosphono-1,2-propanodicarboxylic acid scintigraphy allowing to discriminate 3 groups of diagnosis: CA (n = 50), hypertrophic cardiomyopathy (n = 19) and unspecific cardiomyopathy (n = 45). Seven continuous variables associated with CA (systolic arterial pressure < 130 mmHg; PR duration > 200 ms ; Sokolow index < 12 mV; diastolic left ventricular posterior thickness > 13 mm ; E/Ea ratio > 10 ; global longitudinal strain > -12% and sum of basal longitudinal strain > -47%) were selected according to the best cut-off value. The area under the ROC curve for the diagnosis of CA using the score was 0.933 (95%CI 0.889-0.978). The best cut off value for the score was 3 leading to a sensitivity of 90% and specificity of 81%.
Conclusion: – An integrated evaluation of 7 diagnostic factors to build a diagnostic score is an easily method to discriminate CA in patients with LVH.

variables associated with CA

	AUC	IC95%	P-value	Best cut-off value

Diastolic dysfunction in patients with primary antiphospholipid syndrome

A Djokovic[1]; L Stojanovich[1]; S Radovanovic[1]; B Todic[1]; DV Simic[2]; M Zdravkovic[1]
[1]University Hospital Medical Center Bezanijska Kosa, Belgrade, Serbia; *[2]University Clinical Center of Serbia, Clinic of cardiology, Belgrade, Serbia*

INntroduction: The traditional view of atherosclerosis as a lipid storage disease crumbles in the face of extensive and growing evidence that inflammation participates centrally in all stages of this disease. Systemic inflammation in autoimmune diseases exhibits proatherogenic effects by induction of dyslipidemia, insulin resistance, hypercoagulation, endothelial dysfunction and oxidative stress. Patients with antiphospholipd syndrome (APS) are facing the higher risk of development of cardiovascular disease not only due to thrombophilia mediated by antiphospholipid antibodies (aPL) but accelerated atherosclerosis as well.
Objectives: To evaluate left ventricular (LV) diastolic function and presence in APS patients.
Methods: We analyzed 101 APS patients, 16 men (16.0%) and 85 women (84.0%) average age 47.70 ± 13.14. aPL analysis included detection of aCL(IgG/IgM), beta2GPI(IgG/IgM) and lupus anticoagulans (LA). According to the recent guidelines, we considered LV diastolic function normal if none or one available parameter met cut-off values (septal e' velocity >7cm/s, average E/e' >14, tricuspid regurgitation velocity >2.8 m/s, and left atrial indexed volume (LAVI) >34mL/m2). LV diastolic dysfunction was considered intermediate in cases meeting 2 cut-off values. If more than 2 parameters met cut-off values, a diagnosis of LV diastolic dysfunction was made. Results were compared to 32 healthy age and sex matched controls.
Results: Mean values of peak A wave, DT, IVRT as well as septal and lateral E/e' ratio and LAVI were significantly higher in APS patients compared to healthy subjects (p = 0.001, p = 0.0001, p = 0.008, p = 0.018, p = 0.012, p = 0.038 respectively) whereas E/A ratio was significantly lower (p = 0.046). Presence of diastolic dysfunction was significantly higher in APS patients (p = 0.001). aCL IgG positive APS patients had significantly higher values of peak A wave and IVRT (p = 0.008, p = 0.027 respectively), b2GPI IgG positive significantly higher values of peak A wave, IVRT and septal e' velocity (p = 0.011, p = 0.008, p = 0.008 respectively), beta2 IgM positive had significantly higher values of IVRT (p = 0.024), LA positive had significantly lower values of E/A ratio (p = 0.032).
Conclusion: Autoimmune diseases are associated with presence of LV diastolic dysfunction as a main determinant of heart failure with preserved EF (HFpEF). More aggressive education and prevention considering standard risk factors as well as timely cardiac evaluation in this group of patients seems to be of high importance.

P595

Left atrial volume index predicts cardiovascular events in diabetic and general at risk populations

G O' Carroll[1]; E Tallon[1]; S Zhou[1]; L Mc Donald[1]; C Watson[1]; M Ledwidge[1]; V Harkins[1]; J Gallagher[1]; K Mc Donald[1]
[1]St Vincent's University Hospital, Dublin, Ireland

Purpose: Left ventricular diastolic dysfunction (LVDD) is a significant predictor of cardiovascular disease. Left atrial volume index (LAVI) in the absence of atrial fibrillation and significant mitral valve disease is an excellent measure of diastolic function. We hypothesise that LAVI may be more predictive of cardiovascular outcomes in the diabetic population compared with the general at risk population. The aim of this study is to investigate the predictive value of LAVI in determining cardiovascular hospital admissions.
Methods: Patients enrolled in the STOP-HF service between January 2011 and December 2013 were included in this study. Using transthoracic echocardiography, we measured LAVI in all participants in addition to standard Doppler-echocardiographic parameters. Echocardiography was performed at baseline and at a predefined follow up visit (2 – 5 years post baseline). Hospitalisation for major adverse cardiovascular events (MACE) was determined using the hospital inpatient enquiry (HIPE) database. Hospitalisation for MACE was determined at least 2 years after the baseline visit. A significant change in LAVI ('LAVI progression') was defined as a change in LAVI > 3.5 ml/m2.
Results: There were 1253 patients enrolled in the service. Four hundred and fifty four (36.2%) of these were diabetic (median age 65.3, 57.7% male). At baseline, the mean LAVI was 26.1 ml/m2 in the diabetic group and 26.8 ml/m2 in the non diabetic group (p = 0.0766). MACE occurred in 7.01% of the diabetic population and 3.13% of the non diabetic population. Stroke/TIA (1.36%) was the commonest cardiovascular hospitalisation followed by arrhythmia (1.20%), myocardial infarction (0.72%) and heart failure (0.72%). A LAVI > 32 ml/m2 was most predictive of cardiovascular hospitalisation. MACE occurred in 6.47% of those with LAVI progression and in 3.59% of those without LAVI progression.
Conclusion: Cardiovascular admissions were twice as common in the diabetic population. Cardiovascular admissions were also more common in patients with LAVI progression. Elevated LAVI was most predictive of cardiovascular hospitalisation in both groups.

MACE Hospitalisations

MACE hospitalisation	LAVI < 28 ml/m2	LAVI 28 - 32 ml/m2	LAVI > 32 ml/m2	LAVI change > 3.5 ml/m2	LAVI change < 3.5 ml/m2

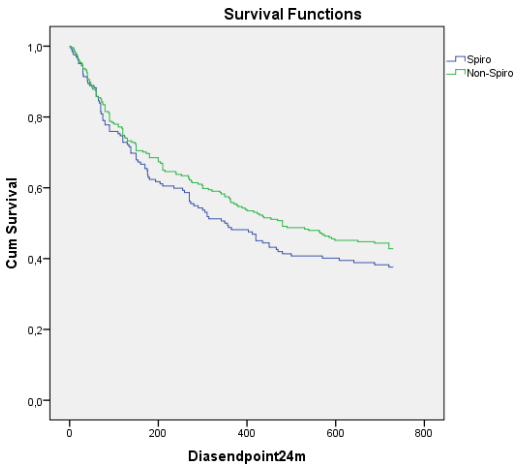
P596

Prognostic impact of spironolactone in patients with heart failure with preserved ejection fraction

H Hugo Antunes[1]; J Gil[1]; ML Goncalves[1]; L Abreu[1]; B Marmelo[1]; I Pires[1]; D Moreira[1]; I Almeida[1]; M Correia[1]; C Cabral[1]
[1]Hospital Sao Teotonio, Cardiology, Viseu, Portugal

Introduction: Therapy for heart failure with reduced ejection fraction (HFrEF) is well established, with a prognostic impact in this group of patients (P). On the other hand, no treatment showed convincingly to reduce the morbi-mortality in P with heart failure with preserved ejection fraction (HFpEF).
Objectives: To evaluate the prognostic impact of spironolactone therapy in P with HFpEF.
Methods: We identified all patients admitted for HF in a single center between 01/01/2009 and 31/12/2014. Only the first episode of each patient was included. Only the P with HFpEF were selected. We considered 2 groups, according to therapy instituted at the time of discharge: Group with Spironolactone (gSpiro) and group without spironolactone (gCONT).
We compared the combined endpoint (death / hospitalization for HF) at 12 and 24 months (M) and the survival curves of each group.
Results: Of a total of 1006 P admitted, 435 cases were included: 61.2% female and mean age 79.4 ± 8.3 years.
In-hospital mortality was 3.2%. The combined endpoint at 12M was 45.7% and 56.9% at 24M.
The gSpiro represented 38.4% of the P. There was a predominance of females in both groups (56.9vs 61.7% in gCONT, p> 0.05), mean age 79.6 ± 8.5 (vs 79.2 ± 8.3, p> 0.05).
The two groups were similar in terms of co-morbidities (Arterial hypertension in the gSpiro 66.2% vs 75.7%; Diabetes 29.6% vs 38.0%; History of ischemic heart disease 13.8% vs 9, 6%; History of stroke 9.2% vs 6.1%; p> 0.05).
Analytically, the sodium value was 139 ± 5 (vs 140 ± 5, p = 0.033), potassium of 4.5 ± 0.71 (vs 4.63 ± 0.66, p = 0.053), urea 60.4 ± 29.7 (vs. 70.47 ± 36.08, p = 0.002) and creatinine of 1.1 ± 0.4 (vs 1.3 ± 0.60, p < 0.001).
There was a greater number of events in the combined endpoint at 12 and 24M in gSpiro (63.5% vs 42.0%, p = 0.006 and 74.6% vs 57.4%, p = 0.024). Survival curves did not show statistically significant differences between the two groups at 12 or at 24M (p> 0.05)
Conclusion: This study showed that spironolactone therapy is associated with a greater number of adverse events at both 12 and 24M, although this difference was not evident when the survival curves of both groups were evaluated.
Thus, in this study, there was no benefit in the introduction of spironolactone in patients with HFpEF.



P597

Economic impact of heart failure with preserved ejection fraction: Insights from the prospective, randomized placebo-controlled ALDO-DHF trial

D Djawid Hashemi[1]; L Dettmann[2]; TD Trippel[1]; A Bobenko[1]; G Gelbrich[3]; R Lindhorst[1]; HD Duengen[1]; R Wachter[2]; G Hasenfuss[2]; B Pieske[1]; F Edelmann[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Department of Internal Medicine and Cardiology, Berlin, Germany; *[2]University Medical Center Gottingen (UMG), Gottingen, Germany*; *[3]University of Wuerzburg, Wurzburg, Germany*

Background: Heart failure accounts to the main diseases in the developed countries and persists as the leading cause of hospitalization among adults >65 years of age in the United States and in the European countries. 50% of these patients are characterized with heart failure with preserved ejection fraction (HFpEF). Despite the increasing prevalence of this syndrome the health care related costs and its implications –in contrast to heart failure with reduced ejection fraction (HFrEF)– remain unclear.
Methods: In this analysis we explore the costs of the clinically stable ALDO-DHF cohort and the effect of spironolactone. This cohort included 422 ambulatory patients (mean age, 67 [SD, 8] years; 52% female) with chronic New York Heart Association class II or III heart failure, preserved left ventricular ejection fraction of 50% or greater, and evidence of diastolic dysfunction. Patients were randomly assigned to receive 25 mg of spironolactone once daily (n = 213) or matching placebo (n = 209) with 12 months of follow-up. We used a single-patient approach to explore the resulting general cost structure and included medication, number of general practitioner and cardiologist visits, and hospitalization in both acute and rehabilitative care facilities.
Results: The average annual costs per patient in this cohort came up to $ 1,300, the median costs were $ 360. We confirmed the main factor was hospitalization and have to conclude that spironolactone did not affect the overall costs. We identified being male, a low hemoglobin level, high oxygen uptake (VO2max), coronary artery disease, hyperlipidemia and especially atrial fibrillation as independent predictors for higher costs.
Conclusion: The costs are far below expected and compared to the HFrEF population. Regarding the ALDO-DHF cohort we have to allow for the relatively young, oligosymptomatic patient selection. The strict protocol excluded patients with major, e.g. pulmonary, co-morbidities leading to a lower limit of the costs. Further investigation is needed regarding the impact of co-morbidities and their effect over a longer period of time. Simultaneously, this analysis shows that early diagnosis and prevention of co-morbidities are necessary to reduce costs in the health care system.

P598

The occurence of interatrial dyssynchrony in heart failure across the spectrum of ejection fraction

M Cikes[1]; D Fabijanovic[1]; I Planinc[1]; B Skoric[1]; D Lovric[1]; J Ljubas Macek[1]; N Jakus[1]; H Jurin[1]; J Samardzic[1]; B Bijnens[2]; D Milicic[1]
[1]University of Zagreb School of Medicine, Department of Cardiovascular Diseases, Zagreb, Croatia; *[2]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain*

Purpose: Heart failure with preserved EF (HFpEF) is characterized by phenotypic heterogeneity. Loss of atrial function is of relevance in HFpEF, and interatrial dyssynchrony (IAD) appears to be one of its aspects. The prevalence of IAD has not been compared between patients with HF and various categories of LVEF.
Methods: Data from 51 patients (24 HFpEF, 6 HFmrEF, 21 HFrEF) diagnosed with HF per current guidelines were analyzed retrospectively. IAD was measured from echo Doppler traces as the difference between the time of transmitral and transtricuspid A wave onsets.
Results: IAD>60 ms was present in 8 HFpEF pts. (33.3%), 1 HFrEF (4.8%) and 1 HFmrEF patient (16.7%) (p = 0.039). Compared to pts. with LVEF<50%, those with HFpEF were older, had higher SBP, heart rate, LVEF, LVmass, smaller LVIDd and lower sPAP; there was no difference in incidence of diabetes, NYHA class, NT-proBNP or eGFR , E/e' or atrial volumes. Higher IAD was associated with a higher proportion of HFpEF, lower heart rate, and higher LVEF (Table 1).
Conclusion: IAD is more prevalent in HFpEF compared to patients with LVEF<50% and does not appear associated with standard clinical parameters, NT-proBNP, LV mass, E/e' or atrial size.

Table 1

	1. Quartile n=13 IAD < -9 ms	2. Quartile n=13 IAD -9 - 24 ms	3. Quartile n=15 IAD 24 - 49 ms	4. Quartile n=10 IAD >49 ms	P value for trend

P599

Is there an association between hidden HFpEF and markers of preclinical atherosclerosis?

AM Jakstaite[1]; J Celutkiene[2]; J Badariene[2]; E Rinkuniene[2]; A Cypiene[2]; I Slyvovskaja[3]; M Miglinas[4]; R Navickas[2]; L Ryliskyte[2]; A Laucevicius[2]
[1]Vilnius University, Medical faculty, Vilnius, Lithuania; *[2]University Hospital Santariskiu Klinikos, Clinic of Cardiac and Vascular Diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania*; *[3]University Hospital Santariskiu Klinikos, Department of Rehabilitation, Physical and Sports Medicine, Vilnius, Lithuania*; *[4]University Hospital Santariskiu Klinikos, Clinic of Gastroenterology, Nephrourology and Surgery, Vilnius, Lithuania*

Background: In 2020 the prevalence of HFpEF is projected to exceed 8% of persons older than 65 years. However, there is a lack of knowledge on early detection of HFpEF and its' relation to cardiovascular risk markers.
Purpose: To investigate the association between early heart failure with preserved ejection fraction (HFpEF) and arterial markers of preclinical atherosclerosis.
Methods: We performed a prospective study and evaluated 148 high cardiovascular risk patients. Inclusion criteria were: metabolic syndrome (MetS), availability of brain natriuretic peptide (BNP) test, cardiopulmonary stress test, echocardiography and arterial markers (pulse wave velocity (PWV), augmentation index (AI), common carotid artery intima media thickness (IMT), common carotid artery stiffness (CAS),

ankle brachial index (ABI), reactive hyperemia index (RHI). We considered patients as having initial HFpEF if peak VO2 value was lower than 90% and/or BNP≥35 pmol/l. All patients were divided into 5 groups: (1) without HFpEF, with normal values of peak VO2 and BNP, (2) with at least one abnormal finding, either VO2 or BNP, (3) with elevated BNP, (4) with decreased peak VO2, (5) with both abnormal findings.
Results: 46 men and 102 women were analysed, mean age 56.41 ± 6.57 years. Group 1 was composed of 52 healthy individuals (35.14%), group 2 – of 96 (64.86%), group 3 – of 43 (29.05%), group 4 - 80 (54.05%), group 5 - of 28 (18.92%) patients. Significant differences were found between group 1 and remaining four groups in values of BNP – in group 2, 3, 4 and 5 (16.22 ± 6.60 vs 31.71 ± 23.15, 50.69 ± 21.90, 27.39 ± 20.93 and 48.59 ± 21.80, respectively; $p < 0.000$), for peak VO2 – in group 2, 3, 4 and 5 (103.11 ± 7.64 vs 82.69 ± 14.03, 87.42 ± 17.40, 78.40 ± 9.25 and 77.89 ± 9.83, respectively, $p < 0.000$). After comparison of arterial markers significant differences were found between groups 1 and 2, 1 and 3. Mean AI values were found as follows: 31.20 ± 9.87 vs. 27.33 ± 7.44; $p = 0.016$ and 31.60 ± 10.16 vs. 27.33 ± 7.44; $p = 0.020$. Average correlation was found between peak VO2 and left ABI (r=0.421; $p = 0.036$), right ABI (r=0.433; $p = 0.040$) in group 3 and weak relation between BNP and right CAS (r=0.300; $p = 0.032$) in group 1.
Conclusions: Two thirds of studied MetS patients had at least one pathological finding indicative of occult HFpEF. A significant relationship between heart failure markers and markers of preclinical atherosclerosis was found.

P600
ST-elevation myocardial infarction: risk factors at admission associated with a prolonged in hospital stay

MJ Maria Joao Vieira[1]; M Madeira[2]; L Reis[2]; P Dinis[2]; J Ribeiro[2]; A Fernandes[2]; F Caetano[3]; M Alves[1]; C Lourenco[2]; R Teixeira[2]; L Goncalves[2]
[1]Hospital Santarém, Cardiology, Santarém, Portugal; *[2]University Hospitals of Coimbra, Hospital Geral, Cardiology, Coimbra, Portugal*; *[3]King's College Hospital, NHS Foundation , London, United Kingdom*

Introduction: The length of hospital stay is an important measure of efficiency in the use of hospital resources as health care costs increase with prolonged hospitalization. Several predictors of length of hospitalization have been described in patients with ST-elevation myocardial infarction (STEMI), but little is known about the risk factors at admission for a prolonged in hospital stay (IHS).
Aim: Determine the risk factors at admission associated with a prolonged IHS in patients (Pts) undergoing percutaneous coronary intervention (PCI) for STEMI.
Methods: We performed a retrospective study of 313 consecutive patients (Pts) presented with STEMI (mean age: 64 ± 13.8, 72.8% male) who undergone PCI. Patients were divided in two groups based on mean in-hospital stay ≤ 5 days (short IHS) and > 6 days (long IHS). Demographic, clinical, laboratory and echocardiographic parameters at admission were evaluated. Statistical analysis was performed using Stata software version 14.1.
Results: Of the population, 229 Pts (73%) were included in the short stay group and 84 Pts (27%) were included in the long stay group. Male gender is associated with a shorter IHS (76,4% short IHS vs 63.1% long stay, P=0.019). Patients with long IHS were older (62 vs 69 years old; $p < 0.001$), were more likely to have prior arterial hypertension (75 vs 61%; P=0.023), prior history of chronic kidney disease (23.8 vs 7.0%, P=0<001). Also, the long HIS group presented at admission higher creatinine levels (118.3 ± 125.1 vs 87.3 ± 34.4 μmol/L; P=0.027), potassium levels (4.47 ± 0.7 vs 4.28 ± 0.4 mmol/l; P=0.007), glucose levels (9.71 ± 5.2 vs 8.1 ± 9.7 nmol/L; P=0.005), NTproBNP levels (6028.1 ± 8232 vs 1854.8 ± 2674.7 pg/ml; $p < 0.001$), troponin I levels (78.6 ± 138.7 vs 38.6 ± 93 ng/ml; $p < 0.004$), C-reactive protein (4.3 ± 6.6 vs 1.2 ± 2.33 mg/dl; $p < 0.001$), white blood cell count (12240.8 ± 3984 vs 10870.3 ± 3377 cells/μL; P=0.003); but lower hemoglobin concentration (13.49 ± 1.97 vs 14.18 ± 1.7 g/dl; P=0.004) and lower left ventricular ejection fraction (42.2 ± 11.4 vs 48.4 ± 9.9%; P=0.001), when compared to short IHS group. In the multivariate analysis, male gender (OR 0.26: 95%CI 0.07-0.96; P=0,043), creatinine level at admission (OR 1.02: 95%CI 1.0-1.05; P= 0.05), and C-reactive protein at admission (OR 1.23: 95%CI 1.004-1.51; P= 0.045) were found to be independently associated with prolonged IHS for patients with STEMI following PCI.
Conclusion: According to our data, in hospital length stay is strongly influenced by baseline characteristics of Pts, namely creatinine level, C-reactive protein and gender. These findings suggest that the assessment of several baseline variables together may represented a better clinical risk profile for in hospital length stay and its evaluation at admission may play an important role in the risk stratification of this Pts.

P601
The severity of myocardial dysfunction following ST-elevation myocardial infarction in patients undergoing acute percutaneous coronary intervention: time delays impact

L Malinova[1]; N Furman[1]; P Dolotovskaya[1]
[1]Saratov State Medical University, Research institute of cardiology, Saratov, Russian Federation

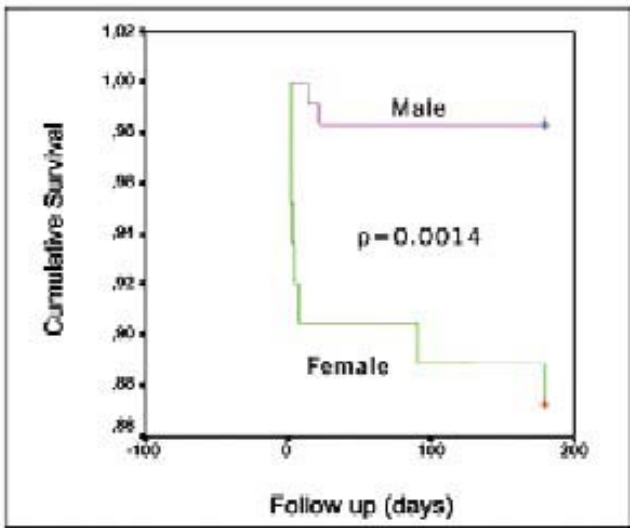
Despite the obvious fact that increased delay from myocardial infarction (MI) symptom onset to reperfusion is associated with worsening of the prognosis, and because of that have been introduced as performance indicator of MI care quality, intimate mechanisms underlying poor outcomes associated with time delays remain discussable.
Purpose of the study was to assess the impact of time delays on severity of myocardial dysfunction following STEMI.
Methods: 80 male patients (54 (47; 60) y.o.) admitted with STEMI were recruited into the study. Patient delay, health care systems delay and total ischemic time were estimated. BNP levels were measured on admission (BNP 1), at ~24 hours from reperfusion (BNP 2), at 7th day of admission (BNP 3, on discharge). The follow-up period was 12 months. Clinical signs and symptoms of heart failure were checked at 1, 6 and 12 months points. Primary endpoint was defined as the new-onset of heart failure according to 2016 ESC guidelines diagnostic algorithm.
Results: All recruited patients report no previous history of coronary heart disease, prior acute coronary event or heart failure. Symptom onset to first medical contact (FMC) time (patient delay), was 120 (40; 240) min. Symptom onset to arrival at hospital time (patient delay + health care system delay #1) was 175 (125; 230) min. Symptom to PCI delay in all recruited patients never exceeded 500 min. All studied time delays revealed moderate to high positive correlations with BNP levels measured at 24 hours from reperfusion and at 7th day of admission, but not BNP level at admission: i.e. patient delay + health care system delay #1 and BNP 2 – Spearman R = 0.63 ($p = 0.006$), patient delay + health care system delay #1 and BNP 3 – Spearman R = 0.72 ($p = 0.024$). Measured STEMI delays negatively correlated with left ventricular ejection fraction (Spearman R -0.57 … -0.791, $p < 0.05$) There were no associations between age, troponin I level, myocardial infarct size or culprit artery and BNP 2 and BNP3 levels as well as between severity of clinical signs of heart failure during follow up and time delays. On admission BNP level was 74.0 (18.1; 275.0) pg/mL. 9 patients (11.25%) reached primary end point within follow up period. Delays in FMC to PCI were associated with increased risk of new-onset of heart failure (HR 2.5 CI 1.5; 4.7, $p < 0.05$) at delays of more than 60 min.
Conclusion: Received data demonstrate significant impact of time delays on severity of myocardial dysfunction and risk of new-onset heart failure following STEMI. FMC to PCI time was associated with increased risk of new onset of heart failure) at delays of more than 60 min.

P602
Primary percutaneous coronary intervention in women. independent risk factors for death and major events after immediate and medium-term follow-up

I P Ivana Picone Borges[1]; ECS Peixoto[1]; RTS Peixoto[1]; RTS Peixoto[1]; ILPB Anjos[2]; AAB Aragao[1]; VF Marcolla[1]
[1]Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil; *[2]Severino Sombra University, School of Medicine, Rio de Janeiro, Brazil*

Background: Coronary heart disease is the leading cause of mortality and morbidity. A higher mortality risk for women with acute ST-elevation myocardial infarction has been a common finding in the past, even after acute percutaneous transluminal coronary angioplasty (PTCA). Prior studies have reported worse results after PTCA in women than in men. However, recent data suggest that this difference is less marked.
Objective: To determine gender-related differences and risk factors for death and major events, both in-hospital and at six-month follow-up, of patients that have been admitted within the first twelve hours of ST-segment elevation acute myocardial infarction (AMI) and primary PTCA in other to set out whether there are gender differences in a real-world comtemporary treatment and outcome.
Methods: For two consecutive years, 199 consecutive patients were enrolled in the study, with ST-segment elevation AMI and primary PTCA without cardiogenic shock. The immediate outcome, in-hospital and six-month follow-up were studied. Multivariate Cox analysis were performed to identify independent predictors of death and major events.
Results: Clinical characteristics were similar in both groups, except that women were older than men (67.04 +/- 11.53 x 59.70 +/- 10.88, $p < 0.0001$). In-hospital mortality was higher among women (9.1% x 1.5%, $p = 0.0171$), as was the incidence of major events (12.1% x 3.0%, $p = 0.0026$). The difference in mortality rates remained the same at six months (12.1% x 1.5%, $p = 0.0026$). The independente

predictors of death in multivariate analysis: were: female gender and age >80 years old. Independent predictors of major events and/or angina were: multivessel disease and severe ventricular dysfunction. Conclusion: After ST-segment elevation AMI and primary PTCA, the independent predictors of mortality throughout the follow-up were female gender and age >80 years, in both in-hospital and six months follow-up



P603

In-hospital mortality in STEMI and NSTEMI: are they so different?

MJ Maria Joao Vieira[1]; P Dinis[2]; L Reis[2]; M Madeira[2]; J Ribeiro[2]; A Fernandes[2]; F Caetano[3]; M Alves[1]; C Lourenco[2]; R Teixeira[2]; L Goncalves[2]
[1]Hospital Santarém, Cardiology, Santarém, Portugal; *[2]University Hospitals of Coimbra, Hospital Geral, Cardiology, Coimbra, Portugal*; *[3]King's College Hospital, NHS Foundation , London, United Kingdom*

Introduction: Many studies have been published on outcomes in acute myocardial infarction (AMI). Most of these studies have shown a higher unadjusted in-hospital mortality rate (IHM) in ST elevation myocardial infarction. However, the impact of age, gender, co-morbidities, clinical findings at presentation and treatment in IHM still needs clarification.
Aim: Compare the in-hospital mortality in a population of patients (P) undergoing percutaneous coronary intervention (PCI) for an AMI according to the presence (STEMI) or absence of ST segment elevation (NSTEMI).
Methods: We performed a retrospective analysis of 580 consecutive P (72% male, 66 ± 13.9 years of age) hospitalized for AMI and submitted to PCI in a tertiary center. P were divided into two groups according to the presence (STEMI group) or absence (NSTEMI group) of ST segment elevation. Demographic, clinical, laboratory and echocardiographic parameters were evaluated. The primary endpoint was IHM and a univariate analysis and multivariate analysis were used to estimate the relationship between baseline variables and the outcome. Statistical analysis was performed using Stata software version 14.1.
Results: Of the sample, 338 P (58%) were included in the STEMI group (72% male) and 242 P were included in the NSTEMI group (72% male). Patients with STEMI were younger (65 ± 14 vs 68 ± 13 years old; P= 0.005) and less likely to have prior arterial hypertension (66 vs 83%; $p < 0.001$), prior history of heart failure (4.7 vs 16.1%; $p < 0.001$) and prior history of chronic kidney disease (13.9 vs 21.5%, P=0.017). At admission the STEMI group had lower systolic blood pressure (129.9 ± 3.0 vs 135 ± 2.6 mmHg; P=0.034), lower creatinine levels (99.1 ± 75 vs 117.2 ± 90 µmol/L P=0.027), lower NTproBNP levels (3745.1 ± 803 vs 7848 ± 2153 pg/ml; P=0.002) and lower left ventricular ejection fraction (46.1 ± 10.9 vs 50.7 ± 12.1%; P=0.004), but higher troponin I levels (48.8 ± 107 vs 8.3 ± 30 ng/ml;$p < 0.001$), glucose levels (8.8 ± 4.8 vs 7.7 ± 3.7 mmol/L; P=0.002), C-reactive protein (1.7 ± 2.4 vs 2.4 ± 4.6 mg/dl; P=0.026) and white blood cell count (11502.7 ± 3965 vs 9521.5 ± 3524 cells/µL; $p < 0.001$) when compared to the NSTEMI group. A total of 32 patients (5.5%) died before discharge. In the STEMI group a higher in hospital mortality crude rate was observed (7.4 vs 2.9%; P=0,019), but this difference was lost (OR: 2.0; 95% CI 0.09-45.1; P= 0.65) after adjusting for age, history of hypertension, prior history of heart failure, prior chronic kidney disease, systolic blood pressure at admission, Killip class at admission, left ventricular ejection fraction, and blood parameters at admission (creatinine, NTproBNP, troponin I, glucose, C-reactive protein and white cell count).
Conclusion: According to our data, there were no differences regarding in-hospital mortality associated with the presence or absence of ST segment elevation in AMI patients. NSTEMI are older and have a higher prevalence of comorbidities that may influence these findings.

P604

Cardiogenic shock in acute myocardial infarction

R Rim Ben Said[1]; B Jedaida[2]; M Mimouni[2]; M Gommidh[2]; N Ben Mansour[2]; R Dahmani[2]; C Chourabi[2]; H Mahfoudhi[2]; N Hajlaoui[2]; A Haggui[2]; D Lahidheb[2]; W Fehri[2]; H Haouala[2]
[1]La Rabta hospital, cardiology, Tunis, Tunisia; *[2]Military Hospital of Tunis, Tunis, Tunisia*

Introduction: Cardiogenic shock (CS) remains the leading cause of death in the acute phase of myocardial infarction (MI). Mortality from CS remains high despite marked advances in the treatment of MI. The aim of our study was to investigate the epidemiological clinical and echocardiographic characteristics of a serie of patients hospitalized for MI complicated by CS as well as the predictive factors of intra-hospital mortality.
Methods: We retrospectively analysed 70 patients affected by AMI complicated by CS admitted to cardiology department of the military hospital between October 2005 and April 2015
Results: A total of 70 patients were included in the study: 56 (80%) patients were male.The mean age was 63 ± 10 years.
Thirty-nine percent were admitted before the 6th hour from the onset of the chest pain, 12% were admitted between the 6th and the 12th hour and 45% were admitted beyond the 12th hour. On admission, 41% of patients were in left ventricular failure and 59% in shock.
The majority of myocardial infarction (45%) were anterior followed by inferior infarction with extension to the right ventricle (34%).
The mean LVEF was 49 ± 14.4%: mean LVEF was 37.8% in anterior MI and 57.6% in inferior MI. Mean LV end-diastolic diameter was 53.17 ± 7.8 mm and the mean LV end-systolic diameter was 36.5 ± 5.1 mm. Two patients had intraventricular thrombus. Ischemic myocardial regurgitation grade I, II was found in 4 patients. 22 patients had right ventricular dysfunction. Mean systolic pulmonary pressure was 37 mm Hg ± 10. Six patients had pericardial effusion.
Thrombolysis was performed in 51% of patients, 57% of them had thrombolysis before the 6th hour.
Seventy-two (72%) of patients underwent angiography and 56.6% had percutaneous coronary intervention (PCI). Of these, 27% were taken for primary PCI and 73 % had rescue PCI. Angiography had identified a single-vessel disease in 28% of cases, double-vessel disease in 44% of cases and multi-vessel disease in 28 % of cases. Revascularization was complete in 37% of cases. The success rate of PCI was 85%. The average of hospital stay was 7 ± 8 days. In-hospital outcome of the study, patients revealed a mortality rate of 47%, occurring on average in the 6th day of hospitalization. We found that renal failure ($p = 0.014$), late onset of shock ($p = 0.031$), hyperglycemia ($p = 0.014$), leukocytosis ($p = 0.02$), use of vasopressors ($p = 0.003$), LVEF ($p = 0.004$) and the anterior territory of MI ($p = 0.003$) were significantly predictive of hospital mortality.
Conclusion: Despite significant advances in the treatment of myocardial infarction, particularly techniques of reperfusion, therapeutic drug, and the advent of several circulatory support techniques, mortality of cardiogenic shock in acute phase of myocardial infarction remains high.

Genome wide association study reveals novel genetic loci associated with renal function in heart transplant recipients receiving calcineurin inhibitor therapy

D David Snipelisky[1]; M Hathcock[1]; W Kremers[1]; A Batzler[1]; G Jenkins[1]; S Kushwaha[1]; N Pereira[1]
[1]Mayo Clinic, Cardiovascular Diseases, Rochester, United States of America

Introduction: Certain genetic variants are associated with a predisposition to developing renal dysfunction in the general population. There have been no genome-wide studies (GWAS) performed that assess the association of common genetic variation with renal function in heart transplant (HTx) recipients receiving calcineurin inhibitors (CNI).
Methods: Clinical and demographic data of patients that underwent HTx between January 1998 and December 2014 and were receiving CNI therapy was assessed.

Genotyping was performed using Illumina Infinium HumanCoreExome v1.0 analysis kit. A GWAS utilizing linear regression models were performed with estimated glomerular filtration rate (eGFR). When eGFR was unavailable, the Modification of Diet in Renal Disease (MDRD) formula was used to estimate it at 1 year as the phenotype after adjusting for baseline eGFR and change to sirolimus therapy.
Results: A total of 287 patients were included, and 314,903 single-nucleotide polymorphisms (SNP) were analyzed. The average age was 50 years (standard deviation, 12.5), most were of European descent (n = 278, 96.9%) and male sex (n = 179, 71%). Significant variants in HMHB1 (rs918378, p = 2.27e-6), C12orf75 (rs1230081, p = 2.76e-6), LOC339894 (rs35649103, p = 2.93e-6), LOC10042392 (rs4617520, p = 6.07e-6), and MMP12 (rs652438, p = 7.05e-6) genes were associated with renal function as assessed by eGFR (Figure 1 and Table 1).
Conclusions: Our first of its kind GWAS demonstrates that genetic variation in five individual genes are associated with renal function in HTx recipients receiving CNI therapy. Larger studies are needed to replicate these findings and aid in the development of a genetics-based risk model for CNI nephrotoxicity.

Coronary heart disease and genetic polymorphisms. clinical, angiographic, procedure technique and long-term follow-up evaluation post percutaneous coronary intervention. major events and restenosis

LLB Bandeira[1]; IP Borges[1]; ECS Peixoto[2]; RTS Andrade[3]; ILPB Anjos[1]; RTS Peixoto[2]; RTS Peixoto[2]; SA Simoes[3]
[1]Medical School of Severino Sombra University, Vassouras, Brazil; *[2]Fluminense Federal University, Niteroi, Brazil*; *[3]Rio de Janeiro State Government, Rio de Janeiro, Brazil*

Background: There are clinic and genetic polymorphism differences in coronary artery disease (CAD). Percutaneous coronary intervention (PCI), clinic, angiographic, procedure technique may influence the evolution, major events (death, AMI, revascularization) and clinical restenosis.
Objective: This study aims to evaluate if genetic polymorphism have some influence in long-term follow-up after PCI.
Methods: A total of 182 patients, the coronary disease group (CDG) with CAD of a closed health system were submitted to PCI from 2001 and 2007 and to genetic follow-up evaluation until 12/31/2008. The control group (CG), with 36 patients, were angiographically normal but they were submitted to genetic evaluation. The polymorphisms evaluated were the ACE I/D and A166C (AT1R). In this period 221 procedures were perfomed in 182 patients. Restenosis was considered as symptoms and/or as a ischemic tests with angiographic restenosis. Qui square, Fisher exact and Student t test were used. Cox multivariate regression analysis were not used because only three clinical characteristics and A166C had P < 0.10.
Results: The CG and CDG patients were: female 20 (55.6%) and 49 (26.9%), (P=0.0007); age 55.9 ± 11.1 and 60.8 ± 10.5(P=0.0100); tabaco smokers 5 (13.9%) and 67 (36.8%), (P=0.0132); diabetes 4 (11.1%) and 48 (26.4%), (P=0.0802); hypertension 29 (80.6%) and 146 (80.2%), (P=0.9631); dyslipidemia 14 (38.9%) and 112 (61.5%), (P=0.0119); family history 12 (33.3%) and 60 (33.0%), (P=0.9659); obesity 9 (25.0%) and 60 (33.0%), (P=0.3476); ACE polymorphism DD 16 (44.5%), DI 17 (47.2%), II 3 (8.3%) and DD 81 (44.5%), DI 70 (38.5%), II 31 (17.0%), (P=0.3612); A166C polymorphism AA 36 (100.0), AC 0 (0.0%), CC 0 (0.0%) and AA 135 (74.2%), 42 (23.1%), 5 (2.7%), (P=0.0026).
Conclusion: In CDG with 221 procedures, there were no difference: between ACE and A166C polymorphism at one, two or three vessel disease; between majors events, deaths, AMI and revascularization; and between restenosis and the mean vessel diameter, lesion extension and bare metal or drug eluting stents (DES), although were implanted in 27 (12.2%) patients, being 15 (55.5%) patients with in stent restenosis and the others with small vessel diameter and long lesions.
In CDG there were more males, older people, more smokers, dislipidemia and they were genetically A166C polymorphism different from CG, the latter did not have CC or AC. There were no differences between the variables studied and illness extension, major events and restenosis in the CDG, even in relation to bare stens and DES, maybe because DES were used to the less favorable lesions and in stent restenosis.

Impact of glutathione S-transferase M1 gene polymorphisms on the chronic heart failure

N Natasa Jankovic[1]; DV Simic[1]; O Gudelj[2]; S Radovanovic[3]; D Djikic[1]; S Suvakov[4]; V Coric[4]; T Djukic[4]; T Simic[4]
[1]Clinical Center of Serbia, Clinic for Cardiology, Belgrade, Serbia; *[2]Military Medical Academy of Belgrade, Belgrade, Serbia*; *[3]Department of Cardiology, Medical Center Bezanijska Kosa, Belgrade, Serbia*; *[4]Institute for Medical Biochemistry, Belgrade, Serbia*

Background: Chronic heart failure (CHF) secondary to ischemic heart disease belongs to oxidative disease. Glutathion S-transferas M1 (GSTM1) is a gene family of phase II metabolic enzymes that detoxify free radicals, particulary in tobacco smoke. Smoking is a potent source od free radicals and well known risk factor for coronary disease. Inactive form of GSTM1 (null genotype) causes lower detoxification, which may be a risk factor for coronary disease.
Aim: To examine influence of different risk factors and GSTM1 polymorphism on the risk of development CHF.
Material and method: The study population consisted of 120 patients with CHF and 69 patients without heart failure in the control group matched for sex and age. The criterion for admission was left ventricular ejection fraction (LVEF) < 45%. Age, sex, smoking history, hypertension, dyslipidemia, diabetes mellitus and obesity were evaluated as risk factors. The genetic polymorphism analyses for the GSTM1 gene were determined by multiplex polymerase chain reaction (PCR). Both patients and controls were dichotomized into GSTM1 null and GSTM1 active genotype. Independent factors on CHF risk were evaluated by multiple logistic regression model.
Results: Frequency of GSTM1 null genotype was higher in CHF patients in comparison to controls (55.8 vs. 49.3%, respectively). GSTM1 null individuals exhibited a higher risk of CHF when compared to carriers of at least one active GSTM1 allele with un-significant of 1.30 (CI:0.72-2.36; p>0.05). Hypertension (OR=7.08; CI:2.89-17.33; p < 0.05), diabetes (OR=8.73; CI:1.79-42.66; p < 0.05), old age (more than 50 year) (OR=6.21; CI:1.45-26.50; p < 0.05) and obesity (OR=2.56; CI:1.16-5.65; p < 0.05) were independent risk factors for CHF. Smoking wasn't independent risk factor for

CHF (OR=1.59; CI:0.77-3.29; p>0.05). GSTM1 null genotype alone wasn't independent risk factor for CHF (OR=1.30; CI:0.72-2.36; p>0.05), but GSTM1 null genotype in smokers was independent risk factor (OR=3.99; CI:1.47-10.85; p < 0.05).
Conclusion: The frequency of GSTM1 null genotype in present study was similar to what was published previously. The presence of GSTM1 null genotype increases the risk of CHF among smokers.

Mutational screening of PKP2 and DSG2 genes in Russian patients with arrhythmogenic right ventricular cardiomyopathy

A G Anna Shestak[1]; O V Blagova[2]; YU A Lutokhina[2]; YU V Frolova[3]; S L Dzemeshkevich[3]; E V Zaklyazminskaya[1]
[1]Russian Research Center of Surgery, Laboratory of Medical Genetics, Moscow, Russian Federation; *[2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*; *[3]Russian Research Center of Surgery, Moscow, Russian Federation*

Funding Acknowledgements: This work was supported by grant RNF 16-15-10421

Background: Arrhythmogenic right ventricular cardiomyopathy (ARV) is an inherited disease characterized by progressive fibro-fatty replacement of right ventricle or both ventricles and leading to electrical instability and sudden cardiac death (SCD). Mutations in five desmosomal genes and seven non-desmosomal genes account about 65% of all ARVC cases. The most common forms of disease are caused by mutations in PKP2 gene and in DSG2 gene which account 25-40% and 12-40% of all genotype-positive cases, respectively. Identification of mutations in ARVC-related genes is one of a major diagnostic criterion (Marcus, 2010).
Methods: Instrumental examination and genetic counseling were performed for 38 Russian patients from 35 unrelated families with definite, borderline or possible diagnosis of ARVC (Task Force Criteria, 2010). Clinical examination had included standard and 24-hours ECG monitoring, Echo-CG, cardiac MRI, myocardial biopsy. Genetic study: PCR-based direct Sanger sequencing of coding exons and adjacent intronic areas of PKP2 and DSG2. Potential role of all genetic variants was evaluated in silico by PolyPhen2, SIFT or NetGen2, BDGP tools. The cascade screening for family members of genotype-positive probands was provided upon request. Results: Screening for mutations in the PKP2 and DSG2 in 35 DNA samples was performed. We found four rare genetic variants in PKP2: two truncating mutations .W538X, .1523_1538del, missense variant p.L582P, and splice-site mutation c.IVS2 + 1G>T. Patients carrying these genetic variants in PKP2 had clinical manifestation at the third/fourth decade of life with high-grade VA; ICDs were implanted in 2 cases. We found four rare genetic variants in DSG2: p.S194L, p.V533I, p.N245H, and p.R49H. Patients carrying these genetic variants in DSG2 also have had clinical appearence at the third decade of life with VT and RV hypertrophy. All variants have not been detected in a healthy cohort (100 samples). Thus, mutations in two genes responsible for most common forms of ARVC were identified in 22.9% of patients. Identification of mutation in DSG2 in male proband of 22 y.o. had led to increase the reliability of the diagnosis from 'possible' to 'definite'. We have analyzed the mutation detection rate in the groups with definite, borderline and possible diagnoses of ARVC and the total contribution of genetic data in the disease diagnosis. Mutational screening for the DSP, DSC2, JUP genes and in non-desmosomal genes for patients with no mutations in PKP2 and DSG2 is in process now. Conclusion: We found 8 genetic variants in 35 Russian ARVC index patients (22,9%). Our findings in Russian patients are consistent with the representation data of two common genetic forms of ARVC in other ethnic groups. DNA diagnostics results were used for verification of diagnosis in probands and their families, even on pre-clinical stages of the disease. Positive results were used for SCD risk stratification and decision on ICD implantation.

P610
(-75)G allele of APOA1 gene is associated with non-attainment of target lipid levels in very high cardiovascular risk patients

M Vorobyeva[1]; O Gigani[1]; M Azova[1]; S Villevalde[1]; Z Kobalava[1]
[1]RUDN University, Moscow, Russian Federation

Objective: Dyslipidemia is recognized as a prominent risk factor for cardiovascular diseases. The recent cholesterol guideline recommends aggressive statin therapy in patients with very high cardiovascular risk. The aim of the study was to investigate genetic predictors of its efficacy in very high cardiovascular risk patients.
Methods: In 58 patients with history of clinically evident cardiovascular diseases and fasting low-density lipoprotein cholesterol (LDL-C) >1.8 mmol/l or non-high-density lipoprotein cholesterol (non-HDL-C) >2.6 mmol/l (62.1% male, 61.9 ± 8.6 (M ± SD) years, arterial hypertension 82.8%, myocardial infarction 69.0%, non-hemorrhagic stroke 34.5%, diabetes mellitus 27.6%, total cholesterol (TC) 5.3 ± 1.5 mmol/l, HDL-C 1.1 ± 0.4 mmol/l, LDL-C 3.3 ± 1.3 mmol/l, triglycerides (TG) 1.9 ± 0.7 mmol/l, very LDL-C (VLDL-C) 0.8 ± 0.3 mmol/l, non-HDL-C 4.2 ± 1.5 mmol/l, previous statin therapy 82.8%) polymorphisms of gene CYP3A4 (encoding a member of the cytochrome P450 superfamily of enzymes) and gene APOA1 (encoding apolipoprotein A1) and efficacy of 1 month of high-intensity statin therapy (atorvastatin 80 mg/day) were assessed. The APOA1 genotypes were determined at two polymorphic sites (G/A at -75 bp, and C/T at + 83 bp). Statistical analysis was performed with SPSS Version 8.0 statistic software package. A value of p < 0.05 was considered statistically significant.
Results: 16 patients (27.6%) attained target LDL-C level < 1.8 mmol/l and 21 (37.6%) patients attained target non-HDL-C level < 1.8 mmol/l after 1 month of therapy. CYP3A4 *1 genotype was identified in all the patients. The allele frequencies for the (-75)G, (-75)A, + 83C and + 83T of gene APOA1 were found to be 0.53, 0.47, 0.94 and 0.06, respectively. No association was found between APOA1 + 83 C/T polymorphisms and response to intensive lipid-lowering therapy. We did not found any impact of (-75) G/A APOA1 polymorphisms on attainment of target LDL-C level. (-75)G allele of APOA1 gene was significantly associated with non-attainment of target non-HDL-C (Fisher's exact test result: p < 0.05(two-tailed), p < 0.01 (one-tailed)). Patients who attained vs did not attained target level of non-HDL-C were more often APOA1 (-75) G allele carriers (73.9 vs 25%, p < 0.001). 26% of APOA1 (-75) G allele carriers and 38.1% of APOA1 (-75) A allele carriers attained target non-HDL-C.
Conclusion: (-75)G allele of APOA1 gene is associated with non-attainment of target non-HDL-C and may be a predictor of resistance to statin therapy in very high cardiovascular risk patients.

Effects of chronic ACE inhibitor treatment on a translational model of heart failure with preserved ejection fraction

NAJAH Harouki[1]
[1]Sanofi R&D, Cardiovasculaire et métabolisme, pharmacologie, Chilly-mazarin, France

Background/Introduction: Heart failure (HF) with preserved ejection fraction (HFpEF) is a major epidemiological clinical issue, which parallels the prevalence of risk factors in the elderly (e.g. diabetes). In contrast to HF with reduced EF, clinical trials targeting neurohormonal activation with RAAS inhibitors or b-blockers have all failed in HFpEF. This failure has been attributed to patient heterogeneity and poor matching of therapeutic mechanisms and primary pathophysiological processes. Moreover part of the challenge relies also on the lack of relevant animal models recapitulating the contribution of cardiovascular and non-cardiovascular co-morbidities in the etiology of the syndrome. ZDF rats have been recently reported to develop an HFpEF phenotype.
Purpose: The objectives of this study were to further characterize cardiac and renal dysfunctions of the ZDF rats and determine whether improving renal function with an ACE inhibitor has a beneficial impact on HFpEF.
Methods: The cardiac function of Zucker Diabetic Fatty (ZDF) and lean animals was assessed after 8 weeks of daily treatment with ramipril (1 mg/kg per os) both in vivo, using echocardiography and PV-loop methodologies, and in vitro, using myocyte calcium contractility recording system after primary cardiomyocytes isolation. Renal and cardiometabolic biomarkers were monitored along the time course of the study and renal as cardiac histological analyses were performed at the end.
Results: We demonstrated that, at the age of 16 weeks, ZDF rats were overtly diabetic and displayed a significant decrease in cardiac output despite a normal ejection fraction and an increased fractional shortening. Moreover, in comparison to lean controls, ZDF rats showed an impairment of left ventricular (LV) diastolic function as documented by alterations of LV filling (decrease in E/A ratio), LV relaxation (increase in isovolumic relaxation time both in vivo and in vitro) and increase in end-diastolic volume and pressure. This diastolic dysfunction was associated with LV hypertrophy and fibrosis. Plasma biomarkers of HFpEF (ANP, BNP and Galectin-3) were also significantly increased in ZDF animals compared to lean littermates.
After 8 weeks of treatment ramipril decreased LV hypertrophy and fractional shortening, increased end diastolic volume and tended to restore cardiac output in ZDF rats. This beneficial effect on cardiac remodeling was not associated with a reduction in plasma ANP, BNP or galectin-3 levels.
Conclusions: In summary, this study confirmed the ZDF model as a promising and reproducible model of HFpEF which displays most of the features of this syndrome. Despite a positive effect on cardiac remodeling, ramipril at 1 mg/kg/d partially improved the cardiac function in this HFpEF model.

Epigenetic therapy reduces angiotensin-II induced cardiac hypertrophy and fibrosis

A Adam Russell-Hallinan[1]; L Shiels[1]; E Mcnamara[1]; C Watson[2]; J Baugh[1]
[1]*University College Dublin, Conway Institute, Dublin, Ireland*; [2]*Queen's University of Belfast, Wellcome-Wolfson Institute for Experimental Medicine, Belfast, United Kingdom*

Funding Acknowledgements: Enterprise Ireland

Background: Heart failure with preserved ejection fraction (HFpEF) is one of the leading causes of global morbidity and mortality. HFpEF is driven by pathological remodelling in the heart where there is hypertrophy of cardiomyocytes (cardiac hypertrophy) and an increased accumulation of extracellular matrix proteins in the interstitium (fibrosis). Recent evidence suggests that epigenetic processes such as DNA methylation are involved in the pathogenesis of cardiac remodelling. Inhibition of DNA methylation may yield a novel therapeutic avenue for the treatment of HFpEF.
Purpose: This study investigated the therapeutic potential of the DNA methyltransferase inhibitor, 5-azacytidine (5aza) to inhibit pathological hypertrophy and fibrosis in the Angiotensin-II (AngII) infusion model, a preclinical model of HFpEF.
Methods: Wild type C57BL6/J mice were implanted with subcutaneous micro-osmotic pumps infusing 1000 ng/kg/min AngII to induce cardiac injury. Saline infusion was used as a negative control and blood pressure was measured weekly in conscious mice via tail-cuff method. Infused mice were treated every four days after pump implantation with intraperitoneal administration of either placebo or 5aza. Cardiac structure and function was examined in vivo using non-invasive echocardiography followed by post mortem histological analysis.
Results: Echocardiographic analysis revealed that AngII infused mice treated with 5aza displayed a significant reduction in the left ventricular (LV) mass, interventricular septal wall and LV posterior wall thickness compared to mice which received placebo treatment. Positive pixel analysis of picrosiris red stained cardiac tissue demonstrated reduced levels of moderate and strong positive staining for collagen in the hearts of 5aza treated mice. 5aza was found to have no effect on blood pressure levels.
Conclusion: Therapeutic options for HFpEF patients are limited. The DNA methylation inhibitor, 5aza, shows therapeutic potential by reducing hypertension-induced cardiac hypertrophy and fibrosis independently of an effect on blood pressure.

P614

Increased plasma clusterin levels in patients with left ventricular remodeling after myocardial infarction has cardiac origin and is due to a defect in proteasome activity

A Annie Turkieh[1]; S Porouchani[1]; P Mulder[2]; M Fertin[3]; O Besemes[1]; M Chwastyniak[1]; P Amouyel[1]; V Richard[2]; C Bauters[3]; F Pinet[1]
[1]*Institute Pasteur of Lille, Risk Factors and Molecular Determinants of Aging-Related Diseases, Lille, France*; [2]*INSERM U1096, ROUEN, France*; [3]*Cardiology Hospital of Lille, Lille, France*

Heart failure (HF) following myocardial infarction (MI) is characterized by alterations of left ventricle (LV) structure and function, named LV remodelling (LVR). Proteomic analysis of plasma of patients from our REVE-2 cohort identified increased plasmatic levels of clusterin (Clu) in patients who have developed high LVR one year after MI. Our aim was to determine if increased clusterin in plasma has a cardiac origin and to analyze the mechanisms of Clu regulation in the heart.
For these purposes, we used a MI rat model induced by ligation of the left coronary artery to analyze Clu expression in the LV of rats at different time post-MI. Clu mRNA level was increased in the LV of rat at 7 days (1.9 fold, $p = 0.001$) and 2 months (1.4 fold, $p = 0.010$) post-MI. Clu precursor form (p-Clu) was only increased at 7 days post-MI (2.2 fold, $p = 0.001$). Clu mature form (m-Clu) was increased at 7 days (2.0 fold, $p = 0.001$) and 2 months post-MI (1.3 fold, $p = 0.035$). Also we observed that Clu mRNA level was positively correlated with ANP and BNP expression at 7 days ($r = 0.93$, $p < 0.001$/ $r = 0.91$, $p < 0.001$ respectively) and 2 months ($r = 0.56$, $p = 0.020$/ $r = 0.60$, $p = 0.011$ respectively) post-MI. p-Clu and m-Clu levels were positively correlated with plasmatic BNP level ($r = 0.73$, $p = 0.001$/ $r = 0.60$, $p = 0.015$ respectively) at 7 days post-MI. m-Clu level was positively correlated with LV end diastolic diameters (0.67, $p < 0.001$) and LV weight/body weight ratio ($r = 0.76$, $p < 0.001$) at 2 months post-MI
Then, we used primary cultures of rat neonate cardiomyocytes (NCM) that we treated with different modulators of protein degradation (PDG) systems in order to estimate their role in Clu expression and secretion in post-MI. Proteasome inhibition (MG132 treatment) of NCM was validated by increased levels of ubiquitinylated proteins. We found increased Clu mRNA (2.2 fold, $p < 0.001$), p-Clu (2.5 fold, $p < 0.001$), m-Clu (1.6 fold, $p = 0.003$) and its secreted form (s-Clu; 4.9 fold, $p < 0.001$) in the treated cells compared to control cells. We have detected another form of clusterin demonstrated by co-immunoprecipitation as ubiquitinylated clusterin only in the MG132 treated cells. We observed a cross-talk between the different PDG systems in the treated NCM with increased LC3II/LC3I ratio corresponding to activation of macroautophagy. To decipher which PDG systems or both are involved in increased Clu, NCM were co-treated with MG132 and 3-MA, an inhibitor of macroautophagy, and we observed increased mRNA Clu (1,7 fold, $p = 0;010$) and m-Clu (1,3 fold, $p = 0.031$) with no difference on p-Clu and s-Clu levels compared to MG132 treated cells.
Our data suggest that the increased plasma levels of Clu in patients with high LVR post-MI has cardiac origin and is mainly due to a defect in proteasome activity in heart. More informations are need to understand the cross-talk between the PDG (proteasome and macroautophagy) systems on the behavior of Clu in heart.

P615

Angiotensin 1-7 might be a new solution in the treatment of chronic heart failure

A Alena Kazak[1]; A Kurlianskaya[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Heart Failure Laboratory, Minsk, Belarus*

Introduction: Cardiac fibroblasts (CF) are the major non-contractile cells present in the myocardium. Proliferation and differentiation of cardiac fibroblasts play a pivotal role in adverse cardiac remodelling. During cardiac remodeling cardiac fibroblasts undergo phenotypic changes: they acquire a myofibroblast character, proliferate and produce extracellular matrix (ECM) proteins. Interactions between cardiac fibroblasts (CF) and cardiomyocytes (CM) are still not fully understood.
Purpose: The first aim of our study was to get more information concerning the specific phenotype of cardiac myofibroblasts. The second aim was to learn changes of properties of CF and CM in co-cultures by the 24-hours stimulation of AngiotensinII (AngII) and Angiotensin 1-7 (Ang1-7).
Methods: We have studied the properties of CF and CM ($n = 24$ experiments) isolated from the hearts of Sprague-Dawley rats with chronic heart failure. With Immunhisto and Western Blot methods we studied the changes of structural proteins such as vimentin, α-smooth muscle actin (α-sma), myosin heavy chain and desmin, and also gap-junctional protein such as Cx43 in P1, P2, P3 of CF and CM co-cultures. At the same time we investigated the quantitative change of these proteins after the 24-hours stimulation of AngII and Ang 1-7 in 10-6 mol / L and 10-7 mol / L concentrations as well as co-stimulation of these therapeutic agents in 10-6 mol / L concentration.
Results: Our study has shown that the quantity of structural proteins such as vimentin, α-sma and myosin heavy chain increases in co-culture of CF and CM from P1 to P3, conversely decreases the quantity of Cx43. Desmin was not detected in all passages. Thus already in P3 the CF transform in myofibroblasts The 24-hours stimulation of Ang1-7 increases the quantity of proteins, but less than angII. It was detected that in co-stimulation of AngII + Ang1-7actin in 10-6 mol / L concentration angiotensin 1-7 has shown the antagonistic property to angiotensinII, which was manifested in less increase of strucrural proteins quantity compared to angII alone stimulation.
Conclusion: Our study has shown that already in P3 the fibroblasts transform in myofibroblasts. Angiotensin 1-7 shows the antagonistic property to angiotensin II. The proof of the positive effect of angiotensin 1-7 might have therapeutic potential. The effects mediated by the action of angiotensin 1-7 could be a new solution in the treatment of chronic heart failure.

SIRT1 protects the heart from endoplasmic reticulum stress-induced apoptosis through eIF2a deacetylation

J Pires Da Silva[1]
[1]*University of Paris-Sud 11, 92296, Chatenay-Malabry, France*

Over the past decade, endoplasmic reticulum (ER) stress has emerged as an important mechanism involved in the pathogenesis of cardiovascular diseases including heart failure. Cardiac therapy based on ER stress modulation is viewed as a promising avenue towards effective therapies for the diseased heart. Here, we tested whether sirtuin 1 (SIRT1), a NAD+-dependent deacetylase, participates in modulating ER stress response in the heart. Using cardiomyocytes and adult inducible SIRT1 knockout mice, we demonstrate that SIRT1 inhibition or deficiency increases ER stress-induced cardiac injury, whereas activation of SIRT1 by the sirtuin-1-activating compound STAC-3 is protective. Analysis of the expression of markers of the three main branches of the unfolded protein response (i.e. PERK/eIF2α, ATF6 and IRE1) showed that SIRT1 protects cardiomyocytes from ER stress-induced apoptosis by attenuating PERK/eIF2α pathway activation. We also present evidence that SIRT1 physically interacts with and deacetylates eIF2α. Mass spectrometry analysis identified lysines K141 and K143 as the acetylation sites on eIF2α targeted by SIRT1. Furthermore, mutation of K143 to arginine to mimic eIF2α deacetylation confers protection against ER stress-induced apoptosis. Collectively, our findings indicate that eIF2α deacetylation on lysine K143 by SIRT1 is a novel regulatory mechanism for protecting cardiac cells from ER stress and suggest that activation of SIRT1 has potential as a therapeutic approach to protect the heart against ER stress-induced injury.

P617

Influence of iron availability in the normoxic versus hypoxic conditions on the morphology and atrophy of skeletal myocytes.

Funding Acknowledgements: Financially supported by the National Science Centre (Poland) grant allocated on the basis of the decision number DEC-2012/05/E/NZ5/00590

Background: Muscle atrophy reflects a systemic response to various chronic diseases, including heart failure (HF). Disease-associated decrease in muscle tissue mass can occur as a result of various pathologies and one of the reported causative factors is hypoxia. Iron deficiency (ID) is one of the potential pathomechanisms contributing to increased skeletal muscle fatigability and impaired exercise tolerance in HF. It is worthy of mentioning that beneficial effects of iron supplementation on the improvement of muscle function in patients with heart failure with ID have already been reported. However, the mechanisms responsible for this phenomenon remain unknown.
Purpose: It is expected that skeletal muscle cell line subjected to different iron availability and/or hypoxic conditions will demonstrate changes in cell morphology and in the expression of atrophy markers.
Methods: L6G8C5 rat skeletal myocytes were cultured in normoxia or hypoxia at the optimal versus reduced versus increased iron concentration. We analysed cell morphology and expression of Atrogin1, MuRF1 [specific markers of muscle atrophy], SMAD4 [gene involved in the maintenance of balance between muscle atrophy and hypertrophy] and Desmin [muscle class-III intermediate filament protein] at the mRNA and protein level using qPCR, Western Blotting and immunocytochemistry.
Results: Hypoxic treatment caused, as compared to normoxic conditions, an increase in expression of Atrogin1($p < 0.01$) and Desmin ($p < 0.001$) and did not affect the expression of MuRF1 and SMAD4 in the cells. Iron-deficient cells displayed morphological abnormalities and demonstrated an increased expression of Atrogin1 ($p < 0.01$), MuRF1 ($p < 0.05$) both in normoxia and hypoxia, indicating activation of the ubiquitin proteasome pathway involved in protein degradation during muscle atrophy. ID combined with hypoxia also causes a decrease in SMAD4 expression ($p < 0.05$) suggesting modifications leading to atrophy. In contrast, cells cultured in a medium enriched with iron during hypoxia exhibited reverse changes in the expression of atrophy markers (all $p < 0.05$) along with increased SMAD4 expression ($p < 0.05$). Desmin was upregulated in the cells subjected to both ID and iron excess in normoxia ($p < 0.01$) and hypoxia ($p < 0.05$), but the greatest augmentation occurred when ID was combined with hypoxia. Notably, in hypoxia an increased expression of Atrogin1 and MuRF1 was associated with an increased expression of transferrin receptor 1, reflecting intracellular iron demand (R=0.76, $p < 0.01$; R=0.86, $p < 0.01$). Further, the expression of desmin during hypoxia was associated with an increased apoptotic activity (estimated by Bax/BCl2 ratio) of skeletal myocytes (R=0.94, $p < 0.001$).
Conclusions: Hypoxia and iron deficiency when combined has the most detrimental impact on skeletal myocytes, especially in the context of muscle atrophy markers. Inversely, iron supplementation in in vitro conditions might act in the protective manner on these cells.

P618

Alterations in natriuretic peptides system in adult stem cells in heart failure

N Khromova[1]; V Galenko[2]; D Smirnov[3]; P Tikanova[1]; T Lelyavina[2]; R Dmitrieva[1]

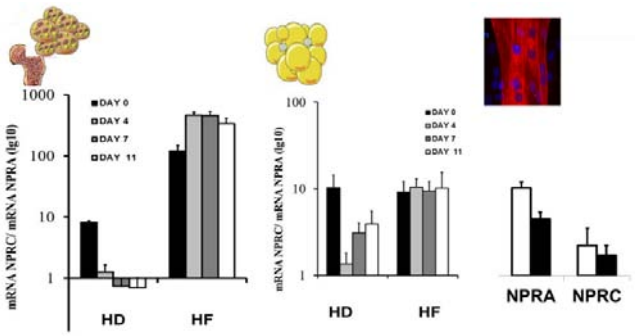
Background and aim: Heart failure (HF) is associated with an increase of myocardial and systemic insulin resistance, mitochondrial disfunction, altered levels of circulating adipocytokines, decrease of metabolism of fatty acids (FA) and a shift toward glucose for ATP generation. Metabolic alterations in HF were demonstrated not only for myocardium, but also for other organs including adipose tissue, skeletal muscles, and bone tissue. Our study was aimed to test the hypothesis that systemic metabolic abnormalities in HF could be related to alterations in signaling pathways known to be important in regulation of metabolism, and regulated by natriuretic peptide (NP) system in adult stem cells derived from skeletal muscle (SC) bone marrow (BMMSC) and subcutenious (ADMSC) adipose tissue from HF patients related to chronic activation of natriuretic peptides system.
Methods: 7 patients with HF and 6 healthy donors were involved in this study. All patients were diagnosed as having HF based on clinical signs of heart failure and echocardiographic or angiographic evidence of impaired left ventricular systolic function, and have a disease history of at least 12 months. To study the dynamics of gene expression, RNA samples were collected at different time points during adipose and muscle in vitro differentiation course.
Results: The dynamics of expression of NPRA/NPRC differ significantly between HF and HD in all tested stem cell samples (SC, BMMSC, ADMSC), as well as in course of in vitro adipose differentiation. Data are summarized in Figure 1: the regulation of natriuretic peptides system in adult stem cells of different origin is altered significantly in HF patients.
Conclusion: the observed low ratio of NPRA to NPRC expression in HF samples could indicate the "switch" in NP-cGMP signaling in adipose and muscle tissue in heart failure patients.



NPRA/NPRC expression in BMMSC, ADMSC, SC

Sacubitril/Valsartan, proved superiority over other conventional heart failure (HF) management treatments, but its mechanisms of action remains obscure.
In this study, we sought to explore the mechanistic details for Sacubitril/Valsartan in HF and post-myocardial infarction (MI) remodeling, using an in silico, systems biology approach.
Myocardial transcriptome obtained in response to MI in swine was analyzed to address post-infarction ventricular remodeling. Swine transcriptome hits were mapped to their human equivalents using Reciprocal Best (blast) Hits, Gene Name Correspondence, and InParanoid database. HF remodeling was studied using public data available in GEO (accession GSE57345, subseries GSE57338), processed using the GEO2R tool. Using the Therapeutic Performance Mapping System (TPMS) thecnology, dedicated mathematical models trained to fit a set of molecular criteria, defining both pathologies and including all the information available on Sacubitril/Valsartan, were generated. All relationships incorporated into the biological network were drawn from public resources.
An artificial neural network analysis revealed that Sacubitril/Valsartan acts synergistically against cardiomyocyte cell death and left ventricular extracellular matrix remodeling via 8 principal synergistic nodes. When studying each pathway independently, Valsartan was found to improve cardiac remodeling by inhibiting members of the guanine nucleotide-binding protein family, while Sacubitril attenuated cardiomyocyte cell death, hypertrophy, and impaired myocyte contractility by inhibiting PTEN.
The complex molecular mechanisms of action of Sacubitril/Valsartan upon post-MI and HF cardiac remodeling were delineated using a systems biology approach. Further, this dataset provides pathophysiological rationale for the use of Sacubitril/Valsartan to prevent post-infarct remodeling.

Chronic heart failure (HF) continues the most important problem of modern medicine. Despite many advances in the management of HF, treatment options for many patients remain limited and new treatment strategies are clearly needed. Gene therapy and therapeutic vascular growth may provide a new treatment option for these patients.
The aim of the present study is to analyse the potential of combined HGF and VEGF gene therapy for stimulation of endogenous mechanisms of cardiac repair after myocardial infarction.
As a proof-of concept we have tried to evaluate VEGF, HGF and HGF + VEGF plasmid based gene delivery to rat ischemic myocardium. We have found that within 14 days post injection combination of VEGF + HGF plasmids was superior to single VEGF or HGF in terms of vascular density increase (both capillary and arteriole), but was unable to significantly reduce post-infarction fibrosis, yet certain trend was observed. HGF and HGF + VEGF injections significantly stimulate accumulation of c-kit + resident cardiac stem cells in border zone and WT1 + epicardial cell activation in compare to VEGF plasmid injections. We have also found the reduction of inflammatory cellular infiltration of border zone in VEGF + HGF group compared to VEGF group, which might indicate decrement of inflammatory response in myocardium. In further in vitro studies using HUVEC and TIME endothelial cells we found that production of pro-inflammatory chemokines MCP-1 and IL-6 is increased by recombinant VEGF and reduced after addition of HGF. Combination of both factors resulted in medium levels of MCP-1 and IL-6 production, thus HGF seems to counteract the pro-inflammatory action of VEGF. As for pro-angiogenic IL-8, both factors had stimulating effect on its production and their combination yielded maximum amount of IL-8 expression and secretion by endothelial cell cultures, which suggests an alternative way for IL-8 regulation involved.
As a result of the study we can conclude that combination of VEGF and HGF has good translational promise for myocardial repair and regeneration. Deeper in-sights into their mechanism of action might show non-canonical properties and modes of action of that combination that may drive its way into practice.

Cardiac progenitor cells isolated from duchenne muscular dystrophy patients with heart failure have impaired intracellular calcium signaling and electrophysiological properties

D Domenico D'amario[1]; F La Neve[1]; A Siracusano[1]; G Perri[1]; A Amodeo[2]; M Massetti[2]; R Piacentini[1]; C Grassi[1]; F Crea[1]
[1]Catholic University of the Sacred Heart, Institute of Cardiology, Rome, Italy; *[2]Bambino Gesu Children's Hospital, Rome, Italy*

Background: Duchenne Muscular Dystrophy (DMD) is an X linked recessive disorder due to mutations of the Dystrophin gene. Heart failure (HF) is emerging as the most relevant clinical challenge. Cardiac progenitor cells (CPCs) appear early during development and are responsible for cardiomyogenesis in fetal life and affect myocardial homeostasis.
Aims: 1. to test whether is possible to isolate and characterize CPCs from patients with DMD and HF
2. to investigate the functional characteristics of the CPCs isolated from DMD patients with HF in terms of intracellular Ca2 + signaling and electrophysiological features.
Methods: 4 consecutive patients with DMD undergoing LVAD implantation were enrolled; the LV core was used for CPCs isolation and characterization. To evaluate the differentiation potential, Confocal Ca2 imaging was performed in human differentiatied CPCs from DMD patients with HF and HF alone (i.e. controls). Intracellular Ca2 + transients were recorded and quantified for each cell. Parameters such as the time-to- peak, the mean peak amplitude and the area underneath the curves were analyzed. The contribution of L- (Cav1.2 subunit) and T-subtypes VGCCs to transient changes in [Ca2 +] were evaluated using a channel blockers (e.g. nifedipine).
Results: CPCs expressed markers of mesenchymal origin. CPCs population doubling time averaged 26.5 hours. Telomere length averaged 7.1 kbp. Telomerase activity was present in all cell lines. Extracellular application of KCl, induced intracellular Ca2 + transients in the 83% of studied differentiated cells at P10 in both groups. No significant transients were observed in undifferentiated cells. CPCs from DMD patients with HF or with HF alone (i.e. control) were analyzed and compared. In control CPCs, these transients, likely due to depolarization-induced activation of voltage-gated Ca 2 + channels had mean peak amplitude, expressed as ΔF/F ratio, equal to 5.9 ± 0.5, and the mean time-to- peak was of 18 ± 1 s. These values were significantly altered in CPCs isolated from DMD patients: the amplitude of Ca 2 + transients was significantly smaller (3.2 ± 0.4; $P < 0.001$) and the response was slower (26 ± 1 s). Nifedipine significantly reduced the mean amplitude of KCl-evoked Ca2 + transients from 5.81 ± 0.54 to 2.16 ± - 0.48 in controls. There was an even higher reduction in DMD-CPCs from 3.40 ± 0.31 to a 0.5 ± 0.2. In order to evaluate the Ca 2 + homeostasis and the contribution of the endoplasmic reticulum, we performed experiments adding caffeine (20nM). Data showed that Ca2 + is reduced in DMD CPCs compared to controls (-0.376 ± 0.33 VS -0.288 ± 0.25 $P < 0.000125$).
Conclusions: CPCs from DMD patients retain significant growth reserve in vitro and have impaired calcium signaling and electrophysiological properties. Moreover, generating personalized functionally competent cardiomyogenic cells from DMD patients may be used as an in vitro cell model for functional studies and drug testing in heart failure.

Inflammation inhibition effects in diabetes induced heart failure

V Cobet[1]; M Popovici[2]; L Ciobanu[2]; L Tacu[1]; V Ivanov[2]; I Popovici[2]; I Moraru[2]; E Cobet[3]; M Ivanov[1]; E Panfile[2]; V Rotaru[1]
[1]State University of Medicine and Pharmacy, Chisinau, Moldova Republic of; *[2]Institute of cardiology , Chisinau, Moldova Republic of*; *[3]State University of Moldova , Biopharmaceutical chemistry , Chisinau, Moldova Republic of*

Background: Inflammation is appreciated as a leading factor regarding cardiovascular disorders triggering and exacerbation. Nevertheless a promising antinflammatory treatment concerning cardiac mismatch improvement is not yet consolidated.
Aim: The in vitro evaluation of cardiac effects of the TNF-alpha antagonist administration during diabetes-induced heart failure (DHF).
Material and methods: DHF was classically reproduced in rats by i/p administration of streprozotocin (50 mg/kg, 5 days) – series 1 (of reference). TNF-alpha antagonist, TNF-McAb (TNF monoclonal antibody, analog of infliximab) has been administered i/p during DHF modeling and 5 days after – series 2. After 10 days animals of both series have been euthanized, and isolated heart was perfused in isovolumic regimen (Langendorff model) or exterior working (Neely-Rovetto model). Cardiac reactivity was assayed in: (1) hemodynamic effort due to pre- and afterload

increase; (2) neuroendocrine activation modulated by action in diverse concentrations of norepinephrine, angiotensin II and endothelin-1 (ET-1); (3) in ischemia (30 min) followed by reperfusion (45 min) syndrome.
Results: TNF-alpha inhibition led to significant increase of cardiac output (CO) in effort with volume and resistance respectively by 23,7 and 26,2% comparatively to reference indices. Systolic pressure of left ventricle (LV) was in series 1 higher in all induced hemodynamic stress levels, but on aortic pressure of 100 and 120 cm H20 the increment was significant and averagely represented 18-19%. DHF was characterized by LV lusitropic function impairment, whose principal parameters, telediastolic pressure (LVTDP) and index of diastolic myocardial rigidity significantly decreased during TNF-alpha inhibition by 26-28%. The norepinephrine action led in DHF to inotrop-chronotropic effect dissociation, but endothelin-1 (ET-1) induced a negative inotropic effect, associated by CO reducing by 10,3%. TNF-alpha inhibition led to appearance of positive inotropic effect to ET-1 action and cardiac output increase by 11%. Myocardial ischemic contracture assayed after 30 min of ischemia thereby of LVTDP is doubly more in DHF vs control pattern (56,3 ± 3,6 vs 28,4 ± 1,9 mm Hg) and remains above on 45th min of reperfusion (39,2 ± 2,5 vs 18,8 ± 1,2 mm Hg). TNF-McAb notably attenuated consequences of ischemia-reperfusion syndrome, leading to LVTDP drop by 29,3% at finish of ischemia and by 26,8% at finish of reperfusion.
Conclusions: 1. TNF-alpha inhibition during diabetes-induced heart failure improved cardiac functionality, confirming the pathogenical role of inflammation and, on the other hand, the therapeutic relevance of TNF-McAb regarding outworn heart functioning in hemodynamic and neuroendocrine efforts.
2. Most conspicuous TNF-McAb benefit has referred to appearance of positive inotropic effect to ET-1 action and significant decrease of LV telediastolic pressure by around 29% in ischemia-reperfusion syndrome.

Funding Acknowledgements: BIH (Clinical Scientist); OptimEx

HF with preserved ejection fraction (HFPEF) constitutes about 50% of HF patients who present symptoms for HF, but normal or near-normal systolic function. No standardized treatment has shown to improve prognosis, and the underlying pathomechanisms are not resolved and may differ with etiology. We postulated that alterations in atrial and ventricular function in vivo are associated with phenotype and disease stage-dependent alterations in cardiomyocyte Ca signaling.
We examined in vivo function and cardiomyocyte Ca transients (Fluo4-AM, field stim) in a clinically relevant rat model of metabolic risk factors and HFPEF. ZSF-1 +/- (lean, hypertension; Ln) and ZSF-1 +/+ (metabolic syndrome, HFPEF; Ob) rats fed with high fat diet at 21 weeks were compared to another series examined at 28 weeks and to wildtype (CTRL).
Results: At 21 weeks, in vivo measurements showed unaltered ejection fraction, LV mass and relaxation in Ln. In Ob ventricular ejection fraction was also preserved, but ventricular relaxation was impaired and LV mass and E/e′ increased, as in HFpEF. This was paralleled by an unchanged cytosolic Ca2+ transient (CaT) peak amplitude (Fpeak), and unchanged SR Ca2+ content in cardiomyocytes isolated from the left ventricle. Diastolic decay of the cytosolic CaT was unchanged in Ln, but significantly slowed in Ob. At 28 weeks, even though in vivo data indicated an HFPEF phenotype in Ob, cardiomyocyte CaT showed significantly reduced Fpeak and SR Ca2+ content indicating that cellular changes in obesity-related HFPEF are highly stage-dependent.
Left atrial size was increased and atrial emptying fraction was reduced vs. CTRL already at 21 weeks in Ob but not in Ln. Interestingly, CaT amplitude in isolated atrial myocytes was increased in both Ln and Ob (2.3 ± 0.2 vs 2.9 ± 0.2 and 2.8 ± 0.2; n=22, 22 and 26 cells; $p < 0.05$). Moreover, time to 50% of maximal Ca release (TF50) was significantly increased in atrial Ln but not in Ob, suggesting a lower number of recruited Ca release sites in Ln. Sodium Calcium exchanger (NCX) and SR Ca ATPase (SERCA) activity, as assessed by application of caffeine were not significantly altered in Ln or Ob. Ca spark frequency after 3 Hz stimulation was significantly increased in Ln (to 1.9 ± 0.4 vs. 1.0 ± 0.2 and 0.7 ± 0.2 Sparks/100µm/sec in ZSF-obese and WT in n=7, 18 and 11 cells resp.; $p < 0.05$) but unchanged in Ob. Tetracaine-dependent SR Ca leak, however, was significantly increased in Ln and Ob suggesting increased spark-independent SR Ca leak in Ob.
Summary: Ventricular diastolic dysfunction in obesity-related HFPEF is associated with altered Ca signaling during excitation-contraction coupling with a time-dependent worsening of the CaT. However, in vivo atrial function deteriorates at early states of remodeling despite increased cardiomyocyte CaT amplitudes. In addition, our data suggest underlying altered local control of Ca in atrial cardiomyocytes from obesity-related HFPEF vs lean rats with metabolic risk factors.

P624

Development of a prototype for remote monitoring of patients with heart failure by short message service in middle-income country: study protocol

LL Pedraza[1]; JRW Moraes[2]; GB Aliti[3]; E Eneida Rejane Rabelo-Silva[4]
[1]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; *[2]Federal University of Rio Grande do Sul, Porto Alegre, Brazil*; *[3]Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil*; *[4]Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Program at the Nursing School, , Porto Alegre, Brazil*

Background/Introduction: Despite advances in the care of patients with heart failure (HF), results after hospitalization are still below expectations, especially in developing countries. Strategies and new approaches are necessary in the current scenario and worldwide panorama of HF epidemiology, in order to prevent both hospital readmissions and morbidities caused by this clinical syndrome. The monitoring program through Short Message Service (SMS) has been successful for HF in developed countries, reducing the number of hospital readmissions. There is currently no knowledge of this strategy being developed with HF patients and recent hospitalization in developing countries. In order to fill this gap, this study will use this SMS approach for the remote monitoring of HF patients.
Purpose: To develop a remote monitoring system that includes information on HF, self-care and adherence to medications for HF patients that can be used in developing countries.
Methods: Clinical variables such as weight, presence of signs and symptoms of decompensation, management of self-care and adherence to regular use of medications will be monitored through SMS. The system features will be divided into two groups: executed automatically by the system and executed through commands from an operator. This monitoring system will be tested with 10 patients through a pilot study.
Results: It is expected that this prototype of SMS remote monitoring can contribute to improve patients' abilities to/in self-care and health management. The attainment of these outcomes may contribute to the reduction of crises of decompensation and unplanned hospitalizations.
Conclusions: There is an opportunity to drive the increasing accessibility of mobile technologies to empower patients to monitor and manage their own health after discharge. If the results are favorable, other countries with a similar profile may benefit from this technology.

Characterization of a porcine model of heart failure with preserved ejection fraction

W Winston Shim[1]; KPMM Ja[1]; CH Lua[1]; SQ Li[1]; P Wong[1]
[1]National Heart Centre Singapore (NHCS), Singapore, Singapore

Funding Acknowledgements: National Medical Research Council Singapore (Industry Alignment Fund)

Background: Heart failure patients with preserved ejection fraction (HFpEF) are increasingly being recognized as a distinct subtype from heart failure patients presenting with reduced left ventricular (LV) ejection fraction. Lack of suitable preclinical large animal HFpEF models is hampering better understanding of this important clinical subgroup of heart failure. We aim to establish and to characterize a porcine model with relevant characteristics of clinical HFpEF.
Methods: and Results: Yorkshire pigs (n = 9) were subjected to aortic banding to achieve defined trans-stenotic pressure gradient and were fed with high salt diet for up to 20 weeks. Baseline and follow-up transthoracic echocardiography showed LV remodeling with end-diastolic diameter remodeled from baseline of 4.0 ± 0.3 cm to 3.8 ± 0.2 cm, 4.0 ± 0.5 cm and 4.8 ± 0.2 cm ($p < 0.005$) at 4-week (n = 3), 12-week (n = 3) and 20-week (n = 3) respectively. There was an increase in LV mass index (LVMI) from 2.5 ± 0.5 to 3.8 ± 0.6, 2.8 ± 0.7 and 3.7 ± 1.0 ($p < 0.05$) respectively during the corresponding follow-up time points. The animals maintained a relatively stable LVEF from 61.8 ± 7.3% to 70.7 ± 7.2%, 65.4 ± 13.8% and 65.0 ± 8.5% during the three follow-up time points, indicating a hypertrophic LV remodeling with preserved systolic function. Compared to diastolic function at baseline, there was a decrease in early (E) and late (A) ventricular filling ratio whereby a reduction in E/A ratio was observed at 20-week follow-up (1.25 ± 0.09 vs. 0.97 ± 0.05, $p < 0.001$), suggesting a restrictive LV filling. This was supported by observation of an increase in LV stiffness constant (β) from 0.02 ± 0.01/ml at rest to 0.04 ± 0.04/ml in response to dobutamine stress at 20-week follow-up as determined by pressure-volume loop

assessment. Myocardial hypertrophy with enlarged myofibers and increased interstitial fibrosis was observed in the LV and left atrium (LA) during follow-up. Consistent with heart failure presentation, histopathological examination revealed pulmonary and hepatic congestion in the HFpEF pig model starting from 12-week follow-up.
Conclusion: We characterized myocardial hypertrophy, fibrotic remodeling, restrictive filling and peripheral congestion in a novel porcine model with characteristics of LV diastolic dysfunction with preserved ejection fraction that are consistent with HFpEF. This may represent a useful tool to study pathophysiological presentation of clinical HFpEF.

