Background: Chronic heart failure (CHF) is the most common cause of hospitalization in people over 65 years old, carrying a severe impact on life quality and expectancy. Patients with CHF remain at a systemic inflammatory state, frequently presenting high levels of ferritin, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) as well as inflammatory cytokines (IL-6, IL-8, TNF alpha). Previous studies have suggested that patients with CHF have a higher incidence of infections. One of the proposed underlying mechanisms is the peripheral tissue hypoxia, which leads to suppression of the cellular immunity and activation of the anti-inflammatory pathways.
Methods: Retrospective analysis of the patients with heart failure admitted to an Internal Medicine ward in the period of one year (between August of 2015 and August of 2016).
Purpose: Clinical audit of a cohort of patients admitted with heart failure to evaluate the relationship between CHF and the incidence of infections.
Results: 225 patients were included. The average age was 78 years old, the majority was female ($n = 125$, 55%) and the average length of hospital stay was 16 days. The most common HF etiologies were hypertensive (33%) and ischemic (26%), being HF with preserved ejection fraction predominant ($n = 124$, 55%). The most frequent causes for HF decompensation were infection, disease progression and anemia. Of the total of 225 patients, 201 (89%) presented with decompensated HF and from these 133 (66%) had an infection, whereas 24 (11%) had no signs or symptoms of decompensated HF and within these 13 (54%) had an infectious illness at admission or during hospital stay. Respiratory and genitourinary infections were the most common identified infections in both groups of patients, being the causative pathogen only identified in 36% of the totality of cases. There was no relationship between CHF decompensation and the occurrence of infection, ($p = 0{,}263$, two-tailed Fisher's exact test, Cramer's V=0,078).
Conclusion: According to literature, patients with CHF are likely to have a higher risk of infection, being this one of the most frequent causes of HF decompensation. However, in our study, there's no evidence of a statistically significant relationship between decompensated HF and frequency of infection.

P1023

Polysomnographic respiratory parameters and left ventricular function in heart failure patients with predominant central sleep apnea

K Simionescu[1]; M Adamek[2]; J Biernat[3]; A Mlynarska[4]; A Drzewiecka[3]; KS Golba[1]
[1]Medical University of Silesia, Department of Electrocardiology and Heart Failure, Katowice, Poland; *[2]Medical University of Silesia, Chair and Department of Thoracic Surgery, Faculty of Medicine and Dentistry, Katowice, Poland*; *[3]7th University Hospital, Department of Electrocardiology and Heart Failure, Katowice, Poland*; *[4]Medical University of Silesia, Department of Internal Nursing, Chair of Internal Medicine, School of Health Sciences, Katowice, Poland*

Introduction: Sleep breathing disorders, including obstructive sleep apnea (OSA) and Cheyne-Stokes respiration with central sleep apnea (CSR-CSA), commonly occur in patients with heart failure (HF). OSA may lead to development or progression of left ventricular (LV) dysfunction whereas CSA is likely a consequence rather than a cause of HF. Therefore CSA in HF with reduced ejection fraction (HFrEF) is highly prevalent and associated with more severe forms of heart dysfunction. There is only few data concerning respiratory parameters of central apnea/hypopnea events and ventricular function in these patients.
Methods: 27 consecutive patients (20 males and 7 females, 63.7 ± 9.7 years) with HFrEF (LVEF < 35%) were enrolled. In 17 cases HErEF resulted from ischemic heart disease, and from non-ischemic cardiomyopathy- in 10. All patients underwent echocardiographic examination using standard protocol and polysomnography.
Results: The average LV ejection fraction (LVEF) was 25 ± 3% (Simpson EF) with mean end diastolic (EDD) and end systolic (ESD) diameters of 69.5 ± 2mm and 59.1 ± 2.5mm respectively and average LV diastolic and systolic volumes of 279 ± 63.5 and 210.6 ± 33.5 respectively. Sleep apnea with predominant CSA was diagnosed in 20 patients, in 3 patients CSA coexisted with OSA and 4 patients had no sleep-breathing disorders. In subjects diagnosed with predominant CSA in 6 cases HF resulted from previous coronary ischemic disease and in 14 was related to non-ischemic cardiomyopathy. In these patients LVEF was 22.1 ± 8.6% with EDD and ESD of 71.15 ± 8.2 mm and 61.2 ± 10.1mm respectively and LV diastolic and systolic volumes of 288.4 ± 94.1ml and 223.35 ± 72.24ml respectively what resulted in stroke volume of 65 ± 35.76 ml. The apnea/hypopnea index (AHI) in CSA patients was 24.88 ± 1.4 compare to AHI of 20.6 ± 2.3 in those without predominant CSA. The total duration of apnea/hypopnea (Total A/H) lasted between 18,9 and 232,1 min and this parameter exhibited no statistically significant correlation to LVEF (r = -0.11; p = 0.64) as well as no correlation to SV was observed (r = -0.06; p = 0.82). Surprisingly, no association was noted between LVEF and minimal oxygen saturation (SO2) during sleep (r = 0.035; p = 0.88) and percentage of SO2 below 90% in total sleep time (SO2 < 90%TST) (r = 0.01; p = 0.68). However, polysomnographic features revealed negative correlation to maximal duration of apnea/hypopnea event (Tmax A/H) and EF (r = -0.51, p = 0.021). No correlation was observed between Tmax A/H and LV diameters as well as LV volumes.
Conclusion: Although central sleep apnea is highly prevalent in more serve forms of systolic heart failure the polysomnographic oxygen saturation parameters has not showed significant association with deterioration of LV function. The maximal duration of apnea/hypopnea event however proofed to be parameter affiliated with progressive retrogression of systolic LV function.

P1024

Clinical outcomes in atrial fibrillation patients with non-vitamin K antagonist oral anticoagulants and heart failure

C Goena Vives[1]; L Quintas Ovejero[1]; R Garcia Martin[1]; I Lluis Serret[1]; J Taboada Gomez[1]; I Rilo Miranda[2]; JR Beramendi Calero[2]; M Telleria Arrieta[2]
[1]Mendaro's Hospital, Cardiology, Mendaro, Spain; *[2]Donostia University Hospital, Cardiology, Donostia, Spain*

Introduction: The efficacy and safety of non-vitamin K antagonist oral anticoagulants (NOACs) in non-valvular atrial fibrillation (NVAF) patients has not been established in a real-world setting, particularly in special patient population.
Purpose: We aimed to evaluate the efficacy and safety of NOACs in Heart Failure.
Methods: A total of 195 consecutive patients with NVAF who had taken NOACs with Heart Failure (HF) (53 cases, 27.2 %) or without (no-HF) (142 cases, 72.8%) were retrospectively reviewed. The efficacy outcome was stroke or systemic embolism. The safety outcome was bleeding or death.
Results: The follow-up days were 498.The mean age, gender and prevalence of renal dysfunction was similar between the two groups. HF patients have a higher predicted stroke and bleeding risks compared with no-HF patients (see table 1). The NOACs used were Dabigatran, Apixaban and Rivaroxaban. Despite differences between groups were not statistically significant, in the HF patients, Apixaban was the most used (59.6%) followed by Dabigatran 25% and Rivaroxaban 15.4 (see table 1). The global incidence of death (10.3 %), systemic embolism (2.5%) and major (3.33%) and minor (6.6%) bleeding was higher comparing the pivotal trials due to de higher predicted risk of our population in the study but there were no differences statistically significant between two groups.
Conclusion: The benefit of NOACs was similar in NVAF patients with and without heart failure, despite the heart failure group has an additional risk for adverse effects. Further study is required on the optimal anticoagulant regimen in HF but these results suggest that NOACs may be a first line treatment option in NVAF and heart failure.

Table 1

	No-HF	HF	p
Gender (Female %)	46.42	37.73	NS
Mean age (years)	75.09 ± 9.90	76.17 ± 9.59	NS

Sexual dysfunction: a reality in the patient with heart failure

T Tatiana Duarte[1]; S Goncalves[1]; A Lourenco[1]; S Correia[1]; D Ferreira[1]; C Sa[1]; R Rodrigues[1]; M Fonseca[1]; R Marinheiro[1]; F Seixo[1]; R Caria[1]
[1]Hospital Center of Setubal, Cardiology, Setubal, Portugal

Introduction: Sexual dysfunction (SD) is a frequent comorbidity in patients (pts) with cardiovascular disease, being the association with coronary artery disease (CAD) and peripheral arterial disease (PAD) well established. The prevalence in pts with heart failure (HF) is unclear, especially in females. This comorbidity is still underestimated by the doctors, despite their impact on quality of life. Aim: To determine the prevalence of SD in a population with HF and to characterize this population. To evaluate the impact of SD on quality of life.
Methods: Anonymous questionnaires for evaluation of sexual function (Female Sexual Function Index: FSFI; International índex of erectile function) were applied, prospectively, to pts followed in a HF clinic. Patients aged > 70 years were excluded, taking into account the high prevalence of SD in this age group. The population was divided in two groups - Group A: with SD; Group B: without SD - and characterized according to baseline characteristics, comorbidities, degree of systolic dysfunction, NYHA class and therapy. The prevalence of SD and the impact on quality of life were evaluated (degrees: none, slight, moderate, very high). Results: Were studied 38 pts (76% (n = 29) male, mean age 59 ± 9 years). SD was diagnosed in 79% (n = 30-Group A) of the pts, with a prevalence of 79% (n = 23) in males and 78% (n = 7) in females. The age and CAD were associated with the prevalence of sexual dysfunction. (Figure 1) There was no difference between the two groups in relation to the others comorbidities (Hypertension, atrial fibrillation, Diabetes mellitus, Dyslipidemia, PAD) as well as to therapeutics, namely betablockers and BNP level. The severity of HF, in terms of ejection fraction and NHYA class, were not associated with a higher prevalence of SD. Sixty percent of the pts (n = 18) of Group A considered that SD had a "moderate" impact on their quality of life.
Conclusion: Sexual dysfunction is a frequent comorbidity in pts with HF and should be valued by the doctors. By the importance in quality of life and prognosis, the evaluation of sexual function should be part of the rehabilitation program for pts with cardiovascular disease. The continuation of the study, including more pts will allow more conclusions.

Variables	Group A (n=30)	Group B (n=8)	p-value

Use of the minnesota living with heart failure quality of life questionnaire in kosovo

A Artan Ahmeti[1]; A Poniku[1]; E Haliti[1]; P Ibrahimi[1]; S Elezi[1]; MY Henein[2]; G Bajraktari[1]
[1]University Clinical Centre of Kosovo (UCC), Department of Cardiology, Pristina, Kosovo Republic of; *[2]Umea University Hospital, Umea, Sweden*

Background and Aim: Quality of life is one of the most important end-points in heart failure (HF) patients. The Minnesota Living with HF Questionnaire (MLHFQ) is the most widely used measurement for assessing the quality of life (QoL) in HF patients. This questionnaire had been translated and validated into the Albanian language. We used this questionnaire to evaluate the QoL in HF patients in Kosovo.
Methods: The study subjects were 103consecutive HF patients (63 ± 10 years, 56 female, 48% hypertensive and 26% ischaemic etiology, classified as NYHA I-III) admitted in outpatient or in-patient clinics at our University Clinical Centre. At the moment of evaluation the patients were clinically stable and on optimized drug therapy. Relationships were tested between questionnaire score and different clinical and demographic factors.
Results: There was no difficulty in the administration of the Albanian version of MLHFQ or in the patient's understanding of the questions. The overall median score of MLHFQ was 51 (mean 50 ± 18). A strong correlation was found between MLHFQ and NYHA functional class (p = 0.002), and it was with a higher score in female patients (p = 0.015). The other biochemical and clinical indices did not correlate with MLHFQ. The MLHFQ did not differ between different etiologies of HF patients.
Conclusions: The Albanian version of the MLHFQ proposed in this study proved to be valid for HF patients and served as a new and important instrument for assessing QoL in Kosovo's patients. The MLHFQ was mildly higher in our patients compared with previous studies. The questionnaire score correlate with functional NYHA class, reflecting the severity of the disease, and is higher in female gender.

P1027

Chronic systolic heart failure rehospitalization rates study from OPTIMIZE HF program: data from two centers

H Hamayak Sisakian[1]; H Hayrapetyan[2]; L Sahakyan[1]; M Hovhanisyan[1]; H Petrosyan[2]
[1]Yerevan State Medical University Hospital 1: University Cardiology Clinic, Department of General and Invasive Cardiology, Yerevan, Armenia; *[2]Erebouni Medical Center, Cardiovascular Center, Yerevan, Armenia*

Heart failure (HF) hospitalization rates considerably decreased in western Europe , but little is known about trends in eastern European countries. OPTIMIZE HF program is a prospective study aiming to assess rehospitalization rates of decompensated chronic systolic heart failure patients after discharge from hospital during 12 month period in eastern European countries. A total of 177 patients from two University affiliated hospitals with HF hospitalization were recorded. (median age -63 years, 36 % female). Mean NYHA functional class on admission was 2,7 and on discharge 2,2. During hospital period patient education programs were conducted for lifestyle and self monitoring of key measurements. Patients were on ambulatory follow up after 15, 30, 90, 180 days from discharge. After a first HF hospitalization any HF readmission rates within 90 , 180 and 1 year were 17.5 , 27.1 and 34,4 % respectively. The most common comorbidities were arterial hypertension (57,6 %) and chronic kidney disease (40,6 %). Permanent atrial fibrillation was found in 16,4 % patients on admission. In 72,3 % of cases, coronary artery disease was the main etiology of HF. Mortality after 1 year period was 22,5 %. 77,4% of patients were on beta blocker, 88,1 % - on RAAS inhibitors and 33 % -on ivabradine.
Conclusions: Rehospitalization trends and mortality may be comparable with western European mataanalysis data due to adherence to guideline based pharmacotherapy , education programes for patients , frequent outpatient monitoring visits.I

P1028

Gender-specific descriptions of chronic heart failure

N Natalia Lareva[1]; A Govorin[1]; E Luzina[1]
[1]Chita State Medical Academy, Chita, Russian Federation

Aim: To evaluate gender-specific etiology, clinical presentation and treatment of chronic heart failure (CHF).
Methods: 200 hospitalized patients with CHF (100 men and 100 women) were included in a retrospective cross-sectional study conducted in our Regional Clinical Hospital. Statistical criteria such as Mann-Whitney, chi-square and Fisher's exact tests were used.
Results: Women with CHF were older than men (61,9 ± 9,8 vs 58,1 ± 12,8 years, p = 0.019), had higher heart rate at admission (83 ± 16,9 vs 77,1 ± 15,3 beats per minute, p = 0.005) and lower glomerular filtration rate calculated by Cockcroft-Gault (77,2 ± 29,9 vs 91,5 ± 30,9 ml/min, p < 0.001). Coronary heart disease was the main reason of CHF, in men it was more common than in women (77% vs 63%, p = 0.045). The frequency of hypertension (20% vs 30%), chronic rheumatic heart disease (2% vs 5%) was the same. Clinical manifestations of heart failure depending on sex have not been identified. The most frequently clinical symptoms were dyspnea (89% men and 91% women), fatigue (49% men and 57% women), tachycardia (48% men and 53% women). Such symptoms as decreased ability to work (30% of men and 25% women) and edema (9% of men and 13% women) were less common. Women more often demonstrated class 3 NYHA (46% vs 29% of men, p = 0.019). The prevalence of heart failure class 2 NYHA was high regardless of gender (56% men and 48% women, p = 0.322). The prevalence of left ventricular diastolic dysfunction was independent of sex (57% of men and 62% of women). Ejection fraction (EF) of the left ventricle in women was somewhat higher than in men (65,2 ± 10,4% vs 61,5 ± 9,8%, p = 0.010), while the number of patients with a reduced EF was similar in men (12%) and women (8%). Pulmonary hypertension was found in 60% of men and 43%of women, p = 0.024. Diabetes mellitus was more common in women (18% vs 7% in men, p = 0.033). In men and women equally often were used β-blockers (82% and 83%), antiplatelet agents (78% and 80%), ACE inhibitors (23% and 22%), ARBs (35% and 41%), aldosterone antagonists (19% and 28%), cardiac glycosides (5% and 7%); while in women diuretics more often were prescribed (51% vs 32% of men, p = 0.010).
Conclusions: Gender-specific descriptions of chronic heart failure are higher age of female patients, more frequent formation of functional class 3 disease in women, more prevalent in women cohort of diabetes mellitus and lower – pulmonary hypertension. Differences in treatment depending on gender practically not observed, and the attention is drawn to the incomplete line therapy to current clinical guidelines for chronic heart failure, necessitating ongoing optimization of therapeutic measures.

P1029

Cognitive function in chronic heart failure: relation to clinical variables

A Alina Lyashenko[1]; L Voronkov[1]; A Solonovych[1]
[1]NSC Institute of Cardiology M.D. Strazhesko, department of heart failure, Kiev, Ukraine

Background: Cognitive impairment is observed in 30-80% of chronic heart failure (CHF) patients (pts) and closely correlates with age and severity of disease. Nevertheless, evidence of association between cognitive function (CF) and other clinical characteristics in CHF is still lacking.
Objective: To establish the relationship between CF and clinical variables and comorbidities in CHF.
Methods: 45 stable CHF pts, NYHA II-IV, with left ventricular ejection fraction (LVEF) < 40% were examined. CF was evaluated with standard MMSE and Shulte tests. Besides routine examination, the 6-minute walk test and interview on the HADS depression questionnaire were performed.
Results: Cognitive dysfunction (abnormal MMSE and Shulte tests) was observed in 68.8% of patients. There were no impact of sex, LVEF, hemoglobin level, diabetes, and, surprisingly, of atrial fibrillation on the results of CF tests. Simultaneously, CF testing results were significantly worse in NYHA III-IV vs NYHA II patients (p = 0.042 for MMSE and p = 0.002 for Shulte test), at age < 60 vs ≥60 years (p = 0.010 for MMSE and p = 0.003 for Shulte) and in hypertensives vs non-hypertensives (p = 0.0027 for MMSE, p = 0.020 for Shulte).
Both MMSE and Shulte tests significantly correlated with the 6-min walk test distance (r=0,30, p = 0.021 and r = -0.21, p = 0.044, respectively) and with the HADS depression score (r = -0.45, p = 0.003 and r=0.44, p = 0.003, respectively).
Conclusion: In stable CHF patients, besides high NYHA class and age ≥60 years, cognitive impairment is associated with history of hypertension, worse exercise tolerance and highest depression score.

P1030

Microalbuminuria and glomerular filtration rate in chronic heart failure: relation to clinical variables

A Alina Lyashenko[1]; L Voronkov[1]; A Dudnik[1]; L Mkhitaryan[1]
[1]NSC Institute of Cardiology M.D. Strazhesko, department of heart failure, Kiev, Ukraine

Background. In contrast to glomerular filtration rate (GFR), the place of microalbuminuria (MAU) in chronic heart failure is not still clear.
Objective: To evaluate the relation of MAU compared to GFR to clinical and laboratory variables in CHF.
Methods: 45 stable patients with CHF (NYHA II-IV, with left ventricular systolic dysfunction (ejection fraction < 40 %) were examined. MAU was detected by immunoturbidimetric method. GFR was calculated by CKD EPI equation.
Results: MAU (albumin 30-299 mg/24 hours) was observed in 100 % of pts. There was no impact of age, sex, hypertension, diabetes or atrial fibrillation on MAU level. MAU was higher in NYHA III-IV vs NYHA II patients: 66 (52-120) vs 158 (50-260) mg/24 hours respectively, (p < 0,001). Moreover, MAU level directly correlated with uric acid (r=0,34, p = 0,024) and myeloperoxidase activity (r=0,37, p = 0,012). Clinically relevant renal dysfunction (GFR < 60 ml/min/1,73 m^2) was observed in 18 (40%) pts. In contrast to MAU, GFR was significantly lower at age ≥ 60 vs < 60 (p = 0,001), in pts with diabetes vs non-diabetes pts (p = 0,012), in pts with hypertension vs normotensives (p = 0,024). GGR was higher in NYHA II vs NYHA III-IV pts

(p = 0,026). Direct correlation was observed between GFR and Minnisota quality of life score (r=0,45, p = 0,004), and between GFR and LVEF (r=0,28, p = 0,06).
Conclusion: Compared to MAU, GFR more closely correlated with variables which reflect both CHF severity and co-morbidities. Simultaneously, direct link between MAU and plasma UA and with myelopeuoxidase activity may reflect possible oxidative stress involvement in MAU mechanism in CHF. In our CHF pts, MAU was the obligate finding.

P1031

Oral iron therapy improves functional capacity of heart failure patients with iron deficiency anemia

L Lita Suryani[1]; BB Siswanto[1]; SB Raharjo[1]; N Hersunarti[1]; R Soerarso[1]; H Angkasa[2]
[1]National Cardiovascular Center Harapan Kita, Cardiology and Vascular Medicine, Jakarta, Indonesia; *[2]University of Indonesia, Faculty of Medicine, Jakarta, Indonesia*

On behalf of: Clinical Cardiology and Critical Care Division of National Cardiovascular Center Harapan Kita

Background: Anemia is a common morbidity in heart failure (HF). Intravenous iron is known to improve patient's condition. However, it is expensive and invasive. This study investigated the effectiveness and safety of oral iron therapy in improving ferritin, transferrin saturation (Tsat), haemoglobin (Hb) and functional capacity in systolic HF patients with iron-deficiency anemia (IDA).
Methods: Double blind randomized controlled trial was conducted in National Cardiac Centre. Fifty-four subjects (age 18-75 y.o) suffering from HF (EF < 50%) and IDA with eGFR>30ml/min/1.73m2 were enrolled and randomized to placebo(n = 27) or oral Ferrous Sulphate (FS;n=27) for 12 weeks. Primary outcome was functional capacity measured by 6-minute walk test distance (6MWT). Ferritin, Tsat,Hb, NT-proBNP and side effects were documented.
Results: Forty-one subjects (placebo n=19;FS n=22) completed the study. Over 12 weeks, against baseline : Hb: -0.0263 ± 0.743g/dl (placebo;p = 0.879) and 1.0591 ± 1.432g/dl (FS;p = 0.002); Ferritin: -11.64 ± 52.42ng/ml (placebo;p = 0.346) and 102.78 ± 74.93ng/ml (FS;p = 0.000); Tsat: 2,99 ± 11,99% (placebo;p = 0,575) and 14,13 ± 9,66% (FS;p = 0,000); 6MWT: -16.84 ± 40.05m (placebo;p = 0.083) and 46.23 ± 35.93m (FS;p = 0.000). Between groups: Hb: 1.085 ± 0.365 (p = 0.005); Ferritin: 114.42 ± 20.52ng/ml (p = 0.000); Tsat: 11,14 ± 3,38% (p = 0,002); 6MWT: 63.07 ± 11.87m (p = 0.000). Little change were seen in NT-proBNP. Adverse effects (2 vs 1, placebo vs FS;p = 0.588) and gastrointestinal side effects were experienced by both groups (9 vs 6, placebo vs FS;p = 0.211).
Conclusion: Oral FS therapy for 12 weeks increased ferritin, Tsat, Hb levels and improved functional capacity of HF patients with acceptable minimal side effects. Oral FS might be a cheaper alternative to intravenous iron for low-to-middle income countries.

Comparison of 6MWT between Groups

Variables	Group	Pre	Post	p Value
Ferritin (ng/mL)	FS	110,36 ± 71,58	213,14 ± 73,93	0,000
Placebo	123,37 ± 68,0	111,74 ± 81,39	0,345

P1032

Common polymorphism RS10519210, RS1739843, RS6787362 in patients of Russian Federation with HFrEF AFTER myocardial infarction

VM Tishkova[1]; MY Sitnikova[1]; AA Kostareva[1]; LV Prokopova[1]
[1]Federal Almazov North-West research centre, heart failure, saint-petersburg, Russian Federation

Introduction: Conducting research of genome-wide studies (GWAS) in patients after MI may identify a group of patients with increased risk of HF and contribute to the development prevention measures.
PURPOSE: of the study: Explore the inhabitants of the North-West Federal District of Russia occurrence of polymorphic alleles HSPB7 (rs1739843), FRMD4B (rs6787362) and locus 15q22 (rs10519210), whose connection with the syndrome of heart failure has been established in the course of GWAS.
Materials and Methods: To study men 30 - 65 years old MI 3 months ago. The main group included 260 patients with HF I-IV functional class, LVEF (Simpson) < 40%, in reference group - 246 patients, without HF and LVEF (Simpson)> 50%. The group of healthy people made 96 donors.
We assessed anthropometric indices, clinical status, ECG, echocardiography, ECG monitoring. Genotyping by PCR was performed in "real time" (Applied Biosystems thermocycler 7500 Real Time PCR System).
Results: Two groups were comparable by prescription of hypertension (11.4 years versus 11.2 years), but different in its prevalence (68.5% and 83.3%, p < 0.01). In the main group there were more patients with heredity (34.23% and 22.88%, p < 0.01), more frequent AF (31.2% and 14.4%, p < 0.001), pulmonary embolism (12.5% and 0.4%, p < 0.001), left ventricular aneurysm (20.6% and 0.9%, p < 0.001). In the group with HFrEF was a wide range of QRS (124.6 ± 259.4 ms and 96.9 ± 53.1 ms, p < 0.001), higher the pressure in the pulmonary artery (46,3 ± 48,7 mm Hg and 30.2 ± 24.8 mmHg, p < 0.001).
There was significant difference between the occurrence of polymorphism rs1736843 of HSPB7 gene depending on the HF and EF: CC genotype was detected in 48.1% of the patients, CT - 10.4% of the patients in the main group, in 80.9% and 7.3% in reference group, and in 80.2% and 4.2% in healthy group, accordingly (p1-2, 1-3 < 0,001). FRMD4B gene exceeded the threshold of significance and prevalence. Genotype AA was detected in the main group in 83.5% of the patients, GG – none, in 87.8% and 2.9% in the reference group , in 89.6% and 0% in healthy group, respectively (p1- 2, 3-2 < 0.01). Prevalence of USP3 gene in groups did not differ between individuals.
Conclusions: The data of the prevalence of the studied genotypes after MI are similar with those in European studies: polymorphisms HSPB7 (rs1739843) and FRMD4B (rs6787362) was significantly associated with development of CHrEF.

P1033

Recurrent heart failure-related hospitalizations in patients with mid-range ejection fraction

M Domingo[1]; P Moliner[1]; J Lupon[1]; M De Antonio[1]; J Nunez-Villota[2]; E Zamora[1]; J Santesmases[1]; B Gonzalez[1]; M Rodriguez[1]; S Altimir[1]; V Diaz[1]; MI Troya[1]; M Boldo[1]; C Diez-Quevedo[1]; A Bayes-Genis[1]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain; *[2]University Hospital Clinic of Valencia, Valencia, Spain*

Introduction: Despite current treatment with evidence-based drugs and devices, patients with heart failure (HF) are frequently admitted to the hospital because of symptom exacerbation, and once admitted, they are often readmitted. Long-term re-hospitalizations of patients with HF and left ventricular ejection fraction (EF) mildly reduced (HFmrEF) is not well known
Objective: To assess HF-related recurrent hospitalizations in ambulatory patients with HFmrEF of different aetiologies attended in a multidisciplinary HF Unit
Patients and methods: 124 patients with HFmrEF were evaluated (89 men and 35 women). Mean age was 65.2 ± 12 years. Median duration of HF was 10.5 months [Q1-Q3 1–46.5]. Ischemic aetiology was present in 57.3%. Eighty-seven (70.2%) and 31 (25%) patients were in NYHA class II and III respectively). We compared HF-related recurrent hospitalizations with those occurred in patients with reduced (HFrEF) and preserved (HFpEF) patients (836 and 92 respectively). Worsening HF-related death was also assessed.
Results: At a mean follow-up of 5 ± 3.3 years, 72 HF-related hospitalizations in 28 patients with HFmrEF (22.6%) were registered. The crude incidence of HF-related recurrent hospitalizations was 1.15 (95%CI 0.90-1.45) per every 10 person-years. This number was significantly lower than that observed in 836 patients with HFrEF followed during 4.7 ± 3.1 years: 1.60 (95%CI 1.48-1.73) per every 10 person-years, p = 0.007; and than that observed in 97 patients with HFrEF followed during 3.9 ± 2.8 years: 2.97 (95%CI 2.44-3.58) per every 10 person-years, p < 0.001. Age- and sex- adjusted Cox regression survival curves for worsening HF-related cause of death showed significant better outcome in HFmrEF patients with in regard to HFpEF patients (HR 0.33 [95%CI 0.13-0.82], p = 0.02), but only a better trend regarding to HFrEF patients (HR 0.56 [95%CI 0.29-1.11], p = 0.1).
Conclusions: While worsening HF-related death was only slightly and non-significantly lower in HFmrEF patients than in HFrEF patients, HF-related

recurrent hospitalizations were significantly lower in the former. Patients with HFpEF showed the worse prognosis, broth from the HF-related morbidity and mortality point of view.

P1034

Androgen status in non-diabetic elderly men with heart failure

G Loncar[1]; B Bozic[2]; A Neskovic[3]; N Cvetinovic[4]; M Lainscak[5]; N Prodanovic[6]; HD Dungen[7]; S Von Haehling[8]; Z Radojicic[9]; T Trippel[7]; B Putnikovic[3]; V Popovic[10]

Funding Acknowledgements: Serbian Ministry of Science (grant 175033).

Purpose: We aimed to evaluate androgen status (serum testosterone (TT) and estimated free testosterone (eFT)) and its determinants in non-diabetic elderly men with heart failure (HF). Additionally, we investigated its associations with body composition, muscle strength, and long-term survival.
Methods: 73 non-diabetic men with HF and 20 healthy men aged over 55 years were studied. Echocardiography, 6-min walk test, grip strength, body composition measurement by DEXA method were performed. TT, sex hormone binding globulin, NT-proBNP, and adipokines (adiponectin and leptin) were measured. All-cause mortality was evaluated at 6-years of follow-up.
Results: Patients with HF and healthy controls were similar of age (67 ± 7 vs. 67 ± 7) and body mass index (28 ± 5 vs. 28 ± 3 kg/m2). Androgen status (TT, eFT) was similar in elderly men with HF compared to healthy controls (4.79 ± 1.65 vs. 4.45 ± 1.68 ng/ml and 0.409 ± 0.277 vs. 0.350 ± 0.204 nmol/l, respectively). In HF patients, TT was positively associated with NT-proBNP ($r = 0.371$, $p = 0.001$) and adiponectin levels ($r = 0.349$, $p = 0.002$), while inverse association was noted with fat mass ($r = -0.413$, $p < 0.001$). TT and eFT were independently determined by age, total fat mass and adiponectin levels in elderly men with HF ($p < 0.05$ for all). There was no correlation between androgen status with skeletal muscle mass and muscle strength. In a multivariate model, androgen status was not predictor for all-cause mortality at 6-years of follow-up.
Conclusion: In non-diabetic men with HF, androgen status is not altered and is not predictive of long-term outcome.

P1035

Clinical characteristics and management of hospitalized patients with heart failure, results from Mongolia

G Ulziisaikhan[1]; O Tsogbadrakh[1]; B Namsrainaidan[2]; B Norpil[1]; M Dagva[3]; DAVID Sim[4]
[1]Third State Central Hospital, Cardiovascular Center, Cardiology, Ulaanbaatar, Mongolia; *[2]National University of Medical Science, Cardiology, Ulaanbaatar, Mongolia*; *[3]Third State Central Hospital, Cardiovascular Center, Ulaanbaatar, Mongolia*; *[4]National Heart Centre Singapore, Heart failure programme, Singapore, Singapore*

Background: Heart failure is a major and growing public health concern in Mongolia. However, there is insufficient information of heart failure locally.
Purpose: The aim of the study is to describe the clinical characteristics and management of hospitalized patients with heart failure in Mongolia.
Methods: Total of 5325 patients case notes were analyzed from general hospitals of 18 out of 21 provinces (rural areas) and 3 out of 9 districts of the capital city, and also The Third State Central Hospital, the national reference hospital for cardiovascular disease. Patients were admitted during January 2013 to December 2015.
Results: 3515 patients (66%) were males, 1810 (34%) were females. The number of patients with heart failure was increasing, 1555, 1810 and 1960 patients in 2013, 2014 and 2015 respectively ($p < 0.0001$). Ischemic heart disease (41.1%), arterial hypertension (19.4%) and valvular heart disease (15.7%) were main causes of heart failure in Mongolian patients. The main co-existing risk factors were hypertension (50%), obesity (46%), atrial fibrillation (35%), smoking (26.5%), excessive alcohol consumption (16.7%) and diabetes mellitus (12.7%).
HFrEF was present in 57.9%, HFmrEF in 20.8% and HFpEF was present in 21.3% of all participants. The mean age of the patients 58.2 ± 12.88 in males and 59.1 ± 14.9 in females. The mean length of hospitalization was 9.03 ± 2.7 days. ACEI/ARBs , MRA and beta blocker usage was 71%, 69% and 46% respectively.
Conclusion: Heart failure poses a significant burden on the healthcare system in Mongolia. Major public health program targeting at improvement of general public education and heart failure management among medical professionals is needed.

P1036

Ambulatory blood pressure monitoring in heart failure with preserved ejection fraction patients

V Vitalina Yarosh[1]; L Yena[1]; I Mudruk[1]
[1]D. F. Chebotarev State Institute of Gerontology NAMS of Ukraine, cardiology, Kyiv, Ukraine

Inadequate control of blood pressure (BP) is an important factor in the development of chronic heart failure (CHF) with preserved ejection fraction (HFpEF). There is evidence that the level of mean ambulatory systolic blood pressure (BP), unlike the office systolic BP (SBP), is independently associated with the development of HFpEF.
Purpose: to study 24-h profile of blood pressure in elderly hypertensive patients with HFpEF.
Methods: 120 patients (mean age $67,8 \pm 1,2$ years), 30 pts with essential hypertension (EH) with no signs of heart failure and 90 pts with EH complicated by HFpEF underwent ambulatory blood pressure monitoring (ABPM), Doppler echocardiography, 6-minute walk test.
Results and discussion The increased values of office SBP were determined in both group patients , but mean 24-h, daytime and nighttime BP values were significantly higher in HFpEF patients compared to hypertensive patients. Office diastolic BP (DBP) values were comparable in two groups and did not exceed the recommended range. Therefore, mean 24-h DBP values slightly exceeded the upper limits in both groups. The distance of 6-minute walk test does not correlate with office BP levels. There is no limiting impact of high blood pressure (in the range up to $154,3 \pm 1,4$ mm Hg) on physical activity in patients with initial stages of CHF.
The 24-h pulse BP was higher in HFpEF pts ($63,2 \pm 0,9$ mm Hg compared with $54,9 \pm 1,4$ mm Hg in EH pts, $p < 0,05$) confirmed the increased risk of cardiovascular events in HFpEF patients.
The normal BP circadian rhythm was recorded significantly more frequent in EH pts (40,0 %) compared with 17,8 % HFpEF pts. 54 HFpEF pts (60,0%) demonstrated abnormal pattern of day/night SBP dynamics and 37 pts (41,1%) - abnormal pattern of DBP, in contrast to patients with uncomplicated EH (13 pts (43,3 %) and 6 pts (20,0 %), respectively).
Conclusions: HFpEF patients demonstrated insufficient control of both office and 24-h BP. 82,2% of HFpEF pts were characterized by pathological types of BP circadian rhythm with dominating non- dipper type.

P1037

A comparison of non-invasive methods of measuring body composition in patients with heart failure, a report from SICA-HF.

V Vennela Boyalla[1]; P Shah[1]; P Pellicori[1]; R Dierckx[1]; J Cuthbert[1]; A Bennett[1]; A Clark[1]; J Cleland[1]
[1]Castle Hill Hospital, Cardiology, Hull, United Kingdom

Funding Acknowledgements: European Union Seventh Framework Programme [FP7/2007-2013]

Background: Cachexia is common in patients with chronic heart failure (CHF) and is associated with a poor prognosis. How best to measure body composition is not clear.
Methods: We characterized body composition in 120 patients [mean age $70 + 10$ years, mean left ventricular ejection fraction (LVEF) $44 + 10\%$, and median N-terminal pro B-type natriuretic peptide (NTproBNP) 845 (interquartile range: 355-1368ng/l) with CHF enrolled in the "Studies Investigating Co-morbidities Aggravating Heart Failure" (SICA-HF). We measured body composition using a multi-frequency segmental body composition analyser (BCA) and dual-energy X-ray absorptiometry scan (DEXA) on the same day.
Results: Mean fat mass (FM) was 27.2 + 11.6 kg by BCA and 31.2 + 12.1 kg by DEXA (mean difference -4.0 kg (95% limits of agreement: -10.2, 2.2; 5% of values outside limit of agreement)); mean muscle mass (MM) was 56.6 + 10.9 kg by BCA and 47.7 + 9.5 kg by DEXA (mean difference of 8.9 kg (95% limits of agreement: 1.9, 15.9; 3% of values outside limit of agreement)). Mean bone mass (BM) was 3.0 + 0.5 kg by BCA and 2.3 + 0.7 kg by DEXA (mean difference of 0.65 kg (95% limits of agreement: -0.15, 1.4; 1% of values outside limit of agreement)). There was

a good correlation for both MM and FM between DEXA and BCA (MM: r = 0.95, p < 0.001; FM: r= 0.97, p < 0.001) but worse correlation for BM between DEXA and BCA (r = 0.79, p < 0.001). Both DEXA and BCA body composition measurements correlated well with other measures of cachexia.
Conclusions: There are differences in the measurements of FM, MM and BM between the two techniques and should not be used interchangeably.

P1038
The quality of life and level of depression of patients with heart failure and comorbid diabetes mellitus type 2

O Afanasiuk[1]; V Shmaliy[1]; V Maslovskyi[1]
[1]*National Pirogov Memorial Medical University, Internal medicine #3, Vinnitsa, Ukraine*

Purpose - to study the QL and level of depression in patients with different stages of HF and comorbid diabetes mellitus (DM) type 2.
Materials and methods: Were examined 62 patients with HF and comorbid DM type 2, mean age 62.5 ± 0.08 years. The patients were divided into three groups depending on left ventricle ejection fraction(LVEF). The first group included 20 patients with LVEF≥50%, the second group – 22 patients with LVEF 40-49%, the third group – 20 patients with LVEF < 40%. Patients themselves filled out the Minnesota questionnaire quality of life with HF (MLHFQ) and the depression scale of Beck (BDI). All studies conformed to the principles of the Declaration of Helsinki of the World Medical Association.
Results: In the analysis of questionnaires MLHFQ was observed that every patient noted a worsening of QL including due to the presence of depression, and were asked to fill the BDI. The dates presented in Table 1.
According to the presented dates, it should be noted that the QL and depression level of patients is much worse depending on the progression of symptoms of HF. Indicators of blood glucose were consistent with the state of compensation and subcompensation and didn't significantly affect the QL and depression level in patients of each group. The level of depression ranged from mild in the first group to moderate in the second and third groups. Patients were offered a psychiatric consultation for the correction of depressive states, but agreed to counseling only 6,45% (n = 4) patients of the third group. Most patients argued the rejection of consultation by psychiatrist worsening of symptoms of HF, but not the manifestations of depression.
Conclusions: Violation of the QL and increase in level of depression in patients with HF and comorbid DM type 2 significantly depends on the symptoms of HF. Contributes to incorrect assessment of their condition by patients, which significantly impairs the compliance between doctor and patient. The influence of depression on the violation of QL in this category of patients requires further study.

Table 1.

Questionnaire	LVEF≥50% (n=20)	LVEF 40-49% (n=22)	LVEF < 40% (n=20)

P1039
Duration of heart failure, hospitalization rate and treatment compliance in elderly heart failure patients with anemia of chronic diseases.

NI Solomakhina[1]; D Shchekochihin[1]; ES Nakhodnova[1]; ZV Taranova[2]; SV Pavlushina[2]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*; [2]*First Veterans Hospital, Moscow, Russian Federation*

Background. Anemia is a common comorbidity in heart failure (HF) patients. It can be attributed to heart failure by itself, iron deficiency conditions and other comorbidities. The aim of present study in to analyze HF duration, rate of hospitalizations and treatment compliance in old and very old patients, presented with HF decompensation and criteria of anemia of chronic diseases.
Materials and methods: 35 patients, aged 76-97 (average 87 ± 10,5 years, 20 women (57,1%)) with decompensated heart failure and anemia of chronic diseases were analyzed. Controls were 35 age and sex-matched patients with decompensated HF without anemia. Criteria of anemia of chronic diseases were decreased hemoglobin (< 12 g/dl) with normal or increased serum ferritin level and normal transferrin saturation.
Results: Patients with anemia and without anemia did not differ significantly in HF presentation, NYHA IV had 46% of anemic patients and 42% of patients without anemia (p = 0,8). More patients with HF and anemia had HF durations of 5-10 years (78 %) versus 34% of non-anemic patients (p = 0,0003). Average HF duration in anemic patients was 6,5 years compared to 4,5 years in non-anemic ones. Anemic patients required more hospitalizations due to HF decompensation than non-anemic. 61% of anemic HF patients were admitted to the hospital 4-5 times during previous year versus 17% of non-anemic HF patients (p = 0,0002). However, anemic HF patients seems to be undertreated by HF medications. Only 5,7% of HF anemic patients received MRAs to the date of current hospitalization compared to 14,3% of non-anemic patients (p = 0,42). The same is true for beta-blockers (31% vs 60%, p = 0,03) and ACEi/ARB (23% vs 46%, p = 0,07).
Conclusions: Old and very old patient with HF and anemia of chronic diseases have longer duration of heart failure compare to non-anemic HF patients. These patients require frequent hospitalization for HF decompensation, probably due to undertreatment by main HF medication. Old and very old patients with HF and anemia of chronic diseases is a high risk group that require special attention in daily clinical practice.

P1040
The study psychological state of patients with chronic heart failure

U Umida Kamilova[1]; SH Kadirova[2]
[1]*Republican specialized scientific-practical Medical Center Therapy and Medical Rehabilitation, Tashkent, Uzbekistan*; [2]*Buhara medical institute, Therapy, Buhara, Uzbekistan*

Purpose. To study the psychological state of patients with postinfarction cardiosclerosis complicated FC I-II chronic heart failure (CHF).
Methods: The study included 42 men with CHF CHD. Assessment of psychological status was performed using Zung Self-Rating Depression Scale and the scale of reactive and personal anxiety Spielberger-Hanin. To assess the psychological protection technique was used "index lifestyle' - Plutchik-Kellerman LSI.
Results: For patients with heart failure has been characterized by an increased degree of denial of existing problems, displacement (with the exception of the idea of consciousness and related emotions), projection, conjugated with aggression and intellectualization, the control of different emotions and excessive dependence on a rational interpretation of the situation. Affective disorders such as anxiety and depression appeared closely linked (r = 0,50; P < 0.001) and were typical of younger patients (r = -0,46; p < 0.05 and r = -0.66; P < 0.001, respectively). The emergence of depression was proportional to the severity of clinical symptoms (r = 0,46; P < 0.05). With the denial of the existence of compensation were associated severity: the higher the show turned out to be the negation of patients with CHF, the expressions were anxiety and depressive disorders.
Conclusions: Thus, there was an association between the severity of depression and the severity of disease in patients with CHF.

P1041
Global analysis of survival of patients of the study remadhe randomized prospective submitted to the DMP with follow-up of 16 years

FDC Fatima Das Dores Cruz[1]; VS Issa[1]; PR Chizzola[1]; GE Conceicao[1]; SF Ayub[1]; EA Bocchi[1]
[1]*Heart Institut, São Paulo, Brazil*

Introduction: The survival of patients with a diagnosis of heart failure is limited around 50% in five years survive, and may present a worse prognosis for most types of cancer.
Objectives: This investigation includes extension of the prospective, randomized, REMADHE study with intervention group, submitted to a telephone education and monitoring program, with analysis of the survival of both groups (control and intervention) from October 1999 to December 2016
Results: 412 patients, 60.5% (MG), with mean left ventricle ejection fraction of 34.7 ± 10.5% and mean age of 50.8 ± 11.7 years, etiology (%): 23.5 ischemia, 18.4 idiopathic, 14.6 chagasic, 13.3 hypertensive, with mean left ventricle ejection fraction of 34.7 ± 10.5% and mean age of 50.8 ± 11.7 years , 4 alcohol, 26.2 others. The survival was 5.5 ± 4.6 years.
Conclusion: Despite the technological and pharmacological advances, heart failure still presents as a syndrome of high mortality.

ADVANCED HEART FAILURE

P1042

Ways of reducing mortality in waiting list of heart transplant

PA Fedotov[1]; MYU Sitnikova[1]; MA Bortsova[1]; YV Sazonova[2]; VE Rubinchik[2]; AE Bautin[2]; AS Yakovlev[2]; GV Nikolaev[2]; ML Gordeev[2]; MA Simonenko[2]; MA Karpenko[2]

[1]Federal Almazov North-West Medical Research Centre, Heart Failure, Saint-Petersburg, Russian Federation; *[2]Federal Almazov North-West Medical Research Centre, Saint-Petersburg, Russian Federation*

From 2010 to 10.2016 in Federal Almazov North-West Medical Research Centre in waiting list of heart transplant (WLHTx) included 151 patients (pts). Heart Transplantation (HTx) was performed in 79 pts, 6 pts refused to transplantation, 19 pts out of the WLHTx (due to the improvement of the appearance or contraindications to HTx), 35 pts died and 12 pts continue to expect a HTx. From 2010 to 2015, the mortality on the waiting list decreased from 33% to 7.5% per year. Purpose: To identify predictors of death in patients WLHTx.

Methods: The mean age of patients was 46 ± 13 years, men - 72% (n = 108). The etiology of heart failure in patients WLHTx: coronary artery disease in 48% of patients (n = 72), DCM - 39% (n = 59), non-compact myocardium - 7% (n = 11), others the Commission - 6% (n = 9). CHF 4[3,4] FC, LVEF 21 ± 10%, VO2peak 11.4 ± 2.9 ml/kg/min, PCWP - 19[14,24] mmHg, TPG - 9[8,14] mmHg, cardiac index (CI) 1.9 ± 0.5 l/min/m2, pulmonary vascular resistance (PVR) of 3.0[2.3; 4.2] Wood units. Duration in WLHTx 107[44;1923] days. In WLHTx received therapy: combined diuretic therapy - 100%, spironolactone - 100%, beta-blockers - 82% (n = 124), ACEI/ARA 52% (n = 78), ivabradine - 15% Amiodaron - 60%, inotropes - 49% (n = 74), 12 pts (10%) implanted CRT-D, 48 pts (32%) – ICD, BiVAD (EXCOR) - 9 patients (6%), physical therapy - 100%. All patients were divided into 2 groups: 1 group (n = 116) patients survived in WLHTx, 2 group (n = 35) - patients who died. Since 2010 it received 378 proposals of potential heart donors. After further examination of the donor, perform coronary angiography and echocardiography evaluation of visiting medical team of our Center the number of effective donors was 79. Results: deceased patients compared with surviving patients at the time of inclusion in WLHTx possessed higher CHF FC (4 [4;4], and 3 [3;4], respectively; p = 0.004), low GFR (64 ± 19 and 81 ± 24, respectively, p = 0.008) greater frequency of use of inotropic support (71% and 42%, p = 0.04), high bilirubin (TBIL) level (34[23; 47] and 17[14;28], p = 0.01), ALT (52[22;502] and 22[14;31], p = 0.008), low-sodium (129 ± 8 and 139 ± 5; p = 0.03), shorter duration before the outcome (29[10; 45] and 106[63; 204], p = 0.0001). Thus, the dead patients for inclusion in WLHTx were initially more severe group of patients. From the selected predictors (CHF FC, GFR, RLA, Hb, TBIL, ALT, AST, sodium, inotropes, days WLHTx) in the patient's death WLHTx greatest force an outcome (death) were: bilirubin (r=0.49; p = 0.01), CHF FC (r=0.47; p = 0.0001), sodium (r=-0.43; p = 0.03), ALT (r=0.37; p = 0.006) , GFR (r=-0.36; p = 0.006). Conclusions: Predictor of death in patients WLHTx are symptoms of right heart failure (hepatic, renal dysfunction) and FC CHF. To increase the percentage of survival to HTx required increase in the frequency of implantation of MCS, increasing the number of effective donors, including from donors with expanded criteria (single-vessel coronary disease with the technical possibilities revascularization).

P1043

Influence of cytomegalovirus infection on long-term mortality and cardiac allograft vasculopathy risk after heart transplant

E Elizabet Mendez Eirin[1]; E Barge-Caballero[1]; MJ Paniagua-Martin[1]; R Marzoa-Rivas[1]; D Couto-Mallon[1]; G Barge-Caballero[1]; A Canizares[1]; JM Vazquez-Rodriguez[1]; MG Crespo-Leiro[1]

[1]University Hospital A Coruna, Cardiology, Corunna, Spain

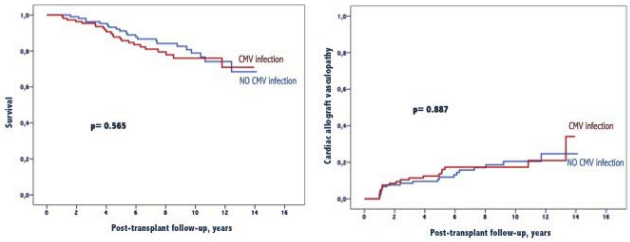
BACKGROUND: Cytomegalovirus (CMV) infection is a major concern in heart transplant (HTx). There is conflicting evidence of the effect of CMV infection on survival and the risk of cardiac allograft vasculopathy (CAV) after HTx.

PURPOSE: The purpose of this study was to evaluate the impact of CMV infection during the first year after HTx on long-term follow-up.

Methods: A retrospective, single-centre study analyzed 222 HTx recipients (mean age 54 ± 12 years, 80 % men) who underwent transplantation between February 2001 and December 2011. The impact of CMV infection during de first year on survival and CAV incidence was assessed. Graft vascular disease was defined as the presence of stenosis > 50% of the luminal diameter of any of the 3 main epicardial coronary vessels or their branches visualized on coronary angiography.

Results: During a mean follow-up of 7.8 ± 3.5 years, 45 (20.9%) patients died and 3 (1.4%) received a second HT [death was of cardiac origin in 20 (44.4%) patients and was noncardiac in 25 (55.6%)] and 38 patients (17.7%) had CAV. No statistically significant differences were observed in the cumulative incidence of death or CAV between recipients with CMV infection during the first year after HTx and patients without CMV infection (figure 1).

Conclusions: The results from this study demonstrate that CMV infection during the first year after HTx is not associated with worse transplant outcomes.



P1044

Long term outcome in patients with cardiac resynchronization therapy

LJ Ljilja Music[1]; N Bulatovic[1]; M Music[1]

[1]Clinical Center of Montenegro, Podgorica, Montenegro

Although cardiac resynchronization therapy (CRT) improves left ventricle (LV) function and short -term prognosis, long -term effect of CRT remains unclear.

55 patients with LV ejection fraction (EF) less than 35% with available pre-CRT and follow up echocardiogram were included in this study. Median follow up interval was 36.9 months. Patients with improvement of LVEF more than 5-10% were categorized as responders. Primary endpoint was cardiac death or heart failure hospitalization. 50 patients (90%) were classified as responders and 5 (10%) patients as non responder. LVEF of responders before CRT was 25,8 ± 9.8% and increased to 38 ± 3.1% after CRT. LVEF of non-responders was 27.7 ± 5.9% and increased to 31.0 ± 1.1% after CRT. Responders showed better survival from cardiac death and heart failure hospitalizations (90% vs. 33%, log rank p = 0.01). In univariate analysis, B-type natriuretic peptide, hemoglobin, serum sodium, serum creatinine, serum albumin, LVEF before CRT and CRT responder were significantly associated with survival free from cardiac death and heart failure hospitalization. In multivariate analysis, CRT responders (HR 0.28 ,95% CI 0.06-0.09, p = 0.03) and BNP (HR 41.1, 95%CI 6.1-327, p = 0.0001) remained significant.

Improvement of LV function in patients undergoing CRT is associated with better survival free from cardiac death or heart failure hospitalization.

P1045

Patient selection for heart transplantation: a survival benefit index accounting for both waiting-list and post-transplantation mortality

L S Lee Son Nguyen[1]; S Varnous[2]; G Coutance[2]; S Ouldamar[2]; N Zahr[3]; P Leprince[2]

[1]Hospital Pitie-Salpetriere, Cardiologie médicale, Paris, France; *[2]Hospital Pitie-Salpetriere, Cardio-Thoracic Surgery Unit and Pathology Department, Paris, France*; *[3]Hospital Pitie-Salpetriere, Department of Pharmacology and CIC-1421,, Paris, France*

Background: Graft shortage requires recipient selection for heart transplantation (HTx). Risk models that can predict mortality on waiting list and post-HTx exist but only separately. We aim to design a survival benefit index (SBI) to assess the benefit expected from HTx on 1-year mortality.

Methods: Patients listed for HTx (2009 to 2014) were included. We assessed 1-year mortality after listing without HTx ("no-HTx mortality") and after HTx ("post-HTx mortality"). We evaluated the discrimination of existing models: 2 for no-HTx, 2 for post-HTx mortality. We then computed 2 new models by logistic regression. The SBI was defined as the relative risk reduction of 1-year mortality.

Results: All existing no-HTx models were discriminative (all p < 0.0001) while none of those for post-HTx were. Derived models from our cohort had discriminative properties of ROC AUC 0.82 (p < 0.0001) for no-HTx and 0.67 (p < 0.0001) for post-HTx mortality, validated with ROC AUC 0.83 (p < 0.0001) and 0.69 (p = 0.002) respectively. The SBI increased with the risk of no-HTx mortality; higher risk patients benefited more than low risk patients (+78% vs. +8%; p < 0.0001).

Conclusion: The SBI may help physicians with heart allocation providing the expected benefit from HTx at one year from data available on the day of listing.

Derived risk models for one-year mortali				
	Coefficient	OR	95% CI	p-value
no-HTx mortality model				
Critical care setting at listing	1.631	5.11	[1.33 - 19.7]	0.018
Urea (per mmol above 7)	0.154	1.17	[1.04 - 1.31]	0.01
Age (per year above 50)	0.056	1.06	[1.01 - 1.11]	0.011
Total bilirubin (per μmol/l above 17)	0.051	1.05	[1.01 - 1.10]	0.022
Intercept	-1.672	-	-	-
post-HTx mortality model				
Age (per year above 50)	0.069	1.071	[1.02 - 1.13]	0.012
Listing urea (per mmol above 7)	0.052	1.054	[1.00 - 1.11]	0.0034
Pulmonary comorbidity	1.208	3.346	[1.12 - 10.0]	0.031
Intercept	-2.388	-	-	-

OR: odd-ratio

Is sidenafil treatment associated with higher rate of vasoplegic syndrome after heart transplantation?

E Sole-Gonzalez[1]; H Capellades-Olivella[1]; S Mirabet[1]; V Brossa[1]; L Lopez[1]; A Sionis[1]; M Rivas-Lasarte[1]; J Alvarez-Garcia[1]; M Gomis-Pastor[2]; MT Rivilla[3]; M Tauron[4]; E Roig[1]

[1]Hospital de la Santa Creu i Sant Pau, Cardiology Department, Barcelona, Spain; *[2]Hospital de la Santa Creu i Sant Pau, Farmacology Department, Barcelona, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Anesthesiology Department, Barcelona, Spain*; *[4]Hospital de la Santa Creu i Sant Pau, Cardiac Surgery Department, Barcelona, Spain*

BACKGROUND. Pulmonary hypertension (PH) prior to heart transplantation (HTx) increases the risk of right ventricular dysfunction after HTx. Sildenafil has been postulate as a non-invasive treatment to reduce PH in candidates to HTx. Due to its systemic effects, sildenafil could induce bleeding and vasoplegia in the acute post-HTx and increase mortality.

Purpose: To assess the effect of sildenafil on vasoplegia at 24h after HTx. A composite endpoint (vasoplegia and haemorrhagic shock) was also evaluated.

Methods: We analysed a retrospective cohort of 63 HTx since 2012 to 2016. Patients were classified according to their haemodynamic situation at 24h post-HTx in: 1)Stable haemodynamic; 2)Cardiogenic shock; 3)Hypovolemic status; 4)Haemorrhagic shock; 5)Vasoplegia. Vasoplegia was defined as: mean arterial pressure >60 mmHg with vasoconstrictors or ≤60 mmHg despite them, with cardiac index ≥2.5 l/min/m2 and central venous pressure ≥10 mmHg.

Results: Sixteen patients (25%) were treated with a mean dose of 88 mg/24h of sildenafil prior to HTx. Receptor age and sex, donor age, proportion of urgent HTx and ischaemic time were similar in the two groups. Other important variables are showed in Table. Comparing the haemodynamic status of the two groups at 24h post-HTx, sildenafil group presented non-significant tendencies of less incidence of cardiogenic shock (6 vs13%;p = 0.7), higher rate of haemorrhagic shock (19 vs 8%;p = 0.4), and vasoplegia (37 vs 21%;p = 0,2). The composite endpoint was significantly higher in the sildenafil group (56 v. 29%;p = 0.05). However, both groups had similar acute mortality (12.5 vs 12.8%;p = 0.97). Regression analysis identified a tendency of sildenafil treatment as predictor of vasoplegia (OR 3.2 [CI95% 0.84-12.47]p = 0.08).

Conclusions: 1)Treatment with sildenafil prior to HTx was associated with higher rate of bleeding and vasoplegia in the first 24h after-HTx. 2)However, sildenafil was not associated with increased acute mortality.

Table. Characteristics of two groups.			
	Sildenafil group (n = 16, 25%)	Control group (n = 47, 75%)	p value
Previous cardiac surgery, n (%)	5 (31.3)	6 (12.8)	0.093
Ischaemic aetiology, n (%)	11 (68.8)	14 (29.8)	0.006
Baseline mean pulmonary pressure (mmHg),x (SD)	38.7 (9.3)	28.9 (7.9)	< 0.001
Baseline transpulmonary gradient (mmHg), median (Q1-Q3)	9.8 (7.8-17.5)	7.3 (4.0-9.8)	0.005
Baseline Woods units, median (Q1-Q3)	2.8 (2.3-4.7)	1.8 (1.1-2.5)	0.002
Treatment with ACEI or ARB, n (%)	11 (68.8)	27 (57.4)	0.425
Systemic vascular resistence index at 24h, median (Q1-Q3)	1258 (1029-1802)	1361 (1196-1647)	0.657
Use of noradrenalin at 24h, n (%)	11 (68.8)	26 (55.3)	0.346

P1047

Identification and treatment of iron deficiency in advanced heart failure patients listed for heart transplantation

A Soltan[1]; J Evans[2]; S Pettit[2]

[1]University of Cambridge, School of Clinical Medicine, Cambridge, United Kingdom; *[2]Papworth Hospital NHS Trust, Cambridge, United Kingdom*

Background. Iron Deficiency (ID) is common in patients with advanced heart failure (HF) and is associated with a worse prognosis. Treatment of ID with intravenous Ferric Carboxymaltose (FCM) has been shown to improve symptoms, quality of life and exercise capacity, receiving a class IIa recommendation in the 2016 European Society of Cardiology guidelines. FCM may be particularly beneficial in patients listed for heart transplantation by reducing the likelihood of blood transfusion and the associated risk of Human Leukocyte Antigen (HLA) sensitisation.

Purpose: The aim of this study was to assess the prevalence of anaemia and ID among patients on the waiting list for heart transplantation, and to describe the response of ID patients to treatment with FCM.

Methods: All outpatients listed for heart transplantation between 01/02/2014 and 01/02/2016 at Papworth Hospital were included in a retrospective, observational study. The results of screening for ID were obtained from hospital records. Anaemia was defined as haemoglobin (Hb) concentration < 13 g/dL (males) and < 12 g/dL (females). ID was defined as Ferritin < 100mg/L, or 100-300mg/L where Transferrin Saturation (TSAT) < 20%. Patients treated with FCM were identified from pharmacy records. Efficacy of FCM was evaluated by comparison of Hb concentration, Ferritin level and TSAT before and after treatment. Data were summarised as mean ± standard error and compared with paired, two-tailed t-tests.

Results: 71 patients were listed for heart transplantation during the study period. All patients were screened for anaemia, but only 57 (80%) were screened for ID. Overall, the prevalence of anaemia was 59% and the prevalence of ID was 51%. Of the 29 patients with iron deficiency, 72% were anaemic and 28% were not anaemic. Use of FCM was sub-optimal during the study period. Only 38% of ID patients were treated with FCM. There were no adverse reactions during administration of FCM. When used, FCM appeared to be highly effective. A single dose of FCM was associated with an increase from baseline in Hb concentration (1.27 ± 0.27 g/dL, p = 0.0001), Ferritin level (225 ± 83 mg/L, p = 0.0187) and TSAT (8.5 ± 2.4 %, p = 0.0043).

Conclusions: ID was present in more than half of advanced heart failure patients who were listed for heart transplantation at a single UK centre. Over a quarter of iron deficient patients were not anaemic. Use of intravenous FCM was associated with an increase in Hb concentration, Ferritin levels and TSAT. Screening for ID and treatment with FCM should be encouraged in this population. Future work should assess the impact of FCM on quality of life and outcomes.

Value of cTnT-hs and sAXL for coronary allograft vasculopathy diagnosis after heart transplantation

S Sonia Mirabet Perez[1]; J Ordonez Llanos[1]; P Garcia De Frutos[2]; L Lopez Lopez[1]; V Brossa Loidi[1]; R Leta Petrarca[1]; E Sole[1]; J Garcia Picart[1]; A Ferrero[1]; M Tauron[1]; E Roig Minguell[1]

[1]Hospital de Sant Pau, Barcelona, Spain; [2]Department of Cell Death and Proliferation, IIBB-CSIC, IDIBAPS , Barcelona, Spain

Cardiac allograft vasculopathy (CAV) is one of the main limiting factors for long-term survival after heart transplantation (HTx). CAV is usually a silent phenomenon, being sudden death or heart failure the first manifestation of the disease. So, invasive monitoring with routine coronary angiography is recommended to detect CAV. The aim of the present study was to evaluate the usefulness of several biomarkers to detect CAV in HTx recipients.

Methods: This is a single center cross-sectional study in HTx patients who had undergone routine CAV assessment by coronary angiography or by coronary multi-slice computed tomography (MSCT) between January 2012 and April 2015. Blood samples were collected at the time that angiography or MSCT were perfomed. sAxl (protein involved in vascular remodeling) , Lp-PLA2 (marker of atherosclerosis), cTnT-hs (biomarker for myocardial necrosis) and GDF 15 (biomaker associated with cardiovascular events) were assessed and correlated with the presence of CAV. CAV was classified according the ISHLT recommendations.

Results: 96 HTx patients were included. Mean time after HTx was 9 ± 7 years. 49 patients had CAV (CAV1 in 26, CAV2 in 6, and CAV3 in 17 patients). In the univariate analysis patients with CAV had significantly higher cTnT-hs values (33 + 33,9 ng/l vs 18 +16,9 ng/l ;p = 0,008) and sAXL values (79 + 42 ng/l vs 65 + 24 ng/l; p = 0,036) than patients without CAV. Patients with severe CAV 2-3 had also higher cTnT-hs and sAXL values (43 ± 39 vs 20 ± 19 ng/L ;p < 001 and 92 ± 54 vs 66 ± 23 ng/L ;p < .001, respectively) than patients without CAV or mild CAV. After adjusting for clinical variables related to CAV, multivariate analysis identified hs-TnT values as the only biomarker associated with CAV, along with younger age at HTx. The ROC curve identified cTnT-hs>21 ng/L as the best cut-off value associated with the presence of CAV2-3, with an area under the curve 0.733 (p < 0.001) and a sensitivity of 65%, specificity 79%, positive predictive value 50%, negative predicted value 88%. There were no significant differences in Lp-PLA2 and GDF15 values between patients with and without CAV.

Conclusion: Monitoring sAXL and cTnT-hs could be usefull for identifying heart transplantation patients with CAV development. In our study, cTnT-hs values < 21 ng/L identify a group of HTx patients with low risk of CAV.

P1049

Quality of life in advanced heart failure- disconnect between patients' and clinicians' perceptions, independent of clinician experience.

R Roslyn Prichard[1]; PJ Newton[2]; PM Davidson[3]; S Goodall[4]; PS Macdonald[1]; FL Zhao[4]; CS Hayward[1]

[1]St Vincent's Hospital, Heart Lung Clinic, Sydney, Australia; [2]University of Technology, Sydney, Faculty of Health, Sydney, Australia; [3]Johns Hopkins University of Baltimore, Nursing, Baltimore, United States of America; [4]University of Technology, Sydney, Centre for Health Economic Research and Evaluation, Sydney, Australia

Background: Quality of life (QoL) is an important consideration for advanced heart failure (AHF) patients and clinicians making decisions about complex therapies, as well as policy makers seeking to fund cost effective treatments. But it is rarely formally assessed outside clinical trial settings. This initial data from a prospective study of frailty and QoL in a pre heart transplant cohort, explores how well clinicians treating AHF patients in a quaternary transplant centre predicted patient reported QoL.

Methods: Patients undergoing frailty assessment (including cognitive and depression screening) completed the EQ5D 5L questionnaire. Clinicians interacting with those patients were asked to complete a proxy-patient version of the EQ5D 5L within 72 hours of assessment. Utility scores were applied and paired proxy/patient results compared. Bland Altman plots, of all 110 pairs stratified by clinician experience (< 10years, >10 years) and presence of ventricular assist device (VAD), were used to determine bias and agreement limits. Spearman r coefficients comparing the clinician estimates and patient reported scores were assessed for correlation.

Results: Only mild to moderate correlations between proxy and patient reported utility scores were observed in 110 pairs (Minimum r = 0.21 for anxiety/depression and Maximum r=0.47 for overall utility) [Table 1]. These did not improve in a sub analysis of 52 pairs where the clinicians had greater than 10 years experience. Bland Altman plots revealed a potential trend to underestimation of patient reported pain and discomfort particularly at higher/ more disabling scores.

Conclusion: There remains a disconnect between patient and proxy clinician assessment of QoL, independent of clinician experience. Introducing a brief QoL questionnaire to routine patient assessments, may help to identify the outcomes that matter most to the patients.

Correlation bias and agreement

	r	95% conf. interval	P	Bias	SD of bias	95% limits of agreement From	To
Mobility all	0.34	0.16 to 0.50	0.00	-0.28	1.21	-2.66	2.10
self care	0.41	0.24 to 0.56	< 0.0001	0.00	0.91	-1.78	1.78
usual activities	0.26	0.07 to 0.43	0.01	-0.03	1.30	-2.57	2.51
pain / discomfort	0.30	0.11 to 0.47	0.00	-0.35	1.05	-2.41	1.72
Anxiety /depression	0.21	0.02 to 0.38	0.03	0.05	0.96	-1.82	1.93
Overall Utility index	0.47	0.30 to 0.61	< 0.0001	0.05	0.22	-0.38	0.49

Paired data points for each QoL domain and overall utility score generated the following correlation, bias and agreement data. (Spearman and Bland Altman analyses)

Predictive ability of pulse wave velocity for arrhythmia recurrence in hypertensive patients with atrial fibrillation

A Shavarov[1]; GK Kiyakbaev[1]; VS Moiseev[1]

[1]RUDN University, Moscow, Russian Federation

Background: Aortic stiffness promotes to adverse left atrial (LA) remodeling that result in the development and persistence of atrial fibrillation (AF).

Purpose: We investigated whether aortic stiffness could predict AF recurrence in patients (pts) with arterial hypertension (AH) and persistent AF.

Methods: The study included 55 pts (40% men) aged 66 (62; 73) years with AH short-term recurrent AF treated with metoprolol (n = 31) and diltiazem (n = 24). All patients underwent clinical and echocardiographic examination, 24-hour (hr) ambulatory blood pressure (BP) monitoring, pulse wave analysis using the SphygmoCor system before and 3 months after treatment. LA structure abnormalities were defined as LA volume index ≥34 mL/m2. LA empting fraction ≤45% and LA expansion index ≤90% were categorized as LA phasic dysfunction.

Results: LA structural and/or functional abnormalities were found in 44 (80%) pts. AF recurrences were documented in 36 (65%) pts during follow-up period. To compare with AF-free group pts with AF recurrence had significantly higher age, CHA2-DS2-VASc score, peripheral and central pulse pressure (PP), PP amplification, time to return of reflected pressure wave (Tr), and carotid-femoral pulse wave velocity (PWV) [p < 0,001 for all cases]; 24-hr mean SBP, peripheral systolic BP, systolic pressure-time integral and augmentation index [p = 0,01 for all cases]; 24-hr mean heart rate, central systolic BP and ejection fraction [p = 0,02 for all cases]. Arrhythmia anamnesis was longer in AF-free group (12 vs 10 month, p = 0,01). Age [odds ratio (OR) 1,07; 95% CI 1,01-1,13; p = 0,02] and PWV [OR 1,46; 95% CI 1,18-1,80; p = 0,0004] were associated with increased risk of AF recurrence in nonlinear regression analysis.

Conclusion: Pulse wave velocity and age could be significantly associated with arrhythmia recurrence in hypertensive patients with short-term anamnesis of atrial fibrillation.

P1051

HsC-reactive protein as a predictor of mortality in patients with atrial fibrillation in heart failure

S Sadat Kurtalic[1]; N Kurtalic[1]; E Jahic[1]; E Malkic[1]

[1]Cantonal Hospital "Dr. Irfan Ljubijankic", Department of Internal Medicine, Bihac, Bosnia and Herzegovina

Background: To determine the predictive value of HSC-reactive protein level in mortality for patients in heart failure with atrial fibrillation.

Respondents and methods: Cross-section study analysed the predictive value of C-reactive protein in 200 patients with heart failure of all ages, both sexes. The study was conducted in the period from January 1, 2012, to January 31, 2014, at the Department of Internal Medicine of Hospital. Considering the leaders of the heart rate, respondents were divided into two equal groups: the first group were patients in heart failure with atrial fibrillation, and the second group were patients in heart failure with sinus rhythm. All patients with heart failure were clinically examined, with electrocardiogram, ultrasound of the heart, and the value of HsCRP in serum was determined. In the study, the value of HsCRP considered normal if < 5.0 mg / l.

Results: The average age of patients in the first group was 65.0 (8.6) years, and in the second group 65.3 (9.1) (t = 0.215, df = 198, p = 0.83). The first group consisted of 47/100 (47%), while the second group had 41/100 (41%) of female respondents, (X 2 = 0.73, df = 1, p = 0.48). There were more male respondents in both groups. The average value of HsCRP in the entire sample was 5.75 (5.68) mg / L (range 0.0 to 28.0 mg / l). The frequency of respondents with elevated HsCRP in the first group was 40 (40%), while the second group was 44 (44%), (X2 = 0.18; df = 1; p = 0.67). In the first group there were 21 (21%) mortality, and 15 (15%) in the second group (X 2 = 0.85, df = 1, p = 0.36). Univariate regression analysis of the first group of respondents HsCRP shown the relation of chances (odds ratio - OR) of 1.13 (95% CI = 1.04 to 1.22; p = 0.003), and when a function of time (hazard ratio - HR) was taken into account, HsCRP as a predictor was 1.10 (95% CI = 1.04 to 1.17; p = 0.001). In the second group of respondents HsCRP showed OR = 1.07 (95% CI = 0.98 to 1.17; p = 0.13), and HR value was 1.06 (95% CI = 0.99 to 1, 14; p = 0.11).
Conclusion: HsC-reactive protein is a significant predictor of mortality in patients with atrial fibrillation in heart failure.

P1052
Atrial fibrillation in patients with heart failure

CC Diaconu[1]; D Berceanu[2]; D Bucur[2]; GN Dediu[3]; MA Iancu[4]
[1]University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Floreasca, Bucharest, Romania; *[2]Emergency Clinical Hospital Floreasca, Bucharest, Romania*; *[3]University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Sf. Ioan, Bucharest, Romania*; *[4]University of Medicine and Pharmacy Carol Davila, Family Medicine, Bucharest, Romania*

Introduction. Atrial fibrillation is a frequent companion of heart failure. Heart failure patients with atrial fibrillation may have some particularities as compared to those with sinus rhythm. The purpose of the study was to analyze the frequency and particularities of patients with chronic heart failure and atrial fibrillation, hospitalized in the Internal Medicine clinic of a University Clinical Emergency Hospital.
Methods: The study included 980 patients with chronic heart failure, consecutively admitted between January 1st, 2016-November 30, 2016. We have retrospectively analyzed the frequency of atrial fibrillation and the clinical correlations in patients with chronic heart failure, using data from the hospital record database and SPSS software. Results. The distribution by sex in the group of study: 49.8% men, 50.2% women. The mean age of the whole group was 74 ± 11.6 years. 39.9% of the patients with chronic heart failure had permanent atrial fibrillation. We have found a statistically significant correlation between the presence of atrial fibrillation and anemia: 27.68% of pts with atrial fibrillation had anemia, as compared to 16.20% (p < 0.001). 85.20% of pts with heart failure and atrial fibrillation had hypertension, versus 54.76% of those without atrial fibrillation (p = 0.001). We have found also a statistically significant correlation between the presence of atrial fibrillation and dyselectrolytemias (p < 0.001), and also between atrial fibrillation and coronary heart disease (p < 0.001). Dysthyroidism was diagnosed in 13.77% of pts with atrial fibrillation versus 4.93% in those without atrial fibrillation (p = 0.001). We have found a weak correlation (p = 0.003) between atrial fibrillation and chronic kidney disease or between atrial fibrillation and pulmonary hypertension (p = 0.029). Conclusions: Atrial fibrillation is a frequent comorbidity in heart failure (40% in our study). Patients with heart failure and atrial fibrillation have a higher frequency of anemia, arterial hypertension, dyselectrolytemias, coronary heart disease and dysthyroidism.

Antithrombotic treatment differences among hospitalized patients with atrial fibrillation and heart failure

A Samaras[1]; E Michou[1]; G Fotos[1]; G Dividis[1]; D Vasdeki[1]; E Kotsi[1]; P Tsoukra[1]; E Forozidou[1]; T Panagiotidis[1]; A Kartas[1]; I Doundoulakis[1]; G George Giannakoulas[1]; H Karvounis[1]; A Tzikas[1]
[1]AHEPA General Hospital, Thessaloniki, Greece

On behalf of: MISOAC Investigators

BACKGROUND Appropriate anticoagulation therapy should be prescribed in all patients with atrial fibrillation (AF) and heart failure (HF) at risk of stroke. According to the 2016 ESC AF guidelines non-vitamin K oral anticoagulants (NOACs) are recommended in preference to Vitamin K antagonists (VKAs) in patients with non-valvular AF who are eligible for NOACs, while antiplatelet monotherapy is not recommended for stroke prevention in AF patients regardless of stroke risk.
PURPOSE: To determine the type of antithrombotic treatment [oral anticoagulation (OAC) and antiplatelet (OAP)] in a "real-world" contemporary observational dataset of patients with AF and to highlight the differences in patients with a history of HF versus no HF and also amongst the three subtypes of HF [heart failure with reduced ejection fraction (HFrEF), heart failure with mid-range ejection fraction (HFmrEF) and heart failure with preserved ejection fraction (HFpEF)].
Methods: We studied consecutive patients who were hospitalized to the cardiology department of a tertiary hospital with any diagnosis and coexisting non-valvular AF. Subjects with HF were classified in three groups according to their LVEF (HFrEF, HFmrEF, HFpEF). Comparisons were made between patients with and without HF, and among HF subtypes.
Results: A total of 510 patients were enrolled between December 2015 - December 2016, of whom 232 (45.5%) had documented HF (HFpEF: 63%, HFrEF: 21%, HFmrEF: 16%). Monotherapy with an OAC was prescribed in 73% and OAP monotherapy in 10% of patients, while 17% were under combination therapy with OAC and OAP. There was a preference for NOACs over VKAs in patients without HF (65% vs 35% respectively, p < 0.05), while NOACs and VKAs were equally prescribed in patients with HF (48% vs 52% respectively). At discharge, there was a trend (p = 0.10) for administration of NOACs over VKAs in HFpEF patients (58% vs 42%) compared to HFrEF (37% vs 63%) and HFmrEF (41% vs 59%). There was a common co-administration of OACs and OAPs in the HFmrEF subgroup (36%), which was significantly higher compared to the HFpEF patients (9%, p < 0.05) but not significantly higher compared to the HFrEF subgroup (12%).
Conclusions: In the "real life" clinical setting, one tenth of hospitalized patients with AF were under OAP, which is not supported by the current ESC Guidelines, while a significant number of patients received combination therapy with OACs and OAPs. Patients with a history of HF were less likely to receive NOAC therapy at discharge compared to patients without HF. Patients with HFmrEF were more likely to be under co-administration of OACs and OAPs in comparison to HFpEF patients.

P1054
Clinical implications from the interdependence between heart failure and atrial fibrillation

D Daniel Seabra[1]; H Guedes[1]; P Silva[1]; L Marques[1]; A Andrade[1]; J Azevedo[1]; P Pinto[1]
[1]Hospital Centre do Tamega e Sousa, Cardiology Department, Penafiel, Portugal

Background/Introduction: Heart failure (HF) and atrial fibrillation (AF) represent two relevant diseases that are growing in cardiovascular medicine. They share common risk factors and aspects of pathophysiology instilling challenge in their clinical approach. When both are present, patients (pts) have a worse prognosis, with a significant impact in healthcare.
Purpose: To assess the clinical impact of AF in pts with heart failure with reduced ejection fraction (EF) and the prognostic implications.
Methods: We conducted a retrospective study based on a cohort of pts from a HF clinic of a single hospital center. Included pts with reduced EF and previous diagnosis for, at least, six months; they were divided in two groups: with permanent AF (G1) and without AF (G2). Evaluated clinical characteristics and major cardiac events – hospitalization from HF (hospHF) or acute coronary syndrome (hospACS) and death from cardiovascular cause (CVm) and non-cardiovascular cause (nCVm). Assessed the relationship with recovery of left ventricle systolic function (LVSF) (defined as EF increase > 10% with respect to the initial value) and size (Q) (defined by quotient between the follow-up [FU] and the initial value of the indexed left ventricle end-diastolic diameter).
Results: Included 290 pts, with a mean age of 60.56 ± 13.25 years and male predominance (75.2%). The prevalence of ischemic etiology was 41%. The mean initial EF was 29.2 ± 10.8%. The FU was 39.9 ± 18.5 months, with a mean EF during FU of 34.9 ± 12.5%.
G1 consisting of 99 pts and 191 in G2. There was a more advanced age in G1 (64.2 vs 58.7 years, p < 0.001) and a predominance of males in both groups (p 0.01). Appreciably higher prevalence of chronic renal dysfunction (glomerular filtration rate ≤ 60mL/min/1.73m2) was observed in G1 (40.4 vs 27.2%, p 0.02). There were no significant differences regarding the etiology of HF and the prevalence of other cardiovascular risk factors between the groups.
The presence of AF correlated negatively with the recovery of the LVEF (21 vs 65 pts; p 0.023). Observed a significant higher Q in G1 (0.98 vs 0.94 ± 0,02, p 0.002). During the FU, G1 had a greater number of clinical events - hospIC (p < 0.001), CVm (p 0.003) and nCVm (p < 0.001); without meaningful differences in hospACS (p 0.552). The presence of AF was associated with worse functional class (p < 0.001) and greater use of diuretic therapy (p 0.002); In the pts with AF, there is predominance of hypocoagulation with vitamin K antagonists (p < 0.001).
Conclusion(s): In this study, the presence of AF has a important influence on HF since it is a limiting element for the recovery of the LVEF and is associated with higher end-diastolic ventricle size. As consequence, it has a close relate relation with worse clinical prognosis and functional class. In pts with AF, the higher prevalence of chronic kidney disease influences the hypocoagulation strategy.

P1055

Increased left atrial volume predicts atrial fibrillation recurrence after transcatheter ablation: a systematic review and meta-analysis

I Ibadete Bytyci[1]; G Bajraktari[1]; MY Henein[2]
[1]*University Clinical Centre of Kosova, Clinic of Cardiology, Pristina, Kosovo Republic of*; [2]*Umea University, Department of Public Health and Clinical Medicine, Umea, Sweden*

Background and Aim: Left atrial (LA) enlargement is associated with atrial fibrillation (AF) incidence and outcome. Trans-catheter ablation has become an established treatment for symptomatic atrial fibrillation (AF) patients who are refractory to drug therapy. However, AF recurrence and the need for repeat procedure are common in these patients. Although a number of predictors of AF recurrence have already been proposed, patient selection remains controversial. The aim of this meta-analysis was to analyze the potential association between LA volumes and AF recurrence after ablation.

Methods: We systematically searched PubMed-Medline, EMBASE, Scopus, Google Scholar and the Cochrane Central Registry, up to December 2016 in order to select clinical trials and observational studies, which reported the predictive role of LA maximal volume (LAVmax) and LAVmax indexed (LAVI) for AF recurrence after catheter-ablation. 3259 patients from 31 studies with paroxysmal AF (PAF), persistent (PeAF) or longstanding persistent AF (L-PeAF) were included.

Results: The pooled analysis showed that after 16.8 ± 10.7 months follow-up, patients with AF recurrence had larger LAVmax and LAVI in comparison with those without AF recurrence, with a weighted mean difference (WMD) of 16.21 ([95% CI 11.70 to 20.73], P < 0.0001) and 4.19 ([95% CI 2.97 to 5.42], P < 0.0001). In subgroup analysis, the difference in LAVI was present according to the type of AF; in PAF WMD was 2.08 ([95% CI 0.48 to 3.55], P < 0.01), in PeAF/L-PeAF was 3.55 ([95% CI 0.68 to 6.43], P=0.0007), with no significant difference between the two subgroups (Chi2=0.85, I2 = 0.0%, p = 0.36).

Conclusions: Left atrial maximal volume and indexed volume correlate with atrial fibrillation recurrence after catheter ablation.

Mutations in contractile proteins have been found to be the cause of a number of common cardiomyopathies including familial hypertrophic cardiomyopathy (HCM) and familial dilated cardiomyopathy (DCM). In most cases the mechanism proposed for causing the disease is derangement of the thin filament-based Ca2 + -regulatory system of the muscle. HCM has been linked to a higher myofilament Ca2 + -sensitivity. In addition we have identified a molecular level dysfunction common to both HCM and DCM-causing mutations. This is an uncoupling of the relationship between troponin I (TnI) phosphorylation and modulation of myofilament Ca2 + -sensitivity, essential for normal responses to adrenaline. We have identified compounds that can specifically reverse these abnormalities in vitro and therefore have potential for treatment.

The first compound studied was Epigallocatechin-3-Gallate (EGCG). We found that this is capable of both Ca2 + desensitisation and re-coupling of HCM mutant myofilaments so as to restore function to the same as native myofilaments, both by quantitative in vitro motility of single filaments and in single myofibrils.

100μM EGCG can restore normal function to troponin from samples with mutations in all the sarcomeric proteins tested including TnI, TnT, TnC, tropomyosin, actin, β-MHC and MyBP-C and in myectomy samples where no mutation has been identified. The restorative effect is species independent, being the same in both human and cat myofilaments.

We have recently identified a number of similar compounds that can also re-couple and/or desensitise HCM mutant myofilaments; moreover we have found that the properties of desensitisation and re-coupling can be separated and that these effects show a preference of one stereoisomer over another. Thus Epicatechin gallate (ECG) is a desensitiser that does not re-couple. In contrast Silybin B, dehydrosilybin B, taxifolin, quercetin and novobiocin are re-couplers that do not have any desensitising activity, whilst Silybin A and dehydrosilybin A are neither desensitisers nor re-couplers.

We propose that the activity of desensitising and re-coupling compounds depends upon their preferential binding to wild-type and mutant, phosphorylated and unphosphorylated troponin. Thus a pure re-coupler may only bind to mutant dephosphorylated troponin. We have mapped EGCG binding to whole troponin by molecular dynamics simulations and find that it is located between the N-terminal phosphorylatable peptide of TnI and the N-terminal Ca2 + regulatory domain of unphosphorylated TnC. In this position it could stabilise and influence the N-terminal TnI interaction with TnC that is involved in modulation of Ca2 + -sensitivity by phosphorylation. Interestingly, Silybin A and B that are not desensitisers, do not bind to unphosphorylated wild-type troponin in MD simulations

Genetic spectrum of diseases underlying diffuse generalyzed form of hypertrophic cardiomyopathy

E Elena V Zaklyazminskaya[1]; M Polyak[1]; ANNA Bukaeva[1]; O Blagova[2]; YU Frolova[1]; M Malikova[1]; S Dzemeshkevich[1]
[1]*B.V. Petrovsky Russian Scientific Center of Surgery of the Russian Academy of Medical Sciences, Moscow, Russian Federation*; [2]*I.M. Sechenov First Moscow Medical Academy, Clinic of Cardiology, Moscow, Russian Federation*

Funding Acknowledgements: This work was partially supported by the Russian Research Foundation, project No 16-15-10421

Background: As many as 65% of primary hypertrophic cardiomyopathy (HCM) cases are associated with mutations in sarcomeric genes. The diffuse generalized form of HCM is a specific anatomical phenotype characterized by diffuse hypertrophy of the interventricular septum and significant hypertrophy of the papillary muscles, with their displacement towards the left ventricular (LV) apex.

Aim: This study also aims to analyze the genetic spectrum of the diseases associated with the diffuse generalized form of HCM.

Methods: From 2009 to 2015, 31 patients with diffuse generalized HCM were examined. Genetic screening of the 10 genes encoding sarcomeric proteins (MYBPC3, TAZ, TPM1, LDB3, MYL2, ACTC1, MYL3, MYH7, TNNI3, and TNNT2) was performed, followed by additional Sanger resequencing of the low-covered regions in order to confirm all detected variants. Mutational testing in additional genes causing some particular genetic syndromes was performed by bidirectional Sanger sequencing.

Results: Mutations in the sarcomeric-encoding genes were detected in 4 cases (13%) what is a low prevalence as compared to the overall prevalence of all of the mutations (60-65%) in the HCM cohort. Multisystemic inherited diseases (progressive myopathies - 2 patients, lysosomal storage diseases - 4 patients, and RASopathies - 4 patients) accounted for 32% of the index cases.

A new reconstructive surgical technique was developed and implemented, allowing for the normalization of both the intraventricular pressure gradient and LV diastolic filling. 26 patients of them underwent the following reconstructive surgery: transaortic extended septal myectomy, longitudinal resection of the papillary muscles with preservation of annulo-papillary contact, mitral valve replacement through the left atrium, and ICD implantation.

Significant normalization of intracardiac hemodynamics was observed in 1, 3 and 5 year follow-ups in 24 patients. Morphological evaluation of the removed mitral valve leaflets showed connective tissue dysplasia. Five patients (19%) experienced appropriate ICD shocks.

Conclusion: The prevalence of classic 'sarcomeric' mutations was less frequent than expected in patients with diffuse generalized HCM. "Non-sarcomeric" genetic

mutations associated with LV hypertrophy were detected in 10 cases (32%). An excessive level of fibrosis may explain the high risk of ventricular fibrillation, and stresses the need for early reconstructive surgery as a primary prevention of sudden cardiac death (SCD).

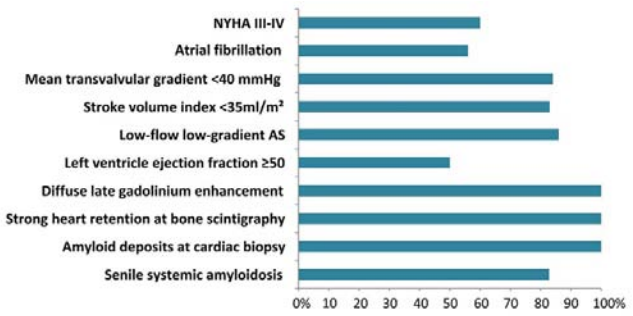
Aortic stenosis and transthyretin cardiac amyloidosis: the chicken or the egg?

A Arnault Galat[1]; AG Guellich[1]; DB Bodez[1]; MS Slama[2]; MD Dijos[3]; DMZ Zeitoun[4]; OM Milleron[4]; DA Attias[5]; JLDR Dubois-Rande[1]; DM Mohty[6]; EA Audureau[7]; JLM Monin[7]; TD Damy[1]

[1]University Hospital Henri Mondor, Cardiology, Creteil, France; *[2]Hospital Antoine Beclere, Clamart, France*; *[3]University Hospital of Bordeaux, Bordeaux, France*; *[4]Hospital Bichat-Claude Bernard, Paris, France*; *[5]Centre Cardiologique du Nord, Saint Denis, France*; *[6]University Hospital of Poitiers, Poitiers, France*; *[7]University Hospital Henri Mondor, Creteil, France*

Background: Aortic stenosis (AS) and transthyretin-cardiac amyloidosis (TTR-CA) are both frequent in elderly. The combination of these two diseases has never been investigated.
Aims: To describe patients with concomitant AS and TTR-CA.
Methods: Six cardiologic French centers identified retrospectively cases of patients with severe or moderate AS associated with TTR-CA hospitalized during the last six years.
Results: Sixteen patients were included. Mean ± SD age was 79 ± 6 years, 81% were men. 60% were NYHA III-IV, 31% had carpal tunnel syndrome and 56% had atrial fibrillation. Median (Q1;Q4) NTproBNP was 4382 (2425;4730) pg/mL and 91% had elevated cardiac troponin level. 88% had severe AS (n = 14/16), of whom 86% (n = 12) had low gradient AS. Mean ± SD interventricular septum thickness was 18 ± 4 mm. Mean left ventricular ejection fraction and global longitudinal strain were 50 ± 13% and -7 ± 4% respectively. Diagnosis of TTR-CA was histologically proven in 38%, and was based on strong cardiac uptake of bone tracer at scintigraphy in the rest. 81% had wild-type TTR-CA (n = 13), one had mutated Val122I and 19% did not had genetic test (n = 3). Valve replacement was surgical in 63% and via transcatheter in 13%. Median follow-up in survivors was 33 (16;65) months. Mortality was of 44% (n = 7) during the whole follow-up period.
Conclusions: Combination of AS and TTR-CA may occur in elderly patients particularly those with a low-flow low-gradient AS pattern and carries bad prognosis. Diagnosis of TTR-CA in AS is relevant to discuss specific treatment and management.



characteristics of AS/CA patients

Hypertrophic cardiomyopathy in the pediatric stage: clinical, electrical and echocardiographic characteristics.

MA Lopez Garrido[1]; N Abdeselam-Mohamed[1]; HN Orellana-Figueroa[1]; V Cuenca-Peiro[2]; B Picazo-Angelin[2]; L Conejo-Munoz[2]; M De Mora-Martin[2]; JI Zabala-Arguelles[2]

[1]University Hospital Virgen de la Victoria , Department of Cardiology, Malaga, Spain; *[2]Regional University Hospital of Malaga, Department of Cardiology, Malaga, Spain*

Background: Hypertrophic cardiomyopathy (HCM) is the most common cause of sudden death in adolescence, appearing generally at that age, and being less frequent in the pediatric stage. The aim of our study was to know the characteristics of HCM patients diagnosed in the pediatric age.
Methods: We studied a sample of patients with MCH from our consultation of Pediatric Cardiology, recording clinical, electrocardiographic, echocardiographic and adverse events during follow-up (death, functional class worsening, cardiac transplantation and / or arrhythmic events). Patients with diagnosis of any metabolopathies or polymorphic syndromes were excluded.
Results: Nineteen patients were studied (mean age 7 years, 16% women). The mean age at diagnosis was 4.5 years old. The most frequent reason for being diagnosed was the family screening (31.6%). The 42.1% had a history of HCM and the 10.5% of sudden death. The 26.3% presented symptoms at the time of diagnosis, being the syncope the most frequent (60%). The 73.7% had signs of left ventricular hypertrophy on the electrocardiogram and 47.4% had alterations in the repolarization. In the echocardiographic study, 15 (78.9%) had an asymmetric distribution of hypertrophy and in 4 (21.1%) was concentric. Anterior mitral systolic movement was observed in 26.3% and a significant dynamic gradient in 36.8%, which was severe in 3 patients (15.8%). The 100% of the patients with the dynamic gradient received beta-blocker treatment, but only 30% achieve an improvement with them. The median follow-up was 14 months (RIC 7-24), without having registered any adverse event.
Conclusions: 1. The most frequent cause of diagnosis of HCM in the pediatric stage was family screening.
2. A quarter part of the patients had symptoms at the time of diagnosis.
3. In a low percentage it was possible to reduce the dynamic gradient after the beta-blocker treatment.
4. There were no adverse events in the follow-up in our series.

Quality of life in outpatients with hypertrophic cardiomyopathy.

M Jacquelinet[1]; A Duva Pentiah[2]; A Coisne[1]; P Lapierre[3]; E Hebbar[2]; M Fertin[2]; H Ridon[2]; D Montaigne[1]; N Lamblin[4]; P De Groote[2]

[1]CHRU Lille, Service d'Explorations Fonctionnelles CardioVasculaires, Lille, France; *[2]CHRU Lille, Service de Cardiologie, Lille, France*; *[3]CHRU Lille, Service d'Addictologie, pôle de Psychiatrie, Lille, France*; *[4]CHRU Lille, Unité de Soins Intensifs Cardiologiques, Lille, France*

Background: Hypertrophic cardiomyopathy (HCM) is a relatively common genetically transmitted heart disease associated with sudden cardiac death, heart failure and atrial fibrillation (AF). Quality of life (QoL) provides subjective information completing traditional measures of health. Very few studies have assessed QoL in HCM patients.
Purpose: To assess QoL in HCM patients and to identity factors associated with QoL.
Methods: A single-center prospective observational study was conducted in HCM outpatients referred to a University Hospital between March 2015 and March 2016. QoL was assessed with the Short-Form 36 Health Survey (SF36) and psychological well-being with the Hospital Anxiety and Depression (HAD) questionnaire. Sociodemographic, clinical, biological, and echocardiographic data were collected.
Results: 78 questionnaires were analyzed. Physical component score (PCS) and mental component score (MCS) of the SF36 were significantly lower in patients with HCM compared to French population (PCS = 44.4 ± 10.3 versus 50.4 ± 9.9, p < 10-4; MCS = 45.8 ± 9.9 versus 48.8 ± 9.9, p = 0.017). Impaired physical QoL was independently predicted by 6 variables that accounted for 60% of the variance: low education level (p < 0.006), impact of disease on a child project, (p < 10-4), AF (p < 0.011), palpitations (p < 10-4), high NYHA functional class (p < 10-4) and high score at the HAD depression subscale (p < 0.032). Impaired mental QoL was independently predicted by 5 variables that accounted for 54% of the variance: family history of HCM (p < 0.012), syncope or presyncopal symptoms (p < 0.013), high number of medications (p = 0.005), and high score at the HAD anxiety (p < 10-4) and depression subscale (p < 10-4).
Conclusion: Physical and psychological QoL are clinically and statistically impaired in patients with HCM. Identification of QoL predictors suggest potential targets to provide more comprehensive health-care strategies for HCM patients.

P1061

Feasibility and benefits and of exercise training in patients with amyloid cardiomyopathy

B Gellen[1]; M Wuliya[2]; H Ben Elhaj[2]; S Guendouz[3]; D Bodez[3]; S Peyrot[2]; T Damy[3]

[1]ELSAN, Polyclinique de Poitiers, Cardiology, Poitiers, France; *[2]Henri Mondor University Hospital Group, Cardiac Rehabilitation, Créteil, France*; *[3]Henri Mondor University Hospital Group, Cardiology, Créteil, France*

Introduction: Cardiac amyloidosis (CA) is a common cause of hypertrophic cardiomyopathy (HCM). Data about the feasibility and benefits of cardiac rehabilitation (CR) in these patients are lacking.
Methods: Consecutive heart failure (HF) patients with confirmed CA addressed for CR were prospectively included in this single centre cohort from 2011 to 2015.

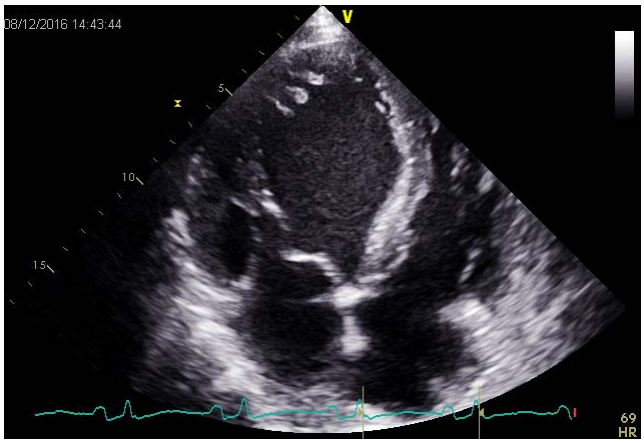
Patients underwent exercise testing on a cycle ergometer before and after participation to a standard group-based CR program. The CR program was considered as feasible if the patient could participate in ≥10 training units without adverse events. The CR program was considered as beneficial in case of a relative increase in peak oxygen consumption (VO2) and/or in maximal workload after CR of ≥16%.
Results: Twenty-seven patients were included (68 ± 12 years, 81% male). Mean left ventricular (LV) ejection fraction was 49.8 ± 12.8%, and mean LV wall thickness was 17 ± 3 mm. The majority of the patients had AL amyloidosis (N=16; 59%). Two-third of the patients had a pacemaker. The maximum workload at the initial exercise test was 49 ± 40 W.
Cardiac rehabilitation was feasible in 19 patients (70%). Patients with feasible CR as compared to patients with CR failure had more pacemaker (84% vs. 25%; p = 0.0061), lower NT-proBNP (2239 ± 8600 vs. 8600 ± 8613 ng/l; p = 0.045), and a longer initial exercise test (360 ± 263 vs. 134 ± 62 sec.; p = 0.0190). Age and type of amyloidosis were not significantly associated with CR feasibility.
Among the patients with feasible CR, nine (47%) showed significant functional benefit, with a 36 ± 23% (25 ± 20W) increase in maximal workload after CR, as compared to 0 ± 17% (2 ± 10W) among those without benefit. Benefit was not significantly associated with the number of training units (27 ± 16 vs. 22 ± 14, n.s.). Benefit was associated with age (63 ± 13 vs. 73 ± 11 years, p < 0.05), NT-proBNP (1080 ± 851 vs. 10516 ± 9810 ng/l, P < 0.05), creatininemia (92 ± 36 vs. 158 ± 83 μmol/l, p < 0.05), and LVEF (57 ± 10 vs. 42 ± 10%, p < 0.05), but not with the type of amyloidosis neither with the degree of LV hypertrophy.
Conclusions: The presence of a pace-maker seems to facilitate cardiac rehabilitation in CA. Elderly CA patients with impaired LVEF seem not to benefit from CR with respect to functional capacity. The type of amyloidosis and the degree of LV thickening are neither associated with CR feasibility nor with functional benefit.

P1062

Surprise after a successful fibrinolytic therapy in acute stroke

R Roland Gal[1]; L Szapary[2]; L Toth[3]; S Szukits[3]; K Toth[1]; T Habon[1]
[1]*1st. Department of Medicine, University of Pécs, Medical Center, Pécs, Hungary*; [2]*University of Pecs, Stroke Center, Department of Neurology, Pecs, Hungary*; [3]*University of Pecs, Department of Radiology, Medical Center, University of Pécs, Pecs, Hungary*

Introduction: Stroke is the third leading cause of death worldwide, and almost 80% of the total cases of strokes are ischemic strokes. Cardiogenic embolism accounts for approximately 20% of ischemic strokes. The most frequent source of cardioembolic stroke is the nonvalvular atrial fibrillation, but many other pathological heart conditions can be an etiological factor. Noncompaction cardiomyopathy is a rare, genetic disease, caused by intrauterine arrest of compaction of the myocardial fibres, resulting in multiple trabeculations, typically the apex in the LV myocardium.
Case report: A 56-year-old regular alcohol drinker patient without significant medical history was admitted, 1-1,5 hours after the onset of symptoms, with ictal left-sided mild hemiparesis and dysarthria. Urgent brain CT scan didn't identify bleeding or early signs of stroke. Thrombolysis was performed within 2 hours. Control CT scan at 24 hours showed extensive lesions in the territory of the right middle cerebral artery. Patient's hemiparesis was completely resolved 2 days after intervention. Echocardiography revealed previously unknown severe left ventricle dysfunction (EF: 24%), diffuse hypo-kinesis of the apex, and extended apical trabeculation with intratrabecular thrombi. The cardiac MRI showed typical morphological pattern of non-compaction cardiomyopathy, but it also supposed ischemic etiology, based on extended, irreversible damaged areas of myocardium (delayed contrast enhancement). With regard to the recent neurological event coronary CT angiography was performed, which identified significant stenosis of LAD and Cx, with extensive calcification. Besides of the tailored, evidence-based heart failure and secondary prevention therapy, we introduced oral anticoagulant therapy as well. The patient was discharged in stable condition (NYHA I-II.), and scheduled for a follow-up MRI and elective revascularization.
Conclusion: Close cooperation between neurologist and cardiologist is crucial during stroke care. In the background of the stroke severe cardiological diseases can often be found. Fast cardiological diagnosis can improve the survival of the patient, can change the treatment or, as in our case, also requires a complex approach.



Trabeculation with thromi

P1063

A new de novo mutation in the MYH7 gene causing dilated cardiomyopathy with mild myopathy in pediatric patient

Y Yulia Rogozhina[1]; M Polyak[1]; E Zaklyazminskaya[1]
[1]*Russian Research Center of Surgery, Moscow, Russian Federation*

Funding Acknowledgements: This work was supported by Russian Science Foundation, grant no.16-15-10421.

Introduction: Dilated cardiomyopathy (DCM) is characterized by left ventricular enlargement and systolic dysfunction. The estimated prevalence of DCM is 1:3,000 and about 35% of patients will have familial disease. For children it is much rare condition and its annual incidence is estimated to be 0.58 cases/100,000 children. Early-onset sporadic DCM is usually considered as a recessive form of disease with 25% risk of recurrence.
Patient and methods: The patient is Russian boy 2 y.o. with dilated cardiomyopathy and primary weaknesses of axial muscles. The proband was examined by pediatrist, neurologist, and geneticist. The clinical evaluation included medical history taking, echocardiogram, creatine phosphokinase (CK) measurement and electromyography. The genetic evaluation included whole genome sequencing (WGS) for the patient, with following confirmation by the Sanger sequencing ofthe findings, cascade familial screening, and predictive in silico analysis of possible clinical impact. Proband's mRNA was extracted from the muscle sample and converted into cDNA using standard molecular methods.
Results: WGS revealed a novel genetic variant c.5655 + 5G>C in the MYH7 gene. Splice site damage was predicted by Netgene2 and SpliceSite Predictor tools. Analysis of cDNA shows the skipping of exon 38 without frameshift (p.1854_1885del). Diagnosis of the MYH7-related myopathy was established based on the clinical evaluation and genetic finding. De novo origin of c.5655 + 5G>C variant was confirmed after the testing of parent's DNA samples. We consider the genetic variant c.5655 + 5G>C as a pathogenic mutation causing dilated cardiomyopathy and myopathy.
Conclusion: Mutation c.5655 + 5G>C in the MYH7 gene causes MYH7-related myopathy with unusually early manifestation. Severe de novo mutations in the MYH7 gene could be responsible for some early-onset DCM with myopathy. It is important to clarify de novo status, because those mutations have a benign prognosis for following family planning.

P1064

The effect of the CHF optimal medical treatment on clinical and functional parameters in pts with peripartum and idiopathic dilated cardiomyopathies

NA Kurbanov[1]; TA Abdullaev[1]; ST Mirzarakhimova[1]; I A Igor Tsoy[1]
[1]*Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan*

The aim: To study the effect of six-month CHF optimal medical treatment (OMT) clinical and hemodynamic parameters of pts with idiopathic (IDCM) and peripartum (PPCM), dilated cardiomyopathies (DCM).
Materials and methods: The study included 93 pts with dilated cardiomyopathy. It were conducted ECG EchoCG, X-ray cardiometry, 6-minute walk (6MWT) and the

assessment of the clinical condition (ACC) by Mareev for CHF pts before and after treatment. All pts received the standard treatment of heart failure and were randomized into two grs: the first gr included 50 pts with peripartum cardiomyopathy (mean age 28,2 ± 0,8 years.), In the second - 43 pts with idiopathic dilated cardiomyopathy (mean age 38. 1 ± 2,1 years; $p < 0.001$).

Results: At the time of study entry, all pts were stabilized on the CHF OMT. By the end of the treatment of the dynamics of reduction of heart rate in both grs was significantly (respectively 32.3% versus 29.7%, both $p < 0,01$), which was accompanied by improved performance of 6MWT in 2.1 times (from 194 ± 10,1 to 412, 5 ± 12m; $p < 0,001$) in pts with PPCM and 2.2 times (from 186 ± 12 to 412 ± 12.6 m; $p < 0,01$) for pts with idiopathic forms of the disease, which are accompanied by an improvement of the clinical condition by ACC (10 ± 0,3 to 3,4 ± 0,3 points and 9,9 ± 0,3 to 3,8 ± 0,2 points, both $p < 0,01$), a decrease FC HF (with 3,4 ± 0,1 to 1,7 ± 0,1 and 3,3 ± 0,1 to 1,6 ± 0,1; are both $p < 0.01$), respectively PPCM and IDCM. Basic therapy HF exerted similar effect on intracardiac hemodynamics, but reliable results were obtained in PPCM pts, increased on 23.2% (from 37 ± 1,3 to 45,6 ± 2% in particular left ventricular (LV) ejection fraction; $p < 0.001$) reduction in the EDD on 4.8% (from 6.5 ± 0.1 cm to 6,2 ± 0,1 cm; $p < 0.05$), the ESD on 15.2% (from 5,3 ± 0,1 to 4,6 ± 0,1 cm; $p < 0.001$) in comparison with idiopathic forms of DCM pts, LVEF increased only on 11.7% (from 34 ± 1,5 to 38 ± 1.6%, $p > 0.05$) with decreasing of ESD on 3.5% (from 5.8 ± 0.1 to 5.6 ± 0.1 cm; $p > 0.05$), while EDD LV practically unchanged. It should be noted that in 19 (38%) pts during treatment with PPCM fully normalized LVEF, which was not observed in the control gr.

Conclusions: Standard therapy for heart failure in 6 months have unidirectional impact on clinical and hemodynamic parameters in both grs, but pts suffering from PPCM showed a significant improvement in myocardial contractility and reduced linear size of the heart.

P1065

Cardiac troponinT in patients with dilated cardiomyopathy

E Martins[1]; A Sousa[1]; P Canedo[2]; L Lopes[3]; M Campelo[4]; B Moura[5]; S Amorim[4]; F Rocha Goncalves[1]; JC Machado[2]; J Silva Cardoso[1]
[1]Faculty of Medicine University of Porto, Porto, Portugal; *[2]Institute of Investigation and Innovation in Health of University of Porto, Porto, Portugal*; *[3]Garcia de Orta Hospital, Lisbon, Portugal*; *[4]H. São João, Porto, Portugal*; *[5]Regional Military Hospital n°1, Porto, Porto, Portugal*

On behalf of: FATIMA investigators

Funding Acknowledgements: Portuguese Foundation for Science and Technology [PTDC/BIM-MEC/0650/2012]

Background: Dilated cardiomyopathy (DCM) is a genetic heterogeneous entity, with variants described in more than 40 genes, including cardiac troponin T gene (TNNT2) in approximately 3% of the cases. As next generation sequencing becomes more widely available, establishing causality for genetic variants becomes increasingly relevant.

Purpose: We aimed to determine the genetic variations in TNNT2 in DCM patients.

Methods: We evaluated 107 unrelated patients with idiopathic DCM (iDCM) or familial DCM (fDCM). Detailed clinical data were obtained. Echocardiographic, resting and 24h-ECG and CMR parameters were collected. Molecular analysis included LMNA/C, MYH7, MYBPC3, TNNT2, ACTC1, TPM1, CSRP3, TCAP, SGCD, PLN, MYL3, TNNI3, TAZ and LBD3 genes. Patients with mutations in TNNT2 gene were comprehensively analyzed.

Results: Six variants in TNNT2 gene were found in 7 (6.5%) patients (5 men, men age 42 ± 13, 4 cases of fDCM). One variant has been previously described in a DCM family (Arg173Trp) and another in association with increased left ventricular (LV) thickness (Ala28Val). One variant (His109Tyr) was present in two patients. Two patients presented 2 genetic variants (TCAP Glu105Gln + TNNT2 His109Tyr and MYBPC3 Arg44His + TNNT2 Ser275Phe). Arg173Trp was classified as likely pathogenic and the remaining of uncertain significance.

Mean age at diagnosis was 31 ± 17 years (vs 39 ± 13 of the remaining patients, $p = 0.221$) and they were mildly symptomatic (5 in NYHA class I and 2 in class II). One had previous hospitalization from HF, one received an ICD and another had had previous heart transplant. Mean LVEDD was 60 ± 7mm (vs 64 ± 9m, $p = 0.257$), LV ejection fraction 40 ± 9% (vs 30 ± 11%, $p = 0.018$) and one patient presented right ventricular (RV) impairment. All were in sinus rhythm and one had left bundle branch block (LBBB). At a median follow-up of 20 months (IQR 13) none presented adverse events.

The patient with the likely pathogenic variant was a 53 year-old man, with fDCM, in NYHA class II that presented LBBB, RV dysfunction and underwent ICD implantation.

Patients with double variants, TCAP + TNNT2 (iDCM) and MYBPC3 + TNNT2 (fDCM), were both in NYHA class I; LVEF/LVEDD were 39%/61mm and 49%/61mm and neither had RV impairment; the latter presented noncompaction criteria and family history of death from HF.

Conclusions: In our series, variants in TNNT2 were more common than previously published. Our patients presented an early onset but, contrasting to the literature, they had higher LVEF and the clinical course was not very aggressive in most instances. This illustrates the uncertainties related to specific genotype/phenotype association and genetic causality in DCM.

Introduction: Decompensated heart failure and ventricular arrhythmias account for majority of sudden cardiac death cases in patients with heart failure due to nonischemic dilated cardiomyopathy (DCM). Myocardial fibrosis among other factors, such as inflammation, may substantially contribute to the development of life-threatening ventricular arrhythmias.

Purpose: The aim of the study was to evaluate the level of fibrosis biomarkers in patients with DCM and healthy controls, amount of myocardial fibrosis according to magnetic resonance imaging (MRI) and its relation to ventricular arrhythmias.

Methods: The study enrolled 35 patients with nonischemic DCM, NYHA class I-II (age 43.2 ± 13.6) and 19 healthy controls (age 29.2 ± 2.6). Heart rhythm disorders were assessed by 24-hour ECG monitoring in all patients. Markers of fibrosis - transforming growth factor $\beta 1$ (TGF-$\beta 1$) and matrix metalloproteinase 9 (MMP-9) were studied in all patients. High-resolution MRI was applied for 15 patients with an assessment of late gadolinium enhancement (LGE; 15-18 min after gadolinium introduction, dose 0.15 mmol/kg), scar zone volume percentage and its ratio to the grey zone.

Results: Total number of ventricular ectopic beats during Holter monitoring in DCM patients was 627 [35; 5246] beats/day. There was no significant difference in MMP-9 level between two groups: 944.3 [557.4; 1506] in DCM patients and 786.2 [434.8; 1331] ng/ml in healthy controls. Although insignificant, there was tendency to a lower level of TGF-$\beta 1$ in DCM patients: 100.2 [47.44; 141.3] ng/ml vs. 148[50.9; 160.4] ng/ml in healthy controls ($p = 0.11$). In DCM patients level of TGF-$\beta 1$ was associated with more frequent ventricular bigeminy and episodes of ventricular tachycardia ($r = 0.47$ and 0.36 respectively; $p < 0.05$). The presence of LGE in patients with DCM was accompanied by a higher level of MMP-9 ($p = 0.076$). According to high resolution MRI volume percentage of the scar zone was 2.7% [0.8; 10.8]. Its association with higher level of MMP-9 was also observed ($r = 0.55$; $p < 0.05$). Volume percentage of the scar zone and it's ratio to the grey zone correlated with the more frequent ventricular pairs ($r = 0.66$; 0.46 respectively; $p < 0.05$).

Conclusion: In the present study we showed association between the extent of fibrosis according to high resolution MRI and the laboratory markers of fibrosis. Both of them were connected to ventricular arrhythmia prevalence. Received data support the concept of myocardial fibrosis importance in ventricular arrhythmia development. Described parameters may be useful for risk stratification of sudden cardiac death in this group of patients and require further investigation.

P1068

Dilated cardiomyopathy with midrange ejection fraction at diagnosis: characterization and natural history

M Merlo[1]; P Gentile[1]; M Marco Gobbo[1]; B Pinamonti[1]; F Ramani[1]; G Barbati[1]; M Gigli[1]; D Stolfo[1]; G Sinagra[1]
[1]University Hospital Riuniti, Cardiovascular department, Trieste, Italy

Background: Heart Failure comprises a wide range of patients classified according to the Ejection Fraction (EF). Patients with a Left Ventricular EF (LVEF) in the range of 40–49% represent a 'grey area', defined as mid–range EF (HFmrEF). Few data on the characteristics and outcomes of HFmrEF patients are available, mostly in the specific group of dilated cardiomyopathy (DCM).

Aims: To define characteristics, evolution and prognosis of DCM patients with HFmrEF at diagnosis.

Methods and results: From 1988 to 2013 we analysed 959 idiopathic DCM patients consecutively enrolled. One hundred and seventy–five (18%) fulfilled the criteria for HFmrEF, while 637 patients had a EF'40%. At baseline, compared with patients

with reduced EF (HFrEF), HFmrEF presented features of a less advanced disease: lower NYHA III–IV classes (5 vs. 29% in HFmrEF vs. HFrEF group respectively, p<0.001), lower left bundle brach block (20 vs. 35%, p = 0.001), less left ventricular end–diastolic volume (69(59;82) vs. 100(81;123) ml/m2, p<0.001), lower rate of right ventricular dysfunction (9 vs. 21%, p = 0.003), of moderate–severe mitral regurgitation (13 vs. 42%, p<0.001), and of restrictive pattern (5 vs. 37%, p<0.001). Furthermore, during a median follow–up of 50(10;118) months, HFmrEF group presented a lower rate of all–cause mortality/heart transplantation (9.1% vs. 36% in HFrEF, p<0.001) and of sudden cardiac death or malignant ventricular arrhthmias (4.5% vs.15.2%, p<0.001). Finally 29 out of 175 HFmrEF patients (17%) evolved to HFrEF after a median follow–up of 70(25;43) months, consistently worsening their long–term prognosis.

Conclusions: HFmrEF identifies a consistent subgroup of DCMs diagnosed in an earlier stage and presenting an apparent better evolution. However, some HFmrEF DCMs patients evolve into HFrEF despite medical therapy and this evolutions leads a worse prognosis.

P1069

Continuous positive airway pressure (CPAP) effect on blood pressure in patients with obstructive sleep apnea syndrome (OSAS)

G Giorgiana Dediu[1]; A Balaceanu[1]; A Iancu[2]; G Aron[1]; S Rujinski[3]; M Bogdan[3]; I Dina[1]; C Diaconu[4]

[1]Emergency Clinical Hospital St John, Internal Medicine, Bucharest, Romania; *[2]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*; *[3]"Marius Nasta" Institute Of Pneumology, Bucharest, Romania*; *[4]Emergency Clinical Hospital Floreasca, Internal Medicine, Bucharest, Romania*

Introduction: Hypertension is present in 50% of patients with OSAS, many cardiologists claiming the need to evaluate the dipper / nondipper profile of patients. Currently several case-control studies showed the antihypertensive effect of CPAP therapy on hypertensive patients with OSAS.

Objectives: To assess the effect of CPAP on blood pressure in patients with OSAS.

Materials and methods: Interventional prospective study that enrolled 52 patients with OSAS. In all these patients, blood pressure was measured at the moment of inclusion in the study. From these 52 patients, 20 were hypertensive. Patients were divided into 2 groups: group A who received CPAP (24 patients) and group B without CPAP (28 patients). Patients were foloowed up at 3 and 6 months.

Results: 32 patients with OSAS had no hypertension, 20 patients were hypertensive. 7 patients with grade 3 hypertension had severe OSAS. From the group of hypertensive patients, 10 patients received CPAP (from group A) (from those 5 have severe OSAS and grade 3 hypertension) and 10 did not receive CPAP (from group B). 3 months after enrollment we observed that no patient from the CPAP group had grade 3 hypertension, from those with grade 2 hypertension one moved in the normal high blood pressure class. At six months, we observed that normotensive patients who received CPAP had the mean systolic blood pressures value decreased by 2 mm Hg.

Conclusion: In our study, 38,46% from the patients with OSAS were hypertensives. CPAP decreased the blood pressure values in hypertensive patients with severe OSAS. Even normotensive patients with OSAS had a reduction of blood pressure values with CPAP.

P1070

Features of left ventricular remodeling in patients with hypertensive cardiomyopathy with and without metabolic syndrome

K Chernyshova[1]; V Bondar[1]; E Yakimenko[1]; V Tbileli[1]

[1]Odessa National Medical University, Department of internal medicine, Odessa, Ukraine

Left ventricular remodeling (LVR) is the most characteristic cardiac damage in patients with hypertensive cardiomyopathy (HC) and influences on the course and prognosis. Left ventricular hypertrophy (LVH) is an independent risk factor for cardiovascular complications. However, the structural and functional features of cardiac remodeling in patients with HC and concomitant metabolic syndrome (MS) have been insufficiently studied. The purpose of our research was to study the characteristics of cardioremodeling processes in patients with arterial hypertension and hypertensive cardiomyopathy in the presence and absence of metabolic syndrome. We examined 128 hypertensive patients with HC and MS, which formed the basic group, and 112 hypertensive patients with HC without MS, which formed the control group. Patients in both groups were performed echocardiography with assessment of basic indicators and types of LV remodeling. Assessment of left ventricular diastolic function was performed in pulsed mode doplerEchoCG. Statistical significance of differences was determined using T-test and Fisher's criteria (φ). The results obtained exhibit more expressed signs of LVH by echocardiography data in the basic group compared to control ($p < 0,01$), the main indicators of LVH in hypertensive patients with HC and MS were: interventricular septum thickness was ($1,30 \pm 0,01$) cm, thickness of left ventricular posterior wall - ($1,26 \pm 0,01$) cm, left ventricular mass index - ($144,3 \pm 5,23$) g/m2. These results are related to chronic increasing of blood pressure, hormonal and metabolic disorders in MS. In hypertensive patients with HC and MS violations of left ventricular geometry were absent in 8 patients (6 %) compared with 15 patients in the control group (13 %) ($\varphi = 1,72$, $p < 0,05$). In patients of control group the incidence of concentric LVH was significantly higher compared to hypertensive patients with HC and MS, 67 people (60 %) compared with 60 patients (47 %), respectively ($\varphi = 1,85$, $p < 0,05$). However, eccentric LVH significantly was more frequent in basic group compared with the control, 56 (44 %) and 19 (17 %) patients, respectively ($\varphi = 4,25$, $p < 0,01$). Concentric left ventricular remodeling most rarely encountered in both groups: 11 patients (10 %) versus 4 (3 %), respectively ($\varphi = 2,09$, $p < 0,05$). Hypertensive cardiomyopathy in combination with metabolic syndrome is accompanied by more expressed cardioremodeling processes. Violation of LV geometry was significantly more frequent in hypertensive cardiomyopathy with metabolic syndrome. In the structure of violations as eccentric and concentric type of hypertrophy are equally often found. In addition, the presence of concomitant metabolic syndrome causes a more expressed diastolic dysfunction.

P1071

Plasma microRNA-155 as biomarker of left ventricular hypertrophy in chronic kidney disease patients. Preliminary study.

D Klimczak[1]; T Pilecki[2]; D Zochowska[2]; A Wirkowska[2]; M Kuch[3]; L Paczek[2]

[1]Medical University of Warsaw, Division of Heart Failure and Cardiac Rehabilitation , Warsaw, Poland; *[2]Medical University of Warsaw, Department of Immunology, Transplant Medicine and Internal Diseases. Transplantation Institute, Warsaw, Poland*; *[3]Medical University of Warsaw, Department of Cardiology, Hypertension and Internal Medicine, Warsaw, Poland*

Funding Acknowledgements: This project has received funding "Young Investigators Grant" from the Second Faculty of Medicine, Medical University of Warsaw in the year 2015-2016

Introduction: Emerging evidence indicates that microRNA play important role in regulation of myocardial growth and repair. Chronic kidney disease (CKD) patients are at increased risk of hypertension and left ventricular hypertrophy compared to the rest of population and may benefit from early diagnosis and interventions. One of prohypertrophic pathways includes angiotensin II acting via angiotensin II receptor type 1 (AGTR1). It has been observed that miR-155 negatively regulates the expression of that receptor. Therefore miR-155 expression level may vary depending on the presence of myocardial hypertrophy.

Aim: To assess the expression of microRNA-155 in plasma of chronic kidney disease patients and evaluate its relationship with left ventricular hypertrophy (LVH).

Material and Methods: We have enrolled 26 patients with stable CKD stage 2-5 (age:60,12 males) and 26 healthy age-matched control subjects (age 54,10 males) in the study. Quantification of plasma miRNA was performed with the use of real time quantitative polymerase chain reaction (RT-qPCR). Relative expression of investigated miRNAs compared with healthy volunteers was calculated using the delta delta Ct method. As the endogenous control we have chosen U6 snRNA. In every patient the left ventricular mass index (LVMI) was calculated based on the transthoracic echocardiography measurements. As LVH we have defined LVMI above 95 g/m2 in women and 115 g/m2 in men. Additionally, we performed 24-hour ambulatory blood pressure measurement in every participant.

Results: The expression of miRNA-155 was upregulated in CKD patients compared to control group (median expression relative to U6 snRNA was 3,39 (Q1-Q3=1.81-6.64). CKD patients had higher LVMI than control subjects (mean 133vs104 g/m2, p = 0.002), higher serum creatinine (1,9 vs 0,8 mg/dl, p = 0.0001), higher average day and night systolic blood pressure, SBP (129vs120, p = 0.008). The groups did not differ significantly in terms of age (p = 0,13) and sex. None of the patients had symptomatic heart failure. Due to non-normal distribution of miRNA-155 expression, we have performed a log transformation of its values. We have observed a trend towards positive correlation between log miR-155 and LVMI (r=0.18) but with no statistical significance (p = 0.37). Patients with LVH were older (62vs 8, p = 0.004) had lower GFR (51vs79 ml/min/BSA, p = 0.003), higher average SBP (127vs120 mmHg, p = 0.04), lower HDL (56vs71 mg/dl, p = 0.02), higher triglycerides level (145vs89 mg/dl, p = 0.001). The LVMI correlated significantly with GFR (r= -0.46,p = 0.001), and age (r=0.32, p = 0.023).

Conclusion: In this preliminary study plasma miR-155 was not associated with LVMI. This may be due to pleiotropic action of miR-155 and heterogenicity of CKD patients. As the study group is relatively small, further studies are necessary to confirm that results. Traditional risk factors seem to be more reliable indicators of LVH in CKD patients so far.

P1072

Circulationg fibrosis biomarkers and transcriptome profile in patients with hypertrophic cardiomyopathy

V Zaitsev[1]; A Runov[2]; M Vonsky[2]; A Gurshchenkov[1]; A Ryzhkov[1]; O Moiseeva[1]; L Mitrofanova[1]

[1]Almazov Federal Heart Centre, Saint Petersburg, Russian Federation; *[2]Institute of Cytology RAS, Saint Petersburg, Russian Federation*

Introduction: There are limited data on the prognostic significance of fibrosis in patients (pts) with hypertrophic cardiomyopathy (HCM). The aim of the study was to evaluate profile of circulating fibrosis biomarkers and candidate gene expression in myocardial tissues depending on the severity of myocardial remodeling in pts with obstructive HCM.

Materials and Methods: 15 pts (56,1 ± 9,7 yrs m:f 6:9). with obstructive HCM after septal myectomy were included. 10 pts without heart pathology were examined as control group (57.6 ± 0.8 yrs). ECHO, cardiac MRI with contrast enhancement, histological and immunohistochemical biopsy analysis, circulating fibrosis biomarkers (TGFß1, MMP-2,9, TIMP-1, galectin-3, sST2, CITP, PICP, PIIINP, NT-proBNP) were performed for all pts. Six candidate genes (MMP2, MMP9, TIMP1, TGFβ1, Gal3, SSTR2) were selected for the study. mRNA content was determined by quantitative PCR after RT-qPCR.

Results: Pts with HCM have max LVOT gradient (85 ± 20 mm Hg), max wall thickness (23 ± 6 mm), IMMLV (169 ± 72 g/m2) and late gadolinium enhancement (LGE) according MRI data. Increased serum PICP, PIIINP levels were revealed in pts with HCM in comparison with the controls. A positive correlation was found between NT-proBNP, galectin-3 and sST2 serum levels. Upregulated expression of MMP2, TIMP1, TGFß1, Gal3 genes was detected, while MMP9 and SSTR2 gene expression was downregulated in HCM myocardial tissue. We also found that downregulated MMP9 mRNA expression was associated with elevated serum MMP-9 level.

Conclusions: Better understanding of pathological processes in the myocardial tissue leading to fibrosis development might provide a clue for novel arrhythmia and heart failure outcomes biomarker discovery.

Clinical characteristics of patients

	Patients with HCMM± n=15	The control groupM± n=10
Galectin-3, ng/ml	8,70±1,28	6,54±2,14
MMP-2,ng/ml	275 (228;369)	306(255;323)
MMP-9,ng/ml	1483(1054;1827)	531(227;647)
TIMP-1, ng/ml	153,5±38,3	148,6±41,2
The ratio MMP-9/ TIMP-1	9,8(7,9;11,3)	5,2(3,2;9,9)
CITP, ng/ml	0,635±0,365	0,444±0,138
PICP, ng/ml	39(28;62)	15(14;20)
PIIINP,ng/ml	11,9(11,0;13,4)	6,6(2,5;8,5)

Pregnancy hypertension is alternative pathway for the development of heart failure.

S Bele[1]; A Rrugia[2]; E Petrela[3]; A Abazaj[2]

[1]University Hospital"Queen Geraldine" Tirana, Tirana, Albania; *[2]University Hospital"Koco Glozheni" , Tirana, Albania*; *[3]University Hospital Centre "Mother Theresa",Tirana, Tirana, Albania*

Background. The combination of increased pressure and volume in pregnancy hypertension explains may be the tendency to eccentric hypertrophy of the LV but it may represent the early manifestation of a cardiomyopathic process

Purpose: To assess heart's structural effects of pregnancy hypertension in the third trimester of pregnancy.

Methods: The study involved 250 pregnant women in the third trimester of pregnancy without hypertension and another disease before pregnancy. ECG, BP, weight gain, BMI, laboratory analyses have all been carried out. Echocardiographic evaluations were performed. Results: From the analysis of echocardiographic data resulted that in pregnancy hypertension eccentric and concentric ventricular remodelling occur with diastolic dysfunction and left atrial size is increased. Women with hypertension during pregnancy had significant altered diastolic function compared to normotensive, We found lower E/A ratio (p = 0,046),longer DTE (p = 0,003) and significantly longer IVRT (p < 0.001) lower Vp(p = 0.012) ,increase E/e′s ratio (p < 0.001). and E/e′l ratio (p < 0.001). LV end-diastolic(168 ± 29) and end-systolic(69 ± 1) volume increased during hypertensive pregnancy to normotensive (151 ± 16/ 58 ± 9); p < 0.001) but these women had normal systolic function. A significant statistical relation was found between LAV and geometric remodulation (r = -0.215, p = 00001) as well as between LAV and diastolic dysfunction (r = -0.267, p < 0.001).

Conclusions: In the present study, the EH of the LV may represent the early manifestation of a cardiomyopathic process. This alternative pathway for the development of heart failure is supported by studies that have demonstrated eccentric hypertrophy to be associated with more severe systolic dysfunction compared with concentric hypertrophy. In spite of the fact that this has not been observed in our cases, the possibility cannot be excluded that this form of the geometric remodeling might cover up a mute form of LV's contractile insufficiency.

P1074

Polymorphism of aldosterone synthase gene and left ventricular hypertrophy in patients with arterial hypertension and hypertensive cardiomyopathy

V Vadym Bondar[1]; K Chernyshova[1]; D Oliynyk[1]; V Vasilets[1]; N Chumachenko[1]; E Kobeleva[1]; V Tbileli[1]

[1]Odessa National Medical University, Department of internal medicine, Odessa, Ukraine

The activation and remodeling of renin-angiotensin-aldosterone system is very important in the pathogenesis of development and progression of hypertensive cardiomyopathy (HC) in patients with arterial hypertension (AH). The influence of polymorphisms of aldosterone synthase gene on aldosterone synthesis and degree of left ventricular hypertrophy (LVH) at the present time is actively studied.

The purpose of the study: the analysis of genotype distribution of the polymorphism C-344T of aldosterone synthase gene and assessment of degree of left ventricular hypertrophy depending on the presence of "normal" or "pathological" genotypes of this polymorphism in patients with arterial hypertension and hypertensive cardiomyopathy in Ukrainian population.

Materials and Methods: we examined 240 patients with AH and HC (ESC/ESH 2013). The analysis of polymorphism C-344T aldosterone synthase gene was determined by PCR. Subsequently, the patients were divided into two subgroups depending on the presence of "normal" (CC) or "pathological" (CT + TT) genotypes. In each subgroup we additionally studied the degree of LVH by echocardiography.

Results: and discussion: in the surveyed group of patients with AH and HC the frequency of "normal genotype" (CC) was (47,5%/114) patients, "pathological genotype" (CT + TT) – (52,5%/126), (p = 0,35). Subgroup 1 (CC) included 114 patients, subgroup 2 (CT + TT) - 126 patients. According to echocardiographic data, in subgroup 2 ("pathological genotype" CT + TT) IMMLV was (142,2 ± 3,4) g/m2, in subgroup 1 ("normal genotype" CC) IMMLV was (130,4 ± 3,2) g/m2, (p = 0,015). The presence of "pathological" genotype was accompanied by significantly more expressed left ventricular hypertrophy and high IMMLV.

Thus, in the surveyed group of patients with arterial hypertension and hypertensive cardiomyopathy in Ukrainian population the "normal" and "pathological" genotypes of polymorphisms C-344T of aldosterone synthase gene were observed with almost equal frequency. The presence of "pathological" genotype is associated with more expressed left ventricular hypertrophy and can be used to predict the severity of hypertensive cardiomyopathy in patients with arterial hypertension.

P1075

Acute left heart failure on pic hypertensive: impact afterload contractile function parameters left ventricular

NABILA Taleb Bendiab[1]; M Boucif Ghomri[1]; A Meziane Tani[1]

[1]University Hospital of Tlemcen, cardiologie, faculty of medicine, University of Tlemcen, Tlemcen, Algeria

Introduction: The appearance of a hypertensive acute pulmonary edema is often sudden , dramatic, and life-threatening. In acute heart failure with hypertensive crisis , signs and symptoms of heart failure are accompanied by high blood pressure and left ventricular systolic function is often preserved.

Materials and Methods: Prospective descriptive study of making a complete echo cardiographic analysis of systolic diastolic function in a total of 35 patients admitted for USIC crisis of acute pulmonary edema in hypertensive origin with a systolic blood pressure greater than 16mmHG and this during and after the crisis.

Results: Of the total , 22 were men and 13 women and the mean age was 65 + / - 12 years. Systolic blood pressure during the was 196 + / - 18 mmHg and after treatment 132 + / - 11.l. Pulse pressure was 70 mm Hg in sup 75% of our population. LVEF during the acute pulmonary edema was 49 % + / - 10 and after the disappearance of symptoms and pulmonary congestion it was 48 % + / - 8. Filling pressures were elevated in almost all patients during the crisis, the calculation of LV mass showed LVH in 28 patients often concentric characters.

Discussion: We found a similar LVEF during and after the crisis , elevated pulse pressure was observed in the majority of patients during the crisis Transient diastolic

heart failure related to the sudden rise of the post load is almost constant. because transient systolic heart failure and / or mitral regurgitation were rare in these patients.
Conclusion:: The occurrence of hypertensive acute pulmonary edema may be life-threatening. The Doppler echocardiography is systematic and , as in any acute heart failure, if possible within 48 hours, so as not to miss a transient systolic dysfunction or ischemic mitral regurgitation.

P1076
Immune-mediated myocarditis in fabry disease cardiomyopathy

AF Frustaci[1]; RV Verardo[2]; CG Grande[2]; NG Galea[1]; IC Carbone[1]; MA Alfarano[1]; MAR Russo[3]; CC Chimenti[1]
[1]Sapienza University, Department of Cardiovascular, Respiratory, Nefrologic and Geriatric Sciences, Rome, Italy; *[2]INMI-IRCCS "Lazzaro Spallanzani", Laboratory of Cellular and Molecular Cardiology, Rome, Italy*; *[3]San Raffaele Pisana Hospital IRCCS, MEBIC CONSORTIUM, Rome, Italy*

Background: Glycosphingolipid accumulation in Fabry cells generates a pro-inflammatory response that may influence disease evolution and responsiveness to enzyme replacement therapy (ERT).
Purpose: Evaluate incidence, mechanism and impact of myocarditis in Fabry disease cardiomyopathy (FDCM).
Methods: Myocarditis, defined as CD3+T-lymphocytes > 7/mm2 associated with necrosis of glycolipid-laden myocardiocytes, was retrospectively evaluated in endomyocardial biopsies of 78 patients with FDCM: 13 with maximal wall thickness (MWT) < 11 mm (Group 1), 17 with 11-15 mm (Group 2), 30 with 16-20 mm (Group 3), 18 with MWT > 20mm (Group 4). Myocarditis was investigated by polymerase chain reaction (PCR) for cardiotropic viruses, serum anti-heart, anti-myosin, antinuclear antibodies and cardiac magnetic resonance (CMR).
Results: Myocarditis was recognized at histology in 48 of 78 patients with FDCM: 38% of Group 1, 41% of Group 2, 66% of Group 3 and 72 % of Group 4. Myocarditis was characterized by positive anti-heart, anti-myosin and anti-nuclear autoantibodies and negative PCR for viral genomes. CD3+ cells/mm2 correlated with myocyte necrosis, anti-myosin autoantibodies' titer and MWT ($p < 0.001$; r=0.7912, $p < 0.001$; r=0.8476, $p < 0.001$ r= 0.6133 respectively). CMR showed myocardial edema in 24 out of 78 patients (31%): 0% of Group 1, 23% of Group 2, 37% of Group 3 and 50% of Group 4.
Conclusions: Myocarditis is detectable at histology in up to 56% of patients with FDCM. It is immune-mediated and correlates with disease severity. It can be disclosed by anti-heart/anti-myosin auto-antibodies and in advanced phase by CMR. It may contribute to FDCM progression and ERT resistance.

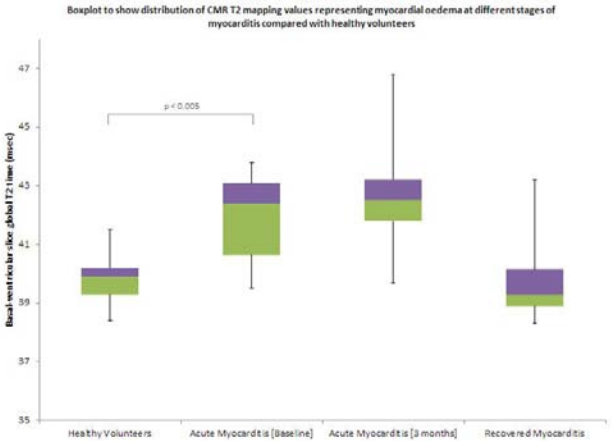
Background: Cardiovascular magnetic resonance (CMR) is a versatile imaging modality that allows assessment of myocardial oedema suggestive of active inflammation. Ongoing inflammation due to viral myocarditis is implicated in the progression to inflammatory dilated cardiomyopathy in one third of cases. Conventional CMR imaging relies upon qualitative visual analysis of T2-weighted images, but recent advances in T2 mapping have improved sensitivity and allow quantitative analysis on a pixel-wise level. In this study, we aimed to evaluate the role of T2 mapping to detect low-levels of ongoing cardiac inflammation at different stages of disease.
Method: Patients were recruited prospectively with confirmed acute myocarditis (chest pain, troponin elevation, unobstructed coronary arteries and CMR evidence of myocardial oedema; 11 inpatients, mean age 34±10 years, all male), and retrospectively with a past history of confirmed acute myocarditis (12 patients, mean age 35±13 years, all male, time from acute presentation 5.7±3.9 years). All patients underwent CMR on a 3T system (MAGNETOM Skyra, Siemens), and troponin-I and BNP were measured on the same day. Prospective patients were additionally re-assessed at 3-months. T2 mapping was performed using T2-prepared balanced steady-state free-single shot-images with 4 T2-prep times (0–75ms). TE/TR=1.1/2.5ms, flip-angle=35o, GRAPPA x2, 6/8ths partial Fourier, 1.9x2.2x8mm resolution, 360x285mm field of view. A global region of interest was manually drawn by a single blinded observer in the basal ventricular slice. Results were compared with 9 healthy volunteers (mean age 27±6 years, 56% male).
Results: In patients with acute myocarditis, mean global T2 was 42±1.4msec compared to 40±1.3msec in healthy volunteers ($p < 0.005$). No difference was found between T2 values at presentation and 3-month follow-up ($p = 0.1$) despite normalisation of troponin in all patients at 3 months. In the retrospective group, mean T2 had normalised to 40±1.5msec with preserved ventricular function, comparable to healthy volunteers. Unlike troponin, BNP remained mildly elevated in 3 patients (mean 23ng/mL) at 3 months, but none in the retrospective group.
Conclusion: Our findings suggest that T2 values remain persistently elevated at 3-months following acute presentation despite normalisation of cardiac troponin levels. Persistent inflammation is known to increase risk of relapse. Further investigation is required to assess whether T2 mapping provides a useful biomarker in this small but important subset of patients.



P1078
The effectiveness of immunosuppressive therapy in the virus-negative and virus-positive patients with lymphocytic myocarditis

OV Blagova[1]; AV Nedostup[1]; EA Kogan[1]; VA Sulimov[1]
[1]I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation

Purpose: to study short-term results and outcomes of antiviral and immunosuppressive therapy (IST) in patients with severe virus-positive and virus-negative myocarditis.

Methods: in 127 patients (81 male, 46.7 ± 12.7 years) with echocardiographic signs of dilated cardiomyopathy (mean left ventricle, LV, end-diastolic diameter, EDD, 6.3 [5.9; 7.0] cm, end-diastolic volume, EDV, 189.7 ± 73.9 ml, end-systolic volume, ESV, 135.8 ± 63.9 ml, LV ejection fraction, EF, 29.3 ± 10.7%, systolic pulmonary artery pressure, SPAP, 43.6 ± 16.4 mm Hg) myocarditis was verified by morphological and/or clinical study. For this purpose were performed morphological study of myocardium (35 endomyocardial biopsies, 12 intraoperative biopsies, 4 examination of explanted heart and 10 autopsies); anti-heart antibodies measurement as well as virus detection in the blood and myocardium (real-time PCR), Echo-CG, scintigraphy (n = 46), cardiac CT (n = 93), MRI (n = 29), coronary angiography (n = 53). We have identified two groups: patients with viral genome (parvovirus B19 and / or herpetic viruses) in the blood / myocardium (n = 52) and patients without virus genome (n = 75). They differ in LV EDD (6.7 ± 0.8 v 6.4 ± 0.7 cm), LV EF (25.9 ± 11.2 v 31.5 ± 9.8%) and SPAP (47.5 ± 16.3 v 40.7 ± 15.9 mm Hg), p < 0,01. The diagnosis of myocarditis was morphologically verified in 73.1% of virus-positive patients and in 30.7% of virus-negative patients.
Results: Pure viral myocarditis was diagnosed only in 7% of patients, immune - in 59%, mixed - in 34%. The anti-heart antibody level was equally high and did not differ significantly from the virus and the virus-negative-positive patients. Antiviral therapy (acyclovir, gancyclovir, IV immunoglobulin) allowed to achieve virus elimination from the blood in 81% of patients. IST was administered in 95 patients (34 virus-positive and 61 virus-negative): steroids (n = 63, 30 [22; 40] and 24 [16; 32] mg/day), hydroxychloroquine (n = 45, 200 mg/day), azathioprine (n = 8, 100 [75; 150] mg/day). At baseline IST and non-IST patients were differed by NYHA class (3 [2; 3] v 3 [3; 4]) and LV EF (30.3 ± 10.6 v 25.3 ± 9.2%), p < 0,05. The mean follow-up was 12 [6; 20] month. Significant (p < 0.05) decrease of LV EDD (6.5 ± 0.7 to 6.2 ± 0.7), SPAP (41.5 ± 16.2 to 34.4 ± 12.2), increase of LV EF (30.3 ± 10.6 to 39.2 ± 11.9), and significantly lower mortality (16.8% and 56.3%, p < 0.001; RR of all-cause mortality 0.55 (95%CI 0.38-0.80)) were found only in IST group. Significant changes of LV size and LVEF due to IST were achieved both in virus-negative and virus-positive patients. Virus-positive patients had significantly higher mortality (42.3 v 16.0%, p < 0.01, RR of all-cause mortality 2.64 (95% CI 1.44-4.86)) and the need for surgical treatment (67.7% and 37.3%, p < 0.01).
Conclusions: IST in patients with myocarditis is effective both with positive and negative viral genome in blood/myocardium; the presence of virus reduced effectiveness of therapy and was unfavorable prognostic factor.

Purpose: Myocarditis can result in dilated cardiomyopathy and heart failure. RAGE (receptor for advanced glycation end products) plays a central role in multiple inflammatory and autoimmune diseases generating oxidative stress and inflammatory responses. Soluble RAGE (sRAGE) comprising only the RAGE ectodomain mainly derives from proteolytic RAGE cleavage by the peptidase ADAM-10 (A Desintegrin and Metalloprotease-10) and MMP-9 (Matrix Metalloproteinase-9), which both can be inhibited by TIMP-1 (Tissue Inhibitor of Matrix Metalloproteases-1). sRAGE is regarded as an anti-inflammatory decoy receptor neutralizing RAGE ligands. Inhibiting RAGE activation via sRAGE has been shown to attenuate experimental autoimmune myocarditis. The aim of this study was to evaluate the serum levels of active ADAM-10 and MMP-9, their inhibitor TIMP-1 and sRAGE levels in patients with myocarditis and post-inflammatory dilated cardiomyopathy.
Methods: Serum samples from patients with endomyocardial biopsy proven acute or chronic myocarditis (n = 20) and patients with post-inflammatory dilated cardiomyopathy (n = 20) were analyzed for sRAGE, active ADAM-10, active MMP-9 and TIMP-1 by Western blot. Healthy volunteers served as controls (n = 20; age-matched). Endomyocardial biopsies were investigated by histopathological analysis and immunohistochemistry; viral genomes were detected by PCR and in situ hybridization.
Results: sRAGE serum levels were significantly decreased in patients with myocarditis as compared to healthy controls (46% decrease). Active ADAM-10 and active MMP-9 were also significantly decreased in myocarditis (-55% and -34% decrease versus healthy controls). TIMP-1 showed an opposite regulation with significatly increased serum levels in patients with myocarditis (50% increase versus healthy controls). In post-inflammatory DCM ADAM-10 and MMP-9-activity was restored, TIMP-1 levels decreased to levels similar to controls and sRAGE levels were significantly improved.
Conclusion: Myocarditis is associated with decreased levels of anti-inflammatory serum sRAGE, with decreased levels of sRAGE-producing active proteases ADAM-10 and MMP-9 and increased levels of their inhibitor TIMP-1 as a possible mechanism affecting sRAGE serum levels in this pathological setting. These new observations might help develop new diagnostic and therapeutic strategies in preventing autoimmune myocarditis.

Funding Acknowledgements: This study was supported by the Specific Masaryk University Research Grant MUNI/A/1270/2015.

Introduction: An improvement in left ventricular (LV) systolic function is seen in approximately 60% of patients with biopsy-proven inflammatory cardiomyopathy (ICM). The improvement in LV function should be associated with a better prognosis.
Objective: To evaluate changes in LV ejection fraction (LVEF) during the first year after the diagnosis of ICM and to assess the prognostic significance of early LVEF changes.
Patients and methods: 86 patients with biopsy proven ICM (77% men, 23% women), LVEF at diagnosis 24.3 ± 7.2%; mean age 44.5 ± 12.6 years, NYHA 2.5 ± 0.6, time from onset of symptoms to diagnosis was 2.3 ± 2.2 months. ICM was defined as the presence 14 LCA + cells/mm2 and / or >7 CD3 + cells/mm2 of the biopsy sample. Echocardiographic controls were carried out at the time of diagnosis (V0) and then in third (V3), sixth (V6) and twelfth (V12) months after diagnostic endomyocardial biopsy.
Results: LVEF improved in the 3rd month to 35.8 ± 9.5%, at 6 months to 39.3 ± 12.1% and in the 12 months to 42.2 ± 12.1% (all p < 0.001 versus baseline). Improvement in LVEF between the controls V0 and V3 were 11.4 ± 9.7% (p < 0.001) and created 63% of the overall improvement in the first year. LVEF increased by 3.8 ± 7.3% (p < 0.001) between controls V3 and V6, and by 1.8 ± 7.7% (p = 0.070) between the V6 and V12 visits. LVEF value at control V3 was a significant prognostic factor for occurrence of the combined endpoint (HR: 0.43; 95% CI: 0.28 to 0.66) based on the 10% increase in LVEF. Similarly, LVEF improvement by 10% between controls V3 and V0 has emerged as the significant prognostic factor (HR 0.51; 95% CI: 0.34 to 0.76).
Conclusion: LVEF improvement occurs dominantly in the first 3 months after the diagnosis which makes almost 2/3 of the entire improvement in one year follow-up. Absolute value of LVEF at 3-month control and the change of LVEF in first three months were proved as the predictors of long-term prognosis.

P1081

Immunomodulatory treatment reduces intramycardial inflammation in patients with virus-negative inflammatory cardiomyopathy resulting in an improvement of LVEF in long-term follow-up: A 10 years observ

F Felicitas Escher[1]; U Kuehl[1]; D Lassner[2]; W Poller[3]; C Tschope[1]; B Pieske[1]; H-P Schultheiss[2]
[1]Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; *[2]Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany*; *[3]University Heart Center Hamburg, Hamburg, Germany*

Aim: To analyse the long-term outcome after immunosuppressive treatment of patients with virus-negative chronic myocarditis or inflammatory cardiomyopathy (CMi).
Methods: and Results: We investigated 114 patients with endomyocardial biopsy (EMB)-proven virus-negative chronic myocarditis or CMi, who were treated with prednisone and azathioprine for 6 months. Myocardial inflammation was assessed by quantitative immunohistology (IH). We examined hemodynamic measurements after 6 month and long-term follow-up periods of up to 10 years (median 10.5 month [95% Confidence Interval (CI) 11.69 – 59.16]). At follow-up, the patients showed a significant improvement of left ventricular ejection fraction (LVEF) compared to baseline after 6 month period (LVEF rising from 44.6 ± 17.3% to 51.8 ± 15.5%, p = 0.006) and in the long-term follow-up (LVEF 52.1 ± 15.6%, p = 0.006). Simultaneously, EMB-analysis revealed significant reduction of quantified inflammatory infiltrates (CD3 + cells 16.03 ± 29.09 to 8.2 ± 9.0/mm^2, p = 0.002; CD2 + cells 12.62 ± 20.01/mm^2 to 6.61 ± 8.47/mm^2, p = 0.001; perforin + cells 3.94 ± 4.65/mm^2 to 1.03 ± 1.47, p = 0.0001), and cell-adhesion molecule HLA-1 (9.91 ± 5.55/Area Fraction (AF) to 6.65 ± 2.81/AF, p = 0.0001). In a subgroup analysis, Patients with initial LVEF ≤45% (n = 53) significantly increased with LVEF at follow-up (29.3 ± 8.8% to 41.7 ± 13.2% to 42.1 ± 13.1%, p < 0.0001, Group I), defined as CMi. Patients with initial LVEF >45%-60% (n = 25) significantly improved further or recovered completely,

regarding LVEF (53.0 ± 3.6% to 59.0 ± 9.4% to 59.8 ± 10.0%, p = 0.03, Group II). Patients with initial LVEF >60% (n = 36) remained stable and did not deteriorate over long-term follow-up (68.8 ± 6.7% to 67.5 ± 10.9% to 68.8 ± 10.7%, p = 0.5, Group III). Group II and III were defined as chronic myocarditis.
Conclusions: In patients with virus-negative chronic myocarditis or CMi we could show the effectiveness and beneficial effects of immunosuppressive treatment. Based on the normalization of the inflammatory process LVEF improvement is lasting for a long-term period of time.

Predictors for adverse events during hospitalization in patients with clinically suspected acute myocarditis: right ventricular systolic function and T wave inversion

D-G Dae-Gyun Park[1]; M-S Park[1]; W-W Seo[1]; S-E Kim[1]; J-H Lee[1]; K-R Han[1]; D-J Oh[1]
[1]Hallym University Kangdong Sacred Heart Hospital, Seoul, Korea Republic of

Background: Previous studies on biopsy-proven myocarditis referred to tertiary center could not reflect clinical course of acute myocarditis in real world due to selection bias. Purpose: we sought to determine predictors of serious adverse events, using serial check of electrocardiography, echocardiography and biomarkers during hospitalization in patients with clinically suspected acute myocarditis or myopericarditis.
Methods: We enrolled 20 patients admitted with clinical suspicion of acute myocarditis or acute myopericarditis. Coronary angiogram was performed to rule out acute coronary syndromes. We performed serially electrocardiography and echocardiography during hospitalization. Right ventricular systolic dysfunction (RVSD) was defined as decrease of tricuspid annular plane systolic excursion (TAPSE < 15 mm) or RV dilation. Cardiac enzymes, B-type nariuretic peptide (BNP), and inflammatory markers were measured. We defined serious events as death or percutaneous cardiopulmonary support (PCPS) use during admission. Results: Mean age was 42 years (male, 70%). Fuliminant myocarditis occurred in 5 patients (25%), of whom 3 patients survived. (PCPS) was applied to 3 patients, of whom one patient died. In total, six patients (30%) died within 3 months. Therefore, serious adverse events such as PCPS use and death occurred in 8 patients (40%). In all patients, mean value of initial left ventricular ejection fraction (LVEF), and septal wall thickness and posterior wall thickness were 41 ± 13%, 12.5 ± 3.0 mm, 12.5 ± 2.4 mm, respectively. We confirmed elevation of mean value of LV wall thickness and LV mass index at initial examination and subsequently significant decrease of mean value of LV wall thickness during follow-up examinations in all patients.. Especially, group without serious adverse event revealed significant decrease of LV wall thickness between initial and follow-up examinations, but group with serious adverse events did not. Those findings indicated recovery from initial edema in no adverse event group. RVSD at follow-up (serious adverse event group, 57% vs. no serious adverse event group, 0%; p = 0.009), absence of T wave inversion on serial electrocardiogram (25% vs. 83%; p = 0.019), peak creatine kinase-MB (132 ± 123 vs. 31 ± 32 ng/ml; p = 0.014), were significantly higher in group with serious adverse events than group without ones, but initial incidence of RVSD (62% vs. 17%; p = 0.052), initial LVEF, LVEF at follow-up (36.8 ± 20.3% vs 53.5 ± 14.7; p = 0.054), LV wall thickness, and BNP were not different statistically. Conclusions: During hospitalization in patients with suspected acute myocarditis, persistent RVSD might be a strongest predictor for serious adverse events such as death and PCPS use, whereas appearance of T wave inversion is suggestive of good prognosis.

P1083
Prospective study with acute myocarditis patients evaluated with cardiac magnetic resonance: meaning of temporal evolution of the imagiological findings

A Ana Marques[1]; I Cruz[1]; AR Almeida[1]; L Lopes[1]; S Alegria[1]; AC Gomes[1]; G Morgado[1]; I Joao[1]; M Ramalho[2]; H Pereira[2]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal; *[2]Hospital Garcia de Orta, Radiology, Almada, Portugal*

Introduction: The natural history of myocarditis remains variable and the predictors of unfavorable outcomes are unknown. The current european guidelines recommend the monitoring of these patients (pts) with both electrocardiogram (EKG) and echocardiogram. Cardiac magnetic resonance imaging (MRI) demonstrated an additional value in the diagnosis of acute myocarditis, however it´s prognostic value is not so well established, namely the presence and extension of late enhancement (LE).
Purpose: To evaluate the clinical evolution and the MRI findings of pts with myocarditis and to identify predictors of adverse events.
Methods: Prospective study with pts admitted in our center with the diagnosis of acute myocarditis according to symptoms, troponin elevation and MRI criteria (Lake Louise), since 1/2013. Selection of those who underwent clinical evaluation and MRI in two moments: acute episode and at least 6 months later (FUP).
Results: Of the 37 pts admitted with acute myocarditis, were included 20 that fulfill our criteria: 14 males (70%), mean age 26 ± 13 years, 3 pts (15%) with previous episode of myocarditis. At presentation 19 pts (95%) had chest pain; 17 (85%) mentioned prodromal symptoms. Only 1 patient evolved with atrial fibrillation and acute heart failure (HF). All pts were in sinus rhythm in the initial EKG, with ST segment elevation present in 16 pts (80%). The mean maximal troponin T was of 983 ± 136 ng/L (Reference value: < 13 ng/L). Coronary angiography was performed at 7 pts (35%), which excluded significant coronary lesions. In the initial MRI, all the pts had LE: 19 (95%) with subepicardial location, 2(10%) with intramyocardial location. FUP MRI was performed at 8.5 ± 6 months. There wasn't significant differences between the means of the left ventricular (LV) ejection fraction (55 ± 6% vs 56 ± 5%, p = 0.53), LV mass (57vs 54 g/m2, p = 0,35), LV end-diastolic volume (84 vs 82 mL/m2, p = 0.57), LV end-systolic (38 vs 36 ml/m2, p = 0.34) or LV systolic volume (47 vs 46 ml/m2; p = 0.76). 17 pts (85%) maintained areas of LE; as expected, there was a reduction in the number of segments with LE in 11 pts (55%) and this number was significantly lower in FUP MRI (4 ± 2.4 vs 2.6 ± 2.3; p = 0.011). In a mean follow-up of 594 ± 245 days, we registered 3 adverse events: 2 pts had very frequent symptomatic premature ventricular complexes and 1 patient evolved with new HF (NYHA class II symptoms). There wasn´t significant association between the occurrence of adverse events with the troponin value, presence of ST segment elevation or the MRI parameters analyzed, namely the presence, extension or location of the LE.
Conclusion: In this population, the rate of adverse events in the medium follow-up was very low and no independent predictors of adverse events were identified. It should be noted that, in most cases, the FUP cardiac resonance showed persistence of areas of enhancement which may constitute a pathophysiological mechanism for future adverse events.

Cardiopsychiatriy: the new cardioncology?

G George Joy[1]; M Bolstridge[2]; A Porras-Segovia[3]; E Whiskey[2]; S Shergill[1]; C Plymen[4]
[1]King's College Hospital, London, United Kingdom; *[2]South London and Maudsley NHS Foundation Trust, London, United Kingdom*; *[3]University of Granada, Granada, Spain*; *[4]Imperial College Healthcare NHS Trust, London, United Kingdom*

Introduction: Clozapine is the most effective drug for treatment-resistant schizophrenia, decreasing morbidity & mortality. Clozapine-associated tachycardia is a very frequent side-effect however, & a common reason for discontinuation of the drug. Studies have suggested that such tachycardia can indicate the development of myocarditis. We sought to look at our practice to determine how/what decisions were made by the reviewing cardiologists in those referred solely for tachycardia.
Method: Retrospective study of 16 referrals to a tertiary cardiology unit of patients whom had developed a tachycardia on starting clozapine: None had LV systolic dysfunction or evidence of myocarditis.
Results: Average heart rate (HR) on review was 105 ± 14bpm. All patients were in sinus rhythm. Median LVEF was 55%. There was no significant difference in HR in those with (109 ± 7bpm;31%) & without palpitation (107 ± 12bpml p = 0.43). 17 cardiologists were involved in decisions relating to patient management (mean visits 3.75). Rate control was used in 44%: Four different agents were used (Table 1). There was no significant difference in HR in those treated (102 ± 12bpm) vs untreated (112 ± 8bpm; p = 0.56.Fig 1). 40% of symptomatic patients were treated 45% of asymptomatic patients were treated. No patient died of cardiac causes during 6 years of follow-up.
Discussion: There are no guidelines to dictate management of clozapine tachycardia. Our study illustrates vastly varied treatment approaches to this complication. Decisions to treat appears to be clinician-dependant & not based on HR or symptomatology. When the decision to rate control was made, agent of choice also appears to be clinician dependent. Clozapine was often discontinued despite rate-control. Absence of clozapine use leads to a well-described higher mortality in treatment resistant schizophrenia, however the benefits of rate control in clozapine tachycardia is unknown. We propose a multidisciplinary approach to the management of those clozapine, similar to Cardioncology; the emerging field with proven positive patient outcomes. This would facilitate evidence based guidelines for all forms of clozapine cardiotoxicity and timely managment, taking into account the implications of stopping life saving psychiatric therapy.

Table 1

Rate control used	% (number) of clozapine tachycardia patients treated, total 9 (56%)	Treating HR (mean)

Assessment of trastuzumab effect on both ventricles by 2D speckle tracking analysis

K Keramida[1]; J Bingcang[2]; R Wensel[3]; P Nihoyannopoulos[4]
[1]Hammersmith Hospital, London, United Kingdom; *[2]Barts Health NHS Trust, Cardiology Department, London, United Kingdom*; *[3]West Hertfordshire Hospitals, NHS Trust, Watford General Hospital, Cardiology, London, United Kingdom*; *[4]Imperial College Healthcare NHS Trust, Hammersmith Hospital, London, United Kingdom*

Cardiac dysfunction as a complication of Trastuzumab therapy in patients with erb2-positive breast cancer is currently assessed by measurement of systolic function predominantly of the left ventricle (LV). Effects on right ventricular (RV) function are less well established. Thirty seven consecutive breast cancer patients with erb-2 overexpression (mean age 55 ± 13years) who received treatment with Trastuzumab were enrolled in this study. Echocardiographic examinations including 2-D, M-mode and tissue Doppler measurements, as well as 2D speckle tracking analysis performed at baseline and repeated after 2 months. In 22 of these patients (59,45%) Trastuzumab resulted in a significant reduction of LV Global Longitudinal Strain (LVGLS) from -21.66 ± 3.38 to -15.41 ± 7.78 (p = 0.001), as well as of RV Global Longitudinal Strain (RVGLS) from -20.53 ± 4.98 to -17.55 ± 4.58, (p = 0.008) and of RV free wall longitudinal strain (RVFWLS) from -24.82 ± 4.61 to -17.47 ± 5.31 (p = 0.045). However, common echocardiographic indices, such as LV ejection fraction (LVEF), Tricuspid Annular Plane Systolic Excursion (TAPSE) and S' wave of the tricuspid valve, as well as the dimensions of the RV were not significantly changed in these patients (Table 1). Furthermore, no significant correlation was found between ΔLVGLS (change) and ΔLVEF and similarly between ΔRVGLS and/or ΔRVFWLS and ΔTAPSE, ΔS' wave or ΔRV dimensions. In the 15 remaining patients (40,55%) LV and RV deformation mechanics and classical indices of systolic performance were not significantly changed after the first dose of transtuzumab (Table 2). Trastuzumab affects deformation mechanics of the RV simultaneously and in a similar way as the LV. Speckle tracking appears to be more sensitive than traditional echo indices in detecting this form of cardiotoxicity.

Carcinoid heart disease: the path to surgery

P Philippe Mortelmans[1]; MC Herregods[1]; F Rega[2]; E Van Cutsem[3]; P Timmermans[1]
[1]University Hospitals (UZ) Leuven, Cardiology, Leuven, Belgium; *[2]University Hospitals (UZ) Leuven, Cardiac Surgery, Leuven, Belgium*; *[3]University Hospitals (UZ) Leuven, Digestive Oncology, Leuven, Belgium*

Background: Neuroendocrine tumors can cause the rare carcinoid syndrome (0.5 -2.0 cases / million / year), characterised by diarrhea and flushing. Development of carcinoid heart disease with valve destruction is the major negative prognostic factor in these patients. The only effective cardiac treatment is valve replacement. However, the selection of candidates and determination of optimal timing remain unclear. Presymptomatic valve operation has not been associated with late survival benefit. Prospective trials are not available for this rare entity.
Purpose: We wanted to document the diagnostic process of carcinoid heart disease patients who underwent valve surgery, as well as their outcome and follow-up, in order to define gaps in current practice.
Methods: We retrospectively analysed the medical records of all carcinoid heart disease patients who underwent valve replacement in the largest tertiary cardiology and oncology center in Belgium between 2000 en 2016.
Results: All patients (n = 15), mean age 64, underwent tricuspid valve surgery. In 14 of them (93%) an additional valve was replaced, most often the pulmonary valve (n = 12). Two patients underwent quadruple valve replacement, one of them for proven left sided carcinoid involvement. Thirteen patients had liver metastases, and symptoms of heart failure were present in 87% (13/15) at the time of cardiac diagnosis. In hospital mortality was 27% (4/15). The survival after 3 and 12 months was 80% and 53% respectively. From those who left the hospital, 70% experienced an improvement of the functional status to NYHA I-II at time of the first follow-up. In patients who did not improve, mortality was 100% six months after surgery. Perioperative mortality was mainly due to infectious complications associated with prolonged critical illness. Thereafter, 3 cases were considered cardiac deaths. Mean preoperative right ventricular (RV) function (TAPSE) was better in the patients who survived more than 12 months (21mm) than in those who died between 3 to 12 months after surgery (16mm). The former group had a shorter mean interval from diagnosis of the carcinoid syndrome to cardiac diagnosis than the latter (13 versus 105 months). A lower mean preoperative chromogranin level was associated with a lower chance of perioperative death and a longer postoperative survival.
Conclusion: Mortality after valve surgery for carcinoid heart disease remains high. A possible cause is late cardiac referral of these oncology patients, whose generally poor condition makes differentiation between general fatigue and heart failure symptoms very challenging without echocardiography. We propose a systematic and multidisciplinary approach to all carcinoid syndrome patients. Our aim for the future is to identify an 'intermediate' group suitable for surgery. Patients with mild heart failure symptoms in combination with severe tricuspid regurgitation but without RV dilatation or dysfunction may be the target population.

Table P1085

Group 1(N=22)	Baseline	2 months after trastuzumab	p value	Group 2(N=15)	Baseline	2 monthsaftertrastuzumab	p value

P1087

Comparison between the two score systems of surveillance, epidemiology and end results (SEER) and national surgical adjuvant breast and bowel project (NSABP) in predicting the risk of trastuzumab-rela

SY Se Yong Jang[1]; JH Sohn[2]; JH Roh[1]; MH Bae[1]; JH Lee[1]; DH Yang[1]; HS Park[1]; Enter your textY Cho[1]; SC Chae[1]
[1]Kyungpook National University Hospital, Daegu, Korea Republic of; [2]Kyungpook National University Medical Center, Cardiology center, Daegu, Korea Republic of

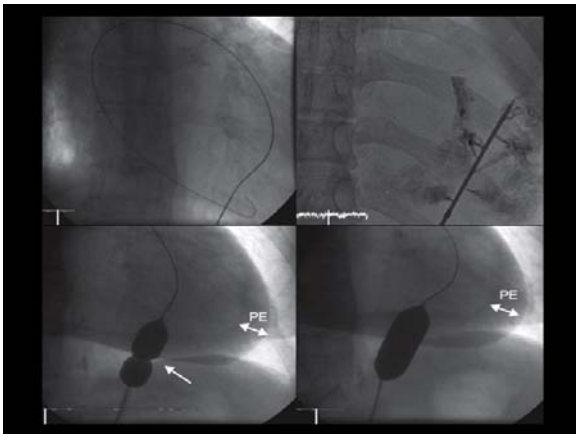
Background: Trastuzumab in an important treatment in patient with breast cancer and overexpress epidermal growth factor-2. Incidence of cardiac toxicity in patients treated with trastuzumab varies according to the patients factors. We aimed to compare two score systems of Surveillance, Epidemiology and End Results (SEER) and National Surgical Adjuvant Breast and Bowel Project (NSABP) in predicting the risk of trastuzumab induced cardiomyopathy in patients with breast cancer.
Methods: Among 458 consecutive patients who treated with trastuzumab between Mar 2011 and Apr 2015, 315 patients (314 female, mean age 51.1 ± 9.7) with breast cancer were available for calculating both score and included in present study. Cardiotoxicity defined as >15% absolute decrease in left ventricular ejection fraction (LVEF) from baseline and ≥10% decrease with LVEF below normal.
Results: During mean follow-up of 846 ± 471 days, 16 (6.0 %) patients experienced trastuzumab-related cardiotoxicity. Incidence of comorbid conditions which can be related to heart failure is low (e.g. 15.9% of hypertension, 5.7% of diabetes, 0.3% of coronary artery disease, 1.0% of heart failure, 0.6% of atrial fibrillation). Mean score of NSABP and SEER was 60.8 ± 14.2 and 2.2 ± 0.7. In univariate Cox proportional analysis model demonstrated only NSABP score is a significant predictor for cardiotoxicity. Receiver operating curve analysis showed area under curve of 0.715 and 0.501 for NSABP and SEER score in predicting trastuzumab-related cardiotoxicity. NSABP score showed better performance in predicting cardiotoxicity compared with SEER (p = 0.004).
Results: NSABP score predicts trastuzumab-related cardiotoxicity better than SEER score in patients with breast cancer and low-comorbidity, probably because SEER score is more largely based on comorbidity factors than NSABP score.

P1088

Minimally invasive treatment for malignant pericardial effusions with poor prognosis

FJ Francisco Javier Irazusta Cordoba[1]; S Jimenez-Valero[1]; D Gemma[1]; P Meras Colunga[1]; V Rial Baston[1]; O Gonzalez Fernandez[1]; AM Iniesta Manjavacas[1]; G Galeote Garcia[1]; A Sanchez-Recalde[1]; R Moreno Gomez[1]; JL Lopez-Sendon[1]
[1]University Hospital La Paz, Cardiology, Madrid, Spain

Introduction and purpose: It is becoming more prevalent in our hospitals to attend patients with right-sided heart failure symptoms due to malignant pericardial effusions. They also have a high recurrence rate after traditional treatment with pericardiocentesis. We sought to confirm the efficacy and feasibility of percutaneous balloon pericardiotomy (PBP) as the initial treatment of choice for these effusions.
Methods: Retrospective analysis of the clinical, echocardiographic, and follow-up characteristics of a consecutive series of PBP carried out in a single center in patients with advanced cancer and right-sided heart failure symptoms.
Results: Forty PBP were performed in 35 patients with a mean age of 61.8 years (55% females). Thirty-four patients had pathologically confirmed metastatic neoplastic disease (26 patients with tumoral cells in the pericardial liquid), seven of them have previously required pericardiocentesis, and in the remaining patients PBP was the first treatment for the effusion. All patients had a severe circumferential effusion (29mm by mean on transthoracic echocardiography [TTE]), and most presented evidence of hemodynamic compromise on TTE. In all cases, the procedure was successful, there were no acute complications, and it was well tolerated at the first attempt. There were no infectious complications during follow-up. One patient developed a large pleural effusion and in another one a pseudoaneurysm was observed in the right ventricle, even though none of them required further treatment. Eight patients needed a new pericardial procedure: 3 had elective pericardial window surgeries and 5 had a second PBP. Eighty per cent of patients died during follow-up (55,7 days by mean from the PBP) regarding their oncological disease
Conclusion: PBP is a simple and safe technique that can be effective in the prevention of recurrence in many patients with severe malignant pericardial effusion. The characteristics of this procedure make it particularly useful in this group of patients to avoid more aggressive, poorly tolerated approaches, since they have a very poor prognosis regarding to their oncological disease.



PBP

P1089

Acute kidney injury among patients hospitalized with acute decompensated heart failure: is it a frequent worsening factor of prognosis?

N Nabil Kraiem[1]; I Fomin[1]; DS Polyakov[1]; AR Vaysberg[1]; FY Valiculova[1]; MV Boldina[1]; NG Vinogradova[1]
[1]Nizhny Novgorod State Medical Academy, Department of internal medicine, Nizhny Novgorod, Russian Federation

Introduction: Major registries (ADHERE, ESC-HF Pilot) had showed that the presence of cardiorenal syndrome type 1 worsens prognosis of patients with acute decompensated heart failure (ADHF).
Purpose: To study the prevalence of acute kidney injury (AKI) among patients with ADHF and evaluate the prognosis of hospitalized patients
Methods: Between July/2014 and July/2015, we studied a total of 308 hospital cases with ADHF. Changed creatinine level (Cr) in 7 days (1.5 fold) or changed Cr for 26.5 μmol/L in 48 hours were diagnosis criteria of AKI.
Results: AKI was found in 23.1% of cases. Patients hospitalized with AKI had an intact hemodynamic: high blood pressure and preserved EF. In Multi variable analyze, AKI was negatively correlated with SBP level at admission (OR = 0.97; 95% CI 0.961-0.993; p = 0.005). Risk of hospital mortality among patients with AKI had a negative correlation with DBP at admission (OR=0.41; 95% CI 0.924-0.958 p < 0.001) and a positive correlation with maximal Cr level at admission (OR = 1.009; 95% CI 1.003-1.014 p = 0.002)
Conclusion: About one of four patients hospitalized with ADHF can develop AKI. Most important predictor of AKI was SBP at admission. Hospital mortality increases in 7.4 folds among patients with AKI (95% CI 2.8-19.3 p < 0.001). The predictors of hospital mortality among patients with ADHF and AKI are DBP and Cr level at admission.

variable	With AKI(n = 71)	Without AKI(n = 207)	P value
Males,%	53.5	43.5	0.14
Mean age, years	72.9±10.5	72.0±10.2	0.52
Cr. at hospitalization	137.0(105.5-182.0)	114.4(96.3-138.7)	< 0.001
Maximal Cr. at hospitalization	191.8(142.0-241.1)	125.3(105.0-149.7)	< 0.001

P1090

Importance of renal dysfunction in a heart failure clinic

D Daniel Seabra[1]; H Guedes[1]; P Silva[1]; L Marques[1]; A Andrade[1]; J Azevedo[1]; P Pinto[1]
[1]*Hospital Centre do Tamega e Sousa, Cardiology Department, Penafiel, Portugal*

Background/Introduction: Cardiovascular homeostasis is guaranteed by the multifactorial relationship between the heart and the kidney, namely by haemodynamic, neurohormonal and inflammatory pathways. Heart failure (HF) and chronic kidney disease (CKD) can co-exist and interaction between them may be critical for treatment approach and patient prognosis.
Purpose: To assess the clinical impact of CKD in patients (pts) with HF with reduced ejection fraction (EF).
Methods: We conducted a retrospective study based on a cohort of pts from a HF clinic of a single hospital center. Included pts with reduced EF and previous diagnosis for, at least, six months. Divided in two groups: with CKD (GA) (defined as glomerular filtration rate ≤ 60mL/min/1.73m2) and without CKD (GB).
Appraised clinical characteristics and major cardiac events – hospitalization from HF (hospHF) or acute coronary syndrome (hospACS) and death from cardiovascular (CVm) and non-cardiovascular (nCVm) cause. Evaluated the relationship with anatomical and function aspects of left ventricle, namely size (indexed left ventricle end-diastolic diameter [LVEDDi]) and left ventricle EF (LVEF) in follow-up (FU).
Results: Included 290 pts, with a mean age of 60.56 ± 13.25 years and male predominance (75.2%). Noted a prevalence of 41% of ischemic etiology. The mean initial EF was 29.2 ± 10.8%. The FU was 39.9 ± 18.5 months with a mean EF during FU of 34.9 ± 12.5%.
GA formed by 92 pts and 198 in GB. GA was associated with female pts (43.1 vs 28%; p 0.017), higher age (67.7 vs 57.2 years, p < 0.001), lower height (164 vs 166 cm, p 0.032) and weight (73.6 vs 77.8 Kg, p 0.016).
CKD was significantly linked with arterial hypertension (p < 0.001) and diabetes mellitus (p < 0.001). There were no significant differences regarding the etiology of HF. The presence of atrial fibrillation (AF) correlated positively with the CKD (65 vs 21 pts; p 0.023). During the FU, GA had higher LVEDDi (34.46 vs 32.66 mm/m2, p 0.008) and significantly inferior LVEF (30.9 vs 36.8%, p < 0,001). Noted a superior number of major clinical events in pts with CKD - hospIC (p < 0.001), CVm (p 0.003) and nCVm (p < 0.001). The presence of CKD limited treatment with angiotensin-converting-enzyme inhibitor and mineralocorticoid receptor antagonists (p < 0.001) but was closely related with greater use of diuretic therapy (p < 0.001). The presence of CKD was associated with worse functional class (p < 0.001).
Conclusion(s): In this population, CKD is associated with cardiovascular risk factors such as hypertension and diabetes, as expected; however, it is noteworthy the relation with female gender and less height or weight. AF is associate with CKD and ventricle size and function appears to be important in cardiorenal link. Coexistence of HF and kidney disease hinders treatment and affects prognosis.

P1091

Treatment of anemic patients with chronic heart failure and chronic kidney disease: criteria of effectiveness

G Ganna Tytova[1]; O Liepieieva[2]; N Ryndina[1]; M B Teclebrhan[1]
[1]*Kharkiv National Medical University, Kharkiv, Ukraine*; [2]*City clinical hospital #27, CCU, Kharkov, Ukraine*

Anemia and renal dysfunction are common comorbid conditions associated with poor prognosis in patients with chronic heart failure (CHF).
Purpose: To analyze the predictive value of clinicoanamnestic indicators due to therapy effectiveness of anemia with CHF and CKD using an oral form of Fe(III)hydroxide complex polymaltose for optimization and providing an individual approach to every patient.
Materials and methods: 68 pts with CHF II-IV FC due to IHD and CKD II-III st. were exemined. Among the causes of CKD were: chronic pyelonephritis in 50 pts, diabetic nephropathy in 18 pts. All pts with CHF and CKD had anemia. Hb level was within 78-91g/l. Diagnosis of anemia was determined by criteria of the Medical Committee of Standards of Hematology (ICST,1989). CHF FC was established by NYHA. Availability and stage of CKD was determined according to the National Kidney Foundation USA (NKF) K/DOQ classification. Pts with CHF and CKD were treated according to the standards. Pts with anemic syndrome received Fe(III)hydroxide polymaltose complex 100 mg orally 1-2 times a day. Hb target level was within 110-120 g/l. The observation period was 3 months. Evaluation of prognostic properties was performed using non-uniform procedures Wald-Genkina. All signs were distributed by gradient with subsequent calculation of prognostic factors (PF) and the general informative features (I).
Results: To assess the prognostic value of clinicoanamnestic parameters, pts (n = 68) that received Fe(III) hydroxide polymaltose complex, at the end of treatment were divided into 2 groups: a) with good antianemic effect (n = 50)-achieved the target level of Hb;b) a satisfactory effect (n = 18)-Hb levels approach to the target one. Very high informational content (I≥6,0) is given to the duration of CHF(I = 9.55),CHF FC (I = 8.03),cardiac cachexia syndrome (I = 7.16). High predictive value (6,0>I≥1,0) to the severity of anemia (I = 5.88),lower extremities edema and dyspnea (I = 5.60), acute myocardial infarction (I = 1,94),post-infarction left ventricular aneurysm (I = 2.82),patient age (I = 2.50),severity of CKD (I = 3.28) and the presence of type 2 diabetes mellitus (I = 1.16). Moderate predictor properties (1,0>I≥0,50) identified in relation to BMI (I = 0.82),history of stroke (I = 0.76) and the presence of permanent atrial fibrillation (I = 0.50).
Conclusion: Clinicoanamnestic indicators revealed a high predictive informational content about the effectiveness of therapeutic correction of anemia with CHF and CKD using an oral form of Fe(III)hydroxide polymaltose complex that allows to include them into predictive algorithms. Most informative criteria: the duration and severity of CHF, cardiac cachexia formation on a background of biventricular cardiac decompensation, progression of renal dysfunction, severity of anemia, which leads to the desirability and feasibility of application of these criteria at all levels of preventive and curative care with the aim of stratification effectiveness of treatment strategies.

P1092

Renal filtration function in patients with chronic heart failure and permanent atrial fibrillation depending on left ventricle ejection fraction.

N Natalia Koziolova[1]; E Polyanskaya[1]; S Berestneva[1]; M Surovtceva[1]
[1]*Medical Academy, Perm, Russian Federation*

Aim: to evaluate renal filtration function in patients with chronic heart failure (CHF) and permanent atrial fibrillation (AF) depending on left ventricle ejection fraction (LV EF).
Methods and materials: 60 patients with CHF and permanent AF were examined. Renal filtration function was evaluated using serum creatinine, estimated glomerular filtration rate (eGFR) by CKD-EPI, and serum cystatin C level. Patients were divided into 3 groups depending on LV EF. The first group consisted of patients who had reduced LV EF < 40% (HFrEF, the average mean 37,2 ± 4,0%); the second one was of patients with mid-range LV EF from 40 to 49% (HFmrEF, the average mean 46,7 ± 5,2%); and the third group included patients with preserved LV EF ≥ 50% (HFpEF, the average mean 57,1 ± 3,8%).
Results: in the group of HFrEF the average serum creatinine was 96,5 ± 14,3 umole/L, eGFR 53,6 ± 7,9 mL/min/1.73m2; cystatin C level 2211,2 ± 128,8 mg/mL. In the second group with patients who had HFmrEF, the average serum creatinine was 91,3 ± 10,7 umole/L, eGFR 59,1 ± 6,4 mL/min/1.73m2; cystatin C level 1873,4 ± 220,6 mg/mL. In the group of HFpEF the average serum creatinine was 77,4 ± 9,9 umole/L, eGFR 63,0 ± 8,5 mL/min/1.73m2; cystatin C level 1405,2 ± 374,5 mg/mL. Statistics analysis with comparison of three groups showed reliable difference in cystatin C level (pmg = 0,004). There were no reliable differences between groups in serum creatinine and eGFR (pmg = 0,611 icy; pmg = 0,098, respectively).
Conclusion: In patients with CHF and permanent AF, worsening of renal function injury (evaluated using cystatin C) revealed along with decrease of LV EF. Levels of both creatinine and eGFR (CKD-EPI) did not have any correlation to LV EF in these patients.

P1093

Risk factors of cardiorenal syndrome at the patients with a chronic heart failure and preserved ejection fraction (HFpEF)

D Dina Shorikova[1]; E Shorikov[1]
[1]*Bucovinian State Medical University, Chernivtsy, Ukraine*

Purpose: to study probability of cardiorenal syndrome development due to the nontraditional risk factors at the patients with a chronic heart failure and preserved ejection fraction (HFpEF) in the Bukovina region (Ukraine).
Methods: 594 patients, all the inhibitants of Bukovina region of Ukraine, with HFpEF, the same anamnesis and severity were included in cohort study. During the 5-year period of investigation (2008-2012) the episodes of glomerular filtration reduction (less than 60 mg/ml/min*1,73m2) were fixed in protocol. It was used a case-control method, tables 2×2, χ^2 criterion, analisys of relative risk (RR) and odds ratio (OR).
Results: At the patients with weight index more than 25,0 kg/m2 RR of kardiorenal syndrome was 1,76 [1,18-2,61], OR - 1,95 [1,22-3,11]. Among nontraditional risk factors estimated the significance of fibrinogen level more than 3,0 g/l (RR - 1,50 [1,02-2,19], OR - 1,75 [1,15-2,66]), prothrombin index (RR - 2,66 [1,11-6,41], OR 2,84 [1,13-7,13]) and increase systolic pressure at the pulmonary artery (RR -2,84 [1,94-4,14], OR - 6,64 [3,51-12,5]). It was, also, set the reliable negative correlation between glomerular filtration and glycated hemoglobin level r = -0,56 (p < 0,05).
Conclusions: Cohort study of patients with HFpEF was shown the reliable risk of low glomerular filtration rate depending of the body mass index, fibrinogen level, prothrombin index, pulmonary artery pressure and glycated hemoglobin.

P1094

Effect of contrast-induced acute kidney injury on long-term outcomes of percutaneous coronary intervention

E Elena Vershinina[1]; AN Repin[1]
[1]*State Research Institute of Cardiology of Tomsk, department of rehabilitation, Tomsk, Russian Federation*

Purpose of the study: determine the impact of contrast-induced acute kidney injury (CI-AKI) on overall survival, survival without fatal cardiovascular events and rate of development large adverse cardiovascular events (MACE: cardiovascular death, acute coronary syndrome, stroke).
Materials and methods: retrospective study including 148 patients who were directed for elective percutaneous coronary intervention from 2009 to 2011. CI-AKI was diagnosed and classified according to RIFLE-AKIN criteria. The risk of CI-AKI was evaluated on a scale R. Mechran. Prevention of contrast-induced nephropathy (CIN) was carried according to the recommendations for the prevention of contrast-induced nephropathy ESC 2010. Long-term outcomes were evaluated in 5-7 years after these interventions.
Results: CI-AKI was found in 23 patients (15.5%), which had an increase in serum creatinine at the 37.8 ± 19.7 umol/l (42.5%). In the analysis of long-term outcomes found that after seven years of follow-up after interventions overall survival in the group of patients without CI-AKI was 87.6%, in patients with CI-AKI - 70%, the rate of survival without fatal cardiovascular events in the group of patients without CI-AKI was 89.4%, in patients with CI-AKI - 80%, the frequency of large cardiovascular events (MACE) in the group of patients without CI-AKI was 39.8%, in patients with CI-AKI - 45%. According to the analysis of Kaplan-Meier curves long-term overall survival and survival without fatal cardiovascular events after endovascular coronary intervention in patients without the development of periprocedural CI-AKI was significantly higher than in the group of patients with CI-AKI ($p \leq 0.05$). Conversely, frequency of large cardiovascular events (MACE) was significantly higher in the group of patients with CI-AKI compared the group without the periprocedural CI-AKI ($p \leq 0.05$).
Conclusion: development of periprocedural CI-AKI associated with adverse long-term outcomes after percutaneous coronary intervention.

P1095

Renal function injury in patients with chronic heart failure and permanent atrial fibrillation depending on brain natriuretic peptide.

N Koziolova[1]; E Polyanskaya[1]; S Berestneva[1]
[1]*Medical Academy, Perm, Russian Federation*

Aim: to study interconnection between renal function injury and NT-proBNP in patients with chronic heart failure (CHF) and permanent atrial fibrillation (AF).
Methods: and materials: 60 patients with CHF and permanent AF were examined. Renal filtration function was evaluated using serum creatinine, estimated glomerular filtration rate (eGFR) by CKD-EPI, and serum cystatin C level. Patients were divided into 3 groups depending on NT-proBNP level. The first group consisted of patients who had NT-proBNP < 125 ng/mL (18.3% of all); the second one was of patients with NT-proBNP from 125 to 800 ng/mL (46.7% of all); and the third group included patients with NT-proBNP >800 ng/mL (35.0% of all).
Results: in the group of NT-proBNP of normal range the average serum creatinine was 83,72 ± 10,05 umole/L, eGFR 68,82 ± 13,18 mL/min/1.73m2; cystatin C level 1063,41 ± 350,11 mg/mL. In the second group with patients who had NT-proBNP 125-800 ng/mL, the average serum creatinine was 86,79 ± 13,15 umole/L, eGFR 61,10 ± 14,83 mL/min/1.73m2; cystatin C level 1568,75 ± 231,64 mg/mL. In the group of NT-proBNP >800 ng/mL the average serum creatinine was 91,90 ± 11,51 umole/L, eGFR 52,22 ± 20,17 mL/min/1.73m2; cystatin C level 1911,76 ± 414,33 mg/mL. Statistics analysis with comparison of three groups showed reliable difference in cystatin C level (pmg < 0,001). There were no reliable differences between groups in serum creatinine and eGFR (pmg = 0,330 icy; pmg = 0,150, respectively). Correlation analysis showed moderate indirect interconnection between NT-proBNP and eGFR (r=-0,51, p = 0,003); and moderate direct interconnection between NT-proBNP and cystatin C (r=0,60, p < 0,001).
Conclusion: In patients with CHF and permanent AF, the progressive worsening of renal function injury (evaluated using cystatin C) revealed along with myocardial stress increase according to NT-proBNP.

P1096

Characteristics, treatments and outcomes of hospitalized and ambulatory heart failure patients with chronic obstructive pulmonary disease in the ESC heart failure long-term registry

M Canepa[1]; PL Temporelli[2]; A Rossi[3]; C Laroche[4]; S Anker[5]; MF Piepoli[6]; AJ Coats[7]; L Tavazzi[8]; A P Aldo Pietro Maggioni[9]
[1]*University of Genoa, Cardiology Unit, Department of Internal Medicine, Genoa, Italy*; [2]*IRCCS Fondazione Salvatore Maugeri, Cardiology Division, Veruno, Italy*; [3]*University of Verona, Department of Medicine, Verona, Italy*; [4]*European Society of Cardiology, EURObservational Research Programme, Sophia-Antipolis, France*; [5]*University Medical Center Göttingen (UMG), Innovative Clinical Trials, Department of Cardiology & Pneumology, Göttingen, Germany*; [6]*Polichirurgico Hospital G. da Saliceto, Department of Cardiology, Piacenza, Italy*; [7]*Australia and University of Warwick, Monash University, Coventry, United Kingdom*; [8]*Maria Cecilia Hospital, GVM Care&Research – ES Health Science Foundation, Cotignola, Italy*; [9]*ANMCO Research Center, Florence, Italy*

On behalf of: ESC-HFA LT HF Registry Investigators

Background. Chronic obstructive pulmonary disease (COPD) is a common comorbidity that worsens the clinical course of heart failure (HF), both in the acute and chronic phases of the syndrome.
Purposes: To describe characteristics, treatments and 1-year outcomes of hospitalized HF (HHF) and chronic HF (CHF) patients with and without COPD enrolled in the ESC HF Long-Term registry.
Methods: This observational registry enrolled HHF and CHF patients presenting to participating European centers from May 2011 to April 2013. Diagnosis of COPD was based on medical history and/or spirometry. Characteristics, treatments and outcomes of HHF and CHF patients with and without COPD were compared using Student's t-test or chi-square test as appropriate, and the independent association of COPD with clinical outcomes was assessed with multivariate Cox analysis.
Results: The registry included 6920 HHF and 9409 CHF patients, with a prevalence of COPD of 19% and 14%, respectively. In both groups, patients with COPD were older, more frequently men, with a worse clinical status and a higher prevalence of comorbidities, including atrial fibrillation, diabetes and renal dysfunction ($p < 0.001$ for all). Left ventricular EF was greater than 45% in about 25% of patients, more frequently in COPD than non-COPD HHF patients (38 vs. 32%, $p < 0.001$) but similarly in CHF patients (23 vs. 23%). At baseline both HHF and CHF with COPD were taking more diuretics, aldosterone antagonists and digitalis than non-COPD. In HHF, the increase at discharge in the use of disease-modifying drugs was greater in non-COPD than in COPD for ACE inhibitors (+14% vs. +7%), beta-blockers (+21% vs. +12%) and aldosterone antagonists (+21% vs. +17%). In CHF patients, beta-blockers were used more frequently in non-COPD patients (90% vs. 82%), balanced by a less frequent use of ivabradine (8% vs. 12%) ($p < 0.001$ for both). At 1-year follow-up, hospitalizations were more frequent in COPD than non-COPD, both in HHF (all-cause: 50% vs. 43%, for HF: 32% vs. 25%, $p < 0.001$) and CHF patients (all-cause: 36% vs. 27%, for HF-cause: 17% vs. 12%, $p < 0.001$). Multivariate analysis confirmed COPD as independently associated with hospitalizations both in HHF (all-cause: 1.16 [1.04-1.29], for HF: 1.22 [1.05-1.42]) and CHF patients (all-cause: 1.26 [1.13-1.41], for HF: 1.37 [1.17-1.60]). All-cause but not CV mortality was higher both in HHF (35% vs. 26%) and CHF patients (11% vs. 8%, $p < 0.001$ for both) with COPD, but this association was not confirmed in both groups after adjustment (p 0.11).
Conclusions: In both HHF and CHF, COPD was associated with a worse clinical profile. There was a gap in disease-modifying treatments between patients with and without COPD, which widened in HHF after hospitalization. COPD was independently associated with an increased risk of both all-cause and HF hospitalizations, but neither in HHF nor in CHF an independent association with all-cause mortality was observed at 1-year follow-up.

P1097

Endothelial function in patients with tobacco and biomass smoke-related chronic obstructive pulmonary disease

G K Perez Cortes[1]; A Orea-Tejeda[2]; DG Gonzalez-Islas[2]; AG Jimenez-Cepeda[2]; L Verdeja-Vendrell[2]; AG Navarrete-Penaloza[2]; RN Sanchez-Santillan[2]; V Pelaez-Hernandez[2]; B Robles-Uribe[2]; FA Figueroa-Herrera[2]; SC Torres-Montiel[2]
[1]*Universidad Autonoma Benito Juarez de Oaxaca, Faculty of Medicine and Surgery, Oaxaca de Juarez, Mexico*; [2]*Instituto Nacional de Enfermedades Respiratorias Ismael Cosio Villegas, Heart Failure and Respiratory Distress Clinic, Mexico City, Mexico*

Background: Endothelial dysfunction (ED) is characterized by impaired bioavailability of vasoactive substances, favoring inflammation, vasoconstriction, increased vascular permeability, platelet aggregation, thrombosis and atherosclerosis. It is also an independent predictor of cardiovascular events. ED is highly prevalent in patients with COPD caused by tobacco (TS) and biomass (BS) smoke. These are the leading etiologies of COPD in Mexico. However, it is unknown whether there is a difference in ED between both etiologies of COPD.
Purpose: To assess the differences in endothelial function among COPD patients from tobacco and biomass.
Methods: A cross-sectional study was conducted in ambulatory patients (age 18 or older) with a diagnosis of COPD GOLD I-III. Subjects with mixed COPD etiology were excluded. Patients were divided into COPD by TS or BS, and underwent medical history and physical examination. ED was assessed using photoplethysmography. Endothelial dysfunction was considered with a pulse wave time of maximum amplitude / total time (TMA/TT) index ≥0.30. Multiple linear regression was performed to

determine the effect of the type of COPD on endothelial function.
Results: 97 patients were evaluated (age: 72.16± 9.95 years), of whom, 53.6% were women. In the BS group, women predominated (90.7% vs 24.1%, p < 0.001), they were older (76.1± 9.1 vs 69.0± 9.5, p < 0.001), had a higher prevalence of hepato-jugular reflux (50 % vs. 20.7%, p=0.022), and history of heart failure (30.2% vs. 16.7%, p=0.113), compared to those in the TS group. The overall prevalence of ED was 78.9%. Prevalence rate was higher in those with BS compared to TS (83.7% vs 75 %, p=0.299), although according to multiple linear regression, patients with BS had 0.04 more TAM/TT index than TS subjects (β: 2.5, CI 95 %; 1.2-3.7, p <0.001).
Conclusions: ED is higher in patients with COPD from biomass smoke than in patients from tobacco smoke. Although, the prevalence between the two groups was not statistically different, the patients in the BS group had a higher prevalence of heart failure, especially right heart failure.

Relationship between endothelial dysfunction and forced expiratory volume in first second (FEV1) in chronic obstructive pulmonary disease patients

RNSS Rocio Nayeli Sanchez Santillan[1]; GID Gonzalez Islas Dulce[1]; AOT Orea Tejeda Arturo[1]; VVL Verdeja Vendrell[1]; NPA Navarrete Penalosa[1]; PHV Pelaez Hernandez Viri[1]; RUB Roble Uribe B[1]; FHA Figueroa Herrera A[1]; TMS Torres Montiel S[1]; PCE Perez Cabanas E[1]; HCR Hernandez Zenteno R[1]; FTF Flores Trujillo F[1]; IVO Infante Vazquez O[1]; MMR Martinez Memije R[1]
[1]National Institute of Respiratory Disease "Ismael Cosio Villeagas", Heart Failure and Respiratory Clinic , mexico cityt, Mexico

BACKGROUND: The characteristic of Chronic Obstructive Pulmonary Disease (COPD) is the chronic inflammation in the small airways and alveoli, this takes to a limitation of the flux that is not reversible. Cardiovascular disease especially heart failure (HF) represents a high mortality and morbidity, being the cause of a worst prognostic in these patients. Has recently been found that an injury of the endothelium can contribute to emphysema and COPD and indirectly relates that the damaged in the pulmonary vasculature can developed such emphysema and COPD.
Purpose: To evaluate the relationship between endothelial dysfunction and respiratory function in patients with COPD and HF.
Methods: Cross sectional study, with 117 patients. The endothelial function was determined by Photopletysmography evaluating the amplitude, maximum amplitude time (MAT), total time of wave (TT), and the relation between both MAT/TT index, >30 was considerate as endothelial dysfunction.
Results: We evaluated 117 patients (mean age 71.4 + 11.09), the 60.7% of them had endothelial dysfunction (ED), and 56.8% were female. Those patients with ED have higher prevalence of cardiovascular disease (47.9% vs 9%, p=0.005), Pulmonary Arterial Hypertension (PAH) 21.6% vs 3% comparing it with those without ED. No significance difference were found in sex, age, weight, high, arterial hypertension, diabetes, obesity. A linear regression determined that these patients with ED has 11 % less of FEV1 comparing with those without ED. (β-11.251 p=0.05)
Conclusion: The patients with ED had a lower FEV1 compared with those without ED. In patients with EPOC those with ED will have a worst degree of EPOC and in which turn to the hypothesis that the ED is not only local but instead is at capillary, alveoli and systemic.

P1099
Association between heart failure and nonalcoholic fatty liver disease

KV Pivtorak[1]; VY Maslovskyi[1]
[1]National Pirogov Memorial Medical University, Vinnitsia, Ukraine

In the last decade the role of alcoholic fatty liver disease discuss as a disease, which determines not only the severity of injury, but associated with the progression of cardiovascular disease (CVD) and the development of type 2 diabetes mellitus (DM) and other system injuries [1,2].
Purpose: to determine the relationship between NAFLD and heart failure
Methods: The study involved 112 NAFLD patients with normal, overweight and obese without of type 2 diabetes mellitus and 64 patients with normal, overweight and obese with type 2 diabetes mellitus. Conducted anthropometric survey measured levels of AST, ALT, GGT, the degree of liver fibrosis using elastography (FibroScan), ECG and echocardiography. The stratification of CVrisk was carried by traditional SCORE scale version for countries with high risk. We determined the level of inflammatory mediators (TNF-α, IL-1, IL-6), markers (CRP, fibrinogen), endothelin -1, the activity of the Willebrand factor (vWF), the thickness of the intima-media complex, presence atherosclerotic plaque and stenosis of the carotid arteries, insulin resistance index HOMA-IR for all examined patients.
Results: In both groups was revealed left ventricular diastolic dysfunction and QT prolongation in patients with NAFLD and type 2 diabetes that was associated with the severity of the disease. Most patients with NAFLD by obesity showed a reduction in endothelium-dependent vasodilation, indicating the presence of endothelial dysfunction. The concentration of pro-inflammatory cytokines such as TNF-α and IL-6 in patients with NAFLD was 3-7 times higher than the similar parameters of patients with a similar degree of obesity, but without evidence NAFLD. The concentration of ET-1 in the blood plasma of patients with NAFLD has a strong direct correlation with the degree of cardiovascular risk of surveyed patients. It is found that many inflammatory mediators (TNF-α, IL-1, IL-6) and markers (C-reactive protein, fibrinogen) highly correlate with the degree of obesity, the concentration of ET-1, vWF and markers of insulin resistance, a predictor for cardiovascular risk.
Conclusions: Presents of diastolic dysfunction of left ventricular and heart failure, disturbances of endothelium-dependent vasodilation, the concentration of ET-1, mediators of systemic inflammation, increase the values of intima-media thickness, an increase the frequency of cardiac arrhythmias is highly correlated with the degree of cardiovascular risk. Presence of NAFLD dictates mandatory screening for cardiovascular disease in these patients.

P1100
Liver stiffness assessed by transient elastography is associated with congestion in patients with decompensated heart failure

A Soloveva[1]; M Bayarsaikhan[1]; I Garmash[2]; S Villevalde[1]; Z Kobalava[1]
[1]RUDN University, Department of Internal Disease Propaedeutics, Moscow, Russian Federation; *[2]RUDN University, Moscow, Russian Federation*

Objective: Heart failure (HF) has a negative impact on liver leading to hepatic fibrosis or even cirrhosis. Studies dealing with assessment of liver stiffness (LS) in decompensated heart failure (DHF) are relatively few and have contradictory results. The aim of the study was to assess LS by the transient elastography (TE) on admission and its associations in patients with DHF.
Methods: LS was measured using TE (FibroScan Echosens, France) in 94 patients with DHF on admission (60 male, 72 ± 10 years (M ± SD), arterial hypertension 96%, myocardial infarction 55%, atrial fibrillation (AF) 63%, diabetes mellitus 45%, known chronic kidney disease 29%, chronic anaemia 30%, left ventricular ejection fraction (EF) 40 ± 14%, EF < 40% 28%, NYHA IV 41%). Ten valid measurements were required with success rate of >60%. LS≤5.8 was considered normal and LS ≥5.9, 7.2, 9.5 and 12.5 kPa are considered fibrosis (F1-F3 METAVIR score) and cirrhosis (F4) according to thresholds in studies with chronic liver disease. Mann-Whitney test was performed. p < 0.05 was considered statistically significant.
Results: The median value of LS was 13.1 (interquartile range 7.4;26) kPa. Normal LS was observed in 15.9% of patients. Abnormal LS ≥5.9, 7.2, 9.5 and 12.5 kPa occurred in 8.5, 13.8, 10.6 and 51.1% of patients respectively.
Patient with vs without LS ≥12.5 kPa had higher incidence of ischemic HF (79 vs 65%, p < 0.05), chronic anaemia (42 vs 19%, p < 0.01), glomerular filtration rate <60 ml/min/1.73 m2 (71 vs 55%, p < 0.05), chronic AF (54 vs 36%, p < 0.01), NYHA IV (52 vs 35%, p < 0.05).
LS ≥12.5 kPa was associated with high incidence of signs of congestion: peripheral oedema (98 vs 87%, p < 0.05), rales (94 vs 74%, p < 0.001), jugular venous distension (44 vs 32%, p < 0.05), hepatomegaly (69 vs 35%, p < 0.01), ascites (33 vs 10%, p < 0.001), severe mitral and tricuspid regurgitation (38 vs 19% and 58 vs 10%, p < 0.001 for both) and higher diameters of inferior vena cava (25 ± 6 vs 21 ± 7 mm, p < 0.05), right and left atriums (64 ± 13 vs 59 ± 15 mm, p < 0.05 and 51 ± 11 vs 47 ± 11 mm, p < 0.001), right ventricular end diastolic diameter (33 ± 5 vs 30 ± 5 mm, p < 0.001), pulmonary artery pressure (56 ± 18 vs 45 ± 13 mmHg, p < 0.001), higher levels of NT-proBNP (4655 (3120;7009) vs 4319 (2500;4961) pg/ml, p < 0.001), serum urea (10.1 (7.3;13.5) vs 7.4 (5.9;9.8) mmol/l, p < 0.05) and creatinine (109 (100;129) vs 105 (88;125) μmol/l, p < 0,05).
Patient with LS ≥12.5 kPa had higher rate of vasopressor therapy (10.4 vs 0%, p < 0.01) and longer length of stay (9 (8;15) vs 9 (6;12) days, p < 0.05).
Conclusions: Abnormal LS was occurred in 84.1% of patients with DHF. LS ≥12.5 kPa was associated with signs of congestion and right-sided HF, higher rate of vasopressor therapy and longer length of stay.

P1101
Central venous pressure is the main hemodynamic determinant of liver function in advanced heart failure.

J K Vishram-Nielsen[1]; T Deis[1]; B Balling[1]; S Boesgaard[1]; K Rossing[1]; F Gustafsson[1]
[1]Rigshospitalet - Copenhagen University Hospital, Department of Cardiology, the Heart Centre, Copenhagen, Denmark

Background: The relationship between liver function (LF) abnormalities and hemodynamics in heart failure (HF) is still incompletely understood as previous studies mainly included patients without contemporary HF medications and did not investigate liver synthetic function.
Methods: We assessed the relationship between LF tests and hemodynamics in 309 consecutive patients with a left ventricular ejection fraction < 45 % treated with contemporary medical HF therapy, and undergoing right heart catheterization using Swann-Ganz catheters. Cardiac output was measured using thermodilution.
Results: Mean age was 50 + 13 years, and 239 (77%) were men. Only 22 (7%)

were treated with inotropes and none were receiving mechanical circulatory support. Median (IQR) alanine transaminase (ALT) was 32 (22-53) U/L, alkaline phosphatase (ALP) 82 (63-122) U/L and the International Normalized Ratio (INR) 1.1 (1.0-1.3). In univariate analysis, ALT related to pulmonary capillary wedge pressure (PCWP; β=0.016, $p<0.05$), but not to central venous pressure (CVP), cardiac index (CI), or mean arterial pressure (MAP). For ALP, there was only a significant relation to CVP (β=0.019, P=0.0004). In a sub-group analysis excluding those receiving warfarin (n=86), INR related to all four hemodynamic parameters: PCWP (β=0.011, $p<0.0001$), CVP (β=0.019, $p<0.0001$), CI (β= -0.073, P=0.0008), and MAP (β= -0.0003, P=0.031). In multivariate analyses including the four hemodynamic parameters, only the associations with CVP remained significant: ALP and CVP (β=0.031, P=0.0002), and INR and CVP (β=0.013, P=0.002).
Conclusion: In advanced HF patients treated with contemporary medical HF therapy, CVP was associated with both markers of biliary excretion and liver synthesis function. Decongestion may be most important to improve liver function in advanced HF.

P1102

Increased liver stiffness by virtual touch quantification method can predict poor clinical outcomes in patients with heart failure

K Kazunori Omote[1]; N Asakawa[1]; T Yoshitani[1]; K Noguchi[1]; Y Tokuda[1]; K Kamiya[1]
[1]Hokkaido University, Sapporo, Japan

Background: Heart failure (HF) is often associated with liver congestion, which has been proposed to increase liver stiffness. Tissue elastgraphy using virtual touch quantification method (VTQ) is a new noninvasive method to measure liver stiffness in HF patients.
Purpose: This study sought to determine the prognostic impact of liver stiffness assessed by VTQ method in HF patients with reduced ejection fraction (HFrEF).
Methods: Thirty two HFrEF patients [54.5± 18.9 years, 23male, left ventricular ejection fraction 34.0± 16.6%, plasma brain-type natriuretic peptide 1090± 1051 pg/ml] due to ischemic (n=5) or non-ischemic (n=27) cardiomyopathy were studied. Liver stiffness was measured from shear-wave velocity (Vs [m/s]) by VTQ. Studied patients were divided into 2 groups according to the median value of Vs; low (<1.46 m/s; n=16) and high (≥1.46 m/s; n=16) Vs groups, and the composite adverse cardiac events of all-cause mortality, ventricular assist device (VAD) implantation, and hospitalization for worsening HF were compared.
Results: During a median follow-up of 547 days, 13 (40%) adverse cardiac events including 4 VAD, 10 hospitalization, and 3 deaths occurred. High Vs group had more a composite adverse cardiac events compared with low Vs group (62.5% vs. 18.8%, p=0.004), and also all-cause mortality and/or VAD implantation (38.0% vs. 0%, p=0.008) (Figure). Univariate Cox regression analysis demonstrated that high Vs [hazard ratio (HR) 5.57; 95% confidence interval (CI) 1.66-25.3; p=0.005], low systolic blood pressure (sBP) (HR 0.97; 95%CI 0.93-0.99; p=0.031), and high serum creatinine (sCr) levels (HR 3.49; 95%CI 1.00-12.1; p=0.049) were significantly correlated with adverse cardiac events. Multivariable Cox regression analysis adjusted by Vs groups, sBP, and sCr levels demonstrated that high Vs was independently correlated with adverse cardiac events (HR 3.75; 95%CI 1.01-18.1; p=0.048).
Conclusion: Increased liver stiffness measured by VTQ can predict poor outcome in HF patients.

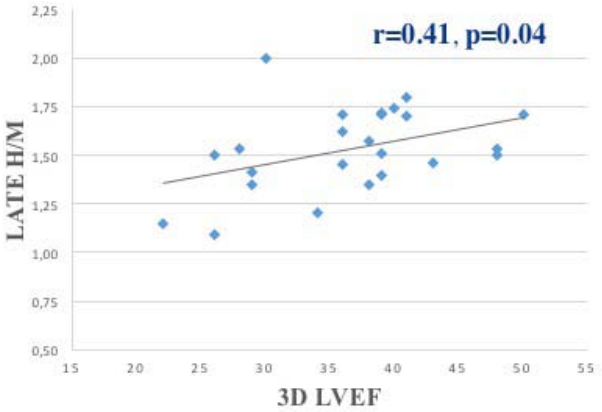
Left ventricular contractility and cardiac sympathetic derangement in patients with systolic heart failure and sleep disorder breathing

C Carmen D'amore[1]; F Marsico[1]; F De Martino[1]; F Renga[1]; S Paolillo[1]; V Parisi[2]; R Formisano[2]; B Trimarco[1]; P Perrone Filardi[1]
[1]Federico II University Hospital, Department of Advanced Biomedical Sciences, Naples, Italy; [2]Federico II University of Naples, Department of TranslationalMedical Science,, Naples, Italy

Funding Acknowledgements: Supported by a research grant provided by The Cardiovascular Pathophysiology And Therapeutics Phd Program.

Background: Sleep-breathing disorders (SBD), either obstructive sleep apnoea (OSA) and central sleep apnoea (CSA), short sleep time and low sleep quality are highly prevalent in heart failure (HF) patients and adversely impact on the disease progression and prognosis. The effects of SBD in HF are mainly mediated through increased sympathetic nervous activity, contributing to the impairment of myocardial contractile function. Three-dimensional speckle tracking echocardiography (3D-STE) has been demonstrated to be more sensitive than 2D echocardiography in identifying impairment of left ventricular (LV) function. Yet, only few studies have investigated the correlation between cardiac sympathetic innervation and LV function abnormalities assessed by 3D-STE.
Purpose: Aim of the present study was to assess the relationship between cardiac adrenergic innervation and LV function measured by 3D-STE in HF patients with and without SBD.
Methods: Patients with HF and reduced systolic function were prospectively enrolled in the study. During the first day patients underwent 2D and 3D transthoracic echocardiography to evaluate LV ejection fraction (LVEF) and nocturnal cardiorespiratory monitoring to assess SBD presence and severity by apnoea/hypopnoea index (AHI). During the second day, cardiac adrenergic innervation was assessed by 123I-MIBG scintigraphy using early and late hart-to-mediastinum (H/M) ratio measurement and washout rate (WR).
Results: Thirty-five patients (33 men; 64±8 years) with systolic HF were included in the study. Of 35 patients, 24 (68%) showed a SDB (17 subjects with prevalent CSA and 7 subjects with prevalent OSA). Using AHI patients were divided into those with absent or mild SBD (AHI ≤15; n=20) and those with moderate to severe SBD (AHI>15; n=15). Patients with moderate-severe SDB had a greater reduction of 3D LVEF (33.2±5.9 vs 41.7±7.2; p=0.001) than patients with mild or absent SDB, whereas 2D LVEF did not reveal significant differences between the two groups (29.6±4.3 vs 32.0±7.2; p=0.261). 3D LVEF (31.3±6.7 vs 38.6±6.6; p=0.023) and 3D strain area (-9.4±2.9 vs -14.7±4.1; p=0.005) were significantly more reduced in patients with OSA compared to patients with CSA. 3D LVEF directly correlated with late H/M ratio in patients with SDB (r=0.41, p=0.04), but not in patients without SDB.
Conclusions: Patients with moderate-severe SDB and systolic HF show significantly more impaired left ventricle contractile function assessed by 3D-STE, compared to patients without SDB, that correlates with the impairment of cardiac adrenergic innervation and is not identified by conventional 2D echo.



CORRELATION BETWEEN 3D LVEF AND LATE H/M

P1104

A comparison between patients with central and obstructive sleep apnea in patients with heart failure: SICA-HF

T Bekfani[1]; CH Schoebel[2]; CH Pietrock[3]; M Valentova[4]; A Sandek[4]; N Ebner[4]; S Elsner[3]; W Doehner[3]; M Noutsias[1]; PC Schulze[1]; SD Anker[4]; S Von Haehling[4]
[1]University Hospital of Jena, Department of Cardiology, Jena, Germany; *[2]Charite - Campus Mitte (CCM), Cardiology, Berlin, Germany*; *[3]Charite - Campus Virchow-Klinikum, Department of Cardiology, Division of Applied Cachexia Research, Berlin, Germany*; *[4]University Medical Center Göttingen, Department of Cardiology, Göttingen, Germany*

On behalf of: SICA-HF

Background: Sleep-disordered Breathing (SDB) is a very common comorbidity in patients with heart failure (HF).
Purpose: The aim of this study was to demonstrate the characteristic differences between central (CSA) and obstructive (OSA) sleep apnea and to evaluate the mortality rate in patients with CSA.
Methods: We prospectively enrolled 111 outpatients (age: 67.6 ± 10.2years, sex: 81 men [73%], body mass index: 27.9 ± 4.4kg/m2, New York Heart Association class: 2.3 ± 0.7) with stable HF as part of SICA-HF study from 03/2010 till 09/2013. Echocardiography, spiroergometry, DEXA-scan and polygraphy (portable monitoring) assessments using the Embletta and Nox-Devices were done in all patients. We re-analyzed the tests of the polygraphy visually (manually) in cooperation with the department of sleep medicine at our hospital. SDB was defined as apnea/hypopnea index (AHI) >5 episodes/hour of sleep. CSA was defined as central AHI> 50% of the total AHI. The same was applied for OSA.
Results: We found that 74 patients have SDB (66.7%). 16 (55.2%) patients with HFpEF (LVEF>50%) and 55 patients (67.1%) with HFrEF showed SDB. Overall, 24 patients had CSA (21.6%), 47 patients showed OSA (42.3%) and 3 patients had mixed sleep apnea (2.7%). Compared to OSA, patients with CSA showed more advanced systolic heart failure as determined by reduced left ventricular ejection fraction (LVEF, 42 ± 15% vs. 28 ± 9%, p = 0.0001), dilated left ventricle [(left ventricle end-diastolic diameter (LVIDd): 64 ± 11 vs. 60 ± 9 mm, p = 0.006)] and thin walls of the left ventricle [interventricular septum diameter in diastole (IVSd) 11.9 ± 2.5 vs. 10.7 ± 2.3mm, p = 0.04; posterior wall diastolic diameter (PWD): 10.9 ± 2.1 vs. 9.6 ± 2.0mm, p = 0.02)]. Furthermore, CSA had worse renal function (GFR 60.1 ± 13.8 vs. 52.8 ± 15.8ml/min, p = 0.045) and reduced fat mass in the arms and legs (arms: 31.1 ± 10.9 vs. 26.7 ± 7.9%, p = 0.085, legs: 32.6 ± 11 vs. 27.6 ± 7, p = 0.047). CSA tended to be more common among patients with a coronary artery disease (p = 0.095). On polygraphy, CSA patients showed higher severity of SDB than those with OSA (higher AHI: 16.2 ± 12.0 vs. 31.5 ± 11.4 episode/h, p = 0.0001, and a higher oxygen desaturation index (ODI): 14.7 ± 11.7 vs. 28.0 ± 11.9 episode/h, p = 0.0001). Compared with those without SDB, patients with CSA showed elevated VE/VCO2 in the spiroergometry: 34.1 ± 7.8 vs. 39.9 ± 8.1, p = 0.047). Defining CSA as AHI>10/h we found a significant increase in the mortality among patients with CSA compared to those with no SDB (p = 0.03).
Conclusions: SDB is a very common comorbidity in patients with HF. CSA is associated with a higher mortality rate, more advanced stage of systolic heart failure and with more severe SDB.

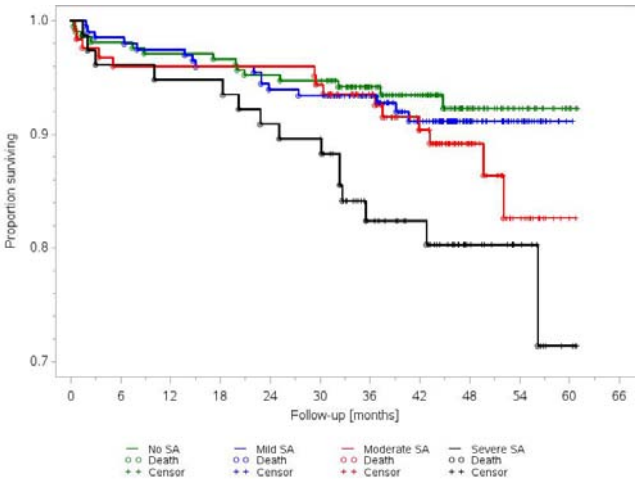
P1105

Sleep apnea and long-term prognosis of acute myocardial infarction

O Ludka[1]; R Stepanova[1]; T Kara[2]; J Spinar[3]
[1]University Hospital Brno, Masaryk University, International Clinical Research Center, Department of Internal Medicine and Cardiology, Brno, Czech Republic; *[2]Division of Cardiovascular Diseases, Department of Internal Medicine, Mayo Clinic and Foundation, Minnesota, United States of America*; *[3]Department of Internal Medicine and Cardiology, University Hospital Brno, Brno, Czech Republic*

Funding Acknowledgements: Supported by the project no. LQ1605 from the National Program of Sustainability II and FNUSA-ICRC (No. CZ.1.05/1.1.00/02.0123)

Purpose: Sleep apnea (SA) has a high prevalence in patients after myocardial infarction (MI). While SA might be a modifiable risk factor, recent data suggest that SA is severely underdiagnosed in patients after MI. There is also limited evidence about long-term prognosis of patients after MI according to SA categories. Therefore we sought to determine the relationship between SA and long-term prognosis among patients presenting with MI.
Methods: We prospectively studied 782 consecutive patients admitted to the hospital with the diagnosis of acute MI. The study was conducted in two tertiary care institutions, where primary percutaneous coronary intervention (PCI) is the standard of care in the treatment of acute MI. All subjects underwent sleep evaluations using a portable diagnostic device after at least 48 hours post-admission, provided they were in stable condition. Patients were followed for median follow-up of 43.3 months. Results: Almost all patients (98%) underwent urgent coronary angiography and 91% of patients underwent primary PCI. 175 (22.4%) patients had technically inadequate limited sleep studies (less than 4 h recording time or inability to score study due to excessive artifact). We therefore analyzed the data from 607 patients who had good quality sleep study records. Using a threshold of AHI > 5 events/hour, SA was present in 65.7% of patients after acute myocardial infarction. Mild SA was present in 32.6%, moderate in 20.4% and severe in 12.7%. There was a relation between the severity of SA and long-term prognosis. Patients after MI with increasing severity of SA had higher total mortality (p = 0.014, log-rank test). The Kaplan-Meier survival curves are presented. There was also a higher total mortality in reduced (REF) than in preserved left ventricular ejection fraction (PEF) patients after MI (21.7% vs 10.6%) in the group of moderate to severe SA (p = 0.033). Conclusion: Mortality of patients after MI significantly increased with increasing severity of SA. Whether treatment of SA after MI will significantly improve outcomes in these patients remains to be determined.



Kaplan-Meier survival curves

The CHA2DS2VASc score predicts cardiogenic shock in patients presenting with ST-segment elevation myocardial infarction

RC Serban[1]; A Scridon[1]; L Hadadi[1]; I Sus[1]; EK Lakatos[1]; Z Demjen[2]; D Dobreanu[1]
[1]University of Medicine and Pharmacy of Tirgu Mures, Tirgu Mures, Romania; *[2]Institute of Cardiovascular Diseases, Targu Mures, Romania*

Funding Acknowledgements: This work was supported by the University of Medicine and Pharmacy of Tirgu Mures Research Grant number 17800/1/22.12.2015.

Background: All factors included in the CHA2DS2VASc score have been associated with increased risk of ST-segment elevation myocardial infarction (STEMI), but their potential to predict hemodynamic status at presentation with STEMI has not been evaluated to date.
Purpose: We aimed to investigate the ability of the CHA2DS2VASc score to predict the presence of cardiogenic shock (CS) on admission for STEMI.
Methods: We evaluated data from 428 consecutive patients admitted for STEMI. For each patient, all factors included in the CHA2DS2VASc score were assessed, and the CHA2DS2VASc score was calculated. Association of these factors with the presence of CS on admission was assessed.
Results: 4.90% of STEMI patients presented CS at admission. Due to selection criteria, all patients presented vascular disease. Age, female sex, history of hypertension, diabetes mellitus, and stroke were not significantly different between patients with and without CS (all p>0.05). However, patients with CS had more frequently a history of heart failure (p < 0.01) and higher CHA2DS2VASc scores (4(2-6) vs. 3(2-4), p = 0.03). In multiple regression analysis, the CHA2DS2VASc score remained an independent predictor of CS (r=0.14, p = 0.004).
Conclusions: With the exception of a history of heart failure, none of the other factors included in the CHA2DS2VASc score correlated with the presence of CS on admission for STEMI. Meanwhile, the CHA2DS2VASc score was a strong, independent predictor of CS. The sum of cardiovascular risk factors, rather than each factor alone, may be a better predictor of hemodynamic impairment in STEMI patients.

P1107

Comparison of prevalence of contrast-induced acute kidney injury in patients undergoing percutaneous coronary intervention depending on definitions

A Anna Gaskina[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Introduction: Contrast-induced acute kidney injury (CI-AKI) is a common complication of intra-arterial administration of iodinated radiographic contrast medium that may prolong hospitalization, increase costs, short- and long-term morbidity and mortality. The prevalence of CI-AKI are not well defined. The aim of the study was to evaluate the prevalence of CI-AKI in patients undergoing PCI using different definitions
Methods: 502 patients (346 male, 64 ± 12 years (M ± SD), arterial hypertension 92%, previous myocardial infarction 38%, diabetes mellitus (DM) 22%, known chronic kidney disease 19%, anemia 16%, heart failure 62%, left ventricular ejection fraction 40 ± 16%) who underwent PCI (stable angina pectoris (SAP), n=50; unstable AP/non-ST-segment elevation myocardial infarction (UAP/NSTEMI), n=236; STEMI, n=216) were examined. CI-AKI was assessed according KDIGO 2012 Guidelines and previously the most frequently used definition (25% increase of serum creatinine (SCr) from baseline or 0.5 mg/dl increase in absolute value within 48-72 hours of contrast administration. Mann-Whitney test was performed. $P < 0.05$ was considered statistically significant.
Results: According KDIGO 2012 definition incidence of CI-AKI was 18 %, in SAP patients 12%; UAP/NSTEMI, 15%; STEMI, 20%, $p < 0.01$. According previously used definition incidence of CI-AKI was: total population 20%, SAP, 16%; UAP/NSTEMI, 16%; STEMI, 18%, $p < 0.01$. Conclusions: The highest prevalence of CI-AKI both on the 2012 KDIGO Guidelines and earlier version was highest among the STEMI patients with primary PCI.

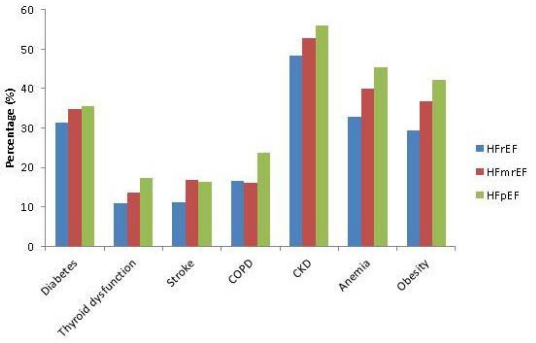
Background: Comorbidities play a major role in heart failure. Whether prevalence and prognostic importance of comorbidities differ between heart failure with preserved ejection fraction (HFpEF), mid-range (HFmrEF) or reduced ejection fraction (HFrEF) is unknown.
Methods: Patients from the index (n = 2516) and validation cohort (n = 1738) of The BIOlogy Study to Tailored Treatment in Chronic Heart Failure (BIOSTAT-CHF) were pooled for the present analysis. Seven non-cardiac comorbidities were assessed; diabetes mellitus, thyroid dysfunction, obesity, anaemia, chronic kidney disease (CKD), COPD and stroke. Patients were classified into 6 groups based on ejection fraction; HFrEF(< 40%), HFmrEF (40-50%) and HFpEF (≥50%), and having less or more than 3 comorbidities. Impact of each comorbidity on all-cause mortality was evaluated by population attributable risk (PAR).
Results: Patients with known LVEF and complete comorbidity data were included (n = 3499). Most prevalent comorbidity was CKD, with a prevalence of 50%. All comorbidities had a higher prevalence in HFpEF, except for stroke. Patients with 3 or more comorbidities had higher all-cause mortality rates in HFrEF (hazard ratio (HR) 1.57, $P < 0.001$) and HFmrEF (HR 1.39, $P < 0.001$), but not in HFpEF (HR 1.02, P=0.902). Highest PARs were seen for CKD in all HF groups, whereas obesity has an inverse PAR in HFpEF. Diabetes and stroke contributed significantly in HFrEF (11% and 6%) but were not significant in HFpEF (-1% and 0%).
Conclusions: Overall, comorbidities are more prevalent in patients with HFpEF, but having more comorbidities is associated with an increased all-cause mortality in HFrEF and HFmrEF, but not in HFpEF. CKD has the highest impact on mortality in all groups. History of stroke and diabetes have a significant impact on all-cause mortality in HFrEF, in contrast to HFmrEF and HFpEF.



Prevalence of comorbidities

P1109

Differences in comorbidities between men and women with heart failure exist.

M Marlies Heiligenberg[1]; JM Maaskant[1]; CHM Latour[1]
[1]*Amsterdam University of Applied Sciences, ACHIEVE — Centre of Applied Research, Faculty of Health, Amsterdam, Netherlands*

Funding Acknowledgements: ZonMw grant no. 633400013

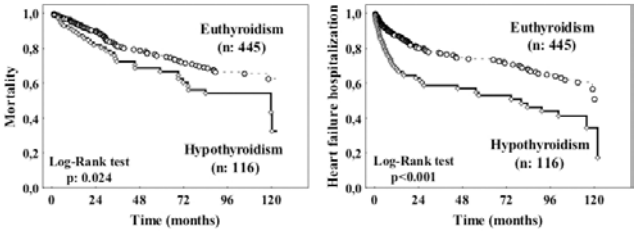
Background: Comorbidities in patients with heart failure (HF) increase morbidity, mortality and healthcare usage. Depression in HF patients is common and associated with negative outcomes. The prevalence of depression is higher in women with HF than in men. However, knowledge about the differences in comorbidities between men and women with HF, and between men and women with depression, is limited.
Purpose: The purpose of our study was to establish (1) differences in comorbidities between men and women with HF, and (2) differences in comorbidities between patients with HF with and without depression. We hypothesized that there are differences in comorbidities between men and women with HF (with and without depression).
Methods: The prevalence of 16 comorbidities was obtained by studying a database with 38.807 participants from 41 research projects in the Netherlands, executed between 2010-2013 (the Older Persons and Informal Caregivers Survey Minimal data set). Out of the 38.807 participants, only those patients who reported HF were included in this study. Mann-Whitney, Kruskal Wallis and Chi-square tests were used to analyze differences between groups.
Results: We included 7010 patients, who had reported HF. The median age was 80 (range 52-102 years), and 56.4% was female. Fifteen percent of the participants came from research projects in the general population, nursing home or retiring community, 25% from projects in a hospital setting and 60% from projects in a primary care setting. The following comorbidities were significant more prevalent in women compared to men: incontinence, osteoarthritis or rheumatoid arthritis, osteoporosis, hip and other fractures, dizziness with falling, vision disorders, and anxiety/panic disorder. Cancer and hearing disorders were more common in men. In addition, depression was registered more often in women than men: 13.0% vs. 9.5%. We compared patients with and without depression on the prevalence of comorbidities. Our results show that for both men and women, patients with depression had a higher prevalence of most comorbidities, than patients without depression. The prevalence of most comorbidities was highest in women with depression. Women with depression had 2 additional comorbidities and men 1 additional comorbidity compared to women and men respectively, without depression.
Conclusion: Women with HF report comorbidities (including depression) more often than men, and women with HF and depression have a higher number of additional comorbidities than men and the highest prevalence of most comorbidities. Patients with HF and depression have a higher prevalence of comorbidities than patients with HF without depression. This information is important for researchers, and warrants additional studies to investigate the effect of depression on combinations of comorbidities in men and women with HF, and whether depression is associated with increased health care usage in men and women with HF.

P1110

Hypothyroidism and heart failure outcome: a study with a long-term follow-up

C Caterina Rizzo[1]; D Grande[1]; P Terlizzese[1]; MS Lattarulo[1]; T Leopizzi[1]; MI Gioia[1]; B Licchelli[2]; E Guastamacchia[2]; V Triggiani[2]; M Iacoviello[3]
[1]*University of Bari, School of cardiology, Bari, Italy*; [2]*University of Bari, School of Endocrinology, Bari, Italy*; [3]*Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic department, Bari, Italy*

Background: Abnormalities of thyroid function has been demonstrated to be associated to heart failure (HF) progression in patients affected by chronic heart failure (CHF). It's not clear the impact of a reduced thyroid function on long term outcome of this group of patients.
Aim of the study: To evaluate the impact of hypothyroidism (HT-H) on the progression of HF during a long-term follow-up.
Methods: From 2006 to 2015,we evaluated 675 consecutive CHF outpatients (523 males,64 ± 13years) in stable clinical conditions(>1mounth) and in conventional therapy. They have been carefully documented the presence of thyroid diseases. During follow-up, thyroid function has been evaluated every 4 months, more frequently (every 6 weeks) in patients receiving Levothyroxine or with high TSH levels, to optimize the TSH values in the normal range. The onset of HT-H during follow-up was defined as detection of TSH values above the upper limit. When HT-H was detected, thyroid replacement therapy was started according to guidelines. During follow-up were also evaluated hospitalizations related to exacerbation of HF and death.
Results: 455 patients(67.7%) were euthyroid at the enrollment and for the entire duration of follow-up,in 80 patients (11.8%) there was previous diagnosis of HT-H and in 40 patients (5.9%) the HT-H was detected at the time of the enrolment. During follow-up,52 patients (7.7%) developed HT-H. The remaining were affected by hyperthyroidism or low T3 syndrome. To avoid confounding effects due to the other thyroid abnormalities, we compared patients in euthyroid status at the enrolment and during follow-up and those with HT-H at the ernollment. Among these,during follow-up (median value of 47 months,maximum 123 months),133 patients died and 186 experienced at least one hospedalization due to acute decompensated HF. At Univariate Cox regression analysis,a significant association between HT-H and the events,i.e. mortality for all causes (HR:1.60;95%CI:1.08-2.38;p:0.019) and hospitalization for HF worsening (HR:2.13;95%CI:1.54-2.96;p: < 0.001) was found. At multivariate Cox regression analyses, HT-H remained associated only with HF hospitalization (HR:1.58;95%CI:1.09-2.29;p:0.015) but not with mortality (HR: 1.05;95%CI:0,67-1,65;p:0.819), after correction to LVEF < 35%, GFR < 60ml/min/m2 NTproBNP>1000pg/ml,NYHAIII,PA < 95mmHg. Figure shows Kaplan-Meier curves for events of patients in euthyroid status at the enrolment and during follow-up and of patients with HT-H at the ernollment.
Conclusion: In a long term follow-up, HT-H is independently associated with hospitalization due to HF worsening but not with mortality. We hypothesized that HT-H is able to induce hemodynamic instability leading to hospitalization, but its correction with thyroid hormone therapy could in part blunt its impact on patients'survival.



