Purpose: In order to investigate the relationship between CRP and PCT and NT-proBNP we have studied these proteins in a population of patients with ACS.
Methods: In our prospective study we have analysed 575 patients at admission in our Coronary Intensive Care Unit for ACS confirmed by laboratory analysis, ECG, echocardiogram and a coronary angiography. Patients with infections were excluded. We divided our population into four groups, according to the levels of PCT and CRP at admission: Group 1 PCT + /CRP + , Group 2 PCT-/CRP + ; Group 3 PCT + /CRP-; Group 4 PCT and CRP normal. In particular we evaluated in these groups the distribution of the levels of NT-proBNP, diabetes and Lp(a).
Results: In Group 1 NT-proBNP (845,85 pg/ml) and Lp(a) (30,25 mg/dl) were more elevated, in comparison with Group 2 (521,35 pg/ml NT-proBNP and 25,45 mg/dl Lp(a)), Group 3 (273,70 pg/ml NT-proBNP and 19,70 mg/dl Lp(a) and Group 4 (329 pg/ml NT-proBNP and 19,25 mg/dl Lp(a)). In Group 1 there were 34% diabetics patients, 28% in Group 2, 29% in Group 3, 21% in Group 4.
Conclusions: Our results suggest that PCT and CRP are particularly elevated in patients with a larger ventricular impairment, as measured by NT-proBNP levels. In our population elevated levels of Lp(a) are related to more severe coronary disease. Our data suggest that PCT and CRP can be considered as stress proteins that rise in patients with increased myocardial damage.

Elevated Levels of urinary 8-oxo-7,8-dihydroguanosin in hospitalized patients with heart failure

H Hua Wang[1]; JF Yang[1]; YY Li[1]; K Chai[1]; JP Cai[2]
[1]*Beijing Hospital,National Center of Gerontology, Beijing, Department of Cardiology, Beijing, China People's Republic of*; [2]*Beijing Hospital,National Center of Gerontology, Beijing , the Key Laboratory of Geriatrics, beijing, China People's Republic of*

Funding Acknowledgements: Funding the National Key Technology Support Program of china. Research subject number: BJ-2012-143

Background: Oxidative stress is known to play a crucial role in the pathogenesis of heart failure. 8-oxo-7,8-dihydroguanosin (8-oxoGsn) is the product of oxidative RNA damage and has high concentration in urine. Recent researches showed that RNA oxidation played an important role in the pathogenesis of many diseases, such as Parkinson, Alzheimer's disease, coronary atherosclerosis and diabetes. However, there is no report on correlation between 8-oxoGsn and heart failure.
Purpose: To investigate whether urinary 8-oxoGsn, a product of oxidative RNA damage, is a clinically useful biomarker for the severity of heart failure and oxidative stress levels in failing hearts.
Methods: We enrolled 149 hospitalized heart failure patients from March 2014 to January 2016,collected clinical data and liquid chromatography tandem mass spectrometry (LC-MS/MS) method established by our laboratory was used to detect the levels of 8-oxoGsn in urine after admission, which was adjusted by creatinine content. Age and sex-matched healthy subjects n=155 were enrolled as the control group. We measured serum NT-proBNP, D-dimer, hemoglobin, interleukin-6 and creatinine, and LVEF were evaluated by echo.
Results: Compared with the control group, the level of 8-oxoGsn in patients with heart failure was significantly increased: [4.68 3.47 6.62 VS. 2.75 2.59 2.85 P = 0.001](Figure 1). We divided the patients with heart failure into two groups at LVEF of 45%, 68 patients with EF≥45% and 74 patients with EF 45%. There was no difference of 8-oxoGsn levels in these two groups[4.02 3.31 5.88 VS. 4.90 3.44 7.67 P=0.082] (Figure1). Correlation analysis showed that 8-oxoGsn level was positively correlated with NT-proBNP and D-dimer and negatively correlated with hemoglobin and creatinine clearance (table 1).

Conclusion: Patients with heart failure had high level 8-oxoGsn in urine, and had independent positive correlation with NT-proBNP, which was an index of ventricular stretch and synthesized in response to wall stress. 8-oxoGsn is a clinically useful biomarker to evaluatethe severity of HF as well as the status of oxidative stress in patients with HFpEF and HFrEF.

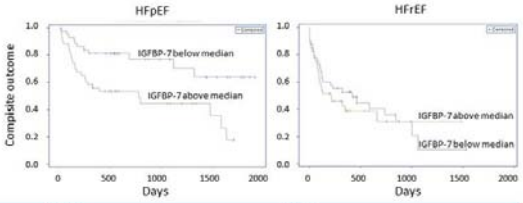
Serum IGFBP-7 is associated with diastolic dysfunction and predicts outcomes in heart failure and preserved ejection fraction

C Camilla Hage[1]; M Bjerre[2]; J Frystyk[2]; H Gu[3]; K Brismar[4]; E Donal[5]; J-C Daubert[5]; C Linde[1]; LH Lund[1]

[1]Karolinska Institutet, Department of Medicine, Cardiology unit, Stockholm, Sweden; *[2]Aarhus University, Department of Clinical Medicine, Medical Research Laboratory, Aarhus, Denmark*; *[3]Karolinska Institute, Department of Clinical Science, Intervention and Technology , Stockholm, Sweden*; *[4]Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden*; *[5]Département de Cardiologie & CIC-IT U 804, Centre Hospitalier Universitaire de Rennes, , Rennes, France*

On behalf of: KaRen group

Purpose: Insulin-like growth factor-binding protein 7 (IGFBP-7), a marker of fibrosis, has been associated with cardiac hypertrophy and diastolic dysfunction in heart failure (HF). We investigated serum IGFBP-7: 1) concentrations in HF with reduced ejection fraction (HFrEF) vs. preserved EF (HFpEF); 2) associations with diastolic dysfunction; 3) and associations with prognosis.
Methods: In the Karolinska Rennes (KaRen) HFpEF biomarker sub-study, consisting of 86 patients with HFpEF (EF ≥45%) and 86 patients with HFrEF, we correlated serum IGFBP-7 with clinical data and diastolic function and assessed associations between IGFBP-7 and the composite outcome of all-cause mortality and HF hospitalization (and in HFrEF transplant or LVAD), using Kaplan-Meier and multivariable Cox regression analyses.
Results: Serum IGFBP-7 (median; IQR) was lower in HFpEF (102; 85-128 ug/L) compared to HFrEF (152; 120-206 ug/L; $p < 0.001$). In both HFpEF and HFrEF, IGFBP-7 correlated with NYHA class (r=0.25; $p = 0.020$ and r=0.25; $p = 0.022$), NT-proBNP (r= 0.53; $p < 0.001$ and r= 0.50; $p < 0.001$), eGFR (r= -0.47; $p < 0.001$ and r= -0.45; $p < 0.001$) and IGFBP-1 (r= 0.30; $p = 0.005$ and r= 0.69; $p < 0.001$). In HFpEF, IGFBP-7 correlated with E/E´ (r=0.31; $p = 0.012$), E/A ratio (r=0.31; $p = 0.011$), and RV end-diastolic area (r=0.27; $p = 0.032$). In HFrEF, but not HFpEF, IGFBP-7 correlated with age (r=0.29; $p = 0.009$) and atrial fibrillation (r=0.34; $p = 0.002$).
Over a median follow-up of 522 (IQR: 238-1089) days in HFpEF and 204 (IQR: 56-415) days in HFrEF, IGFBP-7 predicted the outcome in Kaplan-Meier and multivariable Cox regression in HFpEF, but not in HFrEF (Figure 1).
Conclusions: In HFrEF, serum IGFBP-7 was elevated and associated with HF severity but not prognostic, suggesting a risk marker role. In HFpEF, serum IGFBP-7 was less elevated but independently associated with both severity of HF and prognosis, suggesting that IGFBP-7 may contribute to the progression of HFpEF through oxidative stress and inflammation.



Parameter	HFpEF All-cause mortality or HF hospitalization (n=86)				HFrEF All-cause mortality or HF hospitalization (n=30)

Circulating nitric oxide metabolites predict outcomes of cardiac surgery for heart failure with reduced ejection fraction

S Sergey Mikheev[1]; IA Mandel[2]; VM Shipulin[1]; IV Sukhodolo[3]; YK Podoksenov[1]; Y Svirko[1]; AS Pryakhin[1]; EA Aleksandrova[1]

[1]State Research Institute of Cardiology of Tomsk, Department of cardiovascular surgery, Tomsk, Russian Federation; *[2]Federal Scientific Clinical center of specialized methods medical care and medical technology, Department of anesthesiology and intensive care, Moscow, Russian Federation*; *[3]Siberian State Medical University, Department of morphology and general pathology, Tomsk, Russian Federation*

Introduction: Markers of endothelial function including endothelin-1 (ET-1), nitric oxide (NO) metabolites (nitrate and nitrite) and asymmetric dimethylarginine (ADMA) have been identified as potent predictors of outcome in multiple heart failure models. Cardiac surgery in patient with heart failure with reduced ejection fraction (HFrEF) requires precise evaluation of risks and benefits and is still in need of early predictors of acute heart failure and other complications in postoperative period.
Purpose: We aimed to assess the dynamics of endothelial function markers (NO metabolites, ADMA, ET-1) during coronary artery bypass grafting (CABG) with cardiopulmonary bypass (CPB) in patients with heart failure with reduced ejection fraction to estimate their significance as predictors of acute heart failure and other complications in postoperative period.
Methods: The study included 66 patients subdivided into two groups: patients without heart failure with preserved ejection fraction and normal left ventricle volume, n= 32 (Group I) and HFrEF patients with left ventricle dilation (EF < 35%, left ventricle systolic volume index > 60 mL/m2), n=34 (Group II). All patients had undergone CABG with CPB for multivessel coronary artery disease in 2015-2016. We determined the concentration of ET-1, ADMA and nitric oxide metabolites: total content (NOx.total), nitrite (NO2-) and nitrate (NO3-) in plasma before the surgery, at the end of the surgery and 24 hours after the surgery. The following outcomes were recorded postoperatively: acute heart failure, total ventilation time, neurological disorders, ICU stay length.
Results: The Group II patients presented with significantly lower levels of NOx.total (U=124.4, $p = 0.006$), nitrite (U=102, $p = 0.001$) and nitrate (U=145, $p = 0.23$) at the end of the surgery compared to Group I; there were no differences at the beginning of the surgery and 24 hours after the procedure. No intergroup differences in concentrations of ET-1 and ADMA were found at all control points. In Group II we observed significant decrease of nitrite level by the end of the surgery compared to baseline - 0.57 [0.41; 0.73] vs. 0.89 [0.64; 1.45] μmol/L (Z= -2.48, $p = 0.012$), that returned to initial values 24 h postoperatively - 0.83 [0.61; 1.71] μmol/L (Z= -2.39, $p = 0.016$). Group I demonstrated no significant dynamics of nitrite concentration comparing to baseline values. In Group II end-surgery nitrite level showed a significant negative correlation with cardiopulmonary bypass length ($R = -0.53$; $p = 0.001$), mechanical ventilation time ($R = -0.52$; $p = 0.027$) and ICU stay length ($R = -0.58$; $p = 0.012$). End-surgery nitrite level was independently associated with acute heart failure incidence after surgery (U=32.5; $p = 0.013$).
Conclusion: Decline of nitrite level by the end of the cardiac surgery with CPB may be regarded as an important predictor of complicated course of postoperative period in HFrEF patients.

P1905

HsCRP in patients with heart failure and its associations with outcome

P Pierpaolo Pellicori[1]; A Urbinati[1]; J Zhang[1]; V Nuzzi[1]; P Shah[1]; S Kazmi[1]; AL Clark[1]; JGF Cleland[1]
[1]*University of Hull, Department of Academic Cardiology, Hull, United Kingdom*

Background: Markers of inflammation, including high sensitivity C-reactive protein (hsCRP), are often raised in patients with heart failure (HF); however, little is known about the associations between hsCRP and outcome.
Methods: The prognostic value of hsCRP was studied in consecutive referrals with suspected HF to a specialist clinic serving a local community of ~500,000 people; HF was defined as symptoms or signs with either a reduced left ventricular ejection fraction (LVEF < 45% or left ventricular systolic dysfunction>mild on visual estimate if LVEF could not be calculated) or raised amino-terminal pro-B type natriuretic peptide (NT-proBNP >220 pg/ml).
Results: Of 4463 patients, 3473 fulfilled the criteria for HF. The median (IQR) hsCRP was 4.2 (1.7-9.1) mg/L and 3.9 (1.6-8.8) mg/L in patients with HF and reduced, or preserved LVEF ($p = 0.18$), and 2.9 (1.3-5.3) mg/L in those who did not fulfil criteria for HF ($p < 0.001$). Patients with HF in the highest quartile of hsCRP (range: 9-299 mg/L) were older, had more symptoms and clinical signs of congestion, and higher plasma NTproBNP than those in the lowest quartile (< 0.7 mg/L). LVEF was not an important determinant of plasma hsCRP. During a median follow up of 1490 (IQR: 744-2470) days, 1720 (50%) patients with HF died. In a multivariable Cox model, increasing hsCRP was independently associated with mortality (HR for 10 units change: 1.03 (95% CI: 1.01-1.05), $p = 0.012$). Compared to those in the lowest quartile of hsCRP, those in the highest quartile had a two-fold increase in mortality (HR: 2.23 (95% CI: 1.94-2.55), $P < 0.001$). However, a higher proportion of deaths were non-cardiovascular (CV) in those with elevated hsCRP, regardless of LVEF (At 2 years for hsCRP < 2.5mg/L v >10mg/L; HFrEF - all-cause mortality 11.8% v 34.5%; non-CV 3.0% v 12.4%; HFpEF all-cause mortality 11.8% v 28.3%; non-CV 3.5% v 13.9%).
Conclusions: In patients with HF, higher plasma concentrations of hsCRP are a powerful predictor of mortality, and identify patients with more congestion and higher natriuretic peptides, but who are also more likely to die of non-cardiovascular causes.

P1906

Correlation in biomarkers in patients with chronic heart failure accompanied with depressive disorders.

V Volodymyr Mykhaylov[1]; A Kozhyna[1]
[1]*Kharkiv National Medical University, Kharkiv, Ukraine*

The aim of our research is to study correlation in biomarkers in patients with chronic heart failure (CHF) accompanied with depressive disorders.
For conducting the research 107 CHF patients were involved. The patients were examined with: clinical methods; psycho-diagnostic methods (Hamilton Depression Rating Scale (HDRS), Beck Depression Scale (BDS) State-Trait Anxiety Inventory (STAI), Quality of Life Test); ELISA – to estimate levels of tumor necrosis factor – α (TNF-α) and transforming growth factor -β1 (TGF-β1), levels of serotonin, melatonin, adrenalin, noradrenalin, cortisol. The data were analyzed by descriptive statistical methods.
The results that we got showed that in 47% of CHF patients clinical and psychopathological signs of severe depression and moderate depression were observed. In 10% of CHF patents with severe depression average indicators of HDRS was 28,5 ± 0,7, indicators of BDS – 19,3 ± 0,3, state and trait anxiety indicators of STAI were 46,3 ± 0,3 and 47.5 ± 0,3 respectively. In 37% of CHF patents with moderate depression average indicators of HDRS was 24,5 ± 0,6, indicators of BDS – 16,3 ± 0,3, indicators of STAIT were 32,3 ± 0,3 and 33.5 ± 0,3. In other 53% CHF patients mild depression or absence depression were observed: (HDRS -9,5 ± 0,7, BDS – 10,3 ± 0,4, STAIT - 25,3 ± 0,3 and 28.5 ± 0,3 respectively).
In the CHF accompanied with severe depression levels of serotonin, melatonin, adrenalin were lower than in group of CHF patients with moderate depression and in group of CHF with mild depression or absence depression. Serotonin: 101 ± 8 ng/ml, 112 ± 16 ng/ml, 167 ± 8 ng/ml. Melatonin: 13,6 ± 1,4 ng/ml, 13,9 ± 1,2 ng/ml, 14,6 ± 1,6 ng/ml. Adrenaline: 30,3 ± 7,6 pg/ml, 32,1 ± 8,7 pg/ml, 39,1 ± 8,8 pg/ml respectively. Levels of noradrenalin and cortisol were vice versa higher in groups of SD and MD. Noradrenalin 410 ± 150,2 pg/ml , 363,1 ± 110,3 pg/ml, 210,9 ± 85,8 pg/ml, cortisol: 501 ± 186,1 nmol/l, 473 ± 169,4 nmol/l, 353,7 ± 78,7 nmol/l respectively.
The main levels of TGF-β1 and TNF-α were significantly higher in CHF in patients with severe depression and moderate depression (Severe- 98,71 ± 0,4 pg/ml and 55,45 ± 6,43 pg/ml, Moderate- 78,35 ± 0,4 pg/ml and 44,46 ± 3,23 pg/ml) in comparing with CHF with mild or absence depression (42,3 ± 3,7 pg/ml and 27,2 ± 1,21 pg/ml).
Conclusion: Correlation between biomarker has showed direct dependents between CHF and depression. CHF patients with severe depression and moderate depression characterized by higher indicators of TNF-α and TGF-β1 and leads to more quick development of cardiac hypertrophy and diastolic dysfunction in comparing with CHF patients with mild depression or absence depression.

P1907

Low circulating hepcidin as a measure of iron deficiency in patients with acute and stable heart failure

M Kasztura[1];
M Drozd[1]; P Rozentryt[2]; L Polonski[2]; J Malyszko[3]; E Koc-Zorawska[3]; K Josiak[4]; M Sokolski[4]; J Biegus[4]; R Zymlinski[5]; W Banasiak[5]; P Ponikowski[4]; E A Jankowska[1]

Funding Acknowledgements: Financially supported by the National Science Centre (Poland) grant allocated on the basis of the decision number DEC2012/05/E/NZ5/00590.

Background/Introduction: Hepcidin is a key regulator of systemic iron metabolism. Its elevated level might be involved in pathophysiology of iron deficiency (ID) in some chronic diseases accompanied by inflammation, such as heart failure (HF). There is a scarcity of data on circulating hepcidin level and its relationship with other markers of ID in patients with HF.
Methods: We analyzed data of 291 patients with stable HF (85% men, mean age: 61 ± 11 years, NYHA III-IV: 34%, LVEF: 26 ± 7%) and 165 patients with acute HF (81% men, mean age 65 ± 12 years, NYHA III-IV: 34%, LVEF: 32 ± 7%) and 66 healthy controls (77% men, mean age 60 ± 11 years, LVEF: 64 ± 7%). Sera from all patients were analysed for hepcidin-25 by ELISA validated with a gold standard for hepcidin assessment, liquid chromatography mass spectrometry (LCMS).
Results: Serum hepcidin levels were: 39.6 (27.6 - 61.4) ng/mL (median with lower/upper quartiles) in the control group, 17.7 (4.8 - 45.3) ng/mL, and 57.3 (30.5 – 116.2) ng/mL in all patients in acute and stable HF respectively. In patients with ID as compared to those with optimal iron level hepcidin concentration was significantly lower in acute HF – 11.0 (3.2 – 35.6) ng/mL versus 28.3 (13.3 – 88.7) ng/mL $p < 0.001$, and stable HF – 27.1 (15.6 – 58.4) ng/mL versus 76.2 (42.3 – 131.2) ng/mL, $p < 0.001$. For diagnosis of ID in stable HF group hepcidin ≤31.223 ng/mL had a sensitivity of 58% and specificity of 88% and the area under the receiver operating characteristic (ROC) curve was 0.78 ± 0.03 (95% CI, 0.721-0.839). In acute HF group hepcidin ≤7.998 ng/mL had sensitivity and specificity respectively 48% and 90% and area under ROC curve was 0.703 ± 0.04 (95% CI, 0.623-0.783). Serum hepcidin levels were significantly correlated with ferritin (R=0.55, $p < 0.0001$ for both acute and stable HF) and transferrin saturation (R= 0.26, $p < 0.009$, only for acute HF), and significantly negatively correlated with sTfR level (R=-0.37, $p < 0.0001$ only for acute HF).
Conclusion: Hepcidin concentration is markedly diminished in patients with ID and HF and particularly low in patients with acute HF. Serum hepcidin level might be a useful marker of iron status in patients with HF.

P1908

The role of polymorphism - 634 G/C (rs 2010963) of VEGF-A gene in the carotid intima media thickness changes in chronic heart failure patients

M Maria Iaresko[1]
[1]*L.T.Malaya Institute of Therapy, Kharkiv, Ukraine*

Background: chronic heart failure (CHF) is one of the most common complications of cardiovascular diseases. It is well-known fact that CHF affects various organs and tissues, leads to disruption of their function, that is why it could be in most cases direct cause of death of the patients. It was found that structural changes of the carotid intima media thickness (CIMT) are directly dependent on the level of increasing of endothelin in the blood plasma in CHF patients, which confirms the role of endothelial dysfunction in the development and progression of remodeling processes in the vascular mainstream. One of the major endothelial factors stimulating angiogenesis is a vascular endothelial growth factor (VEGF) – the signal protein produced by the cells to stimulate angiogenesis and vasculogenesis.
Purpose: to examine the effect of genetic polymorphism -634 G/C (rs2010963) of the VEGF-A gene in the development of CIMT changes in patients with CHF.
Materials and Methods: 70 women with CHF in the age from 60 to 65 years were examined. Depending on the genotype, patients were divided into 3 groups: GG - 33 persons, CG - 21 persons, CC - 16 persons. The VEGF concentration was determined by ELISA. The study of the allelic polymorphism -634 G/C (rs 2010963)

VEGF-A gene was performed by polymerase chain reaction with the electrophoretic pattern detection of result. CIMT was assessed sonographically using GE Vivid 7 with 13 MHz.
Results: The study results were showed that in patients with CHF GG genotype polymorphism -634 G/C (rs 2010963) of the VEGF-A gene was dominated. The VEGF level was significantly higher in patients with the GG genotype – 545,2[370,5; 626,4] pg/ml comparing with the genotype CG –232,4[217,5; 394,8] pg/ml and the genotype CC –216,9[137,6; 253,8] pg/ml (p = 0,05). There was no significant differences of the VEGF level among patients with the genotype CG and CC (p>0,05). CIMT assessment has showed that among patients with GG genotype CIMT indicator was significantly higher 1,17 [0,94; 1,25] mm compared with the CC genotype – 0,98 [0,92; 1,04] mm (p = 0,05). There was no significant differences comparing the results of these indicators in CG genotype patients – 1,08 [0,96; 1,11] mm (p-0,05).
Conclusion: it was found that level of VEGF and the CIMT were significantly higher among patients with the GG genotype polymorphism -634 G/C (rs 2010963) of the VEGF-A gene compared with genotypes CG and CC patients. The relationship between the level of VEGF-A, the representatives of GG genotype polymorphism -634G/C (rs 2010963) of the VEGF-A can be regarded as predictors of carotid intima media thickening in patients with CHF.

P1909

5-year prognostic value of different parameters from routine hemogram in patients with idiopathic dilated myocardiopathy and severe systolic disfunction referred to a heart failure unit

JM Sobrino-Marquez[1]; EM Cantero-Perez[1]; E Lage-Galle[1]; D Rangel-Sousa[1]; A Adsuar-Gomez[1]
[1]*University Hospital of Virgen del Rocio, Seville, Spain*

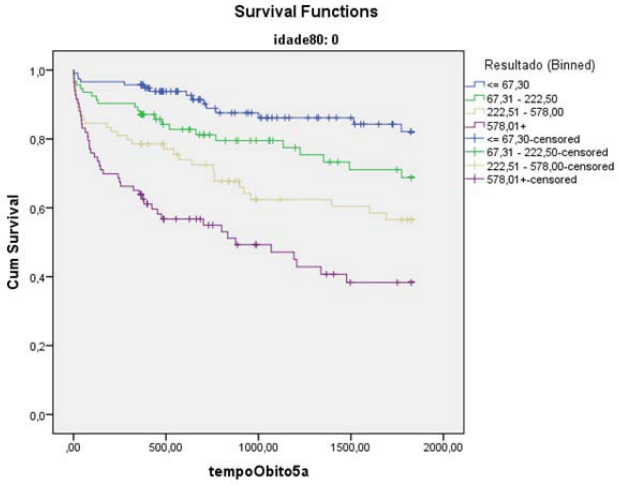
Introduction: We analize the 5-year prognostic value of several parameters from routine hemogram in patients referred for evaluation for non-emergent heart transplantation in our Heart Failure Unit.
Methods: From 2009 to 2011, 87 patients with dilated myocardiopathy and LVEF < 30% were evaluated. Exclusion criteria included coronary artery disease, primary valvulopathies or hipertrophic or restrictive myocardiopathies after echocardiogram, coronariography and cardiac hemodynamics. Evolution after 5 years showed that 49 patients remained in good functional class (group A, 57%), while 38 patients were transplanted or died (group B). We analyzed next parameters from routine hemogram (and indexes derived from them): RDW (red blood cell distribution width), neutrophil count, lymphocite count, neutrophils / lymphocites ratio (NLR) and platelet count. Finally, as part of the BIOSTAT-CHF Scotland Study, NLR and platelet count were chosen for creating the CPNR score, chosing a cut-off value of NLR and platelet count at 3 and 275 respectively. Thus, a patient with both elevated NLR (>3) and platelet count (>275) was allocated a score of 2 (CPNR 2), and a patient shown one or neither was allocated a score of 1 (CPNR 1) or 0 (CPNR 0), respectively.
Results: Median RDW values were 13,9 in group A and 16,3 in group B (p < 0,001). Mean neutrophil count was 5,50 and 6,30, respectively (NS). Mean lymphocite count was 2,22 and 1,64, respectively (p < 0,05) while NLR was 3,33 and 6,06 (p < 0,05). Finally, CPNR didn´t show statistical differences between groups.
Conclusion: In patients with idiopathic dilated myocardiopathy and severe systolic dysfunction referred to a Heart Failure Unit, RDW, lymphocite count and neutrophils / lymphocites ratio show statistically significant differences between patients with good and bad prognosis at a 5-year follow-up.
Discussion: Basic hemogram can be a rapid and available biomarker that could potentially help in risk stratification of CHF patients.

P1910

Applicability of bnp as a biomarker of prognosis for long-term mortality in a comparison between non-elderly, elderly and major-elderly patients in south Brazil.

E Edyuardo Pitthan[1]; HV Hirakata[1]; BJ Barbisan[1]
[1]*Institute of Cardiology of Rio Grande do Sul, Porto Alegre, Brazil*

Introduction: B-type natriuretic peptide (BNP) is used as a short-term biomarker for prognosisin patients with heart failure (HF). The prognostic role for long-term mortality is insufficiently studied.
Objectives: To validate the BNP test as a biomarker of long-term mortality prognosis in patients with suspected HF, comparing the non-elderly < 60 years, elderly (≥60-79 years) with the major-elderly >80 years old.
Methods: The sample consisted of 634 patients with suspected HF, attended at the emergency room between March 2003 and September 2012. The efficacy of BNP to identify patients with heart failure and the association between the level of BNP (POCT Biosite) and long-term prognosis were evaluated. The study was divided into three age groups, Elderly (E) 60-79 (46%) years, major-elderly ≥80years(38%) and Non-Elderly < 60 years old. Cause of death was identified through a search of death certificates in registry offices, informed by the Brazilian Mortality Information System.
Results: Most patients were white (93.1%), female (63.8%), with a mean age of 77.3 (± 8.6) years. HF was diagnosed based on a new gold standard that considered the Framingham and Boston criteria, plus echocardiography and ECG. HF was present in 340 patients (53.5%).Most of these patients (63.5%, n=216) had HF with Preserved Ejection Fraction (HFPEF). In bivariate analysis a BNP> 180pg/ml was associated with a higher risk of mortality. In multivariate analysis BNP> 180pg/ml remained associated with increased risk of mortality,with an HR of 3.4 (CI95%: 1.2 to 9.6;p < 0.02). Survival analysis in 78 months at the end of the study (six years and six months) was performed by Kaplan-Meier curve. The median BNP for the Major Elderly >80 years group with HF was 595pg/ml, with a 27-month mean survival time (MST) and 47% mortality rate. The median BNP for the Elderly between 60-79 years groupwas 369 pg/ml, with a 52-month MST and 38% mortality rate. The Non-Elderly group BNP was 222pg/ml, with an MST >50% and 26% mortality rate.
Conclusion: The BNP level showed association with the mortality index. BNP is an independent prognostic biomarker for long-term mortality in patients with HF in all ages.

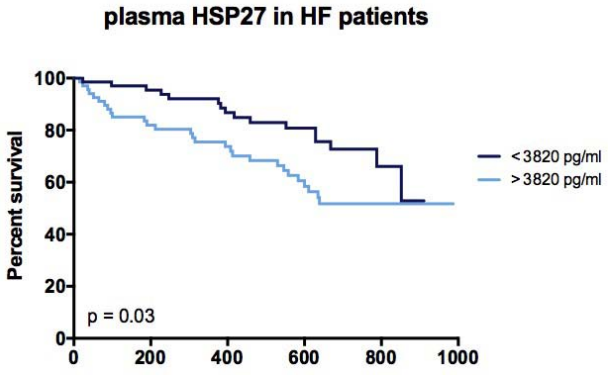


P1911

HSP27 plasma levels as an independent predictor of prognosis in chronic heart failure patients

D Denise Traxler-Weidenauer[1]; M Lainscak[2]; HJ Ankersmit[1]; B Jug[3]
[1]*Medical University of Vienna, Christian Doppler Laboratory for Diagnosis and Regeneration of Cardiac and Thoracic Diseases, Vienna, Austria*; [2]*University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia*; [3]*University of Ljubljana, Division of Vascular Diseases, Department of Internal Medicine, Ljubljana, Slovenia*

Background: Heat-shock proteins (HSP) represent intracellular mechanisms of stress response and are involved in chaperoning and regulating cellular death. However, clinical implications of their overexpression and spill-over into the bloodstream in patients with heart failure (HF) remain elusive, as HSP can represent both protective biological mechanisms as well as biomarkers of disease progression.
Purpose: The aim of this present study was to assess the prognostic impact of HSP27 in chronic HF.
Methods: In outpatients with chronic stable HF (i.e. no change in clinical trajectory for > 3 months) with reduced or preserved left ventricular ejection fraction (LVEF), plasma HSP27 baseline levels were measured using enzyme linked immuno-sorbent assay (ELISA). Patients were followed for a minimum of one year, and multivariate Cox proportional hazards were built for cardiovascular death or HF-associated hospitalisations.
Results: A total of 134 patients with chronic HF (mean age 71 ± 10 years, 34 % female, mean LVEF 36 ± 12 %) were included. During a mean follow-up of 527 ± 260 days, 44 patients (33 %) experienced an event. Mean time to event was 350 ± 236 days. In a Kaplan-Meier survival analysis HSP27 levels above the median (3820.0 pg/ml) indicate a higher risk for an event (p = 0.03). An adjusted Cox proportional hazard model was built using established heart failure parameters (logNTproBNP, LVEF, NYHA classification, age, gender) increased plasma HSP27 levels (HR 2.00, CI 95% 1.02 – 3.90, p = 0.04) emerged as an independent predictor within a multivariate analysis.
Conclusions: HSP27 plasma levels are an independent predictor of prognosis in chronic HF. Our findings suggest that HSP27 may improve risk-stratification in HF beyond known prognostic predictors, such as age, LVEF, NYHA class and natriuretic peptides.



HSP27 Kaplan-Meier survival curve

Association of microcirculation disturbance with IFR and VEGF-A levels in patients with heart failure

MV Kozhevnikova[1]; EA Zheleznykh[1]; YUA Danilogorskaya[1]; AA Shchendrygina[1]; GA Shakaryants[1]; VYU Kaplunova[1]; AO Yusupova[1]; IS Chekneva[1]; VYU Zektser[1]; EV Privalova[1]; YUN Belenkov[1]
[1]*I.M. Sechenov First Moscow Medical State Universityul. Trubetckay , 8, str. 2, 119992 Moscow, Russia, therapy, Moscow, Russian Federation*

Purpose: to assess the association between IFR and VEGF-A levels, parameters of intracardiac hemodynamic and disturbance of microcirculation in patients with heart failure (HF).
Methods: 52 patients (29 men, age 65,78 ± 8.79, EF 50,96 ± 8.7) with HF and 50 controls (28 men, age 65.31 ± 7.22, EF 59.23 ± 5.06) were included in the study. In HF group included: 27 patients (51,9%) with preserved ejection fraction (HFpEF), 18 (34,6%) patients with mid-range ejection fraction (HFmrEF) and 7 (13,5%) patients with reduced ejection fraction (HFrEF). All patients were investigated according standard cardiac algorithm. We estimated IFR and VEGF-A level, assessed microcirculation (occlusion index (IO) and remodeling of arteriols (index of refraction (RI)) by photoplethysmography.
Results: VEGF-A level was significant higher in patients with HFpEF 123,9 ng/mL (71,33: 176,43) vs HFrEF 217 ng/mL (-41.5:94.17) and HFmrEF patients 217,86 ng/mL (118,55:317.15) (p < 0,005). Decrease of IO in HF group (1,4) vs controls (1,6) p = 0,007 was revealed. A positive correlation between RI level and ejection fraction (r=0,33, p = 0,0037) was determined. IFR level associated with RI (r=0,307; p = 0,0073).
Conclusion: 1. The association between IFR and VEGF-A levels, parameters of microcirculation (IO) and intracardiac hemodynamic parameters (EF) were found in patients with HF. 2. VEGF-A level is differ in patient with HFrEF, HFmrEF and HFrEF. 3. It was determined that IO is decreased in patients with HF.

P1913

SERCA2a as non-invasive biomarker of heart transplant rejection

E Esther Rosello-Lleti[1]; E Tarazon[1]; A Ortega[1]; C Gil-Cayuela[1]; E Sanchez-Lacuesta[2]; P Marin[3]; A Hernandiz[4]; L Martinez-Dolz[1]; M Portoles[1]; M Rivera[1]
[1]*Hospital Universitario y Politécnico La Fe, Cardiocirculatory Unit , Valencia, Spain*; [2]*Hospital Universitario y Politécnico La Fe, Hemodynamic Unit, Valencia, Spain*; [3]*Hospital Universitario y Politécnico La Fe, Microscopy Unit, Valencia, Spain*; [4]*Hospital Universitario y Politécnico La Fe, Experimental Cardiology, Valencia, Spain*

Funding Acknowledgements: National Institute of Health [PI13/00100; PI14/01506], CIBERCV [CB16/11/00261], the European Regional Development Fund (FEDER), RETICS [12/0042/0003].

Background: The detection of heart transplant rejection by non-invasive methods represents a challenge since multiple alternatives have been studied but none of them have been able to replace or reduce the number of biopsies in daily clinical practice. Despite of the importance of the study of SERCA2a in the heart, its role as rejection marker in the cardiac rejection has never been analysed.
Purpose: The aim of the study is to analyse if SERCA2a protein could be a marker of cardiac rejection.
Methods: We recruited a total of 127 consecutive endomyocardial biopsies and serum samples from adult patients (>18 years) undergoing cardiac transplantation (49 without allograft rejection and 78 with diagnosis of biopsy allograft rejection: 48 Grade 1 R, 21 Grade 2R, 9 Grade 3R). Serum concentrations of SERCA2a were determined by specific commercial sandwich enzyme-linked immunosorbent assay. We also analysed SERCA2a levels on endomyocardial biopsies by immunofluorescence.
Results: SERCA2a cardiac tissue and serum levels were decreased in patients with acute cardiac rejection. The receiver-operating characteristic analysis showed that SERCA2a strongly discriminated patients with allograft rejection from patients without rejection: normal grafts vs all rejecting grafts (AUC=0.804), normal grafts vs Grade R 1 (AUC=0.751), normal grafts vs Grade R 2 (AUC=0.875), normal grafts vs Grade R 3 (AUC=0.922) p < 0.0001 for all comparisons.
Conclusions: This study demonstrates that a different expression of SERCA2a occurs in rejecting allograft patients, not only at the tissue level but also in the serum, showing their potential role as non-invasive biomarker in heart transplant reject.

P1914

Soluble ST2 in bronchial aspirates of patients with severe respiratory insufficiency and its correlation with acute heart failure

M Navarro Penalver[1]; ME Garcia Garcia[1]; J Sanchez Mas[1]; R Jara Rubio[1]; JJ Santos Mateo[1]; J Sanchez Serna[1]; AM Lax Perez[1]; MC Asensio Lopez[1]; DA Pascual Figal[1]
[1]*Hospital Clínico Univeristario Virgen de la Arrixaca, Murcia, Spain*

Background: Recent studies have demonstrated plasma soluble ST2 (sST2)to be a strong predictor of cardiovascular outcomes in acute heart failure (AHF). However, the main sources of sST2 are not completely Known. The aim of this study was to investigate the presence of sST2 in bronchial aspirates of patients with severe acute respiratory insufficiency and its clinical correlates.
Methods: 34 patients (aged 63 ± 16 years, 61% male) with acute respiratory insufficiency (ARI) requiring intubation were included. Bronchial aspirates and blood samples were obtained at the moment of intubation. sST2 levels were measured using an ELISA assay. ARI etiology was classified as cardiogenic (AHF) or non-cardiogenic. Clinical and laboratory data were also recorded.
Results: sST2 was detected in bronchial aspirates (median 6 [Q1-Q3 2.6–72.2]ng/ml). Patients with AHF showed higher bronchial sST2 levels (bsST2) (n = 12, median 29.6 [Q1-Q3 6-142] ng/ml) than those with non-cardiogenic causes of respiratory failure (n = 22, median 3.8 [Q1-Q3 1.9-16.2] ng/ml) (p = 0.02). We found a strong positive correlation between bsST2 and plasma sST2 (rs= 0.41; p = 0.026). bsST2 also correlated with lactate (rs=0.5; p = 0.007), AST (rs=0.44; p = 0.022), troponin T (rs=0.5; p = 0.04) and LDH(rs=0.26; p = 0.004). A negative correlation with LVEF was also found (rs=-0.57; p = 0.024). There was no association between bsST2 levels and the time needing vasoactive support or non invasive mechanical ventilation. bsST2 did not correlate with NT-proBNP levels, renal function or inflammatory parameters like C-reactive protein or procalcitonin.
Conclusion: sST2 is present in bronchial aspirates from patients with severe ARI showing higher levels in those with AHF. bsST2 correlates with cardiac function, metabolic stress and cellular damage.

Mass spectrometry for detection heart failure with preserved ejection fraction

LK Malinovskaya[1];
A A Bykova[1]; P SH Chomahidze[1]; A L Syrkin[1]; PH YU Kopylov[1]; V B Betelin[2]; YU R Shaltaeva[3]; V S Pershenkov[3]; N N Samotaev[3]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*; [2]*Scientific Research Institute of System Development, Moscow, Russian Federation*; [3]*National Research Nuclear University "MEPhI", Moscow, Russian Federation*

Funding Acknowledgements: This study was supported by Russian Academy of Science

Background: Heart failure (HF) remains the leading cause of poor prognosis and death in developed countries. Early and reliable diagnosis of HF is a relevant and practically significant problem. Numerous prognostic markers of death and HF hospitalization have been identified in patients with HF. However, their clinical applicability is limited and precise risk stratification in HF remains challenging. The diagnosis of HF with preserved ejection fraction (HF-PEF) is still difficult.
Purpose: The purpose of this study was to investigate the correlation between acetone in exhaled breath and N-terminal pro B-type natriuretic peptide concentration in patient with HF-PEF.
Methods: Of 84 patients evaluated between October 2014 and April 2016, 56 patients (HF group) fulfilled inclusion criteria and were compared with healthy subjects (control group, n = 36). Patients with HF were grouped according to ejection fraction (HF-PEF, n = 26; HF with reduced ejection fraction [HF-REF], n = 30) and submitted to exhaled breath collection. Identification of volatile organic compounds

was done by Proton Transfer Reaction – Mass Spectrometry (PTR-MS). All of the patients underwent standart biochemical assessment and biomarkers evaluation (NT-proBNP, Troponin I, Copeptin, Cistatin).
Results: In compare with control group several biomarkers were significantly higher in both HF group. They are acetone, acetic aldehyde, ethanol and propylene. The median (interquartile range) concentration of acetone in HF-PEF group when compared to control group was 1527 ppb [894-2160] vs 1,51 ppb [1,15-1,87], p = 0,001; acetic aldehyde 273 [175-371] vs 2,33 [2,05-2,61], p = 0,001; ethanol 41,9 [13,9-69,9] vs 1,34 [1,23-1,45], p = 0,001; propylene 361 [219-503] vs 2,43 [2,09-2,77], p = 0,001 respectively. Further division into groups with different ejection fraction was analyzed. It has been found that correlation is not significant for HF-REF group (r = 0,12, p = 0,53), while for HF-PEF group is significant correlation (r = 0,54, p = 0,004). The transition to a logarithmic scale, there is a significant relationship between the logarithm of NTproBNP level and the logarithm of acetone in breath (r = 0.294, p = 0.026).
Conclusion: Exaled breath acetone may be a promising noninvasive diagnostic method of HF-PEF, but further investigations are necessary.

P1916

Proteomic biomarker discovery and multiple reaction monitoring assay optimisation to identify diabetic patients with left ventricular diastolic dysfunction

J James O'reilly[1]; C Tonry[1]; E O'connell[1]; AQ Butt[1]; L Murphy[1]; S Pennington[1]; M Ledwidge[2]; K Mcdonald[2]; C Watson[3]; JA Baugh[1]
[1]University College Dublin, Dublin, Ireland; [2]St Vincent's University Hospital, Dublin, Ireland; [3]Queen's University of Belfast, Belfast, United Kingdom

Introduction: The need for biomarkers to identify cardiac dysfunction in patients with diabetes (DM) is becoming increasingly pressing due to the global rise in disease prevalence and reducing healthcare resources to detect and manage these complications. With the risk of heart failure being 2-5 fold greater in those with diabetes, early identification of cardiac dysfunction may facilitate more timely management and reduce or delay future heart failure development.
Methods: Biomarker discovery was carried out in trypsin digested, immuno-depleted human serum on a Q-Exactive mass spectrometer. 200 samples from the Irish STOP-HF cohort were used for the discovery and verification stages. Four pooled age- and gender-matched groups of 50 patients were analysed, with and without DM and with and without asymptomatic left ventricular diastolic dysfunction (LVDD); defined as left atrial volume index ≥34ml/m2 and E' < 10 cm/sec. The subsequent biomarker assay was built on a 6490 multiple reaction monitoring (MRM) mass spectrometer. Proteotypic synthetic peptides (2 per protein), acting as surrogates of the proteins of interest, were pooled and run on an unscheduled method to extrapolate the retention times needed for a scheduled MRM method. Scheduled methods were subsequently run in which collision energies and voltages were analysed. The parameters that resulted in the most reproducibly intense signals while producing the least background were then verified in the original discovery cohort, in the 200 individual samples.
Results: Perseus and MPP software revealed 261 unique proteins from the discovery phase, of which 68 were identified as potential biomarkers for the identification of LVDD in DM. GO-Term enrichment analysis of these 68 proteins revealed the involvement of many inflammatory processes. "Humoral immune response", "complement activation" and "acute inflammatory response" were all significantly over-expressed (q-values: 1.00E-30, 1.00E-30, 1.00E-30 respectively).
The unscheduled run resulted in some peptides being excluded due to poor performance on MRM. Similarly, under the scheduled method some peptides, following optimisation, performed poorly and as such were excluded. At the time of writing, the list stood at 41 proteins of 65 peptides with dot products ≥0.8, consisting of 3 transitions each, all detectable on the same run.
Conclusion: Verification, validation and functional analysis of these protein biomarkers, will lead to the identification of key contributors to pathological processes. Using a biomarker based strategy to identify cardiac dysfunction in patients with diabetes, and the prospect of predicting disease progression has the potential to overcome the cost and access difficulties with cardiac imaging modalities if used as a pre-screen or surrogate for disease.

Serum ST2 levels are associated with myocardial fibrosis in severe aortic stenosis

R Rafael Sadaba[1]; V Arrieta[2]; V Alvarez[2]; F Olaz[2]; M Ciriza[3]; A Ferandez Celis[4]; J Ibarrola[4]; J De Diego[1]; N Lopez-Andres[4]
[1]Hospital de Navarra, Cardiac Surgery, Pamplona, Spain; [2]Hospital de Navarra, Cardiology, Pamplona, Spain; [3]Hospital de Navarra, Radiology, Pamplona, Spain; [4]Miguel Servet Foundation, Cardiovascular Translational Research, Pamplona, Spain

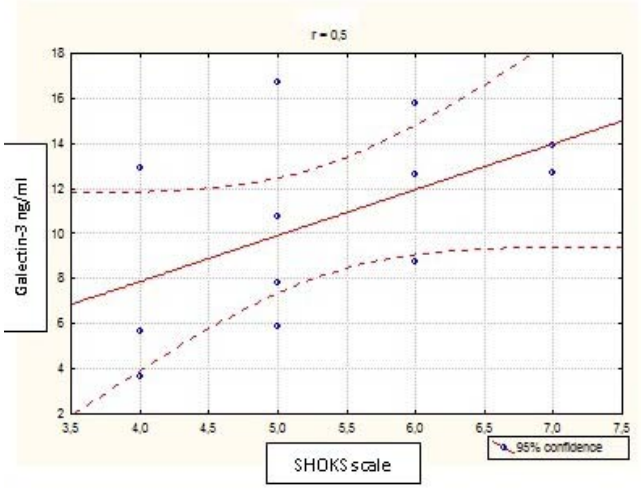
Background/Introduction: Soluble ST2 (sST2) is a biomarker of left ventricular (LV)remodelling, and it has been shown to be a predictor of adverse outcomes in heart failure. Focal myocardial fibrosis (FMF) detected by means of delayed enhancement (DE) cardiac magnetic resonance (CMR) has been proposed as a marker of advanced stage and worse prognosis in patients with severe aortic stenosis (AS).
Purpose: To evaluate the association of sST2 levels and the presence, distribution and severity of FMF in patients with severe AS.
Methods: A consecutive series of 79 patients with symptomatic AS and referred for aortic valve replacement, were prospectively studied with CMR on a 1.5T scanner, obtaining T1 mapping sequences before and 15 minutes after the administration of gadolinium, following a Sh-MOLLI protocol in the ventricular short axis. Blood samples were taken for determination of sST2 levels and other biochemical parameters.
Results: FMF was detected in 42 patients (53%). Patients with FMF showed significantly higher levels of sST2 than patients without FMF (34,6 ± 7,6 vs 17,9 ± 5,6; p < 0,0001). Intramyocardial and subendocardial fibrosis was detected in 23 and 19 patients respectively. Independently of the severity of AS, patients with FMF have higher LV mass (predominantly those with intramyocardial FMF), and LV volume, and less LV ejection fraction (predominantly in those with subendocardial FMF). sST2 levels were higher in patients with intramyocardial FMF. There was a positive correlation between sST2 levels and LV end-diastolic volume (r=0,256; p = 0,041) and LV mass (r=0,28; p 0,0037). Similarly, there was a positive correlation between sST2 levels and FMF mass (r=0,433; p < 0,0001).
Conclusion: In patients with symptomatic AS, there is a relationship between sST2 levels and FMF evaluated by CMR, and between sST2 levels and morphological LV alterations. sST2 may be a prognostic marker of LV remodelling in patients with AS.

P1918

Role of galectin-3 in therapy monitoring of patients with HF

K Karine Gyamdjyan[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Galectin-3 is a novel biomarker of fibrosis and cardiac remodeling that represents an intriguing link between inflammation and fibrosis.
Aim of the study: to assess the association of circulating galectin-3 levels with other clinical parameters and functional performance indicators of patients with chronic HF NYHA II-III.



Methods: 53 patients with HF NYHA II-III were enrolled into single-centre prospective cohort study. Patients underwent echocardiographic evaluation of cardiac structure as well as systolic and diastolic function. Plasma levels of galectin-3 and NT-proBNP were assessed at baseline and at the day of discharge, using enzyme-linked immunosorbent assays. The Mann-Whitney U test was used to compare differences between two independent groups. The relationship between galectin-3 levels and other variables of interest was analyzed using Pearson (Spearman for non-parametric data) correlation analysis/ A p < 0,05 was regarded as statistically significant. All patients were assigned to recieve heart failure standard therapy that included ACEI/ARB, BB, loop diuretics and spironolactone.
Results: Galectin-3 plasma levels significantly decreased after holding standard

therapy of heart failure (p < 0,001). Decrease of galectin-3 plasma levels was observed in 84,3% of patients. Changes in galectin-3 levels positively correlated with changes in scale of evaluation of clinical state in CHF (as modified Mareev VY 2000) (r=0,5, p = 0,1). NT-proBNP plasma levels also decreased at the end of the treatment (p < 0,003). Decrease was observed in 84,2% of patients.
Conclusion: in a small cohort of patients palsma galectin-3 and NT-proBNP levels have decreased after holding of standard heart failure therapy. Changes of galectin-3 levels positively correlated with changes in clinical state of CHF.

NT-proBNP and galectin-3 levels dynamics

Biomarkers	Baseline	Before after standard therapy	p
NT-proBNP, pmol/l	121,47 [43,3; 177,88]	82,69 [31,88; 132,66]	0,003
Galectin-3, ng/ml	8,5 (5,21; 15,72)	6,49 [3,36; 12,79]	0,0008

P1919
Regardless of the fibrosis status 12-month kinetics of serum markers of fibrosis are not different in dilated cardiomyopathy patients

P Pawel Rubis[1]; S Wisniowska-Smialek[1]; E Dziewiecka[1]; K Holcman[1]; A Karabinowska[1]; L Khachatryan[1]; P Faltyn[1]; E Wypasek[1]; P Podolec[1]
[1]*Department of Cardiac and Vascular Disease, John Paul II Hospital, Institute of Cardiology, Krakow, Poland*

Funding Acknowledgements: Grant from the Poland National Centre of Science (no. 2013/09/D/NZ5/00252)

Background: Serial assessment of serum markers of fibrosis may provide insight into dynamics of myocardial fibrosis process. It is unknown whether 12-month patterns of markers of fibrosis differ between dilated cardiomyopathy (DCM) patients (pts) with and without fibrosis.
Methods: We included 70 consecutive DCM patients (pts) (48 ± 12.1 years, EF 24.4 ± 7.4%). All pts underwent right ventricular endomyocardial biopsy (EMB) to study cardiac fibrosis. Markers of collagen type I and III synthesis – procollagens type I and III carboxy- and amino-terminal peptides (PICP, PINP, PIIICP, PIIINP), and ECM metabolism controlling factors – tumor growth factor beta-1 (TGF1-β) and connective tissue growth factor (CTGF) were measured in serum at baseline, and 3- and 12-month follow-up.
Results: Based on the EMB results, two groups of pts were identified: without (n = 46, 65.7%) and with (n = 24, 34.3%) fibrosis. Baseline, 3- and 12-month values of PICP, PINP, PIIICP, PIIINP, TGF-β and CTGF did not differ between two groups (Figure 1).
Conclusions: 12-month kinetics of serum markers of fibrosis are similar in DCM pts with and without fibrosis. Regardless of the time point of measurements, reliable differentiation between DCM pts with and without fibrosis, based on serum markers of fibrosis is questionable. These unexpected findings cannot be easily explain and warrant further studies.

The use of cardiac multimarker testing in patients with non-obstructive hypertrophic cardiomyopathy

R Radek Pudil[1]; M Vasatova[2]; L Horakova[1]; H Rehulkova[3]; P Rehulka[3]; A Fucikova[3]; V Palicka[2]
[1]*Charles University Prague, Faculty of Medicine in Hradec Kralove, 1st Department of Medicine, Hradec Kralove, Czech Republic*; [2]*University Hospital Hradec Kralove, Institute of Clinical Biochemistry and Diagnostics, Hradec Kralove, Czech Republic*; [3]*Faculty of Military Health Sciences, University of Defence, Department of Molecular Pathology and Biology, Hradec Kralove, Czech Republic*

Introduction: The increase of cardiac markers in patients with hypertrophic cardiomyopathy (HCM) is associated with the severity of left ventricle outflow tract obstruction. However, little is known about the cardiac marker levels in patients with non-obstructive type of HCM.
Purpose: The aim of presented study was to analyze cardiac multimarker testing strategy in detection of the initial structural changes in patients with non-obstructive HCM.
Methods: In the group of 47 patients with non-obstructive HCM (58.4 ± 12.4 years, 12 females), plasma concentrations of creatine kinase MB isoenzyme (CKMB), myoglobin (MYO), glycogenphosphorylase BB isoenzyme (GPBB), and heart type of fatty acid binding protein (FABP) were analyzed with the use of protein biochip system.
Results: Left atrium diameter was 48.2 ± 7.2 mm, and it exceeded reference values in 37 (78%) patients. Right ventricle diameter was 26.1 ± 3.8 mm, and it exceeded reference value in 2 (4%) patients. The end-systolic left ventricle dimension was 31.9 ± 7.1 mm, and it exceeded reference values in 4 (8%) patients. Left ventricle end-diastolic dimension was 47.1 ± 7.3 mm, and it exceeded reference values in 3 (6%) patients. The mean of the interventricular septum thickness was 19.4 ± 4.4 mm, and it exceeded recommended thickness for diagnosis of hypertrophic cardiomyopathy (≥15mm) in all patients. Left ventricle mass was 344.8 ± 129.9 g, and it exceeded reference values for two-dimensional method in all patients. Left ventricle mass index was 171.4 ± 60.2g.m-2, and it exceeded reference values in all patients. The mean of the left ventricle ejection fraction was 67.1 ± 9.9%, and, only in 2 (4%) patients, the LV ejection fraction was below the reference values. Left ventricle fractional shortening was 33.7 ± 8.7, and it exceeded the reference values in 3 (6%) patients. None of the patients had left ventricle outflow tract obstruction. In peripheral circulation, we found increase of hsTnT: [median: 9ng/L (IQR: 5 - 16 ng/L), vs. 7 (5 - 9) ng/L, p 0.03]; CK MB [2 (1.4 - 2.7) μg/L vs. 1.6 (1.1 - 2.2) μg/L, p 0.04]; MYO [46.4 (33.3 - 65.2) μg/L vs. 35.6 (22.8 - 43.7) μg/L, p 0.001]; hFABP [1.8 (1.4 - 3.3) μg/L vs. 1.6 (1.3 - 2.1) μg/L, p 0.05], and GPBB [3.9 (2.5 - 6.3) μg/L vs. 2.3 (1.9 - 4.2) μg/L, p 0.001]. Furthermore, we found significant associations of left ventricle mass index and cardiac markers: hFABP (r 0.41, 95% CI: 0.07-0.66, p 0.01) and with CKMB (r 0.33, 95% CI: 0.11-0.59, p 0.05).
Conclusion: This study indicates potential clinical use of the multimarker testing in diagnosis and screening of the hypertrophic cardiomyopathy even in initial stages.

The impact of educational- supportive self-care package on anxiety, depression and stress in myocardial infarction patients hospitalized in Iran, 2016

N Nader Aghakhani[1]
[1]*Urmia University of Medical Sciences, Urmia, Iran (Islamic Republic of)*

Introduction: Although, Myocardial infarction is one of the most common cardiovascular diseases known which can be controlled, patients are always at risk of physical, and socio–psychological stressors.
Purpose: this study carried out to investigate the impact of educational- supportive self-care package on mean of anxiety, depression and stress in myocardial infarction of an hospital in Iran.
Methods: This pre- and post-quasi-experimental study will carried out on 56 hospitalized patients with heart failure selected from an hospital affiliated with University of Medical Sciences were assessed in 2016. They will assign to two groups of experimental (n = 43) and control (n = 43) groups. They are selected through convenience sampling and divided randomly into two intervention and control groups. Any patient in the experimental group received education after 48 hours of admission and after the disease's acute phase through face to face contact and also a booklet and the questionnaires were completed before the intervention, after the intervention, before discharge from the hospital, and two months after discharge through phone calls or visiting patients in the intervention group if the patients requested. The patients in the control group receive no intervention. At the same time, patients and their relatives were taught about social support in four dimensions of emotional support, tools, information and evaluation. Demographic and DASS questionnaires (anxiety,

stress, depression) were used to collect data. Data were analyzed using statistical software spss version 21.
Results: The findings showed that educational- supportive self-care package can reduce anxiety and depression in experimental group after intervention as a lasting effect. On the other hand, the package does not effect on stress meaningfully decrease among the patients of control group, and only causes the decrease through interaction with the factor "time") p >0.05).
Conclusion: The educational- supportive self-care package can reduce anxiety and depression and a part of stress among patients with myocardial infarction. Thus, it is recommended the results of this study be considered by health and treatment setting managers as a key factoring nursing care programs to decrease of stress, anxiety and depression among patients with myocardial infraction.

Our network- An hospital acute heart failure unit, an outpatient clinic, a chronic heart failure consultation envolving hospital and primary care

S Susana Quintao[1]; J Campos[1]; C Bastos[1]; I Araujo[1]; F Marques[1]; C Fonseca[1]
[1]Hospital de Sao Francisco Xavier, Day Hospital, Lisbon, Portugal

Heart failure (HF) a disease with growing prevalence requires specialized management. To minimize readmissions and emergency room visits, we implement a HF clinic.
Day Hospital (DH), in partnership with acute HFunit and chronic HFconsultation has a treatment room with 5 monitored seats, two consulting offices for both doctors and nursing, and an area for clinical trials.
The aim of this facility is a reduction in emergency visits and hospital readmissions.
Protocol: patients are discharged to DH for reevaluation within 2 weeks: clinical/analytic reassessment nursing consultation and HF drugs titration. Special attention is payed to education on disease, warning signs, medication, feeding and how to procede when they recognize decompensation and need to come back (ex. IV decongestion treatment up to 3 consecutive days). Direct connection with GPs was implemented. At discharge GP is notified to reevaluate his patient within 2 weeks. GPs may refere back to DH when decompensation, or send to HFconsultation for specialized evaluation/treatment (done within 2 weeks maximum).
Preliminary results showed that inclusion in our HF multidisciplinar management program reduced one year readmissions in 20% (p:0.0017) We have created an efficient network where patients circulate through a close circuit of people well aware of disease willing to improve their quality of life and survival

P1923
Nursing consultation pre-cardiac catheterization in a university hospital: a retrospective study

VF De Freitas Marcolla[1]; E Ferreira[1]; DC Albuquerque[1]; CBOC Naves[1]; AL Viana[1]; IPB Aragao[2]; GP Lima[1]; CAR Cruz[1]; TJF Oliveira[1]; MB Fernandez[1]; SML Costa[1]; MN Leal[1]; SRF Chaves[1]
[1]Rio de Janeiro State University (UERJ), Rio de Janeiro, Brazil; [2]Governo do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

In a report published by the World Health Organization, in 2015, cardiovascular disease remains responsible for most of the deaths attributed to noncommunicable diseases, resulting in the loss of 17 million lives annually. The anamnesis of patients undergoing cardiac catheterization is a necessary condition for the examination because it has the purpose of preventing intercurrences related to the conditions prior to the examination that may undergo some intervention for modification.
Objective: To evaluate the effectiveness of the nursing consultation to improve the quality of care provided.
Methods: Retrospective study of the nursing consultation records, conducted in the biennium 2015-2016, in a university hospital in Brazil. 1990 examinations were planned, with 1377 performed. Of these, only 35.3% were suspended due to lack of patient; 0.7% due to absence of companion; 25.9% because they did not present laboratory tests; 9.4% for having used hypoglycemic medication; 0.7% for having used anti-coagulant medication; 4.7% because they presented laboratory tests with alterations; 3% due to allergy without desensitization; 6.6% had a clinical condition that made the examination impossible; 6.3% due to lack of space; 10% due to lack of material; And 12% for other reasons, including technical problems with haemodynamic equipment.
Conclusion: Nursing pre-cardiac catheterization allowed nurses to plan care for these clients, decreasing the incidence of cancellation of Cardiac Catheterization procedures on the day of the examination, lack of appropriate preparation orientation, previous evaluation of laboratory test data , Evaluation of the access route, and adequacy in the scheduling of priorities, such as the need for femoral access, hemodialysis, and previous hydration.

POPULATION STUDIES - EPIDEMIOLOGY

P1924
Do patients with midterm HF have profile like HFrEF or HFpEF or they have their individual profile. Data from Russian national register 2012

V Y Mareev[1]; E M Seredenina[1]; Y V Mareev[2]; E N Borisov[1]; Y L Begrambegova[1]; M E Tchaikovsky[3]
[1]Medical Scientific Educational Center of M V Lomonosov Moscow State University, Moscow, Russian Federation; [2]Royal Brompton & Harefield Hospitals, Imperial College, London, United Kingdom; [3]Russian Society of Heart Failure Specialists , Moscow, Russian Federation

Background: In the new ESC guidelines for diagnosis and treatment of acute and chronic heart failure (HF) the new classification of heart failure was proposed which include the new type of heart failure – HF with mid-range LVEF (HFmrEF). At this moment, there is a lack prevalence and epidemiology of these patients.
Methods: we used data from Russian National Register 2012. For this analysis, patients were divided into three groups related to their LVEF: < 40%, HFrEF; 40-49% HFmrEF, ≥ 50% HFpEF.
Results: 2055 patients with heart failure were included in this analysis: 542 had HFrEF, 568 HFmrEF, and 945 HFpEF. Patients with HFmrEF were slightly older than patients with HFrEF and slightly younger than patients with HFpEF (mean 64; 61; 66, $p < 0.01$). The number of men was highest in HFrEF (69%) lower in HFmrEF (60%), and lowest in HFpEF (38%), $p < 0.01$. The rate of myocardial infarction in these patients with was slightly lower than in HFrEF (56 vs. 63%, $p < 0.01$) and dramatically higher than HFpEF (24%, $p < 0.01$). However, the prevalence of hypertension in HFmrEF was close to HFpEF (93% vs 96%, $p < 0.01$) and higher than in HFrEF (83%, $p < 0.01$). The prevalence of VT in patients with HFmrEF (7%) was dramatically lower than in HFrEF (21%, $P < 0.01$) and substantially higher than in HFpEF (2%, $P < 0.01$). Patients with HFrEF and HFmrEF have a higher prevalence of smoking and alcohol abuse, which could reflect the fact that there was the greater prevalence of infarctions and higher proportions of men in these groups.
Conclusion: Results of the work showed that patients with HFmrEF have some difference from both HFrEF and HFpEF and we need study which would find the best treatment for this patients.

P1925
Does heart failure influence the clinical characteristics of admitted patients with atrial fibrillation?

A Kartas[1]; I Doundoulakis[1]; D Vasdeki[1]; A Samaras[1]; E Kotsi[1]; E Forozidou[1]; P Tsoukra[1]; T Panagiotidis[1]; H Karvounis[1]; A Tzikas[1]; G George Giannakoulas[1]
[1]AHEPA General Hospital, Thessaloniki, Greece

On behalf of: MISOAC Investigators

Background: Heart failure (HF), which was trichotomized by recent guidelines into HF with reduced ejection fraction (HFrEF), HF with mid-range ejection fraction (HFmrEF) and HF with preserved ejection fraction (HFpEF), frequently coexists with atrial fibrillation (AF). Studies regarding the epidemiologic consequences of this co-occurrence, under the scope of the new classification, are lacking.
Purpose: To determine the effect of HF and its subtypes on the epidemiologic profile of patients with a history of AF who were admitted to a cardiology ward.
Methods: We assessed the prevalence of HF in consecutive patients, who were admitted to the Cardiology Department with any diagnosis, and had a history of AF. Subjects with HF were stratified to HFrEF, HFmrEF, and HFpEF categories, according to their LVEF. Baseline characteristics were calculated [age, main symptom on admission (dyspnea, angina, palpitations, dizziness, fatigue), number of comorbidities (coronary artery disease, stroke/TIA, chronic obstructive pulmonary disease, chronic kidney disease, diabetes mellitus, hypertension, dyslipidemia, vascular, hepatic, gastrointestinal, endocrine, rheumatic, other disease), CHA2DS2-Vasc and HAS-BLED scores]. Comparisons were made between groups with and without HF, and within HF subgroups (t-test, one-way ANOVA, chi-square).
Results: A total of 510 patients (mean age: 73.3 ± 10.9 years) were enrolled. A history of HF (HFpEF:63%, HFrEF:21%, HFmrEF:16%) was present in 45.5% of admitted patients with AF, of which 54.4% had permanent AF. Patients with AF were more likely to present with dyspnea (36%), with higher frequency in HF versus no HF (41% vs 31%, $p = 0.02$), while there was no difference between HF subtypes. Patients with a history of HF (versus no HF) had more comorbidities (3.9 vs 3.3, mean difference (MD) 95% CI: 0.2- 0.9), higher CHA2DS2-Vasc (5 vs 3.7, MD 95% CI: 0.9-1.7) and higher HAS-BLED (2.9 vs 2.5, MD 95% CI: 0.2-0.7), while there were no significant differences between HF subtypes.

Conclusion: Almost half of admitted patients with AF have a history of HF, with permanent AF and HFpEF being the most common phenotype. Patients with AF in the setting of HF had more prevalent dyspnea, a heavier multimorbidity burden, and a higher thrombotic and hemorrhagic risk, irrespective of HF subtype.

P1926

Incidence and healthcare pathways in patients hospitalized for new onset heart failure in a region of northern italy

D Pavan[1]; E Clagnan[1]; F Valent[1]; G Lardieri[1]; V Moretti[1]; L Massa[1]; C Fresco[1]; A Di Chiara[1]; P Pierluigi Lesizza[1]; L Zanier[1]; A Di Lenarda[1]
[1]*Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy*

Background: Our Regional Social and Health Information System (SISSR) provides reliable information on epidemiology, health care pathways and prognosis of cardiovascular diseases (CV). The objective of our analysis was to describe the admission rate for new onset heart failure (HF) and analyze the provided health care among residents in our region in 2009-10.
Methods: The analyses were made by querying the SISSR using SAS Enterprise Guide 7.1. The new cases of HF in 2009-2010 were identified from the Hospital Discharge Diagnosis Codes of the residents in our region with first ICD-9-CM codes 398.91, 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13, 404.91, 404.93, 428.0-4 , 428.9. For the analyses, SISSR was linked with regional databases of healthcare services and procedures and drug distribution system.
Results: In 2009-2010 there were 5963 admissions for new onset HF (average rate of 2.41 per 1000 person-years; range in 5 Regional Health Authorities 2.14 to 2.72). Hospital admission involved in 86% subjects ≥70 years. Males were prevalent in pts < 80 years, females ≥ 80 years. 82% of the pts were discharged from Medicine, 11% from Cardiology. Comparing the pts of 2009-2010 with those of 2015, prescription of exams (ECG, echocardiogram, chest x-ray, natriuretic peptides) increased from 72% in the 5 years prior to admission to 75% in the 5 years after discharge. The number of pts in CV therapy during the same period increased from 89% to 94%. Comparing the 2009-2010 cohort with 2015, the number of first hospitalizations for HF was reduced by 12%, with a large variability in 5 regional Health Authorities (range -30% - + 3%). The rate x 10,000 pts of age ≥70 years decreased from 117.0 (range 126.2 to 104.8) to 97.4 (range 92.0 to 101.4) while the average stay remained stable (10 days). Among the 5457 who were discharged alive, in 1713 (31%; 28-36%) the home nursing care was active after admission (new activation in 473, 27.6%). Among 1042 GPs working in FVG, 909 (87%) were following at least one patient with HF (39% 1-5 pts; 38% 6-10 pts; 11% >10 pts (average 5.5 pts with HF for each GP, range 0 -22).
Conclusions: The regional data warehouse of our region provides useful information to plan educational activities and improvement of quality of care and clinical pathways. The trend of new admissions for HF is highly variable in the 5 regional Health Authorities, as well as it is clear a lot of room for improvement of post-discharge pathways and care.

Funding Acknowledgements: Hellenic Cardiological Society

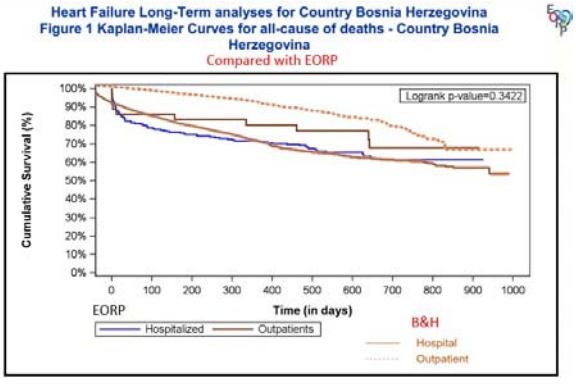
Introduction: As patients with atrial septal defect (ASD) age, prevalence of heart failure (HF) rises.
Purpose: To study the clinical characteristics of elderly (> 60 years) patients with ASD who are under medical therapy for HF and to highlight the predictive factors for prescribing HF pharmacotherapy in this population.
Methods: Data from February 2012 until November 2016 were collected from the national registry of adult congenital heart disease (ACHD) in Greece (CHALLENGE).
Results: A total of 2085 ACHD patients were included, of which 228 (10.9%) were older than 60 years old (63.6% women). ASD was the most prevalent diagnosis (n = 137, 60.1% of elderly patients, mean age 70.4 years, 63.5% women). Percutaneous ASD closure was performed in 27%, surgical repair in 25%, while 48% patients had not undergone any procedure at all. Of elderly ASD patients, 57 (41.6%) were under HF medical treatment. Physicians were more likely to prescribe HF pharmacotherapy in older patients (73.1 vs 69.4 years, $p < 0.001$), in heavily symptomatic patients (76.9% of NYHA III/IV patients vs 33.3% of NYHA I/II, $p < 0.001$), in those who received antiarrhythmic drugs ($p < 0.001$) and in patients with an open defect or surgical ASD closure ($p = 0.001$). Gender did not predict the administration of HF pharmacotherapy. On multivariable analysis, $\nu\nu\eta\alpha$ class III/IV, use of antiarrhythmic drugs and presence of an open defect or history of surgical ASD repair were independent predictive factors for HF pharmacotherapy.
Conclusion: In our national registry, almost 40% of elderly patients with ASD were under HF medical treatment. Advanced functional class and history of arrhythmias were predictors of administration of HF pharmacotherapy, while percutaneous ASD closure was a preventive factor.

P1928

EORP Registar of Bosnia and Herzegovina, comparative differences with other regions included in EORP

E Emir Fazlibegovic[1]; D Pravdic[1]; O Manov[1]; D Zelenika[1]; M Cesko[1]
[1]*Clinical Center Mostar, Mostar, Bosnia and Herzegovina*

Objective: A major goal of EURObservational Research Programme (EORP) is to record and evaluate medical practice in Europe and around the world, based on the collect of real-life data in different countries.
Methods: We did a statistical analysis and comparison of individual patient characteristics in EORP registry of B&H and other countries involved in EORP.
Results: There is a significant difference in the one-year follow-up of patients dying in B&H in relation to the other countries included in EORP in cardiovascular death (93.2%; $p < 0.0001$) between B&H and other countries in the region (51.7% in total and 48.7%). An LVEF in patients in B&H was significantly higher as compared to other countries in the region ($p < 0.0001$) with median EF 51.5%: 37% and the number of patients with an LVEF> 45% was higher in B&H in relation to other countries (59%: 31.6%). Comorbidities have been significantly greater in our patients in relation to other countries with $p < 0.0001$ for the disease: hepatic dysfunction (24.3%: 7.5%), COPD (55.3%: 18. 4%), suffered ICV or TIA (37.3%: 11.7%), peripheral vascular disease (48.6%: 12.3%). Ischemic heart disease was significantly more prevalent ($p < 0.0001$) as a cause of heart failure in 71.4% compared to 53.1% of respondents from other countries. Smoking as a risk factor for CVD were present significant ($p < 0.0001$) with 68.2% of B&H respondents in the registry compared to 50.7% in subjects from other countries. The anemia with hemoglobin < = 12 g / dL (28.3%: 40.6%) was significantly lower in patients B&H in relation to other countries. Intra hospital mortality was significantly represented ($p < 0.0001$) in patients register of B&H 15.3% compared to 4.4% in other countries of the region. Pulmonary edema as a form of hospital presentation was found in 7.5%, while in other countries it was 12.9% ($p < 0.0001$). Significantly ($p < 0.0001$) less application equipment to support heart rate (PM and ICD) in B&H patients in the registry 95.2% compared to 84.8% in other countries. There is significant difference ($p < 0.0001$) in the application of certain pharmaceuticals in the treatment of patients with HF in B&H and other countries, especially diuretics (71.8%: 82%), and inotropic compound (30.2%: 10.6%), especially digitalis (15.3%: 26.4%). One-year survival of patients in the registry EORP and B & H is significantly different as can be seen in the Kaplan-Meier survival curves.(Figure 1)
Conclusions: Education of physicians is necessary to improve treatment and application of modern drugs. In long-term monitoring, we can come up with new knowledge on implementation of specific treatments of the ESC Guidelines for AHF/CHF.



Kaplan Mejer courve of survival

P1929

Predictors of six-month mortality after discharge in patients hospitalized with decompensated chronic heart failure

S Galochkin[1]; S Padaryan[1]; L Babaeva[1]; E Shavarova[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: To evaluate the rate and predictors of mortality in patients hospitalized with decompensated chronic heart failure (DHF).
Material and methods: hospital-based, prospective, observational study using the data from the HF Registry. All patients admitted for two Moscow city clinical hospitals with DHF from January to May 2015 were included into the registry (n = 484). Clinical, demographic, laboratory and instrumental characteristics and medical treatment were evaluated. After 6-month follow up data on mortality are collected by telephone contact with patients or relatives using structured questionary (n = 265).
Results: The median age was 73 years (39, 95); men – 45%. 97% of patients had HF II- IV (NYHA), among them 26% - HF II, 64% - HF III, 10% - HF IV (NYHA). Echocardiography was done in 100% patients with HF. EF < 40% was found in 44% of patients. Uncontrolled arterial hypertension was the main reason for decompensation of chronic HF in 47%, atrial fibrillation - 46%, treatment non-compliance – 36%, coronary artery disease progression – 16%, respiratory infections – 14%, alcohol abuse - 6%, uncontrolled intake of nonsteroidal anti-inflammatory drugs - 2%. 6-month mortality rate was 18,8%. There was no significant difference in mortality rate between groups due to EF (19.1% in HFrEF vs 18.3% in HFpEF). Death due to HF decompensation was the most often reason (53%), among others – 10% - acute coronary syndrome, terminal chronic kidney disease – 5%, advanced cancer - 4%, sudden cardiac death – 4%, not known – 24%. Significant factors for six-month mortality were the following: hemoglobin (Hb) level at admission (p = 0.003), high dose of loop diuretics (p = 0.005), alcohol abuse (p = 0.01). Hb was significantly lower in died pts to compare with survived pts [109 (103; 105) vs 134 (122; 142)] g/l, respectively, p = 0,016). Regression analysis showed association between Hb level and lethal outcomes [OR 1,05; 95% CI 1,01-1,10; p = 0,016] and after adjustment for age, LV EF [adjusted OR 1,05; 95% CI 1,01-1,09; p = 0,027].
Conclusion: in patients hospitalized with decompensated heart failure six-month mortality rate higher in presense of anemia and using of high dose of loop diuretics.

P1930

Admissions to intensive cardiac care units in france in 2014: a cross-sectional, nationwide population-based study.

G Gregoire Mercier[1]; A Riondel[1]; C Delmas[2]; S Manzo-Silberman[3]; G Leurent[4]; M Elbaz[2]; E Bonnefoy-Cudraz[5]; P Henry[3]; F Roubille[1]
[1]*University Hospital of Montpellier, Montpellier, France*; [2]*Toulouse Rangueil University Hospital (CHU), Cardiology department, Toulouse, France*; [3]*Hospital Lariboisiere, Department of cardiology, Paris, France*; [4]*University Hospital of Rennes, Cardiology department, Rennes, France*; [5]*Civils Hospices of Lyon, Cardiology department, Lyon, France*

Background: Intensive Cardiac Care Units (ICCU) are managing patients admitted for heterogeneous and complex pathologies. The available evidence suggests considerable variation in ICCU admission rates within countries. Although a better understanding of this variation would be helpful to cardiologists and policy-makers, its drivers remain largely unknown.
Aim: To explain the geographic variation in the rate of ICCU admission for Heart Failure (HF) in France in 2014.
Methods: This is a nationwide, observational, population-based study based on the French hospital discharge database for the year 2014. All acute inpatient stays for HF with at least one ICCU admission were included. Age- and sex-standardized admission rates were calculated at the departement level and modelled using epidemiological, access and socio-economic variables.
Results: 27,828 stays were included. At the departement level (n = 94), the standardized ICCU admission rate varied between 0.04 and 1.24 per year per 1,000 population. It was positively associated with diabetes prevalence, and negatively associated with the proportion of the population aged 75 years or more and with the driving time to ICCU.
Conclusions: This study sheds light on considerable geographic variation in the ICCU admission rates for HF in France. This variation is explained not only by disease patterns, but by access to ICCU, too. This suggests inequalities of access to highly specialized cardiologic care.

P1931

The proportion of heart failure patients with reduced, mid-range and preserved ejection fraction in a real-life heart failure population

M Szabo[1]; M Dekany[1]; B Muk[1]; D Vagany[1]; T Borsanyi[1]; ZS Majoros[1]; RG Kiss[1]; N Nyolczas[1]
[1]*Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary*

Background: The new ESC guideline for heart failure, published in 2016, introduced the terminology of heart failure with mid-range ejection fraction (HFmrEF) (40%≤LVEF<50%) in addition to the well-known definition of heart failure with reduced (HFrEF) (LVEF<40%) and preserved (HFpEF) (LVEF≥50%) ejection fraction. The diagnostic criteria are the typical clinical signs and symptoms and specific values of left ventricular ejection fraction (LVEF) in every case. In HFmrEF and HFpEF the elevated level of natriuretic peptides and at least one additional criterion of left ventricular hypertrophy and/or left atrial enlargement and/or diastolic dysfunction are necessary.
Purpose: The aim of the study was to identify the proportion of the HFrEF, HFmrEF and HFpEF according to the new ESC guideline in patients with heart failure signs and symptoms, who were not treated for heart failure previously and referred to our heart failure outpatient department.
Patients and methods: We assessed the data of 367 patients (mean age: 63.2 ± 11.8 years, proportion of men: 65.4 %, LVEF: 42.4 ± 12.9 %, NYHA: 2.17 ± 0.35, ischaemic aetiology: 58.3 %, NTproBNP: 2839.6 ± 2935.2 pg/ml) with heart failure signs and symptoms who were not treated for heart failure previously and referred to our heart failure outpatient department between 01.12.2013. and 30.11.2015. HFmrEF and HFpEF were defined if beyond the LVEF criteria NTproBNP>125pg/ml and left atrial enlargement and/or left ventricular hypertrophy exist.
Results: LVEF was under 40% in the case of 173 patients (47.1%), in 52 patients (14.2%) LVEF was between 40% and 50%, and in the case of 142 patients (38.7%) was the LVEF≥50%. In 44 of 52 patients with mid-range ejection fraction NT-proBNP level was elevated, and in 41 cases left atrial enlargement and/or left ventricular hypertrophy were revealed, so in 41 patients HFmrEF was proved. In 104 of 142 patients with preserved ejection fraction NT-proBNP level was elevated, and in 87 cases left atrial enlargement and/or left ventricular hypertrophy were found, so 87 patients were diagnosed as HFpEF. 301 (82.0%) of 367 studied patients were proved to have heart failure and 57.5% of them was HFrEF, 13.6% HFmrEF, and 28.9% HFpEF. In 21.2% of the patients with mid-range ejection fraction and in 38.7% of the patients with preserved ejection fraction heart failure was not verified according to the new ESC guideline criteria.
Conclusion: According to our study, in a real-life heart failure population, the proportion of the patients with HFmrEF is half of HFpEF, and quarter of HFrEF patients. If NT-proBNP and echocardiography criteria are concerned beyond signs and symptoms and LVEF at the diagnosis of HFpEF, the real proportion of the HFpEF patients becomes much lower than it was in the majority of the epidemiological trials.

P1932

Differences between men and women in a our population with heart failure

I Irene Rilo Miranda[1]; JR Beramendi Calero[1]; S Garcia Gutierrez[2]; ANE Anton Ladislao[2]; L Quintas Ovejero[3]; C Goena Vives[3]; M Morillas Bueno[2]; F De La Cuesta Arzamendi[1]
[1]*Hospital Donostia, San Sebastian, Spain*; [2]*Hospital Galdakao-Usansolo, Bilbao, Spain*; [3]*Hospital Comarcal de Mendaro, Cardiology, Mendaro, Spain*

Introduction: This study aims to determine the differential characteristics between men and women among patients with acute heart failure admitted to the Emergency Services 3 hospitals in our network between 2011 and 2013.
Methods: Observational prospective cohort study including 1824 patients presenting to the emergency room of our hospital for acute decompensated heart failure. Outcome variables were considered short-term mortality and readmissions during 3 months.
Results: The sample included 1824 patients. 48% (886) were male and 51% (938) female. Females were older at the diagnosis time 81,72 years vs 77,38 (p < 0.0001) and among female was more frequent Arterial Hypertension (86% vs 80 % (p = 0,0014) and therefore heart failure with preserved ejection fraction was more prevalent: 62,72 % vs 38,94 % (p < 0,0001).Moreover, Diabetes Mellitus was more prevalent in males (35 % vs 31 % p0,0565 and the degree of chronic kidney disease was higher in males 7,34 % vs 4,585 % and the rate of ischemic cardiomiopathy is significantly higher in men 40,74 % vs 25,59 % (p < 0,0001). Despite these data in our study we found no significant differences in short-term mortality (4,80 % in women and 3,73 % in men p = 0,2598) and mortality at 3 months (9,18 vs 9,25 % p = 0.96)
Conclusions: Women were older at the diagnosis and had higher prevalence of arterial hypertension. The rate of heart failure with preserved ejection fraction was higher among females. Men presented a higher percentage of ischemic cardiomyopathy, chronic kidney disease and diabetes mellitus.

Despite the differences between sexes in our study we found no significant differences in short-term mortality and mortality at 3 months

P1933

Determination of level of knowledge of cardiovascular disease risk factors among university students.

S Oguz[1]; G Gulsah Camci[1]; B Bayrak[1]; B Erguvan[1]; G Unal[1]
[1]*Marmara University, Health Science Faculty, Nursing Departmant, Istanbul, Turkey*

Background: If we know cardiovascular disease risk factors in our life and take necessary measures, cardiovascular disease can be reduced.
Purpose: This study was planned as cross-sectional and descriptive in order to determine level of knowledge of cardiovascular disease risk factors among university students.
Methods: This research was carried out among the students who are studying in the University, Faculty of Law and Faculty of Health Sciences, Nursing Department between the February - April 2016 dates. The study was attended by 650 students. Data were collected by a Questionnaire" and "Cardiovascular Disease Risk Factors Knowledge Level scale" (KARRİF-BD). Data was analyzed by using frequency, percentage, mean, t-test and one-way ANOVA
Results: The average age of the students was 20.1 ± 3.9, 71.8% were female, 43.5% studied in the nursing department and 56.5% studied in the law deparment. The average body mass index of students was 21.8 ± 8.4. It was determined that the students who participated in the study; there was no chronic disease in 91.7%, 51.4% didn't know the blood pressure value, 96.4% from the absence of heart disease, there was heart disease 30.9% of student's family, 87.2% of them didn't smoke, 68% of them exercised. The mean score of students to KARRIF-BD scale was 19.5 ± 4.6 (min-max: 2-28). It had moderate knowledge level of the students. There was significant difference between mean scores KARRİF-BD and the section of students ($p < .000$), gender ($p < .003$), who know the blood pressure value ($p < .000$). Nursing students and female students had higher information about the cardiovascular disease risk factors ($p < .000$) and the result of changes in risky behavior ($p < .003$) in category of the scale.
Conclusions: When looking at the average scale scores of KARRIF-BD in nursing and law students, the knowledege of nursing students was higher than the law students. The knowledge of female students was higher than male students.

P1934

Prevalence of subclinical atherosclerosis in persons of working age

NA Koriagina[1]; LM Vasilets[1]; AA Shadrin[1]; OB Melekhova[1]; DV Mikhnevich[1]
[1]*Medical Academy, Perm, Russian Federation*

Objective: To evaluate the frequency of occurrence of subclinical atherosclerosis and atherosclerosis risk factors in people of working age with low cardiovascular risk.
Methods: The study included people of working age from 25 to 50 years, had no complaints on the part of the cardiovascular system. All performed: measurement of office blood pressure (BP), evaluation of anthropometric data, the study of risk factors (RF) of atherosclerosis. For verification of subclinical atherosclerosis (CA) carried ultrasound of brachiocephalic arteries (BCA) and multislice computed tomography (MSCT) with the assessment of coronary calcium.
Results: A total of 100 persons of working age, the average age was 46.5 years, 65% of them women. According to the survey: 40% of patients smoking, hypertension was detected in 36% of the SHA heredity burdened with 28%. CA was detected in 42% of patients. The average values of thickness of intima media complex (IMT) does not exceed normal parameters: IMT right - 0.89 mm, IMT left - 0.81 mm (N < 0,9 mm, depending on age). In 43% of patients with AS compared with healthy individuals were determined by atherosclerotic plaques (ASB) in the carotid arteries with stenosis hemodynamically insignificant. Calcification of the coronary arteries was diagnosed in 12.5% of patients. Abdominal obesity was observed in 30 patients with asymptomatic atherosclerosis, representing 58.8%, while in the group of healthy individuals only three persons. In the group with asymptomatic atherosclerosis revealed significant negative correlations of BMI and waist circumference (OT) with HDL-C ($r = -0,66$; $r = -0,71$, $p < 0.05$).
Conclusions: Thus, in 42% of healthy individuals of working age is revealed subclinical atherosclerosis, which involves the need for the introduction into clinical practice algorithms for early diagnosis and prevention of atherosclerosis.

P1935

Prevalence of prehypertension in young adults students technical high school and college. Related variables.

ILPB Anjos[1]; IP Borges[1]; LLB Bandeira[1]; CS Souza[2]; RTS Peixoto[2]; RTS Peixoto[2]; AAB Aragao[3]; VF Marcolla[3]; SA Simoes[3]; ECS Peixoto[2]
[1]*Severino Sombra University, Vassouras, Brazil*; [2]*Fluminense Federal University, SENAI/CETIQT, Niteroi, Brazil*; [3]*Rio de Janeiro State Government, Rio de Janeiro, Brazil*

Background: Worldwide, several studies have been conducted about the association between hypertension in childhood and adolescence and socio-demographic factors: lifestyle, family history and anthropometry.
Objective: This study aims to identify the prevalence of prehypertension and related variables in young adults.
Methods: Cohort study. The variables were collected by questionnaire or measures. Univariate analysis was performed using the chi square and it was performed five multiple logistic regression models for the variables with $p < 0.10$ in the univariate analysis. The students were from three courses, either college as vocational school, were evaluated: gender, age, course, skin color, income, education, lifestyle, history of hypertension, weight, waist circumference and prehypertension defined as VII Joint National Committee: systolic 120-139 and diastolic 80-89 mmHg.
Results: A total of 394 students were evaluated. There were 309 (78,43%) in the normal group (NG) and 85 (21,57%) in prehypertension group (PH) of students. It was found in NG and PG, respectively: females 254 (85.2%) and 44 (14.8%) ($p < 0.001$); males 55 (57,3%) and 41 (42,7%) ($p \leq 0.001$); age (three age ranges: until 19 years, 20-25 and 25-30) more frequent in older ($p = 0.001$); ethnicity (self declared) black 16 (5.2%) and 11 (12.9%) ($p < 0.001$); 62 mother´s hypertension (20.1%) and 28 (32.9%) ($p = 0.024$); overweight 34 (11.0%) and 17 (20.0%) ($p = 0.045$); obese 3 (1.0%) and 10 (11.8%) ($p < 0.001$); increased abdominal circumference 37 (12.0%) and 19 (22.3%) ($p = 0.024$). At least one of five multiple logistic regression models were associated with absence or presence of prehypertension (OR, 95% CI): females (4,026, 2.373 to 6.828), age (1.081, 1.004 to 1.164), hypertensive mother (1.838, 1.027 to 3.289) and greater waist circumference (1.067, 1.035 to 1.100).
Conclusion: About a fifth of the students were considered to be in prehypertension group. Factors associated with prehypertension this study: male, older, mother with hypertension and increased waist circumference

total studants 394 (100%)	normal group 309 (78,43%)	pre-hypertension group 85 (21,57%)	p

Professional or personal experience increases the awareness of heart failure in the european population

V Vintila[1]; A Vintila[2]; A Cotoban[1]; S Stork[3]; M Lainscak[4]; D Vinereanu[1]
[1]*University of Medicine and Pharmacy Carol Davila, University and Emergency Hospital Bucharest, Cardiology Department, Bucharest, Romania*; [2]*University of Medicine and Pharmacy Carol Davila, Coltea Clinical Hospital, Internal Medicine Department, Bucharest, Romania*; [3]*Comprehensive Heart Failure Center (CHFC), University of Wurzburg, Wurzburg, Germany*; [4]*Faculty of Medicine, University of Ljubljana, , General Hospital Murska Sobota, Murska Sobota, Slovenia*

On behalf of: Heart Failure Awareness Day Initiative

Background: Heart failure (HF) is a common pathological condition. HF Awarness Day represents an European annual event, with the objective to increase the knowledge of the general population regarding HF symptoms and management.
Aim: To demonstrate that working in the medical field or having a previous exposure to HF would increase the HF awareness.
Method: We analysed 3 annual sets of consecutive data, obtained from questionaires filled in by the general population from various European countries, during Heart Failure Awarness Day campaign (from 2013 to 2015). A score was computed from the correct answers. A cut-off of 6 points was considered to prove HF awareness. Two specific subgroups were defined: group A, with professional experience (present or former employment in the medical field); and group B, with personal experience (patients with HF or their relatives with HF).

Results: A total of 7947 subjects were enroled: 1777, 3685, and 2485 subjects, corresponding to the 3 annual sets, with a similar median score of 7.3 ± 4.4, 7.3 ± 4.4 and 7.0 ± 4.4, respectively. High scoring (above 6) was more frequent in both group A and B, for all 3 annual sets (Table).
Conclusion: Professional or personal experience, achieved either through learning or exposure increases awareness of heart failure in the studied European population.

Professional and personal experience

	2013	2014	2015	TOTAL

P1937

The impact of congestive heart failure on health-related quality of life among patients with cardiac-involved light chain amyloidosis

KL Kristen Mccausland[1]; M Yokota[1]; TP Quock[2]; SD Guthrie[2]; MK White[1]; M Bayliss[1]
[1]Optum, Lincoln, Rhode Island, United States of America; *[2]Prothena Biosciences, Inc., South San Francisco, California, United States of America*

Background: Light chain (AL) amyloidosis is a heterogeneous, rare disease characterised by misfolded protein deposits in tissues and vital organs. While any organ can be affected, cardiac involvement is one of the most common and severe forms of the disease. These patients are at risk for developing serious complications including arrhythmias and congestive heart failure (CHF). Deficits in health-related quality of life (HRQoL) have been documented among cardiac-involved patients, but the incremental impact of CHF on HRQoL among AL amyloidosis patients has not been documented.
Purpose: To compare clinical characteristics and HRQoL of patients with cardiac-involved AL amyloidosis by self-reported history of CHF.
Methods: A non-interventional, online study was conducted among patients with AL amyloidosis (N=341) to assess demographics, disease and treatment history and HRQoL, including the Kansas City Cardiomyopathy Questionnaire–Short Form (KCCQ-12), a validated HRQoL measure specific to heart failure. KCCQ-12 items were used to derive a total summary score and the following subscale scores: symptom frequency, physical limitations, social limitations and quality of life. Characteristics of cardiac-involved patients with self-reported CHF (n = 82) and without CHF (n = 85) were compared using chi square and independent samples t-tests. Differences in HRQoL were examined using multivariable generalised linear models.
Results: Approximately 49% of patients with cardiac involvement reported a history of CHF. Patients with and without CHF were similar in demographics, time to diagnosis and duration of disease. In terms of initial symptom burden, a greater proportion of CHF patients reported numbness in their arms and legs as compared to non-CHF patients (53.8% vs. 30.1%, respectively; p = 0.01); however, the prevalence of other commonly reported symptoms was comparable. The prevalence of having complete hematological response (HR) was significantly lower among patients with CHF as compared to those without (42% vs. 62%, respectively; p < 0.01). Among patients with HR, HRQoL did not differ significantly by CHF status; however, KCCQ-12 scores among patients who had not achieved HR were approximately 30% lower among CHF versus non-CHF patients (p < 0.05 for all). The average total KCCQ-12 score among non-CHF, non-HR patients was 55.7, which corresponds to scores previously observed in patients with New York Heart Association (NYHA) functional class II symptoms. In contrast, scores among CHF, non-HR patients (mean=38.6) were equivalent to scores from patients with NYHA functional class III symptoms.
Conclusion(s): Previous research has documented significant HRQoL burden in AL amyloidosis patients with cardiac involvement. These findings indicate that the impact is even worse among patients with CHF. However, differences are attenuated if HR is achieved.

P1938

Caregiver health behaviors of patients with cardiorespiratory failure

B Bernardo Robles-Uribe[1]; V Pelaez-Hernandez[2]; A Orea-Tejeda[2]; D Gonzalez-Islas[2]; R Sanchez-Santillan[2]; GK Perez-Cortes[2]; S Torres-Montiel[2]; A Figueroa-Herrera[2]; L Verdeja-Vendrell[2]; E Perez-Cabanas[2]; A Navarrate-Penaloza[2]; A Jimenez-Cepeda[2]
[1]National Autonomous University of Mexico, Mexico City, Mexico; *[2]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosio Villegas", Heart Failure and Respiratory Distress Clinic, Mexico City, Mexico*

Background: The vulnerability of caregivers is continuously related to the disease process of patients with cardiorespiratory failure (CRF). The disadvantages of the care provided by the caregivers include the lack of support equipment, the amount of time invested and the physical effort. This affects the normal development of the physical, psychic and social areas of the caregivers, making it worn and dysfunctional.
Purpose: To describe the caregivers health behaviors of the patients with CRF
Method: 19 caregivers of patients with CFR (mean age 56.79 ± 2.89, 78.9% women) participated. The caregiver's health survey was used to identify the psychosocial characteristics of the caregiver. It consists of 30 items, of which 18 were selected for health care behaviors. Descriptive statistics were performed, using the statistical package SPSS version 23.
Results: Regarding the care provided by the caregivers, 52% of caregivers are children of patients and 36.6% are spouses. 84.2% of the caregivers share the same house and only take care of one person. As to their activities, caring for their patients (36.8%), house chores (31.6%) work (21.1%) occupy most of their time. With regard to his / her owns health care behaviors, 73.1% have not had any medical examination done in the last 6 months. 47% of caregivers go to the doctor immediately when they feel bad, 26.3% only when they feel "very sick". 78.9% of the caregivers came to the doctor, dentist or nutritionist in the last 6 months at least once. In contrast to mental health care, 84.2% did not go to the psychologist, therapist or psychiatrist in the last 6 months. 63.2% do some physical activity, 94.7% do not smoke, 73.7% do not consume alcoholic beverages and 57.9% do not report a dietary regimen. Despite the fact that 57.9% of the caregivers reported have the same symptoms as their patients in any occasion. The main reasons that they prevented them to take care of their health, are: lack of time (26.3%), having no one to leave their patient (15.8%), lack of money (15.8%), no reason (15.8%), the distance from the hospital / clinic (5.3%). Likewise, the caregivers has not received information or training from the health professionals about the care of their patient (57.9%), about what it is to be a caregiver and what it implies (78.9%) or about taking care of their own health (63.2%).
Conclusion: These characteristics show an inattention to caregivers that can lead to deterioration of the different areas of their life (physical, psychic, social) and to be a risk factor for cardiorespiratory diseases. Permanent attention to the patient causes exhaustion and self-neglects to generate deterioration in their health, which is reflected in the perception of the same symptoms as their patient's symptoms.

P1939

Endothelial dysfunction, skin temperature, and vulnerability to psychological stress in patients with heart and respiratory failure. Preliminary data

E Perez Cabanas[1]; V Pelaez-Hernandez[1]; A Figueroa-Herrera[1]; A Orea-Tejeda[1]; B Dominguez-Trejo[2]; S Torres-Montiel[1]; B Robles-Uribe[1]; D Gonzalez-Islas[1]; GK Perez- Cortes[1]; AG Navarrete-Penalosa[1]; L Verdeja-Vendrell[1]; A Jimenez-Cepeda[1]; RN Sanchez-Santillan[1]
[1]National Institute of Repiratory Diseases, Heart Failure and Respiratory Distress Clinic, Ciudad de Mexico, Mexico; *[2]National Autonomous University of Mexico, Mexico City, Mexico*

Background: A chronic state of psychological stress impacts the endothelial function by increasing the atherosclerotic and pro- inflammatory process of the cardiorespiratory disease, reducing the skin temperature variability (STV) during psychological stress, and also promotes less vasodilatation, which is a prognostic indicator of re-hospitalizations.
Purpose: To investigate the relationship between bilateral STV during psychological stress and endothelial function in patients with heart and respiratory failure.
Method: 11 patients with heart and respiratory failure (mean age of 70.09 ± 12.80 years, 55.5% males and right-handed dominance) participated in this study. Bilateral STV was assessed during a psychophysiological stress profile of three phases of five minutes each (baseline, arithmetic stressor and recovery), while the patients underwent a stress test, considering these indicators for STV: symmetry (difference between both hands in °C), dominance (the highest temperature in the dominate hand), synchrony (difference between both hands at the end of each phase) and gain (increase of the temperature from the beginning to the end of each phase); more than18 points in the total sum of all indicators was considered low vulnerability to

psychological stress. Function endothelial was assessed using photoplethysmography, which consisted of: baseline, ischemia by five minutes and reactive hyperemia. Maximum Amplitude Time / Total Time index (MAT/TT) was taken at 30, 60, 90, 120 seconds after ischemia. Due to the size of sample, we carried out a non-parametric test (U de Mann-Whitney).
Results: The group with high vulnerability (n = 5; mean age of 74.4 ± 10.69 years, 60% females) presented higher MAT/TT index than those with low vulnerability (n = 6; 66.5 ± 14.22 years 66.7% males), at 60(0.41 ± 0.08 vs 0.40 ± 0.04), 90(0.45 ± 0.07 vs 0.37 ± 0.07), and 120 seconds after ischemia (0.41 ± 0.05 vs 0.39 ± 0.07); however these differences were not statistically significant. On the other hand, differences in symmetry throughout psychophysiological stress profile ($p < 0.05$), and gain during baseline ($p < 0.05$) were statistically significant. Patients with high vulnerability to psychological stress were less symmetrical among both hands and they had less temperature gain.
Conclusion: Patients with more vulnerability to psychological stress showed greater endothelial dysfunction and peripheral vasoconstriction, less symmetry and temperature gain, which is related to worse prognosis. However these are preliminary data, and we will continue increasing the sample size.

P1940
Differences in blood pressure levels during psychological stress among patients with cardiopulmonary disease with internal or external expression of anger

F Figueroa-Herrera[1]; E Perez-Cabanas[2]; V Pelaez-Hernandez[2]; B Robles-Uribe[2]; S Torres-Montiel[2]; A Orea-Tejeda[2]; B Dominguez-Trejo[1]; D Gonzalez-Islas[2]; L Verdeja-Vendrell[2]; RN Sanchez-Santillan[2]; A Jimenez-Cepeda[2]; AG Navarrete-Penaloza[2]; KG Perez-Cortes[2]
[1]National Autonomous University of Mexico, Mexico City, Mexico; *[2]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosio Villegas", Heart Failure and Respiratory Distress Clinic, Mexico City, Mexico*

Background: Anger is a psychosocial risk factor for developing cardiovascular disease. The chronic manifestation of anger produces psychological stress that impacts on the heart and reactivity to psychological stress. Two possible forms of anger management are: 1) Internal Expression, in which anger is suppressed; and 2) External Expression, which involves manifesting anger toward people and objects. On one hand chronic suppression of anger has been associated with increased blood pressure and carotid artery stiffness and on the other hand, the expression of anger has positive health outcomes. However, it is unknown how the type of anger expression influences blood pressure in the face of psychological stress.
Objective: To compare systolic and diastolic blood pressure in the presence of psychological stress among patients with cardiopulmonary disease (CD) with internal or external anger expression.
Method: Twenty-six patients with CD participated. The type of anger expression was evaluated with the State-Trait Anger Expression Inventory (STAXI-2). According to the results, the patients were divided into two groups: 1) internal expression (IAE, n = 11 mean age 72.18 ± 17.14, 63.63% women) and 2) external (EAE, n = 15 mean age 67.67 ± 10.17, 53.33% women). A psychophysiological stress profile of 15 min was applied, divided in three phases of 5 min each 1) Baseline (BL), 2) Arithmetic stressor (AS) and 3) Recovery (R). Mean blood pressure was taking from three measurements made during each phase of the profile. A Mann-Whitney U test was tested to determine differences in systolic blood pressure (SBP) and diastolic (DBP) between the types of anger expression.
Results: There were statistically significant differences in DBP in the three phases of the profile between patients with IAE and EAE. It is found that patients with EAE have a higher SBP and DBP compared to those classified in IAE at all stages.
SBPBL: IAE: 119.51 ± 19.18; EAE: 132.31 ± 24.29 ($z = -1.532$, $p > 0.05$)
DBPBL: IAE: 67.51 ± 9.01; EAE: 78.35 ± 10.74 ($z = -2.336$, $p < 0.05$)
SBPAS: IAE: 121.30 ± 18.19; EAE: 132.58 ± 19.18 ($z = -1.636$, $p > 0.05$)
DBPAS: IAE: 70.06 ± 10.71; EAE: 82.42 ± 12.10 ($z = -2.544$, $p < 0.05$)
SBPR: IAE: 118.03 ± 18.19; EAE: 128.26 ± 22.11 ($z = -1.272$, $p > 0.05$)
DBPR: IAE: 66.33 ± 9.20; EAE: 77.95 ± 9.78 ($z = -2.751$, $p < 0.05$)
Conclusion: SBP and DBP are higher in patients classified with EAE than IAE, which is contradictory to what has been reported in other studies. However within the research is not taken into account if the expression of anger is overreacted, which has an effect on blood pressure. Therefore, the results obtained might suggest that patients in this sample overreacted their anger. For the future, it will be considered the intensity of anger expression.

EXERCICE TESTING AND TRAINING

P1941
Reduced cardiac reserve contributes to exercise tolerance in adult patients with sickle cell anemia

A Ceccaldi[1]; S Hatem[1]; K Stankovic-Stojanovic[2]; P Guedeney[1]; F Nicolas-Jilwan[2]; JP Haymann[2]; G Montalescot[1]; F Lionnet[2]; R Isnard[1]; N Hammoudi[1]
[1]Hospital Pitie-Salpetriere, Cardiology, Paris, France; *[2]Hospital Tenon, Paris, France*

Background: Sickle cell anemia (SCA) is associated with marked exercise intolerance. However, mechanisms underlying this functional limitation remain incompletely characterized. We hypothesized that abnormal cardiovascular reserve is an important determinant of SCA exercise capacity.
Objectives: To investigate the cardiac response to exercise in a contemporary adult SCA population.
Methods: We compared 60 SCA patients (median age, 31 years, 60% women) to 20 controls matched for age and gender. All subjects prospectively underwent a symptom-limited cardiopulmonary exercise testing with combined echocardiography. The oxygen uptake (VO2) and cardiac index (Ci) were simultaneously measured. The difference between arterial and venous oxygen content (C(a-v)O2) was calculated using Fick principle. The left ventricular (LV) function was comprehensively studied at rest and during exercise.
Results: Compared to controls, the SCA patients had severe exercise intolerance (median peak VO2, 19.7 versus 34.3 ml/min/kg, $p < 0.0001$). In SCA population the increase in Ci from rest to peak exercise was widely scattered and correlated closely with peak VO2 ($r = 0.71$, $p < 0.0001$); in contrast, the C(a-v)O2 reserve was homogenously reduced and did not correlate with exercise capacity ($r = 0.18$, $p = 0.16$). Compared to controls, SCA patients had chronotropic incompetence, blunted LV preload reserve and higher LV filling pressures. The SCA patients were classified in tertiles according to peak VO2. While hemoglobin level and C(a-v)O2 were similar, SCA patients in the lower VO2 tertile were characterized by an alteration of cardiovascular reserve related to ageing and to left atrial function deterioration (table).
Conclusion: The ability of cardiovascular system to increase Ci is an important determinant of SCA exercise capacity.

	Lower VO2 tertile (n = 20)	Other VO2 tertiles (n = 40)	p
Age(years)	40 [34-48]	27 [22-34]	0.0002
Hemoglobin(g/dl)	8.1 [7.5-9.5]	8.5 [8.1-9.7]	0.09
Peak VO2(ml/min/kg)	15.1 [14.4-16.8]	21.8 [19.7-23.4]	< 0.0001
Rest Cardiac index(l/min/m^2)	4.2 [3.5-5.1]	3.9 [3.4-4.6]	0.33
Peak Cardiac index(l/min/m^2)	9.0 [8.5-9.5]	10.5 [9.2-12.1]	0.0004
Peak Ca-vO2(ml/dl)	6.6 [6.0 - 7.3]	7.3 [6.2-8.0]	0.11
LV ejection fraction at peak(%)	70 [68-74]	71 [67-74]	0.88
Left atrial volume index at rest(ml/m^2)	57 [40-68]	45 [37-52]	0.02

P1942
Haemodynamic effects of a novel, personalised, home-based physical activity intervention for chronic heart failure

NC Okwose[1]; S Cassidy[1]; K Bailey[2]; J Skinner[2]; GA Macgowan[3]; D Jakovljevic[1]
[1]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; *[2]Royal Victoria Infirmary, Cardiology, Newcastle upon Tyne, United Kingdom*; *[3]Freeman Hospital, The Cardiothoracic Centre, Newcastle upon Tyne, United Kingdom*

Funding Acknowledgements: UK NIHR Biomedical Research Centre

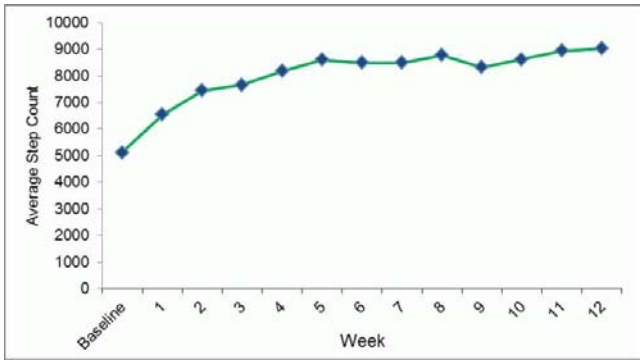
Background/Aim: Exercise-based cardiac rehabilitation programmes are safe and recommended to improve symptoms and outcomes in chronic heart failure (CHF).

However <10% of CHF patients in the UK participate in cardiac rehabilitation programmes due to lack of resources and absence of HF in local commissioning agreements. An effective home-based physical activity intervention may improve current clinical practice and benefit patients. The aim of the present study was to evaluate safety, compliance, and physiological effects of a novel, personalised, home based physical activity intervention in CHF.

Methods: A single-centre pilot study recruited 20 patients (mean age 68±7 years) with stable CHF due to left ventricular systolic dysfunction (LVEF=31±8). At baseline patients underwent maximal graded cardiopulmonary exercise testing with non-invasive bioreactance cardiac output monitoring, assessment of quality of life (Minnesota Living with Heart Failure Questionnaire, MLHFQ), NTproBNP and physical activity level over a 7-day period using pedometers. Following initial assessments, patients were asked to increase and maintain their daily physical activity level by at least 2000 steps per day from baseline for 12 weeks, as this increment has been shown to be associated with a significant 10% reduction in cardiovascular events in high risk patients. All patients were monitored weekly via telephone calls and daily activity levels were recorded using diaries. During the follow-up visit, all assessment performed at baseline were repeated.

Results: Seventeen patients (85%) completed the study, achieved and maintained targeted physical activity level (Figure 1). Number of steps increased significantly from baseline to 3 weeks by 2546 (5108±3064 to 7654±3849 steps/day, p=0.03), and was maintained until week 12 (9022±3942 steps/day). No adverse reactions to increased activity level were reported. On average MLHFQ score decreased by 4 points following intervention (26±18 vs. 22±19, p=0.50), suggesting improvement in quality of life. There was no clinically relevant change in NTproBNP (856±1106 vs 833±1164 ng/L, p=0.95), and O2 consumption at peak exercise (16.8±3.8 vs. 17.6±4.2 ml/kg/min, p=0.54), whereas peak exercise workload and cardiac index increased by 10% and 11% (82±10 vs. 91±19 watts, p=0.21; and 6.8±1.5 vs. 7.6±2.0 L/min/m2, p=0.19). Peak exercise heart rate remained unchanged following intervention (106±19 vs. 107±16 beats/min, p=0.92), while peak stroke volume index increased by 15% (64±14 vs. 75±17 ml/beat, p=0.04). Workload and O2 consumption at anaerobic threshold increased by 16% (49±16 vs. 59±14 watts, p=0.01) and 10% (11.5±2.9 vs. 12.8±2.2 ml/mg/min, p=0.39) after the intervention.

Conclusion: Personalised home-based physical activity intervention has minimal cost implications for the health service and is safe for CHF patients. It increases daily physical activity levels and improves exercise tolerance and hemodynamic response to exercise.



Increase in Physical Activity Levels

P1943

Cardiac rehabilitation programs in left ventricular systolic dysfunction patients: differences between risk profile and functional capacity according to ejection fraction.

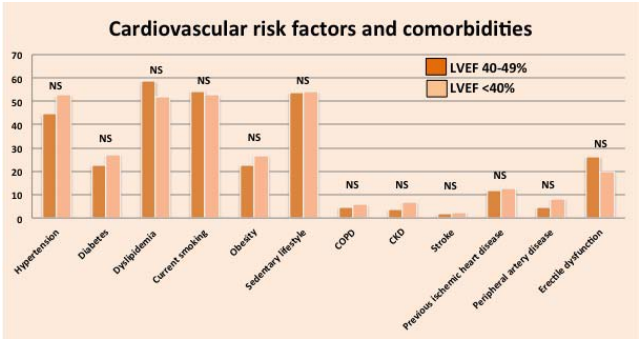
O Oscar Gonzalez Fernandez[1]; FJ Irazusta Cordoba[1]; V Rial Baston[1]; P Meras Colunga[1]; R Dalmau Gonzalez-Gallarza[1]; C Alvarez Ortega[1]; R Mori Junco[1]; S Rosillo Rodriguez[1]; A Castro Conde[1]; JL Lopez-Sendon[1]
[1]*University Hospital La Paz, Cardiology, Madrid, Spain*

Introduction: Cardiac rehabilitation programs (CRPs) in left ventricular systolic dysfunction (LVSD) patients provide optimal medical treatment, as well as supervised exercise, education and counselling. Our purpose was to compare the risk profile and functional capacity according to the ejection fraction (EF) in LVSD patients performing a CRP.

Methods: We made an observational retrospective study including patients with reduced EF (LVEF <40%) and mid-range EF (LVEF 40-49%) admitted to a CRP in our institution between 2006 and 2015. Physical training, optimal pharmacological treatment, medical counselling, nutritional education, and smoking cessation support when needed, were supplied for 8 to 10 weeks. Left ventricular ejection fraction (LVEF) was assessed before and after the program using transthoracic echocardiography, selecting in our study patients with a LVEF <50%. FC was tested before and after the CRP according to the NYHA Functional Classification, in addition to a treadmill stress test (TST). Exercise capacity (EC) was reported in terms of estimated metabolic equivalents of task (METs).

Results: A total of 442 patients were included, mean age 57.93±11.78 years, male 89.6%. Cardiac rehabilitation was performed after a recent acute coronary syndrome in 91.2% of patients. No statistically significant differences depending on the previous cardiovascular risk profile and comorbidities between mid-range EF (mrEF) and reduced EF (rEF) patients were found (table 1). Medical therapy when starting the program showed a significantly higher use of ACEIs/ARBs, MRAs, diuretics and anticoagulants in rEF than mrEF patients (p=0.023, p<0.001, p<0.001 and p=0.003; respectively). Patients with rEF had a worse FC assessed by NYHA class than mrEF patients, class I (43.4% vs 72.4%), II (49.8% vs 25.4%), III (6.3% vs 2.2%), IV (0.5% vs 0%); p<0.001. EC reported in METs was significantly lower in rEF than mrEF patients before (6.22±2.73 vs 7.76±2.38; p<0.001) and after the program (9.82±2.68 vs 10.65±2.42; p=0.003). After completing the CRP an increase in LVEF was observed in both groups (mrEF patients increased LVEF from 43.81±3.09% to 52.53±6.60%, rEF patients from 30.59±5.83% to 42.62±10.75%). FC after the program was significantly higher in the mrEF than the rEF group (I: 92.1% vs 73.4%, II: 7.9% vs 25.5%, III: 0% vs 1.1%; p<0.001). Regarding the heart rhythm, there was a non-significant trend showing an increased prevalence of atrial fibrillation in rEF patients (7.2% vs 3.1%; p=0.06). The dropout rate of the CRP was similar in both groups (11.9% in rEF patients vs 7.8%).

Conclusions: Reduced ejection fraction patients included in a CRP have a lower functional and exercise capacity than mid-range ejection fraction patients, both before and after completing the program. LVSD patients have a high prevalence of cardiovascular risk factors and comorbidities. However, no differences are found according to the left ventricular ejection fraction.



Risk factors and comorbidities

P1944

Long-term effects of cardiac rehabilitation in obese patients

M Marta Braga[1]; A Rocha[1]; H Nascimento[1]; R Pinto[1]; G Pestana[1]; M Tavares-Silva[1]; A Nunes[1]; P Araujo[1]; V Araujo[1]; F Parada-Pereira[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Introduction: Cardiac rehabilitation programs (CRP) improves exercise capacity (EC) and decreases cardiovascular morbidity and mortality after an acute coronary syndrome (ACS). However, some subpopulations are under-represented in CRP, namely obese patients.

Purpose: To compare the EC of obese patients with non-obese patients over 12 months of follow-up after CRP.

Methods: We retrospectively analysed data prospectively collected from patients who underwent CRP after an ACS. Patients were divided in two groups according to their body mass index (BMI): BMI≥30Kg/m2 (obese) and BMI<30kg/m2 (non-obese). EC was assessed with a standard exercise test, including chronotropic index, rate-pressure product, exercise duration, and intensity in metabolic equivalents (METs). EC was evaluated at baseline (T1), end of CRP (T2) and after 12 months of follow-up (T3). The mixed between-within analysis of variance was used to compare groups.

Results: Of a total 469 patients, 108 patients were obese. Except for diabetes and hypertension, there were no additional significant differences at baseline between obese and non-obese patients. Regarding EC, obese showed lower chronotropic index at all three moments (p<0.001), but improved at T2 and T3, like the non-obese group (T1- obese: 63.3±17.0% vs non-obese: 70.6±18.9%; T2- obese: 70.5±13.7% vs. non-obese: 76.6±17.2%; T3- obese: 74.9±16.7% vs non-obese: 77.6±17.7%, within-groups partial Eta square 0.176, p<0.001). The same results

were seen regarding rate-pressure product (T1- obese: 20090 ± 3660 mmHg*bpm vs non-obese: 20600 ± 3910 mmHg*bpm; T2- obese: 22360 ± 4050 mmHg*bpm vs. non-obese: 22410 ± 3930 mmHg*bpm; T3- obese: 23100 ± 4210 mmHg*bpm vs non-obese: 22780 ± 4320 mmHg*bpm, within-groups partial Eta square 0.213, p < 0.001). Both groups improved exercise duration and intensity between T1 and T2, showing a nonsignificant decline in T3 (duration: T1- obese: 7.5 ± 2.1 min vs 8.7 ± 2.2 min; T2- obese: 9.4 ± 1.8 min vs non-obese: 10.6 ± 2.0 min; T3- obese: 9.3 ± 2.0 min vs non-obese: 10.4 ± 2.3 min; intensity: T1- obese 7.8 ± 1.9 METs vs non-obese: 9.2 ± 2.2 METs; T2- obese: 9.4 ± 1.8 METs vs. non-obese: 11.1 ± 2.0 METs; T3- obese: 9.3 ± 1.8 vs non-obese: 11.0 ± 2.2 METs, within-groups partial Eta square 0.47 and 0.38 respectively, p < 0.001). Between-groups comparison showed that non-obese patients achieved a greater duration and intensity than obese patients at all 3 moments (p < 0.001).

Conclusions: Although EC of obese patients was inferior to non-obese patients, our study revealed that CRP significantly improved EC in this population and this benefit persisted after 12 months of follow-up. This data highlights the importance of a greater referral of obese patient to CRP.

P1945

Cardiac rehabilitation in patients with heart failure reduced ejection fraction compared to patients with coronary artery disease preserved ejection fraction: a long term follow up

J Justien Cornelis[1]; C Vrints[2]; E Roelant[3]; T Van Soom[1]; N Possemiers[2]; K Wuyts[2]; E Van Craenenbroeck[2]; P Beckers[2]
[1]*University of Antwerp, Department of Physiotherapy (REVAKI), Antwerp, Belgium*; [2]*University of Antwerp Hospital (Edegem), Department of Cardiology, Antwerp, Belgium*; [3]*University of Antwerp Hospital (Edegem), Department of Scientific Coordination and Biostatistics, Antwerp, Belgium*

Background: Patients with exercise intolerance induced by heart failure reduced ejection fraction (HFrEF) benefit from cardiac rehabilitation as exercise reverses the established prognostic cardiopulmonary parameters assessed through a cardiopulmonary exercise test (CPET). The clinical relevance and prognostic significance of these markers, together with the effect of exercise training in patients with coronary artery disease and preserved ejection fraction (CAD), is dubious.

Methods: The database was searched and 181 patients (CHF: n=35; CAD: n=146) were included between 2004 and 2010. All patients followed an endurance training program in the cardiac rehabilitation centre (38s, 3m, 3x60'/wk, 90%HR@RCP). During the first 24 sessions, the patients trained 5x8´on different training devices. After, exercise time was increased towards 4x10´. At the beginning and the end of the program, a maximal CPET (RER>1.15)(20 or 40 W/min) was conducted. Mortality rate was registered during a 5-year follow-up and survival analyses were performed. Significance was set P < 0.05.

Results: Baseline characteristics of both populations are given for patients with HFrEF (age: 54.8 ± 11.7; EF: 24.2 ± 7.8) and CAD (age: 59.0 ± 10.1; EF: 58.0 ± 9.5). Both groups significantly improved peak VO2, VE/VCO2 slope, HRR-1, Peak PetCO2, half-time of peak VO2, and OUES after 3 months of cardiac rehabilitation. The EqCO2 improved significant in the group with CAD. The patients with CAD improved peak VO2 significantly more (P=0.032) compared to the patients with HFrEF. Secondary parameters improved all significantly in both groups, only for peak(W/VO2) the patients with HFrEF improved significantly (P < 0.001) more. Moreover, the circulatory power improved significantly (P < 0.001) more in CAD. Exercise oscillatory ventilation (n = 4) was present at baseline. The 5-year mortality rate was 17.1% in patients with HFrEF and 5.5% in patients with CAD. The cox-regression analysis illustrated a significant difference (P=0.03) in the 5-year survival comparing both groups. The hazard ratio was 4.9 (P=0.05). Patients who increased their Peak VO2 by 20% (responders) with cardiac rehabilitation were not significant different of the non-responders (P=0.30) and hazard ratio was 0.417 (P=0.31).

Conclusion: A significant positive effect of cardiac rehabilitation in both populations was found. In patients with CAD, exercise training appeared to have more effect on aerobic capacity, circulatory power and EOV, whereas in patients with HFrEF work efficiency enhanced. Despite these improvements, the probability of dying within 5 years was high, however decreased by 58.3% if the patient responded on training. Improvements of prognostic CPET parameters seem to indicate that cardiac rehabilitation benefits all patients with a cardiac disease and perhaps even more the patients with CAD.

P1946

Dynamics of chronic heart failure in patients with rapidly progressive left ventricular remodelling after STEMI

V Valentin Oleinikov[1]; L Salyamova[1]; A Khromova[1]; N Borisova[1]
[1]*Penza State University, Penza, Russian Federation*

Purpose: to study the dynamics of laboratory and functional manifestations of chronic heart failure at 24 weeks in patients with rapidly progressive remodeling of the left ventricle (LV) remodeling after acute myocardial infarction (AMI) with ST-segment elevation (STEMI).

Methods: The study included 62 patients with STEMI. A prerequisite was the presence of hemodynamically significant stenosis of one coronary artery based on the result of coronary angiography. The present study was carried out without a washout period with the full scope of pharmacotherapy on the AMI. All patients underwent echocardiography by MyLab 90 (Esaote, Italy) with the evaluation of end-diastolic volume index (EDV index). Then, the patients were divided into two groups. The first group included 31 people without echocardiographic evidence of left ventricular remodeling and dynamics of EDV index < 8% at 6 months after STEMI. Group 2 consisted of 31 patients with rapidly progressive LV remodeling (EDV index increase >8%). Compared groups were matched for age, sex, number of anthropometric indicators. Initially on days 7-9, and after 24 weeks of follow-up the value of brain natriuretic peptide (BNP) was determined using an immunochemical analysis. A 6-minute walk test was performed at 12 and 24 weeks of myocardial infarction.

Results: at baseline compared subjects did not differ in the level of BNP: group 1 – 24,3 (16,6; 48,2) pg/ml, in group 2 – 32,6 (19,2; 53,8) pg/ml. After 24 weeks in patients without an abnormal growth of EDV index dynamics of BNP was not revealed: 26,6 (18,6; 52,7) pg/ml; in patients with rapidly progressive LV remodeling the values increased to 53,7 (27,0; 96,5) pg/ml (p < 0,05). According to the results of the 6-minute walk test in group 1 after 12 weeks of follow-up the average distance traveled was 506,1 ± 81,1 m. In this case, 0 FC was detected in 29% of cases, 1st FC - in 55%, 2nd FC - 16%. After 24 weeks of STEMI average distance was 612,0 ± 92,9 m (p < 0,05). 0 FC was detected in 46% of cases, 1st FC - in 48%, 2nd FC - 6%. In group 2 initially the average distance was 524,1 ± 67,3 m. 0 FC was detected in 32% of cases, 1st FC - 39%, 2nd FC - 29%. At follow-up, respectively, the values were 514,7 ± 91,3 m, FC 0 - 42%, 1st FC - 23%, 2nd FC - 33%, 3rd FC - 2%.

Conclusion: The patients with rapidly progressive LV remodeling after STEMI showed the deterioration in BNP levels with no significant reduction in tolerance to physical exercise after 24 weeks of follow-up. While in the group without pathological remodeling there was a statistically significant improvement in exercise tolerance in the absence of changes in laboratory signs of heart failure.

P1947

Usefulness of exercised-based cardiac rehabilitation in heart failure patients with preserved ejection fraction

I Burazor[1]; P Seferovic[2]; S Dodic[3]; Y Adler[4]; R Sakurai[5]; Z Cosic[6]; M Moraca[6]; A Kovacevic[6]; S Stevovic[6]; M Andjic[6]; A Ristic[2]

Heart failure is highly prevalent in myocardial infarction survivors and is a major cause of morbidity, mortality and re- hospitalizations. Cardiac rehabilitation (CR) exercise training and CHF self-care counseling have each been shown to improve clinical status and clinical outcomes in CHF.The aim of this study was to evaluate the usefulness of exercise based in house cardiac rehabilitation in patients with heart failure with preserved ejection fraction (HFpEF) after myocardial infarction Patients and methods: Out of 1854 patients who were admitted to our three weeks in- hospital secondary prevention program – exercised based cardiac rehabilitation, we analyze a total of 199 patients who were admitted early after coronary revascularization (percutaneus coronary interventions or coronary bypass surgery) with HFpEF. The majority of patients were males (64%). The oldest patient was 81 years of age. We noted risk factors and co morbidities. Patients were selected for exercise training after six minute walking test (42%) or exercise stress test (CPX). After 3 weeks in hospital cardiac rehabilitation the patients were re-tested.

Results: The major comorbidities in our patient population were as follows: diabetes, hypertension and dyslipidemia. Six minutes walking test was performed and the total distance walked ranged from 160 to 440 meters and the beginning of the program. Patient had 7 -days a week training program. After the 3 weeks in hospital exercise rehabilitation the improvement in the test was ˜35%. Cardiopulmonary test showed also improvement of functional capacity. We noted several rhythm disturbance complications by telemetry (VT, VES, SVES, and new on set of AF) and when needed the amiodaron or beta blockers were added. Also we noted silent ischemia in 6% after CABG with ST segment depression detected by telemetry. None had acutisation of chronic heart failure (with peripheral edema and congestion). All patients fulfilled cardiac rehabilitation program.

Conclusions: The study showed usefulness and safety of exercised –based in-hospital cardiac rehabilitation program in patients HFpEF. Supervised multidisciplinary cardiac rehabilitation program, including an individualized exercise

component is safe and can improve functional status and exercise tolerance in patient.

Prognostic factors for STEMI patients after cardiac rehabilitation in single academic cardiologic center.