P626

Right ventricular histological and molecular alterations in a rat model of HFpEF: effects of exercisetraining

L Rosenbusch[1]; C Besler[1]; S T Bowen[1]; K Rommel[1]; T Fischer[1]; M Von Roeder[1]; N Rolim[2]; U Wisloff[2]; A Linke[1]; G Schuler[1]; V Volker Adams[1]; P Lurz[1]
[1]University Leipzig, Heart Center, Leipzig, Germany; *[2]Norwegian University of Science and Technology, Trondheim, Norway*

Funding Acknowledgements: European Commission: Framework 7 (EU 602405-2)

Aims: Heart failure with preserved ejection fraction (HFpEF) remains a major diagnostic and therapeutic challenge in clinical cardiology. Recent studies suggest that HFpEF is a biventricular disorder with patients also demonstrating impairments of systolic and diastolic function of the right ventricle (RV). However, the underlying mechanisms of impaired RV function in HFpEF are to be characterized. The present study aimed to investigate histological and molecular changes of the RV in a rat model of HFpEF, and to characterize whether exercise training has any impact on these alterations.
Methods: RVs were obtained from obese diabetic Zucker fatty / spontaneously hypertensive heart failure F1 hybrid (ZSF1-obese) rat or ZSF1-lean rats as control group at 20 weeks of age. In a separate group of experiments, ZSF1-obese rats were randomly assigned to either a moderate continuous exercise training or sedentary lifestyle for 8 weeks until the age of 28 weeks. Excised RVs were stained for fibrosis. mRNA expression of TNFα, IL-6 and IL-1β was analyzed by PCR. Quantification of protein carbonylation was used as a measure of reactive oxygen species burden. Expression of pro- and anti-inflammatory enzymes was examined, and TNFα-related profibrotic signaling pathways were characterized.
Results: At the age of 20 weeks, ZSF1-obese rats exhibited signs of HFpEF when compared to the lean counterparts, as evidenced by increased E/e‘ (16.0 ± 2.0 vs. 22.5 ± 1.0), preserved left ventricular ejection fraction (73 ± 2 vs. 71 ± 3%) and reduced exercise capacity, as determined by VO2max (41.4 ± 1.1 vs. 47.8 ± 2.8 ml/kg/min). ZSF1-obese rats displayed a profound increase in RV fibrosis as compared to ZSF-1 lean rats. TNFα levels were higher in RV from ZSF1-obese rats when compared to ZSF-1 lean rats, whereas no change was observed for IL-6 and IL-1 β. Catalase expression was increased in ZSF1-obese rats, suggesting an augmented reactive oxygen species burden in the RVs. Expression of the NADPH oxidase Nox2 homologue did not differ between both groups. At 28 weeks, differences in RV fibrosis between ZSF-1 obese and lean rats persisted. Notably, exercise training led to a decrease in RV fibrosis in ZSF-1 obese rats (11% vs. 8% as compared to sedentary ZSF-1 obese rats, $P < 0.05$), whereas fibrosis in ZSF-1 lean rats was not significantly altered. The favourable effect of exercise training on RV fibrosis in ZSF-1 obese rats was accompanied by decrease in TNFα levels and reactive oxygen species.
Conclusion: The present study is the first to characterize morphological changes of the RV in an in vivo model of HFpEF. The data suggest that inflammation, reactive oxygen species and fibrosis are major characteristics of the RV in HFpEF, and can be reversed by exercise training. The underlying mechanisms are part of ongoing investigations and likely provide important novel insights into the pathophysiology of the disease and potential novel treatment targets for patients with HFpEF.

P627

Protection of cardiomyocytes by E2F6 against drug induced cell death

BS Tuana[1]; JL Major[1]; M Salih[1]
[1]University of Ottawa, Ottawa, Canada

Funding Acknowledgements: Heart and Stroke Foundation of Canada

Background: The E2F pathway impacts the cell cycle to govern growth, differentiation, and death in all cell types but its role in postnatal myocardium in vivo remains elusive. To assess the role of the E2F pathway in postnatal myocardium we expressed a transgene encoding the repressor E2F6 to interfere with endogenous E2F activity. These E2F6 transgenic (tg) mice developed a dilated cardiomyopathy (DCM) in the absence of any apoptosis or growth deficits.
Results: Micro-array analysis and RT-q-PCR revealed a significant increase ($p < 0.05$) in the expression of genes which regulate the DNA damage response including the Chek1 kinase , Rad51 and Blm2 in myocardium from E2F6- (Tg) mice. We examined the sensitivity to apoptotic death of neonatal cardiomyocytes (NCM) isolated from E2F6 tg myocardium to Doxorubicin (Dox) and Colbolt Chloride (CoCl2). Dox treatment of NCMs from Wt and Tg myocytes resulted in caspase 3 activation and p53 induction to a similar level with equivalent effects on cell viability. Surprisingly, Dox (50uM) caused a rapid and dramatic loss of E2F6 protein in cardiomyocytes by 60% at 6hrs ($p < 0.05$) to non detectable levels within 12hrs. On the other hand CoCl2 (at concentrations 0 to 1mM) treatment of neonatal cardiomyocytes isolated from Tg mice demonstrated 6-fold less caspase 3 activation ($p < 0.05$), a 60% lower bax/bcl2 ratio ($p < 0.05$), and higher viability in comparison to their Wt treated counterparts. Although CoCl2 also promoted a dose dependent loss of E2F6 protein in Tg NCMs, it was to a much lesser extent compared with Dox. Unlike CoCl2, Dox activated the p53 death response in cardiomyocytes. In HeLa cells, Dox induced a dose dependent up-regulation of the pro-apoptotic E2F1 protein with a marked reduction in E2F6 levels while CoCl2 caused a reduction in E2F1 without affecting E2F6 levels. In HeLa cells, Dox induced Chek1 and the loss of E2F6 via post-transcriptional mechanisms and this was not observed in NCM.
Conclusion: These data imply that E2F6 may serve to protect cells from apoptosis via distinct mechanisms and strategies to modulate its levels may be a useful therapeutic to mitigate cell death and disease.

P628

Comparison of 12-month kinetics of serum markers of collagen synthesis, transforming growth factor and connective tissue growth factor between patients with recent and chronic dilated cardiomyopathy

P Pawel Rubis[1]; S Wisniowska-Smialek[1]; E Wypasek[1]; E Dziewiecka[1]; P Faltyn[1]; L Khachatryan[1]; A Karabinowska[1]; P Podolec[1]
[1]Department of Cardiac and Vascular Disease, John Paul II Hospital, Institute of Cardiology, Krakow, Poland

Funding Acknowledgements: Grant from the Poland National Centre of Science (no. 2013/09/D/NZ5/00252)

Background: Dynamics of extracellular matrix (ECM) fibrosis process in dilated cardiomyopathy (DCM) may be assessed non-invasively by means of serum markers of fibrosis measurements. Aim: To explore the kinetics of serum markers of fibrosis during 12 month follow-up in DCM.
Methods: We included 70 consecutive DCM patients (pts) (48 ± 12.1 years, EF 24.4 ± 7.4%) with new-onset (n = 35, duration < 6 months) and chronic DCM (n = 35, > 6 months). Markers of collagen type I and III synthesis – procollagens type I and III carboxy- and amino-terminal peptides (PICP, PINP, PIIICP, PIIINP), and ECM metabolism controlling factors – tumor growth factor beta-1 (TGF1-β) and connective tissue growth factor (CTGF) were measured in serum at baseline, 3- and 12-month follow-up. Results: Baseline, 3- and 12-month values of PICP, PINP, PIIICP, PIIINP, TGF-β and CTGF did not differ between pts with new-onset and chronic DCM (Figure 1). Conclusions: Regardless of the disease duration kinetics of serum markers of collagen synthesis, TGF and CTGF were similar in DCM. Better understanding of the kinetics of serum markers of fibrosis in DCM may help to develop tailored therapeutic approach directing ECM fibrosis.

Empagliflozin influence on the course of experimental heart failure in normoglycemic rats

A Aleksandr Kulikov[1]; SV Okovityi[2]; DY Ivkin[2]; AA Karpov[3]; DS Lisitskyi[2]; MM Lubishin[2]; PA Alekseeva[2]; NN Pitukhina[2]; AV Smirnov[1]; IG Kaiukov[1]; EV Parusova[1]

[1]Saint Petersburg Pavlov State Medical University, Saint Petersburg, Russian Federation; *[2]Saint-Petersburg State Chemical Pharmaceutical Academy, Saint Petersburg, Russian Federation*; *[3]Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation*

Purpose: The efficacy of sodium-glucose cotransporter 2 (SGLT2) inhibitor empagliflozin in chronic heart failure in normoglycemic rats was investigated.
Methods: Chronic heart failure (CHF) experimental model in rats was created by permanent ligation of the left coronary artery. Rats were randomly divided into 3 groups: empagliflozin treated CHF group (n = 11), untreated CHF group (n = 11), control group with sham operation (n = 9). Empagliflozin was administered in a dose 1 mg / kg/ per day for 3 months. Echocardiography was performed every month up to the end of the study. Sizes and volumes of the left ventricle (LV), LV ejection fraction, LV stroke volume and minute blood volume were measured. All rats were tested on a treadmill at the end of the experiment to evaluate physical endurance.
Results: CHF model was effective in both study groups, in a month after the surgery rats of the first and the second groups had significantly lower ejection fraction and larger LV sizes than the rats of the control group. At the end of the study animals on empagliflozin treatment had a better exercise tolerance (maximum working time on a treadmill 900 ± 110 s vs. 645 ± 110 s, p = 0.0004), higher minute blood volume at rest (80 ± 30.1 ml / min vs. 57 ± 19,4 ml / min, p < 0,025), bigger LV end-diastolic volume (0,50 ± 0,14 ml vs. 0.39 ± 0,08 ml, p = 0,028) and bigger LV mass (1 09 ± 0.19 g vs 0,69 ± 0,10 g, p = 0,012), than the animals who did not receive treatment. In the course of the empagliflozin treatment an increase of a LV stroke volume, LV end-diastolic volume, LV ejection fraction and minute blood volume were observed. These changes are not documented in CHF rats without treatment.
Conclusion: Antidiabetic drug empagliflozin improves exercise tolerance and the LV functional performance in normoglycemic rats with CHF. Influence of empagliflozin on LV remodeling needs further investigation.

Serum decorin correlates with the heart failure phenotype

P Parminder Chaggar[1]; A Watkins[2]; W Crtichley[3]; A Patel[3]; P Foden[4]; R Venkateswaran[1]; N Yonan[1]; A Trafford[2]; JE Fildes[3]

[1]University Hospital of South Manchester NHS Foundation Trust, The Transplant Unit, Manchester, United Kingdom; *[2]University of Manchester, Division of Cardiovascular Sciences, Manchester, United Kingdom*; *[3]University of Manchester, Manchester Collaborative Centre for Inflammation Research, Manchester, United Kingdom*; *[4]University Hospital of South Manchester NHS Foundation Trust, Department of Medical Statistics, Manchester, United Kingdom*

Background: Collagen deposition is the hallmark of cardiac fibrosis which is a feature of adverse remodeling during heart failure. Increased type I and type III collagen deposition impairs ventricular compliance and promotes dilatation. Decorin is a proteoglycan that binds type I and type III collagens, thereby slowing collagen deposition. The temporal dynamics of decorin during myocardial injury and recovery is unknown and warrants further investigation.
Purpose: This study was conducted to define the pattern of serum decorin during myocardial injury and recovery in an ovine model of pacing-induced heart failure.
Methods: 8 healthy Welsh mountain sheep underwent VVI pacemaker implant and paced at 210bpm until they developed overt clinical signs of heart failure. Pacing was then terminated and the animal was allowed to recover. The severity of LV dysfunction was assessed by serial measurements of fractional shortening (FS) on echocardiography at baseline, heart failure and recovery. FS has previously been validated as an accurate measure of LV function in sheep. Serum decorin was quantified via a protein array at baseline, heart failure and recovery. Temporal changes in FS were analysed using repeated measures ANOVA and temporal changes in serum decorin concentration were analysed using a Friedman test.
Results: FS decreased significantly in heart failure compared to baseline and subsequently increased significantly in recovery. The FS in recovery did not reach baseline FS values (Figure 1A). Decorin increased significantly in heart failure compared to baseline and remained elevated during recovery (Table 1 and Figure 1B).
Conclusion: Serum decorin increases significantly with the development of heart failure and this may represent a physiological response to attenuate the effects of adverse remodeling. This is the first study to demonstrate temporal changes in serum decorin during myocardial injury and recovery in a large mammal. Decorin may serve as a biomarker of myocardial injury and could be a target for therapeutic manipulation. These findings require validation in a larger series.

Serum decorin in ovine tachy-paced HF

Decorin (pg/mL)	Baseline	Heart Failure	Recovery
Median	873	2332*	1455*

Coronary response in the doxorubicin-induced cardiomyopathy

V Cobet[1]; V Lutan[1]; L Tacu[1]; V Rotaru[1]; L Ciobanu[2]; E Cobet[3]; A Rotaru[4]

[1]State University of Medicine and Pharmacy, Chisinau, Moldova Republic of; *[2]Institute of cardiology , Chisinau, Moldova Republic of*; *[3]State University of Moldova , Biopharmaceutical chemistry , Chisinau, Moldova Republic of*; *[4]Harvard Medical School, Cambridge, United States of America*

Background: Coronary reserve and reactivity traits regarding doxorubicin (Dx) cardiotoxicity are less known comparatively to myocardial contraction and inotropic capacities.
Aim: the in vitro evaluation of coronary response to natural vasotropic agent action in Dx-induced cardiomyopathy (Dx-CMP).
Material and methods. Dx-CMP has been reproduced in white rats by Dx administration during 2 weeks (4 i/p Dx injections of 4 mg/kg, cumulative dose 16 mg/kg). The izovolumic isolated heart was perfused by standard Krebs solution according to Langendorff method, and the coronary flow (CF) changes were determined during action of acetylcholine (Ach), adenosine (As), bradykinin (Bk), hydrogen peroxide (H2O2), epoxyeicosatriens 11,12 (EET-11,12) and endothelin 1 (ET-1) in a concentration range of 10-7-10-5 M.
Results: The basal CF in DxCMP did not differ from control index (12,7 ± 0,08 vs 13,4 ± 0,09 ml/min). However, the endothelium dependent coronary functional reserve is impaired, manifested by significant lowered CF value during stimulation by Ach (14,8 ± 0,1 vs 17,3 ± 0,12 ml/min), As (13,9 ± 0,09 vs 15,5 ± 0,11 ml/min) and Bk (13,8 ± 0,08 vs 15,3 ± 0,12 ml/min). Remarkably, the coronarodilation mediated by hyperpolarization was not compromised in Dx-CMP. The coronary reserve inherent to H2O2 action was as 15,7% in Dx-CMP (CF, 14,7 ± 0,12 ml/min) and 14,9% in control series (CF, 15,4 ± 0,13 ml/min). In a similar manner CF increased in response to EET-11,12 action: 14,3% in Dx-CMP (CF, 14,52 ± 0,13 ml/min) and 14,1% in control (CF, 15,29 ± 0,14 ml/min). Thus, the mediated by hyperpolarization coronary artery dilatation could be an alternative tool of coronary functional reserve control in Dx-CMP associated by endothelium dysfunction. Importantly, ET-1 in concentration of 10-7 M determined in Dx-CMP o reduction of CF equal to control pattern (11,3%), but in condition of isolated heart pretreatment by apamin (selective blocker of KCa channels) the coronaroconstriction in Dx-CMP has been more pronounced vs control (-17,1 vs -14,2%). In highest concentration (10-5 M) ET-1 led in Dx-CMP to a bigger decline of coronary flow FC (-16,8 vs -14,5%).
Conclusions: 1. The coronary functional endothelium dependent reserve is significantly reduced in Dx-CMP during Ach, As and Bk action averagely by 39-43,3% comparing to control, but the mediated by hyperpolarization coronarodilation proper to H2O2 and EET-11,12 action is not compromised.
2. In concentration of 10-5 M endoteline-1 induces a bigger fall of CF in Dx-CMP, but in concentration of 10-7 M the decline is similar to control, however CF decreases more if ET-1 action was preceded by KCa channels blocking.

BASIC SCIENCE - THERAPEUTIC APPROACH

Funding Acknowledgements: Università Italo-Francese

Purpose: While acute stimulation of β-adrenergic receptors (β-ARs) increases cyclic adenosine monophosphate (cAMP) and improves cardiac function, their chronic activation in heart failure (HF) is detrimental to the heart, by promoting deregulation of intracellular calcium handling and maladaptive remodeling. Multiple phosphodiesterases (PDEs) finely tune β-AR responses by degrading and compartmentalizing cAMP. PDE2A is increased in HF and blunts β-AR responses and the pro-hypertrophic effect of noradrenaline. In contrast, PDE4B is decreased in cardiac hypertrophy and knock-out mice for PDE4B are more susceptible to develop cardiac arrhythmias. Since chronic treatment with PDE inhibitors increases mortality in HF, we hypothesized that decreasing cAMP levels may have therapeutic effects.
Methods: We explored whether serotype 9 adeno-associated viral vectors (AAV9) mediated cardiac overexpression of PDE2A or PDE4B could prevent maladaptive hypertrophy in a mouse model of chronic isoproterenol (Iso) infusion (60 µg/g/day during 2 weeks). Male C57BL/6 mice were injected in the tail vein with AAV9 to increase PDE2A and PDE4B in the heart. Echocardiography allowed cardiac function exploration. PDE4B protein expression in heart extracts was measured by western blot. Heart sections (10 µm thick) were cut from paraffin-embedded specimens and stained with masson's trichrome to quantify fibrosis.
Results: Six weeks after injection, mice showed a five-fold increase in PDE2A and PDE4B protein levels. In control mice injected with a Luciferase-AAV9, chronic Iso treatment induced cardiac hypertrophy (N=10, $p < 0.01$), fibrosis (N=9, $p < 0.01$), and decreased ejection fraction (EF) measured by echocardiography by $31.6 \pm 3{,}5\%$ (N=10, $p < 0.001$). Overexpression of each enzymes did not prevent cardiac hypertrophy (N=10) but abolished the increase in fibrosis (N=9, $p < 0.05$). More importantly, EF was preserved when either PDE2A (N=10, $p < 0.001$) or PDE4B (N=10, $p < 0.001$) were overexpressed in this pathological model.
Conclusions: Altogether, these results suggest that gene therapy with AAV9 encoding PDEs is a potential therapeutic approach for cardiac maladaptive hypertrophy.

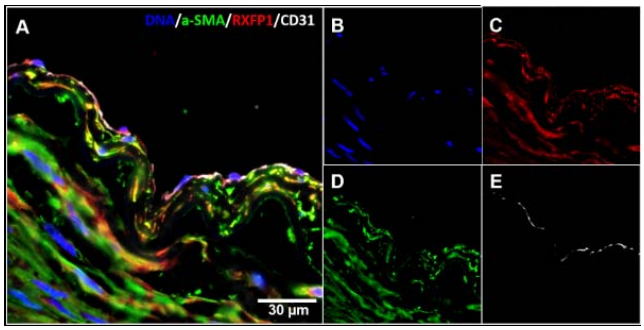
Acute and subacute functional effects of relaxin-2 on human mammary artery

F Francisco Pereira Goncalves[1]; R Martins[1]; L Mendonca[1]; T Laundos Santos[2]; M Pintalhao[1]; F Vasques Novoa[1]; P Pinho[1]; MJ Amorim[1]; DS Nascimento[2]; A Leite Moreira[1]; P Castro Chaves[1]
[1]Faculty of Medicine University of Porto, Departamento de Cirurgia e Fisiologia, Porto, Portugal; *[2]Institute for Research and Innovation in Health, Porto, Portugal*

Introduction: Despite classically associated with pregnancy, relaxin is a hormone with pleiotropic properties and an increasingly unveiled role in the pathophysiology of several cardiovascular diseases. Previous clinical trials have explored its therapeutic role on acute heart failure. However, the exact actions of relaxin on the human vascular territory are scarcely known.
Purposes: To study the acute and subacute functional effects of relaxin-2 on the vasoreactivity of the human mammary artery (HMA). To assess the expression of RXFP1, its main receptor, in this vascular territory.
Methods: HMA from 37 patients subjected to coronary artery bypass graft surgery (median age 69.3 years; 7 female) were sectioned into 2mm rings and mounted on a myograph (DMT myograph system). On one protocol, the vessels were exposed to increasing concentrations of relaxin (10-10-10-7M) or vehicle after pre-contraction with phenylephrine (10-5M), n=5. On a different protocol, the rings were treated for 24h with relaxin (10-7M) or vehicle and afterwards subjected to increasing concentrations of vasoconstrictors (10-9-10-5M) - phenylephrine ($n = 8$), endothelin-1 ($n = 6$) and angiotensin II ($n = 11$) – and of vasodilators (10-10-10-5M) - acetylcholine ($n = 8$) and sodium nitroprusside ($n = 11$). Vessel rings were also incubated for 24h with relaxin or vehicle after endothelium removal, and their response to nitroprusside evaluated (10-10-10-5M; n=7). Immunofluorescence labelling of RXFP1 was performed along with labelling for CD31 (endothelial cells) and α smooth muscle actin (smooth muscle cells). Functional responses are expressed as mean $\pm$ standard error(%).
Results: After acute exposure to relaxin, no differences in the developed active tension were observed between relaxin or vehicle treated groups. Following 24h treatment with relaxin or vehicle, vascular viability and the vasoconstrictor effects of phenylephrine, endothelin-1 and angiotensin II were similar between groups. However, vessel rings treated with relaxin showed higher relaxation when compared to vehicle treated rings, both in response to acetylcholine ($59.1 \pm 6.1\%$ vs $46.2 \pm 6.2\%$; $p < 0.01$) and nitroprusside ($128.9 \pm 4.8\%$ vs $118.7 \pm 5.1\%$ $p < 0.05$). The higher response to nitroprusside was preserved when treatment with relaxin followed endothelium removal ($143.3 \pm 4.1\%$ vs $132.8 \pm 3.3\%$; $p < 0.01$). Immunofluorescence showed labelling for RXFP1 on smooth muscle and endothelial cells (see Figure).
Conclusion: Treatment with relaxin-2 for 24h potentiates HMA vasodilatation without interfering with the effects of several vasoconstrictors, and this effect is at least partially independent of the endothelium. We have also identified for the first time the presence of RXFP1 on the endothelium and smooth muscle cells of HMA. Besides shedding further light on relaxin's role on human vascular physiology, this project may have implications in the understanding of HMA's physiology, an important conduct for coronary revascularization procedures.



Expression of the RXFP1 receptor on HMA

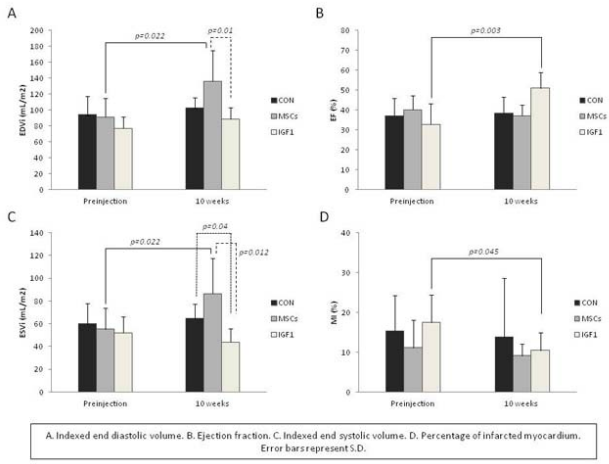
Funding Acknowledgements: European Commission FP7-HEALTH-2009-1.4-3, Grant Agreement 242038, RIC (RD12/0042/0025) and CIBER CV (CB16/11/00494)

Background: Mesenchymal stem cells (MSCs) have been demonstrated to ameliorate left ventricular remodeling in patients with ischemic cardiomyopathy, with some studies reporting better results after low cell dose administration. Nevertheless, regenerative cardiology is nowadays focusing on cell-less treatment strategies. Insulin-like growth factor-1 (IGF1) has been shown to possess angiogenic effects on endothelial cells. Its microencapsulation allows for sustained release over a specific time.
Purpose: The aim of the study was to evaluate and compare the effect of low-dose allogeneic MSCs and IGF1 loaded microspheres (MSPs) in a porcine myocardial infarction (MI) model.
Methods: Infarcted female pigs (90 minutes mid-LAD occlusion) received an intracoronary (IC) injection of MSCs (30x10^6, n=7), IGF1 loaded MSPs (95µg per MSP, 5x10^6 MSPs, n=8) or saline (CON, n=5) 48 hours after infarction. Safety was evaluated using clinically available tools (ECG and TIMI flow). Cardiac function was studied by magnetic resonance (MR) before injection and at 10 weeks: Indexed end diastolic volume (EDVi), indexed end systolic volume (ESVi), ejection fraction (EF) and percentage of infarcted myocardium (%MI).
Results: Injection was successful in all cases, in absence of major adverse cardiac events. Changes in ECG were seen in one pig belonging to the MSCs group. TIMI flow decreased in 2 animals from the MSCs group (TIMI 2 and TIMI 0), versus 4 swine in the IGF1 group (TIMI 2, n=3 and TIMI 1, n=1), and none in CON. Evolution of cardiac function parameters is shown in the

figure. No differences were seen between groups in any MR-derived parameter before injection. At 10 weeks, however, ESVi was significantly lower in IGF1 (43.82 ± 11.93mL/m2) than in CON (64.60 ± 13.00mL/m2, p = 0.04) and MSCs groups (86.55 ± 31.24mL/m2, p = 0.012). EDVi was significantly different between IGF1 and MSCs groups (88.73 ± 14.23mL/m2 vs. 136.37 ± 38.11mL/m2, p = 0.01). Comparison between pre and 10 weeks post-injection revealed an improvement in EF in IGF1 (32.83 ± 10.41% vs. 50.96 ± 7.89%, p = 0.003), a reduction in %MI (17.50 ± 6.87% vs. 10.50 ± 4.44, p = 0.045) and a limited dilatation with no significant changes to EDVi and ESVi over time, while MSCs animals suffered a significant worsening in EDVi (91.30 ± 23.56mL/m2 vs. 136.37 ± 38.11mL/m2, p = 0,022) and ESVi (55.39 ± 18.44mL/m2 vs. 86.55 ± 31.24mL/m2, p = 0.022). No statistically significant differences were observed in any cardiac function parameter over time in the case of CON group.

Conclusion: Both the IC delivery of MSCs and IGF1 loaded MSPs could impair coronary flow on the short term after experimental MI. Nevertheless, IC administration of 5x10^6 IGF1 loaded MSPs was successful in alleviating myocardial dysfunction over time (limiting ventricular volumes) compared to CON or low-dose MSCs.



Evolution of cardiac function parameters

Pharmacological activation of sphingosine 1-phosphate receptor 1 (S1pr1) enhances arteriole formation and improves cardiac function after myocardial infarction (MI)

L Zhang[1]; LE Bao[1]; XL Li[1]; YZ Zhang[1]; HM Fan[1]
[1]*Tongji University School of Medicine, 1. Research Center for Translational Medicine, Shanghai East Hospital, Shanghai, China People's Republic of*

On behalf of: Research Center for Translational Medicine, Shanghai East Hospital, Shanghai, People's Republic of China
Funding Acknowledgements: National Natural Science Foundation of China 81470472, 81670234

Background and purpose: Sphingosine 1-phosphate (S1P) is a lipid metabolite and a ligand of five G protein-coupled cell surface receptors S1pr1 to S1pr5. It has been shown that S1P/S1pr1 signaling played an essential role in vascular remodeling during development. However, it is unknown whether S1pr1 regulates vascular remodeling and therefore influences cardiac function after myocardial infarction. We aimed to investigate the effect of pharmacological activation of S1pr1 by SEW2871 in a mouse model of acute myocardial infarction.
Methods: We performed left anterior descending artery (LAD) ligation to induce acute myocardial infarction in mice. We treated operated mice with 5 mg/kg/day S1pr1 agonist, SEW2871, or placebo (DMSO) i.p., respectively, for 4 weeks. We performed echocardiography to investigate cardiac function. We also carried out histological analysis to study vascular remodeling in MI model.
Results: Echocardiography showed that cardiac function was significantly reduced in MI mice (ejection fraction (EF): 76.15 ± 1.65 % Sham group vs. 49.47 ± 2.42 % MI-DMSO group. P < 0.05). S1pr1 agonist, SEW2871, significantly improved cardiac function 4 weeks after myocardial infarction (EF: 49.47 ± 2.42 % MI-DMSO group vs. 60.23 ± 2.38 % MI-SEW2871 group. P < 0.05). Mason's trichrome staining showed that SEW2871 treatment significantly reduced the infarct size: 21.13 ± 1.52 (%) MI-DMSO group vs. 17.01 ± 1.27 (%) MI-SEW2871 group. P < 0.05). Our further isolectin B4 (iB4) antibody staining showed that capillary density in peri-infarct myocardium was similar between MI-DMSO group and MI-SEW2871 group. However, co-staining of iB4 antibody and alpha smooth muscle actin (alpha-SMA) antibody showed that arteriole density in peri-infarct myocardium was significantly increased in MI-SEW2871 group compared to MI-DMSO group.
Conclusions: Our results demonstrate that activation of S1pr1 enhanced arteriole formation and improved vascular remodeling after myocardial infarction, which might contribute to the beneficial effect of S1pr1 agonist on cardiac repair after MI, suggesting that S1pr1 signaling is potential target to therapy post-MI heart failure.

Funding Acknowledgements: DFG KA 4024/3-1 AOBJ:619981; HOMFOR 2016

Background: Myocardial fibrosis plays a central role during maladaptive cardiac remodeling. Quantitative Trait Loci (QTL) analyses in BXD recombinant mouse lines identified Raf Kinase Inhibitor Protein (RKIP) as marker of fibrosis.
Methods: To characterize the underlying signaling, 10-week-old C57BL/6 -RKIP-deficient (RKIP-/-) N and RKIP-/- J mice were subjected to transverse aortic constriction (TAC). In the myocardium, reverse-mode nicotinamide nucleotide transhydrogenase (Nnt) is the dominant source for ROS during pressure overload. Due to mutation of the Nnt gene, the C57BL/6J-, but not the N-strain, is protected from oxidative stress.
Results: Myocardial fibrosis, expression of collagen Iα2 mRNA, Ki67 + fibroblasts and markers of oxidative stress such as 8-hydroxyguanosine positive fibroblasts were markedly reduced in RKIP-/- N mice post TAC. The number of fibrocytes in the peripheral blood and bone marrow was also reduced in RKIP-/- N TAC. RKIP-/- N adult cardiac fibroblasts demonstrated decreased migration and fibronectin production. RKIP-/- N TAC showed a two-fold increase of the nuclear expression of nuclear factor erythroid 2-related factor 2 (Nrf2), the main transcriptional activator of antioxidative proteins. In contrast to these findings, the Nnt-deficient RKIP-/- J TAC mice revealed diminished oxidative stress, increased LV fibrosis, collagen Iα2 mRNA and enhanced basal nuclear expression of Nrf2, which was not further increased by TAC. The expression of the gene coding for RKIP, Pebp1, was markedly higher in the N compared to the J mouse strain consistent with increased basal oxidative stress. In human left ventricular myocardium from both non-failing and failing hearts, RKIP-protein correlated negatively with the nuclear expression of Nrf2.
Conclusions: Under conditions of Nnt-dependent enhanced myocardial oxidative stress in response to pressure overload, RKIP plays a maladaptive role for fibrotic myocardial remodeling by suppressing the Nrf2-related beneficial effects.

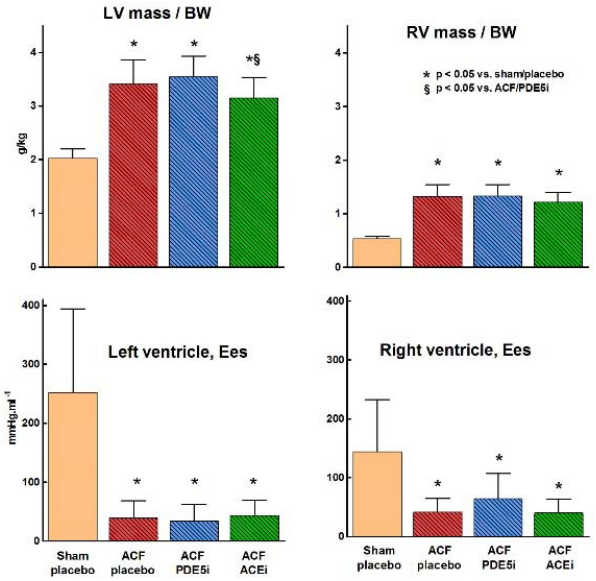
P637

The impact of long-term phosphodiesterase 5 inhibition on right and left ventricular remodelling in chronic heart failure due to volume overload

T Tereza Havlenova[1]; M Kotrc[1]; P Skaroupkova[1]; L Cervenka[1]; V Melenovsky[1]
[1]*Institute for Clinical and Experimental Medicine (IKEM), Prague, Czech Republic*

Background: Chronic inhibition of phosphodiesterase 5 (PED5i) prevents hypertrophy and dysfunction of pressure-overloaded heart, but its impact on volume-overload (VO) induced hypertrophy is unknown. It is also unclear whether right (RV) and left (LV) ventricle differ in their responses to chronic VO or antihypertrophic therapy.
Aim: To elucidate the effect of chronic VO on cardiac structure and function and to address the effect of PED5i and ACEi in VO rat model due to aorto-caval fistula (ACF).
Methods: ACF/sham procedure was performed on 8-week old male HanSD rats. ACF animals were randomized for PDE5i sildenafil (80 mg/kg, n=20), ACEi trandolapril (6 mg/l H2O, n=30) or placebo (n = 30). After 20 weeks, echocardiography and pressure-volume analyses (Millar, AD-Instruments) were performed and animals sacrificed to obtain organ weights and tissue samples for cGMP level measurements. Separate rat cohort (n = 10 - 40/group) served for survival analysis.
Results: ACF led to marked eccentric LV and RV hypertrophy (by 70% and 150%) and reduced load-independent systolic function (end-systolic elastance, Ees, by 85% and 70%, figure). Although RV stroke work increased relatively more than

LV (7x vs. 4x), there was no increase in RV end-diastolic pressure, suggesting better RV adaptation to VO. ACEi, but not PDE5i, attenuated pulmonary congestion, LV dilatation and dysfunction. VO and drug-induced changes in RV and LV mass were proportional, arguing against chamber-specific effects. Median survival in ACF/placebo, ACF/PDE5i and ACF/ACEi was 26, 27 and 37 weeks (p0.05 ACF/ACEi vs. ACF/placebo). ACF/PDE5i rats had increased cGMP levels (by 150%) in the lungs, but not in RV or LV.
Conclusions: Sildenafil had neutral effect on survival, structure and function of the LV and RV and failed to increase myocardial cGMP levels. Cardiac hypertrophy due to volume overload is not cGMP-dependent. Volume overload leads to similar changes in LV and RV mass and contractility.



P638

BRaf inhibitors, dabrafenib and SB590885, enhance ERK1/2 signalling in cardiomyocytes and increase angiotensin II-induced cardiac hypertrophy.

MA Hardyman[1]; SJ Fuller[1]; SJ Leonard[1]; PH Sugden[1]; A Angela Clerk[1]
[1]*University of Reading, Reading, United Kingdom*

Funding Acknowledgements: British Heart Foundation

Purpose: ERK1/2 are phosphorylated and activated by MKK1/2 that are themselves phosphorylated and activated by Raf kinases. The ERK1/2 cascade promotes cardiomyocyte hypertrophy and is protective, but also promotes cancer. V600 mutations in BRaf are commonly found in cancer, and drugs targeting the enzyme are in clinical use (e.g. dabrafenib, SB590885). Some inhibitors have a paradoxical effect and activate ERK1/2 at low concentrations rather than inhibit it. Such activation could be cardioprotective, whilst inhibition is likely to be damaging. Our aim is to determine the effects of BRaf inhibitors on cardiomyocytes and the heart to establish if they may affect cardiac function either alone or in the context of pre-existing hypertension.
Methods: Rat neonatal cardiomyocytes were exposed to dabrafenib or SB590885 and the effects on activation of MKK1/2 or ERK1/2 examined by immunoblotting with antibodies to phosphorylated (i.e. activated) or total kinases. The effects of dabrafenib (3 mg/kg/d) on mouse hearts (male C57Bl6; 12 weeks) in vivo were compared with a MKK1/2 inhibitor, trametinib (1.6 mg/kg/d), alone or in the presence of angiotensin II (AngII, 0.8 mg/kg/d) as a hypertensive model. Echocardiography was performed with a Vevo 2100 system to assess cardiac function. M-mode images of the short axis view were used for analysis of cardiac dimensions. Results. In cardiomyocytes, 10 μM dabrafenib inhibited MKK1/2 and ERK1/2 up to 45 min, but this was followed by a small paradoxical activation. At 0.1 μM, dabrafenib enhanced ERK1/2 signalling to a small degree. SB590885 activated MKK1/2 and ERK1/2 to a greater degree than dabrafenib despite it having a lower IC50 for inhibition of BRaf. SB590885 had a greater effect on cardiomyocyte hypertrophy, increasing myofibrillar organisation and surface area, consistent with increased ERK1/2 signalling. The Raf paradox and potential mechanism will be discussed. In mouse hearts in vivo, dabrafenib enhanced MKK1/2 phosphorylation and increased ANF and BNP mRNA expression, consistent with the in vitro data. Over 10 d, neither dabrafenib nor trametinib alone affected any of the cardiac parameters studied by echocardiography. However, in the presence of AngII, dabrafenib increased ejection fraction and fractional shortening, increased left ventricular (LV) wall thickness in diastole and systole, and this was associated with enhanced reduction in LV volume and internal diameter. This contrasted with the effects of trametinib which reduced the increase in LV thickness induced by AngII and for which there was notable mortality absent from all other groups. Conclusions. Dabrafenib and SB590885 alone do not significantly inhibit ERK1/2 signalling in cardiomyocytes, but enhance the signal and promote hypertrophy. In vivo, the effects are more apparent in the context of hypertension. Thus, cancer patients receiving the BRaf inhibitors alone may experience enhanced cardiac hypertrophy if they are hypertensive.

P639

Espindolol improved cardiac function and survival in a rat cancer cachexia model

J Ishida[1]; M Saitoh[1]; S Palus[1]; N Ebner[1]; S Von Haehling[1]; S Anker[1]; J Springer[1]
[1]*University Medical Center Gottingen (UMG), Department of Cardiology and Pneumology, Gottingen, Germany*

Background and aims: Cancer cachexia (CC) is a complex syndrome, characterized by increased proteolysis, lipolysis and anorexia. Moreover, cardiac wasting associated with CC leads to poor prognosis, while both bisoprolol, a beta-1 selective beta blocker, and formoterol, a beta-2 agonist, have recently shown cardioprotective effects in this condition. Purpose: The aim of this study was to investigate the effect of espindolol, a non-selective beta blocker with beta-2 intrinsic sympathetic activity, on cardiac function and survival in a rat model of CC.
Methods: After intraperitoneal injection of 108 Yoshida AH-130 hepatoma tumor cells, Juvenile Wister Han rats were randomized to receive placebo, espindolol 0.3 mg/kg/day (LD) or 3 mg/kg/day (HD). Body weight and body composition were assessed at baseline and day 14, and cardiac function was evaluated by echocardiography on day 11. Results: Espindolol improved survival (hazard ratio [HR] 0.29, 95% confidence interval [CI] 0.16-0.51, $p < 0.001$ for HD; HR 0.51, 95% CI 0.26-1.00, $p = 0.051$ for LD, vs placebo) and preserved lean body mass (170.0 ± 13.5 g, $p < 0.001$ for HD; 145.7 ± 10.4 g, $p = 0.01$ for LD, vs. 118.5 ± 1.6 g for placebo) and fat mass (12.0 ± 2.7 g, $p = 0.02$ for HD; 8.3 ± 1.7 g, $p = 0.57$ for LD, vs. 6.4 ± 0.3 g for placebo). In addition, espindolol increased heart weight (612 ± 40 g, $p = 0.01$ for HD ; 548 ± 27 g, $p = 0.14$ for LD vs. 506 ± 8 g for placebo), improved cardiac systolic function assessed by left ventricular ejection fraction (69 ± 3 %, $p < 0.001$ for HD; 59 ± 4 %, $p = 0.13$ for LD vs. 52 ± 2 % for placebo) and raised cardiac output (71 ± 8 mL/min, $p = 0.001$ for HD; 53 ± 10 mL/min, $p = 0.29$ for LD, vs. 42 ± 3 mL/min for placebo).
Conclusions: Espindolol dose-dependently prevented cardiac wasting as well as loss of skeletal muscle and adipose tissue, and improved survival in a rat model of CC. Espindolol can be a promising treatment option for cardia dysfunction associated with CC.

P640

Cardioprotective effect of LCZ696 versus valsartan on left ventricular remodeling in experimental model of chronic heart failure

L Lenka Hoskova[1]; V Melenovsky[1]; J Kautzner[1]; I Malek[1]; Z Huskova[2]; L Sedlakova[2]; L Kopkan[2]

Introduction: The renin-angiotensin-aldosterone system (RAAS) plays a key role in the pathogenesis of chronic heart failure (CHF) and its inhibition improves cardiac function and survival. Consequences of RAAS activation are antagonized by endogenous natriuretic peptides. Sacubitril/valsartan (LCZ696) is a new drug that combines angiotensin receptor blocker valsartan (VAL) with sacubitril that inhibits breakdown of natriuretic peptides by neprilysin. The cardiac effects of LCZ696 on volume overload-induced CHF are unknown.
Purpose: To evaluate the effects of LCZ696 or VAL on left ventricular function and geometry in an experimental model of CHF induced by volume overload from aorto-caval fistula (ACF) in rats.
Methods: CHF was induced by ACF in 26 male Sprague-Dawley (SD) rats at 8 weeks of age. Four weeks after ACF, administration of LCZ696 was started in 8 rats (ACF-LCZ group) in a standard dosing at 68 mg/kg/day and valsartan in 8 rats (ACF-VAL, at dose 31 mg/kg/day) for next 16 weeks. Other 10 ACF rats were administered with vehicle. The remaining 8 rats without ACF comprised a control group. At age the end of study protocol (20 weeks), the animals were weighed and anaesthetized, and echocardiography was performed using a 7.5 MHz probe (Vivid

7, GE). Left ventricular (LV) internal dimensions (LVIDd), fractional shortening (FS), stroke volume (SV) and LVmass (LVm) were measured.
Results: In comparison to controls, untreated ACF group displayed marked LV dilatation, (LVIDd 6,2 ± 0,1 vs. 11,9 ± 0,5 mm, p < 0,01). Both SD groups treated with LCZ or VAL exhibited significantly lower LVIDd (9,5 ± 0,5 mm and 10,1 ± 0,3 mm; respectively, p < 0,05). We also observed significantly reduced LV function (FS: 35,2 ± 1,1 vs. 59,9 ± 1,2 %, p < 0,01) and increased SV (1274 ± 164 vs. 225 ± 15 µl/beat, p < 0,01) in untreated ACF group compared to control. In both treated ACF groups, we observed an improvement in LV systolic function, where FS increased in ACF-LCZ (44,3 ± 1,5 %, p < 0,05) or in ACF-VAL (42,5 ± 2,1 %, p < 0,05) and SV significantly decreased in ACF-LCZ (757 ± 122 µl/beat , p < 0,05) and ACF-VAL (835 ± 68 µl/beat, p < 0,05). The LVm was significantly reduced in both ACF-LCZ (1844 ± 129 mg, p < 0,05) and ACF-VAL (1850 ± 58 mg, p < 0,05) compared to untreated ACF (2196 ± 52 mg). We did not observe any adverse effect during the treatments with VAL or LCZ696 confirming the safety of these drugs in this model.
Conclusion: In this animal model of heart failure, both treated normotensive ACF groups (LCZ696 and VAL) showed significant reverse LV remodeling. However, we did not observe any additional effects of treatment on cardiac function with LCZ696 compared to VAL in short term follow-up. Prolonged treatment period is advised to verify cardioprotective benefits of LCZ696 vs.VAL.

Funding Acknowledgements: National Institute of Health [PI13/00100; PI14/01506], CIBERCV [CB16/11/00261], the European Regional Development Fund (FEDER), RETICS [12/0042/0003].

Background: In previous studies, we showed that several molecules participating in the nuclear-cytoplasmic transport (EXP-1, IMP-β3, and Nup160) were closely related to ventricular dysfunction in human heart failure. We found the genomic signature of these alterations and the corresponding changes in gene expression, particularly XPO1 (the gene that encodes EXP-1), to be highly related to left ventricular function in patients with heart failure of ischemic etiology.
Purpose: We aim to investigate whether highly significant relationship between XPO1 and ventricular function is a component of causality.
Methods: We induced chronic myocardial infarction (n = 10) by coronary ligation in Sprague-Dawley rats, five of these rats received AAV9-shXPO1 intravenously after four months. Sham rats (n = 5) were healthy non-failing controls and received the placebo AAV9-scramble intravenously. Furthermore, 5 infarcted rats did not receive treatment. Serial echocardiographic assessment was performed before, as well as, two and five months after intravenous injection.
Results: AAV9-shXPO1-treated rats showed improved fractional shortening (16.8 ± 2.8 vs 24.6 ± 4.1%, P < 0.05) and left ventricular systolic (5.10 ± 0.79 vs 3.52 ± 0.88 mm, P < 0.05) and diastolic diameters (6.17 ± 0.95 vs 4.70 ± 0.93 mm, P < 0.05) when comparing measurements obtained before injection and five months after AAV9 injection. We did not observe this improvement in untreated infarcted rats. EXP-1 levels in heart, brain, skeletal muscle, and liver of all rats were determined by western blot. Compared to controls rats, in AAV9-shXPO1-treated rats, EXP-1 levels in cardiac tissue were lower (P < 0.05).
Conclusions: At the five months follow-up, ischemic AAV9-shXPO1-treated rats showed partial recovery of left ventricular myocardial function. No secondary symptoms attributable to AAV9-shXPO1 were observed in the cardiac-related organs. Our findings provide a therapeutic option for patients with ischemic cardiomyopathy.

Funding Acknowledgements: This study was supported by the National Research, Development and Innovation Office of Hungary (NKFIA; NVKP-16-1-2016-0017).

Introduction: Diabetic cardiomyopathy is a consequence of diabetes mellitus (DM). Comparison of animal models of T1DM and T2DM may contribute to a deeper pathophysiologic understanding of diabetic cardiomyopathy.
Purpose: We aimed at comparatively investigate diabetic cardiomyopathy by left ventricular (LV) pressure-volume (PV) analysis and by the non-invasive speckle-tracking echocardiography (STE) in rat models of type-1 (T1DM) and type-2 DM (T2DM).
Methods: Rat models of T1DM (induced by 60mg/kg streptozotocin, n=7) and T2DM (32-week-old Zucker Diabetic Fatty rats, n=6) and corresponding control animals (n = 5 and n=8, respectively) were compared. Echocardiography and LV PV analysis were performed. LV short-axis recordings were used for STE analysis. Global circumferential strain (GCS), peak strain rate values in systole (SrS), isovolumic relaxation (SrIVR) and early diastole (SrE) were measured. LV contractility, active relaxation and stiffness were measured by PV analysis.
Results: In T1DM, contractility and active relaxation were deteriorated to a greater extent compared to T2DM. In contrast, diastolic stiffness was impaired in T2DM. Correspondingly, STE described more severe systolic dysfunction in T1DM. Among diastolic STE parameters, SrIVR was more decreased in T1DM, however, SrE referring to diastolic stiffness was more reduced in T2DM. In T1DM, SrS correlated robustly with contractility, SrIVR with active relaxation, while in T2DM SrE was closely related to cardiac stiffness.
Conclusions: Diabetic cardiomyopathy is characterized by overt systolic dysfunction and impaired active relaxation in T1DM, while with increased diastolic stiffness in T2DM. STE corresponds to PV analysis by unveiling key differences between cardiac dysfunction caused by T1DM and T2DM.

A preclinical animal model of heart failure mimics distinct clinical phenotypes of heart failure in humans

X Xiuying Ma[1]; S Tannu[1]; J Allocco[1]; J Pan[1]; M Flaim[1]; E Crain[1]; P Wong[1]
[1]Bristol-Myers Squibb, Cardiovascular Drug Discovery, Pennington, United States of America

Mouse models of chronic heart failure (CHF) post myocardial infarction (MI) have been widely used in HF research. However, current CHF models, most often using the C57Bl/6 mouse strain, do not always resemble the clinical phenotypes observed in patients with HF. Previous findings suggested that BalbC mice may be a preferred mouse strain suitable for HF research, which showed increase in lung weight and the worst cardiac function post-MI among different mouse strains (van den Borne SWM, Cardiovasc Res 2009;84:273-282). The goal of the present study was to fully characterize survival rate, cardiac function, and pulmonary congestion post-MI in BalbC mice with or without enalapril treatment, the current standard of care therapy for patients with HF. After induction of MI by permanent ligation of the left coronary artery, cardiac function was longitudinally assessed by echocardiography: heart weight, lung weight, and pulmonary oedema were all measured at the end of the study. In addition, survival rate was continuously monitored throughout the study. Following MI surgery, the mortality was significantly increased from week 1 to week 7 (4% vs. 30%) compared to sham-operated animals. Cardiac function in the surviving animals started to decline 7 weeks post-MI (stroke volume: 38.2 ± 3.3 vs. 38.3 ± 1.8, 48.2 ± 5.9 vs. 42.2 ± 2.7, and 47.0 ± 4.5 vs. 34.3 ± 3.5 µl at week 1, 4, and 7, sham vs. MI, P < 0.05). Lung weight and water content in the lungs were also significantly increased (152.5 ± 4.5 and 118.9 ± 3.2mg vs. 258.9 ± 22.3 and 204.3 ± 17.8mg, respectively, sham vs. MI, P < 0.05) 7 weeks post-MI indicative of the development of pulmonary congestion. In a subsequent study, survival rate, cardiac function, pulmonary congestion, and plasma BNP concentration were further evaluated in the presence of enalapril (20mg/kg/day, subcutaneous osmotic mini-pump) administered 4 weeks post-MI for 6 weeks. Compared to vehicle, enalapril significantly improved survival (73% to 97%, P=0.009), reduced water content in the lungs (223.9 ± 14.3 vs. 165.7 ± 7.1mg, P < 0.05), plasma BNP concentration (522.9 ± 42.7 vs. 273.8 ± 32.5mg, P < 0.05) and preserved cardiac function. The results presented demonstrate that BalbC mice develop deterioration of cardiac function and pulmonary congestion along with elevated plasma BNP levels post-MI (typical of clinically observed HF in humans) not seen in C57Bl/6 mice and that administration of enalapril effectively improves these parameters. In summary, these data suggest that BalbC mice may provide a better tool to successfully identify novel targets for the treatment of CHF.

Heart failure progression and regression in zebrafish

I Ernens[1]; L Zhang[1]; A Lumley[1]; Y Devaux[1]; DR Wagner[2]
[1]Luxembourg Institute of Health, CVRU, Strassen, Luxembourg; *[2]Hospital Centre, Luxembourg, Luxembourg*

Introduction: Current medications used to treat heart failure patients can reverse left ventricular hypertrophy to some extent but are still ineffective against the escalating epidemic of heart failure. New therapeutic strategies are needed to prevent heart failure development or induce heart failure regression. Unlike mammals, zebrafish possess the incredible ability to regenerate cardiac tissue. Thus, this model has been widely used to study cardiac regeneration. Yet, the usefulness of zebrafish to study heart failure progression and regression has not been reported. The aim of this study was to systematically characterize heart failure progression and regression in zebrafish to enable the discovery of new therapeutic targets for patients.
Methods: Eight to ten month-old wild-type AB male zebrafish were treated with phenylhydrazine hydrochloride (PHZ) to induce heart failure development (n = 100-130). Control fish were maintained under normal conditions (n = 20). After 5 weeks of treatment, PHZ was withdrawn and fish were followed for 2 weeks. Hearts were imaged in living fish by ultrasound to assess ventricle size and function. Functional capacity was evaluated in a dedicated swim tunnel. After sacrifice, hearts were collected either to follow tissue morphology and cellular changes or to generate transcriptomics profiles by microarray analysis.
Results: Five weeks of PHZ-treatment led to a significant increase in ventricle size (+33%) and ventricular wall thickness (+229%), and caused a decrease in heart rate (-11%), fractional shortening (-24%) and swim capacity (-29%) (all $p < 0.05$). Expression of atrial and brain natriuretic peptides was upregulated ($p < 0.05$). Further, greater numbers of apoptotic and proliferative cells were found in the myocardium of PHZ-treated fish. Two weeks following PHZ withdrawal, the ventricle regained its basal size. Cardiac function, tissue morphology and the expression of cardiac stress genes returned to basal levels within 1 week. The figure shows well-defined time-specific transcriptomics clusters in the expected order for the heart failure progression (red arrow) and regression (green arrows) processes.
Conclusion: We showed that the zebrafish constitutes an ideal experimental model to study heart failure progression and regression. This model represents a unique opportunity to study the mechanisms of heart failure and to test novel therapeutic strategies. Through microarray analysis, we identified dozens of new potential therapeutic targets for further analysis.
Figure legend: principal component analysis of microarray data performed at baseline (=normal heart), after 5 weeks of PHZ treatment (=failing heart), and 2, 5 and 9 days post PHZ treatment (=dpt). N=3 per time-point. PC: principal component.

Introduction: Cardiac tissue engineering, which combines cells and biomaterials, is promising for limiting the sequelae of myocardial infarction (MI).1 In this context, decellularized tissues offer a natural microenvironment, driving cellular attachment, survival, migration, proliferation, and differentiation.2,3
Purpose: We assessed myocardial function and histological and immunohistochemical analysis after implanting two different natural decellularized scaffolds in a swine MI model.
Methods: The two tested scaffolds are made of decellularized human pericardium and decellularized porcine myocardium. Forty-eight pigs were distributed into 5 groups as follows: Pericardium + MI (Per-MI) (n = 17), Myocardium + MI (Myo-MI) (n = 8), Pericardium (Per-SHAM) (n = 4), Myocardium (Myo-SHAM) (n = 2), and Control-MI (n = 17). Left ventricular ejection fraction (LVEF), cardiac output (CO), stroke volume (SV), left ventricular end diastolic volume (LVEDV) and left ventricular end systolic volume (LVESV) were evaluated non-invasively using magnetic resonance imaging (MRI). Additionally, infarct size, fibrosis, and scaffold vascularization were explored by histopathology.
Results: Upon sacrifice one month after the intervention, MRI detected significant differences between 30 days of follow up and baseline among Per-MI, Myo-MI and Control-MI in LVEF (4.91 ± 1,86% vs. -7.98 ± 4.29% vs. 2.99 ± 3.45%; P=0.015), and ESV (0.56 ± 1.21 mL vs. 8.89 ± 4.95 mL vs. 7.79 ± 2.76 mL; P=0.046). At 30 days, significant differences between groups in LVEF (60.32 ± 1.76% vs. 52.85 ± 2.22% vs. 50.55 ± 2,27%; P=0.005), CO (2.60 ± 0.12 mL vs. 2.88 ± 0.16 mL vs. 3.33 ± 0.21 mL; P=0.010), EDV (54.93 ± 2.84 mL vs. 66.97 ± 5.11 mL vs. 65.59 ± 2 mL; P=0.038), and ESV (21.52 ± 1.28 mL vs. 32.25 ± 3.59 mL vs. 32.26 ± 1.18 mL; P=0.001) were found. Left ventricular infarct size was similar between Per-MI, Myo-MI, and Control-MI animals (P=0.293) (Figure 1). Correct adhesion of the implanted graft with subjacent myocardium after sacrifice was observed in all animals, and, upon sacrifice, scaffolds from Per-MI, Myo-MI, Per-SHAM, and Myo-SHAM animals showed neovessel incorporation. After fibrosis analysis in infarct zone, significant differences between Per-MI, Myo-MI, and Control-MI groups in collagen I (Col I) (P=0.001), collagen III (Col III) (P=0.001), collagen volume fraction (CVF) (P=0.039), collagen I/ collagen III ratio (Col I/Col III) (P=0.050) were detected. Scaffold collagen deposition was also significantly different between Per-MI, Myo-MI, Per-SHAM, and Myo-SHAM in Col I (P=0.019), Col III (P=0.029), CVF ($P < 0.001$), and Col I/Col III (P=0.024).
Conclusions: Human pericardial decellularized scaffold improved cardiac function in a pre-clinical model of MI. These positive results were confirmed by less fibrosis in infarct area, and also in the implanted scaffold. Moreover, the natural decellularized scaffolds, no matter origin, were well-integrated and re-vascularized after 30 days of follow-up.

The characterization of adipose tissue via an obesity-induced cardiomyopathy minipig model

TW Wu[1]; SJ Li[1]; CY Wang[1]; JW Chen[1]; CY Chen[1]
[1]*National Taiwan University, Taipei, Taiwan ROC*

Funding Acknowledgements: MOST 104-2313-B-002-038-MY3 (from Ministry of Science and Technology, Taiwan)

Background and objective: Distribution of adipose tissue plays an important role in metabolic regulation, however, surplus adipose tissues cause metabolic dysfunction. Excess visceral adipose tissue (VAT) contributes to the pathogenesis of metabolic-related diseases; while epicardial (EAT) and pericardial adipose tissue (PAT) is highly associated with the progression of cardiovascular diseases, thus

attracting more attention recently. We previously established an obesity-induced cardiomyopathy minipig model, and found greater lipid deposited around the heart of obese pigs. To elucidate the link between adipose tissue and cardiac injury induced by obesity, we studied the characteristics of adipose tissues (VAT, EAT and PAT) via our obesity-induced cardiomyopathy minipig model.

Materials and methods: Four-month-old Lee-Sung minipigs were randomly assigned to two groups: control diet (C) and Western diet (W), for a 5-month experimental period. Minipigs were sacrificed and the adipose tissues were isolated for analysis in the end of experiment.

Results: Compared with C group, W pigs exhibited dyslipidemia and cardiac fibrosis. W pigs deposited more VAT and PAT than C group, while C and W pigs deposited similar amount of EAT. The frequency of adipocyte size were equally distributed in PAT and EAT, whereas larger adipocyte size was found in VAT (area >7000 um2). C and W pigs exhibited similar fatty acid composition in EAT and PAT: saturated fatty acids (SFA)> polyunsaturated fatty acids (PUFA) > monounsaturated fatty acids (MUFA). In the VAT of W pigs, higher proportion of MUFA and lower SFA were observed compared with those of the C pigs. Among tissue sites of W pigs, higher PUFA and lower ratio of SFA to PUFA were found in EAT and PAT than those in VAT, suggested that unsaturations in EAT and PAT form the mechanical flexibility to protect the coronary artery against the torsion induced by cardiac contraction. Thiobarbituric acid reactive substances (TBARS) was used as the marker of oxidative stress. Compared with C pigs, W pigs exhibited higher levels of TBARS in the blood and PAT, while no differences were found in the EAT. In the W pigs, the TBARS levels were PAT> VAT > EAT, demonstrating that systemic and local oxidative stress were induced in W pigs, and the local effect from PAT could not be ignored. Interleukin 6 (IL6) was applied as the inflammatory marker. Greater IL6 levels were found in the plasma, PAT and VAT of W pigs than those in C pigs. In the W pigs, PAT secreted more IL6 than VAT did. These results indicated a potential contribution of PAT to the cardiac inflammation.

Conclusion: PAT played a critical role in the obesity-induced cardiomyopathy via the induction of local oxidative stress and inflammation.

Funding Acknowledgements: European Commission FP7-HEALTH-2009-1.4-3, Grant Agreement 242038, RIC (RD12/0042/0025) and CIBER CV (CB16/11/00494)

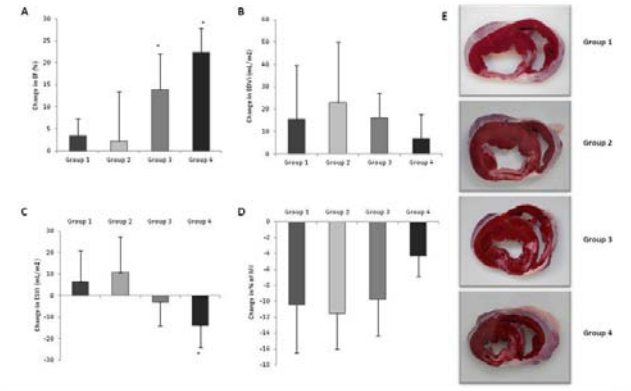
Background: Insulin like growth factor 1 (IGF1) is known as one of the most promising growth factors for promoting cardiorepair, since it decreases ischemia-reperfusion damage and could have angiogenic effects. Intracoronary (IC) infusion of microencapsulated IGF1 allows for site-specific and sustained release of the therapeutic agent over a precise time, which could improve results with a single procedure.

Purpose: We undertook this study to evaluate whether early administration of microencapsulated IGF1 could ameliorate or prevent adverse cardiac remodeling after experimental myocardial infarction (MI).

Methods: Female swine surviving a 90 minutes mid-LAD balloon occlusion received an IC infusion of saline (Group 1; G1, n=7) or IGF1 loaded microspheres (MSPs) (Group2; G2: $3x10^6$, n=4; Group 3; G3: $5x10^6$, n=4; Group 4; G4: $5x10^6$ + nitroglycerin, n=4) two days post-MI. IGF1 dose was 95μg per 10^6 MSPs. Safety was determined by ECG, TIMI flow and troponin I (TnI) values. Cardiac function was evaluated by magnetic resonance (MR) before and 10 weeks post-injection (infarct size (IS), ejection fraction (EF), indexed end diastolic (EDVi) and systolic volumes (ESVi), treatment effect on EF (EF), EDVi (EDVi), ESVi (ESVi), IS (IS). At 10 weeks, TTC staining was performed and tissue samples were obtained from healthy myocardium, border and infarct zones for vascular density analysis with Isolectin B4 immunostaining.

Results: ECG and TnI levels did not reveal significant changes, in any case. While TIMI flow did not alter in G1, it decreased in one pig from G2 (TIMI 2), one animal from G3 and 3 swine belonging to G4 (TIMI 1 or 2). EF improved over time in G3 (40.26 ± 9.12% vs. 54.13 ± 3.81%, p = 0.021) and G4 (25.43 ± 4.86% vs. 47.80 ± 10.20%, p = 0.021). Accordingly, EF was significantly better in G3 (13.90 ± 8.08%) and G4 (22.38 ± 5.48%) compared to G1 (3.48 ± 3.73%) and G2 (2.15 ± 11.24%) (p = 0.018). At 10 weeks the increase in cardiac volumes was limited in G3 and G4, significantly so in the case of EDVi (G1: 121.70 ± 26.09mL/m2; G2: 109.99 ± 14.36 mL/m2; G3: 88.56 ± 14.98 mL/m2; G4: 88.88 ± 15.76mL/m2; p = 0.042). G3 and G4 exhibited an improvement in ESVi (G3: 43.21 ± 9.42mL/m2 vs. 40.26 ± 4.16 mL/m2; G4: 61.16 ± 12.50mL/m2 vs. 47.37 ± 16.77mL/m2) over time, resulting in a trend towards lower systolic volumes compared to G1 (66.09 ± 15.74mL/m2 vs. 72.72 ± 27.18mL/m2) and G2 (54.21 ± 15.99mL/m2 vs. 64.99 ± 5.42mL/m2). TTC staining evidenced that the scar tissue was mixed with viable areas in G3 and G4, but less so in G1 and G2. Quantitative analysis of vascular density revealed no differences between groups.

Conclusion: In this experimental setting, a dose of 5x10^6 IGF1-loaded MSPs was able to improve cardiac function and limit left ventricular remodeling despite an absence of angiogenesis. The IC infusion of IGF1-loaded MSPs may impair coronary flow and caution must be exerted when considering clinical translation.



A. Magnitud of change in EF. Treatment effect was significantly greater in groups 3 and 4 compared to groups 1 and 2; *p<0.05. **B.** Magnitud of change in EDVi. No significant differences were seen. **C.** Magnitud of change in ESVi. Treatment effect was significantly greater in group 4 compared to groups 1 and 2; *p<0.05. **D.** Magnitud of change in percentage of infarcted myocardium. No significant differences were seen. Error bars represent S.D. **E.** Representative TTC-stained heart slice from each group. Mixture of viable and infarcted tissue that is more evident in groups 3 and 4.

Role of QSOX1 in cardiac adaptation to pressure overload

M Sadoune[1]; P Matteo[2]; C Luc[1]; E Polidano[1]; R Merval[1]; A Mebazaa[1]; J-L Samuel[1]; A Caillard[1]
[1]Hospital Lariboisiere, INSERM UMR-S942, Paris, France; *[2]Université Paris-Sud Orsay, Paris, France*

QSOX1 has been identified as a diagnostic marker of heart failure (ICA), better than BNP in its gray zone in humans. Murine models have shown that the expression of QSOX1 is specifically induced in the heart during the ICA. Moreover, acute cardiac stress by injection of isoproterenol (ISO) combined with a "Knock down" of QSOX1 aggravates the dysfunction of the treated animals. It was possible to demonstrate induction of QSOX1 at 12 days after rat aorta stenosis, correlated with ICA signs. The objective was to study the consequences of an invalidation of this gene in a model of pressure overload induced by aortic stenosis (TAC) in a murine model in order to better define the role of QSOX1 in cardiac function.

The animal model uses 9 week-old male mice (C57BL/6JRj strain) WT and QSOX1 - / - having constricted thoracic aorta (TAC) for 10 days (n = 10 / group) and a control group Sham. A functional and anatomical exploration was performed by transthoracic echocardiography and quantitative phenotypic analysis by RT-qPCR and qualitative by Immunohistology.

In the basal state, QSOX1 - / - mice are viable but in the adult stage they show signs of cardiomyopathy with alteration of the shortening fraction with some signs of endoplasmic reticulum stress and perivascular inflammation. After a TAC, the cardiac phenotype is substantially similar between the WT and QSOX1 - / - mice. On the other hand, the signs of coronary remodeling are more marked in the QSOX1 - / - mice.

These preliminary results show that the expression of QSOX1 is important for a normal function of the heart and moreover it protects the myocardium and more particularly the coronaries against a stress linked to a sudden overload of pressure.

P649

NLRP3 inflammasome mediated mitochondrial damage in pressure overload-induced heart failure

L Bosch[1]; JJ De Haan[1]; M Brans[1]; SCA De Jager[1]; H El Azouzzi[1]; F Arslan[1]
[1]University Medical Center Utrecht, Experimental Cardiology, Utrecht, Netherlands

Introduction: The NLRP3 inflammasome, responsible for IL-1β and IL-18 maturation, is involved in the pathophysiology of various cardiovascular diseases. However, the role of the inflammasome in pressure overloaded heart failure has never been studied.
Methods: Wild type and NLRP3 deficient C57BL/6J mice underwent transverse aortic constriction (TAC) to induce pressure overload. Cardiac function and geometry was assessed using 3D echocardiography and left ventricular global longitudinal strain (LV GLS) was determined by speckle tracking. Tissue integrity and hypertrophy was determined using immunofluorescence. On left ventricular myocardial tissue, RNA sequencing for whole genome profiling and electron microscopy (EM) for abnormal mitochondrial morphology was performed. Quantification of abnormal mitochondrial morphology was based on the percentage of mitochondria with reduced or abnormal lamellar structure.
Results: NLRP3 deficient mice showed less adverse remodeling after pressure overload: end systolic volume was lower (38.4 ± 11mm3 vs 51.8 ± 12mm3, $p < 0.001$) and ejection fraction higher ($42.1 \pm 11\%$ vs $30.9 \pm 10\%$, $p < 0.001$) compared to wild type mice 6 weeks after TAC. Already 3 weeks after TAC, NLRP3 deficient mice showed improved systolic function by LV GLS compared to wild type ($-15.9 \pm 4\%$ vs $-12.3 \pm 2\%$ respectively, $p = 0.005$). Hypertrophy was less pronounced in the knock-out mice (average cardiomyocyte size: 386 ± 47um2 vs 419 ± 36um2, $p = 0.056$). Furthermore, RNA sequencing revealed increased expression of the mitochondrial respiratory chain in NLRP3 deficient compared to wild type mice 6 weeks after TAC. Preliminary data of mitochondrial numbers assessed by EM 10 weeks after TAC did not show any differences, however mitochondrial morphology did seem to be less affected in the NLRP3 knock-out compared to wild type ($53 \pm 2\%$ vs $32 \pm 19\%$ abnormal mitochondria, n=2, p = NS).
Conclusion: These data indicate a role for the NLRP3 inflammasome in adverse remodelling and the pathophysiology of pressure overload-induced heart failure. A possible mechanism is inflammasome mediated mitochondrial damage. Further studies will have to confirm the influence of inflammasome activation on mitochondrial function in heart failure.

P650

Exosomes are involved in the transport of miR-21-5p and miR-222-3p in left ventricular remodeling post-myocardial infarction.

H Henri Charrier[1]; E Dubois-Deruy[1]; O Beseme[1]; P Mulder[2]; M Chwastyniak[1]; P Amouyel[1]; V Richard[2]; F Pinet[1]
[1] *Institute Pasteur of Lille, INSERM U1167, Lille, France*; [2] *University of Rouen, INSERM U1096, Rouen, France*

Background: After myocardial infarction (MI), 30% of patients develop left ventricular remodeling (LVR) that is difficult to predict in clinical practice and may lead to heart failure (HF) and death. Previous studies have shown that miR-21-5p and miR-222-3p are up-regulated in plasma (x6.2, $p = 0.003$; x103, $p < 0.0001$ respectively) and LV (x2.3 and x2.1, $p = 0.002$ respectively) of HF rats at 2 months post-MI (induced by left coronary ligation), compared to sham-rats.
Purpose : Our main objectives were i) to identify cardiac cells involved in modulation of miR-21-5p and miR-222-3p and ii) to determine the extracellular transporters (exosomes) of these miRNAs.
Methods: We used an in vitro model of cardiac cells : H9c2 cardiomyoblasts in which hypertrophy was induced by isoproterenol, and neonatal rat fibroblasts. Exosomes from culture medium of both cell types were isolated by filtration-ultracentrifugation.
Results : The levels of miR-21-5p and miR-222-3p were not modulated in hypertrophied H9c2 compared to control H9c2, suggesting that the cardiomyocytes are not the sources of these miRNAs.
Morphological characterization of the isolated vesicles by nanoparticule tracking analysis revealed an exosomal diameter of 115 ± 3.8 nm ($n = 3$), slightly overestimated due to their aggregation observed by electron microscopy. Biochemical characterization of isolated vesicles showed that they express the exosomal biogenesis marker CD63 but not CD9 or TSG101 suggesting a specific exosomal biochemical profile of cardiac cells. The isolated exosomes also express the YB-1 protein known to be a transporter of miRNAs. To validate the potential of cardiac exosomes as extracellular transporters of miRNAs, we quantified the levels of miR-21-5p and miR-222-3p in the exosomes isolated from H9c2 cardiomyoblasts and neonatal rat fibroblasts. The levels of miR-21-5p and miR-222-3p were 25% more expressed in exosomes isolated from fibroblasts compared to H9c2 cells, suggesting that fibroblasts may be the main source of miR-21-5p and miR-222-3p in the circulation. In addition, miR-21-5p appeared to be 100 fold more expressed than miR-222-3p in exosomes derived from fibroblasts. Exosome membranes isolated from fibroblasts were labeled with a fluorescent dye: PKH67, and their integration in H9c2 cells was followed.
Conclusion : These results confirm the role of exosomes in the transport of miR-21-5p and miR-222-3p into the circulation. This preliminary data suggests their role in fibroblast-cardiomyocyte paracrine communication and underlines the potential of cardiac exosomal content as new biomarkers of LVR post-MI.

Home telemonitoring in patients with heart failure: the experience of a region of northern italy in the EU funded project smartcare

D Radini[1]; GM Apuzzo[1]; K Stellato[1]; G Sola[1]; N Delli Quadri[1]; E Fragiacomo[1]; A Di Lenarda[1]
[1]*Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy*

Background: The care of patients (pts) with chronic non-communicable diseases (CNCD) is one of the main challenges of the future in Europe and in Italy. The EU funded Project SmartCare ("Cohort study on integrated health and social care supported by ICT for European citizens") involved as lead our region with the aim of improving integrated social and health care through the implementation of home telemonitoring (TLM), empowerment, self-care and self-management of heart failure pts.
Methods: The SmartCare project in our region has developed as a cohort study, prospective, randomized, controlled trial that enrolled from 11/2014 to 2/2016 201 pts in home care (>50 years, at least 1 severe CNCD (HF, COPD or diabetes) and ≥1 missing BADL) to intervention arm (INT - automatic BP monitoring, weight, FC, SO2, ECG: n = 100) or usual care (UC; n = 101). The drop-out were 19 (7 UC; 12 INT; p = NS). The patients were followed up by a multiprofessional team (nurses - including a case manager-, GPs, social workers, district doctors and specialists) and stratified for "short term" post-discharge TLM (3-6 months - average 4 ± 1; n = 101) or "long-term" (6-12 months - average 10 ± 3; n = 100) for chronic frail pts already in home health care.
Results: The patients enrolled were elderly (81 years, 54% males), with HF (79%), diabetes (68%) or COPD (38%) and multimorbidity (44% Charlson Index ≥5; 58% ≥7 drugs/day). 58% had a primary level of education, 38% lived alone and 43% were not self-sufficient. In the follow-up of 7 ± 4 months (119 pt-years) were recorded 16 deaths (13.4/100 pt-years) and 126 hospital admissions/access to intermediate care (1758 days of hospitalization). The home care nurses has recorded 3053 contacts (2.14/pt-months; 2417 -79.2% - home accesses of which 160 (6.6%) unplanned; 536 -20.8% - phone calls). In pts enrolled in "long term" INT, TLM has not proven effective. In contrast, in pts enrolled in the "short-term" post-discharge INT was demonstrated a significant reduction in hospital stay (0.9 vs 2.8 pt-months; p = 0.048), due to a reduction of the length of stay (10.2 vs 19.2 days; p = 0.01), associated with a significant increase in unplanned contacts (1.15 vs 0.03/pts; p = 0.04). In particular, each month there was a saving of 1.9 hospital days at the "cost" of 0.7 contacts per patient for control of devices and clinical stability. The same significance was present only in pts with HF.
Conclusion: A postdischarge intensive TLM system supported by ICT of pts with CNCD and in particular with HF, on top of home care, is able to significantly reduce the hospital stay with significant but modest increase use of territorial nursing resources.

691

Effects of telemonitoring and disease management on self-care, anxiety and depression: results from the IN TOUCH study

E Edita Lycholip[1]; IT Aamodt[2]; I Lie[2]; H Hillege[3]; I Kraai[3]; A De Vries[3]; J Celutkiene[4]; A Stromberg[5]; T Jaarsma[6]
[1]*Vilnius University, Clinic of Cardiac and Vascular diseases, Vilnius, Lithuania*; [2]*University of Oslo, Oslo University Hospital, Department of Cardiothoracic surgery, Oslo, Norway*; [3]*University Medical Center Groningen, University Hospital Groningen , Groningen, Netherlands*; [4]*Vilnius University, Clinic of Cardiac and Vascular diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania*; [5]*Linkoping University, Department of Medical and Health Sciences, Linkoping, Sweden*; [6]*Linkoping University, Department of Social- and Welfare studies, Norrkoping, Linkoping, Sweden*

Introduction: Self-care, depression and anxiety are important patient reported outcomes (PRO's) for heart failure (HF) patients and these PRO's might be effected by disease management and/or telemonitoring. Previously no influence of the intervetion on the primary outcomes (mortality, HF-readmission and health-related quality of life) in the IN TOUCH study was reported. However, patient-reported self-care, anxiety and depression were not analysed yet.
Aim: To assess whether telemonitoring (TM) and an Information Communication Technology guided disease management system (ICT-guided-DMS) had effect on self-care behaviour, anxiety and depression and to investigate factors contributing to changes in self-care.
Methods: In the IN TOUCH study 177 patients were randomized to ICT-guided-DMS or to TM + ICT-guided-DMS with a follow-up of nine months. Current analysis included 118 participants who filled the 9-item European Self-care Questionnaire (EHFScBS_9) and Hospital Anxiety and Depression scale (HADs) (mean age 69 ± 11.5 years; 70% male; 81% in NYHA class III–IV; mean left ventricular ejection fraction [LVEF] 27.2 ± 9.9%).
Chi-square, Student's t test, Wilcoxon and Mann–Whitney tests were used. The association of study co-variates including age, quality of life evaluated by Minnesota Living with HF Questionnaire (MLHFQ), NYHA functional class, NT-proBNP level, LVEF, HADs score with the changes in self-care was assessed using multivariable stepwise logistic regression analysis.
Results: The baseline level of self-care was significantly lower in the ICT-guided-DMS group (n = 60) compared to TM + ICT-guided-DMS group (n = 58, p = 0.023) as assessed by the total score of EHFScBS_9. In the course of intervention self-care behaviour significantly improved in the ICT-guided-DMS group (p < 0.01), but not in TM + ICT-guided-DMS group. ICT-guided-DMS significantly improved the consulting behaviour subscore (p < 0.05). During the trial the prevalence of depression and anxiety decreased from 33.8% to 26.3% and from 25.4% to 22.9% respectively. Level of anxiety significantly decreased in the whole study group (p < 0.05), without statistical significance in the separate intervention groups. Self-care behaviour worsened in 46 participants (19 in ICT-guided-DMS and 27 in TM + ICT-guided-DMS group [p = 0.210]). The following baseline factors were significantly associated with decreasing self-care behaviour from baseline to the end of study: physical subscale of MLHFQ (OR 1.76, 95% CI 1.143 – 2.712, per 10 points, p < 0.05), LVEF (OR 0.75, 95% CI 0.587 – 0.959, per 5%, p < 0.05), NYHA class (OR 0.251, 95% CI 0.089 – 0.711, III versus II class, p < 0.05).
Conclusions: ICT guided disease management may improve patients' self-care, specifically in the subscale consulting behaviour, and reduce anxiety, both with and without telemonitoring. Worse physical aspect of quality of life, lower ejection fraction and lower NYHA class were factors associated with poorer self-care.

693

Quality of life and fragility in patients with heart failure and mid-range ejection fraction

B Gonzalez[1]; P Gastelurrutia[1]; J Lupon[1]; M Rodriguez[1]; P Moliner[1]; C Rivas[1]; M De Antonio[1]; M Domingo[1]; V Diaz[1]; E Zamora[1]; T Armesto[1]; M Puertas[1]; M Cachero[1]; A Morales[1]; A Bayes-Genis[1]
[1]*Germans Trias i Pujol University Hospital, Badalona, Spain*

Background: Heart failure (HF) is a chronic condition with poor prognosis and is one of the most important chronic diseases that cause quality of life (QOL) impairment. As HF is highly prevalent among older people, fragility is often present among HF patients. Even young HF patients show a high degree of fragility, that also contributes to QoL impairment.
Objective: As the 2016 Heart Failure (HF) ESC Guidelines boost to investigate the "new" subgroup of patients with HF and left ventricular ejection fraction (EF) mildly reduced (HFmrEF) our aim was to assess QoL and the prevalence of fragility in outpatients with HFmrEF, compared with those with HF with reduced EF (HFrEF) and with preserved EF (HFpEF).
Methods: The Minnesota Living with Heart Failure Questionnaire (MLWHFQ) was used for QoL evaluation. Fragility was defined as having at least one abnormal evaluation among four standardized geriatric scales. Predefined criteria for such scales

were: Barthel Index < 90; OARS scale < 10 in women and < 6 in men; Pfeiffer Test >3 (± 1, depending on educational grade); and ≥1 positive response for depression on the abbreviated Geriatric Depression Scale (GDS). The MLWHFQ and the basic geriatric evaluation were performed at the first visit to the Unit.
Results: 185 patients with HFmrEF were evaluated (127 men and 58 women, mean age 67.7 ± 11.7 years, median duration of HF 12 months [Q1-Q3 2–44], ischemic aetiology 58%, 119 (64.3%) and 59 (31.9%) in NYHA class II and III respectively). The mean score in the MLWHFQ was 30.1 ± 18.3. Ninety patients (48.6%) fulfilled fragility criteria. Forty-five patients (24.3%) had a Barthel Index < 90; 25 patients (13.5%) had an anomalous OARS Scale; the score in Pfeiffer Test was abnormal in 10 patients (5.4%); and 60 patients (32.4%) had a positive depression response in abbreviate GDS. Fragility prevalence in HFmrEF patients tended to be higher when compared with 1058 patients with HFrEF (41.9%, p = 0.09) and similar when compared with 162 patients with HFpEF (54.3%, p = 0.29). In contrast QoL was similar when compared with HFrEF patients (MLWHFQ score 30.8 ± 18.5, p = 0.61) and better when compared with HFpEF patients (MLWHFQ score 36.5 ± 20.7, p = 0.003).
Conclusions: HFmrEF patients showed a similar impairment of QoL than HFrEF patients and lower when compared with HFpEF patients. In HFmrEF a high prevalence of fragility (48.6%) was observed, near to that found in HFpEF patients and slightly higher than that observed in HFrEF patients.

694

Gender related differences in the prevalence of frailty syndrome among patients with heart failure and cardiac resynchronization

A Mlynarska[1]; R Mlynarski[2]; KS Golba[1]
[1]Medical University of Silesia, Katowice, Poland; *[2]Upper Silesian Cardiology Center, Katowice, Poland*

Frailty is a common geriatric syndrome that embodies an elevated risk of catastrophic declines in health and function among older patients. Frailty's occurrence may vary according to a number of factors and is more often in heart failure population. AIM: to examine gender-related differences in the prevalence of frailty syndrome among patients with advanced heart failure which are treated by cardiac resynchronization (CRT).
Methods: The study included 106 consecutive patients over 60 years (average age 74,9 ± 6,3; 17% women) with implanted cardiac resynchronization therapy devices. All patients had EF < 35%, left bundle branch block and NYHA functional class ≥ 2. In all patients frailty was evaluated by using Tilburg Frailty Indicator. Analysis were performed in three domains: physical domain, psychological domain and social domain. Values ≥ 5 were recognized as frailty syndrome.
RESULTS: In 75% of men and 67% of women frailty syndrome was diagnosed (p = 0,7719). There were no statistically significant differences in the prevalence of frailty syndrome among men and women – exact results are presented below. Analysis of the influence of the ejection fraction of the value of TFI showed significant correlation (the higher value of frailty, the lower ejection fraction) for the entire population r = -0,3083, p = 0,0013 and for the subgroup of men r = -0,2794, p = 0,0084. There was no statistically significant correlation for women (r = -0,4068, p = 0,0939).
Conclusion: Patients with heart failure and implantable cardiac resynchronization are particularly vulnerable to the frailty syndrome presence. There are no gender differences in the prevalence of frailty syndrome. Higher intensification of frailty syndrome is related to reduced ejection fraction.

Tilburg Frailty Indicator results

	Women	Men	p
Global TFI	5,89 ± 2,11	6,19 ± 1,92	0,5476

Meta-synthesis of the invalidating factors that influence quality of life in patients with an implantable cardioverter defibrillator

M Michela Barisone[1]; AB Bagnasco[1]; G Aleo[1]; G Catania[1]; M Zanini[1]; V Bressan[1]; L Sasso[1]
[1]University of Genoa, Genoa, Italy

Background/Introduction: In 2012, 75% of the health expenditure of the United States was used to cure chronic diseases (CDC, 2013). With regard to heart diseases, the number of patients with Chronic Heart Failure (CHF) is increasing, especially older people with poor health conditions who are often repeatedly readmitted to hospital due to heart failure. The indication to use implantable cardioverter defibrillators (ICDs) to prevent sudden death is now consolidated, although there is no unanimous agreement regarding their impact on quality of life (QoL). Various clinical studies have evaluated the impact of ICDs on patient mortality, survival, and their beneficial effects. Instead, few studies investigate the QoL in patients with ICDs.
Purpose: The purpose of this study is to describe the experiences and perceptions lived by patients with an ICD through a qualitative literature meta-synthesis.
Methods: A qualitative meta-synthesis adopting Confidence in the Evidence from Reviews of Qualitative Research (CERQual) developed by the Grading of Recommendations Assessment Development and Evaluation (GRADE) working group to evaluate the strength of the evidence was conducted. The following database were systematically search: PubMed, CINAHL, and PsycINFO, to identify qualitative studies published between January 2005 and October 2016 that investigate the experience of people living with an ICD. Each selected study was assessed for quality by two reviewers independently using the Critical Appraisal Skills Programme (CASP, 2014)
Results: A total of 17 papers were selected. Five main themes emerged: Sensation of great uncertainty and insecurity, emotional involvement, accepting new life conditions, living with ICD shocks, and need to receive information and advice from physicians.
Conclusion(s): According to the literature, patients' experience with ICDs is very complex and it is often difficult for them to adjust to this new life condition. In fact, the presence of the ICD causes feelings of dependency, psychological discomfort and fear. The patients' most frequent feelings were anxiousness, depression, and self-imposed limitations for some activities of daily living. These results should be used to help clinicians and researchers to develop and explore new research strategies and health policies to improve QoL in these patients.