Kaplan-Meier curves

P1111

Epicardial obesity as a factor of structural and functional heart remodeling

T YU Kuznetsova[1]; M A Druzhilov[1]
[1]*Petrozavodsk State University, Petrozavodsk, Russian Federation*

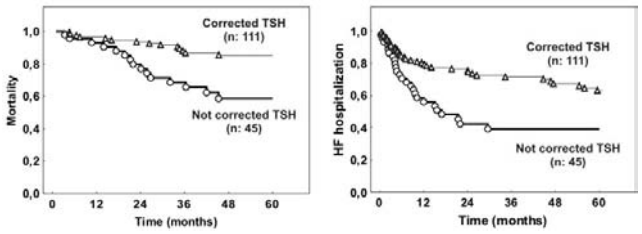
Background: Epicardial fat is considered as an independent risk factor, regardless of the severity of obesity in general. Several studies have demonstrated the possibility of myocardial lesion in epicardial obesity (EO) as a result of mitochondrial dysfunction and oxidative stress, apoptosis of cardiomyocytes, inflammation and fibrosis, disorders of adipokines and cytokines secretion.
Purpose: The aim is evaluate the association of EO with the presence of structural and functional heart remodeling.
Methods: 108 normotensive men without cardiovascular diseases were examined (age 48,7 ± 2,0, body mass index 31,6 ± 3,3 kg/m2, waist circumference 106,1 ± 5,7 cm). The diagnostic tests included the lipid and glucose profiles evaluation, echocardiography, bifunctional daily blood pressure monitoring with evaluation of arterial stiffness indicators (average daily aortic pulse wave velocity, augmentation index). Epicardial fat was visualized behind right ventricular free wall in B-mode at the parasternal position along left ventricular long axis at the end of systole. EO was diagnosed when epicardial fat thickness (EFT) was equal to or exceeded 75 percentile value (5,8 mm).
Results: Average EFT was 5,0 ± 1,2 mm. In patients with EO (n = 27) higher values of left ventricular mass index (119,4 ± 8,9 g/m2 vs 100,4 ± 15,9 g/m2, p < 0,001), left atrial volume indexed to body surface area (22,3 ± 3,4 ml/m2 vs 20,1 ± 2,2 ml/m2, p < 0,01), average daily aortic pulse wave velocity (8,4 ± 0,4 m/s vs 7,6 ± 0,4 m/s, p < 0,001), augmentation index (-39,4 ± 12,2 % vs -46,3 ± 10,6 %, p < 0,01). Compared groups did not differ in the systolic and diastolic blood pressure levels (118,4 ± 7,4/74,3 ± 4,8 mm Hg vs 117,5 ± 4,3/73,4 ± 4,2 mm Hg). In the EO group left ventricular hypertrophy and left ventricular diastolic dysfunction were detected more frequently: 25,9 % vs 6,2 % (p < 0,01) and 66,7 % vs 11,1 % (p < 0,01) respectively.
Conclusions: EO is associated with the parameters characterized the structural and functional heart remodeling. Higher values of left ventricular mass and left atrial volume indexes, higher frequency of left ventricular hypertrophy and left ventricular diastolic dysfunction were found in patients with EO diagnosed by measuring EFT.

P1112

The correction of TSH with thyroid replacement therapy is associated with a better outcome in chronic heart failure patients

D Dario Grande[1]; C Rizzo[1]; P Terlizzese[1]; MS Lattarulo[1]; T Leopizzi[1]; MI Gioia[1]; B Licchelli[2]; E Guastamacchia[2]; V Triggiani[2]; M Iacoviello[3]
[1]*University of Bari, School of Cardiology, Bari, Italy*; [2]*Polyclinic Hospital of Bari, Endocrinology and Metabolic Diseases Unit, Interdisciplinar Medicine Department, Bari, Italy*; [3]*Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy*

Background: It has been previously demonstrated that thyroid hormone deficiency is associated with a worse outcome in patients affected by chronic heart failure (CHF). However, few data are available about the effects of thyroid replacement therapy on the prognosis of patients.
Aim of the study: The aim of the study was to evaluate the relationship among thyroid replacement therapy, correction of thyroid stimulating hormone (TSH) serum levels and outcome of a series of CHF outpatients.
Methods: We screened CHF outpatients in stable clinical conditions (>1 month) and in conventional therapy. All patients underwent a baseline clinical evaluation, a 12-lead ECG, an echocardiogram and routine blood tests. Thyroid hormones were assessed at the enrolment and routinely during follow-up (every 3-4 months or every 6-8 weeks if TSH level was altered at the previous control). All patients with history or newly diagnosed hypothyroidism were managed by endocrinologists. We considered hypothyroidism corrected when TSH serum levels were normalized by thyroid replacement therapy (levothyroxine).
Results: Out of 712 patients, in 180 patients (121 males, 67 ± 12 years, left ventricular ejection fraction, LVEF, 33 ± 10%, NYHA class 2.5 ± 0.5, NTproBNP 2125 ± 2975 pg/ml, GFR-EPI 64 ± 22 ml/min*1.73m2) hypothyroidism was diagnosed. Twenty-four patients were excluded because they were lost at follow-up or died within the first 3 months or because endocrinologists did not prescribe levothyroxine for TSH values not high enough. Among the remaining 156 patients in which levothyroxine was prescribed, in 111 patients a normal TSH value was obtained. During a mean follow-up of 38 months, 29 patients died (25 for cardiovascular causes) and 62 experienced at least one admission for acute decompensated heart failure. The failure in TSH correction was associated with an increased risk of all cause of death (HR: 3.31; 95%CI: 1.59-6.86; p: 0.001) and of heart failure hospitalization (HR: 2.27; 95%CI: 1.36-3.79; p: 0.002). At Cox multivariate analysis the failure in TSH correction remained associated with all cause mortality (HR: 2.57; 95%CI: 1.20-5.51; p: 0.002) and with heart failure hospitalization (HR: 1.78; 95%CI: 1.05-3.01; p: 0.03) after correction for NYHA class 3, LVEF < 35%, NTproBNP>1000, systolic blood pressure < 100 mmHg and GFR-EPI < 60. In the figure Kaplan Meier curves of patients with and without TSH correction are shown.
Conclusion: Our results support the possibility that hypothyroidism correction could improve the prognosis of CHF patients, although randomized controlled trials should be designed in order to demonstrate this hypothesis.

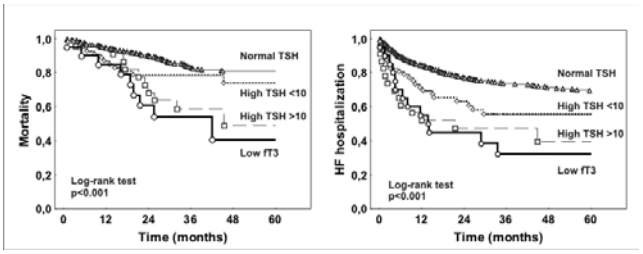


P1113

Thyroid hormones deficiencies and poor outcome in chronic heart failure outpatients

P Paola Terlizzese[1]; D Grande[1]; C Rizzo[1]; T Leopizzi[1]; MS Lattarulo[1]; MI Gioia[1]; B Licchelli[2]; E Guastamacchia[2]; V Triggiani[2]; M Iacoviello[3]
[1]*University of Bari, School of Cardiology, Bari, Italy*; [2]*Polyclinic Hospital of Bari, Endocrinology and Metabolic Diseases Unit, Bari, Italy*; [3]*Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy*

Background: Impairment of thyroid function is by far the second most common endocrine comorbidity in patients suffering from chronic heart failure (CHF). However, the cut-off of TSH serum levels associated with worse outcome is still debated as well as the different impact of hypothyroidism and low T3 syndrome (LT3).
Aim of the study: to evaluate in a large sample of CHF patients the association between thyroid hormone deficiencies and poor outcome.
Methods: and results: From 2006 to 2015, we screened 712 consecutive CHF outpatients (551 males, 64 ± 14 years, left ventricular ejection fraction (LVEF) 33 ± 10%, NYHA class 2.3 ± 0.6, NTproBNP 2153 ± 4696 pg/ml, GFR-EPI 71 ± 25 ml/min*1.73m2) in stable clinical conditions (> 1 month) and in conventional therapy. All patients underwent assessment of thyroid stimulating hormone (TSH), free triiodothyronine (fT3) and free thyroxin (fT4). While 34 patients were excluded for hyperthyroidism, among the remaining 678, 58 (9%) showed a TSH level above the upper normal limit, but below 10 microU/ml, 23 (3%) a TSH value above 10 microU/mL, and 20 patients (3%) low fT3 (LT3) levels without changes in TSH levels. During a mean follow-up of 38 months, 122 patients died (101 for cardiovascular causes) and 202 experienced at least one admission for acute decompensated heart failure. TSH >10 microU/mL (HR:2.96; 95%CI: 1.54-5.68; p: 0.001) and LT3 (HR: 3.79; 95%CI: 1.91-7.54; p < 0.001), but not high TSH < 10 microU/mL (HR: 1.59; 95%CI: 0.871-2.91; p:0.13), were associated with an increased risk of death at univariate analysis. At multivariate Cox regression analysis, after correction for the presence of NYHA class 3, LVEF < 35%, NTproBNP >1000, systolic arterial pressure < 100 mm Hg and GFR-EPI < 60 mL/min, only LT3 remained significantly associated with events (HR: 2.75; 95%CI:1.38-5.49; p: 0.004). When the occurrence of heart failure hospitalization was considered, high TSH levels with a value < 10 microU/mL (HR 1.82; 95% CI: 1.18-2.83; p < 0.01), TSH>10 microU/mL (HR 2.84; 95%CI:1.61-5.01; p < 0.001) and LT3 (HR: 3.33; 95%CI: 1.89-5.88; p < 0.0001) were all associated with events at univariate regression analysis. At multivariate regression analysis TSH>10 microU/mL (HR: 1.91; 95%CI:1.06-3.46; p:0.03) and LT3 (HR: 2.39; 95%CI: 1.36-4.24; p:0.002), but not high TSH with value < 10 microU/mL, remained associated with HF hospitalization. Figure 1 shows Kaplan-Meier curves reporting the relationship between thyroid hormones levels and both outcomes.
Conclusion: in this observational study performed on a large cohort of CHF outpatients, we found that impaired thyroid function, particularly when very high levels of TSH (>10 microUI/mL) and low T3 levels are considered, has an independent adverse impact on CHF events. These results, if confirmed by future RCTs, could suggest a new therapeutic approach when dealing with TSH correction in CHF patients.



P1114

Influence of chronic comorbidities on the mortality of patients admitted for heart failure in a general hospital.

JJ Juan Jose Martinez Diaz[1]; ML Fernandez Gasso[1]
[1]*Hospital General Universitario de Santa Lucia, Cardiology, Cartagena, Spain*

BACKGROUND: The influence of comorbidities on the prognosis of patients admitted due to heart failure is unclear.
PURPOSE: To study the influence of chronic comorbidities in in-hospital and long-term mortality of patients admitted with a diagnosis of heart failure.
Methods: 256 patient with main diagnosis of heart failure were recruited. Demographic data, cardiovascular risk factors, prior cardiovascular disease, chronic comorbidities (COPD, renal failure or neoplasic disease) and mortality rates were analyzed.
RESULTS: The baseline characteristics of the sample are shown in Table 1. 23 patientes died during their hospital stay, 52 of them died during the following year. Those variables that showed a relationship with in-hospital mortality in a Chi-square analysis were included in a binary logistic regression model: COPD (OR 2.68, p = 0.045) showed to be a risk factor for in-hospital mortality. In a proportional hazards model of Cox, COPD (HR 2.3, p = 0.02) and renal failure (HR 2.65, p = 0.003) showed to be risk factors for mortality during the first year. A long-term survival analysis was performed (Kaplan Meier method) with similar results (Figure 1).
CONCLUSION: In patients admitted with main diagnosis of heart failure, COPD has been shown to be a risk factor for both in-hospital and one-year mortality as well as renal failure is a risk factor for mortality at one year.

Table 1

	Frequency	Percentage
Age 78,2 ± 9.8		
Men	127	49,6
Women	129	50,4
Arterial hypertension	238	93

P1115

Different types of heart failure, different treatments?

S Sara Blasco[1]; FJ Camacho[1]; I Lobo[1]; C Collado[1]; P Gonzalez[1]; JA Sanchez-Brotons[1]; I Perez[1]; E Martinez De Morentin[1]; M Iravedra[1]; M Maestre[1]; J Lozano[1]; P Martinez Romero[1]; FJ Morales[1]
[1]*Puerto Real Hospital, Cardiology, Puerto Real, Spain*

Introduction: The latest Heart Failure and Cardiovascular Prevention ESC Guidelines have shown the benefits of empagliflozin in preventing and slowing down the progression of Heart Failure (HF) and reducing cardiovascular mortality. Our goal is to analyze whether the ESC Guidelines recommendations are being followed and if there are any differences according to the ejection fraction (HFrEF, HFmrEF, HFpEF).
Material and methods: Prospective and descriptive study of type 2 diabetic patients hospitalized in the Cardiology Service from June 15th to December 31st, 2016, comparing patients with HFrEF, HFmrEF and HFpEF..
Results: From June 15th to December 31st, out of a total of 121 diabetic patients hospitalized, 58 either had chronic heart failure or de novo HF. Average FEVI was 50% ± 14%, and according to the latest classification 29% had HFrEF,18% HFmrEF, and 51% HFpEF. There were significant differences in regards to gender (77% males in HFrEF, 70% HFmrEF, 50% HFpEF), HTA (77% of patients with HFrEF vs. 90% in patients withHFmrEF and 86% in patients with HFpEF), and creatinine clearance (ClCr < 60ml/min in 33% of patients with HFrEF vs. 60% in HFmrEF and 53% HFpEF), while there were none in age (67 ± 10 in HFrEF, 72 ± 12 in HFmrEF and 72 ± 10 in HFpEF), nor other cardiovascular risk factors such as dyslipidemia, smoking or obesity. All patients were being properly treated with Beta blockers, ACE inhibitor, and MRA drugs. Still, nearly a 50% of the hospitalizations in all DM 2 patients were due to Heart Failure. Regarding previous antidiabetic drugs, none of the patients were being treated with an SGLT2 inhibitor. 72% of HFrEF patients were under Metformin (22% on its own), 22% sulfonylureas, 11% DPP4 inhibitor and 44% under insulin. As for HFmrEF, 80% were under Metformin (20% as single-drug treatment), 20% sulfonylureas, 10% DPP4 inhibitor drugs and 40% under insulin. And finally, 50% of HFpEF patients were under Metformin (13% on its own), 13% under sulfonylureas, 16% under DPP4 inhibitor drugs and 43% under insulin. Nevertheless, 55% of HFrEF patients, 40% of HFmrEF patients and 23% of HFpEF had HbA1c levels out of the target range. At discharge, anti-diabetic treatment was modified in 19% of the patients, adding an SGLT2 inhibitor drug to 12% of the patients. We did not detect any complications, nor had to interrupt the treatment at the moment of publication.
Conclusions: We've detected that ESC guidelines aren't being followed in the use of anti-diabetic drugs in patients with cardiovascular diseases, unlike other cardiovascular risk factors that have well-established treatment protocols. Most of our patients could benefit from the use of the SGLT2 inhibitor. In this regard, there were no differences found after treatment modifications, but longer tracking period and bigger sample size are needed to validate these findings.

CYTOKINES AND INFLAMMATION

P1116

Inflammation and intestinal bacterial overgrowth in heart failure

A Anna Mollar Fernandez[1]; MP Villanueva[2]; G Minana[1]; A Villaescusa[1]; D Escribano[1]; P Palau[1]; E Santas[1]; A Bayes-Genis[3]; E Nunez[1]; F Mora[4]; M Minguez[4]; J Sanchis[1]; J Nunez[1]
[1]*University Hospital Clinic of Valencia, Cardiology, Valencia, Spain*; [2]*University Hospital Clinic of Valencia, clinical biochemistry, Valencia, Spain*; [3]*University Hospital Trias i Pujol, Cardiology, Barcelona, Spain*; [4]*University Hospital Clinic of Valencia, Gastroenterology, Valencia, Spain*

Background: Intestinal bacterial overgrowth has been related with poor prognosis in heart failure (HF); however, the pathophysiology of this association remains unclear. Along this line, some authors have postulated bacterial overgrowth might be implicated in the systemic inflammatory activation seen in HF. In this work, we aimed to determine whether inflammatory biomarkers were related with exhaled hydrogen (H2) and methane (CH4) after lactulose breath test as surrogates of intestinal bacterial overgrowth.
Methods: We enrolled 102 patients with advanced HF (stage C-D as per the ACC/AHA classification), NYHA II-IV and no signs of active infection. We analyzed plasma interleukin-1b (IL-1b), interleukin-6 (IL-6), interleukin-10 (IL-10), tumor necrosis factor alpha (TNF-α), C-reactive protein (RCP) , procalcitonin (PCT), leukocytes and lymphocytes together with the assessment of exhaled H2 and CH4 after lactulose administration. Multivariable linear regression analysis was assessed to determine the risk factors that predicted the logarithm of the area under the receiving operator curve of H2 and CH4 (logAUC-H2 and logAUC-CH4, respectively).
Results: LogAUC-H2 was modest and significantly correlated with: IL-1b ($r = 0.21$, $p = 0.032$), TNF-alfa ($r = -0.23$, $p = 0.018$) and IL-10 ($r = 0.22$, $p = 0.029$). LogAUC-CH4 correlated with IL-1b ($r = 0.24$, $p = 0.018$). Non-significant correlation were found for IL-6, RCP, PCT, leukocytes and lymphocytes. In a multivariable setting, logAUC-H2 and logAUC-CH4 were both significant and positively associated with IL-1b ($\beta = 0.032$; IC= 0.0001-0.0025; $p = 0.002$) and ($\beta = 0.042$; IC= 0.016-0.068; $p = 0.002$).
Conclusions: In patients with HF, exhaled H2 and CH4 after a lactulose breath test were independently associated with surrogate markers of inflammation.

P1117

Predictive value of leukocyte count for in-hospital mortality in patients hospitalized for acute heart failure

M Monica Chivulescu[1]; L Antohi[1]; C Radulescu[1]; I Cosei[1]; A Covaliov[1]; R Radu[1]; AP Ambrosy[2]; C Macarie[1]; O Chioncel[1]; M Gheorghiade[3]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*; [2]*Duke University Medical Center, Durham, United States of America*; [3]*Northwestern University, Chicago, United States of America*

Background: A large randomized clinical trial showed that low lymphocyte count during hospitalisation for acute HF (AHF) is an independent predictor of poor outcomes in the early post discharge period, but the data regarding the relationship between total leukocyte count and prognosis in this setting is limited.
Aims: The aim of this study was to characterize the relationship between leukocyte count and in-hospital mortality in patients hospitalized for AHF.
Methods: RO-AHFS registry prospectively enrolled 3224 consecutive patients with primary diagnosis of AHF. This is a post-hoc analysis of 2984 patients who had leukocyte count available at admission. Patients were stratified by quartiles of leukocyte count measured at admission (Table 1). In hospital mortality was determined in each quartile and compared by regression analysis.
Results: In univariate analysis, no liniar relationship has been found between leukocyte count and in hospital all cause mortality (HR=1.18 95% CI (0.93 -1.28) P=0.43). When mortality was analysed by each quartile, patients in the highest quartile experienced the highest rate of adverse hospital events and the worst outcome as compared to the patients from the lowest quartiles. (Q2 vs Q1 HR=0.98 CI 95% (0.83-1.08) P=0.71; Q3 vs Q2 HR=1.07 CI 95% (0.96-1.16) P=0.60; Q4 vs Q3 HR=1.09 CI 95% (1.04-1.11) P=0.048).
Conclusion: In addition to other known predictors, stratification by leukocyte count may help to identify patients at risk for in-hospital mortality. Future research, including prospective studies, may refine determinants of this relationship.

Background: Inflammation is a shared mechanism in coronary artery disease (CAD) and subsequent heart failure (HF) and circulating monocyte and lymphocyte counts predict CAD severity and outcomes.
Purpose: The aim of this study was to investigate whether the monocyte-to-lymphocyte ratio (MLR) correlates with biomarkers of HF and extent of CAD, as well as future HF hospitalizations in patients undergoing coronary angiography.
Methods: We studied 1754 patients undergoing coronary angiography for stable CAD, unstable angina or myocardial infarction. MLR was determined at blood draw prior to angiography and related cross-sectionally to HF biomarkers (ejection fraction [EF], N-terminal pro-B-type natriuretic peptide [NTproBNP] levels) and CAD severity, as well as longitudinally with risk of HF hospitalizations during follow-up.
Results: In the entire cohort, median (interquartile range) MLR was 0.32 (0.24-0.43). High MLR was defined as the upper quartile and significantly associated with non-stable CAD (unstable angina [Odds ratio=1.13; 95% confidence interval 1.06-1.21] or myocardial infarction [OR=1.10; 1.04-1.16]), more severe CAD (OR=1.39; 1.15-1.68), poorer EF (OR=1.63; 1.29-2.05) and higher NTproBNP levels (β=0.78; 0.59-0.96), all $p < 0.001$. The associations with non-stable CAD and NTproBNP remained highly significant after covariate adjustment. Over a mean follow-up of 1.3 years, 46 HF hospitalizations occurred. A high MLR was significantly and independently predictive of HF hospitalizations during follow-up (HR 2.1 [1.1-4.1], $p = 0.039$) after adjustment for covariates.
Conclusions: MLR is strongly related to HF markers and predicts HF hospitalizations during follow-up in coronary angiography patients. This supports a key role of monocyte and lymphocyte-mediated inflammation in the progression towards HF in patients with CAD.

Background: The pathogenic role of T cells in heart failure (HF) has been well documented in recent animal studies. However, it is unclear which subpopulation of T cells contributes to pathogenesis in patients with HF. Therefore, we studied immunologic characterization of various subsets of T cells from consecutively enrolled acute HF patients.
Methods: We analyzed the frequency of senescent T cells in 37 acute HF patients (21 male, mean age 66 ± 16 years) and 37 healthy control subjects (21 male, mean age 61 ± 14 years) by multicolor flow cytometry. The immunological characteristics of T cells were evaluated by surface immunophenotyping and intracellular cytokine staining.
Results: The frequency of CD4 + CD57 + T cells was significantly increased in patients with acute HF compared to healthy control (CD4 + CD57 + T cell fraction: 4.97 ± 3.80% vs. 3.84 ± 3.28%, $p = 0.03$), while other senescent T cell fraction showed no significant difference. Functional reactivity of CD4 + CD57 + T cells from acute HF revealed that the frequency of IFN-γ or TNF-α secreting cells in the CD4 + CD57 + T cell population was significantly greater than that in the CD4 + CD57- T cell population. Moreover, both the baseline and 6 month follow-up CD4 + CD57 + T cell fraction and polyfunctional T cell signature were significantly related with the left ventricular ejection fraction recovery in patients with acute HF.
Conclusion: CD4 + CD57 + T cells are increased and associated with clinical outcome in patients with acute HF, suggesting a role for T cell driven inflammation in HF. A more detailed characterization of senescent CD4 + T cells may offer new opportunities for the prevention and treatment of HF.

Left ventricular mechanics in mitral valve prolapse

M Maxime Poilane[1]; C Cueff[1]; N Piriou[1]; P Jaafar[1]; D Guijarro[1]; JC Roussel[1]; JN Trochu[1]; T Le Tourneau[1]
[1]*University Hospital of Nantes Nord Laennec, Cardiology, Nantes, France*

Objective: Valve apparatus alterations may influence left ventricular (LV) mechanics in mitral valve prolapse (MVP). To assess LV mechanics and ventriculo-valvular interaction in MVP.
Methods: Patients with MVP (leaflet displacement > 2 mm above the annulus) and no significant MR (NoMR-MVP, regurgitant volume < 10 ml) and controls without MVP were prospectively enrolled. Patients with hypertension, diabetes, obesity (BMI ≥ 30), or known ischemic or non ischemic myocardial disease were not included. A comprehensive echocardiography was carried out with 2D speckle tracking myocardial longitudinal strain assessment, 2D mitral valve apparatus analysis, and ventriculo-atrial disjunction. Global and regional longitudinal strain were compared between the two groups and the determinants of myocardial deformation alteration were sought.
Results: 80 adult patients with NoMR-MVP and 96 controls were included. Patients did not differ with regard of age, sex, body surface area, heart beats or blood pressure. Posterior (PML) and/or anterior (AML) mitral leaflet prolapse were present in 71 (89%) and 32 (40%) patients, respectively. PML and AML positions averaged -4.9 ± 2.7 mm and -1.6 ± 2.8 mm, respectively. Ventriculo-atrial disjunction was found in 33 (41%) patients and averaged 5.0 ± 1.1 mm. Left ventricular end diastolic diameter indexed to body surface area (bsa) was slightly increased in noMR-MVP (28.7 ± 3.3 mm/m^2 vs 27.6 ± 2.8 mm/m^2 in Controls, $p = 0.014$). Posterior wall thickening tended to increase in NoMR-MVP with frank wall bulging in 30 patients (38%). Despite the third left chamber (between mitral annulus and prolapsed leaflets) forward stroke volume was preserved and even increased in NoMR-MVP (42 ± 8 ml/m^2 vs 39 ± 6 ml/m^2 in Controls, $p = 0.003$). Global Longitudinal Strain (GLS) was clearly better in NoMR-MVP (-21.4 ± 2.9 vs -19.8 ± 1.8%, $p < 0.0001$) compared with Controls, and LS was better in the basal as well as mid-ventricular or apical regions compared with controls (all $p < 0.0001$). Differences were greater in infero-lateral and lateral walls. In univariate analysis, GLS (in absolute value) was associated with male gender (β=0.18, P=0.019), anterior mitral leaflet length/bsa (β=0.19, P=0.011), the magnitude of PML prolapse (β=0.33, $p < 0.0001$) or AML prolapse (β=0.29, $p < 0.0001$), and the magnitude of atrio-ventricular disjunction ($\beta = 0.39$, $p < 0.0001$). In multivariate analysis, male gender (β=0.16, P=0.057), and the magnitude of

atrio-ventricular disjunction ($\beta = 0.38$, $p < 0.0001$) were determinants of GLS.
Conclusion: In No-MR MVP with no other myocardial disease, MVP and associated abnormalities have a significant impact on LV structure and mechanics. The chronic increase in GLS may be the witness of myocardial wall function and structure remodelling in MVP independently of the presence of MR.

P1121
Outcomes of sutureless aortic valve replacement (SU-AVR) in moderate-to-high risk patients with unexplained postoperative thrombocytopenia

P Puwadon Thitivaraporn[1]; S Chiramongkol[1]; C Kittayarak[1]; N Pornpatrtanarak[1]; J Namchaisiri[1]; S Singhatanadgige[1]; P Ongcharit[1]; V Benjacholamas[1]

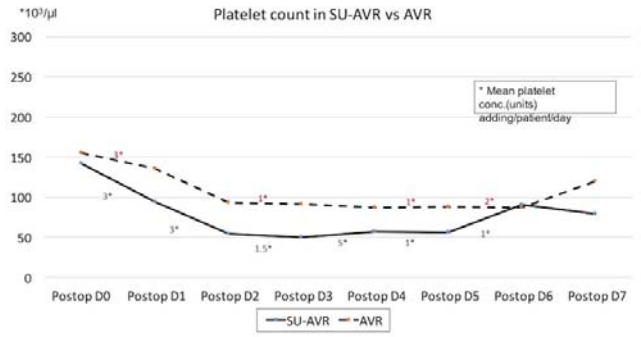
On behalf of: Chula Cardiac Center

OBJECTIVES: The aim of this study was to compare perioperative and postoperative outcomes of first series SU-AVR and AVR in developing country.
Methods: We conducted a retrospective study of SU-AVR in moderate-to-high risk patients (pts). Data of those underwent AVR or SU-AVR from January 2013 to May 2016 were obtained. A 1:1 propensity matching with sex, age and Society of Thoracic Surgeons (STS) score in same period study of AVR group. Preoperative, intraoperative and post-operative echocardiograms (day 3-7) were obtained. Primary outcome was 30-day mortality. Secondary outcomes were perioperative, intraoperative outcomes and complications. After matching, demographics, comorbidities and outcomes of interest were compared using x2 (Fischer's exact) and student t-tests for categorical and continuous variables, respectively.
Results: 277 pts in both AVR and SU-AVR groups. Until now, there are 10 patients (5 were male, median age of 81.5 years) undergone SU-AVR with propensity compared to AVR in the same period of study. Sutureless valve were successfully implanted in 9/10 pts. The subjects were 50% male and 50% female with mean age at 81.5 years old. The median STS score in SU-AVR group was 5.77 (2.1-79) vs 5.81 (2.5-34.8) in AVR group. The most common presenting symptom was progressive dyspnea at mean functional class 3. The median Cardiopulmonary bypass (CPB) time was 120 min (48-276) in SU-AVR vs 148 min (103-261) in AVR, $p = 0.61$. The median cross-clamp duration was 93.5 min (37-157) in SU-AVR vs 124 min (73-168) in AVR, $p = 0.14$.
Postoperative: echocardiogram demonstrated impressive outcomes in SU-AVR group, defined as reduced mean pressure gradient from 53.1 to 12 mmHg without left ventricular impairment (from 57% pre-operatively to 61% post-operatively vs $p = 0.41$). 30-day mortality was 20% in both SU-AVR and matched AVR group ($p = 1.00$). All patient in SU-AVR developed postoperative thrombocytopenia. Platelets level decreased from 225 *103/µl preoperatively to 94.5, 54.5, 50.1 at postoperative day (POD) 1, 2 and 3, respectively compared with 135.5, 93.4, 91.8 in AVR group ($p = 0.04$, 0.16 and 0.20, respectively). The maximal drop of platelets was found on POD 3. The requirement of platelets transfusion was higher in SU-AVR group compared to AVR (Leucocyte-poor platelet concentration 14.5units vs 4units) ($p = 0.04$).
Conclusion: There was no difference in 30-day mortality among moderate-to-high risk SU-AVR vs AVR. Despite SU-AVR was associated with favorable CPB and clamp time, SU-AVR found related to postoperative thrombocytopenia in all patients.

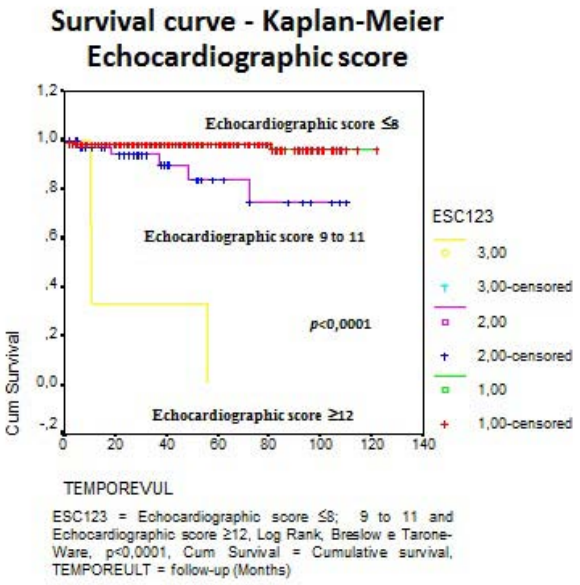


SUAVR vs AVR platelet level

P1122
Percutaneous mitral balloon valvotomy. echocardiographic score, risk factors for death and major events in long-term follow-up.

I P Ivana Picone Borges[1]; ECS Peixoto[1]; RTS Peixoto[1]; RTS Peixoto[1]; AAB Aragao[1]; LLB Bandeira[2]; ILPB Anjos[2]; VF Marcolla[1]
[1]*Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil*; [2]*Severino Sombra University, School of Medicine, Rio de Janeiro, Brazil*

Percutaneous mitral balloon valvotomy (PMBV) has emerged as an alternative to surgical treatment of mitral stenosis.
Objective: To dentify the independents predictors of death and combined events (death, new mitral balloon valvotomy, or mitral valve surgery) in long-term follow-up of patients undergoing PMBV.
Methods: From 1987 to 2013 a total of 317 patientes were followed-up 156 ± 144(1987 e 2013) months. The techniques were the single-balloon (84.4%), Inoue-balloon (13.8%),and double-balloon techniques (1.7%). The total group was divided in two: echocardiographic score >8 and ≤ 8 points groups. Multivariate Cox regression analysis were performed to identify independent risk factors of long-term survival and event free survival.
Results: The mean age were 38.0 ± 12.6 years old (range, 13 to 83). Before the procedure, 84,42% patients had echo score ≤ 8, and 15.57% score> 8. Females comprised 85%, and 84% patients were in sinus rhythm. During follow-up, survival of the total group was 95.5%, echo score group ≤ 8 was 98.0% and echo score > 8 was 82.2% ($p < 0.0001$), whereas combined event-free survival was 83.4%, 86.1%, and 68.9%, respectively (p 8 and the presence of severe mitral valve regurgitation during the procedure. The predictors of combined events were a previous history of mitral valvular commissurotomy, atrial fibrillation, the presence of severe mitral valve regurgitation during the procedure and post procedure mitral valve area < 1.5 m2.
Conclusion: PMBV is an effective procedure. Survival was high, even higher in the group with lower echocardiographic scores. Over 2/3 of the patients were event-free at the end of follow-up. Independents predictors of survival were pre procedure echo score ≤ 8 and the absence of severe mitral valve regurgitation during the procedure.



P1123
Long-term evaluation of the Ross procedure: clinical and echocardiographic follow-up at 20 years

S Sara Guerreiro[1]; R Ribeiras[1]; J Queiroz E Melo[1]; M Canada[1]; E Horta[1]; C Reis[1]; M Castro[1]; J Carmo[1]; J Mesquita[1]; N Vale[1]; D Matos[1]; C Strong[1]; JP Neves[1]; M Mendes[1]
[1]*Hospital de Santa Cruz, Lisbon, Portugal*

Background: Ross surgery is a technically complex procedure used in children and young adults requiring replacement of the aortic valve (AV), in which the native pulmonary valve is switched to the aortic position - autograft (Ag) - and a cryopreserved homograft (Hg) is implanted in a pulmonary position. This procedure offers

some advantages compared to mechanical prostheses: absence of anticoagulation, low risk of endocarditis and thrombogenicity and equivalent survival. However, the durability and incidence of re-operation remains a major concern. The aim was to evaluate the long-term clinical and echocardiographic results of Ross procedure.
Methods: Single-centre retrospective study that included a cohort of 52 adult patients: mean age at surgery of 44 ± 12 years old, 58% men, 33% rheumatic disease and 29% congenital aortic disease. Clinical endpoints included global mortality and the need for valve reoperation due to failure of one graft. Echocardiographic follow-up included the presence of the aortic Ag or pulmonary Hg deterioration by at least moderate regurgitation or stenosis with a mean gradient≥20mmHg. The median clinical follow-up was 20 ± 3 years (1040 patients/year) and the echocardiographic follow-up was 19 ± 4 years.
Results: The indication for surgery was in 40% the predominance of AV stenosis, in 21% prevalence of regurgitation and 31% mixed aortic disease. The subcoronary technique was the most used in 85% of the cases. The median time of cardiopulmonary bypass was 151 ± 34 min and the median time of hospitalization was 8 ± 3 days. Concomitant mitral surgery was performed in 21% of patients. During the follow-up, the overall survival was 81% and the free survival of graft re-operation was 83% - Figure 1. Of the patients who were not re-operated and were alive at the end of follow-up, 11 patients (31%) had moderate AV regurgitation; 6 (15%) moderate pulmonary regurgitation and only 1 patient with moderate pulmonary stenosis - Figure 1.
Conclusion: In the long-term follow-up of the Ross procedure, the subcoronary approach proved to have excellent clinical and hemodynamic results with low rates of reoperation. Moderate aortic regurgitation was a frequent and concordant finding amongst other studies with no clinically significant impact on the mean follow-up and at the 20 years follow up mark.

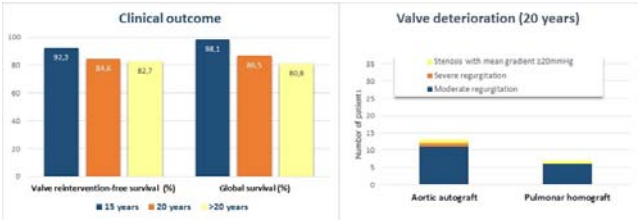


Figure 1

P1124

Indexed device landing zone calcium volume predicts moderate/severe aortic regurgitation after tavi with 1st and 2nd generation self-expandable prosthesis

S Sara Moura Ferreira[1]; J Almeida[2]; P Fonseca[2]; T Dias[2]; C Guerreiro[2]; R Barbosa[2]; P Teixeira[2]; N Pelicano[1]; N Ferreira[2]; R Faria[2]; P Braga[2]; V Gama[2]
[1]Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal; [2]Hospital Center of Vila Nova de Gaia/Espinho, Cardiology, Vila Nova de Gaia, Portugal

Introduction: Calcification of the device landing zone (DLZ) is linked to residual aortic regurgitation (AR) after transcatheter aortic valve implantation (TAVI). The mechanisms remain incompletely understood and the performance of next-generation transcatheter heart valves (THV) has not been thoroughly investigated.
Aim: We aimed to (i) clarify the influence of calcification patterns on the incidence of moderate/severe AR (ii) assess the performance of different first- and next-generation systems self-expandable prosthesis regarding calcium at the DLZ and residual AR.
Methods: Retrospective, observational study including all patients with severe aortic stenosis submitted to TAVI with self-expandable prosthesis between August 2007 and October 2016. Calcification of the DLZ was quantified for all available contrast scans, using a dedicated software (3mensioValvesTM), with a threshold for calcium detection set at 850 Hounsfield Units. All patients underwent transthoracic echocardiography within 1–3 days following the procedure. We used a Mann Whitney U test to compare DLZ calcium volume between patients with moderate/severe AR and patients with milder degrees of AR after being submitted to TAVI. A receiver operating characteristics (ROC) curve was used to obtain the best cut-off value of DLZ calcium volume to predict ≥moderate AR after TAVI with Self-Expandable Prosthesis. Then DLZ calcium volume was transformed into a categorical variable with 2 groups and a binary logistic regression analysis was conducted to test the strength of prediction of the projected value of DLZ calcium volume to assess development of AR ≥moderate after TAVI.
Results: TAVI with self-expandable prosthesis was performed in 180 patients in our centre (47,8% male, mean age 79.7 ± 7.8 years old). Most of the devices implanted were 1st Generation Self-Expandable Prosthesis (n = 112, 62.2%). The incidence of moderate/severe AR after TAVI was 15.8%. Body surface area (BSA) indexed DLZ calcium volume was significantly different between patients with moderate/severe (231.7 ± 53.9) and those with milder degrees of AR (138.4 ± 11.2), (p = 0.01). Area under the curve (AUC) for BSA indexed DLZ calcium volume was 0.64 (95% CI 0.53–0.75 p < 0,05). We considered the best cut off point for BSA indexed DLZ calcium volume to be 107.1 (sensitivity 73.1%, specificity 52.6%). In a binary logistic regression model, an BSA indexed DLZ calcium volume equal or above 107.1 was associated with 3 times increase in the probability of moderate/severe AR after TAVI with self-expandable prosthesis. Importantly, there were no significate differences in the incidence of moderate/severe AR after TAVI with self-expandable prosthesis, regarding device generation (X2 (1)=0.1, p = 0.83).
Conclusion: Calcification of the DLZ predicts moderate/severe AR after TAVI with Self-Expandable Prosthesis; the incidence of moderate/severe AR did not differ significantly between 1st and 2nd generation devices.

P1125

The improvement of right ventricular function in heart failure patients following percutaneous mitral valve repair using MitraClip system

O M Galuszka[1]; S Rutschow[1]; M Gross[1]; D Steffens[1]; U Rauch-Krohnert[1]; U Landmesser[1]; M Kasner[1]
[1]Charite - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany

Background: Chronic mitral regurgitation (MR) often results in right ventricular (RV) dysfunction due to long-standing pressure and volume overload. Previous studies showed that concomitant tricuspid regurgitation (TR) and pulmonary hypertension in patients undergoing conventional surgery for mitral valve (MV) increases morbidity and mortality, especially in case of a poor right ventricle. It is widely known that percutaneous mitral valve repair(PMVR) improves left ventricular function, but to what extent this affects the right ventricle, remains the area of current research.
Aims: The main objective of present study was to investigate the role of preprocedural right ventricular dysfunction and pre-existing severe pulmonary hypertension assessed by means of two-dimensional echocardiography for patient clinical recovery following PMVR. Moreover, we tried to assess the potential for right ventricular remodeling after volume and pressure overload due to MR has been reversed.
Methods: 48 patients (52% women, 76 ± 6 years) with moderate-to-severe mitral regurgitation (MR 2+) undergoing PMVR using the MitraClip system underwent transthoracic echocardiography at baseline and at and six-months follow-up. Right heart echocardiographic parameters included RV diameter, RV systolic strain, TAPSE (tricuspid annular plane systolic excursion), tricuspid regurgitation grade and right atrial volume (RA Vol) whereas severe pulmonary hypertension was defined as systolic pulmonary arterial pressure (sPAP) > 60mmHg.
Results: MitraClip© implantation resulted in significant improvement of RV systolic strain (-15.7 ± 2.3% vs. -19.1 ± 2.9%, p < 0.001), improved New York Heart Association (NYHA) class (3.0 ± 0.5 vs. 2.3 ± 0.7, p < 0.05), diminished RA volumes (46 ± 10ml vs. 38 ± 10 ml, p < 0.001) as well as reduced estimated pulmonary pressure (sPAP; 52.5 ± 11.5 mmHg vs. 42.5 ± 14.1 mmHg, p < 0.05). However, no change in TR grade was noted. In the subgroup of patients with pulmonary hypertension(PAH, n=12 patients) baseline RV systolic strain was lower, yet showed a tendency for improvement (-13.7 ± 2.1% vs. -16.1 ± 2.7%, p < 0.001), accompanied by reduced sPAP (68.1 ± 7.5 mmHg vs. 55.7 ± 7.2 mmHg, p < 0.05). Most importantly, neither improvement in terms of NYHA class nor significant changes in any of the other RV parameters was observed in patients with severe PAH.
Conclusions: Our results confirm that percutaneous MV repair, in contrast to conventional MV surgery, is beneficial for heart failure patients by improving RV function. Due to the reduction in RV afterload, PMVR alleviates pressure overload thus leading to reduced RA volumes, improved RV contractility and ameliorated patient clinical status. In PAH patients, PMVR reduces sPAP and improves RV systolic function, but adversely affects NYHA functional class. Basing on our results, one might conclude that patients with pre-existing severe PAH, and thus RV failure, exhibit little clinical benefit from the procedure.

P1126

Prior surgical mitral commissurotomy and echocardiographic score influence in mitral balloon valvuloplasty

I P Ivana Picone Borges[1]; ECS Peixoto[1]; RTS Peixoto[1]; RTS Peixoto[1]; AAB Aragao[1]; VF Marcolla[1]; SA Simoes[2]; LLB Bandeira[3]; ILPB Anjos[3]; M Nascimento[1]
[1]Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Rio de Janeiro State Government, Military Undersecretary from Rio de Janeiro State Government, Rio de Janeiro, Brazil; [3]Severino Sombra University, School of Medicine, Rio de Janeiro, Brazil

Background: Percutaneous mitral balloon valvuloplasty is effective in mitral stenosis
Objective: to evaluate prior mitral surgical commissurotomy (PMC) and echocardiographic score (ES) in the results and complications of mitral balloon valvuloplasty (MBV).

Methods: From 1987 to 2013, 526 procedures with Inoue balloon, double or single Balt balloon technique; 480 without PMC named primary MBV group (PMBVG) and 46 that have been submitted to PMC, the PMC group. The PMCG was older than PMBVG (42.7 ± 12.4 vs 36.9 ± 12.5 years, p = 0.0030). Gender, atrial fibrilation and NYHA functional class were similar. In PMBVG and PMCG, respectively, ES were 7.2 ± 1,4 and 7.7 ± 1.5 points (p = 0.0158) and mitral valve area (MVA) 0.94 ± 0.21 and 1.00 ± 0.22 cm2 (p = 0.0699).
Results: - Pre-MBV: mean pulmonary artery pressures (MPAP) were 37.8 ± 14.2 and 37.6 ± 14.4 mmHg, p = 0.9515; mean gradient (MG) 19.6 ± 6.9 and 18.3 ± 6.9 mmHg, p = 0.2342; MVA 0.90 ± 0.21 and 0.93 ± 0.19 cm2, p = 0.4092, respectively, whem compare PMBVG and PMCG. Post-MBV: MPAP were 26.8 ± 10.2 and 26.6 ± 10.9 mmHg, p = 0.9062; MG 5.4 ± 3.5 and 6.3 ± 4.2 mmHg, p = 0.1492; MVA 2.04 ± 0.42 and 1.92 ± 0.41 cm2, p = 0.0801, respectively. Mitral regurgitation (MR) were similar pre and post-MBV. Severe MR post-MBV in 10 patients: 8 in PMBVG and 2 in PMCG, p = 0.2048. As there were not found significant diferences, the total group were divided in ES ≤ 8 and >8 groups: Pre-MBV: MPAP 37.5 ± 13.9 and 39.3 ± 16.6 mmHg, p = 0.4041; MG 19.7 ± 6.8 and 18.3 ± 7.3 mmHg, p = 0.1753; MVA 0.90 ± 0.21 and 0.94 ± 0.20 cm2, p = 0.0090 respectively. Post-MBV: MPAP 26.7 ± 10.1 and 28.0 ± 10.6 mmHg, p = 0.3730, MG 5.5 ± 3.6 and 5.5 ± 3.3 mmHg, MVA 2.06 ± 0.42 and 1.90 ± 0.40 cm2, p = 0.0090.
Conclusions: The groups with and without prior mitral commissurotomy in MBV were compare and no differences were found in pre- and post-procedure, as mean pulmonary artery pressure, mean mitral gradient, mitral valve area, and mitral regurgitation. Although PMCG was older, with higher ES, its hemodynamics datas were similar. Whem the entire group was divided based on echo scores, those with echo scores >8 had highse MV (p = 0.0090). and smaler mitral valve areas post-valvuloplasty. The valve anatomy were more important than prior commissurotomy

P1127

Emergent balloon mitral valvotomy in pregnant women presenting with refractory pulmonary edema

M Majed Hassine[1]; M Boussada[1]; M Ben Messoud[1]; M Mahjoub[1]; Z Dridi[1]; F Betbout[1]; H Gamra[1]
[1]Cardiology A Department – Fattouma Bourguiba University Hospital, monastir, Tunisia

Background: Mitral stenosis is the most common valvular heart lesion found in pregnancy. When severe, it leads to significant risk of mortality for both mother and fetus, since the hemodynamic adaptations to pregnancy are badly tolerated. Many pregnant women with mitral stenosis present in a critically ill condition. The role of balloon mitral valvotomy (BMV) in such patients is ill-defined.
Objectives: We sought to evaluate the feasibility, efficacy and safety of emergent BMV in pregnant patients with refractory pulmonary edema and to determine maternal and fetal outcome.
Methods: Of 88 patients undergoing BMV during pregnancy from January 1990 to December 2011 in Cardiology A Department of Monastir Hospital, 28 women were in New York Heart Association functional class IV and underwent emergent BMV. During the procedure, radiation exposure was minimized by means of total abdominal and pelvic shielding.
Results: The mothers's mean age at the time of BMV was 28.86 ± 5.7 (range 19–43) years, and the gestation period was 30 ± 5.1 (range 20 –39) weeks. Ten patients were primiparas. Mitral valve (MV) was assessed using the Wilkins score which averaged 7.4 ± 1.8 (range 4 to 14). Fluoroscopy time was 7.8 +/-1.9 minutes. The BMV procedure was successful in 25 (89.3 %) patients with a dramatic improvement in patient symptoms. The mitral valve area increased from 0.8 ± 0.2 cm2 to 2.2 ± 0.42 cm^2 (p < 0.0001). The mitral valve pressure gradient decreased from 22.2 ± 9.3 to 5.7 ± 4 mm Hg (p < 0.0001). The left atrial pressure decreased from 29.4 ± 9.3 to 15.4 ± 7.3 mm Hg (p < 0.0001). The pulmonary artery pressure decreased from 58.8 ± 21.1 to 37.2 ± 14.3 mm Hg (p < 0.0001). One patient developed severe mitral regurgitation and required urgent mitral valve replacement. There was no maternal mortality or significant foetal morbidity. Pregnancy was uneventful in all patients, all babies were born at full term by spontaneous vaginal delivery in 24 cases (85.7 %) and by cesarian section for obstetrical reasons in 4 (14.3%), with no obvious malformations (4 of them were twin babies). None of the babies needed intensive care monitoring. The average Apgar scores at 1 min were 8.6 ± 1. The mean birth weight was 3.1 Kilograms ranged from 1.9 to 3.8 kg.
Conclusion: During pregnancy, emergent BMV is safe and feasible in patients with symptomatic mitral stenosis and severe pulmonary edema. There is marked symptomatic relief, along with excellent maternal and fetal outcomes.

Impact of permanent pacemaker implantation on clinical outcome among patients undergoing transcatheter aortic valve replacement

E Munoz-Garcia[1]; M Munoz-Garcia[1]; AJ Antonio Jesus Munoz Garcia[2]; A Ruiz-Salas[2]; JM Garcia-Pinilla[2]; L Morcillo-Hidalgo[2]; MF Jimenez-Navarro[2]; JH Alonso-Briales[2]; JM Hernandez-Garcia[2]; J Alzueta-Rodriguez[2]; E De Teresa-Galvan[1]
[1]Department of Cardiology , Malaga, Spain; [2]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Very few data exist on the clinical impact of permanent pacemaker implantation (PPI) after Transcatheter Aortic Valve Replacement (TAVR). The aim of this study was to assess the impact of PPI after TAVR on late outcomes in a large cohort of patients.
Methods: and Results — A total of 531 consecutive patients without prior PPI undergoing transcatheter aortic valve replacement were included. Of them, 125 patients (23.5%) required a PPI within the first 30 days after TAVR, median time 3 days (2.82-5.53 days) and 15 patients required a PPI in the follow-up, median 274 days (225-958 days). At a mean follow-up of 37 ± 25 months, there was a tend more mortality in patients with PPI (40% vs. 32.5% p = 0.067), but no association was observed between the need for PPI and all-cause mortality (hazard ratio, 1.15; 95% confidence interval, 0.839–1.576; P=0.381), cardiovascular mortality (hazard ratio, 0.992; 95% confidence interval, 0.539–1.824; P=0.979), and it was associated with more rehospitalisation for heart failure (hazard ratio, 1.942; 95% confidence interval, 1.023–3.686; P=0.042). There were 5 cases of unexpected (sudden or unknown) death was observed in patients without PPI. Patients with new PPI showed a poorer evolution of left ventricular ejection fraction over time. Mean left ventricular ejection fraction increased from 59.4 ± 14 % to 62.6 ± 9% after TAVI and decreased to 60.9 ± 10% at 1 years and 59 ± 6 at 4 years (p for post-TAVI trend 0.034).
Conclusions: The need for PPI was a frequent complication of TAVR and it was associated with increased admission for heart failure, and rehospitalization for heart failure after. A new PPI did have a negative effect on left ventricular function over time. However, but not associated with any increase in overall or cardiovascular death, a mean follow-up of 2.84 years.

Long-term outcomes after TAVR in patients with severe aortic stenosis and a reduced left ventricular ejection fraction

E Munoz-Garcia[1]; M Munoz-Garcia[1]; AJ Antonio Jesus Munoz Garcia[2]; F Carrasco-Chinchilla[2]; AJ Dominguez-Franco[2]; JM Garcia-Pinilla[2]; I Rodriguez-Bailon[2]; MF Jimenez-Navarro[2]; JH Alonso-Briales[2]; JM Hernandez-Garcia[2]; E De Teresa-Galvan[2]
[1]Department of Cardiology , Malaga, Spain; [2]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Left ventricular systolic dysfunction is associated with increased peri-operative risk in patients undergoing surgical aortic valve replacement. Recently, Transcatheter Aortic valve Replacement (TAVR) has emerged as an alternative to surgical aortic valve replacement for patients considered at high or prohibitive operative risk. We aim to analyze impact of a low ejection fraction in patients undergoing TAVR.
Methods: Between April 2008 and December 2016, 582 patients with symptomatic aortic valve stenosis who were considered high risk or non-surgical candidates underwent implantation with the auto-expandable prosthesis. Echocardiographic data were collected before and after the procedure. Impaired LV function was defined by a left ventricular ejection fraction (LVEF ≤ 40%). In 104 patients (17.9%) had reduced left ventricular ejection function
Results: The patients with reduced LVEF had more comorbidities compared with normal function: Charlson index 4 ± 1.8 vs. 3.2 ± 1.7, p = 0.001; Karnosfky index 49.8 ± 18 vs. 63.7 ± 17, P = 0.001), Frailty 30.8% vs. 19.2%, p = 0.009, worse Logistic EuroSCORE 27.1 ± 17 vs. 15.4 ± 9., p < 0.001, were more often males (60.6% vs. 36.4%, p = 0.001, more symptomatic (NYHA class IV 55.8% vs. 24.3%, p < 0.001, were younger (76.6 ± 9 vs. 80 ± 5, P = 0.001) and had a higher prevalence of prior coronary artery disease (63.5% vs. 40%, p = 0.001). Patients with reduced LVEF showed a good evolution of left ventricular ejection fraction over time (pre, post-procedure and 1 years): 33.8 ± 5 vs. 44.3 ± 11 vs. 51.6 ± 12%, respectively p = 0.001 No difference was observed between the 2 groups in mortality at 30-days (5.8% vs. 2.9%, p = 0.150). At a mean follow-up of 37 ± 25 months, there were non-significant differences with late mortality (29.6% vs. 34.1%, p = 0.395).
Conclusions: In patients with severe aortic stenosis and a low ejection fraction, TAVI is associated with better LVEF recovery and the immediate and long-term outcome after TAVR not seem to differ between patients with an impaired and preserved LVEF

Cardiac resynchronization therapy (CRT) is one of recent advancements in heart failure (HF) treatment. However, the clinical improvement has proved to be highly variable and insufficiently predictable. Despite application of established selection criteria, 20–40% of the patients do not respond to CRT. The our aim was to test a hypothesis on the influence of lead positioning in the ventricular walls on CRT response. We examined 53 first-time CRT recipients with NYHA class III-IV HF, with sinus rhythm, left bundle branch block, QRS duration>120 ms, left ventricular ejection fraction (LV EF) <35%. Response to CRT was defined in 6 months after operation as: a decrease in the LV end-systolic volume≥15%, a relative increase in the LV EF, a decrease in the functional class of chronic HF. All patients were classified as responders (n=28) or non-responders (n=25). The anatomic inter-lead distance, the horizontal and vertical components (Fig. 1) were determined with using patient chest radiographs recorded in the antero-posterior (AP), 30° left anterior oblique (LAO) and 30°right anterior oblique (RAO) positions. All individual measurements for a patient were normalized by the end-diastolic LV linear dimension (LVLD) to take into account differences in the heart size between patients. A comparison between groups was made with using SPSS 22.0 software packages. The data are presented as Mean±SD. The area under the ROC-curves (AUC) was used to assess diagnostic significance of the parameters. No correlation between the interventricular lead distance and response to CRT was found (Table1). We could speculate that not only the leads position in the ventricles are essential for CRT success, but functional characteristics of myocardium and patho-physiological factors have to be accounted to predict CRT responders. These hypotheses will be further tested by our group.

Inter-ventricular lead distance

Position	Inter-lead distance (normalized by the LVLD)	Responders	Non-responders	p (t-test)	AUC
AP	Anatomic	0.81 ± 0.4	0.75 ± 0.3	0.606	0.53
	Horizontal component	0.54 ± 0.4	0.54 ± 0.3	0.997	0.53
	Vertical component	0.48 ± 0.4	0.42 ± 0.3	0.564	0.58
LAO	Anatomic	1.08 ± 0.4	1.26 ± 0.4	0.184	0.56
	Horizontal component	0.95 ± 0.5	1.11 ± 0.4	0.290	0.52
	Vertical component	0.37 ± 0.3	0.46 ± 0.3	0.439	0.58
RAO	Anatomic	0.82 ± 0.4	0.69 ± 0.2	0.216	0.59

The effect of CRT on mitral valve geometry: Incidence and predictors of reversed mitral remodeling

O Karaca[1]; B Cakal[1]; O Omaygenc[1]; HM Gunes[1]; SD Cakal[1]; F Kizilirmak[1]; E Ibisoglu[1]; U Savur[1]; F Celebi[1]; DD Naki[1]; F Kilicaslan[1]
[1]Medipol University Faculty of Medicine, Cardiology Clinic, Istanbul, Turkey

Background: Improved valvular geometry by CRT possibly impacts on mitral regurgitation (MR) response. We aimed to establish the precise definition, incidence, and predictors of reversed mitral remodeling (RMR), as well as the association with MR response and short-term CRT outcome.
Methods: Ninety-five CRT recipients were analyzed for the end-point of MR response defined as the absolute reduction in regurgitant volume (RegV) at 6 months. To identify RMR, changes in mitral deformation indices were tested for correlation with MR response and further analyzed for functional and echocardiographic CRT outcomes.
Results: Overall, MR response was observed in 50 patients (53%). Among the echocardiographic indices, the change in tenting area (TA) had the highest correlation with the change in RegV ($r=0.653$, $p<0.001$). The mean TA significantly decreased in MR responders (4.15 ± 1.05 cm^2 to 3.67 ± 1.01 cm^2 at 6 months, $p<0.001$) and increased in non-responders (3.68 ± 1.04 cm^2 to 3.98 ± 0.97 cm^2, $p=0.014$). The absolute TA reduction was used to identify patients with RMR (47%) which was found to be associated with higher rates of functional improvement ($p=0.03$) and volumetric CRT response ($p=0.036$) compared to those without RMR. Non-ischemic etiology and the presence of LBBB independently predicted RMR at multivariate analysis.
Conclusion: Reduction in TA is a reliable index of RMR, which relates to MR response, and functional and echocardiographic improvement with CRT. Both LBBB and non-ischemic etiology predict RMR.

	Univariate Analysis		
Variable	Odds Ratio	95% CI	p value
Non-ischemic etiology	4.083	1.709 - 9.759	0.012

On behalf of: MultiSENSE Study Investigators

Background: A multi-sensor algorithm based on implanted device based sensor data has been shown to detect impending worsening Heart Failure (HF) events. The objective of this analysis was to characterize the "normal" range of these sensor values when patients were estimated to be clinically stable, and compare it to pre-HF event periods.
Methods: The MultiSENSE trial enrolled 900 patients implanted with a COGNIS CRT-D and followed them up to 1 year. Device software was modified to permit collection of chronic diagnostic sensor data including heart sounds, respiration, thoracic impedance, heart rate and activity. HF status was assessed by in-office physical assessment at routine follow-up visits scheduled either every three months if the patients had remote monitoring, or 6-8 weeks if not. Patients were deemed to be clinically stable between successive follow-up visits if their NYHA classification was unchanged, weight change was within 5 lbs (2.27kg) and no adverse events were reported between the visits. Sensor data from clinically stable epochs were compared with 7 day average sensor data prior to independently adjudicated worsening HF events defined as HF admissions or unscheduled visits with intravenous HF treatment using 2 sampled t-test.
Results: Of 900 patients, 676 patients yielded 1667 clinically stable epochs of duration 60 ± 22 days, while 88 patients had 146 HF events. Table summarizes sensor data during clinically stable epochs and prior to worsening HF as mean (μ) ± standard deviation (σ).
Conclusions: All individual HF diagnostic sensors used in the multi-sensor algorithm are different when patients are clinically stable versus when they are experiencing worsening HF events. Additional studies are needed to investigate if interventions in response to early recognition of these changes will reduce HF events.

Daily Trend	Clinically Stable epochs	Prior to worsening HF	p values

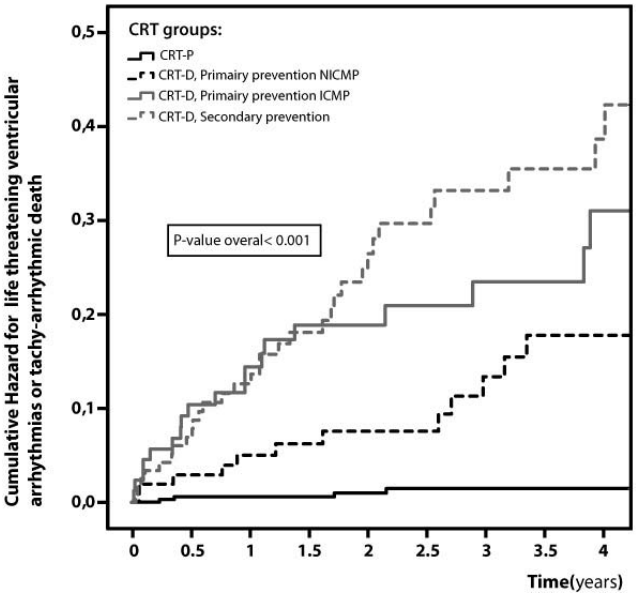
Funding Acknowledgements: Pieter Martens is supported by a doctoral fellowship by the Research Foundation – Flanders (FWO, grant-number: 1127917N

BACKGROUND: Both Cardiac resynchronization therapy (CRT) and implantable cardio-defibrillators (ICD) reduce mortality. However, the incremental value to one-other remains a topic of debate.
Methods: Baseline characteristics, mode of death and device interrogations were retrospectively evaluated in consecutive CRT-Pacemaker (CRT-P) and CRT-Defibrillator (CRT-D) patients implanted between October, 2008, and August, 2015. Preference for implant of CRT-P was given in older patients with multiple comorbidities or pacing induced non-ischemic cardiomyopathies. For patients with a primary prevention indication of the CRT-D, independent predictors associated with a clinical context of reduced benefit of the ICD-component were determined, defined as absence of non- lethal (detected on device interrogation) and lethal ventricular tachy-arrhythmias (mode of death analysis) during follow-up.
Results: A total of 687 patients were followed for 38 ± 22 months. CRT-P was implanted in 361 (52.5%) and CRT-D in 326 (47.5%). CRT-P recipients were older (75.7 ± 9.1 versus 71.8 ± 9.3; < 0.001) and had a higher comorbidity burden (p < 0.001). During remote tele-monitoring follow-up, 4 CRT-P patients were detected with episodes of sustained ventricular tachycardia for which semi-elective upgrade to CRT-D occurred. All-cause mortality was higher in CRT-P versus CRT-D patients (p = 0.003). However, mode of death analysis revealed a predominant non-cardiac mode of death in CRT-P recipients (70% versus 38% in CRT-D, p = 0.002) with only one patient dying from tachy-arrithmic death in the CRT-P group. Figure 1 illustrates the hazard for ventricular arrhythmias (combined from all device interrogations) or tachy-arrithmic death in CRT-P vs. CRT-D. Indicating a

lower burden in CRT-P vs CRT-D patients, with additional differences in the latter group between primary prevention indication (non-ischemic or ischemic etiology of heart failure) or secondary prevention indication for the ICD-component. Regression analyses revealed that the presence of advanced age, NYHA class IV, intolerance to beta-blockers and underlying non-ischemic cardiomyopathy independently associates with a reduced benefit of the primary prevention CRT-D on top of CRT-P.
Conclusions: The majority of contemporary heart failure patients as currently selected for CRT-P exhibit mainly non-cardiac driven mortality and low ventricular arrhythmia burden, suggesting little incremental value of the addition of a defibrillator.



Arrhythmia burden in CRT-P vs CRT-D

On behalf of: RESPOND-CRT investigators
Funding Acknowledgements: The study was sponsored by LivaNova CRM

Purpose: RESPOND-CRT is a prospective, double-blinded, multi-center, non-inferiority trial designed to assess the safety and efficacy of the SonR system in heart failure (HF) patients (pts) eligible for cardiac resynchronization therapy (CRT). SonR is a contractility sensor-based system that automatically adjusts atrio-ventricular (AV) and inter-ventricular (VV) timings according to pts needs.
Methods: After implant, pts were randomized (2:1) to receive repetitive, automatic AV and VV optimization with SonR versus AV and VV Echo-guided optimization at discharge. We conducted a secondary analysis on time to first event of cardiovascular (CV) deaths or CV hospitalizations in subgroups of pts with renal failure (RF - Glomerular Filtration Rate GFR < 60), and history of atrial fibrillation (AF). An adjusted Cox regression analysis was performed on all adjudicated events up to 24 months. The type of CV events is presented.
Results: The study randomized 998 pts to either SonR (n = 670) or Echo (n = 328). For CV deaths or CV hospitalizations, in pts with history of AF (153 patients), SonR was associated with 56% risk reduction (HR=0.44, 95%CI: 0.26-0.76, p < 0.01) and in pts with RF (165 patients), 44% risk reduction (HR=0.56, 95%CI: 0.36-0.88, p = 0.01). HF and A/V rhythm disorders were the main reasons for CV hospitalization (table).

Conclusion: CRT optimization using the SonR contractility sensor was associated with additional benefits through significantly reduced risk of CV deaths or CV hospitalizations in pts with history of AF or RF.

Impact of left ventricular scar and synchronization parameters on reverse lewft ventricular remodeling

W Walid Ahmed[1]; W Samy[1]; O Tayeh[1]; N Behairy[2]; A Hassan[1]
[1]Cairo University Hospitals, Critical care department, Cairo, Egypt; *[2]Cairo University Hospitals, Radiology department, Cairo, Egypt*

BACKGROUND: Left ventricular dyssyunchrony and scar could predict response to cardiac resynchronization therapy (CRT)
PURPOSE: Explore role of LV dyssynchrony and scar impacts on reverse LV remodeling
Methods: Thirty patients received CRT. Assessment of left ventricular (LV) dyssynchrony by Gated SPECT LV phase analysis. Cardiac magnetic resonance with late gadolinium enhancement technique to examine LV scar burden.
Results: Thirty patients received CRT (mean age 58.7 ± 9.0, 24 males). Reverse LV remodeling (decline ≥15% from baseline LV end-systole) was documented in 19 patients. Temporal changes in LV dyssynchrony parameters were correlated to LV reverse remodeling. Non-responders showed higher scar burden by CMR (41.2 ± 7.8 vs 30.3 ± 11.1, P. 008). Left ventricular phase analysis parameters were correlated to summed rest score and CMR scar burden. Multivariate regression showed CMR scar burden (P < .001), delta change in histogram BW (P. 006) and delta change in histogram SD (P. 005) were independent predictors of reverse LV remodeling. Predicting CRT non-response showed a cutoff 36.5% of global LV scar burden had a sensitivity of 81.8% and specificity of 68.4%.
Conclusion: Reverse LV remodeling was associated with temporal improvements in LV dyssynchrony parameters. LV scar had an unfavorable impact. Improving dyssynchronous contractions resulted into better reverse LV remodeling.

Changes and predictive value of filtered qrs duration for mortality in non ischemic heart failure patients with cardiac resynchronization therapy

YM Minami[1]; A Suzuki[1]; T Shiga[1]; K Ejima[1]; M Shoda[1]; N Hagiwara[1]
[1]*Tokyo Women's Medical University, Department of cardiology, Tokyo, Japan*

Introduction: Cardiac resynchronization therapy (CRT) improves quality of life, and reduces the risks of hospitalization for heart failure (HF) or death in selected heart failure patients. The Aim of this study is to evaluate the association between changes of filtered QRS duration (fQRS) recorded by signal averaged electrocardiograph (SAECG) after Cardiac resynchronization therapy (CRT) and mortality.
Methods: This study included 103 consecutive non-ischemic HF patients who implanted CRT between 2004 to 2015. Patients were divided into narrowing fQRS and widening fQRS groups according to the changes of fQRS before and after CRT. The impact of narrowing fQRS on all-cause mortality was investigated.
Results: During a median follow-up time of 33 [18-50] months, 27 (26%) patients died from any cause. 50 (49%) patients with widening fQRS after CRT had more frequently ischemic heart disease and had shorter fQRS before CRT than patients with narrowing fQRS after CRT. There is a significantly higher rate of patients with reverse remodeling in patients with narrowing fQRS after CRT than patients with widening fQRS. Cox proportional hazards analysis found that widening fQRS was a significantly associated with reduced mortality (HR: 2.98, 95% CI 1.21-7.35, $P < 0.05$).
Conclusion: After CRT, HF patients with narrowing fQRS showed significantly higher responder rate than patients with widening fQRS. Narrowing fQRS is an independently associated with reduced mortality in HF patients receiving CRT.

Cardiac resynchronization therapy optimization by pressure recording analytical method: feasibility, efficacy and correlation with electrocardiographic and echocardiographic methods

D Castagno[1]; M Bisi[1]; PG Golzio[1]; C Budano[1]; A Bissolino[1]; M Anselmino[1]; F Ferraris[1]; C Giustetto[1]; F Gaita[1]
[1]*Division of Cardiology, Department of Medical Sciences, University of Turin, Turin, Italy*

BACKGROUND: Nonresponse to cardiac resynchronization therapy (CRT) affects up to 40% of system recipients. Suboptimal device programming has been identified as one of the main determinant factors of poor CRT response.
PURPOSE: To investigate the efficacy of AV and VV optimization performed using haemodynamic parameters obtained with the pressure recording analytical method (PRAM), a new, minimally invasive technique allowing beat-by-beat stroke volume (SV) and cardiac output (CO) monitoring from the pressure signals recorded in femoral or radial arteries.
Methods: After implant, consecutive CRT recipients (patients with symptomatic heart failure despite optimal medical therapy, in sinus rhythm and with complete left bundle branch block) underwent PRAM-based device optimization aiming at the highest SV and CO. Correlation between PRAM-based, standard ECG (QRS axis, QRS duration and presence of R wave in lead V1) and echocardiographic (mitral and aortic velocity time integral [VTI], Ritter's method, myocardial performance index [MPI]) CRT optimization was also investigated.
Results: Twenty-five patients (mean age = 67 ± 11 years, female = 8, mean LVEF = 29% ± 5%, ischaemic aetiology = 8) had CRT implanted. Simultaneous biventricular pacing with standard programming (AV 110/130 ms, VV 0 ms) determined a significant improvement in cardiac performance which was further enhanced after PRAM-based AV and VV delays optimization (Table). Mitral and aortic VTI showed the best correlation with PRAM-based optimization which was only poorly correlated with MPI and Ritter's method (Figure).
Conclusions: PRAM-based optimization is effective in maximizing CRT hemodynamic response and may be useful in reducing nonresponse.

	Baseline	Standard AV/VV	PRAM-based AV optimization	PRAM-based VV optimization	P-value for trend
Stroke volume (ml)	63.4	66.6	71.4	75.5	< 0.001

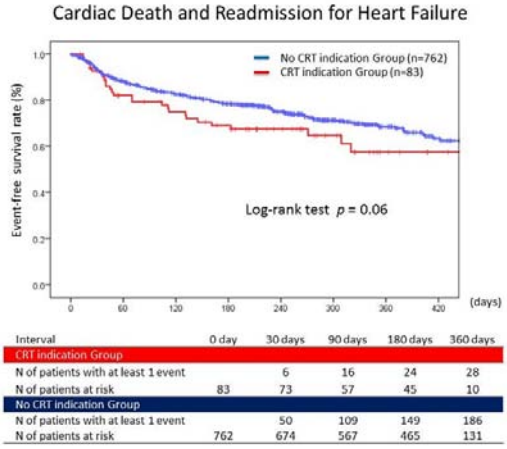
The prognosis of patients with acute decompensated heart failure indicated for cardiac resynchronization therapy

R Reo Hata[1]; Y Kawase[1]; H Tasaka[1]; T Tada[1]; K Kadota[1]
[1]*Kurashiki Central Hospital, Cardiology, Kurashiki, Japan*

Background: The prognosis of patients with acute decompensated heart failure (ADHF) with reduced ejection fraction and wide QRS indicated for cardiac resynchronization therapy (CRT) remains unclear.
Purpose: To determine the prognosis of ADHF patients indicated for CRT.
Methods: We retrospectively analyzed 864 consecutive patients hospitalized for ADHF between February 2015 and June 2016 and divided them into two groups based on having CRT indication or non-CRT indication, excluding 19 patients undergoing CRT: 83 patients with CRT indication as CRT group and 762 patients with non-CRT indication as non-CRT group. CRT indication was defined as left ventricular ejection fraction ≤35% and QRS width ≥120 msec, which was equivalent to classes I and IIa of the Japanese Circulation Society's CRT indication guidelines. We compared cardiac events (CE), defined as a composite of cardiac death and readmission for heart failure, between the two groups.
Results: The median follow-up period was 243 days. The 180-day cumulative CE-free survival rate tended to be lower in the CRT group than in the non-CRT group (68.0% versus 77.4%, p = 0.06). Subgroup analysis in CRT group was performed to further stratify cardiac events. CRT group was divided into two groups: CE group (n = 37) and CE-free group (n = 58). Between the CE group and CE-free group, significant differences were found in the rates of readmission for HF (61% vs. 36%, p = 0.04), prior ventricular tachycardia/fibrillation (38% vs. 12%, p < 0.01), the

level of hemoglobin < 11 g/dL (61% vs. 31%, p = 0.01), and estimated glomerular filtration rate (eGFR) < 45 ml/min/1.73m2 (79% vs. 40%, p < 0.01). Multivariate Cox proportional hazards model showed that prior ventricular tachycardia/fibrillation (hazard ratio, 3.04; 95% confidence interval [CI], 1.37 to 6.74; p = 0.01), and eGFR < 45 (hazard ratio, 4.11; 95% CI, 1.58 to 7.70; p < 0.01) were independent predictors of CE.
Conclusion: ADHF patients with CRT indication tended to have poorer prognosis than those with non-CRT indication. Prior ventricular tachycardia/fibrillation and decreased renal function were predictors of poor prognosis of ADHF patients indicated for CRT.



P1139
Atrial fibrillation at follow-up does not worsen the prognosis of cardiac resynchronization therapy

B Belen Alvarez[1]; FJ Garcia Seara[1]; D Iglesias Alvarez[1]; RA Abellas Sequeiros[1]; L Gonzalez Melchor[1]; M Rodriguez Manero[1]; XA Fernandez Lopez[1]; A Martinez Monzonis[1]; A Varela Roman[1]; JL Martinez Sande[1]; JR Gonzalez Juanatey[1]
[1]University Clinical Hospital of Santiago de Compostela, Department of Cardiology, Santiago de Compostela, Spain

OBJECTIVES: The aim of this study was to evaluate the impact of atrial fibrillation (AF) in the follow-up in patients with heart failure receiving cardic resynchronization therapy (CRT).
BACKGROUND: CRT has been demostrated good outcomes in sinus rhythm (SR). However, the prognosis of patients who develop AF at follow-up is unknown. Although it is believed that they have a worse prognosis
Methods: We investigated the long-term outcomes HF or mortality in 328 consecutive patients implanted with a CRT device in a single terciary center between 2001 and 2015. We categorize the patients into three groups: SR, basal AF and AF in the follow-up. Multivariable Cox proportional hazards models were used to determinate the effect on rhythm on the clinical outcomes.
Results: 138 (37.7%) patients were on SR, 123 (37.5%) were on basal AF and 67 (20.4%) were on AF at follow-up. Baseline characteristis were shown in Table 1. Basal AF was associated with an increased risk of HF/mortality in unadjusted analysis (HR 1.80, CI95% 1.28-2.54, p0.001) and adjusted analysis(HR 1.70, CI 95%1.21-2.65,p0.004) compared with SR. AF at follow-up was not associated with an increased risk of HF/mortality in unadjusted analysis (HR 1.39,CI95%0.94-2.08,p0.103) and adjusted analysis compared with SR (HR 1.45, CI95% 0.93-2.25, p0.103)
Conclusions: Patients with basal AF was associated with worse outcomes in HF/mortality events compared with SR. However, AF at follow-up was associated with similar risk of HF/mortality than SR

Effects of tailored telemonitoring in patients with heart failure: an 8-year follow-up

A Arno Gingele[1]; HPB Brunner-La Rocca[1]; BR Ramaekers[1]; CK Knackstedt[1]; JB Boyne[1]
[1]Academic Hospital Maastricht, Department of Cardiology MUMC, Maastricht, Netherlands

On behalf of: TEHAF investigators
Funding Acknowledgements: The Province of Limburg in The Netherlands; the Annadal Foundation Maastricht, Astra Zeneca [an unrestricted grant]; the Rescar Foundation

Aims: There is evidence that telemonitoring decreases mortality and heart failure (HF) related hospital admission in patients with HF. Nevertheless, most studies follow their patients for only several months. Thus, little is known about the long-term effects of telemonitoring.
Methods: and Results: In 2007, the TEHAF study was initiated to compare tailored telemonitoring to usual care with respect to time until first HF-related hospital admission. Totally, 382 patients were included with a follow-up period of 1 year. No differences in time to first HF-related admission between intervention and control group could be found. In order to investigate long-term effects of telemonitoring, a retrospective analyses was performed. Primary endpoint was time to first hospital admission. Secondary endpoints were, amongst others, HF and all-cause mortality, hospital admission due to HF and days alive and out of hospital (DAOOH). Electronic files of all included patients were reviewed between October 2007 and September 2015. No difference in time to first HF-related hospital admission (log-rank test, p = 0.15), all-cause mortality (log-rank test, p = 0.43) or DAOOH (two-sample t-test, p = 0.87) could be found. Patients of the intervention group had significant less HF-related hospital admission (Incident rate ratio 0.54, 95%CI 0.31-0.88). However, HF related mortality was non-significantly higher in the intervention group (log-rank test, p = 0.058).
Conclusion: Telemonitoring did not significantly influence long-term outcome in our study, but there were some interesting, though controversial results on HF-related event. Therefore, sufficiently large studies with long-term follow-up period are needed to estimate the effect of telemonitoring on HF-related outcome.

P1143
Daily non-invasive hemodynamic-telemonitoring objectifies the efficacy of mitral clip-implantation in patients with advanced heart failure

E Herrmann[1]; B Luu[1]; A Ecke[1]; S Fichtlscherer[1]; AM Zeiher[1]; B Assmus[1]
[1]JW Goethe University, Cardiology, Frankfurt am Main, Germany

Patients with advanced systolic heart failure frequently suffer from concomittant progressive mitral regurgitation (MR), which increases the risk of hospitalization for cardiac decompensation. Treatment of severe MR with mitral clip-implantation

can considerably improve the clinical symptoms and possibly reduce the risk of rehospitalization. We report on our intial experience in patients with an implanted pulmonary artery pressure sensor (PAP), who developed severe MR requiring correction. Due to severe comorbidity, the heart team proposed an interventional approach using mitral clip-implantation. Here, we report on the possibility to directly measure the efficacy of the interventional mitral clip-procedure using ambulatory hemodynamic-telemonitoring.
Methods: Patients fitted with a PAP-sensor and severe, symptomatic MR received a mitral clip-implantation.
Results: 4 patients (mean age of 66 (±6) years) with advanced systolic heart failure (NYHA III, LVEF 21 ± 3%, cardiac index 1.8 ± 0.3) previously fitted with an implanted PAP-sensor received mitral clip-implantation for severe MR (VCmean 7 ± 1 mm). In comparison to the PAP values 4 weeks before the mitral clip-procedure, PAP was profoundly and significantly reduced in all 4 patients both after 30 days (delta PAPsys -16 ± 4, delta PAPmean -11 ± 5, delta PAPdiast -7 ± 3 mmHg, $p < 0.02$) as well as after 90 days (delta PAPsys -19 ± 4, delta PAPmean -13 ± 4, delta PAPdiast -9 ± 2 mmHg, $p < 0.02$). Reductions in PAP were accompanied by a significant clinical and echocardiographic improvement. No patient died and there was no hospitalization for cardiac decompensation.
Conclusion: In patients with advanced heart failure, the success of the interventional mitral clip-procedure on clinical symptoms can be confirmed by hemodynamic-telemonitoring demonstrating a profound and significant reduction of pulmonary artery pressure using an implanted PAP-sensor. Thus, daily non-invasive hemodynamic-telemonitoring allows for the first time a continuous investigation of the efficacy of interventional therapies in patients with chronic heart failure.

Axillary implantation of Impella CP allows early rehabilitation of patients in cardiogenic shock bridged to heart transplantation.

D Couto-Mallon[1]; F Estevez-Cid[2]; C Velasco-Garcia[2]; JM Herrera-Norena [2]; C Iglesias-Gil[2]; M Solla-Buceta[3]; L Seoane-Quiroga[3]; V Aller-Fernandez[3]; S Fojon-Polanco[3]; M Balsa-Canto[4]; E Barge-Caballero[1]; G Barge-Caballero[1]; MJ Paniagua-Martin[1]; MG Crespo-Leiro[1]; JJ Cuenca-Castillo[2]
[1]University Hospital Complex A Coruña, Cardiology, A Coruña, Spain; *[2]University Hospital Complex A Coruña, Cardiac Surgery, A Coruña, Spain*; *[3]University Hospital Complex A Coruña, Intensive Care, A Coruña, Spain*; *[4]University Hospital Complex A Coruña, Rehabilitation, A Coruña, Spain*

Introduction: Axillary implantation of Impella CP device (Abiomed, Inc) is a novel implantation method for patients in cardiogenic shock (CS), which facilitates a better placement of the device and allows mobilization of patients while on support.
Purpose: To describe our pilot experience using axillary implantation of Impella CP as a bridge to heart transplantation (HT) allowing better rehabilitation on support
Methods: Retrospective single-centre descriptive study of CS patients bridged to HT on support with Impella® CP through axillary artery between March and December of 2016. We collect data about survival, time of mechanical ventilation after HT, days in ICU, days to hospital discharge and major complications including bleeding or infection.
Results: 4 patients were bridged to HT with a transaxillary Impella® CP. Data of patients are in the table below. All Impella CP devices were surgically implanted using a Dacron graft. Patients 1, 2 and 3 had received an intraaortic balloon pump before Impella® CP. All patients were extubated immediately after Impella® CP implantation and started an early rehabilitation program consistent in kinesitherapy, respiratory physiotherapy and active movements. Median time on device support was 13.5 days (IQR 11.25 to 15.5). In one patient the device had to be repositioned because of displacement. Median time of ICU stay after HT was 7.5 days (IQR 5.5 to 9.75 days) and median time to hospital discharge after HT was 29.5 days (IQR 26 to 33.5 days). All patients were discharged alive. Major complications after HT were bleeding in one patient with cardiac tamponade and an ischemic stroke in other patient with significant bilateral carotid stenosis. Patient recovered without neurologic sequelae.
Conclusion: Axillary implantation of Impella® CP seems to be a valid strategy for bridging patients in INTERMACS 1 and 2 for HT allowing early initiation of rehabilitation therapy while on support.

Morphological and functional features of left ventricular remodeling after ventricular assist devices support

V Valeriya Krachak[1]; A Smalenski[2]; L Shestakova[1]; O Yudina[2]; D Krachak[1]
[1]Republican Scientific and Practical Centre of Cardiology, Extracorporeal circulation, Minsk, Belarus; *[2]City Clinical Pathologoanatatomic Bureau, Minsk, Belarus*

Introduction: 38 ventricular assist devices (VAD) implantations as a bridge to transplantation and a bridge to transplant candidacy were performed in our center between 2009-2016. Currently, 18 (47.4%) patients were transplanted, 14 (36.8%) died and 6 (15.8%) are on VAD support.
Purpose: The purpose of this study was to evaluate the left ventricular (LV) remodeling after VAD implantation, using echocardiography parameters and myocardial biopsies.
Methods: Morphological and functional parameters were studied in 18 VAD patients, the mean age of the patients was 47,1 ± 12,9 years, 99% of them were men, with ischemic cardiomyopathy (ICM) in 50%, dilated cardiomyopathy (DCM) in 43,75% and giant cell myocarditis (GM) in 6,25%. VADs were implanted for 213,5 (118.5: 370) days and then heart transplantation was performed. Echocardiographic parameters, such as left ventricular ejection fraction (LVEF), end-diastolic volume of the left ventricle (LV EDV), end-systolic volume of the left ventricle (LV ESV) before VAD implantation and after VAD explantation were analyzed in all patients as signs of cardiac remodeling. Myocardial biopsies were collected from the LV apex during VAD implantation and explantation in 8 of 18 patients. Diameters of cardiomyocytes, which were determined in transversally sectioned cells as indicators of myocardial hypertrophy degree were evaluated.
Results: Baseline echo parameters before VAD implantation were: LV EF - 17.5 (13: 18.75)%, LV EDV -281.5 (223: 402.5)ml, LV ESV- 230.5 (185.75: 353) ml. During mechanic support LV EF changed to 34 (18:40)% ($p < 0.02$) and LV EDV - to 165 (104.5: 231.5) ml ($p < 0.02$), LV ESV - to 108 (60: 191) ml ($p < 0.02$). Diameter of cardiomyocytes was 28,82 ± 7,25 mm before VAD implantation and after explantation it was 18,86 ± 4,31 mm ($p < 0.001$). Changes in diameter of cardiomyocytes were -5.13 (-11.09: 1.41) mm. There was a negative correlation between the duration of VAD use and the diameter of cardiomyocytes ($r = -0.86$, $p < 0.02$).
Conclusions: Prolonged VAD support was associated with LV myocardial remodeling such as an increased LVEF, reduced LV EDV and ESV, as well as decreased myocardial hypertrophy, as evidenced by a decline of cardiomyocyte diameter. In addition, there is a notable correlation between the prolonged VAD use and the diameter of cardiomyocytes.

P1146
mortality in patients with cardiogenic shock treated with the impella cp microaxial pump for left ventricular failure

JT Jan-Thorben Sieweke[1]; D Berliner[1]; J Tongers[1]; LC Napp[1]; U Flierl[1]; F Zauner[1]; J Bauersachs[1]; A Schaefer[1]
[1]Hannover Medical School, Cardiology and Angiology, Hannover, Germany

Background: Despite advanced therapies cardiogenic shock (CS) is still associated with high mortality. It is to be noted that out-of-hospital cardiac arrest and right ventricular (RV) failure in addition to left ventricular (LV) failure impair prognosis. Data indicating benefit of mechanical circulatory support in CS, but the choice of the device is still challenging. The Intra-aortic balloon pump had been frequently

P 144 Patients bridged to HT

Patient	Gender	Age	Heart condition	INTERMACS profile at implan tation	Time of support (days)	Intubation after HT (hours)	ICU stay after HT (days)	Days to discharge after HT	Complications
1	Male	65	Idiopathic dilated cardiomyopaty	2	20	11	6	30	Cardiac tamponade
2	Male	68	Ischemic cardiomyopathy	1	6	72	9	44	Ischemic stroke
3	Male	55	Idiopathic dilated cardiomyopathy	2	13	96	12	29	None
4	Male	56	Eosinophilic myocarditis	2	14	12	4	17	None

ICU: Intensive care unit; HT: Heart transplant.

used in CS, but was previously found to provide no mortality benefit. Many shock centres now prefer active LV support as provided by the Impella microaxial pump. A recent underpowered prospective trial, however, demonstrated no mortality benefit for Impella over balloon-pump in CS, but all patients in the Impella cohort (vs. 83% in the balloon-pump group) had been resuscitated before implantation.

Methods: and Results: We investigated consecutive patients (58 ± 13 years) with cardiogenic shock presenting at our institution, who received an ImpellaCP for isolated LV support (n = 62). 61% had been resuscitated before Impella insertion. In a hierarchical analysis we assessed all patients supported on ImpellaCP for CS irrespective of the necessity for resuscitation before implantation, as well as patient subgroups stratified by resuscitation before LV support. Overall survival was 48% at hospital discharge, 43% after 6 months and 38% after 12 months. 30-day mortality increased after out-of-hospital cardiac arrest (resuscitated: 65%: non-resuscitated: 21%), with concomitant RV failure (RV+: 100%; RV-: 33%), and when Impella implantation was performed after PCI in case of ischemic CS (pre-PCI: 40%; post-PCI 61%). Patients in our local registry, who fitted the inclusion/exclusion criteria of the SHOCK-II trial had a markedly lower mortality (24% at 30 days) compared to the published trial.

Conclusion: Active hemodynamic support with ImpellaCP in singular LV failure results in lower than previously reported mortality rates. RV failure or pre-implantation cardiac arrest critically influences observed mortality and should be taken into account when performing clinical trials aiming to address mortality in CS patients.

P1147

A proposed algorithm to assist first responders in resuscitation of patients with left ventricular assist devices (LVADs)

K Chu[1]; SA Schaffer[1]

[1]*St. Boniface General Hospital, University of Manitoba, Winnipeg, Canada*

Background: The prevalence of patients with left ventricular assist devices (LVAD) is increasing. If a LVAD patient collapses, emergency personnel must decide if immediate cardiopulmonary resuscitation (CPR) is safe, necessary, and effective. Even within implanting centers, expertise on LVAD emergencies is limited to the advanced heart failure and cardiovascular surgical units.

Purpose: To propose an addition to the Advanced Cardiac Life Support algorithm specifically for LVAD patients and determine its application in case examples.

Methods: We reviewed and summarized the literature to devise an addition to the current Advanced Cardiac Life Support algorithm specific to LVAD patients. We then applied it to three cases.

Results: Continuous flow LVAD patients inherently do not have a pulse. Its absence cannot be used as a marker of hypoperfusion and need for CPR. As long as the LVAD is operating, there should be blood flow into the LVAD and out of the heart. Uncertainty in how to manage this population may lead to delayed resuscitative measures reducing probability of favorable outcomes. In our proposed algorithm, priority is to determine if an unconscious patient has adequate perfusion and to restore it quickly prior to neurological injury if necessary. Unconsciousness may be related to low cardiac output from LVAD malfunction, but non-LVAD related causes remain on the differential. LVAD malfunction is associated with audible alarms and visible messages on patient controllers. If the patient controller indicates normal functioning (lights on, no alarms), absolute LVAD failure and low output is unlikely. If unconsciousness is due to low cardiac output resulting from LVAD malfunction or primary cardiac pathology (e.g. right ventricular arrhythmias, low LV pre-load) immediate efforts to restore perfusion is essential. CPR has a theoretical risk of cannula dislodgement and should be deferred if alternative therapies are immediately available. Published case series have not demonstrated this. The controller should be quickly identified and examined. Check all connections from patient to driveline to controller to batteries/power base. Given the complexity and risk of controller exchange and rarity of failure, routine exchange without confirmation of malfunction is discouraged. If connections are intact, LVAD lights are off or alarming and no LVAD hum is auscultated, start immediate compressions. If a dysrhythmia is suspected and defibrillator is quickly accessible, this can be delayed. We applied our algorithm to cases involving an unconscious, spontaneously breathing patient in an outpatient hospital lab, a cardiac arrest called to the emergency room, and paramedics arrival to a patient with the LVAD alarming.

Conclusion: CPR in LVAD patients is safe and sometimes necessary. Our proposed algorithm assists first responders to provide timely and life-saving medical care to this special group of patients.

Acute kidney injury early after CF-LVAD implantation is associated with high mortality rates: a multicenter study.

R Rahat Muslem[1]; K Caliskan[1]; S Akin[1]; A Constantinescu[1]; GJ Whitman[2]; RJ Tedford[3]; DA Hesselink[4]; AJJ Bogers[5]; SD Russell[3]; OC Manintveld[1]

[1]*Erasmus Medical Center, Cardiology, Rotterdam, Netherlands*; [2]*Johns Hopkins University of Baltimore, Cardiothoracic Surgery, Baltimore, United States of America*; [3]*Johns Hopkins University of Baltimore, Cardiology, Baltimore, United States of America*; [4]*Erasmus Medical Center, Nephrology, Rotterdam, Netherlands*; [5]*Erasmus Medical Center, Cardiothoracic Surgery, Rotterdam, Netherlands*

Purpose: Data on the consequence of acute kidney injury (AKI) after continuous-flow left ventricle assist devices (LVAD) are scarce and inconsistent. In the current study, the incidence and predictors of AKI and its impact on mortality and renal function in the first year after LVAD implantation was evaluated.

Methods: A retrospective multicenter cohort study was conducted, including all patients (age ≥18) undergoing LVAD implantation (91% HeartMate II, 9% HVAD). The definition proposed by the Kidney Disease Improving Global Outcome criteria (KDIGO) was used to define AKI.

Results: Overall, 241 patients (mean age 52.4 std. 12.9 years, 76% male, 64% BTT) were included. AKI criteria was met in 169 (70%) LVAD patients, of who 109 (45%) had AKI stage I, 22 (9%) stage II and 38 (16%) stage III. The need for inotropic support and pre-existent severe kidney failure (eGFR <30 ml/min/1.73 m2) were independently associated with the development of AKI and subsequent higher AKI stages. One-year mortality rates in patients without AKI, AKI stages I, II and III were 18.7%, 26.4%, 23%, 51%, respectively (log-rank p = 0.001, Figure 1A). In multivariable analysis AKI stages ≥ II were independently associated mortality (HR 2.2 (95% CI 1.1-4.5), p = 0.027) and worse renal function (β -7.4 (95% CI -12.6 to -2.1), p < 0.01) at 1 year.

Conclusion: AKI is highly frequent after LVAD implantation. More severe AKI stages are associated with higher mortality rates and impaired renal function at one year after LVAD implantation.

Outcomes of patients with or without implantable cardioverter defibrillators on continuous-flow left ventricular assist device support

VJ Goh[1]; CP Lim[2]; D Sim[2]; KL Kerk[2]; TE Tan[2]; C Sivathasan[2]; JL Soon[2]; L Teo[2]
[1]*Duke-NUS Graduate Medical School Singapore, Singapore, Singapore*; [2]*National Heart Centre Singapore, Singapore, Singapore*

Background/Introduction: The role of Implantable Cardioverter Defibrillators (ICDs) in patients implanted with continuous-flow Left Ventricular Assist Devices (LVADs) remains controversial. Pre-LVAD ventricular arrhythmia (VA) was shown to be a major predictor of post-LVAD VA, suggesting that patients with pre-LVAD VA could benefit from ICD implantation. There is, thus far, little evidence for the routine implantation of ICDs for patients undergoing LVAD surgery.
Purpose: We aimed to study whether ICD implantation in patients with or without pre-LVAD VA affected the outcomes of patients on LVAD support.
Methods: We performed a retrospective analysis of 72 consecutive patients receiving LVADs between May 2009 and April 2016 in a single tertiary hospital in Singapore. Data analysed included demographic variables, ICD reports, and other clinical attributes. Group A was defined as patients who received ICD implantation pre-LVAD surgery, while group B did not have ICDs implanted going into LVAD surgery. Outcomes assessed included all-cause mortality, all-cause hospitalisation and clinically significant VA (defined as any post-LVAD VA resulting in hospitalisation, cardioversion, ICD implantation, or ICD therapy occurring ≥30 days post-LVAD implantation).
Results: Our cohort comprised of majority (81%) male, 49% with ischaemic cardiomyopathy, 43% INTERMACS profile 1 or 2 at LVAD implantation with a median of 22 months (IQR 12, 39) on LVAD support. Half of the patients had ICD implanted prior to LVAD surgery. Group A (n = 36) was older (53 ± 12 vs. 47 ± 13, p = 0.04), had higher incidence of pre-LVAD VA (47% vs. 22%, p = 0.05), and larger pre-LVAD end-diastolic left ventricular internal diameter (LVIDd) (7.1 ± 1.0 vs. 6.5 ± 1.3, p = 0.02). There was no significant difference between the two groups in terms of all-cause mortality and hospitalisation (Group A vs. Group B: 22% vs. 8%, P=0.2 and 86% vs. 86%, P=1.0, respectively). However, there was a higher rate of clinically significant post-LVAD VA in Group A than Group B (44% vs. 11%, p = 0.003). Compared to patients without pre-LVAD VA, a higher proportion of patients who had pre-LVAD VA tended to experience clinically significant VA post-LVAD in Group A (71% vs. 21%, p = 0.006) but not Group B (13% vs. 11%, P=1.0). However, pre-LVAD VA did not result in a difference in mortality in either group (Pre-LVAD VA vs. none: Group A 18% vs. 26%, P=0.7; Group B 0% vs. 11%, P=1.0) (Figure 1). The presence of ICD did not confer a mortality benefit in patients with pre-LVAD VA (Group A 18% vs. Group B 0%, p = 0.5).
Conclusion(s): ICD implantation pre-LVAD surgery did not confer a mortality benefit regardless of presence of pre-LVAD VA. Our findings do not support the practice of routine ICD implantation prior to LVAD surgery.

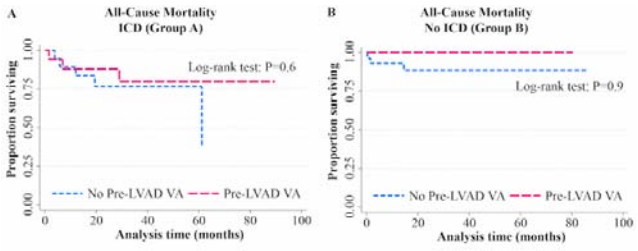

Figure 1

P1150

Bridge to transplantation versus standard heart transplantation: heart transplantation performed after ventricular assistance device is associated with improved survival.

T Petroni[1]; C D'alessandro[2]; A Combes[3]; JL Golmard[4]; N Brechot[3]; E Barreda[2]; M Laali[2]; P Farahmand[2]; S Varnous[2]; P Weber[2]; A Pavie[2]; P Leprince[2]

Aim: Mechanical circulatory support is an alternative strategy as a bridge-to-transplantation for critical situations such as circulatory shock or graft shortage. The purpose of this study was to evaluate long-term results and outcome after heart transplantation performed in patients with ventricular assistance device (VAD) versus no mechanical circulatory support.
Methods and Results: All the patients who underwent heart transplantation between 2005 and 2012 were included in this monocentric retrospective study. We compared 52 VAD patients who underwent heart transplantation to 289 patients transplanted without VAD. Mean age was 46 ± 11 years in the VAD group vs 51 ± 13 years in the standard group (p = 0.01) and 17% of the VAD patients were women vs 25% (p = 0.21). Ischemic time was longer in the VAD group (207 ± 54 vs 169 ± 60 min, p < 0.01). There was no difference of primary graft failure (33% vs 25%, p = 0.22) and 1-year mortality (17% vs 28 %, p = 0.12). Independent risk factors for 1-year mortality were preoperative VAD (OR 0.40 [0.17-0.97], p = 0.04), recipient age>60 years (OR 0.2.35 [1.34-4.14], p < 0.01), recipient creatinine (OR 1.005 [1.001-1.010], p = 0.02), BSA mismatch (OR 4.85 [1.34-17.54], p = 0.02) and ischemic time (OR 1.005 [1.001-1.010], p = 0.02). Five-year survival was 66% in VAD group vs 60% in standard group (p = 0.72). Independent risk factors for 5-years survival were recipient age>60 years (HR 1.570 [1.05-2.34], p = 0.02), recipient creatinin (HR 1.005 [1.002-1.008], p = 0.02) and ischemic time (HR 1.004 [1.001-1.007], p = 0.01).
Conclusion: Bridge-to-transplantation by VAD reduced one-year mortality and improved mid-term survival rate after heart transplantation.

Risk Factor	OR (95% CI)	p
Group VAD	0.399 (0.165-0.967)	0.02
Recipient Age > 60 years	2.353 (1.339-4.135)	< 0.01
Recipient Creatinin	1.005 (1.001-1.010)	0.02
BSA Mismatch > 0.15	4.847 (1.340-17.536)	0.02
Ischemic Time	1.005 (1.001-1.010)	0.02

Cangrelor use in the treatment of left ventricular assist device pump thrombosis

CM Christopher Bianco[1]; BP Dhakal[1]; M Zacharias[1]; SG Al-Kindi[1]; R Barcelona[1]; L Meece[1]; C Elamm[1]; MR Robinson[1]; R Benatti[1]; M Ginwalla[1]; BP Sareyyupoglu[1]; BP Medalion[1]; SG Park[1]; G Oliveira[1]
[1]*University Hospitals Case Medical Center, Cleveland, United States of America*

Background: Left ventricular assist device (LVAD) pump thrombosis (PT) treated with conventional pharmacologic therapy is associated with a 6 month mortality rate of nearly 50%. Pump exchange or transplantation is the definitive therapy, however many patients are suboptimal candidates and an attempt at medical therapy is appealing. Several strategies involving escalating anticoagulants, antiplatelets, or thrombolytics have been utilized; however none has emerged superior. Our group has shown the P2Y12 inhibitor ticagrelor, in conjunction with heparin and aspirin, was beneficial in resolving PT and avoiding pump exchange. However, a relatively long half-life limits its use in expectant medical management with the potential for urgent pump exchange. Cangrelor, a potent, reversible P2Y12 inhibitor that allows rapid restoration of normal platelet function within 1 hour of cessation may facilitate a more effective, safer strategy.
Purpose: LVAD PT is common, however suboptimally treated with conventional medications. A novel treatment strategy utilizing cangrelor may prove effective and safe in cases of suspected PT.
Methods: We performed a case review of patients with suspected PT (evident by sustained power elevations >10W or >2W from baseline with peak elevated LDH >3x ULN) who were treated with cangrelor at a large academic center between

8/2015 and 1/2017. Successful pharmacologic treatment was defined as freedom from death, pump exchange, or transplantation during index hospitalization.
Results: Cangrelor was utilized in 4 patients with 5 episodes of suspected PT. All 4 patients had Heartmate II devices implanted as destination therapy between 8/2014 and 6/2015. Cangrelor treatment was successful in 3/5, while 2/5 required pump exchange. All patients treated with cangrelor remain alive to date. One patient originally treated successfully with cangrelor developed another episode of suspected PT 14 months later, he was treated with cangrelor again, but eventually required pump exchange. There were no major bleeding events during cangrelor infusion, 1 patient who underwent pump exchange had to return to OR for continued post-op mediastinal bleeding. Two patients, both safely and successfully treated, were deemed at elevated risk for major bleeding events, one by history of intracranial bleed and the other with recurrent GIB. A mean of 3.6 antiplatelet or anticoagulant agents were attempted prior to cangrelor initiation. Mean duration of cangrelor infusion was 6 days. Mean decrease of serum LDH from cangrelor initiation to hospital discharge or pump exchange was 45%.
Conclusions: Cangrelor use for treatment of suspected PT is associated with a reasonable success rate and excellent safety profile in this small series. To our knowledge, this is the first reported case series of cangrelor use in PT. Further study of cangrelor use in the management of PT is warranted.

P1152

Heart transplantation: to bridge or not to bridge

M Massimiliano Carrozzini[1]; T Bottio[1]; F Toto[1]; M Comisso[1]; E Manzan[1]; V Tarzia[1]; J Bejko[1]; G Gerosa[1]
[1]*University Hospital of Padova, Cardiac Surgery Unit, Padua, Italy*

Background/Introduction: It is unclear if the use of left-ventricular-assist-device (LVAD) as bridge-to-transplantation can improve post-transplant outcomes.
Purpose: We aimed to compare results of heart transplantation with or without previous bridging with an implantable continuous-flow LVAD.
Methods: All consecutive patients who underwent heart transplantation at our institution between January-2012 and December-2016 were included. LVAD used were Jarvik2000 and HeartWare. Patients were dived in VAD and No-VAD groups according to previous implantation of an LVAD or not.
Results: : Included are 128 patients: 44 VAD and 84 No-VAD. Emergent transplantation ($p = 0.03$), previous staying in ICU ($p = 0.01$) and para-corporeal mechanical support ($p < 0.01$) were more frequent in No-VAD. VAD vs No-VAD had similar 30-day-mortality (7% vs 5%, $p = 0.69$), whereas ICU-stay (6 ± 4 days vs 12 ± 15, $p < 0.01$) and hospital-stay (37 ± 16 vs 45 ± 28, $p = 0,03$) were longer in No-VAD. Postoperative complications were comparable among groups, except for pleural/pericardial-effusion ($p = 0.01$) and tracheostomy ($p < 0.01$), more frequent in No-VAD. After a mean follow-up of 25 ± 19 months mortality was higher in NO-VAD group (5% vs 15%, $p = 0,14$) though not significantly. Rate of cellular-mediated-rejection ($p = 0.17$) and antibody-mediate-rejection ($p = 0.97$) were similar.
Conclusion(s): LVAD as bridge-to-transplantation showed a trend toward better post-transplant outcomes. A larger patient population is needed to confirm our results.

Post-transplant outcomes

	VAD (N=44) N (%) Mean ± SD	No-VAD (N=84) N (%) Mean ± SD	P value
Postoperative ECMO	7 (16)	16 (20)	0,66

Clinical outcomes at 5-years following transcatheter aortic valve replacement in patients with aortic stenosis

E Munoz-Garcia[1]; M Munoz-Garcia[1]; AJ Antonio Jesus Munoz Garcia[2]; AJ Dominguez-Franco[2]; JM Garcia-Pinilla[2]; L Morcillo-Hidalgo[2]; MF Jimenez-Navarro[2]; JH Alonso-Briales[2]; JJ Gomez-Doblas[2]; JM Hernandez-Garcia[2]; E De Teresa-Galvan[2]
[1]*Department of Cardiology , Malaga, Spain*; [2]*University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

The durability of transcatheter heart valves and long-term clinical outcomes are unknown. The aim of this study was to evaluate clinical and hemodynamic outcomes 5-years after Transcatheter Aortic Valve Replacement (TAVR).
Methods: Between April 2008 and December 2011, 224 patients underwent TAVR for the treatment of severe symptomatic aortic stenosis with the auto-expandable prosthesis
Results: the mean age and EuroSCORE were $79.2 \pm$ 6.4 years and 19.8 ± 13% respectively. Mean aortic valve gradient decreased from 50 ± 15 mm Hg to 8.6 ± 3.8 mmHg after TAVI, to $11.1 \pm$ 9 mm Hg at 4 years and $22.7 \pm$ 12 mmHg at 5 years (p for post-TAVI trend 0.03). Mean aortic valve area increased from 0.6 ± 0.16 cm2 to $1.59 \pm$ 0.3cm2 after TAVI to $1.48 \pm$ 0.2 at 4 years and $0.97 \pm$ 0.3 cm2 (p for post-TAVI trend 0.01). Mean left ventricular ejection fraction increased from 61.1 ± 15 % to 65.5 ± 11% after TAVI, to 58.2 ± 17% at 4 years and $60.7 \pm$ 8% at 5 years (p for post-TAVI trend 0.001) Late mortality after a mean of $52.29 \pm$ 28 months was 58.3% and in only 37 patients was cardiovascular mortality. Survival rates at 1 to 6 years were at 86.1%, 77.8%, 70.4%, 64.8%, 53 % and 44.3% respectively. At 5 years, 3 patients had severe prosthetic valve dysfunction (severe stenosis and moderate transvalvular regurgitation). Median survival time after TAVI was 3.91 years (95% confidence interval [CI]: 3.6 to 4.21), and the risk of death was significantly increased in patients with frailty (adjusted hazard ratio [HR]: 3.25; 95% CI: 1.76 to 6.01),$p = 0.001$, Charlson index [HR= 1.24 (95% CI 1.11-1.37), $p < 0.001$], Acute kidney injury after TAVR [HR= 1.942 (95% CI 1.10-3.42) $p = 0.022$] and lef ventricular ejection fraction [HR= - 0.352;(95% CI 0.166-0.745)$p = 0.006$].
Conclusions: Our study demonstrated favorable long-term outcomes after TAVR. Signs of prosthetic valve failure were observed in 1.33% of patients

P1154

Alternative solution for central hemodynamics parameters assessment with a new tacho-oscillometric device

S Padaryan[1]; E Elena Shavarova[2]; Y Kotovskaya[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*; [2]*Russian Peoples Friendship University, Moscow, Russian Federation*

Background and aim: to evaluate blood pressure (BP) parameters, measured with a new tacho-oscillographic device using volume-compressive oscillometry (VCO), compared with Korotkoff auscultation method and parameters of central BP measured with applanation tonometry. The main advantages of VCO comparing to other oscillometry technic of BP registration is formation and recording the curve automatically in synchronism with the cuff inflation and recording the artery response by changing the cuff volume throughout the all period of cuff compression. It could prevents appearing of extra-vibrations and sound phenomenon due to "water hammer". Strong association between hemodynamic parameters measured by VCO and by invasive method of BP registration was found previously: for systolic (SBP) ($r=0.96$, $p < 0.0001$), for diastolic (DBP) ($r=0.92$, $p < 0.0001$) BP.

Methods: 68 subjects were included in the study: 28 young (< 35 yrs) healthy volonteers and 40 elderly hypertensive pts (>60 yrs). BP were measured by a trained health care provider using a mercury sphygmomanometer and the Korotkoff sound technique. Central SBP, DBP were evaluated in supine position with SphygmoCor device. BP measurement was also performed using new tacho-oscillometric cuff-based device EDTV-Hemodin. This device analyses recorded tachooscillogram and evaluates diastolic, mean, lateral (true systolic) and end-systolic pressure.
Results: 65% of subjects were male and mean BMI was 24.9 ± 4.1 kg/m2. Mean SBP, measured using Korotkoff method was 125.97 ± 9.88 mm Hg, DBP - 70.17 ± 9.14 mm Hg. Mean central SBP measured with SphygmoCor 109.9 ± 10.2 mm Hg; mean central DBP - 72.25 ± .63 mm Hg. Mean SBP and DBP measured with EDTV-Hemodin were 111.7 ± 11.83 and 51.37 ± 10.56 mm Hg respectively. We found correlations using Spearman's rank between mean central SBP measured with SphygmoCor and SBP measured with EDTV-Hemodin ($r=0.41$, $p < 0.05$). Correlation, using Bland-Altman's plot was found between SBP measured by SphygmoCor and EDTV-Hemodin (bias -1.87 mm Hg [-5.43; 1.76]). There were no associations between assessment BP using EDTV-Hemodin and auscultation method. Positive correlation in both groups between measurement of central SBP with SphygmoCor (103.67 ± 6.31 mm Hg and 115.94 ± 9.19 mm Hg respectively) and SBP evaluated with EDTV-Hemodin (108,05 ± 11,56 mm Hg and 115.00 ± 11.05 mm Hg respectively) - for the first group bias was - 4.38 [-9.89;1.13] mm Hg; for the second - bias was 0.94 [-4.56; 6.45] mm Hg. Conclusion: SBP and DBP by VCO were significantly lower, than comparing to Korotkoff method. There is association between central SBP measured by SphygmoCor and SBP by VCO. VCO diagram could considered as indicator of aortic stiffness. Further study is required to validation and evaluation of the clinical significance of new tachooscillometric device.

P1155

Cardiac device implantation rate in heart failure patients:A study based on a tertiary cardiology service in Ireland.

D Ranganathan[1]; S Fall[1]; M Carey[1]; B Khan[1]; D Moore[1]
[1]*Adelaide & Meath Hospital, Cardiology Department, Dublin, Ireland*

Background: HFrEF is defined as left ventricular ejection fraction (LVEF) of ≤40%. Goals of therapy in HFrEF are to reduce mortality and morbidity as well as to improve functional status and reduce hospital admissions secondary to decompensation. The European CRT survey showed that patients who received CRT device had symptomatic improvement and overall survival rate >90%, replicating the outcomes shown in randomised control trials.
Purpose: This study aimed to evaluate if patients referred to our Heart Failure Clinic (HFC) were appropriately considered for an implantable device after optimal medical therapy (OMT) as per ESC 2013 guidelines.
Methods: Patient referrals from January 2015 to December 2015 were analysed through an online portal – Cellma. Out of 179 patients referred, 90 patients (50.0%) had HFrEF. Further information (such as NYHA class of symptoms, ECG – looking for evidence of LBBB/QRS interval, medical therapy) was collected through Cellma. 23 patients had incomplete information (missing echocardiography, ECGs) were omitted from the study.
Results: Of 67 patients, 19 patients were female and 48 were male. The mean age was 67.29 years with the oldest patient at 93 and youngest at 33. 53 out of 67 patients had an LVEF ≤ 35% post OMT. 61 patients were on ACEi/ARB, 62 patients on beta-blocker, 4 patients on nitrates and 63 were on diuretics (55 on loop, 50 on potassium sparing diuretic and 41 on a combination of the two). Of these, 19 patients had NYHA class 2-3 symptoms and 12 patients (18% in sinus rhythm) qualified for device therapy. Of these 12 patients, 1 patient passed away prior to treatment, 5 had appropriate device in-situ, 3 patients could have benefitted more from a different device (i.e. resynchronization therapy) and 3 patients despite meeting criteria had no device in-situ (at time of study).
Discussion: In our study, 90% of patients were on appropriate combination of medication for HFrEF. 25% of patients, despite meeting criteria for device therapy, did not have a device in-situ. Furthermore, 25% of patients who had device in-situ could have probably benefitted from resynchronization therapy. Given these patients were followed up regularly in a specialist HF clinic in a tertiary referral university teaching hospital, there is selection biasness and underestimation of the general heart failure population. The low rate of device implantation is not a unique issue highlighted in our study. The Swedish pacemaker and implantable cardioverter-defibrillator registry concluded there is marked variation in the rate of device implantation across Europe and within each country. Italy, which has one of the highest CRT-D implantation rates in Europe, noted reasons including creation of dedicated referral pathway and high number of implanting centers. A more exclusive study exploring the reasons for non-adherence to device implantation guidelines and ways to bridge the gap should be conducted to target this issue.

P1156

Acute effects of spinal cord stimulation on cardiac autonomic control and function in patients with heart failure

J Jan Naar[1]; D Jaye[2]; C Linde[3]; P Neuzil[1]; P Doskar[1]; F Malek[1]; F Braunschweig[3]; L H Lund[3]; L Mortensen[3]; B Linderoth[4]; G Lind[4]; F Kueffer[2]; J Koehler[2]; M Stahlberg[3]
[1]*Na Homolce Hospital, Department of Cardiology, Prague, Czech Republic*; [2]*Medtronic Plc, Cardiac Rhythm and Heart Failure, Minneapolis, United States of America*; [3]*Karolinska University Hospital, Department of Cardiology, Stockholm, Sweden*; [4]*Karolinska Institute, Department of Clinical Neuroscience, Stockholm, Sweden*

Background/Introduction: Heart failure with reduced ejection fraction (HF) is characterized by sympathetic over-activity and baroreceptor desensitization. Spinal cord stimulation (SCS) can reduce sympathetic nerve activity in animal models of HF but data in patients with HF is limited.
Purpose: We aimed at testing the hypothesis that SCS acutely improves heart rate variability (HRV) and baroreceptor sensitivity (BRS) in patients with chronic HF.
Methods: HF patients with a SCS device implanted (Th1-Th4 spinal cord level) were included in this study. SCS was delivered (stimulation amplitude: 90% of maximally tolerated, all eight electrodes active) for 15 minutes. ECG and beat-to-beat non-invasive hemodynamics (finger plethysmography) were recorded continuously during SCS-90% and compared to a 5 min baseline period immediately before SCS (SCS-OFF). This was repeated using different SCS stimulation settings: Output 60% of maximally tolerated (SCS-60%), cranial electrode configuration (SCS-CRAN) and caudal electrode configuration (SCS-CAU).
Results: Fifteen patients (73% males, mean age 65 ± 8 years, mean left ventricular EF 43 ± 14%) were included to this study. SCS-90% did not influence HRV, BRS or hemodynamics (table). Similarly, SCS-60%, SCS-CRAN and SCS-CAU did not change HRV, BRS or hemodynamics compared to SCS-OFF.
Conclusion: SCS delivered acutely at ≤90 % of maximally tolerated output does not appear to improve autonomic balance or baroreceptor sensitivity in patients with heart failure.

Variable	SCS-OFF	SCS-90%	p-value
Heart rate variability (n=11, median [IQR])			
Heart rate (bpm)	65.6 [55.7-70.9]	64.6 [53.6-69.8]	0.06
SDNN (ms)	55.7 [25.5-87.4]	50.9 [35.8-73.9]	0.82
LF power (ms^2)	511 [154-1557]	300 [154-1081]	0.89
HF power (ms^2)	290 [66-821]	322 [97-579]	0.69
LF/HF (ratio)	1.8 [1.1-3.6]	1.7 [0.8-3.7]	0.82
Baroreceptor sensitivity (n=10, median [IQR])			
BRS (ms/mmHg)	10.4 [4.7-12.8]	6.3 [3.0-10.5]	0.35

P1157

Long term performance and effects of single pass VDD pacing leads in cardiac resynchronization therapy

R Sosdean[1]; C Tutuianu[1]; RI Macarie[2]; B Enache[1]; C Mornos[1]; A Ionac[1]; S Pescariu[1]
[1]*Victor Babes University of Medicine and Pharmacy, Clinic of Cardiology, Timisoara, Romania*; [2]*Profilaxis Medical Center, Cardiology, Timisoara, Romania*

Background: The use of single pass VDD leads for cardiac resynchronization therapy (CRT) is suggested in several reports to be beneficial in terms of costs, complication rate, intervention and fluoroscopy time, but data in the literature about the long-term performance and effects is scarce. The problem consists in the possible failure of the floating atrial dipole to properly detect atrial activity, especially in patients with dilated cardiomyopathy (DCM). Also, the lack of atrial pacing capability may result in VVI biventricular pacing in case of severe bradycardia.
Purpose: In this study we aimed to analyze the long term performance of the VDD pacing leads, replacing the right atrium and right ventricle leads, for CRT, in terms of pacing parameters and effects on patients' evolution.
Methods: A number of 20 consecutive patients implanted with VDD CRT pacing systems between 2000 and 2014, with available data at baseline and after at least 2 years of CRT, while in sinus rhythm, were retrospectively analyzed. The analysis concerned the intervention details, pacing parameters, and NYHA class and left ventricular ejection fraction (LVEF) (Simpson method) evolution. We used paired t-test and Fisher exact test to compare numerical and nominal variables, respectively, and Pearson test for correlations ($p < 0,05$ as statistically significant).

Results: All 20 patients with VDD CRT pacing systems, aged 60,8 ± 7,2 years, 18 (90%) with nonischemic DCM, had a normal left atrial function, with a left atrium <5cm (4,66 ± 0,48cm), a normal-sized right atrium, without a documented history of atrial fibrillation. The average acute atrial sensing was 3,12 ± 0,43mV, but the chronic atrial sensing was significantly lower- 1,42 ± 0,58 (p = 0,006). We detected a 98,47 ± 2,24% of CRT pacing (>98% CRT pacing in 16 patients- 80%). Ventricular detection (atrial undersensing and/or ventricular arrhythmias) was found in only 3 patients (15%) and it was responsible for <5% loss of CRT pacing. VVI pacing was detected in 11 patients (55%) (between 1-4,9% in 8 patients- 40%, and between 5-10% in 3 patients- 15%). The LVEF improved significantly by 10,7 ± 7,5% (p < 0,001), with <5% improvement in only 3 patients (15%). 13 patients (65%) clinically improved by 1 NYHA class and 3 (15%) by 2 NYHA classes (p < 0,001). NYHA class failed to improve in only 4 patients (20%). There was no significant negative correlation between the small percent of VVI pacing and the echocardiographic/clinical response (Pearson r= -0.22, p = 0,34 and r= -0,29, p = 0,2, respectively).
Conclusions: In spite of the high variability of the atrial sensing, the VDD pacing lead seems capable of maintaining CRT in a reasonable percent of time, with a significantly favorable clinical and echocardiographic evolution of the patients. VVI pacing intervened in a very low percent without interference with patients' evolution. These results may be a good starting point for future prospective randomized studies.

Caval flow regulator catheter balloon in acute heart failure: echocardiographic data.

J E Jose E Herrera[1]; J A Herrera[1]; I Palacios[2]; M Semigran[2]; R Levine[2]
[1]Unidad de Ecocardiografia ab, Porlamar, Venezuela; *[2]Massachusetts General Hospital, Interventional Cardiology, Boston, United States of America*

Background: We reported the hemodynamic changes of the first 6 CHF case in humans, using Percutaneous Transluminal Caval flow Restriction (PTCR). This innovative method reduced preload in CHF. We are reporting the echocardiographic data results of the 6 consecutive patients with CHF, treated with intermittent preload reduction of flow with Caval restriction with Balloon.
Materials and Methods: 6 patients with CHF who met protocol criteria were evaluated. 4 were ischemic, and 2 non ischemic. We performed baseline echocardiogram, coronary angiogram and right heart catheterization. Caval flow restriction was started, catheter balloon was introduced in the femoral vein and echo guided, placed before hepatic vein drainage. The balloon was inflated to cover Inferior Vena Cava (IVC) remaining area completing 100% occlusion, and 70% (sub-occlusion) during expiration resulting in intermittent flow restriction. The balloon was kept inflated for 30 minutes, right catheterization and echocardiogram were repeated during inflated balloon.
Results: Table 1.
Conclusion: We are reporting our echocardiography datan in 6 patients with CHF treated with intermittent reduction of preload with Caval restriction with Balloon, Hemodynamic and echocardiographic changes obtained in these patients, suggest, that this innovative approach can play a role in the treatment of CHF patients.

Safety of aspirin therapy in patients for elective coronary artery bypass grafting

K Krivoshapova[1]
[1]Research Institute for Complex Problems of Cardiovascular Diseases, Kemerovo, Russian Federation

Objective: To evaluate safety of coronary artery surgeries with preoperative aspirin management.
Materials and Methods: 168 patients, treated with aspirin in the preoperative period, were included in the current study (Group I). The comparison group (Group II) included 218 patients, who did not receive aspirin preoperatively. Intra- and postoperative blood loss, the rate of redo procedures, caused by bleedings, the rate of blood transfusions as well as blood product volumes were evaluated. The data were analyzed sis using the SPSS 13.0 software package for Windows.
Results: The intraoperative blood loss was similar in both groups (495.2 ± 66.8 ml in Group I vs. 490.5 ± 68.6 ml in Group II, p = 0,67), whereas postoperative blood loss within 6 h and 12 h was significantly higher in Group I (within 6 h of surgery - 160.3 ± 92.9 ml, p = 0.0001; within 12 h of surgery – 245.3 ± 150.3 ml, p = 0.0001) compared to Group II (within 6 h – 116.4 ± 55.2 ml, p = 0.0001; within 12 h – 161.0 ± 127.9 ml, p = 0.0001). However, there were no significant differences in the total blood loss within 24 h (314.7 ± 250.8 ml in Group I vs. 250.8 ± 127.4 ml in Group II, p = 0.08; mean difference 63.9 ml, CI 95% from 0.7 to 128.5 ml, p = 0,13). The rates of blood transfusions were significantly higher in Group I (91.9%) compared to Group II (16.2%, p = 0.001); thus, resulting in increased rate of red cell concentrate transfusions (29.8% vs. 7.5% respectively, p = 0.0001) and platelet concentrates transfusions (78.0% vs. 7.5%, respectively, p = 0.0001). However, the rates of fresh frozen plasma transfusion were similar in both groups (29.8% vs. 7.5%, respectively, p = 0.023). It should be noted that the average volume of blood product transfusions for each patient did not significantly differ in both groups. Moreover, the rates of redo procedures, caused by bleedings, were similar in both groups (3.6% in Group I vs. 1.9% in Group II, p = 0.35).
Conclusions: Patients, receiving aspirin before elective CABG, reported a significant increase in postoperative blood loss within 6 h and 12 h as well as increased need in blood product transfusions. Nevertheless, the total blood loss within 24 h as well as the redo rates, caused by bleedings, did not differ significantly.

P1160

Challenges of pregnancy after aortic coarctation repair

H Helena Nascimento[1]; M Braga[1]; V Ribeiro[1]; C Cruz[1]; MJ Maciel[1]
[1]Sao Joao Hospital, Porto, Portugal

Introduction: Major advances in cardiology and cardiac surgery determined an increment of women with corrected heart conditions that are reaching childbearing age. The incidence of foetal and maternal complications during this period is widely variable among female with congenital heart diseases.
Material and methods: A retrospective analysis of pregnant women with the diagnosis of repaired aortic coarctation (CoA), being followed-up in a Grown-up Congenital Heart Disease (GUCH) Centre. Epidemiological and clinical data were collected and inserted in a registry database.
Results: From 46 female patients (pts) (mean current age 39 ± 10 years-old), 25 have been pregnant (54%). Among these patients, 16 pts (64%) presented a concomitant congenital heart defect, being bicuspid aortic valve the most commonly observed (n = 6 pts, 24%), followed by associated ventricular septal defect (VSD) (n = 5, 20%) and ductus arteriosus (n = 5, 20%). Surgical repair of CoA was the intervention of choice for most women (n = 20, 80%). Hypertension was diagnosed in 11 pts (44%). There were a total of 28 pregnancies (2 ongoing). All patients were submitted to foetal echocardiography and in 3 cases foetal cardiac defects were diagnosed in utero (11%). A complex cardiomyopathy associated with major malformations was identified in 2 pregnancies, leading to medically supervised abortions. During childbearing or the peripartum period, there were no cases of eclampsia or pre-eclampsia, vascular complications or dead. There were no contraindications to vaginal delivery because of the congenital heart disease. However, caesarean sections were performed in 48% of the cases. The live-birth-rate was 81% (3 spontaneous abortions). At birth, mean gestational age was 38 ± 2 weeks and mean weight was 2991 ± 3grams.
Conclusion: Our study supports that successful pregnancy is possible for most women with CoA, as long as adequate care during pregnancy, delivery, and postpartum period is provided. This underscores the importance of pregnancy follow-up with a specialized multidisciplinary team in a GUCH centre.

P1161

Elevated postoperative right atrial pressure predicts post-heart transplant 1-year mortality

V Kittipibul[1]; S Puwanant[1]
[1]*Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand*

Background: Mean right atrial pressure (mRAP) is a practical hemodynamic parameter to reflect preload and right ventricular function. Clinical significance of postoperative mRAP in heart transplant has not been well studied.
Objectives: 1) To study the association between postoperative mRAP and post-heart transplant outcomes. 2) To study the trend and natural behaviour of mRAP after heart transplant.
Methods and Results: Fifty-one consecutive de novo adult heart transplant patients (42 ± 13 years, female 35%, cold ischaemic time 236 ± 67 minutes, donor age 27 ± 9 years) at our institution from January 2008 - September 2016 were analyzed. Mean RAP was measured by pulmonary artery catheter after heart transplant. Of 51 patients, 98% (50 patients) had elevated postoperative mRAP ≥ 15 mmHg. Mean RAP continuously increased postoperatively with the highest measured mRAP at 56 (2-396) hours [or 2.3 days] post-heart transplant. The median of highest measured mRAP was 26 (12-39) mmHg. Highest measured mRAP post-heart transplant was not significantly associated with recipient age, cold ischaemic time, preoperative mean pulmonary pressure, preoperative pulmonary vascular resistance, or donor age. The highest measured mRAP was a predictor of 1-year mortality with the area under the ROC curve of 0.65 and the optimal mRAP cut-off of 24.5 mmHg. Patients with highest measured mRAP ≥ 24.5 mmHg had higher 1-year mortality than patients with highest measured mRAP < 24.5 mmHg (35% vs 5%, p = 0.02) (Figure 1). Highest measured mRAP ≥ 24.5 mmHg was associated with 1-year mortality (Hazard ratio was 7.8 [95%CI = 1.01 - 60.5, p = 0.049]). There was no significant difference in intensive care unit length of stay (LOS) (14 ± 10 days vs. 11 ± 5 days, p = 0.2), post-heart transplant hospital LOS (45 ± 30 days vs. 36 ± 18 days, p = 0.2) or acute cellular rejection (ACR) grade ≥ 2R at 1 year post-heart transplant (16% vs 29%, p = 0.4) between patients with highest measured mRAP ≥ 24.5 mmHg and < 24.5 mmHg respectively.
Conclusions: (1) Elevated mean right atrial pressure, mRAP ≥ 15 mmHg, in post-operative de novo heart transplant was common (98%). Mean RAP continuously increased postoperatively with the highest measured mRAP at 2.3 days post-heart transplant. (2) Among post-heart transplant outcomes, highest measured postoperative mRAP ≥ 24.5 mmHg was associated with 1-year mortality. Whether therapies aiming at mRAP reduction improve post-heart transplant survival needs to be further studied.

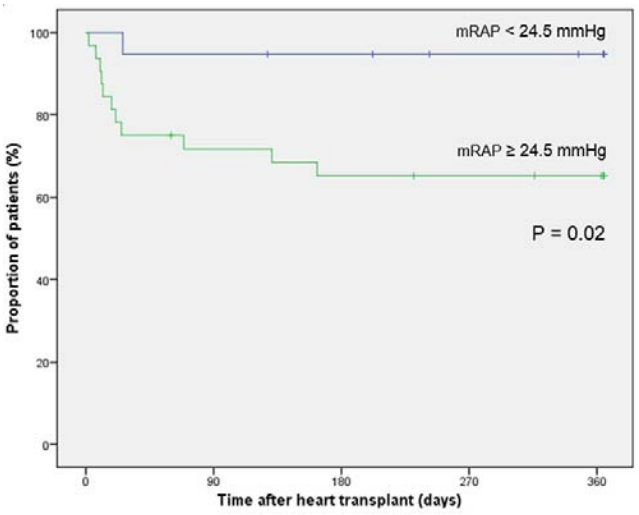

Figure 1:survival after heart transplant

P1162

Long term outcome in adults with repaired coarctation of the aorta

H Helena Nascimento[1]; M Braga[1]; V Ribeiro[1]; C Cruz[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Introduction: Coarctation of the aorta (CoA) accounts for 5 to 8% of all congenital heart defects and is frequently associated with other heart lesions. Even after an initial successful repair or intervention, residua, sequelae and complications may occur.
Material and methods: We performed a retrospective analysis of patients (pts) (>18 years-old) with the diagnosis of repaired CoA, being followed-up in a Grown-up Congenital Heart Disease Centre. Epidemiological and clinical data were collected and inserted in a registry database.
Results: From a total of 117 adult pts, 39.3% were female and the mean age was 34.9 ± 9.2 years old. Concomitant congenital heart disease was present in 89 pts (76%), being bicuspid aortic valve the most commonly observed (52 cases, 44.4%), followed by associated ventricular septal defect (22 cases, 18.8%) and ductus arteriosus (10 cases, 8.5%). Concerning genetic disorders: 4 pts had the diagnosis of Turner syndrome, 1 had Down syndrome and 1 presented Noonan syndrome. Arterial hypertension was highly prevalent in the CoA pts (65 cases, 57.0%) and a combination of 2 or more antihypertensive agents was used in 26 pts (22.2%).CoA correction was surgical in 105 pts (89.7%) and percutaneous in 12 pts (10.3%), with a stent implantation in 75% of the cases. After 25.2 ± 8.1 years of follow-up, the most frequently observed complication was recurring CoA, detected in 18 pts (15.4%). Surgery was the intervention of choice in 10 of the re-CoA pts (55.5%) and percutaneous angioplasty (with stent implantation) was done in the 8 remaining pts (44.5%). In 13 pts a heart re-intervention was conducted, within an average of 17.0 ± 8.6 years, to correct another heart-related condition. Regarding cerebrovascular events, there was only one case of intracranial bleeding from a ruptured vascular aneurysm, repaired with a vascular clip. Other complications: aortic aneurysm (2), pseudo aneurysm (1), aortic dissection (1), stent migration (2) and laryngeal nerve palsy (1). Only two non-cardiovascular related deaths occurred.
Conclusion: The population of pts with a repaired CoA is growing. Our study highlights that despite a good long-term outcome, complications may occur, even many years after the initial repair. Therefore, a close and specialized surveillance of these pts is mandatory in order to allow an early diagnosis and guide an appropriate management.

BETA BLOCKERS

P1163

Increase of beta-blocker dose and QT interval in heart failure - do we really know it all by heart? Results from CIBIS ELD study.

S Apostolovic[1]; D Dragana Stanojevic[1]; S Salinger-Martinovic[1]; R Jankovic-Tomasevic[1]; D Djordjevic-Radojkovic[1]; T Kostic[1]; V Mitic[1]; V Atanaskovic[1]; S Dakic[1]; HD Dungen[2]; E Tahirovic[2]
[1]*Clinic for Cardiovascular Diseases, Nis, Serbia*; [2]*Charite - Campus Virchow-Klinikum, Department of Internal Medicine-Cardiology, Berlin, Germany*

On behalf of: CIBIS ELD

Backgroud. At high heart rates patients on beta-blockers (BB) have a shorter QT-interval than those not using them. QT-interval shortens faster with increasing heart rate in patients on BB. These observations could explain the beneficial effect of beta-blockers on exercise-induced ventricular arrhythmias and sudden death in heart failure (HF) patients.
Purpose: We wanted to investigate what are the effects of increasing BB dosage, during 12 weeks, on QT interval. The second aim was to determine is there a difference between cardioselective (bisoprolol) and non-cardioselective (carvedilol) BB influence on QT interval. Also, we wanted to investigate is there a difference in influence of BB on QT interval in patients with reduced and preserved ejection fraction (HFrEF, HFpEF).
Methods: In CIBIS ELD study 876 patients with HF were enrolled. Prior to randomization participants had to be clinically stable and to be beta blocker (BB) naive or on ≤25% of the guideline-recommended target or equivalent dose. We up-titrated BB (bisoprolol or carvedilol) up to maximum tolerated dose, over three months. 297 patients had HFpEF, average age 73.42 ± 5.9 years and 34.4% were male. 579 patients had HFrEF, average age 72.66 ± 5.6 years, 73.3% were male. ECG was done after 10 minutes of rest in supine position, uncorrected QT interval was measured.
Results: Uncorrected QT interval was 392.41 ± 51.34 ms for the whole study group, 392.10 ± 53.54 ms for males and 392.94 ± 94 ms for females at the beginning of the study. After 12 weeks of BB up-titration QT intervals were 406.11 ± 51.34 ms for the whole group (significantly increased, p < 0.001), 404.90 for males and 408.23 ms for females. Accordingly, heart rate significantly decreased after 12 weeks from 73.79 ± 14.57 to 67.65 ± 12.41 beats per minute (p < 0.001). There were no significant differences between QT intervals at the end of the study in patients treated with different beta blockers (bisoprolol: 408.86 ± 51.80 ms vs. carvedilol: 403.40 ± 50.80 ms) and in those with HFrEF or with HFpEF (401.78 ± 55.61 ms vs. 417.17 ± 36.76 ms). We found no correlation between left ventricle ejection fraction and QT intervals in patients with HFrEF and with HFpEF.
Conclusions: The QT interval is an index of ventricular repolarisation that is directly

influenced by myocardial health and autonomic nervous system activity. In HF, stimulation of central sympathetic drive, a decrease in heart rate variability and baroreceptor function, among other mechanisms, ameliorate QT prolongation (during heart rate increase) which is a risk factor for sudden death. In our HF patients with reduced and preserved ejection fraction, both cardioselective and non-cardioselective BB, had similar effects on QT interval (slight increase at rest, paradoxically) and on heart rate (decrease at rest). It seems that BB exert their beneficial effect on QT prolongation during heart rate increase.

Sechenov First Moscow State Medical University, Moscow, Russian Federation*; *[10]Perm State Medical Academy, Perm, Russian Federation*; *[11]Scientific Research Institute of Cardiology, Baku, Azerbaijan*; *[12]Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*; *[13]Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Background. Hospitalization is an opportunity to optimize heart failure (HF) therapy and to improve the quality of further patient care, and in particular to reduce the readmission rate. The aim of the study was to analyze the effects of the beta-blockers (BBs) and ivabradine combination versus BBs alone in patients with sinus rhythm hospitalized due to worsening HF.
Methods: The international Optimize Heart Failure Care program was designed to improve the outcomes of HF hospitalization through patient education and engagement, and post-discharge planning. This analysis included data collected over 12 months from 414 patients (mean age 61.8 ± 0.9 years, 74.6% male) with sinus rhythm hospitalized due to worsening HF, NYHA II-IV (mean 2.73 ± 0.03), left ventricular ejection fraction (LVEF) < 40% (mean 28.7 ± 0.5%), mean systolic/diastolic blood pressure 124.1 ± 1.5/79.1 ± 0.8 mm Hg and mean heart rate (HR) 83.7 ± 1.1 bpm. Physicians participating in the Optimize Heart Failure Care program were free to choose the strategy of simultaneous use of BBs and ivabradine (Group 1) or BBs alone (Group 2).
Results: In total, 37.2% of hospitalized patients with HF received the combination of BBs and ivabradine (Group 1), and 62.8% were on BBs therapy alone (Group 2). There were no differences in terms of age, sex, NYHA functional class, LVEF between the two groups of patients, however, the baseline HR in Group 1 was significantly higher than in the patients who did not receive ivabradine (88.9 ± 1.3 bpm vs. 78.6 ± 0.9 bpm, $p < 0.05$). After 12 months of follow-up, 76.1% of patients in Group 1 received at least half of the target dose of BBs (compared with 65.5% in Group 2, $p < 0.05$). HR control was more effective in Group 1 than in Group 2 (-17.9% vs. -11.8%, $p < 0.05$). Moreover, after 12 months of follow-up the rate of repeat hospitalizations due to worsening HF was significantly lower in the patients receiving the combination of BBs and ivabradine compared with BBs therapy alone (9.1% vs. 30.4%, $p < 0.01$).
Conclusions: The co-administration of beta-blockers and ivabradine in hospitalized patients with heart failure produces a meaningful reduction of the rate of readmissions for worsening heart failure and may be considered as a promising strategy for this category of patients.

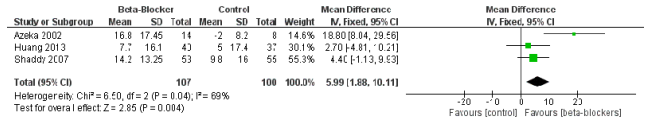
P1165

Are beta-blockers effective in children with congestive heart failure? - A Cochrane review

S Samer Alabed[1]; S Al Dakhoul[2]; A Sabouni[3]; Y Bdaiwi[4]; A Frobel-Mercier[5]
[1]University of Sheffield, Academic Unit of Radiology, Sheffield, United Kingdom; *[2]Leeds Teaching Hospitals NHS Trust, Paediatrics, Leeds, United Kingdom*; *[3]Cairo University, Medicine, Cairo, Egypt*; *[4]Damascus Univeristy, Faculty of Medicine, Damascus, Syrian Arab Republic*; *[5]AstraZeneca, Quantitative Clinical Pharmacology, Mölndal, Sweden*

On behalf of: Cochrane Heart
Funding Acknowledgements: S Alabed holds a National Institute for Health Research (NIHR) Academic Clinical Fellowship (ACF)

Introduction: Beta-adrenergic blockers are considered a cornerstone in the management of heart failure in adults. Beta-blockers reduce the heart rate and contractility consequently lowering the workload of the heart and improving its performance. This effect is estimated to be parallel in children and beta-blockers are used clinically despite lack of proven evidence to support such guidelines. Nevertheless, due to the variances in aetiology, pharmacokinetics and comorbidities between adults and children with congestive heart failure, it is fundamental to determine the safety and effectiveness of beta-blockers in children in a systematic review.
Purpose: A Cochrane systematic review of all randomised controlled trials (RCT) to assess the effect of beta–blockers in children with congestive heart failure.
Methods: The Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, EMBASE, and LILACS were search up to November 2015 for relevant RCTs. Two review authors independently screened the search results, extracted and assessed data from the included trials.
Results: The systematic review includes seven RCTs with a total of 420 participants. Four small studies with 20 to 30 children each, and two larger studies of 80 children each, showed an improvement of congestive heart failure with beta-blocker therapy. A larger study with 161 participants showed no evidence of benefit over placebo in a composite measure of heart failure outcomes. The included studies showed no significant difference in mortality or heart transplantation rates between the beta-blocker and control groups. No significant adverse events were reported with beta-blockers, apart from one episode of complete heart block. A meta-analysis of left ventricular ejection fraction (LVEF) and fractional shortening (LVFS) data showed a very small improvement with beta-blockers. However, the primary outcomes could not be pooled in meta-analyses. There were vast differences in the age, age range, and health of the participants (aetiology and severity of heart failure; heterogeneity of diagnoses and co-morbidities); there was a range of treatments across studies (choice of beta-blocker, dosing, duration of treatment); and a lack of standardised methods and outcome measures.
Conclusion: The available data suggests a trend that beta-blockers might be beneficial in the treatment of paediatric congestive heart failure. However, there is no sufficient evidence to recommend or discourage the use of beta-blockers in children with congestive heart failure or to propose a dosage scheme.



Meta-analysis of LVEF

P1166

Quality of life is similar in patients with chronic stable heart failure on vasodilating and non-vasodilating beta blockers.

R B Pharithi[1]; EEE Egom[1]; T Mannion[1]; L Devaney[1]; S Fall[1]; M Carey[1]; A Jago[1]; S Fay[1]; A Maher[1]; V Maher[1]
[1]The Adelaide and Meath Hospital, Tallaght, Heart Efficiency Unit, Cardiology Department, Dublin, Ireland

Beta-blockers with additional nitric oxide-mediated vasodilating properties are beneficial in patients with heart failure but its unknown if they are better than non-vasodilating Beta blockers.
Aim: To compare quality of life in patients with chronic heart failure stabilised on vasodilating and non-vasodilating beta-blockers.
Methods and Results: 163 patients having chronic stable heart failure for at least 6 months were evaluated according to their treatment with vasodilating or non-vasodilating betablockers. Modified Kansa city cardiomyopathy score was used to assess quality of life. See Table 1
Conclusion: There was no difference in the quality of life of patients on vasodilating and non-vasodilating beta-blockers. While vasodilation should improve quality of life, the lack of difference in our study may reflect that patients may already have maximal vasodilation due to their other therapeutic agents such as ACE or ARBs. This indicates that beta blocker choice is not essential in otherwise optimally treated patients.

P1167

The impact of 12 month beta-blocker therapy on left and right ventricular volumes and ejection fraction and functional status of heart failure patients with midrange ejection fraction

MG Poltavskaya[1]; IYU Giverts[1]; EE Yakubovskaya[1]; AL Syrkin[1]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Objectives: Recently heart failure patients with "grey area" left ventricular ejection fraction (LVEF) in the range of 40-49% were classified as having HF with mid-range EF (HFmrEF). The beneficial effects of beta-blockers on cardiac remodeling and prognosis are well established in HF with reduced but not preserved EF. The aim of the study was to evaluate the impact of beta-blockers (BB) on left (LV) and right ventricular (RV) systolic function and the distance of 6 minute walk test (6mwt) in patients with HFmrEF.
Methods: we performed the retrospective analysis of 38 patients (32 male, 6 female, mean age 58,9 ± 10,0 years) with HFmrEF NYHA class I-III mainly of ischemic origin who were followed up 12 months after the initiation of metoprolol succitate SRXL or carvedilol. Beta-blockers were added to otherwise optimal therapy unchanged for 3 months or more and up-titrated to target or maximal tolerated doses. Standard clinical evaluation, echocardiography (EchoCG), redionuclide ventriculography (RVG) and 6mwt were performed 3, 6 and 12 months after the start of BB therapy.
Results: After 12 months of BB therapy marked improvement of LVEF measured both by echoCG (from 43,5 ± 2,2% to 48,4 ± 6,1%; = + 4,8%; p = 0,003) and RVG (from 41,6 ± 1,4% to 56,4 ± 7,4%; = + 15,4%; p = 0,05) and end-systolic volume by echoCG (from 100,4 ± 40,7% to 80,9 ± 33,8%; =-19,4%; p = 0,018) was observed. The parameters of RV hadn't changed significantly. 6mwt distance increased from 428,6 ± 97,2 to 541,4 ± 79,0m (= + 112,9 m; p = 0,001). Significant improvement of LV parameters and exercise tolerance was found after 3 months of BB therapy and further improved to 12 months.
Conclusions: In patients with heart failure with mid-range EF 12-month beta-blocker therapy is associated with beneficial effect on LV systolic function and exercise capacity similar to that observed in HF with reduced EF.

Bisoprolol compared with carvedilol and metoprolol succinate in the treatment of patients with chronic heart failure

H Hanna Froehlich[1]; L Torres[1]; T Taeger[1]; D Schellberg[1]; A Corletto[1]; S Kazmi[2]; K Goode[2]; M Grundtvig[3]; T Hole[4]; HA Katus[1]; JGF Cleland[5]; D Atar[6]; AL Clark[2]; S Agewall[6]; L Frankenstein[1]
[1]*University Hospital of Heidelberg, Heidelberg, Germany*; [2]*Castle Hill Hospital, Hull, United Kingdom*; [3]*Innlandet Hospital, Lillehammer, Norway*; [4]*Norwegian University of Science and Technology, Medical Faculty, Trondheim, Norway*; [5]*Imperial College London, London, United Kingdom*; [6]*Oslo University Hospital, Oslo, Norway*

Funding Acknowledgements: This work was supported from the AOK within the scope of the junior researcher's academy "health care research Baden-Württemberg" (Germany)

Aims: Beta-blockers are recommended for the treatment of chronic heart failure (CHF). However, it is disputed whether beta-blockers exert a class effect or whether there are differences in efficacy between agents.
Methods: and results: 6,010 out-patients with stable CHF and a reduced left ventricular ejection fraction prescribed either bisoprolol, carvedilol or metoprolol succinate were identified from three registries in Norway, England, and Germany. In three separate matching procedures, patients were individually matched with respect to both dose equivalents and the respective propensity scores for beta-blocker treatment. During a follow-up of 26,963 patient-years, 302 (29.5%), 637 (37.0%), and 1,232 (37.7%) patients died amongst those prescribed bisoprolol, carvedilol, and metoprolol, respectively. In univariable analysis of the general sample, bisoprolol and carvedilol were both associated with lower mortality as compared with metoprolol succinate (HR 0.80, 95% CI 0.71-0.91, p < 0.01, and HR 0.86, 95% CI 0.78-0.94, p < 0.01, respectively). Patients prescribed bisoprolol or carvedilol had similar mortality (HR 0.94, 95% CI 0.82-1.08, p = 0.37). However, there was no significant association between beta-blocker choice and all-cause mortality in any of the matched samples (HR 0.90; 95% CI 0.76-1.06; p = 0.20; HR 1.10, 95% CI 0.93-1.31, p = 0.24; and HR 1.08, 95%CI 0.95-1.22, p = 0.26 for bisoprolol vs. carvedilol, bisoprolol vs. metoprolol succinate, and carvedilol vs. metoprolol succinate, respectively). Results were confirmed in a number of important subgroups.
Conclusion: Our results suggest that the three beta-blockers investigated have similar effects on mortality amongst patients with CHF.

Gender differences in neurohumoral activation in heart failure

L G Sahakyan[1]; RA Mayrapetyan[1]; LUSG Sahakyan[1]; HS Sisakyan[1]
[1]*Yerevan State Medical University after M. Heratsi, Yerevan, Armenia*

Background: Heart failure (HF) is a clinical syndrome that affects both men and women. The differences in neurohumoral activation between men and women are incompletely understood.
Purpose: The aim of this study was to evaluate gender differences in plasma levels of several humoral markers and perform comparative analysis between men and women.
Methods: We examined 80 patients with compensated heart failure II to IV class by NYHA classification (mean age 67 ± 10 years; 33% women) who underwent routine echocardiography and measurement of plasma procollagen type 1 N-terminal propeptide (P1NP), endothelin 1 (ET-1), nitric oxide (NO), tumor necrosis factor-alpha (TNF-A) levels.
Results: Significant differences were observed in plasma levels of ET-1 (p = 0,047) and P1NP (p = 0,010) between men and women. No significant sex-related differences were found in TNF-A (p = 0,317) and NO (p = 0,077) levels.
Conclusions: We found biomarker-related differences between male and female heart failure patients. Plasma levels of ET-1 and P1NP were significantly higher in women compared with men.

Biomarker levels in men and women

-	Male	Female	p-value
ET-1 (pg/ml)	20,7±8,5	24,7±8,5	0,047

Assessment of intact fibroblast growth factor 23 in patients with heart failure with reduced ejection fraction

D Damien Gruson[1]; S Ahn[1]; B Ferracin[1]; M Rousseau[1]
[1]*Saint-Luc University Clinics, Brussels, Belgium*

Background: Biomarkers can contribute to the prognostication of patients with heart failure (HF) and to implementation of more tailored based approach. Fibroblast growth factor 23 (FGF-23) is the most potent phosphaturic hormone and also regulates bone and mineral metabolism. FGF-23 is a strong and independent factor of adverse cardiovascular events and death in HF patients. However, most of the studies were based on the measurement of C-terminal FGF23 and only few have investigated the concentrations of intact FGF-23 (iFGF-23) in HF.
Purpose: We determined the circulating levels of iFGF-23 in patients with HF with reduced ejection fraction (HFrEF) as well as its relation with cardiac biomarkers and adverse cardiovascular events.
Methods: One hundred thirty three chronic HF patients (females n=31; males n=102; NYHA II-IV; mean age: 67 years; etiology: ischemic n=92, dilated cardiomyopathy n=41; mean EF: 23 %) were enrolled in the study. The primary outcome was CV death. Levels of iFGF-23 were measured at baseline with a recently released fully automated and sensitive immunoassay. The 95th percentile of the reference interval of this assay is 81 pg/mL. Levels of 25-hydroxyvitamin D (25OHD), 1,25-dihydroxyvitamin D (1,25(OH)2D), PTH(1-84), B-type natriuretic peptide (BNP), N-terminal proBNP (NT-proBNP), soluble ST2 (sST2) and Galectin-3 (Gal-3) were also determined.
Results: The median plasma level of iFGF-23 was 73 pg/mL and 56 patients (42%) had values higher than the 95th of the reference interval. HF patients NYHA III-IV have significantly higher iFGF23 (81 pg/mL) than NYHA II (57 pg/mL). Concentrations of iFGF23 were not significantly different between dilated and ischemic cardiomyopathies (67 vs. 77 pg/mL). Intact FGF23 correlated with left ventricular ejection fraction (r = -0.18; P = .04), estimated glomerular filtration rate (eGFR; r = -0.43; P < . 001), PTH(1-84) (r = 0.41; P < . 001), (1,25(OH)2D) (r = -0.46; P < . 001), Gal-3 (r = -0.39; P < . 001) but not with age, (25OHD), BNP, NT-proBNP or sST2. After 8 years of follow-up, 106 patients reached the primary endpoint. Concentration of iFGF23 was significantly higher in HF patients who died in comparison to survivors (87 vs 57 pg/mL). In patients with eGFR >60 mL/min levels of iFGF23 remain associated to adverse cardiovascular events.
Conclusions: Intact FGF23 is a strong and independent predictor of cardiovascular mortality in chronic HF.

P1171
Testosterone replacement in patients with advanced heart failure and hormone deficiency

M Marina Navarro Penalver[1]; M Gomez Bueno[2]; P Garcia Pavia[2]; J Lupon Roses[3]; J Comin Colet[4]; E Roig Minguell[5]; D Saura Espin[1]; DA Pascual Figal[1]
[1]*Hospital Clínico Univeristario Virgen de la Arrixaca, Cardiology, Murcia, Spain*; [2]*University Hospital Puerta de Hierro, Cardiology, Madrid, Spain*; [3]*Hospital Universitario Germans Trias i Pujol, Barcelona, Spain*; [4]*Hospital del Mar, Barcelona, Spain*; [5]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Background: Chronic heart failure (CHF) is characterized by progressive anabolic impairment with a decline in testosterone levels, which has been associated with a poor prognosis. We aim to determine wether testosterone therapy improves clinical outcomes in these patients.
Methods: We designed a multicenter randomized double-blind trial including patients with CHF, systolic dysfunction (LVEF < 40%) and both total testosterone (TT) and free testosterone (FT) deficiency (TT < 2.7 ng/ml and FT >59 pg/ml).Patients were assigned to receive 1000 mg of testosterone undecaonate or placebo injected intramuscularly at inclusion,3,6 and 9 months. We evaluated the occurrence of adverse side effects, the imporvement in cardiac function (assesed by echocardiography and NT-proBNP determinations),functional capacity (6 minutes walk test, 6MWT) and quality of life (Minnesota Living with Heart Failure test, MLHF) (clinicaltrials.gov Id:NCT01813201).
Results: 29 ambulatory male patients (age 65 ± 8,62% ischemic etiology,30 ± 6 %LVEF, NYHA II-III) were prospectively recruited. Testosterone deficiency was confirmed in all subjects with a mean TT (2.41 ± 0.9 ng/ml) and median FT (4.35 pg/ml [Q1-Q3 2.9-6.2]). After a 12 month follow-up we found and increase in TT levels (+3.1 vs +0.5, p = 0.002) but not in FT levels (+3.35 vs. +1.45, p = 0.1) in the therapy group. There were any adverse side effects of testosterone administration. During follow-up one patient died and other was admitted to the hospital because of heart failure in placebo group and none in therapy group.4 patients of each group required intravenous diuretics. These differences were not statistically significant. We did not find any differents between groups in NT-proBNP levels, functional capacity or quality of life (table). Only LVEF was slightly higher in placebo group.
Conclusion: Testosterone therapy in CHF patients with hormone deficiency was neither associated with adverse side effects nor improvement of cardiac function, functional capacity or quality of life. Small sample size and improvement in TT levels but not in FT levels might limit study results.

P1172
Initial experience using LCZ696 in real life: tolerability and clinical evolution in a short term.

R Rafael Bravo Marques[1]; F Torres Calvo[1]; S Lopez Tejero[1]; A Valle Alberca[1]; C Corona Barrio[1]; PA Chinchurreta Capote[1]; JR Siles Rubio[1]; FE Mesa Prado[1]; AC Milan Pinilla[1]; AI Perez Cabeza[1]; D Moreno Sanjuan[2]; R Mesa Rico[1]; G Rosas Cervantes[1]; F Ruiz Mateas[1]
[1]*Hospital Costa del Sol, Cardiology, Marbella, Spain*; [2]*University of Malaga, Malaga, Spain*

Introduction: The prevalence of chronic heart failure (HF) has been increased, due to the improvement in the management and treatment of most of heart diseases and the longer life expectancy of the population, becoming an important public health problem. The optimal treatment recommended for patients with HF and ventricular dysfunction, with ACE inhibitors, ARBs, beta-blockers and mineralocorticoid inhibitors, has been shown to reduce the morbidity and mortality of these patients, but it is still necessary to design further treatments that improve prognosis. Recently, clinical practice guidelines of HF have aproved using LCZ 696 in patients with HF with reduced eyection fraction (HfrEF) and functional class (FC) ≥II.
Material and methods: We conducted a prospective observational study of patients with HfrEF assessed in our outpatient clinic, who started treatment with LCZ696 between October-November 2016. We analyzed their baseline characteristics and the one-month evolution in functional class, analytical parameters and drug tolerance.
Results: We analyzed 22 patients, with a mean age of 65.4 ± 10.4 years, being 81.8% male. Fifty percent were hypertensive, 22.7% diabetic and 31.8% dyslipemic. Chronic kidney disease was present in 31.8%, with a mean FG of 81ml/min (Cockcroft-Gault). The cause of heart failure was dilated cardiomyopathy in 72,7% and in ischemic heart disease in 27.3% fh them. The mean telediastolic diameter of left ventricle was 62.4 ± 7.2mm, with an average LV ejection fraction of 34.7 ± 9.9%. Atrial fibrillation was present in 31.8%. defibrillator was carried among 18,1% and cardiac resynchronization therapy at the same proportion. At the beginning, the

majority were in FC II (59.1%) and the rest in FC III. Mean baseline systolic blood pressure was 126.2 ± 20.7mmHg and diastolic 76.9 ± 13.7mmHg and mean heart rate was 66.6 ± 12.5bpm. Pretreatment was optimal in all cases (maximum tolerated doses of ACEI, ARB II, BB, mineralcorticoids). ARNI was started (after stopping ACE inhibitors in 59.1% and the rest ARI II), at low doses in 54.5%, at medium doses 31.8% and the rest at high doses. After one month of follow-up, the goal was improvement in FC, 18.2% of patients were FC I and 63.6% FC II. Concerning analytical parameters, we observed a reduction of NT-ProBNP (from 5575.3 to 3538.6μg/L) and uric acid (from 7.6 to 6.6mg/dL). We found a non-significant decrease in blood pressure (119 ± 17.8/71.0 ± 12.6mmHg), which allowed us to optimize the treatment with LCZ696, being at medium dose 50%, at high dose 36,4% and the rest at low doses. Only one patient stopped taking medication due to economic issues.
Conclusions: The treatment with LCZ696 in a group of patients in real-life was well tolerated in all cases, without a significant decrease in blood pressure, being able to optimize the dose of LCZ696. It was related to improvement in the functional class and in analytical parameters, even with a short follow-up.

P1173
Neck circumference as a predictor of arterial hypertension

AG Abril Guadalupe Jimenez Cepeda[1]; A Orea-Tejeda[2]; D Gonzalez- Islas[2]; G Perez-Cortes[2]; L Verdeja- Vendrell[2]; A Navarrete-Penaloza[2]; R Sanchez-Santillan[2]; V Pelaez-Hernandez[2]; A Figueroa-Herrera[2]; B Robles Uribe[2]; SC Torres-Montiel[2]
[1]*Universidad Autonoma del Noreste, Nutricion Clinica , Saltillo, Mexico*; [2]*Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clínic , Mexico, Mexico*

Background: Neck circumference (NC) is a simple, reliable non invasive and low cost anthropometric method. It has been related to overweight, obesity and metabolic risk factors since it is an etopic fat deposit responsable for large release of systemic free fatty acids. It has been found relation of the NC with the systemic arterial hypertension. However, it is unknown if the NC is realated wich blood pressure (BP) increase Objectives: To determine if there is an increase in BP due to an increase in NC.
Methods: A cross- sectional studio, >18 years old apparently healthy subjects were included. Subjects with diabetes and hypertension were excluded. Weight, height, body mass index, NC and BP were evaluated.
Results: Fifty-four patients were recruited, age 49 ± 13.3 years. 55.5% were women and 44.4% were men. Men had higher weight (83.58 ± 10.6 vs 74.2 ± 14.1 p = 0.01), height (1.7 ± 0.4 vs 1.5 ± 0.06, p < 0.001), NC (40.7 ± 2.2 vs 35.4 ± 2.3, < 0.001), systolic blood pressure (SBP) (132 ± 14.4 vs 119.5 ± 19.1, p = 0.011) and diastolic blood pressure (DBP) (80.1 ± 7.9 vs 72.2 ± 11.6, p = 0.006), than women. According to the linear regression it was observed that for each centimeter in NC increases 2.5 mmHg in SBP, (β: 2.5, CI 95%, 1.2 to 3.7, p < 0.001) and 1.6 the DBP, (β: 1.6, 95% CI, 0.9 to 2.3, p < 0.001). In addition, for each kilogram of weight, the SBP increased by 0.5 mmHg (β: 0.5, CI 95%, 0.2 to 0.8, p = 0.002) and 0.4 mmHg in the DBP, (β: 0.4, CI 95%, 0.2 to 0.6, P < 0.001).
Conclusions: For each centimeter in NC increases 2.5 mmHg the SBP and 1.6 mmHg the DBP.

P1174
Lipid control across very high cardiovascular risk profiles

PM Paulo Maia Araujo[1]; A Nunes[1]; SM Leite[1]; JD Rodrigues[1]; S Amorim[1]; E Martins[1]; M Campelo[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Cardiology, Porto, Portugal*

Introduction: Cardiovascular disease (CVD) is a leading cause of morbidity and mortality worldwide. In the last decades, a significant proportion of the reduction in CVD burden is attributed to cardiovascular (CV) prevention, including a more effective control of CV risk factors, namely dyslipidaemias. With the publication of the "2011 ESC Guidelines for the management of dyslipidaemias" (2011 ESC-G), there were introduced specific LDL targets for each level of CV risk. For patients (pts) at very high CV risk (VHCVR), a goal of LDL < 70mg/dL was defined. The objective of this study was to analyze lipid control in this population, between different groups of pts.
Methods: The study population corresponded to pts at VHCVR, as defined by the 2011 ESC-G. We performed a retrospective evaluation of pts in this category admitted in our department in 3 different time periods: pts admitted in the year prior to the guideline publication (2011: A), in the next year (2012: B) and 5 years after (November/2015-November/2016: C). Data from clinical variables and from lipid control were collected and those 3 groups were compared.
Results: A total of 1143 pts were included in the analysis (315 from A, 342 from B and 486 from C), of whom 821 (71.8%) were male, with a mean age of 67.5 ± 11.7 years. There were no significant differences in gender proportion or mean age between groups. Of the total population, 44% of pts had a prior Acute Coronary Syndrome (ACS), 13% had a prior Stroke, 15% had Peripheral Artery Disease (PAD), 54% were diabetic and 18% had moderate/severe Chronic Kidney Disease (CKD). Only 24.7% (n = 282) had achieved the goal LDL value < 70mg/dL, with no significant differences between the 3 time periods (p = 0.25). In pts with a prior ACS, over time, there was a progressive increase of the achievement of target LDL between the 3 groups: 24% (A) vs 34% (B) vs 39% (C), p = 0.02. However, there were no significant differences between the 3 time periods in pts: with a prior Stroke - 30% (A) vs 36% (B) vs 40% (C), p = 0.54; with PAD - 26% (A) vs 43% (B) vs 32% (C), p = 0.21; diabetics – 23% (A) vs 25% (B) vs 31% (C), p = 0.13; with CKD – 34% (A) vs 30% (B) vs 32% (C), p = 0.88.
Conclusions: Despite what would be expected, 5 years after the publication of the 2011 ESC-G, adequate lipid control is still far from desirable. Only pts with a prior ACS had a significant difference in the achievement of target LDL values over time and were more likely to have adequate lipid control. Particular attention to lipid control should be paid to other pts at VHCVR as well.

P1175
Clinical features of obese and heart failure with reduction ejection fraction (hfref) in mexican patients: a cohort

EJJ Chuquiure[1]; J Oscar Fiscal-Lopez[1]; L Ana Marin-Mejia[1]; R Nayeli Isidro-Hernandez[1]; N Frida Rodriguez-Quiroz[1]; M Maria Jose Chuquiure Gil[2]; M Mendez Gabriela[3]
[1]*Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico*; [2]*Instituto Tecnologico de Estudios Superiores de Monterrey, Escuela de Medicina, Monterrey, Mexico*; [3]*Universidad del estado de México, Medicina, ciudad neza, Mexico*

Purpose: Mexican population has a high obesity rate in childhood as adults. The main purpose of this work is to describe Clinical Characteristics of the impact of Obesity in patients with Heart Failure with Reduction Fraction (HFrEF) in the confirmation of a comparative cohort.
Material and Method: We analyzed consecutively a group of patients from the Instituto Nacional de Cardiologia Heart Failure Clinic. All over 18 years old, both genders with clinical, laboratory and Imaging Diagnosis according 2016 European and AHA-ACC clinical Guidelines. In our Investigation Obesity was defined as BMI greater than 25 Kg/m2. According Age, LVEF and NYHA Class were matched in two groups for a suitable comparison. We describe clinical history, PTCA or CABG records, laboratory findings, echocardiographic diameters, hospitalization feature. The principal point at follow-up was hospitalization for Heart failure impairment. For statistical difference we declare p value equal or less than 0.05.
Results: A total of 257 patients were evaluate, according our matching criteria two group were formed: Obese: 191 (74.31%) and Non-obese: 66 (25.68%). Both groups were homogeneous in: Age 56.79 + 4.87 vs56.79 + 4.23, LVEF: 29.50 + 1.2 vs. 28.19 + 1.1 y NYHA I-II: 91.62% vs. 92.42 (p = ns for all). Gender male were also similar (68.87% both). Expected statistical significance differences in BMI were seen: 29.83 + 3.95 vs 22.53 + 2.10 (p < 0.005). Metabolic Syndrome Clinical Components were evidently more seen in obese group: Diabetes History (19.89% vs. 9.09%, p < 0.05), Hypertension (21.46% vs10.60%, p < 0.05) and Dyslipidemia (17.80% vs. 10.15%, p < 0.05). No statistical differences in Echocardiographic diameters were observed. All non-obese patients were maintained in sinus rhythm compared to 12.5% Atrial Fibrillation in obese (p < 0.05).
Conclusions: The present Cohort is the first report on patients with HFrEF in the Obese Mexican population. High rates of hospitalization in Emergency Room due Heart Failure exacerbation in the obese group were observed, possibly associated with Metabolic Syndrome components.

BMI (25 Kg/m^2)	25- 29.99	30-34.99	35- 39.99	>40.00
REHOSPITALIZATION RATE (%)	14.41	16.66	15.38	28.57

Greater quarterly increases in readmissions at emergency room due to Heart Failure deterioration according BMI

P1176

Prevalence and factors predictive of preclinical diastolic dysfunction (stage B heart failure) in a predominantly Hispanic cohort with type 2 diabetes

S-H Siu-Hin Wan[1]; AS Pumerantz[2]; F Dong[2]; P Vila[2]; C Ochoa[2]; HH Chen[1]
[1]Mayo Clinic, Rochester, United States of America; *[2]Western University of Health Sciences, Pomona, United States of America*

Background: People with type 2 diabetes mellitus (DM2) are predisposed to developing cardiac structural changes, diastolic dysfunction (DD), and heart failure (HF). Prior research has shown that preclinical DD (Stage B HF) is common among people with DM2. However, the characteristics and risk factors of DD development in people with DM2 remain incompletely defined.
Objective: To define the clinical and echocardiographic characteristics of a cohort of adult patients with DM2, and to identify risk factors for development of DD.
Methods: A retrospective analysis of consecutive adults with DM2 in California, USA. Patients without signs or symptoms of heart failure (HF) underwent 2D and Doppler echocardiography screening, and grouped into two cohorts: normal diastolic function and DD. Obesity was defined as a BMI ≥30 kg/m2 and overweight BMI between 25-30 kg/m2. Chronic kidney disease (CKD) was defined as estimated glomerular filtration rate (eGFR, by CKD-EPI equation) <60 mL/min/1.73m2 (i.e., Stages 3A-5). DD was defined as those with medial E/e' ≥15 or left atrial volume index ≥ 34 mL/m2. Multivariate logistic analysis was performed to identify factors associated with the presence of DD.
Results: Among 387 study patients, the mean age was 54.4 ± 12.9 years and 299 (77%) were Hispanic. 37.5% had DD and 62.5% had normal diastolic function. There was no difference in percentage of Hispanics with DD and normal diastolic function (78 vs. 76%, $p = 0.4$). Mean hemoglobin A1c was 8.1% for the DD group and 8.6% for the normal diastolic function group ($p = 0.02$). When compared to those with normal diastolic function, the DD group had more females (66 vs 53%, $p = 0.015$), was older in age (mean 59 vs 51 years, $p < 0.01$), and had longer duration of diagnosed DM2 (12 vs 10 years, $p = 0.01$). Furthermore, those with DD had more cardiovascular comorbidities, including coronary artery disease (14 vs 4%, $p < 0.01$) and hypertension (86 vs 68%, $p < 0.01$). There was also greater proportion of CKD (25 vs 6%, $p < 0.01$) and obese and overweight (70 vs 65% and 25 vs 23%, respectively; $p = 0.04$) among the group with DD. LVMI in the DD group was also greater (118 vs 96 g/m2, $p < 0.01$).
Using multivariate logistic analysis, several significant predictors of DD in adults with DM2 were identified: older age (adjusted OR (AOR) 1.31 [1.18, 1.46]); female gender (AOR 1.72 [1.06, 2.81]); overweight (AOR 3 [1.04, 8.64]) and obesity (AOR 3.86 [1.42, 10.48]); and the presence of at least Stage 3A CKD (AOR 4.9 [2.38, 10.1]).
Conclusions: Preclinical DD (stage B HF) was common (37.5%) among our predominantly Hispanic cohort with DM2. Those with DD were more likely to be female, older in age, obese or overweight, and have at least moderate (Stage 3A) CKD. These findings suggest that populations with similar ethnic and racial demographics, asymptomatic, obese or overweight, middle-aged to elderly women with at least Stage 3A CKD should be screened for preclinical DD (stage B HF).

P1177

Prescription of anti-diabetic-glucose-lowering agents and clinical outcomes in asian patients with heart failure and type 2 diabetes mellitus

Y Yvonne Chia[1]; THK Teng[2]; WT Tay[2]; J Tromp[3]; AM Richards[4]; LH Ling[4]; W Shimizu Sw Park[5]; CL Hung T Ngarmukos[6]; HB Liew S Zhang[7]; C Narasimhan B Siswanto[8]; EB Reyes Cm Yu[9]; I Anand[10]; J Yap[2]; M Macdonald[11]; CSP Lam[2]
[1]Duke-NUS Graduate Medical School Singapore, Singapore, Singapore; *[2]National Heart Centre Singapore, Singapore, Singapore*; *[3]University of Groningen, Groningen, Netherlands*; *[4]National University Heart Centre, Singapore, Singapore*; *[5]Nippon Medical School, Tokyo, Japan; Sejong General Hospital, Bucheon, Korea Republic of*; *[6]Mackay Memorial Hospital, Taipei, Taiwan; Ramathibodi Hospital, Bangkok, Thailand*; *[7]Queen Elizabeth Hospital, Malaysia; Fuwai Hospital, Beijing, China People's Republic of*; *[8]CARE Hospital, Hyderabad, India; National Cardiovascular Center Universitas, Jakarta, Indonesia*; *[9]Manila Doctors Hospital, Manila, Philippines; Prince of Wales Hospital, Hong Kong, Hong Kong SAR People's Republic of China*; *[10]University of Minnesota, Minneapolis, United States of America*; *[11]Changi General Hospital, Singapore, Singapore*

Background: Diabetes mellitus (DM) is a common comorbidity among patients with heart failure (HF). Anti-diabetic agents are important for glycaemic control, but some may worsen HF, whereas newer agents have recently been reported to improve cardiovascular outcomes. The prescription patterns of anti-diabetic agents in Asia are unknown.
Purpose: To determine the prescription patterns of anti-diabetic agents, and their association with mortality and HF hospitalisation, among Asian patients with HF and DM.
Methods: We studied prescription of anti-diabetic and HF medications among 5276 patients with HF and reduced ejection fraction (< 40%) from Northeast Asia (South Korea, Japan, Taiwan, Hong Kong, and China), South Asia (India), and Southeast Asia (Thailand, Malaysia, Philippines, Indonesia, Singapore) in the prospective ASIAN-HF study. Patients were followed for the composite outcome of 1-year all-cause mortality or 1st HF hospitalisation.
Results:DM was present in 2177 (41%) patients (61 ± 11 years old, 21% women), of whom 1493 (69%) were prescribed anti-diabetic agents (761 [51%] monotherapy, 549 [37%] dual therapy). The most common anti-diabetic agents prescribed were metformin (54%), sulfonylureas (53%) and insulin (24%). Prescription varied by geography: metformin and sulfonylureas were more commonly prescribed in South and Southeast Asia (55-68%, compared to 33-34% in East Asia); whereas dipeptidyl peptidase-4 (DPP-4) inhibitors (38% vs 6% in Southeast Asia) and alpha-glucosidase inhibitors (25% vs 5% in Southeast Asia) were more commonly prescribed in East Asia. Patients with anti-diabetic therapy (vs without) were younger (60 ± 11 y vs 62 ± 11 y) and more likely to have hypertension (69% vs 64%) and to receive angiotensin-converting-enzyme inhibitors or angiotensin receptor blockers (76% vs 68%) or beta-blockers (81% vs 74%)(all $p < 0.01$), but similarly likely to have chronic kidney disease and atrial fibrillation. One-year composite outcome occurred in 481 (22%) of 1983 patients with 1-year follow-up. Adjusting for age, sex, body size, blood pressure, EF, NYHA, ischemic aetiology, hypertension and atrial fibrillation, metformin therapy was associated with reduced risk of the primary endpoint (vs no metformin, adjusted HR=0.80, 95%CI 0.66-0.97) while there was no significant association with the usage of sulfonylureas (aHR=0.88, 95%CI 0.72-1.07), insulin (aHR=1.16, 95%CI 0.91-1.48) or DPP-4 inhibitors (aHR=0.77, 95%CI 0.56-1.06).
Conclusions: Wide geographical variation in prescribing patterns of anti-diabetic agents was observed among patients with HF across Asia. The lower hazard of a 1-year composite outcome with metformin support the ESC HF guidelines recommendation to consider metformin as first-line therapy unless contraindicated in these patients.

P1178

Polyunsatturated fatty acids supplementation impairs HDL function in heart failure

R Raphael Wurm[1]; L Schrutka[1]; D Moertl[2]; R Berger[3]; N Pavo[1]; M Huelsmann[1]; K Distelmaier[1]
[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]Hospital St. Polten, Department of Cardiology, St. Polten, Austria*; *[3]KH Barmherzige Brueder, Department of Cardiology, Eisenstadt, Austria*

Aims: The aim of this study was to assess the effects of oral treatment with polyunsaturated fatty acids (PUFA) on the anti-oxidative capacity of HDL in patients with heart failure (HF) of non-ischemic origin.
Methods: Patients with advanced chronic HF who were on stable optimized therapy for ≥ 3 months were randomized in a 1:1:1 fashion to receive 1g/day or 4g/day of n3-PUFA, or placebo, respectively for 12 weeks.
HDL anti-oxidant capacity was measured using a 2',7'-DCF-based cell free fluorescent assay that determined the ability of apo-B depleted serum to inactivate or aggravate previously oxidized LDL
HDL inflammatory index (HII was calculated by subtracting the intensity signal of DCF alone from that of DCF incubated with apo-B depleted patient sera and log-transformed before analysis. A higher HII indicates a poorer anti-oxidative function.
Results: Forty-three patients with a median age of 60 years and a median HDL level of 41 mg/dl were included (Table 1). There was no difference in HII at baseline. After twelve weeks of treatment, we found a significant dose-dependent effect of PUFA treatment on the median change of HII (-0.11 (IQR -0.37 – 0.17) for placebo, 0.13 (-0.01 – 0.28) for 1g/day PUFA, 0.38 (0.08 – 0.51) for 4g/d, $p = 0.03$, Figure 1).
Discussion: Treatment with PUFA impairs HDL anti-oxidative function in a dose-dependent manner. This might provide one explanation for the rather small clinical benefit of this treatment.

[1]Heart Institute of the University of Sao Paulo (InCor), Laboratory of lipid metabolism, Sao Paulo, Brazil

Funding Acknowledgements: CAPES and FAPESP

Background: It is now consensual that the various protective functions of HDL should be explored beyond HDL-cholesterol.
Propose: We investigate plasma lipids, lipid transfers to HDL and BNP levels obtained from patients with HF with those from patients with CAD without HF (non-HF).
Methods: Forty-eight HF patients were studied, 25 with functional class NYHA I/II and 23 with NYHA III/IV, as well as 50 non-HF patients matched for gender and age. All HF had ejection fraction ≤40%. Levels of IL-6, BNP, CETP, LCAT, oxidized LDL (oxLDL) and paraoxonase 1 (PON-1) activity were determined. Transfers of radioactive unesterified and esterified cholesterol, triglycerides and phospholipids from a donor artificial emulsion to HDL was determined by an in vitro assay.
Results: Total, LDL and HDL cholesterol and triglycerides did not differ among the 3 groups, but apo A-I and apo B was lower in both HF groups compared to non-HF ($p = 0.01$, $p < 0.001$).Transfer of esterified and unesterified cholesterol, triglycerides and phospholipids (in %) was lower in HF-III/IV than in non-HF (HF-III/IV: 5.44 ± 1.76, 6.29 ± 2.05, 19.05 ± 2.5, $6,29 \pm 2,05$; non-HF: 6.24 ± 0.85, 7.33 ± 1.48, 20.21 ± 1.43, $7,40 \pm 1,47$; respectively, $p < 0.05$), but transfers were not different between HF-I/II and non-HF. Levels of oxLDL was lower in HF-III/IV than in non-HF ($p < 0.0001$). CETP mass was lower in HF-III/IV than in HF-I/II ($p = 0.0206$). LCAT activity was lower in patients with HF than non-HF subjects ($p = 0.0384$). Transfer of lipids to HDL, apo A-I, apo B, oxLDL and LCAT are inverse correlated with IL-6 and BNP levels. Conclusion: Alterations in the markers related with the plasma lipid metabolism seemed to be more pronounced in the most severe forms of HF. These alterations were correlated with IL-6 and BNP, importants biomarkers of HF, which could suggest that they could play a role in the evolution of the disease.

P1180

Arterial structure is associated with telomere length and glycemic variability in diabetic patients without heart failure

E N Dudinskaya[1]; NV Brailova[1]; ON Tkacheva[1]; ID Strazhesko[2]; SA Boytsov[2]; MV Shestakova[3]
[1]Pirogov Russian National Research Medical University , Moscow, Russian Federation; *[2]National Research Center for Preventive Medicine, Moscow, Russian Federation*; *[3]Endocrinology Research Center, Moscow, Russian Federation*

Background and aims: It is known that telomere length (TL) shortening is a biomarker of cellular aging and associated with vascular changes. Glycemic variability (GV) in type 2 diabetes mellitus (T2DM) patients may be involved in vascular aging, but pathogenic mechanisms of this effect are not well established. The aim of our study was to investigate the association between GV, vascular aging and TL in T2DM patients.
Materials and Methods: The study group included 50 T2DM patients without symptoms of heart failure (mean age 58.4 ± 7.9 years, median diabetes duration - 1.0 year and a HbA1c of 7.27 ± 0.69 %). NT-proBNP was < 100 ng/ml, ejection fraction was > 50%. All subjects were measured for TL by quantitative PCR; arterial stiffness evaluated by carotid-femoral pulse wave velocity (PWV); carotid intima-media thickness (IMT), plaque presence determined by ultrasonography in carotid arteries. The mean amplitude ofglycemicexcursion (MAGE), the standard deviation of blood glucose values (SD) and the continuous overlapping net glycemic action (CONGA) were calculated from continuous glucose monitoring system data for assessingGV. Statistical analyses were performed using SAS 9.1 (SAS Institute, Cary, NC, USA).
Results: The majority of patients with T2DM had subclinical atherosclerosis (78.1%) and shortened telomeres (< the median of TL 9.75) (71.4%). Correlation analysis showed significant association between IMT and TL (r=-0.39, p=0.006), IMT and GV parameters: MAGE (r=0.42, $p = 0.007$), SD (r=0.41, $p = 0.009$), CONGA (r=0.27, $p = 0.093$) and for MAGE this relationship remained significant in multiple linear regression analysis (β=0.040, $p = 0.020$, multiple $R2 = 0.290$). Multiple linear regression analysis also revealed significant independent association between plaque presence and CONGA (β=1.088, $p = 0.040$, multiple $R2 = 0.457$). It was not revealed relationship between vascular stiffness (PWV) and GV. TL was correlated only with CONGA (r=-0.31, $p = 0.054$), but very long telomeres (> the TL 10.00) were associated with all GV parameters: MAGE (r=-0.39, $p = 0.015$), SD (r=-0.43, $p = 0.007$), CONGA (r=-0.42, $p = 0.008$).
Conclusion: Glycemic variability is associated with subclinical atherosclerosis and TL shortening in T2DM patients. Thus, we can suppose that the glycemic variability plays a principal role in TL shortening and vascular aging in T2DM patients without heart failure.

HEART FAILURE IMAGING

Role of MR imaging in the diagnosis and the management of hypertrophic cardiomyopathy

M Attia[1]; I Ines Kasraoui[1]; H Neji[1]; I Kammoun[2]; S Hantous[1]; I Baccouche[1]; K Ben Miled[1]
[1]*ABDERRAHMEN MAMI HOSPITAL, RADIOLOGY, TUNIS, Tunisia*; [2]*ABDERRAHMEN MAMI HOSPITAL, CARDIOLOGY, Tunis, Tunisia*

Background: Hypertrophic cardiomyopathy (HCM) is the most common inherited cardiomyopathy and the most common cause of sudden cardiac death among young people. Clinical manifestations and electrocardiographic findings of HCM are nonspecific and diverse. Traditionally, echocardiography has been the easiest and most reliable technique for establishing a diagnosis of HCM. However, cardiac magnetic resonance (MR) today enables a more accurate and reliable assessment of maximal wall thickness, increasing the diagnostic yield by identifying subtle forms of myocardial hypertrophy. Furthermore, MR may be helpful in risk stratification by identifying massive LV hypertrophy or extensive areas of myocardial fibrosis heralding disease, which further impacts prognosis and patient management.
Purpose: :The aim of this study is to present the MR imaging findings in HCM and to discuss the role of MR imaging in diagnosis, and risk profiling of HCM.
Methods: We reviewed all cardiac MRI studies carried out between May 2015 and January 2017 with a suspicion of HCM due to the results in echocardiography. A 1.5 tesla MRI is used to perform exams (Ingenia, Philips Healthcare). Cardiac MRI studies were performed using the following protocol : Cine imaging with bright blood prepared steady state free precession (SSFP) in the short axis, 2, 3 and 4 chamber plane, Black blood T2 in short axis, PSIR in short axis, 2 and 4 chamber plane ad IR-RT in short axis, 2 and 4 chamber plane.
Results: : The final study group consisted of 16 patients with a median age of 55 years (extremes 33 and 74 years). We found no sex prevalence with female to male ratio = 1. Most common symptoms were atypical thoracic pain, dyspnea and arrhythmia. One patient had a family history (his brother) of sudden death in young age (30 years). Asymmetric sigmoid HCM with septal hypertrophy was the most common phenotype (38%). Septal reverse curve HCM (6%), concentric hypertrophy (19%), mid ventricular hypertrophy (19%), apical hypertrophy (12%) and focal hypertrophy (6%) were less frequent. The mean of the maximal thickness of LV wall was 19.6mm ($\pm$ 3.5). Right ventricular was involved in 2 cases (12%). LV sub aortic outflow obstruction with systolic anterior motion of the mitral valve (SAM) and a high velocity jet (signal void) were found in 9 cases (56%). Involvement of the mitral valve apparatus with increased length of the mitral valve leaflets were seen in 3 cases (16%). One patient presented a "burned out" HCM with impaired systolic function (ejection fraction 28%). All the others patients had preserved systolic function. Delayed myocardial enhancement with gadolinium was found in 10 cases (62%).
Conclusion: : MRI should be considered in patients with HCM at their baseline assessment.

P1182

Association of right ventricular dysfunction in left ventricular dysfunction with chronic obstructive pulmonary disease patients

P Paul Jaime[1]; D Gonzalez-Islas[1]; J Schalch-Ponce De Leon[1]; JR Belmontes-Barraza[1]; A Orea-Tejada[1]; L Verdeja-Vendrell[1]; A Jimenez-Cepeda[1]; GK Perez-Cortes[1]; R Sanchez-Santillan[1]; V Pelaez-Hernandez[1]; B Robles-Uribe[1]; A Figueroa-Herrera[1]; S Torres-Montiel[1]
[1] *National Institute of Respiratory Diseases Ismael Cosio Villegas, Mexico city, Mexico*

Introduction: Right ventricular dysfunction is associated with Chronic Obstructive Pulmonary Disease (COPD) for their effects on cardiac functions, affecting the pulmonary vasculature besides these patients has a major risk to develop pulmonary hypertension.
Objective: To evaluate the association of left ventricular dysfunction in patients with right ventricular dysfunction
Materials and Methods: A cross sectional observational study was conducted on 20 patients older than 18 years old, with confirmed COPD diagnosis, included through history taking, clinical examination, echocardiogram and gated radioisotopic ventriculography or gated myocardial perfusion imaging with Single Photon Emission Tomography/Computed Tomography (SPECT-CT). Statistical analysis was done by linear regression adjusted for pulmonary hypertension.
Results: Right ventricular dysfunction was present in 6 patients, mean age 62.3 $\pm$ 17.28 years, There were not significative difference in comorbidities. Right ventricular dysfunction subjects had higher left ventricular end dyastolic volume ($\beta = 38$ milliliters 95 % IC 11.41 to 64.94, $p = 0.009$) than among the patients without right ventricular dysfunction.
Conclusion: This study shows that the patients with right ventricular failure have a higher left ventricular end diastolic volume than patients without right ventricular failure, then the risk of both, left and right ventricular failure is higher with COPD patients and could be investigated.

P1183

Takotsubo syndrome: cardiac magnetic resonance versus new HFA diagnostic criteria to confirm the diagnosis

MJ Miguel Jose Corbi Pascual[1]; C Urraca Espejel[1]; JJ Portero-Portaz[1]; S Calero-Nunez[1]; C Ramirez-Guijarro[1]; MI Barrionuevo-Sanchez[1]; G Gallego-Sanchez[1]; CM Olmeda-Brull[2]; J Navarro-Cuartero[1]; D Prieto-Mateos[1]; FM Salmeron-Martinez[1]; MA Simon-Garcia[1]; JG Cordoba-Soriano[1]; A Tercero-Martinez[1]; R Fuentes-Manso[1]
[1]*Albacete. University General Hospital, Albacete, Spain*; [2]*Villarrobledo. General Hospital., Villarrobledo, Spain*

Introduction: Takotsubo Syndrome (STK) is an acute reversible heart failure syndrome distinct from acute coronary syndrome (ACS), although the initial presentation has similar features. Many patients (P) are discharge from the hospital with uncertain diagnosis until, recovery of ventricular function in the follow-up, confirm the diagnosis. Given the new evidence, new diagnostic criteria have been proposed by the European Society of Cardiology Heart Failure Association (HFA).
Purpose/Methods: The objective was to compare the degree of accuracy of new HFA diagnostic criteria versus findings in Cardiac Magnetic Resonance (CMR) to confirm the diagnosis in P with suspected diagnosis of STK. We collect all P with suspected diagnosis of STK admitted to our hospital from January 2009 to April 2016.
Results: We included 70 P with suspected diagnosis of STK. The average age was 69 years, 86% women and 54% presented some stressful trigger (emotional most frequently). The 71% was HTA, 19% diabetics, 38% had dislipemy, 6,3% presented a history of ischemic heart disease. Killip class III or IV were observed in 21,4% of P, but only 13% needed administration of, vasoactive amines. 24% of these patients identified as STEMI underwent urgent PCI, 91% of them had normal coronary arteries. ECG showed ST segment elevation in 65% and 92% evolved to T wave inversion. 90% of P presented apical dyskinesia, 8% mid-ventricular and the remaining 2% presented basal dyskinesia. At discharge, 96% were prescribed beta blockers, ACE inhibitors/ARBs, statins or ASA. Regarding follow-up, STK diagnosis was confirmed by HFA criteria in 92% of P. However, it would be confirmed in 84% using the CMR (12% AMI and 4% myocarditis). Three P died (4.28%) of non-cardiac causes during follow-up, and other four had a CV event (ACS, an episode of IC and two STK recurrences).
Conclusions: In our series, STK diagnosis was confirmed by HFA criteria in more than 90% of P. Notwithstanding, CMR findings would reclassify up to 15% of P in other diagnoses. CMR would be of significant utility for the correct diagnosis of these P, because even with the new HFA criteria, some P with other pathologies would be included as STK. CMR should be considered as a new diagnostic criterion in future classifications.

The analysis of parameters of echocardiography of patients with cardiomyopathy after cardiac resynchronization therapy

S M Svetlana Gerasimenko[1]; V I Gerasimenko[1]
[1]*Federal Center of Cardiovascular Surgery, Astrakhan, Russian Federation*

Background: There are areas of controversy exist regarding the imaging assessment of patients (pts) with CRT.The analysis of echocardiographic data about positive CRT responders is still collecting nowadays.
Purpose: The aim of this work is to find out the change of parameters of echocardiography of pts that have cardiomyopathy before and after one year CRT.
Methods: All pts were divided into two groups: group 1-pts with dilated cardiomyopathy(DCM) (24 men and 13 women; aged 54,5 ± 9,4) and group 2-pts with ischemic cardiomyopathy (22 men and 2 women; aged 56,4 ± 8,2) and chronic heart failure (CHF) were included in the study. In the first group, pts with CHF NYHA functional class III were 78%, in the second group 86.3%. The diagnosis is based on clinical researches, that also include coronarography.We compared the values of the EF, LVEDV index ,LVESV index, fractional area change of RV , S', RV basal diameter, the level of SPAP , TAPSE before and after CRT.
Results: (Table 1) The parameters of echocardiography of pts with cardiomyopathy before and after CRT.
Conclusions: We received in a year after CRT it was discovered, that positive dynamic of echocardiographic measures can be observed with DCM pts in comparison with pts with ischemic cardiomyopathy. The pts who have DCM turn out to be more perspective responders for CRT. The extensive research on the topic, and development of new imaging techniques, are likely to contribute to more accurate assessment of these pts, thus improving management.

Evaluation of left ventricular systolic function in Chron disease _ a study of strain analysis by 2D speckle_tracking

M Oliveira[1]; MR Lourenco[1]; O Azevedo[1]; T Curdia Goncalves[1]; MJ Moreira[1]; F Castro[1]; L Calvo[1]; B Faria[1]; P Von Hafe[1]; J Portugues[1]; J Cotter[1]; A Lourenco[1]
[1]*Hospital Guimaraes, Guimaraes, Portugal*

INTRODUCTION: Crohn's disease (CD) is a chronic inflammatory bowel disease that affects the gastrointestinal tract but has also extraintestinal manifestations. Cardiac involvement is considered rare and limited to sporadic cases of myocarditis, endocarditis and pericardial effusion. Myocardial deformation imaging is the most sensitive technique to evaluate left ventricular function. There is only one recent study in literature evaluating left ventricular function by myocardial deformation imaging in CD patients.
OBJECTIVE: The aim of this study was to evaluate left ventricular systolic function with two-dimensional speckle tracking echocardiography in patients with CD and correlate these findings with the activity and extension of disease.
Methods: Cross-sectional study including 40 patients with CD, followed in hospital consultation of Gastroenterology, and no other causes of left ventricular dysfunction. We collected clinical and demographic data. We performed 2D transthoracic echocardiogram including conventional echocardiography and tissue Doppler imaging (TDI). We performed 2D strain analysis by speckle-tracking and determined global longitudinal strain.
Results: Patients were predominantly female (57%), with mean age of 34,4 ± 10,33 years old and mean disease duration of 8,21 ± 6,43years. Harvey-Bradshaw activity index showed that 30 patients were in remission, 8 patients had mild disease activity and 2 patients had moderate disease activity. 32,5% patients had already been submitted to surgery because of CD complications. CD patients had significantly lower ejection fraction than controls (58,18 ± 0,66 vs. 65,58 ± 0,82 %, p < 0.001) but within normal range. TDI systolic velocity (average S') was normal and similar in CD patients and controls (10,75 ± 0,26 vs. 10,50 ± 0,40 cm/s, p = 0,591). CD patients had significantly worst values of global longitudinal strain than controls (-20,03 ± 0,33 vs. -21,81 ± 0,30 %, p < 0.001). In CD patients, global longitudinal strain was not correlated with disease activity (p = 0.390) or disease duration (p = 0.483) nor was associated with past complications (p = 0.592), previous surgery (p = 0.598) or medication (p = 0.484).
Conclusion: Our study showed that CD, like other systemic inflammatory diseases, leads to an impairment of left ventricular ejection fraction and global longitudinal strain. This is one of the first studies evaluating left ventricular systolic function in CD by myocardial deformation imaging.

P1186

Ventricular function according to severity stages of chagas disease: an echocardiographic viewpoint of the natural history

LE Luis Eduardo Echeverria[1]; ZM Roa[2]; LS Calvo[2]; MC Villamizar[2]; C Luengas[2]; AM Chavez[2]; J Rodriguez[1]; R Campo[2]; LZ Rojas[2]
[1]*Foundation Cardiovascular of Colombia, Heart failure and cardiac transplant, Floridablanca, Colombia*; [2]*Foundation Cardiovascular of Colombia, Santander, Floridablanca, Colombia*

Funding Acknowledgements: This research was supported by the Colombian government through COLCIENCIAS, project code 656665740365, CT 648-2014.

Background: There are few studies that assess myocardial deterioration in Chagas patients with different severity stages, especially through techniques such as Global Longitudinal Strain (GLS). Evaluating and understanding the natural history of the disease and the progression of cardiac alterations by means of echocardiographic vision may help early identification of asymptomatic individuals with incipient myocardial changes.
Purpose: Evaluate the echocardiographic characteristics and the myocardial deformity in patients with different severity stages of Chagas disease.
Methods: A cross-sectional study. Continuous variables are expressed as mean ± standard deviation or median (first and third quartile). Chi-square or Fisher test were applicable for categorical variables. An analysis of variance (ANOVA)/Kruskal-Wallis test and Scheffé test were used to identify differences between groups.
Results: A total 121 patients. Left ventricle volume and mass increase was evident throughout the groups, including patients with preserved systolic function with EKG changes typical of Chagas disease (stage B); although these changes were statistically significant when compared to stage D, they were non-significant for stages A and C. Statistically significant SLG alteration was found for all Chagas cardiac disease stages (p = 0.000). Late right ventricular function deterioration was another interesting find, as evidenced by abnormal TAPSE, only in the most advanced stage C and D (p = 0.000) (Table 1).
Conclusions: SLG was the only echocardiographic measure able to differentiate early stages (A vs B) of the disease, suggesting it is an indicator of incipient myocardial damage in this population. However, these findings will require confirmation through a study of larger and randomized sample.

P1187

Value of 3D echocardiography in assessment of super-response to cardiac resynchronisation therapy in patients with chronic heart failure

VA Kuznetsov[1]; DV Krinochkin[1]; AM Soldatova[1]; NN Melnikov[1]; GV Kolunin[1]; TN Enina[1]
[1]*Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Tyumen, Russian Federation*

Background: Cardiac resynchronisation therapy (CRT) is an effective treatment for patients with chronic heart failure (CHF). Selection of patients with the prognosis of favorable response to CRT is one of the important issues.
Purpose: To reveal clinical and functional features in patients with CHF and super-response to CRT.
Methods: The study included 59 subjects (88% men, mean age 52.9 ± 9.0 years): 33 patients with ischemic and 26 patients with nonischemic cardiomyopathy. The main criteria of patients selection: NYHA II-IV functional class; left ventricular (LV) ejection fraction (LVEF) < 35%; signs of mechanical dyssynchrony assessed by 3D echocardiography, duration of QRS complex. 39 subjects had sinus rhythm and 20 patients - permanent atrial fibrillation. Combined CRT/ICD devices were implanted in 40 patients. 3D echocardiography with assessment of systolic dyssynchrony index (SDI) was performed at baseline and 6 months after CRT. Patients were divided into groups: I (n = 18) - increase in LV end-systolic volume (ESV) >30% (super-responders); II group (n = 41) - increase in LV ESV < 30%.
Results: At baseline no significant differences in clinical and functional characteristics were observed between the groups. 6 months after implantation both groups demonstrated reduction in NYHA functional classes (in group I from 2.69 to 2.00, p = 0.001; in group II from 2.70 to 2.18, p = 0.007). In patient with super-response significant increase in 6-minute walk test was observed (from 327 ± 95 m to 407 ± 46 m; p = 0.013), in group II increase in mean distance was not significant (from 329 ± 106 m to 370 ± 127 m, p = 0.126). Significant increase in LVEF and decrease in end-diastolic volume and ESV were found in both groups during CRT. At baseline SDI was significantly higher in patients with super-response (9.8 ± 3.5% vs 7.4 ± 4.4%; p = 0.035).
Conclusion: In the group of patients with super-response to CRT clinical improvement and exercise tolerance were detected along with LV reverse remodeling. More significant LV mechanical dyssynchrony including 3D echocardiography in patients with CHF was associated with super-response to CRT.

P1188

Left atrial minimum volume is more strongly associated with left ventricular filling pressures than the left atrial maximum volume

I Hamdi[1]; K Houissa[1]; C Chourabi[1]; A Belouaer[1]; K Taamallah[1]; L Riahi[1]; A Haggui[1]; N Hajlaoui[1]; D Lahidheb[1]; W Fehri[1]; H Haouala[1]
[1]*Cardiology departement, Military Hospital of Tunis, Tunis, Tunisia*

Aim: Left atrial (LA) maximum volume (LAV max) is an indicator of left ventricular filling pressure. However, systolic function is a determinant of LAV max, whereas the LA minimum volume (LAV min) is directly exposed to left ventricular pressure. Our aim was to demonstrate that LAV min is better correlated to filling pressure than LAV max.
Methods: This prospective study enrolled 49 patients (mean age : 62.7 years, range 44-89, 85% male) with ischemic cardiomyopathy (mean left ventricular ejection fraction : 47.57 %). All patients underwent transthoracic echocardiography and N-terminal pro-B- type natriuretic peptide (NT-proBNP) measurement within 24 hours. All LA volumes measureents were indexed by body surface area, LAV min : LA end-diastolic volume at the first frame after mitral valve closure, LAV max : LA end-systolic volume right before mitral valve opening.
Results: In linear regressions, LAV min was better associated with E/E' (r=0.572, p < 0.0001) than LV max (r=0.434, p = 0.003). LAV min was also more correlated with NT-proBNP (r=0.636, p < 0.0001) than LAV max (r=0.418, p = 0.003). The area under the receiver-operating curve (AUC) to detect E/E' >15 was 0.848 (p < 0.001) for LAV min and 0.721 (p = 0.02) for LAV max. The optimal LAV min cut-off to predict E/E'>15 was 20 ml/m^2 (sensitivity of 85% and specificity of 73%). To detect an NT-proBNP level of 450 ng/L, LAV min yielded a significantly larger AUC 0.75 (p < 0.004) than LAV max (0.608, p = 0.21).
Conclusion: Our findings support that LAV min may be more closely related to left ventricular filling pressures than LAV max in patients with ischemic cardiomyopathy.

P1189

Early reverse remodeling and improvement of echo parameters after introduction of sacubitril/valsartan in 80 stable and well treated HFrEF patients

V Maurin[1]; A Canu[1]; A Bernard[2]; S Lafitte[1]; F Picard[1]
[1]*University Hospital of Bordeaux, Bordeaux, France*; [2]*University Hospital of Tours, Tours, France*

Background: Sacubitril/valsartan is recommended to optimize pharmacological therapy of HFrEF patients, who remain symptomatic despite optimal treatment. If the benefits on prognosis have already been demonstrated in the PARADIGM trial, the effects on cardiac function, chambers dimensions and load conditions are unknown.
Objectives: We report the results of our monocentric cohort of 129 consecutive systolic HF patients, treated with Entresto between October 2015 and July 2016, studied with serial echocardiographic examinations acquired before and after 3 months of treatment. All echo were blind analysed in an external ESC accredited core lab echo.
Results: 129 patients were initiated with Entresto, 5% patients were excluded because of confounding factors (supposed alcoholic or rhythmic cardiomyopathy, concomitant CRT or valvular surgery), 11% discontinued treatment for adverse events, 3.8% were transplanted, 0.5% died of cardiovascular cause and 8% had missing data during the follow up period. 80 patients had finally echocardiographic examination before and after 3 months of treatment. Mean age was 59 years old, 76 % of patients were men, 52% had ischemic HF, and median duration of HF was 9,6 years. All patients were in stable hemodynamic condition with an optimized medical treatment at baseline (97.5% were treated with ACE-I or ARB, 98% with BB and 87.5% with MRA), the mean level of BNP was 531 pg/ml. 5% of the patients were in NYHA class 1, 70% in class 2, and 25% in class 3. At 3 months, 86% of patients received the target dose (97/103 mg), 8% the half dose (49/51mg), and 2% the low dose (24/26mg) whereas the dose of furosemide decreased significantly (83 vs 153 mg, p < 0.0001). Patients exhibited a significant reduction in left ventricular dimensions and volume (LVED diameter: 64.8 ± 10.9 vs 67,2 ± 8.6, p = 0.003, LVED volume: 204.1 ± 79.3 vs 218.8 ± 79.1 mL, p < 0.001, LVES volume: 142.7 ± 70.1 mL vs 158.9 ± 68.0 mL, p < 0.001) while ejection fraction increased by 18% (31.9 ± 8.2 % vs 28.4 ± 7.7 %, p < 0.0011) and global longitudinal strain increased by 9% (8,8 ± 3 vs 7,4 ± 2,7, p = 0,002). Diastolic function improved significantly, left atrial volume was significantly smaller (left atrial volume index: 39,5 ± 13,9 vs 43,7 ± 15,2mL/m^2, p = 0,005) and systolic pulmonary pressures decreased significantly (from 42.5 ± 12.3 to 38.8 ± 12.0 mmHg, p = 0.012). However, no significant change was observed in mitral regurgitation grade (1,1 ± 0,9 vs 1,2 ± 1, p = 0,2), neither in right ventricular dimensions (Right ventricular diastolic area, cm^2: 20.0 ± 4.3 vs 19,5 +/- 4,9, p = 0,64) or function (S', cm/s: 10.0 ± 2.7 vs 9.7 ± 2.7, p = 0,125).
Conclusions: Sacubitril/valsartan induces early reverse remodeling and improves pressure conditions in stable and well treated HFrEF patients.

P1190

Sedation on transesophageal echocardiography: correlation of Midazolam and fentanyl with alcohol

T R Tania Regina Afonso[1]
[1]*Hospital Israelita Albert Einstein, cardiologia MDP, Sao Paulo, Brazil*

BACKGROUND: Transesophageal echocardiography is performed using conscious sedation. Excessive alcohol users are commonly cited as difficult to sedate. Few studies compared and analyzed doses of medication to achieve sedation in these groups. OBJECTIVES: Goal predict the need for a high dose of sedative in patients who use alcohol.
Methods: A prospective study was conducted comparing patients who reported being resistant to alcohol with those who reported not being resistant, the mean dose of fentanyl and Midazolan was analyzed in both groups. RESULTS: A total of 52 patients were analyzed. Comparing groups of patients reporting resistance and nonresistance. The Group that reported resistance to alcohol used the statistically higher sedation dosage to achieve conscious sedation Midazolan mean 8.20 ± 3.12 mg first group and mean 5.30 ± 2.70 in the second group, the dose of anxiolytic did not change Significant mean 53.33 ± 12.91 first group and mean 45.95 ± 19.11 in the second group. Conclusions: Identifying patients who are difficult to sedate before transesophageal echocardiography is important because adequate sedation is associated with a better analysis of the cardiac anatomy and its malformations and patient comfort. In patients using alcohol, it is important to predict the need for higher doses of medication to achieve adequate sedation.

Subclinical functional and structural cardiomyopathy among patients infected with human immunodeficiency virus in the era of highly active antiretroviral therapy

M Maria De Las Nieves Montoro Lopez[1]; CI Soto[2]; R Florez Gomez[1]; A Alonso Ladreda[1]; I Ponz De Antonio[1]; JI Bernardino[2]; E Refoyo Salicio[1]; JJ Rios Blanco[2]; M Moreno[1]; G Guzman Martinez[3]
[1]*University Hospital La Paz, Department of Cardiology, Madrid, Spain*; [2]*University Hospital La Paz, Internal Medicine, Madrid, Spain*; [3]*National Centre for Cardiovascular Research (CNIC), Madrid, Spain*

Background. The development of highly active antiretroviral therapy (HAART) has entailed a significant decrease in AIDS-related complications and mortality. However, cardiovascular disease has become the main cause of mortality in developed countries. This study was aimed to compare echocardiographic parameters among outpatient HIV+ patients on HAART and a control group.
Methods: We conducted an analytic, observational, cross-sectional study in a tertiary hospital in Madrid (Spain). We included HIV infected patients under routine follow-up in the specialized Internal Medicine clinic of our institution. A group of non-infected HIV patients was also included. All of them provided written informed consent and underwent a comprehensive transthoracic echocardiogram (TTE) at the Imaging Unit of the Cardiology department. Clinical data, including cardiovascular risk factors were recorded.
Results: A total of 100 HIV patients and 16 controls were included. Baseline characteristics were similar between both groups. HIV+ patients showed statistically significant higher left ventricle (LV) mass, wall thickness and LV volume values than non-HIV patients. Moreover, the right ventricle (RV) free wall was also thicker in the HIV group compared to control group. Although the mean ejection fraction was similar between both groups, the mean RV fractional area change was significantly lower in the HIV+ group than in the control group.
Conclusion: Outpatient HIV infected patients on HAART show higher values of LV and RV wall thickness, higher LV volumes and lower RV systolic function compared to non-infected patients. The prognostic value of these subclinical abnormalities should be assessed in future studies.

Ecocardiograpghic parameters

	HIV(n = 100)	Controls (n= 16)	p value
LV mass/BSA (g/m^2)	89 (73-105)	69 (61-84)	0.002
LVEDV/BSA (ml/m^2)	56 (50-67)	45 (37-53)	0.001
LVESV/BSA (ml/m^2)	21 (17-25)	16 (12-20)	0.002
LVEF (%)	62 (57-67)	65 (60-68)	0.13
RV free wall thickness (mm)	5.0 (5.0-6.0)	4.0 (3.7-4.7)	0.001
RV fractional area change (%)	40 (36-46)	49 (39-63)	0.01
Tricuspid regurgitation velocity (m/sec)	2.36 (2.04-2.58)	2.10 (1.85-2.50)	0.44

Comparison of conventional echocardiographic variables between the studied groups. LV: left ventricle, BSA: body surface area, LVEDV: left ventricular end-diastolic volume, LVESV: left ventricular end-systolic volume, LVEF: left ventricular ejection fraction, LA: left atrium, RV: right ventricle, TAPSE: tricuspid annulus plane systolic excursion

P1192

Left ventricular hypertrophy predictors after repaired aortic coarctation

H Helena Nascimento[1]; M Braga[1]; V Ribeiro[1]; C Cruz[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Background and purpose: Aortic Coarctation (CoA) is a narrowing of the aorta, most commonly located distal to the origin of the left subclavian artery. Despite successful correction of this vascular defect, left ventricular hypertrophy (LVH) may persist. The primary goal of this study was to determine the predictors of LVH in this group of patients (pts).
Material and methods: This study was based on a retrospective analysis of 117 pts (>18 years-old) with the diagnosis of repaired CoA, followed-up in a Grown-up Congenital Heart Disease Centre. Epidemiological, clinical and echocardiographic data were collected and inserted in a registry base.
Results: From a total of 117 adult pts, 39.3% were female and the current mean age was 34.9 ± 9.2 years old. Surgical repair was performed in 105 pts (89.7%): resection with subclavian artery flap aortoplasty (36); head-to-head anastomosis (21) and woven Dacron patch (18). Remaining 12 pts (10.3%) were submitted to percutaneous intervention. Mean age at CoA correction was 9.7 years old. All pts were in sinus rhythm and electrocardiogram (ECG) voltage criteria for LVH were present in 33 pts (28.2%). LVH voltage criteria on ECG correlated significantly with the presence of LVH on transthoracic echocardiogram (ECO) (OR 7.75, CI 3.04-19.71, p < 0.001). Regarding ECO data, LVH was observed in 29 (24.7%) of the pts, and only two pts had mild to moderate left ventricular systolic dysfunction. Associated ventricular septal defect (VSD) (OR 3.6, CI 1.35-9.82, p = 0.013) was a predictor of LVH on ECO. Likewise, these group of pts presented a superior left atrial diameter (LAD) (37.7 ± 4.9 vs. 34.5 ± 5.4 mm, p = 0.008) and a E/e' (9.6 ± 2.5 vs. 8.1 ± 1.9, p = 0.053). Pts with LVH have been more often submitted to re-intervention (OR 2.53, CI 1.03-6.20, p = 0.053). Other variables as sex, age of repair and type of intervention were not determinants of LVH on ECO. LVH pts had a currently well-controlled blood pressure with a mean systolic blood pressure of 128.7 ± 11.6 mmHg with an average of 1.2 ± 0.7 anti-hypertensive agents. Beta-blocker was the most frequent used drug (70.0%), followed by blockers of the renin-angiotensin system (40.4%).
Conclusion: Our study reinforced that ECG voltage criteria strongly correlated with LVH on ECO LVH. Moreover, LVH on ECO was associated with VSD, higher LAD and re-intervention. Also, despite optimal blood pressure control, patients with repaired CoA may present LVH long after correction, suggesting the need for lower blood pressure targets for these pts.

P1193

Ejection fraction can be accurately detrmined using a cloud based platform on mobile devices

A Salacata[1]; J Kapala[1]; S Panknin[1]
[1]*Mid Michigan Medical Center, Alpena, United States of America*

Despite its shortcomings, left ventricular ejection fraction (EF) remains the most widely used measure of systolic function. Echocardiography remains the most widely used modality for measuring EF given its widespread availability, portability, reliability and low cost. Given the digital nature of echocardiographic data, echocardiograms can potentially be viewed and analyzed using mobile devices. We therefore performed this preliminary study to compare echocardiographic EF derived on a widely available mobile device. METHOD We randomly selected 20 transthoracic echocardiograms (TTE) with regional wall motion abnormalities from which identifying information was removed. All studies were acquired using GE Vivid 7 system then converted from native to mp4 format with a compression ratio of 69:1 using a commercially available web/cloud based service for analysis, archiving and retrieval. They were then interpreted in random order by an echocardiographer with level 3 training on a standard computer display (STRD) with a minimum LCD display size and resolution of 20" x 24" and 1600 x 1200 pixels, and an iPad 2 (MBL) with a screen size and resolution of 5.82" x 7.76" and 1024 x 768 pixels. EF was determined using a previously derived method1 of that scored segmental wall motion in the 4 and 2 chamber views. RESULTS Of the 20 subjects (15 male, mean age 71.2 ± 3.74 years), 3 had suboptimal studies requiring contrast administration for LV opacification. There was no significant difference in the mean EF by STRD vs. MBL (47.9 ± 13.44, range 28.05-66, vs. 45.89 ± 14.25, 24.83-66, p = 0.53). There was good agreement between both methods by regression analysis (R=0.55, p = 0.01), and as demonstrated using a Bland-Altman plot (average difference between methods = 2.0, 95% CI ± 14.07). CONCLUSION TTE EF can be reliably evaluated on a mobile device with results comparable to EF obtained by STRD. This will potentially lead to faster and timelier availability of this important piece of information. Additional studies on a larger number of mobile platforms should also be carried out.

P1194

The value of NT-proBNP in the diagnosis of cardiac disease in patients with alcoholic liver cirrhosis

V Romanova[1]; P Lazarev[1]; G Kiyakbaev[1]; V Moiseev[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Objective: to study the relationship between the level of NT-proBNP and the presence of structural and functional cardiac changes in patients with alcoholic liver cirrhosis (LC).
Methods: Our study included 80 alcoholic LC patients (mean age 53.1 ± 12 years) without any history of cardiovascular and respiratory disease. The number of patients with Child-Pugh classes A, B, and C was 12 (14.8%), 22 (27.2%), 46 (59.2%), respectively. We performed ECG with QTc measurement, echocardiography with assessment of left ventricular ejection fraction (LVEF), left ventricular diastolic function, left ventricular myocardial mass index (LVMI), systolic pulmonary artery pressure (SPAP) and cardiac output [CO = stroke volume (SV) x heart rate]. Plasma values of NT-proBNP were evaluated in 60 patients.
Results: The level of NT-proBNP plasma was elevated (> 125 pg/ml) in 46 (80%) patients, while there was a direct association between the level of NT-proBNP and severity of LC, estimated by MELD (R=0.39, $p < 0.05$) and Child-Pugh (R=0.35, $p < 0,05$) scores. The mean value of NT-proBNP in all patients amounted to 621.5 pg/ml (min 33 pg/ml, max 3849 pg/ml). No correlations between the level of NT-proBNP and parameters reflecting the presence of cardiac changes (size and area of the left and right atrial cavities, end-diastolic size, end-systolic size, thickness of interventricular septum and posterior wall of the left ventricle, LVMI, SV, EF, diastolic dysfunction, global longitudinal LV strain, QTc interval duration). We observed a positive correlation between the CO values and the level of NT-proBNP (R= 0.29, $p < 0.05$).
Conclusion: NT-proBNP increase was observed in majority of the patients with alcoholic LC and directly correlated with the severity of liver disease. The level of NT-proBNP is directly associated with CO and not with other echocardiographic parameters, which suggests that this marker could reflect the overload of sympathoadrenal system, and not heart failure, in this patient population.

P1195

Not changes in heart failure therapy but patient characteristics at admission predict unsuccessful guidance of therapy to a target of more than 30% NT-proBNP reduction

S Susan Stienen[1]; K Salah[1]; YM Pinto[1]; WE Kok[1]
[1]*Academic Medical Center, University of Amsterdam, Department of Cardiology, Amsterdam, Netherlands*

On behalf of: PRIMA II

BACKGROUND: NT-proBNP-guided therapy targeting a reduction of more than 30% from admission to discharge was not superior to conventional therapy for acute decompensated heart failure (ADHF) in the PRIMA II trial (presented at HFSA 2016, not yet published). In the subgroup of NT-proBNP-guided patients who received guidance of HF treatment , we studied which clinical variables predict unsuccessful guidance towards an NT-proBNP reduction of more than 30% at discharge.
Methods: In PRIMA II (NTR3279) 201 and 203 patients admitted for ADHF were randomized at the moment of clinical stability to NT-proBNP-guided versus conventional therapy respectively. Guided therapy (intensification of HF therapy) was performed actively in NT-proBNP-guided patients who failed to have a reduction of more than 30% from admission to randomization (N=68). Baseline characteristics of patients who were successfully guided (N=35) versus unsuccessfully guided (N=33) towards an NT-proBNP reduction of more than 30% were compared. A change in HF therapy was defined as initiation or increase in dosage of HF therapy, and HF therapy consisted of ACEi, beta blockers, MRA, CRT, electrical cardioversion and coronary angiography. Predictors of unsuccessful guidance (less than 30% reduction at both randomization and discharge) were determined using logistic regression analyses.
Results: Independent predictors of unsuccessful guidance were age over 80 years (OR 4.0, 95% CI 1.2-14, $p = 0.03$), rales at admission (OR 8.6, 95% CI 1.4-52, $p = 0.02$), atrial fibrillation at admission (OR 3.8, 95% CI 1.1-13, $p = 0.04$), and lower estimated glomerular filtration rate (per unit decrease: OR 1.05, 95% CI 1.01-1.08, $p = 0.01$). Changes in HF therapy did not predict unsuccessful guidance of therapy.
Conclusion: Non response of NT-proBNP-guided therapy in ADHF patients is dependent on patient characteristics at admission and not on intensification of HF therapy (pharmaceutical or interventional). Future studies should focus on NT-proBNP-guided therapy in patients in whom it is possible to successfully guide therapy.

P1196

Sacubitril/valsartan prevents the acute increase of n-terminal brain natriuretic peptide induced by exercise training in subjects with heart failure

G Giuseppe Caminiti[1]; V Cioffi[1]; G Cascelli[1]; N Punzo[1]; G Campolongo[1]; M Volterrani[1]
[1]*IRCCS San Raffaele Pisana Hospital, Rome, Italy*

Background: long-term administration of sacubitril/valsartan decreases levels of N-terminal brain natriuretic peptide (NT-proBNP). Its effects on changes of NT-ProBNP mediated by exercise training are not known. Aim: to evaluate if the administration of sacubitril/valsartan modulates the acute changes of NT-proBNP induced by exercise training in patients with heart failure and reduced ejection fraction (HFrEF).
Methods: The study enrolled 14 patients with HFrEF, males/females 11/3, NYHA functional class II/III who were elegible for treatment with sacubitril/valsartan. The experimental protocol was conducted in two sessions: the first before starting treatment with sacubitril/valsartan 97/103 bid; the second after a week of aimistration of the drug. At both exercise sessions, blood samples for NT-Pro BNP assessment were collected at rest, between 8:00 and 9:00 am, and 30 minutes after stopping training. The self-perceived dispnoea was evaluated by Borg scale. The exercise session lasted 1 hour during which patients performed endurance training at 60-75% of VO2 peak. Results: At T1 levels of NT-proBNP increased from 1835 ± 145 to 1973 ± 264 ($p = 0.0003$). The T1 Borg'score at the end of training was 4.6 ± 1.1. At T2 levels of NT-proBNP at rest were similar than after training (from 1216 ± 323 to 1288 ± 201; $p = 0.13$). Both NT-proBNP values at T2 were significantly reduced compared to correspondent values obtained at T1. The T2 Borg score was 2.8 ± 0.8. Conclusion: the administration of low doses of sacubitril/valsartan decreased NT- proBNP levels and prevented the acute increase of NT- proBNP and improved dispnoea early after endurance training in patients with HFrEF.

P1197

The diagnostic and economic implications of using a plasma nt-probnp of 300 or 400ng/litre as the threshold for ruling out the diagnosis of heart failure in a non selected british population

J Jessica Webb[1]; J Draper[1]; S Claridge[1]; T Jackson[1]; L Fovargue[2]; S Piper[3]; E Bolca[1]; S Rivolo[2]; R Rajani[1]; S Kapetanakis[1]; A Mcdiarmid[1]; T Mcdonagh[3]; R Razavi[2]; G Carr-White[1]
[1]*St Thomas' Hospital, Cardiology Department, London, United Kingdom*; [2]*King's College London, Division of Imaging Sciences and Biomedical Engineering, London, United Kingdom*; [3]*King's College Hospital, Cardiology Department, London, United Kingdom*

Funding Acknowledgements: VP2HF

Background: The 2014 National Institute of Clinical Excellence (NICE) guidelines on the management of acute heart failure recommend a plasma NT-proBNP threshold of 300pm/ml to assist in ruling out the diagnosis of heart failure (HF), updating previous guidelines recommending using a threshold of 400pg/ml.
Purpose: This study sought to determine the diagnostic and economic implications of using these thresholds in a large unselected UK population.
Methods: In our institution, all consecutive patients with suspected heart failure underwent NTProBNP testing from September 2014 to September 2015. The reason for all the patient's admission was recorded using hospital notes and imaging

results, including the patients with NTproBNP under 400pg/ml. Patient and clinical demographics were recorded as well as clinical outcomes (mean follow-up of 15.8 months (SD 8.7)).
Results: 697 were diagnosed with symptomatic HF following echocardiography and consultant review. From reviewing all the reasons for diagnosis, lowering the threshold from 300 to 400pg/ml would have involved screening an additional 61 patients and theoretically identified 6 patients with symptomatic HF. At 300pg/ml the sensitivity was 0.987 with a positive predictive value (PPV) of 0.396 and an accuracy of 0.467. Using a threshold of 400pg/ml, sensitivity was 0.973, PPV 0.407 and accuracy of 0.492. The economic implications of lowering the threshold would have involved additional costs of £58,116.07 (£952.72 per patient screened or £9686.01 per HF patient identified). The six patients identified with a NTproBNP between 300-399pg/ml were already known to the HF service.
Conclusion: The recent updated NICE guidelines to lower the plasma NT-proBNP threshold of 300ng/litre to rule out the diagnosis of heart failure had a significant impact on the heart failure team and costings, but would potentially improve heart failure detection (additional 6 patients identified).

Costing for different NTproBNP threshold		
Model screening patients with NTproBNP 300-399pg/ml	Number of Patients	Total Costs (£)
Cost of blood tests (£32.64/each)	61	1991.04
HF Team screening review (Nurse review £26.47/hour)	61	1614.67
Number of additional echocardiograms (£65.70/echo)	57	3744.90
Additional length of stay (£400/day x 2 days)	55	44,000
Change in stay for 6 patients correctly identified as having HF (increase by 1 day)	6	2400
Number of patients with HF readmitted within a month (and so no payment made according to BPT - £6179)	0.71	4365.46
OVERALL DIFFERENCE		58,116.07
Cost Implications of lowering the NTproBNP threshold to 300pg/ml		

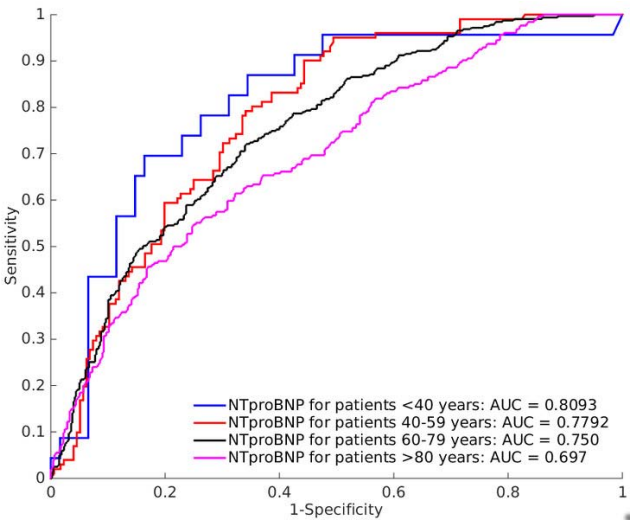
P1198
Natriuretic peptides for detection of heart failure in patients with atrial fibrillation from the community
S Van Doorn[1]; GJ Geersing[1]; AW Hoes[1]; F H Frans Hendrik Rutten[1]
[1]University Medical Center Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands

Heart failure (HF) may develop in patients with atrial fibrillation (AF), and the other way around. Both share shortness of breath and reduced exercise tolerance as key symptoms, and elevated natriuretic peptide levels. We aimed to assess the diagnostic value of amino-terminal pro B-type natriuretic peptide (NTproBNP) for uncovering heart failure in patients with atrial fibrillation.
Methods: Individual patient data from four opportunistic HF screening studies in older high-risk persons from the open population (≥60 years and type 2 diabetes, ≥65 years and chronic obstructive pulmonary disease, ≥65 years and shortness of breath, and ≥65 years and multimorbidity). All participants underwent an extensive clinical assessment, blood testing, electrocardiography, and echocardiography. Presence or absence of HF was established by an expert panel following the criteria of the European Society of Cardiology on HF. We used a two-stage mixed effects regression meta-analysis to calculate discrimination; efficiency; the proportion of missed cases and sensitivity, specificity and predicted values.
Results: In 1,941 individuals with median age 72.3 (IQR 67.4-77.7) years and 49.7% male, 196 (10.1%) cases had atrial fibrillation. Heart failure was uncovered in 82 (42.5%) patients with AF. Median NTproBNP levels of AF patients with and without uncovered HF were 744 pg/mL and 211 pg/mL, respectively. Fourty-three (21.9%) AF patients had NTproBNP value below 125 pg/mL. At this cutpoint, the sensitivity was 93%, specificity 36%, and the positive value and negative predictive value 52% and 87%, respectively.
Conclusion: In older high-risk AF patients from the community the prevalence of unrecognized HF is very high (42.5%), and straightforward echocardiography should be considered.

P1199
Diagnostic accuracy of plasma ntprobnp in patients over 80 years of age in a non selected british population
J Draper[1]; J Jessica Webb[1]; E Bolca[1]; Y Yiu[1]; L Fovargue[2]; S Rivolo[2]; B Porter[2]; B Sieniewicz[1]; S Kapetanakis[1]; A Mcdiarmid[1]; S Piper[3]; R Rajani[1]; T Mcdonagh[3]; R Razavi[2]; G Carr-White[1]
[1]St Thomas' Hospital, Cardiology Department, London, United Kingdom; [2]King's College London, Division of Imaging Sciences and Biomedical Engineering, London, United Kingdom; [3]King's College Hospital, Cardiology Department, London, United Kingdom

Funding Acknowledgements: VP2HF

Background: The current NICE guidelines recommend 300pg/ml for the threshold of ruling out heart failure (HF). However, NTproBNP is known to increase with age although the performance of this biomaker is unclear in very elderly patients.
Purpose: This study sought to define the diagnostic accuracy of plasma NTproBNP in patients over 80 years of age in a large unselected population of HF patients admitted to a Tertiary Hospital in the United Kingdom.
Methods: All 2077 consecutive patients over a 12 month period were screened for HF through our NTproBNP led heart failure service and were followed up for a mean of 15.8 ± 8.7 months, Patients were categorised by age (< 40, 40-59, 60-79 and >80 years old), HF classification, gender, ethnicity (Afro Caribbean, Caucasian and Asian) and outcome (time to HF hospitalisation or all cause death).
Results: Of the 2077 patients screened, 697 patients had symptomatic HF (mean age 72.7 ± 14.5years; 57.8% male) and 36% were over 80 years of age. The AUC of NTproBNP for diagnosis of HF was 0.734 for all heart failure patients. The AUC was calculated for the 4 age categories and there was a reduction seen as age increased ($p = 0.02$ 60-79 v >80: $p = 0.01$ 40-59 v >80; $p = 0.04$ <40 v >80years), Figure 2. There was a 5.3% reduction in receiver operating characteristic curve (ROC) area for patients over 80 years compared to those under 60-79 years of age. All patients with NTproBNP requested were investigated and in patients over 80 years of age, the lowest NTproBNP recorded in a patient with HF was 450pg/ml. At a threshold of 400pg/ml in patients over 80 years of age, the negative predictive value (NPV) was 1, sensitivity 1 and accuracy of the test 0.42. In contrast the NPV was 0.93, 0.95, 0.95 sensitivity 0.97, 0.96, 0.91 and accuracy 0,54, 0.61, 0.67 for patients 60-79, 40-59 and under 40 years of age respectively. Increasing the NTproBNP threshold in patients over 80 years of age for ruling out HF to 500 and 600pg/ml, changed the NPV to 0.94, 0.90, the sensitivity to 0.98, 0.96 and the accuracy to 0.46, 0.48 respectively. Furthermore, increasing the NTproBNP threshold to 500pg/ml in elderly patients resulted in a NPV of 0.95, 0.92 and 1 in Caucasian, Afro Caribbean and Asian patients respectively. Moreover using a NTproBNP threshold of 600pg/ml resulted in NPV of 0.9, 0.87 and 1 for Caucasian, Afro Caribbean and Asian patients respectively.
Conclusions: Over a third of the patients with HF identified in a large unselected UK population were over 80 years of age. All patients were investigated and the lowest NTproBNP recorded in patients over 80 years of age with HF was 450pg/ml, with a difference observed between Caucasian, Afro Caribbean and Asian patients. This data would suggest that the NTproBNP threshold for ruling out HF in patients should be altered if patients are over 80 years of age and according to ethnicity.



AUC for Different Age groups

P1200

Semaphorin 4D levels in heart failure patients: do we have a novel biomarker of heart failure besides BNP?

NA Willner[1]; Y Goldberg[2]; E Schiff[1]; Z Vadasz[3]
[1]*Bnai Zion Medical Center, Internal Medicine Ward B, Haifa, Israel*; [2]*University of Haifa, The Department of Bio-Statistics, Haifa, Israel*; [3]*Bnai Zion Medical Center, The Division of Clinical Immunology, Haifa, Israel*

Background: Semaphorin 4D (Sema4D) is a transmembrane glycoprotein expressed on platelets and T-cells, mainly involved in inflammation processes, axonal guidance during embryonal development, angiogenesis and malignant cells proliferation. Heart failure (HF) is caused by diverse pathophysiological processes including inflammation and neuro-hormonal activation, thus potentially influence Sema4D levels.
Purpose: The study had several aims: 1. Comparing Sema4D serum levels in HF patients with control group, with post-hoc analysis of potential confounders like kidney function, medical comorbidities and ejection fraction. 2. Analysis of the correlation between NT-pro-BNP and Sema4D, in order to examine the possible role of Sema4D as a biomarker for HF. 3. Evaluation of Sema4D serum levels in HF patients- during the acute phase and following remission.
Methods: 60 patients hospitalized with complaints clinically suspected to be HF exacerbation were enrolled for the HF group. 45 patients were diagnosed with HF exacerbation by echocardiographic findings and positive NT-pro-BNP with normal CRP were included in the study. Controls were age matched healthy individuals declaring no chronic diseases or medications. First NT-pro-BNP and Sema4D samples were taken on admission to hospital, and a repeated measurement was done on patients' discharge. Both NT-pro-BNP and Sema4D serum levels were done using commercial kits according to the manufacturer instructions.
Results: In the HF group, mean age was 72.2 ($\pm$3.5) years old, 72.7% were women, and mean NT-pro-BNP levels was 3.5570 ($\pm$0.56) pg/ml, compare with mean age of 76.5 ($\pm$12.5) years old, 42.2% women and mean NT-pro-BNP levels of 1.8 ($\pm$0.26) pg/ml in controls (p value 0.05, 0.07 and $<$0.001, respectively). Sema4D levels were significantly higher in HF patients than healthy controls (2143.04 $\pm$ 1253 ng/ml vs. 762.18 $\pm$ 581.6 ng/ml, $p<0.001$, respectively. Higher creatinine levels were found to predict both higher levels of NT-pro-BNP and Sema4D ($p=0.05$ and $p<0.014$, respectively), while reduced ejection fraction was found to predict higher NT-pro-BNP only ($p<0.001$ and $p=0.87$, respectively). When comparing mean Sema4D levels on admission and discharge, a significant reduction was found (3534.94 $\pm$ 1650.55 and 2455.67 $\pm$ 1424, $p=0.03$); NT-pro-BNP levels did not change significantly (3.41 $\pm$ 0.75 and 3.38 $\pm$ 0.6, $p=0.79$).
Conclusions: Sema4D levels in HF patients' serum are significantly higher than in healthy controls, with the highest levels being in patients with chronic kidney disease. Unlike NT-pro-BNP, Sema4D is not elevated in HF patients with reduced ejection fraction compare with HF patients with preserved ejection fraction. Clinical improvement caused rapid reduction in Sema4D levels, which may be related to the inflammatory process in HF. Further research of Sema4D and HF is essential, but those preliminary findings might indicate a possible role for Sema4D as a biomarker of acute heart failure.

P1201

Copeptin and inflammatory markers in patients with different variants of acute coronary syndrome.

I Irina Sukmanova[1]; IA Sukmanova[1]; OS Tanana[1]
[1]*Altay region cardiologist hospilal, acute infarction, Barnaul, Russian Federation*

Purpose: of the study was to acsess the dynamics of the concentration of copeptin, biomarkers of inflammation and their relationship patients with MI and unstable angina.
Materials and methods: the study included 49 divided into 2 groups: with aim -26 people - the first group, the average age of 64.2 $\pm$ 1.6 unstable angina– 23-the second group, at the age of 62.1 $\pm$ 2.2 years. All patients were assessed on the first and sixth day of hospitalization was estimated the level of CPK MB, troponin I, copeptin, interleukin 1b, IL 6, TNF α, for admission was conducted by ECHO and coronary angiography.
Discussion: Patients of the first group the level of CPK MB and troponin I levels at baseline and after 12 hours was significantly higher than the second group. Peak concentrations of as MB CPK, and troponin I were determined after 12 hours in the first group, the second group in the growth of the concentration of these indicators was not. Concentration copeptin source exceeded the reference values in patients of the first group, the second source and the dynamics were within acceptable values. After 12 hours it was noted the increase in copeptin to 0.7 $\pm$ 0.1 a, which was significantly higher than the corresponding figure of the second group 0,4 $\pm$ 0,01, $p=0.04$. To 6 days, the concentration of copeptin in the first group were close to baseline, but was slightly above normal. There was a slight increase in the concentration of TNF a in patients of the first group (1,3 $\pm$ 0,1 and 1,4 $\pm$ 0,1, $p=$ of 0.219) from the first to the 6th day of hospitalization. In the second group and the source in the dynamics of the concentration of TNF a did not exceed reference values. Patients of the first group there was a significant increase of concentration of IL 1b (from 2.2 $\pm$ 0.1 to 4.8 $\pm$ 0,1,$p=0,032$) and decreased concentration of IL 6 (from 7.6 $\pm$ 1.6 in the first day to 5.7 $\pm$ 0,7, $p=0.026$) to the 6-th day of hospitalization. The level of IL 1b in both groups the source and in the dynamics exceeded the reference values, without significant differences between patients with MI and unstable angina. The level of IL 6 in the source and the dynamics were above reference values in patients of both groups, and in the first group the concentration of IL 6 was the original and 12 hours is slightly higher than in the second group, 6 days decreased the concentration of IL 6 in the first group and increased in the second. In patients and THEY identified a direct relationship to the concentration of copeptin with CRA (r=0.5, P=0.01), creatinine (r=0.46, $p=0.01$), CPK levels occur after 6 hours (r=0.45, $p=0.02$), troponin I (r=0.16, $p=0.04$) and TNF a (r=0.38, $p=0.04$).
Conclusions: the significant increase in the level of copeptin and proinflammatory markers in the dynamics was observed in patients with AMI, also revealed the direct correlation between copeptin with markers of inflammation and damage.

