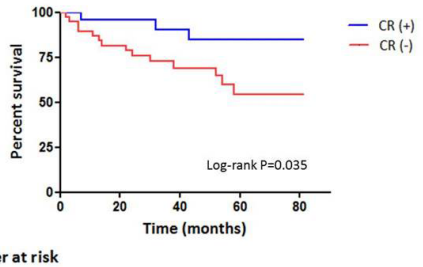
Background: The management of asymptomatic patients with severe aortic regurgitation (AR) and preserved left ventricular (LV) systolic function has remained controversial. We aimed to evaluate the value of exercise stress echocardiography (ESE) in asymptomatic severe AR with preserved LV systolic function as predicting high risk patients who might benefit from early referral for surgery.
Methods: Symptom-limited treadmill ESE was performed in 67 asymptomatic with severe AR (effective regurgitant orifice area >20 mm2, regurgitant volume >30ml), LV end-systolic diameter < 50 mm and preserved LV function (ejection fraction (EF) >50%). Post-exercise EF increase of >4% was defined as contractile reserve (CR). The primary outcome was defined as the composite of development of symptoms, deterioration in LV function (EF < 50%) and aortic valve replacement (AVR) at follow-up. The operation performed within 60 days from ESE was excluded.
Results: CR (+) was noted in 28 and CR (-) in 39 patients. Compared with CR (+), the CR (-) group was older (52.0 ± 14.0 years vs CR 43.8 ± 10.6 years, p = 0.011) and had higher Ln N-terminal natriuretic peptide (NT-proBNP) [CR 5.2 (4.5-5.7) vs CR 4.1 (3.7-5.1), p = 0.001]. Also CR (-) group showed lower exercise time than CR (+) group (576 ± 159 seconds vs 671 ± 108 seconds, p = 0.008). Otherwise, there were no differences in demographics and imaging data between 2 groups according to CR. During follow-up duration of 46 ± 23 months, the primary outcome occurred in 17 (25%) including development of symptoms (n = 9), new onset LV systolic dysfunction (n = 1) and AVR (n = 7). 14 of 17 were CR (-) group. And the survival rate during follow-up was significantly lower in the CR (–) group than in the CR (+) group of asymptomatic severe AR patients (log-rank P = 0.035).
Conclusion: In asymptomatic patients with severe AR and preserved LVEF, the absence of CR in ESE was an independent predictor for deterioration of symptoms or LV systolic function, and suggesting that ESE may be able to further stratify the current guideline for AVR.

Figure. Kaplan-Meier survival curves in asymptomatic severe aortic regurgitation (AR) patients according to the presence of contractile reserve (CR).



Number at risk

CR (-)	39	30	22	11	0
CR (+)	28	22	13	7	0

Left ventricular global longitudinal strain as a predictor of left ventricular reverse remodelling after surgical aortic valve replacement

P Zafirovska[1]; I Milev[1]; L Georgievska Ismail[2]; N Hristov[1]; RA Rosalia[3]; Z Mitrev[1]
[1]*Zan Mitrev Clinic, Cardiosurgery, Skopje, Macedonia The Former Yugoslav Republic of*; [2]*University Clinic of Cardiology, Skopje, Macedonia The Former Yugoslav Republic of*; [3]*Zan Mitrev Clinic, Clinical Research, Skopje, Macedonia The Former Yugoslav Republic of*

Introduction: In aortic stenosis (AS) the left ventricular ejection fraction (LVEF) is commonly used as an indicator of disease severity and the necessity for surgical aortic valve replacement (SAVR). However, impaired LVEF (< 50%) only identifies advanced disease. Thus, more sensitive, cardiac parameters that could identify severe AS at an earlier stage would improve clinical decision making and prognosis.
Purpose: To evaluate left ventricular (LV) global longitudinal strain (GLS) as an independent parameter to assess SAVR procedural success and to determine its pre-operative prognostic significance regarding LV reverse remodelling after surgery.
Methods: We performed detailed pre- and postoperative 2D echocardiography using Philips EPIQ 7, in 30 patients (65.47 ± 10.55 years; 56.7 % males) that underwent SAVR, including evaluation of GLS with speckle tracking. The mean follow-up period was 4.9 ± 0.73 months.
Results: All patients were symptomatic with an LVEF of 59.33 ± 10.74%. The mean pre-operative aortic valve area index (AVAi), LVmass index (LVMi) and GLS were 0.41 ± 0.10 cm^2/m^2, 256.2 ± 81.7 g/m^2 and -16.05 ± 4.23%, respectively. The mean GLS improved to -18.82 ± 3.46% ($p < 0.01$) after surgery which coincided with an increased mean AVAi, 1.72 ± 0.68 cm^2/m^2 ($p < 0.01$) and decreased mean LVMi of 135.1 ± 36.4 g/m^2 ($p < 0.01$). In contrast, mean post-operative LVEF only slightly increased to 63.30 ± 6.61% ($p = 0.022$). Pre-operative GLS showed a positive correlation with the post-operative LVMi ($r^2 = 0.35$, $p < 0.01$), diastolic septal thickness (IVSd) ($r^2 = 0.33$, $p < 0.01$) and GLS ($r^2 = 0.35$, $p < 0.01$).
Applying a cut-off value of -18.9%, in the patients with better pre-operative GLS (>-18.9%) we observed a significant improvement of postoperative LVMi, IVSd and GLS values (Fig. 1) suggesting better LV reverse remodelling compared to patients with a pre-operative GLS of >-18.9.
Conclusion: The GLS of the LV is abnormal in severe AS patients and precedes LVEF deterioration. SAVR improves the LV GLS implicating an improvement of the subclinical systolic dysfunction. Better preoperative GLS values are associated with more successful LV reverse remodelling after surgery.

Prediction of mortality after Transcatheter Aortic Valve Implantation: A comparison of Logistic EuroSCORE, EuroSCORE-II and STS score

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; JM Garcia-Pinilla[1]; AJ Dominguez-Franco[1]; F Carrasco-Chinchilla[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; E De Teresa-Galvan[1]
[1]*University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

Transcatheter aortic valve implantation (TAVI) is an established treatment alternative to surgical aortic valve replacement in high-risk and inoperable in patients with severe and symptomatic aortic stenosis. In addition, in recent years, it has been proposed in patients with intermediate or low risk, whose results are unknown yet. The aim of this study was to analyze the surgical risk of patients treated with TAVI and to evaluate clinical outcomes in according to risk scores.
Methods: Between April-2008 and December-2016, 582 patients with severe and symptomatic aortic stenosis were treated with TAVI. The surgical risk estimation was analyzed through Logistic EuroSCORE, EuroSCORE-II and STS score, and were categorized into low, intermediate and high risk.
Results: In according to logistic EuroSCORE and STS score, 29.5% and 21.3% were high surgical risk, intermediate 40.1% and 61.4% and low 30.4 and 21.3, respectively.
In-hospital and late mortality higher for patients at high surgical risk according into logistic EuroSCORE (2.3% in low risk vs. 1.7% intermediate vs. 7% in high, p = 0.017 and 22.15 vs. 33.3% vs. 45.3%, p = 0.001, respectively. However, there were no significant differences for in-hospital mortality among the different groups according to STS score (5% vs. 2.2% vs. 5.6%, p = 0.667) and for late mortality (25.3% vs. 29.5% vs. 51.3%, p = 0.001). The logistic EuroSCORE and EuroSCORE-II presented an acceptable capacity for in-hospital mortality, the area under the curve was 0.652 (95% CI 0.510-0.795), p = 0.02 and 0.646 (95% CI 0.518-0.774), p = 0.026, respectively. However, STS score did not presented discriminant ability, the area under the curve was 0.560 (95% CI 0.410-0.710), p = 0.365.
Conclusions: In our series, patients categorized into high surgical risk were associated with increase mortality at 30 days. Logistic EurtoSCORE and EuroSCORE-II presented discriminatory power

Long-term outcomes after transcatheter aortic valve replacement in high-risk patients with severe aortic stenosis.

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; F Carrasco-Chinchilla[1]; JM Garcia-Pinilla[1]; AJ Dominguez-Franco[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; E De Teresa-Galvan[1]
[1]*University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

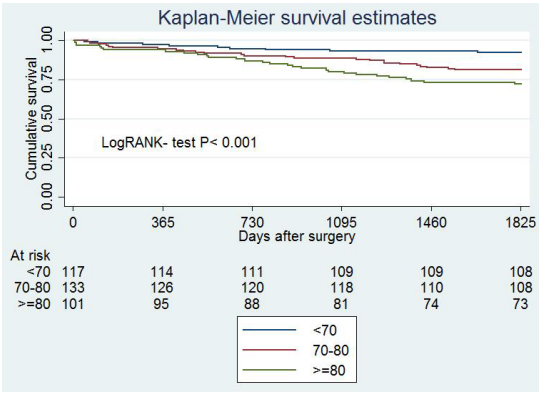
Transcatheter Aortic valve Replacement (TAVR) has emerged as an alternative to surgical aortic valve replacement for patients considered at high or prohibitive operative risk. It is widely known the short and mid-term outcomes, however, is limited about long-term outcomes. The aim of this study was to determine the survival and the factors predicting mortality after TAVR with the CoreValve prosthesis.
Methods: From April 2008 to December 2017, the CoreValve prosthesis was implanted in 620 patients with symptomatic severe aortic stenosis with deemed high risk.
Results: The mean age was 79.5 ± 6.8 years. The logistic EuroSCORE and STS score were 17.4 ± 11% and 6.01 ± 4%, respectively. The implantation success rate was 98.87%. In-hospital mortality was 3.7%, and the combined endpoint of death, vascular complications, myocardial infarction or stroke had a rate of 15.5%. The late mortality (beyond 30 days) was 33.9%. Survival at 1, 2, 3, 4, 5, 6 and 7 years were 89.2%, 82.3%, 70.8%, 62.1%, 54%, 47% and 41.9% respectively, after a mean follow-up of 41.4 ± 27 months. The NYHA functional class improved from 3.1 ± 0.6 to 1.77 ± 0.7 in the follow-up. The predictors of cumulative mortality were: Charlson index [HR 1.18 (95% CI 1.09-1.28), p = 0.001], Acute Kidney Injury [HR 1.83 (95% CI 1.29-2.57), p = 0.001], Frailty [HR 1.67 (95% CI 1.17-2.14), p = 0.001], Left ventricular ejection fraction [HR 1.011 (95% CI 1.051-01.874), p= 0,027], COPD [HR 1.4 (95% CI 1.05-1.87), p= 0,022] and protective factor was a higher Karnosfky index [HR 0.992 (95% CI 0.983-0.998) p= 0.048].
Conclusions: TAVR is associated with significant survival benefit throughout 2.99 years of follow-up. Survival during follow-up depends particularly among patients with associated comorbidities and left ventricular ejection fraction

P1896

Age-dependent morbidity and mortality outcomes after surgical aortic valve replacement

Al Amjad Hussain[1]; AA Auensen[1]; CB Brunborg[1]; LG Gullestad[1]; KIP Pettersen[1]
[1]*Oslo University Hospital, Cardiology, Oslo, Norway*

Objectives: Surgical aortic valve replacement is commonly avoided in patients over 80 years old based on assumptions of increased morbidity and strenuous rehabilitation. To examine the validity of these assumptions, we analyzed predefined outcomes in age-based cohorts of patients who underwent open heart surgery.



Age-dependent survival after SAVR

Methods: This study prospectively enrolled 351 consecutive patients referred for aortic valve replacement. Patients were assessed preoperatively and one year after surgery for symptoms, physical function (6 min. walk test; 6MWT), mental status (mini mental status examination; MMSE), quality of life (QoL; SF36), and adverse events (AEs). Five-year all-cause mortality data was recorded.
Results: One-, three-, and five-year survival rates were 94%, 80%, and 72% in the oldest group, and did not significantly differ from the middle age group (logRANK, P = .10) but were slightly lower than patients < 70y. Symptom score, NYHA class and QoL improved in all groups, while 6MWT and MMSE score declined in patients >80 y. After surgery, length of index stay and readmission rate were similar among the three groups The incidence of delirium and infections was higher in the oldest group, whereas the risks of new pacemaker, TIA/Stroke, myocardial infarction and heart failure were the same across age groups.
Conclusions: Surgical AVR shows comparable prognostic importance in patients of >80 years old versus 70-79 years old. The oldest age group had a significant improvement in symptoms and QoL after surgery, but experienced slightly more delirium and infections post operatively. Active respiratory mobilization and IUC removal might prevent adverse events, and measures to prevent delirium and confusion after surgery should be considered in elderly patients.

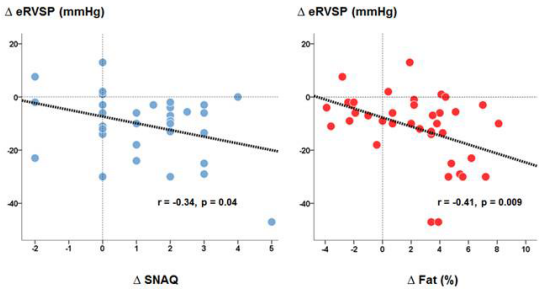
P1897

Changes of body composition after valve surgery in patients with mitral valve disease

KSA Kim[1]; HJW Ha[2]
[1]Hallym University Sacred Heart Hospital, Anyang-Si, Gyeonggi-Do, Korea Republic of; *[2]Yonsei University College of Medicine, Cardiology Division, Seoul, Korea Republic of*

Funding Acknowledgements: a Korea Science and EngineeringFoundation (KOSEF) grant

Background: Patients with chronic heart failure have alteration in body composition as a reduction in fat mass, lean body mass and bone mass. However, body wasting in valvular heart disease and the impact of corrective valvular surgery on body composition has not been investigated.
Purpose: We hypothesized that body wasting in severe mitral valve (MV) diseases is reversible through MV surgery.
Methods: Forty eight patients who were scheduled to undergo MV surgery were consecutively enrolled after excluding patients with combined valvular heart disease, ischemic heart disease, cardiomyopathies, and diseases or who were taking medications that could affect metabolism. All patients were subjected to simplified nutritional assessment questionnaire (SNAQ) for appetite, laboratory tests, echocardiography, and dual-energy X-ray absorptiometrybefore and one year after MV surgery.
Results: One year after MV surgery, the patients showed increased appetite and improved laboratory data as well as hemodynamic improvement. Bone mineral density and body fat percentage were significantly increased, and lean body mass was decreased, despite no changes were observed in body weight. Patients with ?fat = 2% showed significantly higher pre-operative estimated right ventricular systolic pressure (eRVSP) level and greater decrease in eRVSP after surgery than patients with ?fat < 2%. Also, both ?SNAQ and ?fat showed significant negative relationship with ?eRVSP.
Conclusion: In patients with severe MV disease, corrective MV surgery led to favorable outcomes in wasting process as well as hemodynamic improvement. Particularly, right ventricular pressure overload showed a close association with the changes in appetite and body fat percentage



Relationship of ?SNAQ and ?fat with RVSP

P1898

Prognostic impact of pulmonary diseases in the results of transcatheter aortic valve implantation

PM Paulo Maia Araujo[1]; M Braga[1]; S Torres[1]; A Nunes[1]; R Pinto[1]; J Rodrigues[1]; RA Rodrigues[1]; PB Almeida[1]; MB Campelo[1]; JC Silva[1]; MJ Maciel[1]
[1]Sao Joao Hospital, Cardiology, Porto, Portugal

Introduction: Transcatheter aortic valve implantation (TAVI) is an effective treatment for patients (pts) with symptomatic severe aortic stenosis, considered at high surgical risk. Pulmonary disease (PD) is frequent in these pts and can have a post procedural impact on morbi/mortality.
Purpose: To evaluate the impact of PD in complications, mortality, functional capacity and improvement of symptoms after TAVI.
Methods: Retrospective analysis of pts submitted to TAVI in a tertiary care center (October 2014 to December 2016). Clinical, laboratorial and spirometric data were evaluated. All pts had symptomatic severe aortic stenosis prior to the procedure and the decision for referral for TAVI was made by a multidisciplinary Heart Team. PD was defined as the presence of a previous diagnosis of obstructive (COPD, asthma) and/or restrictive pulmonary disease or a significant airway obstruction/restriction in spirometry.
Results: A total of 89 pts were submitted to TAVI during the referred time period. The mean age was 80.2 ± 7.1 years and 51.7% (n = 46) were female. Seventeen pts (19.1%) had PD and in 35.3% of these, PD was the main reason for referral to TAVI, instead of surgery. PD was classified (according to the Chronic Lung Disease classification in the STS score) as: mild in 64.7%, moderate in 23.5% and severe in 11.8%. Baseline NYHA class was similar between patients with/without PD: II - 52.9% vs 59.7% ; III - 47.1% vs 37.5%; IV - 0% vs 2.8% (p = 0.64). The mean EuroSCORE II was significantly higher in pts without PD (6.2% vs 3.5%; p = 0.05), but the mean age was similar (PD - 77.3 y; no PD - 80.9 y; p = 0.48).
During hospitalization, the median stay was similar (PD - 15.2 vs no PD - 14.4 days; p= 0.94). The incidence of complications was tendentially higher in pts without PD (70.8% vs 47.1%), although not significant (p = 0.06). Only one patient had in-hospital mortality (no PD).
At 6-month after discharge, mean BNP was similar between groups (PD: 351 vs no PD: 395 pg/ml; p = 0.67), but LVEF was significantly higher in pts with PD (64% vs 51%; p = 0.05).
At the end of a mean follow-up time of 386 ± 93 days after discharge, PD pts referred significantly lower rates of functional capacity improvement (50.0% vs 87.5%; p < 0.01) and higher rates of NYHA class = 2 (85.7% vs 29.7%; p < 0.01).
Hospitalizations were tendentially higher in PD pts (47.1% vs 24.3%), although not significant (p = 0.06). Cardiovascular mortality and all-causes mortality were similar (PD: 0% vs no PD: 4.3%, p = 0.39; PD: 11.8% vs no PD: 5.7%, p = 0.38).
Conclusion: Pts with PD have similar results in morbi-mortality during hospitalization and in mortality during follow-up. However, one year after the procedure, the PD group has a higher proportion of pts remaining symptomatic and with less improvement in functional capacity. Therefore, in this population, PD has a negative prognostic impact on morbidity after TAVI.

P1899

Clinical characteristics and intermediate term outcomes post mitral valve Clip for high-risk patients with more than moderate mitral regurgitation: single center experience in Saudi Arabia

AA Elasfar[1]; HA Naeim[1]; OA Amoudi[1]; L Khedr[2]; I Alharbi[1]; R Abuelatta[1]
[1]Madina Cardiac Center, Madina, Saudi Arabia; *[2]Tanta University Hospital, Adult Cardiology, Tanta, Egypt*

Background: The current evidence suggests that the primary role for Mitral Valve Clip is to treat symptomatic moderately severe and severe mitral regurgitation (MR) in patients who are either unsuitable or at high risk for MV surgery.
Objectives: We sought to report the clinical characteristics and the one year outcome of high risk patients undergoing percutaneous mitral valve clip.
Methods: This study is a retrospective cohort study for all patients who underwent percutaneous mitral valve clip in our center between June 2013 and October 2016 and who have completed at least one year of follow-up. Symptomatic patients with grades 3 to 4 MR and a high surgical mortality risk, based on the consensus opinion of heart team meeting involving cardiac surgeons, expert interventional cardiologists and echocardiographers were enrolled for percutaneous mitral valve clip.
Results: 62 patients had percutaneous mitral valve clip and completed at least 12 months of follow-up. The average age was 60.56 years, 24.19 were females, 50% were diabetic, 46.77 were hypertensive, 12.90 had ESRD and 11.29 % had anemia. Coronary artery disease (CAD) was present in 59.41 %, prior CABG in 11.67 and prior PCI in 35.48. Technically, the procedure was successful in 96.77 % of cases, 24.19 % had 2 clips and 11.29 had 3 clips. The average EF fraction of the left ventricle was 25% and all patients had at least 3/4 MR. regarding the outcome after 1 year of follow-up; the readmission rate was 25.8% and the mortality rate was 14.5%.
Conclusion: The readmission and mortality rates post mitral valve clip insertion for symptomatic high risk patients with at least moderate severe MR were lower than the internationally published data but the average age of our patients was 10 years younger. Further studies on larger number of patients are needed to confirm the long term outcome after mitral valve clip.

P1900

Impact of paravalvular regurgitation in morbimortality of patients undergoing transcatheter aortic valve implantation

A Alzira Nunes[1]; S Torres[1]; M Braga[1]; P Maia Araujo[1]; J Rodrigues[1]; R Pinto[1]; R Andre Rodrigues[1]; P Bernardo Almeida[1]; D Magalhaes[1]; M Belchior Campelo[1]; J Carlos Silva[1]; M Julia Maciel[1]
[1]Sao Joao Hospital, Cardiology Service, Porto, Portugal

Introduction: Transcatheter aortic valve implantation (TAVI) has emerged as an alternative therapeutic intervention with superior hemodynamic performance for patients with severe, symptomatic aortic stenosis who are at high risk for surgical aortic valve replacement (SAVR). Nevertheless, there are some concerns regarding safety aspects of the procedure such as paravalvular regurgitation (PVR). Although the incidence of significant PVR has declined dramatically with the advent of newer-generation prosthetic valves, mild PVR remains common and its clinical impact has been inconsistent.
Purpose: To assess the impact of PVR after TAVI on morbimortality during hospitalization and follow-up.
Methods: We retrospectively evaluated patients (pts) who were submitted to TAVI in a tertiary care center between October 2014 and December 2016. PVR was assessed at the end of the procedure with aortography. Clinical and laboratorial data were evaluated.
Results: A total of 89 pts, of whom 51.7% (n = 46) were female, with a mean age of 80.2 ± 7.1 years, were included. All pts had symptomatic severe aortic stenosis prior to TAVI. The median EuroSCORE II was 4,5% (0.8-25.9). The implanted valves were: CoreValve Evolut – 67 pts (75.3%), CoreValve - 16 pts (18%), CoreValve Portico - 3 pts (3.4%) and LOTUS Edge Valve System - 3 pts (3.4%). The vascular access was: femoral - 84 pts (94.4%); transaortic - 2 pts (2.2%) and subclavian - 3pts (3.4%). Postprocedural PVR was present in 46 pts (51.7%), mostly of mild degree (44 pts), moderate degree in 2 pts and severe in none. There was a tendency for higher incidence of PVR in the CoreValve Portico valves (100%) comparing to the remaining: CoreValve - 62.5%; CoreValve Evolute - 47.8%; Lotus Valve - 33.3% (p = 0.22). The incidence of PVR was not significantly different between the vascular accesses: femoral - 51.2%; transaortic - 50%; subclavian - 66.7% (p = 0.87). Comparing pts with and without PVR, the mean of length of stay (13 vs 15 days; p = 0.56) and the incidence of complications (65.2% vs 67.5%; p = 0.82) were similar. Only one patient had in-hospital mortality (no PVR). One year after discharge, pts with or without PVR had similar: rates of NYHA class = II (36.6% vs 43.2%; p = 0.5), hospitalizations for cardiovascular (CV) causes (15.2% vs 12.2%; p = 0.68) and CV mortality (4.3% vs 2.4%; p = 0.63). Conclusion: Our study did not show an increase in morbimortality associated with PVR after TAVI. However, we believe that every effort should be made in order to reduce the incidence of this clinical problem.

Background: Iron is indispensable for the maintenance of optimal cellular functioning and stands at the crossroads of the cellular processes such as energy metabolism and inflammation. This issue could be of a particular importance in the context of myocarditis, where the main cells involved in the pathophysiology are cardiomyocytes and cardiofibroblasts, and their functioning is particularly sensitive to changes in iron status.
Purpose: We assessed the expression of genes responsible for intracellular iron metabolism and malfunctioning of cultured human cardiomyocytes (HCMs) and cardiofibroblasts (HCFs) exposed to sera from patients with acute phase of myocarditis and after 6 weeks, compared with healthy controls. We also related their expression with the clinical profile of patients.
Methods: In HCMs and HCFs cultured with sera from patients for 48 hours, we analyzed expression of genes involved in iron metabolism (ferritin heavy chain [FTH], ferritin light chain [FTL] and transferrin receptor 1 [TfR1]) and myocardium malfunctioning (matrix metalloprotease 1 [MMP1], transforming growth factor beta-1 [TGFB1], galectin-3 [LGALS3]) at the mRNA level using qPCR. Iron status of patients was defined by serum iron and serum ferritin.
Results: HCFs exposed to sera from patients in an acute phase of myocarditis compared to those treated with sera from healthy controls, displayed an increased expression of TfR1 ($p < 0.01$), indicating intracellular iron depletion. HCFs exhibited augmented expression of FTH ($p < 0.01$), FTL ($p < 0.05$) as well as upregulated expression of MMP1 ($p < 0.05$), suggesting increased proremodeling potential. Higher expression of TfR1 was associated with increased expression of MMP1 ($R = 0.74$, $p < 0.01$).
HCMs cultured with acute phase sera also exhibited increased expression of TfR1 ($p < 0.05$) , as compared with cells treated with sera from healthy controls. HCMs displayed upregulated expression of TGFB1 ($p < 0.05$) and LGALS3 ($p < 0.05$), also suggesting cardiomyocyte hypertrophy and cell malfunctioning. Further, an upregulation of LGALS3 in HCMs was also strongly associated with TfR1 upregulation ($R= 0,89$; $p < 0.0001$).
When compared with iron profile of patients, increased expressions of TfR1 and LGALS3 in HCMs were associated with serum ferritin level ($R = 0.96$ and $R = 0.89$, respectively; $p < 0.05$). In HCFs, serum iron level was associated with augmented expression of TfR1 ($R= -0.86$; $p < 0,05$) and FTL ($R=-0.83$; $p < 0,05$).
When exposed to sera collected after 6 weeks, both cell lines exhibited a decrease of TfR1 expression ($p < 0.01$ for HCFs, $p < 0.001$ for HCMs), as compared with those cultured with acute-phase sera. Expression of MMP1 ($p < 0.05$), FTH ($p < 0.01$) and FTL ($p < 0.01$) in HCFs also decreased after 6 weeks showing a similar pattern, that their increase was characteristic for acute phase of myocarditis.
Conclusions: The results suggest that iron homeostasis may be associated with malfunctioning of cardiomyocytes and cardiofibroblasts in acute myocarditis.

P1902

The significance of computed tomography with late contrast enhancement in diagnosis of myocarditis and prognosis in dilated cardiomyopathy syndrome

I Indira Alieva[1]; O Blagova[1]; N Gagarina[1]; A Nedostup[1]; E Kogan[1]; V Sulimov[1]; S Ternovoy[1]
[1]*I.M.Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Background: A generally accepted method of noninvasive diagnosis of myocarditis is an MRI, but it is contraindicated in patients with implanted devices and does not assess the coronary arteries. In the same time the possibilities multidetector computed tomography (MDCT) in diagnosis myocarditis in comparison with myocardial biopsy never previously studied.
Purpose: to study the significance of cardiac MDCT in diagnosis of the myocarditis in patients with dilated cardiomyopathy (DCM) syndrome in comparison with myocardial biopsy and its prognostic value.
Methods: 127 patients (92 male, 46.9 ± 11.8 years) with DCM syndrome (LVEDD 6.6 ± 0.8 cm, LVEF 29.7 ± 9.5%) were included. All of them were undergone 320-slices MDCT with an assessment of the late contrast enhancement (LCE), measurement of viral genome, anti-heart antibodies, Echo-CG and MRI (n = 21). MDCT data were compared with the results of coronary angiography in 48 patients. Fifty myocardial biopsies were performed (30 endomyocardial biopsies, 7 intraoperative biopsies, 9 autopsies, 4 examination of explanted hearts). Comparison group included 18 patients with coronary heart disease without DCM (LVEDD 4.7 ± 0.5 cm, LVEF 59.3 ± 4.9%). The mean follow-up was 12 [2; 32] months.
Results: the myocarditis was diagnosed using complex investigation in 81 (63.8%) patients, its combination with genetic DCM in 19 (15.0%) patients, using the morphological study - in 70.0% and 14.0% of patients. Low contrast enhancement was found in 4 patients (type 1). LCE was detected in 72 patients: 12 - subendocardial (type 2), 4 - intramyocardial (type 3), 44 - subepicardial (type 4), 12 - transmural (type 5); 51 patients had no LCE (type 0). There was no LCE in comparison group. Sensitivity and specificity of all types of LCE for diagnosis of the myocarditis were 64.0% and 82.2%, positive and negative predictive value 88.9% and 50.7%, in comparison with biopsy results - 68.2%, 91.7%, 93.8% and 61.1% respectively. MDCT identified also noncompact myocardium (n = 29, 22.8%), coronary atherosclerosis (n = 33, 26.0%), which was confirmed by coronary angiography in 16 patients. LCE correlated with: 1) diagnostic signs: disease duration, acute onset, its association with infection (r=-0.185, 0.196 and 0.332), morphologic signs of myocarditis (r = 0,320, type 3-5); 2) functional signs: NYHA class (r = 0.183), VTI (r=-0.304), 3) mortality (r = 0.176), $p < 0.05$. The mortality in LCE-positive patients was significantly higher than in LCE-negative (19.4% vs 9.1%, $p < 0.05$; RR 1.37 95% CI 0.99-1.89).
Conclusions: MDCT with an assessment of LCE can be used in diagnosis of myocarditis in patients with DCM syndrome, including those with contraindications to MRI. The diagnostic value of MDCT in diagnosis of myocarditis versus the morphological study of the myocardium quite high and comparable to MRI possibilities. The LCE in the myocardium correlated with the presence of myocarditis, the degree of functional disorders and prognosis.

P1903

Mechanical unloading as a novel treatment option for chronic inflammatory cardiomyopathy

C Tschoepe[1]; S Sophie Van Linthout[2]; O Klein[2]; T Mairinger[3]; E Potapov[4]; B Pieske[1]; F Spillmann[1]
[1]*Charité - Universitätsmedizin Berlin, Campus Virchow-Klinikum (CVK) Kardiologie, Berlin, Germany*; [2]*Berlin-Brandenburg Center for Regenerative Therapies, Berlin, Germany*; [3]*Helios Klinikum, Pathologie, Berlin, Germany*; [4]*Deutsches Herzzentrum Berlin, Berlin, Germany*

Background: Short-term mechanical circulatory support is an appropriate method to stabilize patients in shock including those with acute fulminant myocarditis (M) by unloading. Mechanical cues, involving integrins, are major drivers of cardiac fibroblast activation leading to increased production of extracellular matrix.
Aim: We aimed to investigate whether unloading via a percutaneously implanted left ventricle (LV) assist device (Impella-pump system) over 4 weeks is a strategy to improve heart failure due to chronic inflammatory cardiomyopathy.
Methods and Results: An Impella was implanted in a patient with severe M and pre-cardiogenic shock despite immunosuppression. Endomyocardial biopsies (EMB) were taken over time. Impella implantation led to an improvement in LV-EF (from 15 to 53%) and a reduction in NT-pro-BNP levels (from 8700 to 690 pg/ml). During unloading, cardiac immune cell presence decreased, paralleled by a 2.0-fold, 2.0-fold, 3.9-fold, and 6.6-fold drop in a1, a5, a6, and a10 integrin EMB mRNA expression, respectively, an effect, which was abrogated after removal of the pump. Imaging mass spectrometry further revealed a change in total protein muster including the modulation in extracellular matrix production as shown by a decrease in collagen a-2VI and vimentin expression during unloading.
Conclusion: Prolonged unloading with an Impella device offers a circulatory support with additional disease modifying effects important for bridge to recovery in patients with fulminant M.

P1904

Plasma exchange for patients with inflammatory dilated cardiomyopathy

V Viktoriia Kulikova[1]; AV Nedostup[1]; OV Blagova[1]; VA Zajdenov[2]; AG Kupriyanova[3]; IA Nechaev[1]; AA Ragimov[1]
[1]*I.M. Sechenov First Moscow State Medical University, Department of Internal medicine, Moscow, Russian Federation*; [2]*Institute of Transplantology and Artificial Organs, Moscow, Russian Federation*; [3]*Research Clinical Institute of pediatrics, Moscow, Russian Federation*

Purpose: We report the clinical efficiency of plasma exchange (PE) in patients with inflammatory dilated cardiomyopathy (iDCM). It was used either with immunosuppression drugs or without them.
Methods: fourteen patients with iDCM (13 male, mean age 44.8 ± 11.5 years, left ventricular end-diastolic diameter (LVEDD) 6.3 ± 0.6 cm, left ventricular end-diastolic volume (LVEDV) 182.7 ± 33.5 ml, left ventricular ejection fraction (LVEF) 33.5 ± 8.1%, NYHA functional class 2 [1;3]) underwent a single volume PE filled with 0.9% sodium chloride. All the patients had a high level of at least two auto-antibodies (AABs) directed against cardiac nuclear antigens, endothelial, cardiomyocytes, conduction and smooth muscle cells. Patients underwent evaluation including heart CT scan (n = 11), MRI (n = 3), endomyocardial biopsy (EMB) (n = 5), myocardial perfusion scan (n = 4), and coronary angiography (n = 3) to diagnose myocarditis. Clinical and echocardiographic parameters were assessed at baseline a 4.9 ± 2.1 and 13.2 ± 1.9 month follow-up. We also evaluated a 6-minute walk test (6MWT) distance at baseline just after PE and a 6.6 ± 1.5 and 14.3 ± 2.6 month follow-up. AABs level was assessed at baseline a 5.1 ± 1.9 and 12.5 ± 1.0 month follow-up. All patients were required to be under stable oral medication with maximal tolerated dose of ß-blockers/ angiotensin-converting enzyme inhibitor/ aldosterone antagonists at least 3 month before PE. Four iDCM patients were treated by immunosuppressive drugs (hydroxychloroquine, azathioprine or methylprednisolone) before PE. Seven patients got it after PE. The mean dose of methylprednisolone was 8 [8; 17.25] mg per day.
Results: AABs level significantly decreased just after PE and during the follow-up ($p < 0.05$). Patients had significant improvement in LVEF (33.5 ± 8.1% vs. 41.4 ± 8.2% at first follow up, $p < 0.05$, and 46.3 ± 12.7% at second one, $p>0.05$), LVEDD (6.3 ± 0.6 vs. 6.1 ± 0.6 cm and 6.1 ± 0.7 cm, $p < 0.05$), left atrial volume (102.8 ± 40.6 vs. 84.3 ± 25.1 ml, $p < 0.05$, and 98.0 ± 30.8 ml, $p>0.05$), and 6MWT distance (434.2 ± 55.9 vs. 458.0 ± 44.3 m just after PE, 526.0 ± 69.6 m and 502.0 ± 61.8 at first and second follow-up respectively, $p < 0.05$). Seven patients with absolute LVEF improvement >10% were classified as responders. iDCM non-responder patients were characterized by lower systolic pulmonary artery pressure (correlation ratio 0.68, $p < 0.05$). One of them underwent heart transplantation.
Conclusions: PE improves both cardiac function and daily activities in patients with iDCM due to myocarditis. A positive response is observed in 50% of iDCM patients. PE helps avoid using high doses of immunosuppressive medications.

P1905

Prognostic value of global longitudinal deformation in determining the risk of progression of heart failure in the cohort of belarusian patients with hypertrophic cardiomyopathy

S Komissarova[1]; E Zakharava[1]; T Sevruk[1]; I Ustinova[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Background: An algorithm for assessing the risk of sudden cardiac death (SCD) was developed in the latest ESC Guidelines -2014, but there are no recommendations for assessing the risk of other severe complications for hypertrophic cardiomyopathy(HCM), such as the progression of chronic heart failure(CHF). The purpose of our study is to assess the prognostic value of global longitudinal contractility, as a predictor of adverse outcomes associated with the progression of CHF in a cohort of patients with HCM.
Methods: 124 patients with HCM (82 male and 42 female) aged 16 to 79 years (median 48 years) were examined. In addition to the traditional echocardiographic study, all patients underwent 2 D speckle-tracking echocardiography, according to which the global longitudinal strain (GLS) was determined. The main clinical endpoints in this study included mortality associated with CHF and hospitalization for progression of CHF.
Results: Among 124 patients, 17 (12.9%) had symptoms of CHF NYHA class III-IV at initial examination. Progression of CHF symptoms to NYHA FC III-IV in 24 (19.4%) patients with HCM occurred with a preserved systolic function (LVEF> 50%) and only 7 (5.6%) patients had systolic dysfunction (LVEF <50%). During the follow-up period (median follow-up of 3 years), the following adverse outcomes were recorded

in 23(18.5%) of 124 patients with HCMC: SCD developed in 4 patients, SCD with successful resuscitation and ICD implantation in 3 patients, lethal outcome due to progression of CHF up to the "end stage" - in 2 patients, hospitalization due to the progression of CHF symptoms to III-IV NYHA class- 14. Regression analysis was performed to determine the predictors of adverse outcomes associated with CHF mortality and hospitalization due to the progression of CHF. Due to the small number of SCD-related events, the risk of adverse outcomes associated with SCD was not analyzed. Multifactor analysis showed that the following characteristics were independent risk factors for the lethal outcome and hospitalization from the progression of CHF: decrease in global longitudinal deformation <10.5% (RR 0.75, 95% CI 0.62-0.89, p = 0.0015), an increase in the left atrial volume index> 35.1 ml /m2 (RR 1.03, 95% CI 1.00 - 1.06, p = 0.019). The cumulative 3-year probability of developing an adverse event is 7.6 (7.5-7.7)%.
Conclusion: The global longitudinal strain is associated with the development of adverse events associated with the progression of CHF in HCM and can be used to identify patients with a high risk of developing CHF progression and an unfavorable outcome.

P1906
Clinical-pathological profiles responsible for advanced heart failure, heart transplantation, left ventricular assist device implantation and death for heart failure in Hypertrophic cardiomyopathy

G Galati[1]; A Di Lenarda[2]; A Margonato[1]
[1]*San Raffaele Hospital and Scientific Institute (IRCCS), Heart Failure Unit and Division of Cardiology, Cardiothoracic and vascular Department, Milan, Italy*; [2]*Cardiovascular Center A.S.S. 1 of Trieste, Cardiovascular Department, Trieste, Italy*

Background: Over the last 50 years, advanced heart failure (AdvHF) in hypertrophic cardiomyopathy (HCM) was overlooked. Neither large case series nor clinical trials on this topic have been reported. The main clinical-pathological profiles responsible for AdvHF in HCM are: 1) End-stage HCM (ES-HCM) defined by an ejection fraction (EF) = 50%; 2) Left-Ventricular outflow obstruction despite optimal pharmacological and not pharmacological therapy (Refractory HOCM); 3) Nonobstructive HCM with preserved EF (HNOCMpEF).
Purpose: Based on a systematic revision of all published manuscripts on this topic, this study describes the prevalence of the three main HCM phenotypes responsible for AdvHF, heart transplantation (HTx), left-ventricular assist device (LVAD) implantation and death for heart failure (HF) despite the contemporary management of HCM.

Table 1

	Adv HF (= 205)	HTx/LVAD implantation/ HF-Death (= 119)	HTx/LVAD implantation (= 68)	HF-Death (= 51)
ES-HCM	133 (64.9%)	89 (74.8%)	49 (72.1%)	40 (78.5%)
Refractory HOCM	11 (5.4%)	1 (0.8%)	0 (0%)	1 (1.9%)
HNOCMpEF	61 (29.7%)	29 (24.4%)	19 (27.9%)	10 (19.6%)

Methods: The study screened 120 manuscripts in MEDLINE and EMBASE on HCM cases of AdvHF and HTx published since 2000 until December 2017, in adult patients (= 18 years old). The authors identified 8 manuscripts eligible for the analysis, 4 of whom where excluded for incomplete information before HTx. 205 patients with AdvHF due to HCM, despite optimal therapy, were included in the main analysis. AdvHF was defined by severe NYHA symptoms (class III and IV), because in all the manuscripts this definition was used. Minimum reported follow-up was 6.1 years.
Results: Table 1 shows the prevalence of phenotypes responsible for AdvHF/HTx/LVAD implantation/HF-Death. Of 205 HCM patients, 119 (58%) underwent HTx, LVAD implantation or died for HF.
Conclusion: AdvHF in HCM has a poor prognosis. With the current management of HOCM only a very little percentage of these patient experiences AdvHF. Less than 1/3 of HNOCMpEF patients had AdvHF due to restrictive physiology and less than 1/4 of these patients had a poor prognosis. Nowadays, ES-HCM represents the main cause of AdvHF in HCM and the major determinant for poor outcome. Although it has been managed with HTx or LVAD implantation, a significant percentage (78.5%) died for HF. This reflect poor attention and portrays an unmet need for ES-HCM patients. These findings reinforce the emphasis on long-term surveillance of HCM patient in order to timely identify patients at risk of ES evolution and early start the standard HF therapeutic (pharmacological and non-pharmacological) armamentarium

P1907
Does hypertension influence prognosis of hypertrophic cardiomyopathy?

D-G Dae-Gyun Park[1]; W-W Seo[1]; S-E Kim[1]; J-H Lee[1]; K-R Han[1]; D-J Oh[1]
[1]*Hallym University Kangdong Sacred Heart Hospital, Seoul, Korea Republic of*

Backgrounds: Any cardiac or systemic condition increasing left ventricular pressure, for instance, hypertension or aortic stenosis, was excluded from diagnosis of hypertrophic cardiomyopathy by strict definition in the past. However, patients with hypertrophic cardiomyopathy might be accompanied by hypertension over the course because hypertension is so prevalent disease or risk factor in real world.
Purpose: We investigated whether hypertension would give an additional effect on the prognosis of hypertrophic cardiomyopathy. Method: We enrolled 102 patients with hypertrophic cardiomyopathy based on the definition of 2014 ESC guideline except for apical hypertrophy from 1997 to 2015. Patients were divided into hypertensive (H) group and normotensive (N) group. We compared the echocardiographic findings and mortality rates between two groups.
Result: Among 102 patients, there were 53 hypertensive patients (52%) and 49 normotensive patients. Median follow up period was 5.8 years. The mean age of each group was 67.1 ± 12.5 (H) vs. 55.3 ± 15.1 (N) years (P < 0.01). The mean systolic blood pressure of was 129.7 ± 27.0 (H) vs. 126.0 ± 22.6 (N) mmHg (P = 0.51). The mean septal wall thickness of left ventricle was 19.2 ± 3.6 (H) vs. 18.9 ± 3.6 (N) mm (P = 0.66). And the mean posterior wall thickness of left ventricle in each group was 12.1 ± 1.9 (H) vs. 11.2 ± 2.3 (N) mm (P = 0.04). Mortality rate in each group was 41.5% (H) vs. 18.3% (N) (P = 0.01). Hypertensive group showed higher mortality rate and thicker posterior wall thickness than normotensive group, but there was no statistical significance on multivariate analysis. On univariate analysis, old age, female, hypertension, posterior wall thickness and left ventricular mass index were associated with all-causes mortality. Logistic regression analysis revealed that only old age was independently associated with all-causes mortality.
Conclusion: In our study, hypertension did not show statistical influence on all-causes mortality in patients with hypertrophic cardiomyopathy. But, there are some trends in thickening of left ventricular wall and all-causes mortality associated with hypertension.

P1908
Comparison of echocardiographic parameters in patients with obstructive and non-obstructive hypertrophic cardiomyopathy

T-H Tomas Honek[1]; J-K Jan Krejci[1]; J-M Jan Machal[2]; L-G Ladislav Groch[1]; J-S Jan Sitar[1]; J-M Jaroslav Meluzin[1]; L-S Lenka Spinarova[1]
[1]*St. Anne's University Hospital, Department of cardiovascular diseases, Brno, Czech Republic*; [2]*Masaryk University, Department of pathophysiology, Brno, Czech Republic*

Introduction: Hypertrophic cardiomyopathy (HCM) is characterized by thickening of left ventricular walls in the absence of provoking hemodynamic causes. Based on the presence of intraventricular obstruction, we can distinguish obstructive and non-obstructive type of HCM. According to presence and seriousness of symptomatology we can choose one of therapeutic approaches, conservative (lifestyle changes and pharmacological therapy) or invasive, especially alcohol septal ablation (ASA).
Objectives and methodology: The study objective was to compare the development of echocardioagraphic parameters and functional status in one-year, three-years and five-years period in patients with HCM. The set of patients was divided into three groups; the first group consisted of patients with non-obstructive type of HCM (n = 38), the second group with presence of significant obstruction treated conservatively (n = 45) and the third group with obstructive type of HCM treated with ASA (n = 38).
Results: In the non-obstructive HCM group, a significant change in left ventricular outflow tract gradient (LVOTG) or New York Heart Association (NYHA) class did not occur during the follow-up (p = NS). In the obstructive group of patients treated conservatively, LVOTG decreased from 64.4 ± 54.7 mmHg to 51.4 ± 47.5 mmHg in the first year (p = NS), to 45.1 ± 40.1 mmHg in the third year (p < 0.05), and to 60.5 ± 67.4 mmHg in the fifth year (p = NS), respectively. NYHA class remained stationary for all periods (p = NS). In the obstructive group of patients treated with ASA, LVOTG decreased from 76.5 ± 51.2 mmHg to 24.6 ± 18.4 mmHg in the first year, to 23.1 ± 21.3 mmHg in the third year, and to 37.4 ± 48.3 mmHg in the fifth year (all p < 0.001), respectively. Similarly, the improvement in NYHA class was observed (all p < 0.01).
Conclusion: The presence of intraventricular obstruction is one of the most important indicators determining progress and development of this disease. The LVOTG decline after ASA defined the difference in the development of other echocardiographic parameters between both conservatively treated groups (non-obstructive

and obstructive) with the ASA group, and led to the improvement or stabilisation of left ventricular morphology. Likewise, it was observed the improvement in functional status after ASA.

P1909

Predictors of survival in recent-onset idiopathic dilated cardiomyopathy: effect of dose of discharge beta blocker on left ventricular ejection fraction

D-G Park[1]; W-W Seo[1]; S-E Kim[1]; J-H Lee[1]; K-R Han[1]; D-J Oh[1]
[1]*Hallym University Kangdong Sacred Heart Hospital, Seoul, Korea Republic of*

Background: Left ventricular systolic function in more than one-third of patients with recent-onset dilated cardiomyopathy (DCM) recovered in short-term follow-up.
Purpose: We sought to determine clinical or echocardiographic predictors for recovery of left ventricular ejection fraction (LVEF) and all-cause mortality in recent-onset idiopathic DCM. And, we evaluate whether dose of therapeutic drugs such as beta blocker (BB) or angiotensin-converting enzyme inhibitor (ACEI) might affect clinical outcomes.
Methods: We enrolled consecutively 114 patients with firstly diagnosed idiopathic DCM. Exclusion criteria were, as follows, valvular heart disease, acute coronary syndrome, known ischemic heart disease, stress cardiomyopathy or tachycardia-induced cardiomyopathy. We evaluated clinical factors, including comorbidity; laboratory findings, including cardiac enzymes, B-type natriuretic peptide and C-reactive protein; serial electrocardiographic data; echocardiographic parameters at admission and follow-up. At discharge, BB, ACEI or angiotensin receptor blocker (ARB) was recorded, and standardized with carvedilol (25 mg /day) or ramipril equivalents (5 mg/day), and analyzed for predictor of outcomes such as change of LVEF and all-cause mortality.
Results: 51% of all patients demonstrated at least an increase of 8 ejection fraction units with median follow-up of 2.6 years, and 39% of all patients showed an LVEF of = 0.45. At discharge, 67% of all patients were receiving a BB and 95% were receiving ACEI or ARB. In multivariate analysis, absence of complete left bundle branch block (p = 0.022) and high dose of BB (p = 0.007; = 25-mg carvedilol equivalent) were significantly associated with an improvement of LVEF (10% increase of baseline LVEF) during follow-up examinations. On Kaplan-Meir survival curve, with median follow-up of 5 years, cumulative survival rate of improvement group is 96% and 86% at 1 and 3 years, respectively; compared with non-improvement group, 86%, 75% (p = 0.028). In multivariate analyses, lower follow-up LVEF (p = 0.032, hazards ratio = 0.95) and lower body mass index (p= 0.034, hazards ratio = 0.85) were independently related to all-cause mortality.
Conclusions: In our study, half of patients with recent-onset idiopathic DCM showed significant improvement of LVEF during follow-up. Recommended high-dose of BB at discharge was independently associated with an improvement of LVEF which was related to better survival rate. Thus, early recommended high-dose of BB might have a favorable effect on better survival for patients with recent-onset dilated DCM through inducing improvement of LVEF.

P1910

Early changes in echocardiographic parameters predict prognosis in patients with recent onset dilated cardiomyopathy

J Krejci[1]; P Hude[1]; E Ozabalova[1]; H Poloczkova[1]; D Mlejnek[1]; V Zampachova[1]; I Svobodova[1]; K Benesova[2]; J Jarkovsky[2]; L Spinarova[1]
[1]*St. Anne's University Hospital, Masaryk University, Brno, Czech Republic*;
[2]*Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic*

Funding Acknowledgements: Supported by Ministry of Health of the Czech Republic Grant No 16-30537A

Introduction: Prognostic stratification in patients with recent onset dilated cardiomyopathy (RODC) is essential for the timing of additional therapeutic steps, including the implantation of ICD (with or without cardiac resynchronization function), mechanical circulatory support or heart transplantation.
Purpose: To evaluate the significance of the early changes in echocardiographic parameters on the presence of combined mortality-morbidity endpoint in 5-year follow-up.
Patients and Methods: We assessed 212 RODCM patients with left ventricular ejection fraction (LVEF) 24.1 ± 7.1% at the time of diagnosis, mean age 46.9 ± 11.6 years, NYHA class 2.3 ± 0.6 and symptoms duration at baseline control 2.6 ± 2.5 months. An early changes in echocardiographic parameters were defined as the difference between baseline and 3-month examinations. Combined mortality-morbidity endpoint was defined as the presence of death, resuscitation for cardiac arrest, appropriate ICD discharge, heart transplantation or implantation of mechanical circulatory support and unscheduled hospitalization or outpatient visit for cardiovascular reason.
Results: A 10% percent increase in LVEF was associated with reduced incidence of defined endpoint (HR 0.579; p < 0.001), increase in left ventricular enddiastolic diameter by 10mm nearly doubled the incidence of the endpoint (HR 1.923; p = 0.022), similarly 10mm higher left atrial diameter worsened the prognosis (HR 1.926; p = 0.014). On the contrary, the increase in systolic and diastolic mitral annular velocities decreased the incidence of the endpoint (HR 0.811; p = 0.023 and HR 0.859; p = 0.028). Changes in right ventricular diameter and function or E/e'ratio did not change the prognosis.
Conclusion: Early changes in some echocardiographic parameters may help in the risk stratification of patients with RODCM.

P1911

Effect of Ivabradine on left ventricular functional recovery in patients with dilated cardiomyopathy

J Y Jae Yeong Cho[1]; K H Kim[1]; H Park[1]; H J Yoon[1]; K H Lee[1]; D S Sim[1]; N S Yoon[1]; Y J Hong[1]; H W Park[1]; J H Kim[1]; Y Ahn[1]; M H Jeong[1]; J G Cho[1]; J C Park[1]
[1]*Chonnam National University Hospital, Cardiology, Gwangju, Korea Republic of*

Background: Previous studies have shown that ivabradine has a favorable impact on LV reverse remodeling in heart failure with reduced ejection fraction (HFrEF). Left ventricular functional recovery (LVFR) is not uncommon in dilated cardiomyopathy (DCM), but there is lack of data regarding the effect of ivabradine on LVFR of DCM in real clinical practice.
Purpose: Therefore, the aim of this study was to investigate the impact of ivabradine added to conventional HF management on LVFR in patients with DCM.
Methods: Among 335 hospitalized patients with DCM and acute decompensated HF (ADHF), a total of 268 patients who had echocardiography studies at admission and 6 months of follow up were enrolled and divided into two groups; ivabradine group (n = 64, 57.7 ± 16.3 years, 54 males) vs. non-ivabradine group (n = 204, 65.8 ± 14.6 years, 161 males). LVFR was defined as LVEF = 50% at follow-up echocardiography. Baseline characteristics, echocardiographic findings and laboratory findings were compared between two groups.
Results: Baseline clinical characteristics, laboratory, and echocardiographic findings were not different between the groups except for age (ivabradine group vs. non-ivabradine group; 57.7 ± 16.3 vs. 65.8 ± 14.6 years, p < 0.0001). Prescribed medications for HF also were not different. On follow up echocardiography at 6 months, LV function was recovered in 83 patients (31.0%). Diabetes, level of N-terminal pro-B type natriuretic peptide at 3-month follow-up, and LV end-systolic dimension were independent predictors of LVFR in patients with DCM, but the use of ivabradine was not a predictor of LVFR [19 LVFR (29.7%) in ivabradine group vs. 64 LVFR (31.4%) in non-ivabradine group, p = 0.799].
Conclusion: LVFR was not uncommon in DCM (31.0%) and Diabetes, level of N-terminal pro-B type natriuretic peptide at 3-month follow-up, and LV end-systolic dimension were independent predictors of LVFR. However, the use of ivabradine fails to demonstrate additional favorable effects on LVFR in Korean patients with DCM.

P1912

Mutation spectrum of 10 sarcomeric genes in Russian patients with dilated cardiomyopathy

A Bukaeva[1]; M Polyak[1]; N Kotlukova[2]; Y Frolova[1]; S Dzemeshkevich[1]; E Zaklyazminskaya[1]
[1]*Russian Research Center of Surgery, Moscow, Russian Federation*; [2]*Pirogov Russian National Research Medical University , Moscow, Russian Federation*

Funding Acknowledgements: This work was supported by Russian Science Foundation grant ? 16-15-10421

Background: Dilated cardiomyopathy (DCM) is the leading cause of heart failure, with prevalence up to 1:2500. DCM is characterized by high mortality rate and clinical and genetic heterogeneity. To date, more than 50 genes are reported to be responsible for DCM, and sarcomere genes are reported to have the highest rate of mutations found in this cohort of patients.
Purpose: to estimate the prevalence of mutations in sarcomeric genes in Russian DCM patients.
Methods. The cohort of patients included a total of 53 probands with diagnosed DCM, 20 of them were children before age of 18 y.o. (15 boys and 5 girls) and 33 were adult patients (M:F ratio is 20:13). All patients underwent high-throughput semiconductor sequencing using targeted oligoprimer panel flanking the coding area of MYBPC3, TAZ, TPM1, LDB3, MYL2, ACTC1, MYL3, MYH7, TNNI3, and TNNT2 genes. All potentially significant findings and undercovered areas were re-analyzed by direct Sanger sequencing.
Results: We have revealed 13 pathogenic and/or likely pathogenic genetic variants in 12 probands (22% of whole DCM cohort). Eleven patients were heterozygous carriers, and 1 patient had a combination of two heterozygous variants.
In pediatric group we have revealed 6 clinically significant findings in 6 probands (30%), 3 of them were in the MYH7 gene, 1 in the MYBPC3 gene, 1 in the TPM1 and 1 in the TNNT2 gene. Three of these variants were predicted to be deleterious by in

silico analysis: c.5655+5G>C and p.Q1029P in the MYH7 gene, and p.T721I in the MYBPC3 gene. Three other findings (p.E1799K in the MYH7 gene, p.R173Q in the TNNT2 gene, and p.D230N in the TPM1 gene) were previously published mutations associated with dilated cardiomyopathy.
In adult cohort we have detected 7 mutations in 6 (18%) probands. Five of them were found in the MYH7 gene: four are missense changes, and one is non-frameshift deletion (c.5754_5756delCAA in MYH7). One adult male patient carried two changes in the MYH7 gene: an undescribed, in silico predicted damaging, substitution p.V1360D in addition to the known mutation p.P151L. MYH7 gene in our cohort also harbors p.G181R and p.Q419K rare mutations. We have discovered two new variants in the MYBPC3 gene (p.V563A and p.A1632T).
Conclusion. We note that the rate of mutations in 10 sarcomeric proteins were about 20%, what is lower than expected. Further study is needed to prove this mutations rate in Russian DCM patients.

P1913

Frequency and predictors of thromboembolic events in patients with left ventricular noncompaction

NV Varionchik[1]; OV Blagova[1]; EV Pavlenko[1]; AV Nedostup[1]; VP Sedov[1]; NV Gagarina[1]; EA Mershina[2]; VE Sinitsyn[2]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; *[2]Roszdrav Medical Rehabilitation Center, Moscow, Russian Federation*

Background: Left ventricular noncompaction (LVNC) is associated with high risk for heart failure, arrhythmias, thromboembolism, and sudden cardiac death.
Purpose: This study is sought to investigate the frequency and the predictors of thromboembolic events in patients with LVNC.
Methods: A total of 107 patients with LVNC were included (male, 59%); mean age, 45.4 ± 14.9 years, (18-78 years old). In 25 cases 3 visualizing methods were used to diagnose LVNC, in 76 cases - 2 different methods. The mean LV ejection fraction was 38.5 ± 14.4%, LV end-diastolic diameter was 6.0 ± 0.8cm, left atrium (LA) volume was 94.3 ± 37.8ml. Echocardiography (n = 107), computed tomography (n = 84), MRI (n = 41), coronary angiography (n = 28) were performed. The median follow-up was 13 months [3.5; 36.0], from 1 month up to 10 years. The data were analyzed in SPSS21. P values of <0.05 were considered statistically significant.
Results: 14 patients (13.1%) were diagnosed with intracardiac thrombosis; 4 other patients had a previous history of it. Thrombi location involved LA, including auricle, both left and right ventricle. Embolic events occurred in 8.4% patients (n = 9): 6 suffered ischemic stroke, 3 - peripheral embolism (renal artery - 1, ophthalmic artery - 1, embolic myocardial infarction verified at the autopsy together with ischemic stroke - 1). Several other cases of myocardial infarction are also likely to be of embolic etiology. Altogether intracardiac thrombosis and/or embolic events occurred in 20.6% patients (n = 22). LV dilation, systolic and diastolic dysfunction were significantly more frequent in patients with thromboembolic events. They had significantly higher NYHA functional class (class 3 [1.75; 3.0] v class 2 [1.0; 3.0], p <0,05; AUC 0.717), greater LV end-diastolic volume (174.2 ± 55.7ml v 144.1 ± 65.0, p <0.05 AUC 0.663), greater LA volume (116.7 ± 32.5ml v 88.1 ± 37.0ml, p <0.01; AUC 0.834), ?/? ratio (2.4 [2.25; 3.05] v 1.3 [0.9; 1.7], p <0.001; AUC 0.827), lower LV EF (31.4 ± 11.3% v 40.3 ± 14.6%, p <0.05) compared with patients without thromboembolic events. Moreover, they more frequent suffered with microvascular ischemia in the absence of coronary atherosclorosis (36.3% v 15.3%, p <0.05). There was no significant difference in atrial fibrillation (AF) between groups. This was due to early anticoagulant treatment in the presence of AF. Twenty patients were administered antithrombotic therapy: 17 received anticoagulants (warfarin - 13, rivaroxaban - 3 dabigatran - 1); 3 patients received aspirin. In 95% of cases (n = 21) thromboembolic events occurred before anticoagulant prescription.
Conclusion: Thromboembolic events are typical for LVNC. In our group of 107 patients their frequency is 20.6%. Our data demonstrate that LA volume = 90 ml, ?/? = 2.0, LV end-diastolic volume = 130.0 ml, NYHA functional class = 3, and microvascular ischemia should be considered additional indications for anticoagulant treatment in patients with LVNC, besides atrial fibrillation and low LV EF.

P1914

Intramyocardial inflammation correlates with poor prognosis in patients with cardiac AL amyloidosis

F Felicitas Escher[1]; CS Siegismund[2]; DL Lassner[2]; MG Gross[2]; RL Linke[3]; HPS Schultheiss[2]
[1]Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; *[2]Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany*; *[3]amYmed, Reference Center of Amyloid Diseases, Martinsried, Germany*

Aims: To evaluate the influence of endomyocardial biopsy (EMB)-proven intramyocardial inflammation on mortality in patients with cardiac transthyretin amyloid (ATTR) or amyloid light-chain (AL) amyloidosis.

Methods and Results: We included 54 consecutive patients (age mean ± SD, 68.83 ± 9.59 years; 45 men) with biopsy-proven cardiac amyloidosis. We followed up patients from first diagnostic biopsy to as long as 36 months (mean ± SD, 11.5 ± 12) and compared their outcome with information on the all-cause mortality with or without proof of inflammation in EMB. Intramyocardial inflammation was assessed by quantitative immunohistology.
Patients suffering from amyloidosis revealed a significant poor prognosis with proof of intramyocardial inflammation in contrast to those without inflammation (log-rank p = 0.036). A patient's regrouping indicated AL amyloidosis to have a significant impact on the all-cause mortality (log-rank p = 0.012). A multivariate analysis confirmed intramyocardial inflammation and AL amyloidosis as causative parameters of increased mortality. The detailed subgroup analysis showed that patients suffering from AL amyloidosis with intramyocardial inflammation have a significantly worse prognosis in comparison to AL amyloidosis without inflammation and ATTR with or without inflammation, respectively (log-rank p = 0.014, contingency Fisher's exact p = 0.008).
Conclusion: Our study reports for the first time a high incidence (48.1%) of intramyocardial inflammation in a series of patients with cardiac amyloidosis underlying EMB and could show that in patients with AL cardiac amyloidosis, intramyocardial inflammation correlated significantly with increased mortality. Our data have a direct clinical impact because one can hypothesize that additional immunomodulating / anti-inflammatory treatment regimens in patients with biopsy-proven inflammation of heart muscle tissue could be beneficial for patients suffering from cardiac AL amyloidosis.

P1915

Clinical characterization of Takotsubo-syndrome in 84 consecutive patients over 6 years

M Noutsias[1]; F Muehleck[2]; N El-Danasouri[2]
[1]University Clinic Halle (Saale), Mid-German Heart Center, Department of Internal Medicine III (KIM-III), Division of Cardiology, Halle, Germany; *[2]University Hospital of Jena, Jena, Germany*

Background: The pathogenesis of Takotsubo-syndrome (TTS), as well as its diverse clinical presentations, are incompletely understood.
Purpose: Clinical characterization of TTS patients, and of a possible association between the different wall motion abnormality types (TTS-WMAT) with clinical parameters.
Results: We evaluated n = 84 consecutive TTS patients (age: 71.5+12.0 years; females: 79%), as confirmed by left ventricular (LV) angiography (LVEF: 46.9+14.1%) and exclusion of relevant coronary artery disease by acute coronary angiography, being admitted to our tertiary center from 04/2009 until 01/2017 (26% prospective patient evaluation). The majority of patients (69%) presented an apical TTS-WMAT, followed by the midventricular (MV) TTS-WMAT (24%), while the remaining focal (5%) and the basal (2%) TTS-WMAT were infrequent. An acute infection was diagnosed in 24% of the TTS-patients as possible physical stress situation, while an acute emotional stress situation was present in 44% of the patients. The LV enddiastolic pressure (LVEDP) was 26.5+11.9 mmHg. N = 2 patients had been admitted after cardiopulmonary resuscitation, and 14% of the patients had a cardiogenic shock being treated with catecholamines on admission. 52% of the patients had coronary artery disease with stenosis grade >50% at least in one coronary artery, however, no indication for percutaneous coronary intervention was confirmed in any of these patients. The mean Troponin I levels on admission were elevated (1.3+2.0 µg/l), as well as the mean BNP (769.2+1,388.9 pg/l), and the mean CRP (48.6+71.9 mg/l). The statistical analysis of apical or MV TTS-WMAT with various clinical parameters revealed significant associations with age (apical: 74.0+10.5 versus MV: 66.9+10.7 years) and LVEDP (apical: 29.0+11.4 versus MV: 21.4+10.1 mmHg). No significant associations were confirmed among others with type of ECG alterations (i.e. ST-elevations, ST-depression, T-wave inversions), physical or emotional stress, LVEF, cardiogenic shock, Troponin I, BNP and CRP. The 6-months-mortality was 6%, and 1 female patient had a fatal outcome after her third recurrence of TTS (apical TTS-WMAT).
Conclusions: Our data on consecutive 84 TTS patients in our tertiary center confirm that the majority are females (79%) at advanced age, and 93% present with the leading apical, followed by the MV-TTS-WMAT, while the basal and focal TTS-WMAT are infrequent (< 10%). The percentage of cardiogenic shock on admission is considerable in TTS patients (ca. 14%), as well as its short-term mortality (6%). The significant association of lower age and lower LVEDP with the MV- compared with the apical TTS-WMAT might provide clues for a better understanding of the diverse clinical phenotypes of TTS.

P1916

Persistent subclinical myocardial dysfunction after aortic coarctation correction

H Helena Nascimento[1]; M Braga[1]; V Ribeiro[1]; C Sousa[1]; F Macedo[1]; C Cruz[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Background: Aortic coarctation (CoA) adult population is growing, because of major improvements in both diagnostic and therapeutic approaches. However, even after a successful repair, hypertension and left ventricular (LV) myocardial dysfunction may still occur. The aim of our study was to assess the role of 2-D speckle tracking echocardiography (STE) in the early detection of subclinical myocardial dysfunction in patients with CoA repaired.
Material and Methods: This study was based on a retrospective analysis of adult patients (pts) with the diagnosis of repaired CoA, followed-up in a Grown-up Congenital Heart Disease Centre. Patients with significant concomitant lesions (except for bicuspid aortic valve without stenosis) and clinical LV systolic dysfunction were ruled out. Epidemiologic and clinical data were collected and inserted in a registry base. Transthoracic echocardiograms were reviewed in order to assess global longitudinal strain (GLS) using 2-DSTE (Echopac Software, GE). The data were compared with those obtained from14 healthy subjects (7 male;median age 31 years-old, interquartile range: 25-50).
Results: From the twenty-one pts with repaired CoA studied, 12 were women and median age was 35 years-old (interquartile range: 31-40). Bicuspid aortic valve was present in 5 patients (23.8%). Surgical repair was performed in 16 pts (76.2%): resection with subclavian artery flap aortoplasty (7); head-to-head anastomosis (1) and woven Dacron patch (1). Median age at correction was 6 years-old (interquartile range: 3-21). The remaining 5 pts (23.8%) were submitted to percutaneous intervention. Twelve of these patients were controlled hypertensive (57.1%). All pts were in sinus rhythm and LV hypertrophy was observed in 2 (9.5%). Comparing to the healthy controls, CoA pts group presented superior LV wall thickness (ventricular septum: 8.9 ± 1.4 vs. 7.6 ± 1.7mm, $p = 0.033$; posterior wall: 8.5 ± 1.7 vs. 7.3 ± 1.2, $p = 0.026$). Regarding the diastolic function parameters the E/e' is significantly higher in the CoA pts (7.9 ± 1.8 vs. 5.5 ± 1.4, $p = 0.04$). Despite the absence of differences in LV ejection fraction, CoA pts presented a significantly reduced LVGLS (-16.2 ± 4.2 vs. -18.6 ± 1.7, $p = 0.043$). There was no significant correlation between LVGLS and current systolic blood pressure or age of CoA repair.
Conclusion: In spite of a low percentage of LV hypertrophy, significant reduction of GLS was found, consistent with persistent subclinical myocardial dysfunction even long after correction of the defect. Although the significant prevalence of hypertension in these pts, this factor did not appear to play a significant role.

Pulmonary Circulation, Pulmonary Embolism, Right Heart Failure – Clinical

The effect of obstructive sleep apnea on in hospital outcomes of patients with acute pulmonary embolism

M Mario Rodriguez[1]; W Rzechorzek[1]; B Sabharwal[1]; X Wei[1]; A Manguba[1]; C Krittanawong[1]; C Godoy Rivas[2]; E Herzog[1]; J Puma[3]
[1]*Icahn School Of Medicine at Mount Sinai/ Mount Sinai St. Lukes-West Hospital, Department of Medicine, Division of Cardiology , New York, United States of America*; [2]*Cleveland Clinic Foundation, Cleveland, United States of America*; [3]*Columbia University Medical Center, New York, United States of America*

Background: Obstructive sleep apnea(OSA) has been found to be a risk factor for development of pulmonary embolism. Nevertheless, data reporting the in hospital outcomes of patients with obstructive sleep apnea that are admitted with acute pulmonary embolism is limited. There is some data suggesting decreased mortality in patients with OSA and acute myocardial infarction and we might be facing a new paradox in cardiovascular disease.
Purpose: describe the inhospital outcomes of patients with obstructive sleep apnea admitted for pulmonary embolism.
Methods: A retrospective analysis using the 2014 United States Nationwide Inpatient Sample was done. Patients above the age of 18 years with a primary diagnosis of acute pulmonary embolism were included. Patients with secondary diagnosis of pulmonary embolism (surgical) were excluded. Primary outcome was in-hospital mortality. Secondary outcomes included length of stay, cost of stay, shock, use of mechanical ventilation, acute kidney injury, acute kidney injury requiring dialysis(AKID), use of non-invasive ventilation(NIV), cardiac arrest, rate of heparin induced thrombocytopenia, rate of transfusion, rate of inferior vena cava filter use, use of thrombolysis and thrombectomy. Multivariate logistic regression analysis was performed adjusting for obesity, age, race, gender and hospital location using STATA IC 15.
Results: 33,927 patients with primary diagnosis of PE were identified of which 16,275 had a secondary diagnosis of OSA. 42% were female and mean age was 60 years. There was decreased odds of mortality (OR 0.72 $p = 0.03$) along with decreased rates of hemorrhage requiring transfusion(OR 0.68 $p = 0.001$) and cardiac arrest (OR 0.63 $p = 0.02$) in patients with OSA compared to those without. There was also an increased NIV utilization (OR 5.1 $P < 0.001$) along with increased length of stay. A non statiscally significant decreased odds of obstructive shock (OR 0.61 $p = 0.22$), invasive mechanical ventilation (OR 0.85 $p = 0.20$), AKID (OR 0.78 $p = 0.694$), rate of heparin induced thrombocytopenia (OR 0.48 $p = 0.10$), thrombectomy (OR 0.65 $p = 0.42$) and inferior vena cava filter placement (OR 0.92 $p = 0.3$) was also found.
Conclusions: Patients with OSA and pulmonary embolism showed decreased odds of mortality, cardiac arrest and transfusion needs, but an increased NIV utilization and length of stay after adjustment for obesity on multivariate regression analysis. A possible OSA paradox in cardiovascular disease that warrants further studies might be in front of us.

P1918

Acute pulmonary thromboembolism, a manifestation of oncologic disease to be diagnosed?

L Luisa Malvar Goncalves[1]; HUGO Antunes[1]; LUÍS Abreu[1]; JULIO Pereira[1]; INÊS Pires[1]; DAVIDE Moreira[1]; INÊS Almeida[1]; BRUNO Rodrigues[2]; COSTA Cabral[1]
[1]*Hospital Sao Teotonio, Department of Cardiology, Viseu, Portugal*; [2]*Centro Hospitalar Cova da Beira, Cardiologia, Covilha, Portugal*

Introduction: Neoplasia (N) is a risk factor (RF) for mortality (M) of any cause after venous thromboembolism (VTE). Acute pulmonary embolism (PE) may be the first manifestation of a N. Unprovoked (U) PE occurs in the absence of a reversible or temporary RF in the 6 weeks to 3 months preceding. Since VTE is the second cause of death in patients (P) with N, it is important to suspect a N in a P with PE. The differentiation of the type of PE has impact on the duration of the treatment, as so the prothrombotic potential of a N.
Objective: To evaluate the prevalence of N in the follow-up (FU) of PE and its impact on M.
Methods: Selected P admitted in a ICU by PE between 2007-2014, with division in two groups: N in FU (NF) and without N in FU (WF). FU up to 5 years. The active N status was measured in the hospital clinical process and in the computerized process of primary health care in the post-hospitalization period. Were excluded P who died or had active N during the episode, those who lost hospital follow-up and those who did not undergo oncological screening with their primary care physician.
Results: Of 175 P, were selected 126. Average age of 68 ± 18.3 years, 61.1% female. NF group 15.1% (n = 19) and WF 84.9% (n = 107). M in 1 year of 8.7% (n = 11) and in 5 years of 15.1% (n = 19). The most frequent N were the prostate and the lung (2.4% each, n = 3). U PE in 57.8% (n = 68) with 21.4% secondary to trauma / surgery, 10.9% to immobilization and 5.6% to pregnancy / contraceptives.
No differences in admission symptoms or blood tests between the groups. Compared with the WF group, the NF group was characterized by higher prevalence of previous heart failure (31.6% vs 12.3%, $p = 0.042$) and COPD (15.8% vs 3.8%, $p = 0.036$) and older age (69.42 ± 11.24 vs. 61.65 ± 19.1 years, $p = 0.003$). At admission, they had higher systolic blood pressure (129.32 ± 6.9 vs 117.01 ± 2.23 mmHg, $p = 0.042$). They revealed more AF (15.8% vs 3.8%, $p = 0.037$) and less T-wave inversion in V1-V3 (15.8% vs 41.5%, $p = 0.033$) on the ECG. There were no differences in the characteristics of the transthoracic echocardiogram but there was higher prevalence of inferior vena cava reflux (80% vs 40.4%, $p = 0.020$) and greater diameter of the coronary sinus (13.04 ± 0.90 vs 10.95 ± 0.31mm, $p = 0.049$) on CT angiography. The NF group was more frequently associated with PE classified as U (84.2% vs 15.8%, $p = 0.010$) and PESI risk III-V (89.5% vs. 64.5%, $p = 0.031$). No difference in M for any cause at 1 or 5 years after diagnosis.
Conclusion: The presence of N after the diagnosis of PE was 15.1% (22.2% in U PE). The EP may be a first sign of an asymptomatic N. The extensive screening of an hidden N after a TEV appears in the literature as having high sensitivity, although without impact on long-term survival. The integration of more holistic specialties will allow a better identification of those to whom a PE was the first manifestation of a pathology with important vital prognosis.

P1919

Non-invasively assessed pulmonary artery systolic pressure predicts short-term rehospitalizations in acute dyspnea patients

D Gabartaite[1]; J Bugaite[1]; E Paleviciute[2]; K Cerlinskaite[2]; R Norvilaite[3]; D Verikas[3]; G Ziubryte[3]; G Balciunaite[2]; A Krivickiene[3]; J Motiejunaite[3]; D Zaliaduonyte-Peksiene[3]; D Zakarkaite[2]; A Mebazaa[4]; A Kavoliuniene[3]; J Celutkiene[2]

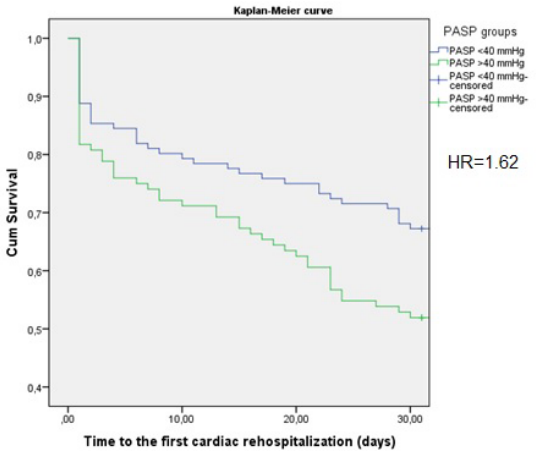
On behalf of: GREAT network

Funding Acknowledgements: The work was supported by the Research Council of Lithuania, grant Nr. MIP-049/2015 and approved by Lithuanian Bioethics Committee, Nr. L-15-01

Introduction: Pulmonary hypertension (PH) is common among patients with heart failure (HF) and predicts worse outcomes. PH may also occur in patients with pulmonary and other diseases causing chronic or acute dyspnea. Significance of non-invasively diagnosed PH in predicting readmissions in the so called "vulnerable phase" (30 days after index hospitalization) has not been analysed.

Table 1	Hazard ratio	Confidence interval	P value
Patients with PASP ≥40 mmHg compared to patients with PASP <40 mmHg			
RH due to all causes in 1-month period	1.54	1.07 to 2.22	0.02
RH due to all causes in 1-month period (adjusted)	1.86	1.23 to 2.82	0.03
RH due to cardiac causes in 1-month period	1.62	1.06 to 2.46	0.026
RH due to cardiac causes in 1-month period (adjusted)	1.78	1.11 to 2.86	0.017



Kaplan-Meier curve

Objective: To investigate the prognostic value of non-invasively assessed PASP for rehospitalizations (RH) at follow up of 30 days in patients with acute dyspnea.
Design and Methods: During the period of 32 months 1482 acutely dyspneic patients were prospectively enrolled in the observational cohort study in two university hospitals. Causes of acute dyspnea were acutely decompensated HF, exacerbation of COPD, pneumonia, pulmonary embolism (PE) and others. In the first 48 hours after admission echocardiography was performed in 482 (32.5%) patients. Patients were divided in two groups: having PASP < 40 mmHg (no and mild PH) and with PASP = 40 mmHg (moderate and severe PH). Hazard ratio was adjusted to gender, age, LVEF and causes of dyspnea.
Results: Of 482 examined patients (mean age 68.6 ± 12.9 years) 193 (40.0%) were female. 64% had acute HF, 6.9% PE. Pulmonary hypertension (PASP >25 mmHg) was detected in 69.3% (n = 334) of patients. Mean PASP was equal to 46.54 ± 16.19 mmHg. The proportion of patients with PASP < 40 and = 40 mmHg was 56.6% (n = 273) and 43.4% (n = 209) respectively. Increased PASP = 40 mmHg was associated with higher rate of RH due to all and cardiac causes in 1-month period (Table 1). In 118 (24.5%) patients, first rehospitalization occured in the first 30 days after discharge, 88 (74.58%) of them were rehospitalized due to cardiac causes (HF 22.9%, atrial fibrillation 11.9%, acute coronary syndromes 5.9%, cerebrovascular diseases 5%, aortic stenosis 5%, PE 4.2%) and 30 (25.4%) due to non-cardiac causes (pneumonia 5.9%, exacerbation of COPD/asthma 3.4%, sepsis 3.4%). 55.08% of rehospitalized patients had PASP = 40 mmHg.
Conclusion: The higher pulmonary artery systolic pressure is a significant short-term predictor of rehospitalizations in acute dyspnea patients admitted to the emergency department.

In-depth hemodynamic phenotyping of pulmonary hypertension due to left heart disease

C Christian Gerges[1]; M Gerges[1]; P Fesler[2]; D Celermajer[3]; IM Lang[1]
[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]University Hospital of Montpellier, Department of Internal Medicine, Division of Nephrology, Montpellier, France*; *[3]University of Sydney, Department of Cardiology, Sydney, Australia*

Background: The commonest cause of pulmonary hypertension (PH) is left heart disease (LHD). However, current definitions of PH-LHD are under scrutiny. Therefore, we performed prospective in-depth invasive hemodynamic phenotyping in order to assess the site of increased pulmonary vascular resistance (PVR) in PH-LHD subsets.
Methods: Based on pulmonary artery occlusion waveforms yielding an estimate of the effective capillary pressure (Pc'), we partitioned PVR in larger arterial (Rup, upstream resistance) and small arterial plus venous components (Rds, downstream resistance). In case of small vessel disease Rup decreases and Rds increases concordantly. Inhaled nitric oxide (iNO) testing was used to assess acute vasoreactivity.
Results: Right ventricular (RV) afterload was significantly higher in combined post- and pre-capillary PH (Cpc-PH, n = 35) than in isolated post-capillary PH (Ipc-PH, n = 20). RV afterload decreased during iNO in Cpc-PH and idiopathic pulmonary arterial hypertension (iPAH, n = 31), but remained unchanged in Ipc-PH. Rup was low in Cpc-PH (66.8 ± 10.8%) and iPAH (65.0 ± 12.2%, p = 0.530) suggesting small vessel disease, and high in Ipc-PH (96.5 ± 4.5%, p < 0.001) suggesting upstream transmission of elevated left atrial pressures (LAP).
Conclusions: RV afterload is driven by elevated LAP in Ipc-PH and is aggravated by elevated small vessel resistance in Cpc-PH. Cpc-PH is responsive to iNO. Our data support current definitions of PH-LHD.

First collaborative registry of pulmonary hypertension in argentina (RECOPILAR)

D F Echazarreta[1]; ER Perna[2]; ML Coronel[2]; ML Diez[3]; A Lescano[3]; N Atamanuk[3]; JA Mazzei[4]; JA Caneva[4]; A Nitsche[5]; D Haag[6]; ML Cazalas[6]; C Stepffer[6]
[1]FAC, Buenos Aires, Argentina; *[2]FAC, Corrientes, Argentina*; *[3]SAC, Buenos Aires, Argentina*; *[4]AAMR, Buenos Aires, Argentina*; *[5]SAR, Buenos Aires, Argentina*; *[6]SAP, Buenos Aires, Argentina*

On behalf of: RECOPILAR
Funding Acknowledgements: Non Financial Support

Introduction: The First Collaborative Registry of Pulmonary Hypertension in Argentina (RECOPILAR) is an inter-institutional project developed between the Argentine Federation of Cardiology (FAC), the Argentine Society of Cardiology (SAC), the Argentine Association of Respiratory Medicine (AAMR), the Argentine Society of Rheumatology (SAR) and the Argentina Society of Pediatrics (SAP) of a multicenter, prospective, observational nature that included patients diagnosed with pulmonary hypertension (PH) including the 5 groups of the Nice 2013 classification. Method: From Jul-14 to Oct-16, incident and prevalent patients with pulmonary hypertension (PH) were prospectively included by 62 investigators from 22 provinces of Argentina. The inclusion criteria were: 1-patients over three months of age; 2 - mean pulmonary arterial pressure (mPAP) at rest = 25 mmHg by right heart catheterization and 3 - clinical stability in the absence of hospitalization in last month.
Results: A total of 627 patients were included, 338 (53.9%) before and 289 (46.1%) after Jul-15 Mean age was 50.8 ± 18.7 years, 434 (69.2%) were females, ethnicity was Caucasian 92.3%, native 7.5% and Asian 0.2%. Referral cases represented 22%, 53% were incident cases and 17.5% did not have social security. WHO functional class III-IV was 69.1% at the time of diagnosis, 33.3 at inclusion and 24.9% at the follow-up. Classification of PH in groups 1 to 5 (Nice) was the following: 64%; 16%; 8%; 10% and 2%. The clinical manifestations were dyspnea 82%, fatigue 54%, syncope 11%, chest pain 15%, palpitations 20% and heart failure in 21%, with previous hospitalization in 33% (half due to heart failure). The overall hemodynamic profile showed a mean pulmonary arterial pressure of 48.30 ± 16.51 mmHg, cardiac index 2.65 ± 0.89 l/min/m2, right atrial pressure 11.75 ± 1.4 mmHg, and vascular pulmonary and systemic resistances of 685.16 ± 456.96 and 1414.86 ± 579.97 dynes/sec/cm-5, respectively. Pulmonary vasorreactivity test was performed in 73% and it was positive in 10%. In patients with pulmonary arterial hypertension (PAH) vs other groups, the use of specific therapy was 80.5 vs 40.8% (p <0.001), including PDF5i in 71 vs 39%, endothelin receptor antagonists in 54.4 vs 14.5, and prostanoids in 14.3 vs 3.1% (all p <0.001). The follow-up was available in 422 patients (67%), with an 3-year overall survival of 74%.
Conclusion: In this collaborative Argentinean registry of PH, the epidemiological profile was similar to other Latin American series, with two thirds of patients with pulmonary arterial hypertension. The diagnostic work-up and therapeutic interventions, with a high use of specific therapy in PAH, were consistent with current recommendations of national and international guidelines. Despite the severity of the disease, the outcome was comparable to other contemporary registries.

On behalf of: RECOPILAR Investigators

A demographic transition to older age in patients with pulmonary arterial hypertension (PAH) has been recently identified. We evaluate the prevalence, clinical profile and management of elderly with PAH in Argentina.
Method: From Jul-14/Oct-16, 399 incident/prevalent patients with PAH were prospectively included by 62 investigators from 22 provinces of Argentina, if they fulfilled all following inclusion criteria: Age >3 months; mean pulmonary arterial pressure = 25 mmHg by right heart catheterization (RHC) and clinical stability with no hospitalization in last month. Elderly group (EG) was defined by age >60 years.

Table 1

Variables	EG	NoEG	p
Pulmonary arterial pressure (Syst/Diast/Mean) (mmHg)	72/30/46	85/38/54	<0.001
Cardiac Index (l/min/m2)	2.7±1	2.8±1	NS
Wedge (mmHg)	12±4	11±5	NS
Right atrial pressure (mmHg)	11±8	12±11	NS
Pulmonary vascular resistance (WU)	8.4±5.6	10.4±6.2	0.012
Distance in 6 Min Walk Test (mts)	313±108	387±116	<0.001

Results: The prevalence of elderly was 26.6% (N = 106). The mean age in EG and noEG was 70 ± 7 vs 39 ± 14 years, females were 85 vs 77% (p = NS), and incident cases were 52 vs 49% (p = NS), respectively. Cardiovascular comorbidities in EG vs noEG were different in hypertension 17 vs 5.5% (p < 0.001), dyslipemia 8.5 vs 3.4% (p = 0.03), diabetes 6.6 vs 2.4 (p = 0.04) and chronic renal failure 3.8 vs 0% (p = 0.005). Subgroups of PAH in EG vs noEG were idiopathic 31.1 vs 43.3% (p = 0.028), heritable 1.9 vs 1% (p = NS), connective tissue disease 42.5 vs 17.1% (p < 0.001); portal hypertension 7.5 vs 2.7% (p= 0.042); HIV 0 vs 6.8% (p = 0.006) and congenital heart disease 17 vs 28.3% (p = 0.021). Clinical characteristics were similar between EG and noEG, with WHO class III-IV in 67.7 vs 63.8%, but with a lower proportion of syncope 5.7 vs 16% (p = 0.007). RHC and functional capacity are in Table 1. The use of specific therapy was similar in EG vs noEG, with no drugs in 19.8 vs 19.5%; monotherapy 33 vs 28.3% and combined treatment 47.2 vs 52.2 % (p = NS). The follow up was obtained in 65% of cases, and the survival in EG vs noEG at 3 years was 72 vs 75% (p = NS).
Conclusion: Nowadays, an important proportion of PAH patients are elderly. They have a particular profile: more cardiovascular comorbidities, similar severity of symptoms, better hemodynamic but worse functional capacity. Despite these differences, specific therapy and outcomes were comparable. These findings suggest an earlier diagnosis and faster decline in elderly with PAH.

Prevention of periprocedural kidney ingury by loading doses of statins in elective percutaneous coronary interventions

EO Vershinina[1]; AN Repin[1]

[1]State Research Institute of Cardiology of Tomsk, department of rehabilitation, Tomsk, Russian Federation

Purpose of the study. To compare the effect of loading doses of atorvastatin and rosuvastatin on the value of the acute kidney injury and acute inflammatory response to elective percutaneous coronary interventions.
Materials and methods. An open prospective comparative study included 68 patients referred for elective percutaneous coronary intervention (PCI). At baseline, all patients had been taking statins for a long time as a standard lipid-lowering therapy. The first group included 33 patients who received a loading dose of 80 mg of atorvastatin (As) 12 hours before the intervention with saving this dose for 2-6 days. The second group included 35 patients treated with rosuvastatin (Rs) 40 mg / day in the same manner. The levels of creatinine and cystatin C in the blood were determined at baseline and 12, 24, 48 and 72 hours after the intervention. HsCRP level was determined at baseline and 5 days after PCI.
Results: AKI was diagnosed in 5 patients (7.94%): 4 patients (12.1%) in group As and 1 patient (3.3%) in group Rs (p = 0.36). The increase of serum creatinine level in the group As patients was 43.4% higher than one in the Rs group patients (p = 0.024). The decrease of glomerular filtration rate (GFR) in group As was 15.5% higher than one in group Rs (p = 0.09). Initially, the level of cystatin C in the groups did not differ (698.9 (560.2-869.6) ng / ml in group As vs 759.5 (673.8-899.9) ng / ml in group Rs, p = 0.75). Significant intergroup differences were found in the level of serum cystatin C 12 hours after PCI (718.3 (555.6-839.6) ng / ml in group As vs 470.6 (378.2-689.4) ng / ml in the Rs group, p = 0.007) that persisted 24 hours after the intervention (732.1 (632.3-887) ng / ml vs 526.4 (357.4-802.7) ng / ml, respectively, p = 0.02). From the second day after PCI, intergroup differences in serum cystatin C disappeared. The level of hsCRP significantly increased 72 hours after the intervention in group As (1.65 (0.9-4) mg / l at baseline vs 4.55 (1.6-8.7) mg / l 72 hours after PCI, p = 0.01). The level of hsCRP did not change significantly at the same time in the Rs group (2.8 (0.8-6.8) mg / l at baseline vs 2.75 (1.5-6.5) mg / l 72 hours after PCI, p = 0.16).
Conclusion. The loading dose of rosuvastatin better prevents periprocedural kidney injury in PCI and more significantly reduces the overall inflammatory response to intervention compared to the loading dose of atorvastatin.

P1924

Va-ecmo for the treatment of cardiac failure in post-cardiotomy patients with infective endocarditis

F S Floris Stefan Van Den Brink[1]; U Sonker[2]; R Van Tooren[1]; MJ Swaans[1]; P Klein[2]; FD Eefting[1]; NJ Breet[1]; E Scholten[3]

[1]St Antonius Hospital, Cardiology, Nieuwegein, Netherlands; *[2]St Antonius Hospital, Cardiothoracic Surgery, Nieuwegein, Netherlands*; *[3]St Antonius Hospital, Intensive Care, Nieuwegein, Netherlands*

Funding Acknowledgements: No funding

Introduction: Treatment of Infective Endocarditis (IE) consists in about a third of the patients of surgical intervention. Surgery for IE is often difficult with great challenges in post-operative circulatory and pulmonary support. Veno-Arterial Extra-Corporal Membrane Oxygenation (VA ECMO) could play a role in improving outcome in these patients, yet data in this regard is virtually non-existent.
Purpose: To gain insight in outcome of patients undergoing surgery for IE and subsequent treatment with VA-ECMO for circulatory support.
Methods: An in-hospital registry was kept between 2009 and 2016 on all patients receiving VA ECMO for circulatory support in our Hospital. All patients undergoing VA-ECMO were analysed retrospectively and were scored on age, gender, medical history, microorganisms involved, clinical outcome, complications, surgical procedure and length of stay.
Results: Between 2012 and 2016, 13 patients were treated with VA-ECMO following surgery for IE. The majority of patients was male (8/13). The median age was 62 years (33-73). A medical history concerning cardiac surgery was present in 9 patients: 8 had previous valvular surgery of whom 2 received concomitant coronary bypass surgery (CABG) as well, 1 patient had coronary bypass surgery alone. Surgical intervention consisted of a Bentall procedure in 10 patients, 2 of which received concomitant mitral valve surgery and another 2 received concomitant CABG. Valvular surgery without aortic involvement was performed in 3 patients: 1 mitral valve replacement, 1 aortic valve replacement and 1 combined procedure. All patients had positive cultures: S. Aureus in 3 cases, E. Faecalis in 3 cases, E. Faecium in 2 cases, E. Coli in 1 case, S. Epidermis in 1 case, S. Mitis in 1 case, H. Parainfluenzae in 1 case and Candida Albicans in 1 case.
Mortality while on VA-ECMO was 62% (8/13). Mortality during ICU stay was 77% (10/13). Survival to the ward was 23% (3/13) and all these patients had survival to discharge. One patient reached the one year survival point. The other two patients who have survived to discharge have not yet reached the one year survival point but are still alive. Patient related complications occurred in 54% (7/13) patients and consisted of haemorrhage at the cannula site in 4 patients, leg ischaemia in 1 patient, haemorrhage at another site in 1 patient and infection of the cannula in 1 patient. ECMO hardware related complications occurred in 1 case consisting of clot formation in the oxygenator. The median time on VA-ECMO was 5 (1-15) days, the median time spent on ICU was 6 (2-29) days and the median time spent in hospital was 16 (5-78) days.
Conclusion: VA-ECMO for the treatment of cardiac failure in post-cardiotomy patients who were operated on for infective endocarditis is feasible but outcome is poor. It could improve survival in selected patients

P1925

Technical approach to endovascular treatment of patients with ostium lesion of coronary arteries

Z KH Shugushev[1]; D A Maximkin[1]; AG Chepurnoy[1]; OO Safonova[1]; AV Mambetov[1]
[1]*RUDN University, Moscow, Russian Federation*

Aim: to increase the effectiveness of endovascular treatment in patients with ostium coronary artery lesions.
Methods: 150 patients were included in the study. Inclusion criteria: ostium atherosclerotic lesions of LAD or LCx > 70% according to QSA and IVUS; stable angina II-III functional class (CCS); silent myocardial ischemia; positive stress test. The main included 108 patients, who were randomized into 2 groups. In I group (n = 54) according to IVUS, atherosclerotic plaque spread from the ostium of LAD and/or LCx to the LMCA, and in group II (n = 54) - the plaque did not spread into the LMCA. In Group I all patients were initially treated with 'Provisional T' stenting of the LMCA, and in Group II - stenting of the ostium LAD or LCx. In retrospectively, the third (III) control group (n = 42) was formed, where the stenting of the ostium of LAD or LCx was performed without IVUS. Drug-eluting stents were implanted in all patients. Long-term results were evaluated on average over a period of 30.04 ± 12.04 months in 50 patients from group I, in 48 patients from group II and in 40 - from group III. Primary endpoints: frequency of MACE (death, MI, revascularizations). Secondary endpoints: frequency of restenosis and late stent thrombosis according to QSA and IVUS.
Results: during hospitalization of complications associated with PCI was not, survival was 100% in all groups. There was no conversion to complete bifurcation stenting. Survival in the long-term period was 100% in all groups. In all patients, in comparison with preoperative data, tolerance to physical activity significantly increased. Nonfatal MI was observed in 7.5% of patients from group III ($p < 0.05$), in the I and II group of cases MI was not recorded. The incidence of stent restenosis and target lesion revascularization (TLR) according to QSA and IVUS was observed in 1 patient (2%) in group I, in 1 patient (2.1%) in group II and in 4 patients (10%) in III group ($p < 0.05$). Frequency of target vessel revascularization (TVR) occurred in group I in 2% of patients, in group II in 2.1%, and in group III in 7.5% ($p < 0.05$). The total frequency of MACE in groups I, II and III was 2; 2.1 and 25%, respectively ($p < 0.05$). Among patients in group III, 1 case of stent thrombosis (2.5%) was verified 12 months after PCI.
Conclusion: the use of IVUS for the analysis of the ostium lesions of coronary artery allows us to choose the optimal stenting technique and also reliably improve the long-term results of endovascular intervention by reducing the incidence of stent restenosis and MACE.

P1926

Oxidative stress and endothelium dysfunctin in patients with coronary artery bypass grafting

YN Maksimovich[1]; TP Pronko[1]; YA Kashcheyeu[1]; NY Maksimovich[1]
[1]*Grodno state medical university, propaedeutics of internal diseases, Grodno, Belarus*

Introduction: It is known that the NO molecule has both pro- and anti-oxidant properties. Since the nitric oxide (NO) is a vascular endothelial anti-thrombotic factor, that can convert in the highly toxic peroxynitrite (ONOO-) it is obvious need to study the changes in nitric oxide level in patients during perioperative period of Coronary Artery Bypass Graft surgery (CABG).
Purpose: The aim of our study was to investigate the role of NOx and Malonic dialdehyde (MD) change in blood serum and the condition of endothelium in of patients with coronary artery disease in the perioperative period of coronary bypass surgery performed with pump on.
Methods. It was investigated the content of nitrites and nitrates, MD in the blood plasma and endothelium dysfunction of 26 patients with coronary artery disease and cardiac ischemia (CI) in condition grafting performed with pump on.
Results: The studies revealed a decrease in [NOx], increase of malonic dialdehyde level as an indicator of oxidative stress in blood plasma of the patients after coronary bypass surgery in period of coronary blood flow restoration in comparison with the period before pump on device was connected. The patients levels of nitrite and nitrate in the recovery period cardiac activity (pump on) was lower (74%, $p < 0,05$), as compared with their concentration in the initial period of operation (before pump on). Decrease of NOx indicates either a low production of NO by vascular endothelium or an increase in its utilization in reaction with superoxide anion and its conversion to peroxynitrite.
Increase in the levels of malonic dialdehyde is the result of the oxidative processes due to increased hemolysis.
In the patients with coronary artery bypass grafting we noticed decrease of endothelium dependent vasodilation in post-surgical period in comparison with the pre-surgical period. This creates conditions for the occurrence of coronary vascular endothelial dysfunction in patients with CABG, thereby predisposing to the development of thrombosis due to a decrease of antithrombotic properties of vascular endothelium generated NO.
Conclusion Decrease of NO levels, appearance of oxidative stress and endothelial dysfunctions are pathogenetic factors of perioperative Myocardial Infarction as the most frequent and dangerous fatal complications in patients with decreased antithrombotic properties of coronary arteries and implanted bypass.

P1927

Similar long-term clinical outcomes after percutaneous coronary intervention in grafts versus native vessels in prior coronary artery bypass grafting patients with diabetes mellitus

D Dong Liu[1]
[1]*Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Cardiology, Beijing, China People's Republic of*

Background Atherosclerosis in diabetic patients with prior CABG progresses fastly. Data on how to choose target vessels of post-CABG PCI in diabetic pateints is sparse.
Methods 157 patients with diabetes and previous CABG, who underwent PCI of either a graft (n = 44) or a native (n = 113) vessel between January 1st 2009 and June 1st 2014 in the National Center for Cardiovascular Disease, China, were studied. In-hospital and long-term clinical outcomes were compared between the groups.
Results Diabetic patients with prior CABG had more percutaneous interventions (PCI) to native arteries, but the proportion of grafts PCI increased as time went on. Both groups had similar baseline characteristics. Group graft vessel (GV) patients compared with group native vessel (NV) had more totally occluded native vessels, less totally occluded grafts and more in-stent restenosis. However, there was no difference in in-hospital mortality and long-term incidence of major adverse cardiac event, cardiac death, nonfatal myocardial infarction (MI), or revascularization. Multivariate logistic regression analysis showed that PCI success (OR = 11.488, 95%CI = 1.135-116.303, $P < 0.05$) was independent predictor of MACE. **Conclusions:** It suggested similar long-term clinical outcomes after PCI in GV or NV in prior CABG patients with diabetes. Thus the vessel with higher estimated PCI success rate should be prioritized by operators.

Assessment of left atrial mechanical function by two-dimensional echocardiography in hypertensive patients

S Antit[1]; S Slama[1]; S Chenik[1]; A Amri[1]; I Boussabeh[1]; M Thameur[1]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*

Aim : To compare left atrial (LA) mechanical function, assessed by two-dimensional echocardiography, in patients with essential hypertension with healthy controls.
Methods : LA volumes were measured echocardiographically in 50 hypertensive patients and 50 age-matched healthy controls using biplane Simpson method. LA volume measurements were done at the time of mitral valve opening (Vmax), at the onset of atrial systole (p wave at the electrocardiogram = Vp) and at mitral valveclosure (Vmin). All volumes were indexed for body surface area, and the following left atrial emptying functions were calculated: LA passive emptying volume = Vmax-Vp, LA passive emptying fraction = LA passive emptying volume/Vmax, conduit volume = left ventricular stroke volume-(Vmax-Vmin), LA active emptying volume = Vp-Vmin, LA active emptying fraction = LA active emptying volume/Vp, LA total emptying volume=(Vmax-Vmin), LA total emptying fraction = LA total emptying volume/Vmax.
Results: Hypertension was associated with an increase of all LA volumes: Vmax ($p < 0.001$), Vp ($p < 0.001$) and Vmin ($p < 0.004$). LA booster pump function was significantly greater in hypertensive patients than in controls with an increase of LA active emptying fraction (35 ± 12% versus 30 ± 12%respectively; $p = 0.032$). The increase of LA booster pump function was found to be greater in hypertensive patients with impaired diastolic function compared to those with normal diastolic function ($p = 0.029$). LA conduct function assessed by LA passive emptying fraction was found to be significantly greater in control group than in hypertensives (32 ± 11% versus 22 ± 12% respectively; $p < 0.001$). There was a negative correlation between left ventricular mass index and LA passive emptying fraction ($r=-0.37$; $p = 0.007$). LA reservoir function evaluated by LA total emptying fraction was similar in both groups while LA total emptying volume was greater in hypertensives than in control group ($p = 0.03$).

Conclusion: Hypertension was associated with a decrease in left atrial passive emptying function, and an increase of systolic pump function. Left ventricular hypertrophy and diastolic dysfunction probably played a major role in these modifications.

P1929

Predictive models for major renal events in patients with significant atherosclerotic renal artery stenosis after renal angioplasty with stent implantation

DO Geavlete[1]; C Beladan[1]; D Deleanu[1]; O Tautu[2]; MR Zaharia[3]; BA Popescu[1]; C Ginghina[1]; O Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania*; [2]*Emergency Clinical Hospital Floreasca, Cardiology, Bucharest, Romania*; [3]*Emergency Clinical Hospital St John, Internal Medicine, Bucharest, Romania*

Introduction: Renal artery stenosis (RAS), due to poor prognosis remains a matter of debate regarding the selection of patients who would benefit the most from renal artery stenting, natriuretic peptide being suggested to be useful in patients' selection.
Purpose: The study was aimed to analyze the response of renal function 12 months' after renal angioplasty with stent in selected patients diagnosed with significant RAS in order to find predictors for major renal events (acute renal failure and need for dialysis).
Methods: 78 hypertensive patients diagnosed with significant uni- and bilateral RAS were prospectively enrolled, resulting in 3 groups (34-unilateral, 28-bilateral RAS and 16-RAS in solitary kidney). Cardiac and renal history, blood pressure, biological profile (including BNP), vascular diseases, comorbidities and hospitalization after revascularization were evaluated. A complete echocardiography was performed in all patients. Renal function was estimated based on the serum creatinine level and glomerular filtration rate (eGFR-CKD-EPI). The mean extended follow-up period was 24.27 ± 12.16 months.
Results: Baseline renal dysfunction was significantly higher in solitary kidney RAS cases when compared to bilateral and subsequently to unilateral RAS($p = 0.001$). Improvement in renal function 12 months' after stenting was observed in 52.7% of all patients, preservation in 43.1% and deterioration in 4.1%, without significant differences between groups (p?0.05). The prevalence of major renal events was 14%. Although a wide range of clinical, biological and echocardiographic parameters were significantly correlated with major renal events, the multivariate regression analysis confirmed only baseline LnBNP as an independent predictor for renal major outcomes ($p = 0.002$). The accuracy of the emerged predictive model as quantified by the area under the receiver-operating characteristics curve (AUC) was 0.95 (95% CI, 0.83-1.01, $p = 0.002$). By removing BNP from the model, an alternative model which included 3 independent predictors was emphasized: history of renal disease, post-revascularization eGRFCDK-EPI value and hospitalization for decompensated cardiac failure. The accuracy of the predictive model as quantified by AUC was 0.95 (95% CI, 0.89-1.00, p?0.001). The presence of preexistent renal disease in the model did not correlate with blood pressure nor with renal function evolution after revascularization.
Conclusions: The present findings demonstrated that BNP could be a valuable biomarker in the assessment of renal deterioration after revascularization as an unique predictor. The alternative model with higher prediction sensitivity was related to the strong relationship between renal events, poor renal function response to renal stenting and cardio-renal syndrome. Preexistent renal disease is distinctively marked in the model, as it probably refers to irreversible parenchyma and vascular renal diseases that lead to renal insufficiency progression.

P1930

The clinical profile and outcomes of acute decompensated heart failure in patients with history of hypertension

S Sergey Kozhukhov[1]; A Alexander Parkhomenko[1]
[1]*NSC "Institute of Cardiology", Kiev, Ukraine*

Background: Most patients with acute heart failure present with history of hypertension (HTN). The aim was to investigate baseline characteristics and impact of HTN in patients with acute decompensated heart failure (ADHF).
Methods: 117 consecutive patients (73.5% hypertensive and 26.5% non-hypertensive) presenting with ADHF were enrolled in a prospective open-label study. The diagnosis of ADHF was classified according to European Society of Cardiology guidelines.
Results: Patients with HTN were older (69.3 vs 62.7 years, $p < 0.05$), more likely to be female, to have diabetes, hyperlipidemia, cerebrovascular disease, prior history of coronary artery disease, but less likely to be smokers when compared with patients without HTN. On admission, HTN patients had lower glomerular filtration rate, hemoglobin and higher blood glucose level. In-hospital mortality was 2.6% without significant difference between groups. The incidence of cardiovascular death and rehospitalization due to heart failure did not differ among patients with HTN in overall ADHF group ($p = 0.212$ by Log rank).
Conclusion: In cohort of ADHF patients HTN was not associated with an increased rate of in-hospital mortality, cardiovascular death and rehospitalization during 2-years follow up.

P1931

The role of epigenetic factors by men with arterial hypertension in the formation of disorders of the central nervous system

V S Potaskalova[1]; NV Khaitovych[1]; MN Seliuk[2]; AP Burlaka[3]; NN Kozachok[2]; OV Seliuk[2]
[1]*National O.O. Bohomolets Medical University, Kiev, Ukraine*; [2]*Ukrainian military medical academy, Kiev, Ukraine*; [3]*R.E. Kavetsky Institute of Experimental Pathology, Oncology and Radiobiology of NAS Ukraine, Kiev, Ukraine*

The effect of ultra-high frequency electromagnetic radiation (UHF-EMR) can be considered as an epigenetic factor in the development of arterial hypertension and worsening of the prognosis of the disease. It is known that during the prolonged exposure of UHF EMR developing disturbances of the central nervous and cardiovascular systems. The study purpose was determining the features of cognitive functions (CF) and sleep of patients with arterial hypertension (AH), working in conditions of UHF EMR.
The study included 125 men, 35 - with AH, who worked under the influence of UHF EMR (group 1), 30 - were healthy men worked in the same conditions (group 2), 30 patients with AH and 30 healthy men without the long-term influence of UHF EMR (group 3, 4). The average age of the subjects $31,2 \pm 5,4$ years. The dose of UHF EMR was within the range of 4320-31065 kW ($17151,7 \pm 7102,4$ kW average). Patients of 1 and 3 groups were treated with antihypertensive therapy according to the recommendations of the European Society of Cardiology 2007, revision 2009. CF were determined by means of neuropsychological tests, specially designed questionnaire of sleep quantity and quality.
Patients of 1 group compared with patients of 3 group showed a reduction in motor function (MF) ($6,4 \pm 1,2$) against ($7,5 \pm 0,8$) points, $P < 0,001$; successive functions (SF) ($7,2 \pm 1,3$) against ($8,2 \pm 0,8$) points, $P < 0,05$ and functions of writing (WF) ($10 \pm 2,4$) against the ($12,6 \pm 1,4$) points, $P < 0,005$. Men from the 2 group also identified changes in the central nervous system: MF was ($8,2 \pm 0,4$) against ($9,2 \pm 0,8$) scores of healthy men, $P < 0,05$; SF - ($8,6 \pm 0,5$) against ($9,6 \pm 0,4$) points, $P < 0,05$, WF - ($13,4 \pm 1,5$) against the ($17,0 \pm 1,6$) points, $P < 0,05$. Diagnosed an inverse correlation between the level of MF ($r = -0,63$; $P < 0,05$), SF ($r = -0,75$; $P < 0,005$) and WF ($r = -0,51$; $P < 0,05$) and time under the conditions of UHF EMR exposure. Among the patients of 1 group sleep less than 6 hours reported 92% (including at least 5 hours - 38%), from 6 to 7 hours - 8% of patients, just 80% of patients of 1 group noted the quality of sleep disturbance. Sleep duration of patients from 2 group duration of 6 to 7 hours reported 86%, 8 and more hours - 14% of patients.
Conclusion: Those men, who worked in conditions of UHF EMR, were diagnosed disturbances of cognitive function, the degree of which correlated with the duration of work in these conditions. Most patients with AH (80%) had insufficient sleep duration and impaired quality of it, which perhaps along with other factors determined the propensity of increasing blood pressure.

Sleep Disorders

P1932

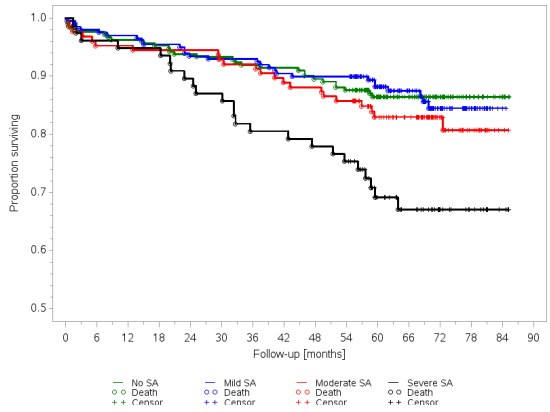
Impact of sleep apnea on five-year prognosis in patients after acute myocardial infarction

O Ludka[1]; R Stepanova[1]; T Kara[2]; J Spinar[3]
[1]*International Clinical Research Center, St. Anne's University Hospital, University Hospital Brno, Masaryk University, Brno, Czech Republic*; [2]*Division of Cardiovascular Diseases, Department of Internal Medicine, Mayo Clinic and Foundation, Minnesota, United States of America*; [3]*Department of Internal Medicine and Cardiology, University Hospital Brno, Brno, Czech Republic*

Funding Acknowledgements: Supported by the project no. LQ1605 from the National Program of Sustainability II and FNUSA-ICRC (No. CZ.1.05/1.1.00/02.0123).

Purpose: Sleep apnea (SA) has a high prevalence in patients after myocardial infarction (MI). While SA might be a modifiable risk factor, recent data suggest that SA is severely underdiagnosed in patients after MI. There is also limited evidence about long-term prognosis of patients after MI according to SA categories. Therefore we sought to determine the relationship between SA and long-term prognosis among patients presenting with MI.
Methods: We prospectively studied 782 consecutive patients admitted to the hospital with the diagnosis of acute MI. The study was conducted in two tertiary care

institutions, where primary percutaneous coronary intervention (PCI) is the standard of care in the treatment of acute MI. All subjects underwent sleep evaluations using a portable diagnostic device after at least 48 hours post-admission, provided they were in stable condition. Patients were followed for median follow-up of 66 months.
Results: Almost all patients (98%) underwent urgent coronary angiography and 91% of patients underwent primary PCI. 175 (22.4%) patients had technically inadequate limited sleep studies (less than 4 h recording time or inability to score study due to excessive artifact). We therefore analyzed the data from 607 patients who had good quality sleep study records. Using a threshold of AHI > 5 events/hour, SA was present in 65.7% of patients after acute myocardial infarction. Mild SA was present in 32.6%, moderate in 20.4% and severe in 12.7%. There was a relation between the severity of SA and long-term prognosis. Patients after MI with increasing severity of SA had higher total mortality (p = 0.002, log-rank test). The Kaplan-Meier survival curves are presented. There was also a higher total mortality in reduced than in preserved left ventricular ejection fraction patients after MI in the group of moderate to severe SA (p = 0.033). Conclusion: Mortality of patients after MI significantly increased with increasing severity of SA. Whether treatment of SA after MI will significantly improve outcomes in these patients remains to be determined.



Kaplan-Meier survival curves

Improved sleep apnoea management in patients newly diagnosed with severe sleep apnoea via device-based pre-screening: a sub-analysis of the RESPIRE study

P Pascal Defaye[1]; A Ghuran[2]; S Vittadello[3]; V Russo[4]; I Heurtebise[5]; D Dey[6]; W Amara[7]
[1]University Hospital of Grenoble, Department of Cardiology, Grenoble, France; *[2]Lister Hospital, Stevenage, United Kingdom*; *[3]Osp. Civile Montebelluna, Treviso, Italy*; *[4]OSP. SS. Annunziata ASL Taranto, Taranto, Italy*; *[5]Centre Hospitalier de Bourges, Bourges, France*; *[6]LivaNova, Clamart, France*; *[7]Centre Hospitalier Intercommunal Le Raincy-Montfermeil, Le Raincy-Montfermeil, France*

On behalf of: RESPIRE Study Investigators
Funding Acknowledgements: LivaNova

Background/Introduction: The diagnosis of sleep apnoea (SA) with polysomnography is costly and often lengthy, making the use of pre-screening methods for SA attractive. The SA monitoring feature in REPLY 200 DR pacemakers detects, analyses and records abnormal breathing events (apnoea and hypopnoea), allowing pre-screening of SA via the measurement of a respiratory disturbance index (RDI).
Purpose: The RESPIRE study investigated the prevalence of severe SA and rates of associated referrals, examinations and treatment in an unselected pacemaker population.
Methods: The study was an 18-month international, single-arm, open-label study of patients implanted with REPLY 200 pacemakers. SA severity was determined from device memory using RDI, the sum of abnormal respiratory events divided by sleep duration. Severe SA was defined as a mean RDI = 20 over 12 months. SA referrals, examinations and treatment were determined at 12 months for patients with versus without severe SA. Patients already receiving SA treatment were excluded from the analysis.
Results: Of the 1147 enrolled patients (56.3% male; 75.7 ± 10.3 years), 1024 patients were analysed. At 12 months, 313 (30.7%) patients had severe SA. In patients with severe SA, 24.6% were referred to a sleep specialist, 21.7% were referred for an SA exam, and 15.3% were treated for SA (Table).
Conclusion(s): Severe SA is prevalent in unselected pacemaker patients. Thanks to pre-screening with device-based SA monitoring, more newly diagnosed patients with severe SA were able to benefit from specialist SA follow-up and subsequent examination and treatment.

	Patients with severe sleep apnoea* N = 313	Patients without severe sleep apnoea* N = 706
Referred to sleep specialist at 12 months	N = 77 (24.6%)	N = 74 (10.5%)

Background/Introduction: Patients (pts) with atrial fibrillation (AF) are often affected by sleep apnoea (SA). The diagnosis of SA with polysomnography is costly and often lengthy. Pre-screening of SA in paced pts, based on the measurement of a respiratory disturbance index (RDI), is possible with certain pacemakers, such as the REPLY 200 DR.
Purpose: The RESPIRE study evaluated the incidence and severity of SA and its association with significant AF in unselected pacemaker pts, and whether the severity of SA affected the occurrence of major serious adverse events (MSAEs).
Methods: RESPIRE was an international, observational, single-arm, open-label study that followed pts for 18 months after implant with REPLY 200 pacemakers. SA severity was ascertained from device memory using RDI, the sum of abnormal respiratory events divided by sleep duration. Severe SA was defined as mean RDI = 20 over 12 months. Significant AF was defined as a cumulative time in AF = 24 hours over 2 consecutive days. The efficacy co-primary endpoint was the difference in significant AF between pts with severe versus non-severe SA at 12 months. The safety co-primary endpoint was all investigator-reported MSAEs. The analysis reports mean intergroup differences [95% confidence intervals] estimated using a one-sided Z test with significance set at $P < 0.025$.
Results: Of 1147 enrolled pts (56.3% Male; 75.7 ± 10.3 years), 1024 were analysed. At 12 months, severe SA was detected in 321 pts (31.3%), and 172 pts (16.8%) had significant AF. Pts with severe SA had a higher incidence of significant AF; there was no difference in the percentage of MSAEs (Table).
Conclusion(s): With pre-screening, almost a third of unselected pacemaker pts were found to have severe SA at 12 months. Severe SA was significantly associated with a higher incidence of significant AF. No relationship was found between severity of SA and occurrence of MSAEs.