S Borodzicz[1]; P Balsam[1]; M Peller[1]; R Glowczynska[1]; L Koltowski[1]; P Lodzinski[1]; KJ Filipiak[1]; M Grabowski[1]; G Opolski[1]
[1]Medical University of Warsaw, 1st Chair and Department of Cardiology, Warsaw, Poland

Introduction: Cardiac rehabilitation (CR) has well-established efficiency in improving the prognosis of patients after ST-elevated myocardial infarction (STEMI).
Purpose: The main aim of our study was to analyse early and late factors which may be related to the improved prognosis of STEMI patients who participated in CR programme.
Methods: It was a retrospective analysis of STEMI patients who underwent invasive coronary angiography and percutaneous coronary intervention (PCI) after STEMI followed by CR in years 2007-2013. The group consisted of 141 patients; the average time of follow-up was 30 ± 14 months (max. 96 months). Individual physical capacity was assessed at the beginning of CR by electrocardiographic exercise test. Information on patients' current activity was assessed with validated International Physical Activity Questionnaire (IPAQ). The analysed early factors included: gender, age, body mass index (BMI), hypertension, diabetes mellitus type 2, atrial fibrillation, history of previous MI or stroke, ejection fraction, type of infarction related artery, localization of MI, peak levels of troponin I (TnI), creatine kinase-MB (CK-MB) mass. Late factors included: initial metabolic equivalent of task score (METs), METs after CR, improvement of METs, number of training sessions (12 or 24). The combined end point consisted of: patient's death or another cardiovascular event (stroke, myocardial infarction, any revascularisation).
Results: Higher BMI was associated with better prognosis of patients (Hazard Ratio HR=0.83; 95% Confidence Interval CI 0.71-0.93; p = 0.012). There was observed a trend for the relation between the improvement of METs and better prognosis of patients (HR=0.57; 95% CI 0.38-0.86; p = 0.007). No statistically significant relation between any of the early and late factors and any form of physical activity was found.
Conclusions: Increased BMI, itself a risk factor for coronary artery disease, is a positive prognostic factor for the outcome of CR (phenomenon known as the obesity paradox). Our study also shows that although the absolute value of METs achieved after CR had no significant impact, the thing that seems to improve prognosis is relative improvement of METs.

P1949

Improvement of functional capacity and other risk factors in the patient with ischemic cardiopathy through the cardiac rehabilitation program

N G Uribe Heredia[1]; J Balaguer Recena[1]; H Alvaro Fernandez[1]; L Gil Fraguas[1]; LG Piccone Saponara[2]; R Arroyo Espliguero[3]; S Moreno Reviriego[3]; E Novo Garcia[3]; M Viana Llamas[3]; C Moreno Vinues[3]; JL Garcia Gonzalez[3]; ME Jimenez Martinez[3]; SM Garcia Ortego[3]; B Tarancon Zubimendi[3]; MA San Martin Gomez[3]
[1]Guadalajara University Hospital, Cardiac Rehabilitation Unit, Guadalajara, Spain; *[2]Hospital General de Ciudad Real, Nefrology, Ciudad Real, Spain*; *[3]Guadalajara University General Hospital, Cardiology Department, Guadalajara, Spain*

Introduction: Coronary heart disease (CHD) is the leading cause of mortality in Europe, causing a significant reduction in physical, psychological and socio-occupational capacity in the short, medium and long term. Cardiac rehabilitation program (CRH) plays an important role in the recovering the patient.
Materials and methods: Observational prospective study. Included all patients with CHD from Sept/2015-Oct/2016 of the CRH. We describe CVRF, demographic, electrocardiographic, echocardiographic; prior and subsequent to the CRH. Statistical analysis SPSS 20. Categorical variables are compared with Chi2. and quantitative (expressed as means ± standard deviation) with Student's T. Statistical significance $p < 0.05$.
Results: 78 patients, mean age 56.9 years, men 92.3%, 60.3% intermediate-high risk, LVEF less than 55%, 34.9% at the start of the CRH, 53.9% NYHA functional class II-III, 52.6% hypertension, 67.9% dyslipidemia, 42.3% obesity, 21.8% diabetes mellitus, 56.4% smokers, 87.9% sedentary, BMI 29.6. At the end of the CRH, NYHA functional class II-III, were reduced to 11,5%. More results in Table 1.
Conclusions: The CRH in patients with CHD is associated with an improvement in functional capacity with better exercise tolerance and fraction left ventricular ejection. In addition to a reduction of resting heart rate, diastolic left ventricular dysfunction, response to exercise, lipid profile, abdominal perimeter, C-reactive protein levels; being these differences statistically significant.

Table 1.

VARIABLES	PRE CRH	POST CRH	P
Functional capacity (METS)	8,3 + 2,5	10,01 + 2,9	< 0,001
Test of 6 minutes (meters)	525,3 + 80,7	572,1 + 95,7	< 0,001
Abdominal circumference (cm)	103,1 + 12,4	101,8 + 12,1	< 0,001
Systolic blood pressure at peak exercise (mmHg)	162,3 + 18,4	158,1 + 14,4	0,04
Diastolic blood pressure at peak exercise (mmHg)	80,9 + 8,1	77,8 + 6,8	< 0,01
Resting heart rate (beats per minute)	71,1 + 10,8	63,6 + 9,8	< 0,001
Recovery time (beats in the first minute)	14,6 + 8,2	18,3 + 8,9	< 0,001
LDL cholesterol (mg/dL)	85,1 + 32,8	72,2 + 26,4	0,003
HDL cholesterol (mg/dL)	39 + 11,2	41,4 + 12	0,005
C-Reactive proteína (mg/L)	3,62 + 4,2	2,04 + 2,6	0,001

Different prognostic predictors in cardiopulmonary exercise testing according to the aetiology of systolic heart failure

CMF Christopher Strong[1]; H Dores[1]; M Mendes[1]; N Vale[1]; M Castro[1]; J Carmo[1]; J Mesquita[1]; S Guerreiro[1]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal

Introduction: The Cardiopulmonary Exercise Testing (CPET) has an important role in the risk stratification and prognostic evaluation of patients with Heart Failure and reduced Ejection Fraction (HFrEF). Several variables in CPET have been validated as independent predictors for a worse prognosis, but, their impact according to the aetiology of the HFrEF has not been established.
Purpose: To evaluate the prognostic value of CPET variables in patients with HFrEF according to the aetiology – Ischemic Vs Nonischemic HF.
Methods: Of all the patients submitted to CPET in our laboratory between 2009 and 2015, those with HFrEF (EF < 40%), NYHA functional class II-III and optimal medical therapy were selected. The following variables of the CPET were studied: Peak VO2, VE/VCO2 slope, exercise oscillatory ventilation, PetCO2 at rest and during exercise, exercise blood pressure response to effort, electrocardiogram changes, heart rate recovery at 1 min and patient reason for test termination. During a mean 44 month follow-up, the independent predictors for the composite endpoint of hospitalization for decompensated heart failure, need for heart transplant and death of any cause, in both groups of patients, were determined using a Cox Regression.
Results: A total of 123 patients were included in the study (average age of 55 ± 11 years; 80% of male gender), 57% with ischemic HFrEF, with the ramped protocol test

being the most commonly used (65% of the cases). Patients with ischemic HFrEF were mostly male, and had a higher mean age. The composite endpoint occurred in 35% of the total sample. In patients with ischemic HFrEF the sole predictor for the composite endpoint was the Peak VO2 (HR 0.79, IC95% [0.69,0.91]; $p < 0.01$), while in those with nonischemic HFrEF the predictors were the Peak VO2 (HR 0.84, IC95% [0.71,0.99]; $p = 0.04$) and the VE/VCO2 slope (HR 1.09, IC95% [1.04,1.14]; $p < 0.01$).
Conclusions: Of the CPET variables studied, the Peak VO2 was an independent predictor for the composite endpoint in both groups, with the VE/VCO2 slope having also been a predictor in the nonischemic HFrEF patients, probably reflecting a lower ventilatory efficiency as a result of the longer chronicity of the cardiac dysfunction.

P1951
Inverse relationship between hemoglobin oxygen saturation measured by pulse oximetry at rest and exercise capacity in the patients with heart failure

N Aizawa[1]; K Nagahama[2]; Y Toma[1]; H Ikemiyagi[1]; T Shinzato[1]; M Iwabuchi[1]; Y Ohya[1]
[1]University of the Ryukyus, Department of Cardiovascular Medicine, Nephrology and Neurology., Nishihara, Japan; *[2]Okinawa Rehabilitation Center Hospital, Okinawa, Japan*

Background: Exercise capacity is a key prognostic factor in the patients with heart failure (HF). Although peak oxygen consumption (peak VO2) measured by maximal symptom-limited cardiopulmonary exercise test (CPET) is the most objective method to determine exercise capacity, a simple tool to predict exercise capacity is required. Hemoglobin oxygen saturation measured by pulse oximetry (SpO2) is a simple and useful tool to evaluate oxygenation. However, the relationship between SpO2 at rest and exercise capacity measured by CPET is unclear.
Purpose: To investigate the relationship between SpO2 at rest and exercise capacity measured by maximal symptom-limited CPET in the patients with HF.
Methods: We examined the association between SpO2 and exercise capacity among 46 patients with HF (age 54 ± 13, male 76%, cardiomyopathy 43%, valvular heart disease 35%, ischemic heart disease 17%) who underwent maximal symptom-limited CPET in our institute.
Results: Peak VO2/weight and peak respiratory exchange ratio were 16.2 ± 5.6 ml/min/kg and 1.2 ± 0.1, respectively. SpO2 at rest inversely correlated with peak VO2/weight ($r = -0.43$, $P = 0.003$). Compared with the patients who had preserved exercise capacity (peak VO2/weight ≥ 11.0 ml/min/kg, $n = 39$), the patients who had low exercise capacity (peak VO2/weight < 11.0 ml/min/kg, $n = 7$) showed significantly higher SpO2 at rest (99.0 ± 0.8 vs 98.0 ± 1.6 %, $P = 0.03$). Multiple regression analysis revealed that higher SpO2 at rest ($\beta = -0.29$, $P = 0.006$), age, BMI and lower hemoglobin, sodium are independent predictors of lower peak VO2/weight.
Conclusion: In patients with HF, higher SpO2 at rest may detect lower exercise capacity.

P1952
Functional testing: comparing the results of 6-minute walk test with handgrip and postural tests

B Leskovar[1]; T Furlan[1]; S Poznic[1]; B Kljucevsek[2]; A Adamlje[1]
[1]Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia; *[2]Trbovlje General Hospital, Department of Hemodialyisis, Trbovlje, Slovenia*

Introduction: 6-minute walk test (6MWT) is most widely used for testing functional capacity of heart failure patients. Some patients can't perform it well or at all due to other non-cardiac comorbidities.
Purpose: We wanted to test the correlation of 6MWT with other functional tests (handgrip test, postural tests).
Methods: We performed 6MWT in 30 hemodialysis patients. They performed the test three times in the same setting (before hemodialysis). Handgrip test was performed before hemodialysis three times in three different positions (standing-up, sitting, lying down) using both arms. Postural testing was performed before hemodialysis using the postural test protocol (balance tests, gait speed, chair stand test). Positional influence on handgrip test results was tested with one-way repeated measures ANOVA and functional tests correlation with Pearson's correlation coefficient. We also tested the influence of AVF on handgrip test results (multiple linear regression). In 22 patients with concurrent end-stage kidney disease and heart failure we evaluated possible correlations between echocardiographic parameters, biomarkers and functional tests (multiple linear regression).
Results: Thirty patients (60% male, mean age 64.4 ± 13.3 years, mean ITM 27.1 ± 4.6 kg/m2) performed the 6MWT (mean 65 ± 18% of predicted distance), handgrip test (right arm 23 ± 10kg; left arm 22 ± 10kg), postural tests (10 ± 3 points (of 12 maximum)). Handgrip results were not influenced by body position (right: $F(2.0,56.5)=0.395$, $p = 0.67$; left: $F(1.4,40.7)=1.573$, $p = 0.22$)), neither by the presence of an AVF (right: $F(2,27)=2.268$, $p = 0.123$, $R2=0.144$; left: $F(2,27)=0.991$, $p = 0.384$, $R2=0.068$). All functional tests had a statistically significant positive correlation with each other. In 22 hemodialysis patients with heart failure (50% men, mean age 65.5 ± 11.7 years, mean NT-proBNP 1425 ± 1226 pg/ml, mean LVEF 57.1 ± 13.0%, 45% with HFrEF), high troponin was the most important prognostic factor of lower LVEF, lower VTI and higher E/A. NT-proBNP was a statistically significant prognostic factor of lower Em and higher E/Em. None of the tested laboratory or echocardiographic parameters were associated with hospitalization rate due to heart failure in the last two years or the results of functional tests. Low VTI was a prognostic factor of longer hospital stay due to heart failure in the last two years.
Conclusion(s): 6MWT can be replaced with other functional tests (handgrip test, postural test) to evaluate functional capacity. This is particularly useful in elderly disabled patients, where 6MWT results are often influenced by their disability to walk for 6 minutes continuously. In addition, handgrip test is not influenced by body position or presence of AVF. In patients with concurrent end-stage kidney disease and heart failure, troponin T was a better prognostic factor of chronic heart failure and none of echocardiographic or laboratory parameters were associated with the results of functional tests.

P1953
Impact of short-term physical training on functional capacity, natriuretic peptids and endothelin in heart failure patients with diabetes mellitus

D Dragan Marinkovic[1]; M Deljanin-Ilic[1]; B Ilic[1]; V Stoickov[1]; S Stojanovic[1]
[1]University of Nis, Medical Faculty, Institute of Cardiology Niska Banja, Nis, Serbia

The positive effects of physical training in patients (pts) with chronic heart failure (CHF) are reflected in improving exercise tolerance, reduce symptoms and less hospitalization, increasing survival and improving quality of life. It has been confirmed that CHF is 2-3 times higher in patients with diabetes mellitus (DM), than for those who do not have DM.
Aim: To evaluate the effects of short-term physical training on physical exercise tolerance and level of markers of neuro-humoral activation and endothelial function, in CHF pts with diabetes mellitus type 2.
Patients and method: The study involved 20 pts (14 males), mean age 62.3 ± 5.7 years, mean EF 36.75 ± 3.34%, NYHA II and III, with DM type 2, and 32 compatible non-diabetic pts with CHF who were assigned to a control group. The mean duration of DM in study group was 10.2 ± 3.6 years. All patients were included in three-week rehabilitation program at the residential center, based on strictly controlled and individually prescribed physical training. Before and after rehabilitation, all patients were underwent exercise stress test, and from the veins blood samples, biochemical parameters, atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP) an endothelin (ET) were determined.
Results: At the end of rehabilitation, the concentration of neuropeptides, ANP and BNP, were significantly higher compared to the baseline values, in both groups, in a group of diabetics pts and in non-diabetic group, also. (ANP $p = 0.018$; BNP $p = 0.042$). In the group of diabetic pts, there was significantly higher value of BNP compared to the control group after rehabilitation ($p = 0.032$), while there was no significant difference in the values of ANP (ns), between two groups. In contrast, the concentration of ET, after rehabilitation was lower in both groups, but the statistically significance was only in the group of diabetic pts ($p = 0.035$). In both groups, exercise tolerance was improved ($p < 0.005$) as well as quality of life assessed by Minnesota Living With Heart Failure Questionnaire ($p < 0.005$).
Conclusion: Opposite to long, short-term exercise training induced transitory increase of ANP and BNP, and decrease of endothelin in diabetic CHF pts after cardiac rehabilitation. These effects are associated with improvement of exercise tolerance and quality of life.

P1954
Analysis of physical rehabilitation efficiency in patients with chronic heart failure

VL Galenko[1]; TA Lelyavina[1]; MY Sitnikova[1]
[1]The North-Western Federal Medical Research Center named after V.A.Almazov, the research laboratory of chronic heart failure , Saint-Petersburg,, Russian Federation

Introduction: In the world practice, the selection of physical training intensity of CHF patients is based on anaerobic threshold achievement during cardiorespiratory test (CPET). But the majority of patients with severe CHF are not able to achieve it, that requires the use of certain indicators in the appointment of physical training. This alternative indicator can be lactate threshold, which achieved first during the CPET.
Purpose: To evaluate aerobic physical exercise efficiency in CHF patients, selected on the basis of achievement the lactate threshold during CPET.

Methods: 77 patients, CHF NYHA II-III were randomized into two groups - primary (aerobic training) and control (standard treatment of CHF). Main group - 64 patients, mean age 54 ± 12,5 years, body mass index (BMI) 26,46 ± 6,4 kg/m2, among them 46 patients (72%) had III CHF functional class and 18 patients (28%) – II CHF functional class. The control group - 13 patients, age 53 ± 17 years, BMI was 25,4 ± 6.8 kg/m2, 12 patients had III CHF functional class, 1 patient – I. The original estimated results of physical examination, laboratory parameters. CPET, quality of life (QOL), exercise tolerance (ET) was assessed at baseline and after 1,3,6 months of follow-up. The CPET served on tredmile using hardware "Oxycon Pro", Jaeger, Germany. Echocardiography (EchoCG) were performed at baseline and after 6 months. The data were statistically processed using software package "Statistika, 6.0".
Results: In the main group after 6 months of training EF increased by 7.5 ± 0.5% and End-diastolic volume decreased by 6 ± 2.0 ml from baseline, QOL was changed by 17.5 ± 8 points (significant regression of symptoms), ET increased by 9 ± 1 points and VO2 peak increased by 4.4 ml/min/kg. In the control group showed an increase EF 4 ± 1,1%, End-diastolic volume decreased by 68 ± 14,8 ml, the change of QOL 14 ± 7,22 points, the increase in ET at 1.5 points, VO2 peak decreased by 1,7 ml/min/kg. Revealed a strong positive correlation between the initial values of VO2 peak and EF (rEF=0,4, p), and between baseline levels of sodium, hemoglobin and the of physical rehabilitation efficiency (rNa= 0,41, p,0,05; rHb = 0,45, $p < 0,05$). There was a positive impact of the initial content of red blood cells (rEr=0,6, p = 0.03), sodium (rNa=0,4, p = 0.05), LV EF (r=0.5, p = 0.05) and level VE at the peak of exercise load (r=0.5,p = 0.01) on training efficiency.Conclusion. Aerobic physical exercise in CHF patients, selected on the basis of lactate threshold achievement during the CPET, is effective in improving values of CPET, EchoCG, QOL and increasing exercise tolerance.

Funding Acknowledgements: National Institute of Health Research (NIHR) Research for Patient Benefit (RfPB)

Background: Chronic heart failure patients have limited treatment options and struggle to adhere to exercise training programmes. Low Frequency Electrical Muscle Stimulation (LF-EMS) may have the potential to reduce breathlessness and increase exercise capacity in this cohort. However, the practical feasibility of a randomised controlled trial (RCT) of LF-EMS in this debilitated population has not been established.
Methods: Using a double blind, randomised study design, 60 severe heart failure patients (New York Heart Association class III-IV) were assigned to 8 weeks (5 x 60 mins per week) of either LF-EMS intervention (4Hz, continuous) or SHAM placebo (skin level stimulation only) of the quadriceps and hamstrings muscles. Participants used the LF-EMS straps at home and were supervised weekly. Recruitment, adherence and tolerability to the intervention were measured during the trial as well as physiological outcomes (6 minute walk, quadriceps strength, quality of life and physical activity).
Results: 12 (20%) of the 60 patients (4 LF-EMS, 8 SHAM) withdrew. Reasons for dropout were: deterioration in health (n = 6) family problems (n = 2) device implantation (n = 1) and found the stimulation intolerable (n = 3) Forty One patients (68.3 %), adhered to the protocol for at least 70% of the sessions. The physiological measures indicated improvement in the LF-EMS group in 6 minute walk distance, and quality of life, although not significantly.
Conclusion: Chronic heart failure patients can be recruited to and adhere to LF-EMS studies and find it tolerable. A larger Randomised Controlled Trial (RCT) in the advanced heart failure population is therefore feasible.

Outcome measures all timepoints

Residual pulmonary hypertension after endarterectomy: what remains to be clarified?

S Sofia Alegria[1]; MJ Loureiro[1]; AR Almeida[1]; F Ferreira[1]; O Simoes[1]; D Repolho[1]; L Lopes[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal

Introduction: Chronic thromboembolic pulmonary hypertension (CTEPH) is potentially curable by pulmonary endarterectomy (PE). However, residual pulmonary hypertension (PH) after surgery is common, and its impact on long-term outcome is unknown.
Objectives: Evaluate the impact of residual PH and its predictors, as well as the predictors of functional improvement and decrease in NT-proBNP levels.
Methods: Longitudinal analysis of CTEPH patients followed in a reference center for the treatment of PH, submitted to PE abroad. Logistic regression was used to identify predictors of residual PH and of improvement in functional class, NT-proBNP levels and 6-minute walk test (6MWT) distance.
Results: Twenty-one patients (62% females, age 54 ± 12 years) were included. Before surgery 86% were in WHO functional class III or IV, the mean distance walked in the 6MWT was 352 ± 157 meters, NT-proBNP was 1532 ± 1817 pg/mL, mean pulmonary artery pressure (mPAP) was 44 ± 13 mmHg and pulmonary vascular resistance (PVR) was 11.0 ± 5.4 WU. After surgery, 57.9% of the patients had residual PH (mPAP ≥ 25 mmHg and/or PVR> 3 WU), which was associated, among other preoperative parameters, with female gender (p = 0.045), pulmonary artery systolic pressure (PASP) estimated by echocardiogram >79 mmHg ($p < 0.001$) and NT-proBNP >128 pg/mL (p = 0.017). There was no association with cardiopulmonary bypass time. The only predictor of residual PH maintenance was NT-proBNP >128 pg/mL (OR 18.0, 95% CI 1.2-271.5, p = 0.037). During a follow-up of 971 ± 802 days, cardiovascular mortality was 4.8% (n = 1). The presence of residual PH was not associated with overall or cardiovascular mortality, and both functional class improvement and NT-proBNP decrease were similar in patients with and without

residual PH. However, patients with residual PH were more likely to have an increase in 6MWT distance above the mean (90 meters) (p = 0.038). Echocardiographic PASP >81 mmHg (OR 16.5, 95% CI 1.1-250.2, p = 0.043) and invasive PASP >67 mmHg (OR 13.3, 95% CI 1.05-169.6, p = 0.046) were preoperative predictors of improvement of at least 2 functional classes, whereas sildenafil therapy (OR 21.0, 95% CI 1.5-293.3, p = 0.024) was a predictor of increased distance in 6MWT >90 meters. On the other hand, right ventricular systolic dysfunction (OR 20.0, 95% CI 1.4-282.4, p = 0.027), distance in 6MWT < 300 meters (OR 55,0; IC 95% 2,8-1068,4; p = 0,008), and cardiac index < 1.95 L/min/m2 (OR 22.0, 95% CI 1.5-314.3, p = 0.023) were predictors of a decrease in NT-proBNP levels above the mean (1200 pg/mL).

Conclusions: Although the majority of patients submitted to PE mantain residual PH, this is not associated with increased mortality or lack of clinical or laboratory improvement. It remains unclear which hemodynamic cut-offs predict long-term prognosis. This study also suggests that patients with worse clinical, echocardiographic and hemodynamic profile before surgery are those with greater benefit after intervention.

Circulating biomarkers for the detection of the pre-capillary component in patients with pulmonary hypertension due to left heart diseases

JL Melero Ferrer[1]; S Dolz Gimenez[2]; A Cervero Rubio[1]; IJ Sanchez Lazaro[1]; R Lopez Vilella[1]; V Martinez Sales[2]; L Martinez Dolz[1]; L Almenar Bonet[1]
[1]Hospital Universitario y Politécnico La Fe, Unidad de insuficiencia cardiaca y trasplante. Servicio de Cardiología., Valencia, Spain; *[2]Hospital Universitario y Politécnico La Fe, Instituto de investigación sanitaria La Fe. Unidad de Hemostasia y trombosis., Valencia, Spain*

Funding Acknowledgements: This study was supported with a grant from the Instituto de Salud Carlos III (ISCIII PA 14/0184)

Pulmonary hypertension due to left heart diseases (PH-LHD) is a prevalent disease, which supposes important morbidity and mortality and is associated with right ventricular function impairment. PH-LHD can be classified in post-capillary PH or combined PH, attending to the presence or not of a pre-capillary component (PCP). This component implies the existence of intrinsic pulmonary vascular disease, with serious consequences for the right chambers. It is assumed that in pre-capillary PH-LHD an endothelial dysfunction occurs playing a key role for its development.

The aim of this study is to assess if there is an association among the blood levels of several circulating biomarkers and the presence of PCP.

Fifty five patients with advanced heart failure who underwent a right heart catheterization (RHC) were included. A blood sample from the pulmonary trunk was drawn. Fourteen proteins related with the physiopathological mechanisms of PH-LHD were selected (von Willebrand factor, ADMA, ET-1, VEGF, angiopoietin like 4 –ANGPLT 4 -, cathepsin B, galectin 1, TIMP2, MMP7, osteocrin, NT-proBNP, troponin T, fibrinogen and D-dimers and their levels measured by enzimoimmunoassay (ELISA). Protein levels association with PCP (considered as a transpulmonary gradient –TPG- ≥12 mmHg or a diastolic pressures difference –DPD- ≥ 7 mmHg) was analysed using T-student test.

Among the included patients, 25 had dilated cardiomyopathy (DCM) and 30 had ischemic cardiomyopathy (ICM). In the DCM group, two proteins achieved significant differences; osteocrin (p = . 01) when PCP presence was measured by calculating the TPG, and ANGPTL-4 when PCP presence was measured by using the DPD. In the ICM group three were the proteins that achieved differences; TIMP-2 (p = . 01) using TPG, and VEGF (p = . 02) and D-Dimers (p = . 03) using DPD.

There are several proteins that could be of potential use as biomarkers for detection of thePCP. Based on the aetiology of the heart failure, the selected proteins would be ANGPTL-4 and osteocrin for DCM, and TIMP-2, VEGF and D-Dimers for ICM.

The valuable cardiac magnetic resonance imaging parameter for the noninvasive assessment of pulmonary hypertension severity

AV Kazimli[1]; A V Ryzkov[2]; AV Berezina[2]; AV Naymushin[2]; OM Moiseeva[2]
[1]Azerbaijan Medical University, therapy, Baku, Azerbaijan; *[2]Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation*

Pulmonary hypertension characterized by structural and mechanical changes in pulmonary vascular bed. Invasively calculated pulmonary artery (PA) stiffness indeces are associated with mortality in pulmonary hypertension. CMRI-derived pulmonary artery distensibility (PAD) index reflects vascular remodeling in patients with pulmonary hypertension (PH). The aim of the study was to evaluate the relationship between noninvasive PAD index and invasive PA stiffness indeces and basic determinants of PH severity.

Methods: We included 48 pts with PH (mean age 42.8 ± 14.7 yrs, m:f= 13:35): 27 idiopathic pulmonary arterial hypertension (IPAH) pts, 5 scleroderma (Sc) PAH pts, 6 pts corrected congenital heart disease (CCHD) and 10 pts with inoperable CTPEH. All pts underwent 6-min walk test (6MWT), right heart catheterization (RHC), ECHO, CMRI, cardiopulmonary exercise testing (CPX) and serum NT-proBNP level. PA stiffness index and elastic modulus were calculated using data from RHC and CMRİ. PA distensibility index (%) were derived from cross-sectional images of the main pulmonary artery on CMRI and was defined as [(maximum cross sectional area (CSA)-minimum CSA)/ minimum CSA].

Results: We revealed increased PA stiffness index 6.1 (4.6–10.2) and elastic modulus 424 mm Hg (254-678), decreased PAD index in PH pts 10% (9 –16.5). There was a significant negative correlation between PAD index and PA stiffness index (r = –0.90; p < 0.0001), so we derived the formula to calculate the invasive PA stiffness using noninvasive PAD index: PA stiffness index= 102.4/ PAD index. There was also a negative correlation between PAD and elastic modulus (r = –0.91; p < 0,0001). Patients with decreased PAD index < 20 % had higher NT-proBNP level (1558 (738-4341) versus 306 (178-370); p < 0.05) , also ECHO signs of RV systolic dysfunction:lower TAPSE (1.7 ± 0.4 cm versus 2.0 ± 0.4 cm; p = 0,04), tricuspid annular systolic velocity (10 ± 2 versus 12 ± 1 cm/sec; p = 0,007), global RV myocardial deformation (13 ± 4% versus 21 ± 5%; p=0,001) and RV fractional area change (24 ± 7%; p=0,02) and reduced cardiac output which were determined by RHC (4.0 ± 1.1 versus 4.9 ± 1.2 l/min; p < 0,05). Decreased PAD index < 20 % was associated with VO2peak reduction (15 ± 4 vs 20 ± 4 ml/min/kg, respectively; p = 0,04).

Conclusions: Noninvasive CMRI-derived PA distensibility index strongly correlated with PA stiffness indeces, and may be used for noninvasive assessment of PH severity and progression.

P1959

Early ultrasound diagnostic venous pulmonary hypertension

V Kirillova[1]

[1]*Ural State Medical Academy, biochemistry, Ekaterinburg, Russian Federation*

Interstitial and alveolar pulmonary edema is the result of elevated pulmonary veins pressures. The early and correct diagnosis of venous pulmonary hypertension prevents the one of the most common reasons for hospitalization of patients with heart failure and decreases high risk of mortality. The aim of the study was the development early non-invasive diagnostic venous pulmonary hypertension. We investigated pulmonary vein's minimal diameter during atrial systole and pulmonary vein's maximal diameter during heart's diastole by transthoracic echocardiography in 92 chronic heart failure patients (65.4 ± 6.4 years) with preserved left ventricular ejection fraction, complicated by hypertensive disease. All patients hadn't chronic and acute respiratory diseases. The patients were divided into 2 groups: 50 heart failure patients with X-ray signs of pulmonary venous congestion, and 42 heart failure patients with normal pulmonary X-ray pattern. The control group is a 34 people (45.2 ± 5.3 years) without cardiovascular diseases. Values are expressed as means ± SEM. T-test was used when comparing means. $p < 0.05$ was considered statistically significant.

In the present study, we visualized three pulmonary veins: left superior pulmonary vein, left lower pulmonary vein and right upper pulmonary veins by the transthoracic echocardiography. The maximal pulmonary vein's diameter of heart failure patients with X-ray signs of pulmonary venous congestion was increased compared to patients of the control group (24.7 ± 1.1 mm vs 14.7 ± 0.2 mm ($p < 0,001$) and heart failure patients with normal pulmonary X-ray pattern (24.7 ± 1.1 mm vs 15.6 ± 0.6 mm ($p < 0,01$). The minimal diameter of visible pulmonary vein during atrial systole of heart failure patients with X-ray signs of pulmonary venous congestion was increased compared to patients of the control group (14.1 ± 1.0 mm vs 6.4 ± 0.3 mm ($p < 0,001$) and heart failure patients with normal pulmonary x-ray pattern (14.1 ± 1.0 mm vs 7.5 ± 0.7 mm ($p < 0,01$).

The pulmonary vein diameter during heart's diastole is more than 18 mm and the pulmonary vein diameter during atrial systole is greater than 9 mm were observed in the 95% heart failure patients with X-ray signs of pulmonary venous congestion. Thus, if heart failure patients have maximal pulmonary vein's diameter more than 18 mm, and minimal pulmonary vein's diameter greater than 9 mm we can to diagnose venous pulmonary hypertension with probability of 95%. Thus, early diagnosis of venous pulmonary hypertension by the transthoracic echocardiography allow timely will initiate therapy and decreases hospitalizations from decompensated left heart failure.

Prevalence of pulmonary hypertension and associated comorbidities in mexican patients hospitalized in a tertiary-referral hospital

G K Perez Cortes[1]; L Verdeja-Vendrell[2]; A Orea-Tejeda[2]; DG Gonzalez-Islas[2]; AG Jimenez-Cepeda[2]; AG Navarrete-Penaloza[2]; RN Sanchez-Santillan[2]; V Pelaez-Hernandez[2]; B Robles-Uribe[2]; FA Figueroa-Herrera[2]; SC Torres-Montiel[2]

[1]*Universidad Autonoma Benito Juarez de Oaxaca, Faculty of Medicine and Surgery, Oaxaca de Juarez, Mexico*; [2]*Instituto Nacional de Enfermedades Respiratorias Ismael Cosio Villegas, Heart Failure and Respiratory Distress Clinic, Mexico City, Mexico*

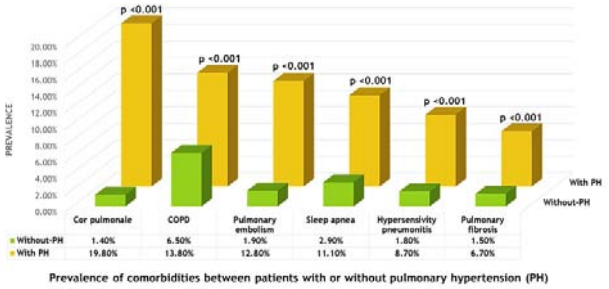
Background: Pulmonary hypertension (PH) is associated with poor quality of life and decreased survival, which vary according its severity and etiology. However, there are only a few large-scale reports on the incidence, prevalence and underlying etiologies of PH.

Purpose: To determine the prevalence of PH and its main comorbidities in Mexican patients hospitalized in a tertiary-referall hospital.

Methods: A cross-sectional study was conducted in hospitalized patient between the years 2014-2016. Comorbidities were assessed according to International Statiscal Classification of Diseases and Related Health Problems 10 th Revision. Subjects older than 18 years were included; subjects with congenital heart defects were excluded.

Results: We included 8,681 patients (age 49.85± 17.90 years). PH prevalence was 3.43% (n = 298). Those patients with PH were older (57.46 ± 15.19 vs. 49.58 ± 17.93, $p < 0.001$) ranging from 18 to 94 years; 60.7% were women. Compared with those without PH, patients with PH had a higher prevalence of cor pulmonale (19.8% vs. 1.4%, $p < 0.001$) and COPD (13.8% vs. 6.5%, $p < 0.001$), of which more than half (56.09% vs. 39.29%, $p < 0.001$) presented with acute exacerbation; pulmonary thromboembolism (12.8% vs. 1.9%, $p < 0.001$); sleep apnea (11.1% vs. 2.9%, $p < 0.001$); hypersensivity pneumonitis (8.7% vs. 1.8%, $p < 0.001$); pulmonary fibrosis (6.7% vs. 1.5%, $p < 0.001$); deep venous thrombosis (3.7% vs. 1.0%, $p < 0.001$); ischemic heart disease (2.3% vs. 1.0%, p 0.042); systemic lupus erythematosus (2.0% vs. 0.4%, $p < 0.001$). The in-hospital stay was 13.62 ± 8.58 days in the PH group and 11.90 ± 12.16 in those without PH.

Conclusions: PH is a condition associated with multiple comorbidities and these are related to higher morbidity and mortality, hence early detection and timely treatment is necessary to reduce economic impact and mortality.



Prevalence of comorbidities between patients with or without pulmonary hypertension (PH)

Pulmonar hypertension - A strong predictor of mortality among patients admitted with acute coronary syndrome

G Abreu[1]; P Azevedo[1]; C Rodrigues[1]; I Campos[1]; C Braga[1]; C Arantes[1]; J Martins[1]; A Gaspar[1]; J Marques[1]

[1]*Hospital de Braga, Cardiology, Braga, Portugal*

Background: Pulmonary hypertension (PH) is a complex pathophysiological condition, that may result from several scenarios, whose prevalence will likely expand with population aging and heart failure burden.

Aim: To evaluate how pulmonary hypertension can affect the prognosis of patients admitted with acute coronary syndrome.

Methods: We analysed 673 patients admitted consecutively in our coronary care unit with a diagnosis of acute coronary syndrome in a five-year period. Patients were divided in two groups according to pulmonary systolic arterial pressure (PSAP) evaluated by echocardiography. Group 1 – patients with PSAP ≥ 40mmHg (n = 227, 33.7%) and Group 2 – patients with PSAP < 40mmHg (n = 446, 66.3%). For each group we compared clinical and laboratory features, treatment and adverse events. Primary endpoint was the occurrence of 6-month death; follow-up was completed in 97%.

Results: Patients with high PSAP were older (71 ± 13 vs 65 ± 13 years, $p < 0.001$), more frequently obese (23.6% vs 16.7%; $p = 0.037$), had higher prevalence of hypertension (75.3% vs 59.4%; $p < 0.001$), diabetes (36.6% vs 27.1%; $p < 0.001$), and history of previous infarction (22% vs 13.2%; $p < 0.001$). They were under treatment more frequently with diuretics, ACE-inhibitors and calcium channel blockers. On admission, those patients with higher PSAP presented more often with Killip > 1 (38.8% vs 15.0%; $p < 0.001$), anaemia (41.0% vs 25.6%; $p < 0.001$) and renal insufficiency (eGFR < 60 ml/min) (51.8% vs 23.6%; $p < 0.001$). About two thirds had left ventricle dysfunction (62.4% vs 36.9%; $p < 0.001$). Regarding right ventricle function, there were no statiscally differences. During hospitalization, the group with PSAP ≥ 40mmHg presented more frequently atrial fibrillation (22.9% vs 8.7%; $p < 0.001$) and respiratory tract infection (10.6% vs 3.8%; $p = 0.001$), needed more frequently aminergic support (11.5% vs 5.4%; $p = 0.008$) and non-invasive and invasive ventilation support ($p < 0.001$). In-hospital (8.8% vs. 1.6%; $p < 0.001$) and 6-month mortality (18.6% vs. 5.2%; $p < 0.001$) were higher in patients with PSAP ≥ 40mmHg. In multivariate analysis and after adjusting for different baseline characteristics; pulmonary hypertension was related with higher risk of mortality [2.08 HR, 95% CI (1.13 - 3.81), $p = 0.018$].

Conclusion: Pulmonary artery hypertension reveals to be an independent predictor of overall 6-month mortality.

P1962

Pulmonary endarterectomy across borders: results of a program for chronic thromboembolic pulmonary hypertension

S Sofia Alegria[1]; MJ Loureiro[1]; AR Almeida[1]; F Ferreira[1]; O Simoes[1]; D Repolho[1]; L Lopes[1]; H Pereira[1]

[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Introduction: Although it has never been evaluated in randomized trials, pulmonary endarterectomy (PE) is the first-line therapy for chronic thromboembolic pulmonary hypertension (CTEPH). Significant benefits are reported after surgery.

Objectives: To evaluate the clinical, laboratory, echocardiographic and haemodynamic results of PE.

Methods: Longitudinal analysis of CTEPH patients followed in a reference center for the treatment of pulmonary hypertension (PH), submitted to PE abroad.
Results: Twenty-one patients (62% females, age 54 ± 12 years) were included. Before surgery, 85.7% were in WHO functional class III or IV, the distance in the 6-minute walk test (6MWT) was 352 ± 157 meters and the mean NT-proBNP was 1532 ± 1817 pg/mL. On echocardiographic analysis the pulmonary artery systolic pressure (PASP) was 85 ± 20 mmHg, 42.1% had compromised right ventricular (RV) systolic function, 76.5% right atrial (RA) dilatation and 20.0% pericardial effusion. Right heart catheterization revealed a reduced cardiac index in 70.0%, mean pulmonary artery pressure (mPAP) of 44 ± 13 mmHg and pulmonary vascular resistance (PVR) of 11,0 ± 5,4 WU. 43% were medicated with phosphodiesterase-5 inhibitors, 28.6% with endothelin-1 receptor antagonists and 14.3% with prostanoids. The mean cardiopulmonary bypass time was 269 ± 54 minutes and the disease was classified as Jamieson type 2 in the majority of patients (72.7% on the right pulmonary artery and 81.8% on the left). During 971 ± 802 days of follow-up, cardiovascular mortality was 4.8% (n = 1), with death of the only patient undergoing reoperation. After surgery, all patients were in WHO functional class I or II, there was an increase of the distance in 6MWT of 90 ± 107 meters (p = 0.004), NT-proBNP decreased by 1204 ± 1816 pg/mL (p = 0.006) and PASP assessed by echocardiography decreased by 45 ± 22 mmHg (p < 0.001). Recovery of RV systolic function and normalization of AD dimensions were both observed in 44.4% of the patients and none had pericardial effusion. In the haemodynamic evaluation, there was a reduction of the mPAP by 19 ± 12 mmHg (p < 0.001) and of the PVR by 7.3 ± 5.5 WU (p < 0.001). Nevertheless, 57,9% of the patients maintained residual PH (PAPm ≥ 25 mmHg and/or PVR >3 WU). In comparison with the 12 months before PE, there was a reduction in the number and days of hospitalization in the 12 months after surgery (p = 0.014 and 0.018, respectively). Compared to a control population of 10 CTEPH patients not submitted to PE, similar in terms of baseline characteristics, there was a greater improvement in the 6MWT (+90 ± 107 vs. -30 ± 119 meters; p = 0.025), functional class (no patients in class III-IV vs. 62.5%; p < 0.001), mPAP (19 ± 12 vs. 6 ± 3 mmHg; p = 0.032) and PVR (7.30 ± 5.48 vs. 2.09 ± 2.6 WU; p = 0.036), and a reduction in cardiovascular mortality (p = 0.001).
Conclusion: PE was associated with a significant improvement in clinical, laboratory, echocardiographic and haemodynamic parameters, as well as reduction of admissions and mortality.

P1963
Echocardiographic pulmonary artery pressure estimation and risk of recurrent hospitalizations in acute heart failure

E Enrique Santas Olmeda[1]; R De La Espriella[2]; E Valero[1]; A Mollar[1]; J Gonzalez[1]; I Cardells[1]; A Paya[1]; R Heredia[1]; G Minana[1]; A Bayes-Genis[3]; J Lupon[3]; J Sanchis[1]; FJ Chorro[1]; J Nunez[1]
[1]Hospital Clinic Universitari. Universitat de València, Valencia, Spain; *[2]Hospital General Universitario de Valencia, Valencia, Spain*; *[3]Germans Trias i Pujol Hospital, Badalona (Barcelona), Spain*

Background: Pulmonary hypertension (PH) is a strong predictor of mortality in patients with heart failure (HF). However, the relationship between PH assessment, through echocardiographic pulmonary artery pressure (PASP) estimation, and readmission risk burden in acute HF patients remain unclear.
Methods: We prospectively included 2343 consecutive patients discharged for acute HF. PH was estimated by echocardiography through PASP determination in the index admission. Patients were categorized as follows: non-measurable PASP, normal PASP (PASP≤35 mmHg), mild (PASP=36-45 mmHg), moderate (PASP=46-60 mmHg), or severe PH (PASP>60 mmHg). Negative binomial regression method was used to evaluate the association between PASP and recurrent hospitalizations. Estimates were reported as incidence rate ratios (IRRs).
Results: Mean age of the cohort was 72.8 ± 11.2 years, 50.5% were women, and 53.4% exhibited a left ventricular ejection fraction (LVEF) ≥50%. PASP was accurately registered in 1234 (52.7%) patients. Of them, 306 (13.1%) displayed normal PASP, whereas 369 (15.7%), 368 (15.7%), and 191 (8.1%) patients showed mild, moderate or severe PH, respectively. At a median follow up of 2.26 years (interquartile range: 0.77-4.47), 1114 (47.6%) patients died, 4427 all-cause readmissions in 1567 (66.9%) patients, and 1834 HF related-rehospitalizations in 943 (40.2%) patients were recorded. After multivariable adjustment, and compared to patients with normal PASP, only those with severe PH exhibited a higher risk of recurrent admissions (IRR=1.52; 95% confidence interval, 1.14-2.03; p = 0.004). No significant interaction was found with regard to LVEF status (<50% vs. ≥50%; p = 0.803).
Conclusions: Acute HF patients with severe PH, as estimated by echocardiography-derived PASP, are associated with an increased risk of recurrent hospitalizations.

Prevalence of prognostic factors in pulmonary hypertension

A Adrian Lescano[1]; H Santa Maria[1]; A Lavalle Cobos[1]; D Crippa[1]; N Gonzalez[1]; A Ferro[1]; G Damianich[1]; G Romero[1]; I Constantin[1]; I Fernandez[1]; E Besmalinovich[1]; V Daru[1]; M Gonzalez[1]; H Grancelli[1]
[1]Finochietto Clinic, Buenos Aires, Argentina

Pulmonary hypertension (PH) is a multi-factorial condition associated with high morbidity and mortality. It requires for its diagnosis and treatment a multidisciplinary approach. In the past decades there have been many advances in the epidemiological, pathophysiological and therapeutic knowledge of the disease. However, there is little information available regarding clinical and prognostic factors in patients diagnosed with PH in Latin America.
Pourpose: Determine the prevalence and clinical characteristics of adverse prognostic factors in a population with recent diagnosis of PH.
Methods: Patients with recent diagnosis of PH (< 7 days) confirmed by right heart catheterization, with a mean pulmonary-artery pressure (MPAP) ≥ 25 mm Hg (using a Swan Ganz Catheter) from three heart failure and pulmonary hypertension services were analyzed between March 2012 and December 2016. According to the recommendations of international guides, the following data were recorded: Personal data, PH group (G), clinical features: symptoms, functional class FC. Direct hemodynamic parameters: pulmonary pressures (PP), wedge pressure (WP), right atrium pressure (RA) and cardiac index (CI). Functional: 6 minute walk (6MW) test distance. Echocardiographic variables: right ventricle systolic function (RVSF), tricuspid annular plane systolic excursion (TAPSE), systolic pulmonary pressure and presence of pericardial effusion (PE). Data obtained were analyzed with BioEstat 5.3 program. Adverse prognosis factors identified were: history of heart failure (HF), syncope, advance functional class (III-IV), performance in the 6MW test < 350 m, presence of PE, TAPSE ≤15 RA ≥ 12 e CI ≤ 2,2.
Results: Multicenter, observational, descriptive, consecutive and prospective study. 107 patients where included. 74% women. Mean age was 58,8 (± 19) years, 33% ≥ 70. The mean delay in diagnosis was 24 months after the first sign or symptom recorded. PH group distribution: GI 63%, GII15%, GIII9%, GIV6% and GV6%. FC of presentation: I4%, II 40%, III34% and IV20%. History of HF in 72%, syncope in 23%. 6MW mean distance walked was 320 (± 148) meters, 47 % performed ≤ 350 meters. RHC: MPAP 48.3 (± 16) mmHg, RAP 9.7 mmHG (± 5,2) and ≥ 15 mmHg 27%; CI 2,78 litres/min/mt2 (≤ 2,2 23%). Ecocardiographic data show: 79% impaired FSVD (42% slight, 18% moderate and 19% severe). Mean TAPSE 17.8 (± 4) mm, ≤ 15 mm 37 % and PE in 25%.
Conclusions: In our population with confirmed pulmonary hypertension, with a predominance of group I, we had a high presentation in over 70 years of age. At diagnosis time a high number of patients present adverse prognosis factors. This findings remark the need to use early diagnosis and therapeutic strategies.

P1965
Pulmonary hypertension due to left heart disease and etiology of heart failure

MI Marta Izabela Kaluzna-Oleksy[1]; J Migaj[1]; M Dudek[1]; E Straburzynska-Migaj[1]
[1]Poznan University of Medical Sciences, Ist Department of Cardiology , Poznan, Poland

Introduction: Heart failure (HF) is a clinical condition with a miscellaneous background. The most prevalent cause of HF in Europe is coronary artery disease (CAD). Depending on etiology of HF, its natural history may vary. Left heart disease (LHD) is the main cause of pulmonary hypertension (PH), which in turn is considered a risk factor for worse outcomes in patients with heart failure (HF).
Aim: Evaluation of HF patients with reduced ejection fraction (HFrEF) undergoing qualification for heart transplantation with and without pulmonary hypertension due to left heart disease with regard to etiology of HF.
Methods: This was a prospective analysis of 211 patients (both genders) with HFrEF (left ventricular ejection fraction < 40%), with ischemic (ICM) (43%) and non-ischemic cardiomyopathy (NICM) (57%), hospitalized at a tertiary health care center, undergoing qualification process for heart transplantation. The following items were analyzed: medical history, epidemiological data, laboratory test results (including BNP), and chosen parameters obtained in echocardiography, cardiopulmonary exercise testing (CPET) and RHC (thermodilution method). PH was diagnosed according to the ESC guidelines.
Results: Mean age of analyzed population was 51.7 ± 10.3 years. Most patients were men (88%), 73% were in NYHA class 3 and 4. Patients with ICM were significantly older (p = 0.005) and without any gender differences with lower BNP level (p = 0.005) and higher mean aortic pressure measured invasively (p = 0.036). Patients presented PH and ischemic etiology of HF were older (p = 0.005), had lower BNP (p = 0.006) and TSH (p = 0.004) and higher mean pulmonary artery pressure (p = 0.035) and transpulmonary gradient (TPG) measured invasively without any significant differences in echocardiography or CPET.
Conclusions: PH occurred with the same frequency in ICM and NICM group, but

ischemic etiology of HF in PH patients was associated with lower level of BNP and with higher PAPm and TPG with no differences between in echocardiography or CPET.

Funding Acknowledgements: This study was supported with grants from the Instituto de Salud Carlos III, FEDER "Unión Europea, Una forma de hacer Europa" (PA 14/0184)

Background/Introduction: Nowadays, analyzing security and efficacy of macitentan after administering it for any reason is considered to be of special relevance.
Purpose: To describe the clinical profile and the follow-up results (security and efficacy) of patients with PH treated with macitentan.
Methods: From the 1st of July 2015 to the 31st of December 2016 all patients treated with macitentan who were prescribed during hospitalization were retrospectively and consecutively recruited. Demographic, echocardiographic, hemodynamic and clinical data and functional status were assessed.
Results: 13 patients were assessed. 6 patients had group I PH and 6 had group II PH. Table 1 shows the clinical profile, treatment indication and tolerance of 13 patients. It was a well-tolerated treatment for most patients (92%), and 11 of 13 patients (85%) improved their functional class with respect to previous status without having prescribed macitentan. In the follow-up 4 deaths (31%) were registered. Causes of death are shown in table I.
Conclusions: Macitentan is an approved drug for PAH. Nevertheless, our patients have also shown positive results for group II PH. It is a well-tolerated drug in most of our patients, and it has been related with an improvement of the functional class in most cases. Studies with longer follow-up and a larger sample are needed.

Exercise echocardiography to evaluate right ventricular afterload in post pulmonary endarterectomy patients

A R Ana Rita Almeida[1]; L Lopes[1]; MJ Loureiro[1]; D Repolho[1]; AR Pereira[1]; S Alegria[1]; F Ferreira[1]; P Fazendas[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Almada, Portugal

Introduction: Despite near normal resting mean pulmonary artery pressures (mPAP) and pulmonary vascular resistance (PVR) after pulmonary endarterectomy (PEA), abnormal increase in right ventricular (RV) afterload may be apparent during exercise and may explain the reduced exercise capacity that persists in many patients. Right ventricular afterload is better described using measures of both resistive (PVR) and pulsatile load (pulmonary arterial compliance (PAC).
Purpose: Evaluate RV afterload at rest and during exercise in patients after PEA and demonstrate that we can do this evaluation non-invasively with exercise echocardiography (EE).
Methods: Study using information recovered from EE. EE was done using treadmill ergometer and modified Bruce protocol until exhaustion. During exercise they went symptoms, arterial pressure and ECG monitoring
To evaluate RV afterload we used measures of: • total pulmonary vascular resistance (TPVR) = mean pulmonary artery pressure (mPAP)/cardiac output (CO); for this we had to evaluate mPAP = PSAP (pulmonary systolic artery pressure) x0.6 + 2, where PSAP=RV/RA (right atrium) gradient + RA pressure estimate and CO=LVSV(left ventricular stroke volume) (LVOT VTI x LVOT area) x heart rate. RA pressure estimate is as: IVC (inferior vena cava) $<$21 mm and collapsibility index (CI) $>$50% - RAP = 3 mmHg; IVC $>$21mm and CI $<$50% - RAP = 15 mmHg; intermediate values = 8 mmHg.
• compliance pulmonar (PAC) = RVSV (right ventricular stroke volume)/pulmonary pulse pressure (PPP); where RVSV=LVSV in shunt absence and PPP=PSAP-PDAP (pulmonary diastolic artery pressure), where PDAP=PA/RV gradient (in late diastole using pulmonary regurgitation jet) + RA pressure estimate.
We analyze results using SPSS version 21.
Results: The group of post PEA patients consisted of 13 patients at least 6 months after PEA, with mean age of 57.0 ± 11.7 years, 7 females. We verified a significant increase in mPAP (16.2 ± 5.7 at rest (R) vs 36.8 ± 10.3mmHg at peak exercise (PE) ($p < 0.001$)) and in CO (3.8 ± 1.0 at R vs 9.7 ± 2.7 L/min at PE ($p < 0.001$)). The TPVR didn't decrease (4.5 ± 2.0 (R) vs 4.1 ± 1.8 UWood (PE) ($p = 0.512$) and PAC decreased significantly (2.5 ± 3.5 (R) vs 1.3 ± 1.0 (PE) ml/mmHg ($p = 0.01$)).
Conclusions: In patients after PEA, TPVR does not decrease significantly with exercise, unlike what succeeds in healthy people; and CPA decrease significantly, both factors contributing to increase in RV afterload with exercise. It is possible to study TPVR and CPA using exercise echocardiography.

P1969

TAPSE as a simple echocardiographic parameter predicting exercise capacity in patients with advanced heart failure

A Anna Drohomirecka[1]; M Lipczynska[1]; T Rywik[1]; K Kozuch[1]; K Zukowska[2]; K Kodziszewska[1]; K Komuda[1]; T Zielinski[1]
[1]Institute of Cardiology, Warsaw, Poland; *[2]Medical University of Warsaw, Warsaw, Poland*

Funding Acknowledgements: The study was supported by Institute of Cardiology statutory grant no. 2.45/VII/15

Background: Reduced physical activity is an obvious consequence of disease progression in patients with heart failure, as impaired left ventricle function leads to deterioration of mechanisms that regulate response to increased physical exertion. The aim of this study was to determine the echocardiographic factors that affect exercise capacity in patients with advanced heart failure.
Material and methods: Fifty patients referred for evaluation for heart transplantation – 42 men and 8 women (aged 55.5 ± 7.6 years) with advanced heart failure (NYHA II-III/IV, EF≤35%, mean 21.7 ± 5.4%) underwent complex cardiologic assessment, including laboratory tests, echocardiography, cardiopulmonary exercise test (CPX) and right heart catheterization. CPX was performed on a bicycle ergometer according to RAMP protocol 10 Watt/min, measuring i.e. maximum workload, pVO2, pVO2 adjusted for age and sex, anerobic threshold, VE/VCO2 slope, RER, VO2/HR, VO2(WR) slope. Left and right ventricle function and size were assessed using 2D-mode, tissue Doppler and speckle-tracking echocardiography. Statistical correlation between echocardiographic and capacity indexes was tested.
Results: Among all echocardiographic parameters, the tricuspid annular plane systolic excursion (TAPSE) and tissue Doppler-derived right ventricular systolic excursion velocity S' were the most strongly correlated with exercise capacity indexes – statistically significant correlations were noted with, respectively, six and five out of 8 estimated parameters (for example, TAPSE positively correlated with pVO2; r=0.41, $p = 0.003$). Moreover, in patients whose pVO2 value was above the median value in the whole study population, TAPSE was on average 2.2mm higher than in the group with pVO2 below the median (18.04 ± 3.14 vs. 15.83 ± 3.28, $p = 0.02$). Other echocardiographic parameters were correlated with none (i.e., LVEF, LVEDV), only with one (i.e., left and right ventricle GLS) to a maximum of three (i.e., RVOT dimension or RVOT ACT) capacity indexes.
Conclusion: Exercise capacity of patients with advanced heart failure strongly depends on right ventricle function, which can be simply assessed by measuring TAPSE.

P1970

Exercise echocardiography to evaluate right ventricular function in post-pulmonary endarterectomy patients

A R Ana Rita Almeida[1]; L Lopes[1]; MJ Loreiro[1]; D Repolho[1]; AR Pereira[1]; S Alegria[1]; F Ferreira[1]; P Fazendas[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Almada, Portugal

Introduction: Right ventricle (RV) contractile reserve has not been quantified in post-pulmonary endarterectomy (PEA) patients, despite RV function being the main predictor of outcome and exercise capacity, irrespective of any change in PVR.
Purpose: Evaluate RV function at rest and during exercise in patients after PEA, trying to understand the mechanisms that can limit functional capacity and demonstrate that we can do this evaluation non-invasively with exercise echocardiography (EE).
Methods: Study using information recovered from EE. EE was done using treadmill ergometer and modified Bruce protocol until exhaustion. During exercise they went symptoms, arterial pressure and ECG monitoring.
To evaluate RV function we used measures of: RVSVI (right ventricle stroke volume indexed to body surface area) = LVSVI (left ventricle stroke volume indexed to body

surface area)= (left outflow tract (LVOT) area x LVOT VTI)/body surface area; tricuspid annular plane systolic excursion (TAPSE); free RV wall S wave (S wave) and RV fractional area change (RVFAC).
Results: The group of post-PEA patients consisted of 13 patients at least 6 months after PEA, with mean age of 57.0 ± 11.7 years, 7 females.
We verified a significant increase in RVSVI (25.2 ± 7.1 at rest (R) vs 34.7 ± 6.9 mL/m2 at peak exercise (PE) ($p < 0.001$)), in TAPSE (15.6 ± 2.0 (R) vs 20.6 ± 3.3mm (PE) ($p < 0.001$)) and in S wave (9.1 ± 2.6 (R) vs 14.3 ± 3.4 cm/seg (PE) ($p = 0.001$)). RVFAC didn't change significantly with exercise (43.6 ± 9.2 (R) vs 48.5 ± 10.7% (PE) ($p = 0.217$)).
Conclusions: It is possible to study RV function using exercise echocardiography. In patients after PEA the longitudinal function of RV seems to be more preserved than radial function.

P1971

Higher arterial stiffness predicts non-recovery of left ventricular longitudinal function in patients after myocardial infarction treated with percutaneous coronary intervention

E Zharikova[1]; S Villevalde[1]; ZH Kobalava[1]
[1]RUDN Univercity, Moscow, Russian Federation

Objective: Functional recovery or irreversible negative remodeling of injured myocardial segments has different prognostic implication in patients with myocardial infarction (MI) undergoing coronary percutaneous intervention (PCI). Increased pulse wave velocity (PWV), a non-invasive index of arterial stiffness, is one of the important risk factors of cardiovascular events in different clinical conditions. The aim of the study was to assess the relationship between PWV and changes of left ventricular (LV) systolic function in patients with acute MI.
Methods: In 112 patients with acute MI and PCI (68% male, age 61.1 ± 9.5 years (M ± SD), 57.2% with ST-elevation MI (STEMI), smokers 35%, arterial hypertension 83%, diabetes 7%, blood pressure (BP) 128 ± 8/82 ± 87mmHg, LV ejection fraction (LVEF) 48.2 ± 4.6%) arterial stiffness was assessed using applanation tonometry. Global longitudinal peak strain (GLPS) by speckle tracking echocardiography (STE) was calculated in a 16-segment LV model as the average segmental value on the basis of three apical imaging planes. Cardiac adverse remodeling was defined by ratio [follow up - initial LV end diastolic volume (LVEDV)] / initial LVEDV) more than 20%. Mann-Whitney and Spearman tests were considered significant if $p < 0.05$.
Results: Baseline GLPS >20% was not detected in any patient. GLPS increased from 14.4 ± 2.4 to 17.4 ± 3.5% in 4 weeks ($p < 0.05$) and to 18.1 ± 2.7 in 6 months after PCI ($p < 0.05$). GLPS normalized (>20%) in 31 (28%) patients after 4 weeks and 6 months. After 6 months adverse cardiac remodeling was found in 81 (72%) patients (53% STEMI). Achieved GLPS differed significantly in patients with vs without adverse cardiac remodeling (16.7 ± 1.9 vs 21.4 ± 1.2%, $p < 0.001$). Mean carotid-femoral PWV decreased from 11.1 ± 2.1 to 8.7 ± 1.8 m/s, $p < 0.05$. Patients without vs with GLPS normalization in 6 months after PCI were older (62.5 ± 8.5 vs 60.6 ± 9.9 years, $p < 0.05$), more frequent male (71 vs 66.2%, $\chi 2$=11.1; $p < 0.05$), smokers (36.2 vs 31.2%, $\chi 2$=3.4; $p < 0.04$), STEMI (58.7 vs 53%, $\chi 2$=7.7; $p < 0.05$), had higher systolic BP (134 ± 10 vs 130 ± 6 mmHg, $p < 0.03$), baseline PWV (11.4 ± 1.9 vs 10.4 ± 2.6 m/s, $p < 0.03$), lower baseline EF (47.6 ± 4.9 vs 49.6 ± 3.5%, $p < 0.05$). A significant correlation was found between decreased Δ speckle tracking and higher PWV (r=-0.31, $p < 0.05$) and speckle tracking and LVEDV after 6 months (r=-0.75, $p < 0.05$).
Conclusions: 65 % of patients with MI treated with PCI failed to normalize GLPS after 6 months. Adverse cardiac remodeling was revealed in 72% of patients and they more often had non-recovery of left ventricular longitudinal function. Higher baseline PWV is associated with less effective recovery of LV function.

P1972

Left ventricular function in patients with coronary slow flow

A Ali El Sharkawi[1]; MANSOR M Moustafa[2]; M I Mokarrab[2]; N F Ismail[2]; A S Abuarida[1]
[1]National Heart Institute, Cairo, Egypt; *[2]Al-Azhar University, Cairo, Egypt*

Background: The coronary slow flow phenomenon(CSFP) has been linked to myocardial ischemia, life-threatening arrhythmias, sudden cardiac death and recurrent ACS. Hypothesis of its mechanism including early atherosclerosis, microvessel dysfunction, imbalance between vasoconstrictor and vasodilatory factors and platelet function disorder were proposed. How and to what extent do these etiological factors affect left ventricular (LV) function.
Aim: To evaluate LV function in SCF patients.
Material and methods: 100 patients with CSFP and 50 subjects with angiographically normal coronary arteries constituted the control group were included in the study. All are subjected to echocardiography study to determine left ventricular functions.
Results: As regard systolic function measured by modified Simpson's method, ejection fraction was similar in both groups(62.2 ± 5.1 vs 64.4 ± 4.6, $p = < 0.22$. As regard diastolic function, echocardiography showed significantly lower maximal velocity of early diastolic filling (E) and ratio of maximal early to late diastolic filling (E/A)(in the patient group(54.6 ± 6.9 cm/s vs 74.5 ± 12.5 cm/s, $p < 0.001$ and 1.1 ± 0.25 vs 1.44 ± 0.17, $p < 0.001$ respectively). Maximal velocity of atrial diastolic filling (A) and deceleration time of early diastolic filling (DT) were similar. Among tissue Doppler parameters, E' was significantly lower in the patient group(8.6 ± 1.6 cm/s vs 14.9 ± 2.8 cm/s ,$p < 0.001$), E/e' was significantly higher in the patient group (6.4 ± 0.78 vs 5.03 ± 0.83, $p < 0.001$).
Conclusion: Coronary slow flow phenomenon is associated with left ventricular diastolic dysfunction.

Systolic left ventricular dysfunction in isolated mitral stenosis

N Nada Tabebi[1]; R Hammami[1]; B Rekik[1]; L Abid[1]; S Kammoun[1]
[1]Hedi Chaker University Hospital, cardiology, Sfax, Tunisia

Mitral stenosis is a long term complication and the most important sequel of acute rheumatic fever.The dogma is that there is no left ventricular deficiency during mitral stenosis (MS). The aim of the study is to determine left ventricular (LV) dysfunction by tissue Doppler imaging (TDI) and speckle tracking echocardiography (STE) in MS patients who had no clinical signs of heart failure.
Methods: Our study was an observational study. The population included 44 patients with isolated mitral stenosis and mitral valve area < 2 cm2 (Group 1) and 44 healthy control subjects (Group 2). Standard echocardiographic methods, TDI and STE were performed to assess LV functions in all participants.
Results: Mean age was 39 years old ± 12 with female predominance. Left ventricular (LV) ejection fraction (EF) was in the normal ranges in both groups (60.04 + - 4.8% vs61,75 ± 6,9% , $p = 0,21$).
Systolic myocardial velocity was significantly lower in Group 1 than in Group 2 (10.1 ± 1.7 cm/sec vs 11.29 ± 1.6 cm/sec, $p = 0.04$).The peak of global longitudinal strain GLS was significantly lower in Group 1 than in Group 2 ($p = 0.009$). Indeed, the apical systolic strain was significantly lower in Group 1 than in Group 2 (-22.49 + - 8.22 % vs-26.75 + -5.35, $p < 0.001$ f). The same results were found with basal and median systolic strain ($p < 0.001$ both). There is no correlation between severity of MS and the degree of systolic dysfunction particularly between mean GLS and mitral area (r=0.157, $p = 0.31$).
Conclusion: Through our study, we demonstrated that LV dysfunction in patients with isolated MS and normal EF. The speckle tracking imaging may be useful to detect LV function in early stage of mitral stenosis.

P1974

The impact of chronic cytomegalovirus infection on left ventricular hypertrophy

R Siliste[1]; C Carmen Cristescu[2]; C Dita[2]; AM Vintila[1]; C Grancea[2]; S Ruta[2]
[1]Coltea Clinical Hospital, Cardiology, Bucharest, Romania; *[2]Stefan S Nicolau Virology Institute, Virology, Bucharest, Romania*

Background: Recent studies revealed a possible relationship between cytomegalovirus (CMV) infection and cardiac disease, more specific atherosclerosis, hypertension and left ventricular hypertrophy (LVH). Characterized by a lifetime latency in mieloid cell lineage cells, but with high propensity for fibroblasts and

epithelial cells, and ability to periodically reactivate in subclinical events, CMV maintains a permanent, variable inflammatory response that contributes to arterial wall damage.
The aim of our cross-sectional prospective study was to demonstrate the impact of chronic cytomegalovirus infection on hypertension and left ventricular hypertrophy.
Methods: One hundred and three patients aged between 22 and 65 years old, 55 women and 48 men, mean age 55.5 years old, with or without known cardiac disease were enrolled in the study from february to december 2016. An informed consent approved by the local Ethics Commitee was signed by every patient before the participation to our study. At enrollement each patient filled a questionary concerning risk factors for cardiac disease (cigarrette smoking, alcohol, diabetes, obesity, serum cholesterol levels, family risk factors). All patients underwent blood tests to determine their cholesterol levels and a quantitative immunoenzymatic test for specific CMV IgG antibodies (Dia.Pro Diagnostic Bioprobes SRL, Italy) and all of them carried out a complete physical examination with arterial blood pressure measurement and a cardiac ultrasound. Left ventricular mass and left ventricular mass indexed to total body surface area were determined using the Devereaux modified formula. IBM SPSS version 19 softwear was used for the results' database and for their processing.
Results: IgG CMV antibodies were positive in all patients enrolled in our study demonstrating a very high seroprevalence for CMV in Romanian population in the fifth decade of life. From the total of 103 patients, 76 were diagnosed with hypertension (45 women and 31 men) and only 30 with LVH (20 women and 10 men). The ROC curve for LVH and hypertension did not demonstrate a very good accuracy for CMV as a prediction factor alone for any of these two conditions, but had a higher sensitivity for LVH.
Conclusions: Our study showed that chronic CMV infection can not be considered a prediction factor alone neither for hypertension nor for left ventricular hypertrophy in a 100% positive population for IgG CMV antibodies. However, in addition to other cardiac risk factors, chronic CMV infection might bring its contribution to the severity of cardiac disease by reactivation (high titers of IgG specific antibodies with positive titers of IgM antibodies) and this is why further studies need to be conducted.

Background/Introduction: Dyspnea is one of the most common symptoms of acute heart failure patients presenting to emergency rooms. If the severity of acute dyspnea is associated with the type of heart failure according to the new classification of the 2016 ECS Heart failure guidelines, remains unclear.
Purpose: We aimed to determine if the severity of acute dyspnea could be a predictor of the specific type of heart failure as distinguished in the new ESC classification.
Methods: Prospective observational cohort study enrolled consecutive patients admitted to the emergency department with acute dyspnea due to decompensated heart failure (HF) and other reasons. Study parameters: left ventricular ejection fraction (LVEF), dyspnea points and presence of atrial fibrillation (AF) were collected at the time of admission. Data of 387 study patients (mean age 70.3 years) with final HF diagnosis were included in the study and divided into three groups according to LVEF, measured at the time of admission or using latest available echocardiography data: HF with reduced ejection fraction (HFrEF) group with LVEF less than 40% (n = 173), HF with mid range ejection fraction (HFmrEF) with LVEF 40-49% (n = 47) and HF with preserved ejection fracture (HFpEF) with LVEF >50% (n = 167). Patients were asked to rate dyspnea by visual-analog dyspnea scale (VADS) from 1 to 10 points; point range of 0-3, 3-6 and 6-10 was defined as low, moderate and high intensity dyspnea, respectively. Using random number generator, 47 patients were randomly selected to each of three groups. Subsequently, data of 141 patients were analyzed using SPSS v23 statistical package with One-way ANOVA.
Results: Of 141 examined patients 65 (46.1%) were female, 76 (53.9%) were male. Heart failure with mid range ejection fraction was found in 12.1%, HFrEF in 44.7% and HFpEF in 43.2% of study population. Mean of dyspnea points in HFrEF group was 6.3 ± 2.9, in HFmrEF group 7.3 ± 2.3 and in HFpEF group 7.5 ± 7.5 with no statistically significant difference (p = 0,053).
Conclusion: In the prospective observational cohort the majority of acute HF patients complained of high intensity dyspnea with no differences of intensity between the three types of heart failure.

	Dyspnea severity		Gender		AF

Effect of drug treatment on quality of life in heart failure with preserved ejection fraction: a systematic review and meta-analysis of randomised controlled trials

S Zheng[1]; FTS Chan[2]; S Ayis[3]
[1]King's College London, London, United Kingdom; *[2]Imperial College Healthcare NHS Trust, London, United Kingdom*; *[3]King's College London, Department of Primary Care and Public Health Sciences, London, United Kingdom*

BACKGROUND: Clinical drug trials in heart failure with preserved ejection fraction (HFpEF) have failed to consistently demonstrate mortality-reducing effects. Improvements in quality of life are of equally significant clinical importance and an outcome that has not been the focus of clinical trials.
Purpose: To examine whether clinical trials in HFpEF demonstrate improvements in quality of life compared with placebo or standard medical therapy.
Methods: We systematically searched MEDLINE, Embase and CENTRAL for randomised controlled trials (Jan 1996 to May 2016) assessing pharmacological treatments in HFpEF on quality of life. Inclusions/exclusions were adjudicated and data extracted by two independent investigators. The primary efficacy outcome examined was mean difference in quality of life (measured using the Minnesota living with heart failure questionnaire) between treatment and control groups. Trials were classified by drug type: beta-blockers (BB), angiotensin-converting enzyme inhibitors (ACEi), angiotensin receptor blockers (ARB), mineralocorticoid receptor antagonists (MRA) and other drug classes.
Results: Of 3561 articles identified in the search, nine trials reported the treatment effects on quality of life as measured by the MLHFQ, including a total of 3510 patients (BB: 116, ACEi: 166, ARB: 2460, MRA: 444, Other: 324). Overall estimate showed that treatment was associated with statistically improved mean difference favouring treatment group (MD: -1.63, 95% CI: -2.94 to -0.31, P=0.001) (Figure 1). By individual class, only ARBs showed statistically significant difference favouring treatment (-1.84, 95% CI -3.55 to -0.14), with ACEi and MRA showing a non-significant trend favouring treatment.
Conclusion: While quality of life scores were improved in HFpEF patients in clinical trials, the clinical significance of this small difference is uncertain. Trends in improvements were found with other drug classes that block renin-angiotensin-aldosterone axis (ACEi and MRA), though this was limited by small numbers of patients. Our study found that few trials measured quality of life as an outcome. It will be of increasing importance to determine if there are other benefits of treatments beyond mortality-reducing effects, including their effects on hospitalisation rates and exercise capacity.

Prognostic impact of blood pressure values in patients with heart failure with preserved ejection fraction

H Hugo Antunes[1]; ML Goncalves[1]; L Abreu[1]; B Marmelo[1]; J Gil[1]; I Pires[1]; D Moreira[1]; I Almeida[1]; M Correia[1]; C Cabral[1]
[1]*Hospital Sao Teotonio, Cardiology, Viseu, Portugal*

Introduction: Arterial hypertension (HT) is an important cardiovascular risk factor, with an increased risk of morbidity and mortality, especially with the increased risk of ischemic heart disease and stroke.
Objectives: To assess the impact of blood pressure (BP) values in patients (P) with heart failure with preserved ejection fraction (HFpEF).
Methods: We identified all P admitted for HF in a single center between 01/01/2009 and 31/12/2014. Only P with HFpEF were included. We considered 2 groups, according to BP values at admission: Systolic blood pressure (sBP)> 140 mmHg (gHyper) and sBP < 120 mmHg (gHypo). We excluded all P with sBP < 90 mmHg at admission and those who had intermediate sBP (between 120-139 mmHg).
Clinical, imaging and analytical parameters were evaluated. We compared in-hospital mortality (IHM), the combined endpoint (death / hospitalization for HF) at 12 and 24 months (M) and the survival curves of each group.
Results: Of a total of 1006 P, 350 met the inclusion criteria, 59.7% female, 79.4 ± 8.5 years.
In-hospital mortality was 3.7%. The combined endpoint at 12M was 46.0% and 58.6% at 24M.
The gHyper represents 68.6% of the P. Female predominance was found in both groups (gHyper 60% vs 59.1%, p> 0.05), mean age 79.3 ± 8.6 years (vs 79.6 ± 8.2 years, p> 0.05) and mean sBP of 167.2 ± 24.1 mmHg (vs. 109.5 ± 8.7 mmHg).
Evaluating comorbidities, 39.6% of gHyper had diabetes and 83.8% had previous diagnosis of hypertension, compared with 24.5% (p = 0.006) and 52.7%, respectively (p < 0.001). There was a trend for gHyper to have a history of ischemic heart disease more frequently (11.7% vs 5.5%, p = 0.055). Prevalence of atrial fibrillation in gHypo (65.7% vs 54.2%, p = 0.044). The two groups were similar in the remaining comorbidities.
The value of BNP in gHyper on discharge was 282 ± 354 (vs 433 ± 609, p = 0.043) and the urea value on admission was 61.9 ± 30.9 (vs77.5 ± 39.4, p < 0.001). The gHyper evolved more frequently with acute renal injury (21.8% vs 10.9%, p = 0.014). There was no statistically significant difference in hospital mortality between the two groups (gHyper 2.9% vs 5.5%, p = 0.244). There were a greater number of events in combined endpoint at 12 and 24M in gHypo (54.2% vs 46%, p = 0.05 and 67.0% vs 55.0%, p = 0.048). Survival curves showed that P with sBP < 120 mmHg had worse outcome at 12 and 24 M (p = 0.028 and p = 0.021, respectively).
Conclusion: This study showed that although gHyper have a higher number of cardiovascular risk factors, they appear to have a more favorable short and medium-term prognosis. Survival curves showed that gHypo have a greater number of adverse events at both 12 and 24M.
These results raise the hypothesis that aggressive BP control could be unfavorable in P with HFpEF.

Exercise training in diastolic heart failure (Ex-DHF): rationale and design of a multicentre, prospective, randomized, controlled, parallel group trial

F Edelmann[1]; A Anna Bobenko[1]; G Gelbrich[2]; G Hasenfuss[3]; C Herrmann-Lingen[4]; A Duvinage[5]; S Schwarz[5]; T Trippel[1]; R Lindhorst[1]; D Morris[1]; E Pieske-Kraigher[1]; HD Duengen[1]; R Wachter[3]; M Halle[5]; B Pieske[1]
[1]*Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany*; [2]*University Julius Maximilian of Wurzburg, Institute for Clinical Epidemiology and Biometry, Wurzburg, Germany*; [3]*University Medical Center Gottingen (UMG), Department of Cardiology and Pneumology, Gottingen, Germany*; [4]*University Medical Center Gottingen (UMG), Depatment of Psychosomatic Medicine and Psychotehrapy, Gottingen, Germany*; [5]*Technical University of Munich, Depatment of Prevention, Rehabilitation and Sports Medicine, Munich, Germany*

Aims: Heart failure with preserved ejection fraction (HFpEF) is a common disease with high incidence and increasing prevalence. Patients suffer from functional limitation, poor health-related quality of life (HRQoL), and reduced prognosis. A pilot study in a smaller group of HFpEF patients showed that structured, supervised exercise training (ET) improves maximal exercise capacity, diastolic function and physical quality of life. However, the long-term effects of ET on patient related outcomes remain unclear in HFpEF.
Methods: The primary objective of Ex-DHF is to investigate whether a 12-months supervised ET can improve a clinically meaningful composite outcome score in HFpEF patients. Components of the outcome score are maximal exercise capacity, NYHA functional class, global self-rated health, diastolic function, hospitalizations and all-cause mortality.
After undergoing baseline assessments to determine whether ET can be performed safely, 322 patients in 11 trial sites with stable HFpEF were randomized 1:1 to supervised ET in addition to usual care or to usual care alone. Patients randomized to ET perform supervised endurance/resistance ET (3 times/week at a certified training centre) for 12 months. At baseline and during follow-up, anthropometry, echocardiography, cardiopulmonary exercise testing and HRQoL evaluation are performed. Blood samples are collected to examine various biomarkers. Overall physical activity, training sessions, and adherence are monitored and documented throughout the study using patient diaries, heart rate monitors and accelerometers.
Conclusions: The Ex-DHF trial is the first multicentre trial to assess the long-term effects of a supervised ET program on different outcome measures in patients with HFpEF.

Inclusion/exclusion criteria of Ex-DHF
Inclusion criteria-Stable symptomatic heart failure with preserved ejection fraction (diagnosis according to the recommendations of the European Society of Cardiology):· a.NYHA II-III, peakVO_2 <25ml/kg/min· b.LVEF ≥ 50%·c. E/e' > 15 or 15 ≥ E/e' > 8 and any of the following: NT-proBNP > 220 ng/L or atrial fibrillation-Age ≥ 18 years-Symptom severity and heart failure medication were stable during the last 4 weeks-General ability of the patient to declare willingness to participate in this trial-Written informed consentExclusion criteria-Non-cardiac causes for heart failure like symptoms:· a.chronic obstructive pulmonary disease (COPD) GOLD stages ≥ II· b.Anaemia (Hb < 11mg/dl)· c.Significant renal dysfunction (eGFR < 30 ml/min/1.73m^2 BSA)· d.Significant peripheral artery disease (Fontaine ≥ IIb)· e.Musculoskeletal disease that contribute to reduced exercise performance· f.Specific cardiomyopathy (e.g. amyloidosis etc.)· g.Haemodynamically significant valvular disorders-Significant coronary artery disease (current angina pectoris CCS ≥ II or positive stress test, myocardial infarction or coronary artery bypass graft within the last 3 months)-Any inability or contraindication to participate in CPET or in an exercise program (e.g. physiological, mental) or to supply essential information (e.g. questionnaire, diary)-Ineffective control of resting blood pressure (BP ≥ 140/90mmHg or BP ≥ 160/100mmHg with ≥ 3 antihypertensive drugs) or of resting heart rate (HR ≥ 100bpm)-Expected low compliance (e.g. by travel distance to trial site; planned absences longer than 4 weeks during follow up) or ongoing drug abuse-Pregnant or nursing women-Concomitant participation in other interventional clinical trials

peakVO2: maximum oxygen intake; LVEF: left ventricular ejection fraction; eGFR: estimated glomerular filtration rate; BSA: body surface area; CCS: Canadian Cardiovascular Society; CPET: cardiopulmonary exercise testing; BP: blood pressure; HR: heart rate

Left atrial volume index predicts major adverse cardiovascular events in patients with ischemic chronic heart failure with preserved ejection fraction and renal dysfunction

D Dmytro Lashkul[1]; VD Syvolap[1]
[1]*Zaporizhzhya State Medical University, Zaporizhzhya, Ukraine*

The incidence of heart failure and chronic kidney disease has been steadily increasing and will further increase due to ageing of the general population and better treatment of acute cardiac and renal diseases. Identification of new reliable markers for diagnosis, analysis, prognosis of mortality and prevention of hospitalization is still necessary, it is not well known whether left atrial volume index (LAVi) has predictive value for prognosis in patients with ischemic chronic heart failure with preserved ejection fraction (HFpEF) and renal dysfunction.
Purpose: This study was aimed to assess the association between LAVi and outcomes in ischemic HFpEF with renal dysfunction patients.
Methods: We enrolled a total of 243 (80.3% men, mean age 58.7 ± 9.3 years) in-hospital patients diagnosed as HFpEF is due to ischemic heart disease. Clinical and echocardiographic data at baseline were collected. Glomerular filtration rate (eGFR) calculated by the formula MDRD (Modification of Diet in Renal Disease). Mean GFR was 78.1 ± 18.1 ml/min/1.73m^2, mean ejection fraction 59.2 ± 8.4 %.The patients were followed for the development of major adverse cardiovascular (CV) events, including hospital readmission for decompensate heart failure, acute myocardial infarction, sudden cardiac death, stroke.
Results: During 3-year follow-up period, 54 adverse CV events occurred (32 hospital readmission for heart failure, seven sudden cardiac death, five fatal and five non-fatal AMI, five stroke). In a multivariate Cox model, LAVi ≥12.96 cm^3/m^2 [OR: 9.69, 95% CI: 2.5-37.5, p = 0.001], eGFR ≤71.25 ml/min/1,73m^2 (OR: 6.91, 95% CI: 1.73-27.5, p = 0.006) were independent predictors for major adverse CV events in ischemic HFpEF patients with renal dysfunction.
Conclusions: LAVi is a predictor of major adverse CV events independent of clinical and other echocardiographic parameters in ischemic HFpEF patients with renal dysfunction.

P1980

The comorbidity in patients with heart failure and preserved ejection fraction depending on age

Y Yulia Kushnir[1]; A Anduyschenko[1]; A Homeniuk[1]
[1]*Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine*

The aim of our study was to analyze the frequency of comorbid diseases and the characteristics of treatment of patients with chronic heart failure (HF) and preserved ejection fraction (EF) depending on age.
Background: Despite the advances in medicine, heart failure is still the most common complication of many cardiovascular diseases and a major factor of mortality of old people. Number of patients with chronic heart failure and preserved ejection fraction is increasing, but there are no approved treatment recommendations yet.
Methods: retrospective analysis of 198 patients with heart failure and preserved ejection fraction (m - 106 pts, f - 92 pts). Patients were divided into 3 groups according to age: 1st - 40-59 years old (n = 74), 2nd - 60-75 (n = 73), 3rd - >75 years old (n = 51). The average EF (M ± m) - (63,8 ± 6,3)%. The presence of arterial hypertension, anemia, chronic obstructive pulmonary disease (COPD), diabetes, thyroid dysfunction, body mass index, renal dysfunction, intracardiac hemodynamics diseases were analyzed.
Results: Comorbidity was observed in all examined patients. 169 pts had arterial hypertension. Revealed age changes in the comorbidity: prevalence increases with age changes in renal function (29,7% in the 1st group, 26% in 2nd and 29,4% in the 3rd), hypothyroidism (25,7% in the 1st group, 38,4% in the 2nd group and 23,5% in the 3rd), COPD (2,7% in the 1st group, 10,2% in the 2nd group and 7,8% in the 3rd), anemia (16,3% in the 1st group, 32,9% in the 2nd group and 39,2% in the 3rd group), hyperuricemia (16,2% in the 1st group and 21,6% in the 3rd). Thus in all age groups more than half of patients had obesity, hypertension, stable angina and a quarter of patients - diabetes. Heart attack and atrial fibrillation are more common for patients aged 60-75 years (31,5%). End-systolic size and end-systolic volume were the highest in the second group, than may indicate bad prognosis (41,8% and 21,3% accordingly). Increased size of the left atrium, the average pressure in the pulmonary artery and aortic root changes were higher among patients over 75 years (4,4 ± 1,1 sm, 34,2 ± 4,3 mmHg and 13% accordingly). Appointment of medical therapy met the requirements in virtually all cases. Determined increase in prescription of loop diuretics in the 3rd group (70,5%) and low frequency of use of beta-blockers in the 1st group (63,5%). Metabolic therapy which does not meet the requirements of evidence is still used very often (from 50% in the 1st group and 25,5% in the 3rd).
Conclusions: A high level of comorbidity in patients with chronic heart failure and preserved ejection fraction that increases with age was revealed.

P1981

Machine-learning based exploration of variability of longitudinal myocardial velocities in heart failure with preserved ejection fraction

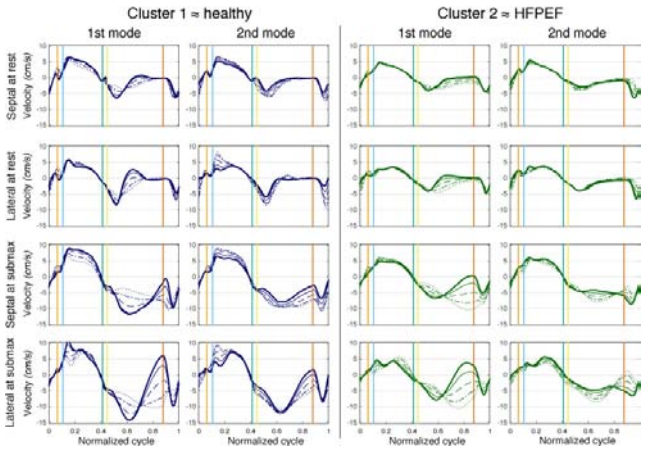
Purpose: Current diagnosis of heart failure with preserved ejection fraction (HFPEF) is suboptimal since the consensus recommendations oversimplify abnormalities by only considering simplified key markers of disease, often derived from myocardial velocity patterns (e.g., E/e' and E/A ratio, deceleration time). These diagnostic criteria are based on the expertise of highly trained cardiologists. However, complex mechanical interactions or subtle discriminative markers of disease could pass unnoticed even to the most expert eye. We investigate whether a comprehensive machine-learning based analysis of multiple myocardial velocity profiles, acquired during stress echocardiography, can identify characteristic patterns of cardiac (dys-)function.
Methods: Longitudinal velocity traces from 33 healthy subjects (67 ± 4 years) and 72 HFPEF (72 ± 6 years, diagnosed according to the Consensus Statement on HFPEF, 2007) were examined. Data came from tissue Doppler acquisitions at rest and submaximal exercise at the basal septum and lateral wall of the left ventricle. Each cardiac phase was identified and used to temporally align the velocity profiles. Unsupervised machine learning (multiple kernel learning algorithm) was used to fuse the heterogeneous velocity patterns and to reduce their complexity. Agglomerative hierarchical clustering was performed on this set to identify naturally-occurring groupings within the population. The variability explained by the identified groups was reconstructed by means of advanced regression techniques.
Results: The agreement between the found groups and the clinical diagnosis was high (Kappa = 72.6%). In the figure, the curves range from -2 (solid line) to +2 (dotted line) standard deviations along the indicated modes of each group. The HFPEF group with respect to the healthy group showed: lower overall velocity amplitude; more pronounced diastolic fusion, especially prominent in the septal velocity at exercise; higher diastolic delay, especially in the exercise patterns; and more frequent inter-atrial contraction delay. A detailed analysis of cases classified differently by the algorithm, compared with the clinical labels, confirmed that they had subtle abnormalities that had been overlooked when applying current diagnostic criteria.
Conclusion: The method proposed is automatic, objective, and independent of the diagnosis suggested by the consensus recommendations. The variability analysis of the velocities within each of the identified groups was consistent with the clinical knowledge about the HFPEF mechanical abnormalities, and revealed possible diagnostic features non-considered to date, as is the case of the delay in the atrial contraction dynamics – recently suggested as an indicator of HFPEF. Furthermore, our study confirms that machine-learning based assessment of the cardiac function at exercise is helpful when characterizing the HFPEF syndrome.



P1982

Left atrial pacing for the treatment of heart failure with preserved ejection fraction associated with interatrial dyssynchrony. Results from a randomized cross-over study

J-C Jean-Christophe Eicher[1]; B Mouhat[1]; G Bertaux[1]; M Montoy[1]; S Hassam[1]; G Laurent[1]

[1]*University Hospital Center (CHU) Dijon, Dijon, France*

Background: Heart failure with preserved ejection fraction (HFpEF) is still an orphan disease. We recently reported that interatrial conduction delay (IACD) could be a causal factor in some patients.
Purpose: To confirm the effects of left atrial (LA) pacing in patients with HFpEF associated with IACD.
Methods: Patients presenting with HFpEF (LVEF > 50%, NYHA III, or NYHA II and ≥ 1 hospitalization for CHF during the past year) were enrolled if echocardiography showed 1) an interatrial mechanical delay > 70 ms (difference between P-A' intervals at the mitral and tricuspid annulus); 2) a shortening of the mitral A wave duration > 30 ms (difference between the tricuspid and mitral A wave durations). After informed consent, a double chamber pacemaker (PCM) was implanted with the atrial lead screwed into the coronary sinus. After 1 month, baseline parameters were collected, then a randomized, double-blind crossover study was conducted with 3-month duration periods (PCM on then off vs off then on). At the end of the crossover, patients were asked which mode they preferred. Echocardiographic parameters, 6-minute walking distance and Nt-proBNP levels were studied at the end of each period.
Results: 15 patients were studied. 1 patient was excluded because of definitive atrial fibrillation (AF). 3 patients had acute CHF during the off period requiring the activation of the PCM. Compared to the baseline and "off" periods, the active period resulted in significant improvements of most parameters (table). At the end of the study all the patients chose the "on" mode.
Conclusion: LA pacing in patients with HFpEF and IACD improves LA emptying, LV filling, 6-min walking distance and Nt-proBNP levels. This technique could represent a promising treatment in some selected patients.

Table

	"off" mode	"on" mode	p
aortic VTI (cm)	23.6 ± 6.1	23.2 ± 6.5	NS
mitral E wave velocity (cm/s)	123.8 ± 23.5	107.2 ± 19.4	0.03

Latent class echocardiographic phenotypes predict adverse outcomes in heart failure with preserved ejection fraction: A secondary analysis of TOPCAT

DP David Peter Kao[1]; KM Flint[1]; M Merrill[1]

[1]*University of Colorado Denver, Denver, United States of America*

Funding Acknowledgements: University of Colorado Center for Women's Health Research Seed Grant

Background: Heart failure with preserved ejection fraction (HFpEF) is associated with structural and functional myocardial remodeling. Primary combinations of remodeling components in HFpEF have not been described.
Purpose: To identify complex echocardiographic phenotypes in HFpEF.
Methods: 647 patients with symptomatic HF and an LVEF ≥45% enrolled in the Americas underwent echocardiography. Phenotypes were identified using latent class analysis based on LV structure, global longitudinal strain, left atrial volume index (LAVIx), diastolic dysfunction (DD), average E/E', and RV fractional area change. The primary outcome was a composite of CV death, aborted cardiac arrest, or HF hospitalization.
Results: 4 phenotypes were identified (Table), which corresponded to subjects with little LVH, no DD and RV dysfunction (206, 31.8%); intermediate LVH with (76, 11.7%) and without DD (246, 38.0%), and significant LVH with DD (119, 18.4%). Other defining factors included LAVIx and E/E' average, suggesting variation in LV filling pressure. Phenotypes were associated with significantly different rates of the primary outcome (27-42%, chi-square p = 0.025).
Conclusions: Cluster-based echocardiographic phenotyping identified subpopulations of HFpEF patients with varying combinations of LVH, DD, LV filling pressure and RV function that were predictive of poor clinical outcomes.

Aims: Understanding the probability for not just randomly changes in key parameters from echocardiography (E/e', E/a), cardiopulmonary exercise testing (CPET) (peak VO2, VE/VCO2,VO2 AT) and six minute walk test (6-MWT) (walking distance, borg scale) is very important for the interpretation of clinical trials' results after interventions in heart failure patients with preserved ejection fraction (LVEF < 50%).

Table 1

	Mean Difference	Standard Deviation	Upper limit	Bottom limit	T-test significance
E/e'	0,14	1,48	3,07	-2,72	0,016
E/a	0,001	0,19	0,38	- 0,38	0,9
Peak VO2(ml/kg/min)	0,18	1,50	3,09	-2,81	0,062
VE/VCO2 slope(ml/kg/min)	0,05	3,73	7,36	-7,25	0,77
VO2 AT	0,09	2,12	4,23	-4,06	0,41
6-MWD	8,63	41,31	72,34	- 89,60	< 0.001
Borg	0,18	1,29	2,36	2,71	0,006

Altman plots could not be uploaded

Methods: We analysed the results from the repeatingly after a week performed echocardiography, CPET and 6-MWT on 422 patients of the Aldo DHF trial with a mean age 67 years and NYHA II-III. The examiantions at baseline and after a week (+/- 1 day) were implemented under stable clinical conditions without any changes in medication. To visualize the values of E/e', E/a, peak VO2, VE/VCO2,VO2 AT, walking distance, borg scale and their limits Bland Altman analysis were used.
Results: As the Altman plot indicates one could not find any systematic bias for the different measurements. There is a low-retest probability for 6-MWT's distance and Borg scale as well as for the common used echocardiographic value E/e' (t-test significance: 0,016). Only CPET shows a good reliability for peak VO2, VE/VCO 2 slope and VO2 AT (t-test significance: 0,062/0,77/0,41) and e/a (t-test significance: 0,9).
Conclusion: We have to rethink our concept regarding the usefulness E/e' for any finding in clinical trials for HfpEF populations since it is not reliable, suprisingly. CPET parameters in contrast to the commonly used E/e' seem to be reliable with a high retest probability and therefore are strongly recommended for evaluation of clinical trial's interventions in cohorts with HfpEF. Changes in value within the the mean difference and the standard deviation are likely to be random findings and have no significance for any intervention's influence. Since 95 % of variations in measurements with no intervention are within the values of the upper and bottom limits of the table 1, you will expect the opportunity of 'real' findings beyond these limits.

P1985

Heart failure with preserved ejection fraction as risk factor of mortality after cardiothoracic surgery

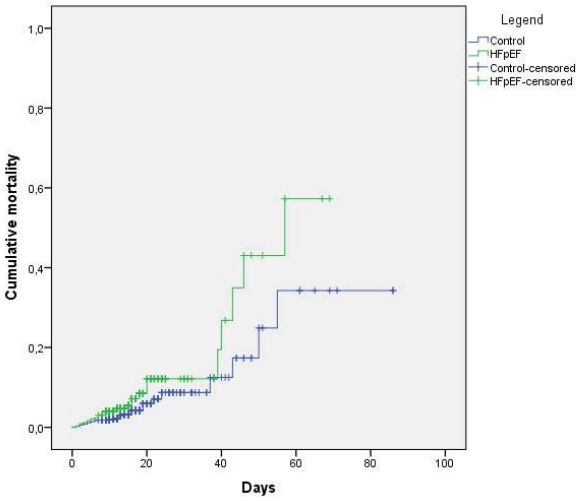
F Nicot[1]; P Baudinaud[1]; A Brusset[1]; P Estagnasie[1]; P Squara[1]; L S Nguyen[1]
[1]Clinique Medico-Chirurgicale Ambroise Pare, Critical Care Department, Neuilly sur Seine, France

Background: Heart failure (HF) with preserved ejection fraction (HFpEF) is a syndrome that occurs in one-half of all patients with HF. While considered an important risk factor of adverse medical outcomes, its prognostic role in cardiac and thoracic surgery is still unclear. We aimed to investigate its prognostic value after cardio-thoracic surgery.

Baseline characteristics

	Control (n = 1316)		HFpEF (n = 427)	
Age (years)	67,3	+/-11,3	71,5	+/-10,8
Male gender	975	(74,1%)	263	(61,6%)
Weight (kg)	77,6	+/-15,0	74,3	+/-15,6
Height (cm)	169,7	+/-8,9	167,7	+/-9,4
EuroSCORE II	2,4	+/-3,4	4,5	+/-5,7
Brain natriuretic peptide (pg/ml)	168,7	+/-376,4	481,8	+/-604,1
Aortic surgery	58	(4,4%)	11	(2,6%)
Isolated CABG	719	(54,6%)	66	(15,5%)

continuous data presented as mean +/- standard deviation, categorical data as number (%). HFpEF: heart failure with preserved ejection fraction; CABG: coronarby artery bypass surgery



Cumulative mortality

Methods: In a four-year prospective cohort, among patients having LVEF ≥ 50%, we compared postoperative intrahospital mortality after cardiothoracic surgery between HFpEF and control patients. HFpEF was defined as symptomatic HF with LVEF ≥ 50%, New York Heart Association functional class ≥ 2 and elevated BNP (above 100 pg/ml). Cox model regression was used for statistical analysis with adjustment on EuroSCORE II.
Results: 1743 patients were included, among whom 427 (24.5%) presented HFpEF. Global postoperative intrahospital mortality was 4.1%. Mortality was higher among HFpEF patients (7.0% vs 3.2%, p-value < 0.001). In multivariate analysis, HFpEF was independently associated with postoperative intrahospital mortality (adjusted hazard-ratio=1.6 (95CI 1.0-2.6), p = 0.049).
Conclusion: In our cohort, HFpEF was a risk factor of mortality after cardio-thoracic surgery.

P1986

Prognostic stratification in heart failure with preserved ejection fraction: an attainable score in daily clinical practise

P Paula Martinez Santos[1]; I Vilacosta[2]; E Batlle Lopez[3]; A De La Rosa Riestra[1]; B Sanchez Sauce[3]; B Herreros Ruiz Valdepenas[3]; E Espana Barrio[3]; J Jimenez Valtierra[3]; MD Martin Rios[4]
[1]Hospital de Fuenlabrada, Cardiology, Madrid, Spain; *[2]Hospital Clinic San Carlos, Cardiology, Madrid, Spain*; *[3]University Hospital Alcorcon Foundation, Cardiology, Madrid, Spain*; *[4]Foundation Jimenez Diaz, Madrid, Spain*

Background an aim: Several variables have been related to a poor prognosis among heart failure with preserved ejection fraction (HFpEF) patients. We aimed to develop a score to select those with the highest clinical risk among hospitalized HFpEF patients.

Table 1. Prognostic index

Risk factor	Yes	No
Age >80	16 points	0
NT proBNP ≥ 2087 ng/l	16 points	0
Long term supplemental oxygen therapy	13 points	0
TAPSE < 15 mm	17 points	0
TOTAL	62 points	0
Risk stratification		
	n	Mortality
Low risk	2	7,4%
Moderate risk	5	18,5%
High Risk	20	74,1%

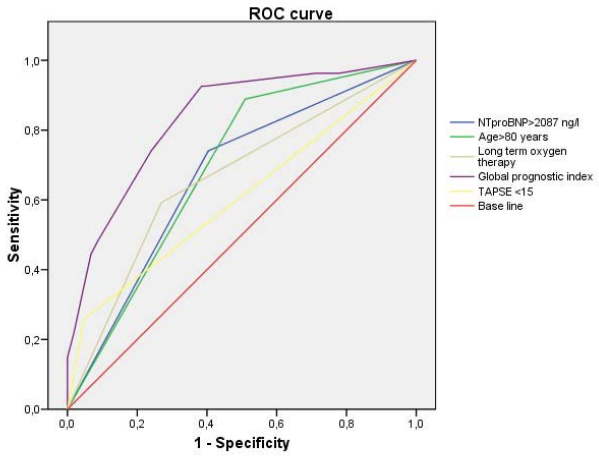


Figure 1

Methods: We prospectively included 154 consecutive patients who were admitted for HF and had a left ventricular ejection fraction (LVEF) >50%. All patients were followed during one year after hospital discharge. We analysed the information on cardiac and comorbid candidate prognostic predictors in a multivariable model to predict 1-year outcome. Then, we multiplied the model regression coefficients by 10 according to the formula: Prognostic index score = 10xβ1 (variable1) + 10xβ2 (variable2) + … 10xβn (variablen). ROC plot analysis compared the prognostic utility of the factors related to a poor prognosis.
Results: Mean age was 81 years (SD 9) and 63% were female. The mortality rate was 25.2%. In the multivariable analysis, four variables were associated to a higher risk of mortality: age over 80 years (OR 5.27; 1.38-20.06 CI 95%, p = 0.015), plasma NT proBNP higher than 2087 ng/l (OR 5.42; 1.79-16.38 CI 95%, p = 0.003), indication of chronic oxygen therapy (OR 3.98; 1.39-11.38 CI 95%, p = 0.010) and right ventricular systolic dysfunction (OR 5.48; 1.21-24.78 CI 95%, p = 0.027). We established three risk categories based on 50th and 75th percentiles. Table 1 summarizes the results from the risk stratification according to the amplified formula of the logistic regression coefficients model for 1-year mortality. The ROC curve (Figure 1) was 0.83 (95% CI, 0.74 to 0.92, p < 0.0001).
Conclusions: Our score, based on accessible clinical characteristics, allows the prediction of 1-year mortality among HFpEF hospitalized patients.

P1987

Possibility of the CAVI as the risk factor of development of heart failure with preserved left ventricular ejection fraction

K Takagi[1]; N Sato[1]; S Ishihara[1]; W Shimizu[2]
[1]Nippon Medical School Musashi-Kosugi Hospital, Department of Cardiology and Intensive Care Unit, Kanagawa, Japan; [2]Nippon Medical School, Department of Internal Medicine and Cardiology, Tokyo, Japan

Backgrounds: Heart failure (HF) is pandemic with high morbidity and mortality, and is becoming a worldwide economic burden. Although many studies have been conducted to identify characteristics of patients with HF with reduced ejection fraction (HFrEF), characteristics and pathophysiologic features of patients with HF with preserved ejection fraction (HFpEF) remain unclear. Hypertension(HT) and diabetes mellitus(DM) are the most important risk factors for developing HFpEF, comprehensive risk factors are still lacking. Cardio-ankle vascular index (CAVI) has been widely applied to assess arterial stiffness in patients with known cardiovascular diseases. Therefore, we investigated the relationship between CAVI and several parameters of HFpEF.
Methods: We defined the HF patients whose left ventricular EF(LVEF) was less than 50 as HFrEF, and the patients whose LVEF was more than 50 as HFpEF. We enrolled the patients who were hospitalized for acute heart failure and examined CAVI from April 2013 to March 2015. And during the same study period, HT or DM or dyslipidemia patients with preserved LVEF who did not present with HF symptoms and had never been diagnosed or treated for HF were also enrolled as patients without HF. We excluded patients with atrial fibrillation, aortic regurgitation and also excluded the patients whose ankle brachial index was less than 0.9, because these patients' CAVI are unreliable. And the exclusion criteria included HFrEF. A total of 46 patients with HFpEF and 230 patients without HF were enrolled in this study.
Results: There were no differences in age (74 ± 11, 69 ± 12), sex (male: 58.7%, 58.7%) between HFpEF and without HF. The CAVI was significantly higher in patients with HFpEF compared with patients without HF (10.07[9.00-10.60] vs. 9.15[7.91-10.10]; P=0.001) (Fig. 1).
Conclusion: Thus, the present study demonstrated that CAVI was closely related to HFpEF, suggesting that arterial stiffness might be involved in the development of HFpEF.

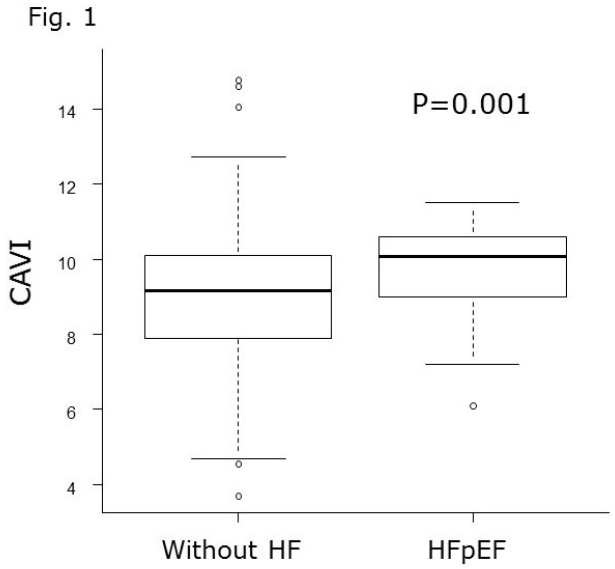

Fig. 1

P1988

Association of levels of BNP plasmatic with prediction of mortality in study cohort in south Brazil

E Eduardo Pitthan[1]; HV Hirakata[1]; BJ Barbisan[1]
[1]Institute of Cardiology of Rio Grande do Sul, Porto Alegre, Brazil

Background: The diagnosis of HF in elderly patients in clinical basis is difficult due to comorbidities. The BNP is used as a diagnostic and prognostic tool in HF, but is not sufficiently studied in the elderly.
Objective: To evaluate the association of plasma BNP levels with diagnostic accuracy of HF and long-term prognostic validation.
Methods: Six hundred and thirty-four consecutive patients presenting with suspected HF in the Emergency Room of a tertiary hospital in southern Brazil participated in this cohort study. All patients underwent BNP measurement (Biosite - POCT) as the institution protocol were included between March 2006 and September 2012. Following the Gold Standard (Fig.1) for diagnosis of HF, consisting of history and physical examination, ECG, chest X-ray, echocardiogram Uni and Two Dimensional Color Doppler. The sample was divided into 3 groups: SHF (Systolic Heart Failure), HFPEF (Preserved Ejection Fraction Heart Failure) and NHF (In Heart Failure), and patients were followed for 78 months. The study endpoint was mortality identified by the certificate of death of the Mortality Information Service (SIM).
Results: Most patients (59.6%) were female, the mean age was 77 ± 8 years, 40.5% over 80 years. The majority (46.8%) had a diagnosis of HFPEF and BNP median 335 pg/ml, 25% presented SHF and BNP median of 573 pg/ml and 28% did not meet the criteria for NHF and median BNP 45 pg/ml (Kruskal-Wallis's test; p < 0.005) fig. 1. Ejection fraction less than 44% was observed in 18.6%. BMI was greater than30kg/m^{2}in 38.6% and less than 22kg/m^2 at 13%. Cardiomegaly was prevalent in 72.7%, congestion in 70.7%, 52.5% had pleural effusion, and 18% EEC less than 30ml/h. Half of the deaths were caused by HF. In the group with SHF was 79 deaths (49%) with a BNP median of 800 pg/ml (Fig.2) and the 80 survivors median 383 pg/ml (p < 0.005). In HFPEF group occurred most deaths that computed 157 deaths (52% of the group) with a median of BNP 380 pg /ml and 140 survived with a median 245 pg/ml (p < 0,005). The NHF group had 40 deaths (22% of the group) with BNP median of 59pg/ml and 138 survivors, median of 36 pg/ml (p < 0,005).Survival analysis in 78 months (6.5 years) was performed by Kaplan-Meier curve. Two hundred seventh six deaths were recorded in the total group (42%) (Fig3).The group SHF with a 27-month mean survival time (MST), the group HFPEF with a 52-month MST, the NHF group more than 50% survived.
Conclusion: The BNP level showed association with the mortality index. BNP is an

independent prognostic biomarker for long-term mortality in patients with HF in all ages. The BNP shows good accuracy for diagnostic to HF.

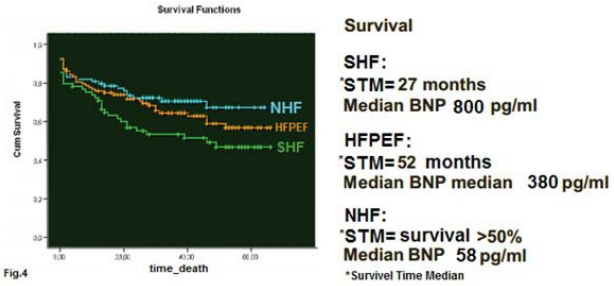

Fig.4

P1989

Results of 3-week rehabilitation in patients with heart failure with reduced and preserved ejection fraction

Y Yuriy Dovgalyuk[1]; IE Mishina[1]; SL Archipova[1]; MV Kudryashova[1]; AA Guduhin[1]; LY Kornilov[1]; LL Yarchenkova[1]; VV Belova[1]; NN Panueva[1]
[1]*Ivanovo State Medical Academy, Ivanovo, Russian Federation*

Objective: to evaluate the impact of 3-week cardiac rehabilitation (CR) program on the exercise tolerance, lipid blood profile, blood pressure in patients with heart failure and reduced ejection fraction (HFrEF) and in patients with heart failure and preserved ejection fraction (HFpEF).
Methods: 26 patients with HFrEF (mean age – 57.3 ± 11.2 years; men – 80.8%, women – 19.2%) and 94 patients with HFpEF (mean age – 59.2 ± 6.1 years; men – 70.2%, women – 29.8%) were underwent an inpatient 3-week CR program. The CR program consisted of physical exercise, lifestyle modification, and pharmacotherapy. Exercise tolerance, serum lipoproteins, blood pressure were assessed at baseline and follow-up.
Results: Patients with HFrEF compared to those with HFpEF more often had risk factors such as diabetes mellitus (23.1% vs. 11.7%, p < 0.0001) and smoking (57.7% vs. 22.3%, p < 0.0001). The rate of patients that achieved lower LDL cholesterol (<100 mg/dl), total cholesterol (<200 mg/dl) and triglyceride (<150 mg/dl) values at discharge was high in patients with HFrEF compared to those with HFpEF (88.5% vs. 75.5%, p < 0.05). There was no difference in blood pressure between two groups at baseline. At discharge systolic blood pressure was substantially lower in the HFrEF group compared to the HFpEF group (115.6 ± 27.2 vs. 127.1 ± 14.2 mmHg, p = 0.01). Maximal power during exercise test improved substantially both in HFrEF group (from 89.8 ± 21.2 to 127.4 ± 34.0 Watts, p < 0.01) and in HFpEF group (from 99.7 ± 12.1 to 130.2 ± 16.8 Watts, p < 0.001). The distance covered in the 6-min walk test was significantly greater after the 3-week cardiovascular training both in patients with HFrEF (393.4 ± 78.7 vs. 452.9 ± 92.5, p < 0.05) and in patients with HFpEF (420.7 ± 48.6 vs. 474.6 ± 57.1, p < 0.05).
Conclusion: patients with HFrEF and HFpEF both benefited from participation in 3 week CR program, as their lipid profile, blood pressure and exercise tolerance improved.

P1990

Clinical pattern of HF-pEF and role of comorbidity in development of HF-pEF

Y Dubolazova[1]
[1]*the National Research Center for Preventive Medicine, Moscow, Russian Federation*

Purpose: To study clinical pattern and role of comorbidity in development of HF-pEF, to evaluate association between comorbidity and NT-proBNP and galectin-3 in HF-pEF.
Methods: 30 patients with HF-pEF (>50%) (17 women, 13 men, age 65 ± 8) were included in the study. All patients were undertaken physical examination, evaluation of comorbidity, clinical state rate scale, 6 minute walk test, echocardiography, tissue doppler imaging, evaluation of plasma NTproBNP and galectin3 levels.
Results: The mean age was 65 years. Main complaints were dyspnea and fatigue (100% and 83%). Dyspnea at rest, edema, orthopnea were found in 6%, 46% and 6% of patients. Decompensation in HF-pEF patients was accompanied by weight gain in 30%. Small bubbling rales was found in 53%, tachycardia in 30%, third heart sound in 7 %, jugular venous distention in 40%, hepatomegaly in 20% of HF-pEF patients. Mean exercise tolerance was 334 m. by 6 minutes walk test. Dyslipidemia was found in 70%, obesity in 53% and fatty liver in 60% of patients. T2DM in 13%. Arterial hypertension was found in 93%, CAD in 60%, COPD in 16% of HF-pEF patients. History of ACS and stroke had 16% and 10% of patients. Atrial fibrillation was found in 23%, HF NYHA I-II in 53%, HF NYHA III-IV in 46%. The mean NT-proBNP level was 153,2 fmol/mL. Mean galectin3 plasma level was 0,98 ng/mL. The higher mean NT-proBNP level was associated with more expressed signs and symptoms of HF (r = 0,46, p < 0,05, 95% CI). The higher mean NT-proBNP level is associated with lower exercise tolerance in HF-pEF patients (r = –0,41, p = 0,02, 95% CI) and worse clinical state (r = 0,48, p = 0,006, 95% CI). Direct correlation between plasma level of NT-proBNP and dyslipidemia (r=0,47, p = 0,007, 95%CI), fatty liver (r=0,42,p = 0,02, 95%CI) and obesity (r=0,34,p = 0,05, 95% CI) was found. Direct correlation between mean plasma level of galectin3 and LV EF in HF-pEF patients was found (r = 0,45, p = 0,012, 95% CI). There was no correlation between galectin3 mean plasma level and signs and symptoms of HF, exercise tolerance and clinical state in HF-pEF patients.
Conclusions: Clinical pattern of HF-pEF is indistinct. Main comorbidities are obesity, AH and CAD. Obesity, dyslipidemia and fatty liver probably could lead to development and progression of HF-pEF. NT-proBNP could be used to identify decompensated HF-pEF. Galectin3 cannot be used as biomarker of decompensation of HF, but can help to indentify HF-pEF patients. Combined use of NTproBNP and galectin3 allows identifying patients with decompensated HF-pEF.

P1991

Heart failure in patients with hypothyroidism

NINO Latsabidze[1]
[1]*Elizabeth Blackwell Hospital, Cardiology, Tbilisi, Georgia Republic of*

The cardiovascular system is the main target organ of thyroid hormone. Overt hypothyroidism decreases myocardial contractility, and diminished myocardial contractility reduces thyroid hormone metabolism. Subclinical hypothyroidism also exhibits impairment of left ventricular diastolic function that returns to normal after thyroid hormone replacement. We investigate 12 with overt hypothyroidism, 15 with subclinical hypothyroidism subjects. The patients were evaluated for cardiac disease by physical examination, electrocardiography, and echocardiography. Serum samples were taken for free thyroxine (fT4), TSH, NT-pro BNP before and after achievement of euthyroidism in patients.
Results: Basal mean NT-pro BNP level of overt hypothyroid group was significantly higher than the subclinical hypothyroid group (98.8 ± 63.0 vs 43.40 ± 23.66 pg/ml, P < 0.001). Mean NT-pro BNP significantly decreased after achievement of euthyroidism in both group (P=0.002). Basal NT-pro BNP level was negatively correlated with heart rate in hypothyroid group (r: –0.6, P=0.03).
Conclusion: Studies to date suggest that thyroid hormone is one of the important factors that regulate serum NT-pro BNP level. Thus, in patients without severe cardiac dysfunction, elevated NT-pro BNP level may be suggestive for both group - as overt hypothyroid, as subclinical hypothyroidism too.

P1992

Heart failure with preserved ejection fraction in black african people. what is the profile?

K A Kassi Anicet Adoubi[1]; E Soya[1]; C Konin[1]; A Adoh[1]
[1]*Institut de cardiologie d'Abidjan, Abidjan, Cote d'Ivoire*

Background: regional variations exist in heart failure with preserved ejection fraction (HFpEF).
Objectives: To determine clinical characteristics of HFpEF among black African patients.
Methods: We analyzed data from 302 consecutive black African patients hospitalized for heart failure in our institute (Ivory Coast) and followed up during one year. We considered HFpEF (group1), heart failure with mid-range (HFmrEF), group 2 and reduced ejection fraction (HFrEF), (group3) as defined in 2016 ESC guidelines for HF.
Results: Forty seven patients (18.7%) had HFpEF, 44 (17.5%) HFmrEF and 160 patients (63.7%) HFrEF; Fifty-one patients had excluding structural heart diseases. There was no gender difference (36.2% of female (group 1), 45.5% (group 2), and 32.5%, p = 0.28) but HFpEF patients were older (62.1 ± 17 years (group 1), 60 ± 15.2 (group 2), 52.2 ± 1.2 (group 3); p < 0.0001). These patients were more often admitted with pulmonary edema (27.7% (group 1), 9.1% (group 2), 11.3% (group 3), p = 0.01) and had more often comorbidities (4.1 ± 1.7 (group 1), 3.9 ± 2.1 (group 2), 3.3 ± 1.7 (group 3) p = 0.004). Hypertension was its most frequent aetiology (63.8%).

Survival was better (569.9 ± 38.4 days (group 1) vs 456.1 ± 24.7 days (group 3); (log-rank = 4.61; p = 0.032).

P1993

The effect of pharmacological KATP channels activation on contractile function and gene expression of isolated neonatal rat cardiomyocytes under doxorubicin induced oxidative stress

T Drevytska[1]; K Tarasova[2]; O Linnyk[1]; V Dosenko[1]
[1]*Bogomoletz Institute of Physiology, Department of general and molecular pathophysiology, Kiev, Ukraine*; [2]*National O.O. Bohomolets Medical University, Kiev, Ukraine*

Doxorubicin (DOX) is one of the most effective chemotherapeutic agents. This drug is anthracycline antibiotic and at the same time cardiotoxic agent due to activation of the free-radical oxidation that leads to the progressive heart failure. This requires the search of the grounded approaches for its' use in pharmacological correction of the heart activity. The activator of ATP-depended potassium (KATP) channels contradicts to the doxorubicin action normalizing the biochemical indexes of oxidative stress and histological changes in the heart. The aim of the work is to study the mechanisms of the potential cardioprotector - fluorine-containing analogue of diazoxide - action on the contractile function of cardiomyocytes and gene expression in these cells under DOX induced oxidative stress. Ventricular myocytes were isolated from 2-days-old Wistar rats by enzymatic digestion. After 48-hours of cultivation cardiomyocytes were treated for 1 h with doxorubicin hydrochloride (2.5μM) and with or without fluorine-containing analogue of diazoxide – 7-difluoromethoxy-3-methyl-1,2,4-benzothiadiazine-1,1-dioxide (40 μM). Mechanical properties of rat ventricular cells were assessed using the Myocyte Contractility Recording System IonOptix. RNA isolation was performed using phenol-chloroform extraction with guanidine isothiocyanate. cDNA was synthesized by reverse transcription. Real-time PCR was for quantitative evaluation of HIFs subunits, GLUT-1, GLUT-4, and TERT mRNA. Data are present as means ± SE of four independent experiments. The analysis of variance was performed using one-way ANOVA. The equality of variances between groups was analyzed using the Level test. Cardiomyocytes under the administration of DOX contracted more frequently and arrythmically comparing to the control, but their shortening was significantly weaker. Cells perfused with the solution containing diazoxide analogue, demonstrated increase of the shortening amplitude comparing to the control and decrease of the contraction and relaxation time. Combined action of DOX and diazoxide analogue improved cardiomyocytes contractile activity (lowered the beating rate, stabilized the rhythmicity of contractions) and increased the velocity parameters comparing to the DOX and control groups. Combined action of DOX and diazoxide analogue increased expression of mRNA of HIF-1α, GLUT-1, GLUT-4 and TERT genes and reduced the expression of HIF-3α comparing to the use of DOX only. The data obtained allow us to suppose that the significant antiarrythmic and cardioprotective effects of the KATP channels activator can be explained in particularly by its' property to suppress mRNA of HIF-3α gene expression. These results might represent a potential therapeutic approach for the protection of the heart from the doxorubicin-induced free-radical oxidation and progressive heart failure.

Role of platelet surface receptor expression and blood group in predicting risk of bleeding with aspirin

R Khalil[1]; E Dunne[2]; D Kenny[3]
[1]*Royal College of Surgeons in Ireland, School of Medicine, Dublin, Ireland*; [2]*Royal College of Surgeons in Ireland, Department of Molecular and Cellular Therapeutics, Dublin, Ireland*; [3]*Royal College of Surgeons in Ireland, Clinical Research Center, Dublin, Ireland*

Aspirin (ASA) is the first-line therapy for the secondary prevention of cardiovascular events(1). Platelet response to ASA is highly variable between individuals, and is associated with varying risks of bleeding. This study examined the role of platelet surface receptors and blood group in determining this risk of bleeding attributable to ASA.

Platelet GPIb-IX-V receptor binds Von Willebrand Factor (VWF) and initiates platelet aggregation by capturing platelets to damaged subendothelium. GPIIb/IIIa receptor binds fibrinogen and is essential in the formation of a primary platelet plug by mediating cross-linkage of platelets. We recruited 20 healthy volunteers and administered 300mg ASA. We evaluated the standard response of ASA to Arachidonic Acid-induced platelet aggregation using Light Transmission Aggregometry. Plasma TxB2 (product of activated platelets) and Glycocalicin (soluble GPIb normally found in plasma) were measured using ELISA. The surface expression of GPIIB/IIIa and GPIb were measured using flow cytometry.

LTA and post-ASA TxB2 demonstrated standard effects of ASA on platelet aggregation ($p < 0.0001$, student t-test, n=19 and $p < 0.0001$, student t-test, n=20 respectively). Donors with blood group O had significantly less surface expression of GPIb counts compared to non-O donors ($p = 0.0288$, student t-test, n=10). Interestingly, both groups had almost identical Glycocalicin post-ASA, suggesting that the reduced GPIb expression in blood group O can't be explained by shed plasma GPIb.

Our results suggest for the first time that blood group plays a crucial role in platelet CD42b receptor expression, independent of plasma Glycocalicin levels. This can be used to possibly determine the individual risk of ASA bleeding.

Assessment of grafts patency and diastolic dysfunction in patients after coronary artery bypass grafting and cell-based therapy.

A Nemkov[1]; V Komok[1]; S Beliy[1]; V Lukashenko[1]; YI Zhang[1]; A Kobak[1]; E Babenko[1]; B Afanasiev[1]
[1]*St-Petersburg State Pavlov Medical University, St-Petersburg, Russian Federation*

Background: It is very little known about influence of cell-based therapy on diastolic dysfunction in patients after coronary artery bypass grafting (CABG) and intramyocardial injection of bone marrow stem cells (BMSC).

Purpose: Assessment of grafts patency and diastolic dysfunction in patients after CABG and cell-based therapy.

Methods: Patients with coronary artery disease were randomly divided on 3 groups: group 0 - control n=36, patients received only CABG; group 1- patients received CABG and intramyocardial injections of BMSC n=25; group 2- patients received CABG and intramyocardial and intracoronary injections of BMSC n=17.

1 year after operation clinical assessment, echocardiography and angiography was performed.

Preliminary results. All patients are alive. Decreasing of functional class of angina pectoris, graft patency, improvement of diastolic dysfunction was more dramatically achieved in patients of group 2.

Conclusion: intramyocardial and intracoronary injections of BMSC is a safe and useful procedure during CABG for patients with coronary artery disease and diastolic dysfunction.

High-intensity lipid-lowering therapy prevents pathological left ventricle remodeling after STEMI

AN Parkhomenko[1]; OI Irkin[1]; IA Iaroslav Lutay[1]; AA Stepura[1]; SP Kushnir[1]; DA Bilyy[1]
[1]*National Scientific Center "M.D. Strazhesko Institute of cardiology, MAS of Ukraine", Kiev, Ukraine*

According to current guidelines, statin therapy is indicated for all ACS patients regardless of the initial cholesterol level. However, the effects of different lipid-lowering regimes on left ventricular remodeling in patients after STEMI have been insufficiently studied.

The study involved 135 STEMI patients admitted an average of 4.5 hours after symptoms onset and treated with primary PTCA. Lipid-lowering treatment was prescribed immediately after hospital admittance. Patients were randomly assigned to one of four groups treated by average (group I and group II) or high (group III and group IV) intensity lipid-lowering therapy. Group I (26 patients) was assigned to atorvastatin 10 mg /ezetimibe 10 mg combination, group II (24 patients) - to atorvastatin 40 mg, group III (42 patients) - to atorvastatin 40 mg/ ezetimibe 10 mg combination, and group IV (43 patients) – to atorvastatin 80 mg. Echocardiography was performed to all the patients during the first 24 hours after symptoms onset and 90 days after MI development. LV dilatation was defined as at least 25% increase of end-diastolic volume.

Patients from groups III and IV showed a tendency to the reduction of post-MI LV dilatation after 3 month of treatment (figure 1). High intensity lipid-lowering therapy (figure 2) reduced the risk of LV remodeling by 30% ($p < 0.05$), that was also associated with significantly higher LDL reduction. Without initial differences,

on the 90th day the average LDL level was 1.63 ± 0.1 in pts with high intensity treatment vs. 2.21 ± 0.2 mmol /l in patient with therapy of average intensity ($p < 0.01$).

Conclusion: The use of high-intensity lipid-lowering therapy with achievement of target LDL levels after STEMI can reduce the incidence of post-MI LV dilatation and may prevent heart failure development.

Can we predict heart failure after anterior ST-elevated myocardial infarction?

S Snezana Tadic[1]; A Stojsic-Milosavljevic[1]; A Ilic[1]; M Stefanovic[1]; S Stojsic[1]; M Sladojevic[1]; R Jung[1]; J Dejanovic[1]
[1]*Institute of CVD Vojvodina, Sremska Kamenica, Serbia*

Objective: Patients with ST-elevated myocardial infarction (STEMI) treated by primary angioplasty (pPCI) will develop left ventricular remodeling in one third of the cases, which is main cause of heart failure (HF) and mortality. The purpose of this study is to determine early angiographic predictors.

Methods: 210 patients with a first acute anterior STEMI were included. All participants underwent echocardiography after 6 months, after which they were divided into two groups: remodeling (n = 55; 26%) and non-remodeling (n = 155; 74%). The criteria for remodeling was increasing of left ventricular end-diastolic volume >20% after 6 months.