P1202

C-reactive protein decrease during hospitalization predicts medium and long term mortality only in heart failure patients with preserved ejection fraction

P Lourenco[1]; J Pereira[1]; A Ribeiro[1]; J Ferreira-Coimbra[1]; I Barroso[2]; JT Guimaraes[3]; P Bettencourt[3]
[1]*Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal*; [2]*Sao Joao Hospital, Department of Biochemistry, Porto, Portugal*; [3]*Faculty of Medicine University of Porto, Unidade de Investigação e Desenvolvimento Cardiovascular do Porto, Porto, Portugal*

Background: Inflammation has been associated with heart failure (HF) progression and worse prognosis. The prognostic role of high sensitivity C-reactive protein (hsCRP) in the acute HF setting is less well established and the impact of its variation widely unknown. We aimed to study the prognostic impact of hsCRP variation and if it differed in patients according to left ventricular function.
Methods: We analyzed patients prospectively included in an acute HF registry. All patients were drawn a venous blood sample at admission and discharge and an echocardiogram was performed during hospitalization. Both patients with HF with reduced ejection fraction (HFrEF) and those with HF with preserved ejection fraction (HFpEF) were eligible. Patients with acute coronary syndromes causing acute HF, patients with primary valvular disease, and those with missing data regarding admission or discharge hsCRP were excluded. Relative variation of hsCRP (ΔhsCRP) during hospitalization was calculated using the formula: [(admission hsCRP – discharge hsCRP)/ admission hsCRP]X100. Patients were followed up to 3 years and the endpoint under analysis was all cause-death. A multivariate Cox-regression model (variables in the model: age, gender, discharge BNP and hsCRP, NYHA class and infection occurrence) was used to assess the prognostic impact of ΔhsCRP (both as continuous and as a categorical variable: cut-off 40% decrease ¯ median value) and a stratified analysis according to left ventricular function (HFrEF and HFpEF) was performed.
Results: We studied 439 patients, mean age 75 years, 50.1% male and 69.2% had HFrEF. Median admission hsCRP was 20.0mg/L, and median discharge hsCRP was 12.4mg/L. HsCRP decreased during hospitalization in 294 (67.0%); median (IQR) ΔhsCRP was 38 (-22 to 73) %. During the 3-year follow-up 247 patients (56.3%) died, 73 (54.1%) in HFpEF patients and 174 (57.2%) in those with HFrEF. The multivariate-adjusted HR of 3-year mortality in HFpEF patients with hsCRP decrease$\geq$40% during hospitalization was 0.56 (95% CI: 0.32-0.99). A decrease$\geq$40% in hsCRP was not mortality-associated in HFrEF patients - HR=0.90; 95% CI: 0.64-1.26. There was interaction between ΔhsCRP and left ventricular dysfunction; p for interaction was of 0.02. Similar results were obtained when ΔhsCRP was analyzed as a continuous variable.
Conclusions: A decrease$\geq$40% in hsCRP in acute HF associated with a 44% decrease in the 3-year death risk in HFpEF patients. No association between ΔhsCRP and prognosis existed in HFrEF patients. The prognostic impact of hsCRP decrease was significantly different between HFpEF and HFrEF patients. Our results suggest that inflammation plays a different role according to left ventricular function.

P1203

Is there a c-reactive protein value beyond which one should consider infection as the cause of acute heart failure?

J Pereira[1]; A Ribeiro[1]; J Ferreira-Coimbra[1]; I Barroso[2]; JT Guimaraes[3]; P Bettencourt[3]; P Lourenco[1]
[1]*Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal*; [2]*Sao Joao Hospital, Department of Biochemistry, Porto, Portugal*; [3]*Faculty of Medicine University of Porto, Unidade de Investigação e Desenvolvimento Cardiovascular do Porto, Porto, Portugal*

BACKGROUND: Heart Failure (HF) is a condition that courses with low-grade inflammation.High sensitivity C-reactive protein (hsCRP) is an established inflammatory marker widely used in clinical practice. A cut-off value of hsCRP beyond which an infection should be sought has never been studied in HF. We aimed to determine the best CRP cut-off for infection prediction in acute HF.
Methods: We analyzed patients prospectively included in an acute HF registry. All patients were drawn a venous blood sample upon admission,hsCRP was measured. An infectious condition was considered according to the discharge diagnosis list as judge by the attending physician.A ROC curve was used to determine the best hsCRP cut-off for infection prediction. Variables associated with infection in acute HF were assessed using logistic regression analysis.RESULTS: We studied 615 acute HF patients. Mean age 76 years, 45.2% male,60.3% had systolic dysfunction. Median admission hsCRP was 20.3 (9.5-55.5)mg/L and in 41.6% an infection was the cause of decompensation. The area under the ROC curve for admission hsCRP in the prediction of infection was 0.79 (0.76-0.83). The best hsCRP cut-off for infection prediction was 25mg/L with a sensitivity of 72.7%, a specificity of 77.2%, a positive predictive value f 69.4% and a negative predictive value of 79.9%. Age and elevated hsCRP (continuous and categorical)were the only variables independently associated with concomitant infection(Table).
Conclusions: We suggest 25mg/L as a cut-off beyond which an infection should be sough as the cause of acute HF decompensation. Almost 80% of the patients with CRP < 25mg/L are not infected and 69.4% of those with higher CRP have a concomitant infection.

	OR (95% CI)	p-value
Age, per year	1.02 (1.00-1.04)	0.01
hsCRP≥25mg/L	8.96 (5.91-13.56)	< 0.001
Male sex	0.69 (0.44-1.08)	0.11
Diabetes mellitus	0.89 (0.72-1.09)	0.25
Coronary heart disease	0.69 (0.45-1.06)	0.09
Admission systolic blood pressure, per mmHg	1.00 (0.99-1.00)	0.24
Haemoglobin, per g/dL	0.94 (0.85-1.04)	0.26
BNP per 100 pg/mL	1.00 (1.00-1.02)	0.35
Creatinine per mg/dL	0.89 (0.68-1.17)	0.40

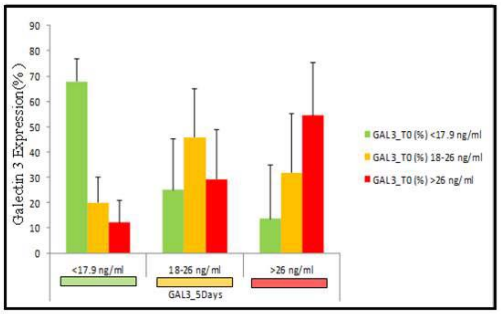
Galectin-3 levels at presentation and left ventricular ejection fraction (LVEF) prediction in patients with STEMI/NSTEMI acute myocardial infarction. An observational study.

M Ciaccio[1]; B Lo Sasso[1]; BD Leoni[2]; C Scazzone[1]; L Agnello[1]; G Bivona[1]; D Butera[1]; S Favero[2]; C Bellia[1]
[1]*University of Palermo, Palermo, Italy*; [2]*Abbott Diagnostics , Rome, Italy*

Background and Aim: The role of circulating Galectin-3 (Gal-3), a fibrosis marker, as a predictor of Left Ventricular Ejection Fraction (LVEF) in patients with acute myocardial infarction (AMI) is poorly investigated. The aim is to investigate serum Gal-3 levels in patients presenting at the Emergency Department with AMI (STEMI and NSTEMI) in relationship with LVEF.
Patients and Methods: We enrolled 152 patients diagnosed with AMI and with either preserved (HFPEF, n=80) or reduced (HFREF; n= 72) ejection fraction, of whom 44 and 55 with STEMI and 36 and 17 with NSTEMI respectively. Serum Gal-3 levels were assessed by Architect i1000SR (ABBOTT Laboratories) at the baseline and after 5 days from presentation. A logistic multivariate curve regression model (MCRM) was developed for investigating Gal-3 and type of infarct contribution on early LVEF prediction. The diagnostic performance was assessed by ROC curve analysis.
Results: Independently from primary Percutaneous Coronary Intervention (pPCI) and AMI type, Gal-3 remained constant in nearly 60% of patients (< 17.8 ng/ml and >26 ng/ml). In NSTEMI patients log-transformed Gal-3 serum levels was higher in REF than PEF (P < 0.01). MCRM showed that Gal-3 (OR=0.974, 95% CI: 0.954-0.995 P=0.01) and infarct type NSTEMI/STEMI (OR=0.213, 95% CI: 0.125-0.471), P < 0.001), were independent influencing factors of the basal LVEF. ROC curve best cut point was at 22.8 ng/ml (AUC 0.658; 95% CI 0.513-0.803; Sensitivity= 0.88; Specificity= 0.47) in NSTEMI.
Conclusions: In NSTEMI patients serum Gal-3 basal values at presentation could be predictive of preserved or reduced LVEF with high sensitivity, but in STEMI this was not observed.



Gal-3 dynamics after 5 days

P1205

Predictors of adverse cardiac events in heart failure patients of different functional class

M G Kaliadka[1]; A K Alena Kurlianskaya[1]; T L Denisevich[1]; Y P Ostrovsky[1]
[1]*Research & Practical Centre "Cardiology", Minsk, Belarus*

Aim: To reveal predictors of adverse cardiac events in pts with different functional class (FC) of severity of heart failure (HF) by NYHA.
Methods: The study involved pts with HF: I-II FC – 70 pts, III-IV FC – 68 pts. We performed biochemical blood analysis: NT- proBNP, ST2, Galectin-3, Cardiac troponin-I. The clinical course was evaluated on the start and within 6 months of observation. Adverse cardiac events - death, cardiac transplantation, emergency hospitalization with decompensation. By applying the statistical module "Classification Trees" we identified predictors of adverse cardiac events (ACE) in pts with CF of different FC. Results and Conclusions: Within 6 months 18.8 % of patients with HF developed ACE, precisely I-II FC – 11.4% of cases, III-IV FC – 26.5% of cases. Classification Trees (CT) were built to minimize the errors of false classification. We used dimensional branching algorithm by the method of CART (Classification And Regression Trees). Importance (rank) of the selected predictors was scored (maximum rank - 100 points). As a result, there were received 3 statistically significant decision trees. The predictors revealed basing on the CT analysis were presented in table 1. I-II FC of HF pts - the predictors of unfavorable course included of NT-proBNP (rank-78) considering end-diastolic volume of the left ventricle (EDV) (rank - 100). III-IV FC of HF pts - 2 statistically significant CT. The first decision tree included the following predictors of unfavorable cause of the disease: concentration of ST-2 (rank - 87) and myocardial mass index of the left ventricle (MMI LV) (rank - 100). The second CT for III-IV FC of HF showed the highest classification accuracy (100%) and was based on the sequential analysis of the following laboratory parameters: Galectin (rank-60), of NT-proBNP (rank-72) and atherogenic factor value (rank-100).

The predictors of unfavorable course

FCCHF	Predictors	favorable outcome	unfavorable outcome	Classification accuracy
I-II	NT-proBNP≥4683 pg/ml	100%	78.0%	96.4%
I-II	NT-proBNP < 4683 pg/ml and EDV≥411 ml	100%	78.0%	96.4%
III-IV	ST-2≥53 pg/ml	96.5%	100%	97.3%
III-IV	ST-2 < 53 pg/ml and MMI LV≥262	96.5%	100%	97.3%
III-IV	Galectin≥16 ng/ml and NT-proBNP≥1587 pg/ml	100%	100%	100%
III-IV	Galectin < 16.2 ng/ml and atherogenic factor≥5.5	100%	100%	100%

Five years risk prediction in patients with heart failure: clinical data and biomarkers interaction

M Maria Coronel[1]; J Blanchet[1]; E Perna[1]; J Cimbaro Canella[1]; S Macin[1]; B Gonzalez Arjol[1]; F Medina[1]; M Brizuela[1]; L Borgo[1]
[1]*J.F. Cabral Cardiology Institute, Corrientes, Argentina*

Chronic heart failure (CHF) and acute heart failure (AHF) are associated with high short- and long-term morbidity and mortality. However, there are few data in our country about long term follow up of this condition.

Objectives: 1-To characterize long-term follow up of patients with heart failure. 2-To identify clinical variables and biomarkers related with long-term prognosis.
Methods: Between January and August 2011, 100 patients with CHF and 144 with AHF were prospectively included. At admission, high sensitivity Troponin T (HsTnT, ROCHE), BNP, CA 125 and urinary NGAL (ABBOTT) were measured. The end points were 5-years survival (SUR) and 5-years hospitalization free survival (HOSP-S).
Results: Mean age was 67 ± 13 years, male 68%, 41% had ischemic etiology, and 22% with ejection fraction ≥ 50%. The mean follow-up was 42 ± 23 months, median 54, interquartil range 16-62 months. The SUR at 66 months was 47 ± 3,5% and the HOSP-S was 28 ± 3%, without significant differences between CHF and AHF. The variables associated with SUR were COPD (p = 0.02), anemia (0.002), atrial fibrillation (0.002), hospitalization for AHF during last year (0.004), previous functional class (FC) 3-4 (0.001), age (< 0.001), creatinin (< 0.001), sodium (0.002), CA125 > 14 U/ml (0.02) and HsTnT > 23 ng/l (0.005): Independent predictors for mortality were COPD (p = 0.031; HR=1.6; 95%CI=1.05-2.5), FC 3-4 (< 0.001; 2.3; 1.5-3.4), age (0.001; 1.03; 1.01-1.04), creatinin (0.001; 3.6; 1.1-1.7), sodium (< 0.001; 0.94; 0.91-0.97) and HsTnT >23 ng/l (0.019; 1.69; 1.09-2.63). The variables associated with HOSP-S were COPD (p = 0.02), anemia (0.01), atrial fibrillation (< 0.001), hospitalization for AHF during last year (0.001), FC 3-4 (< 0.001), age (0.002), creatinin (< 0.001), sodium (0.04), BNP > 180 pg/ml (0.03) and HsTnT >23 ng/l (< 0.001). Independent predictors for HOSP-S were FC 3-4 (p < 0.001; HR=2.2; 95%CI=1.5-3.0), atrial fibrillation (0.001; 1.7; 1.2-2.4), age (0.029; 1.02; 1.01-1.03), creatinin (0.003; 1.2; 1.1-1.5), sodium (0.006; 0.96; 0.92-0.98) and BNP >180 pg/ml (0.003; 1.7; 1.2-2.4).
Conclusions: The five years follow up of patients with heart failure evidenced that only one out two survive, and one out three survive without hospitalization for AHF. Simple clinical variables could help to the early identification of poor outcome. A biomarker of myocardial damage appeared as mortality predictor whereas one of myocardial stress was associated with combined events

P1207

Abnormal potassium level predicts short-term readmissions in patients with acute dyspnea

[1]Vilnius University, Faculty of Medicine, Vilnius, Lithuania; [2]Vilnius University, Clinic of Cardiac and Vascular diseases, Center of Cardiology and Angiology, Vilnius, Lithuania; [3]Lithuanian University of Health Sciences, Faculty of Medicine, Kaunas, Lithuania; [4]Lithuanian University of Health Sciences, Department of Cardiology, Kaunas, Lithuania; [5]University Paris Diderot , U942 Inserm, Hospital Lariboisière, Paris, France

On behalf of: GREAT network
Funding Acknowledgements: The work was supported by Research Council of Lithuania, grant Nr. MIP-049/2015 The work was approved by Lithuanian Bioethics Committee, Nr. L-15- 01.

Introduction: Potassium imbalance is included in some clinical risk scores to assess the prognosis of acute heart failure (AHF) patients. The importance of hypo-/hyperkalemia in prediction of short-term outcomes in a wide population of acute dyspnea patients is less clear.
Purpose: We aimed to evaluate the prognostic value of abnormal blood potassium levels in prediction of short-term mortality and readmissions in acute dyspnea patients.
Methods: Prospective observational cohort study enrolled consecutive patients admitted to the emergency department with acute dyspnea due to AHF and other reasons. Blood potassium levels at the time of admission and number of deaths and rehospitalizations due to cardiovascular and other reasons in 1 and 3 months of follow up were collected. Data of 445 study patients (mean age 68 years) were included in the analysis. Hypokalemia and hyperkalemia were defined as blood potassium level <3.8 mmol/l and >5.2 mmol/l, respectively. Data were analyzed using SPSS v23 statistical package with binary logistic regression.
Results: Of 445 patients (185 female) 101 subjects (22.7%) were hypokalemic, 330 – normokalemic, 14 (3.1%) had hyperkalemia. AHF was diagnosed in 243 patients (54.6%); other diagnoses in 201 (45.2%) remaining participants included atrial fibrillation (7%), exacerbation of COPD/asthma (11.4%), pulmonary embolism (6%), pneumonia (16.4%), acute coronary syndromes (6.2%). Hypo- and hyperkalemia were found in 21.4% and 2.9% of AHF patients. Regardless of the presence of AHF diagnosis hypokalemia was associated with significantly increased risk of 3-month cardiovascular readmissions and 1-month non-cardiovascular readmissions, OR=1.024 (CI 0.998;1.050) and OR=2,189 (CI 1.023;4.686), respectively (p < 0.05). Hyperkalemia was a significant predictor of 3-month cardiovascular readmissions with OR=4.489 (CI 1.319;15.274). No significant association of abnormal potassium level with 1- or 3-month all-cause or cardiovascular mortality was found.
Conclusions: In prospective observational cohort one in four patients with acute dyspnea were found to have abnormal potassium level at admission. Both hypo- and hyperkalemia independently of final diagnosis are associated with higher rate of short-term readmissions due to cardiovascular as well as non-cardiovascular reasons.

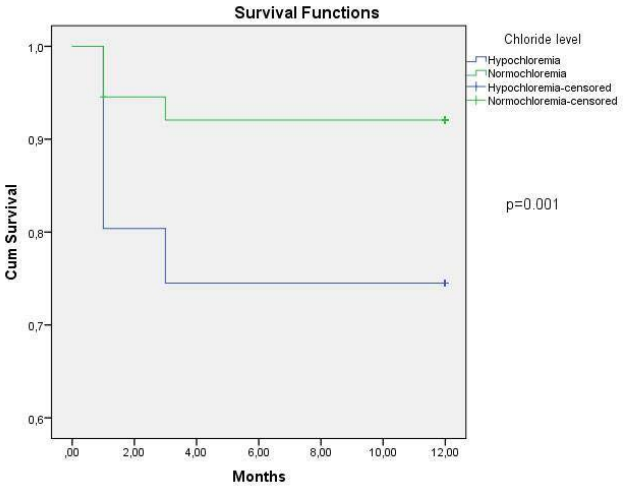
P1208

Prognostic value of hyponatremia and hypochloremia in patients with dyspnea

J Bugaite[1]; D Gabartaite[1]; V Juknevicius[2]; A Mebazaa[3]; J Celutkiene[2]
[1]Vilnius University, Faculty of Medicine, Vilnius, Lithuania; [2]Vilnius University, Clinic of Cardiac and Vascular diseases, Center of Cardiology and Angiology, Vilnius, Lithuania; [3]University Paris Diderot , U942 Inserm, Hospital Lariboisière, Paris, France

On behalf of: GREAT network
Funding Acknowledgements: The work was supported by the Research Council of Lithuania, grant Nr. MIP-049/2015 and approved by Lithuanian Bioethics Committee, Nr. L-15-01.

Introduction: Hyponatremia and hypochloremia have been reported as important predictors of mortality in acute heart failure (AHF). The prognostic significance of low sodium and chloride level in a wider population of patients with acute dyspnea is unknown.
Aim: To evaluate whether hyponatremia and hypochloremia had a significant value in predicting short-term rehospitalizations and mortality of patients with acute dyspnea admitted to the emergency department.
Methods: Prospective observational cohort study enrolled consecutive patients admitted to the emergency department with acute dyspnea due to decompensated HF, exacerbation of chronic obstructive pulmonary disease (COPD), pneumonia, pulmonary embolism and other reasons. Electrolyte concentration on admission and rate of mortality and rehospitalizations at 1 and 3 months follow up were collected. Data of 307 study patients (mean age 68.4 ± 12.7 years) were included in the analysis. The study group consisted of 143 women (46.6%) and 164 men (53.4%). Data were analyzed using SPSS v23 statistical package using Cox proportional-hazards regression analysis. A p-value < 0.05 was considered statistically significant.
Results: On admission 8.8% of patients had hyponatremia (sodium concentration < 134 mmol/l) and 16.6% were hypochloremic (chloride concentration < 98 mmol/l). Patients with hyponatremia had greater chance to be rehospitalized due to all causes (hazard ratio [HR] = 2.6; 95% confidence interval [CI]: 1.48 to 4.55; p = 0.001) and due to cardiovascular causes during 3 months period (HR = 3.31; 95% CI: 1.45 to 7.58; p = 0.005). There was no statistically significant association between hyponatremia and patients' mortality in three months period. Admission serum chloride level during hospitalization for acute dyspnea was independently associated with 3-month mortality (HR = 3.36; 95% CI: 1.62 to 6.99; p = 0.001), but not with rehospitalizations. AHF was the main cause of admission to the hospital in hyponatremic and hypochloremic groups (respectively 81.48% and 78.43%), other causes were pulmonary embolism, COPD, hydrothorax, pneumonia, bronchitis, sepsis, pulmonary carcinoma and B cell lymphoma. In hyponatremia group patients with AHF were rehospitalized more often than non-AHF patients (p = 0.045). However, there was no statistically significant difference in deaths of AHF and non-AHF patients with hypochloremia. No statistically significant correlation between blood electrolytes concentration and diabetes mellitus or renal disease was found.
Conclusion: Sodium and chloride concentrations are significant predictors of outcomes in acute dyspnea patients admitted to the emergency department. Hypochloremia is more hazardous to patients' outcomes compared to hyponatremia.



Kaplan-Meier curve of survival

Following acute myocardial infarction (AMI), a significant proportion of patients develops heart failure (HF) due to left ventricular remodelling (LVR). The early identification of patients developing LVR is essential for evidence-based intervention and pharmacological therapy. Novel biomarkers might pave the way for improved prediction approaches. Since the discovery of their stability in the bloodstream, miRNAs, short oligonucleotides which down-regulate gene expression, have been extensively studied for their potential to diagnose AMI. We previously identified a panel of 4 circulating miRNAs (miR-16-5p/27a-3p/101-3p/150-5p) able to significantly improve the prediction of post-AMI LVR by a multivariable clinical model including N-terminal pro-brain natriuretic peptide (Nt-pro-BNP). In the present study, we aimed to confirm the predictive value of the 4-miRNA panel in an independent cohort obtained from the MITOCARE study, a prospective randomized clinical trial conducted from 2011 to 2013. We enrolled 90 patients with STEMI treated by primary PCI. The HTG EdgeSeq targeting sequencing platform was used to assess the levels of miRNAs in plasma samples collected 3 days after AMI. Cardiac function was assessed by echocardiography at discharge and after 1 month. Left ventricular ejection fraction (LVEF) at 1 month was used to classify patients into 3 categories: LVEF < =40 (n = 14), LVEF between 41 and 50 (n = 34) and LVEF>50 (n = 41). Random forest model was used for predictive modelling and individual AUC, and confidence intervals (CI) were calculated for each miRNA. miR-16-5p/27a-3p/101-3p/150-5p individual AUC were 0.81, 0.75, 0,84 and 0,61, respectively. The combination of the set of 4 miRNAs showed an average AUC of 0.83 (CI 0.80-0.85). Combining the 4 miRNAs with NT-pro-BNP resulted in an AUC of 0.87 (CI 0.75 and 0.99). In conclusion, we here confirm the independent predictive value of the 4 miRNAs (miR-16-5p/27a-3p/101-3p/150-5p) for the prediction of HF development after AMI. HTG EdgeSeq technology proves to be an efficient and clinically-applicable tool to measure circulating miRNAs. These results motivate the development of molecular diagnostic kits based on miRNAs to aid in outcome prediction after AMI.

Funding Acknowledgements: EuroTransBio

Introduction: Early diagnosis, Percutaneous Coronary Intervention (PCI) and biomarkers have contributed substantially to the treatment of Acute Myocardial Infarction (AMI) by reducing the size of the infarct and mortality due to cardiac ischemia. Despite advances in care, prognosis in term of Heart Failure (HF) remains poor. Once HF has developed, 30 to 40% of patients die within one year and 60 to 70% within 5 years of diagnosis. The earlier patients who are prone to develop HF are identified, the more efficiently a prophylactic treatment can be adapted.
Aim: The aim of this project is to identify new biomarkers for the prediction of HF and translate this into a diagnostic test for risk stratification, prognosis and monitoring of treatment response for AMI patients after PCI treatment.
Material and Methods: Blood samples and patient data were collected in the frame of the CardioSAVE study, a prospective 12-months longitudinal study, for risk stratification of AMI patients undergoing PCI, with a one year follow-up conducted at our Heart Center. Patients were selected according their LVEF < 40% or >50% at 6 months (M6) assessed by echocardiography. Plasma samples collected on day 3 (D3) after MI were analyzed for 92 biomarkers (BM) on the Proseek Multiplex CVD II (human cardiovascular and inflammatory markers) panel from Olink on the Biomark HD Platform. This innovative technology is based on a dual recognition of antibody-pairs and oligonucleotides called proximity extension assay.
Results: Six AMI patients with LVEF < 40% and 6 AMI patients with LVEF>50% at 6 months were analyzed. A differential expression was observed for 20 BM between both groups. Five BM exhibit an increase of the expression at D3 in the group with reduced ejection fraction at M6, whereas 15 BM decreased their expression at D3 in the group with reduced ejection fraction at M6.
Conclusion: The selected biomarker panel profile will be further investigated and developed on a diagnostic prototype. The reliability and accuracy of the novel diagnostic kit will be tested in a clinical setting to achieve Proof of Concept. Upon complete validation, this tool may serve as a personalized medicine device focusing on HF allowing the identification and risk stratification of AMI patients in low- and high risk groups after undergoing PCI.

P1211

Echocardiographic and neurohormonal correlations of plasma galectin-3 in adult patients with congenital heart disease.

A Alexandra Frogoudaki[1]; I Pantelakis[1]; D Birba[1]; V Bistola[1]; I Ikonomidis[1]; J Parissis[1]; D Alexopoulos[1]; G Filippatos[1]; J Lekakis[1]
[1]Second Cardiology Department, Athens University, ATTIKON University Hospital, Athens, Greece

Introduction: Galectin-3 is a β-galactoside–binding lectin and is best known for its role as a mediator of tumor growth and metastasis. In addition galectin-3 plays a role in inflammatory and immune-mediated disorders as well as in fibrogenesis, mechanisms involved in the progression of heart failure and cardiac remodelling. It has an important and significant prognostic value in identifying patients with heart failure at elevated risk for subsequent morbidity and mortality. However, no efficient data exist regarding the relationship of plasma galectin-3 levels and cardiovascular abnormalities in congenital heart disease.
Aim of the study was to look at echocardiographic and neurohormonal correlations of plasma galectin-3 in adult patients with congenital heart disease.
Methods: We studied 57 clinically stable patients (31 men, mean age 37.1 ± 16.9) with congenital heart disease. Fourty-nine had systemic left ventricle, 5 systemic right ventricle and 3 single ventricle physiology. All patients underwent echocardiographic study and NTproBNP and galectin-3 plasma levels were measured. For parameters with normal distribution Pearson correlation analysis was performed while for parameters withoutnormal distribution Spearman correlation analysis was performed.
Results: Mean galectin-3 value was 16,93 ± 6.39ng/ml. Mean NTproBNP value was 265.25pg/ml (range 18.7 pg/ml-3788pg/ml). Plasma galectin-3 levels correlated with LogNTproBNP (r=0.469, p = 0.001) and left atrial diameter (r=0.316 p = 0.025). Galectin-3 plasma levels didn't correlate with age, systemic ventricle ejection fraction, subpulmonary ventricle pressure, and subpulmonary ventricle function indices (annulus systolic excursion and systolic tissue Doppler velocity).
Conclusion: Galectin-3 plasma levels correlated with plasma NTpro BNP as well as left atrial diameter indicating that systemic ventricular fibrosis and/or left atrium may be included in the causes of increased systemic ventricle end-diastolic pressure in adult patients with congenital heart disease.

P1212

Prognostic value of Galectin-3 as predictor of acute kidney injury in acute heart failure hospitalization

J Juan Sanchez Serna[1]; M Navarro Penalver[1]; JJ Santos Mateo[1]; MT Perez Martinez[1]; A Lax[1]; MC Asensio Lopez[1]; J Sanchez Mas[1]; DA Pascual Figal[1]
[1]Hospital Clínico Univeristario Virgen de la Arrixaca, Cardiología, Murcia, Spain

Background: Elevated levels of Galectin-3 (Gal-3) have been associated with worse prognosis in acute heart failure (AHF). These may be influenced by the presence of

renal failure. However, it is unknown if Gal-3 can identify a worse renal prognosis.
Purpose: We intend to study whether Gal-3 concentrations in AHF admissions identify patients at higher risk of acute kidney injury (AKI).
Methods: We studied 111 patients admitted for AHF (61% men, 71 ± 11 years, LVEF 45 ± 15%). Gal-3 determinations were made on admission with a commercial assay (Biomerieux). Serum creatinine (Cr) value and glomerular filtration rate (GFR) during admission and baseline values before admission were collected. Two validated criteria were used to define AKI: RIFLE (increase ≥1.5 times of Cr or decrease of GFR ≥25% respect to baseline values or diuresis ≤0.5 mL/kg/h for 6 hours) and AKIN (increase ≥0.3mg/dl or ≥150% Cr within 48 hours of hospitalization or diuresis ≤ 0.5 mL/kg/h for 6 hours).
Results: Gal-3 levels at admission were 20.7 ± 11.9 ng/mL. During hospitalization, 24 (21.6%) patients presented AKI according to the AKIN criteria; 43 (38.7%) according to RIFLE criteria; and 46 (41.4%) according to AKIN and/or RIFLE. Based on the AKIN/RIFLE criteria, Gal-3 levels were higher in patients who developed AKI (18.79 vs 23.32, $p = 0.049$) (Figure). The ROC analysis showed an area under the curve of 0.66 (95% CI 0.55-0.76, $p < 0.01$). The best prediction point was 17.2 ng/mL. Considering this value, patients with higher levels had an increased risk of AKI (OR 2.83, 95% CI 1.28-6.23, $p < 0.01$). In the multivariate analysis taking into account age, sex, normal LVEF (> 55%) and preserved renal function (GFR> 30 ml/min/1.73m2), the predictive value of Gal-3> 17.2 ng/mL lost the statistical significance (OR 2.23, 95% CI 0.93-5.33, $p = 0.07$).
Conclusions: In patients admitted for AHF, Gal-3 on admission identified an increased risk of deterioration of renal function during hospitalization. After adjustment for known renal dysfunction factors, Gal-3 levels maintained a non-significant trend, suggesting the need for new studies with larger populations.

P1213

Biomarkers of systemic inflammation, hemodynamic stress, degradation of the extracellular matrix and adverse left ventricular remodelling in primary anterior STEMI patients

M Kercheva[1]; T Ryabova[1]; A Gusakova[1]; V Ryabov[2]
[1]Research Institute for ?ardiology, Emeregency cardiology department, Tomsk, Russian Federation; *[2]National Research Tomsk State University, Translational laboratory of cellular and molecular medicine, Tomsk, Russian Federation*

Purpose: to assess the impact of matrix metalloproteinases (MMP)-2, 3, 9, ST2, IL1β, hCRP, NTproBNP on the adverse left ventricular remodeling (LVR) in patients with acute primary anterior STEMI.
Methods: 21 pts with primary anterior STEMI (mean age 60.5 ± 7.4) were enrolled. Blood samples were determinated by the immunoassay - on the 1st (T1), 3d (T2), 7th (T3), 14th (T4) days of STEMI and 6 month after STEMI (T5). Echocardiography with 2D speckle tracking imaging was performed at the same period, without the point T1 ('Vivid E9'). Pts were divided into 2 groups: ST2>35 ng/ml and ST2 < 35 ng/ml at T1.
Results: All of them had urgent reperfusion therapy, in third of events it was during the first 3 hours. MMP-2 from T1 to T5: 224.9 ± 84.1→190.6 ± 63.9→224.5 ± 90.1→233.3 ± 70.3→262.9 ± 96.3 ng/ml ($p > 0.05$). MMP-3 increased from T1 to T3, then to T5: 14.2 ± 14.4→19.9 ± 14.9→23.3 ± 8.7 ng/ml ($p < 0.05$). MMP-9 decreased at the same terms: 905.9 ± 772.4→538 ± 520.6→365.5 ± 449.4 ng/ml ($p < 0.05$). IL1β decreased from T1 to T4:1.2 ± 0.4→0.9 ± 0.4 pg/ml ($p < 0.05$). NTproBNP and hCRP decreased from T1 to T5 and T1 to T4, respectively: 456.8 ± 359.3→198.8 ± 139.5 pg/ml ($p < 0.05$) and 7.1 ± 3.7→3.4 ± 2.8 mg/l ($p < 0.05$). ST2 decreased from T1 to T5: 90.5 ± 83→46.3 ± 35.4→30 ± 11.3→28.7 ± 7.8→28.7 ± 8.8 ng/ml ($p < 0.05$). Assessment of echocardiography shown, that in groups ST2>N and ST2<N:>
Conclusion: The dynamics of markers had the different directions. The level of MMP-2 was without significant dynamics. The level of MMP-3 increased to T3 and it have been continued to T5, however the level of MMP-9 had the reverse dynamics at the same period. IL1β and hCRP decreased to T4, as NTproBNP, but to T5. ST2 decreased at all observation period to T5. In addition, ST2 had the most predictive value. Its level more than 35 ng/ml at T1 was associated to the presence of the systolic dysfunction – the bigger value of wall motion score index, end-systolic volume, 2D global longitudinal strain and the smaller value of ejection fraction in the early post-infarction period.</N:>

P1214

Biomarkers of fibrosis, inflammation, renal dysfunction and its correlations in patients with HFpEF and HFmrEF

EA Medvedeva[1]
[1]Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation

There is extensive research on biomarkers in heart failure (HF) patients. However, only a few studies have reported an association between different biomarkers in HF with preserved and mid-range ejection fraction.
Objective: To evaluate concentrations of biomarkers of fibrosis, renal dysfunction, inflammation, and their correlation in patients with chronic heart failure (CHF) with prior myocardial infarction (MI) and ejection fraction (EF) ≥40%. Design and Methods. The study included 103 patients with HF with preserved (HFpEF, EF>50%) and mid-range ejection fraction (HFmrEF, EF: 40-49%). Criteria of inclusion were prior MI and primary PCI in history, NTproBNP level>125pg/ml. As a comparison group we included 51 patients with prior MI and PCI, without signs of HF and with level of NT-pro BNP < 125pg/ml. All patients underwent a comprehensive clinical assessment, echocardiography. There was valued the level of galectin-3, ST-2, hs-CRP and cystatin-C by immunoassay analysis. The estimated glomerular filtration rate (e-GFR) was calculated using Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. All statistical analysis was performed with Statistica 6.0. Continuous variables were described by median (1st -3rd quartile). Comparisons of continuous variables were performed using Mann-Whitney, U-test. Spearman's rank correlation coefficient was calculated to measure dependence between two variables.
Results: In the study group (1st), the level of NT-proBNP was 445.23 (245.9-896.93) pg/ml, in a comparison group (2nd) - 67.16 (40.17-86.61) pg/ml. The plasma level of ST-2 in the 1st and 2nd groups were 40.70 (33.45-49.27) ng/ml and 39.21 (32.64-46.38) accordingly, we did not observe significant difference between groups ($p > 0.05$). We found significant correlations between the level of biomarkers for fibrosis and myocardial stress only in patients with CHF: ST-2-NT-proBNP ($r1 = 0.36$, $p < 0.01$), galectin-3-NT-proBNP ($r1 = 0.38$, $p < 0.01$). Renal dysfunction was observed in both groups. The plasma concentration of cystatin C in the 1st group was 987.67 (854.68-1161.19) ng/ml, e-GFR - 58.5 ml/min/1.73m2 (44.0-79), there was not significantly different from 2nd group. The correlation analysis showed the following significant correlations: strong negative correlation in a pair of galectin-3-e-GFR ($r1 = -0.49$, $p < 0.01$) and positive between galectin-3 and cystatin C ($r1 = 0.62$, $p < 0.01$) in patients with CHF. Moreover, galectin-3 correlated with plasma level of hs-CRP ($r1 = 0.56$, $p < 0.01$), in the comparison group significant correlations were not observed.
Conclusions: The levels of biomarkers for fibrosis, inflammation and renal dysfunction in patients with prior MI and PCI were comparable in groups with HF with EF>40% and without HF. The plasma concentration of ST-2, galectin-3 correlated with the concentration of NTproBNP in HF patients. Galectin-3 also correlated with renal dysfunction and inflammation in HFpEF/HFmrEF patients with prior MI.

Lower platelet-to-lymphocyte and platelet-to-neutrophil ratios in ST-segment elevation myocardial infarction complicated with cardiogenic shock

A Scridon[1]; RC Serban[1]; L Hadadi[1]; I Sus[1]; EK Lakatos[1]; Z Demjen[2]; D Dobreanu[1]
[1]University of Medicine and Pharmacy of Tirgu Mures, Tirgu Mures, Romania; *[2]Institute of Cardiovascular Diseases, Targu Mures, Romania*

Funding Acknowledgements: This work was supported by the University of Medicine and Pharmacy of Tirgu Mures Research Grant number 17800/1/22.12.2015.

Background: Low platelet-to-neutrophil (PNR) and platelet-to-lymphocyte (PLR) ratios have been associated with worse prognosis in patients with coronary artery

disease. However, it remains unknown if they are also able to predict more severe status at presentation with ST-segment elevation myocardial infarction (STEMI).
Purpose: We aimed to investigate whether PNR and PLR are associated with the presence of cardiogenic shock (CS) on admission for STEMI.
Methods: We evaluated data from 428 consecutive patients admitted for STEMI. Total and differential leukocyte and platelet count were obtained for all patients at hospital admission, within 24-h after symptoms onset, and PNR and PLR were evaluated. Association of these markers with the presence of CS on admission was assessed.
Results: CS was present at admission in 4.90% of STEMI patients. Patients with CS had more frequently a history of myocardial infarction ($p < 0.01$), heart failure ($p < 0.01$), and chronic kidney disease ($p = 0.02$). CS on admission was associated with higher leukocyte ($p < 0.0001$), lymphocyte ($p = 0.02$), and neutrophil ($p = 0.001$) counts and lower platelet count ($p = 0.02$). PNR (17.03 ± 7.82 vs. 31.61 ± 14.13, $p < 0.0001$) and PLR (90.68 ± 62.83 vs. 157.06 ± 129.44, $p = 0.001$) were both significantly lower in patients presenting with CS. In multiple regression analysis, both lower PNR (r=-0.20, $p = 0.0001$) and PLR (r=-0.14, $p < 0.001$) remained independent predictors of CS.
Conclusions: In patients with STEMI, the presence of CS on admission was associated with significantly lower PNR and PLR values. The potential of these readily available blood markers to predict the severity of hemodynamic impairment at presentation with STEMI deserves to be further studied.

P1216
Correlation between blood levels of S100b protein and incidence of heart failure or IMA in a cardiology unit

S Sebastiano Quartuccio[1]; E Imbalzano[1]; E Di Salvo[1]; G Trapani[1]; G Lizio[1]; M Casciaro[1]; S Gangemi[1]
[1]*University of Messina, Department of Clinical and Experimental Medicine, University of Messina, Italy, Messina, Italy*

Background/Introduction: Chronic heart failure is one of the most common consequence of myocardial infarction, and is characterized by a reduction of the heart ability to face peripheral blood distribution. Chronic heart failure (HF) and myocardial infarction (IMA) are often associated to the augmentation of inflammation markers. S100B is an alarmin secreted by damaged cardiomyocites. Serum S100B levels were increased in the pathogenesis of heart disease and involved their pathogenetic mechanisms. S100B is a tissue-specific protein (chondrocytes, adipocytes, skeletal myofibers, cardiomyocytes, dendritic cells, etc.); it was largely demonstrated to be released after a damage and the consequent remodelling involving cardiac tissue.
Purpuse: We examined the correlation between S100B protein serum levels and the incidence of acute heart failure and IMA in symptomatic patients.
Methods: We conducted a prospective study on 90 patients aged between 50 and 72 years accepted to our Unit referring cardiac associated symptoms (thorax pain, dyspnea, arrhythmic symptoms). They were divided in three groups: healthy subjects (group A), chronic heart failure patients (group B) and IMA patients (group C). CRP, NT-proBNP, and routine exam were performed in every patient. Moreover it was made a S100B dosage was made.
Results: Results demonstrated different levels among healthy subjects. However in chronic heart failure patients the alarmin levels were higher but not significantly augmented. Instead AMI patients had mean values of S100B doubled than the other two groups and significantly augmented.
Conclusions: According to our data S100B as the potential to be, in a near future, be considered as an acute myocardial infaction marker in addiction to the ones existing. However more studies are needed to identify possible byas elements in S100B serum dosage. This together with other elements are guiding us to a better understand of micro-structural changes in damaged heart in order to consider new therapeutic targets.

Tab. Groups

	Group A	Group B	Group C
Patients	30	30	30
Nt-pro-BNP	45 + 23	800 + 150	230 + 67

P1217
The apelin relations with cardiac remodeling in the hypertension patients with type 2 diabetes

K Kostiantyn Yushko[1]; S Koval[1]; T Starchenko[1]
[1]*L.T.Malaya Institute of Therapy, NAMS of Ukraine, Kharkiv, Ukraine*

Purpose. The peptide apelin has antihypertensive and antidiabetic properties, but its role in the processes of cardiac remodeling in patients with hypertension and type 2 diabetes (T2D) isn't understood. The aim of the study was to investigate apelin levels in patients with hypertension and T2D and to determine its relations to heart structural parameters and types of cardiac remodeling.
Methods: We examined 63 hypertension patients grades 2-3 with concomitant T2D (33 men and 30 women), aged 43 to 70 years. The investigation complex included physical examination, standard transthoracic echocardiography and determination of apelin serum levels by ELISA. Types of cardiac remodeling we determined according to ESH/ESC 2013. Control group consisted of 16 volunteers.
Results: The apelin levels in patients with hypertension and T2D were significantly lower than in volunteers (0,882(0,788;0,924) ng/ml versus 1,097(0,944;1,171) ng/ml, $p < 0,001$). Negative correlation relations of apelin with septal wall thickness (r=-0,50, $p < 0,001$), posterior wall thickness (r=-0,46, $p < 0,001$), left ventricle (LV) mass (r=-0,39, $p < 0,01$), LV mass index (r=-0,42, $p < 0,001$) and left atrium size (r=-0,45, $p < 0,001$) have been observed. Among patients with hypertension and T2D concentric remodeling of LV was observed in 10 patients (16%), concentric LV hypertrophy was observed in 29 patients (49%) and eccentric LV hypertrophy was observed in 24 patients (38%). In patients with concentric remodeling of LV apelin levels were 0,918 (0,892; 0,984) ng/ml, with concentric LV hypertrophy – 0,855(0,722;0,899) ng/ml, with eccentric LV hypertrophy – 0,884(0,856;0,929) ng/ml ($p < 0,05$, $p < 0,001$, $p < 0,001$ versus control respectively). Patients with concentric LV hypertrophy had significantly lower apelin levels than patients with concentric remodeling of LV, $p < 0,05$.
Conclusion: In hypertension patients with T2D compared with healthy individuals the significant reduction of apelin blood levels has been found. Reduced blood levels of apelin are accompanied by the development of cardiac remodeling primarily concentric LV hypertrophy. Negative correlation of apelin with major heart structural parameters that characterize the LV remodeling and size of left atrium have been observed. The data allow us to consider apelin as an important prognostic marker of progression of hypertension with T2D, the development of pathological remodeling of the left ventricle and left atrium of the heart.

P1218
Can serum prolactin level determine the severity of acute decompensated heart failure?

M Chitsazan[1]; A Amin[1]; F Shioukhi[1]; M Chitsazan[2]
[1]*Rajaei Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Heart Failure and Trasnplantation, Tehran, Iran (Islamic Republic of)*;
[2]*Shahid Beheshti University of Medical Sciences, Tehran, Iran (Islamic Republic of)*

Background: Recent investigations have shown increased serum prolactin (PRL) level in chronic heart failure. However, data regarding PRL level and its prognostic implications in patients with acute decompensated systolic heart failure are lacking.
Purpose: The aim of this study was to evaluate the association between serum PRL level and functional, biochemical and echocardiographic indices of severity of heart failure in patients admitted with acute decompensated systolic heart failure.

Methods: All patients with advanced systolic heart failure [left ventricular ejection fraction (LVEF) of <30%) who were admitted for a recent acute decompensation were enrolled. The serum PRL level was measured on admission.
Results: A total of 86 patients (73% male), aged 48 ± 19 years with median LVEF of 15% (IQR, 10-20) were included. The median PRL level was 20.31 ng/mL (IQR, 14.77-33.53). The male and female patients had statistically similar PRL levels [18.80 ng/mL (14.38-28.90) versus 23.44 ng/mL (14.98-43.40)] (p = 0.21). The PRL levels were also statistically comparable among patients with NYHA function classes of II, III and IV (p = 0.07). No significant correlations were found between PRL level and LVEF (r=0.03, p = 0.75), NT-proBNP (r=0.07, p = 0.51), high-sensitivity C-reactive protein (r=-0.06, p = 0.67), erythrocyte sedimentation rate (r=0.05, p = 0.59), sodium (r=-0.04, p = 0.69), creatinine (r=0.04 , p = 0.66) uric acid (r=0.10, p = 0.39) and duration of hospitalization (r=-0.01, p = 0.89).
Conclusion: The serum PRL level does not seem to be an indicator of severity of acute decompensated systolic heart failure.

Theoretical and practical training of students from vocational public high school to care for cardiac arrest: a prospective study in a developing country

VF Vanessa De Freitas Marcolla[1]; ER Santos[1]; LP Moura[1]; IPB Aragao[1]; DC Albuquerque[2]; E Ferreira[2]; ILPB Aragao[3]; AA Aragao[1]; CBOC Naves[2]; EPS Porto Neto[1]; ECS Peixoto[1]; AL Viana[1]
[1]Governo do Estado do Rio de Janeiro, Rio de Janeiro, Brazil; *[2]Rio de Janeiro State University (UERJ), Rio de Janeiro, Brazil*; *[3]Severino Sombra University, Vassouras, Brazil*

Cardiovascular diseases are the leading cause of death in the world, sudden cardiac arrest is a major contributor to this index. Training reduces the ignorance and fear, increasing safety to recognize that the victim is not breathing properly, so as to trigger the help and start CPR as soon as possible.
Objective: To apply a theoretical-pratical trainning of vocational public high school, to work correctly, quickly and safely before a cardiopulmonary arrest, resuscitation maneuvers running efficiently, in order to save lives.
Methods: This study was designed as a prospective investigation in more than 1800 students of vocational public high school, between 2012 and 2015. The program of theoretical and practical training lasts 2 hours. Each student attends a lecture with video on the subject for 30 minutes after 30 minutes of classroom practice. Then, using practical training mannequin, which are assessed through a performance checklist. A questionnaire was distributed before the start of training to see if the student had prior knowledge about a rescue in the event of cardiac arrest.
Results: A half of this students did not have any knowledge about the subject. This evaluation showed that after 2 hours of training and analyzed the performance checklists: 84% knew how to perform the procedures call for help effectively, 27% were able to recognize the absence of breathing, 31% positioned themselves and began of chest compressions recommended form.
Conclusion: Students from that school are represented by 90% of adolescents when trained are able to act in the scene of a cardiac arrest, multiply the knowledge to family and community and save lives. However, according to the international recommendations of retraining as an ideal that does not exceed two years.

P1220
Oral health assessment and referral guidelines: an evidence-based practice change

SJ Jasmine Demos[1]
[1]Sinai Hospital, Heart Failure Center, Baltimore, United States of America

Background: The World Health Organization (WHO) and the Institute of Medicine (IOM) have identified oral health disease as a growing epidemic of systemic disease burden on individuals and a cost burden onto the health care system. Significant correlations exist between improved oral hygiene and the reduction of morbidity and mortality from cardiovascular disease. The poor dental health status of outpatient clinic patients continues to be an unaddressed clinical concern encountered by health care providers. Individual barriers to obtaining dental health care include cost and the inability to access preventative dental services.
Purpose: Identify the incidence of oral health disease in an outpatient clinic setting, utilize an evidence-based practice (EBP) solution, and implement an effective intervention to address this concern.
Methods: A convenience sample of 36 adult English speaking outpatient clinic patients at an urban hospital in Maryland were included in the 6 week pilot study. The mean age of the participants was 53.5, 41.66% Males (n = 15), and 58.33% Females (n = 21), of which 66.6% were African Americans (n = 24), and 33.3% were Caucasians (n = 12). The Brief Oral Health Status Examination (BOHSE) tool was utilized as a valid and reliable oral screening tool to identify poor dental conditions needing urgent dental referral. A 10 item Dental Health Knowledge Questionnaire (DHKQ) was completed by participants prior to and after receiving dental education, and results were obtained via a comparative trend analysis.
Results: All participants, (100%, [n=36]) identified with oral health disease, received dental health education and were referred for low cost dental intervention. Statistical analysis of the effectiveness of the EBP change was determined by a paired-samples t-test. The mean dental knowledge scores improved from a pre DHKQ score of 78.3 % to a mean post DHKQ score of 98.4%. A significant increase in participant dental health knowledge, (p = 0.001) from the pre DHKQ to the post DHKQ, was demonstrated. The EBP change initiative was successful, providing participants with significantly improved dental health knowledge, promoting nursing staff education in the use of the BOHSE tool, and implementing dental referrals for patients with oral health disease identified by the BOHSE tool.
Conclusions: Outpatient clinic patients presenting with loose teeth, dental decay, and/or periodontal disease can successively receive dental education with dental health referral for disease intervention. The Maryland Dental Health Smiles Program and other local programs offer low cost dentistry to individuals with low incomes. Dental health education is critical for patients to understand the oral health and systemic health connection. Oral health assessments with referral guidelines are needed in all cardiac clinical settings to promote individual self-care management behaviors, improve patient health outcomes, and decrease health care costs.

P1221
Factors associated with the thirst distress in patients with heart failure

NP Kato[1]; N Waldreus[2]; MH Van Der Wal[1]; K Kinugawa[3]; T Jaarsma[1]
[1]Linkoping University, Department of Social and Welfare Studies, Linkoping, Sweden; *[2]Karolinska Institute, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden*; *[3]University of Toyama, Department of Cardiology, Toyama, Japan*

Background: Thirst distress can decrease quality of life in patients with heart failure (HF). To develop effective interventions to improve thirst distress, more information is needed on factors that are associated with thirst distress.
Purpose: To determine risk factors associated with the thirst distress in HF patients.
Methods: A cross-sectional survey was performed in the Netherlands, Sweden and Japan in stable HF patients. Thirst distress was evaluated by the 8-item thirst distress scale for HF patients (TDS-HF) which is a reliable and valid scale with higher scores indicating more thirst distress (range, 8-40). Demographic and clinical data were collected from the medical chart. Doses of loop diuretics were normalized to approximately equivalent doses of furosemide. Patients were divided into the three groups: non-usage, lower dose (less than 40 mg) and higher dose (40 mg or more) of loop diuretics groups. To determine risk factors associated with the thirst distress, firstly univariate analysis was performed using spearman's correlation coefficient, Mann–Whitney U test and Kruskal Wallis test. Afterwards, a multiple logistic regression analysis (cut-off value, TDS-HF score ≥16) was conducted, in which we included variables associated with the TDS-HF scores at p < 0.20 in the univariate analysis.
Results: Data from 232 HF patients (age 72 ± 11, male 70%; 28% NYHA class III/IV; LVEF 39% ± 15) were analysed (n = 99 the Netherlands, n=69 Sweden, n=64 Japan). In total 63% of the patients had fluid restriction and 65% was prescribed loop diuretics. The median of the TDS-HF score was 14.0 (Q1-Q3, 9.0-20.8) and 45% of patients (n = 104) had mild to moderate thirst distress (TDS-HF score ≥16). There were no significant differences in the TDS-HF scores among the three countries [the Netherlands 15.0 (9-21), Sweden 12.0 (8-19.5) and Japan 15.0 (10-20), p = 0.49,]. In univariate analysis, age (p = 0.17), NYHA class, dose of loop diuretics and fluid restriction (all p < 0.05) were associated with the TDS-HF score. A multiple logistic regression analysis showed that lower age [odds ratio (OR) = 0.97, p = 0.03], having NYHA class III/IV (OR=2.35, p = 0.01), higher dose of loop diuretics (40 mg or more in furosemide equivalent dose OR=2.12, p = 0.03) and fluid restriction (OR=2.06, p = 0.02) were independent risk factors for mild to moderate thirst distress (TDS-HF score ≥16).
Conclusions: Patients with lower age, higher dose of loop diuretics, more severe HF and fluid restriction might be in need of additional support to relieve their thirst distress. Re-assessment of the need to have a fluid restriction and the dose of loop diuretics might help to relieve the thirst distress in patients with HF.

P1222
Evaluation of a nurse-led cross intervention program in heart failure.

C Ortiz[1]; M Diaz[2]; MA Delgado-Nicolas[3]; L Moran-Fernandez[1]; J De Juan-Baguda[1]; I Ponz[1]; A Rodriguez-Chaverri[1]; D Lora-Pablos[2]; MD Garcia-Cosio[1]; MD Garcia-Cosio[1]; J Delgado-Jimenez[1]

Funding Acknowledgements: Instituto de Salud Carlos III, Spanish Ministry of Economy and Competitiveness, through PI 10/00777 and the Red de Investigación Cardiovascular (RIC)

Background: Heart failure (HF) is one of the most important public health problems due to its associated morbidity, mortality and high health care cost, with more than two thirds of this cost attributed to medical expenditures. Several trials have evaluated the effect of disease management programs (DMPs) in HF, with diverse results. Although recent meta-analyses have shown a consistent reduction in hospital readmission, data concerning overall mortality reduction are inconclusive. Among DMPs, those based on multidisciplinary interventions have the highest evidence, while nurse-led interventions have insufficient evidence.
Objectives: The aim of this study was to develop a simple nurse-led clinic cross intervention program (health education and drug treatment optimization) for patients with heart failure and assess whether this intervention positively affects the prognosis of patients, their care costs (hospital readmissions) and perceived quality of life.
Methods and results: Between 2011 and 2013, 127 patients with reduced ejection fraction were prospectively randomly allocated (1:2) to standard care or intervention program. Primary composite endpoint was mortality and hospital readmissions from any cause. Secondary endpoints were mortality from any cause, hospital readmissions from any cause, readmissions for heart failure, time to first admission and quality of life improvements (assessed by Minnesota Living with Heart Failure Questionnaire). Mean age ± SD was 75 ± 12 years and 69% were males. An intention-to-treat analysis was performed and after 2-years median follow-up no differences were found in the primary composite endpoint (58% vs. 57%; p = 0.99). Likewise, there were no differences between groups in mortality from any cause or admissions from any cause (28% vs. 25%; p = 0.79 and 55% vs. 49%; p = 0.55 respectively). Time to first admission was similar in both groups (mean ± SD: 277 ± 235 days vs. 249 ± 224 days; p = 0.72). However, in the intervention group, admissions for heart failure were reduced (35% vs. 18%; p = 0.04) and quality of life related to health was higher (MLHFQ 23.46 vs. 19.8; p = 0.04).
Conclusions: Nurse-led cross intervention programs significantly improve perceived quality of life and reduce hospital admission for HF with no effect in all-cause mortality.

P1223

How does sacubitril/valsartan improve submaximal functional capacity measured through six-minute walk test?

M Mercedes Faraudo[1]; P Beltran[1]; R Freixa[1]; O Guri[1]; E Mena[1]; A Contra[1]; L Ceresuela[1]; J Masip[1]
[1]*Hospital de Sant Joan Despí-Moises Broggi, Haert Failure Unit, Sant Joan Despí, Spain*

Background: Sacubitril/Valsartan has been considered class I B in the recent 2016 ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure (HF) for stable HF patients with left ventricular ejection fraction (LVEF) < 35%, who remain symptomatic after the standard therapy, based on the results of the PARADIGM trial. This study showed a significant reduction in the risk of cardiovascular death and hospitalization for HF in patients treated with Sacubitril/Valsartan compared to those treated with enalapril. Although the study reported to improve the quality of life and NYHA functional class, it was not tested the functional capacity with any functional test. The 6-minute walk test (6MWT) is a validated test and an easy method to objectively measure patients' submaximal functional capacity because of its reproducibilty, simplicity, and cost-effectiveness.
Purpose: To analyse the impact of Sacubitril/Valsartan on functional capacity in patients with chronic HF.
Methods: Since October 2016, when the drug was marketed, all the patients referred to our HF-Unit who accomplished the 2016 HF ESC guidelines criteria for Sacubitril/Valsartan were included in the study. A 6MWT was performed before starting the treatment and after three months of having optimized the dose. Physiological parameters and blood analysis were also measured during up-titration and at these time points.
Results: 41 patients were screened and 23 of them entered in the study. These patients had the following characteristics: mean age 71, 91% were males, mean LVEF was 31%, isquemic etiology of HF 56%, mean maximal tolerated dose 98mg/day. The results of the 6MWT, physiological parameters and blood samples are presented in the Table 1.
Conclusion: Patients treated with Sacubitril/Valsartan improved their submaximal functional capacity at three months of treatment. Safety criteria such as hypotension or impaired renal function were not observed. More studies are needed to confirm our data.

Table 1

	Baseline	After 3 months	p
6MWTmean (m)	274	335	< 0.05
patients walking < 300 m	52 %	30 %	< 0.05

Health and community care utilization in patients hospitalized due to heart failure

E Emma Safstrom[1]; T Jaarsma[1]; A Stromberg[1]
[1]*Linkoping University, Linkoping, Sweden*

Funding Acknowledgements: Nyköping Hospital and Linköpings University

Introduction: Patients with heart failure (HF) are often elderly and fragile, suffering from multiple illnesses leading to polypharmacy, frailty and increased need of community and health care. There is a lack of knowledge on HF patients' community- and health care utilization prior and post hospitalization.
Purpose: To describe health and community care utilization before and after hospitalization in patients hospitalized due HF.
Methods: The study had a cross-sectional design. Patients who had been hospitalized due to de novo or deteriorating HF were consecutively included. Data were collected by structured telephone interviews and medical chart review one week after discharge and review of health care utilization 30 days after discharge.
Results: A total of 121 patients were included in the study (mean age 82.5 ± 6.8 years, 49% women 2.6 additional co-morbidities, length of hospital stay 5.7 ± 4.8 days). Review of health care utilization before the index hospital admission revealed that a majority of the patients had not visited any health care facility the month preceding the hospitalization and 13% of the patients had been hospitalized. A total of 40% of the patients received assistance from community care or home health care prior hospitalization and 52% after discharge. At discharge, 10% of the patients had no documented plan for follow up, 48% were referred to the primary care and 36% to the outpatient medical clinic. Health care utilization seems to be increasing after hospitalization; review of health care utilization 30 days post discharge revealed that 55% of the patients had visited a health care facility and 35% of the patients had been hospitalized or visited the ER without being admitted.
Conclusion: This "real world" study from a non-academic hospital revealed that most patients had not visited any health care facility the month prior to the index hospital admission. The number of patients who received assistance at home increased after hospitalization and patients were most often referred for follow up in primary care. Health care utilization increased significantly after hospitalization.

P1225

The value of nurse-based patient education in the success of multidisciplinary heart failure programs in developing countries

B Bassam Atallah[1]; M Khalil[2]; ZG Sadik[1]; R Ferrer[3]; J Stapleton[3]; L Tbishat[4]; F Bader[2]
[1]*Cleveland Clinic Abu Dhabi, Pharmacy Services, Abnu Dhabi, United Arab Emirates*; [2]*Cleveland Clinic Abu Dhabi, Cardiovascular Medicine, Abu Dhabi, United Arab Emirates*; [3]*Cleveland Clinic Abu Dhabi, Nursing, Abu Dhabi, United Arab Emirates*; [4]*Hamad Medical Corporation, Doha, Qatar*

Background: Heart failure (HF) readmissions are associated with significant morbidity and mortality burdens. Adequate heart failure education on adherence and self-care behaviors can reduce readmission rates and nurses are at the frontline of patient education. Such education is valuable when establishing heart failure programs in developing countries, in light of the challenging socio-economic differences compared to the developed world. Purpose: This study aimed (a) to evaluate the level of heart failure knowledge that nurses have at a cardiac center; (b) to assess patients' baseline knowledge; and (c) to evaluate the effectiveness of structured nurse- driven education on knowledge acquired by patients.
Methods: A total of 131 cardiac center-based nurses and 30 chronic HF patients participated in the nurse and patient surveys, respectively. Patients were also surveyed a second time 3 to 6 months later, while being followed at an advanced heart failure clinic. Results: The majority of the nurses (80%) had not received heart failure

education previously and they did not know the NYHA functional classification (86%) even though they were able to recognize most of the heart failure symptoms (table 1). As for participating patients, significant improvement in knowledge has been noted between the initial and follow-up surveys (table 2). Conclusion: When establishing advanced heart failure programs caring for patients with mostly low levels of education, nurse-led educational efforts can still result in significant improvement on disease awareness and self-care behaviors. The success of such efforts and thus reducing readmissions can be enhanced through improving nursing knowledge beyond HF clinics.

Table 1

Symptom	Number (%)
Shortness of breath	129 (98)
Light Headedness	27 (21)
Leg swelling	115 (88)
Abdominal Swelling	61 (47)
Weight gain	112 (85)
Weakness, fatigue	116 (89)
Chest pain	71 (54)
Poor appetite	51 (39)
Poor sleep	82 (63)
Inability to lie flat	119 (91)

Knowledge of different HF symptoms by cardiac center nurses participating in the survey (total of 131).

Table 2: Responses of patients on the initial and follow up surveys to questions on adherence and self-care

Question	Choices	Initial	Follow up
How much salt should you approximately take per day?	2 grams or less	9	27
	5 grams	2	1
	Any amount of salt	3	0
	Don't Know	16	2
How many liters of fluid you can consume per day?	Up to 2 Liters or 2000ml	12	25
	2to 3 Liters (2000-3000ml)	3	3
	More than 3 Liters(3000ml)	0	1
	Don't Know	15	1
How often do you check your weight?	Every day early morning after passing urine and before breakfast	9	20
	Several times per week	0	3
	Once every week	4	5
	Whenever they find weighing scale	0	0
	Never	17	2
If your weight increases by 2 Kg or more over 2 days, what should you do?	Take extra water pill	6	5
	Call the heart failure nurse within 24 hours	4	23
	Wait until the next visit to tell the doctor	5	1
	Don't Know	15	1
Do you know who to contact if your heart failure symptoms (e.g. shortness of breath, weight gain, chest pain, palpitations) worsen?	Physician	15	12

P1226

Effective interventions to improve self-care in patients with heart failure

L Klompstra[1]; N Sedlar[2]; A Stromberg[3]; J Martensson[4]; M Lainscak[5]; J Farkas[5]; T Jaarsma[1]
[1]Linkoping University, Department of Social and Welfare studies, Linkoping, Sweden; [2]National Institute of Public Health, Ljubljana, Slovenia; [3]Linkoping University, Department of Medical and Health Science, Linkoping, Sweden; [4]Jonkoping University, School of Health and Welfare, Jonkoping, Sweden; [5]General Hospital Murska Sobota, Department of Cardiology, Murska Sobota, Slovenia

Background: Effective heart failure (HF) self-care is important for maintaining health and to prevent HF exacerbation. An increasing number of intervention studies to improve self-care are published and we aimed to systematically summarize outcomes of studies that measured self-care using the European Heart Failure Self-care Behaviour Scale (EHFScBS)

Methods: A literature search was undertaken between June 2003 (when the EHFScBS was first published) and November 2015 in the databases PubMed, Scopus and ScienceDirect, using search terms: ("self-care" OR "self-care behaviour" OR "self-care behavior" OR "European Heart Failure Self-care Behaviour Scale" OR EHFScBS OR "EHFScBS-9") AND ("chronic heart failure" OR "heart failure"). Articles were excluded if they were not focused on interventions increasing self-care or were not RCT studies. 2154 articles were initially found, 14 were included in the analysis.

Results: Of the 14 studies included, 7 interventions found a significant ($p < 0.05$) increase in the self-care in the intervention group compared to the control group. The average number of patients included in the studies was 225 (range 82-602) and the follow-up period ranged between 3 and 12 months. Of the 7 interventions with positive effects on self-care, 2 studies were telemonitoring interventions, 3 studies were nurse-led educational intervention and 2 studies were multidisciplinary educational interventions. One telemonitoring intervention included a system monitoring symptoms, knowledge and behaviour and the second study included monitoring of weight, diuretic medication and well-being. The nurse-led and multidisciplinary educational interventions included education, multiple home visits and telephone follow-up. The seven studies that were not effective to increase self-care were four nurse-led/multidisciplinary educational interventions, one pharmacist educational program, one educational program for general practitioners and one telemonitoring study.

Conclusion: There are several interventions that have shown to be effective to increase self-care in patients with HF, such as telemonitoring, nurse-led or multidisciplinary-led educational programs. However, at the same time there is a considerable amount of interventions, including the same components as the effective interventions, which did not work to increase self-care. Future research is needed to assess the difference in factors known to influence self-care between the effective and non-effective interventions, such as experience with the illness, physical functioning, depression and anxiety, social support, daytime sleepiness, and attitudes. Research is also needed to assess the effectiveness of interventions with follow-up longer than 12 months. Because the EHFScBS can pick up the benefits of different interventions, the scale can be used the for intervention effect assessment.

P1227

An end of year review of patients with left ventricular systolic dysfunction secondary to cardiotoxic cancer therapy in a cardiac tertiary centre

VJ Chambers[1]; H Pryse-Hawkins[1]; L Fallon[1]; RK Sharma[1]; SD Rosen[1]; AR Lyon[1]
[1]Royal Brompton Hospital , London, United Kingdom

Our Cardio-Oncology clinic provides cardiology management plans for patients with cardiac complications of cancer therapy and for patients with pre-existing cardiac conditions who receive cardiotoxic therapy. We present data regarding the patients diagnosed with left ventricular systolic dysfunction (LVSD) in whom the LV ejection fraction on echocardiogram is $< 55\%$.

Aim: To consider whether care provided by a Heart Failure Clinical Nurse Specialist (HFCNS) can be applied to patients with LVSD secondary to cardiotoxic cancer therapy.

Method: The HFCNS discusses symptom recognition, self-care and medication purpose and side effects with the patient in the clinic. An opportunity is provided to answer further questions and also contact numbers for the HFCNS are provided in case of symptom occurrence or problems with medications. Subsequent HFCNS review with up titration of heart failure medication in between cardiology appointments is arranged with the patient attending an in person consultation or a telephone consultation. In addition the HFCNS liaised with the oncology CNS or the patient's primary care physician.

Results: In 2016 169 new patients were referred and reviewed as new patients. Twenty-eight were diagnosed with LVSD. From this group of patients 22 (78%) received cardiotoxic cancer treatments for current disease. Table 1 demonstrates the cardiotoxic agents that this group of patients received, the way in which the patients were reviewed by the HFCNS and the cardiac medication prescribed. After their first consultation in the clinic 100% of patients continued with their oncology treatments as documented in table 1.

Conclusion: The role of the HFCNS is an established part of the heart failure team; however there is very limited literature on the role of HFCNS care for Cardio-Oncology patients. This is an evolving service and we hope that we have demonstrated that established heart failure nursing care can be applied to this group of patients with successful results as demonstrated by improved medication compliance, concordance and titration. The HFCNS, through effective collaboration with appropriate local services, may contribute to the optimal and holistic management of this care group.

P1228

B-type natriuretic peptide as a tool to increase the diagnostic accuracy of nursing in congestive heart failure patients

MELINA Trojahn[1]; SLS Barilli[1]; GB Aliti[1]; DS Bernardes[2]; LL Pedraza[3]; E Rabelo-Silva[1]

[1]Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Program at the Nursing School, , Porto Alegre, Brazil; *[2]Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil*; *[3]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

Background: Systemic congestion is the main factor related to decompensation of patients with heart failure (HF). The main clinical manifestations resulting from congestion are dyspnea, orthopnea, tiredness, distension of jugular vein, and edema. These signs and symptoms, are part of the diagnosis of Excess Fluid Volume (EFV) often established in congested patients. In the context of clinical congestion in patients with HF, the B-type Natriuretic Peptide (BNP) is a reliable tool for the diagnosis of dyspnea, becoming also an important clinical indicator to EFV ND. This study was planned in order to improve the accuracy of this nursing diagnosis.
Purpose: To clinically validate the blood marker BNP as a tool to diagnose EFV in patients congested with HF.
Methods: Cohort study conducted in the emergence of a public university hospital, of a Southern Brazilian University Hospital. We included patients with HF diagnosis, reduced or preserved systolic function, who were hospitalized by acute decompensation. The collection was systematized through a clinical evaluation at admission and discharge, containing the signs and symptoms already clinically validated for this diagnosis in patients with HF. Blood samples were also collected for BNP measurements.
Results: 64 patients were included, with mean age of 69 ± 13 years, and fraction ejection of the left ventricular of 50 ± 16%. The frequency of signs and symptoms of the EFV ND on admission (11,32 ± 2,8) and discharge (7,5 ± 3,2) were statistically significant $p < 0{,}001$. The median of the BNP values were reduced significantly:381(202-707) pg/ml in admission and 309(180-640) pg/ml in discharge, $p < 0{,}001$.
Conclusion: The results indicated a reduction in the congestive state observed by the decrease of frequency of the signs and symptoms of the EFV as well as in BNP values. These findings indicate that this blood marker can be used as a clinical indicator in congested patients, improving diagnostic accuracy.

Mortality in ischemic heart failure patients with moderately reduced ejection fraction - A nationwide multicentre retrospective study.

F Fernando Montenegro Sa[1]; C Ruivo[1]; L Graca Santos[1]; A Antunes[1]; F Campos Soares[1]; J Morais[1]
[1]*Hospital Santo Andre, Cardiology, Leiria, Portugal*

On behalf of: National Acute Coronary Syndrome Registry Investigators

Introduction: Moderately reduced ejection fraction (mrEF) patients were recently defined by the European Society of Cardiology as a new subgroup of left ventricle systolic dysfunction to stimulate research on its particular characteristics and prognosis.
Aim: To compare, in post-acute coronary syndrome (ACS) patients, the in-hospital mortality (IHM) according to the ejection fraction (EF) and to identify, in mrEF patients, IMH predictors.
Population and methods: The authors analyzed a cohort of a multicentre national registry between 1/10/2010 and 30/09/2016. Patients with previously known heart failure or with no echocardiography EF evaluation were excluded. 9429 patients were included and classified in (1)EF>50%, (n = 6113, 65%), (2)EF 40-49% (n = 1922, 20%) and (3)EF < 40% (n = 1390, 15%). To determine IMH predictors for group 2, multivariate logistic regression was performed, including pre-hospital, clinical and laboratorial data, ACS classification, coronary anatomy when known and pharmacological treatment.
Results: Overall mortality was 2.8% (n = 263): 0.9% (n = 53) in group1, 2.4% (n = 37) in group2 and 11.4% (n = 159) in group3. IMH predictors are described in the enclosed table. Previous medication with aspirin, in-hospital beta blockers administration and coronariography had a positive impact in prognosis. The presented statistical model has a >80% sensitivity and specificity for event prediction in this population.
Conclusion: Patients with mrEF after an ACS are an intermediate risk group. The identified mortality predictors define a subgroup of patients with a higher risk, that similarly to reduced EF patients benefit the most of optimized therapeutic measures.

Table - In hospital mortality predictors

	OR	CI95%	P-value
Age>73 years	9.69	2.78-33.81	< .001

ExTraHF survey. The european survey on implementation of exercise training in heart failure patients: regional differences.

A Verde[1]; SM Binno[1]; U Corra'[2]; P Seferovic[3]; GQ Villani[1]; T Jaarsma[4]; G Filippatos[5]; PP Ponikowski[6]; MF Piepoli[1]
[1]*Guglielmo da Saliceto Hospital, Heart Failure Unit, Department of Cardiology, Piacenza, Italy*; [2]*Fondazione Maugeri, Department of Cardiology, IRCCS Scientific Institute of Veruno, Veruno, Italy*; [3]*University Belgrade Medical School, Department of Cardiology, Clinical Center of Serbia, Belgrade, Serbia*; [4]*Linkoping University, Department of Social and Welfare Studies, Linkoping, Sweden*; [5]*Attikon University Hospital, Heart Failure Unit at the Department of Cardiology, Athens, Greece*; [6]*Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland*

On behalf of: Committee on Exercise Physiology & Training of the Heart Failure Association and endorsed by the Cardiac Rehabilitation Section of the ESC

Background. In heart failure (HF), exercise training programmes [ETP] are well-recognised intervention to improve symptoms, but still poorly implemented. The Heart Failure Association promoted a survey to investigate whether and how cardiac centres in Europe are using ETP in their HF patients.
Methods: A 12-item web-based questionnaire was distributed using the coordinators of the HF working groups of the Countries affiliated to the ESC who distributed and promoted the survey in the key cardiac centres. Forty-one country coordinators out of 46 contacted replied to our questionnaire (89%). This accounted for 170 Cardiac Centres, in charge of 77,214 HF patients.
Results: The majority of the participating centres (82%) were general cardiology units and the rest were specialised rehabilitation units or local health centres. Sixty-seven (40%) centres (in charge of 36,385 [48%] patients) did not implement ETP. This was mainly attributed to the lack of resources (25%), largely due to lack of staff or of financial coverage. The lack of national or local pathway for such programme was the reason in 13% of the cases and in 12% the perceived lacks of evidence on safety or benefit were advocated. When implemented, in only 55% of the centres it was proposed to all HF patients, with restriction according to severity, or aetiology.
In the regional sub analysis: a larger implementation of ETP was observed in cardiac centres located in the North and Central Europe (69% and 67%) vs South and East Europe (59% and 45%) (P=0.5%)
No differences were observed between University, General or Community Hospitals (59%, vs 57%, vs 60%) (p = NS)
Conclusions: With respect to previous surveys, there is evidence of increased supply of exercise training programmes in HF in Europe, although still too many patients are denied a highly recommended therapy, mainly due to lack of resources or logistics, mainly in the South and East European Regions.

P1232

Clinical characteristics and in-hospital outcomes of HF with mid-range versus preserved and reduced ejection fraction: a subgroup analysis from Journey HF-TR study

M Zoghi[1]; U Y Umit Yasar Sinan[2]; DC Gurbuz[3]; O Celik[4]; HA Cakmak[5]; S Kilic[6]; S Inci[7]; G Gok[8]; MS Kucukoglu[2]

On behalf of: Journey HF-TR Study

Background: We aimed to investigate the clinical characteristic, concomitant conditions, and in hospital mortality of patients with HFmrEF in Turkish population.
Method: The patients who were hospitalized with the diagnosis of acute heart failure were compared based on new EF-related classification: HFrEF (EF < 40%), HFmrEF (EF 40-49%) and HFpEF (EF ≥50%).
Results: The 1606 patients (male: 57.2% mean age, 67.8 ± 13 years old) in 37 centers of Turkey were enrolled in this study. The age was similar between HFmrEF and HFpEF patients (p = 0.805). However, the patients with HFmrEF were older (p = 0.05) and a greater proportion were male compared to patients with HFrEF (p = < 0.001). The De novo clinical presentation was lowest in patients with low EF but similar between HFmrEF and HFpEF groups. The prevalence of anemia and hypertension were higher in HFmrEF and HFpEF groups than HFrEF group (p < 0.001 and 0.001 respectively). However, they were similar between HFmrEF and HFpEF groups. On the contrary, the CAD was more prevalent in HFrEF group than in HFpEF and HFmrEF groups (p < 0.001), but it was similar between HFpEF and HFmrEF groups. The mean length of stay was significantly longer (p < 0.001 and in-hospital mortality was lower (p = 0.01) in HFmrEF patients than the other study groups.
Conclusion: Not only the clinical characteristics but also in hospital clinical outcomes are different in patients with HFmrEF when compared with patients with low or preserved EF.

P1233

Heart failure in intravenous drug users with infective endocarditis: etiology, clinical characteristics and outcomes

T S Getiya[1]; AS Pisaruk[2]; PV Lazarev[2]; EO Kotova[2]; I Merai[2]; GK Kiyakbaev[2]; VS Moiseev[2]
[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation; *[2]RUDN University, Moscow, Russian Federation*

Intravenous drug (IVD) use is a known risk factor for infective endocarditis (IE). The prevalence, clinical characteristics and prognostic implications of heart failure (HF) in IVD users with IE are not well studied.

Purpose: To study risk factors, clinical features and outcomes of HF in IVD users with IE.

Material and methods: The study included 53 IVD users hospitalised with IE (Duke criteria 2015). The numbers of patients with right-sided, left-sided and both-sided IE were 32 (60.4%), 15 (28.3%) and 6 (11.3%), respectively. HCV infection was present in 49 (92.5%) participants.

Patients: were divided into 2 groups: 29 patients with HF [group 1; median age 33.0 (28.5-40.0) years, 21 (72.4%) male] and 24 patients without HF [group 2; median age 33.5 (30.0-35.8) years, 21 (66.7%) male]. All patients underwent transthoracic and transesophageal echocardiography and laboratory investigation with measurement of NT-proBNP and markers of inflammation. Mortality and complication rates were calculated after 1-year follow-up.

Results: History of previous IE was more common in HF patients [8 (27.6%) vs. 4 (16.7%), p = 0,51]. They more often had dyspnea [28 (96.6%) vs. 14 (58.3%), p < 0.05] and edema [12 (41.1%) vs. 2 (8.3%), p < 0.05] than patients without HF. Patients in group 1 also had a higher frequency of hepatomegaly [27 (93.1%) vs. 18 (75.0%), p = 0.12] and splenomegaly [22 (75.9%) vs. 13 (54.2%), p = 0.15]. Systolic BP on admission was significantly lower in group 1 [105.0 (100.0-110.0) vs. 110.0 (100.0-120.0) mmHg, p < 0.05]. Glomerular filtration rate (CKD-EPI) was similar – 79.6 (55.5-106.4) ml/min/1.73 m^2 in group 1 and 86.0 (53.2-117.8) ml/min/1.73 m^2 in group 2 (p = 0.526). WBC and Hb values were comparable in both groups (p>0.05). However, platelet count was lower in HF patients [171.0 (61.5-199.5) vs. 228.0 (191.0-364.0) 10^9/l, p < 0.05]. Median NT-proBNP values were 1706.5 (280.3-4302.0) ng/ml in group 1 and 379.0 (58.0-998.8) ng/ml in patients without HF (p = 0.166). NT-proBNP positively correlated with inflammatory markers [CRP (rho=0.69), p = 0,05; rheumatoid factor (rho=0.75), p = 0.04]. Pulmonary artery systolic pressure was higher in group 1 [32.0 (23.0-50.5) vs. 25.0 (19.5-36.8) mmHg, p = 0.08], although left ventricle EF values were similar [58.0 (54.5-63.0) % in group 1 vs. 60.0 (58.0-62.0) % in group 2, p = 0.37]. IE caused by Staphylococcus spp. was diagnosed in 19 (65.5%) patients in group 1 and in 16 (66.7%) patients in group 2 (p>0.99), while the rate of S. aureus etiology was higher in HF group [19 (65.5%) vs. 10 (41.7%), p = 0.10]. The presence of HF conferred a higher risk of thromboembolic events [21 (72.4%) vs. 11 (47.8%), p = 0.09] and mortality [6 (20.7%) vs. 1 (4.2%), p = 0.11].

Conclusion: IE in patients with a history of IVD use is often complicated by HF that is associated with a higher rate of thromboembolism and 1-year total mortality. Risk factors for HF development could include S. aureus infection and higher degree of inflammation.

P1234

Younger heart failure population with higher in-hospital mortality

U Y Umit Yasar Sinan[1]; A Ekmekci[2]; B Ozbay[3]; F Akcay Ayyildiz[4]; L Bekar[5]; Y Koza[6]; I Bolat[7]; U Kocabas[8]; M Zoghi[3]

On behalf of: Journey-HF Study Group

Background: In this study, we aimed to evaluate the overall clinical characteristics, management and in-hospital outcomes of hospitalized patients with AHF in a large sample of Turkish population.

Methods: The Journey HF-TR study is a cross-sectional, multicenter, non-invasive and observational trial that was conducted in intensive/coronary care units and cardiology wards. The patients who were hospitalized with the diagnosis of acute heart failure in intensive/coronary care units between September 2015 and 2016 were included in our study.

Results: The 1606 patients (male: 57.2% mean age, 67.8 ± 13 years old) who were diagnosed with AHF (NYHA III-IV:75.2%) in 37 centers, in seven geographical regions of Turkey were enrolled in this study. Seventeen percent of patients were admitted to hospital with diagnosis of new onset AHF. Hypertension (67%) and coronary artery disease (59.6%) were the most frequent underlying diseases. Acute coronary syndrome accompanying to heart failure (14.7%), infection (29.3%), arrhythmia (25.1%), cardio-renal syndrome (23%) and non-compliance with medication (23.8%) were the precipitating factors. Biomarkers were used in 41% of patients at admission for diagnosis. The mean EF was 32.7 ± 14.1%. The median length of stay (LOS) in ICU was 3 days (IQR 1-72) and was 7 days (IQR 0-72) for in hospital's journey. The guideline recommended medications were less likely used (< 73%) before admission and were similar to European and US registers at discharge. In-hospital mortality rate was 7.6%.

Conclusions: Although our study population was younger than other registers, in-hospital mortality was high. Hypertension and coronary artery disease were the most frequent underlying diseases.

Imparting information to the HF patient; lessons learned from the cardiovascular ward round

G Gemma Reddin[1]; G O Carroll[1]; N Baroni[1]; C Keane[1]; K Mc Donald[1]
[1]St Vincent's University Hospital, Dublin, Ireland

Introduction: Inpatient ward rounds are an invaluable part of the hospital day allowing for daily assessment of each patient, evaluating treatment and basing clinical decisions on this information. Perhaps the most crucial role of the ward round is information transfer, which is particularly important in the management of chronic diseases such as heart failure, where poor lifestyle and treatment adherence directly impacts health outcomes. With the ward round being an important vehicle to transmit information to the patient, it is interesting that little objective analysis of the ward round has been undertaking.

Purpose: This study aimed to investigate inpatient's perception of the cardiology ward round, in order to identify strengths and weaknesses and in particular to assess how effective the ward round is in delivering information to the patient.

Methods: Initially, open interviews with in-patients were conducted to explore areas of concern and satisfaction surrounding the round. Repeated themes were identified and used to develop a relevant questionnaire which analysed four pertinent aspects of the ward round: Information-Giving & Communication, Emotional Reaction, Professionalism and Privacy.

Results: 98 cardiology inpatients completed the questionnaire. Patients had been admitted through the ER for a variety of cardiovascular emergencies including acute decompensated heart failure, ACS and arrhythmia. Professionalism and privacy were the highest scoring categories, with an average positive response rate of 79% and 81% respectively. Emotional reaction towards the ward round scored an average positive response rate of 69%. A considerable weakness was revealed under the category information giving and communication; the average positive response rate was only 60%. This low score was attributed to the use of medical jargon, apparent time constraints and patients perceived in-opportunity to ask questions; almost half of patients found the language used by staff difficult to understand, 58% felt that the ward round was rushed and 30% of patients felt they

did not have the opportunity to ask questions.
Conclusion: The presented data underlines a significant deficiency in knowledge transfer to the patient during the ward round. While other aspects of the round score scored satisfactorily, the noted deficiency in communication could potentially have a detrimental impact on post discharge morbidity especially in heart failure where understanding and treatment adherence is critical to effective self-care. Improving information-giving and communication is vital to establishing the ward round as a practice of significant importance in the hospital day in order to deliver superior, safe patient-centered care.

P1236

Depression and all-cause mortality in patients with congestive heart failure with implanted cardiac devices

GS Pushkarev[1]; VA Kuznetsov[1]; AM Soldatova[1]; TN Enina[1]; YA Fisher[1]
[1]Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Russian Academy of Scienc, Tomsk, Russian Federation

Background: It is well known that depression is associated with high risk of cardiovascular mortality and morbidity. However the impact of depression on mortality in patients with implanted cardiac devices has not been fully evaluated. The purpose was to assess the association between depression and all-cause mortality in patients with congestive heart failure (CHF) and implanted cardiac devices.
Methods: The study enrolled 253 patients (mean age 56.8 ± 10.1 years, 83% men) with CHF and implanted cardiac devices (149 patients with implanted cardiac devices for resynchronisation therapy, 104 patients - with implantable cardioverter defibrillators). Mean duration of follow-up was 49.5 ± 31.7 months. The Beck Depression Inventory (BDI) was used to measure depressive symptoms. Depression was considered absent for a score between 0 and 9, mild to moderate between 10 and 18, significant – if more 19. Cox proportional hazards regression model was used to estimate hazard ratios (HR) with 95% confidence interval (95% CI) for impact of depression on all-cause mortality. HR was calculated after adjustment for the following confounders: age, gender, smoking status, hypertension, diabetes mellitus, body mass index, hypercholesterolemia, left ventricular ejection fraction, number of hemodynamically significant lesions of the coronary arteries and the type of the implanted cardiac devices.
Results: During follow-up period 37 patients died (11.4%). Adjusted HR for all-cause mortality on depression score was 1.04, 95% CI 1.01 – 1.08. Patients without depression were accepted as a reference group with HR=1.0 for analysis of categorical indicator. HR was 1.07, 95% CI 0.46 – 2.50 in patients with mild depressive symptoms and 2.72, 95% CI 1.14 – 6.47 in patients with significant depressive symptoms.
Conclusion: Increased depressive symptoms are associated with all-cause mortality in patients with CHF and implanted cardiac devices.

P1237

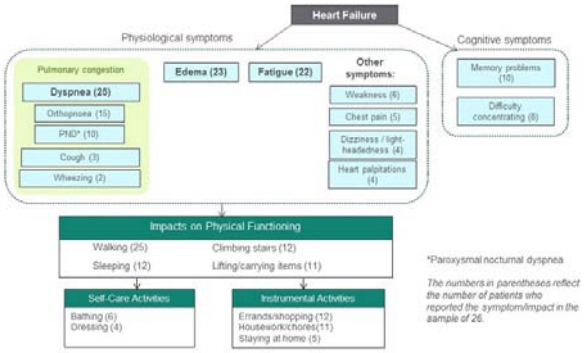
Understanding the symptoms and impacts of acute and stable heart failure patients: results from a concept elicitation study

K Benjamin[1]; O Moshkovich[1]; K Hall[1]; R Murphy[1]; B Boris Gorsh[2]; V Sikirica[2]; D Sprecher[3]; R Saini[3]; R Von Maltzahn[2]
[1]ICON Commercialisation & Outcomes, Clinical Outcomes Assessments, Dublin, Ireland; *[2]GlaxoSmithKline, Value Evidence and Outcomes, Collegeville, United States of America*; *[3]GlaxoSmithKline, Collegeville, United States of America*

Funding Acknowledgements: GlaxoSmithKline

Purpose: To qualitatively elicit the important symptoms and impacts of HF directly from patients recently discharged after a hospitalization for acute decompensating heart failure (ADHF) and patients with HF without a recent ADHF hospitalization ("stable" patients). Elicitation was used to inform development or adaptation of a patient reported outcome (PRO) measure.
Methods: HF patients were recruited across three US clinical sites and patients provided informed consent. Acute patients had been discharged from an ADHF hospitalization≤ 45 days prior to enrolment; stable patients had no ADHF hospitalization in the past 6 months and no unplanned medical encounter due to HF in the past 3 months but had at least 2 HF encounters in the past 2 years. One-on-one telephone or in-person interviews were conducted to obtain patient perspectives on their HF experience. Interviews focused on the symptoms of chronic HF and ADHF, and how these symptoms affected patients' lives and functioning using a semi-structured open-ended interview guide. Interviews were recorded and transcribed for analysis. Data were analyzed in MaxQDA, a qualitative research software program.
Results: Twenty-six patients with HF participated, including 18 stable and 8 acute patients. The sample included patients from all NYHA classes, with most in Class II (46%) or Class III (34%). The majority were male (65%), mean age was 67 years (range 41-91), and 61% were non-Hispanic White. The majority of patients reported shortness of breath (SOB) (n = 25, 96%), fatigue (n = 22, 85%), and edema (n = 23, 88%) across both groups. Cognitive changes (memory problems / difficulty concentrating) were reported by 14 patients (54%).Other symptoms were less common (reported by≤ 6 patients). A subset of acute (n = 8) and stable (n = 6) patients, provided a description of their last acute HF episode. Of this subset, SOB was the symptom most frequently leading to hospitalization (n = 10, 71%). Patients reported impacts in physical functioning, including walking, climbing stairs, sleeping, and carrying items. These impacts were associated with difficulties with daily activities, including bathing, dressing, housework, running errands, and social outings. Patients reported curtailing recreational activities and fitness, and several stopped driving. Impacts to emotional well-being included frustration, worry about the future, depression, irritability, fear, and anxiety. Despite distinct subgroups, few differences in symptoms and impacts were identified across stable and ADHF patients. No new symptoms or symptom impacts were reported by the 18th interview, confirming concept saturation. A conceptual model of HF symptoms and impacts for the potential development or adaptation of a PRO measure is summarized in Figure 1.
Conclusion: Across a broad group of HF patients, three symptoms were consistently reported: SOB, fatigue, and edema. The conceptual model presented can serve as a starting point for further PRO development.

Figure 1. Conceptual Model of HF Symptom and Symptom Impacts



P1238

Influence of heart failure into quality of life of patients with heart rhythm disorders

R Mlynarski[1]; A Mlynarska[2]; KS Golba[2]
[1]Upper-Silesian Cardiology Center, Katowice, Poland; *[2]Medical University of Silesia, Katowice, Poland*

Influence of heart failure into quality of life was described many times, however no complex analysis in subpopulation of patients with serious heart rhythm disorders qualified for pacemaker implantation were performed.
Methods: 107 patients aged 70,72 ± 11,35 (47 women) with advanced heart rhythm disorders qualified for pacemaker implantation (ESC criteria) were included into the trial. Two subpopulations according symptoms of heart failure and ejection fraction were created: without heart failure (nHF) and with heart failure (HF). Ejection fraction was evaluated by echocardiography. In all quality of life was evaluated by using Minnesota Living with Heart Failure Questionnaire which describes self-assessment of how heart failure affects daily life. Analysis was performed in a two subgroups: related to the physical symptoms (physical domain) and related to the psychological distress (emotional domain). Fewer points mean better quality of life.
Results: General quality of life was statistically (p = 0,0255) lower in the group of heart failure (45,00 ± 10,68) if compare to these without heart failure group (40,48 ± 8,84). Similar relationship, however without significance, were noted in the physical group of quality of life: 20,47 ± 5,43 (HF) vs. 18,92 ± 4,22 (nHF); p = 0,1147, as well as emotional group 10,53 ± 4,43 (HF) vs. 8,86 ± 4,22 (nHF); p = 0,0686. Gender-dependent analysis did not show statistical differences – general quality of life in women (43,70 ± 9,47 (HF) vs. 39,48 ± 8,79 (nHF); p = 0,1926 and in men 45,59 ± 11,35 (HF) vs. 41,45 ± 3,97 (nHF); p = 0,1237. Quality of life domains-related exact results are presented in the table below.
Conclusion: Presence of heart failure worsen the quality of life patients with heart rhythm disorders qualified for pacemaker implantation.

	Women	Men				
	HF	nHF	p	HF	nHF	p
Physical domain	19,40±6,08	18,32±4,01	0,5056	20,95±5,19	19,50±4,39	0,3797
Emotional domain	11,60±4,45	8,81±4,33	0,0791	10,04±4,45	8,92±4,17	0,3297

HF - heart failure (HF); nHF - without heart failure

EXERCICE TESTING AND TRAINING

P1239

Monitoring changes of end-tidal pressure of carbon dioxide in patients with chronic heart failure and chronic obstructive pulmonary disease during six minute walk test

KA Kira Ageeva[1]; VN Abrosimov[1]; IB Ponomareva[1]; NN Peregudova[1]
[1]*Ryazan State Academician Medical University, Therapy Department, Ryazan, Russian Federation*

Background: Exercise tests are used to determine exercise tolerance in patients with chronic heart failure (CHF) and in patients with chronic obstructive pulmonary disease (COPD). Breathlessness of is one of the most common reason patients who stopped during 6-minute walk test (6MWT). Dyspnea is combined with changes of pulmonary ventilation and gas exchange of CO2. Significance of end-tidal CO2 (PETCO2) is a constant, which shows the activity of respiratory system.
Methods: We studied 52 patients with CHF in New York Heart Association (NYHA), age 58 ± 3,24 years (25 patients (48,1%) in NYHA class II, 22 patients (4,3%) in NYHA class III, 5 patients (9,6%) in NYHA class IV). Also we studied 42 patients with COPD II-III, age 60 ± 3,48 years (1st group - 22 patients (52,4%) with COPD II, 2nd group – 20 patients (47,6%) with COPD III). Control group 30 patients, age 48 ± 3,42 years. Standard 6MWT was performed. Dyspnea was evaluated on a scale of Borg , MRS and VAS. We recorded capnogram before, during, after the 6MWT and in the recovery period.
Results: Significance of PETCO2 in patients with CHF in NYHA class II was 38,2 ± 2,13 mm Hg, in patients in NYHA class III was 34,4 ± 2,22 mm Hg, in patients in NYHA class IV was 32,4 ± 1,14 mm mm Hg. Significance of PETCO2 in 1st group patients with COPD was 36,2 ± 2,43 mm Hg, in 2nd group patients was 34,1 ± 1,22 mm Hg. All patients performed 6MWT. The 6MWT distance in patients with CHF in NYHA class II was 384 ± 10,56 m, in NYHA class III was 290 ± 17,24 m, in NYHA class IV was 142 ± 3,51 m. The 6MWT distance in 1st group patients with COPD was 440 ± 15,48 m, in 2nd group was 384 ± 15,42 m. There is reduction PETCO2 in all patients with CHF during the 6MWT. PETCO2 in patients with CHF in NYHA class II was 33,34 ± 2,51 mm Hg, in NYHA class III was 31,75 ± 2,89 mm Hg, in NYHA class IV was 28,8 ± 1,32 mm Hg. 69,2% patients reported dyspnea as the main reason for a stop during the 6MWT. There is increase PETCO2 in all patients with COPD during the 6MWT. After the 6MWT the significance of PETCO2 in 1st group was 43,21 ± 2,81mm Hg, in 2st group was 45,05 ± 3,26 mm Hg. All patients reported dyspnea as the main reason for a stop during the execution 6MWT. When we analyzed the trend of PETCO2 we found that these patients showed signs of periodic breathing than control group.
Conclusion: Thus, capnography increases the diagnostic value of the 6MWT, helps to make interpretation of dyspnea in patients with CHF and COPD.

P1240

Cardiac rehabilitation: don't forget the ones that went away

H Helena Nascimento[1]; A Rocha[1]; M Braga[1]; G Pestana[1]; M Tavares-Silva[1]; R Pinto[1]; A Nunes[1]; P Araujo[1]; V Araujo[1]; F Parada[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Introduction: Cardiac rehabilitation program (CRP) is an intervention designed to promote a healthy lifestyle. In spite of a strong commitment from health-professionals, a significant number of patients (pts) leave the program. Our goal was to evaluate the socio-demographic and clinical features of pts not completing the CRP.
Methods: We analysed data from a prospective registry of 840 consecutive pts enrolled in a CRP after an acute coronary syndrome (ACS), between 2008 and 2016. Forty-two pts were excluded from the CRP due to medical reasons.
Results: From the total of 798 patients, 86% male and mean age 54.5 ± 9.9 years old. Most pts were actively working (55,4%) and married (92,8%). The prevalence of the classic cardiovascular risk factors was high with 59.9% dyslipidemic; 55.8% active smokers; 42.6% hypertensive; 24.9% obese and 18.5% diabetic. The dropout rate from CRP was 7,9% (63 pts). Main reasons for dropping out were lack of economic means or transportation constraints (23.8%), need to return to work (7.1%) and available exercise sessions schedules (2.9%). Women were slightly more prone to leave CRP ($p = 0.05$). Pts leaving the CRP were younger (51.2 ± 9.1 vs 54.3 ± 9.8 years old, $p = 0.011$), more often lived alone (38.1% vs 17.1%, $p < 0.001$) and were unemployed/retired (55.6% vs 41.8%, $p = 0.046$). Prevalence of active smokers (73.0% vs 54.3%, $p = 0.005$) and obese (42.9% vs 22.7%, $p = 0.001$) was also higher among these pts. Although there was no difference in functional capacity in baseline exercise testing (METs 8.9 ± 2.3 vs 8.4 ± 2.6, $p = 0.084$), at 1-year follow-up, those completing CRP showed better performance (METs 10.7 ± 2.3 vs 9.0 ± 2.2, $p < 0.001$). Independent predictors of non-completion of CRP by multivariate logistic regression modelling were obesity (OR 2.7, 95% CI 1.6-4.6, $p < 0.001$), smoking (OR 2.4, 95% CI 1.3-4.3, $p = 0.004$), unemployment (OR 1.9, 95% CI 1.1-3.2, $p = 0.017$) and living alone (OR 2.9, 95% CI 1.6-5.0, $p < 0.001$).
Conclusion: The benefits of CRP enrollment after an ACS are undeniable. However, dropout rates remain high and are a source of concern in CRP. Identifying those at higher risk of non-compliance, especially those with social and economic disadvantages might steer a redesign of CRP programs, and alternatives to reduce costs and inequities in access to this cost-effective treatment option.

P1241

The effects of long-term aerobic training designed with individualized method based on lactate threshold definition

T Tatiana Lelyavina[1]; MYU Sitnikova[1]; VL Galenko[1]; PS Kozlovps[1]
[1]*Almazov Federal Center of Heart Blood & Endocrinology, Saint Petersburg, Russian Federation*

Objective: to evaluate the effects of long-term aerobic training, designed with individualized method based on lactate threshold definition, on exercise capacity, HF severity and ergoreflex activity.
Methods: We evaluated 196 HF patients, mean age 51 +/-1.1, 132 men, with NYHA class III, LVEF 38,8 +/-0,8%. CPET performed on a treadmill ("Oxycon Pro") at baseline, in every 8 weeks and after 9 months. The cubital venous catheter was inserted before CPET. Blood samples were taken at baseline and at 1-minute intervals during test. Lactate concentration in blood was measured using analyzer i-STAT, cartridge CG4 (Abbot, USA). All patients were randomized into following groups: 109 patients of study group (SG), who underwent physical rehabilitation program (PRP), calculated due to lactate threshold; and 87 HF patients control group (CG), who underwent physical training, calculated based on VO2 percentage. Results: At baseline CPET results in both groups did not significantly differ. VO2 at lactate threshold and VO2peak were 8.7 +/-0,5; 13,5 +/-0,9 ml/min/kg and 8.9 +/-0.9; 13,6 +/-1,2 ml/min/kg in study group and control group, respectively (p1=0,08, p2=0,07, respectively). After 36 weeks of training VO2LT and VO2peak were better in the study group than in control group: the increase was 16% and 24% in the main group, and 4% and 7% in the control group, respectively ($p1 < 0,01$, $p2 < 0,01$). The ergoreflex activity at baseline did not significantly differ in two study groups. After long-term aerobic training we recorded a more marked reduction in the ergoreflex activity in study group: for DBP it was 35% and 20%, VE - 48% and 25%, VE/VCO2 - 39% and 12%, in the study group and control groups, respectively. By the 24th week of training in 91 (85%) patients of the study group the severity of HF was reduced to NYHA class II, and among the patients in the control group such dynamics was observed only in 43(50%) patients. Conclusions: aerobic exercise, designed with individualized method based on lactate threshold definition, increase exercise tolerance, reduces HF severity and ergoreflex activity more than aerobic training, calculated based on VO2peak percentage.

Endothelial and muscular alterations in a cardiometabolic obese rat model of heart failure with preserved ejection fraction (HFpEF)

V Volker Adams[1]; C Herz[1]; Z Schmederer[1]; TS Bowen[1]; NPL Rolim[2]; T Fischer[1]; S Werner[1]; A Linke[1]; U Wisloff[2]
[1]*University Leipzig, Heart Center, Leipzig, Germany*; [2]*Norwegian University of Science and Technology, Trondheim, Norway*

Funding Acknowledgements: EU Commission Framework 7 (EU 602405-2)

Despite normal left ventricular ejection fraction patients with heart failure with preserved left ventricular ejection fraction (HFpEF) present exercise intolerance which can be attenuated by exercise training. Alterations in the peripheral skeletal muscle as well as in the vascular system have been described with conflicting results and the molecular mechanisms mediating the beneficial effects of exercise training after disease onset is still unknown. The present study, therefore, used a cardiometabolic rat model to further elucidate: 1) alterations in the skeletal muscle (EDL) and the

vascular system induced by HFpEF; and 2) the effects of exercise training during secondary prevention. After 20 weeks, obese Zucker diabetic fatty/spontaneously hypertensive heart failure F1 hybrid (ZSF1) rats (n = 12) were compared to their lean counterparts (n = 8), with a further 3 groups of obese ZSF1 rats assessed 8 weeks later following sedentary behavior (n = 15), moderate-continuous training (MCT; n=11) or high-intensity interval training (HIIT; n=11). Obese rats displayed signs of HFpEF including diastolic dysfunction, LV hypertrophy, exercise intolerance ($P < 0.05$) and preserved LVEF. Compared to leans, obese rats showed a significantly impaired endothelial-dependent vasodilation associated with reduced eNOS activation ($p < 0.05$) and a trend towards elevated expression of gp91phox ($p = 0.09$). Exercise, independent of modality, improved endothelial function, which was associated with a reduction in gp91phox expression (r=0.42, $p = 0.01$). Compared to controls HFpEF animals showed signs of skeletal muscle atrophy (lower muscle weight, lower CSA) and reduced maximal absolute force, but maximal specific force was elevated ($p < 0.05$). AT the molecular level a significant higher actin expression and creatine kinase activity was detected whereas xanthine oxidase activity was reduced ($p < 0.05$). Exercise training had no significant effect. To conclude, a cardiometabolic obese model of HFpEF was associated with impaired endothelial function and still preserved specific skeletal muscle force generation. Exercise training (independent of protocol) was able to reverse these alterations in the endothelium but had no significant effect on the skeletal muscle.

P1243

The combination of characteristics of exercise oscillatory ventilation is associated with the severity of chronic heart failure

N Panagopoulou[1]; E Karatzanos[1]; V Zarvalias[1]; P Ferentinos[2]; C Kapelios[3]; S Dimopoulos[1]; A Ntalianis[4]; I Chaveles[5]; S Nanas[1]; A Sideris[6]
[1]Cardiopulmonary Exercise Testing & Rehabilitation Laboratory, NKUA, Athens, Greece; *[2]Carnegie Faculty , School of Sport, Leeds Beckett University, Leeds, United Kingdom*; *[3]Laiko General Hospital of Athens, Cardiology Department, Athens, Greece*; *[4]National & Kapodistrian University of Athens, Department of Therapeutics, School of Medicine, Athens, Greece*; *[5]Evaggelismos General Hospital of Athens, 1st Cardiology Department, Athens, Greece*; *[6]Evaggelismos General Hospital of Athens, 2nd Cardiology Department, Athens, Greece*

Introduction: The pattern of exercise oscillatory ventilation (EOV) can be described by the length (λ) and amplitude (h) of cyclic fluctuations. The clinical significance of the severity of these characteristics has not been adequately described in chronic heart failure (CHF).
Purpose: To investigate the relationship between the combination of these EOV characteristics with indices of CHF severity.
Methods: 357 consecutive patients with systolic CHF were evaluated with maximum, symptom-limited exercise testing (CPET) of which 179 presented EOV (age:55 ± 13 years, VO2peak:17.9 ± 9.7 ml/kg/min). Cyclic fluctuations in ventilation with an amplitude during exercise ≥15% of the average resting amplitude, lasting ≥60% of total exercise duration, were considered as EOV. The average length (λ) and amplitude (h) of EOV for each patient was also calculated. Patients were divided into two severity groups (S: severe, M: mild) for each of these characteristics, based on their median value [Sλ: $\lambda \geq 41.4$sec, Mλ: $\lambda < 41.4$ sec; Sh: h≥6.5 L/min, Mh: h < 6.5 L/min]. Consequently, four subgroups resulted from the combination of characteristics and severity that were compared for CPET indices: VO2peak, VO2AT, VE/VCO2slope, PetCO2AT, PetCO2peak and VO2/t slope. Values are expressed as means ± SD.
Results: Significant between-group differences were observed for all indices examined ($p < 0.05$, Table 1). MλMh differed from MλSh and SλSh in some variables ($p < 0.05$) but not from SλMh (p>0.,05). MλSh differed from SλSh and SλMh ($p < 0.05$), while SλSh did not differ from SλMh (p>0.05).
Conclusions: The combination of different levels of length and amplitude, as characteristics of EOV -mainly the length- is related to the severity of CHF. Further investigation on larger sample is necessary to clarify these findings and define reference values for average length and amplitude of EOV in relation to CHF severity.

Table 1. Comparison within and between subgroups (based on EOV characteristics and severity) for parameters examined.

Different predictors of exercise capacity in HFpEF compared to HFrEF

A Batalli[1]; P Ibrahimi[1]; I Bytyci[1]; A Ahmeti[1]; E Haliti[1]; S Elezi[1]; M Henein[2]; G Gani Bajraktari[1]
[1]University Clinical Centre of Kosova (UCC), Service of Cardiology, Pristina, Kosovo Republic of; *[2]Heart Centre and Department of Public Health and Clinical Medicine, Umea University, Umea, Sweden*

Background and Aim: Quality of life is as important as survival in heart failure (HF) patients. Controversies exist with regards to echocardiographic predictors of exercise capacity in HF, particularly in patients with preserved ejection fraction (HFpEF). The aim of this study was to prospectively examine echocardiographic parameters that correlate and predict functional exercise capacity assessed by 6 min walk test (6-MWT) in patients with HFpEF.
Methods: In 111 HF patients (mean age 63 ± 10 years, 47% female), an echo-Doppler study and a 6-MWT were performed in the same day. Patients were divided into two groups based on the 6-MWT distance (Group I: ≤ 300 m and Group II: >300 m).
Results: Group I were older ($p = 0.008$), had higher prevalence of diabetes ($p = 0.027$), higher baseline heart rate ($p = 0.004$), larger left atrium - LA ($p = 0.001$), longer LV filling time - FT ($p = 0.019$), shorter isovolumic relaxation time ($p = 0.037$), shorter pulmonary acceleration time - PAAT ($p = 0.006$), lower left atrial lateral wall myocardial velocity (a') ($p = 0.018$) and lower septal systolic myocardial velocity (s') ($p = 0.023$), compared with Group II. Patients with HF and reduced EF (HFrEF) had lower hemoglobin ($p = 0.007$), higher baseline heart rate ($p = 0.005$), higher NT-ProBNP ($p = 0.001$), larger LA ($p = 0.004$), lower septal s', e', a' waves, and septal MAPSE, shorter PAAT ($p < 0.001$ for all), lower lateral MAPSE, higher E/A & E/e', and shorter LVFT ($p = 0.001$ for all), lower lateral e' ($p = 0.009$), s' ($p = 0.006$), RV e' and LA emptying fraction ($p = 0.012$ for both), compared with HFpEF patients. In multivariate analysis, only LA diameter [2.676 (1.242-5.766), $p = 0.012$], and diabetes [0.274 (0.084 - 0.898), $p = 0.033$] independently predicted poor 6-MWT performance in the group as a whole. In HFrEF, age [1.073 (1.012 - 1.137), $p = 0.018$] and LA diameter [3.685 (1.348 - 10.071), $p = 0.011$], but in HFpEF, lateral s' [0.295 (0.099 - 0.882), $p = 0.029$], and hemoglobin level [0.497 (0.248-0.998), $p = 0.049$] independently predicted poor 6-MWT performance.
Conclusion: In HF patients predictors of exercise capacity differ according to severity of overall LV systolic function, with left atrial enlargement in HFrEF and longitudinal systolic shortening in HFpEF as the the main predictors.

PULMONARY HYPERTENSION

White blood cell count in pulmonary arterial hypertension: relation to pulmonary vascular resistance

H Gungor[1]; H Kaya[2]; M Meric[3]; YT Yaylali[4]; O Yazici[5]; AS Babu[6]
[1]Adnan Menderes University, Faculty of Medicine, Department of Cardiology, Aydin, Turkey; *[2]Cumhuriyet University, Cardiology, Sivas, Turkey*; *[3]19 May University, Cardiology, Atakum /SAMSUN, Turkey*; *[4]Pamukkale University, Cardiology, Denizli, Turkey*; *[5]Adnan Menderes University, Chest Disease, Aydin, Turkey*; *[6]Manipal University, Physiotheraphy, Karnataka, India*

AIM: Pulmonary vascular resistance (PVR) is an important hemodynamic variable used in the diagnosis and mangement of patients with pulmonary hypertension (PH). The positive relationship between WBC count and cardiovascular disease has been observed in several studies.
Methods: 20 patients (16 females) from four centers undergoing right heart catheterization having a mean age 56.20 ± 17.5 years, all belonging to group 1 PH [idiopathic

pulmonary arterial hypertension (PAH) (n = 11) and congenital heart disease (n = 9)] were retrospectively studied. Patients with associated PAH and anyone receiving anti-inflammatory treatment were excluded. All eligible patient records contained complete blood counts obtained using an automated blood counter. Parameters recorded were total white blood cells (WBC), neutrophils, lymphocytes and platelets, platelet-to-lymphocyte ratio (PLR), neutrophil-to-lymphocyte ratio (NLR) were. In addition, six minute walk distance (6MWD) was assessed and recorded.

RESULTS: The 6MWD mean pulmonary arterial pressure and mean PVR values were respectively 185.72 ± 121.10 meters, 41.79 ± 10.80 mmHg, 6.33 ± 3.00 WU (median=5.4) respectively. PVR showed significant correlation with WBC and neutrophil count. An inverse correlation was observed with PVR and age. However, ratios suggesting inflammation (i.e., NLR and PLR) were not correlated with PVR. When patients divided into two groups as PVR>5.4 WU and PVR < 5.4; age, platelet count, WBC and neutrophil count were significantly different between the groups. In a multivariate analysis only WBC count was found to be an independent predictor of PVR>5.4 WU (Table 1).

Conclusion: Our study suggests that high WBC count appears to be additive to predict higher PVR values in patients with PAH.

Table 1

		Univariate			Multivariate	
Statistically significant variables	p	OR	95%CI	p	OR	95%CI
White blood cell	0,038	2,042	1,042-4,002	0,029	5,198	1,187-22,771
Platelet	0,088	1,012	0,998-1,027			
Variables which correlated with PVR						
Age	< 0,001	0,972	0,958-0,986			
Neutrophil count	< 0,001	1,046	1,024-1,069			
SPAP	0,103	1,056	0,989-1,128			

Univariate and multivariate logistic regression analyses for predicting PVR>5.4 All the variables from Table 1 were examined and only those significant at P < 0.100 level and correlated with PVR are shown in univarite analysis.

Correlation betwen cardiac index and right ventricular sistolic function in pulmonary hypertension

HGSM Hector Gomez Santa Maria[1]; AF Alejandra Ferro[1]; GD Guido Damianich[1]; ALC Augusto Lavalle Cobo[1]; NG Nicolas Gonzalez[1]; GR Guadalupe Romero[1]; DC Diego Crippa[1]; MG Miguel Gonzalez[1]; HG Hugo Grancelli[1]; VD Victor Daru[1]; AL Adrian Lescano[1]

[1]Finochietto Clinic, Buenos Aires, Argentina

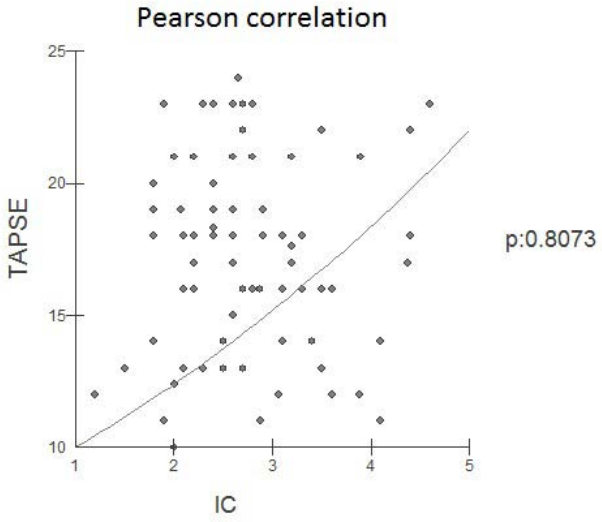
Pulmonary hypertension (PH) is a multifactorial desease defined as mean pulmonary arterial pressure ≥25 mmHg mesured by right heart catheterization.(RHC) International Guidelines recomend doppler ecocardiography as the method of screening to estimate the value of systolic pulmonary pressure and right ventricular systolic function (RVSF). The Tricuspid Annular Plane Systolic Excursion (TAPSE) is an indicator of RVSF, although it has been removed from the HP guidelines. The cardiac index (CI) is also an indicator of the right ventricular function and a marker of mortality. The question that arises is if there is a correlation between both techniques as indicators of RVSF.

Objective: To determinate the correlation between TAPSE and CI in our population, with the diagnosis of PH.

Material and methods: We conducted a multicenter, observational, prospective study that enrolled patients derived to our service with diagnosis of PH between March 2012 and Junary 2017. The following data were obtained: PH classification group, clinical features, hemodynamic variables, distance in the six minutes walk test (6MWT), functional class (FC), and echocardiographic measurements, according to guidelines. Echocardiographic variables were obtained by three experienced operators, with 2 ultrasound equipments (Vivid 5s) and a 3.5 mherz transducer, assessing: RVSF, TAPSE, pulmonary pressure and presence of pericardial effusion (EP). We performed RHC to confirm PH by measuring mean pulmonary artery pressure. We also recorded right atrium, systolic and diastolic pulmonary pressure (PP); wedge pressure, cardiac index (CI), pulmonary and systemic vascular resistance. Studies were performed with a difference of less than 24 hours and the physicians did not know echocardiography results. The results were incorpored into an Excel database. Bioestat 5.0 statistical package was used and linear correlation variables were analyzed.

Outcomes: We included 86 cases with hemodynamic diagnosis of HP. The average age of the population was 57.5 years (SD 19), 57.3 % were female. The diagnosis of HP was: Group (G) I 62.5%, G II 15%, G III 7%, and G IV and V 5% to 8%. In relation to clinical features 79% of p presented heart failure (HF) and 26% had syncope. Direct hemodynamic mean measurements were: systolic PP 76 mm Hg, MPP mean 46 mm Hg (SD 15.2), diastolic PP 32 mm Hg, right atrial pressure 9.1 mm Hg and cardiac index 2.86 (4.6-1.2) l / min / m2. The TAPSE average was 17.9 mm (30-10). The Pearson correlation coefficient between TAPSE and CI was: r 0.02 (95% CI 0.20-0.25), with a p = 0.08.

Conclusion: In our study population with established diagnosis of PH we observed a bad correlation between TAPSE and CI. This data support the need of cardiac catheterization to quantify right ventricular systolic function.



Pearson correlation

P1247

Prevalence and predictors of pulmonary hypertension in a general community based population

S Sebastiano Quartuccio[1]; E Imbalzano[1]; G Mandraffino[1]; G Trapani[1]; A Lo Gullo[1]; A Saitta[1]; M Vatrano[2]; VA Ciconte[2]; R Ceravolo[2]

[1]University of Messina, Department of Clinical and Experimental Medicine, University of Messina, Italy, Messina, Italy; *[2]Civil Hospital of Pugliese, UTIC and Cardiology , Catanzaro, Italy*

Background/Introduction: The exact prevalence of PH in Italy is not known. Echocardiography is useful in the screening of patients with suspected PH by estimation of the pulmonary artery systolic pressure (PASP) by regurgitant tricuspid flow velocity evaluation, according to the simplified Bernoulli equation.

PURPOSE: We conducted a retrospective study to estimate the prevalence of PH in 7005 patients who underwent echocardiography.

Methods: Clinical data and echocardiographic results were used to determine etiological group of PH. Clinical data and echocardiographic results were used to determine etiological group of PH. PH causality was coded using criteria and subcategories of the ESC classifications.

Results: The mean age of the study population was 57.1 ± 20.5 years with 55.3% male. The prevalence of intermediate probability of PH was 8.6%, with nearly equal distribution between men and women (51.3 vs 48.7 %; P=NS) whereas the prevalence of high probability of PH was 4.3%, with slightly but not significant higher prevalence in female patients (43.2 vs 56.8; p = ns); PH is more prevalent in patients with chronic obstructive pulmonary disease (COPD) or left ventricle (LV) systolic dysfunction. PH prevalence increased with age. Also, sPAP was significantly associated with left atrial enlargement, left ventricular ejection fraction and, in addition, an increased sPAP was related to an enlargement of the right atrium and right ventricle.

Conclusion(s): PH as measured by echocardiography has low prevalence in our general population, but the estimates may be higher in specific subgroups. Analysis of the registry data could be an instrument for quality control and might help identify weak points in assessment and treatment of these patients.

P1248

New insights into inpatient symptom burden in pulmonary arterial hypertension

MA Mahesh Chandrasekhar[1]; C Barnett[1]; G Ruiz[1]; K Walker[1]; H Groninger[1]
[1]*Washington Hospital Center, Cardiology, Washington, United States of America*

BACKGROUND: Despite the high symptom burden in patients with pulmonary arterial hypertension, there is a relative paucity of research in the inpatient palliative care needs of this population. The aim of this study was to assess the palliative care needs of a pulmonary arterial hypertension cohort by retrospective review.
Methods: Patients with PAH receiving PC consultation were retrospectively evaluated from a large single center advanced heart failure (AHF) center in the United States. The PC team (specially trained physician, nurse practitioner, pharmacist, social worker, chaplain) is embedded within the AHF clinical program. Data on symptom burden was collect via a modified Edmonton Scale. Data on length of stay, palliative care interventions, and final disposition were evaluated using descriptive statistics.
Results: Consultations were performed on 11 PAH (median hospital length-of-stay 6 days) from January to December in 2015. Two patients developed PAH secondary to scleroderma, one patient developed PAH secondary to systemic sclerosis, and the rest of the cohort had idiopathic PAH. In all cases, reason for PC consultation was either goals of care (4 patients), pain control (6 patients) or non-pain symptom management (1 patient). In regard to pain control, 64% reported moderate to severe pain at time of consult; at 48 hours after consult, pain was resolved or reduced to mild pain in only 43% of patients. In regard to non-pain symptom management, 27% of patients were evaluated for moderate or severe dyspnea, 9 % moderate or severe depression, and 9% moderate or severe constipation. As a result of PC evaluation, 73% of patients received psychological counseling, 64% of patients received spiritual counseling, 27% participated in discussions that facilitated a change in resuscitation status, and 9% of patients were referred to hospice.
Conclusions: Patients with Pulmonary Arterial Hypertension have a unique and significant symptom burdens and palliative care needs in the inpatient setting.

P1249

Invasive and non-invasive characteristics of heart failure patients, related to pulmonary hypertension due to left heart disease, in qualification process for heart transplantation

J Migaj[1]; MI Marta Izabela Kaluzna-Oleksy[1]; M Dudek[1]; E Straburzynska-Migaj[1]
[1]*Poznan University of Medical Sciences, Ist Department of Cardiology , Poznan, Poland*

Introduction: Left heart disease is the main cause of pulmonary hypertension (PH). PH is considered a risk factor for worse outcomes in patients with heart failure (HF). Initial evaluation of PH patients involves non-invasive methods including echocardiography and B-type natriuretic peptide tests(BNP); however, the final diagnosis requires right heart catheterization(RHC).
Aim: Characterization of patients with heart failure with reduced ejection fraction (HFrEF) considered for heart transplantation (HTX)with and without PH. Evaluation of the role of non-invasive tests in diagnosis of PH in HFrEF patients.
Methods: This was a prospective analysis of 211 patients with HFrEF (left ventricular ejection fraction $<40\%$), with ischemic(ICM) and non-ischemic cardiomyopathy(NICM) undergoing qualification process for HTX. Following items were analyzed:epidemiological data, laboratory results (including BNP), and chosen parameters obtained in echocardiography, cardiopulmonary exercise testing (CPET) and RHC (thermodilution method). PH was diagnosed according to the ESC guidelines.
Results: The mean age of the analyzed patients was 52 ± 10 years, and most were men(88%); 72% had NYHA class 3 and 4. There were 141 patients(70%) with PH, including 138 with post-capillary PH and 3 with combined pre- and post-capillary PH. The patients with PH did not differ significantly from those without as to age, gender or cause for HF. They had more often NYHA class 3 and 4 (79%vs56%;$p = 0.002$) and showed significantly higher BNP (992vs361 pg/mL;$p < 0.001$), larger right ventricle in echocardiography (36 mmvs32 mm;$p < 0.001$) and higher right ventricular systolic pressure (RVSP) (47vs36;$p < 0.001$). There were no significant differences as to left ventricle and EF. There were no significant differences in CPET, but PH patients tended to show worse results: pVO2(14vs20 ml/kg/min;$p = 0.112$) and VE/VCO2 slope 40vs37;$p = 0.077$). BNP showed significant positive correlations with mean pulmonary arterial pressure (mPAP) (r=0.21), mean right atrial pressure (r=0.28), and pulmonary capillary wedge pressure (PCWP) (r=0.27). There was no significant correlation between BNP and transpulmonary gradient (TPG), pulmonary vascular resistance(PVR) and mean right ventricular pressure. RVSP measurement in echocardiography correlated positively with mPAP, diastolic PAP, mean right atrium pressure (mRAP), RVP, PCWP, TPG and diastolic pressure gradient(DPG) measured in RHC. There were also significant correlations between RVSP and pulmonary vein resistance (PVR) (r=0.44).
Conclusions: Non-invasive test results like BNP, echocardiographic and CPET parameters correlate with invasive RHC parameters in patients with HFrEF. Patients with HFrEF and PH present higher NYHA class and higher BNP levels, despite similar LVEF or LV size in comparison to those without PH. Combined non-invasive parameters provide a useful and feasible tool for evaluation of HFrEF patients to differentiate those with PH and without.

Puprose: The aim of study was to evaluate the impact of pulmonary hypertension (PHT) on early and late results after heart transplantation (HTx).
Methods: From 2010 to 2016 we performed 80 HTx (57 – male, 23 – female). Causes of heart failure were ischemic heart disease (47,5%; n=38), dilated cardiomyopathy (32,5%; n=26), non-compacted myocardium (11,3%; n=9) and others (9%; n=7). Recipients separated into 2 groups according to right heart catheterization results: 1st group - patients with PHT ($n = 54$; mean PAP $>$ 25 mm Hg) and 2nd group - without PHT ($n = 26$; mean PAP $<$ 25 mm Hg). Mean age of recipients in 1st group was $45,6 \pm 15,0$ yrs, pulmonary vascular resistance (PVR) – $3,6 \pm 1,4$ WU, PVR after reduction test (Iloprost 20 mkg, NO 80ppm) – $2,7 \pm 1,0$ WU, pulmonary artery systolic pressure (PASP) – $49,3 \pm 12,7$ mm Hg, pulmonary artery wedge pressure (PAWP) – $20,5 \pm 7,0$ mm Hg. In 2nd group mean age of patients was $46,9 \pm 11,9$ yrs, PVR – $2,1 \pm 0,8$ WU, PASP – $28,2 \pm 4,8$ mm Hg, PAWP – $11,9 \pm 4,3$ mm Hg. Outcomes were estimated by the time in ICU, results of TTE, frequency of right heart failure (RHF) and vasodilator indications.
Results: After HTx there was no significant difference in how much time patients with PHT or without spent in ICU (8 [4;49] days vs. 7 [4;36] days). But time spent in ICU in 1st group was more complicated: RHF occurred in 9% cases due to they were implanted extracorporeal membrane oxygenation (ECMO) support, 7% - underwent tricuspid valve repair due to severe tricuspid regurgitation. There was no indications in 2nd group to implant ECMO. Levosimendan treatment was successfully used in patients with PHT and without (41% ($n = 22$) vs. 15% ($n = 4$), $p < 0,05$). During 6 months after HTx 13% ($n = 7$) of recipients from 1st group treated by Sildenafil. Six months after HTx TTE results got to normal values in both groups: PVR (1st group - $1,8 \pm 0,5$ WU vs. 2nd group – $1,6 \pm 0,4$ WU, $p>0,05$), PASP ($34,8 \pm 6,7$ mm Hg vs. $35,1 \pm 4,4$ mm Hg, $p>0,05$), PAWP ($12,2 \pm 5,9$ mm Hg vs. $11,1 \pm 3,9$ mm Hg, $p>0,05$). Six months after HTx PASP significantly decreased in 1st group from $49,3 \pm 1,8$ mm Hg to $34,8 \pm 1,0$ mm Hg ($p < 0,001$), the same as PVR – from $3,6 \pm 0,2$ WU to $1,8 \pm 0,9$ WU ($p < 0,001$). There was no significant difference in TTE results in 6 months and in 1 yr after HTx.
Conclusions: Time in ICU of patients with PHT is complicated and development of RHF is more frequent what require specific treatment. After HTx PHT full regressed.

P1251

Clinical and echocardiographic correlates of pulmonary hypertension in heart failure patients

O A Kushimo[1]; AC Mbakwem[1]; JNA Ajuluchukwu[1]
[1]*Lagos University Teaching Hospital, Lagos, Nigeria*

Background: Pulmonary hypertension (PH) is highly prevalent amongst heart failure (HF) subjects and now recognized as an independent predictor of poor prognosis. Not much is known presently in our environment about the frequency and correlates of PH in HF, its effect on management and impact on outcomes. Studies on this subject will help us in better risk stratification, management and prognostication of our heart failure patients.
Purpose: To determine the frequency of PH in an academic hospital in our environment and assess its correlates using echocardiography.
Methods: Heart failure patients, 219, in New York Heart Association (NYHA) class II-IV were consecutively recruited from the emergency room and the cardiology out-patient clinic. Those with other co-morbidities that could cause PH were excluded. Data on demographic parameters, clinical features and

echocardiography were obtained. Correlation between elevated pulmonary artery systolic pressure (PASP), mean pulmonary artery pressure (mPAP) and selected clinical/echocardiographic parameters were further interrogated.
Results: The frequency of PH was determined by two criteria. PH using a PASP cut off of >36mmHg was present in 85 (38.8%) of subjects. However, using the mPAP criterion of ≥ 25mmHG, PH was present in 135 (61.6%) of subjects. Heart failure subjects with PH were more likely to be male ($p = 0.03$) with a lower body mass index ($p < 0.01$), lower systolic blood pressure ($p < 0.01$) and a worse NYHA functional class ($p < 0.01$) compared with subjects without pulmonary hypertension. Heart failure subjects with PH also had significantly higher left ventricular (LV) filling pressures, (higher left atrial volume index and E/e'ratio), more severe mitral regurgitation (higher mitral regurtitant volume), poorer LV systolic function, and worse parameters RV structure and function compared with those without PH. Echocardiographic variables that correlated significantly PASP include parameters of LV filling pressures ($p < 0.001$ for all), mitral regurgitant volume ($r = 0.269$, $p < 0.001$) LV and ejection fraction ($r = -0.239$, $p > 0.001$). Similar correlations were obtained with mPAP. On multivariate analyses, the left atrial volume index and E/e' ratio were independently associated with PASP, while the LV ejection fraction, E/e' ratio and the left atrial volume index were independently associated with mPAP.
Conclusion: PH is quite common amongst heart failure subjects in our environment with a variable frequency depending on the assessment method employed. It is associated with higher LV filling pressure, more severe MR, poorer LV systolic function and worse RV remodeling. Routine screening for PH amongst heart failure patients is recommended for better risk stratification and management.

P1252
How different responses of total pulmonary vascular resistance to exercise can influence right ventricular inotropic reserve and functional capacity in post pulmonary endarterectomy patients?

A R Ana Rita Almeida[1]; MJ Loureiro[1]; L Lopes[1]; D Repolho[1]; F Ferreira[1]; S Alegria[1]; AR Pereira[1]; P Fazendas[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Almada, Portugal

Introduction: After pulmonary endarterectomy (PEA) there is an abnormal pulmonary hemodynamic response to exercise, even in patients (pts) with near normal resting hemodynamics, causing excessive afterload of the right ventricle (RV) and exercise limitation.
Purpose: Determine if different responses of total pulmonary vascular resistance (TPVR) to exercise can affect RV inotropic reserve and functional capacity during exercise echocardiography (EE) in pts after PEA.
Methods: EE was done using treadmill ergometer and modified Bruce protocol until exhaustion. During exercise pts went symptoms, arterial pressure and ECG monitoring. To evaluate RV function we used right ventricle stroke volume indexed to body surface area (RVSVI); tricuspid annular plane systolic excursion (TAPSE); free RV wall S wave (S wave) and RV fractional area change (RVFAC). To evaluate total pulmonary vascular resistance (TPVR) = mean pulmonary artery pressure (mPAP)/cardiac output (CO); for this we have to evaluate mPAP = systolic pulmonary artery pressure (PSAP)x0.6 + 2, where PSAP=RV/RA (right atrium) gradient + RA pressure estimate and CO=LVSV(left ventricular stroke volume) (LVOT VTI x LVOT area) x heart rate. We used test duration to define functional capacity. We defined 2 groups of pts according to variation of TPVR during exercise, one in which TPVR increased and other in which TPVR decreased and compared variables of RV function and test duration between them using t'student test for independent samples.
Results: The group of post' PEA pts consisted of 13 patients at least 6 months after PEA, with mean age of 57.0 ± 11.7 years, 7 females. When compared the 2 groups, we verified that pts in whom TPVR increased with exercise (3 pts) had significant lower functional capacity (test duration of 606.7 ± 46.5 vs 777.6 ± 179.6 sec. ($p = 0.02$)), significant lower increase in TAPSE (1 ± 2.6 mm vs 6.2 ± 3.1 mm ($p = 0.02$)) and significant lower increase in RVSVI (3.4 ± 2.5 mL/m2 vs 11.2 ± 4.6 mL/m2 ($p = 0.02$)). We didn't verify significant differences in variation of RVFAC and S wave between the 2 groups.
Conclusions: Pts in whom TPVR increased with exercise had lower functional capacity and lower RV inotropic reserve than pts in whom it decreased with exercise. Perhaps different responses of TPVR to exercise can be used to differentiate post' PEA pts with different prognosis.

P1253
Pulmonary hypertension in end-stage renal disease patients undergoing haemodialysis via arterio-venous access

A Amin[1]; M Chitsazan[1]; H Navid[1]; M Chitsazan[1]
[1]Rajaei Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Heart Failure and Trasnplantation, Tehran, Iran (Islamic Republic of)

Background: Pulmonary hypertension (PH) has been described in a considerable proportion of end-stage renal disease (ESRD) patients on hemodialysis and has been associated with worse prognosis. Our objective was to determine the right heart catheterization-derived hemodynamic data in ESRD patients on regular hemodialysis.
Methods: Fifty-five patients with ESRD who were on maintenance hemodialysis through an arteriovenous fistula underwent screening for PH with trans-thoracic echocardiography (TTE). Patients who were found to have PH on screening TTE (i.e., pulmonary arterial systolic pressure of >25 mmHg and tricuspid regurgitant velocity of >3.8 m/s) underwent diagnostic right heart catheterization (RHC) for evaluation of their hemodynamic status.
Results: Out of 55 patients, 30 (54%) patients had PH in initial screening with TTE (mean age of 39 ± 11 years). Of these 30 patients, 24 patients (80%) had post-capillary pulmonary hypertension (Class II PH) and 6 patients had pre-capillary pulmonary hypertension (Class I PH); based on the RHC findings. The RHC findings are demonstrated in Table1.
Conclusion: ESRD patients on maintenance hemodialysis therapy have a substantial risk of developing PH which in the vast majority of cases appears to be post-capillary.

On behalf of: GICC

Objectives: To investigate the prevalence and the determinants of pulmonary arterial hypertension (PAH) in acute and chronic heart failure (CHF) in France.
Background: The epidemiology of PAH in France in CHF is poorly described.
Methods: FRESH is an on-going multicenter survey collecting exhaustive data in both acute and chronic HF (NCT01956539). Estimate of systolic pulmonary artery pressure(SPAP) was attempted routinely by echocardiography and was divided in three classes: ≥45mmHg (Gr3), <45mmHg (Gr2) and not measured/able (Gr1). The diagnosis of CHF was based on symptoms, signs, echocardiography NT-proBNP. Comparisons were performed using chi^2 tests for categorial variables and ANOVA or non-parametric Kruskal Wallis test for continuous variables. Logisticregression-wasused to identify factors associated with PAPS≥45mmHg (Gr3).
Results: 2093 patients were included in FRESH. 1690 (81%) had an echocardiography of whom 596 (35%) were in AHF, of whom 29%, 34%% and 37% were respectively in Gr1, Gr2 and Gr3 and 1094 (65%) were in CHF of whom 31%, 48%, 21% were respectively in Gr1, Gr2 and Gr3. Independent factors associated with Gr3 (vs Gr1 and Gr2 pooled) were mitral insufficiency, High grade NYHA (III/IV), increased BNP, increased LVEDD and reduced TAPSE.
Conclusion: Using a definition of PASP>45mmHg, 37% of patients with AHF and 21% of CHF had pulmonary hypertension, which was associated with LV remodeling and mitral insufficiency leading to right ventricle failure. Whether PAH a target for therapy in these populations remains to be elucidated.

RIGHT VENTRICULAR FUNCTION

P1255

Persistent right ventricular dysfunction in patients with acute pulmonary embolism: does it have effect on prognosis?

J Simoes[1]; J Bicho Augusto[1]; M Borges Santos[1]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal*

Background: Right ventricular (RV) dysfunction is found in at least 25% of patients with acute pulmonary embolism (PE). The presence of RV dysfunction at diagnosis of acute PE is a determinant of the severity and early clinical outcome and its detection is useful for risk stratification of the disease. However, the effect on prognosis of persistent RV dysfunction after the standard treatment for acute PE has not been defined so well.
Purpose: To evaluate the effect of persistent RV dysfunction, at the time of discharge, in patients hospitalized for acute PE. The effect was measured by post-discharge all-cause mortality.
Methods: Retrospective review of 428 consecutive patients admitted for acute PE in a single-center hospital for two years until October 2016. We identified those who underwent transthoracic echocardiogram and who were found to have RV dysfunction at the moment of hospital admission (n = 103, 24.1%). RV dysfunction was defined as the presence of either RV dilatation, TAPSE < 16 mm, S' tricuspid < 10 cm/s or maximum tricuspid velocity regurgitation > 2.6 m/s. A second transthoracic echocardiogram was performed at discharge in 45 patients (43.7%) and the persistence of RV dysfunction was looked for. Patients were categorized in one of two groups: group 1 - those in whom RV dysfunction was present at the moment of their hospital admission, but not at discharge (n = 19; 42.2%); and group 2 - those in whom RV dysfunction was present at the moment of hospital admission and persisted at discharge (n = 26; 57.8%). Primary outcome was defined as the occurrence of all-cause mortality after discharge.
Results: We included 45 patients with acute PE and RV dysfunction at admission who were successfully discharged (mean age 66.2 ± 17.8 years, 28.9% males). Median follow-up time was 495 (interquartile range (IQR) 417) days. Mortality rate after discharge was 8.9%. Median proBNP was significantly superior in group 2 than in group 1 (median 12.597 vs. 293 pg/mL; p = 0.029). Similarly, patients in group 2 had significantly higher mortality rate than patients in group 1 (0.0 vs. 21.1%; p = 0.026).
Conclusions: In patients admitted for acute PE, mortality seems to be higher in those who have persistent RV dysfunction before discharge. Although these results must be confirmed by better-designed, prospective study cohorts, we believe our study may point to the relevance of further risk stratification of patients whose RV dysfunction is present at the initial echocardiographic evaluation and persists before discharge from the hospital.

P1256

Short-term prognostic value of shock index in normotensive oncologic patients with pulmonary embolism: keep it simple

S Moura Ferreira[1]; J Ferreira[2]; V Marinho[2]; P Marques[2]; N Silva[3]; R Baptista[2]; MJ Ferreira[2]; M Pego[2]
[1]*Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal*; [2]*University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*; [3]*University Hospitals of Coimbra, Internal Medicine, Coimbra, Portugal*

INTRODUCTION: The Shock Index (SI), although not included in the standard risk assessment of PE, showed better performance than the ESC model in normotensive patients suffering for acute PE. The value of SI to predict short-term mortality in normotensive oncologic patients with symptomatic PE is currently unknown. In this study, we aimed to assess the value of SI to predict 30-day all-cause mortality in normotensive oncologic patients with acute symptomatic PE.
Methods: Retrospective, observational study that included all normotensive cancer patients with acute PE diagnosed during emergency room stay by MDCT between January 2010 and December 2011. Demographic and clinical data, MDCT variables and blood tests results were collected for all patients. The primary endpoint of this study was 30-days all-cause mortality. We used a t test to compare means of SI between patients that died at 30-days and those that have survived. A receiver operating characteristics (ROC) curve was used to test SI as a predictor of the primary endpoint and to obtain the best cut-off value. Then we transformed SI into a categorical variable with 2 groups and conducted a Cox regression survival analysis to test the strength of prediction for 30-days overall mortality.
RESULTS: Between January 2010 and December 2011, 69 normotensive patients (42 males, median age 73 years) were diagnosed with acute PE by MDCT during emergency room stay. 19 (27.5%) patients died at 30 days of FU. There were significant differences in Mean Arterial Pressure (100.15 ± 2.55mmHg vs 88.37 ± 3.24mmHg, p = 0.01), Log Lactates (0.18 ± 0.03mmol/L vs 0.34 ± 0.06mmol/L, p = 0.02) and SI (0.68 ± 0.03 vs 0.83 ± 0.04, p < 0,01) between survivors and non-survivors at 30 days of follow-up. There were no other significant differences between the 2 groups, including cardiac biomarkers and a sPESI score≥2. As there was a significant interaction between SI, Log Lactates and Mean Arterial Pressure, only SI was included in cox regression analysis. The area under the curve (AUC) for SI was 0,71 (p < 0,01), yielding moderate discriminative power. We considered the best cut off point to be a SI of 0.62 (sensitivity 94,7 and specificity 42,0). In a cox regression analysis a SI equal or greater than 0.62 was strongly associated with a worse prognosis during the first month of follow-up (unadjusted OR 10.37 with a 95% confidence interval 1.38 – 77.71, p = 0,02).
Conclusion: SI is simple and strong independent predictor of 30-day all-cause mortality in normotensive cancer patients admitted in the emergency room with acute PE. In our population, a sPESI≥2 was not a predictor of fatal outcome at 30 days of FU.

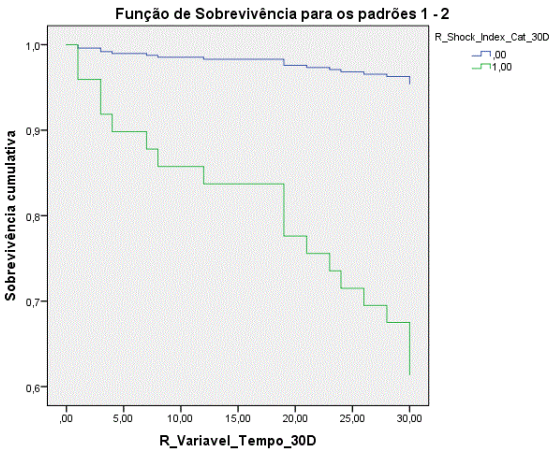

Figure 1

P1257

Late ventricular potentials in patients with arterial hypertension and coronary artery disease

VA Kuznetsov[1]; LG Evlampieva[1]; EI Yaroslavskaya[1]; EA Gorbatenko[1]
[1]*Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Tyumen, Russian Federation*

Background: Late ventricular potentials (LVPs) recorded by signal-averaged electrocardiography (ECG) are used as a prognostic factor for ventricular arrhythmias in patients with arterial hypertension (AH) and with coronary artery disease (CAD). However, the impact of combination of both diseases on LVPs has not been fully studied.
Purpose: To reveal factors influencing on LVPs in patients with AH and CAD.
Methods: The study enrolled 190 patients: 85 with AH, 39 with CAD and 66 with combined CAD and AH. All patients were divided into 2 groups: 41 subjects (mean age 44.3 ± 13.2 years) with LVPs (group I) and 149 subjects (mean age 44.6 ± 12.6 years) without LVPs (group II). Signal-averaged ECG was recorded using the standard Simson method. ECG signal averaging has been applied for 300 complexes using three orthogonal leads system. Enhanced, averaged and filtered with a bandwidth of 40-250 Hz signals were combined into vector amplitude of these orthogonal leads. Based on the automatic algorithm the quantitative evaluation of three parameters was performed with the following criteria for LVPs: filtered QRS complex duration (F QRS d) longer than 120 milliseconds; duration of low amplitude signals lower than 40 μV (LAS40) >38 ms, and less than 20 μV of the root mean square signal amplitude in the last 40 milliseconds of the filtered QRS complex (RMS40). A patient was considered to show LVPs if at least two criteria were present.
Results: Group I patients were higher than patients of group II (175.6 ± 6.84 vs 171.1 ± 8.02 cm, p=0.001). Significant differences were detected in group I compared to group II in the number of men (40 (97.6%) vs 124 (83.2%), p = 0.018); previous myocardial infarction (18 (43.9%) vs 40 (26.8%), p = 0.036); right ventricular (RV) dimension (25.00 ± 2.94 vs 23.45 ± 4.35 mm, p = 0.049); aorta size (34.37 ± 4.20 vs 32.93 ± 3.73 mm, p = 0.037); left ventricular ejection fraction (LVEF) (56.76 ± 6.98 vs 59.95 ± 7.23%, p = 0.003), as well as the tendency for difference in left ventricular size was observed (51.17 ± 3.92 vs 49.68 ± 4.44 mm, p = 0.057). No difference between the groups was found in age, smoking status, AH, angina and circulatory insufficiency. LVPs recorded in patients with AH was 15 (17.6%) vs 7 (17.9%) in patients with CAD and 19 (28.8%) in patients with CAD and AH. Logistic regression showed the association of probability of LVPs with RV enlargement (OR 1.16, 95% CI 1.01 to 1.34; p = 0.042) and with reduced LVEF (OR 0.953, 95% CI 0.909 to 0.999, p = 0.049).
Conclusion: LVPs were independently associated with RV dimension and LVEF in patients with AH and CAD.

P1258

Shock Index is an independent predictor of long-term mortality in normotensive oncologic patients with pulmonary embolism

S Sara Moura Ferreira[1]; J Ferreira[2]; V Marinho[2]; P Marques[2]; N Silva[3]; R Baptista[2]; MJ Ferreira[2]; M Pego[2]
[1]*Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal*; [2]*University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*; [3]*University Hospitals of Coimbra, Internal Medicine, Coimbra, Portugal*

Introduction: The Shock Index (SI), although not included in the standard risk assessment of PE, showed better performance than the ESC model in normotensive patients suffering for acute PE in a recently published study. The value of SI to predict long-term mortality in normotensive oncologic patients with symptomatic PE admitted in the emergency room is currently unknown. In this study, we aimed to assess the value of SI to predict 1-year all-cause mortality in normotensive oncologic patients with acute symptomatic PE.
Methods: Retrospective, observational study that included all normotensive cancer patients with acute PE diagnosed during emergency room stay by MDCT between January 2010 and December 2011. Demographic and clinical data, MDCT variables and blood tests results were collected for all patients. The primary endpoint of this study was 1-year all-cause mortality. We used a t test to compare means of SI between patients that died at 1 year of follow-up and those that have survived. A receiver operating characteristics (ROC) curve was used to test SI as a predictor of the primary endpoint and to obtain the best cut-off value. Then we transformed SI into a categorical variable with 2 groups and conducted a Cox regression survival analysis to test the strength of prediction for 1-year overall mortality.
Results: Between January 2010 and December 2011, 69 normotensive patients (42 males, median age 73 years) were diagnosed with acute PE by MDCT during emergency room stay. 38 (55.1%) patients died at 1 year of FU. There were significant differences in Mean Arterial Pressure (103.31 ± 3.39mmHg vs 91.68 ± 2.44mmHg, p < 0.01), Log Lactates (0.16 ± 0.05mmol/L vs 0.34 ± 0.060.27 ± 0.04mmol/L, p < 0.05) and SI (0.65 ± 0.04 vs 0.77 ± 0.03, p = 0,02) between survivors and non-survivors at 1 year of follow-up. There were no other significant differences between the 2 groups, including cardiac biomarkers and a sPESI score≥2. As there was a significant interaction between SI, Log Lactates and Mean Arterial Pressure, only SI was included in cox regression analysis. The area under the curve (AUC) for SI was 0,66 (p = 0,02), yielding fair discriminative power. We considered the best cut off point to be a SI of 0.73 (sensitivity 71.1 and specificity 65.5). In a cox regression analysis a SI equal or greater than 0.73 was strongly associated with a worse prognosis during the first year of follow-up (unadjusted OR 3.11 with a 95% confidence interval 1.54 – 6.30, p < 0,01).
Conclusion: SI is simple and strong independent predictor of 1 year all-cause mortality in normotensive cancer patients admitted in the emergency room with acute PE. In our population, a sPESI≥2 was not a predictor of fatal outcome at 1 year of FU.

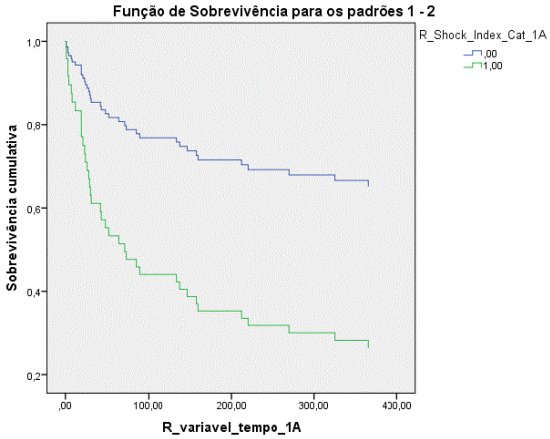

Figure 1

P1259

Does fibrinolytic therapy improves right ventricular function in acute pulmonary embolism?

J Simoes[1]; J Bicho Augusto[1]; M Borges Santos[1]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal*

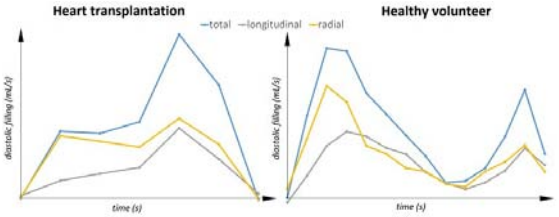
Background: Right ventricular (RV) dysfunction is found in at least 25% of patients with acute pulmonary embolism (PE). The presence of RV dysfunction at diagnosis of acute PE is a determinant of the severity and early clinical outcome and its detection is useful for risk stratification of the disease. However, it is not well known whether RV dysfunction at diagnosis of acute PE is improved by fibrinolytic therapy.
Purpose: To evaluate the effect of fibrinolytic therapy on RV function in patients with acute PE and echocardiographic signs of RV dysfunction.
Methods: Retrospective review of 428 consecutive patients admitted for acute PE in a single-center hospital for two years until October 2016. We identified those who underwent transthoracic echocardiogram and who were found to have RV dysfunction at the moment of hospital admission (n = 103, 24.1%). RV dysfunction was defined as the presence of either RV dilatation (defined as RV end-diastolic diameter >30 mm in parasternal long-axis or short-axis views, right-to-left ventricular end-diastolic diameter >0.9 in apical or subcostal 4-chamber views, or hypokinesis of the right ventricular free wall), tricuspid annular plane systolic excursion (TAPSE) <16mm, velocity of the tricuspid annular systolic motion (S') <10 cm/s or tricuspid regurgitant jet systolic velocity >2.6 m/s. Patients found to have RV dysfunction at the moment of hospital admission were further categorized in one of two groups: those who have undergone fibrinolysis (group 1) and those who have not undergone fibrinolysis (group 2). A second transthoracic echocardiogram was performed at discharge and the persistence of RV dysfunction was looked for.
Results: We included a total of 45 patients with acute PE and RV dysfunction at admission who had a reevaluation echocardiogram at discharge (mean age 66.2 ± 17.8 years, 28.9% males). Among these, 14 patients underwent fibrinolysis (31.1%). We found no differences in terms of RV dysfunction persistence between patients in group 1 and group 2 (42.9 vs. 41.9%, respectively; p = 0.954). There were no differences in proBNP values between the two groups (mean 9973 vs. 8694pg/mL; p = 0.901).
Conclusions: In acute PE, fibrinolytic therapy seems not to improve RV function in patients found to have RV dysfunction at admission. Given the fact that fibrinolytic therapy is not devoid of risk, these results may stress the current recommendation of restricting fibrinolysis to carefully selected patients.

P1260

Functional shift in right ventricular longitudinal versus radial contribution to diastolic fillling in heart transplant recipients

B K Balint Karoly Lakatos[1]; Z Toser[2]; M Tokodi[1]; A Assabiny[1]; B Sax[1]; A Kosztin[1]; B Merkely[1]; A Kovacs[1]
[1]*Semmelweis University Heart Center, Cardiovascular Imaging Group, Budapest, Hungary*; [2]*Eötvös Loránd University, Department of Software Technology and Methodology, Budapest, Hungary*

Previous studies reported the altered contribution of radial versus longitudinal motion to right ventricular (RV) global systolic function in patients underwent heart transplantation (HTX). However, the diastolic wall motions of the RV may be of high interest as well. Our aim was to quantify the longitudinal and radial components of diastolic RV wall motion in HTX patients compared to healthy volunteers. 47 heart transplant recipients (HTX, median of 258 days after HTX) were enrolled in the study, and 35 age- and gender matched healthy volunteers (CTL) served as the control group. Full volume datasets of the RV were acquired and 3D beutel models were created and exported volume-by-volume. Beyond conventional echocardiographic parameters, such as RV end-diastolic volume (EDV) we have determined the early (E) and late (A) diastolic filling volumes as well. Using our custom method, we were able to decompose the motion of the RV along the three orthogonal axes and quantify the relative contribution of radial and longitudinal motion to the two phases of diastolic filling (Erad, Elong, Arad, Along) and also the overall contribution of these components (Diarad and Dialong). Compared to CTL, HTX patients have significantly higher EDV (HTX vs. CTL 96 ± 28 vs. 79 ± 26 mL, $p < 0.01$). In the CTL group, the early diastolic filling volume was significantly higher, while in HTX patients the late diastolic filling was more dominant (E: 21 ± 9 vs. 28 ± 10 mL A: 20 ± 12 vs. 11 ± 5 mL, both $p < 0.01$) suggesting impaired relaxation. By decomposing the wall motions contributing to RV filling, we found that the two groups have different patterns: in early diastole, the HTX group has significantly lower Elong (5 ± 3 vs. 11 ± 4 mL, $p < 0.0001$) with comparable Erad (14 ± 6 vs.14 ± 7 mL, p = NS), and in late diastole both the Along and Arad are significantly higher compared to CTL (Along: 6 ± 4 vs. 3 ± 2 mL, Arad: 9 ± 7 vs. 4 ± 3 mL, both $p < 0.01$). The overall effect of longitudinal motion to diastolic filling is significantly lower in the HTX group, however, an increased radial contribution is present (Dialong: 10 ± 8 vs. 14 ± 4 mL; Diarad: 23 ± 8 vs. 17 ± 7 mL, both $p < 0.001$). Based on these findings, HTX results in a complex change in right ventricular diastolic function with an altered contribution of longitudinal and radial motion in early and late diastole as well.



HTX vs. CTL in diastole

LEFT VENTRICULAR FUNCTION

Changes in systolic and diastolic function in gestational hypertension and reversibility of these changes after delivery

A Ilic[1]; S Stojsic[1]; K Pavlovic[1]; A Stojsic-Milosavljevic[1]; T Miljkovic[1]; M Bjelobrk[1]; D Grkovic[1]; B Radisic[1]; S Tadic[1]; M Stefanovic[1]; DJ Ilic[2]; J Papovic[3]; A Milovancev[3]
[1]*Institute of CVD Vojvodina, Sremska Kamenica, Serbia*; [2]*Clinical Center of Vojvodina, Department of Gynecology and Obstetrics, Novi Sad, Serbia*; [3]*Institute of pulmology Vojvodina, Sremska Kamenica, Serbia*

Background: It was well known that diastolic function changed during pregnancy complicated by hypertension. The data about systolic function in gestational hypertension (GH) are more contradictory. Purpose: The purpose of this study was to establish whether systolic function was also impaired in GH and to determine the reversibility of these changes after delivery.
Methods: This study included 90 pregnant women, 60 with GH (defined as blood pressure ≥140/90 mmHg that was appeared after 20th week of gestation and disappeared within six weeks postpartum) and 30 normotensives as control. All participants underwent a complete echocardiography that was used to assess diastolic function: the left ventricular (LV) filling index E/e', IVRT, E, A, E/A, DTE; systolic function: EF, IVCT, ET, stroke volume index (SVi), cardiac output index (COi), Vcf, longitudinal systolic velocity at septal and lateral mitral annulus: s's and s'l; and global cardiac function: Tei index. The echo was performed in the third trimester and 6 weeks after delivery. Results: Participants with GH had more impaired systolic and global LV function. Tei index was higher in women with GH (0,48 ± 0,06 vs 0,36 ± 0,02; $p < 0,0005$), also IVCT was longer (61,13 ± 9,88 vs 49,9 ± 6,04; $p < 0,0005$). Hypertensive women had lower EF (62,8 ± 2,79 vs 64,3 ± 1,83; $p = 0,002$), shorter ET (289,28 ± 14,42 vs 300,17 ± 16,15; $p = 0,002$), reduced s's (0,088 ± 0,009 vs 0,098 ± 0,014; $p = 0,001$) and s'l (0,09 ± 0,015 vs 0,11 ± 0,01; $p < 0,0005$). There weren't significant differences in Vcf, COi and SVi between groups. Diastolic function was also more impared in GH compared to normotensives with high statistically differences. IVRT was longer (78,15 ± 12,42 vs 60,07 ± 4,55; $p < 0,0005$), also as DTE (176,72 ± 23,45 vs 157,6 ± 18,44; $p < 0,0005$), E/e' was higher (8,0395 ± 1,3035 vs 7,151 ± 1,252; $p = 0,003$), while women with GH had reduced E/A ($p < 0,0005$). There weren't significant differences between groups in the following parameters after delivery: EF, longitudinal systoloc velocity, IVCT, ET, E/e' and DTE. Also all changed echocardiographic parameters became improved six weeks after delivery, the difference persisted in women who had GH compared to normotensives in IVRT (62,1 ± 4,54 vs 57,9 ± 2,92; $p < 0,0005$), Tei index (0,38 ± 0,02 vs 0,36 ± 0,02; $p < 0,0005$) and E/A ($p = 0,004$). Conclusions: Both systolic and diastolic function changed in gestational hypertension. After delivery differences still remained present in global and diastolic cardiac function, while in systolic function there wasn't significant differences between women with gestational hypertension and controls.

P1262

Association of subclinical left ventricular dysfunction in type-2 diabetic patients with nighttime blood pressure pattern

A Angelina Stevanovic[1]; M Dekleva[2]
[1]*Railway Health Care Institute, Belgrade, Serbia*; [2]*University Clinical Center Zvezdara, Department of Cardiology, Belgrade, Serbia*

The authors aimed to discover subclinical left ventricular (LV) dysfunction in diabetic patients, and estimate risk stratification of patients according to LV dysfunction and nocturnal blood pressure (BP) pattern.
Methods: A total of 109 asymptomatic normotensive diabetic patients were divided into two groups according of ambulatory BP pattern: group of dippers (n = 71) and group of non-dippers (n = 38). Conventional and Tissue Doppler (TDI) echocardiography as well as Global longitudinal strain (GLS) was performed in all patients. Comparisons between two study groups in clinical, laboratory and echocardiographic parameters were assessed. Follow up period for all patients was three years for adverse cardiac events.
Results: Value of GLS was significantly lower (-17,0 ± 2,55 vs -18,1 ± 1,56, $p = 0.009$) and ratio of early diastolic velocities from mitral inflow and from annular TDI (E/Em) significantly higher (11,2 ± 3,34 vs 9,4 ± 2,37; $p = 0.001$) in non-dipping group. Using the GLS cut-off value of -17% as index of LV systolic dysfunction in 29% of whole patients (32/109) decreased GLS values were found, even 45% in non-dippers (17/38) ($p < 0.001$). By multivatiate model analysis, peak GLS and E/Em were two independent predictors for cardiac outcome.
Conclusions: Subclinical LV systolic dysfunction in non-dipping group is significantly common than in dipping group. GLS is a powerful parameter in early detection of subclinical systolic dysfunction and stratification of patients at higher risk for the future cardiac events.

P1263

Left ventricular-arterial uncoupling is associated with early cardiac remodeling in patients with myocardial infarction treated with percutaneous coronary intervention

E Zharikova[1]; S Villevalde[1]; ZH Kobalava[1]
[1]*RUDN Univercity, Moscow, Russian Federation*

Objective: Left ventricular (LV) remodeling is the precursor to developing heart failure and an important prognostic factor after myocardial infarction (MI). The value of modern non-invasive indices of LV and arterial system function in contemporarily treated patients with MI is not established. The aim of the study was to determine the relationship of adverse remodeling with the left ventricular-arterial coupling (VAC) in patients with MI treated with percutaneous coronary intervention (PCI).
Methods: In 112 patients with MI (64 (57.2%) with STEMI) and PCI (68% male, age 61.1 ± 9.5 years (M ± SD), smokers 35%, diabetes 7%, arterial hypertension 83%) 2-dimentional echocardiography was performed to assess arterial elastance (Ea) and end-systolic LV elastance (Ees) on admission and in 4 weeks and 6 months. VAC was assessed as the ratio Ea/Ees. Cardiac adverse remodeling was defined by ratio [follow up - initial LV end diastolic volume (LVEDV)] / initial LVEDV more than 20%.

Results: Baseline LV ejection fraction (LVEF) was 48.2 ± 4.6%, Ea 1.7 ± 0.3 mmHg/ml/m2, Ees 2.1 ± 0.3 mmHg/ml/m2, VAC 0.88 ± 0.2. At baseline all patients had LVEF >40% and VAC in optimal (0.5-1.2) range. In 4 weeks after PCI VAC >1.2 was revealed in 24 (29%) patients (33% STEMI), adverse LV remodeling - in 12 (10%) patients, all of them with VAC >1.2. After 6 months VAC ≥1.2 was found in 67 (75%) patients (68.6% STEMI), adverse LV remodeling - in 81 (90%) patients (71.6% with VAC >1.2). Achieved VAC >1.2 was associated with adverse cardiac remodeling (odds ratio 6.16; 95% confidence interval 2.47-15.37; p < 0.0005). In patients with achieved VAC >1.2 Ees significantly decreased (from 1.9 ± 0.3 to 1.3 ± 0.2 mmHg/ml/m2, p < 0.001) and Ea significantly increased (1.7 ± 0.3 to 2.1 ± 0.5 mmHg/ml/m2, p < 0.001). Conclusions: In patients with MI treated with PCI impairment of functioning of cardio-vascular system assessed by increased value of VAC >1.2 was revealed 75% of patients in 6 months. Increase of VAC was associated with decrease of Ees and increase of Ea. Increased VAC index >1.2 indicating LV-arterial uncoupling may be considered as early marker of adverse LV remodeling.

P1264
Longitudinal and circumferential myocardial strain in patients with STEMI with various types of left ventricular remodeling

V Valentin Oleinikov[1]; V Galimskaya[1]; E Melnikova[1]; N Burko[1]
[1]Penza State University, Penza, Russian Federation

Aim: to explore the changes of global longitudinal and circumferential deformation of the heart at 6 months after STEMI by two-dimensional Strain in patients with various types of left ventricular (LV) remodeling.
Methods: The study included 53 subjects with STEMI (53,2 ± 9,7 years). Inclusion criteria were the absence of hemodynamically significant stenoses of the coronary arteries except the infarct-related, previous myocardial infarction and other cardiovascular diseases. Echocardiography was performed on the ultrasonic scanner MyLab 90 (Esaote, Italy) at 7 days and 6 months from the onset of the disease. Global longitudinal (GLS) and global circumferential strain (GCS) were determined using X-Strain ™ software. Among the traditional indicators the end-diastolic volume index (EDV index) was analyzed.
Results: According to the degree of LV dilatation at 6 months 2 groups of patients were allocated conditionally: group 1 (N=23; 43,4%) which was characterized by rapidly progressive remodeling with an increase of EDV index on 8% or more; Group 2 (N=30; 56,6%), without remodeling when EDV index increased less than 8% since STEMI. GLS initially in groups 1 and 2 had the value (-14,6) ± 8,4 and (-15,7) ± 4,7%; GCS - (-17,2) ± 8,6 and (-20,4) ± 8,3%. After 6 months, these values corresponded to GLS (-16,7) ± 6,5 and (-17,8) ± 5,1%, GCS - (-19,02) ± 8,3 and (-22 4) ± 6,7%. And GLS dynamics in groups 1 and 2 was 12.6 and 11,8%, respectively, GCS - 9,6 and 8,9%.
Conclusion: In groups of patients with STEMI rapidly progressive LV remodeling and absence of remodeling the global longitudinal and circumferential deformation does not have significant differences, and after 6 months of follow-up their values have not changed significantly.

P1265
Determination of minimal allowable hemoglobin level in patients undergoing CABG surgery

NA Beley[1]; OA Loskutov[1]; OM Druzhyna[1]; DO Loskutov[2]; BM Todurov[3]
[1]National Medical Academy of Postgraduate Education, Anesthesiology and Intensive Care, Kiev, Ukraine; *[2]National O.O. Bohomolets Medical University, Kiev, Ukraine*; *[3]Heart Institute of the Ministry of Healthcare of Ukraine, Kiev, Ukraine*

Background. The research proved that the reduction of gas transport function of the blood caused by low level of hemoglobin has a significant negative effect on myocardial contractility. But there is no clear minimal Hb level which would help to balance between myocardial contractility and blood gas transport function.
Purpose: Determination of the minimal level of Hb for providing functional myocardium state in accordance to oxygen transport blood function.
Methods: The explorations have been conducted on 72 patients who underwent isolated CABG with the imposition of three aorto-coronary grafts. The average age of the patients was 66,96 ± 1,81 years, average weight – 86,5 ± 1,44kg. In our study we took into consideration Hb, cardiac index (CI), contractility index (ΔS), left ventricular stroke work index (LVSWI), oxygen delivery index (ODO2). In order to calculate the minimum permissible level of Hb we used the method of least squares and linear programming. Unknown quantities were identified in the following manner: Hb - z, CI - x1, ΔS - x2, LVSWI - x3, IDO2 - x4.
Results: After the calculating of dependence z=a0 + a1x1 + a2x2 + a3x3 + a4x4 with the least squares method we obtained the next variables' coefficients: a0=9,250213; a1=0,2195560; a2=0,4048034; a3=0,1035031; a4=2,831839 10-3. Resulting equation was as follows: z=9,250213 + 0,2195560x1 + 0,4048034x2 + 0,1035031x3 + 2,831839 10-3x4. The coefficient of determination was d=R2=0,90012; correlation coefficient R=0,948747. The closeness of the correlation coefficient to 1 showed that the mathematical model shows the relationship between the parameters. For calculating minimal Hb level we used simplex method with the following limitations: x1≥3; x2≥32; x3≥27; x4≥400 for solving the linear programming task. As a result, the following figure of zmin=89,7583 was obtained.
Conclusions: To sum up, in observed group of patients, minimum allowed level of Hb is 90g/l providing myocardial contractility function needed for marinating normal systemic hemodynamics.

HYPERTENSION - LV HYPERTROPHY - RENAL DENERVATION

P1266
Orthostatic hypertension is associated with masked hypertension in the very elderly treated hypertensives

N Ezhova[1]; YV Kotovskaya[2]; SV Villevalde[2]; ZD Kobalava[2]
[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation; *[2]RUDN University , Moscow, Russian Federation*

Objective: Masked hypertension (MHT) and isolated nocturnal HT are associated with increased risk of target organ damage and cardiovascular events. We investigated prevalence and predictors of those blood pressure (BP) phenotypes in very elderly treated hypertensives. Methods. Office BP evaluation (simultaneous bilateral brachial BP measurement in supine position and then after 2 minutes of standing) and 24-h ambulatory BP monitoring (ABPM) were performed in 67 treated hypertensive subjects older than 80 years (age 84.1 ± 3.1 (M ± SD) years, 25.5% male, mean office brachial systolic BP 134.8 ± 23.2 mm Hg) with a validated oscillometric cuff-based device. Patients with left ventricular ejection fraction < 40% and severe comorbidities were not included. Orthostatic hypotension (OH) was defined as a decrease in systolic BP of at least 20 mm Hg upon standing and orthostatic hypertension (OHT) as a corresponding increase.
Results: The prevalence of MHT was 47.7 % in the entire study population and 71.1% among patients with office-controlled hypertension (BP < 150/90 mm Hg). 78.2% patients with MHT had isolated nocturnal HT. Orthostatic reaction was abnormal in 34.3% subjects: 22.4% had OH while incidence of OHT was 11.9%. OHT was significantly associated with MHT (odds ratio 1.7, 95% confidence interval 1.14-2.78).
Conclusion: OHT is predictive for MHT in the very elderly treated hypertensives. Evaluation of orthostatic reaction in very elderly may help to detect a population that would benefit from ABPM.

P1267
Gene polymorphism ABCB1 polymorphic marker C3435T, antihypertensive efficacy and safety of amlodipine in hypertensive patients

T Tatiana Morozova[1]; NV Shikh[1]; DA Sychev[2]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; *[2]Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation*

Purpose: To explore the relationship of polymorphism ABCB1 gene polymorphic marker C3435T, antihypertensive efficacy and safety of amlodipine in patients with arterial hypertension (AH) I-II degree.
Methods: 100 patients with hypertension I-II art. (M.- 36, w.- 64) between the ages of 47 to 73 years (av. age 53 ± 4 years) with various gene polymorphisms ABCB1 evaluated parameters efficacy and safety of amlodipine in a daily dose of 5 mg. Genotyping of polymorphic marker C3435T ABCB1 gene was performed by polymerase chain reaction. Antihypertensive efficacy is excellent at lowering blood pressure < 140/90 ; good - with a decrease in blood pressure of 10 mm Hg, but without achieving the target values.; satisfactory - with a decrease in blood pressure of 10 mm Hg; unsatisfactory - in the absence of blood pressure dynamics. Safety was assessed by the incidence of adverse drug reactions (ADR) according to the survey. The duration of observation - 3 months. Statistical processing was performed on the basis of IntelPentium 4 processors using package 'INSTAT' statistical programs.
Results: Excellent and good antihypertensive efficacy in patients with genotype TT polymorphic marker C3435T ABCB1 gene was 76.1%, SS - 47.1%, CT - 67.0%. Significant group differences in the Mann Whitney SSvsCT p = 0.06; CCvsTT p = 0.04; CTvsTT p = 0.5; ANOVA p = 0.04. According to the office BP measurement SBP decreased in patients with the CC genotype at 7,36 ± 2,9%, CT - on 9,07 ± 3,1%, the TC - on 8,40 ± 3,1%; DBP to 4,12 ± 1,2%; 5,46 ± 2,7% and 4,98 ± 2,4% respectively (p < 0.05 in all cases). ADR rate with genotype SS was 35.3%, CT - 6.7%, CT - 11.3%. On multivariate ANOVA analysis revealed significant differences CC and TT genotypes in the degree of decrease in SBP (p = 0.02), antihypertensive

efficacy parameter (p = 0.02), an increase in dose requirements (p = 0.04) and the incidence of ADR (p = 0.05).
Conclusions: Thus, in patients with genotype TT marked the highest efficiency of amlodipine on the background of the least amount arising ADR.

P1268

Renal sympathetic denervation improves LV filling pressures in patients with resistant hypertension and LV diastolic dysfunction

Funding Acknowledgements: This research is funded by the European Social Fund under the Global Grant measure (VP1-3.1-ŠMM-07-K-03-041).

Background: Renal sympathetic denervation (RSD) is a procedure aimed at treating resistant arterial hypertension (RAH) by ablating and thus lowering sympathetic activation of renal artery wall nerves. Current clinical trials are evaluating the potential effect of RSD on other diseases associated with an overactive sympathetic drive. It is known that abnormally activated sympathetic tone can alter diastolic function of the heart and worsen prognosis of heart failure patients. The aforementioned activation particularly increases during exercise. We performed the present study to examine RSD effect on diastolic function of the left ventricle (LV) during stress.
Purpose: To investigate the RSD effect on LV filling pressures during stress in patients with RAH and LV diastolic dysfunction.
Methods: Prospective study enrolled 15 patients with RAH (age 56 ± 7 years, 8 male, using 5.7 ± 1.2 antihypertensive drugs, mean 24-hour ambulatory blood pressure (BP): systolic 161.92 ± 16.78 mmHg, diastolic 99.25 ± 11.08 mmHg), who underwent bilateral RSD. All 15 patients had diastolic LV dysfunction (13 patients had impaired relaxation, 2 – pseudonormal diastolic function) and preserved systolic LV function, confirmed by echocardiography. LV filling pressures during stress were determined by performing exercise echocardiography at workload of 50 Watts and assessing indirect estimates of LV filling pressures: estimated pulmonary capillary wedge pressure (PCWP, mmHg) by Nagueh equation (1.24×(E/e'lateral) + 1.9) and the difference between the duration of pulmonary venous atrial reversal wave and the duration of the mitral valve A-wave (ARdur-Adur, ms) before and 6 months after the procedure. Continuous variables were checked for normal distribution by Shapiro-Wilk statistic. Normally distributed variables were compared by paired Student's t-test, while non-normally distributed variables were compared using the Wilcoxon signed rank test. A p value <0.05 was considered statistically significant. Data was analysed using SPSS v22 statistical package.
Results: Mean ambulatory BP decreased significantly 6 months after RSD: systolic BP decreased to 151.58 ± 20.32 mmHg (p = 0.039), diastolic BP to 91.75 ± 8.92 mmHg (p = 0.009). Peak stress systolic, diastolic BP and heart rate were 201.5 ± 25.5 and 198.7 ± 24.9 mmHg, 100.5 ± 14.5 and 102.7 ± 14.3 mmHg, 103.3 ± 13.4 and 104.5 ± 10.4 bpm at baseline and after 6 months, respectively (p>0.05 for comparison). Estimated PCWP reduced significantly at six months after the procedure (from 16.16 ± 4.17 to 12.19 ± 3.27 mmHg, p = 0.007), as well as ARdur-Adur (from 18.23 ± 25.78 to -9.62 ± 24.98 ms, p = 0.002).
Conclusions: In addition to lowering 24-hour ambulatory BP, our study revealed that renal sympathetic denervation reduces LV filling pressures during stress in patients with resistant arterial hypertension and LV diastolic dysfunction. This effect could be of benefit in halting the progression of heart failure in patients with resistant hypertension.

P1269

Fixed dose combination nebivolol/hydrochlorthiazide improve diastolic function in elderly hypertensives with heart failure with preserved ejection fraction and high pulse pressure

L Livia Popescu[1]; H Balan[1]
[1]*University of Medicine and Pharmacy Carol Davila , Bucharest, Romania*

BACKGROUND: Heart failure with preserved ejection fraction (HFpEF) is common, increasing in prevalence, and unfortunately, no disease-specific therapy exists to improve prognosis. Hypertension is worldwide spread and represents the leading cause of death and of HFpEF. High blood pressure is associated with left ventricular hypertrophy and diastolic dysfunction. Epidemiological evidence suggests increasing proportion of elderly people. Hypertension occurs in one half/two thirds of them. High pulse pressure is a marker of central arterial stiffness and a predictor for mortality. Old people are in high risk, have high pulse pressure and comorbidities. ESC/ISH guidelines suggest the use of fixed dose combination from the beginning in the therapy of hypertensives at high risk because fixed dose combination ensures a better and quicker therapeutic effect, a better compliance, with diminished adverse effects and simplification of therapy.
PURPOSE: The aim of our study was to evaluate the efficacy of the fixed dose combination nebivolol/hydrochlorthiazide 5/12.5 mg (N/H) on BP, pulse pressure, left ventricular hypertrophy and diastolic dysfunction in elderly hypertensives (over 65 years old) with HFpEF, and high pulse pressure.
Methods: We performed a prospective study, lasting 3 months, in which 56 never-treated elderly hypertensives, with high pulse pressure (≥ 60 mmHg), and HFpEF (EF ≥50%), medium age 72 ± 4.5 years, received once a day fixed combination N/H. The assessment of echocardiographic parameters of left ventricle was performed at baseline and after 3 months of treatment. Office blood pressure and pulse pressure ware monitored every month.
Results: Blood pressure was significantly reduced by treatment, both systolic (167.5 ± 22.5 vs 134 ± 11.5 mmHg, $p<0.01$) and diastolic (95 ± 10 vs 83 ± 12 mmHg, $p<0.01$). Pulse pressure decreased from 67 ± 15 mmHg to 58 ± 19 mmHg ($p<0.03$). LVMI decreased from137.5 ± 17 to 113.5 ± 14.3 g/m^2 ($p<0.001$). E/A ratio increased from 0.98 ± 0.05 to 1.19 ± 0.04 ($p<0.05$). Treatment was well tolerated.
Conclusions: Treatment with fixed dose combination nebivolol/hydrochlorthiazide in elderly hypertensives with HFpEF and high pulse pressure ensured a good control of BP, and already after 3 months, a regression of cardiac hypertrophy with improvement in LV diastolic function.

P1270

Effects of antihypertensive treatment on ventricular-arterial coupling in hypertensive patients

A Bogomaz[1]; Y Kotovskaya[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Objective: To evaluate left ventricular-arterial coupling in hypertensive patients after therapy with a beta-blocker and its fixed dose combination (FDC) with amlodipine.
Design and methods: 28 patients (age 53,9 ± 7,2 (M ± SD), 20 males, blood pressure (BP) 149 ± 13/97 ± 14 mmHg, heart rate (HR) 83 ± 10 bpm, abdominal obesity in 56%, dyslipidemia in 53%, smoking in 42%) with untreated uncomplicated hypertension underwent simultaneous echocardiography and BP measurement at baseline, after 4 weeks of bisoprolol 5-10 mg monotherapy and after 8 weeks after switching to bisoprolol 5-10/amlodipine 5-10 mg FDC. Doses were titrated to reach BP <140/90 mmHg. Arterial elastance (Ea) and LV elastance (Ees) at rest were calculated as end-systolic pressure (ESP)/stroke volume and ESP/end-systolic volume. Ventricular-arterial coupling (VAC) was assessed as Ea/Ees. VAC optimal range is considered as 0,5-1,2. Mechanical efficiency of left ventricle (ELV) and peripheral arterial resistance (PAR) were evaluated. $p<0,05$ was considered significant.
Results: After monotherapy with bisoprolol BP decreased to 146 ± 15/85 ± 11 mmHg (p>0,05 vs baseline), HR decreased to 60 ± 8 bpm ($p<0,05$ vs baseline), after FDC – to 132 ± 11/76 ± 11 mmHg and 65 ± 7 bpm, respectively ($p<0,05$ vs baseline). Bisoprolol decreased Ees from 4,45 ± 1,9 to 3,67 ± 0,98 mmHg/ml/m2 ($p<0,05$) whereas Ea (1,88 ± 0,39 vs 1,92 ± 0,38 mmHg/ml/m2), PAR (137,1 ± 35,3 vs 128,9 ± 36 dyn·s·cm−5) did not change significantly. Ea/Ees increased significantly from 0,47 ± 0,16 to 0,55 ± 0,14 ($p<0,05$). Switching to bisoprolol/amlodipine FDC resulted in decrease of Ea to 1,48 ± 0,17 mmHg/ml/m2, PAR – to 105,6 ± 28 dyn·s·cm−5. Ees did not change from that on bisoprolol. Ea/Ees returned to baseline values (0,45 ± 0,1). ELV did not change significantly throughout a study.
Conclusions: In untreated patients with uncomplicated arterial hypertension monotherapy with bisoprolol reduces initially increased Ees without negative effect on Ea and PAR. Switching to bisoprolol/amlodipine FDC results in additional Ea reduction. Thus the study confirms potential benefits of bisoprolol/amlodipine combination in arterial hypertension in terms of cardiovascular.

HFPEF - HEART FAILURE WITH PRESERVED EJECTION FRACTION

P1271

Another look at heart failure based on the study of ESPVR

R M Rachad M Shoucri[1]
[1]*Royal Military College of Canada, Mathematics and Computer Science, Kingston, Ontario, Canada*

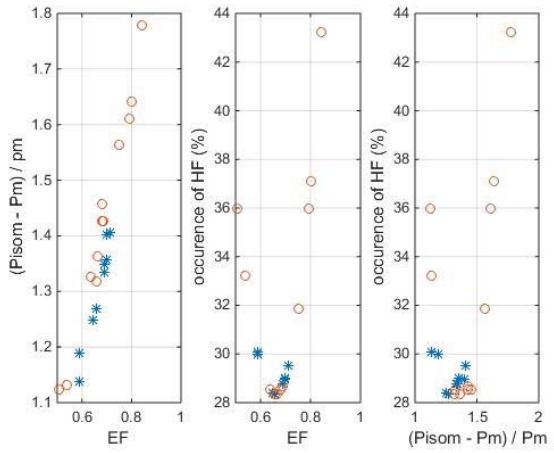
Background: Another look at the problem of heart failure with normal or preserved ejection fraction (HFpEF) was made possible by the study of new relations derived between the ejection fraction (EF) and the parameters describing a non-linear model of the end-systolic pressure-volume relation (ESPVR), the relation between ventricular pressure Pm and volume Vm when the myocardium reaches its maximum state of activation during contraction.

Purpose: A relation between percentage of heart failure (HF) and EF is extended to obtain other new relations between percentage of HF and indexes derived from the parameters of the non-linear ESPVR.
Methods: The approach used is based on the theory of large elastic deformation of the myocardium, the active pressure Pisom generated by the myocardium is included in the formula describing the ESPVR. Ratios of pressures can be calculated in a non-invasive way, which allows non-invasive clinical applications.
Results: Application to clinical data is shown in the Figure. From a relation between EF and the percentage occurrence of HF (Figure center), and between EF and the ratio (Pisom – Pm)/Pm (Figure left), the relation between percentage of HF and (Pisom – Pm)/Pm was derived (Figure right); data are for cases of aortic stenosis (o) and normal group (*). Notice the minimum of the curve of percentage of HF around the normal group for EF $\asymp$ 0.67 and (Pisom – Pm)/Pm $\asymp$ 1.3, while the cases of aortic stenosis appear more scattered into three subgroups in and around the normal group. Calculations indicate optimal value of SW/SWx $\asymp$ 0.8 (SW = stroke work, SWx = maximum stroke work), and optimal value of tang/eam $\asymp$ 4 (tang = slope of the tangent to the ESPVR, eam = max. arterial elastance). SWR = SWx – SW measures the stroke work reserve and TW is the total area under the ESPVR curve, the quantities SWR/SW $\asymp$ 0.25 and SW/TW $\asymp$ 0.5 were also calculated; estimated optimal values of some indexes (minimum of the percentage of HF curve) are summarized in the Table. These indexes can be used for classification of clinical groups into normal, mildly depressed and severely depressed state of the ventricle.
Conclusion: The EF is commonly used to assess the performance of the heart ventricles. Many indexes derived from the ESPVR can also be calculated in a non-invasive way and can be used for the same purpose. Bivariate (or multivariate) analysis of indexes is a better approach for studying HFpEF. The curve of the percentage of HF can easily be implemented for classification of clinical groups in a non-invasive way.

Estimated optimal value of some indexes

EF	$(P_{isom} - P_m)/P_m$	SW/SWx	SWR/SW	SW/TW	tang/eam
0.67	1.3	0.8	0.25	0.5	4

Symbols are defined in text.



EF, % of HF and (Pisom-Pm)/Pm relations

P1272
The association of cardiac autonomic neuropathy and left ventricular diastolic dysfunction. : from Korean women's chest pain registry (KoROSE)

MN Kim[1]; DH Cho[1]; HL Kim[2]; SM Park[1]; MS Shin[3]; MA Kim[2]; KS Hong[4]; KJ Shin[5]; WJ Shim[1]
[1]Korea University, Anam Hospital, Seoul, Korea Republic of; *[2]Boramae Hospital, Cardiology, Seoul, Korea Republic of*; *[3]Gachon University, Cardiology, Incheon, Korea Republic of*; *[4]Hallym University, Chuncheon, Korea Republic of*; *[5]Ewha University, Seoul, Korea Republic of*

On behalf of: KoRean wOmen'S chest pain rEgistry

Background: The clinical implications of cardiac autonomic neuropathy (CAN) had been repeatedly studied in patients of heart failure with reduced ejection fraction and diabetes mellitus. But the association between diastolic dysfunction (DD) and CAN has not been well investigated. The aim of this study is to evaluate the relation of CAN with DD in patients who presented with exertional dyspnea and chest tightness but had no significant coronary stenosis
Methods: 347 patients (F/M=268/81, 58.5 ± 10.5yrs) who had ≥50% of left ventricular ejection fraction and no significant coronary stenosis were included from KoRean wOmen'S chest pain rEgistry. Treadmill exercise test (TET) and transthoracic echocardiography were performed in all patients. The diastolic function was classified as normal, indeterminate and DD by 2016 ASE/EACVI guideline. Autonomic dysfunction was assessed by heart rate recovery (HRR1min: maximal heart rate - heart rate at 1minute after exercise) and blood pressure response (BPR3min: systolic blood pressure (SBP) at 3 minute after exercise / maximal SBP)
Results: Among 347 patients, DD was present in 21 patients (6%) and 52 patients (14.9%) were belonged to indeterminate group. The presences of diabetes and hypertension were more common in patients with DD (diabetes: 28.6% vs 7.7 % in indeterminate vs 8.8% in normal, P=0.03, and hypertension: 57.1% vs 55.8% in indeterminate vs 36.5% in normal, P=0.004 respectively). HRR1min was progressively disminished from normal, indeterminate and to DD group. BPR3min also progressively decreased from DD to normal group. (Figure1). During TET, exercise duration was lower in DD group than that of indeterminate and normals (6.54 ± 2.3 vs indeterminate: 8.23 ± 2.0 vs normal: 8.68 ± 2.3 minute, P < 0.001). There was significant relation between HRR1min and exercise duration (R=0.283, P < 0.001), but BPR3min was not (R=-0.46, P=0.428). HRR1min was independently related with DD after adjusting age, sex, hypertension, diabetes, body mass index by multivariate analysis (RR=0.93, 95% CI=0.88-0.99, P=0.02).
Conclusion: The patients with DD had impaired cardiac autonomic function. These association was irrelevant to age, diabetes, hypertension and was related with decreased exercise tolerance. It could be concluded that CAN may be one of contributors for developing and worsening symptoms of heart failure with preserved ejection fraction.

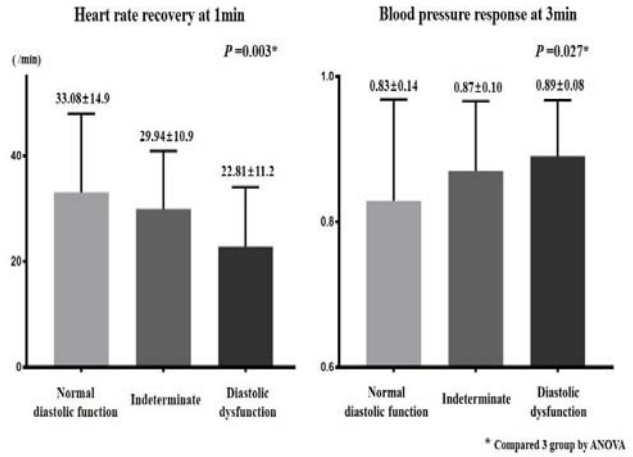


Figure 1

P1273
Effect of obesity on left ventricular longitudinal myocardial strain using speckle tracking echocardiography in patients with heart failure with preserved left ventricular ejection fraction

L Ljubica Georgievska-Ismail[1]; P Zafirovska[2]; Z Hristovski[3]
[1]University clinic of cardiology, Skopje, Macedonia The Former Yugoslav Republic of; *[2]Special Hospital for Surgical Diseases Filip II, Skopje, Macedonia The Former Yugoslav Republic of*; *[3]Acibadem Sistina Clinical Hospital, Skopje, Macedonia The Former Yugoslav Republic of*

Background. Obesity has been shown to be an important risk factor for the development of heart failure irrespective of the presence of other cardiovascular risk factors.
Purpose: The aim of this study was to determine the direct role of obesity in the subclinical impairment of left ventricular (LV) systolic function in patients with heart failure with preserved left ventricular ejection fraction (HFpEF).
Methods: We assessed myocardial systolic and diastolic function in 252 patients (62.2 ± 9.7 y; 39.7% men and 60.3% women) with unexplained dyspnea and/or exercise intolerance who fulfill clinical and/or echocardiographic criteria of HFpEF presence using 2D echocardiography and tissue Doppler imaging. Myocardial deformation was assessed using 2D speckle tracking software (STE). All the

patients were divided into three groups according to their body mass index (BMI): normal-weight patients (BMI < 25 kg/m2; n=28, 11.1%), overweight patients (BMI 25-29.9 kg/m2; n=110, 43.7%), and obese patients (BMI ≥ 30 kg/m2; n=113, 44.8%).
Results: Obese patients were significantly younger (p = 0.001), but despite higher percentage of hypertension, dyslipidaemia and/or diabetes there was lack of any significant difference in comparison to the overweight and those with normal BMI. We couldn't find more pronounced diastolic dysfunction in overweight/obese groups compared to the normal BMI group. However, patients who were obese showed significantly reduced global LV longitudinal strain (GLS) in comparison to those either overweight or with normal weight (-16.1 ± 4.3%;-17.9 ± 3.3%-18.9 ± 2.8%;p = 0.0001, respectively) as well as there was significant correlation between GLS and BMI (r=0.230, p = 0.0001). Multivariate regression analysis adjusted for age, hypertension and diabetes presence, showed a direct and independent effect of BMI on GLS (β= 0.311; 95%CI: 0.210-0.412; p = 0.0001).
Conclusion: Obesity is independently related to more pronounced subclinical LV systolic dysfunction expressed as reduced GLS in patients with HFpEF; thus may implicated increased risk and/or worse prognosis.

P1274
Quantitative assessment of myocardial stiffness using transthoracic shear wave imaging in healthy and hypertrophic cardiomyopathy adults

O Villemain[1]; M Correia[1]; E Mousseaux[2]; JEROME Baranger[1]; S Zarka[3]; I Podetti[1]; G Soulat[2]; T Damy[4]; M Tanter[1]; E Messas[3]; MATHIE Pernot[1]
[1]Waves and Acoustics Laboratory Institute Langevin, Paris, France; *[2]European Hospital Georges Pompidou, Radiology, Paris, France*; *[3]European Hospital Georges Pompidou, Cardiology, Paris, France*; *[4]University Hospital Henri Mondor, Cardiology, Creteil, France*

Objectives: Myocardial stiffness is an important prognostic and diagnostic parameter in heart failure. Up to now, there is no noninvasive tools for quantitative evaluation of this parameter. We introduced recently a new ultrasound based technique called Shear wave imaging (SWI) to quantitatively assess the intrinsic tissue stiffness. The goal of our study was to investigate the potential of Myocardial SWI to quantify non-invasively the diastolic myocardial stiffness (MS, kPa) in healthy adult volunteers (HV) and in hypertrophic cardiomyopathy populations with heart failure with preserved ejection function (HCM-HFpEF).
Methods: We included prospectively 80 adults: 60 HV (divided into three groups: 20-40 yo (n = 20); 40-60 yo (n = 20); 60-80 yo (n = 20)) and 20 HCM-HFpEF. An echocardiography, a cardiac magnetic resonance imaging (CMR) and a biological exploration were achieved in all the study population. The MS estimation was performed using an ultrafast ultrasound scanner with cardiac phased array, on the basal antero-septal segment during the end-diastole, in long and short axis views. Fractional anisotropy (FA) of shear wave speed was also estimated.
Results: For 20-40, 40-60, and 60-80 yo group respectively, the mean MS was 2.59 ± 0.58 kPa, 4.70 ± 0.88 kPa, 6.08 ± 1.06 kPa (p < 0.01 between each group). MS strongly correlated with age (r=0.88). For the HCM-HFpEF group (mean MS=12.68 ± 2.91 kPa), the MS was significantly higher than in the healthy volunteer (p < 10-4), with a cut-off identified at 8 kPa (AUC=0.993, Se=95%, Sp = 100%). The FA was lower in HCM-HFpEF (mean=0.170 ± 0.082) than in HV (0.289 ± 0.073), p < 0.01. Positive correlations were found between the MS and parameters in echocardiography (E/e', r=0.783; E/Vp, r=0.616; left atrial volume index, r=0.623) and CMR (late gadolinium enhancement, r=0.804).
Conclusion: Quantitative assessment of MS was shown feasible non-invasively in healthy and HCM-HFpEF adults using shear wave imaging. MS was found to increase with age in healthy population. A MS cut-off of 8 kPa was found to differentiate healthy and HCM-HFpEF patients. This new noninvasive parameter could help to better diagnose the diastolic function and its prognosis in clinical practice. (Non-Invasive Evaluation of Myocardial Stiffness by Elastography: NCT02537041)

P1275
Impact of changes in consensus diagnostic recommendations on the echocardiographic prevalence of diastolic dysfunction

O Huttin[1]; A Fraser[2]; S Coiro[3]; E Bozec[1]; C Selton-Suty[4]; Z Lamiral[1]; Z Frikha[1]; P Rossignol[1]; F Zannad[1]; N Girerd[1]
[1]INSERM, Centre d'Investigations Cliniques 9501, Université de Lorraine, CHU de Nancy, Institut Lorrain du cœur et des vaisseaux, Nancy, France and INI-CRCT F-CRIN Network, Vandoeuvre-les-Nancy, France; *[2]Cardiff University, Wales Heart Research Institute, Cardiff University, Cardiff, UK., Cardiff, United Kingdom*; *[3]University of Perugia, Division of Cardiology, University of Perugia, School of Medicine, S. Andrea delle fratte, Perugia, Perugia, Italy*; *[4]Hospital Brabois of Nancy, Department of Cardiology, Vandoeuvre les Nancy, France*

AIMS: Evaluation and scoring system for preclinical and symptomatic diastolic dysfunction are still under debate due to the lack of evidence-based grading systems. 2016 ASE/EACVI guidelines considerably changed the diastolic grading system. However, the impact of these changes on the prevalence and severity of diastolic dysfunction in healthy patients has not been studied.
Methods and Results: Participants from the community-based prospective STANISLAS Cohort France underwent 2-dimensional transthoracic echocardiography with comprehensive diastolic function evaluation. Patients without a history of heart failure and with LVEF >50% were classified according to the presence and degree of diastolic dysfunction following the 2016 ASE/EACVI guidelines scoring system and compared with previously published diastolic dysfunction evaluation systems. Of the 1485 study participants, (47 ± 14 years), 20 (1.3%) had diastolic dysfunction according to 2016 criterias, and the proportion of diastolic dysfunction significantly increased with higher age. The prevalence of diastolic dysfunction using previous guidelines were respectively of 8.8%, 5.7% and 5.9% according to Appleton definition, 2007 consensus statement and 2009 ASE/EACVI guidelines (when only considering 2 and 3rd grade of diastolic dysfunction). When considering the subset of participants aged >60, the proportion of diastolic dysfunction was 3.1% using the 2016 criterias vs 9.1%, 10.2% and 12.9% according to Appleton definition, 2007 consensus statement and 2009 ASE/EACVI guidelines.
Conclusion: The choice of published algorithms used for diastolic dysfunction identification has a wide impact on the proportion classified as having diastolic dysfunction. Outcome based studies might help identify a consistent, evidence-based and clinically useful definition of diastolic dysfunction in the future.

P1276
The value of combined cardiopulmonary end stress-echocardiography testing in discovering latent hfpef in patients with hypertension and normal LV systolic and diastolic function at rest

M Marko Banovic[1]; I Nedeljkovic[1]; J Stepanovic[1]; V Giga[1]; M Nedeljkovic[1]; M Petrovic[1]; N Dikic[1]; B Beleslin[1]
[1]University Institute for Cardiovascular Diseases, Belgrade, Serbia

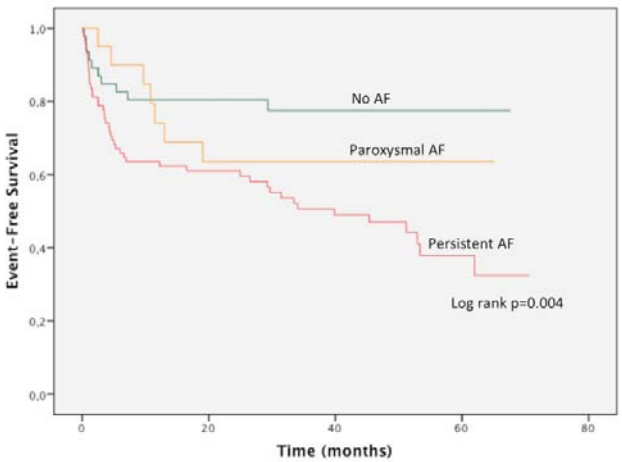
Background/Aim: Heart failure with preserved ejection fraction (HFpEF) is often associated with hypertension (HTA). Exercise stress-echocardiography (ESE) and cardiopulmonary exercise-testing (CPET) appear to be useful in assessment of HFpEF. The aim of our study was to assess the value of combined ESE-CPET in discovering exertional dyspnea and latent HFpEF in patients with HTA and normal LV systolic and diastolic function at rest
Method: 101 patients underwent combined ESE-CPET testing (supine bicycle, Ramp 15 protocol, 15W/min with 3min of unloaded pedalling). Echocardiography measurements were performed at rest and at peak load. The E/E' >15 at peak exercise was a marker for latent HFpEF. Expiratory gases were collected on breath by breath analysis and analysed by metabolic card (Schiller CS 200, Germany).
Results: The mean age was 55.9 years, 62 males (61.38%). There were no differences in echocardiographic parameters at rest (LVEF 68.1vs 65.7%, E/E' 6.01 vs 6.74, deceleration time 198.7vs 166.6, p = ns). Increase in E/E' > 15 during ESE-CPET occurred in 10 patients (9.9%). Those patients also had lower peak VO2 (14.67 vs 20.39; p = 0.005), lower workload (123 vs 159W, p = 0.01), and higher VE/VCO2 slope (35.25 vs 26.55, p < 0.001). Patients with Increase in E/E' > 15 during ESE-CPET were more often diabetic (50% vs 15.4%, p = 0.008).
Conclusion: Combined ESE-CPET testing is reliable and useful tool in discovering latent HFpEF in patients with HTA and normal LV systolic and diastolic function at rest.

P1277
Persistent atrial fibrillation in heart failure with preserved ejection fraction - Association with extracellular volume accumulation, invasive hemodynamics, and outcome

R Schoenbauer[1]; F Duca[2]; A Kammerlander[2]; S Aschauer[2]; C Binder[2]; C Zotter-Tufaro[2]; M Koschutnik[2]; L Fiedler[1]; FX Roithinger[1]; D Bondermann[2]; J Maschauerbauer[2]
[1]Landesklinikum Wiener Neustadt, Cardiology, Wiener Neustadt, Austria; *[2]Medical University of Vienna, AKH – Vienna, Cardiology Clinic, Vienna, Austria*

Background and Objectives: Heart failure with preserved ejection fraction (HFpEF) and atrial fibrillation (AF) frequently occur together. However, data on AF subtype and its association with comorbidities, extracellular volume (ECV) by cardiac magnetic resonance imaging (CMR), hemodynamics, and relation to outcome in HFpEF are sparse.
Methods: and Results: From 2011 to 2015 152 consecutive HFpEF patients were enrolled in our prospective observational registry. All patients underwent echocardiography, left and right heart catheterization (RHC), and CMR including T1 mapping with the modified Look-Locker inversion recovery (MOLLI) sequence.

Patients with significant coronary artery disease were excluded. 105 patients (69%) suffered from AF, 85 (56%) had persistent and 20 (13%) had paroxysmal AF. Patients with persistent AF were in worse New York Heart Association functional class (p = 0.006), and more often suffered from chronic obstructive pulmonary disease (p = 0.018) than patients with paroxysmal AF or sinus rhythm. They had higher levels of N-terminal pro-brain natriuretic peptide (NTproBNP) (p = < 0.001), and worse renal function (p = 0.041). Invasive hemodynamics showed higher right atrial pressures (p = 0.014) and pulmonary capillary wedge pressures (p = 0.050). Echocardiography revealed more pronounced atrial dilatation (p = < 0.001) as well as a more dilated right ventricles (p = 0.001) and higher systolic pulmonary artery pressures (p = 0.037). By CMR left and right atria as well as the right ventricle were more dilated (p = 0.001, 0.002, and 0.001, respectively) and left and right ventricular ejection fractions were lower in patients with persistent AF (p = 0.002, < 0.001 and 0.005 respectively). Furthermore, these patients had higher levels of ECV by T1 mapping (p = 0.018). After a median follow-up of 46 months (13-71) 63 patients (41%) reached the combined endpoint defined as hospitalization for HF and/or cardiovascular death. By multivariate Cox regression analysis only persistent AF (p = 0.039, HR 2.013, 95% CI 1.035-3.915) and six-minute walk distance (p = 0.013, HR 0.997, 95% CI 0.994-0.999) were independently associated with outcome.
Conclusion: More than 50% of HFpEF patients suffer from persistent AF. Persistent but not paroxysmal AF is significantly related with markers of disease severity, extracellular volume accumulation, and worse cardiovascular outcome.

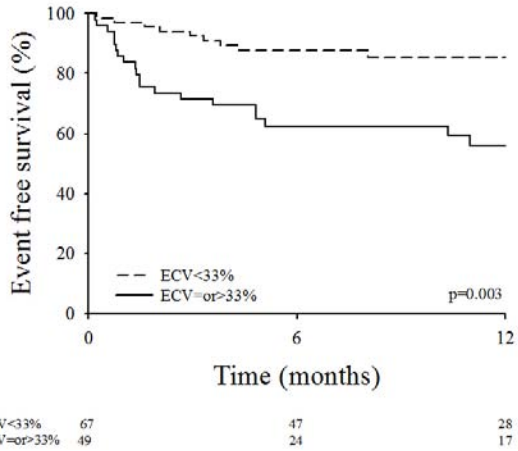


Kaplan-Meier plot, event-free survival

P1278
Prognostic significance of diffuse myocardial fibrosis evaluated by cMR in patients with heart failure with preserved ejection fraction.

C Clotilde Roy[1]; A Slimani[1]; C De Meester[1]; M Amzulescu[1]; A Pasquet[1]; D Vancraeynest[1]; C Beauloye[1]; J-L Vanoverschelde[1]; B Gerber[1]; A-C Pouleur[1]
[1]*Cliniques Saint-Luc UCL, Cardiology, Brussels, Belgium*

Background: Myocardial fibrosis is known as one of the potential pathophysiologic mechanisms in heart failure with preserved ejection fraction (HFpEF). The aim of this study was to evaluate the prognostic significance of diffuse fibrosis estimated by extra cellular volume (ECV) in HFpEF patients.
Methods: Between January 2015 and October 2016, we prospectively enrolled 118 consecutive patients with HFpEF (78 ± 8 years, 63% women) defined by ESC guidelines. Diffuse myocardial fibrosis was estimated by ECV quantified by 3 Tesla cMR with the Modified Look-Locker Inversion Recovery sequence. High level of diffuse fibrosis was determined by an ECV age- and sex-adjusted cutoff value (cutoff = 33%) corresponding to mean + 2 standard deviations in 26 age- and sex-matched volunteers (76 ± 5years, 65% women) without previous cardiac history. Patients were followed up for overall survival and a composite outcome of all-cause mortality and first HF hospitalization.
Results: Mean ECV value in HFpEF patients was 32.9 ± 4.8%. During a mean follow-up of 11 ± 6 months, we observed 43 events (11 all-cause deaths and 32 first HF hospitalizations). Cox analysis identified hemoglobin level (HR=0.62 [0.44-0.89], p = 0.009), ECV ≥33% (HR= 14.18 [1.78-112.7], p = 0.012) and BMI (HR= 0.86 [0.76-0.97], p = 0.015) as significant predictors of all-cause mortality.
Thirty eight patients (32%) reached the combined end point. Presence of diabetes (HR= 1.98 [1.04-3.76], p = 0.038) and hemoglobin (HR= 0.81 [0.67-0.98], p = 0.028) were significantly associated with the composite outcome even after adjusting for important clinical and imaging covariables. The ability of ECV≥33% to improve this model was then tested and added significant prognostic information (χ^2 4.457, p = 0.035). Kaplan Meier event free survival curves showed that HFpEF patients with ECV≥33% have poorer 1-year prognosis than those with ECV<33% (56 ± 8% vs 82 ± 5%, p = 0.001, Figure).
Conclusion: Among HFpEF patients, high level of fibrosis defined by ECV ≥33% was associated with all cause mortality and poor prognosis with higher rate of all cause death and first HF hospitalization, suggesting that the evaluation of diffuse myocardial fibrosis could be useful for the risk stratification. Besides, hemoglobin level was a strong predictor of short term composite outcome, as often demonstrated in HFrEF.



Event free survival in HFpEF patients

P1279
Sex specific differences in quality of life and diastolic function in HFpEF

U Ljung Faxen[1]; C Hage[1]; ED Donal[2]; CD Daubert[2]; C Linde[1]; LH Lund[1]
[1]*Karolinska Institutet, Department of Medicine, Stockholm, Sweden*; [2]*University Hospital of Rennes, Département de Cardiologi & CIC-IT U 804, Rennes, France*

Funding Acknowledgements: Société Française de Cardiologie, Medtronic Bakken Reseach Center, Swedish Research Council, Swedish Heart and Lung Foundation

INTRODUCTION: Heart failure with preserved ejection fraction (HFpEF) is relatively more common in women. However, sex differences within HFpEF remain poorly characterized.
PURPOSE and Methods: In the Karolinska-Rennes (KaRen) Study of HFpEF, we performed a comprehensive assessment of gender differences in clinical, biomarker, echocardiography, quality of life, therapy and prognostic data.
Results: Among 425 patients, 241 were women (57%). Women were older, median (IQR), 79 (73-84) vs. 77 (68-82) years, p = 0.011, had higher heart rate, 70 (60-70) vs. 65 (60-75), p = 0.027, and lower diastolic blood pressure (mmHg), 70 (63-80) vs. 75 (67-85), p = 0.011. NT-proBNP (ng/L) levels were similar, 1409 (509-2443) vs. 1376 (517-2802), p = 0.438. Prevalence of atrial fibrillation/flutter (AF) (62 vs. 64%), hypertension (80 vs. 79%), diabetes type 2 (DM2) (27 vs. 31%), history of myocardial infarction (12 vs. 18%) and stroke (10 vs. 12%), were similar; while coronary artery disease (CAD) was less common in women, 28% vs. 38% (p = 0.028). Despite similar New York Heart Association class, women rated lower quality of life (QoL) than men in ED-Q5, 50 (45-70 vs. 60 (50-75), p = 0.011. Female gender predicted ED-Q5D below 50 independent of age and NTproBNP, OR 1.90, 95% CI 1.08-3.35, p = 0.026. There was no difference in use of heart failure medication or diuretics. Ejection fraction was higher in women; median (IQR), 64 (57-68) compared to men, 62 (57-66), p = 0.020. Female gender was associated with diastolic dysfunction measured as E/e', OR 1.11 (95% CI 1,06 -1.17), p < 0.001 but not LAVI, nor E/A ratio. Over a median follow-up of 893 (515-1208) days, there was no difference in survival free from HF hospitalization (Figure 1) in univariable (HR 0.81, 95% CI 0.610-1,072, p = 0.140) or multivariable (HR 0.79, 95% CI 0.57-1.10, p = 0.159) analyses, adjusted for age, NTproBNP, eGFR, AF, DM2 and CAD.
Conclusion: In this un-selective HFpEF cohort, men and women were similar in most regards, including prognosis, with the notable distinction of worse quality of life and more pronounced diastolic dysfunction in women.

Gender differences in heart failure with preserved ejection fraction-insights from a prospective registry

F Franz Duca[1]; C Zotter-Tufaro[1]; AA Kammerlander[1]; S Aschauer[1]; C Binder[1]; B Koell[1]; J Mascherbauer[1]; D Bonderman[1]
[1]Medical University of Vienna, Cardiology, Vienna, Austria

Background: Approximately half of all heart failure (HF) patients present with a near normal ejection fraction (HFpEF). It is known that more women than men suffer from HFpEF, but studies investigating further gender differences in this disease are scarce.
Methods: Between December 2010 and November 2016, 260 consecutive patients with HFpEF were included in our study. Patients underwent clinical assessment including 6-minute walk test (6-MWT), left and right heart catheterization and spirometry. Study participants were prospectively followed for up to 48 months. The primary outcome was a composite endpoint of HF hospitalization or cardiac death.
Results: Median age of the total cohort was 73.0 years (IQR: 76.0 - 77.0), 181 (69.6%) were female, median NT-proBNP was 1169 pg/mL (IQR: 557 – 2072) and 170 (65.4%) study participants were in NYHA class ≥III. Men had lower percentages of their predicted 6-MWT distance (66.7% versus 78.1%, $p = 0.036$). With regards to co-morbidities, men had higher incidences of atrial fibrillation (69.6% versus 54.7%, $p = 0.024$), anemia (73.4% versus 60.8%, $p = 0.050$), sleep apnea (20.3% versus 5.0%, $p < 0.001$), COPD (46.8% versus 27.1%, $p = 0.002$) and smoking history (46.8% versus 27.1%, $p = 0.009$). No differences with respect to concomitant medication could be found. Among invasive hemodynamic parameters men had a higher diastolic pressure gradient (3.0 versus 1.0, $p = 0.010$). Amidst spirometry parameters men had lower forced expiratory volumes (65.0 versus 78.0, $p < 0.001$) and had more often a severely impaired diffusion capacity for carbon monoxide (3.8% versus 2.8%, $p = 0.028$). During a median follow-up of 17.0 months, 87 events occurred, of which 24 were cardiac deaths. Men had a worse event-free survival, both for the combined endpoint (Fig. 1A, $p = 0.031$) and cardiac death (Fig. 1B, $p = 0.011$). No difference could be detected for all-cause death (Fig. 1C, $p = 0.629$). Also, men were more likely to die from cardiac death as compared to women (16.5% versus 6.1%, $p = 0.008$) and less likely die from non-cardiac death (2.5% versus 10.5%, $p = 0.030$).
Conclusion: Among a well-characterized typical HFpEF study population we could detect several differences among clinical, hemodynamic and spirometry parameters between men and women. Additionally, we could show that men rather die from HFpEF as compared to women, who rather die with HFpEF.

Funding Acknowledgements: Funding the National Key Technology Support Program of china

Background Heart failure with preserved ejection fraction (HFpEF) is the dominant form of heart failure in the older population.
PURPOSE: To summarize the cardiac pathological features of elderly HFpEF patients , analyze pathological changes associated with coronary heart disease (CHD) and coronary artery lesion characteristics by autopsy, and evaluate the differences between clinical diagnosis and pathological diagnosis.
Methods: We retrospectively analyzed 1485 patients'autopsy reports from April 1969 to October 2013. Each autopsy was approved by signing the consent forms by relatives of the deceased. 154 elderly patients aged from 60 to 99 years old were diagnosed HFpEF. The diagnostic criteria of HFpEF were: 1) Clinical history of previous hospital discharge diagnosis included heart failure or last hospitalization were diagnosed with heart failure; 2) the last echocardiography at the end of patients' lifetime indicated that LVEF≥50%.. All P values < 0.05 were accepted as statistically significant.
Results: Among 154 elderly patients with HFpEF aged from 60 to 99 years old, there were 142 male(92.2%) and 12 female(7.8%) with mean age of 85.7 ± 7.4 years old. According to pathological criteria, the incidence of CHD among HFpEF cases was 68.2% (105/154), incidence of AMI was 12.3% (19/154), incidence of OMI was 50.6% (78/154), incidence of chronic myocardial ischemia was 18.2% (28/154) (Figure 1). Grade III and more severe stenosis of left anterior descending branch were very common, reaching 51.9%(Figure 1).Clinical diagnosis of CHD were 81.8%(126/154) among HFpEF patients, missed diagnosis rate of CHD was 9.5% and misdiagnosis rate was 63.3%. Missed diagnosis rates of AMI and OMI were 57.9%, 57.7% respectively, misdiagnosis rates were 10.4% and 23.7% respectively.(Table1)
Conclusions: The incidence of CHD was high in the elderly patients with HFpEF and severe stenosis of anterior descending branch was common. Misdiagnosis rate of CHD in HFpEF was high and missed diagnosis rates of AMI and OMI were high. Further coronary artery evaluation should be emphasized in elderly patients with HFpEF.

Differences between clinical and autopsy

Differences between clinical diagnosis and pathological diagnosis in HFpEF with CHD

	Both clinical diagnosed and pathological diagnosed	missed diagnosis (%)	misdiagnosis (%)	diagnosed neither by autopsy nor clinical
CHD	95	109.5%	3163.3%	18
AMI	8	1157.9%	1410.4%	121
OMI	33	4557.7%	1823.7%	58

P1282

Sex differences in long-term health status in heart failure with preserved ejection fraction

K Kelsey Flint[1]; M Merrill[1]; D Kao[1]
[1]*University of Colorado, Cardiology, Aurora, United States of America*

Background: Little is known about sex differences in health status over time in heart failure with preserved ejection fraction (HFpEF).
Purpose: 1. Describe longitudinal sex-specific patterns of global- and heart failure-specific health status 2. Identify factors associated with reduced health status in women with HFpEF.
Methods: Data source: TOPCAT trial. Health status was measured at 0 and 12 months. Health status measures were Kansas City Cardiomyopathy Questionnaire (heart failure-specific; KCCQ) and visual analog scale (global; VAS). Analysis was restricted to Americas due to very low event rates in Russia/Georgia.
Results: Compared to men, women with HFpEF were older, and had more non-cardiac comorbidities. Men had more CV risk factors and CV disease. Overall comorbidity burden was similar (Table). KCCQ was moderately reduced in women compared to men at each time point (Figure) despite a greater increase in KCCQ in women over time. VAS did not differ by sex at any time point. The relationship between sex and 12-month KCCQ was attenuated ($p = 0.543$) when controlling for BMI ($p < 0.001$), depression ($p < 0.001$) and eGFR ($p < 0.001$).
Conclusion: Women with HFpEF have worse KCCQ but not VAS scores. Further study is needed to evaluate the relationship between health status and obesity, depression, and renal function in women with HFpEF.

P1283

Determinants of heart failure in patients with arterial hypertension and type 2 diabetes mellitus

A Vintila[1]; M Dobrovie[2]; D Vasiliu[2]; C Tudorica[2]; V Vintila[3]
[1]*University of Medicine and Pharmacy Carol Davila, Coltea Clinical Hospital, Internal Medicine and Cardiology, Bucharest, Romania*; [2]*Coltea Clinical Hospital, Bucharest, Romania*; [3]*University of Medicine and Pharmacy Carol Davila, University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania*

Background: The association between arterial hypertension and type 2 diabetes mellitus is frequent and determines synergistic alterations in myocardial properties. This leads to subclinical cardiac remodeling, which may evolve into heart failure, worsening the prognosis of these patients.
Purpose: We aimed to investigate the prevalence of heart failure and factors correlated to its development in a cohort of hypertensive patients with type 2 diabetes mellitus.
Methods: We evaluated 60 consecutive patients with arterial hypertension and type 2 diabetes mellitus, mean age 68± 9 years, hospitalized for hypertension related problems. We recorded demographic data, clinical characteristics, resting ECG and transthoracic echocardiography with Tissue Doppler imaging at the level of the lateral and septal mitral annulus. Blood tests have been performed as clinically indicated.
Results: Heart failure was diagnosed in 28 out of 60 patients (46.7%). 18 patients (64.3%) were in NYHA class III, while 10 (35.7%) were in NYHA class II. Left ventricular ejection fraction was preserved in 19 out of 28 patients with heart failure (67.9%). Presence of heart failure was correlated with age ($r = 0.373$, $p < 0.001$), diagnosis of atrial fibrillation ($r = 0.420$, $p = 0.001$), left atrial diameter ($r = 0.506$, $p < 0.001$) and volume ($r = 0.526$, $p < 0.001$), right atrial diameter ($r = 0.466$, $p < 0.001$), right ventricular diameter ($r = 0.307$, $p = 0.017$), E/E' ratio ($r = 0.391$, $p = 0.004$), lateral MAPSE ($r = -0.478$, $p < 0.001$), septal MAPSE ($r = -0.461$, $p = 0.001$), TAPSE ($r = -0.502$, $p < 0.001$) and myocardial systolic velocities at the level of the lateral

mitral annulus (r = -0.302, p = 0.032) and septal mitral annulus (r = -0.362, p = 0.013). It was also correlated with glomerular filtration rate estimated by MDRD formula (r = -0.425, p = 0.001), plasma HDL-cholesterol (r = -0.285, p = 0.033), thrombocyte count (r = -0.269, p = 0.037) and mean platelet volume (r = 0.277, p = 0.032). Using stepwise linear regression, we computed a model for prediction of heart failure, with 3 independent predictors: left atrial diameter, plasma HDL-C level and mean platelet volume (R2 = 0.866, p < 0.001).
Conclusions: Development of heart failure is frequent in patients with arterial hypertension and type 2 diabetes mellitus. Left ventricular ejection fraction is preserved in the majority of patients. Prediction of heart failure in this population could be realized based on three independent predictors: left atrial diameter, plasma HDL-cholesterol level and mean platelet volume.

P1284
Hypertensive left ventricular hypertrophy is a risk factor for the development of a HFPEF but not a depressed left ventricular ejection fraction within eight years

AG Artem Ovchinnikov[1]; MV Ojerelyeva[1]; FT Ageev[1]
[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation

Background. Hypertensive heart disease is a major cause of the development of heart failure with preserved ejection fraction (HFPEF). However, rate and determinants of the transition from asymptomatic left ventricular hypertrophy (LVH) to HFPEF and whether LVH is a common precursor to depressed LVEF is poorly understood.
Purpose: to determine rate and predictors of the transition from asymptomatic hypertensive LVH to HFPEF and whether LVH is a risk factor for the development of a reduced LVEF.
METHODS AND RESULTS. From 2002 through 2010, 350 patients at our Out-Patient Department underwent echocardiography and had asymptomatic hypertensive concentric LVH and normal LVEF. Of these, 223 had a follow-up clinical and echocardiographic assessment by March 2016. The primary outcomes were the development of HFPEF or depressed LVEF. After a median follow-up of 8.1 years, the most of patients with asymptomatic concentric LVH (161, or 72%) developed HFPEF. Transition from asymptomatic LVH to HFPEF was associated with deterioration of LV diastolic dysfunction (DD): increase of DD grade occurred in 51% patients, and an increase of DD grade provided 100% sensitivity for predicting HFPEF. Multivariable analysis identified three independent predictors of the development of HFPEF namely, an old age, an increase of LV mass index >10% during follow-up, and an absence of taking of statins (P < 0.05 for all). Yet, 34 (15%) patients developed low LVEF, but only in 16 of them (7% of whole group) it occurred without interval myocardial infarction (MI). All these 16 patients had only mild systolic dysfunction (LVEF >40%) and all but only one patient had concentric LVH. Independent predictors of the development of low LVEF by this 'internal' mechanism were chronic atrial fibrillation and high mass body index (P < 0.05 for both).
Conclusions: In hypertensive heart disease, the transition from asymptomatic LVH to HFPEF was very frequent (72%) after long-term follow-up, and was related to deterioration of LVDD and an absence of taking of statins. The transition from a normal LVEF to a low LVEF, however, was infrequent (7%) in the absence of interval MI and did not result in a change in the LV geometry from a concentric to an eccentric phenotype.

P1285
Exercise hemodynamics and 6 minute walk distance in patients with HFpEF: importance of workload corrected pulmonary capillary wedge pressure

E Wolsk[1]; D Kaye[2]; BA Borlaug[3]; D Burkhoff[4]; DW Kitzman[5]; J Komtebedde[6]; CSP Lam[7]; P Ponikowski[8]; SJ Shah[9]; F Gustafsson[1]
[1]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark; *[2]Baker IDI Heart and Diabetes Institute, Melbourne, Australia*; *[3]Mayo Clinic, Rochester, United States of America*; *[4]Cardiovascular Research Foundation, New York, United States of America*; *[5]Wake Forest University, Winston-Salem, United States of America*; *[6]Corvia Medical, Inc, Boston, United States of America*; *[7]Duke-NUS Graduate Medical School Singapore, Singapore, Singapore*; *[8]Military Hospital of Wroclaw, Wroclaw, Poland*; *[9]Northwestern University, Chicago, United States of America*

BACKGROUND: Patients with heart failure (HF) and preserved ejection fraction (HFpEF) are characterized by an abnormal hemodynamic response to exercise and varying degrees of functional impairment. The 6-minute walk test (6MWT) serves as a standardized test for functional capacity quantification in HF patients, and is associated with cardiovascular outcomes. However, the association between 6MWT and hemodynamic parameters at rest and during exercise in HFpEF patients is unknown.
Objective: Identify invasive hemodynamic variables at rest, light to moderate exercise, and peak exercise associated with 6MWT in patients with HFpEF.
Methods: We studied 64 patients enrolled in the REDUCE LAP-HF trial who completed a 6-minute walk test (6MWT) at baseline and cardiac catheterization with measurement of hemodynamic variables at baseline, light to moderate exercise (20 W), and at peak supine exercise. Univariate linear regression models were used to assess the associations between 6MWT and measured or derived hemodynamic variables at baseline, light to moderate exercise (20 W), and at peak supine exercise. Variables were added to multivariable models with stepwise forward selection (p < 0.1).
Results: The average 6MWT distance was 318 ± 106 meters. At rest, only pulmonary capillary wedge pressure (PCWP) was associated with 6MWT (p = 0.033) in a multivariable model. During light to moderate exercise, mean pulmonary artery pressure (mPAP) was associated with 6MWT in a multivariable model (p = 0.033). During peak exercise, central venous pressure (CVP), cardiac index (CI), and PCWP/CI correlated with 6MWT, however the workload corrected PCWP (PCWL) was the only variable independently associated with 6MWT (Figure; r=-0.42, p < 0.001, multivariable, p = 0.002). Changes in CI and mPAP from baseline to peak exercise were associated with 6MWT after multivariable adjustment (p = 0.0027 and p = 0.052, respectively).
Conclusion: Workload corrected PCWP correlated best with 6MWT performance. While non-cardiac factors clearly play a role in determining 6MWT distance, this study suggests that workload corrected PCWP could be an important target for intervention when aiming at improving functional capacity in HFpEF.

Gender differences in left ventricular remodeling features in patients with stent restenosis following primary percutaneous coronary intervention

N Nino Sharashidze[1]; B Tsinamdzgvrishvili[1]; G Saatashvili[1]; N Mamamtavrishvili[1]; R Abashidze[1]; D Trapaidze[1]; N Chanturidze[1]; A Kordzadze[1]; Z Gachava[1]
[1]Iv.Javakhishvili Tbilisi State University, Tbilisi, Georgia Republic of

We aimed to compare Left Ventricular (LV) remodeling and function between genders in patients with in stent re-stenosis who underwent primary percutaneous intervention (PCI) due to acute coronary syndromes (ACS).
Methods: Patients who developed in stent re-stenosis during 12 months after PCI due to acute coronary syndromes were studied. Study subject (total number 70) were included in groups according gender (52 males and 18 females). Gender differences in rate of LV hypertrophy (LVH), systolic and diastolic dysfunction and Heart Failure (by Killip I-III and chronic HF II-III by NYHA). LV remodeling and function were assessed using ultrasound-Doppler modality. Statistics: Student T –test, Fisher's exact test and regression analysis were performed.
Results: rate of LVH was 0.50 in women and 0.46 in men (P=0.79). Rate of reduced EF (< 40%) was 0.38 in women and 0.17 in men (P=0.06). Diastolic dysfunction rate measured by mitral flow velocities was 0.44 and 0.28 in females and males respectively (P=0.21). Rate of heart failure in acute settings I-III by Killip was found in women and men 0.11 and 0.14 respectively (P=0.73).Rate of Chronic HF II-III by NYHA was

0.50 in females and 0.21 in males (P= 0.019.)Regression analysis showed association of chronic HF with stent re-stenosis in women OR 3.67 (95% CI 1.19-11.27).
Conclusions: Differences in rates of LVH, reduced EF, diastolic dysfunction and HF in acute settings did not differ significantly between female and male patients who developed in stent re-stenosis after primary PCI due to ACS. However, statistically significant difference was revealed by prevalence of chronic HF between genders and association of chronic HF with in stent re-stenosis in women was found.

P1287
Hepatitis-c virus infection is a risk factor for coronary artery disease in egypt

A M Abdelmohsen Moustafa Abdou Aboualia[1]; MO Kayed[1]; MS Rehan[1]; M Abood[2]; M Attia Mohamed[3]
[1]Al-Azhar University, cardiology department, cairo, Egypt; *[2]Al-Azhar University, Radiology department, Cairo, Egypt*; *[3]Al-Azhar University, clinical pathology, Cairo, Egypt*

Aim of the work: is to study the presence of atherosclerotic coronary artery disease in patients with chronic hepatitis C virus infection.
Patients and methods: This study included two main groups of patients with symptomatic ischemic heart disease (according to HCV serology), presented as Acute coronary syndrome or for elective or emergent coronary angiography : Group 1: 100 HCV seropositive patients as a test group and group 2: 32 HCV seronegative patients as a control group. All patients were studied along the following scheme: informed consent, full history taking, complete physical examination, full routine labs, HCV rapid test, resting twelve lead ECG, transthoracic echocardiography, pelvi-abdominal ultrasound and coronary angiography.
Results: the two groups were matched in age after exclusion of diabetes, hypertension, chronic renal diseases, clinical liver cirrhosis and history of ischemic heart disease. There was male predominance in group I with statistical significance. In this study 99% of patients with HCV seropositive had abnormal coronary angiography while 65.6% of HCV seronegative had abnormal coronary angiography and this difference showed statistical significance (< 0.001). The number of the affected vessels was higher in HCV seropositive than seronegative groups (1 vessel disease (49% versus 56.3%, 2 vessel disease 25% versus 6.3% and multivessel 25% versus 3.1% in HCV seropositive and seronegative respectively) with $p < 0.001$. LM was present in 5 patients in group I and no patient in group II. In this study univariate logistic regression analysis the predictors of coronary artery disease were sex ($P < 0.0001$), smoking ($P = 0.037$) and HCV seropositivity ($P = 0.041$). Also in multivariate logistic regression analysis the predictors of coronary artery disease were smoking ($P = 0.011$) then HCV seropositivity ($P = 0.032$) and lastly age ($p = 0.40$).
Conclusion: Hepatitis C virus is a risk factor for coronary artery disease and associated with increased angiographic burden of coronary artery disease in patients with HCV seropositivity.

P1288
34 minutes is the mean door to needle time in Egyptian patients with first attack of STEMI who showed myocardial recovery after receiving thrombolytic therapy

A Ahmed Al-Habbaa[1]; M El-Abbady[1]; M Mostafa[1]; ABD Shereidah[1]; W Attia[1]
[1]Al-Azhar University, Department of Cardiology, Cairo, Egypt

Objectives: We aimed to assess the time table of patient care who presented with acute first attack of STEMI.
Patients and methods: The study included 42 patients with first attack of STEMI admitted to our CCU unit who showed symptoms and signs of successful reperfusion after pharmacological thrombolytic therapy, the patients were classified into two groups; group I included 28 patients with with improvement of RWMA score, group II included 14 patients without improvement of RWMA score. All patients had been subjected to the following: informed consent, personal, demographic data collection, time table from ER entrance till beginning of thrombolytic therapy, reperfusion therapy by streptokinase I.V., baseline conventional transthoracic echocardiography evaluation, 2D speckle tracking echocardiographic study within 72 hours after the successful reperfusion, medical follow-up for 3 months and follow-up conventional transthoracic echocardiography for RWMA score assessment.
Results: The baseline clinical characteristics were matched in both groups. Group I who showed myocardial recovery had mean door to needle time of 34.28 ± 7.9 minutes while group II who showed no myocardial recovery had a mean door to needle time of 51.42 ± 17.3 minutes.
Conclusion: The shorter the door to needle time the more was the recovery of myocardial function in patients with first attack of STEMI. We are getting more to the ideal door to needle time of 30 minutes, as we still have thrombolytic therapy as the wide used option in Egypt.

P1289
Primary coronary percutaneous intervention in diabetic versus nondiabetic patients. Outcome and follow-up. independent predictors of survival and event free survival

I P Ivana Picone Borges[1]; ECS Peixoto[1]; RTS Peixoto[1]; RTS Peixoto[1]; ILPB Anjos[2]; VF Marcolla[1]; AAB Aragao[1]
[1]Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil; *[2]Severino Sombra University, School of Medicine, Rio de Janeiro, Brazil*

Background: Some studies showed that diabetic patients (D) group (DG) had a worse outcome when compared to nondiabetic (ND) patients group (NDG), after primary percutaneous coronary intervention (PCI).
Objectives: to compare mortality and major coronary events (MACE) at 30 days and 1 year of DG and NDG submitted to primary PCI and to study whether another conditions were related to worst outcome of patients in 30 days or one year.
Methods: Prospective study with 450 consecutive patients submitted to PCI from 01/01/2001 to 12/31/2006 (121 D and 329 ND) with ST-segment elevation acute myocardial infarction (AMI) in the first 12 hours of symptoms presentation treated with balloon catheter or bare metal stent and without cardiogenic shock. We used in statistical analysis: Student t test, chi-square test, Fischer exact test, and multivariate analysis: logistic regression and Cox analysis.
Results: DG and NDG had similar age (63.1 ± 10.0 and 62.3 ± 11.7 years, $p = 0.443$), male gender (63.6% and 69.9%, $p = 0.205$) and multivascular disease (66.1% and 60.8%, $p = 0.301$). The diabetic group had more dyslipidemia (65.3% x 51.7%, $p = 0.009$) and severe left ventricular dysfunction (15.7% x 8.2%, $p = 0.019$). The stent implantation rate was (83.5% and 81.1%, $p = 0.863$) and glycoprotein (GP) IIb/IIIa inhibitors utilization (79.3% and 82.2%, $p = 0.831$) were similar. The mortality at 30 days (2.5% and 2.7%, $p = 1.000$) and at 1 year (5.0% and 6.7%, $p = 0,650$) and MACE at 30 days (4.1% and 6.4%, $p = 0,496$) and at 1 year (19.4% and 15.4%, $p = 0,3492$) were similar. The absence of TIMI III flow after the procedure (procedure failure) was the only independent hospital mortality (30 days) predictor ($P < 0,001$, OR=8,045, CI95 2,327-27,816). Procedure failure ($p = 0,023$, HR=3,364, CI95 1,182-9,578) and age $\geq$ 65 years (P=0,035, HR=3,391, CI95 1,091-10,543) were independent predictors of mortality at 1 year. The multivessel coronary disease ($p = 0,023$, OR=4,218, CI95 1,223-14,545 and procedure failure ($P < 0,028$, OR 3.155, CI95 1,132-8,799) were independent predictors of MACE at 30 days and multivessel coronary disease was independent of MACE at 1 year ($p = 0.034$, HR=1.854, CI95 1.048-3.280).
Conclusion: The diabetic patients submitted to primary PCI had mortality rate and MACE similar to none diabetic patients at 30 days and 1 year. The absence of TIMI III flow were predictor of mortality at 30 days and 1 year and age $\geq$ 65 years at 1 year. Independent predictors of MACE at 30 days were multivessel coronary disease and absence of TIMI III flow (procedure failure) and at 1 year was multivessel coronary disease

One-step or two-step myocardial revascularisation in patients with ACS without ST-segment elevation with multivessel coronary artery disease

Z Shugushev[1]; D A Maximkin[1]; T Chernigina[1]; R Goloshchapo-Aksenov[1]; A Faibushevich[1]; N Sturov[1]; R Bachoo[1]; A Nikitin[2]
[1]RUDN University, Moscow, Russian Federation; [2]Central Clinical Hospital Russian Academy of Science, Moscow, Russian Federation

Aims: to evaluate the results of endovascular treatment of patients with acute coronary syndrome without ST-segment elevation with multivessel coronary artery disease.
Methods: AND RESULTS: 346 patients were enrolled in the study and initially randomized into 3 groups. Group 1 included 100 patients in whom complete myocardial revascularization was performed during initial PCI. Group 2 consisted of 124 patients, in whom complete myocardial revascularization was performed during initial hospitalization and group 3 included 122 patients in which complete revascularization was performed at different periods after the initial hospitalization. Criteria: patients with ACS without ST-segment elevation with multi-vessel coronary artery lesion (SYNTAX score=23-32); high and medium risk on GRACE scale; no history of myocardial revascularization. Long-term results were assessed in 192 patients. After 12 months in patients of group 3 had significantly more often cardiovascular complications and re-intervention on the target vessel was needed. It was revealed that the implementation of complete myocardial revascularization later than 30 days from a day of diagnosed acute coronary syndrome, adversely affects the prognosis of the disease (r=0,58, p < 0,05). Risk factors that adversely affect the prognosis of patients with ACS without ST-segment elevation with multi-vessel coronary artery lesion include: Subtotal stenosis in asymptomatic arteries, circulatory insufficiency- Killip class III, history of myocardial infarction, high risk on the GRACE scale, the extent of lesions in the asymptomatic arteries more than 20mm, diabetes, the degree of risk on a SYNTAX scale score>25, overweight/obesity and hypercholesterolemia>6.5 mmol/L.
Conclusions: when performing PCI in patients with ACS without ST-segment elevation with multi-vessel coronary bed lesion, the implementation of complete myocardial revascularization later than 30 days from a day of diagnosed acute coronary syndrome, adversely affects the prognosis of the disease.