Physical training reduces microvascular ischemia and improves left ventricular systolic function in patients with non-ischemic dilated cardiomyopathy and microvascular dysfunction

MV Marcus Vinicius Simoes[1]; EEV Carvalho[1]; JC Crescencio[1]; DM Tanaka[1]; LFL Oliveira[1]; PV Schwartzmann[1]; CQ Bertini[1]; A Schmidt[1]; L Gallo-Junior[1]; JA Marin-Neto[1]

[1]Medical School of Ribeirão Preto - University of São Paulo, Brazil, Ribeirão Preto, Brazil

Background: Myocardial ischemia with normal coronary arteries at angiography, characterizing the presence of coronary microvascular dysfunction (CMD), may be detected in 30-50% of patients with non-ischemic dilated cardiomyopathy (DCM) and is a marker of worse prognosis. However, there is a lack of studies assessing the impact of therapeutic measures targeting CMD in this clinical context.
Purpose: We aimed at testing the effect of physical training over the extent/severity of myocardial perfusion defects and left ventricular systolic function in patients with CMD associated to DCM.
Methods: We prospectively investigated 20 patients with DCM presenting CMD characterized by chest pain, normal coronary arteries at angiography, and detection of = 2 myocardial segments with reversible perfusion defects during stress-rest Tc-99m-Sestamibi myocardial perfusion-SPECT imaging (MPI). Patients were assigned to a Training Group (TG - n = 11, 5 men, age = 60.0 ± 7,8 y. o., mean NYHA functional class = 1.8 ± 0.4) and Control Group (CG - n = 9, 5 men, age = 55.8 ± 12 y.o., mean NYHA functional class = 2.0 ± 0.5). At baseline and 3 months afterwards, both groups underwent MPI including evaluation of left ventricular ejection fraction (LVEF) by using gated-SEPCT images, cardiopulmonary exercise test (CPT) and quality of life (QOL) evaluation by using the SF36 questionnaire. The patients of the TG were submitted to aerobical physical training during 3 months, consisting of 1-hour treadmill sessions, 3 times/week, moderate intensity (60 to 85% of the peak-VO2). The myocardial perfusion defects were visually graded using a semi-quantitative score (0 = normal uptake; 4 = absent uptake) in a left ventricular 17-segment model. Summed reversibility score (RS) was calculated by subtracting the rest summed score from the stress summed score.
Results: The CG presented no significant difference between the baseline and post 3 months evaluation for all investigated variables. However, the TG patients exhibited significant reduction of the RS from baseline to the post-training evaluation (7.7 ± 3.9 to 2.4 ± 4.7, respectively, p = 0.003), reduction of the number of segments with reversible defects (6.9 ± 2.9 to 2.9 ± 4.1, respectively, p = 0.007), increasing of the LVEF (39.6 ± 20.5 to 44.8 ± 20.7%, respectively, p = 0.02), increasing of the physical capacity measured by the peak-VO2 (16.3 ± 3.9 to 18.7 ± 3.5 ml/Kg/min, respectively, p < 0.003) and by the VO2 at the anaerobic threshold (10.4 ± 2.0 to 12.9 ± 3.0 ml/Kg/min, respectively, p = 0,001). We observed significant improvement in all domains of the SF-36 scores.
Conclusions: Physical training was associated to significant reduction of the extent/severity of reversible myocardial perfusion defects in patients with DCM and coronary microvascular dysfunction. This positive effect was also associated to improvement of the LVEF and QOL scores. Our results suggest that physical training is a relevant therapy for coronary microvascular dysfunction in DCM patients.

The Efficacy of Exercise-Based Cardiac Rehabilitation in heart failure patients with mid-range ejection fraction

I Burazor[1]; R Sakurai[2]; S Stevovic[1]; M Moraca[1]; A Kovacevic[1]; Y Adler[3]

[1]Institute for Rehabilitation, Cardiology, Belgrade, Serbia; [2]International University of Health and Welfare, Tokyo, Japan; [3]Chaim Sheba Medical Center, Tel Hashomer, Israel

Heart failure is a major cause of morbidity, mortality and re- hospitalizations and is highly prevalent in myocardial infarction survivors. Cardiac rehabilitation based on exercise training and heart failure self-care counseling have each been shown to improve clinical status and clinical outcomes. We aimed to evaluate the usefulness of exercise based in house cardiac rehabilitation in patients with heart failure with mid-range ejection fraction (HFmrEF) after myocardial infarction.
Patients and Methods: Out of 2253 patients who were admitted to our three weeks in- hospital secondary prevention program - exercised based cardiac rehabilitation, we analyze a total of 109 patients who were admitted early after coronary revascularization (percutaneus coronary interventions or coronary bypass surgery) with HFmrEF. The majority of patients were males (67%).R isk factors and co morbidities were noted. Patients were selected for exercise training after six minute walking testor exercise stress test (cardiopulmonary dominantly to evaluate unexpected exertional dyspnea) . After 3 weeks in house cardiac rehabilitation the patients were re-tested.
Results: The major comorbidities in our patient population were as follows: hypertension, diabetes and dyslipidemia. Six minutes walking test was performed and the total distance walked ranged from 120 to 480 meters and the beginning of the program. Patient had 7 -days a week training program. After the 3 weeks in hospital exercise rehabilitation the improvement in the test was ˜32%. Cardiopulmonary test showed also improvement of functional capacity.We noted several rhythm disturbance complications by telemetry (VES, SVES). None had acutisation of heart failure (with peripheral edema and congestion). All patients fulfilled cardiac rehabilitation program.
Conclusions: Supervised multidisciplinary cardiac rehabilitation program, including an individualized exercise component is effective and can improve functional status and exercise tolerance in patient with HFmrEF after myocardial infarction.

P1937

Erectile dysfunction: a forgotten determinant of cardiac rehabilitation program success

H Helena Nascimento[1]; A Rocha[1]; M Braga[1]; R Pinto[1]; M Tavares-Silva[1]; G Pestana[1]; P Araujo[1]; A Nunes[1]; S Torres[1]; J Rodrigues[1]; V Araujo[1]; F Parada[1]; MJ Maciel[1]

[1]Sao Joao Hospital, Porto, Portugal

Introduction: In order to improve cardiac rehabilitation program (CRP) success, it is of paramount importance to identify vulnerable groups of patients. Erectile dysfunction (ED) is a powerful indicator of cardiovascular risk and poor outcome. Therefore, our study main goal was to evaluate ED role as a predictor of functional capacity as a surrogate of CRP success.
Methods: From a registry of 840 consecutive patients (pts) enrolled in a cardiac rehabilitation program after an acute coronary syndrome (ACS), between 2008 and 2016, we studied the male pts. Sociodemographic and clinical data was prospectively collected. Depression was assessed using the HospitalAnxiety and Depression Scale (HADS) and ED through the 5-Questions International Index of Erectile Function (IIEF). ED was defined as an IIEF < 17.
Results: From a total of 637 male pts studied, ED was present in 300 patients (47%). Cardiac event was a ST-elevation ACS in 45.7% and a non-ST-elevation ACS in 54.3%. ED group of pts was significantly older (56.8 ± 9.4 vs. 52.0 ± 9.3 years-old, p < 0.001), has lower educational level (8.0 ± 4.6 vs. 9.1 ± 5.0, p = 0.005) and higher levels of HADS-depression (5.1 ± 3.9 vs. 3.6 ± 3.7, p < 0.001). Regarding the cardiovascular risk factor, hypertension and diabetes were significantly more prevalent in ED pts (p < 0.005). Also,coronary artery disease was more severe in this group (number of coronary vessel disease: 1.5 ± 0.8 vs. 1.3 ± 0.6, p = 0.001). In terms of functional capacity, the ED pts performed worse both at the beginning (METs 8.6 ± 2.3 vs. 9.5 ± 2.2, p < 0.001) and at the end of the CRP (METs 10.2 ± 2.0 vs. 11.4 ± 2.4, p < 0.001). Nevertheless, the CRP program significantly improved the functional capacity (degree of METs improvement 1.6 ± 1.8, p < 0.001) and reduced the HADS depression levels (1.1 ± 4.2, p = 0.014) in these pts.
Conclusion: ED is a highly prevalent condition inACS population and its impact on quality of life is undeniable. Moreover, it must be recognized as a predictor of poorer performance in CRP programs. Therefore, sexual function assessment should

integrate ACS patient evaluation,and tailored strategies ought to be conceived in order to achieve CRP success.

The role of the cardiac rehabilitation program in improving functional capacity

A Alzira Nunes[1]; P Maia Araujo[1]; H Nascimento[1]; M Braga[1]; R Pinto[1]; M Tavares Silva[1]; G Pestana[1]; A Rocha[2]; V Araujo[1]; M Belchior Campelo[1]; M Julia Maciel[1]
[1]Sao Joao Hospital, Cardiology Service, Porto, Portugal; [2]Sao Joao Hospital, Physical Medicine and Rehabilitation, Porto, Portugal

Introduction: The Cardiac Rehabilitation Programs (CRP) occupy a prominent position in the prevention of cardiovascular disease and in the control of its risk factors. A significant part of its effectiveness is due to its positive impact on the functional capacity (FC) of patients (pts), which results in a significant improvement in their prognosis.
Purpose: To assess the functional capacity of pts with ischemic heart disease undergoing a CRP over a 12-month follow-up.
Methods: We retrospectively analyzed pts who integrated the CRP between August 2008 and August 2016. We compared two groups of pts: those who maintained their FC and those who lost = 10% of their FC, taking into account the difference between the duration of the exercise testing at the end of the PRC and at the end of the 12-month follow-up. Then we performed univariate and multivariate analysis in order to found the predictors of that evolution.
Results: We recruted a total of 549 pts, 86.5% of whom were men, with an average age of 54 ± 9.8 years. In 49.1% of the cases, the diagnosis that led to hospitalization was an acute myocardial infarction with ST segment elevation. We performed a univariate analysis with sociodemographic, clinical and physical activity variables. The family history of coronary disease (p = 0.056), systolic function at the first echocardiogram (p = 0.055) and moderate physical activity in the 12-month review (p = 0.037) were identified as predictors of functional capacity loss. After a multivariate analysis, the previous history of coronary disease (p = 0.056) and the number of damaged vessels (p = 0.033) were the only predictors of this evolution.
Conclusions: This study reinforces the excellence of CRPs in the secondary prevention of cardiovascular disease by demonstrating that the majority of pts who integrate that ones show a significantly favorable evolution of FC. It is imperative to identify the different predictors of this outcome in order to enhance the effectiveness of the CRP.

P1939
Cardiac rehabilitation after an acute coronary syndrome: eight years of a real-life experience

M Marta Braga[1]; A Rocha[1]; H Nascimento[1]; P Araujo[1]; A Nunes[1]; S Torres[1]; R Pinto[1]; J Rodrigues[1]; V Araujo[1]; F Parada-Pereira[1]; MJ Maciel[1]
[1]Sao Joao Hospital, Porto, Portugal

Background: Cardiac rehabilitation programs (CRP) are essential interventions in secondary prevention of patients with acute coronary syndrome (ACS). Contemporary CRP includes baseline patient assessments, psychosocial and nutritional counselling, cardiovascular (CV) risk factor management, and exercise training. The purpose of this study was to describe the baseline characteristics and evaluate the impact of a CR in CV risk profile and functional capacity (FC) in patients after ACS.
Methods: We prospectively collected data from patients who underwent a CR program after an ACS, from 2008 to 2016. FC was assessed using a standard exercise test (ET), including exercise duration and intensity in metabolic equivalents (METs). We used paired sample T-Test to study the effect of a CR program.
Results: Among the 867 patients included, 85.1% were males. The mean age was 54.7 ± 10.0 years. About 16.2% were unemployed. Regarding to the prevalence of CV risk factors, hypertension was present in 42.7%, smoking in 54.3%, dyslipidemia in 60.2%, and obesity in 25.5% of patients. Mean LDL-cholesterol was 122.8 ± 38.9 mg/dL, while HDL-cholesterol was 41.6 ± 11.8 mg/dL. Mean body mass index was 27.8 ± 4.0. Only 18.8% of cohort were diabetic, and their mean glycated haemoglobin was 7.6 ± 1.5%. Main diagnosis of patients was ST-segment elevation myocardial infarction. Percutaneous myocardial revascularization (MR) was performed in 80.9% of patients, and only 8.4% of patients had been submitted to a surgical MR. Most patients had preserved left ventricular systolic function. The results of the first ET showed mean maximal ET duration of 8.4 ± 2.1 min and mean intensity of 9.0 ± 2.3 METs. Approximately 85% of the patients completed an exercise training, showing a statistically significant improvement of FC after the CRP. Final ET showed mean maximal ET duration of 10.2 ± 2.2 min and mean intensity of 10.7 ± 2.1 METs. After a CRP there was a significant reduction in LDL-cholesterol, and in mean body mass index. There was also a reduction in mean glycated haemoglobin in diabetic patients, as well as a tendency for increase in HDL-cholesterol (without statistically significance).
Conclusions: Patients with ACS had a high prevalence of CV risk factors. CRP had an important role in reduction of modifiable CV risk factors and improvement of FC , as wel as in reducing CV morbidity and mortality. This study emphasizes the need to increase referral of ACS patients to the CRP.

P1940
Left ventricle systolic dysfunction and physical training: efficacy of secondary prevention cardiac rehabilitation program

I Burazor[1]; R Sakurai[2]; M Moraca[1]; S Stevovic[1]; A Kovacevic[1]; Y Adler[3]
[1]Institute for Rehabilitation, Cardiology, Belgrade, Serbia; [2]International University of Health and Welfare, Tokyo, Japan; [3]Chaim Sheba Medical Center, Tel Hashomer, Israel

Secondary prevention based on cardiac rehabilitation (CR) exercise training programm and chronic heart failure (CHF) self-care counseling have each been shown to improve clinical status and clinical outcomes in CHF. The aim of this study was to evaluate the efficacy of exercise based in hospital cardiac rehabilitation in patients with left ventricle dysfunction
Patients and Methods: A total of 217 patients who were admitted to our three weeks in- hospital rehabilitation program, early after coronary revascularization (percutaneus coronary interventions or coronary bypass surgery) with ejection fraction below 40%. The majority of patients were males (60%). The oldest patient was 75 years of age. Ejection fraction below 25% was detected in 15%. We noted risk factors and co morbidities. Patients were selected for exercise training after six minute walking test (92%) or cardiopulmonary exercise test. After 3 weeks in hospital cardiac rehabilitation the patients were re-tested.
Results: The major comorbidities in our patient population were as follows: diabetes, hypertension, atrial fibrillation. Six minutes walking test was performed and the total distance walked ranged from 120 to 400 meters and the beginning of the program. Patient had 7 -days a week training program. After the 3 weeks in hospital exercise rehabilitation the improvement in the test was ˜33%. Cardiopulmonary test showed also improvement of functional capacity. We noted several rhythm disturbance complications by telemetry (VES, SVES) and when needed beta blockers were added. None had acutisation of chronic heart failure (with peripheral edema and congestion). The majority of patients fulfilled cardiac rehabilitation program (99%).
Conclusions: Supervised secondary prevention program based on exercise, including an individualized exercise component is safe and improve functional status and exercise tolerance in patient with left ventricle dysfunction after myocardial infarction.

Autoimmune/Chronic Inflammatory Disorders and Heart Disease

Familial dilated cardiomyopathy in a 32-year-old woman diagnosed with Mucolipidosis III Alpha/Beta by Whole Exome Sequencing

H W Lee[1]; SH Lee[1]; JC Choi[1]; JY Shin[1]; JH Ahn[1]; JS Park[1]; JH Oh[1]; JH Choi[1]; HC Lee[1]; KS Cha[1]; TJ Hong[1]
[1]Pusan National University Hospital, Department of Cardiology, Busan, Korea Republic of

Introduction: Familial DCMP is sometimes combined with systemic genetic syndromes. Among them, for the patients who have skeletal dysplasia, appropriate diagnostic examination should be performed.
Case Report: A 33-year-old woman was presented with cardiac arrest from ventricular fibrillation. She had been diagnosed with DCMP 2 years ago, but she stopped taking medicine for recent 8 months. Although she has been given optimal medication and implantable cardioverter/defibrillator (ICD) several months after resuscitation, her cardiac function remained severely decreased . She was listed for heart transplantation and get transplanted soon. Pathologic examination of explanted heart showed severely dilated left ventricle with severe fibrosis and some inflammatory change, but showed no remarkable coronary and valvular abnormalities. Clinical course after transplantation was good without complications. During hospitalization, a physician noticed her unique morphologic features. She had mild coarse face, low nose, large tongue, and claw hands with contracted major joints in upper and lower extremities. Her height and weight were 153cm and 56kg, respectively. But had no intellectual and sexual dysfunction. She had been treated with spinal surgery from unknown lumbar degenerative disease 8years ago. Her older sister was also diagnosed with DCMP and spinal disease at the age of 35, and died of sudden cardiac death. Turner and Noonan syndrome was ruled out by array Comparative Genomic Hybridization and genetic mutation test. Under the suspicion of mucopolysaccharidosis (MPS) I, diagnostic tests were done. Urine glycosaminoglycans test and a-L-iduronidase activity in serum was marginally diagnostic. Direct sequencing showed c.1898C>T (p.Ser633Leu) heterozygote mutation. Because

such heterozygote mutation was discovered in a patient who was finally diagnosed with MPS I, we started treatment for the patient with enzyme replacement therapy for several months. However, her mother and younger sister who were functionally and morphologically normal were known to have same heterozygote mutation with the patient. Therefore, we performed whole exome sequencing to diagnose genetic mutations which have correlation with familial DCMP and skeletal dysplasia. Heterozygote mutation in GNPTAB gene with c.2715+1G>A and c.3173C>G was found. Mucolipidosis III alpha/beta was finally diagnosed after confirmation of elevated plasma enzyme activity of arylsulfatase A and hexosaminidase, and not elevated plasma activity of ß-glucosidase. Since then, she has been treated with pamidronate. Summary:This is the case of familial dilated cardiomyopathy in a young woman diagnosed with mucolipidosis III alpha/Beta by Whole Exome Sequencing. If several test reveals not to be conclusive, whole exome sequencing may give additional information, and can be sometimes diagnostic as in this case.

P1942

Coronary artery calcium score in rheumatoid arthritis patients: associations with apolipoproteins and disease biomarkers

M Bernardes[1]; A Madureira[2]; A Oliveira[3]; MJ Martins[4]; R Lucas[4]; L Costa[1]; JG Pereira[3]; F Ventura[4]; I Ramos[2]; E Martins[4]
[1]Sao Joao Hospital, Rheumatology, Porto, Portugal; *[2]Sao Joao Hospital, Radiology, Porto, Portugal*; *[3]Sao Joao Hospital, Nuclear Medicine, Porto, Portugal*; *[4]University of Porto, Faculty of Medicine, Porto, Portugal*

Aims and Methods: In rheumatoid arthritis (RA), cardiovascular (CV) comorbidities are a major cause of mortality. Coronary calcium score (CCS) assessed by computed tomography has been associated with RA prognosis. In this work, we aimed to assess CCS in RA patients and determine their associations with different clinical, laboratory and imaging disease parameters.
Results: We evaluated 78 patients, with a mean age of 53.4 ± 11.1 years, 76. 9% females, with a mean Disease Activity Score (DAS28) four variables (4v) and Stanford Health Assessment Questionnaire (HAQ) of 4.359 ± 1.309 and 1.375 ± 0.664, respectively, and disease duration of 14.1 ± 9.9 years.
Mean CCS value was 46.133 ± 122.892. CCS > 10 was significantly associated to CV risk factors [age (OR= 1.076; p = 0.004), BMI = 30 Kg/m2 (OR= 0.072; p = 0.017), HDL (OR= 0.016; p = 0.015), LDL/HDL ratio (OR= 1.767; p = 0.045), apolipoprotein A1 (ApoA1) (OR = 0.970; p = 0.009); apolipoprotein B/ApoA1 (ApoB/ApoA1) ratio (OR= 28.657; p = 0,011), homocysteine (OR= 1.176; p = 0.038), statins use (OR = 3.413; p = 0.03) and diabetes (OR= 13.429; p= 0,019)], disease activity [C Reactive-Protein (CRP) (OR= 1.046; p = 0.022), DAS(4v) (OR= 1.584; p = 0.019) and modified Sharp/van der Heijde Score (SHS) erosion score (OR= 1.012; p = 0.018)], biomarkers [(Dkk-1 (OR = 1.014; p = 0,017) and osteoprotegerin (OR= 1.381; p = 0.031)], bone mineral density [femoral (OR = 0.012; p = 0,014), lumbar spine (OR = 0.009; p = 0,006)] and osteoporosis (OR = 5.476; p = 0,012). After adjustment for age, gender and BMI, significant associations were maintained with ApoA1, ApoB/ApoA1 ratio, statins use, CRP, DAS(4v) and Dkk-1.
Conclusions: Our work reinforces the hypothesis that in RA, CCS may be a useful tool in cardiovascular risk assessment, particularly valuable in poorer controlled patients with certain lipoprotein profile.

P1943

Heart failure needs to be ruled out in HIV-infected patients on antiretroviral therapy

M Maria De Las Nieves Montoro Lopez[1]; C Soto[2]; I Ponz[1]; JJ Rios[2]; G Guzman Martinez[1]
[1]University Hospital La Paz, Department of Cardiology, Madrid, Spain; *[2]University Hospital La Paz, Internal Medicine, Madrid, Spain*

Background: Highly active antiretroviral therapy (HAART) has greatly improved life expectancy among HIV-infected patients, nevertheless, cardiovascular disease has become its first mortality cause in high-income countries. It is known that HIV-patients present higher risk of coronary artery disease but there is scarce data about the prevalence of symptomatic heart failure due to HIV-related cardiomyopathy in the HAART era.
Methods: We conducted a prospective observational study in a tertiary hospital in Spain. A randomized sample of HIV+ outpatients on HAART was selected from the specialized HIV clinic. We performed a test of dyspnoea to select symptomatic patients, in whom we determined NT-proBNP levels, considering positive a value above 125 pg/mL. Patients underwent a transthoracic echocardiogram (TTE) to assess the left ventricle (LV), the right ventricle (RV) and to rule out pulmonary hypertension (PH).
Results: A total sample of 75 HIV+ patients on HAART with dyspnoea was analysed (median age 47y, male 74%; smokers 54%; years on HAART-mean- 15.5; Hepatitis C virus 51%). Ten patients (13%) showed NT-proBNP levels above the upper limit. Out of them, five cases (7%) were diagnosed with either HF or PH: one case mild LV systolic and diastolic dysfunction (DD); one case LV hypertrophy and DD; two cases RV systolic dysfunction (one of them associated with PH); and one case was compatible with isolated HIV-related PH. Five did not present significant cardiac disease by TTE (table).
Conclusion: In our sample of symptomatic HIV+ individuals in routine follow-up, 7% were diagnosed with either HF due to HIV-related cardiomyopathy or PH. Furthermore, this proportion could have risen up to 13% if more sophisticated cardiac tests had been undertaken. This result reinforces the need of cardiac screening protocols and collaboration between cardiologists and HIV-specialists in order to improve the prognosis of this vulnerable population.

Development of providing care of heart failure patients who are in need of extra support

NP Kato[1]; N Takayama[2]; J Iwaki[3]; E Nogami[3]; K Kinugawa[4]; T Jaarsma[1]
[1]Linkoping University, Department of Social and Welfare Studies, Linkoping, Sweden; *[2]University of Tokyo Hospital, Department of Nursing, Tokyo, Japan*; *[3]University of Toyama Hospital, Department of Nursing, Toyama, Japan*; *[4]University of Toyama, The Second Department of Internal Medicine, Toyama, Japan*

Funding Acknowledgements: Lindhés Advokatbyrå AB

Background: Some heart failure (HF) patients do not fit the standard HF management model and might be in need of extra support, for example patients with cognitive disorders, patients with frequent readmissions for HF, and patients with a low level of health literacy.
Purpose: The purpose of this study was to summarize nurses' opinions about how to take care of HF patients who might be in need of extra support.
Methods: The study used an explorative, descriptive design. Two focus group discussions were performed in Japan, including a total of 19 nurses who took care of HF patients. Three cases were discussed: (1) a patient (87 years old, female) with cognitive disorders who lives alone, (2) a patient (91 years old, male) with frequent readmissions due to HF who lives with an elderly family caregiver, (3) a patient (82 years old) with low health literacy who lives alone. The focus groups were led by a moderator and an interview guide was used with questions addressing the care needed, the role of family members and health care professionals and possible use of information and communication technology (ICT) as a tool to support patient's self-care. Data was analysed using qualitative content analysis.
Results: The opinions about how to take care of HF patients who might be in need of extra support could be summarized into four categories, namely 'share goals with patients and their family', 'tailor-made self-care support', 'effective resource utilization' and 'manage social support' The category 'shared goals' included two sub categories: share treatment/care goals and share life goals, describing especially found important for an elderly patient who had frequent HF readmissions. The second category 'tailor-made self-care' included suggestions for the help for taking medication , symptom monitoring, and a healthy balanced diet and these were considered to be relevant in all three cases. A third category 'effective resource utilization' described use of social service (e.g., food delivery service) and healthcare service (e.g., continuous support by home visit nurses and/or outpatient clinics). The fourth category 'manage social support' described a need for social connection and collaboration with other family members. Some nurses thought that ICT would not work for these HF patients with special needs, but other nurses thought that it was up to the ICT devices whether the ICT could support patient's self-care.
Conclusions: HF nurses had specific and dedicated ideas on adaptation of HF management models for patients with special needs. Suggestions included sharing goals with patients and their family, tailoring self-care support, use and develop existing and available resources effectively and to manage social support.

P1945

A new tool to promote preventive behaviours in patients at risk of heart failure.

A Annamaria Bagnasco[1]; M Zanini[1]; G Catania[1]; G Aleo[1]; L Sasso[1]
[1]University of Genoa, Health Sciences, Genoa, Italy

Background. Nurses play an important role in helping patients improve self-management, make sure they confidently and safely manage therapy at home, and consequently contribute to reducing readmissions and costs. We identified the Barrows Cards method, originally used to test decision-making skills and critical thinking in medical students. In this study, we designed a new tool to improve preventive behaviors in patients at risk of developing heart failure.

Purpose: To develop and validate a tool to educate patients already affected by some form of heart disease, but without cardiac structure alterations, to avoid risk behaviours, identify risk factors (e.g. hypertension, diabetes, obesity) and safely manage cardiotoxic drugs at home.
Methods. The Barrows Cards-also known as the 'Portable Patient Problem Pack'-uses a situational card that describes a complex problem and learners can choose from a deck of at least 15 cards each of which describes a possible solution to that problem with the support of a picture. The Barrows Cards method is based on problem-based learning, and we applied this to patients to improve self-management and preventive behaviours through therapeutic education.
Two focus groups with 15 cardiac nurses were conducted to identify the educational competencies to include in the HF Prevention Barrows Cards.
The instrument development and validation process included the following steps:
1) A review of the literature to retrieve scientific evidence to support the purpose of our study.
2) Obtaining support and advice from a group of cardiologists.
3) Obtaining support and advice from a psychologist with regard to the sentences to include in the cards.
4) Checking the nursing records of 30 patients at risk of heart failure.
5) Using a short questionnaire to obtain feedback from patients on their level of satisfaction with the statement and picture on each card in terms of clarity and appropriateness.
6) Check the efficacy of the tool in correcting risk behaviours.
Results: This tool was successfully tested on 30 heart failure patients and all the indications that emerged from the test have been applied in corrective terms and an updated version is currently being tested.
The Barrows Cards aroused in HF patients a good level of interest and compliance, consequently contributing to a higher level of self-care educational efficacy. This was confirmed a reduced number of calls and accesses to the cardiology outpatients clinic requiring major information about drug treatment.
Conclusion: Despite the benefits provided by the new systems that evaluate the ability to prevent risks, there are still important issues linked to the incorrect management of patients at risk of heart failure and who live at home. Therapeutic patient education performed by nurses based on a validated structured model such as the Barrows Cards, can significantly contribute to improve outcomes in vulnerable chronic populations, such as patients with heart diseases.

P1946
Adhere risk model in a public healthy institution in brazil: preliminary data

E R Eneida Rejane Rabelo-Silva[1]; D De Souza Bernardes[1]; C Wahast Avila[1]; C Mirapalheta Ernandes[2]; MA Lumertz Saffi[1]; L Lopez Pedraza[1]
[1]Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Program at the Nursing School, , Porto Alegre, Brazil; *[2]Hospital de Clínicas de Porto Alegre, Multidisciplinary residency, Porto Alegre, Brazil*

Introduction: Patients admitted for acute decompensated heart failure (ADHF) are likely to develop episodes of worsening during hospitalization that require more complex interventions, such as inotropic drugs and / or intravenous vasodilators, or transfer to intensive care units. In this sense, the ADHF requires careful evaluation in the first hours of hospital admission, a practice that is often performed by screening nurses. The "ADHERE risk model" is a score that predicts risk of worsening in-hospital in patients with ADHF. In Brazil, this score has not yet been used in studies.
Objective: To apply the "ADHERE risk model" risk prediction model in hospitalized patients.
Methods: A cohort study conducted in a public and university hospital in Brazil from January 2013 to October 2017 through a retrospective collection in a database of electronic medical records. Data on clinical, laboratorial and sociodemographic variables were extracted at the time of admission. Subsequently, the "ADHERE risk model" was applied, which designated the sample risk. The patients were followed up during hospitalization, in order to verify if some group became worse according to the prediction of the score.
Results: A preliminary analysis of 673 patients from a sample estimated in 1234 was performed. The predicted risk model showed that 320 (47.5%) of the included patients presented risk of developing a worsening of the ADHF during long hospitalization. Of these, 156 (49%) actually worsened ADHF during hospitalization, while in the non-risk group, 271 (77%) of the patients did not develop worsening ($p < 0.001$). Based on the risk estimate, the at-risk group had 3.14 (2.2 - 4.3, 95% CI) times greater risk of worsening of ADHF compared to the non-risk group. Comorbidities, mortality and length of hospital stay were associated with clinical worsening in-hospital.
Conclusion: Preliminary data indicated that the score was shown to be applicable to identify patients at risk of worsening of ADHF. Approximately 50% of the at-risk cases evolved to worsening in-hospital. Only mortality was significant for patients who developed worsening in both groups. The group with risk of in-hospital worsening presented longer hospitalization time.

P1947
Home visits for a cohort of heart failure patients who otherwise could not attend a heart failure clinic, an observation of their management after referral for home visit.

B Bronagh Travers[1]; C Keane[2]; R O Hanlon[3]; P Campbell[1]; S Zhou[2]; M Ledwidge[2]; K Mcdonald[1]
[1]St. Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland; *[2]Heart Failure Unit, Dublin, Ireland*; *[3]Blackrock Clinic, Dublin, Ireland*

Background: Heart failure (HF) is a chronic disease which affects 2% of population, prevalence increases with age . Aging, co-morbidities and or progression of HF, mean some patients find it increasingly difficult to attend hospital appointments for management of HF. Home visits are provided to a small cohort of patients who require nursing home care, lack family support or physically cannot attend HF service.
Method: This observational report looks at a group of HF patients (82) diagnosed with HF either following admission to hospital with ADHF (24.3%) or are referred using other pathways, for diagnosis and management of HF. As a result of aging, increased care requirements, progression of HF or other chronic diseases, a percentage of our patients, who otherwise would refuse follow-up are offered home visits from a HF Nurse Specialist.
Results : Over a five year period, 82 patients have benefitted from home visits, (48 female (49%), 37 (45%) HF with reduced ejection fraction (HFREF). NYHA Class II 10 (12%) at time of referral to home visits. Mean age at time of first review in HF Unit 81.63 years $\pm$ -9.03 and mean age at time to referral for home visits 84.79 $\pm$ -9.02. Mean follow-up from time of referral to service 3.8 years (1-14). Thirty (36.5%) patients required input from specialist palliative care services for management of HF symptoms. In total, 29 (35%) patients died, of these 20 patients (24%) had input from specialist palliative care services, the remainder for non- HF related reasons. Over the five year period, 8 (9.7%) patients were readmitted with one ADHF admission, 5 patients (6%) had more than 2 ADHF admissions. Twenty seven patients (32%) required at least one additional visit, 9 (10.9%) required more than two additional visits and 5 (6.09%) patients required more than 3 home visits outside of routine reviews for further management of their HF symptoms. At time of initial referral to HF service, 9 (10%) were on diuretic, with 72 (87 %) requiring diuretics at time of referral to home visit. Changes in BNP by more than 100pg/ml increased in 9 patients (36%).
Conclusion: A complex cohort of HF patients who otherwise would not be able to continue their link with specialist HF service can be managed at their place of residence, maintaining continuity of care with HF service and quality of life.

P1948
Prediction of risk and diagnostic accuracy in nursing in patients hospitalized for decompensated heart failure

E R Eneida Rejane Rabelo-Silva[1]; C Mirapalheta Ernandes[2]; D De Souza Bernardes[1]; L Lopez Pedraza[1]
[1]Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Program at the Nursing School, , Porto Alegre, Brazil; *[2]Hospital de Clínicas de Porto Alegre, Multidisciplinary residency, Porto Alegre, Brazil*

Introduction: The risk model of the Acute Decompensated Heart Failure National Registry (ADHERE) is a risk prediction model for in-hospital worsening heart failure. In many referral centers, a screening of patients in ready care is performed by nurses. It would be interesting if nurses could combine the use of a score with their clinical evaluation in order to improve their clinical reasoning in the establishment of nursing diagnoses.
Objective: To analyze the diagnostic accuracy in nursing in patients with predicted risk of clinical worsening during hospitalization for acutely decompensated heart failure (ICAD).
Methods: A total of 43 patients were analyzed through an electronic medical record in a retrospective cohort, hospitalized by ICAD in a public university hospital, Brazil (period 2013-2017), which presented a clinical health risk defined by the ADHERE risk model. After the application of the escore and definition of the patients at risk, the Accuracy Scale of Nursing Diagnostics version 2 (EADE v.2) was applied to the nursing diagnoses established during the first 24 hours of hospitalization. The EADE v.2 evaluates and points out the diagnostic accuracy from the analysis of clues (signs and / or symptoms), specificity, relevance and consistency of these, at the end is added the score to establish the category of accuracy: null, low, moderate or high of confirmed diagnoses.

Results: Of the patients with risk of worsening, 22 (51%) did not worsen and 21 (49%) worsened; in both patients with a moderate / high quality diagnosis in 22 (89%) and 16 (88%) of the nursing diagnoses, respectively. The established nursing diagnoses were ineffective respiratory pattern in 27 patients, with 21 (78%) in the High category and 15% in the Moderate accuracy category. Cardiac output decreased and Excess fluid volume was 100% in the high accuracy category with seven and two patients, respectively. Ineffective tissue perfusion: cardiopulmonary with 57% in the category of High Accuracy.
Conclusions: These data allow to conclude with patients with ICAD and risk of clinical worsening during hospitalization are identified with good diagnostic accuracy by nurses. This enables effective planning of interventions.

P1949
Development and implementation of an integrated diagnostic and therapeutic care model for outpatients with pulmonary hypertension

DL Vadala'[1]; C Bessone[1]; C Piccinino[1]; S Miccioni[1]; C Clementi[1]; J Zanaboni[1]; A Dimagli[1]; A Ailia Giubertoni[1]; PN Marino[1]
[1]*Hospital Maggiore Della Carita, Cardiology, Novara, Italy*

Introduction: Pulmonary hypertension (PH) is a severe life-limiting disease. Guidelines recommend early diagnosis for a timely menagement that has proven to be effective in improving prognosis. They also recommend a multidisciplinary approach wich should be referred to an expert centre.
Purpose: To explore the roles of nurses in optimising a patient-centred multidisciplinary model care.
Methods: Patients are referred to our centre because at high risk of developing PH or because already followed-up. The naive patients are recruited by a dedicated specialised nurse who calls back patients in less than 24-48 hours after voicemail or electronic mail massages. She arranges the meeting, provides informations on how they can access the centre and the procedures she planned. The diagnostic pathway includes many interdisciplinary activities previously scheduled in hourly time windows, ending in a clinical summary of findings. Specifically, they undergo comprehensive clinical evaluation including EKG and physical examination, a 6 minute walk test, conventional transthoracic echocardiography, pulmonary function tests (PFTs), gas transfer analyses - diffusion lung CO (DLCO), arterial blood gases and chest X-ray, evaluation of brain natriuretic peptide (BNP). The nurse herself does some tests and works the whole time alongside the medical equipe. All results are stored in a dedicated database. The patients already in specific therapy are enrolled in a nursing telephone follow-up. The nurse ensures that informations to patients and care-givers are updated and plans next meeting. This model has been implemented since 2014.
Results: We recruited 386 patients, 47 new patients in 2017. In 21 cases we started a telephone follow-up. The planned pathway enabled patients to udergo a thorough diagnostic assessment including at least 8 tests and final report in a single day. This policy avoided multiple access to hospital laboratories, provided a better selction of patients to address to right heart catheterization and offset unplanned hospital admissions.
Conclusions: A medical-nursing unit model with the help of an integrated computerised system would allow a higher qualified and more timely diagnostic and therapeutic approach in patients with PH.

P1950
Impact of standardized therapeutic hypothermia protocol on neurological performance after resuscitation from cardiac arrest

T Okasha[1]; W Morsy[1]; H Zaghla[2]
[1]*Cairo University, Critical care and emergency nursing department, Cairo, Egypt*;
[2]*Cairo University, critical care medicine, Cairo, Egypt*

Background: Cardiac arrest remains one of the most dramatic, unexpected, and life threatening events worldwide. Survival and neurological outcome vary widely.Current evidence supports that induction of therapeutic hypothermia in selected patients after cardiac arrest can improve neurological outcome.
Aim: The aim of the study is to evaluate the impact of standardized therapeutic hypothermia protocol on neurological performance after resuscitation from cardiac arrest.
Research hypothesis: Post cardiac arrest patients with GCS score of less than (8) and who will be exposed to therapeutic hypothermia protocol will exhibit improvement in their neurological performance.
Sample:Purposive sample of 17 patients who were fulfilling the inclusion criteria. Design:Quasi-experimental design was used in this study.Setting:critical care units at AlkasarAlaini hospitals.
Tools: Demographic and medical data sheet, Post cardiac arrest health assessment sheet, Bedside Shivering Assessment Scale (BSAS), and Glasgow Pittsburgh cerebral performance category scale (CPC).Result: the mean age was 53 years, 47.1% were arrested because of cardiac aetiology. 35.3% with initial arrest rhythm VT, 23.5% with VF, and 29.4% with A-Systole. a favorable neurological outcome was seen among 70.6% (CPC of 1-2).there was significant difference in WBC, Platlets, PaO2, PaCo2, HCo3, RBS. There was significant difference in ventilator hours across the CPC categories. Initial arrest rhythm, aetiology of cardiac arrest, and shivering status were significantly correlated with CPC
Conclusion: therapeutic hypothermia has positive effects on neurological performance among post cardiac arrest patients with GCS score of less than (8).
Key wards: therapeutic hypothermia, neurological performance, cardiac arrest.

Segmental analysis of longitudinal contractility in assessing left ventricular function

A Alexey Kuchmin[1]; EP Galova[1]; MV Zubakova[1]; DA Galaktionov[1]; KB Evsukov[1]; AA Kazachenko[1]; DY Epelshtein[1]
[1]*The Kirov Military Academy, St-Petersburg, Russian Federation*

Background: Speckle tracking is an important method in assessing left ventricular function along with ejection fraction and parameters of diastolic function. To date the contribution of different segments to the systolic and diastolic functions of the left ventricle has not been studied sufficiently.
Purpose: evaluation of the role of various segments of the left ventricle in the performance of left ventricle systolic and diastolic function in healthy individuals.
Methods: 56 volunteers without signs of cardiovascular pathology, 48 men and 8 women, mean age 33.6 ± 9.3 years were examined. All patients underwent an echocardiographic study using the GE "VividE95" device (USA) in accordance with the recommendations of the European echocardiographic association and the American echocardiographic society. The analysis of longitudinal deformations of the myocardium was carried out, which was determined by the percentage of shortening of the fibers in each segment of the left ventricle, and was visualized on the device with the help of the "bull's eye" technique.
Results: Based on the results of the correlation analysis, the magnitude of longitudinal deformation in the lower-septal segments (3 and 9) correlated with the thickness of the interventricular septum ($r = -0.46, -0.44$, respectively, $p < 0.05$), the thickness of the posterior stack ($r = -0.45$, $p < 0.05$), myocardial mass index ($r = -0.41, -0.44$, respectively, $p < 0.05$), as well as the anterior-posterior size of the LP ($r = -0, 4, -0.48$, respectively, $p < 0.05$).
A negative correlation was found between the left ventricular ejection fraction and the longitudinal strain in the basal anterior-septal (2), basal lower-septal (3), lower basal (4), basal lower-lateral (5), medial lower septal (9) and lower medial (10) segments ($r = -0.24, -0.30, -0.21, -0.19, -0.34, -0.21$, respectively, $p < 0.05$).
Also, correlated with each other, the parameters reflecting the diastolic function of the left ventricle with the values of longitudinal deformation in the segments 2, 3, 4, 9, 10. Moreover, if the correlation was positive for the indicator E '($r = 0.56$, $p < 0.05$), then for E/E 'connection it was negative ($r = -0.52$, $p < 0.05$).
It is important to note that almost all the segments except the basal anterior-septal part comprise the heart area, which is blood supplying from the right coronary artery system.
Conclusions: Not all segments of the left ventricular myocardium have the same effect on the pumping function of the heart. According to our data, the smallest value to healthy individuals has segments of the left ventricle, blood supplying the right coronary artery. The revealed correlation links between the index of longitudinal deformation and the parameters of diastolic function of the heart confirm the relationship between the processes of contraction and relaxation of the myocardium.

P1952
Increased interleukin 6 levels at 24 hours after ST-elevation myocardial infarction are associated with decreased cardiac function at 4 months

HE Hilde Groot[1]; L Al Ali[1]; ICC Van Der Horst[2]; E Lipsic[1]; DJ Van Veldhuisen[1]; JC Karper[1]; P Van Der Harst[1]
[1]*University Medical Center Groningen, Cardiology, Groningen, Netherlands*;
[2]*University Medical Center Groningen, Critical Care , Groningen, Netherlands*

Introduction: Inflammation is considered to be an important player in the pathogenesis of ischemic heart failure (HF). However, the exact mechanism remains to be elucidated. We would like to focus on the role of the interleukin 6 (IL-6) cascade in the development of HF.
Purpose: In order to provide more insight we aimed to investigate the time course and the association of members of the IL-6 cascade (IL-6, soluble IL-6 receptor

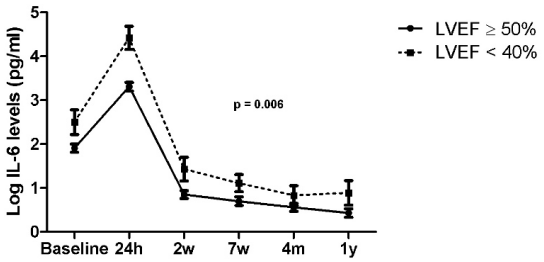
(sIL-6R), soluble glycoprotein 130 (sgp130)) with IS and cardiac function measured at 4 months after ST-elevation myocardial infarction (STEMI).

Methods: In 379 consecutive STEMI patients of the GIPS-III trial IL-6, sIL-6R, and sgp130 levels were measured at baseline, 24 hours, 2 weeks, 7 weeks, 4 months, and 1 year post-PCI. In multivariate models sex, age, BMI, hypercholesterolemia, TIMI (pre- and postintervention), MBG, and ischemic time were included. At 4 months, IS and left ventricular ejection fraction (LVEF) were assessed by magnetic resonance imaging and the ratio of transmitral early flow to early mitral annulus velocity (E/e') was determined by echocardiography'. A 2-tailed p-value of < 0.005 was considered significant. P-value between 0.05 and 0.005 was considered suggestive.

Results: Baseline levels of IL-6, sIL-6R, sgp 130 were 3.7 pg/ml (IQR 2.1 - 6.7 pg/ml), 51.6 ng/ml (IQR 37.3 - 69.0 ng/ml), and 332 ng/ml (IQR 280 - 399 ng/ml) respectively. At 24 hours IL-6 had increased threefold compared to baseline ($p < 0.001$) and subsequently decreased to 1.8 pg/ml (IQR 1.1 - 2.9; $p < 0.001$) at 2 weeks. sIL-6R and sgp130 levels at 24 hours stayed at the same level compared to baseline, and increased at 2 weeks. All biomarkers remained stable between 2 weeks and 1 year.

Regarding the association of biomarkers and IS/cardiac function at 4 months, IL-6 and sIL-6R/IL-6 ratio measured at 24 hours after myocardial infarction, remained independently associated with IS (ß 5.4 (95% CI 3.3 - 7.5); $p < 0.001$, ß -4.0 (95% CI -6.1 - -1.9); $p < 0.001$, respectively). Also, the Q4 of IL-6 at 24 hours remained significantly associated with reduced LVEF after adjustment (ß -4.2 (95% CI -6.7 - - 1.8); $p = 0.001$). Over time course, sIL-6R/IL-6 ratio was lowest in patients with systolic and diastolic dysfunction, measured by LVEF and E/e', compared to other patients ($p = 0.003$; $p = 0.005$ respectively). IL-6 was suggestively higher in these patients (systolic dysfunction: $p = 0.006$; diastolic dysfunction: $p = 0.013$ respectively) (Figure 1). We did not find significant associations with E/e', or associations between sIL-6R levels or sgp 130 alone with either IS or cardiac function, although suggestive associations were observed.

Conclusion: IL-6 and sIL-6R/IL-6 ratio at 24 hours after STEMI are strongly independently associated with IS and cardiac function at 4 months.



Log IL-6 levels in STEMI patients

Cardiac allograft vasculopathy: the way for early diagnosis

M Marzia Cottini[1]; FB Fabio Sbaraglia[2]; VB Vitaliano Buffa[2]; PLM Paola Lilla Della Monica[2]; GDS Giada Distefano[2]; AP Amedeo Pergolini[2]; VP Vincenzo Polizzi[2]; FM Francesco Musumeci[2]

[1]University of Insubria, Department of Surgical and Morphological Sciences, Cardiac Surgery Unit, Varese, Italy; *[2]San Camillo Forlanini Hospital, Rome, Italy*

Background: CAV limits long-term survival after heart transplantation, and screening for CAV is generally performed on an annual or biannual basis. It is usually detected by CCA. CCTA is currently not recommended for CAV screening due to the limited accuracy reported by early studies. Technological advances such as 64-slice dual-source CCTA might justify re-evaluation of this recommendation.

Methods: A retrospective, observational analysis has been conducted on 90 consecutive patients undergone cardiac transplantation at the Cardiac Surgery and Heart Transplant Unit of S. Camillo Forlanini Hospital in Rome, from January 2001 to December 2017. 196 CCTA scans were performed with a multisegment reconstruction in a minimum interval time of 2,7 months (mean time $32,5 \pm 15,1$ months) on the other hand the CCA minimum interval time was 1 month (mean time $9,5 \pm 13,7$ months) after heart transplantation. We considered significant CAV any identifiable plaque at CCTA and any stenosis >50% of the coronary lumen at CCA.

Results: The mean age of the population was $48,3 \pm 12,4$ years (age range 16-67 years), males 74.5% (n = 67), females 25.5% (n = 23). The mean time from heart transplant was $8,32 \pm 4,78$ years. The incidence of CAV in our group was 20%, (n = 18) with mean age $44,9 \pm 11,7$ years, males 80% (n = 12), and mean time from heart transplantation $14,83 \pm 7,93$ years. We evaluated a total of 1991 coronary artery segments with a axial image reconstruction of 0,75 mm slice thickness. CCTA versus CCA showed a mean sensitivities of 98,2% and 95%, specificities of 98.5 and 94.1%, a negative predictive value (NPV) of 98.1% and 99% and a positive predictive value of 87.1% and 88%, respectively.

Conclusions: In clinical practice CCTA could be a valid alternative to coronary angiography for detection of CAV and our experience documented a reliable data of CCTA quality in detection CAV versus CCA.

Funding Acknowledgements: Fapesp São Paulo SP

Left ventricle (LV) may have anatomic and functional alterations secondary to right ventricular hypertrophy.Objective To analyze the anatomical and functional characteristics of the LV in rats with pulmonary artery banding(BAP).
Methods: Wistar-EPM rats were submitted to BAP (BAP = 69 animals) to produce right ventricular hypertrophy (RV) or sham procedure (controls, 56 rats). From 72hours, 2,4,6 and 8 weeks after the procedure, the animals were submitted to echocardiogram(echo)to identify RV hypertrophy and to analyze (LV) echo variables and later to invasive hemodynamic study of the LV and RV. Analysis with mean, standard deviation, and t-test or Wilcoxon; significant if $p < 0.05$.
Results: in the Echo analysis, there was a difference between sham and BAP in the wall thickness (0.12cm, 0.15cm), diastolic diameter (0.76cm, 0.73cm)in D% of the diameters (46.9 %, 49.1%) and in the isovolumic relaxation time TRIV (0.03 sec: 0.06 sec). At catheterization, there was difference between sham and BAP in dP/dt(+) (8745 mmhg: 7801 mmhg) and in dP/dt(-) with (6422 mmHg: 5615 mmHg).
Conclusion: Despite of all these differences, statistical significance was found only in the variable TRIV of the echo. Echo and catheterism at this evaluation did not present a significant performance to characterize structural and functional alterations of the LV in the proposed BAP model in rats.

Adult sox10+ cells contribute to myocardial regeneration in the zebrafish

M Marcos Sande[1]; IM Ines Marques[1]; MG Maria Galardi[1]; NM Nadia Mercader[1]
[1]University of Bern, Developmenta Blology and Regeneration, Bern, Switzerland

During heart regeneration in the zebrafish, fibrotic tissue is replaced by newly formed cardiomyocytes that derive from pre-existing ones. It is unclear whether all cardiomyocytes have an equal capacity to replace lost myocardium. In opposition to mammals, sox10+ neural crest cells were proposed to contribute to the embryonic zebrafish myocardium. Here we examined the contribution of sox10-derived cells to the adult heart. Embryonic sox10-derived cardiomyocytes persisted in adult hearts but did not participate during regeneration. Surprisingly, a resident sox10+ cell pool in the adult heart expanded massively after cryoinjury. Inhibition of collagen maturation impaired this cell expansion and blocked heart regeneration. Finally, genetic ablation of sox10+ cells severely impaired cardiac regeneration. Thus, our results show that rather than being detrimental, transient fibrosis is necessary for regeneration and that sox10 marks a subset of cardiomyocyte with high regenerative potential.

P1956

Relationship between polymorphism of NOS3 gene and primary cardiac conduction disorders

A Anna Chernova[1]; S YU Nikulina[1]
[1]Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation

Background: Inherited cardiac conduction diseases (CCD) are rare but are caused by mutations in a myriad of genes. Nitric oxide (NO) derived from endothelial NO synthase (NOS3) plays a central role in ??D. Nitric oxide is a reactive free radical which acts as a biologic mediator in several processes, including neurotransmission and cardiac activities. Nitric oxide is synthesized from L-arginine by nitric oxide synthases. Multiple transcript variants encoding different isoforms have been found for this gene.
Material and Methods: A family examination was performed in 69 patients with atrioventricular block (AVB). The control group consisted of 220 patients without clinical ECG manifestations of cardiac diseases. All the examinees have undergone ECG, echocardioscopy, electrophysiological examination of the heart.
Results: by results of research it is established that the frequency of carriers of a homozygous genotype on rare allel (4b/4b) among patients with AVB (26,1% ± 5,3) was higher in comparison with control selection (3,2% ± 1,2). The obvious tendency to decrease in carriers of a homozygous genotype on extended allel (4a/4a) among patients with AVB (47,8% ± 6,0) in comparison with group of control (71,4% ± 3,0) is also noted.
Conclusions: In this work we for the first time revealed on clinical - genetic material association between hereditary disturbances of cardiac conduction, such as AVB and polymorphism of NOS3 gene.

Relationship between polymorphism of Connexin40 gene and primary sick sinus syndrome

A Anna Chernova[1]; S YU Nikulina[1]
[1]*Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation*

Background: Sick sinus syndrome refers to a collection of disorders marked by the heart's inability to perform its pacemaking function. Predominantly affecting older adults, sick sinus syndrome comprises various arrhythmias, including bradyarrhythmias with or without accompanying tachyarrhythmias. Intrinsic causes include degenerative fibrosis, ion channel dysfunction, and remodeling of the sinoatrial node.
Material and Methods: A family examination was performed in 67 patients with sick sinus syndrome (SSS). The control group consisted of 615 patients without clinical ECG manifestations of cardiac diseases. All the examinees have undergone ECG, echocardioscopy, electrophysiological examination of the heart.
Results: by results of research it is established that the frequency of carriers of a homozygous genotype on rare allel (44AA) among patients with SSS (35,8 ± 5,9) was higher in comparison with control selection (4,7 ± 0,9). The obvious tendency to decrease in carriers of a homozygous genotype on extended allel (44GG) among patients with SSS (22,4 ± 5,1) in comparison with group of control (57,1 ± 2,0) is also noted.
Conclusions: In this work we for the first time revealed on clinical - genetic material association between hereditary SSS and polymorphism of Connexin40 gene.

Genotypes:	SSS (n = 67)	Control group (n = 615)	?

Background: Gender differences have been intensively investigated during the development of pressure overload-induced left ventricular (LV) myocardial hypertrophy (LVH). However, it is less clear whether female sex also affects the regression of LVH after pressure unloading therapy.
Purpose: In the present study we aimed to investigate the effect of gender on myocardial reverse remodeling following pressure unloading in male and female rats utilizing a rat model of banding and debanding of the abdominal aorta.
Methods: Pressure overload of the left ventricle was induced in male (M) and female (F) Sprague-Dawley rats by abdominal aortic banding (AB) for 6 or 12 weeks. Sham operated animals served as controls. Pressure unloading was evoked by removing the aortic constriction after week 6 (debanded). Serial echocardiography and LV pressure-volume analysis was performed to assess the morphological and functional alterations. In addition, histological and molecular biological measurements were also carried out.
Results: In male (M) and female (F) AB groups, development of LVH at a similar extent was confirmed by increased left ventricular mass, heart weight-to-tibial length ratio (HW/TL) and cardiomyocyte diameter (CD). On the functional level, LVH was associated with diastolic dysfunction in both genders. However, impairment of systolic function could be only detected in male aortic-banded rats. In contrast to the sex-dependent differences in LVH, removal of the aortic constriction resulted in a similar morphological (HW/TL: 0.38 ± 0.01 debanded-M vs. 0.47 ± 0.01 AB-M, $p < 0.05$; 0.28 ± 0.01 debanded-F vs. 0.36 ± 0.02 AB-F, $p < 0.05$), histological (CD: 16.4 ± 0.5 debanded-M vs. 18.2 ± 0.6 AB-M, $p < 0.05$; 14.7 ± 0.4 debanded-F vs. 17.7 ± 0.6 AB-F, $p < 0.05$) and functional reverse remodeling in both genders.
Conclusion: Our results provide evidence that pressure unloading therapy at a relatively early time point leads to myocardial reverse remodeling at a comparable degree in male and female rats.

Gse1, a new player in cardiac development

F Alnour[1]; X Xu[1]; E Baier[1]; M Drignath[1]; M Zeisberg[2]; EM Zeisberg[1]

Purpose: Hypoplastic left heart syndrome (HLHS) is one of the most severe congenital heart diseases. KIAA0182 gene (Gse1 in mouse) was found to be de novo mutated in HLHS. While the function of this gene has not been elucidated yet, Gse1 is known to produce one circular RNA isoform that is highly abundant. Gse1-knockdown in zebrafish revealed a cardiac phenotype. We therefore aimed to explore the biological role of Gse1 gene using a newly generated Gse1 knockout mouse.
Methods: By using targeted gene-trapping strategy we established Gse1-knockout-first mice with the mutated allele (Gse1-tm1a(EUCOMM)Wtsi) as a knockout model for Gse1 on expression level. In these mice the trapping cassette is located just downstream from the second exon of Gse1 that generates its circularized isoform.
Results: After confirming the correct targeting of Gse1 by the trapping cassette, offspring of matings between heterozygous (Gse1 tm1a/+) parents was analyzed, and within 134 newborn mice no homozygous (Gse1 tm1a/tm1a) mice were detected, indicating embryonic lethality. Systematic embryological analysis revealed that the time of lethality spans over the last trimester of pregnancy. Histological analysis revealed cardiac abnormalities comprising hypoplastic and non-compacted myocardium and ventricular septum defect in the majority of homozygous embryos. Gse1 linear mRNA was surprisingly downregulated by less than 50% in homozygous embryos compared to wild type, without any clear difference on protein level. To exclude the possibility of off-target effects due to the trapping cassette in Gse1-tm1a allele, the genes upstream and downstream from Gse1 were tested and none of them was found to be dysregulated in the homozygous embryos. We found, however, a significant upregulation of Gse1 circular RNA in homozygous as compared to wild type embryos, suggesting that the trapping cassette affects the backsplicing process within the circular RNA forming region, and that this circular RNA may be responsible for the observed abnormalities. We next used miRBase database to identify 12 miRNAs that can be bound by Gse1 circular RNA, and the online database miRDB to identify more than 4000 genes potentially affected by these miRNAs. Among these genes, we focused on 5 candidates (WT1, Mef2c, Tfap2b, Hey2 and GATA4), which were previously linked to cardiac development. We found upregulation of WT1 and downregulation of GATA4 in heart samples from homozygous embryos as compared to wild type. This potentially reflects two known functions of circular RNA to either sequester or to protect miRNAs, providing a possible link between Gse1-circular RNA and the cardiac phenotype.
Conclusions: Homozygosity of Gse1-tm1a allele causes embryonic lethality. The observed cardiac phenotype may be caused, at least in part, by the upregulated circular RNA isoform of Gse1. The biological mechanisms behind our results and the exact functions of Gse1 and its circular RNA are still to be further elucidated.

Background: Despite intense research efforts, chemotherapy induced left ventricular dysfunction remains a clinical problem in the field of oncocardiology. Optimal timing of heart failure treatment may play an important role in the prognosis of patients. Still, there is no hard evidence for a prophylactic cardioprotective approach for the vast majority of oncological treatments.
Purpose: In this study we set out to investigate whether a prophylactic or a conventionally scheduled heart failure therapy is more effective in preventing doxorubicin (DOX) induced cardiotoxicity.
Methods: Previously, we developed a rat model for the investigation of the adverse myocardial effects of iv. DOX using concentrations extrapolated from human oncotherapeutic protocols. Here we had 4 groups of animals: saline treated negative controls (CON), DOX treated positive controls, and DOX treated animals scheduled for prophylactic (PRE, started a week before DOX exposure) or conventional cardioprotection (POST, started 1 month after DOX exposure). The cardioprotection was achieved by orally administered, combined heart failure therapy (2.5 mg/kg bisoprolol, 2 mg/kg perindopril, 6.25 mg/kg eplerenone). Baseline as well as follow-up blood pressure, heart rate and echocardiographic measurements were performed. At 2 months the animals were sacrificed, their hearts were excised and frozen for further electronmicroscopic scanning and in vitro force measurements in isolated, skinned cardiomyocytes.
Results: Prophylactic treatment significantly reduced the blood pressure and heart rate of animals in the PRE group compared to all other groups. Similarly to CON, the survival of PRE animals was significantly better than that in the DOX and POST groups. Ejection fraction and longitudinal strain remained preserved in the PRE group. DOX treatment did not result in significant desensitisation of the myofilaments to Ca2+. However, the DOX induced lower rate of the actin-myosin cross-bridge cycle could not be reverted by any drug intervention. The DOX related adverse myocardial remodelling also manifested in pronounced ultrastructural changes such as myofibrillolysis, mitochondrial disintegration and chromatin fragmentation. A substantial reduction of the above abnormalities could be seen in the PRE, but not in the POST group.
Conclusions: Prophylactic cardioprotective treatment has many advantages compared to conventional therapy applied at a later stage in preventing or attenuating adverse myocardial effects induced by DOX.

Hypertrophic Cardiomyopathy (HCM) is caused by mutations in mainly sarcomeric proteins. HCM pathogenesis is assumed to result from functional alterations due to the respective mutation. Yet, a common mechanism how different mutations trigger HCM is still unclear. We hypothesize that myocyte disarray and fibrosis in HCM are triggered by cell-to-cell variation of the fractions of mutated and wildtype protein leading to contractile imbalance among individual cardiomyocytes (CMs).
By analyzing CMs isolated from heterozygous HCM patients' cardiac tissue we could show that mutations in ß-myosin (ß-MyHC) alter calcium-sensitivity, which, however, was highly variable from cell-to-cell. Also, the fractions of mutated and wildtype MYH7-mRNA were highly variable, ranging from cardiomyocytes expressing essentially pure mutant to others with essentially pure wildtype mRNA. As mechanism we propose that stochastic, burst-like transcription which is independent for the two MYH7-alleles produces variable fractions of mutated and wildtype mRNA and protein from cell-to-cell. This was corroborated by analysis of activity of MYH7-transcription sites in individual CMs and by model simulations.
Here we extended our studies to cardiac tissue from a heterozygous HCM-patient with cMyBP-C-mutation c.927-2A>G, which creates a premature stop-codon. Again, calcium-sensitivity of individual CMs was determined. Variable expression of cMyBP-C-protein from cell-to-cell was tested by immunofluorescent labelling against cMyBP-C and a-actinin. For this mutation calcium-sensitivity was increased with a large variability of force from cell-to-cell at submaximal, physiological activation levels. Some cells were essentially indistinguishable from controls, while others generated substantially increased force suggesting reduced levels of cMyBP-C. Fluorescence intensity ratio (IMyBPC/IAlpha-Actinin) was 35% lower in patient's CMs and significantly more variable from cell-to-cell compared to donors. cMyBP-C-fluorescence appeared much patchier in patient CMs, suggesting variable abundance of wildtype-cMyBP-C within patient CMs. No truncated cMyBP-C was found, consistent with mRNA-decay of the mutated transcript.
We propose that the lower fluorescence intensity ratio and patchier appearance of cMyBP-C fluorescence in the HCM-CMs results from random, burst-like transcription of cMyBPC, which is independent for the mutant and wildtype alleles. The resulting highly variable levels of wildtype cMyBP-C in the individual CMs could be the underlying cause of the functional imbalance among the individual CMs. Overall expression of cMyBP-C seems reduced, consistent with the frequently observed haploinsufficiency for cMyBP-C-mutations in HCM.
In the long run, for both, cMyBP-C-mutations and the previously studied ß-MyHC-mutations such contractile imbalance may well induce structural distortions like cellular/myofibrillar disarray and fibrosis, as they are typically observed in HCM.

Background: Compared to the free drug (DOX), liposomal doxorubicin (LDOX) has shown comparable antitumor efficacy and reduced cardiotoxicity, thereby increasing the therapeutic index. LDOX has been developed to reduce drug exposure of healthy tissues. The precise molecular mechanisms of anthracycline-induced toxicity remain incompletely understood.
Purpose: We performed transcriptomic profiling of myocardial samples of a translational pig model after treatment with LDOX or free DOX in order to investigate alterations in gene expression and to identify strategies for cardioprotection.
Methods: We treated juvenile domestic pigs with either DOX (n = 6), LDOX (n = 6), or saline (n = 5, controls) in doses equivalent to human treatment regimes. Heart function and the extent of myocardial fibrosis were assessed by cardiac magnetic resonance imaging with gadolinium late enhancement and transthoracic echocardiography. Serial plasma levels of NT-proBNP and Troponin I were quantified by ELISA. After the completion of three treatment cycles, gene expression profiles of the left and right ventricles were determined by global RNA sequencing with validation by quantitative PCR. Cardiac fibrosis and protein biomarkers were analyzed with immunohistochemistry and immunofluorescence.
Results: We identified an increase of plasma markers NT-proBNP (569 ± 144 and 499 ± 116 vs. 44 ± 5 pg/mL) and Troponin I (1.30 ± 0.85 and 1.39 ± 0.18 vs. 0.01 ± 0.01 ng/mL) in both DOX and LDOX groups, and an impact on body weight of the growing animals after DOX treatment (46 ± 11 and 73 ± 8 vs. 75 ± 3 kg, DOX and LDOX vs. Co, respectively), as indications of anthracycline-induced cardiotoxicity. Altered left ventricular systolic function (LV enddiastolic volume 1.96 ± 0.24 and 1.62 ± 0.41 vs. 1.20 ± 0.13 mL/kg) and E/e' ratio (8.9 ± 1.4 and 5.8 ± 1.3 vs. 5.0 ± 1.3) were found after DOX. In both ventricles, LDOX but not DOX treatment resulted in upregulation of a distinct signature of interferon-inducible genes (IFIT 1, 2, 3, 5, ISG 15, IRF 7 and 9, and others), which are mediating DNA damage repair and promote cell survival. Gene network analysis identified the cardioprotective translocator protein (TSPO) as a central node of differentially regulated genes, linking interferon-induced genes to transcription factors and cell survival genes. While TSPO expression was not significantly altered by LDOX compared to controls, it was inhibited 2.7-fold by DOX. Immunohistochemistry showed slightly increased cytosolic localization of TSPO after LDOX application with persisting predominantly mitochondrial staining.
Conclusions: Our data show transcriptional activation of a DNA damage response pathway through activation of interferon-inducible genes by LDOX, but not DOX,

presumably caused by reduced exposure of the myocardium to the drug. Translocator protein TSPO as a central gene in the identified network might be a feasible target for development of specific strategies for cardioprotection from anthracyclines.

Background: Mechanical stimulation of acute ischemic myocardium by shock wave therapy (SWT) is known to improve cardiac function by induction of angiogenesis. However, SWT in chronic heart failure and underlying mechanisms are poorly understood.
Objective: To study if mechanical stimulation upon SWT improves heart function in a model of chronic ischemic heart failure by induction of angiogenesis and postnatal vasculogenesis and to dissect underlying mechanisms.
Methods: Three weeks after ligation of the left anterior descending coronary artery, SWT was applied to chronic ischemic myocardium. Cardiac function was evaluated using echocardiography and pressure/volume measurements. To study effects of SWT on postnatal vasculogenesis wild-type mice received bone marrow transplantation from GFP donor mice after sublethal irradiation. Functional angiogenesis assays with human umbilical vein endothelial cells and a murine aortic ring assay were used to specify underlying mechanisms.
Results: Echocardiography and pressure/volume measurements revealed improved left ventricular ejection fraction, myocardial contractility and diastolic function and decreased myocardial fibrosis after treatment. Concomitantly, we found upregulation of myocardial vascular endothelial growth factor (VEGF), vascular endothelial growth factor receptor 2, fibroblast growth factor and placental growth factor expression with increased numbers of capillaries and arterioles in treated hearts consistent with induction of angiogenesis. In vitro, SWT enhanced activation of extracellular-signal regulated kinase and protein kinase B/Akt. This resulted in endothelial cell proliferation, enhanced survival, and induction of capillary sprouting in an ex-vivo aortic ring assay. The effects were abolished by the vascular endothelial growth factor receptor 2 inhibitor Vandetanib or by pre-incubation with heparin or heparinase indicating involvement of VEGF signaling and heparan sulfate proteoglycans (HSPGs) in SW-induced angiogenesis. To study effects of SWT on postnatal vasculogenesis wild-type mice received bone marrow transplantation from GFP donor mice after sublethal irradiation. SWT resulted in enhanced expression of the chemoattractant stromal cell derived factor 1 in ischemic myocardium and serum of treated animals. Treatment induced recruitment of endothelial progenitor cells from the bone marrow to the site of injury shown by higher numbers of GFP-positive endothelial cells in treated hearts.
Conclusions: The mechanical stimulus of SWT positively affects heart function in chronic ischemic heart failure by induction of angiogenesis and postnatal vasculogenesis. SWT upregulated pivotal angiogenic and vasculogenic factors in the myocardium in-vivo and induced proliferative and anti-apoptotic effects on endothelial cells. Mechanistically, these effects depend on VEGF signaling and HSPGs. SWT could become a promising treatment option for regeneration of ischemic myocardium.

P1964

Non-hypertrophic and hypertrophic human cardiomyocytes secrete unprocessed ANP and BNP precursors (proANP/proBNP) and exhibit a similar efficiency in their processing

A Semenov[1]; E Feygina[2]; N Tamm[2]; V Filatov[2]; A Katrukha[1]

[1]HyTest Ltd, R&D department, Turku, Finland; *[2]M.V. Lomonosov Moscow State University, Biological faculty, Moscow, Russian Federation*

Background: A- and B-type natriuretic peptides (ANP and BNP) are key cardiac hormones of cardiorenal homeostasis. ANP and BNP are produced as prohormones, proANP and proBNP, which are enzymatically converted to biologically active peptides ANP and BNP, and N-terminal fragments, NT-proANP and NT-proBNP. The diseased heart (e.g. under hypertrophy in heart failure (HF)) secretes high amounts of unprocessed precursors resulting in the lack of physiological natriuretic response in HF patients. The appearance of intact precursors in the circulation can be attributed to their inefficient processing. However, the mechanism of proANP and proBNP secretion and processing in the normal heart remains elusive, since the levels of ANP and BNP under normal conditions are very low and often beyond the detection limits of available assays. One may suggest that a robust and physiologically relevant cell-based model can be used to address these issues.
Purpose: To explore the secretion and processing efficiency of proANP and proBNP in human cardiomyocytes, in both normal and hypertrophic conditions.
Methods: Human induced pluripotent stem (iPS) cell-derived cardiomyocytes were used as an in vitro model to study proANP and proBNP secretion and processing in normal and hypertrophic conditions. Hypertrophy of cardiomyocytes was induced by treatment of cells with endothelin 1 (ET-1) at different concentrations (0.004-1000 pM). The levels of intact proANP and proBNP (i.e. [precursor]) as well as the total levels of the corresponding peptide (i.e. [N-terminal fragment + precursor]) were measured by means of sandwich-type immunoassays in condition media after 20 hours post induction. Antibodies specific to (i) both N- and C-terminal parts of either proANP or proBNP (to measure [precursor] levels), or (2) N-terminal parts only (to measure [N-terminal fragment + precursor] levels) were employed. Recombinant proANP and proBNP expressed in E. coli were used as calibrators. The rate of processing was calculated using the formula: (1 - [precursor]/[N-terminal fragment + precursor])*100%.
Results: ET-1 treated iPS cell-derived cardiomyocytes exhibited dose-dependent increases in total ANP and BNP production: up to 5-fold for ANP and 8-fold for BNP. Secretion of intact proANP and proBNP was observed in both non-induced and ET-1 induced cardiomyocytes. The processing rate of proANP and proBNP in both normal and hypertrophic cells was similar: ˜30% for proANP and ˜60% for proBNP. There was no alteration of processing efficiency in the cells treated with different ET-1 concentrations.
Conclusions: The increases in ANP and BNP production observed in cardiomyocytes under hypertrophy do not result in the alteration of the processing rate of precursor molecules. The present data suggest that intact proANP and proBNP may be also secreted by normal hearts (similarly to what is observed in HF patients) and enable to assume a specific role of intact precursors in the circulation.

The effect of free fatty acids on endogenous angiotensin converting enzyme inhibition

M Fagyas[1]; B Varga[1]; IT Altorjay[1]; A Csongradi[1]; ZS Polik[1]; SI Manyi[1]; Z Papp[1]; A Toth[1]

Angiotensin converting enzyme (ACE) inhibitors have the potential to reduce cardiovascular mortality by up to 40%. We have recently reported that ACE activity is endogenously inhibited by human serum albumin (HSA). We hypothesize that decreased endogenous ACE inhibition associates with development and progression of cardiovascular diseases. Here we aimed to identify and characterize factors influencing HSA-mediated endogenous ACE inhibition.
68 patients with documented cardiovascular diseases were involved into the study. Besides routine laboratory parameters, the extent of endogenous ACE inhibition, free fatty acid (FFA) concentration and composition were also measured.
The extent of endogenous ACE inhibition varied considerably among patients (62-83%, n = 68), but it had no relation with albumin concentration in the samples ($r2 = 0{,}149$). Hence we postulated, that other factors could also influence the extent of endogenous ACE inhibition. Removal of hydrophobic molecules from the surface of albumin significantly decreased the capacity of albumin to inhibit ACE activity (before treatment: $IC50 = 9.91 \pm 1.0$g/L, n = 3, after treatment: $IC50 = 35.8 \pm 2.7$g/L, n = 3, $p < 0.001$). FFA concentrations were measured from the samples and we found no relationship between FFA concentration and the extent of endogenous ACE inhibition ($r2 = 0.089$). We concluded that different types of FFAs may modify the endogenous ACE-inhibiting capacity of albumin to various extents. Treatment of FFA free HSA with different types of FFAs confirmed this hypothesis. Among the examined saturated and unsaturated FFAs, C18:3 cis,cis,cis,?6,9,12 had the most potent ACE-inhibitor modifying effect ($IC50 = 5.5 \pm 0.4$g/L), while the effect of C10:0 treated albumin ($IC50 = 32.3 \pm 1.6$ g/L) was not different from that of FFA free albumin. Our results revealed that FFA-binding to albumin is essential for endogenous ACE inhibition. There are several FFAs, which are able to increase significantly the ACE-inhibitory effect of HSA. Therefore, intake of these FFAs via functional foods may decrease cardiovascular risk and delay the development of cardiovascular diseases.

Beneficial effect of intravenous iron, ferric carboxymaltose, in heart failure

A Paterek[1]; J Kolodziejczyk[1]; M Kepska[1]; U Mackiewicz[1]; M Maczewski[1]
[1]*The Medical Centre of Postgraduate Education, Department of Clinical Physiology, Warsaw, Poland*

Funding Acknowledgements: This work was supported by grant from National Science Centre (2015/17/B/NZ5/00292)

Introduction: Iron deficiency (ID) occurs in up to 50% of patients with chronic heart failure (HF). Unfortunately, causes of this ID in HF remain largely unknown and probably are multifactorial. ID is associated with poor prognosis in HF patients, whereas iron supplementation had beneficial symptomatic effects. The effect of iron on hard endpoints and left ventricular remodeling parameters fundamental for patient's prognosis is still unknown. On the other hand iron is a highly toxic, can participate in the Fenton reaction to form the most reactive oxygen species- hydroxyl radical, so its level in the human body must be strictly controlled. Therefore treatment with intravenous iron in HF is still an open question.
Purpose: To characterize iron status in the rat model of post-myocardial infarction (MI) chronic HF and to assess the effect of 4-week intravenous iron supplementation on post-MI HF.
Methods: Rats were subjected to induction of MI or sham operation and after 4 weeks were randomized into two groups, one received intravenous (i.v.) iron (ferric carboxymaltose, 10 mg/kg body weight) (HF+Fe, Sh+Fe), whereas the other received saline (HF, Sh), a total of 4 doses in 1-week intervals. Echocardiography was performed weekly. Eight weeks after surgery rats underwent final echocardiographic imaging and left ventricular catheterization. Blood was collected and subsequently hearts were excised for biochemical and cellular studies. Serum and liver were also collected for further analysis.
Results: MI alone did not cause anemia, ID or abnormalities of iron turnover (no abnormalities of either myocardial or systemic iron). Iron therapy increased serum Fe, ferritin and transferrin saturation as well as cardiac and hepatic iron content in HF+Fe rats. This was accompanied by: (1) better preservation of left ventricular (LV) ejection fraction and smaller LV dilation, (2) preservation of function of Ca2+ handling proteins in LV cardiomyocytes and (3) reduced level of inflammatory marker, CRP. Furthermore, iron supplementation did not potentiate oxidative stress or have toxic effects on cardiomyocyte function.
Conclusions: Although we did not find any evidence of anemia or iron deficiency in the rat model of post-MI HF, we observed positive effect of iron supplementation in such setting and we confirmed that such supplementation is safe.

Dipeptidyl peptidase 4 inhibitor sitagliptin ameliorates renal function in a model of hypertension-induced cardiorenal disease

D Cappetta[1]; A De Angelis[1]; LP Ciuffreda[1]; G Esposito[1]; A Cozzolino[1]; D D'amario[2]; A Siracusano[2]; F Rossi[1]; F Crea[2]; L Berrino[1]; K Urbanek[1]
[1]*University of Campania "Luigi Vanvitelli", Department of Experimental Medicine, Naples, Italy*; [2]*Catholic University of the Sacred Heart, Department of Cardiovascular and Thoracic Sciences, Rome, Italy*

Background: heart failure with preserved ejection fraction (HFpEF) and chronic kidney disease often share co-morbidities like hypertension and diabetes. Moreover, renal dysfunction in HFpEF is common and is associated with increased mortality. Co-existence of heart and kidney failure is a clinical challenge, because of diagnostic and therapeutic difficulties, since many HF medications may cause, or are contraindicated in the presence of renal failure. Experimental studies have suggested a cardio and renoprotective role of dipeptidyl peptidase 4 (DPP4) inhibitors in various experimental models, which may be independent of lowering blood glucose levels.
Purpose: to examine the effects of DPP4 inhibitor sitagliptin treatment on the progression of heart and kidney disease independently from the effects on glycaemia. To identify molecular mechanisms involved with a particular focus on the potential renal protection. For this purpose, Dahl salt-sensitive (Dahl/SS) rats, reported as an experimental model of HFpEF, were used.
Methods: seven-week-old Dahl/SS rats fed a high salt diet (8% NaCl) for 5 weeks to induce hypertension. Then, rats continued with a high salt diet and were administered with either sitagliptin (10 mg/kg by oral gavage) or vehicle for the following 8 weeks.
Results: treatment with sitagliptin ameliorated both cardiac and kidney injury. During 8 weeks of the treatment with sitagliptin, blood pressure remained markedly elevated, with a slight, but significant reduction observed only at 19 weeks of age. Because of a non-diabetic nature of our model and unaltered blood glucose levels, the cardio-renal protective action of sitagliptin certainly lays beyond its effect on glycaemia. At renal level, expression of pro-inflammatory markers like nuclear factor kappa B, tumor necrosis factor-a and interleukin-6 were elevated in Dahl/SS rats and partially reduced by sitagliptin treatment. Sitagliptin also reduced the grade of endothelial dysfunction as evidenced by the increase of eNOS and the decrease of E-selectin. Moreover, oxidative stress was attenuated by sitagliptin. Oxidative stress and pro-inflammatory status observed in Dahl/SS rats contribute to activation of pro-fibrotic pathways in the kidney. Increase of collagen deposition and activation of pro-fibrotic signalling that leads to a remarkable renal tubulointerstitial fibrosis and glomerulosclerosis in high salt diet-fed rats were reduced with administration of sitagliptin.
Conclusions: sitagliptin reduced inflammatory-related endothelial dysfunction and fibrosis in the kidney and positively modulated myocardial diastolic compliance. The concomitant damage at heart and kidney level puts in evidence the feature of cardio-renal syndrome of this experimental model whilst the protective effects of sitagliptin highlight its action at multi-organ level.

P1968

Neladenoson, a partial adenosine A1 receptor agonist shows renal protection in rodents

K Leineweber[1]; P Kolkhof[1]; A Kretschmer[2]; B E Albrecht-Kuepper[1]
[1]*Bayer AG , Drug Discovery - Cardiology/Heart Diseases, Wuppertal, Germany*; [2]*Bayer AG, Drug Discovery - Clinical Sciences-Global Biomarker Research, Wuppertal, Germany*

Background: Heart failure (HF) is often associated with renal impairment which in itself is also a strong predictor of mortality in HF. Adenosine A1 receptors (A1Rs) are expressed in heart and kidney and mediate several beneficial physiological effects. But A1R activation in the kidney also leads to anti-diuretic effects. Partial A1R agonists have the potential to selectively address only certain physiological effects and thereby show not only cardio- but also reno-protection without disturbances of diuresis in HF patients. Neladenoson is an oral partial A1R agonist currently in PhIIb clinical development for HF.
Purpose: The objective of the described studies was the characterization of acute renal effects of neladenoson in healthy rats and chronic effects in subtotal nephrectomised (SNX) rats, an animal model for chronic kidney disease.

Effects of neladenoson in SNX rats

	Control	Placebo	Neladenoson
n	10-12	10-12	10-11
Urine Volume [ml/kg/h]	1.2±0.1	1.8±0.1	1.8±0.2
Kidney injury marker-1 [rel. expr.]	11±4***	182±54	56±18**
Proteinuria [mg/ml urine/kg BW/h]	1.14±0.25*	2.19±0.51	0.97±0.12*
Heart rate [bpm]	320±10	316±7	291±9
Systolic blood pressure [mmHg)]	119±2***	127±4	126±3
Diastolic blood pressure [mmHg]	91±2***	98±3	95±2

Values are Mean+SEM. *p < 0.05, **p < 0.01 and ***p < 0.001 vs. Placebo. Statistics: One-way Anova with Newman Keuls Multiple Comparison post-hoc test.

Methods: Acute effects were measured in male Sprague Dawley rats treated with a single dose of neladenoson (3 mg/kg body weight, p.o.) and kept in metabolic cages for 24 hrs. Chronic effects were analysed in male Wistar rats randomly allocated to subtotal nephrectomy. Three weeks after SNX surgery, neladenoson (3 mg/kg body weight, p.o., once daily) was given for additional four weeks. At the end of the protocol heart rate and blood pressure and renal parameters were assessed.
Results: Acute treatment with neladenoson resulted in a significant increase of urine volume (neladenoson 77.5+7.4 ml/kg vs. control 35.4+4 ml/kg BW (p <0.001)) over 24 hrs. without any natriuretic effect. Chronic treatment of SNX rats significantly reduced renal expression of the kidney injury marker KIM-1 and proteinuria in comparison to placebo. Additionally, no change in blood pressure and urine volume was observed compared to placebo.
Conclusion: The partial A1R agonist neladenoson improves renal impairment without deterioration of diuresis.

P1969

Passive stiffness of ventricular myocardium in a mouse model of sleep apnea: effects of intermittent hypoxia and ageing

N Farre[1]; J Otero[2]; I Jorba[2]; I Almendros[2]; R Farre[2]; D Navajas[2]
[1]*Hospital del Mar, Department of Cardiology, Municipal Institute for Medical Research (IMIM), Barcelona, Spain*; [2]*University of Barcelona, Unitat de Biofísica i Bioenginyeria. Facultat de Medicina. , Barcelona, Spain*

Funding Acknowledgements: This work was supported in part by the Spanish Ministry of Economy andCompetitiveness (Instituto de Salud Carlos III; PI14/00004 and PI14/00280).

Introduction: Obstructive sleep apnea (OSA), characterized by intermittent hypoxia (IH), is a very prevalent disease associated with heart failure (HF). Diastolic dysfunction is a key feature of HF which can be caused by either prolongation of active myocardial relaxation or increased myocardial passive stiffness. Both the extracellular matrix (ECM) and the cardiomyocytes are potentially determining passive stiffness in the myocardium although their exact contribution in OSA is unknown.
Purpose: The aim was to study whether IH and ageing modulate the passive stiffness of the LV myocardium in an animal model of OSA.
Methods: Two-month and 18-month old mice (N = 10 each) were subjected to IH (20% O2 40s - 6% O2 20s) for 8 weeks (6h/day). Corresponding control groups for each age were kept under normoxia in room air (RA). After sacrifice the hearts were excised and frozen for subsequent analysis. After thowing at room temperature, a strip of ˜8x1x1 mm was cut from the LV wall. One end of the strip was glued with cyanoacrylate to a hook attached to the lever of a servocontroled displacement actuator and the other end was glued to a fixed hook. Stress-stretch (s-?) curves were recorded by measuring the stretched length and the applied force (Aurora Scientific, 300C-LR) after strips were preconditioned. The curves were analyzed with Fung's model which assumes that the Young's modulus (E) increases linearly with stress. The stiffness of the tissue was characterized by computing E at 20% stretch (? = 1.2). After measuring E in native samples, each strip was decellularized (1% sodium dodecyl sulfate solution and 1% Triton X-100). Stress-stretch curves for the decellularized strips were obtained and computed.
Results: E (m ± SE) was 17.28 ± 2.43 (RA) and 37.24 ± 6.53 (IH) (p = 0.007) for young mice and 16.65 ± 3.18 (RA) and 42 ± 5.85 (IH) (p = 0.003) for old mice. Two-way ANOVA analysis found no statistically significant effect of age (young vs. old, p = 0.489) and highly significant effect of respiratory challenge (IH vs. RA, p <0.001) on E. Virtually the same results were found on the decellularized tissue samples, indicating a negligible contribution of cells in E.
Conclusions: The passive elastance of myocardial strips measured before and after decellularization in a mouse model of OSA indicates that IH (but not age) significantly increased LV tissue stiffness and that this effect is mainly caused by changes the ECM.

Introduction: Patients with diabetes mellitus exhibit diastolic dysfunction with decreased nitric monoxide production (diabetic cardiomyopathy). Elevated intracellular cyclic guanosine monophosphate (cGMP) levels can confer cardioprotection in different heart diseases. Here we investigated the effects of vardenafil, a phosphodiesterase-5A (PDE-5A) inhibitor in a rat model of diabetic cardiomyopathy on cardiomyocyte function.
Materials and Methods: Experiments were performed in male Zucker Diabetic Fatty (ZDF) and ZDF Lean (ZDFL) rats (as controls). Seven weeks old animals received either vehicle (ZDFLV) or 10 mg/bwkg vardenafil per os (ZDFV). Functional measurements were performed at the age of 32 weeks. Permeabilized left ventricular (LV) cardiomyocytes were used during isometric force measurements. Maximal Ca2+-activated active force production (Fmax), its Ca2+-sensitivity (pCa50), and Ca2+-independent passive force (Fpassive) were monitored. Western immunoblotting was applied to assess site-specific phosphorylation status of cardiac troponin-I (cTnI) and cardiac myosin binding proten C (cMyBP-C). Total phosphorylation status of titin protein was probed by a ProQ Diamond phosphoprotein staining kit.
Results: No significant differences were observed among Fmax values of the four groups. The pCa50 and Fpassive values were significantly higher in the ZDF rats than in the ZDFL, ZDFLV or ZDFV groups (pCa50 and Fpassive: ZDF: 5.88 ± 0.03 and 1.98 ± 0.12 kN/m2; ZDFL: 5.76 ± 0.01 and 1.02 ± 0.12 kN/m2; ZDFLV: 5.78 ± 0.03 and 1.03 ± 0.14 kN/m2; ZDFV: 5.76 ± 0.02 and 1.40 ± 0.13 kN/m2, P < 0.05, n = 6-7, mean ± SEM). In ZDF rats cTnI phosphorylation levels at Ser22/23, Ser43 and Thr143 sites were significantly lower than those in the ZDFV group (ZDF: 0.77 ± 0.05, 0.77 ± 0.08 and 0.68 ± 0.06; ZDFV: 1.01 ± 0.08, 1.35 ± 0.18 and 1.35 ± 0.16, in relative units, respectively, P < 0.05, n = 4). No significant differences in the site specific phosphorylation status of cMyBP-C at Ser282 and in the total phosphorylation status of titin between the ZDF and ZDFV groups were observed.
Conclusion: Increased passive force and Ca2+-sensitivity of force production developed in LV cardiomyocytes of rats with type 2 diabetes mellitus which could be limited by chronic phosphodiesterase-5A inhibition through increased protein phosphorylation.

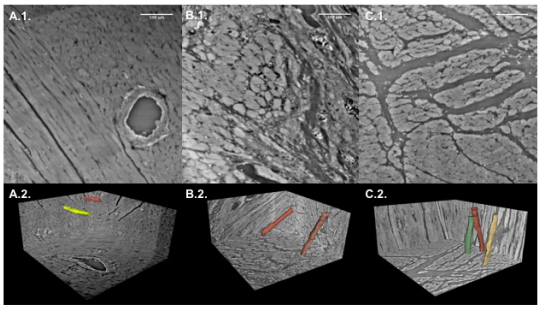
Funding Acknowledgements: We acknowledge the Paul Scherrer Institut, Villigen, Switzerland for provision of synchrotron radiation beamtime at beamline TOMCAT of the SLS

Background: Ischemic heart disease (IHD) is the leading cause of heart failure. The main pathogenic process is negative cardiac remodelling following myocardial infarction (MI). Global remodelling is easy to assess, yet no single technique can aggregate information on both cellular and entire organ level processes. A prominent technique under research is Synchrotron X-ray Phase Contrast Imaging (X-PCI) that can be used for both 3D analysis of whole hearts, as well as cardiomyocytes (CMCs) without tissue processing or destruction. We previously reported on the use of X-PCI for 3D data acquisition of whole rat hearts providing information on cardiac geometry and fibre orientation. We now aim to assess the ability of X-PCI to acquire information on cellular remodelling.



Top row, high resolution X-PCI images of selected areas and bottom row corresponding 3D rendering of selected cardiomyocytes in tissue volumes (400x550x550um). A.1 and A.2 healthy rat control, B.1 and B.2. peri-Mi area and C.1. and C.2 non-MI area of a MI heart

Methods: MI was induced in a well-established rat model of young adult (8-11 w.old) Wister rats by LAD artery ligation through a left thoracotomy. The rats were sacrificed in 2 weeks, and the hearts were excised, immersed in formalin and embedded in a tube with degassed deionized water. X-PCI was performed at an energy of 20 keV with 0.65 μm voxel size in selected regions of interest (ROIs)of the hearts. The projection sets were reconstructed using the Gridrec algorithm, leading to a 3D dataset. When ROIs were larger than the field of view, multiple scans were acquired to cover the full area; reconstructed volumes were merged into a single dataset. The high resolution level achieved by this technique allowed identification and analysis of individual CMCs which were segmented and analysed byopen-source software (3D Slicer and Fiji) allowing us to calculate cross sectional area (CSA). We analysed 2 post-MI rat hearts, and a control healthy rat heart. In post-MI hearts, the CMCs were analysed in the MI area (preserved cells adjoining fibrotic post-MI cardiac tissue - peri-MI zone), and in the contralateral region (the non-affected myocardium). CMCs of corresponding areas were quantified in the normal heart as well. CSA was expressed as the mean value with standard deviation of measurements of 10 CMCs per area.
Results: Average CSA of CMCs in the control rat was 321 ± 75 μm2. In MI rats, average CSA in peri-MI areas was 737 ± 127 μm2 and 499 ± 141 μm 2 in non-MI areas. The results indicate significant (p < 0.001) differences in CSA between peri-MI and non-MI areas of ischemic hearts, as well as compared to the healthy rat, indicating compensatory hypertrophy pronounced in peri-MI area as opposed to contralateral region. CMC CSA were consistent between MI hearts 1 and 2 (peri-MI: 773 ± 118 μm2 (MI rat 1) vs. 701 ± 125 μm2 (MI rat 2), p = 0.07 and non-MI area: 477 ± 53 μm2 (MI rat 1) vs. 521 ± 160 μm2 (MI rat 2), p = 0.255). Conclusion: X-PCI is a valuable imaging technique for assessing cellular hypertrophy in addition to whole organ remodelling in 3D. We showed marked differential compensatory hypertrophy in a rat model of IHD, which should be taken into account when evaluating post-MI hearts clinically.

Secretory products from pericardial adipose tissue of dietary-induced obese minipigs induce cardiomyocyte apoptosis via impairing mitochondrial homeostasis and autophagy

SJ Li[1]; TW Wu[1]; CY Ching-Yi Chen[1]
[1]*National Taiwan University, Taipei, Taiwan ROC*

Funding Acknowledgements: MOST 104-2313-B-002-038-MY3 (from Ministry of Science and Technology)

Objectives: Pericardial adipose tissue (PAT) is positively associated with the cardiovascular diseases and left ventricular remodeling. However, the underlying mechanism is still unknown. The objectives of this study was to examine the effect of PAT secretion from obese minipigs in H9C2 cardiomyoblasts with regard to mitochondrial homeostasis and autophagy.
Materials and Methods: The visceral adipose tissues (VAT) and PAT were collected from the Lee-Sung minipigs with high-fat diet feeding for six months. Conditioned medium (CM) generated from the explant of PAT and VAT were subjected to secretome profiling, or incubated with cardiomyocytes to assess the effect on mitochondrial functions and autophagy.
Results: A similar secretome profile was observed in PAT-CM and VAT-CM. Compared with the complete medium, PAT-CM and VAT-CM exhibited higher level of C16:0 and C18:1, greater lipid peroxidation products, and more inflammatory cytokine IL6 concentration. PAT-CM incubated with H9C2 cardiomyoblasts for 24 hrs induced cell apoptosis and reduced cell viability. A concordant effect was found in the VAT-CM treatment. A significant decrease in the mitochondrial fission-related proteins (Drp1 and Fis1) was found in the PAT-CM treatment. OPA1, a mitochondrial fusion-related protein, was downregulated in the PAT-CM treatment. Similarly, VAT-CM suppressed the expressions of mitochondrial fission and fusion-related proteins. These results suggested that both PAT and VAT impaired the mitochondrial dynamics in the H9C2 cells. Neither Parkin nor Pink1 (markers of mitophagy) was regulated by CM treatment. VAT-CM increased the LC3II/LC3I ratio, , while PAT-CM induced a greater ratio of LC3II to LC3I than VAT-CM did, suggesting that PAT-CM evoked a severer maladaptive autophagy than VAT-CM did.
Conclusion: The present study showed that PAT from obese minipigs displayed the cytotoxic potential as the VAT did. Secretion of pericardial fat evoked cardiomyocyte apoptosis via impairing mitochondrial dynamics and accumulating autophagosomes.

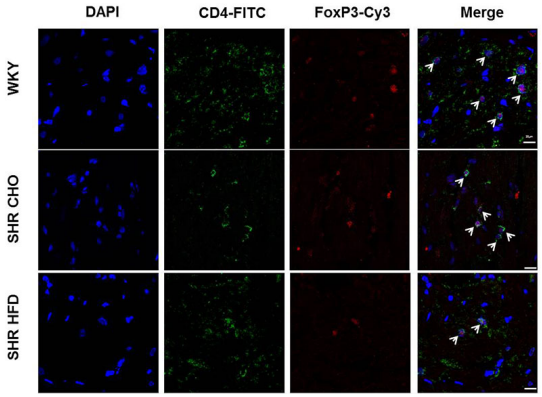
High fat diet downregulates regulatory T cells in the myocardium of spontaneous hypertensive rats.

S-H Sang-Hyun Ihm[1]; SK Hong[1]; EH Choo[1]; KY Chang[1]
[1]*Catholic University School of Medicine, Seoul, Korea Republic of*

Background: Obesity induced myocardial fibrosis may lead to diastolic dysfunction and ultimate heart failure. Cardiac inflammation may play a pivotal role in the pathogenesis of obesity-induced myocardial fibrosis. Regulatory T cells (Tregs) play an important role in cardiovascular complications and inflammatory action with the immune response. However, the role of Tregs and its associated anti-inflammation in obesity-induced myocardial fibrosis has not been elucidated to date. Therefore, we investigated whether high fat diet suppresses Tregs activation in the myocardium of spontaneously hypertensive rats (SHRs), which aggregates myocardial fibrosis.
Methods and Results: We assessed the extent of Tregs response and fibrosis in the myocardium. Eight-week-old male SHRs were fed to either high-fat diet (HFD) or control diet (CHO) groups for 12 weeks. We measured Tregs (CD4+FoxP3+) in the heart and mediastinal lymph nodes (LNs). The flow cytometry analysis confirmed that the SHR-HFD exhibited a decreased Tregs compared with that of the WKY in the heart and mediastinal LNs. In contrast, the SHR-CHO exhibited an increased Tregs compared to that of the SHR-HFD in the heart. Furthermore, SHR-CHO slightly increased the Foxp3+ compared with that of the SHR-HFD in the mediastinal LNs. The CD4 and FoxP3 antigens were used in the immunofluorescence microscopy of Tregs in the heart tissues. In the heart, dual staining for the Treg population was increased more in the SHR-CHO than it was in the SHR-HFD rats. In line with these findings, SHR-HFD significantly exacerbated myocardial fibrosis.
Conclusions: We found that diet-induced obesity typically showed an exacerbated myocardial fibrosis and down-regulation of Tregs pathway in the heart and mediastinal LNs. Therefore, we suggest that the up-regulation of Tregs may be a promising therapeutic approach to preventing obesity induced heart failure.



CD4 and FoxP3 and in rat hearts

P1974

Omega-3 fatty acids and melatonin affect activity of extracellular matrix metalloproteinase-2 in the plasma, aorta and heart of isoproterenol injured normotensive and hypertensive rats.

B Szeiffova Bacova[1]; C Viczenczova[1]; K Chaudagar[2]; M Sykora[1]; T Egan Benova[1]; M Barancik[1]; N Tribulova[1]
[1]*Slovak Academy of Sciences, Institute for Heart Research , Bratislava, Slovak Republic*; [2]*L. M. College of Pharmacy, Ahmedabad, India*

Rationale: Sustained activation of beta-adrenoceptors is accompanied by pathological remodeling and endangering the viability of cardiomyocytes, which increases the incidence of cardiac failure and sudden cardiac death. Our and other experimental studies as well as clinical trials suggest that melatonin and omega-3 fatty acids (PUFAs) are cardioprotective due to their anti-inflammatory, anti-oxidant, anti-hypertensive and anti-arrhythmic effects, but underlying molecular mechanisms are still not fully explored. We hypothesize that both compounds may affect extracellular matrix remodeling by modulation of extracellular matrix metalloproteinases (MMPase) activity.
Purpose: We aimed to explore MMP-2 activity in plasma, aorta and heart in normotensive and hypertensive rats after infarct-like cardiac injury induced by high dose of isoproterenol (ISO) as well as the effects of treatments with PUFA and melatonin.
Methods: In accordance with the rules issued by the State Veterinary Administration of the Slovak Republic and European Union Council Directive 86/609/EEC we used in our experiment Wistar and spontaneously hypertensive rats (SHR) which were divided into four groups. 1) Controls without treatment; 2) Iso-injured rats (118mg/kg totally, s.c., for 7days); 3) Iso-injured rats treated with melatonin (10mg/kg, p.o., 2-mo); 4) Iso-injured rats treated with PUFA (Omacor, 1.68g/kg, p.o.,2-mo). Samples from plasma, left and right ventricles and aorta were used to determine activity of MMP-2 by using gelatin zymography.
Key Results: There was higher plasma but lower heart tissue-related MMP-2 activity in non-treated SHR vs Wistar rats and no difference in aorta. ISO caused an increase of MMP-2 activity in plasma as well as in atria and decrease in left and right ventricles of Wistar rats. In contrast, ISO decreased MMP-2 activity in plasma, aorta and increased in left and right ventricles of SHR. Melatonin and Omacor suppressed plasma MMP-2 activity in Iso-treated Wistar but not in Iso-SHR. Both compounds lowered MMP-2 activity in atria of Iso-Wistar rats but elevated in iso-SHR as well as decreased MMP-2 activity in ventricles of Iso-treated SHR only.
In conclusion, data indicates that both melatonin and Omacor modulate circulating and cardiovascular tissue-related MMP-2 activity and there are strain- and tissue-related differences.

Effect of BGP-15 treatment on hypertension induced cardiac remodeling in an in vivo SHR model

K Katalin Ordog[1]; L Deres[1]; K Eros[2]; O Horvath[1]; T Habon[1]; B Sumegi[3]; K Toth[1]; R Halmosi[1]
[1]University of Pecs, Division of Cardiology and Angiology, 1 st Department of Medicine, Medical School, Pecs, Hungary; *[2]University of Pecs, Szentagothai Research Center, Pecs, Hungary*; *[3]University of Pecs, MTA-PTE Nuclear-Mitochondrial Interactions Research Group, Pecs, Hungary*

Funding Acknowledgements: GINOP-2.3.2-15-2016-00049; GINOP-2.3.2-15-2016-00048; GINOP-2.3.3-15-2016-00025; UNKP-17-4-I-PTE-209

Introduction: Based on previous studies BGP-15 improves cardiac function and reduces arrhythmic episodes in mouse model of atrial fibrillation. BGP-15 treatment improves mitochondrial function. In our present study we investigated the effect of BGP-15 on heart failure.
Methods: 15-month-old male SHR rats received 25 mg/kg/day BGP-15 (SHR-B) or placebo (SHR-C) treatment for 18 weeks. Age-matched Wistar rats (WKY) were used as normotensive control. Echocardiography was performed at the beginning and at the end of the treatment period. Plasma B-type natriuretic peptide (BNP) level was measured, and histological preparations were made from cardiac tissue. The levels of proteins involved in mitochondrial dynamics, the phosphorylation state of GSK-3ß, Akt, PKC and the MAPK cascade were monitored by Western blot technique.
Results: By the end of the study left ventricular (LV) wall thickness and LV mass increased significantly in SHR-C group compared to the initial values ($p < 0.05$), however in SHR-B group these parameters decreased markedly ($p < 0.05$). Ejection fraction (EF%) decreased in both SHR groups, however in SHR-B group this deterioration was only minimal. E/E' ratio - representing the diastolic function - increased in the control group, while in the treated group it decreased compared to the baseline values ($p < 0.05$). BGP-15 treatment reduced plasma BNP levels in the SHR-B group compared to the control animals ($p < 0.05$). The phosphorylation state of Akt-1Ser473 was slightly higher in the control group than in the WKY group, but in the treated group it increased markedly due to BGP-15 treatment ($p < 0.05$).
Discussion: BGP-15 treatment reduced the hypertension-induced cardiac remodeling and heart failure due to its favorable effect on intracellular signaling and mitochondrial function.

Assessment of heart transplant outcomes in long postoperative period

T Tatiana Chumarnaya[1]; A Bykov[2]; E Idov[3]; V Kochmasheva[2]; S Mikhailov[3]; O Solovoyva[4]
[1]Institute of Immunology and Physiology of Russian Academy of Sciences, Ekaterinburg, Russian Federation; *[2]Yekaterinburg Regional Clinical Hospital 1, Yekaterinburg, Russian Federation*; *[3]Urals State Medical University, Ekaterinburg, Russian Federation*; *[4]Ural Federal University, Yekaterinburg, Russian Federation*

Funding Acknowledgements: Research was supported by Act 211 Government of the Russian Federation, agreement ? 02.A03.21.0006

Cardiac transplantation is accepted as the best therapeutic option for end-stage heart failure patients who remain symptomatic despite optimal medical therapy. The function of the transplanted heart will be affected by acute allograft rejection, chronic rejection, high blood pressure and so on. All these factors may induce the remodeling of the left ventricle (LV) that will significantly affect the prognosis of heart transplantation (HT). The LV configuration changes from end diastole to end systole are an important factor of the heart pump function optimization. These changes could be described by the term LV "functional geometry".
The objective of this study is the assessment of outcomes in long time period after HT using parameters of LV functional geometry.
The LV functional geometry in myocardial diseases with different degrees of LV systolic dysfunction has been determined by using two-dimensional echocardiography. The control group (CG) consisted of 24 healthy volunteers without any signs of cardiovascular diseases. The second group(IHDG) with preserved LV systolic function (ejection fraction >50%) consisted of 52 patients suffering from ischemic heart disease. And third group(DCMG) with significant LV systolic dysfunction (ejection fraction < 35%) consisted of 35 patients with dilatational cardiomyopathy.
We used linear discriminant analysis (LDA) to build model for pattern recognition of our groups. The model was based on classic echocardiographic parameters, LV function geometry parameters (sphericity index, Fourier shape-power index showing the complexity of the LV shape, apical conicity index, spatio-temporal heterogeneity indexes), and speckle-tracking-derived LV longitudinal strain and strain rate.
We examined 31 patients after orthotopic HT who had postoperative period from 1 to 9 years. All HT patients underwent pairs of endomyocardial biopsy (EMB) and echocardiographic evaluation on the same day. Group of HT patients were stratificated of our LDA model. One quarter of HT group had normal systolic function and were defined in CG. 44% and 31% HT patients were defined in IHDG and DCMG respectively. In 97% of HT patients the predictions of the LDA model coincided with the state of the allograft obtained by EMB.
LDA model taking into account the parameters of LV functional geometry can facilitate the diagnosis of rejection and reveal deterioration of the allograft condition.

P1977

Main features of pathological myocardial remodeling in chronic heart failure and dilated cardiomyopathy

T Tatiana Kulikova[1]; O Stepanova[1]; A Voronova[1]; M Valikhov[1]; V Sirotkin[1]; A Samko[1]; V Masenko[1]; S Tereschenko[1]
[1]Russian Cardiology Research and Production Complex, cardiology department, Moscow, Russian Federation

Cardiac hypertrophy, fetal gene program reactivation and cardiac energy metabolism alterations are the main features of pathological myocardial remodeling in chronic heart failure (CHF). Although cardiac metabolic alterations are the consequence of the pathological state, they lead in turn to the disease development and contribute to the pathogenesis of CHF. Metabolic alterations ranging from changes in substrate utilization to mitochondrial dysfunction, ultimately resulting in energy deficiency and impaired contractility. Energy depletion is not the only consequence of metabolic alterations during CHF. By providing cellular building blocks and signaling molecules, metabolic pathways control essential processes such as cell growth and regeneration. Thus, alterations in cardiac metabolism may also affect the progression to CHF by mechanisms beyond energy supply. Peroxisome proliferator-activated receptor-gamma coactivator 1 alpha (PGC-1 alpha) controls the energy state and contractile function of heart. The expression of PGC-1 alpha is reduced in HF and during cardiac hypertrophy in vitro model of cardiac hypertrophy. The studies at animal model of CHF have shown the link between pathological cardiac hypertrophy, metabolic alterations and fetal gene program reactivation. PGC-1 alpha has an important regulator role in these processes and PGC-1 alpha expression level decreased. The aim of this work to study pathological cardiac hypertrophy, metabolic alterations and fetal gene program reactivation in patients with DCM and CHF.
Endomyocardial biopsies (18) were obtained from patients with CHF and DCM. RT-qPCR was used to measure gene expression levels. Hematoxylin and Eosin staining (H & E) was used for histopathology study.
Myocardial tissue H & E staining results have shown only the pathological hypertrophy of cardiomyocytes and the absence of fibrosis. PGC-1 alpha expression level decreased in CHF in comparison to human non-diseased myocardium autopsy specimens (5).
These data indicate the occurrence of metabolic alterations in CHF - an energy metabolism shifting from cardiac fatty acid oxidation as primary energy source to glucose. The results demonstrate the reactivation of the fetal gene program, features of fetal heart include the preference of carbohydrates over fatty acids as energy substrate.
Pathological hypertrophy of cardiomyocytes and PGC-1a expression level decreasing revealed by us in patients with HF are in line with data received in animal models that cardiac metabolic alterations, connected with PGC-1a downregulation, occur in cardiac pathological hypertrophic processes, and there is a close link. Metabolic alterations in CHF not only results in impaired cardiac energetics, but also induces other processes implicated in the development of CHF such as structural and cell remodeling. Accordingly, modulating cardiac metabolism in heart failure may have significant therapeutic relevance that goes beyond the energetic aspect.

Introduction: Coenzyme Q10 (CoQ10) is the endogenous compound essential for mitochondrial function and bioenergetics of cells. In the body CoQ10 exists in two forms - oxidized (ubiquinone) and reduced (ubiquinol). The main role in achieving the protective effects of CoQ10 is due to the antioxidant properties of ubiquinol. The innovative water-soluble form of ubiquinol for intravenous administration was developed.
Purpose: Experimental evaluation of the cardioprotective efficacy of the innovative drug form of ubiquinol for intravenous administration.
Methods: The experiments were carried out on the rat model of myocardial infarct (MI) induced by coronary artery ligation. In 10 min after occlusion solubilized

ubiquinol (10 mg/kg, group "MI + ubiquinol ", n = 10) or saline (group "MI + saline", n = 12) was administered by intravenous injection. Sham operated rats were given saline (group "Sham", n = 8). Severity of the myocardium damage, CoQ10 tissue levels were evaluated on the 21st day after coronary occlusion. The CoQ10 content was measured by HPLC with electrochemical detection.
Results: In group "MI + ubiquinol" aneurysm size of the left ventricle (13,19 ± 7,13 %) was much less than in group "MI + saline" (31,55 ± 17,9 %, p <0,05). The interventricular septum in group "MI + ubiquinol " (2,61 ± 0,03 mm) was thinner than in group "MI + saline" (2,83 ± 0,27 mm, p <0,05) and did not differ from "Sham" group (2,51 ± 0,29 mm). Only in the treated animals, there was a correlation between the thickness of the interventricular septum and the level of ubiquinol in the myocardium (R2 = 0.672, p <0.05), that shows that it was the administration of ubiquinol that caused the cardioprotective effect.
Conclusion: Intravenous administration of ubiquinol after coronary artery occlusion reduces the aneurysm size the left ventricle and prevents the development of left ventricular hypertrophy in rats.

Design of models for predicting the development of heart failure with reduced ejection fraction and preserved ejection fraction in patients with acquired heart diseases in the postoperative period

I I Irina Averina[1]; OL Bockeria[1]; MYU Mironenko[1]
[1]Bakoulev Center for Cardiovascular Surgery RAMS, Cardiosurgical , Moscow, Russian Federation

Background: Despite technically successful operations postoperative complications as heart failure are still observed.
Purpose: To identify models for the prediction of cardiac heart failure with reduced ejection fraction (HFrEF) and with preserved ejection fraction (HFpEF) in patients with acquired heart disease in the postoperative period.
Materials and Methods: The study was involved 144 patients (99 men and 45 women) with aortic and mitral valve disease. The median age was 46,7 ± 15,1 years (range from 18 to 72 years). 3 examinations were conducted: befor surgery, in the early postoperative period (8 - 14 days) and 12 - 36 months after the surgery. All patients underwent clinical examination, echocardiography, tissue Doppler (TD), the speckle tracking method (STE), 28 patients also had dynamic contrast-enhanced magnetic resonance imaging (MRI). The patients were divided into prognostic groups according to the presence of complications. Group 0 - favorable prognosis; Group 1 - evolved postoperative HFpEF; Group 2 - evolved postoperative HFrEF.
Results: MANOVA and Cox regression models were applied. The highest quality prognosis model for HFrEF and HFpEF was identified.
It includes the MRI anterior-posterior LV dimension at the papillary muscle level (p = 0,004), LV fraction of shortening (p = 0,001), the early-to-late LV diastolic velocity ratio E/A (p = 0,0005), the diastolic diameter of the mitral annulus (p = 0.001) (for HFrEF); the left atrium average global longitudinal strain GLSt av LA(p = 0,002) and early filling (Et) and early diastolic tricuspid annular velocity (E') ratio (Et/E' ratio) assessed by TD (p = 0,05) (for HFpEF).
All the parameters significantly determine the risk of postoperative HF complications.
Conclusion: HFrEF and HFpEF models from easily obtained variables for prediction in patients with acquired heart disease in the postoperative period were identified.

P1980

Regenerative potential of pluripotent stem cell-derived PDGFRa+ cardiac lineage committed cells in infarcted myocardium

S W Cho[1]; SY Sohn[2]; SP Hong[3]; S Song[4]; JH Park[5]
[1]Inje University, Seoul Paik Hospital, Division of Cardiology, Department of Internal Medicine, Seoul, Korea Republic of; *[2]Hospital Myongji, Division of Endocrinology, Department of Internal Medicine, Goyang, Korea Republic of*; *[3]Korea Advanced Institute of Science and Technology, Biomedical Science and Engineering Interdisciplinary Program, Daejeon, Korea Republic of*; *[4]Korea Advanced Institute of Science and Technology, Daejeon, Korea Republic of*; *[5]Chungnam National University Hospital, Daejeon, Korea Republic of*

Background: Pluripotent stem cell (PSC)-derived cardiomyocytes have become one of the most attractive cellular resources for cell-based therapy to rescue damaged hearts. However, the current yield of cardiomyocytes from PSC has still insufficient to meet clinical requirements because of the limited proliferative capacity of differentiated cardiomyocytes. We newly generated PSC-derived PDGFRa+ cardiac lineage committed cells (CLCs) having proliferative capacity, but morphologically and functionally immature state compared to differentiated cardiomyocytes.
Method: We induced PDGFRa+ CLCs from PSCs using a combination of the small molecules Cyclosporin A, the rho-associated coiled-coil kinase inhibitor Y27632, the antioxidant Trolox, and the ALK5 inhibitor EW7197. We implanted PDGFRa+ CLCs and differentiated aMHC+ cardiomyocytes (CMs) into myocardial infarction (MI) murine model and performed the functional analysis using transthoracic echocardiography (TTE) and histologic analysis.
Results: Compared with MI model, the anterior and septal regional wall motion and systolic functional parameters were notably and similarly improved in the MI hearts implanted with PDGFRa+ CLCs and aMHC+ CMs in TTE. In histologic analysis, the gross sizes of MI hearts implanted with PDGFRa+ CLCs and aMHC+ CMs were smaller than MI heart. Furthermore, MI heart had a thinner ventricular wall (0.20 mm) than did controls while the ventricular walls of MI hearts implanted with PDGFRa+ CLCs and aMHC+ CMs were similarly thicker (0.47 mm and 0.39 mm, respectively) compared to MI heart.
Conclusion: PDGFRa+ CLCs from PSCs having proliferative capacity showed the regenerative potential in infarcted myocardium. Therefore, PSC-derived PDGFRa+ CLCs could be an ideal and optimal cellular resource for cardiac regeneration.