MODERATED POSTER SESSION 2 – THE GLOBAL PROBLEM OF HEART FAILURE

696

Predictors of in-hospital mortality among hospitalized adult heart failure patients in the Philippines

R B Rudy Natividad[1]; BA Tumanan-Mendoza[1]; FER Punzalan[1]; NS Pestano[1]; VL Mendoza[2]; AAA Bermudez-Delos Santos[1]; R Macabeo[1]; LA Shiu[1]
[1]Manila Doctors Hospital, Department of Internal Medicine, Section of Cardiology, Manila, Philippines; *[2]De La Salle Health Sciences Institute, Dasmarinas, Cavite, Philippines*

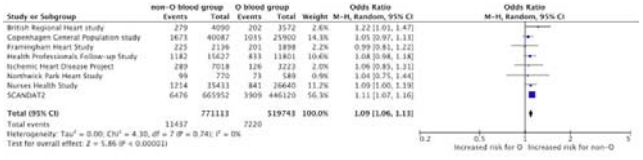
Background: Majority of the large cohort studies on heart failure involved Western countries and developed nations. The ADHERE International Asia-Pacific study was the only major cohort that included Asian nations, 7.1% of which, (out of a total population of 10,171) were from the Philippines. This research was done in conjunction with a nationwide prevalence study on acute heart failure, which is the first heart failure study to be done encompassing the entire Philippine archipelago.
Purpose: To determine the predictors of mortality among hospitalized adult heart failure patients in the Philippines
Methodology: The study is a nationwide retrospective cohort that involved all adult patients aged 19 years old and above hospitalized for heart failure in 2014. Data was collected from the hospitalization claims database of the Philippine Health Insurance Corporation (PhilHealth), a government corporation that administers the health insurance program for the country. Univariate and multivariate analysis was done in determining predictors of mortality
Results: A total of 44,046 hospitalized heart failure patients were included in the study, with an in-hospital mortality rate of 8.2%. Multivariate analysis was done using logistic regression which showed the following independent factors as predictors of increased in-hospital mortality: government hospital admission (odds ratio (OR) 2.14, 95% confidence interval (CI) 1.89 – 2.42), ward stay (OR 1.24, 95% CI 1.10 – 1.40), and regional classification to regions V (OR 1.42, 95% CI 1.07 – 1.87) and VII (OR 1.31, 95% CI 1.05 – 1.62). Independent variables associated with in-hospital survival are shorter length of hospital stay (OR 0.98, 95% CI 0.97 – 0.99), geographical classification under regions I (OR 0.72, 95% CI 0.58 - 0.89), II (OR 0.31, 95% CI 0.20 - 0.49), IX (OR 0.74, 95% CI 0.58 - 0.96), Cordillera Autonomous Region (CAR) (OR 0.59, 95% CI 0.44 - 0.78) and Autonomous Region of Muslim Mindanao (ARMM) (OR 0.41, 95% CI 0.23 - 0.73) and having hypertension (OR 0.68, 95% CI 0.59 - 0.77) and cardiomyopathy (OR 0.17, 95% CI 0.06 - 0.47) as the etiology of heart failure.
Conclusions: Heart failure patients in the Philippines are relatively younger compared to patients in the Western and developed countries. Government hospital admission, ward admission and residing in regions V and VII are the independent predictors of mortality for hospitalized adult heart failure patients in the country. Living in regions I, II, IX, CAR and ARMM and hypertension as the etiology of heart failure independently predict in-hospital survival. Ward admission and hypertension as the etiology of heart failure, as predictors of in-hospital mortality/survival, should be further validated. Future studies on the outcomes of heart failure should include more variables, clinical or non-clinical, to ascertain the most significant predictors of outcomes

697

ABO blood group and cardiovascular outcomes in the general population: a meta-analysis

TM Tessa Marthe Kole[1]; N Suthahar[1]; K Damman[1]; RA De Boer[1]
[1]University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands

Introduction: It has been suggested that carriers of non-O blood groups (ABO groups A, B, and AB) have higher cardiovascular (CV) risk, including risk for myocardial infarction (MI), stroke, heart failure and CV death. However, this assumption is mainly based on case-control studies, which showed a skewed blood group distribution in subjects with CV events, but have a low level of evidence.
Methods: We performed a meta-analysis of prospective studies reporting on blood group and CV events. We searched for terms "ABO blood group" and "myocardial infarction, coronary artery disease, ischemic heart disease, heart failure, stroke, cardiovascular events, cardiovascular mortality and all-cause mortality", and initially retrieved 531 articles. After exclusion of studies with diseased subjects and studies with inappropriate CV endpoints, 9 articles describing 11 prospective cohorts, that reported on CV morbidity and mortality in both O and non-O blood groups, remained.
Results: The total number of subjects included in all studies was 1,362,569, and they experienced 23,154 CV events. The odds ratio's (OR, with 95% Confidence Intervals, CI) for subjects having non-O blood groups compared to O blood group for fatal coronary events, all coronary events and combined CV events were 1.00 (CI 0.85-1.18; p-value: 0.98), 1.09 (CI 1.06-1.13; p-value: <0.00001) and 1.09 (CI 1.06-1.11; p-value: 0.006), respectively. Several sensitivity analyses did not materially change the results.
Conclusion: Our meta-analysis shows that subjects carrying non-O blood group have an increased risk of (nonfatal) CV events, especially myocardial infarction. Underlying mechanisms may vary, although this increased risk has been attributed to a higher concentration of von Willebrand factor and dyslipidemia in subjects with non-O blood group. Further studies should address if the excess CV risk of non O blood group is amenable to treatment.



Coronary events

Real-world evidence on heart failure: findings from 25 thousand patients in a portuguese primary care database

R Raquel Ascencao[1]; F Fiorentino[1]; M Gouveia[2]; J Costa[3]; P Broeiro[4]; C Fonseca[5]; M Borges[1]
[1]Faculty of Medicine, University of Lisbon, Center for Evidence Based Medicine, Lisbon, Portugal; *[2]Catolica Lisbon School of Business and Economics, Lisbon, Portugal*; *[3]Faculty of Medicine, University of Lisbon, Laboratory of Clinical Pharmacology and Therapeutics, Lisbon, Portugal*; *[4]Agrupamento de Centros de Saúde Lisboa Central, Unidade de Cuidados de Saúde Personalizados dos Olivais, Lisbon, Portugal*; *[5]Centro Hospitalar de Lisboa Ocidental, Heart Failure Unit, Department of Internal Medicine and Day Hospital – Hospital São Francisco Xavier, Lisbon, Portugal*

Funding Acknowledgements: The study was funded by Novartis Global. Funding was independent of the study outcome.

Background: Heart failure (HF) is a major health problem in developed countries, accounting for a significant social and economic burden. Published estimates of costs associated with HF patients in the primary care setting are scarce.
Purpose: To determine the clinical and demographic characteristics of adult patients with a HF diagnosis in a Portuguese primary care comprehensive administrative database and to estimate the associated annual costs

per patient.
Methods: Population-based study with real data covering a population of 3.6 million patients attending primary care services in a large health region in Portugal. All adult users coded for HF with at least one visit in 2014 were selected. We analyzed patients' characteristics, comorbidities (anemia, diabetes, hypertension, cerebrovascular disease, atrial fibrillation, ischemic heart disease, cardiomyopathies, valve disease, chronic obstructive pulmonary disease, pulmonary embolism, alcohol abuse), and resource use in 2014 related to medical tests and cardiovascular diagnostic procedures, visits and cardiovascular or anticoagulant medication. Unit costs estimates were based on national sources.
Results: We identified 25,337 patients, with an estimated HF prevalence of 1.4%. This is approximately 30% of number expected according to a previously conducted national community-based epidemiological survey. The difference may be explained by both underdiagnosis and underregistration. Patients with HF are mostly women (58%) and on average 77 ± 11 years old. The large majority of patients (93%) had at least one of the selected comorbidities present, 70% had 2 or more and 38% had 3 or more. About two thirds of patients (65%) had at least one medical test or diagnostic procedure done during 2014. Blood tests, echocardiogram, electrocardiogram and chest x-ray were performed in 61%, 16%, 14% and 11% of patients, respectively. The majority of patients (56%) had at least four office visits during one year. Angiotensin-converting enzyme inhibitor or angiotensin receptor blockers, beta-blockers, and aldosterone blockers were prescribed for 80%, 48% and 20% of patients, respectively. Only 12% of patients were prescribed all three drug classes. The average annual cost per patient was estimated at €552 ± 348, of which 54%, 40% and 6% was associated to medications, medical visits and medical tests or diagnostic procedures, respectively.
Conclusions: This study provides a characterization of patients with HF in a large population in a primary care setting. Surprisingly 70% of the expected number of patients are either not diagnosed or not registered. HF patients are old, mostly women and characterized by multimorbidity. The average annual cost per patient was estimated to be about €550.

Age- and gender-specific risks of all-cause mortality in patients with newly diagnosed heart failure: a population-based case-cohort study inTaiwan

Y-C Yi-Chih Wang[1]; S-R Chen[2]; C-Y Fann[3]
[1]National Taiwan University Hospital, Internal Medicine, Cardiovascular Division, Taipei, Taiwan ROC; *[2]Novartis (Taiwan) Co., Ltd, Taipei, Taiwan ROC*; *[3]Kainan University, Department of Health Industry Management, School of Healthcare Management, Tao-Yuan, Taiwan ROC*

Funding Acknowledgements: Novartis (Taiwan) Co., Ltd, Taipei, Taiwan

Background: The age- and gender-specific risk of all-cause mortality for newly diagnosed heart failure (HF) patients (pts) comparing with general population is lacking. In Taiwan, the national health insurance (NHI) provides a population-based data with longitudinal follow-up for assessing the issue.
Purpose: We evaluated the relative risk (RR) of all-cause mortality between newly diagnosed HF pts and non-HF subjects.
Methods: The age- and gender-matched case-cohort study estimated the RR of all-cause mortality in HF pts by using all insured data between 2002 and 2013. By excluding prevalent HF pts in 2002, incident and new HF cases should have at least three outpatient visits or one hospital admission with HF (ICD9CM code: 428, 402.01, 402.11, 402.91) between 2003 and 2012. The last insured date was the surrogate endpoint of death. The data in 2013 was to sure those withdrawn before 2012 for at least one year. Each HF pt had a control, randomly sampled from the same age- and gender- subgroup. A total of 1,392,334 subjects including 696,167 HF cases were analyzed. RR was estimated by Poisson and negative-binomial regression models. We further used all-cause mortality from the life table in the whole population to estimate the all-cause mortality of HF.
Results: Two thirds of HF pts were diagnosed at 65 years (yrs) or older. Among HF pts, the RR of all-cause mortality was higher in male (1.33, 95% CI=1.31-1.34), and getting higher with aging (45-64 vs. < 45 yrs: RR=1.4; >=65 vs 45-64 yrs: RR=5.2; both $p < 0.05$). When compared with non-HF subjects, the overall RR of all-cause mortality for HF pts was 2.41 (95% CI:2.40-2.43). In both gender (Figure 1A), the RRs of the younger groups were much higher. Although the age-specific RR for HF pts with either gender were similar, the estimated all-cause mortality in male HF pts was higher due to higher age-specific all-cause mortality in male population (Figure 1B).
Conclusions: When compared with non-HF controls, there remains a more than two-fold risk of all-cause mortality for newly diagnosed HF pts. The mortality burden was much greater on the elderly and male gender. The younger HF pts, however, carry a rather high risk of death, when compared to the non-HF younger population. All suggest the diverse but critical age- and gender-specific burdens of HF among the whole population.

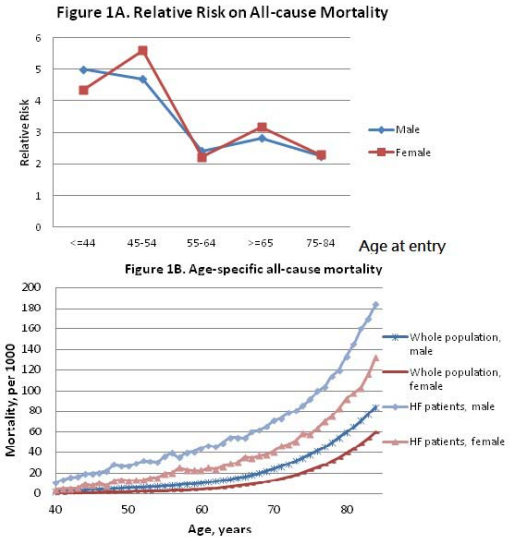

Figure 1A and 1B

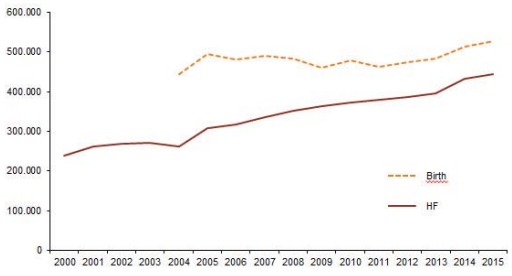
The demographic change in Germany: an analysis by the two leading causes of hospitalisation

S Stoerk[1]; M Doerr[2]; M Christ[3]; HJ Heppner[4]; C Mueller[5]; U Riemer[1]; R Rolf Wachter[1]
[1]University of Göttingen, Göttingen, Germany; *[2]University Medicine of Greifswald, Greifswald, Germany*; *[3]Klinikum Nürnberg-Nord, Notfallmedizin, Nürnberg, Germany*; *[4]Helios Klinikum Schwelm, Schwelm, Germany*; *[5]University Hospital Basel, Basel, Switzerland*

Background: The demographic change, i. e. an increase in elderly people in the general population with an increase in comorbidities, is also reflected within the two leading causes for hospitalization in Germany, which are "Delivery/Birth" (Z38) and "Heart Failure" (I50). We analyzed data available from the German Federal Statistical Office for both diagnoses from 2000 to 2015.
Methods: We used publically available databases for ICD-10-GM diagnoses in Germany and compared the two most common reasons for hospitalization.
Results: Data were available from 2000 to 2015 for heart failure and from 2004 to 2015 for birth. Hospitalization for birth increased by 1.55 %/year from 444,306 (2004) to 526,437 (2015) [+82,131]. Hospitalization for heart failure increased by 4.96 %/year from 260,803 (2004) to 444,632 (2015) [+183,829] effecting heart failure to become the most common cause for disease-related hospitalization in Germany. Should these trends continue, there will be more hospitalizations for heart failure than for birth from 2020 onwards.
Conclusion: The demographic change in Germany will lead to a greater need for comprehensive heart failure care, while the number of hospitalizations for birth only mildly increased at last. Some geographic areas might consider converting labour rooms into comprehensive heart failure clinics.



Trends in Hospitalisation for Birth/HF

701

Is public knowledge about heart failure improving over time?

G Burneikaite[1]; E Lycholip[1]; A Grigaliuniene[1]; R Steponeniene[1]; J Celutkiene[1]; A Kavoliuniene[2]; S Stork[3]
[1]*Vilnius University, Clinic of Cardiac and Vascular diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania*; [2]*Lithuanian University of Health Sciences, Department of Cardiology, Medical Academy, Kaunas, Lithuania*; [3]*University of Wuerzburg, Comprehensive Heart Failure Center (CHFC), Wurzburg, Germany*

Background: Heart failure (HF) is an increasing cause of morbidity and mortality. Data of general public views about HF alone and in comparison with other chronic conditions are insufficient. The lack of basic comprehension of HF and self-care was confirmed in the vast majority in HF patients, which manifests itself in suboptimal outcomes in such patients.
Objectives: The aim of this study was to evaluate the changes in knowledge about HF of general population in Lithuania from 2013 to 2015.
Methods: A cross sectional survey study was performed, by using translated questionnaire designed by the German Competence Network Heart Failure. Participants were asked to complete a questionnaire during European Heart Failure Awareness (EHFA) Day activities. Anonymous information was collected and analyzed keeping confidentiality of participant (no personal sensitive data was obtained). Scans of completed questionnaires were made using a dedicated scanning tool and automatically transferred into a database. Data collected during 2013 and 2015 EHFA Day activities in Lithuania were analyzed. The following questions were selected for analysis: participant's gender, age and work experience in the medical area, answers to multiple-choice questions about treatment options, typical complaints and symptoms of HF. A chi-square test was used for comparison between 2013 and 2015 surveys results.
Results: A total of 1025 attendees in 2013 and 459 attendees in 2015 participated in surveys: 39% and 35.6% males, mean age 58.7 ± 6.7 and 55.4 ± 12.5 years, worked in medical area 15% and 21.4%, respectively. In 2013 survey 79% of attendees had heard about HF, meanwhile 65.9% of 2015 survey attendees had known the symptoms of HF. The correct identification of typical complaints and symptoms of HF significantly improved from 2013 to 2015: shortness of breath from 67.4% to 77.3%, tiredness from 55.2% to 66.5%, respectively ($p < 0.001$). The perception of HF as not normal symptom of old age also significantly increased from 31.8% to 37.1% ($p < 0.001$). Major number of 2015 survey participants assumed, that patients with HF should not avoid sport activities, compared to 2013 (41.4% vs 31.8%; $p < 0.001$). Knowledge about available HF treatment options was similar at both time points: respondents marked pharmacotherapy in 76.6% and 70.6%, pacemaker in 49.9% and 50.2%, heart surgery in 47.7% and 47.5%, of cases in 2013 and 2015 surveys, respectively.
Conclusions: The substantial part of participants has reported basic HF knowledge during 2013 and 2015 HFA Day initiatives, but there is still a room for improvement. Knowledge about HF symptoms and nature of the disease seems to be improving over last years. Activities on education and awareness in general population and in HF patients should be continued.

702

New predictors of left ventricular hypertrophy in normotensive adults with preserved ejection fraction. Insights from an epidemiologic survey-SEPHAR III

O-F Oana-Florentina Tautu[1]; RO Darabont[2]; A Scafa-Udriste[1]; D Dimulescu[3]; C Sinescu[4]; D Pitic[1]; G Tamasescu[1]; L Radulescu[1]; S Onciul[1]; M Stoian[1]; D Cadil[1]; M Dorobantu[1]
[1]*Emergency Clinical Hospital "Floreasca", University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*; [2]*University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania*; [3]*Elias Emergency Universitary Hospital, Cardiology, Bucharest, Romania*; [4]*Bagdasar-Arseni Emergency Hospital, Bucharest, Romania*

On behalf of: SEPHAR III TEAM
Funding Acknowledgements: ROMANIAN SOCIETY OF HYPERTENSION

Introduction: Left ventricular hypertrophy (LVH) is an important cause of heart failure with preserved ejection fraction (HFpEF), associated with age, blood pressure values and ponderal status even in normotensive subjects. Up to date, implications of sodium intake throug volume overload, arterial stiffness and BP variability in the development of LVH development have less been adressed in populational studies.
Purpose: We aimed to evaluate the presence and new predictors of left ventricular hypertrophy (LVH) in normotensive adults with preserved ejection fraction enrolled in SEPHAR III survey.
Methods: Adult subjects enrolled in SEPHAR III survey were evaluated throughout two study visits by: anthropometric measurements, 3 sitting BP measurements per visit according to ESC-ESH guidelines, arterial stiffness measurements (with an oscillometric device), volemia measurements by transthoracic bioimpedance, laboratory workup (lipids, fasting plasma glucose, HbA1c, estimation on 24h sodium excretion from morning spot urine sample using Kawasaki formula) and standard echocardiography. Normotensive state was defined as BP below 140/90 mmHg and lack of HT history or treatment. LVH was defined as indexed left ventricular mass (ILVM) > 95g/m2 in females and > 115 g/m2 in males.
Results: From a total of 1970 enrolled subjects we have identified 828 normotensive subjects with preserved EF (mean age 42.66 ± 16.79, 56.9% females). Mean ILVM values was 77.03 ± 27.31 g/m2. LVH was found in 11,4% of the sample (10.4% in males and 12.1% in females). Binary logistic regression adjusted for age and mean arterial pressure validated as independent predictors for LVH in normotensive adult subjects: smoking (OR 1.89; 95% CI for OR: 1.71-2.09), body mass index (OR 1.04; 95% CI for OR: 1.03-1.05), visceral obesity (OR 2.05; 95% CI for OR: 1.83-2.30), hypervolemia (OR 1,23; 95% CI for OR: 1.13-1.33), s.d. SBP (OR 1.02; 95% CI for OR: 1.01-1.03), PWVao (OR 1.14; 95% CI for OR: 1.12-1.15), aortic pulse pressure (OR 1.03; 95% CI for OR: 1.02-1.03). The prediction model has 83.7% accuracy of predicting the presence of LVH in normotensive subjects. Correlation analysis revealed that PWVao, PPao, s.d. SBP and hypervolemia are directly correlated with estimated 24h sodium excretion (mean value: 198.56 ± 62.60mmol/day estimating a mean NaCl dietary intake of 11.62g/day).
Conclusions: Our study reveals that beyond well recognized determinants of LVH (age, BP values, obesity), increased arterial stiffness, central BP parameters, visit-to-visit BP variability and hypervolemia independently contributes to LVH development in normotensive adult subjects, stressing the need of adequate preventing strategies. More, the correlation between these new predictors of LVH with volume overload urge the reduction of dietary sodium intake in preventing new onset on HFpEF.

703

Comorbidities in heart failure according to left ventricular ejection fraction: analysis of administrative data of a nationwide population

A Esteban Fernandez[1]; C Fernandez[2]; I Vilacosta[2]; V Bertomeu[3]; J Elola[2]; JL Bernal[4]; JV Segura[5]; C Macaya[2]; R Bover[1]
[1]*Hospital Clinic San Carlos, Heart Failure Unit, Madrid, Spain*; [2]*Hospital Clinic San Carlos, Cardiology Service, Madrid, Spain*; [3]*University Hospital San Juan de Alicante, Cardiology Service, Alicante, Spain*; [4]*University Hospital 12 de Octubre, Madrid, Spain*; [5]*University Miguel Hernandez, Elche, Spain*

Introduction: Comorbidities are an important issue in heart failure (HF) patients. Traditionally, it is thought that they are more relevant in HF with preserved ejection fraction (HF-pef) than in reduced one (HF-ref), but both are present in HF patients. We present the prevalence of comorbidities in HF patients according to the left ventricular ejection fraction in a whole country (Spain, 46.77 millions population).
Methods: All the discharges from Spanish hospitals corresponding to 2012-2013 with a primary diagnosis of HF, according to the ICD-9-CM classification, were analyzed. The classification includes: systolic, diastolic, systolic and diastolic, hypertensive disease and not specified HF. For this analysis we only consider systolic (HF-ref) and diastolic (HF-pef). Some of the most relevant comorbidities was considered.
Results: 400,861 hospital admissions were recorded, 77,652 with HF as a primary diagnosis (HF-ref 4241 patients and HF-pef 1752 patients). The basal characteristics and main comorbidities of the patients are included in table 1.
Conclusions: According to the results of this Spanish administrative database, both HF-ref and HF-pef have a similar profile with a relevant prevalence of comorbidities, with slight differences in some of them. However, the poor codification of HF at discharge could limit these results.

Parameter	HF-ref	HF-pef
Age	74.1	78.5
Men	65.7	36.7
Ischemic heart disease	36.7	20.5
Arterial Hypertension	59.1	64.6
Diabetes Mellitus	38.5	41.3
Ictus	0.4	0.2
Chronic kidney disease	32.5	30.6
COPD	17.3	15.9
Malnutrition	0.9	1.2
Dementia and senility	14.0	17.4
Functional disability	3.0	2.9
Peripheral arterial disease	66.9	76.3
Advanced cancer	1.2	1.7
Trauma in the last year	2.4	2.7

Table 1. Distribution of comorbidities (%) according to ventricular ejection fraction.

704

Prediction of heart failure in asymptomatic type 2 diabetics: an 8 year prospective study following cardiac CT angiography

D A Halon[1]; J Ayman[1]; R Rubinshtein[1]; B Zafrir[1]; M Azencot[1]; BS Lewis[1]
[1]*Lady Davis Carmel Medical Center, Department of Cardiovascular Medicine, Haifa, Israel*

Funding Acknowledgements: European Foundation for the Study of Diabetes

Background and Aims: Heart failure (HF) is a severe complication of diabetes mellitus (DM) but prospective data regarding risk of HF in DM and the role of coronary artery disease (CAD) is limited.
Purpose: In a cohort of asymptomatic type 2 diabetics to identify clinical and cardiac CT angiographic (CTA) findings for prediction of hospitalization for HF or cardiovascular death (HF-CVD).
Methods: Baseline CTA was performed in 735 diabetics aged 55-74 years (51.2% women) with no history of CAD and serum creatinine < 1.4 mg/dl. Chamber volumes, coronary artery calcium (CAC), coronary atherosclerosis and stenosis and clinical data were examined for prediction of HF-CVD events over 7.3-9.3 years based on time to event analysis.
Results: CVD-HF occurred in 41 of 735 subjects (5.6%) (31/600, 5.2% of subjects with full CTA data). HF occurred mostly in subjects without prior myocardial infarction (19/23, 82.6%) and preserved LV contraction. Independent predictors of HF-CVD were left/right atrial volume >1 ($p < .0001$), microvascular disease ($p < .0001$) and systolic blood pressure ($p = .035$)(model C-statistic 0.792 (95%CI. 758-.824).
Conclusions: In asymptomatic diabetics followed for 7-9 years: HF-CVD was independently predicted by hemodynamic (systolic blood pressure), anatomic (LA/RA volume ratio) and microvascular (retinopathy, microalbuminuria) factors but not by CAD.

Baseline Predictors of HF-CVD

Baseline variable	HF-CVD (N=41)	No HF-CVD (N=694)	p-value
Duration of DM (years)	13.5±9.6	9.9±7.4	.004
Systolic BP (mmHg)	148.6±21.1	137.7±19.0	.0004
Albuminuria (>30mcg/mg creatinine)	23 (56.1%)	112 (16.1%)	<.0001
Retinopathy	13 (31.7%)	111 (16.0%)	.011
HbA1c (%)	8.5±2.0	7.4±1.5	<.0001
CAC score (Agatston Units) (median, quartiles)	148 (40, 490)	55 (1, 324)	.004
Left/right atria volume >1	22 (71.0%)	187 (32.9%)	<.0001
Total coronary artery plaque volume (mm^3) (median, quartiles)	241 (80, 648)	139 (22, 411)	.050

CAC=coronary artery calcium

The interactive smartphone application for the improvement of self-care in patients with heart failure

A Grebennikova[1]; A Stoliarov[2]; T Jaarsma[3]; Y M Yury Lopatin[1]
[1]*Volgograd State Medical University, Volgograd Regional Cardiology Centre, Volgograd, Russian Federation*; [2]*Volgograd State University, Volgograd, Russian Federation*; [3]*Linköping University, Linköping, Sweden*

Background: Patient education and improvement of self-care are considered as key strategies for preventing further deterioration of heart failure (HF). The aim of our study was to evaluate the effectiveness of an interactive smartphone application (app) based on the Russian version of the 9-item European Heart Failure Self-care Behaviour Scale (EHFScBS) for improving self-care management in patients with HF.
Methods: Consecutive 142 patients (mean age 59± 12.2 years, 63% male) with decompensated HF (61% of ischemic etiology), NYHA II-IV (2.8 ± 0.6) and a mean left ventricular ejection fraction of 32 ± 7.0% were included in this study. All patients were provided with general information about HF such as symptoms, principles of self-care, diet, medical therapy and physical activity according to the Russian HF guidelines. Before discharge from the hospital, the original smartphone support app, based on EHFScBS-9, was downloaded on the mobile phones of 47 patients with HF. Other 95 patients with HF who had refused to use the smartphone app became the control group. There were no differences in demographic and clinical characteristics between both groups of patients with HF. The duration of follow-up was 6 months.
Results: On admission, the mean EHFScBS-9 score was similar in the smartphone app group and the control group – 28 ± 6.6 and 27.7 ± 6.3, respectively. However, after 6 months of follow-up, a significant reduction of the mean EHFScBS-9 score was noted in the smartphone app group (/56.4%, $p < 0.05$) but not in the control group (-13.7%, n.s.). The smartphone app group demonstrated the highest adherence to daily weight control, contact with a physician or a nurse in case of increased dyspnea and control of medication intake. Moreover, the rate of repeat hospitalizations in the control group was 21%, whereas among the patients using the interactive smartphone app there were no readmissions. The patients noted that the app was easy to use; and only 10.6% of patients needed the help of relatives.
Conclusion: The interactive smartphone application based on the 9-item European Heart Failure Self-care Behaviour Scale improves self-care behavior in patients with heart failure, provides their continuous and persistent education and may be considered as promising tool in the management of patients with heart failure.

CLINICAL CASE CORNER 2 – THE HORIZON IN PHARMACOLOGICAL THERAPIES, INTERVENTIONS & DEVICE

706

Inotropes and intra-aortic balloon pump counterpulsation in tako tsubo cardiomyopathy: the right treatment when things go wrong?

CD Chue[1]; HS Lim[1]
[1]*Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom*

Case: A 69-year-old female presented with acute chest pain and breathlessness. An electrocardiogram demonstrated anterior ST elevation and lateral T wave changes. Serum troponin levels were elevated at 487ng/l. Coronary angiography showed smooth, unobstructed vessels. Echocardiography demonstrated apical thinning and akinesia with hyperkinesia of the basal segments consistent with tako tsubo cardiomyopathy. Left ventricular ejection fraction was 39% with normal right ventricular function. Within 24 hours of admission the patient developed persistent hypotension with pulmonary oedema on chest radiography. Despite treatment with intravenous diuretics, dobutamine, noradrenaline and intra-aortic balloon pump (IABP) counterpulsation, there was no improvement and advanced mechanical circulatory support was considered. Repeat echocardiography demonstrated persistent left ventricular systolic dysfunction with moderate mitral regurgitation and flow acceleration in the left ventricular outflow tract (LVOT) due to obstruction from systolic anterior motion (SAM) of the mitral valve (Figure). Obstruction of the LVOT was felt to be the principal mechanism of poor cardiac output, exacerbated by inotropes and IABP support. Weaning of these therapies was accompanied by a subsequent reduction in LVOT gradient on repeat echocardiography. The patient improved haemodynamically and biochemically following cessation of all support after 2 days. Problems: 1) Recognition of LVOT obstruction due to SAM in tako tsubo cardiomyopathy as a contributor to low cardiac output and haemodynamic instability. 2) Despite significant impairment of left ventricular systolic function and low cardiac output, inotropes and IABP counterpulsation have deleterious effects on haemodynamic status in this setting. Discussion: LVOT obstruction occurs in approximately 20–30% of tako tsubo cardiomyopathy cases and is associated with reduced cardiac output and cardiogenic shock. Bedside echocardiography is diagnostic. The mechanism is through SAM of the mitral valve apparatus from compensatory hypercontractile function of the left ventricular basal segments. LVOT obstruction should be considered in the setting of cardiogenic shock or persisting haemodynamic instability despite inotrope therapy. Inotropic agents increase sympathetic activation and myocardial contractility, thus exacerbating LVOT obstruction. Greater flow acceleration through the LVOT can worsen SAM, causing further LVOT obstruction. Inotropes and IABP counterpulsation should therefore be avoided in this setting. Conclusion: LVOT obstruction is a cause of reduced cardiac output and cardiogenic shock complicating tako tsubo cardiomyopathy. Inotropes and IABP support can precipitate clinical deterioration and should therefore be avoided.

Transthoracic echocardiogram

Treatment of patient with acute heart failure due to acute idiopathic giant cell myocarditis using ECMO

NA Beley[1]; OM Druzhyna[1]; OA Loskutov[1]; BM Todurov[2]
[1]*National Medical Academy of Postgraduate Education, Anesthesiology and Intensive Care, Kiev, Ukraine*; [2]*Heart Institute of the Ministry of Healthcare of Ukraine, Kiev, Ukraine*

Introduction and case description: Acute idiopathic myocarditis presents a challenging case for cardiologist often having dramatically fulminant course. Giant cell myocarditis may progress in days to weeks leading to heart failure in 75% of cases. In regard of high rate of refraction to conservative treatment, the use of circulation assisting technologies is highly suggestive. Patient 23 years of age was admitted to our hospital with diagnoses of acute myocarditis and reduced systolic function of left ventricle (EF=18%). On initial examination he presented with dyspnea in rest, lower extremities edema and ascites. No causing factors were found. The disease had acute onset 10 days before. Clinical manifestations were fatigue and drowsiness, dyspnea after walking for 50m. Leg edema and ascites developed by the end of the first week after the symptoms onset. The patient was admitted to the local hospital and on 5th day of treatment he was referred to our Clinic due to worsening of heart failure and lack of response to conservative treatment.
ECG: low voltage, sinus irregular rhythm with HR 100-116 bpm; supraventricular extrasystols; incomplete blockade of right bundle branch.
Echocardiography: end-diastolic volume (EDV) – 100 ml, end-systolic volume (ESV) – 85 ml, stroke volume (SV) – 25 ml, left ventricle ejection fraction (LV EF) – 18%. Polypositional myocardial biopsy shows idiopathic giant cell myocarditis. Brain natriuretic peptide was elevated (1891,6 pg/ml). After two days of conservative treatment with maximum inotropic support, VA ECMO was considered. Beside routine heart failure medications, immunosuppressant therapy was indicated and consisted of cyclosporine 50 mg twice daily and prednisolone with day dosage of 45 mg. ECMO support lasted for 15 days with improving in LV EF from initial 16% to 28% on weaning moment. Patient assessment when discharged shows relative improvement in all investigations. Echocardiography: EDV – 90 ml, ESV – 60%, LV EF – 30%, systolic pressure in right ventricle – 30 mmHg, minimal amount of pleural effusion.
Discussion: Treatment strategy for patients with myocarditis should be guided by etiology, features of clinical course, presence and severity of heart failure. The key point of treatment is hemodynamic correction which is similar to therapeutic approaches for heart failure due to LV dysfunction. Thus, inotropes (dobutamine) is recommended. Failure to support hemodynamics with inotropes suggests consideration of ECMO or mechanical assist devices. These procedures reduce myocardial stress and improve contractile function of myocytes. The main goal of ECMO support is the bridge-to-recovery or the bridge-to-transplant strategy of treatment. Conclusions. ECMO shows effective support in patients with acute idiopathic giant cell myocarditis with fulminant progression in course of heart failure and should be considered as a part of the bridge-to-transplant strategy in such cases.

708

Wet, cold and hypertensive: solving the puzzle with levosimendan

A Afonso Felix-Oliveira[1]; MA Goncalves[1]; C Silva[1]; D Matos[1]; M Trabulo[1]; A Tralhao[1]; MJ Andrade[1]; C Aguiar[1]; J Ferreira[1]; M Mendes[1]
[1]*Hospital de Santa Cruz, Cardiology, Lisbon, Portugal*

Acute heart failure is defined as rapid onset or worsening of symptoms and/or signs of HF. The clinical scenario is one of great heterogeneity, either in primary etiology, cause of decompensation or hemodynamic profile presented. Therapeutic options are tailored to each patient and influenced by local expertise, given the absence of a standardized approach. We present the case of a 52 years-old female patient with late-onset anthracycline cardiomyopathy. She was admitted due to worsening fatigue, with symptoms at rest, and increasing weight within the previous week.

Physical examination was characterized by hypertension with 160/90mmHg, sinus tachycardia with 100bpm (QRS <120ms), SaO2 96%, cold extremities with capillary refill time >2s, absence of pulmonary rales and lower leg pitting edema as well as ascites. The patient's condition had been worsening in the last 12 months despite appropriate therapy with Ramipril 10mg/day, Carvedilol 50mg/day and Espironolactone 50mg/day. In spite of being treated with furosemide 180mg/day, congestive features were frequently present. The patient had also a history of severe resistant hypertension, submitted to renal denervation therapy 6 months before current hospitalization. Transthoracic echocardiogram showed a dilated left ventricle, ejection fraction of 26% and global longitudinal strain -5,3%, with estimated cardiac output of 3,3 L/min. E/e′ ratio of 29 and left atrium volume of 58mL/m2 suggesting elevated filling pressures. Right ventricle dysfunction with TAPSE of 13mm, and PSAP of 65mmHg with dilated inferior vena cava. An unusual finding was the presence of elevated arterial pressure, with systolic pressure persistently above 160mmHg, even with additional therapy with Nifedipine ER 30mg/day od and Clonidine 150mg 4id (usual therapy). To define heart transplant eligibility and detail the haemodynamic profile, the patient underwent right heart catheterization with mean PAP of 23mmHg, mean PCWP of 18mmHg, cardiac output of 3.1 L/min (Fick method), PVR of 1,6 Wood and SVR of 3019,4 dynes/sec/cm-5. Being Levosimendan a potent inodilatator, known to decrease systemic and pulmonary resistance and increase cardiac output, a pulse of Levosimendan was successfully administered. In the following week, the patient reported improved fatigue, changing from NYHA IV to NYHA II, and decreased leg swelling and ascites. Arterial hypertension also decreased. Echocardiographic re-assessment showed improved biventricular function as summarized in table 1. This case illustrates an unusual hemodynamic presentation, where "wet/cold" profile occurred together with severe hypertension and very high systemic vascular resistance. Levosimendan obtained a good response, probably due to its arterial and venous vasodilator potency, reinforcing the important role of this drug in the setting of acute heart failure.

Table 1. Echocardiographic Assessment

	Admission	pre-Discharge
Ejection Fraction (%)	26	32
Globo Longitudinal Strain (%)	5,3	7,1
Cardiac Output (L/min)	3,3	3,9
E/A ratio		
E/e' ratio	29	16,5
Left Atrium Volume (mL/m2)	58	
Tricuspid Annular Systolic Excursion (mm)	13	22
PSAP (mmHg)	65	40

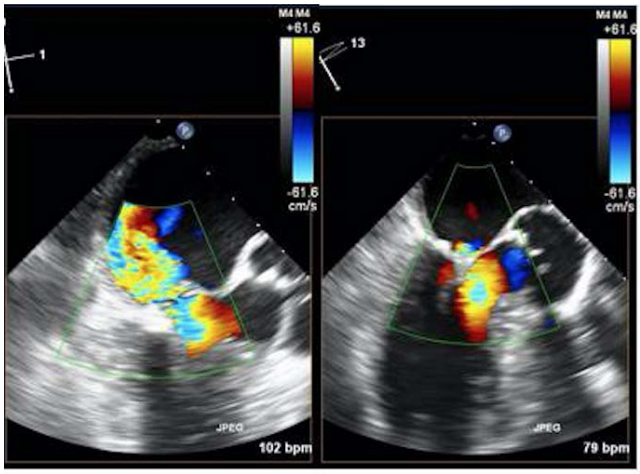
MitraClip for papillary muscle rupture in patient with acute heart failure

K Papadopoulos[1]; M Chrissoheris[1]; P Kourkoveli[1]; K Spargias[1]
[1]*Hygeia Hospital, Transcatheter Heart Valves, Athens, Greece*

Papillary muscle rupture is a devastating and potentially lethal mechanical complication of myocardial infarction that can lead to severe mitral regurgitation (MR) and acute heart failure. An 85 year old woman presented, after several days, to a district hospital with symptoms and signs of myocardial ischemia. The ECG showed a recent anterior STEMI and the patient underwent emergent coronary angiography and revascularization of a totally occluded intermediate (ramus) artery with a drug eluting stent. Echocardiography showed akinetic anterolateral wall with an estimated left ventricular ejection fraction of 40%. On day three post revascularization the patient developed acute pulmonary edema and cardiogenic shock. A transesophageal study revealed partial rupture of the anterolateral papillary muscle with flail anterior leaflet and severe MR. After consideration by the Heart Team, the patient was referred for emergent edge to edge mitral valve repair while being supported with an intra-aortic balloon pump. Two Mitraclips were implanted resulting in marked reduction of MR and dramatic clinical improvement. The patient was discharged home a week later after an uneventful postoperative period. At the 6 month follow up she is clinically well with no re-admissions for heart failure. The case highlights the critical role of edge to edge repair with the MitraClip in patients with acute ischemic mitral regurgitation and refractory heart failure, who are not candidates for surgical repair.



pre and post procedure mitral valve

LCZ696 as a bridge to candidacy to valve surgery in patients with advanced heart failure with reduced ejection fraction: a case report

D Pellegrini[1]; A Villani[2]; M Oldani[2]; P Gerometta[3]; G Malfatto[2]; G Parati[1]
[1]*University of Milan-Bicocca, Milan, Italy*; [2]*San Luca Hospital of Milan, Milan, Italy*; [3]*Clinical Institute Humanitas Gavazzeni, Bergamo, Italy*

Background: Valvular heart disease (VHD) can impair prognosis significantly in patients affected by heart failure (HF), but these patients are often denied surgery due to excessive operative risk. Even if no data have been published so far on this topic, LCZ696 (sacubitril/valsartan) might improve cardiac function in subjects affected by HF with reduced ejection fraction (HFrEF) and VHD, possibly lowering operative risk and allowing eligibility to valve surgery.
Case report: A 76-year-old man was first diagnosed with HFrEF due to anthracyclines-related cardiotoxicity in 2013. Despite optimal medical treatment for HF and cardiac resynchronization therapy, his clinical conditions slowly worsened (NYHA class III), alongside a gradual worsening of a previously mild aortic and functional mitral regurgitation. In September 2015, an echocardiogram detected a dilated ventricle, a severe reduction of EF, pulmonary hypertension and severe mitro-aortic regurgitation (table, column 1). The patient was then referred for valve surgery, but he was deemed ineligible due to an exceedingly high risk (EuroSCORE II 14.05%). Therefore, palliative infusions of levosimendan and furosemide were started, with mild benefits. In January 2016, we introduced LCZ696, up-titrating the dose to 200 mg b.i.d. over 3 months. In the following months, the patient showed a progressive clinical improvement, reporting resolution of dyspnea (NYHA I) and reduction of diuretic dose. In June 2016 (table, column 2), we observed an overall improvement of cardiac performance and a reduction of mitral regurgitation; aortic regurgitation was unaffected. In October 2016, the hemodynamic burden of valve defects increased again (table, column 3), with a progressive worsening of his clinical conditions; thus, the surgical option was re-evaluated. This time, the pre-operative risk was judged acceptable (EuroSCORE II 5.94%): therefore, the patient underwent aortic valve replacement and mitral valve annuloplasty through a traditional sternotomic approach. No major complications occurred. LCZ696 was restarted a few days later at the lowest dose and up-titrated again. After a hospital-based rehabilitation period, the patient was discharged in NHYA class I-II, with good function of the aortic prosthetic valve, no residual mitral valve regurgitation and stable EF (table, column 4).
Discussion: Beneficial effects of LCZ696 on patients with HFrEF are well known from trials, but experience in clinical practice is still limited. This is the first report on the use of LCZ696 as a "bridge to candidacy", to improve the clinical conditions of a patient, aimed at lowering his predicted operative risk and making him eligible to heart surgery. Thus, LCZ696 administration may pave the way to a new therapeutic approach to patients with advanced HF and VHD, granting larger improvement in prognosis and quality of life than traditional strategies.

Effects of LCZ696 on cardiac function

	Baseline (Sept 2015)	After titration of LCZ696 (June 2016)	Before valve surgery (Oct 2016)	After surgery (Jan 2017)
Ejection Fraction	20%	46%	45%	38%
End-diastolic volume (mL)	348	218	275	230
Pulmonary Artery Systolic Pressure (mm Hg)	60	25	45	30
Mitral regurgitation	+ + +	+/+ +	+ +/+ + +	-
Aortic Regurgitation	+ + +	+ + +	+ + +	-
NT-pro BNP (ng/L)	2007	633	2147	1501

Cardiac ultrasound data and NT-pro BNP values at different times during follow-up

Effects of LCZ696 on pulmonary arterial pressures in heart failure with reduced ejection fraction, measured with a novel implantable device: a case report

D Dario Pellegrini[1]; A Villani[2]; G Malfatto[2]; M Oldani[2]; F Brasca[2]; GB Perego[2]; G Parati[1]

[1]University of Milan-Bicocca, Milan, Italy; *[2]San Luca Hospital of Milan, Milan, Italy*

Background: LCZ696 (sacubitril/valsartan) can provide a significant improvement in the prognosis of patients affected by heart failure (HF) with reduced ejection fraction (HFrEF). However, trials did not focus on the direct effects of the drug on hemodynamics and on pulmonary arterial pressures (PAP). Novel implantable devices that allow the remote direct monitoring of PAP represent a valuable opportunity to better understand the effects of LCZ696 in these patients.
Case report: A 54-year-old man affected by ischemic HFrEF was followed-up in our center. Despite optimal medical treatment for HF and cardiac resynchronization therapy, no functional nor clinical improvement was observed. He refused both ventricular assist device and heart transplant, so by December 2014 he was dependent on palliative infusions of furosemide and levosimendan, with a NYHA class II-III and a severe reduction of cardiac function (EF 15%), pulmonary hypertension (systolic PAP 50 mmHg), and moderate mitral regurgitation. In January 2015, he received an implantable device for the direct measurement of PAP. The data provided by the device guided therapy optimization in the following months, granting a reduction of 4 mm Hg of mean PAP. No significant clinical improvement was observed, though. In June 2016, we introduced LCZ696, up-titrating it to the target dose of 200 mg b.i.d.: in the following 7 months of follow-up, remote monitoring showed a progressive and significant reduction of PAP (systolic PAP, from 62.6 ± 5.91 to 48.00 ± 3.3 mm Hg; diastolic PAP, from 35.53 ± 4.18 to 27.4 ± 3.01 mm Hg; mean PAP, from 46.07 ± 5.43 to 33.87 ± 3.16 mm Hg; $p < 0.0001$ for all comparisons). Of note, this hemodynamic improvement was paralleled by a progressive down-titration of diuretics and interruption of levosimendan palliative infusions. We also observed a significant increase of thoracic impedance (TI, from 818 ± 16.94 to 876.2 ± 5.61 Ohm, $p < 0.0001$); furthermore, TI values showed an increased stability over time, and the frequency of triggered alarms of fluid overload decreased. No significant changes were observed with cardiac ultrasound and cardiopulmonary exercise test. 6-Minute-Walking Test showed a slight improvement of performance (from 460 to 511 m). Nevertheless, the patient reported a significant subjective improvement of his conditions, reduction of fatigue, resolution of dyspnea and increased low-intensity physical activity at home.
Discussion: In this case LCZ696 produced a significant and progressive reduction of PAP and increase of TI over a relatively short period. The patient experienced a parallel improvement of his clinical conditions and a reduced need for diuretics. This effect appeared to be independent from changes in cardiac function, and may be due to peripheral vasodilation mediated by the drug. Future studies may provide stronger evidence of the effects of LCZ696 on pulmonary pressures and thoracic fluid overload in patients affected by HF.

712

Recurrent pump thrombosis: a therapeutic dilemma

M D Avila[1]; JC Leoni[1]; P Patel[1]; DS Yip[1]; J Hosenpud[1]

[1]Mayo Clinic, Transplant, Jacksonville, United States of America

Introduction: Pump thrombosis (PT) remains a devastating complication of left ventricular assist devices (LVAD). To date, there are no guidelines or consensus regarding the management of PT.
Case Report: A 53 y/o male with nonischemic cardiomyopathy underwent HeartWare LVAD placement as a bridge to transplantation. 6 months post implantation, he presented PT which was successfully treated with thrombolytics. He now presents with dark urine, haptoglobin < 14 mg/dl, plasma free hemoglobin 99.1 mg/dl, INR 2.8 and lactase dehydrogenase (LDH) 1,304 u/l. He was hospitalized, started on eptifibatide and unfractionated heparin with improvement of his symptoms and LDH. He remained in the hospital as a status 1A exception on the heart transplant list due to PT. On day 36 of his hospital stay, he presented a third episode of PT which was treated with integrilin. He did not improve and required tissue plasminogen activator (tPA) plus vasopressors. His RAMP study showed inadequate left ventricle unloading in spite of increased speeds. Due to failure to medical therapy, he underwent pump exchange with a HeartWare LVAD via left thoracotomy complicated by cardiogenic shock, respiratory failure and acute kidney injury. He had a chest CT angiography that did not showed thrombus but it did showed that his outflow graft had a 90 degree angle turn posteriorly which may represent a site of obstruction. It was decided that stenting was associated to a moderate risk of stroke which may preclude his heart transplant. He was weaned off vasopressors and had a slow recovery. On day 80, he presented a fourth episode of PT. His prognosis was guarded and at this time he was not a candidate for pump exchange. He was started on tirofiban drip which was unsuccessful. Then, tPA was administered but he continued to deteriorate. He received a second bolus of tPA and became hypotensive followed by pulseless electrical activity refractory to supportive measures. He was declared dead.
Problem and Discussion: This case highlights the difficulty of managing PT in spite of aggressive therapeutic measures. Therapeutic strategies currently available include medical or surgical therapy. Some series have reported success rates of medical therapy of 23-50% with mortality rates of 17-52%. Pump exchange considered a highly morbid procedure has demonstrated low early mortality and low complication rates. There is no head to head trial comparing these strategies. The optimal therapy for patients with PT has not been fully clarified in spite of its increasing incidence in the LVAD population.
Conclusion: The treatment of PT is a complex and challenging medical dilemma. At present, it is unclear what is the appropriate treatment for this morbid condition. The choice of initial therapy depends on patient's characteristics, surgical candidacy and mostly on the center's philosophy based on their experience. Further studies are needed to elucidate which strategy is the most effective and less morbid.

713

Role of imaging in patients with a left ventricular assist device implanted

CI Radulescu[1]; L Antohi[1]; A Covaliov[1]; L Chivulescu[1]; R Radu[1]; C Parasca[1]; V Iliescu[1]; O Chioncel[1]

[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania

Introduction: Left ventricular assist devices (LVADs) have revolutionized the treatment of advanced heart failure and LVAD implantation has become a class IIa recommendation therapy in patients with refractory heart failure. A significant number of LVAD recipients have major complications in the first year after the implant, most commonly related to thrombosis/haemorrhage or infections which occur in almost 35% of the patients. Lower rates of infections have been reported for the newer devices, such as HeartWare.
Case Description: This is the case of a 43-years-old man with a history of ischemic cardiomyopathy, severe systolic dysfunction of the left ventricle with an ejection fraction of 20%, implantable cardioverter-defibrillator (ICD) and multiple episodes of decompensated heart failure who became a LVAD recipient (continuous-flow HeartWare device) as a bridge-to-transplantation therapy (9 months prior). The patient presents in the emergency department with signs and symptoms of right ventricular (RV) dysfunction: jugular venous distention (JVD=19 cm), hepatomegaly and peripheral oedema. Systolic blood pressure (SBP) at admission was difficult to assess due to the continuous flow of the device; he also presented with fever, tachycardia and sweating for the last 2 weeks. Chest x-ray showed a large mediastinum, the ICD and the LVAD inflow cannula (Figure 1); initial blood tests asserted leukocytosis with a white blood cell count (WBC) of 16352/µl, a C reactive protein of 80 mg/ml with a high value of the procalcitonin (>10 ng/ml), suggesting an infectious process; we also mention the International Normalized Ratio (INR) of 4,7. The patient was admitted in the Intensive Coronary Care Unit (ICCU) and echocardiography, both transthoracic and transesophageal (Figure 2), revealed a large mass in the anterior mediastinum which compressed the right ventricle with preserved RV systolic function. Computed tomography (CT) scan confirmed the transesophageal echocardiography (TEE) findings and provided more accurate anatomical reports towards the driveline and the inflow cannula (Figure 3,4). Serial blood cultures have been grown and we obtained positive results for Gram-negative pathogens (Pseudomonas aeruginosa). Due to

the urgent situation and the high value of the INR, we decided to perform evacuatory puncture in the fifth right intercostal space with the extraction of a quantity of 600 ml of sero-hemorrhagic fluid. The clinical status of the patient improved significantly immediately after the procedure, ETE showing decompression of the right ventricle (Figure 5). The patient received intravenous antibiotics (ertapenem and moxifloxacin) according to the highest minimum inhibitory concentrations (MIC) for 6 weeks. At the end of the antibiotic treatment the inflamatory blood tests were normalized. The patient remains a candidate for heart transplantation (HTX) without compromising the possibility of performing sternotomy.

Discussions: Right ventricle systolic dysfunction after LVAD implantation has multiple mechanisms, most of them caused by RV contractile dysfunction, but in this case the signs and symptoms of RV dysfunction were produced by extrinsic compression. Mediastinal masses can be the consequences of haemorrhage or systemic infections and distinguishing between them may be clinically challenging. The case is illustrative for managing a difficult complication after LVAD implantation and it attends should be done to conserve the HTX future option.

Percutaneous paravalvular leak closure for aortic regurgitation after transcatheter aortic valve

M Mariana Castro[1]; JP Abecasis[1]; RC Teles[1]; R Ribeiras[1]; P Freitas[1]; M Neto[1]; M Almeida[1]; MJ Andrade[1]; M Mendes[1]
[1]*Hospital de Santa Cruz, Lisbon, Portugal*

Paravalvular leaks (PVL) are well-recognized sequelae of transcatheter aortic valve implantation (TAVI) with important prognosis impact and difficult management. We present a case of an 87 years patient, underwent transfemoral Corevalve Evolut R 29 complicated with complete atrioventricular block with pacemaker implantation. Immediate pos-TAVI transthoracic echo (TTE) show a mild anterior leak. One year after procedure patient was referred with progressive shortness of breath and recent onset heart failure symptoms, NYHA III. At TTE two PVL were evident one anterior and other posterior globally quantified as moderate, although with severe limitations by this method. Cardiovascular magnetic resonance (CMR) was made to accurately quantify PVL severity, with a regurgitant fraction quantification of 27% (Figure1 A and B). Patient was select to percutaneous treatment with the use of real-time echocardiograpy. Pre-procedure transthoracic echocardiogram (TTE) confirms the severity of the regurgitation and helps to describe leaks: one moderate on a posterior position at 1 o´clock and other smaller anterior at 5 o´clock (Fig 1. C and D), together conditioning severe aortic paravalvular regurgitation. Leak repair was made with TTE guidance (Fig1 E plug at posterior leak (arrow), and anterior leak) using 6-French femoral access and an hydrophilic wire, the defects were successfully crossed with a 5-French Multipurpose catheter and two Amplatzer Vascular Plug IV devices were deployed, resulting in abolition of the posterior aortic leak and minimal residual anterior leak (Fig1. F and G), associated with excellent clinical response. Significant post-procedure aortic regurgitation (AR) is and important predictor of adverse outcome following TAVI. Cardiac imaging, especially two- and three-dimensional transoesophageal echocardiography, plays an essential role in the diagnosis and guidance of intervention but it could fail in the correct quantification. CMR is able to perform accurate flow-imaging and volume-based measurements especially relevant in patients with multiple PVL. Paravalvular leak closure is an established procedure for surgical aortic prostheses; few cases describe percutaneous closure of CoreValve PVL that can be successfully treated with AVP4 device as it can be delivered down standard diagnostic catheters, and easily adapt to leak morphology.

715

A rare case of heart failure: loculated pericardial effusion after cardiac surgery achieving cardiac compression with focal constrictive pericarditis and mitral stenosis

A Cecchetto[1]; C Ciccio'[2]; A Chiampan[1]; S Bonapace[1]; L Lanzoni[1]; C Dugo[1]; E Barbieri[1]
[1]*Sacred Heart Hospital of Negrar, Cardiology, Negrar-Verona, Italy*; [2]*Sacred Heart Hospital of Negrar, Radiology, Negrar-Verona, Italy*

The interest in this case lies in the difficulty of discerning the main cause of heart failure and the importance of the interpenetration of different imaging techniques to get to the resolution of the case. A 70-years-old male with a medical history of aortic valve substitution with mechanical prosthesis for severe aortic regurgitation, new onset of atrial fibrillation and hepatic cirrhosis, was subjected to our attention for heart failure with bilateral ankle oedema and dyspnoea. Electrocardiogram showed atrial fibrillation and signs of left ventricular hypertrophy. Laboratory tests showed increased natriuretic peptides and chest X ray demonstrated mild pleural effusion. Transthoracic echocardiogram confirmed normal function of aortic prosthesis; hypertrophic left ventricle with thickening of the posterior wall (Fig 1A) and normal systolic function; right ventricle dilatation with mild pulmonary hypertension. We noted an extrinsic mass pressing the infero-lateral wall (Fig. 1A, B, C arrows) with mitral valve prolapse and mitral moderate stenosis (Fig 1 D). The suspect was a cardiac compression for the presence of septal bounce, borderline respiratory variation of the mitral peak E velocity of 20% (Fig. 1E); dilatation of caval and hepatic vein (Fig. 1F); increased left atrium and initial signs of ventricular interdependence on M-mode view of the septum and infero-lateral wall (Fig. 1G). The patient was subjected to thoracic CT that confirmed an inhomogeneous mass with pericardial thickness and calcification (Fig. 1H). To better define the characteristics of the mass, CMR was executed. It showed a loculated chronic pericardial effusion (Fig. 1 I, L, M, arrows) compressing the lateral wall of the left ventricle with an asymmetric hypertrophy (Fig. 1 I, L, M, stars) and causing anterior mitral leaflet prolapse. Then we saw a thickening of the pericardium (3-4 mm) with calcification in particular in the basal inferior and lateral segments. Finally, on real time cine sequences we noted a flattening of the interventricular septum, with signs of ventricular interdependence (Fig. 1N). The patient was treated with diuretics with a period of benefit. During the follow up, he died for a severe sepsis due to mitral valve endocarditis. Analyzing the case, the possible causes of heart failure in this patient could be a dysfunction of the bioprosthesis, the onset of atrial fibrillation, liver cirrhosis, diastolic dysfunction secondary to ventricular hypertrophy, mitral stenosis, constrictive pericarditis. Probably in this case more elements have contributed to the development of heart failure. However it seemed predominant, also in relation to a predominant right heart failure, focal constrictive pericarditis. Constrictive pericarditis is a condition in which a thickened, scarred, inelastic, and often calcified noncompliant pericardium limits diastolic filling of the ventricles. The etiologies are diverse, including cardiac surgery. In patients with suspected constriction, imaging tests can focus on diagnostic information, including pericardial thickness, interventricular dependence, other associated abnormalities (valvular, myocardial, or coronary artery disease). On the basis of its ability for comprehensive morphologic assessment of the heart as well as the pericardium and hemodynamic characteristics, echocardiography remains the initial imaging test, and can provide a definite diagnosis of constrictive pericarditis for most patients. In those situations in which echocardiographic findings are equivocal, additional imaging testing (CT or CMR) is needed to make the diagnosis with more confidence. In some patients, hemodynamic cardiac catheterization may be necessary to establish the diagnosis.

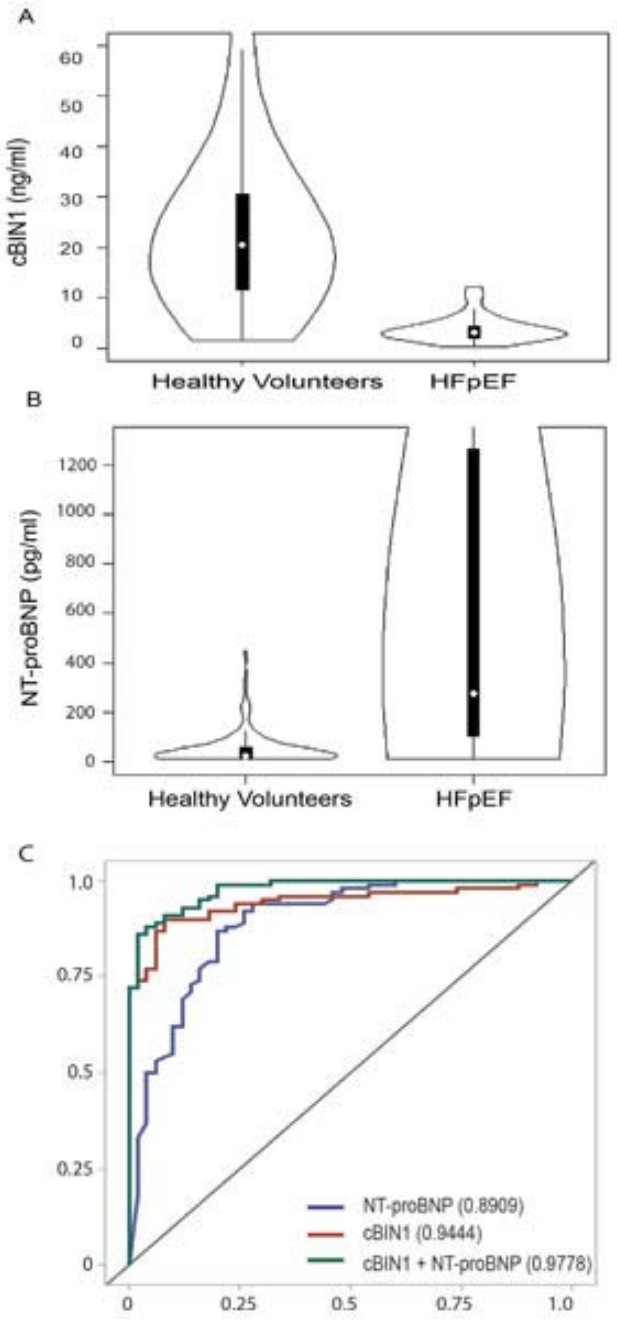
Funding Acknowledgements: American Heart Association, Department of Defense, National Institute of Health, National Heart, Lung, and Blood Institute

Introduction: Heart failure with preserved ejection (HFpEF) is an elusive pathological entity due to lack of diagnostic tools or evidence-based therapies. It accounts for half of the heart failure burden worldwide. Key underlying pathophysiological mechanism in heart failure has been shown to be abnormal calcium regulation. We postulated that a newly found molecular player, Bridging Integrator 1 and particularly its cardiac isoform cBIN1, could be the long-sought marker of myocardial health. cBIN1 is a membrane scaffolding protein which organizes the T-tubule dyads - essential players in calcium cycling.

Methods: The studied cohort (referred to as HFpEF) consisted of 52 patients with various forms of cardiomyopathy with preserved left ventricular (LV) ejection fraction (EF) and stable chronic heart failure symptoms. The comparator cohort included 104 age and sex matched healthy volunteers. IRB approval and full informed consent was obtained from all participants. cBIN1 concentration was determined with a cBIN1 specific ELISA which involved mouse monoclonal anti-cBIN1 exon 17 as capture antibody and a HRP-conjugated exon 13-specific detection antibody. The assay above has been previously validated in our lab. Detailed patient characteristics were obtained per chart review. The HFpEF patients were followed retrospectively for a minimum of 1 year post cBIN1 lab draw or until their most recent clinic visit, whichever is longer.

Results: Plasma cBIN1 levels are substantially reduced in the HFpEF population with a median of 1.62 ng/mL as compared to 10.24 ng/mL in the healthy cohort. Unlike pro-BNP which shows a wider variation in the sick patient cohort, cBIN1 appears to be a better diagnostic test as demonstrated by higher positive and negative predictor value per receiver operator curve. Half of the HFpEF patients had an echocardiogram (TTE) performed within 3 months of cBIN1draw. LV mass as estimated by standard TTE parameters showed an inverse correlation with cBIN1 and no correlation with pro-BNP. cBIN1 correlated well with NYHA class of symptoms and severity of diastolic dysfunction. In addition, cBIN1 level of less than 1.6 was found to be good prognosticator of worse outcomes as shown by the Kaplan Meyer curves of cardiovascular hospitalizations.

Conclusion: cBIN1 is a crucial player in myocardial calcium signaling and it also appears to be a promising new marker for myocardial health. In the current cohort of 52 patients with preserved ejection fraction it performed as well as pro-BNP and showed a better inverse correlation with LV hypertrophy. Additionally cBIN1 < 1.6 appears to be a good prognostic indicator of worse clinical outcomes.



cBIN1 marker in HFpEF patients

Dermal interstitial alterations in patients with heart failure and reduced ejection fraction are associated with volume status

P Petra Nijst[1]; P Martens[1]; P Hilkens[2]; M Olinevic[2]; M Dupont[1]; W Tang[3]; I Lambrichts[2]; JP Noben[2]; W Mullens[1]
[1]*Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium*; [2]*Biomedical Research Institute, Faculty of Medicine and Life Sciences, Hasselt (3500), Belgium*; [3]*Cleveland Clinic Foundation, Cleveland, United States of America*

Background: The occurrence of edema is poorly correlated with cardiac filling pressure in heart failure patients with reduced ejection fraction (HFrEF). Other factors than increased capillary hydrostatic pressure might also determine the occurence of extracellular edema. Large networks of glycosaminoglycans (GAGs) in the interstitium help to regulate water homeostasis. Factors present in HFrEF might increase GAG density and sulphation, leading to interstitial GAG-network dysfunction and fluid accumulation.
Objectives: The aims of this study are to demonstrate in HFrEF patients 1) that interstitial GAG density is increased, 2) that GAG-networks can become dysfunctional contributing to interstitial fluid accumulation and the clinical presentation of edema, and 3) that there is a link between GAG dysfunction and the renin-angiotensin-aldosterone system (RAAS).
Methods: Two punch biopsies of the skin of the lower leg were obtained in healthy subjects (n = 18) and HFrEF patients (n = 29, Left ventricular ejection fraction 32 ± 10%). Alcian blue staining and immunostaining for the angiotensin II type 1 receptor was performed. After obtaining tissue water content (TWC), total interstitial GAG (Uronic Acid (UA)) and sulphated GAG (sGAG) density were quantified with ELISA techniques. A venous blood sample, clinical investigation and echocardiography were simultaneously obtained.
Results: Significant higher interstitial GAG density and sulphation was observed in HFrEF patients compared to healthy controls (UA: 13.1 ± 4.2 vs 9.6 ± 1.6 mg/mg ; $p < 0.0001$; sGAG 15.9 ± 5.9 vs 10.1 ± 1.2 mg/mg; $p = 0.0021$) and in HFrEF patients with versus without presence of lower extremity edema (Table 1). In healthy subjects TWC was stable over a range of interstitial GAG density. In contrast, there was a strong correlation between TWC and UA in HFrEF patients (Figure 1A.). Expression of the angiotensin II type 1 receptor is found on dermal cells responsible for GAG synthesis. Moreover, use of ACE-inhbitors/ARB is associated with significantly lower levels of interstitial GAGs in HFrEF patients (Figure 1B and C).
Conclusion: Interstitial GAG concentration is increased in HFrEF patients compared to healthy control subjects, and correlated with tissue water content and clinical signs of volume overload. Expression of the angiotensin II type 1 receptor was demonstrated on dermal cells. ACE-inhibitors/ARB use is associated with lower levels of interstitial GAGs. A better appreciation of the interstitial compartment might improve current management of volume overload in HF.

	HFrEF without edema (n = 13)	HFrEF with edema (n = 16)	p-value

Employment status at time of first hospitalization for heart failure independently predicts mortality and rehospitalization for heart failure

RASMUS Roerth[1]; EL Fosbol[1]; UM Mogensen[1]; K Kragholm[2]; GH Gislason[3]; C Torp-Pedersen[2]; L Kober[1]; SL Kristensen[1]
[1]*Rigshospitalet - Copenhagen University Hospital, Heart Center, Department of Cardiology, Copenhagen, Denmark*; [2]*Aalborg University, Department of Health, Science and Technology, Aalborg, Denmark*; [3]*Gentofte University Hospital, Department of cardiology, Gentofte, Denmark*

Background: Employment status at time of first heart failure (HF) hospitalization may be an indicator of both self-perceived and objective health status as well as it may potentially impact subsequent disease trajectory in terms of adherence to evidence based therapy and cardiac rehabilitation. In this study we set out to examine the association between employment status and the risk of all-cause mortality and recurrent HF hospitalization in a nationwide cohort of HF patients.
Methods: We identified all patients of working age (18-60) with a first HF hospitalization between 1997-2012 in Denmark and stratified them according to whether they were part of the workforce or not. The primary outcome was death and secondary outcome was recurrent HF hospitalization. Cumulative incidence curves and cox regression models were used to assess outcomes. All analyses were adjusted for age, sex, educational level and comorbidity.
Results: Of 21455 patients with a first hospitalization for HF, 11880 (55%) were part of the workforce at baseline. Patients in the workforce were younger (median age 53 vs 55), more were men (76% vs 65%) and fewer had ischemic heart disease (21% vs 28%) and diabetes (12% vs 23%). During a mean follow-up of 1005 days (SD 742), 1883 (16%) died in the workforce group and 2930 (31%) in the non-workforce group, unadjusted Hazard ratio(HR) 2.09 (95% CI 1.97-2.21). Rehospitalization for HF occurred in 4705 (40%) in the workforce group and 3998 (42%) in the non-workforce group, unadjusted HR 1.10 (95% CI 1.05-1.14). In adjusted analyses, HF patients not part of the workforce at baseline had a 1.5 times increased risk of death (Hazard ratio: 1.49 [1.40–1.59]; $P < 0.0001$; figure 1) whereas the risk of rehospitalization for HF was less markedly increased (Hazard ratio: 1.12 [1.07–1.17]; $P < 0.0001$). Not being part of the workforce was associated with a higher likelihood of death than history of diabetes and stroke; figure 1.
Conclusion: Employment status at time of first HF hospitalization is associated with subsequent mortality and to a lesser degree recurrent HF hospitalization, even after multivariable adjustment including comorbidity and socioeconomic factors.

Extracellular volume expansion in cardiac amyloidosis: validation of cardiac magnetic resonance T1 mapping against endomyocardial biopsy

F Franz Duca[1]; C Zotter-Tufaro[1]; AA Kammerlander[1]; A Panzenboeck[1]; S Aschauer[1]; B Boerries[1]; H Agis[2]; R Kain[3]; D Bonderman[1]; J Mascherbauer[1]
[1]*Medical University of Vienna, Cardiology, Vienna, Austria*; [2]*Medical University of Vienna, Oncology, Vienna, Austria*; [3]*Medical University of Vienna, Pathology, Vienna, Austria*

Background: Cardiac amyloidosis (CA) is caused by extracellular deposition of amyloid fibrils within the myocardium, thus expanding the extracellular volume (ECV). The gold standard for ECV quantification is the histological assessment of

endomyocardial biopsies (EMB). However, this method is limited by procedural risk and therefore not ideal for the monitoring of response to treatment. Cardiac magnetic resonance (CMR) T1 mapping has recently been shown to allow accurate ECV measurement in various cardiac diseases. Thus far it has not been investigated weather CMR-ECV accurately measures ECV in CA.

Methods: Between July 2011 and December 2016, 21 CA patients were enrolled in our study. All patients underwent EMB and CMR for invasive and non-invasive ECV quantification. EMBs were stained with modified Trichrome (n = 21). Additionally, immunohistochemical staining (n = 15) with specific amyloid antibodies was performed. ECV in EMBs was quantified using TissueFAXS software in Trichrome stained (Histo-ECV) as well as in immunohistochemically stained samples (Immunohisto-ECV). ECV by CMR was quantified with T1 mapping using the Modified Look-Locker Inversion recovery (MOLLI) sequence (MOLLI-ECV). Spearman's correlation and Bland-Altman plots were used for correlation analysis and assessment of agreement.

Results: The study population consisted of 7 (33.3%) wild-type transthyretin and 14 (66.6%) light chain CA patients. Median Histo-ECV was 50.2% (IQR: 39.7 – 59.8), median Immunohisto-ECV was 37.4% (IQR: 23.8 – 55.2) and median MOLLI-ECV was of 48.4% (IQR: 41.7 - 59.2). MOLLI-ECV was strongly correlated with Histo-ECV (r=0.774, p < 0.001, Fig.1A) and Immunohisto-ECV (r=0.814, p < 0.001, Fig. 1C). Additionally, MOLLI-ECV showed good agreement with Histo-ECV (Fig. 1B) as well as Immunohisto-ECV (Fig. 1D).

Conclusion: MOLLI-ECV accurately reflects the amount of amyloid deposited within the myocardium. In CA patients, ECV by CMR has the potential of becoming a monitoring tool for new therapeutic agents.

Significant functional mitral regurgitation affects left atrial function and determines clinical status and pulmonary hypertension in HFrEF patients

G Palmiero[1]; L Ascione[1]; G Carlomagno[1]; R Ascione[1]; A Ferro[1]; P Caso[1]
[1] *AO dei Colli-Monaldi Hospital, Department of Cardiology, Naples, Italy*

Functional mitral regurgitation (FMR) is a well-known prognostic factor in patients with HFrEF. Similarly, the left atrial function and the pulmonary hypertension are determinants of outcomes and clinical status in this setting. Aim of this study is to explore the possible interplay between those factors.

Methods: 117 patients with HFrEF, sinus rhythm and FMR were studied with echocardiography. Patients dichotomized based on the presence of SFMR (3-4+). LA volumes were measured at three time-points and the different components of LA function were thus calculated (See Figure 1). The deformation indices were calculated using 2D speckle-tracking.

Results: Patients with SFMR displayed: worse clinical status, larger LV and LA volumes and more impaired LA reservoir and contractile function. LAF was inversely correlated with NYHA class and sPAP. Univariate and multivariate linear regression analysis showed severe FMR, TLAEF and LV filling pressures as predictors of PH, while LA contractile function and the presence of PH were independent predictors of NYHA class.

Conclusions: Our data suggest that the presence of SFMR seems to affect LA reservoir and contractile function HFrEF patients, independently of LVEF. SFMR and the LA dysfunction may play a complimentary role in determining PH and functional impairment in this population.

Refractory electrical storm rescued by venoarterial extracorporeal membrane oxygenation

G Baudry[1]; G Lebreton[1]; G Hekimian[1]; N Brechot[1]; A Nieszkowska[1]; CE Luyt[1]; JL Trouillet[1]; P Leprince[1]; A Combes[1]; M Schmidt[1]
[1] *Hospital Pitie-Salpetriere, Paris, France*

Introduction: Electrical storm refers to a state of cardiac electrical instability characterized by multiple episodes of ventricular tachycardia or ventricular fibrillation within 24 hours despite antiarrhythmic drugs or device-related therapies (defibrillation or anti-tachycardia pacing) and for which overall mortality was 22-82% in previous series. Triggering factors for this condition include worsening heart failure, early postoperative period, electrolyte abnormalities, and myocardial ischemia. Since Venoarterial extracorporeal membrane oxygenation (VA-ECMO) can be used as a rescue therapy in this setting, we reviewed our experience and assessed the outcomes of patients who received VA-ECMO for refractory electrical storm in our center.

Method: We retrospectively collected demographic, pre ECMO, post ECMO data and in-ICU mortality of patients who received VA-ECMO for refractory electrical storm in our 26-bed intensive care unit from March 2007 to March 2015.

Results: Of the 1286 VA-ECMO patients treated in our ICU during the study period, 38 had ECMO for refractory electrical storm after a median time of 24 (8-168) hours. Median age, SAPS II and SOFA scores at admission were 58 (49-62) years, 80 (55-87) and 13 (11-15), respectively. Electrical storm was secondary to myocardial infarction in 26 (68%) patients. Cannulation was performed during and after cardiac arrest in 5 (13%) and 17 (45%) patients, respectively. Overall ICU survival was 47%

(one patient got a heart transplant and one a left ventricular assist device). Survivors spent 5 (4-10) days on ECMO, 14 (9-25) days in ICU and 52 (34-59) days in hospital. Patients discharged alive from the ICU had lower body mass index, lower SOFA score before ECMO and at day 1 and received less inotropes in the 24h following cannulation ($p = 0.02$). No difference was identified between alive and deceased patients regarding pre-ECMO anti-arrhythmic treatments and number of electrical shocks.

Conclusion: Refractory electrical storm is a very severe condition that might be rescued by VA-ECMO support. The 47% ICU survival rate we observed in this series parallels that of other cardiogenic shock populations rescued by VA-ECMO. Earlier ECMO support in the course of the disease might allow a rapid decrease in inotrope doses and less organ failures, which were both associated with more favorable outcomes.

The dimer interface of ERK1/2 provides a potential strategy for selective inhibition of pathological cardiac hypertrophy

A Tomasovic[1]; S Kramer[1]; M Huemmert[1]; HA Katus[2]; O Mueller[2]; K Lorenz[3]
[1]*University of Wuerzburg, Institute of Pharmacology and Toxicology, Wuerzburg, Germany*; [2]*University Hospital of Heidelberg, Internal Medicine III, Heidelberg, Germany*; [3]*Leibniz-Institute for Analytical Sciences - ISAS, Dortmund, Germany*

Background and purpose: The extracellular signal-regulated kinases 1 and 2 (ERK1/2) have a central role in cardiac hypertrophy. This involves ERK1/2 dimerization, a trigger for an autophosphorylation of ERK1/2 at threonine 188 (pERKT188), which was shown to induce pathological hypertrophy. However, it is well known that ERK1/2 are essential for cardiomyocyte protection from cell death. Therefore, it is needed to selectively interfere with the hypertrophic ERK1/2 function. Here, we investigated, the ERK dimer interface as potential strategy for selective pERKT188 inhibition.
Methods: To evaluate the impact of monomeric ERK on cardiac integrity, we used the dimerization-deficient ERK2Δ174/177 mutant and a peptide that interferes with ERK dimerization. Cardiomyocyte size, ERK1/2 activity and target activation by Western blot, TUNEL positive cells and ERK localization using confocal microscopy were analyzed. Mice with cardiac overexpression of ERK2Δ174−177 (ERK2Δ174−177-tg) were generated and characterized in response to transverse aortic constriction (TAC) or running wheel exercise. An adeno-associated virus serotype 9 (AAV9) vector construct was used to evaluate the peptide.
Results: Monomeric ERK2Δ174−177 significantly reduced hypertrophic response to phenylephrine (PE) stimulation in neonatal rat cardiomyocytes (NRCM) but, interestingly, did not exacerbate cardiomyocyte death in contrast to ERK1/2 inhibition by PD98059. Similarly in vivo, ERK2Δ174−177 overexpression attenuated the hypertrophic response to TAC and did not increase apoptosis compared to controls. Moreover, cardiac function of ERK2Δ174−177-tg was well preserved; and even after dobutamine infusion, speed of contraction and relaxation were indistinguishable to control mice. In addition, mRNA levels of collagen and brain natriuretic peptide (BNP) were significantly reduced in ERK2Δ174−177-tg after TAC. In contrast to TAC, a physiological stimulus, i.e. running exercise, did not impair cardiac growth in ERK2Δ174−177-tg.
As monomeric ERK2 seems "save" for the heart, we generated a peptide that interferes with ERK dimerization to test the impact of ERK dimers. In line with our hypothesis, the peptide prevented pERKT188 and nuclear translocation of ERK2. In NRCM, the peptide also reduced pERKT188 and led to an attenuated hypertrophic response to PE compared to control cells. Of note, the peptide neither impaired ERK1/2 activation nor cardiomyocyte survival, but efficiently inhibited nuclear ERK target phosphorylation. The potency of the peptide in vivo was investigated in TAC-induced heart failure: AAV9-mediated gene transfer protected from pathological cardiac hypertrophy, an increase of heart failure markers and impaired cardiac function and even decreased cardiomyocyte apoptosis compared to control mice.
Conclusion: These data indicate that the ERK interface is a promising target for the prevention of ERK1/2-mediated pathological cardiac growth without cardiac adverse effects.

Hypercontractile heart and delayed cardiomyopathy in mice with cardiac-specific ablation of the RIalpha subunit of cAMP-dependent protein kinase

I Bedioune[1]; S Karam[1]; A Varin[1]; M Gandon-Renard[1]; P Lechene[1]; D Mika[1]; P Mateo[1]; G Pidoux[1]; J Leroy[1]; C Stratakis[2]; JJ Mercadier[1]; JP Benitah[1]; AM Gomez[1]; R Fischmeister[1]; G Vandecasteele[1]
[1]*Université Paris-Sud, Université Paris-Saclay, Signaling and Cardiovascular Pathophysiology, INSERM UMR-S1180, Châtenay-Malabry, France*; [2]*National Institutes of Health, Eunice Kennedy Shriver National Institute of Child Health & Human Development, Bethesda, United States of America*

Heart failure (HF) is a major health problem in which excessive activation of β-adrenergic receptors (β-AR) and the cAMP-dependent protein kinase (PKA) are critically involved. PKA is a heterotetramer of two regulatory (R) and two catalytic (C) subunits and comprises two subtypes, PKAI and PKAII, defined by the nature of their regulatory subunits, RI and RII respectively. Whereas PKAII is thought to play a key role in β-AR regulation of cardiac contractility, the function of PKAI remains unclear. To address this question, we generated mice with cardiomyocyte-specific and conditional invalidation of the Prkar1α gene, encoding for the RIα subunit of PKA, the predominant constituent of PKAI in the heart. Tamoxifen injection (40 mg/kg/day during 2 days) in 8 weeks old mice resulted in a >70% decrease in RIα protein without modification of other PKA subunits. In Langendorff-perfused heart preparations, spontaneous heart rate was similar whereas basal LV pressure and maximal rate of contraction, as well as maximal rate of relaxation were increased >2-fold in mutant (RIα KO) versus wild type (WT) mice (N=9 in each group, $p < 0.05$). In paced hearts (650 bpm), β-AR stimulation with isoprenaline (Iso) increased cardiac contraction >3-fold in WT versus 1.5-fold in RIα KO. Basal L-type Ca2+ current density was increased in ventricular myocytes from RIα KO and β-AR stimulation (Iso, 30 nM, 15s) was decreased by ~50% ($p < 0.05$, n=38 cells for WT and 40 for RIα KO). The relaxation phase of Ca2+ transients was accelerated, along with a 3-fold increase in PLB phosphorylation at Ser16 (PKA site) in RIα KO myocytes. With age, RIα KO mice develop a dilated cardiomyopathy with depressed ejection fraction, massive interstitial fibrosis, cardiac dilation, and pulmonary congestion which eventually led to death in 50% of RIα KO mice at 50 weeks (versus 0% in WT, $p < 0.01$). These results indicate that PKAI plays a previously unsuspected role in cardiac excitation-contraction coupling and identify RIα as a critical buffer of C subunits in the heart.

812

Rac1 regulates mineralocorticoid receptor mediated pro-fibrotic remodeling through 11beta hydroxysteroid dehydrogenase type 2

D Daniel Lavall[1]; N Jacobs[1]; A Kazakov[1]; U Laufs[1]; M Boehm[1]
[1]*Saarland University Hospital, Department of Internal Medicine III, Cardiology, Homburg, Germany*

Purpose: The aim of the study was to characterize the role of Rac1 GTPase for the mineralocorticoid receptor (MR) mediated pro-fibrotic remodeling in atrial fibrillation.
Methods and Results: Transgenic mice with cardiac overexpression of constitutively active Rac1 (RacET) develop an age-dependent phenotype with atrial dilatation, fibrosis and atrial fibrillation. Expression of MR was similar in RacET and wild-type (WT) mice. The expression of 11β-HSD2 was up-regulated in the atria ($665 \pm 378\%$ compared to WT, $p < 0.05$) and the left ventricles ($452 \pm 415\%$, $p < 0.05$) of RacET mice. Statin treatment inhibiting Rac1 geranylgeranylation decreased 11β-HSD2 expression ($185 \pm 25\%$ in statin vs. $324 \pm 94\%$ in vehicle-treated RacET, $p < 0.05$). Rac1-bound 11β-HSD2 was enhanced in RacET compared to WT mice ($167 \pm 20\%$, $p < 0.01$). Samples of human left atrial myocardium showed a positive correlation between Rac1 activity and 11β-HSD2 expression (r=0.7169, $p < 0.05$). In cultured H9c2 cardiomyocytes, Rac1 activation with L−buthionine sulfoximine increased ($174 \pm 47\%$, $p < 0.05$), Rac1 inhibition with NSC23766 decreased 11β-HSD2 expression ($21 \pm 7\%$, $p < 0.05$). Connective tissue growth factor (CTGF) up-regulation induced by aldosterone was prevented with NSC23766 ($312 \pm 88\%$ vs. $77 \pm 6\%$, $p < 0.01$). Cardiomyocyte transfection with 11β-HSD2 siRNA abolished the aldosterone-induced CTGF up-regulation ($181 \pm 35\%$ vs. $123 \pm 9\%$, $p < 0.05$). Aldosterone-stimulated MR nuclear translocation was blocked by the 11β-HSD2 inhibitor carbenoxolone ($213 \pm 70\%$ vs. $46 \pm 45\%$, $p < 0.01$). In cardiac fibroblasts, nuclear MR translocation was inhibited by NSC23766 (Aldosterone, 0.84 ± 0.69, vs. Aldosterone + NSC23766, 0.21 ± 0.17, $p < 0.001$) and spironolactone (0.25 ± 0.3, $p < 0.001$). NSC23766 prevented the aldosterone-induced up-regulation of CTGF ($182 \pm 55\%$ vs. $39 \pm 5\%$, $p < 0.01$) and fibronectin ($181 \pm 43\%$ vs. $94 \pm 27\%$, $p < 0.05$).
Conclusion: Rac1 GTPase regulates 11β-HSD2 expression, MR activation and MR-mediated pro-fibrotic signaling.