Incidence, timing, predictors and impact of acute heart failure complicating an acute coronary syndrome

PM Pedro Azevedo[1]; J Bispo[1]; D Carvalho[1]; D Bento[1]; T Mota[1]; J Guedes[1]; S Pereira[1]; W Santos[1]; J Mimoso[1]; N Marques[1]; P Gago[1]; I Jesus[1]
[1]Faro Hospital, Cardiology, Faro, Portugal

Introduction: Acute heart failure (AHF) is a common complication of an acute coronary syndrome (ACS), resulting in higher costs of treatment and poor prognosis. This study pretends to evaluate the incidence, timing, predictors and impact of AHF in a population with an ACS.
Methods: Retrospective, descriptive and correlational study with all patients admitted with an ACS in a Cardiology department between the 1st of October 2010 and 31st of August 2015. Patients with AHF (Killip Class > 1) were compared to patients without AHF, and between patients with AHF at presentation and those who developed in-hospital AHF. The 1-year follow-up was made through phone call by a Cardiologist. We performed a univariate and multivariate statistical analysis of in-hospital mortality, mortality and hospitalization rate at 1-year using SPSS.
Results: 3319 patients with an ACS were included, 2465 (74,3%) men with a mean age of 65,8 ± 13 years. There were 1478 (44,5%) patients with an ST-segment elevation myocardial infarction (STEMI), 1607 (48,4%) with NSTEMI, 116 (3,5%) with unstable angina and 118 (3,6%) had acute MI of unknown location.
AHF was observed in 495 (14,9%) patients. 352 (10,6%) had AHF at admission and 143 (4,3%) only developed AHF in the hospital. AHF was significantly associated with age, female sex, non-smokers, hypertension, diabetes, and several other comorbidities. AHF was also associated with STEMI, anterior wall myocardial infarction, atrial fibrillation and dyspnea on admission.
Patients with AHF had higher heart rate at admission (86,8 vs74,9 bpm, p < 0,01), lower systolic blood pressure (129 vs 141 mmHg, p < 0,01), lower left ventricular ejection fraction (LVEF) (44,9% vs 59,1%, p < 0,01), less coronary catheterization (53,9% vs 78,9%, p < 0,001) and percutaneous coronary intervention (41,2% vs 60,9%) and longer delay between symptoms and revascularization (303,6 vs 256,4 minutes, p < 0,01) in STEMI.
The independent predictors of AHF were female sex (OR 1,7, p < 0,01), higher age, past history of stroke (OR 2,2, p < 0,01) or HF (OR 1.92, p < 0,01), diabetes mellitus (OR 1.3, p = 0,04), STEMI (OR 1.67, p < 0,01), atrial fibrillation (OR 2.2, p < 0,01) and lower LVEF.
The in-hospital mortality rate was higher in patients with AHF (19,9% vs 1,2%, p < 0,01), as was the 1-year mortality (28,6% vs 6,2%, p < 0,001) and hospitalization rate (38% vs 19,2%, p < 0,001).
On multivariate analysis, AHF was the strongest independent predictor of in-hospital mortality (OR 7.89, p < 0,01), and also independently associated with 1-year mortality (OR 2.6, p < 0,001) and hospitalization (OR 1.81, p < 0,01). The timing of AHF had no impact on outcome.
Conclusion: AHF commonly complicates ACS and is independently predicted by older age, female sex, diabetes, STEMI, atrial fibrillation and lower LVEF. In this study, AHF, regardless of its timing, was an independent predictor of in-hospital death and 1-year mortality or hospitalization.

BASIC SCIENCE: ANIMAL EXPERIMENTATION

The status of cerebral arteries, leptin levels and postprandial hypertriglyceridemia in patients with coronary heart disease with preserved systolic function combined with non-alcoholic fatty liver di

M Mariya Grechanyk[1]; NM Grechanyk[2]; YV Filippova[2]; AV Kuryata[1]
[1]Dnepropetrovsk Medical Academy, Dnepropetrovsk, Ukraine; [2]Dnipropetrovsk Regional Hospital Mechnikov, Dnepropetrovsk, Ukraine

Objective: to estimate the frequency of atherosclerosis of cerebral arteries, leptin levels and postprandial hypertriglyceridemia (PPG) in patients with coronary heart disease (CHD) with preserved systolic function combined in combination with non-alcoholic fatty liver disease (NAFLD), depending on the body mass index (BMI).
Methods: The study involved 24 men (mean age 56,2 ± 1,3 years) with CHD with preserved systolic function combined with NAFLD, the control group consisted of 14 patients with coronary artery disease without NAFLD. The study group was divided into 3 subgroups according to BMI (subgroup 1 (33%) - patients who are overweight, 2 (41%) - obesity 1 degree, 3 (25%) - obesity grade 2). Evaluated atherosclerotic changes of the neck vessels, endothelial function, PPG, leptin levels.
Results: In the group of patients with CHD with preserved systolic function and NAFLD point plaques found significantly more often (31%, p = 0,01) when significantly more abuse on the part of endothelial function (47% lower, p = 0,01), than in the control group. In patients with grade 2 obesity identified the highest leptin levels (43,6 ± 20,2, p < 0,05), which is 44% higher than in the subgroup with obesity 1 degree (24,4 ± 14,6, p < 0.05) and 63% greater than in the subgroup with overweight. The greatest increase in triglycerides after fat loading test with fixed subgroup 1 (70%) and in the control group (125%).
Conclusion: Thus, in patients with CHD with preserved systolic function combined with NAFLD leptin and PPG have different levels change depending on body weight. Increasing body weight was not associated with further development of atherosclerotic changes in the cerebral arteries. There was correlation between the endothelial dysfunction and level of leptin (r=0,74, p = 0,04) in a group 2 however in a group 1 and 3 such connection was not observed.

P1294

Acute myocardial dysfunction after ionizing radiation exposure

L Napolitano[1]; A Franco[2]; J Gambardella[3]; A Fiordelisi[3]; D Sorriento[3]; M Ciccarelli[1]; G Iaccarino[1]
[1]University of Salerno, Dept. of Medicine and Surgery, Salerno, Italy; [2]University of Naples Federico II, Dpt of Clinical Medicine, Cardiovascular & Immunological Science, Naples, Italy; [3]Federico II University, Scienze Biomediche Avanzate, Napoli, Italy

In time of programming interstellar journeys, the study of the effect of ionizing radiation (IR) exposition on human physiology and health is relevant. IR causes cardiac dysfunction due to the increased reactive oxygen species production (ROS). Mitochondria, being the primary source of radical oxygen species (ROS) and of energetic substrates for the myocardium, are the possible mechanisms of IR related cardiac dysfunction. To evaluate the possible involvement of mitochondria to mediate the effects of IR exposure on cardiac function, in C57BL/6 mice subjected to IR exposure by X-ray (4 Gy), we performed echocardiography at basal, and 3 and 24 hours post IR exposure. Mice were sacrificed and heart samples collected at each time point for analysis of mitochondria morphology by transmission electron microscopy (TEM) and biochemistry. At 3 h post-IR, we observed increased left ventricle diastolic diameter (LVDd: 39.5 0.3 vs 35 0.15 mm; p < 0.05 vs Basal) with reduced ejection fraction (EF: 45% 2 vs 66% 4; p < 0.05 vs Basal). At 24h post IRI, we found a recovered LVDd (36.2 0.4 vs 35 0.15 mm; ns) and ameliorated cardiac contractile function (EF: 60% 3 vs 66% 4; ns). Morphological analysis by TEM (Fig 1) reveled that, at 3 hours post IR exposure, mitochondria were reduced in number, showing cristae disarrangement with intra-vacuolization and fragmentation. At 24 h post-IR mitochondria number and morphology are recovered with normal cristae and absence of vacuolization. Morphological changes

were accompanied by molecular modifications involved in mitochondria induced apoptosis (Cyt C), mitophagy (p62) and mitochondrial mass (SOD). In particular, Cyt C release was dramatically increased into cytosolic fraction at 3 h post IR and reduced at 24 h. Similarly, p62 was increased in response to stress at 3 h with a partial reduction at 24 h. Inversely, SOD level was reduced at 3h but normalized at 24h as compared to basal, indicating recovering of mitochondrial mass. Mitochondria damage was also evaluated by expression of the different complexes (I to IV) composing the mitochondria respiratory chain through RT-PCR. At 3 h post-IR complex I,II,III and IV are all reduced as well ATPase expression. At 24 hours post-IR, complexes expression and ATPase were recovered. A recently described modulator of mitochondrial survival, GRK2, was investigated in a related in vitro model. In H9C2, over-expression of GRK2, induced a rightward shift in time for mitochondrial alterations and ROS production, which occurred after 8 hours after IR. Opposite, GRK2 silencing lead to anticipated mitochondrial impairment and no recovery occurred at 8h. Mechanistically, IR exposure produced interaction of GRK2 with MFN1 and 2, key molecules of mitochondrial recovery process, at 3h post IR. IR induces an acute cardiomyopathy that is associated to an altered mitochondrial morphology and function.

P1295

Pre-existing systemic inflammation does not influence onset or severity of heart failure

P Parminder Chaggar[1]; A Watkins[2]; W Critchley[3]; M Mohamud[3]; P Foden[4]; R Venkateswaran[1]; N Yonan[1]; A Trafford[2]; JE Fildes[3]

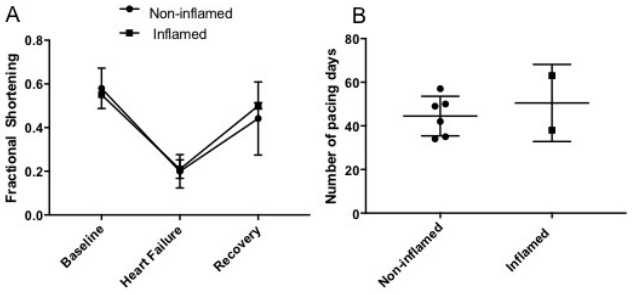
Funding Acknowledgements: The Transplant Unit, University Hospital of South Manchester

Background: The immune system is considered integral to the development of left ventricular (LV) failure. However, whilst inflammation can induce cell death in native tissue, it is also required for repair and therefore may have a bi-directional effect in heart failure. This is supported by trials of anti-inflammatory therapy in heart failure that demonstrate, at best, a neutral effect on clinical outcomes and at worst, an increase in mortality. The relationship between inflammation and heart failure development and recovery is poorly understood and warrants further investigation.
Purpose: This study was conducted to examine if baseline asymptomatic inflammation in healthy sheep would affect the time to development of, the severity of or the recovery from heart failure induced by tachycardic pacing. We hypothesised that pre-existing inflammation would increase susceptibility to the development of heart failure and lead to a more severe disease phenotype.
Methods: 8 healthy Welsh mountain sheep underwent VVI pacemaker implant and paced at 210bpm until they developed overt clinical signs of heart failure when pacing was terminated and the animal was allowed to recover. A panel of cytokines was quantified via a protein array at baseline to determine the degree of asymptomatic inflammation. The severity of LV dysfunction was assessed by serial measurements of fractional shortening on echocardiography at baseline, heart failure and recovery. Fractional shortening has previously been validated as an accurate measure of LV function in sheep. Sheep with high levels of baseline inflammation (upper quartile of cytokine concentrations) were compared to the non-inflamed sheep with regards to the time taken to induce clinical heart failure and changes in fractional shortening.
Results: Of the 8 healthy sheep, the 2 sheep in the upper quartile of inflammation had significantly higher baseline levels of all pro-inflammatory cytokines interferon-gamma, CXCL9, IP10, IL17A and IL21 compared to the remaining 6 sheep. Compared to sheep with low baseline inflammation, sheep with high baseline inflammation demonstrated no difference in fractional shortening (Figure 1A) at any time point or the number of days of pacing required to induce heart failure (Figure 1B).
Conclusion: In this study systemic inflammation had no impact on susceptibility to or severity of heart failure in sheep exposed to tachycardic pacing. This challenges the widely accepted dogma that inflammation would negatively impact heart failure disease progression and severity. These findings need to be confirmed in a larger population and expanded to other models of myocardial injury.



Inflamed versus non-inflamed sheep

Effect of candesartan cilexetil and extract of polygonum sp. on the number of endothelial progenitor cells in vivo

A Aliaksandra Beliayeva[1]; V Afonin[1]
[1]National Academy of Science, Institute of Bioorganic Chemistry, Minsk, Belarus

Background: Cardiovascular diseases are widespread in many countries of the world, therefore development and formulation of new drugs and their combinations, as well as characterization of new properties of available medicines appears extremely relevant.
Purpose: To study the effect of candesartan cilexetil, which is an angiotensin-II receptor blocker, and extract of Polygonum sp. on the contents of endothelial progenitor cells in vivo.
Methods: Male C57Bl/6 mice (n = 80) were selected for the study. They were divided into 8 groups (10 test animals in each). Mice of 7 groups received daily intragastrically candesartan cilexetil and extract of Polygonum sp. for 7 weeks. The substances were dissolved/suspended in 1% starch solution. Group 1 was supplied candesartan cilexetil at 1.5 mg/kg dose, groups 2 – 4 were administered extract of Polygonum sp. at 1 mg/kg, 10 mg/kg and 50 mg/kg doses, respectively, groups 5 – 7 received candesartan cilexetil at 1.5 mg/kg dose coupled to extract of Polygonum sp. at 1 mg/kg, 10 mg/kg and 50 mg/kg doses, respectively. The control group was provided with 1% starch solution. Quantitative evaluation of endothelial progenitor cells (CD117 +) in bone marrow and blood of C57Bl/6 mice was performed by flow cytometry.
Results: In this study we investigated the effect of candesartan cilexetil and extract of Polygonum sp. in different dosages on the number of endothelial progenitor cells. Cell surface marker CD117 (or c-kit) was chosen for analysis. It's a cytokine receptor, KIT gene product. CD117 is expressed on the surface of stem cells, including endothelial progenitor cells. It was shown in this study that candesartan cilexetil at 1.5 mg/kg dose resulted in a significant rise of CD117 + stem cell ratio in blood as compared to the control. Extract of Polygonum sp. at 10 mg/kg and 50 mg/kg doses stimulated generation of CD117 + cells in bone marrow and blood of C57Bl/6 mice in comparison with the control ($p < 0.05$). The first evidence was recorded that concerted application of candesartan cilexetil at 1.5 mg/kg dose and extract of Polygonum sp. at 10 mg/kg and 50 mg/kg doses promoted considerably production of CD117 + cells in bone marrow and blood of C57Bl/6 mice ($p < 0.05$), with the resulting values higher than those obtained for individual substances. The largest increment of the number of endothelial progenitor cells in bone marrow and blood was observed in variant with combination of candesartan cilexetil at 1.5 mg/kg dose and extract of Polygonum sp. at 50 mg/kg dose. Conclusion: It was originally demonstrated that combination of candesartan cilexetil and extract of Polygonum sp. was effective to induce mobilization of endothelial progenitor cells in bone marrow and to increase their ratio in blood of C57Bl/6 mice. The experimental data may be used in formulation of new complex drug for the treatment of cardiovascular diseases, capable to promote the mobilization of endothelial progenitor cells in the body.

P1297

Exercise preconditioning increases serotonin vasoconstriction of isolated pulmonary artery in ovariectomy female rats with hypoxic pulmonary hypertension

N Nadezda Pankova[1]; N Medvedeva[1]; N Terentyeva[1]; A Terentyev[1]
[1]M.V. Lomonosov Moscow State University, Biological, Moscow, Russian Federation

Introduction: Endothelial dysfunction is one of reason of hypoxia pulmonary hypertension (hPAH). There is an imbalance between vasodilators and vasoconstrictors

with the development of this disease. Serotonin is involved in triggering pulmonary hypertension. Exercise training (ETr) may have protective effects in the cardiovascular system. Experiments in the animals have shown that Etr induces endothelium-dependent vascular relaxation via the nitric oxide, prostacyclin, and hyperpolarization pathways. There are conflicting data on the effect of ETr on the development of hPAH.
The aim of the study was to test the hypothesis that ETr will decrease serotonin-dependent constriction of pulmonary vessels and reduce the degree of pulmonary hypertension.
Methods and design. Female Wistar rats were used. They were divided into 7 groups: four were with hPAH (H) and three without (C). Two groups from (H) and (C) rats were gonadectomized (HG and CG) and two were with ovaries (HN and CN). One group from HG,CG,HN,CN were with exercise preconditioning (groups HGEx, CGEx,HNEx) and one group were without exercise (groups HGC,CGC,HNC,CNC) The procedures followed the FELASA/ICLAS for use of the laboratory animals (Guide for use of the laboratory animals, National Academy Press, Washington, D.C.1996). hPAH was induced by exposure to hypobaric hypoxia (10 h a day, 2 wk.,O2 concentration reduced to 10%). For exercise preconditioning rats were subjected to exercise training (aerobic swimming during 30 min/day.) for a period of 2 weeks to hypoxia. Systolic right ventricle pressure (SRVP) was measured. Right ventricular (RV) hypertrophy was calculated as RV weight /heart w. Perfusion pressure of isolated pulmonary and systemic (popliteal) artery to vasoconstrictor serotonin (3,3*10-8 – 10-5M) was measured.
Results Two weeks after chronic hypoxia exposure all (H) groups of rats developed hPAH with different extent of the disease. SRVP was lower by 24% in group HGEx compared with group HGC($p < 0,05$). There are no differences between other hypoxic groups.. Pulmonary artery response to serotonin 3*10-7M in HGC group was less by 59% than in HNC group ($p < 0,05$) without effect in systemic vessels. Pulmonary vessels of gonadectomized rats with hPAN, which had exercise preconditioning demonstrated the increase of vasoconstriction in response to the 3*10-7M serotonin in 4 times $p < 0,05$) than HGC. However, response to serotonin (3*10-6M) in systemic vessels was less by 65% in HGEx group compared with HGC ($p < 0,05$).
Conclusions: Aerobic exercise preconditioning (30 min. swimming) causes a protective effect in isolated systemic vessels without effect in pulmonary vessels. Decreasing SRVP by gonadectomy do not connect with change response vessels to serotonin.

Myosin protein kinases in signaling in heart failure and hypertrophy and in the development of the heart

T Tatiana Kulikova[1]; O Stepanova[1]
[1]*Russian Cardiology Research and Production Complex, cardiology department, Moscow, Russian Federation*

Mechanical forces - play a significant role in signaling in hypertrophy and heart failure (HF), but the link between physical stimuli and biological responses remains not well understood. Various concepts have been introduced to explain signaling at the molecular level, including myosin activating protein kinases participation. Cardiac myocytes differ from other cells in that they contain sarcomeres which are essential for the generation of forces. Sarcomerogenesis is activated in cardiac hypertrophy and HF and is characteristic for development of the heart too. There are hypertrophy changes in HF due to dilated cardiomyopathy (DCM). The phosphorylation of myosin – main protein of cardiomyocyte contractile machinery plays an important role in the sarcomerogenesis regulation. Myosin activating protein kinases can directly phosphorylate myosin - nonmuscle/smooth muscle myosin light chain kinase (MLCK 108), skeletal MLCK and such kinases as Rho-associated protein kinase (ROCK), zipper-interacting protein kinase (ZIPK) and integrin-linked kinase (ILK) with broader specificity. In our study the expression levels of protein kinases ROCK-1, ROCK-2, ILK were determined in endomyocardial biopsies of patients with HF due to DCM using real time PCR. Ten biopsies of patients with HFdue to DCM and five myocardial samples of patients without cardiovascular pathology were analyzed. Significant ILK expression level increase was detected in the myocardial samples of patients with HF due to DCM in comparison with expression level of this kinase in the myocardial samples without cardiovascular pathology. ROCK-1 and ROCK-2 expression levels did not differ from expression levels in the myocardial samples of patients without cardiovascular pathology. The localization of myosin activating protein kinases has been studied by us in cardiomyocytes isolated from human fetal myocardium (8-9 and 13 weeks gestation). It has been established by immunofluorescense approach that MLCK 108, MLCK 210, skeletal MLCK and death associated protein kinase (DAPK) are colocalized with nonmuscle myosin IIB in premyofibrils at 8-9 weeks gestation. These data allow us to propose that nonmuscle myosin IIB may be the substrate for these kinases at this heart development stage, these kinases are likely to jointly regulate the myofibrils formation. MLCK 210 was found in the heart at different gestation stages, MLCK 108 and MLCK 210 relationship was first established at different gestation stages. The approximate time period was revealed when the ratio of MLCK 108 and MLCK 210 varies (between 8-9 and 13 weeks), which may be associated with increased load in heart development. Our results demonstrate that in the postnatal heart ILK serves dual function not only as a mechanoreceptor but also as a nodal regulator of adaptive, prohyperthrophic signaling. MLCK 108, MLCK 210, skeletal MLCK and DAPK jointly regulate sarcomerogenesis in heart development.

AKIP1 promotes physiological cardiac hypertrophy

BD Daan Westenbrink[1]; KT Nijholt[1]; RA De Boer[1]; CWA Van De Kolk[1]; WH Van Gilst[1]; HHW Sillje[1]; HG Booij[1]
[1]*University Medical Center Groningen, Groningen, Netherlands*

Funding Acknowledgements: Dutch Heart Foundation (grant 2012T066)

Background: Overexpression of A Kinase Interacting Protein 1 (AKIP1) promotes physiological hypertrophy in cultured cardiomyocytes by activating AKT-mediated growth pathways. Whether AKIP1 regulates physiological cardiac hypertrophy in vivo is unknown.
Methods and results: Mice with cardiomyocyte-specific overexpression of AKIP1 (AKIP1-TG) and their wild type (WT) littermates were subjected to 4 weeks of voluntary wheel running, whereas control mice remained sedentary. While running time and distance were comparable between AKIP1-TG and WT mice, the induction of physiological hypertrophy after voluntary exercise was markedly increased in AKIP1-TG mice compared to wild type mice (Heart Weight / tibia length 9.5 ± 0.3 mg/mm in AKIP1-TG vs. $8,7 \pm 0.2$ mg/mm in WT mice, $p < 0.05$). The augmentation of exercise-induced cardiac hypertrophy was associated with a 6-fold increase in AKT-phosphorylation and the activation of its down-stream pathways ribosomal rpS6 and translation elongation factor eEF2.
Conclusion: Cardiomyocyte-specific overexpression of AKIP1 promotes physiological cardiac hypertrophy after voluntary exercise by activating AKT. These findings suggest that AKIP1 may serve as a nodal point to induce beneficial reprograming of hypertrophic heart disease.

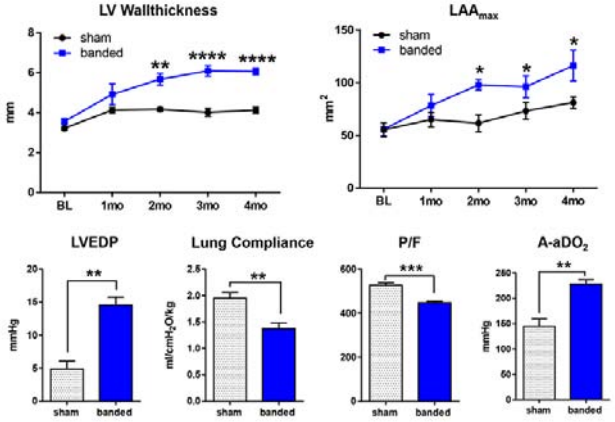
Funding Acknowledgements: SRH: RO1 HL33921; MRW: NHLBI: R01 HL118401-01A1; DoD/ONR: N000141210810; DoD/ONR: N000141210597

Background: Heart Failure with preserved Ejection Fraction (HFpEF) represents a major public health problem. Little is understood about the causative mechanisms and there are no proven effective treatments for HFpEF, partially attributable to the lack of well-established animal models for HFpEF.
Purpose: To establish a feline HFpEF model induced by slow progressive pressure overload and to characterize structural and functional cardiopulmonary consequences in this model.
Methods: Male domestic short hair cats ($n = 17$; 2 months), underwent either sham (S) procedures ($n = 8$) or aortic constriction ($n = 9$) with a customized pre-shaped band (B), resulting in slow progressive pressure overload during growth in contrast to immediate pressure overload. Terminal pulmonary function, gas exchange, and invasive hemodynamic studies before and after dobutamine infusion (5µg/kg/min), were performed 4 months post-banding. Data is presented as mean ± SE.
Results: Terminal 4-month echocardiography revealed preserved global systolic function (fractional shortening: (S) $32.8 \pm 1.3\%$ vs (B) $31.8 \pm 0.70\%$, $p = 0.99$), significant concentric left ventricular hypertrophy (Fig.: LV Wallthickness) and left atrial (LA) enlargement (Fig.: LAAmax) with impaired LA function. Diastolic function was significantly impaired post-banding reflected by inversion of E/A ratio. ProBNP and left ventricular end diastolic pressure (Fig.: LVEDP) were significantly ($p < 0.01$) greater in (B) compared to (S) cats. While cardiac output and dp/dtmax did not differ significantly between groups at baseline, after dobutamine infusion the increase in dp/dtmax was significantly attenuated in (B) (6310 ± 1157mmHg/s) vs (S) cats (9508 ± 430mmHg/s, $p < 0.05$), indicating impaired inotropic reserve. Terminal in vivo measurements of pulmonary function and gas exchange demonstrated marked impairment in (B) cats, reflected by a significant reduction in respiratory compliance, reflective of increased lung stiffness, decrease in the PaO2/FIO2 (P/F) reflective of impaired oxygenation, and an increase in alveolar-arterial oxygen gradient (A-aDO2)

reflective of an increase in intrapulmonary shunt. (B) cats showed a significant increase in the percentage of LV fibrotic and myocyte cross-sectional area.
Summary and Conclusion: Slow progressive pressure overload in cats induces severe LV concentric hypertrophy, LA enlargement and dysfunction without causing LV dilation or systolic dysfunction. The cardiac findings mimic some discriminating clinical hallmarks of HFpEF patients. In addition, this study presents seminal observations of the impact of LA impairment on pulmonary function and gas exchange, which are in agreement with clinical observations of dyspnoea at rest and exercise-induced reduction of diffusion capacity in humans with HFpEF. Collectively, these data support the translational efficacy and potential utility of this novel feline HFpEF model to explore therapeutic options (HDAC inhibition) for humans.



Cardiopulmonary Impairments

Targeting the nitric oxide-unresponsive soluble guanylate cyclase in a rat model of pressure overload induced left ventricular myocardial hypertrophy and heart failure

M Ruppert[1]; T Radovits[1]; S Korkmaz-Icoz[2]; S Li[2]; P Hegedus[2]; BT Nemeth[1]; A Olah[1]; CS Matyas[1]; K Benke[1]; B Merkely[1]; M Karck[2]; G Szabo[2]
[1]Semmelweis University Heart Center, Budapest, Hungary; [2]University of Heidelberg, Department of Cardiac Surgery, Heidelberg, Germany

Background: Chronic pressure overload of the left ventricle induces the manifestation of pathological left ventricular myocardial hypertrophy (LVH) that entails gradual deterioration of cardiac function. Recently, preclinical studies have indicated that the impairment of the soluble guanylate cyclase (sGC) - cyclic guanosine monophosphate (cGMP) – protein kinase G signaling contributes to the development of LVH associated cardiac dysfunction.
Purpose: Therefore we investigated the effect of the sGC activator cinaciguat in a rat model of pressure overload-induced LVH and heart failure.
Methods: Abdominal aortic banding (AB) was carried out to induce pressure overload for 6 or 12 weeks. Sham operated animals served as controls. The experimental groups were treated from the 7th to the 12th postoperative week, with 10 mg/kg/day cinaciguat (Cin) or with placebo (Co) p.o., respectively. The temporal development of LVH and its progression to heart failure was investigated by serial echocardiography. Cardiac function was assessed by pressure-volume analysis. In addition, histological and molecular biological measurements were also performed.
Results: In the cinaciguat treated aortic banded group decreased heart weight-to-tibial length ratio (HW/TL ratio: 0.57 ± 0.02 vs. 0.48 ± 0.02g/cm, $p < 0.05$ AB 12th week-Co week vs. AB 12th week-Cin) decreased cardiomyocyte diameter (CD: 23.94 ± 0.59 vs. $20.02 \pm 0.20 \mu$m, $p < 0.05$ AB 12th week-Co week vs. AB 12th week-Cin) and reduced myocardial expression levels of atrial natriuretic peptide and β/α-myosin heavy chain ratio were detected. Furthermore, we observed, that chronic activation of the sGC by cinaciguat provided protection against the increased interstitial fibrosis (Masson's score: 1.7 ± 0.2 vs. 1.2 ± 0.1, $P < 0.05$ AB 12week-Co vs. AB 12week-Cin) and nitro-oxidative stress. The prevention of the pathological structural alterations was accompined by improved cardiac function (ejection fraction: 47.4 ± 2.7 vs. $63.7 \pm 2.4\%$, $P < 0.05$ AB 12week-Co vs. AB 12week-Cin).
Conclusion: Our results demonstrate that chronic activation of the sGC enzyme prevents the transition from pressure overload-induced LVH to heart failure.

P1302
Sympathetic renal denervation after acute myocardial infarction results in increased myocardial salvage in pigs

L E Pastormerlo[1]; S Burchielli[1]; M Ciardetti[1]; C Grigoratos[1]; F Bernini[1]; A Pucci[1]; E Benelli[1]; G Acquaro[1]; A Giorgetti[1]; P Marzullo[1]; M Franzini[1]; C Passino[1]; M Emdin[1]
[1]Gabriele Monasterio Foundation-CNR Region Toscana, Pisa, Italy

Background: Despite advances in treatment of acute myocardial infarction (AMI), many patients still suffer significant myocardial damage and are at increased risk of cardiac dysfunction following AMI. Sympathetic renal denervation may represent an innovative approach to reduce adverse neurohormonal activation following AMI and its contribution to increased myocardial damage and adverse long term remodeling.
Methods: and Results: Sixteen male farm pigs underwent a 90 minutes left anterior descending artery occlusion followed by reperfusion. They were randomized (1:1) to percutaneous sympathetic renal denervation (RD) procedure immediately after reperfusion. Global and regional LV function, extent of myocardium at risk, and myocardial necrosis were quantified by cardiac magnetic resonance imaging studies performed 5 and 30 days after coronary occlusion. No adverse haemodinamic effects were reported in pigs that underwent RD immediately after AMI. RD and control pigs did not differ in the extent of myocardium at risk (63 and 61% of left ventricle, P=NS). At 30 days, RD significantly reduced the amount of gadolinium delay enhancement (17 versus 31 % of LV, $p < 0.001$) with improved myocardial salvage index (74% vs 44%, $p < 0.001$). Cardiac output in RD pigs was significantly higher than control at 30 days (3.7 ± 0.8 versus 2.66 ± 0.7 L/min, $p < 0.001$), with a trend for lower LV end diastolic volume (98 ± 16 versus 113 ± 31 ml, $p = 0.14$).
Conclusions: RD performed immediately after AMI results in increased myocardial salvage and better cardiac remodeling. The reduction of neurohormonal activation following AMI warranted by RD, may be in cause.

P1303
Interest of colchicine in the treatment of acute myocardial infarct responsible for heart failure in a mouse model

M Akodad[1]; J Fauconnier[2]; P Sicard[2]; F Huet[1]; F Blandel[2]; P De Santa Barbara[2]; S Aguilhon[1]; A Lacampagne[2]; F Roubille[1]
[1]University Hospital Arnaud de Villeneuve, Interventional Cardiology, Montpellier, France; [2]University of Montpellier, U1046, Montpellier, France

BACKGROUND: Inflammation is deeply involved in the pathophysiology of ischemia-reperfusion (I/R) lesions and ventricular remodeling due to an acute myocardial infarction (AMI). Colchicine as a pleiotropic anti-inflammatory molecule may exert cardioprotective effects under acute ischemia. Here, we aimed to evaluate the impact of colchicine on reperfusion injury in a mouse model.
Method: Myocardial ischemia/reperfusion (I/R) injury were induced in C57BL/6 male mice, after 45 min ligation of the left coronary artery followed by reperfusion. 400 µg/kg of colchicine or the vehicle was administrated intraperitoneally (i.p) 25 minutes before the reperfusion (blinded administration). Mice were sacrificed at 24 hours after the acute myocardial ischemia (AMI) and the area at risk (AAR) and the infarcted area (IA) were evaluated after Evans blue/TTC staining. Circulating level of troponin and cytokines profile were assessed 4 hours after the AMI. An echocardiography was performed in a follow-up group mice, 48 hours and 8 weeks after the AMI.
Results: The AAR/total area ratios were similar in the colchicine and the vehicle group ($52.6\% \pm 1.1\%$ versus $50.6\% \pm 0.8\%$ respectively, $p > 0.05$, n=13 per group). The infarct size was reduced in Colchicine treated mice in comparison to control mice with IA/AAR ratios respectively at $39.8\% \pm 3.5$ versus $52.9\% \pm 3.2$, $p < 0.05$. Troponin was significantly lower in the Colchicine treated mice (7015.7 ± 1423.7 pg/mL, n= 5 vs 30723.7 ± 7959.9 pg/mL in the placebo group, n=6; $p < 0.0001$). Fibrosis was decreased in the Colchicine group (24.51 ± 3.13 % vs 11.38 ± 2.46 % in the colchicine group, $p = 0.03$). In the follow-up group mice ($n = 8$), there were no differences between mice treated with placebo ($n = 9$) and mice treated with colchicine ($n = 9$) regarding to cardiac remodelling parameters but outflow approximated by the ITV was higher in the Colchicine group.
Conclusion: In conclusion, colchicine allowed a significant reduction of infarct size in mice, improves haemodynamic parameters and decrease cardiac fibrosis.

P1304
Characterization of the antioxidant effect of eplerenone on adverse cardiac remodeling. Implication of enzyme nitric oxide synthetic (enos)

MC Asensio-Lopez[1]; MC Sanchez-Perez[1]; MT Perez-Martinez[2]; IP Garrido-Bravo[2]; DA Pascual-Figal[2]; AM Antonio Manuel Lax[2]
[1]Biosanitary Research Institute of Murcia (IMIB-Arrixaca)., Cardiology, Murcia, Spain; [2]University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain

Background: Oxidative stress is related to the evolution of cardiac remodeling to heart failure (HF). Although eplerenone (Eple) decreases morbidity and mortality in patients with HF, the molecular mechanisms underlying this protection have not been studied. The aim of this study is to characterize the effect of Eple on the enzymatic system endothelial nitric oxide synthase (eNOS).
Methods: Human left ventricular (LV) explants from patients undergoing transplantation, LV of healthy donors as well as the infarcted LV area of animals from a rat model of myocardial infarction (MI), were analyzed. MI was induced by ligation of the left anterior descending coronary. The animals (n = 10 / group) were distributed within two groups: untreated or treated with Eple from the day of ligation up to 4 weeks (100 mg/kg/day). The control group underwent the same surgery but without ligation. The eNOS expression and activity were evaluated by RT-qPCR and Western blot, respectively. The levels of BH4 and MDA were assessed by colorimetry. The activities of catalase (CAT), glutathione peroxidase (GPx-3) and ROS were measured by fluorimetry. Each value has been referred to the control group and has been expressed as mean ± standard error.
Results: Compared to healthy donors, the failed VIs showed decreased levels of eNOS (32 ± 12) and BH4 (21 ± 9), as well as an accumulation of eNOS in its monomeric (inactive) form and a significant increase in oxidative damage: ROS (4.5 ± 1), MDA (21 ± 3), CAT (34 ± 12%) and GPx-3 (36 ± 8%). In an experimental study, in relation to control, animals submitted to MI showed decreased levels of eNOS (49 ± 13), BH4 (35 ± 9), and an accumulation of eNOS in its monomeric (inactive) form. Besides, this analyzed tissue showed oxidative damage characterized by an increase in ROS (3 ± 0.5), MDA (12 ± 4) and a decrease in CAT (32 ± 12%) and GPx-3 (43 ± 14%). Treatment with Eple increased eNOS expression (89 ± 15) and BH4 levels (78 ± 21), as well as homodimeric levels of eNOS (active). Furthermore, treatment with Eple reduced oxidative damage by decreasing ROS (1.5 ± 0.9) and MDA (3 ± 0.3) and increasing CAT (67 ± 12%) and GPx-3 (78 ± 17%).
Conclusions: Eplerenone, through overexpression and increased activity of eNOS and its cofactor BH4, prevents post-IM adverse cardiac remodeling.

Cardiac bone marrow-derived cell-based therapy associated with scaffold for heart regeneration

I Ines Borrego[1]; A Frobert[1]; J Valentin[1]; G Ajalbert[1]; V Roth[2]; B Fellay[2]; S Cook[1]; MN Giraud[1]
[1]University of Fribourg, Department of Medicine - Cardiology, Fribourg, Switzerland; *[2]Laboratory HFR - Tafers, Hospital Fribourgeois, Fribourg, Switzerland*

Purpose: The development of patched associating of bone marrow derived cells (BMDC) and a substrate/scaffolds provided evidence of beneficial outcomes and optimal delivery approaches on myocardial infarction (MI). Preclinical trials are usually performed with BMDC isolated from healthy donor. However, for clinical application, BMDC isolated from infarcted patients are favoured as an autologous cell source. We hypothesized that the therapeutic capacity of the implanted biological patch may vary with BMDC origin. To test this hypothesis, we compared the regenerative potential of a biological patch composed of BMDC isolated from healthy or infarcted donor as a treatment of MI in a rat model.
Methods: MI was induced by Left Anterior Descending Artery ligation. BMDC were isolated from healthy and infarcted Lewis male rats. MI was induced in 52 female Lewis rats; two weeks post MI, 34 rats with an ejection fraction (EF) between 35-60% were selected and randomised in different treatment groups, sham operation (Sh, n=9), epicardial application of the biological patches obtained with 2 million cells isolated from healthy donors (HD, n=12), or from infarcted donors (ID, n=7) or substrate only (S, n=6). Four weeks post treatment, cardiac function and regional contractility (strain imaging) were measured by high-resolution echocardiography, the infarct expansion was quantify using systematic sampling of total heart and image analyses of trichrome-stained histological sections.
Results: Four weeks post MI, heart function decreased in control groups (ΔEF.Sh=-1.21 ± 3.2% and ΔEF.S=-7.4 ± 6.4%). Cells and substrate significantly induced stabilizations of heart function compared to substrate alone (ΔEF.HD=1.1 ± 5.6%,p = 0.02 and ΔEF.ID=0.99 ± 4.9%,p = 0.4). Nevertheless, it is important to underline that heterogeneity in response to the treatments was observed, 42% responded positively to the treatment (ΔEF≥3%). In addition, the regional LV myocardial contractility showed that the LV non-contractile region decreased significantly for HD group from 10.8 ± 3.3mm to 8.3 ± 4.0mm (p = 0.02). Furthermore, the index expansions (EI) decreased with the implantation of the biological patches, and were respectively EI.Sh=0.21 ± 0.11 vs. EI.HD=0.08 ± 0.04(p = 0.05) vs. EI.ID=0.15 ± 0.07(p = 0.47). Interestingly, the LV volume significantly increased 4 weeks post ID patch implantation. These results suggested that although ΔEF for both biological patches are comparable, LV dilatation observed with infarcted cells may be detrimental in long term.
Conclusion: Our study demonstrated that independent of the cell origin, patches stabilized heart function. However, only healthy donor cells showed a regenerative capacity. Noticeably, LV dilatation following infarcted cell implantation questioned the long-term safety. Heterogeneity of outcomes revealed the presence of respondent and non-respondent subjects to the treatment.

Introduction: We recently identified a set of plasma microRNAs (miRNAs) that are downregulated in patients with heart failure in comparison with control subjects.
Purpose: To better understand their meaning and function, we sought to validate these circulating miRNAs in two different well-established rat and mouse heart failure models, and correlated the miRNAs to parameters of cardiac function.
Methods: The miRNAs let-7i-5p, miR-30e-5p, miR-16-5p, miR-18a-5p, miR-223-3p, miR-652-3p, miR-423-3p, miR-423-5p, miR-26b-5p, miR-27a-3p and miR-199a-3p were measured by means of quantitative real time polymerase chain reaction (qRT-PCR) in plasma samples of 8 homozygous TGR(mREN2)27 (Ren2) transgenic rats and 8 (control) Sprague-Dawley rats, as well as in 6 mice with angiotensin II-induced heart failure (AngII) and 6 control mice. Circulating miRNA levels were compared between the heart failure animals and healthy controls.
Results: Ren2 rats and AngII mice showed clear signs of heart failure, exemplified by increased left ventricular and lung weights, elevated end-diastolic left ventricular pressures, impaired contractility and increased left ventricular relaxation time. All miRNAs except mir-423-5p were detectable in plasma from rats and mice. No significant differences were observed between the circulating miRNAs in the Ren2 rats and AngII-treated mice when compared to the healthy control animals (all P>0.05), and no robust associations with cardiac function could be found.
Conclusions: The previous observation that miRNAs circulate in lower levels in patients with heart failure could not be validated in well-established rat and mouse heart failure models. This should be taken in consideration in the study of circulating miRNAs in heart failure.

P1307
Eplerenone prevents adverse cardiac remodeling through modification of enzymatic NADPH oxidase 4 activity

AM Antonio Manuel Lax[1]; MC Sanchez-Perez[2]; MT Perez-Martinez[1]; F Pastor[1]; DA Pascual-Figal[1]; MC Asensio-Lopez[2]
[1]University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain; *[2]Biosanitary Research Institute of Murcia (IMIB-Arrixaca)., Cardiology, Murcia, Spain*

Background: The prevalence of heart failure (HF) has increased worldwide in recent decades. Although eplerenone (Eple) is used to treat patients with left ventricular (LV) systolic dysfunction following myocardial infarction (MI), the mechanisms involved have not been studied. In this study, we evaluate whether Eple, through the modulation of the NADPH oxidase 4 (mitoNox) activity, prevents adverse cardiac remodeling and development to HF.
Methods: Myocardial infarction (MI) was induced by ligation of the left anterior descending coronary in male Wistar rats. The animals (n = 10/group) were distributed within two groups: untreated and treated with Eple, from the day of ligation up to 4 weeks (100 mg/kg/day). The control group underwent the same surgery but without ligation. In parallel, explants from transplanted human LV, LV from healthy donors as well as the infarcted LV zone of an animal model of MI, were analyzed. The expression levels of mitoNox and gp22phox was evaluated by RT-qPCR and Western blot, while mito-NOX activity was assessed by luminescence. MDA and GSH levels were evaluated by colorimetry. The glutathione peroxidase (GPx-3) activity was assessed by fluorimetry. Each value has been referred to the control group and has been expressed as mean ± standard error.
Results: Regarding healthy donors, the failed LV showed high levels of mRNA and protein for mitoNox (27 ± 8; 5 ± 0.3) and gp22phox (25 ± 9; 4 ± 0.2), mitoNox activation (19 ± 4) and an increase in oxidative damage: MDA (45 ± 15), GSH (40 ± 9), and GPx-3 (36 ± 8). In an experimental analysis, compared to control group, rats with MI showed elevated levels of mitoNox mRNA and protein expression (49 ± 13; 4.6 ± 0.2) and gp22phox (35 ± 9; 4 ± 1); mitoNox activation (21 ± 7) and increased oxidative damage: MDA (55 ± 20), GSH (35 ± 13), and GPx-3 (43 ± 14). Treatment with Eple was associated with a decrease in mitoNox (10 ± 4, 1.2 ± 0.2) and gp22phox (9.5 ± 2, 2.1 ± 0.14) mRNA and protein levels, and a mitoNOX inhibition (5.32 ± 1.4). In addition, Eple reduced oxidative damage by decreasing MDA (12 ± 4) and increasing GSH (85 ± 20) and GPx-3 activity (80 ± 17).
Conclusions: This study demonstrates that Eple through inhibition of mitoNox activity exerts a modulatory role in adverse cardiac remodeling induced by MI.

Background: Diabetes mellitus and obesity are associated with cardiovascular disease, and cardiovascular complications are the most common cause of death in diabetic patients. Diabetes related myocardial fibrosis and fat infiltration has been associated with the development of heart failure.
Purpose: The present study aimed to assess the effect of high-fat/high-cholesterol diet and streptozotocin-induced diabetes on left ventricular (LV) myocardial fibrosis and fat infiltration in Göttingen minipigs.
Methods: Twenty-nine castrated male Göttingen minipigs (5-6 months) were divided into three groups. A control group fed standard pig chow: C (n = 7); and two groups fed high-fat/high-cholesterol diet: HFD (n = 14) and HFD-D (n = 8), the latter group with superimposed streptozotocin-induced diabetes. To avoid severe hyperglycemia, fasting blood glucose was maintained at 12-15mM by treating animals with insulin glargine. After 58 weeks all pigs were euthanized, body and heart weight measured, and myocardial samples from the LV free wall were collected. For each animal the degree of myocardial interstitial fibrosis and fat infiltration as well as perivascular fibrosis and fat infiltration was semi-quantitatively scored as 0/+/++/+++. In addition, degree of epicardial fat infiltration and vascular tunica media fibrosis was evaluated. Vascular changes were reported as an average of evaluated myocardial arterioles and small arteries.
Results: Total plasma cholesterol and triglycerides were higher in HFD [11.82 (9.09-13.18)mM (median and quartiles); P=0.0003; and 0.64 (0.54-0.88)mM; P=0.0004] and HFD-D [17.45 (14.01-27.00)mM; P=0.0022; and 1.22 (0.75-1.64)mM; P=0.0014] compared to C [1.69 (1.36-2.18)mM; and 0.34 (0.29-0.35)mM]. Heart weight was higher in HFD [199 (181-208)g; P < 0.0001] and HFD-D [175 (138-205)g; P=0.02] compared to C [131 (115-142)g]. No differences between groups were found when heart weight was normalized to body surface area. No differences between groups were found in degree of myocardial interstitial fibrosis [C: 7/0/0/0; HFD: 12/2/0/0; HFD-D: 6/2/0/0; P=0.55] or fat infiltration in myocardium [C: 4/2/1/0; HFD: 1/7/3/3; HFD-D: 5/2/1/0; P=0.09]. Likewise, no differences were observed in perivascular [C: 1.00 (0.50-2.00); HFD: 1.58 (1.00-2.29); HFD-D: 1.00 (0.00-1.75); P=0.39] or epicardial [C: 4/1/0/0; HFD: 2/5/6/0; HFD-D: 3/3/2/0; P=0.16] fat infiltration, or in tunica media fibrosis [C: 0.00 (0.00-0.33); HFD: 0.17 (0.00-1.00); HFD-D: 0.00 (0.00-0.25); P=0.32]. The degree of perivascular fibrosis was lower in HFD-D [0.00 (0.00-0.00)] compared to C [0.50 (0.00-0.75); P=0.03] and HFD [0.13 (0.00-0.50); P=0.04]. No difference in perivascular fibrosis was found between C and HFD (P=0.39).
Conclusion: Obesity and diabetes did not increase myocardial fibrosis and fat infiltration in Göttingen minipigs. Further studies are needed to determine the possible influence of breed, sex and exposure time; and the significance of the vascular changes.

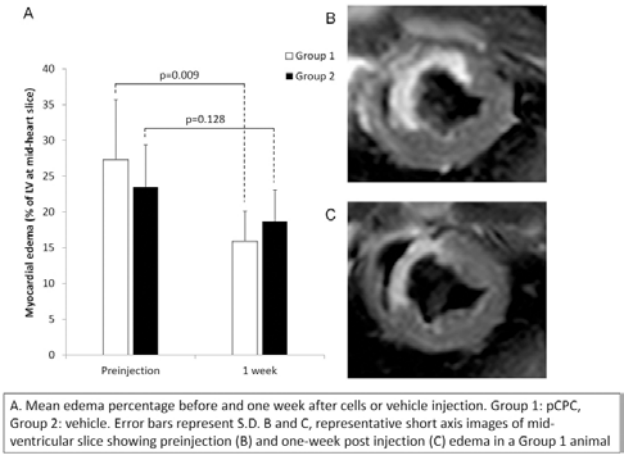
Funding Acknowledgements: European Commission FP7-HEALTH-2009-1.4-3, Grant Agreement 242038, RIC (RD12/0042/0025) and CIBER CV (CB16/11/00494)

Background: Myocardial edema is associated to impaired regional function and conductivity and as such has been proposed as a therapeutic target, since it. On the other hand, intracoronary (IC) allogeneic cardiac progenitor cell (CPC) administration has been recently used for MI therapy in experimental models, and is currently being evaluated in clinical trials.
PURPOSE: We undertook this study to evaluate the effects of IC porcine CPC (pCPC) administration on myocardial edema and its relationship to cardiac function after experimental infarction in swine.
Methods: Female domestic pigs surviving a 90 minutes balloon occlusion of the mid-LAD were subjected to an IC injection of 50x106^ pCPC (n = 7, group 1) or vehicle (n = 7, group 2) one week after AMI. Cardiac MR was performed before injection and one and 10 weeks after. Myocardial edema/area-at-risk (AAR) was calculated as a percentage of the left ventricle in a mid-heart slice using T2-weighted imaging. Other parameters studied included Ejection Fraction (EF), End Diastolic Volume (EDV), End Systolic Volume (ESV) and infarct size. Myocardial Salvage Index (MSI) was then computed as AAR at mid-heart slice minus final infarct size (FIS) in an equivalent slice divided by AAR (MSI=(AAR-FIS)/AAR).
Results: No differences were seen between groups in any MR-derived parameter before pCPC or vehicle injection, thus confirming that both AAR and infarct sizes, and their effects on functional parameters (EF, EDVi and ESVi) were comparable. Injection was successful in all cases, in absence of major adverse cardiac events. There was a significant decrease in edema in the treated group one week after pCPC injection (from 27.29 ± 8.44% to 15.00 ± 4.24%, p = 0.009), while no significant change in this parameter was seen in Group 2 (from 23.43 ± 5.94% to 18.71 ± 4.35%, p = 0.128). At ten weeks there were no significant differences in scar sizes, despite a trend towards smaller scars in treated animals (5.86% ± 4.14% versus 8.29% ± 2.81%). However, MSI was significantly higher in the treated group (MSI=0.63 ± 0.17 in Group 1 and MSI=0.35 ± 0.20 in Group 2, p = 0.01), evidencing a cardioprotective effect of the cells. In terms of cardiac function, a clear trend towards EF recovery was seen in Group 1, that was absent in non-treated animals. Ventricular volumes were also significantly smaller in Group 1 (EF was 50.23 ± 4.92% and 42.14 ± 10.00%, EDVi was 94.01 ± 11.42mL/m2 and 119.03 ± 24.84mL/m2 (p = 0.018) and ESVi was 46.96 ± 8.19mL/m2 and 70.45 ± 25.53mL/m2 (p = 0.018) in Groups 1 and 2, respectively).
Conclusion: The Intracoronary injection of 50x10^6 pCPC one week after experimental infarction could be able to exert a beneficial decrease in myocardial edema, which after 10 weeks is associated to improved cardiac function and a two-fold increase in MSI. The exact mechanisms by which pCPC are related to myocardial edema decrease need to be further clarified, but it could represent another therapeutic target for early cell therapy.



A. Mean edema percentage before and one week after cells or vehicle injection. Group 1: pCPC, Group 2: vehicle. Error bars represent S.D. B and C, representative short axis images of mid-ventricular slice showing preinjection (B) and one-week post injection (C) edema in a Group 1 animal

Evolution of myocardial edema after pCPC

Lower dietary fat intake increases cardiac hypertrophy and left ventricular remodelling in a hypertensive rat model

E Mc Namara[1]; C Watson[2]; L Shiels[1]; A Russell-Hallinan[1]; M Ledwidge[3]; J Baugh[1]
[1]*University College Dublin, Conway Institute, Dublin, Ireland*; [2]*Queen's University of Belfast, Belfast, United Kingdom*; [3]*St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland*

Funding Acknowledgements: UCD SMMS

Background: Much attention has been paid to the clinical effects of lipid intake on the development of coronary heart disease, however, the effects of dietary fats on the development and progression of heart failure have been largely ignored. The present study compares the effect of a high-fat diet (HFD) versus a low-fat diet (LFD) on left ventricular remodelling in the presence of hypertension.
Methods: Experiments were performed with approval from the local animal ethics committee. Adult, male Wistar-Kyoto (WKY, n=10) and spontaneously hypertensive rats (SHR, n=20) were fed low (10 kcal% fat) or high (45 kcal% fat) saturated fatty acid-based diets for 16wks. Cardiac structure and function were determined in vivo using 2D M-mode echocardiography. Excised hearts were weighed, dissected and formalin-fixed. Left ventricular collagen deposition and cardiomyocyte hypertrophy were assessed using a digital image analysis system (Aperio) following Picrosirius red and H&E staining, respectively.

Results: No change in final bodyweight was recorded among groups. SHR exhibited increased arterial pressure vs. normotensive WKY controls (systolic pressure ˜151mmHg vs. 131mmHg). Following 16wks of dietary intervention SHR-LFD displayed left ventricular (LV) remodelling with significantly increased: LV mass, myocyte cross-sectional area, perivascular and interstitial fibrosis compared WKY. These effects were not seen in the SHR-HFD. Correspondingly, echocardiography revealed significantly increased LV anterior and posterior wall dimensions in SHR-LFD.
Conclusion: These results demonstrate that in the presence of hypertension, low dietary fat intake leads to increased cardiac growth and structural remodelling of the left ventricle, effects that are attenuated by high dietary fat intake. Future work aims to elucidate the role of inflammatory mediators in these phenomena.

Erythropoietin reduces collagen deposition after myocardial infarction but does not improve cardiac function in male rats

F Fernanda Pessoa[1]; C Mady[1]; KCB Fonseca[1]; ON Ribeiro[1]; VMC Salemi[1]; MR Jordao[1]; F Fernandes[1]; FJA Ramires[1]
[1]Heart Institute of the University of Sao Paulo (InCor), Cardiomyopathy Unit, Sao Paulo, Brazil

Funding Acknowledgements: FAPESP

Background: Myocardial remodeling includes inappropriate collagen deposition in the interstitium. Erythropoietin (EPO) may have cardioprotective effects. We aimed to assess the role of EPO on myocardial remodeling.
Methods: We studied 60 Wistar rats divided into: Control (CT), Control + EPO (CT + EPO), Infarcted (MI) and Infarcted + EPO (MI + EPO). The interstitial collagen volume fraction (ICVF) and infarct size were quantified. Echocardiography was performed for geometry and ventricular function. Western Blotting was used to evaluate inflammatory proteins (TNFα, TGFβ1) and tissue inhibitors of metalloproteinases 1 and 2 (TIMP-1 and TIMP-2). Zymography was applied for MMP-2. Parametric and non-parametric analysis was performed according to normality test. Results: ICVF was greater in MI groups ($p < 0.001$) and was attenuated by EPO ($p = 0.05$). We did not observe any difference in infarct size, with or without EPO treatment (MI = 30.93 ± 13.26 %, MI + EPO = 34.12 ± 16.21%, $p = 0.65$). In this model, EPO did not show protective effects on ventricular dilatation LVDD (MI vs MI + EPO, $p = 0.79$), LVSD (MI vs MI + EPO, $p = 1.00$) or dysfunction (EF (MI): 41% ± 15, EF (MI + EPO): 40% ± 12, $p = 1.00$). The infarcted groups showed lower values of ejection fraction (EF) and larger LVDD and LVSD compared to the controls. Relative wall thickness did not showed any difference between MI vs MI + EPO ($p = 1.00$) neither Tei index ($p = 0.78$). The inflammatory proteins studied were increased in the infarcted groups but without statistical significant. Again the EPO did not modulate these protein synthesis after 4 weeks of MI (TNF, $p = 0.08$ and TGF, $p = 0.15$). The TIMP-1 had increased amount in the MI + EPO group but with no statistical significance, $p = 0.16$. The TIMP-2 also had no statistical difference, $p = 0.55$. The activity of MMP-2, did not show any difference between groups after 4 weeks of MI, $p = 0.79$. We found a strong positive correlation between EF and TIMP-1 ($p < 0.05$ and $r = 0.95$) and TIMP-2 ($p < 0.05$ and $r = 0.95$) in MI + EPO group. Conclusions: We concluded that EPO attenuated interstitial collagen accumulation, but did not protect from heart dilation or dysfunction. This protection seems to be not related to those studied inflammatory proteins modulation neither to collagen degradation pathways.

P1312
Cyclic GMP deficiency and cardiorenal fibrosis in diabetic cardiomyopathy: an experimental model of type 2 diabetic cardio-nephropathy

S-H Siu-Hin Wan[1]; S Ameenuddin[1]; HH Chen[1]
[1]Mayo Clinic, Rochester, United States of America

Background and Purpose: Cyclic guanosine 3',5'-monophosphate (cGMP) is important in the preservation of cardiorenal function and disruption of this signal transduction process contributes to cardiorenal dysfunction. In type 2 diabetes mellitus (DM), we defined neurohormonal dysregulation leading to cardio-nephropathy.
Methods: Ten genetically designated Zucker diabetic ZDFO rats and ten nondiabetic ZDFL control rats received echocardiography with strain imaging, vital sign monitoring and neurohormonal blood and urine collection over 32 weeks. At conclusion, cardiac and renal tissues were harvested for fibrosis assessment.
Results: DM in the ZDFO rats was confirmed by glucose and HbA1c measurements. There was increased fibrosis in both the left ventricle (LV) and kidney with cardiorenal dysfunction in the DM vs control rats. There was increased 24 hr proteinuria and a trend for worsened early diastolic strain rate in the DM rats. Despite similar plasma BNP levels, plasma cGMP was significantly attenuated in the diabetic vs control rats.
Conclusion: In this Zucker type 2 DM rat model, there was cGMP deficiency with evidence of cardiorenal fibrosis and dysfunction. Future studies are warranted to determine if enhancing the cGMP system with neprilysin inhibition or administration of exogenous natriuretic peptide would improve cardiorenal function.

Characteristics at 32 weeks	ZDFL (Controls, n=10)	ZDFO (Type 2 DM, n=10)	P value

Ovariectomy reduces the passive stiffness of left ventricular myocardial tissue in a post-menopause mouse model

N Farre[1]; I Jorba[2]; M Torres[3]; R Farre[2]; I Almendros[2]; D Navajas[2]
[1]Hospital del Mar, Department of Cardiology, Municipal Institute for Medical Research (IMIM), Barcelona, Spain; *[2]University of Barcelona, Unitat Biofísica i Bioenginyeria, Facultat de Medicina, Barcelona, Spain*; *[3]Hospital Clinic de Barcelona, Department of Pneumology; CIBER de Enfermedades Respi, Barcelona, Spain*

Backgraound: Heart failure (HF) is usually associated with diastolic dysfunction. Although post-menopause women are at increased risk of HF and diastolic dysfunction, poor attention has been paid to clinically and experimentally investigate this group of patients. In particular, whether myocardial stiffness is affected by the loss of sex hormones after menopause is unknown.
Purpose: To characterize the passive stiffness of left ventricular myocardial tissue in a mouse model of ovariectomy (OVX).
Methods: After 6 months of bilateral OVX, 8 mice (C57BL/6J) were sacrificed and passive tension-length curves were measured (Aurora Scientific, 300C-LR) in fresh left ventricular myocardial strips (˜8x1x1 mm). Data were fitted to a constitutive model and tissue stiffness (E) was computed at 20% stretch. To assess the relative contribution of cellular and extracellular matrix components in OVX-induced changes, E was measured in the tissue strips decellularized using a SDS protocol. Tissue stiffness was also measured in a control group of 8 same-age sham-OVX mice.
Results: E (in kPa; m ± SE) in OVX mice was ˜50% lower than in controls (11.7 ± 1.8 and 22.1 ± 4.4, respectively; $p < 0.05$). A lower decrease in E was found in the decellularized tissue (31.4 ± 12.05 and 40.9 ± 11.5, respectively; $p = 0.580$) (Figure 1).
Conclusion: Loss of female sexual hormones in an OVX model induces a reduction in the passive stiffness of myocardial tissue, suggesting that active relaxation should play a counterbalancing role in systolic dysfunction in postmenopausal women with HF.

Background: Chagas' disease is one of the major cause of cardiomyopathy and heart failure in Latin America. It is characterized by intense myocardial fibrosis which is directly related to a complex cascade of pathways, such as inflammation, oxidative stress and apoptosis. As well air pollution leads to intense activation of these same pathways wich would amplify the response against the infection. We aimed to assess the role of air pollution upon progression of Chagas cardiomyopathy in the acute phase (60 days) of the disease.
Methods: 100 females Sirius Hamsters were divided into 4 groups: Control (Ct), Control + Pollution (Ct + P), Infected (Inf) and Infected + Pollution (Inf + P). The animals were exposed to pollution by inhalation of particulate matter produced by burning diesel fuel. Echocardiography and electrocardiogram (ECG) were performed. Survival curve was analyzed during the acute phase. Results: We observed ventricular dilatation (left ventricular diastolic diameter and left ventricular systolic diameter) in infected groups compared to controls, $p = 0.04$ and $p = 0.002$, respectively. However, the pollution did not increase it. The infected groups showed lower values of ejection fraction compared to controls ($p = 0.004$). Again the air pollution did not decrease it. The ECG showed that heart rate (HR) was different between groups ($p = 0.0008$). We observed that infected groups had higher HR than controls, mainly Ct + P vs Inf and Inf + P. Sinus rhythm was similar among groups, and ventricular arrhythmias were the same in all groups at 60 days. Survival analysis showed a high mortality in infected groups (68%) compared to the controls (4%) and air pollution did not increase mortality (Inf=68%, Inf + P=68%). Conclusions: We observed that air pollution at the acute phase of Chagas disease did not worsened ventricular dilatation or function neither increased mortality.

Cardiac fibroblasts (CFs) are the predominant cell types that reside in the interstitial space of the heart. In response to pathological stimuli, CFs are stimulated to undergo phenotypic modulation and become myofibroblasts that are hypersecretory and highly contractile and which deposit excessive extracellular matrix proteins. Ca2 + signals are essential to a diversity of cellular functions, including differentiation, gene expression, cell proliferation, and growth. CaV1.2-mediated L-type Ca2 + current (ICa,L) is a fundamental myocardial calcium entry channel, but CFs do not typically express the voltage-gated Ca2 + channel. Transient receptor potential (TRP) channels are nonselective calcium entry channels, and their function has been studied in many cell types. TRP is expressed in a cell-specific manner, and its role has not been evaluated in human ventricular fibroblasts. Here, we evaluate the role of the TRP channel in the differentiation of human ventricular fibroblasts into myofibroblasts. Concordant with previous studies, Ca2 + was found in the current study to be an essential component in fibroblast differentiation. Intracellular chelation inhibited p-ERK expression and fibroblast differentiation. TRPV4 mRNA was expressed in human ventricular fibroblasts and increased on account of TGF-β1 (2 ng/mL). TRPV4 agonist (GSK1016790A) treatment induced the robust differentiation of fibroblasts into myofibroblasts. TRPV4 antagonist (RN-9893) significantly inhibited TGF-β1-induced p-ERK expression and the differentiation of CFs. Using ratio Ca2 + imaging measurements, we found a robust increase in Ca2 + influx after fibroblasts were treated with TRPV4 agonist (GSK1016790A). These results demonstrate that TRPV4 has a role as a Ca2 + -permeable channel in the differentiation of human ventricular fibroblasts into myofibroblasts, through the ERK signaling pathway.

Background: Dilated cardiomyopathy (DCM) is characterized by chamber dilation and contractile dysfunction. Alterations in myocardial structure and reduced cardiomyocyte adhesions have been previously implicated.
Purpose: We have studied the transcriptomic changes of cell adhesion molecules and the potential relationships with left ventricular (LV) function in DCM patients. We also visualized the intercalated disc (ID) structure and organization.
Methods: Twenty-three explanted LV samples were analysed using RNA sequencing (13 DCM, 10 control [CNT]), to compare the transcriptomic profile, focusing on cell adhesion genes.
Results: We found 29 differentially expressed genes, including a broad set of genes belonging to the ID structure. We further analysed the relationship between the mRNA levels and LV dysfunction and found that the expression of GJA3, DSP and CTNNA3 was directly associated with LV ejection fraction (r=0.741, P=0.004; r=0.674, P=0.011 and r=0.565, P=0.044, respectively), LV systolic (r=−0.746, P=0.003; r=−0.753, P=0.003; r=−0.605, P=0.028, respectively) and diastolic (r=−0.712, P=0.006; r=−0.801, P=0.001; r=−0.616, P=0.025, respectively) diameters. Electron microscopy micrographs showed a reduction in the ID convolution index in DCM patients.
Conclusions: We report a high number of expression changes in cell adhesion genes and found that the ID components GJA3, DSP and CTNNA3 were highly related to LV function of patients. Microscopic observations indicate that ID is structurally compromised in these patients.These findings offer new data for understanding the ventricular depression that characterizes DCM, which may occur as a result of alterations in cell adhesion integrity and machinery, leading to new therapeutic perspectives on these, until now, non-specifically treated patients.

Expression of golgi genes are related to the degree of ventricular remodeling in heart failure

E Esther Rosello-Lleti[1]; E Tarazon[1]; A Ortega[1]; C Gil-Cayuela[1]; F Lago[2]; JR Gonzalez-Juanatey[2]; L Martinez-Dolz[1]; M Portoles[1]; M Rivera[1]
[1]Hospital Universitario y Politécnico La Fe, Cardiocirculatory Unit , Valencia, Spain; *[2]Instituto de Investigación Sanitaria de Santiago, Cellular and Molecular Cardiology Research Unit, Santiago de Compostela, Spain*

Funding Acknowledgements: National Institute of Health [PI13/00100; PI14/01506], CIBERCV [CB16/11/00261], the European Regional Development Fund (FEDER), RETICS [12/0042/0003].

Background. The size and complexity of the Golgi apparatus in cardiomyocytes increase during heart failure. Recently, we have observed morphological changes in human Golgi vesicles that are associated with poorer functional status in patients with dilated cardiomyopathy (DCM).
Purpose: In this study, we examined mRNA expression of Golgi components and it relationship with left ventricular remodeling in patients with DCM and ischemic (ICM) cardiomyopathy.
Methods: We performed RNA-sequencing analysis in patients with DCM ($n = 12$) and ICM ($n = 12$) and healthy controls ($n = 8$) focused on the Golgi apparatus.
Results: We found one hundred thirty-four genes deregulated, of which fifteen and thirteen , respectively, were involved in vesicular secretion in DCM and ICM. Of these, STX5 and AP1M1 mRNA levels related to left ventricular end-systolic and diastolic diameters (both $P < 0.01$) and, more importantly, to systolic function (ejection fraction, $P < 0.05$). Conclusions: In this study we found that changes in expression of some Golgi transport genes in DCM and ICM, STX5 and APM1, are significantly related to the degree of ventricular remodeling and to the left ventricular function. This relationship may lead to an alternative therapeutic approach for a syndrome that currently has no specific treatment; through the manipulation of these genes that may have an important role in ventricular maladaptation to changes in heart wall stress to which the left ventricle is subjected to.

P1318

Role of AQP1 in the left ventricular remodeling

V Montiel[1]; HE Esfahani Hrag[1]; DD De Mulder Delphine[1]; JPD Deglasse Jean-Philippe[2]; OD Devuyst Olivier[3]; JCJ Jonas Jean-Christophe[2]; JLB Balligand Jean-Luc[1]

Aquaporins are a family (AQP0-12) of transmembrane water channels known to mediate rapid water movements following osmotic gradients, as created under a variety of tissular stresses. Some isoforms may be permeable to additional small molecules (e.g. H2O2 in plants) although such function in mammalian Aqp's is undefined. We clearly identified Aqp1 in peripheral membranes of both capillary endothelial and cardiac muscle cells by immunohistochemistry. Aqp1 co-segregated with caveolin and other caveolar residents in lipid rafts/caveolae. Surprisingly, we observed that genetic deletion of Aqp1 in mice produces a striking microcardia, with smaller cardiac myocytes (transverse section area by histological analysis). This was not associated with changes in blood osmolality or free water balance. Moreover, isolated adult myocytes from Aqp1 KO mice failed to build a normal hypertrophic response to phenylephrine. By analogy with plant aquaporins, we hypothesized that Aqp1 mediates transmembrane transport of extracellular H2O2 generated by, and mediating the hypertrophic response to alpha1-adrenergic activation. Indeed, genetic deletion of Aqp1 reduced the intracellular detection of ROS (by H2-DCFDA) or H2O2 (with the specific roGFP2-Orp1 sensor) in cardiac myocytes exposed to graded concentrations of extracellular H2O2, demonstrating a role for Aqp1 in transmembrane transport of H2O2. Notably, incubation of wild-type myocytes with phenylephrine increased ROS/H2O2 signals, but co-treatment with phenylephrine and cell-impermeable (i.e. non-PEGylated) catalase abrogated both the intracellular ROS signals and the hypertrophic response. Similarly decreased ROS/H2O2 signals were observed upon exposure of myocytes from Aqp1 KO mice to phenylephrine (normalized fluorescence, X103: 102 + /-34 vs 400 + /-16 in WT; $P < 0.05$), suggesting that Aqp1 mediates the import of H2O2 produced extracellularly upon alpha1-adrenergic stimulation. To test the functional importance of Aqp1 deletion on cardiac remodeling, we treated Aqp1 KO mice (and WT littermate) with minipump infusion of angiotensin II for 14 days. To control for loading conditions, blood pressure was continuously measured in all mice by implanted telemetry. Ang II resulted in similar increases in BP in both genotypes (SBP in WT: 164 + /-8; Aqp1 KO: 174 + /-13 mmHg; P: ns). WT mice developed cardiac myocyte hypertrophy and fibrosis, which were significantly attenuated in Aqp1 KO (myocyte area (WGA): 462 + /-13µ2 vs 702 + /-23 µ2 in WT; $P < 0.01$). Similar reductions in hypertrophy and fibrosis were observed in Aqp1 KO mice after TAC (myocyte area (WGA): 454 + /-15µ2 vs 762 + /-14 µ2 in WT; $P < 0.01$). We conclude that cardiac aquaporin-1 mediates transmembrane transport of H2O2 and critically modulates the development of myocardial hypertrophy and fibrosis in response to physiologic and pathologic stimuli. Pharmacologic inhibition of AQP1 could be exploited therapeutically to attenuate stress-induced myocardial remodeling.

Notch3 modulates the cardiac adaptation to physiological cardiac growth

C Clement Delacroix[1]; H Ragot[1]; S Guinemer[1]; I Da Costa[1]; E Polidano[1]; R Merval[1]; C Chatziantoniou[2]; J-L Samuel[1]
[1]*Hospital Lariboisiere, Inserm UMR-S942, Paris, France*; [2]*Hospital Tenon, Inserm UMR-S 1155, Paris, France*

Background – The Notch3 receptor plays an important role in differentiation, migration and signal transduction of vascular smooth muscle cells (VSMCs). Notch3 signaling has been recently demonstrated to be essential for the coronary adaptation to pressure overload and in turn prevented acute heart failure (Ragot Hypertension 2016). The objective of the present study was to determine whether Notch3 signaling plays a role in cardiovascular remodeling in response to 2 physiological growth signals: the physical exercise and pregnancy.

Methods: – Male and female mice knocked out for the Notch3 gene (Notch3-/-) or Wild-Type (WT) mice were respectively submitted to treadmill physical-training program for 5 weeks or mated,. Methods included echocardiography, qPCR, western-blot, immuno- and histo-morphometry.

Results: – At baseline, Notch3-/- females exhibited similar cardiac phenotypes than males characterized by an arteriolar rarefaction (-60%, $p < 0.001$) and increased oxidative stress. Pregnancy decreased shortening fraction in Notch3-/- females (-25%, $p < 0.01$ vs post-partum WT). Interestingly, a microvascular adaptation occurred with increase in the capillary density (+25%, $p < 0.05$ vs Notch3-/-). Conversely, moderate physical training did not alter cardiac function in WT and Notch3-/- males. However, the analyses of coronary compartment showed an increased in capillary density (+12%, $p < 0.05$) in the WT mice after training only, these parameters being unmodified in the Notch3-/- mice. The angiogenesis pathway analysis revealed an increased expression in the anti- angiogenic soluble receptor, sFLT1, in the Notch3-/- mice after training (+40%, $p < 0.05$ vs WT + training) whereas it was not induced by the pregnancy in the Notch3-/- females. Conclusion– We provided lines of evidence suggesting that the Notch3 signaling pathway could mediate unique effect according to volume overload stimuli and/or gender which may be due to unique modulation of sFLT1 expression.

P1320

Extracellular signaling regulation of ABCA1 expression

H Hong Yang[1]; ZM Guo[1]
[1]*Meharry Medical College, Nashville, United States of America*

Funding Acknowledgements: NIH SC1HL101431

While increase in cellular cholesterol is able to upregulate ATP-binding cassette transporter A1 (ABCA1) expression, the increased ABCA1 level by this stimulation is insufficient for prevention of foam cell formation. Using a mouse macrophage cell line, we demonstrated a signaling cascade independent of cellular cholesterol level for upregulation of ABCA1 expression. Specifically, activation of very low-density lipoprotein receptor (VLDLR) and apolipoprotein E receptor 2 (apoER2) with apoE, reelin or a reelin subregion containing its receptor binding domain significantly increased ABCA1 mRNA and protein levels. These VLDLR/apoER2 ligands also increased phosphorylation of disabled-1 (Dab1), phosphatidylinositol 3-kinase (PI3K), protein kinase C-ζ (PKC-ζ), and specificity protein 1 (Sp1), and increased PKC-ζ binding with Sp1. Sequential knockdown or inhibition of VLDLR/apoER2, Dab1, PI3K, PKC-ζ and Sp1 diminished the upregulatroy activity of apoE and reelin on ABCA1 mRNA and protein expression. Mutation of the Sp1 binding site in the ABCA1 promoter and inhibition of Sp1 DNA binding suppressed the ABCA1 promoter activity and reduced the ABCA1 mRNA expression level. In addition, VLDLR/apoER2 ligand treatment enhanced phosphorylation of Akt1 and Akt2, but not Akt3. PI3K inhibitors weakened Akt phosphorylation. Inhibition of Akt or knockdown of Akt2 only reduced ABCA1 protein but not its mRNA. Suppression of protein synthesis did not erase the ability of apoE to increase ABCA1 protein level. Further, apoE increased the resistance of ABCA1 protein to calpain-mediated degradation without affecting calpain activity. These data support a model in which activation of VLDLR and apoER2 by reelin and apoE induces ABCA1 transcription via a signaling cascade involving Dab1, PI3K, PKCζ and Sp1, and inhibition ABCA1 protein degradation via a signaling cascade involving PI3K and Akt2. We also observed that apoE, reelin and its subregion accelerated apoAI-mediated cholesterol efflux and inhibited foam cell formation. Thus, upregulation of ABCA1 expression via mechanisms additional to increasing cellular cholesterol level might inform interventions to inhibit foam cell formation and atherosclerosis.

P1321

Identification of upstream kinases that regulate p38-MAPK in cardiomyocytes: H2O2 signals to p38-MAPK via ASK1 whereas interleukin-1-beta signals via TAK1

D N Daniel Nathan Meijles[1]; K A Rostron[1]; A Clerk[1]
[1]*University of Reading, School of Biological Sciences, Reading, United Kingdom*

Funding Acknowledgements: British Heart Foundation

Introduction. Pathophysiological stresses including oxidative stress (e.g. H2O2) and proinflammatory cytokines (e.g. interleukin 1β, IL1β) activate the stress-regulated mitogen-activated protein kinases (MAPKs), p38-MAPKs and c-Jun N-terminal kinases (JNKs) in cardiomyocytes. They also cause cardiac dysfunction and cardiomyocyte death, so components of the pathways are potential therapeutic targets for treatment of heart failure. MAPKs are final components of cascades in which MAPK kinases (MKKs) phosphorylate and activate MAPKs. JNKs are activated by MKK4/7 whilst p38-MAPKs are activated by MKK3/6. MKKs are phosphorylated and activated by upstream protein kinases, MAP3Ks, but the MAP3Ks for activation of p38-MAPKs and JNKs under different conditions are not well defined. Purpose. We aim to identify the MAP3Ks that activate p38-MAPKs and JNKs in cardiomyocytes. Our hypothesis is that different pathological stimuli signal through specific MAP3Ks to MKK4/7 and MKK3/6. Methods and results. Proteomics analysis of neonatal and adult rat ventricular myocytes (NRVMs and ARVMs) detected significant expression of MAP3Ks 1-7 and MAP3K11. MAP3K9, MAP3K12 and MAP3K14 were also detected at the mRNA level. Only MAP3K5 (ASK1) was expressed at a higher relative level in ARVMs, although others including MAP3K7 (TAK1) remained relatively highly expressed in ARVMs. We compared the effects of H2O2 and IL1β on phosphorylation (i.e. activation) of ASK1 and TAK1 in cardiomyocytes by immunoblotting extracts with antibodies to phosphorylated and total kinases. H2O2 promoted phosphorylation of ASK1, but not TAK1 (maximal activation with 1 mM H2O2, 5 min). In contrast, IL1β (25 ng/ml) stimulated phosphorylation of TAK1, but not ASK1 (maximal activation at 5 min). Similar results were obtained in Langendorff perfused adult rat hearts. Phosphorylation of MAP3K3 results in the appearance of a reduced mobility

band on immunoblots. Such a band shift was detected in cardiomyocyte extracts in response to either H2O2 (1mM) or IL1β. To dissect the role of ASK1 in activation of stress-regulated MAPKs, we examined the effects of a small molecule inhibitor of ASK1, selonsertib, on phosphorylation (i.e. activation) of p38-MAPKs and JNKs by immunoblotting cardiomyocyte extracts with antibodies to phosphorylated and total kinases. Selonsertib selectively inhibited activation of p38-MAPK by H2O2 with no effect on activation of p38-MAPK by IL1β and no effect on activation of JNKs by either agonist. Conclusions: Several MAP3Ks are expressed in cardiomyocytes and can signal to stress-regulated MAPKs. Our data identify selective signalling through specific MAP3Ks in response to different stimuli. Thus, oxidative stress signals through ASK1 to p38-MAPKs, not JNKs, whereas IL1β does not activate ASK1, but activates TAK1 instead. It will therefore be important to target different MAP3Ks under different conditions to manipulate p38-MAPK and/or JNK signalling for the management of heart failure.

In vivo silencing of histone deacetylase 1 displays anti-atherosclerotic effects in hypercholesterolemic apolipoprotein E deficient mice

S-A Simona-Adriana Manea[1]; ML Antonescu[1]; MI Fenyo[1]; A Manea[1]
[1]*Institute of Cellular Biology & Pathology Nicolae Simionescu, Bucharest, Romania*

Funding Acknowledgements: Work supported by grants from CNCS – UEFISCDI, project numbers PN-III-P2-2.1-PED-2016-1308, PN-II-ID-PCE-2011-3-0548, PN-II-RU-TE-2011-3-0142.

Background - The beneficial effects of several pan-histone deacetylase (HDAC) inhibitors have been demonstrated in various experimental models of heart failure and hypertension. However, the role of HDACs in atherosclerosis and the rationale of using HDAC inhibitors as therapeutic strategy are not established. HDAC1 is an essential isoform of the HDAC family and control a large number of physiological activities. Up-regulation of HDAC1 induces histone deacetylation resulting in transcriptional repression of genes that normally function in cellular proliferation, differentiation, and apoptosis. In addition, HDAC1 may act on and modulate the function of multiple non-histone proteins such as transcription factors to induce/repress the gene expression.
Purpose: - To establish the specific contribution of HDAC1 isoform in mediating oxidative stress and inflammation in atherosclerosis.
Methods: - A nanotechnology-based procedure was employed for in vivo siRNA delivery in hypercholesterolemic apolipoprotein E deficient (ApoE-/-) mice. Male ApoE-/- mice were randomized to receive normal (ND) or high-fat cholesterol-rich diet (HD) for 10 weeks (intermediary lesions). Aged-matched C57BL/6J mice maintained on normal diet were used as controls. Atherosclerotic ApoE-/- mice (HD) were treated with 0.5 mg/kg of non-targeted (control) or HDAC1 siRNA. One week after siRNA administration, the animals were sacrificed and aorta was analysed by Oil Red O staining and Western blot. To set-up the optimal conditions for systemic siRNA delivery, FITC-labelled siRNA and in vivo imaging (IVIS Caliper, Perkin Elmer) were used. The fluorescence signal was detected at different time points after FITC-siRNA administration to assess the biodistribution and the uptake efficiency of the FITC-siRNA (blood and various organs).
Results: - We found that HDAC1 protein level was significantly elevated in the aorta of ApoE-/- mice fed a HD compared to ApoE-/- mice maintained on ND. Ex vivo imaging revealed that FITC-siRNA was abundant in the blood and several organs (liver, lungs, and pancreas) and to a lesser extent in the kidneys. Systemic delivery of HDAC1 siRNA resulted in a significant decrease in HDAC1 protein expression level in the aorta of atherosclerotic ApoE-/- mice (HD). In vivo silencing of HDAC1 correlated with significant decreases in the expression of NADPH oxidase, a reactive oxygen species-generating enzyme complex (Nox1, Nox2, and Nox4), vascular inflammation (NOS2, MMP9, CD45), matrix deposition and remodeling (fibronectin, MMP9), and cell proliferation (PCNA) markers.
Conclusion: - Our preclinical study indicates that selective targeting of a specific HDAC isoform (e.g., HDAC1) rather than pan-HDAC inhibition may be a novel therapeutic strategy to counteract vascular oxidative stress and inflammation in atherosclerosis.

Protein expression profiling of histone acetyltransferases and histone deacetylases in human and experimental atherosclerosis

A Adrian Manea[1]; S-A Manea[1]; ML Antonescu[1]; IM Fenyo[1]; M Raicu[1]; M Simionescu[1]
[1]*Institute of Cellular Biology & Pathology Nicolae Simionescu, Bucharest, Romania*

Funding Acknowledgements: Work supported by grants from CNCS – UEFISCDI project numbers PN-III-P2-2.1-PED-2016-1308, PN-II-ID-PCE-2011-3-0548, and PN-II-RU-TE-2011-3-0142.

Background. Changes in chromatin conformation due to histone acetylation play a major in epigenetic regulation of gene expression. Histone acetylation is regulated by the activities of two major enzyme families, namely histone acetyltransferases (HAT) and histone deacetylases (HDAC). As general principle, histone acetylation induces chromatin relaxation, a condition that facilitates the accessibility of transcription factors to their cognate DNA elements in the genome. Thus, histone acetylation is associated with active gene expression. Several non-histone proteins such as transcription factors may be the substrates of HAT/HDAC activity. The beneficial effects of various pan-HDAC inhibitors were demonstrated in several experimental models of cardiovascular diseases. Hitherto, the regulation of HAT/HDAC and their implication in atherogenesis and also the rationale of using HDAC inhibitors are not completely understood.
Purpose: The aim of this study was to investigate the protein expression profile of representative HAT (type A: p300, type B: HAT1) and HDAC (class I: HDAC1, HDAC2, class IIa: HDAC4, class IIb: HDAC6, class III: Sirt1, class IV: HDAC11) isoforms and to estimate the overall histone acetylation status in human and mouse atherosclerosis.
Methods: Non-atherosclerotic (superior thyroid artery) and atherosclerotic (carotid artery) samples obtained as discarded tissues from patients undergoing carotid endarterectomy and apolipoprotein E deficient (ApoE-/-) mice were used. At 7 weeks of age male ApoE-/- mice were distributed into experimental groups to receive normal or high-fat cholesterol-rich diet for 10 weeks. Aged-matched C57BL/6J mice maintained on normal diet were used as controls. Oil red O staining was employed to assess lipid deposition within atherosclerotic lesions. The expression/localization of HAT and HDAC subtypes, the level of H3K27ac, oxidative stress and inflammatory markers were determined by Western blot/microscopy.
Results: We found that p300, HAT1, HDAC1, HDAC2, HDAC4, Sirt1, and HDAC11 isoforms were significantly up-regulated in atherosclerotic plaques derived from human carotid artery compared to non-atherosclerotic samples. A similar expression pattern of HAT and HDAC proteins was found in the aorta of atherosclerotic ApoE-/- mice. Interestingly, the increased expression of HAT and HDAC subtypes correlated with the severity of atherosclerotic lesions and plasma cholesterol level in ApoE-/- mice. An overall increase in H3K27ac (marker of active gene expression) level was detected in both human and mouse atherosclerotic lesions as compared to the corresponding non-atherosclerotic controls. Conclusion. Our study provides the first evidence that the histone acetylation system is altered in atherosclerosis. Both HAT and HDAC subtypes are up-regulated in atherosclerosis suggesting the existence of a feed-back mechanism whereby increased expression of HATs is compensated by up-regulation of HDACs and vice versa.

Understanding the poor angiogenic capacity of the mammalian heart

A Ambra Cappelletto[1]; YQ Tang[1]; M Rehman[1]; C Pierro[1]; S Zacchigna[1]
[1]*International Centre for Genetic Engineering and Biotechnology (ICGEB), Cardiovascular Biology, Trieste, Italy*

Purpose: The reason why a hypoxic tumor forms its own vasculature, mainly through the secretion of the Vascular Endothelial Growth Factor (VEGF), whereas an ischemic heart cannot, still remains obscure. We hypothesize that cardiac endothelial cells (ECs) loose their capacity to proliferate soon after birth, similar to what happens to mammalian cardiomyocytes.
Methods and Results: The injection of an adeno-associated vector (AAV) encoding for VEGF into either the adult skeletal muscle or the embryonic heart induced a massive formation of capillaries and arterioles. In contrast, the same vector injected into an adult heart did not result in any increase in endothelial cell proliferation. To understand whether the different angiogenic potential of the three organs depends on intrinsic properties of ECs or rather on the presence of some inhibitory factors within the adult heart, we purified ECs using CD31 magnetic beads. By flow cytometry we could detect the presence of an EC sub-population characterized by high expression levels of VEGFR2 and CD105, two tip cell markers, in the embryonic/neonatal but not in the adult heart ECs. Consistently, the formation of filopodia by tip cells and vessel-like tubular structures in response to VEGF was much more evident for embryonic/neonatal than for adult cardiac ECs. RNAseq data from the three EC types reveal a differential expression profile for coding genes, miRNAs and lncRNAs. ECs purified from the heart of EGFP transgenic pups formed capillaries and integrated into the vascular network of the skeletal muscle but not of the adult heart, suggesting the presence of an anti-angiogenic factor in this latter organ. The expression of VEGFR1 and its soluble isoform sFlt1 was significantly increased in adult compared to embryonic hearts, consistent with the role of sFlt1 in keeping the cornea completely avascular. Cancer cells injected into the heart of adult syngeneic mice grew much less compared to the same number of cells injected into the skeletal muscle, possibly indicating that the impaired angiogenic potential of the heart inhibited tumor growth. Conclusions: Collectively, these results indicate that both cell-autonomous and non autonomous mechanisms halt the proliferation of ECs in the post-natal heart and pave the way to novel therapeutic opportunities to promote angiogenesis in cardiac ischemia and, possibly, to control tumor progression.

Background - In the presence of premenopausal hypertension it may intensify a cardiac dysfunction when estrogen depletion occurs, this study aimed to evaluate the estrogen receptor agonists in the estrogen depletion in normotensive (WKY) and spontaneously hypertensive (SHR) rats.
Methods: Protocols were approved by Animal Care and Use Committee at Universidade. Females WKY or SHR (12 weeks old) were divided into groups, Sham and oophorectomized (OVX) treated subcutaneous with vehicle, G1, PPT or DPN, 24 μMol/kg, 28 days. Diastolic function was determinate by the ratio between early transmitral filling velocity (E) and rapid mitral annular velocity (e') and left ventricular end diastolic pressure (LVEDP). In addiction was analyzed mean blood pressure (MBP). Results - There was uterine atrophy in OVX. There was weight gain in the OVX, WKY and SHR and reduced in WKY-OVX-PPT. The heart/tibia increase in OVX, WKY and SHR compared to Sham, and reduction in WKY-OVX-PPT and SHR-OVX treated with G1 or PPT. The E/e' was elevated in the SHR-OVX compared to SHR-Sham and the SHR-OVX G1 treatment reversed. MBP were increased in SHR-Sham compared to WKY-Sham, from 107.8 ± 14.72 to 112.7 ± 7.54 mmHg ($P < 0.05$), in SHR-OVX was intensified to 143.7 ± 7.66 mmHg ($P < 0.05$). Treatment with G1, DPN and PPT promoted partial reduction of MBP in SHR-OVX. OVX in WKY increased from PVEDF when compared to WKY-Sham from 2.05 ± 0.66 to 8.12 ± 1.7 mmHg ($P < 0.05$), which was not reduced with treatments. We observed that SHR-Sham presented increased PVEDF in relation to WKY-Sham 7.38 ± 0.88 mmHg ($P < 0.05$) and increased in SHR-OVX to 13.81 ± 2.10 mmHg compared to SHR-Sham ($P < 0.05$). SHR-OVX-DPN presented PVEDF reduction to 5.70 ± 0.92 mmHg, ($P < 0.05$) compared to SHR-OVX. Conclusion - We observed improvements in cardiac structure and functional parameters with the different estrogen agonists in equimolar doses.

Introduction: Coenzyme Q10 (CoQ10) plays an important role in the generation of the cell energy – ATP, being part of the electron transport chain in process of oxidative phosphorylation in the internal membrane of mitochondria. Many diseases of the cardiovascular system and congestive heart failure, in particular, depend on decreased content of Coq10 and myocardial CoQ10 content tends to decline as the degree of heart failure worsens. Additionally, CoQ10, through its antioxidant effects, may reduce oxidative stress, which is known to adversely affect left ventricular ejection fraction and alter disease outcomes. The long-term supplementation of CoQ10 in patients with HF seems safe, appears to produce symptomatic improvements, and, more importantly, has been found to significantly reduce major adverse cardiovascular events and mortality. Ubiquinol is the reduced form of coenzyme Q10. This drug is expected to complement coenzyme Q10, which is naturally found in the organism, helping the cells to produce more energy y and thus relieve the symptoms of this disease.
Purpose: – investigation of the pharmacokinetics of ubiquinol, administered intravenously, for the urgent increase of its concentration in blood and myocardium.
Methods: Solution (1%) of solubilized ubiquinol (dose 10 mg/kg) was administered intravenously to male Wistar rats. Samples of blood and myocardium were taken in 0, 0.25, 0.5, 1, 2, 4, 8, 24, 32, 48h after i.v. injection. 5 rats were used for each time point that means 50 rats were used for the study. Levels of ubiquinol were measured by HPLC with an electrochemical detector.
Results: High levels of ubiquinol were detected in blood during the whole period of observation, and it was 10-fold higher than baseline level 48 h after iv administration. The significant increase in the myocardial level of ubiquinol was detected in 15 min after iv injection. The maximal increase in the myocardial level of ubiquinol by 50-80% maintained during 24 h and reached the initial level in 48 h.
Conclusion: Intravenous administration of the solubilized ubiquinol is followed by the fast increase in its concentrations in blood and myocardium that could be used for the treatment of acute heart failure as well as ischemia/reperfusion conditions.

Background: Obstructive sleep apnea (OSA) is associated with increased occurrence of atrial fibrillation (AF) and dysregulation of the circadian rhythm. Repetitive obstructive respiratory events as appearing in OSA are characterized by intermittent hypoxia and hypercapnia. Ineffective breathing attempts against the occluded upper airways result in intrathoracic pressure changes increasing transmural pressure gradients in the heart. Yet it is unknown, whether intermittent hypoxia (IH) per se or negative intrathoracic pressure changes in combination with hypoxia (NTP-H) during obstructive respiratory events are responsible for the development of an arrhythmogenic substrate in the atrium.
Method: In anaesthetized rats, either IH or NTP-H was applied repetitively for one minute via a customized mask by a negative pressure device. In an acute-test-series (ATS), rats had a rest period of four minutes between every maneuver. Eight IH-rats and eight NTP-H-rats were sacrificed instantly after four hours. In a chronic-test-series (CTS), we applied one minute of IH or NTP-H with a rest period of nine minutes for four hours every second day. After three weeks, rats were sacrificed with a recovery period of 24 hours after the last maneuver. Rats with comparable anesthesia without application of IH or NTP-H were used as controls (CTR). Invasive left ventricular pressure measurements were performed and inducible AF-duration by atrial burst stimulation was determined.
Result: In ATS-rats, acute application of four hours repetitive NTP-H resulted in a substantial decrease of atrial anti-oxidative capacity indicated by diminished glutathione-ratio (GSH/GSSG: $p = 0.02$ vs. CTR). However, IH did not influence atrial anti-oxidative capacity. In CTS-rats, chronically applied NTP-H but not IH induced an increase in LA and RA interstitial fibrosis formation (LA: +135% vs. CTR, $p = 0.01$; RA: +125% vs. CTR, $p = 0.04$). Additionally, enlarged LA-myocyte diameters indicated developing hypertrophy in NTP-H-rats (LA: +107%, $p = 0.03$ vs. CTR). This was associated with significantly prolonged inducible AF-duration in rats with chronically applied NTP-H ($p = 0.02$ vs. CTR; NTP-H: 11.65 seconds; CTR: 0.98 seconds) but not with IH ($p = 0.31$ vs. CTR; IH: 1.28 seconds).
Conclusion: During acute obstructive respiratory events, NTP-H but not IH per se results in a transient and rapidly reversible increase in atrial oxidative stress. In the long term, chronically applied NTP-H results in an atrial arrhythmogenic substrate, characterized by increased interstitial fibrosis formation, atrial myocardial hypertrophy and AF-vulnerability.

P1328

An investigation of ca2+ regulation abnormalities underlying hypertrophic cardiomyopathy in cat hearts

A E Messer[1]; J Chan[2]; A Daley[2]; O Copeland[1]; D J Connolly[2]; S B Marston[1]
[1]Imperial College London, Myocardial Function, London, United Kingdom; *[2]The Royal Veterinary College, Small Animal Medicine and Surgery Group, London, United Kingdom*

Background: Hypertrophic cardiomyopathy (HCM) is the most common cardiac disease affecting 1 in 500 humans. HCM is even more prevalent in cats and affects 16% of the outbred population and up to 26% in pedigree breeds such as Maine Coon and Ragdoll. Homozygous MYBPC3 mutations have been identified in these breeds but the mutations in other cats are unknown. At the clinical and physiological level, feline HCM is closely analogous to human HCM, but little is known about the primary causative mechanism.
Purpose: The aim of this project is to compare troponin regulation by Ca2+ and phosphorylation in HCM and wild-type cats with human HCM and to ascertain if treatments that reverse the abnormalities in human samples also work in HCM cats.
Methods/Results: Quantitative in-vitro motility assays were performed with troponin extracted from post-mortem hearts of 8 cats diagnosed with HCM including one Ragdoll cat with a homozygous MYBPC3 R820W mutation and 5 wild-type (WT) unaffected cats. Two cats showed MyBP-C haploinsufficiency, but genotypes are currently unknown. All the HCM cats have a higher Ca2+-sensitivity than the WT cats (EC50 of 0.057 ± 0.003 μM, n=44 compared to 0.092 ± 0.006 μM, n=24) with an average increase of $x2.05 \pm 0.13$. This is equivalent to that found in many studies of Ca2+-regulation in HCM mutations (1.87 ± 0.07 fold, n=71: Marston, Front physiol. 2016; 7(242), 415). This differs from human myectomy samples, where Ca2+-sensitivity is the same as donor, probably due to secondary changes.
A major phenotype of human HCM is that the relationship between troponin I phosphorylation and Ca2+-sensitivity is uncoupled. This uncoupling is also observed in all the HCM cats examined ($EC50P/EC50unP = 1.05 \pm 0.02$, n=25) whereas all the WT cats tested show normal coupling ($EC50P/EC50unP = 1.83 \pm 0.11$, n=8). We showed previously that in myectomy samples the uncoupling was due to an abnormality of troponin T and we have likewise been able to restore coupling in cat HCM by replacing TnT with wild-type (human) protein. Similarities between cat and human HCM are further emphasised by the observation that the enhanced Ca2+-sensitivity and uncoupling due to HCM mutations can be reversed by 100 μM Epigallocatechin-3-gallate (EGCG) in the cat as has been previously demonstrated in human heart muscle ($EC50P/EC50unP$ cat HCM + EGCG $= 2.13 \pm 0.17$, n=12).
Conclusion: To conclude, our result further demonstrate that feline HCM is an excellent model for the human disease both at the fundamental cellular level with respect to Ca2+ regulation of sarcomeric proteins and at the clinical level in disease expression.

Functional mini-gene analysis reveals aberrant splicing due to an infrequent intronic mutation in the cardiomyopathy-associated MYBPC3 gene

M Torrado[1]; E Maneiro[2]; D Salvado[2]; L Monserrat[2]; A Mikhailov[1]
[1]Institute of Health Sciences, University of La Coruna, La Coruna, Spain; *[2]Health in Code Ltd., La Coruna, Spain*

Funding Acknowledgements: This work was partially supported by a grant GRC 2013/061 of the Autonomic Government of Galicia, Spain.

Background: Mutations in the myosin-binding protein (MYBPC3) gene are the most common cause of hypertrophic cardiomyopathy (HCM). There is evidence to suggest that MYBPC3 point mutation localized in the donor splice site of intron 32 (MYBPC3 c.3627+1G>A) is associated with a severe HCM phenotype in patients. Purpose: The aim was to functionally analyze MYBPC3 c.3627+1G>A mutation, as a first step towards understanding whether this mutation could account for a HCM phenotype in vivo.
Methods: Mutation screening of the MYBPC3 gene was performed by bidirectional Sanger sequencing of genomic DNA from a heterozygous patient with HCM undergoing genetic testing at our molecular diagnostic facility. Both MYBPC3 splice-site consensus (control) and c.3627+1G>A mutated regions were amplified from this genomic DNA by PCR and cloned into mini-gene dual tagged (N-terminal FLAG and C-terminal c-Myc) expression plasmids. The resulting plasmids were amplified, endotoxin-free purified, confirmed by DNA sequencing, and transfected into COS-7 cells. The expression of mini-gene plasmids was analyzed in transfected COS-7 cells at the protein (Western blot) and transcript (RT-PCR) level. Results: To verify the potential role of the MYBPC3-c.3627+1G>A mutation identified by genetic screening, we used the multi-algorithm software suite: all five algorithms showed that this mutation impairs the consensus splice-donor site of intron 32 and is expected to lead to disruption in MYBPC3 transcription. Consensus and mutated MYBPC3 allelic mini-genes (900 bp and 1928 bp) were generated using the patient genomic DNA as template. Western blot and RT-PCR analyses at different time points after transfection revealed that: (1) consensus mini-gene constructs were processed as predicted by computer analysis generating intronless transcripts which were translated into the protein detected by both anti-FLAG and anti-Myc antibodies, (2) neither the normally processed transcripts nor FLAG/Myc-tagged proteins were detected in COS-7 cells transfected with mini-gene constructs carrying the c.3627+1G>A mutation, and (3) the length of the mini-gene sequence did not significantly influence the expression response of COS-7 cells transfected by either consensus or mutated plasmids. Conclusions: The results strongly suggest that the intron c.3627+1G>A mutation of the MYBPC3 gene could result in haploinsufficiency, potentially modifying the disease phenotype.

Purpose: Missense mutations in CSRP3, the gene coding for Muscle LIM Protein (MLP), are known to cause Hypertrophic Cardiomyopathy (HCM). MLP is not localised to the myofilaments and this challenges the paradigm of HCM being a disease of the sarcomere. We hypothesise that HCM mutations in signalling proteins such as MLP can cause perturbations in hypertrophic signalling cascades in the heart, resulting in cardiomyopathy. Supporting this hypothesis, MLP has recently been identified as an endogenous inhibitor of protein kinase C and reduction of inhibition may contribute to cardiomyopathy and heart failure.
Methods: A knock-in mouse model was generated by homologous recombination, introducing the C58G mutation into the mouse MLP protein. Heterozygous and homozygous knock-in mice were generated and their cardiac function assessed in vivo by echocardiography and invasive haemodynamic measurements. Tissues harvested from these animals were analysed for molecular markers of hypertrophy and heart failure as well as aberrant activation of protein kinase C alpha signalling (by quantitative PCR, Western blotting and Phos-Tag electrophoresis).
Results: Heterozygous MLP C58G knock-in mice display no overt phenotype and

show a similar hypertrophic response to trans-aortic constriction when compared to wildtype littermates. Homozygous MLP C58G knock-in mice have a phenotype resembling dilated cardiomyopathy, with compensatory activation of hypertrophy. At the molecular level, markers of heart failure and hypertrophic signalling are induced in these mice. Total MLP protein is significantly reduced (approximately 20 % of wild type levels), consistent with previous studies suggesting the mutation causes protein destabilisation. The mutant protein lacks phosphorylation (compared with MLP being 30-50 % in mono-phosphorylated state in wildtype) although protein kinase C alpha activity is elevated.
Conclusion: The mouse model recapitulates aspects of human Hypertrophic Cardiomyopathy caused by MLP missense mutations (such as protein destabilisation) and is a valuable tool to study molecular mechanisms resulting in cardiomyopathy, in particular how MLP integrates protein kinase C signalling into hypertrophic signalling cascades.

Background. Heart transplantation is the last treatment in case of terminal heart failure. Acute rejection after heart transplantation raises several issues due to its occurrence despite immunosuppressive therapies and the requirement of invasive and repeated endomyocardial biopsies (EMB) that have several histological grading limitations. Non-invasive diagnostic and predictive criteria are needed.
Purpose: Characterize acute cellular (ACR) and antibody-mediated rejections (AMR) of cardiac allograft using a molecular approach, in myocardium and peripheral blood.
Methods: We characterized myocardial and peripheral blood gene expression profiles (GEP) during ACR and AMR by mean of microarray analyses. By a retrospective study conducted on a historical EMB collection, we first showed a strong myocardial immunologic modulation during ACR. For the same ACR histological grading, two transcriptional profiles were identified corresponding to distinct inflammation profiles. Moreover, myocardial GEP modifications were observed one month before the occurrence of ACR, while histological characteristics showed no abnormality. A second study conducted on a prospective collection of both EMB and peripheral blood samples confirmed the results obtained on EMB and showed peripheral blood GEP modulations during both ACR and even one month earlier. Finally, we have also shown for the first time in heart transplantation, myocardial and peripheral GEP modulations in AMR, including common pathways between ACR and AMR.
Conclusion: Identification of modulated pathways in both ACR and AMR indicates intricate pathophysiological mechanisms, and should allow for the determination of common rejection biomarkers.

Nesprins 1 and 2 are highly expressed in skeletal and cardiac muscle and together with SUN (Sad1p/UNC84)-domain containing proteins and lamins form the Linker of Nucleoskeleton and Cytoskeleton (LINC) bridge complex at the nuclear envelope (NE). Mutations in nesprin-1 and -2 have previously been found in patients with autosomal dominant Emery–Dreifuss muscular dystrophy 4 (AD-EDMD 4, OMIM 612998) and 5 (AD-EDMD5, OMIM 612999) as well as dilated cardiomyopathy (DCM). In this study, three novel rare variants (R8272Q, S8381C, N8406K) in the C-terminus of the Syne-1 gene (nesprin-1) were identified in 7 DCM patients by mutation screening. Expression of these mutants caused nuclear morphology defects and reduced lamin A/C and SUN2 staining at the NE, and GST-pull down indicated that SUN/lamin/nesprin-1 interactions were disrupted. Nesprin-1 mutations were also associated with augmented activation of the ERK pathway in vitro and in hearts in vivo. During C2C12 muscle cell differentiation nesprin-1 levels are increased concomitantly with kinesin light chain (KLC1/2), and immunoprecipitation and GST-pull down showed that these proteins interacted via an LEWD domain in the C-terminus of nesprin-1. Expression of nesprin-1 mutants in C2C12 cells caused defects in myoblast differentiation and fusion associated with dysregulation of myogenic transcription factors and disruption of the nesprin-1/KLC-1/2 interaction at the outer NE. These findings support a role for nesprin-1 in myogenesis and muscle disease, and uncover a novel mechanism whereby disruption of the NE-LINC complex may contribute to the pathogenesis of DCM.

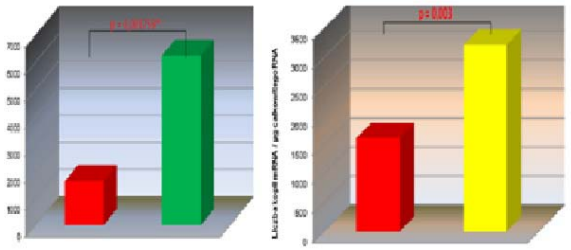
Transforming growth factor beta 1 - new chronic ischaemic heart failure decompensation marker?

J Dabek[1]; M Piechota[2]; M Majewski[1]
[1]*Medical University of Silesia in Katowice, School of Health Sciences, Chair and Department of Cardiology, Katowice, Poland*; [2]*City Hospital in Tychy, Department of Cardiology, Tychy, Poland*

Introduction: Cardiovascular diseases remain important cause of morbidity and mortality in developed countries. Atherosclerosis of coronary arteries is dominant element and often leads to ischemic heart failure (HF). Transforming growth factor beta 1 (TGF-β1) is one of the crucial cytokines in atherosclerosis development and progression as well as in HF formation. Accurate knowledge of its role in these processes may allow for early implementation of appropriate management in order to improve the prognosis of patients with ischemic HF.
Purpose: The aim of the study was to compare TGF-β1 transcriptional activity in patients with ischemic decompensated HF, after their compensation as well as in patients with advanced coronary artery disease without HF, constituting control group.
Methods: Studied group involved all consecutively admitted to the cardiology department patients with HF in the course of coronary artery disease in III and IV NYHA class (n = 52). The control group consisted of patients with advanced coronary artery disease without HF coexistence (n = 23). RNA was obtained from peripheral blood mononuclear cells. Transcriptional activity of TGF-β1 using QRT-PCR method in patients with advanced HF due to coronary artery disease and in patients with coronary heart disease without coexisting HF as well as their expression in the stage of both: decompensation and in compensated period was assesed. Enrolled patients were evaluated within first 24 hours and then after 4-8 weeks since admission, when HF compensation was achieved.
Results: Obtained dada are presented in figure below. To the left, transcriptional activity of TGF-β1, statistically significantly lower in patients with advanced heart failure in the course of coronary artery disease (red color) compared with controls – ischaemic subjects without HF (green) has been shown. To the right side transcriptional activity of TGF-beta 1 in patients with decompensated ischemic HF (red) and during their compensation (yellow) has been presented.
Conclusions: Statistically significant reduction of TGF-β1 transcriptional activity in patients with congestive heart failure and their further reduction during decompensation suggest importance of that gene in the development and decompensation of heart failure, making it useful diagnostic and prognostic clinical marker identifying subjects with coronary coronary heart disease and high risk for HF developing, its decompensation and compensation.



TGF beta 1 transcriptional activity

Purpose: Increased sarcoplasmic reticulum (SR) Ca2 + leak via the cardiac ryanodine receptor (RyR2) has been suggested to have a mechanistic role in the development of heart failure (HF). So we tested the hypothesis whether inhibiting or inducing SR Ca2 + leak modulates HF progression.
Methods: Wild-type C57BL/6J mice, subjected to transaortic constriction (TAC)-induced pressure overload (PO) or permanent coronary artery ligation-induced myocardial infarction (MI), were treated with a selective RyR2 stabilizing Rycal S36. Moreover, Ryr2RS/WT knock-in mice with the patient catecholaminergic polymorphic ventricular tachycardia (CPVT)-associated RyR2 mutation (R2474S) were subjected to shunt-induced volume overload (VO).
Results: In the TAC model, SR Ca2 + leak was significantly reduced in S36- versus placebo-treated mice. However, both treatment groups exhibited comparable contractile deterioration. Interestingly, S36-treated mice exhibited an improved survival after TAC. Implanted ECGs showed a markedly decreased arrhythmia score by ≍ 42%. Arrhythmia inducibility in perfused hearts was dramatically reduced by ≍ 72% post-TAC. Consistently, MI mice, treated with Rycal S36, experienced improved survival and reduced arrhythmias vulnerability. However both MI S36 and MI placebo hearts developed similar pump dysfunction. In the VO model, although SR Ca2 + leak was massively increased in Ryr2RS/WT mice, both WT and Ryr2RS/WT mice had a similar depressed pump function post-shunt.
Conclusions: These results suggest that SR Ca2 + leak may not primarily influence contractile remodeling in three different HF models, whereas ventricular arrhythmias were significantly reduced and survival was improved by Rycal S36 treatment. Thus selective SR Ca2 + leak inhibition via the Rycal S36 might be a promising option for treatment of cardiac arrhythmias in patients with HF and CPVT.

P1335

Autonomic regulation of cardiac activity in patients with prehypertension

BG Hojakuliyev[1]; BN Orayeva[1]; MB Muhammedov[2]
[1]Turkmen State Medical University, Ashgabat, Turkmenistan; *[2]Mary Regional Multi-field Hospital, Myocardial infarction, Mary, Turkmenistan*

Hypertensive disease (HD) is a disease dysregulation, and at the stage of formation of the disease the clinical picture is dominated by manifestations of autonomic dysfunction. The purpose of research - study of heart rate variability (HRV) and to assess the relationship between the sympathetic and parasympathetic divisions of the autonomic nervous system (ANS) in patients with HD and prehypertension (preHTN) emissions during the orthostatic test. The study involved 30 patients with HD (20 men, 10 women), average age 46,6 ± 1,4 years and 25 with preHTN (16 men and 9 women), average age 34,8 ± 2,1 years. The control group consisted of 12 healthy people, the average age of 26,1 ± 3,2 years.All patients conducted daily Holter ECG. The total capacity of the spectrum of neurohumoral modulation in patients with HD was 1253 ± 470 ms2 / Hz, preHTN 2.4 times higher - 3032 ± 978 ms2 / Hz in the control group - 3778 ± 1022 ms2 / Hz. In 55.7% of patients with HD and y 17.3% of patients with preHTN has been a transition to the system of regulation of autonomic reflex level to a lower humoral-metabolic, who is able to quickly provide the homeostasis of the cardiovascular system. In the analysis of the balance of ANS at 71.1% HD patients prevailed activity of the sympathetic division, at 28.8% - with preHTN and 26.9% - the control group. Balanced type of autonomic modulation of cardiac rhythm was observed in 50% of cases with preHTN, in 55.8% - healthy and 25.1% - with the HD; parasympathetic predominance was seen in 21.1% of patients with preHTN and in only 3.8% of HD patients. Thus, in patients with preHTN notes balanced type of autonomic modulation of cardiac rhythm without changing the spectral parameters.

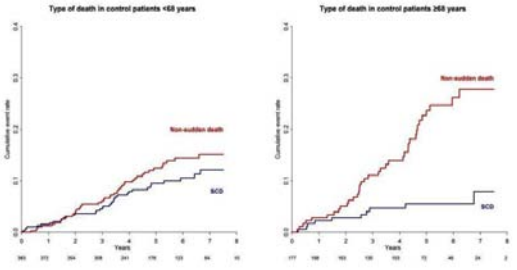
Background: Systolic heart failure carries an increased risk of sudden cardiac death. However, no single study has demonstrated a prophylactic effect of implantable cardioverter-defibrillator (ICD) implantation in patients with non-ischemic systolic heart failure. The recent Danish Study to Assess the Efficacy of ICDs in Patients with Non-ischemic Systolic Heart Failure on Mortality (DANISH) study did not demonstrate an overall effect on all-cause mortality. However, there was a significant interaction between age and implantation of an ICD with a significant mortality reduction in the youngest patients.
Purpose: Further investigation of the relationship between age and the effect of primary prophylactic ICD in patients with non-ischemic systolic heart failure.
Methods: In the DANISH study 1116 patients with non-ischemic symptomatic systolic heart failure and left ventricular ejection fraction (LVEF) ≤35% were randomized to ICD implantation or control. Assessment of interaction between age and ICD implantation was done with age as a continuous variable. Causes of death were divided into sudden cardiac death and non-sudden death (a composite of non-cardiovascular death and non-sudden cardiac death), and compared between the two youngest tertiles and the oldest tertile. Incidence rates were calculated as events per 100 patient years.
Results: There was a linear correlation between the effect of an ICD on all-cause mortality and decreasing age, p = 0.03. Causes of death differed significantly for patients not treated with an ICD and respectively below and above 68 years, p = 0.01. For patients younger than 68 years the rate of sudden cardiac death was 2.0 (1.4 – 2.7) events/100 patients years and the rate of non-sudden death was 2.6 (2.0 – 3.5) events/100 patients years, and for patients older than 68 years the incidence rate of sudden cardiac death was 1.3 (0.7 – 2.4) events/100 patients years and the rate of non-sudden deaths was 4.7 (3.4 – 6.5). Expressed in percent, sudden cardiac death occurred in 12% of patients younger than 68 years, whereas 15% in this age group died from a different cause. In contrast, patients ≥68 years old only 8% died of sudden cardiac death compared to 28% who died in a different way.
Conclusion: In patients with systolic heart failure not caused by ischemic heart disease the effect of ICD implantation decreased with increasing age. Patients younger than 68 years had roughly equal incidence rates of sudden cardiac death and non-sudden death and had a significant reduction in all-cause mortality when treated with an ICD. Patients older than 68 years were relatively more likely to die from other causes than sudden cardiac death which may explain why implantation of an ICD did not benefit survival in this age group.



Type of death by age group

[1]Karolinska Institute, Division of Cardiology; Department of Medicine, Stockholm, Sweden; [2]Karolinska Institute, Division of Renal Medicine, CLINTEC, Stockholm, Sweden; [3]University of Michigan, Ann Arbor, United States of America; [4]University Medical Center Gottingen (UMG), Innovative Clinical Trials, Department of Cardiology and Pneumology, Gottingen, Germany; [5]Linkoping University, Department of Cardiology and Department of Medical and Health Sciences, Linkoping, Sweden

Funding Acknowledgements: The County Council of Stockholm, The Swedish Heart and Lung Foundation and The Swedish Research Council.

Background: Mineralocorticoid receptor antagonists (MRAs) improve outcomes in heart failure with reduced ejection fraction (HFrEF), but may be under-utilized in contemporary clinical practice.
Purpose: To assess predictors of MRA non-use in a large unselected cohort of patients with HFrEF.
Methods: In the nationwide Swedish Heart Failure registry (SwedeHF), we all included patients with HFrEF (EF < 40%) during years 2000-2012. Logistic regression analysis was performed to identify the predictors of MRA non-use among 38 variables (demographical, clinical, treatments). Missing data were managed by multiple imputation.
Results: Of 24,529 patients, 29% were female; mean age was 72 + 12 years; Only 8,102 (33%) patients were receiving MRAs. Demographic, clinical characteristics and concomitant treatments independently associated with MRA non-use are shown in the figure. Notable characteristics were, in descending order of magnitude, no need for diuretics, absence of implantable cardioverter or cardiac resynchronization device, higher ejection fraction, shorter HF duration, higher blood pressure, estimated glomerular filtration rate, older age, lower NYHA class, male gender, followed-up in primary rather than in specialized care, history of ischemic heart disease, higher NT-proBNP levels, concomitant atrial fibrillation/flutter, being registered in internal medicine/geriatrics rather than in cardiology department and being married/cohabitating rather than living alone. There was a trend toward underuse of MRAs in patients with mid-range potassium serum levels (3.5-5.0 mEq/L) vs. those with low (< 3.5 mEq/L) and high (>5.0 mEg/L) levels.
Conclusions: MRAs remain underused in HFrEF. MRAs may be used to supplement diuretics and for K-sparing. Their use does not appear to decrease with elevated K. The underuse may be linked to non-specialist care and follow-up and non-use of other HF interventions, suggesting specialized referral, a better education and understanding of the indications and benefits of MRAs in guideline appropriate HFrEF patients should be encouraged.

Oral anticoagulant use in patients with atrial fibrillation and concomitant heart failure: an analysis of 22,719 patients from the swedish heart failure registry

G Savarese[1]; L Friberg[2]; U Dahlstrom[3]; LH Lund[1]
[1]Karolinska Institute, Division of Cardiology; Department of Medicine, Stockholm, Sweden; *[2]Danderyd University Hospital, Department of Clinical Sciences, Stockholm, Sweden*; *[3]Linkoping University, Department of Cardiology and Department of Medical and Health Sciences, Linkoping, Sweden*

Funding Acknowledgements: The County Council of Stockholm, The Swedish Heart and Lung Foundation and The Swedish Research Council.

Background. Atrial fibrillation (AF) is common in patients with heart failure (HF). HF is considered a risk factor for both thromboembolic and bleeding risk in patients with AF.
Purpose: To assess oral anticoagulants (OACs) use in a large unselected cohort of AF patients with concomitant HF and to identify patient characteristics associated with their non-use.
Methods: We included patients with AF, HF and no previous valve replacement enrolled in the Swedish Heart Failure Registry. Multivariable logistic regression analysis was performed to identify independent predictors of OAC non-use among 39 variables (demographical, clinical, treatment). Missing data were managed by multiple imputation.
Results: Of 22,719 included patients, 37% were female. The mean age was 76 + 10 years. Approximately half of the patients enrolled (52%) had HF with reduced ejection fraction (EF), while the 22% had HF with mid-range EF and 26% had HF with preserved EF. In total, 13,153 patients (58%) were receiving OACs at baseline. The demographic and clinical characteristics and concomitant treatments associated with OAC non-use are shown in the figure. Notable characteristics were, in descending order of magnitude, treatment with platelet inhibitors, absence of implantable cardioverter or cardiac resynchronization device, paroxysmal (vs. permanent) AF, history of severe bleeding, followed-up in a primary rather than in specialized care, low haemoglobin levels, current smoking, living alone (vs. being married/cohabitating), older age (>75 years), no history of stroke/transient ischemic attack or ischemic heart disease, low income, concomitant lung disease, being an inpatient (vs. outpatient), having fewer children, longer HF duration and lower creatinine clearance.
Conclusions: In this nation-wide registry, we found low utilization of OACs among patients with AF and concomitant HF. Platelet inhibitors appeared inappropriately used in lieu of OACs. Some characteristics associated with OAC underuse were linked to older age, history of severe bleeding, lower haemoglobin levels and less use of HF therapy suggesting a generalized fear of OACs in frailer patients, despite their greater stroke risk. Furthermore, there were additional unwarranted predictors of non-use, such as paroxysmal AF and socio-economic conditions.

SGLT2 inhibition differentially reduces extracellular fluid volume relative to blood volume: a hypothesis for heart failure protection

K Melissa Hallow[1]; G Helmlinger[2]; PJ Greasley[3]; DW Boulton[2]
[1]University of Georgia, School of Chemical, Materials, and Biomedical Engineering, Athens, GA, United States of America; *[2]Astrazeneca, Waltham, MA, United States of America*; *[3]Astrazeneca, Mölndal, Sweden*

Introduction. In the EMPA-REG cardiovascular outcomes trial, treatment with the sodium glucose cotransporter 2 inhibitor (SGLT2i) empagliflozin significantly reduced heart failure hospitalization and cardiovascular death. This result was unexpected, and there is currently no consensus understanding of the mechanism for this protective effect. Improvements were apparent very early in the trial, suggesting treatment may have "rescued" individuals who were on the verge of cardiac decompensation.
Purpose: SGLT2i causes osmotic diuresis due to glucosuria. We hypothesize that SGLT2i-induced osmotic diuresis, a distinctly different mechanism than other diuretic classes, results in greater electrolyte-free water clearance, which in turn causes greater clearance of fluid from the extracellular fluid (ECF) space than from the circulation. In heart failure patients, this may result in greater clearance of congestion with minimal impact on arterial filling and organ perfusion.
Methods: 24-hour urinary volume and sodium and plasma sodium data from a previously conducted study in healthy subjects (N=42) administered either the SGLT2i dapagliflozin or the loop diuretic bumetanide for seven days were coupled with a 3-compartment mathematical model of blood, ECF, and peripheral sodium and water, to simulate the effect of each drug on ECF and blood volume. Drug-induced water and sodium excretion with either dapagliflozin or bumetanide were applied as model inputs, with the magnitude and time profile determined by fitting to the clinically measured 24-hour urinary sodium and urine volume. The model was constrained by fitting measured plasma Na + concentration, and ECF volume and blood volume changes were simulated.
Results: With dapagliflozin, the reduction in ECF volume was predicted to be 2-fold greater than the reduction in blood volume, while with bumetanide, the reduction in ECF volume was 22% less than the reduction in blood volume. Model-based analyses further illustrated that, in general, as electrolyte-free water clearance increases, there is a greater reduction in ECF volume relative to blood volume, and that this effect may be mediated by peripheral sequestration of sodium in order to buffer ECF sodium concentration.
Conclusions: These results support the hypothesis that by increasing electrolyte-free water clearance, SGLT2i reduces ECF volume with a smaller effect on blood volume, compared to loop diuretics. Heart failure is often characterized by excess fluid accumulation in both the blood and interstitial space, yet many heart failure patients actually experience arterial underfilling due to low cardiac output, and treatment must balance the need to relieve congestion while maintaining arterial filling. SGLT2i may reduce interstitial congestion without deleterious effects of arterial underfilling, hypotension, reduced organ perfusion, and neurohormonal activation that can accompany excess blood volume depletion with other forms of diuretics.

Chronic oral study of myosin activation to increase contractility in heart failure (COSMIC-HF): dose-escalation phase

J R Teerlink[1]; GM Felker[2]; JJV Mcmurray[3]; SD Solomon[4]; ML Monsalvo[5]; R Palaparthy[5]; J Johnston[5]; J B Kim[5]; FI Malik[6]
[1]University of California San Francisco, Veterans Affairs Medical Center, San Francisco, United States of America; *[2]Duke University School of Medicine, Durham, NC, United States of America*; *[3]University of Glasgow, Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom*; *[4]Brigham and Women's Hospital, Boston, United States of America*; *[5]Amgen, Inc., Thousand Oaks, United States of America*; *[6]Cytokinetics, Inc., South San Francisco, United States of America*

On behalf of: COSMIC-HF Investigators
Funding Acknowledgements: Amgen, Inc

Background: Omecamtiv mecarbil (OM), a novel cardiac myosin activator, has improved cardiac function in patients with acute and chronic heart failure (HF). OM is absorbed rapidly when dosed orally, resulting in high peak-trough fluctuation (PTF). Three modified release formulations were developed to slow absorption and reduce PTF.
Purpose: To select an oral formulation of OM to advance into the dose-expansion phase of COSMIC-HF.
Methods: The COSMIC-HF (NCT 01786512) dose-escalation phase was a randomized, placebo-controlled, multicenter, sequential-cohort, phase 2 study. In each cohort, subjects were randomized to receive 1 of 3 oral formulations BID (M-F1, M-F2, and SCT-F2), or placebo BID for 7 days. Pharmacokinetic (PK) and safety data were reviewed before enrollment into the next dose cohort. Eligible patients were 18-85 years of age, LVEF≤40%, heart failure with 4 weeks of stable optimal medical therapy, NYHA class I-III, and NT-proBNP ≥200 pg/mL (≥1200 pg/mL with atrial fibrillation). PK sampling was performed on days 1 and 7.
Results: Two cohorts were enrolled; Cohort 1 (n = 48) at 25 mg BID and Cohort 2 (n = 46) at 50 mg BID. The mean (SD) age was 65.1 (9.3) years; 21% of patients were women; 87% were white. The PK of the 3 formulations were similar (Table). However, the Cmax and AUC12 of M-F1 had the lowest variability (CV) and PTF (Cmax/Cpredose ratio) at 50 mg BID. The terminal half-life was 24.6 ± 8.7 h (25 mg BID) and 28.6 ± 7.4 h (50 mg BID). Excessive concentrations of OM occurred in one patient (50 mg M-F1) at day 7 (Cmax 1320 ng/mL) compared to the other subjects (n = 9, Cmax: 349 to 654 ng/mL) which was associated with myocardial infarction. This outlier informed the implementation of PK-based titration in the expansion phase of COSMIC-HF.
Conclusions: The M-F1 formulation was selected for additional evaluation in the expansion phase of COSMIC-HF, with further optimization of plasma concentrations using PK-guided dose titration.

1381: PK Parameters on Day 7, Mean ± SD (CV%)

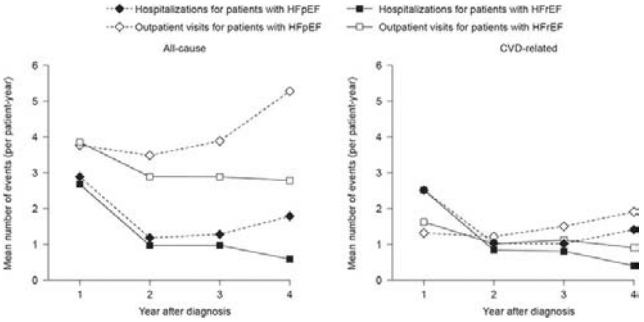
Healthcare resource utilization associated with heart failure with preserved versus reduced ejection fraction: a retrospective population-based cohort study in Sweden

K Boman[1]; K Lindmark[2]; M Olofsson[1]; J Stalhammar[3]; G J Bergman[4]; M Tornblom[4]; S Bruce Wirta[5]; M Costa-Scharplatz[5]; F Calado[6]; G Wikstrom[7]
[1]Umea University, Research Unit, Medicine, Skellefteå, Department of Public Health and Clinical Medicine, Umea, Sweden; *[2]Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden*; *[3]Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden*; *[4]QuintilesIMS, Solna, Sweden*; *[5]Novartis Sweden AB, Stockholm, Sweden*; *[6]Novartis Pharma AG, Basel, Switzerland*; *[7]Uppsala University, Institute for Medical Sciences, Uppsala, Sweden*

Background and purpose: To estimate healthcare resource utilization among patients with heart failure (HF) with preserved (HFpEF) versus reduced (HFrEF) ejection fraction using population data from two Swedish counties.
Methods: Patients with HF were identified via electronic medical records (EMRs) from primary and/or secondary care in Uppsala and Västerbotten, linked via unique identifiers to data from the National Patient Register and Swedish Prescribed Drug Register. Local echocardiography data were used to identify HFpEF (defined as ejection fraction ≥50%) and HFrEF (defined as <50%). Patients aged ≥18 years with ≥2 diagnoses of HF between 01/01/2010 and 31/03/2015 and an ICD-10 diagnostic code of I50 (inclusive of all granular codes), I42.0, I42.6, I42.7, I42.9, I110, I130 or I132 in any position were included. Patients were followed from date of first diagnosis (index date) to end of study period or EMR collection, date of death or loss to follow-up for other reasons, whichever came first. Unadjusted all-cause and cardiovascular disease (CVD)-related hospitalization rates were assessed using a Cox proportional hazards model, accounting for age, sex, setting of first diagnosis (primary vs secondary care), HF phenotype and NT-proBNP level.
Results: In total, 8702 patients with HF were identified. HF phenotype was known in 3167 patients; 64.6% had HFrEF, 35.4% had HFpEF. Patients with HFrEF were younger (mean ± SD: 69.9 ± 13.7 vs 74.2 ± 12.6 years) with a lower Charlson comorbidity index (1.65 vs 1.83) than those with HFpEF. All-cause hospitalization rates were marginally lower for HFrEF than for HFpEF (mean [95% CI] proportion of patients hospitalized within 1 year of diagnosis, 72.5 [70.1–74.8]% vs 73.8 [70.7–77.0]%; hazard ratio [HR] over whole follow-up period, 0.87 [0.79–0.97], p = 0.0093). The proportion of patients hospitalized was higher for those diagnosed in secondary care than in primary care, particularly within 1 year of diagnosis (1-year rate, 69.6 [68.3–71.0]% vs 59.1 [56.8–61.4]%; HR, 1.15 [1.07–1.23], p = 0.0002). Similar trends were observed for CVD-related hospitalization rates for HFrEF vs HFpEF (1-year rate, 69.5 [67.1–71.9]% vs 70.7 [67.5–74.0]%; HR, 0.89 [0.81–0.99], p = 0.0309) and for patients diagnosed in secondary vs primary care (1-year rate, 66.6 [65.3–68.0]% vs 56.2 [53.8–58.5]%; HR, 1.15 [1.07–1.24], p = 0.0001). Numbers of hospitalizations and outpatient visits decreased with time after diagnosis for HFrEF, but increased slightly for HFpEF after 2 years (Figure). The mean ± SD total number of all-cause days of hospitalization during the first year after diagnosis was lower in patients with HFrEF vs HFpEF (19.9 ± 26.1 vs 26.3 ± 34.5 days), while the number of HF-related days of hospitalization was similar (16.0 ± 22.4 vs 17.2 ± 24.0 days).
Conclusions: Number and duration of hospital stays were significantly lower over time in patients with HFrEF than HFpEF; this may be explained by the comorbidity burden in the latter group.

All-cause and cardiovascular disease-related hospitalizations and outpatient visits after diagnosis of heart failure with preserved (HFpEF) versus reduced (HFrEF) ejection fraction in Sweden



1383

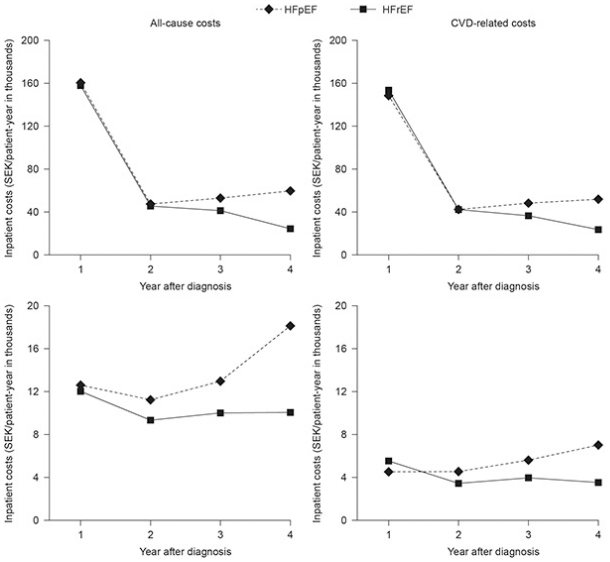
Costs associated with heart failure with preserved versus reduced ejection fraction: a retrospective population-based cohort study in Sweden

K Boman[1]; K Lindmark[2]; J Stalhammar[3]; G Wikstrom[4]; G J Bergman[5]; M Tornblom[5]; M Costa-Scharplatz[6]; S Bruce Wirta[6]; M Olofsson[1]
[1]Umea University, Research Unit, Medicine, Skellefteå, Department of Public Health and Clinical Medicine, Umea, Sweden; *[2]Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden*; *[3]Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden*; *[4]Uppsala University, Institute for Medical Sciences, Uppsala, Sweden*; *[5]QuintilesIMS, Solna, Sweden*; *[6]Novartis Sweden AB, Stockholm, Sweden*

Background and purpose: To implement cost-effective management programmes, it is important to understand the costs associated with heart failure (HF) with preserved (HFpEF) versus reduced (HFrEF) ejection fraction. We aimed to estimate direct costs associated with HFpEF and HFrEF using population data from two Swedish counties.
Methods: Patients with HF were identified via electronic medical records (EMRs) from primary and/or secondary care in Västerbotten, linked via unique identifiers to data from the National Patient Register and Swedish Prescribed Drug Register. Local echocardiography data were used to identify HFpEF (defined as ejection fraction ≥50%) and HFrEF (defined as <50%). Patients aged ≥18 years with ≥2 diagnoses of HF between 01/01/2010 and 31/03/2015 and an ICD-10 diagnostic code of I50 (inclusive of all granular codes), I42.0, I42.6, I42.7, I42.9, I110, I130 or I132 in any position were included. Patients were followed from date of first diagnosis (index date) to end of study period or EMR collection, date of death or loss to follow-up for other reasons, whichever came first. Unadjusted all-cause and cardiovascular disease (CVD)-related (defined by ICD-10 codes) costs associated with secondary care were estimated based on diagnosis-related group codes and price lists. Costs of drug use and comorbidities were available in Uppsala only; impact of the latter on total costs was assessed using a multiple Gamma regression model.
Results: In total, 8702 patients with HF were identified. HF phenotype was known in 3167 patients: 35.4% had HFpEF and 64.6% had HFrEF. Patients with HFpEF were older (mean ± SD: 74.2 ± 12.6 vs 69.9 ± 13.7 years) and had a higher Charlson comorbidity index (1.83 vs 1.65) than those with HFrEF. Total all-cause costs dropped substantially after 1 year after diagnosis. CVD-related costs followed the same pattern, and comprised 85.9% and 89.6% of total costs over 4 years after diagnosis for patients with HFpEF and HFrEF, respectively. Inpatient costs, which accounted for ~90% of total costs, generally decreased over time, whereas outpatient all-cause and CVD-related costs (accounting for ~10%) tended to increase over time, especially for patients with HFpEF (Figure). In Uppsala, drug use in the

year after diagnosis cost SEK 18171.0 and 11109.7 per patient with HFpEF and HFrEF, respectively. Furthermore, anaemia, cancer, chronic kidney disease, chronic obstructive pulmonary disease, diabetes, hypotension and aortic insufficiency were significant drivers of all-cause costs in the year after diagnosis (all $p < 0.05$) in the Uppsala cohort.
Conclusions: This analysis highlights the substantial economic burden of HFpEF and HFrEF. Costs were highest in the first year after diagnosis, and were driven by inpatient costs due to CVD and other comorbidities.

All-cause and cardiovascular disease (CVD)-related inpatient and outpatient costs after diagnosis of heart failure with preserved (HFpEF) versus reduced (HFrEF) ejection fraction in Sweden



1384

Significance of ischemic heart disease in patients with heart failure with preserved, mid-range and reduced ejection fraction - A nationwide cohort study

O Ola Vedin[1]; CSP Lam[2]; AS Koh[2]; L Benson[3]; THK Teng[2]; WT Tay[2]; OÖ Braun[4]; G Savarese[5]; U Dahlstrom[6]; LH Lund[5]
[1]Uppsala University Hospital, Department of Medical Sciences, Cardiology, Uppsala, Sweden; *[2]National Heart Centre Singapore, Singapore, Singapore*; *[3]Karolinska Institute, Stockholm, Sweden*; *[4]Skane University Hospital, Cardiology, Lund, Sweden*; *[5]Karolinska Institute, Department of Medicine, Stockholm, Sweden*; *[6]Linkoping University, Department of Cardiology and Department of Medical and Health Sciences, Linkoping, Sweden*

Funding Acknowledgements: Swedish reseatch council, Swedish Heart-Lung foundation, Stockholm County Council, Swedish Society of Medicine

Background: The importance of ischemic heart disease (IHD) is well established in heart failure with reduced ejection fraction (HFrEF, [EF $<40\%$]). However, its epidemiological and prognostic significance in heart failure with preserved and mid-range ejection fraction (HFpEF [EF $\geq 50\%$] and HFmrEF [EF 40-49%], respectively) is much less certain.
Purpose: We explored the relationship between ischemic heart disease (IHD), all three HF types and outcomes in the nationwide Swedish Heart Failure Registry (SwedeHF).
Methods: A total of 42,987 patients from SwedeHF were characterized according to EF and IHD status at baseline and followed for new IHD events, other outcomes and EF changes. Associations between baseline IHD and HF type and HF type, baseline IHD and outcomes were assessed using multivariable Generalized Estimating Equations and multivariable Cox regression, respectively.
Results: Overall, 23% of patients had HFpEF (52% IHD, 29% prior myocardial infarction [MI]), 21% had HFmrEF (61% IHD, 41% prior MI) and 55% had HFrEF (60% IHD, 43% prior MI). The association with prevalent IHD was similar for HFmrEF and HFrEF (risk ratio [RR] 1.00, 95% CI 0.98-1.01), and lower in HFpEF (RR 0.91 [0.89-0.93] vs. HFmrEF; RR 0.90 [0.88-0.92] vs. HFrEF). During a median follow-up of 2.2 years, there were 9,629 new IHD events; 16,005 HF events; 26,734 cardiovascular events; and 16,866 all-cause death events. Adjusting for prevalent IHD and clinical risk factors, the independent risk of new IHD events was relatively similar for HFmrEF vs. HFrEF (hazard ratio [HR] 0.95, 95% CI 0.90-1.00), and lower in HFpEF (HR 0.89 [0.84-0.95] vs. HFmrEF; HR 0.84 [0.80-0.90] vs. HFrEF). Prevalent IHD was independently associated with increased risk of new IHD events in all EF categories, although more pronounced in HFrEF (HR for IHD vs. no IHD 3.13, 2.87-3.40) than in HFmrEF (HR 2.43, 2.14-2.75) and HFpEF (HR 2.34, 2.10-2.62). Prevalent IHD was also associated with an increased risk of all other events except all-cause mortality in HFpEF. Patients with IHD, particularly those with new IHD events, were more likely to change to a lower EF category and less likely to change to a higher EF category over time.
Conclusion: HFmrEF resembled HFrEF rather than HFpEF with regard to both a higher prevalence of IHD and a greater risk of new IHD events. Prevalent IHD was an important determinant of prognosis in all HF types suggesting that management of IHD is important in these patients and that further evaluation of management strategies is warranted.

Physical activity measured with implanted devices predicts heart failure outcomes

C Linde[1]; A Tang[2]; MR Cowie[3]; T Bergemann[4]; WT Abraham[5]
[1]Karolinska University Hospital, Stockholm, Sweden; *[2]University of Ottawa, Ontario, Canada*; *[3]Royal Brompton Hospital, London, United Kingdom*; *[4]Medtronic, Mounds View, United States of America*; *[5]The Ohio State University, Columbus, United States of America*

Background: There is increasing evidence that physical activity (PA) levels have prognostic value in patients with chronic heart failure (HF). Purpose—The aim of this research is to assess PA as a surrogate endpoint for HF clinical outcomes in patients indicated for cardiac resynchronization therapy (CRT).
Methods: Data from 2,408 randomized patients with implantable cardioverter defibrillator (ICD) with or without CRT enrolled in the RAFT and REVERSE studies were pooled. The devices continuously measured and stored total daily active time (single-axis accelerometer). Average activity measured in minutes per day over a 30-day period at 1 and 6 months post-implant were examined. Statistical analyses were adjusted for age, LBBB, diabetes mellitus, ischemia, NYHA class, and diastolic blood pressure in a multivariable model. The main effect of PA and the interaction between PA and assignment to CRT was tested.
Results: Device data available from 2,249 patients were analyzed (65 ± 10 years; 82% men; left ventricular ejection fraction, $23 \pm 6\%$; 4% NYHA I, 81% NYHA II, 15% NYHA III). Of these patients, 404 died and 445 experienced a HF hospitalization (35 ± 20months of follow-up). For the analysis of 1 month PA, 359 patients were removed due to death prior to 1 month ($n = 25$) or insufficient device data ($n = 334$) and for 6 month data, 350 patients were removed due to death prior to 6 months ($n = 70$) or insufficient device data ($n = 280$). Results are shown in the table. The 1 month PA, 6 month PA and the change in PA were statistically significant predictors of time to death and improvement in NYHA. Both the 1 month PA and 6 month PA were statistically significant predictors of time to death or HF hospitalization. The interaction between PA and assignment to CRT was not statistically significant in any of the models. PA at 6 months was 5 minutes higher per day in patients randomized to CRT, after adjustment for 1 month PA levels (P=0.36).
Conclusions: Physical activity measured at either 1 or 6 months after ICD +/- CRT implantation predicted death or HF hospitalization as well as mortality and improvement in NYHA class in patients with chronic HF.

		Death or HF hospitalization	Death	Improvement in NYHA class at 12 months
Activity variable*	n	HR (95% CI); P-value	HR (95% CI); P-value	OR (95% CI); P-value
One month PA	1890	0.96 (0.94-0.98); $P < 0.0001$	0.94 (0.92-0.95); $P < 0.0001$	1.02 (1.01-1.04); P=0.004
Six month PA	1899	0.96 (0.94-0.98); $P < 0.0001$	0.93 (0.91-0.95); $P < 0.0001$	1.03 (1.02-1.05); $P < 0.0001$
Change in PA from 1 to 6 months	1880	0.98 (0.96-1.01); P=0.24	0.97 (0.94-1.00); P=0.04	1.03 (1.00-1.06); P=0.03

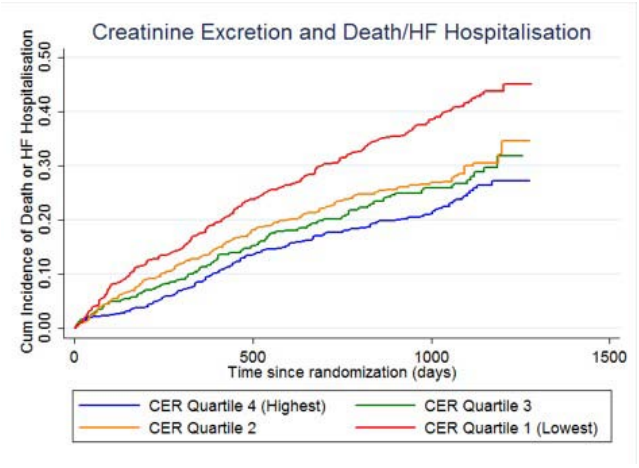
Clinical and prognostic value of spot urinary creatinine in chronic heart failure

J M Jozine Ter Maaten[1]; A P Maggioni[2]; R Latini[3]; S Masson[3]; G Tognoni[3]; L Tavazzi[4]; A P Voors[1]; K Damman[1]
[1]University Medical Center Groningen, Groningen, Netherlands; *[2]ANMCO Foundation For Your Heart, Florence, Italy*; *[3]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy*; *[4]Maria Cecilia Hospital, Cotignola, Italy*

Background: Twenty-four-hour urinary creatinine excretion is an established marker of muscle mass in heart failure and other populations. Spot urine creatinine might be an easy obtainable, cheap marker of muscle wasting and prognosis in heart failure (HF) patients.
Purpose: This study aimed to identify patient characteristics associated with low urinary creatinine in morning spot urine and investigate its association with clinical outcome.
Methods: Spot urinary creatinine concentration was measured in 2130 patients included in the GISSI-HF trial. We evaluated the prognostic value of urinary creatinine and its relation with clinical variables.
Results: Median spot urinary creatinine was 0.80 (IQR 0.50 to 1.10) g/L. Lower spot urinary creatinine was associated with older age, smaller height and weight, higher NYHA class, worse renal function and more frequent spironolactone and diuretic use (all $P < 0.02$). During a median follow-up of 2.8 years, 655 patients (31%) experienced the combined endpoint of all-cause mortality or HF hospitalization. Lower urinary creatinine was independently associated with an increased risk of all-cause mortality or HF hospitalization (Hazard ratio (HR): 1.59 [1.21-2.08] per log decrease, P=0.001), and all-cause mortality (HR: 1.75 [1.25-2.45] per log decrease, P=0.001).
Conclusion: Lower urinary creatinine, measured in morning spot urine in patients with chronic HF, is associated with worse renal function, smaller body size, more severe HF and is independently associated with an increased risk of all-cause death and HF hospitalization. Urinary creatinine might therefore be a valuable marker to assess muscle wasting and heart failure severity.



Creatinine excretion and outcome

On behalf of: RICA investigators group

Introduction: In the recently published European guidelines, a new term has been defined for patients with heart failure (HF) and ejection fraction (EF) between 40-49%: HF with mid-range EF (HFmrEF). Limited data exist on the epidemiology, treatment and short or long-term prognosis of these patients.
Purpose: To describe clinical characteristics, treatment and prognosis in patients with heart failure and mid-range ejection fraction (HFmrEF) discharged after admission for decompensation.
Method: We prospectively included and followed 2753 patients admitted with acute heart failure to Internal Medicine units. They were classified according to ejection fraction into three strata: reduced, EF $<40\%$ (HFrEF); mid-range EF 40-49% (HFmrEF); and preserved EF $\geq 50\%$ (HFpEF). Clinical, echocardiographic and laboratory data, and treatment at discharge were collected, and the three groups were compared. A multivariable analysis was performed to assess the relationship between EF and outcomes at 30 days and one year.
Results: A total of 10.2% of patients had HFmrEF. They were more likely to be men and to have a history of chronic kidney disease and higher levels of NT-proBNP than those with HFpEF. Compared to patients with HFrEF, they had less ischaemic aetiology and chronic obstructive pulmonary disease, and a higher proportion of atrial fibrillation and hypertension. In HFmrEF, the use of beta-blockers, aldosterone antagonists and antiplatelet drugs was lower than in HFrEF, but the use of calcium channel blockers and anticoagulants was higher. There were no differences between groups in 30-day and 1-year readmission rates. However, patients with HFrEF had significantly higher 1-year mortality (28%) than patients with HFmrEF and HFpEF (20% and 22%, respectively, $p < 0.001$, Figure 1).
Conclusion: Clinical characteristics and treatment among patients with heart failure admitted to Internal Medicine departments differ depending on EF. Prognosis of patients with HFmrEF is closer to that of HFpEF, and survival is better than in HFrEF.

Impact of CHA2DS2-VASc and HAS-BLED on oral anticoagulant use and outcomes in patients with atrial fibrillation and concomitant heart failure: an analysis of 22,055 patients from the SwedeHF

G Savarese[1]; L Friberg[2]; M Rosenqvist[2]; U Dahlstrom[3]; LH Lund[1]
[1]Karolinska Institute, Division of Cardiology; Department of Medicine, Stockholm, Sweden; *[2]Danderyd University Hospital, Department of Clinical Sciences, Stockholm, Sweden*; *[3]Linkoping University, Department of Cardiology and Department of Medical and Health Sciences, Linkoping, Sweden*

Background. Atrial fibrillation (AF) is common in patients with heart failure (HF). HF is a risk factor for both thromboembolic and bleeding events in patients with AF.
Purpose: To assess the impact of CHA2DS2-VASc and HAS-BLED scores on oral anticoagulant (OAC) use and outcomes in AF patients with concomitant HF.
Methods: We included patients with AF, HF and no previous valve replacement enrolled in the Swedish Heart Failure Registry. High and low CHA2DS2-VASc and HAS-BLED scores were defined as above/below median. Multivariable logistic regression analysis was performed to assess the association between CHA2DS2-VASc and HAS-BLED scores and OAC use. Kaplan Meier curves and adjusted Cox regression models including 28 baseline variables including OAC use were fitted to evaluate the association between CHA2DS2-VASc (adjusted also for

HAS-BLED) and HAS-BLED (adjusted also for CHA2DS2-VASc) scores and two composite outcomes: all-cause death and stroke; and all-cause death and major bleeding.
Results: Of 22,055 included patients, 37% were female, 48% had ejection fraction (EF) ≤40%, 26% EF 40-49% and 26% EF≥50%. Mean age was 76 + 10 years. In total, 12,756 (58%) patients were receiving OACs. The use of OACs was significantly predicted by CHA2DS2-VASc and HAS-BLED scores. In particular, the likelihood of OAC use was 1.43-fold increased for each 1-unit increase in CHA2DS2-VASc and 2.4-fold decreased (odds ratio 0.35) for each 1-unit increased in HAS-BLED (Fig Panel A). The risk of death/stroke increased progressively from low CHA2DS2-VASc / low HAS-BLED, to low/high, high/low and high/high. The risk of death/major bleeding increased progressively from low/low, to high/low, low/high and high/high. Additionally, 1-unit increase in HAS-BLED and CHA2DS2-VASc determined the same increase in risk of death/major bleeding and death/stroke, respectively (Fig Panel A,B).
Conclusions. In this nation-wide HF registry, only 58% of patients with AF received OAC. Thrombotic and bleeding risk affected both OAC use and outcomes in the expected directions. However, bleeding risk inappropriately affected decision making more than stroke risk.

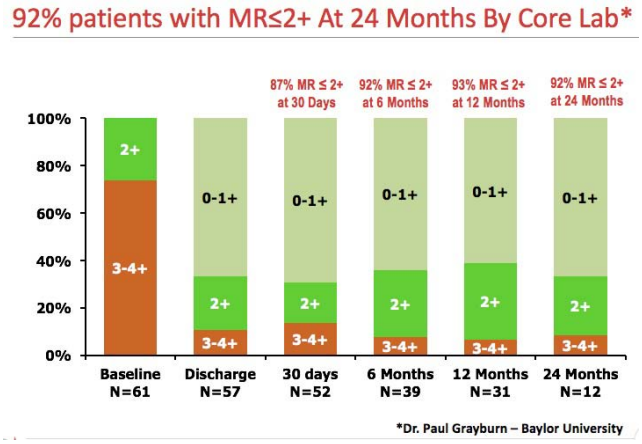
Background/Objective: The Cardioband system enables percutaneous implantation of an adjustable "surgical-like" mitral annuloplasty ring using a transseptal approach. The aim of this multicentre study was to evaluate the feasibility, safety and outcomes up to 24 months of Cardioband implantation in patients with secondary mitral regurgitation (MR).
Methods: Between February 2013 and June 2016, 61 high-risk patients with significant secondary MR were enrolled at 11 European sites. All patients were screened by a heart team using echocardiography and cardiac CT.
Results: Mean patient age was 72 ± 7 years, 44 were males (72%). Mean EuroSCORE II was 7.1%. At baseline, 53 patients (86%) were in NYHA functional class III-IV, with a mean left ventricular ejection fraction of 33 ± 11%. Device implantation was achieved in all patients but one. At discharge, 51 patients (90%) had MR ≤2+. After device cinching, an average 30% reduction in septolateral mitral annular diameter was observed (from 37 ± 4 mm to 26 ± 4 mm; p < 0.01). Thirty-day mortality was 3.3% (2 patients; death adjudicated as unrelated to the device). MR ≤2+ was measured in 29/31 (93%) and 11/12 (92%) patients at 12 and 24 months of follow-up, respectively (Figure). NYHA functional class I-II was present in 26/33 (79%) and 11/15 (77%) at 12 and 24 months, respectively. A significant improvement was observed at 12 months in the mean quality of life score (Minnesota Living with Heart Failure Questionnaire) from 41 to 23 (p < 0.01); and mean six-minute walk distance improved from 299 m to 372 m (p < 0.01).
Conclusions: Transseptal mitral repair with the Cardioband device resulted in significant MR reduction by reconstruction of the mitral annulus. Thirty-day mortality is comparable to other transcatheter mitral procedures. MR severity reduction and clinical benefit remain stable up to 24 months.



Distribution of MR severity over time

Hypoxic-hyperoxic preconditioning: a novel technique for myocardial protection against ischemia-reperfusion injury

I A Mandel[1]; Y K Podoksenov[2]; S L Mikheev[3]; Y S Svirko[3]; N O Kamenschikov[3]; I V Sukhodolo[4]; V M Shipulin[3]
[1]Federal Scientific Clinical center of specialized methods medical care and medical technology, Anesthesiology and intensive care, Moscow, Russian Federation; *[2]Cardiology Research Institute, Anesthesiology and intensive care, Tomsk, Russian Federation*; *[3]Cardiology Research Institute, Cardiovascular surgery, Tomsk, Russian Federation*; *[4]Siberian State Medical University, Morphology and general pathology, Tomsk, Russian Federation*

Introduction: Preconditioning by moderate hypoxia, as well as hyperoxia, constitute an effective drug-free method to amplify adaptive response to various negative influences of cardiopulmonary bypass (CPB) during cardiac surgery.
Purpose: The study aimed to assess the mechanisms and impact of hypoxic-hyperoxic preconditioning (HHP) on functional state of myocardium in patients with coronary artery disease (CAD) undergoing cardiac surgery with CPB.
Methods: The study included 120 patients randomly assigned to two groups: 61 patients received hypoxic-hyperoxic preconditioning before the CPB (HHP group) and 59 patients were not preconditioned (control group). Coronary artery bypass grafting with CPB for multivessel coronary artery disease was performed in all cases (2014-2016). Safety control of the preconditioning procedure included ECG monitoring, invasive blood pressure control, cardiac output, pulse oximetry, capnography, cerebral oximetry, measurement of anaerobic threshold. To monitor acid-base status and metabolic state we measured saturation of arterial and mixed venous blood, lactate and glucose level, plasma pH every 10 min during the HHP procedure; calculated oxygen consumption and delivery indices, ratio between venous-to-arterial carbon dioxide difference to arteriovenous oxygen content difference (ΔPCO2/C(a-v)O2).
Results and Conclusion: Spontaneous sinus rhythm recovery after CPB was registered more often in HHP group - 34 (55.7%) comparing to controls - 19 (32.2 %), X^2=8.38, p = 0.015. The length of inotropic support in early postoperative period was significantly lower in HHP group comparing to control group (12 [9; 15] vs 28 [24; 32] hours, U=98.1, p = 0.001). Mechanical ventilation time in HHP group was 10 [7.25; 15] hours comparing to 16 [10; 24] hours in control group, (U=34.2, p=0.023). Thus, hypoxic-hyperoxic preconditioning with individual parameters selection based on anaerobic threshold in patients with CAD before the main stage of cardiac surgery enhances adaptive response to the surgical stress, facilitates sinus rhythm recovery and provides a faster recovery after surgery.

On behalf of: for the prEserveD left ventricular ejection fraction chronic heart Failure with ivabradine studY (EDIFY) Investigators.

Funding Acknowledgements: It is funded wia grants from SERVIER France

Background. Heart failure with preserved ejection fraction (HFpEF) is prevalent, but no treatment has yet shown to reduce morbidity or mortality in these patients. Elevated heart rate is a predictive factor of worse outcomes and increased mortality in patients with heart failure, including in HFpEF.

Purpose: In this proof of concept, randomised, double-blind placebo-controlled trial, we assessed whether heart rate (HR) reduction with ivabradine improves diastolic function, exercise capacity and reduces NT-proBNP in patients with HFpEF.

Methods: EDIFY (prEserveD left ventricular ejectIon fraction chronic heart Failure with ivabradine study) included chronic HFpEF patients in NYHA class II-III, in sinus rhythm, with a HR $\geq$ 70 bpm, plasma NT-proBNP $\geq$ 220 pg/mL (BNP $\geq$ 80 pg/mL), LVEF $\geq$ 45% and echocardiographic evidence of diastolic dysfunction. Ivabradine (or matching placebo) was titrated to a target dose of 7.5 mg twice daily. Patients were followed for 8 months on the change in three co-primary endpoints: E/e' on Doppler echocardiography, 6 minutes walking distance and plasma level of NT-proBNP.

Results: A total of 179 patients were randomised to ivabradine (n = 95) or placebo (n = 84). One hundred and seventy one patients (87 versus 84) were evaluated for the three co-primary endpoints. Ivabradine reduced HR (-12.1 bpm, SD 8.9) more than placebo (-4.3 bpm, SD 9.8) with a mean between group difference at 7.7 bpm (90% CI -10 to -5.4, $p < 0.0001$). No statistically significant changes were observed in any of the co-primary endpoints. Mean E/e' increased from 13.1 (SD 4.7) to 14.0 (SD 4.9) with ivabradine and decreased from 13.9 (SD 6.9) to 13.0 (SD 5.4) with placebo (mean between group difference 1.4, 90% CI 0.3 to 2.5, p = 0.135); the mean distance on 6MWT (m) changed with ivabradine vs placebo from 305.4 (SD 92.2) to 309.7 (SD 102.8) and from 308.7 (SD 83.3) to 316.6 (SD 100.8), respectively (mean between group difference -3.8, 90% CI -19.1 to 11.6, p = 0.882) and geometric mean plasma NT-proBNP (pg/mL) increased marginally in both groups (from 447.7 to 483.4 with ivabradine and from 390.1 to 420.9 with placebo (geometric mean ratio 1.0 90% CI 0.9 to 1.2, p = 0.882). Ivabradine was well tolerated with no significant safety concern

Conclusion: In patients with HFpEF, HR reduction with ivabradine did not improve E/e', exercise capacity and did not reduce NT-proBNP plasma levels. These findings do not support the use of ivabradine in HFpEF.

Moderated Poster session 4 - Basic Science

1392

stem cells improve kidney function and remodelling in CRS type II

C Castellani[1]; G Vescovo[2]; P Cortiana[1]; M Pozzobon[3]; G Thiene[1]; R Tavano[4]; M Fedrigo[1]; A Angelini[1]
[1]*University of Padua, Dept. of Cardiac,Thoracic and Vascular Sciences, Padua, Italy*; [2]*Hospital S.Antonio, Padua, Italy*; [3]*University of Padua, Padua, Italy*; [4]*University of Padova, Dip. of Biomedical Sciences, Padua, Italy*

Background: we investigate the effects of human amniotic fluid stem cells (hAFS) and rat adipose tissue stromal vascular fraction GFP-positive cell (rSVC-GFP) therapy in a monocrotaline rat model of cardio-renal syndrome type II (CRSII).
Methods: RHF was induced by monocrotaline (MCT) in Sprague-Dawley rats.Three weeks later, four million of hAFS or rSVC-GFP were injected via tail vein. BNP, sCreatinine, kidney and heart NGAL and MMP9, sCytokines, kidney and heart apoptosis (TUNEL technique) were studied. Stem Cells (SC) engraftment was detected with immunofluorescence.Results: SC treated rats showed a significant reduction of serum NGAL and Creatinine (NGAL 335.6 ± 92.60 ng/mL sCrea 0.36 ± 0.05 pg/mL,p = 0.01) compared to CHF rats. In both hAFS and rSVC-GFP group, kidney protein expression of NGAL was significantly lower than in CHF group (SC 2.6*106 ± 1.2*106 vs CHF 5.1*106 ± 1.5*106 A.U., p = 0.0008) and similar to that to controls. In both hAFS and rSVC-GFP treated rats, we observed a substantial number of SC engrafted in the medulla and differentiated in tubular cells. Apoptosis was significantly decreased (hAFS 10.29 ± 10.81 and rSVC-GFP 24.82 ± 25.19 cells/mm2, p = 0.05 vs CHF) and similar to controls (9.85 ± 7.2 cell/mm2). TUNEL-positive cells were mainly located in the kidney medulla. Pro-inflammatory cytokines were down regulated in SC-treated groups (p = 0.05 vs CHF) and similar to controls. In SC treated rats, kidney and heart tissue NGAL was not complexed with MMP9 as showed in CHF groups, suggesting inhibition of MMPs activity.Conclusion: SC treatment produced improvement in kidney function in rats with CRSII. This may be the results of tubular regeneration due to SC engraftment, decrease tubular cells apoptosis and mitigation of pro-inflammatory milieu. Reduction of NGLA-MMP9 complexion mainly to decrease MMPs activity with prevention of further negative heart remodelling

1393

The cross-talk of Salidroside on TGF-beta / Smads and Wnt /beta-catenin signaling pathway in the myocardial fibrosis after AMI in rats and its correlation with Galectin3

J Jie Ma[1]; LH Ma[1]
[1]*Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China People's Republic of*

On behalf of: Departament of TCM,Fuwai Hospital
Funding Acknowledgements: Beijing Administration of Traditional Chinese Medicine "3 + 3" Fundation

Background: TGF-β /Smads pathway is currently recognized as the most important myocardial fibrosis signaling pathway. As another signaling pathway, Wnt/β-catenin also involves the proliferation and fibrosis. Recent experimental studies reported the role of salidroside on the angiogenesis and apoptosis in liver fibrosis, while there was no evidence of salidroside on preventing or reversing myocardial fibrosis, and the underlying mechanism remain unclear.
Methods: The myocardial infarction model of male Sprague-Dawley rats were made by ligation of the left anterior descending coronary artery. Rats were randomly divided into Salidroside low dose (12mg·kg-1)28 days or 56 days group, salidroside high dose (36mg·kg-1)28 days or 56 days group, Carvedilol group, the sham group and the control group. The cardiac function was evaluated by M-mode Doppler echocardiography. HE staining, Masson staining and Sirius red staining analysis were performed and observed for myocardial pathophysiological changes. Expression of TGF-β/Smads and Wnt/β-catenin signaling pathway was detected by Immunohistochemistry and Western blot. The level of Galectin-3 (a novel biomarker of myocardial fibrosis) in peripheral blood was detected by ELISA.
Results: The degree of myocardial fibrosis of the experimental group was attenuated significantly (P < 0.05). Sirius red staining showed that the ratio of collagen I/III in experimental group was significantly lower than that in model group, while it was a slight higher in carvedilol group (P>0.05). Western blot and RT-PCR analysis showed that the expression levels of P-Smad3 and Smad2/Smad3 were down-regulated (P < 0.05) as well as DVL-1 and β-catenin in Wnt/β-catenin Pathway, but the protein/mRNA level of Smad7 did not change significantly in the experimental group, especially in salidrosidehigh dose group (28 days). Compared with the control group, the expression of Smad3 and β-catenin in the non-infarcted myocardium of the group [(17.90 ± 1.36) vs (37.66 ± 2.21), (8.14 ± 1.23) vs (12.39 ± 1.37)μm2] were significantly lower (P < 0.05) with positively correlation. In addition, the number of the experimental group had a lower level of Gal-3 in the peripheral blood both on the 28th day and the 56th day (P < 0.05).
Conclusions: These results show for the first time that Salidroside can improve myocardial fibrosis in ventricular remodeling in experimental AMI rats. It functions through the mechanism of regulation of TGF-β / Smads and Wnt / β-catenin signaling pathway simultaneously. The positive regulation of TGF-B by the crosstalk pathway of Smad3 and β-catenin may serve as a potential target for anti-fibrosis.

Identification and isolation of cycling cardiomyocytes for single cell analysis

M Marion Baniol[1]; J Panula[1]; EL Graham[1]; E Lazar[1]; O Bergmann[2]
[1]Karolinska Institute, CMB, Stockholm, Sweden; *[2]Dresden University of Technology, Dresden, Germany*

Funding Acknowledgements: Karolinska Institutet, the Swedish Research Council, the Ragnar Söderberg Foundation, Åke Wiberg Foundation, and Jeanssons Foundations

Purpose: One of the major goals in cardiac regeneration research is to replace lost ventricular tissue with new cardiomyocytes. However, the rate of cycling cardiomyocytes in adult hearts is too low to efficiently compensate for the loss of functional myocardium in heart disease. We hypothesize that cardiomyocyte proliferation is tightly controlled by regulatory mechanisms that can be reactivated to promote endogenous repair after heart injuries. Unequivocal identification of cycling cardiomyocytes is a fundamental requirement for the investigation of these mechanisms.
Methods: We used preexisting as well as novel transgenic mouse models based on the FUCCI (Fluorescent Ubiquitination-based Cell Cycle Indicator) system to discriminate cycling cardiomyocytes (S/G2/M phases, green fluorescent nuclei) from non-cycling ones (G0/G1 phases, red fluorescent nuclei). In mice ubiquitously expressing FUCCI constructs, we used the myocyte-specific perinuclear marker Pericentriolar Material 1 (PCM-1) to distinguish cardiomyocyte from non-myocyte cells in the heart tissue.
Results: The presented transgenic strategy proved to be efficient for the identification of cycling cardiomyocytes in neonate, juvenile and adult mouse hearts in vitro and in vivo. The validity of transgenes expression was verified in both systems with immunohistochemistry by co-localization of cardiomyocytes and cell cycle markers with FUCCI fluorescence. The FUCCI system allowed us to confirm previous observations of a gradual decrease in the number of cycling CM during the neonatal period. By combining CM isolation from FUCCI mice neonatal hearts and FACS sorting, we were able to separate cycling from non-cycling CM populations, while preserving total RNA integrity, therefore providing a suitable source for downstream analysis such as bulk RNA-seq and single cell RNA-seq.
Conclusion: Strategies that allow to unambiguously identify cycling cardiomyocytes in vitro and in vivo provide important tools to study the regulation of cardiomyocyte proliferation. With the FUCCI system we seek to identify novel molecular targets that could promote cardiomyocyte proliferation, by using transcriptome profiling (RNA-seq) of isolated cycling cardiomyocytes.

Funding Acknowledgements: This study was supported by the National Research, Development and Innovation Office of Hungary (NKFIH; NVKP-16-1-2016-0017)

Background: The incidence of terminal heart failure is continuously growing, thereby increasing the clinical importance of its definitive treatment, heart transplantation (HTX). Pharmacological activation of soluble guanylate cyclase (sGC) and increased cGMP-signalling have been reported to have cardioprotective effects, however, potent sGC activator compounds are still under development. Gemfibrozil, a widely used lipid-lowering fibrate has recently been shown to exert sGC activator properties in vitro.
Purpose: The aim of the present study was to investigate whether pharmacological preconditioning of donor hearts with gemfibrozil could protect against ischemia/reperfusion injury and preserve myocardial function in a heterotopic rat heart transplantation model.
Methods: Donor Lewis rats received p.o. gemfibrozil (150mg/kg BW) or vehicle for 2 days. The hearts were explanted, stored for 1h in cold preservation solution, and heterotopically transplanted. 1h after starting reperfusion, left ventricular (LV) pressure-volume relations and coronary blood flow were assessed to evaluate early post-transplant graft function. Additional histological and molecular biological measurements were performed.
Results: After 1h reperfusion, LV contractility (at 140µl LV volume: LV systolic pressure: 125 ± 14 vs. 77 ± 8mmHg, $p < 0.05$; dP/dtmax: 3260 ± 398 vs. 2116 ± 240mmHg, $p < 0.05$; active relaxation (dP/dtmin: -2233 ± 263 vs. -1184 ± 151mmHg, $p < 0.05$) and coronary blood flow (2.7 ± 0.2 vs. 2.1 ± 0.2ml/min/g, $p = 0.03$) were significantly improved in the gemfibrozil pretreated hearts when compared to controls. Additionally, gemfibrozil treatment effectively reduced nitro-oxidative stress and apoptosis and improved the cGMP-signalling (increased plasma/cardiac cGMP levels) in HTX.
Conclusion: Pharmacological preconditioning with gemfibrozil reduces ischemia/reperfusion injury and preserves graft function in a rat HTX model, which could be the consequence of enhanced myocardial cGMP-signalling. Gemfibrozil might represent a useful tool for cardioprotection in the clinical setting of HTX surgery in the future.

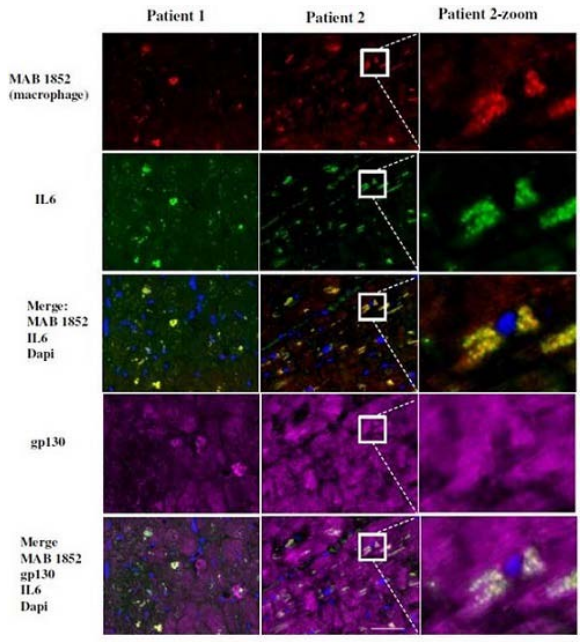
Role of global and local inflammation in cardiac fibrosis induced by aortic stenosis and its impact on LV function in patients referred for surgical aortic valve replacement

A Arnault Galat[1]; AG Guellich[1]; DB Bodez[1]; SG Guendouz[1]; SM Moutereau[2]; EB Bergoend[2]; JPC Couetil[2]; NB Benhaiem[2]; SH Hue[2]; LH Hittinger[2]; JLDR Dubois-Rande[2]; DM Mothy[3]; LL Lipskaia[2]; CR Radu[2]; TD Damy[2]
[1]University Hospital Henri Mondor, Cardiology, Creteil, France; *[2]University Hospital Henri Mondor, Creteil, France*; *[3]University Hospital of Poitiers, Poitiers, France*

Background: Cardiac fibrosis is associated with LV remodeling and dysfunction in aortic stenosis (AS). The pathological process is still unclear.
Objectives: To determine the fibrosis load in patients with AS and to explore its correlation with regional contractile dysfunction, serum and local cardiac inflammation.
Methods: Patients with AS referred for surgical valve replacement were prospectively and onsecutively included. They all had an echocardiography including 2D-strain. Blood samples were collected to measure cytokines and biomarkers using Luminex bead-based assays. Persurgical myocardial biopsy of the antero-septo-basal segment (S1) was performed on which serial sections were stained with Sirius red to quantify collagen. Immunostaignings using specific antibodies against macrophage, glycoprotein (gp) 130 and IL-6 were also performed. Patients were divided into tertiles according to fibrosis (TF1 to 3).
Results: Fifty-eight patients were included. Mean age was 73 ± 11 years. Mean aortic stenosis peak-velocity and mean gradient were respectively 4.5 ± 0.8 m/s and 54 ± 15 mmHg. Mean global strain was -15 ± 4% and mean S1 strain was -10 ± 6 % which was strongly correlated to fibrosis load ($R=0.83$, $p < 0.0001$). TF3 was associated with higher mortality ($p = 0.009$), higher serum CRP and IL-6 and lower gp130 compared to the other tertiles ($p < 0.05$). IL-6 and gp130 were expressed in the heart respectively in the plasma membrane of macrophages and in the cytoplasm of cardiomyocyte.
Conclusion: Cardiac fibrosis is associated with LV dysfunction, poor outcome and inflammation in AS. Strategies aiming at preventing inflammation might be considered to decrease or limit the progression of cardiac fibrosis in patients followed for AS.



Macrophage, IL-6 and gp130 staining

1397

Cardiosphere-derived cells exert anti-inflammatory effects and confer structural and functional benefits in rat hearts with autoimmune myocarditis

E Leventaki[1]; M Nana[1]; N Poulianitis[1]; C Chris Kapelios[1]; S Vakrou[1]; D Rontogianni[1]; AS Manolis[1]; D Perrea[1]; JN Nanas[1]; K Malliaras[1]
[1]*Laiko University General Hospital, Athens, Greece*

Background: Cardiosphere-derived cells (CDCs) exert cardioprotective, regenerative, immunomodulatory and anti-fibrotic effects in hearts with ischemic and non-ischemic cardiomyopathy. The effect of CDC therapy in the setting of myocarditis (a potentially lethal inflammatory cardiomyopathy without effective treatment options) is unknown.
Purpose: To investigate the effects of global intracoronary infusion of CDCs in rats with autoimmune myocarditis.
Methods: CDCs were grown from hearts explanted from healthy Lewis rats using established protocols. Autoimmune myocarditis was induced in Lewis rats by subcutaneous footpad injection of purified porcine cardiac myosin mixed with complete Freund's adjuvant on days 1 and 7. On day 10, rats underwent lateral thoracotomy and were subsequently randomized to undergo global intracoronary infusion of 500,000 CDCs ($n=6$) or vehicle solution ($n=8$). Global intracoronary infusion was achieved through infusion of cells or vehicle solution into the left ventricular cavity during brief aortic clamping. Rats were followed for 3 weeks post-infusion and underwent echocardiography on day 1, day 10 (prior to infusion) and day 28 (3 weeks post-infusion). Afterwards, rats were euthanized, hearts were explanted and underwent histology. Myocardial lymphomononuclear infiltration and interstitial fibrosis were assessed by whole-field microscopy. Myocardial T cell infiltration was assessed by immunohistochemistry.
Results: Histologically-confirmed autoimmune myocarditis was induced in 14/14 rats. Left ventricular ejection fraction was comparable on day 1 ($83\pm2\%$ vs $83\pm4\%$, $p=0.95$) and on day 10 ($81\pm6\%$ vs $79\pm6\%$, $p=0.57$) between the 2 groups. Intracoronary CDC infusion prevented myocarditis-induced functional depression and resulted in significantly higher left ventricular ejection fraction at 3 weeks post-infusion compared to controls ($85\%\pm1\%$ vs $61\pm8\%$, $p=0.02$). Infusion of CDCs resulted in dramatic attenuation of lymphomononuclear infiltration ($8\%\pm7\%$ vs $22\pm4\%$ of the myocardium, $p=0.03$), profound reduction of interstitial fibrosis ($17\%\pm13\%$ vs $38\pm2\%$, of the myocardium, $p=0.01$) and significant reduction of T cell infiltration (30.4 ± 29 vs 125.8 ± 49 per high power field, $p<0.01$) at 3 weeks post-infusion compared to controls.
Conclusions: Global intracoronary infusion of CDCs dramatically attenuates myocardial inflammation, fibrosis and T cell infiltration, while preserving systolic function in rats with autoimmune myocarditis.

Introduction. The phosphorylation of the extracellular signal-regulated kinases 1 and 2 (ERK1/2) at threonine 188 (pERKT188) was identified as a trigger for pathological cardiac hypertrophy. Upon activation, ERK1/2 can dimerize and autophosphorylate at threonine 188, which leads to nuclear translocation and activation of nuclear ERK1/2 targets known to cause cardiac hypertrophy. The "gain-of-function" ERKT188D mutant, mimics autophosphorylation and has been shown to induce pathological cardiac growth.
Purpose: So far, the effect of ERK1/2 was analysed in cardiomyocytes. However, a human heart is mostly composed by non-cardiomyocytes, in particular cardiac fibroblasts, which are known to contribute to cardiac remodelling. For this reason, the impact of cardiomyocyte-specific expression of ERKT188D in an α-MHC promoter driven mouse model (αMHC-ERKT188D-tg) and ubiquitous expression through the CAG promoter (CAG-ERKT188D-tg) was analysed in vivo.
Methods: Transverse aortic constriction (TAC) was used as a model for pressure overload-induced cardiac hypertrophy and heart failure, which was analysed by echocardiography. The mRNA levels of heart failure markers as e.g. atrial natriuretic factor (ANF) and brain natriuretic peptide (BNP) were quantified by real-time PCR. Hematoxylin and eosin (H&E) and Sirius Red staining were used to analyse cell size and fibrosis. Cell proliferation was measured using the 3H-thymidine incorporation assay.
Results: In account of the reduced viability of CAG-ERKT188D-tg after TAC, mice were analysed after ten days already. Despite the short exposure to pressure overload, a non-significant but trend-setting increase in lung and heart weights was detected in CAG-ERKT188D-tg compared to αMHC-ERKT188D-tg or wild-type mice. In addition, echocardiographic analyses revealed a reduced ejection fraction and impaired fractional shortening, increased mRNA expression levels of ANF and BNP as well as an increase in cardiomyocyte size and fibrosis after TAC in CAG-ERKT188D-tg in comparison to the control mice. As these experiments suggest that pERKT188 impacts on cardiac integrity in fibroblasts, we analysed its effect on the proliferation of isolated neonatal rat cardiac fibroblasts by overexpressing ERK2T188D: indeed, by measuring 3H-thymidine incorporation, an increase of proliferation in ERK2T188D transduced cells was detected compared to controls. This result suggests that pERK2T188 is a trigger for fibroblast proliferation. We could confirm the involvement of pERK2T188 in fibroblast proliferation by the use of a peptide that interferes with pERKT188 by preventing ERK dimerization.
Conclusion: These preliminary results show that pERKT188 has – also via non-cardiomyocyte cells – an important impact on cardiac hypertrophy and heart function. Further experiments are needed to elucidate the exact role of pERKT188 in fibroblasts and cardiac remodelling.

1399

Remote ischemic conditioning improves post-ischemic cardiac function: the role of Neuregulin-1

O Hamza[1]; A Kiss[1]; P Pilz[1]; IF Goncalves[1]; M Inci[1]; D Santer[1]; F Nagel[1]; B Podesser[1]
[1]*Ludwig Boltzmann Cluster for Cardiovascular Research, Center for Biomedical Reasearch, Vienna, Austria*

Background: There is substantial evidence that remote ischemic conditioning (RIC) induced by short repeated episodes of ischemia and reperfusion (IR) on the arm is a clinically applicable method to protect the myocardium against acute IR injury. Neuregulin-1 (NRG-1), an endogenously produced polypeptide, is the ligand of cardiomyocyte ErbB receptors, with cardiovascular protective effects. Aims: The present study was aimed to investigate the effect of RIC on post-ischemic cardiac function in association/correlation with the plasma levels of NRG-1.
Methods: Adult male anaesthetized OFA-1 rats were subjected to 30 min left coronary artery occlusion followed by 21 days reperfusion and allocated to (1) sham operated (SOP, without occlusion; n=4); (2) IR ($n=6$) and (3) IR + RIC (3 cycles of 5 minutes of hindlimb ischemia, 5 minutes of reperfusion, started at 5th min of index ischemia; n=7). Functional parameters on the heart such as cardiac output (CO) and external heart work (EHW) were evaluated on an isolated erythrocyte-perfused working heart model. Cardiac pump function was evaluated by rise afterload from 30 to 170 mm Hg in 10 mm Hg steps while CO was recorded. Plasma level of NRG-1 was measured by ELISA. Results: Myocardial IR resulted in significant increase of left ventricle/body weight ratio compared to SOP group ($P<0.05$). This was in line with the reduction in CO (29.6 ± 1.6 ml/min/g heart vs. 43.7 ± 1 ml/min/g heart, $P<0.01$) and EHW (12.8 ± 0.3 ml mm Hg/g heart vs. 21.1 ± 0.7 ml mm Hg/g heart). The concentration of NRG-1 was significantly dropped following IR (2.1 ± 0.5 vs. 6.1 ± 0.6 ng/µl in SOP, $P<0.05$) as well as NRG-1 and CO positively correlated ($r2=0.51$, $P<0.001$, slope 2.6 ± 0.76). RIC markedly improved post-infarcted cardiac function compared to IR group (CO: 39.5 ± 1.6 ml/min/g heart and EHW: 17.8 ± 0.9 ml mm Hg/g heart, $P<0.05$, respectively) in association with enhanced NRG-1 levels (4.3 ± 0.5 ng/µl). Cardiac pump function was significantly impaired following IR (80 mm Hg: 24.4 ± 1.6 vs. 37.9 ± 1.4 in SOP, $P<0.01$) which was reversed by RIC (32.4 ± 2.0, $P<0.05$). Conclusions: We demonstrated for the first time that the improvement of post-infarcted cardiac function initiated by RIC is associated with the plasma levels of NRG-1. This findings might represent a novel cardioprotective mechanism of RIC mediates via the upregulation of NRG-1.

BACKGROUND: A new familial dilated cardiomyopathy (DCM) was recently found related to mutations in the antiapoptotic BAG3 gene. MicroRNAs (miRNAs) are

short non-coding RNAs playing significant roles in cardiac disease, including DCM, thus representing new potential targets of treatment. Circulating miRNAs have been proposed as potential biomarkers of cardiovascular disease. However, no previous study has evaluated the clinical association between BAG3-related DCM and circulating miRNAs.

Purpose: We aimed to evaluate whether the clinical association between BAG3-related familial DCM and the circulating miRNA profile may represent a new tool for the diagnosis and progression assessment of the disease.

Methods: Detailed clinical and echocardiographic information was obtained from 21 patients with familial DCM carrying the BAG3 mutation and 21 age-matched healthy subjects. RNA was isolated from peripheral blood and analysed using ultrasequencing. Bioinformatic analysis was performed to explore the potential molecular pathways related to the miRNA profile.

Results: To determine the miRNA profile in BAG3-associated DCM, the analysis of 1759 circulating miRNA was performed in symptomatic and asymptomatic patients with BAG3 mutation, and compared to healthy age-matched subjects. The expression profiles showed significant differences between controls and BAG3 mutation carriers: miRNAs 3191-3p, 6769b-3p, 1249-ep, 154-5p, 6855-5p, and 182-5p were at least 2-fold downregulated in patients compared to healthy subjects. Endogenous gene targets of these miRNAs are now under investigation, highlighting miR-182-5p,and its target Ankyrin G. No differences were observed in the circulating miRNA profile between symptomatic and non-symptomatic patients containing the BAG3 mutation.

Conclusions: miRNAs emerge as a novel tool to differentiate healthy subjects and patients with BAG3-related DCM. Of particular interest is the downstream analysis of endogenous miRNA targets, the Ankyrin G gene. Inhibition of Ankyrin G is related to sinus node dysfunction, atrial fibrillation, conductional abnormalities, and ventricular arrhythmias. Further investigation regarding the contribution of Ankyrin G and other target genes of the miRNA profile described in BAG3-related DCM will be a key step to deeply understand the contribution of miRNAs in the pathophysiology of familial DCM.

Heart rate reduction opposes acute decompensation of chronic heart failure

N Peschanski[1]; M Lachaux[1]; N Harouki[1]; N Nicol[1]; JP Henry[1]; J Salzmann[2]; F Fougerousse[2]; V Richard[1]; C Thuillez[1]; P Mulder[1]
[1]Inserm U1096, Rouen University Medical School, Rouen, France; *[2]Institut de Recherche International SERVIER, Department of Cardiovascular Translational and Clinical Research, Suresnes, France*

Funding Acknowledgements: SERVIER

Background: Exacerbation of heart failure (HF), better known as acute decompensated HF, is associated with a rapid increase in heart rate (HR) and a further decrease in an already HF-related impaired cardiac function, which only partially recovers over time. However, whether HR reduction (HRR) limits the acute impairment and improves the cardiac recovery is unknown. Objective. We evaluated the effects of HRR induced by S38844 on cardiovascular dysfunction due to acute decompensation in rats chronic HF model.

Methods: Three months after coronary artery ligation, HF rats received water (control) or 1.8 g/kg NaCl (dissolved in 2.5 ml tap water PO) provoking acute decompensation. Left ventricular (LV) end-systolic pressure-volume (LVESPVR) and LV end-diastolic pressure-volume relation (LVEDPVR; Millar), cardiac output (CO, echocardiography), LV tissue perfusion (MBF; MRI) and coronary endothelial function (Ach induced relaxation; Mulvany) were assessed at 1 and 13 days after salt-loading (D1 and D13, resp.) and after S 3844 administration (starting 12 hours after salt-loading for 2.5 days; 12 mg/kg twice a day).

Results: In rats with HF, salt-loading provokes acute decompensation. Indeed, the HF related reductions of CO, MBF as well as LVESPVR were further reduced at D1, while LVEDPVR, was increased. Moreover, the HF-related impaired coronary relaxation was aggravated. Thirteen days after salt-loading, only CO partially recovered, but MBF, LVESPVR, LVEDPVR and coronary relaxation remained aggravated. As soon as 12 hours after administration, S38844 improved CO and MBF, increased LVESPVR and decreased LVEDPVR, while coronary relaxation was increased. Moreover, 11.5 days after interruption of S38844, CO, MBF, LVESPVR, LVEDPVR and coronary relaxation remained improved.

Conclusion: In chronic HF rats, salt-loading provokes immediately a further aggravation of cardiac and coronary dysfunctions, but only the aggravation of cardiac dysfunction only partially recovers over-time. S38844, starting 12 hours after salt-loading immediately re-establishes cardiac and vascular functions which all persist beyond the administration of S38844 and probably results from indirect effects provoked by the increase in MBF.

Acute heart failure and cardiogenic shock induced by ruptured coronary arteriovenous fistula

J-H Ju-Hee Lee[1]; DH Bae[1]; KK Hwang[1]; MC Cho[1]
[1]*Chungbuk National University Hospital, Cardiology, Cheongju, Korea Republic of*

Funding Acknowledgements: SERVIER

Case Summary: A 72-year-old woman was referred to emergency department from outside hospital with a diagnosis of septic shock. Her chief complaint was right upper quadrant abdominal pain for a day. Her BP was 84/64 mmHg and HR was 100/minute. Physical examination revealed hepatomegaly and tenderness at right upper quadrant abdomen. Laboratory tests were as follows: leukocytes 18390/μL; high sensitivity C-reactive protein 0.14 mg/dL; AST/ALT 483/212 IU/L; total bilirubin 0.34 mg/dL. Abdomen CT revealed diffuse wall thickening of gallbladder and perivascular low attenuation in liver. She had admitted infection department with IV meropenem and norepinephrine support under the diagnosis of cholecystitis. At 3rd hospital day, the patient was consulted cardiology department because she complained progressive dyspnea and chest X-ray revealed worsening pulmonary congestion. At that time, ECG showed T wave inversion on anterior leads and cardiac enzymes were slightly elevated: CPK 334 IU/L, CK-MB 18.0 ng/mL, troponin T 0.110 ng/mL. Echocardiography (Fig. 1) showed normal LV systolic function and no regional wall motion abnormality. But we can detect dilated abnormal vasculatures with continuous Doppler flow which is suggesting coronary arteriovenous fistula (CAVF). There was a small amount of pericardial effusion (PE) without hemodynamic significance, and it was reckoned decreased amount compared with previous abdomen CT. Chest CT revealed tortuous vasculature in intrapericardial space and aneurysmal dilatation of the abnormal vessels with thrombus (Fig. 2).
Questions: 1. What is your next plan? 2. What was the cause of elevated cardiac enzyme and changes on ECG and chest X-ray? 3. What caused her abdominal pain and shock? Was there real bacterial infection?
Clinical Course: Our impressions were as follows; 1) High cardiac output heart failure (HF) d/t CAVF, 2) Liver congestion d/t HF, 3) Incidentally detected PE, and we started medical therapy for HF. The patient's dyspnea was improved after the medical treatment and the vital signs were also stabilized. Coronary angiography revealed huge, dilated CAVF originated from both coronary arteries with internal filling defect (Fig 3). We continued conservative management for HF because of stable vital sign and decreased amount of pericardial effusion on the follow up echocardiogram. At 9th hospital day, the patient experienced sudden collapse and refractory hypotension despite full-dose of inotropics. The patient received CPCR and transferred to ICU. On bedside echocardiography, LV systolic function was normal and the amount of pericardial effusion was similar compared with previous day. At that time, we obtained 7cc of bloody pericardial effusion by echo-guided pericardiocentesis. Her vital signs were stabilized immediately, and 250cc of bloody fluid was drained during 24 hours. Our final diagnoses were; 1) Pericardial tamponade d/t ruptured CAVF, 2) High cardiac output HF d/t CAVF, 3) Liver congestion d/t HF. The patient underwent surgical closure of CAVF, and we detected ruptured aneurysmal vessel wall with blood clot.
Discussion: Although most of the patients who have small communications may be asymptomatic, myocardial ischemia or heart failure can be occurred depends on the amount of shunt flow. Although rupture of aneurysmal vessel is very rare complication of CAVF, it should be remembered that shock or cardiac arrest can be caused by small amount of blood.

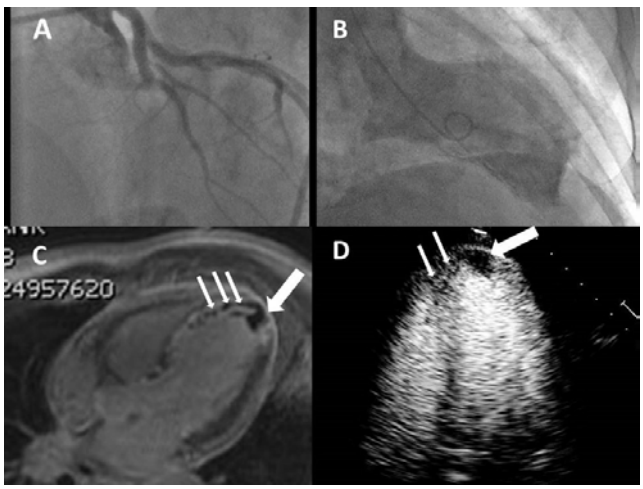
A 47 year old previously healthy male complained of pain in the left shoulder after physical strain. Four days later, the consulted general practitioner referred him to cathlab because of anterolateral ST segment elevation. Subsequently a verified proximal thrombotic occlusion of the LAD (panel 1A) was dilated and treated by bare metal stent implantation. Ventriculography showed a moderately reduced ejection fraction with all apical segments being hypokinetic. Images were characteristic for an apical left ventricular thrombus (panel 1B). A few hours after this angiography, the patient rapidly developed cardiogenic shock. Echocardiography revealed a hemodynamically relevant pericardiac tamponade. The patient was immediately transferred back to cathlab to perform a pericardiocentesis evacuating 500 ml of blood. The subsequent coronary angiography revealed no leakage of contrast agent. After the initial pericardiocentesis no further pericardial effusion occurred and the patient stabilized quickly. Myocardial contrast echocardiography suggested the ventricular thrombus to be plugged in a free wall rupture of the apex (arrow in panel 1C) and septal microvascular occlusions (MVO, small arrows). Contrast enhanced cardiac magnetic resonance imaging confirmed this perception (panel 1D). For further therapeutic purposes the patient was immediately sent to cardiac surgery where the thrombus was being removed and an epicardial patch plastic of the LV apex was successfully performed. The patient was able to return back to working life with only a mildly reduced ejection fraction.



1404

First series of ST-elevation myocardial infarction with acute coronary occlusion and coexisting Takotsubo Syndrome

L C Lars Christian Napp[1]; VL Cammann[2]; M Jaguszewski[2]; J Bauersachs[1]; T Luescher[2]; JR Ghadri[2]; C Templin[2]

Funding Acknowledgements: SERVIER

Takotsubo Syndrome (TS) accounts for an estimated 2% of acute coronary syndromes, and diagnosis was historically believed to require a "clean" angiogram without coronary artery disease (CAD). In contrast, we and others have shown that CAD is indeed present in a significant proportion of TS patients, however in

most cases in coronary arteries not supplying the myocardial segments affected by TS, and the majority of stenoses did not require immediate intervention. Here, we present 3 cases with the rare combination of ST-segment-elevation myocardial infarction (STEMI) with acute coronary artery occlusion and coexisting TS. Case 1: A 52-year-old woman was admitted after out-of-hospital resuscitation for ventricular fibrillation for 35 minutes. After 9 electrical shocks and amiodarone spontaneous circulation returned. ECG showed ST-segment elevation in leads II, III and aVF. Coronary angiography demonstrated thrombotic occlusion of the distal RCA with coexisting apical TS. RCA was treated with angioplasty without stenting. An IABP was inserted and neuroprotective hypothermia was started. The patient was extubated after 2 days, and after 5 days LV function had returned to normal. Case 2: A 62-year-old woman was admitted with acute chest pain and suspected STEMI. Before arrival at the hospital defibrillation for ventricular fibrillation and very short cardiopulmonary resuscitation (< 1 minute) had been necessary. ECG showed ST-segment elevation in leads II, III and aVF. Coronary angiography demonstrated thrombotic occlusion of the proximal RCA with coexisting apical TS. LVEF was 25%. RCA was successfully treated with angioplasty with a drug-coated balloon. CKmax was 1030 U/l. 3 days after PCI acute decompensation developed, which was treated with diuresis and non-invasive ventilation. The patient gradually recovered, and LVEF after 10 days was 51% without regional wall motion abnormalities. Case 3: A 75-year-old woman was admitted with acute chest pain and suspected STEMI. ECG showed ST-segment elevation in leads V5 and V6. Coronary angiography demonstrated thrombotic occlusion of a posterolateral branch of the RCX and coexisting midventricular TS. LVEF was 43%. RCX was treated with angioplasty. 7 days later LVEF had returned to normal, with residual hypokinesia of the posterolateral wall. In summary, as CAD may be present in TS cases as in other causes of acute heart failure, ST-segment-elevation myocardial infarction with coronary artery occlusion is a potential finding in TS patients. This finding is essential to consider for diagnosis and treatment of STEMI as well as of TS patients, who have ST-segment elevation in 50% of cases. In patients with suspected TS coronary angiography is mandatory in most cases, to uncover coexisting coronary lesions. In patients with STEMI, ventriculography is highly recommended to match the angiogram with wall motion abnormalities, in order to make the correct diagnosis.

1405

Coronary vasospasm; a silent enemy in orthotopic heart transplant.

A Arthur Omondi[1]; PV Spinett[1]; J Shin[1]
[1]*Montefiore Medical Center (Bronx), New York, United States of America*

Funding Acknowledgements: SERVIER

Introduction: The etiology of coronary vasospasm (CV) in orthotopic heart transplant (OHT) recipients is unknown. It has been reported in small series of patients, most of them associated with coronary vasculopathy (CAV) or allograft rejection in the setting of an acute coronary syndrome, malignant arrhythmia or cardiac arrest. We report a case of asymptomatic CV in a cardiac transplant recipient.
Case Report: A 37 year-old female with non-ischemic cardiomyopathy presented with transient dizziness 8 years post OHT. Her transplant was complicated by early rejection International Society for Heart and Lung Transplant (ISHLT) 2R/3A treated with steroids. 3 years post transplant she had antibody-mediated rejection with ISHLT 3R/3B treated with steroids, thymoglobulin and plasmapheresis. Left heart catheterization (LHC) 6 years post transplant revealed non-obstructive coronary artery disease (CAD). Biopsy 11 months prior was ISHLT 0. The disequilibrium was transient. Her home medications were tacrolimus, aspirin, atorvastatin, carvedilol and nifedipine. Electrocardiogram revealed normal sinus rhythm with old T wave inversions in leads V1 to V3. Laboratory work-up revealed hemoglobin 8.8 g/dL, white blood cell count 3.6k/uL, Troponin T < 0.01 ng/ml,pro B natriuretic peptide 482 pg/mL - within normal range. LHC revealed severe spasm in the mid to distal left anterior descending artery that was relieved with nitroglycerin.There was no evidence of CAV. Her nifedipine dose was increased to 120mg a day. At one-year follow-up she remained asymptomatic.
Discussion: Coronary vasospasm is rarely described as a cause of acute ischemic syndromes in patients following cardiac transplantation. CAV is a diffuse, accelerated form of CAD characterized by circumferential neointimal proliferation and luminal obstruction along the length of the epicardial coronary arteries of the transplanted heart. CAV is the main cause of late death following cardiac transplantation, due to accelerated atherosclerosis and coronary events. CV is often related to late atherosclerosis in the transplanted heart. Reported cases of CV were symptomatic with patients having angina, myocardial infarction, malignant arrhythmia and cardiac arrest. Our patient presented with transient dizziness and was asymptomatic at the time of catheterization. Autonomic nervous system and cardiac innervation are not essential mechanisms in patients with CV. Circulating catecholamines and/or other metabolic and hormonal products may play an important role in patients with CV. Conclusion. This is the first report of asymptomatic CV in a patient with OHT without CAV, as such, adds to the literature on both the presentation and pathophysiology, demonstrating that the etiology of CV can be related to other factors besides CAV or acute rejection. Clinicians should have a high index suspicion even in asymptomatic patients.

A 70-year-old man was hospitalized with primary anterior STEMI 1h 40 min from the onset pain. Fibrinolysis was held through 2h 20min from the symptoms onset, but ECG did not reveal features of the reperfusion. Rescue PCI (through 4h 20min after the symptoms onset) revealed the occlusion in proximal third of left anterior descending artery and the drug-eluting stent was implanted. Then on the 6-th day of STEMI the recurrent acute pulmonary embolism was occurred. It was confirmed by the increasing of D-dimer to 426 ng/ml, appearance of orthopnea and the hemoptysis, bilateral hydrothorax, subfebrile condition. Simultaneously, the disease was complicated by the following arrhythmias ventricular and subventricular extrasystoles, paroxysms of ventricular tachycardia and atrial fibrillation. Implantable cardioverter-defibrillator was recommended and it was implanted. Transthoracic echocardiography revealed hypokinetic basal inferolateral segment and apex, EF was about 51%. It was not extended the left ventricular thrombus. The patient was discharged on dual antiplatelet therapy, β-blockers, statins, angiotensin-converting enzyme, rivaroxaban and amiodarone. Through 6 months echocardiography was repeated. Two-layered myocardial structure with a thin compacted epicardial layer and non-compacted endomyocardial layer with deep myocardial trabeculae were revealed, EF decreased to 45%, akinetic of apex, septal and anterior wall. The ratio between the trabeculated and normal myocardium was more in 2 times. The data of multi-spiral computed tomography confirmed of non-compacted myocardium. Decrease of global systolic function and bilayer structure of the left ventricular wall with a presence of lots of trabeculae was recorded. This form of cardiomyopathy is rare and usually associated with the failure of the myocardial compaction process at the embryogenesis, which leads to the persistence of numerous trabeculae at the left ventricular cavity. The main clinical manifestations are heart failure, arrhythmias and thromboembolism. The differential diagnosis included other cardiomyopathies (hypertrophic, dilatation), acute myocarditis, fibroelastosis, pericarditis, thrombosis of LV, hypertrophy of LV, tumor, pulmonary atresia, Bland-White-Garland syndrome, additional trabeculae. The case is unique, because this heart pathology has been detected in the elderly man. It is known, that non-compacted myocardium associated with the high frequency of sudden cardiac death at the youth. The specialty of this case was acute the single-vessel coronary artery lesion with probably thromboembolic genesis. It is important, that multi-spiral computed tomography was used in this case to confirm and demonstrate non-compacted myocardium, as long as MRI could not performed due to implanted cardioverter-defibrillator. Thus, non-compacted myocardium could be diagnosed in elderly patients, differential diagnosis of non-compacted myocardium included using of imaging technologies. In cases with contraindication to MRI, the multi-spiral computed tomography would be useful for confirmed echo findings

Post-infarction mechanical complications: a successful case

AC Ana Catarina Gomes[1]; I Rangel[1]; A Marques[1]; S Alegria[1]; G Morgado[1]; I Joao[1]; I Cruz[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Funding Acknowledgements: SERVIER

Introduction: Post-infarction mechanical complications are rare in the era of coronary revascularization but they should be suspected in the appropriate clinical context. Case Report: 62 year-old man with previous history of hypertension and smoking. He came to attention in June of 2016 due to progressive heart failure symptoms (at admission in NYHA class III). The previous history was unremarkable except for a sudden and prolonged episode of severe epigastric pain in the previous month. At admission he presented hypertensive profile, a IV/VI systolic murmur audible in all auscultatory areas and bilateral basal crackles. He was admitted for further study. The analysis were normal besides the T Troponin elevation: 129 ng/L in the first analysis and 136 ng/L in the next evaluation. The electrocardiogram showed sinus rhythm,100 bpm, slow R wave progression, ST-segment elevation and T-wave inversion in precordial leads. The thorax x-ray revealed bilateral interstitial infiltrate and mild bilateral pleural effusion. The thransthoracic echocardiogram showed mildly dilated left ventricle, thin ventricular septum, dyskinesia of all apical segments, medium segments of septum, anterior and inferior walls, hypokinesia of the basal segments of the same walls, severe systolic left ventricular dysfunction (LVEF of 23%), a huge sessile thrombus adjacent to the ventricular septum and anterior wall and a restrictive apical ventricular septum defect with a left-to-right shunt (Figures A and B). The patient was submitted to cardiac magnetic resonance which confirmed the echocardiographic findings described: wall motion abnormalities, a ventricular septal defect (VSD) surrounded by thrombus, lying

the septum and reaching the right ventricle hinge points (confirmed in the early gadolinium enhancement study) and also a small pseudoaneurysm in the anterior wall previously unnoticed (Figures C and D). The late gadolinium enhancement study showed transmural necrosis in the dyskinetic segments. The pre-surgery coronarography revealed an occluded median left anterior descending artery. During hospitalization he remained clinically stable, without electrical complications or need of hemodynamic support. He was submitted to successful surgical repair of the VSD and a single left mammary artery to left anterior descending artery bypass. He was discharged on the 4th post-surgery day and has remained in NYHA class II, under medical therapy. Discussion: Imaging techniques are essential for diagnosis of mechanical complications. Cardiac magnetic resonance is particularly helpful in anatomic diagnosis and functional evaluation, adding prognostic information and guiding patient's management. Conclusion: Although rare, multiple post-infarction complications can occur. Late surgical approach is beneficial in clinical stable patients.

Introduction and case description. In recent years, the remarkable improvement in survival of patients with congenital heart disease (CHD) has led to a continuously growing number of grown-up patients with CHD (GUCH). We present a case of a GUCH patient in whom omission of the coronary arteries (CAs) imaging before cardiac surgery for patent ductus arteriosus (PDA) and severe aortic regurgitation (AR) led to catastrophic consequences. Description of the problem. In 1999, a 23-year-old male patient with history of PDA and severe AR underwent cardiothoracic surgery for his CHD. During the procedure, there was a sudden aortic annulus rupture what resulted in extension of cardiopulmonary bypass duration and need to eventually replace the aortic valve (AV). Intraoperative TEE showed signs of massive infero-lateral myocardial infarction (MI). Left circumflex artery (LCx) ligation during the rescue AV replacement was therefore suspected. After 3 months of hospitalization the patient left the hospital with new AV and iatrogenic heart failure (HF) with reduced left ventricular ejection fraction (LVEF) of 20%. Questions. 1.Was LCx ligation the only possible cause of the massive infero-lateral MI? 2.Should coronary artery assessment be obligatory for GUCH patients prior to interventions? Answers and discussion. 1)Our patient in the following years slowly deteriorated and in January 2014, the Heart Team met to discuss possible options for further treatment. Cardiac computed tomography (CT) was performed as a part of pre-procedural planning. It revealed a surprising finding of LCx being fully patent and originating from the proximal part of the right coronary artery (RCA). Apparently, in 1999 LCx was not ligated, but the lack of knowledge about its anomalous origin resulted in improperly given selective cardioplegia. The ectopic origin of the LCx is a well-recognized variant and considered the second most common coronary anomaly. It can be found in approximately 0.37-0.7% of all patients. The anomalous LCx most commonly arises from a separate ostium within the right sinus or, as it was in our case, directly from the proximal portion of the RCA. 2)Based on the currently available data, ESC practice guidelines recommend routine CAs assessment in valvular heart disease only to diagnose coronary artery disease (CAD) if any of the following is present: history of CAD, suspected myocardial ischemia, LV systolic dysfunction or if patients are men aged over 40 years or postmenopausal women or if they have at least one cardiovascular risk factor. At the time of surgery, none of the above-mentioned situations were present in our case. According to the ESC guidelines in patients with PDA cardiac CT is indicated when additional quantification of LV volumes or evaluation of pulmonary artery anatomy are required. Cardiac catheterization is indicated when PAP is high on echo for estimation of pulmonary vascular resistance. At the time of surgery, also none of the above-mentioned situations were present in our case. So, even though back in 1999 neither of the cited ESC guidelines were available, today going step by step with the guidelines, one can easily imagine such clinical scenario. Conclusions and implications for clinical practice. Our case shows that even in the era of big data, large clinical trials and great guidelines to follow, some GUCH patients remain very challenging. They keep the requirement for individualization of medical therapy, since behind every GUCH patient there is an individualized clinical history and unique coexistence of congenital cardiac defects.

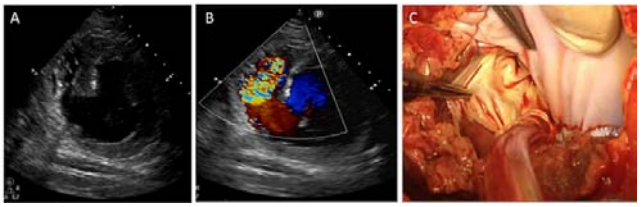
A 72 year-old patient arrived to the emergency department in cardiogenic shock with a three-days history of chest pain and dyspnoea. On physical examination blood pressure of 55/34 mmHg, sinus tachycardia, hypoperfusion and a V/VI pansystolic murmur panfocal were remarkable. EKG showed established an inferior myocardial infarction. Echocardiogram revealed a large ventricular septal defect (2,2 cm) in the basal inferior septum (Image 1, Panel A and B) with bidirectional shunt, moderately depressed left ventricular function and very dilated and dysfunctional right ventricle. Cardiac catheterization showed triple vessel disease, severe distal left coronary artery stenosis, occluded left anterior descending artery from the ostium, severe circumflex stenosis and dominant right coronary artery with subtotal distal lesion with diffuse disease of posterior descending artery. Despite of increasing doses of inotropes and vasopressors and circulatory support with intra-aortic balloon pump patient remained in refractory cardiogenic shock. Therefore peripheral veno-arterial extracorporeal membrane oxygenation (VA-ECMO) was implanted without complications achieving hemodynamic stability. Hypoxemia was corrected and hepatic and renal function improved. After ten days under ECMO support surgical repair was planned. Double coronary artery bypass (saphenous vein graft to left anterior descending artery, and saphenous vein graft to ramus intermedius artery) without

extracorporeal circulation was performed. Afterwards, the patient was cannulated for cardiopulmonary bypass, and the aorta was cross-clamped. Myocardial protection was achieved with intermittent cold blood cardioplegia. Through a posterior left ventriculotomy, ventricular septal rupture was completely closed with a large bovine pericardium patch (Image 1, Panel C). ECMO could be removed and thansesophageal echocardiogram confirmed no residual defect. Post-infarct ventricular septal defect after primary angioplasty development is an infrequent (0,2-0,3%) but usually lethal complication whose mortality reaches up to 90%. Timing of the surgical approach remains controversial due to the difficult balance between maintaining hemodynamic stability and waiting for infarcted necrotic tissue to organised. Usually rapid hemodynamic deterioration limits surgical delay and leads to early repair, frequently unsuccessful, and directly related to mortality rate. VA-ECMO offers circulatory support as bridge to ensure appropriate maturation and fibrosis of infracted tissue, allowing the deferral of surgery. When compared to other assist device, ECMO could be quickly and easily implanted in a crash and burn patient and additionally contribute to improve oxygenation in cardiogenic shock and allows to renal and hepatic recover.



Post-infart ventricular septal defect

Introduction. 58-year old female was referred to our department due to shortness of breath and paroxysmal nocturnal dyspnoea in the last 2 weeks. Her history was remarkable of total right mastectomy followed by chemo- and radiotherapy 2 years ago. She was considered to be cancer-free at present and recently treated for pneumonia. Her 38-year old son was diagnosed with dilatative cardiomyopathy with left ventricle (LV) apical thrombus few years back.

Diagnosis and treatment: Physical examination was unremarkable except for bilateral basal crackles and lower limb pitting oedema. EKG showed normal sinus rhythm and precordial T-wave inversion. Echocardiography revealed severely depressed LV systolic function with ejection fraction of 28% and global longitudinal strain of -7,8. The LV showed typical morphological features of left ventricular non-compaction (LVNC) with multiple trabeculations and deep intrabecular recesses and prominent apical thrombus. We commenced guideline based treatment with iv heparin, ACE, beta-blocker and iv furosemide with rapid improvement. She was offered long term treatment with Vitamin K antagonist (VKA), which she refused, despite all the risks explained, as she did not want to be INR monitored. EKG telemetry revealed paroxismal atrial fibrillation with 3 episodes of about 30 second duration. Her CHADSVASC2 was 3 and her HASBLED score was 1. We offered novel oral anticoagulant (NOAC) treatment as alternative and explained that although appropriate for her atrial fibrillation, NOACs have not been studied in LV thrombosis setting and are off-label. She decided to go for NOAC despite the lack of clinical data explained. Her creatinine clearance was 83ml/min estimated by Cockroft-Gault. She was discharged on bisoprolol 5mg, perindopril 2.5mg, furosemide 40mg and rivaroxaban 20mg all once daily. The LV thrombus was in place and unchanged at the time of discharge of follow up transthoracic echocardiogram. On follow up at 3, 6, 12 months she was clinically stable and her LV thrombus was fully resolved and there were no signs of systemic embolism. The echocardiography of her son was reviewed and was showing same typical features of LVNC, so this was now considered a case of familial LVNC and we offered echocardiography screening to other family members. Her 30-year old daughter was screened, but showed no features of LVNC.

Discussion: NOACs have not been studied in LV thrombosis and remain off-label and not recommended by guidelines in this setting. However, there have been several case reports published, describing patients with LV thrombus treated with NOACs (mainly rivaroxaban), most of them after anterior myocardial infarction, showing thrombus resolution at follow up.

Conclusions and implications for clinical practice: In patients with LV thrombus and LVNC, who refuse VKA or when it is not possible to monitor INR, NOACs may prove as valuable alternative. Off-label NOAC therapy could and probably should be considered in cases of LV thrombosis when there is no possibility of VKA treatment and indications for long term anticoagulation. Of note, we suggest that echocardiographic screening in LVNC may identify other affected family members.

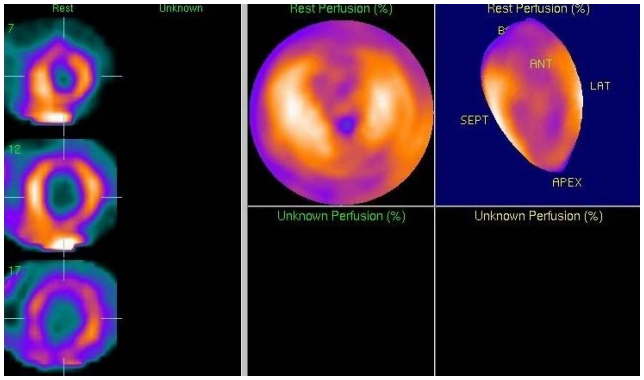
Introduction. Dilated cardiomyopathy (DCM) may be caused by an array of external factors including heavy physical exercise (sports, such as powerlifting) coupled with taking supplements, particularly anabolic agents. Case report description. Patient Kh., a 42 years old male was admitted to inpatient care on 12.08.2016 with chief complain of periodic increase in blood pressure (BP) (systolic BP up to 180-200 mmHg), followed by dizziness, nausea, palpitations, and shortness of breath which were associated with significant physical exertion. He has been a body builder for more than 20 years with a history of taking supplements (anabolic agents) for 10 years. High blood pressure and shortness of breath during intense physical activity were noticed within the last year. Physical Assessment: Height 186 cm, weight 145 kg, body mass index 41.9. The patient is in a stable condition, with blood pressure (BP) of 170/110 mmHg, heart rate (HR) 98/min, heart sounds rhythmic with no murmurs. EKG: see PDF file. Echocardiography: Diffuse left ventricular hypokinesis with ejection fraction (EF) by Simpson's method of 33%. Left atrial volume 135 ml. The thickness of the posterior wall of the left ventricle was 14 mm, the thickness of the interventricular septum was 14 mm, moderate mitral and mild tricuspid regurgitation. Systolic pulmonary artery pressure of 39 mmHg. Computer Tomography (CT): coronary arteries calcium score 138; left coronary artery 138, right coronary artery 0. Myocardial perfusion imaging (at rest) with Technetium-99m: diffuse left ventricular hypokinesis, left ventricular end-diastolic volume 380 ml (N 81-121 ml), left ventricular ejection fraction 25% (N 50%-64%), moderately disseminated areas of hypoperfused regions in the myocardium of left ventricle. Laboratory values: Hemoglobin 195 gr/l; Red blood cells (RBC) 6.1 x 1012/l; Hematocrit (Ht) 59.3%,

Erythrocyte sedimentation rate (ESR) 0.5 mm/h; Total serum cholesterol 4.6 mmol/L (N < 5.2 mmol/L); Creatinine 133 umol/dL (N < 115 umol/dL); GFR (MDRD) 51 ml/min/1,73 m2; level of NT-proBNP not measured. After six weeks of therapy with Ramipril, Bisoprolol, Spironolactone and cessation of powerlifting and anabolic agents use his BP normalized to 125/80 mmHg. Echocardiography: EF was 38%, systolic pulmonary artery pressure was 32 mmHg, moderate mitral regurgitation, mild tricuspid regurgitation. Laboratory values: NT-proBNP 262 pg/mL (N < 125 pg/mL); Creatinine 100 umol/dL, GFR (MDRD) 71 ml/min/1,73 m2.

Problems or possible differential diagnosis: Hypertension in this patient was most likely associated with heavy weights lifting combined with anabolic agents use for a long period of time. These factors, together with the lack of proper hypertension management apparently led to the development of DCM and congestive heart failure. The ban on heavy lifting and cessation of anabolics use together with adequate therapy lowered patient's blood pressure, improved cardiac contractility, and substantially increased blood flow through the kidney and thus improved creatinine clearance rate. The peculiarity of this case report is the inadequately low level of NT-proBNP in response to substantially reduced left ventricular ejection fraction. The above discrepancy is suggesting irreversible changes in the heart muscle; therefore it is unlikely that contractile cardiac function will ever recover fully.

Conclusions and implications for clinical practice: DCM developed as a result of powerlifting combined with anabolic agents use. Elimination of both factors and adequate therapy stabilized the patient's medical condition. However, the relatively low level of NT-proBNP in response to reduced cardiac contractility is the most probable evidence of myocardial fibrosis.



Kh., 42 perfusion imaging

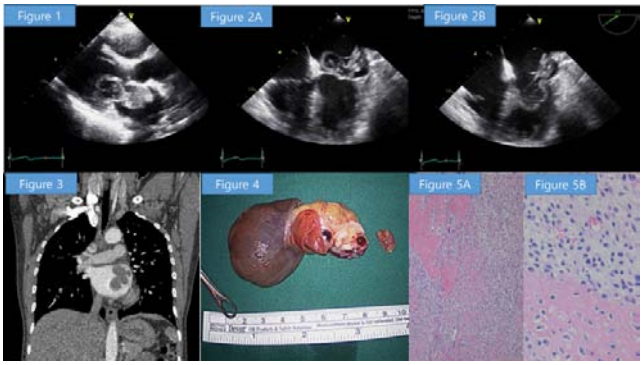
Primary cardiac osteosarcoma

J-H Ju-Hee Lee[1]; DH Bae[1]; KK Hwang[1]; MC Cho[1]
[1]*Chungbuk National University Hospital, Cardiology, Cheongju, Korea Republic of*

Funding Acknowledgements: SERVIER

Case Summary: A 44-year-old women presented in June, 2013 with a 2-week history of chest tightness and shortness of breath to our cardiology outpatient clinic. She denied having hypertension, diabetes mellitus, dyslipidemia, tobacco use, or any family history of atherosclerotic disease. Her vital signs were as follows: blood pressure 124/80 mmHg, heart rate 64/minute, respiratory rate 24/minute, and body temperature 36.5. Physical examination revealed diastolic murmurs at the cardiac apex with grade 2/6. An electrocardiogram was normal and chest radiography showed no active lesion in lung. Transthoracic echocardiography (Fig. 1) showed a broad based mass filling the left atrium, which was attached to the posterior wall of left atrium nearby Q tip. The mass was composed of three different parts; thin-walled cystic portion (2.3 x 2.1 cm), solid portion with lobulating contours and heterogenic echogenicity (2.8 x 2.4 cm), and thick-walled mixed portion (3.7 x 2.9 cm). The mixed portion of the mass was protruding into the LV cavity during diastole and causing severe functional mitral stenosis. Trans-mitral mean diastolic pressure gradient was 5 mmHg and right ventricular systolic pressure was 38 mmHg. Transesophageal echocardiography (Fig. 2A and 2B) showed the heterogeneous feature of the mass more clearly. There was no evidence of invasion to pulmonary vein on transesophageal echocardiography. Thoracoabdominal computed tomography (Fig. 3) revealed an intracardiac mass occupying the left atrium without local invasion and there was no evidence of distant metastasis. X-ray studies did not identify any lesions in the skeletal system. The presumptive diagnosis was a benign cardiac tumor, such as an unusual type of left atrial myxoma and she was referred to cardiac surgeon for surgical removal of the mass. During the operation, we found a 7 x 5 x 4 cm sized huge mass, which have a hard part originated from nearby left atrial appendage and two cystic parts (Fig. 4). Complete excision of the mass and partial endocardiectomy was performed. In pathologic examination, the tumor consisted of proliferating pleomorphic spindle shaped cells suggested sarcoma and there were massive osteoid and chondroid materials produced by tumor cells (Fig. 5A and 5B). High mitotic activity and moderate cytologic atypia were detected and there were scattered hemorrhagic and necrotic foci. The tumor cells invades resection margin. Finally, the tumor was diagnosed as primary cardiac osteosarcoma, chondroblastic type. She received six cycles of systemic chemotherapy with doxorubicin and cisplatin. During 9 months of follow up, the patient remains healthy with no evidence of tumor recurrence.



1452

A successful multidisciplinary approach to pregnancy and delivery in pulmonary artery hypertension.

Pulmonary artery hypertension (PH) frequently affects women of childbearing age. Due to the very high maternal mortality risk, with most of the deaths occurring in the 3rd trimester and within the first 10 post-delivery days, pregnancy should generally be avoided in PH. We describe the case of a 39-year-old woman who was transferred to our department at the 25th week of pregnancy with a severe right heart failure. Since the 14th week she experienced increasing dyspnea, palpitations and generalized edema. She declined termination of the pregnancy after thorough counselling. The echocardiogram showed a dilated, hypertrophic and hypokinetic right ventricle, with a pulmonary artery (PA) systolic pressure 85 mmHg. The clinical status improved with diuretics. A team including cardiologists, obstetricians, anaesthesiologists, neonatologists and staff coordinators was made up. A complete diagnostic work-up for PH was performed: CT scan excluded pulmonary thromboembolism, no evidence of an intracardiac shunt, and blood tests were negative for vasculitis, thyroid disorder, connective tissue disease and thrombophilia. A right heart catheterization demonstrated a PA pressure of 60/42 mmHg, PCW pressure 11 mmHg, a severely elevated PVR at 16.9 WU, and significant reduction of the cardiac output, without any fall in the PA pressure or PVR after inhaled nitric oxide. A complete obstetrical and fetal evaluation excluded other relevant diagnoses. LMW heparin was prescribed. In the following days a step treatment with continuous infusion Epoprostenol and oral Sildenafil was initiated. The PDE-inhibitor was not tolerated after few weeks for flushing and hypotension. An elective caesarean section was successfully performed at the 31st week, under epidural anaesthesia. The baby demonstrated normal growth, development, and birth apgar scores. The patient was discharged from the ICU on day four. The postdelivery course was uneventful and the mother was discharged on day 30. At 6-month follow up, she was a WHO FC-II. This patient was diagnosed with severe PH in an advanced stage of pregnancy. Critical decisions, rapid escalation of the prostacyclin therapy, and the use of an experienced multidisciplinary team led to a successful delivery, with no complications for the mother or baby. The management of these infrequent, but critical situations, should be strictly handled by experienced tertiary referral centers.

A normally healthy 57 year-old male presented with increasing headache, abdominal pain, chest pain and rapidly worsening dyspnoea. His background included long-standing systemic hypertension, well controlled with an angiotensin II receptor antagonist. On arrival he was tachycardic, hypertensive, tachypneic and hypoxic requiring oxygen supplementation. Physical examination was consistent with acute pulmonary oedema, with chest X-ray demonstrating bilateral, diffuse airspace changes. The ECG showed sinus tachycardia with 2mm up-sloping ST depression in the anterior leads. An urgent CT aortogram showed no aortic dissection and bedside transthoracic echocardiography revealed severe global left ventricular impairment with no valvular or pericardial abnormalities. Coronary angiography showed an anomalous right coronary artery origin arising from the left coronary cusp. Left coronary system did not show any significant disease. He was initially managed with intravenous diuretic, glyceryl trinitrate infusion and non-invasive ventilation. Within an hour of presentation he developed respiratory failure requiring intubation for ventilatory support. Progressive haemodynamic collapse followed despite escalating vasopressor support and intra-aortic balloon pump insertion. Veno-arterial extra-corporeal membranous oxygenation (VA-ECMO) was commenced, maintaining adequate perfusion and oxygenation. Transoesophageal echocardiogram showed persisting left ventricular impairment with substantial spontaneous echo contrast and early thrombus formation in the left ventricle and aortic root (Figure). Differential diagnoses at this point included fulminant myocarditis, hypertensive crisis, illicit drug use or stress-induced cardiomyopathy. Over the next 24-hours the patient remained haemodynamically stable, left ventricular function normalised on repeat echocardiography and VA-ECMO and inotropes were weaned. Within 48 hours the patient was extubated with no neurological deficit. A subsequent cardiac MRI showed no myocardial abnormality, normal perfusion and a left ventricular ejection fraction of 66%. The initial CT aortogram was reviewed in further detail, demonstrating a 23 x 20mm left-sided adrenal lesion, intensely active on Iodine-123 meta-iodobenzylguanidine (MIBG) scan. Plasma and urine catecholamine levels were consistent with a phaeochromocytoma. The patient was started on phenoxybenzamine prior to an uncomplicated adrenalectomy with histo-pathology showing no signs of malignancy. At 6-month review he was normotensive and remained well. Phaeochromocytoma classically presents with paroxysmal headaches, sweating, and tachycardia with intermittent or sustained hypertension. On rare occasions, presentation can be acute cardiogenic shock and pulmonary oedema. The precipitating episode can be life-threatening however ventricular dysfunction in catecholamine induced cardiomyopathy is typically resolves upon resection of the tumour. The exact mechanism is unknown; proposed causes include direct catecholamine myocardial toxicity, catecholamine-induced oxygen-derived free radical production or myocardial ischaemia from coronary arterial spasm. This case demonstrates the abrupt deterioration and rapid improvement in catecholamine induced cardiomyopathy secondary to phaeochromocytoma and highlights the importance of prompt escalation of resuscitation measures, including VA-ECMO, for patients with undifferentiated cardiogenic shock.

Constrictive pericarditis due to rheumatoid arthritis 6 years follow up

M Dudek[1]; M Kaluzna-Oleksy[1]; J Migaj[1]; E Straburzynska-Migaj[1]
[1]Poznan University of Medical Sciences, 1st Cardiology Department, Poznan, Poland

Funding Acknowledgements: SERVIER

Pericarditis is one of the most common cardiac complications of rheumatoid arthritis(RA), it's present in 30-50% patients on post-mortem examination. However, in most cases it remains without hemodynamic consequences. Pericarditis occurs more often in male patients with active, seropositive RA. The constriction is thought to be chronic process persisting for years. A 59-year-old man with a 14-years history of seropositive RA was admitted to the cardiology department for evaluation of clinical status in stable state with well-controlled symptoms. RA was diagnosed in 2001. His past medical history include interstitial pulmonary fibrosis (2001), neoplastic process and tuberculosis were excluded. Additionally cholelithiasis, gastritis with H. pylori infection, osteoporosis with pathological, multi-level compression fracture and hip osteoarthritis, depressive syndrome, impaired fasting glucose and permanent AF. In Nov-2009, patient with decompensated congestive HF was admitted to the cardiology clinic. He was referred because of fatigue, increasing shortness of breath (NYHA IV) and chest pain. Examination revealed ascites and pitting oedema of lower extremities, elevated pressure in jugular veins, the irregular heart rate about 80-bpm, BP-120/70mmHg. The electrocardiogram (ECG) showed atrial fibrillation (AF), chest x-ray - compaction at the base of the lungs and enlarged heart. Echocardiography revealed enlarged left atrium (LA), elevated right ventricular systolic pressure (RVSP) and thickness of the pericardium. Patient underwent coronary angiography, which showed no severe stenosis in coronary arteries and calcification in the pericardium. To confirm constrictive pericarditis magnetic resonance imaging (MRI) was taken (Figure 1). Hemodynamic instability lead to partial pericardiotomy thru the median sternotomy in urgent. Pericardial effusion and diastolic restriction of LV were noted in the control echocardiography. After 55-days patient was discharged. In Apr-2013 increasing signs of respiratory failure occurred. Patients was qualified for home oxygen therapy. Three months later (08.2013) reduced global contractility and contraction asynchrony have been noticed in echocardiography, with 45%-LVEF. To evaluate the clinical condition patient was admitted in March-2015. He was stable, with no hospitalization because of worsening HF since 2years. The examination revealed with dry crepitation at the bases of lung bilaterally and irregular heart rate. Laboratory parameters were in norm, expect a small elevation of NT-proBNP-305,0 pg/mL. ECG showed AF, BP-110/90mmHg. MRI revealed thickness of pericardium behind posterior and inferior LV-wall with the features of fibrosis and calcification, enlargement of LA-50mm, flattening of the interventricular septum (IVS) in diastole with shift into the left site during breathing and apical akinesia (Figure 2). Clinical relevant pericarditis is a rare but serious complication of RA. It might be life-threatening condition. This kind of extra-articular disease manifestation should be considered in patients with unexpected cardiac insufficiency. Timely diagnosis and adequate intervention, as highlighted in presented case, can lead to favorable clinical outcomes. Development of MRI technology dramatically improved the visualization of the pericardium, the diagnosis of constrictive pericarditis remains a challenge in many cases.

Introduction: Left ventricular hypertrophy (LVH) is considered as a main feature of heart failure with preserved ejection fraction (EF), largerly attributable to arterial hypertension. However, the heart response to increased blood pressure is highly variabile and depends on associated factors that still need to be defined.
Purpose. We aimed to evaluate the predictors of left ventricular hypertrophy (LVH) in hypertensive subjects with preserved ejection fraction identified in SEPHAR III study which was conducted on a representative sample of the Romanian population.
Methods: Subjects selected on the base of stratified proportional sampling and consented to participate in the study were evaluated during the two study visits. Hypertension was diagnosed according to current ESH-ESC guidelines (≥140/90 mmHg). Visit-to-visit blood pressure variability was assessed as the s.d. of the mean systolic blood pressure (SBP). Pulse wave velocity in the aorta (PWVao) was recorded with an oscillometric device. LVH was defined as indexed left ventricular mass (ILVM) > 95g/m2 in females and > 115 g/m2 in males on standard echocardiography. Hypervolemic state was evaluated by transthoracic bioimpedance and 24h sodium excretion was estimated from spot urine with Kawasaki formula.
Results. From a total of 1970 enrolled subjects we have identified 650 hypertensives with preserved EF (mean age 55.78 ± 15.61, 51.1% females). Mean ILVM values was 90.30 – 27.31 g/m2. LVH was found in 25.8% of the sample. Binary logistic regression adjusted for age and mean arterial pressure validated as predictors for LVH: active smoking (OR 1.45; 95% CI for OR: 1.34-1.57), body mass index (OR 1.03; 95% CI for OR: 1.02-1.03), visceral obesity (OR 1.59; 95% CI for OR: 1.44-1.75), HbA1c (OR 1.04; 95% CI for OR: 1.01-1.08), total serum cholesterol (OR 1.01; 95% CI for OR: 1.01-1.02), LDL-cholesterol (OR 1.08; 95% CI for OR: 1.03-1.09), triglycerides (OR 1.08; 95% CI for OR: 1.07-1.09), s.d. SBP >8.49 mmHg (OR 1.91; 95% CI for OR: 1.86-1.95), PWVao >10m/sec (OR 1.92; 95% CI for OR: 1.87-1.98), aortic pulse pressure (OR 1.02; 95% CI for OR: 1.01-1.02), estimated 24h sodium urinary excretion (OR 1.01; 95% CI for OR: 1.00-1.02), hypervolemia (OR 1.02; 95% CI for OR: 1.10-1.30). Blood pressure control, treatment with ACEIs/ARBs, diuretic treatment with mineralocorticoid receptor antagonists and beta-blockers have been found as protective factors for LVH.
>**Conclusions:** The results of our study indicate that, alongside with conventional risk factors, PWVao, central pulse pressure, increased visit-to-visit SBP variability, hypervolemia and estimated urinary sodium excretion are independent predictors for LVH in hypertensives with preserved ejection fraction. Moreover, these correlations reveals a possible pathophysiologic link between sodium metabolism and arterial stiffness parameters that might be addressed with specific therapeutic strategies in patients with hypertensive cardiomyopathy.