Cardiac regenerative and metabolic processes in chronic heart failure

T Tatiana Kulikova[1]; O Stepanova[1]; M Valikhov[1]; A Voronova[1]; A Samko[1]; V Masenko[1]; S Tereschenko[1]
[1]Russian Cardiology Research and Production Complex, cardiology department, Moscow, Russian Federation

In chronic heart failure (CHF) occur metabolic alterations - an energy metabolism shifting in cardiomyocytes from fatty acid oxidation as primary energy source to glucose. Cardiomyocyte metabolic plasticity is unique metabolic feature of these cells. Plasticity of stem cells also reflects the plasticity of their energy substrate metabolism. There is a clear link between the self-renewal state of stem and dedifferentiated cells, in which cells proliferate without differentiation, and the activity of metabolic pathways. Cell dedifferentiation is accompanied by a shift from oxidative phosphorylation to glycolysis. Transcription factor nuclear receptor peroxisome proliferator-activated receptor alpha (PPARa) of is an important regulator of energy metabolism by regulating genes encoding enzymes involved in fatty acid and glucose utilization. We propose that myocardial metabolism shift results to cardiomyocyte dedifferentiation. As PPARa is a main regulator of energy metabolism, change in its activity shows metabolism alterations and may represent a marker of dedifferentiated cell state, the aim of the work to determine PPARa expression level in CHF, to detect dedifferentiated cardiomyocytes in CHF and the role of TNF-a in activation of cardiomyocyte dedifferentiation.
Human fetal cardiomyocytes were stimulated with inflammatory cytokine TNF-a for up to 24 hours and time dependent changes in the expression of established marker of cardiomyocyte dedifferentiation ANP was assessed by RT-qPCR. Transmission electron microscopy was used for dedifferentiated cardiomyocytes detecting in endomyocardial biopsies (EMB) patients with CHF and DCM. ANP expression level was detected in EMB (15) patients with HF and DCM. RT-qPCR was used to assess PPARa expression level in the same samples.
mRNA levels of ANP increased following treatment with TNF-a. Induction ANP was gradual (peaking at 24 hours). Significant ANP expression level increase was detected in EMB in CHF in comparison with the myocardial samples without cardiovascular pathology. Expression levels of PPAR-alpha decreased in CHF.
Elevated ANP expression levels are associated with cardiomyocyte dedifferentiation. Our results demonstrate that TNF-a directly induces cardiomyocyte dedifferentiation. Cardiomyocytes with hallmarks of dedifferentiation as evaluated by electron microscopy have been found in our study in EMB in CHF. Revealed cardiomyocytes have main features of dedifferentiated cardiomyocytes - changes in size and shape of cardiomyocytes, sarcomere disorganization, enhanced glycogen content and mitochondria disposition. PPAR-alpha expression level decrease shows shift from oxidative phosphorylation to glycolysis, a transition to dedifferentiated state of cardiomyocytes. Identifying the specific metabolic pathways involved in dedifferentiation and differentiation is critical for further progress in the field of regenerative medicine without the requirement of genetic manipulation.

P1982

Cardioprotective and immunomodulatory effects of endomyocardial biopsy- and atrial appendage-derived stromal cells in an acute model of Coxsackievirus B3-induced myocarditis

M El Shafeey[1]; K Pappritz[1]; F Diedrichs[1]; M Seifert[1]; C Stamm[1]; M Haag[1]; M Sittinger[1]; C Tschoepe[1]; S Sophie Van Linthout[1]
[1]*Berlin-Brandenburg Center for Regenerative Therapies, Berlin, Germany*

Background: The atrial appendage (AA) has recently been shown to be a suitable source to generate cardiac-derived adherent proliferating (CardAP) cells for regenerative cell-based therapies. CardAP cells have cardioprotective and immunomodulatory properties and have originally been isolated from endomyocardial biopsies (EMB). The amount of CardAP cells derived from EMB is often limited due to the small EMB size, whereas one AA allows sufficient cells for the treatment of more than 250 patients.
Aim: The aim of the present study was to evaluate the cardioprotective and immunomodulatory potential of EMB- and AA-derived CardAP cells in experimental Coxsackievirus B3 (CVB3)-induced myocarditis.
Methods and Results: Before evaluation of the different CardAP cells in CVB3 mice, we demonstrated in vitro by immune cell co-cultures that EMB- and AA-CardAPs have similar immunogenic and immunomodulatory properties. Intravenous application of 10e6 EMB- and AA-CardAP cells, one day after CVB3 infection at a dose of 10e5 p.f.u. improved left ventricular function in CVB3-infected C57BL/6J mice as shown by a 1.3-fold ($p < 0.005$) and 1.4-fold ($p < 0.0005$) increase of the contractility parameter dP/dtmax, respectively, and a 1.5-fold ($p < 0.005$) and 1.5-fold ($p < 0.0005$) improvement of dP/dtmin, respectively. In parallel, both EMB- and AA-CardAP cells decreased cardiac collagen I expression by 1.6-fold ($p < 0.05$) and 1.7-fold ($p < 0.005$), respectively, leading to a 1.5-fold ($p < 0.05$) and 1.6-fold ($p < 0.005$) drop in collagen I / III ratio versus CVB3 mice. EMB- and AA-CardAP cells reduced the % of splenic TGF-ß-expressing CD68 cells in CVB3 mice by 2.2-fold ($p < 0.0001$) and 2.6-fold ($p < 0.0001$), respectively. Concomitantly, both EMB- and AA-CardAP cells reduced the % of T regulatory cells, defined as CD4CD25FoxP3 cells, to percentages of control mice, a finding which was also seen for CD4-IL10- and CD8-IL10-expressing cells.
Conclusion: The recently defined AA-CardAP cells exert cardioprotective and immunomodulatory effects comparable to EMB-CardAP cells in CVB3 myocarditis mice.

P1983

Influence of candesartan cilexetil and resveratrol on changes in the number of stem cells, cytogenetic and cytokinetic parameters of bone marrow of mice

A Aliaksandra Beliayeva[1]
[1]*National Academy of Science, Institute of Bioorganic Chemistry, Minsk, Belarus*

Introduction: The constant growth of incidence of cardiovascular diseases and increased mortality rate provoked by this pathology urges the need to formulate new drugs, to reassess potential of available medicines and their combinations.
Purpose: To investigate the effect of candesartan cilexetil (angiotensin-II receptor blocker) and resveratrol on the number of stem cells, cytogenetic and cytokinetic parameters of bone marrow of C57Bl/6 mice.
Methods: Male C57Bl/6 mice (n = 80) were chosen for study. Animals were divided into 8 groups (10 mice each). Animals of 7 groups received intragastrically daily for 7 weeks candesartan cilexetil and resveratrol, dissolved/suspended in 1% starch solution. Candesartan cilexetil at 1.5 mg/kg dose was administered to mice of group 1, whereas resveratrol at 1 mg/kg, 10 mg/kg and 50 mg/kg doses was supplied to groups 2, 3, 4, respectively. Animals of groups 5 - 7 were treated by combination of candesartan cilexetil at 1.5 mg/kg dose and resveratrol at 1 mg/kg, 10 mg/kg and 50 mg/kg doses, respectively. Control mice received daily 1% starch solution. Flow cytometry method was used to evaluate the number of CD117+ stem cells (endothelial progenitor cells), apoptotic and micronucleated cells, cell distribution at stages of cell cycle in bone marrow of C57Bl/6 mice.
Results: Candesartan cilexetil at 1.5 mg/kg dose caused no effect on the number of CD117+ stem cells in bone marrow of C57Bl/6 mice. Resveratrol raised the ratio of CD117+ stem cells in bone marrow of C57Bl/6 mice in comparison with the control ($p < 0.05$). It was originally established that combination of candesartan cilexetil at 1.5 mg/kg dose and resveratrol at 1 mg/kg, 10 mg/kg and 50 mg/kg doses stimulated generation of CD117+ stem cells in bone marrow of C57Bl/6 mice as compared to the control ($p < 0.05$). The obtained data were also significantly higher than those recorded for individual compounds. Candesartan cilexetil at 1.5 mg/kg dose increased the number of apoptotic and micronucleated cells in comparison with the control ($p < 0.05$), whereas the combined use of candesartan cilexetil at 1.5 mg/kg dose and resveratrol at 1 mg/kg and 10 mg/kg doses significantly reduced the number of genetically impaired cells induced by exposure to candesartan cilexetil and enhanced proliferation in bone marrow of C57Bl/6 mice.
Conclusion. This study is the first demonstration that concerted use of candesartan cilexetil and resveratrol stimulates the formation of CD117+ stem cells in bone marrow of C57Bl/6 mice. It was originally found that resveratrol reduced cytotoxic effects of candesartan cilexetil in bone marrow of mice. The experimental data might be used to develop new complex drug for treatment of cardiovascular diseases capable to mobilize endothelial progenitor cells and facilitate reparative processes in cardiovascular system.

Cardiac metabolic remodeling in chronic heart failure due to dilative cardiomyopathy and ischemic heart disease

AD Voronova[1]; TG Kulikova[1]; OV Stepanova[1]; MP Valikhov[1]; VP Masenko[1]; RS Akchurin[1]
[1]*Cardiology Research and Production Center, Moscow, Russian Federation*

Funding Acknowledgements: RFBR:?18-015-00198 "Studying of energy cardiac metabolism and cardiomyocyte dedifferentiation in chronic hert failure

The main causes of chronic heart failure (CHF) are dilatative cardiomyopathy (DCM) and ischemic heart disease (IHD). The CHF progression is accompanied with a pathological changes in cardiac energy metabolism - metabolic remodeling characterized by shifting from cardiac fatty acid oxidation as a primary energy source to glucose oxidation. ?ardiac ischemia is the result of hypoxia. What leads to cardiac energy metabolism changes in DCM is unknown. Cardiac energy metabolism is under the transcriptional control of nuclear receptors, such as peroxisome proliferator activated receptors (PPARs) and transcriptional coactivator of PPARs - PPAR gamma coactivator-1-alpha (PGC-1 alpha), PGC-1 alpha plays a critical role in controlling cardiac energy. These factors act as molecular sensors in response to extracellular and intracellular changes, regulating the expression of the target genes. The downregulation of PPAR alpha has been shown in the studies in mice model of ischemic cardiomyopathy. The purpose of our work is to study cardiac energy metabolism alterations in IHD and DCM.
RT-qPCR was used to measure mRNA expression of the nuclear receptor PPAR alpha - a key regulator of fatty acid beta-oxidation, its target genes LCAD, CPT-1, CD36, HFABP and PGC-1alpha, in surgical specimens of auricle from patients with IHD (n = 10), in human endomyocardial biobsy specimens from patients with DCM (n = 37) and in human non-diseased myocardium autopsy specimens (n = 5).
Gene expression levels of PPAR-alpha and LCAD, CPT-1, CD36 decrease in IHD and DCM relative human non-diseased myocardium autopsy specimens. The gene HFABP is upregulated in IHD and DCM. The level of expression of PGC-1 alpha significantly increases in IHD, whereas it decreases in DCM. Significant changes in the levels of expression of PPAR-alpha and its target genes in IHD and DCM may mean that these genes are involved in of cardiac energy metabolism alterations and there is a shift from the use of fatty acids to the use of glucose. The expression levels of the PGC-1 alpha were much higher in IHD than in the normal heart, there is downregulation of this gene in DCM, these data may indicate different coactivator activities in DCM and IHD. It can be assumed that the regulation of the cardiac energy metabolism is possible by acting on PPAR-alpha and its target genes, and apparently the mechanisms of action on PGC-1 alpha should differ. These results of our study are very interesting as the transcriptional coactivator of the PPARs PGC-1 alpha has emerged as a key player in the control of myocardial metabolism and perturbations in the PGC-1 alpha system could predispose to cardiomyopathic remodeling. The importance of the PPARs and PGC-1 alpha in the control of cardiac energy metabolism makes these regulatory pathways attractive for metabolic therapy. Much needs to be learned concerning the intricacies of modulating their activity for optimal therapeutic benefit.

Purpose: Mitochondrial steady-state Ca2+ balances energy production and antioxidative capacity. We hypothesised that increased workload without concomitant Ca2+-elevation impairs mitochondrial redox state, increases ROS-emission and explains side effects of Ca2+-sensitizers. We used EMD-57033 (EMD), levosimendan (levo) and the myosin activator omecamtiv mecarbil (OM).

Methods: Isolated cardiac myocytes (guinea pigs, mice) were field stimulated, while sarcomere length and fluorescence (NAD(P)H/FAD, indo-1) were determined. To pinpoint mitochondrial H2O2, transgenic mice expressing mitochondrially targeted roGFP2-Orp1 were used. For the first time, NAD(P)H and specifically mitochondrial H2O2 were measured live and simultaneously in twitching cardiac myocytes. A statistical model was developed employing regression analyses to estimate the dependency of NAD(P)H on the absolute degree of orp1-sensor oxidation.
Results: EMD (3μM) increased fractional sarcomere shortening, but impaired relaxation (RT50%), without affecting [Ca2+]c. Mitochondrial redox states of NADH, FADH2 and NADPH were oxidized, impairing the electron supply for the respiratory chain (NADH, FADH2) and the antioxidative capacity (NADPH). Accordingly, EMD increased the mitochondrial H2O2 emission, while the compound had no direct effects on isolated mitochondria. Levo had minor effects on sarcomere shortening at micromolar concentrations, while minimal prestimulation of beta-adrenergic receptors increased the efficiency and potency of levo, related to the previously observed inhibitory effect on phosphodiesterase 3. In fact, the increase in cell shortening was related to an increase in [Ca2+]c. Accordingly, the redox state of NAD(P)H and FAD remained stable with Levo, while the occurrence of spontaneous extra beats was increased. OM (0.2-10μM) increased active and passive work (integral over sarcomere length). Mitochondrial redox state was slightly oxidized at therapeutic plasma concentrations (0.2 μM), but provoked only a weak increase in H2O2 emission that was less pronounced compared to EMD at equi-effective concentrations. At therapeutic concentrations, OM did not provoke spontaneous extra-beats, while at supra-therapeutic concentrations (1 μM), it induced substantial diastolic dysfunction, depleted the antioxidative capacity and caused cell death.
Conclusions: "Pure" Ca2+-sensitization (EMD) induces a mismatch between energy supply and demand and depletes NADPH, provoking excess mitochondrial H2O2-emission and cell death. Levo predominantly inhibits PDE, and through elevating [Ca2+]c avoids mitochondrial oxidation, albeit at the cost of arrhythmias. Compared to EMD, OM provokes less oxidation and ROS emission at therapeutic concentrations. At higher OM concentrations, diastolic dysfunction and mitochondrial oxidation induce cell death that may underlie the increase of plasma troponin T in early clinical trials through a mechanism independent of compromised coronary perfusion.

P1986

Downregulation of the mitochondrial calcium uniporter hinders cardiac energy supply-and-demand matching in Barth syndrome

E Bertero[1]; A Nickel[1]; M Kohlhaas[1]; M Hohl[2]; C Krug[2]; A Mueller[3]; M Lafontaine[4]; R Lancaster[4]; R Kappl[5]; K Von Der Malsburg[6]; M Van Der Laan[6]; J Dudek[7]; P Rehling[7]; C Maack[1]
[1]Comprehensive Heart Failure Center (CHFC), Würzburg, Germany; *[2]Saarland University Hospital, Clinic for Internal Medicine III, Homburg, Germany*; *[3]Saarland University Hospital, Clinic for Radiology, Homburg, Germany*; *[4]Saarland University Hospital, Department of Structural Biology, Homburg, Germany*; *[5]Saarland University Hospital, Department of Biophysics, CIPMM, Homburg, Germany*; *[6]Saarland University Hospital, Medical Biochemistry and Molecular Biology, Homburg, Germany*; *[7]Georg-August University, Department of Cellular Biochemistry, Göttingen, Germany*

Background: Barth syndrome (BTHS) is an X-linked disorder caused by mutations in the tafazzin (Taz) gene and characterized by cardiomyopathy, skeletal myopathy and neutropenia. Taz is involved in the remodeling of cardiolipin, a phospholipid of the inner mitochondrial membrane playing a key role in the organization of the electron transport chain complexes. Destabilization of respiratory chain super-complexes and subsequent increase in ROS production may underlie the pathogenesis of the disease. We investigated the consequences of global genetic deletion of Taz in a mouse model of BTHS.
Methods and Results: Left ventricular (LV) function (cardiac MRI) was not impaired in 10 weeks old (wo) mice, but 20 and 50 wo Taz-KD mice displayed a reduction in cardiac output compared with wild type (WT) littermates due to a combination of diastolic and slight systolic dysfunction (LVEF: $55 \pm 6\%$ vs $76 \pm 5\%$, $p < 0.05$) in the absence of cardiac enlargement. Cardiac dysfunction was associated with a 15-fold increase in ANP and 4-fold increase in CTGF mRNA expression. In isolated, field-stimulated Taz-KD ventricular myocytes, myofilament Ca2+ sensitivity was increased, possibly contributing to the diastolic dysfunction observed at a whole-heart level. In isolated cardiac mitochondria, maximal respiration was slightly reduced compared to WT in 10 wo mice, but was unchanged in 20 and 50 wo mice. ROS emission was unchanged at 10 and 20 weeks and even decreased in 50 wo Taz-KD mice. Strikingly, uptake of Ca2+ was virtually absent in isolated cardiac, but not skeletal muscle mitochondria at all time points. This was caused by downregulation of the mitochondrial Ca2+ uniporter (MCU) pore-forming subunit (MCUa) associated with structural rearrangement of the MCU complex (blue native gel), whereas regulatory components of the MCU were unchanged. The mechanism underlying MCU downregulation is not fully resolved, but microRNA-mediated downregulation and defective protein import can be ruled out. In isolated contracting cardiac myocytes, the lack of mitochondrial Ca2+ uptake hampered the Krebs cycle-mediated regeneration of NADH (for ATP production) and NADPH (for H2O2 detoxification) during physiological workload transitions (beta-adrenergic stimulation and 5 Hz stimulation). In 10 wo Taz-KD myocytes, excessive H2O2 emission was prevented by compensatory protein upregulation of H2O2-eliminating enzymes (catalase, glutathione peroxidase), but this upregulation vanished at 50 weeks. Accordingly, at 20 and 50 weeks, the baseline redox state of isolated cardiac myocytes was more oxidized in Taz-KD compared to WT, which remained aggravated during workload transitions.
Conclusions: Redox mismatch due to defective mitochondrial Ca2+ uptake precedes respiratory chain defects in BTHS and may represent a major driver of oxidative stress and thereby, disease progression. Because this defect is heart-specific, this may explain why cardiomyopathy is a dominant feature of the disease.

The ubiquitin ligase TRIM35 is a novel restriction factor for cardiomyocyte proliferation

H Hashim Ali[1]; L Braga[1]; S De Monte[1]; M Vu Deim[1]; S Vodret[1]; P Lesizza[2]; L Zentilin[1]; M Giacca[1]
[1]International Centre for Genetic Engineering and Biotechnology (ICGEB), Trieste, Italy; *[2]University of Trieste, Department of Medical, Surgical and Health Sciences, Trieste, Italy*

Funding Acknowledgements: This work was supported by grant 14CVD04 from the Leducq Foundation Transatlantic Network of Excellence

Purpose: The majority of adult mammals are unable to regenerate their hearts after cardiac injury, largely due to the limited replicative potential of cardiomyocytes after birth. However, some adult vertebrates and newborn mammals are able to repair the lost myocardium through pre-existing cardiomyocyte proliferation. This occurs after partial de-differentiation of these cells, an event that requires disassembly of the contractile sarcomere and remodeling of the actin cytoskeleton. We hypothesized that controlled protein degradation by the ubiquitin-proteasome pathway might play a key role in this process.
Methods: High-througput siRNA screening, Edu incorporation assay, Crispr/cas9-mediated gene silencing, AAV-transduction, qPCR, echocardiography, histology and Co-immunoprecipitation.
Results: To identify the critical regulators in the process of cardiomyocyte de-differentiation that parallels cell proliferation, we performed a targeted RNAi screen based on high-content fluorescence microscopy, using a library of ~600 siRNAs against factors in the ubiquitin-conjugation and proteasome-mediated degradation pathway; screening endpoint was the incorporation of EdU in neonatal mouse cardiomyocytes; validation of hits was later performed testing phospho-histone 3 positivity and Aurora B kinase localization in midbodies during cytokinesis. Using a 2 fold-standard deviation threshold over control for EdU incorporation, we identified 6 siRNAs that stimulate cardiomyocyte proliferation and 10 siRNAs that inhibit it. Most of these siRNAs target cellular E3-ubiquitin ligases with still unidentified targets in cardiac biology. In particular, we found that depletion of the TRIM family member TRIM35 was able to markedly induce proliferation of both mouse and rat cardiomyocytes. Cardiac-specific deletion of the TRIM35 gene in vivo using the Crispr/Cas9 technology delivered through AAV vectors induced remarkable proliferation in the hearts of neonatal mice. Gene knock out in adult mice improved heart function and decreased fibrosis after myocardial infarction.
In conclusion: TRIM35 is a novel ubiquitin-conjugation component restricting cardiac regeneration both in vitro and in vivo.

The characterization of cardiac molecular defects in an in vitro disease model of Vici syndrome and identification of potential therapeutic target

EA Ezzaldin Ahmed Alfar[1]; J Qi[2]; J Gommlich[1]; M Gautel[3]; K Guan[1]
[1]Dresden University of Technology, Pharmacology and Toxicology, Dresden, Germany; *[2]University Medical Center of Göttingen, Cardiology and Pneumology, Göttingen, Germany*; *[3]King's College London, Cardiovascular Division, London, United Kingdom*

Funding Acknowledgements: The project was supported by the DFG IRTG1816 to K.G. and M.G

Purpose: Vici syndrome is a rare disorder characterized by defective autophagy due to mutations in Epg5. As the disease progresses, development of dilated and hypertrophic forms of cardiomyopathies are observed. However, the mechanisms of cardiomyopathies development and possible therapeutic targets remain to be elucidated. Interestingly, previous work in c. elegans showed that targeting the O-GlcNAc transferase (OGT) in Epg5 deficient nematodes restored a functional autophagy. However, the effect of targeting OGT in a human Vici disease model is unknown. The unknown mechanisms of Vici cardiomyopathies and the unknown effect of targeting OGT in a Vici disease model intrigued us to establish a human Vici

disease model. This model allowed us to provide further insight into the mechanisms of cardiomyopathies development and to test the effect of OGT inhibitors in attenuating the Vici cardiomyopathies.
Methods: We obtained Vici patient-specific fibroblasts which we used to generate induced pluripotent stem cells (iPSCs). The iPSC-derived cardiomyocytes served as a human in vitro disease model allowing the characterization of cardiac defects, mechanisms of cardiac defects and testing the effects of potential therapeutic targets.
Results: First, we successfully generated patient-specific iPSC lines, which retained the Epg5 mutation. Then we derived cardiomyocytes from the Vici patient-specific iPSCs, which exhibited defective autophagy as predicted for the Epg5 mutation. In addition, we observed some of the known Vici associated cardiomyopathies including hypertrophy and sarcomere disarray in our in vitro disease model. Given that both oxidative stress and mitochondrial dysfunction are known contributing factors to cardiomyopathies and at the same time potential outcomes of a defective autophagy process, we investigated possible disease mechanisms including mitochondrial dysfunction and cellular oxidative stress. We showed that Vici derived cardiomyocytes accumulates fragmented and dysfunctional mitochondria and exhibit oxidative stress. Next, we tested the effect of several OGT inhibitors on oxidative stress in our disease model. We observed a reduction in cellular oxidative stress in OGT inhibitor treated cells, a result which indicates possible attenuation of the disease phenotype and improvement of mitochondrial function.
Conclusion: In this work, we established an in vitro human Vici syndrome cardiomyopathy model. We observed some of the known disease phenotypes in our disease model, and at the same time, provided further insight into the disease mechanisms. Additionally, we have preliminary results of a possible therapeutic target for Vici syndrome associated cardiomyopathies. Currently, we are characterizing further cellular defects including defective calcium handling, ER stress and reliance on glycolysis. In addition, we are further validating the therapeutic target we identified in attenuating the disease phenotype.

Evaluation of cardiovascular biomarkers transcriptional levels in cardiac tissue of rats as function of age

C Salvadori[1]; M Cabiati[1]; AL Sapio[1]; S Burchielli[2]; C Caselli[1]; L Carlucci[3]; L Mattii[4]; S Del Ry[1]
[1]Institute of Clinical Physiology of CNR, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*; *[3]Sant'Anna School of Advanced Studies, Institute of Life Sciences, Scuola Superiore Sant'Anna, Pisa, Italy*; *[4]University of Pisa, Pisa, Italy*

Background: Chronological age is considered to be one of the major risk factors for cardiovascular disease and mortality in developed countries. During this process cardiovascular system undergoes substantial functional and structural changes altering the levels of some cardiac function biomarkers as natriuretic peptides (PN) and endothelin-1 (ET-1). Recently the adrenomedullin (ADM) system and long non-coding (lnc) RNA have been identified as new biomarkers associated with aging but their role in this process is not yet defined.
Purpose: To evaluate the expression of the PN, ET-1 and ADM system, as well as the analysis of lncRNA MIAT, MALAT-1, CARMEN and XIST in cardiac tissue of rats of different ages.
Materials & **Methods:** Three groups of Wistar male rats were studied: A (n = 6; age = 248+0.00 days-young), B (n = 13; age = 413.8+8.20 days-adult), C (n = 10; age = 597.6+10.3 days-old). Total RNA was extracted from cardiac tissue samples and analyzed by Real-Time PCR. Echocardiographic and biochemical evaluation was performed and histological analyses completed the study.
Results: A significant increase of ANP and BNP mRNA levels was observed only in C and CNP remained in a steady-state in B and C groups, while ET-1mRNA levels increased gradually and significantly as a function of age (A = 0.46+0.15; B = 1.50+0.33; C = 2.01+0.98; p = 0.013 A vs. B; p = 0.018 A vs. C). The three NP receptor subtypes did not show statistically significant differences between the groups studied. Regarding ET-1 receptors, ET-A expression levels were statistically lower in Group B than A (p = 0.04) while ET-B were similar in all the three groups studied. The ADM showed a trend opposite to that of the other peptides studied, decreasing significantly as a function of age (A = 1.46+0.36; B = 0.64+0.17; C = 0.61+0.10; p = 0.04 A vs. B; p = 0.05 A vs. C) and presenting a counter-regulation of its main receptor complex CALR and RAMP-2. The analyzed lncRNAs showed decreased expression levels as a function of age reaching levels of significance in most cases (CARMEN: p = 0.036 B vs. C; MIAT: p = 0.005 B vs. C; MALAT-1: p = 0.0004A vs. B and C) except for XIST. ADM and lncRNA trend suggests that the animals are subjected a "healthy aging" as also confirmed by histological analysis that highlights a slight hypertrophy of cardiomyocytes and an increase in the expression of collagen fibers, a direct and non-pathological consequence of aging. Several significant correlations were observed between the analyzed genes and applying a multivariate logistic regression analysis, only LnANP (p = 0.003) and LnADM (p = 0.023) resulted significantly associated with aging. **Conclusions:** The results obtained identify, for the first time, ADM and ANP as independent aging markers. The study of transcriptional levels of both coding and non-coding RNAs plays a key role in better understanding the molecular mechanisms at the basis of the process, underlining the importance of a multi-label biomolecular approach in the evaluation of aging.

P1990
Reciprocal regulation of GRK2 and bradykinin receptor stimulation modulate Ca2+ intracellular level and permeability in endothelial cells: Role in RAAS antagonist induced angioedema.

M Ciccarelli[1]; J Gambardella[1]; D Sorriento[2]; M Bova[2]; S Loffredo[2]; A Fiordelisi[2]; G Iaccarino[1]
[1]University of Salerno, Salerno, Italy; *[2]"Federico II" University of Naples - Dept of Advanced Biomedical Sciences, Naples, Italy*

Background: Bradykinin (BK) accumulation represents the most frequent cause of reduced compliance to ACE inhibitors in Heart Failure, due to the multiple effects on the endothelium mediators through the Gq protein-coupled receptors B1 and B2,. The G protein-coupled receptor kinase GRK2 can modulate B1 and B2 receptors through desensitization.
Purpose: To evaluate level of GRK2 in peripheral blood mononuclear cells (PBMC) from patients with known history of ACE inhibitors adverse events and to verify the role of GRK2 in regulating endothelial functions in response to BK.
Methods: GRK2 expression levels were assessed in PBMC from patients with or without clinical history of angioedema. The regulation of GRK2 expression and subcellular localization to BK (3nM) was assessed in bovine aortic endothelial cells (BAEC). GRK2 degradation pattern in response to BK, were evaluated by interaction with mdm2 and GRK2 ubiquitination. In the same cells, a specific HJ-loop derived peptide inhibitor of GRK2, we evaluated: BK induced Ca2+ accumulation (Fluo4 AM), NO production (DAF-FM Diacetate), and cell permeability (Millipore).
Results: Patients with history of angioedema show reduced protein level of GRK2 but increased mRNA levels respect to controls. In BAEC. 5 min BK stimulation increases GRK2 levels, in several cellular compartments (Membrane, Mitochondria, and cytosol); at 15 minutes GRK2 returns to baseline levels. BK-induced GRK2 accumulation is dependent upon reduced GRK2 ubiquitination by interaction between GRK2 and mdm2. BK causes Ca2+ cytosolic accumulation which is enhanced by inhibition of the GRK2 by KRXC7 (CTRL: 50,4% vs KRXC7: 72% of fluorescence intensity over basal). Similarly, GRK2 inhibition by pre-treatment for 1 hour with KRX-C7, enhances BKA –dependent in vitro production of NO (BKA+KRX: 20 vs BKA: 10; fold of increase over basal) and permeability of endothelial cells (BKA+KRX: 40% vs BKA: 24%; increase over basal).
Conclusions: BK induces GRK2 intracellular accumulation, which in turn desensitizes BK receptors. Proteasome plays a key role in this negative feedback loop, by acutely regulating GRK2 cellular levels. Inhibition of GRK2 affects endothelial response to BKA, enhancing calcium accumulation, NO production, and cell permeability. Moreover in the context of a personalized medicine, we propose that evaluation of GRK2 levels (protein or mRNA) is a potential tool to identify patients at risk of angioedema with RAAS antagonists.

P1991
Aging and biomarkers: evaluation of opn/mirna-181a transcriptional levels in rats of different age ranges

C Salvadori[1]; M Cabiati[1]; AL Sapio[1]; S Burchielli[2]; C Caselli[1]; L Carlucci[3]; L Mattii[4]; L Sabatino[1]; S Del Ry[1]
[1]Institute of Clinical Physiology of CNR, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*; *[3]Sant'Anna School of Advanced Studies, Institute of Life Sciences, Scuola Superiore Sant'Anna, Pisa, Italy*; *[4]University of Pisa, Pisa, Italy*

Background: It is well-known that human aging is attended by a low-grade systemic in?ammation and the Osteopontin (OPN), an extracellular matrix glycoprotein that plays an important role as cytokine during inflammation, has recently identified as a hepatic damage marker but which is its role in aging is not yet defined. Moreover, the aging process seems to be associated with several non-coding RNA (miRNA and lncRNA).
Purpose: To evaluate, in liver tissue of rats of different age ranges, the expression variations of OPN and miRNA-181a, the transcriptional profiling of the lncRNA GAS-5/miRNA-222 axis and the lncRNA NEAT-1. In addition, to monitoring the senescence process, the telomere shortening and the expression of TERT and TERC mRNA were also measured.
Materials & Methods: Three groups of Wistar male rats were studied: A (n = 6; age = 248+0.00 days-young), B (n = 13; age = 413.8+8.20 days-adult), C (n = 10; age = 597.6+10.3 days-old). Total RNA and miRNA were simultaneously extracted from liver tissue samples and analyzed by Real-Time PCR. Ultrasound and biochemical evaluation were performed in all rats as well as the histological analysis of the hepatic tissues.

Results: The OPN mRNA resulted lower in C (0.65+0.12) with respect to A (1.07+0.12) and B (1.32+0.26; p = 0.03 B vs. C) while the miRNA-181a expression resulted significantly increased as a function of age (A = 0.72+0.29; B = 1.09+0.08; C = 1.33+0.24; p = 0.03 A vs. B; p = 0.02 A vs. C). An increasing of miRNA-222 expression as a function of age (A = 0.9+2+0.22; B = 1.54+0.16; C = 1.94+0.21; p = 0.02 A vs. B; p = 0.003 A vs. C) in parallel with a decreasing of lncRNA GAS-5 expression in young and old rats but not in the adult ones (A = 0.01+0.003; B = 1.89+0.19; C = 0.07+0.01; p <0.001) was also observed while NEAT-1resulted: A = 0.22+0.04; B = 0.24+0.05; C = 0.49+0.09; p = 0.02 B vs. C. A positive correlation was observed between miRNA-181a and miRNA-222 (r = 0.73; p <0.0001). The hepatic ultrasound analysis revealed areas of hyperechogenicity distributed as a function of age. The study of telomeres highlighted a significant shortening of the telomeres as a function of age while the two subunits TERT and TERC expressions showing an opposite trend.
Conclusions: The results showed an indirect back regulation of the OPN miRNA-181a mediated, underlying their role as potential successful markers of inflamm-aging. The different trend observed for lncGAS-5 and miRNA-222 underlying a mutual regulatory feedback between the two targets. The balance between lncGAS-5 and NEAT-1 expression levels indicates the absence of neoplastic formations as also confirmed by the echographic and histological analysis. Although further studies are needed to understand the OPN and non-coding RNA role in the molecular process at the base of aging, this work provides a valid starting point to better understand the physiopathological changes occurring during aging process pinpointing in the OPN/miRNA-181a axis a potential marker of inflammation during aging.

P1992

Association of GSTM1, GSTP1 and GSTT1 polymorphisms with risk of chronic heart failure

N Natasa Jankovic[1]; D Simic[1]; V Coric[2]; S Suvakov[2]
[1]Clinical Center of Serbia, Clinic for Cardiology, Belgrade, Serbia; *[2]Institute for Medical Biochemistry, Belgrade, Serbia*

Background : Oxidative stress, due to an excess of reactive oxygen species (ROS), plays a role in the development and progression of heart failure (HF). 8-hydroxy-2'-deoxyguanosine (8-OHdG) is a marker of oxidative DNA damage caused by ROS. Genes encoding for glutathione transferases (GST) contain several polymorphic variants that may affect their role in protecting cellular DNA against oxidative damage, through altered protein levels or function.
Aim: The aim of this study was to investigate the role of certain GST polymorphisms in the risk of HF development, as well as the association of different GST variants with the level of 8-OHdG among those patients.
Material and methods : GSTM1, GSTT1 and GSTP1 genotypes were determined in 116 patients (100 male, 16 female) with chronic heart failure. The criterion for admission was left ventricular ejection fraction (LVEF) <45%. 166 healthy controls served as a control group. GST genetic polymorphisms were determined by multiplex PCR or qPCR. Byproducts of DNA oxidative damage (8-OHdG) were determined by ELISA method.
Results: The frequency of GSTM1-null genotype was higher in patients with HF (58%) compared to controls (49%), with an adjusted OR of 0.73 (95% CI: 0.33-1.64). Moreover, the GSTT1-null genotype enhanced the risk of HF compared to the GSTT1-active genotype (OR:3.08; 95%CI: 1.23-7.73, p = 0.016).The association of GSTM1-null genotype and level of 8-OHdG was statistically significant (p = 0.013). HF patients with GSTT1-null genotype didn't have statistically higher level of 8-OHdG compared to the HF patients with GSTT1-active genotype (p>0.05). There was no difference in serum 8-OHdG levels with regard to different GSTP1 genotype. On the other hand, HF patients with combined GSTM1-active/GSTP1-referent genotype had statistically higher level of 8-OHdG compared to the carriers of GSTM1-null/GSTP1-variant genotype (p = 0.011).
Conclusion: Although GSTM1 and GSTP1 polymorphisms have not been statistically significant associated with HF risk, GSTT1 polymorphisms was associated with risk of chronic heart failure and GST genotype status was shown to influence the level of 8-OHdG.

Pharmacological inhibition of sphingosine 1-phosphate receptor 2 (S1pr2) enhances angiogenesis and improves cardiac function after myocardial infarction (MI)

L Zhang[1]; XL Li[1]; YS Kuang[1]; HM Fan[1]; YZ Zhang[1]
[1]Tongji University School of Medicine, 1. Research Center for Translational Medicine, Shanghai East Hospital, Shanghai, China People's Republic of

On behalf of: Research Center for Translational Medicine, Shanghai East Hospital, Shanghai, People's Republic of China

Funding Acknowledgements: Discipline Leader Training Program of Pudong Health Bureau of Shanghai (PWRd2017-01), NSFC (81670234, 81470472)

Background and Purpose: Sphingosine 1-phosphate (S1P) is a lipid metabolite and a ligand of five G protein-coupled cell surface receptors S1pr1 to S1pr5. Our preliminary study showed that S1pr1 and S1pr2 were highly expressed in mouse hearts. We have shown that activation of S1pr1 enhanced arteriole formation and improved vascular remodeling after myocardial infarction. However, it is unknown whether S1P/S1pr2 signaling controls cardiac remodeling after myocardial infarction. We aimed to investigate the effect of pharmacological inhibition of S1pr2 by JTE013 in a mouse model of acute myocardial infarction.
Methods: We performed left anterior descending artery (LAD) ligation to induce acute myocardial infarction in mice. We treated operated mice with 5 mg/kg/day S1pr2 inhibitor, JTE013, or placebo (DMSO) i.p., respectively, for 4 weeks. We performed echocardiography to investigate cardiac function. We also carried out histological analysis to study vascular remodeling in MI model.
Results: Echocardiography showed that cardiac function was significantly reduced in MI mice (ejection fraction (EF): 76.15 ± 1.65 % Sham group vs. 50.78 ± 4.85 % MI-DMSO group. P < 0.05). S1pr2 inhibitor, JTE013, significantly improved cardiac function 4 weeks after myocardial infarction (EF: 50.78 ± 4.85 % MI-DMSO group vs. 64.67 ± 2.64 % MI-JTE013 group. P < 0.05). Mason's trichrome staining showed that JTE013 treatment significantly reduced the infarct size: 21.25 ± 1.02 (%) MI-DMSO group vs. 18.31 ± 1.70 (%) MI-JTE013 group. P < 0.05). Our further isolectin B4 (iB4) antibody staining showed that capillary density in peri-infarct myocardium was remarkably more in MI-JTE013 group compared to MI-DMSO group. Moreover, co-staining of iB4 antibody and alpha smooth muscle actin (alpha-SMA) antibody showed that arteriole density in peri-infarct myocardium was significantly increased in MI-JTE013 group compared to MI-DMSO group.
Conclusions: Our results demonstrated that inhibition of S1pr2 boosted post-MI angiogenesis and vascular maturation, and thus improved vascular remodeling after myocardial infarction, suggesting that S1P/S1pr2 signaling aggravates post-MI cardiac remodeling, which is contrary to the beneficial effect of S1P/S1pr1 signaling on post-MI cardiac remodeling. Our investigations indicate that pharmacological modulation of S1P/S1PR1 and S1P/S1PR2 signaling might improve cardiac recovery after myocardial infarction.

Hypotension after coronary artery bypass grafting can be associated with endogenous ACE inhibition caused by cell free haemoglobin

A Csongradi[1]; IM Siket[1]; T Csipo[1]; A Toth[1]; T Szerafin[2]; Z Csanadi[3]; I Edes[3]; Z Papp[1]; M Fagyas[1]
[1]University of Debrecen, Faculty of Medicine, Department of Cardiology, Division of Clinical Physiology, Debrecen, Hungary; *[2]University of Debrecen, Faculty of Medicine, Department of Cardiology, Division of Cardiac Surgery, Debrecen, Hungary*; *[3]University of Debrecen, Faculty of Medicine, Department of Cardiology, Debrecen, Hungary*

Funding Acknowledgements: This work was supported by the Hungarian Scientific Research Fund (PD116212 to M. Fagyas), and the GINOP-2.3.2-15-2016-00043 project.

Background: A common intra-, and postoperative complication in patients undergoing coronary artery bypass graft (CABG) surgery is hypotension. During prolonged cardiopulmonary bypass (CPB) red blood cells are often damaged causing intravascular haemolysis therefore increasing the level of circulating plasma haemoglobin. We hypothesized that cell free haemoglobin can decrease the activity of the angiotensin converting enzyme (ACE) thereby contributing to the reduction of systemic blood pressure during and after CPB.
Purpose: In this study, we examined the effects of free haemoglobin on ACE-activities of sera and recombinant ACE, as well as on tissue bound ACE using saphenous vein rings.
Methods: Serum derived and recombinant ACE-activities were measured by a fluorescent kinetic assay. The inhibition of tissue ACE-activity was tested in unused saphenous vein rings (n = 20) that remained after CABG surgeries (n = 14) using an isometric myograph system.
Results: We found that free haemoglobin decreases ACE-activities in the serum and of recombinant ACE (IC50= 1.7 nM; 1.3 nM, respectively) in vitro. The mechanism of haemoglobin dependent inhibition was identified by Lineweaver-Burk double reciprocal plot as a non-competitive inhibition (common X-axis intersection point). During saphenous vein experiments where contractile responses elicited by angiotensin I in the presence (n = 10 rings) and absence of 0.5 g/L haemoglobin (n = 10 rings) were followed, contractile force was significantly decreased in the haemoglobin treated group in contrast to the control group (relative strength compared to norephinephrine: 39.49 ± 7.14%, 79.25 ± 5.70%; P = 0.0004, respectively). Significant differences between the kinetics of the contractions (control: 0.17 ± 0.04 mN/sec; 0.15 ± .04 mN/sec, P = 0.6849) and desensitizations (control: 5.10 ± 1.04 μN/sec; 6.48 ± 0.96 μN/sec, P = 0.3445) were not found.

Conclusions: : Our findings illustrate haemoglobin as non-competitive inhibitor of the ACE enzyme. In addition, we propose that free haemoglobin can suppress tissue ACE-activity thereby contributing to the development of hypotension during and after CABG in association with haemolysis.

Influence of age and cardiovascular risk factors on digital vascular function in Asians: a community-based study

S L Shir Lynn Lim[1]; SP Chan[2]; TP Ng[3]; CSP Lam[4]; AM Richards[5]; LH Ling[1]
[1]National University Heart Centre, Department of Cardiology, Singapore, Singapore; *[2]National University of Singapore, Department of Medicine, Singapore, Singapore*; *[3]National University Health System, Singapore, Singapore*; *[4]National Heart Centre Singapore, Department of Cardiology, Singapore, Singapore*; *[5]National University Heart Centre, Cardiovascular Research Institute, Singapore, Singapore*

Funding Acknowledgements: Biomedical Research Council, Agency for Science, Technology and Research (03/1/21/17)

Background: The digital reactive hyperemia index (RHI) reflects endothelial function. Studies in Western populations have shown a counter-intuitive positive association of RHI with age.
Purpose: We assessed the clinical correlates of RHI in a multi-ethnic Asian population.
Method: We prospectively studied 988 adult Singaporeans in the community without overt cardiac disease. RHI was measured with the EndoPAT device. A generalized structural equation model was used to assess the association between RHI, age and cardiovascular risk factors (CVRF).
Results (see Table)
Mean RHI was 2.19 ± 0.56; 158 subjects had an "abnormal" RHI (<1.67). Age, Indian ethnicity and growth differentiation factor (GDF) 15 were univariately associated with RHI, but only age (p = 0.008) and Indian ethnicity (p = 0.011) were independently associated. While RHI increased with age, it declined after age 70. This inflection point was absent in those without hypertension, diabetes or = stage 3 chronic kidney disease. Age interacted significantly with CVRF - subjects older than 70 with = 1 of these 3 CVRF had lower RHI compared to those without (coefficient: -0.41, p = 0.001) and non-significantly higher GDF-15 (1396 vs. 1092 ng/L, p = 0.16). The interaction was observed in men (p = 0.001) but not women (p = 0.16).
Conclusion: Age was positively associated with RHI in an Asian population. The interaction between CVRF and age suggests an exhaustion of digital vasodilatory reserve to ischemic stress in older individuals, primarily men, with these comorbidities.

Association between NT-proBNP and arterial stiffness in young healthy adults.

E Evgeniy Borisov[1]; A Alexandrova[1]; Y Orlova[1]; I Strazhesko[1]
[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation

Introduction:
Elevated serum levels of N-terminal fragment of B-type natriuretic peptide (NT-proBNP) and increased arterial stiffness, measured with pulse wave velocity (PWV), are well-known risk factors for future cardiovascular events.
The association between N-terminal pro-B type natriuretic peptide (NT-proBNP) and arterial stiffness is still unclear, especially in young healthy people without hypertension. The aim of this study was to investigate the association between NT-proBNP and arterial stiffness in young apparently healthy adults.
Material and Methods: We investigated 282 healthy young adults, mean age 18,5 ± 1,7 years, 47% male. NT-proBNP, waist circumference, body mass index (BMI), fasting plasma glucose, insulin resistance (HOMA-IR) and lipid profile were measured. PWV was measured with ambulatory blood pressure monitoring device BPLab Vasotens (BPLab, Russia) results. PWV was 9,4 ± 1,4 m/s (M+ SD), NT-proBNP level was 58, 61+2,39 pg/ml (M+m). Multivariate regression analysis showed positive association between PWV and NT-proBNP, BMI, total cholesterol and HOMA-IR (see table 1).
Conclusions: Arterial stiffness appeared to be associated with serum NT-proBNP level even in the young people with normal blood pressure.

Table 1.

Predictor	β	Standart error	p
BMI	0,097	0,040	0,017
Total cholesterol	0,508	0,228	0,029
HOMA-IR	0,371	0,108	0,001
NT-proBNP	0,008	0,005	0,097

Calmodulin-myosin interaction: a novel interaction regulating muscle function

V Vasco Sequeira[1]; S Conijn[1]; C Ottenheijm[1]; J Van Der Velden[1]; C Johnson[2]
[1]VU University Medical Center, Department of Physiology, Amsterdam, Netherlands; *[2]Vanderbilt University, Clinical Pharmacology, Nashville, United States of America*

Purpose: Calmodulin (CaM) is a Ca2+-binding protein that is essential for Ca2+-dependent regulation of cardiac rythm. Consequently, CaM-associated interacting partners include Ca2+-, Na+- and K+-channels, and ryanodine receptors. Perhaps the most surprising, no direct interacting-partner of CaM has been identified at the myofilaments, considering that myofilament volume occupies ¯70% of human myocardium. Here we demonstrate the novel interaction of CaM to cardiac myosin and how their interaction affects myofilament function.
Methods: In silico recognition of apo- (no Ca2+) and Ca2+-CaM binding to a specific sequence of human cardiac myosin was conducted and validated by Nuclear Magnetic Resonance (NMR) spectroscopy (1 μM CaM:5 μM myosin peptide). To assess the functional effects mediated by apo- and Ca2+-CaM in myofilament regulation of myosin, exogenous 1 μM CaM was added to human membrane-permeabilized cardiomyocytes, either in the presence of ADP (but no Ca2+) or Ca2+ (but no ADP), respectively. Furthermore, X-ray fiber diffraction of membrane-permeabilized rat skeletal soleous muscle (mostly cardiac myosin) was used to detect conformational changes to myosin (at the thick-filament region) mediated by addition of 1 μM CaM. Lastly, mass spectrometry of human myocardium was performed to assess CaM:myosin stoichiometry in vivo.
Results: The first IQ-motif region of myosin, localized to the myosin neck (where myosin light chains interact), was recognized as a potential binding region for CaM. NMR demonstrated that apo-CaM promoted conformational changes to the myosin peptide, which were much larger when Ca2+ was present. Human membrane-permeabilized cardiomyocytes showed increased myofilament force production in the presence of apo-CaM, which were exacerbated in the presence of Ca2+-CaM. The latter was shown to coincide with increased structural changes of myosin to the thick-filament, mediated by apo- and Ca2+-CaM, with increased myosin approximation towards actin, as evidence by X-ray fiber diffraction. Mass spectrometry revealed a 1 μM:22 μM ratio of CaM to myosin, consistent with a total 6 μM CaM to 150 μM myosin pool in human myocardium.
Conclusions: Here we provide structural evidence that supports CaM interaction to cardiac myosin. Notably, this interaction mediates conformational changes in myosin that re-positions its head closer to actin with accompanied increased force generation of human cardiomyocytes. Based on stoichiometry levels found in human

myocardium, cardiomyocte pool of CaM is sufficient to regulate cardiomyocte function in vivo.

A novel intronic mutation in the fibrillin 1 gene causes pseudoexon inclusion and premature termination in Marfan syndrome with aortic dilatation

M Torrado[1]; E Maneiro[2]; JP Trujillo-Quintero[2]; A Evangelista[3]; AT Mikhailov[1]; L Monserrat[2]
[1]University of A Coruña, Institute of Health Sciences, A Coruña, Spain; [2]Health in Code, A Coruña, Spain; [3]University Hospital Vall d'Hebron, Cardiology Department, Barcelona, Spain

Funding Acknowledgements: This work was partially supported by a grant GRC 2013/061 of the Autonomic Government of Galicia, Spain.

Background: Mutations in the fibrillin 1 (FBN1) gene are typically associated with Marfan syndrome (MFS), suggesting that genetic testing would be useful for timely diagnosis to prevent life-threatening cardiovascular complications such as aortic dilation/dissection. However, for a proportion of patients, mutation analysis restricted to FBN1 exons fails to identify the genetic cause of MFS.
Purpose: To specifically assess the presence of pathogenic intronic variants of the FBN1 gene in a MFS patient with aortic dilatation.
Methods: DNA from patient saliva was used for target enriched next generation sequencing (NGS) for 34000 bases of FBN1 encompassing 66 exons along with their flanking (200 bp) intron regions. In addition, other 34 genes related to aortic diseases were NGS analyzed. Five independent algorithms for splice signal detection were used to annotate the variants for functionality. Predicted aberrant splicing variants were functionally characterized by minigene splicing assays coupled with RT-PCR and Western blot analyses of the splicing patterns of mutant versus consensus FBN1 constructs after transfection into HeLa and COS-7 cells.
Results: The NGS screening allowed identification of eight variants of FBN1 including seven variants localized in intronic non-coding regions and one synonymous exonic variant which does not influence the amino acid structure of the protein. The identified variants, with the exception of the heterozygous c.2678-15C?A, have been previously described and classified as benign or of uncertain significance. The novel c.2678-15C>A variant was not identified in either healthy relatives or individuals with phenotypes other than MFS who referred to our laboratory for NGS analysis. The computational predictions showed that the heterozygous c.2678-15C?A intronic variant might influence the splicing process by differentially affecting canonical versus cryptic slice site utilization within intron 22 of the FBN1 gene. RT-PCR and Western blot analyses, using FBN1 minigenes transfected into HeLa and COS-7 cells, revealed that the c.2678-15C?A variant disrupts normal splicing of intron 22 leading to aberrant pseudoexon inclusion, frameshift and premature termination codon. The aberrantly spliced transcripts are resistant to nonsense-mediated decay and express unstable truncated proteins, which could only be detected upon proteasome inhibition. Our NGS analysis did not reveal any relevant change in a panel of 34 additional genes related to aortic diseases, supporting the assumption that the c.2678-15C>A variant identified in the FBN1 gene of the investigated MFS patient is the likely cause of the clinical manifestations.
Conclusions: We report a novel variant in the FBN1 gene as pathogenic variant for MFS complicated by aorta dilation - a finding that further expands on the genetic basis of aortic pathology.

P1999

The molecular regulation of RIP3 in necroptosis of vascular smooth muscle cells by cyclic stretch

WP Wen Pin Cheng[1]
[1]Shin Kong Wu Ho-Su Memorial Hospital, Department of Medical Education and Research, Taipei, Taiwan ROC

Funding Acknowledgements: This study was supported, in part, by the Ministry of Science and Technology, Taipei, Taiwan.

Background: Programmed necrosis also termed necroptosis has been reported was responsible for atherosclerosis. In the process of necroptosis, receptor-interacting protein 3 (RIP3) appears to play a major role to regulate the necroptosis.
Purpose: How cyclic stretch affects the regulation of RIP3 in vascular smooth muscle cells (VSMCs) during necroptosis is not fully understood. This study is aim to clarify the molecular regulation of RIP3 under cyclic stretch in VSMCs necroptosis.
Methods: Rat VSMCs grown on a flexible membrane base were stretched by vacuum to 20% of maximum elongation, at 60 cycles/min.
Results: Cyclic stretch markedly enhanced RIP3 protein and mRNA expression. Addition of c-jun N-terminal kinase (JNK) inhibitor SP600125 and JNK siRNA before cyclic stretch inhibited the protein expression of RIP3. Cyclic stretch induced the DNA-binding activity of signal transducer and activator of transcription 1 (STAT1) by electrophoretic mobility shift assay. SP600125, JNK siRNA and interferon-gamma (IFN-gamma) antibody abolished the binding activity induced by stretch. RIP3 promoter activity was induced by cyclic stretch and RIP3-mut plasmid, SP600125 and IFN-gamma antibody attenuated the RIP3 promoter activity induced by stretch. Exogenous administration of IFN-gamma recombinant protein to the non-stretched VSMCs increased RIP3 protein expression similar to that seen after stretch. Addition of RIP3 siRNA reversed the VSMCs necroptosis induced by cyclic stretch.
Conclusion: Our results indicated that cyclic stretch induced RIP3 expression in VSMCs necroptosis. The stretch-induced RIP3 is through by IFN-gamma, JNK and STAT1 pathway.

High-Resolution and Semidynamic Vessel Wall Imaging Kinetics obtained from Stable Radical MRI in ex-vivo Porcine Aorta

M Pali[1]; M Terekhov[1]; C Wittke[1]; N Wagner[2]; A Schroeder[3]; H Walles[3]; S Erguen[2]; A Zernecke-Madsen[4]; LM Schreiber[1]
[1]University Hospital , Chair of Cellular and Molecular Imaging, Comprehensive Heart Failure Center (CHFC), Wuerzburg, Germany; [2]University Wuerzburg, Institute of Anatomy and Cell Biology, Wuerzburg, Germany; [3]Fraunhofer Institute for Silicate Research, Translational Center 'Regenerative Therapies' (TLC-RT), Wuerzburg, Germany; [4]University Hospital, Institute for Experimental Biomedicine II, Wuerzburg, Germany

Funding Acknowledgements: Financial support was obtained from the German Ministry of Education and Research (BMBF) under grant#01E1O1504.

Introduction: Excessive production of Reactive Oxygen Species (ROS) leads to homeostatic breakdown followed by inflammation and cell injury. Increased local ROS level is considered a marker of early stage of atherosclerosis. Nitroxides can react with ROS with conversion from paramagnetic to diamagnetic species and, thus, changing local T1-contrast accessible by MR-imaging. The redox-sensitive properties were explored in organs mostly in spectroscopic based studies due to relatively short time frame available before its reduction by endogenous ROS. MRI of vessel wall using nitroxide radicals might offer a non-invasive method of analyzing both underlying anatomical structure and pathophysiological changes caused by ROS-production in vasculature.
Purpose: We established a protocol for high spatial and temporal resolution dynamic MRI of porcine aorta ex-vivo to visualize: 1) The distribution and diffusion of TEMPOL inside the vessel wall; 2) Kinetics of generated T1-contrast due to the conversion of TEMPOL to hydroxyamide stimulated by exogenously applied ascorbic acid to model of ROS overproduction.
Methods: MRI measurements of porcine aorta were performed on a 7T Bruker preclinical MRI system using a TX/RX 1H-cryoprobe. Excised aortic tissue was kept in isotonic saline solution and MRI scans were performed at 2, 24, 48 and 72 hours post excision. 5mm thick rings of aorta were prepared just before the treatment with low (10 or 30mM) dose of TEMPOL. Subsequent treatment of TEMPOL-perfused probes by 5 to 20mM ascorbic acid demonstrated the possibility of visualizing change of the redox of TEMPOL inside the vascular wall. The incubation times were 180 sec and 30 sec at 37°C for TEMPOL and ascorbic acid, respectively. The subsequent measurements were performed at ambient temperature. Protocols for maximizing spatial and temporal resolution were optimized by adjustment parameters of T1-weighted gradient (GRE) and spin-echo (RARE) sequences depending on time passed after excision and tissue treatment.
Results: Fig. 1a shows an untreated aortic ring with native T1 tissue contrast and with 100μm in-plane spatial resolution. Exposure to TEMPOL initially results in rapid accumulation on the intima and adventitia (Fig. 1b) and concentration-gradient driven diffusion through all aortic layers. Subsequent treatment with ascorbic acid results in conversion of TEMPOL to diamagnetic hydroxyamide clearly observed dynamically by significant T1-contrast reduction in images as ascorbic acid diffuses through the vascular tissue layers (Fig 1c).
Conclusion: High-resolution imaging protocol with 100μm spatial and 30 sec per image temporal resolution was established in ex-vivo porcine aorta using GRE and RARE pulse sequences. Successful proof-of-principle imaging of stable nitroxides as a T1 redox-sensitive contrast agent in porcine aorta provides the method for future in-vivo ROS imaging in vascular tissue.

Increased adipocyte formation in STAT3-knockout hearts can be prevented by EPO administration

E Elisabeth Stelling[1]; M Ricke-Hoch[1]; M Scherr[2]; B Stapel[1]; J-L Balligand[3]; S Erschow[1]; D Hilfiker-Kleiner[1]

[1]Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany; *[2]Hannover Medical School, Department of Hematology, Oncology and Stem Cell Transplantation, Hannover, Germany*; *[3]Universite Catholique de Louvain, Institut de Recherche Experimentale et Clinique (IREC), Pole of Pharmacology and Therapeutics (FATH), Brussels, Belgium*

Funding Acknowledgements: DFG, Rebirth

Purpose: STAT3-dependent secreted factors like erythropoietin (EPO) have an influence on the differentiation potential of the endogenous Sca-1+-cardiac progenitor cell (CPC) population. Male mice with a cardiomyocyte-restricted knockout of STAT3 (aMHC-Cretg/+; STAT3flox/flox, CKO) develop spontaneous age-related heart failure in association with reduced cardiac EPO expression and subsequent impaired endothelial differentiation of CPCs and cardiac capillary density. Here, we evaluated whether reduced cardiac EPO levels in CKO mice promote differentiation of CPCs into adipocytes as increased cardiac fat deposition is frequently observed in failing hearts.

Methods and Results: HL-1 cardiomyocytes with a lentiviral STAT3-knockdown (STAT3-KD) showed reduced EPO expression. Cultivation of the preadipocyte cell line 3T3-L1 with conditioned media from STAT3-KD HL-1 cells significantly enhanced adipocyte formation compared to 3T3-L1 cells cultivated with conditioned media from control cells as measured by oil red absorbance, increased mRNA levels of adipocyte markers FABP4 and AdipoR1 and decreased mRNA levels of the preadipocyte marker Pref-1. The enhanced adipocyte differentiation could be prevented by recombinant mouse EPO (rmEPO) administration (10ng/ml).

CPC clones expanded from single cells were able to differentiate into adipocytes confirming that CPCs have the adipocyte differentiation potential. CPCs from WT (WT-CPC) and from CKO mice (CKO-CPC) were immunomagnetically isolated. After 4 weeks of cultivation a 2-fold increase in adipocytes formation was observed in CPC cultures isolated from CKO hearts (oil red staining, compared to WT-CPCs, *P <0.05). This was associated with increased mRNA levels of adipocyte markers FABP4 (+32%, *P <0.05) and OLR1 (+126%, *P <0.05) in CKO-CPCs.

EPO receptor expression was similar in freshly isolated CPCs from WT and CKO hearts. Addition of rmEPO during cultivation of CKO-CPCs prevented their enhanced adipocyte formation.

Hearts of 6 months old CKO mice displayed increased numbers of adipocytes as determined by adipogenesis assay (2.5-fold compared to WT, *P <0.01). Treatment of CKO mice with the EPO derivative CERA (Roche) in a non-hematocrit influencing dosage (3mg/kgBW) starting at 3 months of age and continued for 3 months completely prevented adipocyte formation in CKO hearts. CERA treatment delayed heart failure in CKO mice but could not prevent it (FS in NaCl-CKO mice at 4 months: 22 ± 9%, FS in CERA-CKO mice: 35 ± 5%, *P <0.05; FS in NaCl-CKO mice at 6 months: 17 ± 5%; FS in CERA-CKO mice: 13 ± 7%, n.s.).

Conclusion: Age related heart failure in CKO mice is associated with enhanced adipocyte differentiation from CPCs. This is in part caused by reduced EPO secretion by STAT3-deficient cardiomyocytes into the cardiac microenvironment. Longterm EPO treatment could prevent enhanced adipocyte formation in hearts of CKO mice and was able to delay but not prevent age-related heart failure in these mice.

Changes in extracellular matrix composition and cell populations parallel aortic valve stenosis progression

A Panzenboeck[1]; J Jakowitsch[1]; R Seitelberger[2]; R Rosenhek[1]; H Baumgartner[1]; IM Lang[1]

[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]University Clinics Salzburg, Department of Cardiac Surgery, Salzburg, Austria*

Background: Aortic valve disease is the most frequent valve disease in Western countries, and the third most frequent cause of cardiovascular death. Although aortic valve degeneration, which ultimately results in calcific aortic stenosis, shows similarities to atherosclerotic processes the underlying biological mechanisms are still unclear. In our study we investigated extracellular matrix (ECM) molecules and cellular markers as important components of atherosclerosis in aortic stenosis.

Methods: Aortic valves were collected at aortic valve replacement surgeries and heart transplantations. For sample stratification echocardiographically obtained mean valve gradients (mvg) at the time of surgery were used. RNA expression profiles of healthy (control), as well as sclerotic (mvg = 6 ± 2mmHg, mean ± SD), mildly (mvg = 22 ± 12mmHg), moderately (mvg = 49 ± 16mmHg) and severely stenotic (mvg = 63 ± 15mmHg) aortic valve leaflets (n = 5 per group) were analyzed using an Affymetrix Human Gene 1.0 ST Array. Array results were validated by Real-time PCR utilizing TaqMan probes.

Results: Collagen types I, III, V, XIV, XV and XXI as well as cathepsin S, B, D and K and perlecan showed a valve gradient-dependent increase of expression. Expressions of collagens type Ia1, Ia2, IIIa1 and Va1 and cathepsins S and D showed a significant correlation with stenosis progression (14,5 (9-17) m/sec/year, median(range), p < 0,05). The antiangiogenic ECM molecule chondromodulin was at a low level across the spectrum of mvgs, while VEGF decreased in parallel to increasing mvg. In addition we observed a valve gradient-dependent increase of osteoblast specific genes like CDH11, POSTN, SPARC and SPP1.

Conclusion: Our data demonstrates a shift in ECM production and composition in parallel with aortic valve degeneration. In addition we could show that while angiogenesis is suppressed, genes enhancing ossification and thereby aortic stenosis progression are increased.

Traditional and biomolecular methods in ethiological diagnostics of infective endocarditis

EO Kotova[1]; MA Sorokina[2]; AS Pisaryuk[1]; EA Domonova[3]; JL Karaulova[1]; AS Milto[4]; V S Moiseev[1]

[1]Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation; *[2]M.V. Lomonosov Moscow State University, Moscow, Russian Federation*; *[3]Central Research Institute of Epidemiology, Moscow, Russian Federation*; *[4]City Clinical Hospital No 64, Moscow, Russian Federation*

Background: Identification of etiological agent in blood is an important criterion for diagnostics and successful treatment of infective endocarditis (IE). We suggest using biomolecular methods, such as polymerase chain reaction (PCR) and cycle sequencing reaction.

Objective: Comparison of bacteriological and biomolecular methods in IE diagnostics.

Material: 67 patients with verified IE (DUKE 2009, 2015), hospitalized and treated in city clinical hospital ?64 in Moscow from September 2012 to January 2017. The biological and biomolecular tests were taken simultaneously for all patients. The DNA of S.aureus, Staphylococcus spp. (MRCoNS), Enterobacteriaceae, E.coli, Klebsiella spp., Proteus spp. and others., Streptococcus spp., A.baumanii, K.pneumoniae, P.aeruginosa, E.coli, S.agalactiae, S.pyogenes, Candida (C.albicans, C.glabrata, C.krusei, C.parapsilosis and C.tropicalis), enterococci (including E.faecium, E.faecalis, etc.) was determinted using PCR method.

Results: We studied 67 patients with IE, age median 62 [34-73], 41 (61,2%) male and 36 (38,8%) female. Etiological agents were detected in venous blood of 35 (52,2%) patients via bacteriological method. Types of agent were: Staphylococcus spp. (n = 20, 57,1%), Enterococcus spp. (n = 6, 17,1%), Streptococcus spp. (n = 2, 5,7%), K.pneumoniae (n = 1, 2,9%) and E.coli (n = 1, 2,9%). 32 (47,8%) cases showed no bacteria growth, and polyflora was detected in 5 (14,3%) cases. 45 (67,2%) had positive results of PCR, in 25 out of 35 (71,4%) cases the results of PCR were concordant with bacteriological study, and in 10 out of 35 (28,6%) - discordant. Full discordance of the results was shown in 4 cases: Enterococcus spp. growth was detected by bacteriological method, but PCR method showed DNA of

MRCoNS, Streptococcus spp. (1), Staphylococcus spp. (1), E.coli, Streptococcus spp. (1), S.gallolyticus (1). In two cases there was a wider specter of agents found by PCR method than by traditional method. In 4 cases, traditional method succeed in the detection of growth of S.aureus MSSA (3), E.faecium, K.pneumoniae (1), but PCR did not manage to identify any DNA. Also, we've received positive results of PCR in 14/32 (43,8%) cases with culture negative IE [S.epidermidis, S.haemolyticus (1); Aspergillus spp. (1); S.aureus MSSA (2); P.multocida (1); S.?galactiae, MRCoNS (1); Enterococcus spp. (2); S.constellatus (1); E.coli (1); Staphylococcus spp. (1); C.albicans, S.epidermidis (1); Staphylococcus spp., A.baumanii, E.coli (1); Enterococcus spp., Staphylococcus spp. (1)]. In 18 (26,9%) patients both methods failed to identify the etiological agent.

Conclusion: Via using traditional bacteriological methods, it was possible to verify etiological agent in venous blood for 52,2% of the patients, via biomolecular - for 67,2%, and with the help of both methods - for 73,1% of patients. Currently we've received both concordant and discordant results, which represents the main challenge in etiological diagnostics of IE.

P2004

Incidence and predictors of tricuspid regurgitation determined by 2D and 3D echocardiography after permanent pacemaker insertion

JP Rangel[1]; VB Flores[1]
[1]*Philippine Heart Center, Adult Cardiology, Manila, Philippines*

Funding Acknowledgements: Philippine Heart Center

Background: Tricuspid regurgitation related to permanent pacemaker insertion (PPI) can occur in 25-29% of patients compared to normal controls, with symptoms of right heart failure developing from one day to ten years after PPI. Proposed mechanisms for this include scar formation or thrombus on the leads impairing TV leaflet closure, neoendocardium formation leading to fibroses and adhesions, thrombosis or edema of TV leaftlets, and perforation or laceration of TV leaflets.

Methods: This is a prospective cohort study on 60 patients admitted for PPI from June to December 2017. Baseline clinical, electrocardiographic and echocardiographic parameters were collected. Patients underwent follow-up 2D and 3D echocardiogram with three days and within one to three months after permanent pacemaker insertion to determine any tricuspid regurgitation (TR) or increase in its severity from baseline.

Results: The mean age is 65.2 ± 13.5 years, majority were females (58%) and majority had PPI due to Complete heart block (75%). Three patients developed mild TR and one patient developed moderate TR within three days postoperatively. On follow-up within one to three months postoperatively, thirteen patients (22%) developed moderate TR and one patient developed severe TR due to lead adherence to the tricuspid leaflet. There was no significant difference in the preoperative and postoperative echocardiographic parameters of the right ventricle and right atrium.

Conclusion: The presence of pacemaker-related tricuspid regurgitation is often under diagnosed as the cause of right-sided heart failure. Pacemaker insertion can produce tricuspid regurgitation and may increase the severity of underlying tricuspid regurgitation. Two-dimensional and 3D dimensional echocardiogram can be utilized to determine any postoperative tricuspid regurgitation and determine its mechanism.

Incidence of Tricuspid Regurgitation

Characteristics	Preoperative Frequency (%) (n = 60)	Postoperative - within three days Frequency (%) (n = 60)	Postoperative - within one to three months Frequency (%) (n = 60)
None	15 (25%)	12 (20%)	5 (8%)
Trivial	22 (37%)	22 (37%)	20 (33%)
Mild	23 (38%)	26 (43%)	21 (35%)
Moderate	0	1 (2%)	13 (22%)
Severe	0	0	1 (2%)

Myocardial Disease - Clinical

P2005

Increased expression toll-like receptor type 2 and type 9 in the myocardium as a marker of chronic active myocarditis

O V Olga Blagova[1]; EA Kogan[1]; N Faisulina[1]; AV Nedostup[1]
[1]*I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation*

Purpose: to study the expression of some structural proteins, cell proliferation and innate immunity markers in the myocardium to evaluate their diagnostic and possible pathogenetic role in patients with chronic myocarditis.

Methods: in 23 patients (16 males, 52.0 ± 12.4 years) with dilated cardiomyopathy and suspected myocarditis (group 1, n = 10) and other noncoronary diseases (valvular heart disease, hypertrophic cardiomyopathy, chronic pulmonary embolism and atrial myxoma), presumably without myocarditis (group 2, n = 13), were performed endomyocardial biopsy of right ventricle (n = 4), intraoperative biopsy of left ventricle (n = 17), and autopsy (n = 2) with histological, immunohistochemical investigation of vimentin, desmin, c-kit, Ki-67 and toll-like receptors (TLR) 2 and 9 types expression. It was also performed investigation of the viral genome and anti-heart antibodies.

Results: Active / borderline lymphocytic myocarditis diagnosed in all patients of group 1 and 6 patients of group 2 (totally in 9 / 7 patients). Viral genome detected in the blood in 4 patients and in the myocardium in 15 patients, including 5 patients without morphological signs of myocarditis (parvovirus B19 in 11 patients, 6 herpes virus type in 4 patients, herpes simplex virus type 1, 2 in 1 patient, Ebstein-Barr virus in 2 patients, and cytomegalovirus in 1 patient).

There was a strong correlation expression of TLR2 and TLR9 with the presence of morphological signs of active myocarditis in the absence of such correlation with expression of the other studied markers. The expression of TLR2 in borderline myocarditis or without him was 0 [0; 0.75] points versus 1.5 [1; 1.5] points in active myocarditis, the expression of TLR9 was 2 [2; 2] and 4 [3; 4] points respectively ($p < 0,001$). In borderline myocarditis the expression of TLR2 and TLR9 was lower than in patients without myocarditis. It may reflect the death / depletion of cardiomyocytes in the later stages of the disease. It is also found a strong correlation the expression of TLR2 and TLR9 between themselves ($r = 0.824$, $p < 0.001$) and with Ki-67 ($r = -0,531$ and $r = -0,702$, $p < 0.01$). TLR2 expression was significantly correlated with the effectiveness of immunosuppressive therapy of myocarditis in the patients of the group 1 ($r = 0.66$, $p < 0.05$). The patients of group 2 did not receive immunosuppressive therapy. There was no correlation with persistence of virus, titers of anti-heart antibodies, and degree of myocardial dysfunction. Conclusion. Detection of the expression of TLR2 and TLR9 in the myocardium may use as a marker of the presence of myocarditis and its activity. Increased expression of innate immunity markers may reflect one of the mechanisms of genetic predisposition to the development of myocarditis and its severe course and may be a potential target for therapy. Increased expression of TLR2 in patients with

inflammatory cardiomyopathy associated with a better effect of immunosuppressive therapy.

P2006

Correlation of genotypes of genetic polymorphisms of angiotensin converter enzyme and aldosterone synthase with echocardiographic subtypes in hypertrophic cardiomyopathy

A Freitas Pereira Gondar[1]; TCP Gil[1]; ALF Sales[1]; MI Bittencourt[1]; R Pozzan[1]; DC Albuquerque[1]; MB Castier[1]; DA Silva[2]; R Mourilhe-Rocha[1]
[1]State University of Rio de Janeiro, Cardiology , Rio de Janeiro, Brazil; *[2]State University of Rio de Janeiro, Laboratório de Diagnósticos por DNA do Instituto de Biologia Roberto Alcântara Gomes, Rio De Janeiro, Brazil*

Funding Acknowledgements: Fundação de Amparo á Pesquisa do Estado do Rio de Janeiro (FAPERJ)

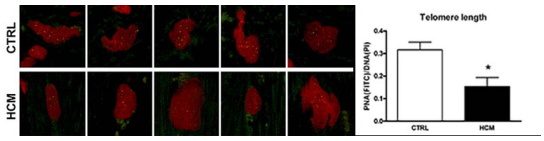
Background: The factors that determine the morphological characteristics and clinical evolution of patients with hypertrophic cardiomyopathy (HCM) are not clarified. It is believed that the genetic polymorphisms of angiotensin converting enzyme (ACE) and aldosterone synthase (CYP11B2) may influence phenotypic expression in individuals with HCM. The aim of this study is to evaluate the frequency of genetic polymorphisms variants ACE and CYP11B2 and to correlate them with echocardiographic subtypes according to the classification proposed by Maron (Am J Cardiol. 1981) in patients with HCM.
Methods: blood samples were collected and transthoracic echocardiography was performed in patients with HCM followed at an outpatient clinic specialized in a university hospital.
Results: Sixty-one patients with a diagnosis of HCM were included. It was observed that the sample was homogeneously composed of individuals of both genders, mean age of 48.41 ± 14.59 years, mostly caucasian (52.5%). The frequency of ACE variants genotypes were DD (24.59%), ID (60.65%), II (14.75%) and CYP11B2 variants genotypes were TT (39.34%), TC (54.09%), CC (6.55%). The most frequent echocardiographic subtypes were type II (31.1%) and III (29.5%). Type I was more frequent in ACE variant genotype II and in CYP11B2 variant genotype TT. Type II was more frequent in the ID genotype and TT. Type III was most observed in DD and CC. Type IV was most observed in II and CC. There was no statistical significance when the correlation of any echocardiographic subtype with the ACE and aldosterone synthase polymorphisms was verified.
Conclusion: the most common ACE variant genotype in our population was ID, while aldosterone polymorphism was TC. There was no correlation of any echocardiographic subtype with the ACE and aldosterone synthase polymorphisms variants. There was a tendency of the CC genotype to be more related to subtype III, the more obstructive subtype.

P2007

Telomere shortening in human hypertrophic cardiomyopathy

C Cristina Chimenti[1]; K Urbanek[2]; R Verardo[3]; C Grande[1]; F Rossi[2]; A Frustaci[1]
[1]Sapienza University of Rome, Rome, Italy; *[2]University of Campania "Luigi Vanvitelli", Department of Experimental Medicine, Section of Pharmacology, Naples, Italy*; *[3]INMI L Spallanzani IRCCS, Rome, Italy*

Background: Telomeres consist of repetitive sequences of DNA at chromosomal ends responsible for maintaining genomic integrity and are considered a marker of biologic aging. Recently, telomere shortening has been associated to different cardiovascular diseases and heart failure.
Purpose: To investigate the role of telomere shortening in patients with hypertrophic cardiomyopathy (HCM).
Methods: Endomyocardial biopsies from 10 patients with HCM (53 ± 5 ys) were analyzed and compared with 10 control hearts (55 ± 7 ys). Telomere length was assessed using fluorescence in-situ hybridization with peptide nucleic acid probe. Senescent cells were identified by the expression of the cell cycle inhibitor p16INK4a and cell death by hairpin 1 and 2. Replication of cardiomyocytes were assessed by Ki67 and MCM5 labeling. Cardiomyocyte cross-sectional area and myocardial fibrosis were also evaluated.
Results: HCM heart showed a reduction in telomere length and an increase in cell death rate compared to control hearts. This was associated with an increased number of p16INK4a positive cardiomyocytes. Cardiomyocyte proliferation was reduced compared to controls. The distribution of myocyte cross-sectional area in HCM patients showed that only a small fraction of cells was less than 150 μm2, while the majority of cells were more than 400 μm2. Myocardial fibrosis was significantly increase compared to controls.
Conclusions: Human HCM is characterized by telomere shortening and premature senescence of cardiomyocytes. Anticipated myocardial aging can contribute to the cardiac dysfunction occurring in the end stage of the disease. Although telomere dysfunction may also affect the regenerative potential of the myocardium, cardiomyocyte proliferation does not play a major role in determining the HCM cardiac phenotype.



Telomere shortening In HCM and controls.

Development and characterization of patient specific iPSC derived cardiomyocyte model systems

A Anna Janz[1]; Y Ueda[1]; N Nose[2]; CK Kwok[2]; P Woersdoerfer[2]; N Knoetgen[3]; F Edenhofer[2]; S Erguen[2]; E Klopocki[3]; B Gerull[1]
[1]Comprehensive Heart Failure Center, Cardiovascular Genetics, Wuerzburg, Germany; *[2]Medical faculty of the University of Wuerzburg, Institute of Anatomy and Cell Biology, Wuerzburg, Germany*; *[3]University of Wuerzburg, Institute of Human Genetics, Wuerzburg, Germany*

Funding Acknowledgements: Bundesministerium für Bildung und Forschung (01EO1504)

Background: Recent advances in genetic technology unraveled novel disease genes for inherited cardiomyopathies (CMPs), in this project for two different forms of dilated cardiomyopathy (DCM):
1.) DCM with ataxia syndrome (DCMA, OMIM #610198) is caused by a homozygous splice site mutation in the gene DNAJC19 (IVS3-1G>C) encoding for a mitochondrial inner membrane import protein.
2.) DCM with juvenile cataract is caused by a homozygous mutation in the LEMD2 gene (c.38C>T, p.L13R) encoding an inner nuclear membrane protein.
For both forms of DCM, the cellular and molecular mechanisms leading to the disease remain widely unknown.
Purpose: The goal of the study is to generate patient specific model system by using human induced pluripotent stem cells (hiPSCs) and their in-vitro derived individual cardiomyocytes (CMs) to discover the complex molecular events leading to the disease. Furthermore, isogenic controls will be generated by CRISPR/Cas9 technology.
Methods and Results: Dermal fibroblasts from patients carrying mutations for two forms of recessive CMPs (DNAJC19 and LEMD2) were obtained and reprogrammed into hiPSCs using Sendai virus. The identity and high purity of the generated hiPSC lines were confirmed by FACS analysis of pluripotency markers (SSEA-4>80%, Tra-1-60 > 94%) and by human G-banding karyotyping. The individual optimal conditions to differentiate patient derived hiPSCs to the cardiogenic path were successfully established to generate a network of contracting CMs in a monolayer as well as in three-dimensional Cardiospheres (CSs). Lactate based metabolic enrichment and verification experiments of CMs including IF, FACS analysis and qPCR for cardiac markers (c-TnT and a-actinin) are currently performed. The patient-derived contracting individual CMs indicate first beating abnormalities kept over prolonged cultivation time. Preliminary data show differences in mitochondrial uptake/storage of radioactive isotopes (18F-FDG, 99mTc-MIBI) between patient and healthy CMs. Next, the effects of the specific mutations within the remaining patient specific genetic background are currently generated by using CRISPR/Cas9 technology via homology directed repair. As an initial approach we successfully knocked-out the cell-junction protein plakophilin-2 - a disease gene for arrhythmogenic cardiomyopathy - in hiPSCs and showed proof of concept technology.
Perspectives: Patient specific CM models will be further developed into more mature/ organotypic model systems and characterized for structural, electrophysiological and molecular changes for the individual diseases. In particular, loss of DNAJC19 will be investigated towards mitochondrial dysfunction, whereas in mutant LEMD2 chromatin remodeling and cell senescence will be examined. The advantage of in vitro hiPSC derived CMs are not only to display clinical aspects of the disease, but also to determine its suitability for drug compound testing.

P2009

Prognostic impact of hypertrabeculation and noncompaction phenotype in nonischemic dilated cardiomyopathy

AR Ana Rita Pereira[1]; AR Almeida[1]; I Cruz[1]; A Marques[1]; S Alegria[1]; AC Gomes[1]; D Sebaiti[1]; A Briosa[1]; O Simoes[1]; LR Lopes[2]; M Ramalho[3]; H Pereira[1]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal; *[2]Barts Health NHS Trust, Cardiology, London, United Kingdom*; *[3]Hospital Garcia de Orta, Radiology, Almada, Portugal*

Introduction: To date, it remains uncertain whether left ventricular noncompaction (LVNC) is a distinct type with different pathophysiology and outcome from other types of dilated cardiomyopathies. Probably due to the improvement of cardiac imaging modalities, myocardial trabeculations and noncompaction are now increasingly reported in adult patients (pts) with dilated cardiomyopathy (DCM). Nevertheless, their prognostic impact remains unknown.
Purpose: To evaluate the impact of hypertrabeculation and LVNC phenotype by cardiac magnetic resonance (CMR) on outcomes of pts with DCM.
Methods: Retrospective unicenter study that included the pts followed for nonischemic DCM with left ventricular (LV) ejection fraction (LVEF) < 40% at the time of diagnosis and submitted to CMR. The DCM diagnosis was established by the presence of LV dilation in the absence of uncontrolled arterial hypertension, hypertrophic or restrictive cardiomyopathy, significant valvular or coronary disease. LV trabeculations were identified by CMR as any endocardial wall contour irregularities present in the end-diastolic phase, distinct from papillary muscles and chordae. LVNC phenotype was established by an noncompacted to compacted (NC/C) length ratio = 2,3 or NC/C mass = 20%, measured on long-axis images. The primary endpoint (PE) was a composite endpoint of all-cause mortality, ventricular arrhythmias (VA) with hemodynamic instability and unplanned heart failure (HF) admission. Secondary endpoint (SE) was LVEF recovery (= 50%). Two groups are compared (group 1 - pts with DCM and LV trabeculations or LVNC phenotype; group 2 - pts with DCM without LV trabeculations or LVNC phenotype).
Results: 49 pts were included: 30 (61,2%) male; mean age 54 ± 12 years. At the time of diagnosis, 30 (61,2%) pts were in NYHA functional class = III with a median NT-proBNP value of 2451 pg/mL [interquartile range (IQR) 2233 pg/mL]. Initial LVEF, measured by transthoracic echocardiogram (TTE), was 25 ± 8%. In CMR, 13 (26,5%) pts presented hypertrabeculation phenotype and 10 (20,4%) LVNC diagnostic criteria. Age was the only baseline characteristic with significant difference between the two groups, being group 1 pts significantly younger than group 2 pts (47 ± 12 years vs 54 ± 12 years, p = 0,04). At a median follow-up (FU) of 26 months (IQR 51 months), there were 22 primary events (5 deaths; 3 AV with hemodynamic instability and 14 unplanned HF admissions). 17 (34,7%) pts recovered LVEF. Mean FU LVEF was 42 ± 15%. No significant difference, between the two groups, was also found in FU time (p = 0,58), PE (p = 0,79), SE (p = 0,23), time until PE (log rank 0,24; p = 0,63) and SE (log rank 1,95; p = 0,16) occurrence.
Conclusions: Cardiovascular outcomes of adult pts with nonischemic DCM do not appear to be influenced by the degree of trabeculation. This argues against a hypertrabeculation/LVNC phenotype designating a more severe form of nonischemic DCM.

P2010
Long-term prognostic value of late gadolinium enhancement in a cohort of patients with nonischemic dilated cardiomyopathy

AR Ana Rita Pereira[1]; AR Almeida[1]; I Cruz[1]; A Marques[1]; S Alegria[1]; AC Gomes[1]; D Sebaiti[1]; A Briosa[1]; LR Lopes[2]; M Ramalho[3]; H Pereira[1]

Introduction: The presence of late gadolinium enhancement (LGE) in cardiac magnetic resonance (CMR), which enables quantification of myocardial fibrosis, is common in patients (pts) with dilated cardiomyopathy (DCM). The presence of LGE has been related with medium to long-term adverse events. However, limited data exist about the role of LGE extension and location.
Purpose: To evaluate prognostic value of the presence, extension and location of LGE in pts with DCM.
Methods: Retrospective unicenter study that included the pts followed for DCM with left ventricular (LV) ejection fraction (LVEF) < 40% at the time of diagnosis and which were submitted to CMR. The DCM diagnosis was established by the presence of LV dilation in the absence of uncontrolled arterial hypertension, hypertrophic or restrictive cardiomyopathy, significant valvular or coronary disease. The primary endpoint (PE) was a composite endpoint of all-cause mortality, ventricular arrhythmias (VA) with hemodynamic instability and unplanned heart failure (HF) admission. Secondary endpoint (SE) was LVEF recovery (= 50%).
Results: Forty-nine pts were included: 30 (61,2%) male; mean age 54 ± 12 years. At the time of diagnosis, 30 (61,2%) pts were in NYHA functional class = III with a median NT-proBNP value of 2451 pg/mL [interquartile range (IQR) 2233 pg/mL]. Initial LVEF, measured by transthoracic echocardiogram, was 25 ± 8%. LGE was present in 26 (53,1%) pts with a median involvement of 1,5 segments (IQR 4 segments). The most frequent distribution pattern of LGE was mid-wall [14 dts (20,4%)] and the basal anteroseptal segment was the most involved [9 dts (18,4%)]. In univariate analysis, baseline characteristics did not significantly differ between the pts with and without LGE. At a median follow-up (FU) of 26 months (IQR 51 months), there were 22 primary events: 5 deaths, 3 VA with hemodynamic instability and 14 unplanned HF admissions. Seventeen (34,7%) pts recovered LVEF. No significant difference was observed in FU time (p = 0,23), PE (p = 0,63) and time until PE (log rank 1,69; p = 0,19) occurrence between the pts with and without LGE. We also found no significant difference between LGE extension and PE occurrence (p = 0,13). Relatively to location, a higher number of PE events was significantly associated with the presence of LGE in the mid anteroseptal (p = 0,02) and inferoseptal segments (p = 0,02) and in the basal segments with the same location (p = 0,01 and p = 0,02, respectively). No significant difference was observed between SE occurrence and the presence (p = 0,71), extension (p = 0,61) and location of LGE.
Conclusions: In this study, the existence of myocardial fibrosis in the mid-basal segments of the interventricular septum was associated with medium to long-term adverse events. These results support a potential role of CMR in the risk stratification of DCM pts but not as a predictor of LVEF recovery.

P2011
Predictors of heart failure in left ventricular noncompaction

P Von Hafe Leite[1]; H Antunes[2]; N Marques[3]; N Craveiro[4]; L Reis[5]; R Guerreiro[6]; R Santos[7]; O Azevedo[1]
[1]Hospital Senhora da Oliveira, Cardiology, Guimarães, Portugal; *[2]Hospital Sao Teotonio, Cardiology, Viseu, Portugal*; *[3]Faro Hospital, Cardiology, Faro, Portugal*; *[4]Hospital of Santarem, Cardiology, Santarem, Portugal*; *[5]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*; *[6]Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal*; *[7]Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*

Background: Left ventricular noncompaction (LVNC) is a rare cardiomyopathy. Heart failure (HF), arrhythmias and thromboembolic events (TE) are the main complications of LVNC.
Purpose: To identify predictors of HF development in LVNC patients.
Methods: Multicentric, retrospective study with 120 patients diagnosed with LVNC. Clinical, genetic, imaging and electrocardiographic parameters were collected. It was evaluated which are associated with the development of HF during the follow-up.
Results: In this study, the patients were predominantly male (58.3%) and had a mean age at diagnosis of 47 ± 18 years.
Patients had a follow-up lasting, on average, 3.7 ± 2.6 years.
About 46% of LVNC patients had HF during follow-up, more frequently in Class II of New York Heart Association (55.4%), and 10.7% presented in class IV.
Patients with LVNC and HF were predominantly males (67.3% vs 32.7%, p = 0.041), complained more frequently of dyspnea at clinical presentation (88.9% vs 7.5%, p < 0.001). On echocardiography, had significantly higher values of end-diastolic volume (EDV) of the left ventricle (LV) (60.4 ± 8.8 vs 50.8 ± 7.1ml/mm^2; t(111)= 6.4, p < 0.001), LV mass (138.4 ± 92.9 vs 100.0 ± 47.8 g/m^2; t(77)= 2.2, p= 0.024), and left atrial volume (LA) (36.1 ± 14.8 vs 27.1 ± 8.1 ml/mm^2; t(55)= 2.8, p= 0.007). As well this patients have higher frequency of diastolic dysfunction (DD) (75.0% vs 28.8%; p < 0.001), mitral valve disease (73.1% vs 31.6%, p < 0.001), aortic valve disease (26.5% vs 10.9%, p = 0.040), and disease of the tricuspid valve (27.3% vs 0%, p = 0.027).
On MRI, patients with HF had a higher LV mass (126.3 ± 76.6 vs 77.9 ± 33.4 g/m^2, t (45) = 2.8, p < 0.001), higher LV end-systolic volume (86.4 ± 50.8 vs. 51.0 ± 30.5 (43.3) = 2.8, p = 0.008) and higher frequency of late septal enhancement (14.3% vs 0%, p = 0.015).
On electrocardiography, patients with LVNC and HF presented more frequently atrial fibrillation (AF) (19.1% vs 0%, p = 0.001), complete left bundle branch block (LBBB) (23.3 vs 8.0%, p = 0.040) and non-sustained ventricular tachycardia (nsVT) (34.1% vs 13.7%, p = 0.020).
Multivariate regression identified, as statistically significant predictors of HF development during follow-up, the presence of dyspnea at clinical presentation (p < 0.001), DD (p = 0.048) and presence of AF (p = 0.013).
Conclusions: Dyspnea at clinical presentation, DD, and AF were independent predictors of HF development in patients with LVNC.

Correlation between right ventricular function assessed by echocardiography and by right heart catheterization among patients with pulmonary hypertension.

COM Christian Oscar Musante[1]; AJL Adrian Jose Lescano[1]; EB Ezequiel Besmalinovich[1]; DC Diego Crippa[1]
[1]Sanatorio Urquiza. Sanatorio Finochetto., Cardiologia., Buenos Aires, Argentina

Correlation between right ventricular function assessed by echocardiography and by right heart catheterization among patients with pulmonary hypertension.

Right ventricular (RV) dysfunction aggravates prognosis in pulmonary hypertension (PH) patients. Cardiac index (CI) assessed by right heart catheterization (RHC) is a robust indicator of RV function and prognosis. The utilization of noninvasive estimation of RV function by Doppler echocardiography (DE) methods such as tricuspid annular plane systolic excursion (TAPSE) or DTIderived tricuspid lateral annular systolic velocity wave (S') are currently supported by the DE practice guidelines. However, in PH patients, there is limited information regarding the precision and accuracy of those noninvasive methods.
To estimate the concordance between RV function assessed by two DE methods (TAPSE, S') and CI assessed by RHC. We included consecutive patients with confirmed PH diagnosis that underwent RHC between March 2012 and July 2017. TAPSE and S' values were obtained using two ultrasound systems and CI value was obtained by RHC. RHC and DE were performed with less than 24 hours of difference between them and the physicians were blind to the other method
Results: We analyzed the numeric variables (TAPSE, S', CI) with bivariate Pearson's correlation to visualize their relationship, reported as correlation coefficient and significance.
A total of 92 patients were included. Mean age was 56 years (SD 18) and 67% were women. PH group (G) distribution was GI 67%; GII 11%; GIII 12%; GIV 7% and GV 3%. Mean values were: TAPSE 17.8 mm (SD 4.0), S' 10.3 cm/s (SD 3.7) and CI 2.73 l/m/m2 (SD 0.76). The concordance correlation coefficient resulted in: r 0.32 ($p < 0.01$) for TAPSE and CI and r 0.29 ($p = 0.01$) for S' and CI. We found a poor relationship between two noninvasive methods (TAPSE, S') and invasive determination of RV function by RHC. These results supports the idea that TAPSE and S' must be used with caution in PH populations. Further investigations are needed to find noninvasive methods to estimate RV dysfunction with better precision in PH patients.

P2013
The process of increasing hematocrit in pulmonary hypertension depends on gender and degree of hypoxia

N Nadezda Pankova[1]; A Popova[1]; M Artemieva[1]; A Andreev-Andreevskiy[1]; E Volynnikova[1]; N Medvedeva[1]
[1]*M.V. Lomonosov Moscow State University, Biological, Moscow, Russian Federation*

Introduction: Hypoxic pulmonary hypertension (hPH) is characterized by an increase in vascular resistance of the lungs and systolic right ventricle pressure (RVSP). It is the body's response to chronic hypoxia. ?ne of the adaptation way to hypoxia is increasing hematocrit (HCT). The purpose of this work was to study the effect of sex on number of red blood cell (RBC) and its volume (MCV), depending on the degree of exposure to intermittent chronic hypoxia (13%,10% and 8% O2).
Method. Female and male gonadectomized Wistar rats were used. The procedures followed the FELASA/ICLAS for use of the laboratory animals (National Academy Press, Washington, D.C.1996). 4 weeks after the gonadectomy, rats were exposed to chronic intermittent hypoxia (10h/day, 2wk) with 13% or 10% or 8% O2 in hypobaric chamber. Wistar rats were divided into 6 groups by parameters: sex and level of hypoxia (8%, 10%, 13% O2). Two weeks after the onset of hypoxia systolic right ventricle pressure (SRVP) was measured as indicator of hPH. Blood hematocrit (HCT), hemoglobin (HGB), RBC and MCV were measured using a blood analyser Gemalait 1280 (Diksion Russia). The statistical analysis of the data was made using the nonparametric criterion for independent variables from the Statistic8 program package. Results Two weeks after the onset of hypoxia all groups of rats developed hPH with different extent of the disease. RVSP was higher by 30% in female 10% O2 group and was not changed in male. Increasing degree of hypoxia from 10 to 8% O2 did not change RVSP of all groups, but enlarged mortality in all groups by 61%. Every increase in the degree of hypoxia was accompanied by increases in HCT. The change in the concentration of oxygen in hypoxic chamber from 13% to 10% increased RBC from $7,1 \pm 0,4$*10^12/L to $9,4 \pm 0,5$ *10^12/L in female rats and did not change ($7,9 \pm 0,5$*10^12/L and $7.9 \pm 0,1$*10^12/L) in male. In this case MCV was not changed in female, and have increased by 24% the male. The change in the concentration of oxygen from 10% to 8% increased RBC from $7.9 \pm 0,1$*10^12/L to $10.1 \pm 0,3$*10^12/L in male without changed it in female rats. ($9,4 \pm 0,5$*10^12/L and $9,4 \pm 0,6$*10^12/L). MCV was increased only in female rats (from $60,2 \pm 0,5$ to $69,7 \pm 1,7$ fL).
Conclusions: Increase the degree of hypoxia in the chamber (from 13% to 8% O2 is accompanied by increasing RVSP only up to certain values (about 60-70 mm Hg). There are gender differences in the mechanisms of adaptive increase in hematocrit in the case of hypoxic forms of pulmonary hypertension. The change degree of hypoxia from 13% to 10% increases female HCT due to the increase in the number of red blood cells, and from 10 to 8% due to the increase of their volume. In males it is the opposite.

Introduction: Despite the fast evolution of mechanical circulatory support devices, heart transplantation (HTX) remains the definitive therapy of end-stage heart failure. Ischemia-reperfusion (I/R) injury occurring during transplantation is a primary determinant of long-term outcome of HTX and primary graft insufficiency. The most important pathobiochemical changes induced by reperfusion in the myocardium of the donor organ are increased production of reactive oxygen species (ROS), intracellular calcium overload, energy deficit and acidosis. Modification of the nitric oxide (NO)/soluble guanylate cyclase (sGC)/cyclic guanosine monophosphate (cGMP) signaling pathway appears to be the most promising among the pharmacological interventional options developed recently. The first clinically applicable member of this group is the sGC stimulator riociguat. We aimed at characterizing the cardio-protective effects of this drug in a rat model of heterotopic heart transplantation.
Methods: Donor Lewis rats were treated orally with either riociguat (10mg/BWkg) or placebo for two days. Hearts were stored for an hour in cold preservation solution (Custodiol) following explantation, then were transplanted heterotopically. One hour after initiation of reperfusion, left ventricular (LV) pressure-volume relations and coronary flow were recorded in order to assess post-transplant graft function. Molecular biological measurements and histological examination were also completed.
Results: LV contractility (LV systolic pressure at 120µl of LV volume: 117 ± 13 vs. 48 ± 5mmHg, $p < 0.001$; dP/dtmax: 2963 ± 221 vs. 1653 ± 159mmHg, $p < 0.001$) and active relaxation (dP/dtmin at 120µl of LV volume: -2014 ± 305 vs. -1063 ± 177mmHg, $p = 0.019$) improved significantly after an hour of reperfusion, while alteration of coronary flow standardized to heart weight (2.52 ± 0.34 vs. 1.67 ± 0.22ml/min/g, $p = 0.06$) showed a strong increasing trend following pretreatment with riociguat. Myocardial expression of antioxidant markers were significantly improved after heart transplantation.
Conclusions: Pharmacological preconditioning with riociguat decreases I/R injury and improves donor organ function in our small animal model of heart transplantation. The observed cardio-protective effect might be attributed to the stimulated sGC and increased myocardial cGMP-signaling. Riociguat therefore might be a potential cardio-protective agent in the inventory of heart transplantation surgery and during cardiac surgical procedures requiring sustained ischemia.

Objective: Abdominal aortic aneurysm (AAA) is a common condition that may be life-threatening when it is unrecognized. The aim of this study is to evaluate and compare the efficacy of ramipril and carvedilol on limiting AAA expansion in mouse model.
Methods and Results: A total of thirty-six experimental AAA mouse model was induced with the continuous infusion of angiotensin II (Ang II) in 20 week-old male apolipoprotein E-deficient (apoE-/-) mice. They were randomly divided into three treatment groups and fed orally for 8 weeks; saline alone, ramipril (2.5 mg/30g/day), or carvedilol (3.125mg/30g/day) respectively. Aortic diameter (AD) was measured by micro-computed tomography (CT) and the level of biomarkers of aortic tissue such as monocyte chemoattractant protein-1 (MCP-1) and tissue inhibitor matrix metalloproteinase-1 (TIMP-1) were evaluated. After treatment, AD of both ramipril and carvedilol group was smaller than in the saline group. The percentage change of AD in both ramipril and carvedilol groups were significantly smaller than that of the saline group. Pathologic examination revealed relatively well-preserved aortic walls in the ramipril group compared to the carvedilol and saline groups. The level of MCP-1 was markedly decreased in both the ramipril and carvedilol groups

compared to the saline group. The level of TIMP-1 was higher in the carvedilol group when compared to either the saline or ramipril groups.
Conclusions: Ramipril and carvedilol treatment shows similar efficacy in limiting AAA expansion in mouse model. Future clinical research would be warranted to validate these results.

Neutrophil extracellular trap formation is enhanced in arterial hypertension via and AT1R and NADPH oxidase-dependent pathway

TM Hofbauer[1]; T Scherz[1]; A Ondracek[1]; J Mueller[1]; L Kascha[1]; C Feist[1]; A Frueh[1]; I Horvat Menih[1]; A Mangold[1]; IM Lang[1]
[1]Medical University of Vienna, Cardiology, Vienna, Austria

Background: Arterial hypertension is a major risk factor for coronary artery disease (CAD). By formation of neutrophil extracellular traps (NETs), neutrophils release their nuclear content into the extracellular space, fighting pathogens. NETs have been implicated in CAD. In preliminary studies of CAD patients, we observed a positive correlation between blood pressure and NETosis ex vivo, implicating blood pressure modulating NETosis. Angiotensin-II (Ang-II) mediates blood pressure via its potent vasoconstrictive properties, but also exerts pro-inflammatory functions via the angiotensin type 1 receptor (AT1R). AT1R is expressed on neutrophils. We thus hypothesized that Ang-II might influence NETosis.
Methods: We stimulated isolated neutrophils with ionomycin ex vivo. NETosis was measured using Sytox® Green, a dye that exclusively stains extracellular DNA, a hallmark feature of NETs. The detergent Triton served as positive control. To assess the role of the Ang-II pathway, we pre-incubated neutrophils with Ang-II, AT1R antagonist losartan or NADPH oxidase inhibitor diphenyleneiodonium (DPI).
Results: We observed a dose-dependent NET release by ionomycin. Irrespective of ionomycin concentration, pre-treatment with Ang-II significantly enhanced NETosis to 80-90% of positive control. Losartan abolished this effect, suggesting an AT1R-dependent pathway. NADPH oxidase is crucial for NETosis due to release of reactive oxygen species. DPI abolished the effect of Ang-II on NETosis.
Conclusion: Our results implicate that via Ang-II, arterial hypertension aids neutrophils to undergo NETosis by increasing intracellular ROS production, which makes neutrophils more susceptible to pro-NETotic stimuli. This provides new insight in how effective blood pressure lowering might lead to more favorable outcomes in CAD.

Obesity

P2017
Sex-related differences in influence of obesity on outcomes of patients with heart failure: results from the Polish cohort of the ESC Heart Failure Long-Term Registry

MI Marta Izabela Kaluzna-Oleksy[1]; JM Migaj[1]; J Nessler[2]; MG Crespo-Leiro[3]; AP Maggioni[4]; J Drozdz[5]; M Lesiak[1]; E Straburzynska-Migaj[1]
[1]Poznan University of Medical Sciences, Ist Department of Cardiology , Poznan, Poland; *[2]John Paul II Hospital, Krakow, Poland*; *[3]Instituto Universitario de Ciencias de la Salud, A Coruna, Spain*; *[4]ANMCO Foundation For Your Heart, Florence, Italy*; *[5]Medical University of Lodz, Lodz, Poland*

Introduction: Many investigators reported an "obesity paradox" presenting improved outcomes of obese patients with chronic diseases including, among others, kidney disease and heart failure (HF). Mechanisms underlying this phenomenon are not known and its existence remains controversial. Men and women differ in incidence and patterns of obesity, which gives strong reasons to suspect sex-related differences in influence of obesity on outcomes.
Aim: The aim of the hereby-presented study was to compare the influence of obesity on outcomes of men and women with HF with both reduced (HFrEF) and preserved (HFpEF) ejection fraction.
Methods: This study is a part of a large prospective European registry of HF patients followed for 12 months. It includes 1030 Polish in-patients and out-patients treated for HF, men (n = 724) and women (n = 304). The subjects have both HFrEF, n = 746, and HFpEF, n = 255. The endpoints were all-cause death (n = 113), hospitalization (n = 425) and both combined (n = 494). This study uses body mass index (BMI) to divide subjects into groups according to WHO 18.5-24.99 (n = 276), 25-29.99 (n = 430) and 30-39.99 (n = 278); there were too few patients with BMI < 18.5 (n = 16) and >40 (n = 28) for further analyzes. Survival analysis was adjusted for markers of poor prognosis - AF, NYHA class, hemoglobin, LVEF, BNP and heart rate. P value of 0.05 was considered significant in all analyzes.
Results: There were no differences in incidence of normal weight, overweight and obesity between men and women (26% vs. 32%, 45% vs. 40% and 29% vs. 28% respectively, NS) and between HFrEF and HFpEF (28% vs. 28%, 40% vs. 45% and 32% vs. 27% respectively, NS). Univariate regression model shows that higher BMI reduced risk of death (HR 0.94, p = 0.001; for men HR 0.94, p = 0.006; for women HR 0.95, NS), the same for obesity (HR 0.72, p = 0.002; for men HR 0.73, p = 0.015; for women HR 0.70, NS). Multivariate regression model showed that higher BMI reduced risk of death (HR 0.96, p = 0.023; for men HR 0.96, p = 0.06; for women HR 0.96, p = 0.23), the same for obesity (HR 0.79, p = 0.036; for men HR 0.83, NS; for women HR 0.76, NS). BMI and obesity do not influence risk of hospitalization (HR 1.00, NS and HR 0.97, NS respectively). Univariate regression model shows that higher BMI reduced risk of death in men with HFrEF (HR 0.92, p = 0.002) and women with HFpEF (HR 0.89, p = 0.029); the same for obesity (HR 0.66, p = 0.004 and HR 0.49, p = 0.011 respectively). BMI and obesity did not influence risk of death and hospitalization in patients with NYHA III and IV and in men with HFpEF and women with HFrEF, and there were no sex-related differences in this group.
Conclusions. Obese patients with HF show reduced risk of death in 12-month follow-up. This phenomenon may be observed mainly in men, particularly with HFrEF, and in women with HFpEF.

Exercise Testing

P2018
Association between oxygen uptake efficiency slope (OUES), an effort-independent measure of cardiorespiratory fitness (VO2max), and robust/pre-frail status in an elderly Chinese population

E Fung[1]; L T Lui[1]; F Yau[1]; J Leung[1]; J Woo[1]
[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong SAR People's Republic of China

On behalf of: Laboratory for Heart Failure and Circulation Research, CUHK

Background/Introduction: Peak oxygen uptake or consumption (VO2max) is a measure of cardiorespiratory fitness that provides prognostic information in heart failure patients being considered for transplant, and is also widely used in exercise capacity testing. However, accurate determination of threshold capacity is effort-dependent, and poses challenges when assessing older adults. Previous studies have shown that calculating the oxygen uptake efficiency slope (OUES) through the use of multiple VO2 data points at different exercise levels in conjunction with minute ventilation (VE) can inform exercise capacity independent of effort and may be superior to VO2max. We hypothesise that OUES in this physiological context can distinguish robust versus pre-frail older adults.
Purpose: To compare VO2max with OUES in a community-dwelling older adult population able to freely ambulate.
Methods: This study included subjects in the Mr & Ms Os Cohort with a complete set of cardiopulmonary exercise testing (CPET) data. OUES ('a') was calculated using the following equation: $VO2 = a \cdot \log(VE) + b$. A 4-point frailty scale was used to classify robust/pre-frail status, and 1 point was assigned for each positive criterion: i) very little or no energy, ii) difficulty in climbing up 10 steps of stairs, iii) inability to walk 100 yards, and iv) presence of 3 or more predefined co-morbidities. A score of zero (0) was considered 'robust', and 1 to 2 points indicated pre-frailty. Four primary measures were used to assess cardiorespiratory fitness against robust/pre-frail status: VO2max, VO2max/kg (or VO2max indexed to body weight in kilograms), OUES, and OUES/kg. Student's t test was used for comparing means between two groups. The study was approved by the institutional ethics review committeee and adhered to the Declaration of Helsinki.
Results: The study included 550 subjects (457 males and 93 females) with a mean age of 76.7 y $\pm$ 5.34. The ratios (or relative proportions) of robust:pre-frail individuals in the male and female subject groups were 3.57 (78.12% vs. 21.88%) and 1.74 (63.44% vs. 36.56%), respectively. The robust group outperformed the pre-frail group in all four measures. Among these, VO2max/kg most strongly differentiated robust/pre-frail status in male (22.6 vs. 19.6, P = 7.32 x 10e−12) and female (20.4 vs. 17.4, P = 2.59 x 10e−5) subjects. OUES did not significantly differentiate robust/pre-frail status in male subjects (1769.9 vs. 1709.9, P = 0.11), and only

modestly in female subjects (1486.8 vs.1259.0, P = 0.001). VO2max and OUES/kg also differentiated robust/pre-frail status to varying extents in both sexes (range, P = 0.0067 to 7.85 x 10e−7).
Conclusion(s) In the manner in which older Chinese adults have been stratified by robust/pre-frail status as used in this study, VO2max/kg (or indexed VO2max) was the most strongly significant metric for differentiating robust versus pre-frail individuals compared with VO2max, OUES or OUES/kg.

Autoimmune/Chronic Inflammatory Disorders and Heart Disease

GRK2 is a novel early marker of cardiotoxicity in response to doxorubicin

A Antonella Fiordelisi[1]; J Gambardella[2]; M De Rosa[1]; M Ciccarelli[2]; B Trimarco[1]; G Iaccarino[2]; D Sorriento[1]
[1]Federico II University of Naples, Department of biomedical sciences advanced, Naples, Italy; [2]University of Salerno, Medicine and surgery, Salerno, Italy

Background: Doxorubicin (DOXO) is common anticancer drug, whose efficacy is limited by a cumulative dose-dependent cardiotoxicity which can lead to severe heart failure and death. The current goal of cardio-oncology research is the identification of early markers of cardiotoxicity to promptly start an effective therapy. In this context, the G protein coupled receptor kinases type 2 (GRK2) is an useful marker of cardiac injury since its levels and activity are elevated in damaged heart. Moreover, it has been shown that myocardial GRK2 expression and activity are mirrored by lymphocyte levels of this kinase and can predict late ventricular remodeling as early as 3 days after Myocardial Infarction proposing this kinase as early biomarker of cardiac injury.
Purpose: The aim of the study is to evaluate the role of GRK2 as early marker of cardiac dysfunction induced by DOXO.
Methods: In vitro, GRK2 and Cleaved Caspase 3 levels were analyzed in cardiomyoblasts (H9C2) after treatment with DOXO 5 uM, by western blot. In vivo, C57B WT mice were treated with a single intraperitoneal injection of DOXO (20 mg/ Kg). Heart and blood from mice were collected at 24, 48 and 72h after treatment. The levels of GRK2 were evaluated by western blot in whole heart lysate and in PBMCs isolated from mice blood. Cardiac gene expression of ANF and MCP1 was evaluated by Real time PCR.
Results: In cardio-myoblasts, GRK2 levels were reduced in response to DOXO at 1 hour from starting treatment while Cleaved caspase 3, marker of damage, increased in a time dependent manner only after 3 hours from starting treatment. Similarly, in vivo, GRK2 levels were decreased in whole heart lysates from mice treated with DOXO compared with controls, at 24, 48 and 72h, when the transcriptional levels of ANF and MCP-1, were not still increased by DOXO administration. Also in PBMCs from mice blood, the levels of GRK2 were reduced after 24, 48 and 72h from starting treatment, reflecting the GRK2 cardiac reduction.
Conclusion: DOXO induces an early decrease of GRK2 levels in cardiac cells. This reduction occurs in a pre-damage phase suggesting the potential role of GRK2 as early markers of cardiotoxicity. Moreover, the correlation between GRK2 levels in the heart and its expression in PBMCs, suggest that this protein could be easily detectable from peripheral blood to indirectly evaluate its expression levels in the heart. These data suggest that the reduction of GRK2 levels in PBMC could be an early marker of DOXO induced toxicity since it arises before the activation of DOXO-dependent damage.

Can the acceptance of the illness increase compliance with non-pharmacological treatment recommendations in patients with heart failure?

B Beata Jankowska-Polanska[1]; B Kowalczyk[1]; K Lomper[1]; A Chudiak[1]; G Mazur[2]
[1]Medical University of Wroclaw, Health Science Faculty, Wroclaw, Poland; [2]Wroclaw Medical University, Department and Clinic of Internal and Occupational Diseases and Hypertension, Wroclaw, Poland

Patients, in particular elderly, affected by heart failure (HF) that are non-compliance to therapeutic treatment are exposed to frequent exacerbations of HF symptoms and consequently to high risk of re-hospitalizations. Non-compliance with non-pharmacological treatment is major problem for HF patients that need caring. Previous studies assessed the importance of pharmacological treatment but only few focused on lifestyle recommendations and depth on the importance of acceptance of illness on compliance with therapeutic treatments according by most recent guidelines of HF. Aim: To assess the effect of acceptance of disease in HF patients related to the compliance to therapeutic treatment.
Methods: 105 participants were enrolled in this study divided into 3 groups depending on the degree of acceptance of illness scale (AIS): I group (AIS 8-18), II group (AIS 19-29), III group (AIS 30-40). Elderly HF patients were recruited in a outpatient cardiovascular clinic in Poland. The acceptance of disease were assessed using Acceptance of Illness Scale (AIS) and the Revised Heart Failure Compliance Scale was used to assess the compliance to the non-pharmacological treatment in 6 domains: sodium restrictions, exercise, appointment keeping, fluid restriction, regular weighing and pharmacological treatment. SPSS software was used to data analysis.
Results: In comparative analysis of HF patients depending on AIS there were statistically significant differences in compliance level especially in sodium restrictions domain (I group 1.3 ± 1.2 vs II group 2.0 ± 1.5 vs III group 2.3 ± 1.3; $p = 0.047$) and exercise (I group 0.5 ± 0.9 vs II group 0.8 ± 1.2 vs III group 1.3 ± 1.2; $p = 0.045$). We no found statistically significant differences in other domains. Moreover AIS is a independent predictor of compliance with the reduction in sodium intake ($\beta = 0.061$; $p = 0.006$).
Conclusions: The acceptance of disease improves significantly the compliance with therapeutic recommendations, especially in the non-pharmacological treatment. Elderly patients with a high level of acceptance have better compliance to non-pharmacological treatment of HF. Assessment of acceptance and compliance level may be useful in planning tailored education in HF patients.

Poster Session 3 - Clinical Cases

Chronic Heart Failure - Pathophysiology and Mechanisms

P2021

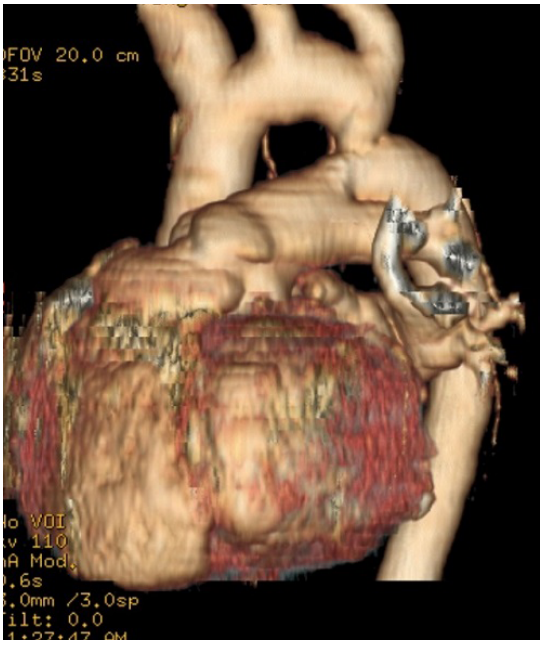
An unexpected cause of heart failure diagnosed in adulthood: the unfortunate poker of cardiac anomalies

M Maria Trepa[1]; I Sa[1]; M Fontes-Oliveira[1]; R Santos[1]; R Costa[1]; VA Dias[1]; S Torres[1]

[1]*Hospital Center of Porto, Cardiology, Porto, Portugal*

Congenital heart disease is particularly challenging due to a vast range of anatomic lesions with different adaptive mechanisms and presentations.

We present the case of a 35 year old female patient referred to cardiology due to dyspnea. Previous history included late-diagnosed phenylketonuria (PKU) resulting in mild cognitive impairment, hypertension and a history of a heart murmur in childhood. At initial consultation she was in class III NYHA. Physical exam revealed



CT_reconstruction

equalized hypertension in all 4 limbs and a grade III systolic murmur. EKG was in synus rhythm and had intraventricular conduction delay and hypertrophy criteria.

The echocardiogram showed several abnormalities: 2D showed a bicuspid aortic valve (BVA), right ventricular (RV) hypertrophy, dilatation of the pulmonary artery (PA) and abnormal septum movement. There was apical hypertrabeculation, moderate left ventricular (LV) dysfunction and RV impairment. Spectral Doppler revealed severe pulmonary hypertension (PH) (PA systolic pressure ~100 mmHg). A close look at the left PA revealed a diastolic retrograde flow from a large patent ductus arteriosus (PDA). Also, a small perimembranous ventricular septal defect (VSD) was seen and, in the supraesternal view, a post-isthmus significant narrowing of the descending aorta with a gradient of ~50mmHg made the diagnosis of coarctation of the aorta (COA).

The subsequent cardiac magnetic resonance confirmed the echocardiographic findings and the high suspicion for a small VSD. The hypertrabeculation was not significant and there was no late myocardial enhancement.