Funding Acknowledgements: National Institutes of Health R01 HL123647, Stealth BioTherapeutics

Background: Elamipretide is a novel mitochondria-targeting peptide currently being investigated in several heart failure clinical trials. This peptide has shown efficacy in improving bioenergetics in explanted failing human heart and across pre-clinical heart failure models. In spite of these promising findings, the mechanism of action is not fully understood. Electron transport chain proteins typically aggregate into functional 'supercomplexes'. Supercomplex formation is postulated to directly influence mitochondrial ROS production, and decreased supercomplex formation has been observed in several cardiac pathologies.
Purpose: Determine whether elamipretide preserved supercomplex-dependent bioenergetics and lowered ROS emission in cardiac mitochondria.
Methods: Mitochondrial supercomplexes were isolated from post-ischemic rat left ventricle, extracted from the blue-native PAGE gel, and placed in a high-resolution respirometer to determine electron transport chain complex-dependent mitochondrial respiration. In separate studies, measurement of mitochondrial ROS production was comprehensively determined using elamipretide concentrations ranging from 1uM to 1pM.
Results: Mitochondrial supercomplex density was significantly lower in post-ischemic hearts compared to control (2321 ± 374 v. 3300 ± 153 AU, respectively; $P < 0.05$), and preserved with elamipretide (3238 ± 173 AU). Complex-I dependent respiration was significantly reduced in supercomplexes isolated from post-ischemic mitochondria (complex I-dependent respiration decreased to $48 \pm 8\%$ of control, $P < 0.05$). Elamipretide treatment significantly improved complex I-dependent respiration to $85 \pm 24\%$ of normoxic control. Complex IV-dependent supercomplex respiration was not impaired in post-ischemic mitochondria, and there was no discernible effect of elamipretide on complex IV-dependent respiration. In separate studies elamipretide significantly reduced mitochondrial production of ROS from complex I. Complex I-mediated ROS production was 5.10 ± 0.13 nmol/mg in untreated mitochondria, and reduced with 1nM (4.16 ± 0.05nmol/mg), 100pM (3.65 ± 0.05nmol/mg), and 10pM (3.53 ± 0.04nmol/mg) elamipretide ($P < 0.05$ for 1nM-10pM). No effect was observed on complex I-dependent ROS production with 1pM elamipretide.
Conclusions: Elamipretide preserved supercomplex integrity, resulting in improved electron transport chain function and reduced emission of ROS. These data highlight the therapeutic potential of this peptide to lower mitochondrial ROS production and improve bioenergetics in cardiac pathology.

Introduction: In response to heart failure (HF), the heart reacts by returning to a more fetal-like gene profile, which is thought to take place by repressing adult and re-expression of fetal genes.
Purpose: In this study we set out to further characterize the fetal-like gene program in HF, and investigate whether identified genes can serve as a therapeutic targets.
Methods: and Results: Genes associated with the fetal-like gene program were identified by means of next-generation RNA-sequencing on RNA from murine cardiac tissue during development and ischemia/reperfusion (IR) induced HF. Our screen identified 5-oxoprolinase (OPLAH), a member of the γ-Glutamyl cycle, that functions by scavenging 5-oxoproline and converting it to glutamate. OPLAH was shown to be expressed during cardiac development, while repressed in cardiac disease. OPLAH was regulated by the nuclear receptor, Estrogen related receptor alpha (ERRα). Administration of the ERRα antagonist, XCT-790, to human ESC-derived cardiomyoctes resulted in a $\pm 60\%$ reduction in OPLAH expression and thereby increasing oxidative stress. OPLAH levels in cultured cardiomyocytes were manipulated by adenoviral transduction of short-hairpin RNA directed at OPLAH or human OPLAH over-expression (hOPLAH) constructs. A depletion in OPLAH lead to a 2-fold increase in oxidative stress, while over-expression displayed a cardio-protective effect. To test the in vivo physiological effects of OPLAH over-expression, αMHC-hOPLAH (TG) mice were developed and exposed to IR injury. The TG mice had less oxidative stress upon myocardial infarction and smaller infarct sizes, ultimately resulting in an improved cardiac function, assessed by cardiac MRI and invasive hemodynamic measurements (Fig 1). Furthermore, the increase in oxidative stress observed in the wild-type (WT) littermates upon cardiac injury was linked to elevated levels of tissue and plasma 5-oxoproline, measured by LC-MS. Interestingly, when measured in a large cohort of HF patients, elevated plasma levels of 5-oxoproline were associated with an impaired outcome (Fig 2).
Conclusions: Collectively these data describe the identification of OPLAH, a novel cardiac gene involved in oxidative stress, possessing a cardio-protective effect post myocardial infarction, and its substrate 5-oxoproline as a putative novel circulating biomarker for HF.

Funding Acknowledgements: National Research, Development and Innovation Office (NKFIH) of Hungary (K 120277)

Background: In contrast with pathological myocardial hypertrophy, long term exercise-induced cardiac enlargement is associated with functional amelioration. Thus understanding the cellular and molecular processes leading to physiological hypertrophy induced by exercise training might provide a novel therapeutic approach to prevent or treat heart failure.
Purpose: We aimed at determining left and right ventricular (LV and RV) cardiac sarcomeric modifications at cellular and molecular levels in a rat model of athlete's heart and additionally, examining the reversibility of the observed alterations.
Methods: Young rats were divided into control (Co) and exercised (Ex) groups. Trained rats swam 200 min/day for 12 weeks. To investigate reversibility, detrained rats remained sedentary for 8 weeks after completion of the training protocol. LV morphology was examined by echocardiography, while in vivo hemodynamic porperties were provided by LV pressure-volume analysis. Force assessments on isolated permeabilized cardiomyocytes and molecular biological measurements (qRT-PCR, Western blot) were applied to reveal underlying mechanisms.
Results: Echocardiographic and post mortem measured organ weight data confirmed training-induced cardiac hypertrophy, while pressure-volume analysis revealed increased LV contractility in exercised hearts. The $Ca2+$-activated force production of isolated cardiomyocytes was improved (Factive: LV 28.0 ± 1.4 kN/m^2 Ex vs. 15.8 ± 0.8 kN/m^2 Co, $P < 0.05$; RV 16.8 ± 1.1 kN/m^2 Ex vs. 12.1 ± 1.0 kN/m^2 Co, $P < 0.05$) along with increased $Ca2+$ sensitivity and rate constant of force redevelopment in trained rats. $Ca2+$-independent passive tension did not differ between the groups. Exercise training did not affect myocardial gene expression of α- and β-myosin heavy chain (MHC). Cardiac troponin I phosphorylation was decreased (cTnI relative phosphorylation level: LV 0.66 ± 0.06 Ex vs. 1.00 ± 0.02 Co, $P < 0.05$; RV 0.65 ± 0.05 Ex vs. 1.00 ± 0.03 Co, $P < 0.05$), whereas the phosphorylation of titin and cardiac myosin binding protein-C was not altered in physiological hypertrophy. Complete reversibility of the observed alterations was detected in detrained rats.
Conclusions: Exercise-induced hypertrophy is associated with increased $Ca2+$-activated force and $Ca2+$ sensitivity of force production of LV and RV cardiomyocytes, which might be associated with hypophosphorilation of cardiac troponin I. Cellular and molecular alterations regressed completely after 8 weeks of detraining.

MODERATED POSTER SESSION 3 – DIAGNOSIS

816

Biomarker profiling in heart failure with mid-range ejection fraction

P Moliner[1]; J Lupon[1]; J Barallat[1]; M De Antonio[1]; J Nunez-Villota[2]; M Domingo[1]; E Zamora[1]; S Altimir[1]; C Pastor[1]; M Rodriguez[1]; M Boldo[1]; M Puertas[1]; MI Troya[1]; V Diaz[1]; A Bayes-Genis[1]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain; *[2]University Hospital Clinic of Valencia, Valencia, Spain*

Background: Recently the ESC created a new classification of heart failure (HF) according to left ventricular ejection fraction (LVEF): reduced (HFrEF) when LVEF is <40%, mid-range (HFmrEF) when LVEF is between 40% and 49%, and preserved (HFpEF) when LVEF is >50%. The intermediate group of HFmrEF has been less studied in the past.
Purpose: We sought to explore a panel of biomarkers in patients with HF based on 2016 ESC HF classification and assess whether they have different prognostic value in HFmrEF.
Patients and methods: 1069 patients were included in the study (age 66.2 ± 12.8 years, 72% male, 51% of ischemic aetiology, mean LVEF 33.5% ± 13.3, 36% with diabetes mellitus). Serum concentrations of NTproBNP (N=1030), high-sensitivity troponin T (hs-TnT) (N=803), ST2 (N=814), Galectin-3 (N=811), high-sensitivity C reactive protein (hs-CRP) (N=773), Cystatin-C (N=804), Neprilysin (N=1069), and soluble transferrin receptor (sTfR) (N=794) were measured in consecutive ambulatory HF patients followed during 4.9 ± 2.8 years (6.6 ± 2.3 for alive patients). All-cause and cardiovascular death and the composite all-cause death or HF-related hospitalization and CV death or HF-related hospitalization were assessed.
Results: Biomarkers levels according to ESC HF classification are shown in the table. NTproBNP in HFmrEF patients was significantly lower than in HFrEF patients and was similar than in HFpEF patients. In contrast, and remarkably, all the other biomarkers were similar between HFrEF and HFmrEFpatients. On the other hand, ST2 and Cystatin-C were significantly lower in HFmrEF patients than in HFpEF patients and Galectin-3 and STfR also tended to be lower, without achieving statistical significance.
Conclusions: Although HFmrEF patients are acknowledged frequently as intermediate between HFrEF and HFpEFclinically, from a multi biomarker point of view HFmrEF seems quite similar to HFrEF except for NTproBNP, that was lower.

Blood concentration of biomarkers

	HFrEF (1) (N=800)	HFmrEF (2) (N=134)	HFpEF (3) (N=135)	P (1-2)	P (2-3)

Aim: Chronic heart failure (CHF) is a life-threatening disease, partly due to sudden cardiac death (SCD). Implantable cardioverter defibrillators (ICD) for primary prevention of SCD have improved overall survival of CHF patients. However, a high percentage of patients never receives appropriate ICD therapy. This prospective multicentre study evaluated whether cardiac sympathetic activity assessed by planar 123I-mIBG scintigraphy could optimize selection for ICD implantation.
Materials and Methods: 135 stable CHF subjects (age 64.5 ± 9.3 years, 79% male, LVEF 25 ± 6%) referred for ICD implantation for primary prevention in 13 European institutions were enrolled. All subjects underwent planar and SPECT 123I-mIBG scintigraphy. Planar images were acquired at 15 minutes (early) and 4 hours (late) after administration of 123I-mIBG. Early and late heart-to-mediastinum (H/M) ratio, 123I-mIBG washout (WO) and late summed scores were calculated. Cross-calibrated phantom study-data were used to correct for different gamma camera-collimator use. The primary endpoint was appropriate ICD therapy. The secondary endpoint was the combined endpoint of all first cardiac events: appropriate ICD therapy, progression of heart failure (HF) and cardiac death
Results: During a median follow-up of 30 months (6-68 months), 24 subjects (17.8%) experienced a first cardiac event (appropriate ICD therapy [12], HF progression [6], cardiac death [6]). The combination of late H/M ratio (HR 0.461 [0.281-0.757]) and LVEF (HR 1.052 [1.021-1.084]) was significantly associated with freedom of appropriate ICD therapy ($p < 0.001$). Late H/M ratio was independently associated with the combined endpoint (HR 0.135 [0.035-0.517], $p = 0.001$).
Conclusion: Planar myocardial 123I-mIBG-derived late H/M ratio and LVEF were associated with freedom of appropriate ICD therapy. In addition there was a significant association between late H/M ratio and the combined endpoint. Therefore, 123I-mIBG scintigraphy seems to be able to optimize the selection of CHF subjects who might benefit from ICD implantation.

Table 1

	Variable	HR (95% CI)	X2	p-value
Freedomofappropriate ICDtherapy	LVEFLate H/M ratio	1.052 (1.021-1.084) 0.461 (0.281-0.757)	17.542	<0.001
Combinedendpoint	Late H/M ratio	0.135 (0.035-0.517)	10.136	0.001

Multivariate Cox regression analysis for freedom of appropriate ICD therapy and combined endpoint of first cardiac events

Enhanced insulin clearance in advanced non-diabetic heart failure

V Vojtech Melenovsky[1]; J Benes[1]; A Tura[2]; B Borlaug[3]; K Kovar[1]; T Pelikanova[1]
[1]Institute for clinical and experimental medicine, Prague, Czech Republic; *[2]CNR, Institute for Neuroscience, Padua, Italy*; *[3]Mayo Clinic, Dept of Cardiovascular Disease, Rochester, United States of America*

Funding Acknowledgements: Supported by Grants GA15-14200S (GACR) and 16-27496A (AZVCR)

Background: The relevance of impaired glucose homeostasis intrinsically caused by heart failure (HF) are poorly understood. The goal of the study were to examine glucose regulation in non-diabetic (DM) patients with advanced HF and to analyze pancreatic β-cell secretory function.
Methods: 140 advanced HF patients without known DM and 21 sex-, age- and BMI-matched controls underwent body composition (DEXA) and oral glucose tolerance (OGT) assessment with measurements of insulin, glucagon, glucagon-like peptide (GLP-1) and pro-insulin split product C-peptide in 0, 60, 90 and 120 min.

Pancreatic insulin secretion was estimated using C-peptide level deconvolution model.
Results: Compared to controls, HF patients were more insulin resistant. Insulin secretion was not impaired (by modeling of β-cell secretory response) and positively correlated with insulin resistance (HOMA-IR), GLP-1 and glucagon. Despite elevated insulin secretion, fasting insulin decreased with increasing HF severity. The ratio of fasting insulin to C-peptide (IRI/CP ratio), that reflect the balance between insulin production and clearance (in liver and systemic circulation), was decreasing with NYHA class (Figure left) or terticles of natriuretic peptides. IRI/CP ratio correlated with low cardiac output, liver impairment, right ventricular dysfunction, BMI (Figure right) and preceeding change of body weight.
Conclusions: Patients with advanced non-diabetic HF may have enhanced insulin clearance, linked to right heart failure. Because insulin is an important anabolic hormone, enhanced insulin degradation in congested liver may be one of the mechanisms promoting cardiac cachexia in advanced HF.

Lifelong arrhythmic risk stratification in arrhythmogenic right ventricular cardiomyopathy: distribution of events and impact of periodical reassessment

C Cappelletto[1]; D Stolfo[1]; A De Luca[1]; B Pinamonti[1]; G Barbati[1]; A Pivetta[1]; M Gobbo[1]; F Brun[1]; M Merlo[1]; G Sinagra[1]
[1]University Hospital Riuniti, Cardiovascular department, Trieste, Italy

Funding Acknowledgements: We deny any relation with the industry and any source of financial support

Aims: The arrhythmic risk stratification of Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) remains controversial. We evaluated the long-term distribution of life-threatening arrhythmic events assessing the impact of periodical risk reassessment.
Methods: Ninety-eight ARVC patients with no previous major ventricular arrhythmias were retrospectively analyzed. Patients were assessed at baseline, at 22 (interquartile range [IQR] 16-26), 49 (IQR 41-55) and 97 months (IQR 90-108).
Results: The primary endpoint was a composite of sudden cardiac death, ventricular fibrillation, sustained ventricular tachycardia or appropriate implanted cardioverter-defibrillator intervention. During a median follow-up of 91 months (IQR 34-222) 28 patients (29%) experienced the composite endpoint. The median time for the primary event was 35 months (IQR 18-86 months), and 39% of events occurred beyond 49 months of follow-up. History of syncope (HR 4.034; 95%CI, 1.488 to 10.932; p value=0.006), non-sustained ventricular tachycardia (NSVT; HR 3.534; 95%CI 1.265-9.877; p value=0.016), premature ventricular contractions (PVC) >1000/24h (HR 2.761; 95%CI 1.120-6.807; p value=0.027) and right ventricular fractional area change (RVFAC; HR 0.945; 95% CI 0.906-0.985; p value=0.008) were found as independent predictors at baseline multivariate analysis. Nevertheless, when the prognostic impact of each variable was reassessed overtime only NSVT (HR 3.282; 95%CI, 1.122 to 9.598, p value=0.023) and RVFAC (HR 0.351, 95%CI, 0.157 to 0.780; p value=0.010) remained independent predictors throughout the whole follow-up.
Conclusions: In our cohort of ARVC patients only NSVT and RVFAC maintained their independent prognostic impact in predicting arrhythmic events during the long-term follow-up. Periodical re-assessment of risk in these patients is strongly recommended.

820

An individual patient data meta-analysis of outcomes in 4 randomized double-blind trials of iron-deficient patients with HFrEF and renal dysfunction treated with IV ferric carboxymaltose

P Ponikowski[1]; IC Macdougall[2]; M Bohm[3]; J Comin Colet[4]; G Filippatos[5]; B Roubert[6]; DJ Van Veldhuisen[7]; SD Anker[8]
[1]Medical University, Military Hospital, Department of Heart Disease, Wroclaw, Poland; *[2]King's College Hospital, Department of Renal Medicine, London, United Kingdom*; *[3]University of the Saarland, Department of Internal Medicine and Cardiology, Homburg/Saar, Germany*; *[4]University Hospital of Bellvitge, Cardiology Department, Barcelona, Spain*; *[5]Attikon University Hospital, Heart Failure Unit, Athens, Greece*; *[6]Vifor Pharma, Department of Biometry, Glattbrugg, Switzerland*; *[7]University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands*; *[8]University Medical Center Gottingen (UMG), Department of Cardiology & Pneumology, Gottingen, Germany*

Background. Renal dysfunction is common in patients with heart failure (HF) and linked with poor outcomes. Iron repletion with IV FCM (ferric carboxymaltose) improves symptoms and functional capacity in iron-deficient patients with HF and reduced ejection fraction (HFrEF), but data on outcomes for those with renal dysfunction are lacking.
Purpose: To assess the effect of IV iron therapy with FCM on hospitalization and mortality in iron-deficient patients with heart failure with HFrEF and renal dysfunction.
Methods: Data from four randomized, double-blind, placebo-controlled trials (FER-CARS-01, FAIR-HF, EFFICACY-HF and CONFIRM-HF) were included in an individual patient data meta-analysis. Each study enrolled ambulatory HFrEF patients (NYHA class II/III) with iron deficiency, randomized to IV FCM or placebo, followed for 12–52 weeks. Event rates in the subpopulation with chronic kidney disease stage ≥3 (estimated GFR [eGFR, CKD-EPI] <60mL/min/1.73m^2) were analyzed using a log-link negative binomial regression model.
Results: In total, 372 patients were included in the analysis (FCM 216, placebo 156): males 52%, mean age 72 years, mean LVEF 33%, mean eGFR 43mL/min/1.73m^2, mean ferritin 62ng/mL, mean TSAT 17.7%, mean Hb 12.0g/dL (median Hb 11.9g/dL). A composite of hospitalization for cardiovascular (CV) reasons and CV death was significantly less frequent with FCM vs placebo (rate ratio 0.55, 95% CI [0.33; 0.90], p = 0.018). FCM was also associated with a lower risk for hospitalization for any CV reason or any death, hospitalization for CV reasons, or hospitalization for worsening HF (Figure). The median length of stay in hospital due to worsening HF was 8.5 vs 13 days in the FCM and placebo groups, respectively. The effect on all-cause mortality was neutral. The safety profile of FCM was similar to placebo based on the incidences of adverse events per 100 patient years (FCM 44.6, placebo 45.9) and study drug-related adverse events leading to study drug withdrawal (FCM 0.7, placebo 0.4).
Conclusions: Correction of iron deficiency with IV FCM in patients with ambulatory HFrEF and renal dysfunction is associated with a reduced risk for CV-related or HF-related hospitalization and mortality, a significantly reduced need for hospitalization, and fewer days in hospital for worsening HF.
Figure: Observed incidence, and rate ratios (RR) [95% CI] based on number of events, for outcomes with FCM vs placebo

Introduction: Amyloidosis is a disease caused by infiltration of tissues by an amyloid protein. The most frequent cardiac amyloidosis are light chain (AL) amyloidosis, hereditary transthyretin (TTR-h) and wild transthyretin (w-TTR).
Objective: Describe baseline clinical, biological, echocardiographic characteristics and prognostic of patients referred for cardiac amyloidosis in the Amyloidosis expert cente.
Methods: From 2010 to July 2016, all patients referred to the expert center of our Hospital for suspected cardiac amyloidosis were included. Baseline demographic, clinical, laboratory and ultrasound characteristics were recorded and patients were followed-up for major events including death, cardiac transplantation and left ventricular assistance implant. Results: Of the 942 patients referred for suspicion of CA, 502 had confirmed CA of whom162 had AL amyloidosis, 203 h-TTR and 141 w-TTR. CA were men in 60%, the median age was 69 years w-TTR amyloidosis were older (83 [79; 87], $p < 0.001$) and more men (86%, $p < 0.001$) than the two other types of CA. NYHA III-IV dyspnea was more frequent in AL amyloidosis (60%) and w-TTR (54%, $p < 0.001$)compared to h-TTR, while neurological symptoms were more predominant in h-TTR (62% $p < 0.001$). Creatinine, NT-proBNP and troponin were higher in AL amyloidosis and w-TTR ($p < 0.001$) than in h-TTR. w-TTR amyloidosis had thicker Interventricular septum thicker, lower LVEF, higher global strain E/A and E/Ea ratios than the two other types of CA ($p < 0.001$). During follow-up 137 major events occured. Median follow-up was 22(8-36) months. The survival without major event was 59% for AL amyloidosis, 79% for w-TTR, 81% for h-TTR versus 88% for patients without amyloidosis ($p < 0.001$). In multivariate analysis, only NYHA class III-IV, hyponatremia, elevation of creatinine, troponin and NTproBNP were independent prognostic factors ($p < 0.001$).Conclusion: Cardiac amyloidosis is more frequent than initially thought, with very different layouts depending on the type of amyloid protein involved. Its prognosis is poor at short term. The challenge is to achieve earlier diagnosis to improve prognosis

Cardiac biomarkers dynamics in amateur marathon runners

E Roca[1]; J Lupon[2]; L Nescolarde[1]; J Lupon[2]; J Barallat[2]; C Pastor[2]; A Bayes-Genis[2]
[1]Polytechnic University of Catalonia, Barcelona, Spain; *[2]Germans Trias i Pujol University Hospital, Badalona, Spain*

Background: Strenuous exercise such a marathon race might induce an increase of the blood concentrations of some cardiac biomarkers usually measured for diagnosis and prognosis prediction of heart diseases. However the behavior of different cardiac biomarkers around a marathon race in people of both genders has not been well elucidated.
Objective: 1) To assess baseline, just after the marathon race and 2 days after the race blood concentrations of NTproBNP, hs-TnT and ST2; 2) Try to find some relationship between the observed changes and demographic and performance characteristics.
Subjects and methods: 79 subjects (72.2% men), with a mean age of 39 ± 6.2 years (70.9% $\geq$ 35 years) were studied. Three blood samples were obtained: 24-48 h before the race, in the immediate hours after the race and 48h hours after the race.
Results: Baseline data: hs-TnT blood levels tended to be higher in women ($p = 0.07$). Only NTproBNP correlated with age ($p = 0.007$). hs-TnT ($p = 0.01$) correlated with weekly training hours and inversely correlated with the real time for completing the race ($p = 0.009$). No biomarker correlated with the years of training. Biomarkers' dynamics: Blood levels of the three cardiac biomarkers significantly increased during the race (Table, $p < 0.001$ for all). NTproBNP and ST2 decreased to similar pre-race values 48h hours after the race, while hs-TnT blood levels decreased but their remained higher than those pre-race (Table, $p < 0.001$). Relationship with biomarker dynamics: We found higher increase of hs-TnT in women ($p = 0.03$). We did not found any significant relationship between increase in the studied biomarkers and age or years of training. We found inverse relationship between weekly training hours and ST2 increase ($p = 0.007$), and direct relationship between race time and hs-TnT ($p < 0.001$) and ST2 ($p = 0.052$) increase. In multivariable lineal regression analyses including age, sex and those variables with a p-value ≤ 0.10 in the correlation analyses, race time remained independently associated with ST2 ($p = 0.031$) and hs-TnT ($p < 0.001$) increase. Conclusions: cardiac biomarkers significantly increased during a marathon race in amateur runners. Such increase reached abnormal values for hs-TnT and ST2, and was significantly associated with worse athlete performance.

	Baseline	Immediately post-race	48 h after race
NTproBNP, ng/L	70 (70-70)	92 (70-147)	70 (70-70)
ST2, ng/mL	34.2 (24.7-40.9)	54.2 (38.2-72.4)	33.7 (28.9-42.3)
hs-TnT, ng/L	2.85 (1.7-7)	46.9 (24.1-91.1)	4.65 (2.4-8.85)

823

Brain natriuretic peptide improves risk stratification of EuroSCORE II in cardiac surgery: beyond statistical significance, clinical relevance

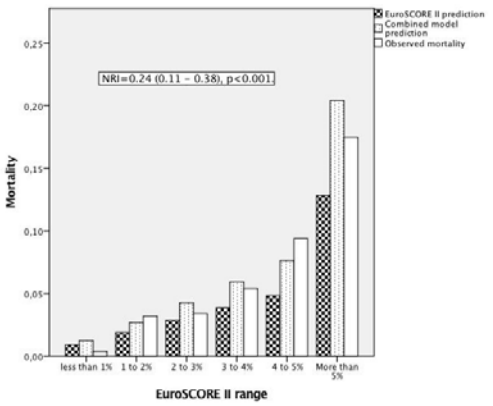
L S Nguyen[1]
[1]Clinique Medico-Chirurgicale Ambroise Pare, Critical Care Department, Neuilly sur Seine, France

Purpose: Our goal was to evaluate the additional prognosis value provided by pre-operative BNP combined to EuroSCORE II regarding intrahospital mortality after cardiac surgery.
Methods: In a prospective cohort of 2209 patients, we validated the performance of EuroSCORE II and a combined model (EuroSCORE II with preoperative BNP). Multivariable logistic regression analysis was used to assess adjusted odd-ratios (OR). Discrimination performance was evaluated using receiver-operator-characteristics analysis area under curve (ROC AUC). Inter-model comparison was performed using the net reclassification index (NRI).
Results: Intrahospital mortality rate was 4.8%. EuroSCORE II had a ROC AUC of 0.81; 95%CI 0.77-0.85, $p < 0.0001$; however there were significant differences between predicted and observed mortality ($p < 0.0001$). Elevated BNP (above 100 ng/l) was an independent risk factor of intrahospital mortality (2.9% vs. 6.5%; adjusted OR 1.83; 95%CI 1.17-2.87, $p = 0.008$). The combined model had a ROC AUC of 0.81; 95%CI 0.78-0.85, $p < 0.0001$. BNP reclassified 1180 (53.4%) patients. Moreover, BNP significantly improved risk stratification of EuroSCORE II with an NRI of 0.24; 95%CI 0.11-0.38, $p < 0.001$.
Conclusion: Preoperative BNP improved the predictive capabilities of EuroSCORE II. Half the patients were reclassified; those with elevated BNP had a theoretical risk multiplied by 1.8 regarding intrahospital mortality after cardiac surgery.

Multivariable logistic regression

	Adjusted OR	95%CI	p-value
Regression with continuous BNP			
EuroSCORE II	1.10	1.07-1.13	< 0.0001
BNP (per 1 log-BNP)	1.45	1.01-2.07	0.04
Regression with categorical BNP			
EuroSCORE II	1.10	1.08-1.13	< 0.0001
Elevated BNP (>100 ng/l)	1.83	1.17-2.88	0.008

BNP as a continuous variable was log-transformed to account for its skewed distribution. Elevated BNP cut-off value was based on the Youden index computed from ROC analysis. OR: odd-ratio; 95%CI: 95% confidence interval.



Observed and predicted mortality

CLINICAL CASE CORNER 3 – METABOLIC ISSUES IN HEART FAILURE: DON'T FORGET PERIPHERY!

824

Acute right heart failure in thyroid storm: warranting early thyroidectomy

O Ossama Abou Hassan[1]; S Mansour[1]; A Zakharia[1]; H Skouri[1]
[1]*American University of Beirut Medical Center, Internal Medicine, Beirut, Lebanon*

Introduction: Thyroid storm may manifest in acute right ventricular failure due to elevated pulmonary vascular resistance. A heightened catecholaminergic state is central to the disease and its cardiac manifestations. We discuss the presentation and management of a patient with idiopathic dilated cardiomyopathy and acute decompensated right heart failure due to thyroid storm.
Description: A 44-year-old man known to have idiopathic dilated cardiomyopathy presents with heart failure exacerbation requiring LVAD procedure. His peri-operative stay is complicated with atrial fibrillation and hyperthyroidism. This is followed by thyroid storm intra-operatively. He developed acute RV failure with intractable ventricular arrhythmias during surgery requiring a temporary RV assist device insertion with emergent thyroidectomy. Questions and Problems: 1. The treatment of atrial fibrillation in bi-ventricular failure sets a challenge due to the pathophysiology of hyperthyroidism in the setting of cardiogenic shock. 2. Should RV afterload reduction be considered in those patients? 3. Inotropic support of bi-ventricular failure in light of a heightened catecholamine state (hyperthyroidism) sets another challenge and requires aggressive measures earlier. 4. The optimal time of LVAD surgery is not studied in patients with hyperthyroidism. Is thyroidectomy warranted before the LVAD in high risk patients?
Discussion: The initial management of hyperthyroidism and thyroid storm is central to all the cardiac manifestation and should be dealt with promptly. The quantitative evidence of thyroid hormone suppression may not help prevent a thyroid storm, and so, the time of surgery should not be linked to the levels of thyroid hormones. Digoxin and beta blocker requirements for treatment of atrial fibrillation may be higher due to increased drug metabolism. In cardiogenic shock, the use of beta-blockers in those patients should be used cautiously. In hyperthyroidism, pulmonary hypertension occurs due to elevated pulmonary vasculature resistance. The role of pulmonary vascular vasodilators should be contemplated in acute event of RV failure. Inotropic support of bi-ventricular failure in the setting of a catecholaminergic state (hyperthyroidism) may be counterproductive and increases the risk of arrhythmias. An earlier bridge through ECMO may stabilize the patient prior to LVAD surgery and thyroidectomy.
Conclusion and Implications: Thyroid storm must always be suspected in refractory cases of cardiac arrhythmia, new onset right sided heart failure or worsening left heart failure. The RV is expected to fail in hyperthyroid states due to the pulmonary vasculature physiology. An ECMO bridge to LVAD is warranted due to the complicated state of heightened catecholaminergic release. We suggest early ECMO followed by combined surgery of LVAD and thyroidectomy with or without a temporary right sided mechanical assist device.

825

It is possible to avoid an ICD implantation with empagliflozine?

J Jose Morgado[1]; JRG Roa[1]; PRO Rodriguez[1]; MTRM Moraleda[1]; JFDF Diaz Fernandez[1]
[1]*Hospital Juan Ramon Jimenez, Cardiology, Huelva, Spain*

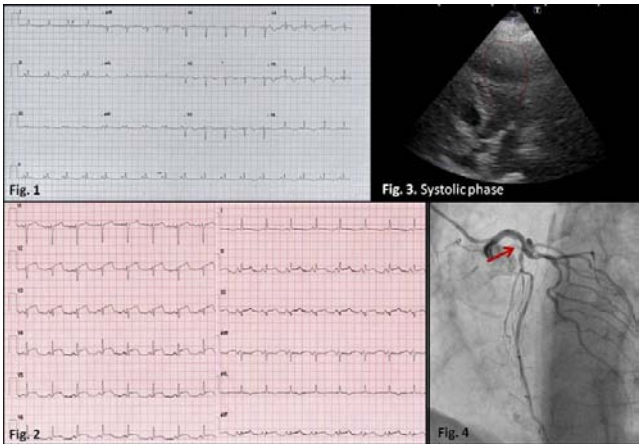
Introduction: We report a case of a 67-year-old female with diabetes mellitus and nonischemic dilated cardiomyopathy. She was being treated with ramipril 10 mg once daily, bisoprolol 10 mg once daily, eplerenone 25 mg once daily, furosemide 40 mg daily and metformine 850 mg three times daily. Her functional class was II of classification of New York Heart Association (NYHA), and had suboptimal metabolic control, with 7.5% of Hemoglobin A1c (HbA1c), her Body mass index (BMI) was 33.5. We decided introduce another oral antidiabetic to improve HbA1c, we choosed empagliflozine due to possible benefits in heart failure (HF) situation, as we learned with is´s clinical trial. She received 10 mg once daily, and one month later 25 mg of empagliflozine once daily. 4 weeks later, she improved her funciontal class, with no symptoms of heart failure, and lower level of natriuteric peptides. We reevaluated the decision of implantable cardioverter-defibrillator (ICD) need, but she had no symptoms of HF, so we refused the implant of ICD. 3 months later, she has no admissions due to heart failure and better metabolic control, with 6.7% of HbA1c. Conclusions and implications for clinical practice Sodium-glucose co-transporter 2 (SGLT2) inhibitors are a new class of diabetic medications indicated for the treatment of type 2 diabetes which had shown benefits in heart failure situation and development of this same. We present a case with improvement in HF situation and metabolic control, being possible the change of indication for ICD therapy.

826

Simultaneous anterior and inferior ST segment elevation during hypoglycemia: myocardial infarction or Tako-tsubo cardiomyopathy?

S Sonia Ferretto[1]; R Turri[2]; C Penzo[2]; L Leoni[1]; S Iliceto[1]; R Bellu[3]
[1]*University Hospital of Padova, Cardiac, Vascular and Thoracic Science, Padua, Italy*; [2]*Mirano Hospital, Mirano, Italy*; [3]*Multi-specialty and Thermal Clinic of Abano Terme, Cardiology, Abano Terme, Italy*

Introduction: Simultaneous ST-segment elevation in the precordial and inferior leads is a rare ECG finding. In literature this aspect is associated to the presence of an occlusion of a "wrapped" left anterior descending artery (LAD) below the first diagonal branch, so to a LAD that perfuses at least one-quarter of the inferior wall. Tako-tsubo cardiomyopathy (TTC) manifests with a clinical scenario mimicking acute myocardial infarction (AMI) and several cases of TTC associated with obstructive coronary artery disease have been reported. We present a case of ST segment elevation occurred during hypoglycemia in which the differential diagnosis between of AMI and TTC results particularly challenging. Case report. An 85-year-old female patient presented to the Emergency Department for pulmonary edema associated with high arterial blood pressure. A routine ECG performed one year ago was completely normal. She had a history of diabetes and hypertension and experienced a severe hypoglycemic episode (glucose 20 mg/dl) two days before. She did not report chest pain episodes. The ECG at the admission showed negative T waves in the precordial leads and slightly negative T waves in the peripheral leads (fig. 1). The echocardiogram demonstrated moderate reduction of the left ventricular ejection fraction due to akynesia of the apical segments and moderate mitral regurgitation. The pulmonary edema resolved with non invasive ventilation, nitrates and diuretics. The Troponin T (TnT) arose until 267 ng/l (normal value < 14 ng/L) in six hours and then decreased. Two days later, during the night, the patient presented a new hypoglycemic episode (glucose 40 mg/dl) severely symptomatic for dyspnea and profuse sweating. She did not report chest pain. The ECG during hypoglycemia showed ST-segment elevation from V2 to V6, in DII, DIII and aVF (fig. 2) that only partially resolved after normalization of glucose level and resolution of symptoms. The echocardiogram showed severe reduction of the left ventricular ejection fraction (25%) due to akynesia of the apical segments (fig. 3). The TnT following this episode continued its descending trend (from 119 ng/l before the episode, to 98 and 94 ng/l three and six hours respectively after the episode). The patient underwent coronary angiography which showed an ulcerated lesion of the left main branch and a subocclusion of the proximal "un-wrapped" LAD (fig. 4), treated with two drug eluted stents. After two days the echocardiographic left ventricular function markedly improved. The ECG at discharge presented negative T waves in the precordial leads. Conclusion. Our case report shows that AMI and TTC are often difficult to distinguish and that the presence of CAD should not be considered an exclusion criteria at all for the diagnosis of TTC, but symptoms, instrumental and biochemical data should be carefully evaluated to formulate the correct diagnosis.



827

Metabolic cardiomyopathy with heart failure: a late, reversible complication of bariatric surgery.

G Pela*[1]; M Li Calzi[1]; P Demola[1]; L Ceriello[1]; MI Gioia[1]; M Gianfreda[1]; F De Rosa[1]; A Crocamo[1]

[1]*University Hospital of Parma, Medicine, Parma, Italy*

Introduction: Dilated cardiomyopathy (DCM) is characterized by cardiac enlargement and impaired left ventricular systolic function, mostly caused by coronary artery disease, which may be effectively treated with myocardial revascularization techniques. However, besides other generally progressive aetiologies of DCM, such as the idiopathic form, there are also reversible causes of DCM, including those secondary to arterial hypertension and alcoholism or to metabolic-nutritional imbalances, such those operating in the present case. Case presentation: We report the case of a 74 years old woman, referred to the University Hospital of Parma because of progressive dyspnoea and peripheral oedema lasting from three months. In her clinical history, almost 30 years before the onset of the symptoms, she underwent a jejuno-ileal bypass surgery for severe obesity, with consequent 40 Kg weight loss. First clinical examination showed an undernourished (body mass index 16 Kg/m2), symptomatic subject with marked peripheral oedema and resting dyspnoea. Blood pressure levels were low (82/59 mmHg). ECG showed a sinus tachycardia with non-specific intraventricular conduction delay and flattened T-waves in the left precordial leads. An early echocardiogram demonstrated a left ventricular dilation with severe systolic dysfunction (end-diastolic diameter 60 mm, ejection fraction 22 %) and severe functional mitral regurgitation (MR) (Fig. 1). Coronary angiogram excluded significant coronary artery disease. Laboratory blood tests showed: normal renal function, markedly reduced values of the main serum electrolytes (2.1 mEq/L potassium; 0.76 mEq/L ionized calcium; 0.6 mg/dL magnesium; 1.4 mg/dL inorganic phosphorus) and of the albumin (1.9 g/dL); significant anaemia (8.7 g/dL haemoglobin) and depletion of iron, folate and Vitamin D; a 346 pg/mL serum concentration of PTH indicated secondary hyperparathyroidism; BNP was elevated (1647 pg/mL), while enzymes of myocardial injury were negative. On the assumption of a malabsorption syndrome as the cause of dilated cardiomyopathy resulting in congestive heart failure, the patient received transfusion of 3 red blood cell units and a three-weeks' lasting intravenous supplementation of potassium, magnesium, calcium, phosphorus, iron and vitamins, with early clinical and laboratory improvement. Then a sustained oral supplementation was initiated and continued after discharge from the Hospital. She also received pharmacological therapy with beta-blocker and angiotensin-receptor blocker (ARB), while loop diuretic treatment, initially needed to control oedema and dyspnoea, was permanently discontinued. At the follow-up the patient felt progressively better with significant improvement of the functional class (NYHA – from IV to I). Serial echocardiographic exams showed a left ventricular ejection fraction rising to 35% within one month, with downgrading of MR to a moderate degree, and to 65% after eight months, with complete regression of left ventricular dilation (51 mm end-diastolic diameter) and a further recovery of MR to a mild degree. Conclusions: This observation reports a rare case of bariatric surgery induced metabolic cardiomyopathy, which completely regressed after correction of nutritional abnormalities.

[1]*Capio Hospital General de Catalunya, Department of Cardiology, Sant Cugat del Vallès, Spain*

Introduction: A 36-year-old female with no significant previous medical history presented to the outpatient clinic complaining of progressive shortness of breath (NYHA III-IV) and weakness for 4 months. No recent history of cold, diarrhea or any other symptom. Blood pressure was 149/94 mmHg and she was not tachycardic. Signs of congestion were noted (mild bilateral lung rales and peripheral oedema). She also presented exophthalmos and reported weight gain in the last months of trunk predominance. No alcohol or other toxics consumption.

Description of the problem, procedures: Electrocardiography showed sinus rhythm with no ischemic signs. Chest radiography revealed cardiomegaly and increased pulmonary vascularity. Blood test evidenced a normal hemogram, kidney and liver function. NT-ProBNP was raised at 2770 ng/L and troponin was negative. Echocardiogram evidenced a dilated left ventricle with severe systolic dysfunction (EF 19%), no segmental abnormalities or valvulophaties. were noted. Cardiac magnetic resonance confirmed the diagnosis and showed no fibrosis areas. Optimal medical treatment for dilated cardiomyopathy was initiated.

Questions, problems or possible differential diagnosis: Facing the diagnosis of dilated cardiomyopathy potential causes of systolic dysfunction such as ischemic heart disease, myocarditis or infiltrative myocardiopathy were rule out. With the initial suspicion of possible thyroid alteration, the patient was referred to Endocrinology. Thyroid function was normal, but plasma and urinary cortisol levels were high, the dexamethasone suppression test showed an abnormal response suggesting an adrenal alteration. Abdominal CT scan confirmed the presence of an adrenal adenoma. Laparoscopic surgical intervention was initially performed, which was complicated by haemorrhagic shock after 48 hours due to a splenic laceration requiring laparotomy and splenectomy. The patient was discharged 8 days after surgery. Over the following months, left ventricular dilation and ejection fraction progressively improved till almost normal values (Figure 1 A and B: chest X ray before-after surgery; C and D: cardiac-MRI before-after surgery).

Answers and discussion: Cushing's syndrome is an uncommon but potentially reversible cause of dilated cardiomyopathy, most often reported in patients with hypercortisolism arising from an adrenal adenoma. After adenoma excision, our patient presented a significant clinical improvement. Left ventricular diameters reduced till normal values, although mild left ventricle sphericity and borderline EF (50%) is still present 24 months after surgery. She is currently in NYHA I.

Conclusions and implications for clinical practice: Dilated cardiomyopathy and left ventricular failure are rare presentations of Cushing's syndrome. It is important to consider this diagnosis because cardiomyopathy can be reversed following successful treatment of Cushing's syndrome, as shown in our patient.

Diabetes, deafness and hypertrophic cardiomyopathy: is it just a coincidence?

V Veronica Angela Rial Baston[1]; AM Iniesta Manjavacas[1]; P Meras Colunga[1]; FJ Irazusta Cordoba[1]; SO Rosillo Rodriguez[1]; L Pena Conde[1]; O Gonzalez Fernandez[1]; JL Lopez-Sendon[1]
[1]University Hospital La Paz, Cardiology, Madrid, Spain

A 45 year-old white female with past history of diabetes mellitus (diagnosed at a very early age) and sensorineural deafness that required cochlear implant, was first diagnosed in 2007 of a non-obstructive hypertrophic cardiomyopathy. The same year, an ablation of three accessory pathways due to Wolff-Parkinson-White syndrome was performed. During follow-up she progressively developed asymptomatic left ventricular systolic dysfunction and in 2012 during an in-hospital admission secondary to a third-degree atrio-ventricular block that required implantation of a definite pacemaker, an echocardiogram was performed revealing severely depressed left ventricular systolic function. In 2015 she was admitted at our center because of acute heart failure. On physical examination, blood pressure was 80/50 mmHg and heart rate was 77 bpm. Heart sounds were rhythmic with no murmurs and pulmonary auscultation revealed bilateral rales at lung bases. NT-proBNP levels rose up to 6903 ng/ml. An electrocardiogram showed ventricular paced rhythm and an echocardiogram revealed severe left ventricular systolic dysfunction and moderate right ventricular systolic dysfunction. Intravenous diuretics were initiated but ACE inhibitors had to be interrupted due to hypotension. She also required conventional analgesics to treat frequent headaches. During hospital admission inquiry of family history was especially striking, as three out of her seven sisters were also diabetic and wore a cochlear implant, therefore suggesting a hereditary disorder. Considering her cardiovascular history (non-obstructive hypertrophic cardiomyopathy and cardiac conduction abnormalities), symptoms such as headaches, hearing impairment and early type 2 diabetes, a mitochondrial disease was suspected. A genetic study was requested revealing mitochondrial mutation in the MT-TL1 gene encoding tRNA, changing adenine to guanine at position 3243 of the mtDNA (m.3243A>G). The diagnosis of MELAS syndrome was then established and the patient was discharged after seven days with low-dose of bisoprolol, eplerenone, oral furosemide and nutritional supplements. During follow-up, an up-grade to TRC-D was scheduled and completion of a cardiac rehabilitation program achieved. Nevertheless, she continued to be on NYHA class III, being then referred to a cardiac transplantation center. Conclusion: Mitochondrial diseases are inherited disorders caused by mutations in mitochondrial DNA which result in an incapacity to generate enough ATP to meet energy needs. They include a wide range of clinical entities which have multi-organ involvement. Despite the importance of an early diagnosis (which would allow genetic counseling), they are often under diagnosed. These disorders must be suspected by cardiologists when they assess patients with cardiomyopathies, cardiac conduction abnormalities and multi-organ manifestations such as: strokes, lactic acidemia, myopathy, deafness or epilepsy.

Case of acute decompensation in patient with diastolic left ventricul dysfunction and extraordinary obesity

O Olha Vasylenko[1]; I Prudkyi[1]; I Katsytadze[1]; YU Sychenko[1]; I Gorda[1]
[1]National O.O. Bohomolets Medical University, Kiev, Ukraine

Case report description: A female patient of 72 years and BMI 68,6 (height 162cm, weight 180kg) was hospitalized in cardiac ICU with acute onset dyspnea, arterial BP 105/60mmHg (office BP 150/95 mmHg), SpO2 - 82-84%. Anamnesis: permanent AFib, diabetus melitus type 2. On ECG: AFib, QIIISI, HR64. D-dimer - 3097 (N≤500), NTproBNP -1843 (N≤125). Echo: MV- mid reg, TV - severe reg, LA - 58×45mm, RA - 54×40mm, RV - 43mm, PAH - 75 mmHg, ESV - 44 ml, EDV - 92ml, EF - 50%, IVS - 12,5mm, PW - 12mm. Diastolic dysfunction, type 1.
Contrast CT of the chest: no data for pulmonary embolism (PE). Excess fatty tissue, compressive atelectasis of posterior segments.
Ultrasound of lower limbs: lymphedema, no data for thrombosis. Central venous pressure: 280mmH2O. In 3 days after hospitalization, respiratory acidosis increased, we found increasing of potassum, creatinine, breath disorders appeared. CPAP-BIPAP ventilation has been started. We marked elevation of plasma renin and low level of aldosterone/renin relation. Description of the problem. The main problem of this case was a 3rd degree obesity and non-specific symptoms of acute decompensated heart failure, in a combination with adrenal insufficiency, diabetus melitus, chronic anemia and severe respiratory acidosis, as well as PE symptoms and also difficulties to correct the main cause of disease. Answers and discussion. First of all, our main goal of the treatment was weight correction and correction of respiratory acidosis with support of effective breathing. In cooperation with dietologists we prescribed optimal diet and in 3 weeks, she lost 22 kg. We started CIPAP-BIPAP lung ventilation, and the problem of acidosis and hypercapnia was solved. Renal function in this case improved in 48-72hours after correction of acidosis, and potassum level decreased to normal ranges accordingly. In a month after admission to hospital, our patient was discharched in well condition with slight symptoms of dyspnoe and normal ranges of SpO2, BP, HR, pH, creatinine and renin levels. NTproBNP dicreased significantly, but still was elevated. In 4 month of follow up, the patient adheres to a diet and has 148kg.
Conclusion: Importance of comorbities in heart failure prognosis is well known, but sometimes the value of their impact is crusial and the only way to imrove cardiac function and regress HF symtoms is a succesful treatment of main causes.

Over-correction of symptomatic hyponatremia in chronic HF that required specific therapeutic adjustments against possible osmotic demyelination syndrome. An apparently counterintuitive approach.

R De Vecchis[1]; C Ariano[2]

[1]*Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy*;
[2]*Neurorehabilitation Unit, Clinica' S.Maria del Pozzo', Somma Vesuviana, Italy*

Introduction: Hyponatremia (serum Na + <135 mEq /L) in chronic heart failure (CHF) is associated with reduced survival and can be accompanied by various neurological symptoms, including postural instability, gait disorders, attention deficit and increased risk of falls, especially if values of ≤116 mEq/L are attained. Moreover, patients with CHF and chronic hyponatremia are more likely to develop complications from rapid sodium repletion, such as osmotic demyelination syndrome(ODS). Case description A female 74 year old patient presented to the emergency department with a CHF clinical picture, coupled with new onset neurological symptoms. In particular, the patient had problems of her motor function ,i.e., inability to walk with staggering posture, and her speech was difficult to understand. Clinical history and diagnosis. The patient was smoker and slightly obese. She suffered from chronic alcoholism and chronic atrial fibrillation. She had been treated with biological prosthetic valve five years earlier for mitral steno-insufficiency. Moreover, along with usual therapy for CHF(digoxin, enalapril , carvedilol, warfarin), she was taking some drugs known to stimulate the arginine vasopressin secretion, such as a thiazide(one tablet/day of hydroclorothiazide 50 mg plus amiloride 5 mg), and an antidepressant drug belonging to the class of SSRIs (fluoxetine, 10 mg/day). The serum Na +, measured on admission, was 98 mEq / L. Based on this laboratory finding and neurological picture as well as the negative results of CT scan of the brain and electromyography, the diagnosis of symptomatic hyponatremia in CHF patient was made. Therapy and clinical outcome A correction of the low serum Na + was programmed. It was planned that the upper limit for the speed of correction should not have exceeded 6 mEq / L per day (NaCl 2M, i.e., 11.6% NaCl; 10 ml vials; 5 vials in electric syringe, 7.5 ml/h, plus furosemide 20 mg as a slow IV bolus twice daily). However, after 72 h, serum Na+ rose to 126 mEq / L, i.e., a value much higher than the expected target. Subsequently the patient developed marked dysarthria, with slowed slurred speech, which was regarded compatible with the initial stage of the osmotic demyelination syndrome (ODS). Thus, the administration of furosemide and hypertonic saline(HSS) was discontinued and the patient was treated with hypotonic solutions (NaCl 0.45%) and subcutaneous desmopressin (a synthetic analog of arginine-vasopressin), at doses of 2 micrograms more times a day for some days. After ten days in hospital, the patient was discharged in NYHA class II, after retrieval of her normal serum sodium levels together with complete regression of the neurologic disorders. Discussion The unexpected very quick correction of hyponatremia was attributed to the combination of the infusion of HSS and the rapid restoration of capacity of producing an adequately diluted urine output. This was presumably caused by the loss of the stimulating effect on arginine-vasopressin secretion by the fluoxetine, that had been stopped, along with the discontinuation of the thiazide diuretic. In this case, chronic hyponatremia required a well-tailored correction because a high speed of Na+ correction could instead be burdened by the risk of ODS.

Conclusions: Considering that even moderate grades of hyponatremia can cause symptoms (dullness, reduced level of attention, postural instability, etc.), hyponatremia occurring during CHF should be systematically treated with appropriate pharmacologic approach while paying attention not to elicit ODS.

RAPID FIRE 3 – ACUTE HEART FAILURE – FROM DIAGNOSIS TO PROGNOSIS

Introduction: Co-morbid conditions are frequent among patients hospitalized for acute heart failure (HF). There is increasing recognition that non-cardiovascular (CV) comorbidities impact the outcomes of patients with HF. We assessed trends in non-CV comorbidities over time regarding the (1) the prevalence; (2) the total burden; and (3) the association with in-hospital outcomes among patients admitted with HF.
Methods: Using data from the GWTG-HF registry from 2005 to 2014, we assessed 6 key non-CV comorbidities (chronic obstructive pulmonary disease [COPD], anemia, diabetes, renal disease, obesity [BMI ≥ 30 kg/m2], and depression). We evaluated the association between the number of non-CV comorbidities (0,1, 2, and ≥3) with in-hospital mortality and length of stay (LOS).
Results: We analyzed 207,984 HF patients with hospitalizations. 18% of patients had 0 non-CV comorbidities, 30% had 1, 27% had 2, and 25% of patients had ≥3. Patients with increasing numbers of non-CV comorbidities were younger and more likely to have HF with preserved ejection fraction. Over 9 years, there was an increase in the prevalence of all non-CV comorbidities over time (figure). There was an increase in the proportion of patients with ≥3 non-CV comorbidities over time (figure). Patients with an increasing number of non-CV comorbidities were at an increased risk of in-hospital mortality and length of stay > 4 days (table).
Conclusion: The increasing burden of non-CV comorbidities among patients hospitalized with HF over time reflects a shift in the profile of patients with HF. Strategies to manage and treat the growing burden of non-CV comorbidities will be required and should be included in the delivery of in-hospital HF care pathway.

Number of non-CV comorbidities	MortalityAdjusted odds ratio (95% CI); p-value	Length of stay > 4 daysAdjusted odds ratio (95% CI)
0	Reference	Reference
1	1.09 (1.00-1.12); p = 0.04	1.16 (1.12-1.19); p < 0.0001

Background: A single measurement of NT-proBNP, either at admission or discharge of a hospitalization for acute decompensated HF (ADHF), has been reported to provide equal prognostic information for patients with either reduced (HFREF) or preserved (HFPEF) ejection fraction. However, HFPEF patients have lower absolute NTproBNP levels and less evidence for prognostically relevant medication. Therefore, the change in NT-proBNP levels is expected to be of lesser magnitude in HFPEF.
Purpose: We assessed the change in NT-proBNP levels in HFPEF versus HFREF, stratified for baseline levels. We readdressed the prognostic significance of NT-proBNP changes compared to levels at admission and discharge, in both groups.
Methods: This study is a pooled individual patient data-analysis assembled from 7 prospective cohorts comprising 1131 patients. The endpoint was all-cause mortality within 180 days after discharge. NT-proBNP levels were measured at admission and at discharge. Patients with LVEF ≥45% were categorized as HFPEF (n = 319) , and those with < 45% as HFREF (n = 812). Percent NT-proBNP reduction from baseline levels was calculated for HFPEF versus HFREF, each stratified for admission NT-proBNP categories. Contributions to prognosis of admission and discharge NT-proBNP levels (in four categories) and of relative NT-proBNP reductions (in three categories) were assessed in both groups by Cox regression analysis.
Results: Patients with HFPEF had significantly lower median NT-proBNP levels than those with HFREF both at admission (4432, vs. 7074 pg/ml, p < .001) and at discharge (2148, vs. 3851 pg/ml, p < .001). All-cause 180-day mortality was non-significantly lower in patients with HFPEF compared to patients with HFREF (12% versus 16%, p = 0.13). Within each NT-proBNP quartile at admission, HFPEF responded with a similar percent reduction in NT-proBNP as HFREF. A ≤30% percentage reduction in NT-proBNP carried similar 180 day mortality risks for HFPEF and HFREF (HR 3.72, 95% CI 1.39-9.97; HR 4.62, 95% CI 2.64-8.08, respectively), adjusted for admission NT-proBNP levels and other known predictors. Similar pattern was found, with somewhat lower HR's, for a ≤30% percentage reduction adjusted for NT-proBNP values at discharge (HR 2.94, 95% CI 0.89-7.27; HR 2.19, 95% CI 1.21-3.95, respectively). Finally, we showed that particularly for HFPEF patients the value of the risk estimates increased after adding the reduction

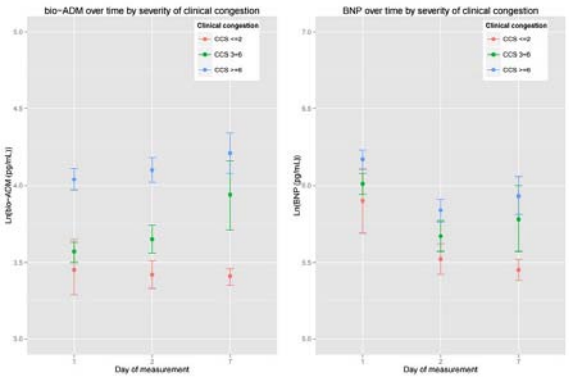
percentage to increasing absolute NT-proBNP levels, while for HFREF patients this effect remained modest.
Conclusions: For patients hospitalized for ADHF, a change in NT-proBNP during hospitalization determines prognosis in HFPEF and HFPEF alike, and these changes in NTproBNP are also equally possible. For absolute NT-proBNP levels HR's apply for both HFPEF and HFREF patients following the concept of the lower the better; adding information of change in NTproBNP is particularly of influence on the prognostic information of absolute levels in HFPEF patients.

878

Bio-ADM: a novel marker of congestion in patients with acute heart failure

D Kremer[1]; BG Demissei[1]; J Rubio-Gracia[2]; J Struck[3]; A Bergmann[3]; JM Ter Maaten[1]; JG Cleland[4]; M Metra[5]; G Cotter[6]; BA Davison[6]; MM Givertz[7]; K Damman[1]; DJ Van Veldhuisen[1]; AA Voors[1]
[1]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; *[2]Clinical University Hospital Lozano Blesa, Servicio de Medicina Interna, Zaragoza, Spain*; *[3]Sphingotec, GmbH, Hennigsdorf, Germany*; *[4]National Heart and Lung Institute, Royal Brompton and Harefield Hospitals, Imperial College, London, United Kingdom*; *[5]University of Brescia, Brescia, Italy*; *[6]Momentum Research Inc., Durham, United States of America*; *[7]Brigham and Women's Hospital, Boston, United States of America*

Background: Congestion is the main reason for hospitalization and the main target of therapy in patients with acute heart failure (AHF). There is an unmet need for a reliable measure of sub-clinical congestion, that can help in clinical decision-making. Adrenomedullin, a vasoactive hormone, is stimulated by volume overload, prevents vascular leakage and oedema and is thus tightly related to congestion.
Objectives: We studied the potential role of plasma biologically active adrenomedullin (bio-ADM), as a marker of congestion in AHF. In addition, we evaluated bio-ADM's added prognostic value on top of predefined models and clinically assessed congestion.
Methods: Plasma bio-ADM was evaluated at baseline, days 2 and 7 in 1562 patients admitted for AHF (enrolled in the PROTECT cohort). Clinical congestion was assessed using a composite score (ranging from 0 to 9) encompassing peripheral oedema, orthopnoea and jugular venous pressure.
Results: Median [IQR] baseline bio-ADM level was 44.1 pg/mL [25.9-82.7] (compared to healthy subjects, median: 20.7 pg/mL, 99th percentile: 43 pg/mL). Amongst a large number of clinical and biochemical variables, bio-ADM had the strongest association with clinically assessed congestion (OR=1.76, 95%CI: 1.56-1.99; $p < 0.001$) and bio-ADM was the strongest predictor of the presence of significant residual congestion by day 7 (OR=1.87, 95%CI: 1.62-2.17; $p < 0.001$). In patients with residual congestion at day 7, bio-ADM levels remained high while BNP levels decreased. At day 7, bio-ADM was an independent predictor of 60-day heart failure rehospitalization on top of predefined predictors and clinically assessed congestion at day 7 (HR=1.30, 95%CI: 1.04-1.63; $p = 0.019$), while BNP was not.
Conclusions: In patients hospitalized for AHF, plasma bio-ADM is strongly associated with clinically assessed congestion and an independent predictor of early rehospitalization.



Bio-ADM and BNP by congestion status

879

Increases in natriuretic peptides precede heart failure hospitalization in patients with a recent coronary event and type 2 diabetes

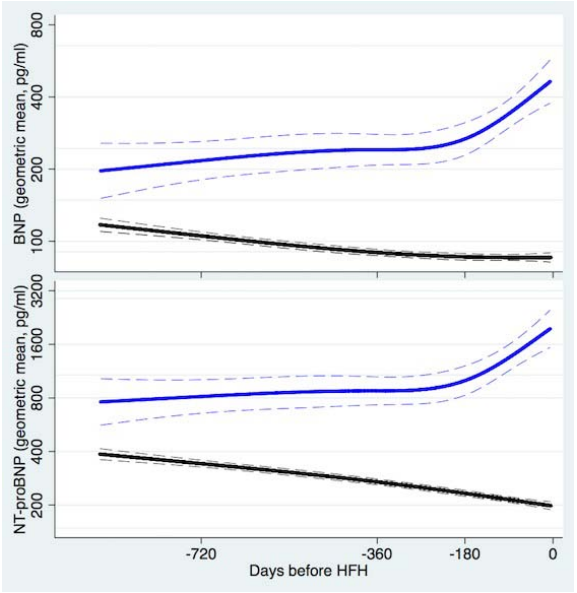
Background: Natriuretic peptides (NP) are used clinically to aid in the diagnosis of heart failure (HF) and considered for monitoring clinical status in patients with this syndrome. The timing of any such changes prior to a HF hospitalization (HFH) remains less well explored. We implemented a novel statistical approach to better characterize temporal changes of NP prior to HFH.
Methods: B-type natriuretic peptide (BNP) and N-terminal prohormone B-type natriuretic peptide (NT-proBNP) were measured in 5450 patients with type 2 diabetes and a recent coronary event in the ELIXA trial (NCT01147250). Measurements were done at baseline and at weeks 24, 76, and 108; patients were included in the present analysis if they had measurements at both baseline and 24 weeks with no intervening HFH. To characterize potentially non-linear temporal changes in NP levels preceding adjudicated HFH, we utilized all measurements available prior to HFH in a post-hoc, retrospective repeated-measures analysis using restricted cubic splines, with non-HFH patients as a control group. NP values are summarized using geometric means at various time points prior to HFH.
Results: During a median follow-up of 26 months, 151 patients (3%) experienced HFH. Patients who experienced HFH had higher baseline NP levels compared to patients without HFH (BNP [234 pg/ml vs. 101 pg/ml, $p < 0.001$]; NT-proBNP [862 pg/ml vs 304 pg/ml; $p < 0.001$]). Geometric mean levels of patients who did not experience HFH declined slowly with time (Figure). In those who experienced a HFH, NP levels remained relatively constant until about 6 months prior to HFH, and subsequently increased approximately two-fold by the time of HFH (BNP: 478 pg/ml, NT-proBNP: 2059 pg/ml) [Figure].
Conclusion: In patients with type 2 diabetes and a recent coronary event, a novel analysis revealed that, while elevated NP levels are associated with future HFH in general, more dramatic increases in NP levels typically precede HFH by about 6 months, suggesting that detectable cardiac deterioration accelerates prior to HFH.
Figure: Geometric mean concentrations (±95% CI) of BNP (panel A) and NT-proBNP (panel B) before HFH – blue line, compared with patients with no HFH – black line (no HFH: n=5299, HFH: n=151).



NP Concentrations prior to HFH

880

The continuous conundrum of hyponatremia in acute heart failure: from depletion to dilution, different phases for different outcomes

G Ruocco[1]; FH Verbrugge[2]; R Nuti[1]; A Palazzuoli[1]
[1]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy; *[2]Hospital Oost-Limburg (ZOL), Department of Cardiology, Genk, Belgium*

Background: Hyponatremia is the most common electrolyte abnormality found in hospitalized patients with acute heart failure (AHF) and is related to poor prognosis.
Purpose: In this study we compared dilutional versus depletional hyponatremia (defined on the basis of hematocrit values) in terms of congestion and renal dysfunction; we also investigated the two pattern respect to short/long term outcome.
Methods: This was a retrospective single center study including subjects, with a primary diagnosis of AHF screened from Diur-HF trial. Serum creatinine, blood urea nitrogen (BUN), serum electrolytes and B-type Natriuretc Peptide (BNP) were assessed with 24 hours from admission and at discharge at a central laboratory. We categorized hyponatremia in dilutional (serum sodium $<$ 135mEq/L with hematocrit values $<$35%) and depletional (serum sodium $<$ 135mEq/L with hematocrit values $\geq$35%). Congestion score was evaluated considering five principal signs and giving for each sign 1 point (third heart sound, pulmonary rales, jugular venous stasis, hepatomegaly, and peripheral edema). Patients were followed for six months and composite outcomes were considered the sum of death or rehospitalization for AHF.
Results: Our definitive sample consisted of 233 AHF patients, and hyponatremic patients were 68. 27 patients had dilutional hyponatremia and 41 patients had depletional hyponatremia. Patients with dilutional hyponatremia showed lower serum levels of admission hematocrit (30 ± 3 vs 40 ± 4 vs 38 ± 6 %; $p < 0.001$), admission hemoglobin (10.0 ± 1.1 vs 13.0 ± 1.4 vs 12.2 ± 2.0 g/dL; $p < 0.001$), admission potassium (3.8 ± 0.5 vs 4.0 ± 0.5 vs 4.1 ± 0.5 mEq/L; $p = 0.04$) and EF (33 ± 8 vs 35 ± 13 vs 38 ± 12 %; $p = 0.04$). Mean furosemide home daily dosage was higher in patients with dilutional hyponatremia respect to patients with dilutional hyponatremia and patients with normal serum sodium levels (181 ± 36 vs 176 ± 21 vs 150 ± 46 mg/die; $p < 0.001$). Univariate and multivariable Cox regression model evaluating 60 days death or rehospitalization showed that dilutional hyponatremia was related to poor outcome (U-HR 2.64 [1.40-4.99]; $p = 0.003$. M-HR 2.17 [1.08-4.37]; $p = 0.03$). Univariate analysis for 180 days death or rehospitalization, univariate analysis demonstrated that both dilutional hyponatremia (HR 2.17 [1.32-3.55]; $p = 0.002$) and depletional hyponatremia (HR 1.71 [1.11-2.62]; $p = 0.01$) were related to poor prognosis; multivariable analysis confirmed the same trend.
Conclusions: Our findings showed that dilutional hyponatremia was related to lower EF, higher congestion degree, higher rate of CKD, higher mean of home furosemide dosage and to poor outcome both 2 and 6 months of follow up. Therefore, dilutional hyponatremia could be defined as the last phase of AHF with severe clinical congestion and diuretic resistance. Depletional hyponatremia represented the previous phase respect to dilitional hyponatremia reflecting better outcome and clinical status.

Clinical characteristics and predictors of one-year outcome in patients hospitalized for heart failure: results from the Polish part of the ESC-HF-Pilot and ESC-HF-LT Registries

S Borodzicz[1]; P Balsam[1]; K Ozieranski[1]; M Peller[1]; A Tyminska[1]; A Kaplon-Cieslicka[1]; M Marchel[1]; J Drozdz[2]; G Opolski[1]; M Grabowski[1]
[1]Medical University of Warsaw, 1st Chair and Department of Cardiology, Warsaw, Poland; *[2]Medical University of Lodz, Department of Cardiology, Lodz, Poland*

Introduction: The Heart Failure (HF) Association of the European Society of Cardiology (ESC) created the Heart Failure Pilot Survey (ESC-HF Pilot) and Heart Failure Long-Term Registry (ESC-HF-LT) which are prospective, multicentre, observational registries aimed to evaluate the clinical profile, pharmacotherapy and one-year outcomes of HF patients in the European countries.
Purpose: The aim of the study was to compare the clinical characteristics and one-year outcome, as well as predictors of mortality and hospital readmissions in patients hospitalized for HF enrolled in the ESC-HF-Pilot or ESC-HF-LT Registry.
Methods: The analysis included hospitalized Polish patients enrolled in the ESC-HF-Pilot Registry and in the phase I of the ESC-HF-LT Registry. The primary endpoint (PE) was all-cause death at one year, while the secondary endpoint (SE) was composed of all-cause death or rehospitalization for worsening HF at one year.
Results: The total Polish cohort of both Registries included 2 019 patients. The final analysis consisted of 1 415 inpatients, 650 from the ESC-HF-Pilot and 765 from the ESC-HF-LT Registries. The PE was reached by 209 of the 1361 patients (15.4%); in the ESC-HF-Pilot Registry the PE occurred in 89 of the 650 patients (13.7%), whereas in the ESC-HF-LT Registry the PE was observed in 120 of the analyzed 711 patients (16.9%; $p = 0.11$). The SE occurred in 423 of the 1172 patients (36.1%), including 201 of the 509 patients from the ESC-HF-Pilot Registry (39.5%) and 222 of the 663 patients from the ESC-HF-LT Registry (33.5%; $p = 0.04$). The independent predictors of PE in the total population from both registries were older age, chronic obstructive pulmonary disease (COPD), higher New York Hear Association (NYHA) class at admission, lower serum sodium at admission, support of inotropics during index hospitalization, lower systolic blood pressure (SBP) at discharge, higher heart rate at discharge, and amiodarone at discharge. The prescription of beta-blockers at discharge was associated with significantly decreased mortality. The independent predictors of SE were diabetes, myocardial infarction, NYHA class at admission, lower serum sodium at admission, lower serum potassium at admission, support of inotropics during index hospitalization, use of diuretics intravenously during index hospitalization and lower SBP at discharge.
Conclusions: The results of the present study reveal, that patients hospitalized for HF remain at high risk for adverse outcomes, including death and HF rehospitalization. The recent progress in diagnosis and treatment of HF changes the patients' clinical profile and frequency of HF readmission.

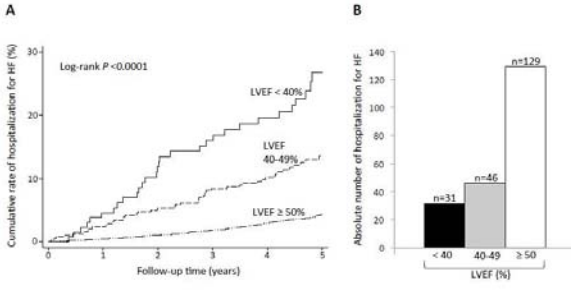
Hospitalization for heart failure in stable coronary artery disease outpatients: determinants, role of interim myocardial infarction, and prognosis

N Nicolas Lamblin[1]; T Meurice[2]; O Tricot[3]; P De Groote[1]; G Lemesle[1]; C Bauters[1]
[1]Lille University Hospital, Institut Coeur Poumon, Lille, France; *[2]Clinique du Bois, Lille, France*; *[3]Centre Hospitalier de Dunkerque, Dunkerque, France*

On behalf of: CORONOR registry group
Funding Acknowledgements: Fédération Française de Cardiologie, Paris, France

Background. There is a lack of recent data on incidence, correlates, and prognosis associated with the development of heart failure (HF) in patients with stable coronary artery disease (CAD).
Objectives: To analyze the risk of hospitalization for HF, together with relevant associated factors, and related mortality, in stable CAD outpatients.
Methods: The multicenter CORONOR registry enrolled 4184 unselected outpatients with stable CAD (ie myocardial infarction (MI) and/or coronary revascularization >1 year previously). Five-year clinical follow-up was achieved for 3785 (98%) of the 3781 patients who had no history of hospitalization for HF at inclusion.
Results: Hospitalization for HF occurred in 6.1% of the patients at 5-year and was a powerful predictor of mortality in a time-dependent analysis (age and sex adjusted HR = 7.62 [6.0-9.68]; $P < 0.0001$). Six variables were independently associated with hospitalization for HF: left ventricular ejection fraction (LVEF), age, diabetes mellitus, atrial fibrillation, history of hypertension, and low estimated glomerular filtration rate. As most patients had a normal LVEF at inclusion (mean=59 ± 10%; 86% with LVEF $\geq$ 50%), although low LVEF was a strong predictor of hospitalization for HF, a majority of them (62%) occurred in patients with preserved LVEF. Interim MI was strongly associated with hospitalization for HF (HR=3.63 [2.17-6.08]; $P < 0.0001$) but was a relatively rare circumstance (7.6% of the patients hospitalized for HF).
Conclusions: HF development remained relatively frequent in patients with stable CAD and was associated with a high risk of mortality. Although the LVEF at inclusion was a strong predictor of HF, we emphasized that the majority of cases of HF occurred in patients with preserved LVEF at inclusion and without an interim MI.



Hospitalization for heart failure

Not all acute heart failure syndromes are the same: de novo acute heart failure vs. acutely decompensated chronic heart failure.

J-H Ju-Hee Lee[1]; DH Bae[1]; KK Hwang[1]; MC Cho[1]
[1]Chungbuk National University Hospital, Cardiology, Cheongju, Korea Republic of

On behalf of: KorAHF Registry Investigators

Background: Acute heart failure syndromes (AHFS) can be classified into heart failure (HF) which presenting for the first time (de novo) or acutely decompensated chronic HF (AD-CHF). We compared the differences between de novo HF and AD-CHF regarding their clinical features and prognosis.
Method: We evaluated the AHFS patients hospitalized in ten regionally-representative tertiary university hospitals who registered in the Korean Acute Heart Failure (KorAHF) Registry from March 2011 to February 2014.
Results: Among the 5,625 patients who were registered at KorAHF Registry, 2,944 patients (52.3%) were classified as de novo HF and 2,681 patients (47.7%) were classified as AD-CHF. AD-CHF patients were older, more often women, and more likely to have hypertension, diabetes, ischemic heart disease, chronic kidney disease and atrial fibrillation. Regarding precipitating factors, infection, renal failure, anemia or bleeding, noncompliance and recent addition of negative inotropic drugs were predominant in AD-CHF, whereas ischemic event, severe hypertension, excessive alcohol or illicit drug use and endocrine abnormalities were predominant in de novo HF. AD-CHF patients showed lower serum sodium and hemoglobin, higher blood urea nitrogen and serum creatinine, and higher B-type natriuretic peptide level. De novo HF patients showed higher LV EF, smaller LV end-diastolic dimension and LA size, and lower RV systolic pressure. Although the use of renal replacement therapy was comparable, de novo HF patients were more frequently supported by mechanical ventilator and mechanical assisting device including IABP, PCPS and AD-CHF patients used inotropes more frequently. While in-hospital mortality was comparable between two groups (5.0% in AD-CHF vs 4.6% in de novo HF, P=0.396), 1-year mortality was significantly higher in AD-CHF patients (22.9% vs 13.9%, P < 0.001). In multivariate analysis adjustment for 13 risk variables including age, sex, and brain natriuretic peptide, the hazard ratio for the mortality was increased in patients with AD-CHF. (Figure)
Conclusion: Independent of other key prognostic variables, AD-CHF had significantly worse prognosis than de novo HF. They also showed many differences in clinical presentation, risk factors and laboratory values. Better understanding on these differences between de novo HF and AD-CHF is needed to improve outcomes for AHFS.

Introduction: Distinctive clinical, echocardiographic and biochemical features of chronic heart failure with preserved and reduced ejection fraction (HFPEF and HFREF) are well known, yet insights into the presentation of acute HFPEF and HFREF are scarce.
Objectives: This study aimed at characterizing acute HFPEF (defined as left ventricular (LV) EF ≥ 40%), HFREF (LVEF < 40%) and acute dyspnea of non-cardiac origin, with special emphasis on congestion, right ventricular (RV) and kidney dysfunction at admission.
Methods: Included patients derived from MEDIA-DHF (NCT02446327), investigating diagnostic and prognostic potential of echocardiographic measurements and biomarkers of congestion (MR-proANP and sCD146) in the initial, early presentation (< 4 hours of admission) of acutely decompensated heart failure (ADHF) and acute non-cardiac dyspnea.
Results: One hundred and forty-six patients with acute dyspnea were included in the study: 101 ADHF patients (60 classified as HFPEF, 41 as HFREF, with LVEF 50% [40-60] and 29% [20-33] respectively) and 45 with dyspnea of non-cardiac origin (LVEF 60% [54–65]). At admission, clinical characteristics were similar in ADHF and non-cardiac dyspnea patients, yet echocardiographic analysis of congestion, RV and LV systolic and diastolic function as well as biochemical analysis of kidney function, inflammation, fibrosis, cardiovascular stress and congestion differentiated between ADHF and non-cardiac dyspnea. Apart from indices of LV systolic function, HFPEF and HFREF patients presented similar echocardiographic alterations at admission, including comparable RV dysfunction (TAPSE 17 mm [14-20] and 17 mm [15-21] respectively, p > 0.05) and comparable signs of hemodynamic congestion (enlarged inferior vena cava and right atrium), except for a larger left atrium in HFREF (29 ± 8 cm2) compared to HFPEF (25 ± 7 cm2; p = 0.015). HFPEF and HFREF had similarly elevated plasma levels of MR-proANP and sCD146 that were both associated with poor outcome. Furthermore, HFPEF and HFREF had similar impairment of eGFR though parameters of congestion associated with kidney dysfunction in HFREF (eGFR and surface right atrium: r = -0.5474; p = 0.0428 ; eGFR and IVC diameter: r = -0.559 ; p = 0.0016), yet not in HFPEF (eGFR and surface right atrium: r = -0.132 ; p = 0.6274 ; eGFR and IVC diameter: r= 0.034 ; p = 0.8557).
Conclusion: In acute conditions, HFPEF and HFREF presented in a comparable state of hemodynamic congestion, with similarly altered RV and kidney function. The circulating biomarkers MR-proANP and sCD146 were reliable markers of global congestion as well as one-year prognosis in ADHF.

Funding Acknowledgements: The research was financially supported from the statutory grant for Department of Heart Diseases, Wroclaw Medical University, Poland (ST-905)

Background: Recent studies in acute heart failure (AHF) challenge a traditional approach connecting every rise in creatinine level with kidney injury/dysfunction and further unfavorable consequences. We apply the new definition of worsening renal function (WRF) linking the changes in serum creatinine with clinical status of the patients.
Purpose: The aim of the study was to characterize prevalence, determinants and prognostic significance of true WRF in AHF.
Methods: In 266 patients (mean age: 67 ± 12 years, 71% men), admitted with AHF, serum levels of creatinine were measured at baseline, day 2, and day 3. Patients who developed WRF (an increase of ≥0.3 mg/dL in serum creatinine or a >25% decrease in the estimated glomerular filtration rate from the baseline value during the first 3 days of hospitalization) were differentiated into those with true WRF (presence of deterioration or no improvement in clinical status during first 3 days) vs. pseudo-WRF (improvement in clinical status).
Results: True WRF and pseudo-WRF occurred in 11 (4%) and in 27 (10%) patients, respectively whereas remaining 228 (86%) patients did not develop WRF. At admission, those with true WRF had more often peripheral oedema (91 vs. 44 vs. 62 %), ascites (36 vs. 4 vs. 18 %), lower ejection fraction (36 ± 16 vs. 43 ± 11 vs. 34 ± 14 %), lower haemoglobin (11.6 ± 1.4 vs. 13.5 ± 2.2 vs. 13.1 ± 1.9 g/dL),lower albumins (3.6 ± 0.4 vs. 4.0 ± 0.4 vs. 3.8 ± 0.7 mg/dL), higher bilirubin (1.6 [0.7-2.3] vs. 0.9 [0.7-1.4] vs. 1.4 [0.8-2.4] mg/dL) and higher concentration of C-reactive protein (29 [19-42] vs. 5 [3-26] vs. 13 [6-33] mg/L) (true WRF vs. pseudo-WRF vs. without WRF, all P<0.05). Regarding treatment before hospitalization and at admission there were no significant differences between groups. During 1-year follow-up all-cause mortality was significantly higher in patients with true WRF (82%) compared to patients

with pseudo-WRF (11%) and those without WRF (27%), P=.00005. The occurrence of true WRF was an independent predictor of all-cause mortality (hazard ratio [95% confidence interval]: 4.43 [2.09-9.42], P=0.00012).
Conclusions: In patients with AHF, only true WRF identifies those with extremely high risk of death whereas development pseudo-WRF does not affect long-term outcome.

886
Functional mitral regurgitation predicts short-term adverse events in acute heart failure patients with reduced left ventricular ejection fraction

R De La Espriella Juan[1]; ES Enrique Santas[2]; GM Gema Minana[2]; AM Anna Mollar[2]; EV Ernesto Valero[2]; SGB Sergio Garcia-Blas[2]; JS Juan Sanchis[2]; SM Salvador Morell[1]; JN Julio Nunez[2]
[1]University General Hospital of Valencia, Department of Cardiology, Valencia, Spain; *[2]University Hospital Clinic of Valencia, Cardiology, Valencia, Spain*

Background: Functional mitral regurgitation (FMR) is a common finding among patients with acute heart failure (AHF) and reduced left ventricle systolic function (rLVSF). However, the short-term prognostic impact of FMR at discharge in AHF remains unclear. We aimed to evaluate the association between the severity of FMR and short-term adverse outcomes following a hospitalization for AHF.
Methods: We prospectively included 1180 consecutive patients with rLVSF discharged with a diagnosis of AHF. Of these, 242 patients (20.4%) with organic mitral valve disease, congenital heart disease or aortic valve disease were excluded, leaving the study sample in 938 patients. FMR was assessed semi-quantitatively by colour Doppler analysis of the regurgitant jet area and its severity categorized as: a) none or mild (grade 0-I), b) moderate (grade II) or severe (grade III or IV). The primary end-point was the composite of all-cause mortality and rehospitalization at 90 days. Multivariate analyses were performed using Cox proportional hazards models.
Results: At discharge, 533 (56.8%), 253 (26.9%) and 152 (16.2%) patients showed none-mild, moderate and severe FMR. At 90-day follow-up, 161 patients (17.2%) either died (49 patients) or were readmitted (112 patients). Rates of the composite endpoint were higher for patients with moderate and severe FMR as is shown in figure below. After multivariable adjustment, compared to patients with none or mild FMR, those with moderate and severe FMR had a significantly higher risk of reaching the endpoint [(HR=1.50; 95% CI: 1.04 – 2.17; p = 0.027 and HR=1.63; 95% CI: 1.07 – 2.48; p = 0.023, respectively].
Conclusion: FMR is a dynamic condition among patients with AHF and rLVSF. According to our results, more than mild FMR present at discharge identify a subgroup of higher risk of adverse clinical outcomes at short-term.

887
High serum bilirubin is associated with short-term mortality following a myocardial infarction complicated by heart failure and/or left ventricular systolic dysfunction

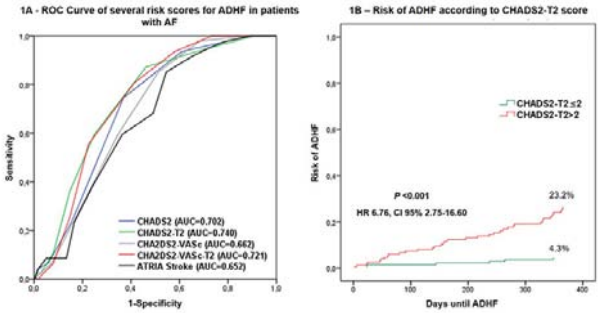
Z Frikha[1]; JP Ferreira[1]; E Bozec[1]; JJ Mcmurray[2]; B Pitt[3]; K Dickstein[4]; P Rossignol[1]; F Zannad[1]; N Girerd[1]
[1]INSERM, Centre d'Investigations Cliniques 9501, Université de Lorraine, CHU de Nancy, Institut Lorrain du cœur et des vaisseaux, Nancy, France and INI-CRCT F-CRIN Network, Vandoeuvre-les-Nancy, France; *[2]University of Glasgow, BHF Cardiovascular Research Centre, Glasgow, United Kingdom*; *[3]University of Michigan, School of Medicine, Ann Arbor, United States of America*; *[4]Stavanger University Hospital, Department of Cardiology, Stavanger, Norway*

Objectives: Higher serum bilirubin has been associated with poorer prognosis in patients with heart failure (HF). We examined the association between serum bilirubin and clinical outcomes in patients with clinical signs of HF and/or left ventricular systolic dysfunction following acute myocardial infarction (MI).
Methods: 7467 patients from the High-Risk MI Database Initiative (which merged the datasets of the CAPRICORN, EPHESUS, OPTIMAAL and VALIANT trials) with an available baseline total bilirubin concentration were studied. The association between baseline bilirubin concentration and cardiovascular mortality, hospitalization for HF and all-cause mortality was assessed using Cox proportional hazards models.
Results: The mean baseline total bilirubin concentration was 12 ± 7 μmol/l and was above the normal range (>17.1 μmol/l) 1053 (14.1%) patients. In multivariable analysis, with adjustment for baseline characteristics (demographic, co-morbidity, Killip score, left ventricular ejection fraction and laboratory variables), patients with bilirubin >17.1 μmol/l were at significantly higher risk for 90-day cardiovascular mortality (HR=1.45, CI=1.14–1.86, p = 0.003), cardiovascular mortality or hospitalization for HF (HR=1.26, CI=1.05–1.51, p = 0.02) and all-cause mortality (HR=1.51, CI=1.20-1.91, p < 0.001). The addition of bilirubin in the survival model was associated with a significant improvement in reclassification to predict cardiovascular mortality (continuous net reclassification improvement=6.4%, CI=0.7%-9.6%, p = 0.04).
Conclusions: In MI patients complicated with HF and/or systolic dysfunction, bilirubin concentration is an independent predictor of mortality and improves risk stratification. This low-cost routinely available biomarker may improve risk assessment in this population.