Results: The group with remodeling had more frequent MACE during one year follow-up: repeated hospitalizations (61.8% vs 22.6%; $p < 0,0001$), myocardial infractions (20% vs 7.1%; $p = 0.007$), repeated coronary angiography (45.5% vs 18.1%; $p < 0,0001$), repeated PCI ((30.9% vs 11%; $p = 0.001$) and mostly re-hospitalizations due to HF (40% vs 2.6%; $p < 0.0001$). Mortality rate was 5.5%. We identified a lot of statistically significant differences between remodeling and non-remodeling groups, among them angiographic parterres: proximal localisation of RIA (63.6% vs 43.9, $p = 0,041$), occlusion of RIA (90.9% vs 69%, $p = 0,001$), lower TIMI flow before pPCI (average 0.09 vs 0.31, $p = 0,001$) and after pPCI (average 2.75 vs 2.91, $p = 0,003$), lower blush grade after pPCI (3.55 vs 3.75, $p = 0,015$), no-reflow phenomenon (40% vs 1.9%, $p < 0,0001$) and use of GP IIb/IIIa (40% vs 24.5%, $p = 0,029$). The most powerful independent early predictors were: no reflow phenomenon (OR=30.031 95% CI, $p < 0.0001$), diastolic dysfunction in the first 24hrs (OR=27.7 95% CI, $p < 0.0001$) and at admission Killip class 2-4 (OR=3.4 95% CI, $p = 0.003$), by multi-variant regression analysis. Also, strong predictors were incomplete ST-resolution- STR (OR 2.0 95% CI, $p = 0,024$) and Wall motion score index (WMSI)>2 (OR 21.6 95% CI, $p < 0.0001$), by uni variant regression analysis.

Conclusions: Some angiographic parameters as: no-reflow phenomenon, proximal localisation and occlusion of RIA, lower TIMI flow and blush grade after pPCI, use of GP IIb/IIIa, can identified high-risk group for post-infarction remodeling in the patients with a first acute anterior STEMI, treated by pPCI. Development of diastolic dysfunction, heart failure on admission, incomplete STR and WMSI>2 are strong predictors too. Remodeling patients will have a more frequent incidence of MACE, heart failure and mortality.

P1998

Myocardial infarction in the elderly (about 120 cases)

A Alaeddine Jalled[1]; NEJEH Ben Halima[2]
[1]*University of Tunis El Manar, cardiology departement, La Marsa, Tunisia*; [2]*IBN EL Jazzar hospital , cardiology departement, kairouan, Tunisia*

Background: Due to high mortality and the increasing aging population, acute myocardial infarction in the elderly is a public health issue; the event is often marked by severe major complications that influence the prognosis in the short and medium term.

Methods: We report a descriptive retrospective study involving 120 patients (55 men and 65 women) aged 75 or more admitted to the cardiology department Kairouan (Tunisia) for a myocardial infarction. They are collected between 2002 and 2013.

Results: The incidence of myocardial infarction in patients over 75 years between 2002 and 2013 is 14.6%. the age means of the population is 78.8 ± 3.05 years, ranging from 75 to 94 years. Hypertension is the most common risk factor found: 65% while 32.5% were diabetics and 16.7% were smokers. Only 40.8% of the population were supported in the first 06 hours while 13.4% after 12 hours. Among 120 patients, reasons for admission to the ED included chest pain(62.5%) , digestive symptoms 16.7%, dyspnea 8.3%, malaise 8.3 % and vigilance disorders in 4.2% of cases. Compared with those who presented with chest pain , patients admitted for other reasons are more women ($p < 0.01$) , diabetics ($p < 0.01$) having kidney failure($p = 0.03$), they waited longer before going to the hospital (prehospital delay >12 hour: 31.5 % vs 6.8 % $p < 0.01$ •A myocardial revascularization treatment was performed in 72 patients (60%). It was a thrombolysis in 35% of cases and angioplasty in 25% of cases, the remaining(40%)were treated medically. During the study period we notice an improvement in the use of reperfusion and a decrease of using medical strategy. At the hospital phase the overall mortality rate was 15.8%,The statistical logistic regression analysis has identified as significant predictors factors of mortality :female sex($p = 0.04$); diabetes($p = 0.01$); kidney failure ($p = 0.05$); the anterior territory of the infarction ($p = 0.02$); the myocadiel infarction complicated by acute heart failure ($p = 0.01$) or cardiac shock ($p < 0.01$) and finally the abscence of a revascularization ($p = 0.01$).

Conclusion: Take charge of elderly patients with STEMI is not easy especially that atypical clinical symptom are common and severe but chronological age should not be an exclusive criteria of decision and even a factor of “loss of chance”. we should use the specific reperfusion treatments which improve the prognosis of these patients.

P1999

Prognostic impact of anemia on long-term mortality in patients with reduced ejection fraction following acute myocardial infarction

L Savic[1]; I Mrdovic[1]; M Asanin[1]; G Krljanac[1]; R Lasica[1]; B Kastel[1]
[1]*Clinical Center of Serbia, Institute for Cardiovascular Disease, Emergency Hospital, Belgrade, Serbia*

Purpose: Anemia is a relatively common disorder in patients with acute myocardial infarction. The aim of this study is to analyse prognostic impact of anemia at admission on five year mortality in patients with reduced ejection fraction (EF) following ST-elevation myocardial infarction (STEMI).

Method: We included 589 consecutive STEMI patients who were treated with primary percutaneous coronary intervention (pPCI). Reduced EF was defined as being ≤40%. Anemia was defined as baseline hemoglobin level <13g/dl in men and <12g/dl in women. Patients presenting with cardiogenic shock were excluded.

Results: Anemia at admission was present in 69 (11.7%) patients. Median hemoglobin on admission was 11g/dl(10-12g/dl) in anemic patients and 14g/dl(13-15g/dl) in patients without anemia, $p < 0.001$. Compared with patients without anemia, patients with anemia were older, and presented more often with heart failure (Killip class II and III); they were more likely to be women to have lower baseline creatinine clearance and lower systolic blood pressure at admission; they had more often 3-vessel coronary disease on initial angiogram. Therapy at discharge and the duration of dual antiplatelet therapy during follow up did not differ among analysed patients. Five year all-cause mortality rate was significantly higher in patients with anemia as compared with those without anemia: 43.9% vs 17.8%, $p < 0.001$ (Figure 1). After multivariable adjustements in Cox regression model anemia at admission was an independent predictor of all-cause mortality-HR 1,95 (95%CI 1,30-3,29), $p = 0.021$, besides (older) age, Killip class II-III at admission, baseline renal dysfunction and postprocedural flow TIMI < 3.

Conclusion: In analysed patients with reduced ejection fraction following STEMI the presence of anemia at admission is associated with 2-fold increase in long-term mortality

Figure 1. Kaplan-Meier curves estimating estimatimg the probabillity of 5-year mortality according to teh presence of anemia

The evaluation of treatment retention to dual therapy with antiplatelet drugs in real clinical practice

SV Malchicova[1]; NS Maksimchuk-Kolobova[1]
[1]*Kirov State Medical Academy, Kirov, Russian Federation*

Objective: to evaluate the retention of patients, who had an acute coronary syndrome (ACS), to dual therapy with antiplatelet drugs (DTAD) in real clinical practice.
Materials and methods: The study involved 41 patients with earlier ACS and whom DTAD was recommended were during 12 months. The average age was 62,3 ± 8,7 years old, from them 23 women and 18 men. Patients were divided into 4 groups depending on the prescription of ACS. 10 patients were involved in the group 1 (1 month after ACS), 13 patients in the group 2 - (3 months after ACS), 10 people in the group 3 and 4 (6 months and no more than 12 months, respectively). Treatment retention was evaluated by use of telephone survey on the number of patients who is taking the drug.
Results: Treatment retention to DTAD was 90% already after 1 month after earlier ACS, and only 60% of patients followed the recommendations for anti-thrombotic therapy by the end of the year after ACS. At the same time, retention to therapy by acetylsalicylic acid was 90% throughout the year. The retention to clopidogrel was 100% at 1 and 3 months after ACS, it decreased to 80% over 6 months , and to 60% over 12 months. The reasons for refused treatment were: 50% of patients stopped taking drugs because of adverse drug reactions fear, 25% because of well-being, for 25% of patients clopidogrel was canceled by doctor.
Conclusions: Nevertheless on the proven effectiveness of DTAD in prevention of complications after ACS and reducing the risk of death, the treatment retention to DTAD is still insufficient in real clinical practice, decreasing to 12 months after ACS until 60%. The main way to increase the treatment retention to DTAD is to hold the explaining actions to physicians by patients about the need to keep to recommendations.

The senescent CD8+ T cell population is expanded in chronic kidney disease patients and correlated with arterial stiffness

JY Kim[1]; JC Youn[2]; SW Choi[2]; SW Han[2]; KH Ryu[2]; S Park[3]; EC Shin[4]
[1]*Yonsei University College of Medicine, Division of Cardiology, Seoul, Korea Republic of*; [2]*Dongtan Sacred Heart Hospital, Division of Cardiology, Hwaseong, Korea Republic of*; [3]*Yonsei University College of Medicine, Division of Cardiology, Severance Cardiovascular Hospital, Seoul, Korea Republic of*; [4]*Korea Advanced Institute of Science and Technology, Laboratory of Immunology and Infectious Diseases, GSMSE, Daejeon, Korea Republic of*

Funding Acknowledgements: Basic Science Research Program through the NRF of Korea funded by the Ministry of Science, ICT & Future Planning (NRF-2015R1C1A1A02036645)

Background: Chronic kidney disease (CKD) is associated with increased arterial stiffness, which is a well-known predictor of future cardiovascular events. However, the underlying mechanisms of arterial stiffening in CKD are not well known. Accelerated immune aging, characterized by expansion of immunosenescent T cell fraction might be involved in the pathogenesis of arterial stiffening in CKD.
Purpose: We aimed to evaluate the relationship between arterial stiffness and immunosenescent T cell (CD8+CD57+ or CD8+CD28- T cell) fraction in patients with CKD.
Methods: Four hundred and twenty-nine consecutive hypertensive patients with CKD (266 male, mean age 61 ± 10 years) who registered in Cardiovascular and Metabolic Disease Etiology Research Center - High Risk Cohort (CMERC-HI, NCT02003781) were enrolled. Arterial stiffness was evaluated by pulse wave velocity (PWV) and the frequency of CD57+ or CD28- senescent T cells in peripheral blood lymphocytes were examined by multicolor flow cytometry.
Results: Senescent CD8+ T cell fraction showed significant tendency to increase according to CKD stages (CD8+CD57+ T cell fraction, $p < 0.001$; CD8+CD28- T cell fraction, $p < 0.001$). Multivariate analysis revealed that CD8+CD57+ T cell fraction is independently associated with PWV even after adjustment with age, gender, body mass index, renal function and systolic blood pressure (β=0.102, $p = 0.038$). Next, we asked if CMV-specific CD8+ T cells correlate with the expansion of senescent T cells and increased arterial stiffness. To this end, we are currently under investigation for CMV-specific CD8+ T cell responses using 9 different CMV antigens (pp65, IE-1, IE-2, UL94, pp150, pp71, glycoprotein B, US3, UL48) by IFN-γ ELISpot assay.
Conclusion: In CKD patients, CD8+CD57+ T cell fraction are expanded and independently associated with increased arterial stiffness. These findings may explain the role of immunosenescence in the pathogenesis of accelerated arterial stiffening in patients with CKD.

Relationship between body composition and endothelial dysfunction in heart failure patients and chronic obstructive pulmonary disease

AG Abril Guadalupe Jimenez Cepeda[1]; D Gonzalez-Islas[2]; A Orea-Tejeda[2]; G Perez- Cortes[2]; A Navarrete-Penaloza[2]; L Verdeja- Vendrell[2]; R Sanchez-Santillan[2]; V Pelaez-Hernandez[2]; A Figueroa-Herrera[2]; B Robles Uribe[2]; SC Torres-Montiel[2]
[1]*Universidad Autonoma del Noreste, Nutricion Clinica , Saltillo, Mexico*; [2]*Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clínic , Mexico, Mexico*

Background: Chronic obstructive pulmonary disease (COPD) is associated with a high risk of cardiovascular mortality and endothelial dysfunction, there is known that when endothelial dysfunction increases the GOLD increase too, in the same way the prevalence of cachexia in patients with Heart failure (HF). However, there is not information about linking body composition and endothelial function, or this mechanisms in patients with HF and COPD.
Objectives: To evaluate if there is a relationship between endothelial dysfunction (ED) and type of body composition in patients with HF and COPD.
Methods: A cross-sectional study included patients older than 18 years with a confirmed diagnosis of COPD and HF who decided to participate. Body composition was classified according to the electrical bioimpedance by vector analysis (BIVA) in 3 groups: normal body composition, obesity and cachexia. Endothelial function was assessed by photoplestimography. ED was considered in those with a time index of maximum amplitude / over total time of the pulse curve (TAM / TT index) > 0.30 at 120 seconds post ischemia.
Results: 88 patients (56.8% female and 43.2% male) were recruited; age mean was 70.89 ± 11.77 years. The most frequent co-morbidities were COPD, 81.8% of which 45.2% were by biomass, 47.9% by smoking, and the rest were mixed; systemic hypertension 55.7%, diabetes 18.2%, obstructive sleep apnea syndrome 15.9%, pulmonary thromboembolism 13.6% and dyslipidemia 12.5%. The prevalence of endothelial dysfunction (ED) was 63.5%. There was a higher prevalence of ED in obese subjects (78.6%) compared to normal and cachectic body composition (78.3% and 52.1%, $p = 0.044$, respectively). The TAM / TT index was 0.38 ± 0.08 in obese subjects, 0.34 ± 0.05 in normal and 0.32 ± 0.06 in cachectic $p = 0.02$.
Conclusions: In this subjects prevalence of ED is high and predominates in obese subjects. Probably caused by adipokines domination upon the endothelium and that may the reason of a high risk in this patients.

Ranolazine partially blunts ado trastuzumab emtansine related cardiotoxicity

N Nicola Maurea[1]; C Coppola[2]; G Piscopo[2]; G Riccio[3]; D Rea[4]; R De Vecchis[5]; C Maurea[2]; G Sorrentino[2]; C De Lorenzo[6]; M De Laurentiis[7]
[1]National Cancer Institute G. Pascale, Naples, Italy; *[2]Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCCS, Division of Cardiology, Naples, Italy*; *[3]Federico II University of Naples, Department of Pharmacy, Naples, Italy*; *[4]Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCCS, Animal Facility, Naples, Italy*; *[5]Elena d'Aosta Hospital, Department of Cardiology, Naples, Italy*; *[6]University 'Federico II', Department of Molecular Medicine and Medical Biotechnology , Naples, Italy*; *[7]Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCSS, Department of Breast Surgery and Cancer Prevention, Naples, Italy*

Background: Ado trastuzumab emtansine (TDM1) is a novel antibody–drug conjugate consisting of trastuzumab (TRAS) covalently linked to the highly potent microtubule inhibitory agent DM1 via a stable thioether linker. TDM1 is used in metastatic ErbB2 positive breast cancer patients, previously treated with TRAS and taxane. Although, the potential cardiotoxic effects of TDM1 have not yet been fully elucidated, they can include all the mechanisms of TRAS-related cardiotoxicity, such as changes in Ca2+ regulation related to blockade of ErbB2, PI3K-Akt and MAPK pathways. Here, we aim to elucidate whether Ranolazine (RAN), administered after TDM1 treatment, blunts or not cardiotoxicity in vivo and in vitro.
Methods: In vitro, human fetal cardiomyocytes (HFC) were treated with TDM1 for 3 days and then treated in the absence or presence of RAN for 3 days. Cell viability was assessed by cell counting and MTT assay. To evaluate cardiac function in vivo, C57/BL6 mice, 2-4 months old, were daily treated with TDM1 (44.4 mg/kg/day). At day 0 and after 7 days, fractional shortening (FS) and ejection fraction (EF) were measured, by M/B mode echocardiography, and radial and longitudinal strain (RS and LS) were evaluated using 2D speckle-stracking. These measurements were repeated after 5 days of RAN treatment (305 mg/Kg/day), started at the end of TDM1 treatment.
Results: RAN reduces TDM1 toxicity in HFC, as evidenced by the higher percentage of viable cells treated with TDM1 + RAN with respect to the cells treated with TDM1 alone ($p < 0.01$). In in vivo studies: after 7 days with TDM1 administration, FS decreased to 53.6 ± 0.9%, versus 61.0 ± 0.8 % (sham), ($p < 0.01$), and EF decreased to 85.5 ± 3.5 % versus 91.0 ± 0.8% (sham), ($p < 0.01$). Moreover, RS decreased to 20.92 ± 3.2 % versus 42.2 ± 10.1% (sham) ($p < 0.01$), and LS decreased to -15.5 ± 2.8 % versus -23.6 ± 6.7% (sham), ($p < 0.01$).
In mice treated with TDM1 and, successively treated with RAN for 5 days, the indices of cardiac function partially recovered: FS 58 ± 2.4 % ($p < 0.05$), EF 88.8 ± 1.7 %, ($p < 0.05$), RS (35.7 ± 8.2 %, $p > 0.05$), whereas the alteration of LS persists even after treatment with RAN (-17.3 ± 3.7 %, $p > 0.05$)
Conclusions: Here we show that in vivo RAN post-treatment reduces cardiotoxic effects due to TDM1, as demonstrated by the recovery of FS, EF and RS values. As expected, RAN increases cell viability of HFC treated with TDM1.

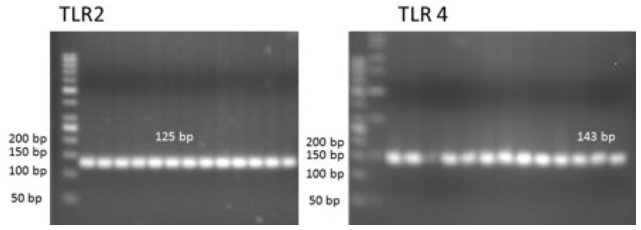
Customized laboratory TLR4 and TLR2 detection method from peripheral human blood for early detection of doxorubicin induced cardiotoxicity

M Trofenciuc[1]; A Pop-Moldovan[1]; D Darabantiu[1]; M Tomescu[2]; R Christodorescu[2]; H Branea[2]; T Pirvanescu[2]; M Puschita[1]
[1]"Vasile Goldis" Western University of Arad, Faculty of Medicine,County Emergency Clinical Hospital, Arad, Romania; *[2]University of Medicine Victor Babes, Timisoara, Romania*

Background: Cancer treatments can have significant cardiovascular adverse effects that can cause cardiomyopathy and heart failure with reduced survival benefit and considerable decrease in the use of antineoplastic therapy.
Purpose: The purpose of this study is to assess the role of TLR2 and TLR 4 gene expression as an early marker for the risk of doxorubicin induced cardiomyopathy in correlation with early diastolic dysfunction in patients treated with doxorubicin.
Methods: Our study included 25 consecutive patients who received treatment with doxorubicin for hematological malignancies (leukemia, lymphomas or multiple myeloma), aged 18-65 years old, with a survival probability > 6 months and with left ventricular ejection fraction > 50%. Exclusion criteria consisted of: previous anthracycline therapy, previous radiotherapy,history of heart failure or chronic renal failure, atrial fibrillation, pregnancy. In all patients, in fasting state, a blood sample was drawn for the assessment of TLR2 and TLR4 gene expression. Gene expression was assessed by qRT PCR using: blood collection, RNA isolation, cDNA reverse transcription, qRT PCR and quantification of the relative expression. At enrolment all patients were evaluated clinically, an ECG and an echocardiography were performed.
Results: The average amount of gene expression units was 0.113 for TLR4 (range 0.059-0.753) and 0.218 for TLR2 (range 0.046-0.269). The mean mRNA extracted quantity was 113,571 ηg/μl. As for the diastolic function parameters, criteria for diastolic dysfunction were present after 6 months in 16 patients (64%). In these patients the mean values for TLR4 were 0,1198625 and for TLR2 0,16454 gene expression units. As for the diastolic function parameters, criteria for diastolic dysfunction were present after 6 months in 16 patients (64%). In these patients the mean value for TLR2 was 0.30 ± 0.19 and for TLR4 0.15 ± 0.04. The corresponding values for the patients who did not develop diastolic dysfunction were 0.16 ± 0.07 for TLR2 ($p = 0.01$) and 0.11 ± 0.10 for TLR4 ($p = 0.2$).
Conclusion: Our study suggests that TLR4 and TLR2 expression is higher in patients under doxorubicin therapy which develop diastolic dysfunction. This may suggest a predisposition to myocardial involvement, a higher sensitivity to doxorubicin cardiac effects.



Genetic amplification

Cardiotoxic effects of the novel anti-ErbB2 agent Ado trastuzumab emtansine

N Nicola Maurea[1]; C Coppola[2]; G Piscopo[2]; G Riccio[3]; R De Vecchis[4]; C Maurea[2]; G Sorrentino[2]; C De Lorenzo[5]; M De Laurentiis[6]
[1]National Cancer Institute G. Pascale, Naples, Italy; *[2]Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCCS, Division of Cardiology, Naples, Italy*; *[3]Federico II University Hospital, Department of Pharmacy, Naples, Italy*; *[4]Elena d'Aosta Hospital, Department of Cardiology, Naples, Italy*; *[5]University 'Federico II', Department of Molecular Medicine and Medical Biotechnology , Naples, Italy*; *[6]Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCSS, Department of Breast Surgery and Cancer Prevention, Naples, Italy*

Background: Ado trastuzumab emtansine (TDM1) is a novel antibody–drug conjugate consisting of trastuzumab (TRAS) covalently linked to the highly potent microtubule inhibitory agent DM1 via a stable thioether linker. TDM1 is used in metastatic ErbB2 positive breast cancer patients, previously treated with TRAS and taxane. Although the potential cardiotoxic effects of T-DM1 have not yet been fully elucidated, they can include all the mechanisms of TRAS-related cardiotoxicity, such as blockade of ErbB2,PI3K-Akt and MAPK pathways. Furthermore, since TDM1 is also used in combination with other anti-ErbB2 agents, the risk of cardiotoxic side effects could be further increased. Here, we aim to assess the cardiotoxic side effects of TDM1 in vitro and in vivo.
Methods: To evaluate the cardiotoxic effects of TDM1 in vitro, human fetal cardiomyocytes (HFC) and cardiomyoblasts (H9C2) were treated, for 3 days, in the absence or in the presence of increasing concentrations of TDM1 and TRAS. Moreover, to assess the cardiac function in vivo, C57/BL6 mice, 2-4 months old, were daily treated with TDM1 (44.4 mg/kg/day). At day 0 and after 7 days, fractional shortening (FS) and ejection fraction (EF) were measured, by M/B mode echocardiography, and radial and longitudinal strain (RS and LS) were evaluated using 2D speckle-stracking.
Results: TDM1 shows a higher toxicity on HFC and H9C2 cells with respect to TRAS. TDM1 clearly causes more marked changes in HFC cell morphology, cells, that indeed lost their typical features to assume distorted forms (rounded-shape). In in vivo studies: after 7 days with TDM1, FS decreased to 53.6 ± 0.9 %, versus 61.0 ± 0.8 % (sham), ($p < 0.01$), and EF decreased to 85.5 ± 3.5 % versus 91.0 ± 0.8% (sham), ($p < 0.01$), RS decreased to 20.9 ± 3.2 % versus 42.2 ± 10.1 % (sham), ($p < 0.01$), LS decreased to -15.5 ± 2.8 % versus -23.6 ± 6.7 % (sham), ($p < 0.01$).
Conclusions: Here we show for the first time the cardiotoxic effects of TDM1, both in in vitro, and in vivo models.

ABSTRACT Doxorubicin induced cardiotoxicity is a well-recognized complication of chemotherapy, and its prevention remains an important challenge in cancer survivorship. An angiogenic hormone prokineticin via its receptor PKR1 promotes angiogenesis, differentiation of cardiac stem cells, and survival of the cardiomyocytes. PKR1 has been recently shown to protect heart against myocardial infarction in mice model. Thus, we hypothesized that PKR1 agonist can be a promising target to prevent doxorubicin-mediated cardiotoxicity.
Methods and Results: In vitro, we showed that IS20 attenuates apoptosis induced by DOX treatment in H9c2 cardiomyocytes and human epicardial derived progenitor cells. However, IS20 does not interfere DOX-mediated cytotoxicity in cancer cell line. In vivo, IS20 administration in juvenile mice model promotes survival, proliferation and differentiation of WT1 + EPDCs into vasculogenic cells. Similarly, IS20 on chronic mice model preserves vascular structure, reduces apoptosis and inflammation. IS20 also improves systolic and diastolic parameters that impaired by DOX.
Conclusions: Multi effects of IS20 on the activation of cardiac progenitor cells, cardiac cells survival, vascular stability and cardiac parameters show a strong cardioprotective potential of PKR1 agonist that can be used in cancer patients during anthracyclines chemotherapy.

P2008

Growth differentiation factor 15 as a predictor of acute kidney injury formation

IR Vishnevskaya[1]; HF Barahmeh[2]
[1]*Government institution "L.T. Malaya Therapy National institute of the National academy of medical sci", Kharkiv, Ukraine*; [2]*V.N. Karazin Kharkiv National University, Kharkiv, Ukraine*

The development of acute kidney injury (AKI) in patient with acute coronary syndrome (ACS), especially in those who underwent angiography, is an actual problem, because it worsens the prognosis. In order to diagnose this condition in time the search for biomarkers is going. Stress-induced marker growth differentiation factor 15 (GDF 15), a member of the transforming growth factor-β cytokine superfamily is being actively studied.
Purpose: to determine the prognostic significance of GDF 15 and other markers in development of AKI in patients with ACS.
Methods: 73 patients were enrolled with different forms of ACS (55 male and 18 female), mean age was 61, 8 ± 1, 3 years. All patients underwent a baseline investigation which includes: standard electrocardiography, echocardiography, angiography and determination of marker of myocardial necrosis – cardiac troponin T. Based on the results of the examination glomerular filtration rate (GFR) was calculated by Chronic Kidney Disease Epidemiology Collaboration formula (CKD-EPI). A group of patients has been selected (n = 54), their creatinine level was determined during the first 24 hours and after 48 hours. All patients were divided into two groups according to acute kidney injury network classification (AKIN): 21 patient in the first group with negative dynamic (1st stage AKIN and higher), 33 patient in the second group without creatinine dynamic. In addition, the level of GDF 15 was determined during the first day of hospitalization (normal range of GDF 15 < 1200 pg / ml).
Results: By comparing selected groups significant difference was found in creatinine level and GFR in both groups ($p < 0.001$; $p < 0.01$, respectively). The effects of various variables were assessed on formation of AKI in patients with different level of GFR. To identify the main risk factors for AKI, we have used logistic regression (LR): ejection fraction of left ventricle (area under curve (AUC) 0.7; $p < 0.01$; 95% confidence interval (CI): 0.560 – 0,842), GDF 15 (AUC 0.77; $p < 0.03$; 95% CI: 0.53 – 0.92) and age (AUC 0.77; $p < 0.01$) were main risk factors for predicting development of AKI. During the statistical analysis the predictive value for estimated parameters was calculated: GDF 15 > 2200 pg/ml (specificity (Spe) 87%, sensitivity (Se) 65%), ejection fraction of left ventricle >46% (Spe 80 %, Se 71 %), age >55 year (Spe 39 %, Se 96 %) We have developed a prognostic model to predict reduced kidney function formation (AUC 0.8; $p < 0.001$). This model with 96% of Se and 68% of Spe can predict development of AKI in patients with different levels of GFR after ACS.
Conclusion: the prognostic multifactor model can be used in clinical practice to improve risk stratification in patients with ACS to prevent formation of AKI.

Neladenoson, a partial adenosine A1-receptor agonist, improves mitochondrial function in skeletal muscle of dogs with chronic heart failure

HN Hani Sabbah[1]; RC Gupta[1]; V Singh-Gupta[1]; K Zhang[1]; J Xu[1]; B Albrecht-Kuepper[2]
[1]*Henry Ford Hospital, Detroit, United States of America*; [2]*Bayer AG, Wuppertal, Germany*

Funding Acknowledgements: Bayer AG

Background: Exercise intolerance (Ex-Int) is a feature of chronic heart failure (HF) and in particular, HF with preserved ejection fraction (HFpEF) and attributable, in part, to skeletal muscle (SM) abnormalities of fiber type composition and mitochondrial (MITO) dysfunction. In patients and dogs with HF, SM aerobic, MITO-dependent, type-I fibers decrease in number while anaerobic type-II fibers increase; a maladaptation that contributes to Ex-Int. We previously showed that chronic therapy with capadenoson, a partial adenosine A1-receptor agonist (pA1RA), improves LV function in HF dogs and therapy with neladenoson (NELA), a novel pA1RA, normalizes MITO function in failing cardiomyocytes. This study examined the effects of NELA on MITO function in SM biopsies from normal (NL) dogs and dogs with microembolization-induced HF.
Methods: Fresh SM open biopsies (˜6 grams) were obtained from the hind leg Vastus Lateralis muscle of 6 NL and 6 HF anesthetized dogs. Samples were cut into thin sections, divided into 4 equal portions, and one portion each incubated in 0 (vehicle), 3, 10, and 30 nM concentration of NELA respectively for one hour at 37°C. At end of incubation, MITO were isolated from SM and their function assessed. MITO ADP-stimulated state-3 respiration (ADPresp) was measured using a Strathklein respirometer, MITO complex-IV (COX-IV) activity was measured polarographically and MITO maximum rate of ATP synthesis (ATPsyn) was measured using the bioluminescent ApoSENSOR assay kit.
Results: Increasing concentration of NELA had no effect on measures of MITO function in SM from NL dogs (Table). In SM from HF dogs, depressed levels of MITO ADPresp, ATPsyn, and COX-IV activity increased significantly in a dose-dependent manner after exposure to NELA (Table).
Conclusions: The results indicate that NELA improves MITO function of SM of dogs with HF. These improvements can potentially reduce/reverse Ex-Int in HF.

Regulation of the balance between cardiac and skeletal muscle triadin by a heart-enriched antisense long non-coding RNA

L Zhang[1]; A Salgado-Somoza[1]; M Vausort[1]; P Leszek[2]; Y Devaux[1]
[1]*Luxembourg Institute of Health, CVRU, Strassen, Luxembourg*; [2]*Institute of Cardiology, the Heart Failure and Transplantology Department, Warsaw, Poland*

Background: Ribonucleic acids (RNAs) are molecules with key roles in cell biology. In the recent years, the so called long non-coding RNAs (lncRNAs), which do not encode for proteins, showed multiple functions in cardiac pathophysiology and they were found to be dysregulated in the failing heart. However, their role in heart failure development is still poorly undrestood.
Purpose To investigate the regulation and function of heart-enriched lncRNAs in the failing heart.
Methods: Public datasets in combination with in-house data were used to identify heart-enriched lncRNAs regulated in heart failure. Biopsies from 43 failing and 23 control human hearts, as well as different mouse organs were used for wet-lab experiments. Gene expression was assessed using quantitative PCR. GapmeRs or

a CRISPR/dCas9-VPR activation approach were used to modulate the expression of lncRNAs in murine cardiomyocytes HL-1.
Results: Analysis of a RNA-seq dataset of 15 Caucasian tissues allowed the identification of 415 heart-enriched lncRNAs. After data mining, we selected a genome region harboring the Triadin (TRDN) gene, that encodes for a protein involved in calcium release from the endoplasmic reticulum and which is associated with cardiac hypertrophy. Five lncRNAs from nonCode4.0 database were localised on the antisense strand of TRDN gene. One of them (arbitrarily named TRDN-AS) was positively correlated with the cardiac isoform of TRDN and negatively correlated with the skeletal muscle isoform of TRDN. Expression levels of TRDN-AS and cardiac TRDN – but not skeletal muscle TRDN – were elevated in biopsies from human failing hearts compared to control hearts (Figure 1a). A mouse homolog of TRDN-AS (Trdn-AS) was identified and found mostly in the nuclear compartment of murine cardiomyocytes HL-1. Activation of the transcription of Trdn-AS using specific guide RNAs in combination with a CRISPR/dCas9-VPR system resulted in an increase of the ratio between cardiac and skeletal muscle isoforms of Trdn (Figure 1b). Down-regulation of Trdn-AS expression using gapmeRs had no effect on the cardiac/skeletal muscle ratio.
Conclusion: We identified a lncRNA named TRDN-AS which regulates the balance between cardiac and skeletal muscle isoforms of TRDN at the epigenetic level. Since TRDN is associated with heart failure, these results suggest a role for TRDN-AS in the development of heart failure. Figure legend. a) Expression levels of TRDN-AS, cardiac and skeletal muscle isoforms of TRDN in left ventricular biopsies from 23 control and 43 failing human hearts. b) Regulation of Trdn isoforms by Trdn-AS. HL-1 cardiomyocytes were co-transfected with SP-dCas9-VPR and gRNA_Cloning Vector with (specific guide RNA, sgRNA) or without (Control) target sequence. Cells were harvested after 48h. 5 independent experiments were performed.

Background: Iron is presumed to play an essential role in the oxidative energy metabolism of cardiomyocytes. Different iron availability introduced to primary human cardiac myocytes is anticipated to affect the expression of genes involved in oxidative and non-oxidative metabolic pathways in these cells.
Purpose: The aim of the study was to investigate the response of genes involved in non-oxidative glycolysis and oxidative mitochondrial metabolism to increased or reduced iron availability in the environment of human primary cardiac myocytes when cultured upon mechanical stretch.
Methods: Primary human cardiac myocytes (HCM) were cultured for 48 hours: 1) in static conditions; 2) upon mechanical stretch; at the optimal versus reduced versus increased iron concentration (iron chelation with100μM deferoxamine, DFO; iron supplementation with 200μM ammonium ferric citrate, AFC). We analysed the mRNA expression of the genes involved in non-oxidative metabolism: pyruvate kinase (PKM2) and lactate dehydrogenase A (LDHA), as well as genes of mitochondrial enzymatic complexes involved in oxidative metabolism: NDUFS1 (subunit of complex I), UQCRFS1 (subunit of complex III), COX4I1 (subunit of complex IV) and ATP5B (subunit of complex V) using qPCR.
Results: HCM cells when exposed to mechanical stretch demonstrated, as compared to the cells cultured in static conditions, an increased mRNA expression of PKM2 ($p < 0.001$) and LDHA ($p < 0.0001$), suggesting an enhanced glycolysis. Additional exposition of the cells to the reduced iron availability caused further increase in mRNA expression of PKM2 ($p < 0.05$) and LDHA ($p < 0.05$). The AFC treatment during mechanical effort resulted, as compared to the cells cultured upon mechanical stretch and optimal iron concentration, in an increased mRNA expression of PKM2 ($p < 0.05$) and a decreased expression of LDHA ($p < 0.05$). Notably, in case of AFC treatment expression of PKM2 increased to a lesser extent compared with that in case of DFO treatment ($p < 0.05$). Upon mechanical stretch HCM demonstrated, as compared to the cells cultured in static conditions, an increase in mRNA expression of NDUFS1, UQCRFS1, COX4I1 and ATP5B (all $p < 0.05$), suggesting an enhanced mitochondrial oxidative pathway. Additional DFO treatment resulted in a decrease in expression of NDUFS, UQCRFS1, COX4I1 and ATP5B (all $p < 0.05$).The analogous alterations were observed upon AFC treatment during mechanical stretching; however, mRNA expression of NDUFS1, UQCRFS1, COX4I1 and ATP5B decreased to a lesser extent compared with that in case of DFO treatment (all $p < 0.01$).
Conclusions: Reduced iron availability during mechanical effort enhances non-oxidative metabolic pathway and resulting lactate formation, whilst decreasing mitochondrial oxidative pathway in human cardiac myocytes. On the other hand, iron supplementation during mechanical effort may act in a protective manner, reducing lactate formation pathway.

P2012

PPARalpha in cardiac energy metabolism regulation in chronic heart failure due to ischemic heart disease

AD Voronova[1]; MP Valikhov[1]; TG Kulikova[1]; OV Stepanova[1]; VP Masenko[1]; RS Akchurin[1]
[1]Cardiology Research and Production Center, Moscow, Russian Federation

One of the main causes of chronic heart failure (CHF) is ischemic heart disease (IHD). Cardiac ischemia is usually the result of hypoxia. The CHF progression is accompanied with alterations in cardiac energy metabolism, failing hearts become energy deprived. Recent scientific studies have shown that the cardiac energy metabolism is under the transcriptional control of nuclear receptors, such as peroxisome proliferator activated receptors (PPARs). These transcription factors act as molecular sensors in response to extracellular and intracellular changes, regulating the expression of the target genes. The downregulation of PPAR-alpha has been shown in the studies in mice model of ischemic cardiomyopathy. Our purpose was to study the role of PPAR-alpha and target genes in the regulation of cardiac energy metabolism in ischemic heart disease.
In order to characterize the metabolic phenotype in IHD, RT-qPCR was used to measure mRNA expression of the nuclear receptor PPAR-alpha - a key regulator of fatty acid beta-oxidation, and target genes: Long-Chain Acyl-CoA Dehydrogenase (LCAD, a key enzyme of beta-oxidation); Cardiac Carnitine Palmitoyl-Transferase-1 (CPT-1, the other principal outer mitochondrial membrane fatty acid transporter); Cluster-of-Differentiation 36 (CD36, also known as Fatty-Acid Translocase (FAT); Heart Fatty-Acid-Binding Protein (HFABP) in surgical specimens of auricle from patients with ischemic heart disease (IHD, $n = 10$) and human non-diseased myocardium autopsy specimens ($n = 5$).
Transcript expression levels of PPAR-alpha, CD36, CPT-1 and LCAD decreased in IHD in comparison to human non-diseased myocardium autopsy specimens. The significant up-regulation of HFABP in IHD was observed in the study.
These data indicate the occurrence of metabolic disorders in ischemic heart disease - an energy metabolism shifting from cardiac fatty acid oxidation as a primary energy source to glucose oxidation. It can be assumed that the regulation of the cardiac energy metabolism is possible by acting on PPAR-alpha, CD36, CPT-1, LCAD and HFABP. Whether downregulation of PPAR-alpha is an adaptive response in IHD remains unclear. It is likely that inhibitors or activators of mitochondrial fatty acid oxidation can be used for metabolic therapy of CHF due to IHD.

Funding Acknowledgements: Fondation Coeur et Recherche

Aims Metabolic syndrome (MetS) is a known risk factor for cardiovascular events. It is characterized by central obesity plus any two of dyslipidemia, insulin resistance, and hypertension. Obese and diabetic patients with MetS have low plasma insulin-like growth factor binding protein 2 (IGFBP2). Our first aim was to investigate IGFBP2 cardiac expression in MetS patients and in a mice model of MetS. The second aim was to assess if gene therapy with adeno-associated virus 9 carrying human

IGFBP2 (AAV9-hIGFBP2) could reduce MetS associated left ventricular hypertrophy in mice.
Methods and Results: We measured plasma IGFBP2 by ELISA and cardiac mRNA IGFBP2 expression in MetS patients by RT-qPCR. Both plasma levels and heart expression of IGFBP2 were decreased in patients with MetS vs. control patients. Further, in a C57BL/6J mouse model of diet-induced MetS, found similar left ventricular mRNA IGFBP2 expression. Finally, we demonstrated for the first time that in MetS mice with decreased cardiac IGFBP2 mRNA levels, human IGFBP2 can be induced by a single AAV9-hIGFBP2 injection, and that the increased IGFBP2 prevents left ventricle wall thickening, hypertrophy and dysfunction.
Conclusions: Human plasma and cardiac IGFBP2 are decreased in MetS patients. In mice, restoration of cardiac IGFBP2 expression level prevents MetS associated left ventricular dysfunction and hypertrophy. These clinical and animal data suggest that IGFBP2 is a new cardiac marker and therapeutic target in MetS to prevent heart remodeling consistent with heart failure.

Association between the gut microbiota composition, low-grade inflammation and blood pressure in patients without heart failure from moscow and moscow region

DA Daria Kashtanova[1]; ON Tkacheva[2]; YUV Kotovskaya[3]; AS Popenko[4]; AV Tyaht[4]; DG Alekseev[5]; SA Boytsov[6]
[1]National Research Center for Preventive Medicine, "Research of Age and Age-associated Conditions" Department, Moscow, Russian Federation; *[2]Russian National Research Medical University, Russian Clinical Research Center for Gerontology, Moscow, Russian Federation*; *[3]Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*; *[4]Federal State Institution "Federal Scientific Clinical Center of Physical-Chemical Medicine (FMBA), Moscow, Russian Federation*; *[5]Moscow Institute of Physics and Technology, Moscow, Russian Federation*; *[6]National Research Center for Preventive Medicine, Moscow, Russian Federation*

Introduction: Mechanisms of interaction between the gut microbiota composition and cardiovascular diseases are actively investigated. The aim of the study was to assess the relationship between the gut microbiota composition, inflammatory markers and level of blood pressure (BP) in apparently healthy individuals living in Moscow and Moscow region.
Materials and Methods: The study included untreated subjects aged from 25 years to 76 years carefully selected through exclusion of cardiovascular diseases by means of clinical and laboratory evaluation, ECG, treadmill test, echocardiography, carotid ultrasound examination. Eight hundred and fifty eight subjects were screened and only 92 met the selection criteria. Highly sensitive C-reactive protein (CRP) concentration was measured (immunoturbidimetry method) and interleukin-6 (IL-6) was measured by immunoenzyme method. DNA was isolated from 2 ml of stool samples. Preparations for further sequencing and sequencing of the V3-V4 variable regions of the 16S rRNA gene were done according to recommended protocol 16S metagenomic sequencing Library Preparation. Statistical analysis was performed on the R programming language, version 3.1.0. Statistical analysis for comparing the groups of samples was performed using the generalized linear models and Mann-Whitney test (corrected for multiple comparisons false discovery rate).
Results: 92 participants were included (26 men), arterial hypertension of 1 degree was detected in 34 participants (37%). Average SBP was 120 ± 18,6 mmHg. Gram-negative opportunistic bacteria of the genus Prevotella were more presented in patients with systolic blood pressure (SBP) >140 mmHg than in normotensive subjects ($p < 0.001$). It was found that SBP was higher in patients whose microbiota contained more bacteria of the genus Blautia ($p = 0.002$). The average CRP level among the participants was 3.50 ± 4.39mg/l. CRP level was ≥5mg/in 12 participants. High CRP levels were positively associated with gram-negative opportunistic pathogens of the Serratia ($p < 0.001$) and Prevotella ($p = 0.002$) genera. Prevotella was also positively associated with IL-6 ($p = 0.008$), which average value was 5.57 ± 5.45 pg/ml, in 24 patients it was ≥10pg/ml.
Conclusions: The results show the relationship between the increased SBP, low-grade inflammation and higher representation of gram-negative opportunistic pathogens which are capable of producing endotoxins and genus Blautia which is able to activate the secretion of tumor necrosis factor-alpha and pro-inflammatory cytokines.

The absence of leukocyte-associated immunoglobulin-like receptor 1 (LAIR-1) does not influence cardiac repair after acute myocardial infarction in mice

GHJM Ellenbroek[1]; JJ De Haan[1]; IE Hoefer[1]; L Timmers[2]; MAD Brans[1]; SM Van De Weg[1]; PAFM Doevendans[2]; G Pasterkamp[3]; L Meyaard[4]; SCA De Jager[1]
[1]University Medical Center Utrecht, Experimental cardiology, Utrecht, Netherlands; *[2]University Medical Center Utrecht, Cardiology, Utrecht, Netherlands*; *[3]University Medical Center Utrecht, Clinical Chemistry and Hematology, Utrecht, Netherlands*; *[4]University Medical Center Utrecht, Immunology, Utrecht, Netherlands*

Background: Heart failure after acute myocardial infarction (MI) depends on infarct size and adverse left ventricular (LV) remodelling, both depending on extent and quality of the inflammatory response. Leukocyte-associated immunoglobulin-like receptor 1 (LAIR-1) is an inhibitory leukocyte receptor. The aim of this study was to investigate the role of LAIR-1 in the extent of inflammation, infarct size and adverse LV remodelling after MI.
Methods & Results: Wildtype (WT) and LAIR-1-/- mice were either subjected to ischemia-reperfusion or permanent left coronary artery (LCA) ligation. In mice subjected to ischemia-reperfusion, infarct size (IS) was comparable between WT and LAIR-1-/- mice as a percentage of the area at risk (37.0 ± 14.5 vs. 39.4 ± 12.2%, $p = 0.63$) and as a percentage of the LV (14.2 ± 7.4 vs. 14.9 ± 7.0%, $p = 0.80$). In mice subjected to permanent LCA ligation, end-diastolic (133.3 ± 19.3 vs. 132.1 ± 27.9 μL, $p = 0.91$) and end-systolic volumes (112.1 ± 22.2 vs. 106.9 ± 33.5 μL, $p = 0.68$) did not differ between both groups, as assessed by echocardiography four weeks after MI. Similarly, no differences were observed in inflammatory cell quantification or collagen deposition in the infarcted area.
Conclusion: The absence of LAIR-1 does not influence infarct size, nor does it affect inflammation, fibrosis formation and adverse LV remodelling four weeks after MI.

P2016
Association of M235T polymorphism of angiotensinogen gene and lipid parameters in heart failure patients with type 2 diabetes mellitus.

OO Medentseva[1]; MM Udovychenko[1]; IS Rudyk[1]
[1]L.T.Malaya Institute of Therapy, Department of Clinical Pharmacology and Pharmagenetics of non-communicable diseases, Kharkiv, Ukraine

Background: Polymorphism of angiotensinogen (ATG) gene M235T could be associated with coronary artery disease (CAD). Dyslipidemia have been reported as one of the main pathophysiological mechanism contributing to CAD. It's well known that arterial hypertension and CAD play an important role in unfavorable course of heart failure with preserved ejection fraction (HFpEF) development. On the other hand, the association of M235T polymorphism of ATG gene and lipid parameters in heart failure patients with type 2 diabetes mellitus (T2DM) is not well researched.
Purpose: To investigate the parameters of lipid metabolism in diabetic and non-diabetic subjects carrying different types of M235T polymorphism of ATG with HFpEF.
Methods: One hundred and thirty-three patients (58 males and 75 females; mean age 61,78 ± 9,7 years) with HFpEF were examined. One hundred patients were carriers of 235T allele (MT + TT genotypes), 33 patients were homozygous carriers of 235M allele of M235T polymorphism of ATG. T2DM had 83 patients and 49 were non-diabetic patients. By using of polymerase chain reaction, different genotypes of M235T polymorphism of ATG were determined. The lipid metabolism parameters were performed by using kits of reagents "NUMAN" (Germany). Continuous variables as median (25th, 75th percentile) are expressed. Mann-Whitney U test was used for nonparametric comparisons. All statistical tests were 2-tailed and $p < 0,05$ was considered statistically significant.
Results: In the group of T2DM subjects levels of serum total cholesterol ((6,00 (5,00 : 6,80) vs to 5,10 (4,30 : 5,90) mmol/l), very low-density lipoprotein-cholesterol ((0,92 (0,62 : 1,33) vs 0,69 (0,47 : 0,83) mmol/l) and triglycerides ((2,10 (1,50 : 2,95) vs 1,6 (1,15 : 1,85) mmol/l, respectively) were increased comparing with the group of non-diabetic patients, carrying the 235T allele of M235T polymorphism, ($p < 0,005$). No significant differences in lipids parameters such as levels of serum total cholesterol ((5,85 (4,57 : 7,05) vs to 5,65 (4,7 : 6,77) mmol/l), very low-density lipoprotein-cholesterol ((0,88 (0,67 : 1,15) vs 0,85 (0,55 : 0,98) mmol/l) and triglycerides ((2,05 (1,80 : 2,57) vs 1,9 (1,22 : 2.20) mmol/l) were found in M235M carriers with T2DM and without it, respectively, ($p > 0,05$).
Conclusions: The most unfavorable lipid parameters profile had diabetic patients with HFpEF and MT + TT genotypes of M2335T polymorphism of ATG.

P2017
Usefulness of CHA2DS2-VASc score in predicting stroke and death in patients with heart failure: the korean acute heart failure registry

H-Y Hyun-Young Park[1]; MK Son[1]; M-C Cho[2]; B-H Oh[3]
[1]Korea National Institute of Health, Department of Cardiovascular and Rare Diseases, Cheongju, Korea Republic of; *[2]Chungbuk National University College of Medicine, Cheongju, Korea Republic of*; *[3]Seoul National University Hospital, Internal Medicine, Seoul, Korea Republic of*

Background: The CHA2DS2-VASc score is commonly used for stroke risk stratification in patients with atrial fibrillation (AF). Its predictive accuracy in patients with heart failure (HF) is unclear.

Purpose: To determine whether CHA2DS2-VASc predicts stroke and death in patients with HF with and without AF.
Methods: The Korean Acute Heart Failure registry (KorAHF), an ongoing, a prospective observational multicenter cohort study from 2011-2014, was used in the study. We excluded patients with a diagnosis of cancer or chronic obstructive pulmonary disease before HF. The study sample comprised 1,840 patients with AF, and 2,756 patients without AF.
Results: During 1-year follow-up period, among HF patients with and without AF, the stroke occurred 3.7% (n = 68) and 2.6% (n = 73), respectively; incidence rate per 100 person-years without AF were 3.7, 1.1, 3.5, 3.1, 3.9, 5.7, and 6.4 for CHA2DS2-VASc scores of 1 through ≥7, respectively. The all-cause death occurred 21.6% (n = 398) and 20.7% (n = 570) in patients with and without AF, respectively; incidence rate per 100 person-years were as follows, for CHA2DS2-VASc scores of 1 through ≥7, respectively: (1) with AF: 12.0, 13.4, 28.2, 27.7, 33.5, 41.0, and 47.7 and (2) without AF: 16.6, 13.9, 17.4, 26.5, 37.5, 41.7, and 51.9. Each 1-point increase in the CHA2DS2-VASc score was significantly associated with increased risk of stroke in HF patients without AF (HR=1.15, 95% CI=1.00–1.32) and all-cause death in HF patients with and without AF (HR=1.18, 95% CI=1.12–1.25 in patients with AF, and HR=1.19, 95% CI=1.13–1.25 in patients without AF, respectively). The CHA2DS2-VASc score performed modestly in this HF population (for stroke without AF, and all-cause death with and without AF, 1-year C statistics, 0.59 [95% CI, 0.52–0.65], 0.62 [95% CI, 0.59–0.65], and 0.64 [95% CI, 0.61–0.66], respectively).
Conclusions: Among patients with HF, the CHA2DS2-VASc was significantly associated with and was able to modestly predict the risk of stroke and death, except stroke in patients with AF.

Clinical application of human iPS cells for the treatment of patients with severe congestive heart failure

K Keiichi Fukuda[1]; J Fujita[1]; S Tohyama[1]; T Seki[1]; S Yuasa[1]
[1]*Keio University School of Medicine, Tokyo, Japan*

Funding Acknowledgements: Grant from Japanese Government

Although heart transplantation can drastically improve the survival, shortage of the donor heart is a serious problem. The regenerative medicine of the failing heart had been long awaited. To address this question, we had developed novel methods to induce human iPS cells from circulating human T lymphocytes using Sendai virus containing Yamanaka 4 factors. We had screened the factor that were expressed in future heart forming area of the early mouse embryo, found several growth factors and cytokines that can induce cardiomyocytes differentiation and proliferation, and applied them to human iPS cells. We performed transcriptome of the metabolic enzymes and fluxome analysis using 13glucose and 13lactic acid on ES/iPS cells and cardiomyocytes, and found that their metabolic pathways were completely different. Based on these findings, we purified cardiomyocytes using glucose-free lactate-supplemented medium. Purity of the cardiomyocytes was >99%, and they did not make teratoma formation. The transplanted cardiomyocytes using our technique can survive in the heart with more than 90%, and can show physiological growth after transplantation. Transplantation of ES/iPS-derived cardiomyocytes into the infarcted myocardium could improve cardiac function in rat and porcine model. We expect the combination of these techniques can achieve future heart regeneration.

The cell death-associated protein kinase, RIPK1, is phosphorylated in cardiomyocytes in response to pro-inflammatory cytokines or oxidative stress.

KA Rostron[1]; SJ Leonard[1]; SJ Fuller[1]; PH Sugden[1]; A Clerk[1]
[1]*University of Reading, School of Biological Sciences, Reading, United Kingdom*

Funding Acknowledgements: British Heart Foundation

Introduction: Myocardial infarction is associated with oxidative stress, inflammation and production of pro-inflammatory cytokines [e.g. tumour necrosis factor alpha (TNFα), interleukin-1 beta (IL1β)]. In T cells, TNFα signals via RIPK1. Ubiquitinylated RIPK1 is protective, activating NFκB, p38-MAPKs and JNKs. Deubiquitinylation of RIPK1 induces apoptosis, whilst phosphorylation and kinase activation switches the mode of cell death from apoptosis to an alternative, more damaging form, necroptosis.
Purpose: Our aims are to determine how RIPK1 is regulated in cardiomyocytes and its role in the cardiomyocyte response to pro-inflammatory cytokines or oxidative stress. Our hypothesis is that RIPK1 is phosphorylated and activated by these stresses, and its activation status influences cardiomyocyte survival vs. death.
Methods and results: Phosphorylation of protein kinases is associated with the appearance of reduced mobility bands on immunoblots. The effects of TNFα, IL1β or H2O2 (a physiologically relevant oxidative stress) on RIPK1 were studied initially in neonatal rat ventricular myocytes (NRVMs). TNFα (20 ng/ml) induced appearance of reduced mobility bands (indicating multiple phosphorylations) in 5-15 min, with return to the basal state by 2 h. IL1β (>1 ng/ml) induced appearance of similar bands in 5-15 min, but the response was greater and more prolonged. H2O2 (>0.2 mM) induced the same degree of response as IL1β, but this was maximal at 1-2 h. These reduced mobility bands are consistent with phosphorylation rather than ubiquitinylation in terms of relative molecular mass. Anion-exchange chromatography also indicated RIPK1 was phosphorylated. Gel filtration chromatography showed RIPK1 (74.8 kDa predicted molecular weight) elutes in a complex of 150-170 kDa in control cells and forms higher molecular weight complexes with IL1β. The degree of RIPK1 phosphorylation in response to IL1β was concentration-dependent. Activation of p38-MAPK was assessed by immunoblotting using phosphospecific antibodies. The concentration-dependency of p38-MAPK phosphorylation in response to IL1β mirrored that of RIPK1 phosphorylation. Moreover, p38-MAPK inhibitors (SB203580, BIRB-796) attenuated the appearance of reduced mobility bands induced by IL1β. The concentration-dependency for this inhibition was similar to that for inhibition of phosphorylation of MAPKAPK2 (an established p38-MAPK substrate). Adult male rat hearts were perfused in the Langendorff mode with IL1β (15 min) in the absence/presence of SB203580. Consistent with the results from NRVMs, IL1β induced the appearance of reduced mobility bands and this was inhibited by SB203580, confirming that the results are relevant for the adult heart.
Conclusions: RIPK1 is phosphorylated in response to IL1β in cardiomyocytes and perfused adult rat hearts, and this is mediated via p38-MAPK signalling. Since p38-MAPK is activated downstream of RIPK1, this is likely to be a feedback system.

Background: Numerous epidemiological and clinical studies have revealed a positive correlation between heart rate (HR) and cardiovascular morbimortality. The autonomic nervous system is the major extracardiac determinant of HR. During sympathetic stimulation, the activation of β-adrenergic receptors (βAR) induces an increase in cAMP levels, leading to a positive chronotropic effect. Among the 5 cAMP-PDE families expressed in the heart, PDE4 is critical for controlling excitation-contraction coupling (ECC) during βAR stimulation in atrial and ventricular cells. PDE4 may also be important for automaticity. 3 genes encode for cardiac PDE4s: pde4a, pde4b and pde4d. Their respective contribution to the regulation of pacemaker activity remains ill-defined.
Methods: The total enzymatic PDE activity was determined in mouse sinoatrial node (SAN) tissue as the cAMP hydrolytic activity measured in the absence of PDE inhibitor and the fraction corresponding to PDE4 activity was assessed by including the PDE4 inhibitor Ro-20-1724 (10 μM). The in vitro pacemaker activity was assessed by measuring the spontaneous Ca2+ transients in Fluo4-loaded-SAN intact tissue. Images were obtained using confocal microscopy.
Results: Ro-20-1724 increased the beating rate of intact mouse SAN and increased PKA-phosphorylation levels of key ECC actors (ryanodine receptor, phospholamban). PDE4 enzymatic activity was found to account for 60% of the total cAMP-PDE activity in SAN. The 3 isoforms PDE4A, 4B and 4D were found to be expressed in mouse SAN. In PDE4D-, but not in PDE4B-deficient mice, Ca2+ homeostasis was altered in control conditions and after βAR stimulation. Indeed, ablation of PDE4D induced a decreased beating rate and an increased Ca2+ spark frequency in control and βAR-stimulated conditions.
Conclusion: Our preliminary results reveal that PDE4 controls pacemaker function in mice and that PDE4D ablation strongly perturbs normal SAN activity.

HFWM: - Title: The natural autophagy-inducer spermidine protects the aging heart and promotes longevity in mice

M Abdellatif[1]; T Eisenberg[2]; A Schmidt[1]; W A Linke[3]; C Muehlfeld[4]; J Sadoshima[5]; S Kiechl[6]; G Kroemer[7]; F Madeo[2]; S Sedej[1]

University Bochum (RUB), Department of Cardiovascular Physiology, Bochum, Germany; [4]*Hannover Medical School, Institute of Functional and Applied Anatomy, Hannover, Germany*; [5]*New Jersey Medical School, Department of Cell Biology and Molecular Medicine, Newark, United States of America*; [6]*Innsbruck Medical University, Department of Neurology, Innsbruck, Austria*; [7]*Centre de Recherche de Cordeliers, Equipe 11 labellisée Ligue contre le Cancer, Paris, France*

Purpose: Aging is associated with increased risk of cardiovascular disease and death. One of the theories of aging postulates an age-dependent decline in autophagy, a major cellular repair process associated with rejuvenation. Here, we tested if dietary supplementation of the natural autophagy-inducer spermidine protects against cardiac aging.
Methods: Spermidine (3mM) was supplemented in the drinking water of pre-aged (18-month-old) C57Bl/6 wild-type male mice for 5 months. Cardiomyocyte-specific autophagy-deficient male mice (Atg5fl/fl/MLC2aCre+, 4-month-old) that were fed spermidine for 3 months were employed to test whether the effects of spermidine are autophagy-dependent. A comprehensive in vivo and in vitro cardiac characterization was performed using echocardiography, invasive hemodynamics, confocal and electron microscopy, immunoblotting, high-resolution respirometry and ultrastructural analysis of cardiomyocytes by design-based stereology. Another subset of C57Bl/6 mice was followed up for lifespan estimation and survival analysis. In humans, a correlational study between dietary spermidine intake (as assessed by food questionnaires) and cardiovascular disease was carried out (Bruneck Study).
Results: Dietary spermidine supplementation extended median lifespan (by ~10%) and exerted cardioprotective effects through reduction of cardiac hypertrophy and preservation of diastolic function in old mice. Spermidine-fed mice showed enhanced cardiac autophagy, mitophagy, mitochondrial respiration and mechano-elastical properties of cardiomyocytes in vivo, coinciding with increased titin phosphorylation and suppressed subclinical inflammation. Age-related effects on subcellular cardiomyocyte composition were reversed by spermidine, as reflected by increased relative mitochondrial and myofibrillar volumes and a reduced (mitochondria- and myofibril-free) sarcoplasmic volume. Spermidine failed to promote cardioprotection in the mice that lack autophagy in cardiomyocytes. In humans, higher spermidine intake was correlated with lower blood pressure and lower risk of cardiovascular disease (e.g. fatal heart failure).
Conclusion: Our results suggest dietary intake of spermidine as a novel and feasible strategy against aging-associated cardiovascular disease.

Introduction: The ubiquitin-proteasome pathway participates in the regulation of protein function and signaling via targeted proteolysis. Increasing evidence suggests that its function is dynamically adjusted in cardiac remodeling and failure. A shared mechanism in hypertrophic remodeling of the myocardium appears to be endogenous proteasome regulation via Lmp2. However, the role of cardiac Lmp2 in hypertrophic remodeling and heart failure is not known.
Purpose: Towards this end, we investigated whether cardiac Lmp2 is required for hypertrophic remodeling in response to continuous β-adrenoreceptor signaling as observed in several cardiovascular disease conditions associated with reduced cardiac output.
Methods & Results: Lmp2 had no apparent impact on cardiac development and function as observed in adult Lmp2 knock out (KO) mice, which were indistinguishable from wildtype littermates (wt). Continuous treatment of those mice with the β-adrenergic agonist isoproterenol for 4 days (30mg/kg/d) increased systolic function as well as posterior wall thickness in both groups. In contrast, chronic isoproterenol treatment for 7 days caused a loss of systolic function in Lmp2 KO animals while cardiac function was maintained in wildtypes (fractional shortening/FS: -32% vs. wt, $p < 0.01$, $n \geq 9$). To attribute a support of cardiac function to proteasome regulation via Lmp2 in cardiomyocytes, Lmp2 expression was reconstituted via cardiotropic gene transfer using adeno-associated virus serotype 9. Furthermore, Lmp2 expression was driven by a recombinant cardiac myosin light chain promoter. Lmp2 gene transfer had the effect that two forms of Lmp2 were expressed in the myocardium: full-length and processed Lmp2. Without isoproterenol, processed Lmp2 levels were similar to those in wt hearts. Upon isoproterenol treatment, full-length Lmp2 decreased reciprocally proportional to an increase in processed Lmp2. Endogenous Lmp2 processing is part of proteasome assembly, indicating that Lmp2 gene transfer restored the endogenous mechanism for proteasome regulation. Lmp2 gene transfer did not impact cardiac function under baseline conditions and upon isoproterenol administration for 4 days. In contrast, Lmp2 gene transfer fully restored systolic function in Lmp2 KO mice treated for 7 days with isoproterenol albeit the mice were born and matured without the gene. In contrast, control gene transfer did not restore systolic function in Lmp2 KO mice treated with isoproterenol for 7 days (FS: +33% Lmp2 vs. luciferase gene transfer, $p < 0.01$, $n \geq 8$). Notably, reduced systolic function was associated with exacerbated hypertrophic remodeling.
Conclusions: Cardiac proteasome regulation via Lmp2 sustains systolic function during hypertrophic remodeling upon chronic β-adrenoreceptor stimulation, but does not interfere with cardiac muscle mass or function under unchallenged conditions and short-term β-adrenoreceptor signaling.

Evaluation of the cardiovascular profile of a novel nitroxyl donor BMS-986231 in chronically instrumented dogs with normal cardiac function and pacing-induced cardiomyopathy

CL Del Rio[1]; JC Hartman[2]; J Reardon[3]
[1]*QTest Labs, LLC, Columbus, Ohio, United States of America*; [2]*Pharmaceutical R&D Consulting, LLC, Loveland, Colorado, United States of America*; [3]*HemoShear Therapeutics, LLC, Charlottesville, Virginia, United States of America*

Funding Acknowledgements: Financial support for this work was provided by Bristol-Myers Squibb

Background: BMS-986231 is a novel nitroxyl (HNO) donor that releases HNO, a molecule linked to positive inotropy, lusitropy and vasodilation.
Purpose: Assess BMS-986231 effects on haemodynamics and load-independent left ventricular (LV) mechano-energetic parameters in conscious, chronically instrumented normal dogs and dogs with pacing-induced heart failure (HF).
Methods: BMS-986231 was given as a 180-min intravenous (IV) infusion (50 μg/kg/min) in 8 dogs with normal cardiac function (CTRL), and at 3 doses (25, 50, 75 μg/kg/min) per animal in 6 dogs with pacing-induced cardiomyopathy (HF). ECG and pressure waveforms were recorded continuously; heart rate, arterial pressure and LV mechanical/geometric indices were measured at baseline and at 30, 60, 90 and 180 mins after infusion start (and at 60 mins post-infusion in HF dogs). After the 180-min infusion in normal dogs, an IV bolus of plasma volume expander was administered to restore cardiac preload and further assess BMS-986231 effects.
Results: (Mean [±SEM] % vs. baseline) BMS-986231 (at 180 mins) led to significant ($p < 0.05$) dose-dependent reductions in mean arterial (CTRL: -14 [1]%, HF: -7 [2] to -15 [1]%) and LV end-systolic pressures (CTRL: -18 [2]%, HF: -8 [2] to -17 [1]%), arterial elastance (CTRL: -23 [3]%, HF: -22 [1] to -35 [2]%) and systemic vascular resistance (CTRL: -16 [2]%, HF: -16 [3] to -29 [2]%), indicating decreased afterload. BMS-986231 also significantly decreased filling pressures (CTRL: ~-4 mmHg, HF: ~-3 to -7 mmHg) and preload. Tau (CTRL: -6 [1]%, HF: -14 [3] to -18 [4]%) and the slope of the end-diastolic pressure volume relationship (CTRL: -28 [7]%, HF: -17 [2] to -39 [6]%) were significantly decreased, suggesting positive lusitropy. Ejection fraction (CTRL: 12 [1]%, HF: 23 [2] to 41 [6]%) and the slopes of the end-systolic pressure volume (CTRL: 19 [2]%, HF: 11 [1] to 29 [1]%) and the preload-recruitable stroke work (CTRL: 12 [1]%, HF: 10 [1] to 22 [1]%) relationships increased dose-dependently with BMS-986231, suggesting positive inotropy. In normal dogs, acute restoration of LV preload by volume expansion significantly increased stroke volume (SV) (16 [4]%) and cardiac output (CO) (17 [3]%), while induced positive lusitropy/inotropy was preserved. In HF dogs, BMS-986231 resulted in significant dose-dependent increases in CO (14 [1] to 20 [2]%) and SV (18 [1] to 28 [5]%). BMS-986231-mediated improvements in load-independent cardiac function, SV and CO in HF were sustained at 60 minutes post-infusion. In all cases, BMS-986231 significantly reduced the pressure volume area (CTRL: -25 [4]%, HF: -28 [10] to -43 [6]%), suggesting decreased myocardial oxygen demand.
Conclusions: BMS-986231 produced significant and dose-dependent vasodilation, as well as inotropic and lusitropic effects, and had no meaningful impact on heart rate or markers of myocardial oxygen demand. BMS-986231 may therefore be useful in treating patients with acute decompensated HF.

Background: Ischemic cardiomyopathy (ICM) leads to impaired contraction and ventricular dysfunction causing high rates of morbidity and mortality. Epigenomics has allowed the identification of epigenetic signatures in human diseases.
Purpose: In this human pre-transplant study, we aimed to analyse the differential epigenetic patterns of ASB gene family in a group of ICM patients and relate these alterations to the hemodynamic and functional status of patients.
Methods: Epigenomic analysis was carried out using 16 left ventricular (LV) tissue samples, 8 from ICM patients undergoing heart transplantation and 8 from control (CNT) subjects without cardiac disease. We increased sample size up to 13 ICM and 10 CNT for RNA-sequencing analysis.
Results: We found two hypermethylated profiles (cg09969882 and cg11189868) in the ASB1 gene that showed a differential methylation of $0.17\Delta\beta$ and $0.26\Delta\beta$, respectively, $P < 0.05$ for both. Notably, the second methylation pattern was strongly related to end-systolic and diastolic left ventricular diameters (r=-0.743, P=0.035 for both), stroke volume (r=-0.929, P=0.001) and LV ejection fraction (r=-0.849, P=0.008). ASB1 showed a down regulation in mRNA levels (-1.2 fold, $P < 0.05$).
Conclusions: Our findings link a specific ASB1 methylation pattern to LV structure and performance in end stage ICM, and provide new insights and raising questions regarding which is the functionally relevant genome for the ischemic failing myocardium.

HFWM: Upregulation of cathepsin A induces left ventricular remodeling

L Lisa Lang[1]; M Hohl[1]; M Mayr[2]; AG Nickel[1]; A Mueller[3]; C Maack[1]; M Boehm[1]; T Sadowski[4]; D Linz[1]
[1]Saarland University Hospital, Internal Medicine III, Homburg, Germany; *[2]King's College London, London, United Kingdom*; *[3]Saarland University Hospital, Radiology, Homburg, Germany*; *[4]Sanofi Aventis, Frankfurt am Main, Germany*

Introduction: The serine carboxypeptidase cathepsin A (CatA) is located in lysosomes and in the extracellular matrix. CatA is involved in multiple pathophysiological processes including degradation of extracellular peptides and oxidative stress response. Additionally, CatA enzymatic activity has been proposed to mediate bradykinin breakdown and alternative angiotensin II production. Therefore, CatA may be an interesting target to prevent arrhythmias, cardiac hypertrophy and heart failure.
Methods: We used a proteomics approach to identify new substrates for CatA. Conditioned medium of cardiac fibroblasts was digested with CatA and analyzed by mass spectrometry. A transgenic mouse model (CatA-TG) was used to investigate the role of a heart-specific CatA-overexpression on left ventricular (LV) remodeling. Transaortic constriction (TAC) was performed in C57/Bl6N mice for 24 hours, 3 days, 5 days, 7 day, 14 days and 42 days to determine the time course of CatA-expression. Afterwards, we conducted TAC for 3 days (acute) and 6 weeks (chronic) and treated these mice with the CatA-inhibitor SAR1 (30mg/kg/day). Placebo-treated mice served as controls. At the age of 6 weeks LV function was determined by magnetic resonance imaging (MRI).
Results: Using proteomics the extracellular superoxide dismutase (SOD3) was identified as a novel candidate substrate due to a substantial downregulation upon CatA-digestion (Ctr: 24084 ± 13731 Vs. CatA: 611 ± 456 $p < 0.0001$). In CatA-TG mice an increased CatA protein expression and activity resulted in a significant decrease in SOD3 protein concentration (WT: 1.03 ± 0.04 Vs. CatA-TG: 0.58 ± 0.04 IOD/GAPDH; $p < 0.01$) and higher levels of oxidative stress (WT: 4.01 ± 0.61 Vs. CatA-TG: 7.51 ± 1.15 μmol/mg tissue/min; $p = 0.05$), which was associated with increased apoptosis and enhanced fibrosis content (WT: 5.41 ± 0.2 Vs. CatA-TG: 6.46 ± 0.31 %; $p < 0.05$). Using a TAC-timeline we observed that CatA expression increased at day 3 (≈1.8-fold; $p = 0.0003$) and went down to baseline after 2 weeks. CatA upregulation went hand in hand with increased expression of the hypertrophy-marker brain natriuretic peptide, profibrotic connective tissue growth factor, and collagens 1a, 3a and 5a. Due to the differential regulation of CatA during TAC, we treated animals for 3 days and 6 weeks (when CatA was down-regulated to control level) with the selective orally available CatA-inhibitor SAR. At 3 days after TAC, SAR-treated animals were protected against up-regulation of collagen 1a (Placebo: 8.74 ± 2.09 Vs. SAR: 1.15 ± 0.19; $p = 0.003$). TAC still induced hypertrophy of cardiomyocytes, increased LV mass and decreased ejection fraction (determined by MRI) in SAR-treated mice.
Conclusions: These findings identified up-regulation of CatA as a novel mechanism causing LV remodeling and SOD3 depletion, which in turn contributes to the cardiac phenotype begetting oxidative stress–dependent LV remodeling. CatA may therefore represent a potential therapeutic target in heart failure.

Relationship among LRP1 expression, Pyk2 phosphorylation and MMP-9 activation in post-myocardial infarction left ventricular remodeling

E Revuelta[1]; CSB Soler-Botija[1]; L Nasarre[2]; A Benitez-Amaro[2]; D De Gonzalo-Calvo[2]; A Bayes-Genis[1]; V Llorente-Cortes[2]
[1]Germans Trias i Pujol Hospital, Badalona (Barcelona), Spain; *[2]Cardiovascular Research Center (CSIC-ICCC), Barcelona, Spain*

Funding Acknowledgements: FIS PI14/01729 and FIS PI14/01682; SAF2011-30067-C02-01; Fundació La Marató de TV3 (201521_10, 201502_30 and 080330)

Introduction: Left ventricular (LV) remodeling after myocardial infarction (MI) is a crucial determinant of the clinical course of heart failure. Matrix metalloproteinase (MMP) activation is strongly associated with LV remodeling post-MI. Elucidation of plasma membrane receptors related to the activation of specific MMPs is fundamental for treating adverse cardiac remodeling post-MI.
Purpose: The aim of current investigation was to explore the potential association between the receptor low-density lipoprotein receptor-related protein 1 (LRP1) and MMP-9 and MMP-2 spatiotemporal expression post-MI.
Methods: A total of 46 male C57/Bl6 mice were used in this study; MI was induced occluding permanently left anterior descending coronary artery. Animals were sacrificed at 1, 10 and 21 days post-operation. In vitro studies were carried out with MEF and PEA13 fibroblasts; cells were exposed to hypoxia in an H35 Hypoxic/Anoxic Workstation with 94% N2 and 5% CO2.
Results: Real-time PCR and Western blot analyses showed that LRP1 mRNA and protein expression levels, respectively, were significantly increased in peri-infarct and infarct zones at 10 and 21 days post-MI. Confocal microscopy demonstrated high colocalization between LRP1 and the fibroblast marker vimentin, indicating that LRP1 is mostly expressed by cardiac fibroblasts in peri-infarct and infarct areas. LRP1 also colocalized with proline-rich tyrosine kinase 2 (pPyk2) and MMP-9 in cardiac fibroblasts in ischemic areas at 10 and 21 days post-MI. Cell culture experiments revealed that pPyk2 protein levels and MMP-9 activity were reduced to minimal levels in LRP1-deficient fibroblasts compared to control fibroblasts. These results indicate that both Pyk2 phosphorylation and MMP-9 activation require LRP1 in hypoxic fibroblasts.
Conclusion: Our results suggest that LRP1 plays a major role in MMP-9 upregulation in cardiac fibroblast post-myocardial infarction and highlight the potential role of LRP1 modulation for treatment of cardiac remodeling.

Funding Acknowledgements: 615708 (EU/ERC)

Following ischemic damage the heart undergoes extensive remodeling in response to the massive loss of cardiomyocytes in the area of injury. This will result in multiple processes including production and activation of the fibroblasts needed for proper infarct healing, however prolonged activation can be detrimental for cardiac contractility and can lead to heart failure. To maintain a proper cardiac function after an ischemic event it is crucial to preserve a proper healing of the infarct but at the same time increase the number of surviving cardiomyocytes.
Here we identify a novel function of the transcription factor Zeb2 in cardiomyocytes that it is necessary for proper infarct healing and for cardiomyocytes survival and function. Our data show that Zeb2, downstream of activated Hif1 alpha, is upregulated in cardiomyocytes in response to ischemic stress and declines 2 weeks after the injury. While cardiomyocyte specific deletion of Zeb2 did not induce an overt phenotype at baseline, after myocardial infarction (MI) deletion of Zeb2 worsened cardiac contractility, infarct healing, and survival. Transcriptome profiling of cardiac tissue of mice subjected to MI indicated that deletion of Zeb2 from cardiomyocytes leads to a significant inhibition of genes involved in fibroblast activation and proliferation, survival of cardiomyocytes and angiogenesis. Conversely AAV9-mediated cardiac delivery of Zeb2 promotes ECM related gene expression that prevents cardiac rupture and dysfunction.
To unveil the molecular mechanisms behind the cardioprotective effect of Zeb2 we performed mass spectrometry on conditioned medium from cardiomyocytes overexpressing Zeb2 and we identified Thymosin beta4 (Tmsb4) as one of the main secreted proteins. In line with this discovery, siRNA mediated Zeb2 inhibition in hypoxic neonatal cardiomyocytes abolished not only Zeb2 but also Tmsb4 expression, further verifying the regulation of Tmsb4 by Zeb2 in hypoxic cardiomyocytes. This is likely due to multiple conserved Zeb2 binding motifs in the 5kB proximal promoter region of the Tmsb4 gene.

Our data indicate that the Hif1 alpha-mediated increase in Zeb2 in cardiomyocytes in response to ischemic stress activates cardiac fibroblasts for proper infarct healing and promotes Tmsb4 secretion from heart muscle cells, which activates a downstream pro-survival response in injured cardiomyocytes. These findings reveal Zeb2 as a cardioprotective factor during ischemic injury, which may hold great promise for future heart failure therapies.

HFWM: Selective HDL-raising gene transfer counteracts cardiac hypertrophy, reduces fibrosis, and improves cardiac function in mice with chronic pressure overload

R Amin[1]; I Muthuramu[1]; F Jacobs[1]; B De Geest[1]
[1]*KU Leuven, Cardiovascular Sciences, Leuven, Belgium*

Funding Acknowledgements: This work was supported by Onderzoekstoelagen grant OT/13/090 of the KU Leuven and by grant G0A3114N of the Fonds voor Wetenschappelijk Onderzoek-Vlaa

Purpose: Epidemiological studies support an independent inverse association between high-density lipoprotein (HDL) cholesterol levels and heart failure incidence. The effect of selective HDL-raising human apo A-I gene transfer on cardiac remodelling induced by transverse aortic constriction (TAC) was evaluated.
Methods: Gene transfer with 5 x 1010 genome copies of an adeno-associated viral serotype 8-human apo A-I (AAV8-A-I) vector containing a hepatocyte-specific expression cassette was performed in C57BL/6 low-density lipoprotein receptor deficient (LDLr-/-) mice at the age of 12 weeks and was followed by TAC or sham operation two weeks later. Invasive hemodynamic measurements and morphometric and immunohistological analysis was performed 8 weeks after TAC or sham operation.
Results: Septal wall thickness was reduced by 16.5% ($p < 0.001$) 8 weeks after TAC in AAV8-A-I mice ($n = 24$) compared to control TAC mice ($n = 39$). The anti-hypertrophic effect of HDL-raising human apo A-I gene transfer was confirmed by a 16.5% ($p < 0.01$) reduction of cardiomyocyte cross-sectional area after TAC. Capillary density was 15.7% ($p < 0.05$) higher and interstitial fibrosis was 45.3% ($p < 0.001$) lower in AAV8-A-I TAC mice compared to control TAC mice. The lung weight in AAV8-A-I TAC mice was not increased compared to sham mice and was 13.3% ($p < 0.05$) lower than in control TAC mice. Atrial weight was 2.05 ($p < 0.001$) higher in control TAC mice than in control sham mice whereas no increase of atrial weight was observed in AAV8-A-I TAC mice. The peak rate of isovolumetric contraction was 18.4% ($p < 0.01$) higher in AAV8-A-I TAC mice ($n = 17$) than in control TAC mice ($n = 29$). Improved diastolic function following selective HDL-raising gene transfer was evidenced by a 17.5% ($p < 0.05$) increase of the peak rate of isovolumetric relaxation, a 15.4% ($p < 0.05$) shortening of the time constant of isovolumetric relaxation, and a significantly ($p < 0.01$) reduced end-diastolic pressure. Moreover, parameters of diastolic function were significantly ($p < 0.05$) better in AAV8-A-I sham mice ($n = 12$) than in control sham mice ($n = 10$). The 3-nitrotyrosine-positive area (%) in the myocardium quantified by immunohistochemistry was increased 7.73-fold ($p < 0.001$) and 3.57-fold ($p < 0.001$) in control TAC mice and in AAV8-A-I TAC mice, respectively. The 3-nitrotyrosine-positive area was 57.6% ($p < 0.001$) lower in AAV8-A-I TAC mice than in control TAC mice, indicating decreased nitro-oxidative stress. Compared to control TAC mice, the number of cleaved caspase-3 positive cells was reduced by 46.7% ($p < 0.05$) in AAV8-A-I TAC mice.
Conclusions: Selective HDL-raising human apo A-I gene transfer exerts anti-hypertrophic effects, reduces interstitial fibrosis, and improves systolic and diastolic function in a model of pressure overload-induced cardiomyopathy.

P2032

HFWM : post-transcriptional regulators of superoxide dismutase 2 as new biomarkers of left ventricular remodeling post-myocardial infarction.

E Emilie Dubois-Deruy[1]; O Beseme[1]; J Fielder[2]; A Pfanne[2]; P Mulder[3]; P Amouyel[1]; V Richard[3]; C Bauters[1]; T Thum[2]; F Pinet[1]
[1]*Institute Pasteur of Lille, U1167, Lille, France*; [2]*Institute for Molecular and Translational Therapeutic Strategies (IMTTS), Hannover, Germany*; [3]*INSERM U1096, ROUEN, France*

Purpose: After myocardial infarction (MI), 30% of patients develop a left ventricular remodeling (LVR) which remains a major complication and a strong predictor of both heart failure (HF) and death after MI. Our main objective is to identify new biomarkers of this pathology.
Methods: We used an experimental HF-rat model in which MI is induced by left coronary ligation to perform a proteomic analysis of left ventricle (LV). By bioinformatical analysis with Ingenuity Pathway Analysis (IPA), we identified 13 microRNAs potentially modulated during HF. We then quantified these microRNAs in left ventricle (LV) and plasma in our rat model of HF post-MI and in a cohort of patients with different degrees of LVR (REVE-2 study).
Results: By proteomic and phosphoproteomic analysis in a HF-rat model, we identified 45 proteins differentially modulated in LV. We then performed a bioinformatical analysis with IPA to identify molecular targets involved in their regulation. We identified 13 miRNA regulating 8 proteins, mostly involved in oxidative stress and metabolism, two main pathways involved in HF progression. We quantified in LV of HF-rats an increased levels of miR-23a-3p (x1.5, $p = 0.029$) at 7 days post-MI, of miR-377-5p (x3.5, $p = 0.014$), miR-21-3p (x2.6, $p = 0.013$) and miR-21-5p (x2.3, $p = 0.004$) at 2 months post-MI and of miR-222-3p at both time (7 days : x3, $p = 0.025$; 2 months: x2.1, $p = 0.005$). To analyze their potential as biomarkers, we quantified these miRNA in plasma and observed a decreased expression at 7 days post-MI and an increased expression at 2 months post-MI for miR-21-5p (7 days : /1.6, $p = 0.002$; 2 months: x6.2, $p = 0.007$), miR-23a-3p (7 days :/3.2, $p = 0.006$; 2 months: x6.6, $p = 0.004$) and miR-222-3p (7 days : /6, $p = 0.0002$; 2 months: x1000, $p = 0.0001$).
Interestingly, these 3 miRNA regulate superoxide dismutase 2 (SOD2), the major mitochondrial anti-oxidant enzyme. We then quantified an increased SOD2 expression in LV of HF-rats at 2 months post-MI (x1.6, $p = 0.029$), without modulation at 7 days post-MI. Plasmatic levels of SOD2 were not modulated in HF-rats.
We then quantified SOD2 and its post-transcriptional regulators in human plasma of patients with or without LVR in REVE-2 cohort. SOD2 increased in plasma of LVR patients 1 year after MI (x6.5, $p = 0.044$). Expression of miR-21-5p, miR-23a-3p, miR-222-3p decreased 7 days after MI (/10, respectively $p = 0.010$; $p = 0.049$; $p = 0.020$) and increased 3 months after MI in plasma of LVR patients (x10, respectively $p = 0.018$; $p = 0.002$; $p = 0.007$). Lastly, we demonstrated direct regulation of SOD2 by miR-222-3p by using mimic and miR-222 inhibitors in human cardiomyocytes.
Conclusion: We demonstrated for the first time the potential interest of miR-21-5p, miR23a-3p and miR-222-3p, 3 microRNAs involved in SOD2 regulation, as new biomarkers of LVR post-MI.

P2033

HFWM: Molecular and functional characterization of MICRA, a circular RNA predicting the development of heart failure after acute myocardial infarction

Y Devaux[1]; M Vausort[1]; A Salgado-Somoza[1]; L Zhang[1]; P Leszek[2]; DR Wagner[3]
[1]*Luxembourg Institute of Health, CVRU, Strassen, Luxembourg*; [2]*Institute of Cardiology, the Heart Failure and Transplantology Department, Warsaw, Poland*; [3]*Hospital Centre, Luxembourg, Luxembourg*

On behalf of: Cardiolinc network

Background: Predicting outcome after acute myocardial infarction (AMI) is challenging. Identification of patients at risk of developing left ventricular (LV) remodelling leading to heart failure would be a major achievement towards personalized medicine. Existing biomarkers such as brain natriuretic peptides have limited applications due to lack of specificity and stability in the few hours following AMI. Novel biomarkers are needed to improve risk stratification. Both microRNAs and long noncoding RNAs circulating in the blood have shown some potential to predict outcome after AMI. Whether circular RNAs (circRNAs), a novel class of noncoding RNAs formed by back splicing, could be used as biomarkers of heart failure was, until recently, unknown. Using in silico bioinformatics analyses, we identified one circular RNA named MICRA for Myocardial Infarction-associated Circular RnA. MICRA was a robust predictor of LV remodelling in two independent cohorts of AMI patients (JACC 2016).
Purpose: To provide a molecular and functional characterization of MICRA.
Methods and Results: MICRA is a 874 nucleotides-long circRNA formed mainly from exon 1 of the zinc finger protein 609 (ZNF609) gene located on chromosome 15q22. The functions of ZNF609 and MICRA are unknown.
First of all, the circularity of MICRA was demonstrated using quantitative PCR with divergent primers, a TaqMan probe spanning the junction site, sequencing, northern blotting, cloning and over-expression in HEK293 cells, and digestion with RNase R (RNase R is able to digest linear RNAs but not circRNAs).
Then, MICRA expression was measured in whole blood samples obtained at admission in 409 AMI patients. MICRA was positively correlated with the ejection fraction (r=0.18, $p = 0.001$) and negatively correlated with the NYHA score at 4 months (OR 0.33 [0.14-0.74], $p = 0.007$), consistent with a protective role of MICRA.
MICRA was predominantly expressed by lymphocytes and was positively correlated with CD8 and FoxP3, markers of suppressive T regulatory cells which are known to play a protective role in the infarcted heart. In CD8 + CD25 + T cells isolated from healthy donors and activated in vitro by anti-CD3/CD28 beads and interleukin-2, MICRA was decreased and IL10 and FoxP3 were increased (Figure).
MICRA was readily expressed in the human heart and was up-regulated in failing ($n = 22$) compared to non-failing ($n = 5$) hearts ($P < 0.01$). MICRA was positively

associated with CD3 and CD8, suggesting that its over-expression in failing hearts was attributable to infiltrated blood lymphocytes.
Finally, MICRA was very weakly expressed or absent in plasma, serum, and exosome-enriched plasma fractions.
Conclusion: We have characterized MICRA, a novel circRNA predicting the development of heart failure after AMI. MICRA is expressed by lymphocytes and may participate in the function of T regulatory cells after AMI. Further investigation of the therapeutic potential of these findings is warranted.

Saliva: linking oral health with heart failure

X Xi Zhang[1]; B Schulz[2]; T Walsh[1]; J Atherton[3]; K Kostner[4]; C Punyadeera[1]
[1]Queensland University of Technology, Institute of Health and Biomedical Innovation, Brisbane, Australia; *[2]University Of Queensland, School of Chemistry and Molecular Biosciences, Brisbane, Australia*; *[3]Royal Brisbane and Women's Hospital, Cardiology, Brisbane, Australia*; *[4]Mater Adult Hospital, Cardiology, Brisbane, Australia*

Background: Heart failure (HF) is a severe complication that affects 26 million people world-wide and the incidence is growing due to an aging population. The lack of early screening program for HF hinders early detection and targeted treatment and contributes greatly to the mortality of HF. Human saliva contains a large number of circulating proteins that can serve as indicators of the body's health and well-being. Previous research from us and others have demonstrated the possibility of detecting cardiac specific biomarkers in saliva. These biomolecules enter saliva through diffusion, active transport or filtration.
Purpose: We aimed to investigate the diagnostic potential of saliva for HF.
Methods: Saliva samples were collected from age-matched healthy controls (n = 20) and HF patients (n = 40). We employed an unbiased approach to investigate the salivary proteomics profiles of HF patients and healthy controls using SWATH-Mass Spectrometry. Potential candidate proteins were identified based on their abundance levels in saliva and their biological functions. These findings have further been validated using biological and technical replications.
Results: This unbiased approach identified six candidate proteins in saliva and this panel of six proteins correlated with disease severity. These six candidates were then combined into a prediction model using logistic regression. At the optimal cut-off point, the panel demonstrated excellent diagnostic performance (sensitivity = 77.1% and specificity = 71.4% and AUC = 0.84).
Conclusion: We were able to identify proteins in human saliva that can distinguish HF patients from healthy controls. Prior to clinical implementations, these findings should be verified in larger asymptomatic patient cohorts. There is evidence that salivary proteins can be used in developing early screening/diagnosing tools for HF.

Reduced bioavailability of nitric oxide is a hallmark of endothelial dysfunction in metabolic and cardiovascular diseases,but its quantification in circulating blood remains a challenge.NO can form iron-nitrosyl complexes with hemoglobin(5-coordinate-α-HbNO) in erythrocytes(RBCs).We hypothesized that this complex,predominantly formed in venous blood,reflects bioavailability of vascular NO and endothelial function in vivo.We developed a modified subtraction method using EPR to quantify it in RBCs from mouse,rat and human venous blood.We HbNO observed in RBC from the three species ex vivo.The circulating concentration was 425nM in rodents and 92nM in human venous blood.NO could be supplied from vascular or intraerythrocytic NOS.We detected eNOS proteins in RBC from rodent and human.To test eNOS functionality,we measured nitrite/nitrate production and HbNO formation in human RBCs and from eNOS(+/+) and eNOS(-/-)mice in vitro and its sensitivity to NOS or arginase inhibitors.Nitrite and HbNO signals increased after arginase inhibition and were abrogated upon NOS inhibition in human and eNOS(+/+) but insensitive to these modulators in eNOS(-/-)RBCs.HbNO signal from venous RBCs was minimally sensitive to NOS inhibitor ex vivo,suggesting that intraerythrocytic NOS contributes little compared with vascular eNOS or other NO sources reaching RBCs in vivo.We found that upon exposure to exogenous NO donor,the formation of HbNO was higher in hypoxic conditions (1%of O2:0.018+/-0.002 μmolHbNO/μmol)compared to room air(0.0036+/-0.0004 μmolHbNO/μmol) and inversely correlated with ratio of oxy- to deoxy- forms of Hb.The stability of pre-formed HbNO was higher under hypoxia(17%degradation after 30 min1%of O2 vs 49%room air),and preserved at 21% of O2 by incubation with catalase (CAT:2μM HbNO/L vs 0.5μM HbNO/L untreated controls),whereas superoxide dismutase had minimal effect.CAT inhibition increased ROS formation in RBCs,measured by FACS analysis of DCFDA fluorescence.This suggested that HbNO formation is sensitive to oxidative degradation,possibly by H2O2.We compared circulating HbNO levels in venous RBCs from normal volunteers or patients with cardiovascular diseases and found decreased HbNO in patients(0.141+/-11μmol/L vs0.22+/-12μmol/L in volunteers;N=38 and48).HbNO was significantly correlated with endothelial function(ENDO-PAT) and(inversely) correlated with major cardiovascular risk factors.We conclude that HbNO reflects exposure of RBCs to NO in vivo and is sensitive to oxidative degradation by H2O2.HbNO could be developed as a biomarker of NO biovailability and/or oxidative stress ex vivo.

P2036
Evidence-based nursing interventions which improve heart failure patients under mechanical circulatory support outcomes: an integrative review

T Teresa Pessoa[1]; T Leal[2]
[1]Hospital Lisbon North, Hospital Santa Maria, Lisbon, Portugal; *[2]ESEL, Lisboa, Portugal*

Background: Heart Failure (HF) is a major and growing issue in Public Health worldwide. Mechanical Circulatory Support (MCS) is a non pharmacologic therapeutic recommended to highly selected patients. Advanced Nursing Practice requires nurses to have actualized scientific knowledge in their specialty area, integrating it with the empirical knowledge derived from daily practice of patient centered care.
Purpose: To identify and describe evidence-based nursing interventions which improve the outcomes of patients with HF under MCS.
Methods: Integrative literature review based on a systematic research in MEDLINE, CINAHL and Cochrane databases and manual search on Google and Researchgate of original articles and literature reviews published between January 1st, 2010 and August 31st, 2016. There have been included studies related to adult HF patients with formal indication or under MCS in which the first author was a nurse. The studies related to patients under MCS devices such as intra-aortic baloon counterpulsion or venovenous extracorporeal membrane oxygenation have been excluded.
Results: From the 41 articles included, the nursing interventions evidence-based found in this integrative review were grouped in four nursing care areas such as perioperative care, patient and caregiver education, post-discharge care and palliative care, particularly focused on clinic and hemodynamic evaluation, MCS device management, anticoagulation management, immobility prevention and control, nutritional support, rehabilitation and functional readaptation, self-care facilitation, infection prevention and control, decision making, advanced directives, end of life support and support of systems.
Conclusion: HF patients centered care under MCS is complex, requires teamwork and relational skills, and it depends on the best available evidence-based scientific knowledge, on stakeholders' life experience and on context and environment specificity in which we find ourselves. Patient outcomes can be improved by prevention and early identification of MCS related complications. There is a need to standardize practices and to develop protocols and guidelines to improve nursing care in this particular group of patients. The creation and implementation of training programs on MCS could be an advisable way to improve advanced nursing practice.

P2037
The protective effect of aerobic exercise preconditioning in female rats with hypoxic pulmonary hypertension depends on the female sex hormone

N Natalia Medvedeva[1]; N Pankova[1]
[1]M.V. Lomonosov Moscow State University, Biology Department, Moscow, Russian Federation

Introduction: The influence of exercise preconditioning on the development of pulmonary hypertension (hPAN) is studied a long time. However, the answer has not been received. It was shown that physical exercise can both positively and negatively influence on the disease. The result depends on the type of pulmonary hypertension, hemodynamic, age and others. It was shown that exercise to improve endothelial function (Mereles 2006). The same mechanism underlies the protective effect of female sex hormones on the development of pulmonary hypertension. Can these influences interact? The aim of current research was to study the effect of aerobic exercise preconditioning on the degree of hPAN in the gonadectomized female rats and rats with preserved ovaries.
Methods and design: Female Wistar rats were used. They were divided into 8 groups, four were with hPAH (H) and four without (C). Two groups from (H) and (C) rats were gonadectomized (HG and CG) and two were with ovaries (HN and CN). One group from HG,CG,HN,CN were with exercise preconditioning (groups HGEx, CGEx,HNEx,CNEx) and one group were without exercise (groups

Table P2038: Parameters of the experimental

	Control	MCT	MCT + G1	MCT effect	Estrogen effect	Interaction effect

Left Ventricular Ejection Fraction (LV EF; %), LV end-systolic pressure (LVESP; mmHg), LVESP-Volume Relation (LVESPVR; mmHg/relative volume unit), LV end-diastolic pressure (LVEDP; mmHg), LVEDP-volume relation (LVEDPVR; mmHg/relative volume unit) RV end-systolic pressure (RVESP; mmHg) RV end-diastolic pressure (RVEDP; mmHg); Coronary relaxation (% at Ach 3.10-5 M). *: p <.05 vs. Lean; †: p<.05 vs. Zucker.

HGC,CGC,HNC,CNC) The procedures followed the FELASA/ICLAS for use of the laboratory animals, hPAH was induced by exposure to hypobaric hypoxia. Rats were housed in a hypobaric chamber at simulated altitude of 5000 m, 10 h a day, 2 wk. (O2 concentration reduced to 10%).For exercise preconditioning rats were subjected to exercise training (aerobic swimming during 30 min/day.) for a period of 2 weeks to hypoxia. Right ventricular (RV) hypertrophy was calculated as RV weight /w.h. Systolic right ventricle pressure (SRVP) was measured.

Results: Two weeks after chronic hypoxia exposure all (H) groups of rats developed hPAH. In rats of (H) groups average SRPV was on78% more than SRPV in rats of C groups ($p < 0,05$). Between rats of all C groups were not difference in the magnitude of SPRV. However the degree of disease was different in groups (H): the magnitude of SRPV was significantly smaller in HGEx rats than in HNEx and HGC (50,58 + 1,54 vs.66,86 + 4,30 vs.61,1 + 5,7 mm Hg $p < 0.05$). There were not differences in SRPV between HNC, HNEx and HGC groups. In hypoxia gonadectomized rats were not difference in RV hypertrophy. But in hypoxia rats with ovaries the magnitude of RV hypertrophy was significantly smaller in group with exercise preconditioning (26,29 + 2.80 vs. 23,49 + 2,51 $p < 0,05$).

Conclusions: Aerobic exercise preconditioning has a protective effect on the development of hypoxic pulmonary hypertension in the female rats. The effect depends on the female sex hormone. A reduction of systolic right ventricle pressure in the gonadectomized rats and a decrease in right ventricle hypertrophy in rats with preserved ovaries observed.

P2038

Activation of a new estrogen receptor (GPER) ameliorates cardiopulmonary dysfunction in female rats with pulmonary hypertension.

G Gisele Zapata-Sudo[1]; AKNA Allan Kardec Nogueira De Alencar[1]; AMS Ananssa Maira Da Silva[1]; GCM Guilherme Carneiro Montes[1]; TLM Tadeu Lima Montagnoli[1]; SM Sabrina Martinez[1]; LV Luiza Villarinho[1]; VNC Valeria Nascimento Cunha[1]; AF Aline Fraga[1]; HW Hao Wang[2]; LG Leanne Groban[2]; CAMF Carlos Alberto Manssour Fraga[1]; RTS Roberto Takashi Sudo[1]
[1]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; *[2]Wake Forest University, Winston-Salem, United States of America*

Funding Acknowledgements: CNPq, CAPES, PRONEX, FAPERJ, and INCT-INOFAR

Introduction: Pulmonary hypertension (PH) is a disease of women, and induces right ventricle (RV) failure. Hypothesis: The activation of an estrogen receptor (GPER) by the agonist G1 was evaluated in monocrotaline (MCT)-induced PH female rats.

Methods: Depletion of estrogen was performed by oophorectomy (OVX; n = 18) in female Wistar rats. Experimental groups included SHAM or OVX rats that received a single injection of MCT (60 mg/kg, i.p.) for PH induction followed by administration of vehicle or G1 (400 μg/kg/day s.c.) for 14 days after PH onset (n = 7 per group).

Results: MCT injection and estrogen loss led to a decrease in pulmonary acceleration time and an increase in RV hypertrophy in PH rats and MCT-related changes were attenuated by treatment with G1 ($P < 0.05$; Table 1). RV pressure (RVP) was higher in MCT-injected rats and this increase in OVX group was higher than that in SHAM. G1 reduced RVP in both SHAM and OVX rats (Table 1). G1 normalized the expression of calcium handling proteins in the RVs (Table 1). G1 reduced pulmonary arteries wall fibrosis and hypertrophy in both MCT-treated SHAM and OVX rats ($P < 0.05$).

Conclusion: G1 reversed cardiopulmonary dysfunction in female rats, a finding that may have important implications for the treatment of PH in women.

P2039

Improved metabolic syndrome-related right and left ventricular dysfunction by the dual ETA-ETB receptor antagonist macitentan.

M Marianne Lachaux[1]; N Harouki[1]; N Peschanski[1]; L Nicol[1]; A Dumesnil[1]; J-P Henry[1]; S Renet[1]; I Remy-Jouet[1]; M Iglarz[2]; V Richard[1]; P Mulder[1]
[1]INSERM U1096, ROUEN, France; *[2]Actelion Pharmaceuticals, Basel, Switzerland*

Funding Acknowledgements: Actelion pharmaceuticals

Background: WHO group II pulmonary hypertension (PH due to left heart disease), represents a major health problem with significant morbidity and poor prognosis. Endothelin (ET) receptor blockade is a promising therapeutic approach, since ET-1 is a key player in PH and is probably involved in the development of left heart disease and cardiac hypertrophy and fibrosis via both ETA and ETB receptors. However, whether ET receptor blockade exerts protective effects on PH due to left heart disease is unknown.

Purpose: To evaluate the effects of dual ET receptor antagonism in a rat model of metabolic syndrome-related right and left ventricular dysfunction.

Methods: We assessed in Zucker fa/fa rats the effects of long-term (90 days) macitentan treatment (ETA/ETB receptor antagonist; 10 mg/kg/day as food additive) on LV and RV remodeling/function (MRI), LV and RV hemodynamics (catheterization) and coronary function (myograph).

Results: After 3 months, untreated Zucker rats presented both LV diastolic dysfunction (elevation of LV End-Diastolic Pressure (EDP) and LV End-Diastolic Pressure Volume Relation (EDPVR) without change in LVESPVR) associated with increased collagen deposition. Simultaneously, left coronary artery relaxation to acetylcholine was impaired. Zucker rats developed PH and RV dysfunction characterized by increases in RVESP and RVEDP. Macitentan significantly prevented LV and RV dysfunctions as well as coronary dysfunction, associated with a reduced LV collagen density (Lean: 0.93 ± 0.10 %; Zucker: 1.32 ± 0.13 %, $p < 0.05$ vs lean; Zucker + macitentan: 0.76 ± 0.06 %, $p < 0.05$ vs Zucker).
Conclusions: The dual ET receptor antagonist macitentan prevents LV diastolic dysfunction and reduces RV pressure in a model of PH due to left heart disease.

P2040

Benefit of combined therapy with Sildenafil and LASSBio-1359 in preventing monocrotaline-induced rat pulmonary hypertension.

RT Roberto Takashi Sudo[1]; FIC Fabio Indias Carvalho[1]; AKNA Allan Kardec Nogueira De Alencar[1]; AMS Ananssa Maira Da Silva[1]; SM Sabrina Martinez[1]; CAMF Carlos Alberto Manssour Fraga[1]; EJB Eliezer Jesus Barreiro[1]; GZS Gisele Zapata-Sudo[1]
[1]*Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*

Funding Acknowledgements: CNPq, CAPES, PRONEX, FAPERJ, and INCT-INOFAR

Background and Purpose: Pulmonary hypertension (PH) is characterized by enhanced pulmonary vascular resistance, subsequent right ventricle (RV) pressure overload, which ultimately results in right-sided heart failure and death. This study was designed to assess if the effectiveness of a combined therapy with sildenafil, a phosphodiesterase type 5 inhibitor (PDE5i), and LASSBio-1359, a new adenosine A2A receptor (A2AR) agonist, is superior to either compound alone in mitigating monocrotaline (MCT)-induced rat PH.
Experimental Approach: For in vitro study, an isobolographic analysis was performed to identify a possible synergistic relaxation effect between sildenafil and LASSBio-1359 in rat pulmonary artery (PA). For in vivo protocol, PH was induced in male Wistar rats by a single intraperitoneal injection of MCT at a dose of 60 mg/kg. Rats were divided into the following groups: control (saline injection only), MCT + vehicle, MCT + sildenafil (34 μg/kg/day), MCT + sildenafil (170 μg/kg/day), MCT + LASSBio-1359 (34 μg/kg/day), MCT + LASSBio-1359 (170 μg/kg/day) and MCT + combination of sildenafil and LASSBio-1359 (34 μg/kg/day each one). Fourteen days after MCT injection, rats were treated daily with oral administration of the regimen therapies or vehicle for 14 days. Cardiopulmonary system function and structure were evaluated by echocardiography. RV systolic pressure (RVSP) and pulmonary artery endothelial function were further measured.
Key Results: Isobolographic analysis showed synergistic interaction between sildenafil and LASSBio-1359 in rat PA arteries. In vivo monotreatment with low-dosages (34 μg/kg/day) of both compounds did not reverse the deleterious effect of PH on PA flow, pulmonary vasculature reactivity, RV structure and function, but combined modality of a PDE5i with an A2AR agonist ameliorated all these PH-related abnormalities of the cardiopulmonary function and structure in MCT-challenged rats.
Conclusion and Implications: In vitro and in vivo synergism interaction between sildenafil and LASSBio-1359 suggest a combined use of both compounds to improve life-quality and outcomes of a higher population of patients with PH in the future.

P2041

Ivabradine improves left ventricular twist and untwist in the hypertrophied heart and preserves contraction-relaxation coupling.

M Jozwiak[1]; J Melka[1];
M Rienzo[1]; A Bize[1]; L Sambin[1]; L Hittinger[1]; A Berdeaux[1]; JB Su[1]; B Bouhemad[2]; B Bijan Ghaleh[1]
[1]*INSERM U 955 Equipe 03, Creteil, France*; [2]*University Hospital of Dijon, Service d'Anesthesie Reanimation, Dijon, France*

Funding Acknowledgements: INSERM, AFM, CODDIM, SFHTA, Fondation de l'Avenir

Background: Tightly coupled and abnormal left ventricular (LV) isovolumic contraction and relaxation are observed during chronic hypertension and LV hypertrophy. These altered systolic and diastolic functions are associated with maladaptive LV responses to tachycardia. However, isovolumic periods do not reflect the whole cycle and more global assessment is needed. Interestingly, LV twist and untwist are LV myocardial deformation that occurs during the overall systole and diastole, respectively.
Purpose: To investigate contraction-relaxation coupling using LV twist and untwist analysis and to determine the effect of acute heart rate (HR) reduction with ivabradine (1 mg/kg iv) on global systolic and diastolic function in a pig model of chronic hypertension.
Methods: Eight chronically instrumented pigs received angiotensin II infusion during 28 days to induce chronic hypertension. LV function was investigated by combining hemodynamic and echocardiographic measurements. All measurements were performed at Day 0 and at Day 28 while angiotensin II infusion was stopped.
Results: Chronic infusion of angiotensin II significantly increased LV posterior and septal wall thicknesses as well as the estimated LV mass, indicating LV hypertrophy. HR increased by 15%. LV untwist was significantly reduced (-104 ± 8 vs. -154 ± 9 °.s-1, at Day 0 vs 28, respectively, $p < 0.05$), showing global LV diastolic dysfunction. Concomitantly, LV twist was also significantly altered (11 ± 1 vs. 16 ± 1 °, at Day 0 vs 28, respectively $p < 0.05$), showing global LV systolic dysfunction. Interestingly, there was a strong relationship between LV twist and untwist so that the ratio between LV twist and untwist remained unchanged between Day 0 and Day 28 (0.107 ± 0.013 vs. 0.108 ± 0.012, p = NS). It suggests that contraction-relaxation coupling was preserved with the development of LV hypertrophy. In this context, ivabradine decreased HR by 25% (from 86 ± 5 to 63 ± 3 beats/min, $p < 0.05$) and significantly improved both LV twist (from 11 ± 1 to 14 ± 1°, $p < 0.05$) and LV untwist (from -104 ± 8 to -146 ± 5°.s-1, $p < 0.05$), showing that HR reduction with ivabradine improved both global systolic and diastolic LV functions. In addition, ivabradine did not alter contraction-relaxation coupling, as shown by the unchanged absolute ratio between LV twist and untwist at baseline and after ivabradine administration (0.108 ± 0.012 vs. 0.100 ± 0.004).
Conclusions: LV twist and untwist were altered in this model of chronic hypertension and LV hypertrophy but they remained tightly coupled. Acute HR reduction with ivabradine improved both LV systolic and diastolic functions without altering contraction-relaxation coupling.

RAPID FIRE 7 - ACUTE HEART FAILURE

2064

The degree of pulmonary congestion measured by non-invasive lung impedance is the key determinant of heart failure hospitalizations: Lessons from the extended IMPEDANCE-HF trial.

M Michael Kleiner Shochat[1]; A Shotan[1]; M Kazatsker[1]; A Asif[1]; I Kleiner[2]; JM Weinstein[2]; I Dahan[1]; D Blondheim[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; [2]Saroka Medical Center, Cardiology, Beer Sheva, Israel

Results of the IMPEDANCE-HF trial have shown that lung impedance (LI)-guided treatment reduces hospitalizations for heart failure (HF) and decreases HF-related mortality. The main trial was extended for an additional year to accrue more data on predictors of hospitalizations due to HF. The main aim of the study was to prove that HF patients with higher degree of long-standing pulmonary congestion are hospitalized more often.

Methods: Study population included 266 patients, with HF and LVEF≤35% in New York Heart Association class II-IV. Patients were randomized (1:1) to a control group treated by clinical assessment and a monitored group whose therapy was also assisted by LI. Patients were examined and LI measured monthly in our outpatient clinics. Noninvasive LI measurements were performed with the high-sensitive device. Assessment of the degree of pulmonary congestion was by the new index LIR, measured at each visit and calculated as LIR = {1- [currently measured LI/ normal baseline (calculated for each patient)] × 100} expressed as percentage. The annual average LIR for each patient was calculated as the mean of all LIR measurements at each consecutive year of follow-up.

Results: The total follow-up period was 634 years in the monitored group and 483 years in the control group ($p = 0.001$). Groups were similar with respect to baseline characteristics. There were 228 and 431 HF hospitalizations (mean 0.54 and 1.29 per × year of follow up) in the monitored and control groups, respectively ($p < 0.001$). There were 54, 35, 22 and 74, 62, 49 all-cause, cardiac and HF-associated death cases in the monitored and the control groups, respectively ($p < 0.001$). Figure 1 shows the dynamics of pulmonary congestion in study groups during the follow-up period as represented by LIR, demonstrating a significantly lower level of pulmonary congestion in the monitored group compare with the control group during the study ($p < 0.001$).

Conclusion: The Extended IMPEDANCE-HF demonstrated that pre-emptive LI-guided therapy of HF patients reduced pulmonary congestion significantly more effectively than by treatment according to clinical assessment only. This effect appeared to be consistent during the whole study period. Since groups were similar with respect to baseline characteristics, we proposed that the main reason for reducing the number of HF hospitalizations and improving survival was better decongestion achieved in the monitored group.

Impact of nitrate use on morbility and mortality in acute heart failure

L Reis[1]; A Fernandes[1]; C Lourenco[1]; R Teixeira[1]; P Dinis[1]; M Madeira[1]; J Ribeiro[1]; L Puga[1]; I Almeida[1]; J Nascimento[1]; L Goncalves[1]
[1]University Hospitals of Coimbra, Coimbra, Portugal

Introduction: The current pharmacological treatment in acute heart failure (AHF) consists mainly of the use of diuretics in addition to vasodilators or inotropes. The drugs recently studied in AHF have shown no impact on the prognosis. For years, nitrates have been used to treat patients (P) with AHF (recommendation IIa according to the guidelines of the European Society of Cardiology of 2016) however, there is limited evidence of the impact of nitrates on morbidity and mortality of these P.

Purpose: To evaluate the prognostic impact of the early administration (first 24 hours) of intravenous nitrates in P admitted by AHF.

Methods: Retrospective study with 264 P admitted in a cardiac intensive care unit, between February 2010 and November 2016. P with adequate arterial pressure were selected for nitrates therapy (systolic arterial pressure> 90mmHg, N=227) and divided into 2 groups - G1: nitrates, N=103 and G2: no-nitrates, N=124. Demographic, laboratory, echocardiographic variables and in-hospital mortality were compared. Clinical follow-up (5 years) was performed targeting for readmission with AHF and mortality.

Results: The population mean age was 69 ± 14 years old with a majority of male (78%). The etiology was ischemic in 28% of the P and 46% had left ventricular ejection fraction (LVEF)≤35%. Readmission with AHF occurred in 42% and in-hospital mortality and during follow-up was 11% and 36%, respectively.

The groups presented similar clinical and analytical characteristics: congestive HF (G1 100% vs 91% G2, $p = 0.52$), presence of cardiovascular risk factors, NT-proBNP values (G1 16972 ± 21511 pg/nL vs G2 19028 ± 41691 pg/nL , $p = 0.357$), creatinine on admission (G1 159 ± 113 μmol/L vs G2 149 ± 192 μmol/L, $p = 0.23$), chronic kidney disease (G1 46% vs G2 44%, $p = 0.25$) and cardio-renal syndrome (G1 56% vs G2 57%, $p = 0.23$). They were similar regarding LVEF (G1 38 ± 12% vs G2 34 ± 14%, $p = 0.10$) and presence of coronary artery disease (G1 47% vs G2 47%, $p = 0.24$). There were no differences in the diuretic dosage (G1 174 ± 119mg vs G2 152 ± 97mg, $p = 0.15$) and in the use of noninvasive ventilation (G1 62% vs 38%, $p = 0.60$).

In-hospital mortality (G1 56% vs. G2 44%, $p = 0.83$) and during follow-up (G1 61% vs G2 39%, $p = 0.58$) were similar, however we found that patients of G1 had a shorter hospital stay (G1 11 ± 7.9 days vs G2 15 ± 15 days, $p = 0.001$) and a lower percentage of readmission with AHF (G1 31% vs. G2 39%, $p = 0.018$).

Conclusions: In our population the early use of intravenous nitrates in P with AHF had no impact on mortality. However, it's associated with a shorter hospital stay and a lower readmission rate due to AHF.

Utilization of proton pump inhibitors in patients with atrial fibrillation is associated with hospitalization for de novo acute heart failure

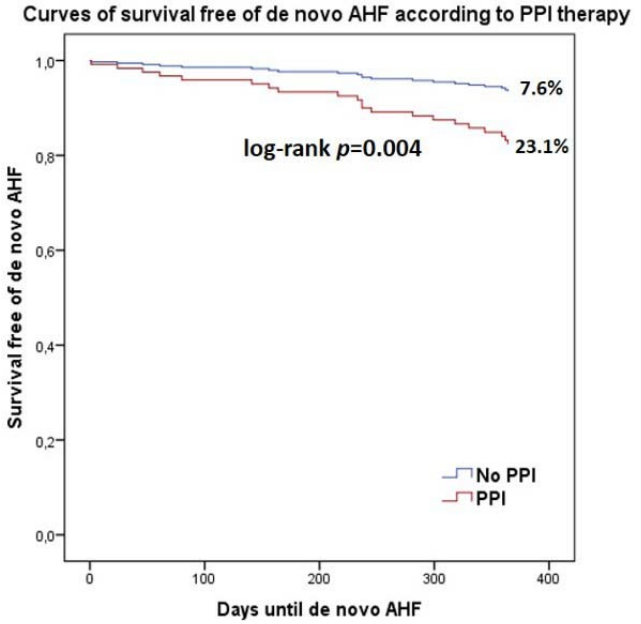
J B Augusto[1]; M Borges Dos Santos[1]; D Roque[1]; D Faria[1]; H Ferreira[1]; J Urzal[1]; C Santos[2]; C Morais[1]
[1]Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal; [2]Hospital Santo Andre, Leiria, Portugal

Background: Proton pump inhibitors (PPIs) are frequently used among patients with atrial fibrillation (AF). In patients under PPI therapy, anaemia due to both iron and vitamin B12 deficiencies may ensue.

Purpose: We aimed to evaluate the incidence of hospitalization for de novo acute heart failure (AHF) at 12-month follow-up in patients with atrial fibrillation who were under PPI therapy.

Methods: We included retrospectively 2181 consecutive patients with AF who were evaluated in our Emergency Department (ED) in a 12 month period. Among them, 423 patients were admitted for in-hospital management. Patients who had previous known heart failure (n = 101), who were under antiplatelet therapy (aspirin, clopidogrel and/or ticagrelor) (n = 109) and those with history of dyspepsia, gastroesophageal reflux, peptic ulcer disease or gastrointestinal bleeding (n = 30) were

excluded. We recorded the haematocrit (Htc) nadir during in-hospital stay. We further determined the proportion of PPI prescription at discharge. Primary outcome was the incidence of hospitalization for de novo AHF 12 months after discharge.
Results: We included 172 AF patients who were successfully discharged and followed for 12 months (mean age of 69.3 ± 12.8 years, 37.2% males). A total of 30.8% (n = 53) had a PPI prescription at discharge. In all of these cases, PPIs were also prescribed during in-hospital stay. Nadir Htc during hospitalization was significantly lower in patients under PPI therapy (median of 37.4 vs. 40.4%; p = 0.003). Kaplan-Meier analysis (Figure) showed that patients with AF who were taking PPIs had a higher incidence of de novo AHF 12 months after discharge (23.1 vs. 7.6%; log-rank p = 0.004). Cox regression analysis controlled for age and chronic kidney disease showed that PPI therapy was an independent predictor of de novo AHF (HR 2.90; CI 95% 1.22 – 6.90; p = 0.016).
Conclusions: Approximately one third of the AF patients were treated with PPI, the vast majority without formal indication. PPI overuse was associated with anaemia and hospitalization for de novo acute heart failure and therefore its use must be carefully weighted in clinical practice.



Survival free of de novo AHF

Funding Acknowledgements: Enterprise Ireland, ResMed, Boston Scientific, Cardiomark

Introduction: Heart failure (HF) admission rates present a major challenge. There is a paucity of data relating to the pre-hospital phase of care prior to admission with ADHF.
Purpose: To achieve a more complete understanding of this pre-hospital period, which may highlight ways we can improve pre-hospital care and thereby prevent admission.
Method: As part of an ongoing multicentre study analysing care pathways in patients admitted to hospital with ADHF (de novo patients, DN, and recurrent admitters, RA), focus was placed on the pre-hospital period to assess duration of symptoms, numbers seeking pre-hospital medical assessment, the nature of any intervention prescribed and (for RA) reporting of weight gain. This analysis is taken from one of the study centres. Data were gathered from clinical patient surveys, conducted by a HF nurse specialist.
Result: Of a total of 113 patients, 57 (50.4%) were DN and 56 (49.6%) were RA. A symptom duration of >3 days was reported in 76.4% (42) of DN and 64.2% (34) of RA. Of RA, 75% (42) reported monitoring their weight and 57.1% (24) of those noted a weight gain of >2kg over two days with their symptoms. Of those who noted a weight gain, 79.2% (19) reported it to a doctor prior to admission. There was a high number seeking pre-hospital medical assessment (via a GP/HF/general cardiology clinic): 66.7% (38) of DN and 67.9% (38) of RA. Cardiology review (general/HF) was more common in RA than DN (39.3% vs. 3.5% respectively, p = 0.000); while more DN were reviewed by a GP only than RA (63.2% vs. 28.6%, p = 0.000). Of DN who were seen by a GP only, 11.1% (4) were prescribed a HF-directed intervention (HFI, commencement of a diuretic or alteration of an established diuretic regimen) and of RA who were seen by a GP only, 12.5% (2) were prescribed an HFI.
Conclusion: Due to the prolonged duration of symptoms and high rate of patients seeking medical advice in the community, there is both time and opportunity in which to implement a more effective HFI. Improved patient education and recognition of HF features by GP's with streamlined access to outpatient specialist assistance may allow for earlier appropriately directed HFI, potentially reducing the risk of admission.

	De Novo (DN)	Recurrent Admitters (RA)
Pre-hospital Assessments(no. of patients, all reviews)	38 (66.7%)	38 (67.9%)
Pre-hospital Assessments(no. of patients, GP only reviews)	36 (63.2%)	16 (28.6%)
Treatment given by GP's*(no. of patients)	HFI: 4 (11.1%) Other**: 15 (41.7%) Nothing: 18 (50%)	HFI: 2 (12.5%) Other**: 4 (25%) Nothing: 10 (62.5%)
*to those 36 DN and 16 RA patients reviewed only by a GP prior to admission**primarily antibiotics with or without steroids

The weekend effect - a distraction to actual associations with in hospital mortality - a large single centre experience

C Broughton[1]; S Davies[1]; CS Kwok[1]; S Anderson[1]; J Brough[1]; N Cotton[1]; F Umar[1]; A Appaji[1]; I Crossley[1]; S Duckett[1]; D Barker[1]; A Patwala[1]; U Kadam[2]; M Mamas[2]; DK Satchithananda[1]
[1]University Hospital North Midlands, stoke-on-trent, United Kingdom; *[2]Keele University, stoke-on-trent, United Kingdom*

Introduction: The data as to whether weekend admissions increase in patient mortality in acute heart failure (AHF) admissions are conflicting. Multi-centre outcomes for weekend admissions may be confounded by multiple institutional factors. We present the largest, single centre data examining whether in hospital mortality is associated with weekend admissions in comparison to other routinely collected patient data.
Methods: Routinely collected hospital episode data were analysed from January 2012 - December 2016 for emergency admissions with AHF to our university teaching hospital serving a population of 600000. Patients were identified by standardised national codes identifying AHF hospitalisation. All patients admitted on Saturday or Sunday were weekend admissions. Comparisons between survivors and all deaths, and weekday vs weekend admissions were made using unpaired Students t test and Chi 2 test as appropriate. P values of <0.05 were statistically significant.
Results: 4417 patients were admitted during the study: 3873 survived to discharge (in hospital mortality 12.3%). 21.3% (941/4417) were admitted at the weekend. The table below demonstrates comparative data for: for the total group, survivors vs. in hospital deaths, all patients weekday vs. weekend admissions. ** = $p<0.05$. There were no significant demographic, length of stay early or late in hospital mortality differences in AHF patients admitted during the weekend. AHF patients surviving to discharge are younger, less co-morbid and have shorter lengths of stay than patients with AHF who die in hospital.
Conclusions: There is no evidence of a 'weekend effect' on in hospital mortality in nearly 4500 admissions with AHF. We have demonstrated that in hospital mortality depends more on: pre-existing patient characteristics (e.g. extreme age, number of co-morbidities) and by in-patient factors reflected in the length of stay than by weekend admission date.

Table 2068

	Total AHF admissions n=4417	AHF survivorsn=3873	AHF in hospital deaths n=544	AHF admitted on a week day n=3476	AHF admitted at weekend n=941
Mean age (sd) in years	76.8(13.2)	76(13.4)**	83 (9.4)	76.6 (13.1)	77.6 (13.3)

Funding Acknowledgements: Abiomed research funding

The prognosis of cardiogenic shock (CS) remains substantial although advances have been accomplished over the past decades. Amongst patients with CS mortality remains more than 40%, which is even worth in cases of refractory CS. In recent years, devices for transient mechanical support such as microaxial pump (Impella) or veno-arterial extracorporeal membrane oxygenation (vaECMO) have changed the field. Timing, efficacy, monitoring, weaning and many other aspects of the management of mechanical support are fairly unknown. This is particularly true for the case of combined mechanical support, where experiences are scarce.

We evaluated 55 consecutive patients (age 53 ± 2 yrs, 45 male/10 female) who were biventricularly supported by vaECMO and Impella microaxial pump due to refractory CS despite goldstandard intensive care. Cardiogenic shock resulted from cardiomyopathy (40%), STEMI (17%), NSTEMI (7%), and arrhythmia (15%). During the ICU-course patients were critically ill: e.g. 93% mechanical ventilation, 53% dialysis, 38% resuscitation. Impella and vaECMO were inserted and removed percutaneously via femoral access (duration of dual mechanical support: 107 ± 72 hrs). The length of ICU-/in-hospital stay was 12 ± 2 and 27 ± 5 days. Following the installation of mechanical support, hemodynamics stabilized while number and dosing of catecholamines could be reduced (dobutamine: BL 5.6 ± 4.2, 24-hrs 2.9 ± 3.1, 72-hrs 2.2 ± 2.7 mg/kg/min, $p < 0.0001$ vs. BL; norepinephrine BL 0.5 ± 0.6, 24-hrs 0.2 ± 0.3, 72-hrs 0.2 ± 0.3 mg/kg/min, $p < 0.0001$ vs. BL). As a measure of an improved periphery, lactate levels normalized rapidly (BL 8.5 ± 6.4, 24-hrs 2.4 ± 1., 72-hrs 2.1 ± 2.4 mmol/L, all $p < 0.05$ vs. BL). Although our patient cohort clearly constitutes a negative selection of CS patients with a devastating prognosis, in-hospital survival in our fragile population was only 42%. By contrast a substantial number of patients at-risk were rescued: 19 patients were bridged to recovery, and another 13 patients were bridged to VAD-implantation. Notably, in not a single patient weaning mechanical support had to be reinstalled after successful weaning, which positively reflects on our weaning concept of mechanical support devices. Furthermore, the safety profile of biventricular support was reasonable (11% DIC, 7% leg ischemia, 7% stroke, 6% compartment). In only 3 patients minor vascular access site problems occurred.

In conclusion, biventricular unloading by combined mechanical support using Impella microaxial pump vaECMO is efficacious in stabilizing and rescuing high-risk patients with refractory cardiogenic shock.

2070

Should we start ECLS and maintain the support after 24h for refractory cardiogenic emergencies?

N Hernandez[1]; JM Conil[2]; B Georges[2]; T Seguin[2]; F Bounes[2]; L Crognier[2]; S Silva[3]; C Biendel[4]; V Minville[3]; B Marcheix[5]; C Delmas[2]

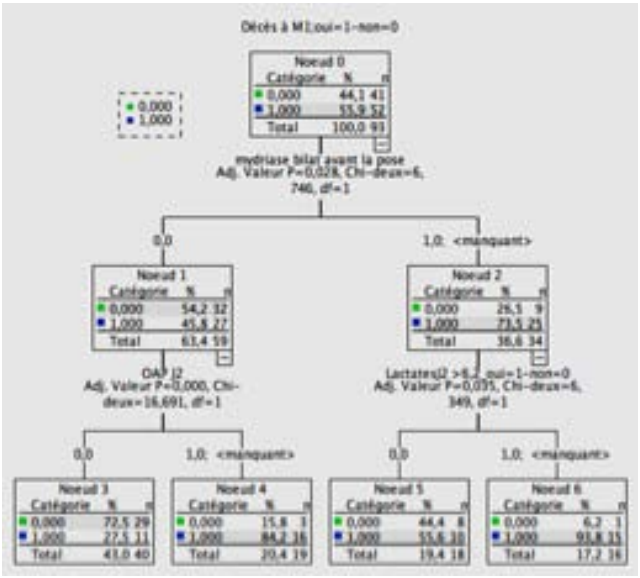
Introduction: Extracorporeal life support (ECLS) has taken an important place in the treatment of cardiogenic shock (CS) or refractory cardiac arrest (CA). Because the decision is taken in extreme emergency, the real challenges are the good patient selection and the early reassessment. The aim of this study was to research prognostic factors of 30-days mortality before and 24h after ECLS implantation for CS or CA.