Cardiac catheterization showed severe COA (gradient through COA ~52 mmHg) and large PDA with bidirectional shunt but mainly right to left (Qp/Qs: 0.77) with severe PH (equal to systemic pressure). Ductal occlusion had no effect on PSAP.

Given the presence of Eisenmenger physiology at initial diagnosis, there was no indication for PDA closure. The patient was started on diuretics, b-blockers, angiotensin converter inhibitors, aldosterone antagonists and pulmonary vasodilators and is currently stable on class II NYHA, with mild cyanosis and eryhtrocytosis. She has also undergone tubal ligation.

Major chromosomal abnormalities were ruled out and she is currently under further genetic testing. The relation to PKU was considered but the only reports associating this metabolic disease with cardiac abnormalities refer to children born from mothers with PKU, which was not the case.

Although congenital cardiac lesions may occur in association, to our knowledge, this is the first report describing this particular combination of multiple anomalies, namely BAV, PDA, COA and VSD. This case is remarkable for its singularity and physiological complexity but also because it highlights the importance of screening cardiac murmurs in childhood to avoid late and irreversible presentations. Timely referral of these patients to an experienced Heart Team in essential.

P2022

Assessment and treatment strategy of heart failure due to combined cardiomyopathy (ischemic,toxic and valvular)

R Rok Stopar[1]

[1]*Izola General Hospital, Cardiology, Izola, Slovenia*

Assessment and treatment strategy of heart failure due to combined cardiomyopathy (ischemic,toxic and valvular)

70 year old male was admitted to cardiologic department of regional hospital with signs of new onset heart failure. In the past he had been diagnosed sarkoidosis without had been treated and arterial hypertension. He had a history of alcochol abuse as well. ECG registered sinus tachicardia without ST alteration. Lab exames showed BNP 2708 pg/ml (100), cTnI 108 ng/L (40), kreatinin 155 μmol/L, urea 11,1 μmol/L, ionogram and blood gas analysis unremarble. Transthoracic echocardiography revealed moderatly dilated left ventricle with severly depressed systolic function (EF 25%), hypokinetic right ventricle, calcified aortic valve with low transvalvular gradient and reduced (AVA 0,9 cm2) indicating possible low flow severe aortic stenosis. Elevated serum transaminase and abdominal ultrasound revealed hepatopathy due to congestion and past alcochol consumption. Kidney failure with GFR 38ml/min/P was also diagnosed. Coronarography showed severe LM, proximal LAD and LCX stenosis. Due to high risk for surgical intervention (ESC II 11,93 %), we decided for step by step approach. First stenting coronary lesions afterward refering to TARV . PCI of LM, LAD and LCX was performed . In mean time patient was treated with high doses of diuretics. Before PCI levosimendan was administerd as well. Therapy with ACE, eplerenon, bisoprolol, atorvastatin, ASA and ticagrelor was prescribed according to ESC guidelines. At discharged our patient was in NYHA class III . CMR was consistent with ishemic cardiomyopathy . 2 months later patient had been recovered to NYHA class II, TTE showed increased both (EF 35%) and (AVA 1 cm2) with only slightly increase of transvalvular gradient. So far TAVR was postponed .

Heart failure may be caused by combined cardiomyopathy that need holistic approach in order to select right treatment strategy for a given clinical situation

P2023

A case of dilated cardiomyopathy suffered attack of cardiac arrest during left ventricular epicardial lead implantation

M-T Ming-Ting Chou[1]; CY Chiang[1]

[1]*Chi-Mei Medical Center, section of Cardiology, Tainan, Taiwan ROC*

A 50–year-old male was admitted through emergency department due to progressive dyspnea with orthopnea for days. He was diagnosed as dilated cardiomyopathy 5 years ago and received regular medical treatment in cardiovascular section. About 2 months ago, he was admitted to cardiovascular surgery section due to progressive bilateral lower leg weakness. Abdominal CT scan revealed occlusion of

bilateral iliac artery.(Fig 1) . Leriche syndrome was diagnosed. He received IV urokinase infusion and symptom improved and shift to oral wafarin treatment. At ER, Chest X ray showed cardiomegaly with pulmonary edema; ECG showed complete LBBB pattern with QRS width about 154msesc. Echocardiogram showed poor LV systolic performance with ejection fraction estimated about 15%. Also LV thrombus was found (fig 2). He received IV diuretic and dobutamine infusion first but without much symptom improvement. Cardiovascular surgery was consulted for possible heart transplant . Biventricular pacemaker implantation was performed 1 week after admission. During the procedure, the 0.36mm PTCA wire can go into the coronary sinus but the 1.3mm LV lead just stop at the coronary sinus ostial site after repeated trial. Coronary sinus ostial stenosis was highly suspected (fig 3). Finally, only RV and RA leads were implanted. So surgical LV epicardial lead implantation was arranged . Sudden cardiac arrest occurred during general anesthesia induction; After successful cardiac-pulmonary resuscitation, VA ECMO implantation was also done. LV epicardial leads was then successfully implanted with good test function. Successful endotracheal extubation and removal of ECMO was done 5 days later. He was later discharged in stable and improved condition. He lived uneventfulty with functional class II status one year later. Follow-up echocardiogram showed improved ejection fraction up to 44% with resolution of LV thrombus .

Bleeding during dabigatran treatment of a patient with acute renal injury induced by a combination of spironilactone and enalapril

P2024

ZK Salpagarova[1]; DA Andreev[1]; AA Bykova[1]; M Chashkina[1]; DA Sychev[2]; AL Syrkin[1]

[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; *[2]Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation*

A 75-year-old man with hypertension, paroxysmal atrial fibrillation, aortic stenosis, type 2 diabetes, and chronic kidney disease stage 3a (glomerular filtration rate (GFR) by the CKD-EPI 52 ml/min/1.72 m2) presented with another episode of acute decompensated heart failure NYHA class 4. The patient also underwent hemicolectomy with colostomy 6 years ago for a colorectal cancer.

On admission in clinical blood analysis there were nothing abnormal detected. The patient was received metoprolol succinate 150 mg / day, digoxin 0.375 mg / day (but was withdrawn due to the frequent ventricular extrasystoles), enalapril 20 mg / day, amlodipine 2.5 mg / day, spironolactone 50 mg / day, furosemide 80 mg / day, atorvastatin 20 mg / day and gliclazid 30 mg / day. Dabigatran 220 mg / day was also prescribed (CHA2DS2-VASc 5 score). Patient status on the top of already administered therapy improved significantly. However, by the day 10 after discharge, severe weakness, shortness of breath and dizziness were occurred, so the patient was rehospitalized.

In blood tests, the following changes were observed: hemoglobin 69 g / l, creatinine 3.6 mg / dL (GFR by the CKD-EPI 18 ml/min/1.72 m2) and potassium 5.5 mEq / L. In the coagulogram: APTT - 2.51 (norm 0.75-1.25), PR - 50% (norm 85-110%), TT > 3 (min 27-33 sec). Fecal occult blood test was strongly positive. Microhematuria had not been detected. Also observed dabigatran concentration in the blood plasm - 980 ng / ml. There were no any pathological changes in the esophagogastroduodenoscopy. A colonoscopy was planned, but the patient refused the procedure. Spironolactone, dabigatran, enalapril were stopped. The patients had received intravenous iron therapy, as well as red blood cell mass and fresh-frozen plasma infusion until the state became stable. All parameters in coagulogram were in normal ranges within five days. The patient was discharged on a stable state without anticoagulant therapy. Three month later, when hemoglobin reached 110 g / l and creatinine decreased to 1.4 mg / dL (GFR by the CKD-EPI 49 ml/min/1.72 m2), warfarin had been started.

Conclusion: 1. Renal injury is a known adverse effect induced by the combined use of angiotensin-converting-enzyme inhibitor and spironolactone, however there is no increased risk of nephrotoxicity in clinical trials. When reduced kidney function, it should be noted the pharmacokinetics of concomitant drugs that have renal clearance. 2. The patient had increased TT, APTT and decreased PR, as well as dabigatran concentration in the blood plasm 980 ng / ml, that indicate an overdose of this drug. 3. Taking into account the inability to predict the safety of NOAK therapy, this patient was assigned warfarin. 4. This case emphasizes the importance of drug-drug interaction in polypharmacy, which is unavoidable in the treatment of chronic heart failure.

P2025

Early and delayed cardiac injuries as a consequence of blunt chest trauma

C Cristina Asla Ormaza[1]; A Elorriaga Madariaga[1]; PM Mendoza Cuartero[1]; A Arregui Lopez[1]; A Andres Morist[1]; RJ Saez Moreno[1]; R Martinez De Bourio Uriarte[1]; L Ruiz Gomez[1]; N Garcia Ibarrondo[1]; G Ramirez-Escudero Ugalde[1]; G Aurrekoetxea Bajeneta[1]; A Ullate De La Torre[1]; I Bravo Martinez[1]; JM Aguirre Salcedo[1]

[1]Hospital de Basurto, Bilbao, Spain

We report a case of a 72-year-old man in outpatient follow up because of nonischemic dilated cardiomyopathy with mild to moderately depressed left ventricular ejection fraction (LVEF) and atrial fibrillation (AF). On the last echocardiogram, one year before the event, he presented an end-diastolic diameter of 70 mm with a LVEF of 42%, but no wall motion abnormalities neither significant valvular disease, and a normal right ventricular systolic function. He used to ride a bicycle 50 kilometres three times per week, until he suffered a cycling accident with blunt chest trauma.

On admission to hospital, the patient was conscious and hemodynamically stable. Electrocardiogram showed AF and rapid ventricular response with incomplete right bundle branch block morphology. Thoracic computed tomography was performed to detect other complications of blunt chest trauma. Along with multiple rib fractures, left clavicle and scapula, mild pericardial effusion was visualized. The patient was transferred to the intensive care unit. Analytics then revealed elevation of cardiac biomarkers, with an initial troponin I of more than 50000, being diagnosed as a cardiac contusion.

Once the patient was stabilized, he was transferred to a hospital ward. Control echocardiogram displayed moderate LVEF with mid and basal inferoposterior akinesia and severe functional mitral regurgitation. Being hospitalized, he developed cardiac tamponade requiring pericardiocentesis with drainage of serohematic fluid. After one month and a half, he was finally discharged home.

Two months later, the patient returned to hospital with heart failure. He already presented a severely dilated left ventricle with an end-diastolic diameter of 80 mm and severely depressed LVEF (28%), with mid and basal inferoposterior scar, severe mitral regurgitation and moderate dilation and systolic disfunction of right ventricle, with moderate tricuspid regurgitation and moderate pulmonary hypertension. Cardiac magnetic resonance was not practiced because of the presence of splinters. A coronary angiogram would confirm absence of coronary lesions.

Although it uses to heal spontaneously, cardiac contusion can sometimes leave delayed sequelae, involving pericardium, atrioventricular and semilunar valves, coronary arteries and conduction system. Heart failure can be an early or relatively late sequel and it is sometimes progressive. Wall motion abnormalities are also rather frequent. Furthermore, trauma can originate or even impair a previous heart disease. In the case we present, cardiac contusion was early identified mainly due to associated chest wall lesions. However, low energy trauma can also cause cardiac contusion which probably goes unnoticed, being more difficult its diagnosis out of the acute phase. As heart injuries following trauma can progress gradually and leave delayed sequelae, considering the possibility of a previous trauma is of the utmost importance in cases of unexplained heart disease.

P2026

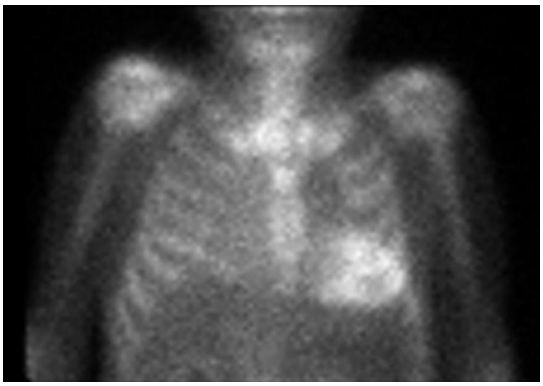
An unrecognized case of infiltrative heart disease

AC Baroncini[1]; A Pratesi[2]; A Lo Forte[1]; C Ghiara[1]; E Carrassi[1]; S Parlapiano[1]; A Herbst[1]; G Biagioni[1]; F Fedeli[1]; M Di Bari[2]; A Ungar[2]; F Orso[2]; S Baldasseroni[2]

[1]University of Florence, Florence, Italy; *[2]Careggi University Hospital (AOUC), Florence, Italy*

Presentation of case: Male, 90 years old, with a history of hypertension, dyslipidaemia, chronic kidney disease stage G2 KDIGO, bilateral carpal tunnel syndrome. Permanent atrial fibrillation (AF) since 2015: at that time main echocardiographic findings were left atrial enlargement, left ventricular hypertrophy (LVH) (interventricular septum (IVS) thickness 14 mm, posterior wall thickness 14 mm), small pericardial effusion. In 2016 appearance, and progressive deterioration, of signs and symptoms of heart failure (HF) and, in june 2017, the patient was sent to our HF clinic: electrocardiography (ECG) revealed AF with a slow ventricular response and low voltages in limb leads while echocardiography revealed left atrial enlargement, progression of LVH (IVS thickness 17 mm, posterior wall thickness 16 mm), diastolic dysfunction, mild pericardial effusion and moderate tricuspid regurgitation. We managed signs and symptoms of HF with optimisation of medical therapy and, considering the rapid progression of LVH, ECG and echocardiographic findings, we started a diagnostic workup in the suspicion of infiltrative disease. Cardiac Troponin I measurement and workup for a monoclonal protein process resulted at the upper

limit of normality; he also underwent 99mTcPYP scintigraphy that revealed a significant diffuse myocardial 99mTcPYP uptake. Furthermore, in july 2017, a pace maker was implanted due to the evidence on Holter ECG of AF with a slow ventricular response and several pauses. Finally, taking into account the history of the disease, the ECG and echocardiographic findings and the diffuse myocardial 99mTcPYP uptake, ATTR cardiac amyloidosis (ATTR-CA) was diagnosed. **Conclusions:** ATTR-CA is a progressive disorder that typically affects white older males leading to significantly reduced survival and quality of life. Acquired wild-type variant (ATTRwt-CA) is often an unrecognized cause of diastolic HF due to hypertrophic restrictive cardiomyopathy, frequently misdiagnosed as hypertensive heart disease or hypertrophic cardiomyopathy. ATTRwt-CA is associated with and increased rates of AF, bundle branch block and varying degrees of heart block, valves thickening, small pericardial effusions and angina with normal coronaries. Carpal tunnel syndrome often precede clinical HF by several years. New diagnosis of hypertrophic cardiomyopathy in an elderly patient may raise suspicion of ATTRwt-CA while the classic hallmark of CA is the combination of low voltage on ECG and increased left ventricular wall thickness on echocardiogram; subsequent laboratory tests or cardiac imaging, in particular 99mTcPYP scintigraphy, are used to confirm the diagnosis. Treatment includes management of cardiac symptoms and treating the underling amyloid disease; significant progress has been made and, given the fact that ATTRwt-CA is more common than previously recognized and even more treatable, early diagnosis and prompt initiation of therapy are important.



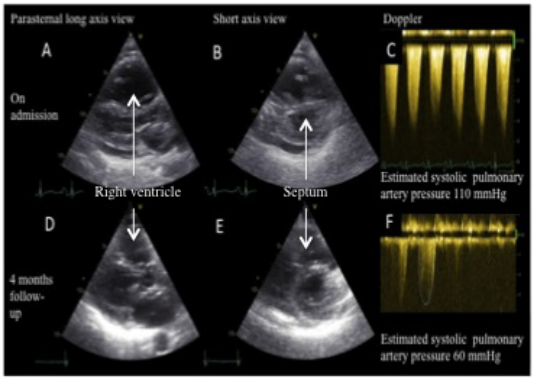
99mTcPYP scintigraphy

P2027

Cardio-oncology; more than left ventricular systolic dysfunction

G Gulati[1]; E Berge[1]; S Holmen[1]; TG Von Lueder[1]
[1]*Oslo University Hospital, Ullevål, Department of Cardiology, Oslo, Norway*

Introduction: A rare but severe complication of treatment for chronic myeloid leukaemia (CML) with dasatinib (a protein kinase inhibitor) is pulmonary hypertension. There is limited evidence on how these patients should be followed.
Case Report: A 29-year-old female with paroxysmal atrial fibrillation was referred to the cardiology department for shortness of breath. The symptoms had started two months previously and deteriorated so that she could barely walk without getting



breathless. The patient had been diagnosed with CML in 2008 and put on imatinib. Due to lack of optimal efficacy and side effects, her therapy had been changed to dasatinib in 2011. On clinical examination a holosystolic murmur was noted over the heart and diminished lung sounds in the base on the right side. Her vitals, including oxygen saturation was normal. Computed tomography excluded pulmonary embolism. Echocardiography revealed a pulmonary artery systolic pressure of 110 mmHg and markedly dilated right ventricle with paradoxical septal motion (Figure 1, panels A, B and C). There was no left ventricular or valvular dysfunction. Pulmonary function test revealed no significant pulmonary disease. Circulating biomarkers of connective tissue disease and HIV were negative. Invasive right heart catheterization confirmed severe precapillary pulmonary hypertension with mean pulmonary arterial pressure of 46 mmHg and pulmonary vascular resistance of 10 WU. On the six minutes walk test the patient achieved a distance of 395m. Dasatinib was discontinued, and the patient commenced therapy for pulmonic hypertension with tadalafil and macitentan. Bosutinib was given for her CML. On follow up four months later her symptoms had greatly improved. Echocardiography showed a marked drop in pulmonary artery systolic pressure at 60 mmHg (Figure 1, panels D, E and F). Repeat right heart catheterization confirmed improvements (mean pulmonary arterial pressure was 31 mmHg and pulmonary vascular resistance 11 WU). Her six minutes walk test showed a marked 25% improvement to 500m.
Problem and Discussion: Despite the abundance of novel effective agents constantly being introduced into oncology, little is known about their potential adverse effects on the cardiovascular system. While the field of cardio-oncology commonly focuses on left ventricular dysfunction, this case of extreme drug-induced precapillary pulmonary hypertension and imminent right ventricular failure illustrates the broad spectrum which cardio-oncology constitutes. High clinical vigilance and a close collaboration between cardiologists and oncologists are vital for optimal management of these patients.
Conclusion: This case of severe precapillary pulmonic hypertension and right ventricular dysfunction in a young female is an important reminder of the rare but severe complication of cancer treatment with dasatinib and the need for multidisciplinary management in cardio-oncology.

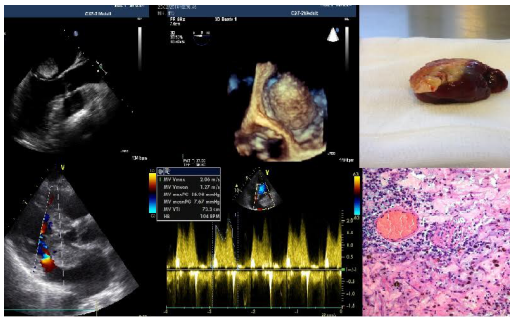
Chronic Heart Failure - Diagnostic Methods

P2028

Incidental atrial myxoma in two asymptomatic patients: a case report

G Muckiene[1]; A Kavoliuniene[1]; D Rimkeviciute[1]
[1]*Lithuanian University of Health Sciences, Department of Cardiology , Kaunas, Lithuania*

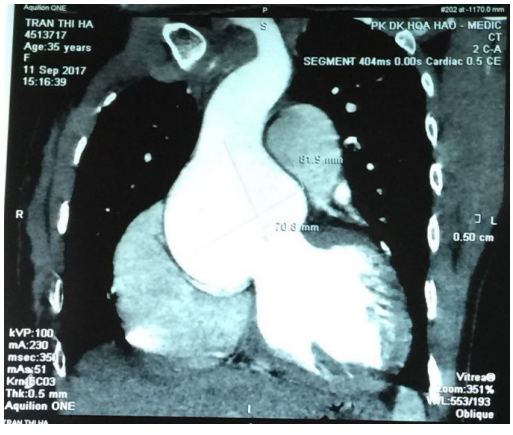
A 60 year-old driver was reffered to preventive examinations in order to prolong his driver's licence. Electrocardiogram showed atrial fibrillation which was asymptomatic, duration and origin unknown. Elective cardioversion and oral anticoagulations were recommended, as where was no previous chonic heart disease. However, termination of cardiac rhythm disturbance with direct current cardioversion and pharmacological therapy failed. Then 2D echocardiography was performed in order to reveal any structural heart disease that could be associated with resistant arrythmia, and the mass of 2,96 x 2,7 cm was revealed, with a stalk attached to the atrial septum in enlarged left atrial (47 mm), no other abnormalities were detected.
Physical examination did not reveale any clinics signs of left atrial enlargement just normorythmic atrial fibrillation.
On trasthoracic echocardiography oval mass of 35 x 27 mm attached to the inferior part of atrial septum in short distance from the aortic and mitral valve annulus. The mass was fixed to the atrial septum.
Preoperative coronarography detected unusual vascularisation of the mass supplying blood from the circumflex coronary artery without significant coronary artery stenosis at age of 60.
Transesophageal echocardiography (TEE) was performed in order to clarify relation with left atrial walls.
The patient was referred to open heart surgery. A large, 3 cm × 3 cm × 4 cm solid encapsulated mass, attached to atrial septum and posterial left atrial wall, was successfully removed, and histopathological examination showed typical morphologic features of myxoma.
Case II. Woman with hypertensive heart disease and incidentaloma
A 58 year-old asymptomatic woman was referred to cardiologist consultation due to hypertension.
Physical examination revealed a loud first heart sound and additional a diastolic rumble.
Echocardiography was performed in order to clarify structural abnormalities characteristic to hypertensive heart disease but revealed incidentaloma - large (30 × 49 mm) and mobile mass with a stalk attached to the interatrial septum. The tumor from the left atrium prolapsed into the left ventricle through the mitral valve during diastole causing obstruction of atrioventricular orifice, thus typical signs of pseudomitral valve stenotic lession was clarified.
Nor coronary artery stenotic lesions neigher vascularisation of the left atrium mass was detected on preoperative coronarography. Open heart surgery was performed resulting in successful removal of the large (3,5 × 4,0 × 3,5 cm) tumor in the left atrium.



Histopathological examination showed typical features of myxoma.
In summary, both case reports illustrate uncommon course of primary cardiac tumors that may remain almost asymptomatic or present with non-specific cardiac conditions.

P2029
A case of aneurysms of the sinus of valsalva
H Thai Hao Phan[1]
[1]*Pham Ngoc Thach University of Medicine, Cardiology, Ho Chi Minh, Vietnam*

Introduction: Aneurysms of the sinus of Valsalva are very uncommon, with an incidence ranging from 0.1 to 3.5% of all congenital heart defects. Such aneurysms account for only 0.14% of all open heart surgical procedures. Aneurysms of the sinus of Valsalva are usually diagnosed as an incidental finding or after an acute rupture into an adjacent cardiac structure. Before rupture, aneurysms of the sinus of Valsalva may present with conduction-system abnormalities attributable to erosion into the interventricular septum, thromboembolism originating in the aneurysm sac, and myocardial ischemia attributable to coronary compression. We report a case of aneurysms of the sinus of Valsalva associated with severe aortic valve regurgitation.
Case: A 35-year–old female with no past medical history was admitted for exertional dyspnea during 2 weeks. There was no relevant family history. Her cardiovascular physical examination was significant for a 4/4 diastolic murmur at at third left intercostal space and other peripheral signs: Corrigan pulse, Hill's sign, Duroziez's murmur. Her admission ECG showed sinus rhythm with a heart rate of 91 bpm, left ventricular hypertrophy. Her portable chest x-ray was significant for cardiomegaly. Because of these abnormal findings the patient underwent a transthoracic echocardiogram, which revealed a massively enlarged aortic root with large sinuses of Valsalva aneurysms measuring 7.5 cm in diameter. Severe aortic regurgitation was present, and left ventricular function was normal. The patient was further evaluated by computerized tomography of the ascending aorta. This imaging modality further confirmed the findings in the echocardiogram. These findings were not previously known by the patient. The patient denied any signs or symptoms of cardiac ischemia or embolic complications such as stroke. Subsequently, the patient will undergo modified Bentall surgical repair of her sinus of Valsalva associated with severe aortic valve regurgitation.



cardiac MSCT

Discussion: Sawyers et al demonstrated a mean survival period of 4 years in patients with untreated ruptured sinuses of Valsalva aneurysms, a finding that favors the need for early surgical intervention in this group. The optimal management of an asymptomatic, nonruptured aneurysm is less clear because of the absence of a precise natural history. Improvements in surgical technique in the past 15 years have resulted in low complication rates with no early mortality (0%) and low morbidity (4%).
Conclusion: Sinus of Valsalva Aneurysms are rare congenital or acquired cardiac defects that have been increasingly diagnosed as a result of improved imaging techniques. This is a case of aneurysms of all 3 coronary sinuses presenting with no clinical signs or symptoms. Despite being asymptomatic and having a favorable course thus far, we recommended that our patient have surgery performed as soon as possible to minimize the risk of future cardiovascular events.

Chronic Heart Failure - Treatment

P2030
CRT and the fight for sinus rhythm to survive
V Lebedeva[1]; T Lubimceva[1]; A Kamenev[1]; K Malikov[1]; S Gureev[1]; D Lebedev[1]
[1]*Almazov National Medical Research Centre, Saint Petersburg, Russian Federation*

A 46-year-old man with a short history (2 months) of persistent left atrial flutter (AF) had progressive fatigue, dyspnea, edema and other symptoms of heart failure (HF) since arrhythmia manifestation. Initial tests revealed raised levels of brain natriuretic peptide (617 pg/mL) and a left bundle branch block (LBBB). An echocardiogram showed left ventricle (LV) diffuse hypokinesia, severe systolic dysfunction (Simpson ejection fraction - EF 23%), left atrium size 55 mm, severe mitral regurgitation, moderate tricuspid regurgitation (TR) and interventricular dyssynchrony. The HF etiology was tachycardia-induced cardiomyopathy.
His congestive symptoms improved with optimal HF therapy only for 1 month and then the patient was urgently hospitalized to hospital with decompensated HF. Coronary angiography showed no signs of atherosclerotic lesions. After 2 months with a target anticoagulant therapy and amiodarone background cardioversion was carried to restore sinus rhythm, but it was failed thrice. CRT-D was implanted with LV electrode in the basal segment of the LV lateral wall. Then radiofrequency (RF) isolation of the pulmonary veins has been made. Sinus rhythm was restored. Patient felt better. However, 2 weeks later recurrence of AF occurred followed by fast HF decompensation. Second RF ablation of AF urgently carried. During the ablation procedure it has been revealed large LV electrode loop in the right ventricle with tricuspid regurgitation increasing from moderate to severe. So, LV electrode reposition was done with the elimination of tricuspid regurgitation. Because of the AF continuing, large left atrial size and HF decompensation patient was a candidate to the atrioventricular (AV) nodal ablation for decreasing the heart rate and proper CRT working. However, it was decided to hold third attempt of left atrial flutter RF ablation. 3 months after the last procedure the patient had stable sinus rhythm, LVEF 46%, no LV dyssynchrony. 5 months later LVEF was 61%, no LBBB, left atrium size became 41 mm and NYHA class I. Eventually patient was operated 5 times during 6 months to keep the sinus rhythm and to reduce heart failure symptoms.
Conclusions: and implications for clinical practice. The tachycardia-induced cardiomyopathy leads to rapid disability and HF progression. AV nodal ablation should not be the first choice for tachycardia-induced cardiomyopathy treatment. Preservation of native AV conduction seems better then artificial AV blockade. Interventional treatment of tachyarrhythmias makes a significant contribution to the HF treatment in spite of the low LVEF and disease severity.

Baseline: left atrial flutter with LBBB

P2031

Use of bromocriptine in a patient with peripartum cardiomyopathy

I Igor Katsytadze[1]
[1]*O. Bogomolet's National Medical University, Kyiv, Ukraine*

Female, 28 y. o., on the 18th day after childbirth (the first pregnancy, the first birth) applied for medical help with complaints of dyspnea at rest, which was intensified during the conversation, expressed swelling of the legs, puffiness of the face, general weakness, cough, palpitation.
Symptoms appeared a week before the childbirth (earlier, according to the words, the patient felt well throughout the pregnancy period),
On a scheduled visit to a gynecologist, the patient's condition was regarded as satisfactory, and the symptoms as a manifestation of functional dystonia.
The patient was hospitalized on a routine basis in the clinic a day before the delivery. The birth took place physiologically.
On the second day of stay in the hospital, the patient felt worse (increasing in the above symptoms, especially dyspnea and tachycardia).
Status objectivus:
•During hospitalization, she is severe dyspnea. Ortopnoe. Acrocyanosis. Generalized edema
•The body mass index is 27.2 kg / m2.
•Blood pressure 100/50 mm Hg . Wet rales less than 50%.
•Heart sounds are arrhythmic (extrasystole beats) , tachycardia with heart rate = 118 beats per minute. Systolic murmur at all points of auscultation, with a maximum of expression at the apex.
•The liver protrudes 3.5 cm below the edge of the right rib, slightly painful. The spleen is not palpable
MRI is attached
ECG, ECHO - will be posted
Treatment :
•Bromocriptine 2,5mg Od, enoxaparin 40mg x2, Levosimendan, Torasemid, ASA 75mg, Eplerenon 25mg, Enalapril 5mg, Carvedilol 2,5mg, Ivabradin 5mg x2
Discharge on 10th day with positive dynamic.
BP- 105/75 mmHg, HR- 80' . Significant reduction of HF symptoms. GFR increased to 106 ml/min/1,73m2.
Further treatment: enalapril, carvedilol, eplerenon, diuretics, rivaroxaban, ivabradin
6 Mo later: No complaints, skin is pale pink, no edema, BP 108/72 mm Hg, HR at rest 63', rhythmic, Vesicular breathing, no crepitation, The border of the heart is not expanded. Positive dynamic on ECHO (LVOT- 22 mm, Ao- 25 m?, LA - 28 m? (V-50 ml), IVS – 9 mm, EF- 44%, EDV - 113 ml, ESV - 59 ml, RV- 39 mm, RA- 31 mm. PAP - 15 mmHg)

Contrast MRI (Tomovist-20 ml) – dilatation of all cavities, global hypokinesis. Absence of ischemic injury, fibrosis, edema is more evidence in favor of cardiomyopathy. Moderate pulmonary hypertension

Stroke and heart failure causing myocardial metastases - a frequent primary tumor with its rare cardiovascular consequences

M Rabai[1]; L Toth[2]; L Szapary[3]; V Sarosi[1]; E Kalman[4]; K Toth[1]; T Habon[1]
[1]*University of Pecs, Medical School, 1st Department of Medicine, Pecs, Hungary*;
[2]*University of Pecs, Medical School, Department of Radiology, Pecs, Hungary*;
[3]*University of Pecs, Medical School, Department of Neurology, Pecs, Hungary*;
[4]*University of Pecs, Medical School, Department of Pathology, Pecs, Hungary*

Introduction: Primary tumors of the myocardium are extremely rare. Metastatic lesions of the heart muscle occur in a few percentages and their diagnoses are usually made in late stages.

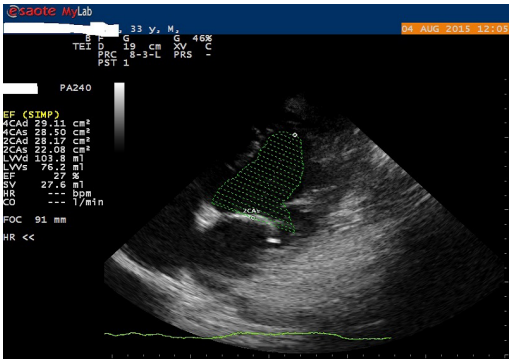
Case history: A hypertensive, formerly smoking 72 year old male patient was admitted to the Stroke Division of Neurology Department, with symptoms of stroke and heart failure. In the background, vascular and cardiogenic origins were also hypothesized. While CT angiography showed significant right carotid artery stenosis, ECG revealed newly diagnosed atrial fibrillation. Echocardiography demonstrated a massive, inhomogeneous and mobile infiltration with thrombotic surface in the heart muscle of the left ventricle and moderate amount of pericardial effusion was noticed, which did not cause cardiac tamponade. Due to the observed changes, a cardiac MRI scan was done showing preserved ejection fraction, nodular infiltration of the heart muscle resulting in myocardial disorganization and metastatic pericardial effusion. Besides the cardiac alterations, a 3x4 cm right sided, central lung cancer with numerous metastases was diagnosed by a chest CT scan. Further investigations were made for histological diagnosis in the Division of Pulmonology, but these diagnostic efforts failed. After that the clinical state of the patient progressively deteriorated and he died in heart failure within a short time. During the autopsy, a planocellular lung carcinoma showing fusocellular appearance with unusual muscle metastases (myocardial, skeletal and lingual) was verified. The massive myocardial infiltration resulted in a thrombogenic endocardial surface causing stroke and a progressive heart failure, which ended in the death of the patient.
Conclusion: Although atrial fibrillation can mostly be seen in the background of a cardiogenic stroke, the routinely performed echocardiography may reveal other rare etiology also.

P2033

Refractory heart failure and ischemic stroke as first symptoms signs undetected cryptogenic chronic endocarditis

N Zlatanovikj[1]
[1]*Private medical practice "Cor-Medico", Skopje, Macedonia The Former Yugoslav Republic of*

Newly diagnosed end stage heart failure in young patients causes numerous diagnostic, therapeutic, and ethical dilemmas. If combined with an ischemic stroke with no apparent reason, the dilemmas multiply.
33 y/o patient was referred to cardiologist office for examination due to persistent, non-productive cough and lying dyspnea. The symptoms occurred 5 days previously, and he was treated with antibiotics for suspected right lobar pneumonia. Patient denies any previous cardiac illnesses, but mentions that year before had a high fever and that the cough is present in lesser extent months ago.
At his physical examination he has tachycardia, few medium cracks in the right hemithorax, mild pretibial edema. The BP was 95/70. ECG registered heart beat 117/bpm with inverse T waves in all precordial leads. Echocardiography revealed dilatation of all heart chambers, thinned walls, severe hypokinesis, LVEDd of 71mm and decreased ejection fraction of 30% (Simpson bi plane). It also revealed mitral regurgitation, moderate aortic and tricuspid regurgitation and still no signs of pulmonary hypertension. Apart from thickened mitral valve leaves, no significant sign of vegetation was observed. Patient was classified in NYHA II-III class. Patient was placed on standard heart failure treatment with loop and Potassium sparring diuretic and beta blocker. He continued to receive medical treatment for his pulmonary ailment.



Ejection Fraction

After 7 days he was referred by his GP to the cardiology clinic for further evaluation. While at the clinic the suffered ischemic stroke which was treated with thrombolysis with good response. Five days later he was discharged in relatively good condition with moderate speech problems and no other neurogical consequences. He was placed on antiplatelet therapy (aspirin) An ACE inhibitor was added. However his echocardiogram has deteriorated with LVEDd now measuring 80mm and EF in 20's % .His physical finding did not reveal any significant changes. His unilateral

lung finding persisted unchanged even after multiple antibiotic therapy. Pulmonary assessment tests suggested partial chronic respiratory insufficiency .
7 days latter due to fall in the blood pressure 70/50mmHg and extreme fatigue he was readmitted to the cardiology clinic, put on i.v. diuretics, positive inotropes. Simultaneously he developed behavioral changes and aphasia suggestive of new cerebrovascular incident, although he is now on anticoagulation therapy. A hemoculture was done and turned positive on Klebsiela species. The patient's condition continues to deteriorate and he passed away of multiple organ failure.
Sudden onset of refractory heart failure accompanied with ischemic stroke with no evidence of septal defects, are highly suggestive of cryptogenic chronic endocarditis. It's diagnosis remains elusive and circumstantial, making the treatment delayed and often futile and prognosis poor.

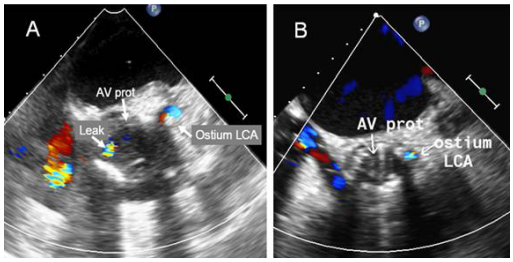
Acute Heart Failure - Diagnostic Methods

P2034

Diagnostics of left main coronary artery occlusion during aortic valve replacement

EV Elena Dzybinskaya[1]; EE Vlasova[1]; RS Akchurin[1]
[1]*National medical research center of cardiology, Cardiovascular Surgery, Moscow, Russian Federation*

Coronary ostial stenosis is a rare but potentially serious complication after aortic valve replacement, whereby the effective intraoperative imaging plays a key role in correct decision making.
A 63 years old man was scheduled for early repeated aortic valve replacement (AVR) because of paravalvular leak. He had fatigue, dyspnea, left ventricular (LV) ejection fraction (EF) 27%, and signs indicating low output state. Pretreatment with Levosimendan was performed one day before surgery.
Repeated AVR was performed under cardiopulmonary bypass (CPB, 137 min) as planned. The weaning from bypass was difficult - visually observable LV failure and arterial hypotension persisted despite the high doses of dopamine (6-12 mcg*kg-1*min-1) and norepinephrine (400 ng* kg-1*min-1). The preliminary version was myocardial failure as a consequence of the preoperatively lowered LVEF. The transoesophageal echocardiography (TOE) showed LV systolic failure (EF <20%) and acutely emerged mitral regurgitation. The partial occlusion of the ostium of the left main coronary artery with prosthetic valve sewing ring was detected to be the cause of these disturbances. The most important diagnostic criterion was the change of the left main flow characteristics from laminar (before CPB, Fig., A) to turbulent (Fig., B) by color flow Doppler. Because the valve function was satisfactory, decision to perform the coronary artery bypass grafting was made. Repeated CPB (151 min) was initiated, left anterior descending and left circumflex arteries were shunted by autovenous grafts. Echocardiographic control demonstrates the LVEF increasing up to 35%, and weaning from CPB was successful with small doses of dopamine. The postoperative course was uncomplicated, and the patient was discharged from hospital with LVEF 43%.
The most important problem, which was solved on time in this case, is the differential diagnostics of causes of severe acute heart failure.
The intraoperative TOE, as a method of anaesthesiological management, is a corner stone of early diagnostics of different types of myocardial dysfunction.

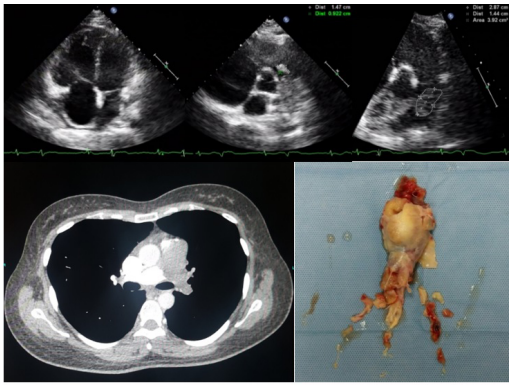


P2035

Right sided heart failure: a tumor or a thrombus?

M J Jhessica Pecson[1]
[1]*Philippine Heart Center, Adult Cardiology, Quezon City, Philippines*

This is a case of a 36-year old female without co-morbidities who presented with sign and symptoms of a right-sided heart failure. Physical examination showed an RV heave, a loud P2 and a holosystolic murmur at the left parasternal border. Sinus rhythm with RV hypertrophy was noted on ECG. Chest X-ray revealed cardiomegaly. Transthoracic echocardiography noted a fluttering echogenic density from the MPA protruding through the pulmonic valve, a dilated RV with signs of pressure and volume overload and severe pulmonary hypertension. Thrombolysis and anticoagulation were administered, however the patient remained symptomatic. Chest CT scan was then done, which showed a large pulmonary artery filling defect in the main and left pulmonary arteries suggestive of thromboembolism, however malignancy cannot be ruled out. Progression of the right heart failure despite medical therapy prompted surgical intervention. The patient underwent pulmonary endarterectomy. Intraoperatively, a pulmonary artery mass consistent with a myofibroblastic sarcoma with myxoid features was noted. Patient succumbed to death due to RV failure on the second post-operative day.



Pulmonary artery sarcoma

Acute Heart Failure - Treatment

P2036

A case of cardiogenic shock caused by anterolateral papillary muscle rupture: when imaging makes the difference.

I Figliuzzi[1]; A Romaniello[1]; G Gallo[1]; M Grimaldi[1]; A D'angelo[1]; M Volpe[1]
[1]*Sant' Andrea Hospital, Division of Cardiology, Department of Clinical and Molecular Medicine, Faculty of Medicine, Rome, Italy*

A previously healthy 55-year-old man, presented to the emergency department with chest pain and shortness of breath started after an intensive exertion. He denied fever and recent infective episodes. His blood pressure was 85/50 mmHg; heart rate was 120 beats per minute. Arterial blood gas analysis showed severe hypoxaemia. The electrocardiogram showed sinus tachycardia with a 3 mm ST depression in leads II, III, aVF, from V3 to V6, and ST elevation in leads I and aVR. Bedside transthoracic echocardiography showed preserved left ventricular ejection fraction without regional wall motion abnormalities, moderate mitral regurgitation posteriorly directed and absence of pericardial effusion. Since the clinical scenario suggested an acute myocardial infarction without ST elevation complicated by papillary muscle dysfunction, the patient underwent emergency cardiac angiography, which showed small intermediate and marginal branches occlusion but percutaneous coronary intervention was not feasible due to their small sizes. To better evaluate mitral regurgitation mechanism, transoesophageal echocardiogram was performed, detecting severe mitral regurgitation with anterolateral papillary muscle rupture. Due to the persistence of cardiogenic shock, orotracheal intubation was performed and noradrenalin infusion was started and progressively uptitrated. Intraortic balloon pump was positioned, obtaining only a mild increase in blood pressure without considerable improving of gas exchanges and lactate levels. Thus, the patient underwent emergency mitral valve replacement with mechanical prosthesis. Histological analysis of native valve and of papillary muscle showed aspecific fibroblastic endocarditis, whereas bacteriological examination assessed an infection by Staphylococcus aureus and Staphylococcus Warneri, treated with antibiotic therapy with Vancomycin. The patient was discharged eventually after about two weeks. The differential diagnosis was challenging and included endocarditis and myocardial infarction. On one hand there is the detection of bacterial infection of the valve, although blood cultures and inflammatory markers were negative, and there were no microscopic or macroscopic signs of bacterial colonisation in the histological analysis, suggesting a possible contamination of the sample. On the other hand the more likely ischemic mechanism, supported by the angiographic finding of small vessels occlusion and troponin I hs peak of 71338 pg/ml, compatible with an acute myocardial injury. Since cardiogenic shock is marked by high mortality rate, it is very important the prompt identification of cardiogenic shock as well as the careful research of the underlying causes, even throughout the use of invasive exams and

procedures. This case also illustrates the importance of early surgery intervention in patients with hemodynamic instability, since medical treatment is associated with poor short- and long-term survival.

Antero-lateral papillary muscle

Coronary Artery Disease - Treatment

P2037

Myocardial infarction with nonobstructive coronary arteries twice in one week

A Gomiscek[1]; M Bunc[2]; G Plevnik[1]
[1]*Izola General Hospital, Department of Internal Medicine, Izola, Slovenia*;
[2]*University Medical Centre of Ljubljana, Clinical Department of Cardiology, Ljubljana, Slovenia*

A 47-year-old female smoker without previous medical history presented to the emergency department (ED) with chest pain lasting for about twelve hours. She described the pain as a substernal pressure sensation (7/10 on VAS), the pain was radiating up to the shoulder and independent of movement or breathing.
Clinical examination was insignificant.
12-lead electrocardiogram (ECG) showed sinus rhythm, T-wave inversion in precordial leads V2 - V6, with poor R-wave progression (Fig. 1).
Troponin I was found as 482 ng/L (cut off 40 ng/L). Other lab work was within normal limits.
Bed-side echo showed akinesia of anteroseptal and apical left ventricular segments (Fig. 1).
The patient was administered 500 mg acetylsalicylic acid, 5000 I.U. heparin and 180 mg ticagrelor and referred to the catheterisation laboratory for coronary angiography.
Angiography was performed 30 minutes after drug administration, at that time the patient had no chest pain any more and was feeling much better. On coronary angiography, non-obstructive coronary artery disease was detected, all TIMI 3 flow, and no culprit lesion (Fig. 1).
After two days, the patient was dismissed home with the diagnosis of NSTEMI with no target lesion found, with most likely spontaneous reperfusion of LAD. As myocarditis could not be ruled out we referred the patient to out-patient cardiac MRI and a follow-up TTE in one month. She was discharged with DAPT, ACE inhibitor, betablocker and statin.
Five days later the patient presented to the ED in the middle of the night with chest pain radiating down the left arm. Clinical examination was unremarkable, ECG showed similar abnormalities as at the first admission, troponin levels were slightly elevated.
We believed that intravascular imaging (either intravascular ultrasound (IVUS) or intracoronary optical coherence tomography (OCT)) should be performed to determine the morphology of non-obstructive LM, LAD and LCX coronary artery disease. As intravascular imaging was not available at our institution we transferred the patient to the University Medical Centre. Coronary angiography was performed, no significant stenosis was visible, IVUS revealed significant thrombotic stenosis of the proximal LAD and one drug-eluting stent was successfully placed.
Conclusion: Myocardial infarction with non-obstructive coronary arteries (MINOCA) should be considered as a 'working diagnosis', and thus prompts further evaluation regarding its underlying mechanism(s). Plaque disruption (rupture or erosion), epicardial or microvascular spasm, coronary thrombembolism, coronary dissection, Takotsubo and myocarditis have to be ruled out. IVUS and OCT are more sensitive methods for presenting intracoronary morphology than angiography. As such they should be performed for the determination of the cause of MINOCA. Additional diagnostic tools as fractional flow reserve (FFR) or instant wave-free ratio (iFR) may also be considered in the acute setting.

P2038

Polyarteritis nodosa coronary vasculitis leading to pericardial tamponade and severe ischaemic cardiomyopathy.

K Be[1]; H Rashid[1]; A Nasis[1]
[1]*Monash Health, MonashHEART, Melbourne, Australia*

We present a rare case of polyarteritis nodosa coronary vasculitis with pericardial tamponade and severe ischaemic cardiomyopathy.
A 34 year old lady presented with acute chest pain, dyspnoea and syncope. She had no previous medical conditions. She had a systolic blood pressure of 60mmhg on arrival. Examination revealed raised jugular venous pressure and pulsus paradoxus. Electrocardiogram revealed low voltage complexes. Urgent echocardiography showed moderate pericardial effusion (maximal 2 cm apically) with features of pericardial tamponade.
Pericardiocentesis drained 250ml which normalised of her vitals. Subsequent echocardiography revealed dilated left ventricle with moderately reduced left ventricular ejection fraction and non-left anterior descending coronary artery territory hypokinesis. Left heart catheterisation revealed all coronary arteries were severely aneurysmal with features of intra-aneurysmal thrombus in the right coronary artery aneurysms. The first obtuse marginal and first diagonal branch had aneurysmal segments followed by chronic total occlusions.
Laboratory analysis revealed that the pericardial fluid was exudative but had negative microbiology and cytology screen. Her erythrocyte sendiment rate was elevated at 50mm/hr but a c-reactive protein of 6mg/L and negative autoimmune screen. Subsequent computed tomography angiography confirmed liver and renal artery aneurysms, consistent with polyarteritis nodosa (ANCA-negative). She was treated with intravenous cyclophosphamide and high dose corticosteroids. Her erythrocyte sediment rate subsequently improved.
A subcutaneous implantable cardioverter-defibrillator was inserted for primary prevention. Follow-up computed tomography coronary angiogram at 5 months revealed persistence of coronary aneurysms and intra-aneurysmal thrombus. At 8 month review her immunosuppressants were successful weaned, her functional status improved with heart failure treatment and repeat echocardiography revealed mildly improved left ventricular ejection fraction.
The alternative diagnosis of Kawasaki disease rarely presents in adulthood, with the coronary sequalae typically resulting in proximal coronary aneurysm dilation with relatively normal distal segments. Other medium sized vessel may be affected, but very rarely the renal or hepatic vessels. Polyarteritis nodosa commonly affects the renal, hepatic, coronary and gastrointestinal tract with multiple microaneurysms suggestive of diagnosis.
Polyarteritis nodosa coronary vasculitis is a rare but serious cause of coronary artery aneuryms with treatment options available to improve outcomes. While diagnosis of polyarteritis nodosa is ideally made with histopathology, classic imaging findings of beading and aneurysms of medium vessel arteries (coronary, hepatic and renal arteries) strongly suggests diagnosis.

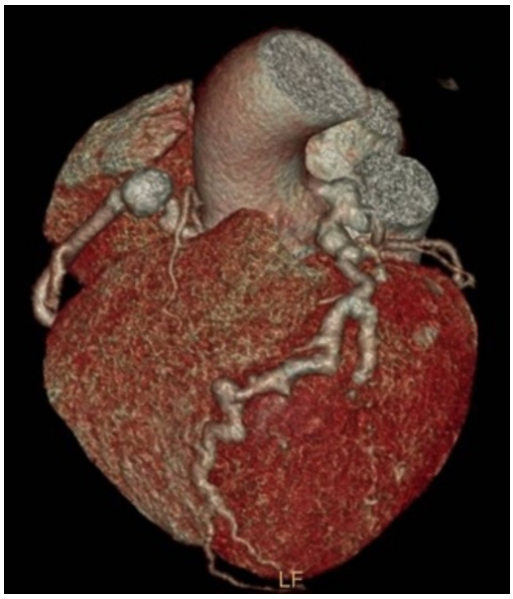

Fig 1

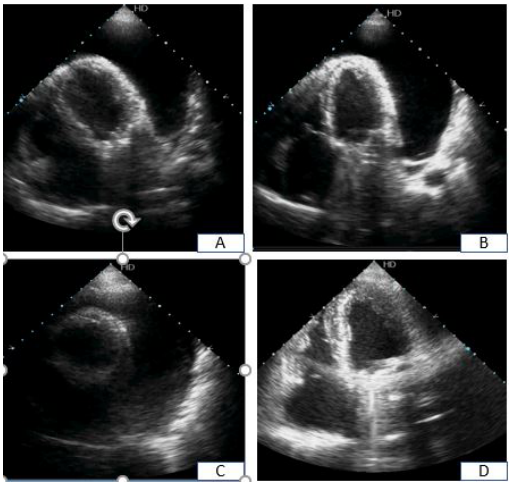
Myocardial Disease - Clinical

P2039
Rare post mitral valve replacement nightmare

A Ahmed Yehia[1]; M Dawood[1]; O Elgebaly[1]; M Hassan[1]; A El Maghraby[1]; F Mohamed[1]
[1]*Alexandria University, Department of Cardiology, Alexandria, Egypt*

The case is 30 years old female whom had mitral valve replacement with mechanical prothesis for correction of severe symptomatic mitral valve stenosis. Postoperatively the patient remained symptomatic with exertional dyspnea grade II that progressed over a course of 1 month to dyspnea grade IV associated with orthopnoea , bilateral lower limb swelling and low grade fever since 3 days.
The patient reports compliance on warfarin with regular check up having INR in the target zone. The patient denied any chest pain, syncope, abdominal pain or any neurological manifestation.
Examination showed blood pressure of 90/70 mmHg, thready pulse at 110 bpm , distant heart sounds , bilateral congested neck veins and bilateral lower limb odema.
Baseline laboratory investigations was unremarkable except for INR of 10 and mildly elevated white cell count 13,000. Chest X ray revealed increased cardiothoracic ratio with flask shaped heart.
Transthoracic echo (TTE) strikingly revealed massive pericardial effusion mainly lateral and apical measuring 5 cm in maximum dimensions as shown in panel (A,B,C) The right ventricle showed normal dimensions, markedly reduced contractility with no pericardial effusion related to the right side. The left ventricle showed severe global hypokinesia with reduced systolic function EF = 25%. Mitral prothesis was well functioning with no visible masses or vegetations. CT chest was done to help characterize the pericardial effusion. CT chest showed fusion of the right ventricle walls to the anterior chest wall explaining the localization of the pericardial effusion and absence of tamponade.
After correction of INR, Pericardiocentesis of 900 ml of straw coloured effusion was done through an apical approach. Analysis of the fluid showed exudate with negative microbiological culture. Pathology of the fluid showed inflammatory smear with abundant neutrophils.
According to characteristics of the aspirate and presence of low grade fever, Post cardiac Inflammatory Syndrome (PCIS). Accordingly treatment with high dose of aspirin 750 mg t.i.d, colchcine 0.5 od, Ramipril, spironolactone, furosemide, pantoprazole was intiated . Regular daily follow up showed absence of effusion recurrence.
2 weeks later, TTE strikingly revealed complete recovery of both left and right ventricular functions with no effusion noted (Panel D).Regular monthly follow up of the patient revealed no interval changes.
To conclude ,PCIS is a very important post operative complication and TTE plays essential rule in diagnosis of this complication. Pericardiocentesis of large post operative effusion is crucial to for symptomatic relief and analysis of pericardial fluid. Although that Post pericardiotomy myocarditis is a very rare condition but its an important cause of post operative LV failure and complete recovery can be anticipated. High dose of aspirin and colchince are the most accepted regimen for intial treatment of PCIS with high success rate.



P2040
Not ischemic, against all odds

AR Ana Raquel Barbosa[1]; P Teixeira[1]; AI Azevedo[1]; M Ponte[1]; N Dias Ferreira[1]; A Dias[1]; M Fonseca[1]; V Gama[1]
[1]*Hospital Center Vila Nova Gaia, Porto, Portugal*

A 75-year-old male patient was referred to our centre due to recent onset heart failure. He had a history of long-standing hypertension, type 2 diabetes mellitus, dyslipidaemia and overweight; he was a former smoker. The patient complained of dyspnoea for ordinary activities for the last 2 months and recent onset oedema. At physical examination an apical systolic murmur and bilateral leg oedema were noted. The electrocardiogram revealed sinus rhythm, first degree atrioventricular block, left anterior fascicular block and right complete bundle branch block. The transthoracic echocardiogram evidenced mild left ventricular dilation with mitral leaflet tethering, particularly of the posterior one, moderate functional mitral regurgitation and lateral, posterior and inferior walls hypokinesis with moderately depressed left ventricular systolic function. Given the clinical and echocardiographic picture, an ischemic aetiology was considered the most likely. However the patient went to a coronary angiogram which showed no epicardial coronary artery disease. He was submitted to cardiac magnetic resonance (CMR) that confirmed left-chambers dilation and depressed left ventricular function (ejection fraction 33%) and showed mural late gadolinium enhancement at basal and mid segments of inferior and inferosseptal walls, suggestive of prior myocarditis.
The patient was started on disease-modifying therapy and symptoms improved significantly. Echocardiogram and CMR were repeated 6 months later and, despite the maintained pattern and extent of late gadolinium enhancement, mitral regurgitation became mild and there was improvement in left ventricular volume and function (ejection fraction by CMR 45%). The aetiology of the myocarditis remained elusive. Myocarditis presents in many different ways, which requires a high degree of suspicion to make this sometimes challenging diagnosis.

Funding Acknowledgements: GINUMED - CORPORACIÓN UNIVERSITARIA RAFAEL NUÑEZ

Introduction: Left ventricular noncompaction (LVNC) is a rare disease with genetic origin, characterized by the presence of numerous myocardial trabeculations probably due to a detention of the normal process of the endomyocardial embryogenesis. **Clinical case:** 38 years-of-age man without pathological history, which had been presented progressive dyspnea, dyspnea at rest and orthopnea since two months

ago. At physical examination, the patient had tachypnea, tachycardia, S3 left ventricular gallop and crackles in the bases of the lungs. The electrocardiogram showed sinus tachycardia and unspecified diffuse changes of ST-T. The thoracic radiography displayed cardiomegaly and signs of pulmonary congestion. Color doppler echocardiography revealed left ventricle severely dilated with multiple trabeculations and intertrabecular spaces. Ambulatory electrocardiography for 24 hours reported sinus rhythm, frequent isolated monomorphic ventricular extrasystoles with episode of monomorphic no supported ventricular tachycardia.
Conclusion: the clinical manifestations, seriousness and the age of beginning of the symptoms of the LVNC are variable. The differential diagnosis must be done with other common pathologies, especially with hypertrophic cardiomyopathy and dilated cardiomyopathy.

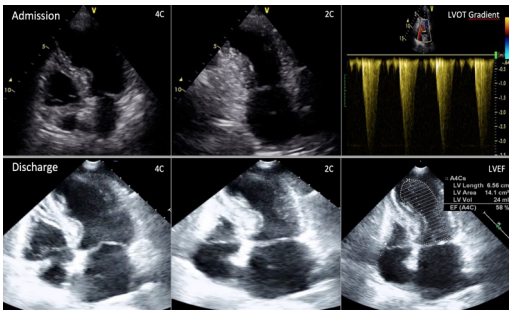
A less common cause of dynamic left ventricular outflow tract obstruction

AR Ana Rita Pereira[1]; AR Almeida[1]; I Cruz[1]; A Marques[1]; S Alegria[1]; AC Gomes[1]; D Sebaiti[1]; A Briosa[1]; I Rangel[1]; F Ferreira[1]; O Simoes[1]; MJ Loureiro[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

A 71-year-old woman, with clinical history of essential arterial hypertension and mixed dyslipidemia, was admitted in our Emergency Department due to a transient, self-limited loss of consciousness, following a familiar discussion, with loss of postural tone resulting in fall and head trauma. After recovering consciousness, the patient (pt) referred oppressive chest pain with dorsal radiation and dyspnea. At hospital admission, she was hypotensive but normocardic with no other relevant findings at clinical examination. Blood tests revealed high-sensitive cardiac troponin T 512 ng/L [normal range (NR) < 13 ng/L] and NT-proBNP 2952 pg/mL (NR < 153 pg/mL). A 12-lead ECG showed sinus rhythm, heart rate of 78 bpm, ST segment elevation in V3 to V5 leads and T wave inversion in V4 and V5. Transthoracic echocardiogram (TTE) demonstrated a normal sized left ventricle (LV), with mild septal hypertrophy, moderate systolic dysfunction and several segmental wall-motion abnormalities (apical segments akinesia, middle segments hypokinesia and basal segments hyperkinesia) conditioning a significant LV outflow tract (LVOT) gradient (peak gradient of 50 mmHg and mean gradient of 26 mmHg). After performing a head computerized tomography to exclude acute traumatic hemorrhagic complications, the pt was submitted to a coronariography that revealed non-significant epicardial coronary lesions. Thus, according clinical and imaging findings, Takotsubo cardiomyopathy (TC) was established as diagnosis. During hospitalization, no complications were observed and beta-blocker therapy was initiated and up-titrated. Pre-discharge TTE showed recovery of LV systolic function (ejection fraction 58%) with segmental contraction improvement (only remaining apical akinesia) and absence of significant intraventricular obstruction. She was discharge, six days after admission, in NYHA functional class II, kept under regular follow-up in Cardiology appointment.
This clinical case is an example of TC which brings together several less common features of this type of cardiomyopathy. On the one hand, the predominant symptom on admission was syncope, unlike most published data in literature that describe chest pain as the most common (75,9%) and syncope occurring only in 7,7% of patients as predominant symptom. On the other hand, dynamic LVOT obstruction has not been described as frequent in TC and lower severity of LV systolic dysfunction is usually observed. Early recognition of dynamic LVOT obstruction is clinically and therapeutically important. Conventional treatment for acute coronary syndrome, the main differential diagnosis of TC, such as nitrates and afterload vasodilators would likely increase the degree of LVOT obstruction, resulting in clinical worsening. Thus, the presenting case intends to highlight the heterogeneity of this clinical entity of increasing interest but there is still a lot to be known about it.

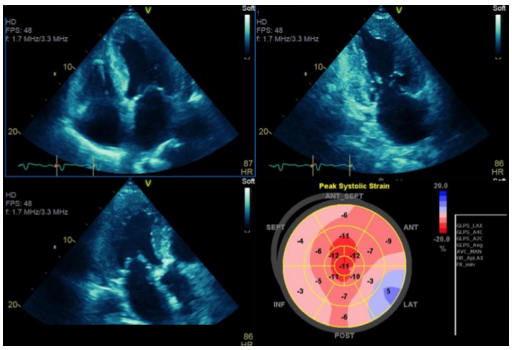


P2043

Left ventricular hypertrophy: the usual suspects, an unexpected culprit

AR Ana Rita Pereira[1]; I Cruz[1]; AR Almeida[1]; A Marques[1]; S Alegria[1]; AC Gomes[1]; D Sebaiti[1]; A Briosa[1]; I Joao[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

We present the case of an 88-year-old man, with clinical history of essential arterial hypertension, referred to our Cardiology appointment owing to an asymptomatic moderate aortic stenosis evaluated by a transthoracic echocardiogram (TTE). At clinical examination, he was hemodynamically stable without any pulmonary or peripheral congestion sign. A grade III/VI, systolic heart murmur with neck radiation were best heard over the aortic area with preserved aortic second sound (A2). A 12-lead electrocardiogram (ECG) showed sinus rhythm, heart rate of 92 bpm, first-degree atrioventricular block (AVB), left axis deviation and complete right bundle branch block. TTE demonstrated a tricuspid aortic valve with thickened and calcified leaflets resulting in moderate aortic stenosis [peak velocity 3,4 m/s; mean gradient 30 mmHg; Doppler velocity index (DVI) 0,3] and moderate aortic regurgitation; a non-dilated left ventricle (LV) with moderate concentric hypertrophy (interventricular septum 16 mm, posterior wall 14 mm) and normal systolic function but diastolic dysfunction and reduced global longitudinal strain (GLS -7); and a normal-sized inferior vena cava with inspiratory collapse. Given the absence of clinical and imaging indications for valvular intervention, the patient was kept under regular outpatient follow-up (FU), remaining asymptomatic under a low-dose of beta-blocker and angiotensin-converting enzyme inhibitor therapy. After 30 months of FU, he was hospital admitted with complaints of progressive worsening exertional dyspnea (at admission, triggered by mild physical activity) and lower limbs oedema with 1 month of evolution. At admission, he was bradycardic and a third-degree AVB was showed by the 12-lead ECG. Due to symptomatic extreme bradycardia, isoprenaline infusion was initiated and a temporary followed by a definitive dual-chamber pacemaker was implanted. The TTE was similar but a "speckling" appearance of the myocardium and a reduced GLS with LV apical sparing pattern were noticed. Considering the LV findings and the cardiac conduction disease, a 99mTechnetium-3,3-diphosphono-1,2-propanodicarboxylic acid (DPD) was performed with a positive result. Thus, the considered final diagnosis was wild-type transthretin cardiac amyloidosis (wt-ATTR).
This clinical case illustrates an increasingly recognized cause of heart failure (HF) with preserved ejection fraction (HFpEF) and cardiac arrhythmias, especially in men over 60 years of age. Given the burden of HF in society and the economic implications for health-care delivery, emerging targeted therapies are currently being studied in multiple clinical trials. Consequently, the recognition of wt-ATTR will likely continue to be of increasing importance. Ultimately, this clinical case also intends to emphasize the importance of the differential diagnosis of LV hypertrophy and HFpEF.



P2044
This time it was a zebra

AR Ana Raquel Barbosa[1]; C Espada Guerreiro[1]; M Passos Silva[1]; A Mosalina[1]; M Ponte[1]; N Dias Ferreira[1]; R Pereira[1]; M Fonseca[1]; A Dias[1]; J Primo[1]; V Gama[1]
[1]*Hospital Center Vila Nova Gaia, Porto, Portugal*

A 55-year-old male went to the emergency department due to palpitations and a poorly defined chest discomfort during the last 5 hours. He had a history of dyslipidaemia, overweight and smoking habits; he had an intense level of usual physical activity, having been an high competition rower for years.
At admission the electrocardiogram revealed a regular wide complex tachycardia (ventricular frequency about 220/per minute), with left bundle-branch morphology and superior axis. The patient was haemodynamically stable with no signs of heart failure. Adenosine and then amiodarone were tried unsuccessfully; the patient became hypotensive and was electrically cardioverted. The eletrocardiogram post-cardioversion showed no significant alterations. The echocardiogram performed revealed normal left ventricular function but a dilated right ventricle, with free wall hypokinesis and depressed systolic function.
A coronary angiogram was performed to exclude coronary artery disease, however given the typical pattern of the ventricular tachycardia and the abnormalities of the right ventricle the most likely diagnosis at this point was a arrhythmogenic right ventricular cardiomyopathy. The angiogram showed an abnormal origin of the right coronary artery, not possible to be selectively catheterized. Therefore the patient went to an angio-computed tomography revealing a right coronary artery originating high in the aortic left coronary sinus and running between the aorta and the pulmonary trunk; a significant luminal stenosis was evident at the origin.
To better characterize the right ventricle a cardiac magnetic resonance was done, showing right ventricular dilation (index telediastolic volume 117 ml/m2) with regional dyskinesia and mild depression of systolic function (ejection fraction of 45%). Late gadolinium enhancement was evident at the basal inferior and mid-basal lateral segments.
Despite the presence of two major criteria for arrhythmogenic right ventricular cardiomyopathy, we assumed this clinical scenario was explained by arrhythmogenic scar tissue in the context of a right ventricular infarction caused by the abnormal right coronary artery with evidence of luminal stenosis.
The patient went to a surgical correction (unroofing) of the coronary anomaly and at the same time a biopsy of the right ventricle (with no evidence of arrhythmogenic right ventricular cardiomyopathy). Because of the presence of arrhythmogenic scar a catheter ablation was attempted, however, given the persistence of a ventricular tachycardia with hemodynamic repercussion a single chamber implantable cardioverter defibrillator was implanted.
At one year follow up the patient had no other episode of ventricular arrhythmia.
This case illustrates the diagnostic complexity of pathologies afflicting the right ventricle, particularly rare ones.

Pulmonary Circulation, Pulmonary Embolism, Right Heart Failure - Clinical

P2045
Pulmonary embolism at patient taking NOACs for atrial fibrillation: why anticoagulation therapy was not rather effective?

G Gulnoza Dussekeyeva[1]; AB Isakhanova[1]; GS Bimagambetova[1]
[1]*Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*

82-year-old male was consulted to the cardiology because of clinics of heart failure (severe symmetric edema on the legs, dyspnea). He had history of hypertension, permanent atrial fibrillation for more than 10 years. Coronary angiography 1 year ago showed no significant stenosis of coronary arteries. He was using rivaroxaban 20 mg daily for prevention of thromboembolism regularly for 6 months. On clinical examination, percussion sound was blunted on right lung upper lobe from third to fifth ribs, vesicular breathing on this side was weaken. He was admitted chest-X-ray. Chest-X-ray showed peripheral wedge of airspace opacity and right lung upper lobe infarction. Patient's hemodynamics was stable. Probability of pulmonary embolism was estimated by Wells criteria and Geneva score. It was moderate, that is why we analyzed D-dimer. The indicator was upgraded. After that we multidetector computed tomography (MDCT) was made. MDCT showed thromboembolism of sub segmental branch of right pulmonary artery with right lung upper lobe infarction. Pulmonary embolism was verified and patient was given rivaroxaban dosage regimen using in the case of pulmonary embolism (15 mg 2 times a day 3 weeks, then 20 mg for this patient permanently). We investigated is there any other factors predisposing pulmonary embolism in the case of this patient, expect of atrial fibrillation. We find that this patient has thrombocytopenia, higher level of lupus anticoagulant and positive antiphospholipid antibodies. Antiphospholipid syndrome was diagnosed and patient was admitted specific therapy (Hydroxychloroquine 200 mg per day).

A challenging case of mitral regurgitation treatment with mitraclip: beyond scientific evidence

A Ana Manuel[1]; C Guerreiro[1]; J Ribeiro[1]; B Melica[1]; M Fonseca[1]; A Dias[1]; D Caeiro[1]; A Rodrigues[1]; P Braga[1]; V Gama[1]
[1]*Hospital Center Vila Nova Gaia, Cardiology, Porto, Portugal*

Introduction: Mitral valve (MV) percutaneous repair with the MitraClip (MC) benefits patients with severe MR and considered inoperable or at high-risk to open mitral valve surgery (oMVS). Some anatomic characteristics that predict better results after MC are: non-commissural primary regurgitant jet, MV area = 4cm2, minimal calcification in the grasping area, no leaflet cleft in the grasping area, flail width < 15mm and gap < 10mm, left ventricular ejection fraction (LVEF) >20% or LV end systolic diameter < 60mm. The absence of these characteristics in inoperable patients with severe degenerative MR is challenging.
Description: A 79-year-old male was referred for the treatment of MR. He had heart failure with preserved LVEF (NYHA class III), poor functional capacity and he was under optimal medical therapy.
Transthoracic echocardiography: severe left atrium dilation, slightly thickened MV with posterior leaflet prolapse due to chordal rupture, resulting in severe MR, moderate tricuspid regurgitation and signs of pulmonary hypertension. Transoesophageal echocardiography (TOE): MV posterior leaflet flail (P3 location) with no cooptation near the medial commissure, severe MR directed to the left auricular appendage and systolic inversion of pulmonary veins flow. Considering his frailty and a porcelain aorta on CT scan, the Heart Team referred him to a MC. One MC was implanted in A3–P3 (commissural) level. Intra-procedural TOE revealed persistence of moderate MR after the 1st MC and a transvalvular mean pressure gradient of 1.8mmHg. Based on this observation, a 2nd clip was implanted in a mid-medial location to improve results and stabilize the 1st clip. After the 2nd MC, TOE revealed optimal results with mild MR. There were no complications. At one-year of follow-up, the patient had a significant improvement on his life quality, NYHA class I and mild MR. Problems: 1) Given the high-risk to oMVS and an unfavorable anatomy to percutaneous intervention, what would be the alternative for the patient then? 2) What possible complications could happen with MC procedure?
Discussion: This case highlights the importance of a careful evaluation, case by case, when screening the optimal candidate for MC. Although, the lesions were located near the medial commissure, the team performed the procedure in a patient otherwise considered inoperable (P1). Clipping mitral leaflets near the commissures may cause severe damage to the MV apparatus which turns the procedure more complex (P2). TOE, with 3D image, was crucial to guide MC procedure, optimize the technique and its final results.
Conclusion: Interventional edge–to–edge repair with the MC in a patient with relatively unfavorable anatomy, showed feasible in this case, with clinical improvement and good results at one year. Patients with MR represent a heterogeneous group and candidates for MC should therefore be selected carefully.

Ruptured Valsalva aneurysm with patent ductus arteriosus - echocardiographic puzzle

M Magdalena Dudek[1]; M Kaluzna-Oleksy[1]; S Stefaniak[2]; J Migaj[1]; M Lesiak[1]; Z Oko-Sarnowska[1]; M Jemielity[2]; E Straburzynska-Migaj[1]
[1]Poznan University of Medical Sciences, 1st Cardiology Department, Poznan, Poland; *[2]Poznan University of Medical Sciences, Department of Cardiac and Transplantology Surgery, Chair of Cardio-Thoracic Surgery, Poznan, Poland*

A 39-year-old male patient without significant previous medical history was admitted to the hospital because of a 3-month-long dry cough and reduced exercise tolerance with cardiomegaly in chest X-ray. Auscultation revealed a loud systolic murmur over the whole heart, and quieter diastolic murmur between the scapulae. ECG showed sinus rhythm 62 bpm and left anterior hemiblock (LAH). In laboratory tests - elevated bilirubin (25.32 μmol/L) and brain natriuretic peptide type B (BNP) (835.3 ng/L).
Transthoracic echocardiography (TTE) showed enlargement of left-sided cardiac chambers and fistula between non-coronary sinus of Valsalva aneurysm (SVA) and right atrium with a small left-to-right shunt. Moreover, patent ductus arteriosus (PDA) between descending aorta and left pulmonary artery (flow velocity 4,5cm/s) was found. Cardiac magnetic resonance imaging (CMR) confirmed the diagnosis and showed the exact position of the connection between aorta and pulmonary artery. CMR pictures, both T1 and T2 related, and SE TSE GRE and cine-MR sequences before and after contrast phase, showed presence of PDA and rupture of the non-coronary sinus into the right atrium. Due to difficult evaluation of CMR because of artifacts, a 64-slice computed tomography angiography (CTA) was performed. CTA showed shunt between descending aorta and left pulmonary artery, 15 mm below the ostium of left subclavian artery. Coronary angiography revealed with no significant stenoses in coronary arteries and blood flow between the non-coronary SVA to the right chambers of the heart . The patient underwent surgical treatment, using the Bentall technique, and PDA ligation. He made a full recovery and was discharged 3 weeks later. Aneurysms of the sinuses of Valsalva are rare and mostly congenital anomalies with the highest incidence among young males. Rupture of a SVA can be caused by physical exertion, chest trauma or infective endocarditis, and usually is an indication for urgent surgical treatment. Main symptoms are dyspnea and reduced exercise tolerance with a sudden onset. Echocardiography plays a key role in initial diagnosis and developing a suspicion of a ruptured SVA, as it is easily accessible. It demonstrates the place and size of a rupture and can show comorbidities and other anomalies, as PDA in this case. Angio-CT or CMR confirm the diagnosis and can provide additional information. The treatment of choice is surgery.

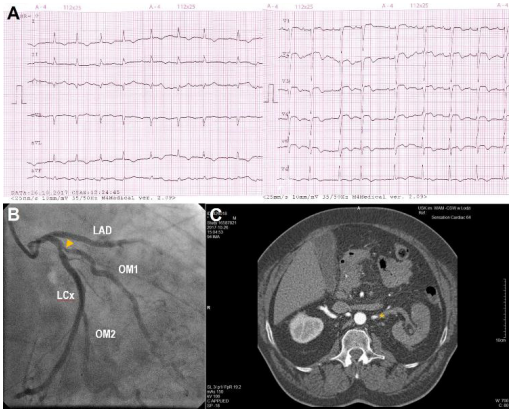
Atrial Fibrillation - Epidemiology, Prognosis, Outcome

P2048

Acute renal artery thromboembolism in the course of untreated atrial fibrillation manifested by Pickering-like syndrome

M Marcin Ksiazczyk[1]; A Debska-Kozlowska[1]; I Karcz-Socha[1]; E Pokrywka[1]; A Lubinski[1]
[1]University Clinical Hospital Military Memorial Academy - Central Veterans' Hospital, Department of Interventional Cardiology and Cardiac Arrhythmias, Lódz, Poland

A 72-year-old man with past medical history of well-controlled arterial hypertension, hypercholesterolaemia, ischaemic cerebral stroke and obesity was admitted to our department because of pulmonary oedema development with concomitant severe abdominal pain localised in the epigastric and umbilical region lasting for about 18 hours prior to admission. On physical examination blood pressure (BP) was 175/100 mmHg, heart rate - 100/min, blood oxygen saturation was 90% with signs of lung congestion and moderate bilateral lower extremities oedema.
The electrocardiogram (ECG) on admission revealed significant ST-segment elevations in precordial leads suggesting acute coronary syndrome (Panel A). Invasive coronary angiography demonstrated insignificant narrowings of the left anterior descending (LAD) and the 1st obtuse marginal (OM1) arteries (Panel B). Echocardiography showed enlarged both atria, left ventricular hypertrophy with global hypokinesis and depressed left ventricle ejection fraction (LVEF) of 30%. In lab tests elevated levels of cardiac troponin T (229 ng/l), D-Dimers (1,77 mg/l FEU) and NT-proBNP (24466 pg/ml) were observed. Because of the persistent abdominal pain, a computed tomography angiography of the aorta was performed - acute aortic syndrome was excluded, but left renal artery was occluded with an uncertain time of occlusion (Panel C).



Pickering-like Syndrome 800x600

On the next day, a patient reported the pain in the left lumbar-sacral area with positive left-side Goldflam's sign; constantly increased BP up to 180/110 mmHg, erythrocyturia and elevated inflammation markers were observed. We concluded that abdominal pain was the consequence of acute renal artery occlusion resulting in left-side renal ischaemia. Co-existing pulmonary pre-oedema condition was a clinical manifestation of Pickering syndrome occurring typically in patients with uni- or bilateral renal artery stenosis. The patient was consulted by vascular surgeon and urologist and both recommended conservational treatment.
It is known that one of the most common causes of renal ischaemia are cardiac diseases including atrial fibrillation (AF). In 24-hours Holter monitoring AF and atrial tachycardia episodes in our patient were recorded so we suggested that documented arrhythmia without previous anticoagulant treatment in combination with a high risk of thromboembolic complications (CHA2DS2-VASc 6 points) could be a potential mechanism of renal artery thromboembolism resulting in acute heart failure manifested by flash pulmonary oedema.
At discharge patient's condition was good: echocardiography showed mild improvement of LVEF up to 35%, lab tests revealed lower levels of NT-proBNP (3829 pg/ml), although a deterioration of renal function was observed (GFR CKD-EPI: 74 ml/min/1,73 m2 at admission; 44 on discharge).
Probably this is the first documented case of Pickering-like syndrome manifested by new-onset heart failure and pre-oedema condition due to acute renal artery thromboembolism.

P2049

Atrial fibrillation and atrial flutter ablation in patient with mitral valve replacement and severe heart failure: you never know what you can do till you try.

O Sapelnikov[1]; O Olga Nikolaeva[2]; D Cherkashin[1]; O Pidanov[3]; D Ardus[1]; T Uskach[2]; I Zhirov[2]; A Chapurnih[3]; I Grishin[1]; S Tereschenko[2]; R Akchurin[1]
[1]Russian Cardiology Research and Production Complex, Cardio-vascular surgery department, Moscow, Russian Federation; *[2]Russian Cardiology Research and Production Complex, Heart failure and myocardial disease department, Moscow, Russian Federation*; *[3]Federal Clinical Hospital under the Business Administration of the President of Russian Federation, cardio-vascular surgery department, Moscow, Russian Federation*

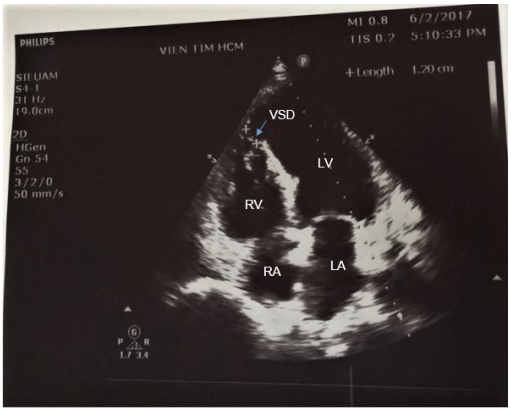
Nowadays endocardial catheter ablation is a 'gold standard' for AF/AFlutter treatment. In most cases the existence of a mechanical prosthesis is a reason for refusal in performing catheter treatment especially in patients with severe heart failure.
We present the patient with a mechanical mitral valve prosthesis and severe reduced left ventricle systolic function. This case demonstrates a possibility and usefulness of performing catheter treatment of AF which allowed to improve a condition and prognosis of the patient.
The 61 years old patient. In 2011 dilated cardiomyopathy was diagnosed. In 2012 a mitral valve chordae abruption occurred. This became a reason for a mitral valve replacement. The same year according to coronary angiography results arteries were intact. Since 2017 patient's condition worsened, including heartbeat, chest pain, dyspnea during small physical activity and leg edema. According to ECG AF/AFlutter with high ventricle rate were registered (average heartbeat was 100 per min.). LV EF was 27 % by echocardiography. Antiarrhytmic therapy was ineffective. The radio frequency anlation was performed. It should be noted that intraoperative INR was 3,2. During procedure AF and AFlutter episodes with 365 mc cycle and left activation front were registered. Under X-ray and intracardiac echocardiography control transseptal puncture was performed. Left atrial electroanatomic map was created. Circular 20-pole catheter Lasso was placed in pulmonary veins and

antral pulmonary vein isolation was performed. Left atrial and right atrial activation map was created. The earliest activation was registered in right atrial on the antero-lateral wall closer to superior vena cava, in place of supposed cannulation of superior vena cava. Intercaval line was performed with short-term sinus rhythm restoration and transformation to AFlutter with 380 mc cycle and right activation front. Cavo-tricuspid isthmus ablation was performed with restoration of sinus rhythm during ablation.In 3 months follow-up patient's condition was satisfying. Sinus rhythm was registered. LV EF was 38%.
Conclusion: Sinus rhythm restoration and maintenance in patients with severe heart failure can significantly improve the quality of life and condition of the patient. ?atheter ablation for AF/AFlutter treatment is possible and safe among patients with mitral valve replacement, so it should not be a contraindication, but such procedure should be performed in high-volume centers by qualified specialists where open heart surgery can be held.

Acute Heart Failure - Clinical

P2050
A case of ventricular septal rupture complicating acute myocardial infarction
H Thai Hao Phan[1]
[1]*Pham Ngoc Thach University of Medicine, Cardiology, Ho Chi Minh, Vietnam*

Introduction: Ventricular septal rupture (VSR) is a rare but lethal complication of acute myocardial infarction (AMI). As acute reperfusion strategies for AMI have evolved, VSR has become increasingly rare and is identified earlier in the post-MI course. Despite significant improvements over the last two decades in overall mortality for patients with AMI, the outcome of patients who develop VSR remains poor. We present a case of ventricular septal rupture complicating acute myocardial infarction.
Case Presentation: A 49-year-old Cambodian, smoker, alcoholic, non-diabetic, hypertensive farmer presented with acute dyspnea after ten days acute myocardial infraction on medical therapy at a hospital in Cambodia. His blood pressure was 109/77 mm Hg, Pulse 113bpm, spO2 99% (air room). Cardiac auscultation revealed a harsh holosystolic murmur, which was heard over the entire precordium. Bibasilar crackles of the lungs.



Results: high sensivity Troponin T 167.9ng/L (<14ng/L), NT-proBNP 3568pg/ml (<125pg/ml). Electrocardiogarphy showed rapid sinus rhythm with ST elevation and T wave inversion in inferior wall. Chest X-ray: PA views showed increase in pulmonary blood flow, cardiac shadow was within normal limits. Left larger than right pleural effusion.Transthoracic echocardiography revealed a left ventricle (LV) with overall preserved systolic function and inferior hypokinesis, a dilated right ventricle, pulmonary hypertension with PAPs 55mmHg and a large, sharply demarcated interventricular septal defect with a large, turbulent left-to-right transseptal flow.
Discussion: the diagnosis is made by a prompt transthoracic echocardiogram identifying drop-out of the ventricular septum in the 2D image and demonstration of flow across the septum using colour Doppler. Evidence of right-ventricular dilation and pulmonary hypertension are also important clues to the diagnosis. The remaining portions of the left ventricle are often hyperdynamic unless there is a large territory of infarction, or previous ischaemic insults have led to compromised function. Colour Doppler evaluation can also be useful to assess the anatomical size of the defect.
Conclusion: Rupture of the interventricular septum is an uncommon complication of MI. VSR occurs in a zone of necrotic myocardial tissue, usually within the first 10-14 days. A high index of suspicion is a loud systolic murmur is heard, usually within the first week after an acute myocardial infarction coincident with the onset of the murmur, the patient's clinical course undergoes a sudden deterioration, with the development of congestive heart failure and, often, cardiogenic shock. Diagnosis is confirmed with the aid of echocardiography and the presence of a left-to-right shunt.

P2051
Clinical case of heart failure due to neoplastic origin in women with uterus adenocarcinoma
I A Leonova[1]; O Chizhova[1]; S Boldueva[1]
[1]*North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation*

Pericarditis of neoplastic origin is often the first manifestation of the disease, when a cancer has not been established yet.
A clinical case of a patient with paraneoplastic pericarditis, hospitalized with a clinical picture of heart failure is presented.
A woman of 56 years was hospitalized to the therapeutic department with complaints of cough without sputum, inspiratory dyspnoe/orthopnea, edema of the lower extremities to the middle of the hips, the increase of the abdomen. Heart failure level was IV. Complaints appeared and intensified within 3 months prior to admission. Additional complaint was bleeding from genital tract during 1 month. Medical history: arterial hypertension II stage, mild chronic iron deficiency anemia. Based on X-ray examination of the chest ("spherical heart shadow "), ECG, Echo CG (divergence of pericardial leaflets for all the walls of 5-6 cm, the walls of the right ventricle and atrium were collapsed, vienna cava inferior didn't response to breathing) pericarditis was diagnosed. By pericardiocentesis more than 2 liters of turbid serous fluid was evacuated. Viral, tuberculosis, bacterial, autoimmune pericarditis were not confirmed. Based on gynecological examination, MRI of the pelvic organs, increase level of tumor markers (CA125, CA19-9), histological examination the diagnosis of endometrial carcinoma was done. After treatment of heart failure patient was referred to an oncologist. Follow-up 2 month after pericardiocentesis on ECH CG dilatation of the left atrium was marked, left ventricle was not enlarged, left ventricular contractile ability of the myocardium is satisfactory. The discrepancy between the sheets of pericardium behind the posterior wall was 4.1 cm; of the inferior wall was 2.5 cm., of the lateral was 4,5 cm., of the right ventricle - 2.3 cm., of the right atrium - 3.0 cm. Vienna cava inferior was expanded, collapsed on inspiration> 50%. The clinical manifestations of heart failure was at level II NYHA.
Thus, the presented clinical case proves once again that when searching for the causes of heart failure, the patient should be aware of the possible genesis of neoplastic lesions of the pericardium.

P2052
Clinical case of Takotsubo cardiomyopathy as an acute form of microvascular angina
I A Leonova[1]; S Boldueva[1]; M Ryzhikova[1]
[1]*North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation*

Features of the etiology, pathogenesis of stress-induced cardiomyopathy currently not well understood.
73 years women was hospitalized to the cardiology department due to the prolonged angina attack. Anamnesis: a long time arterial hypertension III degree. Patient had pressing pain in the chest, shortness of breath during physical exertion, psycho-emotional stress, in cold windy weather during few years. On ECG ST elevation in II, III, aVF, V3-6 was recorded. Troponin test was positive. The diagnosis was acute ST elevation inferior-lateral myocardial infarction. Urgency coronary angiography (CA) was performed: a balanced type of blood supply , the left descending artery without hemodynamically significant changes can be traced all over with a sharp drop in the diameter of the lumen in the distal - apical parts of the branches 3 of the order can not be traced (a symptom of "charred tree"), MPG = 0. Arteries without hemodynamically significant stenoses. Surgical treatment was not performed. Echocardiogram: EF = 49 %, the apex akinesia , hypokinesia of middle segments of all walls, dyskinesia of apex of the right ventricle, severe mitral regurgitation . According to the control echocardiogram on the 12th day the EF was 63 % , hypokinesia of apex of the left ventricle, mitral regurgitation I. Patient felt slight chest pain during exertion and emotional stress. After 1 month on echocardiogram EF was 65 %, there is no violation of contraction zone. Due to the rapid and significant positive trend of disease, the reversibility of the changes according to the echocardiogram, as well as data CA (coronary arteries without hemodynamically significant changes, the lack of branches of order 3 anterior descending artery), the diagnosis of myocardial infarction is excluded. Most likely, the patient had Takotsubo cardiomyopathy due to microvascular angina. To confirm the diagnosis perfusion positron emission tomography of the heart carried out. In a series of cardiac

tomograms performed alone, indicated moderate hypoperfusion of the myocardium in the apex of the heart, local contractility disturbances have been identified. By cold pressor test hypoperfusion in all segments of the anterior and lateral walls of the left ventricle, in the interventricular septum was revealed. Pharmacological test with adenosin: in the 5th minute of the sample registered oppressive chest pain, typical for the patient; revealed hypoperfusion of the myocardium in the apex; contractility zone violation have not been established. Thus, this is a case of acute form of microvascular angina as cardiomyopathy Takotsubo.

Apixaban successfully resolved left atrial appendage thrombus in patients with end stage renal disease with dialysis

YM Park[1]; MS Cha[1]; J Moon[1]; W-J Chung[1]; M-S Shin[1]; IS Choi[1]
[1]*Gil Hospital , Gachon University of Medicine & Science, Incheon, Korea Republic of*

Introduction: We report a patient requiring dialysis with left atrial appendage (LAA) thrombus which was successfully resolved with apixaban
Methods: N/A
Results: A 62-year-old female who had a history of end stage renal disease (ESRD) with dialysis was referred to our electrophysiology department due to paroxysmal atrial fibrillation (AF). Anticoagulation therapy with warfarin was started, because her CHADS2-VASc score was 4 (hypertension, diabetes, congestive heart failure, and female gender) as well as amiodarone for rhythm control. Trans-esophageal echocardiography was performed which revealed thrombus in left atrial appendage (LAA). Tachycardia-bradycardia syndrome was documented, therefore, catheter ablation was planned. Follow up TEE identified still remained thrombus despite approximately 1 year of anticoagulation therapy with warfarin. Therefore, warfarin was switched to the direct factor Xa inhibitor, apixaban 5mg bid. After four months of apixaban treatment, TEE revealed complete resolution of LAA thrombus. Finally, catheter ablation was performed without any complication and the patient has been in sinus rhythm thereafter under continued anticoagulant treatment with apixaban. Neither thromboembolic nor bleeding events did not occur during follow up for > 9 months.
Conclusion: Factor Xa inhibitor, apixaban, can successfully and safely resolve the LAA thrombus refractory to warfarin in patients with ESRD requiring dialysis.

Ventricular Arrhythmias and SCD - Treatment

P2054

Iatrogenic factors induce electrical storm in heart failure patients

SY Songyun Chu[1]; QH Sheng[1]; J Jiang[1]; J Zhou[1]; YS Ding[1]
[1]*Peking University First Hospital, Department of Cardiology, Beijing, China People's Republic of*

Purpose: Electrical storm is multiple episodes of ventricular tachycardia (VT) or ventricular fibrillation (VF) within 24 hours. Exacerbation of heart failure often becomes leading cause of the electrical instability. Iatrogenic factors, however, has not been paid enough attention.
Case: A 60-year-old man presented for palpitations and multiple shocks of ICD within one day. The patient had ischemic cardiomyopathy and ICD implanted after a syncope attack and VT demonstrated in our center 2 year ago. Standard medical therapy including ß-blocker, ACE-inhibitor, aspirin and statin were taken regularly thereafter. The patient had an attack of VT and received a shock at 16th, September, 2015. With heart failure symptoms, he was admitted into local hospital. Because of deterioration of heart function and hypotension, ß-blocker was stopped and dopamine and dobutamineintravenous infusion was started. At 12th, October, 2015, the patient had a VT attack and received 6 anti-tachycardia pacing (ATP) and 1 shock therapy. Bolus dose of amiodarone(300mg)was intravenous injected. Then continuous intravenous infusion of amiodarone(1000mg/h for initial 6 hours and 500mg/h thereafter) was given. Oral amiodarone (600mg/d) was also started to prevent recurrence of VT. Five days later (17th, October, 2015),the patient felt palpitation and lost his consciousness. Continuous ECG monitoring demonstrated VT reoccurred, but ATP therapy has no effect. Eight shocks were delivered from ICD, but also failed to convert the VT. Additional 3 shocks from external defibrillator (200J, biphasic wave) terminated the VT successfully. However,VT reoccurred the following day. ATP therapy was ineffective before a shock from ICD ended the VT. When the patient was transferred to our hospital with amiodarone continuous infusion, QTc was more than 600ms. Amiodarone was stopped. Multiple paroxysmal VTs were noticed when QTc longer than 500ms. QTc decreased gradually with cessation of amiodarone and supplementation of potassium and magnesium. Small dose of ß blocker was initiated and titrated. With the QTc decreased little by little, no more VT was observed.
Conclusion: Keep up with standardized secondary prevention medications are critical for heart failure patients. Withdrawal of ß-blockers was associated with elevated mortality while continuation of them even in patients hospitalized with decompensated heart failure improved treatment success. And intravenous inotropes should only be used as a bridge to further aggressive measures, or in selective patients with evident hypoperfusion or shock.
On the other hand, amiodarone has been demonstrated to significantly improve survival from cardiac arrest and reduce the frequency of ventricular tachyarrhythmia, and it has been recommended as treatment for electrical storm. However, one must be cautious when use amiodarone and keep close monitoring on QTc changes and early warning signs, especially for patients with decompensated heart failure.

Sudden cardiac death due to reversible hypertrophic cardiomyopathy. Could it be possible?

P Paloma Jorda[1]; E Arbelo[1]; A Garcia-Alvarez[2]
[1]*Hospital Clinic de Barcelona, Electrophysiology & Genetic Cardiopathies, Barcelona, Spain*; [2]*Hospital Clinic de Barcelona, Heart failure and cardiac transplantation, Barcelona, Spain*

A case of a 36-year-old man who suffered out-of-hospital cardiac arrest in 2011 is presented. It occurred at rest and first rhythm identified was ventricular fibrillation (VF). He was competing in athletics at that time, with no previously clinical history.
Echocardiography and CMR showed concentric hypertrophy that was severe at inferolateral wall (18 mm at this level, total LV mass 93.6 g). LVEF was normal (53.5%). RV was no hypertrophic or dilated. Non gadolinium late enhancement was observed. Cardiac valves function was normal.
Channelopathies were excluded as flecainide test was negative, ergometry did not induce arrhythmias, QT interval was normal and electrophysiological study showed normal conduction system intervals and no arrhythmias during stimulation were induced.
Sudden cardiac death was attributed to an underlying hypertrophic cardiomyopathy (HCM) and an implantable cardiodefibrillator (ICD) was implanted. Cessation of competition exercise was recommended.
After discharge, the study of infiltrative diseases causing hypertrophy ruled out Fabry disease (normal a -galactosidase activity test) and familial amyloidosis (normal TTR genotype).
Five months after the first episode the patient suffered two ICD discharges while sleeping (at 6 AM) due to VF. Beta-blockers were started. No more discharges have been registered.
The genetic analysis showed a mutation of uncertain significance in the titin gene and a probably pathogenic mutation for Brugada syndrome (BS) in sodium channel a-subunit gene (SCN5A p.825 L>P). No sarcomeric mutations related to hypertrophic cardiomyopathy were found.

During the follow-up, six years after the first event, echocardiography demonstrated that the hypertrophy had reverted from 18 mm initially in the inferolateral wall to a maximum of 12 mm in the septum.

Given the practical resolution of ventricular hypertrophy we have assumed that ventricular hypertrophy observed initially was induced by exercise (HCM phenocopy).

The type of ventricular arrhythmias and the SCN5A mutation (probably pathogenic for BS) point a channelopathy as the underlying cause arrhythmias in this case.

Basal ECG with upper chest leads shows ECG type 2 for Brugada syndrome and atrial stimulation due to sinus dysfunction (typical in BS patients with SCN5A mutation). Negativity in flecainide test in 2011 is possibly a false negative (reported in 36% of cases). Ajmaline test to confirm the diagnosis of BS is pending at the moment of abstract submission.

This case shows the importance and the difficulty in the differential diagnosis of the aetiology of ventricular arrhythmias. In addition, it clearly shows how a hypertrophic myocardium can be observed in a wide spectrum of circumstances. Prognostic and therapeutic implications will be greatly different depending on the underlying condition.

Congestion: how to detect with new technologies

2076

Negative prognostic value of residual congestion by bioimpedance vector analysis at discharge in patients with decompensated heart failure

A Soloveva[1]; M Bayarsaikhan[1]; A Kuchaeva[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Department of Internal Diseases, Moscow, Russian Federation*

Objective: Congestion is the principal cause for admission with decompensated heart failure (DHF). The aim of the study was to evaluate hydration status during hospitalisation, rate and prognostic value of residual congestion in patients with DHF using bioimpedance vector analysis (BIVA).
Methods: 148 patients with DHF (99 male, 71 ± 11 years (M ± SD), arterial hypertension 95%, myocardial infarction 42.5%, atrial fibrillation 65%, diabetes mellitus 42.5%, chronic kidney disease 26%, ejection fraction (EF) 41 ± 14%, EF < 40% 44.6%, baseline NT-proBNP 4148 (1635;5567) pg/ml) were included in 6-month prospective study. Hydration status was assessed by BIVA on admission and discharge, using resistance (R) and reactance (Xc) standardized by height (h). Deviation from the 50th, 75th and 95th vector percentile of the healthy reference population was considered as mild, moderate and severe hyperhydration. Hyperhydration by BIVA at discharge was defined as residual congestion. Outcomes data were available for 138 patients. Mann-Whitney and Pearson chi-squire tests, multiple regression analysis were performed. P < 0.05 was considered significant.
Results: Baseline mild, moderate and severe hyperhydration was revealed in 19, 32.4 and 48.6% of patients. At discharge 1.4 and 34.4% of patients had dehydration and euvolemia, 64.2% - residual congestion by BIVA (mild, moderate and severe in 25.7, 31.1 and 7.4% of cases respectively).
Patients with vs without residual congestion did not differ by clinical and demographic characteristics (except for higher rate of oedema on admission and discharge), comorbidities, baseline NT-proBNP and EF, but had more pronounced baseline BIVA hyperhydration and lower R/h and Xc/h decrease despite more intensive diuretic therapy - longer and higher dose of iv furosemide therapy (7 (5;9) vs 6 (4;8) days, p = 0.037, total dose (640 (420;940) vs 360 (240;780) mg, p = 0.012) and maximum daily dose (100 (80;160) vs 80 (60;120) mg, p = 0.032)), lower rate of switching to per os furosemide therapy (80 vs 94%, p = 0.019) and thiazide therapy (9.5 vs 24.5%, p = 0.042).
Independent predictors for residual congestion were oedema at discharge (odds ratio (OR) 7.35 (95% confidential interval (CI) 2.85;18.98), p < 0.001) and baseline severe hyperhydration by BIVA (OR 4.37 (95% CI 2.08;9.18), p < 0.001).
Patients with vs without residual congestion had higher rate of 6-month all cause death (16.9 vs 4.1%, p = 0.029). Residual congestion was determined to be a predictor for 6-month all cause death (OR 4.76, 95% CI 1.03;22.08), p = 0.048).
Conclusions: Residual congestion was revealed in 64.2% of patients and was associated with more prominent baseline BIVA hyperhydration, lower hydration dynamics, more intensive loop diuretic therapy. Residual congestion had negative impact on 6 month outcomes and was independently associated with higher all-cause death.

2077

The real way to reduce Heart Failure hospitalizations and Heart Failure associated deaths: Lessons from the extended IMPEDANCE-HF trial

M Michael Kleiner Shochat[1]; A Shotan[1]; I Kleiner[2]; JM Weinstein[2]; I Dahan[1]; M Kazatsker[1]; A Asif[1]; S Meisel[1]
[1]*Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel*; [2]*Saroka Medical Center, Cardiology, Beer Sheva, Israel*

Results of the IMPEDANCE-HF trial have shown that lung impedance (LI)-guided treatment reduces hospitalizations for heart failure (HF) and decreases HF-related mortality. The main trial was extended for an additional year to accrue more data on predictors of hospitalizations due to HF. The main aim of the study was to prove that HF patients with higher degree of long-standing pulmonary congestion are hospitalized more often.
Methods Study population included 266 patients, with HF and LVEF = 35% in New York Heart Association class II-IV. Patients were randomized (1:1) to a control group treated by clinical assessment and a LI-guided group whose therapy was also assisted by LI. Patients were examined and LI measured monthly in our outpatient clinics. Noninvasive LI measurements were performed with the high-sensitive device. Assessment of the degree of pulmonary congestion was by the new index ?LIR, measured at each visit and calculated as ?LIR = {1- [currently measured LI/normal baseline (calculated for each patient)] × 100} expressed as percentage. The annual average ?LIR for each patient was calculated as the mean of all ?LIR measurements at each consecutive year of follow-up.
Results The total follow-up period was 642 years in the LI-guided group and 510 years in the control group (p = 0.001). Groups were similar with respect to baseline characteristics. There were 249 and 475 HF hospitalizations (mean 0.39 and 0.93 per × year of follow up) in the LI-guided and control groups, respectively (p < 0.001). There were 56, 22 and 73, 51 all-cause and HF-associated death cases in the LI-guided and the control groups, respectively (p < 0.001). Hazard Ration (HR) for HF hospitalizations was higher in control in compare with LI-guided group [HR = 2.56, 95% CI: 1.8-3.7, P < 0.00001], (Anderson-Gil Model). Figure 1 shows the dynamics of pulmonary congestion in study groups during the follow-up period as represented by ?LIR, demonstrating a significantly lower level of pulmonary congestion in the LI-guided group compare with the control group during the study (p < 0.001). Conclusion The Extended IMPEDANCE-HF demonstrated that pre-emptive LI-guided therapy of HF patients reduced pulmonary congestion significantly more effectively than by treatment according to clinical assessment only. This effect appeared to be consistent during the whole study period. Since groups were similar with respect to baseline characteristics, we proposed that the main reason for reducing the number of HF hospitalizations and improving survival was better decongestion achieved in the monitored group.

2078

Troponin and Lung Impedance based model for prediction Heart Failure readmission

M Michael Kleiner Shochat[1]; A Shotan[1]; M Kazatsker[1]; I Kleiner[2]; JM Weinstein[2]; I Dahan[1]; A Asif[1]; S Meisel[1]
[1]*Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel*; [2]*Saroka Medical Center, Cardiology, Beer Sheva, Israel*

The IMPEDANCE-HF trial has shown that lung impedance (LI)-guided treatment reduces hospitalizations for heart failure (HF) and decreases HF-related mortality. The aim of the current sub-analysis was to evaluate whether troponin level elevation during admission and the degree of pulmonary congestion at discharge after HF hospitalization can predict time to the next readmission.
Methods: Study population included 266 patients with HF and LVEF = 35% in New York Heart Association class II-IV. Noninvasive LI measurements were performed with a high-sensitive device. Assessment of the degree of pulmonary congestion was assessed by the new index ?LIR= {[1-currently measured LI/normal baseline (calculated for each patient)] × 100} expressed as percentage. High sensitive troponin was evaluated 6-12 hours after admission for HF.
Results: There were 155 HF hospitalizations with available troponin level. LI was performed per protocol during every admission. Median troponin level was 44 ng/ml.

Troponin levels during HF hospitalization were divided into 3 categories: 0-13 ng/ml-normal range, 13.1-44.0 ng/ml (mildly elevated < median), and values> 44.0 ng/ml (elevated>median). Pulmonary congestion, assessed by ?LIR at discharge, was defined as mild pulmonary congestion: 0 to -20% (in comparison with normal individual basal LI), moderate pulmonary congestion: -20.1 to -35%, and severe pulmonary congestion: -35.1 to -60%. The respective times to readmission according to troponin groups were 304, 295, and 176 days ($p < 0.001$ only for elevated> median troponin subgroup). Median time to readmission according to the degree of pulmonary congestion at discharge was 496 days for mild pulmonary congestion, 370 days for moderate pulmonary congestion and 44 days for severe pulmonary congestion at discharge ($p < 0.01$). Time to HF death after discharge was not significantly dependent on troponin level but tended to correlate with it ($p = 0.06$). However, it was significantly dependent on the level of pulmonary congestion at discharge ($p < 0.001$). Conclusion Risk stratification of readmission and HF death after hospitalization for HF exacerbation is possible using troponin level during admission and the degree of pulmonary congestion at discharge. Mildly elevated troponin is not useful for risk stratification. The level of pulmonary congestion at discharge for HF hospitalization, as assessed by lung impedance, is a very strong predictor of the time for readmission and HF-associated death.

Funding Acknowledgements: Gangsted Foundation, Internal Funds from Herlev and Gentofte University Hospital, Lundbeck Foundation, Julie von Müllens Foundation

Background: Identification of B-lines by lung ultrasonography (LUS) is useful for assessment of pulmonary congestion, however, the impact of body mass index (BMI) on B-line prevalence is not known.
Purpose: We sought to evaluate the relationship between BMI and B-line prevalence in patients with chronic heart failure (HF) and acute HF.
Methods: We analyzed ambulatory chronic HF (n = 118) and hospitalized acute HF (n = 177) patients (mean age, 70 years, 64% men, mean BMI 29 kg/m^2) undergoing echocardiography (mean ejection fraction, chronic HF: 45%; acute HF: 41%) and LUS examination in 8 chest zones. The sum of B-lines was quantified offline, blinded to clinical findings. Patients were divided into categories of BMI: lean (< 25 kg/m^2), overweight (25 to 29.9 kg/m^2), obese (30 to 34.9 kg/m^2), severely obese (= 35 kg/m^2) and B-line groups: 0-2, 3-6 and >6. Patients with BMI>50 kg/m^2 were excluded (n = 7).

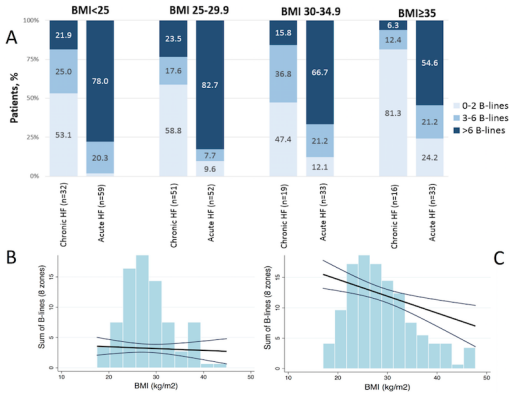

Fig1: (a) barchart (b-c) spline plots

Results: The number of B-lines was lower in patients with chronic HF (mean B-lines 3, range 0-17; P < 0.001) than those with acute HF (mean B-lines 12, range 0-36) (Figure 1a). In chronic HF there was no significant association between either continuous or categorical B-line number and continuous or categories of BMI (P trend = 0.17; rho=-0.16, P = 0.09). These findings remained consistent after adjustment for age and sex (P overall trend = 0.62; Figure 1b). By contrast, in acute HF patients the number of B-lines decreased significantly with increasing BMI both in continuous and categorical analyses (P trend = 0.003; rho =-0.21, P = 0.005) and after adjustment for age and sex (P overall trend = 0.002; Figure 1c). However, in more than half of severely obese patients with acute HF >6 B-lines could still be identified.
Conclusion: Patients with acute HF demonstrated a higher number of B-lines on LUS than those with chronic HF. The relationship between B-lines and BMI among patients with HF is less clear, and should be considered hypothesis generating and further examined in future, larger cohorts.

2080

Dynamic of pulmonary congestion assessed by clinical signs and lung ultrasound in patients with decompensated heart failure

F Cabello Montoya[1]; O Lukina[1]; A Soloveva[1]; A Safarova[1]; S Villevalde[1]; Z Kobalava[1]

[1]Peoples' Friendship University of Russia (RUDN University), Department of Internal Diseases, Moscow, Russian Federation

Introduction: In the past two decades, lung ultrasound (LUS) has emerged as an effective tool in the evaluation of pulmonary congestion. The aim of the study was to assess the incidence and severity of pulmonary congestion by evaluation of B-lines and their dynamic changes during hospitalization in decompensated heart failure (DHF).
Material and Methods: Routine clinical assessment, chest X-ray and lung ultrasound (LUS) were performed in 167 patients with DHF (men 62%, age 69 ± 12 years (M ± SD), arterial hypertension 94%, anamnesis of myocardial infarction 56%, atrial fibrillation 65%, ejection fraction (EF) 41 ± 14%, EF <40% 47%, baseline NT-proBNP 3674 (1466; 6413) pg/ml). Standart eight-zone LUS examination was performed. Sum of B-lines <5 was considered as normal, 6-15, 16-30 and >30 - as pulmonary congestion (mild, moderate and severe respectively). Presence of pulmonary congestion (PC) at discharge was considered as residual PC. Mann-Whitney, McNemar and Wilcoxon tests were performed. P <0.05 was considered statistically significant.
Results: During hospitalization incidence of clinical signs of PC decreased: orthopnoea from 80 to 16%, dyspnoea at rest from 34 to 0%, dyspnea at exertion from 97 to 42%, bilateral pulmonary rales from 82 to 9%, congestion on chest radiographs 65 to 16%, hydrothorax on chest radiographs 44 to 10%, p <0.05.
Presence of at least one of clinical (orthopnoea or rales) or radiological sing of PC was revealed in 34.1% cases.
On admission mild, moderate and severe PC occurred in 4.2, 30.5 and 65.3% of patients respectively. At discharge normal LUS profile was observed in 58.1% of patients. Mild, moderate and severe PC occurred in 31.7, 8.4 and 1.8% cases.
During hospitalization the median of B-lines sum decreased from 35 (27;55) to 5 (3;9) (relative ?-85.7 (-92;-75)%) p <0.001.
Patients with vs without residual PC had higher median of B-lines sum on admission (45 (29;60) vs 34 (25;49), p = 0,002) and at discharge (10 (8;15) vs 3 (3;4), p <0.001), lower relative ?B-lines (-67 (-82;-58) vs -91 (-94;-85)%, p <0.001).
Conclusion: Significant decrease of B-lines and incidence of clinical signs of pulmonary congestion during hospitalization was observed. Pulmonary congestion at discharge was observed in 34.1% by clinical data or chest radiographs and in 41.9% by LUS.

2081

Device measured rapid shallow breathing index reflects changing respiratory patterns but minute ventilation reflects changing activity during worsening heart failure in ambulatory patients

J Boehmer[1]; M Aktas[2]; A Capucci[3]; RS Gardner[4]; M Gold[5]; G Molon[6]; P Thakur[7]; R Sweeney[7]; Y Zhang[7]; Q An[7]; V Averina[7]; S Rials[8]

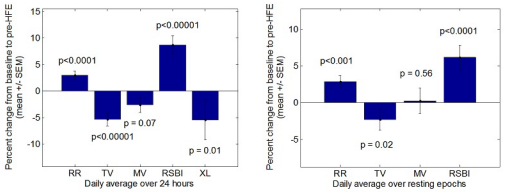
Funding Acknowledgements: Boston Scientific

Background: Respiratory distress is common in heart failure (HF) and a primary driver for HF hospitalizations. Minute Ventilation (MV), a product of respiratory rate and tidal volume, is known to be elevated in HF patients due to ventilation/perfusion (V/Q) mismatch. However, it is not known if changes in MV accurately reflect emergence of rapid shallow breathing patterns in ambulatory patients preceding a HF event.

Methods: The MultiSENSE trial enrolled 900 patients implanted with a COGNIS CRT-D and followed them up to 1 year. Device software was modified to permit collection of chronic diagnostic sensor data including impedance based respiration rate (RR) and tidal volume (TV), which was used to compute MV (= RR*TV) and Rapid Shallow Breathing Index (RSBI = RR/TV), and activity (XL). Daily averages were separately computed over entire 24 hours as well as during resting epochs. HF events (HFEs) were independently adjudicated and defined as HF admissions or unscheduled visits with intravenous HF treatment. Relative changes preceding HFEs were computed between a baseline 30-60 days prior to HFEs (BL) and 3-day pre-HFE (ST) as (ST-BL)/BLx100% and reported as mean ± SEM. Significance was tested using Wilcoxon signed-rank test.
Results: 900 patients followed for a year experienced 192 HFEs. Using 24-hour averages, significant changes were observed in RR, TV and RSBI indicating the emergence of rapid shallow breathing pattern leading up to HFE. MV average over 24 hours showed nonsignificant decrease coincident with decreased patient activity but showed no change when daily averaging was limited to resting epochs. In contrast, RR, TV and RSBI were significantly changed even at rest in directions consistent with the emergence of rapid shallow breathing pattern.
Conclusion: Device measured rapid shallow breathing is significantly elevated in the three day epoch preceding HFEs, whereas minute ventilation is not, in both 24-hour as well as resting period daily averages. Automatic ambulatory longitudinal monitoring of changes in rapid shallow breathing patterns may enable better monitoring for emerging respiratory distress in HF patients.



2082

Device measured rapid shallow breathing index and not minute ventilation reflects changes in dyspnea status in ambulatory heart failure patients

J Boehmer[1]; M Aktas[2]; A Capucci[3]; RS Gardner[4]; M Gold[5]; G Molon[6]; P Thakur[7]; R Sweeney[7]; YI Zhang[7]; Q An[7]; V Averina[7]; S Rials[8]

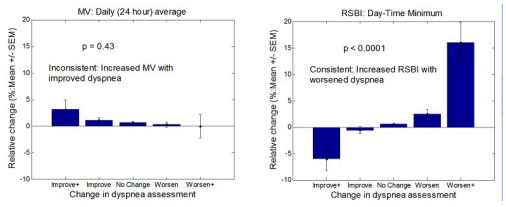
Funding Acknowledgements: Boston Scientific

Background: Dyspnea is common in heart failure (HF) patients and a primary driver for HF hospitalizations. Minute Ventilation (MV), a product of respiratory rate (RR) and tidal volume (TV), is known to be elevated in HF patients due to ventilation/perfusion (V/Q) mismatch. However, it is not known if changes in MV accurately reflect changes in dyspnea status in ambulatory HF patients over time.



Methods: The MultiSENSE trial enrolled 900 patients implanted with a COGNIS CRT-D and followed them for up to 1 year. Device software was modified to permit collection of chronic diagnostic sensor data including impedance based RR and TV, which was used to compute MV (RR*TV) and Rapid Shallow Breathing Index (RSBI = RR/TV). Dyspnea status was assessed on a 3-point scale (0 = No dyspnea, 1 = dyspnea on exertion, 2 = dyspnea at rest) at routine follow-up visits scheduled either every three months if the patients had remote monitoring, or every 6-8 weeks if not. Changes in dyspnea scores between follow-ups were calculated: Improve+ (2->0), Improve (2->1 or 1->0), No change, Worsen (0->1 or 1->2), and Worsen+ (0->2). Relative changes in the respiration parameters between the start (ST) and end (ED) of each epoch were calculated as (ED-ST)/STx100%, reported as mean ± SEM for each category and compared across categories using Kruskal-Wallis test.
Results: Of 4717 total follow-up intervals with dyspnea assessments, 3388 had no change, 561 had 1-point worsening, 41 had 2-point worsening, 689 had 1-point improvement, while 37 had 2-point improvement. 24-hour average MV was not significantly different between dyspnea change categories ($p = 0.42$) and changed inconsistent with expectation (i.e. increased MV with improved dyspnea assessment). In contrast changes in 24-hour average RSBI ($p = 0.03$) as well as day-time minimum RSBI ($p < 0.0001$) were significantly different between categories and consistent with expectation (i.e. increased RSBI with worsening dyspnea)
Conclusion: Changes in RSBI correlated with changes in patient's dyspneic status (i.e. increased rapid shallow breathing with worsening dyspnea status) whereas MV did not. Automatic longitudinal measurements of day-time minimum RSBI may better quantify the dyspneic status in ambulatory HF patients, enabling continuous monitoring of dyspnea in HF patients.