888
CHADS2-T2 - a new risk score to predict acute decompensated heart failure in patients with atrial fibrillation

J B Augusto[1]; M Borges Dos Santos[1]; D Roque[1]; D Faria[1]; H Ferreira[1]; J Urzal[1]; C Santos[2]; C Morais[1]
[1]Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal; *[2]Hospital Santo Andre, Leiria, Portugal*

Background: Atrial fibrillation (AF) is a frequent comorbidity in patients with heart failure (HF). Currently, there are several tools for prediction of acute decompensated heart failure (ADHF).
Purpose: We aimed to evaluate the prognostic value of two new scores (CHADS2-T2 and CHA2DS2-VASc-T2) based on well-known AF stroke risk scores, in the prediction of ADHF in patients with AF at 12-month follow-up.
Methods: 2181 consecutive patients with AF who were evaluated in our Emergency Department (ED) in a 12 month period were included retrospectively in our study. Among them, 423 patients were admitted for in-hospital management. We evaluated medical charts in order to calculate AF stroke scores at discharge: CHADS2, CHA2DS2-VASc and ATRIA Stroke. We added 2 points if there was a documented troponin I exceeding the 99th percentile of the reference population: CHADS2-T2 and CHA2DS2-VASc-T2. Primary outcome was the incidence of ADHF 12 months after discharge.
Results: We included 348 patients who were successfully discharged and who had at least one troponin I measurement during hospital admission (mean age of 71.8 ± 0.7 years, 39.4% males). In receiver-operating characteristic (ROC) analysis (Figure 1A), CHADS2-T2 score performed better than other scores in predicting ADHF (CHADS2 – c-index 0.702, p < 0.001; CHADS2-T2 – c-index 0.740, p < 0.001; CHA2DS2-VASc – c-index 0.662, p = 0.001; CHA2DS2-VASc-T2 – c-index 0.721, p < 0.001; ATRIA Stroke – c-index 0.652, p = 0.002). A CHADS2-T2>2 (Figure 1B) had a sensitivity of 85.7% (CI 95%: 71.5-94.6%) and a specificity of 53.0% (CI 95% 46.6-59.3%) for prediction of ADHF at 12-month follow-up.
Conclusions: The new CHADS2-T2 score is an easy and simple tool with high sensitivity, which can predict the risk of ADHF in patients with AF.



Scores and Risk of ADHF

889
Prognostic impact of right ventricular function in acute heart failure

C Daneluzzi[1]; D Stolfo[1]; M Merlo[1]; C Faggioli[1]; G Barbati[1]; A Scagnetto[1]; V De Paris[1]; P Lesizza[1]; S Albani[1]; P Gentile[1]; J Cristallini[1]; B Ortis[1]; S Franco[1]; A Di Lenarda[1]; G Sinagra[1]
[1]University Hospital Riuniti, Cardiovascular department, Trieste, Italy

Background: Acute decompensated heart failure (ADHF) is a major health problem worldwide. Prognostic stratification in the acute phase remains challenging despite several scores combining demographic, clinical and laboratory parameters have been proposed. Left ventricular (LV) systolic function is not generally a major determinant of outcome and in large registries the prognosis did not clearly diverged among patients with reduced or preserved ejection fraction (EF). On the other hand, right ventricular (RV) function is emerging as a strong outcome predictor in chronic HF but was not previously evaluated in ADHF setting.

Purpose: In the present study we sought to evaluate the impact of RV dysfunction on 2-years survival in a large cohort of patients admitted for ADHF and to assess the short-term in-hospital evolution of RV function after appropriate treatment.
Methods: We retrospectively screened all consecutive patients admitted for ADHF in our Department from January 2009 to December 2014. RV systolic function was assessed on echocardiography <24 h from admission and at discharge (median time 8 days). RV dysfunction was defined by a TAPSE $<$ 16 mm and/or a RV fractional area change $<35\%$. The primary endpoint was 2-years all-cause mortality.
Results: Globally, 560 patients with available RV function assessment were included. Mean age was 69 ± 12 years, 70% were males and 49% were ischaemic. Mean systolic blood pressure (SBP) at admission was 128 ± 26 mmHg, mean creatinine and median BNP values were respectively 1.36 ± 0.64 mg/dl and 776 (95% CI 707-845) pg/ml. RV function was impaired in 241 patients (43% of the overall cohort). In these patients non-ischaemic etiology of HF was more frequent (54% vs 41% of ischaemic, $p < 0.002$). They were younger (age 66 ± 14 years vs 72 ± 10, $p < 0{,}001$) with a lower rate of comorbidities. SBP at presentation was lower (120 ± 23 vs 133 ± 27 mmHg, $p < 0.001$). RV dysfunction was more frequent among patients with reduced LVEF (56%) compared to patients with mid-range EF (20%) and preserved EF (31%). 2-years survival was similar among ranges of LVEF (EF $<40\%$ vs EF 40-49% vs EF>50%, p>0.05), instead patients with RV dysfunction exhibited a worst outcome (2-years mortality 52% vs 40% in patients with preserved RV function, $p < 0.01$). Finally, at a median time of 8 days, RV function was reassessed in 479 patients showing a normalization after therapy in 46 % of patients.
Conclusions: In ADHF right ventricular function rather than LV ejection fraction showed an impact on prognosis. Larger prospective studies are needed to confirm our preliminary data and to assess the effect of targeted supportive therapy for RV function in this specific setting.

890

Early post-discharge ST2 and NTproBNP for predicting 30-day heart failure readmission in a very old and co-morbid population with predominantly HFpEF

C Pacho[1]; M Domingo[1]; R Nunez[1]; J Lupon[1]; E Revuelta[2]; J Barallat[1]; P Moliner[1]; B Gonzalez[1]; M Rodriguez[1]; C Rivas[1]; V Diaz[1]; J Santesmases[1]; M De Antonio[1]; J Tor[1]; A Bayes-Genis[1]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain; *[2]Health Research Institute Germans Trias, Badalona, Spain*

Background: Heart failure (HF) is associated with a high rate of readmissions within 30 days post-discharge. This figure is even higher in the old and co-morbid patients, mainly affected from HFpEF. Attempts to predict short-term outcome in such population have not been particularly successful. Data on biomarkers in such especial population are scarce.

Purpose: To assess the usefulness for predicting 30-day outcome of early post-discharge blood levels of ST2 and NTproBNP in a very old and co-morbid HF population.
Methods: Blood sample were obtained at first visit in the specific HF-Clinic shortly after discharge from a HF-related hospitalization (mean 4.9 ± 2 days). HF-related rehospitalization and the composite end-point all-cause mortality or HF-related rehospitalization were the primary end-points.
Results: 522 patients (57.1% women, mean age 82 ± 8.7 years, 25% older than 88 years) were included. Mean LVEF (available in 390 patients) was $58.8\% \pm 14$. Main aetiologies were: hypertensive (40%), ischemic (29%) and valvular (13%). Diabetes, anaemia and renal failure were present in 53%, 65% and 79% respectively. Mean Barthel index was 70 ± 25 and mean Charlson index was 5.6 ± 2.2. 30-days HF-related re-hospitalization occurred in 36 patients (6.9%), death in 13 (2.5%) and the composite end-point in 45 (8.6%). In the univariate analyses urea ($p < 0.05$), diabetes ($p = 0.006$), Charlson index ($p = 0.001$) and ST2 ($p = 0.002$) were associated with 30-days HF-related rehospitalization, and NTproBNP showed borderline results ($p = 0.07$); whereas diabetes ($p = 0.01$), urea ($p = 0.04$), Barthel index ($p = 0.01$), Charlson index ($p < 0.001$), NTproBNP ($p = 0.001$), and ST2 ($p < 0.001$) were associated with the composite end-point. In the multivariable analyses female sex (OR 2.24 [1.03-4.82], $p = 0.04$), Charlson index (OR 1.27 [1.08-1.48], $p = 0.004$), and ST2 (OR 1.41 [1.03-1.93], $p = 0.03$) were the only independent variables associated with 30-days HF-retated rehospitalization and also with the composite end-point (female sex OR 2.22 [1.11-4.43], $p = 0.02$, Charlson index OR 1.30 [1.12-1.50], $p < 0.001$, and ST2 OR 1.60 [1.20-2.13], $p = 0.001$). The clinical model including age, sex, diabetis, urea, and Charlson index obtained an AUC of 0.67 [95%CI 0.58-0.76] for the risk prediction of HF-related rehospitalization. Adding NTproBNP, ST2 or both biomarkers, the results were 0.71, 0.72 and 0.73 respectively. For the risk prediction of the composite end-point the clinical model including the same variables plus Barthel index obtained an AUC of 0.69. Adding NTproBNP, ST2 or both biomarkers, the results were 0.73, 0.73 and 0.75 respectively.
Conclusions: In a very old and co-morbid population with mainly HFpEF,early post-discharge ST2 performed better than NTproBNP for the risk prediction of 30-days HF-related rehospitalization and for the composite end-point including all-cause mortality. The inclusion of both biomarker in a predictive model improve C-statistics for both end-points.

POSTER SESSION 2

ACUTE HEART FAILURE

P896

Immune-mediated inflammation and acute left ventricular failure in myocardial infarction

AR Aida Babaeva[1]; AA Tarasov[1]; SI Davydov[1]; MA Gordeeva[1]; AL Emelyanova[1]
[1]*Volgograd State Medical University, Volgograd, Russian Federation*;

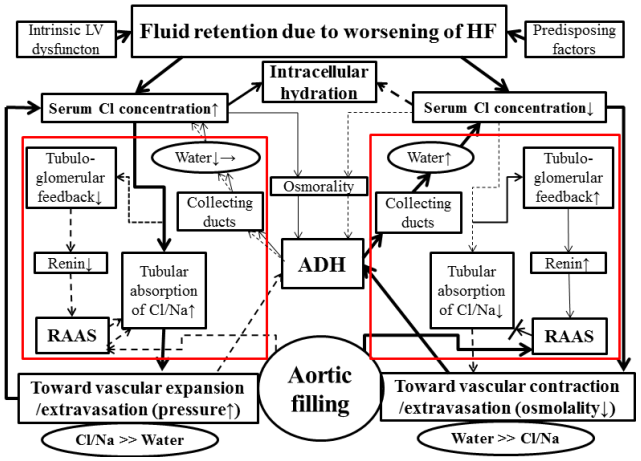
Background: Myocardial infarction (MI) is the commonest cause of acute left ventricular failure (ALVF) and cardiogenic shock. Our previous studies have revealed dramatically elevated levels of circulating pro-inflammatory cytokines and anti-connective tissue antibodies in MI patients.
Purpose: of this investigation was to assess the relationship between circulating markers of immune-mediated inflammation and ALVF in the setting of MI.
Methods: 215 pts with determined MI were included in the investigation. ALVF was diagnosed in 32 (14.88%) pts on the basis of the clinical and echocardiography data. The levels of pro-inflammatory cytokines (TNFα, IL1β, IL6) and anti-connective tissue antibodies (ACTA): antibodies against collagen (ACA), hyaluronic acid (AHA) and chondroitin sulfate (ACSA) were measured by ELISA in sera samples from MI pts and 50 controls.
Results: The serum levels of TNFα, IL1β, IL6, ACA, AHA and ACSA were significantly higher in MI pts than in controls. The most prominent abnormalities were revealed in STEMI complicated by ALVF, especially in cardiogenic shock and in pulmonary edema. There were significant differences between mean levels of key pro-inflammatory cytokines and ACTA in MI groups with ALVF and without one. Moreover the strong correlation was determined between hemodynamic abnormalities according to Killip's classes and levels of IL6 and AHA (r=0.78, 0.72 respectively). Moderate correlation was found between Killip's classes on the one hand and TNFα, IL1β, ACA on the other hand (r=0.56, 0.59, 0.62 respectively).
Conclusion: Obtained data show that ALVF in MI is associated with dramatically increased levels of key pro-inflammatory cytokines and ACTA. This phenomenon can be concerned as reflection of the severity of myocardial damage in MI. Assessment of the serum pro-inflammatory cytokines and anti-connective tissue antibodies can be used for diagnostic and prognostic purposes.

P897

The chloride theory, a unifying hypothesis for renal handling and body fluid distribution in heart failure pathophysiology

H Hajime Kataoka[1]
[1]*Nishida Hospital, Oita, Japan*

Background– A unifying hypothesis for heart failure (HF) pathophysiology based on serum biochemical solute(s) has yet not been developed.
Purpose: Chloride is an established key electrolyte for tubuloglomerular feedback and subsequent body fluid reabsorption in the kidney. Elucidation of the involvement of chloride in body fluid distribution under transition of HF status will contribute to the development of a unifying hypothesis of HF pathophysiology.
Methods: Data from 47 HF patients that experienced worsening and subsequent recovery of HF were analyzed. Blood tests included peripheral blood and serum albumin/solutes (sodium/potassium/chloride/urea nitrogen/creatinine). Relative change in the plasma volume (%PV) was determined by the Strauss method based on changes in the hemoglobin and hematocrit.
Results: (1) Worsening HF–When divided into two groups based on the median %PV, the clinical features of the expansion group (%PV [range 11%-36%]; n=24) included a lower incidence of crackles (13 vs 52%,p = 0.005) and a tendency toward preserved renal function defined by a decrease in serum creatinine (83% vs 57%,p = 0.06) in comparison with the non-expansion group (%PV [range -19% to 10.8%]; n=23). Multivariate logistic regression analysis revealed an independent association between the increase in %PV and the increase in the serum chloride concentration from stability to worsening HF (OR:12.5, 95%CI:1.89-82, p = 0.009). (2) Recovery after HF therapy–Multivariate regression analysis demonstrated an independent association between preserved %PV and an increased or preserved serum chloride concentration after conventional diuretic therapy (OR:8.71, 95%CI:1.20-63.0, p = 0.032).
Conclusions: The present study propose a unifying hypothesis of HF pathophysiology based on the "chloride theory" (Figure). This hypothesis is the first to unify the two main platforms of the body fluid-processing organs through one key electrolyte, chloride, in both 1) the kidney, which reabsorbs body fluid via main control by the renin-angiotensin-aldosterone system, and 2) the body, an organ with dynamic body fluid storage in the intracellular, intravascular, and interstitial compartments.



Chloride theory for worsening HF

P898

Risk factors and outcomes of hospital-acquired heart failure in medical patients with no pre-existing cardiac dysfunction

V Kittipibul[1]; P Torvorapanit[1]; S Gonlachanvit[1]; A Ariyachaipanich[1]
[1]*Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand*

Background: Heart failure (HF) is a common complication in hospitalized patients with known cardiac dysfunction and associated with higher mortality and longer hospital stay. Little is known about new-onset, hospital-acquired or iatrogenic HF in patients with no pre-existing cardiac dysfunction. This study aims to study risk factors, impacts of fluid balance, and outcomes of hospital-acquired HF in patients with no pre-existing cardiac dysfunction.
Methods: We conducted a case-control study by prospectively reviewing consecutive medical patients with no pre-existing cardiac dysfunction who developed new-onset HF during hospitalization for non-cardiac diagnoses from January 2015 to December 2015. Two control patients who have no pre-existing cardiac dysfunction were chosen per case with matched age, gender, and date of admission. When this was not possible, at least 1 control patient was selected. Patient characteristics, treatments, and outcomes were gathered. Chi-square test, T-test, and binary logistic regression were used for analysis.
Results: We identified 27 cases of hospital-acquired HF (mean age 64 ± 20 years and 67% female) with various primary diagnoses (52% infection, 28% cancer, 11%

gastrointestinal bleeding, and 11% pancreatitis) and 45 control patients (mean age 65 ± 17 years and 64% female). There was no significant difference in demographics, primary diagnoses, medications and laboratory values between 2 groups. Median time from admission to the onset of hospital-acquired HF was 3 (range 1 to 19) days. There were no differences in total fluid intake over 1, 3 and 7 days prior to onset of hospital-acquired HF between cases and controls (1,108 ± 226 ml vs 1,341 ± 202 ml; p = 0.229, 7,287 ± 2414 ml vs 7051 ± 3139 ml; p = 0.807 and 8261 ± 4282 ml vs 7,906 ± 6239 ml; p = 0.805, respectively). Positive fluid balance over 1, 3 and 7 days prior to onset of hospital-acquired HF were higher in a case cohort (1,755 ± 1260 ml vs 952 ± 1084 ml; p = 0.008, 4,294 ± 2535 ml vs 1635 ± 2402 ml; p = 0.003 and 4829 ± 2871 ml vs 943 ± 3358 ml; p < 0.001, respectively). Hospital-acquired HF was associated with increased use of urinary catheterization (30% vs 9%, p = 0.024), mechanical ventilation (22% vs 2%, p = 0.005) and prolong hospital stay (27 ± 22 days vs 20 ± 19 days, p = 0.013). There were 2 HF-related mortalities among case cohort.
Conclusion: Positive fluid balance, but not total fluid intake, is associated with developing of hospital-acquired HF in medical patients with no pre-existing cardiac dysfunction. Hospital- acquired HF can lead to morbidities such as the increased rate of urinary catheterization, mechanical ventilation, and prolonged hospitalization.

Biological variation of extracellular matrix biomarkers in patients with stable chronic heart failure

T Tobias Taeger[1]; H Froehlich[1]; A Corletto[1]; HA Katus[1]; L Frankenstein[1]
[1]*University Hospital of Heidelberg, Department of Cardiology, Heidelberg, Germany*

Funding Acknowledgements: Thiw work was supported by a grant by novartis

Background: Extracellular matrix (ECM) biomarkers such as matrix metalloproteinases (MMPs) and their inhibitors (TIMPs) are up-regulated in chronic heart failure (HF). Serial measurements of MMPs and TIMPs may be useful for therapy guidance and risk stratification of patients with CHF. However, interpretation of time-dependent changes requires knowledge about the biological variation of ECM biomarkers.
Methods: We performed measurements of MMP-2, MMP-9, TIMP-1, and TIMP-4 in 50 patients with chronic HF who met rigid criteria for clinical stability at 3-hour, 6-hour, 1-week and 2-week time intervals. In addition, clinical and haemodynamic assessment was performed at baseline, at 1-week and 2-week intervals. Haemodynamic variables were measured using inert gas rebreathing and impedance cardiography. Heart rhythm was monitored with external ECG event recorders throughout the complete study. Reference change values (RCVs) and minimal important differences (MIDs) were determined for MMP-2, MMP-9, TIMP-1, and TIMP-4.
Results: Clinical and haemodynamic variables were stable over time. Depending on the time-interval, RCVs ranged between 4.9% and 11.7% for MMP-2, 26.4% and 56.7% for MMP-9, 10.8% and 30.7% for TIMP-1, and 16.0% and 47.4% for TIMP-4, respectively. The MIDs varied between 43.38 and 65.22 ng/ml for MMP-2, 28.71 and 40.96 ng/ml for MMP-9, 52.32 and 156.07 ng/ml for TIMP-1, and 293.92 and 798.04 pg/ml for TIMP-4, respectively.
Conclusion: The biological variation of ECM biomarkers differs with respect to individual biomarkers and time intervals. MMP-2 may be most suitable for serial biomarker measurements, as the biological variation is low irrespective of the time interval between measurements.

Clinical and analytical patterns and the different mechanisms of cardiorenal syndrome.

H De Barros Viegas[1]; P Freitas[1]; G Amaral Mendes[1]; B Lobao[1]; S Marques[1]
[1]*Hospital Center of Setúbal, Internal Medicine, Setúbal, Portugal*

Background/Introduction: In recent years new data on physiopathology of cardiorenal syndromes has been collected but the impact in acute management is still to be found.
Purpose: We tried to find different patterns using simple clinical and analytical data that could point to the main decompensated mechanism using a retrospective cohort sample of patients from a level 2 intermediate care unit. We also accessed the impact of Non-invasive ventilation (NIV), the need for ultrafiltration and a strategy of diuretic plus slight hydration on these different patterns.
Methods: We selected 110 patients with decompensation of heart or renal function but excluded 53 for not having cardiorenal syndrome or with acute type 5 (sepsis).
Results: We had 56,34% males with a mean age of 76,3 years, mostly type 1 76,74%, fewer type 3 20,93% and 1 case of type 2. 44,19% presented worst renal function at admission (less than 24 hours) and 37,21% after 3 to 5 days, this groups were statistically different. Mortality rate was 27,27%.
Conclusions: More data is being processed and validated but we have found a statistical difference at the time of worst renal function and this was not associated with the degree of basal chronic renal disease or the type of cardiorenal syndrome. It appears to be related with the degree of congestion and with the use of pulsed diuretic. The ones with worst renal function at admission appear to have a better diuresis in response to diuretic therapy. This finds suggest that the different mechanism of cardiorenal syndrome type 1 or 3 can make a difference in the initial approach in an acute setting and this data gives the basis for a much needed prospective study.

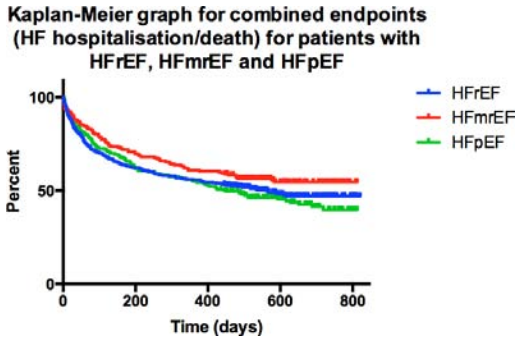
Funding Acknowledgements: VP2HF

Background: In 2016 the ESC published updated guidelines for the diagnosis of patients with heart failure, introducing the category Heart Failure with mid-range Ejection Fraction (HFmrEF).
Aims: This study sought to define the demographics, prognostic variables and clinical outcomes in patients with HFmrEF from a large unselected population of heart failure patients admitted to a Tertiary Hospital in the United Kingdom.
Methods: 2077 consecutive patients over a 12 month period were screened for heart failure through our heart failure (HF) service and were followed up for a mean of 15.8 ± 8.7 months from September 2014 to September 2015. Patients were categorised as heart failure with preserved ejection fraction (HFpEF), HFmrEF and heart failure with reduced ejection fraction (HFrEF) according to the 2016 ESC guidelines. Echocardiography was used to determine LVEF and NTproBNP was measured at presentation. Patient demographics (age, gender, ethnicity), risk factors and outcome (time to HF hospitalisation or all cause death) were recorded.
Results: 632 patients with HF were identified (mean age 72.6 ± 15.4 years, 60% male). 136 patients were identified with LVEF 40-49%; with 87.1% satisfying ESC criteria for diagnosis of HFmrEF with evidence of diastolic dysfunction and/or structural heart disease. These patients with 'true' HFmrEF patients had lower plasma sodium levels (137.6 ± 3.5 v 142 ± 0.1, p < 0.05), higher MCV (91.9 ± 9.4 v 84.5 ± 9.2, p < 0.05) and were less likely to have coronary artery disease (40.8% v 68.8%, p < 0.05) than the 16 patients with HF, raised NTproBNP and LVEF 40-49% but no evidence of diastolic dysfunction and/or structural heart disease.
Demographics and prognostic markers differed by heart failure diagnosis. Compared to patients with HFrEF, patients with HFmrEF were older (70 ± 15.1 v 74.5 ± 13.3, p < 0.05) had lower NTproBNP (12,130.6 ± 16001.8 v 8796.7 ± 12,054.4, p < 0.05) and were more likely to be hypertensive (54.6% v 67.6%, p < 0.05) and/or have obstructive sleep apnoea (2.8% v 8.8%, p < 0.05). Whereas compared to HFpEF, HFmrEF patients were more likely male (42.3% v 52.2%, p < 0.05), less likely to be afrocaribbean (25.3% v 16.9%, p < 0.05), with higher NTproBNP (4670.7 ± 6960.9 v 8796.7 ± 12,054.4, p < 0.05) and fewer risk factors (3.7 ± 1.6 v 3 ± 1.6, p < 0.05).
Patients with HFmrEF had better clinical outcomes than both the HFpEF and HFrEF groups, with higher mortality in the HFrEF population and higher HF rehospitalisation rates in the HFpEF population.
Conclusions: HFmrEF accounted for 16.9% of all the symptomatic heart failure patients admitted from a large unselected population of heart failure patients. When defining patients' demographics, blood tests, risk factors, the HFmrEF population were statistically distinct from the HFrEF and HFpEF population. Patients with HFmrEF had better outcomes, compared to high rates of mortality seen in patients with HFrEF and high rates of HF hospitalisations seen in patients with HFpEF.



Kaplan-Meier graph

P902

Relationship between high admission glucose and in-hospital heart failure in patients with AMI

S Chimed[1]; B Khuyag[2]
[1]*Institute of Medical Sciences, Department of Cardiology, Ulaanbaatar, Mongolia*;
[2]*The State Third Central Hospital, Coronary Care Unit, Ulaanbaatar, Mongolia*

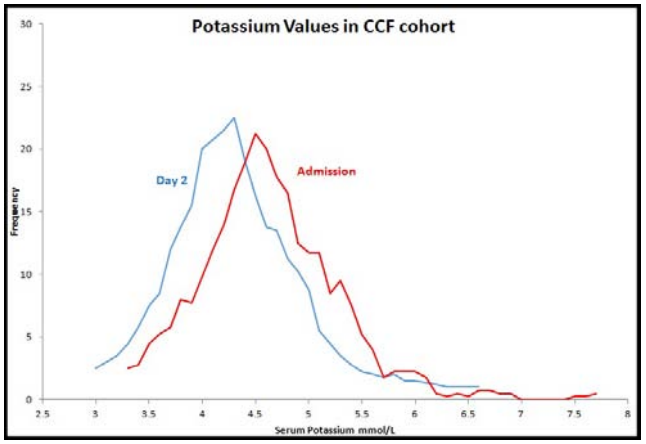
Background: Patients with acute myocardial infarction (AMI) often had high admission glucose, regardless previous history of diabetes mellitus (DM). Previous studies demonstrated that hyperglycemia in patients AMI is associated with adverse outcomes.
Aims: In this study, we aimed to reveal relationship between high admission gluocse and in-hospital heart failure (HF) in patients with AMI.
Material and methods: Patients with AMI who treated by primary PCI were prospectively selected. Plasma glucose level is measured on admission in all patients. Hyperglycemia was defined as admission plasma glucose ≥11.1 mmol/l. In-hospital HF was defined according to the Killip classification. Multiple logistic regression analysis was used to assess relationship between admission glucose level and in-hospital HF.
Results: A total of 428 patients (59 ± 13, 84% male) were included in this study. 122 patients had high plasma glucose (≥11.1 mmol/l) on admission and classified as a hyperglycemia. 306 patients had normal plasma glucose (< 11.1mmol/l) on admission and classified as a normoglycemia. Occurrence of in-hospital HF was significantly higher in patients with hyperglycemia compared with normoglycemia (30% vs. 21%, $p < 0.05$). In multivariable logistic regression analysis was showed that admission glucose level is independently associated with in-hospital HF after adjustment of age, gender, hypertension, previous myocardial infarction, previous heart failure, previous coronary artery disease, chronic kidney disease, heart rate, multivessel disease, LAD culprit vessel and final TIMI flow grade in non-diabetic patients (OR 1.10, 95% CI 1.02-1.18, $p < 0.01$). Furthermore, univariable logistic regression analysis revealed that every 1 unit increase of admission glucose level is associated with 1.07 fold increased probability of in-hospital HF (OR 1.07, 95% CI 1.01-1.15, $p < 0.05$) in non-diabetic patients.
Conclusion: Our results suggest that admission glucose level was independent predictor of in-hospital HF in patients with AMI. However, this relationship is only evident for non-diabetic patients.

P903

Is hypokalaemia during acute exacerbations of heart failure preventable or predictable?

D Daniel O'hare[1]; C O'connor[1]; Z Coyne[1]; G Balan[1]; C Macsweeney[1]; K Tuite[1]; J Fay[1]; R Murphy[1]; C Daly[1]
[1]*St James Hospital, Dublin, Ireland*

Background: Heart failure activates the renin-angiotensin aldosterone system, which leads to hypokalaemia. This is aggravated by upregulated sympathetic drive and the use of increased amounts non-potassium sparing diuretics during acute exacerbations. Mild hypokalaemia has been shown to increase cardiovascular events in a treated heart failure population. In patients with NYHA class I to III patients, elevations of serum potassium have been shown to reduce the incidence of fatal arrhythmias and sudden cardiac death. There is growing evidence that serum potassium levels should be maintained above 4 mmol/l in heart failure patients.
Methods: We performed a retrospective review of all patients admitted to a tertiary refferal centre during a one year period from 1st January 2015 to 31st December 2015, with a principal diagnosis of congestive cardiac failure. A total of 330 patients were included. Blood results on admission, 24 hours and the final result prior to discharge were included for analysis.
Results: On admission, 67 (22%) of the 309 patients with admission bloods had a serum potassium value of less than 4.0 mmol/l. Of the sub-group of patients that had bloods taken at both admission and 24 hours, ($n = 287$) the percentage of patients with a serum potassium less than 4.0 mmol/l at 24 hours significantly increased from 21% to 36% ($p < 0.001$).
The average serum potassium of all patients fell significantly during the first 24 hours from 4.44 mmol/L to 4.17 mmol/l ($p < 0.0001$). This resulted in significantly more patients (11% vs 5%) with a potassium value of less than 3.5mmol/l after 24 hours. ($p < 0.001$)
Patients who had a serum potassium of less 3.5mmol/l after 24 hours had a significantly lower serum magnesium on admission than the patients whose 24 hour potassium result was within the normal range. (0.71 mmol/L vs 0.81 mmol/L, $p < 0.001$)
Of the patients surviving to discharge, over 33% were discharged with serum potassium values less than 4.0mmol/l.
Conclusion: Our results demonstrate that a significant number of patients with heart failure have lower than desirable serum potassium levels on admission, through their inpatient stay and on discharge. Within a cohort of patients hospitalised for exacerbations of heart failure, serum potassium levels fall during the first 24 hours. There is a significant correlation between hypomagnesaemia on admission and the prediction of hypokalaemia 24 hours later. Hypokalaemia has been shown to be an independent predictor of mortality in heart failure. This study highlights the importance of close monitoring of serum potassium levels early in the admission, and suggests that identification of hypomagnesaemia can predict hypokalaemia at 24 hours. The authors advise early consideration of aldosterone antagonists or potassium replacement in these patients.



Visual representation of potassium trend

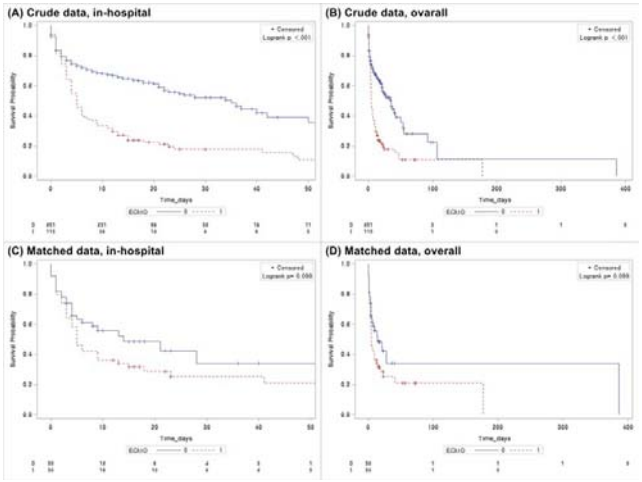
Role of extracorporeal membrane oxygenation in acute myocardial infarction complicated by cardiogenic shock

H W Lee[1]; JW Park[1]; JH Ahn[1]; JS Park[1]; JH Oh[1]; JH Choi[1]; HC Lee[1]; KS Cha[1]; TJ Hong[1]; JC Choi[1]; SH Lee[1]; DY Kim[1]; JY Shin[1]
[1]*Pusan National University Hospital, Department of Cardiology, Busan, Korea Republic of*

Purpose: The role of extracorporeal membrane oxygenation (ECMO) in refractory cardiogenic shock is increasing. Among the various roles, temporary support for myocardial stunning during the peri-myocardial infarction (MI) period is of utmost importance. We evaluated the role of ECMO in such patients.
Methods: Of 11,974 acute MI cases between March 2006 and December 2014 from the Korea Acute Myocardial Infarction Registry, 1,022 patients (8.5%) were complicated with cardiogenic shock (CS) during index hospitalization. Of 766 CS patients with available data, 115 (15%) were in the ECMO group and 651 (85%) were in the NO-ECMO group. Clinical outcomes were survival analysis, and complications during hospitalization. We evaluated both crude- and propensity-matched cohorts. Cox regression analysis evaluated the factors associated with long-term mortality. Results: Patients in the ECMO group were younger, had lower initial mean BP, larger infarct size, and more left-sided coronary artery disease as the target vessel. Crude- and propensity-matched data showed significantly higher major and minor bleeding complications. However, there were no statistical differences in in-hospital and long-term survival between the ECMO and NO-ECMO groups in propensity-matched data. Cox regression analysis revealed that ECMO application was not a significant predictor for mortality (hazard ratio 1.505; 95% confidence interval 0.907-2.498; $p = 0.11$). Conclusions: ECMO application did not affect survival in this study population in spite of increased bleeding risk. Early ECMO application was associated with increased survival.



Clinical outcomes

P905

Outcomes of VA ECMO in cardiogenic shock - Bridging to recovery, ventricular assist device and transplantation

S Jaamaa-Holmberg[1]; B Salmela[1]; R Suojaranta-Ylinen[2]; K Lemstrom[1]; J Lommi[1]
[1]Helsinki University Central Hospital, Heart and Lung Center, Helsinki, Finland; *[2]Helsinki University Central Hospital, Anesthesiology and Intensive Care, Helsinki, Finland*

Funding Acknowledgements: The Finnish Medical Foundation, Governmental grant for research in health/ Helsinki University Hospital, Heart and Lung Center

Background: The use of venoarterial extracorporeal membrane oxygenation (VA ECMO) in refractory cardiogenic shock have expanded rapidly during the last years. Data on its´ benefit in patient subgroups is though still limited.
Purpose: To evaluate the outcome and prognostic factors for ECMO in cardiogenic shock.
Methods: Retrospective analysis of 142 consecutive VA ECMOs in a transplant center in 2007-2016.
Results: Mean age was 51.4 years (SD 12.2), 70% were men, and 92% Intermacs profile 1. Mean duration of ECMO was 7.5 days (SD 6.8) and of ICU stay 21.1 days (SD 22.2). The most frequent indications for ECMO were postcardiotomy shock (26%), acute coronary syndrome (ACS) (23%), cardiomyopathy (18%), primary graft failure (17%), and fulminant myocarditis (11%). In total, 30-day survival was 72%, hospital discharge rate 63% and one year survival 61%. Hospital discharge rates according to indication of ECMO were: myocarditis 81%, cardiomyopathy 75%, postcardiotomy shock 65%, primary graft failure 58% and ACS 50%. 75 (53%) patients were weaned from ECMO with no need to further procedures, 13 (9%) received ventricular assist device (VAD) from ECMO, and 15 (11%) underwent emergency heart transplantation (HTx). Survival rates to hospital discharge for these groups were 87%, 77% and 93%, respectively. For patients bridged with ECMO to VAD, the most frequent diagnosis was cardiomyopathy (54%) while for patients bridged to HTx, cardiomyopathy and myocarditis were equally common, both 27%. 39 (27%) patients died during ECMO, of which 23 (62%) had been resuscitated prior to ECMO.
There was no significant difference in age (50.0 vs 53.1 years, $p = 0.12$), body mass index (27.8 vs 28.1, $p = 0.86$), gender ($p = 0.79$), or duration of ECMO (7.3 vs 7.8 days, $p = 0.71$) between hospital survivors and non-survivors. The amount of red blood cells (RBC) transfused during the ICU stay was significantly higher for non-survivors (mean 6.2 units/day vs 1.4 units/day, $p < 0.001$) than for hospital survivors. Cardiac arrest prior to ECMO implantation ($n = 49$; OR 3.2, $p < 0.01$), initiation of ECMO or emergency perfusion followed by ECMO during resuscitation ($n = 29$; OR 3.7, $p < 0.01$), lower blood HCO3 prior to ECMO (15.0 vs 18.2 mmol/liter, $p < 0.001$) and higher blood lactate (9.8 vs 6.1 mmol/liter, $p < 0.001$) associated with increased hospital mortality. Most frequent complications were stroke (16%), limb ischemia (13%) and need of fasciotomy (8%). Simultaneous use of intra-aortic balloon pump associated with increased risk of lower limb ischemia (OR 3.2, $p < 0.05$).
Conclusions: ECMO can enable recovery to hospital discharge for over 60% of selected patients with severe cardiogenic shock. In our cohort, ECMO benefitted most the patients with myocarditis or cardiomyopathy, both as a bridge to recovery of heart and as a bridge to VAD or HTx. Cardiac arrest, ECMO implantation during resuscitation and need of high amounts of RBCs transfused associated with increased risk of hospital death.

P906

Acute heart failure in the real world: are elderly patients managed in accordance to current guidelines? Data from the ATHENA registry

A Pratesi[1]; S Baldasseroni[1]; S Parlapiano[1]; A Herbst[1]; A Berni[2]; G Ciuti[2]; AC Baroncini[1]; C Ghiara[1]; G Baglioni[1]; L Poggesi[2]; A Moggi Pignone[2]; L Gabbani[1]; C Nozzoli[2]; N Marchionni[3]; F Orso[1]
[1]Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy; *[2]Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; *[3]Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

Background: Heart failure (HF) has a high prevalence in the elderly. Adherence to HF guidelines improves prognosis and is very high in randomised clinical trials (RCTs), it also seems to be quite high in clinical registries which represent the so-called "real world". However, HF registries may maintain a certain level of selection bias by including only patients hospitalised in cardiology wards while administrative data show that the majority of HF patients are admitted to internal medicine and geriatrics wards where adherence to guidelines could be less optimal.
Purpose: to compare adherence to current clinical guidelines in the management of elderly patients hospitalised for acute HF in differnt settings of care: cardiology, internal medicine and geriatrics.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (≥ 65 years) admitted with diagnosis of acute HF to the emergency department (ED) of a tertiary University teaching-hospital and transferred to the above described settings of care. We evaluated adherence to current European Society of Cardiology (ESC) guidelines regarding echocardiogram performance during hospitalisation, body weight measurement on admission and at discharge, follow-up (FU) schedule and evidence based prescriptions at discharge.
Results: 342 patients composed the study population; 17.8% were hospitalised in cardiology, 17.3% in geriatrics and 64.9% in internal medicine. Mean age was 83.7 years, females were 54.1%. 28.1% of the patients had not performed any echocardiographic evaluation during hospitalization: 3.3% in cardiology, 17% in geriatrics and 37.8% in internal medicine ($P < 0.001$). Body weight measurement on admission and at discharge was collected only in 24% of patients and in 44% of patients no information regarding body weight measurement was collected during hospitalisation (1.6% in cardiology, 41.4% in internal medicine and 54.2% in geriatrics; $p < 0.001$). We analysed evidence based prescription rates at discharge in the subgroup of patients with HF with reduced ejection fraction (HFrEF, 49% the total population) for beta-blockers, ACE-inhibitors, angiotensin receptor blockers and mineralocorticoid receptor antagonists that were 81,3% 39,6%, 23,1% and 48,4%, respectively, without significant differences across the considered settings of care. A clinical FU at the discharge was scheduled only in 16.0% of the total study population, 70.0% in cardiology, 7.0% in geriatrics and in 5.0% of those discharged from internal medicine (P=0.001).
Conclusions: in elderly patients hospitalised for acute HF a low adherence to current international guidelines recommendations regarding HF management could be observed particularly in patients hospitalised in non-cardiological settings. This was particularly evident for non-pharmacological strategies that are known to reduce the risk of rehospitalisation.

P907

Protocol of the IMPACT-study: Improve Management of Heart Failure with Procalcitonin

M Mockel[1]; A Anna Slagman[1]; J Searle[1]; S Ebmeyer[2]; J C Wiemer[2]; J O Vollert[2]; A Maisel[3]
[1]Charite - Campus Virchow-Klinikum, Department of Cardiology, Berlin, Germany; *[2]Thermo Fisher Scientific, Global Medical Affairs, Hennigsdorf, Germany*; *[3]University of California San Diego, Division of Cardiovascular Medicine, San Diego, United States of America*

Background: Patients with acute HF and pulmonary infections are not uncommon in the acute health care setting and often present with overlapping signs and symptoms. Procalcitonin (PCT), is a precursor protein of the hormone calcitonin, consisting of 116 amino acids. Procalcitonin blood levels reflect the presence and severity of bacterial infection.
Purpose: To evaluate an advantage of PCT guided antibiotic treatment over established treatment practice with respect to 90-day all-cause mortality.
Methods: The IMPACT study is a prospective, multicentre, randomized-controlled, interventional biomarker study. In patients randomized to the intervention group, antibiotic therapy is guided by PCT-measurements on day 0 and day 1 (figure 1).
Expected study results: 792 patients (396 per group) are planned. The study employs an adaptive design. An interim analysis is conducted to allow for sample size adaptation. At this point in time, the sample size for this study is estimated based on a difference in 90 day mortality between the groups of 7% (11% PCT guided vs. 18% standard care). This effect size was estimated by applying stratified

Cox models to BACH study data. Based on a two-sided chi-square test for two independent proportions 396 subjects per study arm would be sufficient to detect this difference with a power of 80% at an alpha level of 5% in a study design with fixed sample size. The study however employs an adaptive design including an interim analysis after 198 patients per study arm completed their 90 days follow-up to allow for sample size adjustment as required.
Conclusions: The IMPACT study is the first study to evaluate the concept of PCT-guided antibiotic treatment applying a randomized design in this specific setting. Provided that the study result is positive, the IMPACT study will prove the beneficial effect of a PCT-guided antibiotic therapy on top of standard diagnostic and therapeutic procedures in patients with acute decompensated heart failure.

Noninvasive ventilation in acute cardiogenic pulmonary edema

MJ Vieira[1]; L Reis[1]; P Dinis[1]; M Madeira[1]; J Ribeiro[1]; A Fernandes[1]; F Caetano[1]; M Alves[1]; R Teixeira[1]; C Lourenco[1]; L Goncalves[1]
[1]Hospital Santarém, Cardiology, Santarém, Portugal

Introduction: Noninvasive ventilation (NIV) is commonly used to treat patients (Pts) with acute cardiogenic pulmonary edema (ACPE) with some immediate beneficial effects. However, there is some conflicting evidence about the role of NIV in the prognosis of these Pts.
Aim: Determine whether NIV improves in-hospital survival in Pts with ACPE.
Methods: A retrospective analysis was performed, including 81 consecutive Pts hospitalized in a Cardiac Intensive Care Unit with a clinical diagnosis of ACPE as initial presentation. For this study, Pts were divided in two groups according to the use of NIV. Demographic, clinical, laboratory and echocardiographic parameters were evaluated. The primary endpoint was in-hospital mortality (IHM).
Results: In this population, 44 Pts (54%) were treated with NIV (NIV group) and 37 Pts (46%) were treated without NIV (WVNI group). There were no differences between the two groups regarding demographics, cardiovascular risk factors, vital parameters at admission, except for the presence of previous history of coronary disease, which was higher on the WVNI group (35 vs 59%, P = 0.032). Regarding laboratory values at admission, there were no significant differences between both groups, namely in relation to biomarkers such as troponin and NTproBNP, as well as in relation to the left ventricular ejection fraction. Patients in the NIV group had a higher incidence of cardiorenal syndrome (65 vs 39%, P = 0.02), higher maximum daily dose of furosemide (225 vs 120mg, P < 0.001), and increased use of noradrenaline (16 vs 2%, P = 0.026).
Regarding IHM, there were no significant differences between the two groups. Moreover, NIV didn't influenced length of stay. With a multivariate logistic regressions analysis, the development of cardiorenal syndrome was the only independent variable associated with the use of NIV (OR: 2.75; 95% CI: 0.88-7.6; P = 0.049), in a model adjusted for sex, age, previous history of coronary disease and use of noradrenaline.
Conclusion: According to our data, in ACPE patients, the use of NIV was not associated with better in-hospital survival or a shortened length of hospital stay. Some authors have suggested that in patients with high filling pressures, positive pressure ventilation may compromise venous return (a known risk factor for the development of cardiorenal syndrome). In this study, we were able to confirm a higher incidence of cardiorenal syndrome, but the exact mechanism behind this association remains to be clarified.

P909
Acute heart failure in the elderly: real world evidence from the ATHENA registry.

A Herbst[1]; F Orso[1]; S Parlapiano[1]; A Pratesi[1]; F Bacci[2]; G Ciuti[2]; A Berni[2]; A Crociani[2]; AC Baroncini[1]; C Nozzoli[2]; L Poggesi[2]; A Moggi Pignone[2]; L Gabbani[1]; N Marchionni[3]; S Baldasseroni[1]
[1]Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy; *[2]Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; *[3]Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: ATHENA study group

Background: Acute heart failure (AHF) is a common disease that typically affects the elderly. Clinical registries represent the so-called "real world" in contrast to clinical trials that are known to have a selection bias. However, HF registries may maintain a certain level of selection by including only patients hospitalised in cardiology wards. Administrative data show that only a minority of these patients (about a quarter) is hospitalised in cardiology units, with the majority being admitted to internal medicine and geriatrics wards.
Purpose: to compare clinical characteristics and prognosis of elderly patients hospitalised for AHF in the settings of care of usual management: cardiology, internal medicine and geriatrics.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (≥ 65 years) admitted with diagnosis of AHF to the Emergency department (ED) of a tertiary University teaching-hospital and transferred to the above described settings of care in the period 01.12.2014-01.12.2015.
Results: 342 patients composed the study population; 17.8% were hospitalised in cardiology, 17.3% in geriatrics and 64.9% in internal medicine. Mean age was 83.7 years, resulting higher in geriatrics (86.9 years) versus internal medicine (83.6 years) and cardiology (81.0 years), P=0.001. Females were 54.1%: 55.7% in cardiology, 55.0% in internal medicine and 49.2% in geriatrics (P=0.700). Patients with HFpEF were 61.0% and were hospitalised less frequently in cardiology (49.1%) compared to geriatrics (62.5%) and internal medicine (65.0), P=0.116. Total in-hospital length of stay (including subsequent transferral to other wards before discharge) was 9.5 days and was higher for patients initially admitted to cardiology (15.0 days) compared to geriatrics (13.3 days) and internal medicine (7.8 days), p = 0.001. In-hospital mortality was 7.3% and it was higher in cardiology and geriatrics (11.0%) compared to internal medicine (5.0%), (P=0.075). Independent predictors of in-hospital mortality were evaluated using two different models: the ADHERE-like model which showed a significant correlation with age (OR=1.20, CI=1.07-1.34, P=0.002), systolic blood pressure (OR=0.96, CI=0.94-0.98, P=0.005) and Blood Nitrogen Urea (OR=1.01, CI=1.01-1.02, P=0.020) measured at the ED entry; the ATHENA model, which tested these variables with others more typical of geriatric patients (comorbidity and disability scores) and with the setting of care: a significant correlation was confirmed for age (OR=1.18 CI=1.05-1.32, P=0.002), systolic blood pressure measured at the ED entry (OR=0.96, CI=0.94-0.99, P=0.011) and for the setting of care (OR=0.32, CI=0.12-0.87, P=0.025) with a protective effect of cardiology ward assignment.
Conclusions: elderly patients with AHF are significantly different in terms of clinical characteristics and prognosis according to the different settings of care. Multidisciplinar research is needed in this field.

P910
Safety and effectiveness of oral rivaroxaban versus standard anticoagulation for the treatment of acute pulmonary embolism: a propensity-matched analysis of 478 patients

P Pedro Freitas[1]; AR Santos[2]; A Oliveira[1]; M Goncalves[1]; A Santos[2]; J Oliveira[2]; M Gago[2]; R Mamede[2]; D Correia[2]; N Vale[1]; J Mesquita[1]; M Castro[1]; J Brito[1]; J Ferreira[1]; M Mendes[1]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; *[2]Hospital de Sao Francisco Xavier, Lisbon, Portugal*

Background: Real-world data about the safety and effectiveness of oral rivaroxaban for the treatment and secondary prevention of acute pulmonary embolism (APE) is scarce.
Purpose: The objective of this study was to compare the safety and effectiveness of oral rivaroxaban against standard anticoagulation in an unselected real-world population hospitalized with APE.
Methods: We identified 534 patients diagnosed with APE by computed tomographic angiography in a single centre, between 2009 and 2015. A total of 56 patients were excluded because thrombolysis was performed or follow-up was incomplete. All

patients were discharged with oral rivaroxaban or low molecular weight heparin (LMWH)/warfarin for a minimum period of 6 months. A propensity-matched analysis based on 20 covariates was applied (absolute standardized mean difference < 20% for all variables in the paired population). Safety endpoints – total, fatal, major (ISTH criteria) and minor bleeding – and efficacy endpoints – all-cause death or venous thromboembolism (VTE) – at 6 months were analysed according to Cox regression.

Results: A total of 478 patients were included for analysis. Median age was 76 years (IQR 65 – 83), 39% males. Patients treated with LMWH/warfarin had higher prevalence of active cancer. In the propensity-matched population, rivaroxaban was associated with a lower risk of major bleeding (HR = 0.32; 95% CI: 0.087 – 1.182) and all-cause death or VTE at 6 months (HR = 0.24; 95% CI: 0.051 – 1.131) even though statistical significance was not reached. Figure attached summarizes the study findings.

Conclusions: In this retrospective study with a real-world unselected population, rivaroxaban showed to be at least as safe and effective in the treatment of APE as conventional anticoagulation with warfarin/LMWH at 6 months of treatment.

	Overall			Propensity-matched population		
	Warfarin/LMWH (n= 383)	Rivaroxaban (n=95)	P value	Warfarin/LMWH (n=95)	Rivaroxaban (n=95)	P value
Safety Endpoints % (at 6 months)						
Total bleeding	12	7.4	0.188	12.6	7.4	0.208
Fatal bleeding	0.5	0	0.661	0	0	NA
Major bleeding	8.6	3.2	0.086	9.5	3.2	0.087
Minor bleeding	3.1	4.2	0.620	3.2	4.2	0.720
Efficacy Endpoints % (at 6 months)						
All cause death + VTE	8.4	2.1	0.052	8.4	2.1	0.071
All cause death	7.1	1.1	0.057	5.3	1.1	0.135
VTE	2.1	1.1	0.514	3.2	1.1	0.337

The patient view of hospitalisation with acute heart failure. Results from a qualitative study of the acute heart failure pathway.

J Riley[1]; C Keane[2]; M Walshe[2]; J Gallagher[2]; P Kalra[3]; M Cowie[1]; M Ledwidge[2]; K Mcdonald[2]

[1]Royal Brompton Hospital, London, United Kingdom; *[2]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland*; *[3]Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*

Unplanned hospital admissions are expensive for healthcare systems and stressful for the patient and family. To improve the use of healthcare resources and patient experience of care increasing public awareness of the common symptoms of heart failure (HF) and empowering and supporting those with HF to actively engage in their care is encouraged. This study explored the views of patients and GPs to identify issues that could be improved in the acute heart failure (AHF) pathway

Patients where recruited from a large Irish hospital following an unplanned HF admission. An established HF Unit provides monitoring, optimises therapies and provides patient education for 3 months post-discharge. We also interviewed GPs. Data were collected by semi-structured interview and analysed using an inductive, thematic process involving constant comparison.

Twenty-four patients were recruited: Mean age of 81 yr: 12 (50%) > 80 yr: 10 (41%) > 85 yr: Male 15 (63%), 9 (37%) de-novo HF, 17 (71%) had > 3 comorbidities and 8 (33%) > 3 non-cardiovascular comorbidities. 11 (46%) lived alone. 6/15 patients with an existing diagnosis of HF had > 3 admissions in previous 12 months. Seven GPs took part in the study.

Key themes: Understanding of HF. Patients had a poor understanding of HF. They interpreted their symptoms as related to comorbid conditions or age: breathlessness due to lung disease: fatigue due to old age. These symptoms did not fit with patient's views of HF (palpitations or chest pain) or their view of the type of person who developed HF (sedentary lifestyle). This understanding appeared derived from a general knowledge of heart disease.

Continuity of care: Patients described a close relationship with their GP that developed from monitoring related to comorbidities, on-going medication review and ease of access. They viewed the GP as a 'trusted' source of knowledge. The majority turned to the GP when they sought resolution for symptoms. Following hospital discharge the HFU scheduled face-to-face and telephone follow-up. Patients appreciated the regular contact and were reassured by monitoring.

Fragmentation of care: GPs described barriers to obtaining diagnostic tests in primary care. This left them unable to give patients a formal diagnosis or start conversations about HF.

Patients described limited access to the HFU for support or information. Some experienced frustration as they navigated between systems: HFU, GP and ED.

Patients in this study were elderly. They had multiple comorbidities that led to a reliance on the GP. Limited knowledge of HF resulted in them identifying HF symptoms as related to a comorbidity. Fragmentation of care between primary and secondary care were barriers to prompt treatment and to timely provision of information and support. These factors contributed to unplanned hospital admission and provided a negative experience of care. These results are now being validated in a larger population and different healthcare organisation.

P912

Worsening renal function during hospital stay following acute heart failure is associated with decreased venous congestion

E Akiyama[1]; LNL Van Aelst[2]; M Arrigo[3]; J Motiejunaite[1]; E Gayat[4]; MF Seronde[5]; A Mebazaa[4]

[1]Inserm UMR-S 942, Paris, France; *[2]KU Leuven, Leuven, Belgium*; *[3]University Hospital Zurich, Zurich, Switzerland*; *[4]Hospital Lariboisiere, Paris, France*; *[5]University Hospital Jean Minjoz, Besançon, France*

Funding Acknowledgements: This study was supported by a research fellowship from Japan Heart Foundation (E.A.).

Background: Impaired renal function is an important prognostic factor in patients with heart failure (HF) and increased central venous pressure which means venous congestion is associated with worsening renal function in patients with advanced decompensated HF with reduced left ventricular (LV) ejection fraction (EF) (HFREF) who underwent right heart catheterization.

Purpose: The purpose of this study was to investigate correlation between changes in renal function during hospitalization and severity of venous congestion in patients with acute HF (AHF).

Methods and Results: Of 101 hospitalized patients with AHF derived from MEDIA-DHF cohort, 60 had preserved LVEF (HFPEF) and 41 had HFREF. In patients with AHF, renal function worsened during hospital stay (median: estimated glomerular filtration rate (eGFR) 59 [40-75] at admission, 48 [31-67] ml/min/1.73m2 at discharge, $p < 0.001$, Cystatin C 1.50 [1.20-2.27] at admission, 1.78 [1.33-2.59] mg/L at discharge, $p < 0.001$, neutrophil gelatinase associated lipocalin (NGAL) 127 [95-260] at admission, 167 [104-263] ng/mL at discharge, $p = 0.004$, urea nitrogen 8.9 [6.9-13.2] at admission, 10.2 [7.6-16.0] mmol/L at discharge, $p = 0.006$) with few differences between HFPEF and HFREF: Estimated GFR decreased more in HFREF than in HFPEF (HFPEF 59 [40-74] at admission, 53 [28-73] ml/min/1.73m^2; at discharge, $p = 0.02$, HFREF 59 [45-76] at admission, 42 [34-56] ml/min/1.73m^2 at discharge, $p < 0.001$). At the same time, echocardiographic examinations showed signs of venous "decongestion" with decreased inferior vena cava (IVC) diameter at rest and increased respiratory variability of IVC diameter during hospitalization (median: IVC diameter 22 [16-24] at admission, 13 [11-18] mm at discharge, $p = 0.009$, variability 32 [8-44] at admission, 43 [29-70] % at discharge, $p = 0.04$) and no changes in left atrial and right atrial areas (median: left atrial area 25 [21-28] at admission, 25 [20-32] cm^2 at discharge, $p = 0.77$, right atrial area 18 [16-22] at admission, 17 [16-23] cm^2 at discharge, $p = 0.36$). Although eGFR negatively correlated with IVC diameter at admission, eGFR positively correlated with IVC diameter at discharge ($n = 93$, $r = -0.33$, $p = 0.001$ at admission, $n = 20$, $r = 0.47$, $p = 0.04$ at discharge).

Conclusions: Renal function worsened despite echocardiographic signs of venous "decongestion" during hospitalization in patients with AHF.

P913

Dopamine is associated with the worst outcome among inotropes used in acute heart failure: observations from the ESC-HF-LT registry

A Mebazaa[1]; J Motiejunaite[2]; E Gayat[1]; E Akiyama[2]; MG Crespo-Leiro[3]; LH Lund[4]; AP Maggioni[5]; O Chioncel[6]; F Ruschitzka[7]; G Filippatos[8]

On behalf of: on behalf of ESC-HF-LT registry investigators

Introduction: Intravenous (IV) inotropes and vasopressors are widely used in the initial treatment of acute heart failure (AHF). There is a continuing controversy about whether one agent is superior to the other. Our aim was to analyze current real-life use of inotropes and/or vasopressors, and their association with all-cause long-term mortalityin a large AHF cohort.

Methods: The European Society of Cardiology Heart Failure Long – Term Registry (ESC-HF-LT) was conducted between 2011 and 2013 and included 12785 patients (pts) in 21 countries in Europe, Northern Africa and the Middle East. Median duration of follow-up was 381 [363; 457] days. 833 (6.5%) AHF pts who received IV inotropes and/or vasopressors were identified for the post-hoc analysis. Propensity score for inotrope and/or vasopressor treatment was estimated using 35 clinically relevant baseline variables. Matching was made 1:1 on inotropic medication versus no inotropic medication and derived 606 pts in each treatment group. Hazard ratio (HR) for all-cause long-term mortality was estimated.
Results: Mean age of pts was 67(±13) years and 33.4% were women. Mean systolic blood pressure at presentation was 112(±27) mmHg. 45.7% of pts treated with inotropes had signs of hypoperfusion and 19.0% presented with cardiogenic shock. The 3 most widely used inotropes were dobutamine (42.5%), dopamine (24.7%) and levosimendan (13.1%), although their use varied among different regions (table 1). Median duration of treatment was 36.0 hours (h) [23.0; 72.0] for dobutamine, 36.0h [20.0; 72.0] for dopamine and 24.0h [24.0; 24.0] for levosimendan. Adjusted HR confirmed a significant association between the use of dopamine and all-cause long-term mortality (1.628 [1.031-2.572]) in the matched cohort. By contrast, no such association was seen with patients receiving dobutamine or levosimendan (HR 1.055 [0.727-1.531] and 1.229 [0.618-2.445] respectively).
Conclusions: Most commonly used inotropes in AHF patient population were dobutamine, dopamine and levosimendan. Compared to other inotropes, the use of dopamine was associated with markedly higher all-cause long-term mortality.

Inotropes in different regions

IV inotrope	Eastern Europe (n = 303)	North Africa and Middle East (n = 148)	Northern and Western Europe (n = 90)	Southern Europe (n = 292)	All (n = 833)
Dobutamine	40.6%	61.5%	53.3%	31.5%	42.5%
Dopamine	30.4%	23.6%	10.0%	24.0%	24.7%
Levosimendan	6.6%	0.0%	22.2%	23.6%	13.1%
Other	22.4%	14.9%	14.4%	20.9%	19.7%

P914

A novel therapeutic approach with additional tolvaptan for the patients with hypoalbuminemia or proteinuria.

K Takagi[1]; N Sato[1]; N Sato[1]; S Shigihara[1]; S Shigihara[1]; S Ishihara[1]; S Ishihara[1]; W Shimizu[2]; W Shimizu[2]
[1]Nippon Medical School Musashi-Kosugi Hospital, Department of Cardiology and Intensive Care Unit, Kanagawa, Japan; *[2]Nippon Medical School, Department of Internal Medicine and Cardiology, Tokyo, Japan*

Backgrounds: Hypoalbuminemia and proteinuria are independent prognostic factors in hospitalization for heart failure (HHF) and they are related to resistance to loop diuretics. Tolvaptan is an oral non-peptide, competitive antagonist of vasopressin receptor-2. It has been used for the treatment of volume overload in HHF patients in several Asian countries. Several studies have demonstrated marked improvement in congestion in HHF patients. However, it has not been clarified whether or not tolvaptan is useful for HHF patients with hypoalbuminemia and/or proteinuria.
Methods: We examined the diuretic response to tolvaptan in HHF patients with hypoalbuminemia and/or proteinuria. We defined hypoalbuminemia as a serum level of albumin < 2.6 g/dl and proteinuria as positivity by a point-of-care test tape. Fifty-one HHF patients were received additional tolvaptan upon therapies with loop diuretics. The subjects were divided into 4 groups with or without hypoalbuminemia and proteinuria.
Results: The changes in urine output per day were not different between with and without hypoalbuminemia (+610 (range, 100–1032); +742 (505–1247) ml, respectively, P=0.313, Figure1). The serum level of albumin did not correlate with changes in urine output per day after tolvaptan treatment (P=0.276, r=0.156, Figure2). The changes in the urine output per day were not different between with and without proteinuria (476 (range, 100–1020) vs. 834 (534–1309), respectively, P=0.112, Figure3). Fifty one patients were divided into 4 groups: group1, urine protein (-), Alb≥2.6g/dl (n = 18); group2, urine protein (-), Alb<2.6g/dl (n = 12): group3, urine protein (+), Alb≥2.6g/dl (n = 9); group4, urine protein (+), Alb<2.6g/dl (n = 12). The changes in urine output per day were significantly increased in the group 1, 2, and 3 after tolvaptan administration, but not in the group 4. Kruskal-Wallis tests indicated that changes in urine output per day did not differ among those 4 groups (P=0.124, Figure4),
Conclusion: Thus, additional administration of tolvaptan elicited a good diuretic response in HHF patients with hypoalbuminemia and/or proteinuria, although less response in the patients with both hypoalbuminemia and proteinuria. The present study suggested a novel therapeutic approach with additional tolvaptan for the patients with hypoalbuminemia or proteinuria.

Long-term sacubitril/valsartan therapy improved central pulse wave parameters in patients with stable heart failure with reduced ejection fraction

Z Kobalava[1]; S Villevalde[1]; O Lukina[1]; L Babaeva[1]; I Meray[1]
[1]RUDN University, Moscow, Russian Federation

Objective: Angiotensin receptor-neprilysin inhibitor (ARNI) is recommended to further reduce the morbidity and mortality for patients with chronic symptomatic heart failure with reduced ejection fraction (HFrEF) according to the new ESC guidelines. Increased arterial stiffness has been shown to correlate with adverse cardiovascular events. The aim of the study was to assess long-term sacubitril/valsartan effects on parameters of arterial stiffness in patients with stable HFrEF.
Methods: In the open-label follow-up to PARADIGM HF study 16 patients with stable HFrEF (14 male, 69 ± 9 years (M ± SD), arterial hypertension 88%, previous myocardial infarction 88%, diabetes mellitus 43%, dyslipidemia 63%, LVEF 32 ± 6%, serum creatinine 122 ± 23 μmol/l, eGFR 55 ± 13 ml/min/1.73m2, potassium 4.43 ± 0.38 mmol/l) were enrolled. Patients received a stable background treatment for at least a month (ACEI 94%, beta-blockers 100%, aldosterone receptor antagonists 81%, loop diuretics 75%). ACEI treatment was interrupted for 36 h and replaced with sacubitril/valsartan 50, 100 or 200 mg BID according to baseline brachial BP (mean dose 185.7 ± 36.3 mg BID). Arterial stiffness was assessed by applanation tonometry baseline and after 6 and 12 months sacubitril/valsartan therapy. Parameters of LV efficacy were calculated. Wilcoxon and Spearman test was considered significant if $p < 0.05$.
Results: After 6 months of sacubitril/valsartan therapy carotid-femoral pulse wave velocity (PWV) significantly decreased (11.5 ± 2.9 vs 10.2 ± 2.9 m/s, $p < 0.05$) while other parameters of arterial stiffness did not change (p>0.05). After 12 months sacubitril/valsartan therapy was associated with significant decrease of aortic augmentation pressure (AP) (15.3 ± 8.9 vs 10.5 ± 5.0 mmHg, p = 0.002), increase of reflected wave transit time (RWTT) (132 ± 9 vs 143 ± 29 ms, p = 0.02), subendocardial viability ratio (SEVR) (164 ± 25 vs 177 ± 37 % p = 0.009). Changes of PWV between 6 and 12 months were nonsignificant (10.2 ± 2.9 vs 10.8 ± 2.0 m/s; p>.05). There was significant correlation between changes of augmentation pressure and changes of SEVR (R=-0.56), augmentation index (AIx) (R=0.52), stroke volume (R=0.52), potential energy (R=0.71), $p < 0.05$ for all. There was significant correlation between changes of SEVR and stroke volume (R=-0.85), stroke work (R=-0.81), potential energy (R=-0.95), $p < 0.05$ for all. There was statistically significant correlation between changes of RWTT and AIx (R=-0.68).
Conclusion: In stable symptomatic patients with HFrEF long-term sacubitril/valsartan therapy is associated with significant improvement of central pulse wave parameters: decrease of aortic AP, increase of RWTT. Sacubitril/valsartan therapy was associated with beneficial increase of SEVR, index that reflects the subendocardial oxygen supply-demand ratio.

Funding Acknowledgements: unrestricted educational grant provided by Abbott Laboratories Romania

Background: There are few heart failure (HF) registries accurately describing in hospital patient clinical journey. Also, lack of improvement in patient self-assessed symptoms at discharge may also represent a neglected end-point which may relate to hard outcomes.
Aim: To evaluate the value of clinical and biological variables in predicting self assessed symptom improvement during HF-hospitalization.
Methods: The RO-AHFS registry prospectively enrolled 3224 consecutive patients admitted for acute HF over a 12-month period. The clinical course of patients surviving to discharge has been evaluated as: improved, unchanged, worsened. In parallel with patient's self assessment clinical status, body weight, SBP, HR, RR, serum Na, K, BUN and creatinine have been evaluated at admission and discharge.
Results: At discharge 86.3% of patients reported their status to be improved, 5.9% unchanged, 7.8% worsened. When patient self-assessed clinical status was analyzed by clinical profile, substantial variation emerged; patients classified as cardiogenic shock and right HF were less likely to report improvement (55% and 80%, respectively), compared to chronic hospitalized HF (97%). There was minimal variation when patients were stratified by age and ejection fraction. Clinical and biological data collected at admission and discharge, are presented in Table 1. A trend for lower betablocker use was noted in patients that reported their status worsened.
Conclusion: Of the surviving patients, a proportion of 13% do not experience symptom improvement. The variation of known biological prognostic markers does not appear to predict the incidence of this outcome, while the patients clinical course may be more relevant.

P917

Prognostic value of mid-range ejection fraction in patients with acute coronary syndrome and heart failure

RM Rosa Maria Agra Bermejo[1]; A Cordero[2]; JM Garcia Acuna[1]; I Gomez Otero[1]; A Varela Roman[1]; I Gomez Otero[1]; M Rodriguez Manero[1]; JR Gonzalez Juanatey[1]
[1]*UNIVERSITY CLINICAL HOSPITAL OF SANTIAGO DE COMPOSTELA, DEPARTMENT OF CARDIOLOGY, SANTIAGO DE COMPOSTELA, Spain*; [2]*University Hospital San Juan de Alicante, Cardiology, Alicante, Spain*

Background: The new 2016 European Society of Cardiology Heart Failure (HF) Guidelines propose a new HF classification according to the level of LVEF, as follows: HFrEF is < 40%, mid-range HF is an LVEF range from 40–49%, and HFpEF is ≥ 50%. HFmrEF characteristics and prognosis in acute coronary syndrome complicated with HF are unkown.
Purpose: The aim of our study was to analyse the HFmEF in patients with acute coronary syndrome and Killip [3]2.
Material and methods: This is a retrospective observational study of 1444 consecutively patients admitted in for acute coronary syndrome (ACS) and Killip[3]2 in two different hospitals. Baseline patient characteristics were examined for each patient and a follow-up period was stablished for registry of death and re-hospitalization by HF as the primary endpoint. The observed event risk was calculated as a Kaplan–Meier estimate.
Cox regression models performed survival analyses once proportional risk test were verified. Multivariate analysis were performed using all variables that obtained p values < 0.1 in the univariate analysis. The incidence of HF could be affected by patients' death and, therefore, the usual techniques for time-to-event analysis would provide biased or un-interpretable results due to the presence of competing risks. With the aim of avoiding such effects we applied the model introduced by Fine and Gray to test the competing events.
Results: Among the study participants 523 (45,7%) had HFrEF, 123 (10, 7%) HFmrEF and 498 (43,5%) HFpEF. Patients with HFmrEF had a demographic and clinical profile with many intermediate features between HFrEF and HFpEF. They were similar to HFrEF in terms of age, sex, hypertension, hemoglobine, heart rate, STEMI and use of ACEIS, MRAS and diuretics. They were similar to HFpEF in terms of previous HF, Killip II, systolic blood pressure and GRACE score. All other characteristics were similar between groups.
There were no significant differences in terms of mortality or readmission to HF between the three groups.
When we performed the multivariate analyses only the HFpEF was associated with less HF readmission (HR 0,49, CI 95% 0,395-0,624, p < 0,01)
Conclusions: HFmrEF patients represent a small group in acute coronary syndrome complicated with HF. They have intermediate characteristics between HFpEF and HFrEF but not differences between the three groups in terms of mortality or heart failure readmission were observed.

P918

The POP-HF score to predict heart failure expression in patients after coronary artery bypass grafting: A substudy of the POP study

P Predrag Mitrovic[1]; B Stefanovic[1]; M Radovanovic[1]; N Radovanovic[1]; D Rajic[2]; G Matic[2]; I Subotic[2]; N Mitrovic[2]; N Mijic[2]
[1]*University Institute for Cardiovasculari Diseases, CCS, School of Medicine, University of Belgrade, Belgrade, Serbia*; [2]*Clinical Center of Serbia, Institute for Cardiovascular Diseases, Belgrade, Serbia*

On behalf of: The POP Study Group
Funding Acknowledgements: The Belgrade Cardiology Club

Presentation of heart failure (HF) has different influence on new coronary events expression in patients with previous coronary artery bypass grafting (CABG), than in patients without CABG. Heart failure is one of the most important major adverse cardiovascular events (MACE) in patients after previous CABG. This substudy aimed at evaluating the usefulness of the POP-HF score (PostOperative Prognosis-HeartFailure score), originally developed for the prediction of 60-day, 1-year, 5-year, 10-year, 15-year and 20-year MACE, after CABG.
From April 1988, we analyzed 2028 consecutive patients who underwent CABG. Expression of HF was the predefined end point. Models discrimination and calibration to predict HF was tested using receiver-operating characteristics curves and the goodness-of-fit (GoF) test. Sensitivity analyses and 1000-resample bootstrapping were used to evaluate the model's performance. The rate of HF was 44.6 %, respectively. Compared with controls, the cumulative HF group was associated with much higher rates of adverse clinical outcomes at 60-day follow-up (adjusted odds ratio (OR) for death 6.96), at 1-year follow-up (adjusted OR for death 7.18), at 5-year follow-up (adjusted OR for death 7.64), at 10-year follow-up (adjusted OR for death

7.88), at 15-year follow-up (adjusted OR for death 8.26) and at 20-year follow-up (adjusted OR for death 8.32). Internal validation confirmed a reasonably good discrimination and calibration of thePOP-HFscorefor the prediction of HF (area under the curve (AUC) 0.72, GoF 0.34), after CABG.
Conclusion: The risk of HF in patients after previous CABG, could be accurately assessed using the POP-HF score, which might help in deciding upon measures aimed at preventing adverse prognosis.

Fate of acute heart failure patients with mid-range ejection fraction

H B Hye Bin Gwag[1]; GY Lee[1]; JO Choi[1]; ES Jeon[1]; JY Lee[1]; ES Ju[1]
[1]Samsung Medical Center, Cardiology, Seoul, Korea Republic of

On behalf of: KorAHF
Funding Acknowledgements: Research of Korea Centers for Disease Control and Prevention

Background: Outcomes of acute heart failure (HF) with mid-range ejection fraction (EF) are limited, and optimal medical treatment for these patients are not well-established. Especially, there are few data on follow-up left ventricular EF (LVEF) in these patients. Therefore, we investigated mortality and improvement of LVEF in acute HF patients with mid-range EF.
Methods: The study population was selected from the multicenter prospective cohort registry. Patients were categorized into three groups according to baseline LVEF: HF with reduced EF (HFrEF) group (LVEF < 40%), HF with mid-range EF (HFmrEF) group (40% ≤ LVEF < 50%), and HF with preserved EF (HFpEF) group (LVEF ≥ 50%). Follow-up LVEF reported at least 90 days after discharge was used to assess the improvement of LV systolic function in HFmrEF group. 'Improved LVEF' was defined as %LVEF change ≥ 5% with follow-up LVEF ≥ 50%, and 'worsened LVEF' was defined as %LVEF change ≥ 5% with follow-up LVEF < 40%.
Results: Of the 3085 patients included in the present study, 2123 (68.8 %) had HFrEF, 454 (14.7%) had HFmrEF, and 508 (16.5%) had HFpEF. Among 276 patients in HFmrEF group who underwent follow-up echocardiography, 94 (34.1%) showed improved LVEF. Survival rate was significantly higher in HFmrEF patients with improved LVEF than those with no change of LVEF or worsened LVEF. Multivariate analysis showed that improvement of follow-up LVEF, lower blood urea nitrogen level, and maintenance of renin-angiotensin blocker or aldosterone antagonist were significantly associated with better survival.
Conclusion: HFmrEF patients with improved LVEF had better survival rate than those with no change of LVEF or worsened LVEF. Improved LVEF, and maintenance of renin-angiotensin blocker or aldosterone antagonist were independent prognostic factors for mortality in acute heart failure patients with mid-range EF.

P920

Mean platelet volume / platelet count ratio at discharge: a new tool to predict hospitalization for de novo acute heart failure

D Candeias Faria[1]; J B Augusto[1]; M Borgues Dos Santos[1]; D Roque[1]; H Ferreira[1]; J Urzal[1]; C Santos[2]; C Morais[1]
[1]Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal; *[2]Hospital Santo Andre, Leiria, Portugal*

Background: Acute heart failure (AHF) is a powerful predictor of future readmissions and mortality in patients with atrial fibrillation (AF). Mean platelet volume (MVP) / platelet count ratio is associated with coronary occlusion and cardiovascular events in ischemic heart disease. However, there is limited knowledge about its effects in patients with AF.
Purpose: We aimed to evaluate the impact of MVP/platelet count ratio at discharge as a noninvasive predictor of de novo AHF in patients with AF.
Methods: We included retrospectively 2181 consecutive patients with AF who were evaluated in our Emergency Department (ED) in a 12 month period. Among them, 423 patients were admitted for in-hospital management. Patients who had previous known heart failure (n = 101) were excluded. We recorded MPV (fL) and platelet count (normal range 150.000-400.000 platelets/μL) at discharge and calculated MPV/platelet count ratio. Primary outcome was the incidence of hospitalization for de novo AHF 12 months after discharge.
Results: We included 253 AF patients who were successfully discharged and followed for 12 months (mean age of 70.7 ± 12.6 years, 37.5% males). Median MPV/platelet count ratio was 4.63x10^3fL/platelets/μL, interquartile range 2.85 – 3.27x10^3fL/platelets/μL. MPV/platelet count at discharge was significantly higher in patients who were admitted for de novo AHF (mean 1.59x10^3fL/platelets/μL vs 0.74x10^3fL/platelets/μL; p = 0.019). Kaplan-Meier analysis (Figure) revealed that patients who had a MPV/platelet count at discharge >4.0x10^3fL/platelets/μL had significantly more hospitalizations for de novo AHF 12 months after discharge (26.1 vs. 9.6%; log-rank p = 0.011). Cox regression analysis controlled for age and chronic kidney disease revealed that MPV/platelet count was an independent predictor of de novo AHF (HR 2.59; CI 95% 1.03 – 6.490; p = 0.042). There was a significant trend towards a higher mortality rate after discharge in AF patients with >4.0x10^3fL/platelets/μL (26.1 vs. 10.0%; p = 0.034).
Conclusions: MPV/platelet count ratio at discharge is associated with future hospitalizations by de novo AHF in patients with AF

P921

Elevated heart rate at discharge is associated with worse long-term cardiovascular outcomes among patients hospitalized for acute heart failure

A Ravera[1]; C Giacopini[1]; V Carubelli[1]; E Sciatti[1]; CM Lombardi[1]; M Metra[1]
[1]University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health, Brescia, Italy

Background: Drugs acting on heart rate (HR), namely beta-blockers (BB), are among the pillars of chronic heart failure (HF) therapy. However, the effects of HR in acute HF (AHF) have been analysed only in a few studies.
Purpose: This study assessed the relationship between HR measured at discharge and long term outcomes after a hospitalization for AHF.
Methods: We enrolled 938 patients admitted in our hospital for AHF. We evaluated HR at discharge (HRds), and we divided the patients in 2 groups: those with HRds < 70 beats per minute (bpm), and those with HRds≥70bpm. We followed-up the enrolled patients to assess outcomes up to 180 days after discharge. We performed statistical analysis with Cox regression for survival analysis and we used the Kaplan-Meier method to obtain time-to-event curves.
Results: At discharge, 525 subjects (56%) had HRds < 70bpm and 413 subjects (44%) had HRds≥70bpm. Higher HRds was associated with male gender (p < 0.001) and arterial hypertension (p = 0.018). Patients with lower HRds were more likely to have ischemic heart disease and less likely to have valvular heart disease (p = 0.008). No difference was found in age or other important comorbidities between the 2 groups. Patients with higher HRds had higher NYHA class at baseline (p = 0,014) and discharge (p < 0.001). N-terminal pro b-type natriuretic peptide (NT-proBNP) at baseline was similar in the 2 groups, whereas NT-proBNP at discharge was higher in patients with higher HRds (p < 0,001). At discharge 80 subjects with HRds < 70bpm (15.2%) and 129 subjects with HRds≥70bpm (31.2%) were not on BB. Among patients on BB, we found no difference in percent target dose prescribed at discharge (p = 0.776). After adjustment for covariates, we found that HRds ≥70bpm was associated with a significant higher risk of day-180 all-cause (AC) death (adjusted hazard ratio, HR 1.86, 95% confidence interval, CI, 1.10-3.16, p = 0.021) and cardiovascular (CV) death (adjusted HR 2.40, 95% CI 1.34-4.28, p = 0.003). No impact of HRds on day-180 HF hospitalization (HFH) was found. The composite endpoint of CV death and HFH did not demonstrate statistical significance, due to lack of observed effect of HRds on HFH. Among patients with atrial fibrillation (AF), HRds was not significantly associated with any of the evaluated outcomes, after adjustment. In the subset of patients in sinus rhythm (SR), HRds ≥70bpm was significantly associated with day-180 AC death (adjusted HR 2.76, 95% CI 1.31-5.81, p = 0.008) and CV death (adjusted HR 3.57, 95% CI 1.55-8.23, p = 0.003).
Conclusions: Patients hospitalized for AHF with elevated HR at discharge have an increased risk of death. This finding was confirmed in the subset of patients in SR at discharge, whereas among patients with AF, a higher HR at discharge was not significantly associated with higher CV and AC mortality at day 180.

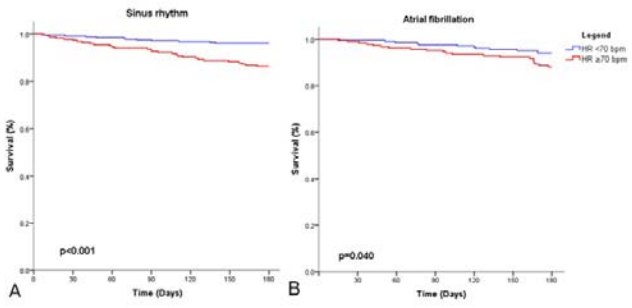

Figure. Kaplan-Meier survival curves for cardiovascular mortality among patients in sinus rhythm (A) and atrial fibrillation (B).

P922

Hemoconcentration during hospitalization is associated with better outcomes in patients with decompensated heart failure

A Klimenko[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: Patients with decompensated heart failure (DHF) are usually admitted with severe systemic congestion. Volume overload is the known main driver for morbidity, mortality and readmission to the hospital. Hemoconcentration (HC) has been proposed as a surrogate marker of decongestion during hospitalization.
Purpose: The aim of the study was to determine the prevalence of HC in DHF patients and to evaluate the impact of HC on short-term (30-days mortality) and long-term (6 months rate of HF rehospitalizations) outcomes.
Methods: In 183 patients admitted with ADHF (125 male, 69 ± 9 years (M ± SD), arterial hypertension (AH) 87%, ischemic heart disease (IHD) 56%, myocardial infarction (MI) 53%, atrial fibrillation 51%, diabetes mellitus (DM) 36%, known chronic kidney disease (CKD) 40%, ejection fraction 44 ± 15%) the prevalence of HC was assessed. HC was defined as increase in both hemoglobin and hematocrit levels between baseline and discharge. Mann-Whitney and multiple logistic regression analysis were performed. $P < 0.05$ was considered statistically significant.
Results: 33% of patients developed HC during hospitalization. There were no differences between groups in clinical presentation of systemic congestion (comparable rates of oedema, orthopnea, S3, pulmonary rales, Rg-hydrothorax), level of EF (47 ± 14 vs 43 ± 15%, p>0.05), level of NT-proBNP (11151 ± 1633 vs 13414 ± 4093 fmol/ml, p>0.05) and frequency of prior HF hospitalizations (70 vs 81%, p >0.05). Patients without HC were older (70 ± 8 vs 67 ± 12 years, $p < 0.05$), had lower resistance R/h (238 ± 61 vs 266 ± 43 Ohm/m, $p < 0.05$) and reactance Xc/h (19 ± 6 vs 25 ± 6 Ohm/m, $p < 0.05$), which were assessed by bioimpedance vector analysis (BIVA). Patients with HC had higher levels of R/h (290 ± 35 vs 261 ± 64 Ohm/m, $p < 0.05$) and reactance Xc/h (27 ± 5 vs 21 ± 6 Ohm/m, $p < 0.05$) at discharge, which correspond to less evident congestion assessed by BIVA. Patients without HC compared to patients with HC had higher rate of acute kidney injury (AKI) during hospitalization (57 vs 20%, ×2= 15, $p < 0.001$), higher rate of 30-days mortality (11 vs 0%, ×2=5, $p < 0.05$) and there was tendency to higher 6 months rate of HF rehospitalizations (39 vs 30%, p>0.05).
Conclusions: 33% of patients admitted with DHF developed HC. Development of HC during hospitalization was not associated with higher level of AKI. HC was associated with better short-term and long-term outcomes and less evident hyperhydration by BIVA at discharge. Evaluation of HC during hospitalization added useful information to standard clinical parameters and could be used as a marker of prognosis in patients with DHF.

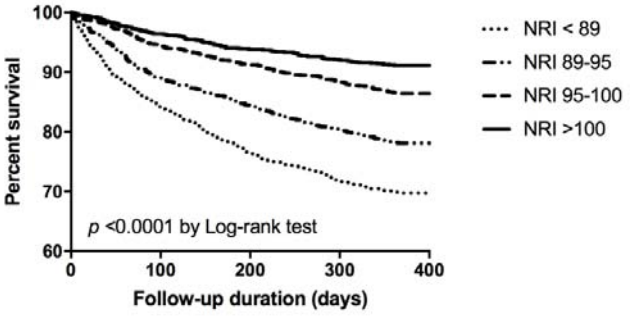
On behalf of: KorAHF registry
Funding Acknowledgements: Korea Centers for Disease Control and Prevention

Background: Nutritional status is associated with adverse clinical outcomes in various cardiovascular diseases. Nutritional Risk Index (NRI) is a useful tool in identifying the patients at risk of malnutrition, but the role of NRI in patients with acute decompensated heart failure (ADHF) has been poorly studied. Therefore, the aim of this study was to investigate the impacts of NRI on long-term mortality in patients with ADHF.
Methods: Among 5,625 cohort patients enrolled in Korean Acute Heart Failure Registry (KorAHF), a total of 5,531 patients who were possible to calculate NRI were enrolled. NRI was calculated by the following formula; NRI = (1.519 x serum albumin[g/dl]) + (41.7 x weight [kg]/ideal body weight [kg]). The patients were divided into 4 groups according to the NRI quartile; Q1 < 89 (n = 1268, 69.9 ± 14.5 years, 632 males), Q2 89-95 (n = 1295, 69.7 ± 14.4 years, 677 males), Q3 95-100 (n = 1570, 68.8 ± 14.0 years, 849 males), Q4 >100 (n = 1398, 65.6 ± 14.5 years, 779 males). Primary end point was all-cause mortality at 1-year clinical follow-up. Results: Proportion of male sex increases with increasing NRI quartile (49.8% vs. 52.3% vs. 54.1% vs. 55.7%, linear p = 0.001). History of ischemic heart disease was more prevalent in lower NRI (29.3% vs. 28.6% vs. 30.1% vs. 24.8%, linear P=0.030). Atrial fibrillation (22.9% vs. 28.6% vs. 28.9 vs. 29.0%, linear p = 0.001), history of smoking (36.3% vs. 37.7% vs. 39.7% vs. 40.5%, linear p = 0.014), and history of alcohol intake (34.2% vs. 34.7% vs. 38.7% vs. 45.1%, linear $p < 0.0001$) were more prevalent in higher NRI quartile. One year mortality was 17.2% in Korean patients with ADHF. The 1-year mortality was significantly increased as the NRI quartile increased, and the highest NRI quartile was associated with the highest 1-year mortality (Q4: 27.5% vs. Q3: 20.9% vs. Q2: 12.9% vs. Q1: 8.7%, linear $p < 0.0001$). On Kaplan-Meier survival analysis, the significant inter-quartile difference was observed ($p < 0.0001$ for all). Conclusion: Poor nutritional status as assessed by NRI and quartile grading of NRI was associated with 1-year mortality in Korean patients with ADHF. The assessment of nutritional status by NRI may provide additional prognostic information and thus would be useful in the risk stratification of the patients with ADHF.