Material and methods: All patients undergoing ECLS in our tertiary center during a 2-year period were prospectively included. The ECLS were managed with a multidisciplinary protocol based on consensus. Clinico-biological data were collected just before and 24h after ECLS implantation. These data were compared between survivors and deceased at one month.

Results: 94 patients were included with predominance of males (66%) and a median age of 53 years. ECLS was implanted for CA under resuscitation (29.8%), acute CS (37.2%), CS after CA (22.3%) and CS due to end-stage heart failure (10.6%). The 30-days mortality was 56.4%. Regarding the data before the implantation, a multivariate analysis (survival Cox model at 30 days) showed the influence of AMI (RR=3.06, IC95% [1.43-6.56]), bilateral mydriasis (RR=2.87, IC95% [1.30-6.31]), and a high lactate rate (RR=1.10, IC95% [1.02-1.18]). Regarding data 24h after ECLS, bilateral mydriasis before ECLS (RR=2.87, IC95% [1.34-6.07]), H24 arterial lactate rate>6.2mmol/l (RR=4.04, IC95% [1.96-8.32]) as well as acute pulmonary edema occurrence in the first 24h (RR=2.37, IC95% [1.20-4.70]) are significative prognostic markers of mortality. CHAID's segmentation method represented the patients' survival using the H24 covariables with a prevision of 75.3% and may help to stop or maintain ECLS after 24h of support (figure).

Conclusion: Simple biological and clinical parameters as initial mydriasis and a high lactate rate could help the ECLS decision. Moreover, the segmentation based on initial mydriasis, H24 lactate>6.2mmol/l and acute pulmonary edema 24h after ECLS support could serve to the early reassessment of the support for CA or CS.



Death prediction after 24h of ECLS

2071

Specialist input is the main determining factor for outcome in patients admitted with acute heart failure

N Al-Refaie[1]; M Phillips[2]; M Ashton[3]; S Lucas-Jones[3]; A Wong[3]
[1]John Radcliffe Hospital, Oxford, United Kingdom; [2]Princess of Wales Hospital, Bridgend, United Kingdom; [3]Princess of Wales Hospital, Cardiology Department, Bridgend, United Kingdom

Introduction: Acute heart failure (AHF) is associated with high mortality rates. UK national heart failure audit has highlighted higher in-patient mortality in patients who were managed by non-specialists, and the importance of specialist follow up.
Purpose: Compare in-patient mortality rates with 30 days, 6 months and 1 year mortality rates based on place of care, and determine the effect of specialist follow up on mortality rates.
Method: Retrospective analysis of data on 250 patients who were discharged with the primary diagnosis of heart failure from year 2014-2015.
Results: Inpatient mortality rate is significantly lower in patients treated in a cardiology ward compared to other medical wards (13% Vs. 23%, p value=0.03), however, 30 days, 6 months and 1 year mortality rates are not significantly different, although the trend still shows preference to the patients who were managed in the cardiac ward (30 days: 21.5% Vs. 25%, p value=0.3) (6 months: 32% Vs. 43%, p value=0.07) (1 year: 39% Vs. 46%, p value=0.16). Patients who were managed in cardiology ward were more likely to be followed up by specialists in the community (table 1). And patients who were followed up by HF specialists, regardless of the place of care were associated with significantly lower 6 months and 1 year mortality rates, compared to patients who were not followed up (6 months: 20% Vs. 35%, p value=0.04. 1 year: 26% Vs. 42%, p value=0.037).
Conclusions: In-patients mortality rate is significantly lower in AHF patients managed in cardiology ward. Similarly, specialist follow up was associated with lower mortality post discharge. These findings are likely to be attributed to better optimization of evidence based medicines, more comprehensive assessment, and patients' monitoring. This study highlighted that importance of specialist input in the management of such complex condition

	Cardiology ward N=158	Other medical wards N=92	P value
ECG	97%	88%	0.0002
Echo	92%	68%	0.0001

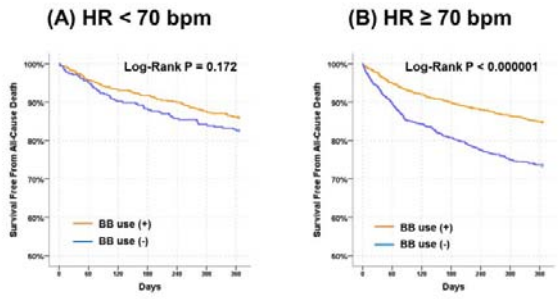
In acute heart failure with reduced ejection fraction beta blocker has no beneficial effect on 1-year mortality in patients with slow discharge heart rate

J J Jin Joo Park[1]; CH Yoon[1]; DJ Park[2]; IH Chae[1]; DJ Choi[1]
[1]Seoul National University Bundang Hospital, Division of Cardiology,, Seongnam, Korea Republic of; [2]Hangang Sacred Hospital, Division of Cardiology, Seoul, Korea Republic of

Funding Acknowledgements: This work was supported by Research of Korea Centers for Disease Control and Prevention [2010-E63003-00, 2011-E63002-00, 2012-E63005-00, 2013-E63003-0

Background: Many hospitalized heart failure patients with reduced ejection fraction (HFrEF) have low heart rate at discharge. Low heart rate may be a sign for reduced sympathetic activity, and the effect of beta blockers may be reduced in those patients as well.
Methods: The Korea Acute Heart Failure (KorAHF) registry consecutively enrolled 5,625 patients hospitalized for acute HF. In this analysis we included patients with HFrEF (LVEF $<40\%$). Low heart rate was defined as <70 beats per minute (bpm). The primary outcome was 1-year all-cause death according to the heart rate.
Results: Of 3,088 patients with HFrEF, 852 (29%) had low heart rate and 57.3% received beta blocker at discharge. There was a significant interaction between discharge heart rate and beta blocker use (P for interaction <0.001). In Kaplan-Meier survival analysis patients with beta blocker had lower 1-year all-cause mortality only in patients with high heart rate, but not in those with low heart rate (Figure). Similar findings were observed both in patients with sinus rhythm and atrial fibrillation.
In a Cox-proportional hazard regression analysis, beta blocker prescription at discharge was associated with 29% reduced risk for 1-year mortality in patients with high heart rate (hazard ratio [HR], 0.71; 95% confidence interval [CI], 0.57-0.89, $P=0.003$), but not in patients with low heart rate (HR, 0.91; 95% CI, 0.61-1.37; $P=0.656$).
Conclusions: In hospitalized patients with HFrEF every third patient has a low heart rate at discharge and the beneficial effect of beta blocker on 1-year outcomes may be limited only to patients with high heart rate at hospital discharge.



Mortality According to Heart Rate

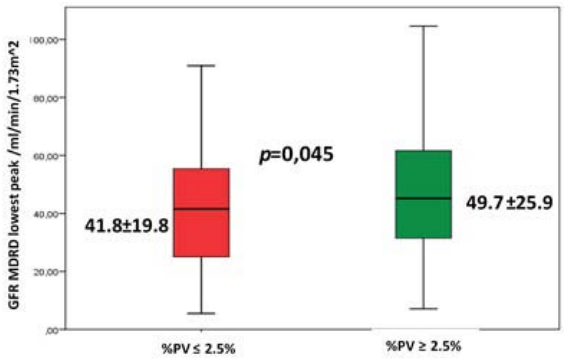
2073

Plasma volume and its relation with glomerular filtration rate in patients admitted with acute decompensated heart failure

D David Cabrita Roque[1]; J Augusto[1]; A Sachetti[1]; D Faria[1]; A Gaspar[1]; L Melo[1]; T Bernardo[1]; P Magno[1]; A Oliveira Soares[1]; C Morais[1]
[1]Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal

Background: Excessive depletion of vascular volume after diuretic therapy for acute decompensated heart failure (ADHF) is common and may lead not only to activation of the angiotensyn-renin-aldosterone system but also to acute kidney injury. Our aim is to evaluate the relation between the degree of contraction of vascular volume, using the percentage of alteration in the plasma volume and the glomerular filtration rate (GFR), after the use of diuretics, in patients admitted with ADHF.
Methods: Retrospective study of 258 patients (74.2 ± 17.3 years, 45.7% male) admitted in the emergency department between January and June 2016, for ADHF, defined by the presence of ≥ 2 signs or symptons of heart failure. All the patients were treated with diuretic therapy. We evaluate the diference between admission and discharge values of hemoglobin (ΔHb), hematocrit (ΔHtc), sodium (ΔNa), and the GFR evaluted by the Modification of Diet in Renal Disease (MDRD). The relative change in plasma volume (%PV) from admission until discharge was estimated by: {([Hb admission/Hb discharge]x[(100-Htc discharge)/(100-Htc admission)])-1}x100.
Results: Of the 258 patients admitted with ADHF, we excluded 11.6% ($n=30$) for missing laboratory values or description of blood loss/need of blood transfusion during hospital stay. After diuretic therapy (average of maximum dose of furosemide administered 69.3 ± 17.3mg), the incidence of increase in the %PV was 61% ($n=139$) and in the decrease was 39% ($n=89$). We further divide the patients in two groups according to the average %PV (2.5%): group 1 with preserved volume [%VP $>2.5\%$ (from $>2.5\%$ to 44%, n=101], and the group 2 with diminished volume [%VP $<2.5\%$ (from -13.8% to $<1.5\%$, n=127]. There were no statistically significant difference regarding ΔNa (average of 0.73 ± 3.52mEq for group 1 vs. 1.52 ± 4.56mEq for group 2, $p=0.396$). Patients in the group 2 showed greater positive variations of ΔHb (group 1 average of -1.34 ± 0.78 g/dl vs. group 2 0.57 ± 1.01g/dl $p=<0.001$) and in ΔHtc (group 1 average of $-4.66\pm2.69\%$ vs. group 2 $2.21\pm3.23\%$, $p=<0.001$). We also conclude that patients in the group 2, with volume contraction, where those who, during hospital stay, had the lowest GFR (average of 49.7 ± 25.9 ml/min/1.73m2 for group 1 vs 41.8 ± 19.8ml/min/1.73m2 for group 2, $p=0.045$, statistically significant).
Conclusions: The present study establish a relation between the percentage of alteration in the plasma volume and the lowest peak value of GFR (acute kidney injury), in patients with ADFH, treated with diuretic therapy. Besides that, the values

of hemoglobin and hematocrit seems to be the most useful laboratory values to evalute congestion vs contraction of volume. The sequential evaluation of the percentage of variation in the PV could be a useful tool to avoid the overuse of diuretic therapy in these patients and prevent the ocorrence of acute kidney injury during hospital admission.

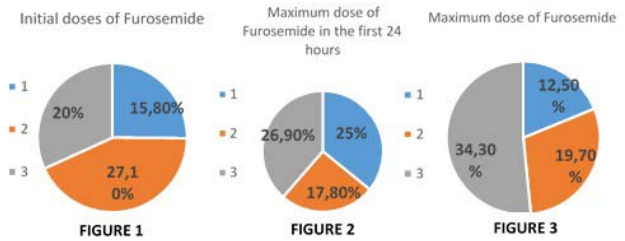


2074

Relation between the dose of loop diuretics and worsening renal function during hospitalization for acute decompensated heart failure

D David Cabrita Roque[1]; J Augusto[1]; A Sachetti[1]; D Faria[1]; A Gaspar[1]; L Melo[1]; T Bernardo[1]; J Simoes[1]; P Magno[1]; A Oliveira Soares[1]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal*

Background: Worsening renal function (WRF) during heart failure (HF) hospitalization is common. Loop diuretics are increasingly being considered as a potential cause of worsened HF outcomes, perhaps via WRF. However, the magnitude of worsening in renal function attributable to loop diuretics is not well defined.
Methods: Retrospective study of 258 consecutive patients admitted in the emergency department for acute decompensated heart failure. Admission, maximum and discharge values of creatinine (Cr) were collected, along with first dose, dose in the first 24 hours of admission and maximum dose of furosemide (Fur), the only loop diuretic in the hospital prescription set. We further divided each of the preceding parameters according to dose of Fur: Group 1 - Low (<40mg); Group 2 - Medium (40-80mg); and Group 3 - High (>80mg). The first Cr value or estimated glomerular filtration rate (eGFR) in the emergency department was considered baseline. A 20% relative decrease in eGFR defined WRF.
Results: We included 228 patients (45.6% male, 74.6±16.4 years). Baseline Cr was 1.47±0.87mg/dl, maximum Cr was 1.79±1.07mg/dl and discharge Cr was 1.38±0.73mg/dl. The average initial dose of Fur was 39.6±32.2mg; the average maximum dose in the first 24 hours was 88.4±73.9mg and the average maximum dose was 69.7±39.2mg. There were no significant association between the various doses of Fur and the incidence of WRF: initial doses of Fur (incidence of WRF: Group 1 15.8% vs. Group 2 27.1% vs. Group 3 20.0%, p=0.137; figure 1), maximum dose in the first 24 hours (incidence of WRF: Group 1 25.0% vs. Group 2 17.9% vs. Group 3 26.9%, p=0.289; figure 2) and the maximum dose of Fur (incidence of WRF: Group 1 12.5% vs. Group 2 19.7% vs. Group 3 34.3%, p=0.128; figure 3).
Conclusions: While loop diuretic exposure and its dose is empirically associated with WRF among hospitalized HF patients, this study demonstrate that the association between WRF and the dose of furosemide, in three separate times during acute decompensated heart failure hospitalization, can not be made, and so, loop diuretics explain little of the variability in renal function during hospitalization.



Incidence of WRF according to group

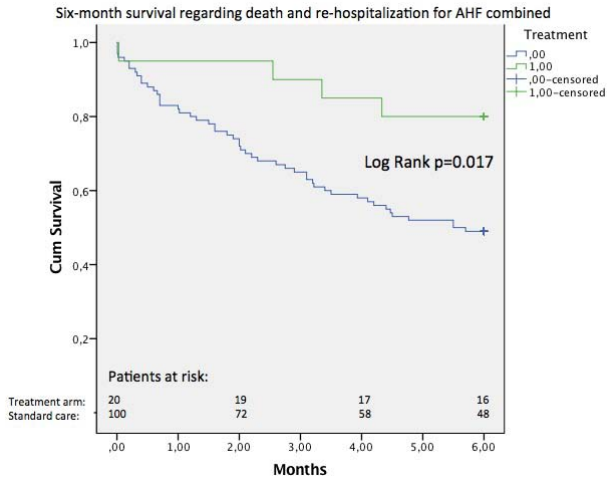
2075

Ultrasound-guided treatment in Acute Heart Failure based on lung ultrasound and cardiac filling pressures- greater decongestion despite shorter hospitalization and improved survival

JG Oehman[1]
[1]*Turku University Hospital, Cardiology , Turku, Finland*

On behalf of: DYSPNEA study group

Introduction: -Treatment for acute heart failure (AHF) is ineffective and hospitalizations long and expensive, as there is virtually no prognostically beneficial treatment available -Lung ultrasound (LUS) and focused echoardiography allow monitoring of pulmonary congestion and cardiac filling pressures during AHF treatment, and may be done sequentially using the same probe -Echo- and LUS-guided therapy could allow aggressive decongestive therapy in AHF while monitoring hemodynamics, but has not been studied to date
Purpose: To investigate the efficacy and safety of ultrasound-guided therapy in AHF using a focused cardiothoracic ultrasound protocol (CaTUS), combining medial E/e', IVC index (based on diameter and respiratory variation) with LUS
Methods: After enrolling 100 AHF patients for follow-up purposes, we enrolled an additional 20 patients who received aggressive decongestive therapy guided by CaTUS, based on a pre-specified treatment protocol-All patients had the CaTUS done on a daily basis, alongside clinical parameters and laboratory samples -The treatment protocol aimed for resolution of pulmonary congestion, normalization of E/e' and a plethoric IVC, while monitoring renal function, electrolytes and clinical parameters
Results: Patients in the treatment arm had a significantly larger mean(±SD) reduction in all congestion parameters, i.e. E/e' (6.48±2.9 vs. 2.62±4.6, p=0.001) , % reduction in BNP (35.9±26 vs. 16.6±61, p=0.029), IVC index (1.91±1,1 vs. 0.38±0.8, p<0.001), cumulative fluid loss (5.47±5.3 vs. 3.07±3.0, p<0.001)(p<0.05 for all) despite a significantly shorter hospitalization (3.7±2.0 vs. 6.9±4.2 days, p<0.001) as compare to patients in the standard care arm -A larger proportion in the treatment arm were also asymptomatic (95 % vs. 72 %, p=0.036) and free of any signs of pulmonary congestion on LUS (80 % vs. 53 %, 0.039), and had a lower mean E/e' (14.4±3.1 vs. 18.0±4.1, p<0.001), mean IVC index (1.02±1.0 vs. 1.82±0.76, p=0.005) and median(25%-75% IQr) BNP (249 (172-408) vs. 426 (242-1015), p=0.011 at discharge, without any significant difference in any of these parameters on admission-There was a trend towards less adverse events in terms of acute kidney injury and symptomatic hypotension in the treatment arm (p=0.617 and 0.378)-Patients in the treatment arm seemed to have an improved six-month survival regarding the combined endpoint of death and re-hospitalization for AHF compared to the conventional treatment group (Figure), although the treatment group was small for prognostic purposes
Conclusion: CaTUS-guided aggressive AHF treatment resulted in greater decongestion during shorter, and thus propaply cheaper, hospitalization, and may be associated with an improved prognosis



6-month survival, combined endpoint

Characteristics and outcome of patients according to the severity of peripheral oedema and breathlessness, a report from national (england & wales) heart failure audit

A Shoaib[1]; M Mamas[2]; S Thackray[3]; M Rashid[1]; R Perveen[3]; A Raza[3]; A Shote[4]; S Hardman[5]; T Mcdonagh[4]; H Dargie[6]; A Mohamed[7]; ALC Clark[3]; JGFC Cleland[6]
[1]Keele University, Academic Cardiology, Stoke on Trent, United Kingdom; *[2]University of Keele, Academic Cardiology, Stoke on Trent, United Kingdom*; *[3]University of Hull, Department of Academic Cardiology, Hull, United Kingdom*; *[4]King's College Hospital, London, United Kingdom*; *[5]Whittington Hospital, Cardiology Department, London, United Kingdom*; *[6]University of Glasgow, Glasgow, United Kingdom*; *[7]Whiston Hospital, Liverpool, United Kingdom*

Introduction: Heart failure is a common reason for hospital admission. Patients presenting with pulmonary and peripheral oedema may be seen as two ends of a spectrum with many patients presenting with a mixed picture. The purpose of the present analysis is to describe patient characteristics according to the severity of oedema and NYHA class, their length of hospital stay and mortality during the index admission and after discharge.
Methods: National Audit Data were collected from April 2007 to March 2013 in more than 90% of hospitals in England & Wales. Patients with a confirmed discharge diagnosis of heart failure were divided by severity of peripheral oedema (severe, moderate, mild and none) and NYHA class (IV, III, II/I) – creating 12 groups. Patients' characteristics and mortality during the index hospital admission for up to three years after discharge were reported.
Results: Amongst 136,790 patients, the median age was 79 years, 58% were women, 81% were treated with ACEi/ARB, 67% with beta-blockers and 40% with MRA at discharge. Only 34% of patients had breathlessness at rest or minimal exertion at the time of admission and 18% had severe peripheral oedema.
Prevalence of LVSD was highest in group I-II/A (71%) and lowest in group I-II/D (49%). Median length of index admission stay was determined by the severity of peripheral oedema rather than NYHA class: 12 days for severe, 9 days for moderate, 7 days for mild and 6 days for no peripheral oedema. The highest index admission mortality during was observed in group IV/D (18%) followed by III/D (13%) and lowest in groups I-III/A (6%). After median follow-up 344 (IQR 94-766) days), mortality was 60% for IV/D and 56% for III/D compared to 46% for IV/A and 40% for III/A (. Hazard ratios for death in the above groups were 2.26, 2.09, 1.49 and 1.28 respectively (for all P- < 0.001) compared to group I-II/A.
Conclusion: The severity of peripheral oedema rather than of breathlessness or LVSD is the more important determinant of length of stay and prognosis in patients with heart failure. However, the prognosis of patients recently hospitalised with heart failure remains poor despite a high uptake of disease modifying medication.

Intravenous ivabradine in low cardiac output syndrome treated by dobutamine following cardiac surgery: a phase II trial

L S Nguyen[1]; P Squara[1]; J Amour[2]; B Cholley[3]
[1]Clinique Medico-Chirurgicale Ambroise Pare, Critical Care Department, Neuilly sur Seine, France; *[2]Hospital Pitie-Salpetriere, Anesthesiology and Critical Care Medicine Department, Paris, France*; *[3]Hôpital Européen Georges Pompidou, Université Paris Descartes, Anesthesiology and Critical Care Medicine Department, Paris, France*

Funding Acknowledgements: Servier

Background: Dobutamine is the first-line treatment for low cardiac output syndrome (LCOS) after cardiac surgery, but induces sinus tachycardia. We aimed to assess the intravenous (i.v.) ivabradine in patients presenting LCOS with dobutamine-induced tachycardia following elective coronary artery bypass graft surgery.
Methods: In a phase 2 multi-center randomized placebo-controlled trial, i.v. ivabradine was infused in patients presenting sinus tachycardia (heart rate (HR) > 100 bpm) after dobutamine initiation. Primary endpoint was the number (%) of patients having their HR reduced between 80 and 90 bpm for > 30 minutes. Secondary endpoints were hemodynamic parameters measured by Swan-Ganz catheter.
Results: Thirteen (93%) patients treated by ivabradine reached the primary endpoint, compared to 2 (40%) in the placebo group ($p < 0.05$). Ivabradine significantly decreased HR (112 to 86 bpm ($p < 0.001$)) while increasing cardiac index (2.5 to 2.9 l/min/m^2 ($p < 0.05$)), stroke volume (38.0 to 60.0 ml ($p < 0.001$)) and systolic blood pressure (110 to 125 mmHg ($p < 0.05$)). These parameters remained similar in the placebo group. Five (35.7%) patients developed atrial fibrillation in the ivabradine group.
Conclusion: Intravenous ivabradine reduced HR in patients presenting with LCOS treated with dobutamine after CABG surgery, without impairing cardiac output. This beneficial effect should be confirmed with larger trials.

Baseline characteristics		
	Ivabradine group (n = 14)	Placebo group (n = 5)
Age (years)	61 [59 ; 67]	54 [53 ; 59]

Effect of tolvaptan administration on renal function in the acute phase of congestive heart failure

Y Kawase[1]; R Hata[1]; T Tada[1]; K Kadota[1]

[1]Kurashiki Central Hopistal, cardiovascular medicine, Kurashiki, Okayama, Japan

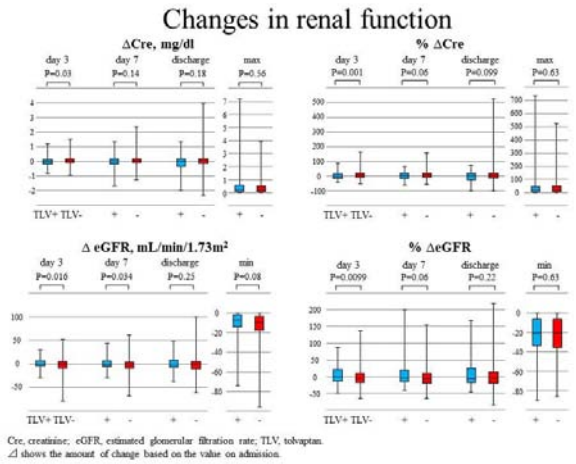
Background: Tolvaptan has been widely used as a diuretic drug in the acute phase of congestive heart failure. However, how it affects renal function has not been clarified sufficiently.

Purpose: To clarify the effect of tolvaptan administration on renal function in the acute phase of congestive heart failure.

Methods: We retrospectively investigated 1038 consecutive patients hospitalized for congestive heart failure between February 2015 and December 2016 and enrolled 556 patients in the study sample, excluding those with end stage renal dysfunction (estimated glomerular filtration rate [eGFR] <15 mL/min/1.73m2), acute coronary syndrome, tolvaptan use prior to admission, and insufficient data. We divided the 556 patients into two groups based on the use and non-use of tolvaptan within 2 days after admission: 111 patients (tolvaptan group) and 445 patients (non-tolvaptan group). The primary outcome measure was defined as $\geq$20% decline in eGFR from the value on admission, and its rate on day 3, day 7, and at the time of discharge was compared between the two groups.

Results: The mean age of the tolvaptan group was 79.3 ± 12.1 years and that of the non-tolvaptan group was 77.2 ± 13.6 years. Renal function on admission was significantly worse in the tolvaptan group than in the non-tolvaptan group (creatinine, 1.22 [0.87 to 1.72] versus 1.01 [0.80 to 1.32], $p < 0.001$; eGFR, 38.7 [24.8 to 54.7] versus 48.7 [35.7 to 63.1], $p < 0.001$). The figure shows creatinine, % creatinine, eGFR, and % eGFR on day 3, day 7, and at the time of discharge, respectively. shows the amount of change based on the value on admission. On day 3, $\geq$20% decline in eGFR was observed in 20% of the study sample (113/556 patients), and its rate was significantly lower in the tolvaptan group than in the non-tolvaptan group (10/111 patients [9.0%] versus 103/445 patients (23.2%), $p < 0.001$). On the other hand, on day 7 and at the time of discharge, there were no significant differences between the two groups. Multivariate analysis showed that tolvaptan administration in the acute phase significantly reduced the rate of $\geq$20% decline in eGFR on day 3 (adjusted odds ratio, 0.35; 95% confidence interval, 0.16 to 0.71, $p = 0.003$).

Conclusion: In the acute phase, tolvaptan administration to patients with congestive heart failure may prevent renal function from worsening.



MODERATED POSTER SESSION 6 - THERAPY

Granulocyte colony-stimulating factor in patients with a large anterior wall acute myocardial infarction to prevent left ventricular remodeling (the RIGENERA trial): 10 years follow-up- FINAL RESULTS

D Domenico D'amario[1]; AM Leone[1]; F Cannata[1]; F Graziani[1]; F Cobianchi Bellisari[1]; M Massetti[1]; L Galiuto[1]; AG Rebuzzi[1]; F Crea[1]
[1]*Catholic University of the Sacred Heart, Institute of Cardiology, Rome, Italy*

Background: Granulocyte-colony stimulating factor (G-CSF) has been clinically tested in ST-elevation myocardial infarction (STEMI) patients with controversial results.
Purpose: Aim of the study was to determine the long-term safety, feasibility and efficacy of stem cell mobilization following G-CSF as a treatment for acute myocardial infarction.
Methods: 41 patients were randomized 1:2 to G-CSF therapy (n = 14) or conventional therapy (n = 27) from June 2003 to May 2006, in order to assess the potential efficacy of G-CSF administration on cardiac function evaluated by conventional echocardiography, in patients with a first large anterior AMI and a LV ejection fraction < 50% despite successful percutaneous revascularization of the infarct-related artery. Exclusion criteria were cardiogenic shock, uncontrolled myocardial ischemia or arrhythmias, malignancies, severe infections, hematologic diseases, splenomegaly on abdominal echocardiography and age >80 years. Patients randomized to G-CSF therapy were treated with lenograstim at a dose of 10 μg/kg/day for 5 days starting ≥ 5 days after AMI and/or a complete revascularization. The 10 year follow-up was completed, 3 patients were lost to follow-up: the final population consisted of 38 patients (12 in G-CSF group and 26 in control group). LV function and NYHA functional class evaluation was performed at follow up, together with quality of life and life expectancy assessed by Minnesota Living with Heart Failure Questionnaire (MLHF) and The Seattle Heart Failure Model (SHFM) respectively.
Results: No differences were found in the two groups in term of LVEF and LVESV. Remarkably, a significant increase was detected in control group when considering the difference (Delta) in LVEDV between baseline and follow up ($p < 0.05$). This result was coupled with a reduction in the incidence of adverse LV remodeling in the G-CSF group (48% Control vs 8% G-CSF; $p = 0.01$). Moreover, patients treated with G-CSF referred a better quality of life and a lower burden of symptoms, compared to control patients, as shown by MLHF score ($p = 0.05$) and NYHA functional class ($p = 0.04$). The mean life expectancy, evaluated with the SHFM, was significantly higher in the G-CSF group then control (15 ± 4 years vs 12 ± 4 years $p = 0.05$). At 10 years, deaths were two fold higher in the control compared to G-CSF group, although this difference was not statistically significant (19% vs 8%; $p = 0.39$), most likely due to the paucity of the population.
Importantly, the incidence of recurrent MI, in-stent restenosis and occurrence of malignancies was similar in G-CSF-treated patients and controls.
Conclusions: The final analysis ot the 10-year data from the RIGENERA trial represent the longest available follow-up on the safety and efficacy of G-CSF treatment in STEMI patients. The administration of G-CSF is not only safe but also associated with a documented reduction of adverse ventricular remodeling after large anterior STEMI and better quality of life.

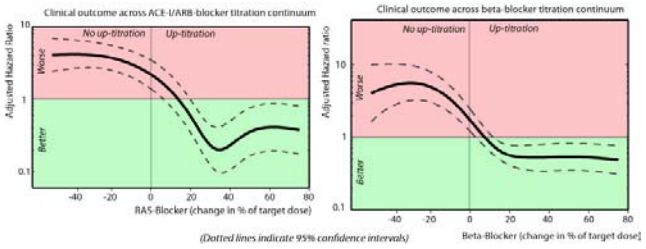
2080

Feasibility and benefit of neurohumoral blocker uptitration following cardiac resynchronization therapy

P Pieter Martens[1]; FH Verbrugge[1]; P Nijst[1]; PB Bertrand[1]; M Dupont[1]; WH Tang[2]; W Mullens[1]
[1]*Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium*; [2]*Cleveland Clinic Foundation, Department of Cardiovascular Medicine, Heart and Vascular Institute, Cleveland, United States of America*

Funding Acknowledgements: Pieter Martens is supported by a doctoral fellowship by the Research Foundation – Flanders (FWO, grant-number: 1127917N

Background: Cardiac resynchronization therapy (CRT) improves mortality and morbidity on top of optimal medical therapy in heart failure with reduced ejection fraction (HFrEF). Although CRT is considered as a step-on option after optimal medical treatment, its beneficial effects with regards to reverse remodelling, could allow for further uptitration of neurohumoral blockers despite optimal baseline of medical therapy.
Methods: Doses of angiotensin-converting enzyme inhibitors (ACE-I), angiotensin receptor blockers (ARB) and beta-blockers were retrospectively evaluated in 650 consecutive CRT patients, implanted between October, 2008, and August, 2015. All 650 patients were on individually optimal dose at the time of implant. Uptitration was calculated as the difference in percent of target dose between CRT-implantation and six month follow-up. Outcome was measured as the combined end-point of heart failure admission or all-cause mortality.
Results: Uptitration was performed in 45.4% (n = 191) of patients for ACE-I/ARB and 56.8% (n = 283) for beta-blockers, in patients who were not at maximal target dose at implantation. ACE-I/ARB were uptitrated on average 39 ± 20% of target dose and beta-blockers 44 ± 20% of target dose. During a mean follow-up of 37 ± 22 months, a total of 148 events occurred for the combined endpoint of heart failure admission and all-cause mortality. Uptitration versus no-uptitration following CRT was associated with an adjusted hazard ratio of 0.54 (0.32-0.91; $p = 0.022$) for ACE-I/ARB and 0.63 (0.41-0.99; $p = 0.044$) for beta-blocker therapy on the combined end-point of heart failure and all-cause mortality. Figure 1 illustrates the relationship between post-implant dose adaptation for ACE-I/ARBs and Beta-blockers, versus the adjusted hazard ratio for the combined endpoint depicted on a continuous scale. Patients in the uptitration group exhibited a similar low risk for death or heart failure admission as patients treated with the maximal dose at the time of CRT-implant (ACE-I/ARB $p = 0.133$, beta-blockers $p = 0.709$).
Conclusions: Following CRT, a majority of patients are capable of tolerating higher dosages of neurohumoral blockers. Uptitration of neurohumoral blockers after CRT implantation associates with improved clinical outcome, even matching patients treated with the guideline-recommended target dose at the time of implant.



2081

Relation of biological and functional LV remodeling to obstruction in hypertrophic cardiomyopathy. A rest and exercise echocardiographic study with longitudinal strain measurement

F Flore Morio[1]; TLT Le Tourneau[1]; NP Piriou[1]; CC Cueff[1]; JMS Serfaty[1]; KW Warin[1]; JNT Trochu[1]
[1]*University Hospital of Nantes Nord Laennec, Nantes, France*

Introduction: Outflow tract obstruction is thought to be involved in left ventricular (LV) remodeling in sarcomeric hypertrophic cardiomyopathy (HCM).
Objective: To determine the influence of obstruction to biological parameters of remodeling and global longitudinal strain (GLS) in HCM.
Material and Methods: Patients with HCM who accepted to participate to this study were included. Transthoracic echocardiography at rest and exercise with GLS measurement was carried out. Blood was sampled before and early after exercise.

Patients were divided into 3 groups according to the presence of an obstruction at rest (OHCM), effort (Latent obstruction: LOHCM), or none (HCM).
Results: We included 40 HCM patients, 7 OHCM, 19 LOHCM and 14 NOHCM. Troponin T and NTproBNP levels at rest were significantly higher in OHCM compared to NOHCM (19.5 ± 10 vs 10 ± 5.8 ng/L, p = 0.017 and 1184 ± 389 vs 520 ± 388ng/l, P=0.005). Troponin T and NTproBNP levels at rest were correlated with the outflow tract peak gradient (r=0.49, p = 0.001 and r=0.41, p = 0.005, respectively) and with the alteration of GLS (r=0.51, p = 0.001 and r=0.46, p = 0.003, respectively). After exercise ST2, IL6, GDF15, Troponin T and NTproBNP increased significantly in OHCM + LOHCM while only NTproBNP increased in NOHCM. In multivariate analysis post-exercise Troponin T (β=0.57, P < 0.0001) was a determinant of GLS at rest. MMP9 (β=-0.44, P=0.004) and TGFβ (β=0.54, P=0.001) at rest, and post-exercise Troponin T (β=0.57, P < 0.0001) were independent determinants of exercise GLS.
Conclusion: In HCM, biological parameters of remodeling are correlated to obstruction and GLS. Exercise in obstructive forms of HCM induces a significant increase in multiple biological parameters of remodeling. Troponin T level is a strong predictor of GLS alteration both at rest and exercise.

Early phase 99Tc-HMDP scintigraphy: a rapid and reliable technique for the diagnosis and typing of cardiac amyloidosis

A Arnault Galat[1]; AVG Van Der Gucht[2]; AG Guellich[1]; DB Bodez[1]; ASC Cottereau[2]; SG Guendouz[1]; LH Hittinger[1]; JLDR Dubois-Rande[1]; VPB Plante-Bordeneuve[3]; EI Itti[3]; MM Meignan[2]; TD Damy[1]; JR Rosso[2]
[1]*University Hospital Henri Mondor, Cardiology, Creteil, France*; [2]*University Hospital Henri Mondor, Nuclear medicine, Creteil, France*; [3]*University Hospital Henri Mondor, Neurology, Creteil, France*

Background: The usefulness of bisphosphonate-scintigraphy in diagnosing and typing cardiac amyloidosis (CA) has been reported in several studies. However, the procedure is time-consuming and may be regarded as inadequate especially in frail patients.
Aims: To compare accuracy of early (10 min) versus late (3h) cardiac fixation of 99mTc-HMDP at scintigraphy in diagnosing and typing CA.
Methods: 135 patients refereed for suspicion of CA were prospectively evaluated using 99mTc-HMDP scintigraphy. Myocardial tracer accumulation was semi-quantitatively measured and visually scored at early and late phases of bisphosphonate scintigraphy.
Results: CA was diagnosed in 19 AL (light-chain) and in 33 wt-TTR (wild type transthyretin). Among m-TTR (mutated transthyretin), 33 had CA, 5 had isolated neuropathy without CA and 3 were asymptomatic carriers. 31 patients with LVH (left ventricular hypertrophy) and without amyloidosis served as controls. Early 99mTc-HMDP cardiac uptake was found in 68 patients whose late visual score was ≥1. Early uptake was undetectable in all the 57 patients with a null visual score at 3h. Early heart retention was strongly correlated to late heart retention (r=0.914, p < 0.0001). An early 99mTc-HMDP heart/mediastinum ratio ≥1.115 predicts a late visual score ≥1 which differentiated CA from other causes of LVH (100% sensitivity, 97% specificity). Early heart / mediastinum ratio ≥1.210 discriminated TTR-CA from AL with perfect accuracy (100% sensitivity and specificity).
Conclusions: Early phase 99mTc-HMDP-scintigraphy perfectly predicts late phase finding. It is accurate to differentiate TTR-CA from AL and from other causes of LVH. This could be of particular benefit for frail patients and in centres with limited avaibility of scintigraphy.

Background: A new technique described as Less Invasive Ventricular Enhancement (LIVE) was performed to reduce and reshape the left ventricle after anteroseptal infarction without cardiopulmonary bypass. Access in the early series was via median sternotomy and later using a hybrid transcatheter approach. We report survival, functional and echocardiographic results at 2 years.
Methods: All patients had MRI or CT demonstrating scars in the anteroseptal wall and symptoms of heart failure NYHA class II/III. Coronary lesions were always treated before the procedure. Significant MR was an exclusion criteria. LIVE was achieved using the Bioventrix Revivent Myocardial Anchoring System. Titanium anchors were delivered to the right side of the interventricular septum. An external anchor was fitted onto a tether to allow apposition of the LV free wall to the scarred septum.
Results: Eighty-six patients were treated from August 2010 till March 2016. Baseline EF was 30 ± 8% and ESVi 72 ± 28 ml/m^2. Four patients (4.7%) died in-hospital and 1 (1.2%) had a stroke. Two-year survival was 89.2%. In 57 patients who completed 2-year follow up, EF improved (+13%) and LVESVI reduced (-27%). NYHA class reduced (2.6 ± 0.5 to 1.8 ± 0.7, P < 0,001), 6-minutes walking test increased (353 ± 108 to 432 ± 102 minutes, P < 0.001) and Minnesota Living with Heart Failure score reduced (41 ± 21 to 24 ± 19, P < 0.001). Serial echocardiograms and functional evaluations (@6,12,24 months) demonstrated sustained improvements.
Conclusions: Excellent survival and sustained improvement of echocardiographic and functional parameters are obtained using the Less Invasive Ventricular Enhancement technique. In patients with no significant MR and/or myocardial ischemia, ventricular reduction and reshaping, when performed off-pump using the Revivent myocardial anchors, demonstrates long term decrease in heart failure symptoms.

A natriuretic peptides clearance receptor agonist reduces pulmonary artery pressures and enhances cardiac performances: new hope for PH due to HF

E Eroum A Egom[1]; T Feridooni[2]; RB Pharithi[1]; V Maher[1]; Y El-Hiani[2]; KS Pasumarthi[2]; H Ribama[3]

Funding Acknowledgements: ECTRS Ltd

In patients with left ventricular heart failure (HF), the development of pulmonary hypertension (PH) is common and represents a strong predictor of death. PH due to HF is a disabling and life-threatening disease for which there is currently no single marketed pharmacological agent approved. Furthermore, despite recent advances in the pathophysiological understanding, there is as yet no prospect of cure of this deadly clinical entity, and the majority of patients continue to progress to right ventricular failure and die. There is, therefore an urgent unmet need to identify novel

pharmacological agents that will prevent the progressively increasing or reverse the already elevated pulmonary artery pressures while enhancing cardiac performance in HF. We here reported, for the first time, that a specific natriuretic peptides clearance receptors (NPR-C)' agonist, the ring-deleted atrial natriuretic peptide analogue, cANF4-23 (cANF) reduces pulmonary artery pressures and enhances cardiac performance including left ventricular inotropy in mice, using a pressure-loop (P-V) conductance catheter system (Table 1). Natriuretic peptides clearance receptors' agonists may therefore represent a novel and attractive therapeutic option for PH due to HF, and have the potential to ultimately improve morbidity and mortality for millions of people affected with PH due to HF.

Effect of aortic valve opening pattern on endothelial functions after continuous flow left ventricular assist device implantation

E Kaya[1]; E Simsek[1]; S Nalbantgil[1]; A Akilli[1]; P Ozturk[2]; C Engin[2]; T Yagdi[2]; M Ozbaran[2]

[1]Ege University, Faculty of Medicine, Department of Cardiology, Izmir, Turkey; [2]Ege University, Faculty of Medicine, Department of Cardiovascular Surgery, Izmir, Turkey

Background And Objective: Recent studies have shown that endothelial functions are negatively affected by decreased pulsatile flow in the arterial system following implantation of continuous flow left ventricular assist device (CF-LVAD). During systole aortic valve opening patterns differs among CF-LVAD patients and effects on endothelial functions of these patterns have not been studied in detail. In this study after CF-LVAD implantation associations with aortic valve opening patterns and endothelial functions are evaluated.

Methods: Forty three CF-LVAD patients (pre-implantation NYHA class III-IV) and as a control group 35 NYHA class II heart failure (HF) patients were included in the study. Control group had just baseline testing however CF-LVAD group had pre implantation and 3 months after post implantation endothelial function testing with flow mediated vasodilatation (FMD) method. CF-LVAD patients were divided into three subgroups according to the opening patterns of aortic valve with echocardiography; as complete opening, intermittent opening, constantly closed; and the effects of these patterns on endothelial functions were investigated.

Results: Mean FMD was significantly lower in pre- CF-LVAD patients than control group. (% 5.4 ± 0,94 vs. % 7.6 ± 1.11, P < 0.001). Three months after CF-LVAD implantation, mean FMD was % 3.7 ± 0,81 and significantly lower than pre implantation. (p < 0.001). Between subgroups of aortic valve opening patterns, patients with closed and intermittent opening patterns had significantly decreased endothelial functions. (% 5.02 ± 1.16 vs. % 3.37 ± 0.91, p = 0.001; % 5.8 ± 1.61 vs. % 4.30 ± 2.46, p = 0.024 respectively) However patients with complete opening aortic valve pattern did not have any statistically difference. (% 4.72 ± 1.06 vs. % 4.67 ± 1.16, p = 0,135) (Table 1)

Conclusions: Diminished pulsatile flow after CF-LVAD implantation impairs endothelial functions. Complete opening of the aortic valve in each systole may provide enough pulsatile flow to the peripheral arterial system to prevent the development of endothelial dysfunction. CF-LVAD implantation should be performed before complete loss of the left ventricular contractility reserve to save complete opening aortic valve pattern and endothelial functions.

Table 1

	BeforeCF-LVAD impl.FMD(%)	AfterCF-LVAD impl.FMD(%)	p
Opening Aortic Valve (n = 18)	4,72±1,06	4,67±1,16	0,135
Closed Aortic Valve(n = 21)	5,02±1,16	3,37±0,91	0,001

Spironolactone reduces all-cause mortality in women but not men with heart failure with preserved ejection fraction enrolled in TOPCAT from the Americas

DP David Peter Kao[1]; KM Flint[1]; M Merrill[1]

[1]University of Colorado Denver, Denver, United States of America

Background: Large clinical trials of treatments for heart failure with preserved ejection fraction (HFpEF) have suggested differences between women and men in several clinical outcomes but not treatment response. Sex differences in outcomes and treatment response in the Treatment of Preserved Cardiac Function Heart Failure With an Aldosterone Antagonist (TOPCAT) trial have not yet been reported.

Purpose: To characterize sex differences in outcomes and treatment response in subjects enrolled in TOPCAT.

Methods: 3445 patients with symptomatic heart failure and an LVEF ≥45% were randomized to spironolactone or placebo with mean follow-up 3.3 years. The primary outcome was a composite of cardiovascular (CV) death, aborted cardiac arrest, or HF hospitalization. Secondary outcomes were all-cause mortality and hospitalization. Outcomes were stratified by sex, treatment arm and enrollment region (Americas vs. Russia/Georgia). Treatment effect of spironolactone was determined using time-to-event analysis.

Results: 1775 women (882 from the Americas) were enrolled vs. 1670 men (785 from the Americas (p = 0.053). Overall, rates of all the primary outcome, all-cause mortality, and hospitalization were significantly lower in women vs. men (17 vs. 22%, 12 vs. 19%, 42 vs 49%, p < 0.001). In subjects from the Americas, rates for women vs. men of the primary outcome (27 vs. 32%, p = 0.04) and all-cause mortality (19 vs. 25%, p = 0.004) were significantly different, but hospitalization was not (59 vs. 61%, p = 0.33). In subjects from Russia/Georgia, rates of the primary outcome (6 vs. 12%), all-cause mortality (6 vs. 11%) and hospitalization (26 vs. 34%) were lower in women than men (p < 0.001 for all). Outcome rates by region, sex, and treatment arm are shown in the Table. Spironolactone was associated with reduced all-cause mortality in women in region 1 only, even when adjusted for age, diabetes mellitus, hypertension, atrial fibrillation, coronary artery disease, and COPD (HR 0.66, p = 0.008). (Figure)

Conclusions: Women with HFpEF had lower rates of most adverse outcomes than men. The benefit of spironolactone previously observed in the Americas appears driven by reductions in mortality in women only.

Intrarenal venous flow alterations during transition from euvolemia to intravascular volume expansion in heart failure patients with reduced ejection fraction

P Petra Nijst[1]; P Martens[1]; M Dupont[1]; W Tang[2]; W Mullens[1]
[1]Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium; [2]Cleveland Clinic Foundation, Cleveland, United States of America

Background: Diuretic capacity relates to intrinsic renal function but also to renal blood flow. Intrarenal blood flow alterations may help better understand impaired volume handling in heart failure (HF).
Objectives: To study 1) intrarenal flow patterns in chronic HF patients with reduced ejection fraction (HFrEF) during the transition from euvolemia to intravascular volume overload, and 2) the relationship between intrarenal flow patterns and diuretic efficiency.

	HFrEF (n = 40)
Baseline characteristics- Age- Ischemic etiology	65±1283%
Laboratory values- eGFR (ml/min + 1.73m2)- NT-proBNP (ng/L)	64±26670[225;1383]
Baseline echocardiographic values- Left ventricular ejection fraction- E/E'- IVC max (mm)- estimated CVP	36±1012±615±5 6±2
Intrarenal doppler ultrasonograpy- Resistive index- venous impedance index- continuous flow pattern	0.6±0.10.2±0.3 68%

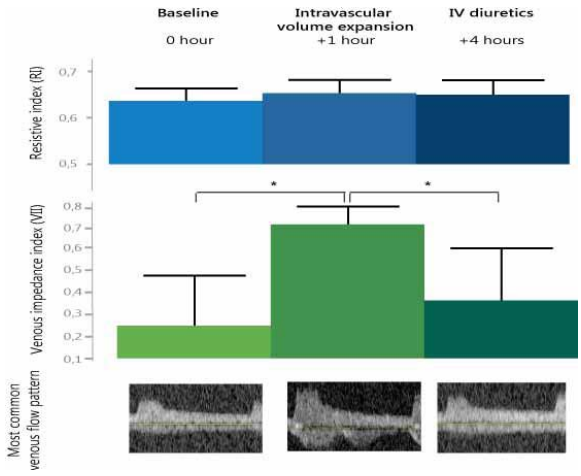

Figure 1

Methods: Arterial resistive index (RI), venous impedance index (VII) and venous flow pattern (continuous vs discontinuous) were assessed in 40 euvolemic HFrEF patients by intrarenal Doppler ultrasonography at baseline, during 3 hours of intravascular volume expansion with 1-liter hydroxyl ethyl starch 6%, and 1 hour after the administration of a loop diuretic. Clinical parameters, echocardiography, and laboratory values were assessed. Cumulative urine output was collected after 3 and 24 hours.
Results: In response to intravascular volume expansion VII increased significantly (0.2 ± 0.3 to 0.7 ± 0.2; p < 0.001) (Figure 1). This was reversed after IV diuretic administration. In contrast, RI changed non-significantly after expansion (0.6 ± 0.1 to 0.7 ± 0.1; p = 0.131). There was a non-significant change in echocardiographic estimates of central venous pressure (from 6 ± 2 mmHg at baseline to 7 ± 2 mmHg during expansion). The median VII during intravascular volume expansion was 0.74. Compared to patients with VII above the median during intravascular volume expansion, patients with lower VII generated a greater spontaneous and loop diuretic-induced amount of diuresis (0.6 ± 0.2 vs 0.4 ± 0.3 L/3 hours; p = 0.025 and 2.5 ± 0.4 vs 1.8 ± 0.5 L/24 hours; p = 0.001) and natriuresis (1.2 ± 0.4 vs 0.7 ± 0.5 g/3u ;p = 0.002 and 5.9 ± 1.2 vs4.1 ± 1.4; p = 0.005).
Conclusion: In HFrEF patients, intravascular volume expansion results in greater rise in VII than RI, before a significant change in cardiac filling pressures could be demonstrated. Impaired renal venous flow is correlated with less diuretic efficiency. Intrarenal venous flow patterns may be of additional interest to evaluate renal congestion.

2088

Therapeutic potential of phosphodiesterase 5 inhibitors in patients with heart failure with preserved ejection fraction (HFpEF) and combined post- and pre-capillary pulmonary hypertension (Cpc-PH).

T Kramer[1]; K Orlova[1]; F Gerhardt[1]; D Dumitrescu[1]; H Ten Freyhaus[1]; S Baldus[1]; S Rosenkranz[1]
[1]Cologne University Hospital - Heart Center, Clinic III for Internal Medicine, Cologne, Germany

Background: The prevalence of heart failure with preserved ejection fraction (HFpEF) is increasing and frequently associated with pulmonary hypertension (PH), which is associated with a poorer prognosis. The current ESC/ERS guidelines subdivide post-capillary PH into isolated post-capillary PH (Ipc-PH) and combined post- and pre-capillary PH (Cpc-PH). The latter is hemodynamically defined by a mean pulmonary artery pressure (PAPm) ≥25 mmHg, a pulmonary artery Wedge pressure (PAWP) >15 mmHg and a diastolic pressure gradient (DPG) ≥7 mmHg and/or a pulmonary vascular resistance (PVR) >3 WU. However, the therapeutic consequences of this subclassification are entirely unclear. Preliminary studies on phosphodiesterase 5 inhibitors (PDE5i) in PH-HFpEF yielded contradictory results. We specifically investigated the efficacy and safety of PDE5i in patients with HFpEF and Cpc-PH.
Methods: In 40 hemodynamically precisely characterized patients with HFpEF and Cpc-PH who were treated with a PDE5i (sildenafil 60 mg/d, n=24 or tadalafil 40 mg/d, n=16) for at least 12 months, the therapeutic effect on 6 minute walk distance (6MWD), WHO functional class (WHO-FC), echocardiographic parameters, right ventricular (RV) function and laboratory parameters (NTproBNP) was evaluated 3, 6, 9, and 12 months after the initiation of treatment.
Results: The average patient age was 73 ± 9 years, 53% were female, and comorbidities were frequent (75% atrial fibrillation, 78% arterial hypertension, 35% diabetes). Initially, 38 patients (95%) were in WHO-FC III and 2 patients (5%) in WHO-FC II. Prior to treatment initiation, PAPm was 45.6 ± 1.6 mmHg, PAWP 20.9 ± 0.8 mmHg, DPG 6.1 ± 1.0 mmHg, PVR 6.1 ± 0.5 WU, and RAP was 12.5 ± 1.0 mmHg. After 12 months of PDE5i therapy, the 6MWD substantially increased from initially 277 ± 17.0 to 340 ± 17.7 m, resulting in a net increase of 63 m (p < 0.001). The proportion of patients in WHO-FC I/II increased from 5% at baseline to 37.5% after 12 months of therapy. In addition, there was moderate improvement in RV function at 12 months (TAPSE 18.8 ± 0.8 vs. 16.9 ± 0.7 mm at baseline, p = 0.01), and NTproBNP levels decreased from 3.191 ± 559 ng/L at baseline to 2.130 ± 472 ng/L at 12 months (-33%, p = 0.004). Importantly, body weight of the patients remained constant throughout the observation period (71.7 ± 3 kg initially vs. 71.5 ± 2 kg at 12 months), so that the changes in measured parameters may not be attributable to optimized volume status and reduced left ventricular filling pressure. No deaths occurred in the investigated group, and the typical side effects of PDE5i (headache, flushing, nasal congestion) were observed.
Conclusion: These data indicate that precisely characterized patients with HFpEF and Cpc-PH who tolerate PDE5i may benefit from targeted therapy. A randomized study in this particular sub-population is warranted.

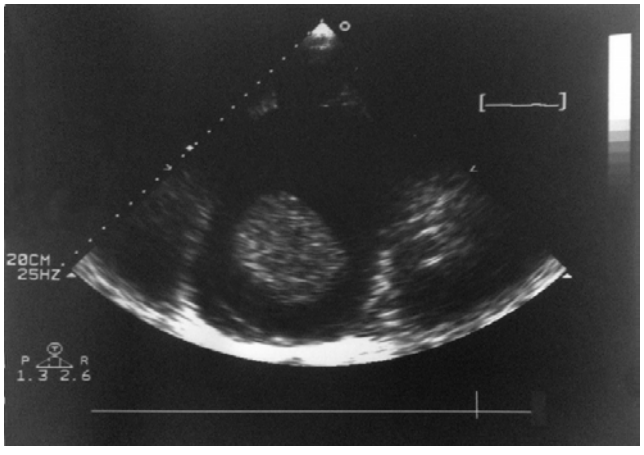
CLINICAL CASE CORNER 6 - HEART (AND PERIPHERAL!) MUSCLE DISEASE

2089

Endomyocardial fibrosis with a giant atrial thrombus

J Jose Costa[1]; A Damasceno[2]
[1]*Sao Joao Hospital, Internal Medicine, Porto, Portugal*; [2]*Maputo Central Hospital, Cardiology, Maputo, Mozambique*

Background: Endomyocardial fibrosis (EMF) is a rare type of restrictive cardiomyopathy that is seen in young people who live in tropical countries. The etiology is still unknown, being nutritional deficit and infections the most discussed hypothesis. It can affect the right, left or both ventricles, and the clinical presentation will depend on which chamber is most affected.The basic histologic lesion is endomyocardial fibrosis that involves the ventricular muscle. This will lead to high ventricular filling pressures and atrioventricular regurgitation with subsequent atrium dilatation. This dilatation is associated with arrhythmic problems and the formation of thrombus that can lead to pulmonary embolism and sudden death.The diagnosis is made with echocardiography that shows a thickened endocardium in the ventricle wall. In right EMF there is an obliteration of the trabecular layer of the right ventricle with a reduction of the diameter and a tricuspid annulus dilatation with severe regurgitation. Clinical case: The authors present the case of a 19 years-old female patient with a 2-year history of dyspnea for large efforts. She denied chest pain, fever, cough or palpitations. She did not have any specific sign on physical examination or any abnormality on laboratorial evaluation. On the X-Ray she presented with cardiomegaly. The EKG presented a right axis deviation, and atrial fibrillation. Echocardiography showed endomyocardial fibrosis of the right ventricle with dilatation of the right atrium with a giant thrombus. She was put on diuretics and heart failure medication, and was proposed for cardiac surgery. Due to the high risk of embolization, the patient didn't take anticoagulant therapy.
Conclusion: EMF is a rare cause of cardiomyopathy of unknown etiology in tropical and underdeveloped countries. It affects mostly young people in some geographical area and carries a very high burden in these communities. This is a rare condition with a low medical awareness. Since the world is going through a globalization process with a high mobility of populations, which can increase the diagnosis of EMF in developed countries, the authors are trying to raise awareness of the medical community to the existence and treatment of EMF, especially in countries that can receive patients from tropical areas.



Atrial Thrombus

A rare etiology of left ventricular hypertrophy: mitochondrial cardiomyopathy

JSS Seo[1]
[1]*Inje University Pusan Paik Hospital, Busan, Korea Republic of*

Mitochondrial disease is a heterogeneous systemic disorder and a rare cause of left ventricular hypertrophy (LVH). A 48-year-old woman with diabetes mellitus underwent evaluation for cardiomegaly. Echocardiography showed concentric LVH and a restrictive diastolic pattern. While left ventricular ejection fraction was preserved, global longitudinal and radial strains were decreased. Cardiac magnetic resonance imaging demonstrated LVH and subepicardial delayed enhancement of the anterolateral and inferolateral walls of the left ventricle. Endomyocardial biopsy with transmission electron microscopy showed accumulation of varying-sized abnormal-shaped mitochondria in the myocytes including electron-dense inclusion and disoriented cristae. DNA sequence analysis revealed heteroplasmy of m.3243A>G and wild type. Therefore, mitochondrial cardiomyopathy, leading to diagnosis of mitochondrial encephalomyopathy, lactic acidosis, and stoke-like episodes (MELAS syndrome). Diagnosis of mitochondrial disease based on cardiac symptoms is unusual because cardiac symptoms or signs present later than other neurologic or systemic symptoms. Referrals for cardiac evaluation typically come from neurologists or geneticists who have diagnosed a mitochondrial disease. Interestingly, in this case, there were no prominent neurologic symptoms. It is unique for prominent LVH without significant neurologic symptoms to suggest MELAS syndrome. In conclusion, we should consider the mitochondrial cardiomyopathy as a rare cause of LVH when there are no definite neurologic symptoms.

2091

A rare case of Fabry cardiomyopathy requiring permanent pacemaker and implantable cardioverter-defibrillator despite enzyme replacement therapy

SH Sang Hyun Park[1]; JY Chin[1]; KT Jung[1]; YJ Choi[1]; WH Kim[1]; KW Kang[1]
[1]*Eulji University Hospital, Daejeon, Korea Republic of*

A 55-year-old male farmer referred to our hospital due to ECG abnormality, dyspnea on exertion and cardiac enzyme elevation after diagnosis of scrub typhus at local clinic. Cardiac troponin-T was mildly elevated (0.169 ng/mL, normal range: 0-0.1 ng/mL). A 12-leads electrocardiogram (ECG) revealed normal sinus rhythm with 1st degree atrioventricular block (AVB), complete right bundle branch block (RBBB) and pathologic Q wave in I, II, aVL, V5 and V6. (Figure 1) Transthoracic echocardiogram showed diffuse severe concentric hypertrophy of the left ventricle (LV) of an average ventricular wall thickness of 30 mm. (Figure 2) A dynamic left ventricular outflow track obstruction LVOT) was observed during the Valsalva maneuver. Right ventricle (RV) was also hypertrophied (RV free wall thickeness, 9mm). Cardiac magnetic resonance imaging revealed diffuse delayed hyper-enhancement with various degrees of transmurality.
More detailed familial history taking informed that his younger brother and older sister suffered from cardiac problem. His oldest sister died of sudden cardiac death at the age of 60. Genetic disorder was suspected and confirmed as Fabry diasese (FD) via GLA gene sequencing. A missense mutation was identified at exon 6 within a GLA gene. The mutation is known to cause FD of a cardiac variant type by literature review. Additionally 4 family members were confirmed to have FD with same mutation.
Index patient initiated enzyme replacement therapy (ERT) with intravenous agalsidase-beta via outpatient department (OPD). Follow-up ECG showed first degree AVB and left bundle branch block (LBBB). (Figure 3) He experienced two episodes of syncope and frequently complained of dizziness during OPD follow-up. ECG revealed complete AVB. (Figure 4) Beta blocker was discontinued more than two weeks after that. However, complete AVB didn't improve. Permanent pacemaker (PPM) which has a function of implantable cardioverter-defibrillator (ICD)

was implanted considering that he has high risk features of sudden cardiac death such as syncope, severe hypertrophy of LV septal wall and family history of sudden cardiac death. Peak pressure gradient of LVOT markedly decreased to 36mmHg after PPM implantation from 63mmHg before that. Symptoms of dyspnea and dizziness also markedly improved.
Progression of Fabry cardiomyopathy can lead to severe conduction dysfunction such as complete AVB requiring PPM despite ERT. It needs to check ECG serially to identify the progression of conduction disturbance in patients with conduction dysfunction at baseline to prevent cardiac events.

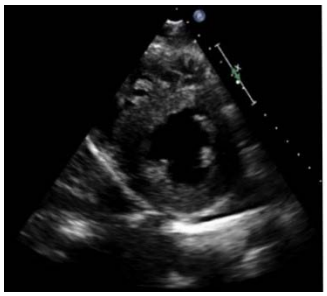
ECG and Echocardiography

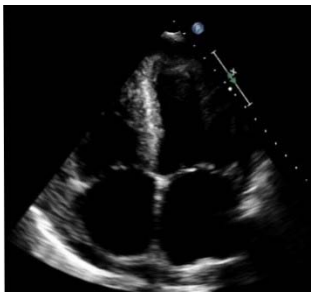
2092

Cardiac amyloidosis: a difficult journey to diagnosis

PM Paulo Maia Araujo[1]; A Nunes[1]; S Amorim[1]; MB Campelo[1]; H Baldaia[2]; P Rodrigues-Pereira[2]; R Bergantim[3]; A Andrade[4]; MJ Maciel[1]
[1]Sao Joao Hospital, Cardiology, Porto, Portugal; *[2]Sao Joao Hospital, Pathology, Porto, Portugal*; *[3]Sao Joao Hospital, Clinical Hematology, Porto, Portugal*; *[4]Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*

The present case refers to a 63-years-old women, with hypertension, dyslipidemia and history of unilateral nephrectomy (for nephrolithiasis), without any other relevant medical history and no family history of cardiac diseases. She was admitted to hospital for progressive dyspnea, with a 3-month evolution time. At admission, she had evident signs of congestive heart failure (HF). Electrocardiogram showed low limb lead voltage and poor precordial R-wave progression. Echocardiogram (TTE) revealed severe left ventricular (LV) systolic dysfunction due to global hypocontractility, without dilatation of cardiac chambers, but with moderate LV hypertrophy (LVH); right ventricular function was preserved. Coronariography excluded epicardial coronary disease. For better characterization, a cardiac magnetic resonance was performed, showing a marked increase in myocardial mass with concentric LVH, global hypokinesia with severe LV dysfunction and subendocardic late gadolinium enhancement, almost circular, in all ventricular plans. These findings were suggestive of infiltrative cardiomyopathy, with a high suspicion of amyloidosis. Laboratorial tests for amyloidosis were all negative, including serum and urinary immunofixation, free light chains (FLC) assay and nuclear imaging with DPD. Tests for another possible etiologies of infiltrative cardiomyopathy were negative as well. Bone marrow biopsy was negative and endomyocardial biopsy revealed an unspecific inflammatory infiltrate, without amyloid deposits. Rectum and abdominal fat biopsies were also negative for amyloidosis. After initial compensation, the clinical status deteriorated again, with progression to severe biventricular dysfunction. Thus, diagnostic workup was repeated and a high FLC lambda/kappa ratio, previously normal, was found. Given the high suspicion of AL cardiac amyloidosis, bone marrow biopsy was repeated, this time showing infiltration of plasma cells with positive immunohistochemistry to lambda FLC. Therefore, it was performed an immunohistochemistry review of myocardial biopsy, that revealed the deposition of lambda FLC also in myocardial tissue, making the definitive diagnosis of AL cardiac amyloidosis. Chemotherapy (Cth) with bortezomib, dexamethasone and cyclophosphamide was initiated. However, there was progression to terminal HF and evaluation for cardiac transplantation (CTr) was started, with the perspective of being followed by autologous stem cell transplantation (ASCT). During evaluation of extracardiac organ amyloid involvement, colonoscopy with rectum biopsy was repeated and it revealed amyloid deposition in the rectum tissue. Given the involvement of an extracardiac organ and the associated absence of hematologic response to Cth, disease progression was assumed and the patient was withdrawn from CTr evluation. After clinical compensation, she was discharged from hospital with indication for comfort measures and 2 months later, the patient died. This case shows that the diagnosis of cardiac amyloidosis remains a clinical challenge, in a disease in which early diagnosis is fundamental to a better prognosis. Laboratory tests may be negative and even analysis of tissue biopsies may give misleading results. These difficulties may lead to delays in establishing a definitive diagnosis, with significant negative effects on the prognosis. Improvements in diagnostic approach can promote the earlier beginning of Cth, slowing the disease progression and allowing therapies, such as CTr and ASCT.





TTE: Thickened and hyperechogenic walls

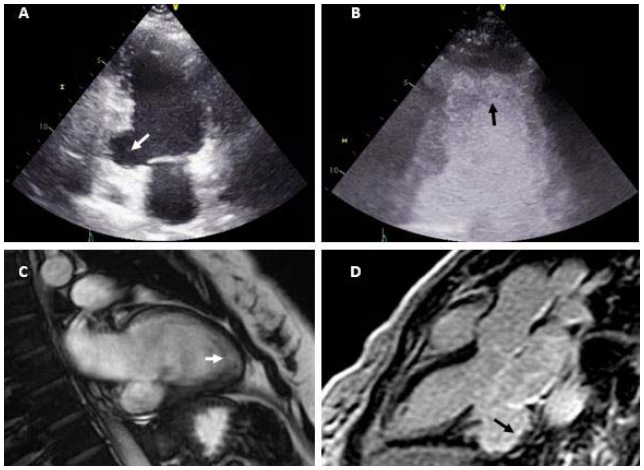
2093

Non-compaction cardiomyopathy with multiple embolic events, a new association to a sarcomeric gene mutation.

R Morales Murillo[1]; E Fortuny Frau[1]; P Pericas[1]; J Pons Llinares[1]; M Noris Mora[1]; M Massot Rubio[1]; R Gonzalez Colino[1]
[1]University Hospital Son Espases, Cardiology, Palma de Mallorca, Spain

Introduction and Case Report Description: Left ventricular non-compaction (LVNC), is a rare form of cardiomyopathy characterized by deep intertrabecular recesses communicated with the ventricular cavity. Since different diagnostic criteria have been proposed, final diagnosis can be challenging. We report the case of a 29-year-old woman, without known cardiovascular risk factors, family history of a brother with degenerative muscle dystrophy and a personal history of pontine stroke of unclear origin, due to the occlusion of the vertebrobasilar artery at the age of 25. No previous history of heart disease was reported. Although she had no cardiovascular symptoms at any time, she was referred to our hospital after the finding of high density monomorphic ventricular ectopic heart beats that were confirmed on an EKG Holter.
Description of the problem, procedures, techniques and/or equipment used: We performed a transthoracic echocardiogram (TTE) that showed a basal inferior aneurism (Fig A). Contrast TTE exposed hyper-trabeculated areas on the lateral and apical walls (Fig B). Cardiac resonance objectivised myocardial thinning involving lateral wall and apex with augmented trabeculation, meeting criteria of non-compaction, and confirmed the presence of an aneurism of 36 x 17mm (Fig C). Left ventricular (LV) function was preserved. Myocardial suppression sequences revealed sub-endocardial late enhancement of the aneurism, which suggested a chronic ischemic origin (Fig D). Coronary angiogram showed normal coronary arteries. The patient had a brother with degenerative myopathy and a father with onset of atrial fibrillation at young age, so we performed genetic testing that found a heterozygous mutation on the sarcomeric gene MYH6. QUESTIONS, PROBLEMS OR POSSIBLE DIFFERENTIAL DIAGNOSIS. It was proposed that the stroke in addition to an asymptomatic myocardial infarction were most likely caused by multiple embolism originated in the left ventricle non-compacted areas and the ectopic heartbeats were originated on the scarred area. Treatment with betablockers was started, substantially diminishing the ectopic heart beats and anticoagulation therapy with warfarin was considered necessary.
Answers and discussions: LVNC is a genetically heterogeneous disorder associated with several gene defects. It is known that MYH6, encoding myosin heavy chain 6, has a vital role in heart development. Mutations in MYH6 have been related to hypertrophic cardiomyopathy, dilated cardiomyopathy and atrial septal defects. Yet, to our knowledge this would be the first case linked to LVNC. Regarding the prognosis, although the classic triad of heart failure, arrhythmias and embolic events has been described, possible clinical presentation are very variable and prevention and treatment of the complications are the main therapeutic goals.
Conclusions and implications for clinical practice. Given that this is the first association of the disease with an MYH6 mutation, it should be considered of uncertain clinical significance. However, it is of big importance its segregation in the progenitors and family susceptible of being carrier of the mutation to determine its implication in the development of the disease. The prevention of embolic events is an issue still discussed, in the past there was a tendency of giving anticoagulants to all patients with LVNC, now days some only recommend it on determined cases like patients with LV dysfunction, atrial fibrillation and previous embolic events. Even

though there is no robust data to support it, anticoagulation therapy in our patient seems to be justified.



2094

A challenging case of rare cardiomyopathy and its clinical implications

A Adriana Covaliov[1]; C Radulescu[1]; L Antohi[1]; R Radu[1]; O Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*

Introduction: Left ventricular non-compaction or 'spongy myocardium' is a rare congenital cardiomyopathy characterized by prominent trabeculations and intertrabecular recesses that communicate with the ventricular cavity rather than the coronary circulation.
Case description: We present a case of 49 years old male with history of an ischemic stroke one month ago, who was admitted to hospital because of clinical signs and symptoms of left heart failure with extreme breathlessness, anxiety and profuse diaphoresis, symptoms developed in the last 12 h during an intercurrent respiratory infection. Physical examination revealed tachypnea, severe hypoxemia, the 3rd heart sound h and crackling rales extended to upper lungs with a systolic blood pressure of 170/90 mmHg. Electrocardiogram showed sinus tachycardia with QRS duration of 130 ms and negative T waves in V5, V6, DI, AVL. First echographic evaluation at the emergency room showed a dilated left ventricle with severe systolic disfunction and the response to initial supportive therapy was good. The levels of brain natriuretic peptide after 24 h from the acute event was 2504 pg/ml. Later transthoracic echocardiogram reevaluation showed a left ventricle enlargement with severe systolic dysfunction (calculated ejection fraction 25%) and proeminent trabeculation, sponge-like appearance, especially in the mid and apical areas of the left ventricle suggestive for non- compaction cardiomyopathy (Fig 1). The mitral and tricuspid regurgitation were mild. Also, transesophageal echocardiogram revealed a mobile, heterogeneous, echodense structure located in intertrabecular recesses, probably thrombi (Fig 2). The patient had no significant arrhythmias during his hospital stay. After evidenced based heart failure theraphy with loop diuretics, ACE inhibitors, spironolactone and b blockers his symptoms improved significantly. Also anticoagulation therapy was added. Follow-up examinations during 6 month showed an improved exercise capacity quantified by cardiopulmonary test and BNP levels dropped with more than 70 percent. Transthoracic and transesophageal echocardiography reevaluation revealed a better systolic function (EF calculated 34 %) with the decrease of end-systolic volume and no more thrombi were seen in the cardiac cavities after 6 month of oral anticoagulation. The aetiological investigations were completed with a normal coronarography exam and a cardiac IRM which confirmed the non-compacted cardiomiopathy in the apical areas. (Fig 3) The patient was advised to continue the evidenced based heart failure therapy treatment with no indication at the moment for cardiac transplantation. All first-degree relatives were advised to undergo screening echocardiogram.
Conclusions: This case illustrates a rare non-compaction cardiomyopathy diagnosed at mid age after clinical presentation with de novo acute heart failure. Evidenced based heart failure theraphy had unexpectably good results which could be explained by the response to neurohormonal therapy for heart failure of the compaction myocardium areas with beneficial effects on metabolic and adrenergic abnormalities. One of the complications of this cardiomyopathy is intraventricular thrombosis complicated in this case with ischemic stroke just one month before diagnostic. Also, the response to anticoagulant theraphy was excellent with no more thrombi seen on follow up and more thromboembolic events.

Rapidly manifested heart failure treated with left ventricle assist device and heart transplantation in patient with Becker muscular dystrophy

V Bajoras[1]; G Zuoziene[1]; V Maneikiene[1]; V Janusauskas[1]; A Zorinas[1]; K Rucinskas[1]
[1]*Faculty of Medicine of Vilnius University, Clinic of Cardiac and Vascular Diseases, Vilnius, Lithuania*

Introduction: We describe a rare case of Becker muscular dystrophy (BMD) which presented by rapidly progressing heart failure (HF), without primary expressed clinical signs of neuromuscular disease and was treated with left ventricle assist device (LVAD) and heart transplantation. Description: 22 y/o previously healthy male presented to our hospital with shortness of breath on exertion (NYHA class III), orthopnoea lasting for a few weeks. Physical examination was unremarkable. Blood tests were in normal range, except for BNP (2132 ng/l), CK (1964 U/l) and CK-MB (31 mcg/l). Transthoracic echocardiography (TTE) and magnetic resonance imaging indicated dilated cardiomyopathy (DCM) with severe restrictive mitral valve (MV) regurgitation, LVEF 25%. VO2 max on spiroergometry was 15.5 ml/kg/min. Endomyocardial biopsy demonstrated non-specific changes of DCM. Successful MV repair was performed. Patient's exercise tolerance improved (NYHA class II), and LVEF increased up to 38% postoperatively with medical HF treatment at one year follow up. At the same visit slightly reduced strength of lower extremities was noted, and BMD was diagnosed clinically as there was no possibility to perform specific genetic examination at the time. HF was progressing gradually and two years after the surgery patient deteriorated to NYHA class IV with LVEF 15%, VO2 9.2 ml/kg/min, PA pressure 80/50, PCWP 44/40mmHg and PVR 8 WU. Patient was listed for heart transplantation and LVAD was implanted as a bridge to heart transplantation. Six months after the procedure patient's condition improved significantly, patient was in NYHA class II with PVR 2.6 WU. Heart transplantation was successfully performed 1 year after LVAD implantation. Patient was treated with a small dose of prednisolone, calcineurin inhibitor (CNI), and mycophenolate mofetil postoperatively. Inherited BMD was confirmed by detecting deletions in dystrophin gene of the patient and his brother. 3 months after heart transplantation, rapid deterioration of kidney function (creatinine 329 mcmol/l), and rapid increase of ALT and AST level (467 and 341 U/l respectively) were observed. Due to possible drug induced kidney and liver injury immunosuppressive therapy was revised and CNI was withdrawn. Subsequently, patient's kidney and liver function improved. Every attempt to initiate CNI or rapamycin resulted in increase of creatinine, liver enzymes and bilirubin. As a consequence of reduced immunosuppression patient developed humoral rejection. Despite treatment with monoclonal antibody therapy and plasmapheresis heart function could not be recovered. After 40 days in the intensive care unit, patient died of multiple organ dysfunction syndrome induced by sepsis.
Conclusions: Becker muscular dystrophy can present with heart failure due to DCM even before symptoms of muscular dysfunction appear. Patients with BMD may be more susceptible to the side effects of immunosuppression and should be considered for LVAD implantation as a destination therapy if they develop severe heart failure resistant to medical treatment.

Cardiac light chain deposition disease relapsing in the transplanted heart

A Alberto Aimo[1]; G Vergaro[2]; A Pucci[3]; A Paolicchi[3]; S Bernazzali[4]; G Buda[3]; C Passino[1]; M Emdin[1]
[1]*Sant'Anna School of Advanced Studies, Pisa, Italy*; [2]*Gabriele Monasterio Foundation, Pisa, Italy*; [3]*University of Pisa, Pisa, Italy*; [4]*Polyclinic Santa Maria alle Scotte, Siena, Italy*

Light chain deposition disease (LCDD) is characterized by the deposition of monoclonal light chains (LCs) causing tissue inflammation and damage. Renal failure is a hallmark of LCDD, whereas heart failure (HF) is infrequent, and has been almost constantly reported in combination with severe renal impairment. Heart transplantation (HT) has never been described in patients with LCDD. Herein, we report a case of undiagnosed LCDD with selective cardiac phenotype, relapsing after heart transplantation. A 44-year-old man was hospitalized because of dyspnoea, cough and ankle oedema, worsening over 4 months. HF with reduced ejection fraction was diagnosed: echocardiography and magnetic resonance showed a dilated left ventricle with normal mass, global hypokinesis, and patchy septal fibrosis; at coronary angiography, epicardial arteries were normal. Biohumoral evaluation disclosed increased plasma N-terminal fraction of brain natriuretic peptide and troponin T, and normal serum creatinine; no clear monoclonal peak was present, but serum protein immunofixation revealed a monoclonal component (IgG kappa).

Endomyocardial biopsy (EMB) demonstrated non-specific interstitial inflammation; negative Congo red stain excluded amyloidosis. Despite guideline-recommended therapy including implanted cardiac defibrillator, declining cardiac function and refractory symptoms required urgent HT, 4 months later. The patient recovered his health for three months, then symptoms and cardiac dysfunction recurred. At that point, cardiac histology was re-evaluated, and immunohistochemistry revealed massive kappa chain accumulation in the native heart. In addition, a borderline positivity for kappa chains was found in an EMB performed 3 months after the HT. The suspicion of LCDD was raised, but was contested because of normal kidney function. Another EMB, 4 months later, resulted slightly positive for kappa chains. A consensus on the LCDD diagnosis was eventually reached 11 months after the HT, when an evident kappa chain accumulation was detected in both a third EMB and a renal biopsy. A therapy with melphalan and desamethasone was then started, causing a transient clinical improvement. Nonetheless, the patient died two months later because of systemic Cytomegalovirus infection. LCDD should be considered whenever unexplained HF is associated with evidence of a plasma cell dyscrasia, even if renal function is preserved. As in this case, rapid deterioration of cardiac function can occur, with just 8 months from the onset of symptoms to urgent HT. We report for the first time that graft dysfunction can develop 3 months after HT and before LC deposits become evident. Early diagnosis and prompt initiation of a treatment for the haematological disorder are probably crucial in order to improve the natural history of LCDD-related HF.

Cardio pulmonary exercise testing detects ventricular tachycardia at peak exercise in 28 year old soccer player

CH Dall[1]; H Rasmusen[2]
[1]*University of Copenhagen, Dept. of Cardiology, Dept. of Physical Therapy & Institute of Sports Medicine, Bispebjerg Hospital, Copenhagen, Denmark*;
[2]*Department of Cardiology, Bispebjerg Hospital, Copenhagen, Denmark*

Background and purpose: Physical exercise plays an important role in preventing chronic disease and in maintaining health throughout life. Nevertheless, in some subjects intensive exercise can trigger a cardiopulmonary event (nausea, syncope or a fatal cardiovascular episode). This occurs primarily in the context of an underlying inherited or genetic cardiac disorder. The purpose of this study is to describe a case challenged by the ability to reproduce symptoms using the conventional assessment techniques.
Case description: A 28 year old male having presented several episodes of syncope and near syncope, while playing soccer, was referred to cardiopulmonary screening. He has no family history of sudden cardiac death.
Outcome: The golden standard assessments (i.e. resting ECG, Holter monitoring, echocardiography, coronary angiography) could not detect arrhythmia or reproduce pathology/symptoms in this case. Conversely a supplementary screening using a Cardio Pulmonary Exercise Test (CPET) reproduced symptoms, so that the subject experienced an episode of ventricular tachycardia (VT) lasting for 11 seconds at peak workload/peak VO2 and the ECG returned subsequently to normal level without intervention.
Discussion: In this case report the CPET reproduced symptoms. None of the conventional assessment techniques detected any arrhythmia or pathology/symptoms when testing at rest. Using the VO2peak and the respiratory exchange ratio as guidance is pivotal in the CPET testing. Especially for athletes, this can be important because the peak workload and VO2peak is much higher than in average subjects. There is a risk that the conventional assessment techniques are not sensitive enough when assessing athletes only presenting symptoms at peak workload.
Conclusion: and implication Measurements that are able to reproduce symptoms should be included as a supplement to conventional assessment techniques particularly in the evaluation of cardiac symptoms in relations to intense physical exercise in athletes. In patients with arrhythmia but without structural changes the CPET becomes important in reproducing symptoms. Based on the reproduced symptoms from the CPET the case subject was referred to either ablation or ICD therapy.

A challenging diagnosis

K Kisa Hyde Congo[1]; R Guerreiro[1]; JF Carvalho[1]; D Bras[1]; AR Santos[1]; B Picarra[1]; P Dionisio[1]; J Aguiar[1]
[1]*Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal*

Forty-two-year-old male, with a history of lung lobectomy, reports to the emergency department after an episode of syncope at rest. He also referred dyspnea for moderate exertion for the last 2 months. No previous episodes of syncope, chest pain, palpitations, orthopnea, nocturnal paroxystic dyspnea and lower limb edema. The initial ECG showed sinus rhythm with a 1st grade AV Block alternating with 2nd degree AV Block Mobitz II and 3rd degree block. The echocardiogram showed dilated left ventricle with diffuse hypokinesia and severely depressed systolic function. He was admitted at a cardiac ward for further studies and therapy. Viral serologies and autoimmune studies were negative. Coronary angiography showed no lesions. Electromiogram and body CT showed no abnormalities. Endomyocardial biopsy showed advanced fibrosis. Spirometry showed small airway disease. Genetic testing for cardiolaminopathies was negative. Cardiac MRI showed marked dilation and biventricular dysfunction, mid-wall and epicardial late enhancement in septal and inferior segments, respectively. Etiological study didn't arrive at a definitive diagnosis, nevertheless the most likely diagnosis is Cardiac Sarcoidosis. Considering the severe left ventricular dysfunction and advanced AV block with indication for definitive pacemaker, a CRT-D was implanted. At 6 months follow-up the patient showed clinical improvement and NYHA I class.

Funding Acknowledgements: This study was supported by a research fellowship from Japan Heart Foundation (E.A.).

Background: Heart failure is a major health problem worldwide and trials to assess novel therapies are increasingly global. However, recent registries suggest that characteristics of acute heart failure (AHF) patients may differ between Asia and Western countries, though direct comparison of mortality after an AHF episode is scarce.
Purpose: This study sought to investigate difference in long-term mortality in AHF patients between East Asia and Europe.
Methods: From the GREAT (Global Research on Acute Conditions Team) registry, patients who were presenting with AHF to the emergency department in East Asia (Japan and Korea) and Europe (Western Europe and Czech Republic) were included in this analysis. Patients were followed up for all-cause mortality at 1-year.
Results: Of 17120 patients, there were 6961 (41%) patients from East Asia and 10159 (59%) patients from Europe. One-year all-cause mortality was lower in East Asia (18%) than in Europe (32%). Furthermore, unadjusted risk of death was lower in East Asia than in Europe (hazard ratio (HR) 0.52, 95%-confidence interval (CI) 0.49-0.56, $P < 0.001$). Long-term risk of death remained lower in East Asia than in Europe after adjustment (HR 0.52, 95%-CI 0.47-0.57, $P < 0.001$), propensity-score matching (unadjusted HR 0.50, 95%-CI 0.42-0.59, $P < 0.001$ and adjusted HR 0.44, 95%-CI 0.37-0.51, $P < 0.001$), or in AHF patients with optimal heart failure therapies (HR 0.40, 95%-CI 0.33-0.49, $P < 0.001$).
Conclusions: In patients presenting with AHF to the emergency department, East Asia has a strikingly better long-term survival compared with Europe. This result will have important impact in the design and choice of recruiting countries in future event-driven AHF trials.

On behalf of: POST-SMIT Study Group

Background: There is growing awareness that comorbidities frequently accompany Heart Failure (HF) and lead to increased morbidity and mortality. While numerous studies focus on a single comorbidity, only few studies examined the prognosis impact of multiple comorbidities in HF patients. Furthermore, Left Ventricular Ejection Fraction (LVEF) is a powerful predictor of cardiovascular outcome in HF patients, but it is not clear if LVEF maintains its predictive value in old patients with multiple comorbidities.
Methods: We enrolled patients who were discharged by 23 Internal Medical Units of Tuscany, an Italian region of 3,7 million inhabitants, in a period of 30 days (30 Genuary-28 February 2014) with the main diagnosis of HF. We recorded epidemiological, instrumental and clinical data and patients were followed over a 12-months period. We considered 7 comorbidities (diabetes mellitus, hypertension, chronic renal failure, chronic obstructive pulmonary disease, atrial fibrillation, anemia, cognitive deficit) and LVEF during hospitalization. For analysis we distinguished the patients in the three categories used in HF ESC guidelines 2016: HF with reduced, mid-range, preserved ejection fraction (HFrEF, HFmrEF, HFpEF, respectively). The endpoints were: a) correlation between number of comorbidities and all-cause mortality at 1, 6, 12 months; b) correlation between LVEF and all-cause mortality at 1, 6, 12 months when adjusted for > 2 comorbidities.
Results: We recruited 451 patients (M= 44.3%) with a mean age of 83 + 8.4 years. Mean LVEF was 44.2 + 11. Mortality was 9.5%, 25.7%, 38.1% at 1, 6, 12 months respectively. In multivariate analysis mortality was significantly correlated with number of comorbidities (for each increase of one comorbidity RR 1.21 $p = 0.07$; RR 1.19 $p = 0.006$; RR 1.16 $p = 0.008$ at 1, 6, 12 months respectively). Patients with > 3 comorbidities had higher mortality compared with < 3 comorbidities at 1 (RR 2.69 $p = 0.03$), 6 (RR 1.63 $p = 0.04$), 12 (RR 1.43; $p = 0.005$) months respectively. Instead, when adjusted for > 2 comorbidities, LVEF did not correlate with mortality: HFrEF vs HFpEF (RR 1.10 $p = 0.89$; RR 1.81 $p = 0.13$; RR 1.35 $p = 0.41$ at 1, 6, 12 months respectively) and HFmrEF vs HFpEF (RR 0.53 $p = 0.18$; RR 1.03 $p = 0.92$; RR 0.96 $p = 0.86$ at 1, 6, 12 months respectively).
Conclusions: In a cohort of old HF patients discharged from Internal Medicine Units and followed over a 12-months period, mortality was significantly correlated with the number of comorbidities, whereas reduced LVEF did not correlate with mortality when adjusted for two or more comorbidities.

P2107

Liver fibrosis score predicts mortality in heart failure patients with preserved ejection fraction

Y Yasuchika Takeishi[1]; A Yoshihisa[1]
[1]Fukushima Medical University, Fukushima, Japan

Background: Heart failure with preserved ejection fraction (HFpEF) has several pathophysiological aspects, including stiffness and/or congestion of multiple organs. Poor prognosis is expected in heart failure patients with liver stiffness, which has recently been assessed by nonalcoholic fatty liver disease fibrosis score (NFS; based on aspartate aminotransferase to alanine aminotransferase ratio, platelet counts and albumin). We aimed to investigate the impact of NFS on prognosis of HFpEF patients, with consideration for the peripheral collagen markers such as procollagen type III peptide (PIIIP), type IV collagen 7S, and hyaluronic acid.
Methods and Results: We performed prospective observational study. Consecutive 492 hospitalized HFpEF patients were divided into four groups based on their NFS: 1st–4th quartile (n = 123, respectively). The 4th quartile group had the highest levels of PIIIP, type IV collagen 7S, hyaluronic acid, and B-type natriuretic peptide ($P < 0.001$ each). In addition, there were significant positive correlations between PIIIP, type IV collagen 7S, hyaluronic acid, B-type natriuretic peptide and NFS ($P < 0.001$ each). In the follow-up period (mean 1107 days), 93 deaths occurred. All-cause mortality increased in all four quartiles (8.1%, 12.2%, 23.6%, and 31.7%, $P < 0.001$). In the multivariable Cox proportional hazard analysis, NFS was an independent predictor of all-cause mortality in the HFpEF patients.
Conclusion: NFS, a novel indicator of liver stiffness, correlates with circulating systemic markers of fibrosis and congestion, and is associated with higher all-cause

mortality in HFpEF patients. NFS can be calculated simply and may be a useful tool to assess liver stiffness and prognosis in HFpEF patients.

P2109
Incidence and predictors of hyperkalaemia in 1600 patients with chronic heart failure

K Kaoutar Kharbouche[1]; K Kharbouche[1]; I Elhaddad[1]; L Azouzi[1]
[1]*chu ibn rochd, cardiology, casablanca, Morocco*

Background: Heart failure (HF) patients are particularly susceptible to electrolyte abnormalities and especially to hyperkalemia. Potassium (K) balance may be lost both through the neurohormonal mechanisms and through the drugs used in the treatment of this illness. Both hypokalaemia and hyperkalaemia are associated with increased mortality, mainly due to a higher risk of potentially fatal arrhythmia. Our goal was to explore the incidence and predictors of hyperkalemia in a broad population of heart failure patients.
Methods: This was a retrospective study of 1600 consecutive patients admitted to the therapeutic unit for heart failure between May 2010 and September 2014. Patients on dialysis and those with an estimated glomular filtration rate (GFR) < 10ml/min/1,73m^2; were excluded. Complete history on admission, age, sex, body weight, physical findings, comorbidities, and laboratory information were collected.
Results: The mean age of our population was 64.4 years (16-100), with a male predominance (64.6%). In 18 patients (1.3%) K was < 3.0 mmol/L, and in 424 patients (30.9%) K was >5.0 mmol/L. Independent of treatment assignement, patients at highest risk for hyperkalemia were those with age 75 years (28.5%), diabetes (33.9%), male gender (25.5%), high potassium at baseline (24.5%), renal dysfunction (44.5%) (identified by creatinine 2 mg/dl or GFR 30 ml/min/1.73m^2), symptomatic HF (28.1%) and those receiving therapy with angiotensin-converting enzyme (ACE) inhibitors (25.3%) or spironolactone (27.2%).
Conclusion: Changes in potassium ion may cause life-threatening arrhythmias. The risk of hyperkalemia is increased in symptomatic heart failure patients with comorbidities or combined renin-angiotensin-aldosterone system (RAAS) blockade. A favorable balance of benefit and risk requires clinical vigilance and closer laboratory monitoring, articularly among these patients.

P2110
In patients with recent ADHF and hyponatremia on admission, failure to normalize serum sodium is associated with increased risk of all-cause death and rehospitalizations during a 30-day follow-up

C Ariano[1]; R De Vecchis[1]
[1]*Cardiology Unit , Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy*

Background: Several studies have shown that hyponatremia is associated with increased risk of rehospitalization and death in patients with heart failure. In these studies, chronic heart failure (CHF) patients with persistent hyponatremia were compared only with CHF patients with a normal sodium level at hospital admission.
Aims: In the present retrospective study, conducted in a cohort of patients with recent acute decompensated heart failure (ADHF), all with hyponatremia ascertained at the time of hospital admission, we aimed to evaluate the effect of the normalization of serum sodium on the composite endpoint of short-term rehospitalization and mortality
Methods: A retrospective study centered on medical records of patients hospitalized for ADHF in the period April 2013 to April 2016 was performed. Data regarding serum sodium measurements had to be collected from medical records of cardiology wards of two hospitals, and were then processed for statistical analysis. As an inclusion criterion for enrollment, patients had to be suffering from heart failure that had required at least one hospitalization. Moreover, they had to be suffering from a state of hyponatremia (serum sodium < 135 mEq/L) at admission on the occasion of the index hospitalization. Patients with hyponatremia at admission were divided into two groups, one comprising patients with hyponatremia that persisted at the time of discharge (persistent hyponatremia) and a second including patients who had achieved normalization of their serum sodium levels (serum Na+ ≥ 135 mEq/L) during hospitalization until discharge. For both groups, the risk of mortality and rehospitalization during a 30-day follow-up was assessed
Results: One hundred and sixty CHF patients with various degrees of functional impairment were enrolled in the study. Among them, 56 (35%) had persistent hyponatremia over the course of hospitalization. At multivariable Cox proportional-hazards regression analysis, the risk of having a 30-day unplanned readmission or death was significantly higher in patients with persistent hyponatremia compared to those who exhibited a sodium level normalized at discharge (adjusted hazard ratio = 3.0743; 95% CI: 1.3981–6.7601; p = 0.0054). Among the other variables included in the Cox regression model, the number of admissions in the last 12 months (p < 0.0001), the length of stay of the index admission (p = 0.0015) and the NYHA class III at discharge (p = 0.0022) were also identified as risk factors associated with the composite endpoint of 30-day unplanned readmission or death.
Conclusions: In the present retrospective study, the risk of 30-day rehospitalization or death was significantly higher in patients with recent ADHF and persistent hyponatremia in comparison with ADHF patients who had had their serum sodium normalized during the hospital stay. This association seemed to be independent of the heart failure severity.

P2111
Prognostic value of right heart catheterization compared with cardiac magnetic resonance in dilated cardiomiopathy

E Eva Rumiz Gonzalez[1]; A Berenguer Jofresa[1]; JV Vilar Herrero[1]; A Cubillos Arango[1]; D Sanmiguel Cervera[1]; P Almela Alcaide[1]; I Lopez Lopez[1]; V Jimenez Cruz[1]; S Morell Cabedo[1]
[1]*Hospital General de Valencia, Valencia, Spain*

Introduction: Cardiac magnetic resonance imaging (CMR) is actually the gold standard technique for the evaluation of dilated cardiomiopathy (DCM). Recently, a new non-invasive model has been proposed to calculate pulmonary vascular resistance (PVR). However, its prognostic role in patients with acute heart failure (AHF) is unknown.
Purpose: Our objective was to evaluate the prognostic role of CMR and RHC in patients with DCM admitted for a first episode of AHF.
Methods: We prospectively included 60 patients who were admitted with a first episode of AHF and in whom a RHC and a CMR were performed the same day. We evaluated PVR, right ventricle ejection fraction (RVEF) and left ventricle ejection fraction (LVEF) using CMR, and mean pulmonary artery pressure, transpulmonary gradient (TPG), cardiac output (CO) and pulmonary wedge pressure were calculated using RHC.
Results: The mean age of our cohort was 64 ± 15 years, 63.3% were males and 35% showed coronary disease. Mean LVEF and mean RVEF were 34 ± 29% and 41 ± 15% respectively. During a median follow-up of 28 ± 5 months, 16 (26.7%) patients suffered a new rehospitalization for AHF and 6 (10%) patients died. After a multivariate analysis, TPG and CO were independly associated with MACE (rehospitalization for HF and/or death) HR: 1.2, CI 95%:1.07-1.54 and HR: 0.45 IC 95%: 0.21-0.93, p = 0.006. PVR assessed by RHC was the unique independent predictor of cardiac death (HR: 1.57 IC 95%. 1.02-2.42, p = 0.040). However, no CMR parameter was independently associated with MACE.
Conclusions: PVR assessed by RHC has shown to be the only independent predictor of rehospitalization for AHF and cardiac death in patients with DCM. Whereas, no CMR parameter was associated with a higher risk of MACE.

P2112
The prognostic value of the clinical presentation with syncope in acute pulmonary thromboembolism

M L Goncalves[1]; LUIS Abreu[1]; BRUNO Marmelo[1]; JULIO Gil[1]; HUGO Antunes[1]; M I Pires[1]; ISABEL Cunha[1]; DAVIDE Moreira[1]; INÊS Almeida[1]; BRUNO Rodrigues[2]; COSTA Cabral[1]
[1]*Hospital Sao Teotonio, Department of Cardiology, Viseu, Portugal*; [2]*Centro Hospitalar Cova da Beira, Cardiologia, Covilha, Portugal*

Introduction: Acute pulmonary thromboembolism (APT) has a heterogeneous and nonspecific clinical presentation, which rarely occurs with syncope (S). In fact, S is not included in the currently validated predictive scores (scores Wells and Geneva). Given the discrepancy between the clinical manifestation and the severity of PE, the question arises whether S, when present, is associated with a more unfavorable clinical situation.
Objective: To evaluate the prognostic impact of patients (P) with APT whose initial clinical presentation coincides with S.
Methos: From a total of 185 D hospitalized for APT in a intensive coronary care unit between 2010-2014, clinical, analytical and imaging information (CT and echocardiogram) were collected retrospectively. Division into groups: P whose initial presentation was with S (group S) vs. P with initial presentation without S (NS group). Association analysis (by chi-square method) was performed between the groups and several demographic, analytical and imaging characteristics.
Results: A mean age of 63.5 ± 18.0 years, 58.9% female, 29.7% with initial presentation with S, 50.3% submitted to fibrinolysis, 5.9% with in-hospital death due to the episode. Length of stay with median of 8 days [1-142].
The following statistically significant associations were established:
Group S had a higher prevalence of presentation with shock (33.3% vs. 10.8% p = 0.042) and a tendency for a greater need for treatment with fibrinolysis during hospitalization (60% vs. 40% p = 0.06). At admission they had lower mean arterial pressure (88.6 vs. 101.4mmHg p = 0.002), systolic blood pressure (109.4 vs. 123.7mmHg p < 0.001) and diastolic blood pressure (66.4 vs. 76.7mmHg p < 0.001). They presented lower pO2 / FIO2 ratio (268.6 vs. 272.4 p = 0.041).

ECG analysis showed a higher prevalence of BCRD (18.2% vs. 7.4% p = 0.033), higher ECGscore (6.3 vs. 3.7 p = 0.001) and higher presence of the S1Q3T3 pattern (36.4% vs. 21.7% p = 0.04).
Angio-CT imaging showed greater reflux of the inferior vena cava (60.6% vs 37.9% p = 0.037), greater interventricular septum bulging (93.9% vs. 72.6% p = 0.013), higher RV / VE ratio (1.62 vs (P < 0.05), greater RV diameter (49.0 vs. 43.8 p = 0.003), lower LV diameter (32.0 vs. 36.9 p = 0.004), higher pulmonary artery / aortic ratio (0.96 vs. 0.88 p = 0.033) and increased angiographic embolic load (Qanadli score 20.5 vs 17.3 p = 0.006).
Analytically, they had a higher prevalence of troponin I values> 0.4 ng / dL (54.5% vs. 34.7 p = 0.013).
Conclusion: P whose initial clinical presentation is with S, are associated with clinical, analytical and imaging characteristics typically associated with a worse prognosis. Thus, the presentation with S should put the hypothesis that we are facing a APT with worse prognosis, with its implications in the approach, monitoring and therapeutic.

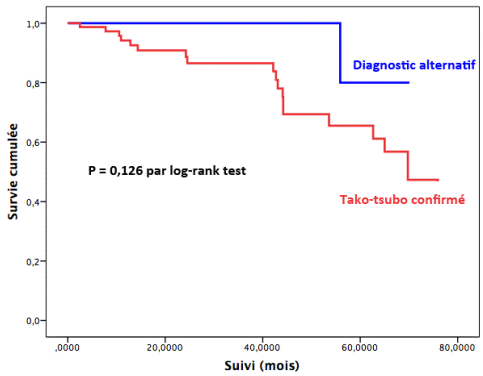
Long-term prognosis in Takotsubo patients: not so benign

C Clement Delmas[1]; G Domain[1]; A Roger[1]; L Marty[1]; C Biendel[1]; M Galinier[1]; D Carrie[1]; O Lairez[1]
[1]*Toulouse Rangueil University Hospital (CHU), Cardiology department, Toulouse, France*

Background: Takotsubo syndrome (TTS) is an improving diagnosis, considered benign despite rare acute complications since its recover in few days or weeks. But although recent large series found 4.1% in-hospital mortality similar to ACS, long-term prognosis is poorly appreciated.
Methods: and results: Between 10.2009 and 03.2016, 113 patients were suspected for TTC according to the Mayo Clinic criteria, and included in a prospective cohort in our tertiary hospital. Patients underwent systematic check up with cardiac MRI, urinary and/or plasma catecholamine, and thyroid balance to differentiate true TTS (n = 91; 80.5%) and alternative diagnosis (n = 22; 19.4%/ myocarditis, spasm, ACS, pheochromocytoma, thyrotoxicosis). 30-days mortality and late mortality were similar with a trends to be more for alternative diagnosis (1.3% vs 0 and 25% vs 5.5%; p = ns). Etiologies of death were shared between cancer (9.1%), heart failure (2.6%), stroke (1.3%) and miscellaneous condition (Table2). Long-term follow-up seems to be similar with more than 60% of NYHA1-2 patients and same re-hospitalisation rate. Moroever long-term medication were similar probably due to same comorbidities.
Conclusion: Patients with confirmed TTS have late complications which seem to be related to older age and comorbidity, and merit special attention. Thus a systematic follow-up seems to be needed.



P2114

Prognosis of pulmonary embolism: risk stratification in non high-risk patients

P Pedro Freitas[1]; AR Santos[2]; M Goncalves[1]; A Oliveira[1]; A Santos[2]; J Oliveira[2]; M Gago[2]; R Mamede[2]; D Correia[2]; N Vale[1]; J Carmo[1]; S Guerreiro[1]; J Brito[1]; J Ferreira[1]; M Mendes[1]
[1]*Hospital de Santa Cruz, Cardiology, Lisbon, Portugal*; [2]*Hospital de Sao Francisco Xavier, Lisbon, Portugal*

Background/Introduction: The prognostic assessment of acute pulmonary embolism (APE) in patients at low or intermediate risk takes into consideration the evaluation of right ventricle dysfunction (RVD) and/or evidence of myocardial injury. Nevertheless, the 2014 ESC guidelines recommendations on risk stratification have not been tested in real-world APE patients.
Purpose: The aim of our study was to compare the PESI classification with the ESC 2014 risk stratification model to predict all-cause mortality at 30-days in non high-risk patients. We also evaluated the role of RVD, elevated troponin and elevated NT-proBNP in the risk stratification of patients with APE.
Methods: We have included 411 patients consecutively diagnosed with APE by computed tomographic angiography (CT-angio) in a single centre, between 2009 and 2015. RVD was evaluated with CT-angio or Echocardiography at admission. The cut-off values for troponin I and NT-proBNP were 0.04 µg/L (99th percentile) and 600 pg/mL. Cardiovascular dysfunction (CVD) was defined as the concomitant presence of RVD, elevated troponin and NT-proBNP. Multivariate analysis was performed using binary logistic regression. Discriminative power was assessed by ROC curves. The studied endpoint was all-cause mortality at 30-days.
Results: Median age was 76 years (IQR 65 – 83), 39% male. All-cause mortality at 30-days was 8.5% (n = 35). RVD was present in 59% (n = 243) of the patients. Troponin I and NT-proBNP were elevated in 50% (n = 205) and 68% (n = 280) of the patients, respectively. CVD dysfunction was present in 30.2% (n = 124). According to the ESC risk stratification strategy, 6.8% (n = 28), 53.8% (n = 221) and 39.4% (n = 162) patients were considered low, intermediate-low and intermediate-high risk, respectively. The PESI score classified 9.5% (n = 44), 13.8% (n = 64), 21.6% (n = 100), 17.5% (n = 81) and 37.6% (n = 174) patients as class I through V, respectively. The discriminative power of the ESC classification was inferior to the PESI classification (AUC = 0.62; AUC = 0.70, respectively; difference between AUC = 0.082; p = 0.07).
Univariate and multivariate analysis are depicted in the table. Only PESI classification and CVD remained independent predictors of all-cause mortality at 30-days. Adding CVD to the PESI classification modestly increased the discriminative power (AUC = 0.73; 95% CI 0.69 – 0.78; p < 0.001) even though AUC difference was not statistically significant (difference between AUC = 0.03; p = 0.16).
Conclusion: In this population, the 2014 ESC risk stratification strategy was not superior to the sole application of PESI classification. The contribution of cardiovascular dysfunction modestly for risk stratification of APE patients was modest.

Table. Univariate and multivariate analysis

	Univariate analysis		Multivariate analysis	
Variables	Odds ratio (95% CI)	P value	Odds ratio (95% CI)	P value
Elevated Troponin I	2.05 (0.99 – 4.2)	0.053		
Elevated NT-proBNP	6.76 (1.5 – 30.1)	0.012		
RVD	1.36 (0.7 – 2.8)	0.408		
Cardiovascular dysfunction	2.6 (1.3 – 5.3)	0.008	2.2 (1.08 – 4.6)	0.03
PESI classification	2.04 (1.4 – 2.99)	< 0.001	1.99 (1.4 – 2.8)	< 0.001
ESC 2014 model	2.2 (1.2 – 4.2)	0.016		

Cardiovascular dysfunction was defined as concomitant presence of elevated Troponin I, elevated NT-proBNP and right ventricular dysfunction.
Multivariate analysis was first performed considering PESI classification, elevated Troponin I and NT-proBNP and right ventricular dysfunction. Only PESI score remained an independent predictor of mortality. A second multivariate analysis was performed with PESI classification and cardiovascular dysfunction.

P2115

Long term survival hypertensive patients after ST-elevation myocardial infarction with preserved ejection fraction

S Sergey Kozhukhov[1]; A Parkhomenko[1]; N Dovganych[1]
[1]*NSC "Institute of Cardiology", Kiev, Ukraine*

Purpose: The immediate and long-term mortality after myocardial infarction (MI) in patients (pts) with hypertension is increased. This is likely to be due at least in part to the frequency of complications such as acute heart failure (AHF). AHF with preserved ejection fraction (EF>40%) accounts for almost 45% of heart failure cases. However, prognostic accuracy in those pts is unknown.
The aim of the present study is to focus on hypertensive patients with ACS, in order to better elucidate whether these patients are at higher risk and deserve a tailored approach for management and follow-up.
Methods: Of the 606 pts (age 54.8 ± 9 years, LVEF 49.1 ± 6.1%) who participated in a prospective study, 299 (49.3%) have history of AH. Patients were divided into 2 groups: 1 - with symptomatic AHF (Killip class II/III) during hospitalization (n = 84), 2 - without AHF (n = 215). Main outcomes were cardiovascular death and nonfatal MI with a median follow-up of 5 year.
Results: Pts with AHF were likely to be older, have history of coronary heart disease and have an anterior wall MI. Time from onset symptoms of MI was 3.9 ± 0.3 h and not differ between groups. Reperfusion therapy (TLT or PTCA) performed in 68.7%. On admission AHF pts presented with higher heart rate and glycemia, lower EF. Also AHF patients had a greater degree of LV hypertrophy and diastolic dysfunction. During hospital stay AHF pts has statistically significant ventricular tachycardia/fibrillation (6.0 vs 0.5 %; p < 0.05), early aneurism of LV (17.9 vs 6.5%; p < 0.01). Fig. 1 shows Kaplan Meier estimates of survival in patients with and without signs of AHF during admission and follow-up.

Conclusions: AHF with preserved EF in hypertensive patients is a frequent complication in STEMI and a powerful and independent predictor of 5 year survival. AHF presence is possible because of greater infarct size and more advanced LV diastolic abnormalities highly prevalent among hypertensive pts.

Funding Acknowledgements: FAPEX - FUNDAÇÃO DE APOIO À PESQUISA E À EXTENSÃO

Background: The use of digoxin as an effective therapeutic agent in acute systolic heart failure remains controversial mainly because of concerns about its safety and the increased risk of death reported in some groups of patients. Purpose: To describe differences in baseline and outcomes aspects in patients admitted for acute heart failure (AHF) according to the use of digoxin during hospital stay.
Methods: This retrospective cohort study included data from 329 patients admitted in three tertiary cardiac referral centres for AHF management between 2009 and 2016. All the data were collected from medical records. Results: The studied data are shown at the table 1. Conclusion(s): Although digoxin patients had more frequently atrial fibrillation, chronic kidney disease and longer hospital stay, there were no differences regarding outcomes in comparison to non-digoxin group. Digoxin use criteria in acute heart failure need to be further studied.

Prognostic significance of left axis deviation in acute heart failure patients with left bundle branch block

KH Ki Hong Choi[1]; GY Lee[1]; JO Choi[1]; ES Ju[1]; YJ Lee[1]; ES Jeon[1]
[1]Samsung Medical Center, Divison of Cardiology, Seoul, Korea Republic of

On behalf of: KorAHF investigators
Funding Acknowledgements: This research was supported by Research of Korea Centers for Disease Control and Prevention [2013-E63003-00].

Purpose: The prognostic impact of left axis deviation on clinical outcomes in AHFS with LBBB is unknown. This study aimed to determine the prognostic significance of left axis deviation in patients with acute heart failure syndrome (AHFS) with left bundle branch block (LBBB).
Methods: Between March 2011 and February 2014, 292 consecutive AHFS patients with LBBB were recruited from 10 tertiary university hospitals. They were divided into groups with no left axis deviation (LAD) (n = 189) or with LAD (n = 103) groups according to QRS axis < -30 degree. The primary outcome was all-cause mortality.
Results: The median follow up duration was 24 months (interquartile range 12 to 35 months). On multivariate analysis, the rate of all-cause death did not significantly differ between the normal axis and LAD groups (39.7% vs. 46.6%, adjusted hazard ratio [HR] 1.01, 95% confidence interval [CI] 0.66 to 1.53, p = 0.97). However, on the multiple linear regression analysis to evaluate the predictors of the LVEF, presence of LAD significantly predicted a worse LVEF (adjusted beta -3.25, 95% CI -5.82 to -0.67, p = 0.01). Right ventricle (RV) dilatation was defined as at least two of three electrocardiographic criteria (late R in lead aVR, low voltages in limb leads, and R/S ratio < 1 in lead V5) and was more frequent in the LAD group than in the normal axis group (p < 0.001).
Conclusion: Among the AHFS with LBBB patients, LAD did not predict mortality, but it could be used as a significant predictor of worse LVEF and RV dilatation.

Predictors of lower LVEF

Variables	Unadjusted Slope (95% CI)	p value	Adsjuted Slope (95% CI)	p value
Normal QRS axis (reference)				
LAD	-3.03 (-5.53 to -0.52)	0.02	-3.25 (-5.82 to -0.67)	0.01
RAD	0.45 (-9.47 to 10.36)	0.93	-0.20 (-10.08 to 9.67)	0.97
Age	0.18 (0.07 to 0.28)	0.001	0.16 (0.04 to 0.27)	0.007
Male	-1.31 (-3.69 to 1.07)	0.28	-0.56 (-3.00 to 1.87)	0.65
Ischemic etiology	2.00 (-0.44 to 4.44)	0.11	0.69 (-1.88 to 3.26)	0.60
Hypertension	2.30 (0.90 to 1.88)	0.16	0.98 (0.65 to 1.49)	0.94
Diabetes mellitus	2.64 (0.23 to 5.06)	0.03	1.57 (-1.08 to 4.22)	0.24
Body mass index≥ kg/m^2	0.98 (-1.83 to 3.78)	0.49	0.89 (-1.97 to 3.75)	0.54
QRS duration≥ 150 ms	-0.26 (-2.73 to 2.22)	0.84	-0.26 (-2.73 to 2.22)	0.83
Creatinine≥ 2mg/dL	1.67 (-1.58 to 4.91)	0.31	1.29 (-1.98 to 4.57)	0.44

CI = confidence interval; LAD = left axis deviation; RAD = right axis deviation

P2118

Possibility of impedance cardiography in prognosis assessment in hypertensive emergency complicated by acute heart failure

I Darmaeva[1]; E Shavarova[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Objective: impedance cardiography is a noninvasive modality utilized changes in impedance across the thorax to assess hemodynamic parameters. The aim of the study was to evaluate the hemodynamic profile of hypertensive emergencies patients complicated by pulmonary edema.
Design and methods: 27 patients with pulmonary edema due to hypertensive emergencies (55% females, mean age 71,5 ± 10,2 years) were selected from all patients hospitalized with hypertensive crises to emergency care hospital for evaluation of cardiac index, systemic vascular resistance (SVR), thoracic fluid content (TFC) by impedance cardiography (Cardio Screen, Germany). Patients with severe valve dysfunctions, aortic balloon pump were not eligible to the study. All parameters were assessed at baseline, after 2 and 24 hours. 26 (96%) patients had arterial hypertension in the past, 20 (74%) were treated regularly. Blood pressure (BP) was measured at initial contact by first aid doctors, then at hospital just after arrival, after 2, 6, 24, 72 hours. Serum creatinine, urea, potassium and ECG, chest X-ray, neurologic examinations were done for all patients. Fundoscopy, echocardiogram, brain computer tomography were done optionally. All patients were treated with loop diuretic furosemide and alfa1-adrenergic receptor inhibitor urapidil.
Results: mean BP at initial contact in patients with hypertensive emergencies was 209 ± 22/119 ± 17 mm Hg, after 2 hours – 178 ± 18/106 ± 21 mm Hg, after 6 hours – 159 ± 11/91 ± 11, after 24 hours – 147 ± 7/93 ± 5, after 72 hours – 143 ± 9/88 ± 7 mm Hg. So decreasing BP < 160/100 mm Hg after 6 hours was observed in 81%. Baseline, after 2 and 24 hours TFC in woman was 38 ± 7, 33 ± 9, 27 ± 5, in man - 45 ± 11, 38 ± 9, 31 ± 10. Baseline cardiac index 3.01 ± 1,02 l/min/m2, after 2 hours - 2,17 ± 1,06 l/min/m2. Baseline SVR was 3381,9 ± 1012,7 after 2 hours - 2502,2 + 1272,2 dyn × s × cm(-5) × m2. In-hospital mortality was 22% (n = 6). The median cardiac index in nonsurvivors was significantly less than for survivors. The AUC for cardiac index in predicting mortality was 0.76 (95% CI 0.51-0.91, p = 0.033). A cardiac index cut-off value < 2 l/min/m2 had sensitivity of 46% and specificity of 97% in lethal outcomes prediction.
Conclusions: ICG may be a helpful, noninvasive tool in noninvasive monitoring hemodynamic parameters and prognosis evaluation in patients with pulmonary edema due to hypertensive emergency.

P2119

Prognostic value of acute kidney injury and blood urea nitrogen/creatinine ratio in patients with acute heart failure

IR Lala[1]; DA Darabantiu[1]; A Pop-Moldovan[1]; M Puschita[1]
[1]*Vasile Goldis Western University, Cardiology, Arad, Romania*

Purpose: The aim of this retrospective study was to evaluate whether elevated admission blood urea nitrogen/creatinine ratio (BUN/Cr) or acute kidney injury (AKI) during hospitalization is predictive of in-hospital mortality in patients hospitalized with acute heart failure.
Methods: In this study we evaluated consecutive patients from the regional heart failure registry, enrolled during 2015 at our clinical county hospital with a primary diagnosis of acute heart failure. For all patients, BUN/Cr ratio was calculated at admission and correlated with clinical variables and in-hospital mortality. Afterwards patients were divided into two groups: with or without acute kidney injury (defined as an increase of serum creatinine by ≥ 0.3 mg/dl within 48 hours). For statistical analysis we used independent t test for comparison of continuous values, Pearson x ^{2} test for comparison of categorical values, multivariate logistic regression, survival curves and Cox regression for predictors of in-hospital mortality.
Results: A total of 184 consecutive patients with acute heart failure (males and females) were enrolled. Mean age was 69 ± 10 years and mean ejection fraction was 33 ± 10%. The percentage of patients with AKI was 31% and without AKI was 69%. The AKI group presented higher heart rate at admission compared to the non-AKI group (105 b/min vs. 95 b/min, p = 0.012). Higher admission BUN/Cr ratio was associated with lower systolic blood pressure (136 mmHg vs 149 mmHg, p = 0.015) and with the "wet and cold" clinical profile of acute heart failure (p = 0.043). Patients with AKI had a significantly worse survival profile during hospitalization (log-rank test, p < 0.0001) and Cox proportional hazards modelling showed a crude HR = 5.3 (95%CI [2.2.-12.4], p < 0.0001) for in-hospital mortality. Higher admission BUN/Cr ratio proved to be a significant factor for in hospital mortality also, with a crude HR=3 (95% CI [1-8], p = 0.028).
Conclusions: Acute kidney injury during hospitalization in patients with acute heart failure is responsible for worse in-hospital survival rates and is associated with increased heart rate at admission. Elevated BUN/Cr ratio at admission is linked with an increased risk for in-hospital mortality being associated with lower systolic blood pressures and the "wet and cold" clinical profile in patients with acute heart failure.

P2120

Measurement of Circulating endothelial progenitor cell and endothelial microparticles can predict the improvement of ischemic heart failure

YS Yun-Seok Choi[1]; AMI Kwon[1]; CS Park[1]; MY Lee[1]; HJ Youn[1]; WS Chung[1]
[1]*The Catholic University of Korea, Seoul, Korea Republic of*

Introduction: Endothelial microparticles (EMP) are small vesicles shed from activated or apoptotic endothelial cell. We wonder elevated EMP and EPC level is possible to predict the improvement of ischemic heart failure.
Methods: total 354 patients (age 63 ± 11, male 255(72%)) who diagnosed as ischemic heart failure (EF < 45%, three vessel disease) were divided as two group. Group 1 showed improved ejection fraction (mean Δ6.3 ± 1.1%) after optimal medical therapy. Group II did not show improvement of ejection fraction (Δ0.3 ± 0.4%). Mean follow duration was 6.2 ± 2.1 months. EMP and endothelial progenitor cells(EPC) are determined in peripheral blood by anti CD31-PE and anti CD42-FITC. MPs were defined as CD31 + /CD42- particles with a diameter < 1.5μm, being MP size calibrated with flow cytometry size calibrations. The values of EMP, EPC, and EMP/EPC ratio in patients with ischemic heart failure were compared with control group.
Results: Group I (n = 185, mean age 64 ± 11) and Group II (n = 169, mean age 62 ± 10) did not show differences in terms of medication. There were no significant differences in coronary risk factors such as age, DM, HBP, dyslipidemia, smoking between groups. The level of EMP(%) was lower in Group I than Group II [(1.33 ± 0.71) in group I, (1.54 ± 0.96) in Group II, p = 0.03]. But EPC values were similar between two groups. [(0.042 ± 0.016) vs (0.049 ± 0.022, p = 0.11)] and EMP/EPC ratio were significantly different [(49.4 ± 14.3) in Group 1 vs (62.1 ± 22.2) in Group II, p = 0.02]. EMP/EPC ratio had significant predictive value to detect the improvement of ischemic heart failure. (OR, 1.88. 1.32-1.99, p = 0.01)
Conclusion:. Improvement of ischemic heart failure after optimal medical therapy might be predicted by measuring the circulating endothelial microparticle and progenitor cell ratio.

P2121

Serum potassium levels at admission and in-hospital all-cause mortality in patients hospitalised for acute heart failure (insights from RO-AHFS registry).

I Iulian Cosei[1]; L Antohi[1]; R Radu[1]; C Radulescu[1]; M Chivulescu[1]; A Ravasel[1]; AP Ambrosy[2]; C Macarie[1]; SP Collins[3]; O Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*; [2]*Duke University Medical Center, Durham, United States of America*; [3]*Vanderbilt University, Nashville, United States of America*

On behalf of: RO-AHFS study investigators

Background: Previous data coming from randomized controlled trials raised some controversies related to the prognostic value of serum potassium levels in patients hospitalised for acute heart failure (AHF).
Purpose: To assess the prognostic value of serum potassium levels at admission in patients hospitalised for AHF regarding in-hospital all-cause mortality in a "real world" national registry.
Methods: RO-AHFS was a prospective, national, multicenter registry that included 3224 consecutive patients admitted for AHF over a 12 month period. This is a post-hoc analysis of 3188 patients who had potassium levels measured at admission. We analyzed in-hospital all-cause mortality in this population stratified by quartiles of serum potassium concentration.
Results: The demographic and clinical characteristics of patients stratified by potassium levels quartiles are shown in Table 1. No linear relationship between in-hospital mortality and serum potassium levels at admission was identified (HR=0.89; CI 95% 0.73-1.26). Also, in-hospital all-cause mortality did not vary significantly across quartiles: the mortality in quartiles Q1, Q2, Q3 and Q4 was 7.9%, 7.2%, 7.8% and 8.1% (p = 0.425) respectively.
Conclusions: In the present analysis we didn't find any relationship between in-hospital mortality and serum potassium levels at admission, finding which may be reflective to the observational nature of the registry.

Table 1

	Q1 n=797	Q2 n=797	Q3 n=797	Q4 n=797	p value

Background/Introduction: The search for risk and/or prognostic markers in acute heart failure (or exacerbation of chronic heart failure) – AHF - has been a constant in the last decades. Inflammation plays a major role in HF and contribute to the occurrence of adverse events. The neutrophil/lymphocyte ratio (rN/L), a simple and easy to perform marker of "inflammation", has been considered promising in small studies including populations affected by diverse cardiovascular diseases, namely in HF.

Purpose: To evaluate the usefulness of rN/L as a predictor of prognosis [rehospitalization (reH) and mortality] in a population hospitalized for AHF.

Methods: Discharge notes of 100 patients (pts) consecutively admitted for AHF (cardiology ward, tertiary hospital center), discharged alive and prospectively followed, were analysed. Pts with infection on admission (n = 25) were excluded. Demographic, clinical, laboratorial and echocardiographic data were evaluated and their relation to rN/L was established (Mann-Whitney and Spearman tests). The influence of rN/L on mortality and reH during post-discharge follow-up was determined (Cox regression analysis and Kaplan-Meier survival).

Results: Seventy five pts (58.7% men, 66.7 + 13.3 years) were included in the final analysis. There were no in-hospital deaths. During a mean follow up (Fup) period of 14.1 ± 5.7 months, the reH rate for HF was 29.3% and all cause reH was 57.7%. The mortality rate during the Fup was 13.3%. The median of rN/L on admission was 4 (3-5). The rN/L did not correlate with age, functional class (NYHA) on admission, or in-hospital lenght of stay, and only a weak correlation with plasma NT-proBNP values (Pearson R= 0.27; p = 0.03) or presence of pulmonary congestion on admission (p = 0.036) was observed.

A value of rN/L> 5.5 on admission was a non-independent predictor of long-term mortality (AUC= 0.95, CI= 0.9-0.99, p < 0.01); also NT-ProBNP> 6500 pg/mL on admission did not independently predict mortality during Fup (AUC= 0.79, CI=0.65-0.93, p = 0.014).

A rN/L> 4.5 was an independent predictor of both rehospitalization for HF (HR= 4.16, CI 1.44-11.98, p = 0.008) and all cause rehospitalization (HR= 3.16, CI 1.4-7.14, p = 0.006); NT-ProBNP> 4000pg mL (AUC= 0.68, CI= 0.57-0.79, p = 0.014) was a non-independent predictor of HF rehospitalization.

Conclusion: In patients admitted to hospital with AHF, rN/L on admission revealed prognostic utility given the ability to predict future rehospitalization, although it did not show a significant association with other clinical and laboratorial parameters at admission, namely with NT-proBNP values. The rN/L may be useful as a marker of "fragility" in the identification of AHF patients who may benefit from closer follow-up in the outpatient setting.

Predictors of prolonged hospitalization in acute heart failure

I Aguiar-Ricardo[1]; J Agostinho[1]; P Alves[1]; J Rigueira[1]; I Goncalves[1]; AR Francisco[1]; T Guimaraes[1]; M Nobre-Menezes[1]; G Lima Da Silva[1]; R Santos[1]; A Ferreira[1]; F Veiga[1]; M Mendes-Pedro[1]; D Brito[1]; J Fauto Pinto[1]

[1]Hospital Universitário de Santa Maria/CHLN, CAML, CCUL,Faculdade de Medicina, Universidade de Lisboa, Cardiology, Lisbon, Portugal

Background/Introduction: Acute heart failure (AHF) is an increasing cause of hospital admission requiring sometimes prolonged hospitalization. This has an impact on quality of life, it is associated with significant economic burden and may contribute to higher mortality.

Purposes: To identify factors associated with a longer stay in patients admitted for AHF and to assess the possible repercussion of length of stay on the long-term prognosis.

Methods: Retrospective, unicentric study, with 100 consecutive patients (pts) hospitalized for AHF in a tertiary hospital cardiology center. Demographic, clinical, laboratorial and echocardiographic characteristics were evaluated at admission. By logistic regression, the relationship with the length of stay [duration greater than 7 days (LOS> 7d) and greater than 14 days (LOS> 14d)] was analyzed. The relationship between length of stay and the rate of rehospitalization and post-discharge mortality, through Cox Regression and Mann-Whitney test, were evaluated.

Results: The included population (55% men, 68 ± 13 years) was followed for 14.2 ± 5.5 months after hospital discharge. The median length of stay was 8 days (5-17); 54 pts had LOS> 7d and 28 had LOS> 14d. There was no in-hospital mortality and the post-discharge mortality rate was 14%. The predictors of LOS>7d were: acute renal failure (ARF)(p = 0,003), infection (p = 0,004), systemic congestion (SC) (p = 0,008), creatinine >1,3mg/dL (p = 0,032), alkaline phosphatase (AP)>105mg/dL (p = 0,011) and GGT > 73mg/dL (p = 0,011). By multivariate analysis, the presence of SC (OR = 3.4, CI: 1.0-10.4, p = 0.047), infection (OR=5,6; CI:1,4-22,6; p = 0,015) and AP >105mg/dL (OR=4,4; CI:1,3-15,8; p = 0,021) were independent predictors of LOS> 7d.

The predictors of LOS> 14d were: severe aortic stenosis (p = 0,042), anemia (p = 0,001), chronic kidney disease stage >3 (p = 0,011), ARF (p < 0,001), SC (p = 0,005), infection (p = 0,001), creatinine >1,3mg/dL (p = 0,002) and urea >100mg/dL (p = 0,009). The presence of SC revealed to be an independent predictor of LOS> 14d (OR=6,1; CI:1,4-26,5; p = 0,015).

The length of first hospitalization was not associated with mortality or rehospitalization during follow-up.

Conclusion: The presence of SC was an independent predictor of prolonged hospitalization for AHF, making it imperative to improve strategies for SC control. Infection and PA> 105mg / dL also have the capacity to predict LOS> 7d.