2083

Longitudinal function and right ventricular remodeling ratio in acute heart failure: a non invasive measurement of right dysfunction and outcome

A Alberto Palazzuoli[1]; G Ruocco[2]; M Beltrami[2]; O De Vivo[2]; R Nuti[2]
[1]Santa Maria Alle Scotte Polyclinic, Siena, Italy; *[2]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy*

Background: In acute heart failure (AHF) the development of right ventricle (RV) dilation and failure is a signs of advanced disease and poor prognosis.
Purpose: In this study we sought to evaluate a new index including TAPSE and end diastolic diameter (EDD) of RV with respect to the well known TAPSE/PASP ratio; to compare these two formulas (TAPSE/PASP and TAPSE/EDDRV) in terms of outcome prediction in patients with preserved (pEF) or reduced ejection fraction (rEF).
Methods: Patients with AHF were included in this study. In each subject, the echocardiography was performed within 12 hours from admission, by two experienced cardiologists according to the instructions provided by the American Society of Echocardiography. We estimated the systolic PASP by continuous Doppler at tricuspid valve level. The TAPSE was obtained by placing the M-mode cursor lateral tricuspid annulus. EDD of RV was measured at the basal level by 4 chamber view. Patients were classified in pEF or rEF on the basis of EF cut-off 50%. We also assessed the diastolic function pattern by the analysis of transmitral and tissue Doppler waves.
Results: Of 157 patients enrolled, 90 had HFrEF and 67 had HFpEF, median age was 80 [77-85] years and 53% were women. Overall, the median BNP was 1,007 [768-1,540] ng/L, median TAPSE/PAPs 0.408 [0.305-0.533] and the median TAPSE/EDD RV was 0.454[0.356-0.591]. ROC curve analysis showed that the increase of PASP (AUC 0.60[0.51-0.69];$p = 0.03$), EDDRV (AUC 0.71[0.63-0.79];$p < 0.001$) and BNP (AUC 0.62[0.53-0.71];$p = 0.01$) were able to predict poor outcome; conversely, a reduction of TAPSE was related to poor prognosis (AUC 0.38[0.29-.46;$p = 0.01$). Univariate analysis showed that both a TAPSE/EDDRV < 0.454 (HR 3.36 [1.90-5.95]; $p < 0.001$) and a TAPSE/PASP < 0.408 (HR 2.16 [1.28-3.65]; $p = 0.004$) were related to poor outcome. After adjustment for potential confounders, multivariable analysis confirmed the prognostic role of TAPSE/EDDRV < 0.454 (HR 3.76 [1.60-8.84]; $p = 0.002$) and persistence of congestion at discharge (HR 4.23[2.04-8.77]; $p < 0.001$).
Conclusions: In AHF the poor RV longitudinal function/diameter ratio is an additional criteria for identification of RV dysfunction and elevated pulmonary pressure. This new formula appear to predict outcome in both pEF and rEF patients.

2084

Liver stiffness is associated of with hyperhydration and does not reflect liver fibrosis in decompensated heart failure

A Soloveva[1]; ? Bayarsaikhan[1]; M Naumenko[2]; A Abramov[1]; I Garmash[1]; S Villevalde[1]; Z Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), Department of Internal Diseases, Moscow, Russian Federation; *[2]Vinogradov City Clinical Hospital, Department of Pathology, Moscow, Russian Federation*

Objective: Over the last several years the relationship of liver stiffness (LS) with congestion in decompensated heart failure (DHF) have been discussed. The aim of the study was to assess LS by the transient elastography (TE) and its associations with hyperhydration by bioimpedance vector analysis (BIVA) in DHF.
Methods: LS by TE and hydration status by BIVA were measured in 123 patients with DHF on admission and discharge (81 male, 71 ± 11 years (M ± SD), arterial hypertension 94%, myocardial infarction 45%, atrial fibrillation 69%, diabetes mellitus 44%,

chronic kidney disease 25%, left ventricular ejection fraction (EF) 41 ± 14%, EF < 40% 46%, baseline NT-proBNP 3820 (1840;5486) pg/ml). In TE 10 valid measurements were required with success rate of >60%. LS = 5.8 was considered normal and LS = 5.9, 7.2, 9.5 and 12.5 kPa was considered as fibrosis (F1-F3 METAVIR score) and cirrhosis (F4) according to thresholds in studies with chronic liver disease. Hydration status was assessed by BIVA using resistance (R) and reactance (Xc) standardized by height (h). Wilcoxon adn Spearman tests were performed. P < 0.05 was considered significant.

In 6 patients died during hospitalisation liver biopsy was reviewed. Hematoxylin-eosin slides from liver autopsy specimens were examined in 6 persons died during hospitalisation. Pathologist didn't know of LS values. Histologic features of cardiac hepatopathy and congestive hepatic fibrosis score (CHFS) based on the pattern of fibrosis were assessed.

Results: On admission normal LS was observed in 21.1% of patients, abnormal LS = 5.9, 7.2, 9.5 and 12.5 kPa - in 8.1, 11.4, 11.4 and 48% of patients. At discharge normal LS was observed in 24.4% of patients, abnormal LS = 5.9, 7.2, 9.5 and 12.5 kPa - in 15.4, 11.4, 16.3 and 32.5% of patients.

During hospitalisation the median value of LS decreased from 12.3 (interquartile range 6.3;25.1) to 9.2 (5.9;14.4) kPa (?LS=-2.8 (-10.4;0.3) kPa), p < 0.001. R/h and Xc/h increased from 250 ± 64 to 287 ± 58 Om/m and from 21 ± 8 to 26 ± 7 Om/m (?R/h 37 (10;64) Om/m, ?Xc/h 4.7 (1.2;8.9) Om/m), meaning decongestion (p < 0.001 for both comparisons). Patients' weight decreased from 87 ± 20 to 82 ± 18 kg, p < 0.001 (?weight -4(-7;-2) kg).

?LS correlated with ?R/h (r=-0.42), ?Xc/h (r=-0.44) and ?weight (r = 0.46).

In 6 died patients LS was >12.5 kPa, in 1 case - 8 kPa. Liver fibrosis was observed in all slides but was not associated with LS. CHFS 2B (moderate portal fibrosis and central zone fibrosis, with accentuation of fibrosis in the portal zone) was revealed in 5 cases with corresponding LS 25.7, 22.3, 21.8, 16.9 and 8 kPa, CHFS 3 (bridging fibrosis) - in 1 case with LS 20.4 kPa and CHFS 4 (cirrhosis) - in 1 case with LS 17.3 kPa.

Conclusions: LS was associated with congestion by BIVA and didn't correlate with degree of histology liver fibrosis. During hospitalization decrease of LS correlated with decrease of weight and decongestion by BIVA parameters.

Aims: There is no universal method to assess and grade congestion. We used the clinical value of different clinical signs of congestion to construct a congestion score, and determined its relationship to novel biomarkers reflecting different disease pathways.

Methods and Results: Patients enrolled in The BIOlogy Study to TAilored Treatment in Chronic Heart Failure (BIOSTAT-CHF) were clinically assessed at baseline. Apart from the 3rd heart sound, each clinical sign of congestion was associated with an increase in all-cause mortality (ACM) or the composite of ACM and HF hospitalisation (HFH).

A congestion score was constructed for those with a complete set of relevant data (1589 patients (63%), based on lung auscultation (normal or presence of crepitations at a single or both lung bases), jugular venous pressure (not visible, uncertain, raised), peripheral oedema (none, ankles, below or above knees), hepatomegaly (absent or present) and orthopnoea (absent or present) with one point attributed for each degree of severity and a total possible score of nine.

124 in-patients (11%) and 202 out-patients (43%) were free of congestion and had the lowest risk of ACM (8% and 6% respectively) and of ACM/HFH (26% and 10% respectively) at 1 year. Risk increased progressively with increasing congestion score; overall, those who scored = 4 had roughly a 3-fold higher risk of ACM (HR: 3.33 (95%CI: 2.39-4.64, p < 0.001) or ACM/HFH (HR: 2.71 (95%CI: 2.12-3.47), p < 0.001) than those who scored 0.

Serum concentrations of all 31 measured biomarkers correlated significantly with clinical congestion score; natriuretic peptides, endothelin and some novel biomarkers of inflammation or fibrosis (Pentraxin-3 and WAP4C) had the strongest associations.

Conclusions: Clinical congestion score provides strong prognostic information but their evaluation may require considerable clinical skill. Serum concentrations of many biomarkers are associated with congestion, which might explain their association with prognosis. Whether other biomarkers add value to natriuretic peptides for tracking changes in the severity of congestion is uncertain

Blood glucose values spanning hypoglycemia and hyperglycemia during a heart failure hospitalization is associated with prolonged length of stay in patients with history of diabetes

S Sarkar[1]; J Koehler[1]
[1]*Medtronic Plc., Moundsview, United States of America*

Introduction: Patients with diabetes are at an increased risk for worsening heart failure (HF). We investigated whether changes in blood glucose during HF hospitalization influences length of stay (LOS).
Methods: HF hospitalizations (HFH) were retrospectively identified in patients with cardiovascular disease from the de-identified Optum EHR database during 01/2011-03/2017. HFHs were included for analysis if patient had history of diabetes prior to admission and if there was administration of intravenous acute HF therapy (diuretic or vasodilator or inotrope) during hospital stay. Valid fasting and random blood glucose measurements during hospital stay were included for analysis and postprandial measurements were excluded. The minimum and maximum glucose values during each hospital stay were categorized into 6 groups (table) using well established thresholds of 90 mg/dL and 140 mg/dL. The median LOS in the 6 groups were compared using Kruskal-Wallis Test and pairwise comparisons were performed using the Wilcoxon Rank Sum Test.
Results: A total of 164,178 HFH identified in 102,437 patients (72 ± 12 years, 51% male) met inclusion criteria and had a valid glucose measurement during HFH. The number and % of HFH in each blood glucose group and their associated length of stay statistics are shown in table. Over half of HFHs had blood glucose spanning both < 90 mg/dL and >140 mg/dL during the hospital stay. Median length of stay is different between different range of blood glucose values ($p < 0.001$) with patients with a large range of blood glucose values spanning from hypo to hyper glycemia having two-time longer LOS compared to patients with blood glucose in normal range during HFH ($p < 0.001$).
Conclusion: Large proportion of HFHs have a range of blood glucose that spans from hypo to hyper glycemia during hospital stay and these patients had a longer LOS in the hospital. Whether stricter management of blood glucose during HFH will lead to more effective acute HF therapy during admission needs further investigation.

		Length of stay (days)	
Blood glucose groups (thresholds in mg/dL)	Number of HFH (%)	Median (IQR)	Mean (SD)
maxGlucose < 90	297 (0.2)	3 (2-4)	3.4 (4.2)
minGlucose < 90 and maxGlucose ≥ 90 and maxGlucose ≤ 140	7925 (4.8)	4 (3-7)	5.8 (10.9)
minGlucose < 90 and maxGlucose > 140	82961 (50.5)	6 (4-11)	10.4 (22.7)
minGlucose ≥ 90 and maxGlucose ≤ 140	7592 (4.6)	3 (2-5)	3.9 (4.8)
minGlucose ≥ 90 and minGlucose ≤ 140 and maxGlucose > 140	56163 (34.2)	4 (3-7)	5.8 (9.1)
minGlucose > 140	9240 (5.6)	3 (2-4)	3.4 (3.0)

Worsening renal function during decongestion among patients hospitalized for heart failure: findings from the escape trial.

M Marat Fudim[1]; SJ Doerfler[1]; A Coles[1]; SJ Greene[1]; LB Cooper[1]; M Fiuzat[1]; CM O'connor[1]; JG Rogers[1]; RJ Mentz[1]
[1]*Duke Clinical Research Institute, Cardiology, Durham, United States of America*

Funding Acknowledgements: American Heart Association and NIH T32

Background: Worsening renal function (WRF) is commonly encountered as patients are decongested during a hospitalization for acute heart failure (HF), but the incidence and prognostic implications of WRF in the setting of different measures of decongestion are unclear.
Purpose: Compare the agreement rate between various measures of decongestion and compare the prognostic implications of WRF in the setting of these measures of decongestion.
Methods: Patients (N = 433) from the Evaluation Study of Congestive Heart Failure and Pulmonary Artery Catheterization Effectiveness (ESCAPE) were included and classified into 4 groups by measures of decongestion during hospitalization: hemodynamic (right atrial pressure = 8 mmHg and/or wedge pressure = 15 mmHg at discharge), physical exam (= 1 sign of congestion at discharge), hemoconcentration (any increase in hemoglobin) and estimated plasma volume using the Hakim formula (5% reduction in plasma volume). WRF was defined as creatinine increase > 0.3 mg/dl during hospitalization. The association between WRF and 180-day all-cause death was assessed using Cox proportional hazards regression analysis adjusted for age, sex, and BMI stratified by decongestion status via this different measures.
Results: Successful decongestion was observed in N = 124 (60%) of patients by hemodynamics, N = 204 (49%) by clinical exam, N = 173 (47%) by hemoconcentration and N = 165 (45%) by plasma volume. There was no agreement between the hemodynamic assessment and other decongestion measures in up to 43% of cases. WRF was observed in 41% of patients, with a lower rate among patients with successful decongestion and higher rate (up to 60%) among patients with unsuccessful decongestion. Inadequate decongestion at discharge was associated with worse outcomes (Figure). Among patients decongested at discharge, in-hospital WRF was not significantly associated with the hazard of all-cause death at 180 days, irrespective of the measure of decongestion examined (Figure).
Discussion: In this clinical trial cohort of patients hospitalized for HF, although there was disagreement across common measures of decongestion, in-hospital WRF was not associated with increased hazard of all-cause mortality among patients successfully decongested at discharge.

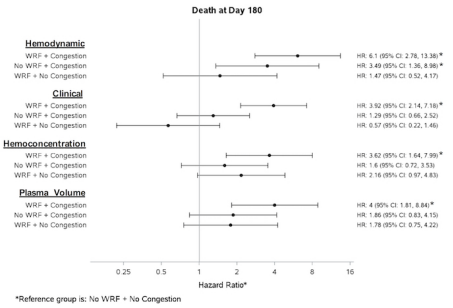

Figure: Adjusted 180 day all-cause death stratified different measures of congestion/decongestion. Proportional hazards regression analysis adjusting for age, body mass index and sex. * indicates a significant association with reference (No WRF and no Congestion) p<0.01, rest p>0.05. CI=confidence interval, HR=hazard ratio, WRF=worsening renal function.

Neurocognitive deficits in cardiogenic shock are not acutely reversed with haemodynamic optimisation

M R Monique R Robinson[1]; H Khalid[1]; S Alkindi[1]; L Njoroge[1]; T Schwab[1]; M Khayata[1]; GH Oliveira[1]
[1]*University Hospitals Cleveland Medical Center, Cardiology, Division of Heart Failure and Transplantation, Cleveland, United States of America*

Background: Cardiogenic shock (CS) is characterized by altered mentation secondary to poor cardiac output and decreased cerebral perfusion. There is a paucity of data to demonstrate the relationship of haemodynamic (HD) parameters, including cardiac output and index and formal metrics of neurocognitive function (NCF) for patients with CS.

Purpose: Evaluate neurocognition in patients with CS and monitor NCF changes that occur with HD optimisation of CS.
Methods: The Montreal Cognitive Assessment (MoCA) is a validated tool for assessing global and subcategories of NCF (abstract thought, naming, data recall, and orientation). For patients with cardiogenic shock admitted to a specialised heart failure intensive care unit, with a cardiac index of = 2.2 L/min/m2), HD monitoring, and clinical optimisation was undertaken. MoCA assessment was done prior to the inception of standardised medical therapies and daily until HD monitoring was completed.
Results: A total of 21 patients were enrolled: 19% were female, 67% Caucasian, 72% with non- ischaemic cardiomyopathy. One patient had a history of cerebrovascular accident and 3 patients had a history of antecedent depression. Mean left ventricular ejection fraction (LVEF) was 23 ± 16 % , baseline HD assessment demonstrated central venous pressure (CVP) 13 ± 6 mmHg, pulmonary artery systolic pressure (PASP) 53 ± 15 mmHg, pulmonary artery diastolic pressure (PADP) 26 ± 8 mmHg, pulmonary capillary wedge pressure (PCWP) 22 ± 6 mmHg, cardiac output (CO) 3.6 ± 1 L/min, cardiac index (CI) 1.8 ± 0.1 L/min/m2, systemic vascular resistance 1748 ± 547 dynes-sec/cm5 , pulmonary arterial O2 saturation (SvO2): 54 ± 7 %. The average duration of HD monitoring was 2.7 ± 2.4 days. Baseline global MoCA score was 21 ± 4 and there was subnormal performance in each subcategory of NCF. Following medical management for CS, there was statistically significant HD improvement with CVP 13 ± 6 vs. 9 ± 6 mmHg p 0.008, PASP 53 ± 15 vs. 48 ± 15 mmHg p 0.06, PCWP 22 ± 7 vs. 15 ± 6 mmHg p 0.014, CO 3.6 ± 1 vs. 5.2 ± 1.2 L/min p < 0.001, CI 1.8 ± 0.1 vs. 2.6 ± 0.6 p < 0.001
Despite HD improvement, there was no significant difference in MoCA scores 21 ± 4 vs 23 ± 5, p 0.11.
Baseline MoCA scores correlated with baseline SVR (Spearman's rho = 0.6, P = 0.009), but there was no significant correlation between post-optimization hemodynamics and MoCA.
Conclusions: Patients with cardiogenic shock have demonstrable neurocognitive deficits that persist even following acute intensive care haemodynamic optimisation. Future work is required to explore the role that sustained HD stability plays in improving NCF.

2089

Worsening renal function prevalence and risk factors among brazilian patients with decompensated heart failure

On behalf of: Best Clinical Practice in Cardiology (BPC) Program
Funding Acknowledgements: Brazilian Health Ministry (PROADI-SUS), American Heart Association (AHA), Brazilian Society of Cardiology (SBC)

Background: Worsening renal function (WRF) is associated with poorer prognosis in patients admitted with decompensated heart failure (DHF). Little is known about its incidence and risk factors in Brazil.
Purpose: To determine the incidence and risk factors to WRF at discharge among patients included in the Best Clinical Practice in Cardiology Program (BPC).
Methods: Longitudinal prospective study. Patients admitted for DHF between February 14, 2016 and December 24, 2017, in 15 centres throughout Brazil, were included in the study. WRF was defined as an absolute increase of = 0.3mg/dL in serum creatinine (SCr) between admission and discharge. Uni- and multivariate analyses were performed to identify WRF risk factors.
Results: 807 were included in the BPC Program, 11(5.3%) were under HD, 75(9.3%) died during the hospitalization and 64(7.9%) missed admission or discharge SCr measurements and were excluded from analysis. Data from the remaining 657 patients showed that 58.1% were male; with mean age of 59.7 +/- 14.5 years, 21.9% ischemic aetiology with a median ejection fraction of 33.0 %(25.0-48.0%). WRF incidence was 20.2%. It was associated with diabetes mellitus (46.3 x 35.9, p 0.034), previous use of hydralazine (15.0 x 9.2%, p 0.047), nitrates (23.3 x 13.7, p 0.007) or loop diuretics (78.2 x 68.5, p 0.033), haemoglobin (12.2 x 12.9mg/dL, p0,003), SCr (1.21 x 1.27, p < 0.0001), systolic (121 x 117mmHg, p0,009) and diastolic (80x70mmHg, p 0.033) blood pressure at admission, in univariate analysis. In multivariate analysis only previous use of loop diuretics remained associated with WRF (p 0.049). The WRF group had a longer length of stay 19 (9-32) x 15 (8-30) days (p 0,047). Conclusion: Previous use of loop diuretics was the only risk factor identified for WRF. Patients discharged with WRF had a longer hospital stay.

Relationship between changes in brain natriuretic peptide and worsening renal functions in acute heart failure

Y Horiuchi[1]; N Wettersten[1]; P Murray[2]; A Maisel[1]
[1]University of California San Diego, Division of Cardiovascular Medicine, San Diego, United States of America; [2]University College Dublin, Department of Nephrology, Dublin, Ireland

Funding Acknowledgements: Abbott Laboratories and Alere, Inc.

Background: In acute heart failure (AHF), relationships between changes in brain natriuretic peptide (BNP) and worsening renal function (WRF) and its prognostic implications have yet to be fully determined.
Purpose: We aimed to investigate the prognostic value of WRF in relation to changes in BNP.
Methods: The Acute Kidney Injury NGAL Evaluation of Symptomatic heart failure Study (AKINESIS) was a prospective, international, multicenter study of AHF patients. We analyzed the relationship between a decrease in BNP and WRF in relation to in-hospital and 1-year mortality. Severe WRF was a sustained increase of = 0.5 mg/dl or = 50% in creatinine and non-severe WRF was a non-sustained increase of = 0.3 mg/dl or = 50%. WRF with clinical deterioration was non-severe WRF with renal replacement therapy, inotrope use or mechanical ventilation. Decreased BNP was defined as a = 30% reduction in the last measured BNP compared to admission BNP.
Results: Among 814 patients, the incidence of WRF was not different between patients with or without decreased BNP (non-severe WRF, 33% vs. 31%, p = 0.549; severe WRF, 11% vs. 9%, p = 0.551; WRF with clinical deterioration, 8% vs. 10%, p = 0.425). Decreased BNP was associated with better in-hospital and 1-year mortality regardless of WRF, while WRF was associated with worse outcomes only in patients without decreased BNP (Table 1 and Figure 1). In multivariate Cox regression analysis, decreased BNP, severe WRF, and WRF with clinical deterioration were significantly associated with 1-year mortality.
Conclusions: Decreased BNP was associated with better in-hospital and long-term outcomes. WRF was only associated with adverse outcomes in patients without decreased BNP.

Table 1. In-hospital mortality

	non-severe WRF (+)	non-severe WRF (-)
Decreased BNP	0%	1%
Non-decreased BNP	13%	3%
	severe WRF (+)	severe WRF (-)
Decreased BNP	0%	1%
Non-decreased BNP	22%	5%
	WRF with clinical deterioration (+)	WRF with clinical deterioration (-)
Decreased BNP	0%	1%
Non-decreased BNP	30%	4%

BNP, brain natriuretic peptide; WRF, worsening renal function

Clinical characteristics and in-hospital outcomes of elderly patients with acute heart failure admitted to different settings of care: data from the ATHENA registry

A Herbst[1]; F Orso[1]; A Pratesi[1]; G Biagioni[1]; F Fedeli[1]; S Parlapiano[1]; C Ghiara[1]; A Lo Forte[1]; G Ciuti[2]; C Tozzetti[2]; F Bacci[2]; M Di Bari[1]; N Marchionni[3]; A Ungar[1]; S Baldasseroni[1]

[1]Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy; *[2]Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; *[3]Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: ATHENA Study group

Background: Acute heart failure (AHF) is a common disease that typically affects the elderly. Clinical registries should represent the so-called "real world", however, HF registries may maintain a certain level of selection bias by including only patients hospitalised in cardiology wards. Administrative data show that only a minority of these patients (about a quarter) is hospitalised in cardiology units, with the majority being admitted to internal medicine and geriatric settings of care.
Purpose: to compare the clinical characteristics and in-hospital prognosis of elderly patients hospitalised for AHF in the settings of care of usual management: cardiology, internal medicine and geriatrics.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (= 65 years) admitted with diagnosis of AHF (worsening or de novo) to the Emergency department (ED) of a tertiary University teaching-hospital and transferred to the above described settings of care in the period 01.12.2014-01.12.2015.
Results: 401 patients composed the study population; 15.2% were hospitalised in cardiology, 14.7% in geriatrics and 70.1% in internal medicine. Mean age was 83.5 years, resulting higher in geriatrics (86.9 years) versus internal medicine (83.4 years) and cardiology (81.0 years), P = 0.001. Females were 52.6%: 55.7% in cardiology, 52.7% in internal medicine and 49.2% in Geriatrics (P = 0.770). Patients with HFpEF were 47.4% and were hospitalised less frequently in Cardiology (36.8%) compared to geriatrics (55.1%) and internal medicine (48.6), P = 0.147. In-hospital mortality was 8.9% and it was higher in geriatrics (18.6%) compared to cardiology (14.8%) and internal medicine (5.7%), (P = 0.002). Independent predictors of in-hospital mortality were evaluated using multivariate analysis adjusting for age, gender and comorbitidies (Charlson comorbidity score). Barthel index (an index of functional status) (OR 0.98, 95%CI 0.97-1.00, p = 0.028), systolic blood pressure in the emergency department (OR 0.96, CI = 0.93-0.99, p = 0.014), cognitive impairment (OR 5.33, CI = 1.16-24.40, p = 0.031) and the setting of care were found to be correlated with in-hospital mortality. Particularly, a protective correlation could be observed with the admission to cardiological setting of care (geriatrics vs cardiology OR 13.23, 95%CI 1.80-97.07, p = 0.011; internal medicine vs cardiology OR 12.32; 95%CI 2.25-67.54).
Conclusions: elderly patients with AHF differ significantly in terms of clinical characteristics and in-hospital prognosis according to the different settings of care. In this population in-hospital mortality seems to be correlated with clinical variables already known to impact prognosis, but also with typical geriatric variables such as functional status and cognitive impairment and with setting of care of assignment after the emergency department, with a protective effect of management in cardiological settings.

2092

Relationship between sleep-disordered breathing or its treatment and post-discharge outcomes in patients hospitalized due to acute decompensated heart failure

H Matsumoto[1]; T Kasai[1]; S Suda[1]; A Murata[2]; S Yatsu[2]; M Shimizu[2]; J Shitara[2]; T Kato[2]; M Hiki[2]; H Daida[2]

[1]Juntendo University School of Medicine, Department of Cardiovascular Medicine, Cardiovascular Respiratory Sleep Medicine, Tokyo, Japan; *[2]Juntendo University School of Medicine, Department of Cardiovascular Medicine, Tokyo, Japan*

Funding Acknowledgements: Resmed, Philips-Respironics, Fukuda-Denshi

Introduction: In patients hospitalized due to acute decompensated heart failure (ADHF), Residual risk for worse post-discharge clinical outcomes remains to be clarified. However, limited data regarding influence of sleep-disordered breathing (SDB) and its treatment by positive airway pressure (PAP) on post-discharge clinical outcomes in patients hospitalized due to ADHF are available.
Hypothesis: In patients hospitalized due to ADHF, presence of SDB is associated with worse post-discharge clinical outcomes, which can be reversed by PAP therapy.
Methods: After the initial improvement of ADHF, overnight polysomnography was performed on consecutive hospitalized patients whose left ventricular ejection fraction (LVEF) = 45% between May 2012 and December 2014. SDB was defined as an apnea-hypopnea index = 15. Patients with SDB were subdivided into those with or without PAP treatment. The risk for composite of all-cause mortality and readmission were assessed by stepwise multivariable Cox proportional model.
Results: Overall, 114 patients including 76 with SDB (28 with PAP treatment) and 38 without SDB were enrolled. At a median follow-up of 6.8 months, 44 patients had clinical events (39%). In the stepwise multivariable analysis, SDB was associated with increased risk of clinical events (hazard ratio [HR], 3.41; P = 0.005). Among SDB patients, stepwise multivariable analysis showed that PAP treatment was associated with reduced risk of clinical events (HR 0.37; P = 0.027).
Conclusion: In patients with reduced LVEF hospitalized due to ADHF, presence of SDB affected post-discharge clinical outcomes adversely, which may be reversible by PAP therapy. Thus, following ADHF, hospitalized patients with reduced LVEF should be evaluated for SDB and considered for SDB treatment prior to discharge.

Identification of a novel LAMP2 gene variant: key role of genetic testing in the diagnosis of Danon disease

V Novelli[1]; A Bisignani[2]; G Pelargonio[2]; G Primiano[3]; FD Tiziano[4]; P Zeppilli[5]; S Servidei[3]; F Crea[2]; MG Genuardi[4]
[1]Polyclinic Agostino Gemelli, Centro Benito Stirpe per la morte improvvisa del Giovane Atleta- Institute of Genomic Medicine, Rome, Italy; *[2]Polyclinic Agostino Gemelli, Polo di Scienze Cardiovascolari e Toraciche, Rome, Italy*; *[3]Polyclinic Agostino Gemelli, Department of Neurology, Rome, Italy*; *[4]Catholic University of the Sacred Heart, Institute of Genomic Medicine, Rome, Italy*; *[5]Catholic University of the Sacred Heart, Institute of Sport Medicine, Rome, Italy*

Danon disease (OMIM 300257) is an X-linked lysosomal storage disorder, characterized by hypertrophic cardiomyopathy (HCM), skeletal myopathy and variable intellectual disability. This condition accounts for ~ 4% of HCM patients, affecting both genders, with a severe and early onset phenotype in males. Genetic variants in LAMP2 gene are the main cause of this fatal condition. Here, we describe a novel LAMP2 pathogenic variant, demonstrating the utility of including this gene in the HCM genetic testing.
A 16-year-old male, with a family history of sudden cardiac death (SCD), was referred to our center with a diagnosis of HCM of one year ago when he was admitted for palpitations in a secondary hospital. His mother died for suspected post partum dilated cardiomyopathy (DCM) when she was 24 years old. Upon admission to our institution, the patient was symptomatic for palpitations, with evidence of biventricular hypertrophy on the echo and atrial tachycardia during ECG monitoring. Neurological examination revealed mild intellectual disability, mild weakness of distal upper and lower limb muscles and bilateral pes cavus. Because the phenotype was unclear, suggesting an early onset HCM, with a suspected family history of SCD, genetic testing was performed. A custom HCM sequencing panel including 12 genes associated with HCM and related phenotypes was adopted.
Results of the genetic testing showed a novel hemizygous 1 bp deletion, c.453delT, in LAMP2.
These results have rapidly driven the clinics through the diagnosis of Danon disease. Further analysis, including muscle biopsy (Figure 1), confirmed the diagnosis of this fatal condition, providing the indication for a heart transplant.
In conclusion, this case highlights the clinical utility of genetic testing in the differential diagnosis of conditions in the spectrum of HCM, suggesting the importance of including the LAMP2 gene in targeted NGS panels used for genetic diagnosis of HCM.

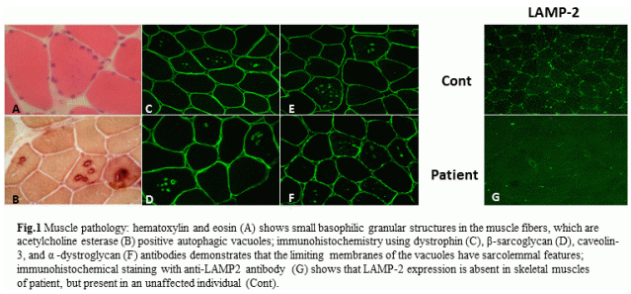

Fig.1 Muscle pathology: hematoxylin and eosin (A) shows small basophilic granular structures in the muscle fibers, which are acetylcholine esterase (B) positive autophagic vacuoles; immunohistochemistry using dystrophin (C), β-sarcoglycan (D), caveolin-3, and α -dystroglycan (F) antibodies demonstrates that the limiting membranes of the vacuoles have sarcolemmal features; immunohistochemical staining with anti-LAMP2 antibody (G) shows that LAMP-2 expression is absent in skeletal muscles of patient, but present in an unaffected individual (Cont).

Hypertrophic obstructive cardiomyopathy: a disguise for fabry disease?

S Sebatian Militaru[1]; R Adam[1]; R Trambitasu[2]; A Munteanu[1]; A Dulamea[3]; E Rusu[3]; R Jurcut[1]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; *[2]County Emergency Hospital of Brasov, Brasov, Romania*; *[3]Fundeni Clinical Institute, Bucharest, Romania*

Hypertrophic cardiomyopathy can be the expression of many etiologies, called phenocopies, and identifying and differentiating them can be a challenge.
We present the case of a 49 year-old patient, with perioral angiokeratoma, acroparesthesia, a history of cryptogenic stroke and obstructive HCM (diagnosed 6 years prior), who was referred to our center for cardiac evaluation. Family history included: a sister deceased at 54 while on dialysis, who's eldest son also died at age 27 while on dialysis.
Lab work-up showed slight renal dysfunction (small proteinuria, normal creatinine), and above normal levels of Troponin I (0.024 ng/ml) at resting state. The ECG showed sinus rhythm, LVH, short PR interval (~120 ms), without a delta wave. Echographic evaluation: concentric LVH, papillary muscle hypertrophy, normal systolic function, longitudinal dysfunction and a gradient of 48 mmHg in the LV ejection tract in Valsalva at rest. Ophthalmologic evaluation showed cornea verticillata, a FD specific sign. The patient was tested with genetic and enzymatic tests of Fabry disease, which confirmed the diagnosis: a heterozygote pathogenic mutation of the GLA gene was detected (c.[797A>C](p.[Asp266Ala]), aGal levels of 1,2 μmol/L/h (cut-off > 1,2 μmol/L/h) and Lyso-Gb3 level of 6,3 ng/mL (cut-off 0 - 3,5 ng/mL). During family screening, the patient's son was evaluated clinically, ECG and echocardiographicaly, and showed no cardiac involvement, but had angiokeratoma, acroparesthesia and anhydrosis, mild renal involvement and aGal level of 0. The second son of the patients sister was also found by family screening to have chronic kidney disease with creatinine levels of 2.3 mg/dl and proteinuria, and a confirmed diagnosis of FD. The patient, her son and her nephew all began enzyme replacement therapy, which can improve their life expectancy.
The main problem illustrated by this case is the importance of differential diagnosis in cardiomyopathies, as it has been proven that early enzyme treatment in Fabry disease can stop or slow disease pregression.
Fabry disease diagnosis can be suspected using clinical and paraclinical "red flags", in the present case these are: history of stroke at a young age, family history of renal failure, angiokeratoma, acroparesthesia, short PR, slightly high troponin level, proteinuria, concentric LVH with papillary muscle hypertrophy. Correct diagnosis of a phenocopy of HCM can save or prolong the life of FD pts by starting enzyme therapy, especially when accompanied by careful family screening.

Perioral angiokeratoma

Introduction: and case report: Left ventricular hypertrophy (LVH) unrelated to pressure overload leads to a first diagnosis of hypertrophic cardiomyopathy (HCM), but carefully putting together the puzzle of clinical picture, family history, electrocardiography and multimodality imaging can point further, revealing the path to the right diagnosis and therapeutic approach.
We present the case of a 49 years old female who presented to our clinic complaining of exertion dyspnea and palpitations in the last year. The patient has also been complaining of distal paresthesia for the last 5 years. From her family history we retain the mother who died at 49 years old after progressive severe loss of mobility and 4 maternal uncles with neuropathy.
The ECG showed sinus rhythm, low voltage in limb leads and trifascicular block (Ist degree AV block, LAFB, RBBB). Echocardiography revealed non obstructing HCM with maximal wall thickness of 16 mm, preserved left ventricular (LV) ejection fraction (50%), restrictive pattern of diastolic dysfunction, severely decreased wall motion velocities, LV global longitudinal strain -12.1%, with apical sparring. Biologically: BNP 141 pg/ml, normal creatinine and plasma protein electrophoresis and immunofixation. The 99Tc-HDP nuclear scan showed moderate late cardiac enhancement suggesting TTR amyloidosis. The PCR genetic test was positive for the mutation Glu54Gln (GAG-CAG) on the Third exon of TTR gene, a mutation known as specific to the Romanian population.
Discussion: Behind the diagnosis of HCM can sit either sarcomeric forms, or a large variety of metabolic or other genetic or non-genetic disorders. Sometimes, finding the right diagnosis leads to specific therapeutic possibilities. Genetic TTR amyloidosis is a differential diagnosis to AL amyloidosis and wild-type, senile amyloidosis. Red flags which led to diagnosing this phenocopy of HCM were LVH combined with low voltage and conduction disturbances on ECG, apical sparing on LV longitudinal strain map and finally cardiac enhancement at 99Tc-HDP nuclear scan, all in association with neurological symptoms in the patient and the family. Comparing to AL amyloidosis without treatment, TTR amyloidosis carries out a better outcome, but often progresses to intractable heart failure and death due to systolic heart failure or dysrhythmia. Not all cases present cardiac involvement, most patients having only neurological symptoms (also depending on the exact mutation - interestingly, our patient has a region-specific genetic variant). Several therapeutic options exist for TTR amyloidosis, some are still under development.
Conclusion: The present case illustrates how a red flag approach including multimodality imaging, combined with inter-specialist collaboration can lead to the right diagnosis.

Funding Acknowledgements: GINOP-2.3.2-15-2016-00039

Hypertrophic cardiomyopathy (HCM) is a primary myocardial disease typically caused by gene mutations encoding proteins of the cardiac sarcomere. HCM-like phenocopies, e.g. the cardiac manifestation of Fabry disease, make differential diagnosis of HCM cases particularly challenging.
In this case report we describe the detailed genetic analysis of a female patient with a HCM phenotype. At first presentation, the 49 years old female patient complained permanent chest pain, shortness of breath and very low exercise capacity. Cardiac evaluation proved hypertrophic cardiomyopathy with severe asymmetric left ventricular hypertrophy (LV max at the anterior septum: LVmax: 27 mm), without left ventricular outflow tract obstruction. During regular follow up, the patient had no episodes of cardiac decompensation, however echocardiography revealed grade II. diastolic dysfunction with a maximum NTpBNP level of 244 pg/ml. Cardiac MRI confirmed increased left ventricular mass (LVM: 169 g) and the significant hypertrophy of the anterior septum in the basal and mid segment. Though the patient had no dermatological, ophthalmological, audiological and renal symptoms; electroneurography indicated low-grade polyneuropathy. Based on this, genetic screening was performed for Fabry disease, which revealed a c.376A>G (p.Ser126Gly) pathogenic mutation in the GLA gene. Levels of lysoGb3 (= 1,8 ng/ml) was repeatedly in the normal range. In order to prove the cardiac involvement of Fabry disease unequivocally, myocardial biopsy was performed, which did not show histological evidence of Fabry disease. Subsequently, extended screening of 103 cardiomyopathy genes with next generation sequencing proved a most likely pathogenic frameshift mutation, p.Ala1056fs, of the MYBPC3 gene.
Based on the above findings, it is probable that hypertrophic cardiomyopathy was due to the MYBPC3 sarcomere gene mutation and not the cardiac manifestation of Fabry disease in this case.

Double silent threat- case report of asymptomatic patient with cardiac transthyretin amyloidosis and multivessel coronary artery disease

M Monika Gawor[1]; M Franaszczyk[2]; M Spiewak[3]; B Milosz-Wieczorek[3]; M Marczak[3]; M Opolski[4]; Z Bilinska[5]; J Grzybowski[1]
[1]Institute of Cardiology, Department of Cardiomyopathies, Warsaw, Poland; *[2]Institute of Cardiology, Department of Medical Biology, Warsaw, Poland*; *[3]Institute of Cardiology, CMR Unit, Warsaw, Poland*; *[4]Institute of Cardiology, Department of Interventional Cardiology and Angiology, Warsaw, Poland*; *[5]Institute of Cardiology, Unit for Screening Studies in Inherited Cardiovascular Diseases, Warsaw, Poland*

A 49-year-old male was referred to our institution for further evaluation because of abnormalities in the standard 12-lead electrocardiogram (ECG). The patient suffered from recurrent rhinitis due to deviated nasal septum- ECG was performed in preparation for septoplasty. Otherwise, he was completely asymptomatic, without fatigue, exertional dyspnoea, chest pain or syncope.
On physical examination the patient was normotensive, lungs were clear on auscultation, the liver was not enlarged, jugular veins were normal, there was no oedema of lower extremities. The baseline level of NT-proBNP was 925,8 (range 0-125) pg/mL, and hs-cTnT was 38.2 (range 0-14) ng/L. No significant pathology was present on chest X-ray. ECG demonstrated sinus rhythm with low QRS voltage in the limb leads and nonspecific ST-T wave changes (Fig. 1A). Echocardiography revealed concentric hypertrophy of left ventricle (LV) with a maximal wall thickness of 16 mm at interventricular septum. Posterior wall diameter was 14 mm. Left atrial anterior-posterior diameter was 42 mm. Cardiac magnetic resonance (CMR) scan confirmed the presence of concentric LV hypertrophy with a maximal wall thickness of 16 mm and increased myocardial mass indexed for the body surface area (LV mass index [LVMI] 101 g/m2, range 58-91). Systolic function of the LV was decreased with EF 40%. The right ventricular function was in normal range. Moreover, diffuse subendocardial areas of late gadolinium enhancement (LGE) was found. Results of CMR suggested cardiac amyloidosis (Fig. 1B).
Coronary computed tomography angiography showed chronic total occlusion in the middle segments of the right coronary artery (RCA). Moreover stenosis in the left main coronary artery, in the middle segments of the left anterior descending artery (LAD), in the proximal segments of the first diagonal branch and in the proximal segments of the left marginal artery were detected. Patient underwent invasive coronary angiography with fractional flow reserve (FFR) evaluation. Only stenosis in the LAD was identify hemodynamically relevant (FFR = 0.77). Percutaneous coronary intervention using drug eluting stents was performed for occlusion in RCA and for stenosis in LAD (Fig. 1C, 1D). Endomyocardial biopsy was also performed. Transthyretin (TTR)-related amyloid deposits was detected. Genetic analysis revealed Phe33Leu mutation in the TTR gene. Neurological and haematological examination revealed no abnormalities. Patient was referred to the liver transplantation.
The case we describe underscores the importance of ECG as a screening tool in cardiology. Our patient would not have underwent the whole diagnostic process that led to such fatal discovery, unless ECG had been performed in the first place. Although several months after diagnosis patient was still completely asymptomatic, with good exercise tolerance during ECG exercise testing, follow-up showed further deterioration of LV function and increase in NT-proBNP and hs-cTnT levels.

Surgical treatment of hypertrophic obstructive cardiomyopathy in a patient with prior alcohol septal ablation and artificial cardiac pacemaker

K Rudenko[1]; V Lazoryshynets[1]; L Nevmerzhytska[1]; P Danchenko[2]
[1]*Amosov Institute of Cardiovascular Surgery AMS of Ukraine, Kiev, Ukraine*;
[2]*National O.O. Bohomolets Medical University, Kiev, Ukraine*

Introduction: 18-year-old female patient, hospitalized on 07.08.2017, and presented with complaints on chest pain at rest, exertional dyspnea, periodic attacks of palpitations, limited physical activity, and dizziness.
Instrumental examination data were the following:
- TTE: Hypertrophic obstructive cardiomyopathy (HOCM), systolic pressure gradient (SPG) = 80 mm Hg. Systolic anterior motion of the anterior leaflet of the mitral valve. EDV = 59 ml; ESV = 22 ml; SO = 37 ml; EF = 62%. IVS: basal part = 2 cm; medial part = 1,0 cm.
- Coronaroventriculography: Intramural passage of the mid-third of LAD LCA with 50-70% systolic compression.
- Heart CT: Asymmetric hypertrophy of LV myocardium (width = 20 mm, length = 125 mm). Significant trabecularity of the anterior wall of the LV myocardium (non-compacted myocardium).
- ECG: Sinus rhythm, HR = 67/min, singular ventricular extrasystoles. Complete right His bundle branch block.
The following diagnosis was established: hypertrophic cardiomyopathy, obstructive form, mild mitral valve regurgitation, initial stage of pulmonary hypertension, state after implantation of artificial cardiac pacemaker, state after alcohol septal ablation, heart failure, functional capacity III, objective assessment B (NYHA). On 16.08.2017 there was conducted a surgical treatment. The extent of surgical intervention included: extended superficial myectomy of interventricular septum (0,5 cm ? 1,0 cm ? 1,0 cm), resection of 5 secondary chordae of the anterior leaflet of the mitral valve, mobilization of the anterior and posterior groups of papillary muscles of the mitral valve (applying approach of professor P. Ferrazzi, Monza, Italy), LAD LCA debridging, plastic of P2 segment of the posterior leaflet of the mitral valve with transseptal approach. Intraoperative TEE showed no clinically significant SPG on LVOT and mitral valve (SPG = 20 mm Hg, mild mitral valve regurgitation).
In post-operative period patient received antibacterial, antiarrhythmic, antianginal, antihypertensive, and anticoagulation therapy. Follow-up examination in 10 days showed decrease of the degree of mitral regurgitation (SPG = 28 mm Hg) and absense of systolic compression of LAD LCA. On 26.12.2017 there was performed an extraction of the artificial cardiac pacemaker and implanted a dual chamber ICD for the purpose of prophylaxis of sudden cardiac death.
Summary. Surgical intervention is a "gold standard" of treatment of HOCM. Performance of extended superficial myectomy of the IVS with resection of secondary chordae of the anterior leaflet of the mitral valve followed by mobilization of the anterior and posterior groups of papillary muscles of the mitral valve (applying approach of professor P. Ferrazzi, Monza, Italy) is the most optimal choice for definitive repair of this pathology. Debridging can be successfully performed in patients with obstructive form of hypertrophic cardiomyopathy in case of LAD LCA systolic compression.

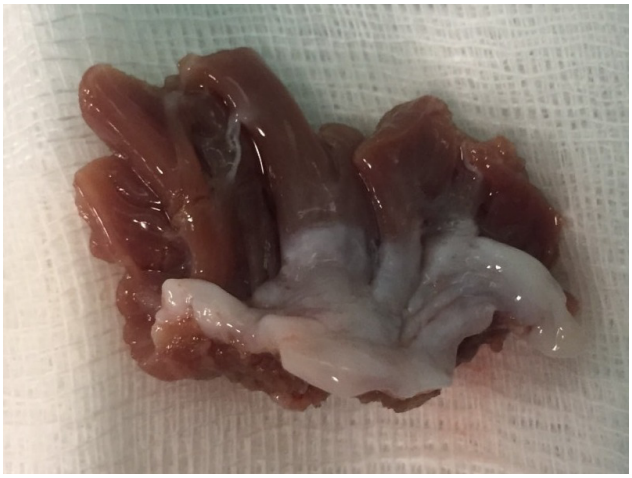

Fig. 1. A part of resected myocardium

Shortness of breath: a common presentation of an uncommon form of cardiac amyloidosis

X Xin Zhang[1]; A Jaffe[1]
[1]*Mayo Clinic, Rochester, United States of America*

Introduction: Dyspnea is a common initial complaint in the cardiologist's office. We present a case of cardiac amyloidosis presenting as isolated dyspnea in an elderly man.
Case Presentation: An 84-year-old man presented to cardiology clinic for one year of progressive dyspnea on exertion without other associated symptoms. His past medical history was notable for coronary artery bypass grafting (CABG) in 2007. Physical exam revealed a blood pressure of 161/78, heart rate 75 bpm at rest, and an oxygen saturation of 96% on room air. After walking 10 feet on flat ground, he became tachycardia to 102 bpm and his oxygen saturation fell modestly to 93%. The remainder of his exam was unremarkable. He demonstrated no signs of valvular heart disease or congestive heart failure by physical examination.
A chest x-ray demonstrated an AV pacemaker and mild cardiomegaly. ECG was consistent with dual chamber pacemaker. Transthoracic echocardiogram (TTE) showed left ventricular ejection fraction of 60 % and thickened left ventricular walls. Left and right coronary angiogram revealed patent bypass grafts.
A technetium Pyrophosphate (PYP) scan was obtained to evaluate for possible transthyretin (TTR) amyloidosis given the patient's advanced age and thickened left ventricular myocardium. PYP scan showed increased uptake in the left ventricular myocardium consistent with TTR cardiac amyloidosis. Furosemide was started for management of volume status. He is currently exploring long term treatment options, including doxycycline /tauroursodeoxycholic acid (TUDCA).
Discussion: Wild type transthyretin cardiac amyloidosis is responsible for sporadic cardiac amyloidosis in the elderly. Also termed "senile amyloidosis," it affects 25-36% of patients older than 80 years although severe symptoms are less common [1]. Consequently, it is less frequently considered as a cause of dyspnea. Presenting symptoms include heart failure, angina, and arrhythmias [1]. While amyloid deposition on histopathology is the gold standard, PYP scan has been shown to have 97% sensitivity and 100% specificity for TTR amyloidosis in some studies [1]. Treatment is currently focused on management of heart failure symptoms, but there are investigational drugs that target TTR production and degradation under study [1] [2].
Conclusion: It is important to consider TTR cardiac amyloidosis in elderly patients who present with unexplained heart failure symptoms. PYP scan is a non-invasive tool for diagnosis and may mitigate the need for a tissue biopsy.

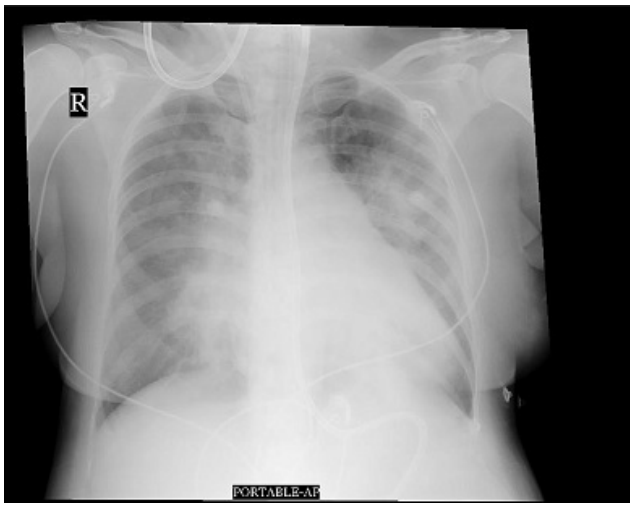
Acute massive pulmonary edema and cardiogenic shock: an unusual presentation of hypertrophic obstructive cardiomyopathy

VIPIN Mughilassery Thomas[1]; IJAZ Majeed[1]; FAHD El Sayed[1]; DOAA Elkholy[1]
[1]*Al Ain Hospital, Cardiology, Al Ain, United Arab Emirates*

Case Summary: This 58- year-old female known to have some cardiac disease was transferred from a peripheral hospital in acute pulmonary edema and cardiogenic shock. She was intubated and mechanically ventilated following respiratory failure. She presented there with history suggestive of respiratory infection of one week followed by progressive shortness of breath of two days duration. She received

intravenous Furosemide and was on Dopamine infusion from the referring hospital. But her condition deteriorated and hence shifted to our Center. On arrival in the ER, her Blood Pressure was 77/48 mm Hg and Chest x-ray showed massive pulmonary edema. ECG showed left ventricular hypertrophy(LVH) with strain pattern. Her WBC count and CRP were elevated.Trans Thoracic Echo demonstrated severe concentric LVH with asymmetrical septal hypertrophy (ASH), severe left ventricular outflow tract (LVOT) obstruction with peak gradient of 100 mmHg, small LV cavity and systolic anterior motion (SAM) of mitral valve with severe MR. LV systolic function was normal with impaired LV relaxation. Patient was admitted to ICU. She was on Dopamine and Nor-epinephrine Infusion but remained resistant to treatment. Both medications were discontinued and started her on Phenylephrine Infusion. Intravenous Furosemide and fluids were administered judiciously. In order to relieve the dynamic LVOT obstruction, Esmolol bolus and infusion were started and overlapped with oral beta blocker therapy. Subsequently her condition improved and repeat Echocardiography showed marked reduction in LVOT gradient and MR. Her coronary angiography was normal. Patient had a protracted course of illness due to cardiogenic shock leading to multi-organ involvement but she recovered over a period of time and underwent Trans-Mitral Surgical Myectomy and Mitral Valve repair following cardiac MRI.



Conclusion: This unusual case illustrates the complex hemodynamics and challenging management of HOCM presenting with acute pulmonary edema and cardiogenic shock. LVOT obstruction in HOCM is dynamic and the degree of obstruction depends more on cardiac contractility and loading conditions.Decrease in LV preload and augmentation of myocardial contractility increase the LVOT obstruction. Usual inotropes and vasopressors are contraindicated in such situation with the exception of Phenylephrine. Betablocker and Phenylephrine increase the ventricular volume and decrease the LVOT obstruction. Patient was resistant to treatment with standard medical therapy and the use of beta blocker and Phenylephrine helped to reduce the LVOT gradient and improve the condition of the patient.

Hypertrophic cardiomyopathy or light chain cardiac amyloidosis?

A Ntalianis[1]; E Repasos[1]; E Tseliou[1]; E Kastritis[1]; D Ziogas[1]; E Papadopoulou[1]; M Tselegkidi[1]; Z Tsoumani[1]; A Koutsoukis[1]; N Makris[1]; I Stamoulopoulos[1]; A Cohen[1]; MA Dimopoulos[1]; S Toumanidiss[1]; I Paraskevaidis[1]
[1]*University of Athens Medical School, Dept of Clinical Therapeutics, Alexandra Hospital, Athens, Greece*

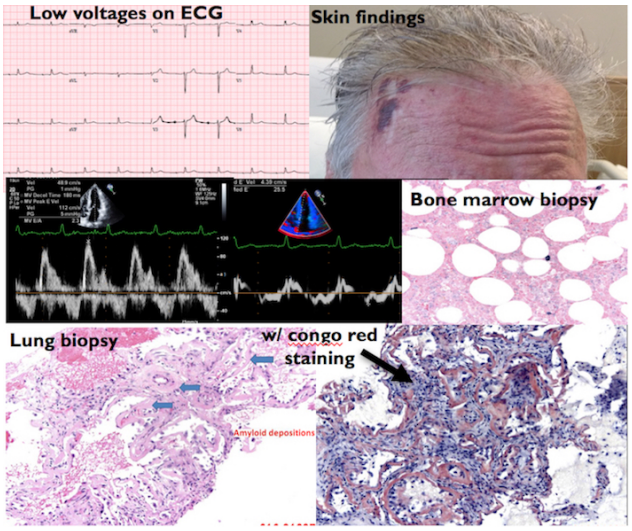
A 54 year old female with a history of hypertrophic cardiomyopathy, thrombopenia and transient ischemic attack presents in the outpatient heart failure clinic because of deteriorating shortness of breath the last 6 months. Her ECG showed LV hypertrophy, her chest X-ray right pleural effusion, NT-proBNP was measured at 5852 pg/mL, hemoglobin at 12.3 mg/dL and heart echo showed a sparkling hypertrophic interventricular septum (22 mm) with left ventricular outflow tract obstruction (with a peak gradient of 101 mmHg) and right ventricular hypertrophy. Protein immunoelectrophoresis showed an increase of IgM ?. Fat and bone marrow biopsy revealed amyloid deposits. The suspicion for cardiac amyloidosis with pre-existing hypertrophic cardiomyopathy was raised but cardiac MRI was non-diagnostic. Heart biopsy was finally decided which showed hypertrophic cardiomyopathy and the patient was finally and successfully submitted to surgical myectomy.

2101

Piecing out the puzzle of AL amyloidosis

PP Poorna Pushkala Natarajan[1]; MT Slawsky[1]; J Hernandez-Montfort[1]
[1]*Baystate Medical Center, Cardiology - Advanced heart disease, Springfield, United States of America*

A 66 year old male with type 1 diabetes, coronary artery disease status (CAD) post stenting of left anterior descending artery in 2010 and B/L carpal tunnel surgery presented with chills, drenching sweats and shortness of breath (SOB) at rest. On further history, his SOB had progressed gradually over 2 years from class I then to class IV with associated fatigue and lower extremity weakness. Workup over 1.5 years including stress echo, lower extremity doppler and lumbar spine MRI were normal. In the interim 2 years between initial onset of SOB and current presentation, he developed orthostasis and hypotension leading to discontinuation of anti hypertensives. Hypoglycemic episodes became frequent and was attributed to long standing autonomic neuropathy from diabetes. Atrial fibrillation was diagnosed and symptomatic junctional bradycardia led to pacemaker placement. He endorsed easy bruising and spontaneous cutaneous bleeding thought to be from sun exposure. During his current admission, he was treated for pneumonia without improvement.



Amyloid Echo and Histology

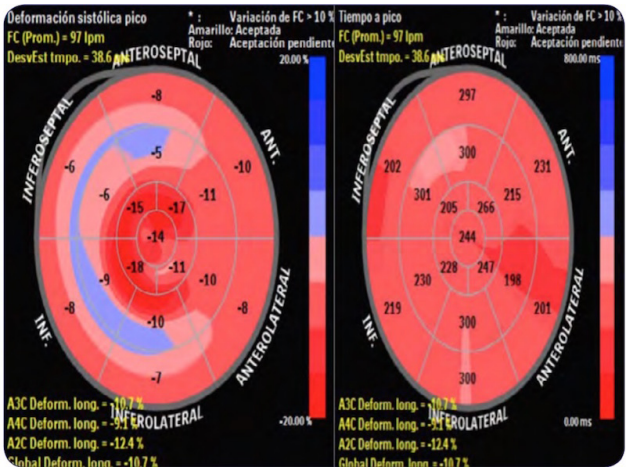
On exam, he appeared ill with Kussmauls sign, bibasilar crackles and lower extremity edema. Labs revealed CKD, and disproportionately elevated NT Pro BNP at 25184 pg/ml. Electrocardiogram (ECG) had low voltage complexes. Echo showed mild concentric left ventricular hypertrophy, preserved ejection fraction, Grade III diastolic dysfunction and low e' velocity (4 m/s). Chest CT showed ground glass opacities that were biopsied, which revealed amyloid deposition in alveolar septa. Kappa fraction of free light chain was elevated with kappa/lambda ratio of 52.95. 99mTc PYP scanning was negative. Bone marrow biopsy showed 15% plasma cells and 14 : 16 translocation. A diagnosis of AL amyloidosis was made. Diuresis and chemotherapy with bortezomib was initiated. Renal function worsened with proteinuria, and kidney biopsy showed amyloid casts. He underwent plasmapheresis. Patient deteriorated quickly and ultimately succumbed to this disease.
Amyloidosis results from extracellular deposition of amyloid fibrils which are misfolded precursor proteins with proteolytic resistant beta pleated sheet configuration. The prognosis is determined by the organ involved and type of amyloid. It is increasingly recognized that up to 13 % of heart failure with preserved ejection fraction cases are misdiagnosed cardiac amyloidosis. AL amyloidosis most commonly affects the kidneys, but 60 % of cases can involve the heart. In our patient, despite classical features such as carpal tunnel syndrome, orthostasis, low voltage on ECG, heart block, autonomic neuropathy and progressive dyspnea, diagnosis was delayed due to the symptoms of amyloid being shared by type I diabetes and preexisting CAD. This emphasizes the importance of unbiased evaluation of clinical presentation, attention to subtle clinical and non cardiac clues, education among cardiologists since early referrals and diagnosis can improve the prognosis of the disease.

2102

Cardiac amyloidosis

D David Gonzalez Calle[1]; P Luengo Mondejar[1]; E Villacorta Arguelles[1]; M Sanchez Ledesma[1]; A Elvira Laffond[1]; M Lopez Serna[1]; A Barrio Rodriguez[1]; I Cruz Gonzalez[1]; PLM Sanchez Fernandez[1]
[1]*University of Salamanca, Salamanca, Spain*

A previously healthy 43-year-old patient presented to the emergency department he refers progressive dyspnea.
Physical examination suggested systemic congestion. On the electrocardiogram, low voltages were observed, while chest X-ray findings were signs of pulmonary congestion and enlargement of the cardiac silhouette.
With the diagnosis of first episode of congestive heart failure, and a deposit disease being suspected, the patient is admitted to the cardiology department in order to complete the study. Imaging diagnostic tests performed were highly suggestive of deposit disease: on echocardiogram, moderate ventricular hypertrophy, together with a strain pattern and restrictive dysfunction were observed (picture 1), while on cardiac magnetic resonance imaging (cMRI) a late enhancement ring pattern affecting the free wall of the right ventricle was present. Given these results, amyloidosis was the main suspected diagnosis. Therefore, a proteinogram was performed, in which a monoclonal l light chain peak was observed. Bone marrow aspiration confirmed the presence of Multiple Myeloma (15% plasma cells, 94% malignant). A myocardial biopsy was performed, and histologic analysis revealed the presence of extracellular material positive for Congo red stain and apple-green birefringence.



Picture 1

At the moment, with the diagnosis of Multiple Myeloma and AL Amyloidosis, chemotherapy with bortezomib, cyclofosfamide and dexametasone is initiated, considering the possibility of a sequential transplantation (heart and hematopoietic). After beginning chemotherapy, the patient's clinical condition deteriorates, with progressive worsening of his hemodinamic status despite of increasing-dose inotropic support. A intraaortic balloon pump (IABP) is placed, persisting heart failure (INTERMACS 1). It is decided to refer the patient to the reference centre for transplantation. Upon arrival to the transplantation centre, given the patient's clinical situation and progression in spite of inotropic treatment and IABP, bridge therapy with central ventricular assistence (centrimag) is placed. The patient remains hemodinamically stable for two weeks, when cardiac transplantation is performed. After 30 days of hospital admission, the patient is discharged with good medical state. New cycles of chemotherapy were administered, and after six months of treatment, autologous stem cell transplantation was performed, without further complications. Ten months after stem cell transplantation, the patient remains stable and asymptomatic, and is currently being followed in outpatient consultation.
As cardiac amyloidosis is a low-incidence disease, studies performed are series of cases with a small number of patients. However, from our experience -albeit limited-, we deem it necessary to initiate agressive treatment from the beginning, given the poor prognosis of the disease, being cooperation between different professionals essential for the adequate management of the patient.

2103

Cardiac sarcoidosis: don't lose sight of the forest for the trees

S Ng[1]; J Pan[1]
[1]*St Thomas' Hospital, London, United Kingdom*

Sarcoidosis is a systemic non-caseating granulomatous disease of unknown aetiology with an estimated prevalence of 10 - 20 per 100,000 population. Cardiac involvement (cardiac sarcoidosis (CS)) is observed clinically in 5% of patients with systemic sarcoidosis but autopsy studies have reported that subclinical CS is observed in up to 70% of cases. As CS has diverse clinical presentations, its diagnosis can be a major challenge to clinicians.
We describe an anxious but otherwise fit and well 43 year-old African lady who presented with worsening dyspnoea, intermittent palpitations and dizziness. Her admission 12-lead electrocardiogram (ECG) showed fixed T-wave inversions in precordial leads V4-V6 and ST depression in the inferior leads II, III and AVF with non-dynamic serum troponins. Her chest X-ray revealed bilateral hilar lymphadenopathy with reticular shadowing in the right lower zone. She had asymmetric left ventricular hypertrophy of the posterolateral walls with normal ejection fraction and no evidence of LVOT obstruction on an echocardiogram. On the coronary care unit, the patient developed recurrent symptomatic monomorphic ventricular tachycardia (VT) despite commencing intravenous amiodarone. An endomyocardial biopsy revealed non-caseating granuloma confirming cardiac sarcoidosis. The patient had an implantable cardioverter-defibrillator due to poor response to trials of steroids.
This case highlights the dilemma in diagnosing a concurrent presentation of cardiac and pulmonary sarcoidosis. Non-specific symptoms of dyspnoea and palpitations with a suggestive chest X-ray focuses clinicians' on the diagnosis of isolated pulmonary sarcoidosis. This delays initiation of corticosteroids or immunosuppression as spontaneous remission of pulmonary sarcoidosis occurs in 90% of patients. This is further complicated by the rarity of systemic sarcoidosis, especially CS, with more common diagnoses such as pulmonary embolism, myocardial infarction and lower respiratory tract infections considered before cardiac sarcoidosis.
Whilst myocardial involvement with sarcoidosis is more frequent in patients with cardiac symptoms, asymptomatic cardiac involvement is not uncommon. Hence, early and accurate diagnosis of cardiac involvement in sarcoidosis is crucial to prevent associated morbidity and mortality. The diagnosis of CS is often difficult with non-specific ECG and echocardiographic findings. As such, there should be a low index of suspicion for cardiac involvement in all patients with systemic sarcoidosis. Advanced cardiac imaging modalities have an increasingly important role in evaluating for cardiac sarcoidosis. However, the role of advanced imaging in diagnosing and guiding treatment remains unclear. A risk-stratification method is needed to guide therapy and aid decision-making to prevent sudden cardiac death, such as in the case highlighted above, with an ICD implantation.

2104

An unusual clinical presentation of hypertrophic cardiomyopathy

A E Vijiiac[1]; C Iorgulescu[1]; DA Radu[1]; M Guran[1]; M Dorobantu[1]
[1]*Emergency Clinical Hospital Floreasca, Cardiology Department, Bucharest, Romania*

The most frequent, well-studied and fearsome complications of hypertrophic cardiomyopathy (HCM) are complex ventricular arrhythmias, while little data exist on the prevalence of severe cardiac conduction disturbances in patients with HCM. We report the case of a patient whose presentation with symptomatic high grade atrioventricular (AV) block led to the diagnosis of obstructive HCM.
A 51 year-old previously healthy male was admitted for a 48-hour history of near syncope, intense fatigue and dyspnea on minimal exertion. His family history was unremarkable. On physical examination, he had a heart rate of 40 beats/min, a blood pressure of 140/70 mm Hg, a respiratory rate of 25 breaths/min and a soft systolic murmur at the left lower sternal border. His ECG revealed a Mobitz II second degree AV block, with electrical criteria of left ventricular hypertrophy. His echocardiography showed a septal thickness of 18 mm, with a dynamic left ventricular outflow tract (LVOT) gradient (25 mm Hg at rest, 82 mm Hg at the Valsalva maneuver) and systolic anterior motion of both mitral leaflets with severe eccentric mitral regurgitation. Coronary angiogram was normal. A permanent DDD pacemaker was implanted with apical placement of the ventricular lead, with prompt resolution of the patient's symptoms. The follow-up echocardiography showed a decrease of the LVOT gradient to 50 mm Hg.
Proposed mechanisms for AV block in HCM are: fibrosis, necrosis or cystic abnormalities of the conduction system, luminal narrowing of the intramural coronary arteries or iatrogenic complication of septal reduction therapies. Consequently, (pre)syncope in HCM can be explained not only by LVOT obstruction and tachyarrhythmias, but also by bradyarrhythmias. There seems to be a connection between the occurrence of conduction disturbances and certain mutations in HCM, such as PRKAG2 mutation or those leading to neuromuscular disorders or Fabry disease. In our patient, genetic study was not performed because he refused testing. However, he did not have any extracardiac manifestation suggestive of a phenotype consistent with the above-mentioned mutations.

DDD pacing can treat both the outflow obstruction and the AV block. In our patient there was a moderate decrease in LVOT gradient, but as he remained asymptomatic, we decided to optimize the beta-blocker therapy, without referring him for a septal reduction strategy. His clinical course was proof that the mechanism of his symptoms was the conduction disturbance.

While the incidence of malignant arrhythmias in HCM is well established, conduction disturbances may also occur, although far less frequently. Furthermore, this association might prompt to certain mutations, especially when corroborated with specific clinical features. One must keep in mind AV block as a possible cause of sudden death or syncope in patients with HCM. It might be prudent to monitor for the development of abnormal AV conduction in these patients.

Atrial Fibrillation - Epidemiology, Prognosis, Outcome

P2111

Antithrombotic therapy improves long-term prognosis in patients with atrial fibrillation and heart failure -A report from the CHART-2 Study-

T Takashi Shiroto[1]; Y Sakata[1]; K Nochioka[1]; R Abe[1]; T Oikawa[1]; S Kasahara[1]; M Sato[1]; H Aoyanagi[1]; M Miura[1]; J Takahashi[1]; S Miyata[2]; H Shimokawa[1]
[1]Tohoku University Graduate School of Medicine, Department of Cardiovascular Medicine, Sendai, Japan; *[2]Tohoku University Graduate School of Medicine, Department of Evidence-based Cardiovascular Medicine, Sendai, Japan*

On behalf of: The CHART-2 Investigators
Funding Acknowledgements: Japan Agency for Medical Research and Development

Background: Atrial fibrillation (AF) is one of the major comorbidities in patients with heart failure (HF). Antithrombotic agents, especially anticoagulants (ACs), are widely used for AF patients to prevent thromboembolic events including stroke. However, it remains to be fully elucidated whether ACs, anti-platelets (APs), and their combination improve long-term prognosis in AF patients, especially in those with HF.
Purpose: To elucidate whether antithrombotic therapy (ATT) improves long-term prognosis of AF patients.
Methods: Our Chronic Heart Failure Analysis and Registry in the Tohoku District (CHART) -2 Study is a multicenter observational study, enrolling cardiovascular patients with and without HF in Japan (N = 10,219). In the CHART-2 Study, we examined the merits and demerits of the contemporary ATT in 3,221 consecutive AF patients with and without HF.
Results: We divided AF patients into 4 groups based on ATT at enrollment; without ATT (w/o ATT, N = 368), ACs alone (N = 1,073), APs alone (N= 838), and both of them (ACs & APs, N = 942). As compared with w/o ATT group, all other 3 groups had significantly improved all-cause mortality (adjusted hazard ratio (aHR) 0.66, 0.75, and 0.67 for ACs, APs, and ACs & APs, respectively, all $P < 0.05$) and cardiovascular mortality (aHR 0.64, 0.62, and 0.57, respectively, all $P < 0.05$), and the beneficial effects of ATT were noted only in AF patients with HF but not in those without HF (Table).
Conclusions: These results indicate that ATT improves long-term prognosis in AF patients with HF but not in those without HF.

Background: Atrial fibrillation (AF) is the most common arrhythmia in heart failure (HF). AF increases risk of stroke, impairs cardiac function and worsen the outcome of HF pts.
Purpose: of our analysis was to evaluate clinical profile and real-life management strategies in the subgroup of pts with non-valvular (NV) AF w/ or w/o concomitant HF.

Comparison of cardiovascular mortality between AF patients with and without HF
*adjusted with age, BMI, BNP, diabetes mellitus, diastolic BP, diuretics, eGFR, Hb, history of brain disorder and HF, LA dimension, LV dimension, LVEF and NYHA functional class. **adjusted with age, BMI, BNP, diastolic BP, LA dimension, LV dimension, LVEF, eGFR, Hb, history of brain disorder and HF and NYHA functional class. ***adjusted with age, BNP, diabetes mellitus, diuretics, Hb, history of brain disorder, ischemic HF, LV dimension and paroxysmal AF. Abbreviations: ACs, anticoagulants; AF, atrial fibrillation; APs, antiplatelets: ATT, antithrombotic therapy; BMI, body mass index; BNP, brain natriuretic peptide; BP, blood pressure; CI, confidence interval; eGFR, estimated glomerular filtration ratio; Hb, hemoglobin; HF, heart failure; HR, hazard ratio; LA, left atrium; LV, left ventricle; LVEF, left ventricular ejection fraction; NYHA, New York Heart Association.

Methods: All 1975 consecutive pts with NVAF that visited 150 out-patient cardiology clinics during 10 days period were included into national cross-sectional registry.
Results: Subgroup of 587 pts (29.79%) suffered from HF; 146 pts (24.9%) classified as non-ischemic cardiomyopathy (non-iCMP), 411 pts (70%) as ischemic cardiomyopathy (iCMP) and 30 pts (5.1%) w/ other cause. Most NVAF/HF pts had preserved left ventricular ejection fraction (LVEF) = 50% (252 pts; 42.9%), HF group of mid range LVEF 40-49% comprises of 189 pts (32.2%) followed by 114 pts (19.4%) with systolic HF (LVEF <40%; HFrEF). HFrEF was more frequent among pts with non-iCMP compared to iCMP (28.8% vs. 19.5%, p <0.001). DC cardioversion in HF pts was not associated with more TE events when compared to pts w/o HF (12.5% vs. 12.6%), but NYHA = III pts had much more TE events than those with less severe HF (58.3% vs. 22.6%, p = 0.017) irrespective of LVEF. Among NVAF/HF pts, only 4(0.7%) underwent AF ablation and only 15(2.6%) were implanted with ICD/CRTD. All 587 NVAF/HF pts fulfilled ESC 2016 criteria for anticoagulation, but anticoagulants were used in 512 pts (87.2%); Warfarin 216 (36.8%), Dabigatran 116 (19.8%), Rivaroxaban 90 (15.3%), Apixaban 90 (15.3%). Clinical characteristics and outcomes are summarized in table.
Conclusion: HF is important concomitant condition in almost 1/3 of pts with NVAF. Such pts have higher risk of TE as well as bleeding events. Thanks to our real-life analysis it was possible to identify pts at highest risk of adverse outcome and underuse gaps of current AF/HF therapies that have an impact on morbidity and mortality.

P2113
Relevance of device detected atrial arrhythmias in patients with cardiac implantable electronic devices (CIEDs) in a real world scenario.

SHYAM Sasidharan[1]; V V Radhakrishnan[1]; K Sunitha Viswanathan[1]; P N Gupta[1]; A George Koshy[1]
[1]Government Medical College, Thiruvananthapuram, Cardiology, Thiruvananthapuram, India

Introduction: : CIEDs with an atrial monitoring lead offers the advantage of continous monitoring of atrial rhythm.However the clinical and therapeutic implications of High Rate Atrial Events (HRAE) or Device Detected Atrial Fibrillation (DDAF) is unclear.
Purpose: To study the frequency,pattern and treatment of device detected atrial arrhythmias and its association with clinical outcomes.
Methods: 155 patients with CIEDs with an atrial lead were recruited.Those with a minimum duration of 3 months of interrogated data were included and those with clinically detected atrial arrhythmias were excluded from the study.Relevant information were obtained by direct interview of the patient,with a prespecified proforma during their routine follow up visits.All patients underwent device interrogation and the electrograms(EGM) of all reported HRAEs were meticulously examined.
Results: 155 patients were enrolled in the study.The mean age of the study population was 58 years.Majority (97.4%) had a dual chamber pacemaker implanted and the most common indication for device implantation was SA nodal disease(77.4%).The mean duration of interrogated data was 6.7 months.HRAEs were reported in 69(44.5%) of which 28(18.1%) were atrial fibrillation(DDAF),16(10.3%) were artifacts and 25(16.1%) were other supraventricular tachyarrhythmias. In the present study stroke/Transient Ischemic Attacks/peripheral embolism/heart failure/Acute coronary syndromes were the clinical events which were studied.Among those with Device Detected Atrial Fibrillation(DDAF) 9 patients (32.14%) had 10 events and in the group without DDAF ,17 patients (13.4%) had 17 clinical events.This association of Device Detected Atrial Fibrillation(DDAF) with a composite of all clinical events were found to be significant (?2 = 7.2471,df = 1,p = 0.007102).However no significant association between DDAF and incidence of stroke or heart failure independently, could be demonstrated (p = 0.093).The mean CHA2 DS2 VaSc score in patients with DDAF was 2.11 ± 1.8 . Most (71.2%) of the patients with DDAF were never evaluated further for Atrial Fibrillation and they were not on any treatment for AF.
Conclusion: The study reveals that DDAF is frequently found in patients with CIEDs.A composite of all clinical outcomes studied was found to be significantly associated with DDAF.The study also reveals that the current clinical practice often overlooks the presence of DDAF ,as evidenced by the large number of untreated patients with device detected atrial fibrillation,despite having a high risk of stroke.

Implantable Cardioverter / Defibrillator

P2114
Predictors of implantable cardioverter defibrillator intervention for life-threatening ventricular arrhythmias in systolic heart failure: role of reverse remodelling.

G Gianluca Mirizzi[1]; A Aimo[1]; V Castiglione[1]; A Giannoni[2]; G Vergaro[2]; M Piacenti[2]; L Panchetti[2]; U Startari[2]; A Rossi[2]; C Passino[1]; M Emdin[1]
[1]Sant'Anna School of Advanced Studies, Pisa, Italy; [2]Gabriele Monasterio Foundation, Department of Cardiovascular Medicine, Pisa, Italy

Background: Implantable cardioverter defibrillators (ICD) recognize and treat life-threatening arrhythmias in systolic HF. In primary prevention, however, the rate of appropriate ICD intervention is low, with complications potentially offsetting their benefit; more accurate prediction of arrhythmic events is thus highly anticipated. The impact of reverse remodelling (RR) well above the guidelines-recommended threshold of three months in predicting ICD intervention has not been properly assessed.
Purpose: to evaluate the impact of RR on ICD- treated life-threatening ventricular arrhythmia occurrence in systolic HF patients above three months.
Methods: patients with systolic HF (left ventricular ejection fraction - LVEF - < 40%) who underwent ICD implantation for primary prevention were evaluated regularly (6-months or yearly basis) via in-site device interrogation. ICD intervention for life-threatening ventricular arrhythmia (shocks for ventricular tachycardia - VT - or fibrillation -VF) were collected. Basal and 1-year echocardiograms were performed; RR was defined as an improvement of left ventricular end-systolic volume index (LVESVi) of at least 15%. Primary outcome was defined as appropriate ICD intervention for VT/VF (whatever came first).
Results: among 812 patients (83% males, 57% ischemic etiology, age 68 ± 10 years, LVEF 28 ± 6%, median NT-proBNP 1383 ng/L, interquartile range -IR- 733-3170, 87% betablockers, 82% ACE-inhibitors/angiotensin receptor blockers, 72% mineralcorticoid receptor antagonists), single chamber ICD were implanted in 14% of patients, dual chamber in 25%, subcutaneous in 1%, cardiac resynchronization therapy (CRT) devices in 60%. Shocks for VT were recorded in 7.3%, for VF in 7.1%, for aggregate VT/VF in 11.4%. RR occurred in 12.3% of patients; it occurred in 7.8% of patients with ischemic HF and in 18.2% of non-ischemic HF (p < 0.001). No treatment differences were found; CRT was however more common in non-ischemic group (71.9% vs. 51.1, p < 0.001). At follow-up (27 months, IR 11-55), systolic pulmonary arterial pressure (PAPs) and RR, but not LVEF, were independent predictors primary outcome occurrence (respectively, odds ratio - OR - 1.03, 5-95th confidence interval 1.01-1.06, p = 0.02 and OR 0.24, CI 0.06-0.99, p = 0.05) independently from CRT status. Primary outcome occurred in 8.3% of patients with RR and ischemic HF (3 out of 36 patients), while no events occurred in patients with RR and non-ischemic HF (0 out of 63 patients).
Conclusion: ICD intervention rate for VT/VF is low among patients with systolic HF and contemporary treatment; RR is associated with a reduced risk of ICD intervention, especially among patients with non-ischemic HF. Evaluation of left ventricular RR above 3 months could help identify a subgroup of patients with reduced risk of future life-threatening arrhythmias.

Funding Acknowledgements: Only Departmental Funding

Background: Patients scheduled for ICD implantation often suffer from a low ejection fraction with a critical preload/afterload balance. Intraoperatively, low left ventricular (LV) reserve and intravascular fluid shifts and negative inotropic effects make these interventions hazardous. Desflurane is an inhalational anaesthetic with favourable effects to ventricular contractility. In comparison with other inhalational anaesthetics, xenon results in a better cardiovascular stability.
Purpose: The aim of this study was to test the hypothesis patients with severely impaired LV systolic function show a better cardiovascular status with xenon versus desflurane anaesthesia. To the best of our knowledge, this is the first study comparing those two anaesthetics.
Methods: In this study, patients, scheduled for ICD implantation for malignant ventricular arrhythmias, were included. All showed a LV ejection fraction of < 0.35. Before induction of anaesthesia, an arterial line was inserted. Patients were assigned randomly to either xenon or desflurane anaesthesia, in conjunction with sufentanil. After induction of anaesthesia, a multiplane TOE probe was inserted, connected to an echocardiograph (Vivid Q, GE). Following variables were assessed before surgery after induction and haemodynamic stabilization, and after obtaining 1 MAC xenon or desflurane: aortic valve flow velocity (AVmax), time velocity integral (TVI),

Comparison between Xenon and Desflurane

N = 49	pre-xenon (n = 17)	xenon (n = 17)	pre-desflurane (n = 17)	desflurane (n = 17)
SV (ml)	59±24	57±69	73±34	51±78 *
CI (l/min.m^2)	2152±742	1699±1773 *	2598±977	1872±3317 **

LVESWS (g/cm^2)	64±68	62±74	72±157	77±182
Strain (%)	14.8±5.6	13.4±7.0	12.5±5.2	16.6±12.9 *#

* p < .05 pre versus inhalation anaesthetic; ** p < .01; # p < .05 between xenon and desflurane anaesthesia.

stroke volume (SV) and cardiac index (CI) calculation, arterial elastance (Ea) and LV end-systolic wall stress (LVESWS).

Results: Due to incomplete data sets or impossibility to analyze data, 17 patients remained in each subset to be analyzed.

Conclusions: Whereas SV decreased significantly after induction of anaesthesia, strain increased considerably only with desflurane. Xenon anaesthesia appears not to induce strain alterations.

Cardiac Resynchronization Therapy

P2116

Active fixation lead can improve clinical response to cardiac resynchronization therapy

M Mezzetti[1]; M Morelli[1]; L Caccamo[1]; M Casale[2]; P Busacca[1]
[1]*Santa Maria della Misericordia, Cardiology Division, Urbino, Italy*; [2]*Universitá di Messina, Dipartimento di medicina clinica e sperimentale, Messina, Italy*

In cardiac resynchronization therapy (CRT) the final location of a traditional passive fixation left ventricular lead (PFix) usually selected according to stability criteria, favourable pacing threshold and absence of phrenic nerve stimulation can be suboptimal because pacing is delivered far from the latest electrical activated site.

The most delayed sites, usually located in lateral (L) or posterolateral (PL) basal segments of the left ventricle (LV), can pose problem in terms of both stability and pacing threshold. The recently introduced active fixation lead (AFix) could overcome these issues, leading to a better electrical resynchronization (EResync) and ultimately improved response to CRT.

Objective: Electrical and clinical performances of 91 consecutive PFixs were compared with 42 consecutive AFixs in 133 heart failure (HF) patients with systolic dysfunction and prolonged QRS duration candidates to CRT.

Methods: The parameters assessing EResync were: (1) local LV activation time (LAT) calculated from QRS onset (QRSo) to the electrogram registered from the distal bipole of LV lead positioned in the final site, (2) LAT to QRS duration ratio (LAT/QRS), (3) duration of QRS obtained with biventricular pacing (QRSbiv) and (4) QRSbiv to QRS ratio (QRSbiv/QRS). The clinical endpoint was all cause mortality and/or unplanned HF hospitalizations.

Results: Clinical, echocardiographic and ECG parameters, number of coronary sinus veins (CSVs) and types of implanted devices (87 defibrillators, 65,5%) were similar in the two groups.

AFix achieved significantly better EResync parameters compared to PFix. In particular LAT was 119,8 ± 27 vs 99,3 ± 37msec (p = 0,002) respectively for AFix and PFix; LAT/QRS was 0,71 ± 0,13 vs 0,60 ± 0,19 (p = 0,002); QRSbiv was 135,3 ± 20 vs 143,34 ± 15msec (p = 0,04) and QRSbiv/QRS was 79,5 ± 11% vs 92 ± 15% (p < 0,001). L or PL vein was targeted in 97,2% with AFix vs 74,4% with PFix (p = 0,003) and basal segment was the target site in 30,6% and 5,2% with AFix and PFix respectively (p = 0,001). There was one dislodgment in PFix group vs no dislodgment in AFix group. AFix reduced significantly HF hospitalizations plus all-cause mortality compared to PFix (3,7% vs 40%, p = 0.038).

Conclusion: AFix was able to deliver LV pacing from significantly later activated sites located in L and PL basal LV segments compared to PFix, leading to a better electrical resynchronization and therefore to an improved clinical response to CRT.

Early prediction of cardiac resynchronization therapy response by non-invasive electrocardiogram markers

V Victor Perez Rosello[1]; NOA Nuria Ortigosa Araque[2]; VDT Victor Donoso Trenado[1]; JO Joaquin Osca[1]; OCP Oscar Cano Perez[2]; CF Carmen Fernandez[2]; AG Antonio Galbis[2]; LMD Luis Martinez-Dolz[1]
[1]*Hospital Universitario y Politécnico La Fe, Valencia, Spain*; [2]*Polytechnic University of Valencia, Valencia, Spain*

Cardiac resynchronization therapy (CRT) is an effective treatment for those patients with severe heart failure. Regrettably, there are about one third of CRT do not respond to it, which adversely affects the utility and cost-effectiveness of CRT.

In this project we assess the ability of a novel surface ECG marker, called energy of QRST, to predict

CRT response. This marker is obtained by mathematical analysis of the QRS, ST segment and T wave using the Stockwell transform.

We performed a retrospective exploratory study of the ECG previous to CRT implantation in 43 consecutive patients with ischemic (17) or non-ischemic (26) cardiomyopathy.

We defined response to CRT as an increase in LVEF= 5% or one who presented an improvement in NYHA functional class = 1 in absence of death by any cardiovascular cause, heart transplantation, or hospital admissionfor heart failure during a follow-up period of one year. We consider as super responders those patients with an increase in LVEF = 15% without cardiovascular death, heart transplantation, or hospital admission for heart failure.

This ECG marker showed statistically significant lower values for non-responder patients and, joint with the duration of QRS complexes (the current gold-standard to predict CRT response).

In this manner, the proposed ECG marker may be useful to predict positive response to CRT in a non-invasive way, in order to minimize unsuccessful procedures.

Median measure of energy of QRST

	Responders energy of QRST	Not responders enegy of QRST	p value
All	747.32	174.69	0.0134
Ischemic	1397.30	142.73	0.0068
Non ischemic	464.71	249.25	0.5408
With left Bundle branch block	576.16	178.05	0.0500

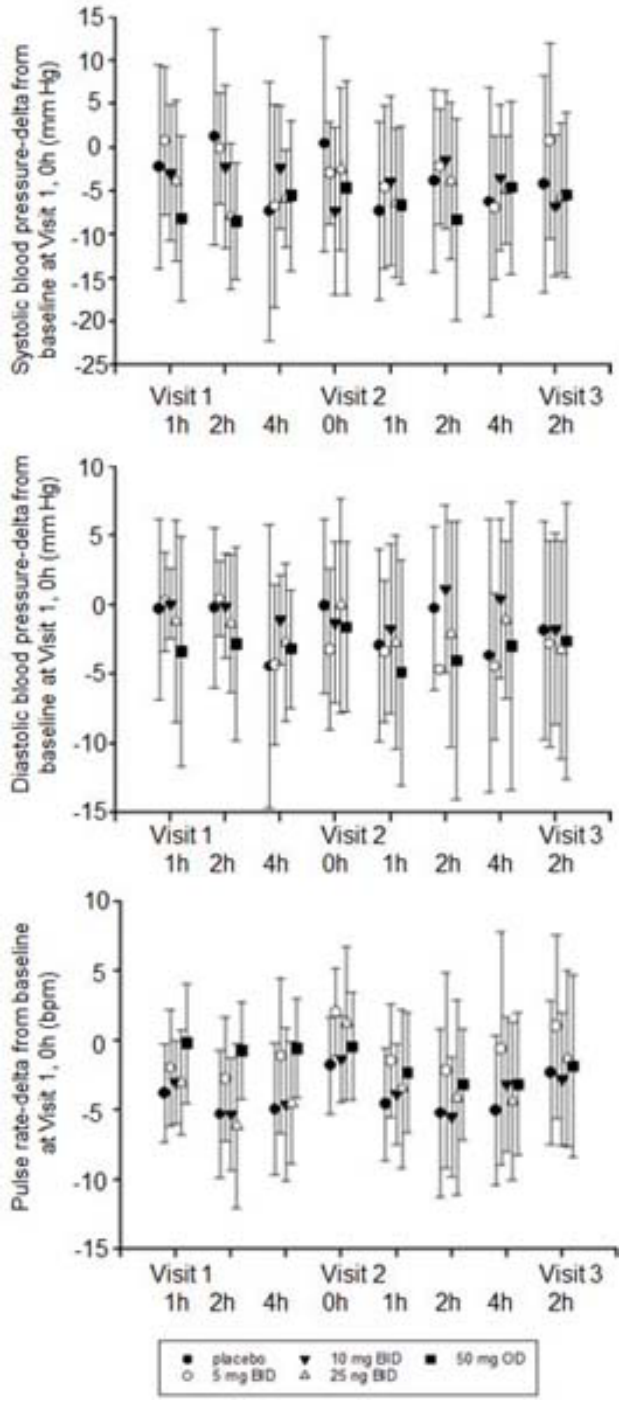
Funding Acknowledgements: This study was funded by its sponsor BAYER AG.

Introduction: Adverse cardiac remodelling represents the most important risk factor for the development of heart failure after myocardial infarction (MI). Chymase, a chymotrypsin-like serine protease, is secreted after tissue injury and generates



locally pro-fibrotic factors (such as angiotensin II (Ang II), TGF beta, and matrix metalloproteases) that contribute to adverse cardiac remodelling. An orally available chymase inhibitor is currently in clinical development as a first in class treatment for left-ventricular dysfunction (LVD) after acute MI. In healthy volunteers, it did not interfere with systemic Ang II levels or blood pressure. As chymase activity is increased in arteriosclerotic plaques and thus may contribute to systemic ANG II generation, it is currently unknown whether chymase inhibition would interfere with vital signs (blood pressure, pulse rate) in patients.

Purpose: This phase IIa study examined safety and tolerability of a novel chymase inhibitor in a chronic patient population suffering from LVD after MI.

Methods: A multicentre, multinational, randomized, placebo-controlled study was performed in clinically stable patients (40-79 years of age, LVEF = 45% due to MI in medical history at least 6 or more months before randomization) who were on stable evidence-based standard of care therapies for LVD post MI. These included an angiotensin converting enzyme inhibitor or angiotensin receptor blocker at doses of at least half the recommended target dose. Patients were treated for 2 weeks with either placebo (n = 12) or 4 different doses of the chymase inhibitor (5 mg twice daily (BID), n = 9; 10 mg BID, n = 9; 25 mg BID, n = 10; 50 mg once daily, n = 9). Four ambulatory visits (incl. one follow up visit) were performed. Safety and tolerability were monitored by ECG, safety lab, urinalysis, and adverse event questioning. Vital signs were measured in triplicates at selected time points before and after study drug administration on the ambulatory visits and at patients' home. Blood samples for pharmacokinetic and exploratory biomarker analyses were collected at the ambulatory visits.

Results: The chymase inhibitor was safe and well tolerated at all examined doses. 58.3% of patients treated with placebo and 27.0% of patients treated with active compound reported treatment emergent adverse events of mild to moderate intensity. There were no significant effects on potassium levels, biomarkers or vital signs (see attached Figure depicting deltas from baseline values as mean ± SD) compared to placebo treatment. Mean plasma concentrations of the chymase inhibitor increased with the administered dose.

Conclusion: The safety and tolerability profile as well as the absence of hemodynamic effects in a chronic patient population suffering from similar comorbidities and receiving similar co-medication as the envisaged later target population support future clinical trials with this chymase inhibitor in patients suffering from LVD after acute MI.

P2119

The relations between pro- and anti-inflammatory cytokines contractile ability of the myocardium in patients with coronary artery disease

VI Ruzov[1]; LG Komarova[1]; A Andrey Vorobev[1]; MV Krestyaninov[1]; H Khalaf[1]; M Mulenga[1]

[1]*Ulyanovsk State University, Ulyanovsk, Russian Federation*

Introduction: Studies have shown sufficient details describing cardio-depressive effects of TNF-alpha and there are conflicting reports on the relationship of pro-inflammatory cytokines IL-1b, IL-6 and anti-inflammatory cytokine IL-10 with myocardial dysfunction as the leading pathogenetic link of heart failure.

The aim of this study was to investigate the relation pro-inflammatory cytokines IL-1b, IL-6 and anti-inflammatory cytokine IL-10 with left ventricular ejection fraction which is an integral indicator of myocardial contractility.

Materials and Methods. The study involved 45 patients with coronary artery disease who underwent coronary revascularization in the form of bypass and stenting. The mean age of patients was 57 ± 8 years. According to their ejection fraction (EF), the patients were divided two groups: < 50% (10 patients) and 60% or more (35 patients).

The study of cytokines IL-1ß, IL-6, IL-10 was carried out using solid phase ELISA using the corresponding reagent kits. Ejection fraction was evaluated using Simpson's method.

The patients were on standard treatment regimens of the underlying disease - ACE inhibitors or Sartana, selective ß-blockers, statins, and antiplatelet agents.

Results: There was an inverse relationship between the concentrations of pro-inflammatory cytokines and EF. The most significant changes were observed with respect to the concentration of IL-6.

Thus, in patients with EF up to 50% the average value of the concentration of IL-1ß was 0.87 ± 0.69 pg / ml and 0.90 ± 1.62 pg / ml - in patients with EF above 60%

The mean value of IL-6 concentration in patients with EF up to 50% was 3.34 ± 2.50 pg / ml and 3.08 ± 1.93 pg / ml - in patients with EF above 60%.

Thus, variations in average values of IL-1ß in the patient groups with different ejection was 5%, and IL-6 was 10%. With regard to IL-10, we found a direct correlation between its concentration and EF. In the group of patients with an ejection fraction up to 50% the average value of IL-10 concentration was 3,91 ± 4,34 pg / ml, and 5,31 ± 4,57 pg / ml in patients with EF above 60%.

Fluctuations in the average value of IL-10 between the groups of patients with different ejection fraction was 25%.

Conclusions: We found a direct correlation between the contractile ability of the myocardium and the level of anti-inflammatory cytokine.

There is a feedback between the anti-inflammatory cytokines and the contractile ability of the myocardium.

Preservation of contractile ability of the myocardium is associated with high anti-inflammatory cytokine (IL-10) and low values of pro-inflammatory cytokines (IL-1ß and IL-6), which are comparable with the values of EF.

P2120

Predictors of galectin-3 in patients with heart failure and reduced ejection fraction

I Alexanian[1]; I Parisis[2]; V Bistola[2]; G Bakosis[2]; N Cholevas[2]; F Tzifi[1]; N Karamichalakis[1]; P Niarchou[1]; S Xydonas[1]; L Pappas[1]; K Letsas[1]; M Efremidis[1]; A Sideris[1]; G Filippatos[2]

[1]Evangelismos General Hospital of Athens, 2nd Department of Cardiology, Athens, Greece; *[2]Attikon University Hospital, Department of Cardiology, Athens, Greece*

Background: Immunoinflammatory activation has been recognized as an integral feature of heart failure (HF) pathophysiology. Galectin-3, a ß-galactoside-binding lectin, has been implicated in myocardial inflammation and fibrosis.
Purpose: We sought to determine the association between galectine-3 and clinical, echocardiographic and laboratory parameters in HF patients with reduced ejection fraction (Left Ventricular Ejection Fraction < 40%) (HFREF).
Methods: Clinical, echocardiographic and laboratory parameters were assessed in 87 consecutive patients with HFREF (age: 65.01 ± 9.58years, 56% ischemic HF) visiting our outpatient clinic. Galectin-3 concentrations in serum were determined by an automated quantitative test (VIDAS® Galectin-3, bioMerieux SA, France) using the ELFA technique. Statistical analysis was performed using SPSS 19.
Results: Serum galectin-3 levels were 21.77 ± 13.12ng/ml. Patients with NYHA III-IV had significantly higher serum galectin-3 than NYHA I-II (23.95 ± 14.63 vs. 16.20 ± 6.13, p = 0.001). HFREF patients of ischemic etiology had significantly increased serum galectin-3 compared to those with dilated cardiomyopathy (25.39 ± 15.30 vs. 17.11 ± 7.52, p = 0.001). In univariate analysis, right ventricular diameter (RVD) (r = 0.291, p = 0.036), pulmonary artery systolic pressure (PASP) (r = 0.396, p = 0.004), logNT-proBNP (r = 0.416, p = 0.001), serum urea (r = 0.730, p < 0.001) and creatinine (r = 0.723, p < 0.001) were positively correlated with serum galectin-3 concentrations, whereas Hgb (r= -0.249, p = 0.032) and serum Na (r= -0.330, p = 0.004) were negatively correlated with serum galectin-3. In multiple linear regression analysis, serum urea (B:0.302, 95%CI for B: 0.200 - 0.404, P < 0.001) was the only independent predictor of serum galectin-3 levels.
Conclusion: Serum urea independently predicted galectin-3 in HFREF patients after adjusting for NYHA, etiology of HF, RVD, PASP, logNT-proBNP, creatinine, Hgb and Na. This underscores that galectin-3 is a pleotropic molecule mediating immune response, inflammation, and fibrogenesis rather than specific to cardiac performance alone.

P2121

The role of Response-to-Diuretic in predicting prognosis in discharged heart failure patients after an acute decompensation.

M Feola[1]; M Testa[1]; S Ariotti[2]; C Ferreri[3]; GL Rosso[4]

[1]Cardiovascular Rehabilitation-Heart Failure Unit, Fossano, Italy; *[2]Cardiology Division, Mondoví, Italy*; *[3]School of Geriatry University of Turin, Turin, Italy*; *[4]Emergency 118 ASLCN1, cuneo, Italy*

The diuretic response demonstrated to be a robust independent marker of cardiovascular outcomes in acute heart failure (ADHF) patients. The objectives of this clinical research, will aim to: a) include diuresis into the formula for diuretic response (R-to-D) ; b) add to R-to-D the value of a pre-discharged determination of galectin-3 and BNP in predicting mid-term clinical outcome.
Methods: consecutive patients discharged alive after an ADHF were enrolled. All patients underwent BNP and galectin-3, a 6-minute walk test and an echocardiogram together with diuresis and body weight during diuretic administration. Death by any cause, cardiac transplantation and worsening HF requiring readmission to the hospital were considered cardiovascular events.
Results: 141 patients (95 males, age 73.8) were analysed (follow-up 17 months). During the follow-up 45 (31.9%) events were scheduled (19 cardiac deaths, 26 re-hospitalisation for HF). Patients who experienced CV-event had a worst renal function (p = 0.003), an higher BNP (p = 0.006) and galectin-3 (p = 0.008). At multivariate analysis, only R-to-D, galectin-3 and BNP showed a significant correlation with worst clinical prognosis (respectively p = 0.043; OR 6.01; p = 0.01; OR 8.9; P = 0.02 OR 10.38), independently to age and renal function. Kaplan-Meier curves depicted the powerful stratification using a R-to-D >1.2 kg/40mg furosemide (log rank 10.96 ; p = 0.0009). Adding R-to-D>1.2 mg/40 mg furosemide to galectin-3>17.6 pg/ml and BNP>500 pg/ml the predictive value improved (log rank 23.59; p = 0.0001).
Conclusion: adding R-to-D to Gal-3 and BNP, a single pre-discharge strategy testing seemed to obtain a satisfactorily predictive value in alive HF patients discharged after an ADHF episode.

Mobile cardiopaging in toxic cardiomyopathy diagnostics in cancer patients

N Lyamina[1]; S Lyamina[2]; E Kotelnikova[1]; V Senchikhin[1]; T Lipchanskaya[1]

[1]Research Institute of Cardiology Saratov State Medical University named after V.I. Razumovskiy, Saratov, Russian Federation; *[2]Moscow State University of Medicine and Dentistry named after A.I. Evdokimov, Moscow, Russian Federation*

Background: The use of modern high-efficient cancer chemotherapy treatment in 5-35% of cases is accompanied by cardiotoxic effect varying from asymptomatic electrocardiography (ECG) changes to the development of acute coronary syndrome (ACS) and heart failure (CHF) that significantly impair the patients' life expectancy.
Purpose: Assessment of the feasibility of cardiopaging using due to improve the effectiveness of cardiotoxic effect diagnostics in cancer patients.
Methods: Remote management effectiveness was assessed in cardio-oncological patients with heart failure (CHF) (22 patients: 12 men, 10 women, 52.6 ± 5.5 y.o., NYHA 2.04 ± 0.25, ejection fraction 48.6 ± 6.5%). Patients were included in the study from 2 to 12 months after the chemotherapy start with 6 months follow-up period. Cardiopaging was performed on the principle of autotransmitting mobile devices and Internet application ECG Dongle. Asynchronous telecardiologic platform "CardioCloud" was used for information storage and analysis, telemedicine counseling. In CHF/chemotherapy group standard therapy was administered considering the patients' clinical status. ECG was registered 5 times a week. ECG was registered in addition in the case of any clinical symptoms present or according to the patients' desire. ECG registration duration was 10-20 minutes. ECG data were analyzed by an external doctor (an employee of the Cardiology Research Institute). Analysed data included mean heart rate, any rhythm or conduction disorders, dynamics of ST changes, QT duration. If necessary, medication was prescribed.
Results: Within 6 months not previously documented ECG changes were remotely registered in all CHF/chemotherapy patients. Among them sinus tachycardia was predominant (88%). Against the background of sinus tachycardia ventricular extrasystole of various gradations (38%), supraventricular extrasystole (24%), transient tachy-dependent bundle-branch blockages (9%) were registered. Atrial fibrillation paroxysms were observed in 2 patients. In 55% of patients complicated ECG disorders were registered in the form of sinus tachycardia and supraventricular rhythm disorders (extrasystole, episodes of atrial fibrillation) combination, and sinus tachycardia, ventricular extrasystole and ST depression. The majority pf detected violations were symptomatic (65%), in other cases patients did not complain. Within the framework of office counseling 7 (70%) patients had arterial hypertension (AH) of I-III degree. ß-blockers and ACE inhibitors were prescribed to correct the identified violations and AH.
Conclusions: Remote dynamic management of cancer patients with chemotherapy including ECG registration (= 5 times/week, 10-20 min) on the base of mobile cardiopaging combined with doctors' counseling is a sufficiently effective and accessible method of cardiotoxicity phenomenon diagnostics. The main advantage of the method is the possibility of early pharmacological correction in asymptomatic cardiovascular disorders.

P2123

Use of sacubitril valsartan in heart failure due to post-chemotherapy symptomatic ventricular dysfunction

V Gregorietti[1]; A Rojo[2]; R Coronel[2]; L Saglieti[2]; M Gregorietti[1]; M Muzzio[2]; A D Ortencio[3]; P Roura[1]; S Perrone[4]; AJ Daniele[3]
[1]Instituto Argentino de Diagnostico y Tratamiento, Cardiologia, Buenos Aires, Argentina; *[2]Sanatorio Sagrado Corazon, Cardiologia, Buenos Aires, Argentina*; *[3]Instituto de Oncologia Angel Roffo, cardiologia, Buenoa Aires, Argentina*; *[4]Hospital El Cruce, Trasplante Cardiaco, Hipertension Pulmonar, Florencio Varela, Buenos Aires, Argentina*

Background and objetives: Heart failure is a term used to define a constellation of symptoms and signs that are commonly attributed to the inability of the heart to produce a cardiac output that meets the demands of the body. It remains a deadly disease, affecting between 1-2% of the population, and is more common in the elderly, with around 6-10% of patients over 65 suffering from the condition. Sacubitril / valsartan (LCZ-696) is a combined neprilysin inhibitor and angiotensin AT1 receptor blocker approved in recent years for the treatment of chronic heart failure with reduced ejection fraction. In an area where there have been limited pharmacological advances in the last 10 years, this drug was a game changer and a great one. The optimal use of sacubitril / valsartan in clinical practice needs further investigation, in particular for patients with Cardiomyopathy induced by chemotherapeutic toxicity, as such patients are usually poorly represented in clinical trials.
Methods: 490 consecutive patients(p) with a history of breast cancer, who received treatment with chemotherapy, were enrolled prospectively from June 2016 to June 2017.
Ventricular dysfunction was detected through clinical, echocardiographic and laboratory tests.
For the statistical analysis the SPSS was used.
Results: 490 p, aged 69 ± 7.2 years, female 482(98.3%). 14 p presented ventricular dysfunction refractory to conventional treatment, all were optimally treated with beta-blockers, being with an average heart rate of 61 ± 9 bpm, so in this group it was decided to rotate the angiotensin II receptor blocker treatment to the sacubitril-valsartan combination, whose titration was adjusted to the clinical response and the hemodynamic parameters.
He was followed up at 14, 28 days and at 3 and 6 months.
It was observed that at 3 months the patients improved the ejection fraction of the left ventricle (average 23% to 36%). Improvement of ProBNP 934 pg / ml (basal), with an average reduction of 30% at follow-up, normalizing in 100% of patients followed up at 3 months. Improvement of CF III-IV to CF I-II is observed in 100% of patients. The dose of loop diuretics was reduced in all patients.
Conclusions: In patients with ventricular dysfunction secondary to chemotherapy and refractory to the tried-and-tested therapy, sacubitril valsartan has shown a good safety profile with excellent results in follow-up; and it would be a promising alternative in this cohort of patients.

P2124

Effect of severe functional mitral Regurgitation on novel hemodynamic findings in heart transplant candidates

Z Zubeyde Bayram[1]; C Dogan[1]; RD Acar[1]; B Guvendi[1]; T Unkun[1]; A Karaduman[1]; C Onal[1]; OY Akbal[1]; A Hakgor[1]; C Kaymaz[1]; N Ozdemir[1]
[1]Kartal Kosuyolu Heart Education and Research Hospital, Department of Cardiology, Istanbul, Turkey

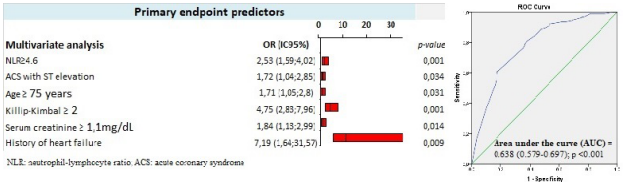
Background: A severe functional mitral regurgitation had additive factor for left ventricular filling pressure and pulmonary arterial pressures. We aimed to investigate the relationship between severe functional mitral regurgitation (FMR) and left ventricle stroke work index (LVSWI), left ventricular cardiac power index (LVCPI),right ventricle stroke work index (RVSWI), pulmonary artery pulsality index (PAPi), pulmonary arterial capacitance (PAC) and pulmonary arterial elastance (PAE) in patients who were heart transplant candidates. Methods and results. A total of 238 patients with left ventricle ejection fraction (LVEF) = 25%, NYHA class III-V and INTERMACS IV -VII were included to study and they were divided into two groups; namely; those with severe and non-severe FMR.The severe FMR was defined as effective regurgitation area = 20 mm2 and regurgitation volume = 30 ml. Seventy six patients had sever and 162 patients had non-severe FMR. There was no difference in terms of LVEF, NYHA and INTERMACS grades and heart failure duration among to groups (p>0.05). The CO, CI, SV, SVI, LVSWI and LVCPI were lower in severe FMR compared to non-severe FMR [3.1 ± 0.7 vs. 3.5 ± 0.89, p = 0.005; 1.6 ± 0.3 vs. 1.8 ± 0.5, p = 0.021; 35.0 ± 9.1 vs. 44.7 ± 15.8, p = 0.001; 19.0 ± 4.5 vs.23.4 ± 8.9, p = 0.003; 13.1 (10.8-18.5) vs. 17.1 (12.4-24.9), p < 0.001 and 0.32 (0.27-0.44) vs.0.38 (0.31-0.48), p = 0.004]. The systemic vascular resistance (SVR) was similar among to groups (22.0 ± 8.2 vs. 21.5 ± 7.9, p = 0.656).The pulmonary arterial systolic pressure, pulmonary wedge pressure were higher in patients with severe FMR than those with non-severe FMR (58.3 ± 16.0 vs. 49.3 ± 18.6, p = 0.001; 38.4 ± 11.5 vs. 30.7 ± 11.0, p < 0.001 and 25.9 ± 7.0 vs. 21.5 ± 7.4, p < 0.001). The RVSWI and PAPi were similar among to groups (6.5 ± 2.9 vs. 6.2 vs. 3.1, p = 0.416; 3.2 ± 2.0 vs. 3.7 ± 2.5, p = 0.232). The patients with severe FMR had higher PVR and PAE value and lower PAC than patients with non-severe FMR [4.0 (2.3-6.8) vs. 2.6 (1.2-4.3), p = 0.001; 1.5 (1.1-2.3) vs. 1.1 (0.79-1.68), p < 0.001 and 1.1 (0.78-1.74) vs. 1.5 (1.0-2.3), p = 0.001].
Conclusions: The patients with severe FMR had lower left ventricular cardiac performance assessed by CI, LVSWI, and LVCPI without increase in afterload (SVR), while they had higher pulmonary afterload assessed by PVR, PAC, and PAE without increase in right ventricular work defined by RVSWI and PAPi.

P2125

Neutrophil-lymphocyte ratio as a predictor of left ventricular systolic dysfunction and mortality after acute coronary syndrome

L Luis Graca Santos[1]; C Ruivo[1]; F Montenegro Sa[1]; R Ribeiro Carvalho[1]; J Correia[1]; F Saraiva[1]; A Antunes[1]; J Guardado[1]; F Soares[1]; S Pernencar[1]; J Morais[1]
[1]Hospital Santo Andre, Cardiology, Leiria, Portugal

Introduction: Inflammation plays a key role in the atherosclerotic process. Evidence supports the relationship between elevated inflammatory parameters and mortality in the context of acute coronary syndrome (ACS), which can be partially explained by higher levels of left ventricular systolic dysfunction (LVSD).
Purpose: To evaluate the association between the neutrophil-lymphocyte ratio (NLR), LVSD, and mortality in patients (pts) with ACS.
Methods: Unicentric and longitudinal retrospective study of 514 consecutively admitted pts with ACS and submitted to coronary angiography between January 2014 and December 2016. Clinical, demographic and laboratory data were obtained. NLRis defined as the ratio between absolute neutrophil count and lymphocyte count in peripheral blood at admission. The primary endpoint (PE) was a composite of LVSD (ejection fraction < 40%), in-hospital death from any cause or 1-year death from any cause. Two groups were defined according to the occurrence (or not) of the PE, and their characteristics compared. Statistically significant variables (p = 0.05, bilateral) were included in a binary logistic regression model in order to obtain predictors of mortality and LVSD. The estimated probabilities of model response were then analyzed using the Receiver Operator Characteristics (ROC) curve.
Results: The mean age was 65 ± 13 years, of which 373 were male (72.60%). The type of ACS was with ST elevation (STE) in 306 cases (59.50%). At the end of the follow-up, 122 (23,7%) pts reached PE. Mean RNL was higher in the cohort that reached PE (7.71 ± 6.59 vs. 5.11 ± 4.61, p = 0.001). The NLR cut-off that best predicted the PE was estimated at = 4.60 through ROC curve analysis, with a sensitivity of 65.6% and specificity 60.1% [area under the curve (AUC) = 0.638 (0.579-0.697); p < 0.001]. After multivariate analysis, NLR = 4.6 remained an independent predictor of mortality, as well as age = 75 years, ACS with STE, signs of heart failure (HF) at admission (Killip = 2), HF history, and creatinine = 1,1 mg/dL [picture]. A risk model encompassing all variables showed good discrimination (AUC 0.783 (0.735-0.832, p = 0.001) [picture]).
Conclusion: According to the present unicentric series of patients with ACS, NLR was an independent predictor of both LVSD and/or death from all causes in the short or medium term. It may be speculated that a greater neutrophilic inflammatory response leads to a worse prognosis in the ACS scenario, conjecturing it as a potential therapeutic target.



Primary endpoint predictors and ROCcurve

P2126

The effectiveness of coronary arteries revascularization in patients with chronic heart failure depending on a left ventricle ejection fraction

G Igimbayeva[1]; N Makhadiyeva[1]; A Zhashkeyev[2]; A Magzumov[2]; A Muhamediya[1]; A Akmaral Zhumabayeva[1]
[1]Karaganda State Medical University, Department of Therapeutic Disciplines, Karaganda, Kazakhstan; *[2]Karaganda Regional Cardiosurgery Centre, Karaganda, Kazakhstan*

Background: Coronary heart disease (CHD) is one of the main causes of mortality and morbidity all over the world, (Wolff G., Dimitroulis D., Andreotti F. and others;

Circulation: Heart Failure, January 2017). The great bulk of patients with CHD have a certain degree of chronic heart failure (CHF), and therefore CHF is a problem of public health. (Mosterd A., Hoes A.W. Clinical epidemiology of heart failure. Heart. 2007). Echocardiography is most often used diagnostic method of CHF, which able to assess left ventricle (LV) systolic function. It is advisable to study this problem, due to insufficiency of literature data about the effect of myocardial revascularization at various degrees of CHF in patients with CHD.

Purpose: To assess the effectiveness of coronary arteries revascularization in patients with CHF depending on left ventricle ejection fraction (LVEF).

Methods: We conducted retrospective study of 300 patients' medical histories with hemodynamically significant coronary artery stenosis requiring revascularization with balloon angioplasty and stenting, and with various functional classes of CHF. Stenting of one or more coronary arteries was undergone in all patients in Karaganda Regional Cardiosurgery Centre in 2015-2016. Every patients underwent echocardiography before stenting and 6 month after stenting. All patients were divided into 3 groups, accordingly to LVEF degree. The first group consisted of patients with a preserved LVEF (<50%), the second group consisted of patients with intermediate LVEF (49-40%), the third group patients were with reduced LVEF (< 40%). Pharmacological (dobutamine) stress echo was conducted in the third group patients to determining myocardial viability. Withdrawal criteria: patients with decompensated diabetes mellitus, reduced glomerular filtration rate (< 60 ml/min/1,73m^2 CKD EPI) and with severe disorders of liver function.

Results: According to the research data it was revealed that among 300 patients 56.3% were men and 43.1% were women. In each group the amount of patients were equal to 100 (33.3% in each group). Increasing of LVEF registered in patients of the first and the second groups (consequently from 53.78% to 59.31% and from 44.87% to 48.12%) 6 months after stenting. According to stress echocardiography in 78% of the third group patients there was identified no survival of the myocardial viability function in the zone of the blood supply affected artery. Accordingly, in the third group, there was no increase of LVEF after revascularization. It was registered the increasing of the LVEF from 25.36% to 41.12% in patients with preserved viability of the myocardium, after the stenting of the coronary arteries.

Conclusions: Therefore, the determination of myocardial viability function by echocardiographic data is important in determining the decisive tactics of managing patients with CHF. Revascularization is more effective in patients with preserved LVEF, which leading to LV systolic function increasing.

P2127

Relationship between diastolic dysfunction and electrophysiological remodeling of heart in patients with rheumatoid arthritis

L Liutsiia Feiskhanova[1]

[1]*Kazan State Medical University, department of hospital therapy, Kazan, Russian Federation*

Rheumatoid arthritis is autoimmune rheumatic disease characterized by injury not only the joints but also other organs, including the heart. It is known that the presence of rheumatoid arthritis increases the risk of fatal cardiovascular complications by 1.5 times compared to the general population.

Objective: to identify features of development of diastolic dysfunction in patients with rheumatoid arthritis.

Material and Methods: we examined 180 patients with rheumatoid arthritis. The activity of disease was defined according to the scale of the DAS-28. By echocardiography in 101 patients (group 1) were identified diastolic dysfunction of the left or both ventricles and in 79 patients (group 2) it was absent. Both groups were matched for age and sex. We determined the following echocardiographic parameters: mitral E/A, tricuspid E/A, end-diastolic dimension of left ventricle. In addition to echocardiography, patients underwent the vectorcardiography with the assessment of electrophysiological parameters: the squares of loops P, QRS, T, maximum vector (MV), MV-azimuth and MV- ascent. To compare two independent groups on quantitative grounds used nonparametric methods, the rank correlation and Mann-Whitney test. Differences were considered to be valid when p <0.05.

Results: when comparing the groups revealed that in the 1st group, DAS-28 was higher than in the 2nd (p <0,05): 5,575 [5,17; 6,15] and 5.32 [4,8; 5,8] respectively. In the 1st group, the square of loop QRS and the MV- ascent directly correlated with E/A of mitral valve (p <0.05), whereas in the 2nd group, we have established a direct relationship with end-diastolic dimension (p <0.05).