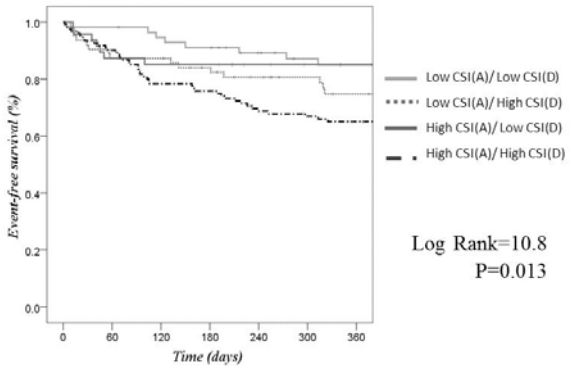


P924

Congestion trajectories and long-term outcomes in acute heart failure evaluated by chest radiographic congestion score

MK Kobayashi[1]; MW Watanabe[1]; YI Ito[1]; YI Iwasaki[1]; AY Yamashina[1]
[1]*Tokyo Medical University Hospital, Tokyo, Japan*

Aims: Residual pulmonary congestion has association with poor prognostic value in heart failure (HF), but there is challenging to evaluate the quantification of congestion by a simple and accurate measure. The aim of this study was to assess the prognostic value of chest radiographic congestion and to investigate the relationship between congestion trajectories and outcomes.
Methods and Results: 292 ADHF patients retrospectively enrolled with clinical examination, echocardiography, laboratory findings and chest roentgenogram that was blindly scored for the presence and severity of lung edema at both admission and discharge. Patients were stratified by radiographic congestion score index (CSI) of both admission (median=1.33) and discharge (median=0.33). The study group were CSI(A) < 1.33/ CSI(D) < 0.33 (n = 57), CSI(A) < 1.33/ CSI(D)≧0.33 (n = 63), CSI(A)≧1.33/ CSI(D) < 0.33 (n = 48), and CSI(A)≧1.33/ CSI(D) ≧0.33 (n = 124). Hb, eGFR, BNP, EF and PASP were not significant differences both these groups. Concerning about one-year event-free survival for the primary endpoint (all-cause death and HF hospitalization), high CSI(A)/high CSI(D) group had a highest risk of developing the events (log rank=10.8, P=0.013). In multivariable Cox regression analysis, CSI(D) was associated with the combined endpoint (HR [95% CI], 1.91 [1.07 to 3.4]; P=0.029).
Conclusion: Residual pulmonary congestion assessed by chest radiographic scoring may predict poor prognostic value beyond BNP and physical assessment. Discharge congestion identifies cardiac prognosis for 1-year cardiovascular outcome compared with admission congestion.



survival curve for the combined outcome

Peak exercise oxygen uptake predicts recurrent admissions in heart failure with preserved ejection fraction

P Palau Sampio[1]; E Dominguez Mafe[1]; JM Ramon Ferrandis[2]; L Lopez[3]; J Melero Lloret[1]; J Gonzalez[2]; R Heredia[2]; A Bellver[1]; E Santas Olmeda[2]; E Valero Picher[2]; E Nunez Botero[2]; FJ Chorro[2]; J Nunez Villota[2]

[1]Hospital General de Castellón. Universitat Jaume I, Cardiology Department, Castellón, Spain; *[2]Hospital Clínico Universitario, INCLIVA. Universitat de València, Cardiology Department, Valencia, Spain*; *[3]Universitat de València, Facultat de fisioteràpia, Valencia, Spain*

Background: Heart failure (HF) with preserved ejection fraction (HFpEF) is a highly prevalent syndrome with elevated morbimortality risk. To date, there is scarce evidence about the role of peak exercise oxygen uptake (peak VO2) for predicting the morbidity burden in HFpEF. We sought to evaluate the association between peak VO2 and risk of recurrent hospitalizations in patients with HFpEF.
Methods: A total of 74 stable symptomatic patients with HFpEF underwent a cardiopulmonary exercise test between June 2012 and May 2016. Negative binomial regression method was used to determine the association between percent of predicted peak VO2 (pp-peak VO2) and recurrent hospitalizations. Estimates of risk were reported as incidence rate ratios (IRR).
Results: Mean age was 72.5 ± 9.1 years, 53% were women and all patients displayed NYHA II-III. Mean peak VO2 and median pp-peak VO2 were 10 ± 2.8 ml/min/kg and 60% (47-67), respectively. During a median follow-up of 276 days (IQR: 153-1231), 84 all-cause hospitalizations in 31 patients (41.9%) were registered. A total of 15 (20.3%) deaths were also ascertained. In a multivariate analysis, accounting for mortality as a terminal event, pp-peak VO2 was independent and linearly associated with the risk of recurrent admissions (figure 1). Thus, and modeled as continuous, a 10% decrease of pp-peak VO2 increased by 32% the risk of recurrent hospitalizations [IRR: 1.32 (1.03-1.68), p = 0.028]
Conclusions: In symptomatic elderly patients with HFpEF, pp-peakVO2 predicts all-cause recurrent admissions.

Mortality risk of patients with heart failure with mid-range ejection fraction following a hospitalization with acute heart failure

I Ingrid Cardells Beltran[1]; E Santas Olmeda[1]; A Paya Chaume[1]; R Heredia Cambra[1]; D Escribano Alarcon[1]; G Minana Escriva[1]; A Bayes Genis[2]; J Lupon Roses[2]; J Sanchis Fores[1]; FJ Chorro Gasco[1]; J Nunez Villota[1]

[1]University Hospital Clinic of Valencia, Valencia, Spain; *[2]University Hospital Trias i Pujol, Barcelona, Spain*

Introduction. According European Society of Cardiology guidelines, patients with left ventricular ejection fraction in the range of 40-49% are now defined as heart failure with mid-range ejection fraction (HFmEF). There is scarce information about the long-term prognostic course of these subset of patients, especially after an episode of acute heart failure (AHF).
Purpose: In this work, we aimed to compare the risk of long term all-cause and cardiovascular (CV) mortality among patients with acute heart failure and reduced (HFrEF), mid-range and preserved ejection fraction (HFpEF).
Methods: We prospectively included 2642 consecutive patients with AHF in a single teaching center. Left ventricular ejection fraction (LVEF) was assessed by two-dimensional echocardiography during index hospitalization. Patients were grouped according LVEF status: < 40% (HFrEF), 40-49% (HFmEF) and ≥50% (HFpEF). Traditional Cox and Cox adapted for competing events were used to evaluate the risk of total and CV-death, respectively.
Results: Patients with HFrEF, HFmEF and HFpEF represented the 31.3%, 15.3% and 53.4% of the sample, respectively. During a median follow-up of 2.3 years (0.8-4.2), 1322 (50%) deaths were registered (73.7% of them were of CV etiology). Similar rates (per 100 person-years) across the 3 categories were found for all-cause [16.4, 18.8 and 17.1 for HFrEF, HFmEF and HFpEF, respectively (log-rank p = 0.591) and CV-mortality [12.8, 14 and 12.1, respectively (log-rank p = 0.486)]. After a multivariate adjustment, compared to patients with HFrEF, patients with HFmEF showed a similar risk of total (HR:1.07, CI 95%: 0.78-1.24, p = 0.446) and CV-death (HR:0.98, CI 95%: 0.90-1.27, p = 0.882).
Conclusion: Patients with AHF and HFmEF show a similar mortality burden than patients with HFrEF and HFpEF.

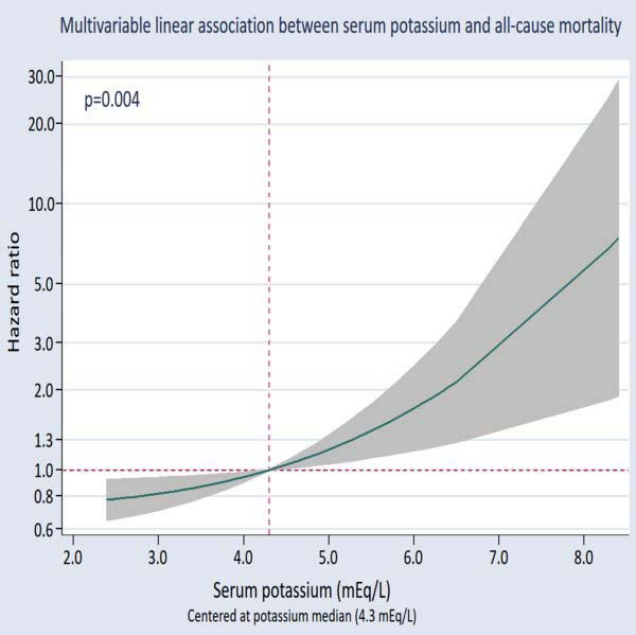
P927

Serum potassium levels and 6-month mortality in acute heart failure

J Jana Gummel[1]; R Farcasan[1]; J Parra[1]; A Paya[1]; R Heredia[1]; G Minana[1]; I Cardells[1]; A Mollar[1]; E Santas[1]; S Garcia-Blas[1]; E Valero[1]; FJ Chorro[1]; J Sanchis[1]; J Nunez[1]

[1]University Hospital Clinic of Valencia, Valencia, Spain

Background: Serum potassium abnormalities are frequent in patients with acute heart failure (AHF); however, information about its prognostic meaning is limited. In this work, we sought to evaluate the independent association between serum potassium on admission and the risk of 6-month all-cause mortality.
Methods: Potassium at admission was prospectively measured in 1090 patients with AHF. Patients were grouped according to low potassium (<3.5 mEq/L), normal potassium (3.5 to 5.0 mEq/L), and high potassium (>5.0 mEq/L) levels. The independent association between serum potassium and 6-month mortality was assessed through Cox regression analysis. The gradient of risk along the continuum of serum potassium was evaluated by fractional polynomials.
Results: The mean age of patients was 73.6 years, 53.5% were men and 50.8% showed left ventricular ejection fraction (LVEF) ≥50%. Median (IQR) N-terminal pro brain natriuretic peptide (NT-proBNP) was 3631 pg/ml (1694-8292). Low potassium was present in 84 patients (7.7%), normal potassium in 871 (79.8%), and high potassium in 136 (12.5%). At 6-month follow-up, a total of 126 patients (11.6%) died. Compared to patients with normal and low potassium, those with potassium >5.0 mEq/L almost doubled the rates of death [10.5%, 11.9% and 19.8% for normal, low and high potassium, respectively (p = 0.014)]. After a multivariate adjustment that included established prognosticators and important potential confounders (final model included the following covariates: age, prior admission for AHF, systolic blood pressure, LVEF, hemoglobin, NTproBNP, and treatment with antialdosteronics and angiotensin converting enzyme inhibitors or angiotensin receptor blockers), the association lost strength, but patients with potassium >5.0 mEq/L remained showing a statistical trend to higher risk of 6-month mortality compared to patients with normal potassium (HR=1.49; CI 95%: 0.94-2.38, p = 0.088). When evaluated as continuous, serum potassium was significantly associated with the endpoint; this association is best described as monotonically positive (Figure 1) with exponential increments from 6 to 6.5 mEq/L and up.
Conclusion: In patients with AHF, high serum potassium at admission is associated with higher risk of 6-month death. This association is especially attributable to very high potassium levels.



P928

N-terminal pro-B-type natriuretic peptide is no related with prognosis in patients hospitalized for heart failure with mid-range ejection fraction. The REDINSCOR II Registry.

I Gomez Otero[1]; A Varela-Roman[1]; R Agra Bermejo[1]; A Ferrero-Gregori[2]; D Pascual-Figal[3]; J Delgado Jimenez[4]; J Alvarez Garcia[2]; F Worner Diz[5]; F Fernandez Aviles[6]; R Vazquez Garcia[7]; M Rivera[8]; J Cinca[2]; JR Gonzalez-Juanatey[1]

Funding Acknowledgements: ISC III

Background/Introduction: The prognosis impact of the N-terminal pro-B-type natriuretic peptide (NT-proBNP) during hospitalization for acute heart failure (HF) is controversial. The new ESC HF guidelines include a new HF category with mid-range EF (HFmrEF) (LVEF 40-49%). To date has not been described the NT-proBNP levels and the prognosis in this group.
Purpose: We describe the NT-proBNP levels and the prognosis of HFmrEF hospitalized for acute HF in the REDINSCOR II Registry.
Methods: A prospective observational study was conducted with 1420 patients classified according to ejection fraction as follows: HFrEF <40%; HFmrEF, 40%-49%; and HFpEF, ≥50%. Baseline patient characteristics and outcomes at 1-, 6-, and 12-month follow-up were examined.
Results: Among the study participants, 583 (41%) had HFrEF, 227 (16%) HFmrEF, and 610 (43%) HFpEF. The mean value of NT-proBNP during hospitalization was 6242.4 pg/ml in HFrEF, 4349.3 pg/ml in HFmrEF and 2845.9 pg/ml in HFpEF, p < 0.001. Despite these differences there were no significant differences in all-cause mortality, or heart failure readmissions (table 1).
Conclusions: Despite marked differences in NT-proBNP levels between three categories during hospitalization for acute HF, no significant differences in the prognosis were observed during 1-year follow up. Our findings suggest a limited value of NT-proBNP levels in HFmrEF patients in these setting.

	HFrEF < 40% n=583 (41,1%)	HFmrEF 40 to 49% n=227 (16,0%)	HFpEF >=50% n=610 (43,0%)	P

P929

The association of baseline hyponatremia with ethnicity and gender in acute heart failure admissions

V Vikas Sunder[1]; R Alvarez[1]; E Carabelli[1]; M Weiner[1]; E Hamad[1]

[1]Temple University School of Medicine, Cardiology, Philadelphia, United States of America

Background: Hyponatremia, defined by a serum sodium concentration less than 135 mEq/L, is an electrolyte abnormality seen in approximately 25% of patients admitted with congestive heart failure (CHF). Baseline hyponatremia on admission has been shown to increase in-hospital mortality and to be an independent predictor of 6-month mortality in CHF patients. Prior work has shown that CHF patients with baseline hyponatremia are more likely to be Caucasian, but without further investigation. Heart failure does not impact patients of different ethnic backgrounds in the same manner. African-Americans have more than twice hospitalization rate of Caucasians. Given its prognostic significance and pathophysiologic role in the heart failure syndrome, hyponatremia and its association with patient characteristics warrants further study
Purpose: To examine the association between baseline hyponatremia and the patient characteristics ethnicity and gender in a sample of heart failure admissions
Methods: Administrative data from admissions to Temple University Hospital between August 2011 and July 2015 was extracted and merged with inpatient laboratory data. We queried for unique admissions with a DRG code of "291-293" to represent a heart failure admission. We identified unique heart failure admissions that had a first sodium lab value after admission available. We used the identifiers "Ethnicity" and "Gender" to categorize the data. Chi-square tests were performed to examine association between first Na < 135 mEq/L and ethnicity, gender, or ethnic/gender sub-group. All statistical analyses were performed with SAS 9.4 (SAS Institute, Cary, NC). Statistical significance was defined as $p < 0.05$.
Results: 976 CHF admissions with a first Na lab value were identified. 884 admissions were identified by ethnicity as either "African-American", "Caucasian (Non-Hispanic)" or "Hispanic". There was no association between first Na < 135 and ethnicity (Chi-squared=2.31; p = 0.31). 976 admissions were identified as either "male" or "female". There was no association between baseline hyponatremia and gender (Chi-squared=1.17; p = 0.27). 768 patient admissions could be classified by both ethnicity and gender. The "African-American/ Female" sub-group had the lowest proportion of admissions with first Na < 135 at 10.4%.The association between baseline hyponatremia and ethnic/gender sub-group did not achieve statistical significance (Chi-squared=9.49; p = 0.09)

Conclusion(s): Our study demonstrates no statistically significant association between baseline hyponatremia and the patient characteristics ethnicity and gender in a small sample of heart failure admissions. There was a trend toward a lower proportion of "African-American/Female" admissions having baseline hyponatremia as compared to other ethnic/gender sub-groups. Further examination of the association between hyponatremia and patient characteristics is needed using a larger sample

Funding Acknowledgements: Veneto Region

Objective: to examine clinical characteristics and long term prognosis of patients with heart failure (HF) and preserved left ventricular ejection fraction (HFpEF), and compare them to patients with HF and reduced LVEF (HFrEF).
Methods: The ABC 3-Study on Acute Coronary Syndrome is an ongoing, prospective investigation designed to reflect, as closely as possible, an unbiased population of patients with acute coronary syndrome (ACS). The present study includes 529 patients with ACS, enrolled in three intensive coronary care units, followed up for 17 years. HF was evaluated according to Killip classification: class 1: no HF, class 2: pulmonary rales, class 3: pulmonary oedema, class 4: cardiogenic shock. We considered left ventricular ejection fraction (LVEF)=45% as a cut-off, higher values were considered as preserved systolic function. Baseline, clinical and laboratory data were all obtained within the first 7 days of hospitalization. All patients were followed up to 17 years of observation or time to death. Only 3 patients did not complete the follow-up and their time was censored before 17 years. Survival analysis was realized using Cox regression models. All analyses were made with STATA 14.
Results: Among the 529 ACS-patients, 87 (48%) had HFpEF, and 95 (52%) had HFrEF. All the other patients had Killip class=1. We did not observe differences between the two groups regarding age (mean ± SD: 69.7 ± 10.1 years; 71.8 ± 10.7 years respectively, $p = 0.16$); gender, $p = 0.27$; BMI, $p = 0.46$; presence of hypertension, $p = 0.49$; diabetes mellitus $p = 0.70$; total plasma cholesterol, $p = 0.65$. Remarkably, the CK-MB peak (log-transformed), an indicator of necrosis extension, did not differ between the two groups ($p = 0.78$), while indicators of renal function (estimated glomerular filtration rate (eGFR)=77.7 ± 31.6 and 64.8 ± 28.3 respectively, $p = 0.002$) and endothelium dysfunction ,evaluated by means of 24-hours urinary albumin to creatine ration (ACR)=39.8 ± 74.1 mg/g and 71.6 ± 116.1 mg/g respectively, $p = 0.009$ in log-transformed data) showed relevant divergence. Among HFpEF patients, 62 (71.3%) died during the follow-up, while 89 (93.7%) died among those with HFrEF, chi2=16.1, $p = < 0.0001$.
At Cox surviving analysis, we observed lower mortality risk among HFpEF patients (HR=2.3; 95%CI=1.7-3.3; $p < 0.0001$). In the adjusted model (age, gender, ACR, GFR) still the risk difference remained consistent (HR=1.8; 95%CI=1.2-2.5; $p = 0.001$).
Conclusion: We observed that HFrEF patients had worse renal function and endothelium dysfunction in comparison with HFpEF patients. Besides, patients with HFrEF showed higher long-term mortality risk as compared to those with HFpEF.

P931

In ADHF patients, difference between serum BNP on admission and the one that is detected at discharge predicts six- month mortality more reliably compared to BNP on admission

R De Vecchis[1]; C Ariano[1]; G Di Biase[2]
[1]Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy; *[2]Neurorehabilitation Unit, Clinica" S.Maria del Pozzo", Somma Vesuviana, Italy*

Background According to some authors, a single isolated measurement of serum B-type natriuretic peptide (BNP) executed on hospital admission would not be a sufficiently accurate method to predict the outcome of patients with acute decompensated heart failure (ADHF).
Aims: For verifying this assumption, a retrospective study was conducted on patients hospitalized for ADHF. Our main objective was to ascertain whether there was any difference in midterm mortality among patients with rising BNP at discharge as compared to those with decreasing BNP at discharge.
Methods: Medical records were examined so as to make a partition of the ADHF patient population into two groups, the former characterized by a rise in BNP during hospitalization, and the latter exhibiting a decrease in BNP in the measurement taken at hospital discharge.
Results: 177 patients were enrolled in a retrospective study. Among them, 53 patients(30%) had increased BNPs at the time of discharge, whereas 124 (70%) showed decreases in serum BNP during their hospital stay. The group with patients who exhibited BNP increases at the time of discharge had higher degree of congestion evident in the higher frequency of persistent jugular venous distention and persistent orthopnea at discharge. Moreover, patients with increased BNP at the time of discharge had a lower reduction in inferior vena cava maximum diameter [1.58 ± 2.2 mm vs. 6.32 ± 1.82 mm; p (one-way ANOVA)=0.001]. In contrast, there was no significant difference in weight loss when patients with increased BNP at discharge were compared to those with no such increase. A total of 14 patients (7.9%) died during the six-month follow-up period. Multivariable Cox proportional-hazards regression analysis revealed that BNP increase at the time of discharge was an independent predictor of six-month all-cause mortality after adjustment for persistent jugular venous distention, persistent orthopnea, reduction in inferior vena cava maximum diameter at discharge, weight loss, serum urea, systolic blood pressure at admission and BNP at admission (hazard ratio= 30.5424; 95% CI: 1.7409 – 535.8294, $p = 0.0199$).
Conclusions: Among patients with history of ADHF, more elevated BNP levels at the time of discharge from the hospital compared to those detected at admission identify a patient subset with higher grade of congestion and higher six-month mortality.

P932

Transient versus persistent worsening renal function during hospitalization in acute heart failure: different phenotypes for different outcome

G Ruocco[1]; R Nuti[1]; M Beltrami[1]; A Giambelluca[1]; C Daniello[1]; B Franci[1]; A Palazzuoli[1]
[1]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy

Background: Role of Worsening renal function (WRF) in acute Heart Failure (HF) is still debated: it could be an index of over-diuresis but also a poor prognostic index. Our hypothesis is that the timing of WRF development could differently influence clinical decongestion and outcome.
Purpose: The aims of this study were: 1- to evaluate transient WRF versus persistent WRF in terms of clinical decongestion efficacy in acute HF patients; 2- to compare transient WRF and persistent WRF in relation to rate of adverse events at six months.
Methods: We enrolled 161 patients admitted to our department with diagnosis of acute HF screened from DiurHF Trial. All patients underwent systematic clinical congestion scoring and laboratory assessment (BNP, creatinine, BUN) at admission and at discharge. WRF was defined as creatinine increase ≥ 0.3 mg/dL at any time during hospitalization. Persistent WRF was defined as a sustained rise above this level throughout the hospitalization whilst transient WRF was defined as creatinine increase ≥ 0.3 mg/dL within 72 hours from the initiation of loop diuretics with return to creatinine levels below this threshold. Congestion score was evaluated using 5 signs (peripheral edema, pulmonary rales, jugular venous distention, third heart sound, hepatomegaly). Efficacy decongestion was considered when at least 3 signs resolving by the time of discharge. All patients were followed for six months for death or re-hospitalization due to cardiovascular causes.
Results: Of 161 patients, 12 patients were excluded for lacking laboratory or follow-up data. 93 patients (62%) experienced adverse events during 180 -days follow-up period. Among all patients developing WRF (n = 71) 48 had persistent and 23 had transient WRF. Patients who developed persistent WRF demonstrated similar rate of decongestion compared to those with transient or no WRF (72% vs 73% vs 74% respectively $p = 0.984$). Conversely transient WRF patients had lower adverse events rate respect to patients with persistent WRF and stable creatinine (30 % vs 81% vs 60%; $p < 0.001$). Stratification of the groups by previous Chronic Kidney Disease (CKD) revealed a significant lower rate of basal renal dysfunction in transient WRF group respect to persistent WRF and stable creatinine groups (21% vs 45% vs 50%; $p = 0.05$). Cox regression analysis showed that persistent WRF was related to poor outcome (U-HR 1,70 [1,11-2,61]; $p = 0.01$. M-HR 1,75 [1,12-2,74]; $p = 0.01$) oppositely transient WRF was related to improved prognosis (U-HR 0,42 [0,19-0,93]; $p = 0.03$. M-HR 0,42 [0,18-0,98]; $p = 0.04$). Kaplan-Meier survival curves confirmed the same trend.
Conclusions: Our data suggest that the timing of WRF has different prognostic significance: Transient WRF is associated with lower adverse events rate. Conversely persistent WRF is related to poor prognosis. These findings suggest the prognostic relevance of WRF is related to timing evaluation and it could reflect true and false renal dysfunction.

P933

Mean systolic blood pressure after admission for myocardial infarction is associated with one year mortality among elderly patients.

B Basile Mouhat[1]; C Guenancia[1]; M Zeller[1]; G Cartigny[1]; G Porot[1]; L Lorgis[1]; C Toucas[1]; M Benalia[1]; L Rosier[1]; C Khalil[1]; T Pommier[1]; Y Cottin[1]
[1]*University Hospital of Dijon, Department of cardiology, Dijon, France*

OBJECTIVE: Optimal blood pressure after acute myocardial infarction (AMI) is still debated. After admission for AMI, the target mean systolic blood pressure (mSBP) is unknown, especially in the elderly patients.
Methods: All patients older than 75 years admitted for AMI in our university hospital from 01/02/2012 to 31/01/2015 were screened to participate at this prospective observational study. Exclusion criteria were cardiogenic shock, end-stage renal disease, less than 3 collected blood pressure values. We completed a one-year follow-up. The primary endpoint was all-cause mortality at one year while additional criteria were major adverse cardiac and cerebrovascular events at one year. The mSBP was defined by the mean of at least 3 measurements over the first 48 hours following admission for AMI.
RESULTS: In our population, a ROC curve study on the relationship between mSBP and one-year mortality suggested a cut-off value of mSBP of 125 mmHg. 517 patients (mean age 82 years) were divided into 2 groups according to mSBP (<125mmHg vs ≥125mmHg). There was a higher rate of one year all-cause mortality in the mSBP<125mmHg group with 58 deaths (22.3%) versus 31 (12.1%)(p = 0,002) in the mSBP≥125mmHg group, and also an increased cardiovascular mortality in the mSBP<125mmHg group with 43 deaths (16.5%) versus 22 (8.6%) (p = 0,006). A multivariate analysis identified 4 independents factors of all-cause mortality at 1 year after AMI: initial GRACE score > 140, LVEF < 40%, history of stroke and mSBP<125mmHg.
Conclusions: In our elderly AMI population, low mSBP within 48 hours after admission was an independent and powerfull predictor of one-year mortality. Our results raise the question of the timing implying the introduction of usual pharmacological therapies in this high-risk population. Our cut-off of mSBP remains to be validated in further studies.

Trends in gender differences in cardiac care and outcome after acute myocardial infarction in western Sweden

E Elmir Omerovic[1]; O Angeras[1]; P Petursson[1]; I Haraldsson[1]; C Dworeck[1]; J Odenstedt[1]; D Ioaness[1]; P Albertsson[1]; B Redfors[1]
[1]*Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: Cardiovascular disease is the most common cause of death for both genders. Debates are ongoing as to whether there exists sex-specific differences in clinical course, diagnosis and management of acute myocardial infarction (AMI) and to what extent these differences can be alleviated by changes in clinical praxis.
Methods: We compared all men and women who were treated for AMI at a cardiac care unit in Västra Götaland County between January 1995 and October 2014 by obtaining data from the prospective SWEDEHEART registry (Swedish Websystem for Enhancement of Evidence-Based Care in Heart Disease Evaluated According to Recommended Therapies). We performed unadjusted and adjusted Cox proportional hazard and logistic regression analyses on complete case data as well as on imputed datasets.
Results: 48.118 patients (35.4% women) were diagnosed with acute myocardial infarction and were included in the analysis. Women as a group had better age-adjusted prognosis than men but this survival benefit was absent for younger women (<60 years) and for women with ST-elevation myocardial infarction (STEMI). Compared to men, younger women and women with STEMI were more likely to develop pre-hospital cardiogenic shock (adjusted OR 1.67, 95%CI 1.30 – 2.16, p < 0.001 and adjusted OR 1.31, 95%CI 1.16 – 1.48, p < 0.001) and were less likely to be prescribed evidence based treatment at discharge (p < 0.001 for beta blockers, angiotensin converting enzyme inhibitor/angiotensin receptor antagonist, statins and P2Y12 antagonists). Differences in treatment between the genders did not decrease over the course of the study period (p>0.1 for all treatments).
Conclusions: Younger women and women with STEMI have higher risk to develop cardiogenic shock and have worse short- and long-term prognosis after acute myocardial infarction. Women are less likely than men to be prescribed evidence based treatment after acute myocardial infarction.

P935

Dynamics of epidemiological characteristics of the prevalence of cardiovascular and some noninfectious diseases among the women of fertile age in Fergana Valley

S Saidrakhim Lukmonov[1]; O Usmonov[1]; I Xaydarov[1]; M Usmonova[1]; M Rozikova[1]; D Mamedov[1]; SH Shamsiyev[1]; M Turdikulova[1]; M Ismailov[1]; A Ismatov[1]; E Mirzakarimov[1]; D Toirova[1]; G Suyunova[1]; N Melikova[1]; S Mingbayeva[1]
[1]*Tashkent Medical Academy, Department of faculty and hospital treatment, medical and pedagogical faculty, Tashkent, Uzbekistan*

Purpose: To study 9-year dynamics of prevalence of main cardiovascular and non-infectious diseases (MCNID) among the population of women of fertile age (FAW) in Fergana Valley.
Material and methods: During epidemiological study with use method of monitoring there was evaluated 9-year dynamics of MCNID prevalence among FAW (912 women in Andijan-city and 2360 women in Namangan). In two researches with interval 9 years the lists of election campany before onset of investigations were the resources for formation of the selection. There were used epidemiological criteria for diagnosis of MCNID (Oganov R.G. et al, 2003).
Results: During the period from 1996 to 2004 in FAW the statistic significant increase in prevalence of MCNID by 5,4% was found (from 26,1% to 31,5% respectively from 1 to 2 investigation, P < 0,05). This grow of MCNID formed due to their increase in various patterns in the following age groups: from 10,1 - 19,2% or by +9,1% at 15 years-19 years (P < 0,05); from 17,2 -29,4%, or by +12,2% - at 20-29 years (P < 0,05); from 24,0 to 37,8% or by 13,8% - at 30-39 years (P < 0,05) and from 16,6% to 28,8% or by 12,2% at 40-49 years (P < 0,05).The marked growth of MCHID was noted in age group of 30-39 years, comparatively less this grow was observed in groups of women of 15-19 years, 20-29 and 40-49 years.
Conclusion: During the 9-year follow-up of FAW in comparison with initial data the growth of cases of MCNID was significantly accelerated – from 9,1% (15-19 years) to 13,3% (30-39 years) in dependence on age. These results may be recommended for optimization of the strategy of preventing programs or for determination of the groups of high risk for development of chronic multiple diseases in women of the age 15-49 years.

P936

Prognostic role of cystatin C and other biomarkers in heart failure

A Adriana Tamburello[1]; G Carollo[1]; G Novo[1]; F Ricupati[1]; S Novo[1]
[1]*University Hospital Paolo Giaccone, Cardiology, Palermo, Italy*

Background: Cystatin C is a valid alternative to test renal function and it recently showed some features, in terms of long-term predictive value of mortality and re-hospitalization for acute heart failure, compared to measurement of serum creatinine and/or levels of NT-proBNP.
Materials and methods: We studied 79 patients (Men= 38, Women= 41; average age 74.10 ± 8.45 years) consecutively admitted at the Cardiology Unit for heart failure. The final diagnosis of heart failure was made in accordance with the recent ESC Guidelines 2016, based on clinical history, signs, symptoms experienced, and echocardiographic alterations (Abnormalities in E/e′ ratio and/or increased left atrial volume were also considered)
We evaluated serum concentrations of cystatin C and NTproBNP within 24 hours of hospitalization and at discharge, the classification of the New York Heart Association (NYHA), the speed ratio of the transmitral flow (ratio E/A) to assess diastolic function.
It was conducted a one year follow-up with telephone interview, regarding any re-hospitalizations or mortality for all-causes or cardiac causes.
Results: The levels of Cystatin C, NT-proBNP were significantly related to NYHA class and lower ejection fraction (r = 0.603 P < 0.001, r = 0.331 P < 0.001 and r = 0.321 P < 0.001, respectively).
Patients with Cystatin C levels less than 1.5 mg/l had a higher E/A ratio than those with cystatin C levels greater than 1.5 mg/l. Cystatin C was significantly associated with both NYHA classification and E/A ratio even after adjusting for creatinine clearance.
We found an area under the ROC curve of 0.741 (SE 0.0969, 95% CI 0.610 to 0.846) for NTproBNP and 0.824 (SE 0.0596, 95% CI 0726-0897) for Cystatin C. In these conditions, the values with the high prognostic accuracy appear to be> 590 pg/ml for NTPRO-BNP (95.9% sensitivity, 87.0% specificity) and cystatin C> 2.16 mg/L (sensitivity 89.1%; specificity 88.2%).
Conclusions: Both Cystatin C and NT-proBNP are related to worse NYHA classification, ejection fraction and increased rate of MACEs and mortality. Independent of renal function, higher serum concentrations of cystatin C correlates with days of hospitalization (P = 0,0002) and abnormal cardiac diastolic properties in patients with heart failure.

P937

Association between iron deficiency and post-discharge outcomes in patients hospitalized for heart failure

M Monica Chivulescu[1]; L Antohi[1]; I Cosei[1]; C Radulescu[1]; J Butler[2]; G Tatu-Chitoiu[3]; IM Coman[1]; SP Collins[4]; M Gheorghiade[5]; O Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*; [2]*Stony Brook University Medical Center, Stony Brook, United States of America*; [3]*Emergency Clinical Hospital Floreasca, Bucharest, Romania*; [4]*Vanderbilt University, Nashville, United States of America*; [5]*Northwestern University, Chicago, United States of America*

Background: Iron deficiency (ID) is common in chronic heart failure (HF) patients and is associated with a negative prognosis, but its prevalence and clinical relevance remain unknown in hospitalized patients with worsening chronic heart failure (WCHF).
Aims: To determine the prevalence of ID in a cohort of patients hospitalized for WCHF and to describe the epidemiological characteristics of this sub-population. The relationship between ID and post-discharge outcomes was prospectively evaluated.
Methods: FERIC-RO study was designed as a prospective national observational study which enrolled 138 consecutive patients hospitalized for WCHF. Iron status was assesed at discharge in all patients and ID was defined as ferritin < 100 mcg/L or 100-299 mcg/L and TSAT < 20%. Patients were divided in two groups according to the presence or absence of ID.
Results: A proportion of 54% of the patients had ID, and of these 19% had ID without anemia, while 35% had ID and anemia. Differences in baseline characteristics between ID+ and ID- are shown in Table 1. Patients with ID had higher 3-month mortality compared to those without ID (9.9% vs 7.9% P=0.002). In univariate analysis, ID was predictive for 3-month mortality (HR=1.21; 95% CI 1.04-1.32). When adjusted for 9 clinical variables including demographic, baseline treatments, history and left ventricular ejection fraction, ID wasn´t found as a predictor of 3-month all cause mortality (HR=1.12; CI 95% 0.98-1.19)
Three month-HF rehospitalizations were higher in patients with ID as compared with patients without ID (12.0% vs 9.1% P=0.002). ID was independently predictive for 3-month HF rehospitalizations even after adjusting for the same clinical variables (HR=1.38; CI 95% 1.11-1.46).
Conclusion: ID is a common comorbidity in patients hospitalized for WCHF and it is associated to higher risk for post-discharge adverse events. ID should be regularly checked at discharge and may be a therapeutical target in WCHF.

On behalf of: the GREAT network
Funding Acknowledgements: The work was supported by the Research Council of Lithuania, grant Nr. MIP-049/2015 and approved by Lithuanian Bioethics Committee, Nr. L-15-01.

Introduction: Heart failure (HF) is a major and growing public health problem. Currently, HF is the main reason of hospitalisation for patients aged over 65 and it imposes a significant economic burden on health care systems. Medication nonadherence is associated with an increased risk of all-cause mortality and cardiovascular hospitalisations in patients with HF.
Purpose: We aimed to investigate adherence to HF guidelines for drug therapy and the association between adherence and length of hospital stay for HF patients hospitalised due to acute dyspnea.
Methods: Prospective observational cohort study enrolled 837 consecutive patients admitted to the emergency department with acute dyspnea between March 2015 and December 2016. Out of 837 examined patients, 187 patients (22.3%) were included in the analysis after being hospitalised and discharged with final diagnosis of acute HF with reduced left ventricular ejection fraction (LVEF <40%). Patients presenting dyspnea related to HF with LVEF >40% (9.2%), cardiac arrhythmia (8.8%), pulmonary embolism (6.9%), pulmonary infection (6.8%), acute coronary syndrome (4.5%), chronic obstructive pulmonary disease (4.3%), cancer (3.0%), hypertension (1.8%), anxiety (1.6%) were excluded. Adherence was evaluated using guideline adherence indicator (GAI3), which is defined as the proportion of care across main three therapeutic classes (angiotensin-converting-enzyme inhibitors (ACEIs), beta-blockers (BBs) and mineralocorticoid receptor antagonists (MRAs)) according to current European Society of Cardiology (ESC) HF treatment guidelines. Patients were categorised into 3 groups based on the GAI3 values (good, 100% intermediate, 50–67% poor, 0-33%). A general linear model was used to assess the effect of pre-hospital GAI3 on the length of hospital stay.
Results: We evaluated 187 patients (mean age, 69.1 years, 66% men) with the mean GAI3: pre-hospital – 56.7% (23%, 40% and 37% showed good, intermediate, and poor adherence, respectively), at discharge – 68.4% (34%, 43% and 23% showed good, intermediate, and poor adherence, respectively). BBs (68%) were used more frequently in pre-hospital HF treatment than ACEIs (60%) and MRAs (42%). This trend was also observed in medication prescribed at discharge (BBs 81%, ACEs 66%, MRA 58%). The length of hospital stay was significantly longer in poor adherence patients group (11.7 ± 0.98 days) in comparison with intermediate (8.1 ± 0.84 days) and good (10.8 ± 1.59 days) adherence groups ($p < 0.05$).
Conclusions: Pre-hospital and discharge treatment showed intermediate adherence to HF treatment guidelines. Poor adherence to ESC HF guidelines could be associated with increased length of hospital stay.

P939

ST-segment elevation in baseline electrocardiogram predicts mortality in cardiogenic shock

T Javanainen[1]; HEV Tolppanen[1]; VP Harjola[2]; J Lassus[3]; T Tarvasmaki[1]; MS Nieminen[1]; J Spinar[4]; A Sionis[5]; M Banaszewski[6]; R Jurkko[1]
[1]*Helsinki University Central Hospital, Helsinki, Finland*; [2]*Helsinki University Central Hospital, Emergency medicine, Helsinki, Finland*; [3]*Helsinki University Central Hospital, Heart and Lung Center, Helsinki, Finland*; [4]*University Hospital Brno, Department of Internal Medicine and Cardiology, Brno, Czech Republic*; [5]*Hospital de la Santa Creu i Sant Pau, Intensive Cardiac Care Unit, Cardiology Department, Barcelona, Spain*; [6]*Institute of Cardiology, Warsaw, Poland*

Background: The most common aetiology of cardiogenic shock (CS) is acute coronary syndrome (ACS), but 20 % of CS is caused by other disorders. ST-segment deviations in electrocardiogram (ECG) have previously been investigated in patients with CS caused by ACS but not in those with other CS aetiologies.
Purpose: The aim was to explore the prevalence of different ST-segment patterns and their association with the aetiology and 30-day mortality in CS.
Methods: We analysed the baseline ECG of 196 patients who were included in a multinational prospective cohort study of CS. The patients were divided into three groups according to their ECG: 1) ST-segment elevation (STE): ST-segment elevation at the J point in two contiguous leads with following cut-points: ≥ 0.1 mV in all leads other than leads V2 – V3 where the following cut points apply: ≥ 0.2 mV in men ≥ 40 years; ≥ 0,25mV in men < 40 years, or ≥ 0.15 mV in women. 2) ST-segment depression (STDEP): horizontal or down-sloping ST-depression ≥ 0.05 mV in two contiguous leads. 3) No ST-segment deviation or ST-segment impossible to analyse (NSTED). The multivariable model was adjusted for age, gender, left ventricular ejection fraction and comorbidities.
Results: Mean age was 66 years, 74 % were men, and 81 % had ACS as CS aetiology. The prevalence of any ST-segment deviation was 80 % (n = 157). Half of the patients had STE (n = 105, 54 %) and one fourth had STDEP (n = 52, 27 %). Remaining 20 % (n = 39) comprised NSTED group. The prevalence of ACS aetiology was higher in patients with STE (93 %) in comparison with STDEP (71 %, p < 0.01) and NSTED (59 %, p < 0.01). Overall, 30-day mortality was 36%; in STE group 42 %, STDEP 31 % and NSTED 28 % (p = 0.18). In multivariable analysis, STE was an independent predictor of mortality (HR 2.09, 95 % CI 1.25 - 3.51) along with increasing age, previous ischaemic heart disease and left ventricular ejection fraction (Figure).
Conclusions: Most CS patients have ST-segment deviations in baseline ECG. STE is strongly associated with ACS aetiology. Interestingly, CS aetiology was other than ACS in one third of patients with STDEP. Furthermore, CS was caused by ACS in over half of the NSTED patients. Importantly, STE is an independent predictor of 30-day mortality.

On behalf of: FRESH group
Funding Acknowledgements: French Survey on Heart Failure

New ESC guidelines pointed out the need to specify what are heart failure (HF) patients with mid-range left ventricular ejection fraction (mrLVEF) – defined by LVEF 40 to 49%- as compared to patients with preserved LVEF (pLVEF) and reduced LVEF (rLVEF). By using French Survey on Heart Failure (FRESH), we aim to compare characteristics of these 3 subgroups in acute HF.
Methods: FRESH is an on-going multicenter survey collecting exhaustive data in both acute and chronic HF (NCT01956539). Comparisons were performed using chi^2 or Fisher test for categorial variables and ANOVA or non-parametric Kruskal Wallis test for continuous variables. Multinomial logistic regression was performed.
Results: Among 595 chronic HF patients, 50% had rLVEF, 15% had mrLEVF and 35% had pLVEF.
There were significant differences across LVEF subgroups in clinical scenario at admission as well as age, gender, underlying cardiac disease, comorbidities, heart rate, arrhythmia, blood pressure, haemoglobin, natremia, BUN, natriuretic peptides, and use of medications during hospitalization and at discharge. The table shows significant results of the multivariate analysis.
Conclusion: Acute HF patients with mrLVEF exhibit some significant differences with both HF-rEF and HF-pEF, which deserves further investigations.

	Odd ratio	95%CI	p

Hypercapnia in patients admitted in the emergency department for acute decompensated heart failure

D David Cabrita Roque[1]; J Augusto[1]; A Sachetti[1]; D Faria[1]; A Gaspar[1]; L Melo[1]; T Bernardo[1]; J Simoes[1]; P Magno[1]; A Oliveira Soares[1]; C Morais[1]
[1]Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal

Background: Blood gas assessment (BGA) is recommended in the evaluation of patients with acute heart failure only in those where oxygenation cannot be readily assessed by pulse oximetry, and when a precise measurement of O2 and CO2 partial pressures is needed. We aim to evaluate the prevalence and characteristic of hypercapnia in acute decompensated heart failure (ADHF).
Methods: Retrospective study of 258 consecutive patients admitted in the emergency department for acute decompensated heart failure. We included patients in whom a BGA was performed at admission. Hypercapnia was defined as pCO2 at admission > 45mmHg. The HF profile was assessed as according to the recent guidelines.
Results: 206 patients with ADHF as the primary reason for hospitalization performed BGA at the hospital admission (46.1% male, 74.7 ± 16.9 years). 201 (97.6%) patients were classified as profile B (wet and warm); of these 135 patients (65.5%) were classified as having acute pulmonary edema (APE). Profile C was less common (2.4%). Hypercapnia was observed in 70 patients (30.7%), more frequently in patients with APE (50.7% vs 25.9%, p = 0.001). Of the group of patients in APE, the use of bi-pressure airway ventilation was 55.9% for those with hypercapnia and 12.1% for those without hypercapnia (p < 0.001).
Conclusion: Hypercapnia is present in up to one third of the patients admitted with ADHF, more frequently in those with APE. The potential need for the use of bi-pressure airway ventilation and its prevalence in this population suggest that the knowledge of the CO2 level may be important in these patients.

P942

Chitotriosidase enzyme can be a negative acute phase protein in acute heart failure unlike coronary artery diseases

S Sara Cetin Sanlialp[1]; M Sanlialp[2]
[1]pamukkale university, cardiology, Denizli, Turkey; *[2]denizli government hospital, cardiology, denizli, Turkey*

Introduction: Heart Failure (HF) is a complex, neurohumoral and inflammatory syndrome. Recent studies show that proinflammatory cytokines contribute heart's systolic or diastolic dysfunction causing cardiac depression. Chitotriosidase (CHIT), an enzyme released from active macrophages, plays a role in many diseases involving inflammation (lysosomal storage diseases, sphingolipidoses, sarcoidosis, tuberculosis, thalassemia, multiple sclerosis etc.). Therewithal, it has been observed that CHIT activity in plasma is significantly high in ischemic heart diseases with arterial inflammation and ischemic strokes.There are no studies invastigating the relationship between conjestive heart failure and CHIT enzyme as much as day-to-day; this study aims to figure out the role of CHIT in HF and the relationship between other cytokines.
Method: 43 Newyork Heart Association (NYHA) class III/IV acute heart failure (AHF) patients who were hospitalized in the coronary intensive care unit (CICU) between 01.05.2014-01.11.2014, 48 chronic heart failure (CHF) patients and 45 healthy controls included in the study. All participants' detailed echocardiography, doppler and tissue doppler measurements were performed and left ventricular ejection fractions (LVEF) were calculated by Simpson method. All participants' plasma CHIT IL-1β, TNF-α, IL-6, Hs-CRP and NT-proBNP levels were determined by ELISA method.
Results: The highest CHIT activity in plasma (876,937 ± 820,938 ng/ml) is observed among chronic heart failure patients whereas the lowest CHIT activity in plasma (527,876 ± 323,04 ng/ml) is observed among AHF patients. It was observed that when LVEF of acute heart failure patients decrease their CHIT activity levels decrease as well. Also a negative correlation (p = 0,038 and r=-0,32) occurred between CHIT activity levels and NYHA class levels. In acute heart failure a negative correlation (p = 0,038 and r=-0,32) between plasma hs-CRP levels and CHIT activity occurred.
Conclusion: CHIT enzyme may play a role as a negative acute phase protein in AHF. Plasma CHIT value of AHF patients decreases when left ventricular systolic dysfunction increases and it is negatively correlated with NYHA values.

Regression analyse of AHF vs Controls

Regression Analyse	Odd's Ratio	Confidence Interval	P Value
NT-proBNP	1,03	1,01-1,06	0,002
Hs-CRP	2,83	5,37-1,49	0,042

Advanced acute heart failure and ketogenic diet: a case series of a single centre initial experience

J Jonida Bejko[1]; T Bottio[1]; M Comisso[1]; M Carrozzini[1]; V Tarzia[1]; E Manzan[1]; D Gregori[1]; FP Francini[1]; G Gerosa[1]
[1]*University Hospital of Padova, Padua, Italy*

BACKGROUND: Ketogenic diet (KD) is an effective treatment for drug-resistant epilepsy. Recently, clinical indications have been increasing. Little is known on the contribution in cardiac metabolism.
Material and Methods: Seven adult pts affected by acute heart failure (HF), unresponsive to conventional medical and surgical therapy, were enrolled to observe the effects of KD as additional treatment. Pts demographics, diuresis, urine ketones, laboratory studies, diet duration, side effects and echocardiographic studies were recorded.
Results: Two pts presented biventricular failure after heart transplantation (HTx). Five pts presented right ventricular failure (RVF) after LVAD implantation. One pt was female (n = 1; 14%). Age range was 45-72 yrs. All pts were naïve to diet therapy. At 6 days of treatment pts responded to KD on: RVF (range 4-60% of TAPSE increase, p = 0.015); LV in two HTx (increase of 10-26% respectively,p = 1); glucose variability (GV) (p = 0.03). Hyperlipidemia was observed in 2 pts (28,6%, p = 0.015). Weight loss and increase in diuresis volume were common in all pts but not statistically significant (p = 0,4).
Conclusions: Perceived benefits of KD were improved RV function and reduced serum GV. These cases demonstrate that the use of KD for treatment of refractory HF can be undertaken safely and is well tolerated in different administration forms. Future research with proper numbers and identification of pts is necessary.

Outcomes

Frequency of etiological and precipitating factors in patients with acute de-compensated heart failure

M Muhammad Rauf[1]; KHAN Noman[1]; M Hafizullah[1]
[1]*Hayat abad Medical Complex , Cardiology, Peshawar, Pakistan*

Methodology: This cross sectional descriptive study was carried out at Cardiology Department, from October 2011 to April2012. Patients presented with ADHF were assessed and investigatedfor the causes and factors that precipitate heart failure (HF).
Results: Out of 291 patients, 153(52.5%) were males. Age ranged from 13-90 years with mean age 53.59 ± 18.98 years. The underlying etiology of HF was coronary artery disease (CAD) 29.2%, hypertension 18.5%, rheumatic heart disease (RHD) 13.7%, dilated cardiomyopathy (DCM) 11.0%, other cardiomyopathies 9%,multiple causes 12.4%, and others 6.1%. Most common precipitating factor for de-compensation was infections (28.2%) followed by poor compliance to medications (17.5%). Other precipitating factors include dietary indiscretion(11%), arrhythmias(13.7%), pregnancy(7.2%) and anemia(5.1%). No precipitating factor was found in 10% patients.
Conclusion: coronary artery disease, Hypertension, rheumatic heart disease and dilated cardiomyopathy are main etiological factors of ADHF. Infections, poor compliance to medications and arrhythmias are major precipitating factors.

P945

Is pulse pressure associated with short-term re-admission after index hospitalisation for acute heart failure syndrome?

L Cowie[1]; M Pang[1]; A Sultan[1]
[1]*Royal Albert Edward Infirmary, Cardiology, Wigan, United Kingdom*

Introduction: The prognostic value of pulse pressure has been investigated in chronic heart-failure patients, however, it's reliability as prognostic marker in patients with acute heart failure is unknown.
Hypothesis: We aimed to evaluate the effect of pulse pressure, at baseline and at discharge, on re-admission in 30-days after an index hospitalisation for unselected patients with acute heart failure (AHF) in the local population.
Patient selection and characteristics: We identified a total of 61 consecutive patients (mean age 78 years, 55.4% females) over three months period who were hospitalised for a mean of 7.6 days at a large district general hospital. 58.9% of patients were hypertensive, 34.1% were diabetics, 59% were known for previous chronic heart failure. 39.2% had myocardial infarctions, 55.7% had known atrial fibrillation and 16.0% had chronic obstructive pulmonary disease. Nearly 32.5% had acute kidney injury, but there was significant improvement in creatinine levels (123.7 mmol/l vs 113.1 mmol/L; p = 0.004) at the time of discharge. Interestingly, at discharge, a significant reduction in prescription for betablockers (87.1% vs 85.5% on discharge) was noted. Increasing number of patients received angiotensin converting enzyme-inhibitor (ACEi) or angiotensin receptor blockers (ARB) (66.2% vs 83.9%). Only 19.3% patients had aldosterone receptor inhibitors and 8% had Ivabadrine.
Results: Mean BP was reduced significantly from 138/78 mmHg to 123/68 mmHg (p < 0.01). Heart rate reduction was significant (88 beats per minute (bpm) to 74bpm; p < 0.0001), nonetheless it was still higher than the 70 bpm as suggested by SHIFT trial. 30-days all-cause mortality after an index admission was 9.6% and re-admission rate was 32.3%.
The mean pulse pressure drop was not significant (60.2 mmHg on admission vs 55.3mmHg at discharge, p = 0.09). Logistic regression analysis (MedCalc) showed pulse pressure on discharge (P < 0.0001) was significantly related to re-admission in 30 days after an index admission for AHF.
Conclusions: The results of this small study suggest that the prediction of re-admission after hospital discharge for acute heart failure could be improved based on pulse pressure at discharge. These results need confirmation in a larger study.

P946

Predictors of a longer lenght of stay in acute heart failure: a colombian experience

C I Clara Ines Saldarriaga[1]; JS Parada Zuluaga[2]; AM Quintero[1]; K Marisancen Carrasquilla[2]; AM Velez Granda[2]; EM Canas[2]; AM Agudelo[1]
[1]*Cardiovascular Clinic Santa Maria, Universityof Antioquia cardiology department, Medellin, Colombia*; [2]*Universidad Pontificia Bolivariana, Cardiology, medellin, Colombia*

Funding Acknowledgements: Clinica CardioVID and University pontificia bolivariana

Acute heart failure (AHF) is the leading cause of hospitalization for people aged 65 or older. Hospital length of stay (LOS) is a key determinant of higher hospitals costs.
Objective: To describe the clinical profile of patients admitted for AHF in a Colombian reference center and to identify the characteristics that predict a longer length of stay.
Methods: A prospective cohort study was performed
Results: 183 patients were hospitalized during a period of 5 months with diagnosis of AHF, the mean age was 67.6 +/- 15.3 years , 55.7% were males, the mean EF was 30.4% +/- 14,6 Most of the population had HFr EF. The clinical profile of the patients was : warm-dry: 3.8%, warm-wet: 78.7%, cold -dry: 3.8%, cold-wet 13.7%. Inotropes were prescribed in 15.8% and 5.5% presented new onset atrial fibrillation. the average LOS was 5 days and 53% of the population had a longer LOS. The 30 days mortality was 7%, 54.6% of the patients had at least one previous hospitalization. The most frequent comorbidities are presented in table 1. Multivariate and univariate analysis was performed and the presence of acute renal failure was the only predictor of a prolonged length of stay (Relative risk 1.66 CI 1.28 - 2.14)
Conclusion: Our population of AHF had a mean of stay of 5 days, were predominantly males, with reduce EF and a lot of comorbidities. Acute renal failure was the only predictor of a long stay.

Table 1

Comorbidities	Percentage
Hypertension	76.6%
Diabetes	32.2%
Atrial fibrillation	50.3%
COPD	21.9%
Coronary Artery disease	44.8%
Acute renal Failure	31.7%
Chronic renal failure	31.1%

Is tako-tsubo cardiomyopathy induced during dobutamine stress echocardiography a high-risk situation?

A Kassongo[1]; A Kone[1]; C Bensouda[2]; P Meimoun[3]; D De Zuttere[1]; H Lardoux[4]
[1]Institut Franco Britannique , LEVALLOIS PERRET, France; *[2]Clinique A.Paré, Neuilly sur Seine, France*; *[3]University Hospital of Compiegne, Compiegne, France*; *[4]Institut Mutualiste Montsouris , Cardiology , paris, France*

Background: Life-Threatening complications due to hemodynamic instability may occur early in Tako-Tsubo cardiomyopathy (TTC). Dobutamine Stress Echocardiography (DSE) is a non-invasive test to detect myocardial ischemia. TTC induced during DSE is a rare issue. Our purpose is the evaluate the frequency and severity of acute Left Ventricular (LV) dysfunction and its possible deleterious evolution in TTC induced during TSE

Patients and methods: From an exhaustive search and review, using key words "apical ballooning, stress cardiomyopathy and DSE", we identify 23 clinical reports of DSE induced TTC from 2008 to 2016, and we added one personal case.

Results: This cohort of 24 patients (pts) was homogenous as they all presented TTC during DSE. Collected observations came mostly from USA (n = 10) and Europe (n = 9). DSE tests, protocol and indications were conventional: thoracic pain (16/24) and pre-operative assessment (5/24). Symptoms occurred mostly at peak dose, 30 or 40 gammas/kg/mn (22/24) or rarely during recovery (3/25). Demographic and clinical data show: mean age= 63.5 ± 13 years - from 41 to 85; female=92%; female > 50 years = 84%. EKG ST elevation: 70.8%. All patients underwent emergency coro-angiography and all coronary angiogram were normal, with markedly depressed LV angio Ejection Fraction (LVEF): 33 ± 8% (not calculated for 10 pts). LV angiographic ballooning pattern was: apical n=15 (62%); mid n=5(20%), unknown (18%). Mean troponin peak was 3.87 (0.8 -9) ng/ml; Death occurs in one pt. (4.1%), at day 2, the eldest woman (85y) of the group because of cardiac failure. LVEF recovery was constant between day 2 and 30. New imaging techniques are still rarely added: Magnetic Resonance imaging (n = 4) and 2D longitudinal strain (n = 2)

Conclusions: TTC induced during DSE is a rare, but severe entity. It gives the rare opportunity to observe TTC at its very acute phase in all patients. Normal coronary arteries, acute LV dysfunction with apical or mid ballooning, low troponin levels, are typical markers of TTC. In this cohort, despite severe acute LV dysfunction, death remains rare. LV function normalizes rapidly and completely. Dobutamine infusion, psychological stress during DSE, may contribute to the occurrence of TTC during DSE but precise mechanism of this acute situation remains unknown.

P948

Persistent diastolic dysfunction following st elevation myocardial infarction

F Fathia Mghaieth Zghal[1]; F Azeiz[1]; B Rekik[1]; S Boudiche[1]; M Ben Halima[1]; N Khadher[1]; S Ouali[1]; A Farhati[1]; N Larbi[1]; MS Mourali[1]
[1]Rabta Hospital, Tunis, Tunisia

Objective: We performed serial Doppler echocardiography during hospitalization and at least one month following acute myocardial infarction (STEMI). The aim was to assess the correlation between persistent diastolic dysfunction and the infarct location, the peak of CPK and the left ventricular global longitudinal strain.

Design and method: In a prospective study, 127 consecutive patients (58.13 ± 11.92 years, 23 females, mean ejection fraction of left ventricle= 44.9 ± 9.9%) were enrolled. Echocardiography was performed several months (7.03 ± 6,70 months) after STEMI and the diastolic function was assessed according to the 2016 guidelines of the European Association of Cardiovascular Imaging.

Results: 65 patients (51%) sustained an anterior myocardial infarction. Only 25 patients (19%) had normal diastolic function (or a transient regressive dysfunction), 54 (42%) had grade 1 dysfunction, 11 (8%) had grade 2 dysfunction and 10 (7%) had grade 3 diastolic dysfunction. The diastolic function was indeterminate in 27 patients. The presence of diastolic dysfunction was associated with higher peak of CPK during the acute phase of myocardial infarction (938,40 ± 659,66 U/L vs 2060,95 ± 1348,17 U/L, p < 0,0001) and lower global longitudinal strain (-16,12 ± 2.73 vs -11,60 ± 5,29, p < 0,0001). There was no statistical significant correlation to the anterior infarct location (p = 0,18).

Conclusions: Left ventricular diastolic persistent dysfunction was present in the majority of STEMI patients. The extent of the infarction and the global longitudinal strain best identified patients with abnormal diastolic function.

CHRONIC HEART FAILURE

P949

Reliability of biomarkers (Nt-proBNP, Gal-3, NGAL, hsTnT, AVP, ST-2, MDA) in patients with HFrEF, HFpEF, diabetic nephropathy and arterial hypertension

S Litmeier[1]; F Weisrock[1]; M Fritschka[2]; S Beckmann[1]; D Djawid Hashemi[1]; J Wagner[1]; E Tahirovic[1]; S Radenovic[1]; A Busjahn[3]; B Pieske[1]; W Dinh[4]; HD Duengen[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Department of Internal Medicine and Cardiology, Berlin, Germany; *[2]German Heart Institute of Berlin, Department of Cardiology, Berlin, Germany*; *[3]Health Twist, Berlin, Germany*; *[4]BAYER Pharma AG, Pharmaceutical Division, Wuppertal, Germany*

Background: Several biomarkers are available for the evaluation of diagnosis, supervision of therapy and risk prediction in various cardiovascular disease. Further, they may serve as a surrogate parameter in clinical trials. Although NT-proBNP, Gal-3, NGAL, hsTnT, MDA, ST-2 and AVP are well established, little is known about the test-retest reliability in patient cohorts with a high cardiovascular risk profile. The aim of the study was therefore to determine the biological reliability of biomarkers in different subgroups of cardiovascular disease.

Methods and Results: All biomarkers were measured in patients with heart failure with preserved ejection fraction heart failure with preserved ejection fraction (HFpEF) (n = 25), heart failure with reduced ejection (HFrEF) (n = 24), diabetic nephropathy (n = 20), and arterial hypertension (aHT) (n = 23). A second measurement took place about 7 days later (d4 to d14) combined with a physical examination, an extensive anamnesis, an initial echocardiography, a laboratory assessment and an electrocardiogram. Blood was taken from a venous puncture, stored at -80°C and biomarkers determined by the specific assay. Intraclass-Correlation for all biomarkers regarding all subgroups exceeded ICC > 0.80 (NT-proBNP=0.96, Gal-3=0.90, NGAL=0.91, hsTnT=0.95, ST-2=0.83, AVP=0.87) except for MDA (ICC=0.63). Gal-3 presented a strong reliability in aHT (ICC=0.93) and HFpEF (ICC=0.93), whereas there was a limited reliability in HFrEF (ICC=0.69). Regarding the subgroups the lowest reliability was achieved in aHT.

Conclusion: We confirm that the biological reliability of all examined biomarkers was strong, except for MDA. Our data suggests that Gal-3 is more reliable in HFpEF patients and should be considered more carefully in HFrEF patients. NGAL and AVP data showed the opposite pattern between the 2 heart failure entities. Hereby the study highlights the importance of selective use of biomarkers.

P950

Altered intestinal microflora in the progression of chronic heart failure

BI Bakhodir Narziev[1]; AG Gadaev[1]
[1]Tashkent Medical Academy, Cardiology, Tashkent, Uzbekistan

Background. An involvement of the gut in the progression and clinical evolution of heart failure has been discussed for years. Although the pathogenetic role of the gut microbiome and function have only recently started to be investigated in more detail in patients with chronic heart failure (CHF), data are accumulating to suggest that the gut plays an important pathophysiological role in both chronic inflammation and malnutrition in CHF.

Purpose: Identify changes in luminal and the wall microflora of the colon in patients with different heart failure functional classes (FC).

Methods: In total 34 CHF patients with were examined. 11 patients (32%) were in functional classes III-IV (NYHA) and others 23 (68%) were in functional classes I-II (NYHA). All patients were tested on bacteria in stool. Microbiological study of feces was carried out on the crop nutrient in the dilutions -1, -3, -5, and -7. After 48-hour incubation at 370C the estimation results. Microorganisms were identified by enzyme activity, as well as by microscopic examination of smears stained by Gram.

Results: The total number of Enterobacteriaceae level in patients with CHF FC I-II was -109 colony forming units (CFU)/g, and in patients with III-IV CHF FC - 106 CFU/g. The growth of enterobacteria marked mainly by E. coli - 106 CFU / g (I-II FC HF), against 109 CFU / g (III-IV CHF FC) (p < 0.0005), different types of Klebsiella - 104 CFU/g (I-II FC HF) and 107 CFU/g (III-IV CHF FC) (p < 0.001), citrate assimilating enterobacteria - 106 CFU/g (I-II FC HF) and 108 CFU/g (III- IV FC CHF)

($p < 0.001$). In addition, concentration of enterococci and fungi of the genus Candida were significantly differed. However, concentration of Bifidobacteria was 103 in FC III-IV against 107 in FC I-II ($p < 0,005$).
Conclusion: Gut microflora alternation is associated with clinical course of CHF, exactly, with increasing FC CHF occurs increase of Gram-negative microorganisms.

P951
Studying the relationship of endothelial NO synthase gene polymorphism and endothelial dysfunction in patients with chronic heart failure

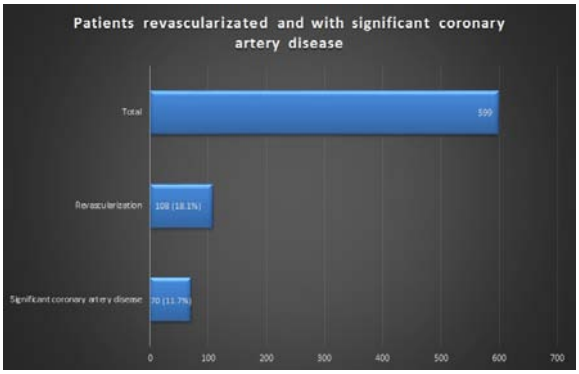
CH Abdullaeva[1]; G Yarmuhamedova[1]; U Kamilova[2]
[1]Tashkent Institute of doctors' improvement, Functional Diagnostics, Tashkent, Uzbekistan; *[2]Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, cardiology, Tashkent, Uzbekistan*

Purpose: Examination of influence of inducible gene NO synthase (iNOS) and endothelial gene NO synthase (eNOS) polymorphism on endothelial function at patient with CHF.
Material and methods: 72 male patients at the age of 40 to 55 years old with postinfarction cardio sclerosis (PICS) have been examined. All patients were divided into two groups by functional class (FC) CHF in compliance with New York classification of cardiologists (NYHA) under conduction of test for 6 minutes walking (TSW): 1st group included 35 patients with CHF II FC and 2nd group included - 37 patients with CHF III FC by NYHA classification. Control group included 20 healthy volunteers. Vasomotion of brachial artery endothelium was assessed by D. S. Celemajer (1992) method on Acuson 128 apparatus (USA).
Results: Dysfunction of endothelium at CHF patients was connected with progressing of disease and characterized by reduce of endothelium-dependent vasoconstriction, which were more expressed at patients with III FC CHF. It was revealed that the amount of Glu polymorphous locus 298Asp eNOS gene in homozygous condition is associated with CHF severity. Homozygotes by Glu alleles of 298Asp eNOS gene showed more expressed failures of endothelium-dependent vasoconstriction in comparison with the same one at carriers of 298Asp alleles.
Conclusions: So, associative correlations of polymorphism of iNOS and eNOS genes with CHF severity flow have been established and polymorphism of eNOS (Glu298Asp) gene is associated with the failure of endothelium-dependent vasoconstriction.

P952
Asymptomatic left ventricular dysfunction, coronariography and significant coronary artery disease

D J Daniel Jorge Nascimento Matos[1]; S Madeira[1]; RC Teles[1]; J Brito[1]; N Vale[1]; M Castro[1]; P Freitas[1]; P Goncalves[1]; L Raposo[1]; H Mesquita Gabriel[1]; M Almeida[1]; M Mendes[1]
[1]Hospital Santa Cruz, Cardiology, Carnaxide, Portugal

Introduction: Coronary angiography is commonly performed to exclude coronary artery disease in the work-up of left ventricle dysfunction of unknown aetiology. The clinical yield of this approach is unclear in contemporary practice.
Purpose: We sought to determine the prevalence and predictors of clinically significant coronary artery disease in patients with left ventricle dysfunction of unknown aetiology referred for invasive diagnosis.
Methods: Single centre retrospective analysis including 599 patients with left ventricle dysfunction without angina or documented ischemia, who underwent coronary angiography, between 2005 and 2015. Clinically significant CAD was defined as left main stenosis >50%, left anterior descending artery (LAD) stenosis >70% or three vessel disease (proximal or middle LAD, circumflex and right coronary stenosis >70%). Predictors of clinically significant coronary artery disease were identified using binary logistic regression.
Results: The mean age of the studied population was 66 (±12) years old and 69% of the patients were males. The prevalence of diabetes, hypertension, dyslipidaemia and tobacco consumption was 35.4%, 66.1%, 43.7% and 40.2%, respectively. The most common presentations were fatigue in 53% and dyspnoea in 35% of the patients. Mild, moderate and severe depression of the ejection fraction was present in 31%, 37% and 32%, respectively. Forty-nine percent of the patient presented some degreed of coronary atherosclerosis and 18,1% had at least one lesion > 50%. Seventy patients (11,7%) had significant CAD. In univariate analysis, CAD population were older, had more syncope and less fatigue and COPD. After correction for other variables, age (OR 1,034 95%CI 1,009-1,06, $p = 0.008$) and tobacco use (OR 1,02 95%CI 1,009-3,1, $p = 0.044$) were independent predictors of significant CAD, on the other hand patients who presented with fatigue (OR 0,473 95%CI 0,273-0,82 $p = 0.008$) and with COPD (OR 0,22 95%CI 0,065-0,73 $p = 0.0138$) had less CAD.
Conclusion: The prevalence of significant CAD among patients with left ventricle dysfunction referred for coronary angiography for coronary disease exclusion is high and probably supports the use of this invasive approach in this setting.



P953
The role of galectin-3 in heart failure

F Federica Ricupati[1]; S Salvatore Novo[1]
[1]Università degli Studi di Palermo , Cardiology, Palermo, Italy

Aims: Biomarkers are increasingly being used in the management of patients with chronic heart failure (HF). Galectin-3 is implicated in the processes of fibrogenesis and ventricular remodeling in patients with heart failure. The objective of this study was to investigate the prognostic role of Galectin-3 in patients with reduced EF (< 50%) and preserved EF (> 50%).
Methods and Results: The study included 86 patients with clinical diagnosis of heart failure. The plasma levels of galectin-3 were measured in all patients at admission and at discharge.
The follow-up has had an average duration of 33 days.
At follow-up were recorded 19 cases of death from cardiovascular causes that involved 10 women and 9 men. The statistical analysis showed a strong correlation between the levels of Galectin-3 measured at admission and at discharge and adverse events at follow-up ($P < 0.001$).
These results were independent of the etiology of heart failure, the ejection fraction or the presence of cardiovascular risk factors.
Conclusions: High concentrations of galectin-3 correlate with a worse short-term prognosis in patients with heart failure regardless of etiology of heart failure and ejection fraction.
This biomarker thus looks promising as a prognostic factor in this set of patients, allowing the identification of patients at highest risk.

P954
Practical confirmation of the predictive accuracy of a 400 ng/L NTproBNP threshold for heart failure

A Abdallah Al-Mohammad[1]; D Rogers[1]; N Lewis[1]; A Charalampopoulos[1]; J Mant[2]
[1]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom; *[2]University of Cambridge, Department of Public Health and Primary Care, Cambridge, United Kingdom*

Background and Purpose: Until 2012, both the European Society of Cardiology (ESC) and the National Institute of Health and Care Excellence (NICE) proposed that the diagnostic threshold for diagnosing heart failure (HF) using NTproBNP should be 400ng/l. A health technology assessment, published by one of the authors in 2009, calculated the predictive accuracy of that threshold in diagnosing HF to be 75%. We assessed the predictive value in a large cohort of patients attending our incident heart failure clinic
Methods: Consecutive patients referred to our institution with suspected new onset HF and NTproBNP > 400 ng/l were studied. Patients underwent detailed echocardiography and assessment by a HF consultant cardiologist. Patients were classified as having heart failure if the clinical and echocardiographic features supported the diagnosis of heart failure syndrome.
Results: 3939 patients were seen between 13th of April 2012 and 31st of December 2016. 935 patients (24%) did not have any evidence of heart failure. We assessed the stability of that percentage annually and found that the percentage of patients presenting to the diagnostic HF clinic with no evidence of heart failure was 20%, 25%, 23%, 23% and 27% in the years 2012, 2013, 2014, 2015 and 2016 , respectively.
Conclusions: The old threshold for NTproBNP of 400 ng/l predicted heart failure with 76% certainty, in a large consecutive cohort over a period of 5 years. This confirms previously published predicted values.

P955

Multi-layer longitudinal strain for noninvasive diagnosis of coronary allograft vasculopathy in heart transplant recipients: a comparative study ultrasound versus angiography.

N Nicolas Bonnet[1]; M Kerneis[1]; S Ouldamar[1]; F Huang[1]; F Laveau[1]; R Isnard[1]; P Leprince[1]; JP Collet[1]; S Varnous[1]; N Hammoudi[1]
[1]*Hospital Pitie-Salpetriere, Paris, France*

Background: Cardiac allograft vasculopathy (CAV) is associated with high morbidity in heart transplant (Htx) recipient. Coronary angiography is the reference method to diagnose CAV, however this procedure is invasive and requires the use of nephrotoxic contrast agents. The multi-layer strain is a new ultrasound technology allowing in particular the functional assessment of the sub endocardial left ventricular layer which is very sensitive to ischemia.
The aim of the study was to evaluate the value of multi-layer longitudinal strain to diagnose CAV in heart transplant patients as compared to angiography.
Methods: In this observational prospective study, 106 HTx patients (mean age, 53 ± 11.2 years; years since heart transplant = 7.0 ± 5.3 years) referred for routine coronary angiography were included. CAV was classified according to International Society of Heart and Lung Transplantation guidelines. In addition, all patients had an echocardiography within 24 hours before the angiography. The examinations were analyzed off-line by an independent operator, blinded to clinical history and coronary angiography results. The global longitudinal strain (GLS) of the different myocardial layers was measured. We included also 42 healthy subjects as control group.
Results: Compared to controls, sub-endocardial mid-myocardial and epicardial GLS were reduced in HTx patients (all p values=0.0001). Among 106 HTx patients, CAV was diagnosed in 47 (43 %) patients. Among CAV patients, 22 patients had grade 1 CAV (CAV 1) and 25 patients had higher CAV grade (CAV 2-3). There was no difference in sub-endocardial GLS between HTx patients with or without CAV (-19.94 ± 3.7% versus -19.43 ± 3.0% respectively, p = 0.45). The GLS of the other myocardial layers was also similar in both groups. Moreover, the GLS in HTx patients with CAV 2-3 was not different compared to patients without CAV or patients with CAV 1.
Conclusion: Compared with controls, multi- layer GLS is reduced in HTx patient. However, in HTx this technology appears not useful for the noninvasive diagnosis of CAV.

P956

Feseability and safety of right and left heart catheterization via an antecubital fossa vein and the radial artery in patients with heart failure: a single centre retrospective cohort study.

D Domenico D'amario[1]; F Burzotta[1]; AM Leone[1]; G Niccoli[1]; A Ruggio[1]; I Porto[1]; C Trani[1]; M Massetti[1]; F Crea[1]
[1]*Catholic University of the Sacred Heart, Institute of Cardiology, Rome, Italy*

Background: Heart failure is the leading cause of hospitalization among patients older than 65 years of age. A significant proportion of patients require heart catheterization for diagnostic, therapeutic and prognostic purposes. To determine the feasibility and safety of full arm-arm catheterization access, we aimed to compare this approach with other established catheterization approaches.
Materials and Methods: In this retrospective cohort study, 493 consecutive patients with heart failure requiring right and LHC were studied and analyzed. Subsequently, all patients were divided into three groups based on the catheterization approach used: full arm-arm, hybrid arm-leg, and full femoral access.
Results: The three groups did not significantly differ in their baseline clinical, demographic or risk factor characteristics. The full arm-arm catheterization procedures were significantly longer when compared to hybrid arm-leg and full femoral approach (73 vs. 68 vs. 67 min., respectively, p = 0.039) but remarkably provided significantly less fluoroscopy radiation dose (40 337 ± 64799 vs. 62270 ± 120420 vs. 156077 ± 566495 cG/cm2, respectively, p = 0.039). Although the full arm catheterization group showed the lowest number of complications, their rates did not significantly differ among groups (p = 0.446). Finally, in patients in which the arm-arm approach was utilized, a significant earlier ambulation was achieved compared to the others groups (p = 0.021).
Conclusion: This is the first study to date that compared the safety and feasibility of full arm-arm access to femoral-femoral and hybrid arm-femoral approach in a population of HF patients that required simultaneous bilateral heart catheterization. Our results showed that a full catheterization access from the upper limb is a safe and feasible alternative to other catheterization approaches when accessing heart bilaterally. Moreover, this access provided significantly less radiation burden to patients and was associated with the lowest number of complications and shortest time to ambulation.

P957

The incremental shuttle walk test for the evaluation of people at risk of developing heart Failure: a HOMAGE sub-study.

B Beatrice Mariottoni[1]; P Pellicori[2]; JP Ferreira[3]; J Cuthbert[2]; J Verdonschot[4]; L Jacobs[5]; JG Cleland[6]; F Zannad[3]
[1]*Santa Margherita La Fratta Hospital, U.O.Cardiology, Cortona, Italy*; [2]*University of Hull, Hull, United Kingdom*; [3]*University of Lorraine, Nancy, France*; [4]*Maastricht University Medical Centre (MUMC), Maastricht, Netherlands*; [5]*University of Leuven, Leuven, Belgium*; [6]*Imperial College London, London, United Kingdom*

On behalf of: The HOMAGE investigators
Funding Acknowledgements: Funded by the European Commission under the Health Cooperation Work Programme of the 7th Framework Programme (Grant Agreement n°305507)

Background: - The six minute walk test is a potentially useful method for assessing functional capacity in most people with heart failure. It does not require specialized equipment but may not be a good test of cardiorespiratory limitation for those with good functional capacity. The incremental shuttle walk test (ISWT) may be a better method of assessing cardiorespiratory performance in people without severe limitation. There is extensive experience of this test in patients with lung disease (Singh et al 1992) but experience in heart failure is limited. The Heart 'OMics' in AGE-ing (HOMAGE) study aims to evaluate the effects of spironolactone on biomarkers in patients at risk of developing heart failure and includes an ISWT at screening.
Methods: This is an interim report on the first cohort of patients screened for HOMAGE, a trial evaluating spironolactone in patients at risk of developing heart failure; age >60 years with coronary artery disease or equivalent (eg:- long-standing type-2 diabetes mellitus and hypertension). Baseline treatments could include ACE inhibitors, calcium channel blockers and beta-blockers but neither MRA nor diuretics. Only patients in sinus rhythm with elevated plasma concentrations of natriuretic peptides (eg:- NT-proBNP >125ng/L) are included. The ISW is a standardised, progressive, incremental walking test for patients comprising up to 12 levels and 102 shuttles. Patients walk around a 10m shuttle course marked by cones, in time with a series of bleeps played from a CD. It produces a higher peak heart-rate and Borg Dyspnoea score as well as a more graded cardiorespiratory response to exercise compared to the 6 minute walk test (6MWD) (Singh et al., 1992). Changes of 50-70 metres are considered clinically significant (Singh et al., 2008). There is a learning effect. Results are reported according to quartiles (Q) of completed shuttles.
Results: Of 124 patients screened, mean age was 74 ± 6 years and 23% were women. The median (Q1-Q3) number of shuttles at screening was 45 (23 -61). Patients in each quartile were of similar age, had similar baseline heart rate (62 ± 10 bpm) and systolic blood pressure (146 ± 24mmHg) but patients in the lowest quartile of exercise capacity were more often women, had lower haemoglobin and tended to have higher plasma NT-proBNP [Q1: 298 (193-422) v Q4: 198 (147-305)ng/L; p = 0.16). Prior to exercise, patients reported a similar degree of breathlessness on moderate exertion during daily activity in each quartile. Immediately after exercise, perceived exertion was generally rated 'sort of hard' or 'hard' on a Borg scale for each quartile but post-exercise heart rate (Q1: 70 ± 14 v Q4: 88 ± 17 bpm; p = 0.0017) and systolic blood pressure (Q1: 158 ± 28 v Q4: 188 ± 34mmHg; p = 0.0012) were higher in those who completed more shuttles.
Conclusions: - Further experience with the ISWT is required.

P958

Echocardiographic diagnostic criteria for heart failure with preserved ejection fraction: does one-size fits all?

B Neves[1]; N Hammoudi[1]; F Pousset[1]; P Balagny[1]; L Legrand[1]; M Komajda[1]; R Isnard[1]
[1]*Hospital Pitie-Salpetriere, Cardiology Department, Paris, France*

Introduction: Heart Failure with preserved-ejection fraction (HFpEF) remains a diagnostic challenge in many situations as its symptoms can be confounded with other entities and no single exam has got perfect accuracy for the diagnosis. Echocardiography is an essential tool to identify signs that may support the diagnosis. Recent ESC guidelines propose structural and functional criteria in this setting. Our aim was to evaluate the different echocardiographic criteria sensitivity for HFpEF diagnosis on a cohort of patient hospitalized for HF decompensation and left ventricular ejection fraction (LVEF) ≥40%.
Methods: A cohort of patients admitted for HF decompensation between June 2015 and June 2016 on a tertiary HF center was analyzed. Electronic medical records and echocardiograms were retrieved. All patients with HF decompensation as a main diagnosis and echocardiographic evidence of EF ≥40% were included. Exclusion criteria included history of previously reduced EF, moderate valvular heart disease, constrictive pericarditis, congenital heart disease and previous cardiac transplantation.
Results: 225 patients had the clinical diagnosis of HFpEF decompensation as assessed by their attending physician. Among those with complete data, 82% had

indexed atrial volume ≥34ml/m2 and indexed-LV mass was elevated on 59%. Evidence of elevated filling pressure as assessed with E/E' ≥13 was noticed in 51% and average E' <9 cm/s in 67%. At least one structural criteria was abnormal in 90% and at least one functional criteria was abnormal in in 85% (sensitivity for either approach was not different, p = 0.199). When taking into account all the criteria, at least one structural or one functional criteria was abnormal in 99% of the patients.
Conclusions: HFpEF is a heterogeneous entity and single echocardiographic criteria may not be appropriate for every cases. We confirmed in our population that the strategy proposed in the last ESC HF guidelines of finding at least one structural or one functional criteria showed excellent sensitivity (99%) and good agreement with clinical diagnosis.

P959

Nurse-led cardiovascular disease management program impact of 30-day readmission in patients with heart failure

R Raed Odeh[1]; M Alkhateeb[1]; M Bdier[1]
[1]*King Abdulaziz Medical City, Riyadh, Saudi Arabia*

Background: Few studies have examined the potential benefits of nurse-led cardiovascular programs impact on readmission and outcomes in patients with heart failure (HF). However no studies have been conducted in this region to examine the benefits of such programs.
Objective: The purpose of this study was to evaluate the impact of nurse led cardiovascular disease management program (CVDMP) on 30-day readmission in patients with diagnosis of HF.
Methods: This is an observational retrospective cohort study included all admissions with the diagnosis of HF in 2014 and 2015 in a Cardiac center with the diagnosis of HF with reduced ejection fraction ≤ 45% or with symptoms of HF or with pulmonary edema during the time period of 2014 and 2015. All elective and planned admissions were excluded from the study. Patients were divided into two groups those with 30-day readmission and no readmission. As well as patients who have follow up in our nurse-led program and who are not. Data was extracted from the cardiac center electronic data-base included age, gender, diabetes mellitus, hypertension, date of admission, diagnosis of HF, history of cerebral vascular accident (CVA/stroke), length of stay, systolic and diastolic blood pressure (SBP and DBP) measurement, heart rate (HR), the use of guidelines medical therapy including, Ace Inhibitors/ Angiotensin Receptor Inhibitor (ACEi/ARBs), Beta blockers, Antiplatelet, Statins, potassium sparing diuretics, etiology of HF, creatinine clearance, and first creatinine.
Results: This study included the index admission of 786 patients (pts) who met the inclusion and exclusion criteria with 825 index admissions to the cardiac center with decompensated HF between January 1, 20014, and December 31, 2015. Of these admissions, 35 admissions (30 pts) (4.2%) and 790 admissions (756 pts) were categorized into 30-day readmission and no re-admission; respectively. 30-day readmission rate was 4.2%. Patients who are followed up in the nurse-led HF program had lower re-admission rate. Stroke and longer length of stay were associated with higher rate of 30-day readmission rate.
Conclusion: Our nurse-led program was associated with reduced 30-day readmission rate and with improved utilization of guidelines medical therapy. Further research is recommended to confirm these findings.