A description of characteristics of very elderly patients newly diagnosed with heart failure: a retrospective population-based cohort study in Sweden

M Olofsson[1]; K Boman[1]; K Lindmark[2]; G Wikstrom[3]; G J Bergman[4]; M Tornblom[4]; C C Proenca[5]; B Balas[6]; F Calado[6]; J Stalhammar[7]
[1]Umea University, Research Unit, Medicine, Skellefteå, Department of Public Health and Clinical Medicine, Umea, Sweden; *[2]Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden*; *[3]Uppsala University, Institute for Medical Sciences, Uppsala, Sweden*; *[4]QuintilesIMS, Solna, Sweden*; *[5]Wellmera AG, Basel, Switzerland*; *[6]Novartis Pharma AG, Basel, Switzerland*; *[7]Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden*

Background and purpose: Over a quarter of patients with heart failure (HF) in Sweden are very elderly (defined as aged ≥85 years). Evidence on the demographic and clinical characteristics of these patients, and on the diagnostic procedures they receive in clinical practice, is scarce.

Methods: Patients with HF were identified via electronic medical records from primary and/or secondary care in Västerbotten, linked via unique identifiers to data from the National Patient Register and Swedish Prescribed Drug Register. Local echocardiography data were used to identify patients with HF with preserved (HFpEF, ≥50%) and reduced (HFrEF, <50%) ejection fraction. Patients aged ≥18 years with ≥2 diagnoses of HF between 01/01/2010 and 31/03/2015 and an ICD-10 diagnostic code of I50 (inclusive of all granular codes), I42.0, I42.6, I42.7, I42.9, I110, I130 or I132 in any position were included. The date of the first diagnosis was the index date. ICD-10 codes were also used to identify comorbidities. A 10-year look-back period was used to exclude prevalent HF cases. Patient characteristics were assessed at index, except comorbidities (in the 5 years before index) and pre-diagnosis comedications (in the first year before index).
Results: In total, 8702 patients with HF were identified; 27.7% were aged ≥85 years. Compared with patients <85 years, more patients ≥85 years were female (60.2% vs 40.6%) and fewer were overweight (BMI >25 kg/m^2, 42.3% vs 63.5%). In both groups, HF was more commonly diagnosed in secondary than in primary care, but patients ≥85 years were more often diagnosed in primary care than those <85 years (31.2% vs 20.9%). Fewer patients ≥85 years than those <85 years received an echocardiogram at diagnosis (19.3% vs 42.9%); of those who did, more patients ≥85 years than <85 years had HFpEF (46.8% vs 33.4%). Patients ≥85 years had a comorbidity burden similar to those <85 years (mean number of comorbidities/patient, 2.4 vs 2.3); prevalence of atrial fibrillation (32.0% vs 30.4%), hypertension (53.2% vs 53.0%) and ischaemic heart disease (20.5% vs 22.5%) were also similar in both age groups. N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels and systolic blood pressure (BP) increased with age, and diastolic BP and estimated glomerular filtration rate decreased. Potassium and sodium levels did not differ between age groups (Table). The most common pre-diagnosis comedications were β-blockers, antithrombotic agents and diuretics; β-blockers were less frequently prescribed in patients ≥85 years (59.6% vs 64.4%), and antithrombotic agents and diuretics were more frequently prescribed in those ≥85 years (antithrombotic agents, 57.0% vs 54.3%; diuretics, 50.1% vs 43.1%).
Conclusions: Very elderly patients with HF in Sweden are clinically different from younger patients, with a higher prevalence of HFpEF and higher NT-proBNP levels (as expected). Most importantly, very elderly patients seldom receive an echocardiogram at diagnosis.

Laboratory measures at the index date, by age.

Parameter	Age group (years)				
	18–54	55–64	65–74	75–84	≥85
NT-proBNP (pg/mL)	4133.5 (9187.6)	3750.4 (6433.5)	4681.0 (8788.2)	4953.5 (7927.7)	5942.8 (8415.5)
Systolic BP (mmHg)	132.2 (30.1)	134.6 (25.7)	136.9 (23.6)	139.0 (24.6)	141.8 (25.8)
Diastolic BP (mmHg)	82.2 (19.1)	81.0 (15.1)	79.4 (14.8)	78.0 (14.7)	77.0 (14.3)
eGFR (mL/min/1.73 m^2)	74.9 (29.5)	68.5 (27.9)	59.0 (26.4)	48.0 (22.3)	42.2 (20.2)
Potassium (mmol/L)	4.1 (0.5)	4.1 (0.5)	4.1 (0.5)	4.2 (0.6)	4.2 (0.6)
Sodium (mmol/L)	139.4 (3.3)	139.0 (4.2)	139.4 (3.8)	139.5 (4.1)	139.2 (4.2)

Data are presented as mean (standard deviation).
BP, blood pressure; eGFR, estimated glomerular filtration rate; NT-proBNP, N-terminal pro-B-type natriuretic peptide.

Background: Mitochondrial dysfunction contributes to myocellular abnormalities through the generation of reactive oxygen species (ROS) in the failing human heart. We have previously shown significant abnormalities in human heart cardiolipin (CL) content that are thought to play a mechanistic role in mitochondrial abnormalities. Elamipretide is a cardiolipin-targeting peptide currently being investigated in several

Phase 2 clinical trials for heart failure. In vitro and animal studies demonstrate improvements in mitochondrial ROS with elamipretide treatment independent of improvements in CL content.
Purpose: To determine whether acute elamipretide treatment of the human failing heart improves supercomplex function and lowers reactive oxygen species.
Methods: Human ventricular tissue was rapidly harvested in the operating room at the time of cardiac transplantation for end-stage heart failure with left ventricular dysfunction (F), or from age-matched donor hearts (NF) not implanted for technical reasons. Tissue was rapidly divided for elamipretide treatment or vehicle control. Immediately following treatment high-resolution respirometry was performed with simultaneous measurement of mitochondrial ROS. Tissue from each treatment arm was rapidly frozen at -80°C for MS/MS analysis of CL content.
Results: In vehicle treated samples the supercomplex coupling factor (SC CCF), a measure of the integrity of the mitochondrial supercomplex, was 35% lower in the F ventricles than NF tissue (1.11 ± 0.14 vs 1.75 ± 0.25, $p < 0.03$). Treatment with elamipretide improved SC CCF in the F human heart (1.58 ± 0.12, P=0.007) with no significant change in the NF heart (1.96 ± 0.19). Total mitochondrial ROS generation in the oligomycin-induced leak state was 44% higher in the F than NF heart (3.42 ± 0.62 vs 2.38 ± 1.34 mM H2O2) and was substantially lower following elamipretide treatment (2.51 ± 0.35 mM H2O2, P=0.06) and similar to elamipretide treated NF tissue (2.44 ± 0.34 mM H2O2). Importantly, acute elamipretide treatment did not change total, tetralinoleoyl- or monolyso-CL content in the F or NF human heart.
Conclusion: Elamipretide treatment improves supercomplex integrity and reduces mitochondrial ROS in the failing human heart in the absence of changes in total CL or expression of critical CL isoforms. These findings suggest that stabilizing the mitochondrial supercomplex, in the absence of changes in CL content, can reduce oxidative stress and represents a novel treatment for improving mitochondrial function in human heart failure.

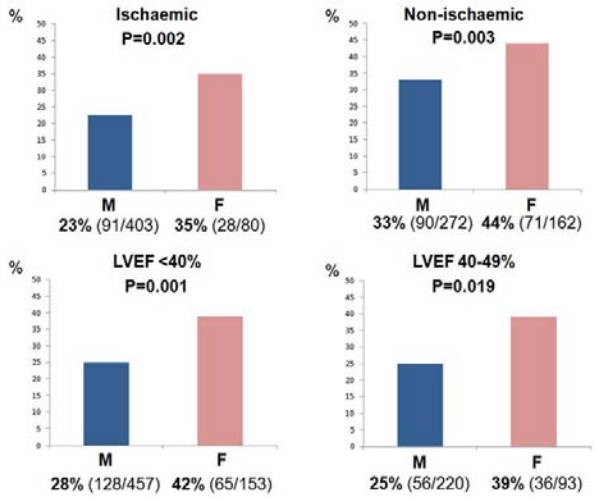
Sex, reverse remodeling and prognosis in chronic systolic heart failure

A Alberto Aimo[1]; G Vergaro[2]; V Castiglione[1]; A Barison[2]; A Giannoni[2]; R Poletti[2]; V Chubuchny[2]; L Zyw[2]; S Maffei[2]; C Passino[1]; M Emdin[1]
[1]Sant'Anna School of Advanced Studies, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*

Background: Both female sex and reverse remodeling (RR, i.e. the reversal of ventricular dilation and dysfunction in response to treatment) are associated with better prognosis in heart failure (HF).
Purpose: To determine the relationship between sex and RR and to evaluate the prognostic impact of RR.
Methods: Data from stable systolic HF patients (left ventricular ejection fraction - LVEF $< 50\%$), undergoing two transthoracic echocardiograms (TTE) within 12 ± 2 months, were analyzed. RR was defined as indexed LV end-systolic volume reduction $\geq 15\%$. The follow-up started with the second TTE. The primary endpoint was a composite of all-cause death or heart transplantation (HT), and the secondary endpoint was a composite of cardiovascular death or HT.
Results: Out of 927 patients (age 68 ± 12 years, LVEF $34 \pm 9\%$), 250 were females (27%). Ischaemic aaetiology was less represented among females (33% vs. 60%; $P < 0.001$), while most other baseline clinical and pharmacological characteristics did not differ significantly. Across the two TTE examinations, females had a higher incidence of RR in the whole population (41% vs. 27%; $P < 0.001$), among patients with either ischaemic or non-ischaemic aetiology, and in the subgroups with either LVEF $< 40\%$ or $\geq 40\%$ (Figure). In the whole population, female sex was an independent predictor of RR (odds ratio - OR 1.542 [95% confidence interval - CI 1.114-2.135], P=0.011) in a model including the univariate predictors of RR (non-ischaemic HF aetiology, lower disease duration, no left bundle branch block - LBBB). Over a 33-month [IQR 15-59] follow-up, females showed a better prognosis for both endpoints (P=0.002 and 0.005, respectively), achieved in 188 (20%) and 126 (14%) patients, respectively. In a model including age, HF aetiology and duration, LBBB, LVEF, and N-terminal fraction of pro-brain natriuretic peptide, female sex and RR were both independent predictors of all-cause death or HT (OR 0.580 [95% CI 0.356-0.944]; P=0.028 and OR 0.649 [95% CI 0.415-0.992]; P=0.048). Only RR independently predicted cardiac death or HT (OR 0.573 [95% CI 0.333-0.987]; P=0.045).
Conclusions: In systolic HF, RR is more frequent among female patients. Female sex is an independent predictor of RR and all-cause death or HT.



Sex and reverse remodeling

The clinical meaning of selected single nucleotide polymorphisms in patients with hypertension and heart failure with preserved and mid-range ejection fraction

A Bielecka-Dabrowa[1]; A Sakowicz[2]; M Misztal[3]; T Pietrucha[2]; J Rysz[4]; M Banach[1]
[1]Department of Hypertension, Chair of Nephrology and Hypertension, Medical University of Lodz, Lodz, Poland; *[2]Medical University of Lodz, Department of Medical Biotechnology, Lodz, Poland*; *[3]University of Lodz, Chair of Statistical Methods, Faculty of Economics and Sociology, Lodz, Poland*; *[4]Medical University of Lodz, Department of Nephrology, Hypertension and Family Medicine, Lodz, Poland*

Funding Acknowledgements: research grant no. 502-03/5-139-02/502-54-008 of the Polish Ministry of Science and Higher Education

Aim: This study aimed to assess the clinical meaning of the single nucleotide polymorphisms (SNPs) reflecting different pathophysiological pathways in hypertensive patients with diastolic heart failure: inflammation (-174 G/C IL-6 rs1800795, TNF-608 G/A rs1800629), fibrosis (Arg25Pro TGFβ rs1800471), endothelial function (-786 T/C NOS rs2070744), glucose and lipid metabolism (Pro12Ala PPARγ rs1801282), vitamin D metabolism (CYP27B1 C-1260A).
Methods: 110 patients (mean age 63 years, 69% males) with heart failure (HF) with preserved and mid-range heart failure (HFpEF and HFmrEF) were recruited. Functional polymorphisms were selected from six candidate genes: IL-6, TNF alpha, TGF beta, NOS3, PPAR gamma, CYP27B1. We also assessed the levels of selected HF biomarkers and performed echocardiographic examinations.
Results: Homozygotes GG in 174 G/C of IL6 polymorphism are characterized by higher values of GFR MDRD and systolic mitral annuar velocity ($p = 0{,}01; p = 0{,}03$). HF patients with A allelle in TNF-308 G/A rs1800629 polymorphism had lower systolic blood pressure and higher incidence of paroxysmal atrial fibrillatio ($p = 0{,}006; p = 0{,}005$). Patients with HF and CC profile of TGF beta polymorphism had higher LV mass and higher level of TNF alpha in plasma ($p = 0{,}04; p = 0{,}04$). Patients with C allelle in NOS polymorphism had higher class according NYHA classification, lower blood pressure, higher level of cystatin C and lower GFR, lower LVEF compared to patients without C allele ($p = 0{,}04; p = 0{,}03; p = 0{,}02; p = 0{,}02; p = 0{,}02; p = 0{,}008$). Patients with AA profile in C-1260A of CYP27B1 polymorphism had lower values of eGFR (MDRD) and higher levels of uric acid compared to CA and CC profile ($p = 0{,}03; p = 0{,}02$). In multivariate analysis CG genotype for 174 G/C of IL-6 (odds ratio OR=7,5; 95% CI:1.1-50; $p = 0.03$), A allele in C-1260A of CYP27B1 (OR=4,3; 95%CI: 1,3-13,8; $p = 0.01$), higher GFR (MDRD) (OR=0,96; 95%CI:0,92-1,0; $p = 0{,}05$), lower level of cystatin C (OR=6.6; 95%CI: 1,2-35,2; $p = 0.02$) and higher level of TGF beta 1(OR=0,96; 95%CI: 0,57-0,84; $p = 0.001$) were independent risk factors of worse course of heart failure.
Conclusions: These data confirm the importance of the selected SNPs in aggravation and complications of hypertension. The CG genotype for 174 G/C of IL-6 and A allele in C-1260A of CYP27B1 are SNPs independently associated with worse course of HFpEF and HFmrEF.

Association between troponin I and left ventricular global longitudinal strain in outpatients with heart failure

J Jensen[1]; H Bosselmann[2]; J Rasmussen[3]; ML Johansen[3]; F Gaborit[1]; M Jurgens[3]; K Iversen[1]; F Gustafsson[4]; G Soletormos[5]; C Kistorp[3]; M Schou[1]
[1]Herlev-Gentofte Hospital, Department of Cardiology, University of Copenhagen, Herlev, Denmark; *[2]North Zealand Hospital, Department of Cardio-, Nephro- and Endocrinology, University of Copenhagen, Hillerod, Denmark*; *[3]Herlev-Gentofte Hospital, Department of Endocrinology and Internal Medicine, University of Copenhagen, Herlev, Denmark*; *[4]Rigshospitalet, Department of Cardiology, University of Copenhagen, Copenhagen, Denmark*; *[5]North Zealand Hospital, Department of Research, University of Copenhagen, Hillerod, Denmark*

Background: Troponin I (TnI) is an established prognostic marker in heart failure (HF). However, the pathophysiological mechanisms of TnI elevations in compensated HF are poorly understood. Hence, it is unknown whether TnI elevations are associated with an impaired left ventricular function evaluated by echocardiography or only reflect frequently present comorbidities.
Purpose: To test the hypotheses that TnI is associated with an impaired left ventricular function estimated by left ventricular (LV) global longitudinal strain (GLS) in outpatients with compensated HF.
Methods: We prospectively enrolled 112 patients with reduced left ventricular ejection fraction (LVEF) referred to an outpatient HF clinic. LV GLS was assessed by two-dimensional speckle tracking, plasma concentrations of TnI were analyzed on frozen plasma with a standard contemporary TnI assay. The cut-off value at the 99th percentile of concentrations obtained among healthy individuals is 45 ng/L. Baseline data were collected. The association between plasma concentrations of TnI and LV GLS was evaluated in logistic regression models before and after adjustment for important confounders (age, sex, renal function, anemia, atrial fibrillation, NT-proBNP, diabetes and ischemic heart disease).
Results: The patients had a median age of 70 years (interquartile range: 64-75), 26.5% were female, median LVEF was 33% (27-39%) and 29% were in New York Heart Association (NYHA) class III-IV. TnI was detectable in 36%. Of the patients with detectable plasma concentrations of TnI, 63% had a markedly impaired LV GLS (>/= -11%) and this was only the case for 31% of the patients with undetectable TnI ($P < 0.001$). In univariate analyses, LV GLS and TnI were closely associated (Odds ratio (OR): 3.86 (95% Confidence Interval (CI): 1.71-8.68, $P < 0.001$), and the association remained significant in a multivariate adjusted analysis (OR: 3.45 (95% CI: 1.24-9.62, $P < 0.018$). Detectable TNI was not associated with any comorbidity (renal function, anemia, atrial fibrillation, diabetes and ischemic heart disease) in an adjusted statistical model ($P>0.05$ for all).
Conclusions: Detectable TnI is independently associated with impaired LV GLS and may, therefore, reflect impaired left ventricular function rather than comorbidities. Future trials should use TnI to identify high risk patients since detectable TnI is both associated with a poor outcome and impaired left ventricular function in compensated HF.

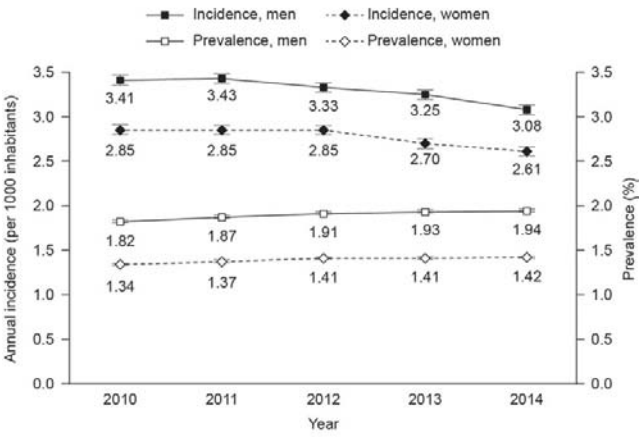
1525

Epidemiology of heart failure in Sweden: a retrospective population-based cohort study

K Lindmark[1]; K Boman[2]; M Olofsson[2]; G Wikstrom[3]; G J Bergman[4]; M Tornblom[4]; E Gullberg[5]; D Johansson[5]; R Schlienger[6]; J Stalhammar[7]
[1]Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden; *[2]Umea University, Research Unit, Medicine, Skellefteå, Department of Public Health and Clinical Medicine, Umea, Sweden*; *[3]Uppsala University, Institute for Medical Sciences, Uppsala, Sweden*; *[4]QuintilesIMS, Solna, Sweden*; *[5]Novartis Sweden AB, Stockholm, Sweden*; *[6]Novartis Pharma AG, Basel, Switzerland*; *[7]Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden*

Background and purpose: Considering the limited and conflicting data on temporal trends in the incidence, prevalence and mortality of heart failure (HF) in Sweden, we aimed to provide an update on the epidemiology of HF in Sweden.
Methods: Patients with HF were identified using data from secondary care from the National Patient Register (NPR, primary care was not covered), linked via unique identifiers to primary and secondary care data from the Cause of Death Register. Patients aged ≥18 years with ≥2 diagnoses of HF between 01/01/1997 and 31/12/2014 (for incidence and prevalence) or between 01/01/2005 and 31/12/2013 (for mortality) and an ICD-10 diagnostic code of I50 (inclusive of all granular codes), I42.0, I42.6, I42.7, I42.9, I110, I130 or I132 in any position were included. The date of the second HF diagnosis was the index date for incidence and prevalence; the date of the first HF diagnosis was the index date for mortality. ICD-10 codes also identified comorbidities occurring in the 5 years prior to index. Annual incidence and prevalence estimates were assessed for the years 2010–2014 using a look-back period from 2000 onwards. Estimates were age-standardized to the Swedish population in 2015. Age-adjusted hazard ratios (HRs) for all-cause and cardiovascular disease (CVD)-related mortality was estimated using a Cox proportional hazards model.
Results: Data from 845 276 patients with HF were extracted from the NPR. Of these, 174 537 patients (20.6%) did not have a diagnosis of HF in the look-back period and were considered to be newly diagnosed (median age: 79.9 years; 46.9% women). The most common comorbidities were hypertension (36.3%), atrial fibrillation (26.1%) and ischaemic heart disease (22.9%). Overall annual incidence (95% confidence interval [CI]) of HF decreased over the 5 years from 3.20 (3.16–3.24) to 2.91 (2.87–2.95) per 1000 inhabitants, and prevalence increased over the 5 years from 1.61 (1.60–1.62)% to 1.72 (1.71–1.72)%. Incidence and prevalence estimates were higher in men than in women (Figure). All-cause mortality over 1 and 3 years (95% CI) was 19.7 (19.5–19.9)% and 40.5 (40.2–40.7)%, respectively; 1- and 3-year CVD-related mortality was 11.8 (11.6–11.9)% and 25.9 (25.7–26.1)%, respectively. All-cause mortality was higher in women than in men (1-year mortality, 21.1 [20.8–21.4]% vs 18.4 [18.2–18.7]%; 3-year mortality, 43.3 [42.9–43.6]% vs 38.0 [37.6–38.3]%), as was CVD-related mortality (1-year mortality, 12.9 [12.6–13.1]% vs 10.8 [10.5–11.0]%; 3-year mortality, 28.3 [27.9–28.6]% vs 23.8 [23.5–24.1]%). However, age-adjusted HRs (95% CI) suggested mortality was higher in men than women (all-cause, 1.12 [1.10–1.13]; CVD-related, 1.11 [1.10–1.13].
Conclusions: Increasing prevalence of HF with decreasing incidence indicates improved survival. Incidence, prevalence and age-adjusted mortality of HF were higher in men than in women.

Annual incidence and prevalence of HF in men and women in Sweden from 2010 to 2014



Error bars indicate 95% CIs.

Health Science Foundation, Cotignola, Italy*

On behalf of: IN-HF Outcome Investigators
Funding Acknowledgements: The study was partially supported by an unrestricted grant by Novartis, Abbott, and Medtronic, Italy

Background. ESC guidelines identify patients (pts) with heart failure (HF) and ejection fraction (EF) between 40 and 49%, defined HF 'mid-range' (HFmrEF), confirming the values for HF with preserved EF (≥50% HFpEF) and HF with reduced EF (<40% HFrEF).
Aims: To compare in outpts with chronic heart failure (CHF) clinical characteristics and outcomes of HFmrEF pts with those of HFpEF or HFrEF.
Methods: Data derived from the Italian Network on Heart Failure (IN-HF) Outcome Registry which collected data of pts with HF and any level of EF.
Results: 2135 HF outpts had EF data: pts with HFmrEF were 23.9%, 59.7% had HFrEF and 16.4% HFpEF. Mean age was 69 ± 12 years, 68 ± 12 years and 72 ± 12 respectively ($p < 0.0001$), prevalence of females in HFmrEF was 26.1% compared to 18.5% and 39.9% in HFrEF and HFpEF respectively ($p < 0.0001$). Ischemic aetiology was more frequent in HFrEF (49.8%) and HFmrEF pts (46.1%) than in HFpEF pts (26.8%), $p < 0.0001$, which had a higher rate of hypertensive etiology. Pts with

HFpEF also had a higher prevalence of history of atrial fibrillation (39.1% vs 26.5% of HFmrEF and 26.4 of HFrEF, p < 0.001). There were no differences in the rates of HF hospitalisations in the previous year among the three groups. NYHA III and IV were less frequent in HFmrEF (9.4%) compared to HFrEF (23.6%) and HFpEF 21.9%, p < 0.0001. Drug treatments are reported in the table. Pts with HFmrEF were treated similarly to those with HFrEF with respect to ACE-I/ARBs or BBs while they were less treated with diuretics and digoxin compared to the other two groups of HF pts. MRAs were more frequently prescribed in HFrEF while in HFmrEF the prescription is similar to HFpEF pts. At 12 months follow-up, HFrEF pts were more frequently hospitalized (25.9%) compared to HFmrEF (14.5%) and HFpEF (19.7%), p < 0.0001. All-cause mortality was reported in 6.7% in HFrEF pts versus 3.3% of HFmrEF versus 3.7% of HFpEF (3.7%), p = 0.006.

Conclusions: Pts with HFmrEF represent a significant portion of HF outpts, they are currently treated similarly to those with HFrEF. One year mortality of HFmrEF pts seems to be better than that of HFpEF and particularly HFrEF pts.

Drug	Total n=2135	HFrEF n=1274	HFmrEF n=510	HFpEF n=351	p value
ACE-I/ARBs, %	90.3	91.2	91.2	85.8	0.007
BBs, %	80.9	84.8	80.0	68.1	< 0.0001
MRAs, %	43.5	50.8	34.9	29.3	< 0.0001
Diuretics, %	86.0	91.2	77.3	80.1	< 0.0001
Digoxin, %	18.9	20.8	13.7	19.4	0.003

On behalf of: PARADIGM-HF investigators
Funding Acknowledgements: The PARADIGM-HF study was funded by Novartis

Background: Estimated plasma volume (ePV) derived from haematocrit and body weight correlates well with PV measured using 125Iodine labelled human serum albumin. We calculated ePV and relative PV (rPV), which is ePV as a fraction of ideal PV (iPV), in patients with HFrEF enrolled in PARADIGM-HF and examined the association between rPV and outcomes, as well as the effect of randomized treatment on rPV.

Methods: iPV was calculated as: iPV = c × weight (kg) where c=39 in males and c=40 in females. ePV was calculated using subjects' haematocrit and weight as follows: ePV = (1 − haematocrit) × [a + (b × weight in kg)], where haematocrit is a fraction, a=1530 in males and a=864 in females, and b=41 in males and b=47.9 in females. rPV was the relative deviation of EPV from iPV where 0% means ePV and iPV are the same, a negative value indicates an ePV less than iPV and a positive value an ePV greater than iPV. The relationship between rPV quartile and the primary composite outcome of CV death or HF hospitalization was examined in a multivariable Cox regression model (including age, sex, race, region, HF duration, NYHA class, LVEF, HR, BMI, ischaemic aetiology, history of MI, AF, stroke, KCCQ Score, ICD, eGFR, NTproBNP). We also examined absolute change in rPV at 12 months of follow-up.

Results: PV indices were available for 8071 of the enrolled patients (96%). The median ePV at screening was 2717 (IQR 2416, 3039) ml compared with an iPV of 3081 (IQR 2640, 3588) ml; the median rPV was -11.6% (IQR -17.7, -4.7) and 87% of patients had a rPV < 0%. The primary composite outcome occurred in 480 (24%), 451 (22%), 489 (24%), and 534 (27%) of patients in quartiles 1-4 of rPV, respectively (where Q4 had the highest rPV). Using quartile 1 as reference, adjusted hazard ratios (HR) for the composite outcome were HR 1.00 (95% CI 0.87-1.15) for Q2, HR 1.18 (1.02-1.37) for Q3 and HR 1.27 (1.08-1.49) for Q4 (Figure). There was no interaction between rPV quartile at screening the benefit of sacubitril/valsartan over placebo (p = 0.56). Change in median rPV from screening to 1 year in the enalapril group was from -11.8% to -11.3%, an increase of 0.5%; in the sacubitril/valsartan group rPV changed from -11.8% at screening to -12.2%, a decrease of 0.4% (P < 0.001).

Conclusion: Estimating PV using a simple calculation based on haematocrit, sex and bodyweight provided incremental predictive information on morbidity/mortality in patients with HFrEF. Compared with enalapril, sacubitril/valsartan led to a reduction in rPV.

Aims/hypothesis: – Adrenomedullin (ADM) is a vasoactive peptide with vasodilator and natriuretic properties. Plasma concentration of ADM is increased in the acute phase of heart failure and is a predictor of the risk of short-term mortality. Here, we evaluated the prognostic value of plasma midregion-pro-ADM, MR-proADM (a surrogate for ADM) for the occurrence of severe congestive heart failure (CHF) necessitating hospitalization, in people with type 2 diabetes.

Methods: Plasma MR-proADM concentration was measured in baseline samples of two cohorts of type 2 diabetes patients recruited in France: SURDIAGENE (n = 1438, median follow-up 5.3 years) and DIABHYCAR (n = 2962, median follow-up 4.7 years).

Results: – The incidence rate of CHF was 2.5 (95% CI 2.2-2.9) for SURDIAGENE and 1.0 (95% CI 0.8-1.1) per 100 person-year for DIABHYCAR, respectively, corresponding to 206 and 127 events, respectively. The highest tertile of plasma MR-proADM concentration at baseline was associated with the risk of CHF during follow-up in both cohorts (log-rank test: p < 0.0001 and p = 0.01, respectively). The associations of MR-proADM with CHF remained significant in Cox regression analyses when adjusted for other risk factors for CHF, such as a history of coronary heart disease, proteinuria and decline of renal function (HR in pooled cohorts: 1.99 (1.58-2.50); p < 0.0001). MR-proADM also contributed significant supplementary information to the prediction of CHF, when we considered the clinical risk factors of CHF identified in the UKPDS study (IDI: 0.013 ± 0.006, p = 0.02).

Conclusions/interpretation: – MR-proADM is a predictive biomarker for occurrence of severe heart failure in people with type 2 diabetes.

Prognostic value of malnutrition screening tools in patients with chronic heart failure

S Shirley Sze[1]; P Pellicori[1]; AS Rigby[1]; S Kazmi[1]; AL Clark[1]
[1]*Castle Hill Hospital, Hull, United Kingdom*

Background: Cachexia in heart failure (HF) is associated with adverse outcomes. Malnutrition is common in HF patients and contributes to cachexia but it is not part of the routine assessment of patients. There is no consensus on how best to screen for malnutrition in patients with HF.

Purpose: To evaluate the prevalence, clinical associations and prognosis of malnutrition using three common multi-dimensional malnutrition indices in a large cohort of well-characterised patients with chronic heart failure (CHF).

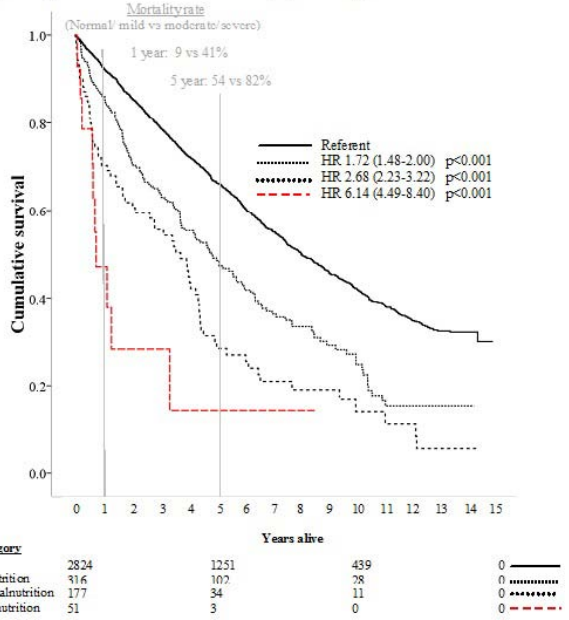
Methods: Consecutive referrals to a community HF clinic between 2000 and 2016 were analysed. HF was defined as signs or symptoms and evidence of cardiac dysfunction, either a reduced left ventricular ejection fraction at echocardiography (LVEF, < 50%) or raised NTproBNP (>125 ng/L). Patients were screened for malnutrition using the geriatric nutritional risk index (GNRI), the controlling nutritional status (CONUT) score and the prognostic nutritional index (PNI).

Results: 3386 patients had CHF (61% males, median age 75 (interquartile range (IQR): 67-81) years, median NTproBNP 1573 (IQR: 702-2799) ng/L). Of these, 1198 (35%) and 1458 (43%) patients had HF with reduced (HeFREF, LVEF < 40%) and normal (HeFNEF, LVEF≥50%) ejection fraction, respectively. According to the GNRI (≤91), CONUT score (>4) and PNI (≤38), 6.7%, 10.0% and 7.5% patients were moderately to severely malnourished, respectively. Patients with HeFREF were at higher risk of malnutrition than those with HeFNEF. (8-12% vs 5-8%, respectively) Compared to normal patients, malnourished patients were older, had lower body

mass index (BMI), worse symptoms and renal function; more likely to have atrial fibrillation, anaemia and reduced mobility. Worsening malnutrition correlated with increasing NTProBNP levels regardless of HF phenotypes.(R2 = 0.36-0.45(CONUT), 0.28-0.43(GNRI), 0.37-0.43(PNI), all p < 0.001) During a median follow-up of 1573 days (IQR: 702-2799 days), 1723 (50.9%) patients died. We created 25 prognostic Cox regression models using K-fold cross validation (k=25). CONUT and GNRI category (worse outcome with worsening malnutrition categories) were independently associated with outcome in 100% of the models while PNI category was an independent predictor in 19 models (76%). A base model for predicting mortality including variables with an inclusion frequency > 18 of 25 (>70%) models: age, sex, diastolic BP, heart rate, NYHA class III& IV vs I&II, urea, logNTProBNP, stroke and peripheral vascular disease had a C statistics of 0.72. Amongst the malnutrition indices, GNRI improved model performance most compared with base model. Patients who were severely malnourished according to GNRI had over 6 times greater mortality risk than normal patients. (Figure)

Conclusion: Malnutrition is common amongst patients with CHF and is strongly related to mortality. Screening for malnutrition using GNRI should be routine adopted during assessment of HF patients to guide management.

Figure. Kaplan-Meier curve for all-cause mortality by GNRI categories.



GNRI category and all-cause mortality

One-year change in ejection fraction and long-term outcomes in patients with heart failure with mid-range ejection fraction

N Farre[1]; J Lupon[2]; E Sole-Gonzalez[3]; J Gonzalez-Costello[4]; J Vila[5]; S Perez[5]; S Ruiz[6]; M Domingo[2]; A Mendez-Fernandez[3]; C Sanchez-Enrique[4]; C Enjuanes[1]; E Roig[3]; E Zamora[2]; A Bayes-Genis[2]; J Comin-Colet[1]

[1]Hospital del Mar, Department of Cardiology, Municipal Institute for Medical Research (IMIM), Barcelona, Spain; *[2]Germans Trias i Pujol University Hospital, Department of Cardiology, Badalona, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Department of Cardiology, Barcelona, Spain*; *[4]University Hospital of Bellvitge, Barcelona, Spain*; *[5]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain*; *[6]Hospital del Mar, Department of Cardiology, Barcelona, Spain*

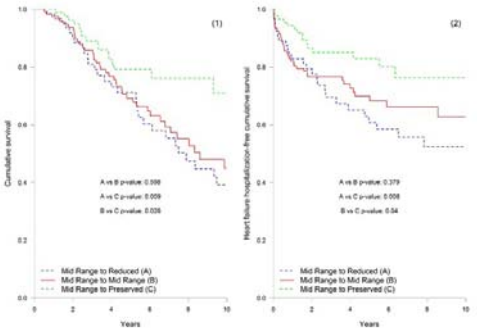
Background: In patients with heart failure (HF) and reduced ejection fraction (HFrEF) an improvement in ejection fraction (EF) has been associated with better outcomes. Whether this is true in patients with mid-range EF (HFmrEF) is unknown.

Purpose: To analyze the effect of 1-year change in EF in outcome of patients with HFmrEF (defined as EF 40-49%).

Methods: Prospective observational study of HF patients followed up at 4 university hospitals with a dedicated Heart Failure Unit. Baseline characteristics, 1-year EF and outcomes were collected.

Results: Fourteen percent (n = 504) of the 3580 patients included in the study had HFmrEF. Mean age was 68 ± 13 years (compared with 66 ± 13 in HFrEF (defined as EF < 40%) and 74 ± 11 in HFpEF, defined as EF>50%), 40% were female (30% in HFrEF and 57% in HRpEF), both p < 0.001. As expected, among 1-year survivors only 40% of patients with HFpEF had EF measured at 1 year follow-up, and the majority (85%) had EF>50%. The majority of patients with HFrEF (62%) still had EF < 40% at 1-year follow-up. Interestingly, EF of patients with HFmrEF had the greatest variation: 24% had reduced EF, 43% maintained EF 40-49% and 33% had EF >50%. Figure 1 shows Kaplan-Meier curves for long-term outcome. Of the 2409 patients with EF < 50% that survived 1 year, 1561 (65%) had an echocardiogram performed. In this group, after adjustment for age, sex and baseline EF, hazard ratios for survival for change in EF was 0.97 (95% CI 0.96-0.98, p < 0.001).

Conclusions: At 1-year follow-up patients with HFmrEF had the greatest variability (up and down) in EF and this change was associated with survival.



1531

HLM as a new staging system for heart failure. Comparison with NYHA

P Paolo Severino[1]; M Alfarano[1]; M Pucci[1]; I Ferrari[1]; S Peroni[1]; S Calcagno[1]; A Fusto[1]; D Alunni Fegatelli[2]; A Vestri[2]; S Sciomer[1]; M Mancone[1]; F Fedele[1]

[1]Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrology, Anesthesiology and Geriatric Sciences, Sapien, Rome, Italy; *[2]Sapienza University of Rome, Department of Public Health and Infectious Diseases, Rome, Italy*

Background. Although NYHA is the most used classification for heart failure (HF), it does not include patients clinical features and other organs involvement. We proposed a new staging system for HF, named HLM (JACC 2014;20;63(19):1959-60), analogous to the TNM classification used in Oncology. HLM refers to heart damage (H), lung involvement (L), and malfunction of peripheral organs, such as kidney, liver, brain and hematopoiesis.

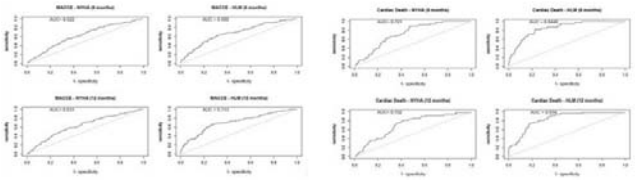
Purpose: The aim was a preliminary comparison between HLM and NYHA to achieve the most accurate prognosis of HF patients in terms of rehospitalization and mortality.

Methods: We performed an observational registry of consecutive 780 patients with diagnosis of heart failure or at risk for it. All parameters for cardiac heart (systolic and diastolic left ventricular function and volumes, structural damage, left ventricular remodeling, biventricular dysfunction), lungs (hemodynamic or clinical pulmonary congestion, cardiac lung) and peripheral organs (i.e. kidney, liver, central nervous system, and hematopoietic system) function have been examined. Each patient has been classified according to NYHA and HLM. The MACCE (major adverse cardiovascular and cerebrovascular events) and cardiac death rates were calculated at 6 months and 12 months follow up.

Results: Among 780 enrolled patients, the etiology for heart failure was: 52% coronary artery disease, 17% hypertensive cardiomyopathy, 13% dilated cardiomyopathy, 11% valvular heart disease and 7% other. At 6 months follow-up, comparing to NYHA, HLM showed a greater area under the ROC curve (AUC) for rehospitalization (HLM AUC= 0.680 vs NYHA AUC= 0.622) as well as for cardiac death (HLM AUC= 0.844 vs NYHA AUC= 0.721), with significant differences regarding L (p = 0.03, OR= 7.103) and M (p = 0.02, OR= 12.439) and NYHA IV (p = 0.016, OR= 12.801); similar findings have been observed at 12 months follow-up (for rehospitalization HLM AUC= 0.713 vs NYHA AUC= 0.631; for cardiac death HLM AUC= 0.834 vs NYHA AUC= 0.702) (Fig. 1). Cardiac death has been assessed separately for each parameter (H, L and M): L and M showed the most accurate prognostic power; at 1 year-follow-up, L1 was significantly correlated (p = 0.027, OR=0.3.554) with cardiovascular mortality as well as L2 (p = 0.001, OR= 6.358), L3 (p = 0.000, OR= 11.231), M2 (p = 0.008, OR= 7.736) and M3 (p = 0.005, OR= 9.972).

CONCLUSIONS. Basing on the preliminary results, compared to NYHA classification, HLM nosology appears as more accurate to stratify risk of rehospitalization for MACCE and of cardiac death for HF patients. Interestingly, only NYHA IV presented significant results. Regarding HLM, any lung involvement (L1-3) and two or more

organs dysfunction (M2-3) presented the most accurate prognostic power. This means that a wider and systemic approach should be used in HF patients, giving up the "cardiocentric" methodology of NYHA. Those preliminary data need to be confirmed in a greater population with a longer follow up.



ROC curves at 6 and 12 months follow up.

Prevalence and clinical consequences of dysglycaemia in nondiabetic patients with chronic heart failure

M Mohan[1]; FATIMA Baig[1]; U Bhalraam[1]; CHIM Lang[1]
[1]*University of Dundee, Division of Cardiovascular & Diabetes Medicine, Ninewells Hospital, Dundee, United Kingdom*

On behalf of: BIOSTAT-CHF Investigators
Funding Acknowledgements: European commission Seventh Framework Programme (FP-7)

Background & Aim: Chronic heart failure (CHF) and diabetes mellitus (DM) frequently co-exist and its clinical consequences has been undoubtedly established in the past. CHF is a state of insulin resistance and it is believed that glucose abnormalities are very common in CHF patients even in the absence of DM, exposing them to a higher risk of developing DM. This study sought to establish the prevalence and risk related to prediabetes among nondiabetic CHF patients.
Methods: 1805 CHF patients (age 74 ± 11, 34% females, 64% IHD aetiology; 57% in NYHA III/IV; BMI 29 ± 6 kg/m^2, 42% all-cause deaths) were evaluated prospectively from the BIOSTAT-CHF Scotland study. Pre-diabetes was defined using the new glycosylated haemoglobin A1C (HbA1c) criteria (6.0-6.4%) proposed by the International Diabetes Expert Committee (IEC). Patients with a diagnosis of DM (33%) or undiagnosed DM (5%, baseline HbA1c≥ 6.5 %) and patients with no baseline HbA1c (14%) were excluded from the study. Cox regression models were used to assess all-cause mortality rates, adjusting for significant covariates.
Results: After exclusion, prevalence of prediabetes was 33% by IEC criteria in our cohort of CHF patients (n = 876). During a median follow-up period of 4.7 years (IQR 4.5, 4.9), there were 39% all-cause deaths. A Kaplan- Meier analysis showed that mortality rates were significantly higher (46% vs 35%; p = 0.006) in prediabetic CHF patients as compared to normoglycemic (NG) CHF patients. Prediabetic CHF patients had more symptomatic CHF (% of patients in NYHA III-IV, 62% vs 52%, p = 0.009) as compared with NG-CHF patients. A Cox regression model, adjusted for significant covariates showed that prediabetic CHF patients were at higher risk of deaths (HR 1.3 [1.02 – 1.7]; p < 0.05) compared to NG-CHF patients.
Conclusion: In patients with CHF, high-normal baseline HbA1c levels in the absence of DM have a significantly increased risk of all-cause mortality. Targeted therapeutic strategies to prevent or delay the onset of DM is urgently needed in these CHF patients identified to have pre-diabetes.

MODERATED POSTER SESSION 5 - TIPS AND TRICKS TO PREVENT READMISSIONS

Interleukin-1 blockade in recently decompensated systolic heart failure: the recently decompensated heart failure anakinra response trial (REDHART)

B Van Tassell[1]; J Canada[1]; S Carbone[1]; C Trankle[1]; LF Buckley[1]; C Oddi Erdle[1]; N Abouzaki[1]; DL Dixon[1]; D Kadariya[1]; S Christopher[1]; H Billingsley[1]; J Regan[1]; A Bhatnagar[1]; E Lesnefsky[1]; A Abbate[1]
[1]*Virginia Commonwealth University, Richmond, United States of America*

Funding Acknowledgements: National Institutes of Health - National Heart, Lung, and Blood Institute

Background. An enhanced systemic inflammatory response (i.e. elevated plasma levels of C reactive protein [CRP]) in patients with decompensated heart failure (HF) predicts worse outcomes. We hypothesized that inhibiting Interleukin-1 (IL-1) activity using recombinant human IL-1 receptor antagonist (anakinra) would improve aerobic exercise capacity in patients with recently decompensated systolic HF and systemic inflammation.
Methods: We randomly assigned 60 patients with recently hospitalized HF who had been discharged in the prior 14 days, had reduced left ventricular ejection fraction (LVEF $<50\%$), and elevated CRP levels (>2 mg/l) to daily subcutaneous injections with anakinra 100 mg for 12 weeks, anakinra for 2 weeks followed by placebo for 10 weeks, or placebo for 12 weeks. Patients underwent clinical assessment, transthoracic echocardiography, non-invasive hemodynamic testing, and cardiopulmonary exercise testing (CPX) at 2, 4, 12, and 24 weeks.
Results: Fifty-two patients (87%) completed the first 14 days of treatment and repeated CPX allowing to measure the interval change in peak oxygen consumption (pVO2 [mL/kg/min]) and ventilator efficiency (VE/VCO2 slope, co-primary endpoints). Treatment with anakinra significantly reduced CRP by>80% ($P<0.01$) but did not affect pVO2 or VE/VCO2 (P>0.20) at 2 weeks. At 12 weeks, a significant improvement in pVO2 (from 14.5 [10.5-16.6] to 16.1 [13.2-18.6], P=0.008) and VE/VCO2 slope [from 34.9 [29.4-41.4] to 31.7 [27.3-34.2, P=0.035), and not in the placebo nor in the anakinra in 2-week groups (all P>0.15). The incidence of death or HF admission was 30% (placebo), 31% (anakinra 2-week), and 6% (anakinra 12-week, Log-Rank test P=0.104). An analysis measuring events while on-treatment showed lower events while on anakinra [combined] versus on placebo (1 [3%] vs 7 [21%], P=0.024). Anakinra treatment was also associated with improvements in E/E' ratio, LVEF, and quality of life measures at 12 weeks. Non-invasive hemodynamic testing revealed significant improvements with anakinra in ventriculo-arterial coupling and stroke work efficiency at 12 weeks.
Conclusion: IL-1 blockade with anakinra in patients with recently decompensated HF failed to improve peak aerobic capacity measured at 2 weeks. Treatment with anakinra for 12 weeks was associated with a clinical improvement at 12 weeks and a signal for reduced hospital readmission for HF. Further studies are needed to confirm these findings and explore the therapeutic value of IL-1 blockade on clinical outcomes.

1534

Correlation between degree of pulmonary congestion and rate of heart failure hospitalization in heart failure patients with reduced left ventricle ejection fraction: results from extended impedance-

M Michael Kleiner Shochat[1]; A Shotan[1]; M Kazatsker[1]; I Kleiner[2]; JM Weinstein[2]; D Blondheim[1]; A Asif[1]; I Dahan[1]; S Meisel[1]
[1]*Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel*; [2]*Saroka Medical Center, Cardiology, Beer Sheva, Israel*

Results of the IMPEDANCE-HF trial have shown that lung impedance (LI)-guided treatment reduces hospitalizations for heart failure (HF) and decreases HF-related mortality. The main trial was extended for an additional year to accrue more data on predictors of hospitalizations due to HF. The main aim of the study was to prove that HF patients with higher degree of long-standing pulmonary congestion are hospitalized more often.
Methods: Study population included 266 patients, with HF and LVEF$\leq$35% in New York Heart Association class II-IV. Patients were randomized (1:1) to a control group treated by clinical assessment and a monitored group whose therapy was also assisted by LI. Patients were examined and LI measured monthly in our outpatient clinics. Noninvasive LI measurements were performed with the high-sensitive device. Assessment of the degree of pulmonary congestion was by the new index LIR, measured at each visit and calculated as LIR = [currently measured LI/ normal baseline (calculated for each patient) -1] $\times$ 100 expressed as percentage. The annual average LIR for each patient was calculated as the mean of all LIR measurements at each consecutive year of follow-up (FU).
Results: The cumulative FU period was 634 patient×years in the monitored group and 483 patient×years in the control group ($p=0.001$). Groups were similar with respect to baseline characteristics. There were 228 HF hospitalizations in the monitored group (mean 0.54 per year) and 431 HF hospitalizations in the control group (1.29 per year, $p<0.001$). Rate of HF hospitalization was divided into 5 categories as follows: Q0: no HF hospitalizations during FU period, Q1: 0.01-0.3; Q2: 0.31-0.8; Q3: 0.81-1.7, and Q4 >1.7 HF hospitalizations/ per year of FU. Number of patients in Q0:Q1:Q2:Q3:Q4 were 53 (40%), 29 (22%), 25 (19%), 16 (12%) and 10 (8%) in the monitored group and 41 (31%), 17 (13%), 21 (16%), 21 (16%) and 33 (25%) in the control group, respectively ($p<0.01$, Figure 1). Results show that the level of congestion according to LIR during FU period was low in subgroup Q0 while increasing progressively from Q1 to Q4 in both groups ($p<0.001$). On the other hand, no difference in the level of congestion between the same quartile groups was measured. Conclusions (1) LI-guided treatment of HF patients significantly reduces the incidence of HF hospitalizations. (2) Preemptive LI-guided treatment cases a shift of patients from Q3-4 to Q0-1-2 in the monitored group in comparison with the control group. (3) There were no significant differences in the degree of pulmonary congestion between monitored and control patients of the same quartile. (4) As a result of the above, the main predictor for HF hospitalizations is the degree of pulmonary congestion during the FU period.

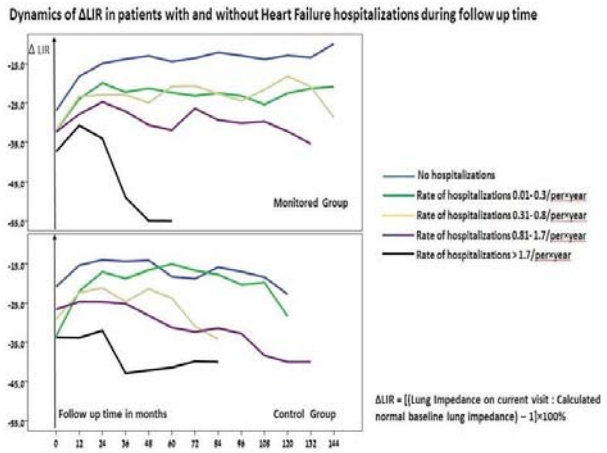

Figure 1

Usefullness of a discharge check-list in acute heart failure

L Chaufourier[1]; K Blanchart[1]; D Legallois[1]; JJ Parienti[2]; A Belin[1]; P Milliez[1]; R Sabatier[1]
[1]*University Hospital of Caen, Cardiology, Caen, France*; [2]*University Hospital of Caen, Department of biostatistics and clinical research, Caen, France*

Background: Besides significant in-hospital mortality reduction in acute heart failure (AHF), rehospitalization rate remains a powerful predictor of mortality. AHF ESC guidelines recommend pre-discharge and long-term management to prevent early readmissions.
Purpose: We hypothesized that the systematic use of a discharge checklist (CL) after an AHF could have an impact on cardiovascular mortality and readmission rates.

Methods: Our checklist was designed according to ESC recommendations in order to promote treatment optimization and the development of a careplan after discharge (Fig 1). We included 240 patients hospitalized for AHF in our center: 137 patients from June to December 2014 before introduction of the CL, and 103 patients from July 2015 to January 2016 after introduction of the CL. The primary endpoint was cardiovascular death at 6-month. Propensity score matching was performed using a logistic regression model.
Results: Mean age was 77 ± 12 years, 56% were male, and 57% were HFrEF patients. There was a significant reduction in cardiovascular death at 6 months in the CL group (OR 2.1, IC 95 [1.1 to 3.98], p = 0.02). There was a non-significant decrease in the 6-month AHF re-admissions rate in the CL group (29.1 vs. 32.1%, p = 0.57), but the increased death rate in the control group may have reduced this impact. Disease management program was more often used in the CL group (36,3% vs 15,4%, p = 0.0002). At discharge, 82% of patients among CL group had a medical appointment within a month, compared to 33% of patients in the control group (p < 0,0001). Therapeutic optimization was better in the CL group, especially for patients with HFrEF: ARB/ACE-I and beta-blockers were more often prescribed or up-titrated according to ESC guidelines (p = 0,016 and p = 0,03).
Conclusion: In unselected patients hospitalized for AHF, the use of a standardized checklist reduced cardiovascular mortality at 6 months. It also improved therapeutic optimization at discharge and increased systematic follow-up plan utilization. Larger studies are needed to demonstrate a significant reduction in re-admission rates.

Comparison of ultrafiltration versus diuretic treatment in patients with acute decompensated heart failure - A meta-analysis

B Bastian Wobbe[1]; L Czopf[1]; K Farkas[2]
[1]*University of Pécs, 1st Department of Medicine, Division of Angiology and Cardiology, Pécs, Hungary*; [2]*University of Pécs, Institute of Bioanalysis, Pécs, Hungary*

Background: Diuretics are the number one treatment choice for patients hospitalized with acute decompensated heart failure (ADHF) presenting with signs and symptoms of volume overload. Inconsistent responsiveness to diuretic treatment and treatment-related side-effects have led to the development of new and potentially safer treatment options. Several studies investigated the effectiveness and safety of the use of ultrafiltration (UF) on decongestion in patients with ADHF so far. But, due to the heterogenic study outcomes, uncertainty remains, whether UF is a safe and valid alternative to the standard diuretic treatment.
Purpose: We conducted a systematic meta-analysis with the primary goal of assessing the impact of extracorporeal UF compared to the standard diuretic treatment using diuretic agents.
Methods: We searched EMBASE, the Cochrane Registry and PubMed to identify studies comparing UF with the usual care therapy using diuretic agents in patients hospitalized for ADHF. We used the search terms "acute heart failure", "ultrafiltration", "diuretic agent" (for EMBASE and Cochrane) or "diuretics" (for PubMed) and filtered for "randomized controlled trials". The date of the search was the 17.10.2016.
Results: We identified 9 randomized controlled trials enrolling 820 participants, of whom 402 (49%) were randomized to UF and 418 (51%) to control. Overall, UF treatment lead to significantly larger amount of fluid removal (Difference in means: 1325 ml, 95% CI: 817 to 1833 ml, p = < 0.001) and weight loss (Difference in means: 1.52 kg, 95% CI: 0.27 to 0.99 kg, p = < 0.001). Furthermore, we found significant lower incidences of worsening heart failure in patients treated with UF (OR: 0.63, 95% CI: 0.43 to 0.94, p = 0.022). However, further analysis of adverse events showed no difference between groups concerning incidences of renal impairment (OR: 1.44, 95% CI: 0.91 to 2.28, p = 0.117), cardiovascular disorders except heart failure (OR: 1.57, 95% CI: 0.92 to 2.68, p = 0.097) and potentially treatment-related adverse events (including hypotension, syncope and electrolyte disorders) (OR: 1.17, 95% CI: 0.64 to 2.14, p = 0.614). No differences were observed in the analysis of all-cause mortality (OR: 1.13, 95% CI: 0.75 to 1.71, p = 0.546). The treatment with UF was associated with a significant reduction in heart failure related re-hospitalizations compared to diuretic treatment (OR: 0.543, 95% CI: 0.362 to 0.815, p = 0.003).
Conclusion: Compared to diuretic therapy, UF induces larger weight loss and fluid removal, reduces the number of heart-failure related re-hospitalizations and the risk of worsening heart failure in congestive patients. The available evidence suggests that ultrafiltration is a safe and effective treatment option for volume overloaded heart failure patients.

Serum chloride and sodium interplay in patients with acute myocardial infarction and heart failure with reduced ejection fraction: an analysis from the high-risk myocardial infarction database initiat

JP Ferreira[1]; N Girerd[1]; K Duarte[1]; S Coiro[1]; JJV Mcmurray[2]; H Dargie[2]; B Pitt[3]; K Dickstein[4]; JM Testani[5]; F Zannad[1]; P Rossignol[1]
[1]*Clinical Investigation Centre Pierre Drouin (CIC-P), Nancy, France*; [2]*Cardiovascular Research Centre of Glasgow, Glasgow, United Kingdom*; [3]*Northwestern University, Chicago, United States of America*; [4]*Bergen University College, Bergen, Norway*; [5]*Yale University, New Haven, United States of America*

On behalf of: High Risk MI initiative

Background: Serum chloride levels were recently found to be independently associated with mortality in heart failure (HF).
Methods: and Results: We investigated the relationship between serum chloride and clinical outcomes in 7195 subjects with acute myocardial infarction (MI) complicated by reduced left ventricular function and heart failure (HF). The studied outcomes were all-cause mortality (ACM), cardiovascular mortality (CVM), and hospitalization for HF (HHF). Both chloride and sodium had a non-linear association with the studied outcomes (p < 0.05 for linearity). Patients in the lowest chloride tercile (chloride ≤100) were older, had more comorbidities, and lower sodium levels (p < 0.05 for all). Serum chloride showed a significant interaction with sodium with regard to all studied outcomes (p for interaction < 0.05 for all). The lowest chloride tercile (≤100 mmol/L) was associated with increased mortality rates in the context of lower sodium (≤138 mmol/L) [adjusted HR (95%CI) for ACM = 1.42 (1.14-1.77), p = 0.002], whereas in the context of higher sodium levels (>141 mmol/L), the association with mortality was lost. Spline-transformed chloride and its interaction with sodium did not add significant prognostic information on top of other well established prognostic variables (p >0.05 for all outcomes).
Conclusions: In post-MI with systolic dysfunction and/or HF, low serum chloride was associated with mortality (but not HHF) in the setting of lower sodium. Overall, chloride and its interaction with sodium did not add clinically relevant prognostic information on top of other well established prognostic variables. Taken together, these data support an integrated and critical consideration of chloride and sodium interplay.

Prognostic impact of glucose in acute myocardial infarction complicated by cardiogenic shock - A substudy of the IABP-SHOCK II-trial

A Abdin[1]; J Poess[1]; G Fuernau[1]; S Desch[1]; T Ouarrak[1]; S De Waha[1]; I Eitel[1]; U Zeymer[2]; M Boehm[3]; H Thiele[1]
[1]University Hospital of Schleswig-Holstein , Heart Center Lubeck, Lubeck, Germany; *[2]Hear Center Ludwigshafen, Ludwigshafen, Germany*; *[3]Saarland University Hospital, Homburg, Germany*

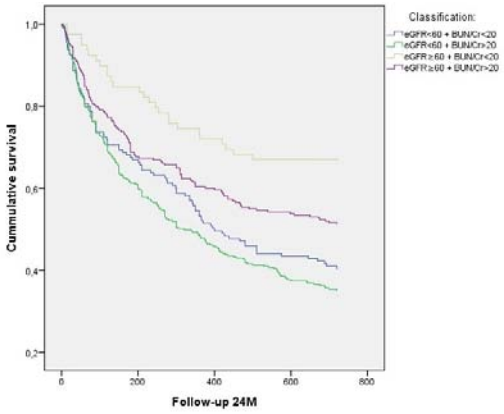
Background: In the setting of acute illness and as a stress response, glucose levels have been shown to be significantly increased. Data from observational studies suggest an association between glucose levels and prognosis of patients with cardiogenic shock (CS). Aim of the present study was to investigate the prognostic role of glucose at admission with respect to 30-day mortality in patients with CS complicating acute myocardial infarction (AMI) included in the large, randomized Intraaortic Balloon Pump in Cardiogenic Shock (IABP-SHOCK II) trial.
Methods: In IABP-SHOCK II, 600 patients with CS complicating AMI undergoing early revascularization were randomized to therapy with either IABP or no IABP. There were no differences between the groups with respect to the primary and secondary endpoints. Glucose levels at admission were available in 513 patients. The investigated endpoint was 30-day mortality.
Results: Out of the 513 patients, 213 (41.6%) died. Compared to survivors, non-survivors had higher glucose levels at admission (median [interquartile range (IQR)]: 13.0mmol/L [9.2; 18.2] vs. 10.5mmol/L [7.8; 15.5]; p = 0.0004). Patients with glucose concentrations above the median (11.5 mmol/L) had higher 30-day mortality compared to those below the median (47.7% vs. 36.5%; p = 0.005). This negative prognostic impact of increased glucose remained significant in a multivariate analysis adjusted for several factors which were associated with mortality in univariate analysis, such as age, renal function, Thrombolysis In acute Myocardial Infarction (TIMI) flow after percutaneous coronary intervention (PCI), and arterial lactate concentrations (Hazard ratio for each 10mmol/L increase of glucose 1.2; 95% confidence interval; 1.01-1.46, p = 0.039). In total, 33.7% of the patients had diabetes. Patients with diabetes had higher glucose levels compared to those without diabetes (median [IQR]: 13.1 [9.5-18.3] vs. 10.8 [7.8-15.4], p = 0.0003). Notably, the adjusted prognostic impact of increased glucose levels at admission was not influenced by presence or absence of a diabetes mellitus (p for interaction=0.41).
Conclusions: In patients with CS complicating AMI included in IABP-SHOCK II, increased glucose concentrations at admission were independent predictors for 30-day mortality, independently of the diabetic state.

1539

The application of ratios urea/ creatinine and BUN/ creatinine in acute heart failure

M L Goncalves[1]; JULIO Gil[1]; LUIS Abreu[1]; HUGO Antunes[1]; BRUNO Marmelo[1]; M I Pires[1]; ISABEL Cunha[1]; DAVIDE Moreira[1]; INÊS Almeida[1]; COSTA Cabral[1]
[1]Hospital Sao Teotonio, Department of Cardiology, Viseu, Portugal

Introduction: Worsening renal function (WRF) is an important comorbidity that is often seen in acute heart failure (AHF). The pathological mechanism is multifactorial, not completely understood, and is defined by an increase in creatinine>0.3mg/dL or a fall in eGFR>20%. WRF is not always clinically dangerous. Urea (U), creatinine (Cr) and BUN have been classically used as proxies for RF assessment with low specificity, limited by external factors. In acute kidney injury, BUN/Cr ratio>20 is indicative of pre-renal injury. The objective of this study is to investigate the usefulness and prognostic implications of U/Cr and BUN/Cr ratios in P with AHF.
Methods: Included 1006P hospitalized for AHF in a Cardiology ward between 2009-2015. Excluded P undergoing renal replacement therapy or eGFR by CKD-EPI < 15mL/min/1.73m2. The values of BUN, eGFR and ratios were calculated. Ratio BUN/Cr was considered elevated when >20, and U/Cr when >100. Division into groups accordingly with ratios (increased vs. normal) and eGFR (≥60 vs < 60). Follow-up of 24 months. The groups were compared in relation to in-hospital death (IHD) and long-term survival.
Results: Sample of 983D. 51.7% male, mean age 76.5 ± 9.8 years, mean U 69.0 ± 35.5mg/dL, mean Cr 1.3 ± 0.5mg/dL, mean BUN 32.2 ± 16.6mg/dL, mean BUN/Cr 25.8 ± 9.4, mean U/Cr 55.2 ± 20.1, eGFR 55.3 ± 22.7mL/min/1.73m2. WRF in 17%, 6.4% IHD, 16.2% death at 24 months. There was no statistically association between the elevated U/Cr and BUN/Cr ratios and the development of WRF throughout hospitalization. The BUN/Cr and U/Cr ratios alone were not shown to be associated with IHD. There was no difference between P-eGFR < 60 and ≥60 in relation to IHD, although there was a trend in favor of the higher number of IHD in P-eGFR < 60 (X2=2.7, p = 0.09). However, when subgroup analysis was performed, P-eGFR < 60 and elevated BUN/Cr ratio had a statistically significant association with IHD (X2=4.3 p = 0.04) when compared with P-eGFR < 60 and normal ratio. For the same population the high U/Cr ratio also had a statistically significant association with IHD (X2=4.07, p = 0.04). In the survival analysis, it was found that: high BUN/Cr ratio was associated with lower survival at 24 months (Kaplan-Meier X2=6.8, p < 0.09), whereas high U/Cr ratio was not. When eGFRr was stratified (graphic), P-eGFRr < 60 and increased BUN/Cr had lower survival than P-eGFRr < 60 without increased BUN/Cr ratio, and these had a lower survival rate than P-eGFR≥60 and increased BUN/Cr, and that P-eGFR≥60 and normal BUN/Cr ratio had the best survival rate at 24 months (Kaplan-Meier X2=36.9, p < 0.001). In relation to the U/Cr ratio, there was no difference in survival in subgroup analysis.
Conclusion: It has been shown that high BUN/Cr and U/Cr ratios are associated with IHD. In the long term, the BUN/Cr, but not the U/Cr, has an additive value to the isolated eGFR evaluation and can be used to improve the prognostic stratification in AHF.



Kaplan-Meier survival 24Months

A new model to predict readmission for heart failure

M Michael Kleiner Shochat[1]; A Shochat[1]; M Kazatsker[1]; I Kleiner[2]; JM Weinstein[2]; A Asif[1]; D Blondheim[1]; I Dahan[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; *[2]Saroka Medical Center, Cardiology, Beer Sheva, Israel*

Background Readmission of Heart Failure (HF) patients comprises a medical burden. Aim To assess the hypothesis that the extent of improvement of pulmonary congestion during hospitalization for HF as evaluated by lung impedance (LI) can predict readmission rate.
Methods: This was a randomized, single blinded 2-center study. Study population included 256 patients with HF and LVEF ≤35% in NYHA class II-IV randomized to conventional or LI-guided therapy.
Results: Baseline LI was calculated and used to derive LIR reflecting the degree of pulmonary congestion. The difference between LIR at admission and at discharge was used to assess improvement in the pulmonary congestion. The improvement in LIR was graded by quartiles (Q1 < 4.9%; Q2: 4.9-10.2%; Q3: 10.3-15.7%; Q4>15.7%). Improvement in NYHA class at discharge was graded as 1 or 2, in weight as < 3 or >3 kg, leg edema as 1-3 and level of lung rales as 1 or 2. Patients of group 1 (n = 128) were treated according to LI and group 2 (n = 128) by clinical assessment only. Mean follow-up was 56 ± 31 and 46 ± 28 months in group 1 and 2 (p < .001), accounting for 225 vs. 411 HF hospitalizations, respectively (p < .001). There were 29 and 52 HF-related and all-cause deaths in the group 1 and 50 and 71 deaths in the group 2, respectively (p < .01). Rate of readmissions according to Q1-4 was 97, 36, 2, 0% and 96, 43, 4, 0% within 1 month (p < .0001 within groups and p < .02 between groups), 100, 91, 61, 22% and 100, 99, 86, 35% (p < .0001 within groups and p < .001 between groups) within 12 months in group 1 and 2, respectively. Average times from discharge to readmission at Q1-4 were 14, 65, 244, 706 days and 11, 60, 189, 589 days for group 1 and 2 (p < .0001 within and between groups). Hazard ratios (HR) for HF hospitalizations at the level of improvement Q2, Q3, Q4 compared to Q1 were 0.21, 0.001, 0.0001 (within 1 months), 0.3, 0.1, 0.02 (within 12 months) in group 1 and 0.19, 0.01, 0.0001 (within 1 months), 0.35, 0.2, 0.04 (within 12 months) in group 2, p < .001 within and between groups, respectively. Improvement in NYHA classes, weight reduction, lung rales and leg edema improvement during HF hospitalization also reduced the probability of HF readmissions within 1 and 12 months (p < .01, within and between groups), but predictive power was weaker (HR = 0.3-0.7).
Conclusion: The extent of improvement in pulmonary congestion during HF admission assessed by LI is a strong and accurate measure for readmissions within 1and 12 months for both groups. LI-guided treatment significantly reduced HF readmissions but only if moderate or significant improvement in pulmonary congestion was achieved (Q3-4). Discharge of patients of both groups at the Q1 level of pulmonary congestion improvement resulted in an unacceptable readmission rate of 98% within one month. Prognostic power of changes in such clinical parameters as NYHA class, lung rales, weigh and leg edema is significantly lower than LI.

CLINICAL CASE CORNER 5 - CANCER AND CANCER THERAPY: A DOUBLE EDGED SWORD

Exercise cardiac MRI with pulmonary artery catheter monitoring in early manifestation of carcinoid heart disease: a first in men case report

PH Timmermans[1]; T Petit[2]; J Bogaert[3]; E Van Cutsem[4]; J Van Cleemput[1]; F Rega[5]
[1]University Hospitals (UZ) Leuven, Cardiology; heart failure and transplantation, Leuven, Belgium; *[2]University Hospitals (UZ) Leuven, Cardiology, Leuven, Belgium*; *[3]University Hospitals (UZ) Leuven, Radiology, Leuven, Belgium*; *[4]University Hospitals (UZ) Leuven, Digestive oncology, Leuven, Belgium*; *[5]University Hospitals (UZ) Leuven, Cardiac surgery, Leuven, Belgium*

INTRODUCTION A first report about the use of an exercise cardiac MRI with pulmonary artery catheter measurements to investigate carcinoid heart disease. CASE REPORT A 58 years old woman was referred from the oncology department to the heart failure clinic because of progressive dsypnea on exertion. She was diagnosed with a neuro-endocrine tumor and liver metastases 4 years earlier. After several treatment cycli, she had a stable disease at the time of presentation. The dyspnea was present since a few weeks. There were no signs of heart failure on clinical examination. ECG showed only minor alterations. Echocardiography revealed a structurally normal left heart, but severe tricuspid regurgitation (TR) with retraction of the leaflets. RV function was normal, there was no RV dilatation but a clear diastolic D-shaping of the interventricular septum – indicative of volume overload. CPET showed a VO2 max of 27.3 ml/min/kg (86% of pred max). Invasive investigations were started to evaluate the patient for valve surgery. Coronary angiography did not show any significant stenoses, and right heart pressures were within normal range. However, we were still convinced that the severe tricuspid insufficiency should have an hemodynamic impact on the heart, given the complaints of the patient. Moreover, we recently analysed the results of carcinoid valve surgery executed in our centre the last 16 years (cfr separate abstract submitted to Heart Failure 2017) and concluded that late referral for valve surgery could lead to high perioperative mortality. We organized an exercise test in the cardiac MRI with measurements of the intracavitary pressures using a MRI-compatible pulmonary artery catheter. Results are shown in figure 1. Apparently, early manifestation of severe isolated TR without RV dysfunction leads to a decrease in RVESV but an increaese in RVEDV during excercise, resulting in an absence of stroke volume increase – cleary an abnormal finding - without left or right sided systolic dysfunction or congestion. Left sided volumes and pressures hardly changed during excercise; this is likely caused by a lack of LV preload increase. Based on the symptoms of our patients and the results of the CMR, our patient was referred for surgery. She underwent a tricuspid valve replacement with an bioprothesis size 29. The postoperative period was uneventfull, with extubation on day 1 and discharge from the ICU on day 3 after surgery. Further hospital stay was without complications. Symptoms of dyspnea on exertion improved after cardiac rehabilitation. She is currently in ambulatory FU more than 2 years after surgery. There are no signs of prostetic valve dysfunction on TTE. Her exercise capacity on CPET has recently dropped (VO2 max 23.6 ml/min/kg, 75% of pred max) because of both chronotropic incompetence (she is now on a low dose of b-blocker) and, unfortunately, a progressive malignancy for wich SIRS (selective intrahepatic radiation with spheres) is planned. Conclusion: Early detection of carcinoid heart disease is important for a timely referral for valve surgery. After onset of valvular manifestation, these patients may have a limited time frame in which they have a stable oncological process, a still preserved RV function and general acceptable and non-cachectic clinical condition to survive cardiac surgery and still benefit from the intervention. Multidisciplinary disease programs and exercise cardiac MRI, possibly without invasive pressure measurement, can identify the patients best suitable for valve surgery.

Toxic influence of cancer chemotherapy on heart function and hemodynamic parametres

I Igor Katsytadze[1]; K Filonenko[2]; I Prudkyi[1]; O Vasylenko[1]; YU Sychenko[3]; L Samoylenko[3]
[1]O. Bogomolet's National Medical University, Kyiv, Ukraine; *[2]National Institute of Cancer, Kiev, Ukraine*; *[3]Kiev Alexander Clinical Hospital, Kiev, Ukraine*

Case report description. Toxic influence of chemotherapy (ChT) in cancer patients is very common and has a wide range of manifistations. Toxic damage of cardivascular and neuro systems is one of the most serious and prognostic unfavorable complications. We represent a clinical case of a man of 46 years old with Hodgkin's Lymphoma verified with CT (conglomerates of mediastinal lymp nodes) and biopsy of lymph node (Hodgkin's cells, CD20-, CD30+, Ki-67 20%, Pax5+) (pic.1). The patient was terated according BEACOPP-esc ChT sceme which includes ethopozide, doxorubicine, cyclophosphamide, etc during 6 courses for 14 days each one. After the start of 4th course of ChT, the patient began to complain of a violation of sensitivity in hands and stumbling while walking, palpitations, difficulty breathing, weakness, aching pain in the heart.
Neuro Status: Peripheral signs of distal symmetric sense-motoric polyneuropathy Neurotoxicity II type. HR -124, arrhythmic, BP - 100/60, SpO2 - 91%
ECG: AFib, low voltage ECG. Echo: ESV- 72ml, EDV - 124ml, EF -42%, LA - 3,6, RV - 32mm, Ao - 26mm, PA - 32 mmHg, IVS - 10,5mm, PW - 10mm. Hypokinesia of all walls. Troponin I - 3,12 ng/ml ("grey zone"). NTproBNP - 2456 pg/ml (high positive). Questions, problems. The problem of this case is a wide area of backside effects of chemotherapy in the middle of course of cancer treatment. The main questions: should we continue chemotherapy or change doses? how can we improve cardiac function and stop AF? how can we reduce neuro symptomatic? As a consilium decission we've stoppet 4th course of chemotherapy, delayed 5th course of 2 weeks, changed BEACOPP-esc sceme to ABVD (low dose of doxorubicine, bleomicine, vinblastin, dacarbazine). Amiodaron iv infusion (600mg) was started to restore synus rhythm. Enoxaparine 40mg bd was added as well as Furosemide 40mg iv, Eplerenone 25mg. After 24 hours, synus rhythm was restored with HR 86' BP 105/64mmHg. Amiodarone was changed to bisoprolol (2,5mg od) and was added ivabradine 2.5mg twice a day. On 3rd day of treatment coronary angiography was performed (no serious stenosis). For the improvement of systolic function infusion of levosimendan (Lv) was started. In 3 days after Lv infusion and concominent treatment , HR 70, BP 125/75mmHg, SpO2 96% Perindopril was added 5mg od.

Neurogical treatment included vitamine B, phosphates, α lipoic acid, anticholinergic drugs, anticonvulsants.

Answers: In 8 days, the patient was discharged and directed to the oncologist. with regression of neurological and cardiac sympoms, improvement of systolic function and synus rhythm.

Conclusions: Only close cooperation of different specialists may leads to success story Unfortunately, database of this patients is not significant and all the concominent treatment should be studied. Moreover, toxic effects of ChT may be observed for a long time after finishing the cancer treatrment and needs for follow up monitoring. Post hoc examination of the patient (1,5 year later) showed an stable remission of Lymphoma, no signs of heart failure, regress of neurogical symptoms.

Echo and labs data

	D0	D1	D5	Discharge	M18
EF, %	58	42	43	50	51

Cardiac hemorrhagic tamponade in a young adult male

A M Neagoe[1]; K Wustmann[1]; S Bloechlinger[1]; D Reineke[1]; T Suter[1]
[1]*Bern University Hospital, Cardiology, Bern, Switzerland*

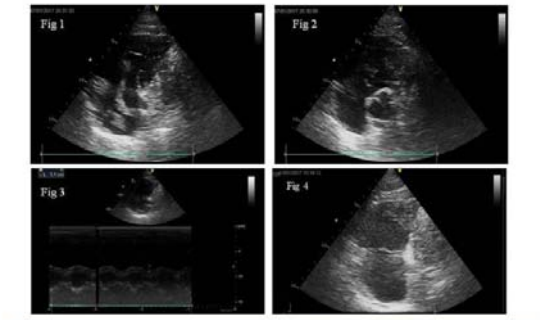
A 26-year old male, with no medical history, was admitted by ambulance after he suffered a syncope. He had been complaining about chest pain and dyspnea over the previous 6 days. During transport to the hospital the patient showed signs of bradycardia and lost his consciousness for 5 sec. Diagnostic : Transthoracic echocardiography (TTE) performed in the shock room showed tamponade. By emergency pericardiocentesis hemorrhagic fluid was removed and a drain inserted. By thoracic computed tomography (CT) an aortic dissection was ruled out, but a heterogeneous mass within the right atrium (RA) was apparent in an otherwise unremarkable scan. Cardiac magnetic resonance (CMR) revealed a 23x25x39mm sized tumor of inhomogeneous appearance with oedema in the native sequences, remarkable perfusion in the first-pass and inhomogeneous late enhancement with central necrosis, suspicious of an highly vascularized malign tumor. No other evidence of malignancy was found in a whole-body PET-CT. Work-up of the pericardial effusion revealed activated mesothelial but no malignant cells. Therapy: The tumor was removed in toto (Picture 1), the right atrium reconstructed with a pericardial patch and local pericardectomy was performed. Histopathology determined a high grade angiosarcoma of the RA with clear margins of resection. After 18 days of hospitalization, the patient was discharged in good conditions for rehabilitation. Further development: Adjuvant chemotherapy is planned. Conclusion: Pericardial effusion is a common clinical finding in young patients, frequently due to pericarditis. However, tamponade and in particularly hemorrhagic pericardial effusion is uncommon and warrants further work-up. In our patient the echocardiogram and CT scan revealed a tumor in the right atrium. Cardiac MRI was critical for further differentiation of the findings. Based on morphology and perfusion characteristics we suspected a malignant tumor, possibly an angio- or fibrosarcoma. A myxoma, lipo- or myosarcoma appeared less likely. Primary tumors of the heart are rare, and only 25% of cardiac tumors are malignant and occur mostly in adulthood. The most common malignant tumor of the RA is an angiosarcoma. There is only limited data on optimal treatment and prognosis of this disease. However, complete resection and an adjuvant, anthracycline-containing chemotherapy is currently standard of care.

1544

Acute right ventricular failure in an oncological pacient

A Andreea Rachieru[1]; B Zamfirescu[1]; R Aflorii[1]; D Rednic[1]; A Linte[1]; D Dimulescu[1]; A C Popescu[1]
[1]*Elias Emergency Universitary Hospital, Cardiology, Bucharest, Romania*

We present the case of a 63 year old woman, hypertensive, diabetic, with radical hysterectomy, admitted for shortness of breath and extreme fatigue, also dry cough and fever, denying chest pain or syncope. The patient was on chemotherapy for clear cell endometrial cancer, a rare and aggressive type of neoplasm. She was in a severe state, hypoxic (oxygen saturation of 86%), diminished breath sounds bilaterally, low BP (85/50 mmHg), tachycardia (100 bpm), oliguric and without valvular murmurs or signs of deep vein thrombosis (DVT). ECG showed sinus tachycardia, incomplete RBBB, Q wave in DIII and T wave inversion in the precordial and inferior leads. At that moment (based on findings and also 7 points on Wells score), pulmonary embolism (PE) was taken into consideration. Transthoracic echocardiography showed dilated right heart cavities, indirect signs of pulmonary hypertension, normal LVEF but severe dysfunction of the right ventricle (hypokinesia, TAPSE = 11 mm), and also a mobile structure (4.5/1 cm) extending from the RA to the RV through the tricuspid valve. CT angiogram confirmed bilateral massive pulmonary embolism with right heart trombus, thrombosis of portal and superior mesenteric veins and also hepatic secondary tumors. Biologically – there is moderate iron deficiency anemia, high ESR, positive I troponin, high NT pro-BNP, mild renal dysfunction and dyslipidemia. Even though the diagnostic was bilateral massive pulmonary embolism with high risk, due to patient's comorbidities (active cancer, moderate anemia), the management was anticoagulant therapy with unfractioned heparin, dobutamine and dopamine for acute right heart failure, oxygenotherapy, red blood cell transfusion in order to correct anemia. Ultrasonography of the lower limb veins showed no signs of DVT. Despite all of the mentioned predictors of poor prognosis, the evolution was good, with improvement of dyspnea and progressively decreased doses of inotropic agents. Follow-up showed better RV function and the disappearance of intracardiac thrombus, possibly by embolisation of the fragmented thrombus into the pulmonary circulation without additional clinical impact. After 2 weeks, a whole-body CT scan was made, confirming regression of endoluminal thrombi, but with infarction in the left superior pulmonary lobe, and also advanced peritoneal carcinomatosis. The patient was transferred to the Oncology Department for palliative care with the recommendation for indefinite anticoagulation with LMWH. The particularity of this case is that even though mortality rate is high in patients with PE and right heart thrombi-in-transit, this patient survived and improved clinically under anticoagulant therapy.



Transtoracic echocardiography performed during evolution shows in fig 1-3 – mobile structure from RA to RV; dilated right cavities and RV severe disfunction (reduced TAPSE); in fig 4 the mobile structure mentioned is no longer seen.

Echocardiography - evolution

Primary pericardial mesothelioma presenting as infective pericarditis

A Krivickiene[1]; A Mikalauskas[1]; J Justina Motiejunaite[1]; A Kavoliuniene[1]
[1]*Hospital of Lithuanian University of Health Sciences, Cardiology, Kaunas, Lithuania*

Introduction: Primary pericardial mesothelioma (PPM) is a rare disease (the prevalence 0.0022%), with only 350 patients reported in the literature to date. We describe a case of a woman who presented with infective pericarditis and was diagnosed with PPM.

Case report description: 37 year old woman was referred to emergency department because of nausea, epigastric pain and fever up to 39.5°C. These symptoms started suddenly and had been lasting for 4 days. She denied any previous diseases. The laboratory tests showed inflammation (C-reactive protein 248 mg/l). Echocardiography exam revealed a large accumulation of pericardial fluid - up to 3.4 cm at left ventricle (LV) with echocardiographic signs of cardiac tamponade (Fig.1). Additional investigations were performed in order to determine the source of infection. The chest computed tomography (CT) revealed left pleural effusion up to 3.5 cm and pericardial effusion up to 1.6 cm at LV and up to 0.5 cm at right ventricle (RV) (Fig.1). Diagnostic pleural puncture with biochemical, microbiological and cytological analyses showed non-specific characteristic of exudate without atypic cells or microorganisms. While differentiating from other pericardial diseases, additional tests showed no findings for autoimmune, haematological and genitourinary diseases, viral infection or thyroid dysfunction. Diagnosis of acute infectious effusive pericarditis, complicated by asymptomatic cardiac tamponade was confirmed. Antibiotics, non-steroidal anti-inflammatory drugs and diuretics were prescribed. During the initial pharmacotherapy the clinical condition of the patient improved significantly. Inflammatory markers decreased and pericardial effusion diminished from 3.4 cm to 1.3 cm. Nevertheless, episodes of fever up to 38°C were still observed. Left thoracotomy was performed due to suspicion of purulent pleuritis and pericarditis, but the purulent process was not proven. Biopsy of both 2 pleural layers and pericardium was performed. Histological examination confirmed the diagnosis of pericardial mesothelioma. Chemotherapy with cisplatin and pemetrexed was initiated, in total 6 courses have been administered. Follow-up for additional 6 months didn't show any spread of PPM. The young woman is in a stable medical condition and continues follow-up.

Conclusions: This case highlights the diagnostic challenges of PPM and a rare case of successful treatment. Diagnosis of PPM is challenging primarily because of its rarity. While CT and MRI are useful tools for diagnosis of PPM, histological examination is required to obtain a definitive diagnosis. No standard treatment guidelines for PPM have been established yet. Novel chemotherapeutic agents have demonstrated sufficient efficacy. PPM carries a poor prognosis due to its late presentation and limited treatment options. Most patients die within 1 year of presentation. Our patient is has been stable for 21 months since the diagnosis of PPM.

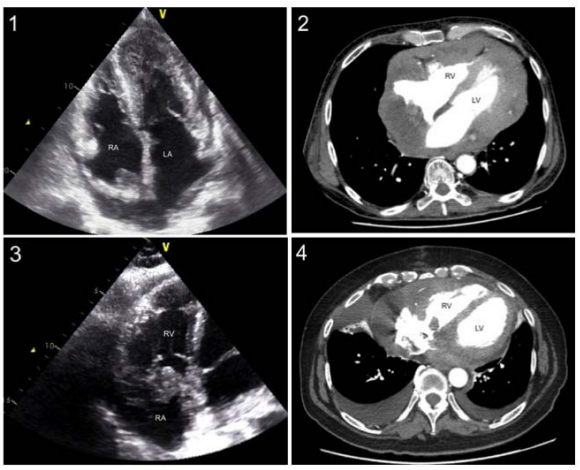
1546

Burkitt lymphoma presenting as an intracardiac mass: two cases

I Ilaria Battistoni[1]; D Contadini[1]; M Marini[1]; M Francioni[1]; L Angelini[1]; S Moretti[1]; A Gili[1]; M Dottori[1]; GP Perna[1]
[1]*University Hospital Riuniti, G.M.Lancisi Hospital, Department of Cardiology, Ancona, Italy*

Introduction: the intracardiac masses represent a rare clinical disease. They are usually due to infectious, thrombi or tumour metastasis and less frequently to primary tumours. A correct differential diagnosis is crucial to establish the appropriate therapy. We report two cases of intracardiac masses recently presented to our attention. Case 1: 57-year-old man, infected with human immunodeficiency virus (HIV) from 8 years. His previous history revealed two episodes of pericarditis in the last two months. On admission, he referred worsening dyspnoea on exertion in the last week and presented signs and symptoms of superior vena cava syndrome. ECG revealed no specific alterations. Transthoracic echocardiography (TTE) showed a slight pericardial effusion and an abundant solid tissue in the pericardial space with "ab-estrinsic" infiltration of heart wall chambers, origin of aorta and both vena cava. Moreover a pseudonodular mass with irregular margins and size of 2x2.8 cm was inside the right atrium (Figure 1). The right ventricle was hypokinetic (TAPSE 12 mm, Fractional Area Change (FAC) 30%). The left ventricle ejection fraction (LVEF) was 48%. Mild tricuspid regurgitation was noted with systolic pulmonary arterial pressure (PAPs) of 38 mmHg. Transesophageal echocardiography (TEE), computed tomography (CT) scan (Figure 2) and magnetic resonance imaging (MRI) confirmed our findings. Case 2: 55-year-old man with diabetes mellitus. He was admitted in our intensive care unit with signs of cardiac tamponade. The patient underwent urgent pericardiocentesis. On admission, ECG revealed a sinus tachycardia and low voltage QRS complex. TTE revealed a solid extra- and intracardiac mass (4.5x3.2 cm) on the atrioventricular groove near the lateral portion of the tricuspid annulus (Figure 3). A slightly dilated and hypokinetic right ventricle was also observed (TAPSE 6 mm, FAC 28%). The LVEF was 40%. Mild tricuspid valve regurgitation with PAPs of 45 mmHg was also present. The findings were confirmed by a TEE. A positron emission tomography (PET-CT) scan revealed in the mass an intense hypercaptation extended to the mediastinum (Figure 4). Both patients underwent an uncomplicated ultrasound-guided endovascular biopsy. Pathology report revealed a diffuse tumour proliferation of large lymphatic B cells. Intense mitotic activity was noted with areas of apoptosis. The diagnosis in both cases was Burkitt lymphoma with primary cardiac localization. The immunohistochemical essays confirmed the diagnosis too. Chemotherapy was immediately started next to the support cardiological therapy (fluids, diuretic, dopamine and norepinephrine in the first case) and fluids, diuretic, dopamine and dobutamine in the second one).

Discussion: Burkitt lymphoma is infrequent accounting for less than 1% of all non-Hodgkin lymphomas and 25-30% of the lymphomas in HIV-affected population. Primary cardiac lymphoma localization is extremely rare with non-specific signs and symptoms and can often be overlooked or underappreciated. Due to the very rapid growth of Burkitt lymphoma, a prompt diagnosis and treatment are crucial to get good prognostic outcomes. A multidisciplinary involvement (cardiologist, oncologist and radiologist) is essential to achieve optimal outcomes.



TTE and CT scan of the two cases

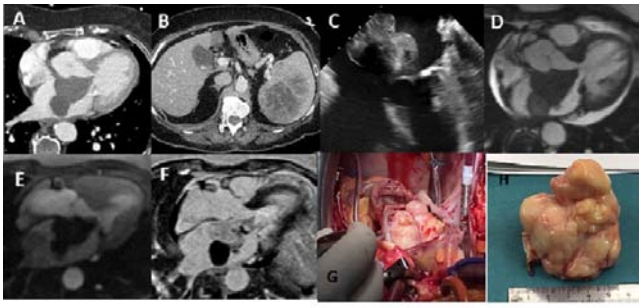
Two times cancer: is a third time a relapse or a primarius?

A M Alexandra Maria Neagoe[1]; L Hunziker[1]; D Reineke[1]; S Bloechlinger[1]; V Eigenmann[1]; T Suter[1]; K Wustmann[1]
[1]*Bern University Hospital, Cardiology, Bern, Switzerland*

Case: A 75yo female with history of rectal and uterus carcinoma (1999 and 2008) presented with progressive dyspnea, palpitations and newly diagnosed anemia. Diagnosis: By thoracic computed tomography (CT) pulmonary embolism was ruled

out, but showed a large left atrial (LA) mass and calcified posterior mitral valve (MV) leaflet. Abdominal CT slices revealed an heterogeneous splenic mass without evidences of metastases. Transthoracic echocardiography depicted a severe "mitral" stenosis (mean grad. 16mmHg) caused by the hypo-echogenic LA mass. In suspicion of a thrombus, anticoagulation was started and the patient referred to our hospital. Transoesophageal echo demonstrated adherence of the LA mass to the atrial septum and anterior MV leaflet. A cardiac magnetic resonance (CMR) was performed which showed that the LA mass contained 2 parts: one 50mm sized with attachment to the LA septum and anterior MV leaflet, and a smaller one pinned to the main part, mild pericardial effusion. By native and contrast enhanced CMR, the tumor appeared inhomogeneous, moderately vascularized and presented areas of inhomogeneous late enhancement expecting a myxoma or metastasis or sarcoma with adherent thrombus. Splenic fine-needle biopsy was inconclusive. Interdisciplinary, LA tumor resection (Picture 1) because of hemodynamic reasons firstly and splenectomy secondly was decided. Therapy: Surgical treatment was attempted. Histopathology confirmed an undifferentiated sarcoma and R1-resection. Further development: After splenectomy, angiomadoid nodular transformation without malignant transformation was diagnosed. Further investigations showed liver dysplasia without evidence for hepatocellular carcinoma. New resection of the remaining cardiac tumor would be surgically impossible. Interdisciplinary, it was discussed that chemotherapy is contraindicated because of high toxicity. Radiotherapy is recommended for the expected high relapse risk, although related to high cardiotoxicity. Conclusion: Most LA masses in elderly patients represent either a thrombus or myxoma. Our patient had an high suspicion for a LA thrombus or metastasis. Against our first thoughts, a new primary cardiac tumor was diagnosed by histopathology. Interdisciplinary work-up and integrative cardiac imaging is highly recommended in cases with large cardiac masses – and also when something seems obviously.



CT scan of the heart (A) and splenic lesion (B), transoesophageal echocardiography (C), CMR – native SSFP cine still frame (D), perfusion (E), late enhancement (F), intra-operative (G) and removed tumor (H).

A rare case of cardiac malignant fibrous histiocytoma

A Andreea Ravasel[1]; E Stoica[1]; C Voica[1]; L Parascan[1]; O Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*

Introduction: Primary cardiac tumors are rare entities with a reported incidence of 0.4% to 0.7% of all cardiac tumors. 25% of primary cardiac tumors are malignant, and, of these, 75% are sarcomas and have a poor prognosis. Malignant fibrous histiocytoma is a sarcoma that constitutes less than 3% of primary cardiac tumors.
Case report description: A 37-year-old female presented with increasing dyspnea on exertion, cough and fever for 1 month. She received treatment with antibiotics and nonsteroidal anti-inflammatory drugs for the suspicion of pneumonia, without improvement of symptoms. Additionally, she was diagnosed with paroxysmal atrial fibrillation, and was referred to our institution for cardiologic evaluation. On clinical examination, the patient had a blood pressure of 100/60 mmHg, heart rate of 100 beats per minute, irregular, with a grade II/IV diastolic murmur in the mitral valve area, decreased respiratory sounds of the lower lungs, jugular vein distension, mild peripheral edema, temperature 37.7°C. A chest radiography showed bilateral pleural effusion with a normal cardiac area. The electrocardiogram demonstrated atrial fibrillation, without repolarization abnormalities. NT proBNP was 1612 pg/ml. Transthoracic and transesophageal echocardiogram (TEE) showed a large tumor mass (5 cm) attached to the posterior wall of the left atrium with prolapse through the mitral valve (Figure 1). Mean and peak gradients across the mitral valve inflow were 22 mmHg and 12 mmHg, respectively (Figure 2). Small pericardial effusion was found without signs of pericardial tamponade. Cardiac CT (Figure 3) confirmed TEE findings. No other tumor was found in the chest. She was operated with presumptive diagnosis of atrial myxoma. At surgery a large polylobulated tumor was found with a large base of implantation at the level of the postero-lateral left atrial wall, without contact with interatrial septum. The differential diagnosis was between atrial myxoma and a malignant tumor which was more probable because of the macroscopic characteristics suggesting sarcoma. The tumor was resected as completely as possible. Postoperatively she had an uneventful recovery. Echocardiography after surgery was normal. She was discharged after a week. Biopsy revealed that the tumor consisted of malignant cells with marked atypia. The histopathologic diagnosis was malignant fibrous histiocytoma (Figure 4). Following cardiac surgery, the patient began adjuvant chemotherapy.
Discussion: Among malignant cardiac tumors, malignant fibrous histiocytoma of the heart is rare and occurs almost exclusively within the left atrium. Signs and symptoms of left sided heart failure (HF) are the most common manifestation. This tumor can be clinically and histologically confused with atrial myxomas, the most common primary cardiac tumor. It is attached more commonly along the posterior atrial wall in comparison to the interatrial septum. Surgical resection is the mainstay of diagnosis and treatment, but in the most cases the resection is incomplete. Chemotherapy can prolong survival, especially when only an incomplete resection is possible. Patients with unresectable primary malignant cardiac tumors who are free of metastases may be considered for heart transplantation. Comprehensive imaging protocols made in emergency settings may be crucial for understanding the rare etiologies of acute HF.

Right heart failure due to large left atrial myxoma

BP Dhakal[1]; CM Bianco[1]; B Sareyyupoglu[1]; BD Hoit[1]; GH Oliveira[1]; CA Elamm[1];
[1]*University Hospitals Cleveland Medical Center, Case Western Reserve University, Cleveland, United States of America*

Introduction: Cardiac myxomas is a neoplasm arising from multipotent mesenchymal cell and account for about 30-50% of primary cardiac tumors and affects mostly females (65%). Myxomas are most often single, arising from the fossa ovalis of the interatrial septum and protruding into the left atrium (LA). The clinical presentation can vary depending upon the location of the tumour. Here we present a case of large LA myxoma presenting as presyncope and right heart failure (HF) symptoms.
Case presentation: A 59 year old female with no prior medical history presented as a transfer from outside hospital for a LA mass detected on echocardiogram. She had a 3-month history of worsening shortness of breath, dyspnoea on exertion, orthopnoea and bilateral lower extremity oedema. She reported being completely healthy and without symptoms until two years ago when she found herself getting progressively dyspnoeic with ambulation and with minimal exertion. She reported a long history of presyncopal episodes which she presumed to be related to her poor eating habits but developed one episode of syncope two weeks prior. She was admitted with HF symptoms and work up revealed NT proBNP of 12369 pg/ml, BNP of 716 pg/ml, EKG with signs of RV strain and chest x ray showed cardiomegaly. Transthoracic echocardiogram revealed preserved left ventricular (LV) systolic function with LV ejection fraction of 64% but right ventricle (RV) was severely dilated and had severely reduced function (RV mid 3.9 cm, RV base 4.5 cm, RVs' 0.12 m/sec). LA was also moderately dilated with 4x4 cm mass protruding through mitral valve into the LV, the appearance of which was consistent with myxoma. There was severe tricuspid regurgitation (velocity 4.19 m/sec) and severe pulmonary hypertension. Patient was started on intravenous diuresis with furosemide and was planned to undergo resection of the LA mass due to symptoms of syncope and RV failure. Coronary angiogram revealed no stenosis. Resection of the LA mass was done under cardiopulmonary bypass. Pathology revealed irregular lobulated soft mass with a glistening tan-pink outer surface measuring 6.5x5x3.8 cm and weighing 57 grams. Postoperative course was uneventful and during 2 months follow up, she had no HF symptoms and did not require any diuretics. Follow up echocardiogram did not show any regrowth of myxoma.
Answers and Discussion: Cardiac myxomas can occur in all age groups, but present most frequently between the third and sixth decades of life. Myxoma usually occur the LA and less commonly in the right atrium, LV and RV or multiple sites. The clinical features depend upon the location of myxoma, size, and mobility. Patients may have only constitutional symptoms such as fever, weight loss, fatigue, myalgia, arthralgia and muscle weakness. They may present with signs of tumour embolism or intracardiac obstruction causing dyspoea, palpitations, chest pain, pulmonary oedema, syncope or even sudden death. Our patients had near syncopal episodes for many years which could be due to progressively enlargement of the myxoma causing obstruction of the mitral valve during diastole. Severe pulmonary hypertension and RV enlargement suggested prolonged subclinical stage in our patient which necessited urgent surgery. This case suggests that RV failure and syncope can be the complication of LA myxoma. Follow up echocardiogram is necessary to document complete resection and to rule out any recurrence particularly in suspected familial form and those with multiple myxomas. We are planning to get another follow up echo in our patient to see if RV failure improved after surgery.

Progressive heart failure and accelerated myocardial ischemia with repeated in-stent restenosis in a case of multiple myeloma

M Valcovici[1]; S Dragan[1]; R Christodorescu[1]

[1]*University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania*

A 70 year-old man with IgG kappa stage IIIB multiple myeloma, diagnosed after onset of acute renal failure, presented with dyspnea and severe chest pain, two days after concluding the second cycle of triple association: bortezomib 1,3 mg/m2 + melphalan 9mg/m2/d + prednisone 60mg/m2/d. His ECG demonstrated sinus tachycardia, left atrial enlargement and ST-T elevation in V2-V4. Troponine I hs was 29,5 ng/ml. Acute anterior STEMI was diagnosed. Coronary angiography revealed 85% occlusion of proximal LAD, followed by PTCA with BM Integrity stent 3.0/18mm. His echocardiogram revealed diastolic dysfunction type I, moderate left atrial enlargement, anterior wall and septal motion abnormality, no valvular abnormalities, a moderately enlarged LV (VTD=149ml) with a borderline low ejection fraction (EF) of 42%. A prior echocardiogram at initiation of MM treatment revealed normal LV volume and EF. The patient was put on betablocker, ACE inhibitor, statin and double antiplatelet therapy and after one month the treatment of MM was resumed. During the 5th cycle the patient again presented chest pain with extensive subendocardial ischemia. Troponine I hs was 0.019 ng/ml and unstable angina IIIB2 was diagnosed. Coronary angiography revealed early in-stent 90% restenosis in the proximal LAD and multiple non-significant 30-50% stenoses in the RCA and in the CXA. PTCA in the proximal LAD was performed with an Xience stent. His echocardiogram at this stage revealed further increase of LV volume and decrease of EF (170ml and 40% respectively), while renal function and platelet count continued to deteriorate. A skeletal survey performed after discharge revealed multiple lytic lesions in the pelvis and skull. It was decided to add biphosphonate 4mg/cure to his therapy. However, the condition of the patient allowed only three more cycles, due to the severe side-effects, including two upper digestive tract hemorrhages, anemia and low platelet count. During the 8th cycle the patient again presented severe anginal pain with subsequent subendocardial ischemia. Coronary angiography revealed late in-stent 85% restenosis in the proximal LAD and PTCA was performed again with an Xience stent. At echocardiography LV volume was 180 ml and EF continued to decrease to 38%. The markers of bone turnover osteoprotegerin (OPG) and receptor activator of nuclear factor-kappa B ligand (RANKL) were increased to 3,9 pg/ml, respectively decreased to 0,67 pg/ml. One week after discharge the patient developed massive anterior myocardial infarction followed by cardiac arrest and death.

Discussion: The natural history of multiple myeloma (MM) is one of progressive bone destruction, refractory cytopenias, and renal end-organ damage. This patient had disease-, treatment- and age-related increased risk for cardiac events. His disease was refractory to treatment and presented frequent relapses with intense bone destruction. The increase of biomarker of bone turnover OPG has been linked to increased cardiovascular risk in several studies. It may contribute to increased vascular rigidity and accelerate the atherosclerotic process. Collagen fragments released from the bone matrix during extensive resorption may also explain early and late in-stent restenosis. Proteasome inhibitors increase risk of ischemic heart disease and congestive heart failure and alkylating agents increase the risk of cardiomyopathy and reduce left ventricular EF. In this patient, acute anterior STEMI occurred early after initiation of treatment for MM and EF was decreased at onset of myocardial ischemia and continued to deteriorate throughout the progression of disease. OPG is a marker of both bone turnover and vascular rigidity and may be useful as predictor of ischemic events in patients with MM.

RAPID FIRE 6 - ADVANCED HEART FAILURE

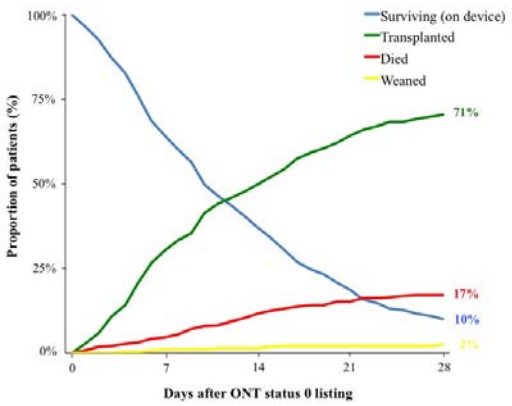
Background: In Spain, high-urgency listing for heart transplantation (HT), the so-called ONT status 0 protocol, is allowed for candidates dependent on temporary mechanical circulatory support (T-MCS). We sought to analyze the clinical outcomes of this strategy.
Methods: We conducted a nationwide, retrospective, case-by-case review of clinical records of 291 patients listed for first, single-organ high-urgent HT while on T-MCS during the period 2010–2015 in 16 Spanish institutions. Pre- and post-transplant survival was analyzed.
Results: At the time of listing, 169 (58%) patients were supported on veno-arterial ECMO, 70 (24%) on temporary left ventricular assist devices (T-LVADs) and 52 (18%) on temporary biventricular assist devices (T-BIVADs). Seven patients transitioned from ECMO to T-VADs while on the waiting list. Mean time on T-MCS was 13.1 ± 12.6 days. Mean time from listing to HT was 7.6 ± 8.5 days. Overall, 230 (79%) patients were transplanted, 54 (18.5%) died during MCS and 7(2.4%) were weaned. Competing outcomes over 28-day follow-up are shown in the Figure. In-hospital postoperative mortality after HT was 33%, 12% and 26% for patients bridged on ECMO, T-LVADs and T-BIVADs, respectively (p = 0.008). Overall survival from listing to hospital discharge was 54%, 79%, and 56%, respectively (p = 0.022). By means of backward stepwise Cox´s regression analysis, T-LVAD support at the time of listing was identified as an independent predictor of 1-year survival after listing (HR 0.52, 95% CI 0.30–0.92).
Conclusions: In a setting of short waiting list times, the use of T-MCS as a direct bridge to high-urgent HT is a feasible strategy. In our experience, listing under T-LVADs is associated with better outcomes than listing under T-BIVADs or VA-ECMO.



Competing outcomes after listing

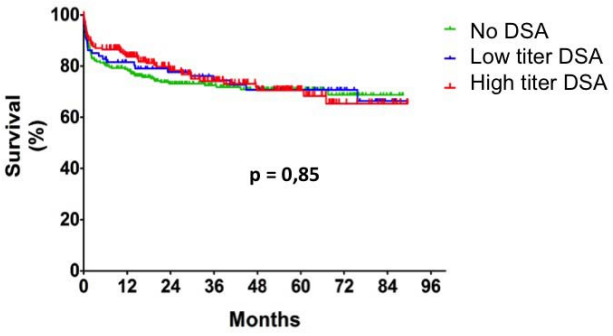
Background: In France, emergency access to heart transplantation is limited to 4 days ("high emergency 1"). To limit waiting time on list and increase the chances of transplantation, we accept grafts with high immunological risk (pre-formed donor antiHLA specific antibodies - DSA). Our purpose is to analyze the efficiency of a prospective desensitization program in patients transplanted with DSA.
Methods: Patients transplanted with low titer DSA (mean fluorescence intensity – MFI – 500 to 1000) received intravenous immunoglobulins (IVIg, 2 g/kg) and patients transplanted with high titer DSA (MFI > 1000) were treated with plasmapheresis (1 before transplantation, 4 after) and IVIg (2 g/kg) on top of standard immunosuppression regimen. We included all patients with a first isolated heart transplantation from 01/01/2009 to 31/12/2015. The primary endpoint was survival after heart transplantation.
Results: From 2009 to 2015, 523 first isolated heart transplantations were performed at our centre. Patients were mostly males (n = 404, 77%). Mean age was 50 +/- 12 years. 241 patients (46 %) were transplanted without DSA, 88 patients (17 %) with low titer DSA and 194 patients (37 %) with high titer DSA. Compared to other groups, patients transplanted with high titer DSA were younger, female sex and long term assist devices were more common. Mean follow-up was 3.7 +/- 2.1 years. Survival was similar between groups even after adjustment on age, sex and assist device before transplantation (survival at one year and at the end of follow-up respectively for no DSA group: 79 and 73 %, DSA score 4 group: 80 and 72 %, DSA score 6/8 group: 84 and 76%, p = 0.85).
Conclusion: Heart transplantation in patients with low or high titer pre-formed DSA is safe when performed with a specific desensitization program. Such a protocol might increase the chances of transplantation during the short period of high emergency 1.



1589

Incidence and prognostic impact of adverse clinical events associated to mechanical circulatory support in patients bridged to transplantation on temporary devices: a nationwide Spanish registry.

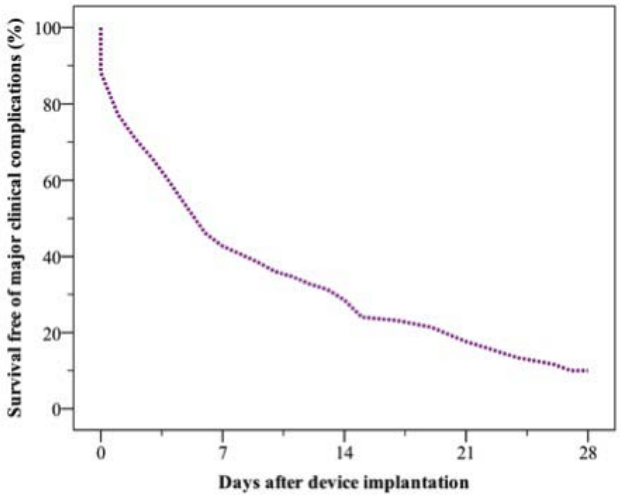
Background: In Spain, high-urgency listing for heart transplantation (HT) is allowed for candidates dependent on temporary mechanical circulatory support (T-MCS). We sought to analyze the incidence and prognostic impact of adverse clinical events (ACE) associated to T-MCS in this setting.
Methods: We conducted a nationwide, retrospective, case-by-case review of clinical records of 291 patients listed for first, single-organ high-urgent HT while on T-MCS during the period 2010–2015 in 16 Spanish institutions. The incidence and survival repercussion of T-MCS associated ACE were studied.
Results: At the time of listing, 169 (58%) patients were supported on veno-arterial ECMO, 70 (24%) on temporary left ventricular assist devices (T-LVADs) and 52 (18%) on temporary biventricular assist devices (T-BIVADs). Seven patients transitioned from ECMO to T-VADs while on the waiting list. Mean time on T-MCS was 13.1 ± 12.6 days. The overall incidence rate of T-MCS associated ACE was 59 (95% CI 42–67) per 1000 devices-day, being significantly higher among VA-ECMO supported candidates than among T-LVAD ones (71 vs. 47 events per 1000 devices-day, p = 0.008); but not significantly different than among T-BIVAD ones (71 vs. 57 events per 1000 devices-day, p = 0.199). The incidence rate of T-MCS associated major ACE –device dysfunction, stroke, bleeding or infection– was 50 (95% CI 43–58) per 1000 devices-day. Patients who experienced major ACE showed lower rates of transplantation (71.7% vs. 92.3%, p < 0.001), higher rates of death during T-MCS (25.2% vs. 6.7%, p < 0.001), lower survival from listing to hospital discharge (55.1% vs. 70.2%, p = 0.012) and lower 1-year survival after listing (52.5% vs. 66.5%, log rank p = 0.007). Survival free of major ACE after T-MCS initiation is represented in the Figure.
Conclusions: In patients bridged to high-urgent HT on T-MCS, associated ACE events are frequent, impacting the chance of getting and organ and survival.



Major ACE associated to T-MCS

1590

Hypochloremia in advanced heart failure: association with hemodynamics and prognosis

H S Hoong Sern Lim[1]; T Musa[1]; M Mukadam[1]
[1]Queen Elizabeth Hospital, Birmingham, United Kingdom

Background: Low chloride (Cl) levels are associated with poor outcomes in heart failure (HF). We hypothesized that low Cl is associated with greater hemodynamic abnormalities, which may explain the prognostic implication of low Cl in advanced HF.
Methods: 306 consecutive patients with advanced HF were included. Cl levels were measured at the time of catheter study. Cardiac power output index (CPOi)= (mean blood pressure x cardiac index/451. Primary outcome was survival free from transplantation/ mechanical support (MCS).
Results: The patients were divided into 3 groups based on Cl tertiles: T1: < 94.3 (80.1-94.2), T2: 94.3-98.6 and T3: >98.6 (98.7-105) mmol/l [TABLE]. T1 patients had lower ejection fraction, lower use of medical therapy, higher furosemide dose, lower CPOi and higher right atrial pressure (RAP). Cl level is associated with the primary outcome but only CPOi (HR 0.025, 95%CI 0.004-0.172) and RAP (HR 1.054, 95%CI 1.025-1.085) were significant on multivariable proportional hazards model. By ROC analysis, a CPOi < 0.341 and RAP≥15 were associated with survival (C-statistic about 0.6). Patients with both CPOi < 0.341 and RAP≥15 had the worst survival (Group 1), Survival was intermediate when 1 of 2 criteria was present (Group 2) and best in patients with both CPOi≥0.341 and RAP < 15 (Group 3) [FIGURE]. Cl < 94mmol/l identified patients with CPOi < 0.341 and RAP≥15 (C-statistic 0.8).
Conclusion: Low Cl is associated with worse survival free from transplantation/ MCS in advanced HF due to the association with low CPOi and high RAP.

What is the best hemodynamic predictor of survival in patients with advanced systolic heart failure ?

E Hebbar[1]; T Mercier[1]; A Duva Pentiah[1]; M Fertin[1]; C Goeminne[1]; A Vincentelli[1]; N Lamblin[1]; P De Groote[1]
[1]*Lille University Hospital, Institut Coeur-Poumon, Lille, France*

Background: In patients with advanced systolic heart failure (SHF), right heart catheterization (RHC) is mandatory before possible listing for cardiac transplantation. It is admitted that a reactivity test must be performed (either with inotropes or vasodilators) in patients with elevated pulmonary vascular resistance (PVR) > 3 Wood units (WU). An increase in PVR is a predictor of mortality in SHF but also in the post-operative period after heart transplantation. Few studies have analyzed the prognostic impact of hemodynamic parameters including both patients on the waiting list for heart transplantation and patients in the post-operative period of heart transplantation.
Methods: We included all the consecutive stable patients with optimal medical therapy admitted for RHC before possible either cardiac transplantation or ventricular assist device (VAD) implantation. An inotropic challenge was performed (dobutamine +/- milrinone) in patients with a baseline PVR > 3 WU.
Results: We included 425 patients with a mean age of 53 ± 11 years old, 43% had ischemic cardiopathy and LVEF was 29.4 ± 12.2%. 120 patients had an inotropic challenge because baseline PVR was > 3 WU, of whom 75 had a decrease of PVR ≤ 3 WU. During a follow-up period of 1.58 years [0.49 -4.41], there were 107 cardio-vascular deaths, 122 cardiac transplantations and 11 VAD implantation. Major events were the combination of cardio-vascular deaths (n = 107) or deaths during the hospitalization for VAD implantation (n = 3) or for cardiac transplantation (n = 24). Patients with a baseline PVR > 3WU had a worse prognosis whatever the results of the inotropic challenge on PVR (Figure). At baseline, independent predictors of survival were right atrial pressure (with a cut-off value of 9 mmHg) and PVR. After inotropic challenge, the best hemodynamic predictor of survival was mean pulmonary artery pressure (PAPm), with a cut-off value of 30 mmHg (Figure). Independent predictors are presented in the Table. In conclusion, for the selection of the most severe patients with stable advanced systolic heart failure, we propose to use a two steps hemodynamic algorithm using PVR at baseline (≤ or > 3 WU) and PAPm after inotropic challenge (≤ or > 30 mmHg). This algorithm must be prospectively validated in an independent population.

Independent predictors of survival		
HR [95%CI]	HR [95%CI]	p
Baseline right atrial pressure (9 mmHg)	2.44 [1.64 - 3.62]	< 0.0001
BaselinePVR≤ 3 WU (reference)	1	< 0.0001
InotropesPVR > 3 WU and PAPm≤ 30 mmHg	2.14 [1.21 - 3.77]	0.009
InotropesPVR > 3 WU and PAPm> 30 mmHg	2.44 [1.61 - 3.71]	< 0.0001

Intermittent scheduled low-dose levosimendan infusions improves event-free survival in advanced chronic heart failure: a propensity score matching analysis.

N Barras[1]; K Sotiropoulos[1]; J Regamey[1]; P Vogt[1]; R Hullin[1]; PO Patrick Yerly[1]
[1]*University Hospital (CHUV), Department of cardiology, Lausanne, Switzerland*

Introduction: Advanced chronic heart failure (ACHF) is characterized by poor quality of life (QOL) and high mortality. Improved QOL can be obtained with usual inotropes like Dobutamine, but at the price of increased myocardial O2 demand and finally lower survival. By contrast, Levosimendan (Levo) doesn't increase myocardial O2 consumption. Nevertheless, neither single 24-hours nor short intervals (2 weeks) repeated 6-hours infusions of high dose Levo (0.1-0.2 μ/kg/min) showed any survival benefit in randomized-controlled trials (RCT), possibly because of dose-related side effects.
Purpose: In this study, we sought to assess the efficacy of long intervals repeated 24h low dose Levo (0.05 μg/kg/min) infusions on 1 year event-free survival.
Methods: we conducted a retrospective case control study based on our institutional HF database. Cases (n = 42) were eligible if they had their 1st Levo infusion at the time of decompensated HF in addition to standard of care (SOC) with at least 1 further infusion scheduled, and if they had ACHF, defined as LVEF < 40% not responding to > 3 months optimal therapy. They received 4.37 (range 2-12) Levo infusions at 4 weeks intervals after initial hospitalization. They were compared 1 to 1 in a propensity score matching analysis with ACHF controls matched for age, sex, ischemic heart disease, LVEF, sinus rhythm and creatinine but who received only SOC without levo. A composite endpoint of mortality, unscheduled HF-related hospitalization and LVAD implantation 1 year after 1st Levo infusion was defined for outcome.
Results: demographic and biological variables were not different between the 42 SOC + levo cases and the matched 42 SOC controls (Table). The composite endpoint was reached by 14 SOC + levo patients (33.3%) as compared to 27 SOC controls (64.3%) (HR=0.49; 95% CI 0.26-0.93) (Figure).
Conclusion: low dose 24-hours Levo (0.05 μg/kg/min) during hospitalisation for decompensated HF and regularly repeated on a scheduled basis thereafter may improve outcome as compared to SOC in ACHF patients. These data must be confirmed by larger RCTs.

	Standard of Care N = 42	SOC + Levo N = 42	P value
Age	63,8 years	60,8 years	0,19
Male sex	32/38 (84%)	34/38 (89%)	0,37
Ischemic heart disease	22/38 (58%)	20/38 (53%)	0,19
LVEF	22,50%	21,40%	0,51
Sinus rythm	26/38 (68%)	28/38 (74%)	0,13

Differentiated approach to the treatment of patients with end-stage heart failure

O Olesya Shatova[1]; A Kurlianskaya[1]; L Rachok[1]; Y Ostrovsky[1]
[1]*Republican Scientific and Practical Centre of Cardiology, heart failure, Minsk, Belarus*

Background: The life expectancy of patients with end-stage heart failure is determined by the possibility of using different bridges to heart transplantation (HT). Pharmaceutical and mechanical bridges to HT are widely used nowadays. Surgical valve repair as the bridge to transplantation is still not good investigated.
Purpose: to access the efficiency of surgical valve repair as the bridge to HT.
Methods: Our study includes 159 patients with end-stage heart failure in the clinical status UNOS 2 during the period 2009-2015 years with the mean data end diastolic volume = 251 ± 15,8 ml, end systolic volume=188 ± 10,2ml, ejection fraction=25,6 ± 3,1%, proBNP level=1307 ± 112pg/ml, VO2peak=12,8 ± 3,1l/min. All patients were included in the waiting list and had medical unnecessary in surgical revascularization. Patients were randomized into 2 groups: 77 patients from the 1 group underwent surgical valve repair, 82 patients were on optimal medical treatment (2 group). In the 1 group surgical valve correction was used as the bridge

to the HT. The patients' death and the HT are two endpoints of our study. The results are presented as absolute and relative frequencies, standard error of the proportion (p ± Sp). Quantitative data are presented as median and interquartile range (Me (LQ-UQ)). the comparative analysis indicates that the median function of survival after surgical valve correction (without HT) is 27 months (17,6-34,8) and is significantly higher than in patients who receive an optimal medical therapy (4 months of 1.9 to 10.1) ($p < 0.001$). (Picture 1) The surgical valve correction in patients with end-stage heart failure allows in 50% cases to delay the HT up to 2 years.

Conclusions: The data analysis of the results shows that the successful applications of the surgical valve repair in patients with end-stage heart failure with unnecessary of revascularization could be used as a bridge to HT and in 50% cases allows to delay the HT up to 2 years.

Clinical outcomes and right ventricular function in patients with persistent pulmonary hypertension after heart transplantation

JB Ivey-Miranda[1]; EJ Flores-Umanzor[1]; M Farrero-Torres[1]; M Hernandez-Enriquez[1]; P Sanchez-Somonte[1]; A Garcia-Alvarez[1]; MA Castel-Lavilla[1]
F Perez-Villa[1]; [1]*Hospital Clinic de Barcelona, Barcelona, Spain*

Background: Pulmonary hypertension in heart transplant recipients is associated with worse prognosis after transplant. This study evaluated clinical outcomes and right ventricular function in patients who remained with pulmonary hypertension after heart transplantation (HT).
Purpose: To describe clinical outcomes in patients with persistent pulmonary hypertension (PPH) after HT.
Methods: We included patients with severe pulmonary hypertension that were treated with oral pulmonary vasodilators (sildenafil and/or bosentan) before heart transplant. For the aim of this study, invasive pulmonary hemodynamics were recorded at two time points: the most recent pre-transplant right heart catheterization and invasive monitoring parameters 24h post-transplant. Post-transplant persistent pulmonary hypertension (PPPH) was defined as sustained high PVR, requiring pulmonary vasodilator treatment after a month post-transplant. Post-transplant echocardiographic right ventricular failure and clinical outcomes were compared between patients with and without PPH.
Results: Twenty-five patients were included. Although 20 patients (80%) required post-transplant pulmonary vasodilator for five days post-transplant, only 10 patients (40%) showed PPPH and required therapy after a month post-transplant. The remaining 15 patients were considered as a no-PPPH control group.
Baseline pulmonary vascular resistances (PVR) were not different in patients with and without PPPH (4.0 ± 1.6 vs. 3.7 ± 1.1 Wood units, respectively, $p = 0.553$). After HT, right ventricular dysfunction prevalence was not different between patients with PPPH or without PPPH at one month and one year (50% vs. 40%, $p = 0.622$ and 30% vs. 27%, $p = 0.856$, respectively).
Although glomerular filtration rate (difference between baseline and at the time of end-point glomerular filtration rate) at one month was significantly different between groups (-13 ± 24 ml/min in PPPH vs. + 5 ± 19 ml/min in no PPPH, $p = 0.035$), there was not a significant difference after one year follow-up (-18 ± 14 ml/min in PPPH vs. -8 ± 20 ml/min in no PPPH, $p = 0.162$).
At a median follow up of 29 months, survival was 100% in both groups. In Kaplan-Meier analysis, the PPPH group showed a trend towards less hospitalization rate than the no-PPPH group (40 ± 16% vs. 67 ± 12%, $p = 0.165$).
Conclusions: In this study, patients with PPPH showed similar post-transplant outcomes compared to patients with no PPPH. Careful assessment and treatment of PPPH with pulmonary vasodilators may account for good outcomes in this high-risk population.

Levosimendan improves exercise performance in patients with advanced chronic heart failure

M Mapelli[1]; E Spadafora[1]; S Paolillo[1]; S Mushtaq[1]; S Farina[1]; E Salvioni[1]; C Vignati[1]; A Del Torto[1]; N Corrieri[1]; C Fiorentini[1]; P Agostoni[1]
[1]*Cardiology Center Monzino IRCCS, Milan, Italy*

Background: Cardiopulmonary exercise test (CPET) provides several functional variables such as peak VO2 and ventilation/CO2 production (VE/VCO2) slope, which are strong prognostic parameters for patients with stable advanced chronic heart failure (ACHF). The inodilator levosimendan combines positive inotropic, vasodilatory and cardioprotective effects, without significant changes in myocardial oxygen requirements and it has been shown to improve symptoms and haemodynamics in patients with acute HF. Levosimendan might also be used for patients with ACHF.
Purpose: In the present study we analyzed the effects of levosimendan treatment on exercise capacity, alveolar capillary gas diffusion (DLCO) and B-type natriuretic peptide (BNP) in a population of patients with ACHF in stabilized clinical condition.
Methods: We enrolled consecutive patients with ACHF (peakVO2 < 12 mL/min/kg). Every patient received i.v. infusion levosimendan 12.5 mg (in 500 mL 5% glucose). The patient NYHA class, BNP, haemoglobin, creatinine, and blood urea nitrose levels were determined at baseline and after treatment. The patients underwent CPET, standard spirometry and DLCO, before and 24h after the end of the infusion. DLCO values were corrected for haemoglobin levels.
Results: We enrolled a total of 65 patients (medium age 70.45 ± 8.99 years; male 86%). Haemoglobin, BUN and creatinine showed no changes before and after the treatment. BNP levels showed a significant decrease (1277.06 ± 994.02 to 578.03 ± 591.01 pg/ml; $p < 0.01$). Minor improvement was observed for spirometry measurements, but not for DLCO. PeakVO2 showed a significant increase while VE/VCO2 slope showed a significant decrease.
Conclusions: Levosimendan treatment significantly improve peakVO2 and reduces VE/VCO2 slope and BNP in patients with ACHF without significant impact on alveolar capillary gas diffusion.

Variables changes after infusion

n=65	Pre-infusion	Post-Infusion	p.value

Adjusting preoperative risk models of post heart transplant survival to a european cohort in the age of a new cardiac allocation score in europe

F Felix Schoenrath[1]; J Stein[1]; TA Sargut[1]
[1]*Deutsches Herzzentrum Berlin, Cardiothoracic and Vascular Surgery, Berlin, Germany*

Purpose: Organ allocation for heart transplantation is one of the most difficult procedures in modern cardiology. Several risk models target this issue to predict post transplant survival, but none of these scoring systems have been validated in a large homogenous European cohort in a long-term approach. This aspect seems of utmost importance in a time of planned switch of the Eurotransplant allocation system from a binary system (high urgent versus transplantable status) to a scoring system similar to the Lung Allocation Score (LAS) for lung transplantation.
Methods: Our institutional transplant registry provided the patient data. Analysis included data of 761 heart transplant recipients aged 18 years or older during the time period 01/1996 to 02/2015. The primary outcome was graft failure, which was defined as death or retransplantation. In a first step we assessed 30-day, 1-year, 5-year and 10-year survival and compared different risk models including the Index for Mortality Prediction After Cardiac Transplantation (IMPACT) and Columbia Risk Stratification Score (RSS). In a second step we adjusted the risk models with different variables using a multivariable logistic regression model to achieve a better predictive value.
Results: Thirty-day, 1-year, 5-year and 10-year survival rates were 78.3 ± 1.5%, 67.7 ± 1.71%, 59.1 ± 1.8% and 44.1 ± 1.9, respectively. The 1-year incidence of graft failure in accordance with the five Columbia score risk strata was 14.1%, 25.2%, 37.4%, 28.3% and 50%. The 1-year survival stratified by three-point increments of the IMPACT score showed incidence rates varying from 22.9% (0-2 points) to 57.1% (>15 points). Area under the curve for the IMPACT was 0.59 (95% CI 0.54-0.64) and 0.62 (95% CI 0.57-0.66) for the RSS. Our adjusted risk score showed an AUC of 0.69 (95% CI 0.64-0.72) with the following variables: coronary artery disease, use of BVAD, diabetes mellitus, eGFR, sex, donor age.
Conclusion: IMPACT and Columbia risk score were suitable to predict post transplant survival but ROC curve showed only intermediate prediction accuracy. Use of the above risk factors showed improved accuracy in predicting graft failure in our cohort.

1597

Prognostic accuracy comparison of the IMPACT risk score, MELD XI score and INTERMACS profiles in candidates for heart transplantation: argentinian single centre analysis

M Peradejordi Lastras[1]; L E Favaloro[1]; P Morejon Barragan[1]; D Absi[1]; MF Renedo[1]; AL Guazzone[1]; RD Ratto[1]; M Lopez Rosetti[1]; J Abud[1]; RR Favaloro[1]; AM Bertolotti[1]
[1]*University Hospital Favaloro Foundation, Intrathoracic Transplantation and Heart Failure Division, Ciudad Autónoma de Buenos Aires, Argentina*

Introduction: In the last decade there has been an increased risk in the clinical profile of orthotopic heart transplant (HTx) recipients. Risk Predictors scores can be a useful tool to optimize the timing in waiting list registration and a strategy in allocation due the disparity between available heart donors and recipients.
Purpose: We aimed to evaluate the prognostic accuracy of the Index for Mortality Prediction after Transplantation (IMPACT), Model for End-stage Liver Disease excluding international normalized ratio (MELD XI) and Interagency Registry for Mechanical Circulatory Support (INTERMACS profiles) in the estimation of mortality risk after HTx at 1 year. Secondary outcome included 30-day mortality.
Methods: We retrospectively analysed HTx adult recipients, between December, 2005 and December, 2015. The risk scores were calculated for each patient with advanced heart failure according to different clinical variables. Patients were stratified into categories: IMPACT <5; 5-10 y 10; MELD XI in interquartile range and INTERMACS profiles 1, 2-3 y 4. Logistic regression was performed to assess the predictive accuracy of these scores. Afterwards we compared the scores using a receiver operating characteristic (ROC) curve thus obtaining the area under the curve (AUC) and the respective 95%CI. The AUC of risk models were compared using the non-parametric test of DeLong et.al.
Results: In our cohort of 227 HTx adult recipients, mean age (±SD) was 50 ± 13 years, 73% were men. The cumulative mortality rate was 19% at 1-year and 8% at 30-days. The overall cohort had a mean IMPACT risk score of 6.4 ± 4.5 and mean MELD XI score of 12.5 ± 3.4 (Interquartile range 9.44 to 14.21).
The models had in predicting mortality similar outcomes at 1-year, the AUC obtained from the ROC curves of IMPACT, INTERMACS and MELD XI were 0.63 (95% CI: 0.57-0.70); 0.61 (95% CI: 0.54-0.67) and 0.61 (95% CI: 0.54-0.67), respectively (p = NS). The area under the ROC curve demonstrated that IMPACT, INTERMACS and MELD were no significantly different in predicting 30-day mortality; 0.68 (95% CI: 0.62-0.74); 0.67 (95% CI: 0.60-0.72) and 0.58 (95% CI: 0.51-0.64), respectively.
In the logistic regression analysis mechanical ventilation pre-transplant was significantly associated with 30-day and 1-year mortality after HTx (OR: 5.35; 95%CI: 1.86-.15.35; p = 0.02) (OR: 2.87; 95%CI: 1.04-.7.93; p = 0.04).
Conclusion: In our analysis, IMPACT risk score, INTERMACS profiles and MELD XI score, were similar in predicting 30-day and 1-year mortality risk after HTx. There is scarse data comparing the prognostic accuracy of these models.

1598

Toxoplasma gondii serostatus is not an independent predictor of survival in heart transplant recipients: analysis of the Spanish Heart Transplant Registry

On behalf of: Spanish Heart Transplant Registry Investigators
Funding Acknowledgements: Working Group in Heart Failure of the Spanish Society of Cardiology

Background: A long-standing controversy exists about a potential negative impact of pre-transplant Toxoplasma Gondii (TG) seropositivity on long-term survival of patients undergoing heart transplantation (HT). We sought to test this hypothesis in a large, multi-institutional registry.
Methods: Post-transplant outcomes of 4048 patients aged > 16 years who underwent first, single-organ HT in 17 Spanish institutions from 1984 to 2014 were analyzed. Long-term post-transplant survival and long-term survival free of cardiac death or cardiac retransplantation of 2434 (60%) TG seropositive recipients and 1614 (40%) TG seronegative recipients were compared by means of univariable and multivariable Cox´s regression.
Results: Before HT, TG seropositive recipients were older, had higher body mass index, and presented higher prevalence of hypertension, hypercholesterolemia, COPD and CMV seropositivity. In univariable analysis, pre-transplant TG seropositivity was associated with increased post-transplant all-cause mortality (non-adjusted HR 1.15; 95% CI 1.04–1.26; p = 0.004). Kaplan-Meier non-adjusted survival curves of TG seropositive (blue line) and TG seronegative (red line) recipients are represented in the Figure. However, this effect was not statistically significant after multivariable adjustment by age and sex (adjusted HR 1.01, 95% CI 0.92–1.11, p = 0.842). Extended multivariable adjustment by other potential confounders did not change significantly the result (adjusted HR 0.99, 95% CI 0.89–1.11, p = 0.925). Neither a statistically significant effect of TG seropositivity on the composite outcome cardiac death or retransplantation was observed (non-adjusted HR 1.08, 95% CI 0.95–1.24, p = 0.235; sex and age-adjusted HR 1.08, 95% CI 0.95–1.24, p = 0.231). The distribution of the causes of death was comparable in TG seropositive and TG seronegative recipients.
Conclusions: This analysis of a large, multi-institutional registry did not show an independent effect of pre-transplant TG serostatus on long-term post-cardiac transplant survival.

Non-adjusted post-transplant survival

How does functional mitral regurgitation affect pulmonary hemodynamic parameters in heart transplantation candidates?

Z Zubeyde Bayram[1]; C Dogan[1]; C Dogan[1]; RD Acar[1]; RD Acar[1]; C Onal[1]; C Onal[1]; B Guvendi[1]; B Guvendi[1]; A Karaduman[1]; A Karaduman[1]; OY Akbal[1]; OY Akbal[1]; F Yilmaz[1]; F Yilmaz[1]; C Kaymaz[1]; C Kaymaz[1]; K Kirali[1]; K Kirali[1]; N Ozdemir[1]; N Ozdemir[1]
[1]Kartal Kosuyolu Heart Education and Research Hospital, Department of Cardiology, Istanbul, Turkey

Background: It remains unknown whether there is an association between pulmonary hypertension (PHT) and functional mitral regurgitation (FMR) The aim of the present study is to determine the association between significant functional MR (FMR) and PHT, and to evaluate the effect of FMR on other right heart catheterization (RHC) findings in patients with end-stage heart failure. Methods and Results: A total of 153 patients with end-stage heart failure undergoing evaluation for heart transplantation were stratified into two groups; namely, those with and without FMR, and all of the patients underwent RHC. Fifty one patients had significant FMR and 102 patients had non-significant or no FMR. PHT was detected in 110 patients and PVR was equal to or higher than 3 in 70 patients. There was no difference in terms of left ventricular ejection fraction, NYHA and INTERMACS grades between patients with and without significant FMR (20.9 ± 5.1 vs 21.4 ± 6.7 $p = 0.286$, 3.7 ± 0.45 vs. 3.7 ± 0.44 $p = 0.74$, 4.8 ± 1.6 vs 4.7 ± 1.4 $p = 0.68$, respectively). The means of systolic, mean and diastolic pulmonary arterial pressures, pulmonary capillary wedge pressure were higher in patients with significant FMR compared to those with non-significant FMR (56.1 ± 15.2 vs. 48.9 ± 18.9 $p = 0.012$, 37 ± 11.0 vs. 31.1 ± 11.1 $p = 0.003$, 25.7 ± 9.2 vs. 21.0 ± 9.0 $p = 0.02$, 26 ± 7.7 vs 21.8 ± 7.9 $p = 0.001$). The means of PVRs, right atrial pressures, transpulmonary gradients and diastolic pulmonary gradients were similar in both groups (3.8 ± 2.4 vs 3.2 ± 2.5 $p = 0.11$, 12 ± 5.9 vs 9.8 ± 6.6 $p = 0.08$, 11 ± 6.7 vs 10.4 ± 7.7 $p = 0.125$, 5.7 ± 1.9 vs 5.5 ± 2.3 $p = 0.67$, respectively). Among the 83 patients with PVR lower than 3, 23 patients had significant FMR and among the 70 patients with PVR equal to or higher than 3, 28 patients had significant FMR, and there was no statistical difference between the two groups ($p = 0.108$). Conclusion: The presence of significant functional mitral regurgitation appears to increase pulmonary artery pressures in patients with end-stage heart failure without any effect on PVR. Therefore, the presence or absence of mitral regurgitation does not seem to be unfavorable risk factor for PVR in pre-transplantation patients.

1600

Managing critical cardiogenic shock with long term mechanical circulatory support: where is the limit?

P Piergiorgio Tozzi[1]; C Banfi[2]; K Ahmadov[1]; R Hullin[3]; PH Meyer[4]; CH Huber[2]; M Kirsch[1]
[1]University Hospital Centre Vaudois (CHUV), Cardiac Surgery, Lausanne, Switzerland; *[2]University of Geneva, CardioVascular Surgery, Geneva, Switzerland*; *[3]University Hospital Centre Vaudois (CHUV), Cardiology, Lausanne, Switzerland*; *[4]University of Geneva, Cardiology, Geneva, Switzerland*

Background: The INTERMACS registry stratifies patients in end-stage heart failure (HF) according to the severity of the clinical conditions: from profile 1 (critical cardiogenic shock) to profile 7 (ambulatory advanced HF). Patients implanted in profile 1 are at higher risk for mortality after implantation relative to less sick patient profiles. Before 2010, 29% of LVAD recipients were in profile 1, but since 2012, that proportion has diminished to 15%, reflecting the reluctance to implant a durable device in the crash-and-burn setting. However, with the appropriate strategy, it should be possible to improving clinical results even in critical cardiogenic shock patients.
Purpose: We report our management strategy in treating critical end-stage HF patients with long term mechanical circulatory support (MCS).
Methods: Prospective study to evaluate the survival to 90 days on the LVAD of critical cardiogenic shock patients (primary endpoint). Secondary endpoints were MACE related to pump activity. Patients suffered from chronic end-stage HF and met the criteria to be enrolled in the heart transplant/destination therapy programs. Device implantation criteria were persistent low output syndrome despite optimal medical treatment (LV ejection fraction $< 20\%$; cardiac index < 2.0 l/min/m2; inotrope dependent). All patients received appropriate volume and inotropic support to avoid right heart failure. Postoperative anticoagulation guidelines included starting intravenous heparin to reach a PTT of 45-55 sec (or anti-factor Xa of 0.2-0.45 U anti-Xa/ml), when bleeding was less than 50ml/h for 3 consecutive hours. The PTT was progressively increased in postoperative day 3 until it reached 65 sec. Once the patient was able to take oral medications, Aspirine (100mg daily) and anti-vitamin K were administered with a targeted INR of 2.5 to 3.0. All patients were monitored for pump flow, selected laboratory parameters, major adverse events and device malfunctions.
Results. Out of 57 patients that received LVAD, 10 were in INTERMACS profile 1 to 3 (2 were under V-A ECMO). The indication was bridge-to-transplant in 7 patients, and destination therapy in 3. All had last generation of fully magnetically suspended centrifugal LVAD implanted under CPB, on beating heart. Two patients (20%) received concomitant aortic valve surgery. Five patients (50%) required temporary right ventricle support (tRVAD) for a mean of 8 ± 1.5 days. Bleeding requiring surgical revision occurred in 5 (50%) patients, 3 during the tRVAD support. At the 90-day endpoint survival was 90%, one (10%) died due to respiratory failure. Three (30%) experienced critical illness polyneuropathy. Two (20%) had late driveline infection.
Conclusions. Morbidity rate was high. However, the 90% survival rate at 90 days endorses the assumption that, with the appropriate strategy and last generation centrifugal LAVD, even the crash-and-burn patients have excellent possibility to benefit from long term MCS.

Reversibility of fried's frailty domains post-intervention among patients with advanced heart failure

S R Sunita Jha[1]; MK Hannu[1]; PJ Newton[2]; K Wilhelm[3]; CS Hayward[1]; E Kotlyar[1]; A Keogh[1]; K Dhital[1]; M Connellan[1]; E Montgomery[1]; A Smith[1]; M Harkess[1]; P Tunicliff[1]; PM Davidson[4]; PS Macdonald[1]; *[1]St Vincent's Hospital, Heart and Lung Transplant Unit, Sydney, Australia*; *[2]University of Technology, Sydney, Sydney, Australia*; *[3]St Vincent's Hospital, Psychiatry, Sydney, Australia*; *[4]Johns Hopkins University of Baltimore, Faculty of Nursing, Baltimore, United States of America*

Aim: The aim of this study was to evaluate the reversibility of frailty in AHF patients undergoing bridge-to-transplant ventricular-assist-device (BTT-VAD) implantation or heart transplantation (HTx).
Methods: Since 2013, all AHF patients referred to our centre were assessed for frailty pre- and post- BTT-VAD/HTx. Fried's five physical domains: exhaustion, grip-strength, mobility, appetite and physical inactivity (frail $\geq$ 3/5), as well as cognitive impairment (MoCA $\leq$ 26) and depression (DMI $>$ 9) were assessed.
Results: 24 frail pre-intervention patients were followed-up post intervention for reversibility: 12 VAD (124 ± 77 days post-VAD) and 12 HTx (177 ± 135 days post-HTx). Among the VAD patients there was a significant improvement in frailty score (4.2 ± 0.8 to 1.7 ± 1.1, $p < 0.003$); with significant improvements across all frailty domains except grip-strength after pump implant. Among the HTx patients, there was also a significant improvement in frailty score (3.3 ± 0.5 to 0.8 ± 0.1, $p < 0.002$); with significant improvements seen in exhaustion, appetite and physical activity after HTx. A non-significant improvement was seen in depression, and less so cognitive impairment in both the frail pre-VAD/HTx groups.
Conclusion: Frailty associated with AHF is amenable to improvement post-intervention. Improvements in appetite and physical activity were the major contributors to improved frailty score. In contrast, improvement in HGS was small and non-significant.

POSTER SESSION 3

ACUTE HEART FAILURE

P1602

ultrasound of the lungs for acute heart failure diagnosis in the early phase of ST-elevation myocardial infarction

M Teterina[1]; I Meray[1]; LA Babaeva[1]; AF Safarova[1]; AS Pisaryuk[1]; OI Lukina[1]; IV Shevchenko[1]; AS Milto[1]; ZHD Kobalava[1]
[1]Peoples Friendship University of Russia (PFUR), Cardiology, Moscow, Russian Federation

Introduction: Evaluation of heart failure in STEMI (ST elevation myocardial infarction) patients in real clinical practice is based primarily on subjective methods of investigation. In this respect, it is highly important to implement fast objective bedside methods of pulmonary congestion evaluation. One of them is the technique of sonographic quantification of total number of B-lines for detection of interstitial-alveolar syndrome.
Objective: To estimate frequency of detected pulmonary venous congestion by means of bedside sonographic investigation of the lungs in STEMI patients and compare the results with data received by both physical examination and well-known instrumental assessment methods.
Results: The study included 109 STEMI patients with Killip I (40%) and Killip II (60%) acute heart failure. Patients with Killip classes III and IV were excluded from the study. In addition to clinical and radiological assessment of pulmonary congestion, in the first days of myocardial infarction all patients were performed pulmonary ultrasound with the quantification of B-lines. Thus, 64% (n = 28) patients with Killip class I did not show any sonographic signs of pulmonary congestion (less than 5 B-lines), whereas 36% (n = 16) patients had congestive heart failure with total number of B-lines over 15. Of these patients, 11% (n = 5) had expressed severe congestion (B-line score≥30). Among Killip class II patients, 97% showed signs of congestion, of them 23% had severe interstitial-alveolar syndrome. In the following 2-3 days after MI onset, all patients with Killip I class and presenting with B-lines score≥6, developed signs of pulmonary congestion, confirmed by physical and/or X-ray methods of investigation.
Conclusion: Ultrasound assessment of the lungs with sonographic quantification of B-lines is an available method of early heart failure diagnosis in STEMI patients.

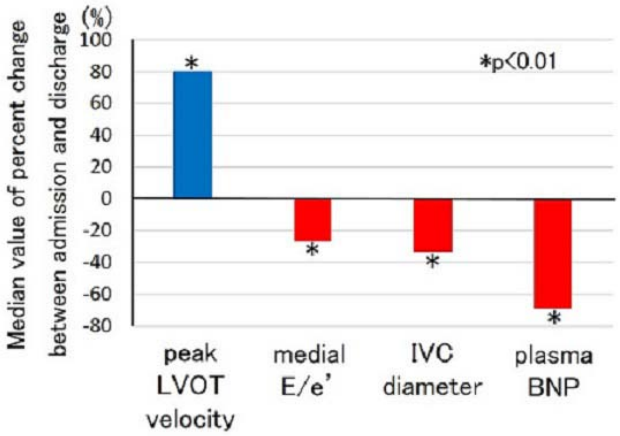
P1603

Changes in echocardiographic parameters and biomarkers during hospital stay in patients with acute heart failure

E Akiyama[1]; LNL Van Aelst[2]; M Arrigo[3]; J Motiejunaite[1]; E Gayat[4]; MF Seronde[5]; A Mebazaa[4]
[1]Inserm UMR-S 942, Paris, France; *[2]KU Leuven, Leuven, Belgium*; *[3]University Hospital Zurich, Zurich, Switzerland*; *[4]Hospital Lariboisiere, Paris, France*; *[5]University Hospital Jean Minjoz, Besançon, France*

Funding Acknowledgements: This study was supported by a research fellowship from Japan Heart Foundation (E.A.).

Background: Because congestion plays an important role in pathogenesis of acute heart failure (AHF), decongestion is primary treatment in patients with AHF. Echocardiographic parameters and biomarkers are useful for evaluation of congestion and diagnosis of heart failure, however, changes in these parameters according to decongestion therapy in patients with AHF are poorly defined.
Purpose: The purpose of this study was to investigate changes in echocardiographic parameters and biomarkers during hospital stay in patients with AHF.
Methods and Results: Of 101 hospitalized patients with AHF derived from MEDIA-DHF cohort, 60 had preserved left ventricular (LV) ejection fraction (EF) (HFPEF) and 41 had reduced LVEF (HFREF). Concerning echocardiography, although LVEF was unchanged during hospital stay (median: 38 [29-55] at admission, 41 [30-57] % at discharge, p = 0.37), peak LV outflow tract (LVOT) velocity and tricuspid annular plane systolic excursion (TAPSE) improved during hospitalization (median: peak LVOT velocity 0.63 [0.58-0.69] at admission, 1.13 [1.04-1.29] m/s at discharge, p = 0.005, TAPSE 16 [15-19] at admission, 19 [17-21] mm at discharge, p = 0.04). Medial E/e' decreased during hospitalization (median: 21.1 [15.8-29.6] at admission, 16.6 [11.7-24.3] at discharge, p = 0.004). Inferior vena cava (IVC) diameter at rest decreased and respiratory variability of IVC diameter improved during hospitalization (median: IVC diameter 22 [16-24] at admission, 13 [11-18] mm at discharge, p = 0.009, variability 32 [8-44] at admission, 43 [29-70] % at discharge, p = 0.04). The results were similar in HFPEF and HFREF, except that TAPSE improved in only HFREF patients (median: HFPEF 17 [13-20] at admission, 17 [16-19] at discharge, p = 0.34, HFREF 16 [15-18] at admission, 19 [18-25] mm at discharge, p = 0.06) and medial E/e' decreased in only HFPEF patients (median: HFPEF 21.3 [16.0-30.5] at admission, 14.3 [11.5-24.3] at discharge, p = 0.007, HFREF 21.0 [14.0-25.5] at admission, 19.2 [12.0-22.0] at discharge, p = 0.20). Concerning plasma biomarkers, B-type natriuretic peptide (BNP), mid-regional pro-atrial natriuretic peptide (MR-proANP), and soluble CD146 levels all significantly decreased during hospitalization (median: BNP 935 [514-2037] at admission, 308 [183-609] pg/mL at discahrge, p < 0.001, MR-proANP 449 [274-653] at admission, 366 [242-549] pmol/L at discharge, p < 0.001, soluble CD146 528.0 [405.9-653.8] at admission, 449.8 [373.9-529.2] ng/mL at discharge, p = 0.003). The results were consistent between HFPEF and HFREF.
Conclusions: Echocardiographic parameters and biomarkers which indicate the severity of congestion and cardiac function significantly improved during hospital stay in patients with AHF.



P1604

Performance of early change of cardiac output in the diagnosis of acute heart failure (AHF) in patients with acute dyspnea

EZ Ezzina[1]; EM Malek Echeikh[1]; ZW Zhani[1]; AN Azaiez[1]; SA Sekma[1]; BAA Ben Abdallah[1]; BK Beltaief[1]; MMA Msolli[1]; DZ Dridi[1]; BH Boubaker[1]; GMH Grissa[1]; BW Bouida[1]; NS Nouira[1]
[1]*university of monastir, monastir, Tunisia*

On behalf of: great network

Purpose: To evaluate the performance of cardiac output (CO) change with dynamic and pharmacological maneuvers in the diagnosis of AHF in patients admitted to emergency department (ED) with acute dyspnea.
Methods: A prospective study conducted in the emergency department (ED) including patients over 18 years admitted for acute dyspnea. We measured CO using thoracic bio impedance: at baseline, during supine position (SP), leg rising (LR), under Valsalva maneuver (VM) and after administration of sublingual nitroglycerin (NTG test). Heart failure (HF) is defined on the basis of clinical findings, serum levels of pro-BNP and echocardiographic criteria.
Results: 395 patients were included, 212 patients with HF. Cardiac output at baseline was higher in the non-AHF group ($p < 0.01$). The effects of the various maneuvers on COwere summarized in the figure.
Conclusion: Early changes of cardiac output with VM and NTG can be a simple method to recognize HF in patients who are admitted to ED for acute dyspnea

P1605

Value of systolic time intervals in the prediction of 30 day mortality after hospital discharge in Acute Heart Failure patients

I Imen Trabelsi-Bchir[1]; MS Messous[1]; BK Beltaief[1]; MMA Msolli[1]; SA Sekma[1]; BN Bziouich[1]; FN Fredj[1]; EZ Ezzina[1]; EM Echeikh[1]; GMH Grissa[1]; BH Boubaker[1]; BR Boukef[1]; BW Bouida[1]; NS Nouira[1]
[1]*university of Monastir, monastir, Tunisia*

Background: Acute heart failure (AHF) is one of the leading causes of unscheduled hospitalization and is associated with frequent readmissions and substantial mortality. Simple and noninvasive measurements of systolic time intervals (STI) could be helpful to predict these complications in patients admitted to the emergency room (ER). The present study assessed the prognosis performance of STI in AHF patients.
Patients and methods: We included all patients over 18 years old admitted to the ER for AHF. The diagnosis of AHF was determined on the basis of clinical examination, echocardiography, and brain natriuretic peptide value. Measurement of STI included the pre-ejection period (PEP), left ventricular ejection time (LVET), and systolic time ratio (STR=PEP/LVET). STI were determined by thoracic bio-impedance method, at admission in all included patients. Survival status data at 30 days was prospectively collected. The values of STI were compared between survivor and non survivors patients in order to determine their prognostic value.
Results: A total of 500 AHF patients were included, with a mean age 68,41 ± 12 years, sex ratio (M / F) 1,04. Compared to survivors, Non survivors patients had higher STR (48.7 ± 17 vs 43.2 ± 11, $p < 0.01$) values. LVET and PEP values were not significantly different between both groups.
Conclusion: Only STR value could be considered as a meaningful non invasive method to predict mortality 30 days after hospital discharge in AHF patients.

Primary percutaneous coronary intervention (PPCI) in patients with acute ST-elevation myocardial infarction (STEMI), resumes coronary flow in the infarct related artery (IRA) and myocardial perfusion which both determine left ventricular (LV) function and prognosis.
Objective: Evaluate LV diastolic function, coronary velocity parameters and their inter-relationship in the infarct related and non-infarct related coronary artery.
Methods: Eighty patients with acute STEMI, 60 anterior and 20 non-anterior, treated with PPCI were studied. Complete transthoracic Doppler echocardiography and sampling of blood velocity in the left anterior descending (LAD) coronary artery were performed immediately after PPCI and 5 days later.
Results: In the control group, LAD velocity and diastolic function parameters did not change during hospitalization and were unrelated. In the study group these parameters were dynamic; LAD diastolic time velocity integral and diastolic pressure half time increased, E wave deceleration time increased before discharge while A wave peak velocity decreased. TIMI grade < 3 was associated with larger mitral E-wave velocities, $p < 0.02$, Early after PPCI, longer LAD diastolic deceleration time was associated with longer mitral E-wave deceleration time, $p < 0.04$, ST-Elevation resolution>70% was associated with longer late mitral E-wave deceleration time, $p < 0.04$. Killip Class>1 was associated with lower mitral annular E-velocities, $p < 0.04$. E/Ea>8 and PCWP>12 were related to larger late LAD systolic velocities, $p < 0.05$, and longer early pressure half time, $p < 0.02$.
Conclusions: IRA flow and LV diastolic function are dynamic and interrelated but not non-IRA.

P1607

Interest of a systematic investigation when a tako tsubo syndrome is suspected

C Clement Delmas[1]; L Marty[1]; C Biendel[1]; M Elbaz[1]; D Carrie[1]; M Galinier[1]; O Lairez[2]
[1]*Toulouse Rangueil University Hospital (CHU), Cardiology department, Toulouse, France*; [2]*Toulouse Rangueil University Hospital, Cardiac Imagery Center, Toulouse, France*

Background: Diagnostic criteria for Tako Tsubo Cardiomyopathy (TTC) exist since 2004, but there is currently no recommendation of learned societies as the minimum balance required. Exponential increase of TTC diagnoses assumes the risk of misdiagnosis and delayed appropriate management.
Aim: Determine the prevalence of differential diagnosis in a "real life" population of patient with suspected TTC.
Methods and Results: Between 10.2009 and 01.2016, 8726 patients were admitted for acute coronary syndrome (ACS) with troponin elevation in our center. Among them 144 (1.7%) patients were suspected for TTC and were included in a prospective cohort. According to the initial presentation, cardiac MRI, urinary and/or plasma catecholamines and thyroid balance were conducted. Among them, 26 (18%) diagnosis and therefore management were changed after the completed assessment. Fourteen (9.7%) patients were reclassified as ACS (2 with spastic angina), 3 (2.1%) as myocarditis, 2 pheochromocytoma (1.4%), 6 misceallenous diagnosis (4.2%) and 1 thyrotoxisis (0.7%). MRI was the most efficient exam to catch misdiagnoses in 14 cases (9.7%).
Conclusion: Differential diagnosis in patients with suspected TTC represents more than 15% of these population and need to perform a minimum check-up with MRI and catecholamines measurement.

P1608

Clinical characteristics and in-hospital outcomes among patients hospitalized for acute heart failure stratified by clinical response to initial therapy

CI Radulescu[1]; L Antohi[1]; M Chivulescu[1]; I Cosei[1]; A Covaliov[1]; R Radu[1]; A Ambrosy[2]; S Collins[3]; C Macarie[1]; O Chioncel[1]; M Gheorghiade[4]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania*; [2]*Duke University Medical Center, Cardiology, Durham, United States of America*; [3]*Vanderbilt University, Emergency Medicine, Nashville, United States of America*; [4]*Northwestern University, Cardiology, Chicago, United States of America*

Introduction: Patients hospitalized for acute heart failure (AHF) have variable in-hospital trajectories as a result of different etiologies and precipitating factors. There are limited data adressing the heterogeneity of in-hospital course by initial therapy.

Objective: To identify clinical characteristics and in-hospital outcome of patients hospitalized for AHF and stratified by clinical response to initial intravenous (IV) therapy.
Methods: The Romanian AHFS (RO-AHFS) registry prospectively enrolled 3224 consecutive patients admitted for AHF over a 12-month period. Based upon clinical response in the first 24 hours to initial IV therapy, patients were divided into four subgroups: A. persistent improvement, B. initial improvement followed by clinical decompensation, C. continuous worsening, and D. refractory signs and symptoms. In-hospital outcomes included all cause mortality (ACM) and length of stay (LOS).
Results: Overall, the breakdown of patients included 75.1% in group A, 16.1% in group B, 3.4% in group C, and 5.4% in group D. Baseline characteristics and in-hospital management are shown in Table 1. In-hospital ACM was 6.8% in group A, 8.2% in group B, 34% in group C, and 27% in group D. Similarly, median (25th, 75th) LOS was 6 (3, 9) days in group A, 8 (4,12) days in group B, 9 (3,18) days in group C, and 12 (7, 22) days in group D.
Conclusions: Although the vast majority of AHF patients substantially improved in response to initial IV therapy, some patients experienced a persistently unfavourable or a deteriorating in-hospital trajectory. A better characterization of the pathophysiology of AHF may facilitate targeted aplication of existing therapies and development of novel interventions in patients at-risk for an unfavourable clinical course.

Funding Acknowledgements: Eurobio society

Background: The prevalence of heart failure (HF) is about 1-2%. It is a major cause of health burden representing between 2 billions euros per year in France. 63% of these costs are due to hospitalization. The sST2 (member of Interleukine-1 receptor family) is a potent predictor for survival in HF, probably better than natriuretic peptides. In this trial we aim at evaluating the sST2-guided therapy as a help for the physician to optimize the recommended treatments in order to prevent readmissions.
Methods: The trial will be a prospective biomedical interventional randomized open-labelled trial of evaluation of the two strategies with two parallel arms: conventional (sST2 is not known from the clinician) versus sST2-guided therapy (sST2 assessed at day 4 is known from the clinician). It will be conducted in the University Hospital of Montpellier. The study will include adults hospitalized for HF. If ST2 at day 4 is > 37 ng/mL, the clinician will be encouraged to optimize the therapy as much as the patient tolerates it. If ST2 is < 37 ng/mL, no incentive to optimize the treatment will be made. Based on the hypothesis of a 50% reduction of readmissions, 300 patients will be included.
Discussion: Many tools have been proposed to decrease the burden of readmission in patients with HF but the cornerstone remains the optimization of recommended medical treatment with improvement of survival: beta-blockers, ACE-inhibitors or ARA-2 inhibitors, mineralocorticoid inhibitors, ivabradine and sacubitril-valsartan. The higher the sST2 is, more likely is the impact of drugs with antiremodeling effect. The optimal dosage of these agents in individuals is guided largely by subjective indices, namely the clinician's assessment of symptoms, bedside signs and tolerability. There is therefore an interest in a biomarker (sST2) to guide the management of patients admitted for HF, in order mainly to reduce the burden of readmissions. It is the first time that this kind of approach is evaluated in patients with HF.

P1610
Use of invasive mechanical ventilation in acute heart failure: the experience of a referral cardiological centre

G Giulio Binaghi[1]; D Congia[1]; A Muroni[2]; A Pani[1]; D Pasqualucci[1]; E Serra[1]; M Porcu[1]
[1]G. Brotzu Hospital, Department of Cardiology, Cagliari, Italy; [2]University of Cagliari, Cagliari, Italy

Acute heart failure (HF) refers to rapid onset or aggravation of symptoms and signs due to elevated intracardiac pressures and/or a reduced cardiac output. It is a life-threatening condition requiring urgent evaluation and treatment. Data from registries of HF showed that up to 16% of cases need an invasive mechanical ventilation (IMV). Our aim is to perform a retrospective evaluation of clinical and haemodynamic characteristics and outcomes of patients (pts) hospitalized in an 8-bed CCU of a referral cardiological centre from January 2014 to May 2016 for acute HF, who underwent IMV. During the study period 1437 pts have been hospitalized for any cause, of them 54 (3,8%) need an IMV because of acute HF. Mean age of pts was 68 ± 16 years, 36 (67%) were males and in 52% of cases, HF was due to acute coronary syndrome. Arrhythmia was the reason of decompensation in 26% of pts, in 2 (3,7%) cases the cause of HF was a myocarditis and in other 2 a pulmonary embolism. 35% of pts were diabetics, 57% had a history of cardiopathy, while 28% had a chronic kidney disease and 15% a COPD. Before hospitalization, 44% of pts were treated with a RAAS-blocker (ACE-I or ARB), 41% with a B-blocker, 41% took an anti-platelet drug, 46% followed a diuretic treatment and 24% an anticoagulant regimen. At the time of intubation, mean systolic blood pressure and heart rate were 114 ± 33 mmHg and 96 ± 33 bpm respectively. Lab tests showed that the mean value of serum creatinine was 1,8 ± 1 mg/dl and of hemoglobin was 12,3 ± 2 g/dl. First blood-gas-analysis performed displayed an acidosis in 23 cases (59%). In 28% of pts, ECG showed a ST-elevation and in 9,3% a presumed new left bundle branch block. During IMV, in 49 pts (91%) a sedative agent was employed and about in 2/3 also a neuromuscular blocking drug was necessary. In the hospitalization, 59,3% (n: 32) of cases need an inotrope: adrenaline was the most used (42,6%; n: 23), then noradrenaline (27,8%; n: 15) and dobutamine (25,9%; n: 14). Levosimendan and dopamine have been used much less commonly (13% and 7,4%). 24 pts (44,4%) underwent coronary angiography and 66% of those (n: 16) need a PCI. 11 (21%) pts had a renal replacement treatment and 6 (11,1%) necessitated the use of IABP. The mean time of IMV was 3,9 ± 3,3 days and the average length of hospitalization was 16,7 ± 15,3 days. The intra-hospital mortality registered was 42,6% (n: 23), but only 10% (n: 5) in pts requiring IMV due to an arrhythmic storm. Our data show that a patient hospitalized in a CCU for HF and requiring IMV is not so common. However, according to data from registries of HF, his management is very complex, not only for the treatment of HF's etiology, but also for the comorbidities, the failure interesting other organs and the different therapies, pharmacological and not, used. In order to better manage these cases, multiplies skills are required to cardiologist that necessitate a wide and correct knowledge of pathophysiology of whole organism.

P1611
Right heart failure and cardiogenic shock contribute to longer length of stay in patients with acute heart failure

B Bambang Widyantoro[1]; I Firdaus[1]; SS Danny[1]; DA Zamroni[1]; I Irmalita[1]; DPL Tobing[1]; DA Juzar[1]
[1]Dept of Cardiology and Vascular Medicine, Universitas Indonesia-NCVC Harapan Kita Hospital, Jakarta, Indonesia

Morbidity and mortality of patients admitted with acute heart failure (AHF) remains high. The aim of this study was to describe patient profiles and predictor of length of stay in patients with AHF.
We examined 1846 patients hospitalized in CVCU of our National Cardiovascular Center in 2015. Among those, 697 (37.76%) were patients with AHF, with acute coronary syndrome as the most prevalence cause (62.13%). Median age was 60 (32-89) years old, and 81.8% were male. Hemodynamic profiles showed 68.15% patient had wet and warm presentation, and 7.6% had cardiogenic shock. The most prevalence co-morbid are diabetes (44.8%), chronic kidney disease (6.31%) and pneumonia (21.52%). Median length of stay in CVCU was 3 (1-75) days, and patient with cardiogenic shock and right HF stay longer in CVCU [6.5 (1-50) days and 7 (6-21) days, respectively]. These 2 groups of patients also need more inotropes and vassopressors, and morelikely to have acute kidney injury that need continuous renal replacement therapy. In conclusion, we observed that patient with right heart failure and cardiogenic shock who need renal replacement therapy during hospitalization contributed to longer length of stay in hospital among all patients with acute heart failure.

P1612

Twenty percent of patients with acute decompensated heart failure (ADHF) do not receive appropriate treatment in the emergency department (ED)

J Mc Cambridge[1]; C Keane[1]; M Walshe[1]; P Campbell[1]; PR Kalra[2]; MR Cowie[3]; J Riley[3]; R O' Hanlon[1]; M Ledwidge[1]; J Gallagher[1]; K Mc Donald[1]

Funding Acknowledgements: Enterprise Ireland, ResMed, Boston Scientific, Cardiomark

Introduction: Increasing heart failure (HF) admission and ED attendance rates present a major challenge. It is generally accepted that early appropriate intervention reduces length of hospital stay and time to clinical stability.
Purpose: To evaluate the numbers being diagnosed with ADHF and numbers receiving HF-directed treatment in those presenting to ED with ADHF.
Method: This analysis is taken from one of the centres in an ongoing multicentre study evaluating clinical care pathways for patients admitted with ADHF. It focuses on the patient experience in ED. Specifically, we looked at patients' initial diagnosis (ADHF, mixed respiratory infection/ADHF, respiratory infection alone, acute coronary syndrome, other), numbers receiving diuretics/nitrates in ED and time from presentation to treatment. A p value < 0.05 was taken as significant.
Result: This analysis included 84 patients presenting to ED with ADHF, of which 47 (55.9%) had a new diagnosis of HF (de novo, DN) and 37 (44.1%) had a known history of HF (recurrent admitters, RA). Median age for this group was 75 years (71 for DN, 78 for RA). RA had a higher median number of co-morbidities (4) compared to DN (3). The time from presentation to first medical contact in ED was documented in 78.6% (66) of patients, with no significant difference between the median times for DN and RA (101 minutes and 91 mins respectively, $p = 0.381$). Only 80.95% (68) of all patients were initially diagnosed as either ADHF or mixed respiratory infection/ADHF. RA were more likely to be diagnosed as either ADHF or respiratory infection/ADHF than not when compared to DN (89.2% vs. 74.5% respectively, $p = 0.044$). Of the entire cohort, 81.7% (67) received some sort of HF-directed therapy (oral/intravenous diuretic and/or transdermal/intravenous nitrate). RA received a HF-directed therapy more often than DN (88.6% vs. 76.6% respectively, $p = 0.246$) and RA also received IV diuretics more often than DN (82.9% vs. 70.2% respectively, $p = 0.192$), though neither difference reached statistical significance. DN tended to receive HF-directed therapy earlier with a median time-to-treatment of 232 mins (IQR 301 mins) compared to 324 mins (IQR 214 mins) with RA ($p = 0.202$).
Conclusion: One fifth of patients presenting to ED with ADHF were not initially diagnosed with ADHF and did not receive HF-directed therapy as part of their initial management. RA were more likely to be diagnosed with ADHF than DN. Earlier recognition and treatment of ADHF in ED may be improved via increased clinician awareness/comfort with the features of HF, easier access to a patient's HF record (for RA) and training ED doctors in the use of rapid, focussed echocardiography.

P1613

The Beacon patient management system for outpatient heart failure monitoring

FA Frank Mcgrew[1]; SC Sandra Harlton[1]; LLR Letitia Redden[1]; HS Norman[2]
[1]Stern Cardiovascular Foundation, Germantown, United States of America; *[2]Medtronic, Little Rock, United States of America*

Background: Acute Heart Failure (HF) management often results in expensive emergency room visits and hospitalizations. Remote patient managing systems could permit outpatient management of acute worsening of CHF with significant economic savings.
Purpose: Demonstrate how the use of the Beacon Patient Management System for outpatient HF monitoring can permit heart failure management in an outpatient setting and prevent emergency room visits and hospitalizations.
Methods: The beacon outpatient monitoring system uses transtelephonic monitoring of multimodality information, which can be integrated by the patient's physician and allied health personnel managers. The ability to monitor various components of the patient's status including heart rate variability, percentage of atrial and ventricular pacing, and thoracic impedance are utilized to "trigger" communication with the health care providers to permit resolution of HF rapidly and economically.
Results: A sample case of a 65 yo female with renal insufficiency, hypertension, multiple sclerosis, and severe systolic HF requiring intermittent inotropic infusions, and limited ambulatory status was monitored using the beacon system. Serial transmissions eventually showed her ventricular pacing declined, impedance index increased, and heart rate variability indicated clinical instability. As a result of these remote monitoring transmissions the patient was brought to an outpatient facility where her ventricular lead capture was reprogrammed to 100% pacing, atrial fibrillation frequency was treated with amiodarone and anticoagulation therapy, and milrinone infusions were adjusted from intermittent to continuous. Within two weeks beacon transmissions confirmed impedance index returned to normal, atrial fibrillation frequency dropped to zero, and ventricular pacing had risen to 100%.
Conclusions: The Beacon system offers a remote monitoring system, which is rapid and provides accurate assessment of a patient's HF status. This permits prompt changes in device programming, initiation or adjustment of anticoagulation, medication adjustments, and optimum scheduling of subsequent care. This not only provides a method with extreme patient acceptance, but also a major economic advantage. In this further use of remote monitoring can greatly enhance congestive HF management. The beacon management system transmissions information made it possible to easily treat clinically unstable symptoms in an outpatient setting ($300.00) resulting in considerable financial savings to the patient as compared to the high cost of an inpatient hospitalization ($4000.00).

P1614

Management features of postoperative right ventricular failure after tetralogy of fallot repair

S Sardor Ibragimov[1]
[1]Republican Specialized Centre of Surgery , Intensive Care Unit, Tashkent, Uzbekistan

Objective: The aim of the study was to develop the diagnostic and treatment algorithm for patients with right ventricular (RV) failure (RVF) in an early postoperative period after tetralogy of Fallot repair (TFR) in an Intensive Care Unit.
Methods: We studied early postoperative period of 48 patients who underwent TFR during 2015. In 6 patients the postoperative period was complicated by the development of RVF. After surgery, all patients received on prolonged mechanical ventilation. Data of hemodynamics and echocardiography served as diagnostic criteria of postoperative RVF. Drug therapy includes the use of vasopressor and inotropic agents. Oxygen therapy was in accordance with the concepts of "safe ventilation", "safe hypoxemia", and by using different modes of ventilation.
Results: One of the most important principles in managing postoperative RVF is to be able to maintain systemic blood pressure while minimizing RV dilation. Other important principles include reducing RV afterload, minimizing blood transfusions and optimizing ventilator settings. It is also essential to tailor therapy to the specific etiology of postoperative RVF.
Norepinephrine combined with dobutamine showed good results in maintaining systemic blood pressure, increasing cardiac index and decreasing pulmonary pressure in patients with RV failure and hypotension associated with acute or chronic increased pressure in the pulmonary artery.
An inhibitor of phosphodiesterase - milrinone, at the same time having a positive inotropic action, and the ability to normalize the myocardium compliance, allowed to significantly increase the drug therapy efficiency of RVF.
Non-invasive respiratory support in CPAP mode (NiCPAP) is an effective method, which is in complex of adequate intensive and pharmacotherapy allows to quickly stabilizing the clinical condition, respiratory and hemodynamic status of patients with RVF after TFR.
Conclusions: Modern and comprehensive monitoring of cardiac hemodynamics in the early postoperative period allows to detect a RVF development after TFR, with the establishment of its causation.
Designed treatment algorithm of managing RVF after TFR allows to maximum use of the entire drugs' arsenal of hemodynamic correction and methods of respiratory support, and significantly improve a treatment outcomes of this serious complication.

P1615

The efficacy of urapidil in the treatment of acute heart failure complicated with hypertension in elderly patients

J Jing Gao[1]; QI Hua[1]; XIAO H Liu[2]
[1]Xuan Wu Hospital, Capital Medical University, department of cardiology, Beijing, China People's Republic of; *[2]Yuquan Hospital of Tsinghua University, Cadre ward, Beijing, China People's Republic of*

Objective: To assess the efficacy of urapidil in the treatment of acute heart failure complicated with hypertension in elderly patients.
Methods: 140 cases of acute heart failure complicated with hypertension in elderly patients were randomized into urapidil or nitroglycerin group. All patients were monitored for systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR), situation at the time of before treatment,24h,48h,72h,7d after treatment,and contrasted to observe the changes in N-terminal pro-B-type natriuretic peptide raw (NT proBNP) and left ventricular ejection fraction LVEF in elderly patients with acute heart failure of urapidil at the time of before treatment, 48h and 7d after treatment.
Result: The level of SBP DBP and HR in urapidil group was significantly lower on hour 24,hour 48, hour 72 and day 7 after treatment than before treatment $P < 0.05$. The level of BNP in urapidil group was significantly lower on hour 48 and day 7 after treatment than before treatment $P < 0.05$. The level of LVEF in urapidil group

was significantly higher on day 7 after treatment than before treatment P < 0.05.The effect of urapidil was significantly lower than that of nitroglycerin on SBP P < 0.05).
Conclusion: The effect of urapidil is obvious on reducing and stabilizing SBPDBPHR and improving cardiac function in elderly patients with hypertension accompanying acute heart failure.

P1616

Utilization of mechanical ventilation in patients hospitalized for acute heart failure

M Monica Chivulescu[1]; L Antohi[1]; C Radulescu[1]; RI Radu[1]; C Macarie[1]; AP Ambrosy[2]; M Gheorghiade[3]; O Chioncel[3]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania; [2]Duke University Medical Center, Durham, United States of America; [3]Northwestern University, Chicago, United States of America

Background: During hospitalization for acute heart failure (AHF), in some patients hypoxemia may be too severe or may not be promptly improved by pharmacotherapies and these patients are emergently requiring invasive mechanical ventilation(IMV) via intubation. Although in this setting IMV may be a life-saving therapy, it is associated with an immediate decrease in cardiac output and later on with in-hospital complications including barotrauma and pulmonary infections.
Aim: To identify clinical variables independently associated to need of IMV during hospitalization for AHF.
Methods: The Romanian AHFS (RO-AHFS) registry prospectively enrolled 3224 consecutive patients admitted for AHF in 5 academic and 8 community hospitals, over a 12-month period. A multivariate logistic regression model was developed to identify baseline clinical variables predictive of in-hospital utilization of IMV.
Results: IMV has been performed in 113 (3.5%) of patients during hospitalization for AHF. Patients who required IMV had higher respiratory rate(RR) (30 +/-11 vs 21 +/-7;p = 0.006) and lower systolic blood pressure(SBP)(101 +/-22mmHg vs 143 +/-27mmHg;p < 0.001) at presentation compared to patients who did not require IMV.
A proportion of 43% of patients in IMV group were in cardiogenic shock (CS) at presentation, distinct to 3.9% CS in patients without IMV.
IMV has been associated to higher in-hospital mortality (24.7% vs 7.1%;p < 0.001) and with longer median length of stay(14 vs 6 days).
Using a multivariate logistic regression model, sodium at admission (HR=1.26;95%CI= 1.12-1.41), EF < 40% (HR=1.55;95%CI= 1.33-1.82), respiratory rate (HR=1.79;95%CI= 1.63-1.85), need of inotropic agents (HR=3.94;95%CI= 2.91-6.15) were found to be independent risk factors for need of IMV during hospitalization.
Conclusions: In present study, rate of MV utilization was lower compared to other registries. Clinical variables associated to hemodynamic abnormalities were highly predictive for subsequent utilization of IMV and may be useful for disposition decision-making pathways.

P1617

Clinical characteristics and outcome of decompensated heart failure patients according to ACE-inhibitor titration

R M Christodorescu[1]; IR Lala[2]; D Darabantiu[2]; A Pop-Moldovan[2]; AM Apostolescu[3]; M Trofenciuc[2]; S Dragan[1]
[1]University of Medicine Victor Babes, Timisoara, Romania; [2]Vasile Goldis Western University, Arad, Romania; [3]Institute of Cardiovascular Diseases, Cardiac Rehabilitation Clinic, Timisoara, Romania

Background and purpose: ACE inhibitors are currently the standard therapy for HF patients. The aim of the study was to evaluate in-hospital management and outcome of patients hospitalized with chronic decompensated heart failure according to ACE-inhibitors therapy.
Methods: In this study we evaluated consecutive patients, enrolled during 2015 in a county hospital with a primary diagnosis of decompensated heart failure. Patients were divided according to ACE-inhibitor therapy during hospitalization: group 1 (no initiation, maintained or lowered doses of ACE-inhibitors), group 2 (initiation or uptitration of ACE-inhhibitors doses). Both groups were evaluated at baseline and reevaluated at 6 months follow-up (heart failure rehospitalizations, death). For statistical analysis we used independent t test for comparison of continuous values, Pearson x^2 test for comparison of categorical values, and multivariate logistic regression for predictors of in-hospital mortality.
Results: A total of 109 consecutive patients (63%males) with chronic HF hospitalized for a decompensation episode were enrolled. Mean age was 66 ± 11 years and mean ejection fraction was 33 ± 13%. 63% of patients had no ACE inhibitor therapy at admission. Patients in group 1 (n = 69) had a significantly lower glomerular filtration rate)(60 ± 22 vs 69 ± 20 ml/mim, p = 0.024) than in group 2 (n = 40). Patients in group 1 had a lower SBP (131 ± 29 vs 146 ± 28 mmHg, p = 0.037) than in group 2. By logistic regression, at 6 months of follow-up, lack of initiation or lowering of ACE-inhibitors doses did not influence mortality while initiation or uptitration of ACE-inhibitor treatment proved to be a protective factor for outcome (p = 0.049, OR=0.2).
Conclusions: ACE-inhibitor initiation or uptitration during hospitalization for decompensated heart failure is safe and improves short-term outcome while no initiation or lowering doses does not influence the short-term outcome. ACE inhibitors are still underused in HF treatment and guidelines recommendations are not routinely followed for these patients.

P1618

Clinical inertia following discharge of patients with acute heart failure

E Berthelot[1]; JC Eicher[2]; M Saval[3]; P Degroote[4]; R Isnard[5]; T Damy[6]; JN Trochu[7]; E Donal[7]; M Galinier[8]; D Damien Logeart[1]
[1]AP-HP - Hospital Lariboisiere, Department of cardiology, Paris, France; [2]Hospital Bocage, Cardiology, Dijon, France; [3]University Hospital of Grenoble, Grenoble, France; [4]Cardiology Hospital of Lille, Lille, France; [5]Hospital Pitie-Salpetriere, Paris, France; [6]University Hospital Henri Mondor, Creteil, France; [7]University Hospital of Nantes Nord Laennec, Nantes, France; [8]Toulouse Rangueil University Hospital (CHU), Toulouse, France

On behalf of: OFICA

Background: after acute heart failure (AHF), most patients are often discharged early and before treatment is optimized. Thus, following months are critical for optimization of care. Using a cohort of patients admitted for AHF, we analyzed treatments at discharge, during the next 3 months and relationships with mortality in patients with reduced left ventricular ejection fraction (LVEF)
Methods: a single-day national HF survey was conducted in a sample of 170 hospitals. Clinical characteristics including LVEF as well as treatment at discharge and at 3 months were obtained. Vital status was also obtained at one year. Data was recorded during both hospitalizations and one-year follow up.
Results: early changes in HF treatment was recorded and analyzed in 275 patients admitted with AHF and LVEF ≤ 40% (age 72 ± 14y, 66% males). At discharge, ACE-I or ARB were prescribed in 80% with daily mean dose reaching 36 ± 31% of target dose, beta blocker (BB) in 70% with daily mean dose of 27 ± 51% of target dose, aldosterone antagonists (AA) were prescribed in 23% and loop diuretics in 88% cases. At 3 months, there was relatively few changes in rates of prescriptions as well as doses as compared to discharge: loop diuretics were started/increased and stopped/decreased in 7/25% and 6/7% of patients respectively, ACE-I or ARB in 6/21% and 9/7% respectively, beta-blockers in 8/23% and 8/8% respectively, and aldosterone antagonists in 7% and 5% respectively. All cause mortality at 12 months was 19% with differences according to prescription or not of ACE-I/ARB at 3 months (15 vs 29%, p = 0.002) as well as BB (15 vs 27%, p = 0.008). After adjustment on clinical characteristics, only the lack of ACE-I or ARB was related to mortality (OR 2.50 [95%CI 1.33-4.73], p 0.005).
Conclusion: individual treatments remain poorly optimized after discharge and such inertia impacts outcome. These results suggest a large room to improve HF management in the daily practice, especially in the post-discharge period.

P1619

Predictive factors for in-hospital mortality in patients hospitalized for acute heart failure and treated with iv inotropes

CI Radulescu[1]; L Antohi[1]; M Chivulescu[1]; I Cosei[1]; A Covaliov[1]; R Radu[1]; A Ambrosy[2]; C Macarie[1]; M Gheorghiade[3]; O Chioncel[1]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; [2]Duke University Medical Center, Cardiology, Durham, United States of America; [3]Northwestern University, Cardiology, Chicago, United States of America

Introduction: Although, intravenous inotropes/vasopressors are used in the initial management of patients with acute heart failure (AHF), their utilization is associated to increased short-term mortality.
Aim: We sought to assess clinical predictors of in-hospital mortality in patients hospitalized for AHF and who received intravenous (iv) inotropes/vasopressors during hospitalization.
Methods: The Romanian AHFS (RO-AHFS) registry prospectively enrolled 3224 consecutive patients admitted for AHF in 5 academic and 8 community hospitals, over a 12-month period. This is a post-hoc analysis of 571 (17.7%) patients who received inotropes and/or vasopressors during AHF hospitalization. A multivariate logistic regression model was developed to identify clinical variables predictive of in-hospital mortality.
Results: Inotropes/vasopressors administered in the registry were: Dobutamine (61%), Dopamine (45%), Noradrenaline (14%) and Levosimendan (2%). Differences in baseline characteristics based on utilization of inotropes are shown in Table 1.
In-hospital mortality in patients treated with inotropes/vasopressors was significantly higher compared to patients not requiring inotropes during hospitalization (23.8% vs 5.4%; p < 0.001).

Independent clinical predictors of in-hospital mortality among AHF patients treated with inotropes/vasopressors included: age (HR = 1.09, 95% CI 1.04-1.13), ischemic aetiology (HR = 1.42, 95% CI 1.14-1.73), QRS duration >120msec (HR = 1.78, 95% CI 1.54-1.93), non-academic clinical settings (HR = 1.91, 95% CI 1.74-2.23) administration for more than 24 hours (HR = 2.02, 95% CI 1.74-2.51).
Conclusions: Association between utilization of inotropic agents and in-hospital mortality reflects a complex relationship between cardiac electromechanical abnormalities and variation of indication in different clinical settings.

Table 1

	Inotropes/ vasopressors + (n = 571)	Inotropes/ vasopressors- (n = 2653)	P
Age(years)	71 + /-8	69 + /-9	0.02

Temporal trends in nitrate utilization for acute heart failure in elderly emergency patients: a single-centre observational study

N Najla Lemachatti[1]; B Bloom[2]; P Hausfater[1]; B Riou[1]; P Ray[3]; Y Freund[1]
[1]Hospital Pitie-Salpetriere, Emergency department, Paris, France; *[2]Queen Mary University of London, London, United Kingdom*; *[3]Hospital Tenon, Emergency department, Paris, France*

Background: We previously conted a pilot study that reported the safety of isosorbide dinitrate boluses for elderly emergency patients with acute heart failure syndrome.
Aims: To assess the temporal trend in the rate of elderly patients treated with isosorbide dinitrate, and to evaluate subsequent outcome differences.
Methods: This was a single-centre study. We compared patients aged > 75 years who attended the emergency department with a primary diagnosis of acute pulmonary oedema in the years 2007 and 2014. The primary endpoint was the rate of patients who received isosorbide dinitrate boluses in the emergency department. Secondary endpoints included in-hospital mortality, need for intensive care and length of stay.
Results: We analyzed 368 charts, 232 from patients included in 2014 (63%) and 136 in 2007 (37%). The mean age was 85 ± 6 years in both groups.There was a significant rate in the number of patients treated with isosorbide dinitrate between 2007 and 2014 : 97 patients (42%) in 2014 vs 24 patients (18%) in 2007 (p < 0,01). Comparing the two periods, we report similar in-hospital mortality rates (8% vs 11%, p = 0,5), rates of admission to the intensive care unit (13% vs 17%, p = 0,3) and lengths of stay (10 days in both groups).
Conclusion: We observed a significant rise in the rate of elderly patients treated with isosorbide dinitrate boluses for acute heart failure. However, we did not observe any significant improvement in outcomes.

On behalf of: Cardiovascular Emergencies and Critical Cardiology Council

Objetives: To analyze preferences of utilization of Pulmonary Artery Catheter and Echocardiography as monitoring tools in patients requering vasoactive drugs admitted to REINA registry.
Methods: Population: There were included patients over 18 years old admitted in 21 argentinean institutions due to vasoactive drugs requirements. REINA registry was a prospective, observational and multicenter evaluation with hemodynamic scenarios previously defined as: hypovolemia, cardiogenic, non septic distributive, septic distributive, mixed pattern (cardiogenic plus distributive), isolated right ventricle failure, left ventricle obstruction and hypotensive, normotensive and hypertensive hypervolemia.
Results: There were included 376 patients from 21 centers, with an average age of 66.1 years, being 77.4% of them males. The observed prevalence for each scenario and the use of pulmonary artery catheter and echocardiography were respectively: distributive non sepsis 30(7.9%)patients, 43.3% and 33.3%, distributive sepsis 16(4.2%)patients, 18.7% and 68.7%, isolated failure of right ventricle 10(2.6%) patients, 60% and 70%, hypertensive hypervolemia 39(10.3%) patients, 7.6% and 64.1%, hypotensive hypervolemia 22(5.8%)patients, 59% and 67.2%, normotensive hypervolemia 29(7.7%)patients, 13.7% and 79.3%, hypovolemia 82(21.8%)patients, 26.8% and 59.7%, left ventricle obstruction 1(0.2%)patient,100% and 100%, mixed pattern 36(9.5%)patients, 41.6% and 55.5% and cardiogenic 111(29.5%)patients, 47.7% and 71.1%.
Two hundred and eighty four cardiovascular patients presented with hypotensive states corresponding 112 of them to medical scenarios and 172to surgical ones. The pulmonary artery catheter was utilized in 56(50%) medical patients against 67 surgical (38.9%) ones (P=0.03) while echocardiography was used in 91 medical(81.2%) patients against 86 surgical (50%)patients (P < 0.0000001).
Conclusions: an elevated utilization of both methods was detected. The observed use of pulmonary artery catheter was largely over the referred numbers of the literature. In patients with hypotension it was observed a superior use of both methods in medical conditions over surgical ones.

P1622

Risk factors for in-hospital worsening heart failure in patients hospitalized with acute heart failure

CI Radulescu[1]; L Antohi[1]; M Chivulescu[1]; I Cosei[1]; A Covaliov[1]; R Radu[1]; A Ambrosy[2]; S Collins[3]; C Macarie[1]; O Chioncel[1]; M Gheorghiade[4]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; *[2]Duke University Medical Center, Cardiology, Durham, United States of America*; *[3]Vanderbilt University, Emergency Medicine, Nashville, United States of America*; *[4]Northwestern University, Cardiology, Chicago, United States of America*

Introduction: Although most patients hospitalized for acute heart failure (AHF) respond to standard therapy, a subset of patients may clinically decompensate and experience in-hospital worsening heart failure (WHF), placing them at substantial risk for in-hospital mortality.
Objective: To identify clinical variables associated with in-hospital WHF in patients hospitalized for AHF.
Methods: The Romanian AHFS (RO-AHFS) registry prospectively enrolled 3224 consecutive patients admitted for AHFS over a 12-month period. In-hospital WHF was defined as worsening of signs or symptoms of HF necessitating intensification of intravenous (IV) diuretics and/or initiation of IV vasodilators and/or inotropes, assisted ventilation, and/or mechanical circulatory support. Clinical predictors of in-hospital WHF were identified using multivariate logistic regression analysis.
Results: The incidence of in-hospital WHF was 16.1% and the majority of episodes occurred within 3 days of hospitalization. Patients experiencing in-hospital WHF tended to be older (72 ± 9 vs. 69 ± 11 years; p = 0.04), have an ischemic etiology of HF (59% vs. 55.8%; p = 0.05) and lower ejection fraction (35 ± 9 vs. 38 ± 10%; p < 0.001), and have a previous HF hospitalization within the last year (69% vs. 51%; p = 0.01). In-hospital all cuse mortality was higher in patients experiencing in-hospital WHF (8.8% vs. 7.1%, p = 0.03). Independent risk factors for in-hospital WHF included older age (HR = 1.02, 95% CI 1.01-1.09), an ischemic etiology of HF (HR = 1.31, 95% CI 1.12-1.54), left bundle branch block on admission ECG (HR=1.51; 95% CI 1.42-1.78), baseline serum Na + < 135mEq/l (HR = 1.68, 95% CI 1.24-2.03), and signs and symptoms of hypoperfusion at presentation (HR = 3.05, 95% CI 1.72-4.38).
Conclusions: In-hospital WHF occurred in 16.1% of patients hospitalized for AHF and was associated with higher in-hospital mortality. The ability of clinical variables readily available at initial presentation to risk stratify patients for in-hospital WHF should be studied prospectively.

Clinical outcomes of de novo and acute decompensated heart failure patients according to ejection fraction

KH Ki Hong Choi[1]; GY Lee[1]; JO Choi[1]; ES Ju[1]; YJ Lee[1]; ES Jeon[1]
[1]*Samsung Medical Center, Divison of Cardiology, Seoul, Korea Republic of*

On behalf of: KorAHF investigators

Funding Acknowledgements: This work was supported by Research of Korea Centers for Disease Control and Prevention [2013-E63003-00]

Purpose: To compare the outcomes of patients with de novo acute heart failure (AHF) or acute decompensated HF (ADHF) according to preserved ejection fraction (HFpEF, EF ≥50%), or reduced EF (HFrEF, EF <40%) and to define the prognosis of HF patients with a mid-range EF (HFmrEF, 40≤ EF <50%).
Methods: Between March 2011 and February 2014, 5,625 consecutive AHF patients were recruited from 10 university hospitals. A total of 5,414 (96.2%) patients with EF data were enrolled, which consisted of 2,867 (53.0%) patients with de novo and 2,547 (47.0%) with ADHF. Each of the enrolled group was stratified by EF (HFpEF, HFrEF, or HFmrEF).
Results: In de novo, all-cause death rates were not significantly different between HFpEF and HFrEF (adjusted hazard ratio [HR] 1.15, 95% confidence interval [CI] 0.96 to 1.38, p = 0.14). However, among ADHF patients, HFrEF had a significantly higher mortality rate compared to HFpEF (adjusted HR 1.25, 95% CI 1.06 to 1.47, p = 0.007). Also, in ADHF, HFmrEF was associated with a significantly lower mortality rate within one year compared to HFrEF (adjusted HR 0.76, 95% CI 0.60 to 0.96, p = 0.02), but a significantly higher mortality rate after one year compared with HFpEF (adjusted HR 1.42, 95% CI 1.05 to 1.93, p = 0.02).
Conclusions: HFpEF may indicate a better prognosis compared with HFrEF in ADHF, but not in de novo AHF. For ADHF patients, the prognosis associated with HFmrEF was similar to that of HFpEF within the first year following hospitalization and similar to HFrEF one year after hospitalization.

Prognosis of HFmrEF in ADHF

	HFmrEF	Comparison group	Adjusted HR(95% CI)	P value
Comparison with HFpEF (n = 996)				
All cause death	171 (44.6)	245 (40.0)	1.15 (0.94 to 1.42)	0.17
Death within 1 year	88 (23.0)	144 (23.5)	0.97 (0.73 to 1.28)	0.81
Death after 1 year (n = 764)	83 (28.1)	101 (21.5)	1.43 (1.05 to 1.94)	0.02
Comparison with HFrEF (n = 1934)				
All cause death	171 (44.6)	694 (44.7)	0.91 (0.77 to 1.09)	0.30
Death within 1 year	88 (23.0)	430 (27.7)	0.76 (0.60 to 0.96)	0.02
Death after 1 year (n = 1415)	83 (28.1)	264 (23.6)	1.14 (0.88 to 1.46)	0.33

CI = confidence interval; HFmrEF = heart failure mid-range ejection fraction; HFpEF = heart failure preserved ejection fraction; HFrEF = heart failure reduced ejection fraction; HR = hazard ratio

On behalf of: the GREAT Network

Purpose: To analyze hemodynamic alterations and 90-day mortality in cardiogenic shock (CS) complicated by acute kidney injury (AKI).
Methods: CS patients with serial plasma samples (n = 154) from the prospective CardShock study were included. AKI was defined according to the Kidney Disease: Improving Global Outcomes (KDIGO) criteria: >0.3 mg/L or >50% increase in creatinine from baseline value (AKI-crea) or urine output <0.5 ml/kg/h for 6 h (AKI-UO). Creatinine was analyzed from the plasma samples at baseline (0 h), 12 h, 24 h, 36 h and 48 h. Urine output was recorded in 6-h intervals until 24 h from baseline. Changes in mean arterial pressure (MAP), central venous pressure (CVP), and cardiac index (CI) over time until 96 h from baseline were compared between patients with and without AKI by linear mixed modeling. Poisson regression with robust variance was used to estimate relative risk (RR) of 90-day mortality in AKI adjusting for gender, systolic blood pressure and CardShock risk score.
Results: The mean age was 66 (12) years, 74% were men, and 81% had acute coronary syndrome as CS etiology. Median baseline creatinine was 1.11 (0.87-1.54) mg/dl. Overall, the 90-day mortality was 38%. The incidence of AKI-crea was 31% and of AKI-UO 50%. Differences in patient characteristics between AKI and non-AKI were few: AKI patients were older and they had worse renal function, higher lactate levels and lower arterial pH at baseline. Patients with AKI had higher 90-day mortality than those without AKI: 70% for AKI-crea vs 24% for non-AKI-crea (p < 0.001), and 46% for AKI-UO vs 29% for non-AKI-UO (p = 0.034). The association of 90-day mortality with AKI-crea, but not AKI-UO, remained after multivariable adjustment: RR 2.8, 95% CI 1.6-3.3 (p < 0.001). Figure 1 shows average values of MAP, CI and CVP within time intervals, and their evolution over time in patients with and without either AKI-crea (upper row) or AKI-UO (lower row). Overall, MAP and CI levels were constantly lower while CVP levels higher in patients with than without AKI (p < 0.05 for all pooled between-group comparisons).
Conclusions: AKI is frequent in CS and AKI-crea predicts a very poor outcome. Development of AKI is associated with persistent hemodynamic alterations reflecting venous congestion and hypoperfusion.

P1625

Impact of atrial fibrillation in hospital evolution of decompensated heart failure patients: Insights from CONAREC XVIII registry.

E J Zaidel[1]; GE Perez[1]; IM Cigalini[1]; M Galli[1]; M Altamirano[1]; LR Corradi[1]; M Bernal[1]; JC Jauregui[1]; DG Cornejo[1]; RMA Colque[1]
[1]*CONAREC. Argentine Council of Cardiology Residents., Buenos Aires, Argentina*

Introduction: Altough atrial fibrillation (AF) is a frequent arrhythmia in patients hospitalized for decompensated heart failure (HF), the information about its impact in prognosis is conflicting, and there is lack of information in this regard in Latin America.
Objective: The main objective was to analyze if chronic AF modifies hospital evolution (mortality, lenght of stay) of HF patients in a contemporary population from Argentina. A key secondary objective was to find clinical predictors of death in AF – HF patients.
Methods: An analysis of the database of the prospective registry CONAREC XVIII, developed by residents of cardiology from 64 centers from Argentina was performed. The baseline characteristics and hospital evolution were analized. The AF diagnosis and treatment before hospital admission was coded as "chronic AF", and first episodes of AF were excluded from the analysis. In a second time the factors related to hospital mortality in AF-HF patients were evaluated. The statistical analysis was conventional for descriptive and comparative analysis, and a multivariable model was developed to search for predictors of death. A p value of ≤ 0.05 was considered significative.
Results: Of 1160 consecutive HF patients recluted at 64 cardiology residency centers in two consecutive months, 415 (35 %) had chronic AF (AF group) and 745 did not (non-AF group).
The median age was 78 years in the AF group vs 70 in the non-AF group ($p\leq 0.01$). 43% in the AF group were female (vs 38 %, $p\leq 0.01$). The AF group had higher rate of HF with preserved ejection fraction (53 vs 38 %, $p\leq 0.01$), and the rates of all the comorbidities analyzed (renal failure, COPD, thyroid diseases) were higher in AF patients. No differences in the length of hospitalization (median 6 days in both groups) or in mortality (10.4% vs 11.8 % p = NS) were found: In the multivariable analysis, shock, renal failure, and prior use of digoxin were independent predictors of death in AF patients (OR= 6.59, 2.05, and 2.07, respectively, all $p\leq 0.05$).
Conclusion: Prior AF does not modify hospital evolution of decompensated heart failure patients. Patients with AF and HF represent a high-risk population, with higher rates of comorbidities, and among them, digoxin use was independently associated with hospital mortality.

P1626

Hyponatremia and long-term outcomes in heart failure

K Kaoutar Kharbouche[1]; I Elhaddad[1]; K Kharbouche[1]; R Habbal[1]; L Azouzi[1]
[1]*chu ibn rochd, cardiology, casablanca, Morocco*

Background: Hyponatremia (serum sodium [Na]≤135mmol/L) is a predictor of morbidity and mortality in patients with heart failure (HF), but the long term outcomes associated with hyponatremia are less clear. We aimed to evaluate the long-term outcomes of hyponatremic patients in a large HF cohort.
Methods: a descriptive study was carried from May 2008 to November 2014. 1600 patients presenting clinical and echocardiographic signs of heart failure and followed at the heart failure unit were included. Serum sodium measurement at the time of catheterization was used to assess sodium status. Baseline characteristics and outcomes for patients with hyponatremia were compared to those without hyponatremia. Kaplan-Meier survival estimates were generated out to 6 years, with a median follow-up time of 3.8 years in the study population.
Results: 1600 patients were enrolled. For the entire cohort median age was 61; 70% were male; median EF was 27%. 16% of the patients had hyponatremia. The hyponatremic group had significantly worse survival at 6 years (p = .0001).
Conclusion: Hyponatremia was associated with worse survival for HF patients in our cohort. Hyponatremia is an important risk factor for poor outcomes and a potential target for the development of new therapies

P1627

Survival in heart failure according to ejection fraction: the mid-range gains its place - seven years follow up.

L Lucas Celia Petersen[1]; B Donay[2]; E Magedanz[2]; VE Closs[3]; AV Azevedo[1]; NMB Kreuz[4]; LC Bodanese[1]; MH Miglioranza[5]; LC Danzmann[6]
[1]*Hospital Sao Lucas, Cardiology, Porto Alegre, Brazil*; [2]*Hospital Sao Lucas, Nursing, Porto Alegre, Brazil*; [3]*Hospital Sao Lucas, Nutricion, Porto Alegre, Brazil*; [4]*Lutheran University of Brazil, Cardiology, Canoas, Brazil*; [5]*Institute of Cardiology of Rio Grande do Sul, Cardiology / Echocardiography, Porto Alegre, Brazil*; [6]*Lutheran University of Brazil, Hospital Sao Lucas, Cardiology, Canoas, Brazil*

Introduction: Although ejection fraction may not be ideal to stratify heart failure (HF) patients, it has a historical importance to guide therapy and prognosis in clinical practice. Recently, the European Society of Cardiology defined a new HF category – the mid-range ejection fraction (EF). However, there may be few studies evaluating the long-term survival in this new category.
Purpose: To analyze characteristics and long-term survival in HF patients with mid-range (40-49%) EF in comparison with reduced (<40%) and preserved (>50%) EF categories.
Methods: A historical cohort from a registry of consecutive patients admitted with acute heart failure in a tertiary hospital from January 2009 to December 2011. The follow up time was 7 years. Categorical variables were compared with Pearson chi-square and continuous with ANOVA tests. A Kaplan-Meier survival curve was analyzed according to ejection fraction.
Results: Mid-range EF was present in 17%, reduced in 33% and preserved in 50% of the 381 patients analyzed. There was no statistical difference on comorbidities, presence of atrial fibrillation and causes of decompensation. Patients with preserved EF were older, mostly females, with non-ischaemic aetiology, admitted with higher blood pressure and had a smaller diastolic diameter. Patients with reduced EF were younger, mostly males, admitted with lower blood pressure and had a higher diastolic diameter. Ischaemic aetiology was similar between patients with reduced and mid-range EF (table). Survival was worse in patients with mid-range EF (mean 0,8 years with 95% CI 0,5 – 1,0) when compared with patients with reduced EF (mean 1,3 years with 95% CI 1,0 – 1,6)(P=0,027)(figure).
Conclusion: Patients with mid-range ejection fraction had worse survival when compared with patients with reduced EF in our preliminary analysis.

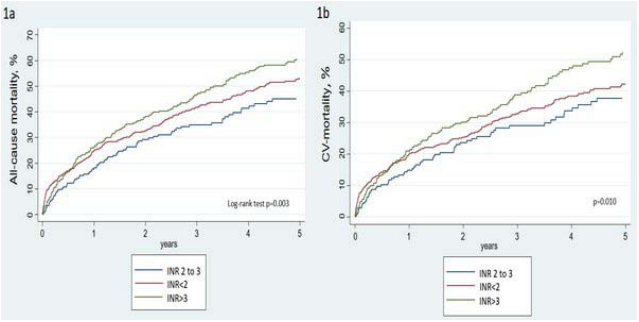
International normalized ratio at admission and mortality risk in patients with acute heart failure

E Enrique Santas Olmeda[1]; A Paya[1]; R Heredia[1]; J Gummel[1]; R Farcasan[1]; I Cardells[1]; E Valero[1]; D Escribano[1]; G Minana[1]; A Bayes-Genis[2]; J Lupon[2]; J Sanchis[1]; J Nunez[1]
[1]*Hospital Clinic Universitari. Universitat de València, Valencia, Spain*; [2]*Germans Trias i Pujol Hospital, Badalona (Barcelona), Spain*

Introduction: Anticoagulation control in heart failure (HF) patients on treatment with vitamin K antagonist (VKA) is often suboptimal, especially in the setting of acute HF (AHF). However, evidence regarding the prognostic value of international normalized ratio (INR) at admission in patients with AHF is scarce. In this work, we aimed to evaluate the association between INR and the risk of long-term mortality in patients with AHF treated with AVK.
Methods: In this observational study, we retrospectively assessed INR on admission in 1137 consecutive patients with AHF on treatment with acenocoumarol. INR was categorized according to the degree of anticoagulation quality: a) low-INR:<2, b) normal-INR: 2-3 and, c) high-INR:>3. Cox regression and Cox regression adapted for competing events were used for evaluating the association among INR categories and the risk of all-cause and cardiovascular mortality, respectively.
Results: Mean age was 74 ± 10 years, 51.1% were females, 62.4% showed left ventricular ejection fraction>50% and 50.2% were previously admitted for AHF. Median NT-proBNP was 4174 pg/ml (2450-7813). Normal, low and high-INRs were found in 660 (58%), 210 (18.5%) and 267 (23.5) patients, respectively. During a median (interquartile range) follow-up of 2.3 years (0.8-4.3), 568 (49.9%) patients died (74.8% of them of CV-etiology). Compared to patients with normal-INR, cumulative risk of all-cause and CV-mortality were higher for those patients belonging to low and high-INRs categories (Figure 1a and 1b, respectively). In multivariate analysis, both patients with infra and supratherapeutic INR showed an independent increase of risk of all-cause mortality (HR= 1.56, CI 95%:1.23-1.98, p = <0.001, and HR=1.52, CI 95%: 1.17-1.96, p = 0.002, respectively), and CV-mortality (HR= 1.40, CI 95%: 1.06-1.82, p = 0.016 and HR=1.30, CI 95%: 1.01-1.73, p = 0.045, respectively).
Conclusion: In AHF patients on treatment with AVK, INR<2 and >3 at admission are associated with higher risk of all-cause and CV-death. Further studies are warranted to clarify the pathophysiological mechanisms behind these findings.

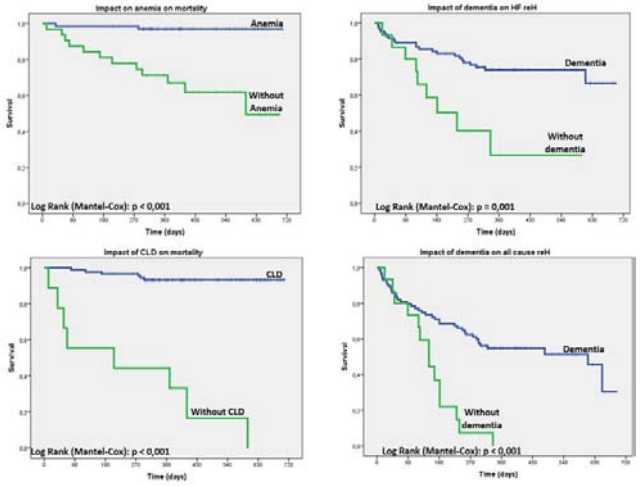


P1629

Comorbidities in heart failure patients: the impact on re-hospitalization and long-term mortality

J Agostinho[1]; P Alves[1]; J Rigueira[1]; I Ricardo[1]; T Guimaraes[1]; I Goncalves[1]; N Andre[1]; R Santos[1]; F Veiga[1]; M Pedro[1]; FJ Pinto[1]; D Brito[1]
[1]*Hospital Universitário de Santa Maria/CHLN, CAML, CCUL,Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*

Introduction: Hospitalization for heart failure (HF) is associated with high in-hospital and post-discharge mortality rates, regardless the documentation of a reduced or preserved left ventricular ejection fraction (EF). Comorbidities, particularly non-cardiovascular, have a major role in the post-discharge event rates of HF patients (pts), especially regarding readmissions (reH) and mortality, although these outcomes may not be necessary related.
Purpose: To evaluate the burden of comorbidities in long-term mortality and reH in pts discharged from hospital after an episode of acute/chronic decompensated HF (AHF).
Methods: Demographic, clinical, laboratorial and echocardiographic data of 100 pts consecutively admitted for AHF (cardiology ward, tertiary hospital center) and discharged alive, were retrospectively analyzed. The influence of comorbidities on post-discharge events occurring during the follow up was determined (Cox regression, Kaplan-Meier survival analysis and Mann-Whitney test, were applied).
Results: The included population (55% men, 68.3 ± 13.1 years) was followed during a period of 14.2 ± 5.5 months after hospital discharge. The post-discharge mortality rate (MR), HF reH, and all cause reH was 14%, 31% and 54%, respectively. The median number of comorbidities was 4 (2-6) per pt.
Anemia (HR= 12.7, CI= 1.99-81.5, p = 0.007) and chronic liver disease (CLD) (HR= 25.9, CI= 5.1-130.4; p < 0.001) were independent predictors of long-term mortality. Dementia was the only independent predictor of HF reH (HR= 2.9, CI= 1.3-6.8, p = 0.013), or all cause reH (HR= 2.5, CI= 1.2-4,9; p = 0.01).
In particular, in the subgroup of patients with preserved EF (n = 35), CLD was an independent predictor of long-term mortality (HR = 7.6; CI: 1.3-45.8; p = 0.027), and dementia was an independent predictor of HF reH (HR= 5.5, CI= 1.2-24.4, p = 0.025).
No independent predictors of mortality were found in pts with reduced EF or mid-range EF.
Anemia (p = 0.027), history of cancer (p = 0.023), CLD (p < 0.001), dementia (p = 0.002), previous stroke (p = 0.003), and the presence of more than 4 comorbidities (p = 0.026), correlated with the number of all cause reH.
Conclusion: The presence of multiple comorbidities correlate significantly with post-discharge adverse events in pts admitted to hospital with AHF. In this series, anemia and CLD were associated with increased mortality, and dementia with increased rate of reH. Noncardiovascular morbidities are related to the clinical course of pts with HF, some may be preventable, and need to be timely diagnosed and managed.



P1630

One month prognosis after decompensated heart failure through the assembly of artificial neural networks

J John Sprockel[1]; A Fandino[1]; W Chaves[1]; J Diaztagle[1]
[1]*Hospital San Jose, Medicina Interna, Bogota, Colombia*

Introduction: Heart failure is the main reason for hospitalizations in people aged 65+. Physicians usually overestimate the risk of death in these patients. The individual determinants of risk are not sufficient to determine an accurate global prognosis. Artificial intelligence has gained a position as an alternative to statistical tools, promising a better performance.
Objective Train and validate a system based on the assembly of a set of artificial neural networks for the prognosis of mortality one month after decompensated heart failure.
Methodology: Prognostic evaluation study based on a prospective cohort of patients that were admitted into the emergency service between 2010 and 2013 diagnosed with decompensated heart failure, aged 18+, who met the Framingham criterion. The population was divided into 70% (323 patients) for training and tests for the different neural networks and 30% (139 patients) for the validation of the assembly mechanism. The neural networks were trained using a genetic algorithm, its architecture consisted of 15 input variables, a hidden layer, and an output neuron. The 11 networks exhibiting the best performance in the tests were selected for assembly through three systems: simple voting, weighted voting by predictive values, and likelihood ratio. The operational characteristics were calculated for the

prognosis of death after 30 days and were compared with two clinical prediction rules and a logistic regression applied on the same population.
Results: The average age was 72.4, 51.9% were females, 80% had hypertension, 23.3% diabetes, and 87 coronary disease. 30 days mortality was 13,8%. The different methods of assembly exhibited better results in the prognosis than the individual networks that were part of them. Weighted voting by predictive values had the best global performance (See table).
Conclusion: The assembly of neural networks through weighted voting by predictive values showed satisfactory performance for the prognosis of death after 30 days in acute heart failure, improving the results obtained by two clinical prediction rules and a logistic regression.

Risk stratification post cardiac arrest: comparison of CASS (cardiac arrest survival score) and CAHP (cardiac arrest hospital prognosis) score.

M Manoj Thangam[1]; BH Hsi[1]; A Dasilva-Deabreu[1]; B Alhafez[1]; V Gacad[1]; A Dhoble[2]; Y Zhao[2]; S Arain[2]; K Charitakis[2]; HV Anderson[2]; R Smalling[2]; P Doshi[2]; P Balan[2]
[1]The University of Texas Medical School, Internal Medicine, Houston, United States of America; *[2]The University of Texas Medical School, Cardiovascular Medicine, Houston, United States of America*

Background: Mortality post cardiac arrest (CA) remains alarmingly high. Few prognostic tools have evaluated patients with return of spontaneous circulation (ROSC) post CA. Although the CAHP score has been utilized in this population, its cumbersome calculations have impaired wide spread adoption.
Methods: CASS- a novel prognostic score- was developed based on established CA risk factors and implemented via an easy to use web-application available on smart phones. This score was prospectively compared to the CAHP score in 43 patients who suffered CA with ROSC. The primary end point was in-hospital mortality. We evaluated the discrimination between both scores using the area under the receiver-operating characteristic (ROC) curve. Additionally, Hosmer-Lemeshow goodness-of-fit was used to determine calibration between CASS and CAHP score.
Results: The AUC were similar between CASS (AUC=0.63, 95% CI (0.45-0,81)) and CAHP (AUC=0.70, 95% (0.52-0.87)). Additionally, the calibration of CASS (p-.47) was better then CAHP ($p = 0.08$).
Conclusion: Both CASS and CAHP perform similarly in prognostication of mortality in patients post CA with ROSC. However, CASS offered additional benefits including ease of use, automated calculation, and inter-specialty communication via a downloadable web application.

Blood pressure variation and mortality from acute decompensated heart failure in case of first and second hospitalization

N Nabil Kraiem[1]; I Fomin[1]; DS Polyakov[1]; FY Valiculova[1]; AR Vaysberg[1]; MV Boldina[1]; NG Vinogradova[1]
[1]Nizhny Novgorod State Medical Academy, Department of internal medicine, Nizhny Novgorod, Russian Federation

Introduction: For patients with damaged target organs can be J or U dependence between blood pressure (BP) level and cardiovascular death (OPTIMIZE-HF register).
Purpose: evaluate systolic BP (SBP) and diastolic BP (DBP) and their changes between hospitalizations on patients prognosis with acute decompensated heart failure (ADHF)
Methods: Between July/2014 and July/2015, we studied a total of 852 hospital cases with ADHF. Patients cases were divided on quartiles (Q) depending from BP level: Q1 SBP≤120 and DBP≤75 mmHg; Q2 121≤SBP≤140 and 76≤DBP≤80mmHg; Q3 141≤SBP≤160 and 81≤DBP≤90mmHg; Q4 SBP≥160 and DBP≥90mmHg.
Results: The risk of hospital mortality had a negative correlation with Q SBP and Q DBP. The maximum risk level was in Q1. Median of time interval between hospitalizations was 104.5 days. At readmission to hospital, Q SBP decreased in 43.6% of patients and Q DBP decreased in 51.3% of patients. Q SBP and Q DBP remain without change in 34.6% and 25.6% of patients respectively. Q SBP and Q DBP increased in 21.8% and 23.1% of patients respectively. Hospital mortality was associated with decreased or not changing Q SBP and Q DBP. Were analyzed etiologies of chronic HF among different Q patients. We found that patients having lower Q SBP and Q DBP had much prevalence of target organs damage (myocardial infarction, dilated cardiomyopathy, chronic atrial fibrillation, valvulopathy, chronic obstructive pulmonary disease and asthma). Moving to higher Q SBP and Q DBP, the prevalence of hypertension, diabetes mellitus and non-complicated coronary artery disease had increased.
Conclusion: Patients with low Q SBP and Q DBP had a serious damage of target organs. Hospital mortality among patients with ADHF was significantly associated with the lowest Q SBP and Q DBP. At readmission, almost 50% of patients had a tendency to move at lower Q SBP and Q DBP, what increased the hospital mortality rate.

Quartiles (Q)	H. mortality for QSBP %	Increase of risk	H. mortality for Q DBP %	Increase of risk

Biomarkers in the prognosis of acute heart failure

M Manuel Lobo Gonzalez[1]
[1]University Hospital of Virgen Macarena, Cardiology, Seville, Spain

Recurrent heart failure (RHF) is a main problem in the heart failure specter, and every new event worsens the vital prognosis and the subsequent functional class. Develop strategies to early detentions of those patients at risk for RHF is critical. Biomarkers such as B-type natriuretic peptide precursor (pro-BNP), high-sensitivity troponin T (Tn-T), and C-reactive protein (CRP) assessed at discharge may be useful.
114 patients with heart congestive heart failure admitted to our coronary care unit and with pro-BNP, Tn-T and CRP measure prior to discharge were included. Patients within acute coronary syndrome evidences were excluded.The management of patients was made according to European Clinical Practice Guidelines.The primary endpoint was HF hospitalization at 3 months from discharge.
67 of 109 patients included were men, the mean age was 70 ± 15 years. The primary endpoint was observed in 22 patients (20,18%). Patients with the event were older (79 ± 6 vs 67 ± 4 years, p < 0.001) had more risk factors (hypertension 72% vs 49% p = 0.02; and diabetes 74% vs 32% p = 0,009),

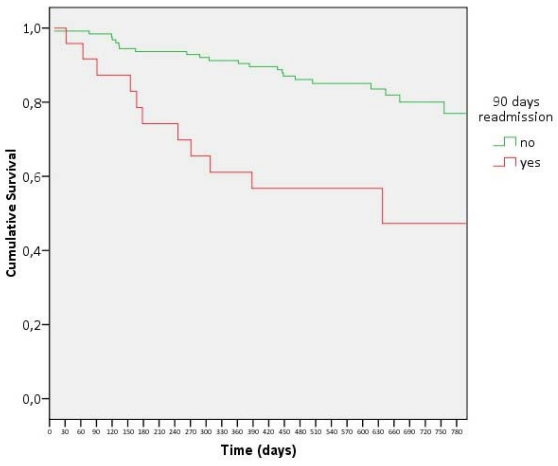
had more severe valvulopathies (78,5% vs 60,6% p = 0,02). No other significant differences in the clinical characteristics of the patients were found. Patients who presented the primary endpoint had higher levels of Tn-T (129,78[118,9-140,8]ng/L), pro-BNP(16.987,89[12.954-17.956]pg/mL), and also in CRP(89,12[78,76,09-98,01]mg/dL) compared to those patients without events (Tn-T 69,08[55,09-78,3]ng/L), pro-BNP(9.548,01[8.498-10.655]pg/mL, CRP(38[28,06-48,09]mg/dL)) p = 0.03, p < 0.001, p < 0.04 respectively).In the univariate analysis each one marker was associated with the occurrence of the primary endpoint at 3 months (odds ratio : 1.9 [1.1-2.1] , p = 0.002). This relationship remained in the multivariate analysis (OR 1.5 [1.2-2.1], p = 0.009)
Pro-BNP,Tn-T, and CRP assessed at discharge could be useful for early detection of patients at risk of recurrences and design a close follow-up after hospitalization. These suggestions should be validated in large studies.

P1634

Early readmission and poor prognosis in acute decompensated heart failure patients.

A Alfonso Varela Roman[1]; R Agra Bermejo[1]; I Gomez Otero[1]; R Gonzalez Ferreiro[1]; N Lopez Canoa[1]; C Abou-Jhok Casas[1]; M Moure Garcia[1]; A Blanco Seoane[1]; JR Gonzalez-Juanatey[1]
[1]*Clinical University Hospital. Service of Cardiology, Santiago de Compostela, Spain*

Background: despite the advances in management and improved prognosis of chronic heart failure (HF) in the past decades, patients with acute decompensated HF continue to have a high mortality and readmission rate, at 90 days post-discharge.
Purpose: the aim of this study is to evaluate the readmission rate at 90 days, the characteristics and the outcome of this group of patients.
Material and methods: we analyzed 150 consecutive patients (mean age 69,9 years, 61% men) admitted to a cardiology service for acute decompensated HF, 54 with previous HF hospitalization (36%), 116 with hypertension (HTA) (77%); 69 diabetic (DM) (46%); 140 class III or IV NYHA (93%), and 42 ischemic etiology (28%), with mean left ventricular ejection fraction (LVEF) 42,9%.
Results: at 90 days 24 patients (16%) were readmitted. This group of patients were more frequently men (79,2% vs 57,1%, p = 0,05); diabetic (66,7% vs 42%, p 0,027); with ischemic etiology (45,8% vs 24,6%, p = 0,034), previous cardiovascular disease (54,2% vs 27,0%, p = 0,009), and HF hospitalization (58,3% vs 31,7%, p = 0,013), compared with those without readmission. Also glomerular filtration rate (MDRD) (55,2 vs 72,2 ml/min/1,72m2, p = 0,007), plasmatic sodium levels (138,6 vs 141,0 mMol/l, p = 0,019), and NT-proBNP levels (10.269,7 vs 4.291,8 pg/ml, p < 0,001) were statistically different. Age, history of hypertension, NYHA III-IV class, heart rhythm, haemoglobin levels, LVEF were no statistically different.
After a mean follow-up of 18,3 ± 6,9 months, 34 patients died (22,7%), 11 (45,8%) in the readmitted group and 23 (18,3%) in the not readmitted group. The analysis by Kaplan-Meier curves, and log rank test, showed that these differences were statistically significant (p < 0,001) (Figure 1). Multivariate cox regression analyses showed that 90 days readmission (hazard ratio (HR): 3,82, CI 95% (1,78-8,24), p = 0,01); age (HR: 1,05, CI 95% (1,01-1,09), p = 0,024); and history of previous HF hospitalization (HR: 2,10, CI 95% (1,04-4,21), p = 0,037) were independent predictors of mortality.
Conclusions: early readmission is associated with poor prognosis in acute decompensated HF patients. This results underscored the need of reducing readmission with the aim of improving HF prognosis.



Kaplan-Meier curves (mortalitty)

P1635

Is there any difference between the new three groups of heart failure? A single center experience.

SM Pereiro Gonzalez[1]; SM Mettini[1]; DA Fernandez[1]; L Lapadula[1]; IL Ramella[1]; MG Masuelli[1]; G Sumay[1]; P Diaz Uberti[1]; C Cejas[1]; L Secco[1]
[1]*Hospital Center Churruca-Visca, Buenos Aires, Argentina*

Background: In 2016, the new European guidelines differentiate 3 groups in heart failure, those with ejection fraction (EF) over 50%, those between 40 and 49% and those with less than 40%. We analyzed if the middle group has any special difference between the others in our particular population.
Method: It is a prospective analysis of 474 patients admitted for decompensated heart failure, consecutively, in our Cardiology Department, from June 2012 to November 2016, with a median follow up of 26 months (Q1 13 - Q3 33). We divided 3 groups (G) according to their EF: G1 ≤39% (206 p), G2 40-49% (61 p) and G3 ≥50% (122 p). Quantitative variables with normal distribution were expressed with medium and with standard deviation (analyzed by test Fisher's Test); those with not normal distribution, were expressed with median (m) and quartiles (analyzed by Mann Whitney's Test). Dichotomous variables were analyzed by Chi^2.
Results: We observed the same median age between G1 and G2, but differences statistically significant (DSS) between G2 and G3 (p = 0.0059), with same amount of elders (>75 years old) in G1 and G2, but bigger with G3, and no DSS in gender. The main data found was there were no DSS between G in hospital follow up, but there were DSS between G2 and G1 in rehospitalization (p = 0.035, G1 25,5% vs G2 12,3%), but not with G3. The intermediate group appears to be similar to G1 in cardiovascular risk factors, previous infarction, clinical presentation, treatments and etiology of myocardiopathy. On the other hand, G2 is similar to G3 on hematocrit, renal function, the presence of LBBB, RBBB and treatment. The differences observed between G2 and G1 were the cause of decompensation (progression, p = 0.01 -G1 18,4% vs G2 5%-, and arrhythmias, p = 0.0482 -G1 10.2% vs G2 20%), the presence of hiper bilirubin (p = 0.01, G1 60,3% vs G2 41,7%), hyperthyroidism (p = 0.0000, G1 13,3% vs G2 22,2%) and LBBB (p = 0.0042, G1 36,3% vs G2 16,7%). The ones between G2 and G3, were age (p = 0.0059, G2 70 years old vs G3 77 years old), diabetes (p = 0.028, G2 39,3% vs G3 23,8%), history of infarction (p = 0.0092, G2 31,1% vs G3 14,8%), etiology (different to ischemic or valvular, p = 0.043, G2 13,1% vs G3 26,2%) and presence of sinus rhythm (p = 0.048, G2 64,4% vs G3 48,8%). None of the G had DSS in presence of previous devices, renal clearance, use of mechanical ventilation or non-invasive one and renal evolution.
Conclusions: We observed that in our population, patients with intermediate EF, 40-49%, are similar to both G in some characteristics, but on the evolution, they behave like those with normal EF.
We think we should compare both extremes into G2 (those near EF41% and those near 49%), but our sample is still too small.

P1636

Prognostic significance of B-type natriuretic peptide and pulmonary arterial pressure in patients with acute heart failure

D Petrovic[1]; M Deljanin Ilic[1]; S Ilic[1]; S Stojanovic[1]; D Marinkovic[1]; D Simonovic[1]
[1]*Institute for treatment and rehabilitation Niska Banja, Clinic for cardiology, Nis, Serbia*

Background: Natriuretic peptide has become the gold standard for diagnosis in patients with acute heart failure due to antifibrotic and antiproliferative actions. There are few studies that have investigated the significance of the parameters of the right ventricle in predicting the mortality of patients with ahf.
Purpose: To investigate association B-type natriuretic peptide (BNP) level with pulmonary arterial pressure (PAP) and to estimate their prognostic significance on one-year mortality in patients with acute heart failure (AHF).
Methods: The prospective study evaluated 225 patients (pts) (70.29 ± 9.74 years) who were admitted to Intensive care unit due to signs and symptoms of AHF during three years. The values of BNP were determined during the first 24 hours after admission in all subjects. Two-dimensional and doppler echocardiography was performed in all patients. Post-discharge mortality was observed one year. All medical therapy was documented, and for this analysis, we focused on the impact BNP, the right ventricular diameter, PAP on one-year mortality.
Results: Out of 225 pts, those with PAP < 40 mmHg (n = 104) had lower value of BNP, than pts (n = 121) with PAP≥40 mmHg (P < 0.001). Pts with right ventricular diameter ≤30 mm (n = 158) had lower value of BNP than pts (n = 67) with right ventricular diameter >30 mmHg (P < 0.001). Total one-year mortality was 34.7% (78 pts). As compared with the group of survivors (n = 147) the group of non-survivors had higher values of BNP (853.10 ± 384.92 vs 1399.68 ± 464.44 pg/mL, P < 0.001), right ventricular diameter (27.02 ± 3.93 vs 31.09 ± 5.60 mm, P < 0.001) and PAP (40.09 ± 8.24 vs 49.67 ± 10.65 mmHg, P < 0.001). There was a significant positive correlation BNP and PAP (ρ=0.255, P < 0.001) and BNP and right ventricular diameter (ρ=0.304, P < 0.001). After multivariate adjustment, using age, sex, body mass

index, blood pressure, right ventricular diameter as covariates, logistic regression analysis independent predictors for one-year mortality were: BNP (OR 1.003, CI 1.002-1.004, P < 0.001), and PAP (OR 1.099, CI 1.038-1.164, p < 0.001). The cut-off value of BNP≥ 1062.04 pg/ml was associated with a higher risk of one-years mortality (AUC=0.820, P < 0.001; sensitivity 74.4%, specificity 72.8%). The cut-off value of PAP≥44.5 mmHg was also associated with a higher risk of mortality (AUC=0.776, P < 0.001).

Conclusion: Our results show that BNP levels are strongly associated with pulmonary arterial pressure in hospitalized patients with acute heart failure. The most significant and independent predictors of one-year mortality are BNP and the PAP in patients with AHF.

The simultaneous application of echocardiography (parameters of right ventricular function) and laboratory biomarkers (BNP) in the early phase of hospitalization, can help fast and accurate diagnosis od AHF.

P1637

Impact of community-acquired pneumonia on prognosis of patients with acute decompensated heart failure.

N Nabil Kraiem[1]; I Fomin[1]; DS Polyakov[1]; AR Vaysberg[1]; FY Valiculova[1]
[1]*Nizhny Novgorod State Medical Academy, Department of internal medicine, Nizhny Novgorod, Russian Federation*

Introduction: Community-acquired pneumonia (CAP) is a factor that has to be taken into consideration when evaluating the prognosis of patients with acute decompensated heart failure (ADHF). NIS cohort (USA 2001-2009) showed pneumonia like most frequent comorbidity in patients with ADHF.

Purpose: evaluate CAP on prognosis of patients with ADHF

Methods: In one year period, was analyzed 852 medical records of patients hospitalized for ADHF.

Results: the prevalence of CAP among patients was 16.5% not age depending. Patients having decompensated heart failure and CAP had a longer hospitalization period (13.1 vs 11.9 days; p= 0,009), higher risk of readmission to hospital (OR 1.9; p = 0.02) and higher hospital mortality (OR 13.5; p < 0.001).The mortality at the first day of hospitalization was significantly higher when HF is associated with CAP.During one-year follow-up, the combination of ADHF and CAP makes the risk of death higher (OR 4.8; p < 0.001).

Conclusion: CAP is a factor worsening the one year prognosis and hospital prognosis of patients with acute decompensated heart failure.

Variable	CAP - %	CAP + %	P value
Male sex, %	57.3	38.7	< 0.001

Deterioration of renal function does not condition poor prognosis in acute decompensated heart failure patients with previous renal insufficiency

A Alfonso Varela Roman[1]; R Agra Bermejo[1]; I Gomez Otero[1]; R Gonzalez Ferreiro[1]; N Lopez Canoa[1]; CH Abou-Johk Casas[1]; A Seoane Blanco[1]; M Moure Gonzalez[1]; JR Gonzalez-Juanatey[1]
[1]*Clinical University Hospital. Service of Cardiology, Santiago de Compostela, Spain*

Background: renal insufficiency is one of the main prognostic factors in heart failure (HF). However, the prognostic value of worsening renal function during episodes of HF decompensation is controversial.

Purpose: the aim of this study is to analyse the rate of renal function impairment during acute HF episodes and its impact on prognosis depending on previous renal function.

Material and Methods: we analysed 150 consecutive patients (mean age 69,9 years, 61% men) admitted to a cardiology service for acute decompensated HF, 54 with previous HF hospitalization (36%), 116 with hypertension (HTA) (77%); 69 diabetic (DM) (46%); 140 class III or IV NYHA (93%), and 42 ischemic aetiology (28%), with mean left ventricular ejection fraction (LVEF) 42,9%. We classified the patients into two groups based on the glomerular filtration rate (MDRD) ≥ 60 or < 60 mL/min/1,73m2. Worsening of renal function was defined as the occurrence of both a > 25% and a > 0.3 mg / dL increase in serum creatinine from admission.

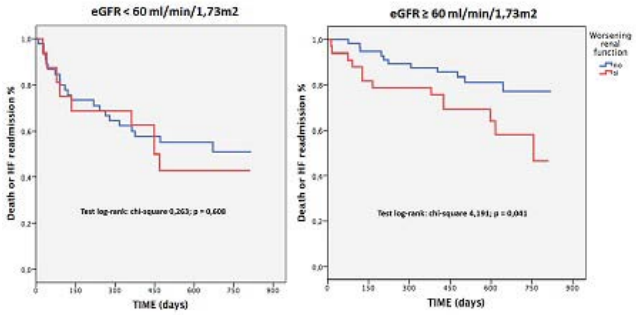
Results: 89 patients had MDRD ≥ 60 mL/min/1,73m2 and 61 patients had MDRD < 60 mL/min/1,73m2. When we compared the two groups we found that patients with MDRD < 60 mL/min/1,73m2 had more frequently previous HF hospitalization (45,9% vs 29,0%, p = 0,036), were less frequently treated with ACEIS/ARBS (82% vs 94%, p = 0,016), betablockers (70,2% vs 84,3%, p = 0,043), mineralocorticoid recpetor antagonists (78,7% vs 91%, p = 0,013), and more frequently treated with hydralazine (4,9% vs 0%, p = 0,035). Also they have lower levels of haemoglobin (12,6 ± 1,9 vs 13,5 ± 1,8 g/dL, p = 0,007) and higher levels of NT-proBNP (7822,86 ± 8448,81 vs 3474,45 ± 3966,87 pg/mL, p < 0,001).

Age, sex, history of hypertension, diabetes, NYHA III-IV class, ischemic aetiology and left ventricular ejection fraction were no statistically different between the two groups.

During the hospitalization worsening of the renal function was observed in 49 patients (32,7%): 16 (26,2%) in the group with MDRD < 60 mL/min/1,73m2, and 33 (37,1%) MDRD ≥ 60 mL/min/1,73m2 (p = 0,164).

After a mean follow-up of 18,3 ± 6,9 months, 54 (36%) patients had an event (exitus or HF readmission). In the MDRD < 60 mL/min/1,73m2 group, 30 patients (49,1%): 9 out of 16 (56,2%) who suffered worsening of renal function and 21 out of 45 (46,7%), without it, had an event. In the MDRD ≥ 60 mL/min/1,73m2 group 24 patients (27,0%): 13 out of 33 (39,4%) who worsening of renal function and 11 out of 56 (19,6%), without it, had an event. The analysis by Kaplan-Meier curves, and log rank test showed that these differences were only statistically significant in MDRD ≥ 60 mL/min/1,73m2 group (p = 0,041) (Figure 1).

Conclusions: Worsening of renal function is not associated with poor prognosis in acute decompensated heart failure patients with previous renal insufficiency.



Kaplan-Meier curves

On behalf of: the GREAT network

Introduction: Acute right ventricular (RV) failure is a complex clinical syndrome which has been poorly studied worldwide. So far just few data have been published on the incidence and characteristic of the RV dysfunction including its association with clinical outcomes, functional parameters of left ventricle (LV) and co-morbidities.