Conclusion: the results indicate that increased activity of rheumatoid arthritis contributes to the development of diastolic dysfunction of the myocardium. In addition, the decrease in E/A observed in diastolic dysfunction, accompanied by electrophysiological remodeling and reduction in electrical activity of the myocardium of the left ventricle, diagnosed during registration of vectorcardiogram. Moreover, even in the absence of diastolic dysfunction, a tendency to its development in the presence of electrophysiological remodeling. This demonstrates the relationship between early electrophysiological, structural-geometric changes in patients with rheumatoid arthritis. Early diagnosis allows for timely start prevention of remodeling in patients with rheumatologic diseases.

P2128

Heterogeneity of cardiac macrophages during wound healing following myocardial infarction: clinical data

A Aleksandra Gombozhapova[1]; Y Rogovskaya[1]; M Rebenkova[2]; J Kzhyshkowska[3]; V Ryabov[1]

[1]*Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, Russian Federation*; [2]*National Research Tomsk State University , Tomsk, Russian Federation*; [3]*University of Heidelberg, Heidelberg, Germany*

Funding Acknowledgements: This work was supported by the Foundation for Assistance to Small Innovative Enterprises (contract ?11854GU/2017)

Introduction: Modern efficient acute care leads to reduction of acute infarct mortality but has contributed to an increase in the prevalence of heart failure. The necessity of better prevention and treatment of heart failure resulted in exploration of new therapeutic strategies to repair the infarct heart. Myocardial regeneration has become one of the most ambitious goals in prevention of adverse cardiac remodeling and consequent heart failure. Macrophages play a key role in transition from inflammatory to regenerative phase during wound healing following myocardial infarction (MI).

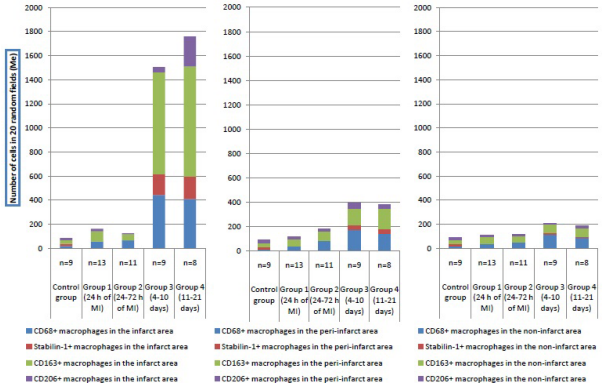


Figure 1

We have accumulated data on macrophage properties ex vivo and in cell culture. However, there is no clear information about phenotypic heterogeneity of cardiac macrophages in patients with MI.

Purpose: The purpose of the project was to assess cardiac macrophage infiltration during wound healing following myocardial infarction in clinical settings taking into consideration experimental knowledge.

Methods: The study included 41 patients with fatal MI type 1. All patients were divided into 4 groups depending on the timeline of MI histopathology. In addition to routine histopathological analysis, macrophages infiltration was assessed by immunohistochemistry. We used CD68 as a marker for the cells of the macrophage lineage, while CD163, CD206, and stabilin-1 were considered as M2-like macrophage biomarkers. Nine patients who died from non-cardiovascular causes comprised the control group.

Results: The figure (Figure 1) demonstrates results of immunohistochemical analysis. The intensity of cardiac macrophage infiltration was higher during the regenerative phase than during the inflammatory phase. In the control group the number of CD68+ and CD163+ macrophages was lower than in the infarct (IA), peri-infarct (PIA), and non-infarct areas during all phases of MI (p < 0.001). Simultaneously, the quantity of stabilin-1+ cells in the control group was higher in all the areas during inflammatory phase of MI (p = 0.01). In the control group the number of CD206+ macrophages was lower in all the areas during the reparative phase of MI (p = 0.003). We noticed that numbers of CD68+, CD163+, CD206+, and stabilin-1+ macrophages depended on MI phase. The number of CD68+ cells correlated with the day of MI in the IA (R = 0.67, p = 0.001) and in the PIA (R = 0.55, p < 0.001). There was similar relationship for CD163+ (IA: R = 0.61, p = 0.001; PIA: R = 0.66, p < 0.001), CD206+ (IA: R = 0.4, p = 0.02), and stabilin-1+ cells (IA: R = 0.6, p < 0.001; PIA: R = 0.42, p = 0.007).

Conclusions: Cardiac macrophage response following MI reminded a murine model. We observed heterogeneity of M2-like cardiac macrophages in patients with MI. Our study supported prospects for implementation of macrophage phenotyping in clinic. Improved understanding of phenotypic heterogeneity might become the

basis of a method to predict adverse cardiac remodeling and the first step in developing myocardial regeneration target therapy.

P2129

Relationships of angiotensin-(1-7) with left ventricular remodeling and diastolic disfunction in patients with arterial hypertension and type 2 diabetes

K Iushko[1]; S Koval[1]; I Snihurska[1]; T Starchenko[1]; D Miloslavskiy[1]
[1]L.T.Malaya Therapy National Institute of the NAMS of Ukraine, Department of Arterial Hypertension, Kharkiv, Ukraine

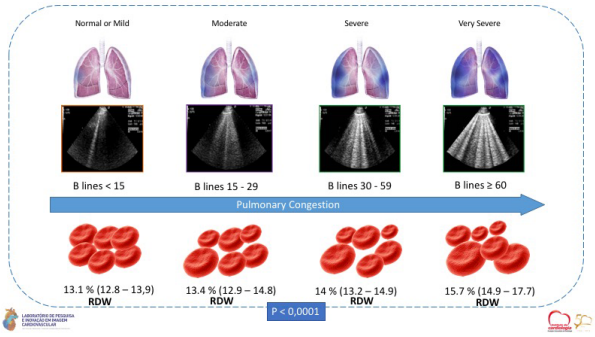
Introduction: Left ventricular (LV) remodeling and LV diastolic disfunction are the initial stages of the development of the heart failure in patients with hypertension. The angiotensin-(1-7) is the novel part of renin-angiotensin system, the metabolic product of angiotensin-II and the important protective cardiovascular factor, but its role in the development of both LV remodeling and LV diastolic disfunction in such combined pathology as arterial hypertension (AH) with type 2 diabetes (T2D) is not clear.
Purpose: The aim of the study was to determine the levels of angiotensin-(1-7) in patients with AH with concomitant T2D and to investigate its relationships with parameters of LV remodeling and LV diastolic disfunction.
Methods: The study involved 70 patients with AH of 2-3 degrees with concomitant T2D (34 men and 36 women) aged 40 to 70 years. The investigation complex included general clinical examination methods, the echocardiography with determination of the LV internal dimension at end diastole (LVIDed), septal wall thickness at end diastole, posterior wall thickness at end-diastole and calculation of the relative wall thickness, the LV mass (LVM) and LVM index. The types of cardiac remodeling we determined according 2013 ESH/ESC Guidelines. The LV diastolic function assessed using Doppler transmitral inflow pattern. Control group consisted of 16 healthy volunteers. The levels of angiotensin-(1-7) determined using ELISA.
Results: The levels of angiotensin-(1-7) in patients with AH and T2D were significantly lower than in the control group - 105,51(89,13;121,17) ng/l versus 128,77(120,02;276,49) ng/l, p <0,05. The correlation analysis revealed significant negative relationships of angiotensin-(1-7) levels with LVIDed (r=-0,37, p <0,01), LVM (r=-0,40, p <0,001) and LVM index (r=-0,41, p <0,001). Among the examined patients concentric remodeling of LV observed in 10 patients (14,3%), concentric LV hypertrophy - in 35 patients (50%), eccentric LV hypertrophy - in 25 patients (35,7%). The patients with concentric LV hypertrophy and eccentric LV hypertrophy had significant lower levels of angiotensin-(1-7) than in patients with concentric remodeling of LV - 107,5(88,2;119,6) ng/l and 101,4(84,2;111,8) ng/l versus 129,3(117,5;136,8) ng/l (? <0,01 and ? <0,01 respectively) but did not differ between themselves (p?0,05). Among examined patients the LV diastolic disfunction defined in 49 persons (70%). The levels of angiotensin-(1-7) in patients with LV diastolic disfunction were significantly lower than in patients with normal diastolic function - 101,1(87,9;116,6) ng/l versus 121,1(105,5;128,9) ng/l, ? <0,01.
Conclusion: The decreasing levels of angiotensin-(1-7) and negative relationships with LV parameters in patients with AH and T2D have been observed. The study showed, that angiotensin-(1-7) can plays an important pathogenetic role in the development of both LV remodeling and LV diastolic disfunction in hypertension patients with T2D.

P2130

The degree of pulmonary congestion assessed by lung ultrasound is directly correlated with the red cell distribution width

MH Marcelo Miglioranza[1]; RMM Vilela[1]; DL Shuha[1]; LH Saito[1]; RS Monteiro[1]; GMC Rovieri[1]; SG Alves[1]; VM Martins[1]; TJN Gomes[1]; TLL Leiria[1]; MM Rover[1]; CG Pereira[1]; RT Sant'anna[1]; RAK Kalil[1]
[1]Institute of Cardiology of Rio Grande do Sul - University Foundation of Cardiology, Porto Alegre, Brazil

Background: Measurement of red cell distribution width (RDW) has emerged as a promising prognostic marker in patients with cardiovascular disease and heart failure. However, the mediating mechanism of this interaction remains controversial. We aimed to determine if the degree of pulmonary congestion is directly correlated with higher RDW in heart failure outpatients with reduced ejection fraction (HFREF).
Methods: Cross-sectional study of HFREF outpatients. The outpatient evaluation included a complete clinical examination, NT-proBNP, echocardiogram and lung ultrasound (LUS) assessment. The degree of pulmonary congestion was obtained by LUS considering the sum of the number of B lines identified in 28 thoracic windows on the anterior and lateral sides of the right and left hemithorax.
Results: 97 patients (61% men, mean age 53 ± 13 years, 29% NYHA III-IV, average left ventricular ejection fraction 28 ± 4%, and 54% with dilated cardiomyopathy) were evaluated. The RDW indices were significantly correlated ($p < 0.001$) with NT-proBNP ($r = 0.56$), LUS ($r = 0.6$); E/e' ($r = 0.4$); right atrial pressure ($r = 0.47$). Clinically significant pulmonary congestion by LUS (B lines = 15) was present in 68% of the patients, which presented a higher RDW values than non-congestive patients: 14% (13-16) vs 13.1% (12-14) $p < 0.0001$. Severely congested patients (B lines = 30) had an even higher RDW values: 15% (13-16) $p < 0.0001$. Was also observed that patients with RDW = 14.05% had significantly more extravascular lung water than patients with RDW < 14%: 51 (30-96) vs 16 (7-31) B lines by LUS respectively ($p < 0.0001$). Conclusion: In an HFREF outpatient sample, RDW indices were proportionally higher as the number of B lines by LUS increased, suggesting that the degree of pulmonary congestion may contribute to the interaction mechanism of RDW as a prognostic marker.



Pulmonary Congestion Degree and RDW

Background: The treatment of heart failure (HF) with reduced ejection fraction (HFrEF) has recently changed with the introduction of sacubitril/valsartan (SV), an inhibitor of neprilysin and the angiotensin receptor (ANRI) enhancing the cardioprotective effect of natriuretic peptides as well as inhibiting the renin angiotensin system. This drug is recommended as a replacement for an ACEi or ARBs in ambulatory patients with symptomatic HFrEF despite optimal treatment. Patients with a recent hospital admission due to HF have an increased risk of new HF admissions, major adverse events and worse short-term prognosis.
Purpose: To analyse a subgroup of patients with HFrEF started on ANRI, with one or more hospital admissions or visit to the emergency department (ED) due a decompensation of HF, within one year prior to the initiation of ANRI.
Methods: A multicentre, ambispective study of 106 patients with HFrEF was carried out. After an initial analysis, 44 patients had at least one or more admissions or visits to the ED in the previous year of using the drug due to worsening HF. Patients were recruited between September 2016 and December 2017.
Results: In this cohort 77.3% were males with mean age 64.5 ± 11 years, and a mean follow-up time of 196 ± 132 days. 79.5% had hypertension, 53.2% diabetics, 59.1% dyslipidaemia, 36.4% AF, 25% ICD and 22.7% CRT. The most frequent etiology was ischemic heart disease (56.8%), idiopathic dilated cardiomyopathy 36.4%, 4.5% valvular etiology and 2.3% chemotherapy induced cardiotoxicity. The average baseline LVEF was 30%, the left ventricular end-diastolic diameter was 64.38 mm.
Regarding the side effects, we observed 13.6% symptomatic hypotension, 6.8% acute renal failure, 4.5% hyperkalemia, 4.5% nausea and vomiting and one patient asymptomatic hypotension. Likewise, we observed that 4 patients died during the follow-up period, and one of them due to HF.
Conclusions: Patients with recent admissions showed significant improvement of the functional class, less hospital admissions or visits to the ED related to HF, and lower NT-proBNP levels. It is important to identify these patients with worse prognosis, which could benefit at most of the treatment.

Hospital admissions and biochemistry	BeforeSV	AfterSV	P value
Admissionor visits to the ED (mean)	2.0	0.52	< 0.001
NT- proBNP (mean) pg/mL	4932	2317	0.004
Glomerularfiltration (mean)mL/min	66.22	63.14	0.088

Dyspnea Severity and Survival

P2132

Dyspnea severity in chronic heart failure outpatients is mainly related to prognosis than to pulmonary congestion degree

MH Marcelo Miglioranza[1]; MM Rover[1]; TJN Gomes[1]; GMC Rovieri[1]; LH Saito[1]; RMM Vilela[1]; RS Monteiro[1]; DL Shuha[1]; SG Alves[1]; VM Martins[1]; TLL Leiria[1]; RT Sant'anna[1]; RAK Kalil[1]

[1]Institute of Cardiology of Rio Grande do Sul - University Foundation of Cardiology, Porto Alegre, Brazil

Purpose: Dyspnea is one of the main symptoms assessed during a heart failure outpatient visit. However, data are scarce on literature demonstrating the association between dyspnea severity with pulmonary congestion or prognosis. Our aim was to determine the dyspnea scale accuracy in determining extravascular lung water and prognosis in heart failure outpatient clinic.
Methods: Ninety-seven patients admitted to a heart failure clinic due to advanced systolic HF (61% men, mean age 53 ± 13years, 27% postischaemic and 54% idiopathic cardiomyopathy) were enrolled. Dyspnea analog visual scale (100mm) evaluation was independently performed during the outpatient regular visit and correlated to lung ultrasound B lines (LUS), NTproBNP, E/e' ratio, NYHA class and Minnesota scale. Patients were followed up for a median period of 106 ± 12days (interquartile range: 89115days).
Results: Overall AVDS severity was 21mm ± 22, being higher in patients with significant pulmonary congestion at LUS (total Blines number>15) 24mm ± 24 vs 13mm ± 16 (p = 0.005). AVDS C statistic to determine pulmonary congestion at LUS was 0.63 (0.50.75) with 14mm cutoff (57% sensitivity and 61% specificity). AVDS was correlated with Minnesota (r = 0.42), NYHA class (r = 0.34), LUS (r = 0.36), E/e'ratio (r = 0.22) and NTproBNP (r = 0.24). During the follow-up period, 21 heart failure admissions occurred. The severity of dyspnea at AVDS was related to events with HR = 5.2 (1.8 15; p = 0.003) (see figure). AVDS C statistic to determine adverse events was 0.69 (0.56 0.83) with 14mm cutoff (76% sensitivity; 63% specificity; 90% negative predictive value; positive likelihood ratio = 2).
Conclusion: In an HF outpatient setting, dyspnea assessment by AVDS may help mainly to identify patients most likely to be admitted than to identify patients with pulmonary congestion. Due to the multifactorial dyspnea physiopathology, this simple evaluation could help to recognize patients at risk, whose treatment should be intensified.

The effect of resveratrol on non-invasive cardiologic and laboratory parameters in systolic heart failure

R Halmosi[1]; R Gal[1]; L Deres[1]; O Horvath[1]; D Praksch[1]; ZS Marton[1]; B Sumegi[2]; K Toth[1]; T Habon[1]

[1]University of Pecs, Medical School, 1st Department of Medicine, Division of Cardiology, Pecs, Hungary, Hungary; [2]University of Pecs, Medical School, Department of Biochemistry and Medical Chemistry, Pecs, Hungary

Funding Acknowledgements: GINOP-2.3.2-15-2016-00048, UNKP-17-4-I-PTE-209

Introduction: The positive effects of resveratrol on heart failure have already been evaluated in several experimental animal models, however, in human clinical trial they have not been confirmed.
Aim: The primary aim of our study was to assess the effect of resveratrol supplementation on left ventricular function in patients with heart failure with reduced ejection fraction (HFrEF).
Methods and materials: We enrolled 60 patients (age: 66.7 ± 11.04 years, 17 women and 43 men), who had heart failure with left ventricular systolic dysfunction (ejection fraction <40%). They were randomized into two groups. Daily 2x50 mg resveratrol was administered orally in the first group (n = 30) and placebo in the other group (n = 30). 56% of the enrolled patients had ischemic HFrEF. During the whole study period patients received optimal medical therapy for heart failure (ACEI/ARB, BB, MRA) in the same dose as before the randomization. On the day of randomization and 3 months later we performed echocardiography, lab test, impedance cardiography (ICG), six-minute walk test (6MWT) and quality of life questionnaire (QoL test).
Results: After the 3-month follow-up period the left ventricular ejection fraction improved significantly in the resveratrol group versus the placebo group (p <0.001). Lab test analysis showed that resveratrol supplementation significantly reduced the total cholesterol level (p <0.05), the LDL-C level (p <0.05) and the HDL-C level also (p <0.05) and had no overt effect on other metabolic parameters. 6MWT (p <0.05) and QoL test (p <0.05) significantly improved in the resveratrol group compared to the placebo group (p <0.05). ICG parameters did not show significant changes in either of the groups.
Conclusion Our results revealed that resveratrol supplementation added to standard medical therapy resulted in the improvement of left ventricular systolic function, exercise capacity and quality of life.

The rates of use of drugs that reduce mortality in patients with reduced ejection fraction in turkish population

T Kivrak[1]; MA Kobat[1]; O Karaca[1]; I Karaca[1]

[1]Firat University, Department of Cardiology, Elazig, Turkey

Background: Heart failure(HF) is associated with significant morbidity and mortality despite the use of medical therapies such as angiotensin-converting enzyme inhibitors, beta-adrenergic blockers, angiotensin receptor blockers, and mineralocorticoid receptor antagonists.
Purpose: Our purpose is to determine the number of patients receiving optimal medical treatment at first admission to heart failure policlinic to our hospital.
Methods: We collected demographic, laboratory, drug history, physical examination and echocardiographic parameters data at first admission to our heart failure policlinic(Table 1 and 2).We assessed 187 patients with reduced ejection fraction.
Results: In our trial, 51% of the patients were using ACE or ARB, 70% of the patients were using Beta-blocker, and 40% of the patients were using mineralocorticoid receptor antagonists(Table 3).The average ejection fraction was 29% in our trial.92% of the patients were NYHA class II and above(Table 4).
Conclusions: In our country, heart failure patients with reduced ejection fraction don't receive enough treatment.There are many reasons for this situation.In Turkey, general cardiologists treat about 80-100 patients in a day.However, many centers have not heart failure policlinic.For this reason, cardiologists can not leave enough time for chronic illness like heart failure.Heart failure policlinics in our country should become widespread, and these patients should be directed to heart failure policlinics.

TABLE

Drugs	Frequency(N:187)	Percent	Cumulative Percent

The association of ejection fraction change with clinical outcomes in heart failure with mid-range ejection fraction patients

JC Jeong Cheon Choe[1]; JH Choi[1]; SH Lee[1]; J Ahn[1]; JS Park[1]; HW Lee[1]; JH Oh[1]; HC Lee[1]; KS Cha[1]; TJ Hong[1]
[1]*Pusan National University Hospital, Department of Cardiology, Pusan, Korea Republic of*

Background: Heart failure with mid-range ejection fraction (EF) (HFmrEF) has been proposed as new category in recent guideline.
Purpose: We investigated the association of EF change with clinical outcomes in HFmrEF patients.
Methods: Of 252 consecutive patients with primary diagnosis of HFmrEF (EF 40-49%) and baseline and follow-up echocardiogram in an urban tertiary referral center from October 2013 to March 2017, 79 (31.3%) were in HFmrEF with improved EF (EF = 50% at follow-up echocardiogram) (iHFmrEF), 132 (52.4%) were in HFmrEF with consistent EF (EF 40-49% at follow-up echocardiogram) (cHFmrEF), and 41 (16.3%) were in HFmrEF with reduced EF (EF <40% at follow-up echocardiogram) (rHFmrEF) groups. We compared the characteristics and composite event (cardiovascular death and cardiovascular readmission).
Results: Compared with rHFmrEF or cHFmrEF groups, iHFmrEF group had significantly higher rates of female and coronary artery disease (CAD) with revascularization. There were similar in other characteristics among 3 groups. Composite event occurred in 100 patients (39.7%). After risk adjustment, iHFmrEF was associated with decreased risk of composite event compared with cHFmrEF (hazard ratio [HR] 0.586, 95% confidence interval [CI] 0.351-0.978, p = 0.041) and rHFmrEF (HR 0.325, 95% CI 0.172-0.613, p = 0.001). Significant contributors for improved EF included female (odds ratio [OR] 0.404, 95% CI 0.233-0.699, p = 0.001), CAD with revascularization (OR 0.361, 95% CI 0.208-0.630, p <0.001), and spironolactone use (OR 0.434, 95% CI 0.234-0.805, p = 0.008).
Conclusions: In HFmrEF patients, improved EF at follow-up echocardiogram was observed in approximately one-third of patients. Moreover, it was predictive for better clinical outcomes and affected by gender, CAD with revascularization, and spironolactone use.

Echocardiographic profile of heart failure patients with mid-range ejection fraction

VV Venzheha[1]; NT Vatutin[1]; AN Shevelok[1]; AN Zagoruiko[2]
[1]*Donetsk National Medical University, Hospital Therapy, Donetsk, Ukraine*;
[2]*Institute of Urgent and Recovery Surgery na V.K. Gusak , Donetsk, Ukraine*

Background: The 2016 European Society of Cardiology heart failure guidelines introduced the term "heart failure with mid-range ejection fraction" (HFmrEF) to refer to patients with heart failure and mildly reduced ejection fraction (EF). While structural and functional characteristics of heart failure with preserved and reduced EF are well described, echocardiographic pattern of HFmrEF remain unclear.
Purpose: The purpose of our trial was to study the echocardiographic profile in patients with HFmrEF.

Methods: The study included 110 patients (90 men and 20 women, mean age 60.4 ± 13.5 yaers) with stable coronary arterial disease and HFmrEF (40-49 %). All patients were screened by transthoracic echocardiography using the M-mode, bidimensional echocardiography and Tissue Doppler Imaging measurements with assessment of the main echocardiographic parameters: end-diastolic (EDV) and end-systolic volumes (ESV) and left ventricular (LV) dimensions indexed by body surface area (BSA), left ventricular myocardium mass index (LVMMI), left atrium (LA) anterior-posterior size, degree of mitral regurgitation (MR), pulmonary artery (PA) pressure, the presence and type of LV diastolic dysfunction (DD).
Results: According to echocardiographic results 27 % (95 % confidence interval (CI) 19.3 ± 36.0 %) patients with HFmrEF had severe LV dilatation (LV EDV index = 97 ml/m2). More than half (55 %, 95 % CI 45.1-63.8 %) of all patients had LV hypertrophy, the mean LVMMI was 144.3 ± 35.51 g/m2. Clinically significant (= 2 degree) mitral regurgitation and LA enlargement were revealed in 73 % (95 % CI 64.0-80.7 %) of cases, the mean value of LA size was 46.5 ± 8.15 mm. The first and second degree of pulmonary arterial hypertension (PAH) was registered in 45 % (95 % CI 36.2-54.9 %) and 18 % (95 % CI 11.5-26.0 %) of patients respectively, the mean PA pressure was 36.66 ± 12.58 mm Hg. LV DD was observed in 91 % (95 % CI 84.8-95.6 % patients, mild and moderate type were found with equal frequency (36 %, 95 % CI 27.6-45.6 %), while the prevalence of severe LV DD was 18 % (95 % CI 11.5-26.0 %).
Conclusion: About a quarter of patients with HFmrEF have severe LV dilatation. The prevalence of clinically significant mitral regurgitation and LA dilatation achieves 73 %, while the prevalence of PAH is about 63 %. Every second patient with HFmrEF has the LV hypertrophy. In most of cases (91 %) mildly reduced of LV EF combined with the LV DD.

P2137

Soluble ST2 in patients with heart failure with preserved ejection fraction and its prognostic value: results from the Aldo-DHF trial

F Baehr[1]; L Schleussner[1]; A Bobenko[1]; J Petutschnigg[1]; V Holzendorf[2]; R Wachter[2]; K Nolte[2]; A Duvinage[3]; HD Duengen[1]; C Hermann-Lingen[4]; M Halle[3]; G Hasenfuss[4]; B Pieske[1]; F Edelmann[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany; *[2]University of Leipzig, Leipzig, Germany*; *[3]Technical University of Munich, Munich, Germany*; *[4]Georg-August University, Gottingen, Germany*

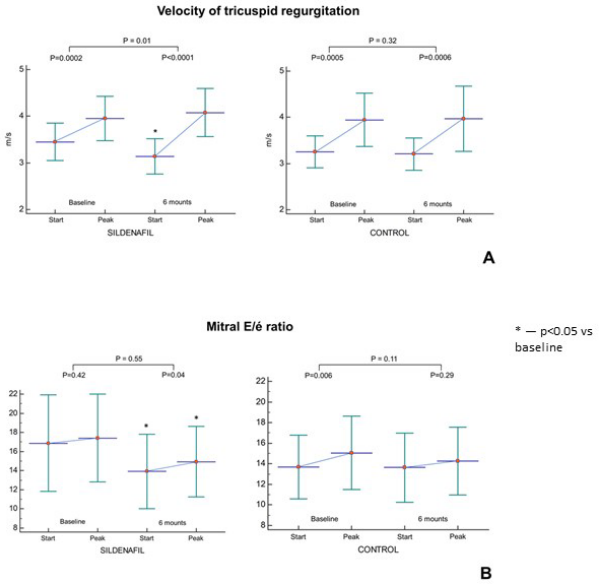
Background: sST2 is a novel serum biomarker that has been shown to be linked to myocardial dysfunction and fibrosis. Elevated sST2 levels are associated with an increased risk of mortality in heart failure with reduced ejection fraction. Myocardial fibrosis is a key contributor in the genesis of Heart failure with preserved ejection fraction (HFpEF) but data on ST2 in chronic HFpEF is scarce. The aim of this analysis was to define sST2 plasma levels in patients with stable HFpEF and its association with patient characteristics and outcome. Furthermore we investigated the interaction between spironolactone treatment and sST2 levels over time.
Methods and Results: sST2 levels were measured at baseline, at 6 and at 12 months in 415 patients of the Aldosterone in Diastolic Heart Failure trial (Aldo-DHF, n = 422). The association between different baseline sST2 levels (low (< 29.5ng/ml) middle (29.5-38.5ng/ml) and high (<38.5ng/ml) he change in sST2 and all-cause death or hospitalization, as well as the effect of treatment with spironolactone on sST2 levels were evaluated. Baseline sST2 was significantly higher in male patients. Furthermore,sST2 levels correlated positively with uric acid concentration (7,88ng/ml per 10mg/dl uric acid, p = 0,008), left ventricular ejection fraction (2,03ng/ml per 10% LVEF, p = 0,001) and left atrial volume index (LAVI)(0,12ng/ml per 1ml/m2, p = 0,031). After multivariable adjustment, sST2 showed no significant correlation to clinical parameters such as NYHA class, 6 min walk distance or Short Form 36 Health Survey- physical functioning. Difference in baseline sST2 level had no impact on all-cause death or hospitalization during 12 months follow up. Further analysis showed no significant effect of long term spironolactone treatment to sST2 levels.
Conclusion: In stable HFpEF patients sST2 levels are significantly higher in males than in females and are associated with uric acid, LVEF and LAVI. However, during 12month follow up sST2 did not show prognostic value for the combined endpoint all-cause death or hospitalization. Surprinsigly, long term treatment with spironolactone did not effect sST2 levels.

P2138

Sildenafil improves functional capacity and exercise hemodynamics in patients with HFpEF and predominantly combined pre- and post-capillary pulmonary hypertension

AG Artem Ovchinnikov[1]; AV Potekhina[1]; SV Gavryushina[1]; FT Ageev[1]
[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation

Aims: Data on clinical effectiveness of phosphodiesterase 5 (PDE5) inhibitors in heart failure with preserved left ventricular ejection fraction (HFpEF) show controversial.
Results: PDE5 inhibition targets pulmonary vessels and improves right ventricle function in pulmonary hypertension (PH). We aimed to investigate whether therapy with PDE5 inhibitor sildenafil improves exercise tolerability and exercise hemodynamics in patients with HFpEF and PH (presumably combined pre- and post-capillary [Cpc] as assessed via echocardiography).
Methods: In present randomized, controlled open single-center 6-month study we enrolled 28 patients with stable HF in NYHA functional class II?III; preserved EF



Changes in PASP (A) and PCWP (B).

(<50%); and PH due to left heart disease determined via echocardiography as high filling pressure (LV diastolic dysfunction grade II/III) and pulmonary artery systolic pressure (PASP) >40 mm Hg. According to pulmonary vascular resistance (PVR) >3 Wood units and/or transpulmonary gradient (TPG) >15 mm Hg, the presumable Cpc phenotype of PH was suggested. Patients were assigned to sildenafil group (25 mg TID for 3 months followed by 50 mg TID for 3 months; n = 16) or to control group (n = 12). At baseline and after 6 months all patients exercised supine cycle ergometry at 60 rpm starting at a 3-min period of low-level 25-W workload followed by 10-W increments in 1-minute stages to maximum tolerated levels.
Results: Both exercise time and peak ergometry workload were increased after 6 month of therapy in sildenafil group (+ 75 [95% CI 23 to 130] s, P = 0.008 and + 11 [95% CI 3 to 20] Watts, P = 0.013, respectively vs. baseline) but not in control group (−3 [95% CI 95% CI −39 to 33] s, and −1 [95% CI −7 to 6] Watts, respectively). At baseline, the exercise was associated with a prominent increase in PASP (estimated by TR velocity) in both groups but with only modest increase in PCWP (estimated by mitral E/é ratio; Figure). At 6 month stress test in sildenafil group the resting TR velocity was lower, although exercise TR velocity elevation was greater vs. the data at baseline stress test (Figure). The same dynamics were observed for mitral E/é ratio - lower resting values but greater exercise elevation (Figure). No changes in resting or peak exercise TR velocity or mitral E/é ratio were detected in control group.
Conclusion: In patients with HFpEF and predominantly Cpc-PH, 6-month therapy with sildenafil improved exercise capacity and was associated with resting PASP and PCWP decrease, but paradoxically with a significant increase in exercise PASP and PCWP, presumably reflecting the increased pulmonary blood flow due to improvements in RV contractile reserve and the restoration in LV preload during exercise.

Plasma natriuretic peptides relate to distinct patterns of left ventricular dysfunction in chronic heart failure with preserved ejection fraction

E Elisa Dal Canto[1]; L Van Heerebeek[2]; K Kortekaas[2]; MT Waddingham[1]; WJ Paulus[1]
[1]VU University Medical Center, Physiology, Amsterdam, Netherlands; *[2]Hospital Onze Lieve Vrouwe Gasthuis, Cardiology, Amsterdam, Netherlands*

Funding Acknowledgements: CVON (Cardiovasculair Onderzoek Nederland), Dutch Heart Foundation, The Hague (RECONNECT, EARLY HFPEF).

Background: In HFpEF patients plasma levels of natriuretic peptides (NP) are frequently normal, and in several HFpEF trials outcomes differed between patients with low and high NP levels.
Purpose: To assess whether in chronic HFpEF low and high NP plasma levels underlie distinct cardiac structural and functional abnormalities.
Methods: Echocardiographic data of 67 stable HFpEF patients were derived from outpatient clinic visits. An age and gender matched control group was identified.
Results: Median NT-proBNP was 161 pg/ml with 35.8% of HFpEF patients below the diagnostic cut-off value of 125 pg/ml and 70.1% of HFpEF patients below the eligibility threshold used in several trials (<300 pg/ml). Compared to controls, HFpEF patients with below median NT-proBNP had left ventricular (LV) concentric remodeling, worse systolic function, slower relaxation and higher diastolic stiffness, which was evident from higher E/E' at comparable LV EDVI and from LA dilatation and dysfunction (Table). When HFpEF patients with below median NT-proBNP were compared to those with above median NT-proBNP, LV concentric remodeling, systolic function and relaxation were comparable but diastolic stiffness continued to deteriorate.
Conclusions: In patients with above median NT-proBNP, the halted progression of LV concentric remodeling, systolic dysfunction and slow relaxation suggests the continuing deterioration of stiffness to no longer result from cardiomyocyte dysfunction but from interstitial fibrosis. Unequal involvement of cardiomyocytes and interstitium could explain different outcome of trials in HFpEF patients with low and high NP.

P2140

Are radial artery flow mediation dilatation and shear rate the new imaging biomarkers in patients with stage B heart failure?

R Olszewski[1]; M Szubielski[2]; M Parol[3]; B Gambin[1]; W Secomski[1]; Z Trawinski[1]; A Nowicki[1]
[1]IPPT Polish Academy of Sciences, Department of Ultrasound, Warsaw, Poland; *[2]District Hospital, Cardiology, Siedlce, Poland*; *[3]District Hospital, Cardiology, Grodzisk Mazowiecki, Poland*

Funding Acknowledgements: NSC(Poland)Grant "Determination of factors of reactive radial artery response to hyperaemia in assessment of hypertension and coronary artery disease"

Background: There is growing interest in the application of non-invasive clinical method and tools to assess endothelial dysfunction as a new imaging biomarkers preceding heart failure. There are commercially available ultrasound scanners allowing measurements of the brachial artery flow mediation dilatation (FMD) and shear rate (SR) normalized FMD using 7.5-12 MHz linear array transducers; however the attainable precision in estimating the changes in artery dilation does not exceeds 0.2 mm, far beyond the required one. We are introducing a novel, high frequency scanning using a linear array 20 MHz imaging combined with 20 MHz pulsed Doppler, improving the axial resolution to be better than 0.1 mm. We expect that this approach to the measurements of FMD and SR in radial artery can help to predict early vascular disease.
Purpose: To evaluate the degree of radial artery FMD and FMD/SR after 5 minutes of reactive hyperaemia in healthy subjects and in patients with stage B heart failure (HF).
Methods: The studies were carried on 14 healthy volunteers (40-71 yr. old) and 14 patients (36-77 yr. old) with stage B heart failure due to coronary artery disease. A standard reactive hyperaemia protocol was employed in the right arm, followed by 3 min measurements of the subject's radial artery dilation and Doppler blood flow velocity measurements. FMD and SR calculations were performed offline. The FMD results were normalized using AUC of shear rate at the radial artery wall.
Results: In the healthy group the peak dilated radial artery diameter was in the range (1.97-3.57) mm, mean ± std was in the range 2.64 ± 0.43mm corresponding to a mean increase in overall radial artery diameter of FMD = 15 ± 4.8% (95% CI: 13.3-17.2%), at peak reactive hyperaemic states. The AUC shear rate calculated in time span from cuff release till peak dilation was equal 42730 ± 23630, median 37393 (95% CI: 33383-52078). In the patient's group the peak dilated radial artery diameter was in the range (2.37-3.27 mm), mean ± std was 2.85 ± 0.3mm corresponding to increase in overall radial artery diameter via FMD = 4.6 ± 4% (95% CI: 2.45-6.7%), at peak reactive hyperaemic states. The SR was equal 47761 ± 35871, median 42584, (95% CI: 26084-69438). The FMD/SR, for the healthy group was equal 5.365 ± 4.835·10-4, and in patient's group 1.3 ± 0.89·10-4.
Conclusions: In healthy volunteers the mean increase in radial artery diameter measured via FMD was 15 ± 4.8% while in patients with stage B heart failure FMD was much smaller and was 4.6 ± 4%. The SR normalized FMD, FMD/SR, was equal 5.365 ± 4.835·10-4 and 1.3 ± 0.89·10-4 for healthy volunteers and patients, respectively. Both parameters, FMD and FMD/SR showed highly significant univariate association with the occurrence of HF (P < 0.001). Radial artery flow mediation dilatation and shear rate should be considered as new imaging biomarkers in patients with stage B heart failure.

P2141

The retrospective analysis of chronic heart failure therapy, prior hospitalization for acute coronary syndrome in patients with atrial fibrillation

J Julia Dorofeeva[1]; EI Tarlovskaya[2]; SV Malhcikova[1]
[1]Kirov State Medical Academy, Internal medicine, Kirov, Russian Federation; *[2]Nizhny Novgorod State Medical Academy, Internal medicine, Nizhny Novgorod, Russian Federation*

Objective: To retrospectively evaluate the therapy of chronic heart failure (CHF) in patients with atrial fibrillation (AF) prior to hospitalization for acute coronary syndrome (ACS).
Materials and Methods: The analysis retrospectively included 163 patients with AF who were admitted to medical rehabilitation for ACS at the clinic of the Kirov Medical University from vascular centers. Criteria for inclusion - the passage of rehabilitation for ACS, the presence of AF. Exclusion criteria - absence of OP, prescription of ACS for more than 1 month. We have calculated M ± O, x2. Outpatient and inpatient patient cards were used. The average age of the patients was 64.9 ± 9.7 years. Of these, 55.8% of men and 44.2% of women.
Results: CHF before hospitalization had 133 (81.59%) patients (68 (51.13%) men and 65 (48.87%) women). Most CHF was combined with AF, ischemic heart disease and hypertension - 84 (63.16%) people. The average age of patients with CHF was 65.65 ± 9.8 years, the average length of the disease was 2.74 ± 2.8 years. XPS at the level I functional class (FC) had 42 (31.58%), II FC - 55 (41.35%), III FC - 36 (27.07%). No treatment was received at all for CHC 29 (21.8%) patients (I FC - 12 (28.57%), II FK-9 (16.36%), III FK-8 (22.22%)).Therapy with angiotensin-converting

enzyme (ACE inhibitors) / aldosterone receptor antagonists (APA) received a total of 57.9% of patients (I FC-23 (54.76%) patients, II-FC 30 (54.55%), III FC-24 66.67%)). Therapy with ß-adrenoblockers (BAB) / ivabradine at I FC 20 (47.62%) patients, although it was not shown to them, at II FK - 33 (60%), at III FK - 17 (47,22%). 15% of patients (I FC - none, II FC - 9 (16.36%) patients received therapy with mineral-corticoid receptor antagonists (AICM), although it was not shown to them, III FC - only 11 (30.56%) patients). Therapy with loop diuretics (PD) received in total 15 (11.3%) patients (I FC - none, II FK - 8 (14.55%) patients, although she was not shown them, III FC - only 7 (19,44 %) patients). Thus, out of 133 patients with CHF, therapy, corresponding to clinical recommendations received only 40 (30.08%) patients.

Conclusions: • In the group of patients with AF, hospitalized for ACS, during the previous hospitalization there was a very low quality of CHF therapy, especially III FC.

•Before the hospitalization, only 104 (78.2%) patients with CHF received treatment with CHF, and only 40 (30.08%) of them had rational therapy.

•Very rare was the use of AMPK (11 (30.56%) patients) and PD (7 (19.44%) patients) in patients with III FC of CHF.

P2142

Is loss of glycocalyx density associated with mortality in chronic heart failure?

PP Wadowski[1]; M Huelsmann[2]; IM Lang[2]; R Wurm[2]; J Pultar[1]; C Schoergenhofer[3]; C Weikert[1]; T Gremmel[1]; R Koppensteiner[1]; M Schwameis[3]; B Steinlechner[4]; B Jilma[3]

[1]Medical University of Vienna, Division of Angiology, Department of Internal Medicine II, Vienna, Austria; *[2]Medical University of Vienna, Division of Cardiology, Department of Internal Medicine II, Vienna, Austria*; *[3]Medical University of Vienna, Department of Clinical Pharmacology, Vienna, Austria*; *[4]Medical University of Vienna, Division of Cardiothoracic and Vascular Anaesthesia and Intensive Care, Vienna, Austria*

Funding Acknowledgements: The conduct of this study was in part supported by a grant from the Austrian Science Funds (FWF SFB 54-P04).

Background: Microcirculatory changes contribute to clinical symptoms and disease progression in chronic heart failure (CHF). We hypothesized that changes in cardiac microcirculation might also be reflected by a systemic reduction of capillaries and visualized by sublingual videomicroscopy. The aim was to study in vivo perfused and total capillary density and glycocalyx dimensions in patients with CHF vs. healthy controls.

Methods: Fifty-three patients with ischemic and non-ischemic cardiomyopathy and conservative treatment were compared to thirty-five healthy age-matched subjects in a prospective cross-sectional study. Sublingual microcirculation was visualized using a Sidestream Darkfield videomicroscope. Perfused (functional) and total capillary densities were compared between patients and controls. A reduced glycocalyx thickness was measured by an increased perfused boundary region (PBR).

Results: Median functional and perfused total capillary densities were 31% and 46% respectively lower in patients with cardiomyopathy (both $p < 0.001$). Dimensions of the glycocalyx were marginally lower in CHF patients than in healthy controls (< 7% difference). Loss of glycocalyx was significantly associated with overall death after a mean follow up time of 27 months (PBR: 2.05 vs. 1.86µm, $p = 0.006$). Furthermore, PBR correlated significantly with inflammation markers (fibrinogen: $r = 0.54$; C-reactive protein: $r = 0.36$), platelet counts ($r = 0.38$), and inversely with measures of liver/renal function such as bilirubin (r=-0.39) and albumin (r=-0.30) or estimated glomerular filtration rate (r=-0.34) in CHF patients.

Conclusion: CHF patients have got a markedly lower perfused and total capillary density in sublingual microvasculature when compared to controls. In addition, decreased glycocalyx thickness is related to poor overall survival.

P2143

Soluble interleukin-1 receptor-like 1 (ST2) and left ventricular remodeling after ST-segment elevation myocardial infarction: A cardiac magnetic resonance study

J Gonzalez D' Gregorio[1]; G Minana[1]; J Nunez[1]; A Bayes-Genis[2]; E Revuelta[2]; E Nunez[1]; MP Lopez-Lereu[3]; JV Monmeneu[3]; FJ Chorro[1]; J Lupon[2]; E Valero[1]; S Garcia-Blas[1]; C Rios[1]; J Gavara[1]; V Bodi[1]

[1]University Hospital Clinic of Valencia, Cardiology Department, INCLIVA. Medicine Department, University of Valencia., Valencia, Spain; *[2]Germans Trias i Pujol Hospital, Cardiology Department and Heart Failure Unit, Badalona (Barcelona), Spain*; *[3]ERESA, Valencia, Spain*

Funding Acknowledgements: This work was supported in part by grants from CIBER CV 16/11/00420, 16/11/00403 and FEDER and PIE15/00013.

Background: The association of soluble interleukin-1 receptor-like 1 (ST2), with left ventricular (LV) remodeling is unclear in unselected patients with a first STEMI.

Objetive: The aim of this work was to assess the relationship between ST2 a marker of inflammation and (LV) remodeling, by cardiac magnetic resonance (CMR) imaging 6 months after a STEMI.

Methods: We prospectively evaluated 109 patients with a first STEMI treated with primary percutaneous coronary intervention who had ST2 assessed within 24 h. All patients underwent CMR imaging 1 week and 6 month after STEMI. The associations between ST2, LV diastolic and systolic volumes, and LV ejection fraction (LVEF) were evaluated by linear mixed models.

Results: The mean age was 59 ± 12 years, 85 patients (78%) were male, and 13 (11.9%) had a LVEF = 40%. The median (IQR) of ST2 was 55.3 (38.7-94.1) pg/mL. After comprehensive adjustment, ST2 was positively associated with increasing 6-month LV volume indices ($p = 0.025$ and $p = 0.018$ for diastolic and systolic volumes, respectively, Fig. 1a, 1b) and inversely associated with the 6-month LVEF (Fig. 1c)($p = 0.06$). The effect of ST2 on the endpoints was greater in patients with a larger infarct size, extensive microvascular obstruction, and a LVEF = 40% at 1-week.

Conclusions: In patients with a first STEMI treated with primary percutaneous coronary intervention, soluble ST2 predicted the changes in LV volumes and LVEF at 6 months. Future studies must assess whether targeting interleukin-1 leads to lower ST2 levels and less LV remodeling.

Effect of ST2 in LV volumes and EF

Chronic Heart Failure - Epidemiology, Prognosis, Outcome

P2144

Socio-economic factors and outcomes in heart failure: Insights from the ASIAN-HF registry.

WT Tay[1]; THK Teng[1]; J Tromp[1]; JJL Yap[2]; MR Macdonald[3]; C Chandramouli[1]; E Geelhoed[4]; AM Richards[5]; IS Anand[6]; CSP Lam[7]
[1]National Heart Centre Singapore, National Heart Research Institute, Singapore, Singapore; *[2]National Heart Centre Singapore, Singapore, Singapore*; *[3]Changi General Hospital, Singapore, Singapore*; *[4]The University of Western Australia, School of Allied Health, Perth, Australia*; *[5]National University Health System, Cardiovascular Research Institute, Singapore, Singapore*; *[6]University of Minnesota, Veteran Affairs Medical Center, Minneapolis, United States of America*; *[7]University Medical Center Groningen, Duke-NUS Medical School, National Heart Centre Singapore, Singapore*

On behalf of: ASIAN-HF Investigators
Funding Acknowledgements: National Medical Research Council (Singapore); A*STAR Biomedical Research Council; Boston Scientific; Bayer

Background: Epidemiological evidence in Western nations suggests socio-economic deprivation is associated with poorer health outcomes. However, there is a paucity of data from Asia.
Aim: We examined the association of household income and educational status with quality of life (QoL) and 1-year all-cause mortality in patients with heart failure (HF) from 11 regions in Asia recruited in the prospective, multi-national ASIAN-HF registry.
Methods: Household income (in US$) was grouped as < 1000, 1000-2999, 3000-4999 and >5000. Educational status was grouped as no formal or primary only, secondary, pre-university and degree or higher education. Health-related QoL was assessed using the Kansas City Cardiomyopathy Questionnaire. Multivariable regression models, incorporating adjustment for comorbidities and pharmacotherapy, were used to examine the association of socio-economic factors with QoL and mortality.
Results: Among 5598 Asian patients (mean age: 61.5 ± 13.4 years, 27% women) with HF, 55.4% and 19.4% were in the two lowest monthly household income categories. One-third of the cohort had no formal or only primary education and another third had received secondary education. Lower household income was related to lower educational status. Patients in the lowest income category or no/primary only education were likely to be older, have more severe HF (NYHA Class III/IV), and more comorbidities (i.e. CKD, anaemia, hypertension, CAD and diabetes) but less likely to receive evidence-based HF medications.
Household income and educational status were not correlated with overall QoL and symptom burden/frequency. No/primary only education was however, associated with poorer self-efficacy and greater physical limitation domains (5-15 points lower adjusted mean scores) of QoL, compared to degree-holders or those with other higher education, in univariable and multivariable models.
454 (8.1%) of the cohort had died at one year. Crude hazard ratios (HR) were 1.96 (95% CI 1.10-3.49) and HR 1.75 (95% CI 1.31-2.36) in those with the lowest (>$1000) vs. highest (<$5000) income category and no/primary only vs. degree or higher educational status, respectively. Those with both low educational status (no/primary only) and low household income (>$1000) had 47% increased hazards of 1-year mortality, as compared to secondary or higher education and household income=$1000 - a difference that remained significant even after multivariable adjustment.
Conclusions: These first prospective multinational data across Asia show that socio-economic factors (household income and educational status) are related to outcomes in heart failure. Low education status negatively impacted patients' self-care behaviour, whereas excess mortality was observed in those with both less education and low household income.

P2145

Patient-reported outcomes in patients with heart failure - associated with demographics?

Funding Acknowledgements: Aarhus University Hospital, Department of Cardiology and the Danish Nursing Counsil

Background
A range of clinical and sociodemographic prognostic factors are well-established in heart failure (HF), while a substantial need for clarifying the prognostic significance of self-reported information from the patients.
Patient-reported outcomes (PRO) data reflects the patient's subjective assessment of health status and quantifies the patient's perspective on the disease, anxiety and depression, symptoms and impact on everyday life.
Purpose: To study the association between demographic patient characteristics and PRO in a Danish population of patients with HF.
Methods: A cross-sectional cohort study based on the nationwide DenHeart Questionnaire Survey. Patients with a HF diagnosis, completing the DenHeart Questionnaire at discharge from one of the five heart centres in Denmark in the study period from April 2013 to April 2014, were included. Anxiety and depression was assessed by the Hospital Anxiety and Depression Scale (HADS), with a cut-off at = 8 points, indicating symptoms of anxiety and depression. Health-related quality of life was assessed by using HeartQol, where a global score < 2 points, is defined as a low quality of life. The Charlson Comorbidity Index categorised comorbidity: none (0 conditions), moderate (1-2 conditions) and high (= 3 conditions). Questionnaire data was linked to The Danish Civil Registration System, The Danish National Patient Registry and medical records. The statistical analysis included chi-squared tests and multivariable logistic regression analysis
Results: A total of 1.506 patients with HF with a mean age of 66.2 ± 12.2 years, 74.2% males, and 30.8% living alone, were included. In total 73.6% had an ejection fraction (EF) < 40% and 62.2% >1 comorbid condition. Symptoms of anxiety and depression was reported by 34.3% and 25.2% of the patients, respectively, while 70.5% suffered from low health-related quality of life. Regression analysis identified female gender (adjusted OR: 1.5 95% CI: 1.2-2.0), and a high comorbidity level (adjusted OR: 1.7, 95% CI: 1.2-2.3) to be associated with symptoms of anxiety. The same risk factors were associated with symptoms of depression: female gender (adjusted OR: 1.5, 95% CI: 1.2-2.0), a moderate comorbidity level (adjusted OR: 1.4, 95% CI: 1.1-1.9) and a high comorbidity level (adjusted OR: 1.9, 95% CI: 1.4-2.8). Finally, being female (adjusted OR: 1.4, 95% CI: 1.0-1.8), living alone (adjusted OR: 1.3, 95% CI: 1.0-1.7), an EF < 40% (adjusted OR: 1.4, 95% CI: 1.1-1.9), a moderate comorbidity level (adjusted OR: 1.5, 95% CI: 1.2-2.0) and a high comorbidity level (adjusted OR: 2.9, 95% CI: 2.0-4.2) was associated with low quality of life.
Conclusion: The patients reported symtoms of anxiety and depression and low health-related quality of life. Further efforts are warranted to clarify the potential additional prognostic information that PRO may represent. This may potential identify vulnerable patients with HF, who could benefit from a closer contact to the healthcare system.

P2146

Cardiologists perspectives on discussing prognosis with heart failure patients

MHL Van Der Wal[1]; L Hjelmfors[1]; A Stromberg[2]; T Jaarsma[1]
[1]Faculty of Medical and Health Sciences, Department of Social and Welfare Studies, Linköping, Sweden; *[2]Linkoping University, Department of Medical and Health Sciences , Linkoping, Sweden*

Purpose: Recent Heart Failure (HF) ESC guidelines recommend that HF patients should be invited to discuss prognosis and end-of-life. However, it is unknown what the cardiologists' attitudes are regarding discussing this with their patients. Therefore, the purpose of this study was to describe the cardiologists' attitudes on discussing prognosis with HF patients with focus on barriers and how difficult they experience these conversations.
Methods: A total of 125 HF cardiologists in the Netherlands were invited by email to participate. The questionnaire used was adapted from a previously validated questionnaire developed for HF nurses. The cardiologist were asked to fill in a 10-item questionnaire about communicating prognosis, including experienced barriers in these communications. They also were asked to select a time in the HF trajectory when they would discuss prognosis for the first time with the patient. Finally they were asked to rate their experienced difficulty with discussing prognosis on a scale ranging from 1 (not difficult at all) to 10 (very difficult).
Results: A total of 43 cardiologists (response rate 34%) filled in the questionnaire (mean age 51 ± 9; 23% women). Most of the cardiologist (95%) stated that discussions about prognosis should be initiated by the patients own cardiologist although 72% also reported that another cardiologist could discuss this with the patient in case of a hospitalization, or the nurse at the HF clinic (58%). Although the mean reported difficulty in discussing prognosis was rather low (mean 3,7 ± 2), about a quarter of the cardiologists rated a 6 or higher. With regard to timing of the discussion of prognosis, half of (49%) of the cardiologists stated that prognosis should be discussed at time of diagnosis, although 23% found the first period of decompensated HF or HF hospitalization the best time to discuss it with the patient. Sixteen percent suggested that they only would discuss it in case of a serious deterioration of the HF condition. The most reported barrier to discuss prognosis were cognitive

P2146 Effect of cardiovascular risk factors

	CV risk factor	Impact of CV risk factor	P	Effect size women vs men	P for effect in women	P for effect in men	P for inter-action
GLPS	Obesity	+0.7%	<0.001	+0.9% vs. +0.7%	<0.01	<0.01	0.69
Hypertension	+0.3%	ns	+0.7% vs. -0.1%	<0.01	ns	0.004	
Dyslipidemia	+0.3%	<0.001	+1.2% vs. +0.3%	<0.001	ns	0.03	
Systolic SR	Obesity	+0.04 s-1	<0.001	+0.06 s-1 vs. +0.01 s-1	<0.001	ns	0.047
Hypertension	+0.03 s-1	<0.01	+0.06 s-1 vs. +0.02 s-1	<0.001	ns	0.02	
Dyslipidemia	+0.03 s-1	<0.05	+0.05 s-1 vs. +0.01 s-1	<0.01	ns	0.07	
Early diastolic SR	Obesity	-0.12 s-1	<0.001	-0.14 s-1 vs. -0.12 s-1	<0.001	<0.001	0.72
Hypertension	-0.72 s-1	<0.001	-0.24 s-1 vs. -0.10 s-1	<0.001	<0.001	<0.001	
Dyslipidemia	-0.12 s-1	<0.001	-0.19 s-1 vs. -0.2 s-1	<0.001	ns	0.001	
Late dia-stolic SR	Hypertension	+0.09 s-1	<0.001	+0.11 s-1 vs. +0.06 s-1	<0.001	<0.001	0.02

Effect of cardiovascular (CV) risk factors on global longitudinal peak systolic strain (GLPS), systolic, early diastolic, and late diastolic strain rate (SR). ns = not significant.

problems of the patient (56%), too little time to discuss the subject (53%) and that the patient was not ready for it (53%). Other important reasons that made it more difficult were the unpredictability of the disease (50%) and fear that the patient would be worried or lose hope (50%).
Conclusion: Most cardiologists did not find it very difficult to discuss prognosis with their patients and suggest to discuss it when the diagnosis is assessed. Barriers to discuss prognosis were related to organization (lack of time) or condition of the patients (cognitive problems, not being ready). Most of the cardiologists reported that the own cardiologist should discuss prognosis with the patient, although also other health care providers (cardiologist on the ward, HF nurse) could discuss this. Therefor a multidisciplinary team approach seems important to improve discussing prognosis with HF patients.

P2147

Impact of cardiovascular risk factors on systolic and diastolic myocardial deformation Results from the population-based STAAB cohort study

C Morbach[1]; B Walter[1]; M Breunig[1]; G Gelbrich[2]; T Tiffe[2]; M Wagner[2]; PU Heuschmann[2]; S Stoerk[1]
[1]University Hospital Wuerzburg, Comprehensive Heart Failure Center and Dept. of Medicine I, Wuerzburg, Germany; *[2]University of Wuerzburg, Institute of Clinical Epidemiology and Biometry and Comprehensive Heart Failure Center, Wuerzburg, Germany*

Funding Acknowledgements: German Ministry of Education and Research (BMBF 01EO1004 and 01EO1504)

Background: Hypertension, smoking, obesity, dyslipidemia, and diabetes mellitus impact adversely on cardiovascular health and are related to heart failure (HF).
Purpose: We determined the impact of these cardiovascular risk factors (CVRF) on myocardial deformation assessed by echocardiography.
Methods: The Characteristics and Course of Heart Failure STAges A/B and Determinants of Progression (STAAB) cohort study recruited a representative sample of the population of Würzburg, Germany, aged 30-79 years and reporting no previous history of HF. Participants underwent detailed cardiovascular phenotyping and transthoracic echocardiography (Vivid S6, GE). Segmental and global longitudinal peak systolic strain (GLPS), systolic (sSR), early (edSR) and late diastolic strain rates (ldSR) were derived from 2D speckle tracking analysis.
RESULTS In 1219 of 1818 participants (49% male, mean age 54 ± 12 years) strain analysis could be performed. In a linear model, dyslipidemia, obesity, and hypertension but not diabetes mellitus and smoking showed a significant association with myocardial deformation (table).
CONCLUSION We observed sex-specific alterations of different aspects of myocardial deformation by CVRF. The female myocardium might be more vulnerable to hypertension and dyslipidemia regarding both systolic and active diastolic deformation. Late diastolic SR increased in individuals with hypertension - most likely in response to impaired early diastolic function. Obesity was the single CVRF exhibiting the most consistent adverse impact on systolic and diastolic deformation in both sexes.

P2148

Coronary artery bypass surgery versus percutaneous coronary intervention in patients with ischemic cardiomyopathy. Long term outcome depends on severity of heart failure.

C Christian Roth[1]; M Schneider[1]; D Dalos[1]; C Gangl[1]; R Berger[1]
[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria

Aims: Registries and a meta-analysis suggested a similar survival benefit from percutaneous coronary intervention (PCI) compared to coronary artery bypass graft surgery (CABG) over medical therapy alone for treatment of ischemic cardiomyopathy. The severity of heart failure may impact the long-term results of these different revascularisation strategies.
Methods and Results: Patients with moderate to severe left ventricular systolic dysfunction and multivessel disease who underwent either PCI with drug-eluting stents (DES) or CABG were selected from the catheter laboratory database of the Medical University of Vienna. The primary outcome was long-term all-cause death. Among 398 patients (340 PCI, 58 CABG) the mode of revascularisation did not contribute to the prediction of death (univariate analysis - p = 0.336; Kaplan-Meier analysis - p = 0,442 during a median observation period of 1,495 (819/2,458) days), whereas NT-proBNP was the strongest predictor of long-term all-cause death. In patients with advanced heart failure (NTproBNP > median 3042pg/ml, n = 199) the mode of revascularisation was an independent predictor of death. In the Kaplan-Meier analysis patients with CABG had a better long-term survival compared to patients with PCI (p = 0.035).
Conclusions: Among patients with ischemic cardiomyopathy, PCI with DES had comparable long-term survival compared with CABG. However, patients with advanced heart failure may benefit from CABG compared to PCI.

P2149

Does NYHA class predict health-related quality of life?

A Gallagher[1]; R Lucas[2]; MR Cowie[1]
[1]Imperial College London, London, United Kingdom; *[2]Royal Brompton Hospital, London, United Kingdom*

Background: Improving quality of life is a primary aim of heart failure management. Evaluation of health-related QoL (HR-QoL) is recommended in guidelines, however, advice on implementation is lacking. Despite the use of validated HR-QoL instruments in clinical trials, their use in routine practice is yet to be widely adopted. Conversely, functional assessment using New York Heart Association (NYHA) classification is standard in the monitoring and treatment pathways of heart failure patients.
Purpose: To investigate the acceptability and feasibility of using validated HR-QoL instruments in heart failure outpatient clinics, and to examine the clinical predictors of HR-QoL.
Methods: 163 patients attending two specialist heart failure clinics, between May 2015 and 2017, were invited to complete three HR-QoL assessments: the Minnesota Living with Heart Failure questionnaire (MLHFQ); the EuroQoL 5D-3L (EQ-5D-3L); and the Kansas City Cardiomyopathy questionnaire (KCCQ). Data on the patient demographics, co-morbidities, NYHA class, plasma BNP (B-type natriuretic peptide), renal function and echocardiographic parameters were recorded.
Results: 94% of patients were willing to participate. The EQ-5D-3L questionnaire had all questions answered by 92%, compared to 86% for the MLHFQ and 49% for the KCCQ. 32% of patients requested assistance in completing the

questionnaires. There was no association between age, gender, body mass index (BMI), left ventricular ejection fraction (LVEF), plasma BNP or renal function with HR-QoL. NYHA class significantly correlated with each of the QoL assessment tools (MLHFQ r = 0.59; KCCQ r = -0.61; EQ-5D-3L r = -0.44, all p < 0.01). However, there was a wide spread of HR-QoL outcome scores for each NYHA class (Figure 1).

Conclusion: Although NYHA class correlated significantly with HR-QoL scores, in each class there was high variability in the HR-QoL scores between individual patients. NYHA classification is a focused functional assessment made from the perspective of the clinician as opposed to the patient, with consequent drawbacks. Therefore, the incorporation of validated methods to assess health-related QoL into clinical practice is required. This study confirms the acceptability and feasibility of using validated HR-QoL instruments in heart failure clinics and highlights the limitations of NHYA classification.

Heart failure prevalence in general population - interim report of the Screening Of adult urBan pOpulation To diAgnose Heart Failure (SOBOTA-HF) study

D Omersa[1]; J Farkas[2]; A Zupan Meznar[3]; N Sedlar[4]; M Lainscak[2]
[1]General Hospital Jesenice, Department of Internal Medicine, Jesenice, Slovenia; *[2]General Hospital Murska Sobota, Department of Research and Education, Murska Sobota, Slovenia*; *[3]General Hospital Celje, Department of Cardiology, Celje, Slovenia*; *[4]National Institute of Public Health, Ljubljana, Slovenia*

Funding Acknowledgements: Slovenian research agency grants 630-84/2015-1 and J3-7405

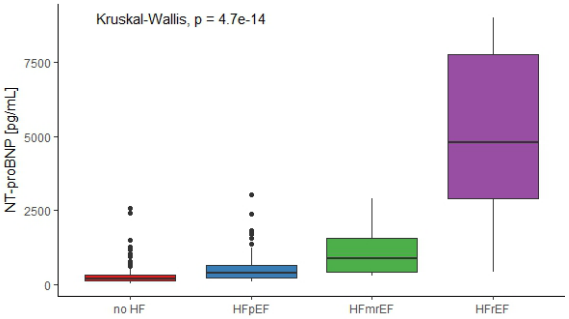
Background: The estimated heart failure (HF) prevalence of 1-2% in general population is based on studies that primarily used clinical criteria and many of them were conducted in specific populations. In view of continuous ageing of the population and diagnostic algorithm that is now based on natriuretic peptides and echocardiography, prevalence estimates are higher but were not investigated in contemporary general population.

Purpose: The purpose of this study was to assess the HF prevalence in general population aged 55 years or more.

Methods: SOBOTA-HF study is an ongoing cross sectional epidemiological study in city residents aged 55 years or more (N = 1282, 29% of the city population). In this interim report we present the data from a representative sample of residents, who were invited for screening with NT-proBNP. Those with NT-proBNP >= 125 pg/mL were invited for a detailed diagnostic visit with echocardiography, history and physical examination and electrocardiogram. HF diagnosis was based on 2016 European Society of Cardiology guidelines to calculate the HF prevalence.

Results: A total of 702 participants (response rate of 55%) completed the screening visit. Of those, 266 (38%) had NT-proBNP = 125 pg/mL and were invited for diagnostic visit. HF diagnosis was established in 83 participants with a prevalence of 11.4% in the study population. After an extrapolation to the whole population, an estimated HF prevalence was 4.6% (with the assumption that the HF prevalence in people < 55 years is 0%). Of those with HF, 8.5% had HF with reduced ejection fraction, 7.2% had HF with mid-range ejection fraction and 84.3% had HF with preserved EF. Between the participants without HF and HF groups, there were significant differences in the values of NT-proBNP (Figure).

Conclusion: The prevalence of HF in residents aged 55 years or more is 11.4% and 4.6% in all residents, mainly with preserved EF.



P2151

Prognostic value of ventilation equivalent of carbon dioxide slope in overweight heart failure patients

A Antonio Valentim Goncalves[1]; R M Soares[1]; T Pereira-Da-Silva[1]; R Ilhao Moreira[1]; J Feliciano[1]; P Rio[1]; A Abreu[1]; S Aguiar Rosa[1]; T Mendonca[1]; M Coutinho Cruz[1]; R Cruz Ferreira[1]
[1]Hospital de Santa Marta, Lisbon, Portugal

Introduction: Pulmonary function and ventilation mechanics are not normal in overweight patients, leading to a decreased hypercapnic ventilatory response which would lower the VE/VCO2 slope but worsen prognosis.

Purpose: The aim of this study was to compare the prognostic ability of the VE/VCO2 slope and pVO2 between normal and overweight heart failure (HF) patients.

Methods: Patients followed in NYHA class II-III with LVEF = 40%, underwent a prospective evaluation including a CPET. All patients were followed for 5 years and the combined endpoint was death and urgent heart transplantation.

The VE/VCO2 slope and pVO2 were analysed as potential predictors of the combined endpoint in 1, 3 and 5 years (Cox regression) and their predictive power was compared (area under the curve (AUC)) in the subgroups with body mass index (BMI) of 18.5-24.9kg/m2 (G1) and = 25kg/m2 (G2).

Results: Of the 270 enrolled patients (males 75.9%; mean BMI 26.93 ± 4.21kg/m2; mean NYHA 2.21 ± 0.46), G2 group were older (50.55 ± 14.28 vs 55.23 ± 10.42; p = 0.006), with higher LVEF (25.55 ± 6.93 vs 28.28 ± 7.41; p = 0.004) and higher HFSS (8.43 ± 0.57 vs 8.78 ± 0.94; p = 0.004).

There were 88 major events during the 5 years (G1 = 38.0% vs G2 = 29.8%; p = 0.170). The discriminative power of VE/VCO2 slope and pVO2 in G1 and G2 are presented in the Table.

The VE/VCO2 slope had at least as good AUC values as pVO2 in both groups. The comparison of VE/VCO2 slope between G1 and G2 revealed a significant lower predictive power at 3 and 5 years for G2 patients (p = 0.022 and p = 0.044, respectively).

Conclusion: Despite VE/VCO2 slope provides a discriminative power at least as good as pVO2 for predicting adverse events in both normal and overweight HF patients, a significant lower predictive power was found in overweight patients in long-term outcomes.

Prognostic value of random urine sodium in predicting outcomes of patients with acute decompensated heart failure

M J Jhessica Pecson[1]; MC Torres[1]
[1]*Philippine Heart Center, Adult Cardiology, Quezon City, Philippines*

Background: Heart failure is an urgent public health need being the leading cause of hospitalization and an important cause of morbidity and mortality in the world.1 The science of prognostication attempts to identify patient's clinical and biological characteristics that are associated with poor outcome. Risk prediction in patients admitted with acute decompensated heart failure remains a challenge hence this study was conducted to determine association between urine sodium (Na+) level of patients admitted for acute decompensation of heart failure and outcome.
Method: All patients >19 years old admitted at a heart center for acute decompensation of heart failure with normal creatinine level at admission and with consent to participate were included in the study. Random urine sodium level was determined during first 24 hours of hospitalization. Patients were then followed up and clinical outcomes noted.
Results: Study included 150 patients which were grouped into three groups. First group included 31 patients with low urine Na+ <30 mmol/L, 48 patients in the second group with normal urine Na+ 31-90 mmol/L and 71 patients in the third group with high urine Na+ >90 mmol/L. Baseline characteristics of the three groups were similar. The primary composite outcome of death occurred in 42 patients (28%): 13 patients (42%) in the 1st group, 11 patients (23%) in the 2nd group and 18 patients (25%) in the 3rd group which was statistically significant (p = 0.002) (Table 1).
Conclusion This prospective cohort study showed significant prognostic value of random urine sodium on cardiovascular mortality on patients with acute decompensated heart failure. Low urine sodium level (uNa+ < 30 mmol/L) is associated with poor outcome

Association of urine sodium to outcome

Parameters	Low Urine Na+ (< 30 mmol/L) n = 31	Normal Urine Na_+ (31-90 mmol/L) n = 48	High Urine Na+ (>90 mmol/L) n = 71	P value
Frequency (%); Mean + SD				
Death	13 (42)	11 (23)	18 (25)	0.002
Readmission	13 (42)	19 (40)	25 (35)	0.889

P2153

Can cardiac biomarkers improve the diagnostic value of a clinical base model in diagnostically naive patients with suspected heart failure?

C Morbach[1]; S Demirbas[1]; D Oder[2]; V Holzendorf[3]; C Prettin[3]; S Stoerk[1]; G Ertl[1]; C Angermann[1]
[1]*University Hospital Wuerzburg, Comprehensive Heart Failure Center and Dept. of Medicine I, Wuerzburg, Germany*; [2]*Department of Internal Medicine I / Center of Cardiovascular Medicine, Würzburg, Germany*; [3]*Clinical Trial Center, Leipzig, Germany*

Background: Up to date, little is known about the prognostic significance of modern cardiac biomarkers in diagnostically naïve patients who present to their general practitioner (GP) with signs and symptoms potentially indicative of heart failure (HF).
Methods: N-terminal B-type natriuretic peptide (NT-proBNP), mid-regional pro-atrial NP (MR-proANP), mid-regional pro-adrenomedullin (MR-proADM), high sensitive C-reactive protein (hsCRP), tumor necrosis factor alpha (TNF a), and copeptin were determined from stored (-80°) blood of participants of the Handheld-BNP study, diagnostically naïve individuals who attended their GP with suspected HF.
The prognostic significance of individual biomarkers was compared with that of a base model consisting of age at baseline (years), sex, body mass index ((= vs >30kg/m2), renal failure (glomerular filtration rate = vs < 60ml/min./1.73m2), anaemia (haemoglobin = vs < 12mg/dL in females and = vs < 13mg/dL in males), arterial hypertension (systolic blood pressure >140mmHg and diastolic blood pressure >90mmHg or on antihypertensive drugs), diabetes mellitus (history or on antidiabetic drugs), New York Heart Association (NYHA) classes III-IV, vascular disease (stroke, peripheral artery disease or myocardial infarction), and atrial fibrillation. Further the prognostic value of a multimarker model with all biomarkers ± the base model was tested.
Results: 854/917 (93.1%) individuals (68 ± 12 years, 63% female) qualified for the present analysis. 15.8% died during the observation period of 72.2 (68.5-72.2) months. The base model alone predicted all-cause death with an area under the curve (AUC) of 0.797 which was higher than AUCs for each biomarker or a combination of all biomarkers (AUC= 0.584-0.755, and 0.754, respectively). Combination of the base model with individual biomarkers improved the AUC (e.g. addition of MR-proANP AUC = 0.809). Mortality risk was best predicted by a combination of the base model and all biomarkers (AUC 0.815).
Conclusion: Diagnostically naïve patients who present to their GP with signs and symptoms potentially indicative of heart failure have a higher mortality risk compared to the same age group of the general population (6.6%, Federal Statistical Office). The base model, which is easy to evaluate by a GP, predicted the 5-year mortality risk more accurately than each biomarker or the combination of all biomarkers. Nevertheless, addition of the biomarkers to the base model positively impacted on prognostic value and mortality risk was best predicted by a combination of the base model and all biomarkers.

P2154

Predictors of mid-term rehospitalization and mortality rates in Bulgarian patients with heart failure and preserved ejection fraction: a single-center study

R Pancheva[1]; N Runev[1]; E Manov[1]; B Stoimenov[1]; D Vassilev[2]
[1]*University Hospital Alexandrovska, Cardiology Clinic, Department of Propaedeutics of Internal Diseases , Sofia, Bulgaria*; [2]*University Hospital Alexandrovska, Department Cardiology, Sofia, Bulgaria*

Background: Chronic heart failure (CHF) is a major cause of death and recurrent rehospitalization. Hospitalized HF patients are becoming a significant economic burden. About half of the people who develop HF die within 5 years of diagnosis in spite of current optimal medical therapy. Moreover, recent epidemiological studies have demonstrated that nearly 50% of all HF patients have preserved left ventricular ejection fraction (HFpEF), with survival rates similar to those of patients with reduced EF.
Purpose: We aimed to analyze the reasons, predictors and rates of mortality and rehospitalization of patients with HFpEF in the Bulgarian population.
Methods: An observational study of patients with decompensated HFpEF, admitted at our Department between January 2012 and June 2013, was conducted. Among the risk factors, co-morbidities, clinical, echocardiographic and hemodynamic indicators, predictors of their mortality and rehospitalization rates were investigated.
esults: A total of 680 patients, mean age 67.2 ± 11.3 years, were studied. The demographic characteristics were as follows: 95.9% had arterial hypertension (AH)

(1.5% I grade; 70.1% II grade; 24.4% III grade); 23% type 2 diabetes mellitus (DM); 41.5% suffered from coronary artery disease (CAD), of whom 11.0% with previous myocardial infarction (MI); 27.9% had valvular heart disease (VHD); 57.5% atrial fibrillation (AF) and 43.7% elevated pulmonary artery systolic pressure (PASP) (<40 mmHg). In the follow-up period with average duration of 5.1 years, 178 patients (26.2%) died. For independent predictors of the 5.1-year mortality in our HFpEF group, the following were found: age>78 years, previous MI, mitral valve disease (MVD) and combined mitral and aortic valve disease (AVD), anemia, left atrium (LA) parasternal diameter >42 mm, LA length >57 mm, PASP >45 mmHg, permanent AF and CHA2DS2VASc >3 points.
In the clinical follow-up period with average duration of 1.2 years, 78 patients (11.5%) experienced rehospitalization because of an exacerbation of congestive HF. Using a multivariate logistic regression analysis, the following independent predictors of rehospitalization were found: prosthetic VHD (OR 4.58; 95% CI, 2.18-9.62; $p < 0.01$), HF NYHA classes III and IV (OR 7.90; 95% CI, 1,10-56.86; $p < 0.05$), LA diameter >43 mm (OR 1.64; 95% CI, 1.0-2.67; $p < 0.05$), LA length >54 mm (OR 1.87; 95% CI, 1.10-3.21; $p < 0.05$), and paroxysmal AF (OR 3.38; 95% CI, 1.95-5.86; $p < 0.01$).
Conclusion: Because of the lack of national registry of the HF population in Bulgaria, we performed this single-center study of patients with HFpEF. The analysis has revealed that the 5.1-year mortality rate is predicted by the advanced age (<78 years), presence of MVD and combined MVD + AVD, history of MI, anemia, as well as LA enlargement with AF and pulmonary hypertension. The mean 1.2-year rehospitalization rate has been found to be highly dependent on prosthetic VHD, NYHA III and IV, and increased LA size with paroxysmal AF.

P2155
Analysis of the China Heart Failure Surgery Registry Study (China-HFSR):from 2012 to 2017

H Hanwei Tang[1]; J Hou[1]; S Hu[1]
[1]*Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China People's Republic of*

On behalf of: China Heart Failure Surgery Registry Study Collabrative Group
Funding Acknowledgements: National Key Reserch Project (2016YFC1300900)

Background
The cardiac surgery in heart failure patients in China is growing, but data on these patients have been limited.
Objective
To clarify the real-world etiology, clinical characteristics and real-world treatment patterns of Chinese HF surgery patients.
Methods: We used the China Heart Failure Surgery Registry Study(China-HFSR) database to obtain the demographic and clinical characteristics and treatment patterns of Chinese HFf surgery patients.
Results: From January 2012 to June 2017, data on 13 665 patients have been received from 94 participating centre. The median age was 59.2, and 26.9% were women. The most frequently performed operation was isolated coronary artery bypass graft (CABG) which was received in 47.8% patients, while the isolated valve surgery was 27.1% and CABG combined with valve surgery was 6.6%.Median length of stay (LOS) was 23 days and in-hospital mortality was 4.1%, with the highest mortality in north-east region (7.7%) and the lowest in south-west region. Perioperative implantaion of intra-aortic balloon pump (IABP) was in 6.9% patients, and the use of extracorporeal membrane oxygenation (ECMO) was 6.9%. The postoperation ß-blockers was used in 42% patients while the use of angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blockers was 23%.
Conclusions: The China-HSFR has described the real-world clinical characteristic of Chinese HF surgery patients. Currently ,there is a relatively small amount of heart failure surgery and perioperative extracorporal life-assistant device use in China, with nonadherent to HF medications use and regional variations in outcomes. Therefore, there is a demand for quality-of-care improvement.

P2156
Guideline-recommended drug therapy in patients with chronic heart failure

G Gerald Gredinger[1]; C Trischak[1]; S Wieser[1]; S Reitter-Pfoertner[1]
[1]*Wiener Gebietskrankenkasse, Competence Center Integrierte Versorgung, Vienna, Austria*

Background: Chronic heart failure is associated with frequent hospital admissions as well as high mortality. The implementation of guideline-recommended drug therapy was shown to reduce both, hospital admission rates and mortality. Nevertheless, guideline-recommended drugs often remain underused in clinical practice.
Purpose: Evaluation of guideline-conform treatment and its impact on hospital admission and mortality in our patient population.
Methods: We used data from the 13 bigger Austrian health insurance funds and identified 19,314 hospitalized patients (79.1 years ± 11.5, 44.8 % men) for whom a discharge diagnosis of chronic heart failure has been reported between January 1, 2015 and December 31, 2015. For these identified patients we retrieved information on prescribed medication for one year after the first discharge from our records. Multivariate Logistic Regression was performed to explore the relationship between drug therapy, demographic characteristics, hospital readmission rates and mortality.
Results: Overall, 27.1 % of the patients were readmitted to hospital due to heart failure within 1 year; 33.7 % died within 1 year. Regarding guideline-conform treatment, 55.4 % of the patients were prescribed angiotensin-convertin-enzyme inhibitors (ACE-I) or angiotensin-receptor blockers (ARB), 53.22 % had beta-blockers, 35.2 % aldosterone-antagonists and 56.0 % diuretics. Multivariable variable logistic regression analysis showed that the prescription of ACE-I/ARB in combination with beta-blockers significantly lowers the mortality risk. In the readmission context no significant results could be detected.
Conclusion: It can be concluded that a combination of ACE-I/ARB with beta-blockers has a beneficial impact on mortality. Unfortunately, this therapy remains underutilised in our population.

P2157
Rapid pharmacological therapy optimisation in newly diagnosed severe left ventricular systolic dysfunction through seamless heart failure care:Effects on left ventricular function and 1-year mortality

C Chee Lim[1]; T Hunt[1]; K Hann[1]; A Baker[1]; L Jenkins[1]; L Hardy[1]; M Dewhurst[1]
[1]*North Tees and Hartlepool NHS Trust, Stockton-on-Tees, United Kingdom*

Background :
Delays in achieving optimised pharmacological therapy (OPT) for left ventricular systolic dysfunction (LVSD) lead to increased mortality. Patients with severe LVSD have worse outcomes than those with milder dysfunction. There are sparse data examining the beneficial effects of rapid achievement of OPT on LVSD and outcomes. Integrated heart failure (HF) services are recommended in international guidance to improve patient experience and efficiency in care delivery, and we have recently moved to an integrated model.
Purpose: The aim of this study was to assess whether an integrated heart failure service enabled rapid achievement of OPT in patients with severe LVSD and how this impacted upon improvements in left ventricular function on repeat imaging and mortality at 1 year.
METHODOLOGY :
We performed retrospective analysis of consecutive patients with newly-diagnosed severe LVSD (EF = 35%) over a six-month period after HF service integration (HF specialist nurses providing working across both primary and secondary care). Data was obtained from our local HF specialist nurse patient database and corroborated through data submitted to the national HF database. Time from first diagnosis (initial echocardiogram) to repeat imaging was calculated, subtracting 3 months from this to calculate time to OPT (repeat imaging recommended 3 months post OPT). Mortality data at 1 year was recorded. Factors influencing time to OPT, improvement in LVSD and outcome were assessed.
Results: 38 patients had newly diagnosed severe LVSD, of which 27 had repeat imaging. Mean age was 69(range 34-98), 61%(23) male. Mean time from diagnosis to OPT was 2.5 months for in-patients and 4.3 months for out-patients. 20/27 (74%) showed improvement in LVSD from severe to at least moderate on repeat imaging. 1 year mortality was 10.5%. Factors reducing time to OPT include being in-patient at diagnosis, no requirement of dosette box and use of perindopril versus ramipril. Factors increasing chances of LV improvement include non-ischaemic aetiology, higher medication dose achieved, lower Charlson co-morbidity score and narrow QRS. Factors increasing chances of mortality include number of hospital admissions, inability to tolerate target dose 'triple therapy' medication and higher Charlson score. reason for not having repeat imaging include patient choice, multiple comorbidities and poor prognosis.
Conclusion: An integrated HF service contributes to the rapid achievement of OPT. The prevalence of LV improvement in this modern service is significantly higher than historic data in the literature, and the 1 year mortality rate much lower.

Chronic Heart Failure - Diagnostic Methods

P2158
Complications in endomyocardial biopsy - a single center experience

CDJ Christophe Denis Josef Capelle[1]; F Duca[1]; C Binder[1]; C Zotter-Tufaro[1]; C Nitsche[1]; AA Kammerlander[1]; S Aschauer[1]; L Schachner[1]; B Oeztuerk[1]; C Dona[1]; J Mascherbauer[1]; D Bonderman[1]
[1]*Medical University of Vienna, Internal Medicine II, Division of Cardiology, Vienna, Austria*

Background: According to current literature endomyocardial biopsy (EMB) is a relatively safe procedure when performed by experienced physicians. Previous studies investigating EMB-related complications have included relatively young and healthy patient populations. However, EMB is often necessary in clinically compromised patients in order to establish a correct diagnosis (e.g. cardiac amyloidosis versus heart failure with preserved ejection fraction). Whether EMB is safe in an elderly, clinically compromised patient population is not known.
Purpose: The present study aimed to assess the frequency and severity of EMB-associated complications in an elderly, clinically compromised patient population.
Methods: Consecutive patients who underwent EMB at the Division of Cardiology at the Medical University of Vienna were analyzed for the present study. Clinical as well as invasive hemodynamic parameters were assessed at the time of EMB.
Results: Between May 2010 and September 2017, 106 patients were analyzed for our study. The study population consisted of 44 (41.5%) female and 62 (58.5%) male patients. Median age was 67.0 years [Interquartile range (IQR): 55.0 - 74.0] and median N-terminal prohormone of brain natriuretic peptide (NT-proBNP) was 1725 pg/mL (IQR: 572 - 4239). Mean pulmonary arterial pressure was 30.5mmHg (IQR: 24.0 - 38.0). The vast majority of EMBs were performed with left heart catheterization via femoral access [n = 96 (90.6%)]. Further EMBs were acquired during surgery [n = 8 (7.5%)] or right heart catheterization using a jugular access [n = 2 (1.9%)].
In total, 23 (21.7%) EMB-associated complications occurred. The most common complication was pericardial effusion [n = 12 (11.3%)] followed by stroke/transient ischemic attack [n = 5 (4.7%)], vascular or nerval damage at site of puncture [n = 4 (3.8%)], death [n = 1 (0.9%)], and contrast agent induced renal failure [n = 1 (0.9%)] (Figure 1).
Patients who experienced complications had higher NT-proBNP levels as compared to patients without [2838 pg/mL (IQR: 783 - 9065) versus 1473 pg/mL (IQR: 433 - 4049)]. However, this was only borderline significant (p = 0.065). No further differences regarding clinical or invasive hemodynamic parameters were detected between patients with and without complications.
Conclusion: A significant number of patients experienced EMB-related complications in our patient cohort. Patients with complications showed a trend towards higher NT-proBNP levels. Therefore, we should be aware of a possibly greater rate of complications and question the necessity for EMB in clinically compromised patients.

Funding Acknowledgements: CVON DOSIS, grant 2014-40; CVON SHE-PREDICTS-HF, grant 2017-21; CVON RED-CVD, grant 2017-11; NWO VIDI, grant 917.13.350

Background: N-terminal pro-B-type natriuretic peptide (NT-proBNP) is an established biomarker for diagnosis and risk stratification of cardiovascular diseases. It is known that NT-proBNP levels increase with age, and are inversely related to obesity. Whether the obesity association varies by sex remains unclear. We investigated sex-specific associations of obesity and NT-proBNP levels in a large community-based cohort.
Methods: We measured NT-proBNP in 7608 participants (3824 women) from the Prevention of Renal and Vascular End-stage Disease (PREVEND) cohort (free of heart failure), and studied its relationship with obesity-associated parameters in the overall population, and in males and females separately, accounting for various age categories.
Results: NT-proBNP levels were significantly higher in females (50.7pg/mL, 28.4-86.8; median, interquartile-range) than in males (23.7pg/mL, 10.0-53.6; P < 0.001). NT-proBNP was lower in heavier individuals - but this could largely be explained by the fact that females have a lower body weight whilst having higher NT-proBNP levels. NT-proBNP levels displayed a "U-shaped" relationship with increasing waist circumference (WC) and were not associated with body-mass index (BMI) in the overall population; sex-stratification significantly altered these relationships. Age is an important confounder and increasing age is associated with higher NT-proBNP levels in males than in females (P < 0.001). In multivariable analyses, the inverse association of NT-proBNP levels and obesity was modified by sex. Specifically, NT-proBNP levels were lower with increasing waist circumference (Pinteraction < 0.001) as well as increasing BMI (Pinteraction = 0.002) and weight (Pinteraction = 0.040) among women compared with men.
Conclusions: Obesity-associated reduction in NT-proBNP has a strong sex-related component, and NT-proBNP levels decline more in obese females than in obese males. Age-associated increase in NT-proBNP is greater in males than in females. Sex and age should be considered while interpreting NT-proBNP in obese individuals.

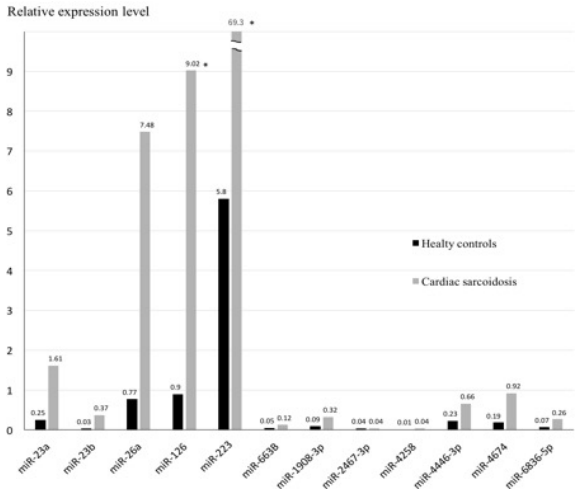
Serum microRNA-126 and -223 as new generation biomarkers for cardiac sarcoidosis

W Wakaya Fujiwara[1]; Y Kato[1]; M Hayashi[1]; Y Sugishita[1]; S Okumura[1]; M Yoshinaga[1]; T Ishiguro[1]; R Yamada[1]; S Ueda[1]; M Harada[2]; H Haruse[2]; J Ishii[2]; Y Ozaki[2]; H Izawa[1]
[1]Fujita Health University, Banbuntane Hotokukai Hospital, Nagoya, Japan; *[2]Fujita Health University, Toyoake, Japan*

Background: Sarcoidosis is a multisystem inflammatory disorder of unknown etiology with a wide range of manifestations in a variety of organs. Although cardiac sarcoidosis is associated with poor prognosis, diagnosis of the disease is challenging and the sensitivity and specificity of diagnostic modalities are limited. This study was performed to evaluate the potential of Serum micro RNAs (miRNAs) as diagnostic biomarkers for cardiac sarcoidosis.
Methods and Results: We performed genome-wide expression profiling for 2565 miRNAs (Human-miRNA ver.21) using peripheral blood samples from 5 patients with cardiac sarcoidosis (61 ± 9 years) and 3 healthy controls (54 ± 7 years). From this screening study, we selected 12 miRNAs that were significantly related to cardiac sarcoidosis. Next, we performed real-time Polymerase chain reaction (PCR) on blood samples from 15 new patients with cardiac sarcoidosis and 4 healthy controls to quantify the expression of these 12 miRNAs. In the screening study, 12 miRNAs were differentially expressed (p < 0.01) in all 5 patients with cardiac sarcoidosis, showing greater fold-change values (< 4 or < 0.25) compared with the expression in the 3 healthy controls. Analysis of the real-time PCR for blood samples from the other 15 patients and 4 controls using Mann-Whitney U tests revealed that the expression



Figure

of miR-126 and miR-223 was significantly higher in the patients than in the healthy individuals.

Conclusions: The results demonstrated the potential of serum miR-126 and miR-223 as new-generation diagnostic biomarkers for cardiac sarcoidosis.

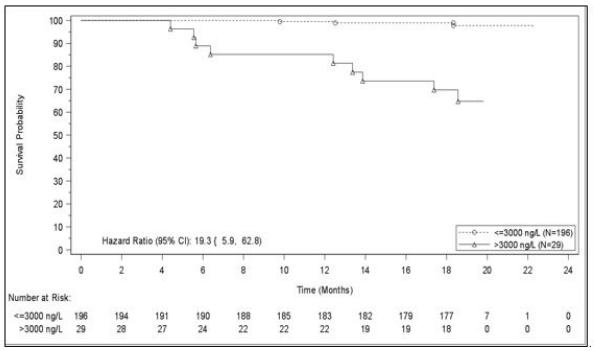
Background/Introduction: Hereditary transthretin-mediated (hATTR) amyloidosis is a multi-systemic, heterogeneous, fatal disease resulting in multi-organ TTR amyloid deposition. Clinical manifestations include sensorimotor and autonomic neuropathy, gastrointestinal symptoms, as well as cardiomyopathy, a major cause of death. N-terminal pro-brain natriuretic peptide (NT-proBNP), a cardiac biomarker, has shown prognostic value in cardiac diseases and has been clinically validated as a biomarker. Clinical studies in patients with light chain (AL) amyloidosis have shown NT-proBNP to be predictive of clinical outcome and survival in patients with cardiac involvement, thus suggesting its use as a surrogate endpoint for treatment efficacy. A recent analysis supports the proposition that NT-proBNP levels are also predictive for mortality for both hATTR and wild-type ATTR amyloidosis where survival in patients with serum NT-proBNP levels of >3000ng/L was associated with poorer survival compared to patients with NT-proBNP < 3000ng/L. Furthermore, a recent study in 27 hATTR amyloidosis patients demonstrated that NT-proBNP is a marker for cardiac involvement.

Purpose: To determine the predictive value of baseline NT-proBNP on survival in patients enrolled in the APOLLO study.

Methods: APOLLO was a Phase 3, randomized (2:1), double-blind study of patisiran 0.3mg/kg or placebo IV q3W in patients with hATTR amyloidosis patients with polyneuropathy (NCT01960348). The majority of patients likely had cardiac involvement on the basis of prespecified criteria: left ventricular (LV) wall thickness = 13mm and absence of aortic valve disease or hypertension. APOLLO enrolled 225 patients: mean age 61 years, 57% non-V30M mutation, NT-proBNP geometric mean 531 ng/L (range: 25, 16500). To assess the prognostic significance of baseline factors on survival, univariate and multivariate Cox regression analyses were conducted. NT-proBNP was evaluated as a continuous variable following logarithmic transformation as well as a binary variable using a cut off value of 3000 ng/mL.

Results: The median survival follow-up duration was 18.7 months. Of 13 deaths in total, 6 (8%) and 7 (5%) were observed in the placebo and patisiran arms, respectively. NT-proBNP was the key significant factor predictive of survival based on univariate and multivariate analyses. The risk of death increased with higher baseline NT-proBNP (hazard ratio = 2.9 [95% CI: 1.8, 4.8, p-value = 8.7x10-7] per unit increment in log(NT-proBNP). Patients with NT-proBNP > 3000 ng/L (n = 29) had a 19.3-fold [95% CI 5.9, 62.8, p-value = 8.7x10-7] increased risk for mortality compared with those below 3000 ng/L (n = 196) (Figure 1).

Figure 1: Survival by Baseline NT-proBNP Threshold (mITT)



Conclusion(s): Based on the data from the APOLLO study, baseline NT-proBNP serum levels in hATTR amyloidosis patients are predictive of survival. These data underscore the importance of diagnosing and potentially treating patients early in the course of the disease.

P2162

Albumin-to-globulin ratio as an independent predictor of mortality in chronic heart failure

J T Niedziela[1]; B Hudzik[2]; B Szygula-Jurkiewicz[1]; J Nowak[1]; L Polonski[1]; M Gasior[1]; P Rozentryt[3]
[1]Medical University of Silesia, SMDZ in Zabrze, 3rd Department of Cardiology, Silesian Centre for Heart Disease in Zabrze, Katowice, Poland; *[2]Medical University of Silesia, Department of Nutrition-related Disease Prevention, School of Public Health in Bytom, Katowice, Poland*; *[3]Medical University of Silesia, Department of Social Medicine and Prevention, School of Public Health in Bytom, Katowice, Poland*

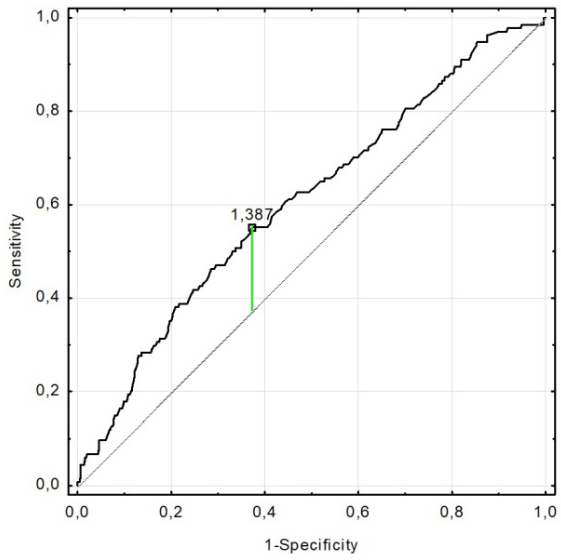
Background: Albumin-to-globulin ratio (AGR) is considered to be a marker of impaired prognosis. Low AGR is associated with poor prognosis in oncology patients and in general population. There are only sparse studies of AGR in cardiovascular diseases. AGR is related to worse survival after non-ST segment elevation myocardial infarction or stroke.

Purpose: We determined the predictive value of AGR in patients with heart failure with reduced ejection fraction (HFrEF) in one-year follow-up.

Methods: The study included 999 patients with HFrEF. Patients with infection, fever, trauma or urgent hospitalization in the last 3 months were excluded. Malnutrition or body wasting were also considered as exclusion criteria. AGR was calculated using formula AGR = Albumin/(Total serum protein-Albumin). Quartiles (Q) of AGR were defined as Q1 < 1.25, Q2 = 1.25 and < 1.48, Q3 = 1.48 and < 1. 75 and Q4 = 1.75. One-year mortality between AGR quartiles was compared using log-rank test. Multivariate survival analysis in Cox's regression model was applied with Q1 as a reference. Receiver operating characteristic (ROC) analysis was also performed.

Multivariate survival analysis

Parameter	HR	95% CI	p
Age [years] per 1 year increase	1.03	(1.01-1.05)	0.006
Serum sodium [mEq/L] per 1 mEq/L increase	0.95	(0.91-0.99)	0.02
NT-proBNP [pg/ml] per 1000 pg/ml increase	1.07	(1.03-1.12)	0.0008
peak VO2 [ml/kg/min] per 1 ml/kg/min increase	0.89	(0.85-0.93)	0.000001
LVEF [%] per 1% increase	0.95	(0.92-0.98)	0.001
AGR per 0.1 decrease	1.07	(1.01-1.13)	0.01



ROC analysis - AGR in 12-month mortality

Results: AGR found to be an independent risk factor for one-year mortality with 7% increase of risk of death for each 0.1 AGR decrease (Table). ROC analysis revealed moderate diagnostic value of AGR in predicting one-year mortality with cut-off < 1.38 and area under curve (AUC) 0.61 (0.58-0.64), p = 0.0001 (PPV 17.7, NPV 90.4) (Figure).
Conclusion: AGR had a moderate prognostic value and remained an independent predictor of one-year mortality in HFrEF patients.

P2163

Serum parathyroid hormone levels predict treatment failure in acute decompensated heart failure

H Altay[1]; F Ozkalayci[1]; S Pehlivanoglu[1]
[1]*Baskent University Istanbul Hospital , Cardiology, Istanbul, Turkey*

Background: Treatment failure is not uncommon in patients with acute decompansated heart failure (ADHF), due to very heterogenous patient population regarding cardiac pathology and existing comorbidities, and limited effective treatment modalities. Also predictors of treatment failure is not well defined in this patient population. Increased paratahyroid hormone (PTH) level is associated with advanced heart failure which forms most of difficult to treat ADHF patients.
Purpose: In this study we aimed to investigate the predictors of treatment failure and also investigate whether the assessment of serum PTH could enable us to identify patients likely to develop treatment failure during inhospital treatment of ADHF.
Method: Thirty three consecutive patients who were hospitalized with ADHF were enrolled as a part of prospective non-randomised study. Baseline patient demographic and clinical characteristics including serum levels of PTH and amino-terminal pro-B-type natriuretic peptide (NT-proBNP) were measured during 24 hours of admission. All patients were given standarised treatment including intraveneous continuous furasemide infusion, along with inotrope-inodilator and vasodilator drugs according to prespesified criteria regarding left ventricular (preserved vs low EF) and renal function (serum creatinine level), hemodynamic status (BP). "Treatment resistance" (TR) was defined according to clinical criteria; hemodynamic detoriation, or inadequate decongestion or diuresis at the end of 72 hours of treatment. Baseline characteristics were analysed in order to investigate the predictors of TR in this population.
Results: 10 out of 33 patients (30,3%) were found to have treatment resistance (TR+) and 23 (69,7%) had favorably responded to the treatment (TR -). Elevated mean levels of PTH were found in TR+ patients (129,9 ± 30 vs 88,9 ± 39 pg/ml; (p = 0,006). Patients who developed < 30% reduction in NT-proBNP were found to have higher PTH level compared to patients developed >30% reduction (127,52 ± 47,95 vs 88,40 ± 31,93 pg/ml, p = 0,028). In univariate analysis, blood urea nitrogen (BUN), creatinine (cr), presence of left bundle branch block (LBBB) on electrocardiogram and PTH were found to be predictors of TR+. In multivariate logistic regression analysis, PTH level (hazard ratio 1,045 , 95% confidence interval 1,009-1,084) p = 0.015) and LBBB (hazard ratio 12,410, 95% confidence interval 1,0-154,1, p = 0,045) were associated with presence of TR+. In receiver operator characteristics curve analysis, the optimal cut-off value of PTH to predict presence of TR+ was >119 pg/ml, with 80,0% sensitivity and 82,61% specificity.
Conclusion: An elevated admission PTH level, could identify patients hospitalized with ADHF likely to experience to have "treatment resistance". Thereby early implementation of alternative pharmacologic or non-pharmacologic decongestive therapies can be considered in these patients.

P2164

Prognostic role of cardiac troponin in acute heart failure

JP Jose Pedro Sousa[1]; M Madeira[1]; L Reis[1]; C Negrier[1]; L Goncalves[1]
[1]*Centro Hospitalar e Universitário de Coimbra - Hospital Geral, Cardiology, Coimbra, Portugal*

Introduction: Troponins I and T (cTnI e cTnT) are well-established biomarkers of cardiac injury. Testing for either of the two has long been a core component of both diagnosis and prognosis of acute myocardial infarction. However, their value in heart failure (HF) is not without controversy, particularly when not measured using the new high sensitivity assays.
Purpose: To determine the short term prognostic significance of non-high sensitivity cTnI at hospital admission in the setting of acute HF.
Methods: Retrospective single-center study comprising patients consecutively admitted into a cardiac intensive care unit, during six years, presenting with de novo or decompensated acute HF. Demographic, clinical, laboratory, echocardiographic and prognostic data were evaluated. Follow-up (FU) was performed targeting hospital readmission for acute HF and all-cause mortality. All statistical analysis was performed using SPSS version 23 (IBM Corp., Armonk, NY, USA).
Results: 264 patients were included. Mean age was 70 ± 14 years and 22% were female. Median FU was 10 months. In-hospital mortality was 15%, while readmission for HF and death in FU occurred in 46.7% and 42% of patients, respectively. Median troponin was 0.07ng/mL. No difference was found between cTnI levels in males and females and there was no significant correlation between cTnI and age. Ischemic etiology was not found to influence cTnI, whereas acute cardiogenic pulmonary edema (p < 0.001) and cardiogenic shock (p 0.027) were associated with higher troponin levels. Correlation between cTnI and both serum creatinine and NT-proBNP, at admission and discharge, was statistically significant but negligible (p < 0.003 / rho 0.13-0.16 for creatinine and p < 0.001 / rho 0.208-0.209 for NT-proBNP). Furthermore, left ventricular ejection fraction, measured using echocardiography, at admission, was not associated with cTnI. Higher serum troponin levels were found in those who died during hospitalization (p 0.024), but not in patients who were readmitted for HF or died during FU.
Conclusions: Non-high sensitivity cTnI at admission is a biomarker of severity in acute HF, with higher levels predicting acute cardiogenic pulmonary edema, cardiogenic shock and mortality during hospitalization. However, it seems to be of no value for FU.

Funding Acknowledgements: La Marató de TV3 (PI201510.10), Primary Healthcare University Research Institute IDIAP-Jordi Gol, Catalan Society of Family and Community Medicine

Background: Detection of B-lines at lung ultrasound (LUS) is emerging in recent years as a new complementary tool in the diagnostic process for heart failure (HF). However, there are no data on the application of LUS in the first diagnosis of HF in primary care (PC).
Purpose: To explore if detection of pulmonary congestion by LUS may improve the efficiency of the diagnostic process in outpatients with first suspicion of HF.
Methods: Consecutive patients referred by their PC physician to NTproBNP test for suspected HF were included. We performed all the standard tests, including LUS with a pocket device, and echocardiography. LUS was applied by examining 6 chest areas per side, including 2 anterior (A), 2 lateral (L) and 2 posterior (P). Each area was considered positive when = 30% of the corresponding scan showed B-lines. We applied 4 different criteria of positivity for pulmonary congestion (on both sides): C1= 2 positive out of 4 AL areas (as recommended by the International Consensus in acute dyspnoea); C2 = 2 positive out of 6 ALP; C3 = 3 positive out of 12 ALP (involving both hemithorax); C4 = sum of B-lines' percentage of 12 ALP (= 30% affectation in each hemithorax). We measured the accuracy of these criteria

in predicting the final diagnosis of HF adjudicated by a cardiologist blinded to LUS results who had access to echocardiography and NTproBNP data.
Results: 211 patients were studied (66.8% women; median 75.8 years [IQR 69-83]), 55.6% already under diuretic treatment. LUS was positive in 7 (C1), 19 (C2), 37 (C3) and 45 (C4) patients. HF diagnosis was confirmed in 52 patients (24.6%), mean LVEF 59.3%.
Conclusions: In our PC setting, LUS showed low sensitivity for HF but excellent specificity, depending on the used criteria. Our patients are mainly scarcely symptomatic and already treated at home. For these reasons, a possible role of LUS may be to confirm the disease, while it is insufficient to rule-out it. Integration with clinical evaluation and other tests may be a promising strategy, as well as defining criteria for patients in the community.

Pulmonary congestion criteria by LUS

	Sensitivity	Specificity	PPV	NPV	Accuracy	AUC
C1 = 8 areas (2 per hemithorax)	0.12	0.99	0.86	0.77	0.78	0.55 (0.46-0.65)
C2 = 12 areas (2 per hemithorax)	0.29	0.97	0.79	0.80	0.80	0.63 (0.54-0.72)
C3 = 12 areas (3 involving both hemithorax)	0.44	0.91	0.62	0.83	0.80	0.68 (0.59-0.78)
C4 = 12 areas (≥ 30% per hemithorax)	0.54	0.88	0.62	0.86	0.81	0.72 (0.62-0.80)

Right atrial mechanics in chronic thromboembolic pulmonary hypertension: the right measure?

P Patricia Alves[1]; AV Marinho[1]; C Domingues[1]; J Milner[1]; JA Ferreira[1]; R Baptista[1]; G Castro[1]
[1]*University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*

Background: Regardless of etiology, right ventricular (RV) dysfunction is considered the major determinant of morbidity and mortality in pulmonary hypertension (PH).
Purpose: To assess RV function and right atrium (RA) mechanics through 2-dimensional speckle-tracking echocardiography (2D-STE) in different groups of PH.
Methods: We included all 91 PH incident cases followed in our center in the previous 5 years, group 1 (pulmonary arterial hypertension - PAH) (n = 63) and group 4 (chronic thromboembolic PH - CTEPH) (n = 28). RV global longitudinal strain (RVLS) and RA mechanics were assessed through 2D-STE. Global atrial strain and atrial strain rate during systole (RA ?sys and SRs), early diastole (RA?e, SRe), and late diastole (RA?a, SRa) were measured, corresponding to RA reservoir, conduit and contractile functions, respectively. These parameters were correlated to clinical, analytical and right heart catheterization (RHC) data.
Results: Mean age was 48 ± 19 years for PAH and 59.7 ± 16 years for CTEPH; 62% were women. Mean tricuspid annular plan systolic excursion (TAPSE) and tricuspid regurgitation velocity (TRV) did not vary between groups. RVLS values were numerically better in CTEPH (-13 ± 4% vs -10 ± 9%, p = 0.170). RA mechanics was globally and statistically superior in CTEPH patients (table 1). In the global cohort, BNP values (r2 = 0.53, p = 0.003) and RHC-derived cardiac index (CI) (r2 = 0.51, p = 0.039) at admission were correlated to RA ?sys, but not to RVLS. In CTEPH patients, BNP values were only moderately correlated with RV diameter (r2 = 0.33, p = 0.005), TAPSE (r2 = 0.42, p = 0.003) and RA volume (r2 = 0.50, p <0.001), but were strongly correlated with RVLS (r2 = 0.57, p= 0.018), RA ?sys (r2 = 0.67, p = 0.027) and RA?a (r2 = 0.59, p = 0.004). A similar pattern of correlation was seen for CI [TAPSE (r2= 0.3, p = 0.02), RVLS (r2 = 0.56, p = 0.041), RA ?sys (r2 = 0.64, p = 0.036) and RA?a (r2 = 0.58, p = 0.004)]. Pulmonary vascular resistance (PVR) was only associated to RA?a (r2 = 0.56, p = 0.007) and mean pulmonary artery pressure (mPAP) to RA?e (r2 = 0.72, p = 0.012).
Conclusions: : 2D-STE derived RVLS and RA mechanics demonstrated stronger correlations with established prognostic factors in CTEPH, as BNP or RHC-derived indexes, than currently used morphological parameters, as TAPSE or cavity dimensions.

	CTEPH	PAH	P value
RA ?sys (reservoir)	15.0±4.2	12.4±4.1	0.011
RA ?e (conduit)	7.5±3.8	5.2±3.6	0.009
SRs	0.8±0.4	0.6±0.3	0.04
SRa	-1.3±0.6	-0.8±0.4	<0.001

P2167

The role of cardiac index assessed by echocardiography in the predicion of mortality and morbidity in heart failure

B Szabo[1]; E Marosi[1]; K Vargova[1]; N Nyolczas[2]
[1]*University Hospital Örebro, Heart-Lung Clinic, Örebro, Sweden*; [2]*State Health Centre, Budapest, Hungary*

Background: Echocardiography is a basic diagnostic method and provides important data in the diagnosis of heart failure (HF). Left ventricular ejection fraction (LVEF) is the most frequently used parameter despite high intra- and interobserver variability. Cardiac index (CI) is referred in the literature as a potential alternative for LVEF despite limited evidence, mainly extrapolated from trials with invasive CI-measurement. Thus, further research is needed to define its role in clinical practice.
Purpose: To assess and compare the predictive accuracy of LVEF and echocardiographically assessed CI in HF patients.
Methods: A retrospective cohort study was performed in patients hospitalized for acute HF between 2010-2016 at the Heart-Lung Clinic of University Hospital Örebro. Patients were eligible regardless of LVEF if they had an echocardiography after the first HF-admission in the study period, if stored images were available for the assessment of CI, and if they had no significant aortic valve disease or hypertrophic obstructive cardiomyopathy. LVEF was collected from initial echocardiography reports and CI measured retrospectively according to current echocardiographic recommendations. Cox proportional hazards models were created to predict cardiovascular (CV) death or first HF-readmission using LVEF or CI and adjusted for traditional risk factors, identifying independent risk factors and providing associated relative risks (RR). Prognostic accuracy was assessed by c-index and compared by unpaired t-test.
Results: 334 patients were included in the study (age: 75.8 ± 10.0 years, male: 65.3%, ischemic etiology: 49.4%, diabetes: 31.7%, atrial fibrillation: 42.8%, GFR: 55.8 ± 25.2ml/min/1.73m^2, COPD: 14.1%, heart rate: 78.0 ± 17.8/min, LVEF: 35.7 ± 14.7%, CI: 2.17 ± 0.73l/min/m^2). 58.7% had HF with reduced LVEF (HFrEF). Patients were on ACE-inhibitor/ARB in 86.5%, betablocker in 86.8%, mineralocorticoid antagonist in 45.8%, diuretics in 84.7%. 10.2% had cardiac resynchronization therapy and 9.9% had an implantable defibrillator). Neither LVEF nor CI had any association with CV death, neither in the overall cohort, nor in HFrEF or non-HFrEF patients. CI was an independent predictor of HF-readmission in HFrEF patients (RR: 0.653 /0.428-0.998/, p = 0.049) as well as in the non-HFrEF group (RR: 0.634 /0.416-0.967/, p = 0.034) while LVEF was not predictive for HF-readmission. Both LVEF and CI-based Cox-models had moderate prognostic accuracy for HF-readmission in the overall cohort, with a slight but statistically significant benefit for CI (c-index: 0.675 vs 0.690, p <0.001).
Conclusion: Neither LVEF nor CI proved to be predictive of CV death in this real-life elderly cohort of HF patients. CI provides a slight improvement of the prediction of HF-readmission compared to LVEF. Our results suggest that CI provides additional information on disease severity and may be an important new tool in the assessment of HF patients regardless of LVEF.

P2168

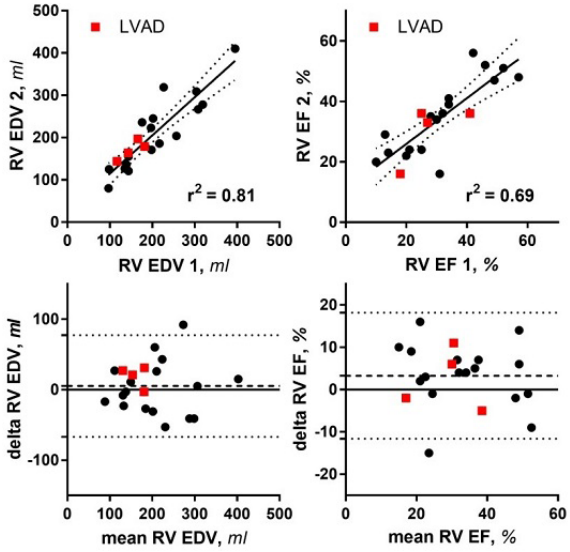
Evaluation of right ventricular function in advanced heart failure: gated blood-pool SPECT ventriculography

T Tereza Havlenova[1]; M Tupy[1]; L Mlateckova[1]; M Buncova[1]; J Ters[1]; J Kidery[1]; I Netuka[1]; J Kautzner[1]; V Melenovsky[1]
[1]*Institute for Clinical and Experimental Medicine (IKEM), Prague, Czech Republic*

Funding Acknowledgements: This study was supported by Ministry of Health of the Czech Republic, research grant AZV 12-28784A, NV16-2749A and MZ 15-27682A.

Background: Accurate estimation of right ventricular (RV) function and volumes plays a critical role in management of advanced heart failure (HF) patients. However, it's often challenging, especially in subjects with left ventricular assist device (LVAD).
Purpose: In present study, we aimed to assess the performance of quantitative 3-dimensional gated blood-pool single photon emission computed tomography (SPECT) imaging of the RV employing a novel high-resolution SPECT camera (D-SPECT).
Methods: A total of 21 advanced HF patients were enrolled (age 61 ± 11 years, 76% males, body mass index 28 ± 4 kg/m2, LV EF 28 ± 16%, 4 patients after LVAD

HeartMate III implantation). All subjects received intravenous injection of stannous pyrophosphate (Technescan PYP) followed after 30 minutes by intravenous administration of 740 MBq 99mTc isotope to in-vivo label the erythrocytes (radiation dose was 5-6 mSv). After that, the hearts were imaged by D-SPECT camera (Spectrum Dynamics, Israel) with Cadmium-Zinc-Telluride detector. Volume analyses of 3D reconstructed ventricles were conducted using semiautomatic plug-in software (QBS Cedars-Sinai, USA). To measure reproducibility, both data acquisition and analysis were performed twice in all study subjects.



Results: The ventricles were successfully imaged even in subjects after LVAD implantation; however, in 2 LVAD patients the device caused intermittent interference with surface ECG gating, requiring manual ECG cable repositioning. The acquisition time was uniformly set for 8 minutes. In data processing, no (in 2/3 of patients) or minimal manual intervention was necessary. The figure below shows that the RV end-diastolic volume (EDV) and ejection fraction (EF) correlated well between the 2 consecutive measurements (R2: 0.69-0.81). In Bland-Altman plots, both measures displayed only minimal bias and acceptable confidence limits. Reproducibility was comparable in both LVAD and non-LVAD groups.
Conclusion: This study provides evidence that the gated blood-pool SPECT ventriculography is fast and reproducible tool in evaluation of RV function even in advanced HF patients with serious RV remodelling or after LVAD surgery.

P2169

Role of stress test echocardiography in the evaluation of myocardial function in hypertensive patients.