Prognostic implication of changes in renal function in patients with acute decompensated heart failure

SY Jang[1]; NK Kim[2]; JH Sohn[1]; JH Roh[2]; MH Bae[2]; JH Lee[2]; DH Yang[2]; HS Park[2]; Y Cho[2]; SC Chae[2]

[1]Kyungpook National University Medical Center, Cardiology center, Daegu, Korea Republic of; *[2]Kyungpook National University Hospital, Daegu, Korea Republic of*

Background: There are conflicting data about whether worsening renal function (WRF), as well as improving renal function (IRF), is related to poor prognosis. The purpose if this study was to evaluation the prognostic impact of WRF and IRF on prognosis of patients with acute decompensated heart failure.
Methods: Patients hospitalized for acute decompensated heart failure between January 2009 and June 2015 were retrospectively analyzed. Patients with initial serum creatinine more than 2.5mg/dl were excluded. A total of 846 patients (66.8 ± 15.0 years-old, 430 men) included in the final analysis. WRF and IRF were defined as decrease and increase of >20% from baselines estimated glomerular filtration rate, respectively. The composite event of all-cause mortality and re-hospitalization for heart failure was assessed for the prognosis of the patients.
Results: Among the patients, 135 and 170 patients were included in WRF and IRF, respectiveluy. A total of 193 adverse events (22.8%) were observed during the 1-year follow-up. WRF, IRF and stationary renal function (SRF) group respectively showed 32.6%, 21.8% and 20.7% of adverse event rate. Kaplan-Meier analysis showed significant difference in prognosis among the three groups (p = 0.003). The difference comes from the different prognosis between WRF and SRF (Bonferroni corrected p = 0.002) and there was no significant difference between IRF and SRF (Bonferroni corrected p = 1.000). Cox-proportional hazard model showed WRF was independently associated with poor prognosis (hazard ratio [HR] 1.497 [1.001-2.228], p = 0.047) together with age, ischemic etiology, beta blockers, loop diuretics, natriuretic peptide, and serum hemoglobin level. However, IRF did not showed a distinct prognostic difference compared to SRF group (HR 1.004 [0.678-1.487], p = 0.983).
Conclusion: WRF renal function was associated with poor prognosis in patients with acute decompensated heart failure, whereas IRF was not.

Background: Age has been described as an important prognosis factor in Heart Failure (HF). Nevertheless, the modern approach in pharmacotherapy and quality of care has improved hospital treatment among heart failure individuals and it is not clear if the age, by itself, is associated with worse outcomes among Acute Heart Failure (AHF) inpatients.
Purpose: To evaluate differences in baseline, treatment and prognosis aspects between younger (≤45 years) and very elderly (≥75years) patients admitted for AHF.
Methods: Retrospective cohort study included data from 107 patients admitted in three tertiary cardiac referral centres for AHF management between 2009 and 2016.
Results: All the data are shown at table 1.
Conclusions: Although we noticed some differences among baseline characteristics as higher frequencies of prior comorbidities and higher prevalences of ischemic and hypertensive etiologies among very elderly patients, younger and very elderly patients showed no clinically relevant differences with regard to hospital outcomes.

Multimorbidity and polypharmacy as readmission and mortality factors in acute heart failure

M Mendez[1]; B Chiva-Ballesteros[2]; L De Pedro Alvarez[2]; P Delgado-Paimar[2]; J Marco[1]; FJ Martin-Sanchez[2]; A Esteban[1]; R Bover[1]; E Calvo[1]

[1]Hospital Clinic San Carlos, Madrid, Spain; *[2]Complutense University of Madrid, Medicine, Madrid, Spain*

Introduction and aims: The aim of our study was to evaluate multimorbidity and polypharmacy as factors associated to readmissions and in-hospital mortality in AHF.
Methods: A total of 199 patients with a primary diagnosis of heart failure ICD code, who were discharged from Internal Medicine of our Hospital in 2014 (from January 1 to December 31, 2014), were included. A descriptive analysis was performed. Subsequently, a bivariate analysis was carried out to compare the characteristics of patients who were readmitted or died with respect to those who did not. T-student statistical tests were used for the quantitative variables and Chi-square for the

qualitative ones with a statistical significance $p < 0.05$. Finally, a multivariate logistic regression analysis was performed with the clinical variables that were associated with readmission or in-hospital mortality with the variables of age, sex, associated comorbidity and other variables with statistical significance ($p < 0.05$). The analysis was carried out using the program SPSS version 21.
Results: The study was conducted in a total of 199 patients, with an average age of 82.7 years, of which 61.8% were women. 85% of the patients had a LVEF>40%, with an average NT-proBNP of 9.101.3 pg/ml. 64.3 % of the patients had atrial fibrillation. 30.2 % of the patients were readmitted, with an average of readmissions per year of 1.45 (±0.86). In-hospital mortality during one year of follow-up was 25% of the patients. Regarding the factors associated with in-hospital mortality, older age was the most outstanding variable, OR 1.050 (1.002-1.101) ($p = 0.04$). Polypharmacy 1,137 (1,017-1,272) ($p = 0.024$) and multimorbidity disorders criteria 4,974 (1,396-17,730) ($p = 0,013$) were the most significant factors associated to readmissions.
Conclusions: In our investigation, advanced age was the main factor associated to in hospital mortality. Multimorbidity and polypharmacy have been the factors most associated to hospital readmissions.

Pre and post hospitalization care pathways for acute heart failure patients

O Olivier Thebault[1]; DG Guijarro[1]; JPG Gueffet[2]; LLG Le Gloan[1]; NP Piriou[1]; BD Delasalle[1]; MP Poilane[1]; JNT Trochu[1]
[1]*University Hospital of Nantes Nord Laennec, Cardiology, Nantes, France*; [2]*Nouvelles Cliniques Nantaises, Nantes, France*

Introduction: Acute heart failure (AHF) is a serious condition with high mortality and a very high rate of early re-admissions. The aim of our study was to analyze the care pathway, general characteristics and 3-month morbidity and mortality of AHF referred to a French tertiary hospital.
Material and Methods: Consecutive patients hospitalized for AHF patients during two 8-week periods, autumn-winter and spring-summer were included. The overall characteristics and data specific to the care pathway were collected. A 3-month follow-up was carried out to study combined total mortality and unplanned cardiovascular re-hospitalizations at 3 months.
Results: 237 patients, mean age 72 ± 13 years old, 43.2 % HFpEF, 39.2 % HFrEF were included and followed. No significant differences were found between the patients' clinical characteristics between the 2 periods of inclusion. Patients were mostly referred to the hospital by a general practitioner (27%) or a cardiologist (27%), 20.3% after an emergency call, 36.2% of the patients reached the cardiology department after an admission in the emergency department, 38.0% were admitted to the intensive care unit. The average length of hospital stay was 10.8 ± 8.1 days, 77% went back home directly, 15.2% were transferred to a rehabilitation center. An outpatient visit with a cardiologist was scheduled upon discharge for 68.9% of patients within an average of 48 ± 37 days, 10 % of the patients entered a cardiovascular rehabilitation program, 6.3% were included in a multidisciplinary management programme. Combined total mortality or unplanned cardiovascular re-hospitalization was 28.9 %. Chronic heart failure (OR = 2.25 ; $p = 0.01$), early re-hospitalization (< 1 year) (OR = 2.18 ; $p = 0.01$), renal insufficiency (OR = 2,77, $p = 0.001$) and cardiogenic shock (OR = 2.49 ; $p = 0.04$) were identified as risk factors for this criterion. Cardiovascular rehabilitation appeared to be a protective factor (OR = 2.14 ; $p = 0.03$).
Conclusion: Heart failure rehospitalization is frequent and cardiovascular mortality high after an index HF hospitalization with a limited access to an organized care plan after hospitalization, underscoring the importance of the implementation of high quality transition care and better identification of high risk patients.

P2128
Characterization of any cause dyspnea in the emergency department and factors predicting the need for mechanical ventilation

C Cristian Militaru[1]; L Antohi[1]; R Radu[1]; M Chivulescu[1]; C Radulescu[1]; R Botea[1]; S Bubenek[1]; C Macarie[1]; O Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*

Background: Dyspnea is the most common symptom of patients presenting with acute heart failure (AHF). Despite this fact, there is no definitive data about how to correctly quantify dyspnea, and whether the parameters currently used are able to predict outcomes or measure treatment efficiency. Mechanical ventilation (MV) has been shown to ameliorate hypoxemia, correct acidosis and alleviate symptoms in patients with significant respiratory distress.
Method: This was a single-center, prospective, observational, cohort study, which enrolled consecutive patients presenting with dyspnea of any etiology to the emergency room (ER). Dyspnea was evaluated clinically and biologically at baseline, at 5 minutes and 30 minutes, by parameters such as respiratory rate, oxygen saturation, pH, lactate, PaO2, and a patient-subjective visual analog scale (VAS). The aim of this paper is to clinically and biologically characterize dyspnea and to determine which acute-phase parameters obtained in the ER could predict the need for mechanical ventilation.
Results: There were a total of 104 patients enrolled, 57.7% male, mean age 66.8 years, with the majority (65.3%) having a history of HF. The clinical profile classification of the dyspnea was: 61% dyspnea at rest, 18% paroxysmal nocturnal dyspnea, and 21% effort induced dyspnea. Mean baseline parameters were: blood pressure 143/81 mmHg, respiratory rate 23.1 bpm, pH 7.39, SaO2 93.4%, PaO2 77.9%, lactate 1.3 mmol/L, NTproBNP 5280 pg/mL, left ventricle ejection fraction 45.8%. The majority of the patients (79%) had a significant improvement of dyspnea at 30 minutes (as derived from the VAS), in contrast to 4.8% who experienced worsening symptoms. Seven patients (6.7%) required mechanical ventilation (invasive or non-invasive). The only parameters that were predictive for mechanical ventilation after multivariate analysis were PaO2<70%, HR=1.72 (CI95% 1.58-2.91) and respiratory rate>29 bpm, HR=1.53 (CI95% 1.19-2.53).
Conclusions: In AHF patients presenting with dyspnea of any etiology to ER, the need for MV can be predicted by baseline PaO2 and respiratory rate.

P2129
Insulin-like growth factor-1 in acute coronary syndrome complicated by acute heart failure

G Guzeliya Kayumova[1]; V Razin[1]
[1]*Ulyanovsk State University, Ulyanovsk, Russian Federation*

Introduction: Coronary heart disease is the leading cause of morbidity and mortality in economically developed countries. For risk stratification and diagnosis of acute coronary syndrome are actively studied new markers, in particular insulin-like growth factor 1 (IGF-I).
Purpose: analysis of IGF-I in plasma in patients with acute coronary syndrome (ACS)
Material and methods: The study included 71 patients with ACS, the mean age was 57 ± 8.5 years. All cases of ACS were classified according to international nomenclature and was allocated 37 patients with Infarction acute phase STEMI, and 34 patients with Infarction acute phase non STEMI. Acute heart failure are divided into groups according to Killip: I – 17 (23.9 per cent), II – 17 (23,9%), III – 32 (45,1%) , IV - 5 (7,1%). In the blood plasma of patients was determined by IGF-I. Blood sampling was performed at the time of admission of the patient to verification of the final diagnosis. The concentration of IGF-I were determined by ELISA using kits company "Diagnostic Systems Laboratories" (USA).
Results: IGF-1 in patients with Infarction acute phase non STEMI had the highest 179,15 ± 41,29. 37 patients with Infarction acute phase STEMI ardent concentrations of IGF-1 was slightly lower 156,05 ± 44,78. Decreased levels of IGF-I in 9 cases of death from acute myocardial infarction - the concentration of IGF-I was 126,06 ± 15,12. Regression of levels of IGF-1 is also observed in groups with acute heart failure: I – 172,45 ± 31,93, II – 182,82 ± 50,76, III – 156,33 ± of 45.90, IV - 144,52 ± 40,64. For all the results, obviously, reduced the plasma concentrations of IGF-1 in patients in a serious condition.
Conclusions: IGF-I is a new highly sensitive biochemical marker of vascular inflammation and damage, can be used in everyday medical practice, as the stratification factor of ACS.

P2130
The difference of benefit of tolvaptan for acute decompensated heart failure within different etiologies

Y Yoriyasu Suzuki[1]; Y Ochiumi[1]; S Kano[1]; S Murase[1]; A Murata[1]; T Ito[1]
[1]*Nagoya Heart Center, Nagoya, Japan*

Background: the benefit of tolvaptan (TLV) for acute decompensated heart failure (ADHF) has been reported, however, the difference of benefit of tolvaptan for ADHF within different etiologies has not been investigated.
Aim; the purpose of this study is to compare the efficacy of TLV for ADHF within different etiologies.
Methods: the consecutive 234 volume-overload ADHF (clinical scenario 2 or 5) was investigated. We divided into 2 groups (TLV (-); n=103. TLV (+); n=131) and compared between both group and different etiologies of ADHF.
Results: the results are shown in figure.
Conclusion: treatment with TLV for ADHF could prevent WRF and shorten the duration of CCU stay. Especially treatment with TLV could be effective in the patients with DCM, IHD, and VHD.

Community pharmacists identifying worsening heart failure symptoms, using novel symptom screening tool

R Rocco Hadland[1]; R Lawrance[2]; K Masri[3]; P Ruiz Canela[3]; A Williams[3]; M Oldfield[4]; J Welstand[2]; D Higman James[1]
[1]Cardiff University, Cardiff School of Pharmacy and Pharmaceutical Sciences, Cardiff, United Kingdom; *[2]Betsi Cadwaladr University Health Board, North Wales, United Kingdom*; *[3]Rowlands Pharmacy, North Wales, United Kingdom*; *[4]Johnstown Pharmacy, North Wales, United Kingdom*

Purpose: Early detection and treatment of worsening heart failure (HF) symptoms can reduce the need for hospitalisation. We aimed to utilise a newly developed novel HF symptom screening tool for use by community pharmacists to detect worsening HF symptoms, using a strategy of collaborating with the local HF pharmacist.
Methods: Pilot study. Patients included were prescribed, loop diuretics, beta blockers, angiotensin converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) and mineralocorticoid receptor antagonists (MRAs). At the time of inviting patients to participate the community pharmacist had no prior knowledge of whether the participant had a diagnosis of HF. The screening tool was designed to identify worsening symptoms during the previous month. and included six questions pertaining to breathlessness, nocturnal breathlessness, signs of oedema, tiredness and weight gain. Participants with suspected worsening HF symptoms were referred to the local HF pharmacist who acted as triage to the general practitioner (GP) referrals.
Results: 28 patients participated out of 40 that were invited to participate, across 5 community pharmacies in North Wales over a 2-month period. 6 patients were identified with suspected HF symptoms and were all referred to their GP by the HF pharmacist. All 6 participants that were referred to a GP resulted in an intervention by the GP. The GPs interventions were: 2 patients required changes to HF therapies, 1 patient required a change to a non-HF treatment, 3 patients were referred to a cardiologist, with 1 participant subsequently diagnosed with HF with preserved ejection fraction. Retrospective review of the participants' medical notes indicated that 16/28 had a confirmed diagnosis of HF. The screening tool had a sensitivity of 65% and the specificity of 73%.
Conclusion: The community pharmacy HF screening tool identified worsening HF symptoms in existing HF patients and also lead to the eventual new diagnosis of HF with preserved ejection fraction. A larger randomised trial is required to fully assess the outcomes of the screening tool.

Purpose: Loop diuretics represent one of the mainstay of therapy in acutely decompensated chronic heart failure (ADCHF) patients (pts), but despite increased doses a proportion of pts represents diuretic resistance (DR) manifested with persistence of systemic congestion with important respiratory, hepatic and renal dysfunction and poor prognosis. The aim of the study was to investigate diuretic resistance in ADCHF population, and to explore a prediction model for DR development.
Methods: we prospectively analyzed clinical and laboratory data of 637 consecutive ADCHF pts on previous chronic loop diuretics therapy from January 2014 to November 2016. The MELD score evaluation was performed on a daily basis. A logistic regression model was used to determine independent predictors of DR, ROC curves were used for evaluation of prediction models of DR entering consecutively independent variables. A MELD score > 7 was considered abnormal. Primary liver disorders were excluded. DR was identified on clinical criteria.
Results: DR was identified in 116 (18,2%) pts.: between DR and non DR pts there were no significant differences in age (67.4 ± 0.3 vs 65.8 ± 0.7, NS), sex (males) (62% vs 59.7%, NS), diabetes (31.7% vs 30.1%, NS), but there were significant differences in MELD score (38.2 ± 7.7 vs 16.3 ± 9.5, $p < .0001$), hyponatremia (132 ± 2.7 vs 128 ± 9.3 mEq/L, $p < .001$), Charlson Comorbidity index (CCI) = 4 (68.1% vs 47.2%, $p < .001$), right ventricular function (TAPSE 21.5 ± 3.7 vs 12.3 ± 6.8 mm, $p < .001$), presence of metabolic alkalosis (89.7% vs 41.5%, $p < .0001$), rehospitalisations for AHF 4 (2 to 6) vs 2 (0 to 3), $p < .05$. Independent predictors of DR in multivariate analysis were an abnormally high MELD score HR 2.94 (95%CI: 1.36 to 5.62), low RV function HR 2.36 (95%CI: 1.28 to 4.37), hyponatremia HR 1.83 (95%CI: 1.13 to 3.5), metabolic alkalosis HR 1.67 (95%CI: 1.09 to 3.12). From ROC curve analysis for MELD score model AUC was 0.84 (95%CI: 0.73 to 0.91), when entering the model the presence of low RV function, hyponatremia and metabolic alkalosis AUC reached 0.91 (95%CI: 0.85 to 0.97) indicating a good ability to discriminate patients at risk of DR.
Conclusions: despite advances in AHF treatment, DR remains an ominous sign of the overall prognosis, hence a reliable prediction model of DR development would be an important diagnostic tool in clinical practice. We suggest from our study that an improved model incorporating simple clinical and laboratory values could help to stratify better patients at risk.

P2133

Metabolic therapy impact on the manifestation of heart failure in patients with acute myocardial infarction presented with ST-segment elevation

T Svanidze[1]; T Saralidze[1]
[1]Tbilisi State Medical University (TSMU), Department of Internal Medicine N 1, Tbilisi, Georgia Republic of

Mild heart failure (HF) usually accompanies acute myocardial infarction presented with ST-segment elevation (STEMI), but in some cases its severity increases in the first week of infarction. It is well known, that spectrum of myocardial injury depends not only on the intensity of impaired myocardial perfusion but on the existing metabolic state as well.
Our aim was to diminish the onset of HF in the course of acute myocardial infarction. For this aim we used metabolic therapy with Mildronat and Trimetazidine just from the first day of STEMI.
Evaluation of the functional condition of heart was based on ECG and echocardiographic data received before and after treatment. We observed 40 patients with STEMI who did not undergo reperfusion therapy because of different reasons. These patients did not have diabetes mellitus and HF did not exceed Killip class II. 20 patients were treated routinely, but without metabolic therapy (control group) and 20 were treated in addition with Sol. Mildronat 10% - 5 ml/day i.v. and Trimetazidine MR 35 mg twice a day.
Our research showed that in patients with STEMI treated with metabolic therapy normalization of S-T segment elevation was begun on the second day (in 40% of patients), on the 5th day it was observed in 70% and its normalization ended on the 7th day of treatment. In control group normalization of S-T segment elevation was begun on the second day in 20% of patients, on the 5th day it was revealed in 50% and it ended on the 10th day of treatment. Investigation of echocardiographic data in dynamic (before treatment and after a week) showed improvement of ejection fraction (EF) by 5,6% and stroke volume (SV) by 8,6% in patients with STEMI treated with metabolic therapy while in control group EF increased by 2,5% and SV by 4,5%. In patients treated with metabolic therapy end diastolic diameter (EDD) was decreased by 2,8%, end systolic diameter (ESD) - by 3,5%, end diastolic volume (EDV) - by 5,5% and end systolic volume (ESV) - by 7,8% while in control group EDD was decreased by 0,9%, ESD - by 1,4%, EDV - by 1,8% and ESV - by 2,6%. The received data make it relevant to include the complex metabolic therapy for effective treatment of HF in patients with STEMI. Metabolic therapy not only improves the course of disease, but diminishes rehabilitation period as well.

non-prescription of aldosterone receptor blocker following acute heart failure: high serum potassium levels during admission as a determinant factor

R Farcasan[1]; J Gummel[1]; J Parra[1]; A Paya[1]; R Heredia[1]; G Minana[1]; I Cardells[1]; A Mollar[1]; E Santas[1]; S Garcia-Blas[1]; E Valero[1]; F Chorrro[1]; J Sanchis[1]; J Nunez[1]
[1]University Hospital Clinic of Valencia, Valencia, Spain

Background: Mineralocorticoid receptor antagonists (MRA) constitute one of the cornerstones of the treatment for heart failure and reduced left ventricular ejection fraction (HFrEF). However, despite its proven efficacy, they are often underused. In this work, we aimed to evaluate whether high serum potassium levels found during hospitalization for acute heart failure (AHF) are determinant of MRA prescription at discharge.
Methods: We prospectively included 584 consecutive patients discharged after an episode of AHF and left ventricular ejection fraction ≤40%. The maximum level of potassium (Kmax) along the hospitalization was selected as the exposure. Independent factors related with the odds of prescribing MRA at discharge were evaluated by multivariate logistic regression analysis.

Results: The mean (SD) of age, minimum estimated glomerular filtration rate (eGFR) and maximum potassium during admission were 71 ± 12 years, 55 ± 22 ml/min/1.73m2 and 4.5 ± 0.6 mmol/L, respectively. The proportion of males, ischemic heart disease and MRA prescription upon discharge were 67.1%, 42% and 56.2%, respectively. Patients with potassium >5.0 mmol/L (17.5%) showed lower prescription of MRA (45.1% vs. 58.5%, p = 0.001). In multivariate analysis, adjusting for age, ischemic heart disease, systolic blood pressure < 100 mmHg, (eGFR) and left ventricle ejection fraction, Kmax showed to be independently associated with the odds of non-prescribing MRA. Functional form of Kmax revealed a positive and non-linear gradient of risk, with a greater magnitude of risk above 5 mmol/L as is shown in the figure below. Compared to patients with Kmax ≤5mmol/L, those with Kmax >5.0 mmol/l were about two-fold increase odds of non-MRA prescription (OR=1.83; CI 95%: 1.13-2.98, p = 0.015).
Conclusion: In patients with AHF and reduced LVEF, high serum potassium levels during hospitalization predict lower prescription of MRA at discharge. Potassium lowering strategies in selected patients may increase the use of MRA following the episode of AHF.

Funding Acknowledgements: Verizon

Introduction: The rising prevalence and cost of heart failure (HF) has increased the desire to improve self-care management skills and behaviors. This program aimed to document an improvement in patient engagement and compliance through the integration and implementation of three disparate remote monitoring systems.
Purpose: High HF readmission rates reflect patient vulnerability in the 30 days post-discharge. The inability to effectively manage and influence patient behavior, and patient's inability to identify signs of worsening HF are major hurdles to improving outcomes and minimizing readmissions. This study was designed to utilize remote monitoring technologies to foster patient self-care management skills. This is a model of supported, low touch/high tech care to bridge patients to home and help keep them out of the hospital.
Methods: Patients admitted with acute decompensated HF were enrolled over a 13 month period beginning November 2015, and agreed to be monitored for 30 days post-discharge. All patients wore a wireless cutaneous telemetry sensor. Those discharged to home performed daily health check-ins using a telehealth scale, blood pressure cuff, and pulse oximeter. Questions regarding symptoms and HF education where included in these check-ins. Patients discharged to a nursing facility performed daily health check-ins using a mobile monitoring application on a tablet. Arrhythmia data was monitored, and study staff notified if data met specific parameters. Telehealth check-in data was sent wirelessly, and reviewed by a nurse in a web portal. Clinically significant biometrics prompted a phone call or home visit for additional assessment and intervention. Patient surveys were administered at enrollment, and upon completion of the 30 day program. ER visits and hospital readmissions were tracked.
Results: 31 patients participated in the program with a mean age of 78.5 years, 58% being 80 years old or older. Of the participants, 7 withdrew prematurely. The readmission rate of patients that did not withdraw early was 20.8%. 100% of the patients who completed the program found it helpful based on patient surveys. Post program follow up reflected patient plans to continue monitoring activities, based on improved self-confidence and learned self-care management skills. In addition, twelve program participants and caregivers became involved in an outpatient HF support group, which led to continued engagement in disease management.
Conclusion: The use of mobile monitoring tools can be an effective way of improving HF patient engagement, ownership of disease management, and deliver strengthened partnerships between patients and healthcare providers.

P2136
Are the risk stratification's methods effective to diagnose pulmonary embolism in patients with heart failure?

A Attila Pandur[1]; B Banfai[1]; B Radnai[1]; J Betlehem[1]
[1]*University of Pecs, Institute of Emergency Care and Pedagogy of Health , Pecs, Hungary*

Background/Aims: Pulmonary embolism is connected with high morbidity and mortality. Prognostic assessment is important for the management of patients with pulmonary embolism. Pulmonary embolism often has a nonspecific clinical presentation. The use of diagnostic testing in an attempt to avoid missing the potentially life-threatening diagnosis increases both cost and use of medical resources. Various score systems exsist to evaluate the probability of pulmonary embolism, which can be used for risk stratification, to get the most accurate diagnosis. The aim of our study was to review the evidence for existing prognostic models in acute pulmonary embolism and determine validity and usefulness for predicting patient outcomes.
Materials and Methods: We performed a retrospective analysis of pulmonary embolism in three hungarian emergency departments. Data from 519 patients were included for this retrospective analysis. The Wells, Geneva, Padua score systems were used to reevaluate retrospectivly the risk of pulmonary embolism. The diagnosis of pulmonary embolism was accurate, when the CT verified it. We allowed the weighted probability of the score systems. We analyzed which score system is the most specific for the risk stratification of pulmonary embolism in our cases. Data were analyzed with a SPSS 20.0 statistical software. In our study, chi-square test, Independent-Samples T-test, ANOVA, korrelation interpretation were performed. P values of < 0.05 were considered to be statistically significant.
Results: 238 (45,8 %) men and 281 (54,2 %) women patient-documentation were participated in the study. 156 patients got into the ED due to heart failure. In 68 cases (43,5 %) the CT verified pulmonary embolism. Padua score indicated in 16 cases (p = 0,2), Geneva score in 29 cases (p = 0,05) and Wells score in 6 cases (p = 0,1) a high probability of pulmonary embolism, from the 68 cases, where the CT is positive for PE.
Conclusions: Our study showed that Genfi score(which was calculated from the patients complaints, medical history and physical examination) had the closest correlation with the diagnosis. Finally we can conclude that risk-evaluation is indispensable in acute heart failure because pulmonary embolism can be in the backround as the root cause.

P2137
Acute Heart Failure and cardiogenic shock are independent predictor for in-hospital mortality in patient admitted with ST-elevation myocardial infarction

B Bambang Widyantoro[1]; I Firdaus[1]; SS Danny[1]; D Zamroni[1]; I Irmalita[1]; DPL Tobing[1]; DA Juzar[1]
[1]*Dept of Cardiology and Vascular Medicine, Universitas Indonesia-NCVC Harapan Kita Hospital, Jakarta, Indonesia*

Despite aggressive intervention, morbidity and mortality of patients with acute coronary syndrome (ACS) remain high. Various clinical condition may contribute to the outcomes during acute phase. The aim of this study was to analyze the in-hospital outcomes predictors of patients with ST-elevation MI (STEMI).
We examined 1590 consecutive patients admitted with ACS in CVCU of our National Cardiovascular Center in 2015. Multivariable logistic regression was used to analyze predictors for in-hospital mortality.
Among 1590 patients, 910 (57.2%) were STEMI and 680 patients were UA/NSTEMI. Most of them are male (82.4%), below 65 years old and had hypertension (59.6%). Overall in-hospital mortality for STEMI were 6.6% (60 of 910). Revascularization with primary percutaneous intervention (Primary PCI) were performed in 521 (57.2%) of STEMI patients, with median door to device time 83 (65-103) minutes. Fifty two (5.71%) patients received fibrinolytics treatment with door to needle time 24 (18-42) minutes with successful rate of 84.6%. Those with failed fibrinolytics underwent rescue PCI. The other 14 patients underwent urgent CABG. Among patients treated with PPCI, 89.3% achieved TIMI 3 flow, while 5 (1%) patients have no-reflow due to high grade thrombus. About 245 (26.9%) patients were not revascularized

due to very late onset of presentation. Most of STEMI patients who failed to survive during hospitalization more likely to have diabetes, more late presentation (>9 hours), suffered from acute heart failure (AHF, 32.6%) and cardiogenic shock (7.4%). After multivariable risk adjustment, AHF and cardiogenic shock remain independent predictors for in-hospital mortality (odds ratio 7.64; 95%CI 3.41-17.13 and 11.45;95%CI 5.61-23.36 respectively).
In conclusion, we observed acute heart failure and cardiogenic shock as predictors for in-hospital mortality among STEMI patients.

P2138

Impact of the potassium concentration in drug titration of heart failure patients

G M Gustavo Miguel Rocha Rodrigues[1]; AT Tralhao[1]; NV Vale[1]; MC Castro[1]; JM Mesquita[1]; CA Aguiar[1]; AV Ventosa[1]; MM Mendes[1]
[1]Hospital Santa Cruz, Cardiology, lisboa, Portugal

Heart failure patients have multiple comorbidities which hamper the titration of drugs with proven impact on clinical outcomes. The renin angiotensin aldosterone system (RAAS) blockage is crucial in these patients, but hiperkalemia often troubles the use of recommended drugs and dosages. New potassium lowering drugs are being evaluated in order to allow the recommended titration of the RAAS blockage. We aimed to assess the possible usefulness of these new drugs in a population of heart failure patients. We reviewed the records of 196 outpatients followed in a specialized HF clinic between January 2013 and December 2014. We excluded 108 patients with left ventricular ejection fraction (LVEF) >35%. Of the 88 patients with HF-REF (LVEF<35%), median age was 65 ± 13.8 years, 73 (82%) are male, 33 (37%) are diabetic, 51 (57%) are hypertensive, 39 (44%) have dislipidemia, 43 (48%) have chronic kidney disease and 25 (28%) have atrial fibrillation. Median LVEF was 28.5 ± 5.2%, median [K+] was 4.7 ± 0.44 mmol/L and 66% of the patients had the RAAS blockage titrated. 34% were not on a titrated dosage of angiotensin-converting-enzyme inhibitors (ACEI) or angiotensin II receptor blocker (ARB) and 43 (49%) patients weren't on a titrated mineralocorticoid receptor antagonist (MRA). Of the patients without titrated ACEI/ARB, 2 were hypotensive (ST≤95 mmHg), 10 had [K+] ≥5 mmol/L and 8 had GFR ≤ 30 ml/min/1.73 m2. Most of those with high [K+] (n = 8), were not hypotensive or had severe chronic kidney disease (CKD). 16 of the patients without titrated MRA had [K+] ≥5 mmol/L, 4 had hypotension and 7 had severe chronic kidney disease (GFR ≤ 30 ml/min/1.73m2). Most of the patients with [K+] ≥5 mmol/L (N=14) were not hipotensive or had severe CKD. (table1) In this cohort, a high level of [K+] was the most probably cause to the lack of titration of the RAAS system blockage. This aspect highlights the possible clinical benefit of potassium lowering drugs on heart failure patients.

P2139

Intra-aortic balloon pump and dose of amiodarone in post-operative atrial fibrillation

K Kevin Domingues[1]; A Kontogeorgis[2]; TC Aw[2]; S Price[2]
[1]Hospital of Santarem, Cardiology, Santarem, Portugal; *[2]Royal Brompton Hospital, London, United Kingdom*

Introduction: Atrial fibrillation (AF) is the most common arrhythmia in the post-operative period of cardiac surgery, with amiodarone being the most frequently used drug for its control. However, its use is widely heterogenous, and it is unknown which factors demand higher doses in critical patients in this context. The intra-aortic balloon pump (IABP), still frequently used after cardiac surgery, is preferably ECG-triggered, and arrhythmias are potentially a cause of inferior effectiveness.
Aim: To determine if the use of intra-aortic counter pulsation influences amiodarone doses during hospital admission in critical patients with AF after cardiac surgery.
Methods: Retrospective study of patients admitted to a level III cardiothoracic intensive care unit in the post-op period after cardiac surgery, between September 2012 and February 2015, which were medicated with amiodarone because of AF. Demographic and clinical data were analysed.
Results: We included 177 patients, predominantly male (68.6%), with mean age of 67,3 ± 12,5 years. The surgery involved more than one procedure in 50.3% of the cases and, in total, 49.7% had revascularization surgery (CABG), 28.2% aortic valve surgery and 25.4% mitral valve surgery. The most frequent main diagnosis of admission to the unit were arrhythmic complications (31.1%), haemorrhagic complications (25.4%) and left and/or right ventricular dysfunction (20.3%), with 20.3% of the patients having the need of IABP during their stay.
The median total dose of amiodarone was 2275 mg, with a median of 102 mg per day in hospital. Patients who had IABP had significantly higher total doses of amiodarone (4981 vs 1610 mg; p = 0.016) and higher doses of amiodarone per day in hospital (183 vs 87 mg; p < 0.001).
In the multivariate analysis, with age, sex, type of surgery and main diagnosis of admission, the use of IABP was independently associated with a need of an average amiodarone dose of >200 mg per day (p = 0.025). There was also a positive correlation between the total amiodarone dose and the time with IABP (r=0.409, p = 0.025).
Conclusion: In this population of critical patients, those who required IABP also required higher doses of amiodarone, possibly due to the need of rhythm stability for mechanical optimization.

P2140

Screening for the Improve Management of heart failure with Procalcitonin (IMPACT)-study

A Anna Slagman[1]; M Bolanaki[2]; J Frick[2]; F Holert[2]; M Mazelka[2]; H L Neumeier[2]; S Rabsch[2]; F Ruggaber[2]; J Searle[2]; C Thomas[2]; S Toro[2]; C Werk-Wenzel[2]; M Mockel[1]
[1]Charite - Campus Virchow-Klinikum, Department of Cardiology, Berlin, Germany; *[2]Charité - Universitätsmedizin Berlin, Division of Emergency Medicine (CVK, CCM); Department of Cardiology (CVK), Berlin, Germany*

Funding Acknowledgements: This study was sponsered by Thermo Fisher Scientific

Background: The IMPACT-study evaluates an advantage of PCT guided antibiotic treatment over established treatment practice in patients with acute decompensated heart failure. The primary endpoint is 90-day all-cause mortality.
Purpose: To investigate the proportion of successfully screened patients and the main reasons for non-enrollment.
Methods: Patients who present to the Emergency Department (ED) with leading symptom dyspnea and suspected or known heart failure are eligible for the study. These patients were screened in two EDs of the Universitätsmedizin between March 2015 and December 2016. Inclusion criteria: 1. MR-proANP>300 pmol/L, BNP>350 ng/L or NT-proBNP>1800 ng/L; 2. Patient has given written Informed consent within study timelines to allow antibiotic treatment within 8 hours; 3. Adult patients (i.e. >18 years of age); 4. Hospitalization for at least 1 overnight stay planned. Exclusion criteria: 1. Patient participates in any other interventional clinical trial; 2. Trauma related shortness of breath; 3. Patient diagnosed with lung or thyroid cancer; 4. Known terminal disease with life expectancy of less than 6 months, e.g. advanced metastasized cancer disease; 5. Organ transplant requiring immunosuppression; 6. Abdominal, vascular or thorax surgery within the last 30 days; 7. End stage/advanced HF – defined by planned heart transplantation, or cardiogenic shock; 8. Female patients who have given birth within 3 months before study enrolment; 9. Current use of antibiotics or requirement of immediate antibiotic therapy before randomization and measurement of PCT; 10. End stage renal failure requiring dialysis; 11. Patient is not willing, or it is not possible or advisable for the patient, to follow the study schedule, including antibiotic therapy and 90 days follow up; 12. Patient has already participated in the clinical trial previously; 13. Pregnant or lactating women; 14. Patients who are institutionalized by official or judicial order; 15. Dependants of the sponsor, the CRO, the study site or the investigator
Results: Overall, 1,918 patients were screened for the IMPACT study within 22 months. Of these, 7.5% (n = 143) were enrolled. The proportion of enrolled patients differed between both study centres: 8.5% of all screened patients were enrolled at the Campus Virchow Klinikum (CVK; 112 out of 1,212) and 5.1% at the Campus Charité Mitte (CCM; 31 out of 605). The main reason for non-enrollment were low values of natriuretic peptides (26% at CVK and 30% at CCM). Other reasons for non-enrollment differed only slightly between both EDs and are depicted in figure 1.
Conclusions: The IMPACT study is the first study to evaluate the concept of PCT-guided antibiotic treatment applying a randomized design in this specific setting. Despite the high number of patients with dyspnea in the investigated EDS, many patients cannot be included especially due to low natriuretic peptide values.

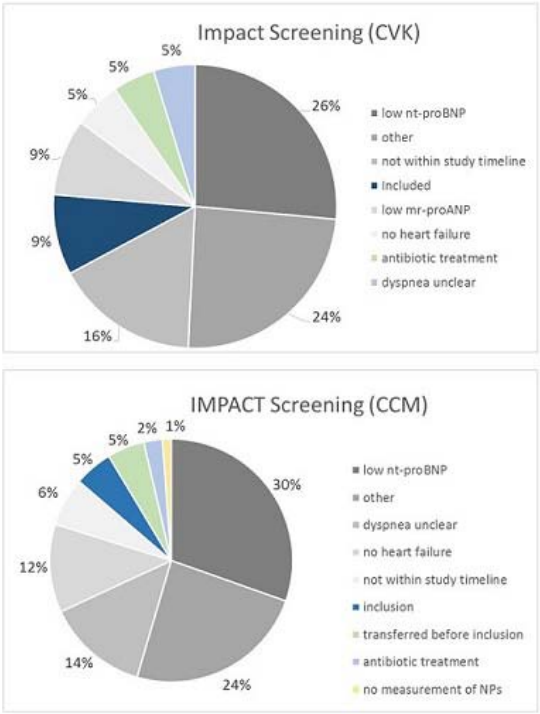

Figure 1: Results of IMPACT-Screening at both Campi of the Charité Universitätsmedizin Berlin (CVK and CCM)

P2141

Lung echocardiography in the initial evaluation of acute respiratory failure using a pocket ultrasound device: what is wrong the heart or the lungs?

M Manuel Lobo Gonzalez[1]

[1]*University Hospital of Virgen Macarena, Cardiology, Seville, Spain*

Background and purpose: Acute respiratory failure (ARF) is a very common cause of illness in the emergency department, sometimes, it is difficult to elucidate its etiology. A rapid diagnosis that allows to differentiate between the cardiac or extracardiac origin is fundamental to begin an early managed treatment. The aim of this study is to evaluate the ability of lung ultrasound with pocket device (PD) to classify patients with respiratory failure in cardiac origin (heart failure) or not.
Methods: 46 patients with ARF (dyspnea and oximetry below 90%) admitted to our emergency unit and studied at bedside with PD were included. The interstitial lung water was determined by counting the B-lines according to BLUE and FALLS protocol; according to the ultrasound analysis, the patients were classified into heart failure or not. The management of patients and the final diagnosis was made according to the clinical presentation, personal history, physical examination and the rest of complementary tests.
Results: 30 of 46 patients included were women, the mean age was 62 ± 17 years. According to findings in pulmonary ultrasound, 21 patients (45,65%) were classified as heart failure and 25 patients as non cardiac ARF. After clinical exams and the others complementary test, 22 patients (47,82%) had a final diagnosis of heart failure. The pulmonary ultrasound classified correctly as cardiac failure at 20 patients, with 1 false positive (sensitivity of 90%). In the non-cardiac failure group, 2 false negatives were generated by the test (specificity of 95%). Although not the objective of this study, lung echography identified 3 pneumotorax, 5 consolidative pneumonies, and 3 pleural effusions in the non-cardiac group.
Conclusion: Our results are consistent with those previously reported. Lung ultrasonography assessed with a PD may represent a fast and reliable diagnostic tool in ARF, Allowing to classify the cause as cardiac or non-cardiac, and thus instituting an early managed treatment.

P2142

Acute heart failure in the elderly: which are the main precipitating causes of heart failure? Real world evidence from the ATHENA registry

AC Baroncini[1]; F Orso[1]; A Pratesi[1]; C Tozzetti[2]; F Bacci[2]; A Herbst[1]; S Parlapiano[1]; A Cortese[2]; G Baglioni[1]; C Nozzoli[2]; L Gabbani[1]; L Poggesi[2]; A Moggi Pignone[2]; N Marchionni[3]; S Baldasseroni[1]

[1]*Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy*; [2]*Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; [3]*Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: ATHENA study group

Background: Heart failure (HF) is very common in the elderly population, and is characterized by frequent re-hospitalization which worsen prognosis. In clinical trials precipitating causes leading to hospitalisations are mainly cardiovascular. In cardiological clinical registries precipitating causes are also more frequently cardiovascular, even if the percentage of hospitalisations due to non-cardiovascular causes grows significantly. On the contrary, "real world" administrative data suggest that precipitating causes may be mainly non-cardiovascular.
Purpose: to compare precipitating causes in elderly patients hospitalised for acute HF in the settings of care of most frequent management: cardiology, internal medicine and geriatrics.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (≥ 65 years) admitted with diagnosis of acute HF (worsening or de novo) to the emergency department (ED) of a tertiary University teaching-hospital and transferred to the above described settings of care in the period 01.12.2014-12.01.2015. We evaluated the main precipitating causes of HF reported in literature comparing cardiology, geriatrics and internal medicine wards.
Results: 342 patients composed the study population; 17.8% were hospitalised in cardiology, 17.3% in geriatrics and 64.9% in internal medicine. Mean age was 83.7 years, females were 54.1%. In the attached table we report the main precipitating causes of HF.
Conclusions: In geriatric and internal medicine wards the main precipitating causes are non-cardiovascular, as pneumonia and sepsis. In cardiology, cardiovascular causes, such as ACS, are prevalent. Precipitating causes seem to be a criteria for admittance to different setting of care in elderly HF patients.

Precipitating causes of HF

	Total N=342	Cardiology N=61	Geriatrics N=59	Internal Medicine N=222	P Value
Pneumonia (%)	39.7	20	52.1	42.6	0.001
Sepsis (%)	5.9	0	4.2	8.1	0.001
AKI (%)	3.6	3.3	8.3	2.5	0.001
ACS (%)	6.2	21.7	2.1	2.5	0.001
AF (%)	9.2	3.3	4.2	12.2	0.001
Poor Compliance (%)	3.3	1.7	2.1	4.1	0.001

AKI, acute kidney injury; SCA, acute coronary syndrome; AF, atrial fibrillation

P2143

Value of systolic time intervals in the diagnosis of heart failure in the emergency department patient with undifferentiated dyspnea

ZW Zhani[1]; ZZ Ezzina[1]; EM Malek Echeikh[1]; AN Azaiez[1]; BAA Ben Abdallah[1]; BK Beltaief[1]; MMA Msolli[1]; DZ Dridi[1]; BH Boubaker[1]; GMH Grissa[1]; BW Bouida[1]; NS Nouira[1]

[1]*university of monastir, monastir, Tunisia*

On behalf of: great network

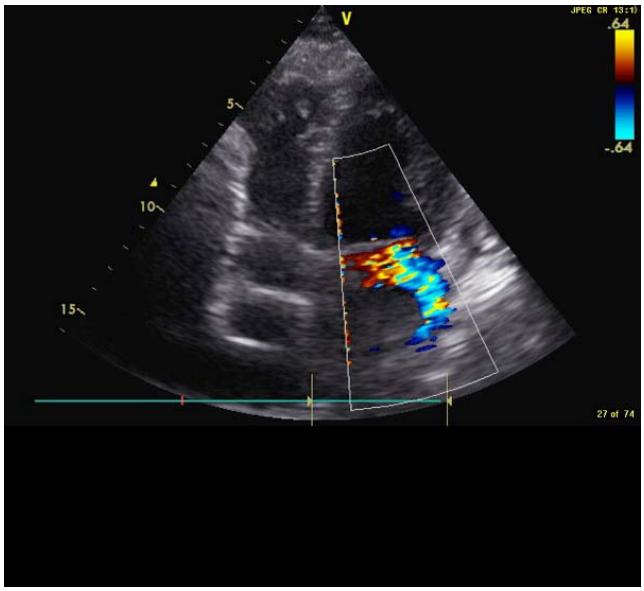
Background: The diagnosis of heart failure in the emergency department (ED) is challenging. Our objective is to determine if systolic time intervals (STI) can predict heart failure (HF) in ED patients with dyspnea.
Methods and Results: A total of 658 patients with suspected HF were prospectively enrolled. They underwent echocardiographic measurements of left ventricular ejection fraction (LVEF), B-type natriuretic peptide (BNP) testing and computerized phonoelectrocardiography to assess STI including electromechanical activation time (EMAT), left ventricular ejection time (LVET) and their ratio (EMAT/LVET). Diagnostic accuracy was calculated including sensitivity, specificity, likelihood ratio and receiver operating characteristic (ROC) curve.
Patients with HF (n = 402) had significantly higher EMAT and lower LVET compared to no HF patients. ROC curve c-statistic was 0.74, 0.72, and 0.78 respectively for EMAT, LVET, and EMAT/LVET. Sensitivity and specificity of EMAT/LVET at a cut-off=40%

were 64% and 82%. EMAT/LVET had the highest correlation with LVEF(r = -0.48). Patients with preserved LVEF (≥50%) had STI values not significantly different from those of patients without HF. In patients with intermediate BNP(n = 107), EMAT/LVET increased positive likelihood ratio from 1.8 with BNP alone to 3.6 with combined parameters.
Conclusion: STI provide rapid and useful information that assist noninvasively prediction of HF in ED patients with dyspnea especially when BNP values are in the gray zone and echocardiography not readily available.

P2144
Pulmonary edema as a manifestation of an acute mitral insufficiency in a woman in puerperium the unthinkable cause of pulmonary edema

M J Maria Juliana Rodriguez Gonzalez[1]; LA Medina Lopez[1]; MM Botia Osorio[1]
[1]*Fundación Cardiovascular de Colombia, Santander, Bucaramanga, Colombia*

Mitral insufficiency is not a common cause of pulmonary edema during pregnancy or the puerperium. The principal etiologies are preexisted congenital heart defect, valvular conditions not previously diagnosed, pregnancy related conditions poorly understood as peripartum cardiomyopathy and finally coronary heart disease.
Coronay heart disease has increased by incidence because of the reproductive tecniques and the women advanced age. The Acute coronary syndrome during pregnancy and puerperium has a high mortality range from 5- 37%. The principal etiology is not the same to the observed in other situations.
In previous case series it has been reported coronary artery disease (43%), thrombus (21%), normal epicardial vessels (29%), coronary artery disection (16%).
Spontaneous coronary artery dissection (SCAD) is a rare cause of acute coronary syndrome. The condition affects women more commonly than men, with 70% of cases occurring in young women of childbearing age. The relationship between SCAD and gestational and puerperal period varies among populations, ranging from 0 to 18%. occurring predominantly in late pregnancy or the early postpartum period. The etiology of SCAD is poorly understood, it is interrelated with other factors including connective tissue disorders, vasculitis, extreme physical and emotional stress, and cardiac stress.
The most common coronary artery affected is the left anterior descending (LAD) branch, but there are some case series where they describes RCA, left circunflex , Obtuse marginal; most of them single vessel disease.
There is not consensus in its management, some of them are managed in a conservative way and some of them with stents or CABG. We report a single case that it presented in the emergency department as an acute pulmonary edema in the puerperium with an ST inferior acute myocardial infarction. She is a pleasant 32 female patient who was admitted at cardiology Ward; coming from the gynecology service. She was admitted with pre- eclampsia. She was in her 4th day after Caesarean section and presented an intense chest pain, 30 min duration, severe dyspnea with some electrocardiographic changes (st elevation in inferior leads no right ventricular extensión; these changes were intermittent). Positive troponin (2797 ng/l) , Chest X-ray with interstitial edema. At that time we decided to take an echo which was informed with severe mitral insufficiency and segmentary contractility alterations (inferior Wall), she was taking to the cath lab and the findings were spontaneous coronary artery disection of a single vessel (right coronary artery), having an IVUS with 100% vessel lumen compromised ant the heart team decided to implant 2 medicated stents; proximal and distal trying to seal the disection with a good angiographic result.
Conclusions: SCAD can be a cause of acute mitral insufficiency knowing the anatomical issues of its papillary muscles irrigation.



mitral insufficiency

P2145
Patterns of dyspnoea onset, clinical characteristics and the outcomes in patients with acute heart failure- implications for clinical trials

JM Krzysztofik[1]; M Sokolski[1]; R Zymlinski[2]; J Biegus[1]; P Siwolowski[2]; S Nawrocka- Millward[2]; W Banasiak[2]; EA Jankowska[3]; P Ponikowski[1]
[1]*Wroclaw Medical University, Department of Heart Diseases, Centre for Heart Disease - Clinical Military Hospital, Wroclaw, Poland*; [2]*Centre for Heart Disease - Clinical Military Hospital, Wroclaw, Poland*; [3]*Wroclaw Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wroclaw, Poland*

Funding Acknowledgements: The research was financially supported from the statutory grant for Department of Heart Diseases, Wroclaw Medical University, Poland (ST-905)

Background and purpose: Dyspnoea is the most common presenting symptom related to hospital admission for acute heart failure (HF). We investigated whether the patterns of dyspnoea onset are associated with clinical characteristics and the outcomes.
Methods: We investigated 137 patients (mean age– 65 years, 110 [80%] men) hospitalized for acute HF, whose major reported symptom was orthopnea. Patients were divided according to the time of onset of orthopnea into 3 groups: rapid (n = 26), acute (n = 72) and subacute onset (n = 39) – i.e. within 24 hours, 2-7 days and > 7 days preceding hospital admission, respectively.
Results: On admission, patients with a rapid onset of orthopnea had higher systolic blood pressure (154 ± 38 vs. 132 ± 29 vs. 121 ± 32 mmHg, P < 0.001), faster heart rate (101 [80-140] vs. 88 [75-100] vs. 90 [72-103] beats/min, P < 0.05), more moderate-severe pulmonary congestion (69 vs. 19 vs. 8 %, P < 0.05), less moderate-severe peripheral oedema (23 vs. 58 vs. 62 %, P < 0.001), ascites (4 vs. 10 vs. 28 %, P < 0.01) and lower level of serum bilirubin (0.73 [0.59-1.14] vs. 1.13 [0.82-1.72] vs. 1.27 [0.87-2.06] mg/dL, P < 0.01) (rapid vs. acute vs. subacute onset of orthopnea, respectively). There were no differences in the history chronic HF, the presence of co-morbidities, LVEF, and serum NT-proBNP levels between groups. Those with a rapid onset received lowest dose of iv furosemide within first 48 hours (100 [60-160] vs.120 [80-200] vs. 200 [80-240] mg, P < 0.05), and were treated more often with iv vasodilators (65 vs. 33 vs. 36 %, P < 0.01) (rapid vs. acute vs. subacute onset of orthopnea, respectively). Patients with a rapid onset of orthopnea reporter greater dyspnea relief after 6, 24 and 48 h (P < 0.001 in all time points vs. remaining groups) and there were less worsening HF during hospital stay in this group (8 vs. 15 vs. 39 %, P < 0.01). During one year follow-up, cardiovascular mortality was highest in patients with subacute onset (23 vs. 19 vs. 41 %, P < 0.05), but the rate of hospital re-admissions due to acute HF was marginally higher in those with rapid onset (46 vs. 24 vs. 36 %, P=0.08) (rapid vs. acute vs. subacute onset of orthopnea, respectively).
Conclusion: In patients admitted with acute HF, pattern of dyspnoea onset is associated with significant differences in clinical characteristics, in-hospital response to standard treatment and the long-term outcomes. This is relevant information for planning clinical trials in acute HF.

P2146

The incidence and profile of cardiotropic viruses in the myocardium in patients with decompensated chronic heart failure with systolic dysfunction of ischemic origin

EV Kruchinkina[1]; VV Ryabov[2]; YU V Rogovskaya[3]; TR Ryabova[1]; RE Batalov[1]; MS Rebenkova[1]; SV Popov[1]; RS Karpov[1]
[1]*Cardiology Research Institute, Tomsk National Research Medical Center, Tomsk, Russian Federation*; [2]*Siberian State Medical University, Tomsk, Russian Federation*; [3]*National Research Tomsk State University, Tomsk, Russian Federation*

Background: Tremendous evidence has emerged over the past decades that HF is associated with inflammation. However, anti-inflammatory therapy widely lacks positive outcomes. No reports on exploration of the molecular and cellular phenotypes of myocardial inflammation (viral, viral and autoimmune, and autoimmune types of inflammation) in patients with acute decompensated chronic heart failure (ADHF) and ischemic cardiomyopathy.
The purpose of study to determine the frequency of occurrence of inflammation and the profile of cardiotropic viruses in the myocardium by immunohistochemistry.
Methods: This open-label, nonrandomized, single-center, prospective trial — NCT02649517. This trial includes ADHF patients with ischemic systolic dysfunction underwent percutaneous coronary intervention/coronary artery bypass graft with optimal results not earlier than 6 months after surgery and acute coronary syndrome. Patients receive standard treatment of ADHF according to ESC guidelines. All patients undergo invasive coronary angiography to exclude the progression of coronary heart disease as the cause of ADHF. Endomyocardial biopsy (EMB) and following immunohistochemical analysis were performed to determine type of inflammation in the myocardium. The following parameters are assessed during hospitalization: inflammatory infiltrate in the myocardium.
Results: The subanalysis of the 12 patients (8% female, 92% men, left ventricular ejection fraction 29.17 ± 9.4%) with ADHF hospitalized from January 2015 to August 2016. The average age of our patients was 61.08 ± 7.84 years. All of the patients underwent endomyocardial biopsy which revealed signs of myocarditis in 7 patients (58.33%) and no myocarditis in 5 patients (41.67%). Viruses in the myocardium were determined in 9 cases (81.82%). The most common combinations were Enterovirus with Epstein-Barr virus in 4 patients (36.36%) and Enterovirus with Human herpesvirus 6 in 4 patients (36.36%). The correlation between the inflammatory infiltrate in the myocardium and Enterovirus, and Epstein-Barr virus ($p < 0.05$, $r = 0.62$ and $r = 0.58$ respectively). At the moment, the results showed that 7 patients hospitalized for ADHF had signs of myocarditis 58.33%.
Conclusion: The results showed the frequency of occurrence of myocardial inflammation 58.33% and cardiotropic viruses 81.82% in myocardium in patients with ADHF. The most encountered viruses in myocardium were Enterovirus and Human herpesvirus 6.

CHRONIC HEART FAILURE

P2147

Cardiac coherence by breathing in heart failure patients during cardiac rehabilitation

L Simone[1]
[1]*University Hospital of Strasbourg, Strasbourg, France*

Background: Heart rate variability (HRV) represents the fluctuations in heart rate (HR) from beat-to-beat, measured in milliseconds. HRV is a non-invasive measure of the autonomic nervous system by assessment of the balance between sympathetic and parasympathetic influences on the intrinsic rhythm. Low HRV related to autonomic dysfunction, which is frequent in chronic heart failure (CHF) patients, is associated with increased cardiac morbidity and mortality. Since the HRV can be influenced by many situations, like decreased with smoking or hypertension, HRV could be improved by deep breathing, as demonstrated in heart coherence training. By breathing 6 times per minute, with a respiratory frequency at 0,1 Hz, heart is synchronized with breath (state of cardiac coherence), which lead to an amplified HRV curve.
Objective: Explore the relationship between heart coherence training (HCT) and cardiac coherence ratios (low, medium, high) in CHF patients, and factors associated with high ratios.
Method: Patients with ventricular dysfunction < 45% were randomly separated in 2 groups: one into conventional cardiac rehabilitation (no HCT group) and other into cardiac rehabilitation plus HCT (HCT group) sessions consisting of daily abdominal breathing practice, 3 sessions of 5 minutes a day, during 3 weeks. Patients with atrial fibrillation, diabetes, chronic kidney failure and depression were excluded. Coherence ratios and spectral density power were measured with a biofeedback software before and after program.
Results: 18 patients were included (10 in HCT group). Baseline characteristics were similar for both. The HCT group show a significant increase in medium or high coherence ratios (90% vs 20%, p = 0,012). Analyze of spectral density power showed an increased in high frequencies in HCT patients, which can be considered as a reflect of parasympathetic component. In HCT group, patients had a significatively lower HR (p = 0,004), lower brain natriuretic peptid > 30% (p = 0,023) and blood sodium was higher by 3 mmol/L (p = 0,011). No differences occurred with quality of life, ejection fraction, or dyspnea.
Conclusion: In CHF patients with autonomic dysfunction, cardiac coherence by breathing exercises seems to improve coherence ratios, and as a consequence, could have a positive effect on HRV amplitude.

P2148

Cardiopulmonary exercise testing, right heart catheterization and etiology of heart failure

M Dudek[1]; MI Marta Izabela Kaluzna-Oleksy[1]; J Migaj[1]; E Straburzynska-Migaj[1]
[1]*Poznan University of Medical Sciences, Ist Department of Cardiology , Poznan, Poland*

Introduction: Heart failure (HF) is a clinical condition with a miscellaneous background. The most prevalent cause of HF in Europe is coronary artery disease (CAD). Depending on etiology of HF, its natural history may vary. In evaluation of HF patients there are used as well noninvasive as invasive diagnostics methods.
Aim: Characterization of patients with heart failure with reduced ejection fraction (HFrEF) qualified to the heart transplantation. Evaluation the role of noninvasive and invasive procedure in assessment of HF patients related to the etiology of HF.
Methods: This was a prospective analysis of 211 patients (both genders) with HFrEF (left ventricular ejection fraction < 40%), with ischemic (ICM) and non-ischemic cardiomyopathy (NICM), hospitalized at a tertiary health care center, undergoing qualification process for heart transplantation. The epidemiological data, laboratory test results (including BNP), and chosen parameters obtained in echocardiography, cardiopulmonary exercise testing (CPET) and RHC (thermodilution method) were analyzed related to the etiology of HF.
Results: Mean age of analyzed population was 51.7 ± 10.3 years. Most patients were men (88%), 73% were in NYHA class 3 and 4. Patients with ICM were significantly older (55 vs. 49, p = 0.005) and without any gender differences (males 94% vs. 89%, NS). Had lower BNP level (721 vs. 1253, p = 0.005) and higher mean aortic pressure measured invasively (40 vs. 36, p = 0.036). The RHC parameters like PAPm and TPG were higher in ICM without any significant differences in echocardiography or CPET.
Conclusions: Ischemic etiology of HF is associated with lower level of BNP but with worse result of RHC, and there are no differences between ICM and NICM in echocardiography or CPET. PH occurred with the same frequency in ICM and NICM group.

P2149

Determinants of cardiovascular death risk in dialysis patients.

M Merita Rroji[1]; S Seferi[1]; N Spahia[1]; M Cafka[1]; M Barbullushi[1]
[1]*University Hospital Center Mother Theresa, Department of Nephrology, Cardiology, Tirana, Albania*

Background: Dialysis patients have a higher risk of morbidity and mortality related to cardiovascular disease (CVD) than the general population. The aim of the current study was to characterise the role of traditional and uraemia-specific CV risk factors in this patient population.
Methods: In this prospective case study we enrolled all adult patients who were on long-term dialysis (hemodialysis and peritoneal dialysis) for more than 3 months. Cardiovascular mortality was assessed during a 2-year follow-up period. Factors predictive of cardiovascular mortality were identified by a logistic regression model. P values less than. 05 were considered significant.
Results: There were 129 participants, of whom 86 (66%) were on hemodialysis. Cardiovascular mortality during the follow-up was 15.5% (19 events). The main causes of cardiovascular death were sudden deaths (31.5%) followed by deaths from ischemic heart disease and stroke (26.3%). In 15.7% of the patients, heart failure was found the cause of death. We didn't found difference in CV mortality between patients in two dialysis modalities (log rank (Mantel- Cox) p = 364. Multivariable analysis showed that C-reactive protein (OR, 1.06; 95% CI, 1.01 to 1.10; P = .01), pulse pressure (OR, 1.01; 95% CI, 1.0 to 1.26; P = .046), Phosphate (OR,1.11; 95% CI, 1.01 to 1.26; P = .033) and left ventricular mass index (OR, 1.03; 95% CI, 1.01 to 1.21; P = .03) were independent risk factors for cardiovascular mortality.
Conclusions: We found Inflammation, arterial stiffness, Phosphate and LVH as independent risk factors in Cardiovascular mortality. These factors are interrelated and both contribute to increase mortality and cardiovascular death risk of dialysis patients.

P2150

The effects of ferrous sulfate supplementation on left ventricular intrinsic function by global longitudinal strain in systolic heart failure patient with iron deficiency anaemia

RS Sagita[1]; LD Suryani[1]; BB Siswanto[1]; LD Liastuti[1]; NH Hersunarti[1]; RS Soerarso[1]
[1]National Cardiovascular Center Harapan Kita, cardiology and vascular medicine , Jakarta, Indonesia

Background: Iron deficiency is common in heart failure (HF) and associated with impairment of myocardial functional parameters and dimension of the left ventricle (LV).Speckle tracking echocardiography assesses myocardial deformation and LV systolic function by measuring global longitudinal strain (GLS). But the improvement of intrinsic LV function using GLS in systolic HF patient with iron deficiency anaemia (IDA) due to oral iron treatment is not yet known.
Objectives: To evaluate improvement in intrinsic LV function measured by GLS after oral Ferrous Sulfate (FS) treatment.
Methods: This is a single center, randomized controlled trial that enrolled HF (LVEF < 50%), IDA (Ferritin < 100ng/mL or 100-300 ng/mL with Tsat < 20%) and Hb < 13 g/dl) patients at outpatient clinic of Harapan Kita Hospital between January to November 2016. Patients were randomized 1:1 to treatment with FS or placebo for 12 weeks. Echocardiography was performed before and after treatment to measure GLS.
Results: We performed analysis of 37 patients that complete follow up period, Treatment Group (n = 21) and Control Group (n = 16). There was no significant improvement in GLS in treatment group compared to control group (-9,17 ± 3,71 vs -8,83 ± 4,07;p = 0,876). Interobserver variability for GLS was small with mean of difference of 0,32(CI95%: -0,09-0,75;p = 0,106).
Conclusions: There was no significant improvement in GLS after oral FS treatment in systolic HF patient with IDA.

Comparison of GLS between groups

	Group	Pre-Treatment	Post-Treatment	P value
Apical 4 Chamber (%)	FS	-8,42± 3,82	-8,79± 4,03	0,588
Control		-8,16± 3,45	-8,08± 3,81	
Apical3 Chamber(%)	FSC ontrol	-7,20 (-14,10-0) -8,05 (-21,70-(-4,00)	-8,40(-14,00-(-3,10) -8,70 (-20,70-(-3,70)	0,783
Apical2 Chamber(%)	FS Control	-8,76 ± 4,70 -8,68 ± 3,32	-9,86 ± 4,44 -9,1 ± 4,01	0,592
GLS(%)	FS	-8,19 ± 3,73	-9,17 ± 3,78	0,876

P2151

Body composition in heart failure and chronic obstructive pulmonary disease patients

AG Navarrete-Penaloza[1]; A Orea-Tejeda[2]; D Gonzalez-Islas[2]; L Verdeja-Vendrell[2]; A Jimenez- Cepeda[2]; GK Perez-Cortes[2]; R Sanchez-Santillan[2]; V Pelaez-Hernandez[2]; B Robles-Uribe[2]; A Figueroa-Herrera[2]; S Torres-Montiel[2]
[1]Autonomous University of Puebla, Puebla, Mexico; [2]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Distress Respiratory Clinic , Mexico City, Mexico

Background: Heart Failure (HF) and Chronic Obstructive Pulmonary Disease (COPD) patients present an endothelium function imbalance. This populations presents a pro-catabolic metabolism which is associated with the progression disease. Both population present a high cachexia prevalence characterized by loss skeletal muscle and and fat mass. There also exists a dismish in phase angle which is a marker of nutritional status and cell membrane. Cachexia and phase angle are associated with a worse prognosis in HF and COPD patients. However, ther exists few body composition evidence related with HF and COPD. Objective: To evaluate body composition in subjects with HF and COPD compared with COPD subjects.
Methods: A Cross – sectional study, 77 subjects older than 18 years olds, with confirmed HF and / or COPD diagnosis, and those who attend to outpatient visits were included. Asthma subjects were excluded. Body composition were assessed by BIVA, endothelial function by photopletysmography. Results: 77 were randomized, mean age 71.2 ± 11.57 years, 69.43% with COPD and 30.57% HF and COPD. Subjects with HF and COPD had high prevalence of diabetes (21.6 vs 9.5, p = 0.07), pulmonary hypertension (29.7 vs 9.5, p = 0.005), obstructive sleep apnea syndrome (35.1 vs 10.7, p = 0.001) compared to subject which present only COPD. There were not significative difference in other variables. In body composition the prevalence of cachexia were 57.1% in both groups, 20.8% obesity and normal composition 22.1%. Subjects with HF and COPD presented a lower phase angle (4.15 ± 1.2 vs 4.73 ± 0.89, p = 0.05) and higher endothelial dysfunction (0.361 ± 0.086 vs 0.325 ± 0.064, p = 0.035) than COPD subjects. Respect to fluid corporal distribution subjects with HF and COPD reported low total corporal water (46 ± 8.23 vs 51.06 ± 8.64, p = 0.019) and high extracellular water (3.12 vs 3.03, p = 0.006) compared to COPD subjects. Conslusions: Body composition with HF and COPD subjcets showed a high deterioration which can benefit a worse diagnosis.

P2152

Association of diastolic dysfunction and cognitive function in heart failure

MS Mi-Seung Shin[1]; JS Kim[2]; MJ An[3]; SH Kim[4]; JL Shim[4]; JK Park[5]
[1]Gachon University Gil Medical Center, Incheon, Korea Republic of; [2]Gachon University, College of Nursing, Incheon, Korea Republic of; [3]Chonnam National University College of Nursing, Gwangju, Korea Republic of; [4]Hanyang University, College of Nursing, Seoul, Korea Republic of; [5]Hanyang University, Department of Internal Medicine, Seoul, Korea Republic of

Background and purpose: Poor cognitive function is a common comorbid condition in heart failure (HF) associated with progressive deterioration of cardiac function and prolonged cerebral hypoperfusion. The relevance of cardiac functional markers to the cognitive performance was primarily focused on systolic functional markers, such as ejection fraction (EF) or cardiac output, while specific diastolic functional influence on cognitive declines in HF are lacking. To examine whether systolic and concomitant diastolic dysfunction were associated with poor cognitive performance in memory, attention, and executive function among patients with HF.
Methods: Using a correlational study design, 90 persons with HF completed face-to-face interviews for neuropsychological testing for cognitive evaluation and echocardiographic evaluation for systolic and diastolic function.
Results: Sixty one patients (67.8%) and 29 patients (32.2%) had mild-to-moderate and severe systolic dysfunction, using cutoff values of EF≥30% and < 30%, respectively; 22 (26.8%) had severe diastolic dysfunction using a cutoff value of peak velocity of early mitral inflow/early mitral annular velocity ratio>15. Those who had severe systolic dysfunction had significantly lower scores for attention (Digit Span Test [DST] backward, t=2.54, p = .013); those with a concomitant severe diastolic dysfunction had significantly lower attention (DST backward, t=2.01, p = .048), verbal fluency (t=3.13, p = .002) and executive function (Korean-Trail Making Test Part B) (t=-2.38, p = .02), compared with those without severe diastolic dysfunction. After controlling for age and education, HF patients with a concomitant presence of systolic and severe diastolic dysfunction had poorer cognitive function in verbal fluency than those free of severe diastolic dysfunction (F=4.45, p = .038, partial eta=.057).
Conclusions: Poor cognitive performance, particularly executive function was more substantial in HF with systolic dysfunction when diastolic dysfunction concomitantly presented. Monitoring and surveillance of diastolic dysfunction and cognitive screening are warranted in routine clinical practice of HF management.

P2153

Interventions to enhance medication adherence in older heart failure patients, a systematic review

RL Roberta Fulton[1]; T Kroll[2]; MET Mcmurdo[1]; G Molloy[3]; MD Witham[1]
[1]University of Dundee, Ageing & Health, Dundee, United Kingdom; [2]University College Dublin, Dublin, Ireland; [3]National University of Ireland, School of Psychology, Galway, Ireland

Funding Acknowledgements: Chief Scientist Office, Scottish Government Health Directorates

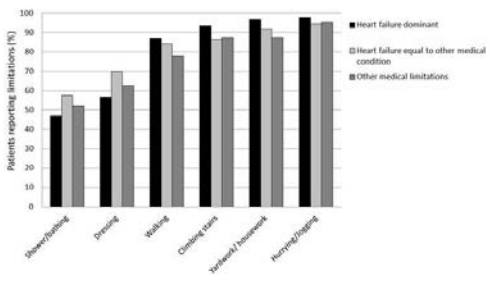
Introduction: While there is clear evidence that pharmacotherapy improves survival and reduces hospitalisation due to heart failure, medication adherence is sub-optimal. With increasing numbers of effective self-administered treatments available, there is a need for better understanding and management of non-adherence to medication. The purpose of this systematic review was to establish which interventions are effective in enhancing medication adherence in heart failure patients
Methods: We conducted a systematic review of randomised controlled trials (RCTs) searching for all-language publications in electronic databases (Medline, CINAHL, Embase, Cochrane Central Register of Controlled Trials and PsychINFO) up to the end of April 2015. We included RCTs where an intervention was compared to usual care or a clearly justified comparison group and where the intervention strategy clearly had a primary or secondary aim of increasing adherence to heart failure medication. Included trials required to have enrolled patients'≥ 18years, with a clinical diagnosis of heart failure, who did not have their daily medication administered by a healthcare professional. Two independent reviewers examined

lists of retrieved articles extracting study characteristics and results for adherence. Methodological quality was examined using the Cochrane Collaboration risk of bias tool. Studies were critically reviewed and assessed for validity of their findings.
Results: From the initial 1,801 identified papers 21 trials, containing data on 4346 patients (mean ages 56 to 85 years), were included. The median sample size was 148 patients (range 50 to 902); the median follow-up time was 9 months with 9 of the 21 (43%) trials having follow-up times of ≤6 months. Medication adherence improvement was reported in 8 of 21 trials. 5 of these 8 were categorized as intensified patient care, with these studies specifically designed to increase the contact time between participant and health care professional. Heterogeneity of interventions and outcome measures precluded meta-analysis of results.
Conclusions: While it is possible to improve medication adherence in heart failure patients, the current litetrature does not allow reliable conclusions to be drawn as to the best intervention. Heterogeneity in both intervention techniques and measurement methodology leave us unable to identify reliable and efficacious intervention approaches. Future studies should aim to build on the methodologically stronger studies so that a cumulative set of findings can emerge.

P2154
Patients in nyha III report substantial limitation to routine daily activities which may not be related to heart failure

R R T Castro[1]; E Joyce[2]; M Givertz[1]; GC Stewart[1]; NK Lakdawala[1]; E Lewis[1]; LW Stevenson[1]
[1]Brigham and Women's Hospital, Boston, United States of America; *[2]Cleveland Clinic Foundation, Cleveland, United States of America*

Background: Left ventricular assist devices (LVADs) are effective in improving survival and patient-reported outcomes in refractory heart failure (HF). Although LVAD implantation is not currently indicated in patients labeled as NYHA Class III, this physician designation may not always capture patient-reported limitations in specific activities. Furthermore, these activities may be limited by conditions other than HF. This study aimed to analyze how often patients labeled as NYHA Class III describe limitations to routine daily activities, and to determine how often these patients ascribe the major limitation of their quality of life (QOL) to HF or to combination with other medical conditions.
Methods: During routine HF clinic visits, ambulatory pts completed questionnaires including a graded scale for self-perceived limitations to daily activities, QOL on a visual analog scale (0-100), and their impression of whether their limitation was due mostly to HF or to other medical conditions. This analysis was restricted to those patients labeled by their HF physicians as having NYHA class III symptoms. Results between groups were compared by Student's T test or chi-square test.
Results: Patient symptoms were described by physicians as NYHA Class III in 162 patients. Patients who rated HF as a dominant limitation to QOL (n = 97) had similar QOL (46 ± 25 vs. 51 ± 29, p = 0.138) to the ones who rated limitation as due equally to HF and other medical condition (n = 40), and the ones whose major limitation was not HF (n = 25; QOL=57 ± 28). Limitation was described for bathing for 50.3% of patients and 60.9 % for dressing. There was no difference of daily activities' limitations between groups.
Conclusion: Patients in NYHA III have substantial limitations to daily activities and to QOL. When these limitations are due to HF, it may be reasonable to consider advanced therapies. However, it is important to identify those patients with HF that have other conditions limiting their daily activity, which would not improve with HF advanced therapies.



Limitations reported by NYHAIII patients

P2155
Predictors of 6- and 12-month mortality in chronic heart failure

N Nataliya Tkach[1]; L Voronkov[1]
[1]NSC Institute of Cardiology M.D. Strazhesko, Heart Failure department, Kiev, Ukraine

Background: Despite good knowledge about predictors of long-term mortality in chronic heart failure (CHF) the comparable value of them in dependence of patients follow-up duration is still non-well investigated.
Aim: The purpose of study was to identify the predictors of 6- and 12-month mortality in CHF.
Methods: 95 clinical, echocardiographic and laboratory variables in 267 CHF patients with left ventricular ejection fraction LVEF < 40 % were analyzed. Predictors of 6- and 12-month mortality were determined in stepwise multiple logistic regression model.
Results: Table 1.
Conclusion: HOMA index is an important predictor of CHF patients as 6 and 12 months. "Hemodynamic-linked" predictors (low LVEF, high LVEDVI) are valuable only in relation to 6-month mortality prognosis. The predictive value of elevated plasma UA and level blood lymphocyte < 21% is the more important to 6-months mortality; according to follow-up duration, the predictive value of low BMI, HR > 75 beats p.m. and LA size > 49 mm. are increased

Predictors of 6- and 12-month mortality

6 month	OR	12 month	OR
UA>450μmol/l	7.86	HOMA>2,65	8.48
HOMA>2,65	6.18	HR>75 beats p.m.	7.9
Blood lymphocyte <21%	5.15	SAP<100mmHg	5.4
LVEF <30%	3.4	BMI<22kg/m^2	3.59
BMI<22kg/m^2	3.33	UA>500μmol/l	3.125
LVEDVI	3.23	Blood lymphocyte <21%	2.69
6 min walk distance <360m	2.66	6 min walk distance <360m	2.43
		LA>49mm	2.18

* Only significant predictors are included (p < 0.05). UA - uric acid; BMI - body mass index; LVEDVI - left ventricular end diastolic volume index; HR - heart rate; SAP - systolic arterial pressure; LA - left atria size; LVEF - left ventricular ejection fraction.

P2156
The role of hibernation in potential recovery of ischemic myocardium in chronic heart failure as a manifestation of coronary artery disease

E Elena Stefanovic[1]; P Otasevic[1]; L Lausevic-Vuk[1]; P Milojevic[1]; M Jovic[2]; V Kanjuh[3]; P Seferovic[3]
[1]Institute for Cardiovascular Diseases Dedinje, Belgrade, Serbia; *[2]Military Medical Academy of Belgrade, Belgrade, Serbia*; *[3]University of Belgrade, Belgrade, Serbia*

Background: The aim of this study was to investigate the morphologic characteristics of the hibernating human myocardium and ,thrue the correlation its with dobutamine stress echocardiography (DSE), to study the potential for myocardial recovery in coronary artery disease.
Methods and Results. We evaluated 15 patients with coronary disease (58 + /-12 years old, ejection fraction 38 + -/14%) with a corresponding wall motion abnormality on DSE (up to 10 micrograms kg (-1) min(-1) before coronary bypass surgery. During surgery, transmural myocardial biopsies from hypokinetic or akinetic area were perfomed (n = 37). The samples of myocardium were analyzed by histopathology and immunohistochemestry to investigate the extent of interstitial fibrosis, intracellular and interstitial proteins. Among the 15 patients included in the study, 7 recovered function as assessed with an echocardiography, one month after bypass surgery, 8 with DSE viability showed less fibrosis and less vimentin expression,more glycogen, a higher ration of alpha-smooth muscle actin, actin and desmin then those without recovery. The degree of severity of the morphological changes (three stages) correlated well with the demonstration of inotropic reserve during DSE and with the extent of postoperative functional recovery (wall-motion score index, NYHA).
Conclusion: Myocardial hibernation as the adaptation to a reduced oxygen supply in coronary artery disease, have an important role in potential recovery of ischemic myocardium after coronary artery bypass surgery, as shown by more favourable histopathologic features.

P2157

Metabolic treatment elderly patients with congestive heart failure with preserved systolic function and non severe aortic stenosis

OV Olena Soya[1]; OV Kuryata[1]
[1]*Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine*

Background: Calcific aortic stenosis (AS) is the most common valvular abnormality in the geriatric age group. Like the AS, the prevalence of congestive heart failure (CHF) with preserved systolic function increases with age. Meldonium is cardioprotective drug with anti-ischemic and stress-protective effects in treating various cardio-vascular diseases and other pathologies. The aim of this study was to assess effect of meldonium treatment on cardiovascular function and exercise capacity in elderly patients with non severe AS and CHF with preserved systolic function.
Methods: In study were included 112 patients (male 61, female 51, age 79.8yrs+/-1.8) with non critical AS (mean gradient 31.1+/-5.1 mmHg) and with NYHA II-III functional class CHF due to ischemic heart disease or arterial hypertension. All patients have had left ventricular ejection fraction>45%. Patients were divided in two groups: in 1-st group – 58 patients got a standard combined CHF therapy, in 2-nd group – 54 patients got standard CHF therapy in combination with meldonium 1,0 g daily. Plasma level of insulin was measured before and after 4 months treatment with meldonium or placebo. RESULTS: There were no differences in baseline characteristics including hemodynamic parameters between 2 groups. After 4 months the elderly patients with AS and meldonium treatment demonstrated improved CHF functional class (50.1% vs 27.3%, $p < 0.01$) and exercise capacity by 6 minute walk test (39.3% vs 24.7%, $p < 0.01$) compared with standard therapy group. Patients receiving placebo demonstrated increasing insulin level (263/-31 pmol/l vs 381+/-39 pmol/l, $p < 0.01$). In contrast, in patients receiving meldonium, plasma level of insulin did not change.
Conclusion: Metabolic treatment with meldonium could have positive effect on cardiohemodynamic and exercise capacity in elderly patients with non severe aortic stenosis and CHF with preserved systolic function. Besides, meldonium prevents increasing plasma insulin level which could be significant negative prognostic marker.

P2158

Rheumatoid arthritis and congestive heart failure

TH Theodoros Michailidis[1]
[1]*General Hospital of Veria, Department Of Internal Medicine, Veria, Greece*

Introduction: It is widely accepted that Congestive Heart Failure (CHF) and Rheumatoid Arthritis (RA) are associated. There are studies that have examined the importance of RF and the anti – TNF treatment in the development of CHF in RA.
Purpose: Our purpose was to examine Greek women with RA and CHF and determine whether RF(+) women were at greater risk of developing CHF than those who were RF(-) independently of the presence of other cardiovascular risk factors.
Methods: We studied two groups of women with RA. Group A included 22 women from 55 to 74 years old, non-smokers, suffering from hypertension and dyslipidemia, who were RF positive and anti-ccp positive, receiving DMARDs treatment per os. Group B included 21 women, with similar age (55-75 years old) and history of CV risks, who were anti-ccp(+) and RF seronegative and were receiving similar to group A DMARDs treatment. All of the women were submitted to CMR (cardiovascular magnetic resonance).
Results: The results have shown that 17 women from group A suffered from stage A to stage D CHF whereas only 5 group B women had CHF compatible CMR imaging. Having ruled out the possible role of anti TNF treatment in CHF development (some women had pastly received anti-CD 20 and abatacept, adalimumab, anakinra and golimumab therapy when none of them received etanercept), the difference of the presence of CHF in the two groups was statistically important ($p < 0,01$)
Conclusion: Therefore, although the population sample examined was not huge, we have concluded that RF(+) Greek women, older than 55 years and suffering from RA have a much greater risk at developing CHF than RF(-) Greek women with RA. The determination of RF seropositivity in such women should always concern the cardiologist involved.

Heart failure development and rs2274273 in the vicinity of LGALS-3 locus, LGALS-3 relative mRNA expression in patients with first myocardial infarction

MD Dekleva[1]; AD Djordjevic[2]; MZ Zivkovic[2]; AS Stankovic[2]; NM Markovic Nikolic[1]; TD Djuric[2]
[1]*University Clinical Center Zvezdara, Department of Cardiology, Belgrade, Serbia*;
[2]*Insitute for Nuclear Science "Vinca", Belgrade, Serbia*

Background: Previous research has shown an association between circulating galectin-3 and fibrosis, apoptosis, cardiac dysfunction and heart failure (HF) after first myocardial infarction (MI)
Aims: Authors investigated an association of the genetic variant potentially affecting galectin-3 levels-rs 2274273 (C>T) as well as LGALS-3 mRNA with adaptive or maladaptive LV remodeling, functional LV dynamics and heart failure occurrence.
Methods: The prospective study enrolled 166 patients with first acute MI. Clinical, laboratory, ECG echocardiographic and angiographic data were obtained at admission time and after 6 months follow up. Rs 2274273 and LGALS-3 mRNA expression were detected by real time PCR.
Results: T allele according to dominant model was significantly associated with LV enlargement (diameter and volume) ($p = 0.037$, $p = 0.034$), global radial strain ($p = 0.003$) and LV spherical index ($p = 0.032$). LGALS-3 mRNA expression was significantly higher in: patients with maladaptive remodeling ($p = 0.045$), apical LV dilatation and remodeling (0.046) and in patients who developed HF after six month follow up ($p = 0.021$).
Conclusions: Our exploratory results suggested that rs 2274273 T allele and LGALS-3 mRNA could bear the risk for more severe post MI LVR and HF development. Further replication and validation in a larger group of patients is inevitable.

P2160

The relationship between blood pressure, heart rate and clinical status in patients with chronic heart failure with reduced left ventricular ejection fraction

M Michal Bohdan[1]; A Kowalczys[1]; M Gruchala[1]
[1]*Medical University of Gdansk, 1st Dept of Cardiology, Gdansk, Poland*

Introduction: The effects of increased heart rate (HR) and blood pressure (BP) on cardiovascular mortality have been thoroughly studied for many years. The impact of BP on clinical status and prognosis of patients with CHF still needs further investigation.
Purpose: The aim of the study was to assess the relationship between BP as well as HR and clinical status including: major adverse cardiac events (MACEs), left ventricular ejection fraction (LVEF), brain natriuretic peptide (BNP) and six-minute walk test (6MWT) distance in stable patients with CHF.
Methods: There were 80 patients: 73 (91%) men and 7 (9%) women (mean age: 59 ± 12 years) with stable CHF and mean NYHA class 2.15 ± 0.57, with reduced LVEF recruited for the study. Coronary artery disease (CAD) was the main CHF cause. The majority of patients were nondiabetic ($n = 56$, 70%). All patients underwent following examinations: medical history, physical examination, laboratory tests including BNP, 12-lead electrocardiogram, echocardiogram, six-minute walk test (6MWT). We obtained: BP, systolic and diastolic (SBP, DBP) and HR as determined in 24-hours ECG and blood pressure monitoring (50% of patients) or telemetry monitoring and BP measurements 5 times a day (in the rest of the group). All patients were treated according to ESC guidelines. Most of them received β-blockers ($n = 71$, 89%). The median follow-up period was 6 months. MACEs were defined as: death of all causes, cardiovascular death, hospitalization due to the heart failure exacerbation.
Results: There was sinus rhythm in the majority of patients (55%) while atrial fibrillation was found in 16 (22%) patients. The LVEF $\leq$35% (mean 23 ± 6%) was confirmed in all patients as well as elevated BNP level (742 ± 701 pg/ml). Median 6MWT distance was 351 ± 110 m. Median heart rate was 75 ± 14.3/min. Median SBP was 114 ± 14mmHg and DBP: 70 ± 9.5mmHg. The percentage of patients with heart failure exacerbation was 13% at 3 months and 24% at 6-month follow-up. The mortality rate was 4% at 3 months and 6% at 6-month follow-up. We found positive correlations between SBP and: LVEF (R=0.4, $P = 0.0002$), 6MWT distance ($R = 0.33$, $P = 0.0056$) and negative between SBP and BNP ($R = -0.03$, $P = 0.0068$). We also revealed positive correlation between DBP and EF ($R = 0.26$, $P = 0.0182$). Although there was no relationship between HR and EF, BNP, 6MWT, we confirmed negative correlation between HR and LVEF ($R = -0.35$, $P = 0.0089$) in the subgroup of patients with atrial fibrillation. After 3-month but not 6-month follow-up there was a significant correlation between DBP and all-cause mortality ($P = 0.048$) as well as CHF decompensation ($P = 0.0004$) in the whole group. We have not found any significant relationship between HR or SBP and MACEs.
Conclusions: Blood pressure is strongly associated with clinical status of patients suffering from CHF. Moreover, DBP may be helpful in prediction of heart failure exacerbations in stable patients with CHF with reduced ejection fraction in short-term observation.

P2162

Liver dysfunction at chronic heart failure patients

K Kaoutar Kharbouche[1]; I Elhaddad[1]; K Kharbouche[1]; L Azouzi[1]; R Habbal[1]
[1]*chu ibn rochd, cardiology, casablanca, Morocco*

Introduction: Comorbid conditions such as anemia. Liver and renal dysfunction are significantly influence on chronic heart failure (CHF) prognosis.
Objectives: To studying of a liver function at patients with CHF.
Methods: 1600 patients from 22 to 58 yrs (mean 44,21,8, males/females 61/21) are included. CHF has been caused by ischemic (n25) and idiopathic dilated cardiomyopathies (DC, n56). The hepatic function was assessed by determination of

aspartate (AsT) and alanine transaminase (AlT), total bilirubin (TB), and albumin plasma concentration. After initial investigation all patients are divided on two: I (with liver abnormalities, n28; 43,72,1 yrs) and II (without hepatopathy, n54, 41,41,9 yrs) groups.
Results: Apparently, the prevalence of liver dysfunction characterized by increasing of TB and/or transaminase levels was 37,2% and at 6 (5,8 %) from them had cirrhosis signs. The most typical markers of hepatic damage at our patients was hyperbilirubiemia, registered at 25 (89%) pts of I gr. At the same time, increase of transaminase was less expressed (at 18 pts). It is noticed, that at I gr patients decreasing of plasma albumin (3,30.12g/l vs 3.80,15g/l) and total cholesterol (allocated as adverse predictor at CHF patients) levels was more expressed (123,89,7mg/dl vs 147,36,8mg/dl, both p0.05). Comparative analysis of diseases severity showed that differences of NYHA class was non significant, but I gr pts characterized by reduction of distance by 6 minute walking test on 16.3% (168.79.3m vs 20210.2m accordingly, p0.04).
Conclusion: The 37.2% pts with various etiology CHF had signs of hepatic dysfunction, including cirrhosis. It is noticed, that the hyperbilirubiemia is frequent display of hepatopathy. Increasing of liver markers associated by hypoalbuminemia, hypocholesterolemia and physical tolerance worsening.

P2163
Cardiac resynchronization therapy in heart failure patients

R Kallel[1]; R Hammami[1]; M Akrout[1]; J Jedidi[2]; N Mallek[1]; L Abid[1]; S Kammoun[1]; J Dammak[2]
[1]Hedi Chaker Hospital University, Department of cardiology, Sfax, Tunisia; *[2]Hedi Chaker Hospital University, Departement of Epidemiology and community Medicine, Sfax, Tunisia*

Background: Patients with symptomatic heart failure and severe depression of left ventricle ejection fraction despite optimal medical treatment can benefit from cardiac resynchronization.
However, the increase use of implantable cardiac electronic devices was associated with an increase in complications and mortality.
Purpose: Our goal was to determinate the rate and the predictors of complications in patients with cardiac resynchronization therapy (CRT) in a real-world study.
Methods: Patients who received CRT-D/P between January 2009 and December 2013 were included in the study. We identified all complications during the follow up. Appropriate statistical tests were applied to identify the rate and the predictors of complications. We are particularly interested with the subgroup of patients with cardiac resynchronization therapy.
Results: 64 complications in 53 patients were noted over the period of the study, in fact 11,5% of patients receiving an implantable cardiac device (n = 462) experimented complications. Twenty six patients received a cardiac resynchronization therapy; just ten ones got defibrillation function. Patients with CRT experienced outcomes with higher rates (9 cases, 34%) compared to other implanted patients (13%). Infectious complications were registered in 11,5% of patients with CRT versus 1,37 % in patients with non CRT devices (p = 0,03). Independent risk factor of infections were heart failure (OR= 9) and diabetes (OR=4). Only one patient (3,8%) presented with left ventricle's lead dislodgement. The same patient had coronary artery dissection and then failure of resynchronization. Neither pocket hematoma nor complication linked to route access was noted in CRT patients over the study period. Mortality linked to complications of cardiac stimulation reached 13,2% especially with infectious outcomes (p = 0,04). However heart failure (p = 0,25) and resynchronization therapy (p = 0,95) were not directly associated to mortality due to complications.
Conclusion: Patients receiving cardiac resynchronization devices are subject to experience higher rates of complications compared to other types of implantable cardiac devices. Heart failure is an independent risk factor of complications. Comorbidities especially diabetes are an additional risk factor. Nevertheless, centers with low volume of implantation have particularly a high complication rate.

P2164
Myopathy and iron deficiency in chronic heart failure: dynamic 31P MR spectroscopy study of the skeletal muscle

K Katerina Hlavata[1]; P Sedivy[2]; M Dezortova[2]; M Hajek[2]; J Kautzner[1]; V Melenovsky[1]
[1]Institute for Clinical and Experimental Medicine (IKEM), Cardiology Department, Praque, Czech Republic; *[2]Institute for Clinical and Experimental Medicine (IKEM), Magnetic Resonance Imaging, Praque, Czech Republic*

Funding Acknowledgements: GA CZ 15-14200S, MZ CZ - RVO (00023001 IKEM)

Introduction: The effect of sideropenia on myopathy due to chronic heart failure (CHF) is unclear.
Purpose: determine whether CHF leads to disruption of energetic metabolism of skeletal muscle, whether the abnormalities are affected by presence of sideropenia and whether these abnormalities disappear after correction by intravenous administration of ferric-carboxymaltose (FCM).
Methods: 25 healthy volunteers (49 ± 15y, 28 ± 4kg/m2, 70%) and 44 CHF patients (55 ± 16y, BMI 27 ± 6kg/m2, 75% men) underwent blood sampling and 31P MR spectroscopy of gastrocnemius muscle at rest and during exercise. In13 sideropenic patients examination was repeated 1 month after administration of FCM.
Results: HF was associated with reduction of high-energy phosphates content, acidosis and slower recovery of PCr after exercise, corresponding to CHF myopathy (table). The factors with highest impact on PCr-tau in CHF were: age, diabetes and male sex. Iron deficient HF patients had lower peak muscle strength, significant decrease of PCr during exercise and trend toward slower PCr recovery.
Conclusion: The administration of FCM led to a correction of sideropenia, improved functional capacity and muscle strength, but did not influence on energy metabolism in skeletal muscle, or redistribution of iron into skeletal muscle requires a longer period than 1 month.

Assessment of causes of increased myocardial fibrosis, left ventricular dysfunction and poor prognosis after valve replacement for acquired heart disease

Il Irina Averina[1]; OL Bockeria[1]; SA Aleksandrova[1]; MU Mironenko[1]; LG Geletsian[1]
[1]*Bakoulev Center for Cardiovascular Surgery RAMS, Cardiosurgical , Moscow, Russian Federation*

Background: Despite technically successful operations postoperative complications as heart failure, sudden death are still observed. Dynamic contrast-enhanced MRI with gadolinium-based contrast and 2D speckle tracking echocardiography (Echo) can be reliable tools for evaluating fibrosis, LV dysfunction and possible poor prognosis after valve replacement.
Aim: Assessment of reasons for increased or maintained myocardial fibrosis, left ventricular dysfunction and poor prognosis after valve replacement based on the dynamic contrast-enhanced MRI with gadolinium-based contrast and 2D speckle tracking echocardiography
Methods: 144 (99 men, 45 women; age 47 ± 15) patients with aortic and mitral valve disease were included. In all cases 2D speckle tracking Echo was performed. 28 patients also underwent pre- and post-op MRI with gadolinium. Prognostic groups were considered: 0–no complications, 1–arrhythmia, 2–heart failure, 3–death. MRI fibrosis score was used: A–none, B–moderate, C–moderate-severe, D–severe. The global longitudinal, circumferential strain (LSt, CSt), strain rate (SR), rotation rate and torsion were obtained with Echo. Statistical analyses were done. Remodeling was considered as positive with reduced volume, increased ejection fraction, as negative with increased volume, decreased ejection fraction.
Results: The prognostic factors of high risk of heart failure: increased left ventricular systolic volumes index before surgery (IESV=45 ml/m2, AUC=0,84 ± 0,05), diminished basal septum motion (LSR = −0.4 c-1, AUC=0,7 ± 0,1), decreased apex rotation rate (37°/c, AUC=0,88 ± 0,1), diminished circular function of LV basal part (CStav= −14 %, AUC=0,8 ± 0,1).
Reverse remodeling was observed in 26% of pts. with moderate fibrosis. It was positive, but with persisted moderate-severe fibrosis in 62%, and negative with increased fibrosis in 12%. In persistent fibrosis LV IESV fell from 45 ml/m2 to 34 ± 15 (p = 0.001) With fibrosis increasing residual LV volume was higher (43 ± 8), despite its reduction from the initial (p = 0.001). LV LSt, CSt did not improve in persistent or increased fibrosis occurrence. Focal fibrosis was the most discernible at the junction of the septum with LV and RV free walls
Conclusion: Initial irreversible stretching LV is the main cause of incomplete remodeling and the heart failure in the postoperative period. Pointed values, shown incomplete reverse remodeling, fibrosis and preservation of the heart failure after surgery were: IESV–45 ml/m2, IEDV–99.89 ml/m2, LSt La–26.8%. Initial IESV ≥ 59 ± 8.9 ml/m2 was the reason for the increase of fibrosis in the postoperative period. Initial IESV ≥ 45.3 ml/m2 ± 14.9 was the cause of persisted myocardial fibrosis. The valve/ventricular approach may be needed to counteract.

P2166

Predictors of left ventricular function recovery in patients followed in a heart failure clinic

H Henrique Guedes[1]; D Seabra[1]; P Silva[1]; L Marques[1]; A Andrade[1]; P Pinto[1]
[1]*Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*

Background: Chronic Heart Failure (HF) remains a major worldwide problem with high prevalence and incidence. It is the end stage of many diseases. The recovery of left ventricular systolic function (LVSF) is important for the prognosis of these patients (pts), with relevance in the morbidity and mortality associated with HF.
Purpose: To evaluate the factors with impact on the recovery of LVSF (rLVSF) in pts with chronic HF and reduced ejection fraction (EF).
Methods: Retrospective study where were including pts followed in a HF clinic (HFC) from a single center. The pts had reduced ejection fraction and were admitted in the HFC with a previous diagnosis of HF for at least 6 months. Pts with follow-up (FU) of less than 12 months were excluded. The rLVSF was measured by echocardiography and defined as an increase of ≥ 10% with respect to the initial value. The pts were divided into 2 groups: rLVSF (G1) and not rLVSF (G2). The groups were compared as to their clinical and echocardiographic characteristics and occurrence of hospitalization for HF (hHF), hospitalization for acute coronary syndrome, cardiovascular mortality and non-cardiovascular mortality. To analyze the relationship of the qualitative variables we used Fisher's exact test, while the Student t test was used to analyze the influence of the quantitative variables. It also appealed to the Cox regression model for multivariate adjustment (SPSS 22.0)
Results: Included 290 pts, mean age 60.6 ± 13.3 years. 75.1% were male. 41% had ischemic etiology, 34.1% permanent AF and 63.8% severe depression of LVSF. The mean initial EF was 29.2 ± 10.8%. Mean FU time was 39.9 months ± 18.5 months. 86 pts (29.7%) presented rLVSF (initial EF 25.3 ± 10.8% vs current EF 44.7 ± 12.5%). There were no significant differences in the composition of the two groups. In the univariate analysis, rLVSF was more common in patients with non-ischemic etiology (p = 0.007), sinus rhythm (p = 0.023), lower left ventricular end-diastolic diameter index (LVEDDi) at the end of the follow-up (30.4mm/m2 vs 34.4mm/m2, p < 0.001), lower prevalence of chronic kidney disease (defined as glomerular filtration rate ≤ 60mL /min/1.73m2, p < 0.001), less hHF (p = 0.008), lower functional class (≤2, p = 0.004), higher percentage of patients receiving angiotensin converting enzyme inhibitors / angiotensin receptor blockers (ACEi/ARB, 94.2% vs 85.3%, p = 0.034) and less with diuretics (64.0% vs 76.5%, p = 0.034). When used logistic regression, the non-ischemic etiology (p = 0.011), LVEDDi (p < 0.001), hHF number (p = 0.047) and ACEi/ARB therapy (p = 0.035) were significantly associated with rLVSF.
Conclusion: In this study, the non-ischemic etiology, lower LVEDDi, less hHF and ACEi / ARB therapy were predictors of rLVSF.

P2167

Heart failure as predictor of sudden death in patients with myocardial infarction after prior CABG; 27-year experience

P Predrag Mitrovic[1]; B Stefanovic[1]; M Radovanovic[1]; N Radovanovic[1]; G Matic[2]; D Rajic[2]; I Subotic[2]; N Mitrovic[2]; N Mijic[2]
[1]*University Institute for Cardiovasculari Diseases, CCS, School of Medicine, University of Belgrade, Belgrade, Serbia*; [2]*Clinical Center of Serbia, Institute for Cardiovascular Diseases, Belgrade, Serbia*

On behalf of: The POP Study Group
Funding Acknowledgements: The Belgrade Cardiology Club

To elucidate the clinical predictors of death, 1080 patients (pts) with acute myocardial infarction (AMI) after prior coronary artery bypass grafting (CABG) have been selected from the pts consecutively submitted from April 1990 to January 2017.
Methods: In this group of patients with AMI after prior CABG mean age was 59.4 ± 6.4 yrs. There were more males (79.6%). The pts with early perioperative AMI were excluded from the study. The average time interval from CABG to AMI was 94.8 ± 11 months. The average number of grafts was 3.3 grafts/pts. All pts were divided in 3 groups: pts died from sudden cardiac death, pts died from cardiac causes of death and pts died from non-cardiac causes of death. The mean interval of survival was 12.4 ± 5.2 months.
Results: In 180-months follow-up period 220 (20.4%) pts died after AMI and previous CABG. One hundred and forty-three pts (65%) died in first five years after AMI and the more often cause of death in these pts was sudden cardiac death (132/143 pts, 92.3%). Seventy-nine total of 220 pts (35.9%) died from cardiac causes of death. The most frequent cause of death in this group of pts was congestive heart failure (64/79 pts, 81%). Fifteen pts (19%) died from reinfarctus. In twelve pts (5.5%) the cause of death was non-cardiac. One hundred and thirty patient (59.1%) died from sudden cardiac death. Analyze of events which might be causes of death in pts died from sudden cardiac death shown that: angina pectoris was present in all 132 pts, atrial fibrillation was present in 60/132 (45.5%) pts and congestive heart failure in 105/132 (79.5%) pts. Conclusion: the most frequent cause of death in 220 patients died after AMI and previous CABG was sudden cardiac death; congestive heart failure is one of very important predictor of sudden cardiac death in this patients.

P2168

ST2 in HFpEF and HFrEF, similarities and differences

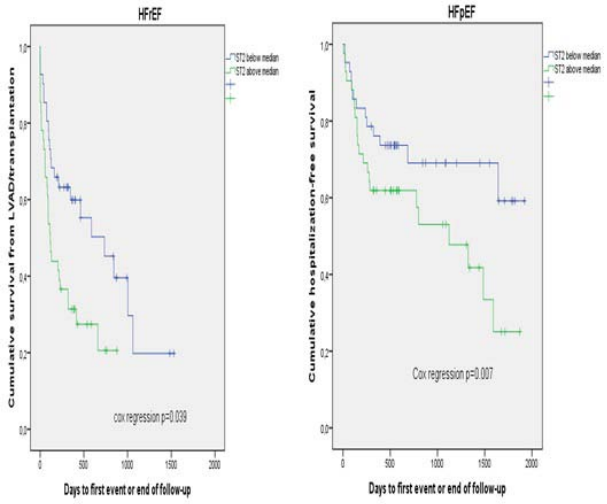
E Emil Najjar[1]; LH Lund[1]; UL Faxen[2]; C Hage[1]; E Donal[3]; J Daubert[3]
C Linde[1]; [1]*Karolinska University Hospital, Department of Cardiology, Stockholm, Sweden*; [2]*Karolinska University Hospital, Department of Anesthesia and Intensive Care, Stockholm, Sweden*; [3]*University Hospital of Rennes, Département de Cardiologie & CIC-IT U 804, Rennes, France*

Funding Acknowledgements: The Swedish Research Council, the Swedish Heart Lung Foundation and the Stockholm County Council

Background: Soluble suppression of tumorigenecity 2 (ST2) reflects myocardial stress, ventricular remodeling and fibrosis. It is prognostic in heart failure with reduced ejection fraction (HFrEF) but poorly studied in HF with preserved EF (HFpEF).
Purpose: To evaluate ST2 concentrations, correlations with biomarkers and associations with outcome in HFpEF compared to HFrEF, and associations with echocardiographic measures of diastolic function in HFpEF.
Methods and Results: Eighty-six patients with HFpEF from the prospective KaRen cohort (median age 73 [67-80] years, 51% women), 86 patients with HFrEF (median age 63 [52-68] years, 19% women) and 21 controls (median age 67 [59-70] years, 57% women) were included.
Concentrations of ST2 were lower in HFpEF (median and interquartile range); 23 (17; 31) μg/L and controls 25 (21; 32) μg/L, compared to HFrEF; 35 (23; 52) μg/L, overall p < 0.001. NT-proBNP was also lower in HFpEF; 1000 (465; 2335) ng/L vs.

HFrEF, 3290 (1405; 6115) ng/L, p < 0.001.
In both HFpEF and HFrEF, ST2 showed a significant positive correlation with NT-proBNP (HFpEF r = 0.36, p = 0.001 and HFrEF r = 0.453, p < 0.001) but not with eGFR in HFpEF or HFrEF. In HFpEF, ST2 correlated to indexed left atrial volume (r = 0.27, p = 0.020) but not to E/E′, nor to left ventricular mass index.
ST2 was significantly associated with survival free from hospitalization for HF in HFpEF and survival free from heart transplant or left ventricular assist device in HFrEF (Figure); hazard ratio (HR) per log increase in ST2 10.04, 95% confidence interval (CI) 1.89-53.44, p = 0.007, and 3.28, 95% CI 1.06-10.16, p = 0.039, respectively. In HFpEF, but not in HFrEF the association persisted after adjustment for NT-proBNP and age, HR 7.2, 95% CI 1.1-43.28, p = 0.032.
Conclusions: We confirm previous studies that ST2 is prognostic in HFrEF but this may not be independent of covariates. We show that ST2 is independently prognostic in HFpEF.

Figure: Kaplan-Meier estimates of survival free from hospitalization for HF in HFpEF and survival free from heart transplant or left ventricular assist device in HFrEF.



P2169

Increasing the efficiency of treatment of patients with chronic heart failure through the changes of control systems of patients.

N Nabil Kraiem[1]; I Fomin[1]; NG Vinogradova[1]; M Zhirkova[2]; S Allahverdiyeva[2]; A Krylova[2]; A Subbotin[2]; A Kozlova[2]; N Anyutochkina[2]
[1]Nizhny Novgorod State Medical Academy, Department of internal medicine, Nizhny Novgorod, Russian Federation; *[2]Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russian Federation*

Introduction: It was proved that treatment of chronic heart failure (CHF) is less effective on the ambulatory period; therefore, it is important to consider some methods to make ambulatory treatment more effective.pgtaghb**Purpose:** To compare the treatment efficiency of patients with CHF in specialized center of CHF treatment and in real clinical practice.
Methods: Patients, after being discharged from hospital for acute decompensated heart failure (ADHF) were under observation in a specialized center of CHF treatment (group1, n=244) in period of 8 months and patients (group2, n = 243) under observation in real practice conditions. Hemodynamic parameters, frequency of recommended treatment use and outcomes (total and cardiovascular death) were identified in both groups. In specialized center, the nurse made structured calls to patients from group 2 one time every month.
Results: Mean age of patients was 70.1 ± 10.4 years in group 1 and 72.5 ± 11.8 in group 2 (p = 0.006). Quantity of patients according to NYHA classification was comparable in both groups: 15.4% and 7.1% in first class, 30.2% and 39.3% in second, 41.6% and 46.4% in third, 12.8% and 7.2% in fourth for group 1 and group 2 respectively. Results, depending of ejection fraction (EF) were comparable: 68.6% and 68.6% of patients had conserved EF, 18.5% and 21.6% with mid-range EF, 12.9% and 9.8% with reduced EF in group 1 and 2 respectively.Hemodynamic parameters (Systolic blood pressure, Diastolic blood pressure, Heart rate) were similar. After 8 months, administration frequency of Renin Angiostensin Aldosteron system blockers, Beta Blockers and Mineralocorticoid Receptor Antagonist in group 1 increased from 84.3% to 93.8% (p < 0.001), form 78.5% to 87.4% (p = 0.01) and from 63.1% to 70.3% (p = 0.09) of patients respectively. In group 2, there was a decrease from 86.4% to 50.5% (p < 0.001), from 79.6% to 54.9% (p < 0.001), and from 64.5% to 24.1% (p < 0.001). After 8 months, 70.5% of patients continue to use loop diuretics in group 1 (p < 0.001), in group 2 only 38.5% (p < 0.001). Total mortality during 8 months was 1.9% and 13.9% in group 1 and 2 respectively (OR=8.5 CI 95% 2.7-26.6, p < 0.001). In group 1, causes of cardiovascular mortality were ADHF, sudden cardiac death and pulmonary embolism (PE). In group 2, ADHF was in 58.3% of cases, PE in 16.7%, stroke in 16.7% and myocardial infarction in 8.3% of cases.
Conclusion: during the period of observation, the recommended treatment was less used among patients under observation in conditions of real clinical practice comparing with patients under observation in specialized center of CHF. After ADHF, patients are having bad prognosis, that's why, in Russian Federation, there is a big need in changing the strategy of treatment and observation of patients with CHF and developing of a specialized health care system.

P2170

Utilization of evidence based therapies in patients hospitalized for worsening heart failure

CI Radulescu[1]; L Antohi[1]; R Radu[1]; M Chivulescu[1]; I Cosei[1]; A Covaliov[1]; G Tatu-Chitoiu[2]; D Vinereanu[3]; D Dobreanu[4]; O Chioncel[1]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; *[2]Emergency Clinical Hospital Floreasca, Cardiology, Bucharest, Romania*; *[3]University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania*; *[4]Institute of Cardiovascular Diseases of Targu Mures, Cardiology, Targu Mures, Romania*

Background: In real world setting, the rate of use of evidence based heart failure therapies (EBHFT) is lower than guidelines recommendations, suggesting the unmet need of further improving of medical education.
Aim: To evaluate the pattern of in-hospital use of EBHFT in patients hospitalized for worsening HF (WHF).
Methods: Romanian National Observational Study of In-Hospital Heart Failure (SONIC-RO) enrolled 1222 consecutive patients, over one month period, admitted with a primary diagnosis of WHF, from 41 hospitals (9 academic and 32 community), representative for the Romanian cardiological network. The rate of prescription and the doses of EBHFT (beta blockers (BB), ACE inhibitors/sartans and aldosterone antagonists (AA)) were collected at admission and discharge. A multivariate logistic regression model was developed to identify baseline clinical variables predictive for the utilisation of EBHFT.
Results: The proportions of BB, ACEI/sartans and AA prescription on admission were 63%, 51%, and 43%, respectively; only 18% were prescribed all 3 medications. At discharge proportions were 74%, 57%, and 54%, respectively, and only 26% of patients had been prescribed all three classes. We identified the following variables that influence the rate of prescription for these medications – for BB use: age (HR = 1.21, 95% CI 1.14-1.33), admission in a community hospital rather than an academic one (HR = 1.24, 95% CI 1.09-1.30), the presence of chronic obstructive pulmonary disease (HR = 1.32, 95% CI 1.14-1.53), and NYHA IV functional class (HR = 1.94, 95% CI 1.75-2.31); for ACEI/sartans use: age (HR = 1.02, 95% CI 1.01-1.05), NYHA IV functional class (HR = 1.22, 95% CI 1.10-1.31), chronic kidney disease (HR = 1.65, 95% CI 1.41-1.82), and systolic blood pressure < 100mmHg (HR = 2.21, 95% CI 1.94-2.53); and for AA use: chronic kidney disease (HR = 1.35, 95% CI 1.21-1.56), and systolic blood pressure < 100mmHg (HR = 1.52, 95% CI 1.34-1.73) respectively.
Conclusion: In present study, patients with higher cardiovascular risk at admission are less likely to receive optimal EBHFT. Distinct to clinical severity, non-academic clinical setting seems to influence in-hospital utilization of EBHFT, which should be considered by future educational programs.

P2171

B-natriuretic peptide and its prognostic value in coronary patients with heart failure, irrespectively of renal function; the interaction with heart failure phenotype; hellenic heart failure study

M Kouvari[1]; C Christina Chrysohoou[2]; H Kosyfa[1]; G Kalogirou[1]; P Aggelopoulos[1]; I Kotsiopoulou-Xaritou[1]; G Georgiopoulos[1]; S Iosifidis[3]; A Filippou[3]; E Tsiamis[1]; D Tousoulis[1]
[1]University of Athens, First Cardiology Clinic, School of Medicine, Athens, Greece; *[2]University of Athens, Athens, Greece*; *[3]Harokopio University, Nutrition Science - Dietetics, Athens, Greece*

On behalf of: Hellenic Heart Failure study

Background/Introduction: Although important advances have been performed in the interpretation and understanding of the pathophysiology behind heart failure,

this chronic disease remains a challenge in the area of prognosis stratification. In this context, renal function and B-natriuretic peptide (BNP) remain predictors of much interest. Purpose: to evaluate the role of renal function, through glomerular filtration rate (GFR) and BNP on the 10y ACS mortality of coronary patients with heart failure.
Methods: from May 2006 to March 2009, 1,000 consecutive patients who were hospitalized at a Cardiologic Clinic in Athens with ACS diagnosis were enrolled in the study. In 2016, the 10y follow-up (2006-2016) was performed in 745 participants. GFR was evaluated through the MDRD formula. Heart failure phenotype was defined according to baseline ejection fraction (EF); heart failure with reduced EF (i.e. < 40%) (HFrEF), preserved EF (i.e ≥50%) (HFpEF) and mid range EF (i.e. 40-49%) (HFmrEF). Results: 10y ACS mortality was 21%. Patients who suffered from a new fatal episode within the decade had significantly lower GFR and higher BNP values at baseline, compared with their alive counterparts (all ps < 0.001). In multivariate logistic regression analysis, GFR remained an independent predictor for the incidence of ACS death within the decade, after adjusting for potential confounders (OR=0.98 95%CI (0.97, 1.00), p = 0.04). Additionally, since BNP levels were strongly associated with both the primary outcome and the GFR (p < 0.001 from Spearman's correlation test), BNP was forced included in the multivariable model as a covariate with possible mediating effect. After adjusting for baseline BNP, GFR lost its significance whilst BNP levels (expressed per 2 fold increase) independently predicted ACS mortality (OR=1.39 95%CI (1.15, 1.67), p = 0.001). What is more a significant interaction was observed between EF and BNP levels on the tested outcome (p for interaction < 0.001). In stratified analysis the aforementioned significant predictive value of BNP retained only in HFmrEF (OR=1.43 95%CI (1.01, 2.03), p = 0.04) and in HFpEF (OR=1.80 95%CI (1.15, 2.82), p = 0.01).
Conclusion: BNP values were highlighted as an important predictor in long term prognosis of coronary patients with heart failure, namely those with better performance of left ventricle for whom further investigation is highly demanded.

P2172

Red cell distribution width change during hospitalisation and 1-year mortality in chronic heart failure

P Lazarev[1]; E Kotova[1]; A Shavarov[1]; YU Karaulova[1]; G Kiyakbaev[1]; V Moiseev[1]
[1]*RUDN University, Moscow, Russian Federation*

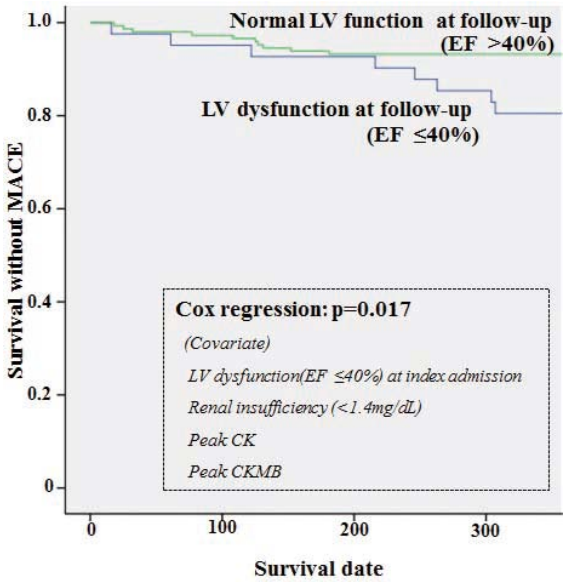
Background: Red cell distribution width (RDW) is considered to be one of the novel predictors of adverse events in chronic heart failure (CHF) patients. However, the role and significance of RDW change during hospital stay has not been completely identified.
Purpose: We aimed to evaluate the influence of in-hospital RDW change on 1-year mortality in CHF patients.
Methods: Our study included 351 consecutive hospitalised CHF patients [46% male, mean age 72 ± 11 years old, mean left ventricular ejection fraction (LVEF) 53 ± 14%, 24% anemic]. RDW measurements were obtained at least twice during hospitalisation: within 24 hours of admission and on discharge, respectively. The association between in-hospital RDW change and 1-year total mortality was tested with ROC-curve analysis and logistic regression, with further adjustment for possible confounders (routine clinical, laboratory and instrumental findings). If no cut-off value was established in the ROC-curve analysis, RDW change of > or < 1% was considered to be significant. Correlation was estimated with the use of Spearman's rank correlation coefficient (rho).
Results: On admission 118 (34%) patients had NYHA class II heart failure, 115 (50%) – class III and 58 (16%) – class IV disease. Association between in-hospital RDW change and 1-year total mortality was not found to be significant both in ROC-curve and linear trend analysis (p = 0.364). An increase in RDW was noted in 92 (26%) patients and conferred a higher risk of the negative outcome [odds ratio (OR) 2.07, 95% confidence interval (CI) 1.02-4.18, p = 0.046] compared to 185 (53%) patients with insignificant RDW change. This increased risk lost statistical significance after adjustment for other risk predictors (OR 3.56, 95% CI 0.80-5.97, p = 0.097), among which the measures of kidney function and echocardiographic parameters reflecting left and right ventricular function were the most potent. No correlation was found between changes in RDW and hemoglobin (rho=0.093, p = 0.206) or MCH (rho=-0.029, p = 0.692) values. However, weak positive association was present between changes in RDW and MCV readings during hospitalisation (rho=0.177, p = 0.015).
Conclusion: RDW increase during hospitalisation in CHF patients is a weak predictor of 1-year mortality in comparison to other risk factors.

P2173

Left ventricular dysfunction and cardiac outcomes one year after successful percutaneous coronary intervention in patients with acute ST elevation myocardial infarction

H-J Hwang[1]; C-B Park[1]; IS Sohn[1]; J-M Cho[1]; C-J Kim[1]
[1]*Kyunghee University East-West Neo Medical Center, Cardiology, Seoul, Korea Republic of*

Background: Preferred treatment for patients with ST-segment elevation acute myocardial infarction (STEMI) is primary percutaneous coronary intervention (PCI). However, some patients after successful PCI have suffered several attacks due to heart failure.
Purpose: We investigated predictors related to left ventricular (LV) dysfunction at follow-up echocardiography within one year and the association between LV dysfunction and one-year major adverse cardiac events (MACE) (composites of all cause of death, non-fatal myocardial infarction, and revascularization) in patients who underwent primary PCI successfully in diagnosis of STEMI.
Methods: A prospective cohort of 1736 consecutive patients who were successfully received primary PCI following a diagnosis of STEMI between January 2008 and March 2012, and underwent follow-up echocardiography from 30-days to one year was analyzed from Korea Working Group on Myocardial Infarction (KorMI) registry.
Results: Among 1736, 243 (14%) patients had LV dysfunction [LV ejection fraction (EF) ≤40%] at follow-up echocardiography. In multivariate analysis, independent predictors of LV dysfunction at follow-up were LV dysfunction at index admission, renal insufficiency (creatinine ≥ 1.4mg/dL), peak creatine kinase (CK), and peak CKMB. Independent predictors for the deterioration of LVEF at follow-up (absolute 5% decrease less than LVEF at index admission) were dyslipidemia, LVEF at index admission, peak CK, and peak troponin I, whereas independent predictors for the improvement of LVEF at follow-up (absolute 5% increase more than LVEF at index admission) were the male, no history of coronary artery disease, pre-TIMI flow, LVEF at index admission, peak CKMB, and peak troponin I. One-year major adverse cardiac events (MACEs) were significantly increased in patients with LV dysfunction at follow-up on Cox-regression analysis (Figure).
Conclusions: Persistent LV dysfunction after successful primary PCI was related with poor clinical outcomes at one-year clinical follow-up. We should evaluate post-infarction patients more meticulously for selection of the possibility of persistent LV dysfunction and to facilitate more appropriate treatment.



MACE by LV dysfunction

P2174

Heart failure with mid-range ejection fraction: clinical profile and mid-term outcome.

MA Miguel Antonio Lopez Garrido[1]; A De Vicente-Ortega[2]; AI Molina-Ramos[1]; V Garcia-Ruiz[1]; VM Becerra-Munoz[1]; A Ruiz-Salas[1]; L Morcillo-Hidalgo[1]; M Jimenez-Navarro[1]; JJ Gomez-Doblas[1]; E De Teresa-Galvan[1]; JM Garcia-Pinilla[1]
[1]*University Hospital Virgen de la Victoria , Department of Cardiology, Malaga, Spain*; [2]*Faculty of Medicine, University of Malaga, Malaga, Spain*

Background: The ESC Heart Failure (HF) Guidelines of 2016 introduce the term HF with mid-range ejection fraction (HFmrEF) as a separate group with characteristics between HF with reduced and preserved ejection fraction. This is a population that probably has primarily mild systolic dysfunction, but with features of diastolic dysfunction. We conducted this study in order to know the the clinical characteristics and mid –term outcome of this population.
Methods: We studied all the patients with HFmrEF at follow-up in the HF Unit of our Hospital in the years 2010-2014, recording their clinical characteristics,

comorbidities and adverse events during follow-up (mortality, functional class worsening, HF hospitalization, coronary acute syndrome and arrhythmias).
Results: Of the 114 patients (68 years, 24.6% women), 57 (50%) had ischemic etiology, 18 (15.8%) dilated cardiomyopathy and 17 (14.9%) valvular disease as etiology of the HF. 35 (30.7%) had previous hospitalization for HF and 17 (14.9%) had severe systolic dysfunction. In terms of cardiovascular risk factors, 81 (71.1%) had high blood pressure, 52 (45.6%) diabetes mellitus, 63 (55.3%) dyslipidemia, 25 (21.9%) had smoking habits, being the mean BMI 28.1 ± 4.8 kg/m2. Analyzing the comorbidities, 25 (21.9%) had atrial fibrillation, 29 (24.4%) chronic kidney disease, 25 (21.9%) anemia and 12 (10.2%) protein malnutrition, being the mean Charlson Index 5.7 ± 2,4. In the echocardiogram, 29 (25.4%) had dilated left ventricle, 34 (29.8%) left ventricular hypertrophy, 45 (39.%) dilated left atrium and 22 (19.3%) hemodynamically significant mitral regurgitation. 105 (92.1%) were treated with ACE inhibitors or ARBs, 95 (83.3%) with beta-blockers, 44 (38.6%) with MR antagonists and 74 (64.9%) with other diuretic treatment. The median follow-up was 39 months (IQR 29-52), presenting recovery of ejection fraction 23 patients (20.2%). In 3 years of follow-up, the global mortality was 15.7%. 23.4% of the patients presented decompensation of HF, 18.8% HF hospitalization, 14.5% acute coronary syndrome, 8.9% atrial fibrillation and 3.9% ventricular tachycardia or sudden cardiac death.
Conclusions: 1. The most frequent etiology in HFmrEF was ischemic heart disease. 2. There is a high prevalence of comorbidities in this population. 3. Echocardiogram showed both signs of systolic and diastolic dysfunction. 4. In our series this group had a high percentage of adverse events in the follow-up.

P2175
Precipitants of ADHF in era of disease management programs

F Faizan Rathore[1]; K Mcdonald[1]; R O'hanlon[1]; P Campbell[1]; C Keane[1]; F Ryan[1]; M Walsh[1]
[1]*St Vincent's University Hospital, Department of Cardiology, Dublin, Ireland*

Background/Introduction: Disease Management Programs (DMP) have been shown to improve prognosis in heart failure with significant reduction in hospitalizations. Insight into how to further improve this intervention will be helped by understanding the precipitants of admission in patients enrolled on these programs. To date,analysis of precipitants have been confined to general population. The aim of the study was to identify the precipitants of hospitalization in patients enrolled on a DMP. As a comparison we look at patients presenting for first time as Denovo diagnosis, who have not yet been enrolled on a DMP.
Methods: In an ongoing study we are prospectively enrolling patients admitted with ADHF to our unit. Patients are classified as being enrolled on a DMP or Denovo Heart Failure determined by history. Possible precipitants of decompensation are defined as follows; Infection, Arrhythmia (documented on ECG & clinically felt to be contributing),Ischemia(presence of suggestive symptoms & significant new ECG changes , with or without typical pattern of troponin release), Medication Alteration (reduction in diuretics) ,Medication Adherence (assessed using Morisky 8 point,MMAS8 scale, defining Low Adherence as score < 6) & Unknown. Adherence to immunisation advice (defined as receipt of influenza vaccine in the preceding year & receipt of pneumococcal vaccine at all in the past) was also analyzed.
Results: To date we have enrolled 46 patients (65.2% males, mean age 75.3 years, 54.35% Denovo HF). Infection was noted to be the major precipitant in both groups (Denovo 40%,DMP 28.6%).In Denovo category higher prevalence of Arrhythmia (Denovo 32% DMP 4.8%) & Ischemia (Denovo 16% DMP 9.5%) was noted.In DMP category higher prevalence of Medication Alteration (Denovo 4%, DMP 23.8%) was noted.Failure to identify a precipitant was noted in 4% Denovo & 33.3% DMP population. MMAS8 scoring classified 9.5% of the DMP group as Low Adherence.Adherence to immunisations was marginal for Influenza vaccine (Denovo 52%, DMP 71.4%) & low for Pneumococcal vaccine. (Denovo 16%, DMP 19%).
Conclusions:
Results: so far demonstrate that Infection, predominantly Respiratory, was the major precipitant of hospitalization in both groups, followed by Arrhythmia and Ischemia in Denovo & Medication alteration in the DMP group.It is encouraging to see medication adherence is not a major issue in the DMP group, reflecting good insight to HF self care, however continued under utilizations of vaccines need to be addressed through improved education and reinforcement.

P2176
Sleep disordered breathing (SDB) in heart failure with preserved ejection fraction (HFpEF) the tip of the iceberg

MA Barandiaran Aizpurua[1]; VPM Van Empel[2]; BLM Schroen[3]; M Van Bilsen[1]
[1]*Cardiovascular Research Institute Maastricht (CARIM), Cardiology, Maastricht, Netherlands*; [2]*Maastricht University Medical Centre (MUMC), Cardiology , Maastricht, Netherlands*; [3]*Maastricht University, Cardiology , Maastricht, Netherlands*

Background: The prevalence of sleep disordered (SDB) in heart failure is high and is related to a poor prognosis, higher prevalence of hypertension, arrhythmias, specially atrial fibrillation, coronary artery disease and worse diastolic left ventricular function. However, there is very little known about the prevalence and effects of SDB in heart failure with preserved ejection fraction (HFpEF).
Purpose: This study aims to investigate the prevalence of SDB in the HFpEF population and the influence on the objective exercise tolerance.
Methods: From January 2015 to December 2016, 115 patients were included in the HFpEF cohort of our dedicated HFPEF out-patient clinic. SDB was screened using an ApneaLink tool. 9 patients were already diagnosed with SDB. 40 patient underwent a ApneuLink test without polisomnography (PSG), 46 patients got both, ApneuLink test and PSG and 11 patients got directly a PSG. We classified the severity of the SDB using the Apneu - Hypopneu Index (AHI): No SDB if AHI < 5 per hour, mild SDB if AHI ≥ 5, but < 15 per hour, moderate SDB if AHI ≥ 15, but < 30 per hou and severe SDB if AHI ≥ 30 per hour. We preferively used the AHI results of the PSG, but if it was not conducted we used the results of the ApneaLink test. We compared the basaline characteristics of a total of 94 patients: 53 without or with a mild SDB versus 41 patients with a moderate or severe SDB. We measured the objective exercise tolerance using the six minute walking test (6MWT).
Results: We observe that SDB patients are more frequently men (46,3% vs 20,8% p = 0,008) and have a higher body mass index (BMI) (31 vs. 28,6 p = 0,01). There are not any significant differences in the rest of co-morbidities, echocardiographic characteristics of exercise capacity.
This is the first study using ApneaLink Plus in a HFpEF population to determine the prevalence of SDB. We measured a high prevalence SDB (65,2%) in a general outpatient HFpEF population in a Dutch academic hospital. Also, this is one of the few studies investigating the influence of moderate to SDB on objective exercise tolerance in HFpEF patients. SDB is highly prevalent in a HFpEF population, but so far SDB does not seem to affect objective exercise tolerance.