Purpose: To evaluate the association of longitudinal RV systolic dysfunction (RVSD) with 1-year rehospitalisations and deaths in patients with acute dyspnea; to study clinical findings and co-morbidities typical for patients having RVSD.
Methods: Prospective multicentre observational cohort study enrolled consecutive patients admitted to the emergency department in two university hospitals with acute dyspnea due to decompensated heart failure, exacerbation of chronic obstructive pulmonary disease, pneumonia, pulmonary embolism and other conditions. Demographic, clinical, echocardiographic data, co-morbidities and clinical outcomes of 307 patients were included in the analysis. Echocardiography was performed during the first 48 hours after the presentation to hospital. The longitudinal RVSD was defined by reduced tricuspid annular plane systolic excursion (TAPSE) of <17 mm. Rehospitalisations and deaths were assessed after 1-year follow-up period. For statistical analysis Mann Whitney U and Pearson Chi-Square tests were used. P-value < 0.05 was considered statistically significant. Kaplan-Meier curves illustrate the survival analysis.
Results: In analysed cohort mean age was 69.1 ± 12.3 years and 189 pts (61.56%) were female. The first (I) study group consisted of 166 (54.1%) patients with longitudinal RVSD; in the second (II) group 141 (45.9 %) patients had normal RV longitudinal function (TAPSE ≥17 mm).
Rehospitalisations and deaths in 1-year follow-up period occurred significantly more often in the group with longitudinal RV dysfunction than in group II: 37 (15.0 %) vs. 14 (5.7 %), (p = 0.002) and 11 (9.4 %) vs. 3 (2.5 %) (p = 0.029), respectively (Fig. 1).
Atrial fibrillation had a tendency to be more frequent in group I (84 [27.5%] vs. 50 [16.3%], p = 0.049), meanwhile the frequency of other co-morbidities (diabetes mellitus, arterial hypertension, chronic obstructive pulmonary disease, smoking, obesity) did not differ between the both groups (p>0.05). Heart rate at presentation was significantly higher (92.7 ± 26.0 bpm vs. 86.9 ± 21.2 bpm; p = 0.01) and pulmonary rales were more frequent (81 [26.4%] vs. 54 [17.6%], p = 0.033) in group I. Left ventricular ejection fraction was significantly lower in group I than in group II (33.1 ± 15.2 % vs. 44.4 ± 12.9 %, p = 0.006).
Conclusion: Patients with acute dyspnea and longitudinal RV dysfunction demonstrated significantly worse clinical outcomes with higher rate of rehospitalisations and deaths during 1-year follow-up, more severe LV dysfunction and unfavourable clinical profile.

Utility of bio-adrenomedullin (bio-ADM) and penKidephalin (penKid) in evaluating congestion grading and acute kidney injury in patients admitted for acute heart failure

S Navarin[1]; R Marino[1]; S Santarelli[1]; G Zoccoli[1]; A Bergmann[2]; O Hartmann[2]; J Struck[2]; S Di Somma[1]
[1]Faculty of Medicine and Psychology, Sapienza University, Sant'Andrea Hospital, Rome, Italy, Department of Medical Sciences and Translational Medicine, rome, Italy; [2]Sphingotec GmbH, Neuendorfstr. 15a, 16761 Hennigsdorf, Germany, Hennigsdorf, Germany

Background: Bio-Adrenomedullin (bio-ADM) and PenKidephalin (penKid) have already proved to be good predictors of short-term mortality and worsening renal failure respectively in patients with acute heart failure (AHF). No data are available so far on the utility of the combination of the two biomarkers in detecting congestion, acute kidney injury (AKI) and in-hospital mortality.
Purpose: In patients hospitalized for AHF, objective of this study was to assess the value of bio-ADM in grading total body congestion amount and of penKid in predicting AKI, main reasons of AHF worsening.
Methods: This was a prospective, observational trial conducted in intensive care unit. We enrolled patients admitted for AHF from the emergency department (ED) of Sant'Andrea hospital in Rome. Clinical and laboratory data including Clinical Congestion Score (CCS: peripheral edema, jugular vein distension and orthopnea), diuretic treatment, BNP, bio-ADM and penKid values were collected at arrival and patients were followed until hospital discharge.
Results: 209 patients with a final diagnosis of AHF were recruited (44% male, mean age 78.4 ± 9.5). 49.7% of patients had prior history of heart failure, 58% had reduced systolic function, 17% presented with pulmonary edema. 17,5% presented AKI at ED arrival, while 20.8% developed AKI, defined as serum creatinine (sCr) increase by 0.3 mg/dl within 48 hours after hospitalization. 22.6%, 38.1%, 21.4% and 17.9% of patients presented with a CCS of 0, 1, 2 and 3, respectively. Compared to patients with a CCS between 0-2, bio-ADM resulted higher in patients with a CCS of 3 (p = 0.01) and in patients with vena cava index >1 (p = 0.05), suggesting a potential role of bio-ADM in the detection of congestion, that is considered the main cause of death and re-hospitalization for heart failure patients. Moreover, higher levels of bio-ADM were linked to increase in furosemide treatment at home and to higher rate of in-hospital mortality, probably related to congestion amount (p = 0.002 and p < 0.001, respectively). PenKid values proved to be significantly related to the presence of chronic kidney dysfunction, AKI detection at ED arrival, and furosemide use (p < 0.001). When considering patients with both Cre >1 mg/dl and penKid > 80pmol/l at ED arrival, we were able to increase the detection of AKI.
Conclusions: In patients hospitalized for AHF, bio-ADM and penKid seem to be suitable biomarkers for early detection of congestion severity and AKI occurrence, respectively, and for risk prediction of in-hospital mortality. For AHF patients, the role of the two biomarkers in predicting in-hospital death seems to be linked to the pathophysiological mechanism of congestion for bio-ADM and of renal dysfunction for penKid, respectively.

P1641

Acute myocardial infeartion of complicated with heart failure in women

SM Macin[1]; G Aristimuno[1]; M Onocko[1]; ML Coronel[1]; ER Eduardo Perna[1]; DM Burguener[1]; F Falcon[1]; N Cristaldo[1]; Y Parisi[1]; G Pozzi[1]; N Chatich[1]
[1]J.F. Cabral Cardiology Institute, Corrientes, Argentina

Objective: To evaluate clinical characteristics and hospital evolution in women with acute myocardial infarction complicated by HF
Material and method: Prospective, observational study of of 328 patients with acute myocardial infarction admitted to the ICU of the Institute of Cardiology of Corrientes, between August 1, 2012 and May 20, 2014 within 24 hours of onset of symptoms, 91 pts were female, of which 22% had HF, representing group I: women with HF, and the remaining Group II. Group 1 (women with HF, 22%) and the remaining conform Group 2. Both groups were different in age (71.2 ± 10 vs. 68.8 ± 11years, p = 0.017), diabetes (50 vs 23.9%, p = 0.024), obesity (23.1 vs 16.2%, p = 0.04), cholesterol at admission (164.5 ± 54 vs 144.7 ± 25 mg / dl, p = 0.029), previous location (50 vs 29.4%, p = 0.012) and rales (40 vs 11.3, p = 0.003).
There were no differences regarding the use of angiopraphy (90.5 vs 92.6%, p = 0.40) and primary angioplasty (39.4 vs 41.7%, p = 0.10). Group 1 had more frequent death (35 vs 2.8%, p < 0.0001), pulmonary edema (26.3 vs 1.2%, p < 0.001), BCR (10.5 vs 2%, p = 0.008), Ventricular atrial block complete (25 vs 2.8%, p = 0.01), Sustained ventricular tachycardia (15 vs 2.8%,p = 0.04), required more invasive procedures such as hemodynamic monitoring (18 vs 6.1%, p = 0.01) and mechanical ventilation (4 vs 1.4%, p = 0.009), were more need Cardio-defibrillator (4.6 vs 0%, p = 0.32). Ejection Fraction was different in both groups (45 ± 18 vs 59 ± 12, p < 0.001). At admission were predictors of development to Heart Failure: anterior location (OR=3.15, 95% 1.5-5.7, p = 0.002), and diabetes (OR=2.8, 95% CI,1. 2-7.1, p = 0.023).
Conclusions: Women with acute myocardial infarction who develop HF are older, more obesity, had more frequency of diabetes, in spite of being treated in an invasive form in a similar way had worse in-hospital evolution. Anterior location and diabetes were independently predictors was development to HF

P1642

Do the gender differences in laboratory parameters in patients with myocardial infarction with acute heart failure influence on outcomes?

A Galyavich[1]; Z Galeeva[1]; L Baleeva[1]; E Kharisova[1]
[1]State Medical University, Kazan, Russian Federation

Background: It is the question of gender differences in laboratory parameters in patients with myocardial infarction with acute heart failure and outcomes.
Methods: In our study of 135 patients with acute heart failure were included - 56 women aged 74.4 ± 8.9 years and 79 men 59.6 ± 13.1 years. 52% men and women had inferior myocardial infarction. The levels of laboratory parameters have been analyzed: blood urea, creatinine, transaminases, cholesterol, low-density lipoproteins, prothrombin by Quick, thrombin time, the acid-base balance.
Results: Women with acute heart failure had significantly higher levels of aspartate transaminase, serum creatinine, low-density lipoprotein cholesterol. Men with acute heart failure had significantly higher levels of total bilirubin, activated partial thromboplastin time, thrombin time. In the group of women with acute heart failure was 6 deaths ((10.7%), in the group of men with acute heart failure were 3 deaths (3.8%). Regression analysis showed no relationship between the studied parameters and outcomes with the exception of age.
Conclusion: In patients with myocardial infarction with acute heart failure there are some gender differences in biochemical parameters, but they do not affect the outcomes. The main factor of poor prognosis of patients with myocardial infarction with acute heart failure is age.

P1643
High-dose loop diuretics at discharge is associated with cardiovascular mortality in patients with heart failure

T Toshitaka Okabe[1]; T Kido[1]; T Yakushiji[1]; Y Oyama[1]; W Igawa[1]; M Ono[1]; S Ebara[1]; K Yamashita[1]; MH Yamamoto[1]; S Saito[1]; K Amemiya[1]; N Isomura[1]; M Ochiai[1]
[1]*Showa University Northern Yokohama Hospital, Division of cardiology and cardiac catheterization laboratories, Yokohama, Japan*

Background: Few studies have reported on the impact of high-dose loop diuretics at discharge on prognosis in Japanese patients with heart failure (HF).
Purpose: Our purpose was to assess the relationship between loop diuretic dose at discharge and cardiovascular mortality in patients with HF.
Methods: We enrolled decompensated HF patients who were admitted to our hospital between April 2010 and March 2015. High loop diuretic dose was defined as >40 mg/day of oral furosemide at discharge. We compared HF patients that were received high-dose loop diuretics at discharge (HL group) with low-dose loop diuretics at discharge (LL group) with regard to risk of cardiovascular mortality, all-cause mortality, and the rate of readmission due to HF.
Results: A total of 301 patients with HF were admitted to our hospital. We excluded 13 patients who died during hospitalization and 73 patients who did not receive loop diuretics at discharge. The median follow-up duration was 631 days. Cardiovascular mortality was significantly lower in the LL group than in the HL group (2.3% vs. 25.0%, $P < 0.001$). In addition, all-cause mortality was significantly lower in the LL group than in the HL group (10.6 % vs. 32.1%, $P < 0.001$). High-dose loop diuretics was associated with cardiovascular mortality in multivariate Cox proportional hazards model (hazard ratio, 8.905, 95% confidence interval 2.5 to 42.1; $P < 0.001$). High-dose furosemide was also associated with all-cause mortality (P=0.01) and rate of readmission (P=0.039).
Conclusion: High-dose loop diuretics at discharge was a strong predictor of long-term cardiovascular mortality in patients with HF.

P1644
Acute heart failure: who die?

L Cardoso[1]; L Reis[1]; C Lourenco[1]; R Teixeira[1]; P Dinis[1]; M Madeira[1]; J Ribeiro[1]; L Puga[1]; A Rodrigues[1]; L Goncalves[1]
[1]*University Hospitals of Coimbra, Coimbra, Portugal*

Background: Acute heart failure (AHF) is characterized by its heterogeneity and complexity, being associated with both high morbidity and mortality. Despite multiple treatment options, mortality remains high.
Purpose and methods: From a population admitted to a cardiac intensive care unit, in the setting of AHF, the cases resulting in death were studied. Clinical parameters and therapeutic strategies were evaluated.
Results: 264 consecutive patients (P) (78% male, age 69 ± 14 years) were admitted along 6 years. The in-hospital mortality was 11% and during follow up was 36% (112 P - 80% male, age 73 ± 11 years). Hospital length of stay was 14 ± 11 days.
The most frequent aetiology of HF in the deceased P was ischemic heart disease. The median evolution time of HF was 6 years and 55% of those P had been previously admitted with decompensate HF. 48% had concomitant chronic kidney disease, 77% were hypertensive and 34% diabetic. 15% had an ICD and 3,8% a CRT-D.
At admission, 33% of P were in acute pulmonary oedema and 13% in cardiogenic shock. Infection was the precipitating factor in 36% of patients. Analytically: 54% had lower haemoglobin (< 12.0 g/dL); 48% had a lower glomerular filtration rate (GFR) (< 30 ml/min/1.73m2) and 39% had a GFR 30-60 ml/min/1.73m2; 30% of P had hepatic cholestasis and 15% hypoperfusion and NTproBNP 20 855 ± 23 703 pg/nl.
Transthoracic echocardiography showed LVEF < 35% in 46% of P and a restrictive pattern of filling in 23%; moderate/severe mitral regurgitation was present in 38%, and 52% had moderate to severe pulmonary hypertension.
Regarding therapy: furosemide infusion was used in 55%, being the maximum daily dose 294 ± 203mg, despite association with other diuretic; 42% were treated with levosimendan, 35% with dobutamine and 15% required noradrenaline. Non-invasive ventilation was used in 52% and invasive in 11%; renal replacement therapy was required in 12% of patients.
Hospitalization was complicated with cardiorenal syndrome in 62% and with hospital acquired infection in 54%.
The cause of death was end stage heart failure in 69% of P and infection in 31%.
Conclusions: Our study highlights the progressive deterioration of patients with chronic heart failure, being admitted several times previously to the final admission, when they present with multi-organ dysfunction. This population deserves a special look concerning how far we should go with them in escalating therapies, and when is it time to start palliative care.

P1645
Predictors of high Killip class after ST segment elevation myocardial infarction in the era of primary reperfusion.

L Vicent[1]; J Velasquez-Rodriguez[1]; MJ Valero-Masa[1]; F Diez-Delhoyo[1]; H Gonzalez Saldivar[1]; F Fernandez-Aviles[1]; M Martinez-Selles[1]
[1]*University Hospital Gregorio Maranon, Cardiology, Madrid, Spain*

Background/Introduction: Primary percutaneous coronary intervention (PCI) has improved outcomes after ST segment elevation myocardial infarction (STEMI), but patients with high Killip class still have a poor prognosis, and those ≥II benefit from a closer monitoring in a specialized cardiac care unit.
Purpose: We aimed to determine the predictors of Killip class in a group of patients admitted for acute STEMI.
Methods: Non-interventional registry in a Coronary Intensive Care Unit. Patients were consecutively included from January 2010 to April 2015. Multivariate analysis was performed to determine independent predictors of high Killip Class.
Results: From 1111 patients, 230 (20.7%) were in class II or higher. Mean age was 64.0 ± 14.0 years and 853 (76.8%) were male. Primary PCI was performed in 991 (89.2%), and 120 (10.8%) only received thrombolysis as acute reperfusion therapy. Independent predictors of high Killip class are depicted in table I. In-hospital mortality increased with Killip class (I 1.5%, II 3.7%, III 16.7%, IV 36.7%).
Conclusion: In patients with STEMI Killip class can be predicted with variables available at the time of presentation and is strongly associated with in-hospital prognosis.

Independent predictors of Killip Class>I

	Killip I, N (%)	Killip>I, N (%)	OR (95% CI)	P value Cox
Previous medical history				
Age >65 years	365 (41.4)	152 (66.1)	2.1 (1.4-3.0)	< 0.001
Female sex	180 (20.4)	78 (33.9)	1.6 (1.1-2.2)	0.017
Diabetes	166 (18.8)	72 (31.3)	1.4 (1.0-2.1)	0.05
History of heart failure	13 (1.5)	20 (8.7)	3.2 (1.4-7.2)	0.006
Chronic kidney disease	46 (5.2)	35 (15.2)	2.0 (1.1-3.6)	0.016

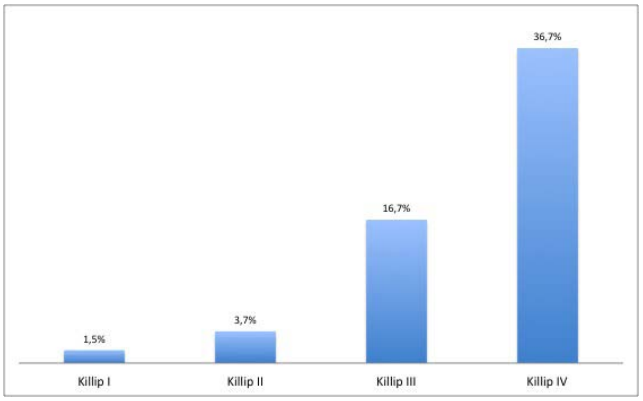
LVEF < 40%	148 (16.9)	129 (57.3)	4.6 (3.1-6.7)	< 0.001

OR: Odds Ratio; CI: Confidence Interval, LVEF: Left Ventricular Ejection Fraction. Chronic kidney disease: glomerular filtration rate <60 mL/h Anaemia: haemoglobin <12 g/dL in women and 13 g/dL in men



Mortality according to Killip Class

P1646

Lactate levels in patients admitted in the emergency department with acute decompensated heart failure

D David Cabrita Roque[1]; J Augusto[1]; A Sachetti[1]; D Faria[1]; A Gaspar[1]; L Melo[1]; T Bernardo[1]; J Simoes[1]; P Magno[1]; A Oliveira Soares[1]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal*

Background: Acute decompensated heart failure (ADHF) may lead to subclinical tissue ischemia due to hypoperfusion from inadequate forward flow or congestion. The aim of this study is to evaluate if the lactate levels are elevated in patients admitted in the emergency department with ADHF and if there is a relation between these levels and in-hospital mortality.
Methods: Retrospective study of 258 consecutive patients admitted in the emergency department for acute decompensated heart failure. We considered the lactate levels collected in the first medical contact. Profiles were assessed according to the recent guidelines.
Results: 196 patients had lactate levels collected after first medical contact (40.3% male, 75.2 ± 16.3 years). 67 (34.2%) had an elevated lactate level. Of the patients in profile B (wet and warm, n=189), 32.3% had an elevated lactate whereas of those in profile C (wet and cold, n=7), 85.7% had an elevated lactate ($p < 0.001$). There were no differences in hospital mortality among patients with and without elevated lactate levels (4.8% vs 6.1%, respectively, $p = 1.000$), nor in heart rate at admission (mean 93.5 vs 104.4bpm, respectively, $p = 0.440$) or maximum heart rate (mean 124.3 vs 109.8bpm, respectively, $p = 0.960$) during in-hospital stay.
Conclusion: Only one third of patients with ADHF had an elevated lactate on presentation, mainly those in the profile C, a known state of hypoperfusion ("cold"). However, there were no differences in hospital mortality between patients with and without elevated lactate on presentation, probably associated with the fast implementation of therapy in this patients.

P1647

Serum levels of exocrine pancreatic enzyme in patients with heart failure

M Masaru Hiki[1]; T Kasai[1]; S Yatsu[1]; H Matsumoto[1]; A Murata[1]; T Kato[1]; S Suda[1]; H Daida[1]
[1]*Juntendo University School of Medicine, Cardiovascular Medicine, Tokyo, Japan*

Background: Heart failure (HF) can damage systemic organs through the poor perfusion and/or congestion. Recently, interactions between HF and such other organs, especially lungs, kidneys and liver have been focused. However, there are no data regarding interaction between HF and exocrine pancreatic insufficiency which may impair fat and protein absorption and possibly cause malnutrition.
Hypothesis: We hypothesized that serum levels of exocrine pancreatic enzyme as suggestive of exocrine pancreatic function can be lower in patients with HF compared with those without HF, and that there are correlations between serum levels of exocrine pancreatic enzyme and indices of cardiac function in HF patients.
Methods: We collected serum levels of exocrine pancreatic enzyme such as amylase and lipase from patients who admitted to the cardiac intensive care unit (CCU) due to HF or to non-HF causes. Patients undergoing dialysis and those with neoplasms were excluded. Serum levels of amylase and lipase were compared between those two groups. Then, only in HF patients, stepwise multiple linear regression analyses including either natural logarithm transformed serum levels of amylase or lipase as a dependent variable and the other baseline characteristics, blood test and echocardiographic parameters as independent variables was carried out.
Results: Finally, data from 137 patients including 102 HF and 35 non-HF were analyzed. HF patients had significantly lower serum amylase (median [interquratile range], 54 [33] IU/L versus 68 [21] IU/L, P=0.001) and lipase (25 [21] IU/L versus 31 [16] IU/L, P=0.018) as compared with those without non-HF causes. Multivariable regression analysis in HF patients showed that the significant independent correlates of the lower amylase level were lower blood urea nitrogen (BUN) (coefficient, 0.552; $P < 0.001$) and albumin (coefficient, 0.233; P=0.020) levels, greater uric acid (coefficient, -0.328; P=0.001) and B-type natriuretic peptide (BNP) (coefficient, -0.227; P=0.024) levels, and that the significant independent correlates of the lower lipase level were the presence of atrial fibrillation (coefficient, 0.254; P=0.011), the lower BUN level (coefficient, 0.377; $P < 0.001$) and the greater BNP level (coefficient, -0.364, $P < 0.001$).
Conclusion: These findings suggest that HF patients may be suffering from exocrine pancreatic insufficiency in association with the severity of congestion, which may affect malnutrition.

P1648

Hyperadiponectinemia in de novo heart failure is associated with malnutrition

RM Rosa Maria Agra Bermejo[1]; R Gonzalez Ferreiro[1]; A Varela Roman[1]; I Gomez Otero[1]; E Alvarez[1]; M Rodriguez Manero[1]; S Eiras[1]; JR Gonzalez Juanatey[1]
[1]*University Clinical Hospital of Santiago De Compostela, Department of Cardiology, Santiago De Compostela, Spain*

Background: Adiponectin (ADPN) is an adipose tissue hormone that regulates energy metabolism and body composition with cardiovascular protector role. However, in heart failure (HF) patients, high adiponectin levels are paradoxically associated with advanced disease, elevated N-terminal pro B-type natriuretic peptide (NT-proBNP), and increased mortality.
Purpose: The aim of our study was to study the relationship between adiponectin levels and nutritional status in patients with de novo HF.
Methods: We analysed 78 patients admitted consecutively to a cardiology department for de novo HF. Patients were classified according to sex and adiponectin ng/mL levels in three groups: hypo- (Men, 0-11, Women 0-9), normo- (men; 11-20 and women 9-15) and hyperadiponectinemia (men>20, women>15). Nutritional status was measured with the CONUT method, a validated scale based on laboratory testing (albumin; cholesterol; lymphocytes) during hospitalization. The mean of follow up was 416 ± 256 days. Cox regression analyses were employed to calculate the estimated hazard ratio (HR) of death or readmission with 95% confidence interval (CI).
Results: Patients with hyperadiponectinemia had higher presence of hypertension, hyperlipidemia and worse nutritional status (moderate-severely malnourished 50%) compared with those with normo- (17%) or hypoadiponectinemia (33%), $p = 0.019$. We did not find differences regarding BMI among three groups. Moreover, patients with hyperadiponectinemia had worse renal function (creatinine= 1.2 ± 0.3 mg/dl, eGRF= 64.5 ± 22 ml/mi/m2) and lower insulin levels (259.2 ± 62.2 pg/mL) compared with those with hypo (creatinine= 1.0 ± 0.4 mg/dl, eGRF= 76.7 ± 28.5 ml/mi/m2, insulinemia 668 ± 509 pg/mL) or normoadiponectinemia (creatinine= 0.8 ± 0.2mg/dl, eGRF=97.4 ± 46.8 ml/mi/m2, insulinemia 855 ± 70.9 pg/mL) ($p < 0.005$). Also adiponectinemia is strongly related to nutritional status (r=0.411, $p < 0.001$) and proBNP levels (r=0.324, $p = 0.004$) but not with BMI (r=-0.098, $p = 0.394$). Hyperadiponectinemia patients had worse prognosis in terms of death or rehospitalization HR=1.755, CI 95% (1.13-2.77), $p = 0.012$.
Conclusions: In de novo HF, malnutrition state was associated with hyperadiponectinemia that determines a poor outcome in terms of death or rehospitalization.

P1649

Infective endocarditis complicated by heart failure

A Alaeddine Jalled[1]; MAJED Hassine[2]; MEJDI Ben Messoud[2]; MAROUA Mahjoub[2]; ZOHRA Dridi[2]; FETHI Betbout[2]; HABIB Gamra[2]
[1]*University of Tunis El Manar, cardiology departement, La Marsa, Tunisia*;
[2]*University of Monastir, cardiology A departement, Monastir, Tunisia*

Introduction: Despite the progress in the field of antibiotic and the respect for hygiene rules, endocarditis remains a common and serious disease. Heart failure is the most common but also the most serious complication, representing the leading cause of death identified in clinical and autopsy statistics. This heart failure is mainly related to valvular mutilation created by grafting infectious and hemodynamic disturbances
Patients and methods: From the infective endocarditis' register of our service comparing 241 patients and responding to criteria of DURAK DUKE university which collected retrospectively, we included patients with heart failure on admission, namely dyspnea greater or equal to NYHA stage 3. A total of 85 patients were enrolled in the heart failure and 156 in the infective endocarditis group without heart failure group.

Results: The average age of our patients was 42 ± 18 years. A male predominance was noted with a sex ratio of 2.14. Heart failure complicating infective endocarditis of native valve had occurred in 66 cases (77.6%). The preexisting valvular heart disease was the main underlying observed in 38 patients (44.7%).. On admission, 59 patients (69.4%) were in heart failure and heart regurgitation occurred in 29 cases 34.1%. The gateway was suspected in 66 patients (32.9%); the most frequently found was dental in 28 patients (32.9%). The multivariate study of predictors of heart failure occurred identified the following factors; the affected aortic valve, the presence of vegetation, the presence of Staphylococcus aureus and prosthesis disinsertion. Besides antibiotic treatment, 56 of our patients underwent surgical treatment with an average of 24.8 days. The indication for surgery was hemodynamics in 46 cases and septic in 10 cases. The total mortality in our registry was 19.5%, but higher in the group with heart failure (28.2%) with a significant difference p = 0.011. The realization of a multivariate analysis of independent determinants of mortality of infective endocarditis complicated by heart failure group concluded the significant influence of anemia (OR = 5, 95% CI = 0.8 - 27; p = 0.06), Staphylococcus aureus (OR = 5, 95% CI = 0.8 to 29.8; p = 0.07) and the protective role of surgery (OR = 0.15, 95% CI = from 0.025 to 0.99; p = 0.05).
Conclusion: Our results support the conclusion that heart failure remains an independent predictor of hospital mortality at 1 year. It is more common in infective endocarditis of mitral seat and she is associated with severe regurgitation. Early surgery is associated with reduced mortality and should be widely considered to improve results

P1650
Modified systolic index is an independent predictor of acute heart failure and in-hospital mortality in patients with ST-segment elevation myocardial infarction

PM Pedro Azevedo[1]; J Bispo[1]; D Bento[1]; T Mota[1]; D Carvalho[1]; J Guedes[1]; W Santos[1]; S Pereira[1]; J Mimoso[1]; N Marques[1]; I Jesus[1]
[1]*Faro Hospital, Cardiology, Faro, Portugal*

Introduction: Acute heart failure (AHF) and cardiogenic shock (CS) remains a dreadful complication of ST-segment elevation myocardial infarction (STEMI). In these patients, a modified shock index (MSI) ≥ 1.3 have been associated with higher mortality rates and AHF. Our study aims to assess the predictive value of MSI ≥ 1.3 for AHF, in-hospital mortality and 1-year mortality and hospitalization rate in patients admitted with STEMI.
Methods: Retrospective, descriptive and correlational study with all patients admitted with a STEMI in a Cardiology department between the 1st of October 2010 and 31st of August 2015. The baseline characteristics and hospitalization data of patients with MSI (heart rate / mean arterial pressure) ≥ 1.3 were compared to patients with a MSI < 1.3. The 1-year follow-up was made through phone call by a Cardiologist. We performed a univariate and multivariate statistical analysis of in-hospital mortality, mortality and hospitalization rate at 1-year using SPSS.
Results: A total of 1478 patients were included, 1138 (77%) were men with a mean age of 63,93 ± 13,39 years. A MSI ≥ 1.3 was present in 96 (6.5%) patients and was more common in females (10,9% vs 5,2%, p < 0,01) and older patients (65,6 vs 63,8 years, p = 0,2). It was also associated with diabetes mellitus, past history of stroke and dementia.
On admission, patients with a MSI ≥ 1.3 had more frequently an anterior MI (71,9% vs 41,1%, p < 0,001), atrial fibrillation (17,7% vs 4,1%, p < 0,01), a Killip Class ≥ 2 (49% vs 8,3%, p < 0,001) or CS (29,2% vs 1,7%, p < 0,01) and lower hemoglobin levels (13,3 vs 14,1, p < 0,001).
Patients with a MSI ≥ 1.3 had lower left ventricular ejection fraction (43,95% vs 56,46%, p < 0,001), more malignant arrhythmias (6,3% vs 1,6%, p < 0,01), and had less coronary catheterization (74% vs 87,4%, p < 0,001) and percutaneous coronary intervention (67,7% vs 82,2%, p < 0,001). They had more frequently left main occlusion (3,1% vs 0,5%, p = 0,002). There was no relation between a MSI ≥ 1.3 and other coronary artery disease.
These patients were more frequently treated with invasive mechanical ventilation (14,6% vs 3,0%, p < 0,001) and non-invasive ventilation (6,3% vs 0,7%, p < 0,001).
Regarding outcomes, a MSI ≥ 1.3 was strongly associated with in-hospital mortality (28,1%vs4,3%, p < 0,001) but not 1-year mortality (12,8% vs 7,1%, p = 0,15) or hospitalization rate (27,7% vs 17,2%, p = 0,07). On multivariate statistical analysis, a MSI ≥ 1.3 was a strong independent predictor of AHF at admission or during hospitalization (OR 3.66 95% CI 1.7-8.1, p = 0,001) and in-hospital mortality (OR 4.48, 95% CI 1.8-11.1, p = 0,001).
Conclusion: In our study, a MSI ≥ 1.3 was a strong independent predictor of AHF and in-hospital mortality among STEMI patients, although it was not associated with 1-year outcomes. It is an easily accessible tool that can help identify more critical patients and monitor them more closely during hospitalization.

P1651
Hypertonic saline solution in the management of severe decompensated heart failure in the elderly

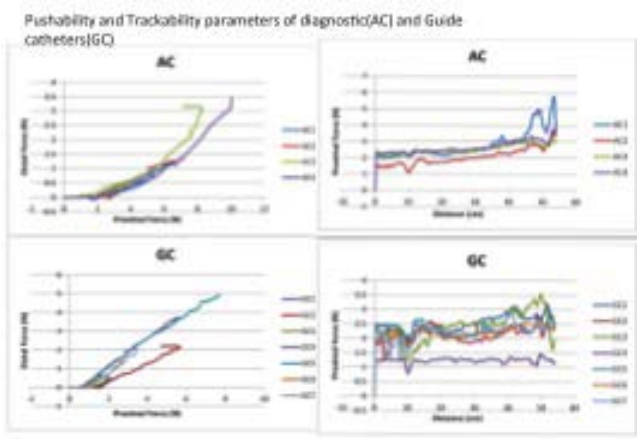
GR Gerald Roul[1]; JJVH Von Hunolstein[1]
[1]*New Civil Hospital, Cardiovascular Medico-Surgical Activities, Strasbourg, France*

Introduction: Low plasma sodium level is frequent in heart failure and is a marker of bad prognosis. Its treatment with hypertonic saline solution has been proposed in previous studies.
Aim: In this study, we compared the outcomes of low plasma sodium level associated with heart failure treated as usual or using hypertonic saline.
Methods: This is an observational, retrospective and single centre study from 2013 to 2015. We included patients admitted for heart failure with low plasma sodium level at entry or treated with hypertonic saline solution during hospitalization.
Results: 167 patients (78 years; 45% of women) were included: group 1 (n = 156 usual care), and group 2 (11 patients treated with hypertonic saline solution). Group 2 patients had a higher BNP and a worse kidney function. Hypertonic saline solution normalized plasma sodium level (137 ± 7 mmol/L vs. 129 ± 3 mmol/L; p < .007), decreased body weight (median 73 kg vs 80; p < .008). Compared to group 1, group 2 patients had a prolonged length of stay (median 21 days vs. 10 days). The hypertonic saline solution group had a high morbidity and mortality rate (odds ratio = 6.8 for mortality or being hospitalized during the 2-year period of the study) explained by the severity of these patients' condition.
Conclusion: Our study does show a benefit of the hypertonic saline solution to rapidly correct sodium level, with kidney function preservation. It underlines the bad outcomes associated with low plasma sodium level. A large-scale randomized controlled study should be realized to conclude.

P1652
Primary and emergency angioplasties with 30 ml contrast using cordis 6F diagnostic coronary catheters and bench evaluation of catheters

MC Mark Christopher Arokiaraj[1]
[1]*Pondicherry Institute of Medical Sciences, Pondicherry, India*

Aims: To safely perform primary and emergency angioplasties with low contrast volume using cordis 6F diagnostic catheters. To perform bench evaluation of cordis guide and diagnostic catheters with 3-bend test, distal tip softness and pushability and trackability tests.
Methods and Results: In 53 patients primary angioplasty, pharmaco-invasive and emergency angioplasties were performed with cordis 6F diagnostic catheters. Angioplasty and stenting was performed in left anterior descending (25), Left main (2), left circumflex (10), ramus (3) and right coronary artery(13) arteries and in total 61 stents were used. The contrast volume was kept to the minimum with only required pictures, which is the routine for the operator. This is to reduce contrast induced nephropathy as well as hemodynamic problems and cardio-renal syndromes. In 75% of cases Iodixanol was used. All injections were given by hand. Regular follow-up of the patients was performed at 30 days. The procedures were performed in femoral route only. Pre-dilatation was performed in 12 cases with semi-compliant balloons (2 mm x 10 mm and lesser sizes) and in 1 case, 2.5 x 10mm in one patient. In cases with difficulty in wire crossing balloon-mediated wire crossing was performed where in the balloon and wire were taken to the tip and with gentle manipulation the wire crosses the lesion. The length of the stents varied from 12 mm to 28mm, and the diameter of the stent varied from 2.25 mm to 4.0 mm. IVUS and OCT were not performed. Aspirin, clopidogrel, tirofiban and low molecular weight heparin were used in appropriate doses. Successful revascularisation of the target lesion was achieved in all cases. No mortality was observed at 30 days. The mean contrast volume was 30ml (± 10ml). Contrast induced nephropathy was observed in only one patient. Cardiogenic shock was seen in 2 cases, which was successfully managed with inotorpes, and IABP support was kept as backup. Distal vessel spasm was seen in 4 cases, which were managed with low dose of nitrates. Mild pulmonary edema was seen in 5 cases, which were managed with medications. Ventilator support was not required in any cases. Mild distal stent edge dissection was seen in one case and it was managed with a stent. Groin hematoma was seen in one case requiring blood transfusion. Distal vessel dissection was seen in one patient, which was managed with additional stent. Rise in creatinine (from 1.3 to 1.8 mg/dl) was seen in only one patient, which subsided in few days. Bench evaluation of the cordis guide and diagnostic catheters was performed with 3-bend tests, distal tip flexion tests and pushability and trackability. The results showed balanced parameters with diagnostic catheters compared to guide catheters.
Conclusions: Emergency angioplasty can be performed safely in patients using diagnostic catheters using low volume of contrast. Low contrast volume usage would result in lower incidence of contrast induced nephropathy and cardiac failures.



P1653

Liver function tests in patients admitted with acute decompensated heart failure

D David Cabrita Roque[1]; J Augusto[1]; A Sachetti[1]; D Faria[1]; A Gaspar[1]; L Melo[1]; T Bernardo[1]; J Simoes[1]; P Magno[1]; A Oliveira Soares[1]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal*

Background: Episodes of acute decompensated heart failure (ADHF) can affect multiple organs in an unfavorably way, which may have an adverse impact on outcomes. We aim to analyze the prevalence and implications of abnormal liver function tests (LFT) in patients during hospitalization for ADHF.
Methods: Retrospective study of 258 consecutive patients admitted in the emergency department for ADHF. The liver function tests included aspartate aminotransferase (AST) and alanine aminotransferase (ALT), which were evaluated during hospitalization (maximum values of AST and ALT) and at discharge. The cut-off values were those used by the central laboratory of our hospital (AST 15-37 U/L and ALT 12-78 U/L).
Results: The prevalence of abnormal LFT (above upper limit of normal for AST and ALT) was: during hospitalization AST 34.5%, ALT 14.3%; and at discharge AST 11.2%, ALT 6.2%. Abnormal LFT during hospitalization were associated with a higher risk of in-hospital death (12.4 vs. 0.8%, $p < 0.001$ for AST, 13.5 vs 3.8%, $p = 0.032$ for ALT).
Conclusions: Abnormal LFTs are frequent in ADHF during hospital stay and predict worse outcomes, probably in association with a state of more severe hypoperfusion and/or the use of drugs that affect the liver function. However, whether this association is causal and what are the true underlying mechanisms involved require further study.

P1654

Symptoms and signs of heart failure in patients presenting with acute decompensation who were receiving contemporary guidelines recommended therapy

Y Yuksel Cavusoglu[1]; ME Altinbas[1]; F Mutlu[1]
[1]*Eskisehir Osmangazi University, Eskisehir, Turkey*

Purpose: Evidence-based guidelines recommended therapy improves not only survival, quality of life and functional capacity in heart failure (HF), but it also improves symptoms and signs of HF. In general, symptoms and signs of acute decompensated HF have been reported in all comers admitted to the hospital regardless of having HF medication. In this study, we aimed to evaluate symptoms and signs of HF in patients presenting with acute decompensation who were receiving contemporary guidelines recommended therapy.
Methods: In this descriptive study, 446 patients admitted to the hospital with the diagnosis of acute decompensated HF, NYHA III-IV, LVEF $< 40\%$ and >18 years of age who were receiving contemporary guidelines recommended therapy were included in the analysis and HF patients' clinical characteristics, background therapy and signs and symptoms have been evaluated.
Results: Mean age of HF population was 67 ± 12 years. Comorbidities were CAD, previous MI, hypertension, diabetes, COPD and chronic renal disease in 68.6%, 55.3%, 60.1%, 41.9%, 29.9% and 35.9% of the cases respectively. 24.7% had atrial fibrillation. Mean EF was $25.4 \pm 7.9\%$, NT-proBBNP was 7667 ± 9876 pg/mL, creatinine level was 1.41 ± 0.88 and hemoglobin level was 12.4 ± 2 gr/dL. During admission, the use of beta blocker, ACEI/ARB, MRA, diuretic, ivabradin and digoxin were 93.7% (n = 418), 68.6% (n = 306), 46% (n = 205), 38.6% (n = 172), 12.8% (n = 57) and 21.1% (n = 94) respectively. At the time of initial presentation, 87.4% of patients (n = 390) reported dyspnea, 49.6% (n = 221)- ortopnea, 40.8% (n = 182)- paroxysmal nocturnal dypnea, 39.9% (n = 178)- dizziness, 37.7% (n = 168)- palpitation and 35.2% (n = 157)- chest discomfort. In terms of signs of HF, Juguler venous distension was found in 21.5% (n = 96) of patients, peripheral oedema- in 50.4% (n = 225), pulmonary crepitations- in 54% (n = 241), S3- in 11.7% (n = 52), S4- in 3.8% (n = 17), cardiac murmur- in 41.5% (n = 185), cold extremities- in 10.8% (n = 48), asites- in 18.2% (n = 81) and pleural effusion- in 22.2% (n = 99).
Conclusions: These results suggest that despite to high rates of the use of contemporary guidelines recommended HF therapy including diuretics, the most prevalent symptoms and signs in acute decompensation are still systemic and hemodynamic congestive symptoms and signs, in which dyspnea is the most frequently seen symptom and peripheral oedema and pulmonary crepitations are the most frequently sings of acute decompensated HF in current clinical practice.

P1655

Relationship between early drop in systolic blood pressure through the first 24 hours during admission and worsening renal function in patients with acute heart failure

T Kido[1]; T Okabe[1]; Y Oyama[1]; M Ono[1]; W Igawa[1]; S Ebara[1]; K Yamashita[1]; M Yamamoto[1]; S Saito[1]; K Amemiya[1]; T Yakushiji[1]; N Isomura[1]; H Araki[1]; M Ochiai[1]
[1]*Showa University Northern Yokohama Hospital, Division of Cardiology and Cardiac Catheterization Laboratories, Yokohama, Japan*

Background: Worsening renal function (WRF) is associated with poor prognosis in patients with heart failure (HF). We hypothesized that early drop in systolic blood pressure (SBP) is associated with WRF in patients with acute HF.
Purpose: Our purpose was to identify predictors of WRF including early drop in SBP.
Methods: We retrospectively investigated predictors of WRF in patients hospitalized for acute HF between April 2010 and March 2015. WRF was defined as a relative increase in serum creatinine of at least 25% or an absolute increase in serum creatinine ≥ 0.3 mg/dL from the baseline. SBP was measured at baseline and each 4 hours and early drop was defined as drop in SBP within first 24 hours.
Results: A total of 301 patients with acute HF were enrolled. The mean age was 71 ± 14.5 years and 56% were male. WRF occurred in 118 patients (39%). Univariate Cox regression analysis showed that early drop in SBP (odds ratio (OR), 1.018 per 1 mmHg; 95% confidence interval (CI), 1.010 to 1.026; $P < 0.001$), age, hemoglobin level, dose of intravenous furosemide, inotropic agents, and tolvaptan were associated with WRF. Multivariate Cox regression analysis showed that early drop in SBP (OR, 1.023 per 1 mmHg; 95% CI, 1.012 to 1.035; $P < 0.001$), inotropic agents (OR, 4.77; 95% CI, 1.809 to 13.45; P=0.002) and tolvaptan (OR, 2.96; 95% CI, 1.392 to 6.43; P=0.005) were associated with WRF.
Conclusion: Early drop in SBP may be one of the predictors of WRF in patients with HF.

P1656

Heart rate reduction and diastolic function in patients with decompensated systolic heart failure and left bundle branch block

D Darabantiu[1]; R Lala[1]; A Pop Moldovan[1]; RM Christodorescu[2]
[1]*Vasile Goldis Western University, Arad, Romania*; [2]*University of Medicine & Pharmacy Victor Babes, Timisoara, Romania*

Background and purpose: Patients with systolic heart failure and left bundle branch block (LBBB) have more severe diastolic dysfunction than patients without LBBB. Recent experimental studies have suggested that increased heart rate aggravates diastolic dysfunction in patients with LBBB. The purpose of our study was to evaluate the effect of heart rate reduction on diastolic function in patients with decompensated systolic heart failure and LBBB.
Methods: This prospective study recruited 50 consecutive patients admitted for decompensated heart failure, with left ventricular systolic dysfunction, sinus rhythm and heart rate > 70 b/min under guideline medical therapy, in whom heart rate reducing therapy with ivabradine was initiated. Patients were divided into 2 groups: group 1 (n = 22) with LBBB and group 2 (n = 28) without LBBB. For both groups echocardiography was recorded at baseline and after 6 months of ivabradine therapy. Parameters of diastolic function (mitral E velocity, E/A ratio, e' velocity, E/e' ratio, E deceleration time) were assessed and compared for both groups. Clinical characteristics and concomitant heart failure therapy were also assessed in both groups. Statistics: data were expressed as mean $\pm$ standard deviation or

percentages, comparisons between baseline and follow-up data were done with Student's paired and unpaired t test.
Results: Mean age was 64 ± 13 years in group 1 and 57 ± 11 years in group 2, heart rate at baseline was 88 ± 9 b/min in group 1 and 90 ± 9 b/min in group 2 (p = 0.4). After 6 months heart rate decreased to 68 ± 12 b/min in group 1 and 73 ± 10 b/min in group 2. Echocardiographic changes of diastolic function parameters in both groups of patients are illustrated in the table below. Concomitant heart failure therapy was similar in both groups. Mean ivabradine dose at 6 months was 11 ± 3 mg/day in group 1 and 10.8 ± 3 mg/day in group 2 (p = 0.6).
Conclusion: In patients with decompensated systolic heart failure, LBBB and sinus rhythm, heart rate reduction with ivabradine seems to improve diastolic function at 6 months.

	Group 1 (LBBB +)		Group 2 (LBBB-)			
	Baseline	Follow-up	Differences(p)	Baseline	Follow-up	Differences(p)
E velocity (cm/s)	84±24	75±24	0.09	85±20	80±21	0.4
E/A ratio	1.7±1.1	1.1±0.8	0.02	2.1±1.1	1.5±1.1	0.1
e' velocity (cm)	5.6±1.5	6.8±1.6	0.03	6.4±1.7	7.4±1.6	0.2

CHRONIC HEART FAILURE

P1657
Asymptomatic left ventricular dysfunction is a predictor of short and long-term mortality among patients with myocardial infarction in southeast Asia: Is there a difference between gender?

J Jakrin Kewcharoen[1]; V Kittipibul[1]; P Suttirut[1]; V Lertsuwunseri[1]; S Srimahachota[1]; A Ariyachaipanich[1]
[1]*Chulalongkorn University, Bangkok, Thailand*

Background: Decreased left ventricular ejection fraction (LVEF) is associated with worse outcomes in patients with ST-elevation myocardial infarction (STEMI). However, little is known about this association in developing countries.
Purposes: The aim of the study was to evaluate the impact of LVEF on mortality rate in patients undergoing primary percutaneous coronary intervention (PCI) and its differences between gender.
Methods: We conducted a retrospective study of all patients with a diagnosis of STEMI who underwent primary PCI at a tertiary care hospital in Thailand from January 2011 to December 2015. Patient characteristics, treatments, and outcomes were gathered. T-test, and Chi-square were used to analyze.
Results: A total of 755 patients (mean age 60.2 ± 13.6 years, 74.8% male, 55.4% hypertension, 30.8% diabetes mellitus and 70% dyslipidemia) were included. Mean LVEF was 50 ± 13%. The LVEF was ≥50%, 35-49% and < 35% in 53.4%, 33.1% and 13.4% of patients. The 30-day mortality rate was higher in patients with LVEF between 35-49% and <35% (Odd ratio 2.3 and 8.4, p = 0.02 and < 0.001, respectively). There were also statistically significant higher 6-month and 1-year mortality rates in patients with lower LVEF. At baseline, the LVEF was not different between male and female (49.7 ± 13.7 vs 50.9 ± 14.3, p = 0.30). LVEF < 35% was associated with 30-day, 6-month and 1-year mortality in both male and female patients (p < 0.05 for all).
Conclusions: In this single center experience, LVEF appeared to be a predictor of short-term and long-term outcomes among patients with STEMI who underwent primary PCI in Thailand. The effect of LVEF on mortality rate was relatively the same between gender.

P1658
Clinical features of patients with heart failure with very reduced ejection fraction (hfvref)

EJJ Eduardo Julian Jose Chuquiure[1]; J Oscar Fiscal-Lopez[1]; R Nayeli Isidro-Hernandez[1]; L Ana Marin-Mejia[1]; N Frida Rodriguez-Quiroz[1]; N Gabriela Mendez[2]; J Maria Jose Chuquiure Gil[3]
[1]*Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico*; [2]*Universidad del estado de México, Medicina, ciudad neza, Mexico*; [3]*Instituto Tecnologico de Estudios Superiores de Monterrey, Escuela de Medicina, Monterrey, Mexico*

Purpose: At present the diagnostic criteria of Heart Failure include patients with Left Ventricular Ejection Fraction (LVEF) less than 40%. But in our Unit we detected a population with very low ejection Fraction (<25%) (HFvrEF). The principal purpose is to describe a patients with HFvrEF.
Material and method: We analyzed consecutively Mexican patients from Heart Failure Clinic of the Instituto Nacional de Cardiología. All over 18 years old, both genders with clinical, laboratory and Imaging Diagnosis according 2016 European and AHA-ACC clinical Guidelines. Both Groups based on LVEF criteria: HFvrEF: LVEF < 25% and HFrEF : LVEF >25.1% -40%. We determine retrospectively: Natural History, Clinical characteristics, follow-up from diagnosis, pharmacological treatment, hospitalizations and re-admissions. For statistical difference we declare p value equal or less than 0.05.
Results: According criteria, we describe 109 patients with HFvrEF and 131 with HFrEF. HFvrEF ranges were 8 -25%. Both groups were homogeneous in: General characteristics, Gender, Obesity Rate, Sinus rhythm, Diabetes,Hypertension, Dyslipidemia, Smoker History, Myocardial Infarction and BMI. More Valvular Heart disease patients were seen in HFvrEF group. Transplant and LVAD program were not available for patients.
Mean Follow-up: HFvrEF : 5.80 + 0.63 years (2mo-17.56 y) vs HFrEF: 6.16 + 0.78 years (3mo -18.53y), observing annualized re-hospitalization rates 18.34 vs. 11.80 (OR 1.68 ,p < 0.05). Admissions to Emergency Room (greater than 2) were more frequent in HFvrEF group 5.50% vs. 3.47%. Also in HFvrEF group compared to HFrEF group, a higher event rate was observed at follow up in: Renal Failure (3.67% vs. 1.38%), Dialysis (1.83% vs. 0.69%), PTCA (11.93% vs. 10.42%) and CABG (1.83% vs. 0.96%).
According with new recommendations of 2016 guidelines our therapeutics pattern included: Sacubitril/Valsartan (HFvrEF 16.51% vs HFrEF 6.94%) and Ivabradine (HFvrEF 3.67% vs HFrEF 2.08%).
Conclusions: Of our experience we propose Heart failure Group with Very Low ejection Fraction, Observed under exclusively pharmacological treatment for a mean period of 5.80 years. We determined a higher index of clinical events. We suggest the need to evaluate long-term clinical characteristics such as the new therapeutic strategy.

P1659
Heart failure with mid range ejection fraction (HFmrEF): a retrospective observational study in a single centre in the eastern province of Saudi Arabia

MM Alqaseer[1]; SM Abouzobeida[1]; ZA Al Naser[1]; MA Allwaim[1]; M Hussain[1]; B Mushannen[1]; M Alkharasani[1]; U Ismail[1]
[1]*King Fahad Specialist Hospital, Cardiology Department, Dammam, Saudi Arabia*

Background: The recent ESC/HFA heart failure guidelines have introduced a new suggested classification, where patients are divided into three categories: heart failure with reduced Ejection Fraction (HFrEF), preserved EF (HFpEF), and mid range EF (HFmrEF). The new entity described as HFmrEF includes patient with an EF between 40 and 49%. There is scarcity of research describing this cohort of patients. To better understand this particular patient population, we have analyzed all the heart failure patients in a single center in the Eastern Province of Saudi Arabia who qualify as HFmrEF.
Methods: Retrospective observational study looking at consecutive patients with heart failure who had an echocardiogram done between January 1st and December 1st 2015 with an ejection fraction quantified between 40 and 49%. Demographic data of those patients were collected along with their comorbidities, risk factors, and anti-failure therapies, if any.
Results: 348 patients with HFmrEF were identified. 52.58% were male. Out of 348 patients, 146 were diabetic, constituting 41.95% of the total population. The majority of the patients, 71.26% of the cohort, were hypertensive. 40.51% had renal impairment, defined by an eGFR < 60. 41.09% of the patients had received cardiotoxic cancer therapies and were labeled as chemo-induced cardiomyopathies. With regards to medications, 61.20% were on BB, 56.60% were on ACE-i/ARB, and 18.39% were on MRA. 43.1% were on diuretic therapies. The majority of the patients that were on anti-failure therapies were those with a lower EF ranging between 40-44%.
Conclusion: We present our descriptive data of patients with HFmrEF in a single institution in the astern province of Saudi Arabia. The sample might not be representative as our center is a tertiary cancer and renal transplant facility that may account for the large prevalence of chemo-induced cardiomyopathy and renal impairment. Interestingly, the patients with EF of 40-44% are the ones that are predominantly receiving the conventional anti-failure therapies and treated in a similar fashion to HFrEF patients. Further follow up studies are needed to assess their outcomes.

P1660

A systematic review of clinical prediction rules for the diagnosis of chronic heart failure in the community and their validation in a novel cohort

J Gallagher[1]; D Mccormack[2]; S James[1]; S Zhou[1]; C Keane[1]; C Watson[1]; M Ledwidge[1]; K Mcdonald[1]
[1]University College Dublin, Dublin, Ireland; *[2]University College Dublin, gHealth Research Group, Dublin, Ireland*

Background: Early diagnosis of heart failure in the community may be hampered by lack of access to diagnostics. Clinical predication rules, which have been included in diagnostic guidelines, may help rationalise access to diagnostics for those who are most likely to have heart failure.
Purpose: This study sought to review the literature for clinical prediction models for the diagnosis of patients with heart failure in the community. It also sought to validate the models in a novel cohort of patients with a suspected diagnosis of heart failure referred to a rapid access diagnostic clinic from the community.
Methods: MEDLINE and EMBASE were searched from 1946 to Q2 2016 followed by hand searches of retrieved reference lists, and consultation with experts in the area. Studies were eligible if they contained at least one multivariable model for the diagnosis of chronic heart failure. Studies relating to acute heart failure were excluded. We also sought to validate the models in a novel cohort of patients with a suspected diagnosis of heart failure referred to a rapid access diagnostic clinic.
Results: In total, 5055 articles were identified with nine articles subsequently meeting the eligibility criteria. Three models had undergone internal validation and four had undergone external validation. No clinical impact studies have been completed to date. Area under the curve (AUC) varied from 0.74 to 0.93. Four rules were validated in a novel cohort. AUC varied from 0.60 to 0.65 in the novel cohort for clinical models alone with AUC up to 0.89 in combination with ECG and BNP. The AUC for B-type natriuretic peptide (BNP) was 0.86 (95% confidence interval 83.3%-88.6%).
Conclusion: This review demonstrates that there are a number of clinical prediction rules relevant to the diagnosis of heart failure in the literature. Clinical impact studies are required to compare the use of clinical prediction rules and biomarker strategies in this setting.

P1661

Test-retest-Reliability of explorative measurement of CEC and EPC from peripheral blood in patients with systolic and diastolic heart failure, diabetic nephropathy and arterial hypertension

J Wagner[1]; M Farinnaci[2]; S Beckmann[1]; S Litmeier[1]; F Weisrock[1]; M Fritschka[3]; S Radenovic[1]; D Djawid Hashemi[1]; E Tahirovic[1]; B Pieske[1]; W Dinh[2]; HD Duengen[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Department of Internal Medicine and Cardiology, Berlin, Germany; *[2]BAYER Pharma AG, Wuppertal, Germany*; *[3]German Heart Institute of Berlin, Department of Cardiology, Berlin, Germany*

Background: We distinguish between HF with reduced ejection fraction (HFrEF, LVEF < 45%) and preserved EF (HFpEF, LVEF≥45% and echocardiographic evidence of diastolic dysfunction).HF in particular is the most common reason for elderly for hospitalization and its prevalence is rising.
Circulating endothelial cells (CEC) and endothelial progenitor cells (EPC) have been described as new non-invasive markers of endothelial damage. They are measureable in peripheral blood and correlate with other markers of endothelial function. Therefore, CEC and EPC can depict the presence and extent of vascular damage.
Ability to estimate, quantify and observe changes in CEC and EPC levels reliably will open new doors in the screening, treatment and follow-up of patients with heart failure and other cardiovascular diseases.
However, uniform procedures to isolate and determine the number of CEC still have to be established.
Aim: We carried out a test-retest-study in which we applied the same method of estimating CEC levels twice and compared the results.
Methods: Endo-CEC was an observational trial in HFrEF patients, HFpEF patients, patients with diabetic nephropathy and patients with arterial hypertension. Blood samples were obtained from in total 101 patients and CECs and EPCs were determined in the peripheral blood from 25 HFpEF patients, 25 HFrEF patients, 25 patients with diabetic nephropathy and 26 patients with arterial hypertension.
To evaluate the test-retest-reliability blood was taken at two points of time and CEC and EPC levels were estimated and expressed both in CEC/EPC per ml and as a percentage of peripheral blood mononuclear cells.
Results: Out of 101 patients included in this analysis, 25 had Diabetic nephropathy of which 21 (84%) were male and 4 (16%) were female, out of 25 HFrEF patients, 20 (80%) were male and 5 (20%) were female. In the group of HFpEF patients, 15 (60%) were male and 10 (40%) were female while the group of arterial hypertension was evenly distributed with 14 (54%) men and 12 (46%) women.
Comparing the CEC/ml and CEC/PMNC levels of the visits, no correlation between the two visits could be detected (ICC CEC/ml: 0.077; ICC CEC/PMNC 0.19).
The intraclass correlation of EPC measurements was statistically significant in each group (EPC/ml: Arterial Hypertension: ICC=0.683; DiabNeph; ICC=0.946; HFpEF: ICC=0.665; HFrEF: 0.946).
Conclusion: This method of determining the number of CEC via flow cytometry is not reliable to use it as a prognostic marker or follow-up-parameter for the treatment period of heart failure or diabetic nephropathy patients.
Therefore, there is still need to enhance the method of measuring CECs by identifying disturbing factors or reasons.
As understanding and estimating the occurrence of CEC and EPC promise high potential for further treatment and supervision of heart failure and other diseases associated with endothelial dysfunction, there is absolute necessity to do further research.

P1662

Time trends in the use and appropriateness of natriuretic peptide testing in primary care

F H Frans Hendrik Rutten[1]; MJM Valk[1]; NP Zuithoff[1]; BJ Broekhuizen[1]; A Mosterd[1]; AW Hoes[1]
[1]University Medical Center Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands

Diagnosing heart failure (HF) is difficult, relying on medical history, symptoms and signs only. Clinical guidelines recommend natriuretic peptides (NPs) as an additional diagnostic test, notably to exclude HF in suspected patients. NP testing is available since 2003 for primary care in the Netherlands, but little is known about its uptake.
Aim: To evaluate the trend in ordering and appropriateness of NP testing in primary care.
Methods: An observational study performed between January 2005 and December 2013. Nine Dutch general practices participated, with 21,000 registered persons (≈4,300 aged 65 years and over). The total number of patients undergoing NP testing each year was calculated per 1,000 patient years (PY) based on the total practice population. NP-levels were used to assess whether NP-testing was applied to exclude or confirm HF.
Results: The number of NP testing increased from 2.5 per 1,000 PY in 2005 to 14.0 per 1,000 PY in 2013, with a peak in 2009 of 15.6 per 1,000 PY. The proportion of subjects with NTproBNP below 125 pg/mL (the exclusionary threshold recommended by the European Society of Cardiology HF guidelines) was on average 30%, and highest in the first year with 47%.
Conclusions: After a rapid uptake of NP testing in primary care from 2005 onwards, the use of it seemed to stabilize after 2009. Although guidelines recommend NP testing to rule out heart failure, the percentage of patients with NTproBNP < 125 pg/mL suggests that GPs use it more often as a confirmatory test.

P1663

Non-invasive monitoring of peripheral and cardiac influence on exercise limitation in patients with heart failure with preserved ejection fraction

SB Beckmann[1]; F Weisrock[1]; M Fritschka[2]; J Wagner[1]; D Djawid Hashemi[1]; E Tahirovic[1]; S Radenovic[1]; A Busjahn[3]; B Pieske[1]; T Krahn[4]; W Dinh[4]; HD Duengen[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Department of Internal Medicine and Cardiology, Berlin, Germany; *[2]German Heart Institute of Berlin, Department of Cardiology, Berlin, Germany*; *[3]Health Twist, Berlin, Germany*; *[4]BAYER Pharma AG, Pharmaceutical Division, Wuppertal, Germany*

Background: Heart failure (HF) is a major reason for mortality and morbidity in societies all over the world and will gain importance in an aging society. About half of HF patients suffer from heart failure with preserved ejection fraction (HFpEF) which is till now neither fully understood nor treatable. The main symptom of these patients is exercise limitation. Current data provides evidence that this limitation is caused by both cardiac and peripheral influences. Monitoring of these influences in cardiopulmonary exercise testing (CPET) can therefore be of big interest, e.g. when assessing effects of a yet to develop HFpEF therapy.
Methods: To provide an insight into the limitations caused by HFpEF, we recruited 51 subjects of same gender and BMI distribution that suffered from either arterial hypertension (HT) without any sign of HF ($n = 24$, 58% male, BMI 29.3 ± 6.4) or HFpEF ($n = 27$, 56% male, $p = 1.000$, BMI 28.2 ± 4.1, $p = 0.455$) for the ENDO-CEC trial. To assess their individual grade of exercise limitation all subjects performed a standardized six minute walking test (6-MWT) and completed CPET protocol in which non-invasive cardiac output monitoring (NICOM) by bioreactance was conducted simultaneously.
Results: As expected, HFpEF subjects were significantly limited in all exercise related parameters. They reached a lower maximum power stage at CPET (HT: 121 ± 10, HFpEF: 100 ± 20 Watt, $p = 0.001$), had a lower maximum cardiac index (HT: 6.8 ± 1.3, HFpEF 6.0 ± 1.2 l/min/m^2, $p = 0.029$), a lower VO2 at maximum exertion (HT: 22.7 ± 5.9, HFpEF: 17.9 ± 2.0 ml/kg/min, $p = 0.001$) and a higher

VE/VCO2 slope (HT: 29.8 ± 4.1, HFpEF: 33.0 ± 4.8, p = 0.019). Additionally they covered a shorter distance in 6-MWT (HT: 538 ± 81, HFpEF 470 ± 67m, p = 0.005). Non-invasive monitoring of cardiac function shows us that the lower maximum cardiac index in HFpEF patients is not caused by reduction in stroke volume recruitment (HT: 151 ± 16, HFpEF 176 ± 53, percentage of maximum stroke volume compared to minimal stroke volume, p = 0.036) but only by a reduced peak heart rate (HT: 81 ± 10, HFpEF: 71 ± 14 percent of predicted maximum heart rate, p = 0.011). HFpEF subjects were furthermore slightly but insignificantly limited peripherally, meaning in their arteriovenous oxygen difference (AVDO2) calculated using the Fick principle (HT: 134 ± 33, HFpEF 121 ± 28, milliliter oxygen difference per liter blood flow per minute p = 0.155). When looking at the AVDO2 alone one finds that 57% of all HFpEF subjects had an AVDO2 below average with only 33% of HT subjects respectively. The lowest AVDO2 values were all reached by HFpEF subjects while the highest values were reached by HT subjects.
Conclusion: NICOM during CPET can show that HFpEF subjects are both centrally and to a certain extent peripherally limited during exercise compared to HT subjects. This is why a combined CPET and NICOM assessment can be of use for monitoring changes in HFpEF patients, e.g. in interventional pharmacological trials.

P1664
Arterial stiffness indices in a chronic heart failure population: a comparison between preserved and reduced ejection fraction population

L C Luiz Claudio Danzmann[1]; TS Moreira[1]; EL Garcia[2]; RSA Fonseca[1]; MG Menezes[2]; V Predebon[1]; BO Burmeister[1]; AJ Lagoeiro Jorge[3]; ET Mesquita[3]; LJ Santos[1]; E Bartholomay Oliveira[1]
[1]Universidade Luterana do Brasil, Porto Alegre, Brazil; *[2]Hospital de Clínicas de Porto Alegre - UFRGS, Porto Alegre, Brazil*; *[3]Universidade Federal Fluminense, Niteroi, Brazil*

Funding Acknowledgements: CardioS Research Foudation and FAPERGS

Background: patients with heart failure with preserved ejection fraction (HFpEF) have important influence of arterial stiffness (AS) that may impair the left ventricle-arterial coupling.
Purpose: to test differences between AS indices of a population with HFpEF and heart failure with reduced ejection fraction (HfrEF).
Method: the population were outpatients met heart failure (HF) Boston Criteria, clinically stable, consecutivelly admited in a HF clinic, wich were dichotomized according to LVEF measured by echocardiography. AS indices were estimated by previously validated logarithmic equation from the measurement of blood pressure (BP) by brachial oscillometric method (Wassertheurer S, et al.). The indices studied were the central blood pressure (Central SBP); total vascular resistance (Vasc Res Total); BP augmentation and pulse wave velocity (PWV). To test the difference between the means was used the Student's T test, qui^2 and a P $<$0.05 was considered statistically significant.
Results: 77 patients were included, mean age was 63 ± 13 years old, 58% were male, and 52.2% were ischemic and 52% were NYHA class II. The HFpEF population had higher prevalence of hypertension (71,4% x 92,3%, P=0,02). The indices central SBP and Total Vasc Res were significantly higher in patients with HFpEF.
Conclusion: In this preliminary analysis of our population of outpatients with heart failure we found out a the indices Central SBP and Total Vasc Res significantly higher in the group with HFpEF.

Arterial stiffness in HFrEF and HFpEF

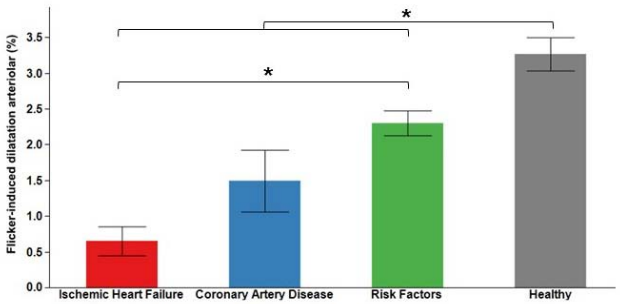
Arterial stiffness indices	LVEF $<$ 50%	LVEF≥50%	P
Central SBP (mmHg)	109,22±18,33	119,57±18,75	0,03
Total Vasc Resistance (mmHg/ml)	1,25±0,19	1,37±0,25	0,04
Augmentation BP(mmHg)	8,68±7,87	12,76±10,27	0,07
PWV (m/s)	7,59±1,85	8,10±1,46	0,25
Central PP (mmHg)	34,80±14,5	38,90±14,6	0,25

HFrEF- heart failure with reduced ejection fraction; HFpEF-heart failure with preserved ejection fraction; LVEF - left ventricle ejection fraction; SBP-systolic blood pressure; Vasc-vascular; BP - blood pressure;PWV-pulse wave velocity; PP- pulse pressure.

P1665
Severe retinal endothelial dysfunction in patients with ischemic cardiomyopathy

J Jens Barthelmes[1]; MP Naegele[1]; V Ludovici[1]; I Sudano-Noll[1]; F Ruschitzka[1]; AJ Flammer[1]
[1]University Heart Center, Cardiology, Zurich, Switzerland

Background: Heart failure (HF) is the most prevalent heart disease worldwide with coronary artery disease (CAD) being the most frequent aetiology. Endothelial dysfunction is associated with cardiovascular risk factors; it is important for the development and progression of atherosclerosis and its presence is a prognostic marker for future cardiovascular events. Endothelial function is commonly measured by Flow-mediated vasodilatation (FMD) of the brachial conduit artery. Retinal vessel analysis (RVA) is a novel and unique method allowing to assess microvascular function by measuring endothelial dependent flicker-light induced vasodilatation (FLID) using videography of the retinal vessels. However, whether retinal vascular function is associated with the severity of CAD is not known.
Purpose: We therefore studied FLID of the retinal arteries in patients with severe disease (heart failure due to CAD), in patients with documented CAD, and in patients with CV risk factors, as well as in healthy controls.
Methods: Patients were examined with a dynamic vessel analyser (Germany). Mydriasis was induced with 0.5% tropicamide in one randomly selected eye. Retinal arteriolar dilatation was measured after provocation with 12.5 Hz optoelectronic flicker light. Temporal segments of one retinal arteriole and venule that were 0.5 to 2 optic disc diameters away from the optic disc were analysed. After acquisition, the results from the three flicker periods were averaged and percent dilatation of arteriole from baseline (i. e. arterial FLID) was calculated.
Results: 277 participants (median age M=63.8 ± SD=8.0, 36.8% female) were included in this study (41 patients with CAD and heart failure [LVEF mean 35.4 ± 11.5%, median NYHA=II], 18 patients with CAD, 142 with cardiovascular risk factors and 76 healthy controls). RVA revealed significant group differences (ANOVA F(3, 67.94)=25.7, p $<$ 0.001) in arterial flicker-light induced vasodilatation: healthy controls M=3.27% ± SD=2.02%; risk factor patients 2.30 ± 2.08% , CAD patients 1.42 ± 1.76%, and ischemic HF: 0.65 ± 1.30%, cf. Figure 1. Post-hoc Tukey tests showed significant group differences in arterial FLID between healthy individuals and all other groups (max. p = 0.0034) as well as the risk factors group and ischemic HF (p $<$ 0.001).
In FMD no significant differences (ANOVA F(3, 273)=1.91, p = 0.1278) were found between groups although the same trend from healthy to HF was visible.
Conclusions: In this preliminary study, we demonstrate significant and profound retinal microvascular dysfunction in patients with heart failure due to CAD, although all patients were treated with state-of-the art medication. Furthermore, FLID seems to mirror the severity of CAD, with gradual reduction from healthy, to patients with RF and overt CAD disease. Therefore, dynamic retinal vessel changes to flicker light is a promising new tool for the assessment of the severity of disease in CAD. More studies in this field are warranted.



Progressing microvascular dysfunction

P1666
Lipids, oxidative stress and inflammation as sex-specific predictors of systolic left ventricular dysfunction in acute coronary syndrome

N Semerdzieva[1]; S Denchev[2]; M Gospodinova[2]; S Dimitrov[3]; V Lozanov[4]; R Abrashev[5]; J Hristova[6]
[1]University Hospital Alexandrovska, Clinic of Cardiology, Sofia, Bulgaria; *[2]Medical Insitute of the Ministry of Internal Affairs, Clinic of Cradiology, Sofia, Bulgaria*; *[3]Second MHAT, Department of Invasive Cardiology, Sofia, Bulgaria*; *[4]Medical University of Sofia, Department of Biochemistry, Sofia, Bulgaria*; *[5]Bulgarian Academy of Sciences, Stefan Angeloff Institute of Microbiology, Sofia, Bulgaria*; *[6]Medical University of Sofia, Central Clinical Laboratory, Sofia, Bulgaria*

Backgroud: Antioxidant and lipid-lowering effects of estrogen are mechanisms for the resistance of women to atheroma growth. Oxidative stress and inflammation have sex-specific influence on acute coronary syndrome (ACS) prognosis.
Purpose: The study examined the relationship of lipids with oxidative, inflammatory markers and coronary disease severity and their significance as predictors for development of left ventricular systolic dysfunction after ACS.

Methods: Indices of systolic function, serum lipids (total cholesterol, TChol; high-density lipoproteins, HDL; low-density lipoproteins, LDL; triglycerides, TG), oxidative (oxidized LDL, oxLDL; extracelluar superoxide dismutase activity, ecSOD) and inflammatory (white blood cell count, WBC; high-sensitive C-reactive protein, hsCRP) markers were measured in 274 (128 women, 46.7%), 111 (40.5%), 68 (24.8%), 200 (72.9%) and 173 (61.1%) acute coronary syndrome patients, respectively. The methods used were 2D-echocardiography, enzyme and immunologic laboratory tests. Repeated echocardiography at the six month was available in 147 (43.6%) patients. SYNTAX scores were calculated based on 241 (87.9%) coronary angiographies performed. At baseline 65.8% patients were on statin therapy.
Results: In the female group several serum lipid fractions correlated considerably with coronary atherosclerosis severity (r= - 0.300, p = 0.033 for HDL; r= 0.336, p = 0.016 for TG), acute rise of oxLDL (r=0.268, p = 0.049 for TChol; r=0.359, p = 0.016 for TG) and hsCRP (r=0.369, p = 0.007 for TG); in the male group the only significant association was of TChol with leukocytosis (r=0.234, p = 0.043). Among the acute (WBC, SYNTAX score in men; WBC, hsCRP and SYNTAX score in women) and chronic systolic dysfunction predictors (LDL, TG, hsCRP, SYNTAX scores in men; TChol, WBC, SYNTAX scores in women), after multivariate regression analysis only SYNTAX score predicted abnormal ejection fractions in acute phase in male patients (OR 1.066; CI 1.102-1.124; p = 0.016); inflammatory markers were related to both the acute (hsCRP OR 1.036; 95% CI 1.003-1.070; p = 0.032; WBC OR 1.230; CI 1.024-1.478; p = 0.027) and chronic (WBC OR 1.357; 95% CI 1.002-1.837; p = 0.049) contractile dysfunction in female patients. The recorded incidence of systolic dysfunction was independent of the usage of statin therapy at baseline (men - 23.1% vs 41.7%, p = 0.103; women - 17.5% vs 30.4%, p = 0.232).
Conclusion: In ACS lipids may have indirect sex-specific role for myocardial damage through oxidative stress and inflammation. Inflammatory markers are characteristic for female sex predictors of acute and chronic systolic dysfunction.

Wearable defibrillator protected optimization of therapy and development of LVEF in newly diagnosed heart failure

HN Naegele[1]; DS Stierle[1]; MAK Khan[1]; KK Krause[1]
[1]*Albertinen Hospital, Heart Centre, Dpt. Heart Failure & Device Therapy, Hamburg, Germany*

Introduction: Guidelines recommend that prophylactic defibrillator (ICD) implantation in patients with newly diagnosed heart failure (HF) should be postponed after an intervention and a period of optimization of medical therapy. The wearable defibrillator (WD) offers arrhythmic protection during that time. Duration and efficacy of such a strategy is currently under discussion.
Method: We analyzed data of all patients who received a WD in the years 2014-2016 in our center (n = 141) for newly detected HF (mean LVEF 26 ± 8%) under further medical therapy only (n = 62) or an additional intervention (coronary stenting, bypass or valve surgery; n=79). Patients were re-evaluated at 1 and 3 month, or later and medical therapy was up-titrated whenever possible.
Results: Mean wear time of the WD was 65 ± 39 days. Neither death nor any arrhythmia needing shock therapy was observed. In 72% of patients the LVEF increased >35% and ICD implantation could be omitted. Some patients needed >6 month for that improvement. LVEF increased similarly in interventional (+ 53%) and medically treated patients (+ 73%).
Discussion: Therapy can be safely optimized in newly diagnosed HF patients with reduced LVEF. ICD implantation can be omitted in the majority of these patients. The probability of a WD discharge seems to be low in this cohort.

P1668

Remote results of percutaneous coronary interventions at patients chd with reduced of the left ventricle contractility

HG Fozilov[1]; T Abdullaev[1]; I A Igor Tsoy[1]; RSH Bekbulatova[1]; AM Karimov[1]
[1]*Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan*

The purpose: to study clinical efficiency percutaneous coronary interventions and its influence on myocardial contractility at pts CHD with low left ventricle ejection fraction (LVEF) in the remote period (12-24 Mec) without estimate viability of the myocardium.
Materials and Methods: 1266 pts with various forms of CHD were included. At pts CHD with reduced of LV contractility of the left ventricle PCI have been executed at 11.9 % (138) pts. In the research conducted by us it has been included 65 (47.1 %) pts with low LVEF (less than 45 %) at which it was possible to study the remote results. Pts of a male have made - 80.0 % (52), and female – 20.0 % (13). The age of pts fluctuated from 39 until 76 years, and has on the average made 59.5 ± 8.4 years. From the standard risk factors most often met an arterial hypertensia - at 87.7 %, (57) pts, hyperlipidemia – at 90.7 % (59); a diabetes mellitus at 40 % (26) pts. The LVEF fluctuated from 27.3 % to 45%, and has on the average made 38.5 ± 4.9%. In 44.6 % (29) cases PCI have been executed at pts with acute myocardial infarction; in 40% (26) cases at a stable angina of pressure II-IV FC, and in 15.4 % (10) cases at an unstable angina. Three-vascular defeat of a coronary channel took place in 47.7% (31) cases, two-vascular in 29.2% (19) and one-vascular defeat in 23.1% (15) cases. At pts with multivascular defeat (n = 50) in 62% (30) cases the incomplete functional is executed; in 20 % (11) cases full functional and in 18 % (9) cases full anatomic myocardial revasculization were performed. In total it has been implanted 115 stents (on the average 1.8 stents on one pt) from them of 80% (92) drug eluting stents; 15.7 % (18) bare metal stents and 4.3 % (5) bioresorbable vascular skaffolds.
Results: In our research frequency of angiographic success at implantation stents at pts CHD with low LVEF has made 92.3 % (60), and clinical success at a hospital stage - 85.7 % (59). Frequency of development of complications has made 12.3 % (8) cases; from them dissection a coronary artery has developed in 62.5 % (5) cases; the 'no-reflow' phenomenon has developed in 25% (2) cases and in 1 case the bleeding from a gastroenteric path took place. Frequency of development myocardial infarction type 4 and a lethal outcome equaled - 0. In the remote period the LVEF fluctuated from 30% to 61.5 %, and has on the average made 43.5 ± 6.9 % (p=0.000). Increase the fraction of emission LV was observed at 60% (39) pts, decrease at 15.4 % (10) pts and at 10.8 (7) pts of LV ejection fraction has not changed. The lethal outcome has developed at 8 (12.3%) pts, operation CABG is executed at 1(1.5%) the pt.
The conclusion: Thus, frequency of clinical success at a hospital stage of supervision has made 85.7% (59) cases. In the remote period authentic increase of an average index of fraction of ejection left ventricle to 43.5% ± 6.9 % was marked at initial 38.5 ± 4.9 % (p=0.000).

Heart failure nurses, luxury or necessity? a substudy of the INTERACT-in-hf (improving knowledge transfer to efficaciously raise level of contemporary treatment in heart failure) study

K Baldewijns[1]; HP Brunner La Rocca[2]; S Bektas[2]; L De Maesschalck[1]; J Boyne[2]
[1]*Thomas More Kempen, Mobilab, Geel, Belgium*; [2]*Maastricht University Medical Centre (MUMC), Department of Cardiology, Maastricht, Netherlands*

Background: The complex nature of heart failure (HF) and its high burden challenge the management of national health systems. To address these questions, international associations of cardiology developed guidelines for best practice in heart failure care. However, implementation of these guidelines is a challenge, partly due to health care organizations.
The INTERACT-in-HF study was set up to investigate current practice in chronic HF care from different perspectives in three different European regions (Flanders (Belgium), region Maastricht and Aachen). This study showed that HF nursing is well established in the Netherlands and less established in Flanders and Germany.
Purpose: The ESC guidelines state that it is important to provide HF-patients with disease specific information in order to improve self-care and to make them able to make their own justified lifestyle decisions. Educating patients is supposed to be an important role of HF-nurses.
This substudy investigates the knowledge and implementation of guidelines concerning patient education and the role of HF-nurses according to patient education.
Methodology: A quantitative research design was used. All HF-nurses in Flanders, the Netherlands and Germany, being members of respectively the Belgian working group on cardiovascular nurses, the Dutch Nursing Cardiovascular Association and German association of HF-nurses, were approached in order to fill in a digital questionnaire about their knowledge and implementation of guidelines concerning patient education.
Data were analysed using SPSS v 23.0 (IBM).
Results: 23 Flemish, 59 Dutch and 7 German HF-nurses with cardiology experience participated in our survey. Almost every HF-nurse knows and implements the ESC-guidelines and their own national guidelines. Little regional differences were found between HF-nurses concerning knowledge and implementation of existing guidelines. Flemish nurses educate their patients significantly more about vaccination than their Dutch or German colleagues (X2, p = 0,003) and information about sexuality is mentioned less by all of them.
Conclusion: Despite the fact that ESC guidelines recognize the role of HF-nurses, few of them are actually active in Flanders and Germany. Though there are regional differences in health care organization between the Netherlands, Flanders and Germany, all HF-nurses in the participating centres offer education, and little difference was found regarding knowledge and implementation of guidelines.

A French national observational study on 2013 ESC Heart Failure guidelines: Impact on therapeutic management of chronic heart failure patients by office based cardiologists: RECO-Coeur study

P De Groote[1]; J Gauthier[2]; A Achouba[3]
[1]*Lille University Hospital, Institut Coeur-Poumon, Lille, France*; [2]*CNCF, Cannes, France*; [3]*Novartis Pharma S.A.S, Rueil-Malmaison, France*

On behalf of: RECO-Coeur study

Aim of the study: to determine the prescription rates of different drugs in a group of ambulatory patients with stable chronic heart failure (CHF) in NYHA class II-IV followed by French cardiologists.
Methods: Non-interventional, multi-center, cross-sectional study carried out with office based French cardiologists. Each investigators had to include the first 8 consecutive eligible patients seen in outpatient. Data from medical records and study visit were collected and recorded through an electronic case report form.
Results: 263 cardiologists included from 07/15/2015 to 10/28/2016, 2562 patients, age: 73.4 ± 11.9 years old, 1624 (63.4%) male, NYHA class II: 66%, hypertension: 62%, diabetes mellitus: 28,5%, renal impairment: 21%, coronary artery disease: 43%, peripheral arterial disease : 14%, COPD: 15,5%, depression or cognitive disorder: 10%. Mean LVEF was 43.1 ± 12 %, 941 patients (37%) had a LVEF < 40%, 845 (33%) a LVEF between 40 and 50% and 776 (30%) a LVEF ≥ 50%.
Prescription rates and doses achieved for each classes of drugs are presented in the Table.
In conclusion: there is no great difference in prescription rates of CHF drugs in subgroups of patients divided according to LVEF. In comparison to previous French registries, in patients with LVEF < 40%, there is a small increase in prescription rates of recommended CHF drugs and in recommended doses but there is still room for improvement, particularly for betablocker therapy.

Treatment of the study population

Drugs	LVEF < 40%	LVEF 40-50%	LVEF ≥ 50%
ACE-I	66%	59%	45.5%
Target doses	49%	51%	52%
≥50% target doses	31%	29%	32%
ARB	19%	22%	28%
Target doses	22%	27%	28%
≥50% target doses	31%	30%	28%
Betablockers	84%	81%	73%
Target doses	27%	24%	23%
≥50% target doses	37%	39%	39%
MRA	35.5%	26%	21%
Diuretics	76%	66%	74%
Ivabradine	5%	6%	3%
LCZ696	2.7%	2%	0.1%
Digoxin	5%	6%	10%

Optimisation of guidelines adherence is associated with better prognosis in outpatients with heart failure with low ejection fraction (HFrEF): the QUALIFY registry

M Michel Komajda[1]; MR Cowie[2]; L Tavazzi[3]; P Ponikowski[4]; SD Anker[5]; GS Filippatos[6]
[1]*AP-HP - Hospital Pitie-Salpetriere, University Pierre & Marie Curie Paris VI, Dept of Cardiology, Paris, France*; [2]*Imperial College London, Royal Brompton Hospital, London, United Kingdom*; [3]*Maria Cecilia Hospital-GVM Care and Research, Ettore Sansavini Health Science Foundation, Cotignola, Italy*; [4]*Wroclaw Medical University, Faculty of Public Health, Wroclaw, Poland*; [5]*University Medical Center Gottingen (UMG), Innovative Clinical Trials, Department of Cardiology and Pneumology, Gottingen, Germany*; [6]*Attikon University Hospital, Athens, Greece*

On behalf of: QUALIFY Investigators
Funding Acknowledgements: It is funded wia grants from SERVIER France

Aim: Implementation of HF guidelines is associated with improvement in outcomes but remains suboptimal in clinical practice. We assessed the impact of physicians' adherence to treatment guidelines on clinical outcomes in HFrEF.
Methods and results: QUALIFY is an international prospective observational survey of 7.092 CHF outpatients recruited 1-15 months after HF hospitalization from 36 countries. We analysed the relationship between 6 month outcomes and baseline adherence score for the use of ACEIs or ARBs, BBs, MRAs and ivabradine (if indicated) in in 6669 patients with data available at six months. Score was calculated for each patient by summing the points attributed: 0 for non-prescription in the absence of contraindications, 0.5 point for the use of < 50% of target dosage (TD) (< 100% of TD for MRA) or 1 point for use in ≥ 50% of TDs (TD for MRA). The table presents the relationship between 6 month outcomes and adherence score (Cox proportional hazards regression model on time to event - multivariate analysis conducted by selecting only covariates significant at 1% in univariate analysis).
Conclusion: Among outpatients with HFrEF, a good adherence to pharmacologic treatment guidelines as determined by prescription of ACEI/ARB, BB, MRA, ivabradine with at least 50% of recommended dosages was associated with improved clinical outcomes during 6 month follow up.

	Univariate analysis	Multivariate analysis

LCZ696 compassionate use progamme at mater dei hospital, malta

A M Alice May Moore[1]; L Buttigieg[1]; S Xuereb[1]; RG Xuereb[1]
[1]*Mater Dei Hospital, Cardiology, Msida, Malta*

Background: LCZ696 is a combination drug for use in Heart Failure with reduced ejection fraction (HFrEF) consisting of valsartan and sacubitril. It has been included in the treatment algorithm of the 2016 ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure. The trial PARADIGM-HF has shown a 20% risk reduction in death from CV cause and 21% HF hospitalization risk reduction when LCZ696 was compared to Enalapril.
Purpose: to assess the effect of LCZ696 in HF patients included in the Compassionate Use Programme at Mater Dei Hospital.
Method: Patients that attend the HF Clinic were selected between October 2015 and May 2016. Inclusion criteria included: Age>18; NYHA Class II-IV; LVEF < 35%; at least one hospitalization for HF within the last 12 months; ACE-inhibitor or ARB therapy with a stable dose for prior 4 weeks. The patients were reviewed regularly at the HF clinic. Symptomatology, blood pressure, renal function, potassium and NT pro BNP levels were monitored.
Results: A total of 21 patients were included: 16 males, 5 females. The average age was 56.8 years. 71% had a diagnosis of dilated cardiomyopathy and in 29% the cause of HF was ischaemic heart disease. The mean ejection fraction (EF) was 24%. The choice of the starting dose depended on renal function, potassium levels and blood pressure readings. 29% of patients were started on 50mg twice daily, whereas 71% were started on 100mg twice daily. 81% of patients reached target dose within an average time of 37.5 days. The patients who were started on a lower dose required an average of 60 days to reach target dose, compared to an average of 32 days to target dose in patients who were initiated on 100mg twice daily. 19% of patients did not reach target dose in view of hypotension and hyperkalaemia respectively.
57% had a significant decline in NT pro BNP levels after 6 months of treatment with LCZ696. We managed to stop loop diuretics in 15% of patients and reduce the dose in 45%. Since starting LCZ696, only 2 patients required hospitalization for HF exacerbation. 30% of patients experienced hypotension and 33%hyperkalaemia. Only 1 patient had a significant deterioration in renal function. LCZ696 had to be stopped in 2 of the patients. This was due to significant impairment in renal function and persistent hyperkalaemia respectively despite adjustment of other medication.
Conclusion: The introduction of LCZ696 had an overall positive effect on HF management with reduction in NT pro BNP levels, number of hospitalizations and reduced need of loop diuretics. Further follow-up will include the use of Kansas

City Cardiomyopathy Questionnaire to assess effect on quality of life and repeat of echocardiograms to assess ejection fraction after treatment with LCZ696.

Comparison of ischemic and non-ischemic heart failure outpatients in a Turkish cohort

C Cihan Altin[1]; H Kaya[2]; L Bekar[3]; H Altay[1]; MB Yilmaz[2]
[1]Baskent Univercity Faculty of Medicine, Ankara, Turkey; *[2]Cumhuriyet University, Cardiology, Sivas, Turkey*; *[3]Hitit University, Cardiology, Corum, Turkey*

On behalf of: TREAT-HF investigators

Purpose: to compare the data of ischemic and non-ischemic subgroups of outpatients with chronic stable heart failure (HF).
Methods: The data of 1253 outpatients with the mean age of 61.58 ± 13.70, obtained from Turkish Research Team-HF (TREAT-HF) multi-centered, prospective, observational, cohort study were analyzed to compare ischemic and non-ischemic subgroups.
Results: Comparison of ischemic (n = 564, male 76.8%) and non-ischemic (n = 689, male 66.9%) subgroups regarding demographics, clinical characteristics, risk factors, symptoms and medications were given in Table. Medications except high usage of statin, acetylsalicylic acid in ischemics diuretic, digoxin in non-ischemics, and achieving the target dose rates were similar between the groups.
Conclusion: Medications which improve survival in HF including newly recommended drugs like ivabradine usage and achieving the target dose rates were similar between the groups but the rates still seem not to be enough according to current guidelines.

Table: Comparison of our study groups

	Non-ischemic (n = 689)	Ischemic (n = 564)	P value
Age (years)	59.80±14.92	63.66±11.78	< 0.001

Quality of life predicts exercise capacity in heart failure patients

A Artan Ahmeti[1]; A Batalli[1]; E Haliti[1]; A Poniku[1]; P Ibrahimi[1]; S Elezi[1]; MY Henein[2]; G Bajraktari[1]
[1]University Clinical Centre of Kosovo (UCC), Department of Cardiology, Pristina, Kosovo Republic of; *[2]Umea University Hospital, Umea, Sweden*

Background and Aim: Chronic heart failure (HF) is associated with poor quality of life (QoL). The Minnesota Living with HF Questionnaire (MLHFQ) is the most widely used measurement for assessing the QoL in HF patients. This prospective study aimed to assess relationship of QoL with clinical, echocardiographical and exercise capacity in HF patients.
Methods: The study subjects were 103consecutive HF clinically stable patients (63 ± 10 years, 56 female, 48% hypertensive and 26% ischaemic etiology, classified as NYHA I-III). The MLHF questionnaire was administered during the same day of complete clinical, biochemical and echocardiographic assessment of the patient. A six minute walk test (6-MWT) distance was performed in all patients. Patients were divided into two groups based on the 6-MWT distance (Group I: ≤ 300 m and Group II: >300 m).
Results: The MLHFQ correlated with 6-MWT (r=0.45, p < 0.001) and was higher in female patients (p = 0.015). The NYHA class (P=0.001) and lateral left ventricular long axis amplitude (p = 0.004) differ in MLHFQ tertiles.
Increased MLHFQ [1.070 (1.025-1.117), p = 0.002], older age [1.106 (1.022-1.196), p = 0.012], enlarged left atrium [2.448 (1.171-5.120), p = 0.017] and the presence of diabetes [4.857 (1.287-18.338), p = 0.02] independently predicted poor 6-MWT performance in HF patients. A MLHFQ ≥50 was 74% sensitive and 62% specific (AUC 0.75, p < 0.001) in predicting poor exercise capacity in HF patients.
Conclusions: Quality of life assessed by MLHFQ is the best correlate of exercise capacity assessed by 6-MWT. These findings suggest that exercise capacity and quality of life indices are closely related in HF patients.

Building bridges between primary and secondary/tertiary care: technology driven integrated care in the area of heart failure

E Etain Quigley[1];
K Mcdonald[2]; M Ledwidge[2]; C Keane[2]; J Gallagher[2]; S James[2]; C Hecht[1]
[1]University College Dublin, Applied Research for Connected Health, Dublin, Ireland; *[2]St Vincents University Hospital, Heart Failure Unit, Dublin, Ireland*

Funding Acknowledgements: Enterprise Ireland, Boston Scientific, Resmed and Cardiomark.

Background: Heart failure (HF) is a significant public health issue with more than 20 million people around the world affected by the disease. The increasing prevalence rates for HF and the other chronic diseases has led to the development of new policy frameworks in many countries and these have emphasised the need for integrated care and a greater role for primary care in disease management.
The HF Virtual Clinic (HFVC) provides access for General Practitioners to specialist opinion and thus assists with the management of patients in the community. In this respect the HFVC enhances integrated care and meets the demands of the new chronic disease frameworks related to HF. The HFVC was designed in line with the Extension of Community Healthcare Outcomes (ECHO) Project which was established in the US with the aim of supporting collaborative medical education and care management. ECHO facilitates clinician empowerment by providing support within the community thus reducing the need for secondary/tertiary care referrals.
Purpose: The purpose of this paper is to outline findings from an evaluation conducted on an HFVC in Ireland. The paper highlights the simple and yet effective approach that this model adopts and is a prime example of where technology can enhance integrated care and support General Practitioners in optomising their skillset.
Methods: This study adopted a mixed methods approach, combining quantitative surveys, a vignettes based decision making approach, and qualitative interviewing. The HFVC had been in operation in Ireland for approximately 24 months at the time of data collection and had thus provided somewhere close to 48 sessions. A total of 17 General Practitioners were involved with the study.
Results: The HFVC was considered to be a positive and supportive integrative care model. It was perceived as a professionally useful means of disseminating and gathering patient management and condition relevant information. Participants discussed the models ability facilitate peer interaction and a group learning environment. It was outlined as a means of connecting primary/secondary/tertiary care and thus facilitating integrative care. Participants highlighted the models impact in terms of increasing General Practitioner's knowledge base and confidence when treating and managing patients in the community. The model was outlined as a key strategy for reducing referrals to secondary and tertiary care systems.
Conclusion: This paper highlights the potential for such a model in terms of bridging the gap and increasing expertise across primary, secondary and tertiary care. It is an example of where technology can facilitate efficient and effective communication pathways which have the potential to benifit the patient as well as the system.

P1676
Characteristics, treatments, and outcomes of patients hospitalized for heart failure: a report from the OPTIMIZE-HF Registry (Azerbaijan)

G Gulnaz Dadashova[1]
[1]Scientific Research Institute of Cardiology, Heart Failure, Baku, Azerbaijan

Objectives: The aim of this study was to investigate characteristics, treatments, and outcomes of patients with reduced systolic function heart failure (HF).
Methods: This is a single-centre retrospective analysis of 50 patients admitted with decompensated heart failure over 1 year from November to March 2016. We evaluated clinical characteristics of patients according to left ventricular ejection fraction at least 50 or less than 50%. Outcomes as defined by evolution of NYHA class, quality of life (by Minnesota),1-year mortality and re-hospitalization rates for heart failure were compared between the before discharge , and then after 12 months.
Results: The median age was 57.1 years, 66% were men, and 46% had ischemic etiology. Comorbidities were frequent, including hypertension in 82%, diabetes mellitus in 53%, and chronic obstructive pulmonary disease in 29%. HF origin was ischemic in 46% of enrolled patients. The mean range of heart rate (HR) was before discharge 93.1 ± 1.7, after 12 month 73.8 ± 0.6. Ivabradine was administered in 52.1%. Mean left ventricular ejection fraction was 0.41 ± 1.1. After 1 year mortality occurred in 30%. Multivariable predictors of mortality included age, heart rate, systolic blood pressure (SBP) , creatinine. A scoring system was developed to predict mortality. It was found that among hospitalized patients with heart failure has taken an important place modern neurohormonal therapy. ACE inhibitors are used more often than ARB ($p < 0.001$). Aldosterone antagonists eplerenon are used much less frequently in comparison with spironolactone (<0.001). More likely to prescribe loop diuretics than thiazide ($p < 0.001$). Often administered digoxin, levosimendan was not used. Rate of re-hospitalization 1 after year was 34%.There were no significant relationships between discharge use of angiotensin-converting enzyme inhibitor/angiotensin receptor blocker or beta-blocker and before discharge and after 1 year mortality and rehospitalization rates in patients with HF.
Conclusions: Risk of in-hospital mortality for patients hospitalized with HF remains high and is increased in patients who are older and have low SBP or sodium levels and elevated heart rate or creatinine at admission. Postdischarge clinical outcomes also did not significantly vary by day of hospital discharge. Application of this risk-prediction algorithm might help identify patients at high risk for in-hospital mortality who might benefit from aggressive monitoring and intervention.

P1677
Diagnosis of myocardial viability in patients with chronic heart failure: search for the best methods

Y Rustamova[1]; V Azizov[1]; D A Daniil Maximkin[2]; A Faibushevich[2]
[1]Azerbaijan Medical University, Baku, Azerbaijan; *[2]Peoples Friendship University of Russia (RPFU), Moscow, Russian Federation*

AIMS: to reveal the significance and efficiency of different diagnostic methods of myocardial viability.
Methods and Results: 214 patients are included in study. Inclusion criteria: stable angina class II-III(CCS): occlusion or subtotal stenosis of one or more coronary arteries by angiography,previous myocardial infarction (OMI) associated with congestive heart failure (CHF). Patients with acute coronary syndrome, multivessel disease (SYNTAX score ≥32) were excluded of the study.All patients are randomized in 3 groups. At 1group (n = 76) myocardial viabilitywas determined by cardiac magnetic resonance (CMR) with delayed enhancement,at 2 group (n = 78) – two-dimensional low dose Dobutamine stress echocardiography (LDDSE), at III group (n-60) both of methods. Coronary revascularization was performed to all patients with viable myocardium. Late follow-up of intervention was planned for 18 months after procedure.
The mass of hibernating myocardium was able to identify only in groups I and III, where in indicators was 36 and 44% accordingly ($p > 0.05$). At hospitalization period patients surviving was 100% with no complications. Late follow-up were done in 193 of 214 patients, from which 70 included in I group, 68 – II group, 55 – III group. Control methods matched to initials. Summary frequency of cardiovascular complications was 2.8, 8.8 and 5,45% according to groups ($p < 0,5$), but by frequency of non-fatal MI wasn't revealed any significantly differs, but repeated intervention on stented segment of arteries differs at I and II groups (1,4 and 5.9% accordingly; $p < 0.05$).To the end of observation dynamic of recovery of wall motion abnormality was more significant at I and III groups, nearly more than 30% compared to the II group($p < 0.05$). Positive myocardial remodeling and significant increasing of EF (Ejection Fraction) was marked in all groups. Strong positive correlation between duration of myocardium hibernation and its function's recovery time was revealed. ($r=0.54$, $p < 0.05$). I and III groups patient's hibernating myocardium mass was significantly decrease to 37 and 34% accordingly ($p < 0.05$)
Conclusions: CMR with delayed enhancements safe and effective method of detection of myocardial viability, compared to low dose Dobutamine stress-echocardiography allows significantly better estimate dynamic functional recovery of hibernating myocardium and it's remodeling after coronary revascularization.

P1678
Safety and effectiveness of sacubitril/valsartan in real-life practice

J Jenna Berger[1]; T Huynh[1]; V Nguyen[1]; M Rasti[1]; V Cyr[1]; N Giannetti[1]
[1]McGill University Health Centre, Montreal, Canada

Introduction: The most recent medical addition to heart failure management, in those with reduced left ventricular ejection fraction, has been the use of Sacubitril/Valsartan.
Methods: Several clinical parameters were investigated, including some that were not studied in PARADIGM. Our goal was to perform a single center, retrospective, descriptive study, evaluating our patients' clinical outcomes, on Sacubitril/Valsartan.
Results: Demographics From December 2015-December 2016: Sacubitril/Valsartan was initiated in 140 patients. More than half of the patients (51%) suffered from ischemic cardiomyopathy; 21% were females. The mean age and left ventricular ejection fraction were 62 and 25%, respectively. The majority were NYHA 2 and 28% were NYHA 3.
Diuresis Following initiation of Sacubitril/Valsartan, 16% were able to have doses of diuretics decreased, 12% had to have diuretics dosage increased, 58% had unchanged doses of diuretics (6% were not on diuretics before initiation of Sacubitril/Valsartan). Blood pressure Sacubitril/Valsartan was initiated in 19 patients with systolic blood pressures of less than or equal to 100mmHg. The lowest measured blood pressure at initiation was 84/53. The medication was well tolerated in 79% of these patients and 52% were able to have up-titration of Sacubitril/Valsartan Left ventricular Ejection Fraction Of 31 patients who obtained repeat left ventricular ejection fraction (LVEF) measurement, 13 (42%) had improved LVEF.
Cardiac Transplantation On our transplantation and Ventricular assist device (VAD) list, 17 patients were on Sacubitril/Valsartan. 4 of these patients were deactivated from the transplant list, once on Sacubitril/Valsartan due to improving clinical status. 3 of these patients reached maximal dose Sacubitril/ Valsartan, while 1 patient reached medium dose.
Conclusion: In this single-center retrospective cohort study, we showed that Sacubitril/Valsartan was well tolerated even in patients with baseline hypotension. We observed decreases of diuretics requirement and improvement in LVEF in several patients. Moreover, there was no further need for cardiac transplantation and/or LVAD in some patients. Overall, our data suggested that Sacubitril/Valsartan had good safety and effectiveness in "real-life" practice.

P1679
Efficacy and safety of angiotensin II receptor-1 blockers administration in patient with chronic heart failure due to coronary artery disease combined with chronic obstructive pulmonary disease

V Evdokimov[1]; A Evdokimova[1]; E Kovalenko[1]; E Fedorova[1]; K Tebloev[1]
[1]State University of Medicine & Dentistry, Moscow, Russian Federation

Purpose: to compare clinical efficacy and safety of sartans in patient with chronic heart failure due to coronary artery disease combined with chronic obstructive pulmonary disease.
Methods: after enrollment in this trial 48 patients (31 men and 17 women), aged 63.6 ± 4.9 years, with CHF classes II to III combined with moderate to severe COPD (GOLD-2015) with initial ejection fraction of the left ventricle (LVEF) less than 45%, were randomized into two groups – losartan (56 ± 6,5 mg daily, n=22) and candesartan (10 ± 2,7 mg daily, n=26). Patients of both groups received the complex CHF treatment comprising torasemide, nebivolol, cardiac glycosides (if necessary) and basic COPD therapy (LABA + LAMA). Echocardiography, exercise tolerance (6-min walk distance), 24-hour electrocardiography and blood pressure monitoring were assessed at baseline and after 6 months of treatment, respiratory function test was assessed at baseline, after 1 month and after 6 months. The quality of life was evaluated by MYHFQ, SGRQ and mMRC.
Results: after 6 months of therapy the improvement of clinical condition and quality of life were marked in both groups. In 1st and 2nd group LVEF was increased by 8.5% and 11.2%, pulmonary hypertension decreased by 9.2% and 12.4%, episodes of silent myocardial ischemia decreased by 21% and 26.8%, respectively. Towards the end of the observation period, there was no deterioration of respiratory function during therapy in both groups, 6-min walk distance increased by 19.6% and 26,2% accordingly. Patients showed statistically significant and clinically meaningful reduction of SGRQ score (15.7% and 16.4%) and MYHFQ score (22.8% and 28.4%), significant improvements in MMRC dyspnea grade (17.2% and 20% respectively). All treatments were well tolerated and side effects of therapy in patients in all groups was comparable.
Conclusions: the losartan and candesartan inclusion in the structure of complex therapy in patients with CHF combined with COPD raises efficiency of treatment, improves quality of life and basic parameters of central hemodinamics. Efficacy and

safety of losartan and candesartan in patient with CHF due to CAD combined with COPD are similar.

P1680
Ivabradine and heart failure: experience from a real practice

L Lilyana Mircheva[1]; YY Yotov[1]; YB Bocheva[2]
[1]*Medical University of Varna, Varna, Bulgaria*; [2]*University Hospital St. Marina, Clinical Laboratory, UMHAT St. Marina, Varna, Bulgaria, Varna, Bulgaria*

Introduction: Chronic heart failure (CHF) is the most common diagnosis at admission in patients above 65 years. The introduction of ivabradine as a new medication is expected to cope with HF.
Aim: To assess the effect of ivabradine (Iv) after 6 months in patients with CHF NYHA class III-IV post hospitallization.
Materials: We followed 180 patients with CHF for 6 months in an out-patient program. Of them, 80 were in sinus rhythm (SR). The baseline and 6 months levels of NTproBNP, ejection fraction (EF), 6 min walking test (6MWT), NYHA functional class, and renal function were evaluated.
Results: Iv was initiated in 40.3% of patients with SR. After 6 months, the 6MWT improvedt (62.5 m in the Iv vs 23.5 m in the non-Iv group; $p = 0.043$), NTproBNP reduced with median 680 pg/ml and 552,5 pg/ml ($p = NS$), respectively, and EF increased in Iv with 4.02% and decreased with 1.14% in non-Iv, $p = 0.06$. After 6 months, 77% of the Iv patients were in class II, whereas only 45% of the controls were in class I-II ($p = 0.023$).
Conclusions: Ivabradine in CHF leads to subjective improvement, increases the systolic function, improves the quality of life and functional NYHA class.

P1681
Mapping heart failure: patient-level costs of an integrated care pathway

D Daniel Regan[1]; E Quigley[2]; C Keane[3]; M Walshe[3]; J Gallagher[3]; P Kalra[4]; M Ledwidge[3]; M Cowie[5]; K Mcdonald[3]
[1]*University College Dublin, School of Psychology, Dublin, Ireland*; [2]*University College Dublin, Applied Research for Connected Health, Dublin, Ireland*; [3]*St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland*; [4]*Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*; [5]*Royal Brompton Hospital, London, United Kingdom*

Funding Acknowledgements: Enterprise Ireland; Boston Scientific Corporation; ResMed; Cardiomark Ltd.

Background: Heart failure (HF) is a significant public health issue worldwide. The global economic cost of HF (2012) was $108 billion, with direct costs accounting for 60%. In Ireland total costs of HF (2012), were estimated at €660 million. In spite of high costs, a comprehensive understanding of the HF care-pathway (HF-CP) is currently lacking.
Purpose: To address this, comprehensive maps of HF patient care were developed, relating to: 1) immediate pre-hospitalisation, 2) in-hospital (emergency department/inpatient at an Irish public university hospital), and 3) post-discharge. These maps were then used to calculate the granular cost of patients' journeys.
Method: An interdisciplinary approach was adopted: Time-driven activity-based costing (TDABC) from economics/accountancy, and vignette-based surveying from the social sciences. Within a framework of seven patient vignettes ('paper patients'), developed to represent 'typical' severe/acute decompensated HF patients, TDABC was used to identify the granular activities in the pathway.
Activity-data were collected through participant observations and approximately 100 semi-structured interviews with healthcare professionals (HCPs). Cost-data were collected from publicly available sources, and from the hospital finance department.
Results: Individual-level maps (per HCP-role), were developed, and when combined, produced an integrated HC-CP. Costs per vignette patient ranged from €2,868.92 to €9,427.11. Findings suggest that bedday costs, while still a key factor, are less costly than often estimated. The admission process/referral system of HF patients at the ED level was identified as another cost driver.
Conclusions: Mapping of an integrated HF care pathway through the Irish public healthcare system was conducted for the first time. Recommendations for management and future research are outlined.

P1682
Are our heart failure patients with preserved ejection fraction ready to be included in trials?

B Neves[1]; N Hammoudi[1]; F Pousset[1]; P Balagny[1]; L Legrand[1]; M Komajda[1]; R Isnard[1]
[1]*Hospital Pitie-Salpetriere, Cardiology Department, Paris, France*

Introduction: Heart failure with preserved ejection fraction (HFpEF) is a heterogeneous entity and many clinical trials have been done so far, all with negative results. Heterogeneity is pointed out as an explanation for this, making inclusion and exclusion criteria especially important in this setting. Our aim was to evaluate the inclusion and exclusion rates of a cohort of patients admitted for HFpEF if they would be proposed to enter three major trials on HFpEF (I-PRESERVE, TOPCAT and PARAGON).
Methods: A cohort of patients admitted for HF decompensation between June 2015 and June 2016 on a tertiary HF center was analyzed. Electronic medical records and echocardiograms were analyzed for data introduction. HF was defined as current ESC criteria guidelines. We selected patients with left ventricular ejection fraction (LVEF) ≥45% and excluded a priori those with history of previously reduced LVEF, more than moderate valvular heart disease, constrictive pericarditis, congenital heart disease and previous cardiac transplantation. We applied inclusion and exclusion criteria of 3 major trials to this population
Results: Among 176 patients with HFpEF criteria and LVEF ≥45% and without taking into account longitudinal blood pressure values criteria, rates of inclusion would be 25% for PARAGON, 47% for TOPCAT and 84% for I-PRESERVE. The main reasons for exclusion were rapid atrial fibrillation (21% in TOPCAT), anemia (19% in PARAGON), COPD (15% in TOPCAT and PARAGON), elevated creatinine (13% in TOPCAT and 4% in I-PRESERVE) and lower age (7% in I-PRESERVE and 3% in TOPCAT and PARAGON).
Conclusions: The low inclusion criteria rate on this real world cohort illustrates the complexity of addressing these patients and raises uncertainty about these important clinical trials conclusions when generalized. Disease heterogeneity and associated comorbidities should be taken into account on future clinical trials to make clinical practice decisions easier.

P1683
CHIC trial: Can a single outpatient visit, 8 to 15 days after the hospitalization for acute heart failure, decrease the number of re-hospitalizations?

A Gueye[1]; J Charles[1]; O Milleron[1]; C Bouleti[1]; F Arnoult[2]; I Dehedin[1]; K Ghezali[1]; G Phan[1]; G Caligiuri[1]; C Morgant[1]; A Dechanet[3]; F Tubach[3]; G Jondeau[1]
[1]*Hospital Bichat-Claude Bernard, Equipe Insuffisance Cardiaque, Paris, France*; [2]*Hospital Bichat-Claude Bernard, service d'exploration fonctionnelle, Paris, France*; [3]*Hospital Bichat-Claude Bernard, Unité de Recherche Clinique Paris Nord, Paris, France*

On behalf of: Equipe Insuffisance Cardiaque, Service de cardiologie, Hôpital Bichat Claude Bernard

Among people suffering from congestive heart failure (CHF), the first 6 months after a hospitalization is the most critical period for the risk of recurrences.
This prospective randomized study aims to evaluate if a single outpatient visit, with echocardiography 8 to 15 days after discharge for CHF hospitalization, decreases the number of re-hospitalizations during the following 6 months.
Between 2013 and 2016, 326 patients hospitalised for acute heart failure in Bichat Hospital, with either a none-optimal treatment for CHF according to the practitioner in charge or NT-proBNP value upper than 3500 ng/l at discharge were included. These 233 men and 93 women were randomized 1/1 into 2 groups, one "interventional" (162 with scheduled additional outpatient visit, ECG and echocardiography 8 to 15 days after hospitalization) and one "standard" (165 pursuing the standard of care). Follow-up included phone calls at 3 and 6 months after hospital discharge.
In the first 100 patients included, age ranged from 26 to 97 years old (mean age 68 ± 14), and hospitalisation lasted 2 to 77 days (mean 13 ± 8). Reasons for inclusion were high Nt-ProBNP in 44% or non-optimal therapy at discharge in 56%. Hypertension was present in 63% and diabetes mellitus in 48%. Decompensation was de novo in 51%. LVEF was preserved in 27%. Main aetiologies of heart failure were ischemic and dilated cardiomyopathy (1/3 of cases each) and cardiac arrhythmias in 14%.
At discharge, 74% of patients received an ACEI, 15% an ARB (renin angiotensin system blocker 89%), and 91% a beta-blocker. Follow-up is started and complete baseline data will be presented during the meeting. Prevalence of heart failure with preserved ejection fraction appears to be lower than anticipated in patients not selected in the Cardiology department, but these patients were considered as being amenable to optimisation of therapy in the idea of the practitioner in charge.

P1684
General practitioner perceptions of services for patients with advanced heart failure: a qualitative study

J J Jingwen Jessica Chen[1]; KO Orr[1]; CS Stone[2]; JD Doherty[2]; LG Graham[2]; KMG Mcglade[1]; PD Donnelly[3]
[1]*Queens University Belfast , Medicine, Dentistry and Biomedical Science, Belfast, United Kingdom*; [2]*Marie Curie Hospice, Belfast, United Kingdom*; [3]*South Eastern Health and Social Care Trust , Cardiology, Belfast, United Kingdom*

On behalf of: Queens University Belfast Research Group

Background: The holistic needs and healthcare service support of patients with advanced heart failure are often neglected. Collaboration and communication between Primary Care, Cardiology and Palliative Care Services is likely key in meeting the multidimensional needs of patients. It is unclear if such a model of care exists in this region.
Purpose: This qualitative study assessed current services models available within one geographical region and explored the adequacy of these models in meeting the needs of patients and carers with heart failure, as perceived by General Practitioners (GPs).
Method: Semi-structured interviews were conducted with GPs recruited via the medical school and postgraduate deanery. Selected GPs represented each healthcare trust area in the region, ensuring a snapshot of perception was achieved. Interviews were transcribed, independently coded using NVivo 9TM and analysed using a six-step thematic analysis approach. Key themes were identified inductively.
Results: Twenty semi-structured interviews were conducted between June and August 2016. A number of recurring themes emerged. Care provided by the heart failure nursing team (HFT) was highly regarded. However, access to this service was limited to patients under the care of a Cardiologist, thus excluding those with advanced disease no longer seen by a Cardiologist. This lack of community facing HFT was associated with inadequate handover of care from the HFT to GPs at discharge. Such a disjointed primary and secondary care service model has created a perception that access to timely advice and appropriate services for patients, is limited in an elective setting, frequently resulting in inappropriate admission for acute service support. Discussions about end of life care are frequently neglected by Cardiologists and GPs. GP's reported that this may be due to poor awareness of the need for these discussions and lack of clarity regarding who is responsible. It was reported that at all stages of heart failure management, the emphasis is on medical treatment, rather than holistic assessment of underlying needs. Linked to this was a poor awareness of the role of Specialist Palliative Care (SPC) services in the management of heart failure in the community. GP's perceptions that SPC services are overstretched, cancer focused and lack expertise in heart failure lead to its limited utilisation. Barriers to referral for SPC include difficulties identifying palliative care needs and a fear of causing distress.
Conclusions: GPs describe significant shortcomings in the delivery of holistic care to patients with advanced heart failure in the region. There is a clear need to review existing service models within the region, with a focus on collaborative service planning, education, effective communication, role delineation and greater access to specialist palliative care.

P1685

Personalized approach to heart failure with preserved ejection fraction (HFpEF), the Maastricht experience

MA Barandiaran Aizpurua[1]; VPM Van Empel[2]; BLM Schroen[3]; M Van Bilsen[1]
[1]Cardiovascular Research Institute Maastricht (CARIM), Cardiology, Maastricht, Netherlands; *[2]Maastricht University Medical Centre (MUMC), Cardiology , Maastricht, Netherlands*; *[3]Maastricht University, Cardiology , Maastricht, Netherlands*

Background: Heart failure (HF) with preserved ejection fraction (HFpEF) is one of the main dilemmas in modern cardiology. The recently postulated paradigm gives to co-morbidities a central role being the cause of low grade systemic inflammation producing endothelial and microvascular dysfunction, alteration of myocardial signalling and involvement of other organs; lungs, skeletal muscle and kidneys.
Purpose: The absence of effective treatment leads to pursue a different approach to the HFpEF patient. Multidisciplinary strategies have been proven to reduce mortality and hospitalization significantly and are recommended by the ESC HF guidelines. Nevertheless these efforts have mostly been focused on HFrEF. A multidisciplinary, individualized approach to HFpEF patients could be the answer that is lacking.
Methods: In Maastricht University Medical Center a specific HFpEF out-patient clinic have been implemented. Suspected patients are referred from their general practitioner, cardiologist or another medical specialist to the HFpEF out-patient clinic. An intense and complete medical assessment is performed: electrocardiogram, cardiac echography, lung function test, six-minute walking test, exercise testing, twenty-four hour Holter monitoring, ApneaLink, Hospital Anxiety Depression Subscale score and laboratory tests including biobank analysis. If coronary artery disease is suspected a coronary computed tomography or coronary angiography will be performed. The patient gest a medical consultation with a dedicated HF specialist. Once a week in a multidisciplinary meeting all patients get discussed with all HF specialist and internal medicine or pulmonologists if needed. If co-morbidities have been diagnosed, these will be treated. Sometimes the diagnosis of HFpEF remains uncertain. In these cases, a right heart catheterisation will be performed.
Results: After one year we have screened 144 patients of which 115 had HFpEF according to the last ESC HF guidelines. In the baseline characteristics, we can observe most patients are women (67,8%), obese 48,3% with a BMI above 30 kg/m2 and 15,7% above 35 kg/m2, have hypertension (84,3%), type II diabetes (37,4%), atrial fibrillation (61,7%), sleep apnoea (47,8%) and iron deficiency (50%). Echographically most patient have an increased left atrium volume index (85,2%) increased E/E' above 13 (37,1%). Increased left ventricular mass index is only present in 20% of the patients. The mortality rate after 1 year is 5,4%, the half related to cardiovascular disease; pulmonary hypertension of right ventricular failure. 31 patients got hospitalized in the first year (26,9%).
In conclusion, the characteristic of our HFpEF population does not differ from the patients included in the main HFpEF trials. However, our mortality and hospitalization rate are lower. This could be related to a diagnosis in an earlier stadium, selection bias or to an intensified treatment regime of the different co-morbidities.

P1686

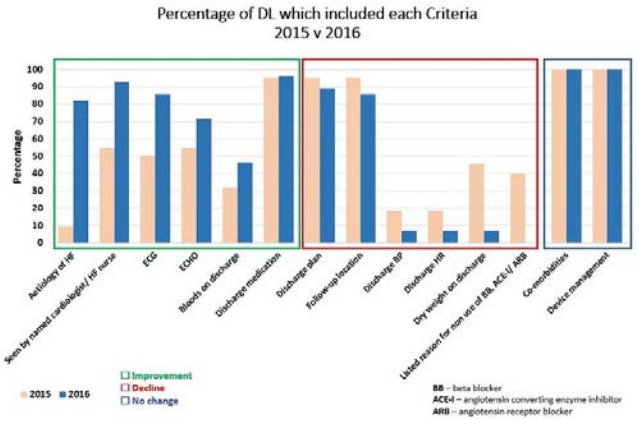
Hospital discharge letter quality - An important standard between hospital and community heart failure teams

A Aysha Gomaa[1]; D R Duncan[2]
[1]Barts and The London School of Medicine and Dentistry, London, United Kingdom; *[2]Mid Essex Hospital NHS Trust, Cardiology Department, Chelmsford, United Kingdom*

Introduction: Heart failure (HF) admissions are increasingly prevalent. Discharge Letters (DL) are an important communication between secondary care and community teams for the ongoing management of HF patients, and as a dataset for National HF audits. This audit sets out to assess the quality of DL at a district general hospital in the UK.
Methodology: DL for patients admitted with symptoms of HF to the joint cardiology and renal ward were analysed for meeting criteria (figure 1) deemed as 'good practice standards' by the National Institute for Cardiovascular Outcomes Research (NICOR) and National HF Audit. The initial audit evaluated DL from September 2015 and was re-audited in September 2016 following actions to improve quality of DL. These included promoting the aide-memoire of the required criteria through a screensaver on trust computers, hospital doctor induction and placing hard and electronic versions on computers.
Each criterion was scored using a 3 point scoring system and a total score was calculated and standardised by converting to a percentage. The scores were analysed by looking at the total DL score as well as analysis by criteria.
Results: September 2016 DL scores showed an improvement compared to 2015 (p-value = 0.359) as shown in table 1; 93% of DL had a score over 50% in 2016 compared to only 45% in 2015. A notable increase can be seen in the percentage of DL which included each criteria in 2015 and 2016 (figure 1), most markedly the first four criteria. Patient vital signs and medication are areas requiring more work.
Conclusion: This audit demonstrates that educational activities improve inclusion compliance of the majority of HF data standards within DL. This is likely to improve communication between hospital and community HF teams which is important in optimising the management of HF patients. Compliance in data standards within DL still has room for improvement, and further systems to improve this can be explored.

DL Scores 2015 v 2016

	2015	2016	% change
Number (n) of HF DL (total)	11 (131)	14 (135)	
Highest score	92.3	84.6	- 8
Lowest score	30.8	46.2	+ 50
Average score	55.4	61.7	+ 14
n DL scoring 25 - 49.9%	6	1	- 83
n DL scoring 50 - 74.9%	2	12	+ 500
n DL scoring 75 - 100%	3	1	- 67



Criteria included in DL 2015 v 2016

P1687

Heart failure specialist versus general cardiologist in the management of chronic heart failure in Russia

E Elena Lyasnikova[1]; M YU Sitnikova[1]; MA Trukshina[1]; AV Yurchenko[1]; DV Duplyakov[2]; EV Shlyakhto[1]
[1]Federal Almazov Medical Research Centre, Heart Failure Department, St-petersburg, Russian Federation; *[2]Samara Regional Cardiology Dispanser, Samara, Russian Federation*

Purpose: HF is responsible for considerable mortality rates and resource utilization. The aim of this study is to identify differences in HF management practices and outcomes between general cardiologists and cardiologists specializing in the treatment of patients with HF in real Russian clinical practice (from the Russian hoSpital Heart Failure Registry (RUS-HFR).
Methods: HF patients (included in the RUS-HFR from Oct 2012 to Jan 2014) discharged from cardiology wards and were followed-up (FU) in outpatient HF clinic (1 group - St.Petersburg(n = 74) were compared to patients who were under the supervision of a general cardiologists (2 group – St.Petersburg (n = 186), 3 group – Samara (n = 130). Mean age 59.0 ± 8.3 yrs; 80% men; most patients with HF III NYHA, LVEF≤40%. The average duration of FU was 30 month.
Results: After 2.5 yrs the survival of patients was 77% vs 65% ($p>0.05$) vs 40% ($p<0.01$) and HF hospitalizations were 33% vs 28% ($p>0.05$) vs 103% ($p<0.01$) in the groups 1,2,3, respectively. Among all groups more than 88% and 79% patients regularly visited the doctor and had HF NYHA II-III. There were important differences between the practice patterns of cardiologists and HF specialists. HF specialists treat patients more aggressively. Cardiologists reported that 68%-78%, 81-85%, 52-54% and 60-79% of their patients were taking RAS blockers,β-AB, MRAs and diuretics compared to 89%, 91% , 63% and 88% by HF specialists. Also, HF specialists were more likely than cardiologists to titrate RAS blockers and β-AB to higher doses: 46% vs 26-38% and 74% vs 52-56%, even in the presence of renal dysfunction and hypotension.
Conclusion: Cardiologists and HF specialists in Russia generally manage their patients in conformity with guidelines. However, in many areas, such as RAS blockers and β-AB use, HF specialists do so more aggressively. These approaches may, in part, explain the success of the outpatient HF clinic model in post-discharge mortality and raise the question of improve HF management in RF through to organize network of HF specialists and HF clinics throughout the country.

P1688

Left ventricular assistance device for destination therapy: results in the west region of France

P Pierre Teruin[1]; L Mabire[1]; M Michel[1]; JC Roussel[1]; T Senage[1]; E Flecher[2]; A Belin[3]; JN Trochu[1]
[1]University Hospital of Nantes Nord Laennec, Nantes, France; *[2]Hospital Pontchaillou of Rennes, Rennes, France*; *[3]University Hospital of Caen, Caen, France*

Background: Left ventricular assist device (LVAD) for destination therapy is a validated procedure in patients with advanced heart failure and contraindicated for transplantation. The aim of our study was to implement a destination therapy registry for patients implanted with an LVAD in 3 teaching hospitals of the west region of France from December 2005 to October 2015.
Results: 63 patients, 65 ± 7 years old, contraindicated for cardiac transplantation and implanted with a continuous flow LVAD as destination therapy were included. Preoperatively 92% were in NYHA class 3B or 4, 77% had a 3 or 4 INTERMACS profile, 61% had a stage 3 or 4 renal insufficiency, 38% liver failure, 35% type 2 diabetes, 19% peripheral arterial disease and 17% chronic pulmonary disease. Contraindications to transplantation were age (68%) and comorbidities (35%). Postoperatively, 78% of the patients were in NYHA class 2. Most common adverse events included bleeding (76%), ventricular arrhythmias (63%), right ventricular dysfunctions (56%), strokes (38%), driveline infections (25%) and pump thrombosis (13%). At 24 ± 24 months of follow-up, 56% of patients had died and 3 had been transplanted. 28% of early deaths were related to right ventricular failure (56%) and 18% of total deaths were related to pump failure. Overall survival was 65.4 ± 6.1% at one year and 53.9 ± 6.7% at 2 years. Increases in pre-implant mean pulmonary arterial pressure, pulmonary vascular resistance, and total bilirubin were significantly correlated ($p<0.05$) with lower survival.
Conclusion: Our study constitutes a French register of 63 patients implanted with LVAD as destination therapy, with results comparable to literature. Despite frequent complications, LVADs allow an improvement in survival and functional capacities.

P1689

NT pro BNP - a decision factor in preventing heart failure at diabetic patients

I Dimitriu[1]; D Voiculescu[1]; A Lacraru[1]; C Sinescu[1]
[1]Carol Davila University of Medicine and Pharmacy , Cardiology, bucharest, Romania

Background: To prove the importance of NTproBNP for preventing heart failure at diabetics.
Materials and Methods: We included 174 patients who were presented at hospital during two years, with diabetes. We excluded patients who are already diagnosed with heart failure or who had current symptoms of heart failure. We randomized patients into 2 equal groups: a control group and an intervention group. NTproBNP value was determined for all patients. In the intervention group patients were treated according to the NTproBNP. Patients with NTproBNP <125 pg/dl (38 patients) received standard treatment for their symptoms. Patients with NTproBNP>125 pg/dl (49 patients) were the ones on which we intervened to prevent heart failure. They were investigated by cardiac ultrasound and other tests and they received specific treatment. Patients in the control group received standard treatment regardless of the NTproBNP value.
Results: After two years, the end points were: diagnosis of heart failure left ventricular dysfunction, death from any cause, the rate of hospitalizations for cardiovascular pathology. After two years in the control group were eighteen (20.6%) patients who developed heart failure compared to ten (11.42%) patients in the intervention group. Twenty-eight (27.5%) patients were diagnosed with left ventricular systolic dysfunction, compared to eighteen (20.6%) in the intervention group. Also, and rate of admissions for cardiovascular pathology was higher in the control group thirty-four (39%) versus twenty-seven (31%) in the intervention group.
Conclusions: Patients in the intervention group, in which the value of NTproBNP was used in choosing therapeutic management, had lower rate of incidence of heart failure or cardiovascular events than patients in the control group. The NTproBNP value in patients without heart failure can detect patients at risk of developing heart failure. And more, medical intervention guided by NTproBNP can prevent or delay heart failure.

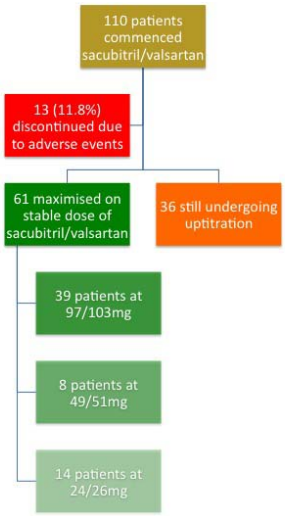
P1690

Use of sacubitril/valsartan in a dedicated heart failure centre - real world experience from the first 110 patients

M J Barrett[1]; S Earls[2]; S Zhou[2]; K Mcdonald[2]
[1]St Vincent's University Hospital, Cardiology, Dublin, Ireland; *[2]Heartbeat Trust, Dublin, Ireland*

Background/Introduction: Sacubitril/valsartan is a novel therapy which has been shown to reduce major adverse cardiovascular events and mortality in patients with reduced ejection fraction heart failure (HFrEF). Most data regarding tolerability comes from clinical trials. Experience in a real world population is less-well described.
Purpose: To assess the tolerability and success in achieving maximum target dose of sacubitril/valsartan, as well as detailing the side effect profile in a real world population.
Methods: Sequential patients attending a dedicated specialist heart failure unit with a therapeutic indication for sacubitril/valsartan were included. Electronic records (including electronic prescriptions) were reviewed to determine final achieved dose in patients who were maintained on sacubitril/valsartan. Any patient who had sacubitril/valsartan discontinued had the reason for discontinuation recorded along with any relevant laboratory or clinical investigations at the time.
Results: 110 patients were deemed suitable to commence sacubitril/valsartan. Of these, 9 (8.2%) were commenced on 49/51mg twice daily and the remaining 101 (91.8%) on 24/26mg twice daily.

At follow-up, 61 patients had been stabilised at maximum tolerated therapy. Of these, 39 (63.9%) achieved the maximum dose of 97/103mg twice daily. A further 8 patients (13.1%) reached the 49/51mg dose and 14 (22.9%) remained on the 24/26mg strength without tolerating a dose increase. 36 patients (32.7%) were still in the process of being uptitrated to the maximum tolerated dose.
13 patients (11.8%) discontinued sacubitril/valsartan. The commonest reason was a composite of hypotension, presyncope or sycnope (9/13, 69.2%). In this group, the mean drop in systolic blood pressure (SBP) at follow-up after commencement of sacubitril/valsartan was 17mmHg (range 0-45mmHg).
In patients in whom blood pressure effect was the predominant reason for discontinuation, half were noted to be concommitantly prescribed non-cardiac medications in which hypotension was a known side effect.
Other reasons for discontinuation included gastrointestinal disturbance (n = 3), acute kidney injury (n = 1), hyperkalaemia (n = 1) and back pain (n = 1). 2 patients had more than one indication for discontinuation of sacubitril/valsartan.
Conclusion(s): Sacubitril/valsartan is a well-tolerated medication in the majority of patients in our heart failure population. True hypotension was the dominant cause for discontinuation. Caution should be taken to consider reducing diuretics if clinically justifiable or rationalise other medications with anti-hypertensive side-effects to ensure that suitable patients only have the medication discontinued if truly intolerant.
Reassuringly, rates of hyperkalaemia and kidney injury were not higher than for standard angiotensin-blocking therapy and only a single patient developed an idiosyncratic side-effect.



P1691

Advanced age attenuates the aggravating role of salt on acute coronary syndrome patients with heart failure; results from hellenic heart failure study.

M Kouvari[1]; C Christina Chrysohoou[2]; H Kosyfa[1]; G Kalogirou[1]; P Aggelopoulos[1]; A Filippou[3]; S Iosifidis[3]; E Tsiamis[1]; D Tousoulis[1]
[1]*University of Athens, First Cardiology Clinic, School of Medicine, Athens, Greece*; [2]*University of Athens, Athens, Greece*; [3]*Harokopio University, Nutrition Science - Dietetics, Athens, Greece*

On behalf of: Hellenic Heart Failure study

Background/Introduction: Dietary salt restriction is arguably recommended in the prevention and management of heart failure. Nonetheless, salt is a dietary product which is highly associated with appetite. Considering that anorexia and cardiac cachexia is usually presented in heart failure patients, namely those in advanced age, to what extend salt restriction is a recommendation for all remains questionable.
Purpose: the role of discretionary and hidden salt intake on 10 year prognosis of Acute Coronary Syndrome (ACS) patients was investigated.
Methods: from May 2006 to March 2009, 1,000 consecutive patients who were hospitalized at a Cardiologic Clinic in Athens with ACS diagnosis were enrolled in the study. In 2016, 10y follow-up (2006-2016) was performed in 745 participants. A validated food frequency questionnaire was used, to assess, among other dietary habits, discretionary salt intake (i.e. addition in cooking or in table) as well as consumption of major hidden-salt food sources (i.e. processed / fried meat products, canned food, feta cheese, yellow-cheese, salted nuts, bread and other bakery products).
Results: 10y fatal/non fatal ACS events were 60% in heart failure patients who reported use of salt shaker in table and 47% in patients who avoided this habit (p = 0.03). Multivariate logistic regression analysis highlighted that patients who reported were twice as likely to develop a new cardiac episode within the decade (OR=2.19 95% CI (1.12, 4.3), p = 0.02). Principal component analysis was performed for major hidden-salt-sources. Salt addition during cooking did not reach significance. Two out of four patterns identified, reached significance in a multivariate analysis; a pattern characterized by processed/fried meat products, fast food and salty yellow cheese was associated with unfavorable ACS prognosis (OR=1.4 95%CI (0.97, 2.04)) whilst a pattern with healthier food choices (i.e. nuts, canned fish/vegetables, olives and feta cheese) was inversely associated with 10 year recurrent events (OR=0.55 95%CI (0.37, 0.82)). A significant interaction was observed between age and addition of salt in table as well as the aforementioned hidden salt patterns (all ps for interaction>0.05). Stratified analysis revealed that use of salt shaker retained its significance only in younger patients (OR=2.80 95% CI (1.18, 5.3), p = 0.02). Additionally, the potential protective effect of healthy, yet rich in salt, food choices reached significance in patients >65 years old (OR=0.27 95% CI (0.10, 0.71), p = 0.008).
Conclusion: salt, mainly this added in table, seemed to have an aggravating role in 10y prognosis of heart failure. Nonetheless, considering its detrimental role in appetite, instead of a general strict restriction, priorities should be set for a more efficient treatment approach.

P1692

Oral use of high doses of Furosemide as an alternative to intravenous or subcutaneous way in patients with severe Congestive Heart Failure

M Magdalena Fernandez Martinez De Mandojana[1]; S Llavina Farres[1]; J Muguerza Iraola[1]; B Ferro Castro[1]; I Serna Diez[1]; M Del Hierro Baleztena[1]; L Juaristi Azpiazu[1]; A Gonzalez Penagaricano[1]; E Coll Viciosa[1]; D Camacho Madueno[1]; A Aranzabal Lasagabaster[1]; ML Txakartegi Ibarloza[1]; J Taboada Gomez[2]; A Sanchez Gonzalez[1]; G Uranga Hernandez[1]
[1]*OSI Debabarrena - Mendaro Hospital, Home Hospitalization, Mendaro, Spain*; [2]*Hospital Comarcal de Mendaro, Preventive Medicine, Mendaro, Spain*

Background/Introduction: ACCF/AHA 2013 Heart Failure guidelines recommend initial dosing of oral Furosemide of 20-40 mg, once or twice daily, and a maximum total daily dose of 600 mg. In the last few years, several patients with severe Congestive Heart Failure had income in our Home Hospitalization Service with high doses of continuous parenteral Furosemide infusion. When we got the patient stability, we explored the option of using the oral way to administer high doses in an attempt to use a non-invasive way in patients with a long term treatment.
Purpose: The aim of this work is to describe our experience in a local Home Hospitalization Service in the orally use of high doses of Furosemide (higher than 750 mg daily) as an alternative to intravenous or subcutaneous use, in patients with severe Congestive Heart Failure (NYHA 3-4) and a high probability of death within the first year (PALIAR INDEX 3-4). We also want to study the impact of this therapy over renal function, survival rates and hospital return rates.
Methods: We conduct a retrospective study of 33 months of following (2013-2016). We recruited patients with severe Congestive Heart Failure, NYHA 3-4 and PALIAR INDEX 3-4, who required high doses of continuous parenteral Furosemide (iv/sc) to stabilize and have been sequenced with oral Furosemide at equivalent doses for which we used the vials of 250 mg diluted in water that patient takes along the day (respecting sleep).
Results: Our cohort included 32 patients with an average age of 83 (SD: 6,41) years. Sixty eight percent were men. Regarding to the etiology, almost the 50% were due to valvular disease. The median of monitoring was of 284,5 days (IQR: 332) and an average daily dose of Furosemide of 800 (SD: 575) mg. Baseline creatinine was 1.72 and after a month of treatment there was a slightly increase (1.76) but was not statistically significant. Sixty two percent of patients suffered hypokalemia that recovered with supplementary intakes. The readmission rate was of 37%. The global mortality was of 56%.
Conclusion(s): In our limited experience, we have found that the use of high doses of oral furosemide in patients with severe Congestive Heart Failure is a good therapeutic option, with very good clinical and analytical tolerance.

P1693

Why are heart failure patients in a district general hospital not being discharged on mineralocorticoid receptor antagonists?

E H Elen Hanna Hughes[1]
[1]*Countess of Chester Hospital, Cardiology, Chester, United Kingdom*

Background: The UK National Heart Failure Audit found that all criteria for the management of chronic heart failure patients were being met in a district general hospital, except the recommendation that patients with heart failure with reduced

ejection fraction should be treated with a mineralocorticoid receptor antagonist (MRA) if they are still symptomatic and have an ejection fraction of <35%. The project looked to try and ascertain why less than the national average of patients in a district general hospital were being discharged on MRAs, and whether there were any practical measures that could be put in place to ensure the national guidelines are being met in future to help optimise the treatment of the chronic heart failure patients.
Purpose: The project was undertaken to try and address any factors that might be contributing to a district general hospital's below-average rate of prescription and discharge on MRAs. It was also done to see whether any practical measures could be implemented to ensure optimal treatment of the chronic heart failure patients in a district general hospital.
Methods: The data from the National Heart Failure Audit was extrapolated and used in order to analyse any variables that may be contributing to the difference in the numbers of patients being discharged from hospital on MRAs elsewhere in the country compared to the district general hospital. The data provided a sample size of 81 patients.
Results: The biggest factor in patients not being discharged on an MRA was their place of care. A majority (55%) of patients who were discharged on an MRA were discharged from a dedicated cardiology ward. Those patients who were not discharged on an MRA were mainly cared for on other wards (68%), implying that specialist cardiology care is vital in discharging patients appropriately on an MRA.
Conclusion: There is evidence to support the hypothesis that a patient's place of care impacts their optimal drug therapy for chronic heart failure. One of the outcomes of the project is to aim to increase awareness and education regarding the use of MRAs in chronic heart failure among non-cardiological medical specialties, in order to optimise chronic heart failure management post-discharge.

P1694
Pending heart failure clinic opening: care performance measures in real-life practice

S Padaryan[1]; S Galochkin[1]; N Soseliya[1]; E Shavarova[1]; S Villevalde[1]; A Milto[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Aim: to compare real clinical practice with current guidelines for the diagnosis and treatment of chronic heart failure (HF) before the HF Clinic opening.
Material and methods: all patients admitted for two Moscow city clinical hospitals with decompensated HF from January to May 2015 were included into the registry (n = 484). Clinical, demographic, laboratory and instrumental characteristics and medical treatment before and during hospitalization were evaluated, as well as recommendations contained in the discharge summary. Performance measures included left ventricular ejection fraction (LVEF) documentation in medical history, any beta-blocker for patients with HF with reduced EF (HFrEF); evidence-based beta-blocker for patients with HFrEF; inhibitor of the renin-angiotensin-aldosterone system (RAAS) for patients with HFrEF; warfarin for patients with atrial fibrillation; aldosterone antagonist for patients with HFrEF; implantable cardioverter-defibrillator for patients with EF ≤35%; and referral to outpatient disease management.
Results: the median age was 73 years (39, 95); men – 45%. 97% of patients had HF II- IV (NYHA), among them 26% - HF II, 64% - HF III, 10% - HF IV (NYHA). Echocardiography was done in 100% patients with HF. EF<40% was found in 44% of patients. 21% of the patients did not receive medical treatment before admission. 56% of patients with HFrEF received ACE inhibitors/angiotensin receptor blockers (ARBs), of which only 25% - in effective dose. beta-blockers were prescribed in 67% of HFrEF patients, among them 25% - in the target dose, two-thirds were treated with evidence-based beta-blocker. 38% of patients needed in mineralocorticoid receptor antagonists (MRA) received spironolactone. During hospitalization 82% of HFrEF patients received ACEI therapy, 11% – ARBs, 92% – beta-blockers, 89% – MRA, 83% – loop diuretics and 15% – thiazide diuretics. According to the discharge summary 5% of patients did not receive post-discharge inhibitor RAAS without explanation in the medical documentation. Evidence-based beta-blocker was prescribed to 70% of HFrEF patients. Spironolactone was recommended after discharge in 89% of HFrEF patients. Warfarin for patients with atrial fibrillation and high CHA2DS2-VASc score risk was recommended in 52%. Necessity of cardioverter-defibrillator implantation for patients with EF ≤35% was discussed in 4% of discharge summaries. All discharge summaries contained recommendation of outpatient clinic visit but only in 15% of them exact date and place were mentioned.
Conclusion: Treatment of HF is one of the main areas targeted for improvement. Such registry is a valuable tool for optimizing the management of HF patients.

P1695
The difference between drug usage in patients with HFrEF and HFmrEF: results from TREAT HF

A Celik[1]; H Kaya[2]; L Bekar[3]; H Gunes[4]; MB Yilmaz[2]
[1]*Mersin University, Cardiology, Mersin, Turkey*; [2]*Cumhuriyet University, Cardiology, Sivas, Turkey*; [3]*Hitit University , Cardiology, Corum, Turkey*; [4]*Kahramanmaras Sutcu Imam University, Cardiology, Kahramanmaras, Turkey*

On behalf of: TREAT HF

Purpose: Heart failure with mid-range ejection fraction (HFmrEF) is a new defined type of heart failure. There was no clear data and no evidence about the usage of heart failure drugs in this population. TREAT HF (Turkish Research Team-HF) data were analyzed for the assessment of any usage difference between heart failure drugs in patients with HF and reduced ejection fraction (HFrEF) and HFmrEF.
Methods: TREAT HF is a network which undertakes multicenter, national, observational studies designed to evaluate HF patient's clinical characteristics and current treatment modalities. 1074 patients with the diagnosis of HFrEF and HFmrEF were included in this analysis. 84 of these patients had HFmrEF and 990 of them had HFrEF according to their left ventricular ejection fraction (LVEF) and additonal ESC criteria.
Results: Patients with HFrEF had higher usage of ACEi/ARB, digoxin and loop diuretics than patients with HFmrEF (Table 1). No significant difference were seen in patients with HFrEF and HFmrEF according to the usage of beta blockers, MRAs, tiazide diuretics, and ivabradin.
Conclusions: These results show that beta blockers, MRAs, tiazide diuretics and ivabradin usage of patients with HF did not change according to LVEF. But the HF patients with reduced EF were using higher rate of ACEi/ARBs, digoxin and loop diuretics than with mid-range EF.

The drug usage of patients with HF

Drug usage (%)	HFrEF (N=990)	HFmrEF(n = 84)	P value
ACEi/ARBs	72.5	60.7	0.031
Beta blockers	82.3	76.2	0.107
MRAs	50.7	47.6	0.650
Ivabradin	13	8.4	0.300
Digoxin	24.1	11.9	0.010
Loop diuretics	73	60.7	0.022
Tiazide diuretics	34.7	37.3	0.633

P1696
The effects of prolonged daytime fasting on clinical and laboratory parameters of heart failure patients treated with diuretics

G Gabra[1]; B Bassam Atallah[2]; ZG Sadik[2]; R Ferrer[3]; J Stapleton[3]; M Soliman[1]; F Bader[1]
[1]*Cleveland Clinic Abu Dhabi, Cardiovascular Medicine, Abu Dhabi, United Arab Emirates*; [2]*Cleveland Clinic Abu Dhabi, Pharmacy Services, Abnu Dhabi, United Arab Emirates*; [3]*Cleveland Clinic Abu Dhabi, Nursing, Abu Dhabi, United Arab Emirates*

Background: Religious fasting during the month of Ramadan necessitates that one refrains from eating and drinking during daytime. Since Ramadan is determined by the lunar calendar (354 days), it will start 11 days earlier each year on the solar calendar. In 2016, Ramadan fell in June and fasting was for about 15 hours daily. Although not mandated by sick patients, some still insist on fasting. We investigated whether this negatively affects chronic heart failure (CHF) patients on diuretics.
Methods: Patients with CHF requesting to fast were told to decrease their diuretic dose by half. We then prospectively followed them for clinical as well as laboratory parameters at the beginning and at the end of the month.
Results: A total of 23 systolic CHF patients were included (17 males and 6 females). Mean age was 54.4 ± 11.5 years. The mean baseline dose of furosemide was 108 ± 133.3 mg daily. All patients reduced their dose by half. There were no admissions for heart failure among study patients. There was no significant change in weight from baseline (87.4 ± 21.8 kg vs. 88.1 ± 21.5 kg, p = 0.47), neither was there a significant change in renal function, serum Hb, as well as serum electrolytes (table 1).
Conclusion: Despite long hours with no oral intake, patients with CHF tolerated fasting well while requiring less diuretics. Larger studies are needed to determine if patients would normally drink less fluids if treated with less diuretics and if self-management with diuretics influences outcomes compared to strict regimens.

Table 1

Variable	Before	After	p Value
Weight (Kg)	87.4 ± 21.8	88.1 ± 21.5	0.47
Hb (g/dL)	13.35 ± 1.69	13.41 ± 1.67	0.76
Na+ (mmol/L)	137.96 ± 3.6	137.9 ± 4.2	0.90
K+ (mmol/L)	4.64 ± 0.47	4.64 ± 0.62	0.99
BUN (mmol/L)	7.87 ± 3.90	6.74 ± 2.96	0.08
Cr (μmol/L)	100.82 ± 48.42	93.95 ± 33.61	0.24
Mg ++ (μmol/L)	0.84 ± 0.10	0.82 ± 0.10	0.38

Variables before and after a month of daytime fasting. Values are expressed in mean ± SD

P1697

Impact of Ivabradine to improve the heart rate variability in patients with chronic heart failure

K Hristova[1]; R Marinov[1]; RB Singh[2]; G Cornelissen[3]; TZ Katova[1]; V Kostova[1]
[1]National Heart Hospital, Sofia, Bulgaria; *[2]Halberg Hospital and Reaserch Institut , Moradabad, India*; *[3]University of Minnesota, Minneapolis, United States of America*

Heart Rate Variability (HRV) is a noninvasive and sensitive technique to evaluate cardiovascular autonomic control and major determinant of cardiovascular health.Reduced HRV is an independent risk factor for heart disease and increased risk of mortality after a diagnosis of CHF or LV dysfunction

The aim of the study is to analyze this circadian pattern in the HRV in patients with CHF and severe LV dysfunction (EF < 35%) in patients with HFrEF and analyzed the effect of Ivabradyne to improve the reduced HRV.

Methods: Were evaluated 30 pts mean ages 58.5 ± 3.5y with EF% 33.5 ± 2.3 % in sinus rhythm. Holter ECG monitoring for 48 hours were performed in all pts in order to analyze the HRV before treatment with Ivabradin (7,5 mg two times per day),1.st week and also a month after therapy. HRV was assessed based on the RR intervals and ECG signal was recorded using leads, to obtain a predictive value of reduced HRV by measuring 48 h standart deviation of N-N intervals (SDNN), also HRVindex, derived by dividing total heart rate intervals by the high of histogram. The echocardiography with speckle tracking imaging was performed basal and 1mFU in order to extract longitudinal strain.

Results: All patients with HFrEF are with reduced SDNN -55, 6 ± 5 ms and reduced GLS- 12.93 ± 3 %. The highest value for SDNN (>70 ms) and HRV index are around 6.00 am and the lowest value are around 6.00 pm (< 40 ms). Considering results from all SDNN and HRV index before and after treatment with Ivabradine, the lowest values occurs, on average, around 06:00 p.m., circadian rhythm is found for all parameters before treatment and follow up (1wFU, 1mFU). After 1mFU therapy with Ivabradyn were found significant improvement ot reduced HRV - SDNN 65.5 ± 3.6 ms , also in HRV index – 41.1 ± 1.2 ms. Reduced HRV is fairly correlated with EF % ($p < 0.01$, r= 0.65) and GLS % ($p < 0.01$, r=0.47) .

Conclusions: This is the first study to assess global physiological consequences of the circadian clock specifically within the myocardial deformation and HRV.We provide evidence that the cardiomyocyte circadian clock influences not only heart rate and the responsiveness of the heart to increased workload, but and circadian pattern of regional dysfunction and deformation, which is important for global ventricular function. Ivabradin has positive effect to increase reduced HRV in patient with HFrEF.

Circadian clock and variability

1mFU	06:00	12:00	18:00	24:00
GL Strain (%)	-13.22±3.19	-12.99±2.3	-12.76±3.19*	-12.95±2.86
SDNN	-65.93±4.91	-40.78±5.45	-28.42±6.73*	-30.53±4.45
HRVindex	41.99±1.26	40.06±1.12	37.04±1.34*	39.31±1.28

P1698

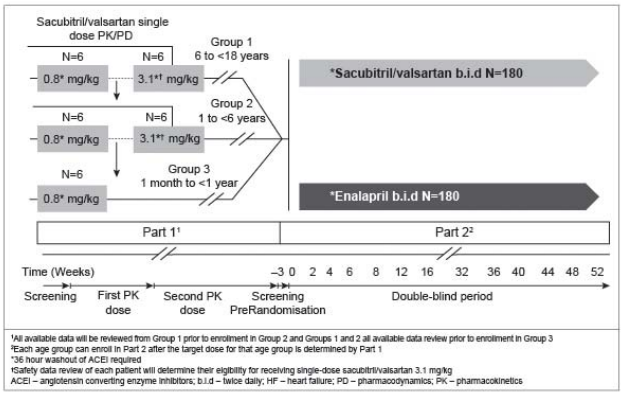
Effects of sacubitril/valsartan vs. enalapril in paediatric patients with heart failure due to systemic LV systolic dysfunction: Design and rationale of the PANORAMA-HF study

R Shaddy[1]; F Chen[2]; C Canter[3]; N Halnon[4]; J Rossano[1]; P Kantor[5]; D Bonnet[6]; M Burch[7]
[1]The Children's Hospital of Philadelphia, Philadelphia, United States of America; *[2]Novartis Pharmaceuticals Corporation, East Hanover, United States of America*; *[3]Washington University, MO, United States of America*; *[4]UCLA, Los Angeles, United States of America*; *[5]University of Alberta, Edmonton, Canada*; *[6]Necker Hospital University, Paris, France*; *[7]Great Ormond Street Hospital for Children, London, United Kingdom*

Background: Paediatric heart failure (HF) is characterised by significant morbidity and mortality, frequent hospitalisation, and poor quality of life. The rationale for medical therapy of paediatric HF primarily comes from adult studies. Sacubitril/valsartan (LCZ696) reduced mortality and delayed HF progression vs. enalapril, and was generally well tolerated in the PARADIGM-HF trial in adults with HF with reduced ejection fraction.

Study Design: This multicentre study will use an adaptive seamless, two-stage design (Figure). In part 1, an open-label, single-dose study with 36 paediatric HF patients (1 month to < 18 years) stratified into 3 age groups (Group 1: 6 to < 18 years; Group 2: 1 to < 6 years; Group 3: 1 month to < 1 year) will receive sacubitril/valsartan in a sequential overlapping fashion and in descending age group order. The doses for Group 1 and 2 (0.8 mg/kg and 3.1 mg/kg) corresponds to ˜50 and 200 mg dose of sacubitril/valsartan in an adult with 65kg bodyweight. Group 3 will only be assessed with the 0.8 mg/kg dose of sacubitril/valsartan. The dose for Group 2, and subsequently for Group 3, may be adjusted based on safety information from the previous group(s). Pharmacokinetics/pharmacodynamics and biomarkers (N-terminal pro-B-type natriuretic peptide and cyclic guanosine monophosphate) will be evaluated. Part 2 is a 52-week randomised, double-blind, parallel-group, active-controlled study. Eligible patients (N=360) will be stratified by age and functional classification and randomised to receive either sacubitril/valsartan or enalapril (target dose: 0.2 mg/kg twice daily (b.i.d); maximum dose 10 mg b.i.d). As there is no generally agreed, validated clinical efficacy endpoint for this patient population, a Global Rank primary endpoint has been developed; this will be derived by ranking patients (worst to best outcome) according to clinical events such as death, listing for urgent heart transplant or mechanical life support, worsening HF, and measures of functional assessment (New York Heart Association/Ross) and patient-reported outcomes (Patient Global Impression of Severity and the paediatric Quality of Life Inventory [physical functioning]). Additional patients will be enrolled to ensure that a minimum of 80 patients with clinical events are obtained. Safety areas of interest include identified risks common to both sacubitril/valsartan and enalapril such as hypotension, hyperkalaemia, worsening renal function, and angioedema.

Conclusion: This adaptive study design will determine if sacubitril/valsartan can offer a greater clinical benefit vs. enalapril in children with HF.



P1699

Safety of sacubitril/valsartan in patients receiving statins in the PARADIGM-HF trial

H Streefkerk[1]; D Anand[2]; W Zhou[2]; B Balas[1]; H Schwende[1]; V Shi[2]
[1]Novartis Pharma AG, Basel, Switzerland; *[2]Novartis Pharmaceuticals Corporation, East Hanover, United States of America*

Funding Acknowledgements: This study was funded by Novartis Pharma AG

Background: Sacubitril/valsartan (S/V) reduces mortality and morbidity in patients with chronic heart failure with reduced ejection fraction (HFrEF). Healthy human studies showed that co-administration of S/V increased the Cmax of atorvastatin and its metabolites by up to 2-fold and AUC by up to 1.3-fold but did not find a similar increase with simvastatin. Both statins are widely used in patients with HFrEF.
Purpose: To determine if concomitant use of statins with S/V was associated with a higher incidence of adverse events (AEs) in the PARADIGM-HF trial.
Methods: In the double-blind (DB) PARADIGM-HF trial, 8442 eligible patients with symptomatic HFrEF were randomised, after consecutive run-in with enalapril (ENA) and S/V, to receive S/V or ENA in addition to other background therapy. In this post hoc analysis, potentially statin-related AEs and serious AEs (SAEs) were compared by treatment group, statin use (yes/no) at baseline and statin dose level (highest dose defined as 80 mg atorvastatin or simvastatin) in patients treated in DB period. The homogeneity of risk ratios (RR, S/V vs. ENA) of potentially statin-related AEs was evaluated by Breslow-Day test.
Results: Of the 8432 patients exposed to study treatment, 4653 (55.2%) received statins at baseline (most frequently atorvastatin or simvastatin). Common statin-related AEs including rhabdomyolysis, hepatitis and pancreatitis were low in both S/V and ENA groups (table). Rhabdomyolysis was reported in the S/V (n = 4) and the ENA (n = 3) group, with 1 case in each treatment group occurring without statin treatment. Medical review of rhabdomyolysis cases reported with S/V did not support a potential causal association with the drug (either an improbable temporal relationship with study drug, or presence of confounding factors). None of the assessed statin categories including statin vs. no statin, highest dose statin, atorvastatin, simvastatin or the combination demonstrated a statistically significant signal ($p < 0.05$) for an interaction between S/V and statins. The overall incidences of AEs and SAEs were higher in patients on a highest dose statin than in patients not taking statins but generally comparable between S/V and ENA treatment groups. The rate of overall AEs and potentially statin related AEs were also consistent across the frequently used statins.
Conclusions: Irrespective of concomitant statin treatment or statin dose level, no clinically meaningful differences in the AE profile were seen between S/V and ENA groups.

Achievement of optimal medication doses during the heart failure titration process

S O'leary[1]; M Griffin[2]; J O'neill[3]; M Bermingham[1]; C Blaine[3]; G Ryan[3]
[1]University College Cork, School of Pharmacy, Cork, Ireland; *[2]Connolly Hospital Blanchardstown, Pharmacy Department, Dublin, Ireland*; *[3]Connolly Hospital Blanchardstown, Heart Failure Clinic, Dublin, Ireland*

Background: Patients newly diagnosed with heart failure (HF) are initiated on disease-modifying drug therapies and are gradually up-titrated to target doses. The success of this approach varies with studies reporting between 31-53% of patients achieving ACE inhibitor or angiotensin receptor blocker (ACEi/ARB) target dose and between 18-91% of patients achieving beta-blocker target dose.
Purpose: To determine (i) the extent to which prescribing of recommended HF therapies and achievement of target doses of these agents is accomplished in patients attending a nurse-led outpatient HF clinic and (ii) the rate of adverse effects experienced by patients and the effect of adverse effects on titration to target doses.
Methods: This was a retrospective cohort study of HF patients post- de novo HF hospitalisation who first attended a nurse-led outpatient HF clinic in an Irish teaching hospital from January 2014 - June 2015. Chart review confirmed medications and doses prescribed, clinical and biochemical parameters. Target dose was defined from the 2012 European Society of Cardiology heart failure guidelines where available or from the Summary of Product Characteristics of the originator product.
Results: Data were available for 51 patients (average age 65.3 ± 14.5 years, 67% male). Of these, 42 patients had heart failure with reduced ejection fraction (HFrEF) and 9 had heart failure with preserved ejection fraction (HFpEF). Median duration of titration was greater in HFrEF patients (89 days) compared to HFpEF patients (47 days). At the end of the titration period, an ACEi/ARB was prescribed to 93% of HFrEF and 78% of HFpEF patients. A beta-blocker was prescribed to 93% of HFrEF and 67% of HFpEF patients. In the HFrEF group 33.3% of patients were titrated to target ACEi/ARB dose, 9.5% to target beta-blocker dose and 4.8% to the target dose of both medications. An adverse effect was experienced by 92.2% of all patients during titration. The most common adverse effects were excessive reduction in blood pressure (n = 31, 60.8%), excessive reduction in heart rate (n = 26, 51.0%), high serum potassium level (n = 18, 35.3%) and deterioration in renal function (n = 20, 39.2%). No patient experienced adverse changes to pulmonary function. Taking into account titration limiting adverse effects, an individualised maximum tolerated ACEi/ARB and beta-blocker dose was reached in 90.5% and 78.6% of HFrEF patients respectively.
Conclusion: Over an average period of three months, a nurse-led HF clinic successfully titrated HFrEF patients to target medication doses which were maintained over one-year follow-up. The majority of patients were titrated to maximum tolerated doses of HF medications however there remain patients who are not reaching these individualised doses. Adverse effects were the main burden preventing titration in both HF patient groups.

P1701

Frusemide adjustment in heart failure HF) during ramadhan: effectiveness and safety pilot study.

MK Othman[1]; SL Yang[2]; HB Liew[1]; CH Yen[2]; KK Chow[1]; JRJ Jinuin[1]; BC Beh[1]; MH Mohd Asnawani[1]; SL Tan[3]; JH Chi[3]; QL Goh[3]
[1]Queen Elizabeth II Hospital, Cardiology, Kota Kinabalu, Malaysia; *[2]Clinical Research Centre Queen Elizabeth II, Kota Kinabalu, Malaysia*; *[3]Queen Elizabeth II Hospital, Pharmacy, Kota Kinabalu, Malaysia*

Funding Acknowledgements: Self funded

Background and Objectives: Compliance to medication and fluid restriction are important to prevent HF exacerbations1. During Ramadhan months, Muslim are fast from dawn to sunset2. There are no published guidelines/consensus in adjustment of medication during Ramadhan. Our study aim to evaluate the effectiveness and safety of standardized approach to individualise HF medications to twice-a-day regime, especially frusemide.
Methodology: Thirty patients recruited from outpatient HF clinic in a tertiary hospital. Convenience sampling for both fasting (n = 17) and non-fasting (n = 13) patient whom fulfilled selection criteria. Subjects were followed up before, during and after Ramadhan. Clinical variables and HF outcomes were measured at baseline and follow-up. Frusemide is adjusted to bid regime with 2/3 total daily dose at break of fast.
Findings: Mean age was 56.3 year-old; 90% male. Half of the patients have ischemic cardiomyopathy. 86.7% in sinus rhythm. Comorbidities includes hypertension (70%), diabetes mellitus (40%), dyslipidemia (43.3%), chronic kidney disease (23.3%) and thyroid dysfunction (3.3%). Pre-exsiting HF medication includes beta blocker (94%), ARB/ACEi (88%), MRA (94%), nitrates (24%) and frusemide dose were 70% od, 18% bid and 12% tid. Majority (88%) were steady medication for minimum 6 months. All patients were warm and dry at baseline. 60% has no prior HF-related hospitalization. Among fasting patients, there were no differences throughout study in blood pressure, heart rate and body weight. However, one hospitalization due to dehydration secondary to overdiuresis, another patient required frusemide uptitration as outpatient. Majority (87%) were able to comply to adjusted regime. 14% of the patient reported not thirsty and 43% very thirsty.
Conclusions: In our study, individualized frusemide adjustment among HF patient during Ramadhan is well-tolerated, effective and safe. However this study is limited by small sample size therefore further study is required to support wider practice recommendation.

P1702

Rationale and design of TRANSITION: a multi-center, randomised, open-label study comparing pre- versus post-discharge initiation of sacubitril/valsartan in hospitalised patients with ADHF and HFrEF

DP Figal[1]; R Wachter[2]; M Senni[3]; J Belohlavek[4]; A Noe[5]; D Carr[5]; D Butylin[5]
[1]Hospital Universitario Virgen de la Arrixaca, Universidad de Murcia, Murcia, Spain; *[2]Department of Cardiology, University Hospital Göttingen, Gottingen, Germany*; *[3]Heart Failure and Heart Transplant Unit ASST Papa Giovanni XXIII , Bergamo, Italy*; *[4]General Teaching Hospital, Charles University in Prague, Prague, Czech Republic*; *[5]Novartis Pharma AG, Basel, Switzerland*

On behalf of: TRANSITION study investigators
Funding Acknowledgements: This study was funded by Novartis Pharma AG

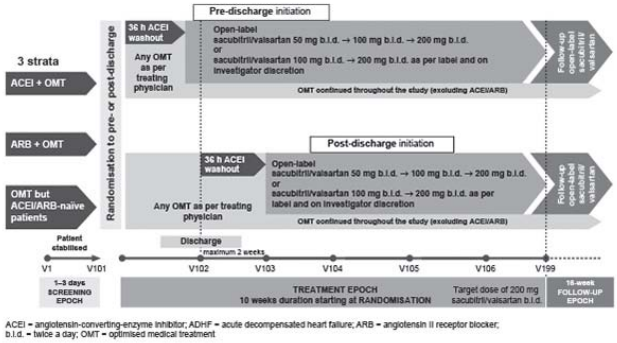
Background: Despite short-term symptomatic improvement with current treatments, the prognosis for hospitalised patients with acute decompensated heart

failure (ADHF) remains poor, with over 15–20% mortality and 30–40% readmission rates in the first year post-discharge. In the PARADIGM-HF trial, the angiotensin-receptor-neprilysin inhibitor sacubitril/valsartan was well tolerated and, compared with enalapril, was found to provide highly significant reductions in rates of mortality and HF hospitalisation, and to delay HF progression. Given that PARADIGM-HF enrolled only patients who were ambulatory at the time of inclusion, there is limited evidence at present on the safety and tolerability of initiating sacubitril/valsartan treatment in patients hospitalised due to ADHF.

Methods: TRANSITION is a randomised, multi-centre, open-label clinical trial designed to compare pre- versus post-discharge sacubitril/valsartan treatment initiation in patients hospitalised for ADHF, including patients with newly diagnosed HF. The study aims to randomise 1000 hospitalised patients with HF with reduced ejection fraction (HFrEF, LVEF ≤ 40%) after hemodynamic stabilisation (defined as no need for intravenous diuretics in 24 hours prior to screening and systolic blood pressure > 110 mmHg for at least 6 hours prior to randomisation). All patients are stratified by pre-admission treatment status: on an angiotensin converting enzyme inhibitor (ACEI), on an angiotensin receptor blocker (ARB), or ACEI/ARB-naive. Patients are randomised 1:1 within each stratum for initiation of sacubitril/valsartan treatment either pre-discharge (no later than 12 hours before discharge) or within 1–14 days post-discharge. The study design is represented in Figure 1. The primary endpoint is the proportion of patients achieving the target dose of 200 mg sacubitril/valsartan twice daily at 10 weeks after randomisation. Key exploratory endpoints will assess among others, patterns of biomarkers (N-terminal pro B-type natriuretic peptide and high-sensitivity-troponin-T), signs and symptoms, re-hospitalisations and other health resource utilisation parameters.

Current status: Presently, 244 patients have been randomised in 16 countries and 132 centres at the time of abstract submission.

Conclusion: TRANSITION study will provide evidence on the safety and tolerability of initiating sacubitril/valsartan treatment pre-discharge or shortly after discharge, in hemodynamically stabilised patients with HFrEF hospitalised for ADHF.



ACEI = angiotensin-converting-enzyme inhibitor; ADHF = acute decompensated heart failure; ARB = angiotensin II receptor blocker; b.i.d. = twice a day; OMT = optimised medical treatment

A double-blind, randomised, two arm parallel group trial to determine the effects of torasemide versus furosemide on one marker (PIP) of cardiac fibrosis in patient with HFpEF and T2DM

T D Trippel[1]; S Von Linthout[1]; R Lindhorst[1]; A Sandek[2]; A Bobenko[1]; B Pieske[1]; F Edelmann[1]; C Tschoepe[1]
[1]*Charite - Campus Virchow-Klinikum, Department of Internal Medicine-Cardiology, Berlin, Germany*; [2]*University Medical Center Gottingen (UMG), Department for Cardiology and Pneumology, Gottingen, Germany*

Funding Acknowledgements: FP7 Project ID 261409 within the MEDIA (The MEtabolic Road to DIAstolic Heart Failure)

Background: Heart failure with preserved ejection fraction (HFpEF) accounts for 50% of HF cases. HFpEF is associated with diastolic dysfunction and myocardial remodeling. Serum propeptide of procollagen type I (PIP) strongly correlates with the turnover of extracellular cardiac matrix proteins and ongoing cardiac remodeling and PIP may reflect the rate of extracellular synthesis of collagen type I as a surrogate parameter. Loop diuretics such as torasemide and furosemide have been described to alter PIP levels. We evaluated the effects torasemide vs. furosemide on serum PIP levels in patients with HFpEF and diabetes mellitus type II.

Material and Methods: We performed a monocentric, double-blind, randomized, two-armed, parallel-group, active controlled clinical trial in 35 patients to determine the effects of a 9 month treatment with torasemide 5 mg (test medication) versus furosemide 20 mg (active control) on one marker (PIP) of cardiac fibrosis.

Results: 15 of enrolled patients were female (42%), mean age in DROP-PIP was 69 yrs, mean was BMI 34,7 kg/m2, 83% were NYHA class II/III. Echocardiographic characteristics at baseline showed a mean LVEF 61%, LVMI 121,7 g/m2, E/E' 14, and LAVI of 40 ml with a NT-proBNP of 174 ng/l and a 6MWT distance of 421 m. 28 patients completed the trial per-protocol. On average patients treated with Furosemide experienced a non-remarkable absolute increase for PIP of 1.15 ± 38.1 (paired t-test, $p = 0.9062$), in contrast Torasemide treated patients show a negligible absolute reduction of -1.25 ± 29.1 ($p = 0.8854$) in the per -protocol population. Both Treatment groups did not show a significantly different treatment effect regarding a change in absolute PIP levels from baseline to follow-up ($p = 0.8583$). Key secondary endpoints were neutral.

Conclusion: In the present patient population with HFpEF and T2DM, loop diuretic therapy did not significantly affect PIP serum levels as a marker of cardiac fibrosis. Torasemide and furosemide did not show significant differences in the effect exerted on serum PIP level.

P1704

Comparative efficacy of long-term digoxin and ivabradine therapy on prognosis, left and right heart functional parameters in patients with chronic heart failure and preserved ejection fraction

LR Liana Tumasyan[1]; KG Adamyan[1]
[1]*Institute of Cardiology, Yerevan, Armenia*

The aim of study was to assess the comparative efficacy of long-term digoxin (D, 0.25 mg) and ivabradine (I, 15 mg) therapy on prognosis, left (LV) and right ventricular (RV), left atrial (LA) and right (RA) atrial parameters, NT-pro-BNP and high sensitivity C-reactive protein (hsCRP) levels in pts with III NYHA functional class chronic heart failure (CHF) and preserved LV ejection fraction (PEF).

Methods: 165 pts (age 63.2) with symptomatic CHF and PEF in sinus rhythm with heart rate (HR)>70 bpm were randomly assigned to groups A ($n = 55$, receiving D), B ($n = 53$, receiving I) and C ($n = 57$, non-receiving both drugs) in addition to ACE inhibitors, beta-blockers and diuretics. RV fractional area change (FAC), tricuspid annulus plane systolic excursion (TAPSE), pulmonary artery (PA) ejection (ET) time, RA and LA functional index (FI), relation of pulmonary vein (PV) systolic and diastolic fraction (S/D), PV systolic contribution (SC),difference between duration of reversal atrial flow (Ar) and late (A) transtmitral filling, NT-pro-BNP and hsCRP levels were assessed at baseline, 12, 24 and 36 months.

Results: 1-year, 2-year and 3-year mortality were 29.1%, 36.4% and 43.6%; 30.2%, 37.7% and 45.5%; 35.1%. 42.1% and 52.6% in groups A, B and C, respectively. 1-year, 2-year and 3-year hospitalization rates were 41.8%, 52.7% and 61.8%; 43.4%, 54.7% and 62.3%; 63.2%, 75.4% and 82.5% in groups A, B and C, respectively. Event-free analysis showed lower probability (RR reduction) of 1- year, 2- year and 3-year hospitalization at 33.9% and 31.3%; 30.1% and 27.5%; 25.1% and 24.5%, respectively, in groups A and B compared to group C ($P < 0.05$) and trend to reduction of 1-year, 2-year and 3-year mortality at 17.1% and 14%, 13.5% and 10.5%, 13.5% and 17.1%. 1-year I and D treatment increased (%) RV FAC at 28.5 and 27.2, TAPSE at 42.1 and 40.1, PA ET at 17.9 and 16.2, PV SC at 39.9 and 38.1, RA FI at 48.8 and 46.4, LA FI at 46.7 and 45.4, PV S/D at 35.2 and 33.4, decreased Ar-A at 82.7 and 79.1, levels of NT-pro-BNP at 36.1 and 34.9 and hsCRP at 40.1 and 39.9 ($p < 0.05$ for all). Reduction of NT-pro-BNP, hsCRP≥40% and HR≥25% was associated with significant improvement of morbidity compared to decrease of NT-pro-BNP, hsCRP < 25% and HR < 15% (RR 0.35, 0.33 and 0.32, $p < 0.05$), respectively. Similarly, changes of RA and LA FI, PV SC≥50%, PAET at≥25% and Ar-A ≥80% were associated with significant improvement of hospitalization compared to changes of RA and LA FI, PV SC < 30%, PAET < 15% and Ar-A < 60% (RR 0.37, 0.36, 0.35, 0.34, and 0.33, $p < 0.05$, respectively).

Conclusions: 1) Changes of Ar-A ≥80%, RA and LA FI, PV SC≥50%, NT-pro-BNP, hsCRP≥40; PAET and HR≥25% identified pts with hospitalization risk reduction. 2) I and D use associated with similar significant reduction of morbidity and trend to reduction of mortality due to significant improvement of RV, LA and RA functional parameters, neurohormonal and inflammation status and HR reduction.

P1705

Results of a single center experience on 200 consecutive patients treated with Entresto (sacubitril/valsartan).

A Canu[1]; V Maurin[1]; P Dos Santos[1]; F Picard[1]
[1]*University Hospital of Bordeaux, Bordeaux, France*

Background: Guidelines for the treatment of chronic heart failure (HF) currently recommend Entresto as replacement of ACE-I or ARB in patients with HFrEF who remain symptomatic despite optimal treatment to reduce the risk of HF hospitalization and cardiovascular death. However, the detail of the improvement sequence of patients treated by angiotensin receptor neprilysin inhibitor remains unknown due to the lack of data during the run in period before the randomization in the PARADIGM trial.

Objective: We report the results of our monocentric cohort of 200 consecutive systolic HF patients treated with Entresto. Between October 2015 and September 2016, 200 patients received Entresto, 180 were evaluated one month after introduction, 157 three months after, and 99 after six months of follow up.
Results: All patients were in stable hemodynamic condition with an optimized pharmacological therapy at baseline (95% were treated with ACE-I or ARB, 93.5% with betablocker and 80% with MRA). 81% were men, mean age was 59 years old. 51% of patients had ischemic HF and the median duration of HF was 8.5 years. 2.5% of the patients were in NYHA class 1 (but with poor prognosis factor such as elevated BNP level), 68% were in class 2, and 29.5% in class 3. During the follow-up period, 8.5% patients discontinued treatment for adverse events, 6% were heart transplanted, and 6% died of cardiovascular cause. Entresto was initiated at half dosage or less depending on the fragility of the patient, (78% at 49 mg/51 mg twice daily and 22% at 24 mg/26 mg twice daily). Patients attended a first follow-up appointment after one month of treatment. If tolerance was good, dosage of sacubitril/valsartan was increased. At 3 months, 82% of patients received the target dose of 97 mg/103 mg, 14% the half dose (49/51mg) and 4% the low dose (24/26mg). After 1 month of treatment, functional class improved significantly with 4.5% NYHA 1, 81% NYHA 2, and 14.5% NYHA 3 ($p = < 0.001$), as the 6 minutes walk distance (511 vs 461m, $p < 0.0001$). These improvements occurred from the first month of treatment with the half dosage of sacubitril/valsartan and were still significantly present after six months of follow up. Regarding tolerance, systolic blood pressure decreased (105 vs 109mmHg, $p < 0.001$) and serum creatinine increased significantly after one month of treatment (117 vs 108 μmol/L, $p < 0.001$). After six month of treatment, the dose of furosemide decreased (114mg vs. 74mg, $p < 0.0001$) and the BNP did not significantly change (587pg / ml vs. 709, $p = 0.14$).
Conclusion: The results of this "real life" cohort confirm the benefits of the treatment by Entresto in stable systolic heart failure patients. These changes seem to appear very early after introduction of the treatment and to be maintained over time.

P1706
Collaboration cardiologists-pharmacists for improving heart failure medication management.

Y Yohan Audurier[1]; B Mathieu[1]; N Chapet[1]; F Leclercq[2]; JL Pasquie[2]; A Jalabert[1]; G De Barry[1]; C Breuker[1]; K Solecki[2]; F Roubille[2]
[1]University Hospital Arnaud de Villeneuve, Pharmacy department, Montpellier, France; *[2]University Hospital Arnaud de Villeneuve, Cardiology department, Montpellier, France*

A recent retroactive study led by the unit of cardiology of our universitary hospital center had shown an underprescription for patients with heart failure (HF). So, we decided to confirm these results with a prospective study. For improving medication management, one senior pharmacist and one junior pharmacist, located in the unit, were associated to the cardiology medical team.
The aim of this study was to identify factors of underprescription for drugs recommanded in HF pharmacotherapy (ESC 2012 then 2016). In the same time, listed therapeutic optimization realized by the collaboration between clinical pharmacists and cardiologists.
This prospective study is currently in progress. Preliminary results were extracted on nine month (march to december 2016). Each patient admitted in cardiology units (79 beds) with a diagnostic of HF were checked by pharmacy team. All discrepencies with recommandations established by ESC about HF medication management were registred. Reasons of underprescription were recorded and if necessary a proposition of correction was addressed to the prescriber.
In the preliminary results 395 patients were included. During hospitalization, 129 patients (32.7%) didn't have B-blocker prescription and 186 patients (47.1%) didn't have ACE inhibitor/Angiotensin II receptor antagonist prescription. Mains reasons of underprescription were HF with preserved ejection fraction (EF), hemodynamic intolerance, acute renal failure, asthma/chronic bronchopneumonia, atrioventricular block, aortic stenosis. Moreover, 137 patients had spironolactone or eplerenone in their prescription (34.68%). Others drugs recommanded were less prescribed, sacubitril/valsartan (22), ivabradine (7), digoxine (6). Several patients didn't have medical reason for these discrepencies, so 24 pharmaceutical optimizations (PO) had been realized : 12 concerned ACE inhibitors, 9 B-blockers, 1 sacubitril/valsartan and 1 about ivabradine. These PO concerned introduction drugs or dose increasing.
Discussion: We can see that medication management of HF wasn't perfect. Most of underprescriptions were medically justified but an important number didn't have medical reason of this lack. The collaboration between physicians and pharmacists can improve medication management of HF patients. Others results are in progress especially about proportions of underprescription reasons for patients with reduced EF and iron supplementation.
Conclusion: This collaboration is a complete success, physicians and pharmacists will continue to work together about medication management of HF and others studies about therapeutic education are in progress.

P1707
Loop diuretic down-titration in stable chronic heart failure: role for spot urinary chloride analysis?

FH Frederik Hendrik Verbrugge[1]; P Martens[1]; L Boonen[1]; P Nijst[1]; D Verhaert[1]; P Noyens[1]; P De Vusser[1]; M Dupont[1]; WHW Tang[2]; W Mullens[1]
[1]Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium; *[2]Cleveland Clinic Foundation, Cardiovascular Medicine, Cleveland, United States of America*

Background: Loop diuretic efficiency, defined as natriuresis per dose of loop diuretics administered, is a powerful predictor of clinical outcome in chronic heart failure (CHF), irrespectively of underlying renal function. A poor natriuretic response to loop diuretics may indicate either true diuretic resistance, which is associated with residual congestion and poor clinical outcome, or alternatively thorough decongestion and relative sodium depletion. Therefore, a preserved natriuretic response to loop diuretics in CHF may indicate subclinical congestion or high salt intake, indicating the need for continued diuretic treatment.
Purpose: This study investigated spot urinary chloride concentration, assessed with a simple point-of-care test strip, in euvolemic CHF patients after intake of maintenance loop diuretics. It was hypothesized that lower urinary chloride levels would predict successful down-titration. Urinary chloride instead of sodium concentration was measured because no point-of-care test is available for sodium and both urinary sodium and chloride are strongly correlated.
Methods: This prospective cohort study included 50 ambulatory CHF patients on maintenance loop diuretic therapy without recent (<3 months) hospital admission, clinical signs of volume overload, or recent adjustment in neurohumoral blocker or diuretic therapy. Spot urinary samples were collected immediately after loop diuretic intake. Subsequently, maintenance loop diuretic dose was reduced with 50% or stopped if ≤40 mg furosemide equivalents. Successful down-titration was defined as persistent dose reduction after 7 days, without body weight increase >1.5 kg. Patients were followed for up to 30 days.
Results: Urinary chloride concentration was 3,045 ± 1,271 mg/L overall. Patients with a higher versus lower urinary chloride concentration showed not differences in baseline characteristics, took the same dose of loop diuretics [40 mg (20 40 mg) furosemide equivalents; P-value=0.509] and had similar plasma NT proBNP levels [1,179 ng/L (311 2,195 ng/L) versus 900 ng/L (255 1,622 ng/L), respectively; P-value=0.461]. Down-titration was successful in 72% versus 76% in both groups, respectively (P-value=1.000). At 30 days, loop diuretic dose remained reduced in 59% versus 76% of patients, respectively (P-value=0.238). The proportion of patients that was free from any diuretic therapy at 30 days was 45% versus 62% in the high versus low chloride concentration group (P-value=0.265).
Conclusion: Successful loop diuretic down-titration could be performed in 3 out of 4 euvolemic CHF patients, irrespectively of urinary chloride concentration on spot samples collected after diuretic intake. The need for long-term diuretic use may be reduced in patients with low urinary chloride concentrations.

P1708
One-year outcome in patients with heart failure with mid-range ejection fraction hospitalized due to worsening heart failure

M Michal Marchel[1]; A Tyminska[1]; A Kaplon-Cieslicka[1]; K Ozieranski[1]; M Peller[1]; P Balsam[1]; MG Crespo-Leiro[2]; AP Maggioni[3]; J Drozdz[4]; KJ Filipiak[1]; G Opolski[1]
[1]Warsaw Medical University, Warsaw, Poland; *[2]Complexo Hospitalario Universitario A Coruña (CHUAC), A Coruna, Spain*; *[3]Centro Studi ANMCO (Associazione Nazionale Medici Cardiologi Ospedalieri), Florence, Italy*; *[4]Medical University of Lodz, Lodz, Poland*

Background: Heart failure (HF) comprises a wide range of patients (pts), from those with normal to those with reduced left ventricular ejection fraction (LVEF). According to 2016 European Society of Cardiology (ESC) HF guidelines, pts with LVEF in the range of 40-49% represent a "grey area," which is defined as heart failure with mid-range ejection fraction (HFmrEF). Little is known about the clinical characteristics and prognosis in the HFmrEF group.
Purpose: Our aim was to determine the incidence of HFmrEF in the group of pts acutely hospitalized due to worsening heart failure as well as to assess the prognosis and prognostic factors in this group.
Method: This study was based on two multicenter prospective observational surveys of the ESC: ESC-HF Pilot Survey and ESC-HF Long-Term Registry conducted in 211 European cardiology centers, including 35 centers from Poland. The current study included Polish pts from both ESC registries, admitted to hospital for new-onset or worsening HF. Pts were divided into three groups based on LVEF: the HFpEF group (LVEF ≥50%), the HFmrEF group (40-49%) and the HFrEF group

(< 40%). We compared in-hospital and one-year outcomes in all 3 groups. The primary endpoint was all-cause death at one year. The secondary endpoint was a composite of all-cause death and hospital readmission for HF worsening at one year. We assessed the frequency of the primary and the secondary endpoints and their predictors in the HFpEF, HFmrEF and HFrEF group.
Results: We included 1306 pts. 230/1306 pts with HFmrEF represented 17,6%, 340/1306 HFpEF 26,0% and 736/1306 HFrEF 56,4% of the whole analyzed group. Median LVEF in HFmrEF was 43% (40-45). Median hospitalization length was 7 (4-11) days. 10,7% HFmrEF pts met the primary endpoint, comparing to 17,5% in HFrEF and 14,4% in HFpEF (p = 0,02) pts. 33,7% met the secondary endpoint, comparing to 41,1% and 30,3% for HFrEF and HFpEF respectively (p = 0,09). A history of revascularization (PCI or CABG) and NYHA class at admission were predictors of the primary (HR 0,11; 95%CI 0,01-0,85, p = 0,04 and HR 2,58; 95%CI 1,14-5,82, p = 0,02 respectively) and secondary (HR 0,11; 95%CI 0,01-0,91, p = 0,04 and HR 1,77; 95%CI 1,13-2,77, p = 0,01 respectively) endpoints, while male gender was a predictor for the secondary endpoint (HR 0,47; 95%CI 0,28-0,79, p = 0,01) in HFmrEF.
Conclusions: Patients with HFmrEF represent one sixth (17,6%) of all HF patients hospitalized due to acute decompensation. 34% of HFmrEF either died or were rehospitalized in one year and 11% died in 12 months. Revascularization in the past was associated with a more favorable patients' outcome.

P1709
Heart failure with recovered ejection fraction: clinical characteristics, determinants and prognosis.

RM Rosa Maria Agra Bermejo[1]; E Gonzalez Babarro[2]; E Gonzalez Babarro[2]; JN Lopez Canoa[1]; JN Lopez Canoa[1]; A Varela Roman[1]; A Varela Roman[1]; I Gomez Otero[1]; I Gomez Otero[1]; M Oro Ayude[1]; M Oro Ayude[1]; P Parada Vazquez[1]; P Parada Vazquez[1]; I Gomez Rodriguez[2]; I Gomez Rodriguez[2]; O Diaz Castro[2]; O Diaz Castro[2]; JR Gonzalez Juanatey[1]; JR Gonzalez Juanatey[1]
[1]University Clinical Hospital of Santiago De Compostela, Department of Cardiology, Santiago De Compostela, Spain; *[2]Hospital Center of Montecelo, Cardiology, Pontevedra, Spain*

Background: The magnitude and the prognostic impact of recovering left ventricular ejection fraction (LVEF) in patients with heart failure (HF) and systolic dysfunction is unclear.
Purpose: The aim of our study was to evaluate the clinical characteristics and prognosis of patients with HFrecEF in a HF population.
Methods: We selected 449 consecutive patients with the diagnosis of HF and evaluation of LVEF in the previous 6 months, who were referred to two HF units. Patients with systolic dysfunction were only considered if a second echocardiogram was performed during the follow-up.
Results: At the time of diagnosis, 207 patients had LVEF >40% (HFpEF) and 242 had LVEF ≤40% (HFrEF). After 1 year, the LVEF was re-evaluated in all 242 patients with a LVEF ≤40%: in 126 (52%), the second LVEF was >40% (HFrecEF), and the remaining 116 (48%) had LVEF ≤40% (HFrrEF). After 58 ± 27 months of follow-up patients with recovered LVEF had a significantly lower mortality rate (HFpEF vs. HFrecEF: Hazard Ratio (HR)=.,286, 95% confidence interval (95%CI), 1.264–4.145, p = 0.019; HFrrEF vs. HFrecEF: HR=2.222, 95%CI, 1.189–4.186, p < 0.001) and hospitalization rate (HFpEF vs. HFrecEF: HR=1.411, 95%CI, 1.046–1.903, p = 0.024; HFrrEF vs. HFrecEF: HR=1.388, 95%CI, 1.002–1.924, p = 0.049). The following are predictors of LVEF recovery: younger age, lower functional class, treatment with renin-angiotensin-aldosterone system inhibitors and beta-blockers, absence of defibrillator use, and non-ischemic etiology.
Conclusions: Approximately half of the patients with HF and reduced LVEF who were re-evaluated after one year showed significant improvement in their LVEF, having a more favourable prognosis than HF with preserved and reduced ejection fraction.

P1710
Features of congestive heart failure in patients with post-MI one year after

AI Chesnikova[1]; ES Godunko[1]; VA Safronenko[1]; OE Kolomatskaya[1]; AV Khripun[1]; VP Terentyev[1]
[1]State Medical University of Rostov-on-Don, department of internal medicine 1, Rostov-on-Don, Russian Federation

It is on record that myocardial infarction (MI) contributes to the development of congestive heart failure (CHF) in most patients due to the maladaptive character of cardiac remodeling with progressive left ventricular dilation, violation of its geometry and decreased pumping function. It is important to measure the concentration of NT-proBNP to confirm congestive heart failure especially with preserved left ventricular ejection fraction. NT-proBNP secretion increases in accordance with the intensity of post-infarction heart changes.
The aim of the study was to investigate features of congestive heart failure in patients with post-MI one year after with distinct methods in the acute period.
Methods: 101 patients with acute myocardial infarction with ST- segment elevation were enrolled in the study. Their congestive heart failure clinical signs were assessed as well as their exercise tolerance and level of NT-proBNP at hospital discharge and one year after. Mean age was 56 ± 9, 99 years; with 81.9 % of men. All the patients depending on availability and revascularization method in acute myocardial infarction were divided into 3 groups: Group 1 (n = 28; 27.7 %) consisted of patients who underwent thrombolytic therapy (TLT), Group 2 (n = 42; 41.6 %) of patients with percutaneous coronary intervention (PCI), and Group 3 included patients without myocardial revascularization (n = 31; 30.7 %).
Results: Analysis of the results revealed NT-proBNP level exceeding the threshold. NT-proBNP ≥125 pg / ml was found in 76.2 % of patients in Group 1, in Group 2 - in 69 % of cases, in Group 3 in 85 % of patients.
The average concentration of NT-proBNP was significantly lower in patients who underwent PCI (150 ± 90, 1 pg / ml), compared with an average level of NT-proBNP 470 ± 117, 6 pg / ml in patients without reperfusion (p = 0.000). In addition, there is a clear tendency towards accuracy by comparing the average NT-proBNP level of Groups 1 and 2 (p = 0.072) with the lowest value in patients with a history of PCI.
Analysis of CHF clinical manifestations showed that in patients of Group 1 and 2 after a year of observation there was a significant decrease in the average score on the rating scale of clinical state by 24% (p = 0.000) and 30% (p = 0.000) respectively and an increase in the average distance in the six-minute walk test (SMWT) in Group 1 by 10.5% (p = 0.000), in Group 2 - by 11.7% (p = 0.000). This indicates a reduction in the severity of CHF symptoms and enhanced exercise tolerance. However, in patients of Group 3 there was observed deterioration in exercise tolerance (p = 0.021) and more pronounced CHF symptoms (p = 0.022) over time.
Conclusion: Patients with PCI had a lower NT-proBNP level as well as less pronounced congestive heart failure as compared with the values in the experimental groups. Thus, it can be argued that there is a positive effect of the invasive strategy on congestive heart failure development and progression.

P1711
Prognostic value of different cardiohepatic syndrome variants during the chronic heart failure

Y Yuliya Shaposhnikova[1]; I A Ilchenko[1]; L Bobronnikova[1]
[1]Kharkiv National Medical University, Kharkiv, Ukraine

The aim of the study was to assess the influence and prognostic values of different variants of cardiohepatic syndrome (CHS) during the chronic heart failure (CHF). Design and method: A prospective analysis of the main symptoms and signs of CHF within 1 year in 86 patients were done (35 female (40.7%), 56.5 ± 10.7 years (M ± SD)). 52 patients with essential arterial hypertension (AH), 38 with atrial fibrillation (AP), 18 with myocardial infarction in anamnesis. Only ALT and/or AST increase was considered as hepatocellular CHS, only GGT and/or alkaline phosphatase (AP), direct (BDP) and / or total bilirubin (TB) increase – as cholestatic CHS. The simultaneous increase of markers of cytolysis and cholestasis was considered as mixed CHS.
Results: CHS was observed in 76 (91.9%) patients, mixed CHS prevailed - 51 patients (67.1%), less was cholestatic CHS - 23 patients (30.3%), only 2 patients were identified hepatocellular CHS (2.6%) presented. Cholestatic CHS more often than mixed CHS developed in obese patients (respectively 63.2% and 25.8%), in patients with diabetes (respectively 46.1% and 29.5%), chronic obstructive pulmonary disease (respectively 42.1% and 23.6%). Meanwhile mixed CHS more than cholestatic CHS developed in smokers (respectively 61.7% and 29.3%); in patients with atrial fibrillation (respectively 64.1% and 31.7%). Patients with mixed CHS worse than hepatocellular CHS was myocardial contractility (ejection fraction decrease, respectively: 60.4% and 32.7%). Manifestations of CHF associated not only with systemic congestion but also with peripheral edema more likely were observed in patients with hepatocellular CHS. Violations of the functional state of the liver were most significant in mixed CHS in comparison with cholestatic CHS and hepatocellular CHS. They characterized by more significant AST increase (respectively: 42.8 ± 2.4; 22.5 ± 2.1; 36.8 ± 2.7 U / L), ALT (respectively: 49.4 ± 4.8; 32.8 ± 1.7; 20.8 ± 1.8 U / l), DB (respectively: 10.8 ± 2.2; 8.2 ± 0.4; 4.4 ± 2.0 mmol / l) and TB (respectively: 29.8 ± 1.3; 26.4 ± 2.0; 14.4 ± 1.7 mmol / l). Also mixed CHS it was worse than cholestatic and hepatocellular CHS coagulation and blood parameters (prothrombin index, respectively: 69.8 ± 2.4; 78.2 ± 3.6; 82.5 ± 4,3%) and hypoalbuminemia (respectively: 36.8 ± 1.8; 47.2 ± 2.1; 43.4 ± 1.7 g / l). Indicators CHF markers - NT-proBNP were worse in patient with mixed CHS than cholestatic CHS (respectively: 879.48 ± 26.16 ng / ml; 642.52 ± 34.28 ng / ml control 154.22 ± 12.14 ng / ml (p < 0.05). The frequency of readmissions during the year was comparable in patient with mixed CHS and cholestatic CHS, but mortality was higher in patients with cholestatic CHS than with hepatocellular CHS (respectively 26.4% and 18.4%).
Conclusions: Patients with CHF and mixed variant CHS have a worse prognosis

and significantly worse functional state of the liver that is associated with higher levels of NT-proBNP.

P1712

Validation of the seattle heart failure model (SHFM) in an Iranian heart failure population

MH Soltani[1]; M Mirzaei[1]; M Seyed Hosseini[1]; R Omidvar[1]; A Dehghani[2]
[1]*Shahid Sadoughi University of Medical Sciences, Yazd, Iran (Islamic Republic of)*; [2]*Shahid Beheshti University of Medical Sciences, Department of Statistics, Shahid Beheshti University, Tehran, Iran (Islamic Republic of)*

Background: The accuracy of Seattle Heart Failure Model (SHFM) in Iranian heart failure patients is unclear. This study aims to validate SHFM for Iranian heart failure patients.
Methods and Results: We evaluated SHFM for 176 ambulatory patients with systolic heart failure (ejection fraction ≤40%), who presented to a Heart Center clinic located in Iran. Their one year mortality chance was calculated by the SHFM on their enrollment in the study. The patients were followed for one year for all cause mortality. All cause mortality was compared with predicted SHFM mortality to assess validity of the tool.
The mean age of participants was 58.2 ± 10.5 years and 119 (67.6%) were male. Mean ejection fraction was 24.7 ± 6.1. Etiology of heart failure in 61% of the patients was ischemic and 123 patients were in NYHA class II. Eight patients died during one year follow up. Sensitivity of the model for our population was 97% and specificity was 87.5%. The positive predictive value was 95.6% and negative predicted value was 20%. The overall accuracy of the model was 73.2%.
Conclusion: The SHFM can predict the one-year survival of Iranian heart failure patients reasonably accurate. However, the mortality prognostic ability of the model is poor in our population.

P1713

Frailty conferred incremental prognostic significance in Chinese heart failure patients with advanced heart failure

K Fan[1]; M Wong[1]; K Cheng[1]; C Chow[1]; KL Leung[1]
[1]*Grantham Hospital, Hong Kong, Hong Kong SAR People's Republic of China*

Background: Despite increased emphasis on comprehensive management of heart failure (HF), current assessment of HF focuses solely on disability. Frailty has been increasingly recognized as an important indicator of adverse prognosis in HF patients (pts). Recipients of heart transplants or ventricular assist device (VAD) are the best population to assess for potential improvement of HF-related frailty. Frailty among advanced HF in Chinese patients is unknown.
Method: Patients referred for consideration of heart transplantation or left ventricular assist device (LVAD) from May 2015 to Oct 2016 underwent frailty assessment. Physical frailty was defined as a positive response to 3 or more of the following 5 components: weak hand grip strength, 6-minute walk test <400m, poor appetite, physical inactivity and exhaustion. Cognitive assessment (Montreal Cognitive Assessment-Hong Kong version) and depression screening (Hospital Anxiety and Depression Scale) were also performed with positive response being MoCA score <22 and depression score ≥8 respectively. Total frailty score ranges from 0-7. All patients were prospectively followed for clinical outcomes.
Results: Fifty pts (38 men: 12 women; mean age 48.4 ± 10.4 years; left ventricular ejection fraction 21.1 ± 13.6%; 54% New York Heart Association Class IV; 42% required inotropic support) underwent frailty assessment. Physical frailty could be identified in 27 (54%) pts while 17 (34%) pts obtained total frailty score ≥4. Overall frailty score ≥ 4 was associated with positive clinical events ($p = 0.041$) including death (n = 2), LVAD implantation (n = 7), heart transplant (n = 4) and left ventricular reduction surgery (n = 2).
Conclusion: Frailty is prevalent among non-elderly younger Chinese patients with advanced heart failure referred for heart transplantation or LVAD implantation. It provides added prognostic value in HF pts at risk for poor outcomes and high medical consumption.

P1714

Is serum uric acid level an independent predictor for prognosis in advanced systolic heart failure patients with diabetes mellitus?

G Guliz Kozdag[1]; D Ural[2]; O Argan[3]; I Karauzum[1]; K Karauzum[4]; E Ural[1]; U Bildirici[1]; T Kilic[1]; T Sahin[1]; A Agacdiken Agir[1]
[1]*Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey*; [2]*Koc University, Cardiology, Istanbul, Turkey*; [3]*Izmit Seka Public Hospital, Cardiology, Kocaeli, Turkey*; [4]*Kocaeli Government Hospital, Cardiology, Kocaeli, Turkey*

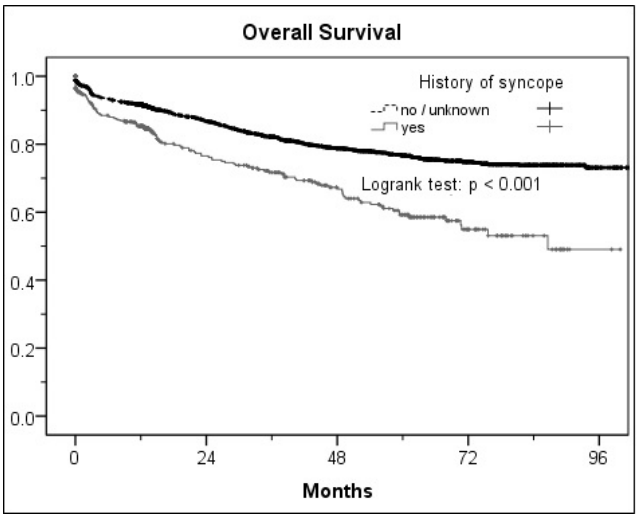
Heart failure (HF) is a major public health problem responsible for high morbidity and mortality rates. Therefore, the importance of survival predictors in directing the treatment of HF is gradually increasing. Serum uric acid levels elevated in patients with heart failure. %30-40 of patients with HF has diabetes mellitus. Our objective was to evaluate the association between levels of uric acid and mortality in advanced HF patients with diabetes mellitus.
Study Design: 250 patients (mean age 67 ± 10 years, 151 male, 99 female, mean ejection fraction (EF) 25 ± 9%) with advanced systolic heart failure and diabetes mellitus were included to the study. Clinical, echocardiographic, and biochemical parameters were measured at baseline, and all patients were followed. Cardiac death was established as the end point of the study.
Results: 121 patients (48 %) of the cohort died during a median follow-up duration of 52 months. Serum uric acid levels were significantly higher in the deceased patients compared to the patients who survived in advanced HF patients with diabetes (8.4 ± 2.3 vs. 7.0 ± 1.8 mg/dl, $p < 0.001$).
After adjusting for multiple confounders multivariate Cox regression analysis showed that the serum uric acid level was the strongest parameter predicting prognosis (HR-1.21, 95% CI 1.11- 1.31, $p < 0.001$) in the patient group.
Conclusion: Serum uric acid level is a very important predictor to determine mortality in advanced systolic HF patients with diabetes mellitus.

P1715

The history of syncope as a risk factor for hospitalization and mortality - A robust predictor for all heart failure patients?

D Hashemi[1]; M Blum[1]; M Mende[2]; S Stoerk[3]; CE Angermann[4]; S Pankuweit[5]; R Wachter[6]; F Edelmann[1]; B Pieske[1]; HD Duengen[1]
[1]*Charite - Campus Virchow-Klinikum (CVK), Department of Internal Medicine and Cardiology, Berlin, Germany*; [2]*University of Leipzig, Institute for Medical Informatics, Statistics and Epidemiology (IMISE), Leipzig, Germany*; [3]*University of Wuerzburg, Department of Internal Medicine I, Wurzburg, Germany*; [4]*Comprehensive Heart Failure Center (CHFC), Wurzburg, Germany*; [5]*University Hospital Giessen and Marburg, Department of Internal Medicine-Cardiology, Giessen, Germany*; [6]*University Medical Center Gottingen (UMG), Department of Cardiology and Pneumology, Gottingen, Germany*

Introduction: Data from small cohorts suggested that a history of syncope (HoS) of any origin is associated with a higher risk for sudden death in patients (pts) with advanced heart failure (HF). It is known that among HF pts with a HoS left-ventricular (LV) systolic dysfunction is more prevalent than in those without HoS. However little is known about the role of syncopes in pts with HF with preserved EF (HFpEF) despite approximately 50% of HF pts account for HFpEF. We aimed for the differences between the HF entities and the prognostic effect in a large pooled patient cohort.
Methods: We pooled data from 4659 subjects from several heart failure trials of the competence network HF. Excluding insufficient follow-up details we evaluated 4256 pts (1576 HFrEF, 584 HFpEF). HFrEF was defined as LVEF < 35% plus at least one symptom due to HF, HFpEF as LVEF>50% plus E/é>15 plus at least one symptom due to HF. We evaluated baseline characteristics including age, sex, NYHA class, medication, co-morbidities, device therapies, lab work and echo parameters plus HoS with a logistic regression model.
Results: 13.2% of the pts reported a HoS. We learned that pts with HoS took more often distinct medication (diuretics, antiarrhythmics and glycosides), were more often female, older, hypotensive, anemic and suffered from both CKD and structural heart disease. NYHA classes were positive correlated with syncopes. Our data confirms that the HoS was more prevalent in HFrEF pts than in controls ($p < 0.001$) and in HFpEF pts ($p = 0.029$). In contrast, in HFpEF pts. it was not different from healthy controls ($p < 0.125$). After adjustment for age, gender, NYHA Class, medication, device therapy, history of CAD or AMI, present anemia and depression, our results remained consistent and showed that HoS is independent from these confounders. Pts with HoS at baseline were more likely to suffer 1.from syncope during follow-up regardless of HF entity (noHF [$p = 0.004$], HFrEF [$p < 0.001$], HFpEF [$p < 0.001$]), 2. from a worse overall ($p < 0.001$) and 3. a worse hospitalization-free survival ($p < 0.001$) after 96 months.
Discussion: Taking into account the lower prevalence of HoS in HFpEF pts the explanation for syncopes in HF pts remains unclear. With stroke volume being impaired in both HFrEF and HFpEF chronic borderline cardiac output is unlikely to describe the mechanism of action. It has been shown that a low LVEF is associated with arrhythmia and sudden cardiac death. This explains the high numbers of ICDs, RV and LV pacemakers and antiarrhythmic drugs in our HFrEF data. The idea of arrhythmic episodes leading to hemodynamic instability among the HFrEF population as an explanation for both HoS and worse outcome is confronted with the statistical adjustment for ICD therapy in these pts which did not reduce the effect of HoS. In conclusion, the pathophysiology remains undefined and further assessment of HoS as a highly promising tool in the setting of HF in prospective trials is required.



Overall Survival

Endothelial progenitor cells and apoptotic endothelial cell-derived microparticle as biomarker of chronic heart failure phenotype

A E Alexander E Berezin[1]; A Kremzer[1]; T Berezina[2]; T Samura[1]
[1]State Medical University, Zaporozhye, Ukraine; [2]Private medical center VitaCenter, Zaporozhye, Ukraine

Background: Chronic heart failure (HF) remains a leading cause of cardiovascular (CV) mortality and morbidity worldwide. The aim of the study was to investigate whether the pattern of angiogenic endothelial progenitor cells (EPCs) and apoptotic endothelial cell-derived microparticles (EMPs) would be able to differentiate HF with reduced (HFrEF) and preserved (HFpEF) ejection fraction.
Methods: One hundred sixty four chronic HF subjects met inclusion criteria. Patients with global left ventricular ejection fraction ≥50% were categorized as the HFpEF group (n = 79) and those with ≤45% as the HFrEF group (n = 85). Therefore, to compare the circulating levels of biological markers 35 control subjects without HF were included in the study. All control individuals were age- and sex-matched chronic HF patients. The serum level of biomarkers was measured at baseline. The flow cytometric technique was used for predictably distinguishing circulating cell subsets depending on expression of CD45, CD34, CD14, Tie-2, and CD309 antigens and determining endothelial cell-derived microparticles. CD31 + /annexin V + was defined as apoptotic endothelial cell-derived MPs, MPs labeled for CD105 + or CD62E + were determined as MPs produced due to activation of endothelial cells.
Results: In multivariate logistic regression model T2DM (R2 = 0.26; P=0.001), obesity (R2 = 0.22; P=0.001), previous MI (R2 = 0.17; P=0.012), galectin-3 (R2 = 0.67; P=0.012), CD31 + /annexin V + EMPs (R2 = 0.11; P=0.001), NT-proBNP (R2 = 0.11; P=0.046), CD14 + CD309 + cells (R2 = 0.058; P=0.001), and CD14 + CD309 + Tie-2 + cells (R2 = 0.044; P=0.028) were found as independent predictors of HFpEF. Using multivariate Cox-regression analysis adjusted etiology (previous myocardial infarction), cardiovascular risk factors (obesity, type 2 diabetes mellitus) we found that NT-proBNP (OR 1.08; 95% CI = 1.03 – 1.12; P = 0.001) and CD31 + /annexin V + EMPs to CD14 + CD309 + cells ratio (OR 1.06; 95% CI = 1.02 – 1.11; P = 0.02) were independent predictors for HFpEF.
Conclusion: We found that CD31 + /annexin V + EMPs to CD14 + CD309 + cells ratio added to NT-proBNP, clinical data, and cardiovascular risk factors has exhibited the best discriminate value and higher reliability to predict HFpEF compared with NT-proBNP and clinical data / cardiovascular risk factors alone.

P1717

N-terminal fragment of proBNP holds prognostic value in very elderly patients with systolic heart failure

A Alessandro Valleggi[1]; G Vergaro[1]; A Aimo[2]; C Arzilli[1]; R Poletti[1]; A Giannoni[1]; A Gabutti[1]; L Zyw[1]; C Prontera[1]; C Passino[1]; M Emdin[1]
[1]Gabriele Monasterio Foundation, Department of Cardiovascular Medicine, Pisa, Italy; [2]Azienda Ospedaliero-Universitaria Pisana, Cardiotoracico, Pisa, Italy

Background: Natriuretic peptides (namely brain natriuretic peptide, BNP and N-terminal fragment of proBNP, NT-proBNP) are widely recognized as useful biomarkers for diagnostic, prognostic and therapeutic management of heart failure (HF) patients. Nonetheless, few data are currently available on their prognostic role in the very elderly population, likely representing a significant subset of HF patients in the next future.
Purpose: We aimed to test whether the prognostic value of NT-proBNP was maintained independently from age in a large systolic HF cohort.
Methods: We prospectively enrolled 2364 patients with systolic HF, defined as left ventricular ejection fraction (LVEF) ≤50% (age 68 ± 13 years, 75% males, LVEF 35 ± 10% [mean ± SD]), who underwent a complete clinical, biohumoral and echocardiographic evaluation. Patients were then followed-up for the combined end-point of cardiac death and heart transplantation. The prognostic value of NT-proBNP was assessed in the subgroups aged either <80 or ≥80 years by means of Cox regression analysis.
Results: In our cohort, 395 (17%) patients aged ≥80 years. Compared to younger patients, the very elderly subgroup had more severe symptoms (NYHA class III/IV 59% vs 37%, p < 0.001), higher LVEF (36 ± 9% vs 34 ± 10%, p = 0.002), worse kidney function (estimated glomerular filtration rate by Cockcrof-Gault formula, eGFR 33 ± 18 vs 67 ± 35 ml/min/1.73m2, p < 0.001) and higher NT-proBNP (3182 ng/L, 1496-7543 vs 1181 ng/L, 432-2979 [median, IQR], p < 0.001); further, they were less frequently treated with ACE inhibitors (ACEi) or angiotensin receptor blockers (ARBs) and mineralocorticoid receptor blockers (75% vs 87%, p < 0.001 and 55% vs 63%, p = 0.004, respectively). During the follow-up period (39 months, IQR 17-80), the end-point occurred in 514 patients (487 deaths, 27 heart transplantations). At multivariate analysis, eGFR (p = 0.022), VE/VCO2 slope at cardiopulmonary test (p = 0.029) and NT-proBNP (p = 0.036) were independently associated with the end-point in younger patients. NT-proBNP was also an independent predictor of cardiac death and transplantation in patients aged ≥80 years (p < 0.001), together with haemoglobin (p = 0.034), LV end-systolic/diastolic diameters (p = 0.002 and p = 0.008, respectively) and lack of therapy with ACEi/ARBs (p = 0.001). At receiver operating characteristic analysis, the best prognostic cut points were set at 1646 ng/L (AUC 0.707, sensitivity 64%, specificity 67%) and at 4055 ng/L (AUC 0.637, sensitivity 62%, specificity 63%) in patients aged <80 and ≥80 years, respectively.
Conclusions: NT-proBNP holds long-term independent prognostic value in very elderly systolic HF patients. A higher prognostic cut-off is likely to be considered in such population, possibly because of the higher prevalence of comorbidities (in particular kidney failure) influencing circulating NT-proBNP levels.

P1718

Low serum chloride levels in patients with heart failure: clinical associations and prognostic significance

JJ Cuthbert[1]; P Pellicori[1]; AL Clark[1]
[1]University of Hull, Academic Cardiology, Hull, United Kingdom

Background: Low serum chloride levels might be common in patients with chronic heart failure (CHF). It may be a consequence of treatment or a marker of disease severity.
Aim: We assessed the prevalence, clinical associations and prognostic significance of low serum chloride in patients referred to a heart failure (HF) clinic with suspected HF.
Methods: Patients with baseline echocardiogram and serum chloride were evaluated (n = 5613). CHF was defined as the presence of signs or symptoms compatible with the diagnosis and either left ventricular systolic dysfunction (LVSD), defined as heart failure with reduced ejection fraction (HeFREF) or LVSD absent or at most mild and NT-pro-BNP >125 ng/L, defined as heart failure with normal ejection fraction (HeFNEF). Hypochloraemia was defined as greater than 2 standard deviations below the mean chloride level in normal distribution (< 96 mmol/L).
Results: Of the 5613 patients, 908 patients did not have HF, 1988 had HeFREF, and 2717 had HeFNEF (table 1). The prevalence of hypochloraemia in patients with HF was 10.7%; it was more common in HeFREF (12.6%) than HeFNEF (9.3%) (P < 0.001). Compared to those in the higher quartiles, patients in the lowest quartile of serum chloride (median 96 mmol/L (range 76-99 mmol/L)) had higher NT-pro-BNP and were more breathless and congested on assessment. The annual mortality rate for HeFREF and HeFNEF was 12.9% and 9.4% (P=0.001) respectively. Chloride predicted both all-cause mortality (ACM) (hazard ratio (HR) 0.97 (95% confidence interval (CI) 0.95-0.99), P=0.001 for HeFREF and HR 0.97 (95% CI 0.95-0.98), P= < 0.001 for HeFNEF) and the combined end-point of mortality or heart failure hospitalisation (HR 0.97 (95% CI 0.96-0.99), p = 0.006 for HeFREF and HR 0.96 (95% CI 0.95-0.98), P= < 0.001 for HeFNEF) independent of the variables in table 1, loop diuretic use, serum sodium, potassium and bicarbonate, and renal and liver function.
Conclusions: Low serum chloride levels are independently associated with increased all-cause mortality and hospitalisation for heart failure in patients with CHF, regardless of left ventricular ejection fraction.

Patient characteristics			
Variable	HeFREFN=1988	HeFNEFN=2717	p
Average age - years (SD)	71 (11)	75 (10)	< 0.001
Male - %	75	52	< 0.001
NYHA class III/IV - %	35	24	< 0.001
NTproBNP - ng/L (IQR)	1750 (750-3984)	734 (289-1672)	< 0.001

HeFREF - Heart failure with reduced ejection fraction; HeFNEF - Heart failure with normal ejection fraction; SD - standard deviation; NYHA - New York Heart Association; IQR - interquartile range.

Upgrade of the Barcelona-Bio-HF-calculator: incorporating risk of HF hospitalization and extending risk prediction up to 5 years

J Lupon[1]; M De Antonio[1]; J Vila[2]; I Subirana[2]; A Galan[3]; E Zamora[1]; P Moliner[1]; M Domingo[1]; B Gonzalez[1]; M Boldo[1]; C Rivas[1]; J Barallat[1]; J Santesmases[1]; C Diez-Quevedo[1]; A Bayes-Genis[1]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain; [2]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; [3]University Hospital Marques de Valdecilla, Santander, Spain

Background: Estimation of the risk of heart failure (HF) hospitalizations has been historically much more difficult than predicting the risk of death. The BCN-Bio-HF-calculator incorporating NTproBNP (marker of myocardial stretch), high-sensitivity cardiac troponin T (marker of myocyte injury), and soluble ST2, (reflective of myocardial fibrosis, remodeling and inflammation) was developed 3 years ago for better estimating the risk of death up to 3 years.
Purpose: The combination of clinical and routine laboratory data with biomarkers reflecting different pathophysiological pathways might also improve the prediction of HF-related hospitalizations.
Methods: Several clinical and treatment variables and extension of prediction to 5-year was performed in order to assess 1-, 2-, 3-, 4- and 5-year risk of all-cause death, HF-related hospitalization and the composite end-point all-cause death/HF-related hospitalization. Model performance was evaluated using discrimination, calibration, and reclassification tools.
Results: The BCN-Bio-HF-calculator was derived from 864 consecutive outpatients (72% men) with mean age 68.2 ± 12 years (65.5%/26.2% NYHA class II/III, LVEF 36%). The follow-up for the present up-graded version was 5 years for the alive patients. During follow-up 363 deaths and 210 HF-related hospitalizations were observed. 430 patients suffered at least one event of the composite end-point. Three new clinical variables (duration of HF in months, number of HF-related hospitalizations in the precedent year, and presence of diabetes mellitus) and 4 new treatments (mineralcorticoid receptor antagonists, angiotensin-2 receptor blocker neprilysin inhibitor [ARNi], cardiac resynchronization therapy and implantable cardiac defibrillator) were added to the previously included variables. Beta-values for ARNi treatment were derived from the benefit observed in the Paradigm Trial. As with the former BCN-Bio-HF-calculator, eight independent models were developed and the calculator may run with the availability of none, one, two, or the three biomarkers. The calculated risk of all-cause death, HF-related hospitalization and the composite end-point significantly improved by additive biomarker data. The average C-statistic for the model with the 3 biomarkers using the 'dxy' Somers rank correlation which incorporates information from censored data (time-to-event outcome) was 0.79 for all-cause death, 0.73 for HF-related hospitalization and 0.76 for the composite end-point, while the AUC at 5 years considering each event as a binary outcome (logistic regression models) were 0.85, 0.75 and 0.84 respectively.
Conclusions: A new version of the BCN-Bio-HF-calculator that incorporates some new clinical variables together with 3 biomarkers reflecting different pathophysiological pathways better allowed individual prediction of all-cause death, HF-related hospitalization and the composite end-point at 1, 2, 3, 4 and 5 years.

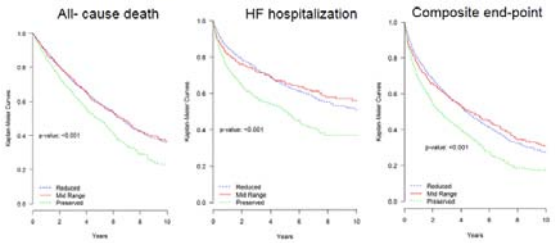
P1720

Clinical characteristics and outcomes of patients with heart failure with mid-range ejection fraction.

N Farre[1]; J Lupon[2]; E Sole-Gonzalez[3]; J Gonzalez-Costello[4]; J Vila[5]; S Perez[5]; M De Antonio[2]; E Roig[3]; C Sanchez-Enrique[4]; C Enjuanes[1]; P Moliner[2]; A Bayes-Genis[2]; D Luiso[6]; S Mirabet[3]; J Comin-Colet[1]
[1]Hospital del Mar, Department of Cardiology, Municipal Institute for Medical Research (IMIM), Barcelona, Spain; [2]Germans Trias i Pujol Hospital, Department of Cardiology, Badalona (Barcelona), Spain; [3]Hospital de la Santa Creu i Sant Pau, Department of Cardiology, Barcelona, Spain; [4]University Hospital of Bellvitge, Barcelona, Spain; [5]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; [6]Hospital del Mar, Department of Cardiology, Barcelona, Spain

Background: Controversy exists as to whether patients with heart failure with mid-range ejection fraction (HFmrEF), defined as ejection fraction (EF 40-49%), represent a distinct heart failure (HF) phenotype.
Purpose: To analyze baseline characteristics and outcome of patients with HFmrEF compared to patients with preserved (HFpEF, EF>50%) and reduced (HFrEF, EF < 40%) ejection fraction.
Methods: Prospective observational study of HF patients followed up at 4 university hospitals with a dedicated Heart Failure Unit. Baseline characteristics and outcomes were recorded.
Results: Fourteen percent (n = 504) of the 3580 patients included had HFmrEF. In this group mean age was 68 ± 13 years (compared with 66 ± 13 years in HFrEF and 74 ± 11 in HFpEF, p < 0.001) and 40% were female (30% in HFrEF and 57% in HRpEF, p < 0.001). Functional class (NYHA III-IV) was similar between HFmrEF and HErEF (34% and 33% of patients, respectively), but worse in HFpEF (44%), p < 0.001. NTproBNP was highest in HFrEF (median 1898 [769-4465] ng/L) and decreased as EF increased (1484 [532-3866] ng/L in HFmrEF and 1320 [635-2818] in HFpEF), p < 0.001. The main etiology for HF was ischemic in HFrEF and HFmrEF (52%) whereas it was hypertension in HFpEF (42%). As expected, use of beta blockers, ACEI and MRA were higher in HFrEF, and its use decreased in HFpEF. Median follow-up was 3.66 [1.69-6.04] years. In the whole cohort, all-cause death, HF hospitalization and the composite end-point were 47%, 35% and 59%, respectively. Outcomes were worse in HFpEF, without differences between HFrEF and HFmrEF (Figure 1). However, after multivariate analysis, no differences in outcomes were seen between the three groups.
Conclusions: Patients with HFmrEF have a clinical profile in between HFpEF and HFrEF. There were no differences in all-cause mortality and HF hospitalization between the three groups.

Figure 1: Kaplan-Meier curves for long-term outcomes divided by ejection fraction.



P1721

The prognostic impact of subclinical hypothyroidism in heart failure

M L Goncalves[1]; HUGO Antunes[1]; JULIO Gil[1]; LUÍS Abreu[1]; BRUNO Marmelo[1]; M I Pires[1]; ISABEL Cunha[1]; DAVIDE Moreira[1]; INÊS Almeida[1]; COSTA Cabral[1]
[1]Hospital Sao Teotonio, Department of Cardiology, Viseu, Portugal

Introduction: The treatment of comorbidities is a key component with a prognostic impact (PI) in heart failure (HF). These include thyroid disorders, which should be accessed in HF. The importance and approach of its subclinical forms is still not well defined.
Objective: To evaluate the PI of suclinical hypotyroidism (SH) in patients (P) with HF.
Methods: Included P hospitalized between 2009-2015 for acute HF (AHF) in a Cardiology ward. Were excluded P without thyroid function (TF) assay on admission, and P receiving amiodarone/ anti thyroid drugs/ thyroid hormones. Division into 2 groups, according to TSH and freeT4 value: Euthyroidism (E) - normal TSH and T4f; SH - elevated TSH [≥5.5mUI / L] and normal T4f. Endpoints: death of any cause, readmission (R) for AHF or combined endpoint (occurrence of one of these events). Follow-up (FU): 2 years. Analysis of association, survival and risk estimation.
Results: Of a total of 1006P hospitalized, 236P were selected. 54.2% male, mean age 76.5 ± 10.4 years, in-hospital death 4.7%. In the FU: death 20.1%; R by AHF 35.6%; Combined endpoint - 50.2%. Groups descriptives are in table. There were no differences in age or other clinical, analytical or echocardiographic characteristics. There is an association between SH and a higher number of R by

AHF at 12M, 18M and 24M (X2 = 6.10 p = 0.013, X2 = 11.22 p = 0.001, X2 = 9.77, p = 0.002 respectively) in relation to the E group. No association between death and SH in FU was found. In Cox regression, high levels of TSH were associated with a higher risk of reaching the combined endpoint (HR: 1.1, IC95: 1.0-1.7, p = 0.05). The survival rate of P with SH was lower than that of P with E (Kaplan-Meier Log-Rank: X2 = 5.33, p = 0.021).
Conclusion: A negative PI of SH was observed in the HF P, which may correspond to a decompensation factor or HF marker of severity. This study emphasizes the importance of dosing TF at all P and the more rigorous follow-up of P with SH. In the future it will be important to evaluate whether the therapeutic intervention in SH has a positive impact on the adverse prognosis of these P.

Aldosterone receptor antagonists decrease mortality and CV hospitalizations in CHF with reduced left ventricular ejection fraction(LVEF), but not in CHF with preserved LVEF. A metaanalysis of RCTs

R De Vecchis[1]; C Cantatrione[1]; D Mazzei[1]; C Ariano[1]; N Maurea[2]
[1]Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy; *[2]Division of Cardiology,Istituto Nazionale "Fondazione Giovanni Pascale" IRCCS, Naples, Italy*

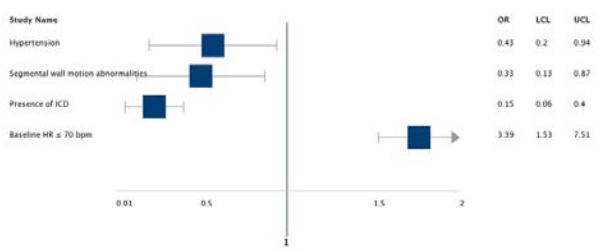
Background Aldosterone receptor antagonists(ARAs) have been associated with improved clinical outcomes in patients with heart failure with reduced left ventricular ejection fraction (HFREF), but not preserved left ventricular ejection fraction(HFpEF). With the aim to study this topic more deeply , we carried out a meta-analysis of selective and nonselective ARAs in HFREF and HFpEF.
Methods: We searched Pubmed and Scopus databases. We decided to incorporate in the metaanalysis only randomized controlled trials(RCTs) of ARAs in patients with CHF if they met the following criteria: experimental groups included patients with CHF treated with ARAs in addition to the conventional therapy ; control groups included patients with CHF receiving conventional therapy without ARAs. Outcomes of interest were all-cause death, hospitalizations from cardiovascular cause, hyperkalemia, or gynecomastia.
Results: We detected 15 studies representing 15671 patients. ARAs were associated with reduced odds of all-cause death(OR=0.79; 95% CI= 0.73-0.87) and hospitalizations from cardiovascular cause (OR= 0.73; 95% CI = 0.61-0.89). However, a subgroup analysis showed that these advantages were limited to HFREF (all- cause death : OR=0.77, 95% CI=0.69-0.84; hospitalizations from cardiovascular cause: OR= 0.66, 95% CI=0.51-0.85), but they did not affect the HFpEF group (all-cause death: OR= 0.91, 95% CI= 0.76-1.1; hospitalizations from cardiovascular cause: OR = 0.85, 95% CI= 0.7-1.09). ARAs increased the risk of hyperkalemia(OR= 2.17; 95% CI= 1.88-2.5). Nonselective ARAs, but not selective ARAs increased the risk of gynecomastia (OR = 8.22; 95% CI=4.9-13.81 vs. OR = 0.74, 95% CI= 0.43-1.27).
Conclusions: ARAs reduced the risk of adverse cardiac events in HFREF but not HFpEF. In particular, ARA use in HFpEF patients is questionable, since in this CHF type no significant improvement in all –cause death and cardiovascular hospitalizations was demonstrated with ARA treatment , in the face of the well-known risks of hyperkalemia and/or gynecomastia that chronic ARA therapy entails. Selective ARAs are equally effective as nonselective ARAs, without a risk of gynecomastia.

P1723

The importance of heart rate as a predictor of cardiac functional recovery in newly diagnosed heart failure

AV Valika[1]; KP Paprokas[1]; DV Villines[1]; M R Maria Rosa Costanzo[1]
[1]Advocate Heart Institute, Cardiology, Naperville, United States of America

Background: Left ventricular ejection fraction (LVEF) predicts outcomes in HF patients. In patients with HF and reduced LVEF, rates of LV recovery (LVR) range between 19% and 50%, but factors predictive of LVR remain unclear.
Methods: Review of the electronic medical record identified between 2006 and 2016 224 consecutive patients aged > 18 years, new HF diagnosis and a LVEF ≤ 35% who received guidelines-directed medical therapy (GDMT) and were followed ≥ 1year. LVR was defined as a rise in LVEF ≥ 40%. Stress-induced cardiomyopathies were excluded. After determination of LVR rates, patients with LVR were compared with those with persistent LV dysfunction (LVD) in terms of clinical characteristics and the composite outcome of death and HF hospitalization using the log-rank test. Multivariate logistic regression analysis was utilized to identify baseline clinical variables predictive of LVR. LVEF was serially measured by echocardiogram. GDMT target doses were per published guidelines.
Results: Population characteristics were: age = 63 ± 13; 38.5 % female; 83.2% Caucasian; 38.1% ischemic HF; baseline LVEF = 23% ± 6%; baseline heart rate = 75 ± 13 bpm. Background GDMT: ACE inhibitors (ACEi) = 74.3%; Angiotensin receptor blockers (ARB) = 19.7%; Beta blocker (BB) = 95.4%; Aldosterone antagonist (AA) = 34.0%; the % of patients achieving target doses of ACEi and BB were, respectively, 33.7 and 40.2. LVR occurred in 154/244 patients (63.1%), and the median time to LVR was 9.0 months (IQR = 4.5-19.0). Average final EF in LVR patients was 49% ± 6%. Compared to LVD, LVR included fewer patients with ischemic HF (54.4% vs. 28.6%, p < 0.001) and CKD (3.9% vs. 11.1%, p = 0.028), and more subjects on ACEi (67.4% vs. 80.3%, p = 0.025), and target BB doses (30.9% vs. 46.1% p = 0.029). By multivariable analysis baseline heart rate < 70 bpm was the only independent predictor of LVR (OR = 3.39, 95% CI = 1.5-7.5, p = 0.003); hypertension, segmental wall motion abnormalities, and ICD were negative predictors of LVR (Fig). Presence or absence of ARB or AA and target doses of ACEi, ARB, or AA did not predict LVR.
Time to HF hospitalization or death was significantly longer in LVR than LVD subjects (105.5 ± 3.8 days vs. 90.6 ± 6.2 days, p = 0.04). This composite endpoint was less frequent in those who achieved target BB doses (5.4% vs. 16.7%, p = 0.027). Time to all-cause mortality was longer for LVR than LVD patients (115.8 ± 2.6 days vs. 96.4 ± 5.5 days, p = 0.001).
Conclusions: LVR rates in contemporary HF patients are higher than previously reported. Whereas hypertension, segmental wall motion abnormalities and ICD decrease the likelihood of LVR, a baseline HR ≤ 70 bpm is the sole independent predictor of LVR. These findings suggest that early modulation of heart rate in de-novo HF patients may facilitate LVR.



Predictors of Left Ventricular Recovery

P1724

Prognostic implication of right and left-sided hemodynamic congestion in patients with heart failure

P Rozentryt[1]; JU Nowak[1]; J Niedziela[1]; B Hudzik[1]; P Leszek[2]; T Rywik[2]; EA Jankowska[3]; W Doehner[4]; S Von Haehling[5]; SD Anker[5]; M Gasior[1]
[1]III Department of Cardiology, Silesian Centre for Heart Diseases, Zabrze, Poland; *[2]National Institute of Cardiology, Warsaw, Poland*; *[3]Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland*; *[4]Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany*; *[5]University Medical Center Gottingen (UMG), Department of Innovative Clinical Trials, Gottingen, Germany*

Introduction: Hemodynamic congestion remains a key prognostic factor in heart failure (HF). Recent findings from ESCAPE trial suggest a congestive burden (CB), taken as a sum of right atrial (RA) and pulmonary capillary wedge pressure (PCWP) be of prognostic value in HF. However, the relative association of RA and PCWP with prognosis and with other typical prognosticators remains poorly understood.
Aim: We sought to investigate the separate association of RA and PCWP with prognosis at different levels of global congestion as represented by CB and to compare them with traditional risk factors.
Material & methods: 239 HF patients (age: 52 ± 10 years, female: 14%, NYHA: 2.9 ± 0.9, LVEF: 25 ± 11%) were electively admitted to the hospital for right-sided catheterization as part of heart transplantation work-up. All were on best tolerated medical therapy and received electrical interventions according to current guidelines. Using Swan-Ganz catheter and thermodilution technique we measured right- and left sided pressures. In each patient we have calculated CB and RA/PCWP (Ratio). All patient were allocated to 1 out of 4 groups according to median value of CB (21 mmHg) and RA/PCWP (0.33): 1 – both CB and Ratio bellow medians, 2 – low CB and high Ratio, 3 – High CB and low Ratio, 4 – both CB and Ratio above medians. During 3 years of follow-up 84 (35%) patients died (all-cause). We compared Kaplan-Meir survival curves for each group. Cox method was and used to estimate adjusted relative risk of death for groups taking as a reference the group with best survival on Kaplan-Maier.
Results: Kaplan-Maier analysis showed best survival in group 3 (log rank p = 0.02). The risk of death in groups with high Ratio remained significant after adjustment for powerful prognosticators (Table 1).
Conclusion: The high RA/PCWP is associated with poor prognosis, the reason for elevated ratio may be attributable either to high RA or low PCWP.

Prognostic value of presence, amount and location of myocardial fibrosis detected by contrast enhanced cardiac magnetic resonance in patients with idiopathic dilated cardiomyopathy

L Lupi[1]; M Piazzani[1]; D Farina[1]; E Gavazzi[1]; M Bonavita[1]; I Papa[1]; M Metra[1]; M Maroldi[1]; S Savina Nodari[1]
[1]University of Brescia, Brescia, Italy

Background: Myocardial fibrosis detected by contrast-enhanced cardiac magnetic resonance (CE-CMR) has been related to adverse clinical outcomes in patients with idiopathic dilated cardiomyopathy (DCM), but there are few data about the association between the amount and location of myocardial fibrosis and prognosis.
Purpose: the aim of our study was to evaluate the prognostic role of the presence, the amount and the location of late gadolinium enhancement (LGE) in patients with DCM and left ventricular systolic dysfunction.
Methods: We enrolled retrospectively patients suffering from DCM with left ventricular ejection fraction (LVEF) ≤45% underwent CE-CMR followed at our HF Department from January 2012 to December 2015. We evaluated demographic, laboratoristic and imaging parameters (presence of LGE, as indicator of fibrosis, LVEF, right ventricular ejection fraction, ventricular volumes and myocardial mass). The amount of LGE was calculated by manual planimetry at each left ventricle short axis section. We considered the 17-segments model of the American Heart Association to evaluate the localization of fibrosis. The composite endpoint was death from any cause and hospitalization for arrhythmic causes or heart failure.
Results: We enrolled 179 pts (71% male, mean age 55 ± 15 years). 90 pts (90.3%) showed left ventricular LGE. At univariate analysis, atrial fibrillation (p = 0.005), diabetes (p = 0.005), chronic kidney disease (p = 0.005), presence of LGE (<0.0001), LVEF (p = 0.003), right ventricular ejection fraction (p = 0.006) and myocardial mass (p = 0.002) were predictive of events. At multivariate analysis, only the presence of LGE confirmed its prognostic value (HR 4.597; IC 95% 2.167–9.749; p < 0,0001). LGE area and the number of myocardial segments involved by LGE were both associated with the composite endpoint (trend p = 0.03 and 0.05 respectively). Septal localization was significantly associated with hospitalizations for ventricular arrhythmias (p < 0.0001 compared to other localizations), while lateral wall localization was associated with hospitalizations for heart failure (p = 0.001).
Conclusions: Myocardial fibrosis is an independent predictor of death and hospitalization for heart failure and arrhythmias and its negative prognostic value raises with increasing amount of fibrosis. Septal and lateral wall LGE was associated with a significantly worse prognosis compared to other localizations.