F A Federico Angelo Immordino[1]; S Tumminello[1]; G Evola[1]; S Novo[1]
[1]*University Hospital Paolo Giaccone, Department of emergency, Division of Cardiology, Palermo, Italy*

Introduction: There are few data assessing the role of stress echocardiography (echo) in the evaluation of myocardial function in hypertension. Therefore, it should be useful to study if mild dyspnoea or fatigue during exercise may be a prelude of diastolic dysfunction in hypertensive patients without signs or with subclinical cardiac dysfunction at rest.
Purpose: To evaluate the role of stress echo to identify early changes in cardiac function, PAPs, filling and systemic pressure as a possible cause of exercise dyspnoea and as marker of incoming diastolic dysfunction.
Methods: We enrolled 70 hypertensive patients (BP > 140/90 mmHg or under antihypertensive treatment) without history of major cardiovascular events and with EF > 55%. Patients reported to be symptomatic for mild dyspnoea during moderate physical activity. Sixty-eight patients have already been under pharmacological treatment. Each patient performed a supine bike stress echo following the standard protocol (increase of 25 Watt each 2 minutes). All the tests were performed until maximal heart rate or symptoms. We acquired data at baseline and at peak of exercise. Patients were finally divided in 2 groups according to E/e' ratio at peak (G1 E/e' ratio >14; G2 E/e' ratio < 14).
Results: No significant differences were shown between the groups concerning age, gender, blood pressure (BP), history of smoking, diabetes or hyperlipidaemia nor in the classes of drugs used (P > 0,05). At baseline were shown difference in DBP (G1 = 80,8 mmHg ± 7,4; G2 = 70,5 mmHg ± 11; P < 0,04); PAPs (G1 = 29,5 mmHg [23,5-33]; G2 = 24 mmHg [20-29]; P < 0,01); e' (G1 = 0.06 [0,04-0,07]; G2 = 0,08 [0,07-0,1]; P < 0,001); E/e'(G1 = 11,86 [11,18-13,99]; G2 = 7,33 [5,8-8,9]; P < 0,001). At exercise peak G1 patients have higher SBP (204,3 mmHg ± 17,3; P < 0,0001), DBP (90,2 mmHg ± 9,8; P = 0,01), PAPs (46,12 mmHg ± 8,84; P = 0,0001), TR velocity (3,24 m/s ± 0,38; P < 0,0001) and e' (0,07 [0,05-0,08]; P < 0,0001) showing several differences compared to patients still in range during the test, potential risk of evolution to the hypertensive cardiomyopathy and diastolic dysfunction. Moreover G1 patients have higher increases in ?PAPs (P = 0,002), ?TR velocity (P = 0,03), and ?SBP (P < 0,001). In multiple regression analysis the increase in PAPs seems to be dependent from ?E/e' ratio (P = 0,007) and heart rate (?HR) (P = 0, 04).
Conclusions: The stress echo seems to be a valid test to detect patients with subclinical signs of hypertensive cardiomyopathy and/or diastolic dysfunction, enabling an early diagnose and, in the end, a better management. The increase in filling pressure due to the cardiac dysfunction during exercise may explain the symptoms of these patients.

P2170

Features of myocardial dissynchrony in patients with chronic heart failure and atrial fibrillation

T Tatyana Troyanova-Shchutskaia[1]; A Kurlianskaya[1]; T Asmalouskaya[1]; T Denisevich[1]; O Shatova[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Background: Myocardial dissynchrony (MD) is one of the important causes of chronic heart failure (CHF) contributing to the progression of the disease.
Purpose: to explore MD in patients with CHF NYHA III, permanent atrial fibrillation (AF) vs. sinus rhythm (SR).
Methods: The study included 29 patients with SR and 50 patients with AF. Initially the groups did not differ in sex, age, and parameters of echocardiography. Determination of myocardial dissynchrony was performed in all cases.
Results: Presystolic aortic delay in group with QRS 130-149ms was 161 (140; 168)ms in patients with AF and 118 (90; 155)ms with SR (p = 0,021). In group with QRS = 150 ms and AF it was 211 (183; 223)ms and in patients with SR - 119 (104; 154)ms (p <0,001). Presystolic delay on pulmonary artery valve was higher in patients with SR. Interventricular delay (IVD) was higher in patients with SR and QRS 130-149 ms - 65 (55; 78)ms vs. 56 (33; 58)ms (p = 0,063). In group with QRS = 150 ms IVD was higher in patients with AF (86 (69; 95)ms vs. 63 (45; 74)ms, p = 0,002). Table demonstrates parameters of intraventricular dissynchrony.

P2169 Intraventricular myocardial dissynchrony

Delay, ms	QRS 130-149 ms	P	QRS≥150 ms	P		
Atrial fibrillation	Sinus rhythm	Atrial fibrillation	Sinus rhythm			
Septal lateral	72 (41; 85)	72 (43; 121)	0.629	92 (51; 143)	87 (44; 115)	0.344
Septal posterior	63 (46; 84)	79 (57; 116)	0.081	36 (15; 78)	70 (20; 140)	0.164
Maximal basal	107 (87; 151)	125 (115; 145)	0.244	109 (64; 154)	140 (124; 162)	0.148
Basal dely index	49 (40; 77)	63 (52; 73)	0.120	77 (52; 87)	67 (50; 74)	0.273
All segments standart deviation	146 (117; 198)	174 (149; 209)	0.292	212 (195; 222)	178 (160; 222)	0.093
All segments standart deviation	64 (47; 76)	71 (58; 78)	0.211	80 (74; 87)	63 (53; 82)	0.146
Basal septal lateral	100 (60; 160)	85 (40; 100)	0.607	90 (65; 165)	80 (60; 120)	0.169
Basal antero-inferior	110 (60; 160)	100 (80; 200)	0.532	106 (85; 140)	100 (80; 150)	0.796
Medium septal lateral	100 (80; 180)	98 (80; 120)	0.912	145 (120; 185)	100 (50; 140)	0.016
Medium antero-inferior	110 (50; 160)	125 (80; 160)	0.573	140 (95; 210)	130 (90; 140)	0.366
basal antero-septal infero-lateral	90 (40; 160)	100 (40; 140)	0.607	85 (35; 135)	90 (70; 140)	0.772
Medium antero-septal infero-lateral	110 (60; 160)	115 (70; 180)	0.769	100 (70; 175)	120 (90; 200)	0.518

Conclusions: The features of mechanical myocardial dissynchrony were revealed in patients with AF versus SR. In patients with AF the severity of mechanical dissynchrony depends on the width of the QRS complex: presystolic aortic delay, IVD and all segments maximum delay were higher in patients with wide QRS. The frequency and duration of presystolic aortic delay in patients with AF was significantly greater than in persons with sinus rhythm.

P2171

Thoracic Bioreactance in clinical practice - Test-retest reliability in patients with hypertension, heart failure with preserved ejection fraction and healthy controls

H-D Duengen[1]; MT Coll Barroso[2]; MT Hoppe[2]; T Krahn[3]; F Kramer[4]; E Tahirovic[1]; A Busjahn[5]; S Beckmann[1]; C Kiefer[6]; T Mondritzki[3]; M Karoff[2]; P Boehme[4]; W Dinh[4]

Purpose: Thoracic bioreactance (TB), a noninvasive method for hemodynamic measurement, shows good test-retest reliability in healthy adults under research conditions. Here we evaluate the test-retest reliability of TB in healthy adults, subjects with hypertension (HT) and heart failure with preserved ejection fraction (HFpEF) under routine conditions.
Methods: 75 sublects (25 healthy, 26 HFpEF, 24 HT) performed a symptom-limited graded cycling test on two different days separated by one week. Cardiorespiratory (power output, VO2peak) and hemodynamic parameters (heart rate, stroke volume, cardiac output, mean arterial pressure, cardiac power output) were measured at rest and continuously up to maximum exercise using a breath-by-breath gas-analyzer and bioreactance cardiograph.
Results: There was no systematic bias in all parameters under all conditions (effect size: 0.03-0.6). We found that all noninvasively measured hemodynamic parameters showed acceptable test-retest-reliability (intraclass correlation coefficient: 0.53-0.98; typical error: 0.3-1.8). The key value derived from TB, cardiac output (CO) showed a satisfying reliability in all groups at rest and during maximum exercise (healthy: intraclass correlation coefficient: 0.80-0.85; effect size: 0.9-1.1, HT: 0.66-0.91, effect size: .14, typical error: 1.37, HFpEF: 0.19-0.76, effect size: 0,14, typical error: 1,79). Moreover, peak cardiac power output showed a superior reliability (intraclass correlation coefficient: 0.80-0.85; effect size: 0.9-1.1) then the underlying physiological single parameters (intraclass correlation coefficient: 0.59-0.98; effect size: 0.3-1.8) and was found to be independent to traditional cardiopulmonary exercise parameters.
Conclusion: Our findings suggest that TB might be suitable method to noninvasively monitoring hemodynamic status in clinical practice in heart failure patients.

Novel method with a microwave radar for a non-contact monitoring of jugular venous pulse: clinical implication for heart failure practice

M Masaaki Hoshiga[1]; K Sakane[1]; N Ishizaka[1]; S Suzuki[2]

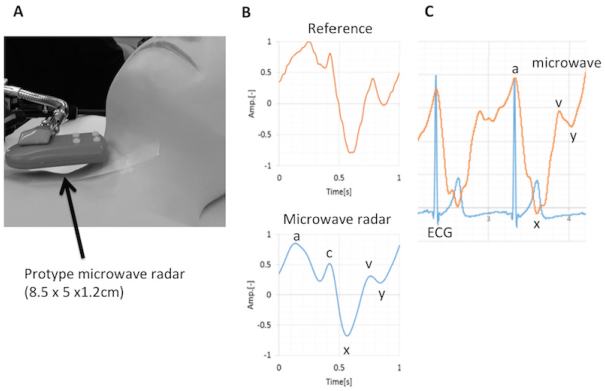
Funding Acknowledgements: JSPS KAKENHI

Background: The jugular venous pulse (JVP) provides a window of the right heart and its assessment is important in patients with heart failure. Very recently, impact of right ventricular distensibility, detected as the prominent 'Y' decent of JVP, has been suggested on HFpEF (Harada et al. Heart and Vessels, 2017). However, the conventional method to monitor JVP waveform such as pulse transducer requires skill and is not frequently used.
Purpose: We herein propose a novel method using a microwave radar, which has been recently applied to a non-contact vital sign monitoring, for JVP assessment. The aim of this study is to evaluate this new method for a non-contact monitoring of JVP in cardiology patient simulator and healthy volunteer.
Methods: A microwave radar system consists of three of an antenna (Figure A), A/D converter, and PC. We recorded JVP waveform in Cardiology Patient Stimulator "K" known as "Ichiro" (Kyoto KAGAKU Co. Ltd) and 10 healthy subjects (20-24 y.o. male) using a pulse transducer (TY-501, FUKUDA DENSHI) as a reference and a microwave radar.
Results: JVP waveform determined by a microwave radar showed normal wave patterns with 3 waves (a,c,v) and 2 descents (x, y), identical with reference (Figure B). Simultaneous recording of ECG and JVP waveform by a microwave revealed that "x" is deeper than "y" in all the 10 healthy subjects (Figure C). The amplitude of each waveform measured by microwave radar correlated significantly with that measured by pulse transducer (r = 0.65). Conclusion: The proposed method seems to be promising for a non-contact JVP monitoring and useful in the clinical setting, especially heart failure practice.



Microwave Radar for JVP Monitoring

Chronic Heart Failure - Treatment

P2173

Comparison of therapeutic effects between urapidil and nitroglycerin for treatment of acute heart failure with hypertension and atrial fibrillation in elderly patients

Q Qi Hua[1]; ZICHEN Wang[1]
[1]Xuan Wu Hospital, Capital Medical University, cardiology, Beijing, China People's Republic of

Background and objective: Acute heart failure (AHF) is a complex clinical syndrome and frequently complicated by hypertension and atrial fibrillation (AF). The aim of this study was to evaluate whether urapidil provides additional therapeutic benefits compared to nitroglycerin (NG) in the treatment of AHF with hypertension and AF in elderly patients.
Methods: 58 elderly patients from 10 hospitals were randomized into 2 groups. Control group (n = 30) were treated with NG, while other group (n = 28) were treated with urapidil. We monitored systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR), N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels and carry out echocardiogram before and 24 h, 48 h, 72 h and 7 d after treatment with either NG or urapidil. Lipid profile, liver and kidney function, blood glucose levels in nitroglycerin and urapidil groups were examined before and 24 h, 48 h, and 7 d after treatment.
Results: Patients receiving urapidil had lower SBP than that in NG group ($P < 0.05$). Compared with NG group, patients in urapidil group showed increased LVEF ($P < 0.05$), CO, SV and CI ($P < 0.05$), but no significant differences in LVEDD and EDV. NT-proBNP was decreased following the treatment of urapidil or nitroglycerin, and the difference of NT-proBNP level was significant between the two groups ($P < 0.01$) at 7 d. Urapidil had trend to decrease blood glucose after 7 d.
Conclusions: Urapidil demonstrated better efficacy and fewer side effects than nitroglycerin on lowering and stabilizing systolic BP, attenuating cardiac afterload and improving cardiac function.

Obstacles to mineralocorticoid receptor antagonists in a community based heart failure population

H Norberg[1]; A Anna Jonsson[2]; E Berghdal[2]; K Lindmark[2]
[1]Umea University, Department of Pharmacology and Clinical Neuroscience, Umea, Sweden; *[2]Umea University, Department of Public Health and Clinical medicine, Umea, Sweden*

Funding Acknowledgements: This work was supported by the Heart Foundation of Northern Sweden.

Background: The cornerstones of heart failure (HF) treatment consist of angiotensin converting- enzyme inhibitors (ACE-I) or Angiotensin-receptor blockers (ARB), beta blockers and MRA. Previous studies and national assessments indicate an under-treatment of MRA in heart failure with reduced ejection fraction (HFrEF).

Purpose: In order to offer our patients the best available HF treatment and to reduce morbidity, mortality, health care costs and patient suffering, we want to investigate the reasons why MRA is not used to full extent.
Methods: A community based heart failure population in Sweden was studied. Approximately 90 variables were collected and medical records were scrutinized to identify reasons for not prescribing MRA.

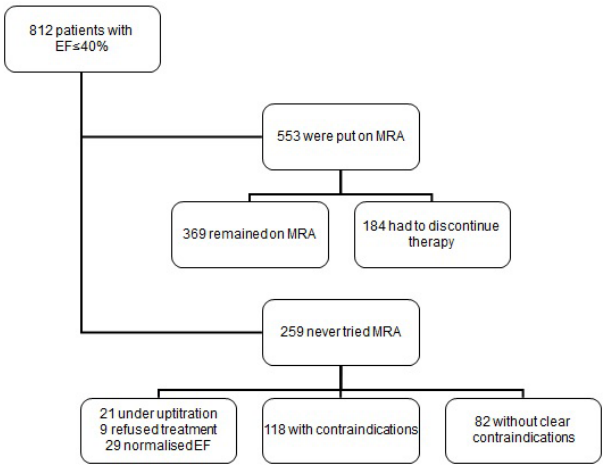

Figure 1

Results: Of 2029 patients, 812 had EF = 40 %. 553 patients (68%) tried MRA at some point but 184 (33%) of these discontinued therapy. There were 259 patients that never tried MRA, of which 177 had a listed explanation or contraindication. 82 patients, 10% of the total HFrEF population, had no clear contraindications. They were older, had less HF hospitalizations and less treatment with ACE-I/ARB and beta blockers and fewer patients reached standard therapy target doses compared to patients on MRA ($p < 0,05$). 26 of the 82 patients (32%) did not have any follow up at the cardiology clinic. Contraindications to MRA were renal dysfunction (93 patients), hypotension (28 patients) and hyperkalemia (25 patients). Only six patients had hyperkalemia without renal dysfunction. Of the patients with renal dysfunction, 66 (72%) had an estimated glomerular filtration rate (eGFR) > 30 ml/min.
Conclusions: The reasons why MRA are underutilized were mainly because of contraindications. However, the data indicate that the physicians are overly cautious about adverse effects with MRA in patients with moderately reduced kidney function. We propose education on the risk-benefit ratio of moderate renal dysfunction and minor hyperkalemia vs the risks of not receiving complete heart failure treatment. We believe that we could reach a higher degree of MRA usage with better and regular monitoring of these patients. There seems to be a 10% avoidable undertreatment with MRA, especially for elderly patients that are admitted to hospital for other reasons than HF. The fact that these patients had lower doses of basic heart failure therapy could be a partial explanation to why these patients did not receive treatment with MRA, but in previous MRA studies not all patients received maximum doses of ACE inhibitor/ARB but there was still a survival benefit in the MRA-arm. Furthermore, the data suggests that patients with heart failure would benefit from routine follow up at a cardiology clinic.

Prognostic value of diuretic dose in stable chronic heart failure

L Lupi[1]; E Rocco[1]; I Papa[1]; R D'ortona[1]; G Arabia[1]; M Piazzani[1]; L Branca[1]; M Metra[1]; S Nodari[1]
[1]*University of Brescia, Department of Clinical and Surgical Specialities, Cardiology section , Brescia, Italy*

Background: High daily diuretic dose (DDD) in chronic heart failure (HF) patients is related to cardiac and renal dysfunction but its relationship with outcomes in this population is still not completely understood
Purpose: To evaluate the prognostic implications of DDD in patients with chronic HF
Methods: We conducted a retrospective analysis of patients (pts) with HF and reduced Left Ventricular Ejection Fraction (LVEF < 45%) followed at our outpatient HF Clinic. Inclusion criteria were optimized therapy and clinical stability (neither events nor therapeutic changes) in the previous three months. We evaluated clinical, laboratory, echocardiographic and therapeutic parameters. Hypervolemic or euvolemic status was defined according to the Framingham Score, calculated by assigning a score of 0,5 or 1 for each of the following signs or symptoms: orthopnea, paroxysmal nocturnal dyspnea, reduction in exercise tolerance, resting sinus tachycardia, increased jugular venous pressure, hepatojugular reflex positive, third heart sound, basal crackles, hepatomegaly, peripheral oedema; a score = 2 indicates a state of hypervolemia. DDD was considered as continuous and categorical variable (ROC analysis was perfomed to identify optimal cut off of DDD for prognosis). The composite endpoint considered was all cause death (ACD) and hospitalization for Heart Failure (HHF) or cardiovascular causes (HCV).
Results: A total of 570 pts (mean age 67 ± 12 years, 84% male) were included. Almost all of the pts received guideline-recommended therapy for HF. After a mean follow-up of 43 ± 14 months, the composite endpoint occurred in 255 pts (54%). At Univariate analysis advanced age, dyspnea at rest or for minumum effort, atrial fibrillation, higer heart rate, a state of congestion evidenced by echocardiography or by a Framingham Score = 2, furosemide DDD, lower level of haemoglobin, glomerular filtration rate and serum sodium, lower LVEF and higher degree of mitral regurgitation were significantly corralated with the occurrence of the composite endpoint ACD + HHF + HCV. In the multivariate model only LVEF (HR 0.97; CI 0.94-0.99; p = 0.029), DDD (HR 1.002; CI 1.005-1.004; p = 0.011) and Framingham Score (HR 2.58; CI 1.52-4.39; p < 0.001) were independently associated with adverse events. The ROC analysis identified a furosemide DDD of 87 mg as optimal cut-off to predict the development of events (AUC 0.65, sensitivity 47%, specificity 78%). A DDD > 87 mg was associated with adverse prognosis only in the subgroup of euvolemic patients (Framingham Score < 2) (HR 1.49; CI 1.08-2.07)
Conclusions: In pts with chronic stable HF, DDD is associated with adverse outcome, expecially in euvolemic pts. In hypervolemic pts high DDD are likely to be indirect marker of the severity of the disease. The goal of diuretic therapy is to ensure the persistence of hemodynamic stability and DDD should be adjusted periodically in oder to avoid decompesated HF but also excessive diuretic dosage.

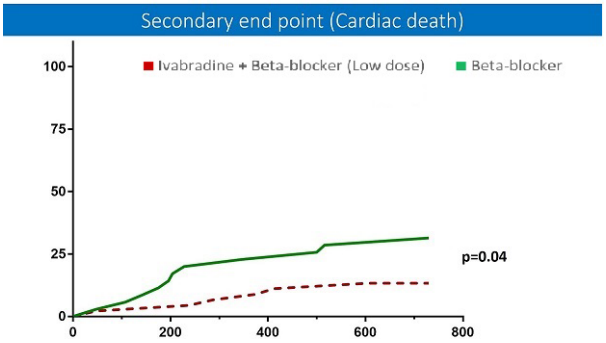
P2176

Two-years outcome of patients with heart failure and severe left ventricular dysfunction treated with ivabradine and low doses of beta-blocker

FM Melillo[1]; C Godino[1]; A Sisinni[2]; A Salerno[1]; A Cappelletti[1]; G Fragasso[1]; A Margonato[1]
[1]*San Raffaele Hospital of Milan (IRCCS), Milan, Italy*; [2]*University Vita-Salute San Raffaele, Milan, Italy*

Funding Acknowledgements: none

Background: Uptitrating beta-blockers (BB) to target dose is threatening in patients with heart failure (HF) and markedly depressed left ventricular function. No data are available in patients with intolerance or poor BB tolerability in whom ivabradine is used to achieve heart rate reduction alone or in addition with low BB doses.
Methods: In this single-centre observational study we included patients with chronic HF (stable from = 2 months) and markedly depressed EF (= 30%) referred to our Heart Failure Unit from August 2010 to December 2015. Patients with acute HF and transient causes of EF depression were excluded. BB used were bisoprolol, nebivolol and carvedilol. Low BB dose corresponded to less than 25% of the BB target dose. Among patients included in the registry, two sub-cohorts were considered for the present analysis, according to ivabradine and BB use: group 1) patients treated with high BB dose (<25% of BB target dose) alone; group 2) patients treated with ivabradine and low BB dose. Primary end-point was the combination of hospital admission for acute HF and cardiac death at 1 and 2 years.
Results: A total of 145 patients were included in the registry during the index period. For the present analysis 105 patients (45 pts group 1 and 60 pts group 2) were eligible. Mean BB dose was 45% of the target dose in group 1 and 7% in group 2 (p = 0.0001). Most baseline clinical characteristics were well balanced between the two groups: age (71.8 ± 9.1 vs 69.3 ± 12.3 years), EF (26.0 ± 5.5 % vs 25.0 ± 5.5 %), LVEDV (216.4 ± 55.4 vs 202.8 ± 53.9 ml), TAPSE (17.8 ± 0.9 vs 8.2 ± 0.9 mm), severe mitral regurgitation (26.7% vs 28.3%), history of myocardial infarction (44.4 vs 48.3%), creatinine clearance (57.9 ± 25.6 vs 62.4 ± 32.3 ml/min), loop diuretics dose (90.1 ± 88.1 vs 92.3 ± 90.7 mg/die). Patients in group 2 had less concomitant use of ACE inhibitor or angiotensin receptor blocker (61% vs 80%, p = 0.04), due to inadequate tolerability. In terms of primary endpoint, there was any difference between groups at 1-year (40.0 vs 33.0%, p = ns) and 2-years (54.3 vs 48.9%, p = ns) follow-up. Conversely, a statistically significant difference was detected in terms of cardiac death at both 1-year and 2-years (20.0 vs 5.9% and 31.4 vs 13.3%, p = 0.04 and p = 0.05 respectively). The rate of hospital admission for acute heart failure were similar (32.5 vs 27.5%) at 1 year and (42.9 vs 40.0%) at 2 years.
Conclusion: In this study population including patients with advanced HF and poor BB tolerability, we observed no beneficial effects of uptitrating BB compared to adding ivabradine to low BB doses.



Kaplan-meier analysis of cardiac death

Effectiveness of Sacubitril/Valsartan in real-life practice: experience of a single center

JN Joana Neiva[1]; IGO Gomez-Otero[2]; AVR Varela-Roman[2]; MMG Moure Gonzalez[2]; ASB Seoane Blanco[2]; JRGJ Gonzalez-Juanatey[2]
[1]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal; *[2]University Hospital of Santiago de Compostela, Centro de Investigación Biomédica en Red de Enfermedades Cardiovasculares (CIBERCV), Santiago de Compostela, Spain*

Introduction: Sacubitril/valsartan (SV) reduced mortality and hospitalizations in the PARADIGM-HF trial as compared to enalapril in patients (P) with chronic heart failure with reduced ejection fraction (HFrEF). ESC guidelines currently recommend SV for P with ongoing symptomatic HFrEF, despite first line medical therapy.
Purpose: Evaluate effectiveness of SV, regarding impact on functional capacity and on HF related outcomes and healthcare resource utilization.
Methods: Retrospective and descriptive study extended to all P on SV in a specialized HF unit in a single center since October 2016. Demographics, medical history, concomitant treatment and final dose were analyzed. Clinical parameters such as functional class of New York Heart Association (NYHA) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) were assessed at each evaluation. Outcomes assessed were: HF hospitalization, non-elective hospitalization for any reason; death for any cause; cardiovascular (CV) death and emergency department (ED) visits due to decompensated HF. Descriptive statistics and Kaplan-Meier curve were used for analysis.
Results: Within a population of 106P (79% male; 68,2+10,7 years; 45,3% ischemic etiology; mean left ventricular ejection fraction (LVEF) 29,5%), 75,5% had NYHA II and 23,6% NYHA III at baseline. Mean baseline NT-proBNP was 2415pg/mL. 99,1% of P were on ACEI/ARB, 98,1% with beta-blockers and 89,6% on MRA. 52,8% had implantable cardioverter defibrillator and 31,1% cardiac resynchronization therapy system. The mean follow-up time was 194 days (4 - 421). Up-titration to maximum dose was achieved in 45,3%. 41,5%P had subjective improvement in symptoms and quality of life. NYHA class improved in 35,5%P (2P upgraded two classes); in 25,3%P it occurred early on first month. NT-proBNP did not significantly change (2415 vs 2104pg/mL). The mortality rate was 2,8% - all 3P had sudden death, HF hospitalization occurred in 2,8% (3P), hospitalization for all reasons in 6,6% (42,8% for non CV etiologies) and 2,8% (3P) had ED visits due to acute HF. Of 13P who obtained repeated LVEF measurement, 8 (61,5%) had improved LVEF (increase of 8,3%).
Conclusion: Our data suggests that SV is effectiveness in real-life. The overall outcomes rates were lower when compared to PARADIGM-HF trial, however our mean follow-up period was significantly shorter and our population is monitored closely in an HF specialized consultation.

P2178

Non-response predictors to physical rehabilitation in heart failure patients

VL Galenko[1]; TA Lelyavina[1]; MY Sitnikova[1]
[1]North-west state medical university, Saint-Petersburg, Russian Federation

Funding Acknowledgements: Project was funded by Grant RSF 16-15-10178

Introduction: In the world practice, physical training is widely used in CHF patients. But in most cases, is not taken into account the influence of the initial clinical status of patients (gender, age, CHF NYHA, peak oxygen uptake, comorbidity) on the results of physical rehabilitation.

Purpose: To reveal the most significant predictors of inadequate response to physical rehabilitation in CHF patients, selected on the basis of achievement the lactate threshold during CPET.

Methods: 90 patients, CHF NYHA II-III were randomized into two groups - primary (aerobic training) and control (standard treatment of CHF). Main group - 77 patients, mean age 52 ± 12,5 years, body mass index (BMI) 25,3 ± 5,4 kg/m2, among them 55 patients (72%) had III CHF functional class and 22 patients (28%) - II CHF functional class. The control group - 13 patients, age 51 ± 13,4 years, BMI was 25,4 ± 5.2 kg/m2, 12 patients had III CHF functional class, 1 patient - II. The original estimated results of physical examination, laboratory parameters, comorbidity. CPET, quality of life (QOL), exercise tolerance (ET) was assessed at baseline and after 1,3,6 months of follow-up. The CPET served on tredmile using hardware. Echocardiography (EchoCG) were performed at baseline and after 6 months. The data were statistically processed using software package "Statistika, 9.0".
Results: In the main group after 6 months of training EF increased by 8.7 ± 0.5% and End-diastolic volume decreased by 6 ± 2.0 ml from baseline, QOL was changed by 17.5 ± 8 points (significant regression of symptoms), ET increased by 9.5 ± 1 points and VO2 peak increased by 4.4 ml/min/kg. In the control group showed an increase EF 4 ± 1,1%, End-diastolic volume decreased by 68 ± 14,8 ml, the change of QOL 14 ± 7,22 points, the increase in ET at 1.5 points, VO2 peak decreased by 1,7 ml/min/kg. Revealed a strong positive correlation between the initial values of VO2 peak and EF (rEF = 0,4, p), and between baseline levels of sodium, hemoglobin and the of physical rehabilitation efficiency (rNa= 0,41, p,0,05; rHb = 0,45, p <0,05). There was a positive impact of the initial content of red blood cells (rEr = 0,6, p = 0.03), sodium (rNa = 0,4, p = 0.05), LV EF (r = 0.5, p = 0.05) and level VE at the peak of exercise load (r = 0.5,p = 0.01) on training efficiency. BNP level and a long history of CHF had a negative effect on the result of physical training (rBNP=-0,7, p = 0.05; rCHF=-0,6, p = 0.05). Significant differences in training performance between patients II and III functional class were not received.
Conclusion: Aerobic physical exercise in CHF patients, selected on the basis of lactate threshold achievement during the CPET, is effective in improving values of CPET, EchoCG, QOL and increasing exercise tolerance. Age, BNP and uric acid levels, CHF duration can be considered as most significant predictors of inadequate response to physical rehabilitation in CHF patients.

P2179

Telemedicine support to patients with heart failure at their self-management at home

M Pusnik-Vrckovnik[1]; C Slemenik-Pusnik[1]; D Rudel[2]; S Pusnik[3]; Z Balorda[2]; M Epsek-Lenart[1]; J Lavre[1]

Funding Acknowledgements: The work was partially co-financed by the European Commission under the United4Health CIP ICT PSP (GA No 325215).

Introduction: - In several scientific publications authors suggest that telemedicine (TeleMed) support to patients with long-term conditions is potentially useful tool for those patients who are likely to benefit from frequent and regular monitoring by health care providers. Some studies have already confirmed that TeleMed can be an effective add-on tool also in self-management of heart failure (HF) at home.
Purpose: - This study aimed at analyzing potential impact of TeleMed support to HF patients at their self-management at home when provided in addition to the standard care.
Methods - A TeleMed support was provided to a group of 130 HF patients (intervention group) for a minimum of 12 months. The median age of the patients was 72 years, 65% were male. The patients measured daily their blood pressure (BP), heart rate (HR), body weight and oxygenation. Data were immediately transferred to a telemedicine monitoring. In case of exceeding the personally set values the patients were called and advised on changing their lifestyle, nutrition, physical activity or to change the prescribed medication. The comparative group (N = 201) was the intervention group itself with 71 additional patients in the period of one year prior to the patients' inclusion into the TeleMed service. In the observed period patients in both groups received equal standard support through the existing long-term HF care programme. For the control period data on BP and HR for the patients involved in were obtained from a hospital HF register. To assess potential effects of TeleMed support LVEF ultrasound measurements and clinical marker proBNP were measured at three milestones: one year before the enrollment of patients into the TeleMed programme (-1y), at the enrollment (0y), and then after 12 months (+1y). Data on BP, HR, LVEF and proBNP were statistically analysed using descriptive statistics. Changes in average values of the measured values at milestones (-1y, 0y and +1y) were compared.
Results - After the observed 12 months period of using TeleMed support the average values of BP and HR did not changed with statistically significance neither in the intervention nor in the control group, but the intervention group changed its characteristics. Some patients moved from the high level BP (above 140/90 mmHg) to the normal BP level group (below 140/90 mmHg). Number of patients with normal BP measurements was 36% higher after 12 months of TeleMed support. Number of patients with normal heart rate measurements was 64% higher after 12 months of TeleMed support. The average LVEF increased from 41,6% to 44,7% (improvement

by 7,5%). The ProBNP clinical marker was reduced from 2.780 pg/ml to 1.795 pg/ml (improvement by 35%).
Conclusion –TeleMed support to HF patients at their self-management at home provided in addition to the standard care positively influenced the patients' health conditions. This was confirmed by the periodic external ultra sound and laboratory measurements.

P2180
Physical rehabilitation efficiency in heart failure patients

VL Victoria Galenko[1]; TA Lelyavina[1]; MY Sitnikova[1]
[1]*North-west state medical university, Saint-Petersburg, Russian Federation*

Funding Acknowledgements: Project was funded by Grant RSF 16-15-10178

Introduction: In the world practice, the selection of CHF patients physical training intensity is based on anaerobic threshold achievement during cardiorespiratory test (CPET). But the majority of patients with severe HF are not able to achieve it, that requires the use of certain indicators in the appointment of physical training. This alternative indicator can be lactate threshold, which achieved by every HF patient during the CPET.
Purpose: To evaluate aerobic physical training efficiency in CHF patients, selected on the basis of achievement the lactate threshold during CPET.
Methods: 90 patients, CHF NYHA II-III were randomized into two groups - primary (aerobic training) and control (standard treatment of CHF). Main group - 77 patients, mean age 52 ± 12,5 years, body mass index (BMI) 25,3 ± 5,4 kg/m2, among them 55 patients (72%) had CHF NYHA III, 22 patients (28%) - II. Control group - 13 patients, age 51 ± 13,4 years, BMI was 25,4 ± 5.2 kg/m2, 12 patients had CHF NYHA III, 1 patient - II. The original estimated results of physical examination, laboratory parameters, comorbidity. CPET, quality of life (QOL), exercise tolerance (ET) was assessed at baseline and after 1,3,6 months of follow-up. The CPET served on tredmile using hardware. Echocardiography (EchoCG) was performed at baseline and after 6 months. The data were statistically processed using software package "Statistika, 9.0".
Results: Main group - after 6 months of training EF increased by 8.7 ± 0.5% and End-diastolic volume decreased by 6 ± 2.0 ml from baseline, QOL was changed by 17.5 ± 8 points (significant regression of symptoms), ET increased by 9.5 ± 1 points and VO2 peak increased by 4.4 ml/min/kg. Control group - EF increased by 4 ± 1,1%, End-diastolic volume decreased by 68 ± 14,8 ml, QOL changed 14 ± 7,22 points, ET increased at 1.5 points, VO2 peak decreased by 1,7 ml/min/kg. Revealed a strong positive correlation between the initial values of VO2 peak and EF (rEF = 0,4, p), and between baseline levels of sodium, hemoglobin and the of physical rehabilitation efficiency (rNa= 0,41, p,0,05; rHb = 0,45, p <0,05). There was a positive impact of the initial content of red blood cells (rEr = 0,6, p = 0.03), sodium (rNa = 0,4, p = 0.05), LV EF (r = 0.5, p = 0.05) and VE level at the peak of exercise load (r = 0.5,p = 0.01) on training efficiency. BNP level and a long history of CHF had a negative effect on the result of physical training (rBNP=-0,7, p = 0.05; rCHF=-0,6, p = 0.05). The most significant impact on physical training efficiency of CHF NYHA III patients had a CHF duration (rCHF =-0,4, p = 0,05). Significant differences in training performance between patients CHF NYHA II and III were not received.
Conclusion: Aerobic physical exercise in CHF patients, selected on the basis of lactate threshold achievement during the CPET, is effective in improving values of CPET, EchoCG, QOL and increasing exercise tolerance.

Devices for objective assessment of physical activity in patients with heart failure: a systematic review

M Martha Kyriakou[1]; L Klompstra[2]; T Jaarsma[2]; N Middleton[1]; M Piepoli[3]; E Lambrinou[1]
[1]*Cyprus University of Technology, Limassol, Cyprus*; [2]*Linkoping University, Linkoping, Sweden*; [3]*Cardiology Unit, Guglielmo da Saliceto Hospital, Piacenza, Italy*

Devices for objective assessment of physical activity in patients with heart failure: A systematic review
Introduction
Heart Failure (HF) is associated with severe impairment of exercise capacity and reduced exercise tolerance, functional ability and health-related quality of life (HR-QoL). Low levels of physical activity (PA) are a sensitive indicator of poor prognostic outcomes in HF. Currently, most interventional studies assess PA subjectively and not objectively.
Aim of the study: To identify all intervention studies which used objective tools to assess PA of patients with HF. It was also examined whether changes in PA were associated with exercise capacity, health related- quality of life (HR-QoL) and psychological status
Methods: A systematic search of PubMed, CINAHL, Scopus and Web of Science was performed to identify studies which assessed the functional status in patients with HF using accelerometry, published in the English language. The search was conducted in September and October 2017 and the following terms were used: ("accelerometer" OR accelerometry OR "motion sensor" OR "activity monitor") AND ("heart failure"). Two researchers independently reviewed the results and a third one adjudicated, in case of lack of consensus. The Cochrane tool was used to assess the risk of bias of each study. Meta-analytic methods were used to extract, graphically display and explore data, but not to estimate an overall effect due to the small number of studies.
Results: Eight intervention studies (5 randomized control trials) were identified. A large heterogeneity was observed regarding the intervention period, the way chosen to measure the outcomes and the intervention as such (e.g. complexity and intensity). All studies measured the primary outcome: physical activity. Secondary outcomes, (i.e exercise capacity, HR-QoL and psychological status) were measured in seven, three and four studies, respectively. Heterogeneity in study estimates was also confirmed by a forest plot.
Conclusions: Heterogeneity among the few studies extracted suggests that more and better designed studies which assess physical activity with the use of objective measures are needed.

P2182
Restoration of sinus rhythm as a predictor of effectiveness of crt in patients with severe heart failure and persistent atrial fibrillation

D Lebedev[1]; M Lebedeva[1]; S Popov[1]
[1]*Cardiology Research Institute, Tomsk National Research Medical Center of RAS, Tomsk, Russian Federation*

Objective: To evaluate the effect of sinus rhythm restoration on the effectiveness of cardiac resynchronization therapy in patients with severe heart failure and persistent atrial fibrillation. Materials and Methods. The study included 150 patients (76 women) with mean age of 47.7 ± 10.9 years, Chronical Heart Failure (CHF) NYHA functional class III, dilated cardiomyopathy (DCM), and persistent atrial fibrillation (AF). The width of the QRS complex varied from 146 to 240 ms (mean 183 ± 32 ms); left ventricular ejection fraction (LVEF) was 30.1 ± 3.8%; and End-diastolic volume (EDV) was 272.4 ± 49.8 mL. The 6-min walk distance was 247.8 ± 57.3 m. Optimal drug therapy for CHF was ineffective for a period of three to six months. CRT-devices were implanted in all patients. A follow-up examination in the presence of biventricular stimulation was performed at 36 months.
Results: An analysis of CRT results at 36 months showed that sinus rhythm spontaneously restoration in 115 patients (76.7%) who had pre-treatment AF and ineffective antiarrhythmic therapy. In this group of patients, three-year follow-up showed that EF increased by 18% from 29.0 ± 3.8% to 42.5 ± 4.2% (p <0.0001); EDV decreased by 48 mL from 215.9 ± 58.1 to 177.1 ± 26.6 mL (p <0.0005). AF persisted in 35 patients (23.3 %) for 36 months after beginning of CRT. In these patients, three-year follow-up showed that LVEF increased by 9% from 29.0 ± 3.8% to 38.7 ± 2.1%; EDV decreased by 15 mL from 215.9 ± 58.1 to 200.7 ± 39.1 mL (p <0.0005).
Conclusion: Our study demonstrated that achieving sinus rhythm provided a stable increase in EF and a decrease in EDV during the entire period of CRT in patients with DCM and severe heart failure. Therefore, achieving sinus rhythm should be considered an important task in this category of patients.

P2183
Changes in quality of life in patients with chronic heart failure after cardiac resynchronization therapy

GS Pushkarev[1]; AD Sapozhnikova[1]; YA Fisher[1]; AM Soldatova[1]; TN Enina[1]; VA Kuznetsov[1]
[1]*Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Russian Academy of Scienc, Tomsk, Russian Federation*

Background: Chronic heart failure (CHF) is a serious medical problem associated with high rates of mortality and low quality of life in patients. Cardiac resynchronization therapy (CRT) is one of promising new methods for heart failure treatment. Thus, the study on assessment of quality of life in patients with CHF after CRT is a vital and pressing issue.
Purpose: To assess the quality of life (QoL) changes in patients with CHF one year after CRT.
Methods: The study included 82 patients (68 males and 14 females) aged from 30 to 74 (mean age 55.8 ± 9.2 years) who underwent implantation of a biventricular cardiac pacemaker for CRT. The SF-36 questionnaire was used to measure QoL. The results of the questionnaire were represented as scores over the eight subscales: physical functioning (PF), role-physical functioning (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role-emotional (RE), and mental health perceptions (MH). The QoL assessment was performed before and one year

after CRT. Student's paired t-test was applied in statistical analysis for comparing normally distributed values, while the Wilcoxon nonparametric test was used when the sample data were not normally distributed.
Results: Patients with CHF one year following CRT had significantly higher rates of improvement in PF QoL (PF before CRT 46.28 ± 26.16; PF one year after CRT 53.05 ± 27.65 p = 0.023). The statistical tendency towards QoL improvement was revealed: VT (VT before CRT 47.07 ± 20.12, VT after CRT 51.83 ± 20.07, p = 0.081), SF (SF before ??? 61.58 ± 25.06, SF after CRT 67.07 ± 24.57, p = 0.088). No significant differences were found in paired comparisons of other QoL indicators.
Conclusion: Significant increase in PF index and statistical tendency towards increase in VT and SF were detected in patients with CHF one year following CRT.

P2184

Transcranial doppler findings in heart failure patients with ventricular assist devices

NK Doan[1]; V Rosta[1]; BA Bruckner[1]; AB Lumsden[1]; Z Garami[1]
[1]The Methodist Hospital, DeBakey Heart and Vascular Center, Houston, United States of America

Introduction: Left ventricular assistance device (LVAD) implantation is a "live saving" approach for patients (pts) with heart failure waiting for cardiac transplantation, although cerebral vascular events continue to be frequent sequelae. Transcranial Doppler (TCD) is a novel method for studying cerebral hemodynamics and embolization in these patients.
Methods: The Methodist LVAD TCD diagnostic protocol examined major intracranial arteries in 19 segments. TCD data and embolic signals were interpreted using previously published and validated TCD criteria. TCD results were then correlated to clinical, laboratory and imaging findings.
Results: Thirty-three patients (19 Male, 14 Female; average age: 53.4 years) underwent LVAD placement. Fourty-seven TCD studies were performed (10 pts had multiple tests) on LVAD recipients (35 HeartMate, 4 DeBakey, 4 Thoratec, 1 Novacor, 1 Ventracor, 1 Biomedicus, 1 Levitronic) an average of 202 days (range: 1-840 days) after implantation. Only one patient did not have an adequate acoustic window for the transtemporal examination. There were 4 neurological events during the observation period [3 TIA in 2 pts (1 DeBakey, 1 HeartMate) and 1 stroke (DeBakey)]. We detected 33.2 microembolic signals/minute in 2 of the 3 TIA and in 1 pt under deep sedation. After therapeutic dose adjustment of heparin, microembolic signals were no longer detectable in 3 of 6 pts. Contrast echocardiography shortly before TCD may have contributed to false microembolic signal detection in 2 cases. Bilateral severe middle cerebral artery stenosis was detected in the stroke patient and contributed to her seizures and death. By detecting oscillating flow patterns in 2 pts, we could confirm a brain death diagnosis.
Conclusions: TCD can be used to guide anticoagulation therapy and the replacement of older, embolizing LVADs. Eliminating emboli might prolong symptom-free periods for our patients.

P2185

Applying virtual reality to increase physical activity in Left Ventricular Assist Device (LVAD) supported patients: Is it feasible?

B Ben Avraham[1]; T Jaarsma[2]; S Donnenhirsh[1]; L Klompstra[2]; I Mats[1]; V Yaari[1]; M Abu-Hazeira[1]; D Golub[1]; A Stromberg[2]; T Ben Gal[1]
[1]Rabin Medical Center, Sackler faculty of Medicine, Tel Aviv University, Heart Failure Unit, Cardiology Department, Petah Tikva, Israel; [2] Linköping University, Division of Nursing, Department of Social and Welfare Studies, Linköping, Sweden

Background: Rehabilitation of patients after LVAD implantation is of major importance but seldom applied. The usefulness of physical training in an out-patient setting is limited mainly by transportation issues but also by the huge variability of the post operative physical condition and the need for specialized staff for training and managing of the LVAD supported patients. Virtual reality applications (exergaming) might provide encouragement to increase physical activity and give the opportunity to play at home at the time and level that are most suitable for the individual patient. However, the feasibility of applying this new form of exercise for LVAD supported patients is not known.
Purpose: The aim of the study is to evaluate the feasibility and patient experience of a virtual reality exergame to encourage physical activity in LVAD supported patients.
Methods: A feasibility study is performed with previously used standardized observations and questionnaires to evaluate practical application and experiences of patients. After introducing the virtual reality exergame during a regular LVAD clinic visit, the computer-game was installed at the patient's home. Patients were instructed to play the game for 40 minutes 4 times a week. Feasibility and patient experiences are assessed after 1 month of exergaming at home. The interview guide includes questions about frequency of exergaming, enjoyment, barriers for exergaming, experiences and symptoms (e.g. pain) and LVAD specific practical challenges (e.g. if the controller bag interferes with the physical activity). Descriptive statistics and content analysis are used to present and analyze the data.
Results: Preliminary results show that patients supported with an LVAD can be instructed to play exergames as a mode of physical activity at home. The computer-game was installed at the patient's home by a dedicated instructor. Patients manage to play the exergame and first results show that they enjoy exercising with an exergame. In total, 10 patients are included in this feasibility study and currently followed. Additional data are collected and will be presented during the conference.
Conclusion: Applying virtual reality exergaming in LVAD supported patients seems feasible and is encouraging physical activity in those patients. Our study will enable us to assess the usability of such promising modern technology in engaging LVAD patients in regular physical activity thus improving their physical fitness and prognosis.

P2186

Evaluating community health practitioners perspective of the heart failure pathway

E Lennon[1]; R Kernan[1]; J Gallagher[2]; M Walshe[2]; JP Reily[3]; C Keane[2]; M Ledwidge[2]; PR Kalra[4]; MR Cowie[3]; K Mc Donald[2]
[1]University College Dublin, Dublin, Ireland; *[2]Heart Failure Unit, Dublin, Ireland*; *[3]Imperial College London, London, United Kingdom*; *[4]Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*

Funding Acknowledgements: Enterprise Ireland

Background: There is growing interest in building community capacity to manage Heart Failure (HF). As well as patient/caregiver engagement, the Community Pharmacist (CP) and General Practitioner (GP) play a central role in the community care of HF. As part of a care-pathway mapping programme for HF, we aimed to describe GP/CP perspectives and identify areas for development.
Purpose:/Method
We administered an internally validated questionnaire to eighty CPs and GPs of consecutive consenting HF patients admitted with an acute decompensation. These patients were participating in a prospective care-pathway mapping project in the Heart Failure Unit of a large teaching hospital. Questionnaires were conducted by post. The responses were then analyzed. Response rates were 57.5% (46) and 40% (32) of GPs and CPs respectively.
Results: In terms of enablers of better community HF care, 93%(43) of GPs felt that they could improve diagnosis and management of HF in the community if they had routine access to Natriuretic Peptide testing and the support of same-day HF services. Eighty-five percent (39) stated that if they had access to Echocardiography they would be better enabled to screen for heart failure. A further perceived barrier to optimal HF care within the community amongst 83% (38) of GPs was the patient's own lack of HF education and understanding of their diagnosis. Furthermore, 67% (31) of GPs felt that there should be an increase in the number of outpatient HF clinics.
Almost half of CPs, 45%(14) did not have access to information regarding the patient's diagnosis of HF, requiring confirmation before medicines management. Prescription changes were needed in half of cases (16) and just under half of pharmacists reported spending 30-60 minutes seeking information from medical and healthcare professionals regarding HF issues. Changes related to discharge prescription errors, omitted regular medications, inappropriate medications and incorrect dosages. Conversely, 45% (14) of CPs reported no access t the hospital team regarding medication queries yet, almost half of CPs (16) reported that GPs did not have adequate information regarding the HF plan. Most 72%(23) of CPs felt that it should be standard of care for teams making a medication change on a HF patient's script, to communicate this change and reason for it to the community pharmacist.
Conclusion: These results describe significant gaps in the community HF care pathway amongst healthcare professionals with the most frequent HF patient contact. Most of the barriers relate to information flows, care coordination and access to diagnostics with negative consequences on community care management and resources. Identifying areas for targeted improvement along each stage of this pathway will improve outcomes, efficiencies and the experience of care for HF patients.

Heart Failure Virtual Consult; A tool for delivering specialist opinion but also transferring knowledge to community practitioners

C Keane[1]; J Gallagher[1]; M Hammond[1]; P Campbell[1]; M Ledwidge[1]; K Mcdonald[1]
[1]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland

Funding Acknowledgements: Health Service Executive Ireland

Heart failure (HF) is a highly prevalent disease, affecting the elderly in particular. Early diagnosis of HF is important so that treatment can be initiated on time in order to delay disease progression to overt HF. In Europe, most patients with HF first present in primary care. At present HF diagnosis and treatment is often inadequate in primary care and General Practitioner (GP) confidence of managing HF can be low. The increasing prevalence rates for HF means a greater role for primary care in disease management. The Heart Failure Virtual Clinic (HFVC) provides access for GPs to specialist opinion and thus assists with the management of patients in the community. Importantly the HFVC also facilitates GP empowerment and education by providing support within the community thus reducing the need for secondary/tertiary care referrals. The HFVC is distinct from other eHealth initiatives as it has a dual function, it is not only a system to provide an appropriate health care intervention but also acts as a system for knowledge dissemination, dispersing knowledge and improving GP confidence levels.
The established HFVC (ongoing for 36 months) has recently expanded its geographical reach. In a 9 month period 75 GPs engaged with the service. There were 160 individual patient referrals received and 270 patient appointments in total, 72 virtual clinics took place. Two hundred and thirty CME credits were awarded, with some GPs attending, not to present cases, but to observe the 10 minute CME presentation at the beginning of each session and the anonymised cases presented by their GP colleagues. For patients travel saved was 15,781km (particularly important for this frail, elderly population). If the HFVC were not available then68.75 % of these patients would have been referred to Cardiology Outpatients or Emergency Departments. Another 26.25% of patients would have had unsupervised intervention such as echocardiogram or medication titration. Five per cent would not have been referred anywhere. In relation to knowledge and confidence 83% of GPs said the HFVC had impacted their ability to identify HF patients to a high degree, 80% said due to participation in the HFVC they are now very competent in their ability to treat HF patients and manage side effects.
This expansion of the HFVC demonstrates the potential for such a model in terms of bridging the gap and increasing expertise across primary, secondary and tertiary care, while upskilling community based clinicians. It clearly has the potential to benefit the patient as well as the system.

P2188

Optimizing standards of care of heart failure in general practice. Results of the OSCAR-HF pilot study.

M Miek Smeets[1]; B Aertgeerts[1]; S Janssens[2]; J Penders[3]; J Vercammen[4]; W Mullens[4]; B Vaes[1]
[1]KU Leuven, Department of public health and primary care, Leuven, Belgium; *[2]Gasthuisberg University Hospital, Department of Cardiovascular diseases, Leuven, Belgium*; *[3]Hospital Oost-Limburg (ZOL), Departement of Clinical Biology, Genk, Belgium*; *[4]Hospital Oost-Limburg (ZOL), Departement of Cardiology, Genk, Belgium*

On behalf of: OSCAR-HF study group
Funding Acknowledgements: Unconditional grant of Novartis to finance the HF nurses and data manager working in region Leuven. Cobas h232 devices are provided by Roche.

Background Heart failure (HF) imposes a burden for patients and health economics. General practitioners (GPs) are confronted with the broadest range of HF management. The European Society of Cardiology (ESC) guidelines recommend implementation of multidisciplinary disease management programs to optimize quality of HF care. However, until now, HF care in Belgium is not organized as such.
Purpose: We implemented a multifaceted intervention to support GPs in the implementation of evidence-based HF guidelines.
Methods: The OSCAR-HF pilot study is a non-randomized, non-controlled prospective observational trial (6 months follow-up). The multifaceted intervention consisted of an audit and feedback method to detect previously unrecognized patients with HF in the electronic health record (EHR) and to increase awareness for proactive HF management, an NT-proBNP point-of-care test (Cobas h232) to improve detection and adequate diagnosis of patients with HF and a specialist HF nurse to assist GPs in the education of patients, optimization of treatment and follow-up after hospitalization. All patients aged 40 years and older with a confirmed diagnosis of HF by their GP based on the clinical audit were eligible for participation.
Preliminary results Eight general practices (51 GPs) participated; four in region Leuven, four in region Limburg. The study started in the first practice on 1/1/2017 and ended in the last practice on 30/11/2017. By searching on a registered diagnosis of HF in the EHR 333 patients (prevalence 1.8%) were identified. After the extended clinical audit, GPs confirmed the HF diagnosis in 538 patients, our study population (prevalence 3.0%). The mean age of our study population was high (78 ± 11) and 50% (n = 269) were men. In the past 5 years 457 patients (85%) underwent an echocardiography. Based on the echocardiography results in the EHR 20% (n = 105) were classified as HF with reduced ejection fraction (HFrEF) patients (EF < 40), 13% (n = 71) as HF with mid-range EF (HFmrEF; EF 40-50) and 53% (n = 285) as HF with preserved EF (HFpEF; EF>50). The remaining 77 patients (14%) were not classifiable. Out of 105 HFrEF patients 92 (88%) were treated with a B-blocker and 88 (84%) with renin-angiotensin-aldosterone system (RAAS) blockade. However, target doses were only reached in 15% of HFrEF patients (n = 16) for B-blockade and 36% (n = 38) for RAAS-blockade. Practices were encouraged to objectify uncertain HF diagnoses, increase awareness for new HF diagnoses and optimize care. To support them in these goals an NT-proBNP POC test and support by a specialist HF nurse were offered to each practice. As a results, during the study course, GPs performed 395 NT-proBNP POC tests and the HF nurses did 60 interventions. Data analysis is ongoing and will be finalized april 2018.

P2189

An integrated chronic heart failure and palliative care approach. Is this the way forward?

M Al Barjas[1]; J Roy[2]; F Hodson[2]; P Hansford[2]; S Karwatowski[3]; R George[2]
[1]King's College Hospital, London, United Kingdom; *[2]St Christopher's, Palliative Care, Kent, United Kingdom*; *[3]Princess Royal University Hospital, Farnborough, United Kingdom*

Aim: A pilot study to assess the benefits of integrating chronic heart failure care with palliative care for patients in NYHA class III and IV.
Heart Failure is a chronic illness and cause of death despite the many advances in pharmacological, device based and surgical therapies. People living with long term conditions such as heart failure require an integrated approach to their care with a robust care pathway to meet their needs, from diagnosis through to end of life care. A series of target GP practices encompassing a range of different 'styles' / approaches to managing HF patients and different demographic and deprivation profiles has been identified
A growing consensus has emerged in the literature that confirms the need to extend multidisciplinary management beyond the early targets of reducing heart failure-related mortality and morbidity.
Criteria for patients inclusion:
a. Have been reviewed by the cardiology / heart failure team AND have a confirmed diagnosis of heart failure
b. Know they have a diagnosis of heart failure and can engage in the process of managing their care
c. Agree to the referral
All referrals were discussed in a joint meeting of the heart failure and palliative care teams.
Results: 37 patients were included in the study.
Age - Median 85 yrs (46-100) , Gender - 56% male, ethnicity - 86% White
1 patient 15% risk dying in 1 year; other 7 had 37-60% risk dying that year
MAGGIC average score (SD) 31 (5.8). 4 patients scores < 25
Anxiety scores ranged from 0 to 13 (median 8) with an average of 7 (± 3.9)
Depression scores ranged from 0 to 15 (median 8) with an average of 8 (± 4.2)
−25 patients contacted within 7 days of referral
−9 within 7-14 days of referral
−3 contacted >14 days (wrong contact info, admitted to hospital day after referral, awaiting cardiology review before accepted onto pilot). 5 haven't been contacted yet (awaiting further cardiac information).
−27 patients were seen in under 7 working days
−5 within 7-14 days
−4 > 14 days. One patient requested to be contacted in one month and is awaiting first assessment; one patient died before being seen and 5 are waiting cardiology assessment prior to acceptance on the pilot.
Patients' needs were:
Pain / Symptom Control 45 (87%), carer Support 17 (33%), psychological / Emotional Support 12 (23%) social / financial 4 (8%), rehabilitation 3 (6%) and terminal Care 2 (4%)
8 patients died at the following locations:
•5 died at a local hospital.
•1 died in the hospice.
•1 died at home with family present
•1 died in a Nursing Home
average length of care was 38.4 (± 20.7) days
•30/35 patients with decision not to resuscitate
•5/35 patients remain for resuscitation.
Discussion and conclusion:
•Patient population is older, frail, with comorbidities.
•The pilot study demonstrate significant improvements in palliative care outcome score. MAGGIC score did not predict referral or clinical outcomes in this cohort

P2190

Psychological interventions to improve psychological outcomes in patients with heart failure: a systematic literature review

N Sedlar[1]; M Lainscak[2]; J Farkas[3]
[1]*National Institute of Public Health, Ljubljana, Slovenia*; [2]*General Hospital Murska Sobota, Department of Internal Medicine, Murska Sobota, Slovenia*; [3]*General Hospital Murska Sobota, Department of Research, Murska Sobota, Slovenia*

Funding Acknowledgements: Heart failure epidemiology in Slovenia: prevalence, hospitalizations and mortality, J3-7405 - financially supported by the Slovenian Research Agency

Background: A growing body of evidence supports the association between psychological symptoms and adverse outcomes in patients with heart failure. As a consequence, the importance of psychological interventions, aiming to assist with the disease adjustment and general well-being improvements (ie. reducing depression, improving quality of life) has been emphasized in the recent years.
Aims. To review literature on psychological interventions in patients with heart failure and identify most commonly used psychological intervention features.
Methods: PRISMA guidelines were used to search major health databases (PubMed, Scopus, ScienceDirect, PsycInfo) for randomized controlled trials evaluating psychological interventions in patients with heart failure. Interventions were analyzed based on their success in producing a significant change ($p < 0.05$) in outcomes, in the hypothesized direction; outcome measures included total or cardiac-related mortality, cardiac morbidity, depression, anxiety, health-related quality of life. The reviewers examined intervention features such as setting, format, duration, interventionist, as well as psychological components and education strategies.
Results: We identified 15 studies that were included in the review. Interventions used different approaches, including cognitive behavioral therapy, motivational interview, supportive counselling/psychoeducation, stress management and mindfullness-based therapy. Thirteen studies reported on depression and HRQOL, nine on anxiety and four on total or cardiac-related mortality/morbidity. Positive outcomes were obtained in less than half of the studies reporting on the outcomes; six studies reported significantly ($p < 0.05$) improved HRQOL, five reduced depressive symptoms, four reduced anxiety symptoms and one reduced mortality/morbidity in the intervention group compared to the control group. Most interventions were hospital- or home-based, delivered by nurse, using one-on-one format and less than six months in duration. Guidance on successful behaviour change, self-awareness/self-monitoring, emotional support/client led discussion, cognitive challenge/cognitive restructuring techniques and homework exercises were most commonly used psychological components. Most frequently used educational strategies included mutually-agreed goal-setting, situational problem-solving, lecture-based teaching, feedback and use of diaries.
Conclusion: Due to the heterogeneity of published studies, individualized nature of psychological interventions and various outcome measures our study highlights the need for further exploration regarding most effective types of psychological intervention and their benefits.

P2191

Overweight/obesity paradox in Acute Coronary Syndrome prognosis; not a truth for each heart failure phenotype. Results from Hellenic Heart Failure study.

C Christina Chrysohoou[1]; M Kouvari[2]; P Aggelopoulos[1]; I Haritou Kotsopoulou[1]; H Kosyfa[1]; E Tsiamis[1]; C Pitsavos[1]; D Tousoulis[1]
[1]*University of Athens, Athens, Greece*; [2]*Harokopio University, Nutrition Science - Dietetics, Athens, Greece*

Background/Introduction: Weight management is arguably recommended in the primary prevention of chronic diseases; yet this is not the case in the treatment spectrum of diseases like heart failure, usually, characterized by a high catabolic state. In such cases, overweight/obese subjects are to have a survival advantage. However, to what extent this is a truth for all raises many doubts.
Purpose: to evaluate the role of body mass index (BMI) in coronary patients prognosis with established heart failure and to investigate potential interactions with left ventricle performance.
Methods: in 2006-2009, 1,000 consecutive patients, hospitalized at a Cardiologic Clinic in Athens with ACS diagnosis were enrolled in the study. In 2016, 10y follow-up (after intermediate follow up in 1 month, 1 & 2 years) was performed (75% participation rate). Overweight was defined as 25 = BMI = 29.9 kg/m2 while obesity as BMI>29.9 kg/m2. Heart failure phenotype was defined according to baseline EF; heart failure with reduced EF (i.e. <40%) (HFrEF), preserved EF (i.e = 50%) (HFpEF) and mid range EF (i.e. 40-49%) (HFmrEF).
Results: BMI status and ACS prognosis followed a J-shape association. Ranking from normalweight to overweight and to obese subjects, the aforementioned association was evident in case of in hospital mortality (7%, 4% and 5%, $p = 0.09$), 2y ACS prognosis (50%, 32% and 36%, $p = 0.009$) and 10y ACS prognosis (65%, 52% and 58%, $p = 0.03$); fatal/non fatal ACS events within the decade were 65%, 52% and 58% ($p = 0.009$). Focusing on long term prognosis (i.e. 10y), multivariate logistic regression analysis, revealed that overweight patients had significantly better ACS prognosis compared with their normalweight counterparts (OR = 0.45, 95%CI (0.23, 0.90)), whilst obese patients did not have significant differences compared with the reference group. Significant interactions were observed between left ventricle performance (i.e. ejection fraction) and BMI on 10y ACS prognosis (p for interaction <0.001). With heart phenotype as strata, the aforementioned association remained significant only in HFrEF patients (OR = 0.35, 95%CI (0.13, 0.89)). HFmrEF and HFpEF patients did no reach significance. Conclusion: overweight paradox was highlighted in 10y ACS prognosis of heart failure patients. However, certain prerequisites were indicatively stated, with the aforementioned association being more evident in heart failure patients with the highest catabolic state (i.e. HFrEF); yet not being the case in patients with better left ventricle performance.

P2192

Safety profile of novel angiotensin II type-1 receptor neprilysin inhibitor lcz696 (sacubitril/valsartan) - a collaborative summary from clinical trials

A Z Barano[1]; E N Putri[2]; M F Addai[3]; M Abduh[4]; D Ilmasari[5]
[1]*Bergerak Badau Hospital, Kapuas Hulu, Indonesia*; [2]*Hermina Hospital, Bekasi, Indonesia*; [3]*Johar Baru Primary Health Care, Jakarta, Indonesia*; [4]*Dr. M. Yunus General Hospital, Bengkulu, Indonesia*; [5]*Hardjolukito Central Air Force Hospital, Yogyakarta, Indonesia*

Background: LCZ696 (Sacubitril/Valsartan) is a first-in-class inhibitor of the angiotensin II type-1 receptor and neprilysin.
Purpose: We aim to evaluate the safety profile of novel medication, LCZ696 (Sacubitril/Valsartan).
Methods: Pubmed database were searched for Clinical Trials of LCZ696 (Sacubitril/Valsartan). We required the trials to report adverse events (AEs) of the medication. The data was compiled in IBM SPSS Ver 21. Continuous data were reported in number of samples (n) and percentage (%).
Results: Twelve clinical trials were included with a total of 14,447 patients. The majority of patients were suffering from hypertension and heart failure. Numbers of reported serious AEs 0.27% (39), Discontinuation 1.41% (203), and death 0.007% (1, caused by acute myocardial infarct). Total numbers of AEs were 19.57% (2827). Cardiovascular and Respiratory AEs were the most common AEs, respectively 9.07% (1310) and 8.6% (1242). Numbers of reported AEs (< 1% for each AE) were contributed by Neurology, Gastrointestinal, Skin, Locomotor, Renal and urinary tract, Hypersensitivity and autoimmune, psychology problem. Based on AEs, Hypotension 8.95% (1293), Cough 6.77% (978), and Nasopharyngitis 1.052% (152) were the most reported AEs, while other AEs (< 1% for each AE) were dizziness, URTI, headache, angioedema, diarrhea, hematuria, pharyngitis, etc. The reported laboratory result changes were 13.878% (2005). Electrolyte and renal function were the most reported changes related with laboratory results, respectively 11.05% (1596) and 2.5% (362). The other reported laboratory changes (< 1% for each changes) were changes in liver function, lipid profile, uric acid, and blood glucose level. The most commonly reported electrolyte profile changes were Increase in potassium level 10.65% (1539), followed by other (< 1% for each changes) reported decrease potassium level, increase sodium level, and decrease sodium level. The most commonly reported changes in renal function were increase in creatinine level 2.39% (345), and other (< 1% for each changes) changes were increase in blood urea nitrogen level.

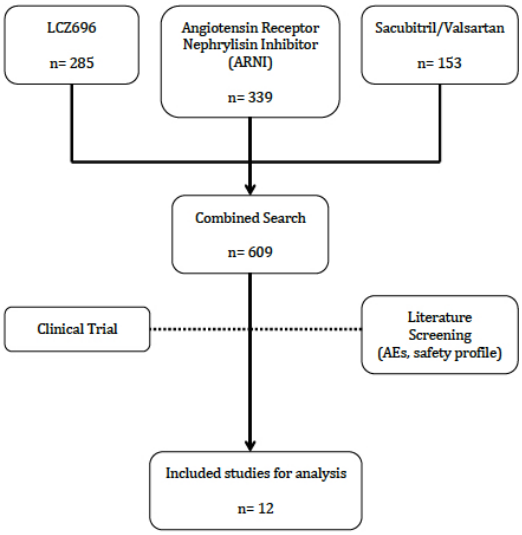

Figure 1. Flow diagram of systematic literature searching

Funding Acknowledgements: AHA 14GRNT20380495

Background: Left ventricular assist devices (LVADs) exert high shear stress on blood components. However, the impact of LVADs on the entire complement of circulating proteins, i.e., the plasma proteome, is unknown.
Purpose: We used discovery-based, quantitative proteomics to evaluate changes in the abundance of plasma proteins following LVAD implantation.
Methods: We enrolled patients undergoing HeartMate II LVAD implantation. Whole blood was collected prior to LVAD implant (baseline), and at days 14, 30, 60, and 90 post-implant. We used Tandem Mass Tag (TMT) labeling of peptides and LC-MS/MS analysis for relative quantification of plasma protein abundance. Data were analyzed using a mixed model to estimate protein level differences.
Results: The study included 18 LVAD recipients (14 men; 14 Caucasian; mean age = 57 ± 14 yrs). 280 total proteins were identified. After adjustment for multiple comparisons, 14 plasma proteins changed significantly over time (table). Acute-phase and inflammatory proteins (e.g., C-reactive protein) increased immediately following LVAD implant and then subsequently decreased relative to baseline. Conversely, proteins regulating proteolysis (e.g., gelsolin) and complement activation (e.g., Ig gamma-4 chain C region) decreased after implant and then increased over time. Time-dependent changes in other proteins are shown in the table.
Conclusion: Proteomic analysis yields insight into the changes in underlying biological processes following LVAD implantation. Additional studies evaluating associations between the identified plasma proteins and LVAD-related clinical outcomes are warranted.

Failure to achieve guideline directed beta blockade early post hospitalization

C Carsten Jungbauer[1]; LS Maier[1]; K Emoto[2]; MJ Mirro[3]
[1]University Hospital Regensburg, Cardiology, Regensburg, Germany; *[2]Zoll Medical Corporation, Pittsburgh, United States of America*; *[3] Parkview Health System, Fort Wayne, United States of America*

Funding Acknowledgements: ZOLL Medical

Introduction: Guidelines for the treatment of heart failure (HF) recommend the titration of beta-blockers (BB) to a target dosage shown to be effective in clinical trials. The benefit of beta-blockers is associated with heart rate (HR) control, with a target resting HR < 70 bpm.
Purpose: To assess the ability to achieve guideline-directed BB usage in the early post hospitalization period in patients (pts) indicated for wearable cardioverter defibrillator (WCD) use.
Methods: The WCD platform allows continuous recoding of HR. To assess the adequacy of BB, HR's were evaluated at rest (nighttime: midnight-7am; daytime: 7am-midnight), during normal daily activities, and during a 6 minute walk test (6MWT). HR's during normal daily activity (ADL) were collected from WCD pts that wore the WCD for = 5 weeks (n = 1449) between 2015 and 2017. Activity of daily living episodes were defined as a contiguous period (= 60 secs) where the device accelerometer records a = 60 milligravity (mG) mean amplitude deviation, and median peak HR/week was calculated. Peak HRs at the end of a six minute walk test (6MWT) are reported as median HR per patient (n = 115 pts).
Results: First, 684,922 activity episodes from 1449 pts were analyzed. Resting HRs averaged 69 bpm and increased to 94 bpm during ADL at the last week of WCD use. 43% of pts had an average daytime resting HR = 70 bpm at the last week of WCD use. During ADL, in 14% of pts HR exceeded = 110 bpm, and 6% exceeded = 120 bpm. HR during the 6MWTs averaged 90 bpm (range: 45-151), and exceeded 110 bpm in 9% of pts. When comparing individual peak HR during the first week of WCD use to the last week, there was no difference. Graph below demonstrates HR after median of 73 and 90 days of use for the two groups.
Conclusion: In the early post hospital discharge period 43% of pts do not meet target HR control, indicating they are not effectively managed with BB. Remote HR monitoring during WCD use may help physicians to adequately titrate beta blockade thus improve clinical outcomes.

Chronic Heart Failure - Clinical

Effect of heart failure reversal treatment as add-on therapy in patients with chronic heart failure:A randomized, open-label study

RM Sane[1]; R Mandole[2]; A Aklujkar[3]; A Patil[4]
[1]Madhavbaug Multidisciplinary Cardiac Care Clinics and Hospitals, Mumbai, India; *[2]Vaidya Sane Ayurved Labs Pvt Ltd, Thane, India*; *[3]Bhaktivedanta Hospital, Thane, India*; *[4]Shri Sai Baba Heart Institute, Nasik, India*

Funding Acknowledgements: Vaidya Sane Ayurved Labs Pvt Ltd

Objectives: The present study was designed to evaluate effect of heart failure reversal therapy (HFRT) using herbal procedure (panchakarma) and allied therapies, as add-on to standard treatment (SCT) in chronic heart failure (CHF) patients.

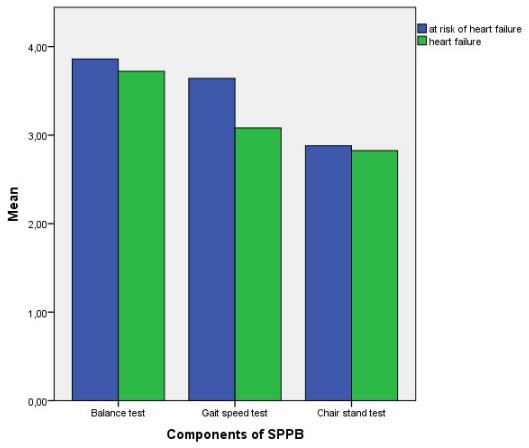
Methods: This open-label, randomized study conducted in CHF patients (aged: 25-65 years, ejection fraction: 30%-65%), had 3-phases: 1-week screening, 6-week treatment (randomized [1:1] to HFRT+SCT or SCT-alone) and follow-up (12-week). Twice weekly HFRT (60-75 minutes) consisting of snehana (external oleation), swedana (passive heat therapy),hrudaydhara (concoction dripping treatment) and basti (enema) was administered. Primary endpoints included evaluation of change in metabolic equivalents of task (MET) and peak oxygen uptake (VO2peak) from baseline, at end of 6-week treatment and follow-up at week-18 (non-parametric rank ANCOVA analysis). Safety and quality of life (QoL) was assessed.
Results: Seventy CHF patients (n = 35, each treatment-arm; mean [SD] age: 53.0 [8.6], 80% men) were enrolled in the study. All patients completed treatment phase. Add-on HFRT caused a significant increase in METs (least square mean difference [LSMD], 6-week: 1.536, p = 0.0002; 18-week: -1.254, p = 0.0089) and VO2peak (LSMD, 6-week: -5.52, p= 0.0002; 18-week: -4.517, p = 0.0089) as compared with SCT-alone. Results were suggestive of improved functional capacity in patients with HFRT (QoL; Mean [SD] HFRT+SCT vs. SCT-alone; 6-week: -0.44 [0.34] vs. -0.06 [0.25], p < 0.0001 and 18-week: -0.53 [0.35] vs. -0.29 [0.26], p = 0.0013). Seven treatment-emergent adverse events (mild severity) were reported in HFRT-arm.
Conclusion: Findings of this study highlight therapeutic efficacy of add-on HFRT vs. SCT-alone in CHF patients. The non-invasive HFRT showed no safety concerns.

P2196

The short physical performance battery and nutritional status assessment in patients with heart failure

E Eva Dora[1]; J Farkas-Lainscak[2]; D Omersa[3]; M Lainscak[2]
[1]Faculty of Medicine, University of Maribor, Maribor, Slovenia; *[2]General Hospital Murska Sobota, Murska Sobota, Slovenia*; *[3]General Hospital Jesenice, Jesenice, Slovenia*

Introduction: Sarcopenia is characterised by progressive and generalised loss of skeletal muscle mass and is an independent risk factor for mortality in patients with cardiovascular disease. The Short Physical Performance Battery (SPPB) is a simple and objective tool to assess sarcopenia with a cut-off at score = 8 that is indicating the presence of sarcopenia. Limited data is available about SPPB performance in populations at risk and with heart failure (HF).



Objectives: To investigate the prevalence of sarcopenia using SPPB and to compare individual SPPB components in patients with HF and those at risk of HF.
Methods: A cross sectional study assessing the prevalence of HF in general population aged 55 years or more has been conducted in city of Murska Sobota. Overall, 702 persons were screened with NT-proBNP and 290 had concentration = 125 pg/mL; they underwent detailed diagnostic visit with echocardiography, history and physical examination and electrocardiogram. HF diagnosis was based on 2016 European Society of Cardiology guidelines. SPPB, body mass index (BMI), handgrip strength and nutritional status (with Mini Nutritional Assessment (MNA) questionnaire with a cut-off at 23.5 points indicating risk of malnutrition) were used in all participants.
Results: We analysed 290 participants (71 ± 8 years, 35% male, BMI 28.6 ± 5.1 kg/m2); 86 were diagnosed with HF and 204 were at risk of HF. Higher proportion of patients with HF had SPPB score = 8 (26.7% vs 13.9%, p < 0.001), handgrip strength below 30 or 20 kg for men and women, respectively (53.9% vs 25%, p < 0,001), and MNA score < 23.5 (16.3 vs 4.0% p < 0.001). Patients with HF had lower SPPB score (9.63 ± 2.02 vs 10.32 ± 1.62, p = 0.002), handgrip strength (27.0 ± 8.9 vs 23.7 ± 10.5 kg, p = 0.006) and MNA score (25.8 ± 2.43 vs 27.11 ± 1,93, p < 0.001). In individual SPPB components (figure), patients with HF had lower gait speed (0.8 ± 0.2 vs 1.0 ± 0.2 m/s, p < 0.001) but comparable balance test and chair stand test score (p>0.1 for both) than persons at risk of HF. Gait speed test (r=-0.220, p < 0.001) but not SPPB score (r=-0.097, p = 0.082) or MNA score (r = 0.049, p = 0.396) was significantly correlated with NT-proBNP.
Conclusions: Prevalence of sarcopenia and risk of malnutrition is higher in patients with HF than in those at risk of HF. Gait speed test differs most between persons with HF and those at risk of HF.

P2197

Iron deficiency predicts skeletal muscle-derived hemojuvelin in men with heart failure with reduced ejection fraction

M Tkaczyszyn[1]; M Drozd[1]; K Wegrzynowska-Teodorczyk[2]; I Flinta[3]; M Kasztura[1]; M Dziegala[1]; K Kobak[1]; W Banasiak[4]; P Ponikowski[5]; EA Jankowska[1]
[1]Wroclaw Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wroclaw, Poland; *[2]University School of Physical Education of Wroclaw, Department of Physiotherapy, Wroclaw, Poland*; *[3]Wroclaw Medical University, Department of Physiology, Wroclaw, Poland*; *[4]Military Hospital, Cardiology Department, Centre for Heart Diseases, Wroclaw, Poland*; *[5]Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland*

Funding Acknowledgements: Financially supported by the National Science Centre (Poland) grant no 2012/05/E/NZ5/00590

Introduction: In patients with heart failure iron deficiency (ID) can negatively impact muscle performance. Protein hemojuvelin (HJV; produced mainly in the liver) regulates the expression of hepatic hepcidin (key modulator of iron metabolism). Interestingly, HJV is also noticeably expressed in cardiac and skeletal muscle, where its role for health and disease remains largely unknown.
Purpose: We investigated whether ID predicts muscle-derived HJV in men with heart failure with reduced ejection fraction (HFrEF).
Methods: Study population comprised of 50 men with stable HFrEF (left ventricular ejection fraction [LVEF]: 30 ± 7%; age: 64 ± 11 years; NYHA class I or II: 84%; ischaemic aetiology: 82%). Patients were asked to rhythmically handgrip the electronic dynamometer for 300 seconds at 50% of predetermined maximal voluntary contraction (150 squeezes). Before the exercise we catheterized (in a retrograde fashion) superficial vein in the antecubital fossa (which is connected to deep veins draining forearm muscles) to collect blood and measure HJV (ELISA) - before and immediately after exercise (muscle-derived HJV). HJV was also measured in standard peripheral blood. All other laboratory parameters were measured normally in peripheral blood. Iron deficiency (ID) was defined as serum ferritin < 100 μg/L or ferritin 100-299 μg/L with transferrin saturation (TSAT) < 20%.
Results: Concentration of HJV in peripheral venous blood (3.17 ± 0.39 ng/mL) was lower than muscle-derived HJV either before (3.62 ± 0.47 ng/mL) or after (3.55 ± 0.39 ng/mL) handgrip exercise (both p < 0.001), whereas muscle-derived HJV before and after exercise were similar (p = 0.4). In univariable linear regression analyses circulating (peripheral) HJV was not related to HFrEF symptoms, LVEF, laboratory parameters, iron status, and comorbidities (all p>0.05). Muscle-derived HJV before exercise was related to haemoglobin (Hb, ß = 0.34, p = 0.01) and estimated glomelural filtration rate (ß = 0.31, p = 0.03), and there was a trend (all p < 0.1) towards higher HJV in patients with serum ferritin = 100 vs. < 100 μg/L. Muscle-derived HJV after handgrip session was associated with serum ferritin (ß = 0.53, p < 0.001), hepcidin (ß = 0.34, p = 0.02), TSAT (ß = 0.35, p = 0.01), and the presence of ID (ß=-0.45, p = 0.001), and there was a trend (all p < 0.1) towards higher concentration of HJV in patients with higher Hb, lower tumor necrosis factor alpha, and in non-diabetics vs. diabetics. Interestingly, the more fatiguing was the exercise for the patient, the higher concentration of muscle-derived HJV after exercise was measured.
Conclusion: After fatiguing handgrip session men with HFrEF and ID have lower concentration of HJV in venous blood originating from exercising forearm muscles as compared with patients without ID. The interplay between muscle HJV and systemic iron status in HFrEF (in the context of symptomatology, muscle performance, and exercise capacity) needs further mechanistic studies.

P2198

The effect of treatment optimization on the prevalence of sleep disordered breathing and on its phenotype among patients hospitalized with acute decompensated heart failure

B Muk[1]; A Terray-Horvath[2]; P Bogyi[1]; D Vagany[1]; ZS Majoros[1]; B Szabo[3]; A Sztaniszlav[3]; D Pilecky[4]; M Szabo[1]; M Dekany[1]; Z Szakacs[2]; RG Kiss[1]; N Nyolczas[1]
[1]Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary; *[2]Medical Centre, Hungarian Defence Forces, Neurology, Budapest, Hungary*; *[3]Orebro University Hospital, Cardiology Clinic, Orebro, Sweden*; *[4]Klinikum Passau, Internal Medicine and Cardiology, Passau, Germany*

Background: Sleep disordered breathing (SDB) is known as an underdiagnosed comorbidity associated with poor outcome in patients with heart failure. The recently published SERVE–HF study pointed out that adaptive servo-ventilation therapy, targeting central sleep apnea in HFrEF, might aggravate cardiovascular mortality in patients with stable HFrEF. Therefore, it is important to assess the existence of SDB in HF patients and determine its phenotype.
Aim: The aim of this study was to investigate the prevalence of SDB, the ratio of central and obstructive sleep apnea among patients hospitalized with acute decompensated heart failure (ADHF) during hospitalization and after treatment optimization (TO).
Methods: 122 consecutive HFrEF patients hospitalized due to ADHF (age:61.9 ± 17.0years, LVEF:28.7 ± 10.3%, NYHA:3.0 ± 0.6, ischemic etiology:39.3%, hypertension:56.5%, atrial fibrillation:26.2%, BMI:29.3 ± 6.5kg/m2, NTproBNP:8535 ± 3380pg/ml) were assessed for SDB with polysomnography (PSG) during hospital stay. Patients diagnosed with SDB underwent repeated PSG after TO of HFrEF in outpatient setting.
Results: During hospitalization 103 (84.4%) patients were found to have SDB with apnea-hypopnea
index (AHI) = 5/h and 60 patients (49.2% of the whole cohort) had SDB with AHI = 15/h. Forty (38.8%) of the patients diagnosed with SDB showed central–dominant pattern. No significant difference in the clinical, laboratory, or echocardiographic parameters was found between the SDB patients with different PSG patterns. LVEF (31.4 ± 10.0%) increased as well as NTproBNP (4736 ± 501pg/ml), AHI and central apnea index decreased significantly (29.0 ± 13.2/h vs. 21.7 ± 5.6/h, 14.6 ± 8.1/h vs. 3.6 ± 2.0/h, respectively) after TO (beta-blockers: 91.7%, ACEi/ARBs: 87.7%, MRAs: 73.7%) during the follow-up period. The number of patients with AHI = 15/h decreased from 60 to 48 (39.3% of the whole cohort) after TO, the ratio of central–dominant pattern was reduced to 19.4% (20 patients).
Conclusions: Compared to the results of the recently published heart failure registries, among our patients hospitalized with decompensated heart failure, SDB is highly prevalent comorbidity. In the effect of TO the ratio of patients having moderate or severe SDB decreases. A clear conversion from central to obstructive pattern in sleep apnea evaluated by PSG can be observed. Re-evaluation of SDB after TO, may help to identify those patients with HFrEF who can have benefit from positive airway pressure therapy.

P2199

Determinants of poor outcomes in patients with heart failure and iron deficiency

A Rakisheva[1]; S Berkinbayev[1]; A Klimenko[2]; A Mussagaliyeva[1]; G Junnusbekova[1]
[1]*Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*; [2]*RUDN University, Moscow, Russian Federation*

Background: Iron deficiency (ID) is very important and common comorbidity in patients with heart failure (HF). The presence of ID is associated with poor prognosis in HF patients. The aim of the study was to assess the determinants of long-term outcomes (6 months mortality rate and 6 months rate for HF rehospitalization) in HF patients with ID.
Methods: 40 patients with HF and ID (31 male, 59 ± 7 years (M ± SD), arterial hypertension (AH) 100%, ischemic heart disease (IHD) 75%, atrial fibrillation (AF) 38%, diabetes mellitus (DM) 30%, known CKD 38%, ejection fraction (EF) 37 ± 9.1) were included. ID was defined using 2016 ESC HF Guidelines (1) serum ferritin < 100 mg/L (absolute ID), 2) serum ferritin 100-299 mg/L and TSAT < 20% (functional ID)). Patients were divided into two groups depending on the presence/absence of ID treatment with i.v. iron (1000 mg once) in addition to standard HF therapy. The outcomes were assessed in 6 months. Mann-Whitney and multiple logistic regression analysis were performed. P < 0.05 was considered statistically significant.
Results: All 40 patients with HF had absolute ID (mean ferritin level 52.7 ± 46.7 mg/L). There were no differences in main patient's characteristics between groups (age 60 ± 6 vs 59 ± 8 years, p>0.05; smoke 25 vs 20%, p>0.05; IHD 85 vs 65%, p>0.05; AH 80 vs 70%, p>0.05; DM 40 vs 20% p>0.05), as well as in clinical presentation of HF symptoms and signs (dyspnoea 60 vs 70%, p>0.05; oedema 25 vs 40%, p>0.05; 6 min walking test 349 ± 110 vs 312 ± 90 m, p>0.05; NYHA II 70 vs 60%, p>0.05; NYHA III-IV 30 vs 40%, p>0.05; EF 39 ± 10 vs 36 ± 9 %, p>0.05, NT proBNP 1433 ± 525 vs 1708 ± 775, p>0.05) and ID criteria (ferritin 56 ± 66 vs 49 ± 27 mg/L, p>0.05 and TSAT 17 ± 10 vs 18 ± 11 %, p>0.05). There was lower rate of poor outcomes in group with i.v. iron (5 vs 26%, p < 0.05). The patients without i.v. iron therapy had higher 6 months mortality rate (5 vs 0%, p < 0.05) and higher 6 month rate for HF rehospitalizations (21 vs 5%, p < 0.05). DM (OR 2.6 95%CI 0.64-10.97), CKD (OR 1.33 95%CI 0.58-1.97) and absence of i.v. iron therapy (OR 2.3 95%CI 1.01-2.94) were determined to be significant and independent factors for poor outcomes in patients with HF and ID.
Conclusions: Diabetes mellitus, chronic kidney disease and absence of ID therapy are among main determinants of long-term outcomes in patients with HF and ID. The use of predictive factors might be useful for the clinician to suspect the patient population with higher risk of poor outcomes and to apply adequate preventive strategy.

P2200

Prevalence of depressive symptoms in patients hospitalized with heart failure in a Greek tertiary hospital amidst the financial crisis

G Michas[1]; K Grigoriou[1]; T Thomopoulos[1]; E Malaxianaki[1]; K Panourgia[1]; A Trikas[1]
[1]*Elpis General Hospital, Cardiology, Athens, Greece*

Funding Acknowledgements: Hellenic Cardiological Society

Background/Introduction: Heart failure (HF) is a global pandemic affecting more than 26 million patients worldwide and its overall burden is expected to increase over time. Depression remains a major public health problem and by 2020 it will be the second leading cause of world disability. In Greece, since the beginning of the financial crisis there has been a steep increase in one-month prevalence of major depression (MDD) in the general population from 6.8% in 2009 to 12.3% in 2013. The average prevalence of MDD in HF patients is estimated at 33.6% when questionnaires are used.
Purpose: The purpose of the study was to estimate the prevalence of depression in HF patients using the Patient Health Questionnaire-9 (PHQ-9), which is proposed by the American Heart Association as a screening tool of depression in HF, and to explore potential associations of depressive symptoms with socio-demographic and clinical characteristics of HF patients.
Methods: The study sample consisted of 104 HF patients who were hospitalized in the Cardiology Department of a tertiary hospital in Athens, Greece within a period of ten months. Inclusion criteria were diagnosis of HF, age = 18 years, and sufficient understanding of the Greek language. Patients were excluded if they were diagnosed with another life-threatening disease (e.g. cancer) or a chronic severe psychiatric condition (e.g. psychosis), had a history of alcohol abuse or dependence in the past six months, and were receiving antidepressant medication. Data collection was performed using a questionnaire consisting of three parts: The socio-demographic and clinical characteristics, the results of laboratory and diagnostic work-up, and the PHQ-9 scale.
Results: Of the 104 HF patients, 66 (63.5%) were males and 38 (36.5%) females with an average age of 71.4 ± 13.6 years. Proportion of patients with NYHA classes I, II, III, and IV were 7.8%, 45.1%, 40.2%, and 6.9%, respectively. When the ejection fraction (EF) was considered, the proportion of patients with reduced, preserved, and mid-range EF were 56.7%, 26%, and 17.3%, respectively. A staggering 75% reported depressive symptoms (PHQ-9 score = 5), whereas the prevalence of MDD was 47.1% (PHQ-9 score = 10). Among the factors examined, worse self-reported heath status (p = 0.001), NYHA class (p = 0.014), and lower folate levels (p = 0.03) were associated with the presence of MDD.
Conclusion(s): The medical community must take measures to identify, evaluate and manage depression in HF patients, the prevalence of which is particularly high in this population. Furthermore, HF patients with certain characteristics seem to be more prone to MDD. A recent study conducted in Greece showed that 24.2% of HF patients suffered from MDD; our study findings suggest that this prevalence has almost doubled within the last four years. The financial crisis might have exerted a negative effect on the prevalence of depression amongst HF patients.

P2201

The association of iron deficiency in patients with different types of heart failure

O Ozcan Orscelik[1]; EE Sahin[1]; H Uyar[1]; IT Ozcan[1]; A Celik[1]
[1]*Mersin University, Cardiology, Mersin, Turkey*

Introduction: Iron deficiency (ID) is common in patients with chronic heart failure and it is associated with poor functional status and quality of life. Although there are many studies showing that the incidence of ID is high in heart failure patients with reduced-preserved ejection fraction, insufficient studies are in the literature related to ID linked other types of heart failure. This study aimed to show the iron deficiency in patients with different types of heart failure.
Methods: This is a single center observational study included the consecutive 138 patients with HF. Iron deficiency was defined as follows: serum ferritin <100 mg/L, or transferrin saturation <20% in case of serum ferritin level is 100-299 mg/L. We divided the patients into three groups as according to HF types (HFrEF, HFmrEF and HFpEF).
Results: 78 of 138 patients had HFrEF, 28 patients had HFmrEF and 32 patients had HFpEF. There was no significant difference in age, gender, hemoglobin, MCV, Na, K, Cre, AST levels, pro-BNP and diastolic blood pressure between groups of heart failure. ID was seen in 68% patients in HFrEF group, 82.1% patients in HFmrEF groups and 68.8% patients in HFpEF group and there was no statistical significant difference between the three groups (Table 1, Figure 1A). When all heart failure patients were examined for ID, it was seen that ID was not affected by sex, diabetes

and hypertension. However, higher iron deficiency ratios were seen in patients with ischemic HF than non-ischemic heart failure. (Figure 1B).
Conclusion: Iron deficiency is a common comorbidity in all types of heart failure. The patients with ischemic HF might be more related to iron deficiency.

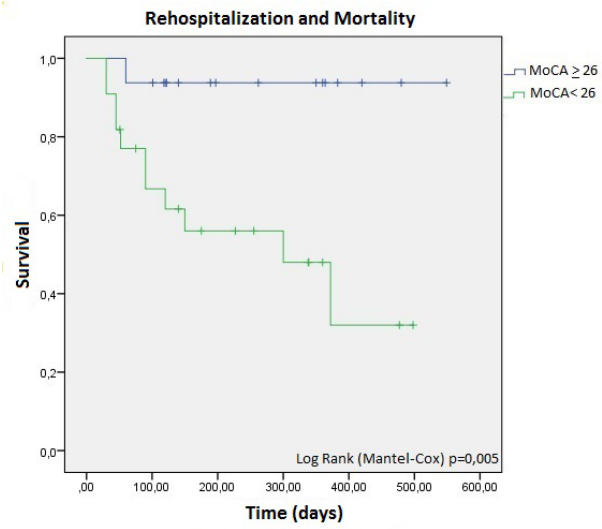
On behalf of: RICA-HFTeam

Introduction: Cognitive impairment (CI) is common in patients with heart failure (HF), and may be associated with deterioration of quality of life and a negative prognosis.
Aim: To evaluate the prevalence of CI in a population of patients with HF and to identify the most affected cognitive domains and their prognostic impact.
Methods: Single center prospective study of patients admitted for acute or chronic decompensate HF (index-admission), who gave written informed consent to be included in a post-discharge HF-program (by protocol).
Cognitive function was assessed at hospital discharge and at 12+3 months during follow-up, using the validated Portuguese version of the Montreal Cognitive Assessment (MoCA), which defines CI by a score < 26. Correlations between CI and HF therapy prior to admission, blood tests results, chronic anxiety/ depression (Hospital Anxiety and Depression Scale, validated Portuguese version), and rehospitalization and/or mortality during follow-up, were looked for. Statistics: Cox regression, Kaplan-Meier survival analysis, Spearman, Mann-Whitney and Wilcoxon correlation analysis, were used.
Results: 43 patients included, mean age 67+11.3 years, 68.9% men; 48.9% had CI, focused mainly on the following cognitive domains: visuospatial, language and delayed recall. Men appeared to perform better at MoCA (p = 0,026), as well as patients on ACE inhibitors/ARB therapy prior to index-hospitalization (p = 0,009).
CI was associated with HbA1c (p = 0,021, r= 0,395), albumin (p = 0,07, r= -0,76) and bilirubin (p = 0,04, r= -0,48). Anxiety and depression were not associated with CI.
Patients with a better MoCA performance showed greater ability to deal with their disease status (assessed by the Kansas City Cardiomyopathy Questionnaire) (p = 0,38).
During follow-up there was no significant difference in the CI score, but a decline in the naming ability was observed (p = 0,031). The rates for rehospitalization and mortality were 31% and 2.3%, respectively. The presence of CI predicted the occurrence of rehospitalization/mortality (p = 0,026).
Conclusion: CI was frequent in HF patients, may be related in part to the nutritional profile, and was associated with a reduced capacity to deal with their HF condition, being a predictor of rehospitalization and/or mortality in this population.



P2203
Importance of an intradialysis changes of cardiac troponin-t measured by sensitive assay in anuric hemodialysis patients

S K R Vamsi Varahabhatla[1]; INGRID Prkacin[2]; A Savuk[2]; TOMO Svagusa[3]; PETER Fekete[4]; PAVAO Findri[4]
[1]Zaporizhzhya State Medical University, General medicine , Zaporizhzhya, Ukraine; *[2]Clinical hospital Merkur , Internal medicine , Zagreb, Croatia*; *[3]University Hospital Dubrava, Internal medicine , Zagreb, Croatia*; *[4]University of Zagreb School of Medicine, Internal medicine , Zagreb, Croatia*

Background: Compared with the general population cardiac morbidity and mortality is much higher in hemodialysis patients (HD pt). Improved survival after acute myocardial infarction(AMI) with structural cardial abnormalities have led to an increased incidence of heart failure (HF): 1-3% in general population, 10% of elderly and approximately 40% of HD pt. In 25-87% HD pt regional left ventricular dysfunction developed early during HD and is associated with worse outcome and progressive HF. Levels of cardiac troponins in plasma are often elevated in hemodialysis (HD) patients without evidence of AMI. We hypothesized that

systemic inflammation could be explanation of elevated troponins in HDpt because of negative effects on endothelial function of the myocardial microcirculation.
Aim: We investigated the effect of hemodialysis (HD) on elimination of cardiac troponin T (TnT-hs) in anuric patients.
Patients and Methods A total of 45 adult (= 18 years) anuric patients without cardiac symptoms of 2 Dialysis Center in Croatia were on maintenance HD for more than 3 months and gave informed consent were eligible for this prospective study.
The median age was 66 (IQR 56.5-75.5) years and 17 (35%) of patients were female. Patients were on bicarbonate dialysis for a median of 2.5 years. 91% patients had hypertension.Patients with recent acute myocardial infarction or with heart failure NYHA class 3-4 were excluded. The concentration of high sensitive troponin T (hsTnT) was determined by the immunochemical method with electrochemiluminiscent detection on a Roche cobas® e411 analyzer using Roche Diagnostics Troponin T high sensitive (TnT-hs) assay. Blood samples for TnT-hs and hematocrit were collected before (preHD) and at the end (postHD) of the first dialysis session of the week. Samples were centrifuged within 30 min of collection at 3,500 rpm for 10 min. Plasma levels of cTnT were corrected for hemo-concentration.
Mann-Whitney U test and Student T test analyses were used for the comparison of parametric and non-parametric variables to identify factors that were associated with intradialysis changes in concentration of TnT-hs.
Results: Cardiac TnT-hs was elevated in all patients before HD (100 %). The difference between median concentration of TnT-hs pre (82.99 ± 47.44 ng/L) and postHD (82.39 ± 44.91 ng/L) was not statistically significant (Z -0.38228, p = 0.70394). The difference between the mean value of the total measured TnT-hs concentration pre and postHD was 113.275ng (CI 84.34-142.21ng. Difference in total quantity of TnT-hs in pre and postHD was statistically significant (t = 7.8906 uz p < 0.001).
Conclusions: The mechanism why cTnT levels are elevated in HDpt is not clear but it may be related to the HD procedure and end stage kidney disease. Future studies should address whether HD-related factors are associated with changes in troponins and possible impact on earlier prevention of silent HF .

P2204
Association of atrial fibrillation and chronic heart failure, FAR NHL registry - FARmacology and NeuroHumoraL activation

R Labrova[1]; J Spinar[1]; J Parenica[1]; L Spinarova[2]; F Malek[3]; O Ludka[1]; K Labr[2]; M Spinarova[2]; J Jarkovsky[4]
[1]Masaryk University, Faculty Hospital Brno, Department of Internal Cardiology Medicine, Brno, Czech Republic; *[2]St. Anne's University Hospital, Brno, Czech Republic*; *[3]Na Homolce Hospital, Prague, Czech Republic*; *[4]Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic*

Background: Atrial fibrillation is a very common accompanying disease of heart failure and affects one another negatively. Each of these diseases can be the cause and consequence of the other. Increasing age in the population and better treatment of cardiovascular disease leads to more and more frequent occurrences in the population in both of these diseases. Patients hospitalized with heart failure have three times more often atrial fibrillation than patients without heart failure. It is not entirely clear whether atrial fibrillation is an independent risk factor for death in patients with heart failure.
Methodology and Results: Three 1050 patients with chronic systolic heart failure with moderate or severe left ventricular dysfunction - with EF less than 50% - were enrolled in three university hospitals within the FARmacology and NeuroHumoraL activation registry (FAR NHL) over 12 months. Patients had to be stable for at least one month for established medication. Men were 848 (80.8%), mean age 63.9 (SD + -12.0), BMI 29.1 (SD + -4.9), average heart rate 73.6 / min (SD + -12.8). The main etiological factor for chronic heart failure was 49.4% ischemic heart disease, 42.3% dilated cardiomyopathy, a small part was a combination of both in 0.8%, hypertrophic cardiomyopathy was 0.5%. Diabetes mellitus was present at 38.3%. 13% patients were in New York Heart Association (NYHA) functional class I, 61.3% NYHA II and 25.7% NYHA III and IV. Based on echocardiography, mean left ventricular ejection fraction was 30.6% (SD + -8.8). Atrial fibrillation was present in the enrollement day and / or in a medical history in one third of patients - 362 (34.5%). In patients with chronic heart failure, when compared atrial fibrillation was not and was present, there was a significant difference in heart rate of 71 vs 80 (p < 0.001), betablocker use did not differ significantly in both groups 94.1 vs 92.2% (p = 0.354). There was difference in digoxin treatment 29.0 versus 61.0% (p < 0.001), as well as a combination of beta-blocker and digoxin 27.0 versus 58.9 (p < 0.001). Compared to group of patients without atrial fibrillation present and present atrial fibrillation, hypertension is present in 64.2 vs 73.8%, CMP 9.5 vs 12.1%, COPD 12.8 vs 17.0%, previous hospitalization for heart failure in last year 24.2 vs. 29.8%. This corresponds to the average levels of NTproBNP 1247 vs 2218 pg / ml. Conclusion: According to FAR NHL, patients with chronic heart failure have up to one third of atrial fibrillation. Patients with atrial fibrillation have more comorbidity, their strict treatment is necessary to prevent myocardial remodeling and thus to maintain arrhythmia. In addition, to reduce the risk of CMP, hospitalization for heart failure and reduce mortality. The results of the FAR NHL and the one-year follow-up will be presented at the Congress of Heart Failure 2018 in Vienna.

P2205
The external respiration function in pulmonary hypertension at patients with dilated cardiomyopathy

YR Akhmatov[1]; TA Abdullaev[1]; I A Igor Tsoy[1]; RSH Bekbulatova[1]
[1]Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

The aim: Comparative evaluation of the function of external respiration in pts with dilated cardiomyopathy (DCM), depending on the presence or absence of pulmonary hypertension (PH).
Material and methods: 91 pts with idiopathic DCM (34/57 as w/m, mean age = 46.4 ± 13.7 years old) were included in the study, of which 25 (27.4%) had right ventricular DCM (RVDCM). The 6-minute walking test (6MWT), ECG, EchoCG and ERF were evaluated. I gr - 48 pts with mean pulmonary artery pressure (MPAP)- 48.1 ± 10.7 mmHg. II gr - f 43 pts with MPAP of 25.7 ± 8.3 mmHg. There were 11 (23%) in 1gr. And 14 (32.5%) in 2 gr. with RVDCM
Results: According to EchoCG, it was found that the systolic pressure in the pulmonary artery was 48.1 ± 10.7 mm Hg in I gr. - 71% of cases had PAH of 1 degree and 29% of pts had PAH of II degree. In the 2d. The mean degree in II gr. was 25.7 ± 8.3 mmHg. According to the results of spirometry in pts of I gr there was a significant decrease in every indicators of ERF. Performing the correlation analysis, an inverse relationship was found between MPAP and the Tiffno index (p <0.05), as well as a direct relationship between FVC (53.17 ± 9.21%) and the length of the distance traveled by 6MWT (206.7 ± 80.3 m, p = 0.017). There were significantly higher results in the 2 gr. There were abnormalities of EFR in pts with DCM, characterized as restrictive, i.e. caused by stagnation of blood in the pulmonary system (decrease in FVC, FEV1, ratio of FEV1/FVC). At the same time, There were no signs of bronchial obstruction (FEV1 / FVC was above 75%) in all cases.
Conclusion: Our study shows a high prevalence of secondary pulmonary hypertension (52.7%) in pts with DCM with biventricular heart failure and primary right ventricular lesion. There is a direct statistically significant correlation between the systolic pressure in the pulmonary artery and the Tiffno index as well as in 6MWT.

P2206
Long-term effect of patiromer for hyperkalaemia treatment in patients with HFmrEF and diabetic nephropathy on RAAS inhibitors

B Pitt[1]; M Mayo[2]; D Garza[2]; S Arthur[2]; M Lainscak[3]
[1]University of Michigan, Ann Arbor, United States of America; *[2]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, United States of America*; *[3]General Hospital Murska Sobota, Murska Sobota, Slovenia*

Funding Acknowledgements: Funded by Relypsa, Inc., a Vifor Pharma Group Company

Background: Heart failure (HF) patients (pts) with mid-range ejection fraction (HFmrEF, 40-49%) are an important subgroup requiring further study. Renin-angiotensin-aldosterone system inhibitors (RAASi) have not been shown to reduce mortality in these pts but are often used to manage coexisting conditions, such as hypertension (HTN), diabetes (DM), and CKD, or to provide symptom relief. Chronic hyperkalaemia (HK) and CKD may complicate use of RAASi. Patiromer, a sodium-free nonabsorbed potassium (K+)-binder that uses calcium as the counter-exchange ion, is approved for the treatment of HK, including in the US, the EU, and Australia.

Table

Mean serum K+ over 52 weeks in the subgroup of HFmrEF patients

Timepoint (n)	Mean serum K+, mmol/L (SE)	LSM Δ from baseline in serum K+, mmol/L (SE)
Baseline (n = 44)*	5.21 (0.06)	
Day 3 (n = 42)	4.91 (0.06)	-0.31 (0.06)
Week 4 (n = 40)	4.51 (0.06)	-0.64 (0.09)
Week 24 (n = 37)	4.60 (0.06)	-0.66 (0.08)
Week 52 (n = 31)	4.66 (0.07)	-0.62 (0.10)

From an ANCOVA model with HK stratum at baseline as a fixed effect and baseline serum K+ as a covariate. LSM, least squares mean. Values in parentheses are standard error. *Two patients were excluded from the analysis as they had no central laboratory serum K+ values at baseline.

Purpose: The long-term effects of patiromer on serum K+ in HFmrEF pts on RAASi were examined in a post-hoc analysis of AMETHYST-DN.
Methods: Pts with CKD, type 2 DM and HK (baseline K+ >5.0– < 6.0 mmol/L) were randomized to patiromer starting doses 8.4-33.6 g/d, divided twice daily. Pts with HTN were eligible if uncontrolled at screening (SBP: >130 to = 180mmHg; DBP >80 to = 110mmHg). Pts remained on RAASi during study treatment. Changes in mean K+ (central lab) from baseline through 52 wks were evaluated in the HFmrEF subgroup.
Results: 46/306 randomized pts had HFmrEF (100% Caucasian, 74% male, 72% = 65 yr; mean [SD] EF = 44 [3] % and eGFR = 42 [14] mL/min/1.73m^2). All had HTN (baseline mean BP 154/84 mmHg). K+ was reduced to < 5.0 mmol/L at the 1st post-baseline visit (day 3) and through 52 wks (Table). Thirty-three (72%) pts reported = 1 adverse event (AE); influenza and worsening of CKD were the 2 most common AEs (5 pts each; none severe). Two pts had K+ < 3.5 mmol/L; 1 pt had serum Mg < 0.49 mmol/L. Mean (SE) change from baseline to 52 wks was: eGFR, +5 (4) mL/min/1.73m^2; SBP/DBP, -21 (4)/-10 (2) mmHg.
Conclusions: These post-hoc results suggest that patiromer allows control of HK in HFmrEF pts on RAASi and require prospective evaluation.

Awareness of heart failure is insufficient in Poland-results from awareness survey

MI Marta Izabela Kaluzna-Oleksy[1]; J Migaj[1]; M Dudek[1]; A Gwizdala[1]; A Pietrucha[2]; P Leszek[3]; EA Jankowska[4]; I Uchmanowicz[4]; S Stoerk[5]; E Straburzynska-Migaj[1]
[1]Poznan University of Medical Sciences, Ist Department of Cardiology , Poznan, Poland; *[2]John Paul II Hospital, Krakow, Poland*; *[3]Institute of Cardiology in Anin, Warsaw, Poland*; *[4]Wroclaw Medical University, Wroclaw, Poland*; *[5]University Hospital of Wurzburg, Wurzburg, Germany*

Introduction: Heart failure (HF) is a clinical condition with a diverse background. The most prevalent cause of HF in Europe is coronary artery disease (CAD). Depending on etiology of HF, its natural history may vary; nevertheless, it is always associated with significant morbidity and mortality. The burden of HF is rising globally, which makes general awareness of HF the more significant. Previous studies show that patients' knowledge of heart failure, its incidence, risk and symptoms, seems poor. This study aimed to analyze the HF awareness in general population in Poland and possibly to show the need for improvement of information sources.
Methods: This study analyzed information from surveys conducted during International Heart Failure Awareness Day in Poland (in 2016 and 2017). The questions concerned demographics, knowledge of HF, its symptoms, natural history, and treatment possibilities. Points were awarded for each question concerning the heart failure awareness (awareness score), and the mean results were compared between various demographic groups as well as between the years 2016 and 2017.
Results: 454 and 273 responders completed the HF awareness survey in 2016 and 2017 respectively. The participants were mostly women (65%), young people <65 years (82%) and non-medical profession (77%). Most of the participants declared awareness of the heart failure symptoms (68%). The awareness score showed no differences between both sexes and a better HF awareness in older (= 65 years) and in more educated people in 2016 (both p <0,001), but this relationship was not observed in 2017 (p = 0,42). The mean awareness score was worse in 2017 compared to 2016 (p <0,001).
Conclusions: The knowledge on HF in Poland is relatively poor. Lack of public awareness of symptoms, prognosis, and management of HF may lead to worse self-care and late reaction to exacerbation of the disease. In spite of numerous campaigns to increase the awareness of HF, it has not improved during the last year. Perhaps a multi-level individualized education depending on age should be provided.

Chronic Heart Failure - Other

Health care assistance in heart failure: the mexican perspectives

EJJ Eduardo Julian Jose Chuquiure[1]; C Silva-Ruz[1]; M Chuquiure-Gil[2]; M Gabriela Mendez[3]; R Hernandez-Isidro[1]; E Morales-Hinojosa[1]; K Jacobo-Garcia[1]; O Fiscal-Lopez[1]
[1]Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico; *[2]Instituto Tecnologico de Estudios Superiores de Monterrey, Escuela de Medicina, Monterrey, Mexico*; *[3]Universidad del estado de México, Medicina, ciudad neza, Mexico*

Purpose: In Latin America, there are few data of Heart Failure (HF). The purpose of the present investigation was to obtain information from prominent cardiologists on the prospects of heart failure care in Mexico.
Material and Method: On July 2017, 43 semi-structured surveys were carried out by cardiologists with more than 10 years of experience from different states of the republic. The survey consists of 18 closed (8) and open (10) questions, in five relevant topics: Objectives, Therapeutics, Follow up (Hospital Re-admission and mortality), Guidelines Adherence and Medical Team (guidelines) and Team conformation for the treatment of HF in Mexico.
Results: In this HF Mexican expert consensus, we conclude: 56% of respondents attend 312 to 520 patients-year per center. Quality of life is the most important objective in HF Treatment (44.2%). Main objectives for prevention in general population are: Massive information campaigns and strengthen preventive medicine. On the other hand, Economic factor is the principal negative aspect, due to the high costs of medicines. 81.4% of specialists consider that their adherence to clinical guidelines is good or excellent, to improve clinical practice and unify criteria. We describe that ACE-I / ARB's plus Beta-blockers are the most commonly used drugs (81.4%). Principal objectives: Decrease mortality and hospitalizations, improve the quality of life, and optimize management. The main strategies to avoid hospital readmissions and mortality are: HF specialized Centers Conformation, at all attention's levels, to monitor and manage clinical follow-up. We recommend that communication with the multidisciplinary team is essential, and the creation of a model of care adapted for our Mexican population.
Conclusions: We recognize an inherent need in Mexico, so we propose to organize health services in a planned manner to prevent, intervene, organize and provide optimal treatment for the adverse effects of heart failure

P2209
Needs and burden of informal heart failure caregivers: the HF2Care study

Background: People affected by HF require a high level of care and must perform good self-care to prevent the worsening of the disease and to maintain their psychological well-being. Given this issue, informal caregivers (CG) may offer an important contribution to patients' care. However, knowledge on caregivers' needs-physical, psychological, social, economic and environmental needs-is still poor. Recent literature shows that being a CG imposes a substantial burden that increases over the trajectory of the illness and affects CG quality of life. Despite the importance of CG in HF care, few studies have explored the needs and burdens of HF CG in relation to the CG and patient characteristics.
Purpose: The aim of this study is to describe HF caregivers' needs and burdens, and to associate HF caregivers need and burden to specific caregivers' (e.g., amount of caregiving hours) and HF patients' characteristics (e.g., NYHA class) in three European countries.
Methods: This is an exploratory sequential mixed-method study that is going to be conducted in two phases. The first phase is qualitative and data have been already collected on Spanish and Italian HF caregivers with face-to-face interviews. The interviews, with 21 open-ended questions, have been conducted in each country in the native language, have been digitally recorded and transcribed verbatim. Content analysis will be used to analyse them. The second phase, that is quantitative and is still ongoing, will consist of two data collections at 6 and 12 months from enrolment. Quantitative data will be analysed with descriptive and inferential statistics. Qualitative and quantitative data will finally be merged to understand the complex nature of HF caregiving, matching caregivers'need and burden with patients and CG characteristics.
Results: Spain has already concluded the first phase of the study, while Italy and Netherlands are still enrolling the caregivers. To date, 92 caregiver and patient dyads have been enrolled in Spain. These caregivers were 59.7 (±14.4) years old, mostly females (77.2%), patients' spouses (31.6%) or adult children (60%). HF patients were 82.2 (±8.3) years old and equally distributed among females (50.5%) and males. The caregivers provided their patients with an average of 11.6 (±9) hour of caregiving per week, and most of them declare to live with the patients (52.2%). The 23.9% of caregivers were unemployed because of caregiving and just the 17.4% of caregivers reported enough income which allowed them to live well. Content analysis on the interviews is in progress, results will be available for the Congress.
Conclusion: Results of this study will allow a better characterization of HF caregiver needs and burden. Since literature shows that caregivers'need and burden influence HF patients' outcomes, we expect the results of this study have the potential knowledge to develop interventions for caregiver well-being and indirectly for patients' outcomes.

Acute Heart Failure - Pathophysiology and Mechanisms

P2210
Relationship between early drop 16% in systolic blood pressure and worsening renal function in patients with acute heart failure

T Takehiko Kido[1]; T Okabe[1]; Y Asukai[1]; S Simazu[1]; T Kimura[1]; J Saito[1]; Y Oyama[1]; W Igawa[1]; M Ono[1]; S Ebara[1]; K Yamasita[1]; M Yamamoto[1]; T Yakusizi[1]; N Isomura[1]; M Ochiai[1]
[1]Showa University Northern Yokohama Hospital, Division of Cardiology and Cardiac Catheterization Laboratories, Yokohama, Japan

Background: Worsening renal function (WRF) is associated with poor prognosis in patients with heart failure (HF). We hypothesized that early drop in systolic blood pressure (SBP) is associated with WRF.
Purpose: Our purpose was to identify the association between early drop in SBP and WRF.
Methods: We retrospectively investigated predictors of WRF in patients hospitalized for acute HF between April 2010 and July 2016. WRF was defined as a relative increase in serum creatinine of at least 25% or an absolute increase in serum creatinine ?0.3 mg/dL from the baseline. SBP was measured on admission and each 4 hours. The early drop was defined as drop in SBP within first 24 hours.
Results: A total of 411 patients with acute HF were enrolled. The mean age was 73.0 ± 15.0 years and 60.7% were male. WRF occurred in 139 patients (34%). Mean SBP on admission was significantly higher in patients with WRF than in patients without WRF. However, mean SBP after 24 hour from admission was significantly lower in patients with WRF than in patients without WRF. The receiver operating characteristic curve analysis identified that the optimal cut-off value for WRF was 16% drop in SBP. Multivariate Cox regression analysis showed that early drop in SBP ?16% (OR, 6.565; 95% CI 3.242-14.221; < 0.001), inotropic agents, and tolvaptan were associated with WRF.
Conclusion: Early drop in SBP ?16% was a strong predictor of WRF in patients with HF.

P2211
Dynamic changes in serum chloride concentrations during worsening of heart failure and its recovery following conventional diuretic therapy

H Hajime Kataoka[1]
[1]Nishida Hospital, Oita, Japan

Background: I recently demonstrated that changes in vascular volumes are independently associated with the changes in serum chloride concentration during worsening of heart failure (HF) and its resolution by diuretic therapy (AHA2015/ESC2016). Few data are available, however, regarding the dynamic changes in the serum chloride concentrations in HF pathophysiology.
Purpose: The aim of the present study was to investigate changes in the serum chloride concentration, including its relation to the serum sodium concentration, under worsening HF and its recovery following conventional diuretic therapy.
Methods: Blood test data, including measurements of serum albumin/solutes and b-type natriuretic peptide, at both worsening and recovery of HF status were obtained from 47 HF patients.
Results: Under clinically stable to worsening HF, the serum sodium concentration increased from 139 ± 4.1mEq/L to 141 ± 5.07mEq/L (P < 0.05) and the serum chloride concentration increased from 101 ± 5.36mEq/L to 104 ± 5.44mEq/L (P < 0.01) among all patients. After resolution of worsening HF by treatment with conventional diuretics, both the serum sodium concentration and serum chloride concentration decreased significantly to 138 ± 5.12mEq/L and 99.5 ± 5.33mEq/L, respectively (P < 0.0001 for each). The absolute changes in the serum chloride concentration from clinically stable HF to worsening HF tended to be greater than those in the serum sodium concentration (2.72 ± 6.02mEq/L vs. 1.70 ± 4.34mEq/L, P = 0.079), and absolute changes in the serum chloride concentration from worsening HF to its recovery following treatment with conventional diuretics were greater than those in the serum sodium concentration (-4.45 ± 5.23mEq/L vs. -2.87 ± 4.38mEq/L, P = 0.0068).
Conclusions: Differential changes exist between serum sodium and chloride concentrations under worsening of HF and its resolution by conventional diuretic therapy. The greater changes in the serum chloride concentration than in the serum sodium concentration under HF state transitions suggests that chloride contributes more to serum tonicity and to HF pathophysiology than sodium.