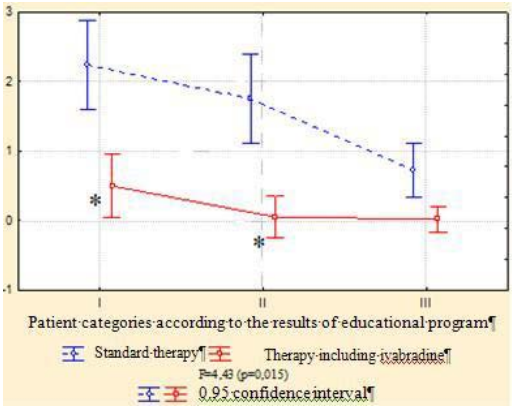
Baseline characteristics

	Totaal (n = 115)	no/mild SDB (n = 53)	moderate/ severe SDB (n = 41)	p-value
Age (years/mean)	76,1 (±6,5)	75,7 (± 7,5)	77,3 (±5,1)	0,38
Sex (% female)	78 (67,8%)	42 (±79,2%)	22 (±53,7%)	0,008
Body mass index (BMI) (kg/m^2) (mean ±SD)	30,02 (±5,3)	28,6 (±5,3)	31 (±4,07)	0,01
6MWT percentage walked (%) (median-IQR)	63,2 (44,7-75,5)	64 (54-78)	58 (45-73)	0,59

P2177
Management of patients with chronic heart failure and mid-range left ventricular ejection fraction

A K Alena Kurlianskaya[1]; T L Denicevich[1]
[1]*Research & Practical Centre "Cardiology", Minsk, Belarus*

Aim: To evaluate the effect of drug therapy including ivabradine and structured education on rates of hospitalization due to chronic heart failure (CHF) in patients with mid-range left ventricular ejection fraction (LVEF).
Methods: The study population of 93 patients with CHF I-IV NYHA and LVEF 40-49% was divided into group 1 – standard drug therapy (19 patients) and group 2 – drug therapy including ivabradine (74 patients). The intervention also included structured education of the patients. Learning capability (LC) was rated on a 4-point scale (1=poor to 4=excellent). LC and need for hospitalization due to CHF (expressed per 10 people) were investigated over 12 months.
Results: The cluster analysis specified 3 categories of patients with different LC: Category I – LC lower than 3 points at the hospital and outpatient stages of education (13 patients), Category II – LC 3-4 points after structured education (22 patients), Category III – LC 3-4 points at the hospital stage with a long learning capability of knowledge (58 patients). The average number of rehospitalizations due to CHF was lower in group 2 than in group 1 (0.8 and 9.0, respectively, P=0.028). Drug therapy including ivabradine reduced the number of readmissions of patients in Category I (Figure). The lowest need for rehospitalization was seen in Category III patients in groups 1 and 2, as well as in Category II patients in group 2: 0.7, 0.2, and 0.3 rehospitalizations due to CHF per 10 people, respectively.
Conclusions: The dynamic education of CHF patients in combination with drug therapy including ivabradine has a positive influence on the course of the disease, as evidenced by a significant decrease in the number of hospital readmissions due to CHF within 12 months.



Dependence of hospital readmission

Initial experience from a novel service for the initiation and uptitration of sacubitril/valsartan

R Richard Crawley[1]; K Guha[1]; P R Kalra[1]; G Morton[1]
[1]*Portsmouth Hospitals NHS Trust, Cardiology, Portsmouth, United Kingdom*

Background: The current ESC guidelines recommend that sacubitril/valsartan (SV) is considered for patients with ongoing symptomatic heart failure (HF), and an ejection fraction persistently ≤ 35% despite first line medical therapy. In England & Wales, SV was recently approved for use by the National Institute for Health and Clinical Excellence (NICE) after a health technology appraisal (TA388).
Purpose: We developed a novel trainee-led service to deliver SV therapy in the setting of limited resources and large numbers of potentially eligible patients.
Methods: Suitable candidates were identified by heart failure consultant cardiologists. Subsequent SV optimisation clinics were delivered by a cardiology registrar under remote supervision. Patients were optimised as per recommendations every 2-4 weeks. At every clinic visit symptomatic status, physical examination, biochemistry and clinical progress were documented. Once patients had been established on the optimal tolerated dose, their SV prescribing care was transferred to their primary care physician. The data reflect an evaluation of the service to date.
Results: 86 patients (mean age 63.1 ± 11.1 years) were initiated on SV. Mean LVEF 27.8 ± 6.5%; mean baseline eGFR 66 ± 22 ml/min/1.73m^2. Prior to initiation of SV, mean baseline ACEi/ARB dose was equivalent to 16.7 ± 6.5 mg enalapril daily. Overall 85/86 (98.8%) prescriptions of SV were compliant with ESC and NICE guidelines. 11 patients (12.8%) stopped the medication due to adverse effects (PARADIGM-HF 17.8%), whilst another 5 patients (5.8%) were down titrated to a tolerable lower dose. 15.1% of all patients experienced symptomatic hypotension (PARADIGM-HF 14.0%). No episodes of angioedema, nor significant deterioration in renal function (≥50% reduction in eGFR) were observed. Only 2 (2.3%) patients were hospitalised with decompensated heart failure symptoms, whilst 4 (4.6%) patients were admitted with syncope resulting from orthostatic hypotension.
A total of 46 patients were discharged to primary care, with a median follow up time of 42 days (IQR 25) from commencement to stable discharge dose – each requiring 1 initiation consultation and a mean of 2.3 ± 1.1 follow-up consultations. The majority of patients (33; 71.7%) were discharged at the highest dose - 97/103 mg BD. 32 (69.6%) of those discharged reported a subjective improvement in symptoms and quality of life.
Conclusions: The data support the creation of a novel trainee-led (with consultant supervision) clinical service to deliver this new added component of HF services. Cautious real-world application of the guidelines leads to many patients being safely established on high doses of SV with similar tolerability to that seen in PARADIGM-HF. However, the lower mean age within this particular population, who were carefully selected, may indicate that such findings are not representative of the entire heart failure population.

P2179

Does allopurinol have any benefit in heart failure patients without hyperuricemia?

M M Ansari-Ramandi[1]; M Maleki[1]; N Naderi[1]; A Alizadehasl[1]; A Amin[1]; S Taghavi[1]; MJ Alemzadeh-Ansari[1]; N Hadavand[1]; M Noori[1]
[1]*Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, Iran (Islamic Republic of)*

Funding Acknowledgements: The study was supported financially by the Research Deputy of Rajaie Cardiovascular Medical and Research Center.

Introduction: Heart failure (HF) is a devastating syndrome leading to hemodynamic abnormality and neuroendocrine activation which affects multiple organs. It has been shown that allopurinol, a xanthine oxidase inhibitor, may improve vascular endothelial and myocardial dysfunction. However, data are still lacking regarding the precise effects of allopurinol on HF patients without hyperuricemia.
Purpose: In this study we sought to assess whether allopurinol could improve biochemical and functional parameters of HF patients without hyperuricemia.
Methods: Thirty five patients with a diagnosis of chronic heart failure were consecutively enrolled according to the following inclusion criteria; Severe left ventricular systolic dysfunction (Ejection Fraction ≤35%), New York heart association functional class I-III, absence of hyperuricemia (above 6mg/dl for women and 6.8mg/dl for men) and presence of guideline directed medical therapies for at least 3 preceding months. Moreover, patients were kept on the same medical regimen during the study period. Patients were excluded if they had; Glomerular filtration rate of less than 60ml/min; severe hepatic failure; use of azathioprine or warfarin; known sensitivity to allopurinol. Allopurinol was administered with a dose of 300mg per day for a week and then was up titrated to 600mg per day and continued for 3 months. Study participants were asked to contact the research team whenever they had any adverse effects.
Results: Finally in this study 30 HF patients with a mean age of 49.37 ± 14.44 years old were evaluated (46.7% male and 53.3% female). No adverse effects were reported except for one case of skin rash after 4 days treatment which was excluded from the study. Four patients were also excluded from the study due to need for drug dose changes. Patients showed significant improvement in six minute walk test, average global longitudinal peak strain and laboratory parameters which are summarized in the table.
Conclusions: It can be concluded that allopurinol could be of great benefit in patients with severe LV systolic dysfunction not having hyperuricemia without significant adverse effects. Randomized clinical trials are needed in future to confirm the results.

Data at baseline and after treatment

Index	Value at baseline	Value after treatment	P value
Uric acid, mg/dl, mean (SD)	5.91 (1.34)	3.15 (0.91)	< 0.001
High sensitivity C reactive protein , mg/l, median (IQR)	4.85 (4.7-5.2)	5.05 (4.1-5.4)	0.71
N-terminal pro b-type natriuretic peptide, pg/mL, median (IQR)	979.33 (522.75-1000)	810.30 (405-895.75)	< 0.001
Average global longitudinal peak strain , %, mean (SD)	-9.38 (3.29)	-10.96 (4.4)	< 0.001
Six minute walk test, meters, mean (SD)	384.5 (81.52)	402.8 (89.61)	< 0.001

SD: Standard deviation, IQR: Interquartile range

Patient reported outcomes, health service utilisation and place of care/death for advanced heart failure patients attending a palliative cardiology clinic or receiving usual care: a feasibility study

MJ Miriam Jane Johnson[1]; P Mcskimming[2]; C Geue[2]; Y Millerick[3]; K Hogg[2]
[1]*University of Hull, Hull, United Kingdom*; [2]*University of Glasgow, Glasgow, United Kingdom*; [3]*Glasgow Caledonian University, Glasgow, United Kingdom*

Funding Acknowledgements: British Heart Foundation

Background: Trials show benefit for advanced heart failure (HF) patients receiving specialist palliative care, but is unknown if cardiology-led models of palliative care are cost-effective.
Purpose: To assess the feasibility of conducting a randomized controlled trial (RCT) testing cost-effectiveness of a palliative cardiology clinic.
Methods: A feasibility study with baseline and 4 month measures from two unmatched patient groups from: G1) cardiology-run palliative assessment and management service, G2) HF liaison service. At enrolment, G1 recruits had been seen at least once in the service.
Eligible patients had HF (LVSD/non-LVSD) and persistent symptoms. Study measures included: symptoms (Edmonton Symptom Assessment Score [ESAS]), HRQoL (KCCQ12; EQ-5D-5L), performance, understanding of disease, anticipatory care planning (ACP), health service costs and survival. Feasibility outcomes; recruitment, retention, data quality, variability/sample size estimation.
Results: 77 (G1=43; G2=34) enrolled over 8 months (53% men; mean age 77 [33 to 100]). Average G1 clinic prior attendance was 8 months. At baseline: fewer in G1

had LVSD (50% vs 97%) than G2; G1 had worse ESAS (43.5 vs 35.2) & KCCQ (35.4 vs 39.9) scores; fewer admissions/past 6 months (32.6% vs 47.1%); G1 understood their care better ($p = 0.003$); more had ACP ($p < 0.001$). All were on optimal cardiac treatment. G2 had a higher screen/consent ratio (1: 2.8 vs 1:1.7) and more 4 month attrition than G1 (29% vs 25%). Data quality was good. Estimated sample size for a future trial: 141 to detect a 1 point clinically important change in ESAS shortness of breath (80% power, 0.05 alpha).
At 4 months ESAS and KCCQ improved in G1 and G2 (change from baseline) but by more in G2, reaching statistical significance for ESAS scores, (G1: -1.5 (14.8) vs G2: -5.6 (16.6), $p = 0.046$), although between group differences were not statistically significant in a repeated measures model.
Documentation of ACP and understanding of care remained better in G1 ($p < 0.001$). There was no difference in survival between the two groups. G1 average NHS costs were lower (£785 cost saving/patient) with fewer nights in hospital, fewer nurse contacts, lower drug costs, but more GP and out-patient contacts and an average decrease in QALYs of 0.012388 (0.01235). Cost savings are likely to be underestimated given the duration of G1 clinic attendance at baseline, reflected in baseline differences in admission. The uncertainty around the findings is too great to draw definitive conclusions and must be seen as exploratory.
Conclusions: This exploratory study shows that a trial in advanced HF patients, to test the cost-effectiveness of a cardiology-driven palliative care assessment and management service using patient-report data as a primary outcome is feasible in terms of recruitment and data quality. An adequately powered trial is warranted.

P2181
Reducing hospital readmissions in heart failure patients: preliminary data from Azienda USL Toscana Centro heart failure pathway

F Grossi[1]; F Zerauschek[1]; L Zampini[1]; A Fornaro[1]; A Giomi[1]; P Francesconi[2]; F Orso[3]; M Milli[1]
[1]*Hospital of Santa Maria Nuova, Cardiology and Electrophysiology Unit, Florence, Italy*; [2]*Regional Health Agency, Florence, Italy*; [3]*Careggi University Hospital, Florence, Italy*

Background: Hospital readmission of patients suffering from heart failure (HF) is a well known problem and it requests new organizational challenges. Such patients are often elderly, with many comorbidities, poor compliance to optimal medical therapy (OMT), social issues. Data from our Regional Health Agency registry (Tuscany – Italy) shows that the percentage of HF patients that are taking OMT is still around 50%. Only 16.1% of patients receive a follow-up evaluation within 30 days after hospital discharge. Mortality from all causes at one year after discharge is to date of 12.1%.
Objectives: With the aim of reducing hospital readmissions we have identified three targets to propose improvement actions.
- Out-of-hospital setting: FAST-TRACK path (cardiology consultancy delivered within 24/72 hours).
- Hospital setting (Emergency Department): stratification of medium-high risk vs low risk HF patients according to a checklist; direct discharge for low risk patients, hospital admission in the appropriate clinical setting only for medium-high risk patients.
- Discharge and follow-up: creation of a web-based score (TAV Centro HF SCORE) to identify patients at high risk for readmission (score>15) that will receive personalized home care. We tested this program in a pilot group of Cardiology and Internal Medicine Units of our Department.
Results: Preliminary data (May-December 2016) showed: 137 consecutive patients discharged with a primary diagnosis of HF, mean age 80.95 ± 11.01 years, weight at admission 72.43 ± 14.13 kg, weight at discharge 69.02 ± 12.53 kg, NT-proBNP at admission 5343.90 ± 6237.42 pg / mL, average TAV Centro HF SCORE at discharge 9.57 ± 2.95. Only 2% of patients were identified at high risk for hospital readmission. Mean lenght of hospital-stay was 8.96 ± 7.30 days. The percentage of hospital readmission in the observation period amounted to 21.4%.
Conclusions: Preliminary results show that the improvement actions taken to reduce hospital readmissions are effective when compared to data found in literature (50% of readmissions at 12 months in EuroHeart Survey II and 30% readmissions at 12 months in IN-HF registry ANMCO). A greater sample size and the involvement of all the Cardiology and Internal Medicine Units of our Department will allow a more meaningful analysis of the clinical and managing impact of such an innovative organizational project.

P2182
Factors of improvement of physical ability after exercice training program in heart failure patients with reduced ejection fraction

E George[1]; J Costa[1]; HT Bui[1]; L Simone[1]; P Nazeyrollas[1]; D Metz[1]
[1]*Robert Debré Hospital, Reims, France*

Background: Exercice training is a fundamental part of heart failure with reduced ejection fraction (HF-REF) treatment. It reduces mortality and hospitalizations and improves functional capacities. The aim of this study was to find predictive factors of improvement of physical ability in HF-REF patients after completion of an exercise training program.
Methods: Functional, clinical, biological and echocardiographic data, were retrospectively analyzed in 50 HF-REF patients who underwent an exercice testing.
Results: Patients were 53.3 +/-12.1 years old with a mean ejection fraction of 34 +/-10% and an average of 18.7 sessions over a 4 month period was performed. Mean pre and post training MET were retrospectively 4.9 +/-1.6 and 6.1 +/-2.3 ($p < 0.001$). At the end of the training period, 22 patients displayed an improved exercise testing. Exercise testing improvement was associated with the absence of arterial hypertension (57% vs 23% $p = 0.04$), and a tendency was seen with lower furosemide daily intake (25.7mg vs 84.3mg $p = 0.05$), and lower Heart Failure Risk of Death at 1-year score (7.02% vs 10.22%). Pre-training exercice capacity was not associated with post-training improvement (4.6 +/-1.5 MET vs 5.2 +/-1.8 MET $p = 0.17$).
Conclusions: HF-REF patients without previous arterial hypertension had more chance to improve physical capacities after exercise training program. A lower furosemide daily dosage, and a lower Heart Failure Risk of Death at one-year score tend to be associated with improvement of physical abilities, so the sooner the better.

P2183
Heart failure virtual consultation - a mixed methods evaluation

J Gallagher[1]; S James[1]; C Keane[1]; A Fitzgerald[1]; B Travers[1]; E Quigley[1]; C Hecht[1]; S Zhou[1]; C Watson[1]; M Ledwidge[1]; K Mcdonald[1]
[1]*University College Dublin, Dublin, Ireland*

Background: A number of studies have identified difficulties in accessing specialist expertise and diagnostics for patiens with heart failure in the community. Modern technologies may help overcome these barriers.
Purpose: We undertook a mixed methods evaluation of a web based conferencing service (heart failure virtual consult -HFVC) between general practitioners and cardiologists in managing patients with heart failure in the community to determine its effect on use of specialist heart failure services and acceptability to general practitioners.
Methods: All cases from June 2015 to October 2016 were recorded using a standardized recording template which recorded patient demographics, medical history, medications and outcome of the virtual consult for each case. Quantitative surveys and qualitative interviewing of 17 participating GPs were also undertaken.
Results: During this time 142 cases were discussed – 68 relating to a new diagnosis of heart failure, 53 relating to emerging deterioration in a known heart failure patient and 21 relating to therapeutic issues. Only 17% required review in outpatient department following the virtual consultation. GPs reported increased confidence in heart failure management, a broadening of their knowledge base and a perception of overall better patient outcomes
Conclusion: These data from an initial experience with HFVC present a very positive impact of this strategy on the provision of heart failure care in the community and acceptability to users. Further research on the implementation and expansion of this strategy is warranted.

P2184
Rationale and design of PREFER: a prospective evaluation of natriuretic peptide based referral of chronic heart failure patients in primary care

FDR Hobbs[1]; C Vitale[2]; H Bueno[3]; B Lequeux[4]; M Pauschinger[5]; Y Pinto[6]; RI Rizwan Iqbal Hussain[7]; F Gustafsson[8]
[1]*University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom*; [2]*Dermopatic Institute of the Immacolata (IRCCS), San Raffaele Pisana, Rome, Italy*; [3]*University Hospital 12 de Octubre, Department of Cardiology, Madrid, Spain*; [4]*Centre Hospitalier Universitaire, Service de Cardiologie, Poitiers, France*; [5]*Paracelsus Medical University, Department of Cardiology, Nuremberg, Germany*; [6]*Academic Medical Center of Amsterdam, Departments of Cardiology and Experimental Cardiology, Amsterdam, Netherlands*; [7]*Novartis Pharma AG, Basel, Switzerland*; [8]*Rigshospitalet - Copenhagen University Hospital, Department of Cardiology, Copenhagen, Denmark*

Background: Heart failure (HF) is a chronic syndrome that affects 1–2% of the population with a high mortality rate and major impact on quality of life (QoL), despite available effective treatments. In many European countries, the daily management of stable HF patients is primarily the responsibility of primary care physicians (PCPs) in collaboration with specialist consultants; however, despite well-defined guidelines for the treatment of HF, adherence to recommendations is often below par leading to sub-optimal management of patients. For this reason, strategies to improve adherence to evidence-based therapies are needed. Here, we report the rationale and design of PREFER, an international, low-interventional study in patients with

chronic HF with reduced ejection fraction (HFrEF) managed in the primary care setting across Europe.
Purpose: The primary objective of PREFER is to assess whether biomarker-guided (≥600 pg/mL N-terminal pro B-type natriuretic peptide [NT-proBNP]) referral of clinically stable HFrEF patients from PCP to a cardiologist improves treatment, as defined by increased adherence to ESC HF management guidelines. Secondary objectives include the assessment of baseline characteristics (demographic, clinical and treatment, NT-proBNP levels, and health-related QoL) of HFrEF patients managed by PCPs across Europe; the impact of patient baseline characteristics on prescribed treatment; the effect of treatment optimisation on NT-proBNP levels; and the proportion of HFrEF patients considered to be clinically stable, defined as requiring no change in HF treatment for ≥3 months prior to baseline visit.
Methods: PREFER will enrol consecutive HFrEF patients ≥18 years with left ventricular ejection fraction ≤40% attended in the PCP setting. Main exclusion criteria are primary management by a cardiologist; co-morbidities including severe renal insufficiency (estimated glomerular filtration rate [eGFR] < 25 mL/min/1.73 m^2 since severely decreased eGFR is known to increase NT-proBNP, thus avoiding this specific confounder), cerebral trauma or cancer; and major surgery, cerebrovascular incident or acute exacerbation of chronic obstructive pulmonary disease within the previous three months. The study comprises three visits over a maximum period of 10 months with patient and disease characteristics and NT-proBNP concentrations documented at Visit 1. Patients assessed as clinically stable by the PCP with NT-proBNP ≥600 pg/mL will be referred to a cardiologist. Treatment changes, health status, and vital signs will be recorded over subsequent visits; QoL will be assessed by means of EuroQol EQ-5D and Kansas City Cardiomyopathy Questionnaire (KCCQ) and NT-proBNP will also be assessed at Visit 3.
Conclusion: To conclude, we report the rationale and design of the PREFER study. Recruitment will begin in June 2016. It is expected that the study will recruit approximately 4,000 patients from a total of ˜20 European countries.

P2185

Reliability of peripheral arterial tonometry for assessment of endothelial function in patients with heart failure with preserved and reduced ejection fraction, diabetic nephropathy and arterial hyper

F Weisrock[1]; M Fritschka[2]; S Beckmann[1]; S Litmeier[1]; J Wagner[1]; D Djawid Hashemi[1]; E Tahirovic[1]; S Radenovic[1]; C Zelenak[1]; A Busjahn[3]; T Krahn[4]; B Pieske[1]; W Dinh[4]; HD Duengen[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Department of Internal Medicine and Cardiology, Berlin, Germany; *[2]German Heart Institute of Berlin, Department of Cardiology, Berlin, Germany*; *[3]Health Twist, Berlin, Germany*; *[4]BAYER Pharma AG, Wuppertal, Germany*

Aims: Endothelial dysfunction plays a major role in cardiovascular (CV) diseases and pulse amplitude tonometry (PAT) offers a non-invasive way to assess endothelial dysfunction. However, data about the reliability of PAT in CV patient populations are scarce. Thus, we evaluated the test-retest reliability of PAT using the natural logarithmic transformed reactive hyperaemia index (LnRHI).
Methods and Results: Our cohort (figure 1) consisted of 92 patients (mean age: 65 ± 9.7 years, 32 % female), who were divided into four groups: those with heart failure with preserved ejection fraction (HFpEF) (n = 25), heart failure with reduced ejection (HFrEF) (n = 24), diabetic nephropathy (n = 20), and arterial hypertension (n = 23). All subjects underwent two separate PAT measurements at a median interval of 7 days (range 4-14 days). LnRHI derived by PAT showed good reliability in subjects with diabetic nephropathy (intra-class correlation (ICC) = 0.864) and satisfactory reliability in patients with both HFpEF (ICC = 0.557) and HFrEF (ICC = 0.596). However, in subjects with arterial hypertension, reliability was poor (ICC = 0.125) (figure 4).
Conclusion: We demonstrated that PAT is a reliable technique to assess endothelial dysfunction in adults with HFpEF, HFrEF or diabetic nephropathy. In subjects with arterial hypertension, we did not find high reliability, possibly related to the greater daytime and heart rate variances in this group of patients.

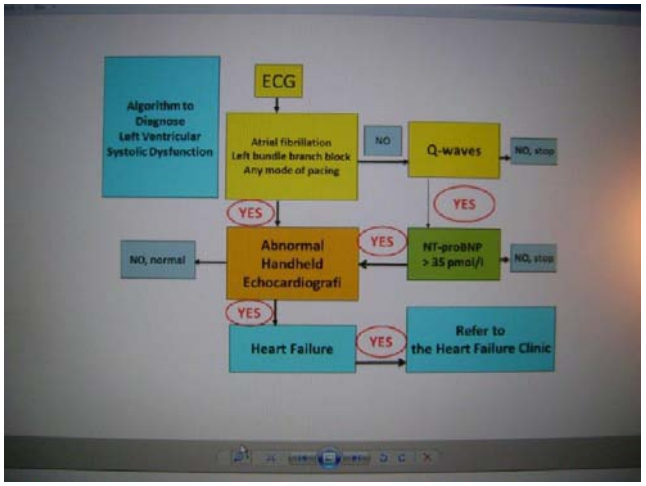
P2186

An algorithm to screen for left ventricular systolic dysfunction in the elderly, based on specific ECG-changes, NT-proBNP and handheld echocardiography

LL Olesen[1]
[1]Zealand University Hospital, Cardiology, Roskilde, Denmark

Funding Acknowledgements: The Region Zealand Research Fundation of Cross-Sectional Health Projects

Background and Introduction: Elderly 75+ are under-represented in the Danish National Heart Failure Registry, which suggests under-diagnosing and under-treatment of Left Ventricular Systolic Dysfunction (LVSD) in the elderly, especially elderly women.
LVSD may be asymptomatic or with non-specific symptoms.The clinical diagnosis is not reliable, especially in the elderly with comorbidities, and there should be looked for effective ways to screen for LVSD in the vicinity of the elderly.
Purpose: To develop a reliable objective method to screen for LVSD in the high-risk and growing geriatric population, in cooperation between the primary and the secondary health care system, to improve diagnosis and treatment of LVSD.
To extract an algorithm to screen for LVSD from previously published studies about this topic.
Methods and Results: A study performed to find a way to screen for LVSD, included 260 elderly (80 years of age (75-92)) from the community and from the local heart failure clinic. In everyone a handheld (HE) and a standard echocardiography (SE) were performed. Even though HE has limited options, HE was comparable to SE (gold standard) in diagnosing LVSD.
Sixty had LVSD and 200 did not have LVSD, and in a case-control study, LVSD was correlated with specific ECG-changes with sensitivity > 90 % and specificity > 80 %. These ECG-changes, atrial fibrillation (AFIB), left bundle branch block (LBBB) and any mode of pacing, were all associated with elevated NT-proBNP. In addition, LVSD was correlated with Q-waves combined with elevated NT-proBNP.
On this background, was evolved the illustrated algorithm to screen for LVSD.
Conclusions: LVSD seems to be under-diagnosed and under-treated in the elderly 75+, with serious consequences not only for the patients, but also for society and the health care systems.
Screening for LVSD in the growing geriatric population should have high priority, because correct diagnosis is the cornerstone of effective treatment, which can reduce symptoms, morbidity and mortality and the overall societal burden of this serious disorder.
The present study suggests a new LVSD-screening-algorithm.
This algorithm recommends that, when LVSD is under suspicion, due to AFIB, LBBB or pacing, or Q-waves combined with elevated NT-proBNP, a handheld echocardiography should be performed. In case of LVSD, the local heart failure clini c should treat the patient and find the cause of LVSD, including a standard echocardiography.
Further studies are needed to validate this algorithm.



Algorithm to screen for LVSD

P2187

Association of serum ADAM-10 with cognitive function in patients with stable chronic heart failure

S M Sonja Maria Wedegaertner[1]; S Selejan[1]; J Karbach[2]; M Boehm[1]; I Kindermann[1]
[1]Saarland University Hospital, Department of Internal Medicine III, Cardiology, Angiology and Intensive Care Medicine, Homburg, Germany; *[2]JW Goethe University, Department of Psychology, Frankfurt am Main, Germany*

Background/Purpose: Patients with stable heart failure show cognitive impairments associated with adverse events like higher mortality rates, worse quality of life, poorer drug adherence, and increased hospitalization rates. Possible pathophysiological causes are cerebral hypo-perfusion and multiple cardiogenic emboli, however the underlying mechanisms are still not fully understood. ADAM-10 (A Disintegrin and Metalloproteinase-10) prevents the generation of neurotoxic amyloid ß peptide and has been described to be reduced in patients with Alzheimer´s Disease. The purpose of the study is to investigate the relation of serum circulating ADAM-10

to the cognitive functioning in patients with chronic heart failure.
Methods: In a cross-sectional study (patients with stable chronic heart failure, n=13, mean age=66.77 years, SD=9.87, 15.4 % females, 54 % ischemic cardiomyopathy, left ventricular ejection fraction ≤ 45 %, NYHA classification II-III), serum levels of ADAM-10 were assessed by Western blot and densitometric analysis and compared to healthy age-matched controls (n = 13). Cognitive abilities (attention, processing speed, executive control, working memory, and intelligence) were assessed in heart failure patients using validated psychological instruments (Frankfurt Attention Inventory [FAIR], Digit Symbol Substitution Test, Stroop Test, Digit Span, Corsi Block Tapping Task, Matrix Reasoning [Wechsler Adult Intelligence Scale]).
Results: Serum ADAM-10 activity was decreased in patients with chronic heart failure as compared to healthy controls (-44 % decrease). Additionally, ADAM-10 protein levels showed a negative correlation (p = 0.03; r=-0.6) with cognitive abilities like attention as assessed by the FAIR in patients with chronic heart failure.
Conclusion: A reduction of ADAM-10 activity might promote neurotoxic processes in patients with chronic heart failure resulting in further cognitive deterioration in these patients.

P2188
Assessment of syndecan-4 expression in the hearts of mice and human subjects with chronic chagas cardiomyopathy

C Macedo[1]; TF Larocca[1]; BS Souza[1]; CM Azevedo[1]; JF Vasconcelos[1]; DC Portella[1]; F Tavora[2]; JD Lima[2]; RR Santos[1]; MBP Soares[1]
[1]Sao Rafael Hospital, Center for Biotechnology and Cell Therapy, Salvador, Brazil; *[2]Hospital de Messejana Dr Carlos Alberto Studart Gomes, Fortaleza, Brazil*

Background: The hallmark of chronic Chagas cardiomyopathy (CCC) is the presence of a multifocal inflammatory reaction, which leads to myocardial fibrosis, often followed by ventricular dysfunction and arrhythmias. The expression of syndecan-4, a transmembrane protein, is increased in the hearts of mice chronically infected with Trypanosoma cruzi, suggesting a role of this protein in the pathogenesis of CCC.
Purpose: Here we aimed to evaluate the pattern of expression of syndecan-4 in heart tissue of mice and subjects with Chagas cardiomyopathy and to correlate with the degree of inflammation and fibrosis.
Methods: First we evaluated the expression of syndecan-4 in the hearts of mice at different time points after infection. C57BL/6 mice (n = 5 per group) were infected by intraperitoneal route with Colombian strain T. cruzi and the heart tissue was evaluated and compared to uninfected controls. We also compared the expression of syndecan-4 in sixty samples of explanted human hearts of subjects with CCC, idiopathic dilated cardiomyopathy (idDCM) and ischemic cardiomyopathy (ICM). Samples were analyzed by confocal microscopy to determine the expression pattern of syndecan-4. Inflammation and fibrosis were evaluated by morphometric analysis.
Results: Syndecan-4 expression was increased after the acute infection and was sustained during the chronic phase, and did not correlate with the intensity of inflammation or fibrosis. Confocal microscopy analysis showed syndecan-4 expression mainly by vascular smooth muscle cells. Confocal microscopy analysis of fragments of explanted human hearts showed a similar pattern of syndecan-4 expression. No correlation between syndecan-4 expression and inflammation or fibrosis was found in the hearts from subjects with CCC. We also compared the expression of syndecan-4 of subjects with CCC, idiopathic dilated cardiomyopathy (idDCM) and ischemic cardiomyopathy (ICM). No differences in the number of syndecan-4 positive vessels/mm2 were found comparing the three subject groups (P=0.466), whereas a statistically significant difference in inflammation was seen (P=0.035). Additionally, no correlation between syndecan-4 and fibrosis or inflammatory cells was found.
Conclusion: We conclude that there is no evidence of correlation between either the degree of myocardial fibrosis or the number of inflammatory cells and syndecan-4 expression. Additional studies are required to determine its role in Chagas disease.

P2189
Analysis of mirna alterations in subjects with chronic chagas disease cardiomyopathy

C Carolina Macedo[1]; CK Nonaka[1]; TF Larocca[1]; BS Souza[1]; MN Rabelo[2]; LC Correia[2]; MI Moreira[2]; A Caldas[2]; JA Torreao[2]; RR Santos[1]; MBP Soares[1]
[1]Sao Rafael Hospital, Center for Biotechnology and Cell Therapy, Salvador, Brazil; *[2]Sao Rafael Hospital, Salvador, Brazil*

Funding Acknowledgements: CNPq

Background: Chagas disease is an anthropozoonosis caused by the flagellate protozoan Trypanosoma cruzi and is considered to be one of the major causes of death due to heart failure in Latin America. To date, there is no effective treatment for chronic Chagas disease. The biological role of microRNAs in the mammalian cardiovascular system has become a rapidly evolving field of research. Several studies in humans and animal models have shown that microRNAs are differentially expressed in heart failure and play a critical role in the pathogenesis of the disease.
Purpose: The objective was to evaluate the expression of different microRNAs in Chagas disease subjects and to investigate possible associations with clinical evaluation.
Methods: This study investigated the expression of 88 microRNAs in serum obtained from eight Chagas disease subjects, selected from a database of the outpatient clinics at Hospital (Brazil). As controls, four healthy subjects, with negative serology for Chagas disease, were selected. The Pick-&-Mix Custom microRNA qPCR Panels (Denmark) was used. MicroRNAs were selected based on the clinical profile of Chagas disease cardiopathy, characterized by inflammation and fibrosis. The 7500 Fast Real-Time PCR (ThermoFisher) was used under standard thermal cycling conditions. Data was analysed using threshold cycle (2-ΔΔCt) method and STATA statistical software.
Results: Of the analyzed microRNAs, 28 presented statistical significance ($p < 0.05$) in relation to healthy individuals. Of these, 22 miRNAs were down-regulated and 6 of them amplified only in the control group. We performed analysis of correlations between the miRNAs and clinical and imaging parameters, such as standard two-dimensional and strain by speckle tracking echocardiography, myocardial fibrosis by nuclear magnetic resonance, NT-ProBNP and galectin levels and Rassi score. Analysis miR-29b and miR-29c showed a negative association with longitudinal global strain only for miR-29c ($r = -0.7553$, $p < 0.05$). In the miR-30 family, miR-30d showed a tendency of a negative association with fibrosis ($r = -0.7115$, $p < 0.07$), whereas miR-30c had a negative association with longitudinal global strain ($r = -0.8308$, $p < 0.05$). We did not find any correlations between miRNAs the other clinical and imaging parameters.
Conclusion: Preliminary data suggest the correlation of miR-29c and miR-30c with longitudinal global strain measurement in Chagas disease. The investigation of the expression from these miRNAs in a larger group of chronic chagasic subjects, as well as in subjects with the indeterminate form is currently being performed in order to expand and validate the results.

Sex-related differences in the systolic function in the setting of acute coronary syndrome

N Semerdzieva[1]; S Denchev[2]; S Dimitrov[3]; M Gospodinova[2]; J Hristova[4]; A Kundurdziev[5]
[1]University Hospital Alexandrovska, Clinic of Cardiology, Sofia, Bulgaria; *[2]Medical Insitute of the Ministry of Internal Affairs, Clinic of Cradiology, Sofia, Bulgaria*; *[3]Second MHAT, Department of Invasive Cardiology, Sofia, Bulgaria*; *[4]Medical University of Sofia, Central Clinical Laboratory, Sofia, Bulgaria*; *[5]Medical University of Sofia, Faculty of Public Health, Sofia, Bulgaria*

Sex-related characteristics of acute coronary disease may contribute to the contrast in heart failure incidence between men and women. We examined the relation of severity of coronary atherosclerosis and inflammatory response to sex-related differences in the myocardial contractile function during acute coronary syndrome (ACS) and after six-month follow-up. Three hundred and twenty one patients (48% women) with ACS were included. They had their acute and chronic phase left ventricular ejection fractions (EF1; EF2), end-systolic and end-diastolic indexed to body surface area volumes (ESVI1; EDVI1; ESVI2; EDVI2) assessed with 2D-echocardiography. Echocardiography at the sixth month - available in 147 (45.8%). Other methods used: immunoturbidimetry - for high-sensitive C-reactive protein, hsCRP; coronary angiography with SYNTAX score calculation - performed in 282 (87.6%). Men had worse systolic function in the acute phase ($55.3 \pm 10.3\%$ vs $58.8 \pm 10.9\%$, $p = 0.001$ for EF1; 29.6 ± 14.9 ml vs 24.5 ± 11.7 ml, $p < 0.0001$ for ESVI1; 65.9 ± 19.1 ml vs 60.6 ± 14.7 ml, $p = 0.013$ for EDVI1) and at the sixth month (33.8 ± 18.8 ml vs 27.1 ± 13.3 ml, $p < 0.0001$ for ESVI2). Inflammatory markers correlated positively with all enzymes of myocardial necrosis. Higher SYNTAX scores of men had a closer association with the myocardial necrosis severity and the contractile function deterioration in acute and chronic phase compared to women. Higher WBC were significantly related to lower EF regardless of sex and increased hsCRP levels - to worse EF and ESVI at the time of ACS and during follow-up only among men (table 1). The severity of coronary atherosclerosis and of the acute inflammatory response contribute in lesser degree among female than among male patients to the systolic function decline after ACS.

Backgroud: Nitroglycerin (NTG) induces extremely slow coronary flow and angina in patients with microvessel dysfunction and normal coronary angiograms. The coronary slow flow syndrome (SCFS) is an angiographic finding characterized by delayed distal vessel opacification in the absence of significant epicardial coronary and myocardial disease.

Purpose: The object of our study was assessment of the response of coronary blood flow to intracoronary injection of NTG in patients with non-obstructive coronary atherosclerosis (including SCFS) with diastolic dysfunction.

Methods: The study included 143 patients: 66 - with SCFS and other 77 – with non-obstructive coronary disease, NCAD (coronary plaques causing < 50% stenoses). The following myocardial perfusion indices defined during selective coronary angiography, SCA (at baseline and after intracoronary administration of 100-200 μg of NTG) were employed: corrected TIMI frame count (cTFC) – assessed in 140 (97.9%) patients; propagation of contrast medium in coronary artery in systole (CPs – 63.6%, n=91) and propagation velocity of contrast in systole (Vcps – 62.9%, n=90). Diastolic dysfunction was defined based on Doppler echocardiographic evaluation of mitral flow and tissue Doppler imaging.

Results: Diastolic dysfunction of impaired relaxation type was found with nonsignificant difference between NCAD and SCFS patients (15.6 % (n = 12) versus 9.1% (n = 6), p = 0.061).

At baseline coronary flow in SCFS was impaired compared to other patients with NCAD (cTFC 37.7 ± 11.9 vs 28.2 ± 13.6 frames, p < 0.0001; a trend for CPs 18.4 ± 9.4 vs 22.6 ± 12.3, p = 0.077). Additional analysis demonstrated impairment of coronary flow after NTG (considerable for Vcps; a trend for CPs) only in the group with non-obstructive coronary disease (including SCFS) having diastolic dysfunction (table 1).

Conclusion: NTG reduces myocardial blood supply in non-obstructive coronary disease with diastolic dysfunction. It should not be given for angina relief to patients without proven on angiography significant coronary stenoses.

ATRIAL FIBRILLATION

P2192

The adequacy of antithrombotic therapy in patients with atrial fibrillation in Uzbekistan

NU Zakirov[1]; RD Kurbanov[1]; TZ Tohir Ganiyev[1]; DB Irisov[1]

[1]*Specialized Cardiology Center of the Republic of Uzbekistan, Cardiac arrhythmia, Tashkent, Uzbekistan*

Background: Epidemiological studies on atrial fibrillation (AF) and prevention of thromboembolism have not been conducted in Uzbekistan (Central Asia).

Objective: To assess the pre-hospital antithrombotic therapy (ATT) in patients with AF, according to the ESC recommendations.

Material and Methods: We retrospectively analyzed the medical data of patients, who were discharged from specialized center of cardiology between 01.10.15 and 30.11.15. The thromboembolic events and bleeding risks were assessed by CHA2DS2-VASc and HAS-BLED scores, respectively.

Results: Among 1298 patients, AF was detected in 161 (12.4%, mean age 65.3 + 8.7 years), of these 75(44.6%) men. In 129 (80.1%) patients were identified non-valvular and in 32 (19.9%) valvular AF. Paroxysmal AF was detected in 45 (28%), persistent in 19 (11.8%) and permanent in 97 (60.2%) patients. Hypertension 1-3 degree was detected in 67.1% of patients (n = 108), heart failure 2-4th FC by NYHA in 69.6% (n = 112), diabetes in 14.9% (n = 24). History of thromboembolism or TIA were present in 9.3% patients (n = 15) and peripheral vascular disease identified by ultrasonography of artery (major and peripheral vessels) in 54.6 % (n = 88). At the time of admission HAS-BLED score > 3 were identified in 13.7 % (n = 22) of patients and the mean HAS-BLED score was 1.7 + 1.2 and CHA2DS2-VASc score was 4.1 + 1.5. At pre-hospital period, ATT was indicated to 157 (97.5%) patients, (125 patients according to CHA2DS2-VASc score). It was found that 28% (n = 45) of patients did not take any ATT. There weren't any patients treated with new oral anticoagulants (NOACs). Only 31.7% (n = 51) of patients received warfarin. Compliance of anticoagulant therapy in patients with valvular AF were superior to non-valvular AF patients (50% vs 21.7%, respectively, p < 0.037). Only 2.5% (n = 4) of patients received aspirin and clopidogrel in combination. 37.9% (n = 61) of patients received antiplatelet agents as a monotherapy. Among patients receiving warfarin INR control from 2.0 to 3.0 revealed only in 7 (13.7%), at the same time 7 (13.7%) patients had an INR > 3 at the time of admission.

Conclusion: Despite, high risk of thromboembolic events and low bleeding risk, 28% of patients with AF did not take any ATT at the time of admission. There weren't any patients treated with NOACs. Only 31.7% of patients requiring anticoagulation, receive warfarin regularly and compliance to anticoagulant therapy was significantly superior in patients with valvular AF. Totally, 4.4 % of patients who had indicated ATT, receive warfarin in selected dose (INR 2.0-3.0) for optimal prevention of thromboembolic events according to ESC recommendations.

P2193

Predictive markers of atrial remodeling and role of PA-TDI duration and NT-proBNP in the assessment of atrial fibrillation reccurences

T Tea Gegenava[1]; M Gegenava[1]

[1]*Tbilisi State Medical University, Tbilisi, Georgia Republic of*

Introduction: Total atrial activation time has been identified as an independent predictor of new-onset atrial fibrillation (AF). Echocardiographic assessment of PA-TDI duration provides an estimation of total atrial conduction time.Recently total atrial conduction time (Total atrial conduction time measured by tissue doppler (PA-TDI duration) has been shown to be predictive marker of atrial remodelling. Pre-procedural assessment of the extent of atrial remodelling could be used to identify patients with a high risk of AF recurrence. Purpose of the present study was to measure and identify new predictors of AF occurrence: PA-TDI duration, also left atrial (LA) volumes, LA function in patients after radiofrequency catheter ablation and with heart failure and elevate level of Natriuretic peptid- NT-proBNP who had undergone ICD implantation.

Methods: we assessed n=80 patients, among them n=65 patients with atrial fibrillation-AF paroxysmal and persistent forms of AF without structural changes and normal NT-proBNP in pre- and post- operative periods of RFCA and electrical and pharmacological cardioversion and n=15 patients with AF with structural

heart disease and elevated level of NT-proBNP with mild to severe heart failure symptoms scheduled for ICD implantation. The PA-TDI duration was assessed by measuring the time interval between the onset of the P-wave in lead II of the surface ECG and the peak A-wave on the tissue Doppler tracing. A long PA-TDI duration corresponded to a long total atrial conduction time. In all patients we performed 24h holter monitoring. Results: an increased total atrial conduction time (PA-TDI > 119ms, mean PA-TDI 139-189) was associated with poor outcome and complications such as symptoms of heart failure $P < 0.001$ and reccurences after RFCA $p < 0.001$ and reccurences after cardioversion in all subgroups -in patients with atrial fibrillation with or without structural heart changes. Increased PA-TDI duration also correlated with NT-proBNP level in patients with heart failure symptoms. It was found correlation between LA size and PA-TDI duration $p < 0.001$, but In 35% of the patient without LA enlargment and prolonged PA-TDI duration we also found AF Reccurences.
Conclusions: An increased PA-TDI duration can be independently associated with AF reccurrence in heart failure patients with history of AF who had undergone ICD implantation and this parameter correlates with elevated NT-proBNP.

P2194
long term outcome of pulmonary vein isolation for atrial fibrillation in patient with left ventricular dysfunction.

Y Yoshifumi Ikeda[1]; R Kato[1]; K Goto[1]; T Nagase[1]; S Tanaka[1]; Y Shiki[1]; S Asano[1]; H Mori[1]; K Matsumoto[1]
[1]*Saitama International Medical Center, Cardiology, Hidaka, Japan*

Pulmonary vein isolation (PVI) is one of the effective option of atrial fibrillation (AF) treatment. The effectiveness of PVI for AF patient with left ventricular dysfunction was reported, but mid to long term outcome is still unidentified. The purpose of this study is to evaluate the mid to long term effectiveness of PVI for AF patient with left ventricular dysfunction.
Methods: Total 828 sessions of PVI for 609 cases were performed in our institute since 2003 to 2015, left ventricular dysfunction, which was defined as left ventricular ejection fraction (LVEF) under 50%, was complicated with in 96 cases. We retrospectively analyzed the patient's characteristics and outcomes in those cases. Results: The average observation period after PVI was 32.7 +/- 25.0 months, longest term was 93 months. The maintenance rate of sinus rhythm was 93.7% (87 cases), 36.8% of those (32 cases) was still under rhythm control treatment. Left atrium dimension (LAD) and left ventricle end systolic volume (LVESV) at least three years after PVI reduced significantly in comparison with pre-procedure (LAD 43.9 + /-7.7 to 40.8 + /-6.3mm ; $p = 0.01$, LVESV 66.8 + /-34.0 to 51.7 + /-27.3ml ; $p = 0.0001$), and LVEF was significantly improved, too(38.9 + /-9.8 to 57.5 + /-14.6 ; $p < 0.00001$). Conclusions: The PVI for AF patient with left ventricular dysfunction contributes to left atrial and left ventricle remodeling, and outcomes are excellent.

P2195
Relation between ventricular-arterial coupling parameters, left atrial remodeling and recurrences of atrial fibrillation in hypertensive patients with preserved left ventricular systolic function

A Shavarov[1]; EV Kokhan[2]; GK Kiyakbaev[1]; VS Moiseev[1]
[1]*RUDN University, Moscow, Russian Federation*; [2]*Lomonosov Moscow State University, Moscow, Russian Federation*

Background: Deterioration of the left ventricular-arterial coupling (VAC) might play a key role in the development of diastolic dysfunction and therefore structural and functional changes of the left atrium (LA). But the data concerning the relationship between VAC parameters and atrial fibrillation (AF) is scarce.
Purpose: To evaluate the relation between VAC parameters, structural and functional changes of the LA and their predictive value for AF recurrence in hypertensive patients with paroxysmal or persistent AF and preserved left ventricular systolic function.
Methods: The study included sixty hypertensive patients [45% male, median age 65 (61; 72) years] with recurrent non-valvular AF and preserved left ventricular systolic function. A group of 30 patients received 200 mg of amiodarone + 50 mg of metoprolol daily, while another group, also consisting of 30 patients, received 160 mg of sotalol daily. All the patients underwent conventional and speckle tracking echocardiography. Global peak LA longitudinal strain (PALS) and strain rate (PALSR) in the reservoir (r) and contractile (c) phases were assessed using 6 segments in the 4-chamber and 2-chamber views. To estimate VAC EaI, EesI, Ea/Ees and also systemic vascular resistance index and total arterial compliance (TAC) were calculated. Follow-up period was 3 months.
Results: Significant relation between EaI and LA size ($r=0.38$, $p = 0.003$), LA end diastolic volume ($r=0.33$, $p = 0.009$) and PALSc ($r=-0.31$, $p = 0.02$) were found. Other VAC parameters were not associated with changes of the LA. 35 (58%) patients maintained sinus rhythm (group 1) throughout the follow-up period, whereas 25 (42%) patients (group 2) experienced at least one AF recurrence. Despite having comparable LA volume index, the patients of group 1 had significantly higher PALSr (15.7 vs 12.6, $p = 0.004$), PALSc (-16.2 vs -13.9, $p = 0.008$), PALSRr (2.44 vs 1.76, $p < 0,001$), PALSRc (-2.4 vs -1.66, $p < 0.001$), TAC (1.26 vs 1.08, $p = 0.04$), whereas Ees corrected by left ventricular mass was higher in group 2 (619 vs 803, $p = 0,004$). Stepwise multiple regression analysis showed a significant association between PALSRc and the efficacy of antiarrhythmic therapy (β=0.38, $p = 0.04$).
Conclusion: Despite the fact that TAC and Ees corrected by left ventricular mass were significantly different between the two groups, they had no predictive value in AF recurrence. PALSRc was the only independent parameter associated with AF recurrence.

P2196
Russian observational survey of heart failure patients with atrial fibrillation (RIF-CHF): clinical characteristic of patients

N Romanova[1]; IV Zhirov[1]; SN Tereshchenko[1]; YUF Osmolovskaya[1]; SP Golitsyn[1]
[1]*Cardiology Research and Production Center, Moscow, Russian Federation*

Background: Atrial fibrillation and heart failure frequently coexist. Both conditions are risk factors for stroke, systemic embolism, and when combined have much worse outcomes. Data on clinical characteristic and compliance with clinical guidelines for heart failure patients with atrial fibrillation in Russian Federation is limited.
Methods: We conducted a registry of consecutive in- and outpatients with heart failure and atrial fibrillation from 38 medical centers in different regions of the Russian Federation. All patients had ECG-documented diagnosis of atrial fibrillation and heart failure. Patients with preserved ejection fraction (≥40%) were eligible for study if they had level of BNP or NT-proBNP larger then100 pg/ml or 300 pg/ml, respectively.
Results: A total of 1003 patients (57% men, mean age 67 years) with heart failure and atrial fibrillation were included in this study between February and December, 2015. Ejection fraction more than 40% was present in 54,8% of patients. In our registry 45,4% of patients had NYHA Class II, 45,7% had NYHA Class III and 8,9% - NYHA Class IV. The commonest associated comorbidities were coronary heart disease (68,9%), hypertension (65%), diabetes mellitus type 2 (26%), previous stroke or TIA (23%) and chronic kidney disease (12,9%). Of the whole cohort, 56,8% of patients had permanent atrial fibrillation, 27 and 9,4 % had paroxysmal and persistent atrial fibrillation, respectively. Of the whole cohort, the mean CHA2DS2-VASc score was $4,2 \pm 1,74$ and the mean HAS-BLED was $1,68 \pm 1,12$. High risk of thromboembolism (CHA2DS2-VASc score ≥ 3) had 77,6% of patients. Oral anticoagulants were used in 81% of patients with CHA2DS2-VASc = 1; 69% patients with CHA2DS2-VASc = 2 and only 58% in CHA2DS2-VASc score ≥ 3.
Conclusions: Based on current guidelines, oral anticoagulation is recommended for the vast majority of patients with heart failure and atrial fibrillation. Compliance with the treatment guidelines for patients with higher stroke risk scores remains suboptimal.

P2197
Management of atrial fibrillation in heart failure

AL Gamez Lopez[1]; JL Bonilla Palomas[1]; MC Lopez Ibanez[1]; M Moreno Conde[1]; Y Pimentel Quezada[1]; A Villar Raez[1]
[1]*Hospital San Juan de la Cruz, Úbeda, Spain*

Background: There are no specific recommendations for the management of patients with heart failure (HF) and atrial fibrillation (AF), not knowing if the management of these patients is similar to that done in patients without HF diagnosis.
Purpose: Describe the characteristics and management of AF in patients with or without HF.
Methods: Observational and prospective study on patients with AF, analyzing differences in the diagnostic and therapeutic approach among patients with or without HF. Sociodemographic, clinical, analytical and echocardiographic variables were collected, and a comparative analysis of the same was performed between both groups.
Results: A total of 915 patients were analized, 144 with HF (15,7%) and 771 without HF (84,3%). No differences between groups were observed in: age, sex, CHADSVASC, HASBLED, renal function, hemoglobin, hypertension or previous bleeding events. The percentage of diabetic patients was higher in the group of patients with HF (39.6% vs 21.9%, $p < 0.001$), with these patients having a larger left atrium size (left atrial area in apical four chamber view: 30,9 vs 26,9 cm2, $p = 0,045$). The rhythm control was used less frequently in patients with HF (2.2% vs 12.6%, $p < 0.001$). Beta-blockers (78.3% vs 58.3%, $p < 0.001$) and digoxin (23.4% vs 12.7%, $p = 0.002$) were more frequently used in patients with FH, with less use of antiarrhythmic drugs in this group (5,7% vs 13,4%, $p = 0,008$). When antiarrhythmic drugs were employed, amiodarone was used in 100% of patients with HF. The most frecuent antiarrhythmic drug in AF without HF was flecainide (46%) followed

by dronedarone (26%) and amiodarone (25%). No differences between anticoagulated patients (90,6% vs 91,7% p = 0,387) or type of anticoagulation prescribed (AVK: 65,7 vs 67%; NOAC :34% vs 33%, p = 0,765) were observed.
Conclusions: Patients with AF and HF are more frequently diabetic and have a larger atrial size. In them the rhythm control strategy is used less frequently, being the antiarrhythmic of choice amiodarone with a greater use of beta-blockers and digoxin.

HYPERTROPHIC CARDIOMYOPATHY

Predictors of ICD-related adverse events in patients with hypertrophic cardiomyopathy

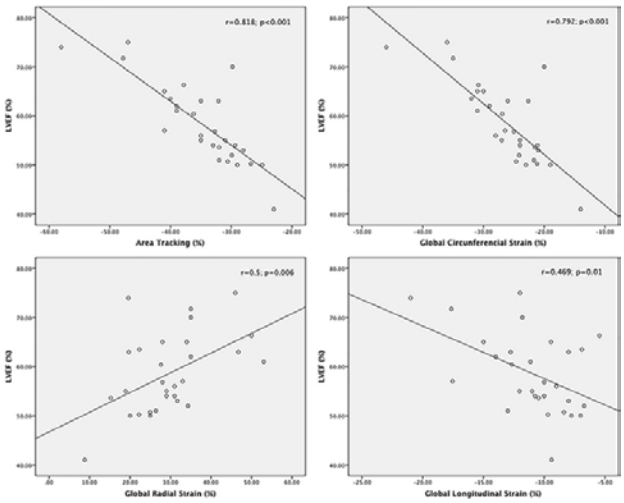
C Cedric Klein[1]; A Duva Pentiah[1]; D Klug[1]; C Marquie[1]; S Ninni[1]; H Blangy[2]; PC Flechon[2]; N Sadoul[2]; P De Groote[1]
[1]Lille University Hospital, Institut Cœur Poumon, Lille, France; *[2]Hospital Brabois of Nancy, Vandoeuvre les Nancy, France*

Background: Hypertrophic cardiomyopathy (HCM) is the most common cause of sudden cardiac death in young patients. Implantable cardioverter-defibrillator (ICD) therapy may be considered in HCM patients at high risk of ventricular arrhythmia.
Aims: To determine predictive factors of transvenous ICD-related adverse events in HCM patients.
Methods: All patients with HCM referred for ICD implantation in two French tertiary centres between May 1992 and August 2016 were retrospectively included. Clinical, electrocardiographic and echocardiographic data were obtained from electronic medical records. 'ICD-related adverse event' was defined as the combination of inappropriate shock and/or other complication related to the device (infection, access-, generator- or lead-related complication).
Results: A total of 177 patients were included. Median follow-up was 45.6 months. One hundred and fifty-six patients received a transvenous-ICD (TV-ICD) and 21 a subcutaneous-ICD. Among the whole cohort, 46 patients (26%) experienced at least one appropriate therapy. Among TV-ICD group, inappropriate shocks occurred in 27 patients (17%) and 41 patients (26%) experienced a total of 51 complications including 14 lead fractures and 7 infections. In multivariate analysis, history of atrial flutter (HR=12.5 [2.3-67.2], p = 0.003), unexplained syncope (HR=5.5 [2.0-15.4], p = 0.001) and young age (HR=0.956 [0.930-0.983], p = 0.001) were associated with TV-ICD-related adverse event. Among S-ICD group, inappropriate shocks occurred in 2 patients (8%) during a follow-up of 12.0 months. After adjusting for year-implantation, no difference was found between TV-ICD and subcutaneous-ICD in terms of device-related adverse events.
Conclusion: We identified three simple and readily available variables that are associated with TV-ICD-related adverse events in HCM patients at high risk of SCD. Considering the model performance in this population, it should be validated in a larger cohort.

P2199
Impact of hypertrophy in left ventricular ejection fraction and myocardial strain: application of three-dimensional wall-motion tracking technology in hypertrophic cardiomyopathy

L Marques[1]; N Moreno[1]; H Guedes[1]; R Santos[1]; A Pereira[1]; D Seabra[1]; R Sousa[1]; P Pinto[1]
[1]Centro Hospitalar do Tâmega e Sousa, EPE, Cardiology Department, Penafiel, Portugal

Introduction: Hypertrophic cardiomyopathy (HCM) is morphologically characterized by a thickened, non-dilated, left ventricle (LV). Myocardial mass seems to be related to deformation parameters, and some authors suggest that circumferential strain, as assessed by three-dimensional (3D) techniques, may be the major component in the maintenance of a normal systolic function in HCM. However, more data are needed to confirm the reliability and reproducibility of 3D strain evaluation in HCM.
Purpose: Using three-dimensional wall-motion tracking (3DWMT) echocardiographic technique, we aimed to assess the impact of indexed myocardial mass in LV ejection fraction (LVEF) and in deformation parameters in a cohort of HCM patients. We also aimed to assess the impact of individual deformation components in LVEF, as assessed by 3DWMT
Methods: Thirty-five (35) HCM patients underwent standard bi-dimensional (2D) echocardiography, followed by 3DWMT evaluation. Using Toshiba Artida echocardiography equipment (Toshiba Medical System), global strain values were obtained for each component [global longitudinal strain (GLS), global circumferential strain (GCS), global radial strain (GRS), area tracking (AT)], as well as LV indexed mass and LVEF. Six patients (17%) were excluded from LVEF analysis. Statistical analysis was performed using Statistics Version 22; the correlations between continuous variables were established by linear regression.
Results: We found no significant correlation between LV indexed mass and LVEF (p = 0.497). Only GLS exhibited a significant correlation with LV indexed mass (r=0.375, p = 0.029). All strain components were correlated with LVEF (AT: r=0.818, p < 0.001; GCS: r=0.792, p < 0.001; GRS: r=0.500, p = 0.006; GLS: r=0.469, p = 0.01) (Figure 1). The strongest correlations were found with AT (r=0.818, p < 0.001) and GCS (r=0.792, p < 0.001)
Conclusion(s): In HCM patients, increased myocardial mass is associated with a decreased GLS, but not with a decreased LVEF. Global circumferential strain and AT exhibited a strong correlation with LVEF, and seem to be important components in LV function preservation. Three-dimensional wall motion tracking technology appears to be a useful tool in evaluation of HCM patients, allowig detection of subclinical dysfunction and providing new insights into LV mechanics.



P2200
Assessment of left ventricular strain by three-dimensional wall-motion tracking technology: a study in hypertrophic cardiomyopathy

L Marques[1]; N Moreno[1]; H Guedes[1]; R Santos[1]; A Pereira[1]; D Seabra[1]; R Sousa[1]; P Pinto[1]
[1]Centro Hospitalar do Tâmega e Sousa, EPE, Cardiology Department, Penafiel, Portugal

Introduction: Hypertrophic cardiomyopathy (HCM) is a genetic disease with an autosomal dominant pattern of transmission. It is histologically characterized by cardiomyocytes hypertrophy, fibre disarray and interstitial fibrosis. These microscopic abnormalities translate into functional abnormalities, not always recognized by conventional cardiac imaging assessment. Thus, quantitative assessment of myocardial dysfunction caused by hypertrophy and heterogeneous fibrosis in HCM remains a challenge.
Purpose: Using three-dimensional wall-motion tracking (3DWMT) echocardiographic technique, we aimed to characterize the left ventricle (LV) global mechanics in a HCM group of patients, and to compare morphological and strain parameters with a group of healthy controls.
Methods: Thirty five (35) HCM patients (HCM group) and 27 healthy controls (control group) underwent standard bi-dimensional (2D) echocardiography, followed by 3DWMT evaluation. Using Toshiba Artida echocardiography equipment (Toshiba Medical System), global strain values were obtained for each component [global longitudinal strain (GLS), global circumferential strain (GCS), global radial strain (GRS), area tracking (AT)], as well as, twist and torsion angle, and LV ejection fraction (LVEF).
Results: We found no age (61.5 ± 10.3 vs 57.5 ± 7.2 years, p = 0.097), gender (p = 0.384) or LVEF (63 ± 9 vs 65 ± 13%, p = 0.437) differences among HCM and control groups. Regarding strain parameters, we found a statistically significant decrease in GLS (-10.6 ± 3.1 vs -16.5 ± 4.3%, p < 0.001) and GCS (-24.4 ± 8.1 vs -28.8 ± 7.3%, p = 0.032) in HCM group. A non-significant trend to lower GRS values was also observed in this group (27.9 ± 11.2 vs 31.0 ± 1 0.7%, p = 0.275). Furthermore, a significant decrease was observed in AT values (-32.9 ± 9.1 vs -39.8 ± 9.8%, p = 0.007). No diferences were verified in twist angle values (5.7 ± 2.9 vs 5.5 ± 2.7°, p = 0.889), nor torsion (1.8 ± 1.1 vs 1.6 ± 0.9°/cm, p = 0.399).
Conclusion(s): Patients with HCM and preserved LVEF exhibit abnormal myocardial

deformation parameters. In the analysed cohort, a significant decrease was found in GLS, GCS and AT values. Three-dimensional wall-motion tracking proved to be a useful and practical tool in the assessment and characterization of LV global mechanics, allowing a better comprehension of HCM pathophysiology, and allowing the detection of subclinical dysfunction.

P2201

Brain natriuretic peptide level in patients with hypertrophic cardiomyopathy

AE Demkina[1]; NS Krylova[1]; NG Poteshkina[1]; EA Kovalevskaya[2]; FM Hashieva[2]
[1]The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation; *[2]City Hospital 52, Moscow, Russian Federation*

In clinical practice, most patients with hypertrophic cardiomyopathy (HCM) have an increased levels of brain natriuretic peptide (BNP) despite of preserved global systolic function of the left ventricle (LV). The relationship of BNP level and clinical-instrumental parameters in patients with HCM is of great interest of investigators.

Purpose: To assess BNP level and its relationship with clinical status and instrumental parameters in HCM patients.

Materials and methods: 55 patients with HCM were examined (13 men (33%), average age 58.0 ± 15.5 years). All patients were treated with bisoprolol (5.5 ± 1.8 mg). In 15 patients (27.2%) obstructive form of the disease was identified. All patients underwent clinical examination, echocardiography with tissue doppler imaging (TDI) and brain natriuretic peptide (BNP) estimation.

Results: 52 HCM patients (94.5%) had an elevated BNP level with average mean 150 (83; 300) pg/ml. There was a significant correlation between BNP level and functional class (FC) of chronic heart failure (CHF) by NYHA (r=0.37, p = 0.04), left ventricular interventricular septum (r=0.40,vp = 0.04), size of the left atrium (r=0.93, p = 0.001), mitral regurgitation (r=0.60, p = 0.006), E/A (r=0.37, p = 0.04) and IVRT of transmitral flow (r=0.30, p = 0.04). There was a correlation between BNP level and right ventricle (RV) Tei index (r=0.48, p = 0.01), tricuspid annulus lateral s' (r=-0.79, p = 0.01), and basal lateral RV wall s' (r=-0.94, p = 0.002), medium lateral RV wall s' (r=-0.73, p = 0.02).

CONCLUSIONS. BNP levels was elevated in 94.5% HCM patients. Increased BNP level was associated with higher functional class of CHF by NYHA, myocardial hypertrophy, increased left atrium size, left ventricle diastolic disfunction and RV longitudinal systolic disfunction.

P2202

Myosin heavy chain and MAP-kinase activating death domain-containing gene polymorphisms in adults with hypertrophic cardiomyopathy

AA Poliakova[1]; VG Davydova[1]; EN Semernin[1]; SA Pyko[2]; AA Kostareva[1]; AYA Gudkova[3]; EV Shlyakhto[1]
[1]Almazov Federal Medical Research Centre, Saint-Petersburg, Russian Federation; *[2]St.Petersburg Electrotechnical University "LETI", Saint-Petersburg, Russian Federation*; *[3]St.Petersburg State Pavlov Medical University, Saint-Petersburg, Russian Federation*

Background and Purpose: Hypertrophic cardiomyopathy is the most common inherited cardic disorder. Phenotypic manifestation of the disease, especially in the adult and eldery group, depends on many inviromental and genetic factors, including co-existing genetic variants such as SNPs. Our aim was to study the genotype and allele distribution in rs2290149, rs10838692, rs7124958, rs753992 of MADD gene and rs2069542 of MYH7 gene in adults with hypertrophic cardiomyopathy (HCM).

Methods: The study group included 154 patients with HCM at the age 45 - 91 years (57,69 ± 11,19 years, men - 48% women - 52%). The diagnosis of HCM was established according to the guideline of the European society of cardiology on the diagnosis and treatment of HCM, 2014. The control group included 257 healthy donors without cardiovascular diseases and other severe pathologies, matched by age and sex with the studied group. Genotyping for rs2290149, rs10838692, rs7124958, rs753992 of the MADD gene and rs2069542 of the MYH7 gene was performed using real time PCR.

Results: We observed a significant increase in frequency of TT genotype of rs10838692 of the MADD gene in patients with HCM compared to healthy group (55.2% vs. 45.3%, p < 0.05). A trend although not reaching a statistical significance was detected towards the predominance of the TT genotype in rs2290149 of the MADD gene in patients with HCM compared to healthy donors (82.5% vs. 73%, p = 0.055). The allele frequency also differs for rs2290149 (T:C = 89.9%:10.1% in HCM and 83.3%:16.7% in control group, p = 0.007) and for rs10838692 (T:C=72.4% : 27.6% in HCM and 63.6%: 36.4% in control, p = 0.008), respectively. We did not detect any difference in genotype and allele distribution for rs7124958, rs753992 of MADD gene and for rs2069542 of MYH7 gene.

Conclusion: In older adults with HCM the T allele of SNP rs2290149 and SNP rs10838692 and TT genotype of rs10838692 of the MADD gene are prevailing compared to control healthy individuals, while polymorphic variants rs7124958, rs753992 of the MADD gene and rs2069542 of the MYH7 gene had no association with HCM.

P2203

The role of soluble st2 and galectin-3 in hypertrophic cardiomyopathy assessed by cardiac magnetic resonance

M Monika Gawor[1]; M Spiewak[2]; M Marczak[2]; K Kozuch[3]; J Janas[4]; J Grzybowski[1]
[1]Institute of Cardiology, Department of Cardiomyopathies, Warsaw, Poland; *[2]Institute of Cardiology, CMR Unit, Warsaw, Poland*; *[3]Institute of Cardiology, Department of Congenital Heart Diseases, Warsaw, Poland*; *[4]Institute of Cardiology, Department of Clinical Biochemistry, Warsaw, Poland*

Funding Acknowledgements: Funded by Institute of Cardiology grant No 2.56/V/2015

Background: Soluble ST2 (sST2) and galectin-3 (Gal-3) are useful biomarkers for prognosis of heart failure. Both of them are involved in cardiac fibrosis and remodeling. Myocardial fibrosis identified on cardiac magnetic resonance (CMR) imaging is present in approximately 70% of patients with hypertrophic cardiomyopathy (HCM) and may play an important role in predicting sudden cardiac death in this population.

Purpose: The aim of this study was to evaluate sST2 and Gal-3 as potential biomarkers in HCM.

Methods: Serum sST2 and serum Gal-3 concentrations were measured in 60 patients with HCM and 20 healthy controls with normal physical examination. The patients with HCM underwent routine evaluation including 12-lead electrocardiography (ECG), two-dimensional (2D) echocardiography, 48-hour Holter ECG monitoring, NT-proBNP and high-sensitivity Troponin T measurements. Additionally, CMR examination was performed in this group to calculate left ventricular (LV) mass, LV mass indexed for the body surface area (LVMI), LV ejection fraction (LVEF), and maximal wall thickness (MWT). The control group underwent 12- lead ECG, 2D echocardiography and NT-proBNP measurements to exclude asymptomatic heart disease.

Results: Concentrations of sST2 and galectin-3 were significantly higher in patients with HCM than in control group (15.0 [9.8 - 18.9] vs. 12.9 [9.4 - 14.8] p = 0.04 and 8.4 [6.8 - 10.0] vs. 6.1 [5.5 - 7.6] p = 0.003, respectively). We observed positive correlations between sST2 levels and CMR-derived parameters: LV mass (r=0.296, p = 0.023), LVMI (r=0.290, p = 0.026) and MWT (r=0.334, p = 0.010). Gal-3 levels were associated only with hs-cTnT concentrations (r=0.257, p = 0.046). We confirmed positive correlations between NT-proBNP levels and LV mass (r=0.328, p = 0.0098), LVMI (r=0.458, p = 0.0002) and MWT (r=0.438, p = 0.0004). There were also positive correlations between hs-cTnT levels and LV mass (r=0.598, p < 0.00001), LVMI (r=0.518, p < 0.00001), MWT (r=0.337, p = 0.008), and negative correlation between hs-cTnT levels and LVEF (r= -0.355, p = 0.005). Patients with non-sustained ventricular tachycardia (nsVT) had higher levels of sST2 (19.0 [9.6 - 22.8] vs. 13.7 [9.2 - 17.4] p = 0.027) and hs-cTnT (24.2 [10.2 - 31.2] vs. 11.5 [7.4 - 22.9] p = 0.039).

Conclusions: Our study confirmed that NT-proBNP and hs-cTnT are valuable biomarkers in HCM. Gal-3 levels were higher in patients with HCM than in control group, but there were no correlations between Gal-3 levels and CMR-derived LV dimensions. We demonstrated a significant correlations between serum sST2 levels and LV mass, LVMI and MWT assessed by CMR in HCM patients. Levels of sST2 were also higher in patients with nsVT. These findings suggest that sST2 may have a potential as a biomarker for better risk stratification in HCM.

Figure1. Correlations between sST2 levels (ng/ml) and CMR-derived parameters: (A) MWT (mm), (B) LVMI (g/m2), and (C) LV mass (g) in HCM patients. Levels of sST2 in patients with nsVT (D).

Valve calcification is associated with parameters of central pulse wave in patients with end-stage renal disease on hemodialysis

N Manukhina[1]; M Trukhanova[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: Arterial stiffness is known marker of poor cardiovascular prognosis. Associations of valve calcification and arterial stiffness in patients with end-stage renal disease (ESRD) are not well studied. The aim if the study was to assess the incidence of valve calcification in patients with and its associations with clinical parameters and markers of arterial stiffness.
Methods: In 68 adults with end-stage renal disease on maintenance hemodialysis for >3 months (45.6% males, median age 58.3 (interquartile range (IQR) 54.6; 61.6) years, dialysis duration 62.7 (47.8;77) months, body mass index 26.8 [25.3;28.3] kg/m2, arterial hypertension 94%, stable angina 26.5%, heart failure 28%, diabetes mellitus 21%, glomerulonephritis 35%, pyelonephritis 25%, multicystic dysplastic kidney 13%, urolithiasis 10%) echocardiography and applanation tonometry was performed. Calcification in mitral, aortic or both valves and parameters of arterial stiffness and central pulse wave were assessed. Mann-Whitney test was performed. $P < 0.05$ was considered significant.
Results: Calcification of the aortic, mitral and both valves was revealed in 46 (67.6%), 34 (50%) and 33 (48.5%) of patients respectively. 20 (29%) patients had no signs of calcification of valves. Patients with vs without calcification of aortic valve were older (65.1 ± 9.5 vs $41.4 \pm 11,9$ years, $p < 0.001$), had higher dialysis duration (51 (8;252) vs 21 (10;38) months, $p < 0.01$), left atrium volume (LAV) (44 (40;70) vs 42 (40;44) ml, $p < 0.05$), right atrium volume (RAV) (44 (39;62) vs 42 (40,5;43) ml, $p < 0.05$), lower stroke volume (SV) (74 (48;108) vs 80 (71;86,5) ml, $p < 0.05$). Patients with vs without calcification of aortic valve had lower peripheral diastolic blood pressure (DBP) (76 ± 17 vs 84 ± 12 mmHg, $p < 0.05$), central DBP (75 ± 15 vs 82 ± 11 mmHg, $p < 0.05$), lower reflected wave transit time (RWTT) (131 ± 17 vs 137 ± 15 ms, $p < 0.05$). Patients with vs without calcification of mitral valve were older (67.8 ± 8.2 vs $47.9 \pm 13,5$ years, $p < 0.001$), had higher dialysis duration (51 (34;111) vs 36 (14;57) months, $p < 0.01$), LAV (45 (43;56) vs 42 (40;44) ml, $p < 0.05$), RAV (44 (43;45) vs 42 (42;43) ml, $p < 0.05$), systolic pulmonary artery pressure (33 (29;37) vs 29 (27;30) mmHg, $p < 0.01$), lower stroke volume (71.9 ± 10.2 vs 78.4 ± 13.6 ml, $p < 0.05$). Patients with vs without calcification of mitral valve had higher carotid-femoral pulse wave velocity ($10.1 \pm 2.$ 7 vs 8.9 ± 3.5 m/s, $p < 0.05$), lower peripheral DBP (73 ± 17 vs 84 ± 14 mmHg, $p < 0.01$), central DBP (72 ± 13 vs 83 ± 13 mmHg, $p < 0.001$), higher central pulse pressure (52 ± 13 vs 45 ± 16 mmHg, $p < 0.05$), lower RWTT (133 (120;130) vs 135 (132;142) ms, $p < 0.05$).
Conclusion: High prevalence of valve calcification (71%) was revealed in patients with ESRD on maintenance hemodialysis. Patients with vs without valve calcification were older, had higher duration of dialysis and more pronounced arterial stiffness.

control of uric acid in the blood - A new lever quality of life of patients with rheumatoid arthritis and chronic heart failure

D Dmitrii Bublikov[1]; D Anchugina[1]
[1]*Altay State Medical University, Barnaul, Russian Federation*

Increased uric acid levels in patients with chronic heart failure and in patients with rheumatoid arthritis - the spread in the clinic. The impact on quality of life of hyperuricemia in patients with chronic heart failure, as well as ways of correction of elevated levels of uric acid in patients by different ways until plasmapheresis and prednisone - study topic. Today, however, it is not clear whether there is a relationship between the level of hyperuricemia in patients with rheumatoid arthritis and chronic heart failure with quality of life. Purpose of the study. To study the effect of hyperuricemia on the quality of life of patients with rheumatoid arthritis and chronic heart failure
Materials and methods: We examined the patients ($n = 79$), including 46 women and 33 men, average age - $55.6 \pm$ 7.2 years, with verified diagnosis of rheumatoid arthritis by ACR criteria (1988). Chronic heart failure and its functional class (for NYHA) exhibited on the basis of complex clinical and laboratory, instrumental methodics that included physical examination of the patient, with the six-minute walking test, echocardiogram, pro-BNP. 77% of patients had hypertension, 23% angina pectoris. 16% had a combination of these diseases. All of the patients at the time of inclusion in the study were 1st functional class of angina and well-controlled blood pressure. Quality of life was assessed by the SF-36 questionnaire.
Results: Found korrelation communication medium strength between the level of uric acid in the group of men surveyed and functional class chronic heart failure ($p = 0.54$). In the subgroup of women this correlation goes missing ($p = 0.12$). In addition, if not statistically different functional class of heart failure, patients with higher levels of uric acid had statistically lessnes indicators by questionnaire SF-36, such as the role functioning ($p = 0.008$), role physical functioning ($p = 0.005$), physical pain ($n = 0.003$), social functioning ($p = 0.002$). Also found a correlation of medium strength, positive between uric acid levels and an indicator on the questionnaire SF-36 mental health.
Conclusion: The results show the effect of hyperuricemia on the functional class of chronic heart failure in men with rheumatoid arthritis. Also, the findings suggest a direct effect of hyperuricemia on the quality of life parameters in patients with rheumatoid arthritis and chronic heart failure and reverse its impact on the mental quality of life parameters.

P2206

Cognitive impairment in heart failure

E Elnur Smajic[1]; M Isabegovic[1]; L Dizdarevic- Hudic[1]; M Avdagic- Piric[1]; D Loncar[1]; D Mrsic[1]; N Mesanovic[1]
[1]*University Clinical Center Tuzla, 75000 Tuzla, Bosnia and Herzegovina*

The early features of brain failure are deterioriation of intellectual capabilities, especially loss of concentration and memory. Cognitive impairment (CI) and dementia are increasing globally. It is one of the primary causes of loss of autonomy and institutionalization of elderly patients in many countries.
The prevalence of CI is higher among patients with Heart Failure (HF) than in those without. CI is often recognized in conjunction with heart failure, but the reported prevalence has varied ranging from 25% to 75%. In the literature, the reported prevalence of cognitive impairment in heart failure patients is at least 15-fold higher. Studies have shown up to a fivefold increase in mortality in HF patients when cognitive impairment is present.
HF and CI share several common pathological processes and risk factors, and cause or consequence. The pathophysiological mechanisms that like it is hypoperfusion and/or micro-emboli seem to play an important role. Atrial fibrillation is independently associated with the onset of cognitive impairment and Alzheimers disease. Another important determinant of cognitive impairment is the presence of cerebral white matter lesions, abnormality of hippocampus, such as reduction in gray matter and cerebral blood flow. Cerebral blood flow is much lower in the posterior part of hippocampus. The hippocampus is one of the regions of the brain most vulnerable to cerebral hypoxia. HF patients showed the loss of gray matter in the different brain regions (cortical and subcortical) than patients with ischemic heart disease. HF patients display more widespread and extensive brain changes than adults with ischemic heart disease.
The spectrum of CI in HF is similar to that observed in the general population and range from delirium to isolated memory or non-memory-related deficits to dementia. The path leading to dementia is often long with a wide spectrum of subclinical and clinical presentation. Vascular dementia is the most prevalent type with 36%. Both HF with reduced ejection fraction and HF with preserved ejection fraction have been associated with defects in different domains of cognition. The main type of heart failure is with preserved ejection fraction, which is more prevalent in those of greater age. No relationship could be demonstrated between type of dementia and type of heart failure. Studies have shown a rise in CI in HF patients with higher New York Heart Association classification.
CI in HF has been associated with higher rates of disability and impairment in self-care activities that increase healthcare cost, hospital readmission and mortality. Morphologic and functional changes in HF patients with CI may be detected at an early stage using cardiovascular and brain imaging techniques. Early detection of CI and appropriate management strategies in HF may help to reduce CI and improve clinical outcomes in HF patients.
Key words: Cognitive impairment, Heart failure, Older age

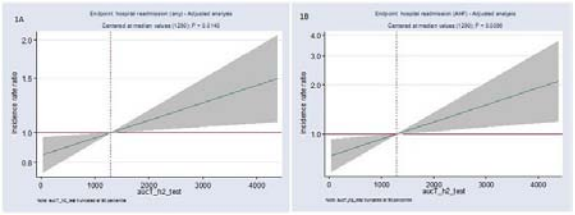
P2207

Intestinal bacterial overgrowth assessed by lactulose breath test and adverse outcomes in heart failure

A Anna Mollar Fernandez[1]; MP Villanueva[2]; G Minana[1]; A Villaescusa[1]; D Escribano[1]; E Santas[1]; P Palau[1]; A Bayes-Genis[3]; J Lupon[4]; M Minguez[5]; F Mora[5]; E Nunez[1]; J Sanchis[1]; J Nunez[1]
[1]*University Hospital Clinic of Valencia, Cardiology, Valencia, Spain*; [2]*University Hospital Clinic of Valencia, clinical biochemistry, Valencia, Spain*; [3]*University Hospital Trias i Pujol, Cardiology, Barcelona, Spain*; [4]*University Hospital Vall d'Hebron, Cardiology, Barcelona, Spain*; [5]*University Hospital Clinic of Valencia, Gastroenterology, Valencia, Spain*

Background: Some evidence endorses the role of gut microbiome in the pathophysiology of heart failure (HF). Indeed, intestinal bacterial overgrowth has been postulated to play a crucial role in the progression of the disease. In this work, we aimed to evaluate whether small intestinal bacterial overgrowth syndrome (SIBO) assessment by measuring the hydrogen (H2) and methane (CH4) exhaled by lungs and measured in breath after a lactulose breath test is associated with the risk of repeated unplanned hospitalizations.

Methods: This is an observational prospective study that enrolled 102 patients with the following inclusion criteria: a) advanced HF (stage C-D as per the ACC/AHA classification); b) at least one previous decompensating episode, c) non-clinical signs of active infection. In all of them, we performed a lactulose breath test collecting breath samples at baseline and every 20 minutes for 2 hours. Negative binomial regression method was used to determine the association between the area under the receiving operator curve of H2 and CH4 (AUC-H2 and AUC-CH4, respectively) and the risk of recurrent hospitalizations. Estimates of risk were reported as incidence rate ratios (IRR).
Results: Median (interquartile range) of AUC-H2 and AUC-CH4 were 1290 (520-2430) and 985 (450-2120), respectively. SIBO prevalence was up to 65.69% of the sample. At a median (interquartile range) follow up of 203 (80-369) days, 100 all-cause readmissions in 49 patients and 51 AHF-readmissions in 26 patients were recorded. In multivariate setting, AUC-H2 was significant, positive and linearly associated with an increased risk of recurrent all-cause (IRR=1,14; CI 95%:1,03-1,27; p = 0,014) and AHF-hospitalizations (IRR=1,27; CI 95%:1,06-1,52; p = 0,010) as is shown in figure 1a and 1b.
Conclusions: In this preliminary study, exhaled H2 and CH4 after a lactulose breath test were independently associated with higher risk of recurrent admissions in patients with HF.



P2208

Prevalence of comorbidities and one-year prognosis based on ejection fraction findings: understanding heart failure with mid-range ejection fraction.

MA Miguel Antonio Lopez Garrido[1]; AI Molina-Ramos[1]; A De Vicente-Ortega[2]; V Garcia-Ruiz[1]; VM Becerra-Munoz[1]; A Ruiz-Salas[1]; L Morcillo-Hidalgo[1]; M Jimenez-Navarro[1]; JJ Gomez-Doblas[1]; E De Teresa-Galvan[1]; JM Garcia-Pinilla[1]
[1]*University Hospital Virgen de la Victoria , Department of Cardiology, Malaga, Spain*; [2]*Faculty of Medicine, University of Malaga, Malaga, Spain*

Background: The ESC Heart Failure (HF) Guidelines of 2016 introduce the term HF with mid-range ejection fraction (HFmrEF) as a separate group with characteristics between HF with reduced and preserved ejection fraction (HFrEF and HFpEF, respectively). We conducted this study in order to know the the differences in the prevalence of comorbidities and events at one-year follow-up in the groups of HF according to their ejection fraction.
Methods: We studied all the patients with HFmrEF at follow-up in the HF Unit of our Hospital in the years 2010-2014, recording their clinical characteristics, comorbidities and adverse events during follow-up. Subsequently we compared its characteristics with patients with HF with preserved and depressed ejection fraction included in the ESC HF Registry in our Hospital during the same period.
Results: The group of patients with HFmrEF had a lower percentage of women than the group of HFpEF (24.6% vs 52.2%, p < 0.001), presenting no differences with HFrEF (24.6% vs 20%, p = 0.56). There were also no significant differences in age compared to HFpEF (69 vs 69 years, p = 0.91) or HFrEF (68 vs 66 years, p = 0.24). The ischemic etiology was the most frequent in the groups of HFmrEF and HFrEF (50% and 41.8%, respectively) and the hypertensive etiology in HFpEF (39.1%). The Charlson Index was higher in HFmrEF than in HFpEF (5.7 vs 4.6, p = 0.003), not existing significant differences with HFrEF (5.7 vs 5.2, p = 0.22). In comparison with the group of HFpEF, HFmrEF patients presented higher prevalence of diabetes (45.6% vs 27.5%, p = 0.019) and peripheral artery disease (19.3% vs 1.4%, p < 0.001), and lower prevalence of atrial fibrillation (21.9% vs 36.2%, p = 0.041). In term of comorbidities there were no differences with respect to the HFrEF group, except in the hypertension that was more prevalent in HFmrEF (71.1% vs 45.5%, p = 0.002). There were no significant differences in the three groups with respect to overall mortality (HFmrEF 6.6%, HFpEF 3.3%, HFrEF 4%, p = 0.59), nor with respect to hospitalization for HF at one-year of follow-up (HFmrEF 11.7%, HFpEF 1.4%, HFrEF 7.5%, p = 0.07), although a higher percentage was observed in HFmrEF patients.
Conclusions: 1. The ischemic etiology was common in the three groups of HF. 2. HFmrEF and HFrEF present similar clinical characteristics in terms of comorbidities. 3. Diabetes and arterial disease was more frequent in HFmrEF with respect to HFpEF. 4. HFmrEF had a higher percentage of mortality and hospitalizations for HF at one-year follow-up, although without statistically significant differences.

P2209

Chronic kidney disease in heart failure is associated with higher CA 125 and hsCRP levels

Y Yuksel Cavusoglu[1]; ME Altinbas[1]; F Mutlu[1]; S Eraslan[1]; K Isgendarov[1]; E Babayigit[1]
[1]*Eskisehir Osmangazi University, Eskisehir, Turkey*

Purpose: Chronic kidney disease (CKD) is a common comorbid condition in heart failure (HF). Plasma levels of carbohydrate antigen 125 (CA-125) have been shown to correlate with clinical, hemodynamic, and echocardiographic parameters in HF. However, less is known with regard to CA-125 levels in patients with HF and CKD. Inflammatory activation has also been shown to involve in the pathophysiological process of HF and elevated level of hsCRP is demonstrated to be present in HF. The aim of this study was therefore to assess possible associations between CKD and plasma levels of CA-125 or hsCRP in patients with HF.
Methods: A total 446 patients with the diagnosis of HF, NYHA II-IV, LVEF < 40% and >18 years of age were included in this study. CKD was defined as an eGFR < 60 mL/min/1.73 m2. Plasma levels of CA-125 and hsCRP levels have been measured from the blood samples. Patients were classified into two groups: patients with CKD (n = 227) and patients without CKD (n = 219).
Results: Mean age of study population was 67 ± 12 years. Mean EF was 25.4 ± 7.9%, NT-proBBNP was 7667 ± 9876 pg/mL, creatinine level was 1.41 ± 0.88 and hemoglobin level was 12.4 ± 2 gr/dL. Median plasma levels of CA-125 were found to be significantly higher in patients with CKD as compared to those without CKD (46.9 [20.9-125.5] U/mL vs 25.4 [13.5-77.7] U/mL, p < 0.002, respectively). hsCRP levels were also found to be significantly higher in patients with CKD as compared to those without CKD (18.2 [6.0-46.3] mg/L vs 8.43 [3.48-19.3] mg/L, p < 0.001, respectively). As expected, NT-proBNP levels were higher in patients with CKD as compared to those without CKD (6634 [2723-15898] pg/mL vs 1482 [554-3665] pg/mL, p < 0.001 respectively). Furthermore, a significant correlation was found between eGFR and CA-125 (r=-,172, p < 0.001), eGFR and hsCRP levels (r=-,253, p < 0.001), eGFR and NT-proBNP (r=-,558, p < 0.001), eGFR and hemoglobin levels (r=,399, p < 0.001), and also eGFR and sodium levels (r=,153, p < 0.001).
Conclusions: The results of this study showed that impaired kidney functions in HF is associated with higher CA-125 and hsCRP levels, suggesting an inflammatory activation and worse clinical status of the disease in HF patients with CKD.

P2210

Plasma ferritin and transferring saturation in chronic heart failure: relation to clinical variables

L Voronkov[1]; A Lyashenko[1]; V Gorbachova[1]
[1]*NSC Institute of Cardiology M.D. Strazhesko, Heart failure, Kiev, Ukraine*

Background: According to FAIR-HF and CONFIRM-HF approach, both plasma ferritin (F) and transferrin saturation (TSAT) are considered to be an iron deficiency (ID) criteria in chronic heart failure (CHF). Nevertheless, it is still a question whether the obligate measurement of both F and TSAT is really necessary in detection of ID in CHF.
Purpose: To establish the relation of F and TSAT to clinical variables in CHF.
Methods: 45 stable CHF patients (pts), NYHA class II-IV, with left ventricular ejection fraction (LVEF) < 40% were examined. Plasma F and TSAT were determined by chemiluminescent immunoassay and colorimetric method, respectively. Beside routine clinical and laboratory examination, 6 min walk test, standardized endurance leg test and flow-mediated vasodilation (FMD) of the brachial artery were performed.
Results: Abnormal levels of F (< 100 ng/mL) were observed in 16 pts (35.5%), while abnormal levels of TSAT (< 20%) - in 31 pts (68.9%). Both F and TSAT levels didn't show significant differencies in regard to the age (< 60 or >60), sex, comorbidities (hypertension, diabetes), atrial fibrillation and hemoglobin level. In contrast to F, TSAT was lower in pts with LVEF <= 30%: 15 (2-37)% vs LVEF > 30%: 21 (8-37)%, p = 0.017; and in hyperuremic pts 15 (2-65)% vs 21 (6-48) % in non-hyperuremic pts, p = 0.022.
Plasma F demonstrated no significant correlations with numerous clinical and laboratory variables. Simultaneously, TSAT demonstrated the significant direct link with endurance leg test (r=0,27, p = 0.033), FMD (r=0.3, p = 0.046) and borderline link with 6 min walk test distance (r=0.27, p = 0.06), as well as with LVEF (r=0.26, p = 0.08).
Conclusions: In contrast to plasma F, TSAT in CHF is related to some important clinical variables that can reflect ID state. Possibly, TSAT alone is a relevant marker of ID, which requires guideline-recommended iron therapy.

P2211

Anaemia is associated with development of acute heart failure in patients with acute coronary syndrome: propensity-score matched study

RA Rui Azevedo Guerreiro[1]; J Pais[1]; K Congo[1]; D Bras[1]; J Carvalho[1]; M Carrington[1]; D Neves[1]; AR Santos[1]; B Picarra[1]; A Caeiro[1]; J Aguiar[1]
[1]*Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal*

Introduction: Anaemia is a prevalent comorbidity in patients with heart failure (HF), associated with worse prognosis as highlighted by 2016 ESC guidelines of HF, which reinforced the importance of its treatment to improve HF patients' outcomes. However, the role of anaemia in the development of acute HF in patients with acute coronary syndrome (ACS) is not well characterized.
Purpose: Authors pretend to evaluate if anaemia at admission for ACS is associated with in-hospital development of acute HF.
Methods: Observational retrospective study, with a sample of 594 consecutive patients admitted for ACS. Patients were divided in two groups: with anaemia, defined as haemoglobin at admission less than 12 g/dL, and without anaemia. Propensity-score was calculated to each patients taking into account age, sex, previous history of smoking, arterial hypertension, diabetes mellitus, hyperlipidaemia, myocardial infarction, percutaneous coronary intervention, coronary artery bypass graft, heart failure, significant valvular disease, stroke, peripheral artery disease, cancer, chronic obstructive pulmonary disease, dementia, family history of coronary artery disease, type of acute coronary syndrome justifying admission, severity of coronary artery disease, degree of revascularization and value of creatinine at admission. Each patient with anaemia was matched with a patient without anaemia with similar propensity-score. Outcome of acute HF was defined as evolution in Killip-Kimball classes 3 (acute pulmonary oedema) and 4 (cardiogenic shock) during hospitalization. The association of anaemia with acute HF was accessed in the matched-pairs with logistic regression and $p < 0.05$ was considered statistically significant.
Results: From the study sample of 594 patients, 120 (20.2%) patients had anaemia at admission. Matching each patient with anaemia with a patient without anaemia with similar propensity-score resulted in 120 matched-pairs of patients and a study sample of 202 patients, due to multiple matching of controls. Matched-pairs on propensity-score were similar in every variable used in the construction of the propensity-score, proving the correct pseudo-randomization. Anaemia at admission was associated with the development of in-hospital acute HF with an odds ratio (OR) of 1.11 (95% CI 1.04 – 1.19, $p = 0.003$).
Conclusion: Patients with anaemia at admission for ACS had in our propensity-score matched study a 11% greater probability of developing acute HF during hospitalization.

P2212

Do we properly treat iron deficiency with intravenous ferric carboxymaltose in clinical practice?

A Esteban Fernandez[1]; M Gonzalez Barja[1]; M Perez Serrano[1]; M Mendez Bailon[2]; C Ramirez[1]; M Garcia[1]; S Ortega[3]; A Travieso Gonzalez[3]; T Luque Diaz[3]; C Olmos Blanco[3]; D Vivas Balcones[3]; J Higueras Nafria[3]; I Vilacosta[3]; C Macaya Miguel[3]; R Bover Freire[1]
[1]*Hospital Clinic San Carlos, Heart Failure Unit, Madrid, Spain*; [2]*Hospital Clinic San Carlos, Internal Medicine Service, Madrid, Spain*; [3]*Hospital Clinic San Carlos, Cardiology Service, Madrid, Spain*

Introduction: Iron deficiency, with or without anemia, is a common finding in patients with heart failure (HF), and its intravenous correction with ferric carboxymaltose has been shown to improve the functional status and quality of life of the patients, according to FAIR-HF and CONFIRM-HF trials. However, there is less data about its effectiveness in clinical practice and the analytical follow-up of these patients.
Methods: We considered the patients in chronic follow-up in the HF Unit of our center in whom iron deficiency was detected in a routine analysis, according to 2016 ESC HF clinical practice guideliens criteria. The analytical and clinical characteristics of the patients were collected. Intravenous ferric carboxymaltose was administered, adjusting the dose according to patient weight and analytical parameters (500 or 1000 mg in a single dose, 15 minutes time infusion in daily hospital of the HF Unit). Then, clinical and analytical reevaluation was performed at 3 months after infusion.
Results: Ferric carboxymaltose was infused in 122 patients, and 80 (62% men) completed the follow-up with control at 3 months. Only one patient presented an adverse effect consisting in local allergic reaction. The mean age was 86 ± 8.4 years old. 7.4 % of the patientes was in NYHA I, 70.4% in NYHA II and 22.2% in NYHA III. The cause of his heart disease was: ischemic 42.3%, valvular 25.6 %, hypertensive 5% and other ones 27.1%. The mean left ventricular ejection fraction was 45.2 ± 17.3 %. The analytical parameters were (baseline-3 months post): Hemoglobin (Hb) 12.2 ± 1.6 vs. 12.8 ± 1.6 (ns); HCM 29.1 ± 2.9 vs. 30.0 ± 2.5 (ns); VCM 90.9 ± 6.9 vs. 93.9 ± 5.6 (ns); Iron 52.9 ± 26.9 vs. 75.2 ± 30.3 ($p = 0.03$); Ferritin 74.7 ± 126.1 vs. 322.8 ± 560.4 ($p = 0.02$); Transferrin 287.3 ± 66.5 vs. 236.7 ± 67.5 (ns); IST% 13.4 ± 6.6 vs. 22.1 ± 10.5 ($p = 0.04$) and NT-proBNP 4845.9 ± 8931.0 vs. 3627.2 ± 4301.1 ($p = 0.04$).
Conclusion: According to our results, the intravenous administration of ferric carboxymaltose in patients with iron deficiency and heart failure is safe and improves the analytical parameters of the ferric profile even 3 months after infusion. The impact on hemoglobin is lower, due to the multifactorial origin of anemia. In addition, there was a significant decrease in cardiac biomarkers.

P2213

Comparison of diagnostic criteria for iron deficiency in heart failure

LNLC Van Aelst[1]; M Abraham[2]; M Sadoune[3]; T Lefebvre[4]; P Manivet[3]; D Logeart[2]; JM Launay[3]; Z Karim[4]; H Puy[4]; A Cohen-Solal[2]
[1]*Catholic University of Leuven, Department of Cardiovascular Diseases, Leuven, Belgium*; [2]*Hospital Lariboisiere, Department of Cardiology, Paris, France*; [3]*Inserm UMR-S 942, Paris, France*; [4]*University Paris Diderot , INSERM U1149, Centre de Recherche sur l'inflammation, Paris, France*

Background: Iron status assessment in routine clinical care of heart failure (HF) patients is mainly based on circulating levels of ferritin and transferrin saturation (TSAT), with ferritin < 100 µg/L being diagnostic for absolute ID and ferritin 100–299 µg/L with TSAT < 20% meaning functional ID. Recently, hepcidin < 14.5 ng/mL and/or soluble transferrin receptor (sTfR) ≥ 1.59 mg/L were proposed to diagnose ID.
Purpose: We compared the diagnostic performance and concordance between ferritin/TSAT and hepcidin/sTfR for ID diagnosis in acutely decompensated and stabilized HF.
Methods: Data derive from a single center study, investigating the evolution of biomarkers upon presentation with ADHF and 30 days of follow-up (FU).
Results: Ferritin/TSAT levels at admission and 30 days of FU were available for 47 patients. At admission, twenty-seven patients fulfilled criteria for absolute ID (57%) and twelve patients for functional ID (26%). At 30 days of FU, 5 patients (11%) and 27 patients (57%) had absolute and functional ID respectively. Circulating levels of hepcidin and sTfR were available for 41 patients at admission. Thirty-four patients (83%) were ID. Twenty-seven patients (66%) were identified as ID by ferritin/TSAT and hepcidin/sTfR. Seven patients (17%) were considered ID based on hepcidin/sTfR yet not based on ferritin/TSAT. Six patients (15%) were considered ID based on ferritin/TSAT but not based on hepcidin/sTfR. There was no significant difference in the sensitivity of ferritin/TSAT and hepcidin/sTfR to detect ID at admission; yet there was only a weak association between both tests ($p = 0.78$, phi coefficient 0.04). Levels of hepcidin and sTfR were available for 46 patients after 30 days of FU; 36 patients were ID (78%) and 10 (22%) were non-ID. When comparing hepcidin/sTfR and ferritin/TSAT to diagnose ID at 30 days of FU, 63% of patients was similarly identified as either ID or non-ID in both assays, 24% was ID using hepcidin/sTfR yet not using ferritin/TSAT; 13% was ID using ferritin/TSAT yet not using hepcidin/sTfR. These differences did not reach statistical significance ($p = 0.2253$; phi coefficient 0.18). Comparing the detection rate of ID using either hepcidin/sTfR at admission and ferritin/TSAT at 30 days of FU, 24 patients (59%) were identified as ID in both assays. Three patients (7%) would be considered false negatives and 10 patients (24%) would be considered false positives using hepcidin/sTfR during ADHF if compared with ferritin/TSAT at 30 days of FU. The difference in ID detection using ferritin/TSAT at 30 days and hepcidin/sTfR at admission was borderline significant ($p = 0.05$), with a moderate measure of association (phi coefficient 0.30).
Conclusion: There is only a moderate correlation at most between ferritin/TSAT and hepcidin/sTfR to assess ID, urging for additional research to adequately detect ID using circulating biomarkers.

P2214

Prevalence of iron deficiency in acute decompensated and stabilized chronic heart failure

LNLC Van Aelst[1]; M Abraham[2]; M Sadoune[3]; T Lefebvre[4]; P Manivet[3]; D Logeart[2]; JM Launay[3]; Z Karim[4]; H Puy[4]; A Cohen-Solal[2]
[1]*Catholic University of Leuven, Department of Cardiovascular Diseases, Leuven, Belgium*; [2]*Hospital Lariboisiere, Department of Cardiology, Paris, France*; [3]*Inserm UMR-S 942, Paris, France*; [4]*University Paris Diderot , INSERM U1149, Centre de Recherche sur l'inflammation, Paris, France*

Background: In clinical studies, the reported prevalence of iron deficiency (ID) varies remarkably. Estimates range between 30-50% in patients with stable chronic heart failure (CHF), whereas 60-80% of patients are reported to be ID in acute decompensated HF (ADHF). We hypothesised that the timing of its assessment influences the reported prevalence of ID.
Purpose: We aimed to depict the spontaneous evolution of biochemical parameters of iron metabolism following presentation with ADHF and ensuing treatment; secondly, we wanted to unravel the pathophysiological processes explaining changing iron status.

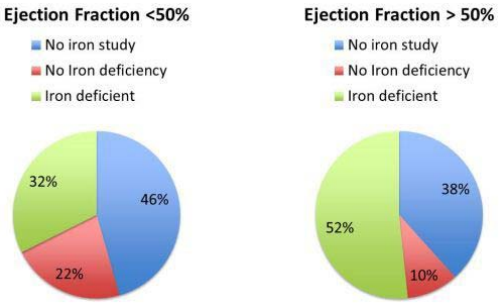
Methods: Data derive from a prospective, observational, single center study, investigating the evolution of biomarkers upon presentation with ADHF and 30 days of follow-up (FU). ID was defined as ferritin <100 μg/L or ferritin 100–299 μg/L with transferrin saturation <20%.
Results: We included 47 patients in the final analysis with a mean age of 70.4 years (y; SD 13.7 y), median ferritin of 93 μg/L (IQR 76 – 107 μg/L) and median brain natriuretic peptide (BNP) of 1004 pg/mL (IQR 652 – 1676 pg/mL) at baseline. At 30 days of follow-up, ferritin levels significantly increased (median: 159 μg/L, IQR 134 – 190 μg/L; $p < 0.0001$), BNP significantly decreased (median: 261 pg/mL, IQR 176 – 462 pg/mL; $p < 0.0001$). Whereas 57%, 26% and 17% of patients had absolute, functional and no evidence of ID respectively at admission, these respective percentages changed to 11%, 57% and 32% at 30 days of FU ($p = 0.00001$). There was only a moderate association between ID status at baseline and 30 days of FU using ferritin/TSAT (phi-coefficient 0.26). Changing ferritin levels between 0 and 30 days correlated with circulating soluble ST2 ($r^2 = 0.1152$; $p = 0.0278$) and TNFα ($r^2 = 0.0950$; $p = 0.0351$), but not with changing levels of mid-regional pro-adrenomedullin, BNP, procalcitonin, interleukin 6, CRP, growth differentiation factor 15, galectin-3, fibrinogen nor myeloperoxidase. Our results implicate systemic inflammation, not dilution, as one causative factor of increased ID prevalence in ADHF compared to CHF.
Conclusion: During ADHF, ID diagnosis based on ferritin levels and transferrin saturation is unreliable: indices of iron metabolism vary and only reach a steady state several weeks after remission of ADHF. Systemic inflammation, not dilution, may be one of the causative factors of altered iron status between admission and steady state. These results suggest that ID diagnosis and correction should only be undertaken at distance of an ADHF episode.

P2215

Assessment and treatment of iron deficiency in patients hospitalised for heart failure

S L Su Ling Tee[1]; N B Leonardo[2]
[1]Queen Elizabeth Hospital, Cardiology, Adelaide, Australia; *[2]Lyell McEwin Hospital, General Medicine, Adelaide, Australia*

Introduction: Iron deficiency (ID) is common in patients with heart failure (HF). Despite current guidelines and existing evidence stating the importance of ID as a co-morbidity in patients with chronic HF, ID has continued to remain under-diagnosed and under-treated by physicians in clinical practice, including in patients hospitalised for acute decompensation.
Purpose: To investigate whether hospitalised patients with HF were screened routinely for ID within 12 months of their admission, and whether they were managed according to the latest recommendations.
Methods: This retrospective observational study included 154 patients who were admitted over a 6-month period with a primary diagnosis of decompensated HF. Anaemia was defined as haemoglobin <13g/dL for men and <12g/dL for women. ID was defined as either serum ferritin <100μg/mL, or serum ferritin 100-299μg/mL and transferrin saturation <20%.
Results: Out of the 154 included patients, 68 patients had an ejection fraction (EF) of <50%, while 60 patients had heart failure with preserved ejection fraction (HFpEF). The other 26 patients' EF was unknown. Slightly more than half (82; 53.25%) of all patients had had a recent iron study. Of the 82 patients who had iron studies performed, 60 (38.96%) had ID. However, only 22 (36.67%) received iron replacement therapy. 100 patients (64.94%) were found to be anaemic, with only 66 of them being investigated for ID. 52 out of the 66 patients (78.79%) were later found to be iron-deficient but only 20 (38.46%) of them were treated. In patients with no evidence of anaemia, iron parameters were only assessed in 15 (27.78%) of them. 7 non-anaemic patients were iron-deficient, but only 1 patient was treated. One patient with HFpEF who had ID and anaemia was treated with blood transfusion only. Patients with ID were more likely to get treated when they were admitted under General Medicine rather than Cardiology (39.13% versus 18.92%).
Conclusion: Although the prevalence of ID in our study was consistent with that described in current literature, we suspect the actual prevalence could be higher, as many patients did not have an assessment of their iron status. Despite its small patient sample, this retrospective study demonstrated that assessment of iron status has continued to remain overlooked in patients with HF, and that strategies to reinforce awareness in treating physicians are necessary.



Assessment of ID based on EF

P2216

Anaemia is associated with higher mortality risk in patients presenting to the emergency department with acute dyspnoea

K Cerlinskaite[1]; G Ziubryte[2]; I Jonauskiene[3]; D Rimkeviciute[3]; L Badgonaite[4]; A Mebazaa[5]; A Kavoliuniene[3]; J Celutkiene[4]

Funding Acknowledgements: The work was supported by the Research Council of Lithuania, grant Nr. MIP-049/2015 and approved by Lithuanian Bioethics Committee, Nr. L-15-01.

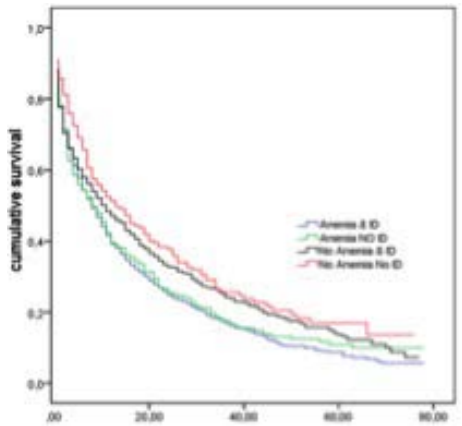
Introduction: Acute dyspnoea or shortness of breath is one of the chief complaints occurring among patients in Emergency Department (ED). Prognosis of the patients often remains uncertain, therefore accurate risk stratification would be of benefit. The AHEAD score is a recently developed simple prognostic scoring system evaluating the role of important co-morbidities in patients with acute heart failure (AHF). We performed a pilot investigation on whether the AHEAD score or any of its independent variables would be valuable in predicting outcomes in broader ED patients' population with acute dyspnoea of any cause.
Purpose: To examine the prognostic value of AHEAD score and its separate parameters in patients with acute dyspnoea presenting to the ED.
Methods: Prospective two-centre observational cohort study enrolled consecutive patients admitted to the ED with acute dyspnoea due to acute heart failure (AHF), exacerbation of chronic obstructive pulmonary disease (COPD), pneumonia, pulmonary embolism (PE) and other conditions. Parameters for AHEAD (A- atrial fibrillation (AF), H – haemoglobin <130 g/l for men and 120 g/l for women (anaemia), E – elderly (age>70 years), A – abnormal renal parameters (creatinine>130 μmol/l), D – diabetes mellitus (DM), each counted as 1 point) score were obtained at the time of admission. Patients (N=266, mean age 68 ± 13 years, 61.3% male) were followed-up after 1, 3 and 12 months. Main outcome was one year all-cause mortality, which was measured by performing logistic regression on AHEAD score and on its five parameters to determine mortality risk and odds ratios (ORs). Data was analysed using SPSS v22 statistical package.
Results: AHF was the main cause of dyspnoea among our patients (47% of the cases), PE was present in 8% of the cases, COPD exacerbation – in 6%, pneumonia – in 5%, while others were less common. The AHEAD score variables were frequent in study population: 48.9% of the patients were >70 years old, AF was present in 47.7% of the cases, anaemia in 35.7%, abnormal renal parameters in 23.7% and DM in 22.9%. The mean AHEAD score was 1.79 ± 1.3. One year mortality rate was 29.3%. There was no statistically significant one year all-cause mortality risk associated with AHEAD total score. When analysing its parameters in logistic regression, anaemia was associated with significantly increased mortality risk with OR 1.83 (95% confidence interval (CI): 1.05 to 3.19, $p = 0.032$) with no other parameter showing statistically significant results. Unadjusted OR for anaemia was 1.87 (95% CI: 1.09 to 3.22, $p = 0.023$).
Conclusions: AHEAD scoring system based on the analysis of the co-morbidities did not prove to be useful in this broad patients' cohort with acute dyspnoea of any cause. Nonetheless, anaemia was associated with significantly higher mortality risk at one year for patients presenting to the Emergency Department with acute dyspnoea. This finding may have a therapeutic implication in this patient population.

P2217

Impact of anemia and iron deficiency on long-term mortality and heart failure hospital re-admissions among patients hospitalized for heart failure: a regional population-based investigation from italy

P Lesizza[1]; MD Tinti[1]; A Cherubini[1]; G Barbati[1]; G Russo[1]; S Tolone[1]; D Del Sindaco[1]; L Tarantini[1]; G Cioffi[1]; G Pulignano[1]; A Di Lenarda[1]
[1]*Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy*

Background: In Registries on acute heart failure (HF), anaemia (AN) and iron deficiency (ID) are common, particularly in patients hospitalized with severe HF, women, elderly and with renal impairment. AN and ID showed in some studies a negative independent prognostic value. Aim of the present study was to analyze the frequency and prognostic relevance of AN&ID in patients admitted in 2009-2014 for acute HF in the area of our city in Northern Italy.
Methods: Data were retrieved from the Cardiovascular Observatory of our city. Different databases were linked: hospital records with discharge diagnosis, cardiological chart, laboratory tests, registry of death. HF diagnosis included ICD-9th codes for heart failure (428.x) and hypertensive heart failure (402.01, 402.11 and 402.91) according to National Outcome Evaluation Program (PNE). Patients were include in the analyses if hemoglobin (Hb), ferritin and TSAT were available. AN was defined as Hb <12 g/dl in females and <13 g/dl in males; ID as ferritin <100 ug/L or ferritin 100-300 ug/L and TSAT $<20\%$. "Worsening" HF (WHF) was classified in presence of at least one HF hospitalization in the 5 years preceding the index admission.
Results: Out of 7466 hospital admissions, 3046 (40.8%) were available for evaluation. AN&ID was present in 49.8% of cases, Only ID in 6.2%, only AN in 10.3%, NO AN & NO ID in 33.7%. Patients with AN&ID vs NO AN & NO ID showed an older age (82.5 vs 79 yo, $p<0.001$), more frequent female gender (61.9% vs 40.5%, $p<0.001$), worsening HF (47.1% vs 34.7%, $p<0.001$), Charlson index ≥ 3 (76.4% vs 62.1%, $p<0.001$), HFpEF (61.2% vs 47.4%, $p<0.001$) and CKD-EPI <60 ml/min (77% vs 56.3%, $p<0.001$). Follow-up was 33 months. KM curves were significantly different among the 4 groups ($p<0.001$). At multivariate analysis age (HR 1.02; 95% CI 1.01-1.03; $p<0.001$), male gender (1.15; 1.01-1.31; $p=0.028$), Charlson index ≥ 3 (1.42; 1.22-1.65; $p<0.001$), worsening HF (1.69; 1.49-1.93; $p<0.001$), BNP ≥ 450 pg/ml (1.36; 1.20-1.55; $p<0.001$) were independently associated to all-cause mortality. AN&ID showed a trend of correlation (HR 1.25; 95% CI 0.96-1-64; $p=0.098$).
Conclusions: AN&ID are frequent in acute HF particularly in elderly female patients, with worsening HF, HFpEF and multimorbidity (specifically renal impairment). AN&ID are less strongly related to mortality. The correlation with symptoms and re-hospitalizations may improve our understanding of the clinical impact of AN&ID on quality of life of HF patients.



AN and/or ID and survival

P2218

Prognostic impact of different trends of renal function before, during and after hospitalization for acute decompensated heart failure: cardio-renal interactions and 180-days cardiac mortality

L Ludovico Lazzari[1]; A Faggioni[2]; D Bovelli[1]; G Ambrosio[3]; E Boschetti[4]
[1]*Az. Osp. "S. Maria", Cardiology Department, Terni, Italy*; [2]*Nottingham University Hospitals NHS Trust, Cardiology Department, Nottingham, United Kingdom*; [3]*Hospital Santa Maria Della Misericordia, Cardiology and Cardiovascular Pathophysiology Division \ University of Perugia, Perugia, Italy*; [4]*Az. Osp. "Santa Maria" Terni \ University of Perugia, Cardiology Department, Terni, Italy*

Background: In the setting of acute decompensated heart failure (ADHF) worsening renal function (WRF) has been associated inconstantly with a poor prognosis; even less is known on improved renal function (IRF) and the association between the two phenomena.
Purpose: to better characterise WRF and IRF (prior, during and after hospitalization) and their associated risk of 180 days cardiovascular (CV) mortality.
Methods: Consecutive patients with a discharge diagnosis of ADHF were reviewed. IRF was defined as a reduction of $\geq$ 0,3 mg\dl in serum creatinine and an improvement by $\geq 20\%$ in glomerular filtration rate (GFR), whereas a worsening in creatinine and GFR by the same cut-offs defined WRF. Patients who received renal replacement therapy, contrast medium or transfusions were excluded from this study. Mortality was judged as CV unless a clear non-cardiac cause was identifiable. Pre-admission and post-discharge lab test within a six-month period of time were collected; chronic renal failure (CRF) was defined as GFR $<$ 60 ml\min for at least three months prior hospitalization.
Results: In a six month period,121 patients were eligible. During hospitalization, 23.9% of them experienced IRF whilst 42.1% WRF. Differently from the in-hospital WRF group, those undergoing IRF had an increased risk of short-term CV mortality (HR = 4.3, 95% CI 1.6–11.6, $p=0.004$; $p<0.05$ even after adjustment for baseline characteristics, in-hospital and discharge medications; for any level of GFR at discharge and for GFR $>$ 30 ml\min on admission). IRF patients showed no difference in the prevalence of signs of venous congestion or medications used; however, they needed more diuretics to obtain a similar diuresis ($p=0.04$) and had a greater neuro-hormonal activation on admission, with a higher BUN\creatinine ratio (56 ± 19 vs 44 ± 15, $p=0.001$) and lower levels of sodium (134.9 ± 5 vs $136.9\pm 3,8$ mEq\L, $p=0.02$). IRF-patients, compared to the WRF group, had a lower GFR on admission (35.1 ± 14.5 vs 64.8 ± 23.6 ml\min, $p<0.001$) but no different values at discharge (58.9 ± 22.2 vs 55.3 ± 21.2 ml\min, p = NS); moreover, the prevalence of CRF was similar (p = NS), thus suggesting a pre-admission WRF in the IRF group. In fact, we found an association between in-hospital IRF, pre-admission WRF (OR = 15, 95% CI 4.6-48, $p<0.001$) and post-discharge WRF (OR = 3.6, CI 95% 1.1-11.6, $p=0.03$). After adjustment for any level of admission GFR, a pre-admission WRF was found to be an independent predictor of CV mortality (adjusted HR=5.9, 95% CI 2–17.4, $p=0.02$).
Conclusion: pre-admission WRF, in-hospital IRF and post-discharge WRF are associated phenomena with an higher risk of CV mortality. We agree with other authors that IRF may represent the resolution of a pre-admission WRF, induced by venous congestion. This trend, together with a marked neuro-hormonal activation, may signify a more advanced stage of heart failure.

P2219

Interrelationship between renin-angiotensin-aldosterone system and oxidative stress in chronic heart failure patients with impaired renal function

M Reina Couto[1]; T Sousa[1]; M Morato[2]; J Afonso[1]; J Carvalho[1]; L Morgado[3]; FB Fernandes[4]; VP Leite[4]; D Casarini[4]; P Bettencourt[3]; A Albino-Teixeira[1]
[1]*University of Porto, Faculty of Medicine, Porto, Portugal*; [2]*University of Porto, Faculty of Pharmacy, Porto, Portugal*; [3]*Sao Joao Hospital, Porto, Portugal*; [4]*Univ. Federal de São Paulo, Dep. Medicina, São Paulo, Brazil*

Introduction: The coexistence of kidney and heart failure (HF) is increasing and represents a major clinical challenge nowadays defined as cardiorenal syndrome (CRS). Chronic activation of the renin-angiotensin-aldosterone system (RAAS) can increase oxidative stress which in turn can lead to renal injury and to a vicious cycle of more sodium and water retention in CRS type 2. Furthermore, accumulating evidence indicates that reactive oxygen species also regulate the activation of RAAS.
Purpose: To evaluate oxidative stress and RAAS in patients with chronic HF and to compare the relationship between these systems in patients with normal (nRF) or impaired (iRF) renal function (estimated glomerular filtration rate $>$ or $<$ 60 mL/min per 1.73 m2, respectively).
Methods: Sixty CHF patients from the Heart Failure Clinic of our hospital consent to participate according to the principles of the Declaration of Helsinki of the World Medical Association. Urinary H2O2 (U-H2O2), plasma and urinary isoprostanes (P- and U-Isop), plasma total antioxidant status (P-TAS), plasma and urinary angiotensinogen (P- and U-AGT), plasma renin activity (PRA), angiotensin converting enzyme (ACE) activity, angiotensin I (Ang I), angiotensin II (Ang II) and angiotensin 1-7 (Ang 1-7), biomarkers of cardiac dysfunction/injury (B-type natriuretic peptide, BNP; troponin I) and renal parameters were evaluated.
Results: Severe CHF patients (New York Heart Association, NYHA, classes III and IV) had higher levels of U-Isop (3.9 ± 0.7 vs 2.6 ± 0.3 ng/mg creatinine, $p<0.01$) and lower levels of ACE activity (11.0 ± 2.7 vs 12.4 ± 3.0 U/L, $p<0.05$) but no differences in other oxidative stress or RAAS parameters. Patients with iRF had higher U-AGT than those with nRF (58 ± 16 vs 15 ± 3 μg/g creatinine, respectively) and presented positive correlations between oxidative stress and RAAS markers (U-H2O2 vs P-AGT, U-Isop vs P-AGT, U-H2O2 vs U-AGT, U-H2O2 vs PRA, U-Isop vs ACE activity, PRA vs aldosterone). In contrast, in CHF patients with nRF, we mainly observed negative correlations between oxidative stress and RAAS parameters

(U-H2O2 vs Ang II; P-Isop vs P-AGT). Of note, we only found positive correlations of oxidative stress or RAAS markers with biomarkers of cardiomyocyte dysfunction/injury (U-Isop vs BNP; U-Isop vs Troponin I; PRA vs Troponin I) or with biomarkers of renal dysfunction (U-Isop vs urinary protein-to-creatinine ratio) in patients with impaired renal function.
Conclusions: CHF patients with renal dysfunction have higher intrarenal RAAS activation, evidenced by increased U-AGT. Furthermore, positive correlations between RAAS and oxidative stress were mainly observed in patients with renal dysfunction. This suggests that the addition of antioxidant treatment to these patients could exert renoprotection in the setting of CRS where no specific therapy was shown to be beneficial until now.

P2220
State of kidney in patients with chronic heart failure

SI Elmurodov[1]; AA Madaliyev[1]
[1]*Tashkent Medical Academy, Cardiology, Tashkent, Uzbekistan*

Background. Chronic heart failure (CHF) is currently one of the main problems of modern cardiology and public health.
Purpose: To study changes in renal function and their relationship with the severity of clinical symptoms and quality of life in patients with chronic heart failure.
Material and methods: The study group included 27 patients with chronic heart failure (CHF), different functional classes with left ventricular ejection fraction less than 40% (LVEF $<40\%$) held in-patient treatment in coronary care and cardiology departments. As a control group examined 25 patients with coronary heart disease (CHD), (stable angina functional class (FC) II-III, postinfarction cardiosclerosis (PICS)), held in-patient treatment in the department of cardiology.
Results: In the study group, 14 patients had serum creatinine concentration within the normal range (71-115 umol / L), 10 patients increased slightly (norm: 123 mmol / l for women and 132 mmol / l for men). When calculating GFR, GFR normal levels (> 90 ml / min) were detected in 4 (13.3%) patients, a decrease in GFR to 60-89 ml / min was observed in 13 (46.6%) ($p \leq 0.05$) of patients to 30-59 ml / min, in 12 (40.0%) ($p \leq 0.05$ in the control group of patients with a creatinine concentration was normal in 27 (90.0% serum) ($p \leq 0.05$) patients and slightly elevated in 3 (10.0%) patients. It highlights the need for calculation of GFR for the timely diagnosis of renal dysfunction in patients with CHF.
Conclusion: The growth of FC in CHF leads to more frequent cases of chronic kidney disease. When FC I and II of heart failure, according to GFR, chronic kidney disease was significantly less, than in patients with chronic heart failure FC III and IV. Reduction of hemodynamic parameters associated with reduced glomerular filtration rate, which indicates the necessity of their correction to reduce the incidence of chronic kidney disease and improve the quality of life in patients with severe FC of CHF.

P2221
Predictors of acute kidney injury in acute cardiorenal syndrome

M Dankova[1]; Z Minarikova[2]; V Hricak[3]; J Gergel[4]; B Zitny[5]; P Pontuch[2]
[1]*The National Institute of Cardiovascular Diseases, Department of Heart Failure and Heart Transplant, Bratislava, Slovak Republic*; [2]*University Hospital, 4th Department of Internal Medicine, Bratislava, Slovak Republic*; [3]*The National Institute of Cardiovascular Diseases, Department of Emergency Cardiology, Bratislava, Slovak Republic*; [4]*Medirex OJSC, Bratislava, Slovak Republic*; [5]*STUVITAL s.r.o., Bratislava, Slovak Republic*

Aim: Aim of the study was to identify independent predictors of acute kidney injury (AKI) in patients with acute heart failure (AHF).
Methods: We analysed clinical, echocardiographic parameters and selected biomarkers in 74 consecutive patients admitted to intesive care unit due to AHF. Mean age of the patients was $69 \pm 10{,}3$ years, with gender distribution 48/26 (M/W). Majority of patients were admitted with de novo diagnosed AHF (55,4%). HFrEF/HFmrEF/HFpEF was in 34/24/16 patients. Mean value of systolic blood pressure (BP) was $140{,}6 \pm 30$ mmHg. Renal damage was defined according to KDIGO guidelines based on creatinine levels and daily diuresis. Patients were divided into two groups AKI + (with renal injury, n=20) and AKI- (without renal injury, n=54). Age, BMI, systolic BP, urinary NGAL, s-NTproBNP, hemoglobin, LVEF were included into the multivariate regression analysis.
Results: The development of AKI was recorded in 27% of patients. These patients were older (median age: 76 vs. 64 years, $p = 0{,}007$), with lower BMI (median: 27 vs.29 kg/m2, $p = 0{,}02$), particularly in HFrEF group (45,8%, $p = 0{,}002$). Urinary NGAL at admission was significantly higher in the AKI + compared to AKI – group (154 vs. 19,5 ng/ml, $p = 0{,}0001$). Except BMI, parameters as age (OR 2,3: 95% CI 1,7-3,7, $p = 0{,}03$), systolic BP (OR 3,0: 95% CI 1,0-5,6, $p = 0{,}02$), u-NGAL (OR 0,97: 95% CI 0,95-0,99, $p = 0{,}0001$) , s-NTproBNP (OR 1,03: 95% CI 0,94-0,98, $p = 0{,}001$), s-hemoglobin (OR 1,4: 95% CI 0,99-1,8, $p = 0{,}04$) and LVEF (OR 1,1: 95% CI 1,02-1,22, $p = 0{,}007$) significantly identified development of AKI.
Conclusions: The predictors of AKI in the AHF patients were age, systolic BP, elevated levels of cardiac failure markers and also renal injury markers together with determination of LVEF and s-hemoglobin at admission.