P1726

Characteristics of heart failure patients in indonesia

B Karim[1]; R Irwan Muin[1]; LH Makmun[1]; M Yamin[1]; M Arza Putra[2]
[1]Cipto Mangunkusumo Hospital, Cardiology Division, Internal Medicine Department, Jakarta, Indonesia; *[2]Cipto Mangunkusumo Hospital, Cardiac Thoracic Division, Surgery Department, Jakarta, Indonesia*

Introduction: Heart failure remains the major problems worldwide. Most of it caused by coronary artery disease. The more prevalence of metabolic disease, the prevalence of coronary artery disease which ends up with heart failure is increased.
Purpose: To identify characteristics of heart failure patients in Indonesia.
Methods: The descriptive study design was consecutively conducted in 104 patients with heart failure who were admitted to the Hospital from January – April 2016. All clinical data were collected, including gender, age, symptoms, echocardiography, treatment, and device implantations.
Results: All 104 patients during period January-April 2016, predominantly male (52.9%) comparing with female (47.1%). Range of age 56-64 years old was dominated the event of heart failure in Indonesia, 69% patients had average systolic blood pressure 100-140 mmHg, most frequent symptoms was dyspnea on effort (66%), fatigue (35%), orthopnea (33%), dyspnea at rest (21%), decreased exercise tolerance (20%), and peripheral edema (16%). Most of the patients have New York Heart Association (NYHA) class II (53%) with the sign of elevated jugular venous pressure (14.4%). Echocardiography examination on heart failure revealed reduced ejection fraction below 30% (21%) and preserved ejection fraction above 50% (38%). Ischemic heart disease is the main cause (76.9%) of heart failure and most of the patients have comorbid hypertension (59%), diabetes (29%), valvular heart disease (14.4%), and atrial fibrillation (9.6%). Almost all of heart failure patients consume diuretic (95.2%) if there were congestion, followed by a beta blocker (92.3%), ACE inhibitor (59.6%), mineralocorticoid receptor antagonist (59%), and ARB (38%). Device Implantation was conducted in 3.8% eligible patients during January-April 2016.
Conclusions: Characteristics of heart failure patients are varied. Ischemic heart disease is a predominant cause and optimal medical treatment and device implantation, if indicated, are very beneficial to improve symptoms.

P1727

Heart failure : the smart versus the not so smart hearts

S S Iyengar[1]; ANAND Chopda[1]; ROOPA Babu[1]; C Chakrapani[1]; ANAND Shenoy[1]; G Sreedhara[1]; SUBASH Chandra V[1]
[1]Manipal Hospital, Cardiology, Bangalore, India

On behalf of: Department of cardiology, Hospital, Bangalore, India

Background: Heart failure with preserved ejection fraction (HFpEF), as compared to heart failure with reduced ejection fraction(HFrEF) continues to be a challenging entity.
Aim: To compare clinical profile, treatment and outcome between patients of HFpEF and HFrEF.

Methods: It was a prospective,observational study comparing patients of HFpEF (LV EF >40%) with patients of HFrEF (LV EF ≤ 40%).Serum BNP was estimated in all patients.
Results: 204 patients were studied , 101 patients in HFpEF group and 103 in HFrEF group. Female patients, 80 in number more often had HFpEF than HFrEF (53.5% vs 26.2%, p < 0.001). HFpEF patients were older than patients with HFrEF (69.5 years vs 66.2 years, p = 0.038). Hypertension (68.3% vs 41.7%, p < 0.001) and COPD (13.9% vs 3.9%%, p = 0.012) were more common in patients with HFpEF, whereas obesity (36.6% vs 45.7%, p = 0.004) was more common in HFrEF group. Other conditions like coronary artery disease, atrial fibrillation, chronic kidney disease and acute kidney injury were similar in both groups. BNP was significantly higher in HFrEF group (921.4 units vs 1204 units, p = 0.023), and in those who died. Beta blockers (55.4% vs 79.6%, p < 0.001), loop diuretics (53.5% vs 82..5%, p < 0.001) and digoxin (0 vs 14.6%, p < 0.001) were more commonly used in HFrEF patients. Antiplatelets, statins, ACE inhibitors/ARB's ,MRA, nitrates were used equally in both groups. ICD was implanted more commonly in HFrEF. 1% vs 8.7%)
Repeat hospitalisation rates at 6 months were similar between the two groups. There was no significant difference in mortality at 6 months between the two group. (9.9 % in HFpEF and 13.6% in HFrEF p = 0.187).
Conclusion: HFpEF patients were older. HFpEF was more frequently seen in female patients, hypertensives and COPD patients, whereas HFrEF patients were more often male patients. Surprisingly BMI was higher in patients of HFrEF. Serum BNP was significantly higher in HFrEF group than HFpEF group.Higher serum BNP values at diagnosis indicated a poor prognosis. BNP is a useful test at diagnosis but should be used and interpreted in the context clinical background as it is an expensive test. ICD was implanted more commonly in patients with HFrEF. Utilization of device therapy was low probably reflecting the economic constraints in our country. There was no difference in morbidity and mortality in patients with HFpEF and HFrEF.

P1728

Review of 115 cases of chronic heart failure with reduced ejection fraction in Tunisian Public hospital

MERIEM Drissa[1]; SANA Helali[1]; MEHDI Mechri[1]; SAMIRA Kaabachi[1]; MEHDI Cheour[1]; HABIBA Drissa[1]
[1]*La Rabta University Hospital, adults cardiology, Tunis, Tunisia*

Introduction: Heart failure (HF) has been singled out as an epidemic and is a staggering clinical and public health problem, associated with significant mortality, morbidity, and healthcare expenditures. Objective of the aim of our study is to identify clinical and epidemiological characteristics of chronic heart failure with reduced ejection fraction(EF) and to demonstrate whether the data found in western countries are also observed in our country.
Methods and materiels: Retrospective, descriptive study, carried out at department of a cardiology Hospital During the period from October 2013 to the October 2015. We enrolled patients with the diagnosis chronic heart failure with reduced ejection fraction(EF < 40%) based on echographic results. The data were entered and analyzed using the SPSS 22 software. We calculated the simple frequencies and the relative frequencies (percentages) for the qualitative variables. We calculated averages, and standard deviations e for quantitative variables. For comparing averages and percentages, the student's "t" test and the Pearson chi-square test were used, and in all statistical tests the significance level was set to 0.05.
Résults: A total of 115 patients' files were analyzed; the patients' mean age was 53 ± 12 years. The male sex was predominant with a sex ratio of 2.6 in favor of men. Tobacco was the most common risk factor as it was observed in 56 cases (51%) followed by hypertension in 46 cases (41%) , diabetes In 45 patients (40%) and dyslipidemia in 28 cases (25%). The main comorbidities encountered in our patients were atrial fibrillation in 32 patients (29%) ,renal failure in 22 patients (20%) and stroke in 7 patients (7%).
Dyspnea was the main symptom noted in 100% of patients followed by palpitation in 72 patients (65%.). Frenquency of heart rate (FC) was about 91 ± 21 beats / min [50-160]. The blood pressure was around 118 ± 23 mm Hg left heart failure signs were observed in 57% of cases, global heart failure in 39% and cardiogenic shock in 4%. Decompensation factors were a bronchopulmonary infection in 42% of cases and was ischemic coronary events in 22 patients.the main etiology was ischemic heart disease in 49 patients (44%) then valvular etiology in 26 patients (24%) ,idiopathic CMD in 19 patients (17%) and hypertensive etiology in 16 patients (15%). The intra-hospital evolution under medical treatment was marked by 10deaths. The average length of stay in hospital was 12.1 ± 6.6 days.
Conclusion: Our study showed that heart failure concerned population were young ,We are witnessing a decline in rheumatic valvulopathies .Coronary disease is the main cause in patients treated at our Tunisian hospital; the most common risk factors were arterial hypertension and diabetes.

P1729

Exercise tolerance determinants, renal function and disease progression in outpatients over 75 years old with chronic heart failure

B Stanula[1]; JDK Jaroslaw Damian Kasprzak[2]
[1]*E. Szczeklik's Hospital, Tarnow, Poland*; [2]*Medical University of Lodz, Lodz, Poland*

Introduction: Variety of signs and symptoms arising from underlying disease, comorbidities and aging process itself limits possibilities of identifying independent prognostic factors in patients (pts) over 75 years with chronic heart failure (CHF). Aim was to identify factors determining exacerbations of stable, moderate CHF and exercise intolerance in the elderly pts with comparison to younger pts (age 60-75).
Methods: We studied 91 stable, ambulatory CHF pts (mostly with preserved left ventricular(LV) function; mean age 74 ± 6, men 51%, BMI 29 ± 4 kg/m2, LVEF 59 ± 11%) split into Group 1 (Gr.1 - >75yo, N=50) and Group 2 (Gr.2 - age 60-75, N= 41). All pts underwent physical examination, assessment of quality of life by EQ-5D-3L questionnaire with visual analog scale (VAS), echocardiogram, electrocardiogram, and laboratory tests panel including brain natriuretic peptide (BNP),creatinine,eGFR,cystatin C,complete blood count,C- reactive protein (CRP), six-minute walk test distance (6MWT) – at baseline and after 1-yr.
Results: There were no deaths during 1-yr follow-up, but hospitalizations were prevalent (17%), together with NYHA class worsening(13%), paralleled by progression of diastolic dysfunction (35%). These endpoints were not significantly more frequent in the elderly. Hospitalized elderly had higher NYHA class (p = 0.009), younger had greater degree of LV diastolic dysfunction (p = 0.009), lower BNP level (p < 0.001),history of myocardial infarction (p = 0.027). Elderly with NYHA class deterioration at baseline had more diastolic dysfunction (p = 0.043), history of smoking (p = 0.033), while Gr.2 had lower values for: NYHA class (p = 0.018), systolic and diastolic blood pressure-SBP, DBP (p = 0.001 and p = 0.042), IVA septal (p = 0.020) by tissue Doppler. Diastolic dysfunction worsening was predicted in Gr.1 by lower DBP (p = 0.031), lower initial 6MWT(p = 0.002), greater initial LVEF (p = 0.045), greater E/A ratio (p = 0.042), less initial diastolic dysfunction (p = 0.002); atrial fibrillation history was more frequent (p = 0.018),ACEIs/ARBs were less frequently used (p = 0.043). Diastolic deterioration in Gr.2 was predicted by higher e' lateral (p = 0.048), less diastolic dysfunction (p = 0.014), more AF(p = 0.042),used more anticoagulants (p = 0.004).
Conclusions: Predictors of deterioration are different for the elderly patients with stable, moderate CHF as compared with group age 60-75, with efficient multifactorial models difficult to construct. Multifactorial predictors involve conventional and local echo parameters (LVEF,s' lateral, Vp, mitral E/A ratio),clinical data (DBP, smoking history,AF), and exercise tolerance estimate from 6MWT.

P1730

The effect of 6-month therapy with sildenafil on the intracardiac hemodynamic and inflammation markers in pts with right ventricular dilated cardiomyopathy

TA Abdullaev[1]; YR Akhmatov[1]; I A Igor Tsoy[1]
[1]*Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan*

The aim. Assess the impact of a 6-month therapy with sildenafil on clinical and functional parameters in pts with dilated cardiomyopathy (DCM) with a primary lesion of the right heart.
Material and methods: blind randomization method were highlighted two: the first (I; n = 12; male / female 10/2; 42,8 ± 12,5goda) and second (II; n = 13; female / male 8/5; 41,6 ± 11.8 years) group. Thus, pts of the second group in addition to standard therapy (PT) obtained CHF sildenafil individually selected dose (from 37.5 to 75 mg / s; average - 45.8 ± 12.5 mg / day). All pts underwent EKG EhoCG, test 6-minute walk test (6MWT) and C-reactive protein in the serum before and after treatment.
Results: of the study. Analysis of spirometry parameters on the background of a 6-month therapy with sildenafil had a positive impact on the parameters of intracardiac hemodynamics. In particular, the peak velocity of early filling (E) na17,1% increased after treatment rate (before treatment - E = 0.63 ± 0.12 m / s, after - E = 0.76 ± 0.13 m / s, p = 0.016), and the contractile function of the right ventricle - on 8.73% (RV EF before - 42,25 ± 3%, after - 4 6,73 ± 73%, p = 0,033). It should be noted that the improvement of inotropic function of the right heart insignificant decrease in LVM contributed 17.7% (up to 143,42 ± 46,38 gr, after - 118,00 ± 33,67gr, p = 0.128) and a decrease in the size of LA on 17.85% (up to - 29,8 ± 2,88 mm after - 24,48 ± 2,63mm, p = 0.045). Namely, the 6-month treatment with sildenafil contributed to the increase in 6MWT on 36.5% (before 173,6 ± 71,34m after -273,6 ± 82,26 m, p = 0.004) and a decrease in respiratory frequency (RF) both at rest and after exercise (BH rest decreased from 22,34 ± 1,76 to 17,8 ± 1,53, and BH heating from 26,35 ± 3,16 up to 21,8 ± 1, 10 p = 0, 1). The level of CRP in the serum during therapy significantly decreased na44,1% (from 8.6 + 1.4 do3,8 ± 0,8 mg / l; p = 0.03).

Conclusions: The additional use of sildenafil for 6 months significantly enhances the EF RV is accompanied by a decrease in the size of the LA and serum levels of CRP, including good tolerance of physical activity

P1731

Insulin resistance evaluation in patients with coronary artery disease and chronic heart failure without evident disorders of carbohydrate metabolism

B Kurmanbekova[1]; G E Osmankulova[1]; M T Duishenalieva[1]; S SH Mamasaidova[1]; A M Noruzbaeva[1]; E Amelin[1]
[1]*National Center of Cardiology and Internal Medicine, Chronic heart failure, Bishkek, Kyrgyzstan*

Background: Insulin resistance (IR) promotes to development of coronary artery disease (CAD), chronic heart failure (CHF) and type 2 diabetes mellitus (T2DM), along with other risk factors. Affiliation of T2DM to CHF impairs prognosis and enhance mortality. Early detection of IR and carbohydrate metabolism disorders (CMD) seems to be relevant.
Study purposes: to evaluate the IR in patients with CAD and CHF without evident CMD. Study methods: we examine 174 patients with CAD and CHF II-IV (NYHA) class without T2DM and glucose-lowering drugs intake in anamnesis, receiving basic for CHF and CAD therapy (statins, ACE inhibitors/angiotensin receptor blockers, beta-blockers, mineralocorticoid receptor antagonists) and define such parameters as: height, weight, body mass index (BMI), systolic and diastolic blood pressure, FINDRISC points, ECG, daily monitor of ECG, echocardiography, fasting and postprandial glucose levels, HbA1C, lipid profile, estimated GFR, daily proteinuria, NT-proBNP, aldosterone and insulin concentrations with assessment of HOMA-IR, standart oral glucose tolerance test (OGTT) was conducted.
Results: Among 174 patients with CAD and CHF II-IV (NYHA) using OGTT, in 50,5% patients was revealed latent CMD: 59 (33,9%) patients had impaired glucose tolerance (IGT), in 29 (16,7%) – T2DM was newly diagnosed, 86 (49,4%) patients were without CMD. The largest number of FINDRISC points was observed in group with newly diagnosed T2DM ($p < 0,000$) compared with patients with IGT and without CMD. Insulin concentrations were increased in each study groups with CAD and CHF, but was significantly higher in patients with CMD compared with patients without CMD ($p < 0,000$). IR was identified in all patients with CAD and CHF, what is more, its level increased with the growth of CMD explicity and was highest in T2DM group compared with IGT and without CMD groups. Elevated levels of NT-proBNP had a linear relationship with CHF severity. Aldosteron levels increased in all patients with CHF regardless of the CMD presence. Correlation analysis determined strong interrelation between IR and: BMI, FINDRISC points, fasting and postprandial glucose levels, HbA1C, insulin concentrations, but not with ejection fraction, NYHA class and CHF duration.
Conclusions: In 50,6% patients latent CMD were determined, from IGT to newly diagnosed T2DM. IR was revealed in all patients, without reference to CMD availability. However, it was direct linear relationship between IR and CMD explicity. Correlation relationship was elicitate between IR and following indicators: BMI, FINDRISC points, fasting and postprandial glucose, HbA1C and insulin concentrations. Thus, early detection of IR and CMD in CAD and CHF patients, with subsequent their correction, may reduce mortality and improve prognosis.

P1732

The role of anti-oxidants in the treatment of congestive heart failure

TH Theodoros Michailidis[1]
[1]*General Hospital of Veria, Department Of Internal Medicine, Veria, Greece*

Introduction: Congestive heart failure and oxidative stress are strongly connected, creating a medical "vicious" circle among each other.
Purpose: Our goal was to examine whether the decrease of the oxidative stress levels via use of antioxidants was connected with a subtler presentation of CHF symptoms.
Methods: We studied two groups of men with stage I CHF (65 to 85 years old). All of them were previous smokers (having quitted for at least two years), suffering from CHF and hypertension. None of them suffered from diabetes, COPD or ischemic heart disease. We measured serum malonyl dialdehyde (MDA) levels and serum carbonyl products (CP) in all our patients twice (once at the start of the study and once after a whole year). The difference between the two groups had to do with the addition of vitamin E to their treatment. Group A (consisting of 32 men) patients received ACE or AT inhibitors, statins, calcium channel blockers, beta blockers and a daily intake of 300mg of vitamin E was added to their treatment. On the other hand, group B (31 men) patients received similar treatment without the addition of vitamin E.
Serum MDA and CP were similar in both groups at the start of the study whereas after a year, both oxidative biomarkers were higher in group B ($p < 0,01$ for MDA and CP as well), depicting a much heavier oxidative stress burden in group B (the ones not receiving vitamin E) patients.
Trying to connect this difference between the two groups with the real life quality, we measured the total amount of times that the patients had visited the ER department or were admitted to the Cardiology department due to cardiovascular problems (pulmonary edema, arrhythmias, hypertensive crises etc.).
Results: Group A had the total amount of 83 times, when at the same chronological period of one year group B patients scored a number of 128. Statistical analysis showed an existent but not so strong ($p < 0,05$) difference between the two groups.
Conclusion: The daily intake of antioxidants definitely decreases the oxidative stress in CHF. The positive role of such a decrease in the patient's quality of life needs yet to be furtherly discussed.

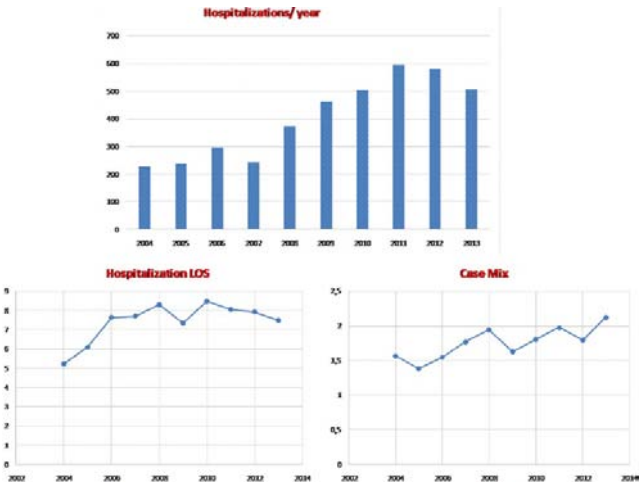
Heart failure hospitalization: a decade-long trend overview in a Tertiary Care Center

G Giuseppe Di Stolfo[1]; S Mastroianno[1]; M Mastroianno[2]; F Giuliani[2]; G De Luca[1]; R Massaro[1]; M Salvatori[1]; DR Potenza[1]; A Russo[1]
[1]*Scientific Institute Casa Sollievo della Sofferenza, Department of Cardiology, San Giovanni Rotondo, Italy*; [2]*Casa Sollievo della Sofferenza Hospital, Information Technology, Innovation and Research Unit, San Giovanni Rotondo, Italy*

Background: Heart failure (HF) is among the most common reasons for hospital admission in the Western World. Investigation of epidemiological tendency represents a fundamental feedback about how we cured in the past to better improve what we would care in the future.
Objectives: This retrospective analysis would focus on decade-long trends in HF hospitalization, length of stay (LOS), in-hospital mortality and Case mix index (CMI) as standard indicator of hospital disease severity in a Tertiary Center Care.
Methods: We retrospectively collected all HF hospitalization in the period 2004-2013, analyzing LOS, CMI, in-hospital-mortality, age and comorbidities as diabetes, hypertension, dyslipidemia, renal disease and atrial fibrillation.
Results: We examined 4026 hospitalizations in a decade-long period. We observed a progressive increase of HF hospitalization prevalence (from 229 to 507 patient/year, $p < 0.01$). There was a significative increasing in LOS (from 5.22 ± 4.61 to 7.49 ± 7.37 days; $p < 0.05$), CMI (from 1.57 ± 1.22 to 2.13 ± 2.17; $p < 0.05$), atrial fibrillation prevalence (from 22.7% to 32.7%; $p < 0.05$) and renal disease prevalence (from 4.4% to 7.3%; $p < 0.05$). There was a slight increase in mean age at admission (from 71.4 ± 12.6 to 74.3 ± 13.3 years) and in-hospital mortality (3.49% to 3.94%). No difference in diabetes, hypertension and dyslipidemia prevalence.
Conclusions: Our retrospective analysis shows an increased burden in heart failure hospitalization, together with a greater case complexity. This finding underlines the urgency to improve health care plan management after discharge with involvement of different clinical care figures sharing a common training and decision process.



HF hospitalization, LOS and CMI

Predictors of non-response to physical rehabilitation in patients with chronic heart failure

VL Galenko[1]; TA Lelyavina[1]; MY Sitnikova[1]
[1]*The North-Western Federal Medical Research Center named after V.A.Almazov, the research laboratory of chronic heart failure , Saint-Petersburg,, Russian Federation*

Introduction: In the world practice physical training is widely used in CHF patients. But in most cases, is not taken into account the influence of the initial clinical status of patients (gender, age, CHFfunctional class, peak oxygen uptake, comorbidity) on the results of physical rehabilitation.
Purpose: To evaluate aerobic physical exercise efficiency, selected on the basis of achievement the lactate threshold during CPET, and to reveal the most significant predictors of inadequate response to physical rehabilitation in CHF patients.
Methods: 77 patients, CHF NYHA II-III were randomized into two groups - primary (aerobic training) and control (standard treatment of CHF). Main group - 64 patients, mean age 54 ± 12,5 years, body mass index (BMI) 26,46 ± 6,4 kg/m2, among them 46 patients (72%) had III CHF functional class and 18 patients (28%) – II CHF functional class. The control group - 13 patients, age 53 ± 17 years, BMI was 25,4 ± 6.8 kg/m2, 12 patients had III CHF functional class, 1 patient – I. The original estimated patient,s initial clinical status. CPET, quality of life (QOL), exercise tolerance (ET) was assessed at baseline and after 1,3,6 months of follow-up. The CPET served on tredmile using hardware "Oxycon Pro", Jaeger, Germany. Echocardiography (EchoCG) were performed at baseline and after 6 months. The data were statistically processed using software package "Statistika, 6.0".
Results: In the main group after 6 months of training EF increased by 7.5 ± 0.5% and End-diastolic volume decreased by 6 ± 2.0 ml from baseline, QOL was changed by 17.5 ± 8 points (significant regression of symptoms), ET increased by 9 ± 1 points and VO2 peak increased by 4.4 ml/min/kg. In the control group showed an increase EF 4 ± 1,1%, End-diastolic volume decreased by 68 ± 14,8 ml, the change of QOL 14 ± 7,22 points, the increase in ET at 1.5 points, VO2 peak decreased by 1,7 ml/min/kg. Revealed a strong positive correlation between the initial values of VO2 peak and EF (rEF=0,4, p), and between baseline levels of sodium, hemoglobin and the of physical rehabilitation efficiency (rNa= 0,41, p,0,05; rHb = 0,45, p < 0,05). There was a positive impact of the initial content of red blood cells (rEr=0,6, p = 0.03), sodium (rNa=0,4, p = 0.05), LV EF (r=0.5, p = 0.05) and level VE at the peak of exercise load (r=0.5,p = 0.01) on training efficiency. BNP level and a long history of CHF had a negative effect on the result of physical training (rBNP=-0,7, p = 0.05; rCHF=-0,6, p = 0.05). Significant differences in training performance between patients II and III functional class were not received.Conclusion. Aerobic physical exercise in CHF patients, selected on the basis of lactate threshold achievement during the CPET, is effective in improving values of CPET, EchoCG, QOL and increasing exercise tolerance. Age, BNP and uric acid levels can be considered as most significant predictors of inadequate response to physical rehabilitation in CHF patients.

P1735

sST2 and copeptin activity closely associated with E/E' changes during NT-proBNP guided therapy in high risk patients with chronic heart failure after acute decompensation

O Narusov[1]; A Skvortsov[1]; D Koshkina[2]; V Protasov[1]; A Sychov[1]; T Goryunova[1]; V Masenko[1]; S Tereshchenko[1]
[1]*Russian Cardiology Research and Production Complex, Moscow, Russian Federation*; [2]*National Research Center for Preventive Medicine, Moscow, Russian Federation*

Objective: to evaluate the biomarkers activity changes and their association with filling pressure during NT-proBNP guided therapy in CHF patients (pts) at high risk after acute decompensation (ADHF).
Methods: In the prospective single-center trial were included 105 hospitalized pts with ADHF III-IV FC NYHA and LV systolic dysfunction due to coronary artery disease, arterial hypertension and dilated cardiomyopathy. After HF symptoms compensation, at discharge, high risk pts (discharge NT-proBNP 1400 pg/ml) were randomized into group of therapy guided by NT-proBNP (group 1) and standard HF therapy (group 2). Pts in both groups didn't differ by the main clinical characteristics. The goal of treatment was to reduce NT-proBNP concentration of < 1000 pg/ml, or at least 50% of the initial before discharge. At discharge, median NT-proBNP concentration was 3651 (2191,5;6613,0) pg/ml in group 1 and 2862,0 (2015,0;4761,50) pg/ml in group 2, p=0,5. Blood sampling to determine the biomarkers concentrations (NT-proBNP, soluble ST2, copeptin, galectin-3, hsTnT and NGAL) were collected at discharge from the hospital, and 3 and 6 months after. Filling pressure was assessed by E/E'.
Results: At the end of the study all pts in groups 1 and 2 have been treated by recommended combination of iACE/ARB + beta-blocker + MRA (100%), but the mean doses up-titration of iACE/ARB and beta-blockers at the 6 months of treatment were significantly higher in NT-proBNP-guided group, p < 0.05. After 6 months of treatment, median NT-proBNP concentration significantly decreased to 1585,5 (976,5;2612,5) pg/ml(Δ% = -53,1%) in group 1 pts, whereas in group 2 only to 2450,0 (2028,0; 3328,0)pg/ml (Δ% = -11,1%), p = 0.024. The same more pronounced biomarkers activity reduction were found in group 1 pts for sST2 (Δ% = -37,1% vs -10,4%, p = 0,0001) and copeptin concentration (Δ%=-29,9% vs -3,4%, p < 0,001). Concentration of galectin-3, hsTnT and NGAL significantly decreased only in group 1: Δ% = respectively -16,8%, -26,5% and -15,1%, p < 0,01 for all. E/E' significantly decreased only in group 1 from 21,2 ± 4,1 to 14,2 ± 2,8 (Δ% = -30,7%, p < 0,001), vs -11,1% in group 2. In all pts Δ% of sST2 and Δ% of copeptin as Δ % of NT-proBNP concentration very closely correlated with each other, and significantly associated with Δ% E/E' (relatively r=0,63, r=0,7, r=0,67; p < 0.01 for all), compared with other biomarkers.
Conclusion: sST2 and copeptin as NT-proBNP activity are more sensitive and closely associated with E/E' changes during long-term NT-proBNP guided therapy in high risk patients with chronic heart failure after acute decompensation, compared with other biomarkers.

P1737

Galectin-3, longitudinal strain and left ventricular remodelling in patients with aortic stenosis

L Agoston-Coldea[1]; K Bheecarry[1]; T Mocan[1]
[1]*"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania, Cluj-Napoca, Romania*

Background: Aortic stenosis (AS) characterized by a progressive narrowing of the aortic valve triggering left ventricular overload and, consequently, changes in ventricular geometry and in longitudinal myocardial strain. New proinflammatory molecules such as galectin-3 could mediate valve calcification in AS.
Purpose: In the current study, we aimed to assess the relationship between left ventricle remodelling parameters, global longitudinal myocardial strain and new proinflammatory molecules in patients with AS.
Methods: We conducted a prospective study on forty two patients with severe AS (mean age 73 ± 6 years, 23 men) and forty two healthy volunteers matched by age, gender, and body surface areas measuring galectin-3 and NT-proBNP serum levels and specific echocardiographic parameters. Left ventricular remodelling was assessed by left ventricular mass index and relative wall thickness. Peak longitudinal myocardial strain was determined by two-dimensional speckle-tracking imaging.
Results: Most patients with SA had concentric left ventricular remodelling. When compared with healthy volunteers, patients with SA have lower global longitudinal strain (-20.5 ± 0.6 vs. -14.8 ± 3.8%, $p < 0.001$), which is correlated with higher left ventricular mass indexed (r=-0.419, $p = 0.001$), relative wall thickness (r=-0.677, $p < 0.001$), E/E' ratio (r=-0.696, $p < 0.001$), left atrium volume indexed (r=-0.757, $p < 0.0001$), NT-proBNP levels (r=-0.709; $p < 0.001$) and galectin-3 (r=0.718; $p < 0.001$). Relative wall thickness was strongly correlated with levels of galectin-3 (r=0.612, $p < 0.001$) and NT-proBNP (r=0.456, $p = 0.001$). In multivariate linear regression analysis, global longitudinal myocardial strain was associated with lower ejection fraction, increased left atrium volume, E/E' ratio and galectin-3 (R2=0.45, all $p < 0.001$).
Conclusions: In patients with SA, markers of left ventricle remodelling such as increased left ventricular mass indexed and higher relative wall thickness are associated with decreased longitudinal myocardial strain assessed by two-dimensional speckle tracking. Galectin-3 levels were positively correlated with wall thickness and concentric hypertrophy geometry, both of which are crucial indicators of geometric remodelling.

P1738

Trends of heart failure hospitalization during a large period of eleven years.

M L Maria Lucia Fernandez Gasso[1]; D A Pascual Figal[2]; L Hernando Arizatela[3]; J A Palomar Rodriguez[3]; J J Martinez Diaz[1]; J A Giner Caro[1]; J A Castillo Moreno[1]; L Consuegra Sanchez[1]; I Hernandez Fernandez[1]; R M Soto Ruiz[1]; I A Garcia-Escribano Garcia[4]; G Clavel Ruiperez[1]; P Ramos Ruiz[1]; J Garcia Gomez[1]; F Fernandez Montero[5]

Background: Heart failure (HF) is a chronic, debilitating, and progressive disease associated with significant mortality and morbidity and represents a burden to the health-care system and it is one of the most important public health problem.
Purpose: To evaluate HF hospitalization during eleven years.
Methods: Study based on the minimum basic hospital discharge data from all hospitals in the Region of Murcia between 2003-2013. Were studied: demographic variables, mortality, length of stay, comorbidities and Elixhauser index.
Results: A total 27.158 HF episodes in 16.827 patients (1,62 cases/person) were identified. Hospital discharge rates were 2,26/1000 people/year, being female gender and elderly (over 75 years) significantly more prevalent. In-hospital average lenght-of-stay was 9.4 days and in-hospital mortality was 9.2%. The Elixhauser index progressive increased from 3.54 in 2003 to 4.37 in 2013. Hypertension, diabetes mellitus, atherosclerosis and dyslipidemia were present in 46.2%, 36.7%, 32.3% and 30.8%.
Conclusions: Between 2003-2013 a change is not observed in terms of length of stay and hospital mortality.The Elixhauser index increased up to one point throughout the period.

Characteristics. Hospitalization for HF

P1739

6 minute walk distance, NYHA class and hemoglobin levels best predict health related quality of life in chronic stable heart failure patients

T Tara Mannion[1]; L Devaney[1]; S Fall[1]; M Carey[1]; A Jago[1]; S Fay[1]; R Pharithi[1]; V Maher[1]
[1]*Adelaide & Meath Hospital, Dublin, Ireland*

Background: Heart Failure patients experience diminished functional capacity which may impair their quality of life (1, 2). However it is not known which parameter best predicts Quality of Life in the heart failure population and if this differs in patient sub groups.
Purpose: We evaluated if correlations exist between indices of cardiac function and HRQoL in all chronic stable heart failure patients surveyed and in different subgroups. Associations were assessed between health related quality of life (HRQoL) and indices of cardiac function including 6MWT, NYHA, Steps per day, Ejection fraction, LV size, ECG rate and rhythm, BNP, hemoglobin (Hb) and renal function.
Methods: 158 clinically stable heart failure patients, whose weight, condition and medications were stable for the previous 3 months, participated. Functional capacity was evaluated via 6 minute walk testing (6MWT), New York Heart Association (NYHA) class and 3 day-accelerometer measuring daily step count (Fitbit). Other indices of cardiac function were also recorded including ECG (rhythm, rate), Echocardiography (LV size, ejection fraction), and biochemical measures (NT pro BNP, Hb, renal function). HRQol was determined using the Kansas City Cardiomyopathy Questionnaire (KCCQ).
Results: Univariate analysis demonstrated significant correlations between HRQoL and measures of functional capacity; 6MWT (Spearman r= 0.36, $p = < 0.001$), NYHA Class (r= 0.31, $p = < 0.001$), but not with daily step count (Fitbit). In addition, this also revealed significant correlation between HRQoL, and Hb (r= 0.35, $p = < 0.001$). No other statistically significant univariate correlations were revealed in relation to ECG, Echocardiography or biochemical measures and HRQoL. In a multivariate analysis of significant univariate correlants, 6MWT distance ($p = 0.012$), NYHA Classification ($p = 0.037$) & Hb ($p = 0.001$) were revealed to be independent predictors of HRQoL. Independent T-Test and one way analysis of variance revealed statistically significant differences of HRQoL in two patient groups; NYHA Class ($p = 0.001$) and Gender ($p = 0.022$).
Conclusion(s): Improving patients HRQol is essential in HF management. This study highlights that 6MWT, NYHA Class and Hb are the best surrogate markers of HRQOL

compared to other indices of cardiac function. Utilizing 6MWT or NYHA Class in clinical assessments of HF patients may therefore be the best way to tailor medication and/or device therapy, in order to optimize patients HRQoL.

P1740

Xanthine metabolism in patients with chronic heart failure and concomitant chronic kidney disease.

A V Alexandr Bilchenko[1]; MV Kolomietz[1]; AA Bilchenko[1]
[1]Kharkiv Medical Academy for Postgraduate Education , Internal medicine and Nephrology, Kharkiv, Ukraine

Background: Patients with chronic heart failure (CHF) and asymptomatic hyperuricemia have higher rates of cardio-vascular death, and all-cause death or rehospitalization due to worsening heart failure. However, the role of hyperuricemia as a risk factor for both renal and cardiovascular outcomes and in the context of the well-established interrelationship between cardiovascular disease and chronic kidney disease (CKD) is debated.
Purpose: The aim of this study was to examine the association between renal function, serum uric acid level and xanthine oxidase activity (XO) in patients with chronic heart failure and chronic kidney disease.
Methods: The study population consisted of 112 patients (51 men, 61 women) aged (72,5 + 8,6) years. Depending on a presence of concomitant CKD all patients with CHF were divided into 2 groups: with CKD (72 patients) and non-CKD (40) participants. XO activity was determined by a coupled enzyme assay, which results in a colorimetric (570 nm)/fluorometric (lex = 535/lem = 587 nm) product, proportional to the hydrogen peroxide generated. XO activity is reported as nmole/min/mL = milliunit/mL, where one milliunit (mU) of XO is defined as the amount of enzyme that catalyzes the oxidation of xanthine yielding 1.0 mmole of uric acid and hydrogen peroxide per minute at 25°C.
Results: The mean serum uric acid level and XO activity for CHF patients with CKD as compared with non-CKD patients was 7,63 + 0,27 mg/dL (95% confidence interval (CI), 7,09 – 8,160) vs 7,46 + 0,39 mg/dL (95% CI, 6,67 – 8,24; p=0,73) and 7,51 + 1,15 mU/ml (95% CI, 6,03 – 9,99) vs 4,69 + 1,16 mU/ml (95% CI, 2,06 – 5,33; p=0,04), respectively. The mean values of estimated glomerular filtration rate (eGFR) in patients with asymptomatic hyperuricemia and without hyperuricemia were 59,9 + 2,95 mL/min per 1.73 m2 and 76,6 + 6,05 mL/min per 1.73 m2 (p=0,007), respectively. Patients with eGFR ≤ 60 mL/min/1.73 m2 have significantly higher serum uric acid levels and XO activity, compared to those with eGFR > 60 mL/min/1.73 m2 ($p < 0,001$). We find out the significant correlations between eGFR and serum uric acid level (r=-0,3, $p < 0,05$), as well as XO activity (r=-0,5 $p < 0,05$) in CHF patients with CKD. Among patients without CKD significant correlation was observed only between eGFR and XO activity (r=-0,4, $p < 0,05$).
Conclusions: Patients with CHF and concomitant CKD had significantly higher XO activity as compared with CHF patients without CKD. Reduced eGFR in patients with CHF was associated with switching of xanthine metabolism towards oxidase pathway and increased xanthine oxidase activity.

P1741

Prevalence geriatric syndromes among outpatients with and without chronic heart failure

V Valentina Ostapenko[1]; ON Tkacheva[1]; NK Runikhina[1]; YV Kotovskaya[2]; NV Sharashkina[1]; AYU Shchedrina[1]
[1]Pirogov Russian National Research Medical University , Russian Gerontology Clinical Research Center, Moscow, Russian Federation; [2]RUDN University, Moscow, Russian Federation

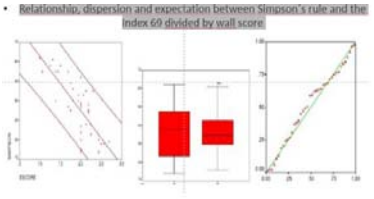
Introduction: The prevalence of heart failure as well as geriatric syndromes increases with age.
Purpose: The aim of our study was to investigate the prevalence of geriatric syndromes in outpatients with and without chronic heart failure (CHF).
Methods: The study includes 356 patients 65-93 years old. Average age was 74.8 ± 6.1 years old, 80.4 % women, 54.8% of them with higher education and 9% still continue to work. Research was conducted in Moscow polyclinic from November 2014 to May 2015. The diagnosis of CHF was determined from medical records. Based on international experience, we have created a 7-item Questionnaire to reveal main geriatric syndromes - weight loss, reduced vision or hearing, causing limitations in daily life, falling, mood disorders, cognitive impairment, urinary incontinence and walking difficulties. For each positive response was given 1 point.
Frailty and pre-frailty was diagnosed by Fried criteria.
Results: One hundred forty-two patients (39,9%) had a diagnosis CHF. The prevalence of frailty and pre-frailty among patients with CHF was higher (frailty 12.4% vs. 6.4%, pre-frailty 66.7% vs. 40.3%, $p < 0.005$). The middle score on the Questionnaire was higher among patients with CHF (3.3 ± 1.5 vs. 2.7 ± 1.5, $p < 0.005$). Significant differences in the responses were obtained for issues about reduced vision or hearing, causing limitations in daily life (66.2% vs. 47.2% $p < 0.005$) and difficulty in movement (59.2% vs. 38.3% $p < 0.005$).
Conclusion: CHF among elderly outpatients is associated with a higher prevalence of geriatric syndromes – frailty and pre-frailty, reduced vision or hearing and walking difficulties.

P1742

Wall motion score index evaluating myocardial performance to assess left ventricular function appropriate to be use at the bedside

CAS Nascimento[1]; B Tura[2]; MG Silva[2]; M Gomes[2]; H Veronesi[2]; APRV Siciliano[2]; AS Silva[2]; A Camarozano[2]; CEV Francisco[2]; MDT Duarte[2]
[1]Oswaldo Cruz Foundation, Evandro Chagas National Institute of Infectious Disease, Rio de Janeiro, Brazil; [2]National Institute of Cardiology, Rio de Janeiro, Brazil

Background: Despite the availability of several, upto date and fast methods to obtain left ventricular ejection fraction (LVEF) values, the subjective impression still the closest one to the physician needing a help number to evaluating their patients tham we show a cardiac formula using the wall score system (WS) to evaluate the LVEF.
Purpose: Evaluate a process to offer to intensivist an archetype number of left ventricular function near to real, because is appropriate to be use in handheld machines at bedside.
Methods: The sample population consisted of 70 hypertensive patients (52.3 ± 10.3 years old , 65% male) with ischemic heart disease with and without failure. We determined the classic wall score system using 17 segments and the LVEF using four different methods (3D, Eyeball, Teichholz and Simpsom Method). 3D measurements were recorded using a GE E9 with V4 transducer and IE33 and portable Phillips CX50 system equipped with a 3.5 MHz transducer and images analyzed by two different observers. The average LVEF was 45 ± 16% by Teichholz and 35 ± 15% by Simpsom Method, Mean Wall Score was 1.7. By regression analysis, we determined a formula that yielded EF calculation using Wall Score system closely resembling the EF obtained by Simpsom rule. The regression equation was Index = 9 0.5 – 27.8 x WS. This formula was further simplified to LVEF = WS divided by 69. Recently we did the same Index in 21(30%) patiens comparing with LVEF obtained by ETT3D with better correlation($P < 0.001$)
Results: In 70% (49 pt)of the patients this last simple formula Index = 9 0.5 – 27.8 x WS or WS divided by 69 yielded a LVEF with very good correlation ($P < 0.02$) with LVEF obtained by, Simpson's rule and the examiner subjective impression (eyeball), and the cardiac performance. LVEF obtained by ETT3D was better correlation($P < 0.001$), increasing the value of the index as it is cheaper and easier to execute.
Conclusions: Calculation of LVEF using wall score is feasible and yields reliable values that can be used in everyday bedside clinical practice with handheld machines without upto date softwares, Another advantage of this method is that we only use the left ventricle segments which are adequately seen.



P1743

Heart failure with mid-range ejection fraction - an echocardiographic finding or a clinical phenotype?

AD Farcas[1]; FP Anton[1]; MA Stoia[1]; CM Goidescu[1]; AF Cocoi[2]; IL Gavrila[2]; LA Vida-Simiti[1]
[1]University of Medicine and Pharmacy, Cardiology Department of County Clinical Emergency Hospital, Cluj Napoca, Romania; [2]Cardiology Department of County Clinical Emergency Hospital, Cluj Napoca, Romania

Background: Clinical data and prognosis for patients with heart failure (HF) with preserved ejection fraction (HFpEF) and reduced ejection fraction (HFrEF) are notably

different. The 2016 ESC Guidelines for HF added a new term – heart failure with mid-range ejection fraction (HFmrEF) to designate patients with EF 40-49% and to bolster the research.
Purpose: The objective of our study is to highlight the features of these patients and to analyze the differences between patients with HFpEF, HFmr EF and HFrEF.
Methods: Our study group included 278 patients (p) with NYHA class II-IV (mean age 66 ± 12y) admitted in the Cardiology Department of CCEH after they signed an informed consent. Clinical exam, echocardiography and lab tests were performed for each patient. Based on the ejection fraction (EF), patients were assigned to three groups: A – 93 p with HFpEF, B – 89 p with HFmrEF and C – 96 p with HFrEF. Study design was approved by the Ethics Committee. Statistical analysis was performed using SPSS 20.
Results: There were no statistically significant differences between groups regarding duration of hospitalization, gender, age and comorbidities (obesity and diabetes). Ischemic heart disease was less frequent (22.4% vs 41%, $p = 0.01$ and 22.4% vs 43.5%, $p = 0.006$) and hypertension was more frequent in group A compared to group B and C (75.1% vs 71.1%, $p = 0.02$ and 75.1% vs 60%, $p = 0.004$). The most frequent cause of decompensation was atrial fibrillation in group B ($p < 0.001$), hypertension in group A ($p < 0.001$) and ischemia in group C ($p < 0.001$). Echocardiography showed that left atrial size (33.9 ± 21.2 vs 25.5 ± 21.3, $p = 0.01$; 33.9 ± 21.2 vs 22.8 ± 19.3, $p = 0.04$), systolic pulmonary artery pressure (43.9 ± 15.1 vs 31.5 ± 12.4, $p = 0.002$; 43.9 ± 15.1 vs 19.4 ± 15.1, $p = 0.02$) and left ventricular diameter (53.7 ± 17.9 vs 36.7 ± 23.1, $p < 0.005$; 53.7 ± 17.9 vs 34.7 ± 21.1, $p = 0.01$) were significantly higher in group C than in group B or A. Beta-blocker doses at discharge were significantly higher in HFpEF patients (32.04 ± 49.95vs 24.16 ± 41.53, $p = 0.02$) and also in HFrEF patients (33.09 ± 37.36 vs 25.93 ± 34.98, $p = 0.019$), but not in those with HFmrEF (31.73 ± 38.57 vs 21.79 ± 31.75, $p = 0.132$). Spironolactone doses were significantly higher at discharge compared to admission in HFpEF (22.39 ± 24.19 vs 15.88 ± 24.36, $p = 0.022$) and HFrEF patients (20.83 ± 23.09 vs 11.25 ± 19.21, $p = 0.001$), but not in those with HFmrEF (18.18 ± 24.42 vs 13.63 ± 25.07, $p = 0.245$). We found no significant difference between ACE-inhibitors/angiotensin-receptor blockers doses at discharge compared to admission.
Conclusions: The treatment strategy for patients with HFmrEF suffered only minor changes during hospitalization compared to those with HFrEF or HFpEF, although they had significant clinical and echocardiographic differences. Future studies involving more patients will provide significant data in this "gray area" regarding phenotype, pathophysiology, prognosis and targeted therapies.

P1744
The frequency of heart failure after acute coronary syndrome in patients with nonobstructive coronary atherosclerosis

S B Gomboeva[1]; A E Baev[1]; Y Rogovskaya[2]; T A Shelkovnikova[1]; W Y Ussov[1]; V V Ryabov[3]
[1]Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, Russian Federation; *[2]National Research Tomsk State University, Tomsk, Russian Federation*; *[3]Siberian State Medical University, Tomsk, Russian Federation*

The aim of the study was to evaluate the frequency of heart failure during 6 months after acute coronary syndrome in patients with nonobstructive coronary atherosclerosis.
Material and methods: It is non-randomized open controlled investigation NCT02655718. We present the results of the subanalysis of this study in which included data of patients admitted at the Emergency Department of Cardiology due to ACS in 2015-2016. Inclusion criteria were nonobstructive coronary atherosclerosis (normal coronary arteries / plaques < 50%), confirmed by invasive coronary angiography, age ≥ 18 years at the time of randomization. The exclusion criterion was previous revascularization of the coronary arteries. Twenty two patients were underwent cardiac MRI.
Primary outcomes were hospital mortality, incidence of recurrent ischemia, stroke, and as final diagnosis acute myocardial infarction, unstable angina, Takotsubo syndrome, and myocarditis. Secondary outcomes were death, reccurent myocardial infarction, stroke, the development of heart failure during 6 month after presence of acute coronary syndrome. During 6 months after discharge was hold telephone monitoring for assessment secondary outcomes. Descriptive statistics was used for analysis of data.
Results: Among 913 people who were hospitalized with acute coronary syndrome at the Emergency Department of Cardiology in 2015 - 2016 4.8% (44) patients had nonobstructive coronary atherosclerosis confirmed by coronary angiography. We present the results of subanalysis this investigation including 23 patients. One patient died. Twenty two patients were underwent cardiac MRI. Finally in 13 (56%) cases were diagnosed acute myocardial infarction, in 3(13%) - unstable angina, and a 1/3 of cases had pseudo-coronary scenario of myocarditis. There were 6 (26%) cases of re-hospitalization in 6 months after discharge due to: unstable angina-2 (9%), recurrent myocardial infarction in 1 (4%); noncardiac causes had 3 (13%) patients. The development of heart failure was observed in half patients: NYHA I-1(8%), II-8 (67%), III-3 (25%), NYHA IV-0.
Conclusion: The proportion of patients with nonobstructive coronary artery disease among patients with ACS in 2015-2016 was 4.8%. Heart failure occurred in half patients in 6 months after acute coronary syndrome.

P1745
The impact of a specialised community service on heart failure admissions

E Chua[1]; A Murphy[1]; B Unger-Graeber[2]; S Khan[1]
[1]West Middlesex University Hospital, Cardiology, London, United Kingdom; *[2]Chiswick Health Practice, London, United Kingdom*

Background: Heart failure (HF) admissions are predicted to rise over the next decade, placing increased pressure on healthcare systems. Studies indicate specialised follow up by a multidisciplinary team reduces hospitalization and possibly mortality.
A nurse-led consultant supported community heart failure service commissioned by our local Clinical Commissioning Group was introduced in our hospital's catchment area in 2014. The team receives referrals from general practitioners, hospitals and tertiary centres and has advantages of earlier follow up, satellite clinics and home visits. It serves a diverse local population and allows greater flexibility in management.
Purpose: To evaluate the impact of this service on emergency heart failure admissions, length of stay (LOS) and in-hospital mortality.
Methods: We conducted a retrospective study of emergency admissions to our hospital with a primary diagnosis of heart failure between May 2013 to April 2014 (pre community service, PC group) and May 2015 to April 2016 (after community service, AC group). Our database identified 382 admissions of 271 patients in the PC group and 408 admissions of 319 patients in the AC group.
The AC group was subdivided into those not known to (237 patients) and those under the community team (82 patients). We also stratified patients by New York Heart Association (NYHA) functional classes and ejection fraction (EF) on echocardiogram.
Results: There was a significant reduction in average number of admissions per patient from 1.41 in the PC group to 1.28 in the AC group ($p = 0.01$). Percentage of admissions with codes for complication and comorbidity increased significantly (44.5% to 64.7%, $p < 0.01$). However, there was no significant change in average LOS per patient (19.9 vs 17.3 days) and in-hospital mortality (19 vs 23 patients).
Comparing admissions by NYHA class and EF, there was a significant reduction in average number of admissions per patient only in patients classed as NYHAII (1.52 to 1.19, $p < 0.01$) and patients with severely reduced EF (1.53 to 1.25, $p = 0.03$).
Within the AC group, patients known to the community team had a longer average LOS per patient (22.4 vs 15.6 days, $p < 0.01$). However, these patients had generally more severe disease as reflected by higher percentage classed as NYHAIII and IV.
Conclusions: In conclusion, a nurse-led specialised community heart failure service can be effective in reducing emergency heart failure admission rates, likely more so in patients with less severe disease and fewer comorbidities. This is especially relevant with the increasing demand for inpatient beds. Hence, future studies looking at long term follow up and cost effectiveness of such services would be extremely useful.

ADVANCED HEART FAILURE

P1746
Sarcubitril-valsartan first treatment after inotripic therapy in Stage D Heart failure patients

R Porcile[1]; R L Levin[1]; G Perez Baztarrica[1]; F Salvaggio[1]; R Mayer[1]; L A Botbol[1]; I Vaca Valverde[1]; M T Zuniga Infantas[1]
[1]Universidad Abierta Intericana, Cardiology and Physiology , Universitary Hospital , Buenos aires, Argentina

Purpose: 1)To evaluate clinical utilization of SarcubitrilValsartan (S/V) like first treatment in patients (p) with stage D systolic heart failure after de use of inotropic and diuretics dugs. 2)To evaluate the clinical evolution in 60 days folow up.
Methods: We enrolled p ischemic cardiomyopathy(IC) and ejection fraction(EF) less than 35% admitted for decompensated heart failure between June and October 2016.Inclusion criteria: IC, age18 years, systolic blood pressure >90 mmHg without vasopressors. Were excluded p with infections, renal failure, anemia, cáncer or in mechanical ventilation support. Hemodynamic monitoring was performed using Swan Ganz catheter (SG). All p required intra venous isotropic drugs (ID) and diuretic treatment (DIU). After the suppression of ID and DIU and verifying normal preload and cardiac index by SW (CI>2.2 L/min/m2) and normal volemia (CVP>10,PCOP >15 mmHg) We start an oral dose of S/V of 50 mg each 12 hours. A 6 minutes' walk test was performed 24 hs before and 60 days after hospital discharge checking clinical status, renal function parameters and NT-Probnp.

Results: 9 patients(8men,1women) aged 63 + /-7 year, EF averaged 28.5%. All p received ID average doses 7G/KG/MIN, the starting oral treatment was carvedilol 12.5 day mg,spleronone 25 mg per day and S/V. Average hospitalization time :9.3 days. 8 p performed the 45th day control 1 p received a heart transplant in the 52 day after inclusion. In 2 p we observed symptomatic hypotension that needs doses reduction. No hospital readmission or death during observation period(TABLE)
Conclusions: 1) S/V like first treatment after inotripic therapy in D p is generally well tolerated 2) No hospital readmission or dead and sustained clinical benefit without serious adverse effect during follow up period.3) 60th day Nt-probnp average remain in not congestive range

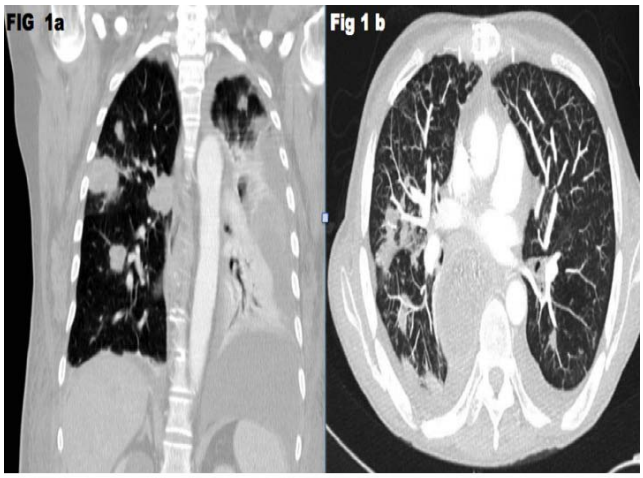
Invasive pulmonary aspergillosis in heart transplant recipients: is mortality decreasing?

E Flores Umanzor[1]; J Betuel[1]; G Caldentey[1]; G Jimenez-Britez[1]; R San Antonio[1]; P Sanchez-Somonte[1]; G Caixal[1]; M Pujol[1]; M Mimbrero[1]; B Carbonell[1]; S Vazquez[1]; L Tirapu[1]; M Farrero[1]; M Sitges[1]; MA Castel[1]
[1]*Hospital Clinic de Barcelona, Cardiology Department, Barcelona, Spain*

Background: Infection remains a major complication among heart transplant (HT) recipients, causing approximately 20% of deaths within the first year after the transplantation. In this immunosuppressed population, Aspergillus species can produce several clinical presentations including invasive pulmonary aspergillosis (IPA), with a high attributable mortality (53% to 78%).
Aims: To establish the characteristics of IPA infection in HT recipients and their outcomes in our setting.
Methods: Of 328 heart transplants in our center between 1998 and 2016, we identified 5 cases of IPA. Patient records were examined and clinical variables were extracted, including age, sex, primary cardiac diagnosis, date of transplant, immunosuppressant regimen, cytomegalovirus serological status, antifungal prophylaxis, known risk factors for IPA, radiographic features, serum galactomannan level, bronchoscopy and microbiology data. Table 1.
Results: All cases were male patients, with mean age of 62 years. The most common indication for HT was non ischemic dilated cardiomyopathy. Productive cough was reported as the main symptom although two patients were asymptomatic. The most commonly reported radiological abnormality was multiple nodular densities on both chest radiography and chest computed tomography (CT) as shown in Figure 1. Serum galactomannan level was abnormally high in 3 of 5 patients. Bronchoscopy was performed in all patients and Aspergillus fumigatus was isolated in 4 cases on BAL culture. Initial treatment included amphotericin in 4 patients with subsequent change to voriconazole in 3 patients, and posaconazol in 1 patient, with total treatment lasting an average of 12 months. Neutropenia was found just in one patient, renal failure was observed in two patients, and concurrent CMV infection occurred in 3 patients. Only two patients received antifungal prophylaxis since they were in the first 30 days after heart transplantation. All patients survived after a mean follow up of 18 months.
Conclusions: IPA represents a potentially lethal complication after HT. An early diagnosis and a promptly aggressive treatment initiation is the cornerstone for a better survival.



P1748
Global longitudinal strain and cardiopulmonary exercise testing predicts exercise capacity and correlates with previous rejection episodes in heart transplant recipients

BP Dhakal[1]; CM Bianco[1]; SG Al-Kindi[1]; A Bojansky[1]; R Kayatin[1]; M Vest[1]; BD Hoit[1]; GH Oliveira[1]; CA Elamm[1]
[1]*University Hospitals Cleveland Medical Center, Case Western Reserve University, Cleveland, United States of America*

Background: Orthotopic Heart transplant (OHT) is the ultimate treatment option for patients with end-stage heart failure (HF). However, OHT recipients may not reach a normal level of exercise capacity. Exercise capacity data with cardiopulmonary exercise testing (CPET) in OHT recipients and the correlation with echocardiographically-measured left ventricular strain are limited.
Purpose: We hypothesized that speckle-tracking echocardiography (STE) global longitudinal strain (GLS) correlates with exercise capacity measured by CPET in OHT recipients. We also postulated that the number of rejection episodes may have association with GLS.
Methods: Seven OHT recipients following up at our advanced HF clinic 6-18 months after transplantation were recruited into the study. All subjects underwent maximal symptom-limited CPET, STE and RHC with endomyocardial biopsy either simultaneously or within a few days apart. Peak oxygen uptake (VO2), ventilatory efficiency, and other ventilatory parameters were obtained from CPET. Echo measurements included indices of ventricular systolic and diastolic function, systolic tricuspid annular tissue velocity (RVS') and GLS. Medical history and ischemic time of the donors, number and types of rejection episodes of recipients were obtained by chart review. Spearman correlation was used to identify correlation between variables and p value <0.05 was considered statistically significant.
Results: Our patient population consisted of younger males, age 38 ± 12 yrs (mean $\pm$ SD), BMI 27.1 ± 3.8 kg/m^2. The time interval between OHT and echocardiography was 349 ± 94 days. During maximal effort CPET as indicated by peak exercise respiratory exchange ratio ≥ 1.0, OHT subjects had an impairment in their exercise capacity with a mean peak VO2 of 21.1 ± 7.6 ml/kg/min (55 ± 14% of predicted). Peak VO2 correlated with basal right ventricular (RV) dimension (r=0.883, $p=0.02$), mid RV dimension (r=0.829, $p=0.04$) and RVS' (r=-0.828, $p=0.04$). GLS had a strong correlation with the Borg Rating of Perceived Exertion (RPE) (r=-0.894, $p=0.04$) and peak minute ventilation (r=-0.771, $p=0.07$) during CPET. GLS was also significantly associated with resting cardiac output measured by Fick method (r=-0.829, $p=0.04$) and mid RV dimension (r=-0.90, $p=0.037$). There was a trend towards lower GLS and number of prior episodes of low grade acute cellular rejection (ACR, 1R) (r=0.77, $p=0.07$). We did not find any relationship between GLS and ischemic time or cardiopulmonary resuscitation time of the donors. There was no statistically significant correlation between GLS and peak VO2 (r=-0.7, $p=0.11$).
Conclusion: In our pilot study of carefully selected heart transplant patients, GLS "predicts" the peak exercise capacity and is negatively correlated with prior episodes of mild ACR. Indicators of RV parameters are associated with peak

Table P1747

Case	Age/Sex	Days since heart transplant	Radiographic findings/Symptoms	Microbiology/Treatment	Immunosuppression	Known risk factors for IPA	Fungal prophy-laxis
1	59/male	5	Multiple micro-nodular densities/Asymptomatic	Aspergillus fumigatus/ Amphotericin	Prednisone, Cyclosporine + Mycophenolate	Concurrent CMV infection: yes/	Micafungin
2	70/male	12	Multiple micro-nodular densities/ Productive cough	Aspergillus fumigatus/ Voriconazole plus Caspofungin	Prednisone, Tacrolimus + Mycophenolate	Concurrent CMV infection: no	Fluconazole
3	51/male	116	Multiple micro-nodular densities/Productive cough and fever	Aspergillus fumigatus/ Amphotericin + Caspofungin	Prednisone, Tacrolimus + Azathioprine	Concurrent CMV infection: yes	None
4	61/male	189	Multiple micro-nodular densities/Asymptomatic	Aspergillus fumigatus/ Voriconazole + Anidulafungin	Prednisone, Tacrolimus + Mycophenolate	Concurrent CMV infection: no/Neutropenia	None
5	71/male	55	Ground-glass pattern/Chest pain	Aspergillus fumigatus/ Amphotericin	Prednisone, Tacrolimus + Mycophenolate	Concurrent CMV infection: yes	None

.

exercise capacity after OHT. Future studies evaluating the association between mild ACR and exercise capacity in OHT recipients are warranted.

P1749
Effectiveness of palliative care in people with persistently symptomatic heart failure: a systematic review

S Datla[1]; A Hoye[2]; M Johnson[2]
[1]*Hull York Medical School, Hull, United Kingdom*; [2]*University of Hull, Hull, United Kingdom*

Background: People with advanced heart failure (HF) are symptomatic, have poor quality of life but, despite recommendations, they have little access to palliative care. The historical lack of evidence for palliative care use in HF patients is a barrier for access to palliative care.
Purpose: To identify the evidence in relation to palliative care for people with persistently symptomatic HF.
Methods: The following databases were searched: Medline, Cochrane database, CINAHL, PsycINFO, HMIC, Care Search Grey Literature. Reference lists, and citations were handsearched and experts contacted. Two independent reviewers screened titles, abstracts and retrieved papers against inclusion criteria. Data were extracted from included papers and studies were critically assessed using the Cochrane risk of bias tool.
Results: Seven phase 3 trials, one phase 2 trial, one quasi-experimental trial, five cohort studies, and one case-control study were included. Studies were heterogeneous in terms of population, intervention, comparator, and outcomes. However, the adequately powered studies, with lower risk of bias, using a multi-disciplinary specialist palliative care intervention showed statistically significant benefit for a variety of patient-reported outcomes such as symptom burden, depression, functional status, and quality of life, as well as resource use and costs of care. Benefit was not seen in studies with a single component/discipline intervention or methodological issues. Possible contamination of controls in some studies may have led to under-estimation of effect. There was no apparent effect on survival.
Conclusion: Results support the use of multi-disciplinary palliative care in managing patients with HF. Across all included studies, findings were inconsistent due to a variety of methodological issues. Further research is needed to identify which patients would benefit most from general and specialist palliative care and the barriers for their access.

P1750
Blood pressure response during cardiopulmonary exercise testing in patients with heart failure predicts failure of medical management

ZJ Zachary II'giovine[1]; N Solomon[2]; AD Devore[2]; D Wojdyla[2]; CB Patel[2]; JG Rogers[2]
[1]*Duke University Medical Center, Medicine, Durham, United States of America*; [2]*Duke Clinical Research Institute, Durham, United States of America*

The prognostic value of peak VO2 and VE-VCO2 slope measured during cardiopulmonary exercise (CPX) testing has been well established in patients with advanced heart failure (HF). Many of these patients also have a blunted blood pressure response (BP) during exercise. This analysis was designed to better understand the prognostic implications of this observation.
We retrospectively studied 166 consecutive ambulatory patients referred to clinic for consideration of advanced HF therapies. Patients underwent cardiopulmonary exercise treadmill testing using either Ekeland or Naughton protocols. Vital sign data was available for 151 patients, which was assessed every 3 minutes during exercise and recovery. Breath-to-breath gas analysis was obtained to measure respiratory exchange ratio (RER), maximal oxygen consumption (peak VO2), and minute ventilation/carbon dioxide production (VE-VCO2).
Patients were stratified into tertiles by change in systolic BP (<13, 13-26, and ≥ 27 mmHg) in response to exercise. Baseline demographics and medications were similar between the groups. Mean exercise time was longer in those with a higher BP response (5.1 vs. 6.0 vs 7.0, respectively, $p = <0.001$). Peak VO2 was lower (10.2 vs. 10.6 vs. 13.6, $p = <0.001$) and VE/VCO2 slope was higher (42.8 vs. 42.1 vs. 36.3, $p = 0.030$) in patients with a lower blood pressure response. Patients with a lower response also had significantly worse survival without transplant or mechanical circulatory support (41% vs. 31 vs. 28%). After multivariate adjustment, an increase in systolic BP up to 20 mmHg was associated with a lower hazard of medical failure (hazard ratio=0.95, $p = <0.0001$ for every 1mmHg increase; failure defined as requirement of left ventricular assist device (LVAD), transplant, or death). When adjusted for an RER >1.05 ($n = 93$), tertiles showed similar progression to death or requirement of LVAD/transplant (42.9% vs. 35.7% vs. 21.4%). Hazard of failure in this subgroup showed a similar but non-significant trend (hazard ratio=0.98, $p = 0.0946$). In conclusion, patients with smaller change in blood pressure in response to exercise were associated with higher rates of death, LVAD, or transplantation.

P1751
Elevated donor C-reactive protein impacts incidence of very early infections following heart transplantation

I Planinc[1]; D Fabijanovic[1]; J Ljubas-Macek[1]; B Skoric[1]; H Jurin[1]; J Samardzic[1]; N Jakus[1]; H Gasparovic[2]; M Cikes[1]; D Milicic[1]
[1]*University of Zagreb School of Medicine, University Hospital Center Zagreb, Department of Cardiovascular Diseases, Zagreb, Croatia*; [2]*University of Zagreb School of Medicine, University Hospital Center Zagreb, Department of Cardiac Surgery, Zagreb, Croatia*

Purpose: Heart transplantation (HTx) donors frequently have elevated C-reactive protein (CRP) and white blood cell counts (WBCC), predominantly due to systemic inflammatory response to a severe underlying clinical condition, however potentially also influenced by an ongoing infection that may yet not be microbiologically

Table 1.

Donors	Recipients					
CRP quartiles (mg/L)	Very early infection(< 5 days)(n = 12)	Early infection(0-30 days)(n = 61)	Intermediate infection(31-180 days)(n = 37)	Late infection(>181 days)(n = 28)	Treated rejection(n = 24)	Vasculopathy(n = 22)
1. 0.5-37.8(n = 35)	8%	25%	32%	31%	25%	18%
2. 37.9-117.0 (n = 32)	17%	25%	24%	11%	29%	27%
3. 117.1-182.4 (n = 35)	25%	26%	22%	29%	29%	37%
4. 182.5-437.4 (n = 35)	50%*	24%	22%	29%	17%	18%
L quartiles (x10 9)	Very early infection(< 5 days)(n = 15)	Early infection(0-30 days)(n = 67)	Intermediate infection(31-180 days)(n = 40)	Late infection(>181 days)(n = 32)	Treated rejection(n = 24)	Vasculopathy(n = 22)
1. 3.8-10.2(n = 41)	27%	26%	22%	19%	29%	22%
2. 10.3-12.9 (n = 36)	20%	22%	13%	28%	25%	32%
3. 13-17.1(n = 36)	40%	28%	37%	19%	29%	23%

Incidence of observed outcomes in HTx rcps per quartiles of donor inflammatory biomarkers. *p = 0.024

confirmed. We aimed to evaluate the potential consequences of elevated donor WBCC and CRP on recipients (rcp) outcomes.

Methods: We have retrospectively studied pre-explant donor WBCC and CRP for 166 consecutive HTx rcp (117 male, mean age 52 ± 13, median follow-up 31.2 ± 27.4 months) transplanted in our centre between January 2008. and December 2016., and their relation to rcp outcomes (infection, rejection, cardiac allograft vasculopathy, and survival). Per institutional protocol, all patients received meropenem + vancomycin prophylactically for a minimum of 7 days.

Results: Very early infection occurred in 15 rcps (sepsis: 10 pts, pneumonia: 4 pts, UTI: 1 pt), with a significantly higher occurrence in rcps transplanted from donors with higher CRP (Table 1.). Rcps transplanted from donors with CRP in upper quartile tend to have worse survival (not statistically significant). Other studied outcomes were not influenced by CRP values. No significant relation of elevated donor WBCC and incidence of any of studied outcomes was found. Positive donor cultures (urine/tracheal aspirate/sputum/blood culture) did not alter the outcomes.

Conclusion: Donor CRP impacts incidence of very early post-HTx infections, and may influence long term survival, thus warranting cautious donor selection and consideration of appropriate use of prophylactic antibiotics in the very early post-HTx period.

P1752

Ordinal interaction effect of pulmonary vascular resistance and pulmonary arterial wedge pressure on pulmonary RC time

S Sara Moura Ferreira[1]; J Ferreira[2]; R Baptista[2]; MJ Ferreira[2]; A Marinho[3]; S Costa[2]; F Franco[2]; M Pego[2]

[1]Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal; [2]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal; [3]University Hospitals of Coimbra, Paediatric Cardiology, Coimbra, Portugal

Introduction: The pulmonary RC time [the product of pulmonary vascular resistance (PVR) and pulmonary arterial compliance (PCa)] represents the time constant of the mono-exponential pressure decay of pulmonary artery pressure after pulmonic valve closure and has been shown to be useful in the characterization of pulmonary circulation hemodynamics. Exceptions to the steadiness of pulmonary RC time have already been published. We aimed to assess if there is an interaction effect between two factors known to affect pulmonary time constant – pulmonary arterial wedge pressure (PAWP) and PVR.

Methods: This is a retrospective single institution study that included end-stage heart failure patients who underwent a right heart catheterization (RHC) study in the setting of evaluation for heart transplant between 2004 and 2012. RHC was performed via the femoral vein and pressure measurements were obtained using 7F balloon-tipped catheters. All pressure tracings were obtained at end-expiration and were manually reviewed by a heart failure specialist. Cardiac output was determined by the Fick method. PVR was calculated by the following formula: (mean pulmonary artery pressure – mean pulmonary artery wedge pressure) / cardiac output. PCa was calculated as the ratio of stroke volume by the pulmonary artery pulse pressure. Pulmonary RC time was calculated as the product of PVR and PCa.

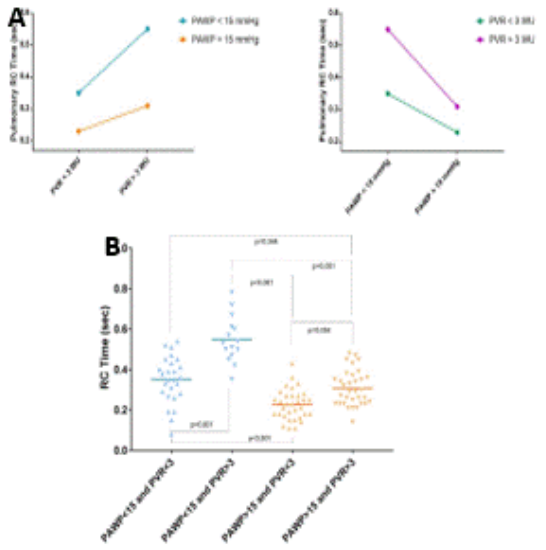

Figure 1. A. Interaction plots showing the mean of pulmonary RC time according to pulmonary vascular resistance (PVR) and pulmonary arterial wedge pressure (PAWP). Non-parallel lines indicate an interaction effect – the effect of one variable on pulmonary RC time is not constant across the second variable. B. Scatter plot of pulmonary RC time according to PAWP and PVR. Each triangle represents a patient; upright triangles – patients with PVR ≤ 3 WU; inverted triangles – patients with PVR > 3 WU; blue triangles – patients with PAWP ≤ 15 mmHg; orange triangles – patients with PAWP > 15 mmHg. Horizontal line – mean of RC time. Statistical significance of the difference of RC time means between each pair is depicted (one way ANOVA followed by Tukey's tests).

Figure 1

Results: 107 patients [83 (78%) men, mean age 51 ± 12 years] were included. The main effect for PAWP yielded a F ratio of F(1, 103) = 90,2, p < 0,001, indicating a significant difference between patients with PAWP ≤ 15 mmHg (RC time 0,42 ± 0,15 s) and patients with a PAWP > 15 mm Hg (RC time 0,27 ± 0,09 s). The main effect

for PVR yielded a F ratio F(1,103) = 54,3, p < 0,001, indicating, also, a significant difference between patients with PVR ≤ 3WU (RC time 0,28 ± 0,11 s) and patients with PVR > 3 WU (RC time 0,38 ± 0,15 s). The interaction effect was significant F(1,103) = 9,3, p = 0,003. This means that the effect of PAWP on pulmonary RC time depends on the level of PVR and vice-versa. The simple effects of PAWP on pulmonary RC time were lower at PVR ≤ 3 WU than at PVR > 3 WU. On the other hand, the simple effects of PVR were lower at PAWP > 15 mmHg than at PAWP ≤ 15 mmHg. Otherwise said, the effects of one variable are not constant across the different levels of the other variable; however, the relative ranking of one variable does not change at different levels of the other, being consistent with an ordinal interaction.

Conclusion: The recognition of an ordinal interaction effect of PVR and PAWP on pulmonary RC time may be important on clinical practice. If pulmonary RC time is used in studies aiming to assess the effect of therapeutic interventions (pharmacological or surgical) on right ventricular afterload, the result may be misleading.

ATRIAL FIBRILLATION

P1753

Catheter ablation of atrial fibrillation in heart failure patients: a first experience.

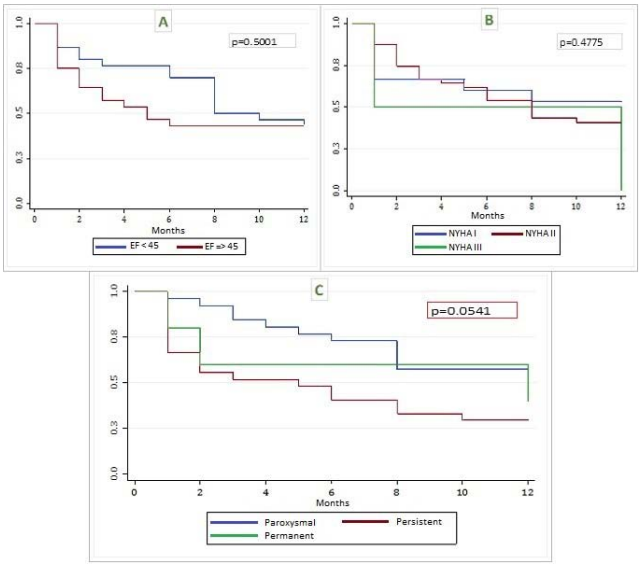
N Nicolas Vecchio[1]; L Ripa[2]; L Tomas[1]; F Cruz[1]; I Mondragon[1]; A Orosco[1]; ML Talavera[1]; A Acosta[1]; S Rivera[1]; G Albina[1]; M Diez[1]; F Scazzuso[1]
[1]Cardiovascular Institute of Buenos Aires (ICBA), Buenos Aires, Argentina; *[2]Central Hospital of Mendoza, Mendoza, Argentina*

Background: Atrial fibrillation (AF) and heart failure (HF) frequently coexist with a significant increase in morbidity and mortality. Rhythm control with pharmacological treatment has failed to keep patients in sinus rhythm (SR).

Purpose: The aim of this study was to assess the efficacy and safety of catheter ablation in patients with AF and HF, and analyze NYHA functional classification (NYHA) and HF hospitalizations during post-procedure follow-up.

Methods: We retrospectively analyzed patients with AF and signs and symptoms of congestive HF or left ventricular ejection fraction (EF) less than 45%, refractory or intolerant to pharmacological treatment, who underwent catheter ablation of AF between July 2009 and March 2016. We excluded patients who did not complete one year of follow-up.

Results: Fifty-eight patients were included. Fifty-five completed at least one year of follow-up. At baseline, mean age was 62.1 ± 10.5 years, 72.4% were men, 67.2% hypertensive and 8.6% diabetics. As a pharmacological treatment, 86.2% were with antiarrhythmics and 55.2% with beta-blockers. Mean EF was 49 ± 13.1% and LA area 26.5 ± 7 cm2. 44.8% had paroxysmal and 46.6% persistent AF. Finally, 70.6% were in NYHA II/III.



Predictors of recurrence at one year

The primary success rate during the procedure was 90.92%. Fifty-five patients were analyzed during follow-up, 33 (60%) had recurrence of AF or atrial flutter after the blanking period. Second catheter ablation was performed in 18 patients and recurrence rate was 44.4%. Therefore, SR rate after two procedures increases to 72.2%. At follow-up, NYHA class in SR group improved significantly more than those in the recurrence group (63.6% vs 36.4%; p = 0.047). No patients in SR had HF hospitalizations, whereas 6 hospitalizations were observed in the recurrence group (0% vs 18.2%, p = 0.07).

Seventy-six ablations were performed between first and second procedures. Eight complications were observed (10.52%), including 3 HF decompensation (3.95%), 2 cardiac tamponade with pericardiocentesis (2.63%), 2 vascular complications (2.63%) and 1 extreme bradycardia (1.32%). No stroke or procedural deaths were observed.

Conclusion: Catheter ablation of atrial fibrillation in heart failure patients refractory or intolerant to antiarrhythmic treatment is a safe procedure with an acceptable success, improving symptoms and decreasing heart failure hospitalizations.

P1754

CHA2DS2VASc score - A strong predictor of new onset atrial fibrillation

G Abreu[1]; P Azevedo[1]; C Rodrigues[1]; I Campos[1]; C Braga[1]; J Martins[1]; C Arantes[1]; M Alvares Pereira[1]; J Marques[1]
[1]Hospital de Braga, Cardiology, Braga, Portugal

Background: The CHA2DS2VASc score is used clinically for stroke risk stratification in atrial fibrillation (AF). Many of the individual risk factors included in this score are also risk factors for atrial fibrillation.

Aim: To examine the CHA2DS2-VASc score performance in predicting new-onset atrial fibrillation in subjects without preexisting diagnosis of atrial fibrillation.

Methods: We analysed 851 patients admitted consecutively in our coronary care unit with a diagnosis of ST segment elevation myocardial infarction in a five-year period. Patients with previous atrial fibrillation (n = 36) or in cardiogenic shock (n = 30) were excluded. CHA2DS2-VASc score was calculated for each patient. The cohort was divided in three groups according to the value obtained: CHA2DS2VASc 0-1 (n = 243, 31%); CHA2DS2VASc 2-3 (n = 334, 42.5%); and CHA2DS2VASc ≥4 (n = 208, 20.5%). For each group we compared clinical and laboratory features, treatment and adverse events. Primary endpoint was the occurrence of new-onset atrial fibrillation after a STEMI.

Results: Patients from CHA2DS2VASc ≥4 group were older (76 ± 9 vs 64 ± 11 vs 55 ± 9 years; p < 0.001). Conventional risk factors were more represented in the higher CHA2DS2VASc score groups: diabetes (51.0% vs 31.1% vs 7.4%; p < 0.001), hypertension (90.9% vs 75.7% vs 37.9%; p < 0.001) and dyslipidaemia (59.6% vs 59.9% vs 42.6%; p < 0.001); except for smoking (8.2% vs 33.2% vs 56.8%; p < 0.001). On admission patients with CHA2DS2VASc ≥4 had more often anaemia (40.1% vs 20.1% vs 12.3%; p < 0.001), renal insufficiency (eGFR < 60 ml/min) (54.6% vs 19.5% vs 3.7%; p < 0.001) and three vessels disease (21.2% vs 17.5% vs 9.1%; p = 0.005). Left systolic ventricular dysfunction was more prevalent (59.1% vs 39.8% vs 34.6%; p < 0.001) in that group. During hospital-stay, patients with CHA2DS2VASc ≥4 developed more frequently heart failure (52.4% vs 24.9% vs 16.9%; p < 0.001), new-onset atrial fibrillation (19.2% vs 11.1% vs 4.1%; p < 0.001); ischemic stroke (2.9% vs 0% vs 0.4%; p = 0.002) and respiratory tract infection (11.1% vs 3.0 vs 5.3%; p < 0.001). In-hospital (8.7% vs 2.4% vs 0.4%; p < 0.001) and 6-month overall mortality (16.7% vs 6.4% vs 2.5%; p < 0.001) were higher in patients with higher CHA2DS2VASc score. In multivariate analysis and after adjusting for different baseline characteristic CHA2DS2VASc score revealed to be an independent predictor of new-onset atrial fibrillation (p = 0.043). Patients with CHA2DS2VASc ≥4 were associated with higher risk of development of new-onset atrial fibrillation [OR 2.90, 95% CI (1.30 – 6.68), p = 0.012]

Conclusion: CHA2DS2VASc score revealed to be a strong predictor of new-onset atrial fibrillation.

P1755

Reduced LA strain predicts atrial fibrillation recurrence after catheter ablation: a systematic review and meta-analysis

G Gani Bajraktari[1]; I Bytyci[1]; MY Henein[2]
[1]University Clinical Centre of Kosova (UCC), Service of Cardiology, Pristina, Kosovo Republic of; *[2]Heart Centre and Department of Public Health and Clinical Medicine, Umea University, Umea, Sweden*

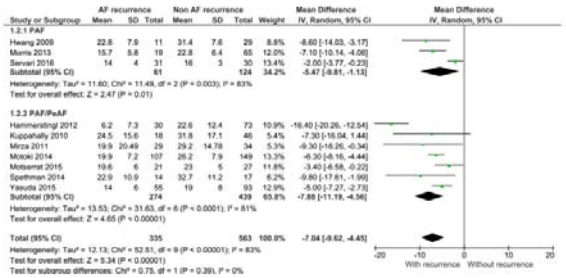
Background and Aim: Despite the improved outcome of patients with atrial fibrillation (AF) who undergo catheter ablation, recurrence of the arrhythmia remains a concern. The aim of this meta-analysis was to assess the potential association between left atrial (LA) strain and AF recurrence after ablation.

Methods: We systematically searched PubMed-Medline, EMBASE, Scopus, Google Scholar and the Cochrane Central Registry, up to December 2016 in order to identify clinical trial and observational studies, which assessed the predictive role of LA strain in AF recurrence after catheter-ablation. The search identified 898 patients form 10 studies, with paroxysmal AF (PAF) and persistent AF (PeAF).

Results: The pooled analysis showed that after a follow-up period of 11.8 ± 8.1 months, patients with AF recurrence had reduced LA strain compared with those

without AF, with a weighted mean difference (WMD) -7.04% ([95% CI -9.62 to -4.45], P < 0.0001). A subgroup analysis showed that LA strain was reduced regardless of AF type; WMD was -5.47% ([95% CI -9.82% to -1.13%], P = 0.003) in PAF and -7.88% ([95% CI -11.19% to -4.56%], P < 0.001) in PAF/PeAF, the difference between these two subgroups was not significant (Chi2=0.75, I2 = 0.0%, p = 0.39). A cut off value of 21% [6% to 30%], was 79% [65-86%] sensitive and 77% [66% to 91%] specific for predicting AF recurrence.

Conclusions: Reduced LA strain significantly predicts recurrence of AF after ablation procedure, irrespective of AF type. This emphasizes the impact of LA wall remodeling on successful ablation.



P1756

Heart failure, left ventricular dimensions and ejection fraction are predictors of thromboembolism in non valvular atrial fibrillation patients treated with direct oral anticoagulants

F Francesco Adamo[1]; N Salvi[1]; R Di Pietro[1]; E Pagliaroli[1]; S Monosilio[1]; I Cardillo[1]; G Benedetti[1]; M Mancone[1]; F Ferrante[1]; F Fedele[1]
[1]*Sapienza University of Rome, Department of Cardiov. & Respiratory Sciences, Nephrology & Geriatrics, Rome, Italy*

Background: The CHA2DS2-VASc score does not always accurately assess the thromboembolic risk in patients with Non Valvular Atrial Fibrillation (NVAF) and, thus, it would be useful to have additional parameters, particularly in patients with CHA2DS2-VASc 1 in whom the need of anticoagulants is debated. We investigated whether the presence of heart failure (HF), left ventricular end-diastolic diameter/BSA (LVEDD/BSA) and left ventricular ejection fraction (EF) both assessed by 2D TTE are predictors of thromboembolic risk in patients suffering from NVAF treated with Direct Oral Anticoagulants (DOACs).

Methods: We evaluated CHA2DS2-VASc, presence of HF clinically assessed, LVEDD/BSA, EF and 1-year incidence of ischemic stroke, TIA or systemic embolism. We used odds ratio (OR), chi-square, linear regression and logistic regression analyses.

Results: Of 273 patients treated with DOACs (129 treated with apixaban, 120 with dabigatran and 24 with rivaroxaban), mean age was 73.1 ± 10.6 years and 152 (55.7%) were males. Mean CHA2DS2-VASc was 3.7 ± 1.7; 81 patients (29.7 %) had HF. Echocardiographic parameters were: LVEDD/BSA 27.6 ± 5.6 mm, EF 48.3 ± 10.6 %. After 1 year of follow up, 6 patients (2.19 %) had a thromboembolic event. Of 6 patients, 5 had HF. A significant association between HF and thromboembolism was found (p = 0.008). The OR of HF patients to have a thromboembolic event was 13.6 (p = 0.008). Linear regression analysis showed significant correlations between CHA2DS2-VASc and both LVEDD/BSA (β = 0.648; 95% CI 0.256 to 1.040) and EF (β = - 2.008; 95% CI -2.727 to -1.289). No significant correlation was found between CHA2DS2-VASc and 1-year incidence of thromboembolism. Logistic regression showed significant associations between LVEDD/BSA, EF and 1-year incidence of ischemic stroke, TIA or systemic embolism (OR 1.15 for each unit increase of LVEDD/BSA; p = 0.001 and OR 0.902 for each unit increase in EF; p = 0.004).

Conclusions: HF and echocardiographic data such as LVEDD/BSA and EF are predictors of thromboembolic risk in patients with NVAF and can be useful parameters in risk stratification, particularly in patients with CHA2DS2-VASc 1 where there is no clear indication to anticoagulation.

P1757

Clinical determinants of B-type natriuretic peptide levels in atrial fibrillation

N Naoki Sato[1]; N Hatori[2]; H Sakai[3]; T Kunishima[4]; Y Hatori[5]
[1]*Nippon Medical School, Tokyo, Japan*; [2]*Kobayashi Hospital, Cardiology, Odawara, Japan*; [3]*Sakai Clinic, Kawasaki, Japan*; [4]*Kunishima Clinic, Kawasaki, Japan*; [5]*Hatori Clinic, Kawasaki, Japan*

On behalf of: the ASSAF-K investigators
Funding Acknowledgements: The Kawasaki Physicians Association

Background: Plasma B-type natriuretic peptide (BNP) levels are elevated not only in atrial fibrillation (AF), but in non-cardiac conditions, e.g., renal dysfunction or obesity. However, it has not been clarified what determine BNP levels in the patients with AF.

Purpose: To examine determinants of BNP levels in AF.

Methods: The ASSAF-K registry, a multicenter, prospective, observational study, was performed to clarify the clinical features of patients with AF in Japan. From this database, 1156 patients were available for the present study. The enrolled subjects were divided two group, i.e., lower and higher BNP groups by the medium level of BNP at 120.8 pg/ml. The association between BNP levels and clinical variables was analyzed using binary logistic regression models.

Results: Clinical features were compared between two groups (table). In multi-variate regression analysis, age (odd ratio (OR) 1.045, 95%CI 1.03-1.06, P < 0.001), persistent AF (OR 2.97, 95%CI 2.20-4.02, P < 0.001), histories of heart failure hospitalization (OR 2.35, 95%CI 1.77-3.13, P < 0.001) and myocardial infarction (OR 1.76, 95%CI 1.03-3.03, P=0.04), hypertrophic cardiomyopathy (OR 5.86, 95%CI 1.97-17.39, P=0.001), and beta-blocker use (OR 2.05, 95%CI 1.54-2.75, P < 0.001) were independent determinants for BNP levels.

Conclusion: Thus, the present study have demonstrated clinical determinants of BNP levels in the patients with AF, suggesting that interestingly the determinants except age are related to cardiac function.

Table

Variables	Lower BNP (N=579)	Higher BNP (N=577)	P-value
Age (yrs)	71.5±10.1	75.5±9.0	< 0.001
Pulse rate (/min)	73.2±13.9	75.7±17.1	0.011
eGFR (ml/min/1.73m2)	62.9±18.7	55.2±18.8	< 0.001
BMI (kg/m2)	23.6±3.7	23.2±3.7	0.062
Persistent AF (%)	54.7	80.2	< 0.001
Heart Failure hospitalization(%)	22.6	49.4	< 0.001
Myocardial infarction(%)	4.7	9.7	0.001
Hypertrophic cardiomyopathy(%)	0.9	5.0	< 0.001
Digitalis(%)	16.4	14.7	0.466
Beta-blocker(%)	28.3	46.3	< 0.001
Calcium channel blocker(%)	9.3	11.6	0.213

Plus minus values:mean ± standard deviation; BNP, B-type natriuretic peptide; eGRF, estimated glomerular filtration ratio; BMI, body mass index; AF, atrial fibrillation.

LA diameter more than 40 mm predicts recurrence of atrial fibrillation after trans-catheter ablation: a systematic review and meta-analysis

G Gani Bajraktari[1]; I Bytyci[1]; MY Henein[2]
[1]*University Clinical Centre of Kosova (UCC), Service of Cardiology, Pristina, Kosovo Republic of*; [2]*Heart Centre and Department of Public Health and Clinical Medicine, Umea University, Umea, Sweden*

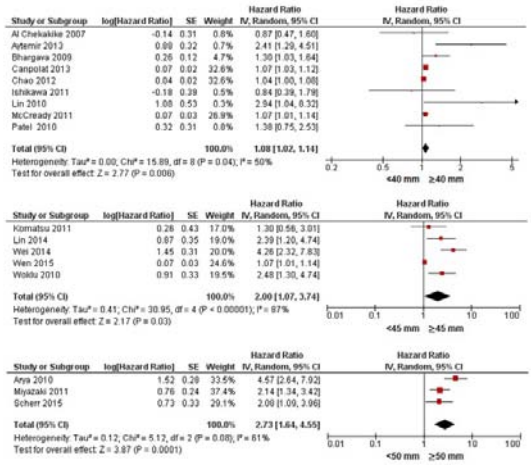
Background and Aim: Left atrial (LA) enlargement is associated with atrial fibrillation (AF) incidence and outcome. Trans-catheter ablation of AF has now become a conventional treatment of AF but its recurrence remains of clinical significance. The predictive role of the LA size in AF treatment is still controversial, hence the aim of this meta-analysis was to analyze the potential association between LA diameter and AF recurrence after ablation.

Methods: We systematically searched PubMed-Medline, EMBASE, Scopus, Google Scholar and the Cochrane Central Registry, up to December 2016 in order to select clinical trial and observational studies, which assessed the predictive role of LA diameter in AF recurrence after catheter-ablation. 13.573 patients from 61 studies with paroxysmal AF (PAF), persistent (PeAF) or longstanding persistent AF (L-PeAF) were included.

Results: The pooled analysis showed that after a follow-up period of 19 ± 7.74 months, patients with AF recurrence had larger LA size compared with those without AF recurrence, with a weighted mean difference (WMD) 0.49 ([95% CI 0.39 to 0.59], P < 0.001), irrespective of the type of AF. A subgroup analysis showed LA diameter to be different; WMD was 2.29 ([95% CI 1.31 to 3.26], P < 0.001) in PAF and 1.51 ([95% CI 1.10 to 1.93], P < 0.001) in PeAF/L-PeAF, the difference between these two subgroups was not significant (Chi2=2.04, I2 = 51.1%, p = 0.15).

LA diameter ≥40 mm predicted AF recurrence HR:1.08 [95% CI 1.03 to 1.14], P=0.006), but the best cut-off value, in all included patients, was ≥50mm HR:2.73 [95% CI 1.64 to 4.55], P < 0.001).

Conclusions: Increased LA diameter significantly predicts recurrence of AF after ablation procedure. While a diameter of 40 mm predicts recurrence, a diameter more than 50 mm is the most accurate predictor.



CARDIOMYOPATHY

P1759

Galectin-3 level and its relationship with clinical status and instrumental parameters in patients with hypertrophic cardiomyopathy

AE Demkina[1]; NS Krylova[1]; NG Poteshkina[1]; EA Kovalevskaya[2]; FM Hashieva[2]
[1]The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation; *[2]City Hospital 52, Moscow, Russian Federation*

Galectin-3 (Gal-3) is a novel marker of cardiac fibrosis and inflammation. The clinical significance of Gal-3 levels is now widely studied. Gal-3 levels in patients with hypertrophic cardiomyopathy (HCM) have been deficiently studied.

Purpose: To assess Gal-3 levels and its relationship with clinical status and instrumental parameters in patients with HCM.

Materials and methods: 30 patients with HCM were examined, (16 men (53.3%), average age 57.0 ± 13.2 years). All patients were treated with bisoprolol (5.5 ± 1.8 mg). In 10 patients (33.3%) obstructive form of the disease was identified. All patients underwent clinical examination, echocardiography with tissue doppler imaging (TDI) and Gal-3 levels evaluation.

Results: Gal-3 level was > 2.28 pg/ml in 17 HCM patients, average mean 4.5 (1.4, 6.9) pg/mL. There was a significant positive correlation between Gal-3 level and following parameters: age (r=0.36, p = 0.05), functional class of chronic heart failure (CHF) by NYHA (r=0.47, p=0.01). There was a negative correlation between Gal-3 level and blood pressure: the history of arterial hypertension (r=0.48, p = 0.01), the maximum values of systolic blood pressure (BP) (r=0.44, p = 0.01) and diastolic BP (r=0.36, p = 0.05) according anamnesis, the level of sistolic BP (r=0.42, p = 0.02) at the office measurement. There was a negative correlation with basal lateral right ventricle (RV) wall s' (r=-0.50, p = 0.05) and medium lateral RV wall s' (r=-0.63, p = 0.009) according to TDI data.

Conclusions: Gal-3 levels was elevated in 56.7% HCM patients. The level of Gal-3 in patients with HCM was assosiated with age, functional class of CHF by NYHA, blood pressure and duration of hypertension anamnesis and RV longitudinal systolic function due to TDI.

P1760

Left atrium characterization in hypertrophic cardiomyopathy: three-dimensional wall-motion tracking technology as a valuable technique

L Marques[1]; N Moreno[1]; H Guedes[1]; R Santos[1]; A Pereira[1]; D Seabra[1]; R Sousa[1]; P Pinto[1]
[1]Centro Hospitalar do Tâmega e Sousa, EPE, Cardiology Department, Penafiel, Portugal

Background: Left atrium (LA) involvement is well established in hypertrophic cardiomyopathy (HCM), with higher volume values and lower deformation parameters being reported. These morphological and functional changes may be the result of secondary pressure overload (due to ventricular diastolic dysfunction, outflow tract obstruction or mitral insufficiency) and/or the result of primary atrial myocardial involvement (pathologically characterized by interstitial fibrosis).

Purpose: Using three-dimensional (3D) wall-motion tracking (3DWMT) echocardiographic technique, we aimed to characterize and compare LA volumes, mass and strain parameters in HCM patients (pts) with healthy controls.

Methods: Thirty-five (35) HCM pts and 27 healthy controls underwent standard bi-dimensional (2D) echocardiography, followed by 3DWMT evaluation. Using Toshiba Artida echocardiography equipment (Toshiba Medical System), global strain values were obtained [global longitudinal strain (GLS), global radial strain (GRS), area tracking (AT)], as well as LA indexed estimated mass, LA indexed end-diastolic volume (EDV), LA indexed end-systolic volume (ESV), LA emptying fraction (LAEF).

Results: We found no age (61.5 ± 10.3 vs 57.5 ± 7.2 years, p = 0.097), gender (p = 0.384) or left ventricular ejection fraction (63 ± 9 vs 65 ± 13%, p = 0.437) differences among HCM and control groups. Regarding volumetric analysis, the HCM group exhibited significant increases in EDV (46.7 ± 14.2 vs 28.0 ± 7.6 ml/m2, p < 0.001) and ESV (32.2 ± 12.0 vs 15.5 ± 5.3 ml/ m2, p < 0.001). In HCM group, LAEF was significantly reduced (31.7 ± 11.4 vs 44.1 ± 12.0%, p < 0.001) and LA estimated mass was significantly higher (17.5 ± 14.5 vs 8.6 ± 1.5 g/ m2, p < 0.001). Regarding strain parameters, we found a significant decrease in GLS of HCM pts (14.0 ± 6.7 vs 24.9 ± 6.3%, p < 0.001).

Conclusion(s): The evaluation of LA by 3DWMT in HCM pts provides detailed information about its volume, mass, function and global deformation parameters. In the analysed cohort, pts with HCM have increased volumes and masses, with a decrease in GLS.

P1761

Comparison between LGE-CMR and histomorphometric quantification of myocardial fibrosis in transplanted hearts for end-stage HCM

G Galati[1]; F Pasquale[2]; O Leone[3]; I Olivotto[4]; F Grigioni[2]; E Pilato[5]; E Biagini[2]; F Cecchi[4]; C Rapezzi[2]
[1]Unit of Cardiology, Cardiovascular Department, IRCCS Policlinico San Donato University Hospital, San Donato Milanese, Milan, Italy; *[2]Institute of Cardiology, Department of Experimental, Diagnostic and Specialty Medicine, S.Orsola-Malpighi University Hospital, Bologna, Italy*; *[3]Division of Pathology, Department of Experimental, Diagnostic and Specialty Medicine, S.Orsola-Malpighi University Hospital, Bologna, Italy*; *[4]Referral Center for Cardiomyopathies, Careggi University Hospital, Florence, Italy*; *[5]Cardiac Surgery, Department of Experimental, Diagnostic and Specialty Medicine, S.Orsola-Malpighi University Hospital, Bologna, Italy*

Background: End-Stage (ES) HCM is one of the main causes of heart failure and represents almost the only indication for heart transplantation in HCM patients. Myocardial fibrosis (MF) and microvascular ischemia are determinant for ES evolution. Recently, our group provided the most accurate histological characterization of extent, distribution, patterns and types of MF in the largest series available in the literature of transplanted ES-HCM patients (n = 30).

Purpose: We conducted a substudy in our cohort with the aim to compare LGE-CMR with histomorphometric quantification of MF in ES-HCM hearts.

Methods: For each heart, a whole midventricular short-axis section (subdivided into 10 samples), 3 samples from basal and 3 from apical level were considered. Histomorphometric MF quantification was performed using a dedicated software and hardware. A 6 SDs threshold exceeding the mean was used to identify LGE areas, which were outlined automatically and artifacts were manually corrected. The total volume was quantified using specific software and expressed as a percentage of LV mass.

Results: In Table 1 are shown the results for the fibrosis detected in the whole heart (overall fibrosis) comparing the two methods.

Conclusion: We documented a good overlap between LGE-CMR and histological quantification of MF in a group of 4 ES-HCM hearts, in particular when a signal intensity of 6 SDs above reference myocardium was used. However, LGE underestimated fibrosis extent in the patient who had mainly interstitial-perimyocyte MF, showing that this method is unable to detect this fibrosis type. Thus, we confirmed that LGE is able to identify only dense scars but cannot capture more diffuse expansion of the extracellular space, such as that is caused by interstitial fibrosis. Any extent of fibrosis >20% of the whole LV should be regarded as high-risk for ES evolution. To sum up, our study highlighted the necessity to use a comprehensive CMR assessment of MF, using both LGE and the new T1-mapping methods, with the purpose to detect both replacement and interstitial-perimyocyte fibrosis and correctly quantify MF in HCM patients.

T1: LGE vs histological MF quantification

	Overall Fibrosis CMR-LGE 6DS Quantification	Overall Fibrosis Histometric Quantification	Difference LGE-Histology	Replacement Fibrosis	Interstitial-Perimyocyte Fibrosis
Patient 1	48%	48.1%	0.1%

Predictors of adverse outcomes and progression of heart failure in patients with hypertrophic cardiomyopathy

EK Kurlianskaya[1]; SM Komissarova[1]; EY Zakharava[1]; TV Ilyina[1]; TV Sevruk[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Background.The identification of clinical variants and outcomes in individuals with hypertrophic cardiomyopathy (HCM) with the signs of progressive chronic heart failure (HF) remains a challenge and has not been fully understood. A number of factors have been proposed to identificate subjects with HCM and high risk of CHF progression to a severe stage.
Purpose: The aim of our study is to assess survival rates, outcomes and the influence of factors associated with progressive HF in patients with HCM. Materials and methods. Clinical data of 345 HCM subjects (199 males and 146 females, median age 47 y.o., range 17 - 72 y.o,) treated in RRPC "Cardiology" in the period between 2006 and 2016 have been studied.
Results: Twelve (3,5%) patients with HCM (mean-age 46 ± 12 y.o., 58,3% males) showed signs of Class III-IV NYHA HF accompanied by severe LV myocardial dysfunction. During the follow-up period (median follow-up period 6.7 years), 8 of 12 (67%) patients with Class III-IV NYHA HF showed adverse outcomes: SCD occurred in 1 patient, fatal outcome due to progressive HF occurred in 6 patients , and 1 patient had a fatal stroke. Median uneventful survival was 4.3 years. During the follow-up, 21 (6.1%) patients had progression of HF symptoms from Class II to Class III NYHA. Based on data obtained from a multifactorial analysis, predictors of CHF symptom progression from Class II to Class III NYHA were: LV EF $<56\%$ (OR 4.8; 95% CI 1.6 - 14.5; <0.001), LA size > 47 mm (OR 9.0; 95% CI 3.0-27.6; <0.005), and pseudonormal diastolic dysfunction (OR 9.6; 95% CI 2.8 - 33.4; <0.001). Percentage area of fibrosis with regard to a total myocardial volume based on cardiac MRI was significantly higher in patients with CHF progression (35,8%) than in patients without CHF progression (5,6 %, $p<0.001$). Percentage area of fibrosis with regard to a total myocardial volume based on cardiac MRI allows for an identification of patients with the risk of adverse remodeling with the threshold level > 25%.
Conclusion: Based on the abovementioned data, the discovered predictors allow to identificate patients with adverse remodeling development and risk of end-stage of the disease progression.

P1763

Chronic heart failure in patients with non-obstructive hypertrophic cardiomyopathy: the effect of the angiotensin-converting enzyme inhibitors/angiotensin receptor blockers

AE Demkina[1]; NS Krylova[1]; NG Poteshkina[1]; EA Kovalevskaya[2]; FM Hashieva[1]
[1]*The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation*; [2]*City Hospital 52, Moscow, Russian Federation*

Angiotensin-converting enzyme inhibitors (ACEI) /angiotensin receptor blockers (ARB) is the first-line therapy (IA) in patients with chronic heart failure (CHF). The possibility of their administration in HF with preserved ejection fraction (HFpEF) in patients with nonobstructive hypertrophic cardiomyopathy (HCM) remains debated (IIaC).
Purpose: To asses the effectiveness and safety of ACEI/ARB in HCM patients with HFpEF.
Materials and methods: We examined 40 patients with nonobstructive HCM and CHF II-III NYHA treated with bisoprolol. Patients were randomized into 2 groups: group I - 20 patients, in which perindopril (3.7 ± 1.4 mg, n=14) or losartan (in case of cough 40.0 ± 13.7 mg, n=6) were added to bisoprolol (5.6 ± 1.5 mg) treatment; group II - 20 patients (control group), who continued to receive bisoprolol (5.0 ± 2.0 mg). All patients underwent clinical examination, echocardiography with tissue doppler imaging (TDI) and evaluation of the BNP level before and after 6 months of ACEI/ARB administration.
Results: There were no significant differences in sex, age, clinical – instrumental data and dose of bisoprolol between groups ($p>0.05$). After 6 months of ACEI/ARB therapy in group I there were significantly reduction of BNP level (from 322 ± 18.3 to 154 ± 10.1 pg/ml, p=0.01), thickness of interventricular septum (from 20 ± 1.0 mm to 18 ± 4.0 mm; p=0.001), LV posterior wall (p=0.0001), index of LV mass (from 145.1 ± 15.3 g to 125.1 ± 9.3 g; p=0.04) and right ventricle (RV) wall (p=0.009), decrease of isovolumic relaxation time (IVRT) of transmitral flow ($p=0,0001$), RV (p=0.03) and LV (p=0,007) Tei index. According to the TDI data there was an increase of lateral systolic s' of mitral annulus (MA) ($p=0.01$), a decrease of ivrt' in septal ($p=0.01$), lateral ($p=0.01$), anterior ($p=0.02$) part of the MA. After 6 months of therapy in group II structural and functional parameters didn't change. During the course of ACEI/ARB therapy no adverse event were recorded.
Conclusions: Adding ACEI/ARA to beta-blockers therapy for 6 months in patients with nonobstructive HCM was safely, accompanied by reduction of the myocardial hypertrophy degree with an improvement of diastolic and systolic function of LV and RV and BNP level decrease.

P1764

Early prognostic factors of left ventricular ejection fraction deterioration in Friedreich ataxia

L Legrand[1]; A Diallo[2]; ML Monin[3]; R Isnard[1]; A Durr[3]; F Pousset[1]
[1]*Hospital Pitie-Salpetriere, Assistance Publique-Hôpitaux de Paris, Institut de cardiologie, Paris, France*; [2]*Hospital Lariboisière, Saint Louis, Assistance Publique-Hôpitaux de Paris,, Clinical Research Unit, Paris, France*; [3]*Hospital Pitie-Salpetriere, Assistance Publique -Hôpitaux de Paris, Fédération de Génétique, Paris, France*

Rational: Friedreich ataxia (FRDA) is a progressive neurodegenerative disease associated with scoliosis, diabetes and hypertrophic cardiomyopathy. Progressive decline of Left Ventricular Ejection Fraction (LVEF) is of worse prognosis. There is a need to find early predictors of LVEF deterioration defined as LVEF≤50%.
Methods: 115 FRDA patients with at least two cardiac evaluations were followed during 13 ± 6 years. At baseline and last visit before deterioration, all patients had an initial LVEF > 50%.
Results: 115 patients were included, they were 30 ± 10y (mean ± sd), with a mean neurological onset: 15 ± 8y, age at wheelchair use: 27 ± 11y and a shorter GAA repeat: 620 ± 238 bases pair. Echocardiographic parameters were: LVEF: 68 ± 7%, LV mass index: 102 ± 31 g/m^2, LV diastolic diameter (LVDD): 43 ± 5mm, septal interventricular wall thickness (SIW): 12 ± 3mm. During a follow-up of 13 ± 6 years, 16 patients died and 12 had LVEF deterioration (LVEF < 50%). In multivariate analysis, determinants of LVEF deterioration at baseline were shorter GAA repeat ($p=0.001$) and at last visit: shorter GAA repeat ($p=0, 0001$), SIW ($p=0,005$) and LVEDD ($p=0, 01$). By multivariate logistic regression modelling, optimal time of good prediction is 4 years before LVEF deterioration with a good accuracy: ROC curve with AUC=0, 91, IC95% [0, 85; 0, 97]. Specific cut off points for shorter GAA, SIW or LEDD were respectively 500 pb, 13.3mm and 52,6mm.
Conclusion: Prediction of LVEF deterioration by echocardiography may help physician to manage these young patients, and to initiate early heart failure treatments with improvement of LV remodelling.

[1]Faculty of Medicine University of Porto, Porto, Portugal; *[2]H. São João, Porto, Portugal*; *[3]Guimares Hospital, Guimaraes, Portugal*; *[4]Garcia de Orta Hospital, Lisbon, Portugal*; *[5]Regional Military Hospital n°1, Porto, Porto, Portugal*

On behalf of: FATIMA investigators
Funding Acknowledgements: PTDC/BIM-MEC/0650/2012

Introduction: Right ventricular (RV) dysfunction has been shown to be an important predictor of worse prognosis in idiopathic dilated cardiomyopathy (DCM).
Purpose: In this work we aimed to evaluate sex-related differences in RV function and volumes, assessed with cardiac magnetic resonance imaging (CMR), in patients with genetic DCM.
Methods: We included 80 consecutive patients diagnosed with idiopathic and familial DCM that underwent a comprehensive CMR with a 3-T scanner, as part of their diagnostic work-up. Ventricular volumes, ejection fraction and mass were measured using dedicated software and were classified as normal or abnormal based on sex and age.
Results: Male and female patients exhibited similar age at diagnosis (36 ± 13 vs 40 ± 14 years, $p = 0.142$), identical proportion of familial cases (55% vs 55%, $p = 0.964$) and positive molecular results (22% vs 26%, $p = 0.730$).
Men and women presented similar mean cardiac index (2.95 ± 0.61vs 2.74 ± 0.83 L/min/m2, $p = 0.0.265$), ventricular mass (78 ± 19 vs 75 ± 24 g/m2, $p = 0.580$), left ventricular (LV) ejection fraction (EF) ($35 \pm 11\%$ vs $32 \pm 11\%$, $p = 0.263$), LV end-diastolic volume (EDV) (126 ± 36 vs 128 ± 38 mL/m2, $p = 0.875$) and LV end-systolic volume (ESV) (83 ± 36 vs 86 ± 38 mL/m2, $p = 0.674$). On the contrary, women presented higher RVEF and lower RVEDV and RVESV ($56 \pm 11\%$ vs $48 \pm 11\%$, $p = 0.008$; 69 ± 21 vs 85 ± 22 mL/m2, $p = 0.006$; 32 ± 20 vs 45 ± 21 mL/m2, $p = 0.012$). The differences in RVEF are particularly significant in the 2nd tercile of LVEF ($29\% \geq$LVEF $< 40\%$) and the differences in volumes, in the 2nd and 3rd tercile of LVEF (Graph: mean right ventricular ejection fraction, mean right ventricular end-diastolic volume and mean right ventricular end-systolic volume according to gender and LVEF terciles).
Conclusions: In patients with DCM, RV functional parameters assessed by CMR are significantly different between genders, particularly in those with LVEF > 29%. These differences might explain the diverse clinical presentations between men and women across the spectrum of LV systolic dysfunction.

Prognostic significance of the evolution of non-invasive hemodynamic profile in patients with dilated cardiomyopathy receiving optimal medical treatment

M Merlo[1]; D Stolfo[1]; M Gobbo[1]; G Gabassi[1]; G Barbati[1]; P Naso[1]; G Secoli[1]; F Ramani[1];
B Pinamonti[1]; M Gigli[1]; G Sinagra[1]
[1]University Hospital Riuniti, Cardiovascular department, Trieste, Italy

Funding Acknowledgements: We deny any relation with the industry and any source of finantial support

Background: Despite the survival improvement of dilated cardiomyopathy (DCM) during the last decades, the prognosis of these patients remains often unpredictable, mostly in the short term after diagnosis.
Aims: To define baseline and short-term "non-invasive hemodynamic" profiles and to assess their possible additive prognostic impacts to clinical and morphological parameters in a large cohort of DCMs.
Methods: We analyzed 385 patients with recently diagnosed DCM (median duration of symptoms: 1 month) from 2005 to May 2015. Baseline and 6-month "non-invasive hemodynamic" profiles were built evaluating the following parameters: significant mitral regurgitation; right ventricular dysfunction; left atrial enlargement (i.e. end-systolic area >13 cm/m2); left ventricular restrictive filling pattern; systolic pulmonary arterial hypertension (i.e. pressure >35 mmHg); E/E' >15. The prognostic values of these models were tested in addition to the clinical and morphological evaluation of patients. The outcome measure of the study was a composite of death or urgent heart transplant
Results: Compared to survivors, patients experiencing death/heart transplant presented a baseline more impaired hemodynamic profile. A rapid significant improvement of all "non-invasive hemodynamic" parameters from baseline to 6-month revaluation was observed. Both baseline and 6-month "non-invasive hemodynamic" models included E/E'>15 and left atrial enlargement as the only independent predictors. Both the baseline and the short-term "non-invasive hemodynamic" models showed an incremental reclassification accuracy vs. the models including only clinical and morphological parameters, mostly in predicting short-term events (event horizon 24 months: baseline models AUC 0.75 vs. 0.41 respectively; $p = 0.002$; 6-month models: AUC 0.90 vs. 0.72 respectively; $p = 0.032$).
Conclusions: E/E' >15 and left atrial enlargement at baseline and their short-term evolution under therapy emerged as the strongest "non-invasive hemodynamic" parameters, significantly improving the prognostic stratification of DCM patients, mostly in the short term.

P1767

Value of electrocardiogram in predicting adverse events in patients with genetic dilated cardiomyopathy

Background: The natural history of patients with dilated cardiomyopathy (DCM) is variable and clinical parameters are poor predictors of clinical outcome.
Purpose: We aimed to determine the prognostic value of electrocardiogram (ECG) in the occurrence of adverse outcomes in patients with idiopathic or familial DCM.
Methods: Multicentric study of consecutive patients with familial DCM ($\geq$ 1 family member with DCM or a first-degree relative with unexplained sudden death $<$35 year) and patients under 50 years with idiopathic DCM, followed at referral centres. Patients underwent extensive clinical evaluation, ECG, 24h-Holter, echocardiogram and cardiac MRI evaluation, when feasible, and molecular analysis. Only patients with follow-up data were included. Assessment of vital status, heart transplantation (HT) and cardiac-related hospitalizations were registered.

Results: We included 99 patients, 59 (60%) male, mean age at diagnosis 38 ± 13 years, mean left ventricle (LV) ejection fraction 34 ± 12% and LV end-diastolic diameter 63 ± 8 mm. Forty-five (46%) patients presented criteria of fDCM (corresponding to 37 families) and 46 (51%) were in NYHA class I. After a median follow-up of 28 (IQR 18) months, 14 (14%) patients experienced adverse events (composite of death, HT and hospitalization from cardiac causes).
Kaplan-Meyer survival analysis showed that sinus rhythm ($p < 0.001$), atrial fibrillation ($p = 0.041$), first-degree atrioventricular block (AVB) ($p < 0.001$) and non-sustained ventricular tachycardia (NSVT) ($p = 0.003$) significantly influenced survival without adverse events (Figure 1-4). Multivariate logistic revealed NSVT as an independent predictor of worse outcome (OR 16.3; 95%CI 1.7-158.3, $p = 0.016$).
Conclusions: In our cohort of DCM patients, 14% experienced an adverse event. Simple ECG data, namely atrial fibrillation, first-degree AVB and NSVT, may help to identify patients at higher risk of worse outcome, whom might beneficiate from a more aggressive clinical vigilance and timely interventions.

Funding Acknowledgements: British Heart Foundation Clinical Research Training Fellowship

Introduction: Cardiopulmonary exercise testing (CPET) is commonly used in the follow-up of patients with dilated cardiomyopathy (DCM). CPET variables have been correlated with poor clinical outcomes, however, little is known about their incremental value in addition to other prognostic markers such as brain natriuretic peptide (BNP), left ventricular ejection fraction (LVEF) and New York Heart Association (NYHA)symptom class.
Purpose: To investigate the incremental value of CPET in addition to other conventional prognostic markers such as LVEF, BNP and NYHA class.
Methods: We recruited patients with a history of DCM referred for CPET between 2007 and April 2016. CPET was performed using maximal treadmill ergometry. Clinical data contemporary to the CPET were used. The primary end-point was a composite of cardiovascular (CV) death, unplanned CV hospitalisation and cardiac transplantation. The association between the end-point and CPET and clinical variables was examined using proportional hazard modelling.
Results: 126 patients (mean age: 43 years, mean LVEF: 45%, 76 male) were followed up for a median of 2.3 years. 15.9% met the primary end-point. Several CPET and clinical variables were associated with the composite end-point on univariable analysis (table 1). After adjusting for significant non-CPET variables, including BNP, LVEF and NYHA symptom status, exercise time (per minute – HR 0.79; 95% CI 0.67-0.93; $p = 0.005$), minute ventilation - carbon dioxide production relationship (VE/VCO2; per unit – HR 1.1; 95% CI 1.0-1.2; $p = 0.04$), peak oxygen consumption (peak VO2; per ml/kg/min – HR: 0.93; 95% CI 0.87-0.99; $p = 0.03$) and anaerobic threshold (per ml/kg/min – HR 0.89; 95% CI 0.79-0.99; $p = 0.04$) remained predictors of the composite end-point.
Conclusion: Total exercise time, VE/VCO2 slope, peak VO2 and anerobic threshold, as measured by CPET provide incremental prognostic information in addition to BNP, LVEF and symptom status in patients with DCM.

	Total	CV Death or Hospitalisation		Univariable Analysis

Surgical treatment of dilated cardiomyopathy: the reverse remodelling operation and 5-years of follow up

S Sergey Dzemeshkevich[1]; A Dzemeshkevich[1]; YU Frolova[1]; M Malikova[1]; T Voronina[1]
[1]Russian Research Center of Surgery, Dpt of Surgical Treatment of Myocardial Dysfunction, Moscow, Russian Federation

Funding Acknowledgements: This work was partially supported by the Russian Research Foundation, project No 16-15-10421

Background: The shortage of the donor hearts for transplantation leads to the search for new solutions for the surgical treatment of patients with dilated cardiomyopathy and severe heart failure. One of the possible methods could be a reconstructive surgery – the reverse remodelling of the heart.
Purpose: This study aims to review the outcome and 5-years follow up of a surgical reverse remodelling of the heart in cohort of DCM patients.
Patients and methods: We have performed reverse cardiac remodelling in patients with dilated cardiomyopathy. The total number of patients operated with this technique was 24 (19 male and 5 female) patients aged 20–75 (average age – 50,7 ± 2,5).
Results: and discussion. All patients have had a heart failure of the high grade (III FC NYHA – 3, IV FC NYHA – 21 patients). Prior the surgery cardiomegaly was diagnosed by echocardiography in all patients: LVEDP was 7,4 ± 0,9 cm, LVEDV was 277 ± 98 ml, left atrial dimension was 7,2 ± 1,3 cm, LVEF was 29 ± 10%, and PASP was 45 ± 15 mm Hg.
We had no intraoperative mortality. Two patients had died in the early postoperative period after the reverse remodelling. 22 patients were discharged from the hospital. Significant normalization of intracardiac hemodynamics was observed in all 22 patients. Upon hospital discharge all patients had lower heart failure class (I–II FC NYHA) and improvement in the physical exercise tolerance. The comparative analysis of transthoracic echocardiography indicators had revealed the reduction of the heart chambers size and volume, significant decrease of the pulmonary artery systolic pressure, the left ventricular ejection fraction had increased as compared the baseline. In the late period (the follow-up period was 5 years) 5 patients died due to heart failure progression, and 3 patients died suddenly due to fatal cardiac arrhythmias.
Conclusion: The reverse remodelling of the heart could be considered as a promising organ preserving surgical technique for a certain group of DCM patients, allowing us in some cases to postpone or to avoid a heart transplantation.

Introduction: Patients with dilated cardiomyopathy (DCM) may present diverse electrocardiogram (ECG) anomalies.
Purpose: We aimed to correlate baseline ECG with left ventricular (LV) and right ventricular (RV) anatomy and function assessed by echocardiogram and cardiac magnetic resonance (CMR).
Methods: Multicentric national study of consecutive patients with idiopathic or familial DCM. Patients underwent extensive clinical evaluation, ECG, Holter, echocardiogram, CMR (in the absence of contra-indications) and molecular study.
Results: We included 111 patients, 48% with familial DCM, 60% males, mean age 47 ± 11 years, with mean age at diagnosis of 39 ± 13 years. Echocardiographic mean LV ejection fraction (LVEF) was 34 ± 11% and LV end-diastolic (LVED) diameter 62 ± 8 mm, CMR mean LVEF was 35 ± 11% and LVED volume 123 ± 30 mL/m2, and 84% presented at least one ECG anomaly.
Patients in atrial fibrillation (10%) presented a higher proportion of RV dysfunction in echocardiogram (46% vs 15%, p = 0.029) and in CMR (100% vs 36%, p = 0.004) and a higher proportion of enlarged RV end-systolic volume (67% vs 24%, p = 0.045). Additionally, patients in sinus rhythm presented higher LVEF in echocardiogram (35 ± 11% vs 30 ± 9%, p = 0.009).
When considering conduction anomalies, 34% and 4% of patients presented left (LBBB) and right bundle branch block (RBBB), respectively, and 28% first-degree atrioventricular block (AVB).
Patients with LBBB presented higher ventricular mass (84 ± 21 vs 72 ± 21 g/m2, p = 0.035) and larger LV volumes (end-diastolic 134 ± 31 vs 117 ± 29 mL/m2, p = 0.025; end-systolic 90 ± 34 vs 74 ± 26 mL/m2, p = 0.036). Curiously, LBBB was associated with better functional RV parameters (RVEF 57 ± 9% vs 50 ± 12%, p = 0.026; RV end-systolic volume 31 ± 10 vs 41 ± 24 mL/m2, p = 0.021).
On the contrary, patients with RBBB presented worse RVEF (42 ± 13% vs 53 ± 11%, p = 0.045) and larger VD (end-diastolic volume 111 ± 34 vs 74 ± 20 mL/m2, p = 0.001). Also, all these patients presented late-gadolinium enhancement (100% vs 34%, p = 0.017).
QRS duration presented a moderate positive correlation with left atrial diameter (r=0.407, p < 0.001).
The presence of first-degree AVB was associated with larger left atrial diameter (47 ± 7 vs 42 ± 8 mm, p = 0.011), worse LVEF (28 ± 11% vs 37 ± 11%, p < 0.001) and a higher proportion of RV dysfunction in echo (43% vs 9%, p < 0.001).
Left atrial anomaly or LV hypertrophy were not associated with any functional LV or RV parameters.
Conclusion: ECG anomalies are frequent in DCM patients. Simple data derived from serial ECG, namely atrial fibrillation, intraventricular conduction delay and first-degree AVB, may be of value in anticipating chamber dimensions and ventricular function evolution, known predictors of outcomes.

The predictors of the response to cardiac resynchronization therapy in patients with dilated cardiomyopathy

P Manca[1]; S Cossa[2]; GF Tola[1]; A Scalone[1]; B Schintu[1]; A Setzu[1]; S Mameli[1]; N Sanna[1]; A Giardina[1]; L Minerba[3]; G Matta[2]; M Maurizio Porcu[1]
[1]G. Brotzu Hospital, Department of Cardiology, Cagliari, Italy; *[2]G. Brotzu Hospital , Department of Imaging, Cagliari, Italy*; *[3]University of Cagliari, Dipartimento di Sanita' Pubblica, Monserrato, Italy*

Background: Cardiac resynchronization therapy (CRT) reduces mortality and morbidity in patients affected by dilated cardiomyopathy (DCM) and left bundle branch block (LBBB). However, approximately 1/3 of the implanted patients do not show any benefit from this treatment. Aim of the study. To evaluate the clinical, electrical, echocardiographic and cardiac magnetic resonance (CMR) predictors of the response to CRT in patients with DCM.
Methods: We retrospectively analyzed thirty-nine heart failure symptomatic patients (21 M, 18 F, mean age 58 ± 11 yrs, NYHA class II-IV), with a diagnosis of DCM, LBBB and QRS >120ms, who had a complete cardiovascular evaluation including clinical examination, blood parameters, ECG, echocardiography and CMR. All patients underwent coronary angiography to exclude significant (>50%) stenosis. Four patients were in atrial fibrillation (AF) with an adequate rate control and two of them had a biventricular pacing < 90%. All patients were treated with optimal medical therapy for at least 3 months (βb 85%, ACE-I/ATII-A 90%, furosemide 92%, AA 67%). Based on the response to CRT, patients were divided into two groups: Responders = improvement ≥ 1 NYHA functional class and/or improvement >15% in the ejection fraction; Non-Responders = no improvement or even worsening of NYHA functional class and improvement < 15% in the ejection fraction.
Results: At a mean follow up of 38 ± 16 months twenty-four patients (62%) were considered responders, while fifteen (38%) did not show any benefit. At CMR, LV fibrosis was present in only 1/4 of patients, involving < 3% of myocardial mass of the whole population. The predictors of non-response were older age (64 vs 56 years; p = 0,036), higher creatinine level (1,36 vs 0,99 mg/dl; p = 0,036) and a more enlarged left atrium (30 vs 24 cm2; p = 0,012). The four AF patients were all Non-Responders (p = 0,008). No other factors, such as baseline QRS duration and post CRT shortening or LV ejection fraction, showed a prognostic value.
Conclusions: These data confirm that more than 30% of DCM patients do not have any substantial benefit from CRT, independently from the presence of ventricular fibrosis. In our experience, older age, renal impairment, atrial dilatation and AF represent negative prognostic factors.

P1772

Takotsubo cardiomyopathy in diabetic patients - Are there differences?

PM Pedro Azevedo[1]; B Faria[2]; B Marmelo[3]; C Ruivo[4]; R Santos[5]; A Gomes[6]; M Vieira[7]; A Marreiros[1]; L Teles[8]; A Almeida[6]
[1]Faro Hospital, Cardiology, Faro, Portugal; *[2]Hospital Guimaraes, Cardiology, Guimaraes, Portugal*; *[3]Hospital Sao Teotonio, Cardiology, Viseu, Portugal*; *[4]Hospital Santo Andre, Cardiology, Leiria, Portugal*; *[5]Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*; *[6]Hospital Garcia de Orta, Cardiology, Almada, Portugal*; *[7]Hospital of Santarem, Cardiology, Santarem, Portugal*; *[8]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*

On behalf of: SUNSHINE

Introduction: Takotsubo cardiomyopathy (TC) is an acute and reversible cardiomyopathy that predominantly affects female patients after a precipitating event, namely physical or emotional stress. The catecholamine-driven coronary spasm and myocardial injury have been considered as possible pathophysiologic mechanisms. Some authors state that TC is less prevalent and severe in diabetic patients due to inherent autonomic neuropathy. This study aims to characterize a population with TC and diabetes mellitus (DM) and evaluate the impact of DM in the prognosis of these patients.
Methods: Portuguese multicenter, prospective, descriptive and correlational study, involving 12 hospitals in which all patients with TC since 2004 were included and divided in two groups: diabetic and non-diabetic patients. The baseline demographic characteristics, clinical data, echocardiographic and electrocardiographic parameters, as well as mortality on follow-up were evaluated. We performed univariate and multivariate statistical analysis through SPSS.
Results: 234 patients with TC were included, of which 44 (11,8%) had DM. 90,9% of diabetic patients were female and had a mean age of 73,5 ± 10,2, similarly with non-diabetic patients. Diabetic patients had more frequently hypertension (84,1% vs 64,2%, p = 0,01) and dyslipidemia (70,5% vs 50,5%, p = 0,017) and were less frequently smokers (2,3% vs 16,8%, p = 0,012), On admission, patients with DM were more likely to present with dyspnea (34,1%vs18,9%, p = 0,03) and less likely to have a precipitating factor (43,2% vs 63,2%, p = 0,015). There was a tendency to less episodes of ventricular tachycardia on admission (27,3% vs 43,2%, p = 0.05). There weren't any differences between the groups regarding the type of Takotsubo, the presence of acute heart failure or left ventricular ejection fraction on admission (LVEF).
Diabetic patients had more frequently a LVEF ≤ 40% on discharge (17,5%vs5,9%, p < 0.02) and LVEF ≤ 50% on the first follow-up echocardiogram (12,9%vs1,5%, p < 0,01)
During a mean follow-up time of 33,15 months, there were no significant differences regarding outcomes, namely in-hospital mortality (4,5% in diabetic patients vs 1,6% in non-diabetic, p = 0,23), Takotsubo recurrence (4,5% vs 4,2%, p = 0,9) and mortality on follow-up (9,1% vs 5,8%, p = 0,42).
Conclusion: In this study, the prevalence of DM in patients with TC is relatively low (11,8%), compared with the Portuguese prevalence data for DM (27% in the population over 60 years), suggesting either underdiagnosis due to the more atypical presentation, or a possible protective effect for the development of TC in diabetic patients. There were no differences in outcomes between the two groups and the differences in LVEF probably reflect diabetic cardiomyopathy. Interestingly, there was a tendency for less ventricular tachycardia, which could be due to sympathetic blunting in these patients.

P1773

Comparison of various non-invasive tools for diagnosing AL cardiac amyloidosis

M Martin Nicol[1]; B Assous[1]; M Baudet[1]; R Dautry[1]; A Cescau[1]; A Cohen Solal[1]; B Arnulf[2]; D Logeart[1]
[1]Hospital Lariboisiere, Paris, France; *[2]Hopital Saint-Louis, Paris, France*

Cardiac involvement is the most important cause of death in light chain amyloidosis (AL) and its early diagnosis is a major issue for therapeutic strategy. Gold diagnostic standards are either invasive (cardiac biopsy) or not widely available (cardiac MRI). We aim to compare diagnostic value of various diagnostic tools in this setting.
Methods: Following diagnostic tests were performed after first diagnosis of AL amyloidogenic disorder: clinical examination, blood testing of BNP and troponin I, EKG, echocardiography, 24-hours EKG Holter, cardiac MRI, cardiopulmonary test. Cut-offs were chosen from literature for parameters with continuous values. Final diagnosis of cardiac amyloidois (CA) was done either by MRI if diffuse late

enhancement was present or by an expert consensus (3 clinicians) using all medical files. Diagnostic values of tests as well as their combination were calculated.
Results: Among sixty consecutive patients (64 ± 10 years, 18 with multiple myeloma and 42 with MGUS), final diagnosis of CA was done in 40 patients. Renal, digestive and neurologic AL involvements were present in 45%, 22% and 20% respectively of patients with CA. The table shows diagnostic values of EKG, BNP and echography as well as their combinations. Usefulness of troponin, Holter or stress test was less relevant.
Conclusion: Combining EKG, BNP testing and echocardiography result in nearly optimal diagnosis of CA.

The genetics of noncompaction cardiomyopathy

N Shcherbakova[1]; O Kulikova[1]; R Myasnikov[1]; A Zharikova[1]; A Kiseleva[1]; M Kharlap[1]; A Meshkov[1]; E Mershina[2]; V Sinitsyn[2]; S Boytsov[1]
[1]National Research Center for Preventive Medicine, Moscow, Russian Federation; *[2]Federal Center of Treatment and Rehabilitation, Moscow, Russian Federation*

Background: Left ventricular noncompaction cardiomyopathy (LVNC), despite being a relatively rare cardiomyopathy, is a major problem in cardiology, due to its high mortality and the presence of serious complications. Despite significant advances in genetic diagnosis, only a small number of patients with LVNC could be successfully genotyped. Although the use of large panels of genes can increase the impact of genetic testing.
Purpose: In our study we performed exome sequencing of patients with a clinical diagnosis of noncompaction cardiomyopathy and their relatives of 1 and 2 degrees of kinship to detect the genetics causes of the cardiomyopathy.
Methods: In the last few years we formed the cohort of patients with noncompaction cardiomyopathy and their relatives of 1 and 2 degrees of kinship. The enrollment of participants was done by cascade and reverse-cascade methods in the heart failure center. Probands should have met echocardiographic criteria and cardiac MRI criteria for noncompaction. All the participants underwent standart clinical examination which included echocardiography, 24-hours Holter monitoring of ECG, collection of blood, serum and plasma specimens. Molecular testing was performed using exome sequencing for members of 9 families (29 participants). Among them 11 patients fulfilled the criteria of noncompaction cardiomyopathy. The signs of excess trabeculation were found in eight relatives and 10 relatives were negative for any signs of cardiomyopathy. For precise evaluation of pathogenic variants 37 genes earlier associated with noncompaction cardiomyopathy were screened.
Results: We have sequenced specimens of 29 participants. After the primary bioinformatics analysis have been done, all the variants in 37 genes associated with noncompaction cardiomyopathy were annotated and filtered according to population data, data of computational predictive tools (SIFT and PolyPhen2), association to any cardiomyopathy and segregation in family. Likely pathogenic variants were determined in 6 out of 9 families. 3 variants were found in TTN gene, 2 variants in FLNC gene and 1 variant in DMD gene.
Conclusion: The improving accuracy of molecular diagnosis in patients with noncompaction cardiomyopathy would have a solid effect on counseling and screening of members of families. Despite considerable progress in diagnosis and treatment of LVNC in the last decade, the understanding of the pathophysiological processes underlying the disease and the identification of novel genetic, biochemical and immunological markers are topics for further scientific research.

Ventricular deformation in type 1 diabetes children

R Rim Ben Said[1]; I Zairi[2]; K Mzoughi[2]; F Ben Moussa[2]; S Kammoun[2]; S Fennira[2]; S Kraiem[2]
[1]La Rabta hospital, cardiology, Tunis, Tunisia; *[2]Habib Thameur Hospital, Cardiology, Tunis, Tunisia*

Introduction: Diabetic cardiomyopathy is a new entity, defined as a form of heart failure with preserved LVEF, observed in diabetic patients, in the absence of coronary artery disease, hypertension and significant valvular heart disease. Application of a new echocardiographic tool, the 2D Strain is being evaluated. The aims of our study were to investigate the global longitudinal Strain (GLS) of the left ventricle (LV) and of the right ventricle (RV) and to determine the correlations between GLS and metabolic control evaluated by HbA1c.
Methods: It was a retrospective study of 24 children with type 1 diabetes. The conventional echocardiographic parameters and GLS were studied. These data were compared to the measured parameters in 24 healthy children matched for age and sex.
Results: The mean age was 11,13 ± 0,54 years. The mean duration of diabetes was 7 years ± 0,54. Mean HbA1c was 8,79% ± 0,25. LVEF was preserved with an average of 67,88 ± 1,18%. The TDE was significantly shorter in the diabetic group (146,54 ms ± 3,69 Vs 161,42 ms ± 2,38 for the control group, p = 0,005). E/E ' ratio was significantly higher in the diabetic group compared with the control group (6,72 ± 0,33 Vs 5,21 ± 0,15, p = 0,0011). RV function was preserved in the diabetic group: TAPSE was 20,33 ± 0,26 mm and S' Wave was 14 cm / s ± 0,002. The study of myocardial deformation showed a significant decrease in the GLS of diabetic patients compared to healthy subjects (-18,53% ± 0,5 Vs -25,52% ± 0,37, respectively; p < 0,001). RV longitudinal strain was preserved (-26,31% ± 0,51). No correlation was found between the GLS of the LV and the HbA1c (r = 152, p = 0,477).
Conclusion: Myocardial deformation analysis by Strain 2D can detect subclinical impairment of LV systolic function. It is an early marker of diabetic cardiomyopathy. It has a contributive value for screening early cases and for optimizing therapeutic management and consequently codifying the subsequent monitoring strategy.

P1776
Serum BDNF levels predicts cardiac death in patients with heart failure due to Chagas disease

H Henrique Costa[1]; MMO Lima[2]; PM Martinelli[3]; ERS Camargos[3]; AL Teixeira[4]; AP Ribeiro[1]; MCP Nunes[1]; MOC Rocha[1]
[1]Federal University of Minas Gerais, School of Medicine, Postgraduate Course of Tropical Medicine, Belo Horizonte, Brazil; *[2]Federal University of Jequitinhonha and Mucury Valleys, Diamantina, Brazil*; *[3]Federal University of Minas Gerais, Department of Morphology, Institute of Biological Sciences, Belo Horizonte, Brazil*; *[4]Federal University of Minas Gerais, School of Medicine, Belo Horizonte, Brazil*

Funding Acknowledgements: CAPES, CNPq, FAPEMIG

Introduction: Serum brain-derived neurotrophic factor (BDNF) is up-regulated in patients with Chagas disease (ChD) by dysautonomia and chronic inflammatory process. However, the prognostic value of BDNF levels have not been established in patients with heart failure (HF) due to ChD.
Purpose: To verify the prognostic value of serum BDNF in patients with HF due to ChD.
Methods: Forty-nine patients with HF due to ChD (50.1 ± 7.5 years, NYHA II-III, LVEF 35 ± 7%) were evaluated by clinical evaluation, echocardiography and Cardiopulmonary Exercise Testing. Serum BDNF levels were determined by ELISA sandwich in all patients. A receiver-operator curve was constructed to determine the cutoff value of the serum BDNF to predict cardiac death and the value was used in the Kaplan-Meier curve. The prognostic role of BDNF levels was verified by uni and multivariate Cox regression analysis.
Results: After 41 ± 12 months of follow-up, 12 patients died. The concentration of 2.49 ng/mL was the optimal cut point value to predict cardiac death (AUC=0.78) with significant difference between low and high serum BDNF levels (p = 0.006). In the univariate Cox regression, age, gender, body mass index, left ventricular end-diastolic diameter and E/e' ratio were not associated with cardiac death. In the multivariate regression, low (≤2.49 ng/mL) serum BDNF levels (HR 2.6, 95% CI from 2.1 to 3.1, p = 0.001), peak oxygen uptake (HR 1.2, 95% CI from 1.1 to 1.3, p = 0.009) and left ventricular ejection fraction (HR 0.9, 95% CI from 0.7 to 0.9, p = 0.001) and were independent predictors of survival in HF due to ChD patients.
Conclusion: Serum BDNF levels seems to provide useful prognostic information in patients with HF due to ChD.

P1777

Significance of hsTNF-alpha testing in the verification of inflammatory cardiomyopathy.

AY Shchedrina[1]; AA Skvortsov[2]; KA Zykov[2]; OY Narusov[2]; SN Tereschenko[2]
[1]Pirogov Russian National Research Medical University , Russian Gerontology Clinical Research Center, Moscow, Russian Federation; *[2]Russian Cardiological research and productive complex, Moscow, Russian Federation*

Aim: To evaluate the role of hsTNFα in the verification of the inflammatory cardiomyopathy (ICMP).
Methods: 35 patients mean age 40,8 ± 11,3 (21 male, 14 female), I-III Class NYHA, mean LVEF 33,8 ± 6,36%, with symptomatic heart failure for median 2,0 [1,0;3,0] years and suspected inflammatory cardiomyopathy underwent endomyocardial biopsy (EMB). EMB specimens were investigated with histological and molecular-genetic methods with PCR detection of cardiotropic viruses. Diagnosis was based on World Health Organization criteria. Leucocytes and macrophages criteria amount was ≥ 14. Sera were taken for testing hsTNFα.
Results: The total number of EMB patients was 35 (100%). ICMP was diagnosed in 15 cases (42, 8%) [9 cases (25, 7%) were virus-positive and 6 cases (17,1%) were virus-negative]. DCMP without signs of active inflammation was revealed in n=20 (57, 1%). [12 cases (34, 2%) were virus positive and 8 cases (22, 8%) were virus negative]. Mean NYHA FC was 2, 06 ± 0, 77 in ICMP pts group and 2, 17 ± 0, 7 in DCMP pts group (p = 0,6). According to EMB results, in the myocardium of patients with ICMP the median of lymphocytes, expressing CD4 + and CD8 + were 13,5[10,0;20,0] and 10,0 [6,0;11,7] relatively, that was significantly higher compared with group of DCMP without active inflammation: relatively 1,8[0,0;3,2] (p < 0,0001) for CD4 + and 3,1 [1,5;4,2] for CD8 + , (p < 0,0001). Between the groups of ICMP and DCMP without active inflammation there was no significant difference in the level of the hsTNFα 3,1[1,3;9,7] versus 1,9 [0,8;3,9] (p = 0,47) relatively. However, according to the quartiles of infiltrating cells/mm^2 of myocardium, the patients were divided into four groups: 1 group (0-4 cells), 2 group (5-10 cells), 3 group (11-17 cells), 4 group (>17 cells).In pts with more than 17cells/mm^2 was identified the maximum level of hsTNFα 5,1[3,2;10,3] versus 1,3[0,4;3,1] in others groups (0,03). In the group of patients with ICMP there were revealed positive correlations of hsTNFα with the total number of infiltrating cells/mm^2 (r=0,5,p = 0,08), particulary CD68 + /mm^2 of myocardium (r=0,68,p = 0,01), with the stage of hypertrophy (r=0,7; p = 0,002) and cardiosclerosis (r=0,6; p = 0,024). In addition there was a trend to correlation with ESV (r=0,5,p = 0,08).
Conclusions: The level of hsTNFα was significantly higher in patients with the most pronounced inflammatory process and associated with the severity of myocardial infiltration. The level of this cytokine reveals the stage of cardiosclerosis and hypertrophy.

Funding Acknowledgements: Supported by the research grant AZV-MZ 15-27682A and IKEM 00023001.

Introduction: Transthyretin cardiomyopathy (TTR-CMP) has been recently recognized as a cause of heart failure with preserved ejection fraction (HFPEF). Availability of non-invasive diagnostics using 99mTc-DPD scintigraphy and emerging modalities of pharmacotherapy have attracted attention of clinicians to this disease. We aimed to analyze our experience with diagnostics and clinical presentation of wild-type TTR-CMP.
Methods: The study group included 16 patients (14 males, 2 females; mean age 80 ± 6 years) diagnosed with wild-type TTR-CMP in our centre from 2010-2016. The diagnosis of TTR-CMP was based on index of maximal myocardial accumulation (IMA) at 99mTcDPD SPECT-CT following administration of 740MBq of 99mTcDPD. IMA was calculated as a ratio of peak myocardial and peak skeletal activity (mean 6.26 ± 2.42; upper limit of normal 1.1 in males and 1.7 in females). In addition, 8 patients (50%) underwent endomyocardial biopsy, which detected transthyretin amyloidosis in all cases.
Results: TTR-CMP was identified in 10 patients (62%) evaluated due to HFPEF. 5 patients (32%) were diagnosed during screening among 80 elderly patients (age > 70 years; 38 males, 42 females) indicated to 99mTcDPD bone scintigraphy due to oncologic diseases (most commonly prostatic and breast cancer). One asymptomatic patient (6%) was diagnosed accidently at echocardiography. 8 patients (50%) had a history of decompensated heart failure, mean NYHA class was 2.2 ± 0.5, median B-type natriuretic peptide BNP 283 ng/l (160-473). Persistent or permanent atrial fibrillation was present in 5 patients (31%), 6 of 11 patients (54%) with sinus rhythm had first-degree atrioventricular block, low QRS voltage was present just in one case. Echocardiography revealed median left ventricular (LV) end-diastolic dimension of 49 mm (45-51), median thickness of interventricular septum of 14 mm (13-16) and median E/Em 13 (8-17). LV ejection fraction was preserved (≥50%) in 13 cases (82%), moderately reduced (40-49%) in 2 cases (12%) and severely depressed (LVEF 35%) in one case (6%).
Conclusion: Diagnosis of TTR-CMP should be considered in elderly patients with echocardiographic signs of myocardial storage disease. Importantly, TTR-CMP can be discovered in almost 6 % of elderly individuals who undergo bone scintigraphy from oncologic reasons.

P1779

EMB-based diagnosis in a large cohort of 2822 consecutive patients with unexplained heart failure : data analysis from 2014-2016

F Felicitas Escher[1]; U Kuhl[1]; U Gross[2]; D Lassner[2]; H-P Schultheiss[2]
[1]Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; *[2]Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany*

Background: The diagnosis of unexplained heart failure is challenging. The current expert consensus statement of the European Society of Cardiology (ESC) maintains that endomyocardial biopsies (EMBs) remain the gold standard for definitive diagnosis of unexplained heart muscle diseases. However, EMB is used infrequently, although histology, immunohistochemical, and molecularbiological analysis of EMB is a prerequisite to make an etiology-driven diagnosis with the aim to identify those patients in whom specific therapy would be appropriate.
Methods and Results: We enrolled n=2822 consecutive patients with unexplained heart failure (2034 men/ 788 women, mean age 51.44 ± 16.04 years) from January 2014 to August 2016, who underwent EMB. The suspected diagnosis had been made by clinicians. EMBs were send to a FDA-proved laboratory (Institute for Cardiac Diagnostic and Therapy Berlin, Germany). Analysis included histology, immunohistochemistry, molecular virology, and gene profiling.
In n=810 patients the suspected diagnosis was acute myocarditis, in 1772 patients myocarditis or inflammatory/dilated cardiomyopathy was suspected. In n=240 patients a storage disorder was suspected.
Based on EMB-results in 58.9% (n = 1664 patients) a specific heart muscle disease could be diagnosed.
In particular, Coxsackie-Adenovirus genomes were present in n=44, Ebstein-Barr-Virus in n=77, Human-herpesvirus 6 (HHV6) in n=426 (including 21 patients with chromosomal integrated (ci) HHV6), and erythrovirus with active viral replication (positive mRNA) in n=649 patients.
Virus-negative intramyocardial inflammation was present in n=810 patients, including a histologically-proven active myocarditis in n=64. Histological proof of giant cells was present in n=20 patients. However, in n=133 patients idiopathic giant cell myocarditis or eosinophilic myocarditis was diagnosed by analysis of myocardial gene expression profile. 116 patients showed evidence of cardiac storage disease.
Conclusions: Based on EMB-results in 58.9% of this large cohort of patients a specific heart muscle disease could be diagnosed. These aetiology-driven diagnoses implicate a specific, causal therapy.
Our data clearly show the necessity of an EMB-based diagnosis, which has a direct clinical consequence regarding a specific therapy in a notable high percentage of patients with unexplained heart failure.

P1780

Evaluation of Th1, Th2, Th17 and Treg cytokines profile in patients with chronic chagas heart disease and systemic arterial hypertension: further studies.

R Bestetti[1]; R Dellalibera-Joviliano[1]; G Lopes[1]; R Furlan-Daniel[1]; K Lopes[2]
[1]University of Ribeirao Preto, Ribeirao Preto, Brazil; *[2]Clinica Sao Rafael, Piumhi, Brazil*

Background: In patients with chronic Chagas cardiomyopathy (CCM), increased plasma cytokines levels have been observed. However, a panel of Th1, Th2, Th17 and Treg cytokines, which encompasses several pro-inflammatory, anti-inflammatory, and regulatory cytokines, has not been determined in patients with this condition. In areas where Chagas disease is endemic, systemic arterial hypertension (SAH) affects 25% of patients with this condition. We have previously observed that a Th1, Th2, and Th17 cytokine panel has been shown to be increased in patients with chronic Chagas disease and SAH. However, this cytokine panel has not yet been determined in patients with CCM and SAH (CCM-SAH).
Purpose: Accordingly, the aim of this study was to evaluate the Th1 (INF-gama, IL-2, IL-12), Th2 (IL-4, IL-10, IL-13, IL-5), Th17 (IL-17, IL-23, IL-6) and Treg (IL-2, TGF-β) cytokines profile in patients with CCM-SAH.

P1781 Cardiomyopathy associated with Shabu

Patient	Shabu consumption pattern	Presentation	Echocardiography	Cardiac Magnetic Resonance	Coronary arteries	
1	41 yearsPhilippineMale	- Chronic.- No consumption last 2 months.	- Acute pulmonary edema.	- LVEF 18%.- Severely dilated left ventricle(LVIDd 74mm).- No improvement in LVEF at 1-year	- Non-ischemic biventricular dilated cardiomyopathy with severe systolic dysfunction.- No LGE.	- CT angiography with no significant coronary lesions.
2	38 yearsPhilippineMale	- Chronic.- Active consumption < 12 hours.	- Heart failure.- Hypertensive crisis.	- LVEF 25%.- Concentric left ventricular hypertrophy (septum 18mm).- Mild ventricular dilatation (LVIDd 60mm).	- Non-ischemic cardiomyopathy with severe systolic dysfunction. Severe left ventricular hypertrophy.- Multiple foci of LGE.	- Coronary angiography with no significant coronary lesions.
3	52 yearsMale	- Chronic.- Active consumption < 12 hours.- Cocaine use.	- Chest pain.- Acute pulmonary edema.	- LVEF 25%.- Concentric left ventricular hypertrophy (septum 15mm).- Mild ventricular dilatation (LVIDd 60mm).	- Non-ischemic cardiomyopathy with severe systolic dysfunction. Moderate concentric hypertrophy.- Foci of LGE in the interventricular union.	- Coronary angiography without lesions.
4	54 yearsPhilippineMale	- Chronic.	- Heart failure.	- LVEF 10-15%.-Severely dilated left ventricle(LVIDd 67 mm).	-Nonischemic biventricular dilated cardiomyopathy with severe systolic dysfunction.- Severe ventricular dilation.- Multiple foci of LGE. Foci of LGE in the interventricular union.	- Coronary angiography without lesions.
5	24 yearsFemale	- Acute consumption < 12 hours.	- Cardiogenic shock.	- LVEF 25%.- Moderate ventricular dilatation (LVIDd 58mm).- LVEF 50% within 30-day.	- Non-ischemic cardiomyopathy.- No LGE.	

CT: Computed tomography; LGE: Late gadolinium enhancement; LVEF: Left ventricular ejection fraction; LVIDd: Left ventricular internal dimension at end-diastole.

Methods: This study focus on 16 patients with CCM, 20 patients with CCM-SAH, and 28 controls. The diagnosis of CCM was based on a positive serology for Chagas disease plus abnormal resting ECG or decreased left ventricular ejection fraction on echocardiogram. The diagnosis of CCM-SAH was done when patients with CCM had a SAH > 140 x 90 mmHg. Quantitative measurements of cytokines were performed on plasma samples using the double-ligand/sandwich enzyme-linked immunosorbent assay (ELISA). The cytokine concentration was expressed in pg/ml by the kit's standard curve.

Results: TNF-alpha levels were 259 ± 1,32 in controls, 412 ± 2,3 in patients with CCM, and 495 ± 3,2 in patients with CCM-SAH ($P < 0.05$). INF-gamma levels were 58 ± 1,57 in controls, 102 in patients with CCM, and 124 ± 2,6 in patients CCM-SAH ($p < 0.05$). IL-1 beta levels were 52 ± 1,33 in controls, 137 ± 3,12 in CCM, and 200 ± 1,56 in patients with CCM-SAH patients ($p < 0.05$). IL-2 levels were 22 ± 1,25 in controls, 45 ± 1,8 in patients with CCM, and 84 ± 2,8 in those with CCM-SAH ($p < 0.05$). IL-6 levels were 77 ± 1,45 in controls, 141 ± 1,8 in patients with CCM, and 195 ± 2,1 in those with CCM-SAH. IL-10 levels were 156 ± 2,8 in controls, 212 ± 2,1 in patients with CCM, and 255 ± in those with CCM-SAH ($p < 0.05$). IL-12 levels were 65 ± 2,1 in controls, 221 ± 2,1 in patients with CCM, and 279 ± 3,2 in those with CCM-SAH ($p < 0.05$). IL-13 levels were 56 ± 1,9 in controls, 84 ± 2,1 in patients with CCM, and 95 ± 2,2 in patients with CCM-SAH ($p < 0.05$). TGF-beta levels were 35 ± 2,2 in controls, 60 ± 2,5 in patients with CCM, and 77 ± 2,3 patients with CCM-SAH ($p < 0.05$). IL-17 were 74 ± 2,5 in controls, 133 ± 2,8 in patients with CCM, and 189 ± 2,7 in those with CCM-SAH ($p < 0.05$). IL-23 levels were 50 ± 2,0 in controls, 144 ± 3,0 in patients with CCM, and 183 ± 3,4 in those with CCM-SAH ($p < 0.05$).

Conclusion: Patients with CCM-SAH have increased plasma levels of pro-inflammatory, anti-inflammatory, and regulatory cytokines in comparison with CCM patients, suggesting a higher level of immunomodulation in patients with CCM-SAH.

P1781

Cardiomyopathy associated with shabu consumption

M Pujol Lopez[1]; L Ortega Paz[1]; EJ Flores Umanzor[1]; M Roque[1]; S Prat Gonzalez[1]; RJ Perea[2]; A Garcia Alvarez[1]; X Bosch[1]

[1]Hospital Clinic de Barcelona, Cardiology Department, Barcelona, Spain; [2]Hospital Clinic de Barcelona, Radiology Department, Barcelona, Spain

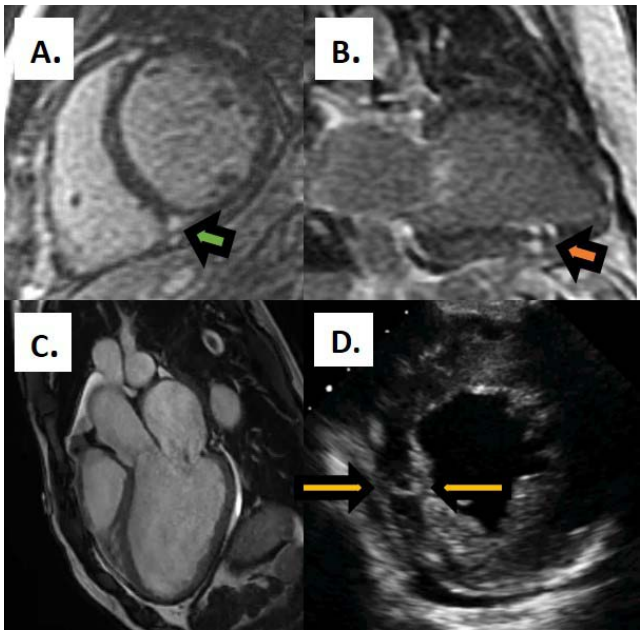
- Shabu is the Philippine name of a high purity methamphetamine also called cristal or ice. Shabu is an emerging drug in Europe with increasing consumption notifications in recent years, especially within Southeast Asian communities (mainly Philippines).

Purpose: To identify the form of presentation and types of cardiopathy associated with the consumption of Shabu in our environment.

Methods: We conducted a prospective inclusion of Shabu consumers who were admitted for heart failure in our hospital during the period from January 2015 to September 2016. We identified five cases of Shabu users with a first episode of heart failure. For diagnosis, an initial urinalysis was performed by immunoassay and confirmed with gas chromatography-mass spectrometry.

Results: The median age of the patients was 42 + 11 years. All patients presented as severe acute heart failure (acute pulmonary edema, cardiogenic shock, or heart failure (NYHA functional class IV)) due to left ventricular dysfunction (mean left ventricular ejection fraction (LVEF) 21 + 5%). Mean left ventricular end-diastolic diameter was 64 + 6 mm. Coronary angiography or computed tomography angiogram excluded obstructive coronary artery disease. Cardiac magnetic resonance imaging identified a non-ischemic cardiomyopathy in all of them with two patterns of late gadolinium enhancement (LGE): foci in the interventricular junction (Fig 1A) or multiple foci of LGE (Fig 1B). All patients presented elevated necrosis biomarkers and QTc interval prolongation (mean QTc 477 + 25 ms). Three types of cardiomyopathy were identified: two patients with dilated (Fig 1C) and two cases with hypertrophic cardiomyopathy (Fig 1D) in chronic consumption and one stress cardiomyopathy in acute consumption.

Conclusions: Shabu related cardiomyopathy presented as severe acute heart failure. All patients presented severe left ventricular dysfunction and QT prolongation. The detection of these five cases of Shabu related cardiomyopathy represents an alert. It should motivate a rapid diagnosis and management of these patients and further, studies on the cardiovascular risk of this drug.



Shabu related cardiomyopathy

P1782

Incidence and predictors of heart failure after acute myocardial infarction in patients without systolic dysfunction and/or history of heart failure

RJ Cobas[1]; B Caneiro[1]; S Raposeiras[1]; E Abu[1]; S Manzano[2]; FE Calvo[1]; M Valdes[2]; A Iniguez[1]

[1]Hospital Álvaro Cunqueiro , Cardiology , Vigo, Spain; [2]Hospital Clínico Univeristario Virgen de la Arrixaca, Cardiology, Murcia, Spain

Introduction: Heart failure (HF) after myocardial infarction (MI) is common and has been associated with excess mortality. The aim of this study was to provide an evaluation of the factors that predict the development of "the novo" HF in patients after MI with pLVEF.

Methods: A total of 3507 consecutive patients discharged from hospital after AMI between January 2011 and December 2015 in two tertiary hospitals were included. We excluded patients with LVEF < 50%, Killip Class ≥ II and patients with prior or "de novo" HF (n = 1283). The final cohort was made up 2,158 patients. Using a competing risk framework for HF occurrence, accounting for death as a competing episode, predictors of follow-up HF development were assessed by Fine-Gray porportional hazards regression analysis. For the multivariate analysis, we used covariates with $p < 0.05$ in the univariate analysis. The adjusted hazard of HF was expressed as subhazard ratios (sHR) with corresponding 95% confidence intervals (95%CI).

Results: During a follow-up of 20.1 ± 11.8 months, 59 (2.8%) patients developed "de novo" HF. Table 1 shows the uni and multivariate Fine-Gray analysis. Age (as continuous variable, being 70 years the best cut-off to predict HF), hypertension, renal disfunction, and atrial fibrillation were independent predictors for HF development. Basing on the presence or absence of these 4 risk factors, we can stratify the risk of "de novo" HF after MI (Figure 1).

Conclusions: In a contemporary cohort of patients surviving an AMI, the incidence of HF is about 3%, and its occurrence can be easily predicted by 4 previous risk factors.

Influence of inflammation on the pathogenesis of cardiac ATTR and AL amyloidosis

K Klingel[1]; A Hehn[1]; M Sauter[1]

[1]Department of Molecular Pathology, Tuebingen, Germany

Background: Amyloidosis describes a group of disorders caused by the extracellular deposition of misfolded proteins, which can severely impair the function of the heart. The correct diagnosis of amyloidosis by immunohistological subtyping in endomyocardial biopsies is decisive as it determines the outcome of the disease and the therapy of the patients.

Purpose: In this study we aimed to identify parameters of pathogenicity in cardiac amyloidosis.

Methods and Results: We investigated 5 unselected patients (43 male, 7 female) with Congo red positive endomyocardial biopsies (EMB) by immunohistochemistry in order to classify the forms of cardiac amyloidosis. In 26 patients (52%) we found an ATTR amyloidosis and in 48% an AL amyloidosis with 17 cases of AL-lambda and 7 cases with AL-kappa. Patients with ATTR amyloidosis had a mean age of 78 years and a mean LVEF of 45%, those with AL amyloidosis had 67 years and a LVEF of 47%. As a part of our routine diagnostic program, we also performed immunohistochemical stainings to identify and quantify inflammatory cells in EMB. Astonishingly,

we found in 21/50 (42 %) patients with amyloidoisis a significant cardiac inflammation. In 7/26 (27%) of ATTR amyloidosis and in 12/17 (70%) of AL-lambda and 2/7 (28%) of AL-kappa amyloidosis we found enhanced levels of CD3+ T cells, CD68+ macrophages and MHCII expression. We have shown that lymphoycytic myocarditis is associated with an upregulation of the cytokines IL-1 and IL-6. As a consequence of IL-1 and IL-6 expression, signaling pathways are induced with enhanced ERK1/2 expression being most prominent in EMB of patients with AL-lambda amyloidosis. ERK 1/2 expression is known to be involved in the molecular switch of necrosis to apoptosis. A significant number of apoptotic cardiomyocytes was identified in ATTR as well as in AL amyloidosis by TUNEL assay as well as by electron microscopy. Virus infections were not prominent in amyloidosis patients. Only 1 patient with ATTR amyloidosis and inflammation and 3 patients with AL amyloidosis and inflammation were positive for viral DNA (PVB19 and HHV6) as determined by PCR.
Conclusions: Our results indicate that inflammation in hearts of patients with ATTR and AL amyloidosis is associated with expression of ERK1/2, finally contributing to the emergence of apoptotic myocytes and myocardial damage.

P1784
NEOD001 demonstrates organ biomarker responses in patients with light chain amyloidosis and persistent organ dysfunction independently of previous haematological response

M Michaela Liedtke[1]; RL Comenzo[2]; H Landau[3]; V Sanchorawala[4]; BM Weiss[5]; JA Zonder[6]; J Walling[7]; GG Kinney[8]; M Koller[8]; DB Schenk[8]; SD Guthrie[8]; E Liu[8]; MA Gertz[9]
[1]Stanford University School of Medicine, Stanford, United States of America; *[2]Tufts Medical Center, Boston, United States of America*; *[3]Memorial Sloan Kettering Cancer Center, New York, United States of America*; *[4]Boston University, Boston, United States of America*; *[5]University of Pennsylvania, Philadelphia, United States of America*; *[6]Karmanos Cancer Institute, Detroit, United States of America*; *[7]JW Consulting, Hillsborough, United States of America*; *[8]Prothena Biosciences Inc, South San Francisco, United States of America*; *[9]Mayo Clinic, Rochester, United States of America*

Introduction: Light chain (AL) amyloidosis is a rare and often fatal disease caused by the accumulation of misfolded light chain aggregates (LCs), produced by clonal plasma cells. Current therapies limit LC production; however, ~75% of patients have persistent organ dysfunction. NEOD001 is a novel investigational antibody that targets misfolded LC and is thought to neutralise circulating LC aggregates and clear insoluble deposits. Here we assessed safety and tolerability and analysed organ responses based on consensus criteria and association between organ responses and previous plasma cell–directed (PCD) treatment.
Methods: Inclusion criteria were that patients complete ≥1 PCD treatment before enrolment, attain partial haematological response (HR) or better to any previous therapy and have persistent organ dysfunction. NEOD001 was administered intravenously every 28 days. During the dose-escalation phase, 27 patients received NEOD001 at 0.5, 1, 2, 4, 8, 16 or 24 mg/kg in a 3+3 study design. An additional 42 patients with renal, cardiac or nerve involvement were enrolled and treated (24 mg/kg) in the expansion phase.
Results: In the overall population (N=69) the median age was 61 years (61% male). Median (range) time since diagnosis was 2.9 (0.4-16.0) years, and 45% of patients underwent ≥3 previous PCD regimens. Median time since last PCD treatment to the start of NEOD001 intervention was 5.8 (range, 0.6-85.8) months. Infusions were administered over a mean of 12.8 (range, 2-35) months. NEOD001 treatment was not associated with dose-limiting toxicities, discontinuations, antidrug antibody development or treatment-related serious adverse events. The most frequent TEAEs were fatigue, nausea, upper respiratory tract infection and peripheral oedema. Best response rate indicating organ response was observed in 53% of cardiac-evaluable patients (n=19/36) and 64% of renal-evaluable patients (n=23/36). Time from patients' best HR to previous PCD treatment did not impact the NEOD001 organ response rate (cardiac/renal: 35.6/30.6 [responders] vs 36.6/32.5 [stable] months; P>0.05). Depth of patients' best HR also did not impact the NEOD001 organ response (cardiac/renal: 47.1/68.8% [CR], 66.7/63.6% [VGPR], 42.9/62.5% [PR]; P>0.05). Similarly, time or depth of patients' last HR did not impact the NEOD001 organ response rate (P>0.05). Patients with NEOD001 organ responses were no more likely to have had their last PCD therapy <6 vs ≥6 months from their first NEOD001 dose. Patients' previous treatment type had no impact on the NEOD001 organ response rate (cardiac/renal: 55.6/61.1% [stem cell transplantation], 52.0/68.8% [bortezomib-based therapy], 50.0/57.1% [other chemotherapy]; P>0.05).
Conclusions: These results demonstrate that NEOD001 infusions were safe, well tolerated and associated with organ responses independently of time since previous chemotherapy, depth of haematological response or predominant type of PCD treatment.

P1785
Assessment of left ventricular function in asymptomatic systemic lupus erythematosus ab patients(about 70 cases)

MERIEM Drissa[1]; SANA Helali[1]; SAMIRA Kaabachi[1]; MEHDI Cheour[1]; HABIBA Drissa[1]
[1]La Rabta University Hospital, adults cardiology, Tunis, Tunisia

Introduction and Purpose: Cardiac disease is common among patients with systemic lupus erythematosus (SLE)..The aim of this study is to assess the systolic and diastolic function of the left ventricular (LV) in asymptomatic systemic lupus erythematosus (SLE) patients.
Methods: We included 35 patients without symptoms or signs of heart failure or angina (groupe I) and 35 healthy subjects (groupe II) ; The two groups had similar mean age ,sex ratio ,mean blood pressure and body mass index. All included subjects had no evidence of diabetes mellitus , valvular or ischemic heart diseases we used standard echocardiography and tissue Doppler imaging(TDI),and speckel traking stain rate
Results: LV diastolic diameter and LV ejection fraction were similar in both group ,however we observed lower mitral annulus systolic velocities measured by TDI in lupus patients (6.2±0.7cm/vs 9±0.9cm/s,p<0.01) reflecting subclinical LV systolic dysfunction. we notated also a lower speckle tracking derived myocardial deformation (strain and strain rate) in lupus patients (-10% vs-17%) reflecting a systolic dysfunction of left ventricular . there was not significant difference in the ratio of early to late diastolic mitral filling velocities E/A and in deceleration time of E between the 2 groups. However mitral annulus early diastolic velocities Ea measured by TDI were markedly reduced in patients suffering fromlupus (6± 1.4cm/s vs. 11.5±1.3 cm/s, p<0.01) WITH function. diastolic impaired suggesting p<o,o1). 8±1.7; ±1.8vs (14.1 velocities Ea E of ratio higher
Conclusion: This study shows the presence of systolic and diastolic dysfunction in asymptomatic systemic lupus erythematosus (SLE) patients. Evaluation of left ventricular function by tissue Doppler imaging ,stain rate is useful to detect infraclincal left ventricular dyfunction during systemic lupus.

Predictors of in-hospital outcome in takotsubo cardiomyopathy, a multicenter study

A L Ana Calvo[1]; O Azevedo[1]; RP Santos[2]; AR Almeida[3]; N Craveiro[4]; B Picarra[5]; R Lima[6]; L Reis[7]; B Marmelo[8]; A Marreiros[9]; N Marques[9]
[1]Alto Ave Hospital Center, Cardiology, Guimaraes, Portugal; *[2]Hospital Centre do Tamega e Sousa, cardiology, Penafiel, Portugal*; *[3]Hospital Garcia de Orta, Almada, Portugal*; *[4]Hospital of Santarem, Cardiology, Santarem, Portugal*; *[5]Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal*; *[6]Centro Hospitalar do Alto Minho, Cardiology, Viana do Castelo, Portugal*; *[7]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*; *[8]Hospital Sao Teotonio, Cardiology, Viseu, Portugal*; *[9]U.Algarve, Algarve Biomedical Center DCBM , Algarve, Portugal*

Introduction: Takotsubo cardiomyopathy (TC) is characterized by a transient left ventricular (LV) dysfunction in the absence of significant coronary artery disease. The predictors of prognosis of TC are not yet fully established.
Purpose: To identify predictors of outcome in patients (P) diagnosed with TC.
Methods: Multicenter study involving 13 hospital centers that included all patients diagnosed with TC in the last 12 years. We assessed demographic data, precipitating factors and clinical presentation, trying to establish the predictors of after discharge outcomes. We define the occurrence of in-hospital outcome of TC patients as a variable that combine the occurrence of death, stroke/TIA, heart failure, atrial fibrillation, LV thrombus.
Results: We included 234 P diagnosed with TC, predominantly female (89.7%). During hospitalization occurred complications: heart failure (24.4%), atrial fibrillation (9.0%), complete atrioventricular block (2.1%), stroke / TIA (1.7%), LV thrombus (1.3%) and death (2.2%). The combine in-hospital outcome is 32.9%.
We found a significant association of the following variables with the combine in-hospital outcome: (i) history of heart failure (7.8% vs 0.0%, p<0.001); (ii) chronic kidney disease (14.3% vs 2.5%, p=0.001); (iii) precipitant physical stress factor (26.0% vs 14.6%, p=0.036); (iv) presentation with dyspnea (41.6% vs 12.1%, p<0.001); (v) higher Killip Kimball (KK) class at admission (p<0.001); (vi) bifascicular bundle block in EKG (2.6% vs 0.0%, p=0.043); (vii) significant valvopathy (18.2% vs 7.0%, p=0.009); (vii) LV dysfunction (p<0.001).
In the multivariate analysis by CHAID method, the following variables were identified as independent predictors of in-hospital complications: (i) higher KK class in admission (p<0.001); (ii) LV dysfunction (p<0.001).
Conclusion: TC has a high rate of complications in the acute phase. Higher KK class at admission and LV dysfunction were the only independent predictors of in-hospital outcome identified in our study.

Introduction: Takotsubo cardiomyopathy (TK) is characterized by transient left ventricular dysfunction that may lead to the development of heart failure (HF). The prolongation of the QRS interval on the electrocardiogram (ECG) is a predictor of adverse outcome in patients (P) with HF and acute myocardial infarction. It has not been established whether the same is true for P with TK.
Objective: To evaluate the impact of QRS duration on the outcome of P with TK.
Methods: A multicenter Portuguese study involving 12 hospital centers. Included P hospitalized with diagnosis of TK since 2004. We divided the P in two groups, according to the QRS duration: normal if QRS≤120ms (nQRS) and prolonged if QRS> 120ms (pQRS). Demographic, clinical, electrocardiographic and echocardiographic parameters were evaluated, as well as complications during hospitalization.
Results: We included 234 patients with TK: 89.7% female and mean age 71.6 ± 11.9 years. The nQRS group represents 91% of the sample.
There were no differences between groups regarding the gender, cardiovascular risk factors, history of coronary disease, heart failure, chronic kidney disease or anemia. Upon admission, there was a trend for pQRS to present more frequently with syncope (14.3% vs 4.7%, p = 0.067). In the ECG, the pQRS group included a greater number of P in atrial fibrillation than the nQRS group (43.6% vs. 3.6%, p < 0.001). There were no differences between the groups regarding the presence of ST elevation in the initial ECG. There were no differences in BNP or troponin values at admission or hospitalization.
There were no differences in ejection fraction (EF) at admission or discharge (left ventricular systolic dysfunction in the pQRS group 52.6% vs nQRS 32.6%, p = 0.08).
About the hospitalization complications, there were no differences regarding the evolution to cardiogenic shock. The pQRS group presented more frequently dysrhythmic complications, namely ventricular tachycardia / fibrillation (VT / VF) (9.5% vs 1.9%, p = 0.034), with odds ratio of 5.54.
Conclusion: In this study, the P admitted with TK and pQRS evolved with a higher number of dysrhythmic complications, namely VT / VF risk when compared to P with nQRS. Thus, the pQRS at admission has an impact on the clinical evolution of the P, which implies a need to a closer surveillance during hospitalization.

P1788

Impact of cardiac 99mTc-HMDP uptake on left ventricular function and filling pressure in patients with transthyretin amyloidosis

O Lairez[1]; S Pradel[1]; S Brun[1]; P Pascal[2]; P Fournier[1]; I Berry[2]; J Roncalli[1]; D Carrie[1]; M Galinier[1]
[1]University Hospital of Toulouse - Rangueil Hospital, Department of Cardiology, Toulouse, France; [2]Toulouse Rangueil University Hospital (CHU), Nuclear Medicine, Toulouse, France

Background: Pathophysiology of 99mTc-labeled phosphate agents cardiac uptake by scintigraphy in transthyretin-related (TTR) amyloidosis remains unclear. The aim of this study was to explore the impact of 99mTc-labeled phosphate agents cardiac uptake on left ventricular (LV) functions assessed by echocardiography.
Methods: Fifty patients with TTR cardiac amyloidosis underwent 99mTc-hydroxymethylene-diphosphonate (99mTc-HMDP) scintigraphy and echocardiography with measure of LV morphology, longitudinal strain (LS), systolic and diastolic functions. Cardiac retention by scintigraphy was assessed by visual scoring and the heart/whole body (H/WB) ratio was calculated by dividing counts in the heart by counts in late whole body images.
Results: Mean H/WB ratio was 12 ± 7. Mean LV ejection fraction and global LS were 51 ± 10% and -10 ± 3%, respectively. H/WB ratio was correlated with global LS (R=0.408, P=0.003), Ea (R=-0.566, P < 0.001) and mean left ventricular wall thickness (R=0.476, P < 0.001) but not with LV ejection fraction (R=-0,109, P=0.453, Figure). Segmental myocardial uptake normalized by H/WB ratio was correlated with segmental LS (n = 850 segments, R = 0.162, P < 0.001). H/WB ratio was not correlated with NT-proBNP levels (R=0.219, P=0.148) neither E/Ea ratio (R=0.204, P=0.184).
Conclusion: In patients with TTR cardiac amyloidosis, myocardial uptake by 99mTc-HMDP scintigraphy is correlated with decrease of myocardial LS.

Funding Acknowledgements: None

Objective: A decreased longitudinal strain in basal segments with a base-to-apex gradient has been described in patients with cardiac amyloidosis (CA). Aim of the study was to investigate the left ventricular (LV) regional distribution of early-phase 99mTc-Hydroxymethylene diphosphonate (HMDP) uptake in patients with transthyretin-related cardiac amyloidosis (TTR-CA).
Methods: All patients underwent a whole-body planar 99mTc-HMDP scintigraphy acquired at 10 min post-injection (early-phase) followed by a thorax SPECT/CT. The relative segmental uptake % was investigated on AHA 17-segment model and 3-segment model (basal, mid-cavity, apical).
Results: Sixty-one TTR-CA patients were included of whom; 29 were wild-type (wt-TTR-CA) and 32 had hereditary TTR-CA (m-TTR-CA). Early myocardial 99mTc-HMDP uptake occurred in all TTR-CA. In all patients, segmental analysis of the LV myocardial distribution of 99mTc-HMDP uptake showed an increased median uptake (interquartile range) in basal/mid-cavity segments compared to the lowest median uptake of apical segments (respectively 79 [72-86] vs. 72 [64-81]; P < 10-6). This pattern was similar in wt-TTR-CA group (78 [70-84] vs. 70 [61-81]; P < 10-6), in m-TTR-CA group (80 [74-86] vs. 73 [66-82]; P < 10-7) and remains constant independently of the TTR mutation's subtype with P ranging 10-5 to 0.03.
Conclusions: Early-phase myocardial scintigraphy identified regional distribution of 99mTc-HMDP uptake characterized by a base-to-apex gradient, corroborating echocardiographic and cardiac magnetic resonance findings. This relative "apical sparing" pattern was similar across TTR-CA and TTR mutations' subtypes.

Ability of 99mTc-DPD scintigraphy to predict conduction disorders requiring permanent pacemaker in patients with transthyretin-related cardiac amyloidosis

S Stephanie Brun[1]; S Pradel[1]; D Carrie[1]; M Galinier[1]; P Maury[1]; P Pascal[1]; G Victor[1]; I Berry[1]; P Mondoly[1]; D Ribes[1]; A Duparc[1]; O Lairez[1]
[1]Toulouse Rangueil University Hospital (CHU), 31, Toulouse, France

Background: Transthyretin-related (TTR) amyloidosis is the second most common cardiac amyloidosis. TTR cardiac amyloidosis is a clinical disorder that arises from the cardiac aggregation of insoluble fibrous deposits of misfolded proteins leading

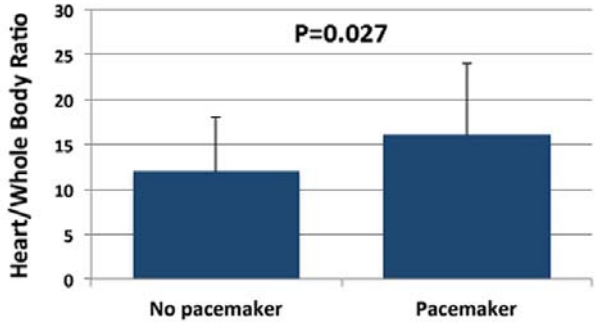
to a high rate of conduction disorders and increased risk of sudden death. TTR cardiac amyloidosis is being increasingly recognized because of the emergence of 99mTc-3,3-diphosphono-1,2-propanodicarboxylic acid (99mTc-DPD) scintigraphy. 99mTc-DPD scintigraphy has been shown to have excellent results in the diagnosis of TTR cardiac amyloidosis but is value to predict conduction disorders was never described.

Purpose: To evaluate the value of 99mTc-DPD scintigraphy to predict conduction disorders in patients with TTR cardiac amyloidosis.

Method – Fifty patients with positive 99mTc-DPD scintigraphy for TTR cardiac amyloidosis were retrospectively included. Cardiac retention was assessed by visual scoring and the heart/whole body (H/B) ratio was calculated by dividing counts in the heart by counts in late whole body images. Electrocardiograms were reviewed for main conduction system disorders requiring permanent pacemaker.

Results: – Mean age was 80 ± 10 year-old. Nineteen (38%) patients had a pacemaker. There was no difference between patients with or without pacemaker for age (79 ± 9 vs. 80 ± 10 year-old, respectively, P=0.417) or visual score (2.9 ± 0.3 vs. 2.8 ± 0.4, respectively, P=0.589). Patients with pacemaker had a higher H/B ratio than patients without pacemaker (16 ± 8 vs. 12 ± 6, respectively, P=0.027). The area under the ROC curve of H/B ratio to predict presence of pacemaker was 0.688 with a best cut-off value of 12 allowing a sensitivity and a specificity of 79% and 61%, respectively.

Conclusion: – Tracer uptake by 99mTc-DPD scintigraphy assessed by H/R ratio could be a sensitive tool in patients with TTR cardiac amyloidosis to predict conduction disorders requiring permanent pacemaker.



P1791

The role of baseline LVEF towards the recovery of left ventricular function and improvement of left ventricular remodelling in peripartum cardiomyopathy patients: starting position matters

H S Hawani Sasmaya Prameswari[1]; TID Dewi[1]; EM Martanto[1]; AP Purnomowati[1]
[1]*Padjadjaran University, Cardiology, Bandung, Indonesia*

Background: Peripartum Cardiomyopathy (PPCM) has been known to have a unique outcome as compared to other forms of cardiomyopathy. Previous studies have stated that, to a certain extent, there is recovery of left ventricular function observed in PPCM patients. It was postulated that baseline Left Ventricular Ejection Fraction (LVEF) plays a pivotal role in recovery of left ventricular function. To date, the definite role of baseline LVEF in left ventricular function recovery is still shrouded in controversy, whereas its role in improvement of left ventricular remodelling remains to be revealed.

Purpose: This study sought to prospectively evaluate the role of baseline LVEF in recovery of left ventricular function and improvement of left ventricular remodelling in PPCM patients.

Methods: This nested case-control study was part of PPCM prospective cohort registry at Hospital in Indonesia. We enrolled 42 PPCM patients from September 2013 through 6 months follow-up until September 2016. The LVEF and Left Ventricular End Diastolic Volume (LVEDv) index were measured using echocardiography with an application of Simpson's method. The role of baseline LVEF toward recovery of left ventricular function was analysed using multivariate logistic regression whereas its role towards improvement of left ventricular remodelling (delta LVEDV index) was analysed using multivariate linear regression analysis.

Results: Forty-two PPCM patients were enrolled in this study and divided into two groups, the recovery group (n = 21, mean age 31 ± 6 years old), and non-recovery group (n = 21, mean age 33 ± 5 years old). The mean baseline LVEF from the recovery group was 37.5 ± 3.78%, and non-recovery group was 28.2 ± 4.6%. There was a significant role of the baseline LVEF (OR 2.11, CI95%, 1.207-3.691;p 0.009) towards recovery of the left ventricular function after adjusting age, parity, and hypertension in pregnancy. Mean baseline LVEDv index from both groups was 96.6 ± 30.9 ml/m2, with no significant difference (p 0.064) between recovery group (88.1 ± 26.2 ml/m2) versus non-recovery group (105.7 ± 33.3 ml/m2). Mean LVEDv index at 6 months from both groups was 75.8 ± 34.9 with significant difference (< p 0.001) between recovery group (51.3 ± 11.2 ml/m2), and non-recovery group (100.3 ± 3.4 ml/m2), and mean ΔLVEDv index from both groups was 21.06 ± 28.17 ml/m2 with significant difference (p < 0.001) between recovery group (36.8 ± 10.6 ml/m2) and non-recovery group (5.4 ± 4.5 ml/m2). Multivariate linear regression analysis showed significant role of the baseline LVEF towards improvement of left ventricular remodelling (b 2.14; p 0.004) after adjusting age, parity, and hypertension in pregnancy.

Conclusion: Baseline LVEF plays a significant role in recovery of left ventricular function and improvement of left ventricular remodelling in PPCM patients.

P1792

Echographic factors of atrial arrhythmia in patients with arrythmogenic right ventricular dysplasia

R Rim Ben Said[1]; A Zaroui[2]; MF Drissi[3]; H Zargouni[3]; R Mechmeche[3]
[1]*La Rabta hospital, cardiology, Tunis, Tunisia*; [2]*Institut Pasteur, Tunis, Tunisia*; [3]*Clinique Pasteur, tunis, Tunisia*

Background: Consequences of of atrial fibrillation (AF) on patients with arrhythmogenic right ventricular dysplasia (ARVD) is not well studied and predictive factors of these arrhythmias are not well defined. We aims to study transthoracic echocardiography (TTE) to predict AF in these patients

Methods and Results: TTEs of 40 patients diagnosed with definite ARVD (2010 Task Force Criteria) we reanalyzed. Data were compared in patients with AF and all other patients. A total of 10 (40%) patients experienced AF during a median follow-up of 4.5years. Kaplan-Meier analysis revealed, in patients presenting AF, reduced RV fractional area <27% (P < 0.001), larger left atrial volume > 45ml (P=0.001) (apical 4-chamber view), and higher right atrial volume ≥22 ml (P= 0.05) (apical 4-chamber view). 3 patients with AF experienced inappropriate implantable cardioverter-defibrillator (ICD) shocks compared with 4 without AF (36% vs. 9%, P=0.03). AF was more prevalent in the patients who present severe events like heart failure, Ventricular arythmia and death (42% vs. 8%, P=0.02)

Conclusions: Atrial fibrillation in ARVD is associated with worst prognostic like heart failure and cardiac death. Evidence of reduced RV function and atrial dilation are a strong predictors of this complication

P1793

Incidence, characteristics, risk factors and outcomes of supraventricular arrhythmias in Takotsubo cardiomyopathy

O Olivier Auzel[1]; HM Mustafic[2]; RH El Mahmoud[1]; RP Pilliere[1]; OD Dubourg[1]; NM Mansencal[1]
[1]*University Hospital Ambroise Pare, cardiology department, Boulogne-Billancourt, France*; [2]*Geneva University Hospitals, Cardiology, Geneva, Switzerland*

Funding Acknowledgements: Dr Auzel was supported by a grant from the Fédération Française de Cardiologie, Paris, France.

Background: Takotsubo cardiomyopathy (TTC) is a medical entity mimicking an acute coronary syndrome (ACS). During the acute phase, several complications may occur, even if the prognosis is generally favorable. Only small studies reported a description of supraventricular arrhythmia (SA) in TTC, and little is known about related incidence. We sought to describe the characteristics, incidence, predictive factors and outcomes of SA in patients presenting with TTC.

Methods: Over a twelve-year period, we reviewed all patients (n = 5484) referred to our coronary care unit (CCU) for a suspicion of ACS. All patients presented with a confirmed diagnosis of TTC and a normalization of left ventricular ejection fraction (LEVF) during follow-up. In CCU, all patients were continually monitored by 12-lead ECG to detect the occurrence of SA

Results: TTC was diagnosed in 88 patients according to the Mayo Clinic criteria, in sinus rhythm at the time of diagnosis. Incidence of SA among TTC was 14%. A difference was observed between patients with or without SA occurrence: age, hypertension, systolic pulmonary artery pressure and duration of hospitalization. Of note, patient with SA had significantly more depressed left ventricular ejection fraction at admission (p = 0.006). A large part of patient presenting SA required the use of diuretic for heart failure during hospitalization (p = 0.026). In multivariate analysis, the factors significantly associated with an increased risk of VA were: age (aOR = 1.19, 95% CI: 1.01 – 1.39, p = 0.029) and LEVF (aOR = 0.89, 95% CI: 0.8 – 0.97; p = 0.037). There was no significant difference in mortality rate between patients with or without SA during follow-up.

Conclusions: SA occurred in 14% of patients at the acute phase of TTC and independent predictive factors of SA were age and LEVF. During the acute phase, identification of high-risk SA patients allows better management, with ECG monitoring and therapeutic intervention in the CCU.

Chemotherapy-induced cardiotoxicity in a Colombian heart failure program

C I Clara Ines Saldarriaga[1]; JA Rivillas[1]; LA Fajardo[1]; C Gallego[1]; AM Agudelo[1]
[1]*Cardiovascular Clinic Santa Maria, Universityof Antioquia cardiology department, Medellin, Colombia*

Funding Acknowledgements: the study has the financial support of our hospital

Cardiovascular toxicity of antineoplastic chemotherapeutic agents is a leading cause of premature morbidity and death among cancer survivors.
Objective: To assess the prevalence, clinical features, treatment, and clinical outcomes in a cohort of patients with cardiovascular toxicity induced by chemotherapy in a Colombian heart failure program
Methods: Observational, retrospective study
Results: In 1.358 patients followed by the outpatient heart failure program over a 4 - year period, 23 patients were identified as affected by chemotherapy-induced cardiotoxicity (1.7% of the population) 78.2% were women with a mean age of 57.7 years. The most common cancers treated were breast (60%), lymphoma (21%), and rectal (8.6 %). Type I cardiotoxicity for anthracycline therapy was present in 65% of patients. Other agents identified were cyclophosphamide and traztuzumab Concomitant chemotherapy plus radiotherapy was identified in 73.9% of patients. Pre-chemotherapeutic preventive measures were implemented by oncology service in only 17% of patients. Mean time between chemotherapy and heart failure debut was 5 years. Mean LVEF at acceptance was 27% and 35% during follow-up. Follow-up time was 2.7 years, and LVEF improved in 69% of patients. Electric stimulation therapy was indicated in 26% of patients. Of these, 83% had a CRT-D, and 17% had a ICD. Beta-blockers, renin angiotensin aldosterone system inhibitor made part of the chronic treatment of all patients in our Study. Overall mortality was 17.3%.
Conclusions: In our population, most of our patients were young women with breast cancer that received the standard treatment recommended by ESC guidelines with an improvement in the EF. Heart failure programs are a good strategy for the follow up of patients with cardiotoxicity induced by chemotherapy

P1795

Cardiovascular monitoring and management in cancer patients: a french national survey

L Jovenaux[1]; J Cautela[1]; F Thuny[1]; F Paganelli[1]; F Barlesi[1]
[1]*Hospital Nord of Marseille, Marseille, France*

Background: Cancer treatments can cause serious cardiovascular adverse events consensual guidelines regarding this issue are lacking. The objective was to analyse pratices and knowledge of oncologists about the monitoring of cancer patients under cardiotoxic agents.
Methods: A survey of knowledge and professional practices was conducted among oncologists between august 2015 and august 2016.
Results: A cardiological assessment was almost systematic before the introduction of treatment (96% for anthracyclines and 99% for trastuzumab). However, the per-treatment (respectively 54% and 95%) and post-treatment (49% and 59%) assessments were less frequent and reserved for patients with high cardiovascular risk. The attitude of oncologists in case of left ventricular dysfunction was often heterogenous, whatever the molecules used, particularly for anti-angiogenic. The recommendations of learned societies were not known by 65% of oncologists. Finally, 88% of oncologists thought that the creation of cardio-oncology clinic could improve the management of cardiotoxicity.
Conclusion: The wide variation in practice among oncologists reflects a lack of consensus on the optimal strategy to manage cardiotoxicity. Guidelines exist but are not well known. The making available of tools of good practices among oncologists and cardiologists and a better collaboration between teams should allow equal access for patients to cardio-oncologic care.

P1796

Subgroups analyses of a prospective long-term study in patients with advanced cancer - the prognostic impact of elevated heart rate.

MS Anker[1]; N Ebner[2]; B Hildebrandt[3]; J Springer[2]; H Riess[3]; U Landmesser[1]; AJS Coats[4]; SD Anker[2]; W Haverkamp[5]; SV Haehling[2]
[1]*Charite - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany*; [2]*University Medical Center Gottingen (UMG), Department of Cardiology and Pneumology, Gottingen, Germany*; [3]*Charite - Campus Virchow-Klinikum (CVK), Department of Hematology and Oncology, Berlin, Germany*; [4]*University of Warwick, Coventry, United Kingdom*; [5]*Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany*

Introduction: Cardiovascular problems like heart failure are frequently observed in patients with advanced cancer. It is often associated with reduced exercise capacity and quality of life. Nevertheless, the role of the resting heart rate in advanced cancer patients remains unresolved. Previously, we have shown that an elevated heart rate in cancer patients had significant prognostic value. We have now conducted additional subgroup analyses.
Methods: We enrolled 145 patients with histologically confirmed cancer (46% female, age 59 ± 10 yrs, tumour stage I/II/III/IV 11/10/32/46%) from 2005 through to 2010, and 59 healthy controls (46% female, age 60 ± 11 yrs). The cancer group consisted of 36 patients with colorectal, 72 with pancreatic, and 37 with non-small cell lung cancer. A thorough cardiology assessment was performed at baseline including a resting ECG. Patients were followed to January 2017. During a mean follow-up of 34 months for all patients (maximum 126 months), 97 (66%) patients had died (1-year mortality 30% [95%CI 22-38%], 3-year mortality 63% [55-71%]).
Results: As demonstrated before, elevated heart rate ≥75 bpm in cancer patients was associated with an increased mortality also here (HR 1.68 [1.10-2.55], p = 0.017, Cox-proportional hazard analysis). In multivariable analyses this effect remained significant. We now identified four subgroups within this effect was significant as well. A body mass index ≤22.0 kg/m2, i.e. the lowest tertile (n = 49, 34 deaths, HR 2.22 [1.05-4.65], p = 0.036), female gender (n = 64, 41 deaths, HR 2.03 [1.06-3.89], p = 0.033), age < 59 years (n = 69, 46 deaths, HR 2.26 [1.14-4.46], p = 0.019), and without anaemia (haemoglobin ≥12.0 g/dL, n=55, 33 deaths, HR 2.98 [1.33-6.67], p = 0.008) were identified as the subgroups who showed a significantly increased mortality, if the heart rate was ≥75 bpm. Other subgroups of patients (high body mass index, male gender, presence of anaemia and higher age did not show these results (p>0.20), but lack of power may in part be the cause (all HRs: 1.25–1.44).
Conclusion: We have shown that the resting heart rate is an important parameter in predicting the patient's increased mortality. This association is particularly strong in patients with low body mass index, female gender, lower age as well as in those without presence of anaemia.

P1797

The cumulative effect of chemoradiotherapy in the risk of developing cardiotoxicity

AC Ana Catarina Gomes[1]; LR Lopes[1]; AG Ferreira[1]; M Correia[1]; I Rangel[1]; P Fazendas[1]; H Mansinho[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Introduction: Cardiotoxicity is an increasingly recognized side effect of chemotherapy (CT), dependent on the type and dose of drugs used as well as radiotherapy (RT).
Aim: To study the left and right ventricular systolic and diastolic function during CT and the specific effect of CT and RT in the risk of developing cardiotoxicity.
Methods: Prospective study including cancer patients submitted to anthracyclines ± taxanes ± RT ± trastuzumab and referred to echocardiographic monitoring (M-mode and 2D imaging, left ventricle ejection fraction (LVEF) and global longitudinal strain (GLS) evaluated by speckle tracking) at different timepoints during treatment: T0 – before CT, T1 and T2 - during CT, T3 – at the end of CT and T4 - 1 year after the end of CT.
Results: 108 patients, 79.6% females, age 52.47 ± 12.2 years. Breast cancer 69.4%, lymphoma 22.2%, gastric cancer 8.3%. Epirrubicine 52.3% and doxorrubicine 47.7%: cumulative dose 506 ± 222 mg/m2. Docetaxel 57.8% and paclitaxel 2.8%: cumulative dose 511 ± 111 mg/m2. 13.9% under trastuzumab. 50.5% submitted to RT - median 50GY. The LVEF progressively decreased during CT (T0 64.14 ± 4.63%, T1 62.09 ± 4.43%, T2 61.34 ± 4.57%, T3 59.93 ± 4.91% (all p < 0.001) with recover at T4: 62.27 ± 4.69 versus T3 (p = 0.027)). The left ventricle also had the same behaviour (SLG: T0 20.73 ± 2.68%, T1 19.53 ± 2.73%, T2 19.12 ± 2.45%, T3 18.38 ± 2.38%, T4 18.52 ± 2.40% (T0-T1 and T1-T2 p <0.001, T2-T3 p < 0.003, T3-T4 p = 0.242, T0-T4 p = 0.041) as well as the right ventricle (based in TAPSE): T0 22.89 ± 2.89 mm, T1 22.30 ± 3.51 mm, T2 22.20 ± 3.47 mm, T3 21.50 ± 3.18 mm, T4 21.41 ± 2.97 mm (p < 0.001 between T0-T1, T1-T2 and T3-T4; p = 0.019 in T0-T4). There was no difference in LVEF, GLS, TAPSE and tricuspid S' variation in the intervals T0-T3 and T0-T4, between patients with or without trastuzumab and/or RT. The RT was not associated with additional left ventricular systolic dysfunction but was associated to a higher variation of tricuspid S' between T0-T4 (p = 0.015), with comparable baseline values (p = 0.462). This difference was independent of anthracycline type (p = 0.72), tumor side (left versus right) (p = 0.246), age (p = 0.845), body mass index (BMI) (p = 0.91), cumulative dose of anthracyclines (p = 0.925) or taxanes (p = 0.989). The heart rate (HR) gradually increased during treatment: T0 76.82 ± 13.65 beats per minute (bpm), T1 78.96 ± 13.30 bpm, T2 80.91 ± 13.84 bpm, T3 83.70 ± 11.88 bpm

(T0 versus T3, p = 0.033). The HR variation (cutoff of 10 bpm) was not associated with gender (p = 0.669), age (p = 0.557), BMI (p = 0.579), type of cancer (p = 0.91), tumor grade (G1, G2, G3) (p = 0.226), dose of anthracyclines (p = 0.482) and taxanes (p = 0.70) and LVEF variation in T0-T3 (p = 0.106).
Conclusion: CT affects systolic biventricular function. RT with shielding was associated with RV systolic dysfunction but not significant LV systolic function variation. The HR increased during CT and was independent of cancer type, demographics and cumulative dose of anticancer drugs.

P1798
Risk factors for heart failure after epirubicin chemotherapy for breast or colorectal cancer

G Gyorgy Fogarassy[1]; A Vathy-Fogarassy[2]; L Hornyak[3]; T Forster[4]

Funding Acknowledgements: Hungarian Government through the project VKSZ 12-1-2013-0012 - Competitiveness Grant

Background: Appearance of dilated cardiomyopathy (DCM) is the most important limiting factor during anthracycline therapy. Incidence of DCM is highly dependent on anthracycline cumulative dose. In a published analysis, epirubicin treatment under dose of 800 mg/ m2 was associated with a low incidence of heart failure (HF). Patients older than 65 years are considered more susceptible for anthracycline-related HF.
Purpose: Our aim was to assess the incidence of HF after epirubicin therapy and to identify the risk factors for HF.
Methods: We conducted a retrospective nation-wide study using the anonymized financial database of the Hungarian National Health Insurance Company. The population and the outcome events were defined with the International Classification of Diseases (ICD) codes. We enrolled all the patients with breast- or colorectal carcinoma by histological confirmation between 1st January 2004 and 31st December 2015. 164 640 patients met enrollment criteria. For eligibility, we specified a chemotherapy-free run-in period of at least 3 years. The patients with assignment of I50 (HF), or I420 (DCM) ICD codes before index chemotherapy were excluded. HF outcome event was established by assignment of I50 ICD code at hospital discharge, or in autopsy report. HF event occurrence was analysed at the subjects with at least 3-year follow-up, or reaching the event earlier. We calculated chi^2 p values for different cumulative doses of concomitant chemotherapies to estimate the dose-dependency of HF. Multivariate binomial stepwise logistic regression was used to calculate odds ratios (OR) for HF.
Results: 8 796 epirubicin-treated patients were eligible for HF analysis. The cumulative incidence of HF was 7.1%. Incidence was highly dependent on epirubicin cumulative dose and age. Epirubicin dose over 709 mg/m2 was proven independent variable with significant association with HF (OR: 1.92, p = 0.007). Risk of HF increased with older age: OR for HF at age 50-59 was 1.84, at age 60-69 was 2.71 and at age over 70 was 5.16, compared to those under 40. The only chemotherapy, besides epirubicin, with cumulative dose-dependency of HF was docetaxel (dose> 510 mg/m2, OR: 1.49, p = 0.034). Other independent variables with significant association with HF (p values ≤0.05) were diabetes mellitus (OR: 1.69), coronary disease (OR: 1.41), capecitabine (OR: 1.45), gemcitabine (OR: 1.73), bevacizumab (OR: 1.49), at paclitaxel a trend to higher HF incidence (OR: 1.23, p = 0.07) was found. Presence of trastuzumab, panitumumab, cetuximab, antifolates, folinic acid, cyclophosphamide, mitomycin, topoisomerase-inhibitors, platinum-containing drugs, vinca alkaloids and dexrazoxane had no significant impact on HF.
Conclusion: We found significant elevation of HF incidence with increasing age, even over 50 years and with epirubicin cumulative dose over 709 mg/m2. The presence of capecitabine, gemcitabine, taxanes and bevacizumab in the treatment was associated with higher risk for HF.

P1799
Improving ventricular function in patients with severe ventricular dysfunction previous to kidney transplantation.

C G Cesar Gerardo Martinez Hernandez[1]; E Toxqui[1]; J Silva[1]; D Ramos[1]; F J Marin[1]; A A Gordillo[1]; F J Rodriguez Quilantan[1]
[1]Mexican Social Security Institute, Internal Medicine - Cardiology, San Luis Potosi, Mexico

Introduction: There is a strong correlation between end stage kidney disease and congestive heart failure associated to severe left ventricular dysfunction. We know now that mortality at three years after hospitalization for congestive heart failure is similar to after acute myocardial infarction. There have been several works evaluating management of left ventricular dysfunction previous to kidney transplantation and an improving of left ventricular function after that is expected. We know that not all the patients improves it and the minor left ventricular function improving, the highest perioperative complications rate and lack of surveillance.
Purpouse: We studied the effect of improving left ventricular function with inotropic agent (levosimendan) previous to kidney transplantation and mobidity/mortality associated to surgery in order to reduce them, and secondary, left ventricular function restoration in order to improve surveillance and life quality.
Methods: We included 6 patients ongoing to kidney transplantation with severe left ventricular dysfunction defined as ejection fraction less than 35%. We practiced a biplanar echocardiography to assess left ventricle ejection fraction pre and post inotropic agent administration. We administered levosimendan with the following scheme: a loading dose of 6mcg/kg/min in a 10 minutes infusion followed by a manteining dose of 0.05mcg/kg/min in a 48 hours infusion. After this, the patients went to a living donor kidney trasnplantation surgery.
Results: The mean ejection fraction was 27.8% pre inotropic agent and the mean ejection fraction post inotropic agent was 51.1%. The morbidity of cardiovascular and all causes was less between those patients with best ventricular function defined by acute pulmonary oedema, cardiogenic shock, miocardial infarction, stroke, acute renal failure or kidney reject. There were no mortality associated to kidney tranplantation. The mean hospitalization days was 7.
Conclusions: Improving ventricular function with inotropic agent before kidney transplantation may reduce morbidity and mortality associated to this one.

P1801
Different clinical profile in heart failure patients with chronic kidney disease

Z Blazquez Bermejo[1]; D Iglesias Del Valle[1]; E Garcia[1]; J De Juan[1]; E De La Cruz[1]; R Cadenas[1]; V Martinez[1]; E Prieto[1]; R Cano[1]; C Casanova[1]; A Garcia[1]; A Martin[1]; I Plaza[1]
[1]University Hospital Infanta Sofia, Cardiology, Madrid, Spain

Introduction: The prevalence of moderate to severe chronic kidney disease (CKD) in heart failure (HF) is as high as 30-60%. The baseline glomerular filtration rate (GFR) is a predictor of mortality in both acute and chronic HF.
Purpose: The aim of this study was to analyze the different clinical characteristics in HF depending on the GFR.
Methods: 112 patients with HF diagnosis were prospectively included in the HF unit at our institution between May 2014 and December 2016. We identified patients with moderate to severe CKD (GFR with the CKD-EPI equation < 60mL/min/1.73m2) at the time of inclusion. Clinical characteristics and medical treatment were compared among patients with and without CKD. Patients were systematically followed-up in the HF outpatient clinic. All changes in clinical status, admissions or deaths were documented. Kaplan-Meier estimates was used to analyze time to first HF admission or death from any cause.
Results: Mean age was 64.3 ± 13.2 years. 35.2% of patients had CKD at baseline. Clinical characteristics and medical treatment were different in these patients (table). Median follow-up was 13 ± 8.4 months. HF admission-free survival was lower in CKD patients (p = 0.017) (figure).
Conclusions: HF patients with moderate to severe CKD are older, have preserved LVEF more often, have more comorbidity and are less likely to receive optimal medical therapy. CKD patients have worse prognosis; nevertheless, these patients are associated with an increased risk profile, which may partly explain the higher risk.

Clinical characteristics and treatment

	GFR CKD-EPI >60ml/min/ 1.73m2	GFR CKD-EPI < 60ml/min/ 1.73m2	
Age (years)	60.0±12.8	72.0±10.4	p < 0.01
Male (%)	72.2	67.5	p = 0.60
Arterial hypertension (%)	59.7	77.5	p = 0.06
Diabetes mellitus (%)	26.4	55.0	p < 0.01
Significant coronary artery disease (%)	29.2	52.5	p = 0.02
COPD (%)	15.3	20.0	p = 0.52
PAD (%)	4.2	25.0	p < 0.01
Anemia (%)	20.8	40.0	p = 0.03
LVEF < 40% (%)	88.9	72.5	p = 0.03
Beta-blockers (%)	98.6	77.5	p < 0.01
ACE-I or ARB or ARNI (%)	91.7	77.5	p = 0.04
MR antagonist (%)	79.2	62.5	p = 0.06

Cardiorenohepatic syndrome is common in patients with decompensated heart failure

A Soloveva[1]; S Villevalde[1]; Z Kobalava[1]
[1]RUDN University, Department of Internal Disease Propaedeutics, Moscow, Russian Federation

Objective: Similar factors such as venous congestion and hypoperfusion are thought to underlie both renal and liver injuries in decompensated heart failure (DHF), known as cardiorenal syndrome (CRS) and cardiohepatic syndrome (CHS). The aim of this study was to assess the prevalence and predictors of combination of CRS and CHS in DHF.
Methods: Kidney and liver function was assessed in 322 patients with DHF (190 male, 69.5 ± 10.6 years (M ± SD), arterial hypertension 87%, myocardial infarction 57%, atrial fibrillation 65%, diabetes mellitus 42%, known chronic kidney disease 39%, chronic anemia 29%, left ventricular (LV) ejection fraction (EF) 37.6 ± 12.6%, EF<35% 39.1%). CRS was diagnosed if serum creatinine decreased ≥26.5 μmol/l in first 48 hours of hospitalization. CHS was considered when at least one of liver function tests (LFT) level exceeded upper normal limit on admission. Simultaneous CHS and CRS were considered as cardiorenohepatic syndrome (CRHS). Mann-Whitney test and multivariate logistic regression analysis were performed. $p < 0.05$ was considered statistically significant.
Results: CRS occurred in 60 (18,6%) patients. CHS was diagnosed in 274 (85.1%) patients. Isolated CHS, isolated CRS and CRHS occurred in 78.4, 1.5 and 20.1% patients with hepatic or kidney injury. Patients with versus without CRHS had lower systolic blood pressure (SBP) (130 ± 18 vs 138 ± 19 mmHg, $p < 0.01$), EF (32 ± 10 vs 38 ± 13%, $p < 0.01$), pulse BP (49 ± 16 vs 56 ± 15 mmHg, $p < 0.01$), higher LV mass index (200 ± 50 vs 178 ± 52 g/m^2, $p < 0.01$), LV end diastolic volume (62 ± 6 vs 56 ± 9 mm, $p < 0.001$), higher incidence of severe mitral regurgitation (64.3 vs 39.6%, $p < 0.001$), signs of congestion – jugular venous distension (57.1 vs 39.6%, $p < 0.05$), hepatomegaly (85.7 vs 70.3%, $p < 0.05$), echo-hydropericardium (46.4 vs 22.5%, $p < 0.001$), vasopressor therapy (17.9 vs 6.3%, $p < 0,01$). The independent predictors of CRHS were baseline GFR<45 ml/min/1.73 m^2 (odds ratio (OR) 3.95, 95% confidential interval (CI) 2.15-7.21, $p < 0.01$), SBP<110 mmHg on admission (OR 3.51, CI 1.55-7.94, $p < 0.05$), vasopressor therapy (OR 3.23, CI 1.35-7.73, $p < 0.05$), echo-hydropericardium (OR 2.98, CI 1.62-5.50, $p < 0.01$) and EF<35% (OR 2.96, CI 1.61-5.44, $p < 0.05$).
Conclusions: Isolated CHS, isolated CRS and CRHS occurred in 78.4, 1.5 and 20.1% patients with DHF and hepatic or kidney injury. The independent predictors of CRHS were baseline GFR<45 ml/min/1.73 m^2, SBP<110 mm Hg on admission, echo-hydropericardium and EF<35%.

Background: Skeletal and respiratory muscle dysfunction (specific myopathy) constitutes an important pathophysiological feature of heart failure syndrome. We assessed the relationships between respiratory muscle function, skeletal muscle mass, and physical fitness in men with heart failure with reduced ejection fraction (HFrEF), and investigated the hypothesis of whether iron deficiency contributes to respiratory muscle dysfunction in these patients.
Methods: We examined 53 male outpatients with stable HFrEF without asthma or chronic obstructive pulmonary disease (age: 64 ± 10 years; New York Heart Association [NYHA] class I/II/III: 36/51/13%; ischaemic aetiology of HFrEF: 83%; all patients with left ventricular ejection fraction [LVEF] ≤40%) and 10 middle-aged healthy men (control group). We analyzed respiratory muscle strength (maximal inspiratory and expiratory pressure at the mouth [MIP and MEP, respectively]), appendicular lean mass (ALM; reflects appendicular skeletal muscle mass; measured using dual-energy X-ray absorptiometry), physical fitness (components of Functional Fitness Test [FFT] for Older Adults - "Up and go", "Chair stand", and "Arm curl", and 2-minute step test), and parameters of iron status.
Results: MIP, MEP, ALM adjusted for body mass index (ALM/BMI), and MIP adjusted for ALM/BMI were lower in men with HFrEF vs. healthy men (74 ± 23 vs. 106 ± 33 cm H2O, $p < 0.001$; 122 ± 23 vs. 161 ± 28 cm H2O, $p < 0.001$; 81 ± 10 vs. 96 ± 11 100*m^2, $p < 0.001$; and 93 ± 27 vs. 117 ± 40 cm H2O/m^2, $p = 0.04$; respectively). MIP (but not MEP) and MIP adjusted for ALM/BMI (but not ALM/BMI) were lower in men with HFrEF with ID compared with those without ID (67 ± 20 vs. 106 ± 33 cm H2O, $p = 0.02$; and 84 ± 22 vs. 103 ± 28 cm H2O/m^2, $p = 0.02$; respectively). In univariable linear regression analyses MIP was related to (all $p < 0.05$): LVEF (r=0.31), ALM/BMI (r=0.35), N-terminal pro B-type natriuretic peptide (NT-proBNP, r=-0.30), haemoglobin (r=0.35), mean corpuscular haemoglobin (r=0.36), serum ferritin (r=0.41), the presence of ID (r=-0.32), reticulocyte haemoglobin content (r=0.45), and percentage of hypochromic red cells (r=-0.31). In a multivariable linear regression model lower serum ferritin remained an independent predictor of lower MIP when adjusted for ALM/BMI, LVEF, NT-proBNP, and haemoglobin (β=0.36, $p = 0.017$, corrected R^2=34%). Importantly, in multivariable linear regression models, lower MIP was also an independent predictor of worse results in FFT when adjusted for ALM/BMI or relevant clinical variables (NYHA class, estimated glomerular filtration rate, NT-proBNP, and haemoglobin).
Conclusions: In men with HFrEF decreased iron stores (as reflected by low circulating ferritin) predict inspiratory muscle weakness independently of skeletal muscle mass. Importantly, the dysfunction of inspiratory muscles in these patients is associated with worse physical fitness independently of either skeletal muscle mass or disease severity.

P1804

Iron deficiency predicts decreased exercise capacity and physical fitness independently of skeletal muscle mass in men with heart failure with reduced ejection fraction

M Michal Tkaczyszyn[1]; M Drozd[1]; K Wegrzynowska-Teodorczyk[2]; A Czarniawska[3]; R Krajewski[3]; TH Menghis[3]; R Rydzyk[3]; U Szydelko[3]; P Wojcik[3]; W Banasiak[4]; P Ponikowski[1]; EA Jankowska[1]
[1]Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland; *[2]University School of Physical Education of Wroclaw, Department of Physiotherapy, Wroclaw, Poland*; *[3]Wroclaw Medical University, Students' Scientific Association, Department of Heart Diseases, Wroclaw, Poland, Wroclaw, Poland*; *[4]Military Hospital, Cardiology Department, Centre for Heart Diseases, Wroclaw, Poland*

Funding Acknowledgements: Financially supported by the National Science Centre (Poland) grant allocated on the basis of the decision number DEC-2012/05/E/NZ5/00590

BACKGROUND: In patients with heart failure concomitant iron deficiency (ID) is associated with decreased exercise capacity. Another important predictor of reduced functional capacity in these patients is skeletal muscle mass loss. We investigated the hypothesis of whether in men with heart failure with reduced left ventricular ejection fraction (HFrEF) ID predicts decreased exercise capacity and physical fitness independently of indices of skeletal muscle mass loss.
Methods: We examined 49 male outpatients with stable HFrEF (age: 65 ± 11 years; New York Heart Association [NYHA] class I/II/III: 39/45/16%; ischaemic aetiology of HFrEF: 86%; all patients with left ventricular ejection fraction [LVEF] ≤40%). We analyzed exercise capacity (6-minute walking test distance - 6MWD), physical fitness

(components of Functional Fitness Test [FFT] for Older Adults - "Up and go", "Chair stand", and "Arm curl" tests, and 2-minute step test [2MST]), indices of skeletal muscle mass (measured using dual-energy X-ray absorptiometry), and parameters of iron status.
Results: Soluble transferrin receptor (sTfR) correlated with 6MWD (r=-0.063, p < 0.001), "Up and go" (r=0.51, p = 0.001), "Chair stand" (-0.56, p < 0.001), "Arm curl" (r=-0.36, p = 0.03), and 2MST (r=-0.45, p = 0.004); serum ferritin - with "Up and go" (r=-0.39, p = 0.008), "Chair stand" (r=0.41, p = 0.005), "Arm curl" (r=0.46, p = 0.002), and 2MST (r=0.39, p = 0.008); and the presence of ID (serum ferritin < 100 μg/L or serum ferritin 100-299 μg/L in combination with transferrin saturation < 20%) - with "Up and go" (r=0.31, p = 0.04), "Chair stand" (r=-0.30, p = 0.046), and "Arm curl" (r=-0.44, p = 0.003). Appendicular lean mass/total lean mass (ALM/TLM) correlated with 6MWD (r=0.44, p = 0.002), "Up and go" (r=-0.34, p = 0.02), "Chair stand" (r=0.37, p = 0.01), and 2MST (r=0.30, p = 0.04); and appendicular lean mass/body mass index (ALM/BMI) with 6MWD (r=0.43, p = 0.003), "Up and go" (r=-0.38, p = 0.009), "Chair stand" (r=0.30, p = 0.04), and 2MST (r=0.34, p = 0.02). In multivariable linear regression models lower serum ferritin was associated with worse results in "Up and go" (β=-0.31, p = 0.045), "Chair stand" (β=0.32, p = 0.04), "Arm curl" (β=0.32, p = 0.03), and 2MST (β=0.42, p = 0.01) independently of skeletal muscle mass (ALM/BMI) and relevant clinical variables (age, haemoglobin, estimated glomerular filtration rate, N-terminal pro-B-type natriuretic peptide, NYHA class). Similarly, higher sTfR was associated with worse results in "Up and go" (β=0.40, p = 0.03) and "Chair stand" test (β=-0.39, p = 0.03), and with shorter 6MWD (β=-0.59, p < 0.001) independently of skeletal muscle mass (ALM/TLM) and aforementioned clinical variables.
Conclusions: In men with HFrEF disordered iron homeostasis is associated with decreased exercise capacity and physical fitness independently of generalized skeletal muscle mass loss.

On behalf of: ASIAN-HF
Funding Acknowledgements: Boston Scientific Investigator Sponsored Research Program, National Medical Research Council of Singapore, A*STAR Biomedical Research Council, Bayer

Background: Anaemia is an important comorbidity in patients with heart failure (HF) in Western populations and is associated with worse outcomes; however data are scarce in multi-ethnic Asian populations.
Aim: To examine the ethnic/geographical variation in prevalence, clinical correlates and prognostic impact of anaemia in Asian patients with HF.
Methods: Asian patients with HF (ejection fraction ≤40%) and anaemia, defined as haemoglobin (Hb) < 13g/dL (men) and < 12g/dL (women) from 11 regions (China, Hong Kong, India, Indonesia, Japan, Korea, Malaysia, Philippines, Singapore, Taiwan, Thailand) enrolled in the ASIAN-HF study were identified. Ethnic groups included Chinese (33.0%), Indian (26.2%), Malay (15.1%), Japanese/Korean (20.2%), and Others (5.6%).
Results: Of the 3886 Asian HF patients (60 ± 13 years, 21% women), 41% were anaemic, with wide variation across ethnicities (32.6-54.4%) (Figure 1A). Indian ethnicity (adjusted OR 3.00; 95% CI 2.17-4.17), age (adjusted OR 1.03; 95% CI 1.02-1.03), presence of diabetes (adjusted OR 1.75; 95% CI 1.47-2.08) and chronic kidney disease (CKD) (adjusted OR 1.71; 95% CI 1.44-2.03) were independently associated with presence of anaemia (all P < 0.001). Ethnicity modified the association of CKD with anaemia (Pinteraction=0.045), with the strongest correlation observed in Japanese/Koreans (adjusted OR 2.86; 95% CI 1.96-4.20; P < 0.001). Anaemic patients had lower Kansas City Cardiomyopathy Questionnaire scores (P < 0.001) and a higher composite endpoint of all-cause mortality and HF hospitalisation at 1 year (25.4% vs. 19.7%, P < 0.001) compared to non-anaemic patients (Figure 1B). The independent association of this composite endpoint with anaemia was modified by ethnicity (Pinteraction=0.02) and was highest in Japanese/Koreans (multivariable HR 1.82; 95% CI 1.14-2.91; P=0.012).
Conclusion(s): This first multi-ethnic Asian HF study shows that anaemia is highly prevalent and adversely impacts quality of life and survival, with striking ethnic differences that deserve further study.

Both heart failure with reduced ejection fraction (HFrEF) and diabetes mellitus (DM) constitute co-morbidities significantly interfering with iron metabolism. It remains unclear whether and how the concomitance of DM in patients with HFrEF affects iron status.
Methods: We analysed the data of 622 men with stable HFrEF (age: 57 ± 11 years, CAD: 71%, NYHA class III-IV: 41%, LVEF: 27 ± 8%, DM: 30%). ID was defined as serum ferritin <100 μg/L, or serum ferritin 100-299 μg/L with transferrin saturation [TSAT] <20%. Additionally, serum levels of hepcidin and soluble transferrin receptor [sTfR] were assessed as biomarkers of iron status.
Results: Patients with DM as compared with those without DM were older, more obese, had more prevalent CAD, more symptomatic HF, more common hypertension and worse kidney function (all p < 0.05), but with no difference in LVEF, uric acid, hsCRP, NT-proBNP and haemoglobin level between these 2 groups. Regarding iron status, men with HFrEF and DM as compared with those without DM demonstrated a similar prevalence of ID (33% vs 34%, p>.2), and a trend towards a higher prevalence of IDA (13%, vs. 9%, p = 0.08). There were no differences in either serum ferritin or TSAT between DM and non-DM men with HFrEF (p > 0.2), whereas DM was accompanied by reduced sTfR (1.19 (0.96-1.60) vs. 1.31 (1.01-1.83) mg/L, p < 0.05), and a borderline higher hepcidin (65 (33-123) vs. 55 (22-111) ng/mL, p = 0.07). STfR > =1.32 mg/L was found in 50% vs 41% of DM vs non-DM men with HFrEF, respectively (p < 0.05), whereas serum hepcidin <14.5 ng/mL was found in 18% vs 5% of DM vs non-DM men with HFrEF, respectively (p < 0,001). In non-DM men with HFrEF, lower hepcidin was related to younger age, whereas such relationship was not seen in DM subjects. In non-DM men with HFrEF, higher sTfR correlated with lower LVEF, sodium, GFR, and total cholesterol, and higher hs-CRP, NT-proBNP and uric acid (all p < 0.05), whereas in DM subjects sTfR was related only to hs-CRP, NT-proBNP, uric acid and total cholesterol (all p < 0.05).
Conclusions: DM does not differentiate iron status in men with HFrEF based on standard biomarkers (ferritin, TSAT), however the measurements of sTfR and hepcidin suggest the higher prevalence of intracellular ID (reflected by high sTfR) and depleted iron stores (reflected by low hepcidin). Importantly, there are different clinical correlates of novel iron status biomarkers in DM vs non-DM subjects with HFrEF, which might indicate the different pathophysiological mechanisms related to these iron derangements.

P1807

Iron status in patients with heart failure with reduced ejection fraction across different age groups

M Drozd[1]; M Kasztura[1]; M Tkaczyszyn[1]; P Rozentryt[2]; J Nowak[2]; L Polonski[2]; J Malyszko[3]; E Koc-Zorawska[3]; W Banasiak[4]; P Ponikowski[5]; EA Jankowska[1]

Funding Acknowledgements: Financially supported by the National Science Centre (Kraków, Poland) grant allocated on the basis of the decision number DEC-2014/13/B/NZ5/03146

Background: Iron deficiency is a common and ominous co-morbidity in patients with heart failure with reduced ejection fraction [HFrEF]. However, it remains enigmatic whether and how ageing interacts with iron status in this group of patients. The aim of this study was to investigate iron parameters and clinical status in different age groups of patients with HFrEF.
Methods: We analysed the data of 736 stable patients with HFrEF (age: 58 ± 11 years, men: 86%, confirmed coronary artery disease: 71%, New York Heart Association [NYHA] Class III-IV: 44%, LVEF [left ventricular ejection fraction]: 28 ± 8%. ID was defined as serum ferritin < 100 μg/L, or serum ferritin 100-299 μg/L with transferrin saturation [TSAT] < 20%. Additionally, hepcidin and soluble transferrin receptor [sTfR] were assessed in peripheral blood as biomarkers of iron status, reflecting iron stores and intracellular iron status, respectively. All patients were prospectively divided into 4 age groups: < 50 (n = 148), 50-59 (n = 301), 60-69 (n = 174), ≥70 years (n = 113), respectively.
Results: There was a trend towards the higher prevalence of ID in elderly patients with HFrEF (36%, 30%, 40% and 41% - in aforementioned respective age groups, p = 0.07). There were no differences in TSAT, sTfR, MCV, MCH, MCHC, hsCRP and NT-proBNP between patients in different age groups (all p>0.2). The older the patients, the higher prevalence of ID-related anaemia (IDA) (4%, 7%, 16% and 14% - in aforementioned respective age groups, p < 0.01). Elderly patients with HFrEF were characterized by lower haemoglobin (14.5 ± 1.6, 14.2 ± 1.4, 13.8 ± 1.5, 13.2 ± 1.4 g/dL, p < 0.0001), ferritin (199 (98, 310), 170 (106, 296), 167 (89, 277), 144 (72, 241 ng/mL) , p < 0.05) and hepcidin (79 (43, 133), 52 (30, 111), 68 (31, 127), 46 (25, 93 ng/mL) , p < 0.05) and higher eGFR (95 ± 27, 79 ± 22, 70 ± 21, 65 ± 31 mL/min/1.73m2, p < 0.01).
Only among patients with HFrEF aged below 50 years, iron-deficient subjects demonstrated high NT-proBNP and low LVEF as well as high uric acid as compared to those with preserved iron status (all p < 0.05), also in this group sTfR was related with uric acid (r=0.2, p < 0.5) and NT-proBNP (r=0.35, p < 0.001), and Tsat correlated with NT-proBNP (r=0.21, p < 0.05). Only among patients with HFrEF aged below 60 years, iron-deficient subjects demonstrated high hsCRP as compared to those without ID (p < 0.05), which was not seen in older age groups. Also patients with HFrEF and ID aged below 70 years had lower total cholesterol as compared to those with preserved iron status (all p < 0.05).
Conclusions: Elderly patients with HFrEF are prone to develop ID and IDA, and ID is reflected mainly by depleted iron stores (as assessed by low serum levels of both ferritin and hepcidin). There are clinical differences in younger versus older iron-deficient patients with HFrEF, which may presume the diverse pathophysiological background in these separate age groups.

P1808

Anemia in heart failure is associated with higher CA 125, NT-proBNP and hsCRP levels

ME Altinbas[1]; Y Yuksel Cavusoglu[1]; F Mutlu[1]; E Babayigit[1]; K Isgendarov[1]; S Eraslan[1]
[1]*Eskisehir Osmangazi University, Eskisehir, Turkey*

Purpose: Anemia is very common in heart failure (HF). Plasma levels of carbohydrate antigen 125 (CA-125) have been shown to correlate with clinical, hemodynamic, and echocardiographic parameters in HF. Higher level of hsCRP is known to be present in the inflammatory process of HF. NT-proBNP is a well-known biomarker of neurohormonal activation in HF. In this study, we aimed to evaluate the relationship between anemia and plasma levels of CA-125, hsCRP or NT-proBNP levels.
Methods: A total 446 patients with the diagnosis of HF, NYHA II-IV, LVEF < 40% and >18 years of age were included in this study. Plasma levels of CA-125, hsCRP or NT-proBNP levels have been measured from the blood samples. Anemia was defined as hemoglobin levels < 12 gr/dL in females and < 13 gr/dL in males. Patients were classified into two groups: patients with anemia (n = 223) and patients without anemia (n = 223).
Results: Mean age of study population was 67 ± 12 years. Mean EF was 25.4 ± 7.9%. Plasma levels of CA-125 were found to be significantly higher in patients with anemia as compared to those without anemia (56.3 [20.8-130.6] U/mL vs 24.5 [12.5-61.1] U/mL, p < 0.001, respectively). NT-proBNP and hsCRP levels were also found to be significantly higher in patients with anemia as compared to those without anemia (6594 [2535-19250] pg/mL vs 1740 [581-4397] pg/mL, p < 0.001 for NT-proBNP and 18 [8.14-43.04] mg/L vs 8.09 [3.45-21.45] mg/L, p < 0.001 for hsCRP, respectively). Furthermore, a significant positive correlation was found between CA-125 and NT-proBNP (r=538, p < 0.001), and also between CA-125 and hsCRP levels (r=225, p < 0.001).
Conclusions: The results of this study showed that anemia in HF is associated with higher CA-125, NT-proBNP and hsCRP levels, suggesting more severe clinical status of the disease in HF patients with anemia as compared those without anemia.

Iron stores and prognosis in a cohort of elderly patients with heart failure and preserved ejection fraction

B Nieto Sandoval[1]; J A Jose Satue[1]; A Perez Martin[1]; JC Belinchon Paraiso[1]; S Gonzalo Pascua[1]; J Marrero Frances[1]; A San Martin Prado[1]; C Gutierrez Landaluce[1]; A Zapatero Gaviria[1]
[1]*University Hospital of Fuenlabrada , Fuenlabrada, Spain*

Background: Iron deficiency and anemia are frequent in Heart Failure with reduced ejection fraction (HF-REF) patients, and are related with a worse prognosis, but there are still few data about its prevalence and prognosis in patients with preserved ejection fraction (HF-PEF). The aim of this study is to determine Iron Deficiency and anemia prevalence, and its relationship with prognosis in a cohort of elderly HF-PEF patients.
Patients and methods: All consecutive patients included into our Hospital HF Care Program after having a HF admission from June 2011 to June 2014 were prospectively recruited and followed up in consult and/or by telephone until June 2015. Demographic data, cardiovascular risk factors, Barthel, Lawton and Pfeiffer scores, clinical, biochemical parameters, treatments at discharge (including oral and/or endovenous iron), new admissions and/or death were registered in a specific database integrated in our electronic medical record system. Anemia and iron deficiency were classified following standard ESC criteria.
Results: 173 patients were included during this period. Mean age was 79.8 years (DS 8 years), 113 (65,3%) were women, mean Charlson score was 2.9 and mean Barthel was 84.1%. Ejection fraction (EF) was measured by echocardiography in 170 (98%) patients; 82 % of patients (139) had HF-PEF (EF >50%), HF-PEF patients were slightly younger, usually women, and had statistically significant higher BMI and lower NT-proBNP levels than non-HF-PEF patients. Mean follow-up was 649 days. 48 (27.7%) patients died during follow up, 33 of them having HF-PEF (23.7% of this cohort). 82 patients (48%) had a readmission during first year of follow up. Iron status was registered in 154 patients (89%); anemia was present in 85 (63%) of HF-PEF patiens, iron deficiency in 92 (67%) and absolute iron deficiency in 67 (48%). Anemia was statistically related to male sex and lower iron levels and transferrin saturation, but higher serum ferritin (165 vs 124, p = 0.28 NS) Increased mortality in our HF-PEF patients was statistically related in univariate analysis with age, previous hospital admissions, dependence in Barthel score, low albumin level, high ferritin level and non use of betablockers. Using a composite end-point of heart failure readmission during first year of follow up or death, lower Barthel Score and albumin values, higher NT pro-BNP and ferritin level, and absence of iron deficiency, had an statistically significant worse prognosis. No one of the treatments registered produced any change in this composite outcome, including betablockers, aldosterone antagonist and oral and/or endovenous iron.
Conclusions: Anemia and Iron Deficiency are usual findings in our elderly HF-PEF patients. In contrast of evidence yet published in HF-REF patients, isolated anemia and/or iron deficiency didn't show a worse prognosis in our patients, and higher levels of ferritin were associated with poor outcomes

P1810

Anemia in heart failure - The underdog of risk predictors?

A Alanoud Alsaud[1]; DALIA Ali[1]; DALIA Ali[1]; IYAD Farah[1]; IYAD Farah[1]; M Bdeir[1]; M Bdeir[1]; A Alameen[1]; A Alameen[1]; A Mahmoud[1]; A Mahmoud[1]
[1]*National Guard Hospital, Cardiovascular Disease Management Program, Riyadh, Saudi Arabia*

Background/Aim: Anemia is frequent in chronic heart failure and has shown to reduce survival in heart failure, particularly in patients with reduced ejection fraction. However, there is paucity of such data in a Saudi heart failure population.
Methods: We studied patients enrolled in a dedicated Heart Failure Disease Management Programme (n = 2727, 72% male). Clinical characteristics and mortality data were analysed for the entire cohort and categorized using WHO Classification of anaemia. Categorical variables were presented as percentages, compared by chi-square test and expressed as odds ratio and 95% confidence intervals. Continuous data were summarized as mean ± SD. Relationship between parameters was analysed using regression analysis. Survival analysis was performed using Kaplan Meir curves. Data was analysed using JMP(SAS for Windows and p < 0.05 considered significant.
Result: Some 35% patients had anemia, of which 10% was severe. Some 20% had Hb>15 g/dl. Patients with anemia were older, more likely to be NYHA Class II-III, have renal impairment and reduced ejection fraction (all p < 0.0001). Anemic patients were

less likely to receive ACEI, beta blockers, aldosterone antagonists (all $p < 0.001$) and more likely to be on diuretics, vasodilators and anti-platelets (all $p < 0.001$). Anemic patients had significantly reduced survival (log rank $p < 0.0001$), as shown by Kaplan Meir curve analysis.
Conclusion: Anemia is quite prevalent in a Saudi heart failure population with a significant preponderance in older patients with significant comorbidities. It is also associated with poor survival compared with those with normal haemoglobin levels.

P1811
Clinical benefits of intravenous iron therapy in patients with defibrillator due to heart failure with left ventricular dysfunction.

A Ruiz-Salas[1]; MA Miguel Antonio Lopez Garrido[1]; A Robles-Mezcua[1]; N Gonzalez-Cruces[1]; L Morcillo-Hidalgo[1]; JM Garcia-Pinilla[1]; JJ Gomez-Doblas[1]; E De Teresa-Galvan[1]; J Alzueta-Rodriguez[1]
[1]*University Hospital Virgen de la Victoria , Department of Cardiology, Malaga, Spain*

Background: Iron deficiency is a commonly present comorbidity in patients with advanced heart failure (HF), and contributes to the existence of a higher mortality and worse quality of life. Many of these patients have high energy devices with remote monitoring that transmit arrhythmic episodes and a series of clinical parameters that try to anticipate the cardiac clinical deterioration and improve the prognosis. We conducted this study in order to know the clinical benefits of intravenous iron therapy in this population.
Methods: We studied all the HF patients with NYHA functional class II-III and iron deficiency which were carriers of high-energy devices (ICD and ICD-CRT) with remote monitoring and who received intravenous iron therapy with ferric carboxymaltose in the years 2012-2015. We recorded their clinical characteristics, parameters of remote monitoring and adverse events during 3 months follow-up.
Results: We studied 32 patients (65 years, 30% women). We observed an improvement in NT-proBNP values at three months of intravenous iron treatment (2369 mg/dL vs 1510 mg/dL, $p = 0.01$). Mean heart rate at night was lower after three months of the treatment (73bpm vs 69bpm, $p = 0.024$), without significant differences in mean heart rate during the day (75bmp vs 72 bmp, $p = 0.2$), number of ventricular extrasystoles (138 vs 136, $p = 0.17$), ventricular doublets (54 vs 45, $p = 0.25$), and non-sustained ventricular tachycardia (8.3 vs 0.2, $p = 0.29$), although a reduction of these was observed after the three months of treatment. An increase in the number of hours of physical exercise performed was objetified after the intravenous treatment (2.2 vs 2.6, $p = 0.021$). Comparing the number of HF decompensations in the year prior to treatment with the events in the subsequent follow-up (decompensation of HF and/or death), a statistically significant reduction was observed (51.4% vs 12.9%, $p < 0.001$). There were no complications associated with the infusion and all patients had good treatment tolerance.
Conclusions: 1. We observed a tendency to reduce the mean heart rate and the number of ventricular extrasystoles and non-sustained ventricular tachycardias assessed by remote monitoring at 3 months of the treatment.
2. After the treatment the patients realized more physical activity and had less decompensations of HF.

P1812
Anaemia and iron deficiency in Heart Failure: role of chronic anticoagulant and antiplatelet therapies.