Ranolazine alone or as an add-on to amiodarone for both prevention and cardioversion of atrial fibrillation in patients with or without chronic heart failure: a metaanalysis of the literature

R De Vecchis[1]; C Ariano[1]; A Cesaro[2]; A Giasi[1]; C Cioppa[1]
[1]*Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy*;
[2]*Department of Cardiology, Second University of Napoli, Monaldi Hospital, Naples, Italy*

Background: The possibility of using ranolazine as an antiarrhythmic drug active against atrial fibrillation (AF) has been investigated by several recent studies. In our meta-analysis, we provide an overview of these studies, taking into account also the efficacy demonstrated by ranolazine in the course of AF that occurs during chronic heart failure.
Methods: The rhythm control strategy was adopted by the studies that used the ranolazine as a therapeutical option against AF either alone or in combination with amiodarone in patients with or without heart failure. In this meta-analysis both randomized controlled trials (RCTs) and observational prospective cohort studies were admitted. The effect size was expressed using the risk ratio, with 95% confidence intervals.
Outcomes of interest: Efficacy endpoints. Five RCTs investigated the preventive effect exerted by ranolazine against AF occuring in the clinical setting of a recent coronary artery bypass graft (CABG) (post-operative AF: 3 studies) or, in alternative, against AF occurring in the absence of CABG(prophylaxis of non- postoperative AF: 2 studies). In addition, 4 RCTs investigated the therapeutic effect of ranolazine on the pharmacological cardioversion of recent-onset AF. Safety endpoints. The investigated safety endpoints were death, adverse events, QTc prolongation and hypotension.
Results: Eight studies(6 RCTs and 2 prospective cohort studies) were collected on the whole. Ranolazine was effective in preventing the occurrence of AF when compared to controls (RR= 0.60; 95% CI: 0.43–0.83; p = 0.002). Subgroup analysis showed a more pronounced prophylactic effect of ranolazine against post-operative AF (RR= 0.39; 95% CI: 0.18-0.84; p = 0.02) when compared to non- postoperative AF (RR= 0.76; 95% CI: 0.63-0.92; p = 0.04). Ranolazine increased the chances of successful cardioversion when added to amiodarone over amiodarone alone (RR 1.27; 95% CI: 1.08–1.50; p = 0.004) and significantly decreased the time to cardioversion(SMD= –2.83 h; 95% CI: –4.69 h to – 0.97 h; p < 0.001). Overall risks of death, adverse events, and QTc prolongation were similar when making a comparison between ranolazine and control group.
Conclusions: Ranolazine proved to be an useful and effective drug either for prophylaxis or conversion to sinus rhythm of AF that occurs in patients with or without chronic heart failure. Ranolazine use seems to be safe and associated with relatively few adverse events.

P961

Guideline-led prescribing among heart failure patients in the long-term care setting

S El Hadidi[1]; D O'sullivan[1]; D O'mahony[2]; E Darweesh[3]; S Byrne[1]; M Bermingham[1]
[1]*University College Cork, School of Pharmacy, Cork, Ireland*; [2]*Cork University Hospital, Department of Geriatric Medicine, Cork, Ireland*; [3]*Future University in Egypt , Faculty of Pharmaceutical Sciences and Pharmaceutical Industries, Cairo, Egypt*

Introduction: Heart failure (HF) may affect up to 45% of elderly residents in long term care (LTC) facilities. However, there are few data available describing such HF patients and the use of HF guideline-led therapy in the LTC setting.
Purpose: This study aims to describe HF care in LTC settings in terms of guideline-led prescribing using a validated tool.
Methods: This is an observational study of elderly patients in 14 LTC facilities in the Cork region of Ireland. Heart failure was documented on patient medical records or identified by prescription of a loop diuretic. Guideline-led prescribing was assessed using the Guideline Adherence Index (GAI) tool. The GAI considers prescription of loop diuretic, ACE-inhibitor/angiotensin receptor blocker (ACEI/ARB) and beta-blocker and it is adjusted to consider contraindications to therapy. High GAI was defined as prescription of ≥2 of these agents. Comparisons between patients were conducted using independent sample t-tests for continuous variables and chi-squared tests for categorical variables. A multivariable logistic regression model, adjusted for age and sex, was used to determine the associates of High GAI and the adjusted odds-ratio (OR) and 95% confidence interval (CI) were determined.
Results: The total number of residents was 732 (average age 83.9 ± 7.7; 30% male). The prevalence of HF was 36.2%. Patients with HF were older than those without HF (84.8 ± 7.4 vs. 83.4 ± 7.9 years, p = 0.024), were more likely to have coronary artery disease, CAD (32.5% vs. 16.1%, p < 0.001), atrial fibrillation, AF (31.3% vs. 16.9%, p < 0.001) and lung disease (23.0% vs. 11.1%, p < 0.001) but were less likely to have dementia (42.3% vs. 49.9%, p = 0.047). Patients with HF were prescribed more medicines than those without HF (12.7 ± 3.5 vs. 10.7 ± 3.7, p < 0.001). There was no significant difference in the rate of hypertension, stroke, diabetes or renal failure between those with HF and those without HF. Loop diuretics were prescribed to 87.5% of HF patients, ACEI/ARBs to 24.2% and beta-blockers to 22.6% while 17% of patients were prescribed all three of these medications. A loop diuretic was prescribed as monotherapy to 40% of HF patients while 5% of patients were not prescribed any HF medications. Average GAI was 56%. High GAI was achieved by 55% of patients. Patients with High GAI had greater number of comorbidities and greater number of prescribed medicines than those with did not achieve High GAI (both p < 0.05). In multivariate analysis, High GAI was associated with higher number of medications (OR=2.30, 95%CI 1.28-4.11), AF (OR=1.79, 95% CI 1.01–3.19) and CAD (OR=2.30, 95%CI 1.28–4.11). Dementia was not associated with High GAI.
Conclusion: In Irish LTC settings, utilisation of loop diuretic was high however there was a low utilisation rate of HF disease-modifying therapies. Presence of CAD and AF was associated with High GAI. However, there was no association between dementia and achievement of High GAI in HF.

ExtraHF survey. The european survey on implementation of exercise training in heart failure patients: regional differences in structure and long term organisation

A Verde[1]; SM Binno[1]; U Corra'[2]; P Seferovic[3]; GQ Villani[1]; G Filippatos[4]; PP Ponikowski[5]; MF Piepoli[1]

[1]Guglielmo da Saliceto Hospital, Heart Failure Unit, Department of Cardiology, Piacenza, Italy; [2]Fondazione Maugeri, Department of Cardiology, IRCCS Scientific Institute of Veruno, Veruno, Italy; [3]University Belgrade Medical School, Department of Cardiology, Clinical Center of Serbia, Belgrade, Serbia; [4]Attikon University Hospital, Heart Failure Unit at the Department of Cardiology, Athens, Greece; [5]Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland

On behalf of: Committee on Exercise Physiology & Training of the Heart Failure Association of the ESC

Background. In heart failure (HF), exercise training programmes [ETPs] are well-recognised intervention to improve symptoms, but still poorly implemented. The Heart Failure Association promoted a survey to investigate whether and how cardiac centres in Europe are using ETP in their HF patients. Aim of this study is to investigate the presence of geographical difference in ETP organisation and long term organisation.
Methods: The study was designed as a web-based survey of cardiac units in countries affiliated to the ESC. The data collected were subsequently divided in five areas, according to the UNO division of the countries involved: Northern, Southern, Eastern and Western Europe, and extra-EU.
Results: 173 centers replied to the survey, in charge of 78,514 patients: Northern 52 centers (15040 patients), Southern 48 centers (27127 patients), Western Europe 34 centers (11769 patients), Eastern Europe 24 centers (12748 patients), ESC countries extra-Europe 14 centers (11830 patients). Cardiologists, nurses, psychologists, exercise physiologist/therapists, dieticians, physiotherapists, are all figures involved, in all settings, in more than 50%, with the exception of the cardiologists that are involved in only 10% in the Northern regions. Consequently cardiologists is the leading figure, responsible for the ETP in all region, but in the Northern region, where nurses are playing this role. A structured long term follow-up programme was absent in most of the European regions, but in the Northern region where these programmes was described in more than 64%, mainly leaded by nurses.
Conclusions: A less expensive and more flexible structures of the organisation of the ETP may play a key roles in promote a larger implementation of this valuable tool.

P963

Treatment patterns in newly diagnosed patients with heart failure managed in the primary care and cardiology settings in France

S Eisenring[1]; C C Proenca[2]; B Balas[3]; F Calado[3]; C Thonnelier[4]; S Bruce Wirta[5]
[1]QuintilesIMS Switzerland, Basel, Switzerland; [2]Wellmera AG, Basel, Switzerland; [3]Novartis Pharma AG, Basel, Switzerland; [4]Novartis Pharma SAS, Rueil Malmaison, France; [5]Novartis Sweden AB, Stockholm, Sweden

Background and purpose: Heart failure (HF) is a progressive syndrome, and patients often receive empirical treatment. Knowledge of treatment patterns in patients newly diagnosed with HF in the primary care and cardiology settings in France will help to identify the unmet needs of patients.
Methods: Electronic medical records from two French databases (a general practitioner [GP] panel and a cardiologist panel) were used to identify patients. All patients (aged ≥18 years) who were newly diagnosed with HF from 1 January 2009 to 30 September 2013 were included. Patient histories available in the databases, from January 1994 (GP panel) or January 1998 (cardiologists) to December 2008, were used to exclude patients with a previous diagnosis of HF. Patient data were extracted for the 6 months before diagnosis and for the 12 months after the first prescription of a HF drug. Patients who were not prescribed a new treatment after diagnosis were excluded. Treatment periods were divided into quarterly windows. The dominant therapy for each patient was defined as that prescribed for the longest period over each quarter. Treatment discontinuation was defined as having no prescription for more than 3 months.
Results: The study population comprised 6566 patients with newly diagnosed HF (GP panel, 4940; cardiologists, 1626). In the 3 months after diagnosis, the most common dominant combination therapy was angiotensin converting enzyme inhibitor (ACEi)/angiotensin II receptor blocker (ARB) plus β-blocker (BB; 26.2%). The most common dominant monotherapies were ACEi/ARB (23.7%), diuretic (15.6%) or BB (12.7%). When treatment was stratified by New York Heart Association (NYHA) class, severe HF was associated with significantly increased use of ACEi/ARB + BB + mineralocorticoid receptor antagonist (MRA) or BB + MRA combination therapy, and ACEi or MRA monotherapy. Most patients had ≥1 treatment modification during the follow-up period (GP panel 63.2%; cardiologist panel 81.6%). Compared with patients treated by the GP panel, a greater proportion of those treated by cardiologists discontinued treatment (75.4% vs 51.2%). Treatment switches were more common in patients treated by cardiologists (14.8% vs 10.5%); treatment add-ons were more common in those treated by GPs (25.0% vs 21.8%). Patients with NYHA class III and IV HF were more likely to have ≥1 treatment modification than those with class I and II HF (71.8% vs 66.4%).
Conclusions: Combination therapies that included MRAs were prescribed to a greater proportion of patients with more severe HF based on NYHA class. Patients with more severe HF symptoms were more likely to experience ≥1 treatment modification than those with less severe symptoms. Treatment modification was more common in patients treated by cardiologists than in those treated by GPs, potentially owing to the greater proportion of treatment discontinuation in cardiology patients.

Psychometric evaluation and health care provider feedback on a symptom tracker for use by patients with heart failure

EF Lewis[1]; T Theresa Coles[2]; S Lewis[2]; LM Nelson[2]; D Stull[3]; C Demuro[2]; S Turner[4]; C Chang[5]
[1]Brigham and Women's Hospital, Boston, United States of America; [2]RTI-HS, Patient-Centered Outcomes Assessment, Research Triangle Park, United States of America; [3]RTI-HS, Health Economics, Data Analytics and Design Strategy, Research Triangle Park, United States of America; [4]Novartis Pharmaceuticals Corporation, Critical Care, Portland, United States of America; [5]Novartis Pharmaceuticals Corporation, Cardiovascular US Health Economics & Outcomes Research, East Hanover, United States of America

Background: Failure to recognize worsening heart failure (HF) symptoms is associated with recurring hospitalization. Few communication tools are available to help patients recognize and communicate HF symptom changes with their health care providers (HCPs) in clinical practice. The HF Symptom Tracker (HFaST), a new patient-reported communication tool, was developed using a comprehensive process (literature review, expert clinician input, and qualitative interviews); patients evaluate symptom changes in 10 items over the previous 24 hours compared to what they usually experience on an 8-point scale (0 = did not experience, 1 = "much better" to 7 = "much worse").
Purpose: To evaluate the psychometric properties of the HFaST in adults with HF,collect feedback from HCPs on the feasibility and importance of the HFaST in clinical practice, and reduce the number of HFaST items to accommodate use in an out-patient setting.
Methods: The HFaST was administered for 7 consecutive days to individuals diagnosed with HF (n = 100 patients) during a multisite, cross-sectional, non-interventional study in the US. Additional patient-reported assessments included: a) Days 1-7: weight, 5 HF symptom severity items; b) Day 7: Kansas City Cardiomyopathy Questionnaire (KCCQ-12), patient global impression of change (PGIC). Test-retest reliability, construct validity, discriminating ability, and responsiveness of the HFaST items were evaluated. Ten HCPs completed a survey assessing the feasibility and importance of the HFaST in clinical practice.
Results: Patient response rate was excellent (98% participation in HFaST for >= 4 study days). Overall, HFaST measurement properties were satisfactory. Test-retest reliability was assessed with weighted kappa statistics (kappa = 0.71 to 0.97), supporting stability of HFaST item-level scores over time in stable patients with HF. Item-level HFaST response distributions were tabulated for subgroups of patients who indicated not experiencing a symptom on the KCCQ-12 (no fatigue, no shortness of breath, no swelling, no added pillows when sleeping). HFaST scores were generally consistent with KCCQ-12 responses, providing evidence for construct validity. The HFaST demonstrated discriminating ability between patients who reported improvement/no change vs. worsening based on the PGIC ($p < 0.05$ for 5 out of 6 items retained). HCPs rated the HFaST as a good (70%) or excellent (30%) means of assisting patients in tracking their HF symptoms. Based on previous qualitative work, the psychometric results, HCP feedback the 6 of the 10 HFaST items were retained, covering concepts such as fatigue, shortness of breath (3 items), swelling, and rapid weight gain.
Conclusions: The HFaST is unique among HF measures in its brevity (reduced to 6 items) and its ability to track symptom change by comparing current symptoms to "usual" state. This study provides evidence that the HFaST will be a useful communication tool in clinical practice.

P965

Identifying potentially inappropriate medicines use among heart failure patients in long term care using a disease-specific tool

S El Hadidi[1]; D O'sullivan[1]; D O'mahony[2]; E Darweesh[3]; S Byrne[1]; M Bermingham[1]
[1]University College Cork, School of Pharmacy, Cork, Ireland; [2]Cork University Hospital, Department of Geriatric Medicine, Cork, Ireland; [3]Future University in Egypt , Faculty of Pharmaceutical Sciences and Pharmaceutical Industries, Cairo, Egypt

Introduction: Heart failure (HF) may affect up to 45% of elderly patients in long-term care (LTC) settings and elderly LTC residents are at risk of potentially inappropriate prescribing. Furthermore, a number of medicines have been identified as contraindicated or cautioned in HF as their use may lead to worsening HF or poorer prognosis.
Purpose: To assess the prescription of potentially inappropriate medicines (PIMs) in

elderly HF patients in LTC using a disease-specific tool and to identify patient factors associated with the prescription of PIMs in these patients.
Methods: This is an observational study of 14 LTC facilities in the Cork region of Ireland. HF was identified when documented on the patient's medical chart or by prescription of a loop diuretic. PIMs were identified using the Potentially Inappropriate Medicines in Heart Failure (PIMHF) consensus tool. The PIMHF is a HF-specific tool that includes 11 medicines or medicine classes. Appropriate HF therapy refers to prescription of ≥2 HF recommended agents (loop diuretic, ACE inhibitor/angiotensin receptor blocker and beta-blocker). Poor renal function was defined as creatinine clearance <50mL/min. Comparisons between patients were conducted using independent sample t-tests for continuous variables and chi-squared tests for categorical variables. Univariable and multivariable logistic regression was used to determine the associates of PIMHF use. The model was adjusted for age and sex and the adjusted odds-ratio (OR) and 95% confidence interval (CI) were determined.
Results: The total number of residents was 732, of whom 265 (36.2%) had HF. Average age of HF patients was 84.8±7.4 years and 30% were male. A PIMHF item was identified in 115 HF patients (43.5%). Of these, 79 (29.8%) were prescribed ≥2 PIMHF items. The most commonly prescribed PIMHF items were non-steroidal anti-inflammatory drugs (n=26, 9.8%); oral corticosteroids (n=21, 7.9%); pregabalin (n=14, 5.2%) and metformin in patients with poor renal function (n=9, 3.3%). Patients prescribed a PIMHF were prescribed more medicines (13.2±3.3 vs.12.3±3.7, p=0.003) and had a greater number of comorbidities (12.4±3.4 vs. 11.1±3.4, p=0.03) than those who were not prescribed a PIMHF. Patients prescribed a PIMHF were also more likely to have diabetes (20.9% vs. 9.3%, p=0.008), be prescribed a beta-blocker (52.2% vs. 0.0%, p<0.001), and be prescribed appropriate HF therapy (68.7% vs. 44.0%, p<0.001). In univariable regression analysis the patient characteristics significantly associated with prescription of PIMHF were: higher number of comorbidities, higher number of medicines, diabetes and prescription of appropriate HF therapy. When adjusted, diabetes (OR=2.37, 95%CI 1.09-5.17) and appropriate HF therapy (OR=2.51, 95%CI 1.46-4.31) were associated with PIMHF prescription.
Conclusion: A disease-specific assessment tool may be of benefit in identifying opportunities to improve prescribing quality in HF patients residing LTC.

P966

OBLIC: a nationwide French prospective cohort of heart failure ambulatory patients managed in private practice

FM Mouquet[1]; D Guedj-Meynier[2]; G Godin[2]; T Beard[2]; M Raphael[2]; D Attias[2]; P Tessier[2]; P Gueranger[2]; L Brottier[2]; M Abi Chacra[2]; A Warembourg[2]; O Hoffman[2]; JP Huberman[2]; J Gauthier[2]; A Cohen Solal[3]
[1]Hopital prive Le Bois, Cardiology, Lille, France; *[2]College National des Cardiologues Francais, Paris, France*; *[3]Hospital Lariboisiere, Cardiology, Paris, France*

Background: Although private cardiologists manage the majority of patients with heart failure (HF) in France, no contemporary epidemiological data are available regarding the characteristics of these patients and the quality of care in private practice.
Purpose: Gathering epidemiological data and assessing the quality of care of HF patients managed in private practice.
Methods: A prospective cohort of HF patients was collected between January and March 2016. Private cardiologists gathered all ambulatory patients with a HF history during 2 consecutive weeks.
Results: A total of 1018 patients were included: 76% were managed for chronic HF with reduced ejection fraction (HFrEF) whereas 24% had history of HF with preserved ejection fraction (HFpEF). 77% had planned visits, 8% came for urgent unscheduled visits and 14% were seen after their hospitalization for decompensated HF. Mean age was 74 years (15-96). 63% among the patients were male. 61% had hypertension, 28% diabetes, 17% COPD, 14% sleep apnoea, 12% chronic renal failure and 8% anoemia. Each co-morbidity was more frequent among patients with HFpEF as compared to patients with HFrEF. Among patients with HFrEF, etiology was ischemic cardiomyopathy for 49%. 13%, 60%, 24% and 2% of patients were in NYHA I, II, II and IV respectively, and 71% had at least one hospitalization for decompensated heart failure. Among patients with an ejection fraction below 35% (n=253, 33%), 85% received a betablocker, 84% an ACEI or ARB, 28% received mineralo corticoid receptor antagonist. 6% received ivabradine. 18% were implanted with CRT and 30% with an ICD. At the end of the consultation, 11% were hospitalized for decompensated HF.
Conclusions: The OBLIC cohort provides epidemiological data from HF patients managed by private cardiologists in France. The patients' characteristics seem to be similar to those managed in hospital, and treatment is in adequation with the last European Society of Cardiology guidelines.

Sechenov First Moscow State Medical University, Moscow, Russian Federation*; *[10]State Medical University of Rostov-on-Don, Rostov-on-Don, Russian Federation*; *[11]Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russian Federation*; *[12]NSC Institute of Cardiology M.D. Strazhesko, Kiev, Ukraine*; *[13]Kharkiv National Academy of Postgraduate Education, Kharkiv, Ukraine*; *[14]Specialized Cardiology Center of the Republic of Uzbekistan, Tashkent, Uzbekistan*

Background: Several factors related to patients, physicians or non-medical reasons might be responsible for the slow implementation of guidelines on the management of patients with heart failure (HF) into clinical practice. This stimulates the search for clinician- and patient-focused tools that would improve evidence-based care in patients with HF. The aim of the study was to analyze the prescription of guideline-recommended medications to patients hospitalized due to worsening HF in Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, Russia, Ukraine and Uzbekistan.
Methods: The Optimize Heart Failure Care program is a 12-month international, multi-center patient support program based on pre-discharge patient education, pre- and post-discharge check-lists, 'My HF Passport' and a smartphone application. 800 patients from the participating countries (mean age 62.4± 0.4 years, 69.6% male), NYHA II-IV (mean 2.71± 0.03), 78.7% in sinus rhythm, hospitalized due to worsening HF were included into this study.
Results: At discharge from the hospital, the prescription rates of angiotensin-converting enzyme inhibitors/angiotensin receptor blockers (ACEIs/ARBs), beta-blockers (BBs), mineralocorticoid receptor antagonists (MRAs) and ivabradine were 91.2%, 90.4%, 92.3% and 29.0%, respectively. The rate of prescription of these agents remained high throughout the 12 months of follow-up. Diuretics and digoxin were used in 72.2% and 7.2% of patients with HF, respectively. However, the proportion of patients at target dose and ≥50% of target dose was low (25.4% and 43.5% for ACEIs/ARBs, 21.1% and 47.2% for BBs, and 5.1% and 26.2% for ivabradine). Moreover, patients with HF treated with ≤50% of target doses of ACEIs/ARBs and BBs demonstrated a high rate of readmission for worsening HF (38% and 35.1%, respectively, vs. 19.3% and 20.3%, respectively, in patients on target doses, p<0.05 for both).
Conclusion: This is the first time such data on guideline-recommended medications in patients with heart failure has been collected in these eight post-Soviet countries. The rate of prescription of the heart failure medications was satisfactory; however, the dosage of guideline-recommended agents was usually suboptimal. Additional efforts are needed to improve the implementation of heart failure guidelines into clinical practice.

Background: Sacubitril/valsartan (LCZ696) reduced mortality and hospitalizations in the PARADIGM-HF trial as compared to enalapril in patients with chronic heart failure with reduced ejection fraction (HFrEF). The introduction of sacubitril/valsartan into real world practice is likely to have a significant impact on the epidemiology of HFrEF and clinical practice. Contemporary data on the epidemiology of CHF in Europe are scarce. Ongoing large registries, including the ESC Haert Failure Long-Term Registry and REPORT-HF sponsored by Novartis , are aimed at

describing the management of HF by hospital-based cardiologists. Here we report the rationale and design of ARIADNE, the first prospective registry describing the management of CHF and the way sacubitril/valsartan is introduced by office-based cardiologists (OBCs) and primary care physicians (PCPs) in a real world setting.
Purpose: The primary objective of ARIADNE is to describe the profile of HFrEF patients initiated on sacubitril/valsartan as compared with patients continued on standard of care (SoC) by OBCs and PCPs in terms of demographics, medical history, clinical status and to identify the baseline characteristics that are associated with the likelihood of reaching the target dose of sacubitril/valsartan 200 mg (97/103 mg) twice daily.
Additional objectives are to describe in these patients with HFrEF: 1) their demographics and medical history; 2) their treatment; 3) the pattern of administration of sacubitril/valsartan during titration and the final dose; 4) HF related outcomes; 5) healthcare resource utilization.
Methods: ARIADNE will enrol 12 000 patients over the age of 18 with HFrEF managed by OBCs and PCPs in 23 European countries. Enrollment will start in each country when sacubitril/valsartan is available for clinical use. The study will describe 6000 patients treated with SoC and 6000 patients started on sacubitril/valsartan.
Sacubitril/valsartan patients will be enrolled consecutively over an expected time of 12 months in each country, while enrolment of SoC patients will be split into 2 phases: the first 50% of SoC patients will be enrolled in parallel with the first sacubitril/valsartan patients; the second 50% of SoC patients in parallel with the last 10% of sacubitril/valsartan patients. By structuring the enrolment in this way, we will observe if the clinical criteria that drive the choice of the treatment change over the months following the introduction of sacubitril/valsartan into clinical practice.
Patients on sacubitril/valsartan and patients enrolled in the second wave of SoC will be followed for 12 months.
Conclusion: We report the rationale and design of the ARIADNE study, the first European-wide registry describing the management of HFrEF among OBCs and PCPs. Enrolment is expected to be completed by July 2018 and follow-up by July 2019. Baseline characteristics of the first 2000 patients will be available in May 2017.

The role of body mass index on a n-terminal pro brain natriuretic peptide-guided versus a symptom-guided management in heart failure patients with reduced ejection fraction

N G H M Nick Marcks[1]; K Armas[2]; HP Brunner-La Rocca[3]
[1]Cardiovascular Research Institute Maastricht (CARIM), Cardiology, Maastricht, Netherlands; *[2]National University of Colombia, Cardiology, Bogota, Colombia*; *[3]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands*

On behalf of: TIME-CHF

Background/Introduction: Overweight and obesity has become an increasing problem in developed countries, affecting both children and adults. The absence of physical activity, diabetes and hypercholesterolemia are risk factors for developing obesity, which are also well known risk factors for developing congestive heart failure (CHF). Patients with obesity are known to have more persistent symptoms and NT-proBNP levels are lower, making it harder for the clinician to guide treatment. Therefore, we want to investigate the role of BMI on a NT-proBNP-guided versus a symptom-guided therapy in patients with heart failure with reduced ejection fraction (HFrEF) and the effect of BMI on NT-proBNP levels.
Methods: We performed a post-hoc analysis of the 'Trial of Intensified versus standard Medical therapy in Elderly patients with Congestive Heart Failure (TIME-CHF)' trial. The TIME-CHF trial included 499 patients with HFrEF. Subjects were NYHA II or higher, aged 60 years or older and an age-adjusted NT-proBNP >400 ng/L (i.e. >800 ng/L depending on age) at the time of inclusion. Patients were included between January 2003 and June 2008. Follow-up was up to 5.5 years. For this analysis, patients were divided into three groups according to their BMI at baseline, i.e. normal weight or BMI <25, overweight or BMI 25-30 and obese or BMI >30.
Results: The main effect of BMI on outcome was a significantly better overall survival for patients with a BMI >25 ($p = 0.034$) and increased HF hospitalization free survival for patients with a BMI 25-30 ($p = 0.022$). Compared to the symptom-guided treatment strategy, a NT-proBNP-guided treatment strategy was beneficial in HFrEF patients with BMI >30 for overall survival (HR 0.426, $p = 0.048$, Wald 3.923), all cause hospitalization free survival (HR 0.406, $p = 0.002$, Wald 9.501) and HF hospitalization free survival (HR 0.311, $p = 0.002$, Wald 9.262). A NT-proBNP-guided treatment strategy was also found to improve HF-hospitalization free survival for HFrEF patients with a BMI between 25 and 30 (HR 0.570, $p = 0.012$, Wald 6.275). Furthermore, baseline NT-proBNP levels were significantly lower in patients with BMI >25 compared to BMI <25 (3144 pg/mL vs. 4845 pg/mL, $p < 0.001$) and remained significantly lower during follow-up (all $p < 0.001$) despite a decrease of NT-proBNP levels in both groups ($p < 0.001$).
Conclusion: We found the beneficial effect of a NT-proBNP-guided treatment strategy to be most positive in obese HFrEF patients (BMI>30) compared to a symptom-guided treatment strategy, whereas no effects were seen in patients with a normal weight (BMI <25). Therefore, a NT-proBNP-guided therapy should be considered to reduce overall mortality, all cause hospitalization free survival and HF hospitalization free survival in obese patients with HFrEF. Furthermore, the HF clinician should be aware of the lower NT-proBNP levels in obese patients.

P970

Ivabradine effect on outcomes in patients with systolic heart failure according to the duration of their disease: analysis from SHIFT

M Bohm[1]; K Swedberg[2]; M Komajda[3]; L Tavazzi[4]; JS Borer[5]; A Moyne[6]; I Ford[7]
[1]Klinik für Innere Medizin III, Universitatsklinikum des Saarlandes, Universität des Saarlandes, Homburg, Germany; *[2]Sahlgrenska Academy - University of Gothenburg, Department of Molecular and Clinical Medicine, Goteborg, Sweden*; *[3]Hospital Pitie-Salpetriere, Department of Cardiology, Université Pierre et Marie Curie Paris VI, Paris, France*; *[4]Maria Cecilia Hospital, GVM Care and Research, Ettore Sansavini Health Science Foundation, Cotignola, Italy*; *[5]State University of New York Downstate Medical Center, Howard Gilman and Schiavone Institutes, New York, United States of America*; *[6]Institut de Recherches Internationales Servier, Suresnes, France*; *[7]University of Glasgow, Robertson Centre for Biostatistics, Glasgow, United Kingdom*

On behalf of: SHIFT Investigators

Background and Purpose: In patients with chronic systolic heart failure (HF) and sinus rhythm, ivabradine reduces the composite of CV death and HF hospitalization. It is unclear whether the duration of HF prior to therapy affects survival or HF hospitalizations or whether the effect of ivabradine is modified by HF duration. We examined outcomes and the effects of ivabradine in patients with systolic HF with different durations of disease, incl. patients with relatively recent onset HF.
Methods: and results: In SHIFT, 6505 patients with CHF (LVEF ≤35%), in sinus rhythm, HR≥70 bpm, treated with guideline-recommended therapy were randomized to placebo or ivabradine. Prior to randomization, 1416 and 1459 patients had short HF duration (<1.5 years); 836 and 806 patients had HF duration from 1.5 to <4 years, and 989 and 999 patients had HF duration 4 years or longer in the ivabradine and placebo group respectively. Patients with longer duration of disease were older (62.5 years) compared with patients with recent HF (59.0 years, $p < 0.0001$), had greater disease severity (NYHA III/IV in 56% vs 44.9% in patients with recent HF, $p < 0.0001$), higher rate of comorbidities (MI: 62.9% vs 49.4%, $p < 0.0001$; renal dysfunction: 31.5% vs 21.5%, $p = 0.0008$; PAD: 7% vs 4.8%, $p = 0.0018$). Use of ACEI and BBs across groups was similar. However, dosages of BBs were lower in patients with recent HF (51% of patients were treated with ≥50% of recommended doses compared with 59% of patients with long duration of HF, $p < 0.0001$). Longer duration of disease was associated with poorer outcome. Ivabradine significantly reduced outcomes independently of duration of disease.
Conclusions: Our results show that duration of HF strongly predicts outcome. However, ivabradine improved clinical outcomes in patients with CHF independent of HF duration, including patients with recent onset HF.

HF duration	Ivabradine (N=3241)		Placebo (N=3264)		Adjusted HR, 95% CI	P	P interaction	
	n	%PY	n	%PY

A state-wide approach to multidisciplinary care: heart failure evaluation and reporting of outcomes (HERO)

A Annabel Hickey[1]; J Adsett[2]; JJ Atherton[2]; C Denaro[2]; T Nunan[3]; R Peters[4]
[1]*The Prince Charles Hospital, Advanced Heart Failure and Cardiac Transplant Unit, Brisbane, Australia*; [2]*Royal Brisbane and Women's Hospital, Brisbane, Australia*; [3]*Nambour Hospital, Nambour, Australia*; [4]*Princess Alexandra Hospital, Brisbane, Australia*

On behalf of: Queensland Heart Failure Services Steering Committee

Background: Collection and reporting of clinical indicators of chronic heart failure (CHF) care in Australia is frequently ad hoc, and difficult to verify or benchmark with other services.[1] Queensland has a CHF steering committee that oversees disease management programs (DMP) supported by a central coordinator. In 2014, the Queensland Cardiac Information Solutions Program agreed to develop systems to support the collection and reporting of clinical indicators.
Purpose: To evaluate the feasibility of the Heart Failure Evaluation and Reporting of Outcomes (HERO) clinical indicator reporting tool.
Methods: Consensus on the content and methods of collecting data was reached following a Delphi method involving all 24 CHF disease management programs in Queensland. Nine process indicators were agreed upon and included: referral follow-up time and review of left ventricular function for all newly referred patients; and prescribing and titration practices at hospital discharge, first outpatient visit and 6 months after referral. All indicators had detailed inclusion and exclusion criteria. Descriptive data included age, sex, indigenous status, referral source and type of heart failure. Outcomes for mortality, length of stay and readmissions is to be obtained by data linkage.
Results: Feasibility was assessed by comparing new referrals numbers with previous manually collected data; reviewing data completion, report quality and frequency. In 2015, the first year of data collection, 4,043 patients newly referred to heart failure DMPs were entered into HERO. This was consistent with manually collected data in the 2013 (n = 3951) and 2014 (n = 3900). Data was incomplete initially but improved to 90% with the introduction of monthly data quality reports sent to clinicians. Reports benchmark individual services to the state median, and provide details about exclusions and contraindications to inform clinical practice. For example statewide data for 2015 for beta-blocker titration not only shows those who have achieved target doses of beta blockers at 6 months post-hospital discharge (42%), but also includes those who are at maximally tolerated doses (31%) and who are still undergoing up-titration (18%), suggesting that the treatment variance statewide is relatively small (9%).
Conclusions: High completion rates suggest that HERO is sustainable and engages clinicians by providing routine reporting that highlights individual site performance benchmarked against state-wide performance with respect to patient follow-up, medication prescription and titration of doses. In the context of a coordinated state-wide approach to CHF-DMPs (which includes data collection and review, education and clinical mentoring) HERO is a powerful tool for achieving best practice.

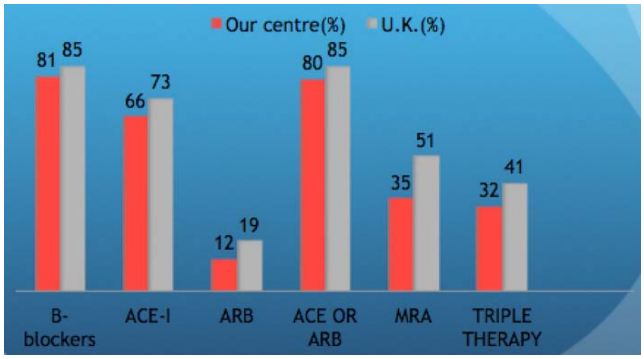
P972

Pharmacological management of heart failure and device therapy in a british district general hospital

A Amrit Chowdhary[1]; A Whittingham[1]
[1]*Doncaster Royal Infirmary, Cardiology, Doncaster, United Kingdom*

Funding Acknowledgements: Limited grant from Servier laboratories

Background: Optimal pharmacological treatment and device therapy in Heart Failure (HF) is associated with a decrease in morbidity and mortality. We aimed to assess the rate of implantation of devices for heart failure and pharmacological therapy received by patients with a left ventricular ejection fraction (LVEF) of < 35% in a British District General Hospital.
Method: All trans-thoracic echocardiograms (TTE) done in our centre from 01/04/2015-30/10/2015 were scanned for patients having a LVEF of < 35%. Information regarding the demographics, pharmacological agents and doses along with existing device therapy was collected and analysed.
Results: A total of 7286 TTEs were reviewed of which 154 showed a LVEF of < 35%. In our sample population (LVEF < 35%), the average age was 71.4 years and 63% of the study population were male. A pacing device was already present in 9 patients (Cardiac Resynchronisation Therapy (CRT) -Defibrillator in 3 patients, CRT- Pacemaker in 1 patient and a permanent cardiac pacemaker in 3 patients). Based on the European Society of Cardiology (ESC) guidelines, a further 54 patients or 35% of the study population would have met the criteria for CRT device therapy. We found that 82% of the study population were on a beta-blocker. Most of these patients were on bisoprolol. However only 13% of the population were on the target dose of bisoprolol. In the population on the lower doses of bisoprolol, the average HR was 75 beats/min and average systolic blood pressure (SBP) was 130mmHg. It was also found that 102 patients were on an ACE-Inhibitor (ACE-I). Most of these patients were on ramipril. The target dose of ramipril was prescribed in only 33% of the population. In patients on less then the target dose of ramipril, the average SBP was 120mm Hg and the average serum creatinine was 98 umol/L. An angiotensin II receptor blocker (AIIRB) was prescribed in a further 19 patients.
It was noted that 53 patients were on a Mineralocorticoid Receptor Antagonist (MRA). Number of patients on triple therapy with a beta-blocker, ACE-I or AIIRB and MRA was 46.
Only a total of 4 patients were on Ivabradine. We identified 40 patients who would have potentially benefitted from addition of Ivabradine.
Conclusion: The rate of device implantation for heart failure in our centre was found to be low. Most of our patients were on appropriate pharmacological agents however, the doses of various agents was sub-optimal. Majority of patients were not on target doses of these medications despite a satisfactory, SBP, HR and serum creatinine.



Prescription of heart failure medication

P973

Effect of carvedilol on metoprolol succinate on mortality in heart failure with reduced ejection fraction

T Tarek Ajam[1]; S Ajam[1]; S Devaraj[2]; S Sawada[1]; M Kamalesh[1]
[1]*Indiana University School of Medicine, Indianapolis, United States of America*; [2]*Ball State University, Indianapolis, United States of America*

Background: Beta-blocker therapy is indicated in all patients with heart failure (HF) due to reduced systolic function as per ACC/AHA guidelines. The relative benefit of carvedilol to metoprolol succinate remains unknown. We conducted a retrospective analysis of the survival benefit of carvedilol to metoprolol succinate in a large Veteran's Affairs (VA) database of patients with HF due to systolic dysfunction.
Methods: VA's databases were queried to identify all patients diagnosed with HF from 2007 to 2015 and treated with either metoprolol succinate or carvedilol. Carvedilol and metoprolol succinate were restricted by the VA pharmacy to patients with a diagnosis of HF and an ejection fraction of less than 40% at the time period of the database query. Study compared 114,745 veterans who were treated with metoprolol succinate matched to patients who were treated with carvedilol using propensity score matching with replacement techniques after adjusting for covariates. Sub-group analyses were performed separately for men, women, elderly, and duration of therapy more than 3 months and duration of therapy more than 6 months.
Results: The adjusted hazard ratio of mortality for metoprolol succinate compared to carvedilol is 1.04 (95% CI: 1.02-1.06, p value: < 0.0001). The sub-group analyses show that the results hold true separately for male, female, over or under 65 years old, therapy duration more than 3 months and more than 6 months, high heart rate, and low heart rate.
Conclusion: Beta-blocker therapy with carvedilol is superior to metoprolol succinate in patients with HF due to systolic dysfunction in terms of mortality.

Hazard Ratio fo Metoprolol v. Carvedilol

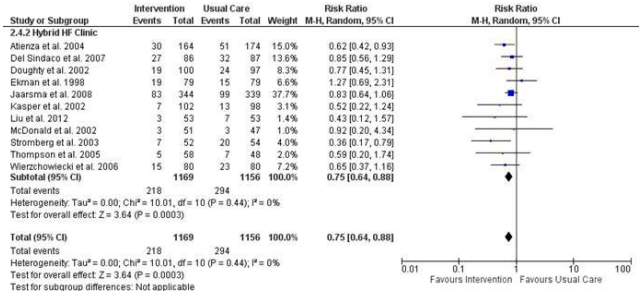
Impact of mode of delivery of disease management programmes on clinical outcomes among patients following hospitalised heart failure: a systematic review and meta-analysis

I O'neill[1]; CP Gale[2]; A Mccallum[3]; H Mcintyre[4]; I Squire[5]; M Cherif[6]
[1]Ionic Reports Ltd, London, United Kingdom; *[2]Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom*; *[3]Gloucestershire Care Services NHS Trust, Gloucestershire, United Kingdom*; *[4]East Sussex Healthcare NHS Trust, St Leonards-on-Sea, United Kingdom*; *[5]Glenfield Hospital & University of Leicester, Leicester, United Kingdom*; *[6]Novartis Pharmaceuticals UK Ltd, Frimley, United Kingdom*

Funding Acknowledgements: Novartis Pharmaceuticals UK Ltd

Background: Disease management programmes (DMPs) for heart failure (HF) are associated with improved clinical outcomes. We investigated whether the benefit of HF DMPs were associated with their mode of delivery.
Methods: Systematic review and random effects meta-analysis of randomised controlled trials (RCTs) examining outcomes after hospitalisation for HF in patients randomised to scheduled DMPs or usual care. DMPs were categorised as: outpatient HF clinic visits alone (standard HF clinic), clinics with home visits (hybrid HF clinic) or home visits alone without clinic attendance (home visits). The primary outcomes were HF re-admissions, all-cause re-admissions, cardiovascular mortality and all-cause mortality.
Results: We identified 33 RCTs (n = 6,547 patients) evaluating standard HF clinics (n = 6), hybrid HF clinics (n = 12) and nurse-led home visits (n = 17). There was no statistically significant difference between standard HF clinics and usual care for the primary outcomes. Compared with usual care, hybrid HF clinics were associated with a reduced risk of HF re-admission (RR 0.74, 95% CI 0.57–0.95; P=0.02), all-cause re-admission (0.75, 0.60–0.94; P=0.01), cardiovascular mortality (0.57, 0.34–0.97; P=0.04) and all-cause mortality (0.75 0.64–0.88; P=0.0003). Nurse home visits without clinic attendance was associated with a lower risk of HF re-admission (RR 0.64, 95% CI 0.51–0.81; P=0.0002), all-cause re-admission (0.84, 0.76–0.93; P=0.0008) and all-cause mortality (0.83, 0.70–0.99; P=0.04). Significant heterogeneity in study outcome was evident (I2, 0%-78%).
Conclusion: Following hospitalisation for with HF, follow-up with home visits or a combination of home visits and HF clinic attendance were associated with significantly reduced mortality and morbidity. HF disease management programmes should include nurse-led home visits to improve outcomes.



Hybrid HF clinics: All-cause mortality

Effectiveness of the 'heartfailurematters.org' website in patients with stable HF

KP Wagenaar[1]; KP Dickstein[2]; BD Broekhuizen[1]; T Jaarsma[3]; AW Hoes[1]; F H Frans Hendrik Rutten[1]
[1]University Medical Center Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands; *[2]University of Bergen, Cardiology, Bergen, Norway*; *[3]Linkoping University Hospital, Cardiology, Linkoping, Sweden*

On behalf of: e-Vita heart failure study group
Funding Acknowledgements: Unrestricted grant from "Care Within Reach"

Background: The ESC/HFA website heartfailurematters.org (HFM website) is widely used, but its effectiveness has never been formally evaluated.
Aim: To assess the effect on self-care of the HFM website on top of usual care provided by heart failure (HF) nurses in outpatient clinics.
Methods: In a randomized controlled we compared usual care + HFM website to usual care in stable HF patients from nine Dutch HF outpatient clinics. The primary outcome was self-care measured with the European Heart Failure Self-care Behaviour Scale (EHFScB scale). Secondary outcomes were health status, and cost-effectiveness.
Results: In total, 300 (150 per group) patients were included. The mean age was 66.8 (SD 11.0) years, 74.2% were male, and 78.8% was classified as NYHA I or II at baseline. Participants had on average three face-to-face contacts per year with the HF nurse. After 3 months follow-up, the mean score on the self-care scale was significantly higher in the usual care + HFM website group compared to usual care: 73.5 vs. 70.8 (difference 2.7, 95%CI 0.6 – 6.2). This effect attenuated during the following 9 months until no difference after one year (difference -0.6, 95%CI -3.7 – 3.4). Quality of life and HF knowledge had a similar pattern as was observed in self-care.
The mean costs per patient were €4,865 and €5,741 per quality-adjusted life years for HFM website + usual care and usual care, respectively. The net monetary benefit was positive (larger than 0) for HFM versus usual care.
Conclusion: The heartfailurematters.org website helps improve self-care in stable HF patient on the short-term when provided in addition to rather intensive usual care provided at HF outpatient clinics, but this effect seems to attenuate over time. Nevertheless, it is cost-effective considering its effects on quality-adjusted life years.

P976

Impact of different therapeutic targets on the prognosis of heart failure patients include in a cardiac rehabilitation program

L Lamia Kesri-Tartiere[1]; MN Bartholomei[1]; M Duport[1]; S Timpone[1]; P Percet-Marrone[1]; L Poirette[1]; JM Tartiere[2]
[1]LEON BERARD HOSPITAL, 83400, HYERES, France; *[2]Hospital Center of Toulon-La Seyne Sur Mer, 83000, Toulon, France*

Aim: Rehabilitation of chronic heart failure(HF) patients is associated with different actions that may affect prognosis. Physical activity, adaptation of drugs and screening of patients requiring defibrillator and/or biventricular pacing (CRT/CRT-D) are all possible modifiable factors during this period.
Method: 88 consecutives HF patients were recruited during a cardiac rehabilitation program. Participation in the entire rehabilitation program (REHAB), maintain or increase of beta-blocker doses(BB), presence of ACE inhibitors/angiotensin receptor blocker(ACEI/ARB) or mineralo-receptor-blocker(MRB), ivabradine, maintain or decrease of diuretics doses and implantation during this period of CRT/CRT-D were studied as univariate and multivariate factors associated with the risk of occurrence(mean follow up 971 ± 343 days) of death or heart transplant(N=19).
Results: Patients were: male(84%), 62 ± 13 years, ischemic cause(56%), NYHA class 3/4(50%), and LVEF 30 ± 9%. REHAB was possible for 86% of patients. Maintain or increase of BB(82%), ACEI/ARB(88%), MRB(56%), ivabradine(13%), maintain or decrease of diuretics(72%), CRT/CRT-D(15%). Adaptation of at least 3 drugs was possible in 78%. Factors associated with a lower occurrence of events were(OR (95% CI)): maintain or increase BB doses(0.41 (0.16-1.09)), ACEI/ARB(0.22 (0.08-0.59)), maintain or decrease diuretics(0.49 (0.20-1.21)), REHAB(0.25 (0.10-0.66)). In multivariate analysis, only ACEI/ARB was significant(0.30 (0.10-0.89)). When each modification of drugs was replaced by the favorable modification of at least three of the five drugs, this parameter was significantly related to survival in multivariate analysis(0.33 (0.13-0.85)), as for REHAB multivariate analysis(0.34 (0.12-0.93)).
Conclusion: During the outpatient rehabilitation for heart failure patients, maintenance or increase of therapeutic and especially for ACEI/ARB with participation in the entire rehabilitation program are associated with better prognosis.

P977

Utilization and outcomes following initiation of sacubitril/valsartan in a newly established heart failure disease management program

B Bassam Atallah[1]; ZG Sadik[1]; R Ferrer[2]; J Stapleton[2]; M Khalil[3]; F Bader[3]
[1]Cleveland Clinic Abu Dhabi, Pharmacy Services, Abnu Dhabi, United Arab Emirates; *[2]Cleveland Clinic Abu Dhabi, Nursing, Abu Dhabi, United Arab Emirates*; *[3]Cleveland Clinic Abu Dhabi, Cardiovascular Medicine, Abu Dhabi, United Arab Emirates*

Background: Sacubitril/valsartan is a combination medication of a neprilysin inhibitor and angiotensin receptor blocker. It was FDA approved in July 2015 to reduce the risk of cardiovascular death and hospitalization for HF in patients with chronic heart failure (NYHA class II–IV) and reduced ejection fraction. At our institution, sacubitril/valsartan was added to the formulary in February, 2016.
Purpose: To evaluate the appropriateness of the prescribing of sacubitril/valsartan and the success in reaching target dose based on our institution set criteria and the PARADIGM-HF trial.
Methodology: This is a retrospective chart review of patients that received a prescription for sacubitril/valsartan between February 1st and December 31st 2016. Data collected included demographics, initial dose, indication, adverse reactions, readmissions, titration or discontinuation. Descriptive statistics were used for analysis.
Results: A total of 61 patients were identified for a mean follow-up period of 126.5 days (SD ± 92.6) with 25% followed for at least 208 days. A total of 48 patients (78.7%) were appropriately initiated, 90.2% were on ACEI/ARB (30.9% of which on target dose) prior to the switch (table 1). Moreover, 41 patients (75.9%) were switched to an appropriate starting dose (figure 1). Four patients (6.6%) experienced adverse drug reactions, including hypotension leading to discontinuation in 3 of them. Overall, 60.7% had sacubitril/valsartan titrated up and 31 patients (50.8%) achieved the target dose by the end of our follow-up period; 6 patients were re-admitted, of which 5 were for elective purposes.
Conclusion: At our institution, sacubitril/valsartan is prescribed for the appropriate indication in most cases. While utilizing our extensive initiation criteria, most patients continued on this medication and many reached target dose. The overall adverse reactions and readmission rate were lower in this cohort of patients when compared to the PARADIGM-HF trial; however our mean follow-up period was significantly shorter.

Table 1

Characteristic	All patients on sacubitril/valsartan
Age (years)	57 ± 13.7
Gender - Male	65.6%
Systolic BP > 100mmHg	95.1%
Prior ACEI/ARB	90.2%
Target Dose ACEI/ARB	30.9%
Recent MI, CVA, cardiac surgery or CRT (within 3 months)	4.9%
Creatinine clearance ≤ 30 mL/min or SrCr increase ≥ 30% baseline	3.4%

Table 1. Baseline characteristics of patients initiated on sacubitril/valsartan

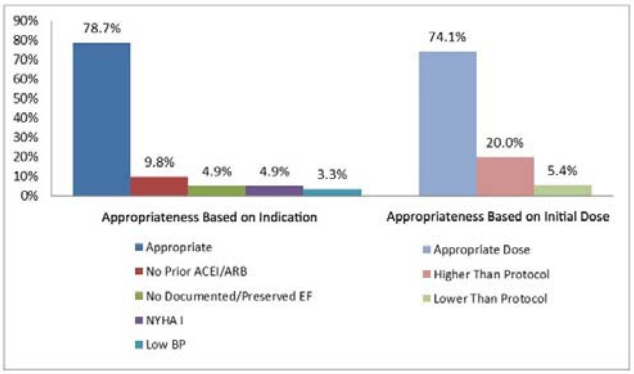

Figure 1

P978

Do we treat heart failure differently according to the ejection fraction?

JR Beramendi Calero[1]; I Irene Rilo Miranda[1]; S Garcia Gutierrez[2]; A Anton Ladislao[2]; C Goena Vives[3]; L Quintas Ovejero[3]; M Morillas Bueno[2]; F De La Cuesta Arzamendi[1]
[1]Hospital Donostia, San Sebastian, Spain; *[2]Hospital Galdakao-Usansolo, Bilbao, Spain*; *[3]Hospital Comarcal de Mendaro, Cardiology, Mendaro, Spain*

Objetive: Regarding the treatment of heart failure, the evidence we have is very different depending on whether the systolic function is preserved or depressed. We have proposed to assess IF we treat heart failure differently according to the ejection fraction.
Methods: A prospective observational cohort study involving a total of 582 patients who come to our hospital for acute decompensated heart failure (acute heart failure and decompensated chronic heart failure). The following variables were collected: sociodemographic, CV risk factors, comorbidities, history of heart disease (ischemic, cardiomyopathy, valvular, arrhythmia) and analytical and echocardiographic data of the emergency department and hospital admission.We compared the treatment to the discharge of 582 patients diagnosed with heart failure admitted to 3 hospitals of the Basque Health Service between 2011 and 2013. We established 3 groups according to the ejection fraction: 188 patients had EF < 40 (Group A) , 101 patient FE between 40 - 49% (Group B) and 193 patients FE> 49% (Group C)
Results: 31.38% of patients in group A, 26.73% in Group B and 28.42% in Group C were treated with ACE inhibitors (p 0.66). 23.40% of Group A, 26.73% of Group B and 23.97% of Group C were treated with ARA II (p 0.80). 38.83% of patients in Group A, 34.65% of Group B and 30.14% of Group C were treated with beta-blockers (p. 14). 48.40% of Group A, 51.49% of Group B and 52.74% of Group C were treated with loop diuretics (p. 64). 31.38% of Group A, 35.64% of Group B and 30.82% of Group C received antiaggregant treatment (p 0.66). 15.43% of Group A, 9.90% of Group B and 13.01% of Group C received antialdosteronic treatment (p. 41). 15.96% of Group A, 25.74% of Group B and 31.16% of Group C were treated with calcium antagonists (p. 0009). Prevalence of hypertension with respect to groups A, B, C: 77.59% vs 79.17% vs 89.47% p 0.0013. Prevalence of Atrial Fibrillation with respect to groups A, B, C: 43.62% vs 55.00% vs 59.66% p 0.0026.Ischemic etiology of heart failure compared to groups A, B, C: 42.55% vs 31.68% vs 25.94% p 0.0007.
Conclusions: 1. Despite the different evidence that we have in the pharmacological treatment of heart failure depending on whether the systolic function is preserved

or depressed, we did not find significant differences in the treatment with respect to ACE inhibitors, ARBs, Beta-blockers, diuretics or anti-aldosteronics.
2. There are a greater number of patients with preserved EF treated with Calcium Antagonists in relation to the higher prevalence of hypertension in these patients.
3. However, we found no difference in antiplatelet or anticoagulant therapy, despite the higher prevalence of ischemic heart disease in the group with depressed EF and atrial fibrillation in the group with preserved EF.

P979
Zero admissions for heart failure

JL Bonilla Palomas[1]; AL Gamez Lopez[1]; M Moreno Conde[1]; MC Lopez Ibanez[1]; CJ Raez Ruiz[1]; R Cruz Arandiga[1]; JP Batres Sicilia[1]; R Ruiz Quero[1]; B Herrador Fuentes[1]; S Gomez Cano[1]; J Leal Helmling[1]; E Ramiro Ortega[1]; A Raez Ruiz[1]
[1]*Hospital San Juan de la Cruz, Úbeda, Spain*

Introduction: Heart failure provoques high number of hospital admissions and is a major cause of mortality and hospital readmissions. The benefits of heart failure units or heart failure programs have been amply demostrated in both observational and randomized studies. The application of a universal model is not feasible because of differences in organizational structures and the available resources. In fact, local conditions are the main determinants of the final model.
Purpose: The main aim of this study was to evaluate the impact of the implementation of the Zero admissions for heart failure project, with which we have tried to optimize the structure of the heart failure unit of our center and improve the coordination of multidisciplinary team.
Methods: Within the Zero admissions for heart failure project we have improved collaboration with primary care, internal medicine and emergency service (training workshops for physicians and nurses, regular meetings with family physicians, provision of interconsultation by telephone), we have redefined integrated care pathways and the work of the expert nurse, day hospital and home care have been strengthened. To evaluate de impact of the project we have compared the number of admissions and the readmission rates at 30 days and 6 months of patients included in our heart failure unit before (2015) and after (2016) the development of the Zero admissions for heart failure project.
Results: 150 patients were hospitalized because of heart failure in our center in 2015 and 115 in 2016 (admission rate decreased by 23,3%). The admission rate at 30 days was 3% in 2015 and 0% in 2016, and at 6 months was 6% in 2015 and 3% in 2016. Between patients with new onset heart failure, the readmission rate at 6 months was 4% in 2015 and 0% in 2016.
Conclusion: Due to the development of the Zero admissions for heart failure project, the complexity of our heart failure unit has grown remarkably in the last year. This has resulted in a reduction of the admission and the readmission rates at 30 days and 6 months with respect the previos year.

P980
The long term protective role of mediterranean diet in first diagnosed acute coronary syndrome patients with heart failure with preserved ejection fraction; results from hellenic heart failure study.

M Kouvari[1]; C Christina Chrysohoou[2]; H Kosyfa[1]; G Kalogirou[1]; P Aggelopoulos[1]; A Filippou[3]; S Iosifidis[3]; E Tsiamis[1]; D Tousoulis[1]
[1]*University of Athens, First Cardiology Clinic, School of Medicine, Athens, Greece*; [2]*University of Athens, Athens, Greece*; [3]*Harokopio University, Nutrition Science - Dietetics, Athens, Greece*

On behalf of: Hellenic Heart Failure study

Background/Introduction: Heart failure with preserved ejection fraction (HFpEF) seems to be associated with similar or even higher morbidity and mortality rates compared with their lower EF counterparts, yet their management remains enigmatic, demanding differential approach. In this context, nutrition has been scarcely investigated. Purpose: The role of Mediterranean diet in first diagnosed Acute Coronary Syndrome (ACS) patients with HFpEF prognosis was examined.
Methods: from May 2006 to March 2009, 1,000 consecutive patients who were hospitalized at a Cardiology Clinic in Athens with ACS diagnosis were enrolled in the study. For the purposes of the present work only n=690 first diagnosed ACS patients were included in the analysis. Follow up was performed in 1, 2 and 10 years. Adherence to Mediterranean diet was assessed through MedDietScore (range 1-55) and categorized in tertiles (i.e. low (0-16), moderate (17-20), high (21-55)). Heart failure phenotype was defined according to baseline EF; heart failure with reduced EF (i.e. < 40%) (HFrEF), preserved EF (i.e ≥50%) (HFpEF) and mid range EF (i.e. 40-49%) (HFmrEF). Results: Ranking from low to high MedDietScore tertile (i.e. 1st to 3rd) 1y, 2y and 10y fatal/non fatal ACS prognosis was significantly lower (all ps < 0.05). Multivariate logistic regression analysis revealed a significant inverse association between MedDietScore and fatal/non ACS incidence in 1y (OR=0.84, 95%CI (0.71, 1.00)), 2y (OR=0.91, 95%CI (0.82, 1.00)) and 10y (OR=0.93, 95%CI (0.85, 1.00)), after adjusting for potential confounders. When EF was included in the analysis MedDietScore lost its significance. Then, analysis was oriented towards heart failure phenotypes. After adjusting for HFpEF phenotype, MedDietScore retained its significance in 1y (OR=0.85, 95%CI (0.95, 0.97)), 2y (OR=0.92, 95%CI (0.84, 1.00)) and 10y (OR=0.96, 95%CI (0.88, 1.00)). Additionally, their prognosis-advantage over their lower EF counterparts was highlighted in long term follow up period only after adjusting for MedDietScore (OR=0.36, 95%CI (0.17, 0.76)). Conclusion: Mediterranean dietary pattern seemed to ameliorate both short and long term ACS prognosis of HFpEF patients. Hence, healthy dietary habits in accordance with this pattern may possess a cost effective supplementary-to-medical rehabilitation approach.

P981
Ivabradine use in patients with HFrEF in the heart failure multidisciplinary program (PIC) in a private hospital: first registration and 3-years follow up, Central American (CA) region.

MOS Speranza[1]; JPD Diaz[1]
[1]*Hospital Clinica Biblica, Cardiology, San Jose, Costa Rica*

Funding Acknowledgements: Fundings for research Hospital Clinica Biblica, Novartis grant

Introduction and objectives: Heart rate (HR) elevation in patients (p) with heart failure with reduced ejection fraction (HFrEF) is related to increased mortality and hospitalization for HF; its reduction improves the filling of the left ventricle, increases the myocardial oxygen supply and reduces its consumption, all of which is beneficial in p with impaired left ventricular systolic function.
Use of ivabradine (IBRA) in p with HFrEF, in sinus rhythm (SR) and HR > 70 beats per minute (bpm), reduces hospitalizations for HF and mortality for HF.
The management of p with advanced HF in PIC ensures a morbidity and mortality reduction with the highest levels of evidence.
The first retrospective analysis in a PIC at a private hospital in CA, during 3 years of all case p with HFrEF who received treatments (tx) recommended by International Guidelines and maintained HR > 70 bpm at rest in SR, with the purpose of reducing it. The use of baseline clinical data, natriuretic peptides (NP) and LVEF at rest, compared with same variables in follow up, in a region where these PICs are borning.
Methods: 26 p with HFrEF for 3 years of PIC. General data, tx, baseline clinical condition, BP, pulse, NYHA, quality of life (QoL), NP, LVEF by Doppler Echocardiography were registered, and IBRA tx response was compared baseline and end. 18 p completed data; 8 incomplete (baseline or follow-up data).
Results: Ambulatory p, with HFrEF (<35%) and SR HR > 70 bpm; age 78 years, 17 men. Tx average time with IBRA 11 months, 53.5% more than 1 year. Baseline medications, 93% ACEIs or ARAs II; 85% beta-blockers and 74% MRA, maximum tolerated doses. No patient used IBRA prior baseline. 20% CRT. Variables behavior assessed: HR (baseline 89 bpm vs 62 bpm after IBRA 2 months); BP (baseline systolic 100 mmHg vs 123 mmHg end; baseline diastolic 55 mmHg vs 65 mmHg end); LVEF (baseline 29% vs 35% end); BNP baseline 7,550 pg/ml vs 1,935 pg/ml end. 5 p improved NYHA III to NYHA I, 5 p improved NYHA III to NYHA II, 3 had deterioration NYHA III; rest remained unchanged. 77% p no dose adjustment required (HR below 70 bpm). 6 p began with 2.5 mg every 12 hours and increased to 5 mg every 12 hours after 15 days. By KCCQ-12 increase 42 to 59 points. 1 discontinuation case of IBRA due to bradycardia (HR < 50 bpm). 2 p were hospitalized, one pneumonia and one HF decompensation. 3 dead: 1 myocardial infarction, 2 HF progression.
Conclusions: 26 p studied, registered and treated with IBRA in the PIC at private hospital in CA, most of them registered metric improvements identified as prognosis factors (HR, BP, LVEF, NP, NYHA and QoL). This assessment, registration and follow up of p with HFrEF with use of IBRA in a PIC, is the first one carried out in CA. Results reflect the usual clinical practice in a PIC, with cardiologists and nurses trained to support and follow-up p, and evidence the importance of PIC when using and prescribing drugs like IBRA, in a region where these PICs are rare.

P982
The role of the crossover of the using the ranolazine and trimetazidine in dynamics of reduced left ventricular function in patients after anterior or lateral myocardial infarction without myocardial

J Jafar Ramazanov[1]; I Pershukov[2]; T Batyraliyev[3]; Z Karben[3]; A Kotvitskiy[4]; N Bosak[5]; L Shulzhenko[5]; A Omarov[6]; B Sidorenko[2]
[1]*Central Hospital of Oil Workers, Cardiology, Baku, Azerbaijan*; [2]*Presidential Medical Centre, Moscow, Russian Federation*; [3]*Sani Konukoglu Medical Center, Gaziantep, Turkey*; [4]*Pirogov Russian National Research Medical University , Moscow, Russian Federation*; [5]*Regional Clinical Hospital, Krasnodar, Russian Federation*; [6]*Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*

Background: A significant proportion of patients (pts) with myocardial infarction (MI) with ST elevation in different countries remains without primary revascularization

currently. Lack of reperfusion in many cases leads to a decrease in left ventricular (LV) systolic function. A lot of the patients with reduced left ventricular ejection fraction (LVEF) refuses of planned revascularization in spite of the severe symptoms of angina and heart failure. For these patients, optimal pharmacotherapy remains the only option for improving quality of life.

Methods: All pts suffered anterior or lateral MI with ST elevation within 2-4 months prior to study. All pts had a LVEF less than 40%. On sonography there were no dyskinesis zones, were hypokinesis and akinesis of LV wall only. Patients hadn't a significant defeat heart valves or severe LV hypertrophy (more than 15 mm). All patients were treated with beta-blockers, ACE inhibitors, statins, ASA and clopidogrel. Design of cross-appointment of trimetazidine (TR) and ranolazine (RN) was as follows: half of the patients (group TR) randomly first administered to TR 70 mg/d bid for 3 months, then follow the control sonography and TR replaced by RN 1000 mg/d bid, which is also used for next 3 months with sonographic control at the end of 6 months. The other half of the patients (RN group) gets back scheme - the first 3 months pts were used RN 1000 mg/d bid, after sonography at 3 months RN was replaced by TR 70 mg/d bid, and after the next 3 months pts get a new sonografic control. In total, 276 pts was included and observed up to 6 months in the study.

Results: Both groups (TR and RN) were includes 138 patients. Women were 20% (TR) and 21% (RN). DM rates were 24% and 22%, respectively, arterial hypertension was 73% (TR) and 78% (RN). Anterior MI was in 56% and 49%, respectively. LVEF at baseline was 34 ± 4% (TR) and 33 ± 4% (RN). After 3 months of therapy LVEF were increased on 3% in the TR group (to 37%), and grew on 8% (to 41%) in RN group. Disposal of observation to 3 months was similar in both groups at 4%. In secondary control after 6 months LVEF increased to 41% in TR group, while it rose up 44% in the RN group. In general, LVEF grew for 6 months by 7% (TR) and 11% (RN). Disposal of 6 months was similar in both groups, amount to 6%.

Conclusions: The use of ranolazine for 3 months gives a significant increase in LVEF (8% vs. 3%, $p < 0.05$ at initial appointment of trimetazidine). After crossing over the subsequent appointment of ranolazine and trimetazidine expressed similar second increase of LVEF (4% and 3%).

P983

Evaluation of an integrated group education program on quality of life for family members of patients living with heart failure

V Vida Sadeghzadeh[1]
[1]*Islamic Azad University- Zanjan Branch, Zanjan, Iran (Islamic Republic of)*

Background: Educational interventions for family members of patients with health problems, leads to reduced distress and discomfort they cause.

Purpose: This study aimed to determine the effect of integrated group education program on quality of life of family members of patients with heart failure.

Methods: This study is a randomized controlled trial. 96 family members of patients were eligible to participate in the study. Before randomization, participants completed initial questionnaire and then were divided in six groups of 16. Hospital anxiety and depression questionnaires were used to measure anxiety and depression and Nottingham Health Profile questionnaire was used to measure quality of life. To determine the reliability of the questionnaire was used test retest and with using correlation test, reliability of the questionnaire was 85%. The internal reliability for anxiety and depression was calculated separately by Cronbach's Alpha. Descriptive and inferential statistics were used for the analysis of data. To examine the differences in the level of anxiety, depression and quality of life with classification variables was used ANOVA. Data was analyzed by SPSS 17 statistical software.

Results: There were significant differences between the education and quality of life and of 6 dimensions in both groups before and after. The results showed that the integrated learning program on quality of life in family members of patients with heart failure in the intervention group was more effective than the control group. The results showed a higher significant correlation between anxiety and depression and quality of life. Results showed that there is a significant correlation between the age of family members of the patients and quality of life ($p < 0.01$).

Conclusions: Nurses are a contributing factor in health promotion and public education to individuals and communities, especially the family members of patients can play an important role to healthy and sustainable behavior change and to identify risk factors, support and provide training to help clients improve their health.

Clnical, hemodynamic and neyrohumoral effects of switching patients with chronic heart failure from angiotensin II reseptor blocker valsartan to azilsartan.

K Kamala Zahidova[1]; FA Guliyev[1]
[1]*The Azerbaijan State Advanced Training Institute for Doctors , Baku, Azerbaijan*

On behalf of: CHFA

Purpose. At present angiotensin II receptor blockers are highly effective and safe drugs that reduce the activity of RAAS.Therefore we have conducted this study in order to accses efficacy of switching patients from therapy with valsartan in dose 40-80 mg/day to azilsartan in dose 20-40 mg/day.

Methods: We studed from therapy 196 patients with CHF II-III NYHA class on standard therapy which included ARB valsartan in dose 40 -80 mg/day.In all patients at baseline and after 6 months of therapy we assessed clinical status,quality of life with Minnesota questionnaire and visual -analog scale, performed 6-min walk test and echocardiography for evaluation of LVEF and measured level of N-terminal fragment of pro-barin natriuretic peptide(NT pro BNP) in blood serum.

Results: Switching patients from valsartan in dose 40-80 mg/day to ARB azilsartan in dose 20-40 mg was associated with significant improvement of clinical status with increase of 6 min walk distance, betterment of parameters of quality of life, and significant rise of LVEF combined with lowering of mean CHF class NYHA (all $p < 0,01$ compared baseline).There was no significant dynamics NT pro BNP level in the whole group but in the subgroup with NT pro BNP values above median significant lowering we noted its significant lowering ($p < 0,05$). No significant association between dynamics of main clinic and laboratory parameters and decrease of sistolic blood presure (SBP) and diastolic blood presure (DBP) was observed.

Conclusion: Therefore, switch of patients with CHF II-III NYHA class from APB valsartan to azilsartan in this disease was associated with improvement of quality of life, clinical status, and LV systolic function. This was combined with lowering of initially elevated NT pro BNP level irrespective of changes of SBP ana DBP.

Effects valsartan and azilsartan in CHF

Parameters	Baseline	After 6 months	p

Impact of early tolvaptan treatment for very elderly patients with heart failure and chronic kidney disease

K Kei Yoshioka[1]; M Yokoi[1]; M Otagaki[1]; T Yoshio[1]; K Matsumura[1]; T Noda[1]; T Sakuma[1]; T Ueyama[1]; Y Iharada[1]; H Park[1]; Y Yamamoto[1]; I Shiojima[1]
[1]*Kansai Medical University, Moriguchi, Japan*

Introduction: Tolvaptan (TVP) was approved in Japan for the treatment of congestive heart failure 5 years ago.Recent years, very elderly patients with heart failure (HF) are increasing in number. Treatment of very elderly patients with HF is relatively difficult since those patients tend to be resistant to conventional treatment regimen including loop diuretics and diuretics therapy is frequently associated with further reduction in kidney function. TVP was used as a final weapon for those patients,and it was very effective. However, it is unclear whether it should be administered TVP from the early stage or late stage for the very elderly patients with HF and CKD.

Hypothesis: To investigate whether TVP administration to the those patients are much better at early stage or late stage.

Methods: Among very elderly patients (defined as aged 80 or older) with HF and CKD, those who were resistant to conventional treatment (including loop diuretics, carperitide (hANP), and vasodilators) or who exhibited impaired kidney function following initial treatment (more than 30% increase in the serum creatinine compared to baseline) were enrolled. Subjects were additionally given oral TVP (7.5-15mg/day). And it was divided into two groups of the early treatment group to which TVP was administered within three days after the start of treatment and the late treatment group to be administered on after that

Results: Forty patients (mean age:86 ± 4.3) were enlored in this study. There were no significant differences in the baseline clinical parameters between the early and late tolvaptan treatment groups. However, the early use of tolvaptan was associated with shorter hospital stay, lower rate of in-hospital death, higher urine volume in 24hours.

Conclusions: Our results suggest that be beneficial to consider administering tolvaptan earlier in very elderly patients with HF and CKD.

P986

Single centre audit of Right Heart study in patients with decompensated heart failure.

WA Ashram[1]; BM Mcadam[1]; KA Alharbi[1]
[1]*Beaumont Hospital, cardiology, Dublin, Ireland*

Background: Recent clinical studies have questioned the routine use of right heart catheterization for the hemodynamic assessment of patient with heart failure to guide therapeutic intervention. The AIM of our audit was to review the use of this procedure in our center to study the impact in patients with advanced heart failure in terms of clinical outcomes, therapeutic interventions and complications.
Methods: and results: We reviewed 137 consecutive patients who underwent 70 right heart studies in our Hospital in 20 months period of time. The age range was between 25 and 92 years with median age of 58 years, with 53 males and 84 females. The main indications for the procedure were heart failure, with either worsening renal function, hypotension and/or low output state with serum creatinine of 137 umol/L +2.7 and interestingly 36 patients (26%) had cardio-renal syndrome and Nt-Pro BNP was elevated in almost all patients with a mean level of 4387pg/ml. 87% had an ECHOs. 32% of them had LVEF > 55% , 45% had LVEF of 35 -55% and 23% had LVEF less than 35%. At least 34% had moderate MR. 45% of the patients had almost normal RV function and 39% had severely reduced RV function. The inpatient mortality rate was high with 44% of this cohort died.
Right femoral vein access was the most common site of assess with 7Fr. system used in three quarters of the patients. Right Brachial Vein access was used in 37 cases (27%) and a 6Fr. catheter was use in most of these cases. There was two immediate complications occurred over this period. One of the patients had a pulmonary hemorrhage and the other had a hematoma at the excess site at the groin. Data obtained from 101patients (73%) showed an elevated PAWP, with median of 17 mmHg. Furthermore, the majority of patients had pulmonary hypertension (57%). Only 42 (30%) cases had cardiac output assessment using TD method with a mean value of 4.5L/min. PVR was greater than 2 Wood units in the 50% of patient who have Cardiac output measures.
Invasive measurement of mean PAWP was 17mmHg indicating volume overload state and mean PA pressure was 27 mmHg + 11.39, this correlated poorly with PA pressure estimation by echo Doppler. One patient was septic with elevated CO and low PVR and required pressors. Another 18 patients had confirmed low output state with elevated PAWP and low cardiac output and were commenced on vasodilator therapies, pressors (Milrinone) and infusion of frusemide in CCU.
Summary/Conclusion: In this selected cohort of patients with heart failure, a significant proportion had heart failure but with preserved systolic function with associated renal dysfunction pulmonary hypertension and RHC was an excellent diagnostic tool with improvement in short term clinical status with positive impact on clinical decision making and therapeutic intervention. Right brachial vein as an access to perform RHS was very convenient for both the operator and the patient without any immediate or late complication.

Hospitalization for heart failure is a strong predictor of mortality and new admissions to the hospital especially in the first three months after discharge; this is the "vulnerable phase" of the disease.
Objective: To identify the efficacy of implementation of OPTIMIZE program at hospital discharge in Colombian population of heart failure patients in the vulnerable phase of disease in terms of clinical outcomes: Left ventricular (LV) ejection fraction, functional class and the composite endpoint of decompensation + readmissions to the hospital after 30 days of follow up. The program included education, material to enhance adherence and early initiation of ivabradine to obtain a goal heart rate of 60 – 70 bpm.
Methodology: Prospective cohort study.
Results: 436 patients were included, 68% were male and 32% were females, the mean age was 66 years with a mean ejection fraction of 32%. Ischemic cardiomyopathy was the cause of heart failure in 40.8% of the patients. 94% of the population was on beta blockers and 42% also received Ivabradine. Only 61.4% of the patients were followed in an outpatient service after 30 days. The impact on clinical outcomes is reported in table 1.
Conclusion: The implementation of OPTIMIZE program and early initiation of ivabradine in the vulnerable phase, from hospital discharge; improve LV function and the NYHA functional class with a reduction in the composite end point of decompensation + hospitalization for heart failure.

Table 1

30-day outcomesN= 268	WithIvabradine N=131	Without Ivabradine N=137	P value
Change in LV ejection fraction	5%	0%	0.005
Improvement in at least 1 NYHA class	42%	12%	0.000
Decompensation + hospitalization	1,53 %	8,57%	0.009

Heart failure: what impact does age have on betablockage and renin-angiotensin inhibition?

J G Julio Gil Goncalves Pereira[1]; L Abreu[1]; H Antunes[1]; ML Goncalves[1]; B Marmelo[1]; I Pires[1]; I Cunha[1]; R Silverio[2]; LF Santos[1]; J Costa Cabral[1]
[1]*Hospital Sao Teotonio, Cardiology, Viseu, Portugal*; [2]*Hospital Sao Teotonio, Internal Medicine, Viseu, Portugal*

Introduction: In heart failure (HF), treatment with Betablocker (BB) and Angiotensin-converting-enzyme Inhibitors (ACE-I) or Angiotensin II receptor antagonists (ARB) are invaluable in the reduction of mortality and re-admission rates.
Purpose: The objective of this study is to evaluate the impact of treatment with BB and/or ACE-I/ARB in patients admitted for HF. The goal is to ascertain if the treatment has the same impact on prognosis in patients older than 80 years old.
Methods: Retrospective study of patients admitted for the first time with the diagnosis of HF. Clinical, analytical and echocardiographical parameters were evaluated. The sample was divide into 3 groups depending on left ventricular ejection fraction (LVEF): HFpEF group with LVEF>50%; HFmrEF with LVEF 40-50%; HFrEF with LVEF < 40%. The patients were further divided based on their medication at discharge: patients without BB or ACE-I/ARB; patients with BB or ACE-I/ARB; patients medicated with both BB and ACE-I/ARB. Kaplan-Meier curves were created to evaluate the occurrence of the combined endpoint of death and/or re-admission for HF at 24month follow-up.
Results: The study was comprised of 1052 patients, 50.8% male, of which 47.5% were older than 80 years old.
In the following table, the percentage of patients in which the combined endpoint occurred is described based on treatment approaches.
In the first row of images, the Kaplan-Meier curves are displayed according to the medication and HF category. In the second row, the same is displayed but for patients over 80 years old.
Conclusion: In the general population, treatment with the combination of BB and ACE-I/ARB has shown to impact prognosis. There was a significant reduction of mortality and re-admission rate in the treatment group. This impact is due to the effect of medication in patients with HF and reduced LVEF (HFrEF). However, that protective effect does not occur in patients over 80 years old, despite LVEF.

	Without BB or ACE-I/ARB	with BB or ACE-I/ARB	with the combination of BB and ACE-I/ARB	P
General Population	67.4%	57.8%	50.7%	0.012

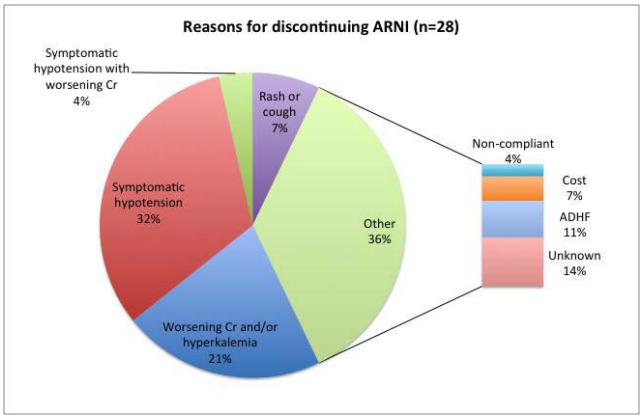
Tolerability and short-term outcomes of angiotensin receptor-neprilysin inhibitor (ARNI) use in a Singaporean cohort

N Natalie Koh[1]; VJ Goh[2]; CK Teoh[1]; LY Teo[1]; CP Lim[1]; D Sim[1]
[1]National Heart Centre Singapore, Singapore, Singapore; [2]Duke-NUS Graduate Medical School Singapore, Singapore, Singapore

Introduction: Following positive outcomes data from the PARADIGM-HF trial, the first-in-class angiotensin II receptor blocker neprilysin inhibitor (ARNI), LCZ696, has entered heart failure pharmacotherapy guidelines as an acceptable substitute for angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) in heart failure with reduced ejection fraction (HFrEF). Use of ARNI was associated with hypotension, renal insufficiency, and angioedema in PARADIGM-HF. Information on the tolerability and outcomes of ARNI use in our local Asian HFrEF population is lacking. We retrospectively studied the baseline characteristics, adverse event rates, and short-term outcomes in a pilot Singaporean HFrEF cohort started on ARNI.
Purpose: We aimed to ascertain the safety, tolerability and efficacy of ARNI in our Singaporean population.
Methods: We reviewed data from 179 patients receiving ARNI up to July 2016, from a single tertiary hospital. Data collected included demographic variables, laboratory investigations, clinical symptoms, and comorbidities. Patients were followed up until they reached either end points of death or LVAD implantation.
Results: The mean age of the study population was 60 years. 78% of the patients were male. The average left ventricular ejection fraction (LVEF) was 23%, with 60% of heart failure due to an ischaemic etiology. Overall, ARNI was discontinued in 28 (16%) patients and dose reduced in 7 (4%) patients due to adverse events. Patients who discontinued ARNI were older (age 65 vs 59 years, $p = 0.026$). There were no other significant baseline differences between the groups such as gender, NYHA functional class, comorbidities, heart failure medications, and other clinical attributes. 5.6% of patients had ARNI discontinued due to symptomatic hypotension, 2.2% due to worsening creatinine, and 1.7% due to hyperkalemia. Other reasons for discontinuation are described in the figure below. Patients who discontinued ARNI had higher rates of all-cause (18% vs 2%, $p = 0.003$) and cardiovascular (15% vs 1%, $p = 0.002$) mortality but no difference in rate of heart failure hospitalizations. Overall, there was no difference in serum creatinine and potassium at baseline and three months. A significant decrease in NT-proBNP was observed at three months compared to baseline (median 3614 vs 1328pg/mL, $p < 0.001$). Finally, more patients were in NYHA class I, and fewer patients in NYHA class III (19% vs 5% and 8% vs 23% respectively, $p < 0.001$), after three months on an ARNI than at baseline.
Conclusion(s): ARNI use is well-tolerated in our Singaporean cohort. The most common reason for discontinuation of ARNI was symptomatic hypotension. Patients who discontinued ARNI tended to be older, and had higher all-cause and cardiovascular mortality. While ARNI seemed to improve NT-proBNP and NYHA functional class in this short-term study, a longer duration of study and larger cohort are needed to further support these findings.



Reasons for discontinuing ARNI

P990

Vasopressin receptor antagonist shortens the lengh of stay and reduces the risk of worsening renal function in hospitalized chronic heart failure patient with hyponatremia : a prospective cohort study

DIAN Y Hasanah[1]; RARSAR Soerarso[1]; NANI Hersunarti[1]; BAMBAN Siswanto[1]
[1]Harapan Kita Hospital, Cardiology, Jakarta, Indonesia

Background: Acute decompensated heart failure (ADHF) is one of the leading causes of hospital admission in the whole world. The primary aim of therapy for ADHF is reduction of the congestive state and diuretics are the corner stone of primary therapy in ADHF. Although this strategy is effective in the acute care setting, diuretics therapy has been associated with adverse effects, including electrolyte abnormality, neurohormonal activation, and renal dysfunction, so called, worsening of renal function. WRF coexisting with ADHF is a common situation, and this complicates the treatment course of heart failure , because WRF leads to diuretics refractoriness , longer length of hospital stay , and increase in mortality and additional hospitalizations during follow-up. Tolvaptan is an oral selective V2 receptor antagonist, and some studies have shown the preferable effects for renal function with tolvaptan which shorten lengh of stay when it is used in heart failure patients with hyponatremia combine with diuretic. This study aims to identify the impact of Tolvaptan for acute heart failure patients with hyponatremia.
Methods: This study was conducted in our Cardiovascular Center. We analyzed 62 hospiltalized chronic heart failure patients with hyponatremia and decrease renal function from 2015-2016, 31 patients were treated with Tolvaptan and furosemide (IV), while the other 31 patients received furosemide (IV) only. The indicators used to measure the impact of Tolvaptan are Creatinin value and Length of Stay (LOS).
Results : Using paired sample t-sample t test, we compare the Cr rate before and after consuming Tolvaptan, the analysis shows that p-value=0.080, less than α=5%. Therefore, we can conclude that there is statistically significant difference in the improvement of renal function. In the first group treated with furosemide (IV) and tolvaptan, creatinine level dropped farther than those in the second group with furosemide only (average delta Cr 0.58 vs 0.18) with p value 0.06 in favor for furosemide (IV) + tolvaptan treatment. Moreover in the second indicator, Based on t-test results, p-value is 0.001 less than α=5% so that we can conclude that there is statistically difference in LOS between the two groups. Patients with furosemide (IV) and Tolvaptan are associated with shorter LOS (average: 3.6 days) compared to patients with furosemide (IV) only (average LOS: 4.9 days).
Conclusion: : Tolvaptan has a significant effect in the improvement of renal function

and shorter LOS in hospitalized heart failure patients with hyponatremia treated with intravenous furosemide.

P991

Ivabradine reduces myocardial hibernation in patients with acute coronary syndrome

GAYANE Gayane Chngryan[1]; TM Solomenchuk[1]; LM Kopchak[1]
[1]*Lviv national medical university n.a. Danylo Halytsky , Lviv, Ukraine*

Methods: The study involved 112 patients with acute coronary syndrome who were divided into 2 groups: group I - 73 patients with viable (hibernating) myocardium , the group II of 39 patients with non-viable myocardium , and each - 2 subgroups. The criterion of myocardial viability was improved left ventricular (LV) ejection fraction (EF) of ≥ 5% in dynamics between the first observation and 21 day. Double performed echocardiography in M-, B- modes and calculated: end - systolic size (ESS), end - systolic volume (ESV), stroke volume (SV), LVEF, wall motion score index (WMSI) was derived as the sum of individual scores divided by the total number of segments analyzed and asynergy index (AInd) (total score segments/16). The patients included in the subgroup IA (n = 34) and II A (n = 14), on the background of standard therapy they received additionally ivabradine, the patients in subgroup I B (n = 39) and II B (n = 25) - did not take ivabradine.
Results: When analyzing received data was observed following dynamics, which are presented in the table.
Conclusions: Ivabradine in patients with myocardial hibernation improves the systolic function (decreasing the ESS, ESV, increasing the SV, LV EF) and improves recovery of regional abnormalities myocardium (WMSI, AInd). In patients with nonviability myocardium admission ivabradine enables not impair this parameters.