P2222
Cardiotoxicity in breast cancer patients receiving trastuzumab - assessing the clinical need for a structured cardio-oncology service

A Mcinerney[1]; D Hughes[1]; P Morris[1]; B Mcadam[1]
[1]*Beaumont Hospital, Dublin, Ireland*

Introduction: Trastuzumab has revolutionised the management of HER2 positive breast cancer. However, cardiotoxicity is a well recognised complication. Many patients also receive anthracyclines which can increase this risk. We reviewed the incidence of left ventricular ejection fraction (LVEF) reduction in patients who received trastuzumab in our hospital to assess the need for a structured Cardio-oncology service.
Methods: Review of charts and all echocardiograms (ECHO) for patients who received trastuzumab therapy between 2010 and 2015.
Results: Between 2010 and 2015, 134 patients completed trastuzumab treatment for breast cancer. Follow up data were available on 109. All were female. The average age at first dose was 52 years (SD 12.8). Ninety nine (91%) were invasive ductal carcinoma with 6 (5.5%) being lobular. Eleven (10%) had metastatic disease, 51 (46.8%) had node positive disease and 47 (43.1%) were node negative. Cardiovascular (CV) comorbidities included six (5.5%) with ischaemic heart disease, twenty-two (20.1%) with hypertension, seventeen (15.5%) with dyslipidaemia, three (2.75%) with type II diabetes mellitus and five (4.6%) with atrial fibrillation. Thirty eight (34.9%) had a smoking history. Prior to chemotherapy, 16 (14.7%) were taking either an ACE inhibitor or an ARB, 12 (11%) a beta blocker, 11 (10%) a calcium channel blocker, 5 (4.6%) a loop diuretic and 5 (4.6%) a thiazide diuetic. Fifteen (13.7%) patients were taking an antiplatelet or an anticoagulant. The average number of trastuzumab doses per patient was 17.87. Thirty four (31.2%) received an anthracycline. Seventy five (68.8%) had chest wall radiotherapy: forty (36.7%) to the left chest. Seven (88.9%) had tumour resection. The average number of ECHO's per patient was 5.7. Four had LVEF of less than 50% pre-chemotherapy. Valvular disease was common (16 patients (14.5%)). Twelve (11%) patients had an EF drop by >10%. Of these, two were being treated for metastatic disease. CV risk factors were identified in eight (66.7%). Two had inadequately controlled hypertension. One of these also had atrial fibrillation and dyslipidaemia. One patient had a left bundle branch block on baseline ECG. Six had a smoking history. Seven patients had received an anthracycline, four had left sided radiotherapy. Two had their trastuzumab discontinued and one had a dose reduction. Seven (59%) patients did not have full recovery of their LVEF. Two patients had a Cardiology referral. Both had assessments for other causes and had evidence based therapies commenced or titrated. The remainder did not.
Conclusion: LVEF reduction occurred in 11% in keeping with previously reported figures. The lack of LVEF recovery was unexpected. This may be due to other causes of LVEF dysfunction which were not investigated. Many had known CV risk factors which were not adequately controlled. This demonstrates the need for a more structured Cardio-oncology service within our institution.

P2223
The effect of cardiovascular risk factors and tumor histologic grade in the risk of cardiotoxicity

AC Ana Catarina Gomes[1]; LR Lopes[1]; AG Ferreira[1]; M Correia[1]; I Rangel[1]; K Congo[2]; P Fazendas[1]; H Mansinho[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*; [2]*Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal*

Introduction: Cardiotoxicity can be a side effect of chemotherapy (CT) including anthracyclines and taxanes for whom the presence of cardiovascular risk factors also impact. The effect of cancer itself in the risk of developing cardiotoxicity remain to be clarified.
Aim: Prospective study including cancer patients submitted to anthracyclines ± taxanes ± radiotherapy (RT) ± trastuzumab and referred to echocardiographic monitoring during treatment: T0 – before CT, T1 – after the first cycle, T2 – after third cycle, T3 – at the end of CT and T4 - 1 year after the end of CT. The effect of cardiovascular risk factors and the histologic grading of cancers in the risk of developing cardiotoxicity was studied as well as the cardioprotective effect of some drugs, used for other indications.
Results: 108 patients, 79.6% females, age 52.47 ± 12.2 years. Breast cancer 69.4% (29.4% right, 23.9% left and 1.8% bilateral breast cancer; tumor grade: G1 3.7%, G2 48.6%, G3 14.7%), lymphoma 22.2%, gastric cancer 8.3%. Epirrubicine 52.3% and doxorrubicine 47.7%: cumulative dose 506 ± 222 mg/m2. Docetaxel 57.8% and Paclitaxel 2.8%: cumulative dose 511 ± 111 mg/m2. Diabetes Mellitus (DM)

7.3%, hypertension 27.5%, dyslipidaemia 20.2%, obesity 40.4%, smoking 15.6% and alcohol intake 14.6%. 50.5% submitted to Radiotherapy (RT) – median 50GY. Left ventricle ejection fraction (LVEF) and global longitudinal strain (GLS) at baseline: 64.14 ± 4.63% e 20.73 ± 2.68%. 22.9% of patients were taking beta-blocker, calcium channel blocker, ACE inhibitors/ARBs or spironolactone due to hypertension and/or statin for dyslipidemia. The hypertensive patients had a higher LVEF variation between T0-T3 (p = 0.02), although similar GLS, TAPSE and tricuspid S' values in the same interval. GLS at T2 and LVEF at T3 in DM patients were significantly lower (p = 0.018 and p = 0.036, respectively). DLP patients had lower lateral and septal e' values at T1 (p = 0.022 e p = 0.020, respectively). The obese patients had significantly lower lateral e' at T1 (p = 0.008), and a trend for higher TAPSE values – reaching statistically significant value at T3 (p = 0.036) and lower GLS variation in T0-T3 (p = 0.026). At T1, GLS was significantly better in G1 tumors versus G2 (p = 0.001). Lateral S' was lower in G2 tumors versus G3 (p = 0.767). T3: TAPSE was superior in G1 tumors versus G3 (24.0 ± 2.65 versus 19.9 ± 1.6, p = 0.008). There was no difference in LVEF, GLS, TAPSE, tricuspid S' variation in T0-T4, between patients with or without cardioprotective drug and/or statins: p = 0.915, p = 0.599, p = 0.268, p = 0.767 respectively.

Conclusion: Hypertension and dyslipidemia were associated with higher left ventricular dysfunction. Obesity seems to be a protective factor in the risk of developing systolic biventricular dysfunction. The tumor differentiation grade also impacted in systolic biventricular dysfunction. The use of cardioprotective therapy previous to systolic dysfunction didn't seem to have benefit in preventing cardiotoxicity.

P2224

Evaluation of routine use of global longitudinal strain for the early detection of subclinical left ventricular dysfunction in cancer patients

LM Michal Laufer-Perl[1]; A Milwidsky[1]; B Sadeh[1]; D Ravid[1]; N Amrami[1]; M Derakhshesh[1]; J Sherez[1]; G Keren[1]; Y Arbel[1]; Y Topilsky[1]
[1]*Tel Aviv Sourasky Medical Center, Cardiology, Tel Aviv, Israel*

Background: Cardiac toxicity from cancer therapy has become a leading cause of morbidity and mortality in survivors, reaching mortality rate as high as 60% in two years. The most commonly used definition is a reduction in left ventricular ejection fraction (LVEF). However, according to the recent American and European Society of Echocardiography Expert Consensus, global longitudinal strain (GLS) is the optimal parameter for early detection of subclinical LV dysfunction.
Objectives: To evaluate the frequency of GLS reduction in cancer patients and its correlation to LVEF reduction and other echocardiography parameters.
Methods: A retrospective, single-center observational study that included 62 consecutive patients evaluated in the Cardio-oncology clinic from February to December 2016. All patients performed at least two echocardiography exams, including GLS. All exams were performed with the same vendor, technician and interpreting cardiologist. Excluded were patients with reduced LV function (Ejection Fraction < 55%) at baseline. We evaluated the frequency of GLS reduction (once by ≥10% and then by ≥15% relative reduction), its correlation to LVEF reduction and if there are other predicting echocardiographic parameters.
Results: Among 62 consecutive patients, 14 patients (23%) had ≥15% relative reduction in GLS, of which 71% had no concomitant EF reduction. Moreover, 22 patients (32%) had ≥10% relative reduction in GLS, of which 68% had no EF reduction. There were no significant differences in the baseline characteristics; however, exposure to chest radiation was significantly correlated to GLS reduction. No other echocardiography parameters (including diastolic parameters, right ventricular function or systolic pulmonary artery pressure) were significant predictors for GLS reduction.
Conclusions: Early identification of cardiac dysfunction is essential for the prevention of symptomatic heart failure. Our study demonstrates that GLS reduction is frequent among cancer patients and precedes the LVEF reduction and cannot be anticipated by other echocardiography parameters. Using GLS routinely during cancer treatment may lead to an early cardio protective treatment and prevention of irreversible LVEF reduction and heart failure.

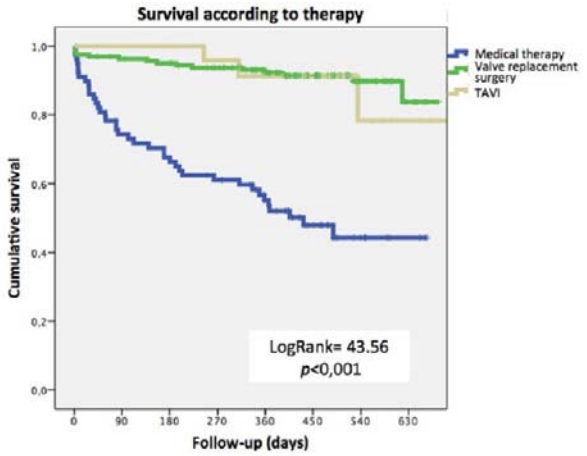
VALVULAR HEART DISEASE (DIAGNOSIS, MANAGEMENT AND INTERVENTIONAL THERAPIES)

P2225

Severe aortic stenosis: experience and outcomes of a tertiary center

J Agostinho[1]; I Goncalves[1]; I Ricardo[1]; J Rigueira[1]; A Ferreira[1]; R Santos[1]; T Guimaraes[1]; G Lima Da Silva[1]; A Francisco[1]; M Meneses[1]; FJ Pinto[1]; A Almeida[1]
[1]*Hospital Universitário de Santa Maria/CHLN, CAML, CCUL,Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*

Introduction: Aortic stenosis continues to be the most prevalent valvulopathy, conditioning high morbidity and mortality. Transcatheter aortic valve implantation (TAVI) remerged as a revolutionary therapy in patients (pts) with high surgical risk, and it may alter the paradigm in the treatment of severe aortic stenosis (sAS). This study aims to characterize the population of pts from a tertiary center with diagnosed sAS during the year 2015 and its therapeutic approach.
Methods: retrospective unicentric study, with inclusion of consecutive pts with sAS (excluding low-flow low-gradient and paradoxical aortic stenosis) diagnosed during 2015 in a tertiary center. Clinical, laboratory and echocardiographic parameters were collected at the time of diagnosis and the type of therapy (medical, surgical, percutaneous) and mortality were evaluated.
Results: A total of 278 pts were included (54% women and 46% men, mean age 74 ± 9 years). The most frequent found comorbidities were hypertension (83.3%), dyslipidemia (67.4%), chronic kidney disease > 3 (34.4%), coronary artery disease (33%), diabetes (32.5%) and smoking (13.7%). Concerning echocardiographic evaluation, the mean left ventricular ejection fraction was 58 ± 11.14% and the peak aortic jet velocity was 4.58 ± 0.5 m/s, conditioning a mean gradient of 52.2 ± 12.7 mmHg. The valve area was 0.75 ± 0.2 cm2 (0.43 cm2/m2 when indexed to body surface area- BSA). The left ventricular mass/BSA mean value was 149.69 ± 41.2 g/m2. 33% of the pts also had significant aortic and/or mitral regurgitation. The majority of the pts was symptomatic, with angor being the most reported symptom (79%) and 43% of pts were in functional NYHA class II. The mean value of NTproBNP was 6911pg/mL.
In this population,167 pts (60.3%) underwent valvular replacement surgery, 4(1.4%) had aortic percutaneus valvuloplasty and 24 underwent TAVI (8.7%). The remaining patients (29.6%, n=82), were maintained under optimized medical therapy and follow-up. The overall mortality rate was 22.1%, and it was significant higher when conservative strategy was adopted (50% vs. 9.3% in pts undergoing surgery vs. 12.5% in pts undergoing TAVI).
Conclusions: This sample, composed of elderly pts with several cardiovascular comorbidities, shows the experience of a tertiary center in the post-TAVI era and reinforces the unequivocal superiority of aortic valve intervention (surgical and/or TAVI) versus conservative medical therapy. TAVI thus emerges as a safe option, comparable to surgery, in this real-life population.



P2226

Epidemiological characteristics; clinical and echocardiographic evaluation of rheumatic mitral stenosis in men

A Abir Abardazzou[1]; S Oummou[1]; A Raouah[1]; S El Karimi[1]; D Benzeroual[1]; M El Hattaoui[1]
[1]*Marrakech University Hospital, the cardiology department , Marrakech, Morocco*

Introduction: In most developing countries, the rheumatic mitral stenosis, sequelae of acute rheumatic fever, is one of the first affections of the young adult. According to the published series, the proportion of women affected mitral stenosis is twice as high as that in men population.
Material and Methods: We report the results of a retrospective study, over 3 years (January 2014 - January 2017), and collected from 300 files of patients with rheumatic mitral stenosis, followed in the cardiology department of University Hospital, MOROCCO.
The objective of our work is to identify the particularity epidemiological; Clinical and echocardiographic of rheumatic mitral stenosis in men.
Results: The series consists of 130 men and 170 women; The average age of women was 38 years compared with 45 years for men; The majority of men (70%) are diagnosed after the age of forty.

The Clinical presentation shows no specificity between the two sexes.
Heart failure and complete atrial fibrillation arrhythmias are the most frequent complications in both sexes; With a clear predominance of the complete atrial fibrillation arrhythmias in women (80%) against 60% of men.
The calcifications of the mitral valve and the shortening of the device under valvular are found in 82% of the men against 52% of the women.
The mitral stenosis was very tight in women (68%) and tight in men (50%).
Associated aortic valvulopathy was more common in men with 80% versus 64% in women.
The left atrial dilation and intra-auricular thrombus were more common in women, whereas that men had more dilated cavities.
Conclusion: Through this study we concluded that in man, the diagnosis of rheumatic mitral stenosis arises later; The rheumatic lesions are more severe and the aortic valvular involvement is more frequently associated.
The repercussion on the right cavities is more frequent, whereas that, the passage in complete atrial fibrillation arrhythmias as well as the intra-auricular thrombus are less observed in the man.

P2227
Predictors and long-term outcomes after transcatheter aortic valve replacement in high-risk patients with severe aortic stenosis

E Munoz-Garcia[1]; M Munoz-Garcia[1]; AJ Antonio Jesus Munoz Garcia[2]; AJ Dominguez-Franco[2]; F Carrasco-Chinchilla[2]; JM Garcia-Pinilla[2]; L Morcillo-Hidalgo[2]; JH Alonso-Briales[2]; JJ Gomez-Doblas[2]; MF Jimenez-Navarro[2]; JM Hernandez-Garcia[2]; E De Teresa-Galvan[2]
[1]Department of Cardiology , Malaga, Spain; *[2]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

Few data exist on the clinical impact of Transcatheter Aortic Valve Replacement (TAVR) in patients with symptomatic aortic stenosis and a high surgical risk. The aim of this study was to determine the survival and the factors predicting mortality after TAVR with the Auto-expandable prosthesis.
Methods: From April 2008 to December 2016, the CoreValve prosthesis was implanted in 582 patients with symptomatic severe aortic stenosis with deemed high risk.
Results: The mean age was 79.4 ± 6.9 years. The logistic EuroSCORE and STS score were 17.5 ± 12% and 7.3 ± 5%, respectively. The implantation success rate was 98.9%. In-hospital mortality was 3.4%, and the combined endpoint of death, vascular complications, myocardial infarction or stroke had a rate of 14%. The late mortality (beyond 30 days) was 32.1%. Survival at 1, 2, 3, 4 y 5 years were 83.3%, 78.3%, 71.8%, 60.7% and 50.3%% respectively, after a mean follow-up of 36.5 ± 25 months. The NYHA functional class improved from 3.1 ± 0.6 to 1.77 ± 0.7 in the follow-up. The predictors of cumulative mortality were: Charlson index [HR 1.2 (95% CI 1.08-1.336), p = 0.001], Acute Kidney Injury [HR 1.94 (95% CI 1.203-3.141), p = 0.007], Frailty [HR 2.33 (95% CI 1.43-3.817), p = 0.001] and protective factors were a higher Karnosfky index [HR 0.987 (95% CI 0.976-0.998) p = 0.002] and Ejection Fraction [HR 0.372 (95% CI 0.203-0.681), p = 0,001]
Conclusions: TAVR is associated with significant survival benefit throughout 2.59 years of follow-up. Survival during follow-up depends particularly among patients with associated comorbidities.

P2228
Redo-MVR operations: a 11-year single center experience

A Artan Bajraktari[1]; I Bytyci[2]; E Prifti[1]
[1]University Hospital Center Mother Theresa, Division of Cardiac Surgery, Tirana, Albania; *[2]University Clinical Centre of Kosovo (UCC), Clinic of Cardiology, Pristina, Kosovo Republic of*

Background and Aim: Major advances have been made in mitral valve (MV) surgical technique, prosthesis design and perioperative care for patients undergoing MV replacement (MVR). Improved survival has inevitably meant that more patients will require redo-MVR during the follow-up. Patients undergoing redo-MVR are a diverse population. The aim of this study was to investigate the indications, clinical and epidemiological data of the patients who underwent the redo-MVR.
Methods: A retrospective review of hospital records was performed for 116 patients with age 49 ± 11 years (20-76 years), who underwent redo-MVR operations between 2004 and 2014. We described proper indications, clinical and epidemiological, preoperative, operative, and postoperative data of the study patients.
Results: Of study patients, 84% were female, 86% in NYHA III and 12% in NYHA IV class. Re-interventions were done for the first time in 89%, for the second time in 7.8 % and for the third time in 3.5 % of the patients. Mean time of the re-intervention was 11 ± 7.5 years from the previous intervention. Planned operation was done in 68%, whereas in 32% of patients it was an emergency. Previous MVR had 44% of patients, 40% were patients after commisurotomy, 2% after mitral valve reparation and 15% of them had concomitant interventions. From study patients, 54% had mitral stenosis, 33% had mitral regurgitation, whereas 13% had combined mitral valve disease (stenosis and regurgitation). Indications for in redo-MVR were: valvular structural degeneration (40%), thrombosis of MV prosthesis (17%), residual MV stenosis (14%), paravalvular fistulas and mitral valve regurgitation (11%, for both). Mechanical MV prosthesis was implanted in 77%, whereas biological MV prosthesis in 12% of patients. Concomitant heart intervention was performed in 40% of operated patients (6 patients had aortic valve replacements, 4 had tricuspid valve replacements, 11 underwent tricuspid valvuloplasty and 3 patients had aorto-coronary by-pass). The prosthetic dimensions were 28.6 ± 1.8 mm. Aortic cross-clamping time was 22 ± 13 minutes, length of stay in intensive care unit was 91 ± 14 hours, whereas the duration of hospitalization was 22 ± 13 days.
Conclusions: Female gender dominates and valvular structural degeneration is the most common indication for redo-MVR operation. The MV prosthesis thrombosis, emergency rate of redo-MVR and the hospital stay remain high in these patients.

P2229
Changes over time in infective endocardites disease

A Ana Marques[1]; I Cruz[1]; I Joao[1]; AL Broa[2]; S Alegria[1]; AC Gomes[1]; G Morgado[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal; *[2]Hospital Garcia de Orta, Internal Medicine, Almada, Portugal*

Background: Epidemiologic profile of patients (pts) with infective endocarditis (IE) has changed in recent years with fewer cases associated with rheumatic disease and a higher incidence in elderly due to degenerative valvular disease and health-care associated procedures.
Purpose: To analyze the main differences between 2006-2010 and 2011-2015 IE pts relative to epidemiology, microbiologic profile, outcomes during hospitalization and in-hospital death rate.
Methods: Retrospective study including consecutive pts with IE admitted to our centre during a 10 year period (2006-2015). Data on demographics, past medical history, clinical presentation, isolated microorganisms and echocardiogram findings were evaluated, as well as hospitalization outcomes. The differences between 2006-2010 and 2011-2015 IE pts were analyzed.
Results: We included 134 pts, 98 (73%) males, mean age 61 ± 16 years.53 pts were diagnosed with IE during 2006-2010 period and 81 pts during 2011-2015 period.
The pts diagnosed between 2011-2015 had a significantly lower median age (59 vs 73 years, p = 0.037), more previous hepatic disease (37% vs 14%, p = 0.001) and HIV infection (23% vs 7%) and fewer past history of arterial hypertension (32 vs 63%, p < 0.001) and coronary artery disease (6 vs 20%, p = 0.022). At admission, comparative to 2011-2015 pts, the 2006-2010 IE pts had less anaemia (9 vs 43%, p < 0.001) and embolization symptoms (11 vs 28%, p = 0.032). The infection was significantly more considered to be nosocomial/health-care associated in 2011-2015 pts (9 vs 31%, p = 0.004).
The right-side valves were more affected in 2006-2010 pts (23 vs 7%, p = 0.007). The mitral and aortic valves, as well as the prevalence of prosthetic and native valve IE weren´t significantly different.
Relative to microbiology, it was observed more IE due to viridans streptococci (4 vs 17%, p = 0.018) and less due to Streptococcus milleri (6 vs 0%, p = 0.03) during 2011-2015 period.
We didn´t observed significantly differences between the two groups relative to echocardiographic findings, mean length of hospital stay, adverse events during hospitalization, number of pts submitted to cardiac surgery and in-hospital death rate.
Conclusion: The IE profile pts had changed during the 10 years period, with more elderly pts, with more cardiovascular risk factors like arterial hypertension and coronary artery disease, more anemia and embolization symptoms at presentation, and more nosocomial/health-care associated infective endocarditis during 2010-2015 period. In this group, the right-side valves were less affected as well as isolation of Streptococcus milleri. On the other hand, the infection due to viridans streptococci was higher.
Unfortunately, we didn´t observed a decrease in length of hospital stay, adverse events during hospitalization and in-hospital death rate.

P2230
Safety and effectiveness of percutaneous mitral commissurotomy for rheumatic mitral stenosis

M Majed Hassine[1]; M Boussada[1]; I Mechri[1]; M Mahjoub[1]; M Ben Massoud[1]; Z Dridi[1]; F Betbout[1]; H Gamra[1]
[1]Cardiology A Department – Fattouma Bourguiba University Hospital, monastir, Tunisia

Background: Percutaneous mitral commissurotomy (PMC) has become the reference treatment for mitral stenosis in patients with favorable valvular anatomy.

Purpose: We sought to evaluate the safety and effectiveness of PMC for patients with mitral stenosis.
Methods: Late results of PMC were assessed in 1035 consecutive patients at our institution. A good immediate result was defined as valve area ≥ 1.5 cm^2 without mitral regurgitation > 2/4. PMC are using a double balloon or the Inoue balloon.
Results: The average age in our population was 35 ± 12 years. Good immediate results were obtained in 92.4%.
The 20-year rate of good functional results (survival without cardiovascular death, mitral surgery, or repeat percutaneous mitral commissurotomy and in New York Heart Association class I or II) was 47.6 ± 2.4%.
A multivariable Cox model identified 3 predictive factors of poor late functional results: Prior commissurotomy ($p = 0.014$), Wilkins score>8 ($p < 0.0001$) and final mitral valve area < 1.8 cm^2 ($p < 0.0001$).
The scoring system was derived from the final multivariable model in the derivation cohort of 987 patients, corresponding to predicted good functional results in the validation cohort.
Conclusions: Twenty years after percutaneous mitral commissurotomy in a population of patients with varied characteristics, 47% still had good functional results. Prediction of late functional results is multifactorial and strongly determined Wilkins score and the quality of immediate results. A simple validated scoring system is useful for estimating individual patient outcome.

P2231
Short-term mortality is not influenced by aminoglycozide decrease in renal function during treatment of prosthetic valve endocarditis

MM Monica Mariana Baluta[1]; E Panaitescu[2]; MM Vintila[3]
[1]*Carol Davila University of Medicine-St Pantelimon Clinical Emergency Hospital-Cardiology Department, bucharest, Romania*; [2]*Carol Davila University of Medicine and Pharmacy , Medical Informatics and Biostatistics, Marketing, Medical Technology , Bucharest, Romania*; [3]*St. Pantelimon Emergency Hospital, Cardiology, Bucharest, Romania*

Introduction: Antibiotic therapy (AT) for prosthetic valve endocarditis (PVE) is standardized by guidelines and depends on the etiology and on the type of PVE. Aminoglycosides (AGs), especially Gentamicin is often included in the antimicrobial combination for the management of PVE.
Purpose: The objective of our study is to quantify the potential nephrotoxic effect of AGs and to verify those speculations from literature about their relationship with mortality and about the safety and efficacy of single dose administration in PVE patients.
Methods: Retrospective analysis of 56 patients admitted with PVE in two university hospitals over 5 years (2000-2004). We divided our patients in two groups: early and late PVE related to time of surgery for valve replacement. We evaluate the influence of antimicrobial therapy with AGs on renal function. Kidney function abnormalities were determined by blood creatinine (Cre). We defined renal injury as low (LRI: Cre < 2 mg/dl), moderate (MRI: cre≥2and < 3 mg/dl) and severe (SRI:cre≥3mg/dl). We analyzed (uni- and multivariate analysis) if the absence of AGs or presence of AGs administered once or multiple doses influenced the renal function. AGs were used according to the antibiogram or with infectious specialist decision. AGs duration was individualized according to renal function and guidelines.
Results: We found 52% patients with early vs 48% late PVE with high rate of negative blood cultures 55.2 % in early vs 48.2% late PVE. Patients outcome: responders to antibiotics: 71%, in-hospital death 2%, transferred due to complications 27%. AT was frequently changed due to side effects but the type of combinations did not influence the overall efficacy of AT. Amikacin was frequently used according to antibiogram but also for negative blood culture endocarditis. LRI was observed fifth times higher in patients with multiple dose AGs compared with those without AGs ($p = 0.01$, $\chi 2 = 6.25$, RR=2.3, OR= 5.56) and similar with them with single dose ($p = 0.2$, $\chi 2 = 3.81$). MRI was observed seventh times higher in patients with multiple dose AGs compared with those without AGs ($p = 0.01$, Fischer, RR=3.6, OR=7.5) and similar with them with single dose ($p >> 0.05$). MRI was more frequent with Imipenem-Amikacin association ($p = 0.008$). SRI was not influenced by type of administration (single dose $p = 0.2$, $\chi 2 = 3.81$; multiple doses $p = 0.1$, Fischer).There was no statistical correlation between mortality and renal impairment determined by AGs.
Conclusions: Multiple dose AGs administration determines more renal function impairment than in patients treated without AGs. Nevertheless, in-hospital mortality was not influenced by AGs decrease in renal function. Single dose AGs does was safe without significant renal function impairment. Amikacin was safe and effective including in negative blood culture PVE. Study limitation: small number of patients and lots of negative blood cultures PVE.

P2232
Relation of frequency and severity of mitral regurgitation to clinical and paraclinical features among patients with heart failure

AN Anass Inchaouh[1]; A Hadadi[1]; R Habbal[1]
[1]*Ibn Rochd University Hospital, Casablanca, Morocco*

Introduction: Mitral regurgitation (MR) is a common finding in patients with heart failure(HF), and it often develops during progressive remodeling and dilation of the left ventricle. However, the association between the presence of varying grades of MR, clinical, paraclinical features and symptoms in patients with HF has not been well characterized. The purpose of this analysis was to determine the frequency of MR in patients with LV systolic dysfunction and clinical HF, and to explore the relations between the presence and severity of MR and cardiovascular profile.
Methods: This is a retrospective study of all patients with HF in combination with MR registered in the therapeutic Unit of Chronic Heart failure in the cardiology department over a period of 3 years. Patients were diveded to 3 groups following the MR grades wich was defined according to the european society of cardiology guidelines into : mild, moderate and severe MR.
Results: The study was conducted in 893 patients with a mean age of 67.9 years and male predominance (56,2%). The group with mild MR was the most presented(52,1%) and was charcterized by older age(70.7 years old), higher prevalence of hypertension, dyslipidemia, stroke, myocardial infarction, renal failure and anemia ; the most prescription of β-blockers and ischemic HF was the most frequent etiology. The group with moderate MR was charcterized by higher prevalence of diabetes, smoking history, number of hospitalization and right ventricular dysfunction; the lowest ejection fraction(EF) and the most prescription of angiotensin-converting enzyme (ACE) inhibitors. The group with severe MR was the younger group, the most symptomatic with frequent class III of NYHA and was characterized by the lowest Cardiovascular risk factors, higher prevalence of left ventricular dilation and the highest EF.
Conclusion: Our study shows that mild and moderate MR is common in patients with HF. Physicians should consider the early management of MR to be a therapeutic target that could favorably affect clinical status and outcome of patients with systolic HF.

How does pulmonary arterial pressure improve after mitral valve surgery in patients with preoperative pulmonary hypertension?

F Lopez Valdiviezo[1]; J Joffrey Eduardo Lujan Valencia[1]; J Hernandez Campo[1]; MA Gutierrez Martin[1]; C Velazquez Velazquez[1]; O Araji Tiliani[1]; JM Barquero Aroca[1]
[1]*Virgen Macarena University Hospital, Sevilla, Sevilla, Spain*

Introduction and objectives: Left heart pathology, including mitral valve disease, causes damage on the pulmonary vasculature and, therefore, the development of pulmonary hypertension. The aim was to compare the reduction of preoperative pulmonary pressures with respect to one year control in patients who underwent mitral valve surgery with diagnosis of pulmonary hypertension.
Methods: We reviewed all patients diagnosed with pulmonary hypertension who underwent any mitral surgery from January 2010 to June 2015. A total of 61 patients were included. Clinical and echocardiographic data both pre and postoperative were collected and compared changes in pulmonary pressure at one year follow up. In addition, a subdivision according to the type of surgery was performed.
Results: Of 61 patients, 36 (59%) were women with a mean age of 66 ± 2.17 years. 72% were in functional class III-IV. Mean preoperative pulmonary arterial pressure was 53.74 ± 3,44mmHg. A perioperative mortality of 18 % was observed. At follow-up, mean pulmonary arterial pressure was 34.44 ± 3,81mmHg (difference of 19.33 ± 4,12mmHg $p < 0.0001$). In the subdivision according to type of surgery the reduction was: 22.2 ± 8,88mmHg for mitral repair, 5,57 ± 18.43mmHg for mechanical prosthesis and 10.75 ± 9,4mmHg for biological prosthesis.
Conclusion: Mitral valve surgery improves pulmonary arterial pressure in patients with preoperative pulmonary hypertension, being more evident with valve repair. Perioperative mortality is high; but patients who are discharged, have excellent survival follow-up.

P2234
Effect of hemodynamic status on postoperative outcome in infective endocarditis: a literature overview

WP Mistiaen[1]
[1]*Artesis-Plantijn University College, Health and Social Care, Antwerp, Belgium*

Purpose: Infective endocarditis (IE) is a serious condition with a high 30-day mortality. Surgery is needed in many patients. The preoperative hemodynamic status

(congestive heart failure or CHF, need for emergent surgery, need for mechanical support, NYHA functional class III/IV) could have an impact on postoperative outcome. Each of these parameters is an indication for the inadequacy of the left ventricle to maintain an adequate circulation.
Methods: A literature search was performed using "endocarditis AND hospital mortality OR outcome AND predictor" and "International Collaboration on Endocarditis – Prospective Cohort Study" in Web of Science database, (2010 to 2016). Manuscripts were excluded if no logistic regression was available or if hemodynamic status was not included in the analysis. This resulted in nine manuscripts. The predictors were ranked according the odd ratios (numerator: place of the parameter, denominator: total of identified predictors).
Results: Most studies are coming from one tertiary center and are retrospective, with different designs. Recruitment periods are long with small patient populations. Definitions of hemodynamic status are not uniform. Need for emergent surgery is mostly labeled as "needed within 24h". Thirty-day mortality varies between 10 and 50%. In almost all papers, the hemodynamic status is ranked as first, according to the odds ratio.
Conclusions: A compromised hemodynamic status is the dominant predictor for 30-day mortality after surgery for IE. However, IE is a heterogeneous condition. In spite of these limitations (listed above), development towards a compromised hemodynamic status could be prevented by timely surgery.

ranking of the hemodynamic status

Author (year)	hemodynamic status	rank	OR	95%CI	p-value

Value of clinical information from cardiac stimulation devices in the heart failure program: the hf + ep team

C I Clara Ines Saldarriaga[1]; H Pino[2]; YA Vasquez[2]; JD Ramirez[1]; JF Agudelo[1]
[1]Cardiovascular Clinic Santa Maria, Universityof Antioquia cardiology department, Medellin, Colombia; *[2]medtronic, heart and rhythm, bogota, Colombia*

Cardiac stimulation devices have clinical information that can be useful in the follow up of heart failure patients.
Objective: to identify the frequency of events detected by cardiac stimulation devices in a cohort of patients from a Colombian heart failure program and the impact of the knowledge of this information in clinical decisions.
Methodology: Prospective cohort study. All patients had a cardiology evaluation plus device interrogation (atrial fibrillation, FV/VT episodes, optivol index, impedance, and hour of daily activity).
Results: 101 patients were included during 4 months; 43.7%% were women with a mean age of 65 years (IR 24 – 89). The types of devices are listed in table 1. 27.7% of the patients had at least 1 alert in the device. 67% were due to arrhythmia, 28% were optivol alerts, and 10% were changes in impedance. In 96.4% of the cases, this information was important and changed medical decision. 42.8% of the patients had a change in medications (increase in beta-blocker dosage or start antiarrhythmic), 42.85% had an increase in diuretic dose, and 14.28% required reprogramming of the device. Hospitalizations of this population during the next three months were 13.8%.
Conclusion: Clinical information from cardiac devices is important for the HF + EP team in detecting predictors of decompensation in heart failure. This provides an opportunity for remote monitoring programs in Colombia.

table 1: type of devices

Device	Percentage
Pacemaker	16.84%
CRT + P	5.94%

VitD Calc a mobile application for patients with heart failure and significant mitral regurgitation which helps to identify those at risk for vitamin d deficiency.

O Mozenska[1]; J Bil[2]; A Segiet[3]; P Podziemski[4]; DA Kosior[1]
[1]Clinical Hospital of the Ministry of Internal Affairs, Cardiology and Hypertension, Warsaw, Poland; *[2]Clinical Hospital of the Ministry of Internal Affairs, Invasive Cardiology, Warsaw, Poland*; *[3]Medical University of Warsaw, 1st Medical Faculty, Warsaw, Poland*; *[4]Maastricht University, Physiology, Maastricht, Netherlands*

Introduction: Vitamin D deficiency is increasingly attracting attention in the field of cardiovascular research. For patients with heart failure (HF) is it a known morbidity and mortality risk factor. At the same time cardiology is one of the fastest and receptive areas of medicine to utilize new and emerging technologies.
Purpose: We aimed for equipping cardiologists in their everyday busy practice with a simple tool to identify amongst patients with HF and significant mitral regurgitation (MR) those at risk for vitamin D deficiency.
Methods: 99 consecutive patients hospitalized in our Department between July and September 2013 were included in the study. Inclusion criteria were: age>18, HF and significant MR assessed with transthoracic echocardiography (TTE) (vena contracta>3mm, effective orifice area (ERO)>0.2 cm2, MR volume>30ml/s). We used uni-and multivariate analysis to look for vitamin D deficiency classifier.
Results: We included 39 patients with severe MR and 60 with moderate MR (39.9% and 60.6% accordingly, median age 75 yrs [Q1-Q3 66.0-81.5], 35.4% were female). Median left ventricular ejection fraction (LVEF) was 50% [Q1-Q3 29.00-62.00], median LV diastolic diameter was 56 mm [Q1-Q3 49.5-65]. Median 25(OH)D3 was 14.8 ng/ml [Q1-Q3 9.93-20.12]. Using multivariate analysis, we found a classifier for vitamin D deficiency in population with HF and significant MR (including radius of PISA, left atrium area in apical 2-chamber view and posterior wall diastolic diameter) with AUC of 89.1% (85.7% specificity and 78.6% sensitivity). We further used the formula and developed VitD Calc – a mobile application available in the Play store (link) which allows clinicians in 3 simple steps to predict probability of vitamin D deficiency in their patients.
Conclusions: Mobile technology and telemedicine are already present in our everyday medical practice. Answering the need for practical implementation of our research results we developed a mobile tool that helps cardiologists in identifying patients at risk for vitamin D deficiency. Further studies are needed to validate our application.

P2238
Cardiac kinematic parameters computed from video of in situ beating heart during coronary artery bypass grafting

G Giacomo Rozzi[1]; L Fassina[2]; S Rossi[3]; S Scacchi[2]; M Galletti[4]; P Colli Franzone[2]; G Petrilli[1]; G Faggian[1]; M Miragoli[3]
[1]University of Verona, Scienze chirurgiche odontostomatologiche e Materno-infantili, Verona, Italy; *[2]University of Pavia, Pavia, Italy*; *[3]University of Parma, Medicina Clinica e Sperimentale, Parma, Italy*; *[4]Italian Workers' Compensation Authority (INAIL), CERT Research Center, Parma, Italy*

Mechanical function of the heart during open-chest cardiac surgery is monitored by transesophageal echocardiographic techniques (TEE). However, little is known about local kinematics, particularly for the reperfused region after an ischemic event. We reported a novel imaging modality, which extracts local and global kinematic parameters from recorded videos of in-situ beating cardiac tissue, displaying live data of the contraction events. A custom algorithm tracks the movement of a circular video-marker positioned ad hoc onto the selected area and analyses, during the entire recording, frequency, contraction trajectory, displacement, velocity, contraction force, and kinetic energy. Furthermore we implemented our algorithm with particles image velocimetry tool (PIV), showing difference for global epicardial tissue vorticity and velocity during systolic and diastolic phases.
After validation in-silico and in ischemic/reperfused rat hearts we applied our technique on beating human hearts, i.e. ten patients underwent coronary artery

bypass graft (CABG, >75% coronary occlusion), and faced the results with the conventional gold-standard TEE approach. While both ejection fraction (EF) and fractional shortening (FS) showed global left-ventricle recovery in all patients (EF: from 37.7 ± 6.2 to 52.4 ± 5.6; FS: from 25.0 ± 5.2 to 40.5 ± 2.6) our technique precisely detected an average improvement for kinetic energy (from 37190 ± 5216 to 40240 ± 7617) and contraction force (from 26260 ± 2862 to 32730 ± 4612) but not for all patients, plausible due to the level of local myocardial stunning. Particle image velocimetry showed an average improvement for velocity (from 1.96 ± 1.16 to 2.58 ± 1.61) after CABG but not for those patients who did not display a recover of the aforementioned kinematic parameters.
Our functional imaging technique adds important kinematic values on cardiac outcomes and supports the intervention in contact-free and non-invasive mode by detecting the level of myocardial stunning. Moreover, it can be easily adopted in the cardiac theater with TEE and does not require particular operator-dependent skills.

Four years of baroreflex activation therapy in advanced heart failure: 3rd long-term follow-up report of a proof-of-concept study

E Gronda[1]; G Costantino[1]; A Alberti[1]; B Baronio[1]; T Staine[1]; G Grassi[2]; G Seravalle[3]; E Vanoli[1]
[1]IRCCS Multimedica, Cardiovascular Departement, Sesto San Giovanni, Milan, Italy; [2]Università Milano-Bicocca, Clinica Medica, Monza, Italy; [3]Istituto Auxologico, Milan, Italy

Funding Acknowledgements: The study was sponsored by CVRx, Inc., Minneapolis, Minnesota, USA.

Background and Purpose: In a proof-of-concept study of eleven heart failure patients with reduced ejection fraction (HFrEF), Baroreflex Activation Therapy (BAT) effectively reduced sympathetic activity in the peroneal nerve (MSNA) at 6 and 22 average months of follow-up. Hospitalization rate was also significantly lower during these follow-up periods relative to pre-implant baseline. The objective of the present study is to extend the long-term follow-up data on this patient cohort over 42 months.
Methods: and Results: Eleven patients were enrolled in the study who presented with optimized, stable, guideline-directed medical therapy, NYHA Class III HFrEF with left ventricular ejection fraction (LVEF) ≤ 40%, and no indication for cardiac resynchronization therapy. For the present report, MSNA, baroreflex sensitivity data and hospitalization rate together with standard clinical data were collected at 6, 21.5 ± 4.2 and 42.5 ± 3.5 months following BAT activation. Four patients died during long-term follow-up. The remaining seven patients (two with ischemic heart disease) maintained the improvements observed at 6 months, including reduced sympathetic activity, reduced hospitalization rate and improved clinical variables as addressed in Table 1. Blood pressure and heart rate did not change over the course of follow-up.
Conclusion: BAT provides chronic reductions in sympathetic activity and restrains utilization of hospital resources in patients with HFrEF. Patient clinical presentation, quality of life and functional capacity are consistently improved and maintained. The temporal association of BAT with sympathetic drive diminution and improvement in objective clinical measures suggests a cause-and-effect relationship that is currently under investigation in a randomized, controlled outcomes trial.

Table 1. BAT long-term follow-up data

	Baseline	21.5 ± 4.7 months	41.5 ± 3.5 months	P-value
MSNA (bursts/min)	41 ± 6	31 ± 8	26 ± 3	< 0.001
Minnesota living with heart failure score	31.3 ± 26.0	17.7 ± 9.2	16.9 ± 7.7	< 0.005
Six-minute walk distance (m)	306 ± 31.4	365 ± 36.2	425 ± 116	0.001
LVEF (%)	31.1 ± 6.0	35.1 ± 3.6	37.1 ± 9.1	< 0.02

The effects of haemoglobin and doxycycline in response to non-physiological shear stress in bovine and human blood

C Christian Robinson[1]; I L Pieper[1]; V Kanamarlapudi[1]
[1]Swansea University, Swansea, United Kingdom

Background: The effects of non-physiological shear stress were evaluated by measuring the activity and integrity of platelets and von Willebrand factor (vWF) in the presence of haemoglobin and doxycycline in human and bovine blood.

Purpose: Left ventricular assist devices (LVADs) exert high levels of non-physiological shear stress on the blood components. However, little is known of the relationship between haemoglobin, doxycycline and vWF.
Methods: Bovine and human whole blood, platelet-rich plasma and platelet-poor plasma containing haemoglobin, doxycycline, both or none were subject to shear stress in vitro. Platelet function and vWF activity and integrity was analysed using ELISA, immunoblotting and ristocetin-induced platelet aggregometry.
Results: Shear stress leads to reduced vWF activity and integrity. However, these effects can be minimised with doxycycline or haemoglobin. Immunoblotting and ELISA indicate that collagen binding activity is preserved. This study suggests that haemoglobin enhances ristocetin-induced platelet aggregation.
Conclusions: Shear stress results in vWF degradation and reduced platelet function, which may be contributing to gastrointestinal bleeding in LVAD patients. Furthermore, haemoglobin seems to be protective of vWF degradation and enhances platelet aggregation. As such, vWF may be lost in platelet aggregates. Thus, haemoglobin levels could reduce the risk of gastrointestinal bleeding, but contribute to the development of thrombosis in LVAD patients.

P2241

The predictive value of proteinuria for mortality or renal failure in patients receiving left ventricular assist devices.

R Rahat Muslem[1]; K Caliskan[1]; S Akin[1]; A Constantinescu[1]; DA Hesselink[2]; G Whitman[3]; RJ Tedford[4]; AJJ Bogers[5]; SD Russell[4]; OC Manintveld[1]
[1]Erasmus Medical Center, Cardiology, Rotterdam, Netherlands; [2]Erasmus Medical Center, Nephrology, Rotterdam, Netherlands; [3]Johns Hopkins University of Baltimore, Cardiothoracic Surgery, Baltimore, United States of America; [4]Johns Hopkins University of Baltimore, Cardiology, Baltimore, United States of America; [5]Erasmus Medical Center, Cardiothoracic Surgery, Rotterdam, Netherlands

Purpose: This study evaluated the predictive value of proteinuria before Left Ventricular Assist Device (LVAD) implantation in relation to renal failure and mortality during the first-year.
Methods: A retrospective multicenter cohort study was conducted, evaluating all LVAD patients (n = 241) implanted in the two participating centers with age ≥18 years and minimal survival >48 hrs. A urinary dipstick was available in 201 (83%) patients within a 7-day period before LVAD implantation. Proteinuria was defined as ≥trace (≥1 +) and renal failure as the need for renal replacement therapy. Exclusion criteria were; positive for microscopic haematuria (>3 RBC/hpf or positive dipstick for haematuria), 28 patients were excluded.
Results: Overall, 173 patients met the inclusion criteria (mean age 52.3 ± 13.3, 78% male, mean eGFR at baseline 60.1 ± 25.9 mL/min per 1.73 m2), of who 42 (24%) had significant proteinuria (mean age 54, 76% male, mean eGFR 60 ± 32.3 mL/min per 1.73 m2). During the first-year 32% of the patients with proteinuria vs. 16% without proteinuria developed severe renal failure (adjusted HR 2.47, 95% CI 1.18 to 5.15, p = 0.016). The 1-year survival was 52% in patients with proteinuria vs. 78% in patients without proteinuria (Log-rank p < 0.001). In multivariate analysis proteinuria was identified as an independent predictor of 1-year mortality (HR 2.09, 95% CI 1.14 to 3.84, p = 0.017).
Conclusion: Proteinuria in patients undergoing LVAD implantation was highly associated with renal failure and mortality.

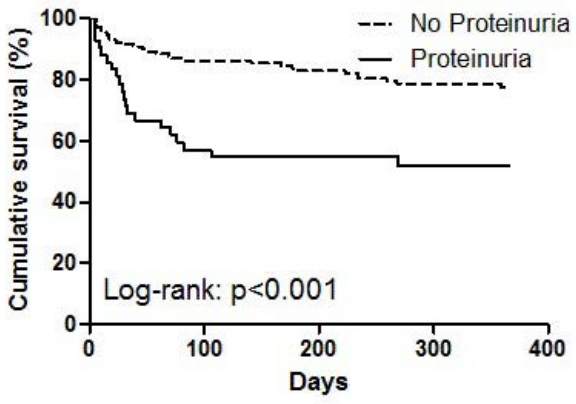

figure 1. survival

Long term outcome of different responses to cardiac resynchronization therapy

V Vera Marinho[1]; J Milner[1]; P Alves[1]; M Santos[1]; C Domingues[1]; N Antonio[1]; M Ventura[1]; J Cristovao[1]; L Elvas[1]; F Goncalves[1]; M Pego[1]
[1]*University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*

Introduction: There is strong evidence that Cardiac Resynchronization Therapy (CRT) reduces mortality and hospitalization, and improves cardiac function in heart failure (HF) patients. However, response to CRT may vary widely (from negative-responders to super-responders). Aim: The aim of this study was to evaluate de long-term prognosis of patients with different responses to CRT.
Population and Methods: Retrospective single-centre study that included all patients submitted to CRT therapy between January 2006 and December 2015. Super-responders were defined as patients with at least a duplication of baseline left ventricular ejection fraction (LVEF) or a LVEF >45% at 6 months echo. Responders included all patients with an increase of LVEF > 25%, without super-response criteria. Non-responders were defined as patients with an increase in LVEF from baseline ≤ 25% and negative-responders as patients with a decrease in LVEF. During a median follow-up of 57 months (IQR=31-78), we evaluated all-cause mortality, transplantation and admission for heart failure. Survival curves were compared using the log rank test.
Results: In this cohort of 431 patients, 103 (23.9%) were submitted to CRT-P and 328 (76.1%) to CRT-D. There were 23.4% super-responders, 28.9% responders, 20.6% non-responders and 27.1% negative-responders. Regarding baseline characteristics, super-responders were more frequently female (48.5% vs 29.8 vs 25.0 vs 19.9%, respectively, p = 0,001), had less ischemic etiology (16.2 vs 29.8 vs 37.3 vs 38.0%, respectively, p = 0.019). The QRS duration was proportion to CRT response (152.3 ± 39.0 in super-responders vs 148.8 ± 30.5 in responders vs 144.3 ± 24.7 in non-responders vs 135.7 ± 27.0 ms in negative-responders, p = 0.045). The were no significant differences in baseline echocardiographic parameters or other baseline characteristics between groups.
During long-term follow-up, there were significant differences in global mortality, heart transplantation and readmission due to heart failure, with a continuum worsening of outcomes from super-responders to negative-responders. The global mortality ranged from 11.8% in super-responders, 25.0% in non-responders to 39.2% in negative-responders (p = 0.002). Heart transplantation rate ranged from 1.5% in super-responders, to 4.8% in responders to 6.7% in non-responders and 13.9% in negative-responders (p = 0.021). The same continuum was observed for the rate of hospitalization for heart failure (19.1% vs 31.3% vs 39.0% vs 55.7%, respectively, p < 0.001). Survival curves comparing the 4 profiles of response to CRT also show this continuum from super-responders to negative-responders (figure 1).
Conclusions: In our study population, the long-term prognosis of super responders was excellent. This study confirms the importance of wide QRS and also suggests non-ischemic etiology as predictors of a positive response to CRT.

External validation of the models in extracorporeal membrane oxygenato (ECMO) from developing country

P Puwadon Thitivaraporn[1]; S Chiramongkol[1]; K Boonthim[1]; W Chiravanich[2]; N Pornpatrtanarak[1]; C Kittayarak[1]; J Namchaisiri[1]; S Singhatanadgige[1]; P Ongcharit[1]; V Benjacholamas[1]
[1]*King Chulalongkorn Memorial Hospital, Cardiovascular thoracic surgery department, Bangkok, Thailand*; [2]*King Chulalongkorn Memorial Hospital, Cardiac Anaesthesiology department, Bangkok, Thailand*

On behalf of: Chula Cardiac Center

Objectives: This study was to describe and evaluate the proper situation, timing and predicted outcomes of extracorporeal membrane oxygenator (ECMO) implantation in developing country and to validate prior proposed models for prediction of mortality.
Methods: Data on ECMO used for cardiopulmonary support and e-CPR in children and adults were extracted from database from January 2012 to August 2016. Demographic data included age, diagnosis, procedure codes, type and aim of ECMO support, pre and post-ECMO mechanical support parameters, postop complications, ECMO cannulation details and technique, and postop patient condition. Data also included time interval from the point that ECMO was indicated to the point that ECMO was initiated. We validated prior proposed 4 models using receiver operative characteristic curve (ROC) and their area under the curve (AUC): 1) Respiratory Extracorporeal Membrane Oxygenator Surviving Prediction (RESP) Score, 2) Extracorporeal membrane oxygenator network (ECMOnet) score for VV-ECMO, 3) Survival After Veno-arterial ECMO (SAVE) score and 4) the Sequential Organ Failure Assessment (SOFA) Score for VA-ECMO. The secondary outcomes were descriptive data of ECMO cost. Associations between each of 4 models and 30-day and one-year survival were determined by hazard ratio (HR) and 95% confidence interval (CI) calculated using Cox proportional hazards regression.
Results: 41 patients received ECMO, of which 23 were male (56.1%) at median age of 29.5 ± 27.4 year. Indication for ECMO were 6/41 for respiratory support, 27/41 for cardiac support and 8/41 in e-CPR group which correspond with VV-ECMO 14.6% and VA-ECMO at 85.4%. ARDS is the most common diagnosis in patients required VV-ECMO while low cardiac output syndrome is the most common diagnosis in VA-ECMO. ECMO was successfully weaned off in 15/41 (36.6%) while the survival to discharge rate was 12/41 (29.3%). VV-ECMO survival rate was 3/6 (50%) and VA-ECMO survival rate was 9/35 (25.7%). Among survivor group, 4/12 patients (33.3 %) needed ventricular assisted device (VAD) implantation (1/4 LVAD and 3/4 BiVADs). AUC of each model were 0.688, 0.664, 0.750 and 0.625 for SOFA, SAVE, ECMOnet and RESP score, respectively. Only ECMOnet score of ≥ 7.5 was associated with increased mortality at 30 days (p = 0.03) and at 1 year (p = 0.03). Median ECMO duration was 125.5 (8-745) hour and median length of stay was 22.00 (2-167) days. The median cost of ECMO was 7,900 USD.
Conclusion: Despite limited resource and ECMO fund, the external validation using data from developing country support prior proposed models compared to data from Extracorporeal Life Support Organization (ELSO). From the 4 models, SOFA, SAVE and RESP were not associated with survival at 30 days and 1 year. However, ECMOnet score of ≥7.5 was associated with increased mortality at 30 days (p = 0.03) and at 1 year (p = 0.03).

Ramathibodi Hospital, Bangkok, Thailand; [6]*Queen Elizabeth Hospital, Malaysia; Fuwai Hospital, Cardiology, Beijing, China People's Republic of*; [7]*CARE Hospital, Hyderabad, India; National Cardiovascular Center Universitas, Jakarta, Indonesia*; [8]*Manila Doctors Hospital, Manila, Philippines; Prince of Wales Hospital, Hong Kong, Hong Kong SAR People's Republic of China*; [9]*Changi General Hospital, Singapore, Singapore*; [10]*University of Minnesota, Minneapolis, United States of America*

Background: Implantable cardioverter-defibrillators (ICDs) are guideline recommended for heart failure (HF) patients with reduced ejection fraction (HFrEF). Yet, little is known regarding sex differences in ICD utilisation and outcomes in Asian patients with HFrEF.
Purpose: In a large prospective multinational cohort of Asian patients with HFrEF, we aimed to compare ICD utilisation, determinants and outcomes between men and women.
Methods: We studied guideline ICD eligible patients with HF and ejection fraction≤35% and New York Heart Association Class II-III from 11 Asian regions (China, Hong Kong, India, Indonesia, Japan, Korea, Malaysia, Philippines, Singapore, Taiwan, Thailand). ICD recipients had an ICD or cardiac resynchronisation therapy with defibrillator (CRT-D) at baseline. Patients were followed for independently adjudicated events including all-cause mortality and sudden cardiac deaths (SCDs). Multivariable regression models were used to examine the impact of sex on ICD utilisation and mortality outcomes.
Results: Among the 3081 (21% women) eligible patients (mean age 58 ± 13 yr), there were 362 (17% women) ICD recipients. Compared to men, women were more likely to have non-ischemic HF (60% vs 38%) and higher ejection fraction (>30% vs ≤30%, 27% vs 22%) but less likely to smoke (91% vs 47%) or consume alcohol (94% vs 66%) (all $p < 0.01$). Educational status predicted ICD uptake (pre-university and above vs below, OR=2.25, 95% CI 1.80-2.83), with interaction by sex (p-interaction=0.03) such that less educated women were less likely to receive an ICD vs men (OR=0.61, 95% CI 0.38-0.98). Over a median follow-up of 394 days, 406 (13%) patients died (88% CV deaths, 29% SCDs). Women were at lower risk for SCDs (HR=0.47, 95% CI 0.26-0.85) compared to men. ICDs reduced all-cause mortality (HR=0.96, 95% CI 0.44 – 0.04) and SCDs (HR=0.35, 95% CI 0.16-0.79) overall. Sex did not modify the effect of ICD on all-cause mortality (p-interaction=0.80) but significantly modified the effect of ICD on SCD (p-interaction=0.02), such that the protective effect of ICD was found in men (HR=0.23, 95% CI 0.08-0.63) but not women (HR=2.18, 95% CI 0.38-12.44) likely due to smaller numbers of events in women.
Conclusions: Among Asian patients with HFrEF, there is sex disparity in ICD utilisation particularly among the less educated. Despite lower usage of ICDs, women were at lower risk of SCD compared to men.

Additional value of contrast-enhanced cardiac magnetic resonance imaging for patients with coronary artery disease and ejection fraction over 35% presenting with unexplained syncope

F Outteryck[1]; S Boule[1]; F Pontana[2]; B Longere[2]; A Coisne[1]; S Ninni[1]; E Drumez[3]; F Brigadeau[1]; C Marquie[1]; D Klug[1]; M Remy Jardin[2]; D Lacroix[1]
[1]*Lille University Hospital, Cardiovascular medicine, Lille, France*; [2]*Lille University Hospital, Cardiovascular imaging, Lille, France*; [3]*Lille University Hospital, Biostatistics, Lille, France*

Background: In patients with coronary artery disease (CAD) presenting with unexplained syncope and preserved left ventricular ejection fraction (LVEF), a programmed ventricular stimulation (PVS) is indicated in those with previous myocardial infarction (MI). Providing evidence of infarct scar remains challenging. Purpose – We investigated the value of Cardiac Magnetic Resonance imaging (CMR) to assess the presence of myocardial scar and to predict the inducibility of ventricular tachyarrhythmia during PVS.
Methods: From June 2011 to April 2014, all patients with CAD and LVEF over 35% presenting for unexplained syncope were included. Assessment of infarct scar was compared between conventional diagnostic work-up (medical history, ECG, echocardiography) and CMR. Results – The study population consisted of 66 patients (age 70 ± 10.6; males 81.8%; LVEF 54 ± 8%). Evidence of myocardial scar was provided by medical history (n = 26; 39.4%), ECG (n = 25; 37.9%) and echocardiography (n = 24; 36.4%). Discrepancies between conventional diagnostic work-up and CMR regarding the diagnosis of infarct scar were reported in 20 cases (30.3%). Among them, 6 had a positive PVS. A lower LVEF on echocardiography (48% vs. 55%, p = 0.04) and CMR (43% vs. 53%, p = 0.009), a greater left ventricular end diastolic volume by CMR (87ml/m^2 vs. 69ml/m^2, p = 0.01) and the presence of Q wave (57.1% vs. 28.9%, p = 0.03) were associated with positive PVS.
Conclusion: Among patients with CAD and LVEF over 35% presenting for unexplained syncope, discrepancies were reported in 30.3% of cases regarding the assessment of infarct scar between conventional work-up and CMR. The additional value of CMR to predict the inducibility of ventricular tachyarrhythmias remains unknown.

P2246

Ventricular arrhythmias after surgical correction of post-infarction left ventricular aneurysms II - III type for M. Di Donato - L. Menicanti in patients with an ejection fraction less than 30%.

A Alexander Kozlov[1]; A Gornostaev Alexander[1]; S Durmanov Sergey[1]; V Bazylev Vladlen[1]
[1]*Penza Center for Cardiovascular Surgery, Penza, Russian Federation*

Patients with coronary heart disease with low ejection fraction and left ventricular aneurysm, constitute a high risk of sudden cardiac death. After surgical treatment of aneurysms II - III type classification M. Di Donato - L. Menicanti survival of patients over a three year period is 51-60%. There are no clear recommendations on the timing of ICD implantation after surgical correction of coronary heart disease in this group of patients.
Aims: To determine the type and timing of ventricular cardiac arrhythmias after surgical treatment of post-infarction left ventricular aneurysms II - III type for M. Di Donato - L. Menicanti in patients with an ejection fraction less than 30%.
Methods: 16 patients with ejection fraction < 30% and left ventricular aneurysms II - III type classification M. Di Donato - L. Menicanti ICDs implanted in the early postoperative period after surgical correction of coronary heart disease. Diagnosis of ventricular cardiac arrhythmias was carried out at full-time follow - up, and with the use of remote monitoring system CareLink. The duration of follow-up was 579,3 ± 285,3 days.
Results: In all the time of observation in 43.7% (7 of 16) patients had life-threatening ventricular arrhythmias. In-hospital ventricular tachycardia occurred in 5 patients. In the intensive care department ward VT recorded in 2 patients, 3 patients in the rehabilitation stage, which required the application of ICD - therapy. In-hospital mortality were not observed in this group of patients. In the late period VT occurred in 2 patients. Total observation time 3 patients died, mortality was 18.7%. In the dead of patients according to the follow - up was not observed ventricular arrhythmias, presumably patients died from progression of chronic heart failure.
Conclusions: In our series of observations after surgical correction of left ventricular aneurysms II - III type for M. Di Donato - L. Menicanti in patients with an ejection fraction less than 30% within one year of ventricular tachycardia occurred in 7 patients (43.7%). In 5 patients, these arrhythmias developed in the early postoperative period (up to 10 days). ICD implantation in the early postoperative period is useful for prevention of sudden cardiac death in these patients.

P2247

Systolic dysfunction in the context of acute coronary syndrome: evaluation of events and implantation of ICD

T Tatiana Duarte[1]; S Goncalves[1]; C Sa[1]; M Fonseca[1]; R Marinheiro[1]; R Rodrigues[1]; L Parreira[1]; F Seixo[1]; R Caria[1]
[1]*Hospital Center of Setubal, Cardiology, Setubal, Portugal*

Introduction: Although the advances in the treatment of coronary arterial disease, arrhythmic events are an important cause of death in this population.
Implantation of a cardioverter defibrillator (ICD) as primary prevention reduces mortality in patients (pts) with moderate-severe systolic dysfunction (LVEF < 35%) after an acute myocardial infarction (AMI). The implantation of device should be delayed at least 40 days after the acute event.
Aim: To evaluate, in a population with systolic dysfunction (LVEF < 35%) after an AMI, the presence of arrhythmics events and death, during the first 40 days after the acute event; To determine the prevalence of ICD implantation.
Methods: Were evaluated consecutive pts admitted to a Coronary Intensive Care Unit in the context of AMI with moderate to severe systolic dysfunction, over a period of 3 years. Patients in whom the LVEF were not quantified were excluded.
The population was characterized according to baseline characteristics, type of AMI, degree of systolic dysfunction and therapy. Were evaluated the presence of arrhythmics events and death in the first 40 days after AMI, the prevalence of ICD implantation and the causes for non-implantation.
Results: We studied 52 pts (77% (n = 40) males, mean age 72 years ± 10). Sixty-two percent of pts (n = 32) had a diagnosis of STEMI and 67% (n = 35) were in Killip class I. The LVEF was quantified between 35-30% in 52% of the population (n = 27); 29-20% in 35% (n = 18) and < 20% in 17% (n = 9).
Six pts (16%) at discharge did not have indication to ICD because life expectancy < 1 year, only 46 pts would be candidates for ICD implantation. No arrhythmics events or sudden death were recorded in the first 40 days after AMI.
An ICD was implanted in 54% of pts (n = 28).
Forty days after the acute event, 26 pts did not have ICD due to: improvement of the LVEF in 46% (n = 12); 27% (n = 7) died in the period between the 40th day and 3

months after the acute event by: recurrent MI with evolution in cardiogenic shock in 29% (n = 2), acute pulmonary edema in the context of heart failure in 42 % (N = 3) and unknown cause in 29% (n = 2). Six patients (16%) lost follow-up by the cardiologist, but remain alive.
Conclusion: In our study, the death between the 40th day and 3 months after acute event was associated to heart failure or recurrent MI but not due to an arrhythmic event. The LVEF was recovered in about a quarter of pts. In this population, the ICD implantation between the 40th day and 3 months after acute event would not have been effective in reducing of the mortality.

P2248
Relation of QRS duration to response to cardiac resynchronization therapy in patients with left bundle branch block

M Matteo Beltrami[1]; B Sassone[2]; M Bertini[3]; L Padeletti[1]
[1]University Hospital Careggi, Dipartimento Cuore e Vasi, Università degli Studi di Firenze, Firenze, Italy; *[2]SS.ma Annunziata Hospital, Azienda Unità Sanitaria Locale Ferrara, Department of Cardiology, Cento (FE), Italy*; *[3]University of Ferrara, S. Anna Hospital, Department of Cardiology, Ferrara, Italy*

Introduction: Cardiac resynchronization therapy (CRT) is an established treatment in patients with drug-refractory heart failure and wide QRS complex as surrogate of left ventricular (LV) mechanical dyssynchrony. However, the relation between the LBBB electrical activation sequence and the consequent mechanical dyssynchrony of the LV is not completely clear, indeed a substantial percentage of patients with LBBB is still not responder to CRT.
Purpose: Our aim was to investigate the relation between QRS duration and LV dyssynchrony in LBBB patients who underwent CRT.
Methods: We retrospectively studied 165 patients with LBBB who underwent CRT implantation according to the current guidelines. A 6-month reduction of LV end-systolic volume ≥15% identified responders to CRT. Baseline LV dyssynchrony was defined as the delay between peak systolic velocities of the septum and lateral wall assessed by color-coded tissue Doppler imaging.
Results: Baseline characteristics of responders (61%) and nonresponders (39%) were comparable except for greater LV dyssynchrony (75 ms [25%–75% IQR 60-90] vs 30.5 ms [25%–75% IQR 14.5-70.5], p = 0.0001) and narrower QRS duration (160 ms [25%–75% IQR 148-171] vs 180 ms [25%–75% IQR 156-190], p = 0.0001) in responders. At multivariate analysis only QRS duration and LV dyssynchrony remained independent predictors of response to CRT. The ROC curve analysis showed that 61 ms was the lower limit of septum-to-lateral wall delay corresponding with the highest accuracy (sensitivity 72%, specificity 70%) to predict response to CRT [area under the curve = 0.705 (95% confidence interval 0.613 to 0.797)]. In patients with nonischemic etiology of cardiomyopathy the linear regression analysis documented a significant inverse relationship between QRS duration and LV dyssynchrony, as dyssynchrony progressively decreased as QRS widening increased (p = 0.006). This was not evident in patients with ischemic etiology.
Conclusion: In LBBB patients with nonischemic etiology and marked QRS widening the absence of LV dyssynchrony may account for a lower response to CRT as compared to patients with intermediate QRS widening.

P2249
Echocardiographic characteristics predictors of delayed response with cardiac resynchronization therapy

J Juan Sanchez Serna[1]; FJ Pastor Perez[1]; M Navarro Penalver[1]; JJ Santos Mateo[1]; E Guerrero Perez[1]; AI Rodriguez Serrano[1]; IP Garrido Bravo[1]; DA Pascual Figal[1]
[1]Hospital Clínico Univeristario Virgen de la Arrixaca, Cardiología, Murcia, Spain

Background: Delayed echocardiographic response (>1 year) to cardiac resynchronization therapy (CRT) has been described as a frequent entity with similar prognosis to initial response (< 1 year).
Purpose: The main purpose of this study is to define the echocardiographic characteristics in patients with non-ischemic dilated cardiomyopathy (NIDCM) who present delayed response to CRT.
Methods: We realized a retrospective study of patients with NIDCM who underwent CRT implantation according to current indications. Echocardiographic data were collected at pre-implantation time (Tbase), approximately one year follow-up (Tini) and end follow-up (Tend). Echocardiographic response was defined by left ventricular ejection fraction (LVEF) if it increased ≥ 10% and by reverse remodeling (RR) if the end-systolic volume (ESV) decreased ≥ 15%. Patients were divided into 3 echocardiographic response groups: mid-term responders (MR) who showed a significant echocardiographic improvement at the 1-year follow-up; long-term responders (LR) who showed no improvement at 1 year but who exhibited significant improvement at end follow-up; and nonresponders (NR) who never displayed significant echocardiographic improvement.
Results: From December 2002 to June 2014, 181 patients with NIDCM underwent CRT device implantation in our center. Of these, 96 had complete follow-up. The mean time from implant to echocardiographic assessment in the Tini was 331.4 ± 173.1 days and until Tend was 1654.6 ± 907.1 days. Considering RR, the distribution was 75% MR, 9.4% LR and 15.6% NR, taking into account the response to LVEF, 63.5% were MR, 9.4% were LR and 27.1% were NR. Regarding to RR, no significant differences were found comparing baseline echocardiograms among LR, MR and NR patients. Considering the response to LVEF, those with LR had larger ventricular volumes than MR (end-dyastolic volume (EDV): 245.3 ml vs 191.4 ml, p = 0.03, ESV: 191.3 ml vs 145.2, p = 0.03), and worse LVEF than the NR (23.1% vs 30.3%, p = 0.04) (Figure).
Conclusions: Delayed response in LVEF improvement after CRT exists and is associated with the presence of worse ventricular function and greater degree of adverse remodeling in the baseline study. However, baseline echocardiographic data do not discriminate patients with delayed RR response.

P2250
The prognostic role of NT-proBNP but not of Global Longitudinal Strain in heart failure patients receiving cardiac resynchronization therapy

NPE Kadoglou[1]; AGW De Lepper[1]; MC De Kleijn[1]; IHF Herold[1]; ARA Bouwman[1]; FALE Bracke[1]; P Houthuizen[1]
[1]Catharina Hospital, Eindhoven, Netherlands

Funding Acknowledgements: Dr Nikolaos Kadoglou was supported as a clinical fellow by the European Heart Rhythm Association.

Background: Cardiac resynchronization therapy (CRT) is highly effective in a specific subpopulation with drug-refractory heart failure (HF). However, its beneficial impact on prognosis is not fully predictable.
Purpose: To investigate the prognostic role of baseline NT-pro-B-type natriuretic peptide (NT-proBNP) and global longitudinal strain (GLS) levels in HF patients receiving CRT-D.
Methods: We enrolled 93 patients, aged 74 ± 10 years, with stable ischemic HF [NYHA class II/III, ejection fraction ≤35%], who underwent CRT-D implantation, fulfilling the current international criteria. At baseline and 3 months after implantation, we assayed NT-proBNP and echocardiographic findings in all patients. Patients with >15% increase of end-systolic volume (ESV) were considered as CRT-responders (n = 67), while the rest as CRT-non-responders (n = 26). During follow-up we recorded deaths (primary end-point) or deaths/HF hospitalizations (secondary endpoint).
Results: At baseline, no significant differences were detected in all parameters between groups (p>0.05). During a median follow-up of 58 months, 23 patients died, while another 17 patients were hospitalized for HF decompensation. A lower percentage of CRT-responders achieved either primary (log rank test p < 0.001), or secondary end-point (log rank test, p < 0.001) compared to non-responders. After adjustment for prognostic factors (age, gender, baseline NYHA class, QRS duration), baseline NT-proBNP levels, were associated with higher occurrence of primary (HR=1.31, 95%CI: 1.18-1.43, p = 0.002) and secondary end-points (HR=1.48, 95%CI: 1.29-1.57, p < 0.001) in the whole cohort. Notably, NT-proBNP remained an independent determinant of mortality (logistic regression analysis: p = 0.032) within CRT-responders group. On the other hand, baseline GLS values were not significantly associated with either response to CRT or prognosis.
Conclusions: In patients with ischemic HF undergoing CRT-D, baseline NT-proBNP levels, but not GLS values, showed an additive prognostic value to routine clinical and electrocardiographic selection criteria. Our findings require further investigation.

P2251

Acute effects of cardiac resynchronization therapy on left atrial size and function as assessed by conventional two-dimensional echocardiography

S Silvia Lupu[1]; I Sus[2]; A Mitre[3]; R Rudzik[4]; I Beke[4]; D Dobreanu[3]
[1]University of Medicine and Pharmacy of Tirgu-Mures, Center for Advanced Medical and Pharmaceutical Research, Tirgu-Mures, Romania; *[2]University of Medicine and Pharmacy of Tirgu-Mures, Tirgu-Mures, Romania*; *[3]University of Medicine and Pharmacy of Tirgu-Mures, Emergency Institute for Cardiac Disease and Transplantation, Tirgu-Mures, Romania*; *[4]Emergency Institute for Cardiac Disease and Transplantation, Tirgu-Mures, Romania*

Funding Acknowledgements: None

Cardiac resynchronization therapy (CRT) has previously been shown to improve left atrial (LA) size and function within months after the procedure, but no data is currently available regarding the immediate impact of CRT. The aim of the current study was to assess acute changes in LA size and function and to provide possible explanations for these variations. We enrolled 25 patients with CRT who were evaluated before and within days after after the procedure. Patients were submitted to an extensive investigation protocol, including echocardiography, which focused mainly on left atrial volumes indexed to body surface were measured at the end of ventricular systole (LAVI max), before atrial systole (LAVI preA), and at the end of ventricular diastole (LAVI min) and further used for calculating the total emptying fraction, active emptying fraction and passive emptying fraction of the LA. LAVI max decreased within days after the implant procedure 45,5 (38,2-56,7) vs. 42,9 (32,1 to 56,2), p <0.05, as did LAVI min – 27,1 (22,9-41,9) vs. 25,9 (17,8-38,1), p <0.05, and LAVI preA – 40,0 (31,3-53,0) vs. 35,5 (25,8-49,1). Mitral regurgitation was also significantly improved (p <0.001). None of the LA function parameters changed significantly within days after CRT. Significant correlations were obvious between LA volumes and the degree of mitral regurgitation before the procedure, but not afterwards. The diastole duration to cardiac cycle ratio was correlated to LAVI max (Spearman's rho= 0,441, p <0,05) and LAVI min (Spearman's rho 0,417, p <0.05) after CRT, but not before. LA indexed volumes regress within days after CRT, most likely as a consequence of immediate mitral regurgitation improvement and atrio-ventricular dyssynchrony reduction, while functional parameters remain unchanged.

P2252

Cardiac resynchronization therapy: what is the prognostic value of ventricular dyssynchrony by echocardiography?

S Sara Guerreiro[1]; M Castro[1]; J Carmo[1]; P Adragao[1]; C Fonseca[2]; N Cardim[3]; F Macedo[4]; D Bonhorst[1]
[1]Hospital de Santa Cruz, Lisbon, Portugal; *[2]Hospital de Sao Francisco Xavier, Lisbon, Portugal*; *[3]Hospital Luz, Lisbon, Portugal*; *[4]Sao Joao Hospital, Porto, Portugal*

Background: Cardiac resynchronization therapy (CRT) is recommended on patients with heart failure, ejection fraction less than 35% and QRS duration greater than 120 ms, independently of echocardiographic evidence of mechanical ventricular dyssynchrony (MVD).
The aim of this study was to evaluate the impact of MVD evaluation by echocardiography before CRT implantation in clinical response of patients.
Methods: Prospective and multicentre national registry in which patients with ejection fraction less than 35% who underwent implantable cardioverter-defibrillator or CRT were included. A sub-population of 82 patients underwent CRT implantation and MVD evaluation by echocardiography (55 men; age 68± 10 years) were analysed. The primary endpoint was the relationship between the degree of improvement of the New York Heart Association (NYHA) functional class during the one-year of follow-up and the echocardiographic parameters of inter- and intraventricular dyssynchrony, determined previous to the device implantation.
Results: In the baseline assessment, 34% of the patients (n = 28) had ischemic cardiopathy of etiology and 44% (n = 36) idiopathic dilated cardiopathy. The mean ejection fraction was 27 ± 6% and the majority of patients were in the class III (62%, n = 51) and in the class II (35%, n = 29) of NYHA. Intraventricular dyssynchrony was present in 67% of patients (n = 55) and interventricular dyssynchrony in 41% (n = 34). The mean duration of the QRS was 150 ± 23ms and 82% of the patients (n = 67) presented left bundle branch block pattern. During a median follow-up of 12 months, there was a significant improvement in functional class in which most patients were classified as class I (20%, n = 16) and II (60%, n = 49) - Figure 1. Intraventricular dyssynchrony was a predictor of NYHA class improvement (HR 6.1; 95% CI, 1.4 - 26.3; p = 0.015), unlike interventricular dyssynchrony.
Conclusion: Intraventricular dyssynchrony evaluated by echocardiography was a predictor of improvement in the symptoms of heart failure after CRT implantation. IT suggests that MVD may be used for a better selection of patients proposed for cardiac resynchronization therapy.

Clinical and ultrasound correlates of cardiac resynchronization therapy in patients with congestive heart failure

D David Mrikaev[1]; E Golukhova[1]; T Mashina[1]
[1]Bakoulev Center for Cardiovascular Surgery RAMS, Noninvasive Arrhythmology, Moscow, Russian Federation

Background: Cardiac resynchronization therapy (CRT) improved greatly symptoms and survival in heart failure (HF) patients. Randomized clinical trials demonstrated that still a lot of patients with standard clinical selection criteria do not respond to CRT favorably. Accordingly, quantification of left ventricular (LV) dyssynchrony by echocardiography has emerged as an important potential tool to predict patient response. The aim of our study was to evaluate prognostic values of echocardiographic parameters for predicting CRT outcomes in heart failure patients with left bundle branch block.
Methods: 40 patients with HF at the mean age of 61.7 ± 10.4 years were enrolled in our study. They were divided into 2 groups: group 1 (n = 25) included patients with dilatation cardiomyopathy (DCM), group 2 (n = 15) included patients with ischemic cardiomyopathy (ICM). The inclusion criteria were: NYHA functional class II-IV, LVEF < 35%, QRS>130 ms. Ultrasound examination included detailed anatomical scan in 2-D and 3-D mode. We calculated LV systolic dissynchrony indexes (SDI and Tmsv-Dif-16) based on the 16-segmental 3D LV model. Systolic dyssynchrony index-Ts-SD was calculated by Strain Rate Imaging, and intraventricular dyssynchrony was estimated by Speckle Tracking.
Results: We revealed, that SDI and Tmsv-16-Dif had an inverse relationship with LVEF. In patients with DCM LVEF increased from 34% ± 3% to 39% ± 10% after CRT with a decrease in SDI from 11.32 ± 4.9% to 8.85 ± 2.11% (p < 0,05), and the Tmsv 16-Dif - from 42.7 ± 4.7% to 25.11 ± 5.6% (p < 0,05). In patients with ICM LVEF increased from 37.4% ± 3% to 42% ± 12% after CRT, while reducing SDI from 12.6 ± 4.4% to 8.1 ± 5.6% and Tmsv-Dif-16 from 37.5 ± 6.9% to 29.3 ± 4.6% (p < 0,05 for both). The Ts-SD in the 1 group was 45.9 ± 15.1ms, in the 2nd group, 35.8 ± 7.2ms. Thus, after the biventricular pacing the dyssynchrony indexes (SDI, Tmsv 16-Diff) decreased and LVEF increased in both groups (r=-0.83, p < 0.05). Patameters of radial dyssynchrony were more important than longitudinal dyssynchrony concerning CRT outcomes. Radial dyssynchrony was initially greater in those patients who subsequently responded to CRT (in patients with ICM). There was a high correlation between LVEF and radial dyssynchrony (r=0.81, p < 0.05) in both groups.
Conclusions: The intraventricular dyssynchrony indexes (SDI, Tmsv 16-Diff and Ts-SD - TDI) were highly effective in predicting CRT outcomes in both groups. For patients with ICM the best predictor of CRT response is the radial dyssynchrony by Speckle Tracking, which appears to be associated with lower LVEF of this group

P2254

New prospects of cardiac resynchronization therapy in patients with mild heart failure

VA Sujayeva[1]
[1]Republican Scientific and Practical Centre of Cardiology, scientific laboratory of chronic ischemic heart disease, Minsk, Belarus

Objective: to carry out complex assessment of a functional condition of the blood circulatory system according to both echocardiography (EhoCG) and Spiro Bicycle Ergometry Test (spiroBET) at patients with mild chronic heart failure NYHA class II in various terms after cardiac resynchronization therapy (CRT).
Methods: The research included 26 patients (6 (23%) – women, 20 (71%) with mild chronic heart failure NYHA class II. 15 (58%) from 26 pts had ischemic cardiomyopathy, 11 (42%) – dilated cardiomyopathy. The age included in a research made from 39 to 67 years (on average 55.0 ± 8,1 years). All patients received optimal medicament therapy including ACE inhibitors, diuretics, beta-blockers. Tolerance to physical loading (TPL) was estimated in spiroBET which was performed at Schiller AG AT-104 ErgoSpiro using Bruce protocol. We also made transthoracic EhoCG with assessment of the standard structural and morphological parameters and also

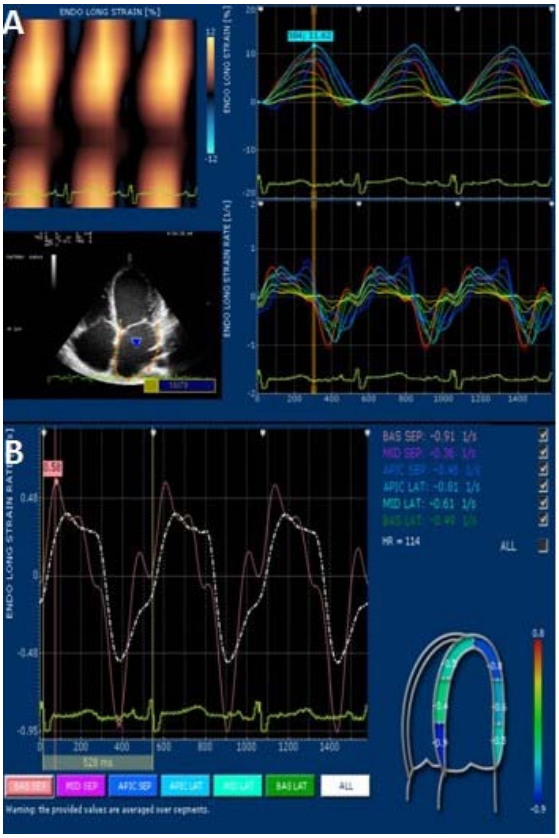
myocardium dyssynchrony was carried out. I test was made before CRT implantation, II test was made at 3 month after, III test – at 6 month and IV test– at 12 month after CRT implantation.
Results: At the I test the Ejection fraction (EF) of Left Ventricle was 29.0 ± 5.9% in averaged on group. TPL according to spiroBET was 61.4 ± 31.4 Wt, the maximal oxygen consumption (VO2max) reached only 8.0 ± 4.2 ml/kg/min. All above demonstrates significant impairment not only myocardial contractility, but also objective TPL and aerobic capacity, despite existence only II NYHA class of heart failure. At the II test 88% of patients had significant improvement in myocardial contractility – EF increased up to 36.7 ± 5.9% ($p < 0.05$). The same tendency was at III and IV test – EF was 34.9 ± 9.7% and 33.6 ± 15.4%, correspondingly ($p < 0.05$). Patients with positive dynamics of contractility were made 'Responders' Group (RG). In others 12% patients significant improvement of structural and morphological parameters we didn't find, they made 'Non-Responders' Group (NRG). At III test the ratio of RG/NRG was 78%/12%, at IV test – 82%/18%, respectively. However, improvement of myocardial contractility didn't bring to either TPL or VO2 max increasing. TPL was 65.6 ± 22.9 Wt at II test, 52.8 ± 26.3 Wt – at III test and 61.4 ± 28.2 – at IV test ($p > 0.05$). VO2 max was 10.3 ± 1.5, 5.8 ± 3.9 and 8.5 ± 3.8 ml/kg/min at II, III and IV test, correspondingly.
Thus, after implantation of CRT, despite significant improvement of myocardial contractility and geometry essential TPL and the aerobic functional capacity didn't increase. It can be bound to a small number of observations. Identification of pathophysiological mechanisms of this phenomenon requires continuation of a research.

HEART FAILURE IMAGING

P2255
Left atrial mechanical function in patients with non-ischemic dilated cardiomyopathy: A speckle tracking echocardiography study

K Wagdy[1]; N Faheem[2]; A Samaan[3]; HM Badran[2]
[1]Aswan Heart Centre, Adult cardiology , Aswan, Egypt; *[2]Faculty of medicine , Cardiology , Menofia, Egypt*; *[3]Cairo University, Cardiovascular, Cairo, Egypt*

Background: Left atrium (LA) plays an integral role in maintaining optimal cardiac performance throughout the cardiac cycle via three major functions; reservoir, conduit and contractile functions. LA volumes and function are well established independent prognostic factors in heart failure patients.
Purpose: Evaluation of mechanical functions of LA in patients with non-ischaemic dilated cardiomyopathy (DCM).
Methods: The study included 73 patients (Median age 36 years, 46 men) with non-ischaemicDCM and another group of 25 age and gender matched healthy volunteers. The study took place in our University. Trans-thoracic echocardiography was used for evaluation of left ventricle dimensions and function, LA antero-posterior diameter, maximal and minimal volumes and LA emptying fraction. Speckle tracking echocardiography was used for assessment of LA global longitudinal strain (S) and strain rate (SR). The left atrium was divided into 6 segments; the global longitudinal strain and strain rate was calculated as the mean value of these 6 segments. LA peak systolic strain (S sys) and systolic SR (SRsys) measured at LV systole were used as a surrogate for LA reservoir function while early diastolic SR (SRe) and late diastole SR (SRa) were used as surrogates for LA conduit and active emptying functions respectively.
Results: In comparison to the control group, DCM patients had significantly larger left ventricular (LV) end diastolic dimension (66.8 ml vs. 45 ml) and lower LV ejection fraction (32% vs. 65%). LA antero-posterior diameter was significantly larger in DCM patients (40.8 cm vs. 27.2 cm) with markedly lower LA emptying fraction (32.29 vs. 62.04). Analysis of LA speckle tracking showed significantly lower LA S sys (12.82% vs 39.6 %)and LA SRsys (0.76 S-1vs. 1.84 S-1), significantly lower SRe (-0.63 S-1 vs. -2.04 S-1) and significantly lower SRa (-0.71 S-1 vs.-1.23 S-1)in DCM patients compared to the control group.
Conclusion: In patients with non-ischaemic DCM, all LA mechanical functions are significantly reduced. Speckle Tracking Echocardiography can be used for assessment of LA mechanical function in these patients for prognostic purposes.



Left atrial strain and strain rate

P2256
Impact of total ischemic time on diastolic function and left atrial volume index in patients with STEMI: late reperfusion is a major determinant of persistent diastolic dysfunction

L Ludovico Lazzari[1]; D Bovelli[1]; G Ambrosio[2]; E Boschetti[3]
[1]Az. Osp. "S. Maria", Cardiology Department, Terni, Italy; *[2]Hospital Santa Maria Della Misericordia, Cardiology and Cardiovascular Pathophysiology Division \ University of Perugia, Perugia, Italy*; *[3]Az. Osp. "Santa Maria" Terni \ University of Perugia, Cardiology Department, Terni, Italy*

Background: Data about the impact of total ischemic time (TIT) on left ventricular diastolic function (LVDF) and on atrial remodelling after a ST-elevation myocardial infarction (STEMI) are lacking.
Purpose: we assessed non-invasive left ventricular filling pressure (LVFP) and left atrial volume index (LAVI) changes over time in patients with a first-ever STEMI, undergoing primary percutaneous coronary intervention (PCI), to determine whether the TIT could be a predictor of persistent left ventricular diastolic dysfunction (LVDD).
Methods: 29 patients (mean age 61 ± 9, 1 female) were enrolled. Exclusion criteria were a TIT > 12 hours, history of coronary artery disease or cardiomyopathy, presence of any moderate or severe valvular disease, age > 75 years old, post-PTCI TIMI flow < 3, a LAVI > 28 ml\m^2 and a left ventricular ejection fraction < 45%. Serial echocardiographic evaluations were performed 48 hours after the onset of symptoms and at a 6 months follow-up (FU). Evaluation of LVDF was based on integrated assessment of trans-mitral Doppler flow pattern, tissue Doppler imaging and PW-Doppler of pulmonary veins. The average E\e' ratio was used as a non-invasive surrogate for LVFP. Patients were divided in two different groups according to the mean TIT (323 ± 154 minutes): early reperfusion group (TIT ≤ 5 hours, 15 patients) and late reperfusion group (TIT > 5 housr, 14 patients). Left atrial enlargement was defined as a LAVI ≥ 28 ml\m^2 at FU.
Results: A normal diastolic function was observed only in the early group at baseline evaluation (26.7% vs 0%, $p = 0.03$). The average E\e' ratio showed no difference at baseline between the two groups (9 ± 2.5 vs 8.6 ± 2.5, p = NS). At FU, the estimated-LVFP (average E\e') remained stable in the early group (-0.4, p = NS), while it showed an elevation in the late group (+1.6, $p = 0.05$), leading to a significant difference (8.6 ± 2.8 vs 10.2 ± 3.2, $p = 0.02$). Likewise, baseline LAVI was similar

in both groups (24.4 ± 2.5 vs. 24.3 ± 2.3 ml\m^2, p = NS) but, while LAVI remained stable at FU in the early group (+ 0.6 ml\m^2, p = NS), a left atrial enlargement was seen in the late group (+ 7,4 ml\m^2, p = 0.04), leading to a significant difference (25 ± 2.3 vs 31.7 ± 1.4 ml\m^2, p = 0.01); suggesting therefore a persistence of LVDD in the late revascularization group. Patients with LAVI ≥ 28 ml/m^2 had longer TIT (386 ± 153 vs 220 ± 86 min, p = 0.003) and higher average E/e' ratio (10.4 ± 3.1 vs. 7.1 ± 1.5, p = 0.004) than those with LAVI < 28 ml/m^2. At FU, the main predictors of a LA enlargement were the TIT (r = 0.532; p = 0.03 – OR = 1.01, 95% CI 1.00 – 1.02, p = 0.01) and the average E/e' ratio (r = 0.520; p = 0.04 – OR = 2.07, 95% CI 1.10 – 3.88, p = 0.02).
Conclusion: TIT affects LVDF and atrial remodelling. An higher TIT lead to a persistent LVDD quantifiable through the progressive increase in estimated-LVFP (average E\e' ratio) and LAVI.

P2257
Is reduced left atrial expansion index the best predictor of increased left ventricular filling pressures ?

I Imen Hamdi[1]; A Belouaer[1]; C Chourabi[1]; K Houissa[1]; H Mahfoudhi[1]; R Dahmani[1]; A Haggui[1]; N Hajlaoui[1]; D Lahidheb[1]; W Fehri[1]; H Haouala[1]
[1]*Cardiology departement, Military Hospital of Tunis, Tunis, Tunisia*

Aim: The aim of the study was to assess the value of the left atrial expansion index (LAEI) for the estimation of left ventricular filling pressures and its relation with N-terminal pro-B- type natriuretic peptide (NT-proBNP) levels in patients with ischemic cardiomyopathy.
Methods: This prospective study enrolled 49 patients (mean age : 62.7 years, range 44-89, 85% male) with ischemic cardiomyopathy (mean Left ventricular ejection fraction : 47.57 %). All patients underwent transthoracic echocardiography and NT-proBNP measurement within 24 hours. The LAEI was calculated as (Vol max –Vol min) x 100% / Vol min, where Vol max was defined as maximal LA volume and Vol min was defined as minimal volume.
Results: Simple regression analysis demonstrated a significant linear correlation between LAEI and Log NT-proBNP (r=0.807, p < 0.0001). Significant but weaker correlations were found between Log NT-proBNP and E/E' (r=0.543, p < 0.0001), indexed LA maximum volume (LAVI max) (r=0.397, p = 0.006), mitral deceleration time (TDE) (r=0.268, p = 0.072), E/A (r=0.347, p = 0.01). Significant correlation was also found between LAEI and E/E' (r=0.517, p < 0.0001).
The area under the receiver-operating characteristic curve showed that LAEI had good diagnostic power for E/E' > 15 at cutoff value of 52%, with a sensitivity of 84% and a specificity of 78%.
In a multiple linear regression model with Log-NT-proBNP as dependent variable and age, E/A, TDE, E/E', LAVI max and LAEI as predictors, LAEI was the only parameter that remaind an independent predictor of elevated NT-proBNP levels (R^2=0.651, p < 0.0001), the relation to LAEI was the strongest (β= -0.807).
Conclusion: Reduced LAEI is an important predictor of elevated left ventricular filling pressures in patients with ischemic cardiomyopathy.

P2258
Is left atrial volume index over late diastolic mitral annulus velocity a useful parameter to predict filling pressures ?

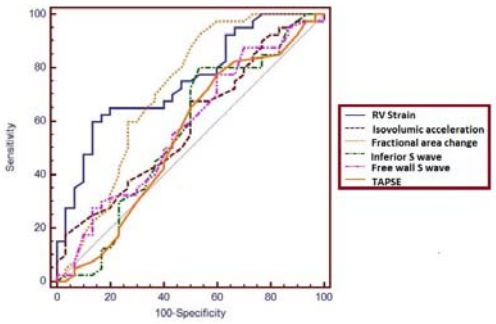
I Imen Hamdi[1]; C Chourabi[1]; A Belouaer[1]; K Houissa[1]; M Ghommidh[1]; N Ben Mansour[1]; A Haggui[1]; N Hajlaoui[1]; D Lahidheb[1]; W Fehri[1]; H Haouala[1]
[1]*Cardiology departement, Military Hospital of Tunis, Tunis, Tunisia*

Aim: Combined interpretation of late diastolic mitral annulus velocity (A') with left atrial volume index (LAVi) may help to predict elevated left ventricular filling pressures. Our aim was to assess the usefulness of the LAVi/A' ratio to identify increased filling pressures.
Methods: This prospective study enrolled 49 patients (mean age : 62.7 years, range 44-89, 85% male) with ischemic cardiomyopathy (mean left ventricular ejection fraction : 47.57 %). All patients underwent transthoracic echocardiography and N-terminal pro-B- type natriuretic peptide (NT-proBNP) measurement within 24 hours.
Results: Significant correlation was found between LAVi/A' and NT-proBNP levels (r=-0.536, p < 0.001). On the receiver operation characteristic curve analysis for the determination of increased NT-proBNP levels, the area under the curve of LAVi/A' was comparable to those of E/E' (0.802 Vs 0.805, p = 0.001).
A LAVi/A' of 3.3 was the best cut-off value to identify NT-proBNP > 450 ng/L, with a sensitivity of 83% and a specificity of 70%.
Conclusion: LAVi/A' may be a useful parameter to identify elevated filling pressures in patients with ischemic cardiomyopathy.

P2259
2D-speckle tracking right ventricular strain to assess right ventricular systolic function in left ventricular systolic dysfunction.

S Mouton[1]; H Ridon[1]; M Fertin[1]; A Duva Pentiah[1]; C Goemine[1]; G Petyt[1]; N Lamblin[1]; A Coisne[1]; C Foucher-Hossein[1]; D Montaigne[1]; P De Groote[1]
[1]*Cardiology Hospital of Lille, Nord, Lille, France*

Background: In patients with left ventricular systolic dysfunction, an accurate estimation of right ventricular (RV) systolic function remains difficult in routine.
Purpose: The aim of the study was to determine the diagnostic accuracy of 2D-speckle tracking RV strain in patients with systolic heart failure.
Methods: Seventy-six patients with dilated cardiopathy and left ventricular ejection fraction ≤ 45% had an analysis of the RV strain. Feasibility, reproducibility and diagnostic accuracy of RV strain were analyzed and compared to other echocardiographic parameters of RV function, taking into account radionuclide RV ejection fraction (± 40%) as gold standard.
Results: RV strain feasibility was 93.9% for the free-wall. RV strain reproducibility was good (intra-observer and inter-observer bias and limits of agreement of 0.16 ± 1.2% [-2.2-2.5] and 0.84 ± 2.4 [-5.5-3.8], respectively). Mean RV strain showed the highest diagnostic accuracy to predict depressed RV ejection fraction (area under the curve (AUC) 0.75) with moderate sensitivity (60.5%) but high specificity (87.5%) using a cutoff value of -16%. It was correlated to radionuclide RV ejection fraction (R = -0.51, p < 0.0001).
Conclusion: RV strain appears as a complementary and more accurate tool than previous RV echocardiographic parameters for the diagnosis of RV systolic dysfunction.



Diagnostic accuraty of RV parameters

P2260
Enlarged left atrium and increased basal heart rate predict exercise capacity in heart failure patients

P Ibrahimi[1]; A Batalli[1]; A Ahmeti[1]; SH Elezi[2]; MY Henein[3]; G Bajraktari[1]
[1]*University Clinical Center of Kosova, Clinic of Cardiology, Prishtina, Kosovo Republic of*; [2]*Faculty of Medicine, University of Prishtina, Clinic of Cardiology, Prishtina, Kosovo Republic of*; [3]*Department of Public Health and Clinical Medicine, Umea University, Umea, Sweden*

Background and aim: Heart failure (HF) is a major and growing health problem characterized by high mortality, frequent hospitalization, reduced quality of life and a complex therapeutic regimen. Six minute walking test (6-MWT) may serve as a reproducible test for assessing exercise capacity in HF patients and can be clinically predicted. The aim of this study was to assess clinical, biochemical and echocardiographical predictors of limited exercise capacity in HF patients.
Methods: The study subjects were 135 consecutive clinically stable HF patients (64 ± 11 years, 66 [47%] female, classified as NYHA I-III). Echocardiography, including tissue Doppler measurements, was performed in all patients. A six minute walk test (6-MWT) distance was performed in all patients, who were divided into two groups based on the 6-MWT distance (Group I: ≤ 300 m and Group II: >300 m).
Results: Patients with limited exercise performance (≤ 300 m) were older (p < 001), more frequent female (p = 0.007) and diabetics (p = 0.003), had lower level of hemoglobin (p = 0.02), larger left atrium (LA, p = 0.003), higher basal heart rate

(p = 0.009), higher E/e' ratio (p = 0.01) and lower septal systolic myocardial velocity (p = 0.03) compared with good performance patients.
Enlarged LA [2.856 (1.439-5.666), p = 0.003], older age [1.110 (1.036-1.188), p = 0.003], increased basal heart rate [1.055 (1.012-1.099), p = 0.012] and the presence of diabetes [3.321 (1.022-10.796), p = 0.046] independently predicted poor 6-MWT performance.
Conclusions: In patients with HF, the limited exercise capacity assessed by 6-MWT, is related mostly to the enlarged left atrium as e reflection of longstanding increased left ventricular filling pressure, increased basal heart rate, in addition to the older age and the presence of diabetes. These findings highlights the need of the optimal medical treatment of HF patients towards the decreasing LV filling pressure and heart rate.

P2261

Left atrial size influences on left ventricular longitudinal tissue velocity

JH Jihyun Yoon[1]; EY Choi[1]; PK Min[1]; BK Lee[1]; HM Kwon[1]; JY Kim[1]; YW Yoon[1]; BK Hong[1]; SJ Rim[1]
[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea Republic of

Purpose: Reduced longitudinal tissue velocity of left ventricle (LV) has been considered early signs of systolic and diastolic dysfunction. However, if Left atrial (LA) superior-inferior dimension increases, longitudinal motion may be restricted within fixed mediastinal space. In this study, we hypothesized that not only myocardial function but also LA size may influence longitudinal tissue Doppler velocity. To verify this hypothesis, we studied patients with Duchenne muscular dystrophy (DMD) who have been known to have dilated cardiomyopathy (DCM), but less heart failure symptoms.
Methods: The study population comprised 100 idiopathic DCM patients (65 men, 57.1 ± 16.6 years) and 101 DMD patients (98 men, 23.8 ± 15.3 years) with left ventricular (LV) ejection fraction (LVEF) < 50 % on echocardiography. Comprehensive echocardiographic measurements of LV chamber and function were performed accompanied with mitral septal annular (S') and early diastolic (e') velocities measurement using tissue Doppler imaging.
Results: Despite no significant difference in LVEF, S' and e' were significantly higher in DMD patients compared to idiopathic DCM patients (6.2 ± 1.4 cm/sec vs. 4.9 ± 1.6 cm/sec, p < 0.001 and 7.9 ± 2.0 cm/sec vs. 4.8 ± 1.9 cm/sec, p < 0.001, respectively). LA volume index (LAVI) was significantly lower in patients with DMD (16.1 ± 11.7 mL/m2 vs. 39.2 ± 20.2 mL/m2, p < 0.001). S' and e' were significantly corelated to LAVI (p < 0.001 for S' and p < 0.001 for e') and its relationship remained significant even after controling for age, gender, LVEF and underlying diseases. (p < 0.001for S' and p = 0.039 for e').
Conclusions: Patients with DCM associated with DMD have relatively preserved myocardial longitudinal function compared to idiopathic DCM as assessed by tissue Doppler. Myocardial longitudinal velocities are influenced by LA size as well as myocardial function.

Exercise-induced atrial remodeling

S Sondes Smaali[1]
[1]La Rabta University Hospital, Tunis, Tunisia

Funding Acknowledgements: the department of cardilogy

Introduction: Athlete's heart is characterized by a geometrical remodeling of the left atrium (LA).
Purpose: To evaluate atrial functional remodeling due to training.
Methods: 85 men aged 18 to 32 years old were included in this monocentric prospective study. 65 athletes (group trained T) training at least 8 hours per week were compared to 20 healthy sedentary subjects (group S). Transthoracic echocardiogram was performed on competitive period.
Results: Group T presented a higher end-systolic volume (83.56 ± 14.00 Vs 52.46 ± 7.39 ml , p < 0.001) compared to group S.
During exercise there was no difference between groups for global systolic function evaluated by ejection fraction (EF) (50.02 ± 1.7 Vs 50.03 ± 1.38 % ,p = 0.09) and for reservoir phase evaluated by the systolic peak velocity of lateral wall derived from DTI (S') (5.76 ± 0.71 5.34 ± 1.01 cm/ , p = 0.08).
Conclusion: Remodeling of LA in athletes was marked by mild enlargement of LA with a preserved global systolic function and sub normal contribution of the reservoir phase for left ventricle filling at exercise.

Echocardiographic parameters of LA

	ATHLETES (T, n=65)	Sedentary (S , n=20)	p

S'(cm/s)	5.76±0.71	5.34±1.01	p = 0.008

LAA: left atrium area , ESV : end systolic volume , EDV : End diastolic volume , LA EF : Left atrium ejection fraction , S': the systolic peak velocity of atrium lateral wall ranged from DTI.

P2263

The results of applying different algorithms for the estimation of left ventricle diastolic function in the group of patients with chronic heart failure and preserved ejection fraction

O A Olga Petrova[1]; V N Larina[2]; M N Alekhin[1]
[1]Central state medical academy of department of presidential affairs, Moscow, Russian Federation; *[2]The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation*

The article presents a comparison of the evaluation of left ventricular (LV) diastolic function (DF) by echocardiography results in patients with chronic heart failure (CHF) and preserved ejection fraction (EF) of the LV using the algorithm of the 2009 European Association of Echocardiography and American Society of Echocardiography (2009 EAE/ASE) guidelines in comparison with the 2016 algorithm of the American Society of Echocardiography and European Association of Cardiovascular Imaging (2016 ASE/EACVI).
Methods: We included 55 patients with CHF (age of 69.6 ± 9.6 years, of whom 26 males), sinus rhythm and preserved LV EF (59.6 ± 3.1%). 43 patients suffered of coronary heart disease, 53 patients had arterial hypertension, 8 patients had an old myocardial infarction. 10 patients had NYHA functional class I, 38 patients were in NYHA class II and 7 were in class III. LV DF was assessed using algorithms the 2009 ASE/EAE and the 2016 ASE/EACVI. Pulsed-wave tissue Doppler early diastolic velocity (e′ velocity) at lateral and septal basal regions of mitral annular (MA), left atrial maximum volume index (LAVI) were evaluated in accordance with the 2009 ASE/EAE algorithm. In addition to the two above-described criteria, E/e′ ratio and peak velocity of tricuspid regurgitation were analyzed in accordance with the 2016 ASE/EACVI algorithm for judging the presence of LV diastolic dysfunction (DD). Identification of 3 or more of the criteria regarded as having LV DD, in the presence of one characteristic was normal LV DF, detection of 2 listed criteria was considered as an indeterminate result.
Results: The velocity parameters of transmitral flow, e′ velocity of MA and LAVI were measured in all patients. The peak velocity of tricuspid regurgitation was adequately measured in 46 patients out of 55. 26 patients (46%) had DD, 5 patients had a normal DF, 24 patients had an indeterminate result in accordance with the algorithm 2009 EAE/ASE. 12 (21%) patients had DD (p < 0.01 compared with the algorithm 2009 EAE/ASE), 31 patients had a normal DD (p < 0.001 compared to the algorithm

2009 EAE/ASE), and 12 patients had an indeterminate result ($p < 0.01$ compared with the algorithm 2009 EAE/ASE) in accordance with the algorithm 2016 ASE/EACVI. Among the 31 patients with normal LV DF 24 patients had one of the signs of DD: in one case the peak velocity of tricuspid regurgitation was more than 2.8 m/s, in 3 cases LAVI was more than 34 ml/m2 and 20 patients had reduced early diastolic velocity MA in accordance with the algorithm 2016 ASE/EACVI.
Conclusion: The algorithm application proposed by the 2016 ASE/EACVI to LV DF assess in the group of patients with CHF and preserved LVEF leads to a significant decrease in the number of indeterminate results (from 43% to 21%, $p < 0.01$) and the number of patients with LV DD (from 46% to 21%, $p < 0.01$) when compared with the algorithm 2009 EAE/ASE.

P2264

Cardiac sympathetic activity and ventricular dyssynchrony in patients with heart failure referred for cardiac resynchronization therapy

K Zavadovsky[1]; V Viktor Saushkin[1]; I Kostina[1]; Y Lishmanov[2]; D Lebedev[3]; S Popov[3]
[1]Cardiology Research Institute, Tomsk NRMC, Nuclear Medicine Department, Tomsk, Russian Federation; *[2]National Research Tomsk Polytechnic University, Tomsk, Russian Federation*; *[3]Cardiology Research Institute, Tomsk NRMC, Department of surgical treatment of cardiac rhythm disorders and pacing, Tomsk, Russian Federation*

Funding Acknowledgements: The study was supported by grant from the Russian Science Foundation (N 15-15-10016).

Background: Cardiac resynchronization therapy (CRT) is currently one of the main treatment modalities for patients with severe heart failure. Unfortunately, about 30% of patients undergoing CRT are non-responders. In our opinion, assessment of cardiac sympathetic activity and ventricular dyssynchrony may help to develop new predictors of CRT outcomes.
Purpose: The aim of the study was to evaluate cardiac sympathetic activity and ventricular dyssynchrony in patients with chronic heart failure before cardiac resynchronization therapy.
Methods: The study comprised 51 patients (mean age of 49 ± 8 years) with severe contractility dysfunction of the left ventricle (LVEF $< 30\%$; NYHA III-IV). All patients underwent a comprehensive clinical and functional examination including gated SPECT myocardial perfusion imaging (gSPECT-MPI), 123I-MIBG imaging and gated blood-pool SPECT (GBPS). Systolic and diastolic functions (EDV, ESV, and EF) as well as mechanical intraventricular dyssynchrony of both ventricles were analyzed. Moreover, we analyzed abnormalities of 123I-MIBG (summed 123I-MIBG score) and 99mTc-MIBI accumulations (normalized SSS and SRS) in the left ventricular (LV) myocardium. All examinations were performed using GE Discovery NM/CT 570C with cadmium-zinc-telluride detectors.
Results: According to stress and rest gSPECT-MPI, all patients had heterogeneous myocardial perfusion pattern. The median values of normalized SSS and SRS were 14% (12-19%) and 5% (2-7%), respectively. Most often, areas of reduced 99mTc-MIBI accumulation were located in the LV apex. In all patients, decreases in contractility and dilatation of both ventricles were detected: median LV EDV was 401 mL (312-511 mL); median right ventricular (RV) EDV was 280 mL (216-388 mL); median LV EF was 26% (17-27%); and median RV EF was 23% (21-44%). Based on GBPS data, severe mechanical dyssynchrony of both ventricles was detected. The median value of LV intraventricular dyssynchrony was 129 ms (103-161 ms); RV intraventricular dyssynchrony was 123 ms (82-152 ms). The value of interventricular dyssynchrony was less than 50 ms. The summed 123I-MIBG score was 25% (21-31%) which was significantly greater than normalized SSS and SRS ($p = 0.03$ and $p = 0.04$, respectively). Areas of reduced 123I-MIBG accumulation matched the myocardial perfusion defects localizations.
Conclusion: Our findings suggest that patients with chronic heart failure had severe ventricular contractility dysfunction and mechanical dyssynchrony of both ventricles. Moreover, sympathetic activity/perfusion disturbances mismatch was detected in these patients. These data will be used in the follow-up study after CRT device implantation in order to develop new predictors of CRT outcomes.

P2265

Role of 123-Iobenguane myocardial scintigraphy in predicting short term left ventricular functional recovery and indication to ICD implantation after coronary revascularization

M Mauro Feola[1]; M Testa[2]; C Ferreri[2]; S Chauvie[3]; A Biggi[3]
[1]Cardiovascular Rehabilitation-Heart Failure Unit, Fossano, Italy; *[2]School of Geriatry University of Turin, Turin, Italy*; *[3]Santa Croce E Carle Hospital, Nuclear Medicine Service, Cuneo, Italy*

123I-Iobenguane myocardial scintigraphy (MIBG), which identifies sympathetic nervous system dysfunction, has been shown to be an effective predictor of sudden cardiac mortality in patient with congestive heart failure (CHF) and could be a useful instrument to early identify adverse clinical events.
Methods: patients with CHF, a New York Heart Association classification (NYHA) of II or III and a left ventricular ejection fraction (LVEF) $\leq 35\%$ were eligible for cardiac defibrillator (ICD) placement under current LVEF-based criteria in the Guidelines. All patients listed for ICD underwent a MIBG before the implantation, in order to assess the prognostic value of an early cardiac MIBG to predict appropriate ICD indication according to recent Guidelines.
Results: 16 patients (100% males; age 65.4 ± 9.6 years) with mean LVEF $29.2 \pm 4.96\%$ entered the study. All patients had a coronary artery disease (CAD) treated by coronary artery bypass graft (CABG) in ten cases (62.5%) , by a percutaneous coronary angioplasty (PTCA) in five and both procedures in one patient. The myocardial perfusion/MIBG scintigraphy has benne performed in the first 15 days after the coronary revascularization. In 15 subjects (93.7%) the heart/mediastinum (H/M) ratio was calculated < 1.6 (mean 1.3 ± 0.17) and the wash-out rate (WR) was $4.91 \pm 4.03\%$. The semiquantitative analysis of the images demonstrated, as previously reported, a larger MIBG uptake defect (summed score $= 26.25 \pm 11.9$) in comparison with Tc99 tetrofosmin uptake defect (summes score$=21.8 \pm 8.9$). The LVEF improved at follow-up from $29.2 \pm 4.96\%$ to $31.3 \pm 7.1\%$ and in 5/16 patients proved to be >35% at 3-month follow-up after CABG or 40-day follow-up after primary PTCA. An ICD was implanted in 10/16 % of patients (one patient refused the implantation). According to the left ventricular functional recovery, the sensitivity, specificity, positive predictive value and negative predictive value of an H/M ratio ≤ 1.25 at MIBG was calculated, respectively, in 87.5%, 83.3%,705, 83.3%.
Conclusion: MIBG myocardial scintigraphy might be a promising method for excluding a short-term left ventricular functional recovery after coronary revascularization, permitting a quick decision about ICD implantation in primary prevention.

99mTc-HMPAO-labeled leukocyte SPECT/CT infective endocarditis evaluation in patients with heart failure

K Katarzyna Holcman[1]; M Kostkiewicz[1]; W Szot[2]; B Malecka[3]; A Zabek[3]; K Boczar[3]; A Lesniak-Sobelga[1]; M Hlawaty[1]; S Wisniowska-Smialek[1]; P Rubis[1]; P Podolec[1]
[1]John Paul II Hospital, Jagiellonian University Medical College, Department of Cardiac and Vascular Diseases, Kraków, Poland; *[2]Department of Hygiene and Dietetics, Jagiellonian University Medical College, John Paul II Hospital , Kraków, Poland*; *[3]John Paul II Hospital, Jagiellonian University Medical College, Department of Electrocardiology, Kraków, Poland*

Background: Infective endocarditis (IE) is one of the most common life-threatening infection syndromes, with remaining high mortality. Single photon emission tomography and computed tomography with technetium99m-hexamethylpropyleneamine oxime–labeled leukocytes (99mTc-HMPAO-SPECT/CT) has an added diagnostic value in patients with suspected IE.
Purpose: The aim of this study was to evaluate 99mTc-HMPAO-SPECT/CT inflammatory lesions in patients withheart failure (HF).
Methods: We included 40 consecutive patients with suspected IE based on standard medical diagnostic process. All participants had measured N-terminal pro-brainnatriuretic peptide (NT-proBNP) serum level. Patients had transthoracic (TTE) and transesophageal echocardiography (TTE). There were evaluated: left ventricle ejection fraction (LVEF), tricuspid annular plane systolic excursion (TAPSE), size of heart chambers, morphology and function of the valves, lesions typical for IE. All patients had 99mTc-HMPAO-SPECT/CT - evaluated for presence and location of increased radioactivity foci, which correspond to accumulation of radiolabeled leukocytes.
Results: 72,5% of patients had diagnosed HF. 40% of 99mTc-HMPAO-SPECT/CTs were classified as positive for IE. Extracardiac foci were observed in 47,5% of patients. They were found in: intestine (26%), vascular system (26%), gallbladder (21%). Extracardiac accumulation of radiolabeled leukocytes was observed statistically significant more often in patients with HF ($p < 0,05$). Occurrence of those foci correlated with LVEF ($p = 0,012$) and both left ventricle end-diastolic diameter (LVED) and end-systolic diameter (LVES) (respectively $p = 0,003$ and $p = 0,005$).
Conclusions: This study highlights the diagnostic value of 99mTc-HMPAO-SPECT/CT in assessing IE suspicion, especially in evaluating the localization of infection. Extracardiac accumulation of radiolabeled leukocytes was observed statistically significant more often patients with HF.

NT-proBNP correlates with LAVi and LVMMi in patients with beta-thalassemia major

MSD Dimova[1]; BNK Kanazirev[1]; VK Kaleva[1]; SG Gercheva[1]; LG Gercheva[1]; KIP Petrova[1]
[1]*Medical University of Varna, Varna, Bulgaria*

Background: The main cause of death of β-thalassemia major patients is early cardiac complications and especially heart failure that have been attributed to secondary iron overload despite optimal chelation.
Purpose: To discriminate high output state from high output failure in patients with β-thalassemia major by means of heart failure biomarkers –NT-proBNP and echocardiographic parameters.
Methods: In 32 treated adult patients (18-62 years) with β-thalassemia major NT-pro BNP was investigated together with echocardiographic parameters to diagnose presence of heart failure. A control group of 28 healthy individuals was also used to compare with patients with both increased (9 patients) (TM NT-pro-BNP +) and normal NT-pro-BNP (TM NT-pro-BNP-).
Results: Left ventricular mass index (LVMi) and left atrial volume index (LAVi) and relative wall thickness (RWT) of TM patients were bigger compared to controls and, and LAVi was significantly greater in TM NT-proBNP + group. Correlations were as follow: NT-pro-BNP with LAVi- 0,672 and 0,399 with LVMMi. Strain, Systolic myocardial velocity (Sm) and end-diastolic diameter (EDD) were increased significantly compared to controls, but not between TM NT pro-BNP- and TM NT pro-BNP + groups. NT –proBNP correlated poorly with MRI iron loading T2*- 0,199.
Conclusions: Left ventricular hypertrophy, structural remodeling and LA volumes were the most significant differences between healthy controls and TM patients. Strain and systolic myocardial velocity were also diminished. The only significant difference between TM NT-proBNP- and TM NT-proBNP + patients were LA volumes.

P2268
Assessment nt-probnp in patients with chronic systolic heart failure depending of the quality of life

V Ivanov[1]; YU Savitska[1]; V Maslovskyi[1]; O Kovalchuck[1]
[1]*National Pirogov Memorial Medical University, Internal medicine #3, Vinnitsa, Ukraine*

Purpose: To assessment the level of NT-proBNP in patients with LV systolic chronic heart failure, depending from the quality of life by MHFLQ and MOS-SF-36 questionnaire.
Materials and methods: The study is based on the results of complex clinical and laboratory examination 113 patients aged 60,2 ± 0,74 with systolic chronic heart failure (CHF) II-III FC by NYHA of ischemic and hypertensive etiology. The basis of allocation of different clinical groups were taken the quality of life (QoL) indicators: total score by MHFLQ, physical (PH) and mental (MH) health determined by MOS-SF-36 questionnaire. The method of variation statistics were allocated 3 gradation changes following parameters: relatively low (RL), relatively satisfactory (RS) and relatively high (RH). Thus was formed the following clinical groups of patients:
— total score MHFLQ: 1st group (RL QoL) — ≥61 points, 2nd group (RS QoL) — 60 — 41 and 3rd group (RH QoL) — ≤ 40 points;
— largest PH of MOS-SF-36 questionnaire: 1st group (RL PH) — index ≤29, 2nd group (RS PH) — 30 — 35 and 3rd group (RH PHC) — ≥36.
— largest MH of MOS-SF-36 questionnaire: 1st group (RL MH) — index ≤44, 2nd group (RS MH) — 45 — 63 and 3rd group (RH MH) — ≥64. All of research corresponding to the principles of the Declaration of Helsinki of the World Medical Association.
Results: Found that levels of NT-proBNP in the cohort ranged from 904 to 3836 pg/ml (in average — 1977.5 ± 88.8 pg/ml).
Analysis the level of NT-proBNP depending on QoL by MHFLQ testified that in the group of RL QoL the indicator of biomarkers and the number of patients with high level (>2130 pg/ml) NT-proBNP dominated by similar values in groups RS and RH QoL (2552 pg/ml vs. 1880 and 1650 pg/ml, p<0,009 and 51.6% vs. 22.6% and 25.8% respectively, p<0,04).
Determining the level of NT-proBNP in groups PH of MOS-SF-36 questionnaire showed higher levels of the marker and frequency of registration of cases the value of NT-proBNP >2130 pg/ml in patients with RL PH compared with the corresponding values in the group is RH PH (2224 vs. 1692 pg\ml, p = 0.008 and 36.4% vs. 12.5%, p < 0.05, respectively).
The analysis parameters NT-proBNP depending from MH of MOS-SF-36 questionnaire showed that the levels of biomarkers in a group with a RL MH more than a group of RH MH (2221 vs. 1714 pg/ml, respectively, p = 0.02). The distribution of the different levels of NT-proBNP in groups MH of MOS-SF-36 questionnaire showed a significant increase in the frequency of cases registered the high level of NT-proBNP in the group of RL compared to the RH MH group (35.4% vs. 11.8% respectively, p < 0.04).
Conclusions: It was shown that in patients with systolic CHF II-III FC by NYHA of ischemic and hypertensive etiology level of NT-proBNP, to some extent, associated with the levels of the quality of life by MHFLQ, physical and mental health determined by MOS-SF-36 questionnaire.

P2269
Effect of sacubitril/valsartan therapy on risk stratification biomarkers in a real-world heart failure population

M J Barrett[1]; M Hammond[2]; S Zhou[2]; R O Hanlon[3]; P Campbell[1]; K Mcdonald[1]
[1]*St Vincent's University Hospital, Cardiology, Dublin, Ireland*; [2]*Heartbeat Trust, Dublin, Ireland*; [3]*St. Michael's Hospital, Heart Failure Unit, Dublin, Ireland*

Background/Introduction: Sacubitril/valsartan is a novel therapy in treatment of patients with reduced ejection fraction heart failure (HFrEF). This compound appears to have different effects on the two commonly used natriuretic peptide (NP) assays. We have few data on biomarker response in a routine clinical population treated with sacubitril/valsartan.
Purpose: To assess the effect of sacubitril/valsartan on cardiac biomarkers in a community population of patients with HFrEF managed in a disease management programme.
Methods: Patients commencing sacubitril/valsartan therapy and achieving maximum tolerated dose were included (n = 61). Baseline measurements of BNP, NTproBNP and ST2 were performed. Once patients were maximized on therapy, serology was repeated. Median time to achieve maximum dose was 66 days.
Results: Our population represent a typical HFrEF cohort with a mean age of 68 years (older than the PARADIGM population – mean age 63.8), 65% male and with a mean left ventricular ejection fraction of 30%. 39 patients (63.9%) achieved the maximum dose of 97/103mg. A further 8 (13.7%) and 14 patients (22.9%) reached maximum tolerated doses of 49/51mg and 24/26mg, respectively. Follow-up biomarker samples were taken 2-4 weeks after patients were deemed stable at

P2267: Comparison between TM NT-proBNP- vs cont

Patients	Heart Rate	NT-pro BNP	EDD	RWT	LVMi	LAVI	EF%	Strain	Sm	T2*
TMNT-proBNP-	81±11***	60,9±31,8***	51±3***	0,50±0,1*	140±20**	29,2±11,9**	63±7*	31,03±9,42*	10,4±1,3*	24,4±8,8

their peak tolerated dose. Biomarker profile at commencement and follow-up are detailed in Table 1, below.
Conclusion(s): Although serum BNP levels were not significantly altered at follow-up, it could be theorized that the greater than 50% fall in NTproBNP reflects a reduction in prohormone secretion, but with reduced degradation of the active BNP moiety resulting in an overall 'balancing' effect.
Analysis of this early experience with a new compound demonstrates similar natriuretic peptide response to that seen in PARADIGM, a response that would,support a positive impact on ventricular function. The failure to observe any chnage in ST2 in this population to date may reflect the short period of follow up but also,indicate persistent high risk in this cohort.

Biomarker profile before / after therapy

	Baseline	Follow-up	P value
BNP (pg/mL)	209	256	>0.99
NTproBNP (pg/mL)	1592	655	0.0078
ST2 (ng/mL)	47.3	58.3	0.3396
Potassium (mmol/L)	4.4	4.3	0.23
Creatinine (μmol/L)	99.8	113.3	0.0188

P2270
B-type natriuretic peptide and stage B heart failure in the prediction of cardiovascular events and death in hypertension.
J Gallagher[1]; C Watson[1]; S Zhou[1]; S James[1]; C Keane[1]; M Ledwidge[1]; K Mcdonald[1]
[1]*University College Dublin, Dublin, Ireland*

Background: The prevalence and morbidity of hypertension continues to grow globally and improved methods of stratifying risk and identifying organ damage earlier are required. Methods such as echocardiography and population based risk scores are suggested by guidelines as approaches to aid in risk stratification. However, biomarkers such as natriuretic peptides may help provide such an approach also.
Purpose: This aim of this study was to determine the role of BNP and stage B heart failure defined as echocardiographic abnormalities in refining risk prediction in a community based population with hypertension and to determine the use of BNP and the SCORE cardiovascular risk prediction model in the cohort of patients with uncomplicated hypertension.
Methods: We analysed data from the STOP-HF cohort including participants with hypertension with and without a history of a cardiovascular event at baseline. We investigated the ability echocardiography abnormalities at baseline and of B-type natriuretic peptide levels in predicting future major adverse cardiovascular events (MACE) and death. We also investigated the use of the European Society of Cardiology cardiovascular risk score - SCORE - to predict these events in the uncomplicated cohort. 81
Results: In total 572 patients (427 with uncomplicated hypertension) were included. Thirty three patients had a MACE or died during follow up. In a univariate analysis, BNP was predictive of MACE and death in all groups. Echocardiography abnormalities were not predictive of MACE and death in any group. Both BNP and SCORE had predictive value. BNP adds to the predictive value of SCORE as determined by likelihood ratios. The net reclassification improvement for BNP compared to stage B heart failure was 0.20.
Conclusion: This study demonstrates that in patients with hypertension, BNP is better than echocardiography abnormalities alone in the prediction of risk of MACE and death in a community-based cohort of patients with complicated and uncomplicated hypertension.

P2271
Features of correlation between NT-proBNP and circadian blood pressure profile in patients with arterial hypertension and chronic heart failure with preserved ejection fraction of the left ventricle
I Gubareva[1]; N Kryukov[1]; E Gubareva[1]
[1]*Samara State Medical University, Internal Medicine Department, Samara, Russian Federation*

The aim of the study is to examine the characteristics of brain natriuretic plasma level (NT-proBNP) in patients with arterial hypertension (AH) and heart failure (HF) with preserved ejection fraction of the left ventricle (HFpEF).
Research methods: the study included 346 men, whose average age was 46,68 ± 10,44 year. The patients were divided into groups: group 1 - patients with AH and without HF (n = 180); group 2 - patients with AH and HFpEF (n = 86). The control group included representative by age healthy men with normal blood pressure, without HF (n = 80). All patients underwent echocardiography, daily monitoring of arterial pressure (MAP), defined NT-proBNP in plasma by ELISA.
Results: most patients of 1 group, according to MAP remained a two-phase rhythm ("dipper") systolic blood pressure (SBP) and diastolic blood pressure (DBP). In 20% of cases there was a lack of decrease in SBP and DBP ("non-dipper"). In group 2 diurnal profiles of BP were heterogeneous for SBP and DBP. In the daily profile of SBP equally met "dipper" 33% and "non-dipper" - 44%. In 21% of cases there was excessive blood pressure reduction at night – the "over-dipper" in 2% of cases – "night-peaker". Circadian profile of DBP was dominated by patients with "non-dipper" - 51% of cases, the "dipper" - 21%. Equally noted excessive reduction and increase of DBP at night "over-dipper" and "night-peaker" - 14%. The level of natriuretic peptides was the highest in the group "non-dipper", "night-speaker" and differ significantly from patients with a normal circadian profile of blood pressure and profile of the "over-dipper" as for SBP, and the circadian profile of DBP. Correlation analysis of the data revealed an inverse relationship of NT-proBNP and the SBP daily index (p = -0,498; p = 0,035), SBP square index (g=-0,474; p = 0,040), the index of SBP variability (p = -0,606; p = 0.006). The regression model to determine diastolic myocardial stress, within the parameters of MAP and the level of NT-proBNP was developed.
Results: Natriuretic peptides are involved in the formation of diurnal profile of arterial pressure and can be used for stratification of a cardiovascular risk in patients with arterial hypertension.