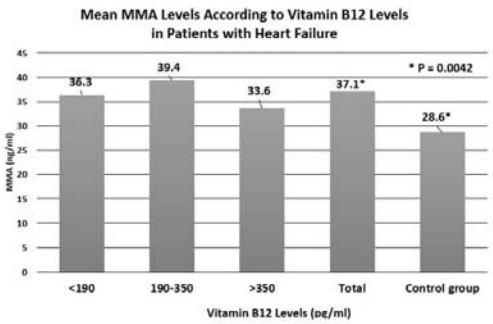
F Nicoli[1]; C Vignati[2]; A Del Torto[1]; N Corrieri[1]; A Bonomi[2]; T Calogero[2]; M Mapelli[2]; D Brusoni[2]; A Apostolo[2]; PG Agostoni[2]
[1]*University of Milan, Milan, Italy*; [2]*Cardiology Center Monzino IRCCS, Milan, Italy*

Introduction: Anaemia and iron deficiency are frequently reported comorbidities of Heart Failure (HF) and adverse prognostic factors associated with an independent risk for HF hospitalization and mortality.
Purpose: It's known the prevalence of anaemia increases with HF severity and other comorbidities (advanced age, female gender, renal disease, diabetes mellitus). We investigated a correlation between anaemia/iron deficiency in HF and chronic anticoagulant and/or antiplatelet therapies, either alone or in combination.
Methods and Results: We retrospectively studied 629 patients hospitalized for HF between Dec 2013 and Aug 2016, 65% men. We collected values of blood count, iron status, creatinine, INR and BNP in different groups based on either anticoagulant or antiplatelet therapy or both: group 1 (no therapy, n=104), group 2 (Vitamin K Antagonists (VKAs), n=194), group 3 (either a VKAs or a Novel Oral Anticoagulant (NOAC), plus antiplatelet therapy, n=65), group 4 (NOACs alone, n=39) and group 5 (antiplatelet therapy alone, n=227). The prevalence of iron deficiency and anaemia were respectively 75.99% (male 73%, female 82%) and 51.35% (male 49.3%, female 55.15%). We found a difference in the prevalence of anemia among HF classes based on LVEF (p 0.0067) and a correlation between the severity of anaemia (moderate anaemia) and female sex (p 0.0114). We found at the multivariate analysis predicting factors of anaemia (age, creatinine and RDW for the presence of anaemia; female sex, RDW and OSAS for the severity) and iron deficiency (RDW alone). Therefore we used Anova analysis corrected by confounding factors to obtain a comparison between all groups' variables, achieving significant differences on INR ($p<0.0001$), as parameter of good accuracy of data collection, but also on ferritin (p 0.015) and transferrin ($p < 0.0001$). In particular we found significant differences in ferritin between group 1 and 2 (p 0.0586) and in transferrin between group1 and 2 (p 0.0013) and between group 2 and 5 ($p < 0.0001$). Haemoglobin had only a typical trend with the highest value in group 4 (adjusted mean 13.3 g/dL, C.I. 95% 12.6-14), which was the same in all the previous sequence analysis.
Conclusion: We analyzed a population with prevalence of iron deficiency and anaemia in perfect line with European data, obtaining predicting factors of them and a different prevalence of anaemia in the HF classification. We demonstrated a correlation between the severity of anaemia and female sex and a significant iron deficiency in VKA patients. Haemoglobin had a typical trend that was maintained in all progressive analysis between groups based on antiplatelet and/or anticoagulant therapies, with the highest value in patients with NOACs therapy alone. The absence of statistical significance may result from the different numeric composition of groups. We expect it will be achieved by increasing the sample size of the population, due to an increasing of NOACs prescription.

P1813
Methylmalonic acid in patients with heart failure

K Polytarchou[1]; D Varvarousis[2]; C Pantziou[3]; C Psachoulia[3]; N Christodoulis[3]; D Oikonomou[4]; G Feredinos[4]; K Manousiadis[4]; K Triantafyllou[4]; N Sakellaris[4]; K Kappos[4]; S Ioannidou[3]; A S Manolis[1]
[1]*Athens University Shool of Medicine, Third Department of Cardiology, Athens, Greece*; [2]*Nikea General Hospital, Second Department of Cardiology, Athens, Greece*; [3]*Evangelismos General Hospital of Athens, Department of Biochemistry, Athens, Greece*; [4]*Evangelismos General Hospital of Athens, First Department of Cardiology, Athens, Greece*

Background: Vitamin B12 deficiency in patients with heart failure (HF) might be underestimated. These patients may have "falsely" normal vitamin B12 serum levels due to coexisting hepatic dysfunction. Methylmalonic acid (MMA) has been identified in several studies as an early indicator of vitamin B12 deficiency. Data regarding vitamin B12 and MMA in patients with HF are scarce.
Aim: To investigate vitamin B12 and MMA serum levels in HF patients.
Methods: 47 consecutive patients admitted to our hospital with symptoms and signs of acute decompensated heart failure were included in the study. Demographic and clinical characteristics as well as echocardiographic parameters were recorded. Blood samples were collected during the first 24 hours of hospitalization and complete blood count, creatinine, vitamin B12, NT-pro BNP and MMA levels were measured. A total of 12 healthy individuals (blood donors) constituted the control group, whereby MMA serum levels were also measured.
Results: Preliminary analysis of data among 47 HF patients (aged 70.5 ± 12.5 years; 50% with ischemic cardiomyopathy) indicated typical systolic dysfunction (redused left ventricular ejection fraction-LVEF $< 40\%$,HFrEF) in the majority (77.7%) of patients, mild systolic dysfunction (mid-range LVEF 40-49%, HFmrEF) in 8.3% and preserved systolic function (preserved LVEF $\geq 50\%$, HFpEF) in 11.1%; right heart failure was present in 57.4%. Mean hematocrit was $38.2 \pm 7.9\%$, creatinine 1.17 ± 0.31 mg/dl, and NT-proBNP levels 4694.4 ± 4260.1 pg/ml. Vitamin B12 levels averaged 358.8 ± 221.8 pg/ml. MMA levels were 37.1 ± 10.1 ng/ml in HF patients and 28.6 ± 2.7 ng/ml in the control group ($p = 0.0042$). In patients with vitamin B12 at lower normal levels (< 350 pg/ml), MMA was high (mean 39.4 ± 9.4 ng/ml) and in patients with higher normal vitamin B12 levels (>351 pg/ml), MMA levels were low (mean 33.6 ± 9.3 ng/ml, $p = 0.08$) , but still higher than control patients (Figure).
Conclusion: Patients with HF may have elevated levels of serum MMA, possibly indicating a subclinical vitamin B12 deficiency state.



Methylmalonic acid (MMA) levels

Sleep-disordered breathing is linked to peripheral endothelial dysfunction and not to myocardial function in ischemic stroke: A mechanistic link complicating the acute phase

N Nadja Scherbakov[1]; A Sandek[2]; N Ebner[2]; M Valentova[2]; AH Nave[2]; E Jankowska[3]; JC Schefold[4]; S Von Haehling[2]; SD Anker[2]; JB Fiebach[1]; KG Haeusler[1]; W Doehner[1]
[1]Center for Stroke Research CSB, Charite University Medical School, Berlin, Germany; *[2]University Medical Centre Göttingen, Innovative Clinical Trials, Department of Cardiology and Pneumology , Göttingen, Germany*; *[3]Wroclaw Medical University, Wroclaw, Poland*; *[4]Bern University Hospital, Bern, Switzerland*

Funding Acknowledgements: German registry for clinical trials number DRKS00000514

Introduction: Sleep-disordered breathing (SDB) after acute ischemic stroke is frequent and may be linked to stroke-induced autonomic imbalance.
Methods: In the present single-center study we assessed SDB by transthoracic impedance records integrated into Holter system. Additionally, peripheral endothelial dysfunction (ED) using reactive hyperemia index [RHI] was assessed using pulse arterial tonometry device in the acute phase of ischemic stroke and one year afterwards in patients without a history of SDB prior the stroke. Cardiac systolic and diastolic function was assessed by transthoracic echocardiography.
Results: SDB was observed in-hospital in 56 (57%) out of 99 patients with acute ischemic stroke (69 ± 11 years, 73% male, median NIHSS 5 [2.25-7.75], BMI 27.8 ± 3.4 kg/m^2). Compared to patients without SDB (68 ± 13 years, 49% males, median NIHSS 3 [2-4], BMI 28.6 ± 5.7 kg/m^2), ED was significantly prevalent in patients with SDB (32%vs. 64%; $p < 0.01$). After adjustment for multiple confounders, presence of SDB remained independently associated with ED (odds ratio 3.38 [CI 1.27-9.01], $p < 0.05$). Forty-one patients underwent repetitive measurements one year after stroke (12.8 ± 0.8 months). The prevalence of SDB decreased from 59% to 14% in this cohort ($p < 0.001$). Compared to patients without SDB, ED remained impaired in stroke patients with persisting SDB ($p < 0.05$). Presence of impaired left ventricular ejection fraction (LVEF) had additional impact on severity of SDB (median AHI 11.3 [IQR 10.75-43.25]) compared to patients with normal LVEF (median AHI 4.7 [2-10]) or preserved LVEF (median AHI 5.1 [7-28], $p < 0.05$). However, no significant difference in prevalence of SDB was observed between all three groups. In addition, LVEF and atrial fibrillation was not associated with presence of SDB in logistic regression analysis.
Conclusions: SDB was highly prevalent in acute stroke. Presence of the SDB was independently associated with peripheral ED but not cardiac function. Peripheral ED improved with the recovery to normal breathing pattern suggesting a mechanistic link of SDB and ED in ischemic stroke.

Sleep apnea syndrome in patients with chronic heart failure

CC Diaconu[1]; D Berceanu[2]; D Bucur[2]; D Belciu[2]; GN Dediu[3]; MA Iancu[4]; AR Zaki[2]
[1]University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Floreasca, Bucharest, Romania; *[2]Emergency Clinical Hospital Floreasca, Bucharest, Romania*; *[3]University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Sf. Ioan, Bucharest, Romania*; *[4]University of Medicine and Pharmacy Carol Davila, Family Medicine, Bucharest, Romania*

Introduction: Sleep apnea syndrome seems to be a frequent comorbidity in patients with heart failure. The purpose of the study was to analyze the frequency and impact of sleep apnea syndrome in patients with chronic heart failure, hospitalized in the Internal Medicine clinic of a University Clinical Emergency Hospital.
Methods: The study included 980 patients with chronic heart failure, consecutively admitted between January 1st, 2016-November 30, 2016. We have retrospectively and comparatively analyzed the frequency of sleep apnea syndrome and the clinical correlations in patients with chronic heart failure, using SPSS software.
Results: The distribution by sex in the group of study: 49.8% men, 50.2% women. The mean age of the whole group was 74 ± 11.6 years. The distribution of comorbidities in patients with chronic heart failure was: 66,84 % arterial hypertension, 39.9 % atrial fibrillation, 32.85 % coronary heart disease, 31.13 % chronic kidney disease, 28.87 % dyslipidemia, 26.23 % type II diabetes, 24.49 % pulmonary hypertension, 21.94 % obesity, 18.16 % bundle branch blocks, 16.94 % anemia, 7.85 % stroke, 7.14 % chronic obstructive pulmonary disease, 4.49 % sleep apnea, 0.51 % asthma. Sleep apnea syndrome was more frequent in men than women ($p < 0.01$). Heart failure patients with dyslipidemia had a higher frequency of sleep apnea syndrome ($p = 0.018$). A total of 392 patients had atrial fibrillation, of which 25 were also diagnosed with sleep apnea syndrome (6.37 %) vs 568 patients without atrial fibrillation, 20 having a diagnosis of sleep apnea syndrome (3.52 %). This difference was statistically significant ($p = 0.029$). 6 patients out of 656 hipertensive patients presented sleep apnea (0.91%) vs 39 patients with sleep apnea out of 324 normotensive patients ($p = 0.004$). 11 from 70 patients with chronic obstructive pulmonary disease were also diagnosed with sleep apnea vs 34 out of 910 patients without chronic obstructive pulmonary disease (15.72 % vs 3.74 %; $p < 0.001$).
Conclusions: Sleep apnea syndrome is a frequent comorbidity in patients with heart failure. Atrial fibrillation was more frequent in patients with heart failure and SAS than in patients with heart failure without SAS.

P1816

Consequences of obstructive sleep apnoea syndrome and hypertension on left ventricular diastolic function

L Mathe[1]
[1]IVth Medical Hospital, Tirgu-Mures, Romania

Study Objectives: Obstructive sleep apnoea syndrome (OSAS) is a frequent sleep disorder that is known to be an independent risk factor for arterial hypertension (AHT). Age, diabetes mellitus and obesity are considered as independent but additive factors. These factors are also contributors to left ventricular hypertrophy (LVH) and LV diastolic dysfunction (LVDD), which are important causes of cardiovascular morbidity. In this review, we present an overview of how OSAS may promote changes in LV geometry and diastolic dysfunction through its best-known cardiovascular complication, arterial hypertension. We hypothesized that the severity of sleep disordered breathing (SDB) would be associated with LVDD even for subclinical SDB.
Methods: This was a prospective long-term observational study. 56 participants had overnight polysomnography followed by transthoracic echocardiography. OSA was characterized by the apnea-hypopnea index (AHI, events/hour). The LVDD was assessed by echocardiography using combined categories with tissue Doppler imaging and left atrial (LA) volume measurement.
Results: 12 (21,4%) subjects were free sleep apnea (SA) AHI (apnea-hipopnea index ≤5/h), 15 (26,7%) had mild SA (AHI = 5-14/h), 17 (30,3 %) had moderate SA (AHI= 15-30/h) and 12 (21,4 %) had severe SA (AHI≥30/h). Among the participants, 27 patients (48,21 %) had LVDD. The prevalence of LVDD increased with the SDB severity from 8.6 % (normal) to 12.7 % (mild) to 40.0 % (moderate-to-severe SDB) ($p < 0.0001$). In the multivariate logistic regression analysis, the odds ratio of having LVDD in the moderate-to-severe SDB group vs. normal group was 5.96 (95 % CI, $P = 0.006$).
Conclusions: OSA is associated independently with diastolic disfunction. Echocardiographic measures of adverse cardiac remodeling are strongly associated with OSA and AHT, but are confounded by obesity. Hypoxia could be a stimulus for hypertrophy in individuals with OSA.

P1817

Elevated B12 levels in systolic heart failure patients - associations with right heart failure and impaired prognosis

D Ural[1]; O Argan[2]; M Aktas[3]; K Karauzum[4]; IY Karauzum[5]; G Kozdag[5]; AA Agir[5]
[1]Koc University, Istanbul, Turkey; *[2]Kocaeli State Hospital, Department of Cardiology, Kocaeli, Turkey*; *[3]Eregli State Hospital, Department of Cardiology, Zonguldak, Turkey*; *[4]Kocaeli Derince Hospital, Kocaeli, Turkey*; *[5]Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey*

Background and Purpose: Unfavorable impact of iron deficiency on the outcome of heart failure (HF) has been well established, but the clinical implications of B12 and folic acid are not clear. The aim of the present study was to investigate clinical correlates and prognostic value of vitamin B12 and folic acid levels in HF patients with reduced ejection fraction HF (HFrEF).
Methods: The study group consisted of 129 chronic stable HFrEF patients with a functional class of NYHA II-IV and 50 controls. Data regarding clinical, echocardiographical and laboratory features with special emphasis on symptoms and signs of right heart failure were recorded for all patients. Vitamin B12 and folic acid levels were estimated by chemiluminescence assay. Primary endpoint of the study was all-cause mortality.
Results: Median ejection fraction of the HFrEF patients was 25% (range 10-45%), and 71 of them (55%) had symptoms or signs of right HF. Median B12 levels in HFrEF patients with were significantly higher compared to controls (270 pg/ml vs. 198 pg/ml; $p = 0.005$), but folic acid was similar between the study groups (7.7 ng/ml vs. 8.5 ng/ml; $p = 0.305$). Univariate correlates of serum B12 were age, ischemic etiology, NT-proBNP, eGFR, uric acid, total cholesterol, direct bilirubin, AST and albumin. In stepwise linear regression analysis, direct bilirubin was the most important independent determinant of serum B12 levels (B 135, 95%CI[B] 93-177; $p < 0.001$) followed by age and ischemic etiology.Patients were followed for a median duration of 16 (13-17) months. Death occurred in 25 patients. B12 levels were significantly higher in deceased patients compared to survivors (379 [274-499] pg/ml vs. 249 [181-399] pg/ml; $p = 0.005$), but folic acid was not different among the two groups. ROC analysis showed that B12 values ≥270 pg/mL had 80% sensitivity and 56% specificity for predicting all-cause mortality (AUC 0.69, 95%CI 0.58-0.80; $p = 0.005$).

In Cox regression analysis, independent determinants of death were age (exp[B] 1.061, 95%CI 1.018-1.107; p = 0.005), presence of abdominojugular reflux (exp[B] 0.291, 95%CI 0.114-0.741; p = 0.010) and severe tricuspid regurgitation (exp[B] 0.068, 95%CI 0.017-0.269; p < 0.000). Despite having a significant univariate association with all-cause mortality, B12 level lost its significance in multivariate analysis.
Conclusions: Increased B12 in HFrEF patients is associated with increased direct bilirubin due to right HF, but neither B12 nor folic acid were independently associated with mortality.

P1818
Chronic kidney disease criteria are common in hospitalized patients arterial hypertension and diabetes mellitus

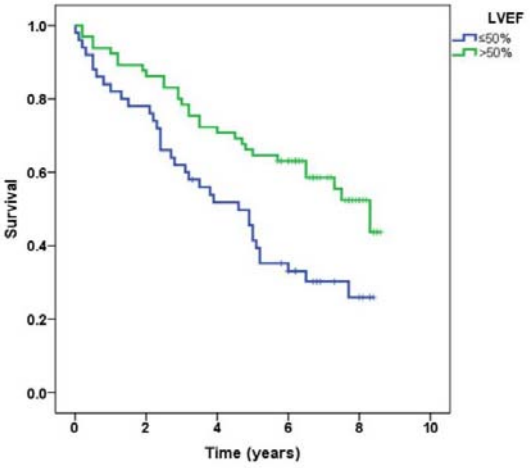
V Kulakov[1]; N Manukhina[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background and aim: Chronic kidney disease (CKD) is accepted as an independent cardiovascular disease (CVD) risk factor. Type 2 diabetes mellitus (T2DM) and arterial hypertension (AH) are leading risk factors for both CVD and CKD. The aim of the study was to assess the prevalence of decreased glomerular filtration rate (GFR) and high/very high albuminuria in patients with AH and T2DM.
Methods: In 319 patients with AH and T2DM admitted in city clinical hospital (37% men, age 65 ± 11 years (M ± SD), body mass index 30 ± 7 kg/m^2, blood pressure 135 ± 16/80 ± 9 mmHg, median AH duration 12 years (interquartile range 10;15), T2DM duration 10 years (4;15), dyslipidemia 70%, chronic heart failure 50%, anemia 28%, atrial fibrillation 20%) GFR was assessed by CKD-EPI equation and albuminuria – by albumin/creatinine ratio (ACR) in spot urine morning sample.
Results: GFR < 60 ml/min/1.73 m^2 was revealed in 127 (39.8%) patients, wherein GFR in the range of 45- < 60, 30- < 45, 15- < 30, < 15 ml/min/1.73 m^2 was found in 18, 17, 5 and 0.6% respectively. ACR>30 mg/g was detected in 123 (39%) of patients, wherein ACR in the range 30- < 300 and >300 mg/g was found in 29 and 10%. CKD criteria (GFR < 60 ml/min/1.73 m^2 and/or ACR>30 mg/g) were detected in 182 (57%) patients. Non-albuminuric CKD (GFR < 60 ml/min/1.73 m^2 without albuminuria) was found in 59 (18.5%) patients, isolated (without GFR decrease < 60 ml/min/1.73 m^2) high/ very high albuminuria - in 55 (17%) patients, combined decreased GFR and high/very high albuminuria – in 68 (22%) patients. Patients with vs without albuminuria were older (67.2 ± 10.8 vs 63.7 ± 10.7 years), more aware of kidney diseases (59 vs 41%), had lower level of hemoglobin (122 ± 23 vs 130 ± 21 g/l), p < 0.05 for all. Patients with vs without CKD criteria were older (67 ± 10 vs 60 ± 11 years), had higher prevalence of anemia (34 vs 10%), heart failure (55 vs 32%).
Conclusions: High prevalence (57%) of CKD criteria was revealed in hospitalized patients with AH and T2DM. GFR < 60 ml/min/1.73 m^2 was found in 39.8% of patients, ACR>30 mg/g – in 39%, combined decreased GFR and high/ very high albuminuria – in 22% of patients.

P1819
Impaired left ventricular function predicts all-cause and cardiovascular mortality in patients with renal failure: a 5-year prospective study

C Chris Kapelios[1]; I Eleftheriadou[1]; A Tentolouris[1]; D Doulgerakis[1]; I Moyssakis[1]; S Chorepsima[1]; S Michail[1]; N Tentolouris[1]
[1]*Laiko University General Hospital, Athens, Greece*

Introduction: Chronic kidney disease (CKD) is a global health problem with major socioeconomic impact. In the last decades intense scientific interest has been dedicated to the increased cardiovascular (CV) mortality of patients with CKD. Numerous studies have attempted to identify risk factors for morbidity and mortality in patients with CKD, especially in patients with renal failure (RF) (estimated glomerular filtration rate [eGFR] < 15 mL/min/1.73 m2). The aim of our study was to prospectively evaluate the prognostic value of indices of LV function in all-cause and CV mortality in patients with RF.
Methods: A total of 133 consecutive patients with RF were included in the study. We recorded a) the baseline characteristics of the patients, including left ventricular function parameters, and b) the long-term outcomes, and used uni- and multi-variate proportional hazards models to identify predictors of all-cause and CV during long-term follow-up. The patients' survival rates were analyzed by the Kaplan-Meier method and compared using the log-rank test. All P values were two-sided and a value < 0.05 was considered statistically significant.
Results: Complete follow-up data was available for 123/133 (92.5%) patients who were included in the final analysis. Mean age of the population was 59.5 ± 14.6 years and 64.2% were males. Diabetes was present in 39% of patients, whereas 58(47.2%) had a history of CVD at baseline. Mean left ventricular ejection fraction (LVEF) was 50.9 ± 6.9% and eGFR was 10.7 ± 1.6 ml/min/1.73m^2. The patients were followed for 4.9 ± 2.6 years (median 5.9 years), A total of 69 deaths were recorded: 36 CV, 21 non-CV and 12 of unknown cause. After adjustment for age, waist circumference, smoking status, history of diabetes mellitus and coronary artery disease, serum glucose and triglycerides, LVEF was identified as an independent predictor of all-cause (HR: 0.950; 95%CI: 0.916-0.985, P=0.006) and CV mortality (HR: 0.935; 95%CI: 0.885-0.988, P=0.018). Based on the mean value of LVEF the study population was divided into two groups. The cumulative survival rates at follow-up were 30% and 55.4% for patients with a LVEF ≤50% vs. >50%, respectively (p = 0.004) [Figure].
Conclusion: LVEF represents an independent risk factor for all-cause and CV mortality in patients with RF. These findings strongly suggest that left ventricular function assessment could be utilized for risk stratification and potential treatment tailoring of patients with RF.



P1820
Cardiac masses in pediatric population

R Rania Hammami[1]; D Abid[1]; B Rekik[1]; F Mroua[1]; F Triki[1]; S Charfeddine[1]; L Abid[1]; S Kammoun[1]
[1]*Hedi Cheker Hospital, Department of Cardiology, Sfax, Tunisia*

Introduction: Infant heart masses are rare. Most are benign tumors. Rhabdomyomas constitute the most common tumor. Malignant tumors are exceptional. Antenatal diagnosis is possible and it requires perinatal monitoring in order to optimize the management and prognosis.
Patients and methods: it was a retrospective study between January 2008 and December 2016, including all patients aged less than 16 years with heart masses diagnosed with transthoracic or fetal echocardiography
Results: Of the 6451 pediatric transthoracic echocardiography and 364 fetal echocardiographs performed during the study period, 12 cardiac masses were identified with an incidence of 0.17%: nine cases of rhabdomyomas, 1 case of intrapericardial immature teratoma,1 case of hydatid cyst and 1 case of cardiac thrombus in a patient with coarctation of the aorta with left ventricular dysfunction. The diagnosis was made in antenatal in 8 cases of rhabdomyoma and in the case of teratoma. Five patients with intraventricle rhabdomyoma showed heart failure symptoms. The evolution was favorable with total or partial regression of all cases of rhabdomyomas, it was fatal in patients with immature teratoma (patient died after tamponade) and with hydatid cyst (patient died following the intracardiac rupture of the cyst). The cardiac thrombus disappeared under anticoagulant treatment and the patient evolved well after surgery of the coarctation.
Conclusion: Clinical presentation, treatment and progression of cardiac tumors are variable. Rhabdomyomas have an excellent prognosis. Fetal echocardiography significantly improved diagnosis and management of such patients.

P1821
Association of genetic polymorphism of TCF7L2 with the severity of cardiac remodeling and adipokines disbalance in comorbidity of essential hypertension and type 2 diabetes

A Shalimova[1]; O Bilovol[1]; L Bobronnikova[1]
[1]*Kharkiv National Medical University, Clinical Pharmacology, Kharkiv, Ukraine*

In recent years the researchers have been paying much attention to study of genetic components of essential hypertension (EH) and type 2 diabetes (DM2) - one of the most common noninfectious diseases in the world. Nowadays one of the worldwide

popular medical studies is the study of the genes responsible for the development of insulin resistance, which is an important part in the formation of DM2. Meanwhile the role of heredity in another pathogenetic link of DM2 – genetic defects in β-cells of the pancreas is still less studied. It is believed that gene polymorphism Transcription Factor 7-Like 2 (TCF7L2) affects the amount and functional activity of the β-cells.

Objective: to establish the association of genetic polymorphism of TCF7L2 with the severity of cardiac remodeling and adipokines disbalance in EH and concomitant DM2 in Ukrainian population.

Design and Method: We examined 320 patients aged from 45 to 60 years old with EH stage II, grade 2 and concomitant DM2, moderate, subcompensated (main study group); 90 patients with EH without DM2 (comparison group) and 31 healthy individuals (control group).

Methods: echocardiography, enzyme immunoassay (determined levels of adiponectin and leptin). Rs7903146 polymorphism of TCF7L2 was assessed by molecular genetic method.

Results: Allele T, which according to some scientists is associated with the development of DM2, occurred in significantly more patients of the main group as compared to the group of patients without DM2 ($p < 0.01$) and the control group ($p < 0.001$): 16.9% of main group patients had homozygous genotype T/T and 47.2% of patients had heterozygous genotype C/T. At the same time C/C genotype was established only in 35.9% of main group patients while in 48.9% of comparison group patients and in 61.3% of control group patients was diagnosed genotype C/C.

It was found that patients with homozygous T/T and heterozygous C/T genotypes had a more pronounced cardiac remodeling than patients with genotype C/C: significantly ($p < 0.05$) lower ratio of the maximum velocity of early and late left ventricle filling (E/A) and significantly ($p < 0.01$) higher ratio of peak e and E on the mitral valve in the spectral and tissue Doppler (E/e). It was also established that patients with genotypes C/T and T/T of TCF7L2 gene had significantly lower levels of adiponectin ($p < 0.001$) and leptin ($p < 0.05$), than carriers of genotype C/C. In comparison group TCF7L2 polymorphism did not affect the severity of cardiac remodeling and adipokines disbalance.

Conclusions: genetic polymorphism of TCF7L2 gene is associated with the development of comorbidity of EH and DM2 in Ukrainian population. Rs7903146 gene polymorphism of TCF7L2 affects the severity of cardiac remodeling and adipokines disbalance in comorbidity of EH and DM2. Patients with EH without DM2 had no significant difference of indicators of cardiac remodeling and adypokines levels depending on polymorphism of TCF7L2 gene.

P1822

Sodium-glucose co-transporter-2 inhibitors as oral antidiabetic in patients wit heart failure

J Jose Morgado[1]; JRG Roa Garrido[1]; PRO Rodriguez Ortega[1]; BMM Martinez Mora[1]; SCF Camacho Freire[1]; TMS Moraleda Salas[1]; ALS Lopez Suarez[1]; JDF Diaz Fernandez[1]

[1]*Hospital Juan Ramon Jimenez, Cardiology, Huelva, Spain*

Background/Introduction: There is a relationship between the prevalence of heart failure (HF) and Diabetes Mellitus Type 2 (T2DM), resulting the most prevalent comorbidity in DM.Furthermore, HF has worse prognosis in patients with T2DM.Recently, a randomized trial with a Co-Transporter-2 Inhibitors(SGLT-2 inhibitors)has reduced cardiovascular mortality and hospitalizations for HF.This class of therapy reduces blood glucose levels,blood pressure,produce an osmotic diuresis and weight loss.

Purposes: Evaluate the efficacy and safety of SGLT-2 inhibitors in patients with T2DM and HF.

We want to assess possible changes of metabolic and HF situation, and check security of this treatment. We quantify: Glycemic control (A1c).

Body mass index (BMI). Improvement in heart failure situation (functional class, value of N-terminal prohormone of brain natriuretic peptide: NTproBNP). Decrease in diuretic dose. Check security of the treatment.

Methods: Prospective, analytical and observational,unicentric study on T2DM patients who do not reach therapeutic objective with oral antidiabetic medications(glycohemoglobin higher 6.5%)and suffer HF(admission for HF in the last 6 months or high level of NTproBNP plus HF symptoms),independent of left ventricular ejection fraction (LVEF). N:11 patients.7 patients received canagliflozine,3 empagliflozine and 1 patient dapagliflozine. We start treatment with SGLT2 inhibitors at stable HF situation, understood as unchanged treatment for heart failure during 3 months. We calculate at beginning and after 90 days next measures: Heart failure situation: NTproBNP, New York Heart Association (NYHA) classification, dose of diuretic.

Metabolic control: A1c, BMI.

Security: hypoglycemia epysodes.

Results: Basal characteristics: Mean age was 66.4 ± 8.6 years, 37 % female, 100% with hypertension. Mean LVEF was 40.4 ± 10%, mean NT-proBNP level was 1430 ± 1243 pg/mL, and the mean of dose of furosemide was 52.7 ± 38.2 mg daily. Mean BMI was 27.9 ± 4.2 kg/m2 and mean A1c 8.45 ± 1.43 %. 73.6% of patients received metformin and 90.9% another oral antidiabetic medication, 63.5% used insulin. Follow-up (90 days): A significant reduction was observed in NT-proBNP values (mean 978 ± 900 pg/mL, $p < 0.05$), BMI (mean 26.7 ± 3.7 kg/m2 , $p < 0.05$), A1c (mean 7.8 ± 0.8 %, $p < 0.05$) and dose of furosemide (mean 53.1 mg ± 37 mg daily, but $p > 0.05$). Furthermore, a significant reduction of rates of admission for Heart Failure was shown (from 1.3 ± 0.8 90 days before to the beginning of SGLT2 inhibitors to 0.01 ± 0.3 90 days after the treatment with SLGT2 inhibitors, $p < 0.05$). It did not show hypoglycaemia epysodes.

Conclusions: This is a pilot study which shows beneficial effects of SGLT-2 inhibitors in patients with Heart Failure and Diabetes Mellitus, improving HF situation and metabolic control. This study has several limitations, specially the short follow-up and small sample size. So, bigger studies, are required to contrast these hypotheses.

P1823

Co-morbidities and fragility are determinants of survival in patients with heart failure and mildly reduced ejection fraction

P Moliner[1]; P Gastelurrutia[1]; J Lupon[1]; X Yang[2]; M De Antonio[1]; M Domingo[1]; S Altimir[1]; B Gonzalez[1]; M Rodriguez[1]; C Rivas[1]; E Fung[2]; E Zamora[1]; J Santesmases[1]; J Woo[2]; A Bayes-Genis[1]

[1]*Germans Trias i Pujol University Hospital, Badalona, Spain*; [2]*The Chinese University of Hong Kong, Hong Kong, Hong Kong SAR People's Republic of China*

Background: Heart failure (HF) is a chronic condition highly prevalent among older people. Due to this fact, fragility and co-morbidities are often present among HF patients. The 2016 Heart Failure (HF) ESC Guidelines boost to investigate the "new" subgroup of patients with HF and left ventricular ejection fraction (EF) mildly reduced (HFmrEF).

Purpose: Our aim was to assess the effect of co-morbidities and fragility on long-term prognosis in ambulatory HFmrEF patients, and to compare it with those observed in HF with reduced (HFrEF) and preserved (HFpEF) EF.

Methods: A score of co-morbidities was created, ranging from 0 to 7, that includes diabetes, hypertension, COPD, renal failure, anemia, peripheral arteriopathy and atrial fibrillation. Fragility was defined as having at least one abnormal evaluation among 4 standardized geriatric scales. Predefined criteria for such scales were: Barthel Index <90; OARS scale <10 in women and <6 in men; Pfeiffer Test >3 (± 1, depending on educational grade); and ≥ 1 positive response for depression on the abbreviated GDS. Median follow-up was 4.9 years [P25–75: 2.5–8.4] for living patients. All-cause death, HF-related hospitalization and the composite end-point of both were assessed.

Results: 169 patients with HFmrEF were evaluated (116 men and 53 women, mean age 67.2 ± 11.8 years, median duration of HF 13 months [Q1-Q3 2–44], ischemic aetiology 58.6%, 104 (61.5%) and 58 (34.3%) in NYHA class II and III respectively) and compared with 999 patients with HFrEF and 146 patients with HFpEF. The number of co-morbidities in HFmrEF patients (2.37 ± 1.6) was similar to that in HFrEF 2.28 ± 1.4 ($p = 0.45$) and significantly lower ($p < 0.001$) than that in HFpEF patients (3.04 ± 1.4). In contrast fragility was more prevalent in HFmrEF (50.3%) than in HFrEF patients (41.5%), $p = 0.03$ and similarly prevalent than in HFpEF (55.5%) patients, $p = 0.36$. During follow-up 78 deaths, 32 HF-related hospitalizations and 85 composite end-points were documented. Co-morbidities and fragility were significantly associated with the 3 end-points: HR 1.56 [1.34–1,82], $p < 0.001$ and HR 2.95 [1.84–4.72], $p < 0.001$ for all-cause death respectively; HR 2.01 [1.58–2.57], $p < 0.001$ and HR 2.27 [1.10–4.67], $p = 0.03$ for HF-related hospitalization respectively; and HR 1.64 [1.41–1.90], $p < 0.001$ and HR 2.80 [1.79–4.39], $p < 0.001$ for the composite end-point respectively. These figures were higher in all the end-points (from 4% to 105%) than that observed in HFrEF and HFpEF patients. In multivariable analysis containing also age, sex NYHA functional class and ischemic aetiology the number co-morbidities remained independently associated with all-cause death ($p = 0.03$), HF-related hospitalization ($p < 0.001$) and the composite end-point ($p < 0.001$) and fragility with all-cause death ($p = 0.01$) and the composite end-point ($p = 0.02$).

Conclusion: Co-morbidities and fragility are determinant of outcome in ambulatory patients with HFmrHF, even more than in HFrEF and HFpEF patients.

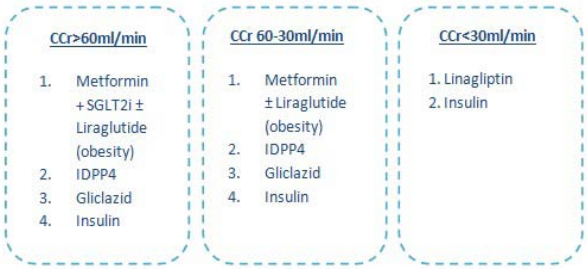
Do we optimize antidiabetic treatment in HF patients?

S Sara Blasco[1]; FJ Camacho[1]; I Lobo[1]; C Collado[1]; P Gonzalez[1]; JA Sanchez-Brotons[1]; I Perez[1]; E Martinez De Morentin[1]; M Iravedra[1]; J Lozano[1]; M Maestre[1]; P Martinez Romero[1]; FJ Morales[1]

[1]*Puerto Real Hospital, Cardiology, Puerto Real, Spain*

Introduction: The latest Heart Failure and Cardiovascular Prevention ESC Guidelines have shown the benefits of empagliflozin in preventing and slowing down the

progression of Heart Failure (HF) and reducing cardiovascular mortality. Our goal is to describe the characteristics of diabetic patients hospitalized in the Cardiology Service, to analyze whether the ESC Guidelines recommendations are being followed, and to suggest new treatment protocols.
Material and Methods: Prospective and descriptive study of type 2 diabetic patients hospitalized in the Cardiology Service from June 15th to December 31st, 2016, comparing patients with chronic HF and de novo HF.
Results: From June 15th to December 31st, out of a total of 121 diabetic patients hospitalized, 33% had chronic HF (due to decompensated heart failure) and 14% were diagnosed with de novo HF. There were no differences found between both groups in regards to age (70 ± 9 vs. 69 ± 14), gender (67% males in chronic HF vs. 50% in de novo HF) nor other cardiovascular risk factors (HTA in 80% patients with chronic HF vs. 77% with de novo HF, 39% of chronic HF patients were or had been smokers vs. 38% with recent HF diagnosis, and nearly 95% of the patients in both groups had IMC ≥ 25). There were significant differences in regards to dyslipidemia (62% with chronic HF vs. 77% with de novo HF), hyperuricemia (42.5% with chronic HF vs. 70% with de novo HF) and creatinine clearance (50% with chronic HF had a creatinine clearance < 60ml/min vs. 38% in de novo HF patients). The average FEVI was 51% ± 13% in chronic HF group vs. 46% ± 17% in patients with de novo HF. Out of the chronic HF patients, 30% had HFrEF, 15% HFmrEF and 55% HFpEF, whereas 27% of the de novo HF patients had HFrEF, 27% HFmrEF and 44% HFpEF. All patients were being properly treated with Beta blockers, ACE inhibitors, and MRA drugs. Still, nearly 50% of the hospitalizations in all Diabetic 2 patients were due to Heart Failure. Regarding previous anti-diabetic drugs, none of the patients were being treated with an SGLT2 inhibitor. 57% of chronic HF patients were under Metformin (15% on its own), 17% sulfonylureas, 15% DPP4 inhibitor and 55% under insulin (15% as single-drug treatment). As for the de novo HF patients, 77% were under Metformin (10% as single-drug treatment), 27% sulfonylureas, 25% DPP4 inhibitor and 33% under insulin. Nevertheless, 40% of the patients with chronic HF and 27% of patients with de novo HF had HbA1c levels out of the target range.
Conclusions: We've detected that ESC guidelines aren't being followed in the use of anti-diabetic drugs in patients with cardiovascular diseases, unlike other cardiovascular risk factors that have well-established treatment protocols. As seen in our study, most of our patients could benefit from the use of the SGLT2 inhibitor to reduce cardiovascular mortality and the development of heart failure. Therefore, we suggest the following treatment protocol.



Anti diabetic treatment protocol

VALVULAR HEART DISEASE (DIAGNOSIS, MANAGEMENT AND INTERVENTIONAL THERAPIES)

Clinical impact of patients with pure native aortic valve regurgitation undergoing transcatheter aortic valve replacement

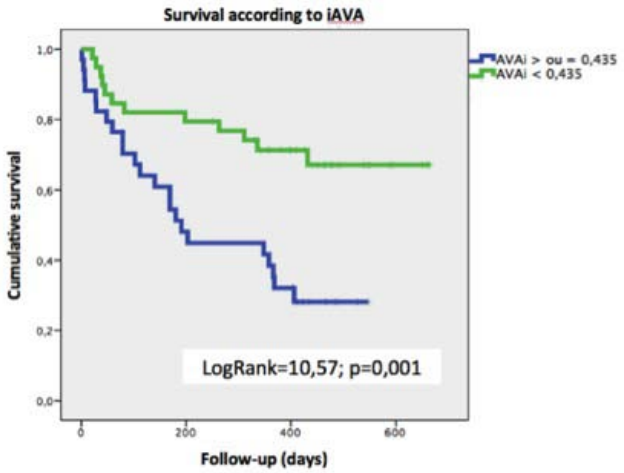
E Munoz-Garcia[1]; M Munoz-Garcia[1]; AJ Antonio Jesus Munoz Garcia[2]; AJ Dominguez-Franco[2]; JM Garcia-Pinilla[2]; L Morcillo-Hidalgo[2]; MF Jimenez-Navarro[2]; JH Alonso-Briales[2]; JM Hernandez-Garcia[2]; E De Teresa-Galvan[2]
[1]Department of Cardiology , Malaga, Spain; [2]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

There are patients with severe aortic regurgitation (AR) and at high or extreme surgical risk for whom conventional surgical aortic valve replacement may be unsuitable and who might benefit from transcatheter-based therapy. The aim this study was to evaluate the clinical outcomes of patients with pure native aortic valve regurgitation undergoing with Transcatheter Aortic Valve Replacement (TAVR) and comparing them with patients with aortic stenosis.
Methods: Between April 2008 and December 2016, 16 consecutive patients with severe pure aortic regurgitation (AR) underwent TAVR with the self-expandable aortic valve prosthesis (CoreValve) and 566 patients with severe aortic stenosis (AS).
Results: The mean age and logistic EuroSCORE were (AR vs. AS) 73.1 ± 17 vs. 79.6 ± 6.2 years, p = 0.001 and 18.2 ± 8.9% vs. 17.49 ± 12, p = 0.818 respectively. There were significant differences in measurement of annulus and ascending aortic size (23.6 ± 2 vs. 22.03 ± 1.8 mm, p < 0.001 and 35.4 ± 5 vs. 31.1 ± 4.6 mm, p = 0.001, respectively). Implantation of prosthesis was performed successfully in all patients with AR and the degree of aortic regurgitation after procedure aortic was: none in 6 patients 37.5%), mild in 5 patients (31.3%), moderate in 3 patients (18.8%) and moderate-severe in two patients (12.6%).
The NYHA functional class improved from 3.37 ± 0.61 (baseline) to 1.37 ± 0.51 (one month) and remained stable at follow-up (1.4 ± 0.54). The mortality at 30 days was 6.3 % in patients with AR compared to 3.4% in patients with AS, p = 0.432 and there was non-significant differences with late mortality (33.3% vs. 33.3%, p = 0.996) after a mean follow-up of 36.5 ± 25 months.
The patients with AR had lower complications after procedure than patients with AS: Occurrence new-onset left bundle branch block 13.3% vs. 50% [OR=0.154 (95% CI 0.034-0.690), p = 0.005], stroke 0% vs. 3.7% [OR=0.971 (95% CI 0.958-0.985) p = 0.433], vascular complications 0% vs. 3.2% [OR=0.972 (95% CI 0.958-0.985) p = 0.468], acute myocardial infarction 0% vs. 1.6% [OR=0.972 (95% CI 0.959-0.986) p = 0.611] respectively.
Conclusions: Patients with pure native aortic regurgitation and and at high or extreme surgical risk might benefit from transcatheter-based therapy. The long-term outcome is favourable compared with patients with aortic stenosis underwent with TAVR.

P1827
Echocardiographic mortality predictors in patients with severe aortic stenosis not submited to valvular intervention

I S S Ines Goncalves[1]; I Ricardo[1]; J Rigueira[1]; JR Agostinho[1]; T Guimaraes[1]; AR Francisco[1]; GL Silva[1]; R Santos[1]; A Ferreira[1]; AG Almeida[1]
[1]Hospital Universitário de Santa Maria/CHLN, CAML, CCUL,Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Introduction: Severe aortic stenosis (AS) is one of the pathologies with the highest morbimortality in Cardiology and aortic valvular intervention (AVi) is the only procedure capable of modifying prognosis. The importance of echocardiography in the diagnosis, classification of severity and follow-up is well established. However, it is not clear how the echocardiographic data can allow to assess the risk in AS and, thus, help to guide the therapy.
Purpose: To determine the echocardiographic mortality predictors in patients (pts) with the diagnosis of AS, prior to AVi.
Methods: A retrospective unicentric study was made, with inclusion of consecutive pts with AS (excluding low flow low gradient and paradoxical aortic stenosis), diagnosed during the year of 2015 at a tertiary center, which were not submitted to AVi untill the end of the follow-up period (November 2016). Clinical, laboratory and echocardiographic parameters were collected, and their relationships with mortality were analyzed, using the Cox regression statistical method and Kaplan-Meier survival analysis.
Results: A total of 278 pts were included (54% women, mean age 74 ± 9 years), 86 of which were not submitted to AVi until the end of the follow-up (mean follow-up of 389 ± 186 days). In this subgroup (58.5% women, mean age 80.9 ± 8.7 years, mean NYHA class of 2), using a univariate Cox analysis, were determined as echocardiographic predictors of mortality: the aortic valve area (AVA) and indexed iAVA (p < 0.001), left ventricular ejection fraction (p < 0.001), moderate or severe mitral regurgitation (p = 0.038) and pulmonary systolic artery pressure (p = 0.018). In the multivariate analysis by Cox regression, the only independent predictor of mortality was iAVA (hazard ratio = 3.78; 95% CI 1.55-9.23, p = 0.004). A cut-off value of 0.435 cm2/m2 was determined as the most accurate value for the occurrence of death, as proven with Kaplan-Meier survival analysis (LogRank = 10.57, p = 0.001).
Conclusions: iAVA was an independent predictor of mortality in the natural history of AS. No other echocardiographic parameters, namely transvalvular gradients, exhibited independent prognostic significance. The use of this parameter for individualized prognostic stratification of patients with AS may be especially useful in oligosymptomatic patients in whom the role of valvular intervention and the optimum timing of its performance is not yet established.



Survival according to iAVA

P1828

Long-term results with conventional treatment approach for prosthetic valve endocarditis in patients with prior heart failure

MM Monica Mariana Baluta[1]; E Panaitescu[2]; MM Vintila[3]
[1]Carol Davila University of Medicine-St Pantelimon Clinical Emergency Hospital-Cardiology Department, bucharest, Romania; *[2]Carol Davila University of Medicine and Pharmacy , Medical Informatics and Biostatistics, Marketing, Medical Technology , Bucharest, Romania*; *[3]St. Pantelimon Emergency Hospital, Cardiology, Bucharest, Romania*

Introduction: The initial management strategy in prosthetic valve endocarditis (PVE) patients remains a matter of debate. Evidence based therapeutic strategies are lacking and difficult to be achieved in multicentric manner because prosthetic valve endocarditis (PVE) is a rare condition. The appropriate therapeutic strategies need ultimately to fit the patient.
Purpose: The aim of our work was to analyze if initial conservative intention to treat with antibiotics (AbT) in patients with PVE may influence short- and long-term prognosis and to identify factors for the adverse outcome of this strategy.
Methods: Retrospective analysis of 56 cases of early and late PVE, from 2000 to 2004, 20 women and 36 men, age 54.64 ± 11.34 years, 51.8% with early PVE and 48.2% with late PVE. 44 PVE episodes (78.6%) were treated with antibiotics only (AbG –antibiotic group) and 12 episodes (21.4%) with combined antibiotic and surgery (SurgG-surgery group). The analysis included data of hospital records. Survival at long-term follow up LTFU (12.87 ± 0.97 years) was obtained from National Insurance Database. Patients lost to follow up (n = 10) were excluded from our analysis.
Results: The cure of PVE was obtained with conventional therapy (antibiotics) for 71% of our patients and was independent of the AbT type (multivariate analysis). In the AbG in-hospital death rate was 2% and transfer rate due to complications 27%. 21.4% of patients referred for early surgery due to hemodynamic instability (58.3%), perivalvular extension of infection (75%), embolism (58.3%), and persisting fever (25%) have had a 66.6% survival rate.
Factors related to short-term mortality in this group were: age (p = 0.04), diabetes (p = 0.016), ischemic heart disease (p = 0.07), heart failure (p = 0.07), hemodynamic instability (p = 0.04), persistent fever (p = 0.06), anemia (p = 0.001). The AbT duration overall was 33.55 ± 12.8 days.
Short-term survival rate overall at the end of initial treatment was 90.4%. Long-term follow up survival rate was 44%, very low and relatively homogenous: 42.8 % SurgG, 44.1% AbG. Factors related to long-term mortality were advanced age (p = 0,0009), diabetes (p = 0.038), mid range LV ejection fraction (p = 0.038) and staphylococcus infection (p = 0.053).
Conclusions: In studied patients, there was a very high long-term mortality rates regardless of therapeutic strategy. Nevertheless, in selected patients, without complications, conservative approach could be adequate in the setting of short-term follows up. Younger and hemodynamically stable patients, with non-staphylococcal PVE and with preserved ejection fraction, who are carefully supervised, may be safely treated with antibiotics alone.
Whether the reasons of poor long-term results can be attributed to the lack of early surgery or to the progression of preexistent heart failure remains biased by the limited number of patient, high rate of lost to follow up and by the absence of current concept of "endocarditis team".

P1829

Patent foramen ovale: red flag in radiologically isolated syndrome

E Elisabeta Koci[1]; G Maresca[2]; E Signoriello[3]; G Puoti[3]; G Lus[3]; A Rapacciuolo[1]
[1]Federico II University Hospital, Department of Advanced Biomedical Sciences, Section of Cardiology, Naples, Italy; *[2]Unità Operativa di Interventistica Cardiovascolare, Presidio Ospedaliero Pineta Grande, Castel Voltu, Naples, Italy*; *[3]Second University of Naples, Multiple Sclerosis Center, II Division of Neurology, Department of Clinical and Experimental Medicin, Naples, Italy*

Objectives: To investigate the association of white matter lesions suggestive of demyelinating disease in magnetic resonance imaging (MRI) with patent foramen ovale (PFO) in migraine patients, with and without aura.
Materials: 22 migraine patients, 19 females and 3 males, with MRI evidence of white matter lesions suggestive of demyelinating disease. In 16 patients Barkhof criteria for dissemination in space were respected. For this reason, all the patients practiced further diagnostics including lumbar puncture, autoimmunity panel, thrombophilic evaluation, cardiological evaluation to detect the presence of PFO. Instrumental and clinical follow-up over three years was practiced and MIPAV software was used to analyse MRI imaging.
Results: 13 of 22 patients (59%) had PFO. Significant association was found between PFO and migraine with visual aura (p = 0.03) and thrombophilia (p = 0.04). None of them had oligoclonal bands in csf (p = 0.014). No difference in number, volume and distribution of the lesions between the patients with and without PFO was noticed and 11 out of 16 patients carrying Barkhof criteria for disseminating in space had PFO. The follow up showed a stationary lesion load in all PFO patients, no infratentorial or spinal cord lesions and no enhancement at any time. The presence of PFO didn't affect the lesions localization (periventricular, iuxtacortical, frontal, occipital, temporal or parietal) and corpus callosum lesion was never detected.
Discussion and conclusions: Migraine is often one of the main symptoms leading the patient to perform MRI, discovering, in most of the cases, white matter lesions of unspecific significance and placing always demyelinating diseases in differential diagnosis. Our study underlines the potential pathogenetic role of PFO in generating white matter lesions in migraine patients (59%), particularly in those with visual aura and thrombophilia. On the other side, with the evidence that 11 out of 16 patients carrying Barkhof criteria for disseminating in space had PFO and no clinical and instrumental diagnosis of demyelinating disease, we state that cardiologic evaluation represents a cardinal toll in differential diagnosis of RIS.

P1830

Risk factors, predictors and outcome of patients with complicated infective endocarditis in intensive care unit

F Farook Ahmad[1]; S Cox[2]; ST Chan[3]; E Abdul Rahman[4]; I Zainal Abidin[1]; MA Sadiq[5]
[1]Universiti Malaya Medical Centre, Division of Cardiology, Department of Medicine, Kuala Lumpur, Malaysia; *[2]HeartCare Partners, Department of Cardiology, Brisbane, QLD, 4066, Australia*; *[3]Putrajaya Hospital, Department of Internal Medicine, Pusat Pentadbiran Kerajaan Persekutuan, Presint 7, 62250 Putrajaya,, Malaysia*; *[4]Universiti Teknologi MARA, Department of Cardiology, Selangor, Malaysia*; *[5]Sultan Qaboos University , Cardiology Unit Department of Medicine, Muscat, Oman*

Introduction: Despite improvement in diagnosis and management, infective endocarditis related mortality and morbidity might occur even after successful treatment especially in patients with complicated IE needing medical intensive care unit (MICU) or coronary care unit (CCU) care. However, no previous study has explored the outcomes (for example, heart failure, myocardial infarction and cardiovascular death) in these patients.
Objective: This study investigates the short term, intermediate and long term outcome in patients with complicated IE admitted to MICU/CCU for medical treatment.
Method: A single – centre retrospective analysis was conducted among patients with complicated infective endocarditis requiring admission to MICU/CCU between 2001 and 2016. All patients fulfilled the modified Duke Criteria for definite diagnosis of IE. All patients undergo both transthoracic echocardiography (TTE) and then followed by transesophageal echocardiography (TOE). TTE was performed within 3 days on presentation to the hospital while TOE was performed within 3 days prior to transfer to MICU/CCU or on the day of transfer itself. The patients were identified via the hospital information system.
Results: 65 patients, with a mean age of 47 ± 10 years, were diagnosed with complicated IE, in which, 39 (60.0%) of them were male. IE survivors were defined as patients who survived after being discharged from MICU/CCU and at 6 months follow up with a documented diagnosis of IE. A total of 30 survivors form total patients

of 65 were identified. 50 patients required inotropic support and 41 patients developed multi-organ failure. 22% of the patients developed mobitz type II heart block or complete heart block. 9 patients of the mobitz type II heart block progressed to complete heart block requiring temporary/permanent pacemaker. Microbiology laboratory investigation showed 95% of the patients grew gram-positive cocci in their blood cultures. Surgical intervention was conducted in 30% of the patients and the remaining was medically treated. Biomarkers of acute infection, APACHE III as well as echocardiographic findings were analyzed. Using multivariate analysis, patients who developed acute kidney injury prior transfer to ICU (OR 9 95% CI 1.19–22.00, P = 0.03) or echocardiographic evidence of vegetation size > 15mm (OR 7 95% CI 1.07-17.71 P = 0.03) were identified as predictors for in-patient death.
Conclusion: In contrast to general IE populations, infectious agents and the type of infected impaired valve are not the main predictors of survival in critically ill IE patients. Our study concludes that markers for severity of illness (scores and organ failure) as well as echocardiographic findings of vegetations size >15 mm are independent risk factors for poor prognosis and mortality. In addition, early utilization of TOE to identify large vegetation prompting a more aggressive treatment approach to prevent septic emboli as well as reducing mortality.

P1831

Mitral balloon valvuloplasty: risk factors for lack of success, severe mitral regurgitation and major complications

I P Ivana Picone Borges[1] ; M Nascimento[1] ; ECS Peixoto[1] ; RTS Peixoto[1] ; RTS Peixoto[1]
[1]*Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil*

Background: Mitral balloon valvuloplasty is not always successful and free from complications.
Objectives: To determine the independent risk factors for an unsuccessful procedure, severe mitral regurgitation and major complications in mitral balloon valvuloplasty.
Methods: Longitudinal prospective study of 518 mitral balloon valvuloplasties performed between July 6, 1987 and December 31, 2004, on 429 (82.8%) female patients and 89 (17.2%) male patients with a mean age of 37.5 ± 12.8 years. Major complications were considered to be: perforation with cardiac tamponade, stroke and severe mitral regurgitation per procedure. The continuous variables were transformed in categorical variables and the chi-square or Fisher exact tests to compare the categorical variables, and logistic regression and multiple logistic regression were used to identify independent factors for predicting success, incomplete procedure, severe mitral regurgitation and major complications.
Results: Success was noted in 452 (94.2%) procedures, with major complications occurring in 22 (4.2%) patients, of which ten were severe mitral regurgitation; there were no per-procedure deaths, with four (0.8%) in-hospital deaths. In the multiple logistic regression, lower age predicted success in the procedure; the only variable that predicted an incomplete procedure was the initial period of the procedure, and a score >11 points predicted severe per-procedure mitral regurgitation. There was no independent predictor of major complications in this study.
Conclusions: Success was related to younger patients, an incomplete procedure to the initial period of the procedure and severe per-procedure mitral regurgitation to an echocardiography score >11 points

P1832

Balloon miral valvotomy for patients with mitral stenosis in atrial fibrillation :immediate and long terme prognosis

ALAEDD Jalled[1] ; MAJED Hassine[1] ; MAROUA Mahjoub[1] ; MEJDI Ben Messoud[1] ; HABIB Gamra[1]
[1]*University of Monastir, cardiology A departement, Monastir, Tunisia*

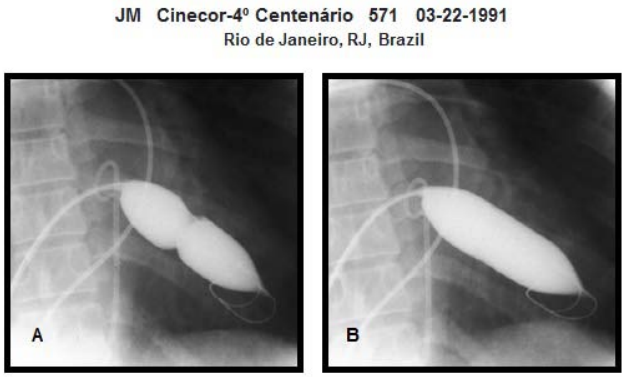
Background: Atrial fibrillation (AF) is a common finding in patients with severe mitral stenosis requiring Ballon Mitral Valvotomy (BMV). Its immediate and long term prognosis remains controversial
Objectivies: We sought to evaluate the effect of AF on immediate and long-term (23years) outcome of patients undergoing BMV
Methods: The immediate procedural and the long-term clinical outcome after BMV of 139 patients with AF were collected and compared with those of 381 patients in normal sinus rhythm (NSR).
Results: patients with AF were older (43.3 vs 29.7 years ; p < 0.001) , had frequently a history of systemic embolisim (9.4% vs 1.6% , p < 0.001) and of mitral commissurotomy (28.1% vs 19.4% , p = 0.035). Symptoms were similar between the tow groups (NYHA>II : 48.9% vs 49.9% , p = 0.648). patients with AF had more frequently a wilkins score >8 (51.4% vs 30.9% , p < 0.001), a larger left atrium (41cm2 vs 32cm2 , p = 0.001) and a lower transmitral gradient (11.1mmhg vs 16.6mmhg ,p < 0.001) BMV was equally successful in the tow groups (90.6% vs 94%, p = 0.187) but resulted in a smaller post BMV areas (2cm2 vs 2.15cm2 , p = 0.012) with a lower mitral valve area gain (0.9cm2 vs 1cm2 , p = 0.015)BMV was not associated with a higher risk of complications (4.3% vs 4.7% , p = 0.844) After a mean follow up of 74 months , patient with AF had the same rate of restenosis (28.3%vs 25.6%, p = 0.96) but required more frequently a mitral valve replacement (16.3% vs 7.7% , p = 0.012) They also experienced higher rates of systemic embolism (3.8% vs 0.6% , p = 0.018) and had a lower rate of event free survival (freedom from death , restenosis and systemic embolism) (52.2% vs 68.8% , p = 0.047). In the group of patients in AF , predictive factors for combined adverse event including death , restenosis , and systemic embolism and mitral valve replacement are : post BMV area < 2cm2 (OR:2.5, 95% CI [1.2; 5.18], p = 0.014) , procedural complication including severe mitral regurgitation and tamponnade (OR:3.95, 95% CI [1.4 ; 11. 13], p = 0.009) and NYHA II ,III during follow up (OR : 3.46 , 95% CI [2.09 ; 5.73], p < 0.001
Conclusion: our data support the fact that patient with AF have worse immediate and long term outcomes after BMV. Post BMV area < 2cm2 , procedural complications and dyspneapredict adverse events during follow up.

P1833

Percutaneous mitral valvuloplasty with balt single balloon and the long-term follow-up. Survival and event free survival

I P Ivana Picone Borges[1] ; ECS Peixoto[1] ; RTS Peixoto[1] ; RTS Peixoto[2] ; AAB Aragao[1] ; ILPB Anjos[3] ; VF Marcolla[1] ; LLB Bandera[3]
[1]*Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil*; [2]*State Institute of Cardiology Aloysio de Castro, Rio de Janeiro, Brazil*; [3]*Severino Sombra University, School of Medicine, Rio de Janeiro, Brazil*

Introduction: Worwire, mitral ballon valvuloplasty is acknowledged, by cardiology guidelines, as an effective treatment for mitral stenosis. Diferents balloons may be safely used. Single balloon technique is a less expensive technique to perform MBV
Objective: To evaluate the long-term follow-up (FU) of mitral balloon valvuloplasty (MBV) with Balt single balloon (BSB) technique and to determine independent predictors of survival and event-free survival (EFS).
Method: From 1987 to 12-31-2013, 526 procedures of MBV were perfomed, 404 (77.1%) with BSB. There were 256 procedures with long-term FU. Balloon diameter: 25 mm in 5 procedures, 30 mm in 251; mean dilatation area: 7.02 ± 0.30 cm^2. FU was 156 ± 144 months. Multivariate Cox analisys to determine IPS and EFS.
Results: Mean age: 38.0 ± 12.6 (13 to 83) years, 222 (86.7%) female gender, 215 (84.0%) sinus rhythm, echo score (ES) 7.2 ± 1.5 (4 to 14) points and echo mitral valve area (MVA) pre-MBV 0.93 ± 0.21 cm^2. Mean pre and post-MVA (Gorlin): 0.90 ± 0.20 and 2.02 ± 0.37 cm^2, respectively (p < 0.001). Success (MVA ≥1.5 cm^2): 241 (94.1%) procedures. Mean pulmonary artery pressure pre and post-MBV: 27 ± 10 and 20 ± 7 mmHg, respectively. Three (1.2%) patients began the FU with severe mitral regurgitation (SMR). At the end of FU 119 (46.5%) patients were in NYHA funcional class (FC) I; 70 (27.3%) in FC II; 53 (20.7%) in FC III; 3 (1.2%) in FC IV; 11 (4,3%) deaths; 17 (8.2%) patients with SMR; 20 (4.7%) were submitted to a new MBV; 27 (10.5%) to mitral valve surgery and 70 (26.3%) without any medicine. Independent predictors of survival were: ES ≤8 points (p < 0.001, HR0.116, 95% IC 0.035-0.384), age ≤50 years old (p = 0.011, HR 0.203, 95% IC 0.059-0.693) and absence of mitral valve surgery in the FU (p = 0.004, HR 0.170, 95% IC 0.050-0.571). Independents of EFS were: absence of prior commissurotomy (p < 0.002, HR 0.318, 95% IC 0.151-0.667), female gender (p = 0.036, HR 0.466, 95% IC 0.229-0.951) and MVA post-MBV ≥1.50 cm^2 (p < 0.001, HR 0.466, 95% IC 4.884-28.457).
Conclusions: Success in 94% of procedures. At the end of follow-up (25 years) only 4,3% of mortality. The independent predictors of survival were: ES ≤8 points, age ≤50 years old and absence of mitral valve surgery in the FU. Independent predictors of EFS were: absence of prior commissurotomy, female gender and MVA post-MBV ≥1.50 cm^2



P1834

Redo percutaneous mitral commissurotomy interventions for mitral stenosis: immediate and one-year results compared to a primary procedure, a prospective observational study between 2010 and 2015

C Cindy Perron[1]; G Bonnet[1]; JP Mouret[1]; E Salaun[1]; JL Bonnet[1]
[1]*Hospital La Timone of Marseille, Marseille, France*

Introduction: Percutaneous mitral commissurotomy (PMC) has virtually replaced surgery in the treatment of mitral stenosis. However, the indications for PMC in the setting of mitral restenosis remain poorly characterized, and a history of PMC is considered to be an unfavorable anatomic feature in the latest european guidelines. Our study has therefore compared immediate and one-year results of redo versus primary interventions.
Methods: All patients in whom PMC was performed for mitral stenosis between 06/02/2010 and 06/02/2015 in University Hospital were included. Patients have been divided into two groups depending on their status: primary or redo PMC. Clinical, echocardiographic and procedural data have been collected in the medical files. Referring cardiologists were contacted to obtain information at one-year follow-up (restenosis, redo intervention, heart failure, and death).
Results: During the study period, 61 patients underwent PMC for mitral stenosis in our center. It was a redo procedure in 21 cases (33%). Baseline characteristics were comparable in both groups. Initial global success rate, as defined by a post-procedural mitral valve area > 1.5 cm2 without mitral regurgitation > 2/4, was 80%. It didn't significantly differ depending on the status (82.9% for a primary versus 73.7% for a redo intervention; OR=1.717 [0.364; 7.599] ; p = 0.49). One-year overall survival without event was 64.4% (65% versus 63.2% ; OR=1.081 [0.29;3.84] ; p = 0.99). There were no significant differences regarding rates of death (14.6% versus 5.3% ; OR=0.329 [0.006;3.045] ; p = 0.41), heart failure (27.5% versus 15.8% ; OR=0.499 [0.078;2.289] ; p = 0.51), restenosis (15% versus 31.6% ; OR=2.568 [0.573;11.653] ; p = 0.17) or reintervention (5% versus 21% ; OR=4.908 [0.628;59.692] ; p = 0.07).
Conclusion: Redo PMC for mitral stenosis doesn't appear to be a risk factor of immediate and one-year procedural failure. These results should be confirmed or invalidated by a larger study.

P1835

Influence of chronic kidney disease on CRT response and clinical outcomes

I Ines Silveira[1]; R B Santos[1]; M Trepa[1]; MJ Sousa[1]; C Roque[1]; A Pinheiro-Vieira[1]; V Lagarto[1]; A Luz[1]; A Hipolito-Reis[1]; S Torres[1]
[1]*Hospital Center of Porto, Cardiology, Porto, Portugal*

Introduction: Chronic Kidney disease (CKD) is common among patients with heart failure (HF) and its presence could have a deleterious impact on outcome. The aim of this study was to evaluate the impact of baseline CKD on cardiac resynchronization therapy (CRT) response and clinical outcomes (composite of global mortality and HF hospitalizations) at 5 years follow up.
Methods: Single-center, retrospective study of patients who underwent CRT implantations between January 2002 and March 2016. A clinical and echocardiographic evaluation were performed previous to CRT and 6-12 months after. CKD was defined as a creatinine clearance ≤ 60 ml/min determined by MDRD formula. CRT response was defined as an increase in LV function ≥5% and an improvement in NYHA class ≥1. Predictors of the composite outcome were determined by logistic regression analysis. Variables with p < 0.1 in univariate analysis were included in multivariate model.
Results: A total of 246 patients were included (mean age 68.8 ± 10.6 years, 63.2% males, 40.7% ischaemic aetiology), with a mean follow-up time of 34.1 ± 21.1 months. CKD was present in 22.4% of patients. Patients with CKD were older (71.7 ± 10.3 vs 67.9 ± 10.6 years p = 0.02), had a higher rate of hypertension (78.3% % vs 65.5% p = 0.022) and had more frequent NYHA class III/IV before CRT implantation (86.8% vs 67.1% p = 0.04), compared to patients without CKD. There were no significant differences regarding gender, cardiomyopathy aetiology, baseline left ventricular ejection fraction or other cardiovascular risk factors. CRT response was similar between groups (43.2 % vs 53.5% p = 0.183). At 5 years follow up, a significant difference was found on composite outcome (44.4% CKD vs 23.0% non-CKD group, p = 0.002). After multivariate analysis, presence of baseline CKD and absence of CRT response were independent predictors of the composite outcome (HR: 2.7; 95% CI 1.3-5.4 p = 0.004 and HR: 0.19; 95% CI 0.06-0.62 p = 0.006, respectively).
Conclusion: Patients with CKD had similar rate of response to CRT but worse prognosis. Presence of baseline CKD was an independent predictor of 5 years HF hospitalizations and global mortality.

P1836

Diastolic function, filling pressures in combination with B-type natriuretic pepetide levels affect cardiac resynchronization therapy response in chronic heart failure patients.

E Hatzinikolaou-Kotsakou[1]; E Reppas[1]; M Kotsakou[1]; G Moschos[1]; P Latsios[1]; G Moschos[1]; TH Beleveslis[1]; M Konstantinidou[1]; A Chantas[1]
[1]*Saint Lukes Private Hospital , Electrophysiology Deparment , Thessaloniki, Greece*

Cardiac resynchronization therapy (CRT) is an established treatment for symptomatic patients (pts) with chronic heart failure (CHF) prolonged QRS duration with Left bundle branch block morphology. Approximately 30% of patients treated with cardiac resynchronization therapy (CRT) do not respond. Identification of 'responders' and 'non-responders' to CRT has attracted considerable attention.
Aim: The aim of the study was to assess and identify if the extent of co-existing diastolic dysfunction and high filing pressures in combination with levels of B -type natriuretic peptide (NT-proBNP) could being best predictors of CRT response.
Methods: A single-center, prospective analysis was conducted in 225 consecutive CRT recipients (CRT-D100%) from January 2007 to October 2015 in a longitudinal CRT database: ischemic cardiomyopathy (n = 128) and DCM (n = .97) Clinical variables and echocardiographic measures were evaluated preimplant and 12 months post implant.All patients underwent conventional 2-dimensional/Doppler echocardiography and Doppler tissue analysis of mitral annular velocities. As a measure of left ventricular filling pressures, the ratio of peak early mitral flow velocity to peak early diastolic mitral annular velocity was derived. NT-proBNP measurements were carried out on a bench-top analyzer. Response to CRT was defined as an absolute increase of >= 5% in left ventricular ejection fraction (LVEF) compared with baseline at 12 months after CRT implantation without heart failure rehospitalization or any cause of death. There were 164 responders (68%) and 61 nonresponders (32%).
Results: Patients responders and non responders did not differ with respect to the cause of CHF or ejection fraction, but in non responders pts deceleration time was shorter (152 +/- 62 vs 218 +/- 88 milliseconds, P = 0. 02) and a restrictive mitral filling pattern was more frequent (35% vs 11%, P = .005). In such patients, the ratio of peak early mitral flow velocity to peak early diastolic mitral annular velocity was higher (16.2 +/- 5.4 vs 11.6 +/- 4.9, P < . 001) and NT-proBNP was elevated 4452 +/- 3825 vs 910 +/- 868 pg/mL, P < 0.012 as compared with responders pts
Conclusions: Severe diastolic dysfuncion, elevated filling pressures associated with higher NT-proBNT levels in pts with CHF could identify responders to CRT. These findings may be used to improve the appropriate use of CRT, to increase the CRT response rate. It is needed our results to be validated on a large prospective multicenter trial.

P1837

Role of global myocardial work in the identification of responders to CRT

E Galli[1]; C Leclercq[1]; A Hubert[1]; A Bernard[2]; O Smiseth[3]; E Samset[3]; E Donal[1]
[1]*University Hospital of Rennes, Cardiology, Rennes, France*; [2]*University Hospital of Tours, Tours, France*; [3]*University of Oslo, Oslo, Norway*

Background: cardiac resynchronization therapy (CRT) has a pivotal role in the management of patients with HF and wide QRS complex, but is affected by still too

many non responders. Aim of the resent study is to evaluate the role cardiac work estimated by pressure-strain loops (PSLs) in predicting CRT response.
Methods: 97 patients with symptomatic heart failure underwent CRT implantation according to current recommendations. Standard 2D and speckle tracking echocardiography were performed before CRTand at 6-month follow-up (FU). PSLs analysis allowed the calculation of global and regional myocardial positive (PosW) and negative work (NegW). A reduction >15% of left ventricular (LV) end-systolic volume at FU defined CRT positive response (CRT+)
Results: at FU, 63 (65%) patients resulted responders to CRT. Global PosW (PosWtot), lateral wall PosW (PosWlat), global NegW (NegWtot), septal NegW (NegWsept) and lateral NegW (NegWlat) were significantly increased in CRT+. At multivariate regression analysis, no regional work parameter emerged as predictor of CRT+, PosWtot >1057 mmHg/% (OR 7.30, p = 0.01) and SF (OR 7.33, p < 0.0001) being the only significant predictors of CRT+. PosWtot was significantly associated to the entity of myocardial remodeling after CRT in both ischemic (r=-0.55, p < 0.0001) and non-ischemic patients (r=-0.65, p < 0.0001).
Conclusions: patients with higher PosWtot, show a favorable response to CRT. These data support the role of residual myocardial contractility in CRT candidates and encourage further studies finalized at the assessment of the myocardial substrate of functional response in CRT candidates

P1838

Level of testosterone as a predictor of response to cardiac resynchronisation therapy

TN Enina[1]; VA Kuznetsov[1]; AM Soldatova[1]; TI Petelina[1]; DV Krinochkin[1]; SM Dyachkov[1]; AY Rychkov[1]; OY Nohrina[1]
[1]Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Tyumen, Russian Federation

Background: Approximately one-third of patients with congestive heart failure (CHF) do not benefit from cardiac resynchronisation therapy (CRT). There is lack information about association of sex hormones, CHF biomarkers levels and response to CRT.
Purpose: To assess the relationship of testosterone level (TES) with effect of CRT in men with CHF.
Methods: In 58 men undergoing CRT (mean age 54.8 ± 9.6 years; 61% ischemic etiology) response to CRT was evaluated as the best decrease of left ventricular end-systolic volume (LVESV) in mean follow-up period 38 [19.0;53.7] months. According to TES level patients were divided into groups: I group (n = 28; 48%) - TES < median (13.82 nmol/L); II group (n = 30; 52%) - TES ≥ median. At baseline, 1, 3 months and each 6 months after implantation echocardiographic parameters, levels of NT-proBNP, interleukin (IL)-1β, IL-6, IL-10, tumor necrosis factor - alpha (TNF-α), matrix metalloproteinase - 9 (MMP-9), tissue inhibitors of MMP 1, 4 (TIMP-1, TIMP-4) were measured. At baseline levels of TES, progesterone (PGN), dehydroepiandrosterone (DHS), estrogen (E2) were evaluated.
Results: The percentage of responders (decrease in LVESV 15-30%) and super-responders (decrease in LVESV ≥30%) was significantly higher in II group (p = 0.05). Increase in left ventricular ejection fraction (p = 0.007) and decrease in LVESV (p = 0.069) were more evident in II group. At baseline levels of IL-1β, IL-10, TNF-α, PGN were higher in II group (all p = 0.05). II group showed decrease of IL-1β level (p = 0.001), IL-6 (p = 0.015), IL-10 (p = 0.001), TNF-α (p = 0.001), TIMP-1 (p = 0.046). In I group only NT-proBNP decreased significantly (p = 0.015). In I group we identified correlations of sex hormones: PGN-IL-10 (r=0.553; p = 0.026), PGN-TIMP-1 (r=0.518; p = 0.048), DHS-NT-proBNP (r=-0.599; p = 0.031), DHS-TIMP-4 (r=-0.671; p = 0.004); in II group: PGN-IL-10 (r=0.710; p < 0.001), PGN-TIMP-1 (r=0.693; p = 0.004), DHS-NT-proBNP (r=-0.566; p = 0.007), DHS-IL-6 (r=-0.543; p = 0.011), E2-IL-6 (r=0.519; p = 0.016). In ROC-analysis level of TES=12.35 nmol/L was identified as a predictor of positive response to CRT with sensitivity of 68.3% and specificity of 52.9% (AUC=0.687; p = 0.026).
Conclusion: Higher level of TES is associated with better effect of CRT and decreased inflammatory activity. Level of TES ≥12.35 nmol/L can be used as a predictor of positive response to CRT. Sex hormones have important physiological role in CHF and response to CRT.

P1839

Multi-biomarkers laboratory strategy for outcome prediction in patients with severe systolic dysfunction submitted to CRT

M Beltrami[1]; A Palazzuoli[2]; A Paoletti Perini[1]; C Tosti Guerra[1]; MG De Gregorio[1]; B Franci[2]; P Pieragnoli[1]; R Nuti[2]; L Padeletti[3]
[1]University of Florence, Cardio-Thoracic and Vascular Department, Florence, Italy; *[2]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy*; *[3]IRCCS Multimedica of Milan, Milan, Italy*

Background: Several biomarkers are studied in order to predict outcome and response to Cardiac resynchronization therapy (CRT). ST-2 is linked to cellular death and fibrosis and it is a new emerging prognostic biomarkers in several Heart Failure (HF) setting, Galectin 3 (Gal-3) is related to myocardial fibrosis and cardiovascular stiffness, and N-terminal portion of the B-type natriuretic peptide (NT-proBNP) represents the more codified biomarker for risk stratification and assessment of the hemodynamic status. Finally, elevated levels of cytokine (IL-6 and TNF-α) have been related to the progression of HF status.
Purpose: 1) to investigate the role of ST-2, Gal3, NT-proBNP IL-6 and TNF-α for outcome prediction in terms of cardiac death, re-hospitalization for HF and sustained ventricular arrhythmias in patients submitted to CRT. 2) to evaluate the impact on renal dysfunction and measured biomarkers on outcome in responders versus non responders.
Methods: We retrospectively evaluated 81 consecutive patients referred for CRT with symptomatic drug-refractory heart failure (NYHA II-IV), left ventricular (LV) systolic dysfunction with ejection fraction (EF) ≤35%, QRS width ≥120 ms. We measured all the aforementioned biomarkers together with creatinine, and estimated the Glomerular Filtration Rate (eGFR) at baseline and after 1 year of CRT. At 1 year an echocardiographic reduction of LV end-systolic volume ≥15% was considered as index of reverse remodeling and used to define a patient as responder to CRT. The outcome was assessed during a mean follow up period of 3 years.
Results: Out of 81 patients submitted to CRT, 51 (63%) were responders. Events rate in responders was 4% respect to 50% in non responders (p < 0.001). None of the studied biomarkers demonstrated a significant difference between responders versus non-responders. Conversely Gal-3 (29.8 + 13.9 ng/mL vs 19.9 + 7.6 ng/mL p = 0.002) and NT-proBNP (5133 + 4300 pg/ml vs 1391 + 1205 pg/ml p < 0.001), together with presence of renal dysfunction (45 + 17 ml/min/1,73 m2 vs 58 + 20 ml/min/1,73 m2 p = 0.008), demonstrated a prognostic significance. Roc curve analyses showed a relation among baseline Gal-3≥23 ng/ml, pro NT-BNP≥1400 and prognosis (AUC 0,65 IC 0,51-0,80 p = 0.04 and AUC 0,69 IC 0,56-0,83 p = 0.01 respectively). The difference between Gal-3 and NT-proBNP from baseline to 12 months was not able to recognize patients with increased risk during 3 years follow up period.
Conclusions: Among patients with HF submitted to CRT the measurement of ST-2 and inflammatory biomarkers do not discern patients with worse outcome. Only baseline Gal-3 and NT-pro BNP may provide additional information for risk stratification.

P1840

Contractile function of the right ventricle as a predictor of the effectiveness of cardiac resynchronization therapy

D Lebedev[1]; S Popov[1]; S Krivolapov[1]; G Savenkova[1]; K Zavadovskij[1]; S Minin[2]
[1]Cardiology Research Institute, Tomsk National Research Medical Center of RAS, Tomsk, Russian Federation; *[2]State Research Institute of Circulation Pathology, Novosibirsk, Russian Federation*

Objective: The objective of the study was to evaluate right ventricular (RV) contractile function in patients with implanted devices for cardiac resynchronization therapy (CRT).
Materials and Methods: The study included 80 patients (49 men) with a diagnosis of dilated cardiomyopathy, mean age of 54 ± 10.5 years, heart failure (HF) functional class (FC) III by NYHA, left ventricular (LV) ejection fraction (EF) of 30.1 ± 3.8%, six-minute walk distance (6MWD) of 290.5 ± 64.3 m, and LV end-diastolic volume (EDV) of 220.7 ± 50.9 mL. Forty five patients had sustained sinus rhythm; 35 patients had chronic drug-resistant atrial fibrillation. All patients had complete blockade of the left bundle branch block; QRS duration ranged from 146 to 240 ms (183 ± 32 ms). CRT devices were implanted to all patients. In patients with persistent atrial fibrillation, complete artificial atrioventricular block was formed. In all patients, LV and RV myocardial contractile functions were assessed using equilibrium radionuclide tomoventriculography prior to CRT and 12 months after CRT device implantation.
Results: Follow-up examination was carried out after 1 year of CRT showing favorable clinical changes: HF FC decreased in all patients from III to II. 69 patients responded to CRT (86.25%); 11 patients (13.75%) did not respond to CRT. The criterion of patient's response to CRT was LV EF increase by 15% or more within 12 months. Responders to CRT showed favorable clinical changes: LV EF increased from 30.1 ± 3.8% to 42.8 ± 4.8% (p ≤ 0.001); LV EDV decreased from 220.7 ± 50.9 mL to 197.9 ± 47.8 mL (p ≤ 0.005). In nonresponders, LV EF did not change significantly (30.1 ± 3.8% vs. 33.8 ± 3.8%, p ≤ 0.001); LV EDV increased from 220.7 ± 50.9 to 227.8 ± 27.8 mL (p ≤ 0.001). All patients were retrospectively divided into two groups: group 1 comprised patients who responded to CRT; group 2 included nonresponders. In patients of group 1, radionuclide tomoventriculography showed that RV peak filling rate (PFR) decreased from 1.8 ± 0.36 to 0.56 ± 0.16 (p ≤ 0.001); mean diastolic filling rate (1/3FR-m) decreased from 0.6 ± 0.2 to 0.36 ± 0.15 (p ≤ 0.001). In patients of group 2, these indices were significantly poorer (by 30% and 60%, respectively). Other parameters did not significantly differ between groups.

Conclusion: CRT in patients with severe HF was significantly more effective in those individuals who had preserved contractility of the right cardiac chambers. The values of RV PFR and RV 1/3FR-m may serve as prognostic criteria for favorable response of patients to CRT.

P1841

Dynamic variation of renal function and novel or old HF biomarkers (ST2, Galectin 3, NT-proBNP) and response to cardiac resynchronization therapy (CRT)

M Matteo Beltrami[1]; A Paoletti Perini[1]; A Palazzuoli[2]; G Ruocco[2]; C Tosti Guerra[1]; P Pieragnoli[1]; G Ricciardi[1]; R Nuti[2]; L Padeletti[1]
[1]University Hospital Careggi, Dipartimento Cuore e Vasi, Università degli Studi di Firenze, Firenze, Italy; *[2]University of Siena, Siena, Italy*

Background: Cardiac resynchronization therapy (CRT) is an established treatment in patients with drug-refractory heart failure (HF), left bundle branch block, and severe left ventricular (LV) dysfunction, although approximately 30% of patients do not respond to such treatment. ST2 is a member of the interleukin-1 family involved in modulating cardiac remodeling and ventricular function. Galectin-3 (Gal-3) is a marker of fibrosis activity and cardiac remodeling. NT-proBNP represents the more codified and measured biomarker for risk stratification and hemodynamic status in HF. However, dynamic changes in the aforementioned biomarkers and structural response to CRT are still poor investigated.
Purpose: To investigate temporal variations of ST-2, Gal-3, NT-proBNP and renal function from baseline to 1-year follow-up, and their interactions with LV reverse remodeling after CRT.
Methods: We retrospectively evaluated 81 consecutive patients referred for CRT according to current Guidelines. We measured ST-2, Gal-3, NT-proBNP, creatinine and estimated Glomerular Filtration Rate (eGFR) at baseline and after 12 months. eGFR was calculated by the CKD-EPI formula. Variations of each marker were calculated as ln(value at 12 months/value at baseline), given the skewed distribution of the data. Echocardiographic response was evaluated at 6 months follow-up, and traditionally defined as reduction of LV end-systolic volume ≥15%.
Results: At baseline, we found significant, mild correlation between Gal-3 and markers of renal function (for eGFR, Spearman's rho -0.348, p = 0.002; for creatinine, rho 0.320, p = 0.004) and with ST-2 levels (rho=0.354, p = 0.001) and stronger correlation with NT-proBNP levels (rho=0.453, p = 0.001). Moreover NT-proBNP showed a mild correlation with eGFR (rho=-0.330, p = 0.003) and creatinine (rho=0.355, p = 0.001). All other correlations were not significant. However, temporal changes from baseline to 12 months for each parameters were not significantly related to each other, except for a very mild correlation between ST-2 and markers of renal function (for eGFR rho=0.236, p = 0.004; for creatinine rho 0.249, p = 0.034). Echocardiographic response was significantly associated with improvement in renal function at 12 months, as compared with baseline (independent sample t-test p = 0.038 for eGFR, p = 0.046 for creatinine), but not with variations in Gal-3 (p = 0.729), ST2 (p = 0.649) and NT-proBNP (0.289). Moreover, percentage changes in eGFR and in creatinine were linearly correlated with percentage changes in LVESV (Spearman's rho 0.229, p = 0.047; rho -0.235, p = 0.041, respectively).
Conclusions: In patients candidates to CRT, markers of renal function, NT-proBNP and Gal-3 are significantly associated before implantation, but their temporal changes at 1-year follow-up are no more correlated. Echocardiographic response to CRT is associated with positive changes in indexes of renal function, but not with changes in NT-proBNP or Gal-3.

P1842

Cardiac resynchronization Therapy pacemaker or defibrillator? Long term follow-upoutcomes

B Belen Alvarez[1]; JR Garcia Seara[1]; RA Abellas Sequeiros[1]; D Iglesias Alvarez[1]; L Gonzalez Melchor[1]; M Rodriguez Manero[1]; XA Fernandez Lopez[1]; I Gomez Otero[1]; JL Martinez Sande[1]; A Martinez Monzonis[1]; JR Gonzalez Juanatey[1]
[1]University Clinical Hospital of Santiago de Compostela, Department of Cardiology, Santiago de Compostela, Spain

Introduction: Cardiac resynchronization therapy (CRT) is a well-established treatment option for patients with advanced HF. The aim of our study is establish wether there were any significant differences in outcomes between CRT-D and CRT-P.

Baseline Characteristics

	CRT-D 172 (52.4%)	CRT-P 156(47.6%)	p-value
Age, y	71±9	70±10	0.326
Sex male, n(%)	127(73.8)	126(80.8)	0.135
Ischemic cardiomyopathy, n(%)	57(33.1)	62(39.7)	0.214
Atrial fibrillation, n(%)	65(37.8)	58(37.2)	0.909
NYHA class II IIIIV	52(30.2) 107(62.2) 13(7.6)	27(17.3) 123(78.8) 6(3.8)	0.004
Betablockers, n(%)	144(83.7)	127(81.4)	0.581
ACEI, n(%)	148(86.0)	135(86.5)	0.897
MRA, n(%)	81(47.1)	73(46.8)	0.957
Amiodarone, n(%)	20(11.6)	21(13.5)	0.616
Glomerular filtration rate	61±24	60±24	0.522
Hemoglobine	13±2	13±2	0.307
QRS duration	165±26	159±26	0.050
LVEF	28±7	26±7	0.063
LVESV	163±62	169±58	0.375

ACEI: angiotensin-converting enzyme inhibitor; CRT-D: Defibrillator with Cardiac Resynchronization Therapy; CRT-P: Pacemaker with Cardiac Resynchronization Therapy; LVEF: left ventricular eyection fraction; LVESV: left ventricular end diastolic volume; MRA: mineralocorticoid receptor antagonist; NYHA: New York Heart Association.

Methods: Our analysis included 328 patientes, who underwent implantation of either a CRT-P (47.6%) or a CRT-D (52.4%) in a single center between August 2001 and April 2015 (follow up 4.7 ± 3.1 year). Patients characteristics and all cause mortality were compared between both groups.
Results: Baseline characteristics are shown in Table 1. The Kaplan- Meier analysis showed no differences of mortality (log Rank p0.425). No-Adjusted all causes of mortality are similar in both groups. (HR 1.14, CI 95% 0.82-1.59, p 0.426), Adjusted all causes of mortality are also similar (HR 0.85, CI 95% 0.58-1.24, p 0.347). Ischaemic cohort did not differences: No-Adjusted all mortality: HR 0.87, CI95%0.52-1.43, p0.571; and Adjusted all mortality: HR 0.79, CI95%0.43-1.43, p0.430
Conclusion: Survival rate was similar with CRT-P and CRT-D, including de the ischemic cohort. No additional impact of ICD were demostrated in our population.

P1843

Predictors of hospitalization for heart failure following cardiac resynchronization therapy

M Maria Trepa[1]; C Gomes[1]; I Silveira[1]; B Brochado[1]; MF Oliveira[1]; R Baggen Santos[1]; VA Dias[1]; C Roque[1]; AP Vieira[1]; H Reis[1]; S Torres[1]
[1]Hospital Center of Porto, Cardiology, Porto, Portugal

Introduction: Cardiac Resynchronization Therapy (CRT) is an established treatment in selected patients with systolic heart failure (HF) and eletrical dyssynchrony. However some patients don't show the expected response and maintain an increased risk for hospitalization for acutely decompensated HF after implantation. The aim of this study was to identify clinical predictors of HF hospitalization after CRT.
Methods: Single-center retrospective observational study including 303 patients who underwent cardiac resynchronization therapy (CRT) between 2002 and 2016. Patients hospitalized for decompensated HF during a 5 year follow-up period were reviewed. The mean follow up time was 34.1 ± 21.1 months. Multivariate models were adjusted for clinical response (improvement in at least 1 NYHA class 6-12 months after CRT), echocardiographic response [improvement of > 5% in left ventricular ejection fraction (LVEF) 6-12 months after CRT], etiology (ischemic vs non-ischemic), chronic kidney disease [(CKD) defined as a creatinine clearance ≤ 60 ml/m2 determined by MDRD formula], diabetes and impaired right heart function after CRT.
Results: During follow-up 57 patients (18.8%) were hospitalized for HF. Regarding baseline characteristics, these patients were more likely to be ischemic (25% vs 14.5%, p = 0.021), diabetic (26% vs 16%, p = 0.05) and have CKD (33% vs 13%, p = 0.01). Age, gender, pré-implantation LVEF, QRS duration and pattern were not statistically different between the groups. Patients who presented worst clinical and echocardiographic response to CRT were at significantly increased risk for hospitalization (respectively: 35.4% vs 15.2%, p < 0.01 and 38.8% vs 7.8%, p < 0.01). Also patients with impaired right heart function after CRT showed more events (28.6%

vs 13.4%). In multivariate analysis absence of echocardiographic response (OR 3.9; p = 0.01) and CKD (OR 3.1; p = 0.03) were independent predictors of HF hospitalization.
Conclusions: Chronic kidney disease and absence of echocardiographic response are independently associated with HF hospitalization. Further studies are needed to assess the usefulness of this findings and its applications.

P1844
Clinical characteristics, predictors, and outcomes of super-responder in cardiac resynchronization therapy of patients with heart failure

J Jaewon Oh[1]; JS Uhm[1]; IC Kim[1]; TH Kim[1]; HN Pak[1]; MH Lee[1]; B Joung[1]; SM Kang[1]
[1]*Yonsei University College of Medicine, Cardiology Division, Seoul, Korea Republic of*

Introduction: Cardiac resynchronization therapy (CRT) can improve cardiac function through reverse left ventricular (LV) remodeling in heart failure (HF) patients with wide QRS duration. Recently, 'super-response' to CRT is known to be associated with improved survival. We assessed clinical characteristics, predictors and outcomes of super-responder in CRT.
Methods: We retrospectively enrolled 76 patients with CRT implantation from January 2010 to October 2015. Pre-defined CRT responders were: responders (decreased LV end systolic volume, LVESV 15-29%), and super-responders (decreased LVESV ≥30%). The response timing before or after 6 months was defined as early or late response, respectively. Clinical outcomes including all-cause mortality and rehospitalizations were assessed during follow-up period (median 555 days)
Results: Mean age, baseline LVEF and QRS duration were 66 ± 11 years, 24.8 ± 6.3% and 164 ± 24ms, respectively. The prevalence of men, LBBB and ischemic origin HF were 46.1%, 69.7% and 14.5%, respectively. At early period, there were 7 (9.2%) responders and 8 (10.5%) super-responders, while 9 (14.3%) responders and 22 (34.9%) supper-responders at late period. There were no mortality cases in early and late overall responders and fewer HF rehospitalization (4.5% vs. 22.2% for responders, p = 0.055) in super-responders. There were not any significant differences between responders and super-responders in terms of the prevalence of men, ischemic origin HF and age, baseline LVEF, QRS duration. However, the follow up QRS duration was significantly narrower (150 ± 20ms vs. 169 ± 21ms, p = 0.037) and the prevalence of LBBB was higher (90.9% vs. 44.4%, p = 0.012) in super-responders than that in responders.
Conclusion: Super-responders of CRT showed favorable clinical outcomes compared to nonresponders or even to responders. The decrease of QRS duration after CRT implantation can be a clinical predictor for super-response to CRT.

P1845
A systematic review of telemonitoring assessment for patients with heart failure

T Farnia[1]; MC Jaulent[1]; O Steichen[2]
[1]*University Pierre & Marie Curie Paris VI, Laboratoire d'Informatique Médicale et Ingénierie des Connaissances en eSanté (LIMICS - UMR_S 1142), Paris, France*; [2]*Hospital Tenon, AP-HP, Sorbonne Universités, UPMC Univ Paris 06, hôpital Tenon, Service de médecine interne, Paris, France*

Funding Acknowledgements: Health regional agency of region Centre Val de Loire and France ANRT ' Technology and research national association '

Background/Introduction: Telemonitoring (TLM) can improve heart failure (HF) management. However proper assessment of TLM services, and their impact on process and outcomes of care, is required. To the best of our knowledge, there is no standardized evaluation framework for TLM services to comprehensively evaluate the various impacts of TLM. The objectives of this systematic review are to list the criteria used in published evaluations of non-invasive HF TLM services, to describe how they are used and to organise them into a comprehensive evaluation framework.
Methods: The articles were retrieved through Medline, Web of Science and Embase from 1990 to August 2015. Articles were eligible if they were English original reports of a HF TLM evaluation study in English language. Reviews, editorials and position papers and studies implantable devices were excluded.
Results: Overall, 121 articles were selected and reviewed, leading to 52 evaluation criteria that were classified along six dimensions: technical, economical, educational, clinical, organizational and users' perspective. The clinical and economical impacts were evaluated in over 65% of studies whereas the educational, organizational and technical impacts were studied in less than 15%. Users' perspective was the most frequently covered dimension in the development phase of TLM projects, whereas study of the clinical and economical impacts were dominating in the later phases (implementation and integration)(Table 1).
Conclusions: TLM evaluation frameworks should cover all of the six dimensions, appropriately distributed along the TLM project life cycle. Our next goal is to build such a comprehensive evaluation framework for non-invasive HF TLM and to test it on an ongoing TLM project.

Table 1

Dimension	All studies (n = 121)	TLM project phase		
	Development (n = 23)	Implementation (n = 69)	Integration (n = 26)	
Clinical criteria	100 (83%)	11 (48%)	61 (88%)	23 (88%)
Economical criteria	84 (69%)	9 (39%)	50 (72%)	22 (85%)
Users' perspective	52 (43%)	19 (83%)	29 (42%)	12 (46%)
Educational criteria	17 (14%)	3 (13%)	9 (13%)	5 (19%)

Implementation of intravenous inotropic protocol in hospitalization unit with telemetry: initial experience

FM Barth[1]; LG Caballero[2]; G Aliti[1]; L Orlandin[1]; LB Silva-Neto[1]; E R Eneida Rejane Rabelo-Silva[3]
[1]*Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil*; [2]*Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*; [3]*Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Program at the Nursing School, , Porto Alegre, Brazil*

Background: Intravenous inotropic therapy plays an important role in the management of hospitalized patients with heart failure (HF). In particular, the use of inotropes at lower doses contributed to the potential expansion of its use, with lower rates of complications. Among patients with advanced HF using intravenous inotropic, severe, but stable cases, may be selected to benefit from continued treatment outside the intensive care setting.
Objective: To report the initial experience of the use intravenous inotropes at the ward unit under telemetry monitoring, in stable patients with advanced HF, in a general, public and university hospital.
Methods: Patients with advanced HF, refractory to conventional pharmacological treatment, clinically stable in the Coronary Care Unit for at least 24 hours with an unchanged (low or moderate) intravenous inotropic dose were selected (milrinone/dobutamine).The protocol was prepared by a multidisciplinary team and implemented in an inpatient unit whose staff was adequately trained. Inotrope was infused through a central inserteted peripheral catheter; once the dose was considered stable, the patient was discharged to the ward.
Results: From 09/2015 to 12/2016, 15 patients with advanced HF were followed with the use of inotrope under this protocol (Mean age 54 ± 17 years, 80% male, left ventricular ejection fraction 24 ± 7%, 40% ischemic etiology, 27% familial, 20% idiopathic). Milrinone was used in 13 patients with a median dose of 0.17 (0.27-0.25) μg/kg/min; dobutamine was used in 2 patients with a dose of 5 μg/kg/min. Of the 15 patients, eight were transplanted, two were discharged from hospital, one returned to the intensive care unit due to clinical worsening related to nephrotoxicity secondary to desensitization therapy and four died. There were no adverse events resulting from the use low dose inotropes with protocol.
Conclusions: The use of this low-dose inotrope protocol use in the ward unit with telemetry proved to be feasible and safe, allowing for the prolonged use of this therapy as a bridge for cardiac transplantation, weaning or palliative care support. Learning from the use of low or moderate doses may reconfigure the role of inotropes as transition therapy for management settings.

P1847
Evaluation of e-health tool for heart failure patients

A Blomqvist[1]; K Sjostrom[2]; E Ohman[2]; M Dahlqvist[2]; S Bergenbrant Glas[2]
[1]*CareLigo, Research, Stockholm, Sweden*; [2]*Norrtälje Hospital, Norrtälje, Sweden*

Background: A home-based tool for heart failure (HF) patients exists, which monitors symptoms, titrates diuretics and educates the patient about HF in an interactive manner, in order to promote a better self-care behaviour. If the system detects deterioration in HF status, the patient is advised to seek health care and told who to contact.
Purpose: The tool has previously been shown to improve self-care behaviour, but we wished to assess its impact on HF related in-hospital days, to evaluate the use of the tool from a quality of care perspective.
Methods: We performed an intervention study with a matched control group, with a total of 62 patients. 31 patients in the intervention group (IG) were equipped with the tool and 31 matched controls (CG), were subject to standard care. The patients were followed for 280 days. The groups were well balanced at baseline, with respect to age, gender and diagnosis.
The mean age was 76 ± 10, with 34 % women in the IG and the mean age was 74 ± 10, with 42 % women in the CG. All hospitalisations for the patients were recorded during 280 days.
Results: After 280 days, a multiple regression analysis was performed, resulting in a risk ratio of [RR: 0.64; 95% CI: 0.47-0.87; $p < 0.05$]. There was a statistically significant reduction of HF related in-hospital days by 36 %, corresponding to an average reduction of 1.3 in-hospital days per patient. In total there were 104 HF days registered for the CG and 62 for the IG. There was no significant difference in risk of admission between the two groups (28 % for IG vs 26 % for CG).
Conclusion: Our findings are very similar to what has been published before. The tool appears to help patients to seek care in time when symtoms are worsening, instead of waiting for an acute episode. This is most likely the underlying cause of the reduction of in-hospital days.

P1848

New concepts for remote monitoring and flow control in left ventricular assist device patients - The Medolution project.

N Reiss[1]; T Schmidt[1]; J D Hoffmann[1]; D Willemsen[1]; F Mueller Von Aschwege[2]; J I Roebesaat[2]; J D Schmitto[3]; C Feldmann[3]
[1]Schuechtermann Klinik, Clinical Research, Bad Rothenfelde, Germany; *[2]Clinic Oldenburg, OFFIS, Oldenburg, Germany*; *[3]Hannover Medical School, Hannover, Germany*

Purpose: An effective outpatient management is the key factor to ensure the long-term success of left ventricular assist device (LVAD) therapy. Ambulatory visits only take place every 3 month so that life-threatening complications (pump thrombosis, driveline infection) can often only be detected and prevented by the patients themselves. In consequence, hospital stays or readmissions are common. Furthermore, flow adaptation during exercise is an unsolved problem in continuous-flow LVAD patients.
It is the intention of the the EU-funded project Medolution, to develop new approaches in order to provide the best possible support for physicians and patients in future.
Methods: Research project: In the meantime, there are different possibilities available for remote monitoring of relevant vital and device parameters in patients with a LVAD. In the future, technical opportunities are increasing. The Medolution project aims to bundle the relevant information (e.g. PAP, INR, thorax-impedance, driveline-pictures, LVAD-data) from different data sources into one platform in order to provide the physician a comprehensive overview of patient situation. In the systems background a big data analysis runs permanently and tries to detect abnormalities and correlations as well. At crucial events, a notification system informs the physician and provides the relevant data via a decision support system. LVAD flow is adapted to the grade of exercise via sensors located in the left atrium.
Results: First results of big data analysis for early detection of pump thrombosis based on LVAD parameters are available. Work on automatic image processing for driveline pictures analysis has started. For experimental tests a mock circulatory loop will be in use to simulate various situations (e.g. hypovolemia or thrombus formation, but also exercise) and to examine sensor connectivity, data transfers, algorithms and notification system.
Currently, both a mobile patient application and an application for the physician are under development.

P1849

Liberal right ventricular assist device extracorporeal membrane oxygenation support for right ventricular failure following implantable left ventricular assist device placement

Q Quentin Fischer[1]; M Kirsch[2]
[1]Hospital Bichat-Claude Bernard, Cardiology, Paris, France; *[2]University Hospital Centre Vaudois (CHUV), Cardiac surgery, Lausanne, Switzerland*

Introduction: Refractory right ventricular failure (RVF) after implantation of left ventricular assist device (LVAD) is a dramatic complication with high morbi-mortality. The addition of right ventricular assist device (RVAD) may help recovery and lead to improve outcomes.
Materials and Methods: From February 2012 to September 2014, 44 patients received a HeartMate II. These patients were retrospectively compared in 2 groups: no t-RVAD group and t-RVAD group according early liberal implantation. Patients in t-RVAD group were treated using extracorporeal membrane oxygenation as a RVAD.
Results: Of the 44 patients, 22 were didn't need RV support (no t-RVAD group), whereas 22 required addition of a temporary RVAD (t-RVAD group). Patients are sicker in the t-RVAD group with higher Michigan risk score (2.61 +/- 2.2 pts vs 1.0 +/- 1.6 pts; $p = 0.013$) and INTERMACs clinical profile (2.1 +/- 0.6 pts vs 3.4 +/- 1.3 pts; $p = 0.0001$). Despite severity of pre-implant conditions in t-RVAD group, clinical outcomes didn't differ in the both groups with similar survival rate at 6 months (60.4 +/- 12 vs 71.4 +/- 9.9 months; $p = 0.585$).
Conclusions: Early and liberal use of temporary RVAD in case of risk factors of RVF allows to improve the prognostic of this pathology with similar survival rate in the both groups.

	LVAD		LVAD + t-RVAD	
	% survival	pts	% survival	pts
1 mths	90.9 ± 6.1	20	85.9 ± 7.5	16
3 mths	76.5 ± 9.2	15	80.5 ± 8.8	12
6 mths	71.4 ± 12.0	11	60.4 ± 12.0	8

Impact of left ventricular assist device implantation on right and left ventricular volumes and functions

C Clement Delmas[1]; P Fournier[1]; S Cazalbou[1]; D Carrie[1]; J Roncalli[1]; M Galinier[1]; O Lairez[2]
[1]Toulouse Rangueil University Hospital (CHU), Cardiology department, Toulouse, France; *[2]Toulouse Rangueil University Hospital, Cardiac Imagery Center, Toulouse, France*

Background: Because the right ventricle is not assisted, its function is a critical determinant of the hemodynamic in patients with left ventricular (LV) assist devices (LVADs) and contributes significantly to postoperative morbidity and mortality. Right ventricular (RV) failure remains a challenge in the area of continuous-flow LVADs. The aim of this study was to evaluate the evolution of RV volumes and function before and after LVAD implantation.
Methods: Ten patients underwent tomographic equilibrium radionuclide ventriculography for the assessment of LV and RV volumes and functions before and after LVAD implantation.
Results: Mean LV and RV ejection fractions before implantation were 20 ± 8 and 46 ± 14%, respectively. LVAD implantation had no impact on RV ejection fraction (46 ± 11% after implantation, P=0.961) but tended to increase LV ejection fraction (31 ± 21% after implantation, P=0.09). LVAD led to a decrease of LV end-diastolic volume (Δ = -136 ± 96 after implantation, P=0.001) and RV end-diastolic volume (Δ=-59 ± 49 after implantation, P=0.004). Conclusion – In patients with preserved RV ejection fraction, LVAD implantation leads to a decrease of RV volumes without impact on RV ejection fraction. The increase of cardiac output induced by the LVAD does not increase RV volumes, which could be explained by the decrease of RV afterload. These results highlight the importance of afterload on the right ventricle in patients with heart failure.

P1851

Allosensitization with new generation left ventricular assist device

M Massimiliano Carrozzini[1]; T Bottio[1]; F Toto[1]; M Comisso[1]; E Manzan[1]; M Cardillo[1]; E Cozzi[1]; V Tarzia[1]; J Bejko[1]; G Gerosa[1]
[1]University Hospital of Padova, Cardiac Surgery Unit, Padua, Italy

Background/Introduction: Impact of HLA-allosensitization in continuous-flow left-ventricular-assist-devices (LVAD) recipients is still under investigation.
Purpose: We sought to assess HLA-allosensitization in patients implanted with Jarvik-2000 or HeartWare as bridge-to-transplantation and compared results in No-VAD patients.
Methods: We included all consecutive patients tested for HLA-allosensitization before heart-transplantation from 2012 to 2016. Tests used were complement-dependent-cytotoxicity on panel-reactive-assay (CDC-PRA) and Luminex.
Results: Included are 119 patients: mean age 51 ± 16 years, 24% female, 62% previously transfused. Forty-one patients entered the VAD group: 26 HeartWare, 15 Jarvik-2000. Seventy-eight patients were No-VAD. Two patients (5%) in the VAD group had a positive CDC-PRA; results in No-VAD group were comparable (8%, p = 0.56). Luminex was positive in 6 VAD patients (15%): HLA-class-I alloantibodies present in 7%, HLA-class-II in 5%, both HLA-class-I and II in 3%. Similar rates were observed in the No-VAD group: 26% positive (p = 0.17), 12% HLA-class-I (p = 0.47), 6% HLA-class-II (p = 0.74), 8% both HLA-class-I and II (p = 0.25). There were no statistical differences both at CDC-PRA (p = 0.25) and Luminex (p = 0.68) between the two LVADs used.
Conclusion(s) Rates of HLA-allosensitization with Jarvik-2000 or HeartWare were lower than those of first-generation LVAD and resulted comparable in No-VAD patients. There were no statistical differences in allosensitization between Jarvik-2000 and HeartWare.

P1852

Success of bridging to transplantation with a continuous- flow left ventricular assist device in a single UK centre

D Brahmbhatt[1]; W Flinn[1]; P Lincoln[1]; A Kydd[1]; C Lewis[1]; J Parameshwar[1]; S Tsui[1]; S Pettit[1]
[1]*Papworth Hospital NHS Trust, Cambridge, United Kingdom*

Background: In the United Kingdom, durable left ventricular assist devices (LVAD) are commissioned for use in patients with advanced heart failure as a bridge to transplantation (BTT) or as a bridge to transplant candidacy (BTC), when elevated pulmonary vascular resistance precludes safe heart transplantation. In 2008, our institution commenced implantation of a single type of continuous-flow LVAD for patients selected by our multi-disciplinary team.
Methods: A prospectively maintained database of all LVAD implants at our institution was interrogated for BTC and BTT continuous-flow LVAD implantation procedures before 1st April 2016 and their follow-up. The data was verified and supplemented by information from medical records. Baseline characteristics including age, aetiology, risk factors, body surface area (BSA) and blood group were recorded. Follow-up was censored at the following events: death, heart transplantation or recovery (LVAD explant). We examined the association between baseline characteristics and success in bridging patients to heart transplantation. T-test was used to compare continuous variable data, and the Chi-squared test was used for categorical data.
Results: During the study period, 64 patients had LVAD implantation, with 41 BTT and 23 BTC. Age ranged from 17 to 66 years old (median 46). 53 patients were male, 11 female. Aetiology was dilated cardiomyopathy (DCM) in 34, ischaemic cardiomyopathy (ICM) in 23, end-stage hypertrophic cardiomyopathy in 6 and restrictive cardiomyopathy in 1. 24 procedures were elective, and 40 were non-elective. The patients had blood groups O (34 patients), A (16), B (10) and AB (4). BSA ranged from 1.45 to 2.47m^2, (mean 1.94). Of 64 implants, one patient had their LVAD decommissioned due to recovery and one patient had their device explanted due to device failure. 54 (84%) patients were listed for transplantation, with 26 (41%) undergoing cardiac transplantation 82 – 1932 days (median 802) after implantation. 22 (34%) patients died during LVAD support 3 – 1598 days (median 171) after implantation. 14 (22%) patients remain on the transplant waiting list, 379 – 2260 days (median 653) after implantation. When comparing baseline characteristics of patients categorised by transplant status, aetiology was the only significant association; patients who were not transplanted were more likely to have an ischaemic cardiomyopathy (47% vs 19%; p < 0.05).
Conclusions: Continuous-flow LVAD may be an effective bridge to heart transplantation in patients with advanced heart failure. Gender, BSA, blood group or indication for LVAD therapy do not appear to impact on the likelihood of successful bridging to transplantation. However, patients with ischaemic cardiomyopathy appear to be less likely to be transplanted compared to other heart failure aetiologies. Further work is needed to investigate complications and adverse events to determine whether they contribute to the differences in transplant rates.

P1853

Percutaneous mechanical circulatory support in cardiogenic shock due to end-stage heart failure and acute myocardial infarction

H S Hoong Sern Lim[1]; T Musa[1]; A Ranasinghe[1]; N Howell[1]
[1]*Queen Elizabeth Hospital, Birmingham, United Kingdom*

Background: 'Pump failure' and consequent cardiogenic shock (CS) is a common mode of death in end-stage heart failure (ESHF). However, there are little data on outcomes of percutaneous mechanical circulatory support (PMCS) in CS due to ESHF, unlike acute myocardial infarction (AMI).
Purpose: To describe contemporary outcome of PMCS bridging with veno-arterial extracorporeal membrane oxygenation (ECMO) and/or Impella in patients with CS due to ESHF and AMI.
Methods: Single centre study of consecutive patients with CS due to AMI (n = 20) and ESHF (n = 23) supported with ECMO and/or Impella as the primary PMCS modality.
Results: There was no difference in characteristics between patients with AMI and ESHF, except for lower LVEF [TABLE]. PMCS included 7 Impella, 30 ECMO and 6 Impella + ECMO with no difference between groups. Of the 43 patients, 7 were bridged directly to heart transplantation (4 AMI and 3 ESHF), 4 directly to durable left ventricular assist devices (1 AMI and 3 ESHF), 13 patients underwent further bridging with temporary ventricular assist devices (4 AMI and 9 ESHF) and 24 patients died with/without transplantation or LVAD (7 AMI and 17 ESHF). 1-year survival was 39% and 65% in ESHF and AMI respectively (p = 0.037, log rank test, FIGURE).
Conclusion: Multiple bridging modalities are common in contemporary management of CS. Mortality is higher in patients with CS due to ESHF supported by PMCS compared to AMI.

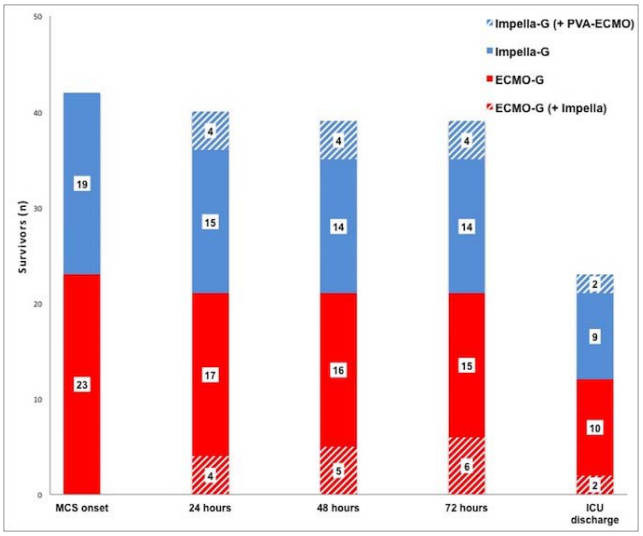
Circulatory support with ecmo and/or impella for hemodynamic compromise during acute coronary syndrome: a heart team strategy

M Mourad[1]; P Gaudard[1]; P De La Arena[1]; J Eliet[1]; N Zeroual[1]; P Rouviere[1]; F Roubille[1]; B Albat[1]; P Colson[1]
[1]*University Hospital Arnaud de Villeneuve, Montpellier, France*

Objectives: Temporary mechanical circulatory support (TCS) is recommended for patients with acute, profound hemodynamic compromise, including during acute myocardial infarction (AMI). ECMO and Impella are possible TCS devices but the device choice and the timing around the percutaneous coronary intervention (PCI) are not definitely established. We evaluate a heart team strategy based on predefined agreement for the use of TCS in AMI with hemodynamic compromise.
Methods: Our heart team has defined a strategy based on a predefined agreement for the use of ECMO or Impella as TCS in AMI admitted for urgent PCI. The strategy was analyzed retrospectively from a cohort of patients who underwent TCS within 72 hours after admission for PCI in AMI, from January 2009 to April 2015, excluding refractory cardiac arrest.
Results: Among 88 TCS-treated AMI patients, 42 had early TCS: 23 ECMO and 19 Impella. Cardiac management including PCI was similar between the groups but ECMO patients were sicker than Impella patients (higher blood lactate level, p 0.02). Most implantation occurred during PCI (43%) or just after (50%). Change of initial TCS choice was required in 10 cases (24%) for assistance upgrading (4 Impella) or left ventricle unloading (6 ECMO).
Conclusions: A heart team strategy based on predefined agreement for the use of ECMO or Impella as TCS for AMI with hemodynamic compromise seems relevant. ECMO is very effective in case of profound cardiogenic shock. Percutaneous Impella may be more appropriate for less severe hemodynamic compromise, possibly to secure hemodynamics during PCI



Survivors through ICU stay follow-up

P1855

Veno-arterial ECMO/ECLS for cardiogenic shock: short term outcomes

A Antoine Defontaine[1]; E Flecher[1]; S M Rehman[1]; N Nesseler[1]; B Lelong[1]; J-P Verhoye[1]
[1]University Hospital of Rennes, Cardiac and Thoracic Surgery, Rennes, France

Objective: Veno-arterial ECMO (Extracorporeal Membrane Oxygenation) or ECLS (Extracorporeal Life Support) is now widely used to treat severe cardiogenic shock with disparate results. The aim of this study was to present the results at our institution and to identify early prognostic factors.
Methods: Retrospective analysis of prospectively collected data for all patients with cardiogenic shock requiring ECLS at our centre. Post cardiotomy ECLS were excluded.
Results: 159 consecutive patients (122 male – 76.7%), aged 53.9 ± 12.6 years, received ECLS between 2005 and 2016. The etiology of cardiogenic shock was myocardial infarction (100 – 62.9%), dilated cardiomyopathy (27 – 17.0%), ischaemic cardiomyopathy (5 – 3.1%), myocarditis (17 – 10.7%), endocarditis (3 – 1.9%) and rhythmic storm (7 – 4.4%). 31 (19.6%) cases followed external cardiac massage (ECM) and 54 (34.0%) patients were implanted under epinephrine.
84 patients (52.8%) were alive at explant time: 52 (61.9%) were weaned, 16 (19.0%) were transplanted and 12 (14.3%) received long term assist device (other 4 – 4.8%) with a mean duration under ECLS of 10.1 ± 5.8 days. At 6 months follow-up, 63 (39.6%) patients remained alive.
There was no difference in survival between males (74 deaths – 60.7%) and females (22 deaths – 59.5%), p = 0.87. Patients who died at 6 months follow-up were older (56.9 ± 10.4) than survivors (49.4 ± 14.2), p = 0.0025. Patients under ECM at time of setup were less likely to survive (n = 8 – 25.8% vs n=55 – 43.0%, p = 0.0015) as well as patients receiving epinephrine (n = 14 – 25.9% vs n=49 – 46.7%, p = 0.0009).
Creatinine at setup time was lower in the group of survivors (155.9 ± 97.3 µmol/L vs 188.1 ± 99.2 µmol/L, p = 0.0332) as well as lactate (4.1 ± 3.2 mmol/L vs 6.5 ± 4.9 mmol/L, p < 0.0001). Aspartate aminotransferase (AST) was lower in survivors (695.6 ± 1072.4 IU/L vs 1292.0 ± 2890.4 IU/L, p = 0.0021). There was no difference in alanine aminotransferase (ALT) (p = 0.14).
At 24 hours follow-up, creatinine was lower in survivors (133.3 ± 109.0 µmol/L vs 204.3 ± 133.6 µmol/L, p < 0.0001). Lactate was also lower in survivors (2.1 ± 2.3 mmol/L vs 3.5 ± 3.6 mmol/L, p = 0.0027). There was no difference in AST (p = 0.07), ALT (p = 0.25).
Between setup time and 24 hours follow-up, creatinine decreased in survivors (-28.0 ± 65.5 µmol/L) while it increased in the deceased (+17.1 ± 86.7 µmol/L, p < 0.0001). AST also decreased in survivors (-184.8 ± 911.1 IU/L) while it increased in the deceased (+788.2 ± 3552.9 IU/L, p = 0.0034). ALT remained stable in survivors (+2.1 ± 471.1 IU/L) while it increased in the deceased (+431.2 ± 1805.9 IU/L, p = 0.0047). There was no significant difference in lactate (p = 0.82).
Conclusion: ECLS results for patients in acute cardiogenic shock were acceptable at our centre. Younger patients without a requirement of epinephrine or prior ECM at time of setup had improved survival. Furthermore, improvement of creatinine and AST at 24 hours favoured better survival.

P1856

Clinical consequence of new-onset persistent left bundle branch block after transcatheter aortic valve replacement

E Munoz-Garcia[1]; M Munoz-Garcia[1]; AJ Antonio Jesus Munoz Garcia[2]; A Ruiz-Salas[2]; AJ Dominguez-Franco[2]; F Carrasco-Chinchilla[2]; JM Garcia-Pinilla[2]; L Morcillo-Hidalgo[2]; JH Alonso-Briales[2]; JJ Gomez-Doblas[2]; MF Jimenez-Navarro[2]; JM Hernandez-Garcia[2]; E De Teresa-Galvan[2]
[1]Department of Cardiology , Malaga, Spain; [2]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Background: Cardiac conduction disturbances can develop after transcatheter aortic valve replacement with expandable prosthesis because the conduction system exists adjacent to the aortic valve. However, the clinical consequence of patients with new onset conduction disturbances is not clear.
The aim of this study was to determine the impact of new-onset persistent left bundle branch block (LBBB) on late outcomes after TAVR.
Methods: A total of 368 consecutive patients who underwent TAVI with a balloon-expandable valve without pre-existing LBBB or permanent pacemaker implantation (PPI) were included. Electrocardiograms were obtained at baseline, immediately after the procedure, and daily until hospital discharge. Patients were followed at 1, 6, and 12 months and yearly thereafter.
Results: New-onset LBBB occurred in 210 patients (57.1%) immediately after TAVI and persisted at hospital discharge.
At a median follow-up of 32 months (range 1 to 78 months), there were no differences in mortality rate between the N-LBBB and no N-LBBB groups (22.9% vs. 27.3%; adjusted-hazard ratio: 0.845 [95% confidence interval (CI): -0.558 to 1280]; p = 0.427. There were no differences between groups regarding cardiovascular mortality HR=-0.511 (95% CI 0.229-1.141),p = 0.102, rehospitalizations for heart failure HR=1.344 (95% CI 0.591-3.058),p = 0.481.
32.9% required PPI in the first month and only 8 patients with N-LBBB required PPI during the follow-up period. There were 3 cases of unexpected (sudden or unknown) death was observed in 2 patients with N-LBBB.
Patients with N-LBBB showed a poorer evolution of left ventricular ejection fraction over time (1 and 3 years) than no N-LBBB group: 61.3 ± 9 vs. 65.1 ± 7,p = 0.011; and 56.2 ± 13 vs. 62.8 ± 7%,p = 0.367, respectively). N-LBBB was also associated with a poorer New York Heart Association functional class at follow-up (1.72 ± 0.7 vs. 1.5 ± 0.5,p = 0.047).
Conclusions: N-LBBB was a frequent complication of transcatheter aortic valve replacement, but it was not associated with any increase in overall or cardiovascular death or rehospitalization for heart failure after a mean follow-up of 2.21 years.

P1857

Predictors of survival and one year outcomes after continuous flow left ventricular assist device implantation

E Nestorovic[1]; N Milic[2]; S Putnik[1]; D Terzic[1]; A Janjic[1]; M Milosevic[1]; D Markovic[3]; J Cumic[3]; A Ristic[4]; D Trifunovic[4]; I Nedeljkovic[4]; M Banovic[4]; S Raspopovic[4]; M Ristic[1]
[1]Clinical Center of Serbia, Department for Heart Transplant, LVAD and ECMO, Hospital for Cardiac surgery, Belgrade, Serbia; [2]Medical Faculty University of Belgrade, Serbia, Department for medical statistics and informatics, Belgrade, Serbia; [3]Clinical Center of Serbia, Belgrade, Center for Anesthesiology and Resuscitation, Belgrade, Serbia; [4] Clinical Center of Serbia, Serbia, Cardiology Clinic, Belgrade, Serbia

Background: The aim of this study was to assess the outcomes of patients with advanced heart failure (HF) treated with continuous flow left ventricular assist devices (CF-LVAD) and to determine factors that may be associated with improved survival, in terms to improve clinical outcomes of CF-LVAD patients.
Methods: This is a prospective study of 47 consecutive patients with advanced HF who received CF- LVAD at our institution. The overall median duration of CF-LVAD support was 13 (9-21) months. In 42 patients CF-LVAD was used as a bridge-to-transplantation (BTT) and in 5 patients as destination therapy (DT). Overall survival and adverse events at 1 year were evaluated. Echocardiographic, functional, renal and liver function outcomes were assessed at 3, 6 and 12 months.
Results: The overall 30 day, 6-months and 1-year survival for both BTT and DT patients were 89%, 85% and 80%, respectively. At 3 months after CF-LVAD implantation, we noticed significantly improvement in dimensions of LV (LVEDD, LVESD), LVEF, BNP, NYHA functional class, blood urea nitrogen and total bilirubin ($p < 0.05$ for all), and they remained normal through all first year of follow-up. Improvements in estimated glomerular filtration rate was significant after 3 months in group of patients with baseline renal dysfunction ($p = 0.004$), with also no further change afterward. Any kind of adverse events were present in 27 (57.4%), with bleeding as the most common complication in 19 (40.4%). In univariate analysis, blood urea nitrogen and renal failure were significant predictors of survival (HR=1.1, $p = 0{,}034$ and HR=14.2, $p < 0{,}001$, respectively). Renal failure was found to be an independent risk factors for the overall survival in multivariate Cox regression analysis (HR= 13.1, $p < 0{,}001$).
Conclusions: CF-LVAD improves functional, cardiac, renal and liver function in patients with advanced HF. As renal dysfunction is common following CF-LVAD implantation and renal failure is an independent risk factor for overall survival, the key of LVAD success is determination of optimal timing of CF-LVAD implantation in order to avoid end-organ dysfunction and achieve better postoperative outcomes.

P1858

Symptoms, physical examination and biomarkers are important determinant of reactions to adaptive servo-ventilation

Y Nishihata[1]; N Komiyama[1]
[1]*St. Luke's International Hospital, Department of Cardiology, Tokyo, Japan*

Background: Adaptive servo-ventilation(ASV) has been reported that it could improve heart failure(HF) condition and prognosis in some small clinical studies. However, a recent large trial showed mortality was increased with ASV. It's not clear what kind of patients should stop or continue ASV.
Purpose: To assesse clinical parameters which could predict the reactions to ASV.
Methods: We investigated 61 HF patients treated with ASV in our hospital between June 2009 and December 2015. We examined patient's background, symptoms, vital sings, laboratory data, cardiac function assessed by echocardiography and clinical responses.
Results: Their mean left ventricular ejection fraction was 37.3± 19.3% and mean NT-proBNP was 8666± 11634 pg/ml. At the time of ASV-initiation, 27 patients felt comfortable (C-group) and 34 felt uncomfortable (UC-group). In C-group, their proportional pulse pressure (PPP) and heart rate (HR) were significantly improved than in UC-group (ΔPPP 6.2± 6.8 vs -0.5± 10.0 mmHg, $p < 0.01$; ΔHR -6.7± 6.4 vs -1.7± 8.2 bpm, $p < 0.01$). Among 32 patients who could continue ASV at least 1 month, patients in C-group showed significant decrease of NT-proBNP than in UC-group ($p < 0.05$). Readmission due to HF under ASV-therapy were observed more frequently in UC-group than in C-group ($p < 0.01$) accompanied by poorer improvement of NT-proBNP ($p < 0.05$). There were 9 patients whose comfortableness became worse and 7 stopped ASV-therapy. The other 2 continued ASV but they were attacked by sudden cardiac death although their NT-proBNP were improved enough. They had might been enough decongested and ASV might worsened their hemodynamics.
Conclusions: Patient's symptoms reflect the hemodynamic responses to ASV, and those could predict the efficacy of ASV-therapy in patients with HF.

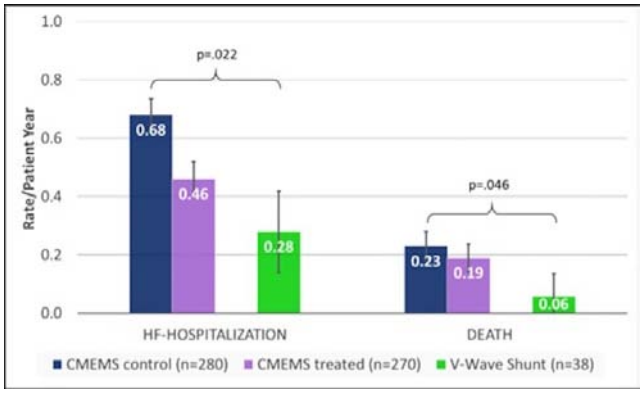
Funding Acknowledgements: V-Wave, Ltd.

Background: We hypothesized that left atrial decompression with a percutaneously implanted interatrial shunt device would reduce HF hospitalizations and all-cause mortality in patients with advanced HF when compared to a well-matched historic controlled cohort.
Methods: Patients with chronic NYHA Class III/ambulatory Class IV HF, regardless of LVEF, on maximally tolerated guideline directed drug and device therapies, and a prior HF hospitalization or elevated neurohormones were enrolled in a single arm open label study at 6 centers. After transseptal catheterization and implantation of the shunt device across the fossa ovalis, patients were followed for 12 months. Demographics and outcomes were compared to the Champion trial cohort of 550 patients enrolled with similar eligibility criteria. Champion was a prospective, randomized, patient blinded controlled study of implantable pulmonary artery pressure monitoring used to guide HF therapy.



Figure

Results: 38 consecutive patients, 97%/3% Class III/IV, and 21% with LVEF >40%, were successfully shunted. Although shunt patients were generally well-matched to the entire Champion cohort with respect to LV function and usage of drugs and devices, shunt patients were older (66 ± 9 vs. 62 ± 9 years; $p = 0.0083$), were more likely to have an ischemic etiology (76% vs. 60%; $p = 0.041$), have diabetes (68% vs. 49%; $p = 0.020$), have poorer renal function (eGFR 54 ± 20 vs. 61 ± 16 ml/min·1.73m2; $p = 0.0062$) and have higher baseline left atrial pressures (PCWP 20 ± 6 vs. 18 ± 5 mmHg; $p = 0.019$). Shunted patients also had other markers of higher risk including a baseline 6-minute walk distance of 289 ± 112m and NT-proBNP of 2640 ± 2301 pg/ml. During an average follow-up of 11.7 months, shunted patients had 10 hospitalizations for worsening HF and 2 deaths. When compared to the entire Champion cohort there were significant reductions in the annualized rates of heart failure hospitalization and mortality (Figure). Baseline and 6-month doses of renin-angiotensin antagonists and beta-blockers were nearly identical between the shunted and Champion control patient cohorts. Shunted patients were on smaller doses of mineralocorticoid receptor antagonists and larger doses of loop diuretics that remained stable over 6 months ($P < 0.012$ for all comparisons).
Conclusions: Shunt patients with similar eligibility criteria generally had higher risk baseline characteristics than Champion patients. Nonetheless, interatrial shunting was associated with significantly lower rates of HF hospitalization and all-cause mortality than the less ill but otherwise well-matched historical controls. These observations are not explained by different dosing of HF medications and may be indicative of a beneficial device effect. If confirmed in larger prospective randomized controlled studies, interatrial shunt implantation could be an important new approach for treating patients with advanced heart failure.

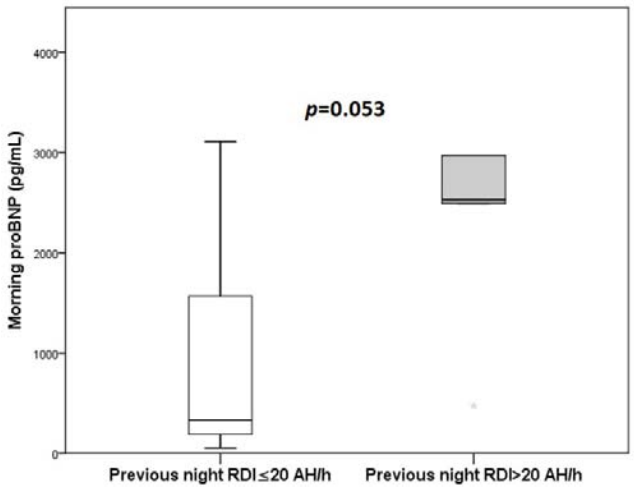
P1860

Antibradycardia pacemaker with sleep apnea monitor: a new tool to evaluate left ventricular filling pressure?

J B Augusto[1]; S Antunes[1]; M Faustino[1]; N Cabanelas[1]; F Madeira[1]; H Vasconcelos[1]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal*

Background: Sleep apnea (SA) is highly prevalent in pacemaker (PM) patients and it is associated with an increased risk of heart failure. Currently, some conventional antibradycardia pacemakers incorporate a SA monitoring (SAM) function, which enables the detection of severe SA.
Purpose: We aimed to validate a SAM function of antibradycardia pacemakers for the prediction of left ventricular filling pressure, based on the determination of

pulmonary capillary wedge pressure (PCWP) and pro B type natriuretic peptide (proBNP).
Methods: We conducted a prospective study of consecutive patients evaluated in a PM consultation who had a single or dual-chamber antibradycardia PM with an incorporated SAM. SAM detects and reports abnormal breathing events during the night, which can be measured as the number of apnea-hypopneas (AH) per hour: the respiratory disturbance index (RDI). We recorded data regarding: absolute number of apnea-hypopneas and RDI from the night before the consultation (defined as between 00h00 and 05h00) as well as the proportion of nights with RDI>20 AH/h since last device reset. In the morning we assessed both mitral E/e' ratio (using transthoracic echocardiogram) and proBNP. PCWP was calculated using Nagueh's formula (1.24x(E/e') + 1.9mmHg).
Results: A total of 30 patients were included (mean age 78.6 ± 12.0 years, 43.3% male and mean body mass index 26.9 ± 3.9 Kg/m^2). In the preceding night, median RDI was 8.0 AH/h (interquartile range (IQR) 5.0-21.0 AH/h). In the morning, median proBNP was 517pg/mL (IQR 223-2750pg/mL) and median PCWP was 15.9mmHg (IQR 11.8-27.0mmHg). Patients who had a higher proportion of nights with RDI>20 AH/h had significantly higher PCWP and proBNP values (r=0.45 and r=0.61, $p = 0.043$ and $p = 0.004$, respectively). In the preceding night, a higher number of AH as well as a higher RDI were associated with elevated values of proBNP in the morning (r=0.70 and r=0.71, respectively, both $p < 0.001$). There was a trend towards an increased PCWP in patients with higher AH and RDI in the previous night ($p = 0.093$ and $p = 0.068$, respectively). ProBNP also tended to be superior in patients with RDI>20 AH/h in the previous night (median 2529 vs. 330pg/mL, $p = 0.053$) (Figure 1).
Conclusions: Pathologic values obtained in sleep apnea monitors available in conventional antibradycardia pacemakers correlate with elevated proBNP and PCWP values. This new tool might be useful in the evaluation of the risk of heart failure, allowing both assessment and guidance in the management of left ventricular overload.



Morning proBNP according to RDI strata

Effects of cardiac rehabilitation on exercise capacity and WHO-quality of life undergoing CABG patients- A quasi-randomised controlled trial
J Jamal Uddin[1]
[1]*Ibrahim Cardiac Hospital & Research Institute, Dhaka, Bangladesh*

The effect of home-based cardiac rehabilitation following coronary artery bypass graft surgery in a low income country: A controlled trial.
Background: More than 85% of global cardiovascular disease deaths occur in low and middle-income countries with coronary heart disease contributing to more than half of these deaths. Few controlled trials of cardiac rehabilitation (CR) have been conducted in low and middle income countries to date.
Methods: We undertook a quasi-randomized controlled trial design and allocated patients 1:1 to either based CR program in addition to usual care (CR group) or (UC group)usual care alone (UC group) according to their date of surgery. We screened all patients who were admitted to the Department of Cardiac Surgery at Ibrahim Cardiac Hospital & Research Institute (ICHRI) in Bangladesh from July 2012 to July 2013.Male and females patients were included if they were admitted for elective coronary artery bypass graft (CABG) surgery aged 25 to 65 years. Patients allocated to the CR group were offered an initial CR class, and provided with an educational booklet that contained details of home-based exercise programme, and received a monthly telephone call from a member CR team over a 12-month period. Data on exercise capacity as measured by maximal oxygen uptake (VO2max), coronary risk factors, health-related quality of life, and mental health status were collected between 3-12-months follow up. Differences in outcomes were compared between CR and UC groups in patients with complete outcome data.
Results: A total of 142 participants participated in the trial - 71 allocated to CR group and 71 allocated to UC group. At 12 months follow up, 61 (86%) and 40 (56%) patients respectively provided complete outcome data.VO2max at 6-months follow up was higher in the CR compared to UC group (mean difference: 7 ml/kg/min, 95% CI: 2 to 11, $P = 0.005$). Compared to baseline, improvements in overall and domain specific health-related on the WHO-QoL-BREF questionnaire, PHQ-9 assessed mental well-being beingon PHQ-9, and CHD risk factors (body mass index, blood pressure, HbA1C, lipids) were significantly greater ($P < 0.05$) for CR compared to UC group patients.
Conclusions: The addition of a home-based CR programme of an educational booklet supported by healthcare professional telephone calls to usual care following CABG surgery was shown to provide important patient benefits compared to usual care alone. In the context of low or middle

Staged or combined carotid endarterectomy in patients undergoing coronary artery bypass grafting
R Rustambek Karimov[1]; A Irnazarov[1]; A Yulbarisov[1]; A Djafarov[1]
[1]*Tashkent Medical Academy, Faculty and Hospital Surgery, Tashkent, Uzbekistan*

Background: Ideal surgical approach for patients with hemodynamically significant carotid and coronary disease remains controversial. We analyzed our 4-year experience and compared early and long-term outcome following staged and combined carotid and coronary artery bypass.
Purpose: To compare the short and long-term results as well as the risk factors of both staged and combined carotid and coronary revascularization.
Methods: Overall 260 patients with combined carotid and coronary artery disease undergoing carotid endarterectomy and coronary artery bypass were prospectively involved in the research. First group patients were scheduled for a staged procedure (carotid endarterectomy followed by coronary artery bypass within 1 week). Patients of second group were deemed to a combined procedure (due to the unstable cardiac status). All patient data including immediate perioperative events, 30-day, and long-term outcome, demographics, risk factors were recorded and then analyzed. Patients in both groups were compared for pre- and perioperative data as well as immediate, 30-day, and long-term survival.
Results: First group included 148 patients and second one included 112 patients. Preoperative demographics and clinical data were similar in both groups except that preoperative cerebrovascular events were more common in the latter (31.4% versus 23.4%) and bilateral carotid disease was more common in the first group. The EuroSCORE was higher in the second group patients (2.91 versus 2.65). Carotid surgery techniques were similar; intraluminal shunting was more frequent in the second group than first one (33.33% versus 9.88%). Additional cardiac procedures in addition to coronary surgery was predominant in patients of second group. 30-day neurological adverse event rates, ICU, and hospital stay were significantly higher in the second group. The 30-day mortality was also sigficantly higher in the second group patients (1.96% versus 4.62%).
Conclusion: Staged and combined surgical manners provide truly comparable outcomes. A staged method of treatment may yield a more favorable neurological outcome with noticeably reduced need for intraluminal shunting. However, long-term outcome is similar for both approaches.

P1863
Acute aortic syndromes - What we know and what we don't know
S Alegria[1]; I Rosario Cruz[1]; R Pereira[1]; AI Marques[1]; C Gomes[1]; G Morgado[1]; D Caldeira[1]; O Simoes[1]; AR Almeida[1]; MJ Loureiro[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Introduction: Acute aortic syndromes (AAS) are emergent conditions, with a very high mortality in the first hours. Given this, a timely diagnosis is critical to improve prognosis. However, there are few contemporary epidemiological data.
Objectives: Characterization of a population of patients with AAS admitted to a tertiary hospital without cardiac surgery and identification of predictors of mortality.
Methods: Longitudinal analysis of patients diagnosed with AAS between 2005 and 2016. Cox regression analysis was performed to identify predictors of 30-day mortality.
Results: A total of 39 patients (mean age 68 ± 16 years, 56.4% males) were identified. 79.5% had type A aortic dissection (AD), 15.4% type B and 5.1% were classified as non-A non-B AD. 94.7% had hypertension, 31.4% smoking habits, 24.2% dilation of the aorta and 21.2% previous manipulation of the aorta

by catheterization and/or surgery. The most frequent symptoms at presentation were anterior chest pain (58.8%) and abdominal pain (26.5%). In 13.2% focal neurological signs were observed, and 20.6% had cardiopulmonary arrest. On admission 31.3% were hypotensive and 28.1% hypertensive. The first imaging test performed was transthoracic echocardiogram in 55.3% of the patients and the exam that confirmed the diagnosis was computed tomography in 81.6% and transoesophageal echocardiogram in the remainder. The diagnosis was established less than 4 hours after admission in 53.6%. The main complications were moderate or severe aortic regurgitation in 18.2%, stroke in 13.2%, acute kidney injury in 35.3%, acute myocardial infarction in 10.5%, pericardial effusion in 54.5% and cardiac tamponade in 18.4%. 32.4% of patients required antihypertensive drugs and 12.5% vasopressor support. Pericardiocentesis was performed in 21.6% and emergent surgery in 68.4% (88.5% with type A AD). Among the non-operated patients, 25.0% died before surgery, 16.7% had uncomplicated type B AD, 16.7% were refused, 8.3% had major stroke with poor neurological prognosis, and in 33.3% the reason was unknown. Mortality at 30 days was 33.3%, at 1 year 45.2% and during the total follow-up (849 ± 1196 days) 48.7%. There was a trend towards higher mortality in the non-operated patients (50.0 vs. 25.0%, p = 0.134). Focal neurological deficits (p = 0.022), hypotension at admission (p = 0.021) and the need for vasopressor support (p = 0.039) were identified as predictors of 30-day mortality. The independent predictors were the presence of focal neurological deficits (HR 7.0, 95% CI 1.4-34.1, p = 0.016) and hypotension at admission (HR 4.4, 95% CI 1.1-18, 4, p = 0.041).

Conclusion: AAS present more frequently with chest pain, however there are several forms of presentation, making this a challenging diagnosis. In this study 30-day mortality was high, and focal neurological deficits and hypotension were identified as independent predictors of mortality.

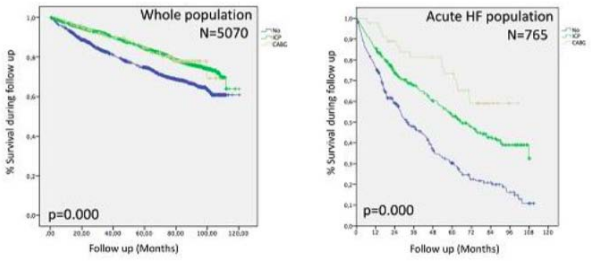
INTRODUCTION. The Killip class classification for heart failure it is used to predict short-term mortality in patients with acute coronary syndrome (ACS)

Objectives: To determine the contemporary long-term prognosis of ACS with acute heart failure graded according to the Killip classification.

Methods: Cohort third level hospital study of consecutive hospitalized patients with ACS diagnosis from 2004 to 2009. Follow-up was done by clinical review or telephone contact and death or cardiovascular events were recorded, as well as the cause of death

Results: 5070 patients were included with a complete follow up after a mean of 5.8 ± 2.6 years. The clinical characteristics were analyzed in relation with Killip class at admission (shown in Table). A stepwise gradient in the adjusted hazard ratio (HR) for mortality was observed with increasing Killip class: class > I HR 4.35 (95% CI 3.81 to 4.97) unexpectedly, in a landmark analysis excluding deaths < 30 days after admission, patients in Killip class IV had a lower adjusted long-term mortality than those in class III (shown in Figure)

Conclusions: The heterogeneity in early versus late risk in patients with Killip class IV that survive at discharge heart failure it is present in our contemporary cohort highlighting the importance of an appropriate early treatment in cardiogenic shock patients



prognosis impact of revascularization

Background: Renin-angiotensin-aldosterone system (RAAS) blockade with angiotensin converting enzyme inhibitors (ACEI) or angiotensin receptor blockers (ARB) is the corner stone in management of patients with heart failure. Some studies proposed the benefit of ACEI/ARB in patients with impaired renal function. However, side effects of those treatment may widely vary depending to the renal replacement therapy. Thus, renal replacement therapy can be important factor in expecting the benefit of ACEI/ARB. We aimed to analyze the different effect of early initiation of ACEI/ARB depending on renal replacement therapy in patients with impaired renal function and heart failure.

Methods: Among 5625 patients from the Korean Acute Heart Failure registry, 426 patients (68.9 ± 13.7 years-old, 253 men) who survived the index hospitalization and had creatinine clearance < 30ml/min/1.73m2 were analyzed. One-year all-cause mortality was used to assess prognosis.

Results: A total of 143 (33.6%) deaths were observed during 1 year follow-up. Among the study cohort, 243 (57.0%) patients with impaired renal function were taking ACEI/ARB at the discharge. Kaplan-Meier survival analysis showed that 1-year mortality was 39.4% and 19.2% for patient with ACEI/ARB and without, respectively (p = 0.0185). ACEI/ARB was significantly related to better prognosis in patients with renal replacement therapy (hazard ratio [HR]=0.462 [0.256-0.835], p = 0.011), whereas it was not in patients without renal replacement therapy (HR 0.756 [0.540-1.421], p = 0.591) in adjusted models (p for interaction=0.045).

Conclusion: Early ACEI/ARB treatment in patients with renal impairment was related to better prognosis especially in patients with renal replacement. Cautions

Influence of long-lasting treatment with ramipril and eprosartan on diastolic dysfunction and insulin resistance

N Nadejda Sapojnic[1]; AP Caraus[1]; A Timbalari[1]; MA Caraus[2]; AN Moiseeva[1]; CD Roibu[3]
[1]Institute of Cardiology , Hypertension, Chisinau, Moldova Republic of; *[2]State University of Medicine and Pharmacy, Chisinau, Moldova Republic of*; *[3]Institute of Neurology and Neurosurgery, Stroke, Chisinau, Moldova Republic of*

Funding Acknowledgements: Academy of Science of Moldova

Hypertensive heart disease (HHD) is a hallmark of target organ damages (TOD) in hypertension (HT) and often coexist with insulin resistance (IR). This "satellite conditions"determines reciprocal enhancement on TOD. Pharmacotherapy should aim both HHD and IR and RAAS inhibitors will be of peculiar utility in such conditions.
Methods: 101 hypertensives with HHD (LVH and DD) and IR were randomly assigned to treatment with ramipril (R-gr; n=56, mean dose=15,3mg ± 1,2 mg/daily) or eprosartan (E-gr; n=45, mean dose=850 ± 12,4 mg/daily). Ambulatory blood pressure monitoring (ABPM), transthoracic echocardiography (TE), and HOMAIR were performed at baseline and after 6, 12-months period. Assessment of diastolic function comprised: left atrium (LA) vol index, isovolumetric relaxation time (IRVT), deceleration time (DT), E/A ratio, E/e' ratio. The threshold value for IR (HOMAIR) was considered >2.5.
Results: At baseline, group did not differ statistically with respect to clinic and hemodynamic status (Fig.1). Both therapeutic regimens have gradually improved indices of DD, as well as HOMA-IR values (p < 0.001), but with greater reduction in E-gr (p < 0.001) (Tab.2). To note, at the end of the study significantly decreased the number of patients with pathologic mitral filling patterns with switching to physiologic one in both studied arms but with superiority in E-gr (95.56% subjects in E-gr vs 64.29% in R-gr, p < 0.001) (Tab.2).
Conclusion: The findings showed that both ACEI Ramipril and ARB Eprosartan progressively improve compromised diastolic function and insulin resistance, but with greater efficiency in the Eprosartan-medicated arm, probably due to additional sympatholytic effect of its moiety.

Real world experience of introducing the new heart failure drug LCZ 696 in ambulatory care setting

L O'connor [1]; J Kelly O' Haire[1]; BF Mcadam[1]
[1]Beaumont Hospital, Department of Cardiology, Dublin, Ireland

Chronic heart failure (CHF) is associated with significant morbidity and mortality. It affects 120,000 people in the Republic of Ireland with the annual estimated cost of €660m to the State. Despite optimal evidence based care, patients continue to experience symptoms and require ambulant IV Frusemide and/or admission for decompensation. The PARADIGM trial reported superiority of LCZ 696 over Enalapril. LCZ 696 is a combined Angiotensin Receptor and Neprilysin Inhibitor (ARNI), reducing the risk of cardiovascular death and hospitalizations with a better tolerability profile. A total of 35 patients were commenced on LCZ 696 (average age 70.6 years, 60% males, 40% females, average EF# 24%, New York Heart Association (NYHA) II-III, NYHA IV (2)) since August 2015 to date. Patients were screened based on criteria from the PARADIGM trial. A standardized protocol for commencement of the ARNI was introduced. A flush out period of 36 hours between the cessation of Angiotensin Converting Enzyme inhibitor and initiation of LCZ696 was initiated. Patients were commenced on the lowest dose 24mg/26mg BD and were followed up closely for any signs of side effects such as hypotension and renal impairment. Of the 35 patients who commenced on LCZ 696, 26 patients tolerated the agent. The average dose was 24mgs/26mgs mg BD, up titration occurred if SBP is > than 100mmHg with only 6 patients reaching the maximum dose of 97mgs/103mgs. The agent was discontinued in 9 patients due to: elevated liver function tests (1), fatigue (2) skin rash (1), symptomatic hypotension (3). Two patients had a significant deterioration in creatinine of over 50%. Three patients died during the time period: 1 due to CHF complicated by an incarcerated hernia, 1 patient died from oesophageal carcinoma, 1 patient died from organ failure and sepsis. Twenty six patients who tolerated LCZ 696 described feeling better and there was a 25% reduction in hospitalizations and need for IV ambulant diuretics for decompensation. One patient on a continuous infusion of Milrinone for the last 6 years was successfully weaned from this infusion following commencement of LCZ 696. There was a significant decrease in natriuretic peptides in patients who tolerated the agent well with 10% of this cohort experiencing a 75 % fall in NT-pro BNP levels, 23% had a 50% drop and 27% had a 25% reduction. A rise in NT pro BNP was observed in reoccurance of atrial fibrillation (1) and decompensation (3). Creatinine levels remained unchanged in 54 % of the patients with 46% having an increase of between 10 and 20%. Summary This is a real world single center experience of the use of ARNI agent in the CHF population. While the patients were selected as per the PARADIGM study, only 6 patients were titrated to the dose achieved in the study. All patients reported feeling better with 5 patients on reduced diuretic doses and most patients maintaining stable renal function with modified responses in natriuretic peptides.

P1868

Changes in hemodynamic parameters and cerebral oximetry during head-up tilt test in heart failure patients: the HARVEST study

H Hannes Holm[1]; E Bachus[1]; V Hamrefors[1]; O Melander[1]; G Taseveska[2]; A Fedorowski[2]; M Magnusson[2]
[1]Skane University Hospital, Department of Clinical Sciences, Lund University, Malmo, Sweden; *[2]Skane University Hospital, Department of Cardiology, Skåne University Hospital, Malmö , Malmo, Sweden*

On behalf of: HARVEST

Aims: Circulatory adaptation to orthostatic stress in congestive heart failure (CHF) has been poorly investigated. We aimed to analyse changes in hemodynamic parameters and cerebral oxygenation in patients with CHF undergoing head-up tilt test (HUT).
Methods: Synchronized non-invasive beat-to-beat hemodynamic monitoring, ECG, peripheral oxygen saturation (SpO2) and near-infrared-spectroscopy (NIRS) were applied to measure hemodynamic changes and absolute frontal cerebral tissue oxygen saturation (SctO2; normal range, 60-80%) during HUT. Forty-seven patients (mean-age: 71 ± 11 years, 79% male) with CHF, New York Heart Association (NYHA) class I–IV (I n=1, II n=16, III=21, IV n=2) and mean ejection fraction (EF) 37 ± 15%, in stable condition were included in the analysis. Twenty-four patients met criteria for heart failure with reduced EF (HFrEF), 9 had heart failure with preserved EF (HFpEF) and 8 had heart failure with mid-range ejection fraction (HFmEF). Differences in continuous variables were compared using Student's t-test
Results: After 3 min of HUT, both systolic (SBP, from 119 ± 28mmHg to 123 ± 23mmHg; p = 0.025), and diastolic blood pressure (DBP, from 64 ± 12mmHg to 69 ± 14mmHg; p < 0.001) significantly increased as also did heart rate (HR, from 70 ± 13bpm to 73 ± 14bpm, p = 0.012). In parallel, SctO2 decreased from 67 ± 5% to 62 ± 5% (p < 0.001). Only 3 patients (7%) met the diagnostic criteria of orthostatic hypotension.
Conclusions: Patients with CHF demonstrated increase in BP and HR paralleled by a significant drop in cerebral saturation during HUT. However, there were no symptoms of orthostatic intolerance reported, which suggests good orthostatic adaptation in patients with stable CHF.

P1869

Prognostic significance of myocardial energy expenditure and myocardial efficiency in patients with heart failure with reduced ejection fraction

MS Cetin[1]; E H Elif Hande Ozcan Cetin[1]; H Sasmaz[1]; A Temizhan[1]; S Aydogdu[1]
[1]*Ankara Turkiye Yuksek Ihtisas Hospital, Department of Cardiology, Ankara, Turkey*

Introduction: In Heart failure (HF) patients, myocardial blood flow (MBF), energy expenditure (MEE), myocardial efficiency has been poorly evaluated because of the necessity of invasive procedures in the determination of these parameters. Transthoracic echocardiography (TTE) can provide reliable data for MEE, MBF (via coronary sinus (CS) flows). Also, myocardial efficiency can be evaluated by the MEE to MBF ratio. We aim to assess MBF, MEE and energy efficiency and the prognostic value of these parameters in HF.

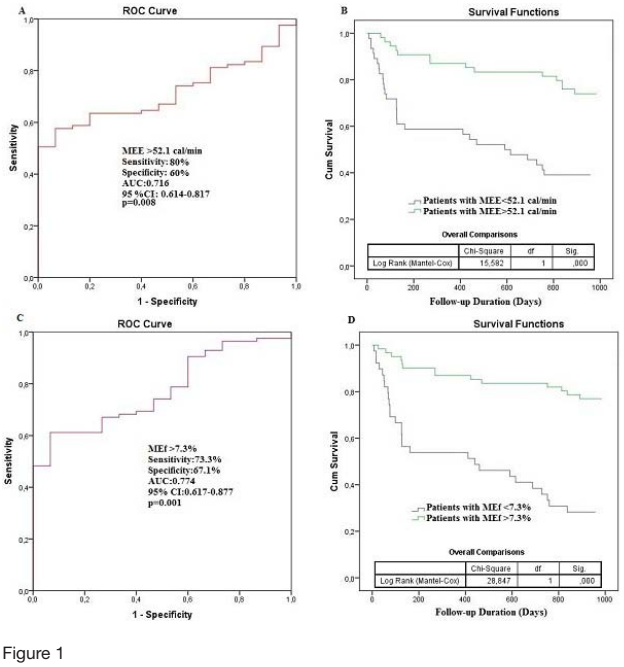

Figure 1

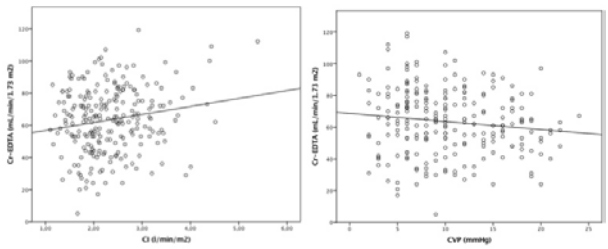
Methods: 80 patients with HF with reduced ejection fraction and 20 healthy subjects were included. Median follow-up duration was 901 ± 361 days. MBF was calculated via coronary sinus blood flow. MEE was measured from circumferential end-systolic stress, stroke volume and left ventricular ejection time. MEE to MBF ratio was determined as MEf.
Results: MEE was lower in HF group than the control group. MBF per minute was higher in HF group whereas MBF per 100 g left ventricular mass was not different. MEf was also lower in HF group. MEE and MEf was significantly correlated with troponin, BNP, uric acid and epicardial fat thickness. In Cox regression analysis, MEE (HR:4.396 (95% CI: 1.230-15.716) and MEf (HR:3.343 (95% CI: 1.025-10.905) were determined as independent predictors of mortality. In ROC analysis for prediction of composite end-point, a cut-off value 52.1 cal/min for MEE had a 80% sensitivity and 60% specificity and a cut-off value 7.3% for MEf had a 73.3% sensitivity and 67.1% specificity.
Discussion: Our study demonstrated that while MEE and MEf diminished in HF, MBF preserved with the symptomatic progression of HF. MEE and MEf were found to be associated with important prognostic markers and independent predictors of mortality in HF. Evaluation of MEE, MBF and MEf with echocardiography may utilize prognostic assessment in HF population.

P1870

Relation between invasive hemodynamics and measured glomerular filtration rate by 51Cr-EDTA clearance in advanced heart failure.

T Tania Deis[1]; L Balling[1]; S Boesgaard[1]; K Rossing[1]; M Schou[2]; F Gustafsson[1]
[1]*Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*;
[2]*Gentofte University Hospital, Gentofte, Denmark*

Background: The interaction between hemodynamics and kidney function in HF is still incompletely understood. In most studies, estimated glomerular filtration rate (eGFR) has been used as a measurement of renal function. Plasma clearance of 51-chromium-labeled ethylenediamine tetra-acetic acid (51Cr-EDTA) is a more accurate measurement of GFR. We investigated the association between invasive hemodynamic parameters and renal function estimated by 51Cr-EDTA in patients with advanced HF. This study tested the hypothesis that patients with reduced 51Cr-EDTA have lower cardiac index (CI) and mean arterial pressure (MAP) as well as higher central venous pressure (CVP) and pulmonary capillary wedge pressure (PCWP).
Methods: We retrospectively studied 242 patients with a left ventricular ejection fraction (LVEF) < 45 % treated with contemporary medical HF therapy, who underwent right heart catheterization (RHC) and had renal function estimated by 51Cr-EDTA-clearance.
Results: Univariate analysis demonstrated a significant correlation between mGFR and CI (r2 = 0.030, p = 0.007 and mGFR and CVP (r2 = 0.017, p = 0.049, figure) but no significant correlation was found between mGFR and MAP or mGFR and PCWP. When multivariate analyses were performed, none of the hemodynamic variables remained significantly associated with mGFR.
Conclusions: While CVP and CI were correlated with mGFR the results suggest that hemodynamics only determines renal function in advanced HF to a minor degree challenging the accepted assumption that renal dysfunction in HF mainly is due to renal congestion.



P1871

Impact of percutaneous coronary intervention on microcirculation in patients with myocardial infarction

ROMAN Viskov[1]; ALEX Mitichkin[1]; ANNA Tektova[2]; NINA Kazunina[2]; RAISA Stryuk[2]
[1]*Inozemtsev City Clinical Hospital, Moscow, Russian Federation*; [2]*Moscow State Medical and Dental University, Moscow, Russian Federation*

Research objectives: To assess the impact of percutaneous coronary intervention and coronary artery stenting (PCI) on of microcirculation (MC) in patients with myocardial infarction (MI).
Materials and methods: The study included 92 patients (61 male and 31 female, the median age 62,5 years [25%;75%:55,0;72,0 years] with a diagnosis of myocardial infarction, confirmed by clinical, laboratory and instrumental methods. 22 patients was underwent PCI, 70 patients received standard medical therapy alone.
All patients on the 1st and 7th days were examined using Laser Doppler flowmetry (LDF) with a laser analyzer LAKK-02, The amplitude-frequency spectrum of

oscillations was computed using wavelet transform; contribution of endothelial (ECMT), neurogenic (NCMT) and myogenic components (MCMT) of microvascular tone and efficacy index of microcirculation (EIM) - the ratio of active and passive mechanisms of vascular tone regulation. Statistica version 8.0 was used for all statistical testing, and statistical significance was considered when $p < 0,05$.

Results: In day 1 in patients undergoing PCI (group 1) it was revealed a significant increase in the amplitude of neurogenic and vascular components of vascular tone (NCMT 6,30[4,25;8,57], MCMT 4,96[3,30;6,38], ECMT 5,48[3,65;8,23], while in patients treated conservatively (group 2), these indicators were significantly reduced (NCMT 4,01[2,27;5,67], MCMT 3,10[2,05;4,29], ECMT 3,59[2,25;6,20], pNCMT=0,026, pMCMT=0,060, pECMT=0,012).

The ratio of active and passive mechanisms in both groups were comparable and not significantly different: EIM 1,60 [1,46; 2,14] vs 1,59[1,14;1,90], respectively.

On the 7th day in PCI (group 1) indicators of endothelial, neurogenic and myogenic components of microvascular tone declined slightly: NCMT 5,37[3,98;7,18], MCMT 4,75[3,42;5,73], ECMT 4,59[3,68;7,24]. In group 2 only neurogenic tone was decreased NCMT 3,79[2,79;6,64], myogenic tone was unchanged - MCMT 3,09[1,95;4,26] and endothelial tone was increased - ECMT 3,77[2,48;5,70]. Comparison of MC indices, characterizing vascular tone, showed, that parameters normalized amplitudes in patients 2 group were lower, but significant difference was obtained only for myogenic tone ($p = 0,004$), but EIM in group 1 was significantly higher 1,82[1,50;4,26] vs 1,37[1,11;1,88], ($p = 0,013$).

Conclusion: PCI patients for MI, compared with patients, who were treated conservatively, had more active microvascular state and less pronounced contribution to passive mechanisms (heart rate, respiration) in the processes of regulation of vascular tone at this level.

P1872

Hemodialysis induced alterations in coronary blood flow and cardiac function

D Dawood Sharif[1]; I Abu-Mokh[1]; Y Sharif[2]; A Sharif-Rasslan[3]; S Storch[1]; U Rosenschein[1]

[1]Bnai Zion Medical Center, Haifa, Israel; *[2]Technion, Haifa, Israel*; *[3]The Academic Arab College, Mathematics, Haifa, Israel*

Heart failure develops in 20-25% of patients on chronic dialysis. Coronary flow reserve is reduced even in the absence of obstructive coronary artery disease in dialysis patients. Sampling of coronary artery flow velocities is feasible using trans-thoracic Doppler echocardiography (TTE).

Aim: To test the hypothesis that dialysis reduces coronary flow and alters cardiac function.

Methods: Twenty five patients, age 71 ± 10yrs, 40% with heart failure were studied. TTE was performed before, during and immediately after hemodialysis. Doppler sampling of blood velocities in the left anterior descending coronary artery (LAD) was performed.

Results: No ischemic or other serious event occurred during or after dialysis. During dialysis, left ventricular end-diastolic diameter, and velocities through the mitral and aortic valves decreased significantly. While right ventricular longitudinal function decreased significantly during dialysis, tricuspid and pulmonary valves velocities remained without change. Myocardial performance index did not change significantly. Diastolic blood velocity in the LAD decreased from 38 ± 12 to 31 ± 10 cm/sec, $p < 0.001$. LAD flow indices as well as myocardial oxygen demand indices decreased significantly keeping their ratio unchanged during dialysis. After dialysis, left atrial diameter and left ventricular diameters were smaller than before the procedure. Blood velocity parameters in the LAD were similar in those with and without heart failure. Similar changes in echo-Doppler parameters occurred in both groups during dialysis.

Conclusion: Hemodialysis is associated with reduction in left side cardiac chamber diameters and velocities; coronary flow velocities is reduced but with maintenance of blood supply/ demand ratio and thus without ischemic events.

P1873

Percutaneous transarterial renal angioplasty in renovascular hypertension. immediate results and in-hospital evolution

I P Ivana Picone Borges[1]; ECS Peixoto[1]; RTS Peixoto[1]; RTS Peixoto[2]; ILPB Anjos[3]; LLB Bandeira[3]; CT Santos[3]; TLS Macedo[3]; DM Rebello[3]; AAB Aragao[1]

[1]Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil; *[2]State Institute of Cardiology Aloysio de Castro, Rio de Janeiro, Brazil*; *[3]Severino Sombra University, School of Medicine, Rio de Janeiro, Brazil*

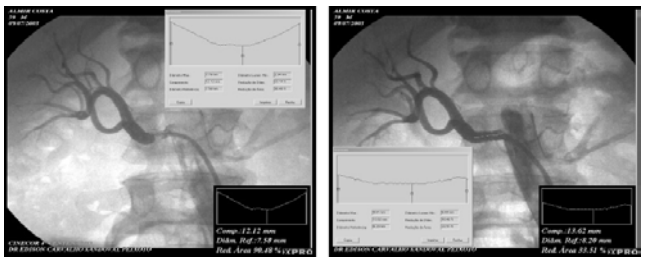
Background: Worldwire, it's not defined the use of stents in all renal vascular hypertension etiologies and the independent variables to predict technical and clinical success.

Objectives: To evaluate percutaneous renal artery intervention outcomes and in-hospital evolution. To identify the independent variables to predict technical and clinical success.

Methods: Eighty eight procedures were analyzed and subdivided into: Group A ($n = 25$), between 1981 and 1992, when the stent was not available; and Group N ($n = 63$), between 1993 and 2006, using balloon and/or stent. The procedures were also grouped by the two principal etiologies: atherosclerosis ($n = 68$) and fibromuscular dysplasia ($n = 11$).

Results: Age and osteal lesion were higher in Group N; Technical success of 98.4% versus 84.0% in N and A group, respectively ($p = 0.0216$), with similar and favorable in-hospital evolution. Pre and post procedure systolic arterial pressures were similar in both groups. Diastolic arterial pressure lower in group N. Whem the atherosclerotic and fibromuscular dysplasia groups were compared: age and osteal lesion were higher in former with similar technical success, in-hospital evolution and pre and post procedure systolic and diastolic arterial pressure in both groups. The systolic and diastolic arterial pressures dropped significantly between pre-procedure and hospital discharge period both etiology, atherosclerotic and fibromuscular dysplasia groups.

Conclusion: Technical success was higher in percutaneous renal artery interventions after the introduction of stents. A balloon angioplasty for fibromuscular dysplasia and, the possibility of implanting a stent for atherosclerotic etiology, constitute efficient renal vascular hypertension treatment



P1874

Association of metabolic syndrome with coronary artery disease extent and severity

A Aferdita Veseli[1]; I Alimehmeti[2]; H Gjergo[3]; J Seiti[1]; E Demiri[4]; S Kabili[5]; B Horjeti[6]; M Lezha[1]

[1]University Hospital Center Mother Theresa, Cardiovascular diseases, Tirana, Albania; *[2]The Faculty of Medicine, Family Medicine and Professional Diseases, Tirana, Albania*; *[3]The Faculty of Medicine, Heart and Vascular Diseases, Tirana, Albania*; *[4]Health Clinic "Neo Style", Tirana, Albania*; *[5]University Hospital "Shefqet Ndroqi", Cardiology, Tirana, Albania*; *[6]American Hospital, Cardiology, Tirana, Albania*

Background: Previous studies have suggested that Metabolic Syndrome (MS) is associated with Coronary Artery Disease (CAD).

Aim: Assessment of the association between MS and angiographic extent and severity of CAD.

Materials and Methods: The study population consisted of 607 consecutive patients who underwent elective coronary angiography in the period November 2011-April 2012. MS was defined according National Cholesterol Education Program (NCEP) Adult Treatment Panel III criteria. Angiographic extent and severity of CAD were quantified employing the modified Gensini score and the percentage of stenosis in the culprit artery.

Statistical Analysis: Data were summarized in the form of mean and percentage for continuous and categorical variables respectively. Linear regression, base and full model, was used to evaluate the correlation of MS and Gensini. Logistic regression, base and full model, was used to evaluate the correlation of MS and CAD. Student's t-test was used for comparing two groups with and without MS.

Results: MS was present in 307 patients (50.6%). Patients with MS consisted of a higher percentage of females (36% vs. 17%, $p < 0.001$), lower prevalence of smoking (44% vs. 56%, $p = 0.017$) and higher prevalence of urban residence (77% vs. 68%, $p = 0.019$). MS patients presented a higher number of diseased coronary arteries (1.5 vs. 1.3, $p = 0.014$) and a higher coronary heart disease Gensini index 9.8 vs 8.4, $p = 0.025$). Logistic regression analysis showed that MS was associated with higher odds of CAD (OR 1.872, 95%CI 1.280-2.737, $p = 0.001$) when adjusted for age and gender. Further adjustment for smoking, socioeconomic and demographic variables slightly increased the association of MS with CAD (OR 1.922, 95%CI 1.301-2.284, $p = 0.001$). Moreover in linear regression, MS proved to be significantly associated with Gensini score both in the basic model (β 2.465, 95%CI 1.246-3.684, $P < 0.001$) and the full model (β 2.344, 95%CI 1.129-3.558, $p < 0.001$).

Conclusion: MS is associated not only with the CAD but also with its extend and severity.

METABOLISM - DIABETES MELLITUS - OBESITY

P1875
Cardiac function in obese pregnant women

K Golinska Grzybala[1]; E Konduracka[1]; J Nessler[1]
[1]*John Paul II Hospital, Department of Coronary Disease and Heart Failure, Krakow, Poland*

Background: During pregnancy cardiovascular system undergoes complex changes including cardiac function and remodelling, left ventricle (LV) hypertrophy, as well as changes in systemic vascular resistance, secondary to growing uteroplacental circulation.
Purpose: The aim of this study was to evaluate the changes in cardiac remodelling, function and systemic vascular resistance throughout gestation in obese pregnant women in comparison to pregnant women with normal weight.
Methods: We conducted a prospective cohort study, which included consecutive 23 obese, pregnant women with singleton pregnancy and 40 pregnant women with normal weight (control group) (mean age 29.1 ± 1.1 vs. 31.1 ± 0.8 respectively, $p = 0.956$). The exclusion criteria were any cardiovascular disease diagnosed before pregnancy, diabetes mellitus, gestational diabetes or gestosis in previous pregnancy, chronic kidney disease, and multiple pregnancy. During pregnancy echocardiography, assessment of blood flow in uterine arteries (pulsatility index (PI) and blood pressure were assessed at two visits (V): V1 between 10 and 14 weeks and V2 between 25 and 30 weeks of gestation.
Results: At V1 we observed higher diastolic blood pressure in obese pregnant women in comparison to control group (82.6 vs. 75.5 mmHg respecticely, $p = 0.016$), as well lower LV cardiac index (LVCI) (2.5 vs. 2.8 l/min/m2, $p = 0.006$) and increased LV mass index (LVMI) (64 vs. 59 g/m2, $p = 0.047$). There was no differences in SVR and PI. At V2 systolic, diastolic and mean arterial pressure were higher than in control group (119 vs. 111 mmHg; $p = 0.017$, 79 vs. 68 mmHg; $p < 0.001$, 92 vs. 82 mmHg; $p < 0.001$, respectively). SVR and PI were increased (1469 vs. 1264 dyns cm-5; $p = 0.015$, 0.68 vs. 0.57; $p = 0.034$, respectively) , LVCI was lower (2.7 vs. 3.0 l/min/m2; $p = 0.033$), in contrast to LVMI (68 vs. 63 g/m2; $p = 0.042$). We observed no differences in LVEF at both visits in study groups, whereas end-systolic meridional wall stress (ESS) (which represents afterload) was significantly increased in obese women at V2 (43 vs. 39, 103 dyn/cm2; $p < 0,001$). What is more, ESS at V2 was positively correlated with LVMI (r=0.423; $p < 0.001$) and PI (r=0.357; $p = 0.001$), also measured at V2.
Conclusions: 1. In obese pregnant women we observed higher blood pressure, systolic vascular resistance and PI in uterine arteries, especially between 25 and 30 weeks of gestation. 2. Myocardial function in these women, expressed by end-systolic wall stress (ESS), LVCI and LVMI is impaired.

P1876
Patterns of left ventricular global longitudinal strain in diabetic patients by speckle tracking imaging.

AHMED Ahmed Elgohary[1]
[1]*research institue of ophthalmology, cardiology, Al Jizah, Egypt*

Introduction: Diabetic patients with normal left ventricular ejection fraction are frequently associated with diastolic dysfunction. Speckle tracking is more sensitive than LVEF in detection subclinical LV systolic dysfunction.
Aim: Detection of different patterns of global longitudinal strain in diabetic patients using global longitudinal strain by speckle tracking.
Methods: fifty two diabetic patients had been referred from internal medicine clinic after they had been tested for HBA1c test and stratified into two groups
Group I: it include26 DM patients with controlled blood sugar.
Group II: it include26 DM patients with uncontrolled blood sugar The two groups had been subjected to the following diagnostic workup: Full medical history, full clinical examination, laboratory assessment , twelve lead resting ECG ,Stress ECG, Echocardiography study, Traditional Tissue Doppler imaging ,Assessment of global longitudinal strain. Patients with IHD, Systolic dysfunction, CHD ,Valvular, Arrhythmia, HOCM ,Pericardial, major systemic disease had been excluded.
Result: there was significant statistical difference in GLS, Age , Diabetic Type ,Diabetic Duration,2HPP Blood sugar level, E/é ratio in controlled DM compared to uncontrolled DM ($p < 0.05$),there was no significant difference in Gender ,FBS. EF, E/A in controlled DM compared to uncontrolled DM.
Conclusion: Diabetic duration was strongly correlated with reduction of global Longitudinal strain. Poor blood glucose control, as indicated by HbA1c>6.5%, leads to reductions in LV global longitudinal systolic strain, which is associated with preclinical LV dysfunction.

P1877
Prevalence and effects of metabolic syndrome in a cardiac rehabilitation program

G Goncalo Neves Pestana[1]; A Rocha[2]; R Pinto[1]; M Tavares-Silva[1]; M Braga[1]; H Nascimento[1]; P Araujo[1]; A Nunes[1]; V Araujo[1]; F Parada[2]; MJ Maciel[1]
[1]*Sao Joao Hospital, Cardiology, Porto, Portugal*; [2]*Sao Joao Hospital, Physical Medicine and Rehabilitation, Porto, Portugal*

Background/Purpose: Cardiac rehabilitation (CR) is an essential tool in the management of patients (pts) after an acute coronary syndrome (ACS), effectively reducing morbidity and mortality. Nevertheless, current data comes from heterogeneous studies and its specific effects in particular subgroups is less clear. Metabolic syndrome (MS) is a pandemic, encompassing a number of cardiovascular risk factors that, together, are associated with a particularly somber prognosis. We looked into the prevalence of MS in a CR population and its effect on response to CR.
Methods: We retrospectively analysed data from a prospective cohort of pts referred to CR within 3 months after ACS and calculated the prevalence of MS as defined by the AHA and related societies in 2009. We then evaluated how this group's response to CR differed from that of pts without MS. Logistic regression and independent samples t-test were used for the statistical analysis.
Results: From a total of 809 pts with available data, 305 (37.7%) met the criteria for MS; these pts were more frequently female (20.3 vs 11.7%, $p = 0.001$) and older (mean age 56 vs 53 years, $p < 0.001$) comparing to pts without MS. Pts with MS were more likely to not complete the CR program, with and odds ratio of 1.74 (95% CI: 1.13-2.67, $p = 0.011$). And while exercise capacity, assessed by treadmill stress test time at baseline and at 3 months follow-up, was also significantly worse in pts with MS, both groups showed significant improvement; indeed, MS pts actually showed a greater relative increase (31 vs 25%, $p = 0.013$). Regarding secondary prevention targets at 1 year of follow-up, according to AHA guidelines, both groups achieved similar proportions of smoking cessation, physical activity, HDL cholesterol, triglycerides and glycaemic control, but blood pressure (86.2 vs 96.5%, $p < 0.001$) and body mass index (BMI, 23.4 vs 52.6%, $p < 0.001$) targets were less frequently attained in MS pts.
Conclusions: Metabolic syndrome is frequent in cardiac rehabilitation patients, but in our cohort they nevertheless showed a greater relative improvement in exercise capacity and similar risk factor profile control compared to those without MS, with the exception of blood pressure and BMI. These findings make it all the more relevant that MS pts seem to abandon the CR program more frequently and they should encourage us to further investigate this association and develop tools to oppose this trend.

P1878
Correlation between glycaemic status and left ventricular diastolic function in type 2 diabetes patients

M M Mohamed Eldeib[1]
[1]*Al-Azhar University, cardiology, Cairo, Egypt*

Background: Diabetes mellitus is considering an important independent factor in developing diastolic dysfunction. Diastolic dysfunction comprises about 30 to 50% of all patients hospitalized for heart failure. The aim of this study was to determine the correlation between glycaemic status and left ventricular diastolic function in type 2 diabetic patients
Methods: our study included (100) subjects,20 normal healthy subjects ,80 known to be Diabetic patients presented in our diabetic outpatient clinic and echocardiographic unit at Al-Hussein University Hospital between November 2010 and June 2011.the patient were classified according glycaemic status in to three groups: Group (A) Normal healthy control subjects. Group (B) well controlled diabetes HbA1C less than 7, Group (C) uncontrolled diabetes HbA1C more than 7.
Results: There was no statistically significant difference between the three groups as regard LVEDD,LVESD and LV EF%. There was statistically significant difference between the three groups as regard LA dimension mean E wave, mean of A wave mean of E/A ratio, mean of DT, mean of IVRT, mean of Em wave, mean of E/Em degree of diastolic dysfunction. There was negative correlation between HbA1c level and E wave, E/A, Em and positive correlation with LA dimension, A wave, IVRT, DT and E/Em.
conclusion: The Glycemic status is well correlated with severity of diastolic dysfunction in asymptomatic type 2 diabetic patients. Tissue Doppler imaging has been shown to be more sensitive and more independent for assessment of diastolic function in asymptomatic type 2 diabetic patients and its results are significant correlated with glycemic state.

P1879

Prevalence and characteristics of diabetes mellitus and insulin resistance in heart failure patients across Europe. A report of the 1st Postgraduate Course in Heart Failure of the HFA.

S Paolillo[1]; C Minoia[2]; K Ablasser[3]; G Di Stolfo[4]; M Merlo[5]; A Vachulova[6]; F Ruschitzka[7]; A Mathe[8]

[1]Department of Advanced Biomedical Sciences, Section of Cardiology, Federico II University of Naples , Naples, Italy; *[2]Sant' Antonio Abate Hospital , Cardiology, Gallarate, Italy*; *[3]Medical University of Graz, Department of Cardiology, Graz, Austria*; *[4]Casa Sollievo della Sofferenza Hospital, Cardiovascular Department, San Giovanni Rotondo, Italy*; *[5]University of Trieste, Cardiovascular Department, Azienda Sanitaria Universitaria Integrata, Trieste, Italy*; *[6]The National Institute of Cardiovascular Diseases, Bratislava, Slovak Republic*; *[7]University Heart Center, Department of Cardiology, Zurich, Switzerland*; *[8]University Hospital of South Réunion, Department of Cardiology, Saint-Pierre, Reunion*

On behalf of: 1st Postgraduate Course in Heart Failure of the Heart Failure Association

Introduction: Glucose metabolism abnormalities are common in heart failure with reduced ejection fraction (HFrEF), and adversely influence long-term prognosis. An increasing interest is focused on the recognition of overt diabetes mellitus (DM) and of insulin-resistance (IR) in HFrEF patients to improve therapeutic management and prognosis.
Purpose: Aim of the present report was to analyze the prevalence and characteristics of these conditions in HFrEF patients enrolled across Europe.
Methods: Six HF specialists of 3 European countries (1 from Austria, 1 from France, 2 from North Italy, and 2 from South Italy) were involved in patients' enrollment. In particular, they enrolled consecutive HFrEF patients seen from November 2016 to January 2017 fulfilling the subsequent criteria: 1) age ≥18 years; 2) EF ≤40%; 3) stable clinical conditions; 4) HF diagnosis since at least 6 months; 5) no acute coronary syndrome in the previous 3 months. On the same day patients underwent venous blood sample collection to assess fasting glucose, fasting insulin and glycated hemoglobin. IR was assessed through the evaluation of HOMA-IR, calculated by the formula [fasting Glucose (mmol/L) × fasting Insulin (mIU/L)/22.5], and the presence of IR was defined as HOMA-IR value >2.5.
Results: Two hundred twenty-two HFrEF patients were included in the analysis (72.5% M, mean age 66.5 ± 12.4 yrs, mean EF 30.9 ± 6.7%). The etiology of HF was ischemic in 131 (59%) patients, an idiopathic dilated cardiomyopathy in 75 (33.8%) subjects, and in the remaining cases other causes were identified; 71% of patients were in NYHA class I-II and 29% in NYHA III. Eighty patients (36%) exhibited DM (93.7% type 2 DM, 6.3% type 1 DM) with no significant differences among countries (47 vs. 37 vs. 34% in Austria, France and Italy, respectively; p = ns). Mean fasting glycemia was 141 ± 44 mg/dl, mean HbA1c 7.5 ± 1.7% and mean fasting insulin 20 ± 22 uUI/ml; 34% were on treatment with oral antidiabetics alone, 20% with oral antidiabetic plus insulin, 21% with insulin alone, and the remaining patients were on diet control. HF was of ischemic etiology in 76% of cases, and an adequate, however not optimal HF therapy was prescribed (59% ACE-i or ARBs, 74% beta-blockers, 40% MRAs, 12% LCZ-696). As regards to IR, among non-diabetics the prevalence of IR was 46% with mean HOMA index of 3.1 ± 2.8, mean fasting glycemia of 95 ± 23 mg/dl and mean fasting insulinemia of 12 ± 10 uUI/ml. HF was of ischemic etiology in 55% of cases and HF treatment was not optimal also in this group (65% ACE-i or ARBs, 73% beta-blockers, 30% MRAs, 0% LCZ-696).
Conclusions: Diabetes mellitus and insulin resistance are common comorbidities of European HF patients with similar distribution across countries and still not optimal HF treatment. More efforts are required to prompt recognize glucose metabolism abnormalities in HF and to optimize HF management in these subgroups to improve patients' quality of life and long-term prognosis.

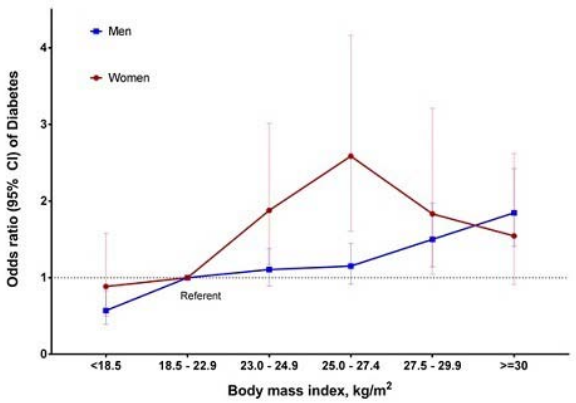
Background: Diabetes mellitus (DM) portends a greater risk of heart failure (HF) in women than men. However little is known about sex differences in the association of DM with quality of life (QoL) and outcomes in HF, particularly in Asia.
Aims: To examine sex differences in clinical correlates, QoL and 1-year composite outcome (all-cause mortality or HF hospitalization) in diabetic Asian patients with HF.
Methods: In the ASIAN-HF Registry, a prospective multinational study of symptomatic HF across 11 Asian regions, we compared diabetic women vs men using WHO BMI cut-offs for Asians (lean : BMI <23; obese : BMI ≥27.5 kg/m2) and the Kansas City Cardiomyopathy Questionnaire (higher scores reflecting better QoL).
Results: Among 5255 Asian patients with HF (mean age 59.6 ± 13.1, 78% men), the prevalence of DM was similar in men (43%) and women (42%). Clinical correlates of DM in both men and women were older age and hypertension (in 67% DM ♂ and 68% of DM ♀). When adjusted for age and BMI, the odds of ischaemic aetiology was greater in DM men than women [OR=1.9 (95% CI 1.6-2.4) and OR 2.5 (95% CI 2.0-3.0) in non-DM men vs women respectively; p-interaction = 0.206]. In contrast, the odds of chronic kidney disease (CKD) was higher in DM women than men [OR = 1.6 (95% CI 1.3-2.1) and OR=1.1 (95% CI 0.9-1.4) in non-DM men vs women respectively; p-interaction = 0.019]. Among lean patients, 37% men and 31% women had DM (p = 0.028). Higher BMI was related to increased odds of DM, and this relationship was modified by sex (pinteraction=0.014). Adjusting for age and comorbidities, compared to BMI 18.5-23 kg/m2, the odds of diabetes increased in women above BMI ≥23 kg/m2 and in men above BMI ≥27.5 kg/m2 (Figure). QoL was poorer in diabetic women than men (overall score 60.4 ± 23.0 vs 63.1 ± 23.6, p = 0.045), particularly in the physical limitation domain (61.5 ± 27.3 vs 67.3 ± 25.9, p < 0.001) and self-efficacy (60.3 ± 28.1 vs 66.9 ± 25.8, p < 0.001). Adjusting for age and comorbidities, DM was associated with higher hazards of 1-year composite outcome in women than in men [HR=2.1 (95% CI 1.5-3.1) vs HR=1.4 (95% CI 1.2-1.6) respectively; pinteraction 0.002].
Conclusions: Diabetes is highly prevalent in Asian men and women with HF, even in the absence of obesity, and impacts QoL and 1-year mortality/morbidity outcomes more in Asian women than men.



Odds of diabetes at BMI levels in sexes

HEART FAILURE IMAGING

Relation between 2-dimensional speckle tracking echocardiography and MPI in diagnosis of coronary artery stenosis and subtle left ventricular dysfunction in stable angina pectoris patients.

M M Moustafa Mohamed Mohamed Eldeib[1]; E Elhefny[1]; A Ibraheem[1]

[1]Al-Azhar University, cardiology, Cairo, Egypt

Background: conventional echocardiography at rest provides little information regarding the presence of coronary artery disease in patients suspected of suffering from stable angina pectoris, Longitudinally orientated myocardial fibers are located subendocardially, the area most susceptible to ischaemia, that is why measurements of longitudinal motion and deformation may be the most sensitive markers of CAD using two-dimensional strain echocardiography (2DSE) The aim of this study was to study the correlation between 2DSE at rest and MPI in diagnosis of CAD in stable angina pectoris patients.
Methods: our study included (80) subjects suspected to be stable angina pectoris patients presented for evaluation of chest pain at Al-Hussein University Hospital – Al-Azhar University – Cairo – Egypt between December 2013 and December 2015
Results: In this study we found there was no correlation between the total number of segments affected in MPI and results of coronary angiography and P value was not significant for the summation of total segments and significant for LAD territory. There was a positive correlation between the number of segments affected in MPI and GLS17, GLS12, GLSr17 and GLSr12; in this study we found there was a positive correlation between the 17 segments in MPI and SLSS and SLSr parameters. In this study we found that strain parameters at BA, BAS, MA, MIS, MAS, AI and AL segments were found to be significant predictor of LAD stenosis and BP and MP were found to be significant predictor of LCX stenosis and BI was found to be predictor of RCA stenosis, also we found that strain rate parameters at BA, MA, MAS, AI, AL and apex segments were found to be significant predictor of LAD stenosis, and BL, BP and ML were found to be significant predictor of LCX stenosis and BI and MI were found to be predictor of RCA stenosis
Conclusion: Using of 2DSE at rest is not inferior to the use of MPI in the non invasive diagnosis of CAD, myocardial deformation imaging based on 2-dimensional longitudinal peak systolic strain analysis may differentiate between ischemic segments and non ischemic segments as compared with SPECT MPI.

P1882
MRI contribution in the diagnosis and left ventricle function evaluation in acute myocarditis

H Henda Neji[1]; M Kilani[1]; M Attia[1]; Z Belhaj[2]; I Kammoun[2]; I Baccouche[1]; S Hantous-Zannad[1]; K Ben Miled-M'rad[1]
[1]Abderrahmen Mami Hospital, Imaging department, Ariana, Tunisia; *[2]Abderrahmen Mami Hospital, Cardiology, Ariana, Tunisia*

Background/Introduction Clinical presentation of acute myocarditis is non-specific. Its diagnosis is challenging because of the overlap with acute myocardial infarction. MRI is nowadays a valuable imaging tool to make an accurate diagnosis of acute myocarditis.
Purpose: The purpose of this work is to describe MRI findings and left ventricle function in acute myocarditis.
Methods: Retrospective review of MRI data of 17 patients referred to imaging department of our institution between June 2015 and December 2016 for high clinical suspicion of acute myocarditis. All exams were performed with a 1.5 T machine. The protocol included STIR, first pass perfusion, early and late enhancement sequences.
The diagnosis of acute myocarditis was made according to Lake Louise consensus Criteria.
Results: Among the 15 patients, 9 (8 men and 1 women) had a positive MRI. Their mean age was 32.2 years. All of them had non-specific chest pain, 7 had a history of recent respiratory tract infection, and 6 had elevated troponins and electric modifications.
Edema presenting as myocardial high signal on STIR sequences was found in 5 patients. Early (on first pass perfusion and/or early enhancement sequence) and late gadolinium enhancement were found in all patients.
All these signs were located to the sub-epicardial myocardium in a linear (7 patients) or patchy (1 patient) presentation. The lateral left ventricle wall was involved in all patients.
Only 2 patients had left ventricle ejection fraction below 50%.
Conclusions: Cardiac MRI is an accurate tool to diagnose acute myocarditis, evaluate the lesions distributions and the left ventricle function.

P1883
Application of Dipirydamole stress Tc99m MIBI SPECT in patients with heart failure and reduced ejection fraction and suspected coronary artery disease

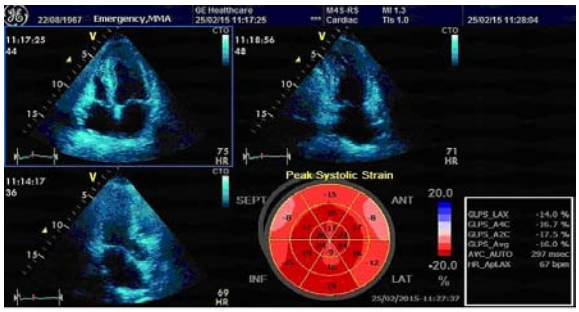
M Kostkiewicz[1]; W Szot[2]; A Lesniak-Sobelga[1]; P Rubis[1]; K Holcman[1]; S Smialek[1]; P Podolec[1]
[1]Institute of Cardiology, Jagiellonian University, John Paul II Hospital, Dpt Cardiovascular Diseases, Krakow, Poland; *[2]John Paul II Hospital, Dept of Nuclear Medicine, Krakow, Poland*

Beckground; Exercise cardiac stress testing in patients with heart failure is generally avoided for safety reasons. Our study aimed to assess overall safety and usefulness of dipirydamole stress myocardial perfusion scintigraphy for detection of possible coronary artery disease and myocardial viability using single-photon emission computed tomography (SPECT) in patients with echocardiographicaly proven heart failure and reduced ejection fraction.
Methods: The study comprised 60 patients with ejection fraction < 35% who underwent a 5-minute dipirydamole infusion (1.5 mg/kg body weight) protocol stress technetium-99m sestamibi SPECT. Visual 17-segment SPECT analysis used a standard five-point scoring system ranging from 0 (normal tracer uptake) to 4 (absent uptake). The SPECT results were considered abnormal if more than two segments had a stress score. All patients underwent coronary angiography procedure. The respective results in the groups were subsequently compared using the U-Mann-Whitney test and Pearson's correlation nonparametric test. Results. Sensitivity in the detection of CAD of gated SPECT study was calculated at the level of 83% , with positive predictive value at 88%. Hemodynamic response during dfipirydamole stress testing demonstrated changes in systolic blood pressure in 30% of patients ,in heart rate in 20% of patients, dyspnea in 25% and incidence of chest pain in 30%. of patients. No serious cardiac events were observed.
Conclusions: Dipirydamole Tc99m MIBI SPECT study was established to be well tolerated, safe and diagnostically accurate in patients with heart failure.

P1884
Two-dimensional speckle tracking echocardiography detects subclinical left ventricular systolic dysfunction among hypertensive patients

I Ivaylo Daskalov[1]; D Stoychev[1]; A Chobanov[1]; M Mladenova[1]; L Demirevska[1]; K Ramshev[1]
[1]MMA, Sofia, Bulgaria

Aim: The aim of this study was to determine a high risk group among hypertensive (HTN) patients on the base of diagnose of subclinical LV systolic dysfunction, defined as reduced global longitudinal strain (GLS) < -19.1%, using two-dimensional speckle tracking echocardiography (2DSTE).
Material and method: Eighty HTN patients were enrolled in the study and compared to 70 healthy volunteers. The participants in both group had preserved EF (>55%).
Results: We did not find significant differences in EF between both investigated groups considering gender and age (p=0.231). The GLS was normal in controls and patients with mild HTN without diastolic dysfunction (DD) (p = 0.897). We found significantly reduced GLS among patients with moderate and severe HTN with DD in different stages (p < 0.01). Multivariate analysis shows that this group has also higher values of BMI (p < 0.01), LVMM (p < 0.001), LAvol (p < 0.001), reduced Sm (p=0.01) and MAPSE (p=0.02).
Conclusion: Two-dimensional STE provides an excellent opportunity for early diagnose of subclinical LV systolic dysfunction among HTN patients. This diagnosis is most common in patients with moderate and severe HTN with DD in different stages when the risk of adverse cardiovascular events is higher, including heart failure. That's the reason to start an early and aggressive treatment as well as strict control of the risk factors.



severe HTN, LV hypertrophy,reduced GLS

P1885
Clinical and prognostic association of total atrial conduction time measured by tissue doppler imaging in patients with heart failure. A report from SICA-HF.

V Vincenzo Nuzzi[1]; P Pellicori[2]; T Nikolaidou[2]; A Kallvikbacka-Bennett[2]; C Torromeo[1]; F Barilla'[1]; K Kaur[2]; D Salekin[2]; L Monzo[1]; J Cleland[3]; AL Clark[2]
[1]Sapienza University of Rome, Rome, Italy; *[2]Castle Hill Hospital, Department of Cardiology, Hull York Medical School (University of Hull), Hull, United Kingdom*; *[3]Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: The total atrial conduction time can be measured as the time from the onset of the P wave on the ECG to the peak of the A wave recorded at the mitral annulus using tissue Doppler imaging (A´; P-A´TDI). A long P-A´tdi predicts incident atrial fibrillation (AF) in the general population; however, it has only received little attention in patients with heart failure (HF).
Purpose: We studied the clinical associations and the predictive role of P-A´TDI measured in ambulatory patients with a broad range of HF severity.
Methods: We retrospectively measured P-A´TDI interval in ambulatory patients with HF and sinus rhythm enrolled in the "Studies Investigating Co-morbidities Aggravating Heart Failure" (SICA-HF) programme.
Results: P-A´TDI measured at the lateral mitral annulus was (mean and interquartile range (IQR)) 120 ms (106-135) in 117 controls. It was longer in patients with heart failure with either reduced (LVEF < 50%, N=141; 126 (112-146 ms); P=0.005) or normal left ventricular ejection fraction (LVEF>50% and NTproBNP>125 ng/l, N=71; 128 (108-145) ms; P=0.026). NTproBNP and creatinine correlated positively with P-A´TDI, but only increasing age, left atrial volume and PR interval were independently associated with prolonged P-A´TDI interval.
During a median follow up of 1251 (956 - 1602) days, 73 patients with HF died (N=42) or developed AF (N=31). In univariable analysis, P-A´TDI was associated with increased risk, but only increasing log [NTproBNP], age and more severe symptoms (NYHA III vs I/II) were independently related to an adverse outcome. Patients in whom both P-A´TDI and left atrial (LA) volume were above the median (127 ms and 64 ml, respectively) had the highest incidence of AF (HR: 6.61 95% CI: 2.27-19.31; P < 0.001) compared to those with both P-A´TDI and LA volume below the median.
Conclusions: Measuring P-A´TDI interval identifies ambulatory patients with HF at higher risk of dying or developing AF during follow-up.

P1886

The value of stress echocardiography in the prognosis stratification of patients with left ventricular dysfunction

B Bebiana Faria[1]; T Lopes[2]; F Castro[1]; M Oliveira[1]; P Azevedo[3]; M Lourenco[1]; J Portugues[1]; L Calvo[1]; P Von Hafe[1]; O Azevedo[1]; A Lourenco[1]
[1]Hospital Guimaraes, Guimaraes, Portugal; [2]University of Minho - Life and Health Sciences Research Institute (ICVS), Student, Braga, Portugal; [3]Faro Hospital, Cardiology, Faro, Portugal

Introduction: Pharmacological stress echocardiography (SE) is a non invasive imaging method widely used for the evaluation of ischemia. The presence of left ventricular systolic dysfunction (LVSD) on resting echocardiography may limit the impact of SE in the prognosis stratification of patients with suspected or diagnosed coronary artery disease.
Objective: Assess the value of SE in prognosis stratification of patients with suspected or diagnosed coronary artery disease and LVSD.
Methods: Retrospective study including 789 consecutive patients who performed dobutamine or dipyridamole SE between 2010 and 2015. To identify prognosis predictors were collected demographic, clinical, electrocardiographic and echocardiographic data. A combined endpoint of cardiovascular events was defined, consisting of cardiac death, non fatal myocardial infarction and percutaneous or surgical revascularization.
Results: The sample included 789 patients, 65% males, average age 64 ± 11 years. About 71% of the patients performed SE with dobutamine and 29% with dipyridamole.
Patients with LVSD (n = 228; 29.7%) were predominantly males (78%) with a mean age of 65 ± 12 years. Of the patients analyzed 42% had mild left ventricular function depression, 32% moderate and 26% severe, with an average value of fraction ejection of 38%. SE was positive in 17% of patients. The average follow-up time was 30.7 ± 19.7 months, events occurred in 24% of patients, with an average time to the first event of 195 days. SE presented a sensitivity of 38.9% and specificity of 89.9% for prediction of events in patients with LVD, with a positive predictive value of 55.3% and a negative predictive value of 82.2%. Event-free survival in patients with positive SE was significantly lower than patients with negative SE (47 ± 4 months vs. 60 ± 2 months, p = 0.004).
In the univariate analysis, the result of SE was a predictor of events. However, after multivariate analysis only the development of symptoms during SE (p = 0.001) and chronic kidney failure (p = 0.038) were considered independent prognosis predictors in patients with LVSD.
Patients with preserved left ventricular function (LVF) (n = 540, 70.3%) were male in 59.6% of the cases and had a mean age of 65 ± 11 years. The average value of fraction ejection was 62%. SE was positive in 10.7% of the patients. The events occurred in 7.8% of the cases, with an average time to the first event of 312 days. Event-free survival in patients with positive SE was significantly lower than patients with negative result (52 ± 3 months vs. 64 ± 2 months, p < 0.001). In the patients with preserved LVF, a positive result in SE (p < 0.001) and a higher number of modifiable vascular risk factors were identified as independent prognosis predictors (p = 0.043).
Conclusion: The result of SE was identified as independent prognosis predictor in patients with preserved LVF, but not in patients with LSVD.

P1887

Contribution of echocardiographic 2D strain analysis to the long-term follow-up of heart transplant patients

C Goeminne[1]; S Langlet[2]; M Fertin[2]; N Rousse[3]; E Robin[1]; G Leroy[1]; M Moussa[1]; E Hebbar[2]; P De Groote[2]; A Vincentelli[3]
[1]Lille University Hospital, Department of Anaesthesiology and Intensive Care Medicine, Lille, France; [2]Lille University Hospital, Department of Cardiovascular Medicine, Lille, France; [3]Lille University Hospital, Department of Cardiac Surgery, Lille, France

Background: Few studies have evaluated the potential role of 2D strain for the long-term follow-up of heart transplant patients.
Aims: We evaluated the diagnostic and prognostic contribution of echocardiographic 2D strain analysis to the long-term follow-up of heart transplant patients.
Methods: The study population consisted of a cohort of 162 heart transplant patients followed-up at an hospital, France. Donor characteristics, as well as clinical, biological and echocardiographic data were collected. Patients with acute allograft rejection were excluded from the analysis. The 2D strain data was acquired by the same operator in all patients. For statistical analysis, we considered that strain was altered when ≥ -13%, according to the litterature. Cardiovascular events (congestive heart failure, arrhythmias, high-degree conduction disturbances) were assessed in a subgroup analysis.
Results: Data of strain was available in 105 patients. The average strain was -15.8 ± 3.6%, strain was ≥ -13% in 22.8% or the patients. Patients with altered strain were treated with higher dosages of loop diuretics (185 ± 138 mg/day vs. 43 ± 27 mg/day; p = 0.005) and were more frequently dialysed (20 % versus 4 %; p = 0.005). Furthermore, these patients had decreased markers of systolic function such as altered S wave in DTI at the tricuspid ring (8.6 ± 1.9 cm/s versus 9.6 ± 2.0 cm/s, p = 0.038), lower subaortic and subpulmonary velocity time integrals (13.8 ± 3.8 cm/s versus 16.6 ± 3.8 cm/s, p = 0.003 and 13.6 ± 4.4 cm/s versus 15.7 ± 3.6 cm/s, p = 0.041, respectively). Strain was more altered in patients who experienced cardiovascular events (-14.1 ± 4.0 % versus -16.2 ± 3.5 %, p = 0.024).
Conclusion: 2D strain alteration seems to be a marker of chronic cardiac graft dysfunction and may be a useful tool for the management and follow-up of heart transplant patients.

Automatic 3D echocardiography for left ventricular ejection fraction assessment in daily clinical practice: the present and the future

FJ Francisco Javier Irazusta Cordoba[1]; T Lopez Fernandez[1]; V Rial Baston[1]; P Meras Colunga[1]; O Gonzalez Fernandez[1]; Z Blazquez Bermejo[1]; J Caron Codon[1]; E Refoyo Salicio[1]; R Dalmau Gonzalez-Gallarza[1]; G Guzman Martinez[1]; F Dominguez Melcon[1]; SO Rosillo Rodriguez[1]; M Moreno Yanguela[1]; JL Lopez-Sendon[1]
[1]University Hospital La Paz, Cardiology, Madrid, Spain

Introduction: The 2D echocardiography (2DE) is the most commonly employed technique for left ventricular ejection fraction (LVEF) quantification. Although the gold-standard in this issue is the cardiac magnetic resonance (CMR). However, its high costs and low availability does not allow becoming the routinary technique for LVEF assessment. Inter and intra-observer variability for LVEF quantification could be improved by new fully automated systems for 3D echocardiography (Auto3DE), and could be an interesting tool for the heart failure outpatient clinic.
Methods: Prospective observational study that analysed 27 patients referred to our institution for LVEF assessment by CMR. In all patients LEVF was also quantified by Auto3DE and 2DE. Simultaneously we evaluated the feasibility of the Auto3DE in other 81 consecutive patients.
Results: Mean age was 49,8 year-old. The most frequent indications for CMR were hypertrophic cardiomyopathy (15,38%), infectious myocarditis (15,38%) and congenital heart disease (23%). The analysis of the left ventricle volume (LVV) and LVEF was 5 times faster by Auto3DE than 2DE, and 10 times faster than CMR (Table 1). Only 35% of the Auto3DE required image edition by a cardiologist during the analysis, compared to the 91% with the 2DE. End-diastolic and end-systolic volumes measured by Auto3DE were significantly closer to CMR measurements than 2DE. Even though LVEF assessment with Auto3DE was lightly overestimated, its correlation with CMR was better (Spearman´s rho: 0,68) than with 2DE (Spearman´s rho: 0,54). Auto3DE was feasible in 70 of the 81 patients (86,5%) and the main limitation was its dependence on acoustic window.
Conclusion: Auto3DE is much faster than other commonly used techniques for LVV and LVEF measurement, with an acceptable accuracy compared with CMR. We could consider it as a useful tool for daily clinical practice.

	CMR	Auto3DE	p	2DE	p
Time (Seconds)	215	22		115	
mean LVEF (%)	58	62	0,08	55	0,05
mean End-Diastolic Vol (mL/m2)	89	77,3	0,1	53,46	0,0001
mean End-Systolic Vol (mL/m2)	40,3	29,68	0,02	21,68	0,0001

P1889

Left ventricular remodeling in normotensive and hypertensive postmenopausal women

N Natalia Lareva[1]; A Govorin[1]
[1]*Chita State Medical Academy, Chita, Russian Federation*

Aim: To asses changes of left ventricle (LV) structure and function in postmenopausal women depending on hypertension presence and blood pressure (BP) circadian profile type.

Methods: 203 postmenopausal women were included in the investigation: 142 women with surgical menopause (44,3 ± 5,4 years, menopause duration 3,8 ± 2,4 years); and 61 women with natural menopause (46,2 ± 4,7 years, menopause duration 4,3 ± 2,1 years). All patients underwent general clinical examination, ambulatory blood pressure monitoring (Cardiotens-01, Meditech, Hungary) with circadian profile type evaluation, echocardiographic examination with systolic and diastolic left ventricular function assessment. Statistical methods such as Cruskell-Walles criteria and $\chi 2$ test were used.
Results: The prevalence of hypertension in women with natural and surgical menopause was the same: 45,9% (28 pts) and 42,3% (60 pts), respectively (p>0,05). Postmenopausal women, regardless of the presence of hypertension, have different types of circadian BP profile: 100pts were dippers, 51 pts were over-dippers, 52 pts had no nighttime BP reduction (49 pts were non-dippers and 3 pts were night-peakers). Only 39 postmenopausal women (19,2%) had normal LV geometry; 89 pts (43,8%) demonstrated LV concentric hypertrophy, 57 pts (28,1%) – concentric remodeling and 18 women (8,9%) – eccentric hypertrophy. The frequency of LV concentric hypertrophy in hypertensive postmenopausal women was wider than in normotensive ones: 60,2% (53 pts) vs 31,3% (36 pts), p = 0,005, while normotensive postmenopausal women more often demonstrated LV concentric remodeling (33,9% (39 pts) vs 20,5% (18 pts), p = 0.042) and LV normal geometry (23,5% (27 pts) vs 12,5% (11 pts), p = 0,034). The presence of eccentric hypertrophy was the same in both groups.
Nobody of included postmenopausal women had LV systolic function failure. Presence of LV diastolic function disturbance did not depend on BP level: 56,8% (50 pts) in hypertensive and 59,1% (68 pts) in normotensive women, p = 0,118. Patients with LV concentric hypertrophy had LV diastolic dysfunction in 84,3% cases (75 pts); with LV concentric remodeling – in 52,6% cases (30 pts), with LV eccentric hypertrophy – in 31,6% cases (6 pts), this difference was statistically significant.
Maximum prevalence of LV concentric hypertrophy was registered in the group of over-dippers – 52,9% (27 pts); in non-dippers/night peakers it was 28,8% (15 pts), in dippers – 47% (47 pts), p < 0.05. The frequency of concentric remodeling formation was maximal in non-dippers/night peakers (48.1%, 25 pts), which was significantly greater than the specified index in dippers (15%, 15 pts, p < 0,01) and overdippers (33,4%, 17 pts, p < 0,01).
Conclusions: LV remodeling regularities in postmenopausal women depend on BP level and circadian BP profile type. LV diastolic function evolution for the most part depends on LV remodeling type, but not on arterial hypertension presence.

Background: Orthostatic hypotension (OH) is a sign of autonomic dysfunction and a common comorbidity in patients with heart failure (HF). We aimed to assess relations between orthostatic blood pressure (BP) responses and echocardiographic changes in a series of patients admitted for HF.
Methods: One-hundred-and-forty-nine patients hospitalized for HF (age 74y; 30% women; mean ejection fraction (EF) 40 ± 16%) were examined with conventional echocardiograms and active-standing test. Associations of cardiac remodeling (left and right atrial volume, left ventricular mass) in relation to the difference between supine and standing (after 3 min) systolic/diastolic BP were examined.
Results: In general, systolic and diastolic BP increased by 2 and 1 mmHg respectively on standing. A total of 34 patients (22.8 %; age 77y) met OH criteria. In regression models adjusted for traditional risk factors and EF, decrease in systolic BP upon standing was associated with greater left atrial volume (β=0.062; p = 0.043) and greater left ventricular mass (β=0.081; p = 0.002). No associations were seen for decrease in diastolic BP.
Conclusions: Orthostatic decline in systolic BP among older HF patients is associated with structural cardiac changes, independently of traditional risk factors and HF severity.

Introduction: There is still a discussion about the best echocardiographic parameters of acute right ventricular systolic dysfunction (RVSD) in acute settings.
Aim: To estimate the prevalence and to characterize RVSD by novel ultrasound parameters of RV longitudinal function, morphometric right heart parameters, association with left ventricular (LV) systolic function and brain natriuretic peptide (BNP) level in acute dyspnea patients.
Methods: Prospective study enrolled consecutive patients admitted to the emergency department of two university centers with acute dyspnea due to decompensated heart failure (HF) and other reasons. Data of 323 patients (mean age 68.8 ± 12.7 years, 39.3% women) were analysed. Echocardiography focused on RV parameters was performed during the first 48 hours after admission. TAPSE (tricuspid annular plane systolic excursion), RV S' (velocity of the tricuspid annular systolic motion), FAC (fractional area change), right atrial (RA) area, RV basal diameter, RV strain of 3 and 6 segments were measured. Blood sample for BNP level was taken during the first 4 hours. The RVSD was defined by reduced FAC <35%, or, if FAC was not available, by TAPSE <1.7 cm.
Results: Two thirds of patients were diagnosed with chronic left HF (n = 216, 66.9%), reduced LV ejection fraction (LV EF) <40% was measured in 104 patients (32.2%). More than half of study patients (n = 167, 51.7%) had RVSD. Most of them (68%) had a history of chronic left HF (n = 114, 35.3%), LV EF <40% was found in 69 patients (21.4%). In patients with RVSD probability to have LV EF <40% was 48.5% (p < 0.001), and BNP level >1000 ng/l – 47.78% (p = 0.006).
Conclusion: Right ventricular systolic dysfunction was found in more than half of the patients with acute dyspnea, in two thirds of cases it coincided with chronic left heart failure. Patients with right ventricular systolic dysfunction had significantly dilated right chambers and decreased right ventricular longitudinal function assessed by tissue doppler and deformation imaging.

Very important markers of cardiac dysfunction and predictors of adverse cardiovascular outcome are size and volume of the left atrium (LA).
Objective: To analyze the function of the LA in patients with medically controlled hypertension (HTA) without a history of paroxysmal atrial fibrillation, adults with prehypertension (PHTA) and normotensive healthy controls (NTA).
Subjects and methods: Anteroposterior diameter of LA, maximum and minimum volume of LA (LAVI max, LAVI min.) were quantitated by echocardiography using the biplane area length method on 4-chamber 2D images, and indexed to the body surface area. Left atrial ejection fraction (LAEF) was defined as (LAVI max-LAVI min.) / LAVI max. X 100 in 67 patients with medically controlled arterial hypertension (age 51 ± 9.3), 36 subjects with prehypertension (age 50.6 ± 10.5) and 44 healthy controls (age 53.5 ± 9.8).
Results: There was no difference in the anteroposterior diameter of LA among subjects with PHTA and NTA, both groups differed in relation to the HTA patients (3.2 ± 0.39 vs 3.4 ± 0.27 vs 3.8 ± 0.40, p = 0.110, p <0.001, p <0.001). LAVI max and LAVI min. were significantly higher in HTA patients and PHTA subjects in relation to NTA controls; there was no significant difference between HTA patients and PHTA subjects concerning the LAVI maks, LAVI min. was significantly higher in HTA patients in relation to PHTA subjects (24.7 ± 6.9 vs 28 ± 7.5 vs 40 ± 6.8, p = 0.092, p <0.001, p <0.001; 8.7 ± 2.2 vs 11.3 ± 2.8 vs 17.8 ± 5.2, p = 0.030, p <0.001, p <0.001). HTA patients and PHTA subjects had significantly lower LAEF in relation to NTA controls, LAEF vas significantly lower in HTA patients in relation to PHTA subjects (55.6 ± 7.3 vs 59.8 ± 5.2 vs 64.8 ± 4.4, p = 0.004, p <0.001, p = 0.011). There were no significant differences among groups in LVEF (66.4 ± 3.8 vs. 64.4 ± 9.3 vs. 64.1 ± 8.1, p = 0.523, p = 0.237, p = 0.978).
Conclusion: Our results demonstrate function of the left atrium expressed as EFLP is reduced in patients with arterial hypertension with no history of paroxysmal atrial fibrillation even when the value of TA is medically regulated. Prehypertensive subjects have decreased EF LP in relation to healthy normotensive. LA EF decreased with increasing LA volume.

Iliescu, Bucharest, Romania; *[2]Vanderbilt University, Nashville, United States of America*; *[3]Wroclaw Medical University, Wroclaw, Poland*; *[4]Stony Brook University Medical Center, Stony Brook, United States of America*; *[5]Northwestern University, Chicago, United States of America*

On behalf of: FERIC RO investigators

Background: There is a large body of evidence suggesting that variation from admission to discharge of N-terminal prohormone brain natriuretic peptide

(NTproBNP) levels in patients hospitalised for worsening chronic heart failure (HF) is a predictor of future cardiovascular events.
Purpose: The aim of the present analysis was to characterise in hospital trajectory of NTproBNP and to identify the relationship between in-hospital variation of NTproBNP and short term outcomes.
Methods: FERIC-RO study was designed as a prospective, multicentric, national, observational study which enrolled 138 patients hospitalised for worsening chronic HF. NTproBNP has been collected at admission and discharge in all patients. The patients were divided in three groups, stratified by the change from admission to discharge of NTproBNP during hospitalization: group A characterised by reduction of NTproBNP by ≥30%, group B characterised by reduction of NTproBNP <30% and group C consisting of patients with increased levels of NTproBNP. The study outcomes were 3-month all-cause mortality and HF-rehospitalisation.
Results: The demographic and clinical characteristics of patients stratified by in-hospital variation of NT-pro-BNP are shown in the Table 1. The 3-month all-cause mortality rates were 8.9% vs. 10.1% vs. 13.7% (p = 0.008), while the 3-month HF rehospitalisation rates were 13.7% vs. 16.7% vs. 21.5% (p = 0.021), for group A, B and C, respectively.
Conclusion: The present study suggests that the variation of NTproBNP from admission to discharge is a predictor of 3-months all-cause mortality and HF rehospitalisation rates. This finding could be useful to further stratify the patients and to intensify treatment during early post-discharge phase.

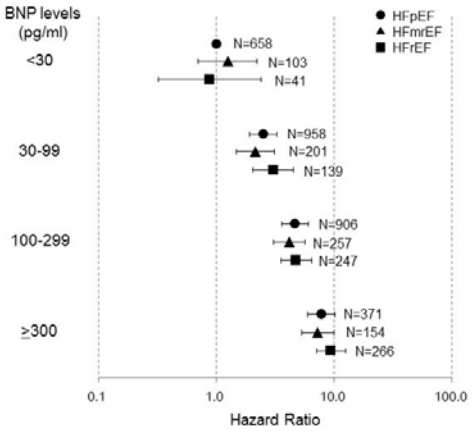
On behalf of: The CHART-2 Study

Background: Although the usefulness of plasma levels of B-type natriuretic peptide (BNP) has been established to estimate the prognosis of patients with heart failure (HF), it remains to be examined whether BNP levels predict the prognosis of HF patients regardless of left ventricular ejection fraction (LVEF). In the past, only one preliminary study showed that, for a given BNP level, the prognosis was comparable between patients with HF with preserved LVEF (HFpEF) and those with HF with reduced LVEF (HFrEF), warranting a further validation study with a large number of patients.
Purpose: To examine the usefulness of plasma BNP levels for long-term risk stratification among HFpEF, HF with mid-range LVEF (HFmrEF), and HFrEF patients.
Methods: The CHART-2 (Chronic Heart Failure Analysis and Registry in the Tohoku District-2) Study is a large-scale prospective observational multicenter cohort study in Japan, in which a total of 10,219 patients with chronic HF or those at high risk for HF were enrolled between 2006 and 2010 and have been prospectively followed up. In the present study, we analyzed the data of 4,301 consecutive Stage C/D HF patients registered in the CHART-2 Study (mean 69 years, male 68%) who were divided into HFpEF (LVEF>50%, N=2,893), HFmrEF (LVEF 40-49%, N=715), and HFrEF (LVEF < 40%, N=693) groups. We performed the Cox proportional hazard models to compare the prognostic impacts of BNP categories among the 3 groups. BNP categories were determined based on the BNP cutoff levels that were indicated to most efficiently discern the mortality risk by the classification and regression trees (CART) analysis.
Results: A total of 1,435 all-cause deaths occurred during the median 6.3-year follow-up. Although median BNP levels were significantly increased from HFpEF to HFmrEF, and then to HFrEF patients (85.3, 127 and 216 pg/ml, respectively, P < 0.001), relationships between log BNP levels and the mortality risk were comparable among the HFpEF, HFmrEF, and HFrEF groups. The CART analysis showed that BNP levels of 28.6, 103, 332 pg/ml were the optimal cut-off levels to discriminate the mortality risk of the patients. Based on these BNP cutoff levels, we divided BNP levels into 4 categories; <30, 30-99, 100-299, and >300 pg/ml. As compared with patients with BNP levels <30 pg/ml in HFpEF (reference), those with BNP levels <30 pg/ml in HFmrEF and HFrEF had comparable mortality risk (hazard ratio (HR) 1.2, P=0.80 and HR 0.87, P=0.45 for HFmrEF and HFrEF, respectively) and those with BNP levels 30-99, 100-299 and >300 pg/ml had comparably increased mortality risks among patients with HFpEF (HR 2.5, 4.7 and 7.8, respectively), HFmrEF (HR 2.1, 4.2 and 7.3, respectively), and HFrEF (HR 3.0, 4.8 and 9.4, respectively) (Figure).
Conclusion: These results indicate that plasma BNP levels have comparable prognostic impacts among patients with HFpEF, HFmrEF and HFrEF.

Figure. Mortality risks among HFpEF, HFmrEF, and HFrEF

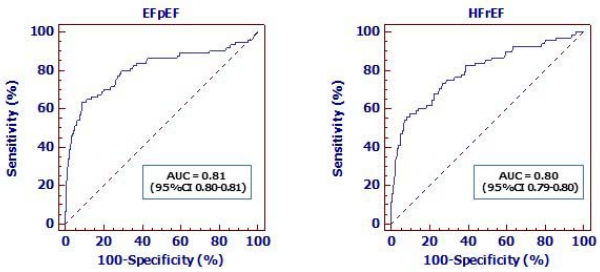


P1895
Plasma B-type natriuretic peptide level is useful to predict incidence for both types of heart failure with and without left ventricular systolic dysfunction in the general population

R Komi[1]; F Tanaka[1]; K Tanno[1]; M Ohsawa[1]; T Onoda[1]; M Ohta[2]; K Ogasawara[1]; A Okayama[3]; M Motoyuki Nakamura[1]
[1]Iwate Medical University, Morioka, Japan; *[2]Iwate Health Service Association, Morioka, Japan*; *[3]Research Institute of Strategy for Prevention, Tokyo, Japan*

On behalf of: Iwate Heart Registry Consortium

Aim: It remains unknown whether the predictive abilities of plasma B-type (BNP) are viable for either heart failure (HF) with preserved ejection fraction (HFpEF) or with reduced ejection fraction (HFrEF) in the general middle-aged and elderly population.
Methods: Participants were recruited from the general population (n = 14,141; mean age=63 years). A Cox regression analysis adjusting for traditional risk factors (age, sex, BMI, hypertension, diabetes, atrial fibrillation, eGFR, smoking) was performed to examine the hazard ratio (HR) of plasma BNP for each type of HF. Moreover, receiver-operating-characteristics (ROC) analysis were used to determine the predictive abilities of plasma BNP for the incidence of two types of HF.
Results: During a median follow-up of 9.0 years, new onset of HF (defined by Framingham criteria) was found in 142 participants (HFpEF, n = 74; HFrEF, n = 68) in the cohort. The HRs for both HF in terms of per one standard deviation (1 SD) increment (as a continuous variable) and values above the 80th percentile (as a categorical variable) of plasma BNP were significantly associated with both types of HF (HFpEF; HR = 3.44 per 1SD, HR = 4.45 at 80th percentile: HFrEF; HR = 7.59 per 1SD, HR = 5.93 at 80th percentile). Moreover, plasm BNP concentration showed optimal predictive abilities for both types of HF (area under curve of ROC analysis: HFpEF= 0.81, HFrEF=0.80) (Figure). In addition, plasma BNP level for the optimal sensitivity and specificity to predict HFpEF or HFpEF was similar (54 pg/ml vs 57 pg/ml).
Conclusion: This study showed that plasma BNP level is a valid predictor for incidence of HF regardless of preserved or reduced left ventricular systolic function in this population.



Area under ROC for HFpEF and HFrEF

P1896

Unbalanced plasma catestatin and norepinephrine predicted adverse outcomes of chronic heart failure

S Songyun Chu[1]; F Peng[1]; L Liu[1]; RX Li[1]; WH Ding[1]
[1]*Peking University First Hospital, Department of Cardiology, Beijing, China People's Republic of*

Background: Catestatin (CST) is a vasopeptide with a broad spectrum of activities in cardiovascular system. The level of plasma CST increased in chronic heart failure patients. And plasma CST increased with NYHA classification escalated with possible protective effect through down-regulation of sympathetic stress. CST might act as a novel biomarker in heart failure. Whether the unbalanced sympathetic status indicated by plasma CST and norepinephrine (NE) related adverse prognosis of heart failure patients, however, is unknown.
Purpose: To investigate the potential predictive ability of ratio of plasma CST and NE on outcomes of heart failure patients.
Methods: We established a chronic heart failure patient cohort of 202 cases who admitted for exacerbation in our center. Plasma CST of these patients was measured with enzyme-linked immune-absorbent assay at admission. After a mean 52.5 months' follow-up, major cardiac adverse events including readmission of heart failure, cardiovascular death and all-cause death were collected. The relationship between ratio of plasma CST and NE level and occurrence of adverse events were analyzed.
Results: There were 117 cases of readmission, 59 cases of all-cause deaths at the end of follow-up, and among them included 49 cases of cardiac deaths. Neither average plasma CST nor NE level was found to have statistical differences between patients with or without readmission. The levels of plasma CST were higher in patients with all-cause death and cardiac death than in survivors (1.06(0.66-1.82) ng/ml vs. 0.75(0.58-1.12) ng/ml, $p = 0.005$ and 1.18(0.69-1.83) ng/ml vs. 0.75(0.58-1.12) ng/ml, $p = 0.002$, respectively). However, there was no significant difference between plasma NE in patients with cardiac or all-cause death and survivors. In univariate Logistic regression, higher plasma CST and NE ratio predicted increased risk of all-cause and cardiac death, the hazard ration (HR) was 1.221 (95% CI, 1.009-1.479, $p = 0.041$) and 1.210 (95% CI, 1.001-1.464, $p = 0.049$), respectively. In multivariate Logistic regression, after adjusted for covariates including age, gender, NYHA function class, eGFR, usage of diuretics, CCB, pulmonary artery pressure, plasma albumin level, CST to NE ratio was not an independent risk factor for cardiac death. For all-cause death, CST to NE ratio was not an independent risk factor, either.
Conclusions: Elevated plasma NE was common in heart failure patients and might indicate for chronic sympathetic activation with little fluctuation. Thus NE alone might not be a good predictor for adverse outcomes. Plasma CST has been known to elevate with the severance of heart failure. And the ratio of CST and NE might be a more sensitive predictor for all-cause and cardiac deaths in heart failure patients and reflect the compensatory mechanisms activated in exacerbation of heart failure. Further studies are needed to understand the effect of CST in heart failure.

Funding Acknowledgements: This study was granted by Roche Diagnostics

Introduction: Originally limited to acute heart failure diagnosis in the emergency room, natriuretic Peptides (NP) are now considered as prognostic markers in various conditions and are recommended to rule out heart failure in patients presenting with acute or chronic dyspnea. In addition they may be helpful to guide therapy of chronic heart failure patients, although not clearly endorsed by guidelines.
Methods: We examined all biological tests performed in two districts from the west part of France, "the French Brittany", covering 13.653km2 and corresponding to a population of 1.723.653 persons. From February 2010 to august 2015, 22 laboratories (including 6 Hospital/clinic laboratories and 16 non hospital/clinics laboratories) performed 3.606.432 analysis prescriptions in 3.606.432 adult patients>20y. All laboratories are equipped with Roche diagnostics platform and measured NT-proBNP as the NP. We report the settings and conditions of NP measurement.
Results: During the study period, 56.653 (1.6%) measurements of NT-proBNP were performed in 27.527 distinct patients; NT-proBNP measurements gradually increased from 9188 in 2011 to 12938 in 2014 ($p < 0.001$).
The same numbers of measurements were done in men versus women (50.0% each), and 39.828 (70.3%) of measurements have been done in elderly patients ≥ 75y. GP ordered >70% of the measurements and 27.0% were performed in hospital/clinics labs, 10.1% in dedicated emergency labs and the remaining 62.9% in non-hospital/clinic labs.
NT-proBNP was re-measured in 10.167 patients (36.9%) after a median of 60 days [IQR 14-217]. Initial NT-proBNP concentration was 1621 ng/L [IQR 560-3926], and the relative variation between the first and second measurement was 1% [95% CI: -29- + 46].
In combination with NT-proBNP, creatinin was measured only 47.680 times (84.2%); other frequently associated dosages were electrolytes (n = 43165), HbA1C (40074), hemogram (23231), and liver enzymes (17195).
Conclusion: Among a very large cohort, we observed a gradual increase of NP measurements over time but NP measurements only accounted for 1.6% of overall analysis prescriptions. The very large majority of NP measurements was performed in elderly patients, was ordered by GP and 16% of measurements were not performed in combination with creatinin. Big data analysis may offer a unique opportunity to improve our knowledge in current practices.

P1898

Association between NT-proBNP and metabolic status in young healthy adults.

A Anna Alexandrova[1]; I Strazhesko[1]; Y Orlova[1]
[1]*M.V. Lomonosov Moscow State University, Moscow, Russian Federation*

Introduction: The B type natriuretic peptide plays an important role in regulating blood pressure, blood volume, and water and salt balance. The association between N-terminal pro-B type natriuretic peptide (NT-proBNP) and metabolic risk factors is still unclear. It has been suggested that obese individuals have reduced natriuretic peptide levels. The prevalence of obesity and other cardiometabolic disturbances among young adults has increased over the past decade. The aim of this study was to investigate the correlation between NT-proBNP and metabolic risk factors in young apparently healthy adults.
Material and methods: We investigated 282 healthy young adults, mean age 18,5 ± 1,7 years, 47% male. NT-proBNP, waist circumference, body mass index (BMI), fasting plasma glucose, insulin resistance (HOMA-IR) and lipid profile were measured.
Results: NT-proBNP level was 58, 61 + 2,39 pg/ml (M + m). Multivariate regression analysis showed a positive association between NT-proBNP levels and fasting plasma glucose ($p = 0.013$), NT-proBNP and high-density lipoprotein ($p = 0.01$). There was no association between NT-proBNP and body mass index, waist circumference, triglyceride, LDL cholesterol, insulin resistance.
Conclusions: Hyperglycemia is a risk factor most closely associated with a damage to cardiac function. It may be the main target in the prevention of cardiovascular diseases in young adults.

P1899

BNP, Galectine-3and ST-2 cut-off values for long term risk assessment in chronic heart failure patients

CS Vella[1]; F Santini[1]; M Oldani[1]; A Villani[1]; G Malfatto[1]; A Faini[1]; E Makil[1]; G Gianfranco Parati[1]
[1]*University of Milano-Bicocca - Cardiology II, S. Luca Hospital, Milano, Italy*

Background: Data on usefulness of Galectine-3 (gal-3) and ST-2 biomarkers in the prognostic evaluation of patients with chronic heart failure (HF) are less than those for natriuretic peptides.
Objective: aim of this study was to assess the plasma levels of BNP, ST-2 and Gal-3 in HF patients referred to our center, and to estimate their prognostic value in relation to cardiovascular mortality over a 20 month follow-up period.
Methods: From March 2014 to July 2016 we assessed BNP, ST-2, Gal-3 in 124 patients with known diagnosis of HF referred to our clinic and receiving optimal treatment according to ESC guidelines. Patients (68% males, 66% ischemic etiology) were 76.0 ± 9.6 years old, with advanced NYHA class (50% III + IV), high rate of CRT/ICD implantation (53%) and reduced FE (<50% in 77% of cases).
Results: During follow-up (12.2 ± 6.8 month, no data censored), 20 patients died for cardiovascular diseases (16%). We used ROC curves to establish optimal cut-off values in terms of sensibility/specificity for each biomarker, i.e. 412ng/L (79%/61%), 39.2ng/L (83%/65%) and 19.7ng/L (85%/66%) for BNP, ST-2 and Gal-3 respectively. By using these cut-off values, we built Kaplan-Meier survival curves ($p < 0.01$ for all, Log-rank test analysis). Through a Cox regression model the estimated Hazard Ratios (HRs) for cardiovascular mortality were 5.24, 8.13 and 10.00 for BNP ≥412 ng/L, ST-2 ≥39.2 ng/L and Gal-3≥19.65 ng/L, respectively (figure).
Conclusions: Our data indicate possible cut-off values of BNP, ST-2 and Gal-3 for the prognostic stratification of patients with chronic heart failure, and suggest the potential role not only of BNP but also of Gal-3 and ST-2 in the management of HF patients. Our results need to be confirmed in the context of longitudinal studies of larger dimensions.

Markers of inflammation are associated with arterial stiffness in young healthy subjects

E Borisov[1]; I Strazhesko[1]; Y Orlova[1]
[1]*M.V. Lomonosov Moscow State University, Moscow, Russian Federation*

Plasma levels of circulating inflammatory molecules, such as high sensitive C-reactive protein (hs-CRP), interleukin-6 (IL-6), fibrinogen (FBG) have been shown to be predictive of future cardiovascular disease (CVD). Chronic inflammation may impair vascular function and lead to an increase of arterial stiffness, an important determinant of cardiovascular risk. The role of arterial stiffness in the development of heart failure was demonstrated recently. There are some studies demonstrated the association between arterial stiffness, measured as increased pulse wave velocity (PWV), increased central blood pressure (BPao), and markers of inflammation in elder people, in subjects with hypertension, rheumatologic diseases. Nowadays there are no enough data about relationship between increased arterial stiffness (early vascular aging) and inflammation in young healthy people.
Material and methods: To explore the relationship between markers of inflammation (hs-CRP, IL-6, FBG) with arterial stiffness, we studied 258 healthy young adults, mean age 18,8 ± 1,6 years, 47% male. PWV and BPao were measured with ambulatory blood pressure monitoring device BPLab Vasotens (BPLab, Russia) and related to plasma levels of inflammatory markers measured by ELISA.
Results: PWV was significantly related to plasma hs-CRP (r=0.14; $P < 0.05$), FBG (r=0.26; $P < 0.001$). There was also a relationship between systolic BPao to hs-CRP (r=0.28; $P < 0.001$), FBG (r=0.25, < 0.001) and diastolic BPao to hs-CRP (r=0.20; $P < 0.001$), FBG (r=0.17, < 0.01). There was no significant association between IL-6 and arterial stiffness. hs-CRP was an independent predictor of PWV and systolic BPao in a multiple stepwise regression model.
Conclusions: Inflammation may be involved in arterial stiffening even in healthy young adults. Anti-inflammatory strategies may, therefore, be of benefit in reducing early vascular aging.

Introduction: The role of Procalcitonin (PCT) and C Reactive Protein (CRP) in Acute Coronary Syndromes (ACS) is not clear. PCT is an inflammatory molecule released both during infections and other acute inflammatory conditions. CRP is a component of the immunitary system, raising in the circulatory system in pathological events (bacterial infections, ischemic events, multiple trauma and major surgery). As atherosclerosis has an inflammatory component, CRP has been considered an important marker and/or factor of atherosclerosis disease.