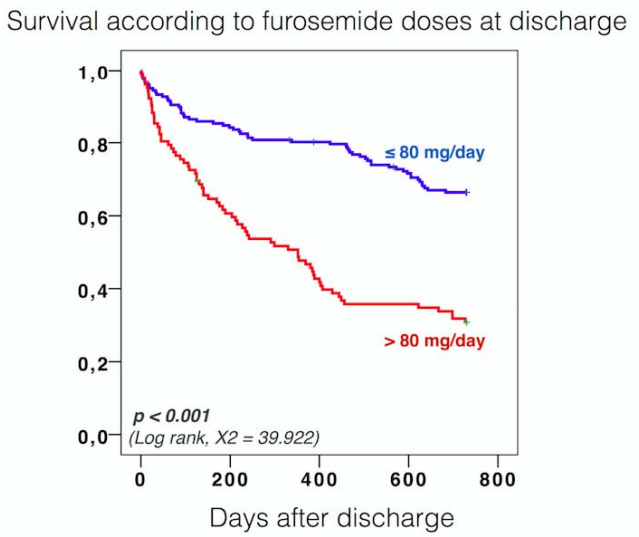
P992

Furosemide doses and long-term mortality after discharge from heart failure episode

J Jerome Costa[1]; L Simone[1]; P Nazeyrollas[1]; D Metz[1]
[1]*University Hospital of Reims, Cardiology, Reims, France*

Background: Heart failure causes congestion, treated by loop diuretics. While there is a lack of evidence supporting the positive impact of these drugs on survival, previous studies suggested that high loop-diuretic doses could be associated with impaired survival of heart failure patients.
Purpose: To determine if furosemide doses > 80 mg/day are associated with higher long-term mortality.
Methods: Clinical, biological and echocardiographic datas were retrospectively analyzed from the electronic medical record of patients discharged after acute heart failure hospitalization in a general cardiology department between January and December 2013, including treatment prescriptions at discharge and time of death within the two-years follow-up.
Results: Among 313 patients discharged (163 men and 150 women, mean age 78.3 years), 132 died within the two-years follow-up (42%). Furosemide was the first treatment on prescription (96%) with daily doses ≤ 80 mg/day for 196 patients (63%, group 1) and doses > 80 mg/day for 114 patients (37%, group 2). In univariate analysis 730 days after discharge, 68.9% patients in group 1 were still alive whereas they were 33.3% in group 2 (OR 4.44 [2.63–7.47], p < 0.001]. After Cox-regression, furosemide doses > 80 mg/day, chronic obstructive pulmonary disease or asthma, impaired left-ventricle ejection fraction, renine system antagonists, dyskaliemia, inflammation and anemia impacted the two-years global survival, with respective OR of 2.39 [1.60–3.57] (p < 0.001), 2.02 [1.28–3.18] (p = 0.002), 1.69 [1.10–2.59] (p = 0.016), 0.60 [0.39–0.90] (p = 0.016), 3.58 [1.80–7.11] (p < 0.001), 2.04 [1.21–3.47] (p = 0.008) and 1.87 [1.17–2.98] (p = 0.008).

Conclusion: At hospital discharge after an episode of acute heart failure, furosemide doses > 80 mg/day is an independent predictive marker of two-years global mortality.



Survival according to furosemide doses

P993

Long-term sacubitril/valsartan therapy is associated with decrease of arterial elastance in stable patients with heart failure with reduced ejection fraction

Z Kobalava[1]; S Villevalde[1]; O Lukina[1]; L Babaeva[1]; I Meray[1]
[1]*RUDN University, Moscow, Russian Federation*

Objective: Angiotensin receptor-neprilysin inhibitor (ARNI) is recommended to further reduce the morbidity and mortality for patients with chronic symptomatic heart failure with reduced ejection fraction (HFrEF) according to the 2016 ESC Guidelines. The aim of the study was to assess the effects of long-term sacubitril/valsartan therapy on parameters of ventricular-arterial coupling and left ventricular (LV) work efficiency in patients with stable HFrEF.
Methods: In the open-label follow-up to PARADIGM HF study 16 patients with stable HFrEF (14 male, 69 ± 9 years (M ± SD), arterial hypertension 88%, previous myocardial infarction 88%, diabetes mellitus 43%, dyslipidemia 63%, LV EF 32 ± 6%, serum creatinine 122 ± 23 μmol/l, eGFR 55 ± 13 ml/min/1.73m2, serum potassium 4.43 ± 0.38 mmol/l) were enrolled. Patients received a stable background treatment for at least a month (ACEI 94%, beta-blockers 100%, aldosterone receptor antagonists 81%, loop diuretics 75%). ACEI treatment was interrupted for 36 h and replaced with sacubitril/valsartan 50, 100 or 200 mg BID according to baseline brachial BP (mean dose 185.7 ± 36.3 mg BID). 2-dimentional echocardiography was performed to assess arterial (Ea) and end-systolic LV elastance (Ees) baseline and after 12 month sacubitril/valsartan therapy. VAC was assessed as the ratio Ea/Ees, optimal range was considered as 0.5-1.2. Wilcoxon test was considered significant if p < 0.05.
Results: Sacubitril/valsartan therapy was associated with significant decrease of Ea (2.20 ± 0.84 vs 1.79 ± 0.63 mmHg/ml/m2, p = 0.005). Ees remained unchanged

P991 Data of echocardiography

* - significant differences in dynamics through 21 day (p < 0.05) # significant differences between subgroups I A and I B in 21 day (p < 0.05)

(1.00 ± 0.34 vs 1.01 ± 0.44 mmHg/ml/m2 and, p>.05). VAC tended to decrease (2.26 ± 0.77 vs 1.86 ± 0.34). Central systolic blood pressure (BP) decreased from 116 ± 19 to 106 ± 10 mmHg (p = 0.001) and central pulse pressure - from 44 ± 15 to 38 ± 7 mmHg (p < 0.05). Parameters of LV work efficiency did not change significantly; although potential energy tended to decrease (5038 ± 1437 vs 4489 ± 2118 mmHg*ml/m2), LV efficacy (ratio stroke work/ pressure-volume area) tended to increase (0.57 ± 0.07 vs 0.62 ± 0.04). Correlation between decrease of Ea and brachial BP decrease was not found. Sacubitril/valsartan was well tolerated and there were no BP-related adverse events.

Conclusion: In stable patients with HFrEF long-term sacubitril/valsartan therapy was associated with decrease of Ea rather than Ees changes. Changes of Ea did not correlate with systolic BP decrease.

P994

How improve quality of medication management in cardiology? Benefit of clinical pharmacist assistance in cardiology units.

Y Yohan Audurier[1]; N Chapet[1]; B Mathieu[1]; F Leclercq[2]; JL Pasquie[2]; F Roubille[2]; A Jalabert[1]; G De Barry[1]; C Breuker[1]; A Castet-Nicolas[1]

[1]University Hospital Arnaud de Villeneuve, Pharmacy department, Montpellier, France; *[2]University Hospital Arnaud de Villeneuve, Cardiology department, Montpellier, France*

Several previous studies have shown that medication management was ofen incomplete for patients with heart failure (HF) or acute coronary syndrom (ACS). In the same time, other studies had reported that clinical pharmacists improved medication quality and safety. So, a pharmacy team was relocated in cardiology units. 1 senior pharmacist, 1 junior pharmacist and 7 student pharmacists were deployed in intensive care of cardiology and complete hospitalization (79 beds).

The aim of this study is to evaluate the impact of clinical pharmacist in cardiology department.

This prospective experience was realized during one year (december 2015-december 2016). Pharmacy team used several clinical pharmacy activities to improve medication management of patients : medication reconciliation, pharmaceutical intervention (PI) during medical examination and medical staff, prescription revision. Pharmacist's interventions were directly classified with ACP-IP, a national tool edited by The French Society of Clinical Pharmacy. This check-list had permitted the analysis of number and type of PI, drugs and cardiovascular diseases involved, and the physicians' acceptance rate.

828 PI were registred for 507 patients. The mean age was 71,6 years. Most frequent type of PI were overdosage (150 ; 18,1%), underdosage (127 ; 15,3%), missed drug (158 ; 19,1%), inappropriate form of administration (74 ; 8,9%) and contraindications (56 ; 6,8%). The physician's acceptance rate was 96,9%. Concerning drugs involved, medications of cardiovascular system were the most important (231 ; 27,9%) followed by medication of alimentary tract and metabolism (152 ; 18,4%) and nervous system (108 ; 13,0%). More precisely for cardiovascular system, Statines were the most important therapeutic class implicated (57 ; 24,7%), followed by ACE inhibitors/Angiotensin II receptor antagonist (53 ; 22,9%) and Beta-blockers (32 ; 13,9%). 51 PI concerned optimization of ACS pharmacotherapy and 52 PI were about management of HF pharmacotherapy.

These results reflect the importance of collaboration between physicians and pharmacists on the medication management of cardiovascular diseases and comorbidities. Others studies about improvement were begun especialy for the medication management of HF patients.

This experience is a complete success, physicians and pharmacists will continue this collaboration to perpetuate works in progress and optimize medication management in cardiology.

P995

Is diuretic resistance a lost battle?

R Rocio Eiros[1]; I Baraibar[1]; A Hernandez[1]; A De La Fuente[1]; E Iglesias[1]; M Palacio[1]; J Ibero[1]; I Garcia Bolao[1]; JJ Gavira[1]

[1]University Clinic of Navarra, Cardiology, Navarra, Spain

Background: Data from a variety of sources have raised concerns about the overall safety profile of diuretics in heart failure (HF). A frequently mentioned complication of diuretic therapy in acute decompensated HF(ADHF) is diuretic resistance(DR), which consists in poor response to diuretic treatment with loop diuretics (LD), although the exact frequency is unknown due to the lack of a single definition. One of the most difficult challenge to face is the presence of chronic kidney disease. We hypothesized that the combination of hydroclorotiazyde(HTZ) and amiloride(A), would be a safe and effective strategy despite renal function, notwithstanding his controversial use in this scenario.

Methods: This retrospective cohort study all patients with DR admitted for ADHF treated with the combination of A(5 mg) and HTZ(50 mg) was made in addition to treatment with LD. Two groups were created according to their basal glomerular filtration rate: (Group A < 60 mL/min/1,73m2, and group B >60 mL/min/1,73m2).The primary efficacy endpoint were first change in net urine output(UOP) at 24 and 48 h from after iniciating treatment and change in body weight at 24 h and discharge. Secondary efficacy endpoint was length of stay, 30-day readmission rate, and in-hospital mortality. Evaluation of sodium, potassium, creatinine(Cr) (mg/dL) and glomerular filtration rate by MDRD in plasma was made at 24 h and at discharge.

Results: 107 patients were included (68 male) with a mean age of 74 ± 12. Ischemic and valvular heart disease were the most prevalent cause of HF (34% vs 30%). Most patients had NYHA class III or IV. Group A was composed by 54 patients and group B with 53 patients. UOP improved more at 24 h in group A (p = 0,022) compared to group B, but on both groups increased statistically significant at 24 h and 48 h. Change in body weight at 24 h and discharge was also statistically significant. Secondary efficacy outcomes were also similar, as there were no significant differences (Table 1). Not statistically significant changes of Cr at 24 h were found neither of MDRD. None of them developed electrolytic disturbances.

Discussion: To our knowledge, this is the first and largest study to demonstrate the efficacy and the safety use of the HTZ/A diuretic despite renal function in patients with ADHF and DR to date. This results give clinicians an attractive option, safe, effective and available worldwide, to overcome such a frequent situation in daily practice as DR.

IVC analysis - a reproducible and clinically relevant metric which deserves greater prominence in heart failure management

M J Barrett[1]; M Iacoviello[2]; F Monitillo[2]; D Grande[2]; C Rizzo[2]; C Hanley[3]; A Kent[3]; J Britton[3]; A Fitzgerald[4]; P Campbell[1]; R O'hanlon[5]; K Mcdonald[1]

[1]St Vincent's University Hospital, Cardiology, Dublin, Ireland; *[2]Polyclinic Hospital of Bari, Bari, Italy*; *[3]Fire1, Dublin, Ireland*; *[4]Heartbeat Trust, Dublin, Ireland*; *[5]St. Michael's Hospital, Heart Failure Unit, Dublin, Ireland*

Background/Introduction: Heart Failure (HF) management has advanced significantly, however hospitalisation rates and mortality remain high. Maintaining euvolaemia is key to preventing decompensation but this is challenging. The Inferior Vena Cava (IVC) represents a pliable reservoir for circulating volume, and changes in its' shape during respiratory cycles are recognized as markers of intravascular volume status – albeit not routinely used in HF management.

PURPOSE: To assess the reproducibility and test the clinical utility of using the IVC as a marker of volume status in a chronic HF population.

Methods: This was a multicentre study conducted between University Hospital in Ireland and A.O.U. Consorziale-Policlinico, Italy. Stable outpatients were enrolled in prospective fashion during routine scheduled heart failure visits. Patients with a HF admission or unscheduled contact with the HF service in the preceding 6 months were excluded.

Reproducibility was measured by three measurements of maximal IVC diameter (IVCd) and collapsibility index (CI) at 0, 1 and 24 hours. Interobserver agreement was measured by two independent physicians analysing recorded 2-D IVC images. IVCd and CI were compared against other indicators of volume status including symptoms, examination and serum natriuretic peptides (NP).

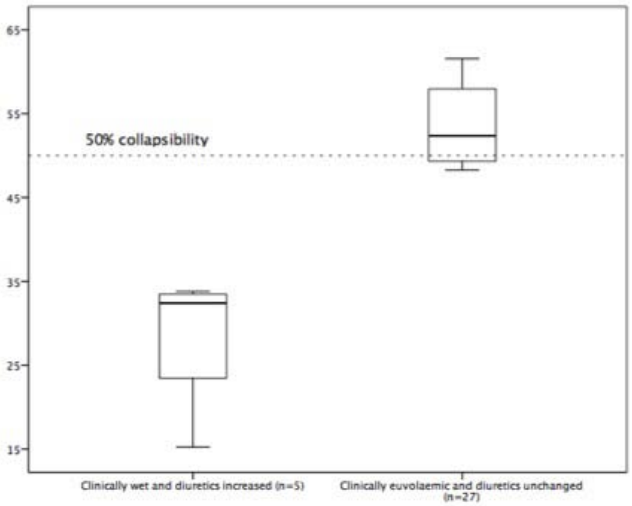
Results: A total of 60 patients were included – 31 from Ireland and 29 from Italy. Mean age was 69.6 years. 71.7% were male and 75% had a diagnosis of heart failure with reduced ejection fraction (HFrEF).

IVCd as measured by independent operators in both centres displayed excellent interobserver agreement with an r2 value of 0.818 (p < 0.001).

Serial IVC measurements over 24 hours showed excellent reproducibility, with an overall average standard deviation around the mean of 1.3mm for maximum diameter and 7% for CI.

Patients were managed according to standard care by an experienced HF physician blinded to the IVC analysis. Five patients of the cohort had intensification of diuretic

therapy based on clinical symptoms and/or signs. The CI of these patients was found to be significantly lower , indicating potential volume overload, than those without clinical congestion (31.1% vs 50.2%, p = 0.022).
When comparing IVC metrics to other markers of volume overload, patients with a dilated or poorly collapsible IVC had a significantly higher N-terminal pro B-type NP (3682 pg/mL vs 490 pg/mL, p = 0.015) and poorer estimated glomerular filtration rate (55 ml/kg/min vs 69 ml/kg/min p = 0.029).
Conclusion(s): Measurement of IVC metrics in stable outpatient HF populations in two international tertiary HF centres appears to be a reliable and reproducible test. Preliminary data suggests clinically relevant correlation with volume status. Use of these measurements may provide a novel treatment target for HF optimisation in the future. Further analyses and extension of the dataset continues at both sites



P997

Un-suggested prescriptions of non-cardio-selective beta-blockers for heart failure in patients with concurrent chronic obstructive pulmonary disease: a danish nationwide retrospective cohort study.

M Maurizio Sessa[1]; A Mascolo[1]; RN Mortensen[2]; MP Andersen[3]; G Rosano[4]; A Capuano[1]; F Rossi[1]; G Gislason[5]; H Enghusen-Poulsen[6]; C Torp-Pedersen[3]
[1]Second University of Naples, Department of Experimental Medicine, Naples, Italy; *[2]Aalborg University Hospital, Department of Clinical Epidemiology, Aalborg, Denmark*; *[3]Aalborg University, Department of Health, Science and Technology, Aalborg, Denmark*; *[4]San Raffaele Pisana Hospital IRCCS, Rome, Italy*; *[5]The Danish Heart Foundation, Copenhagen, Denmark*; *[6]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*

Background: Since 2008, European Society of Cardiology (ESC) clinical management guidelines for acute and chronic heart failure has discouraged the use of non-cardio-selective beta-blockers for heart failure in patients with the chronic obstructive pulmonary disease. Although the pulmonary consequences of beta-2-blockade are well known, it is not known to which extent the international guidelines have been followed. It is important to know whether adherence to guidelines needs to be reinforced. Therefore we conducted a Danish nationwide study of beta-blockers use in patients with obstructive pulmonary disease and heart failure in the period from 2009-2012.
Methods: The study population was followed from index date to death or censoring on 31 December 2012. The index date was defined as the date of co-diagnosis of heart failure and chronic obstructive pulmonary disease and co-treatment with beta-blockers with an indication of heart failure or 1 January 2009 for those patients that fulfill these requirements prior to 1 January 2009. The first primary outcome was the proportion of patients with obstructive pulmonary disease and heart failure that received carvedilol as opposed to beta-1-selective blockers with an indication of heart failure. Also examined were factors important for selection of carvedilol.
Results: In total, 3902 patients received carvedilol in the study period with a restricted mean time persistence of 507 days, of which 1156 (29.6%) were naïve for carvedilol. In total, 5272 hospitalizations for chronic obstructive pulmonary disease occurred during treatment with carvedilol, involving 1729 (44.4%) out of 3902 patients. The hospitalization rate was in average one hospitalization each 165 days. Naïve patients had during exposure to carvedilol an odd of being hospitalized due to worsening of the lung function of 13.14 (95% Confidence Interval [CI] 10.03-17.56) times higher if compared to themselves in an equivalent period prior to carvedilol administration. Patients with heart failure, chronic obstructive pulmonary disease, and concurrent chronic kidney disease had a higher probability of receiving carvedilol (Odds ratio [OR] 1.16; 95%CI 1.04-1.29). Contrarily those with concurrent hypertension (OR 0.75; 95%CI 0.69-0.81), atrial fibrillation (OR 0.62; 95%CI 0.57-0.67), inhalator glucocorticoids (OR 0.75; 95%CI 0.67-0.85), anticholinergics/selective beta-2-adrenoreceptor agonists inhalants (OR 0.80; 95%CI 0.71-0.90) or selective beta-2-adrenoreceptor agonists inhalants short acting (OR 0.88; 95%CI 0.81-0.96) had lower probability of receiving carvedilol.
Conclusion: An increased awareness of administering non-cardio-selective beta-blockers for heart failure in patients with chronic obstructive pulmonary disease and concurrent heart failure should be warranted.

P998

Tolvaptan for heart failure in chronic kidney disease patients: a systematic review and meta-analysis

J Jonathan Sen[1]; E Chung[2]; D Mcgill[3]
[1]Austin Health Hospital, Melbourne, Australia; *[2]University of Toronto, Toronto, Canada*; *[3]Canberra Hospital, Canberra, Australia*

Background: Heart failure (HF) is frequently associated with renal impairment. Tolvaptan, a vasopressin type 2 receptor antagonist is reported to be effective in treating congestion in HF management without significant electrolyte loss compared to conventional diuretics. However, there is a lack of evidence guiding its use in patients with chronic kidney disease (CKD).
Purpose: This systematic review and meta-analysis aimed to evaluate the efficacy and safety outcomes of tolvaptan for HF management in patients with CKD.
Methods: We searched Medline, Embase, PubMed, Cochrane databases, Google Scholar, the New York Academy of Medicine Grey Literature Database, and hand-searched reference lists of articles for observational studies and randomized clinical trials that assessed the efficacy and safety outcomes of tolvaptan against placebo or standard care in adult patients with HF and CKD. Study screening, data collection, quality assessment of included studies were performed independently. Meta-analysis was performed using Comprehensive Meta Analysis, version 2.2.064. Our protocol was registered with PROSPERO
Results: 19 studies were included in the qualitative review and 5 studies were included in the meta-analysis involving 1597 patients. Compared to baseline, tolvaptan appeared to increase serum sodium concentration (5 studies; mean change of 0.58 mmol/L [95% CI: 0.05-1.11]; p = 0.03) and increase urine flow rate (3 studies; 1.36 mL/h [95%=0.76-1.96]; p = 0.00). However, no significant differences in glomerular filtration rate (GFR) (4 studies, 0.06 mL/min/1.73 m2 [95% CI: -0.13 to 0.24]; p = 0.52), serum creatinine (5 studies, -0.04 mg/dL [95% CI: -0.25 to 0.16]; p = 0.68) vs. baseline. Tolvaptan was also associated with a greater change of sodium concentration (3 studies; 0.37 mmol/L [95% CI: 0.04 to 0.70]; p = 0.03) compared to placebo or standard care. No significant difference in change of eGFR (3 studies; 0.13 mL/min/1.73m2 [95% CI: -0.08 to 0.35]; p = 0.23) and serum creatinine (4 studies; 0.13 mg/dL [95% CI: -0.08 to 0.34]; p = 0.21) compared to placebo or standard care. There was also very low heterogeneity. No significant difference in mortality rates were reported in studies. A lower percentage of worsening renal function was found in patients receiving tolvaptan compared to control group (29% vs. 33%, respectively).
Conclusion: Our review offers reasonable support in the use of tolvaptan in patients with CKD. Tolvaptan may offer an improvement in serum sodium without significant change in renal function compared to placebo or standard care in managing HF in CKD patients. However, further research with high quality randomized controlled trials is needed to establish the effect of tolvaptan on long-term efficacy and safety outcomes.

P999

Effect of short daily versus conventional dialysis on cardiac structure and function in patients with diuretic-resistant congestive heart failure.

TH Bampali[1]; CD Gouva[2]; V Foulidis[3]; A Bechlioulis[1]; K Naka[1]; KP Katopodis[2]
[1]University Hospital of Ioannina, 2nd Cardiology Department, Ioannina, Greece; *[2]General Hospital of Artas, Nephrology Department, Arta, Greece*; *[3]General Hospital of Artas, Cardiology Department, Arta, Greece*

Background: Heart Failure (HF) is a problem of growing significance worldwide. Although the efficacy of conventional therapies has been established, an increasing number of patients suffer from frequent re-hospitalizations due to persistent congestion, resistant to high doses of loop diuretics. This diuretic-resistant congestive HF (DR-CHF) is associated with poor prognosis. Alternative non-pharmacological strategies aiming to better control of overhydration based on hemodialysis have been previously considered.
Purpose: The aim of our study was to estimate the effect of short daily hemodialysis (sdHD) versus conventional hemodialysis (cHD) on left ventricular structure and

function indices, blood pressure (BP) and total water homeostasis in patients with DR-CHF and chronic kidney disease stage III-IV.
Methods: Twenty patients (12 males, mean age 65.8 ± 10.3 years) with DR-CHF and chronic kidney disease stage III-IV were enrolled. We performed a non-randomized, controlled study of sdHD (group 1; n=11 patients, 6 sessions/week, 2 hours/session) vs cHD (group 2; n=9 patients, 3 sessions/week, 4 hours/session) with a follow-up period of 6 months. Conventional echocardiography with assessment of left ventricular mass (LVM) and left ventricular ejection fraction (LVEF) was performed and the total water homeostasis was determined in all patients at baseline and follow-up.
Results: The 2 groups did not differ in baseline characteristics. The total weekly ultrafiltrated removed volume did not differ between groups; 6.2 ± 0.6 vs 5.9 ± 0.8 L in groups 1 and 2 respectively (p = ns). Renal function, estimated by creatinine clearance, remained unchanged in both groups at 6 months (45.4 ± 21.3 vs 42.1 ± 18.9 ml/min, p = ns in the sdHD, and 43.6 ± 19.5 vs 37.7 ± 11.2 ml/min, p = ns in the cHD group). In the sdHD group, a significant improvement in BP (systolic / diastolic) was observed at 6 months (150.7 ± 10.7 vs 130.6 ± 9.7 mmHg, p < 0.01 / 88.2 ± 7.6 vs 68.7 ± 10.5 mmHg, p < 0.01) resulting in a reduction in anti-hypertensive drug use, whereas no difference was noted in the cHD group (154.6 ± 9.7 vs 148.3 ± 11.5 mmHg, p = ns / 90.1 ± 5.4 vs 82.7 ± 6.2 mmHg, p = ns). At the end of follow-up, a significant decrease in LVM was observed only in the sdHD group (147.9 ± 47.3 vs 122.6 ± 38.9 g, p < 0.01), but not in the cHD group (152.7 ± 36.9 vs 145.6 ± 31.7 g, p = ns). Similarly, LVEF improved only in the sdHD group (22.5 ± 4.3 vs 38.7 ± 9.6%, p < 0.01),whereas not in the cHD (24.1 ± 3.8 vs 26.9 ± 10.8%, p = ns).
Conclusions: In DR-CHF patients with advanced kidney dysfunction sdHD sessions , in contrast to cHD sessions, were associated with improved BP control and cardiovascular structure and function (reduction in LVM and improvement in EF), despite a similar decongestion effect. None of these therapies improved the renal function. Further larger studies are needed to establish the clinical value of short daily hemodialysis as a potential novel therapeutic tool in the management of this challenging clinical entity.

Determinants and prognostic value of peak oxygen uptake in the current era of heart failure disease modifying therapy

J Roibal-Pravio[1]; E Barge-Caballero[2]; MJ Paniagua-Martin[2]; G Barge-Caballero[2]; D Couto-Mallon[2]; D Martinez-Ruiz[2]; R Fabregas-Casal[2]; P Blanco-Canosa[2]; C Naya-Leira[2]; CM Riveiro-Rodriguez[2]; Z Grille-Cancela[2]; CM Costa-Grana[2]; R Perez-Fernandez[2]; JM Vazquez-Rodriguez[2]; MG Crespo-Leiro[2]
[1]Universidad de A Coruña (UDC), A Coruña, Spain; *[2]Complexo Hospitalario Universitario A Coruña (CHUAC), A Coruña, Spain*

Purpose: To study the determinants and accuracy of peak oxygen uptake (VO2) to predict the outcome of patients with heart failure (HF) in the current era of disease modifying therapy.
Methods: We studied 282 patients with HF who consecutively underwent ergospirometry for prognostic stratification from 2009 to 2015 in a single center. Baseline variables independently associated with peak VO2 were identified by means of lineal regression. Survival was assessed by means of the Kaplan-Meier method and Cox´s regression.
Results: Mean age of studied patients was 52.7 years; 24% were women, 42% had ischemic heart disease and 74% had reduced LVEF (<0.40). NYHA III or IV class was present in 36% cases. 92% patients were on beta-blockers, 79% on ACEI/ARBs and 70% on MRAs. Mean VO2 was 19.6 ± 5.2 ml/kg/min. In multivariable linear regression, age (p < 0.001), NT-pro-BNP (p < 0.001), body mass index (p < 0.001), and female sex (p = 0.027) were independently associated with lower VO2, while TAPSE (p < 0.001) was independently associated with higher VO2. A peak VO2 < 14 ml/kg/min was associated with significantly higher risk of the composite outcome death, heart transplantation or need for mechanical circulatory support during follow-up (HR 2.38, 95% CI 1.10−5.26, p = 0.027).
Conclusions: Peak VO2 retains a significant prognostic value in the current era of HF disease modifying therapy. In our study, age, female gender, body mass index, NTproBNP and TAPSE were identified as independent clinical determinants of peak VO2.

P1001
Pulsatile hemodynamics in heart failure with reduced ejection fraction - determinants and prognostic value

T Thomas Weber[1]; S Parragh[2]; B Hametner[2]; S Wassertheurer[2]
[1]Klinikum Wels-Grieskirchen, Wels, Austria; *[2]AIT-Austrian Institute of Technology, Vienna, Austria*

Background: The findings relating pulse pressure (PP) and outcome in heart failure with reduced ejection fraction (HFrEF) have been controversial.
Purpose: We aimed to clarify the determinants and prognostic value of brachial PP in HFrEF.
Methods: We measured pulsatile hemodynamics (brachial blood pressure (BP), central BP, wave reflections, pulse wave velocity), using radial tonometry, a transfer function and dedicated algorithms, in 81 patients (mean age 61 years, 90% men) with HFrEF, and followed them for 4.1 years. Patients were divided into quartiles (Qu), according to brachial PP. Main outcome was all-cause mortality.
Results: As compared to Qu 2 + 3, patients in Qu1 had lower BP, lower values for antegrade pressure wave, larger left atrium, larger enddiastolic and endsystolic left ventricular volumes, lower EF, and higher nt-proBNPs. The predominant cause of HFrEF in Qu1 was dilated cardiomyopathy.
As compared to Qu 2 + 3, patients in Qu4 were older, had a higher prevalence of hypertension, diabetes and coronary artery disease, had higher blood pressures and higher values for antegrade and reflected waves and pulse wave velocity. Enddiastolic and endsystolic volumes were smaller, and filling pressures were lower, but nt-proBNP levels were higher in Qu4.
In survival analysis (logrank test, p = 0.0009), patients in Qu1 as well as Qu4 had a higher mortality (Qu 1 vs Qu 2 + 3: HR 3.1 (95% CI 1.2-8.1); Qu 4 vs Qu 2 + 3: HR 4.4 (95% CI 1.7 - 11.2)) - Figure. In a multivariate Cox proportional hazards model predicting all-cause mortality, Qu4 (HR 4.65 (CI 1.69-12.80), p = .003), and, of borderline significance, Qu 1 (HR 2.93 (0.96-8.88), p = 0.059), and log nt-proBNP (HR 2.27 (0.94-5.5), p = 0.07), were the independent predictors. Age, gender, presence of ischemic cardiomyopathy, EF, and SBP did not enter the final model.
Conclusion: Lower as well as higher PP is associated with impaired survival in HFrEF. In the first case, the lower PP likely is the expression of a very poor cardiac function. In the latter case, the higher PP stems from an increased pulsatile afterload. Both conditions can be detrimental.

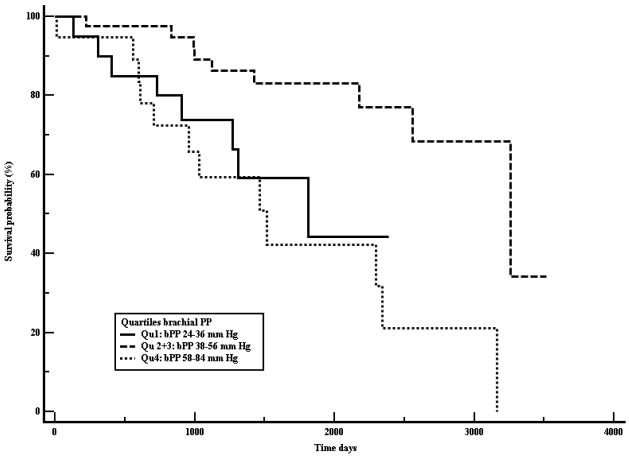

Fig 1

P1002
Mathematical prediction of unfavorable course of chronic heart failure

Z D Zulfya Rasulova[1]; UK Kamilova[1]
[1]Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Cardiology, Tashkent, Uzbekistan

Purpose. Identification of predictive factors of an adverse course of the chronic heart failure (CHF).
Methods: In total were inspected 120 patients with the coronary heart disease with the I-III functional class (FC) of CHF. To all patients carried out: echocardiography with assessment of final diastolic and systolic volumes and sizes of left ventricle (FDV, FSV and FDS, FSS LV), the fraction of emission (FE) of LV, index of systolic and diastolic sphericity (ISs and ISd); when carrying out doppler echocardiography of carotid and cephalic arteries arteries and renal arteries estimated indicator of the thickness of intim of mussel (TIM) at the level of the general carotid artery (GCA), resistive and pulsation index (RI and PI) at the level of the right and left renal artery; determined the level of serumal creatinine (Kr), calculation method of glomerular filtration rate (GFR) by formula MDRD (Modification of Diet in Renal Disease Study) in ml/min/1,73m2.
Results: To assess the significance of the parameters in predicting the course of CHF based on renal function is used method of non-homogeneous sequential procedure with the development of differential diagnostic tables (DT) in three stages is used: the first - research of probability of sign at CHF depending on severity, calculation of the diagnostic coefficients (DC) and determination of informational content (J) of each sign; the second stage - drawing up DT, with inclusion of

the signs which had high J (≥0,5), determination of their sensitivity (Se), the predictive importance (PI); the third stage - choice of diagnostic thresholds (the recreation center sum) which have allowed to make the correct decision. The following diagnostic indicators have been selected: the LV structural and geometrical parameters (FDS, FDV and FSS LV, FE LV, ICs and ICd), parameters of vascular remodeling (TIM at the level of the right and left general carotid artery, RI and PI at the level of the right and left renal arteries) and GFR MDRD.
To study the PI for signs of progression of heart failure symptoms were selected DC which had informative: GFR MDRD less than 60 ml/min/1,73m2, FE LV less than 50%, FDV more than 137 ml, FSS more than 43 mm, ISd, TIM of general carotid artery, more than 1,1 mm.
At the threshold value of DC = +15 and over is predicted unfavorable course of CHF, with the values of DC = - 20 or less it is concluded that a stable flow of CHF. Results of research have shown that the most sensitive signs for definition of the forecast of CHF at patients: availability of FE less than 50% (Se = 1), TIM thickening general carotid artery (Se = 0,96), increase in FDV more than 137 ml (Se = 0,95) and FSS more than 43 mm (Se = 0,95). Conclusions: The analysis of the carried-out mathematical forecasting of adverse current of CHF has shown that the most precursory adverse predictive symptoms are: FE less than 50%, FDV more than 137 ml, FSS more than 43 mm and GFR less than 60 ml/min/1,73m2.

P1003

A white-coat effect for heart rate in heart failure? Characteristics and prognostic implications in idiopathic dilated cardiomyopathy

A Bisson[1]; B Lequeux[2]; N Clementy[1]; M Boyer[1]; C Andre[1]; F Ivanes[1]; D Angoulvant[1]; D Babuty[1]; L Laurent Fauchier[1]
[1]*Tours Regional University Hospital, Hospital Trousseau, Tours, France*; [2]*University Hospital of Poitiers, Poitiers, France*

White coat-effect for blood pressure is defined as temporary increase in blood pressure before and during visit in the clinic, regardless what the average daily ambulatory blood pressure values are. We hypothesized that such a phenomenon may also exist for heart rate (HR) in patients with heart failure (HF) whilst HF guidelines advocate a more aggressive drug management when HR in sinus rhythm is ≥70 bpm, and that white-coat effect on HR (WCHR) might be associated with a different prognosis in patients with idiopathic dilated cardiomyopathy (IDC).
Methods: Among 117 IDC patients (WHO criteria) in sinus rhythm, 24-hour Holter monitoring was performed at enrolment to assess heart rate (HR) and heart rate variability (HRV) parameters. The HR and HRV were measured automatically over 24 hours, during daytime and nighttime periods. We considered mean HR measured during the first hour of recording (HRH1) as possibly being affected by WCHR. The endpoint of cardiac events included cardiac death, heart transplantation and major arrhythmic event (sustained VT/VF).
Results: Among 117 patients with IDC (age 51 ± 12, LVEF 33 ± 12%), 36 (31%) had WCHR ≥5 bpm for HRH1 compared to mean daily HR, and 12 (10%) had WCHR ≥10 bpm. There were 6 patients (5%) with HRH1≥70 bpm whilst daily HR was < 70 bpm. Patients with WCHR ≥5bpm had lower LVEF than those with WCHR < 5 bpm (30 ± 12% vs 35 ± 11%, p = 0.02) and those with WCHR ≥10 bpm were younger than those with WCHR < 10 bpm (42 ± 12 vs 52 ± 11, p = 0.006). With a follow-up of 62 ± 44 months, there were 41 events in 39 patients: 24 cardiac deaths including 12 sudden deaths, 5 sustained VT/VF and 12 heart transplantation. In univariate analysis, HRH1 was a predictor of cardiac events (Hazard Ratio 1.028, 95%CI 1.007-1.049, p = 0.01; C statistic 0.653, 95%CI 0.559-0.738, p = 0.006). However, HRH1 was not an independent predictor after adjustment on age, LVEF, NSVT, NYHA functional class, HR, HRV and QRS duration. Neither WCHR ≥5 bpm nor WCHR ≥10 bpm was an independent predictor of cardiac event.
Conclusions: In patients with IDC, a phenomenon of WCHR is a common finding and may misclassify HR for adaptation of drug therapy according to current HF guidelines in 5% of the cases. Since WCHR was not independently associated with a worse prognosis, we suggest that HR would be better assessed in very stable conditions. Ambulatory monitoring or home HR measurement could result in more accurate evaluation of HR and hence more appropriate treatment.

P1004

Impact of tricuspid regurgitation on survival in patients with chronic heart failure

K Kaoutar Kharbouche[1]; K Kharbouche[1]; I Elhaddad[1]; L Azouzi[1]; R Habbal[1]
[1]*chu ibn rochd, cardiology, casablanca, Morocco*

Purpose: Tricuspid regurgitation (TR) is common in patients with chronic heart failure (CHF). However, data about the prognostic value of significant TR in CHF patients are sparse.
Methods: 1600 consecutive patients with CHF were included between 2009 and 2014. Patients represented an unscreened contemporary cohort of CHR patients treated according to current guidelines in a tertiary heart failure clinic. At study entry detailed clinical and echocardiographic data were collected. The prognostic impact of significant TR was assessed and compared with established risk factors.
Results: TR was common in the study population. 10.6% of patients had severe, 24.0% moderate, and 65.4% of patients had no or mild TR. Kaplan Meier analysis showed a considerably increased mortality rate of patients with moderate and severe TR (p , 0.0001). However, by multivariable analysis NTpro-BNP (p ¼ 0.0054), systolic blood pressure (p ¼ 0.0012), heart rate (p ¼ 0.0152), age (p , 0.0001), serum creatinine, (p , 0.0001), serum sodium (p ¼ 0.0449) and left ventricular function (p ¼ 0.0130), but not TR independently predicted mortality. These independent predictors of mortality were used to define disease severity to analyse the predictive value of TR at different stages of CHF. In patients with mild and moderate CHF, characterized by NT-proBNP concentrations ,500 mg/pg, serumcreatinine levels ,1.5mg/dl, sustained systolic blood-pressure. 100mmHg, heart rate ,90/min, severe TR was highly predictive of mortality (p , 0.0001 for all, except NTproBNP p ¼ 0.00175). In patients with advanced disease, however, significant TR did not add additional information.
Conclusion: The prognostic impact of TR strongly depends on the severity of heart failure. Whereas TR excellently predicts excess mortality in mild to moderate CHF, it has no additive value in advanced CHF when compared with established risk factors. Since it is only in mild to moderate CHF that severe TR is associated with adverse outcome it is this group of patients that might benefit from tailored pharmacological or surgical interventions

P1005

Low incidence of overt heart failure in south italy centenaries is linked with good life style: preliminary data from the ciao study

R Marino[1]; S Navarin[1]; C Bartoli[1]; M Guariglia[1]; R Di Rienzo[1]; A Maisel[2]; L Daniels[2]; S Di Somma[1]
[1]*S. Andrea Hospital - II Faculty of Medicine University La Sapienza., rome, Italy*; [2]*Veterans Affairs San Diego Health Care System, San Diego, United States of America*

On behalf of: GREAT NETWORK

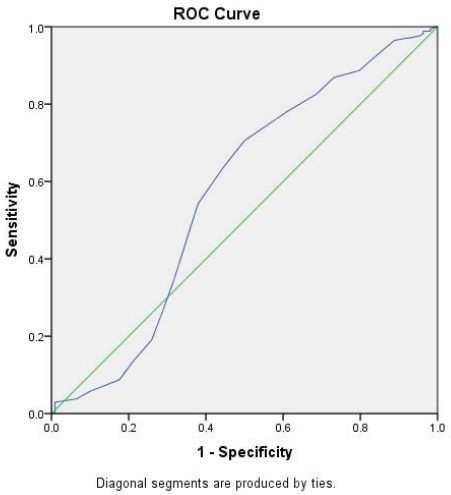
Background: In south of Italy there is a a longer life expectancy compared to the other italian regions and the number of centenaries is exstimate to be of 4-5% of whole in habitants.
Purpose: Aim of our study(Cilento Initiative Aging Outcome(CIAO) was to perform a preliminary evaluation of all reasons of the longevity in this region people. A complete cardiological assessment in order to evaluate the incidence of Heart failure in centenarian from Cilento region compared to their cohabitants of the age between 50 to 70 years old and to link the results with their life-style.
Materials and Methods: 26 centenarians(Cen) and two of their cohabitants (coh) were enrolled in their houses. The centenarians were reached at their home by mean of fully equipped car with cardiological instruments. Clinical assessment was performed including medical history, clinical exam to check signs of congestions, collection of Weight, Height, Blood pressure(BP), Heart rate (HR), respiratory rate (RR), oxigen saturation (SaO2) partial fraction of oxygen (FiO2). Moreover the partecipants underwent: electrocardiogram (EKG) , bioimpedance vector analisys (BIVA), Lung ultrasound test (LUS), ecocardiography to evaluate the heart function and structure and the collapsability of inferior cava vein. Life style of centenarians (including diet and physical activity)were also recorded. A six months later a phone call Follow up was also performed.
Results: 26% of Cen had a diagnosis of chronic heart failure (CHF)but were. Ischemic cardiopathy (CHD) was 4% in Cen and 6% in Coh. Risk factors for heart failure were less present in Cen compared to Coh. Diabetes was present in 8% of Cen compared to 23% in Coh. Hypertension was detected in 48% of Cen and 51 % of Coh. High Colesterol level was 16% in Cen compared to 26 % in Coh. Dispnea at rest was present in only 8% of Cen . The hydration score mean was 76,8 ± 4,36 inCen and 73,9 ± 1,9 in Coh (ns). At Lung ultrasound (LUS) no pleural effusion was detected in both groups. At echocardiography the percentage mean of ejection fraction(EF) and inferior vein cava diameter (IVC) were in the normal ranges for both groups :EF 52 ± 1,9, ad 55 ± 5,63 respectively and IVC: 15 ± 5,51 in Cen compared 15 ± 3,38 in Coh. Regarding life style we found out that compared to Coh Cen had more adherence to strictly mediterranean diet and physical activity. At Follow up no death occurred in Cen but one hospitalization between Cen and two in Coh.
Conclusions: The centenarians of Cilentum, despite of the presence of all typical cardiovascular risk factors, present low incidence of symptoms and signs of overt heart failure probably because of the adherence to mediterranean diet and acvitve life style.

P1006

The role of sodium level and in-hospital mortality in patients with acute, or acute worsening chronic heart failure

M Marija Vavlukis[1]; B Pocesta[1]; H Taravari[1]; E Shehu[1]; D Kitanoski[1]; I Bojovski[1]; I Kotlar[1]; S Kedev[1]
[1]*University Clinic for Cardiology, Skopje, Macedonia The Former Yugoslav Republic of*

AIM of the study: to determine the role of low sodium level (sNa) as a predictor of in-hospital mortality (IHM) in acute and acute worsening chronic heart failure.
DESIGN: observational retrospective study. Included patents admitted to ICU because of AHF. Analyzed variables: demographics: age, gender; co-morbidities, Biochemical: hemoglobin, anemia, renal failure, sodium, creatinine, BUN; Hemodynamic parameters: heart rate, systolic and diastolic BP, LV ejection fraction (based on what patients were divided in PEF-HF and REF-HF), Statistical analyze: descriptive, t-test, Chi square, uni and multivariate logistic regression, ROC Curve. Significance determined at the level of 0.05.
Results: 451pts. at mean age 69,9 ± 10.8, 201(44,6%) females and 250 (55,4%) males were included. Presence of co-morbidities: Afib 41,0%; COPD 23,5%; DM 41,5%; HTA 71,6%; carotid artery disease (CAD) 41,2%; previous symptomatic HF 34,8%; renal failure 12,0%, anemia 31.9%; mean EF 42,9 ± 10,3% (21.3% with PEF-HF (≥50%); HR 109 ± 29 BPM; SBP 143 ± 44, DBP 86 ± 24mmHg; Hgb 13 ± 3.8, BUN 26.8 ± 21.5; creatinine 128.9 ± 124.9mikromol/L; sodium 138 ± 6mmol/L.Pts were divided in two groups reduced sNa < 135 (115 -25.5%), and normal sNa ≤ 135 mmol/L. A total of 108 (23,9%) cardiac deaths were registered (IHD group), with the highest mortality rate during the first 48 hours (68.5%).
Univariate predictors: HLP: beta -.662; p = 0.011, exp(B). 516; HTA: beta -0.751, p = 0.001, exp(B) 0.472; CAD: beta. 931; p = 0.005, exp(B) 2.536; renal failure: beta 0.819, p = 0.007, exp(B) 2.268; sNa < 135: beta 0.743, p = 0.002, exp(B) 2.102; anemia: beta. 930, p = 0.000, exp(B) 2.533; EF categorical: beta 0.746, p = 0.017, exp(B) 2.109; EF (%): beta -.167, p = 0.000; DBP: beta -.299, p = 0.000; SBP: beta -.281, p = 0.000; sodium: beta -.105, p = 0.025; Hgb: -.034, p = 0.000; creatinine: beta. 199, p = 0.000; BUN: beta. 165, p = 0.000. In multivariate analyze as independent predictors for IHM were identified: HLP (p 0.011), high DBP (p 0.000) as negative predictors; CAD (p 0.002), anemia p = 0.042, EF (%) p = 0.005 and sNa < 135mmol/L p = 0.039 as positive predictors. But when we entered low sodium as selection variable, three independent predictors were identified: HTA (p 0.039), DBP (p 0.009) and creatinine (p 0.002).
Variables independently significantly positively associated with low sodium level were low SBP (p 0.002), high BUN (p 0.000), and CAD (p 0.002), while HTA (p 0.025) was independently negatively associated. When we entered IHM as selection variable there were three independently associated predictors added to low sNa: high BUN (p 0.006), creatinine (p 0.026) and presence of CAD (p 0.006). Normal sNa level had good discriminate function (ROC Curve: Area under the Curve. 572, p < 0.024 (CI. 503-.641) (image 1), in predicting absence of IHM.
Conclusion: low sodium is one of the significant independent predictor of in-hospital mortality in patients treated because of acute or acute worsening chronic heart failure.



ROC curve for sNa and IHM

P1007

The beneficial effect of the management of heart failure patients with reduced ejection fraction at an outpatient clinic after hospitalization and applying guideline recommended therapy on mortality

N Nyolczas[1]; B Szabo[2]; M Dekany[1]; D Vagany[1]; T Borsanyi[1]; B Muk[1]; ZS Majoros[1]; M Szabo[1]; RG Kiss[1]
[1]*Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary*; [2]*Orebro University Hospital, Cardiology, Orebro, Sweden*

Background: Mortality of heart failure (HF) is high despite the significant recent advances in pharmacological and device therapy. National data published a few years ago showed nearly 30% annual mortality. The data of European Society of Cardiology Heart Failure Long-Term Registry revealed 23.6% 1-year mortality in patients hospitalized with a diagnosis of HF and 6.4% among patients with chronic stable HF.
Purpose: The aim of the study was to assess the survival data of patients suffering from heart failure with reduced ejection fraction (HFrEF) managed at our HF outpatient clinic after HF hospitalization in the last 15 years.
Patients and methods: We assessed the data of 513 patients with severe HFrEF (LVEF≤40%, NYHA III-IV) managed at our HF outpatient clinic after HF hospitalisation between June of 2001 and June of 2016. At the beginning of the management the patients' characteristics were as follows: mean age 62.6 ± 12.5 years, mean NYHA functional class 3.56 ± 0.45, mean LVEF 27.5 ± 6.9, proportion of men 75.6% and ischemic aetiology 49.8%. We made every effort to achieve the optimal medical and device therapy in all patients. Mean follow-up time was 5.6 ± 4.3 years. Survival was estimated by Kaplan-Meier method.
Results: After optimization of pharmacological therapy 95.6% of patients received ACEi/ARB, 96.8% of them BB and 86.1% MRA. 32.7% of patients on ACEi/ARB therapy got target dose (equivalent to 40 mg enalapril), 80.6% of them received at least the half of the target dose, and mean of the individual value of the ACEi/ARB dose expressed as percent of the target dose was 66.1 ± 33.1%. The target dose of BB was applied in 50.2% of patients, 89.2% of them were treated with at least the half dose, and mean of the individual value of the BB dose expressed as percent of the target dose was 82.2 ± 42.0%. CRTP implantation was performed in 57 patients, CRTD in 64 and ICD in 47 cases. After treatment optimization LVEF (36.4 ± 10.5; p < 0.001) and NYHA functional class (1.75 ± 0.77; p < 0.001) improved significantly. The 1-year mortality was 89.7% and 5-year mortality was 55.0% in this studied patient group.
Conclusion: The mortality rate of severe HFrEF patients managed at an outpatient heart failure clinic after hospitalization and treated with guideline recommended optimal pharmacological and device therapy can be decreased by one third to half compared to the general HF patient population.

P1008

Mortality rate of patients with heart failure with preserved ejection fraction on carvedilol therapy; results from the Croatian heart failure registry

D Markovic[1]; B Jurcevic Zidar[2]; J Macanovic[1]; D Milicic[3]; D Glavas[1]
[1]*University Hospital Center Split, Clinic for heart and cardiovascular diseases, Split, Croatia*; [2]*Public health institute of Split-Dalmatia county, Split, Croatia*; [3]*University Hospital Centre Zagreb, Zagreb, Croatia*

On behalf of: CRO-HF group

Background. The mortality of heart failure (HF) patients is still high in majority countries, despite the quality treatments, new guidelines and continuosly education of medical staff. Treatment for heart failure with reduced ejection fraction (HF-REF) is widely well known and used in medical practice. The treatment approach for heart failure patients with preserved systolic function (HF-PEF), according to recent guidelines and scientific papers, is still not defined.
Purpose: The aim of this study was to analyze mortality rate of HF patients and to investigate how carvedilol therapy in HF-PEF patients influenced on mortality rate after ten-year follow-up from Croatian heart failure (CRO-HF) registry.
Methods: A group of 2203 in-hospital patients with diagnosis of HF (median age 76, 53.3% males, 46.7% females) who were hospitalized at University Hospital Split were analysed. Particularly, after ten-year follow-up, HF-PEF patients on carvedilol therapy were analysed and HF-PEF patients without any beta-blocker on discharge letter were enrolled as control group (119 vs 218, respectively); the data were part of CRO-HF Registry. HF-PEF was classified as EF≥40%. After follow-up, the mortality rate was analysed in the carvedilol and control group.
Results: In-hospital mortality rate of 2203 patients was 13.8%. In-hospital mortality rate was higher in females than in males (females=14.4%, males=12.6%). HF-PEF with EF ≥50% had 37.8% and HF-PEF with EF 40-49% had 24.9% patients. We found significant difference in mortality rate when we compared patients with EF < 50% and EF≥50% (Hi2=4.652; P=0.037; CI=0.069). Patients with EF < 50% had 2.5 higher mortality rate. In the group of patients with EF < 50% mortality rate was 4.2%, and 1.6% in the group of patients with EF ≥50%.

When we compared group on carvedilol therapy with control group we analyzed 337 patients; 159 men and 178 women. The mean age of patients was 77.29 ± 10.2 years. After ten-year follow-up, in carvedilol group 76 patients died and mortality rate was 63%. In the control group 167 patients died and mortality rate was 76%. For comparing these two groups we used chi square test and mortality rate in carvedilol group was significantly lower chi-square=6.212, p = 0.0212.
Conclusion: Ten-year mortality rate of HF patients from CHO-HF registry is still high. We should try to reduce the mortality with quality implementation of guidelines, with better involvement of Heart Failure Association and all society. Carvedilol therapy appears to be associated with lower mortaliy rate in patients with heart failure with preserved systolic function.

P1009
Soluble ST2-receptor (sST2) is more powerful predictor of long-term prognosis in patients with acute decompensated heart failure, compared with copeptin

A Skvortsov[1]; V Protasov[1]; O Narusov[1]; S Nasonova[1]; T Kuznetzova[1]; V Masenko[1]; S Tereschenko[1]
[1]*Russian Cardiology Research and Production Complex, Moscow, Russian Federation*

Background: novel biomarkers sST2 and copeptin are known as powerful predictors of CHF patients (pts) long-term prognosis.Purpose: to evaluate head to head significance of copeptin and soluble ST2 (sST2) in heart failure pts risk stratification in one year follow-up period after acute decompensation (ADHF).
Methods: In the prospective single-center study were included 159 pts with ADHF III-IV FC NYHA. Blood samples to determine NT-proBNP, sST2, copeptin, hsTnT concentration were collected at the admission and at discharge from the hospital, and after 3, 6 and 12 months of follow-up. The combined primary end point of the trial included cardiovascular (CV) death, hospitalization due to HF, episodes of HF deterioration needed additional i/v diuretics and CV death with successful resuscitation.
Results: During 1-year follow-up 56 pts (35,2 %) had 78 (49,1%) cardiovascular events. Biomarker concentrations in low risk pts (without CV events) were significantly lower compared with high risk pts (who have CV events). At the discharge from the hospital sST2 concentrations had the best predictive capacity compared with copeptin and NT-proBNP for the primary end point at 1-year follow-up: AUC=0,768 (95% CI 0,682-0,854) vs 0,735 (95% CI 0,64-0,83) and AUC=0,727 (95% CI 0,637-0,816), respectively, p < 0,001 for all. Lack of copeptin concentration decrease below 28,3 pmol/l and sST2 concentration below 37,8 ng/ml were associated with the highest risk of CV events: respectively HR[95% CI] = 5,14(2,204-11,98), p < 0,0001 and HR[95% CI] = 6,755 [3,026- 15,082], p < 0,0001. Cutting value for NT-proBNP was 1696,0 pg/ml, HR[95% CI] = 4,41 [1,41-9,624], p < 0,0001. Values of sST2 at the discharge additionally to standard clinical model and NT-proBNP levels were the most significant predictor of CV events in long-term follow-up (beta=0,519, p < 0.0001), copeptin was less powerful (beta=0,32, h=0,019). Moreover, in multimarker model, which included all biomarkers only sST2 values had additional significant prognostic information (p = 0,007).
Conclusion: sST2 is more powerful predictor of long-term prognosis in patients with acute decompensated heart failure, compared with copeptin. Discharge values of sST2 from the hospital combined with NT-proBNP have the best predictive capacity to reflect the adverse long term prognosis in patients with ADHF.

P1010
Heart failure and comorbidities in acute coronary syndrome prognosis; a hierarchical analysis of clinical and lifestyle factors per heart failure phenotype, from hellenic heart failure study.

M Kouvari[1]; C Christina Chrysohoou[2]; H Kosyfa[1]; G Kalogirou[1]; P Aggelopoulos[1]; S Iosifidis[3]; A Filippou[3]; E Tsiamis[1]; D Tousoulis[1]
[1]*University of Athens, First Cardiology Clinic, School of Medicine, Athens, Greece*; [2]*University of Athens, Athens, Greece*; [3]*Harokopio University, Nutrition Science - Dietetics, Athens, Greece*

On behalf of: Hellenic Heart Failure study

Background/Introduction: comorbidities in the context of secondary cardiovascular disease prevention highly determines patients' prognosis. Focusing on heart failure and the differential pathophysiology behind its phenotype the "comorbidities" hypothesis remains a scientific field of much interest in the treatment spectrum. Purpose: to investigate the comorbidities in each heart failure phenotype and to classify these clinical as well as lifestyle factors in relation to Acute Coronary Syndrome (ACS) prognosis.
Methods: from May 2006 to March 2009, 1,000 consecutive patients who were hospitalized at a Cardiologic Clinic in Athens with ACS diagnosis were enrolled in the study. In 2016, the 10y follow-up (2006-2016) was performed in 745 participants. Heart failure phenotype was defined according to baseline EF; heart failure with reduced EF (i.e. < 40%) (HFrEF), preserved EF (i.e ≥50%) (HFpEF) and mid range EF (i.e. 40-49%) (HFmrEF). Age, sex, overweight/obesity, current smoking, MedDietScore, physical activity, hypertension, hypercholesterolemia and diabetes mellitus were evaluated in relation to 10y ACS prognosis, in each heart failure phenotype, based on hierarchical classification analysis using Fisher linear discriminant function. Results: The 10y fatal/non fatal ACS incidence was 68%, 53% and 45% in HFrEF, HFmrEF and HFpEF respectively. Crude analysis revealed that ranking from the lowest to the highest EF values (i.e. from HFrEF to HFpEF) patients had higher likelihood to suffer from hypertension (from 62% to 55%, p = 0.04), hypercholesterolemia (from 82% to 73%, p = 0.01) and overweight/obesity (from 32% to 25%, p = 0.10); yet no significant differences were observed as regards diabetes mellitus. In discriminant analysis, in HFpEF patients the predominant predictors associated with 10y ACS prognosis were overweight/obesity (Wilks'Lamda=0.962), current smoking (Wilks'Lamda=0.965), MedDietScore (Wilks'Lamda=0.987) and physical activity (Wilks'Lamda=0.992) (all ps < 0.05). In HFrEF, only hypertension came on the top of the list (Wilks'Lamda=0.954, p = 0.02) whilst the remained factors were not highlighted as important in the classification. In case of HFmrEF results seemed to be closer to their HFpEF counterparts with inconclusive outcomes. Conclusion: ACS prognosis seemed to be highly determined by metabolic comorbidities, namely in HFpEF patients; whilst lifestyle modifications may possess an important supplementary recommendation in the rehabilitation process in this heart failure phenotype.

P1011
Heart failure with reduced LV ejection fraction and atrial fibrillation/flutter, what predicts LV ejection fraction recovery?

D Damon Jackson[1]; P Mottram[1]; C Bowman[1]; J Cameron[1]; E Quine[1]; S Lockwood[1]
[1]*Monash University, Monash Heart, Melbourne, Australia*

Introduction: Heart failure with reduced left ventricular ejection fraction (HFREF) and atrial arrhythmias (Atrial Fibrillation/Flutter) often co-exist, and the relationship between reduced ejection fraction (LVEF) and the uncontrolled heart rate (HR) is unclear.
Objective: To explore the factors associated with recovery of LVEF in patients presenting with both atrial arrhythmia and reduced LVEF (< 45%).
Methods: Patients with HFREF and atrial arrhythmia admitted to a specialist HFREF clinic were included. Treatment was according to Heart Failure guidelines; atrial arrhythmias were managed at physician's discretion. Demographic, clinical and echocardiographic data were collected at baseline and follow up. Patients with improved LVEF (>10% increase) were compared to patients with unchanged LVEF.
Results: 45 patients (64 ± 12 years, 24% female, baseline LVEF 25 ± 9%) were included. At 9 ± 5 months follow-up 47% (n = 21) demonstrated improved LVEF (repeat EF 48 ± 8%, p < 0.01). Improved LVEF pts had greater reduction in HR compared with unchanged LVEF pts (-42 ± 24 vs −8 ± 16 bpm, p < 0.01). Increase in LVEF correlated with reduction in HR (r -0.59) regardless of rhythm. Pts with improved LVEF were less likely to have hypertension, documented IHD or diabetes (all p < 0.01). Left atrial size was similar between groups (p = 0.51) but improved LVEF had smaller LVEDD (p = 0.04) and higher mitral annular velocities (p = 0.01) at baseline.
Conclusions: In patients presenting with HFREF and atrial arrhythmias, improved heart rate control was associated with improvement in LVEF, regardless of rhythm. LVEF was also more likely to improve in those without coronary artery disease, hypertension or diabetes.

P1012
Red blood cell distribution width predicts the risk of heart failure exacerbations but not death in stable patients with chronic heart failure in a short-term observation

A M Anna Maryla Kowalczys[1]; M Bohdan[1]; M Gruchala[1]
[1]*Medical University of Gdansk, 1st Department of Cardiology, Gdansk, Poland*

Introduction: Chronic heart failure (CHF) is one of the most challenging problems in cardiology nowadays. Although many patients are treated optimally, the prognosis still remains poor. There are many biomarkers valuable in predicting the outcome of patients with CHF. Some authors have reported that RDW may be useful for risk stratification in patients hospitalized with acute heart failure. Nevertheless, its role in stable CHF still remains unclear.
PURPOSE: The aim of the study was to assess the relationship between RDW and major adverse cardiac events (MACEs) in stable patients suffering from CHF.
Methods: There were 75 patients: 70 (93%) men and 5 (7%) women (mean age: 59 ± 12 years) with stable CHF, NYHA class 2,1 ± 0,57, with reduced left ventricular ejection fraction (LVEF) recruited for the study. All patients underwent following

examinations: medical history, physical examination, laboratory tests including blood morphology with RDW and BNP, 12-lead electrocardiogram, chest X-ray, echocardiogram, six-minute walk test (6MWT). All patients recruited for the study were treated according to ESC guidelines. The follow-up period was 6 months. MACEs were defined as: death of all causes, cardiovascular death, hospitalization due to the heart failure exacerbation. In order to establish the link strength and direction between variables, the correlation analysis was used in calculating the Pearson and/or Spearman correlation coefficients. In all the calculations the level of significance was set at $P = 0.05$.

Results: The LVEF ≤35% (mean 23 ± 7%) was confirmed in all patients as well as elevated BNP level (762 ± 717 pg/ml). The RDW was increased in the majority of patients and achieved 15 ± 1.8%. The percentage of patients with heart failure exacerbation was 13% at 3 months and 24% at 6-month follow-up. The mortality rate was 4% at 3 months and 6% at 6-month follow-up. We found that RDW value was significantly higher in patients with CHF decompensation during the 6-month observation (16.7 ± 1.5% vs. 15 ± 1.7%, $P < 0.0001$). There was no relationship between RDW value and death during 6-month follow-up in stable patients with CHF.

Conclusions: Red blood cell distribution width may be a potential predictor of subsequent hospitalizations due to heart failure decompensation in stable patients with CHF with reduced left ventricular ejection fraction in short-term observation. No other correlations between RDW and MACEs were found.

P1013

Heart failure in patients with acute coronary syndrome: characterization of population and impact on prognosis.

J Pais[1]; B Picarra[1]; RA Guerreiro[1]; D Bras[1]; J Carvalho[1]; K Congo[1]; AR Santos[1]; M Carrington[1]; J Aguiar[1]
[1]*Hospital Espirito Santo de Evora, Departement of Cardiology, Evora, Portugal*

Introduction: Patients (P) with chronic heart failure (CHF) usually have multiple co-morbidities, so their approach in the context of Acute Coronary Syndrome (ACS) can be an important challenge.

Purpose: To characterize the P with ACS and previous CHF and to evaluate the impact of the presence of CHF on the therapeutic approach, complications and in-hospital mortality.

Methods: We studied 745 P admitted in our Cardiac Intensive Care Unit with the diagnosis of ACS. We considered 2 groups: P with prior CHF and P without previous CHF. The patient's age, gender, personal history, clinical and electrocardiographic presentation of ACS, in-hospital therapy, left ventricular ejection fraction, coronary angiography and angioplasty were recorded. During hospitalization the following complications were defined: heart failure, cardiogenic shock, need of invasive mechanical ventilation, re-infarction, mechanical complications, aborted sudden death, stroke and major haemorrhage. In-hospital mortality was compared between both groups.

Results: P with previous CHF constituted 7.1% (53 P) of the study population. These patients were older (77.3 ± 8.9 vs 66.6 ± 13.6, $p < 0.001$), had higher prevalence of history of arterial hypertension (88.7% vs 76.2%, $p = 0.03$), myocardial infarction (50.9% vs 24.3%, $p < 0.001$), coronary surgical revascularization (18.9% vs 5.2%, $p < 0.001$), valvular disease 22.6% vs 1.4%, ($P < 0.001$), peripheral arterial disease (22.6% vs 5.1%, $p < 0.001$), chronic renal failure (41.5% vs 10.1%, $p < 0.001$), chronic lung disease (22.6% vs 4.2%, $p < 0.001$) and haemorrhage (9.6% vs 1.8%, $p < 0.001$). P with previous CHF presented more frequently with NSTEMI (62.3% vs 45.7%, $p < 0.001$) and indeterminate location myocardial infarction (26.4% vs 4.6%, $p = 0.02$).At admission they also presented Killip-Kimbal class ≥ 2 more frequently (64.2% vs 16.8%, $p < 0.001$) and less frequently with chest pain (58.5% vs 87.7%, $p < 0.001$).

During hospitalization, P with prior CHF underwent less coronary angiography (56.6% vs 86.7%, $p < 0.001$), less radial artery access for coronary angiography (53.6% vs 79.0%, $p = 0.001$), and fewer angioplasties (32.1% vs 68.7%, $p < 0.001$). The presence of prior CHF was associated with lower left ventricular ejection fraction (40.9 ± 10.4% vs 48.2 ± 9.9%, $p = 0.004$), with development of acute decompensated heart failure (47.2% vs 12, 4%, $p < 0.001$), need for non-invasive ventilation (17.0% vs 2.2%, $p < 0.001$) and higher in-hospital mortality (13.7% vs 4.8%, $p = 0.008$). There is no significant statistically differences on re-infarction, mechanical complications, aborted sudden death and stroke.

Conclusion: The clinical and electrocardiographic presentation of ACS seems to be influenced by the presence CHF. The presence of prior CHF was associated with development of acute decompensated heart failure and higher in-hospital mortality.

P1014

Body composition as a risk of prolonged hospitalisations in patients with heart failure and / or respiratory distress

L Leslie Verdeja Vendrell[1]; D Gonzalez-Islas[2]; A Navarrete-Penaloza[2]; A Jimenez-Cepeda[2]; G Perez-Cortes[2]; A Orea-Tejeda[2]; R Sanchez-Santillan[2]; V Pelaez-Hernandez[2]; B Robles-Uribe[2]; A Figueroa-Herrera[2]; S Torres-Montiel[2]
[1]*Autonomous University of Puebla, Puebla, Mexico*; [2]*Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Distress Clinic , Mexico City, Mexico*

Background: The muscle mass of the skeletal muscle decreases around 0.1 - 0.5% per year at the age of 30, and this loss increases starting from the age of 65. Body composition has been identified as a predictor of longer hospital stays on different populations. Malnutrition in patients delays the total hospitalization days, and this results will affect the morbidity and mortality patients. However, in patients with Heart Failure (HF) and Respiratory Distress (RD), it is unknown what type of body changes can prolong hospitalizations days. Objective: To determine if body composition is a predictor of prolonged hospital staying.

Methods: A cross-sectional study involving patients older than 18 years hospitalized with confirmed diagnosis of HF and / or RD. Prolonged hospital staying were defined as more than 7 days. Body composition analysis was performed using electrical impedance by vector analysis (BIVA) and was classified into normal composition, obesity and cachexia. A logistic regression was performed to determine the risk of hospitalization accordingly. Results: 71.7% of the population were women (mean age: 54.6 ± 21.18), of which 68.4% had a hospital stay> 7 days. Those with prolonged hospital staying had a higher prevalence of COPD (56.5% vs 18.2%, $p = 0.008$), HF (45.8% vs 22.7%, $p = 0.100$). Subjects with obesity (OR: 4.68, CI 95%, 1.04 - 21.03, $p = 0.044$) and cachexia (OR: 5.85, CI 95%, 1.22-27.99, $p = 0.027$) had greater risk of prolonged hospital staying compared to subjects with normal body composition. Conclusions: Obesity or cachexia increase the risk of prolonged hospitalization staying in patients with HF and / or RD.

P1015

Genetic predictors of acute and chronic heart failure in patients with acute acute coronary events

NG Lozhkina[1]; V Kozik[1]; EA Glebchenko[1]; MK Khasanova[1]; MI Voevoda[2]; YI Ragino[2]; VN Maksimov[2]; AD Kuimov[1]
[1]*Novosibirsk State Medical University, department of faculty therapy, Novosibirsk, Russian Federation*; [2]*Institute of Internal Medicine, Laboratory of Molecular Genetics, Novosibirsk, Russian Federation*

The purpose of the research is to test SNPs for association with the severity of acute heart failure and decreased ejection fractions in patients with acute coronary syndromes (ACS). Materials and methods. 280 patients with acute coronary syndrome (ACS) admitted to the intensive care unit of Novosibirsk Municipal Clinical Hospital No. 1, of whom 175 were men (mean age, 56.2 ± 5.2 years) and 105 were women (mean age, 62.1 ± 5.3 years). ACS was diagnosed based on criteria developed by the European Society of Cardiology and the American College of Cardiology (2000). Cardiac ventriculography and coronary angiography were performed on day 1–3 following the onset of ACS symptoms. SNPs were detected and identified in real-time PCR assays. The following SNPs were retained for further consideration: rs499818, rs619203, rs10757278, rs1333049, rs1376251, rs2549513, rs4804611, and rs17465637. Results. It has been found that some of the SNPs found quite differently contribute to ACS prognosis. Reliable differences of LVEF average level at carriers of different genotypes both in the general group, and at gender separation were not revealed in the analysis of association of left ventricular ejection fraction (LVEF) with rs1376251, rs17465637, rs619203, rs2549513. Statistically significant differences were not revealed in the analysis of frequencies of genotypes and alleles of studied polymorphisms in groups with the different Killip index without gender separation and separately at men and women.

Conclusions: The genetic markers rs480461, rs499818, rs1333049 and rs10757278 can be used in the prognostic assessment of patients with acute and chronic heart failure at acute coronary syndromes.

P1016

Polimorphism of cyp7a1 gene as marker of cardiovascular complications for hypertensive patients with 2 type diabetes and nephropathy

O Chernatskaya[1]; N Demikhova[1]
[1]*Sumy State University, Medical Institute, Sumy, Ukraine*

Cholesterol 7-alpha-hydroxylase (CYP7A1) is a microsomal cytochrome P450 that catalyzes the first step in bile acid synthesis. CYP7A1 gene encoding CYP7A1 enzyme is located on the 8q11-12 chromosome and it consists of 6 exons and 5

introns. The CYP7A1 genetic variants influenced serum levels of low density lipoproteins and triacylglycerols. Bile acid metabolism was reported to be involved in glucose metabolism homeostasis. However, the exact relationship between bile acid and glucose metabolism as well as insulin sensitivity is not clarified. Participants with insulin resistance had significantly higher risk of hyperbileacidemia.

Aim of study: the determination of interconnection between the level of glycated hemoglobin (HbA1c) and three genotypes of CYP7a1 gene for prevention cardiovascular complications in patients with type 2 diabetes mellitus (DM) and concomitant arterial hypertension (AH).

Methods: We examined 130 patients during our clinical trial. There are 80 patients with type 2 DM and AH in the first (I) group and 50 persons with AH in the second (II). The middle age are (57 ± 0.23) and (69 ± 0.57), t=19.52, p < 0.001 years.

The method for diagnostic different allele variants is polymerase chain reaction.

Results: The genotypes AA, AC and CC are determined in 5 (6.25%), 22 (27.5%), 53 (66.25%)patients respectively in the I group and 20 (40%), 19 (38%), 11 (22%) in the II group. The levels of HbA1c are (6 ± 0.25) % and (4.9 ± 0.31) %, t=2.76, p < 0.01 for AA genotype, (7.3 ± 0.6) % and (5.7 ± 0.42) %, t=2.18, p < 0.05 for AC genotype, (8.2 ± 0.59) % and (6.1 ± 0.45) %, t=2.83, p < 0.01 for CC genotype.

The mean levels of HbA1c were (6.8 ± 0.21)%, (4.2 ± 0.43)%, t=5.43, p < 0,001 for participants from the I,II groups respectively. The mean levels of AI were (3.8 ± 0.04), (3.1 ± 0.02), t=15.65, p < 0,001 for participants from the I,II groups respectively. The levels of systolic BP were (156 ± 0.45)mmHg, (143 ± 0.66)mmHg, t = 16.27, p < 0.001 and of diastolic – (105.3 ± 0.6)mmHg, (94 ± 0.43)mmHg respectively for patients with combination of AH and type 2 DM and for persons with AH. The higher levels of BP, HbA1c and more severe dyslipidemia are the characteristics of patients with AH and type 2 DM in comparing with persons had only AH.

Conclusions: CC allele of CYP7a1 gene is more popular for patients with type 2 DM and concomitant AH. CC genotype is associated with higher levels of HbA1c which is a risk factor of cardiovascular and cerebrovascular events. As a result the combined therapy is necessary for prevention severe complication of DM and AH especially with CC allele of CYP7a1 gene. There is the connection between factors of CVC such as AI, HbA1c, systolic and diastolic BP for patients with AH and type 2 DM. It is very important to define these markers for preventing end points and for improving treatment.

P1017

The relation between the low triiodothyronine syndrome and plasma selenium concentration in HFrEF - Pilot study.

MM Magdalena Maria Fraczek-Jucha[1]; K Zbierska-Rubinkiewicz[1]; KA Plens[2]; R Rychlak[1]; J Nessler[1]; A Gackowski[1]

[1]Jagiellonian University Medical College, Department of Coronary Disease and Heart Failure, John Paul II Hospital, Krakow, Poland; *[2]KCRI, Krakow, Poland*

Background/Introduction: The function of deiodinases - selenoproteins converting tetraiodothyronine (T4) to triiodothyronine (T3) may be disturbed by oxidative stress accompanying heart failure. It is hypothesized that selenium (Se) is used by glutathione peroxidase to eliminate reactive oxygen species. Selenium deficiency causes lack of deiodinase resulting in decreased T4 to T3 conversion.

Purpose: To evaluate prevalence of low T3 syndrome in chronic heart failure and to assess its clinical significance.

Methods: Research conform to the principles of the Declaration of Helsinki of the World Medical Association. The study group consisted of 43 consecutive patients with HFrEF, NYHA III-IV. Exclusion criteria: thyroid dysfunction, severe systemic disease, treatment with amiodarone, steroids or propranolol. Patients with low T3 formed Group 1 and remaining ones - control Group 2.

Results: Group 1 consisted of 6 patients and Group 2 consisted of 37 patients - the prevalence of low T3 was 14%. Patients with low T3 concentration presented higher levels of NT-proBNP (19106.00 vs. 3617.43 pg/ml, p = 0.0004), hsCRP (29.31 vs. 5.17 mg/l, p = 0.0227) and RVSP (55.67 vs 40.64 mmHg, p = 0.0184) but lower Se levels (38.75 vs 57.54 μg/l, p = 0.0078) and LVEF (13.14 vs 27.68 %, p < .0001). Group 1 had higher in-hospital mortality (50% vs 0%), p = 0.0017. Results presented in Table 1 indicate that inflammatory status and Se deficiency may be associated not only with low fT3 levels but also with the poor prognosis in heart failure.

Conclusion(s): Further research concerning coexistence of low T3 syndrome, Se deficiency, deiodinase malfunction and progression of heart failure should be conducted. If the influence of low T3 on prognosis is confirmed, supplementation of T3 and/or Se may become a therapeutic option in selected patients with HFrEF.

P1018

Significance of novel biomarkers for short-term and long-term prognosis in patients after acute heart failure decompensation

V N Protasov[1]; AA Skvortsov[1]; OY Narusov[1]; D E Protasova[2]; TV Kuznetcova[1]; GA Tkachev[1]; VP Masenko[1]; SN Tereshchenko[1]

[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation; *[2]National Research Center for Preventive Medicine, Moscow, Russian Federation*

Background: novel biomarkers are powerful predictors of CHF patients (pts) prognosis.Purpose: to evaluate significance of soluble ST2 receptor, copeptin, galectin-3, hs Troponin-T (hsTn-T), NT-proBNP and NGAL for short-term and long-term prognosis in patients after acute heart failure decompensation (ADHF).

Methods: In the prospective single-center study were included 159 pts with ADHF III-IV FC NYHA. Blood samples to determine NT-proBNP, sST2, copeptin, hsTnT, NGAL, Gal-3 were collected at the admission and at discharge from the hospital. The combined primary end point of the trial included cardiovascular (CV) death, hospitalization due to HF, episodes of HF deterioration needed additional i/v diuretics and CV death with successful resuscitation.Results: During 1-year follow-up 56 pts (35,2 %) had 78 (49,1%) cardiovascular events. Biomarker concentrations in low risk pts (without CV events) were significantly lower compared with high risk pts (who have CV events). The positive predictive values were found for all tested biomarkers. For short-term pts prognosis (90 days) admission hsTn-T values were the best compared with other biomarkers: AUC=0,811 (95% CI 0,707-0,916), p < 0,0001. Cutting value for admission hsTn-T was 33,3pg/ml, OR[95% CI]=9,319 (1,996-43,521), p = 0,001. In long-term period hsTn-T's predictive capacity decreased and at 12 months pts follow-up AUC for end point was only 0,663 (95% CI 0,567-0,758), p = 0.001. For long-term prognosis (1 year) sST2 at the discharge from the hospital had the best predictive capacity compared with NT-proBNP, copeptin and other biomarkers: AUC = 0,768 (95% CI 0,682-0,854) vs 0,727 (95% CI 0,637-0,816) and 0,735 (95% CI 0,64-0,83) respectively, p < 0,0001 for all. Lack of sST2 concentration decrease below 37,8 ng/ml, copeptin concentration below 28,3 pmol/l and NT-proBNP bellow 1696,0 pg/ml, were associated with the highest risk of CV events: respectively OR[95% CI] = 6,755 [3,026-15,082], 5,14[2,204-11,98] and 4,41[1,41-9,624], p < 0,0001 for all. Only one combined biomarkers model in our study significantly increases opportunities in patients long-term risk stratification. The model with combined concentrations of sST2 and NT-proBNP at the discharge had the best predictive value in the medium (180 days), and long-term (365 days) pts prognosis: AUC 0,821 (0,74-0,901), p < 0.0001; HR[95% CI] = 3,33 (1,726-6,434) p < 0.0001 and AUC 0,802 (0,72-0,884), p < 0.0001; HR[95% CI] = 3,54 (2,078-6,035), p < 0.0001, respectively. The highest risk of CV events [OR=11,8 (95% CI 3,16-43,77) p < 0,0001] had pts with discharge and sST2 and NT-proBNP concentrations ≥ cutting values (respectively ≥37,8 ng/ml and ≥1696,0 pg/ml).Conclusion: Admission hsTn-T concentrations are the best predictor of adverse short-term prognosis in pts with ADHF. Combined sST2 and NT-proBNP values at the discharge are more powerful predictor of medium and long-term prognosis in patients after ADHF, compared with other novel biomarkers.

P1019

Evaluation of NT-proBNP role in risk stratification of patients with heart failure in 12 and 18 months follow-up

A Curti Gialdino[1]; FA Immordino[1]; S Novo[1]

[1]University Hospital Paolo Giaccone, Department of Sciences for Promoting Health (PROSAMI), Chair and post-graduate School of Cardiovascu, Palermo, Italy

Background: Patients affected by heart failure (HF) commonly undergo multiple hospitalizations.

Aim: This study want to verify the prognostic role of NT-proBNP levels during hospitalization in a 12 and 18 months follow-up.
Methods: We enrolled 170 patients, 85 with preserved (HFpEF) and 85 with reduced ejection fraction (HFrEF), collecting samples for the evaluation of NT-proBNP levels at baseline and at discharge from hospital. We assessed rates of mortality, new MACE, new hospital admission because of HF and fatal/not fatal events.
Results: In HFrEF patients we found higher predictive values for mortality in both our controls (all $p < 0{,}0001$) while the area under the ROC curve values were always higher at discharge (AUC >0,82). A predictive value of NT-proBNP for MACE and for fatal/not fatal events was also found (all $p < 0{,}002$), with a stronger relationship with discharge assays (all $p < 0{,}0001$). On the contrary, in HFpEF patients only discharge assay seems to have a prognostic role for all outcomes in both our two controls ($p < 0{,}01$) but with lowers predictive values. To assess the independence of our NT-proBNP evaluations we add consecutively our titrations in a multivariate Cox regression models founding the ones with the higher hazard ratio (HR) for all outcomes we evaluated except for new hospitalization because of HF both within 12 and 18 month compared to others variables evaluated (age, sex, haemoglobin, serum creatinine and troponin, systolic blood pressure, heart rate and ischemic etiology). NT-proBNP at discharge always are the one with higer HR compared to admission ones both in HRrEF patients and HFpEF patients.
Conclusions: NT-proBNP titrations during hospitalization are predictive of mortality, MACE and fatal/not fatal events but not for new hospitalization because HF after 12 and 18 month from hospitalization. Discharge assay seems to have the most predictive value compared to admission one.

Choice of an anticoagulant affects endothelial function but not long-term prognosis in patients with acute decompensated chronic heart failure

IV Shevchenko[1]; AA Shavarov[1]; GK Kiyakbaev[1]; VS Moiseev[1]

Objective: to estimate the effect of unfractionated heparin (UFH), enoxaparin or fondaparinux on long-term prognosis in patients, hospitalized with acute decompensated chronic heart failure (ADCHF).
Materials and Methods: The study included 60 ADCHF patients with sinus rhythm, mean age 69 ± 10 years, 35 women (58%), treated with standard ADCHF therapy. Patients with acute exacerbation of chronic diseases and active cancer were excluded from the study. The control group included 20 patients with compensated CHF (NYHA class II or III), mean age 68 ± 9 years, 11 (55%) women, who also received standard CHF therapy. On admission and after anticoagulant treatment had been finished, brachial artery diameter was measured during postocclusion reactive hyperemia (FMD), using a noninvasive echo-Doppler method. Endothelial dysfunction was considered as brachial artery (BA) FMD ratio (artery diameter before/after compression) of less than 10%. Twelve months after the admission all ADCHF patients were contacted by phone for end-points (rehospitalization and/or death).
Results: All ADCHF patients had severe endothelial dysfunction (ED), compared with controls, with baseline FMD ratio of -2.15 ± 2.86 and $9.00 \pm 1.47\%$ ($p < 0{,}001$), respectively. In all three anticoagulant groups there was significant difference between the baseline and 'after treatment' measurements: with -1.5 ± 1.8 and $5.72 \pm 2.03\%$ ($p = 0.0001$) in the UFH group ($n = 20$), -3.1 ± 2.0 and $6.75 \pm 1.47\%$ ($p = 0.0009$) in the enoxaparin group ($n = 20$) and -3.3 ± 2.1 and $7.02 \pm 1.67\%$ ($p = 0.0001$) in UFH group ($n = 20$). Delta FMD ratios were the lowest in the heparin group and the highest in the fondaparinux group, though not statistically significant: 6.70 ± 2.30 vs 9.53 ± 1.45 vs $9.90 \pm 2.07\%$, respectively ($p = 0.06$). Despite the received treatment, within 12 months after hospitalization due to ADCHF, 38 (63%) patients had combined end points: 15 patients in the UFH group, 12 in the enoxaparin and 11 in the fondaparinux group ($p = 0.07$). Thirteen (22%) of them died: 6, 4 and 3 patients, respectively ($p = 0.16$). No significant correlation was found between the chosen anticoagulant: UFH (R=0,17, $p = 0{,}44$), enoxaparin (R=0,13, $p = 0{,}81$) or fondaparinux (R=0,14, $p = 0{,}32$) and long-term prognosis.
Conclusion: In ADCHF patients and sinus rhythm, despite standard treatment, long-term prognosis is still poor. Though the choice of an anticoagulant can affect endothelial function, it does not improve their long-term prognosis by lowering the risk of rehospitalisation or/and death within 12 months. Key words: acute decompensated chronic heart failure, sinus rhythm, endothelial dysfunction, flow-mediated endothelium-dependent vasodilation

Introduction: Heart failure with recovered ejection fraction (HFrecEF) has been recognised as a new classification with distinct clinical characteristics and prognosis. Data on Asian patients remained limited. This study aimed to characterise the HRrecEF population and compare it with those with persistently reduced left ventricular ejection fraction (LVEF).
Methods: This was a retrospective study looking at patients who were followed up in Heart Failure Clinic Hospital from April 2013 to December 2016. HRrecEF was defined as current LVEF ≥40% with previous documented LVEF <40%; those with reduced LVEF (HFrEF) had current and previous LVEF <40%.
Results: Due to limitation of resources, only 74 clinic patients had repeat echocardiograms. From this, 35 patients had HFrecEF and 26 patients had HFrEF. Median age was 62 (IQR 52 - 67). Males ($n = 40$; 65.6%) and Malay race ($n = 33$; 54%) predominated in both groups. Hypertension ($p = 0.006$) and COPD ($p = 0.029$) appeared to be common co-morbidities in the HFrecEF group. Systolic blood pressure <130mmHg ($p = 0.008$) and lower baseline alanine transaminase (ALT) ($p = 0.034$) have been associated with recovery of LVEF. There was also improvement of NYHA class noted in patients with HRrecEF. Hospital readmission rates were significantly lower in the HFrecEF group ($p = 0.029$). No mortality was recorded in both groups.
Discussion: The results highlighted the importance of risk factor control, especially hypertension and smoking, as part of heart failure management. The significance of ALT as a biomarker of recovery is yet to be determined; but this serves as precursor to future studies.
Conclusion: In this cohort of patients with HFrecEF, patients have better outcomes with fewer admissions, however future studies need to be conducted to understand further the nature of this subset of patients.