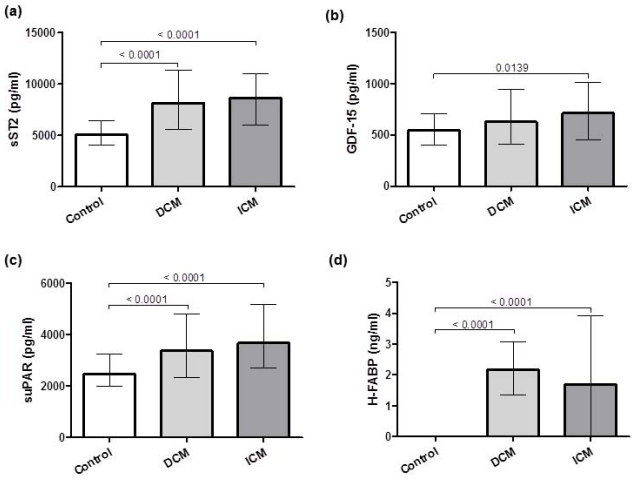
P2272
Brain natriuretic peptide levels and renal function in the diagnosis of heart failure in the elderly
ME Escande[1]; MB Emmanuel Beillard[2]; NE Nathalie Escande Beillard[3]
[1]*Private Hospital Beauregard, HOPITAL PRIVE 13012 MARSEILLE, Marseille, France*; [2]*DUKE-NUS Medical School, singapour, Singapore*; [3]*Institute of Medical Biology ,Biopolis, Singapour, Singapore*

Aim of the study: BNP levels are accurate in the diagnosis of heart failure and useful in clinical practice. Relationship between BNP, heart failure (HF) and renal function are little known in the elderly. Renal function influence the optimal cut point of BNP in patients with a Glomerular Filtration Rate (eGFR) lesser than 60 ml/min/1.73 m 2.
Methodology: A total of 71 patients (mean age = 85 years) were admitted in a Cardiogeriatric Unit. We noted several parameters, age, gender, the presence or the absence of Systolic Heart Failure (clinical history and physical examination), the echographic measure of the left ventricular ejection fraction, the eGFR value calculated by simplified MDRD formula and the BNP value. We divided these patients into six groups according the presence of HF and eGFR value higher than 60ml/min/1.73m 2 ,or between 30 and 60 or between 15 and 30.
Results: Our results show that the BNP value is higher in all the three groups of patients with Heart Failure with or without diminution of the eGFR: for example, 1220 pg/ml in the presence of HF versus 788 pg/ml in the absence of HF in the two groups with the eGFR is calculated between 15 and 30 ml/min/1.73m 2.
Conclusion: BNP is a helpful tool in clinical practice for the diagnosis of Systolic Heart Failure in the presence of renal impairment in the elderly with a higher biomarker cut point.

P2273
Association of the novel cardiovascular biomarkers ST2, GDF-15, suPAR and H-FABP with clinical parameters in heart failure patients
P Jirak[1]; M Lichtenauer[1]; B Wernly[1]; V Paar[1]; I Rohm[2]; C Jung[3]; A Yilmaz[4]; UC Hoppe[1]; PC Schulze[2]; D Kretzschmar[2]; R Pistulli[2]
[1]*Paracelsus Private Medical University, Internal Medicine II, Cardiology, Salzburg, Austria*; [2]*University Hospital of Jena, Department of Cardiology, Jena, Germany*; [3]*Medical Faculty, University Duesseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Duesseldorf, Germany*; [4]*Elisabeth Klinikum , Clinic of Internal Medicine II, Schmalkalden, Germany*

Background: Heart failure (HF) with reduced ejection fraction still remains a major therapeutic challenge and has an impact on morbidity, hospitalisation rates and health-care costs. Biomarkers represent an indispensable tool in the clinical setting for diagnosis and monitoring of treatment in patients suffering from HF.
Purpose: Aim of this study was to investigate the role of novel cardiovascular biomarkers, namely suppression of tumorigenicity (ST2), growth-differentiation factor-15 (GDF-15), soluble urokinase plasminogen-activator-receptor (suPAR) and heart-type fatty acid binding protein (H-FABP) in patients suffering from ischemic cardiomyopathy (ICM) or dilative cardiomyopathy (DCM).
Methods: A total of 200 patients were enrolled in this current study, 65 that were diagnosed with DCM and 59 patients that suffered from ICM were included. 76

patients without coronary artery disease or signs of heart failure that underwent coronary angiography because of angina pectoris were included as controls. Diagnosis of cardiomyopathy was established after a complete diagnostic work-up including coronary angiography for validation of diagnosis. During outpatient visits, plasma samples of all patients were obtained and analyzed for ST2 (assessing hemodynamics and inflammation), GDF-15 (remodeling and inflammation), suPAR (inflammation) and H-FABP (ischemia) by use of ELISA after informed consent.
Results: Levels of ST2, suPAR and H-FABP were significantly higher in ICM and DCM patients compared to the control group ($p < 0.0001$), while GDF-15 showed a significant increase in ICM patients ($p = 0.0139$) but not in DCM patients ($p = 0.176$). However, there were no significant differences between ICM and DCM in biomarker levels (ST2 $p = 0.6725$, GDF-15 $p = 0.3503$, suPAR $p = 0.3521$, H-FABP $p = 0.1191$). Ejection fraction correlated inversely with cardiac biomarkers (ST2 $p < 0.0001$, GDF-15 $p = 0.0394$, suPAR $p = 0.0029$, H-FABP $p < 0.0001$), while BNP levels showed a positive correlation with biomarker levels (ST2 $p < 0.0001$, GDF-15 $p < 0.0001$, suPAR $p < 0.0001$, H-FABP $p = 0.0004$). Similarly, CRP levels showed a positive correlation with cardiac biomarkers (ST2 $p = 0.0006$, GDF-15 $p = 0.0041$, suPAR $p = 0.0258$, H-FABP $p = 0.0002$). Renal insufficiency (ST2 $p < 0.0001$, GDF-15 $p < 0.0001$, suPAR $p < 0.0001$, H-FABP $p < 0.0001$) and diabetes (ST2 $p = 0.0021$, GDF-15 $p = 0.0055$, suPAR $p = 0.0339$, H-FABP $p = 0.0010$) were significantly associated with a rise in cardiac biomarkers, while hypertension seemed to have no effect on biomarker levels in HF-patients (ST2 $p = 0.4911$, GDF-15 $p = 0.4593$, suPAR $p = 0.2410$, H-FABP $p = 0.3141$).
Conclusion: By integrating the information obtained by measuring levels of several important factors in HF, tested novel biomarkers represent a promising opportunity for a more precise diagnosis incorporating different pathophysiological processes present in HF.

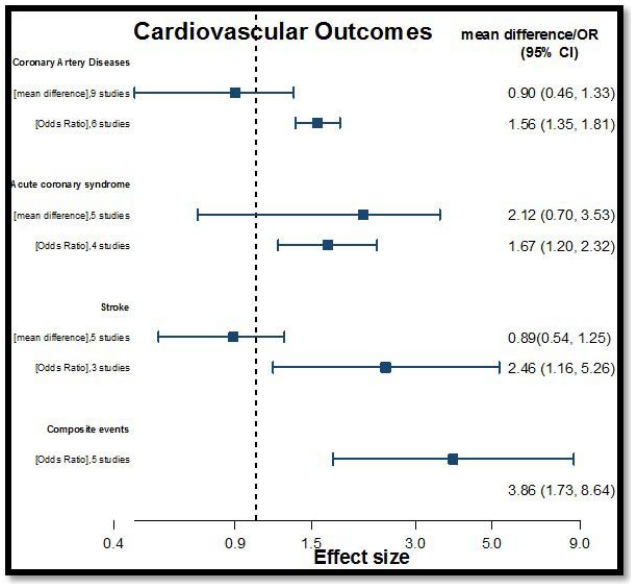


P2274

Neutrophil lymphocyte ratio and risks of cardiovascular diseases: a systematic review and meta-analysi

MS Angkananard[1]; DR Anothaisintawee[2]; DR Thakkinstian[2]
[1]Faculty of Medicine, Srinakharinwirot University, Division of Cardiovascular Medicine, Department of Medicine, , Nakhon Nayok, Thailand; *[2]Ramathibodi Hospital, Section for Clinical Epidemiology and Biostatistics, Faculty of Medicine, Bangkok, Thailand*

Background: Inflammation is a main process in the pathogenesis of atherosclerosis. Neutrophil lymphocyte ratio (NLR) has recently emerged as an inflammatory biomarker to anticipate the risk of cardiovascular diseases (CVDs). Here we quantify the predictive impact of NLR on risk of CVDs.
Methods: Medline and Scopus databases were searched. We included observational studies of adults in any settings with NLR as studied factor. The outcomes of interest were either composite or individual outcome of at least one of the CVDs including cardiovascular(CV) death, acute coronary syndrome(ACS), coronary artery disease (CAD), chronic stable angina, receiving coronary revascularization and any types of stroke. Mean difference and ORs were pooled across studies using a random effect model. Source of heterogeneity was explored by performing a meta-regression and subgroup analysis.
Results: Twenty-eight studies comprising 49,806 subjects were included in this meta-analysis. Patients with higher NLR had a significantly greater odds of having CAD, ACS, stroke and composite outcomes than patients with lower NLR with a pooled odds ratio of 1.56 (95% CI: 1.35, 1.81), 1.67 (95% CI: 1.20, 2.32), 2.46 (95% CI: 1.16, 5.26), and 3.86 (95% CI: 1.73, 8.64), respectively. The weighted mean difference of NLR in patients with CAD, ACS, and stroke outcomes were 0.90 (95% CI: 0.46, 1.33), 2.12 (95% CI: 0.70, 3.53), and 0.895 (95% CI: 0.54,1.25) respectively.
Conclusion: NLR was linearly associated with subsequent risks of CVDs. Thus, it might be helpful in risk stratification, or improvement of risk prediction if putting it in existing CVD predicting models.



Summarized pooling effect of NLR vs. CVD

Funding Acknowledgements: ISCIII(RD12/0042/0009), EC(HEALTH-2010-261409, -2011-278249, -2012-305507, -2013-602904), Scottish Government(CZD/16/6) & Funding Council(HR03006)

Background: No data exists on the associations of the circulating biomarkers of cardiomyocyte injury high-sensitivity troponin T (hs-TnT), annexin A5 (AnxA5), and cardiotrophin-1 (CT-1) with prognosis among patients with chronic heart failure (HF) attributable to hypertensive heart disease.
Purpose: We aimed to determine whether these biomarkers identify patients with non-ischemic hypertensive HF at high risk for adverse outcome.
Methods: The relationship between hs-TnT, AnxA5 and CT-1 and a composite outcome of hospitalization for HF (HHF) or cardiovascular death was examined in 235 patients with hypertensive HF and without obstructive coronary artery disease (CAD) from the Leizaran cohort, with a median follow-up of 5.44 years. The findings were validated in an independent cohort (Generation Scotland) of 60 patients with the same diagnosis.
Results: In the Leizaran cohort, while hs-TnT was associated with the outcome (hazard ratio=1.67, P=0.003) independently of other relevant co-variables, AnxA5 and CT-1 were not. Adding hs-TnT to a basic model, including left ventricular ejection fraction and N-terminal pro-brain natriuretic peptide (NT-proBNP), improved risk discrimination as assessed by Harrell's C-statistics, integrated discrimination and net reclassification improvements ($P \leq 0.04$). Receiver operating characteristic analysis identified hs-TnT$\geq$23.5ng/l as a predictor of outcome in HF patients (HR=2.10,

P=0.006). The prognostic value of hs-TnT was confirmed in the Generation Scotland cohort. In sensitivity analyses, after excluding participants with CAD during follow-up, our findings remained consistent.
Conclusions: Circulating hs-TnT identifies patients with non-ischemic hypertensive HF at high risk of HHF or cardiovascular death for whom more intensive monitoring and management of cardiomyocyte injury may be needed.

P2276
Combined baseline and one-month changes in Big Endothelin-1 and BNP plasma concentrations predict clinical outcomes in patients with left ventricular dysfunction after acute myocardial infarction

A Olivier[1]; N Girerd[1]; JB Michel[2]; JM Ketelslegers[3]; R Fay[1]; JM Vincent[4]; P Bramlage[5]; B Pitt[6]; F Zannad[1]; P Rossignol[1]
[1]INSERM, Centre d'Investigations Cliniques 9501, Université de Lorraine, CHU de Nancy, Institut Lorrain du cœur et des vaisseaux, Nancy, France and INI-CRCT F-CRIN Network, Vandoeuvre-les-Nancy, France; *[2]Inserm, UMRS 1148 University Paris Diderot, Paris, France*; *[3]Universite Catholique de Louvain, Brussels, Belgium*; *[4]Pfizer Inc, New York, United States of America*; *[5]Institute for Cardiovascular Pharmacology & Epidemiology, Mahlow, Germany*; *[6]University of Michigan, School of Medicine, Ann Arbor, United States of America*

Objective: Increased levels of neuro-hormonal biomarkers predict poor prognosis in patients with acute myocardial infarction (AMI) complicated by left ventricular systolic dysfunction (LVSD). The predictive value of repeated (one-month interval) Brain natriuretic peptides (BNP) and Big-endothelin 1 (BigET-1) measurements were investigated in patients with LVSD after AMI.
Methods: In a sub-study of the Eplerenone Post-Acute Myocardial Infarction Heart Failure Efficacy and Survival Study (EPHESUS trial), BNP and BigET-1 were measured at baseline and at 1 month in 476 patients.
Results: When included in the same Cox regression model, baseline BNP (p for trend=0.0003; HR for 3rd tertile vs 1st tertile=9.20 (3.03 - 8.0), $p < 0.0001$) and BigET-1 (p for trend=0.026; HR=3.25 (1.36 - 7.73), $p = 0.008$) as well as the relative changes (after 1 month) from baseline in BNP (p for trend=0.049; HR=2.25 (1.13 - 0.47), $p = 0.02$) and BigET-1 (p for trend=0.045; HR=1.84 (0.91 - 3.73), $p = 0.09$) were predictive of the composite of cardiovascular death or hospitalization for worsening heart failure. Adding baseline and changes in BigET-1 to baseline and changes in BNP led to a significant increase in prognostic reclassification as assessed by integrated discrimination improvement index (5.0%, $p = 0.01$ for the primary endpoint).
Conclusions: Both increased baseline and changes after one month in BigET-1 concentrations were shown to be associated with adverse clinical outcomes, independently from BNP baseline levels and one month changes, in patients after recent AMI complicated with LVSD. This novel result may be of clinical interest since such combined biomarker assessment could improve risk stratification and open new avenues for biomarker-guided targeted therapies.

P2277
Biomarker prognostic value in heart failure with mid-range ejection fraction

M De Antonio[1]; J Lupon[1]; J Barallat[1]; M Domingo[1]; J Nunez-Villota[2]; P Moliner[1]; E Zamora[1]; C Rivas[1]; B Gonzalez[1]; V Diaz[1]; M Rodriguez[1]; J Santesmases[2]; C Diez-Quevedo[1]; C Pastor[1]; A Bayes-Genis[2]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain; *[2]University Hospital Clinic of Valencia, Valencia, Spain*

Background: Recently the ESC created a new classification of heart failure (HF) according to left ventricular ejection fraction (LVEF): reduced (HFrEF) when LVEF is < 40%, mid-range (HFmrEF) when LVEF is between 40% and 49%, and preserved (HFpEF) when LVEF is >50%. The intermediate group of HFmrEF is incompletely characterized.
Purpose: We sought to explore the prognostic value of a biomarker panel in HFmrEF relative to HFrEF and HFpEF.
Patients and methods: 1069 patients were included in the study (age 66.2 ± 12.8 years, 72% male, 51% of ischemic aetiology). 800 patients were classified as HFrEF, 134 as HFmrEF and 135 as HFpEF. Serum concentrations of NT-proBNP (N=1030), high-sensitivity troponin T (hs-TnT) (N=803), ST2 (N=814), Galectin 3 (N=811), high-sensitivity C reactive protein (hs-CRP) (N=773) Cystatin-C (N=804), Neprilysin (N=1069), and soluble transferrin receptor (sTfR) (N=794) were measured in consecutive ambulatory HF patients followed during 4.9 ± 2.8 years (6.6 ± 2.3 for alive patients). The composite end-point of cardiovascular death or HF-related hospitalization was assessed.
Results: 534 patients died during follow-up, 284 of them from cardiovascular causes and 231 suffered a HF-related hospitalization. The composite end-point including cardiovascular death and HF-related hospitalization occurred in 356 patients. Hazard ratios for the different biomarkers in the three groups of the ESC classification are shown in the table. In general the power of risk prediction of all biomarkers was higher in HFmrEF patients than in HFrEF and HFpEF patients, except for Neprylisin, that emerged with better prognostic capacity in HFpEF patients. The difference between HFrEF and HFmrEF was especially big related to hs-TnT, in which the hazard ratio was more than doubled.
Conclusions: Biomarkers commonly used for risk prediction in HFrEFcan be even more useful for stratifying the risk of HFmrEF patients.

	HFrEF (N=800)	HFmrEF (N=134)	HFpEF (N=135)

Funding Acknowledgements: Conflict of interest: the ST-2 ELISA-Kits were provided free of charge by bestbion dx GmbH.

Background: Peripartum cardiomyopathy (PPCM) is defined as heart failure with systolic left ventricular (LV) dysfunction emerging towards the end of pregnancy or in the first postpartal months in previously healthy women. The aetiology of the disease is largely unknown but inflammation, especially increased expression of pro-inflammatory cytokines, i.e. IL-6 and TNFa have been reported in African PPCM patients. In order to get new insights into the pathophysiology and to identify PPCM-specific biomarkers, we performed a multiplex cytokine profiling in serum of PPCM patients from a German cohort and healthy postpartum controls.
Methods and Results: Serum levels of 27 different cytokines were measured using a cytokine mutliplex assay (27-Plex, BioRad) in PPCM patients (n = 51) at the time of diagnosis. Healthy pregnancy-matched postpartum (PP) women served as controls (n = 24). Cardiac function was impaired in PPCM patients with an average LV ejection fraction (LVEF) of 24 ± 7% at diagnosis and 49 ± 11% after 6 months.
The cytokines and chemokines that appeared significantly (Shapiro-Wilk normality test, test for significance using unpaired t-test or Mann-Whitney test) elevated in PPCM patients were: IL-1b (p: 0.001); IL-4 (p: 0.0023); IL-5 (p: 0.0025); CXCL8 (p: 0.0045); IL-9 (p: 0.0011); IL-10 (p: 0.0099); IL-12 (p: 0.0057); IL-13 (p: 0.0045); IL-15 (p: 0.0209); IL-17 (p: 0.0017); CCL11 (p:<0.0001); FGFb (p: 0.0002); GM-CSF (p: 0.0006); IFNg (p: 0.0019); CXCL10 (p: 0.0067); CCL2 (p: 0.0104); CCL3 (0.0003); PDGF (p: 0.0021); CCL4 (p: 0.0047); CCL5 (p: 0.0132); VEGF (p: <0.0001). In contrast, to African patients, neither IL-6 nor TNFa were significantly upregulated in this German PPCM patient cohort.
Next we analysed if baseline cytokine levels could predict recovery from PPCM by stratifying patients with a persistently severely reduced systolic left ventricular function (LVEF≤35%) versus patients with partial or full recovery (LVEF>35% after 6 months follow up. Only CCL4 serum levels at diagnosis were significantly higher (p: 0.0255) in patients with persistently reduced LVEF compared to patients with recovered LVEF.
Conclusion: The broad elevation of immune mediators underlines the importance of inflammatory processes in this German PPCM collective. However, the cytokine pattern differs from African PPCM patients suggesting potential differences in the

aetiology of PPCM from different ethnic or geographic background. CCL4 serum levels may serve as a novel prognostic marker for recovery from PPCM.

P2279

MicroRNA-423-5p levels correlate with markers of hypoperfusion and organ injury and are associated with 90-day mortality in cardiogenic shock.

T A J Toni Antti Juhani Jantti[1]; H Segersvard[2]; T Tarvasmaki[1]; J Lassus[1]; Y Devaux[3]; M Vausort[3]; K Immonen[2]; K Pulkki[4]; I Tikkanen[2]; P Lakkisto[2]; V-P Harjola[1]

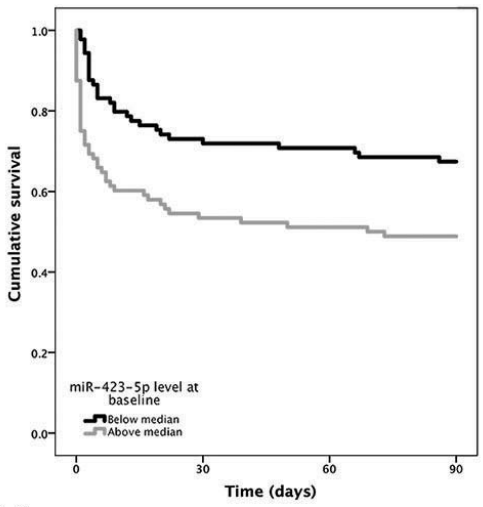
Funding Acknowledgements: This study was supported by grants from the Finnish Foundation for Cardiovascular Research and Aarne Koskelo Foundation.

Background: MicroRNAs (miRNAs) are short non-coding RNAs that have a central role in regulating gene expression. MiRNAs can be detected in plasma, body fluids and tissues. Circulating miRNAs are emerging diagnostic and prognostic biomarkers of cardiovascular disease. Past studies have shown an association between circulating levels of miR423-5p with the diagnosis and prognosis of heart failure. However, there have been no studies of miR-423-5p in cardiogenic shock.
Purpose: To examine the levels of miR-423-5p in cardiogenic shock patients and their potential to predict mortality.
Methods: We measured the admission plasma levels of miR-423-5p in 179 patients enrolled in the prospective European multi-center CardShock study. The associations of miRNA levels with established biomarkers (high- sensitivity troponin T [hsTnT], alanine aminotransferase (ALT), lactate and creatinine), clinical data and 90-day all-cause mortality were analysed using SPSS statistical software.
Results: The etiology of cardiogenic shock was mainly acute coronary syndrome, comprising 79% of the patients in the cohort. The 90-day all-cause mortality was 42,0%. Median miR-423-5p level was 0.005 (interquartile range 0.002-0.013).
MiR-423-5p levels at baseline were significantly higher in non-survivors than in survivors (median for non-survivors 0.008 vs. 0.004 for survivors; Mann-Whitney U-test $p = 0.003$). Patients with above median levels of miR-423-5p also had higher levels of lactate (3.7 vs. 2.4 mmol/L, $p = 0.001$) and lower eGFR (56 vs. 70 mL/min/1.73m2, $p = 0.002$) compared to patients with below median levels of miR-423-5p. Levels of miR-423-5p correlated significantly with markers of hypoperfusion and organ damage, namely ALT, lactate and creatinine (Spearman correlation coefficients (r) 0.38, 0.28 and 0.19, respectively, $p < 0.001$ for ALT and lactate and $p = 0.01$ for creatinine). MiR-423-5p also correlated with hsTnT level at 24 hours ($r=0.33$, $p < 0.001$). In Kaplan Meier analysis, above median levels of miR-423-5p were associated with higher all-cause 90-day mortality (Figure 1). In Cox regression analysis, above median levels of miR-423-5p were associated with all-cause 90-day mortality with an unadjusted hazard ratio (HR) of 1.9 (95% confidence interval (CI) 1.2-3.1, $p = 0.006$). After adjusting for the risk factors included in the CardShock risk score, the association between above median levels of miR-423-5p and all-cause 90-day mortality remained significant (HR 2.0, 95% CI 1.2-3.2, $p = 0.007$).
Conclusions: Circulating plasma levels of miR-423 at baseline are associated with mortality and markers of hypoperfusion in cardiogenic shock and may potentially aid in the early risk stratification in cardiogenic shock.



Survival function for miR-423-5p

P2280

Endovascular shedding markers in patients with heart failure with reduced ejection fraction

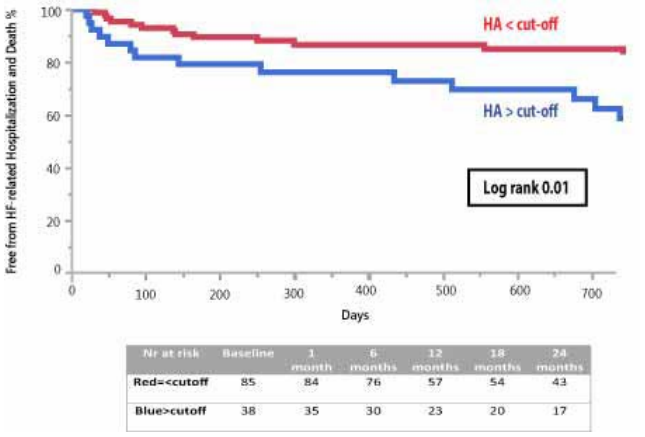
P Petra Nijst[1]; J Cops[2]; P Martens[1]; Q Swennen[2]; M Dupont[1]; W Tang[3]; W Mullens[1]

[1]Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium; *[2]Biomedical Research Institute, Faculty of Medicine and Life Sciences, Hasselt (3500), Belgium*; *[3]Cleveland Clinic Foundation, Cleveland, United States of America*

Background: Increased endothelial glycocalyx degradation has previously been associated with tissue edema formation, endothelial dysfunction, renal impairment and mortality in patients with cardiovascular disease.
Aims: To explore the role of glycocalyx shedding markers; hyaluronic acid (HA) and syndecan-1, in patients with heart failure with reduced ejection fraction (HFREF), and to study their potential association with other HF-related variables and outcome.
Methods: In 123 patients with HFrEF a medical history, clinical investigation and venous blood samples for shedding markers and other HF-related biomarkers were obtained. Cut-off values of normal were derived from a cohort of normal subjects ($n = 30$). The study end point was a composite of all-cause mortality and hospitalization for HF. HFrEF patients were prospectively followed up till 2 years.
Results: The cut-off value of normal for plasma values of HA was 50.2 ng/ml and for Syndecan-1 was 365.4 ng/ml. Median HA levels and syndecan-1 levels in HFrEF patients were respectively 29.4(10.7;61.6) ng/ml and 48.5(33.6;80.8) ng/ml. Overall, HA-levels were significantly higher in HFrEF patients compared to healthy subjects but only 31% of HFrEF patients had HA levels above the cut-off. There was no significant difference among HFrEF patients and healthy subjects regarding syndecan-1 levels. HFrEF patients with elevated HA-levels had worse outcome (log rank=0.01) which remained significant after correction for established risk factors (HR 2.53 (1.13-5.69); $p = 0.024$). Based on multivariate analysis, there was no significant relation between levels of shedding markers and neurohumoral activation (plasma renin activity, serum aldosterone, NT-proBNP), myocardial injury (HS-trop), inflammation (CRP) or other baseline characteristics.
Conclusion: The glycocalyx shedding marker HA is significantly elevated in a subgroup of HFrEF patients and an independent predictor for worse clinical outcome independent of other established risk factors and HF related processes. There was no significant difference between syndecan-1 levels in HFrEF patients and normal subjects.

Adjusted Hazard Ratio

Variable	HR	95% CI	p-value
eGFR < 60 ml/min/1.73m2	4.41	1.68-12.96	0.002
elevated Hyaluronic Acid (>50.2 ng/ml)	2.53	1.13-5.69	0.024
History of myocardial infarction	2.53	0.95-8.78	0.065
NT-proBNP (ng/L)	1.21	0.17-6.47	0.833
Age>75 years	1.09	0.46-2.56	0.836



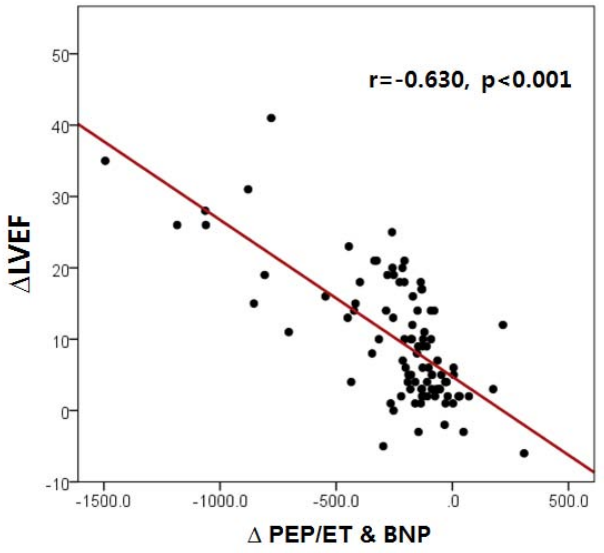
LEFT VENTRICULAR FUNCTION

P2281

Clinical meaning of the ratio of brachial pre-ejection period to brachial ejection time in patients with left ventricular systolic dysfunction: a comparison with BNP

K-H Kyoung-Ha Park[1]; WJ Park[1]; SJ Han[1]; HS Kim[1]; SH Jo[1]; SA Kim[1]
[1]*Hallym University Sacred Heart Hospital, Cardiology, Anyang-Si, Gyeonggi-Do, Korea Republic of*

Background: An increase in the ratio of the brachial pre-ejection period to brachial ejection time (PEP/ET) is correlated with a decrease of left ventricular ejection fraction (LVEF).
Purpose: To investigate whether the change value (Δ) of PEP/ET is a useful predictor of LVEF in patients with LV systolic dysfunction.
Methods: We consecutively enrolled 104 patients with LVEF < 45%. PEP/ET, B-type natriuretic peptide (BNP), and LVEF were evaluated at baseline and at 6-month follow-up.
Results: Compared to the baseline measurements, the 6-month values of ΔLVEF, ΔBNP, and ΔPEP/ET were 9.8 ± 9.0% (from 36.3 ± 9.2% to 46.3 ± 12.5%, p < 0.001), -168.5 ± 255.4 (from 271.4 ± 282.5 to 104.1 ± 129.6, p < 0.001), and -0.060 ± 0.069 (from 0.413 ± 0.097 to 0.358 ± 0.079, p < 0.001), respectively. There were significant correlations between ΔLVEF and ΔPEP/ET (r=-0.515, p < 0.001) and between ΔLVEF and ΔBNP (r=-0.581, p < 0.001). We evaluated about ΔPEP/ET&BNP, which was formulated as ΔBNP added to ΔPEP/ET*1000. The correlation between ΔLVEF and ΔPEP/ET&BNP was significant (r=-0630, p < 0.001). However, ΔPEP/ET&BNP did not have a stronger correlation with ΔLVEF compared to the correlation between ΔLVEF and ΔBNP (r=-0.630, p < 0.001 vs. r=-0.581, p < 0.001; Steiger's Z=0.496, p = 0.620; Figure).
Conclusions: In patients with LV systolic dysfunction, ΔPEP/ET is a useful indicator of changes in LVEF. However, there is no additional benefit to using PEP/ET over BNP.



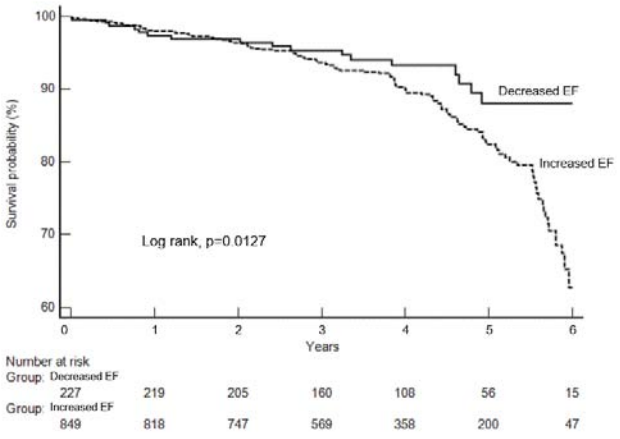
Correlation LVEF_PEP/ET&BNP

P2282

Impact on change of left ventricular function on long-term clinical outcome in patients with preserved ejection fraction after acute myocardial infarction

J J Jin Jin Kim[1]; BH Hwang[1]; SW Jang[1]; J Jang[1]; CJ Kim[1]; YS Koh[1]; PJ Kim[1]; ES Lim[1]; WJ Lee[1]; KB Seung[1]; K Chang[1]
[1]*Catholic University Hospital, Seoul, Korea Republic of*

Background: Left ventricular (LV) dysfunction has been associated with greater mortality after acute myocardial infarction (AMI). However, among patients with preserved ejection fraction (EF) after AMI, few data exist that increased or decreased LV function is altered long-term clinical outcome.
Methods: A total of 5,464 patients with AMI were consecutively enrolled from January 2004 to August 2014. Baseline and follow-up echocardiography were performed when enrollment and 1 year after AMI. After excluded patients with similar LV function, patients with preserved ejection fraction (≥ 50%) were divided according to the difference of baseline and follow-up LV ejection fraction (LVEF). All-cause mortality within a follow-up period of 6 years was examined in groups of patients with increased and decreased more than 5% of LVEF.
Results: Median follow-up duration was 43.1 months (interquartile range 32.4 to 59.1 months). Patients with increased LVEF were more likely to have diabetes, but the two groups did not differ in age, sex, presence of hypertension, and status of smoking. Patients with increased LVEF had greater all-cause mortality (7.5% vs. 13.3%, p = 0.017). Increased LVEF as assessed by echocardiography was an independent predictor of all-cause mortality after adjusting confounding risk factors (hazard ratio: 1.686, confidence interval: 1.010-2.816, p = 0.046).
Conclusion: In patients with preserved EF after AMI, although LVEF is restored, change of LV function increases the risk of all-cause mortality independent of co-existing risk factors.



KM Curve for All-cause Mortality

P2283

The study of drug therapy effectiveness in the correction of morphological and functional myocardium changes in patients with arterial hypertension and bronchial asthma

TEI Tarlovskaya Ekaterina[1]; AAO Odegova Alla[2]
[1]*Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russian Federation*; [2]*Kirov State Medical University, Internal medicine, Kirov, Russian Federation*

Timeliness: The prevalence of bronchial asthma (BA) among patients with arterial hypertension (AH) is about 25-30%. The worsening of bronchial patency in patients with AH associated with BA is accompanied by blood pressure (BP) increase. The frequent using of sympathomimetics leads to heart rate increase and also, as we had seen, to sinus tachycardia, as well as a more rapid onset of remodelling, hypertrophy and diastolic dysfunction of the left ventricle of the heart (LV).
Purpose: To evaluate the effect of therapy by diltiazem-retard and ivabradine on morphological and functional changesof the heart muscle in patients with AH associated with BA. Material and methods. 67 patients with mild and the average degree (1,2 degree) of AH associated with BA were involved in the study. All patients received baseline treatment of BA by inhaled glucocorticosteroids (IGCS) and β2-agonists (β2-AM) short-acting. There was treatment of AH with tablet of indapamide 2.5 mg, and patients observed the recommendations about non- treatment AH therapy.Echocardiography on Acuson 128XP \ 10c equipment (USA) was performed to all subjects. Patients were divided into 2 groups without significant difference by technique of random sampling. Group 1 involved 35 patients with average age is 58.5 + 8.34 years, who received diltiazem-retard. Group 2- 32 patients with average age is 55.2 + 9.21 years, who received ivabradine (Coraxan).The treatment lasted for 24 weeks. Results. There was improvement of morphological parameters of left heart (significant decrease of LVMMI (p=0,01) and IVST (p=0,012)), and alsoimprovement of diastolic function parameters(E/Ap = 0.001, IVRTp = 0.015) during 24-weeks treatment with diltiazem- retard. The changes of systolic function LV was not found in group 1 (p=0,83). As a result of 24 weeks therapy there was decrease of IVST (p=0,021), left ventricle end-diastolic diameter (p=0,034), and also left ventricular posterior wall thickness (p=0,001), LVMMI (p=0,002) in comparison

with baseline measures in group 2. It was noticed the improvement in left ventricular diastolic function as a result of LV hypertrophy regression, such as: increasing the E /A ($p = 0.016$) and decreasing IVRT ($p = 0.011$), as well as decrease of pulmonary artery systolic pressure ($p = 0.015$). The changes of systolic function LV was not found in group 2 (p=0,58).
Conclusions: As a result of 24 weeks treatment with ivabradine in patients with AH associated with BA there was more significant LV hypertrophy regression and improvement of LV diastolic function in comparison with diltiazem therapy.

P2284
Diastolic myocardial dysfunction in patients with chronic heart failure due to arterial hypertension and ischemic heart disease

MA Osadchuk[1]; NP Korzhenkov[1]; IN Vasilyeva[1]; KS Solodenkova[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Purpose: To identify the features of left ventricle (LV) diastolic function (DF) disturbances in patients with chronic heart failure (CHF) caused by arterial hypertension (AH) and coronary heart disease (CHD).
Methods: The study involved 65 pts, mean age – 57.6 ± 2.2 years. The study group consisted of 22 pts with AH in combination with IHD with symptoms of CHF FC I-III by NYHA. Assessment of CHF FC showed that 43.4% of pts had I FC, 50.0% – II FC and 6.6% of pts had III FC. The first comparison group consisted of 22 pts with AH, the second group – of 21 pts with CHD without CHF symptoms. All pts in addition to standard clinical and laboratory tests were performed echocardiography by a standard technique. The study was carried out on the Sonos unit (PHILIPS) using apical access and sectoral sensor 3.5-5.0 MHz.
Results: Comparative analysis showed that the LV DF in pts with CHF due to AH and IHD was broken mainly by hypertrophic type. Comparison with those of other groups showed more pronounced disorders: decrease in the transmitral flow peak velocity ratio (VE/VA MV) in comparison with AH pts – 36.7%, and in comparison with IHD pts - 16.5% ($p < 0.05$). In pts with CHF we observed higher values of linear and volumetric parameters of the left atrium in comparison with pts with isolated forms of disease without heart failure ($p < 0.05$). Furthermore, diastolic dysfunction amplified with increasing of blood pressure degree in pts with AH and CHD. This was confirmed by established correlation relationship between the isovolumetric relaxation time (IVRT), values of atrioventricular index and left ventricular myocardium mass ($r = 0.61$ and $r = 0.60$; $p < 0.05$) in pts with CHD and III degree hypertension indicating an increase of myocardial stiffness. Also, in pts with CHF we established correlation between IVRT and stroke volume index ($r = -0,7455$; $p = 0.007$), which confirms the obvious reduction in the functional activity of the myocardium in the absence of reliable evidence of impaired contractility.
Conclusions: Comparative analysis revealed features of diastolic dysfunction in pts with CHF due to the influence of two diseases. On the basis of this data it can be concluded that it is the state of diastole to a large extent determines the functional reserve of the heart and determines the degree of progression of CHF.

Inhibition of cardiac lymphangiogenesis in imatinib-induced cardiomyopathy

K Urbanek[1]; D Madeddu[2]; S Cavalli[2]; C Frati[2]; A Falco[2]; CA Lagrasta[2]; B Lorusso[2]; G Mazzaschi[2]; D Donato Cappetta[1]; L Berrino[1]; A De Angelis[1]; F Quaini[2]
[1]Second University of Naples, Department of Experimental Medicine - Section of Pharmacology, Naples, Italy; *[2]University of Parma, Department of Medicine and Surgery, Parma, Italy*

Background: Imatinib mesylate (IM) is the backbone drug for the treatment of chronic myeloid leukemia, gastrointestinal stromal tumors and hypereosinophilic syndrome. It inhibits the Abl-tyrosine kinase and possesses a potent activity against mutated oncogenic forms of the receptor tyrosine kinases platelet-derived growth factor receptor (PDGFR). Tyrosine kinase inhibitors that represent a turning point in modern medicine have been implicated in cardiovascular side effects and patients treated with IM may develop periorbital and peripheral oedema. A defective lymphatic drainage might be responsible for the observed fluid retention, and a similar mechanism may be operative within the myocardium that, as a compact tissue, is highly sensitive to changes in lymph flow. The critical role of tyrosine receptor PDGFR signalling in lymphangiogenesis further supports the possibility that PDGFR-targeting drugs can impair cardiac function by affecting the integrity of myocardial lymphatic vasculature.
Purpose: To test whether IM-induced heart failure involves cardiac lymphatics. Analyses were also conducted on hearts from two patients who died of heart failure while under IM treatment.
Methods: Autoptic myocardial samples of two IM-treated patients who died of heart failure were analyzed. For animal studies, 8 week-old male Wistar rats were subjected to i.p. injections of 100mg/kg IM three times a week for three weeks. Hemodynamic data were collected and the heart was collected for morphometric, immunofluorescence and electron microscopy analysis. Immunofluorescence and immunogold staining were performed on myocardial samples incubated with anti-LYVE1 to detect lymphatic vessels and anti-LC3 for autophagy.
Results: Ultrastructural abnormalities of IM-treated human hearts were characterized by interstitial oedema, mitochondrial damage and several features of autophagy in all myocardial cell compartments. Importantly, Masson's trichrome staining did not reveal increased collagen accumulation, indicating that myocardial fibrosis was not a characteristic finding of IM-induced cardiomyopathy. In animal studies, IM treatment affected animal survival in the absence of severe myelotoxicity. Hemodynamic analysis detected altered left ventricular end-diastolic pressure and positive and negative dP/dT, together with a slight decrease in systolic blood pressure. These changes were accompanied by increased theoretical water content and reduced lymphatic vessel density in the myocardium. Finally, matrigel assay on isolated human and rat lymphatic endothelial cells exposed to IM documented reduced cell proliferation and tube formation.
Conclusions: Our findings show that inhibition of tyrosine kinase by IM is translated at myocardial level in structural and functional alterations of cardiac lymphatics in the absence of myocardial fibrosis. These data indicate that defective lymphangiogenesis may contribute to tyrosine kinase inhibition-induced cardiovascular events.

New role of EPAC in the Anthracyclines-induced cardiotoxicity

M Maxance Ribeiro[1]; M Mazevet[1]; M Laudette[2]; B Crozatier[1]; F Lezoualc'h[2]; J Chen[3]; J-P Benitah[1]; A-M Gomez[1]; C Lemaire[1]; E Morel[1]
[1]University of Paris-Sud 11, Signaling and cardiac physiopathology U1180, Chatenay-Malabry, France; *[2]Institute of Cardiovascular and Metabolic Diseases, Toulouse, France*; *[3]University of San Diego, La Jolla, United States of America*

Doxorubicin (Dox) is an anthracycline commonly used to treat many types of cancer; unfortunately this chemotherapeutic agent often induces side effects such as cardiotoxicity leading to dilated cardiomyopathy (DCM). The cardiotoxicity of Dox has been related to reactive oxygen species generation, DNA intercalation and topoisomerase II inhibition, resulting in DNA damage and ultimately in cardiomyocyte death. Therefore, there is a need for new treatment options and strategies aiming at reducing Dox side effects in the heart. Among these mechanisms, β-adrenergic signaling and especially Epac (exchange protein directly activated by cAMP) signaling could be worth investigating as Epac activates small G proteins (Rac1 and Rho A) which are known to be involved in Dox-induced cardiotoxicity. Therefore, we have investigated the time/dose-dependent Dox effect on Epac signaling in both in vivo mice model (C57Bl63/ Knock-out Epac1 mice, iv injections, 12mg/kg cumulative dose) and in vitro (primary culture of neonatal rat cardiomyocytes (NRVM, 24h, Dox 1μM). In vivo, Dox-treated mice developed a DCM (a succession of functional and molecular alterations at 2, 6 and 15 weeks post-treatment with a final DCM development) associated with $Ca2+$ homeostasis dysfunction (increase of $Ca2+$ waves and $Ca2+$ leaks). In vitro, as measured by flow cytometry and western blot, Dox (1μM) induced DNA damage and cell death in NRVM after 24h of treatment. This cell death is associated with apoptotic features including mitochondrial membrane permeabilization, caspase activation, cell size reduction and relative plasma membrane integrity. We also observed that Dox led to a reduction of the expression of Epac1 and Epac2 isoforms, while Epac activity and cAMP level were increased. The inhibition of Epac1 (ESI09, CE3F4), but not of Epac2 (ESI05), prevented DNA/TopIIβ complexes, decreased Dox-induced DNA damage, cardiomyocyte death and loss of mitochondrial membrane potential and apoptosis. These results were confirmed in vivo; indeed, Dox-induced cardiotoxicity was prevented in Epac1 knock-out mice as evidenced by unaltered cardiac function (no DCM) and calcium homeostasis at 15 weeks post-treatment. In conclusion, inhibition of Epac1 could be a valuable therapeutic strategy to limit Dox-induced cardiomyopathy during cancer chemotherapy.

Doxorubicin inhibits protective autophagy through a PI3Kgamma/Akt/Ulk1 pathway downstream of TLR-9

A Ghigo[1]; M Li[1]; V Sala[2]; N Pianca[3]; S Sciarretta[4]; F Morello[5]; M Sandri[3]; T Zaglia[3]; M Mongillo[3]; E Hirsch[1]
[1]University of Torino, Dept. of Molecular Biotechnology and Health Sciences, Torino, Italy; *[2]University of Turin - Molecular Biotechnology Center, Turin, Italy*; *[3]University of Padova, Department of Biomedical Sciences and Venetian Institute of Molecular Medicine, Padova, Italy*; *[4]Sapienza University of Rome, Department of Medical and Surgical Sciences and Biotechnologies, Latina, Italy*; *[5]A.O.U. Città della Salute e della Scienza di Torino, Emergency Department, Torino, Italy*

Purpose: Anthracyclines, like doxorubicin (Dox), are among the most potent anti-tumor drugs, but their clinical use is hampered by severe cardiotoxicity leading to heart failure. We demonstrated previously that genetic inhibition of phosphoinositide 3-kinase γ (PI3Kγ) protects against Dox-induced cardiomyopathy (manuscript in preparation), but the underlying molecular mechanisms are still unexplored. Here, we test the hypothesis that PI3Kγ acts as a sensor of the cardiac damage elicited by anthracyclines and promotes maladaptive remodeling through inhibition of protective autophagy.
Methods: Neonatal cardiomyocytes (NCMs) were isolated from mice expressing a kinase inactive PI3Kγ (PI3Kγ kinase-dead; KD) and wild-type (WT) controls, and treated with Dox (1 mM) or TLR-9 agonist ODN1826 (1 μL/ml) $\pm$ PI3Kγ inhibitor AS605240 (500 nM) or TLR9 antagonist ODN2088 (1 μL/ml), for 1 hour before analyzing Akt/mTOR/Ulk-1 signaling. For in vivo studies, WT and KD mice were treated with 4 mg/kg Dox and hearts harvested for electron microscopy (EM) and signaling studies at 3 days.
Results: We found that in Dox-damaged hearts, PI3Kγ signaling is engaged downstream of toll-like receptors, and in particular TLR-9, which have been previously reported to sense danger signals generated by injured cardiomyocytes, like mitochondrial DNA (mitoDNA)(Oka et al. Nature 2012). In NCMs, Dox significantly increased the phosphorylation of PI3K downstream targets and autophagy inhibitors, Akt, mTOR and Ulk-1. These effects were completely prevented by the TLR9 antagonist ODN2088, the PI3Kγ selective inhibitor AS605240 and genetic PI3Kγ inactivation (KD NCMs). Notably, the TLR9 agonist ODN1826, mimicking mitoDNA, similarly upregulated Akt/mTOR/Ulk-1 signaling in WT but not in KD NCMs. In vivo, enhanced activation of this PI3Kγ-dependent pathway correlated with a significant block of autophagy in Dox-treated hearts. Notably, genetic inhibition of PI3Kγ restored autophagosome formation, as evidenced by enhanced accumulation of LC3II. In addition, EM studies confirmed the presence of autolysosomes containing injured mitochondria in KD but not in WT hearts. This eventually correlated with completely preserved ultrastructure in KD cardiomyocytes in contrast to severe mitochondrial damage and vacuolization in WT controls.
Conclusion: Altogether, these data demonstrate that PI3Kγ prevents autophagic disposal of anthracycline-damaged mitochondria, likely leading to metabolic derangement and, ultimately, to heart failure. We propose PI3Kγ inhibition as a novel strategy to reactivate targeted autophagy and limit cancer therapy-related heart disease. Intriguingly, PI3Kγ inhibitors also have major antitumor properties and might provide the unique opportunity to "kill two birds with one stone" in cancer patients undergoing chemotherapy.

Funding Acknowledgements: SFHTA

Introduction: Acute Kidney Injury (AKI) has been strongly associated with both short and long-term mortality in hospitalized patients. The Cardio-renal Syndrome type 3 (CRS-3) is characterized by an initial AKI that leads to an acute cardiac injury and/or dysfunction. Galectin-3 (Gal-3) is a galactoside-binding lectin and known to be involved in inflammation, fibrogenesis, and cardiac remodeling. Gal-3 has a key role in cardiac dysfunction in a mouse model of CRS-3.
Methods: and Results: In C57Bl6 and Gal-3 KO mice we performed nephrectomy of the right kidney and 25 minutes ischemia of the left kidney followed by reperfusion (IR). Two groups of WT mice were treated by MCP (Modified Citrus Pectin, an inhibitor of Gal-3), 3 days before surgery or one day after surgery. Mice were sacrificed at different time points after reperfusion (3, 6, 12, 24, 48, 72h and 28 days). Renal dysfunction was observed at 24h (increased x10 serum creatinine and Blood Urea Nitrogen levels, $p < 0.001$). Functional renal parameters returned to baseline levels at 2-3 days post-IR. Renal IR induced acute heart damage illustrated by the increase in cardiac markers of injury (BNP and QSOX1-mRNAs, $p < 0.01$) and inflammation (CD68, MCP1 and Galectin-3-mRNAs x2) in WT mice, almost prevented in Gal-3 KO and treated mice, but cardiac function remained normal. As in the kidney, all stress markers returned to basal levels within 3 days post-IR but markers of cardiac inflammation (CD68 and TGFβ x2: $p < 0.01$) remained elevated at day 28 post-IR in WT mice. This sustained inflammation in WT mice was accompanied by a cardiac dysfunction (-10% in fraction shortening, $p < 0.001$) and fibrosis (x3, $p < 0.001$) 28 days after renal IR prevented in Gal-3 KO and treated mice.
Conclusion: Altogether, data indicated that in WT mice a renal IR provokes an early cardiac injury and long-term cardiac dysfunction prevented by the inhibition of Gal-3. Gal-3 seems to have a key role in cardiac dysfunction in this murine model of CRS-3.

P2290
Role of Galectin 3 in acute renal disease.

M Magali Genest[1]; M Prud'homme[2]; S Kinugasa[1]; S Placier[1]; J-L Samuel[2]; M Legrand[2]; C-E Chadjichristos[1]
[1]HOPITAL TENON, INSERM UMR-S 1155, PARIS, France; *[2]Inserm UMR-S 942, Paris, France*

Introduction: Acute kidney injury (AKI), being associated with relatively high short-term mortality is a major problem of public health. It is characterized by a sudden decline of renal function. In the intensive care setting, AKI remains an important predictor of clinical outcomes and results in cardiac dysfunction in type 3 cardio-renal syndrome (CRS3). We recently demonstrated that Galectin 3 (Gal-3) is involved in cardiac inflammation and fibrosis. The objective of this study was to determine Gal-3 role in AKI following renal ischemia / reperfusion (IR) and to analyze its implication in the CRS3.
Materials and Methods: 2-month-old C57B1/6J WT and KO Gal-3 mice underwent right nephrectomy followed by 25-minute ischemia and reperfusion of the left kidney at different time points (6, 24 and 48h), or a sham operation. Mice were divided into 4 groups, WT Sham, KO-Sham, WT-IR and KO-IR.
Results: IR induced a peak of histological and functional renal damage in WT mice 24 hours after reperfusion, as well as an increase in the expression of Gal-3 at both mRNA and protein levels. Immunolabeling showed that Gal-3 was localized in the renal tubular cells and in the macrophages of the injured kidneys. Furthermore, KO Gal-3 mice presented more severe renal damage than WT at 48 h, with more pronounced macrophage infiltration.
Conclusion: The expression of Gal-3 is increased after renal IR. This protein could have a protective role in AKI following an IR, given that Gal-3 KO presents improved renal structure and function. In contrast, we observed less cardiac damage in these mice. Thus, Gal-3 could play a dual role in CRS3.

P2291
RAAS genetic polymorphism and glomeruli filtration reduction in patients with chronical heart failure

SU Volkova[1]; KA Tomashevich[2]; EU Efanov[1]
[1]Tyumen State Medical University, Tyumen, Russian Federation; *[2]"Neftyanic" hospital, Tyumen, Russian Federation*

Aim: To estimate RAAS genetic polymorphism association with glomeruli filtration reduction in patients with CHF. Materials and methods. 51 patients with CHF were included into investigation (27 women, mean age - 73,1 $\pm$ 11,3 years old) with clinical features of CHF, 3-4 NYHA class. Having analyzed genomic DNA with PCR – analysis (PCR-express) followed by electrophoresis detection we estimated type I angiotensin II (AGTR1) A1166C receptor polymorphism, polymorphism of T174M and M235T AGT gen of ACE. Results are presented as genotype (homosygot in allel 1, allel 2 or heterosygot) detection for AGTR1 genes and AGT and in detection allel D-deletion or allel I – insertion Alu – consequences in intron ACE gen. Data were statistically processed with standard methods.
Results: We coincided RAAS genotypes frequency with comorbidity in patients with CHF. We analyzed association of genotypes with chronic kidney disease incidence with glomeruli filtration rate less than 60 ml/min (62.7%) as well as 30 ml/min (11.1%). We found no significant association of RAAS genetic polymorphisms with GFR rate reduction less than 60 ml/min. At the same time heavy kidney impairment (GFR < 30 ml/min) was associated with some polymorphisms of A1166S and Met274Thr. GFR < 30 ml/min was associated with allele 1166Cpresence (A1166S genotypes and 1166C homozygote (11,1%) if GFR < 30 ml/min, Versus 0% of homozygote A1166, $\chi 2$=4,11, p= 0, 043, p (F)= 0, 063) and 174Met allele (11,1% if GFR < 30, Versus 0% of genotype Tht174Thr, $\chi 2$=4,11 p= 0, 043, p (F)= 0, 063). At the same time statistical analysis revealed the tendency to higher blood hemoglobin level in patients with 1166C allele (119,4 $\pm$ 20,14 g/l versus 111,12 $\pm$ 13,3 g/l in patients without it in genotype, p=0,091). We can also say that Met235 allele presence was associated with lower creatinine level (114,2 $\pm$ 47,3 mmol/l versus 151,0 $\pm$ 41,2 mmol/l without it, p=0,036).
Conclusion: In our research we found some RAAS genotypes association with GFR reduction. Assuming that literature data show very controversy results about RAAS genetic polymorphism association with reduced GFR in patients with CHF, further study are actual.

P2292
PI3Kgamma inhibition rescues mice from acute cardiac contractile dysfunction and sudden death caused by calcineurin inhibitors

B Bernadin Ndongson Dongmo[1]; LR Moltzau[1]; KW Andressen[1]; M Baretta[2]; MV Cosson[1]; A Ghigo[3]; M Brodhun[4]; E Hirsch[3]; R Bauer[2]; FO Levy[1]
[1]University of Oslo, Pharmacology, Oslo, Norway; *[2]University Hospital of Jena, Institute of Molecular Cell Biology, Jena, Germany*; *[3]University of Turin, Center of Molecular Biotechnology, Turin, Italy*; *[4]Helios-Klinikum, Pathology, Erfurt, Germany*

Funding Acknowledgements: The research leading to these results has received funding from the European Union Seventh Framework Programme (FP7-PEOPLE-2013-COFUND)

Purpose: Calcineurin inhibitors (CNI) as cyclosporin A and tacrolimus are the most commonly used immunosuppressive drugs following solid organ transplantation and in various autoimmune diseases. But, CNI therapies are also associated with severe side effects like arterial hypertension, atherosclerosis, insulin resistance, brain, liver and renal complications, and cardio-toxicity. However, the effects of CNI on cardiac contractile function are poorly studied. In this study, we have investigated the acute effect of CNI on cardiac contractile function and the beneficial effects mediated by PI3Kg inhibition.
Methods: The intact heart left ventricle contractility (Pressure-Volume-Conductance) was evaluated in mice 5h after intra-peritoneal injection of CNI in WT, PI3Kg KO (total deletion of PI3Kg), PI3Kg KD ("kinase dead"; lacking PI3Kg kinase function) and in WT treated with selective inhibitor of PI3Kg. Thereafter, cardiomyocytes were studied using several biochemical approaches to investigate the beta adrenergic signaling pathway including PLB activation, cAMP production and phosphodiesterase (PDE) activity. Finally a long term follow up with histological studies in cardiac tissue as well as ECG using telemetry and survival analysis was performed.
Results: We intriguingly found 5h after CNI injection an important reduction (<50%) of cardiac contractility (End-systolic elastance; Ees) that was confirmed in vitro with a down-regulation of beta-adrenergic signaling upon cardiomyocyte stimulation with CNI (4h). Interestingly, these effects were completely absent after the same treatment in transgenic mice and cardiomyocytes (PIKg KO, PIKg KD), and in mice and cardiomyocytes treated simultaneously with PI3Kg selective inhibitor. Following up these findings, we have also observed in cardiac sections (H&E, TUNEL) 15h after CNI, the presence of necrotic cells as well as myofibre break-up indicating a possible sign of ventricular fibrillation. Whereas the observed side effects of CNI were correlated with higher mortality, the group of mice simultaneously treated with PI3Kg inhibitor interestingly exhibited a better survival rate ($p < 0.05$).
Conclusion: In this study, we observed an acute cardio-depressive effect of CNI associated with sudden death and established the rationale for PI3Kg inhibition as a potential therapeutic approach.

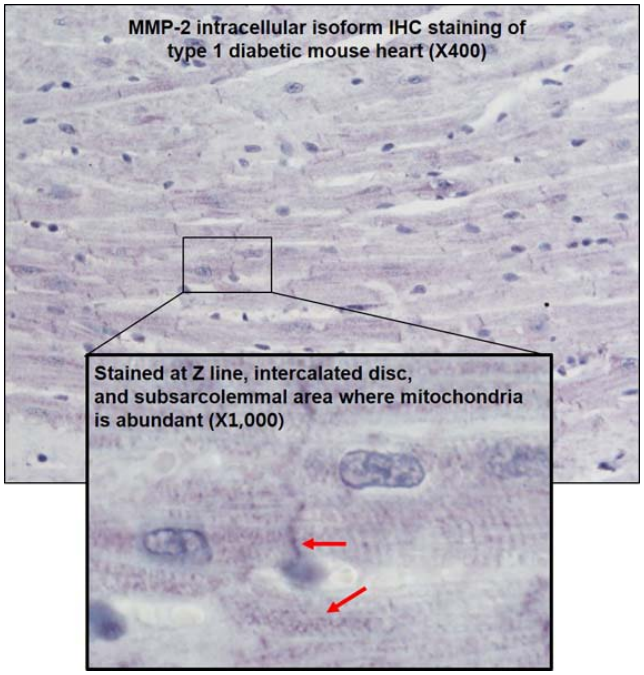
Funding Acknowledgements: This work was supported by a clinical research grant from Medical Research Institute, Pusan National University Hospital (2015).

Background: Diabetic cardiomyopathy (DM CMP) is defined as cardiomyocyte damage and ventricular dysfunction in diabetic condition, which is independent of the concomitant coronary artery disease and/or hypertension. Matrix metalloproteinases (MMPs) are reported to account for pathogenesis of DM CMP by increasing myocardial extracellular collagen contents. Recently, intracellular isoforms of MMP-2 were reported. They are usually located at nucleus and mitochondria induced by oxidative stress, and reported to account for cardiac dysfunction through activating innate immunity and apoptosis at intracellular level in ischemic heart model. Purpose: We hypothesized that intracellular isoforms of MMP-2 are also induced by high glucose stimulation, where oxidative stress is also induced. Therefore, we aimed to evaluate the intracellular isoforms of MMP-2 in vivo and in vitro diabetic heart model.
Methods: Rat cardiomyoblast (H9c2 cell) was cultured with 30mM of high glucose concentration for 24 or 48hours. In vivo type 1 diabetic mouse model was made by 40mg/kg of streptozotocin intraperitoneal injection for consequent 5 days. After sacrificing mouse at 12 and 24 weeks, quantitative real-time polymerase chain reaction (qRT-PCR) of isoforms of MMP-2 and innate immunity/apoptotic markers were done as well as pathological analysis including immunohistochemical (IHC) staining. Results: Quantitative RT-PCR and immunofluorescence staining showed that there was expression of intracellular isoforms of MMP-2 in H9c2 cell compared to negative expression in control group. There was no definite histologic change of diabetic cardiomyopathy. For the IHC staining and qRT-PCR, however, there was distinct expression of intracellular isoforms of MMP-2 in diabetic mouse heart. Conclusion: Intracellular isoforms of MMP-2 were induced by high glucose stimulation in in vitro and in vivo diabetic heart model. Further evaluation of its role in diabetic cardiomyopathy should be followed.



MMP-2 intracellular isoform in tissue

Funding Acknowledgements: This work was supported by project DOCnet (NORTE-01-0145-FEDER-000003), supported by Norte Portugal Regional Operational Programme (NORTE 2020)

Introduction and aims: The progression of chronic pressure overload (CPO) is associated to cardiac cachexia as a consequence of insufficient energy supply. Additionally, some studies demonstrate that the heart secretes cardiokines able to modulate the adipose tissue (AT) structure and function promoting adiposopathy. In this study we investigate the effects of CPO in AT during the early stages of the disease.
Methods: Wistar rats were submitted to ascending aortic banding (Ba group; 0.6mm diameter) or sham procedure (Sham group). After 8 weeks, left ventricular (LV) function and structure (echocardiography and invasive hemodynamics) was evaluated and samples (LV and AT) collected for histological and molecular evaluations. Plasma was obtained for quantification of circulating B-type natriuretic peptide (BNP). Finally, visceral AT from normal rats was incubated with the BNP plasma concentrations detected in the Sham and Ba group (0.27 and 0.47ng/ml respectively) for 24h and then collected for molecular studies.
Results: Eight-weeks of banding increased LV systolic pressure and triggered cardiac remodeling with fibrosis and cardiomyocytes' hypertrophy when compared to Sham animals. The same group was at a compensated stage of the disease with higher ejection fraction, however a stiffer myocardium was observed with increased end diastolic pressure-volume relation and passive force of isolated cardiomyocytes. Despite similar adiposity between the 2 groups, aortic constriction triggered adipocyte atrophy as well as AT increased fibrosis and dysfunction, as observed by overexpression of pro-inflammatory adipokines. The incubation of AT from normal rats with BNP confirmed that the elevated circulatory levels of this cardiokine were able to induced increased expression of pro-inflammatory adipokines by the AT.
Conclusions: We demonstrated that higher circulatory levels of BNP promoted by LV CPO are able to induce adiposopathy characterized by remodeling of the AT and overexpression of pro-inflammatory adipokines.

Effects of ranolazine in a model of doxorubicin-induced left ventricle diastolic dysfunction

D Cappetta[1]; K Urbanek[1]; G Esposito[1]; R Coppini[2]; E Piegari[1]; LP Ciuffreda[1]; L Santini[2]; F Rossi[1]; L Berrino[1]; A De Angelis[1]
[1]Second University of Naples, Department of Experimental Medicine - Section of Pharmacology, Naples, Italy; *[2]University of Florence, Department of Neuroscience, Drug Research and Child's Health (NeuroFarBa) - Division of Pharmacology, Florence, Italy*

Background: Doxorubicin (DOXO) is a highly effective anticancer drug but its clinical application is impeded by cardiotoxicity. Asymptomatic diastolic dysfunction can be the earliest manifestation of DOXO cardiotoxicity. Therefore, a search for therapeutic intervention that can interfere with early manifestations and possibly prevent late cardiotoxicity is warranted. Increased DOXO-dependent reactive oxygen species may explain, in part, Ca2 + and Na + accumulation that contributes to diastolic dysfunction and development of heart failure.
Purpose: We tested whether the administration of ranolazine (RAN), an anti-anginal drug, immediately after completing DOXO therapy, can affect diastolic dysfunction and interfere with the progression of functional decline.
Methods: Fischer 344 rats received a DOXO cumulative dose of 15 mg/kg over a period of 2 weeks. After the assessment of diastolic dysfunction, the animals were administered with RAN (80 mg/kg/die) for the following 4 weeks.
Results: While diastolic and systolic function progressively deteriorated in DOXO-treated animals, treatment with RAN relieved diastolic dysfunction and prevented worsening of systolic function decreasing mortality. RAN lowered myocardial NADPH oxidase 2 expression and 3-nitrotyrosine content. A reduced NCX and Nav 1.5 expression and an increment of SERCA2 were also detected. In addition, RAN lowered DOXO-induced increased phosphorylation and oxidation of Ca2 + /calmodulin-dependent protein kinase II and decreased fibrosis.
Conclusions: RAN, by modulating cardiac Ca2 + and Na + handling proteins and oxidative stress, was effective in attenuating DOXO-induced diastolic dysfunction and prevented the progression of cardiomyopathy.

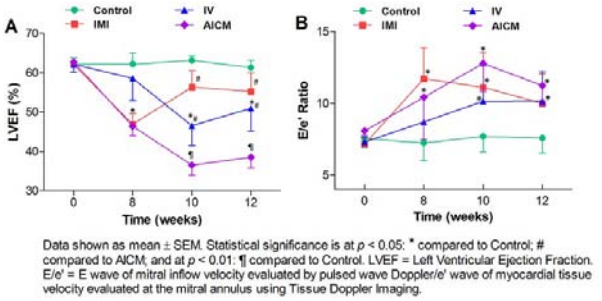
Introduction: Recent data suggests that anthracycline induced cardiomyopathy (AICM) is a stem cell disease affecting the local (myocardial) and systemic stem cell niches, which limits autologous stem cell therapy in this condition. We hypothesized that an allogeneic stem cell transplant approach using amniotic membrane-derived mesenchymal stem cells (AM-MSC) could be an effective therapy for this condition. Using a model of AICM, we evaluated the effects on ventricular systolic and diastolic function as well as survival, of AM-MSC therapy administered via intravenous route (IV), compared to administration via percutaneous contrast echocardiography-guided intramyocardial injection (IMI).
Methods: Cardiomyopathy was induced in New Zealand rabbits with IV daunorubicin (4 mg/kg, weekly for 6 weeks). One group received IV therapy with 5 million/kg AM-MSC (IV Group, n=8), 24 hours after each weekly cycle of daunorubicin. A second group received one dose of 5 million AM-MSC, 8 weeks after the first dose of anthracycline, via contrast echocardiography-guided percutaneous IMI (IMI Group, n=8). A third group received no cell therapy (AICM Group, n=8). A final group neither received daunorubicin nor cell therapy, thus constituting an age-matched Control Group (n = 8). A complete echocardiographic exam was performed at baseline and repeated every two weeks.
Results: In all groups, ventricular systolic and diastolic function was normal at baseline (Figure 1A-B). The IV group did not exhibit significant alterations of myocardial function at 8 weeks, consistent with a cardioprotective effect (Figure 1A-B). In contrast, significant alterations of both systolic and diastolic function by daunorubicin were observed in IMI and AICM groups at 8 weeks, consistent with the development AICM. Whilst ventricular systolic function significantly improved at 10 and 12 week time points in IMI group, it continued to deteriorate in AICM group. Of note, significant alterations in myocardial function were apparent in IV group after 10 weeks, but significantly less conspicuous than in AICM group, suggesting delayed-onset cardiotoxicity. Survival in rabbits from IMI and IV groups was improved (77% and 75%, respectively) compared to AICM group (22%) ($p < 0.04$).
Conclusions: The observation of early cardioprotection from AICM in IV group at 8 weeks, with later decline of LVEF from 10 weeks suggests that anthracyclines induced delayed-onset cardiotoxicity, which affected, at least in part, endogenous as well as exogenous stem cells, thus hindering long term cardioprotection. The significant recovery of LVEF at 10 and 12 weeks in the IMI group, suggest that this is an effective therapy once cardiomyopathy ensues. Further studies with an extended time course of IV administration of allogeneic AM-MSC are required to evaluate whether this therapy may confer prolonged cardioprotection from AICM, as well as to elucidate the mechanisms of delayed-onset cardiotoxicity observed in IV group.



Data shown as mean ± SEM. Statistical significance is at $p < 0.05$: * compared to Control; # compared to AICM; and at $p < 0.01$: ¶ compared to Control. LVEF = Left Ventricular Ejection Fraction. E/e' = E wave of mitral inflow velocity evaluated by pulsed wave Doppler/e' wave of myocardial tissue velocity evaluated at the mitral annulus using Tissue Doppler Imaging.

MicroRNA-155 promotes LPS-induced myocardial NO overproduction and amplifies cGMP-PKG signaling pathway by targeting CD47

F Francisco Vasques-Novoa[1]; R Cerqueira[1]; C Quina-Rodrigues[1]; S Ribeiro[1]; R Soares-Dos-Reis[1]; F Goncalves[1]; TL Laundos[2]; DS Nascimento[2]; AF Leite-Moreira[1]; R Roncon-Albuquerque Jr[1]
[1]University of Porto, Faculty of Medicine, Porto, Portugal; *[2]University of Porto, i3s - Instituto de Investigação e Inovação em Saúde, Porto, Portugal*

Purpose: Sepsis-associated cardiovascular dysfunction (SACVD) remains a leading cause of death in critically ill patients. Among several pathophysiological mechanisms, excessive NO production and signaling have been shown to negatively affect cardiac contractility and vascular reactivity. CD47, a transmembrane receptor for TSP1, mediates a potent inhibitory effect on NO-cGMP-PKG signaling pathway and its role in SACVD remains unknown.
Methods: Protocol 1: Experimental sepsis was induced using LPS injection (40mg/Kg, ip) in C57BL/6J (WT; n=40) and miR-155-/- (KO; n=40) male mice. Cardiac function was evaluated through echocardiography. Myocardial water content and microvascular permeability (Evans blue method) were assessed. Myocardial NO, cGMP levels and PKG activity were evaluated. Quantification of miR-155, CD47, NOS2, NOS3 and phospho-VASP (Ser239) were assessed by immunoblotting (this

analysis was repeated in protocol 2 and 3). Protocol 2: Human cardiac microvascular endothelial cells (HMVEC-C) were incubated with LPS (20mg/mL) or vehicle and NO production was assessed under inhibition of miR-155 (LNA), CD47 activation with TSP1 and knockdown of CD47 (siRNA), with appropriate controls. Protocol 3: Vascular response to TSP-1 was analyzed in mouse aortas and human internal mammary arteries after LPS/vehicle exposition. Dose-response curves to Ach were performed for each group under control or physiological TSP-1 stimulation (2.2nM) conditions.
Results: LPS upregulated miR-155 expression in mouse and human samples. In experimental sepsis, this was accompanied by impaired cardiac contractility and increased myocardial microvascular permeability. MiR-155 KO animals presented with attenuated LPS-induced cardiac dysfunction and edema, compared with WT. CD47 was validated as miR-155 target by a luciferase assay. Experimental sepsis in WT was associated with CD47 downregulation and iNOS upregulation, increased myocardial NOx content, cGMP levels, VASP phosphorylation and PKG activity, all of which were attenuated in KO mice. In HMVEC-C, LPS incubation induced miR-155 upregulation, NO overproduction and CD47 downregulation. MiR-155 inhibition attenuated NO production and iNOS overexpression. TSP-1 incubation decreased NO production in Ctrl cells; this effect was lost with LPS incubation, but regained with miR-155 inhibition. MiR-155-mediated recovery TSP-1 inhibitory effect on NO production was CD47-dependent. In control arterial rings, TSP1 incubation significantly decreased the NO-mediated relaxation – this effect was lost in WT LPS, but preserved in miR-155 KO LPS.
Conclusions: MiR-155 is uprerulated in septic myocardial and vascular tissue. Mice lacking miR-155 present an attenuation of myocardial NO overproduction, edema, contractile dysfunction and mortality. CD47, a previously unappreciated target of miR-155, is downregulated during sepsis, potentiating the depressor effect of cGMP-PKG signaling on myocardium and vascular function.

Background: Abnormal thyroid hormone (TH) metabolism is significantly associated with impaired left ventricular (LV) function and death. Although TH was traditionally thought to be produced exclusively by the thyroid gland, an increasing number of studies report TH production in other tissues.
Purpose: We aimed to determine whether the genes required for TH biosynthesis are expressed in the human heart, and to investigate whether their expression is altered in patients with ischemic cardiomyopathy (ICM) and is related to variations on epigenetic patterns.
Methods: Twenty-three LV tissue samples were obtained from ICM patients undergoing heart transplantation and control donors for RNA sequencing analysis. We increased the LV samples to 27 for the ELISA determination of total T4 and T3 tissue levels. For epigenomic studies, 850K Infinium MethylationEPIC BeadChip platform was performed.
Results: Using RNA-sequencing, we identified the expression levels of all components required for TH biosynthesis in human heart tissue. We observed significantly altered expression of genes encoding thyroperoxidase (TPO; $P < 0.05$) and dual oxidase 2 ($P < 0.05$), the main enzymatic system of TH production, and significant relationships between their altered expression and LV remodeling parameters. In addition, epigenetic analysis revealed a differential methylation pattern in TPO, and triiodothyronine tissue levels were significantly decreased ($P < 0.01$).
Conclusions: These results showed that the human heart expresses the TH biosynthesis machinery, being altered its main enzymatic system in patients with ICM. Given the relevance of TH in cardiac pathology, our results may provide the basis for new therapeutic approaches based on TPO for treating ICM.

Effects of streptozotocin-induced type I diabetes mellitus on the pacemaker of the heart

Y Yu Zhang[1]; YW Wang[1]; Y Joseph[1]; AQ Mohammed[2]; X Cai[1]; N Gardiner[3]; FC Howarth[2]; H Dobrzynski[1]
[1]University of Manchester, Institute of Cardiovascular Sciences, Manchester, United Kingdom; *[2]Medicine and Health Sciences, Department of Physiology, Al-Ain, United Arab Emirates*; *[3]Faculty of Life Science, manchester, United Kingdom*

Purpose: Cardiovascular complications are common in type I diabetes mellitus and, for example, there is an increased risk of bradyarrhythmias as a result of dysfunction of the cardiac conduction system (1). The sinoatrial node (SAN) is the pacemaker of the heart and one component of the cardiac conduction system. We have shown that in vivo there is a decrease in heart rate in the streptozotocin-induced diabetic rat (266 ± 13 versus 316 ± 11 beats/min; $P < 0.05$). The aim of this study was to investigate the cellular basis of the bradycardia in the rat model.
Methods: We generated streptozotocin-induced diabetic rats as previously described (2). We investigated function using the Langendorff-perfused heart, isolated SAN and isolated SAN cell (patch clamp). Protein expression was investigated using immunohistochemistry. We labelled HCN4 (responsible for the funny current, If), Kir3.1 (responsible for the ACh-activated K+ current, IK,ACh) and RyR2 (sarcoplasmic reticulum Ca2+-release channel). The research was conducted in accordance with legislation in UAE and UK.
Results: Compared to control rats, diabetic rats showed a 428% increase in blood glucose and 16% increase in heart to body weight ratio ($n = 16$ control and n=16 diabetic rats; $P < 0.05$). The heart rate measured in the Langedorff heart was decreased by 17.4% in diabetes from 298 to 246 beats/min ($n = 5$ control and n=4 diabetic rats; $P < 0.05$). The beating rate of the isolated SAN preparation was decreased by 17.3% from 305 to 252 beats/min ($n = 4$ control and n=3 diabetic rats; $P < 0.05$). Application of 2 μM ryanodine to the SAN preparation to incapacitate RyR2 caused arrhythmia in the diabetic preparations, but not in control preparations ($n = 4$ control and n=3 diabetic rats). If was measured in nodal cells isolated from 4 control rats ($n = 29$ cells) and 3 diabetic rats ($n = 33$ cells). The If density was 21.0 ± 2.8 versus 14.3 ± 1.2 pA/pF, and the cell capacitance was 20.2 ± 1.0 versus 14.7 ± 0.9 pF in control and diabetic rats, respectively. Immunolabelling of SAN tissue sections showed that HCN4 channel expression was significantly increased by 73%, whereas Kir3.1 and RyR2 expression was significantly decreased by 9% and 34% in diabetes ($n = 4$ control and n=4 diabetic rats). Downregulation of If density and RyR2 could explain the lower heart rate of the diabetic rats.
Conclusions: We conclude that there are complex functionl changes in the SAN in diabetes. Such remodelling may increase the risk of bradyarrhythmia in type 1 diabetes.

Maternal overnutrition programs cardiac dysfunction independently of post-natal diet in mice

E Elena Loche[1]; HL Blackmore[1]; AAM Carpenter[1]; DS Fernandez-Twinn[1]; J Beeson[1]; TJ Ashmore[1]; A Pinnock[1]; SE Ozanne[1]
[1]University of Cambridge, Wellcome Trust-MRC Institute of Metabolic Science, Cambridge, United Kingdom

Purpose: Gestational exposure to maternal obesity increases the risk of cardiovascular disease in the offspring. Exposure to overnutrition during fetal life is likely to be followed by continued exposure to the same calorie-rich environment post-natally. The aim of this project was to characterize the consequences of combined exposure to a maternal and post-natal obesogenic diet on offspring cardiac structure and function.
Methods: A well-established mouse model of maternal diet-induced obesity where C57bl/6 dams are fed a high fat/high simple carbohydrate diet during pre-gestation, gestation and lactation was used. Male offspring from control (C-) and obese (O-) were assigned at weaning to either a control (-C) or obesogenic diet (-O), generating 4 experimental groups (CC, CO, OC and OO). Metabolic profile, cardiac structure and function, gene expression, and blood pressure were assessed in male offspring at 8 weeks of age.
Results: Dams fed the obesogenic diet were significantly heavier on the day of mating ($p < 0.0001$), and remained heavier throughout pregnancy and at weaning compared to controls. Young adult (8 weeks) offspring exposed to maternal overnutrition had heavier hearts (17%) than control mice (effect of maternal diet $p = 0.005$). A post-weaning obesogenic diet also increased heart weight (effect of offspring diet $p = 0.019$). Circulating levels of insulin and leptin were increased by feeding the obesogenic diet, and further elevated by the maternal exposure. Mice born to overnourished mothers developed pathological ventricular remodelling associated with re-expression of cardiac fetal genes (Nppa, Myh7, Myh7:Myh6 ratio), interventricular septum thickening ($p = 0.0004$), increased left ventricular area ($p = 0.02$), cardiac systolic dysfunction with reduced ejection fraction and fractional shortening. Most importantly, up-regulation of genes involved in cardiac contraction was observed in fetuses from obese dams as early as in utero.
Conclusions: Maternal overnutrition programs adverse cardiac remodelling and dysfunction in adult male offspring. These findings suggest that a maternal calorie-rich uterine environment is a critical determinant of cardiovascular disease risk in the next generation.

Cobalamin and folate protect mitochondrial oxidative capacity and contractile function in myocardial dysfunction

J Piquereau[1]; M Moulin[2]; M Moulin[1]; G Zurlo[1]; G Zurlo[2]; P Mateo[2]; P Mateo[1]; M Gressette[1]; M Gressette[2]; J-L Paul[2]; J-L Paul[3]; C Lemaire[1]; C Lemaire[2]; R Ventura-Clapier[2]; R Ventura-Clapier[1]; V Veksler[1]; V Veksler[2]; A Garnier[2]; A Garnier[1]
[1]University of Paris-Sud 11, UMR-S 1180, Inserm, Chatenay-Malabry, France; *[2]University of Paris-Sud 11, Chatenay-Malabry, France*; *[3]European Hospital Georges Pompidou, Paris, France*

Background: As a key regulator of energy metabolism, the transcriptional co-activator PGC-1α appears as a relevant therapeutic target to rectify the chronic energy deficit observed in heart failure (HF). Based on results obtained from a cellular screening assay showing a positive effect of cobalamin (Cb, vitamin B12) on PGC-1α signaling pathway, the present study aimed at investigating the potential protective role of Cb in pressure overload-induced HF.
Methods: and results: Mice were pre-treated with Cb and folate supplemented diet (SD) for 3 weeks before transverse aortic constriction (TAC). Four weeks after TAC, cardiac parameters were measured by echocardiography and animals were sacrificed. TAC-induced left ventricle (LV) hypertrophy and drop of ejection fraction (EF) were significantly lower in mice treated with SD than in mice fed with normal diet. Alterations in mitochondrial oxidative capacity and mitochondrial biogenesis induced by pressure overload were markedly improved by SD. In SD-TAC mice, exploration of the signaling pathways involved in the post-translational regulation of PGC-1α showed a higher activation in AMPK, a lower expression level of the acetyltransferase GCN5 and a higher expression level of PRMT1. This was associated with a lower protein acetylation and a higher protein methylation levels in SD-TAC mice that were accompanied by a sustained expression of genes involved in mitochondrial biogenesis (Tfam, Nrf2, Cox1 and Cox4), suggesting a preserved activation of PGC-1α after TAC in mice fed with SD. Inasmuch as oxidative stress and homocysteinemia were unchanged by SD, it seems that the beneficits procured by SD in this model would not be related to the antioxidant properties and the effect on homocysteinemia of these vitamins.
Conclusion: These results showed that Cb and folate could protect the failing heart by preserving energy status through maintenance of mitochondrial biogenesis.

Cardiac compliance is acutely modulated through cGMP-PKG signalling

A M Andre Mendes Leite Moreira[1]; J Almeida-Coelho[1]; JS Neves[1]; N Hamdani[2]; WA Linke[2]; I Falcao-Pires[1]; AP Lourenco[1]; AF Leite-Moreira[1]
[1]Faculty of Medicine University of Porto, Physiology and Cardiothoracic Surgery, Porto, Portugal; *[2]Ruhr University Bochum (RUB), Cardiovascular Physiology, Bochum, Germany*

On behalf of: ESC Working Group on Myocardial Function

Purpose: Increased diastolic stiffness due to titin hypophosphorylation and low protein kinase G (PKG) activity is a hallmark of heart failure with preserved ejection fraction (HFpEF). Acute load sensitivity is a well-known factor of decompensation in HFpEF which has been mainly ascribed to vascular and systolic stiffening but other factors such as a diastolic stiffness response to volume overload (VO) may be at play. We aimed to investigate whether there is a diastolic response to acute VO, cardiac stretch-induced compliance (SIC), and to ascertain the potential involvement of cGMP-PKG-signalling in this response in several animal models and the human heart.
Methods: Left ventricle (LV) of rat intact hearts, LV and right atrial muscle strips of cardiac surgery patients and rabbit right ventricular papillary muscles were acutely stretched for 15 minutes. Passive tension (PT) was measured in skinned cardiomyocytes extracted from non-stretched and stretched LV before and after incubation with PKG or protein phosphatases (PP). Different groups of rabbit muscles were incubated with a natriuretic peptide receptor-A antagonist (NPRA), an inhibitor of NOS, a NO scavenger, the latter 3 simultaneously or an inhibitor of PKG (PKGi). Titin phosphorylation was assessed in non-stretched and stretched muscles incubated with PKGi. Myocardial cGMP levels and vasodilator-stimulated phosphoprotein (VASP) phosphorylation were quantified in stretched and non stretched samples. Hemodynamic pressure-volume response to VO was assessed in sham and transverse-aortic-constriction (TAC) rats and was also assessed by echocardiography in healthy volunteers and in cardiac surgery patients before and after Trendelenburg positioning and VO, respectively.
Results: After the initial increase in response to stretch/VO, diastolic pressure and PT decreased sustainedly over 15 minutes in all species and experimental preparations. Skinned cardiomyocytes from stretched hearts showed decreased PT which was abrogated by PP incubation while those from non stretched LV decreased PT after PKG incubation. Stretched samples showed increased cGMP levels and hyperphosphorylation of VASP. Titin phosphorylation was higher in stretched samples and lesser by PKGi. SIC was significantly blunted by PKG inhibition or by joint NPRA + NOS inhibition + NO scavenging and was also absent in TAC animals. TAC hearts showed titin hypophosphorylation and no increase upon VO. In humans, healthy volunteers and cardiac surgery patients showed E/E' and end-diastolic pressure decrease after VO, respectively. In patients with severe LV hypertrophy the effect was blunted.
Conclusions: We describe a novel adaptive mechanism of increased myocardial compliance in response to acute VO that is mediated by titin phosphorylation through cGMP-PKG signalling. The mechanism was translated to human physiology and may be abolished in the hypertrophic heart suggesting a potential role in the pathophysiology of HFpEF.

Endothelium-derived C-type natriuretic peptide regulates blood pressure through the maintenance of endothelial function

K Kuwahara[1]; K Nakao[2]; T Nishikimi[2]; Y Nakagawa[2]; H Kinoshita[2]; T Tokudome[3]; N Minamino[4]; T Kimura[2]; K Kangawa[3]; K Nakao[5]
[1]Shinshu University, Department of Cardiovascular Medicine, Matsumoto, Japan; *[2]Kyoto University Graduate School of Medicine, Cardiovascular Medicine, Kyoto, Japan*; *[3]National Cerebral and Cardiovascular Center, Department of Biochemistry, Osaka, Japan*; *[4]National Cerebral and Cardiovascular Center, Department of Molecular Pharmacology, Osaka, Japan*; *[5]Kyoto University Graduate School of Medicine, Medical Innovation Center, Kyoto, Japan*

Funding Acknowledgements: This research was supported by Grants-in-Aid for Scientific Research from the Japan Society for the Promotion of Science (To K. Kuwahara and K. Nakao)

Background: Previously we reported the secretion of C-type natriuretic peptide (CNP) from vascular endothelial cells and proposed the existence of a vascular natriuretic peptide system composed of endothelial CNP and smooth muscle guanylyl cyclase-B (GC-B), the CNP receptor, and involved in the regulation of vascular tone, remodeling and regeneration.
Purpose: In this study, we assessed the functional significance of endothelium-derived CNP in the regulation of blood pressure in vivo.
Methods: We generated and analyzed vascular endothelial cell-specific CNP knockout (CNP ecKO) and vascular smooth muscle cell-specific GC-B knockout (GC-B smcKO) mice.
Results: Both CNP ecKO and GC-B smcKO mice showed neither the skeletal abnormality nor the early mortality observed in systemic CNP or GC-B knockout mice. CNP ecKO mice exhibited significantly increased blood pressures and an enhanced acute hypertensive response to nitric oxide synthetase inhibition. Acetylcholine (ACh)-induced, endothelium-dependent vasorelaxation was impaired in rings of mesenteric artery isolated from CNP ecKO mice. Furthermore, the impairment of ACh-induced vasorelaxation was enhanced in CNP ecKO arteries pretreated with the NOS inhibitor L-NAME and the cyclooxygenase (COX) inhibitor indomethacin, suggesting that the impairment of endothelium-dependent vasorelaxation in CNP ecKO mice involves NO- and prostaglandin-independent pathways, possibly an endothelium-derived hyperpolarization factor (EDHF) system. In addition, endothelin-1 (ET-1) gene expression was enhanced in pulmonary vascular endothelial cells from CNP ecKO mice, which also showed significantly higher plasma ET-1 concentrations and a greater reduction in blood pressure in response to an endothelin receptor antagonist than their control littermates. By contrast, GC-B smcKO mice exhibited blood pressures similar to control mice, and acetylcholine-induced vasorelaxation was preserved in their isolated mesenteric arteries. Nonetheless, CNP-induced acute vasorelaxation was nearly completely abolished in mesenteric arteries from GC-B smcKO mice. Consistent with this finding, acute hypotensive effects induced by intravenous administration of CNP were markedly attenuated in GC-B smcKO mice.
Conclusions: These results demonstrate that endothelium-derived CNP contributes to the chronic regulation of vascular tone and systemic blood pressure by maintaining endothelial function independently of vascular smooth muscle GC-B.

P2304

Pharmacological inhibition of microRNA-132 effectively reverses myocardial infarction-induced heart failure in small and large animal models

AE Foinquinos Marin[1]; J Fiedler[1]; J Remke[1]; K Zimmer[1]; A Just[1]; M Gyongyosi[2]; S Batkai[1]; T Thum[1]
[1]Hannover Medical School, Institute for Molecular and Translational Therapeutic Strategies, Hannover, Germany; *[2]Medical University of Vienna, Vienna, Austria*

Purpose: Adverse remodelling after myocardial infarction (MI) is an essential pathological characteristic in heart failure (HF), and microRNAs (miRs, miRNAs) are known to play a key role in this condition. Previously, our group identified miR-132 as

one of the main regulators of cardiomyocyte hypertrophy and highly elevated in cardiac samples from HF patients. Moreover, mice overexpressing miR-132 developed hypertrophy and fibrosis and died from HF at an early stage. Hypertrophy and fibrosis in the remote myocardium are also mechanisms involved in adverse remodelling in patients post-MI often leading to heart failure. Therefore, we wanted to validate whether miR-132 intervention would be beneficial in this process.
Methods: and Results: Pharmacological inhibition of miR-132 by LNA-based oligonucleotides (antisense or scrambled) was done at day 7 and 14 post-MI in a mouse model of experimental MI. Hemodynamic parameters, measured by echocardiography and left ventricular (LV) pressure volume catheter, were assessed at the study end point 4 weeks post-MI. These results show that post-MI antimiR-132 treatment ameliorated cardiac function: both left ventricular end diastolic volume (LVEDV) and left ventricular end systolic volume (LVESV) were reduced after miR-132 silencing in post-MI mice. We then observed by Longitudinal Strain Rate (LSR) analysis that antimiR-132 treatment led to a recovery of the function in the remote areas after MI. At the molecular and histological level, repression of key genes involved in adverse remodeling highlighted the protective cardiac effects of antimiR-132 treatment. After confirming the efficacy of the treatment in a mouse model, we tested this concept in a clinically relevant large animal model. Domestic pigs had a balloon-mediated occlusion of the left anterior descending artery (LAD) for 90 min followed by reperfusion. AntimiR-132 or placebo treatment were delivered by anterograde slow infusion into the coronary artery by a catheter at day 3 and intravenously 4 weeks post-MI. Based on magnetic resonance imaging (MRI) data, 8 weeks post-MI, the volumes and cardiac mass were well preserved and the expression of hypertrophic genes was decreased after antimiR-132 delivery. In addition, we specifically investigated regional function of the post-MI myocardium using segmental contraction analysis. Segmental velocity was improved in most of the remote area segments. The regional improvements could also be observed by NOGA catheter measurements, giving a functional assessment based on electrophysiological properties.
Conclusions: The presented data show that antimiR-132 treatment is beneficial post-MI and attenuates adverse cardiac remodeling by improving global cardiac performance and reducing hypertrophy. These data provide further evidence of this miRNA's translational and clinical relevance and encourages the future therapeutic testing of miR-132 inhibitors on the road of clinical application in HF patients.

Regulation of beta adrenoceptor evoked inotropic responses by inhibitory g protein, adenylyl cyclase isoforms 5 and 6 and phosphodiesterases

MV Marie Victoire Cosson[1]; HG Hiis[1]; FO Levy[1]; KA Krobert[1]
[1]*Oslo University Hospital, pharmacology, Oslo, Norway*

Funding Acknowledgements: Najsonalforeningen for folkhelsen

Purpose: Our data indicate that inhibitory G protein (Gi) inhibits adenylyl cyclase (AC) independently of the receptor. The two major subtypes of AC in the heart are AC5 and AC6. Compartmentalization of β1-adrenoceptor- (β1AR) versus β2AR differs depending on the subcellular localization of the AC subtypes. Deletion of AC6 impairs left ventricular responsiveness to βAR ligands and it is unknown if AC5 or 6 differentially regulate β1AR- versus β2AR-mediated inotropic responses. Determine if intrinsic Gi inhibition is AC subtype selective and whether there is a differential role of AC5 and AC6 to mediate β1AR- and β2AR-evoked inotropic responses. In addition, determine if there is an interplay between Gi and phosphodiesterases 3,4 (PDE3,4).
Methods: We measured β1AR- and β2AR-mediated changes in contractility in left ventricular muscle strips from wild type (WT), AC5 and AC6 knockout (KO) mice. First, with or without pertussis toxin (PTX) to inactivate Gi and/or after inhibition of PDE3 or PDE4.
Results: AC6KO mice revealed increased noradrenaline potency (EC50) at the β1AR compared to WT and AC5KO. Furthermore, AC6KO mice revealed an adrenaline-evoked β2AR-inotropic response only after PDE3 or PDE4 inhibition whereas both were required in WT and AC5KO. A β2AR-mediated inotropic response was also observed after PTX treatment alone in all groups
Conclusion: Gi tonically inhibits AC since PTX enhances both β1AR- and β2AR-mediated inotropic responses despite Gi not coupling to β1AR. PDE4 seems to be the primary PDE regulating the β1AR response in all groups. Inhibiting Gi and PDE3 or PDE4 appears to synergistically enhance adrenaline-evoked β2AR-inotropic response in WT. We therefore propose that inhibiting Gi and PDEs allows cAMP to leak from the β2AR to the β1AR contractile compartment.

Angiotensin 1-7 blunts in vitro induced acute heart failure.

V Cobet[1]; L Tacu[1]; E Cobet[2]; V Rotaru[1]; L Ciobanu[3]; A Rotaru[4]
[1]*State University of Medicine and Pharmacy, Chisinau, Moldova Republic of*; [2]*State University of Moldova , Biopharmaceutical chemistry , Chisinau, Moldova Republic of*; [3]*Institute of cardiology , Chisinau, Moldova Republic of*; [4]*Harvard Medical School, Cambridge, United States of America*

Background: Angiotensin 1-7 (Ang 1-7) comprises consistent evidences regarding cardiovascular regulatory benefits due to Ang II receptor AT1 modulation via mass receptor.
Aim: Evaluation of the Ang 1-7 cardiac effects in the in vitro induced acute heart failure.
Material and methods: Acute heart failure (AHF) was induced using the model of isolated rat pumping heart perfused by Krebs solution without glucose during 20 min according to Neely-Rovetto model (glucose is a single energetic substrate in this model) – control series. In another series heart has been perfused without glucose, but Ang 1-7 was added till final concentration of 10-7 M – medicated series. Left ventricle (LV) functional parameters were assayed during inotropic stimulation by norepinephrine (NE) and endothelin 1 (ET-1) in concentration of 10-6 M, or ischemia-reperfusion impact (15 min of total ischemia followed by 20 min of reperfusion) reproduced in Langendorff isovolumic isolated heart.
Results: Cardiac output (CO) significantly decreased after 20 min perfusion of isolate heart without glucose by 25,9% ($29,4 \pm 1,3$ vs $39,7 \pm 2,1$ ml/min). Action of Ang 1-7 led to a less decline of CO compared to control ($34,8 \pm 1,6$ vs $29,4 \pm 1,3$ ml/min, $p < 0,05$). NE stimulation induced an increase of control CO by 10,7% associated by LV end-diastolic pressure (LVEDP) elevation of 30,3% while in medicated series response was better: CO increased by 14,4% and LVEDP boosted only by 17,6% (($19,3 \pm 1,6$ (Ang 1-7) vs $27,4 \pm 1,7$ (control) mm Hg, $p < 0,05$). Stimulated by ET-1 control isolated heart responded by a negative inotropic effect, and both systolic LV pressure and CO fallen respectively by 13,2% and 9,6%. Ang 1-7 insured a positive inotropic response during ET-1 action leading to CO and LV systolic pressure increase respectively by 10,5% and 11,7%. Ang 1-7 also improved the dynamics of LVEDP during ischemia-reperfusion. Thus, LVEDP was in medicated series significantly less than control index at finish of both ischemia ($41,3 \pm 3,2$ vs $55,4 \pm 4,4$ mm Hg) and reperfusion ($17,2 \pm 1,4$ vs $28,7 \pm 2,2$ mm Hg) periods.
Conclusion: Angiotensin 1-7 is a component of renin-angiotensin-aldosterone system which has a benefic action on acutely developing heart failure due to energy privation, manifested by improvement of inotropic response of NE and reinstated positive inotropic of ET-1 action as well as significant diminution of LVEDP during ischemia-reperfusion syndrome.

Background: Cardiogenic shock is an unmet clinical need since catecholamines increase mortality in patients with acute heart failure. Newer inotropes target sarcomeres to increase contraction. Levosimendan sensitizes troponin C to calcium (Ca), while EMD 57033 (a "classical" Ca2+ sensitizer) and the novel inotrope omecamtiv mecarbil (OM) act downstream of troponin C at the level of actin-myosin interaction. Since the mitochondrial redox state is under the control of ADP (oxidizing NADH for ATP production) and Ca (stimulating the Krebs cycle to regenerate NADH), and Ca-sensitization may increase work (=ADP) at any given Ca, we evaluated the bioenergetic properties of these inotropes.
Methods and results: Cardiac myocytes were isolated from guinea pig and mouse hearts and field-stimulated at 1-5 Hz and 37°C. EMD 57033 shortened diastolic and systolic sarcomere lengths without affecting cytosolic Ca (measured by indo-1). The redox states of NAD(P)H and FAD (autofluorescence) were oxidized by EMD. This elevated mitochondrial ROS emission (determined by DCF) during β-adrenergic stimulation with isoproterenol (Iso). Levo alone increased sarcomere shortening only modestly at 1 and 10 μM, but its potency and efficacy were substantially increased by pre-incubation with low β-adrenergic stimulation (Iso; 1 nM). Under these conditions, the increase in sarcomere shortening was explained by increases in cytosolic Ca, while the redox states of NAD(P)H and FAD remained stably reduced. At concentrations that cover therapeutic plasma concentrations in clinical trials, OM (0.1-3 μM) prolonged the time and amplitude of sarcomere shortening, but also the time of relaxation, and increased baseline diastolic tension. These effects on sarcomere function were associated with slight (though significant) oxidation of NAD(P)H/FAD, while the mitochondrial membrane potential (measured by TMRM) remained unchanged. Low (1 nM) or intermediate (30 nM) Iso concentrations prevented OM-induced oxidation. However, 30 nM Iso aggravated diastolic dysfunction and provoked arrhythmias in >50% of cases in OM-treated myocytes. In isolated cardiac mitochondria, OM (3 μM) did neither affect respiration, ROS production nor redox state. Conclusions: Pure Ca sensitization with EMD 57033 increases systolic function, but at the same time impairs diastolic function, oxidizes the mitochondrial redox state and elevates ROS emission. Levosimendan requires a PDE-inhibitory effect to increase Ca and sarcomere shortening, but this Ca elevation matches energy supply to demand and prevents mitochondrial oxidation. At concentrations that improve systolic function, OM impairs diastolic function and slightly oxidizes mitochondrial redox state, which may predispose to arrhythmias during substantial (but not low) concomitant β-adrenergic stimulation.

P2308

Potential role of the Nav1.5 sodium channel in cardiopulmonary remodeling in a context of heart failure following myocardial infarction in mice.

A Fonteneau[1]; E Amosse[1]; B Jagu[1]; A Carcouet[1]; A Hivonnais[1]; T Le Tourneau[1]; F Charpentier[1]; G Gilles Toumaniantz[1]
[1]*Research unit of l'Institut du thorax, Nantes, France*

The sodium channel Nav1.5, encoded by the Scn5a gene, is responsible for the initiation and propagation of the cardiac action potential. In heart failure following myocardial infarction, which remains the major cause of morbidity and mortality in cardiovascular field, modifications of ionic channels are described and associated with lethal arrhythmias.
Objectives: – Mutations carried by genes encoding for channels with acquired forms of arrhythmias and post-MI remodeling, are not well characterized. In this context, we have investigated the role of Nav1.5 genetic alterations in the occurrence of ventricular arrhythmias, structural remodeling and cardiac contraction abnormalities during the acute phase of MI.
Methods: The Nav1.5 contribution was evaluated after permanent occlusion of coronary artery performed on mouse model invalidated at the heterozygous state for Scn5a (Scn5a+/- mice; 12 weeks old). After validation of the infarction by echocardiography, these animals were studied in vivo by echocardiography and ECG and in vitro using molecular and biochemical investigations during the first 48 hours post-MI.
Results: Animals placed in this context, revealed that Scn5a+/- animals have a higher mortality due to arrhythmic events. In addition, the ECG recorded by telemetry during 48 hours post-MI revealed that Scn5a+/- mice present an increased incidence of premature ventricular beats (5.6 ± 2.7 & 33.1 ± 11 PVB/hour respectively for WT-MI and Scn5a+/- MI mice) without any difference in structural and functional remodelling compared to WT-MI. However, mRNA expression revealed that Scn5a+/- MI mice present an up-regulation of pro-inflammatory factors IL-6 (3.7 ± 0.9 & 17.4 ± 9.3 Relative Expression respectively) and IL-1β mRNA ($1,8 \pm 0.3$ & 4.6 ± 0.8 RE respectively) and downregulation of Cx43 mRNA (0.61 ± 0.08 & 0.39 ± 0.03 RE respectively) without interstitial fibrosis induction. During our investigations, the Scn5a dominantly expression in heart was confirmed but a significant expression was recorded in lungs, suggesting possible Nav1.5 inter-organ functional implications. Pulmonary function tests on transgenic mice have shown respiratory hypo responsiveness under metacholin (Penh/base=$5,9 \pm 0,8$mN & $3,1 \pm 0,6$mN respectively). The intrinsic pulmonary remodelling was investigated. Modest fibrosis and muscular remodelling are suggested by qPCR and histology and do not appear to be concomitant to inflammatory response.
Conclusions: These observations, 48 hours post-MI, suggest that Scn5a+/- mice present factors for the establishment of a more severe post-ischemic heart failure. In addition, preliminary results obtained on small series of animals revealed that Scn5a+/- mice seem to have a more pronounced LV remodelling at 4 weeks post-MI. Moreover, it would be possible to study in case of loos of Nav1.5 expression and/or function the pulmonary impacts in post-ischemic heart failure via inter-organ implications.

Expression of angiomotin in myocardial infraction: relationship with ki-67 expression and the vascular endothelial growth factor.

A Angelos Tsipis[1]; AM Athanassiadou[1]; E Petrou[1]; D Miliopoulos[2]; A Gkouziouta[2]; P Athanassiadou[1]
[1]*University of Athens, Department of Pathology, Athens, Greece*; [2]*Onassis Cardiac Surgery Center, Division of Cardiology, Athens, Greece*

Introduction: Angiomotin (Amot) is an angiostatin binding protein that promote endothelial cell migration and angiogenesis and has been found to be involved in tumorogenesis. Ki-67 is a nuclear antigen, strictly correlates with cell proliferation and is expressed in all phases of the cell cycle except G0. The aim of this study was to investigate the expression of angiomotin, Ki-67 and VEGF in myocytes after myocardial infarction.
Material and methods: We studied myocardial samples of hearts with histologic findings of acute myocardial infarction (group A, n=50), old myocardial infraction (group B, n=50) and myocardial samples of normal heart (control group, n=20). An immunohistochemical method was performed with the use of Angiomotin, Ki-67, VEGF and Bcl-2 antibodies
Results: Amot expression was observed in the nucleus and cytoplasm of tissue cells.
High concordance of Angiomotin and VEGF expression was detected in 82% of samples with old myocardial infarction ($p = 0.020$). Bcl-2 positive expression was intense at the risk areas in 75% of samples with acute myocardial infarction. In old myocardial infraction the bcl-2 positive samples demonstrated weak staining as in the control group. The expression level of Amot was increased in cases from positive samples with a high level of ki67 ($p < 0,001$).
Conclusions: The increased expression of angiomotin, Ki-67 and VEGF in infracted myocardium, suggest the presence of myocyte proliferation and this may be a compensatory mechanism that could be replace damaged myocardium.

NTU-B alleviates fibroblasts activation during cardiac remodeling

H-C Hui-Chun Ku[1]
[1]*National Taiwan University, Taipei, Taiwan ROC*

Fibroblast is the most common cell type of the connective tissues and the principal source of the extensive extracellular matrix. Differentiation of fibroblast into myofibroblast is a critical event in the progression of diseases that leads to tissue remodeling and dysfunction. Polyphenol has been demonstrated to exhibit free radical scavenging activity; however, the low bioavailability limits the use in clinic. So we modified the chemical structure with side chain to improve stability. In the present study, we examined the effect of the novel compound, NTU-B, on fibroblasts activation. Cardiac fibroblasts were isolated from adult mice hearts, and were incubated with angiotensin II (Ang II), a peptide hormone that cause cardiac remodeling, in the presence or absence of NTU-B. Ang II exposure induced the differentiation of cardiac fibroblasts into myofibroblasts, as indicated by the increased expression of α-smooth muscle actin (αSMA), and this effect of Ang II was inhibited by the pretreatment of NTU-B. NTU-B also decreased Ang II induced NADPH oxidase 4 (NOX4) expression and superoxide generation in cardiac fibroblasts. Furthermore, NTU-B decreased Ang II induced fibroblast proliferation, while using NADPH oxidase inhibitor also found the similar results, indicating that inhibition of superoxide production by NTU-B may contribute to the alleviation of fibroblast activation. Our results provide new insights regarding the cardioprotective effects of NTU-B and provide an efficient therapeutic strategy to attenuate cardiac fibrosis and remodeling.

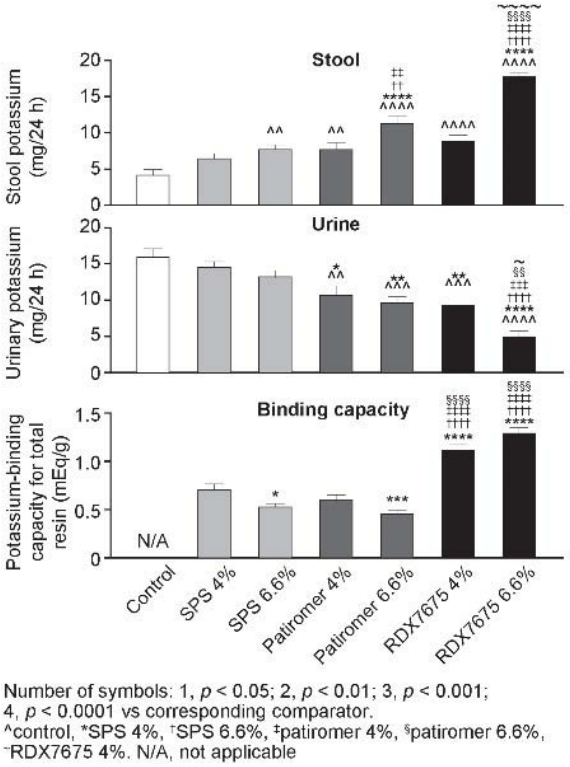
RDX7675 reduces intestinal potassium absorption to a greater extent than patiromer or sodium polystyrene sulfonate in mice

J P Davidson[1]; C Dowd[1]; A J King[1]; P Kumaraswamy[1]; J S Caldwell[1]; R C Blanks[1]; J W Jacobs[1]
[1]*Ardelyx, Inc., Fremont, United States of America*

Funding Acknowledgements: The study was funded by Ardelyx Inc., CA, USA

Background: Patients with heart failure or chronic kidney disease, especially those taking RAAS inhibitors, are at risk of developing hyperkalaemia, which can lead to cardiac arrhythmias and even death. Available therapies for hyperkalaemia include the potassium-binding resins sodium polystyrene sulfonate (SPS), and the calcium salt patiromer (in the US). RDX7675, the calcium salt of a novel polystyrene sulfonate-based resin, is a potassium binder being investigated as a potential treatment for hyperkalaemia.
Purpose: To evaluate the effects of RDX7675 on absorption of potassium and other electrolytes in mice and compare them with SPS and patiromer. We hypothesised that the magnitude of the effects of RDX7675 on potassium absorption would be similar to, or greater than, those of the other treatments.
Methods: Seven groups of eight male mice (CD-1, 8 weeks old) were given either standard chow (control) or chow containing 4% or 6.6% by weight RDX7675, patiromer or SPS for 72 h. To account for the different salt and chemical structures of the ion exchange resins, the weight of the negatively charged resin (active moiety) was used to calculate the dosage. Following a 48-h acclimation period, excreta were collected over 24 h for electrolyte analyses. The potassium-binding capacity was calculated as stool potassium excreted (mEq) per gram of resin administered (calculated as both active moiety, and total resin including counter ion). Statistical analyses were performed using one-way analysis of variance followed by Tukey's test (post hoc).
Results: Compared with control, 24-h stool potassium was higher in all treated groups except SPS 4%, with the highest levels seen in the RDX7675 6.6% group ($p < 0.0001$; Figure). Urinary potassium was lower in mice treated with RDX7675 or patiromer vs control; the lowest level was seen in the RDX7675 6.6% group ($p < 0.0001$; Figure). The potassium-binding capacity of RDX7675 was similar at both doses, and was greater than both patiromer and SPS ($p < 0.0001$; Figure). The SPS groups had a large increase in sodium load, where mean 24-h stool and urinary sodium levels were significantly greater than all other groups ($p < 0.0001$). The RDX7675 and patiromer groups had higher 24-h stool sodium excretion compared with control ($p < 0.05$), and significantly lower urinary sodium levels than control ($p < 0.001$). The effects on potassium and sodium were similar when normalised for wet/dry stool mass and food intake.
Conclusions: RDX7675 reduced potassium absorption to a greater extent, and had higher potassium-binding capacity, than either patiromer or SPS in mice.

Compared with control, calcium-based agents RDX7675 and patiromer reduced intestinal sodium absorption; in contrast sodium-based SPS increased sodium absorption. Studies in humans are required to confirm the potential of RDX7675 as a treatment option for patients with hyperkalaemia.



Number of symbols: 1, $p < 0.05$; 2, $p < 0.01$; 3, $p < 0.001$; 4, $p < 0.0001$ vs corresponding comparator.

The efficiency of growth hormone in pts with heart failure due to dilated cardiomyopathy

I A Igor Tsoy[1]; TA Abdullaev[1]; YR Akhmatov[1]
[1]*Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan*

The aim. To study the clinical efficacy of growth hormone in pts with idiopathic dilated cardiomyopathy (DCM) on a background of optimal therapy.
Materials and methods: 13 pts (Wed age 41,1± 6,4 y.o.) with DCM of both sexes (7/6 as m/f) who were on optimal medical therapy of CHF in the state of compensation over the past year. All pts were on optimally selected basic treatment (the maximum recommended dose reached 92% of pts). We added 12 units of Human Growth Hormone per week as subcutaneous injections. Duration of treatment / follow-up was 1 month. In addition to assessing the clinical condition at the end of a six-minute walking test (6MWT) and the scale of assessment of the clinical status by Mareev, echocardiography assessment of the data was carried out. At baseline and after 1 month of observation the concentration of growth hormone (GH) (originally, 4,2± 2,2 mIU/l) and insulin-like growth factor (IFR1) (originally, 126,4± 12,4mkg / ml) were determined
Results: Tolerability of treatment assessed as satisfactory, in one case there is a violation of elapsed independently after the course. After 1 month IFR1 reliable growth was recorded at 25.1% (up to 168,4± 7,8mkg / ml) and growth hormone - by 37.3% (up to 6,7± 2,05mIU / l, are both p < 0 , 05). At the same time, there was a subjective improvement in well-being pt, reflected in a reduction of weakness, increase of physical activity. Objectively score for Mareev scale decreased insignificantly by 12% (p> 0.05), meanwhile, there is an increase in 6MWT initially 271,3± 22,1 meters, the dynamics of 312.8± 38,2m (p <0,05). The parameters of intracardiac hemodynamics underwent the following changes: the average ejection fraction (EF) of LV rose slightly constituting 33,9± 1,7% and 33,4± 3,1%; p = 0.12, which was accompanied by inaccurate differences in linear dimensions of the heart; EDD 7,12± 0,1 and 7,05± 2,3 cm (p> 0.05). It was noted a marked change from the right heart, where the RV decreased from 3.86± 4,6sm to 3,42± 5,78 cm (p> 0.05), in parallel with the decrease in PASP misleading from 49.6± 12.6 mm Hg to 46,5± 8,6 mm Hg
Conclusions: 1 month course of injections of growth hormone in the treatment of pts with DCM well tolerated, improves both clinical and functional parameters.

ProBNP glycosylation at T71 directly inhibits plasma furin activity and modulates plasma levels of furin targets in heart failure

H Nougue[1]; JM Launay[1]; N Vodovar[1]
[1]*Inserm UMR-S 942, Paris, France*

Background: proBNP glycosylation at threonine 71 (T71) prevents the processing of proBNP into NT-proBNP and BNP by furin through steric hindering of the cleavage site. Our previous work showed that in acute heart failure (AHF), the increased production of proBNP is accompanied by a decrease in proBNP T71 glycosylation and an increase in plasma furin activity, albeit no change in concentration. These results suggested a potential direct inhibitory effect of proBNP T71 glycosylation on plasma furin activity.
Methods: Human furin and proBNP were purified from Human embryonic kidney (HEK293) overexpressing cells. In this system, 54% of proBNP molecules were glycosylated at T71. proBNP was gradually deglycosylated by limited digestion with O-glycosidase (Sigma). ProBNP with various degree of proBNP T71 glycosylation was mixed in vitro with purified furin; furin activity was measured by a fluorescence assay. Furin incubated beforehand with glycosylated proBNP was incubated with the plasma of 6 AHF patients and MR-proAdrenomedullin (ADM), proBNP levels were measured by sandwich immunoassay.
Results: There was a very strong linear negative correlation between furin activity and the degree of proBNP T71 glycosylation ($\rho = -1$, P = 0.016, Figure1A): the higher the T71 glycosylation, the lower the activity. Accordingly, the addition of furin pre-incubated with glycosylated proBNP showed a strong negative correlation between the variations in plasma levels of MR-proADM and proBNP levels, and furin activity ($\rho = -1$, P = 0.016 for both): the higher the glycosylation, the lower the furin activity, and the lower the processing of MR-proADM and proBNP.
Conclusion: Altogether, these data demonstrated that glycosylation of proBNP at T71 not only prevents the processing of proBNP by sterically hindering the cleavage site, but also acts as a direct furin inhibitor. These results strongly suggest that glycosylated proBNP-mediated furin inhibition modulates the plasma levels of furin targets. Since furin targets include biomarkers, this study warrants the development of a compensatory algorithm to estimate the fraction of biomarkers degraded by furin, hence better evaluating the production of these biomarkers. Finally, together with BNP-mediated neprilysin inhibition, these data reinforce "B-type natriuretic peptides" as a regulator of the response to AHF.

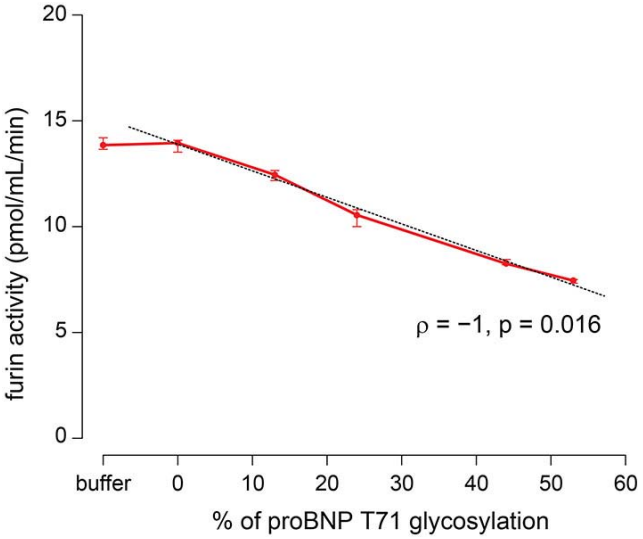

Figure 1

Transcriptomic profile of c-type natriuretic peptide in an in vitro model cell line after exposure to tuscany sangiovese grapevine juice

B Svezia[1]; M Cabiati[2]; E Bertolini[1]; V Lionetti[1]; ME Pe'[1]; S Del Ry[2]
[1]*Sant'Anna School of Advanced Studies, Institute of Life Sciences, Scuola Superiore Sant'Anna, Pisa, Italy*; [2]*Institute of Clinical Physiology of CNR, Pisa, Italy*

Background: Grape juice has vascular protective effect by stimulating endothelial eNOS expression, but the mediator is still unknown. Recent evidence showed that C-type natriuretic peptide (CNP), secreted by the endothelium, is a paracrine mediator of cardioprotection against ischemic injury through activation of endothelial nitric oxide synthetase (eNOS) after binding its specific guanylyl ciclase receptor B (NPR-B).
Purpose: The aim of this study was to evaluate whether Tuscany Sangiovese grapevine juice (SGJ) protects stressed coronary endothelial cells in a CNP-dependent manner.
Methods: Murine coronary endothelial cells (MCEC-1) were long-term (24h) treated with sterile SGJ at increasing concentrations (group A: 10% vol/vol juice; group B: 25% vol/vol juice). Untreated cells were used as control (group C). In additional experiments, MCEC-1 were exposed to hydrogen peroxide (200 μM/24h) in the absence (group D) or presence of SGJ 10% (group E) or 25% vol/vol (group F). MTT assay was performed to evaluate viable cell metabolism. CNP, NPR-B and eNOS mRNA profile was assessed by Real-Time PCR analysis, where each value was normalized with the expression of three mostly stabled genes (Rpl13a, Ppia, Tbp). We also evaluated VEGF transcriptomic profile in order to confirm the oxidative stress condition induces by hydrogen peroxide.
Results: Metabolic cell viability was significantly increased in SGJ-treated cells compared to respective controls (group C and D). CNP and eNOS mRNA levels in group B were higher than in group C: (CNP: 0.527 ± 0.093; eNOS: 2.56 ± 0.822) vs. (CNP: 0.083 ± 0.017; eNOS: 0.287 ± 0.043) with $p = 0.0065$ and $p < 0.0001$ respectively. Similarly, NPR-B gene expression resulted significantly increased by higher dose of SGJ: group B (1.157 ± 0.159) vs. group C (0.383 ± 0.172). In stressed cells, we have observed similar transcriptomic changes: group F (CNP: 0.626 ± 0.161; eNOS: 1.33 ± 0.391 a.u.) vs. group D (CNP: 0.226 ± 0.083; eNOS: 0.56 ± 0.131) with $p = 0.047$ and $p = 0.017$ respectively. NPR-B gene expression in MCEC-1 was stimulated by H2O2 per se (+170%, $p = 0.013$), but treatment with SGJ 10% or 25% vol/vol further increased its expression compared to untreated cells by 168% ($p = 0.008$) and 188% ($p = 0.011$). Significant correlations were observed between CNP and NPR-B in normal and stress conditions ($r=0.948$, $p = 0.014$ and $r=0.791$, $p = 0.011$ respectively).
Moreover, VEGF mRNA expression increased in stressed cells (group C vs. group D, $p = 0.029$). Conclusion: We have demonstrated, for the first time, that grapevine juice from of Tuscany Sangiovese berries enhances CNP and eNOS mRNA levels in coronary endothelial cells at rest and under oxidative stress. Accordingly, the treatment with SGJ stimulates the gene expression of NPR-B and preserves the decay of cell viability following exposure to H2O2. Our data open a new avenue in the development of nutraceutical approach of cardioprotection.

P2315

Amyloid light chain increases brain natriuretic peptide (BNP) expression and induces oxidative stress response in cardiomyocytes

S J Stephen Tam[1]; L Li[1]; M Renz[1]; PJ Dolan[1]; T Nijjar[1]; E Goldbach[1]; GG Kinney[1]; W Zago[1]
[1]*Prothena Biosciences Inc, South San Francisco, United States of America*

Background: AL amyloidosis, the most common form of systemic amyloidosis, is characterised by the accumulation of aggregated, misfolded immunoglobulin light chain (LC) protein (amyloid) in one or more organs. Amyloid deposition in the heart (observed in ~70% of patients) and other organs leads to organ dysfunction and may result in death, associated mainly with cardiac involvement. No therapies are approved for AL amyloidosis, and current approaches do not directly target the misfolded LC protein, which is the underlying cause of organ dysfunction. NT-proBNP measures are used clinically to assess patient prognosis and potential response to treatment and have been recommended by the Amyloidosis Research Consortium for use as a surrogate endpoint predictive of survival in clinical trials. In AL amyloidosis the elevation in NT-proBNP levels is believed to occur in response to a direct cytotoxic effect of light chain species to cardiomyocytes via the p38 MAPK signalling pathway. This response contrasts with congestive heart failure, where NT-proBNP is regulated by mechanical strain and neurohormones.
Purpose: Investigate the potential direct effects of amyloid LC on cardiomyocyte homeostasis by assessing transcriptional regulation of BNP precursor gene and elevation of an oxidative stress response marker.
Methods: Primary rat cardiomyocytes were incubated with a mixture of soluble and insoluble LC aggregates derived from a number of LC sequences described in patients with AL amyloidosis. Both BNP and the oxidative stress marker HO1 transcription were assessed by quantitative real-time PCR.
Results: LC treatment of rat primary cardiomyocytes was associated with significantly increased transcription of prepro-BNP. The effect was dependent on LC sequence, dose and incubation time. LC aggregates also induced a rapid and significant elevation of HO-1, indicative of cellular insult driven by oxidative stress.
Conclusions: We showed that a heterogeneous mixture of aggregated and non-aggregated LC, which recapitulates the presumed extracellular milieu in patients with AL amyloidosis, promoted BNP and HO-1 transcriptional activation. These results support previous findings that NT-proBNP levels are modulated directly by LC-induced cardiotoxicity and may explain the robust correlation between NT-proBNP levels and survival in patients with AL amyloidosis.

P2316

Natriuretic peptide receptor c - could it be the next therapeutic target in heart failure?

K Katarzyna Kodziszewska[1]; P Leszek[1]; B Sochanowicz[2]
[1]*Institute of Cardiology, Warsaw, Poland*; [2]*Institute of Nuclear Chemistry and Technology, Centre for Radiobiology and Biological Dosimetry, Warsaw, Poland*

Funding Acknowledgements: Institute of Cardiology Research Grant

Background: Even though natriuretic peptide receptor C (NPR-C) is responsible for removal of natriuretic peptides (NPs) from the circulation to the same extent as neutral endopeptidase, it is not solely a clearance receptor. The effects of NPR-C include regulation of vascular tone and blood flow. It appears that some of the antiproliferative actions of ANP and electrophysiological effects (i.e. regulation of calcium currents) of CNP are regulated by the NPR-C via modulation of c-AMP-dependent pathways. Aim: We sought to determine whether modulatory effects of NPR-C on adenylyl cyclase (AC) could be observed in cardiac tissue and whether NPR-C function changes in the heart as well as other tissues under pathological conditions of heart failure.
Methods: NPR-C activity was measured by assessing cAMP levels before and after stimulation of the receptor with an NPR-C-specific ligand: cANF4-23. Receptor activity was evaluated in 11 failing hearts (left ventricle) from patients undergoing heart transplantation (HTx) and 11 hearts (left ventricle) of healthy donors not allocated to HTx. For comparison, NPR-C activity was assessed in aortic tissues obtained from 17 heart failure patients and 8 control aortas obtained from heart donors. Results: In heart tissues, no change in cAMP levels was observed in failing or non-failing hearts following NPR-C stimulation compared to baseline (respectively: $p = 0.1153$ and $p = 0.7283$). In aortic tissues, there was no change in cAMP levels from baseline following NPR-C stimulation in specimen obtained from heart failure patients ($p = 0.1519$), while in the aortic tissues of healthy subjects the change was significant ($p = 0.0383$). Conclusions: Our studies suggest that in the heart NPR-C plays predominantly a role of a clearance receptor, while its anti-proliferative actions may be significantly diminished as implicated by lack of response to stimulation. Contrarily, in the vasculature the modulatory action of NPR-C on cAMP levels is retained, but only under physiological conditions. In heart failure the effect is abolished - possibly due to overstimulation by high levels of circulating NPs or receptor regulation by other humoral factors. Therefore, blocking of NPR-C in heart failure is likely to significantly increase NP levels without causing adverse effects on cardiac remodeling or regulation of vascular tone. The in vivo effects of NPR-C blockage are yet to be examined, but the receptor itself seems to be a graceful therapeutic target in treatment of heart failure.

P2317

Cardiac expression of Gal-3, GDF-15 and TIMP1, but not their plasma levels, are related to cardiac function; a heart failure biomarker lesson from mice

H H W Herman Sillje[1]; W Du[1]; RA De Boer[1]
[1]*University medical center Groningen, Groningen, Netherlands*

Background: With the promise of added diagnostic, prognostic and guided therapy potential, heart failure (HF) biomarkers have reached center stage in clinical research. Comprehensive animal studies that allow more in depth investigations, are, however, scarce. We investigated atrial natriuretic peptide (ANP), Galectin-3 (Gal-3), Growth Differentiation Factor-15 (GDF-15) and Tissue Inhibitor of Matrix Metalloproteinases-1 (TIMP-1) at multiple levels and within different tissues in mice post myocardial infarction (MI) and after transverse aortic constriction (TAC).
Methods: For MIs, the left ascending coronary artery was either ligated temporally (small infarcts) or permanent (large infarcts). Mice were analyzed at multiple time points up to 8 weeks. For cardiac pressure overload a constriction was generated at the aortic arch and these TAC mice were investigated at 4 and 8 weeks. Sham operated animals were used as controls. Magnetic resonance imaging, hemodynamic pressure measurements and histochemistry was performed to investigate cardiac function and structure. ANP, Gal-3, GDF-15 and TIMP-1 gene expression and protein levels were determined in multiple tissues, including blood plasma.

Results: ANP, Gal-3, GDF-15 and TIMP-1 cardiac gene expression and protein levels were all increased after TAC and MI and showed significant inverse relations with ejection fraction (EF). Moreover, cardiac protein levels of Gal-3, GDF-15 and TIMP1 correlated with cardiac fibrosis. In plasma, NT-proANP levels correlated with ejection fraction, but plasma levels of Gal-3, GDF-15 and TIMP-1 were not elevated 8 weeks post-MI, despite low EF. Increased plasma Gal-3 and TIMP-1 levels were only observed shortly (within one week) after MI, concomitant with a strong transient increase in cardiac expression. This suggests that cardiac contribution to plasma levels is limited and that other organs, in which these biomarkers were highly expressed, co-determine plasma levels. Importantly, after TAC, plasma levels of TIMP-1 and GDF-15 increased, and this paralleled increased expression of these genes and proteins in the lung.
Conclusions: Only plasma NT-proANP levels were strongly correlated with LV function in mice. Increased Gal-3, GDF-15 and TIMP1 cardiac expression is related to myocardial fibrosis, but cardiac expression does not substantially influence plasma levels. Their increased plasma levels in heart failure most likely reflect stress in other tissues, or only becomes apparent in severely diseased hearts