Acute Heart Failure - Epidemiology, Prognosis, Outcome

P2212
Is there an obstructive sleep apnea paradox in cardiovascular disease? effect of obstructive sleep apnea on outcomes of acute heart failure exacerbations

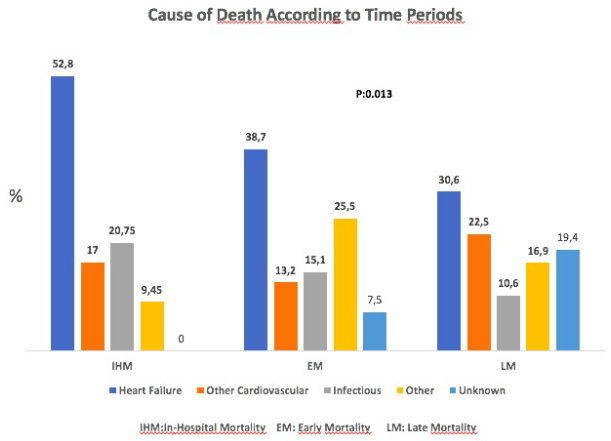
M Mario Rodriguez[1]; W Rzechorzek[1]; C Krittanawong[1]; X Wei[1]; A Manguba[1]; B Sabharwal[1]; C Godoy Rivas[2]; J Puma[3]; E Herzog[1]
[1]Icahn School Of Medicine at Mount Sinai/ Mount Sinai St. Lukes-West Hospital, Department of Medicine, Division of Cardiology , New York, United States of America; *[2]Cleveland Clinic Foundation, Cleveland, United States of America*; *[3]Columbia University Medical Center, New York, United States of America*

Background: Obstructive Sleep Apnea (OSA) is known to increase morbidity and mortality in patients with chronic heart failure, but impact on outcomes during acute heart failure exacerbations is unknown.
Purpose: describe the impact that obstructive sleep apnea has on the outcomes of acute heart failure exacerbations and evaluate the possibility of an OSA paradox in cardiovascular disease.
Methods: A retrospective analysis using the 2014 United States Nationwide Inpatient Sample was performed. Patients above 18 years with primary diagnosis of acute heart failure (AHF), systolic heart failure (SHF) and diastolic heart failure (DHF) and secondary diagnosis of OSA were included. End stage renal disease patients were excluded. Primary outcome was in-hospital mortality. Secondary outcomes included length of stay, cost of stay, shock, utilization of mechanical ventilation, acute kidney injury requiring dialysis (AKID), use of non-invasive ventilation (NIV), cardiac arrest, and short term mechanical circulatory support. Diagnoses were identified using ICD-9- CM codes .Multivariate logistic regression analysis adjusting for obesity, age, race, gender and hospital location was done using STATA 15.
Results: 135,008 patients with AHF were identified. In the overall AHF cohort 101,070 patients had a
history of OSA, corresponding to 43% of patients with SHF and 57% of patients with DHF. 41% of OSA
with AHF patients were female. Mean age was 66 years. Multivariate regression analysis showed decreased odds of death in the AHF(OR 0.68 p < 0.001), SHF (OR 0.65 p < 0.001) and DHF (OR 0.67 p = 0.001) groups, along with decreased odds of mechanical ventilation utilization in the AHF(OR 0.85 p = 0.01) cohort. There was also a trend towards decreased cardiac arrest in the AHF (OR 0.73 p = 0.005) and SHF (OR 0.64 p = 0.01) groups , as well as decreased odds of AKID (OR 0.75 p = 0.02) and short term mechanical circulatory support (OR 0.70 p = 0.02) in the AHF group. NIV utilization odds was increased among the AHF (OR 2.44 p < 0.001) , SHF (OR 2.5 p < 0.001) and DHF (OR 2.2 p < 0.001) groups. There was a non statiscally significant increased in length of stay along with decreased total charge.
Conclusions: Patients with diagnosis of obstructive sleep apnea had decreased mortality and increased
non invasive ventilation utilization during acute heart failure exacerbation. It is unclear if this represents a true paradox after adjusting for obesity or if it represents the effect of non invasive ventilation utilization. Further studies adressing this issue are needed.

P2213
Heart failure mortality: a multi-causative event

E Enrique Fairman[1]; F Delfino[1]; V Mauro[1]; A Charask[1]; Y Castillo Costa[1]; A Raffaeli[1]; F Bottini[1]; A Barsotti[1]; C Barrero[1]
[1]Clinica Bazterrica Clinica Santa Isabel, buenos aires, Argentina

Acute decompensated heart failure is frequently observed in advanced age and portends an ominous evolution, particularly in the first year after the acute event. Nevertheless, in many cases mortality is not attributed to heart failure. The objective of this analysis is to determine the different causes of mortality and their relative prevalence throughout the first year of evolution in patients admitted with acute decompensated heart failure.
Methods: Between February 2010 and December 2016, 865 consecutive patients admitted with heart failure at 2 coronary care units entered this analysis. Vital status within one year, cause of death and time interval where events occurred were recorded. Cause of death comprised: heart failure (HF), other cardiovascular (namely infarction, sudden death, stroke), infectious, miscellaneous and unknown causes. Mortality was analyzed according to time intervals after admission as follows: in hospital (IH), early post discharge (E) (< 90 days after discharge) and late (L) (between 3 months and one year after discharge). Follow-up was performed by a visit or a phone contact at 90 days and at 1 year after admission.



Cause of Death According to Time Periods

Results: Out of 865p, 71(8.2%) were lost to follow- up (with similar baseline characteristics to those who completed follow-up). Finally, 794 p were analyzed with a median age of 81 years (IQR 72-87), 47.1% females, 49.7% with preserved ejection fraction, 25.8% diabetic, 79% hypertensive, 32.9% with atrial fibrillation, 23.4% with chronic renal disease. Annual mortality was 40.15%; 37% of the deaths corresponded to heart failure. Hospital mortality was 6.12% (52.8% of the deaths were due to heart failure), E mortality was 13.64% (38.7% due to heart failure) and L mortality was 25.2% (30.6% due to heart failure). Heart failure was the main cause of death but its relative impact decreased throughout the year ($p < 0.0135$).
Conclusion: In patients with acute decompensated heart failure one year mortality after admission remains high. Although heart failure is the main cause of death, its relative importance decreases throughout the year. Advanced age and comorbidities turn acute decompensated heart failure patients into a vulnerable population where heart failure progression acts not only as a cause of mortality but also as a facilitator of death due to non- cardiac causes. Thus, a comprehensive approach for the management of these patients is mandatory.

P2214

Clinical characteristics and post-discharge outcomes according to diabetes status in patients hospitalized with acute decompensation for systolic heart failure

ISLAM Alsoudi[1]; SVEN Piepenburg[1]; OLIVER Vollrath[1]; STEFAN Stoerk[1]; GEORG Ertl[1]; C E Angermann[1]
[1]Comprehensive Heart Failure Center, Dept. of Medicine I, University Hospital and University of Würzburg, würzburg, Germany

Introduction: & Aim: Diabetes mellitus (DM) is associated with higher rates of incident heart failure (HF), higher prevalence in symptomatic HF, and adverse outcomes. Better understanding of the interrelations of DM and HF is important since some antidiabetic drugs show beneficial, others harmful effects on cardiovascular (CV) and renal outcomes, with respective mechanisms of action remaining largely unclear. To better clarify the pathophysiology driving HF progression and prognosis in patients with DM we compared clinical characteristics and outcomes at 180 days in consecutive patients hospitalized for decompensated HF according to diabetes status.
Methods: & **Results:** All 1022 participants of the Interdisciplinary Network Heart Failure (INH) program (67.9 ± 12.5 years, 28.2% female, left ventricular ejection fraction before discharge = 40%) were included in this post-hoc analysis. Patients were diagnosed with DM when having a history of DM, being on antidiabetic drugs or having HbA1c-values = 6.5%. Univariable Cox regression analysis was used to estimate hazard ratios (HR) and 95% confidence intervals (CI). DM was present in 408 patients (39.5%). Compared with non-DM patients, DM patients were older (70.4 ± 10.2 vs 66.2 ± 13.7 years, $p < 0.001$) and had more often New York Heart Association class III-IV (53.2 vs 37.3%, $p < 0.001$) and ischemic HF etiology (56.6 vs 45.8%, $P < 0.001$), higher mean blood pressure (89.4 ± 12.7 vs 87.4 ± 11.9mmHg, $p = 0.008$) and heart rate (73.6 ± 11.5 vs 71.8 ± 11.2 b/min, $p = 0.009$), more peripheral edema (44.0 vs 28.2%, $p < 0.001$) and pulmonary rales (26.4 vs 15.9%, $p = 0.001$), obesity (= 30 kg/m^2, 32.0 vs 18.2%, $p < 0.001$), renal dysfunction (eGFR < 60ml/min/173m2, 52.2 vs 34.9%, $p < 0.001$), anemia (WHO, 39.2 vs 26.2%, $p < 0.001$), atrial fibrillation (33.7 vs 26.4%, $p = 0.012$), peripheral artery disease/stroke (30.1 vs 18.6%, $p < 0.001$), systemic inflammation (hsCRP: 12.8 (4.2-28.8) vs 7.7 (2.4-20.6) mg/L, $p < 0.001$; interleukin-6: 6.1 (2.4-12.5) vs 4.2 (2.0-9.7) pg/ml, < 0.001), worse quality of life (Kansas City Cardiomyopathy Overall Summary Score 52.9 (35.9-67.3) vs 59.4 (41.3-77.7), $p < 0.001$), and more depression (mean 9-item Patient Health Questionnaire sum-score 8.3 ± 5.7 vs 7.3 ± 5.4, $P = 0.006$). At 180 days, all-cause death had occurred in 57 DM and 47 non-DM patients (13.9 vs 7.7%, HR 1.88, 95% CI 1.28-2.77, $p = 0.001$), and CV death in 35 DM and 31 non-DM patients (8.6 vs 5.1%, HR 1.75 (1.07-2.84), $p = 0.023$), respectively. The composite of all-cause death or hospitalization had occurred in 191 DM and 226 non-DM patients (46.8 vs 36.8%, HR 1.34 (1.11-1.63), $p= 0.002$.
Conclusion: The HF phenotype differs between patients with and without DM discharged from hospital after systolic cardiac decompensation. Higher age, more obesity, and higher prevalence rates of multiple comorbidities with known adverse prognostic impact, systemic inflammation and residual congestion may play a key role to explain the worse 180-day outcomes of DM patients in our cohort.

P2215

Differences in outcomes of acute heart failure with reduced and preserved ejection fraction in patients with non end stage chronic kidney disease: a nationwide analysis

M Mario Rodriguez[1]; W Rzechorzek[1]; A Manguba[1]; S Sabharwal[1]; C Krittanawong[1]; X Wei[1]; C Godoy Rivas[2]; J Puma[3]; E Herzog[1]
[1]Icahn School Of Medicine at Mount Sinai/ Mount Sinai St. Lukes-West Hospital, Department of Medicine, Division of Cardiology , New York, United States of America; *[2]Cleveland Clinic Foundation, Cleveland, United States of America*; *[3]Columbia University Medical Center, New York, United States of America*

Background : There are 915 000 new heart failure cases annually in United States. As the most common diagnosis for hospitalization, acute heart failure and the impact comorbidities have on in hospital outcomes is of tremendous importance. Patients with end stage renal disease have increased mortality during acute exacerbations of heart failure, but data on Non end stage chronic kidney disease patients is limited.
Purpose: Investigate the effect of non end stage chronic kidney disease on the in hospital outcomes of acute heart failure exacerbations
Methods: A retrospective analysis using the 2014 United States Nationwide Inpatient Sample was performed. Patients above the age of 18 with a primary diagnosis of acute heart failure (AHF) were included and further subcategorized into systolic heart failure (SHF) and diastolic heart failure (DHF). Secondary diagnosis of chronic kidney disease (CKD) stage III and IV was done. Stage I and II was not taken into consideration in this study. End stage renal disease were excluded. Primary outcome was in-hospital mortality. Secondary outcomes included length of stay, cost of stay, cardiogenic shock, utilization of mechanical ventilation, dialysis , use of non-invasive ventilation, cardiac arrest and short term mechanical circulatory support. Multivariate logistic regression analysis was done using STATA IC 15.
Results: A total of 271,905 patients with AHF and CKD stage III and IV were identified of which 48% corresponded to SHF and 52% to DHF, 46% were female and mean age was 75 years. Mortality was statiscally significantly lower in the AHF (OR 0.87 $p = 0.002$) and in the DHF group (OR 0.74 $p < 0.001$) but not in the SHF population (OR 0.94 $p = 0.375$). There was a non statistically significant trend towards less invasive mechanical ventilation utilization across the 3 subgroups. Also, increased dialysis requirements across the AHF (OR 1 .69 $p < 0.001$), SHF(OR 1.71 $p = 0.005$) and DHF(OR 1.65 $p = 0.01$) groups was observed, along with a decreased non invasive ventilation utilization in the AHF (OR 0.83 $p < 0.001$), SHF(OR 0.79 $p < 0.001$) and DHF (OR 0.86 $p = 0.001$) group. Length of hospital stay and total charge of hospitalization was also lower among the CKD and heart failure subgroups.
Conclusions: patients with non end stage CKD (stage III and IV) that develop an acute heart failure exacerbation are prone to undergo more dialytic interventions with less non invasive ventilation utilization and a trend towards decreased mortality. length of stay and total charge are lower as well.

P2216

Outcomes of acute heart failure exacerbations in patients with alcoholic and non-alcoholic cirrhosis: a 5 year nationwide analysis

M Mario Rodriguez[1]; W Rzechorzek[1]; B Sabharwal[1]; C Krittanawong[1]; A Manguba[1]; X Wei[1]; C Godoy Rivas[2]; E Herzog[1]; J Puma[3]
[1]Icahn School Of Medicine at Mount Sinai/ Mount Sinai St. Lukes-West Hospital, Department of Medicine, Division of Cardiology , New York, United States of America; *[2]Cleveland Clinic Foundation, Cleveland, United States of America*; *[3]Columbia University Medical Center, New York, United States of America*

Background: Although pathophysiological heart and liver interactions have been described, data on outcomes of acute heart failure patients with secondary diagnosis of cirrhosis is limited
Purpose: evaluate the difference in outcomes of alcoholic and non alcoholic cirrhosis patients presenting with acute heart failure exacerbation
Methods: A retrospective analysis using the 2010-2014 United States Nationwide Inpatient Sample was done. Patients above age 18 with primary diagnosis of acute heart failure (AHF), systolic heart failure (SHF) and diastolic heart failure (DHF) were included. Secondary diagnosis of cirrhosis was generated with further sub division

in alcoholic and non alcoholic cirrhosis. End stage renal disease patients were excluded. Primary outcome was in-hospital mortality. Secondary outcomes included length of stay, cost of stay, shock, utilization of mechanical ventilation, acute kidney injury requiring dialysis (AKID), use of non-invasive ventilation (NIV), cardiac arrest, and short term mechanical circulatory support. Diagnoses were identified using ICD-9- CM codes . Multivariate logistic regression analysis adjusting for age, race, hospital location and gender was done using STATA 15.
Results: 2,778,114 patients with AHF were identified. 45,980 had a history of cirrhosis in general,
corresponding to 71% patients with SHF and 29% patients with DHF. 36% of general cirrhosis with AHF were female. Mean Age was 65 years. Increased mortality was shown in general cirrhosis with AHF (OR 1.6 $p < 0.001$), SHF (OR 1.5 $p < 0.001$) and DHF (OR 1.77 $p < 0.001$). In non alcoholic cirrhosis, odds of mortality was increased in the SHF(OR 1.48 $p < 0.001$) and DHF group(OR 1.5 $p < 0.001$) along with increased odds of AKID in the general AHF(OR 1.43 p=.004) and SHF(OR 1.48 $p = 0.04$) but not statiscally significant in the DHF group(OR 1.31 $p = 0.18$). There was a trend towards decreased non invasive ventilation utilization across the AHF(OR 0.63 $p < 0.001$), SHF(OR 0.68 $p < 0.001$) and DHF groups(OR 0.61 $p < 0.001$). Increase in total charge and length of stay across all heart failure subgroups was shown. Results for shock(SHF OR 1.2 $p = 0.21$), mechanical ventilation (SHF OR 1.02 $p = 0.61$), short term mechanical circulatory support(SHF OR 1.04 $p = 0.85$) and cardiac arrest (SHF OR 1.24 $p = 0.22$) were not statiscally significant. In alcoholic cirrhosis cohort, increased odds of mortality was seen in the AHF(OR 2.03 $p < 0.001$), SHF(OR 1.70 $p = 0.001$) and DHF(OR 2.6 $p < 0.001$) groups. Increased odds of mechanical ventilation in the AHF(OR 1.37 $p = 0.006$) and DHF(OR 1.6 $p = 0.02$) but not in the SHF group(OR 1.33 $p = 0.06$) was seen as well. In the AHF group of alcoholic cirrhotic patients, decreased odds of non invasive mechanical ventilation(OR 0.80 $p = 0.01$) with increased odds of cardiac arrest(OR 1.68 $p = 0.007$) was seen.
Conclusions: acute heart failure exacerbation in patients with alcoholic and nonalcoholic cirrhosis is associated with an increased mortality, length of stay and total cost.

P2217

Killip class on admission in acute coronary syndrome - is there any influence of previous regular use of heart failure medication?

K Kevin Domingues[1]; MJ Vieira[1]; D Durao[1]; M Leal[1]
[1]*Hospital of Santarem, Cardiology, Santarem, Portugal*

On behalf of: Investigators of the National Registry of Acute Coronary Syndrome of the Portuguese Society of Cardiology

Introduction: The prevalence of acute coronary syndromes (ACS) is higher in patients with hypertension, chronic kidney disease and other previous cardiovascular events. These patients are frequently on drugs which are also used in the treatment of heart failure (HF). However, it is unknown whether their previous regular intake influences Killip Class on admission in patients with ACS.
Aim: To assess the influence of previous regular use of drugs which are commonly used in heart failure in the Killip Class on admission in patients with ACS.
Methods: A retrospective study of patients inserted the National Registry of ACS of the Portuguese Society of Cardiology was performed. The sample was divided in two groups: patients with Killip class = 1 (KK = 1) and patients with Killip class > 1 (KK>1). Clinical variables and drug history were analysed.
Results: A total of 16172 patients were included, predominantly men (73.1%), with a mean age of 66 ± 13 years. There was a known history of hypertension in 69.3%, chronic kidney disease in 5.8%, HF in 4.3% and previous ACS in 19.6%. Most patients (84.7%) presented in KK = 1 (II 9.6%; III 3.8%; IV 1.9%).
In total, 24.4% were previously on regular diuretics, 23.7% on beta-blockers (BB), 26.7% on angiotensin-converting enzyme inhibitors (ACEi), 22.5% on angiotensin II receptor blockers (ARB), 12.2% on nitrates, 3.8% on digoxin, 2.6% on mineralocorticoid receptor antagonists (MRA) and 1.9% on ivabradine.
All of these drugs were associated with a higher prevalence of KK>1: BB 30.4% vs 22.5% ($p < 0.001$), ACEi 35.2% vs 25.2% ($p < 0.001$), ARB 25.5% vs 22.0%, ($p < 0.001$), nitrates 18.2% vs 11.1%, ($p < 0.001$), ivabradine 3.4% vs 1.6% ($p < 0.001$), MRA 5.4% vs 2.0% ($p < 0.001$), diuretics 41.3% vs 21.4% ($p < 0.001$) and digoxin 3.8% vs 1.0% ($p < 0.001$).
In the multivariate analysis, with age, sex, comorbidities (including HF) and time from the beginning of symptoms to the first medical contact, only previous regular intake of diuretic drugs ($p = 0.009$, OR = 1.23, CI95 = 1.05-1.40) and digoxin ($p = 0.018$, OR = 1.62, CI95 = 1.09-2.41) were independent predictors of KK>1 on admission.
Conclusion: In this study of ACS patients, previous regular intake of drugs which are commonly used in heart failure was not associated with a lower incidence of KK>1. On the contrary, previous regular intake of diuretics and digoxin were both independent predictors of KK>1 on admission.

P2218

Liver dysfunction assessed by model for end-stage liver disease predicts adverse outcome in patients with acute decompensated heart failure

J Y Jae Yeong Cho[1]; K H Kim[1]; H Park[1]; H J Yoon[1]; K H Lee[1]; D S Sim[1]; N S Yoon[1]; Y J Hong[1]; H W Park[1]; J H Kim[1]; Y Ahn[1]; M H Jeong[1]; J G Cho[1]; J C Park[1]
[1]*Chonnam National University Hospital, Cardiology, Gwangju, Korea Republic of*

Background: Left ventricular functional recovery (LVFR) is not uncommon in patients with dilated cardiomyopathy (DCM). SHIFT trial showed that ivabradine has a favorable impact on LV reverse remodeling. However, there is lack of data regarding the effect of ivabradine on LVFR in real clinical practice.
Purpose: Therefore, the aim of this study was to investigate the impacts of added ivabradine on LVFR in patients with DCM.
Methods: A total of 395 patients consecutively visited a tertiary hospital between May 2011 and March 2013. Hepatic and renal function test including total bilirubin, prothrombin time-international normalized ratio (PT-INR), and serum creatinine were checked in those patients. The MELD score was calculated for all eligible patient and they were divided into two groups by MELD score: high MELD group (n = 66, 70.6 ± 13.8 years, males) vs. low MELD group (n = 163, 68.4 ± 14.1 years, 82 males). Baseline characteristics, echocardiographic findings, and laboratory findings were compared between two groups. In addition, the diagnostic utility of the MELD score was examined through the use of the receiver-operating characteristics (ROC) curves (Figure). Primary end-point was all-cause mortality at 1-year follow-up.
Results: MELD score was quite different between patients with long-term survivor vs. non-survivor (7.0 ± 3.9 vs. 10.7 ± 4.7, $p < 0.0001$). Age and gender were not different between the two groups. Left ventricular (LV) ejection fraction and LV dimension were not different between the two groups. However, left atrial diameter was larger in the high MELD group (49.1 ± 9.2 vs. 45.5 ± 9.2 mm, $p = 0.010$). Hemoglobin level was lower (11.4 ± 2.5 vs. 12.5 ± 2.1 g/dL, $p < 0.0001$) and white blood cell count was higher (10425.4 ± 4906.3 vs. 9078.5 ± 3845.5 /uL, $p = 0.047$) in the high MELD score group. Serum cholesterol level was not different between the two groups. Other liver function testing like ALP level was higher in the high MELD score group (103.3 ± 65.1 vs. 80.7 ± 30.3, $p = 0.046$). Long-term all-cause mortality was higher in patients with high MELD score (42.4% vs. 11.7%, $p < 0.00001$) (Figure). In multivariate analysis using COX proportional hazard model, high MELD score was an independent predictor of long-term all-cause mortality in Korean ADHF patients (HR 3.66, 95% CI 1.90-7.03, $p < 0.0001$).

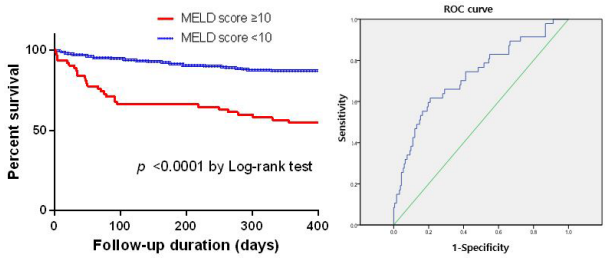


Figure. ROC curve analysis to identify optimal cut-off value of MELD score for predicting long-term mortality in patients with ADHF (Area under the curve=0.727; p <0.0001; Sensitivity 63.8%, specificity 72.0%).

Figure

Conclusion: High MELD score turned out to be an independent predictor of long-term mortality in ADHF patients. Assessment of liver dysfunction using the MELD scoring system has additional value in risk stratification of ADHF patients. Reflection of this result above in establishing novel Korean risk scoring system is warranted.

P2219

Differences in acute heart failure all-cause re-admissions and mortality, between heart failure phenotypes, within northern kuala lumpur

REF Bin Raja Shariff[1]; MK Borhan[1]; MR Yusoff[1]; C Lee[1]
[1]*Hospital Sungai Buloh, General Medicine, Sungai Buloh, Malaysia*

Background: Current phenotypes of heart failure (HF) include heart failure with reduced EF (HFrEF), mid-range (HFmEF) and preserved EF (HFpEF). However, little is known on how the prognosis of all three entities compare within an Asian population.

Purpose: To identify differences in readmissions and mortality, between HF phenotypes in Malaysians.
Methods: A retrospective study was performed on 327 patients with baseline echocardiography, admitted for acute HF to Hospital Sungai Buloh between 1st Jan 2012 to 31st December 2013. Information on demographics, readmission and mortality were compared between HFrEF (n = 186; 56.9%), HFmEF (n = 52, 15.9%) and HFpEF (n = 89, 27.2%) patients.

Precipitants, Readmission and Mortality

Variables	Heart Failure Phenotypes	p-values		
HFrEF (n (%))	HFmEF (n (%))	HFpEF (n (%))		
Precipitants	Non-Compliance	82 (44.1)	28 (53.8)	39 (43.8) 0.425
Acute Coronary Syndrome	58 (31.2)	10 (19.2)	29 (32.6)	0.194
Readmissions	30-days	33 (17.7)	5 (9.6)	14 (15.7) 0.366
90-days	37 (19.9)	9 (17.3)	24 (27.0)	0.300
6-months	37 (19.9)	9 (17.3)	26 (29.2)	0.146
12-months	45 (24.2)	11 (21.2)	24 (27.0)	0.734
Mortality	30-days	20 (10.8)	9 (17.3)	14 (15.7) 0.326
90-days	3 (1.6)	2 (3.8)	2 (2.2)	0.614
12-months	12 (6.5)	3 (5.8)	5 (5.6)	0.958
24-months	7 (3.8)	2 (3.8)	4 (4.5)	0.957
36-months	6 (3.2)	4 (7.7)	6 (6.7)	0.267

Results: The mean age of HFrEF, HFmEF and HFpEF patients were 62.1 (S.D. = 12.4), 63.5 (S.D. = 10.6) and 63.0 (S.D. = 17.7) years respectively (p = 0.387). 108 (58.1%), 29 (55.8%) and 40 (44.9%) patients were male (p = 0.120) respectively as well. Common precipitants in acute HF were non-compliance to fluid restriction and medications, and acute coronary syndrome in all cohorts (Table). There were no significant differences in all-cause readmission at 30-days, 90-days, 6-months and 12-months, between the cohorts and there was also no significant difference in all-cause mortality within 30-days, 90-days, 12-months, 24-months and 36-months as well (Table).
Conclusion: Our study demonstrates similarly poor prognosis (in the context of re-admissions and mortality rates) when comparing acute decompensation in all 3 phenotypes of HF, indicating a need for equal level of awareness and efforts to reduce risk of progression, independent of ejection fraction.

P2220

One-year outcomes in elderly patients with mid-range ejection fraction hospitalized for acute heart failure: data from the ATHENA registry.

F Fedeli[1]; A Pratesi[1]; F Orso[1]; A Herbst[1]; G Biagioni[1]; AC Baroncini[1]; S Parlapiano[1]; C Ghiara[1]; A Lo Forte[1]; A Berni[2]; C Tozzetti[2]; M Di Bari[1]; N Marchionni[3]; A Ungar[1]; S Baldasseroni[1]
[1]Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy; *[2]Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; *[3]Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: ATHENA Study group

Background: Recently, the European Society of Cardiology (ESC) has recognized the presence of a "gray area" of patients with ejection fraction (EF) between 40 and 49% defined "mid-range" (HFmrEF) and has redefined the specific cut off values for HF with preserved EF (= 50%, HFpEF) and HF with Reduced EF (< 40%, HFrEF). Differences in clinical profile and outcomes in this new sub-group of HF pastients are still under investigation.
Purpose: to describe this new population of HF patients by comparing clinical charateristics and long-term outcomes with the other two traditional groups of HF: HF with preserved ejection fraction (HFpEF) and HF with reduced ejection fraction (HFrEF).
Methods: The analysis was based on the retrospective observational ATHENA registry (AcuTe Heart failurE in advaNced Age), which enrolled 401 elderly patients (= 65 years old) with a diagnosis of acute HF during hospitalization. Only the 291 patients with an echocardiographic measurement of left ventricular ejection fraction during hospitalization were considered for this study. One year follow-upwas conducted by phone interviews to evaluate patients' clinical conditions.
Results: During the hospitalization 58 patients (19.9%) had HFmrEF, 95 patients (32.6%) had HFrEF and 138 (47.4%) had HFpEF. The clinical profile of the HFmrEF population was intermediate between the HFpEF and the HFrEF ones. Patient charateristics - such as age, gender and comorbidity rate – were similar to patients of the HFpEF group. An ischemic etiology was as frequent in the HFmrEF group as in the HFrEF population. The mortality rate during follow-up was not significantly different among the three categories, while significant was the difference in disability (p= 0.001), defined as the loss of one or more BADLs. The disability rate was: 85.7% for HFpEF, 76.2% for HFmrEF and 54.3% for HFrEF. In the univariate analysis, age, female gender, history of cognitive impairment, delirium during hospitalization, glycemia on Emergency Department (ED) admission, hemoglobin (Hb) on admission to the ward, Charlson comorbidity index and total number of drugs were associated with disability. In the multivariate analysis, age (OR1.07, 95%CI 0.99-1.15, p = 0.071); glycemia on ED admission (OR 1.01, 95%CI 1.00-1.03, p = 0.031); Hb on admission to the ward (OR 0.77, 95%CI 0.59-0.99, p = 0.021) and 2016 ESC HF classification subgroup (OR 2.37, 95%CI 1.42-3.93, p = 0.001) were independent predictors of disability.
Conclusions: HFmrEF patients have defined clinical characteristics compared to HFpEF and HFrEF patients. One-year mortality rates are very similar in the three groups, while there is a significant difference in the developement disability rate during follow-up with HFpEF group having the highest disability rate.

P2221

Acute heart failure complicating an acute coronary syndrome in elderly patients: prevalence, predictors and prognostic significance

PM Pedro Azevedo[1]; T Mota[1]; J Bispo[1]; J Guedes[1]; D Carvalho[1]; D Bento[1]; S Pereira[1]; W Santos[1]; J Mimoso[1]; I Jesus[1]
[1]Faro Hospital, Cardiology, Faro, Portugal

Introduction: The prevalence of elderly patients with an acute coronary syndrome (ACS) is rising progressively and is a major cause for mortality and morbidity. Acute heart failure (AHF) complicating an ACS has been associated with a worse prognosis. Early identification of patients at higher risk for AHF is of paramount importance to ensure adequate monitoring and prompt therapy.
Purpose: Evaluate the prevalence, predictors and prognostic impact of AHF in elderly patients with an ACS.
Methods: Retrospective, descriptive and correlational study with all patients aged 80 years or older admitted to a Cardiology department with the diagnosis of ACS between the 1st of October 2010 and 31st September 2017. Patients with a Killip class (KK) = 2 at admission or with development of AHF during hospitalization were classified as having AHF and were compared with those without AHF. Univariate and multivariate statistical analysis in SPSS were used to identify predictors and the prognostic impact of AHF in ACS.
Results: 673 patients were included, 360 (53.5%) were male, 239 (35.5%) had ST-segment elevation myocardial infarction (STEMI), 366 (54.4%) had non-STEMI, 12 (1.8%) had unstable angina and 56 (8.3%) had MI of unknown location. 203 (30.2%) patients had AHF, 143 (21.2%) had a KK = 2 on admission and 60 (8.9%) only developed HF later during hospitalization.
Patients with AHF were more frequently female and were more likely to have diabetes, STEMI, a history of ACS, valvular heart disease, HF and chronic kidney disease. They had lower left ventricular ejection fraction (LVEF) (mean 45.3%vs57%, p < 0.001), higher creatinine levels (p = 0.04), lower haemoglobin (p = 0.01) and higher glycemia on admission (p < 0.001).
Patients with AHF were less likely to have coronary angiography and percutaneous coronary intervention (PCI) (23.2%vs41.1%, p < 0.001), and had more frequently atrial fibrillation (AF) (17.7%vs7.4%, p < 0,001), major haemorrhage and need for both non-invasive and invasive ventilation. Overall in-hospital mortality rate was 9.5% (65 patients) and AHF was associated with higher mortality (22.7%vs3.8%, p < 0.001) in univariate and multivariate analysis (OR 2.77, 95%CI 1.15-6.7, p = 0.02)
On multivariate analysis, female sex (OR 1.82, 95%CI 1.12-2.9, p = 0.02), no PCI (OR 2.03, 95%CI 1.15-3.58, p = 0.01), AF (OR 2.82, 95%CI 1.5-5.3, p = 0.001), lower LVEF (p < 0.001) and higher glycemia (p = 0.009) were independent predictors of AHF. In patients admitted in KK 1, STEMI (OR 2.99, 95%CI 1.32-6.8), lower FEVE (p < 0.001) and AF (OR 4.3, 95%CI 1.8-10.3, p = 0.01) were independently associated with HF developing during hospitalization.
Conclusion: AHF is a common complication in octogenarians with ACS and increases in-hospital mortality by almost 3-fold. Female sex, no PCI, AF, lower LVEF and higher glycemia were independently associated with AHF. In patients initially admitted in KK 1, lower LVEF, AF and STEMI predicted the development of AHF during hospitalization.

Acute Heart Failure - Diagnostic Methods

P2222

Indicators of left ventricular remodeling in patients with acute heart failure

K Akmal Koyirov[1]; S R Kenjaev[1]; U SH Ganiev[1]; S SH Khaitov[1]; Z A Kambarova[2]; M S Mirmaksudov[3]
[1]Republican Research Center of Emergency Medicine, Tashkent, Uzbekistan; *[2]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan*; *[3]Tashkent Medical Academy, Tashkent, Uzbekistan*

Aim: The aim is to evaluate echocardiographic parameters in patients with ST-segment elevation myocardial infarction (STEMI), depending on the class of acute heart failure (AHF).
Material and Methods: 79 patients (50 men and 29 women) with STEMI were examined. The average age is 63.8 ± 1.69 years. Depending on the presence of signs of AHF patients are divided into two groups: 1 group - I class by Killip - 47 patients; 2nd group - II-IV class by Killip - 32 patients. The analysis was carried out based on the results of echocardiography (ECHO) after one day from the development of myocardial infarction.
Results: A number of significant differences identified between these groups by comparison of the echocardiographic data. According to results of the analysis, the avarege values of EDV, ESV, ESD, EF in the Killip I group were significantly different from the Killip II-IV group. Thus, the values of EDV in groups Killip I and II-IV were 148.6-163.9 and 165.5-207.1 ml, respectively. ESV were 70.4-83.3 and 90.2-131.2 ml; ESD 3,8-4,2 and 4,4-5,2 cm; EF - 49,1-53,3% and 36,9-45,9%, respectively. Thus, high values of EDV, ESV, and ESD were observed in group II-IV of AHF classes, and ejection fraction of left ventricle was vice versa, was higher in group I of class AHF. There were no significant differences between the groups in the values of EDD, IVS, PWLV, although patients with II-IV classes of AHF showed higher values of these parameters. Comparing the variances of the Killip I and Killip II-IV groups, statistically significant differences in the EDD (p = 0.010), EDV (p = 0.003), ESV (p = 0.0003), IVS (p = 0.005), LVPW (p = 0.04), E/A ratio (p = 0.0001). According to our data, on the basis of EDV and ESV, differences were found, both in the mean values and in the variances.
Conclusion: Thus, left ventricular myocardial remodeling in the early post-infarction period is caused by a complex of structural and functional changes, the main of which are dilatation of the left ventricular cavity, worsening of the contractile function of the myocardium.

Biomarkers in acute cardiorenal syndrome

M Dankova[1]; M Luknar[1]; P Lesny[1]; Z Minarikova[2]; B Zitny[3]; P Pontuch[2]; E Goncalvesova[1]
[1]The National Institute of Cardiovascular Diseases, Department of Heart Failure and Heart Transplant, Bratislava, Slovak Republic; *[2]University Hospital, 4th Department of Internal Medicine, Bratislava, Slovak Republic*; *[3]STUVital, Bratislava, Slovak Republic*

Funding Acknowledgements: Project is supported by Slovak Society of cardiology research grant.

Aim: The aim was to identify independent predictors of acute kidney injury (AKI) in patients admitted due to acute heart failure (AHF).
Methods: We evaluated clinical, echocardiographic parameters and selected biomarkers in 74 patients admitted to ICU due to AHF. In 41 patients (55,4 %) it was newly diagnosed AHF, in 33 patients (44,5 %) - decompensation of chronic heart failure. The average age was 69 ± 10,3 years with gender distribution 48/26 (men/women). HFrEF/HFmrEF/HFpEF was in 34/24/16 patients. Acute kidney injury was defined according to the KDIGO recommendations based on the dynamics of serum creatinine and daily diuresis. Patients were divided into groups without (AKI-, n = 54) and with (AKI+, n = 20) acute kidney injury. Parameters as: age, BMI, systolic blood pressure, u-NGAL, u-TIMP2, u-IGFBP7, s-NTproBNP, s-hemoglobin and LVEF were included into the multivariate regression analysis.
Results: In 27% of patients we observed development of AKI within 72 hours after admission. Patients with AKI + were older [76 vs. 64 years (median), p = 0,007], with lower BMI [27 vs. 29 kg/m2 (median), p = 0,02], more often in the HFrEF group (45,8 %, p = 0,002). Median of urinary NGAL at admission was significantly higher in the AKI+ group compared to patients in the AKI- (154 vs. 19,5 ng/ml; p = 0,0001). Median of u-TIMP2 was 194,1 in the AKI + group versus 42,5 ng/ml in the AKI- group of patients (p = 0,0001). Median of u-IGFBP7 was 379 in the AKI+ verzus 92,4 pg/ml in the AKI- patients (p = 0,001). Except of BMI, parameters as age, systolic blood pressure, u-NGAL, u-TIMP2, u-IGFBP, s-NTproBNP, s-hemoglobin and LVEF significantly identified AKI [AUC ROC]: u-NGAL = 0,89 (p = 0,0001); u-TIMP2 = 0,87 (p = 0,001), u-IGFBP7 = 0,92 (p = 0,0001), EFLK= 0,79 (p = 0,001); s-NTproBNP = 0,73 (p = 0,01); s-hemoglobín = 0,71 (p = 0,01); s-TK = 0,71 (p = 0,02).
Conclusion: Predictors of acute kidney injury in acute heart failure patients were: age, systolic blood pressure, elevated heart failure markers (s-NTproBNP) and renal injury markers (u-NGAL, u-TIMP2, u-IGFBP7) together with LVEF determination and levels of s-hemoglobin at admission.

P2224

Is there a variation of CA-125 levels with changes in glomerular filtration rate in patients with heart failure?

D Carrillo[1]; R Lopez[1]; I Sanchez-Lazaro[1]; C Aguado[2]; B Laiz[2]; L Almenar[1]
[1]Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit, Valencia, Spain; *[2]Hospital Universitario y Politécnico La Fe, Clinical analysis service, Valencia, Spain*

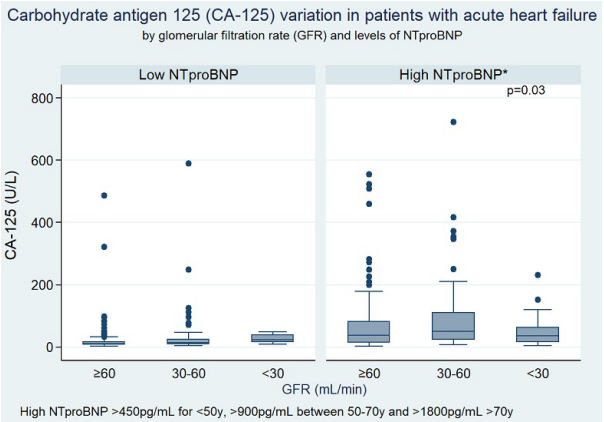
Background/introduction: Carbohydrate antigen 125 (CA-125), known as a tumor marker, is used as congestion marker in heart failure (HF). However, few report exist on CA-125 measurement in patients with HF and impaired renal function.

Multivariate linear regression model.

CA-125	Coeficient	95% Conf Interval	p	
GFR (mL/min)				
≥60mL/min	1			
30-60mL/min	15.16	-2.58	32.92	0.09
<30mL/min	-25.39	-55.52	4.72	0.09
NTproBNP				
Low	1			
High*	55.21	38.34	72.07	0.00

*High NTproBNP >450pg/mL for <50y, >900pg/mL between 50-70y and >1800pg >70y
CA-125 Carbohydrate antigen 125, GFR Glomerular filtration rate.

Purpose: To determine the relationship between CA-125 and glomerular filtration rate (GFR) in patients with HF, considering the levels of NTproBNP.
Methods: Cross-sectional study of patients with acute HF who have the biomarkers NTproBNP, CA-125, GFR in the same blood sample between 01 august to 30 nov 2017. A multivariable linear regression to examine covariates associated with CA-125 results was used. A boxplot of distribution of CA-125 according to the categories of renal function and levels of NTproBNP was done.
Results: 173 patients were included. The median of age was 71 years (interquartile range [IQR] 61-79), 64.74% were male. Median of CA125 was 42.1 U/L (IQR 16.2 to 88) and 54.9% have CA-125 higher than 35 U/L. The median of GFR was 59mL/min (IQR 41-78), NTproBNP 2310 pg/mL (IQR 918-4665). There were differences of the CA-125 levels by GFR categories, in patients with high NT-proBNP (Figure). However, in the multivariable regression model, the GFR categories weren't related to the change of CA-125. Elevated levels of NTproBNP were related to the elevation of CA-125 (Table).



CA-125 in patients with heart failure

Conclusions: CA-125 is a surrogate marker in HF, apparently not affected by GFR. However, further studies including clinical variables are required.

P2225

Monocyte subsets distribution predicts mortality in patients with acute heart failure

KA Konstantin A Krychtiuk[1]; M Lenz[1]; SP Kastl[1]; K Huber[2]; J Wojta[1]; G Heinz[1]; WS Speidl[1]
[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]Wilhelminen Hospital, 3rd Department of Internal Medicine, Cardiology and Emergency Medicine, Vienna, Austria*

Background: The pathogenesis of acute heart failure (AHF) includes a strong activation of the innate immune system. Monocytes are a heterogenous cell population and act as key regulators of innate immunity. According to their surface expression pattern of CD14, CD16 and CCR-2 they can be distinguished into at least three cell populations, namely classical monocytes (CD14++CD16-; CM), intermediate monocytes (CD14++CD16+CCR2+; IM) and non-classical monocytes (CD14+CD16++CCR2-; NCM).
Purpose: The aim of this prospective, observational study was to analyze whether monocyte subset distribution is associated with 30-day survival in patients with AHF.
Methods: We included 81 patients with acute heart failure admitted to a cardiac ICU. Blood was taken at admission and after 72 hours and monocyte subset distribution was analyzed by flow cytometry.
Results: Median age was 64 IQR 50-74 years and 77.8 % of patients were male. Median NT-proBNP was 4896 IQR 1370-14008 pg/mL and 30-day mortality was 33.3%. Monocyte subset distribution at day 0 was not associated with mortality. In contrast, compared to 30-day survivors, patients that did not survive showed a significantly higher percentage of IM (4.2 IQR 2.1-7.7 % vs 7.7 3.9-12.4 %; $p < 0.05$) and a lower percentage of CM (90.7 IQR 85.4-92.1 % vs. 87.2 IQR 79.2-89.0 %). Patients in the lowest tertile of CM showed a 8.9-fold increased mortality risk as compared to patients in the third tertile independent of age, sex, creatinine and NT-proBNP levels.
Conclusion: Monocyte subset distribution is associated with 30-day mortality in AHF patients requiring ICU admission. Thus, activation of the innate immune system may play a major role in the pathophysiology and outcome of this disease.

P2226

The examination about the relation between polyunsaturated fatty acid condition in blood on admission and prolongation of hospitalization in congestive heart failure cases.

Y Kato[1]; K Hayashi[1]; M Hasegawa[1]; N Matsuo[1]; T Fujiwara[1]; M Tanimoto[1]; K Kagwa[1]; Y Nakano[1]; N Onishi[1]; A Atsushi Takaishi[1]; M Ueeda[1]; S Hirohata[2]
[1]Mitoyo General Hospital, Kanonji, Japan; *[2]Okayama University, Graduate School of Health Sciences, Okayama, Japan*

Background: We introduced original clinical pathway(CP) for congestive heart failure(CHF) cases required admission and achieved wide shortening of hospitalization period by reduction of useless medical care. But many cases(43%) still stay over two weeks in our hospital. Although there may be various reasons for prolongation of hospitalization, we can find several reports about relation between the condition of polyunsaturated fatty acid(PUFA) and clinical course of CHF like that of ischemic heart failure.
Purpose: In this study we examined the data of PUFA in CHF cases introduced CP and considered about the characteristics of PUFA data in cases who required long stay in our hospital.
Method: We enrolled 197 patients who admitted with CHF in our hospital and introduced CP at the first time from August 2015 to July 2017 (mean age 81+/-11 years old, male/female 112/85). And we divided them into two groups, S-group(hospitalization was within 14days: 112cases, mean age 82+/-10 years old) and L-group(hospitalization was over 14days: 85cases, mean age 80+/-11 years old). We examined their activity before admission, the prevalence of dementia and cardiac function on admission. And we examined blood test data about lipid and PUFA on adomission. We investigated about the difference of these data between two groups.
Results: In L-group the rate of the cases without activity limitation out of doors was lower(39 vs 60%; $p < 0.05$) and the prevalence of dementia was higher(48 vs 26%; $p < 0.01$) than in S-group. Between L-group and S-group there was no difference about the value of Brain Natrium Peptide in blood(873+/-803 vs 752+/-552 pg/mL) or ejection fraction of left ventricle by echocardiography(52+/-20 vs 51+/-20%). About lipid in blood, the value of triglyceride, low dense lipoprotein(LDL) and oxidized LDL(Malondialdehyde Modified LDL) ware not different between two groups , only the value of high dense lipoprotein(HDL) was lower in L-group(44+/-16 vs 50+/-14 mg/dl; $p < 0.05$). About the value of PUFA arachidonic acid(AA) and docosahexaenoic acid(DHA) ware not different between two groups, but the value of eicosapentaenoic acid(EPA) was significantly lower in L-group(51+/-28 vs 67+/-44mg/dl; $p < 0.01$). The ratio of EPA and AA(EPA/AA) was also lower in L-group(0.34+/-0.19 vs 0.44+/-0.34; $p < 0.01$).
Conclusions: We found the relation between prolongation of hospitalization and high age, low activity before admission or presence of dementia in CHF cases. And we found that the value of EPA or EPA/AA on admission was clearly low in the cases required long hospitalization. It is not still unclear whether the simple supplement of EPA is useful for improvement of acute or chronic prognosis in CHF cases. But we should not only pay attention to general known factor relating to prognosis of CHF. It seemed to be also useful for management of CHF to check PUFA data on admission.

P2227

The value of 24-hour ambulatory blood pressure monitoring in patients admitted with acute heart failure and systolic dysfunction

A Frigy[1]; I Varga[2]; Z Fogarasi[2]; I Kocsis[2]
[1]University of Medicine of Targu Mures, Internal Medicine IV, Targu Mures, Romania; *[2]Clinical County Hospital Mures, Cardiology, Targu Mures, Romania*

Funding Acknowledgements: Research Grant with private financing - nr.15276/03.11.2015 UMF Tirgu Mures

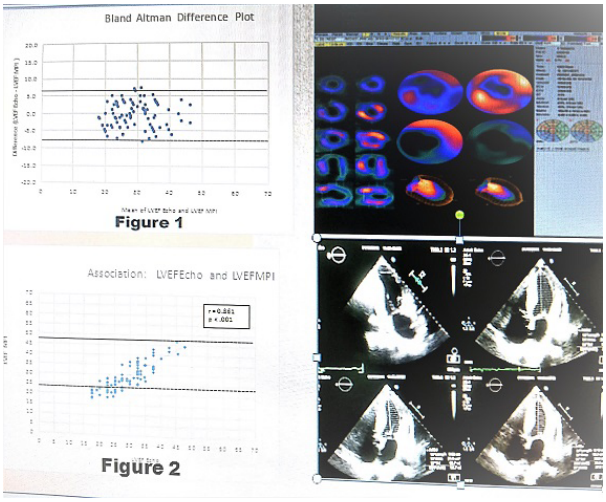
In acute heart failure (AHF), blood pressure (BP) is a major hemodynamic parameter with therapeutic and prognostic implications, however the value of 24-hour BP data has been less studied before.
Methods: In 35 patients (28 men, 7 women, mean age 61.28 years), hospitalized with AHF, 24-hour ambulatory BP monitoring (ABPM, EC-3H/ABP Cardiospy, Labtech) was performed on the day before hospital discharge, when the patients reached a stable hemodynamic status. All the patients had systolic heart failure (mean left ventricular EF 34%) and were free of hypertension. Besides classical ABPM parameters (max, min, mean values), the diurnal index and the standard deviation (a measure of BP variability) were obtained.
Results: The most important ABPM parameters had the following mean values (24-hour, day and night): systolic BP - 113.85 mmHg, 115.08 mmHg, 110.51 mmHg; diastolic BP - 66.58 mmHg, 67.7 mmHg, 63.51 mmHg; pulse pressure - 46.85 mmHg, 46.82 mmHg, 46.63 mmHg. The systolic and diastolic diurnal index was over 10% only in 8 and 11 patients, respectively. 24-hour, day and night standard deviations of systolic and diastolic BP values were smaller with 1 mmHg in average than the reference values found in the PAMELA study.
Conclusions: Patients hospitalized with systolic AHF, prior to discharge, clinically stabilized, are characterized generally by low BP values and a blunted circadian and global BP variability - phenomena related to the decreased cardiac output and neurohumoral activation. Predischarge ABPM could provide useful informations regarding the therapeutical reserve (risk of hypotension) and prognosis (low BP variability).

P2228

Is assessment of left ventricular ejection fraction a reality on an ultra low dose gated rest redistribution myocardial perfusion scintigraphy with ultra fast solid state detector gamma camera

ATUL Verma[1]; S Pandey[1]
[1]Fortis Escorts Heart Institute, New Delhi, India

Aims & objectives: The present study is aimed to assess the efficacy of cardiac dedicated solid state detector SPECT in the estimation of Left Ventricular Ejection Fraction on a gated rest redistribution thallium 201 myocardial perfusion scintigraphy (G-RRT-MPS) used for myocardial viability assessment in patients with gross Left ventricular dysfunction.
Materials and Methods: A group of consecutive patients: (N = 106) irrespective of age & sex with left ventricular failure (LVF) from ICUs/emergency department were subjected to G-RRT-MPS for myocardial viability. All the patients were imaged after iv injection of ultra-low dose Tl201 (1-1.5mCi) immediately & 4 hrs post injection under solid state detector SPECT gamma camera (GE-Discovery NM 530C) with the imaging time of 5 min each. 10 subjects with normal LVEF were subjected to Gated Tc99MIBI SPECT & 2DE for comparing the LVEF by echo & gated MPS to use it as the standard. The images were processed using 3D iterative reconstruction & LVEF were calculated by two nuclear physicians separately using commercially available QGS/QPS software. Similarly, All patients were subjected to 2DE where LVEF was calculated by two echocardiography experts in a double blinded manner using modified Simpsons' rule. The mean results of G-RRT-MPS & 2DE were compared for LVEF.
Results: The results showed mean LVEF of 28.9% ± 07% & 29.3% ± 6.8% for 2DE & G-RRT-MPS respectively which showed almost comparable results($p = 0.293$).



All LVEF measurements by both the modalities showed good correlation (r = 0.861, P= <.001) (fig 1). The concurrence was good as analysed by Bland-Altman method (fig 2). The mean discrepancy between the modalities was -0.4 with a 95% confidence range of -1.2 to 0.4. Discussion: Very few studies have compared 2DE & RRT for LVEF estimation because of low gated image quality on standard SPECT gamma camera. The physical characteristics of solid state detector technology which includes direct conversion of energy into counts & negligible dead time thus resulting into high energy & spatial resolution & hence good quality gated study enables to look at myocardial contractility, thickness as well as centripetal excursion & thus proper estimation of LVEF which shows excellent correlation with that of 2DE.
Conclusion: From the above results the LVEF can be estimated quite accurately & can be used in addition to Myocardial viability.

P2229
Worsening renal function in acute decompensated heart failure patients with regard to its reversibility

E Amosova[1]; I Gorda[2]; A Bezrodnyi[1]; A Sablin[2]
[1]O. O. Bogomolets National Medical University, Kiev, Ukraine; *[2]Kiev Alexander Clinical Hospital, Kiev, Ukraine*

Background: Our purpose was to determine the influence of worsening of the renal function (WRF) on clinical course of the hospital period in "wet and warm" patients with acute decompensated heart failure (ADHF).
Methods: In to the prospective study were included 141 patients with ADHF at the age from 38 to 85 years (mean age 66,4 ± 2,2). Transient WRF was defined as increase of creatinine = 26.5 mmol/L after 48 hours with subsequent decrease to baseline at discharge. Patients with persistent WRF didn't have decrease of creatinine to baseline at discharge. Endpoints were CVP at day 4 (D4), ortho-oedema congestion index Lala, E/E' and NT-proBNP at discharge (Dsc).
Results: WRF occurred in 38 (27%) patients, including 30 pts with transient WRF and 8 pts with persistent WRF. The patients with persistent WRF comparing to patients transient WRF and with no WRF had significantly more increased values of ortho-oedema index Lala, E/E', NT-proBNP, CVP and worse results of decongestion treatment. In the same time the patients with transient WRF didn't have significant differences in main parameters and endpoints (see in table).

P2229	No WRF	WRF transient	P1-3	P2-3	
Ortho-oedema index Lala D1	3,32 ± 0,10	3,47 ± 0,10	3,91 ± 0,12	p <0,01	p <0,01
Ortho-oedema index Lala Dsc	2,3 ± 0,05***	2,12 ± 0,05***	2,72 ± 0,08**	p <0,01	p <0,01
CVP D1	174 ± 10,4	179 ± 10,74	199 ± 11,94	p <0,05	p <0,05
CVP D 4	83 ± 4,98**	91 ± 5,46**	112 ± 6,72**	p <0,05	p <0,05
E/E' D1	18,1 ± 1,09	18,4 ± 1,10	21,1 ± 1,27	p <0,01	p <0,01
E/E' Dsc	12,9 ± 0,77 **	14,3 ± 0,86**	17,2 ± 1,03**	p <0,01	p <0,01
NT-proBNP D1	1147 ± 68	1211± 72,66	1362 ± 81,72	p <0,01	p <0,05
NT-proBNP Dsc	751 ± 45***	783 ± 46,98***	944 ± 56,64**	p <0,05	p <0,05

* - p < 0,05, ** - p < 0,01, *** - p < 0,001 compared to D1;

Conclusion: In the "wet and warm" patients with ADHF only presence of persistent WRF is associated with significantly worse clinical course and outcome comparing to patients with transient WRF and with no WRF

Acute Heart Failure - Treatment

P2230
Spironolactone treatment does not cause significant hyperkalemia at patients hospitalized because of chronic or acute heart failure - a meta-analysis

J Wagner[1]; B Wobbe[1]; I Rostas[1]; N Farkas[1]; P Hegyi[1]; L Czopf[1]
[1]University of Pecs, Division of Cardiology and Angiology and Centre for Translational Medicine, Pecs, Hungary

Background: Chronic heart failure (CHF) patients are shown to benefit from spironolactone treatment, especially if their left ventricular systolic function is significantly decreased (HFrEF). Recent randomized clinical trials at acute decompensated heart failure (ADHF) patients questioned the clinical importance of hyperkalemia as a significant adverse event.
Purpose: We conducted a systematic meta-analysis of the available studies, whether the side effect hyperkalemia is clinically significant at the different dosages of spironolactone in ADHF and CHF?
Methods: We searched EMBASE, the Cochrane Registry and PUBMED to identify randomized controlled studies comparing 25 to 100 mg spironolactone with placebo on top of the usual care therapy at patients hospitalized for ADHF and CHF. Search terms "acute heart failure", "chronic heart failure", "spironolactone" and "randomized controlled trials" were used, and studies until March 2017 were analyzed. 12 randomized controlled trials were identified enrolling 7948 participants. 46.88% (529 with ADHF and 3197 with CHF) were randomized to spironolactone and 53.12% (465 with ADHF and 3757 with CHF) to placebo.
Results: Overall, there was no significant difference between groups concerning the incidences of hyperkalemia (RD: 0.016; 95% CI: -0.017 - 0.049, p = 0.336). Our subgroup analysis showed no increased risk for hyperkalemia for the setting of ADHF (RD: -0.002; 95% CI: -0.036 - 0.032; p = 0.906). However, the subgroup analysis showed an increased risk for hyperkalemia in CHF patients treated with spironolactone (RD: 0.032; 95% CI: 0.003 - 0.060; p = 0.028). As an adverse event a significant risk of hypokalemia was found (RD: -0.029, 95% CI: -0.048 - -0.009; p = 0.004). CHF patients showed a higher incidence of hypokalemia than ADHF patients (RD: -0.046, 95% CI: -0.075 - -0.017; p = 0.002 versus RD: -0.006; 95% CI: -0.043 - 0.031; p = 0.745). At least our subgroups showed a benefit in risk of mortality but there was no significant difference between high dose (50-100 mg/d), medium dose (25-50 mg/d) and low dose (12.5-25 mg/d) spironolactone treatment (RD: -0.021; 95% CI: -0.049 - 0.006; p = 0.134). Meta-regression showed no correlation between mortality and hypokalemia, but between mortality and hyperkalemia on follow up.
Conclusion: Limitation of our study was that we did not differentiate between systolic and diastolic heart failure. Further limitation was the lack of reduction in mortality at the spironolactone group compared to placebo, even if we evaluated only the subgroup of the chronic heart failure patients. Compared to the placebo group spironolactone treatment represented no significant risk of hyperkalemia but was paradoxically rather associated with hypokalemia. The available evidence suggests that the risk of hyperkalemia at spironolactone treatment is clinically not important in ADHF and CHF patients on the usual medium dose but it is influenced by the follow up time.

P2231

Acute heart failure un the elderly: which is the treatment of choice at discharge? Real world data from the ATHENA registry

A Lo Forte[1]; F Orso[1]; A Pratesi[1]; A Herbst[1]; S Parlapiano[1]; G Biagioni[1]; F Fedeli[1]; C Ghiara[1]; AC Baroncini[1]; F Bacci[2]; G Ciuti[2]; M Di Bari[1]; N Marchionni[3]; A Ungar[1]; S Baldasseroni[1]

[1]Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy; *[2]Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; *[3]Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: ATHENA Study group

Background: the prognosis of patients with heart failure (HF) with reduced ejection fraction (HFrEF) has improved in recent years thanks to the availability of evidence based treatments. Currently, equally effective treatments are not available for patients with HFpEF (HF with preserved EF) and for those with HFmrEF (HF with mid-range EF), the new category of patients with HF, recently introduced by the European Society of Cardiology.
Purpose: to evaluate treatments at discharge in a real world setting of elderly patients after an episode of acute HF in the three different groups of HF: HFpEF, HFrEF and HFmrEF.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (= 65 years) admitted with diagnosis of AHF to a tertiary University teaching-hospital in the period 01.12.2014-01.12.2015.
Results: The final study population was composed by 291 patients: 19.9% of them with HFmrEF, 32.6% with HFrEF and 47.4% with HFpEF. Mean age of three group of patients was respectively 84.2, 84.3 and 80.3 years, $p < 0.001$. Pharmacological treatments at discharge in the three HF groups are shown in the attached table. BBs and MRAs were the only two classes of drugs that had a statistically different prescription rate across the three HF groups: patients with HFmrEF received BBs in similar percentage to patients with HFrEF. Instead MRAs prescription rate in HFmrEF was more similar to the one of patients with HFpEF.
Conclusion: at present, in the absence of specifical evidences from randomised clinical trials, patients with HFmrEF are treated similarly to those with HFrEF. Also, a high percentage of patients with HFpEF, receive treatments that only have been to improve prognosis in HFrEF patients. Randomised clinical trials evidences are needed to appropriately treat HFmrEF patients

Drug	Tot n = 291	HFrEF n = 95	HFmrEF n = 58	HFpEF n = 138	P Value

P2232

Pulmonary congestion, VA-ECMO output and outcome after cardiac surgery

W S Walter Stefan Speidl[1]; D Wiedemann[1]; K Lampichler[1]; D Toth[1]; B Steinlechner[1]; G Heinz[1]; G Laufer[1]; K Distelmaier[1]; G Goliasch[1]

[1]Medical University of Vienna, Vienna, Austria

Introduction: Venoarterial-extracorporeal membrane oxygenation (VA-ECMO) is a life-saving method for patients with low-output failure after cardiac surgery. However, VA-ECMO therapy may increase left ventricular afterload due to retrograde blood flow in the aorta, which may lead to progression of pulmonary congestion. The aim of this study was to examine the role of pulmonary congestion in patients that need VA-ECMO support after cardiovascular surgery.
Methods: We included 299 adult patients undergoing VA-ECMO support following cardiovascular surgery. Primary endpoint was 30-day survival. Pulmonary edema was assessed on bedside chest X rays at day 0, 3, 5 after VA-ECMO implantation.
Results: Median age was 65 (57-72) years, 69% of patients were male and 30-day survival was 63%. The median SAPS-3 score and the median EuroSCORE of the study population were 43 (37-52) and 10 (8-13), respectively. At ICU-admission 20% of patients had mild, 54% had moderate and 26% showed severe pulmonary congestion. Pulmonary congestion at day 0 was not associated with outcome (adjusted HR 1.31; 95%-CI 0.89-1.93;P = 0.18), whereas pulmonary congestion at day 3 (adj. HR 2.81; 95%-CI 1.76-4.46;P < 0.001) and day 5 (adj. HR 3.01;95%-CI 1.84-4.93;P < 0.001) was significantly associated with survival independent from SAPS-3 score, ECMO rotation, fluid balance, ECMO cannulation site, use of intra-aortic balloon pump (IABP) and type of cardiovascular surgery. Linear regression revealed that out of left ventricular function, cardiac output, central venous saturation, maximum dobutamine and norepinephrine dose as well as fluid balance solely ECMO rotation was associated with the evolution of pulmonary congestion (P = 0.007).
Conclusion: Pulmonary edema three and five days after ECMO implantation are associated with survival. Interestingly, a high VA-ECMO output was the most important determinant of worsening pulmonary congestion within the first five days.

P2233

Refractory cardiogenic shock: emergency mechanical circulatory support as a bridge to recovery

N S Piatrovich[1]; L G Shestakova[1]; Y P Ostrovsky[1]

[1]Republican Scientific and Practical Centre of Cardiology, Department of extracorporeal blood circulation, Minsk, Belarus

Background: Cardiogenic shock as an extreme degree of LV failure is one of the main causes of death. Out-hospital survival rate is 8-10%. The probability of achieving return of spontaneous circulation decreases after 10 minutes of conventional cardiopulmonary resuscitation(CPR).Extracorporeal membrane oxygenation (ECMO) plays role of a rescue and maintains adequate organ perfusion in catastrophic conditions of deterioration despite inotropes or vasopressors.
Purpose: To evaluate the effectiveness of MCS in patients with refractory cardiogenic shock.
Methods: Comprehensive single-centered retrospective review of 10 patients at the age of 55,7 ± 15,15 years(3 women and 7 men) after peripheral veno-arterial ECMO assisted CPR during the period 2015-2017years. For improvement of residual LV pump function we also used: percutaneous balloon atrioseptostomy (n = 1), intraaortic balloon pumping (n = 2), active drainage of LV (n = 1), combination of methods(n = 1). In 4 cases (40%) patients required renal replacement therapy. Selective antegrade perfusion was performed in 5 cases (50%)to prevent ischemia of lower limbs.
Results: During the period 2015-2017years 52 ECMO were applied.19,23%(n = 10) were used as a resuscitation. Initial characteristic of patients:LVEF 30,2 ± 10,2%, lactate 13,8 ± 5 mmol/l, BE -16,9 ± 4,4 mmol/l, pH 7,11 ± ,13, AP 61 ± 6,4/41 ± 8,8 mmHg. Doses of inotropic agents: dobutamine 5,86 ± 1,5 mcg/kg/min, noradrenaline 0,28 ± 0,22 mcg/kg/min,adrenaline 0,26 ± 0,12 mcg/kg/min. Mean support time was 7,3 ± 5,1 days(7 hours-13,6 days). Stay in ICU was13,9 ± 8,1 days. Stay in hospital- 34,3 ± 7,5 days. We had 2 fatal outcomes because of sepsis, irreversible multiorgan dysfuntion and neurological complications. Hospital survival was 80%.
Conclusions: MCS can be used as an effective rescue tool for stabilization of patients with refractory cardiogenic shock, during cardiopulmonary resuscitation before the return of spontaneous circulation. It gives an extra time for thorough diagnosis and treatment and enhances survival.

P2234

Comparison of the effectiveness of transcatheter aortic valve implantation in patients with pure aortic valve regurgitation versus aortic stenosis

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; JM Pinilla-Garcia[1]; F Carrasco-Chinchilla[1]; AJ Dominguez-Franco[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; E De Teresa Galvan[1]

[1]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

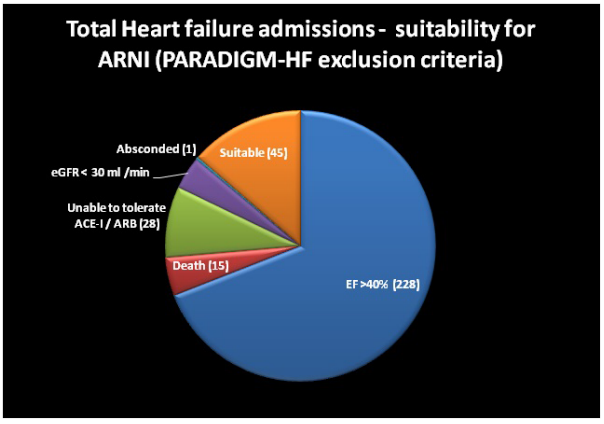
Limited data exist about safety and efficacy of transcatheter aortic valve replacement (TAVR) in patients with pure native aortic regurgitation (AR).
The aim this study was to evaluate the clinical outcomes of patients with pure native aortic valve regurgitation undergoing with Transcatheter Aortic Valve Replacement and comparing them with patients with aortic stenosis.
Methods: Between April 2008 and December 2017, 20 consecutive patients with severe pure aortic regurgitation (AR) underwent TAVR with the self-expandable aortic valve prosthesis (CoreValve) and 596 patients with severe aortic stenosis (AS).
Results: The mean age and logistic EuroSCORE were (AR vs. AS) 73.8 ± 16 vs. 79.6 ± 6.2 years, p = 0.001 and 16.9 ± 9% vs. 17.4 ± 12, p= 0.878 respectively.
There were significant differences in measurement of annulus and ascending aortic size (23.7 ± 2 vs. 22 ± 1.8 mm, p < 0.001 and 35 ± 6 vs. 31.1 ± 4 mm, p = 0.001, respectively). Implantation of prosthesis was performed successfully in 95% patients with AR. The degree of aortic regurgitation after procedure in patients with compared with AS were: none (40% vs. 41.5%) mild (35% vs. 33.6%) moderate (15% vs. 23.4%) and severe (10% vs. 1.5%), p= 0.430
The NYHA functional class improved from 3.2 ± 0.61 (baseline) to 1.37 ± 0.51 (one month) and remained stable at follow-up (1.4 ± 0.54). The mortality at 30 days was 10 % in patients with AR compared to 3.4% in patients with AS, p = 0.157 and there

was non-significant differences with late mortality (27.8% vs. 35.4%, p = 0.348) after a mean follow-up of 41.4 ± 27 months.
The patients with AR had similar complications after procedure than patients with AS: Occurrence new-onset left bundle branch block 27.8% vs. 44.3%, p= 0.05, stroke 5% vs. 3.9% p = 0.533, vascular complications 5% vs. 3.2% p = 0.468, acute myocardial infarction 5% vs. 1.7% p = 0.306, respectively.
Conclusions: Patients with pure native aortic regurgitation and at high surgical risk might benefit from transcatheter-based therapy. The long-term outcome is favourable compared with patients with aortic stenosis underwent with TAVR.

P2235
It is difficult to be first in class - Suitability of heart failure admission patients for ARNI

D Daniel O'hare[1]; S Quinn[2]; C O'connor[1]; R Murphy[1]; C Daly[1]
[1]St James Hospital, Dublin, Ireland; [2]Galway University Hospital, Galway, Ireland

Introduction:
The first in class angiotensin receptor neprilysin inhibitor (ARNI) Sacubitril / valsartan was included in the 2016 European Society of Cardiology heart failure guidelines following the results of PARADIGM-HF. This demonstrated superiority over Enalapril in reducing the risks of death and heart failure admissions in heart failure with reduced ejection fraction (HFrEF).
It has a class 1B indication for the treatment of patients with a reduced ejection fraction (< 40%), who remain symptomatic (NYHA II-IV) despite optimal treatment with an ACE-I, beta-blocker and MRA.
The aim of our study was to assess the indication and suitability of Sacubitril / valsartan in patients presenting with acute decompensated heart failure.
Methods: We performed a retrospective review of all patients admitted to a tertiary referral hospital during a one year period from 1st January to 31st December 2015, prior to the ESC recommendation of an ARNI, with a principal diagnosis of congestive cardiac failure. A total of 330 patients were included. The sub-group of patients with reduced ejection fraction were further analysed to assess suitability for Sacubitril / valsartan.
Results: Heart failure with reduced Ejection fraction (= 40%) accounted for 102/330 (31%) of patients. 15/102 (14.7%) did not survive until discharge and one patient absconded from the hospital. Of the remaining 86 patients, 13 had an estimated glomerular filtration rate (eGFR) less than 30 ml/min/1.73m2.
At the time of discharge of the remaining 73 patients, 62% were on an ACE-I or ARB, 70% were on a beta-blocker, and 34% were on a mineralocorticoid receptor antagonist.
18 out of 73 (25%) were prescribed each of an ACE-I(or ARB), a beta-blocker, and mineralocorticoid receptor antagonist.
Conclusion: The angiotensin receptor neprilysin inhibitor sacubitril/valsartan represents a new option in the pharmacological treatment of HFrEF. When the inclusion / exclusion criteria of PARADIGM-HF are applied to real world heart failure admissions, the majority of patients will be excluded. Only 45/330 or 13.6% of patients in this cohort would have been suitable for commencement on sacubitril/valsartan.
The majority of patients (<70%) in PARADIGM-HF were NYHA class I or II, therefore we must attempt to identify these patients in an outpatient setting prior to their presentation to hospital with an episode of decompensation.



Suitability for Sacubitril / Valsartan

Acute Heart Failure - Clinical

P2236
Differences in quality of life between acute heart failure patients with and without comorbidities

J C Van Den Berge[1]; LC Van Vark[1]; E Boersma[1]; HL Hillege[2]; I Lesman-Leegte[2]; KM Akkerhuis[1]
[1]Erasmus Medical Center, Department of Cardiology, Rotterdam, Netherlands; [2]University Medical Center Groningen, Department of Epidemiology, Groningen, Netherlands

Background: Heart failure (HF) patients with comorbidities have higher morbidity and mortality than those without comorbidities but little is known about differences in quality of life (QoL) between HF patients with and without comorbidities.
Purpose: We compared the QoL and the determinants of Qol of patients with HF with and without comorbidities.
Methods: This multicentre, clinical cohort study included patients with acute HF in the Netherlands. At discharge, patients were asked to complete the Kansas City Cardiomyopathy Questionnaire (KCCQ) and Hospital Anxiety and Depression Scale (HADS). History of cerebrovascular accident, diabetes mellitus, chronic kidney disease and chronic obstructive pulmonary disease (COPD) were considered as the most significant comorbidities.
Results: We included 327 patients (72 years old, 65% male) who completed at least one questionnaire at discharge. Of these, 198 patients (61%) had at least one comorbidity. Patients without comorbidities had lower New York Heart Association (NYHA) class, more depression and higher KCCQ scores, corresponding with better QoL (Table). Male sex, higher NYHA classification, previous HF, ischaemic aetiology, COPD, higher BMI, lower systolic blood pressure and higher NT-proBNP were associated with a worse QoL in the total population. These factors were also determinants of QoL in patients with comorbidities but not in those without comorbidities.
Conclusions: Acute HF patients with comorbidities had higher NYHA class at discharge, worse QoL and more depressive symptoms than patients without comorbidities. Furthermore, the determinants of QoL differed between patients with and those without comorbidities.

Table. NYHA classification and QoL score

		Comorbidity -	Comorbidity +	p value
NYHA class	I/II	71 (66)	88 (54)	0.049

P2237
Evaluation of worsening renal function in patients with acute decompensated heart failure, depending on ngal changes

I Igor Gorda[1]; E Amosova[2]; A Bezrodnyi[2]
[1]Kiev Alexander Clinical Hospital, Kiev, Ukraine; [2]O. O. Bogomolets National Medical University, Kiev, Ukraine

Background: Our purpose was to determine the value of worsening renal function (WRF) depending on the NGAL and in so-called "wet and warm" patients with acute decompensated heart failure (ADHF).
Methods: In 141 patients with ADHF at the age of 38 to 85 years old (mean age 66,4 ± 2,2) were involved in the prospective study. Worsening renal function (WRF) for creatinine occurred in 38 (27%) patients (WRF+), including 23 pts with increasing NGAL on D3 more than 15% relative to D1 (WRF+NGAL+) and 15 pts without (WRF+NGAL-)

P2237

	No WRF	WRF+ NGAL -	WRF+ NGAL+	P1-2	P1-3	P2-3
Dyspnea Borg D1	7,8 ± 0,47	8,1 ± 0,49	8,9 ± 0,53		p <0,05	
Dyspnea Borg Dsc	2,5 ± 0,15***	2,9 ± 0,17***	4,0 ± 0,24***		p <0,01	p <0,05
CVP,D1	174 ± 10,4	177 ± 10,6	196 ± 11,7		p <0,05	p <0,05
CVP D 4-6	83 ± 4,98***	89 ± 5,34***	110 ± 6,60***		p <0,01	p <0,05
E/E' D1	18,1 ± 1,09	18,6 ± 1,12	20,9 ± 1,25***		p <0,05	p <0,05
E/E' Dsc	12,9 ± 0,77 ***	14,1 ± 0,85**	16,8 ± 1,12**		p <0,05	p <0,05
Hospital period	11,8 ± 0,7	14,3 ± 1,0	16,7 ± 1,1	p <0,01	p <0,01	p <0,01

* - p < 0,05, ** - p < 0,01, *** - p < 0,001 compared to D1

Endpoints were CVP at days 4-6 (D 4-6), dyspnoe by Borg scale, E/E' at discharge (Dsc) and duration of hospital period.
Results: The WRF group with elevated NGAL differed from patients with WRF without elevated NGAL in dyspnoe, E/E' and CVP. In the same time the WRF group without elevated NGAL was comparable with no WRF group. The hospital period was the largest in WRF+NGAL+ group (see in table).
Conclusion: In the so-called "wet and warm" patients with ADHF WRF associated with an increase in signs of congestion only in patients with an increase in NGAL after 48 hours.

P2238
Hyperhydration by bioimpedance vector analysis at discharge is common and is associated with severe baseline congestion in patients with decompensated heart failure

M Bayarsaikhan[1]; A Soloveva[1]; V Aleshin[1]; A Metelkin[1]; S Villevalde[1]; Z Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), Department of Internal Diseases, Moscow, Russian Federation

Objective: Relieve of congestion is one of the main targets in treatment of patients with decompensated heart failure (DHF). The aim of the study was to assess the incidence and associations of residual congestion in patients with DHF using bioimpedance vector analysis (BIVA).
Methods: In 148 patients with DHF (99 male, 71 ± 11 years (M ± SD), arterial hypertension 95%, myocardial infarction 42.5%, atrial fibrillation 65%, diabetes mellitus 42.5%, chronic kidney disease 26%, ejection fraction (EF) 41 ± 14%, EF < 40% 44.6%, baseline NT-proBNP 4148 (1635;5567 pg/ml) hydration status was assessed by BIVA on admission and discharge, using resistance (R) and reactance (Xc) standardized by height (h). Less values of R/h and Xc/h mean more severe hydration. Deviation from the 50th, 75th and 95th vector percentile of the healthy reference population was considered as mild, moderate and severe hyperhydration. Hyperhydration by BIVA at discharge was defined as residual congestion. Mann-Whitney and Pearson chi-squire tests were performed. P < 0.05 was considered significant.
Results: 64.2% of patients had residual congestion by BIVA (mild, moderate and severe in 25.7, 31.1 and 7.4% of cases). Patients with vs without residual congestion had higher rate of baseline severe hyperhydration by BIVA (61 vs 26%, p < 0.001), lower baseline R/h (226 ± 49 vs 245 ± 40 Om/m, p = 0.008) and Xc/h (17 ± 5 vs 20 ± 5 Om/m, p = 0.002), achieved R/h (260 ± 48 vs 315 ± 49 Om/m, p < 0.001) and Xc/h (21 ± 4 vs 30 ± 5.5 Om/m, p < 0.001), absolute ?R/h (32 (10;56) vs 63 (43;89) Om/m, p < 0.001) and ?Xc/h (3.6 (1.1;7.1) vs 9.5 (6.3;13.7) Om/m, p < 0.001), relative ?R/h (14 (4;29) vs 26 (19;37) %, p < 0.001) and ?Xc/h (24 (5;53) vs 49 (28;83) %, p < 0.001). Patients with vs without residual congestion more often had oedema on admission (98 vs 89%, p = 0.017) and at discharge (48.4 vs 11.3%, p < 0.001), inferior vena cava (IVC) dilation (62 vs 43%, p = 0.028), hydropericardium (29 vs 13%, p = 0.026), absence of IVC collapsibility (65 vs 43%, p = 0.009), higher IVC diameter (24 (22;27) vs (23 (20;24) mm, p = 0.007) and pulmonary artery pressure (51 (40;68) vs 46 (33;58) mmHg, p = 0.028), received longer and higher dose of iv furosemide therapy (7 (5;9) vs 6 (4;8) days, p = 0.037, total dose (640 (420;940) vs 360 (240;780) mg, p = 0.012) and maximum daily dose (100 (80;160) vs 80 (60;120) mg, p = 0.032), had lower rate of switching to per os furosemide therapy (80 vs 94%, p = 0.019) and thiazide therapy (9.5 vs 24.5%, p = 0.042).
Conclusions: 64.2% of patients with residual congestion had more pronounced baseline BIVA hyperhydration, IVC dilation and diameter, hydropericardium. Despite more intensive loop diuretic therapy patients with vs without residual congestion had higher rate of oedema at discharge and lower R/h and Xc/h dynamics. BIVA can be a useful tool in monitoring congestive status in DHF.

Coronary Artery Disease - Pathophysiology and Mechanisms

P2239
Chronobiology in acute coronary syndromes, is global warming changing our incidence?

JP Gameiro[1]; L Teles[1]; MJ Vieira[2]; JP Sousa[1]; L Puga[1]; J Ribeiro[1]; J Silva[1]; L Goncalves[1]
[1]University Hospitals of Coimbra, Cardiology B, Coimbra, Portugal; *[2]Hospital of Santarem, Santarem, Portugal*

Introduction: The chronobiology of many cardiovascular syndromes is very well described in the literature, with seasonal variations on the incidence of heart failure acute episodes and hypertensive emergencies. However, the data concerning acute coronary syndromes are controversial and dependent on the climate variation of which region.
Purpose: Evaluate the existence of significant differences in the seasonal distribution of acute coronary syndromes at the centre region of Portugal.
Methods: A retrospective study, including all the patients admitted with acute coronary syndrome on the emergency room at one medical centre, between January 2009 and December 2013. We proceeded to the evaluation of the seasonal distribution (spring, summer, autumn and winter) of those syndromes in general and then divided by the 3 types (STEMI, NSTEMI and unstable angina). The statistical analysis was made using SPSS version 23. Significance chi-squared (X2) tests were applied.
Results: In this study, 1281 patients were included with the diagnosis of acute coronary syndrome (mean age of 68 ± 13.2 years) with predominance of the masculine gender (69.5%). Of those episodes, 37% were classified as STEMI, 42% classified as NSTEMI and 17% classified as unstable angina. The autumn season was the one with the most acute coronary syndrome episodes (27.5%). The general distribution of the acute coronary syndromes correlated significantly with the different seasons (X2 = 11.768, p-value= 0,008). The distribution of the 3 types of syndromes, did not presented significant statistical differences during the four seasons (X2 pearson = 11,301, p-value= 0.26).
Conclusions: The different seasons of the year have an impact on the incidence of the acute coronary syndromes. The autumn was the season with most cases, a fact that was not observed on other european countries. The type of acute coronary syndrome (STEMI, NSTEMI and unstable angina) was not influenced by the different seasons.

P2240
Evaluation of the role of ischemia reversal programme in ischemic heart disease using stress myocardial perfusion imaging: A pilot study.

RM Sane[1]; R Rahul Mandole[1]
[1]Madhavbaug Multidisciplinary Cardiac Care Clinics and Hospitals, Mumbai, India

Funding Acknowledgements: Vaidya Sane Ayurvedic Education and Agricultural Trust

Background: Ischemic heart disease (IHD) incidence has increased in India at a rapid speed and shows regional variations, early onset, greater mortality and poor management. Stress thallium test is useful in diagnosing IHD early in patients who may be at risk for a heart attack.T he aim of the present study was to assess the cardiac muscle activity in IHD patients before and after ischemic reversal programme (IRP).
Methods: The present open label study involved fourteen IHD patients who underwent IRP (21 IRP sittings) at multiple centres. The inclusion criteria were patients with known IHD, age group between 40-70yrs, BMI >20kg/m2, and stress test positive for inducible ischemia. However, patients with recent myocardial infarction/ known hypo- or hyper- thyroidism/ chronic kidney disorder were excluded. Stress thallium test was performed after - enrolment, 21 IRP sittings and 25-30 IRP sittings. VO2max

and time of ischemia after stress test were also recorded in all the patients. Further, Seattle Angina Questionnaire (SAQ) was taken via telephonic conversation by research coordinators.
Results: Observations from Stress thallium test showed significant difference in Summed Stress Score [SSS] (13.5 ± 10.3, baseline vs. 10.7 ± 10.1, post 21 IRP sittings; p = 0.01) as well as Summed Difference Score [SDS](8.9 ± 6.2, baseline vs. 6.2 ± 6.3 , post 21 IRP sittings; p = 0.03) in IHD patients. Similarly we observed increase in VO2max levels (12.8 ± 5.7, baseline vs. 19.4 ± 7.8, post 21 IRP sittings and 23.6 ± 6.0, post 25-30 IRP sittings) and time of ischemia in seconds (370.7 ± 201.1, baseline vs. 597.8 ± 201.9, post 21 IRP sittings and 702.0 ± 138.0, post 25-30 IRP sittings).Further assessment of SAQ scores showed significant improvement post IRP (30.2 ± 3.6, baseline vs. 32.7 ± 3.5, post 21 IRP sittings) whereas, ejection fraction score was not found to be significantly changed post IRP as compared with baseline.
Conclusion: Results of the present study suggest an improvement in cardiac muscle activity after IRP in IHD patients and depicts positive role of IRP in IHD management.

Coronary Artery Disease - Treatment

Veno-arterial extracorporeal membrane oxygenation in patients with massive pulmonary embolism: single center experience

J Jorge Garcia Carreno[1]; I Sousa Casasnovas[1]; M Juarez Fernandez[1]; C Devesa Cordero[1]; V Bruna Fernandez[1]; F Diez Delhoyo[1]; R Sanz Ruiz[1]; F Fernandez Aviles[1]; M Martinez Selles[1]
[1]*University Hospital Gregorio Maranon, Madrid, Spain*

Introduction: Massive pulmonary embolism (PE) is a critical condition with a wide mortality range from 25% to 65%, especially in patients with hemodynamic instability or cardiac arrest. Pulmonary reperfusion therapies are indicated in this kind of patients in order to reduce right ventricle afterload and correct ventilation/perfusion mismatch. Systemic thrombolysis is the most validated therapy but its potential benefit is often offset because of its bleeding effects. There is limited data about the use veno-arterial extracorporeal membrane oxygenation (VA-ECMO) in the setting of massive PE.
Purpose: It is difficult to routinely implant VA-ECMO in patients with massive PE and cardiogenic shock because it requires the availability of an interventional cardiologist or a cardiac surgeon, who will cannulate and decannulate the ECMO system, and facultatives with expertise in extracorporeal life support, who will manage the mechanical support in the acute critical care unit. We present our experience in the use of VA-ECMO in patients with high risk PE.
Methods: We conducted a retrospective analysis of data prospectively collected in a tertiary hospital. Massive PE was defined as low systolic blood pressure (< 90 mm Hg) requiring vasoactive drugs. The ECMO system was cannulated percutaneously, by the interventional cardiologist at the hemodynamic lab, using the Seldinger technique under fluoroscopy guidance. The usual approach consisted in advancing a 15-17 French (F) cannula to the descending aorta and placing a 21-23F cannula at the level of superior vena cava, through femoral access. A small anterograde cannula (5-6F) was placed in the superficial femoral artery. Anticoagulation with unfractionated heparin was provided both for the ECMO circuit and as treatment of PE.
Results: From November 2015 to January 2018, VA-ECMO was initiated in nine cases with massive PE, six were male and mean age was 58.2 ± 7.8 years. Every patient had severe right ventricle disfunction at admission. Mean serum lactate before VA-ECMO implant was 11.8 ± 3.2 mmol/L and five patients had cardiac arrest (55.6%). Pulmonary reperfusion either with thrombolytic drugs or mechanical thrombectomy was performed in five patients (55.6%). The mean time with VA-ECMO support was 3.3 days (SD 1.7) and the overall survival at hospitalization discharge was 44.4%. Interestingly, the survival among patients without pulmonary reperfusion, who only received anticoagulation and VA-ECMO support, was 100%.
Conclusion: In our experience, the use of VA-ECMO support in patients with massive PE is feasible, although it implicates high mortality rate. We believe that a "no reperfusion" approach with only VA-ECMO support and anticoagulation is superior to pulmonary reperfusion plus VA-ECMO, due to lesser coagulopathy and hemorrhagic events, resulting in better survival rate at discharge. Nevertheless, further studies with a larger cohort of patients are required in order to confirm these results.

P2242
Effect of different generations of drug-eluting stents on the prognosis of patients with stenting unprotected left main coronary artery.

Z KH Shugushev[1]; D A Daniil Maximkin[1]; AG Chepurnoy[1]; OO Safonova[1]
[1]*Peoples Friendship University of Russia (RPFU), Moscow, Russian Federation*

Aims: to evaluate long-term results of patients who underwent unprotected left main coronary artery (ULMCA) interventions with different generations of drug-eluting stents (DES).
Methods: there is long-term comparative clinical outcome data of percutaneous coronary intervention (PCI) in unprotected left main coronary artery (LMCA) disease treated with the single (provisional-T) stent technique in the drug-eluting stent (DES). The primary outcome was the occurrence of major adverse cardiac events (MACE) defined as total death, non-fatal myocardial infarction (MI), target lesion revascularization (TLR). Data from a single center registry, which included 189 patients, who ULMCA PCI with different generations DES. All interventions were conducted by final 'kissing-balloon' dilatation with high pressure balloons and under IVUS/OCT guidence. Long-term results were assessed by following criteria: frequency of MACE (death, myocardial infarction, re-intervention), IVUS//OCT data (residual area of vessel lumen in the proximal segment of LM, zone of bifurcation, the ostia of LAD and LCx).
Results: there were 72 patients receiving everolimus-eluting stent (EES) second generation ('Xience V'), 68 patients receiving biolimus-eluting stent (BES) third generation ('Nobori'), and 49 patients receiving everolimus-eluting stent (EES) IVth generation ('Synergy'). During 12-months follow-up, the PS adjusted Cox-proportional hazard ratio (HR) was not significantly different between the three groups for total death, cardiac death, TLR and MI. The narrowing of LCX ostial area at follow-up was more pronounced in BES compared with EES (13.2% vs. 2.5%, respectively, p <0.001). Linear regression analysis showed a high correlation between the number of stent struts in LCX ostium and ostial area narrowing (r = 0.771, p <0.001). Re-intervention was required in the LCX ostial area only in 3,1% of cases in group second generation EES and in 5,6% of third generation BES. During 3-years follow-up, there was no statistical difference in major adverse cardiovascular events, cardiac death, myocardial infarction and stent thrombosis between the groups different generations stents (HR: 0.63, 95% Confidence interval (CI): 0.33-1.17; P = 0.149).
Conclusions: The endovascular treatment of patients with unprotected left main bifurcation lesions with different generations of drug-eluting stents is associated with good long-term clinical outcomes. Clinical outcome seems to be independent of lesion complexity and the number of stent struts in LCX ostium. There are no differences in clinical events among patients receiving different generation drug-eluting stents for ULMCA disease.

P2243
The impact of soluable st2 to predict mortality and morbidity in patients with impaired left ventricular function undergoing coronary artery graft bypass surgery

A Ahmet Dolapoglu[1]; E Avci[2]; T Yildirim[3]; H Kadi[2]; A Celik[4]
[1]*Balikesir Ataturk State Hospital, Cardiovascular Surgery, Balikesir, Turkey*; [2]*Balikesir University, Cardiology, Balikesir, Turkey*; [3]*Balikesir State Hospital, Cardiology, Balikesir, Turkey*; [4]*Mersin University, Cardiology, Mersin, Turkey*

Funding Acknowledgements: MeDar Saglik A.S.

Background: This study was aimed to investigate the prognostic value of soluble ST2 (sST2) for perioperative early mortality and morbidity in patients with impaired left ventricular ejection fraction (LVEF) and stable coronary artery disease (SCAD) undergoing coronary artery graft bypass (CABG) surgery.
Methods: 80 consecutive patients with SCAD and impaired left ventricular function (ejection fraction = 45%) underwent on-pump coronary artery bypass graft surgery were included into the study. We measured baseline ST2 preoperatively. The association between baseline sST2 levels and early perioperative mortality, postoperative adverse outcomes and length of stay were assessed.
Results: Patients were divided two group according to sST2 level of 35 ng/ml. Patients with sST2 >35 ng/ml (n = 14 patients) had an increased perioperative early mortality (p = 0.029), need of postoperative inotropic agents (p < 0.0001) and need of intraaortic balloon pump (p = 0.002). While LVEF was significantly lower (p = 0.019), left ventricular end-diastolic diameter (LVEDD), New York Heart Association (NYHA) class, Syntax score and NT-pro BNP levels were significantly higher in this group (p = 0.043, p = 0.0009, p < 0.0001 and p < 0.0001 respectively). And also postoperative complications such as arrhythmia and respiratory failure were more common and postoperative length of stay was significantly longer in patients with elevated ST2 level. In univariate regression analysis, sST2 was associated with increased postoperative mortality risk (p = 0.0068).
Conclusion: Higher sST2 levels were associated with adverse outcomes after CABG in patients with impaired LVEF and SCAD. Preoperative sST2 levels may predict postoperative outcomes after surgery in these patients with other traditional surgical risk scores.

Influence of age on quality of life after operative myocardial revascularization

K Katharina Huenges[1]; A Lorey[1]; B Panholzer[1]; J Jussli-Melchers[1]; P Kolat[1]; T Puehler[1]; J Cremer[1]; A Haneya[1]
[1]*University Medical Center of Schleswig-Holstein, Cardiovascular Surgery, Kiel, Germany*

Background: Relevant coronary artery disease still has a high prevalence in the western world, especially in younger patients surgical strategies might be beneficial for survival and outcome. But the impact of surgery on postoperative quality of life remains vague.
The possible influence of age on quality of life after operative myocardial revascularization (CABG) was evaluated in this study.
Methods: After informed consent and approval of our local ethic committee, patients with operative myocardial revascularization between 2005 and 2012 were analyzed in this retrospective study. Preoperative baseline characteristics, perioperative data and outcome were collected. Postoperative quality of life was assessed with the SF-36 questionnaire. Patients were divided into two groups, group young (age <50 years) and group elderly (>80 years).
Results: A total of 790 patients with operative myocardial revascularization were identified. Patients with combined procedures were excluded. In the young group were n = 305 patients and in the elderly group n = 485 patients. Elective surgery was more often in the elderly group (49.8% vs. 66.2%, p = 0.02). Severe reduced left ventricular function was more common in the young group (8.9% vs. 3.7%).
Perioperative data was comparable within both groups. After discharge and rehabilitation the patients were followed-up for assessment of quality of life.
The SF-36 questionnaire was conducted in 287 patients (young group: n = 175, elderly group: n = 112). It revealed no significant difference comparing the subscales social role functioning (83.7 vs. 79.5, p = n.s.), mental health (72.5 vs. 70.0, p = n.s.) and physical functioning (61.7 vs. 59.2, p = n.s.) between the young and elderly group. But subscale scores were higher in the younger group regarding bodily pain (81.0 vs. 25.1, p <0.01) general health perceptions (76.0 vs. 52.5 p <0.01), physical role functioning (55.2 vs. 20.2, p <0.01, vitality (70.1 vs. 47.4, p <0.01), emotional role functioning (78.2 vs. 68.4, p <0.03)
Conclusion: Even though in the younger patients more often preoperative cardiopulmonary reanimation and emergent surgery were required, young patients seem to benefit from operative myocardial revascularization with higher physical quality of life subscales. However, mental health did not differ between the two groups and also in the octogenarians elderly group satisfying results can be generated with regard to quality of life after operative myocardial revascularization.

Valvular Heart Disease - Epidemiology, Prognosis, Outcome

P2245

The five-year prospective observation of patients with rheumatic heart disease

V Petrov[1]; S Iakushin[1]; E Evgeny Philippov[1]
[1]*Ryazan State Academician I.P. Pavlov Medical University, Ryazan, Russian Federation*

The presence of valvular disease, especially stenosis, leading to pressure overload is an indication for surgical correction of the defect. Questions of medical therapy before a surgical correction of the recommendations discussed little.
Objective: investigate heart failure, quality of life and the possible causes of death in patients with rheumatic heart diseases.
Methods: The study involved 123 persons with rheumatic heart disease (RHD), including 16 patients who died. The average age of patients 57,56 ± 0,98 years; 31 (25.2%) men and 92 (74.8%) women.
Results: Patients at CHF FC as follows: I FC - 25.7%; FC II - 45.7%; FC III - 20,0%, IV FC - 5.7% and the dynamics for 5 years was not observed. Comparison of the results of the test 6 min walk showed no change in functional class CHF. There was only a significant increase in the linear dimensions of the left atrium (LA), from 4,5 to 4,8 ± 0,09 cm.
According to the SF 36 there was no significant difference in the physical health component (from 31,59 ± 1,02 to 32,47 ± 1,18) and the mental component of health (from 38,85 ± 1,67 to 35,85 ± 1,04).
Only 32 (29.9%) patients were operated: from 6 commissurotomy performed, in 26 prostheses. On average, after surgery before the study took 7.5 ± 1.4 years. The age of patients (58,14 ± 1,49 - operated and 56,26 ± 1,3 - non-operated), the size of heart chambers, the test results 6 min walk (359,92 ± 14,3 m - operated and 355 5 ± 18,25 m - non-operated) did not differ significantly.
The frequency of prescribing for HF was next): ACE inhibitors - 73.3%, ßAB - 60.0%, digoxin - 62.7%, spironolactone - 73.3%, loop diuretics - 32%, aspirin - 63 %, amiodarone - 7.4%, verapamil - 4.6%. From ßAB often used metoprolol tartrate - 66,7%, bisoprolol - 16.7%, carvedilol - 5.6% and 5.6% of nebivolol. Because ACE inhibitor enalapril more often used - 52.2% and perindopril - 23.9%, less lisinopril - 17.4% and fosinopril - 4.3%.
In the analysis of 16 patients who died within 5 years following the data obtained in the rheumatology department: the average age of the deceased was 60,6 ± 2,1 years; 12 patients (75.0%) as a cause of death, heart failure decompensation set against the backdrop of the mitral or aortic stenosis. Among frequent concomitant diseases to be noted permanent atrial fibrillation - 75%, and diabetes - 50%. In patients who died echocardiography data differed significantly from that of the whole group: the linear dimensions of the LA (5,24 ± 0,18 cm vs 4,8 ± 0,12 cm) and the area of the mitral orifice (1,19 ± 0,16 cm2 vs 1,73 ± 0,09 cm2)
Conclusions: In patients with chronic rheumatic heart disease for 5 year follow-up there is no progression of chronic heart failure and a significant deterioration in the quality of life, despite the negative trend indicators echocardiography. The combination of atrial fibrillation, type II diabetes, severe mitral stenosis and left atrial dilation increases the risk of death in patients with chronic rheumatic heart disease.

P2246

The impact of the infective endocarditis restrictive prophylaxis in the complication rates

AC Ana Catarina Gomes[1]; I Cruz[1]; AI Marques[1]; S Alegria[1]; R Pereira[1]; D Sebaiti[1]; I Rangel[1]; I Joao[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Background: Despite improvements in management and treatment of infective endocarditis (IE), it is still associated with high morbidity and mortality. There is an increasing number of patients at risk of IE, particularly because of aging, long-term survival in congenital population and both valvular post-operative and post-device implantation. The 2015 ESC guidelines restricted IE prophylaxis to the population at high-risk to develop IE.
Methods: We studied the endocarditis population in our hospital in the last 10 years. The clinical and imaging data were collected as well as the complication rates.
Purpose: To study the difference between IE severity and complications until and after 2015, to assess the effects of less restrictive criteria for IE prophylaxis.
Results: 148 patients, 75% males, 61.5 ± 15.9 years. 51.4% with hypertension (HTN), 18.9% with diabetes mellitus (DM). Etiology of valvular heart disease: 2 patients with previous IE (infective endocarditis), 9 with degenerative disease, 1 with congenital heart disease, 1 with rheumatic heart disease. Comorbidities: heart failure (HF) in 27% (6.8% with HF device), pulmonary disease (PD) in 14%, chronic renal disease (CRD) in 14.9% (3.4% on haemodialysis (HD)), chronic hepatic disease (CHD) in 22.3%, HIV seropositive in 13.5%, cancer in 9.5%, 98.6% on immunosuppression (medical cause or drug-related).
76.4% with single valve endocarditis, 14.9% with double valve endocarditis. 56.8% with aortic valve disease, 39.2% with mitral valve disease and 13.5% with right valve heart disease. Native valve disease in 72.3%.
Echocardiographic presentation: vegetation in 80.4%, abcess in 13.5%, pseudoaneurism in 4.7%, valve obstruction in 6.1%, aneurysm in 3.4%, fistula in 4.1%. Regurgitation was observed in 54.1%.
Endocarditis complications: septic shock in 20.9%, embolic complications in 38.5%, local complications in 41.2%, death in 45.3%. Mortality causes: septic shock 12.2%, HF in 7.4%, septic embolization in 8.1%, tamponade in 0.7%.
The populations were similar in terms of gender (p = 0.56), HTN (p = 0.61), PD (p = 0.47), previously known valvular heart disease (p = 0.60), valvular aetiology (p = 0.29), native valve disease (p = 0.534), CHD (p = 0.36), cancer (p = 0.65), HIV infection (p = 0.58), IV drug use (p = 0.70). After 2015, pts had more DM (p = 0.04) and CRD (p = 0.02).
There was no difference in the total embolization rate (p= 0.03), cerebral embolization (p = 0.64), cardiac abcess (p = 0.72), pseudoaneurism (p = 0.21), fistula (0.56), obstruction (p = 0.32), septic shock (p = 0.12) and global mortality (p = 0.29). Although, there was more HF (p < 0.001) and large vegetations (p < 0.001) from 2015 on.
Conclusion: Patients with endocarditis until and after 2015 were similar in terms of risk factors for endocarditis. Although there were no differences in hard endpoints such as mortality and the majority of complications, we observed more HF and large vegetations in recent years.

Background: Orthotopic heart transplantation is a radical method of treatment of patients with terminal heart failure. Due to this surgical interventions are of particular interest and relevance as a "bridge" to heart tranplantation.
Purpose: to estimate the efficiency of surgical treatment of patients with terminal heart failure (HF).
Methods: The study included 60 patients in the status of UNOS 2. 35 patients with ischemic cardiomyopathy underwent coronary artery bypass grafting and atrioventricular valve repair (group 1). 25 patients with non-ischemic cardiomyopathy underwent surgery mitral valve repair (group 2). All patients underwent echocardiography and 6-minute walktest at baseline and in 6 months after surgery. In addition the quality of life was assessed in both groups of patients with the Minnesota Living with heart failure Questionnaire.
Results: Table 1 demonstrates parameters of intracardiac hemodynamics in both groups. An improvement in the quality of life was noted in 6 months after the surgery. It was confirmed by a decrease in the score on the Minnesota Living with heart failure Questionnaire (at baseline 64 points, in 6 months - 39 points, $p < 0.038$) The results of a 6-minute walk test significant increased (at baseline - 227 (185;290)m, in 6 months - 328 (196;310)m, $p < 0.041$).
Conclusion: Mitral valve repair in combination with myocardial revascularization in patients assigned to status UNOS 2 can be considered as a "bridge" to orthotopic heart transplantation.

Table 1. Characteristic of patients

Characteristics of patients (n = 672)	Values
Age, years*	64.3 ± 11.6
Atrial fibrillation, n (%)	311 (46)
Body mass index, kg/m^2*	26.9 ± 11.8
Chronic kidney disease (GFR < 60 ml/min/1,73 m^2), n (%)	201 (29.9)
Chronic obstructive airways disease, n (%)	69 (10.2)
Coronary artery disease, n (%)	189 (28.1)
Insulin dependent diabetes mellitus, n (%)	21 (3.1)
LV ejection fraction (%)*	56 ± 13
NYHA (classes)*	2.5 ± 0.5
Hemoglobin, g/dL*	13.6 ± 1.1
RDW (%)*	13.85 ± 2.1
Red blood cell count, mln/uL*	4.3 ± 0.6
EuroSCORE II*	3.92 ± 2.51
Postoperative Hs-TnT, ng/L*	417 ± 143
Aortic stenosis, n (%)	243 (36.1)
Aortic regurgitation, n (%)	208 (30.9)
Mitral stenosis, n (%)	112 (16.6)
Mitral regurgitation, n (%)	109 (16.2)

Abbreviations: ESII = EuroSCORE II, Hs-TnT = High sensitivity Troponin T, LV = Left Ventricular, RBC = Red Blood Cell Count, RDW = Red Cell Distribution Width.

P2248

High-sensitivity troponin T is a prognostic marker of postoperative hemodynamic instability in patients undergoing valve surgery

Introduction: Several studies have reported that elevated hs-TnT is associated with poor outcomes in patients with myocardial infarction or heart failure. The usefulness of hs-TnT as a predictor of perioperative hemodynamic instability in patients undergoing valve surgery is currently unknown.
Methods: A prospective study was conducted on a group of 672 consecutive patients with significant valvular heart disease who underwent valvular surgery. The primary end-point at the 30-day follow-up was perioperative hemodynamic instability defined as the need for a supply of catecholamines more than 48 hours after completing the cardiopulmonary bypass surgery.
Results: The perioperative hemodynamic instability occurred in 230 patients. At multivariate analysis: hs-TnT (P = 0.01) and RDW (P = 0.0006) remained independent predictors of the primary end-point.
Conclusions: Elevated postoperative hs-TnT was associated with a poorer outcome in patients following heart valve surgery in a 30-day follow-up.

P2249

TAVI on cardiopulmonary bypass; our experience in patients with a very low ejection fraction .

C Corrado Cavozza[1]; AA Audo[1]; AC Campanella[1]; CM Coscia[1]; BP Bianchi[1]; AC Cardinale[1]; PG Parodi[1]; EM Martuscelli[1]; CZ Zazza[1]; GM Mai[1]
[1]Ospedale SS. Antonio e Biagio e Cesare Arrigo, cardiothoracic and vascular department, Alessandria, Italy

Objective: Severe left ventricular dysfunction negatively impacts short and long-term survival after conventional aortic valve replacement . A subgroup of these patients with very low ejection fraction (EF= 20%) shows the highest operative risk. Transacatheter aortic valve implantation on cardiopulmonary bypass might be beneficial, either allowing better tolerance of rapid pacing and a precise prosthetic valve deployment, either improving the outcome.
Methods: Ten high-risk patients discussed in an interdisciplinary heart team, after informed consent, underwent TAVI using balloon expandable device. According to our institutional TAVI evaluation protocol, in every patient, a preoperative coronary angiogram, a transesophageal echocardiogram and an angio-CT scan were performed.
Results: Transacatheter aortic valve implantation was performed in a hybrid operative theatre by an interdisciplinary team of cardiac surgeons, cardiologists and cardiac anesthesists.
Cardiopulmonary bypass was instituted via femoro-femoral in all patients. The transcatheter valves were implanted using femoral, transapical approach. All patients

survived to the procedure and were discharged from the hospital uneventfully. Left ventricular ejection fraction increased
Conclusions: According to our experience, TAVI on cardiopulmonary bypass allows a safer treatment of high risk patients with a very low ejection fraction, in whom should be contraindicated both conventional AVR and TAVI.

Myocardial Disease - Clinical

P2250
The value of cardiovascular magnetic resonance in myocarditis with different clinical presentation

E M Elena Gupalo[1]; NA Mironova[1]; OV Stukalova[1]; PV Chumachenko[1]
[1]Russian Cardiology Research Center, Moscow, Russian Federation

Clinical manifestations of myocarditis vary from subclinical status to severe heart failure and cardiac arrhythmias also it can mimicking acute coronary syndrome. The diagnosis is based on the endomyocardial biopsy (EMB) which is strongly limited by possibility of complications. The only noninvasive alternative is cardiovascular magnetic resonance (CMR), but its diagnostic value may be different.
Purpose: to determine the value of CMR in patients (pts) with different clinical forms of myocarditis and to compare CMR with EMB data.
Methods: and Materials: 11 pts (group I, mean age 32.8 ± 11.1 years, 8 male) with infarct-like clinical presentation (troponin positive chest pain, changes on ECG, preserved contractility, normal coronary angiography); 48 pts (group II, mean age 43.1 ± 12.7, 31 male) with heart failure and sighs of non-coronary dilated cardiomyopathy (end diastolic diameter 7.0 ± 0.84 sm, left ventricular ejection fraction (LV EF) 30.1 ± 7.6%,) and 20 pts (group III, mean age 39.5 ± 14, 12 male) with sustained or non-sustained ventricular tachycardia, decreased LV EF (42.8 ± 8.8%) and excluded coronary artery disease underwent CMR with assessment of myocardial edema (ME), early (EGE) and late gadolinium enhancement (LGE). In 38 pts EMB was performed.
Results: CMR had maximal diagnostic value in group I pts : subepicardial or midwall, inferolateral or septal LGE lesions indicated inflammation in 9 (81.8%) pts. In 8 (72.7%pts) LGE was accompanied with ME, in 4 (36.3%) pts EGE was detected. In group II various LGE lesions (the most common were subepicardial or midwall, sometimes in combination with subendocardial or transmural) were found in 27 (56.3%), EGE - in 7 (14.6%) and ME in 10 (20.8%) pts. In group III 17 (85%) pts were LGE, 4 (20%) were EGE positive and in 7 (35%) pts ME was detected. LGE lesions were various and reminded the LGE lesions in group II. According to CMR data we denoted active inflammation in the presence of = 2 positive MRI criteria (n = 21), in pts with isolated LGE - resolved inflammation (n = 33), in pts with = 1 phenomenon (EGE or ME only) - minimal structural changes (n = 25). EMB confirmed active inflammation in 13 (34.2%) of pts (Fig 1A). In 11 (28.9%) pts EMB revealed resolved myocarditis with huge areas of fibrosis (Fig. 1B). In 14 cases (36.8%) the sighs of active inflammation were not detected and the morphological changes were minimal (Fig. 1C). According to above mentioned classification for both EMB and CMR data the total sensitivity of cardiac MRI was 76.9% with 66.7% specificity.
Conclusion: CMR gives key diagnostic information in pts with infarct-like clinical presentation of myocarditis. In pts presented with heart failure of ventricular tachycardia the introduced classification (active or resolved inflammation, minimal structural changes) increases the value of CMR and may be used in the definition of further diagnostic steps (f.e. EMB or ICD implantation

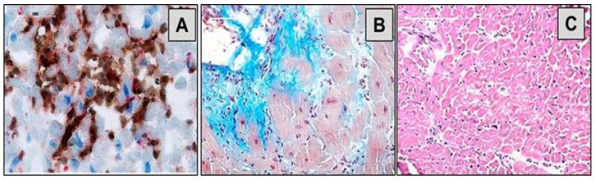

Fig. 1. The EMB samples. A – EMB samples of pts with **active myocarditis** manifesting with focal inflammatory cells infiltration (immunohistochemistry double staining for CD3+ (pink) and CD68+ (brown) cells); B – EMB samples of pts with **resolved myocarditis** (no inflammatory cells infiltration) and huge areas of focal fibrosis. Masson's trichrome staining (collage fibers are stained blue); C – EMB sample of patient with **minimal morphological changes.** Hematoxylin and eosin staining.

P2251
Immunosuppressive therapy of biopsy proved immune-mediated lymphocytic myocarditis in the virus-negative and virus-positive patients

O V Olga Blagova[1]; AV Nedostup[1]; EA Kogan[1]; AE Donnikov[2]; VV Kadochnikova[2]; VA Zaidenov[3]; AG Kupriyanova[4]
[1]I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation; *[2]DNA technology, Moscow, Russian Federation*; *[3]Institute of Transplantology and Artificial Organs, Moscow, Russian Federation*; *[4]Moscow Institute for Paediatry and Pediatric Surgery, Moscow, Russian Federation*

Purpose: to study the effect of immunosupressive therapy (IST) in the virus-negative and virus-positive patients with biopsy proved immune-mediated subacute / chronic lymphocytic myocarditis.
Methods: in 60 patients (45 male, 46.7 ± 11.8 years, mean left ventricle, LV, end-diastolic diameter, EDD, 6.7 ± 0.7 cm, LV ejection fraction, EF, 26.2 ± 9.1%) active/borderline myocarditis was verified by endomyocardial biopsy (n = 38), intraoperative biopsy (n = 10), examination of explanted heart (n = 3) and autopsy (n = 9). Anti-heart antibodies measurement as well as virus detection were performed. Indications for IST determined individually based on histological, immune, viral activity. The mean follow-up was 19.0 [7.25; 40.25] months.
Results: The viral genome in the myocardium was detected in 32 patients (V+ group), incl. parvovirus B19 in 23. The degree of histological activity did not differ depending on the presence of the viral genome in the myocardium. At baseline V+ patients had greater LV EDD compared with V- patients (6.8 ± 0.7 v 6.4 ± 0.7 cm) and lower EF (24.2 ± 9.1 v 29.5 ± 8.3%), p <0.05. The anti-heart antibody level was equally high in the V+ and V- patients. Antiviral therapy was administered in 24 patients. IST (in 22 V+ and 24 V- patients) include steroids (n = 40, 30 [20; 40] mg/day), hydroxychloroquine (n = 20, 200 mg/day), azathioprine (n = 21, 150 [75; 150] mg/day). The significant decrease of NYHA class (3 [3;3] to 2 [1;2], ? <0.001), LV EDD (6.7 ± 0.7 to 6.4 ± 0.8), systolic pulmonary artery pressure (48.9 ± 15.5 to 39.4 ± 11.5 mm Hg, ? <0,01), increase of LV EF (26.5 ± 0.9 to 36.0 ± 10.8), and significantly lower mortality (23.9% and 64.3%, p <0.01; RR 0.37, 95% CI 0.19-0.71) were found only in IST group. The best result is received in group V- patients with IST (EF increased from 28.2 ± 9.2% to 40.7 ± 9.8%, p <0.001). Significant improvement due to IST were achieved not only in V-, but also in V+ patients (EF increased from 24.7 ± 9.0% ?? 31.0 ± 9.8%, p <0.01). Only in V+ patients without IST no positive dynamics were observed, there was a trend to a decrease in EF. The mortality and the need for surgical treatment were highest in the V+ patients not receiving ICT. V+ patients had significantly higher mortality in comparison with V- patients (42.3 v 16.0%, p <0.01, RR 2.64, 95% CI 1.44-4.86). But mortality was lower in V+ patients receiving IST in comparison with V+ patients without IST (36.4% v 70.0%, p = 0.082)
Conclusions: IST in patients with immune-mediated lymphocytic myocarditis is effective and is associated with lower mortality both in virus-negative and virus-positive patients. The presence of the viral genome in the myocardium (especially herpes virus, but not parvovirus B19) followed by more severe dysfunction, less pronounced effect IST and higher mortality. The virus-positive patients in the absence of IST had no clinical improvement. The increasing in ejection fraction in the first 2 months of more than 10% associated with a good prognosis.

P2252
heart failure connected death in hypertrophic cardiomyopathy: clinical phenotype and mutation range

S Svetlana Komissarova[1]; N Chakova[2]; S Niyazova[2]; E Zakharava[1]
[1]Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus; *[2]Institute of Genetics and Cytology of NAS, Minsk, Belarus*

Purpose: to assess clinical phenotype and mutation range in genes encoding sarcomere proteins of cardiomyocytes in patients with hypertrophic cardiomyopathy(HCM) with CHF progression to III-IV functional class(NYHA).
Methods: structural and hemodynamic parameters were examined in 345 unrelated patients with HCM(199 males and 146 females,age from 17 to 72 years,median age 47 years) by echocardiography,heart MRI, 24-hour ECG-monitoring.Mutation search in encoding sequences of genes CTC1, MYBPC3, MYH7, MYL2, MYL3, TNNI3, TNNT2 and TPM was carried out by next generation sequencing(NGS) for 15 patients with CHF.Revealed mutations in near relatives were identified by the method of automatic Sanger sequencing.
Results: for the observation period(median of observation 6,7 years) adverse outcomes were registered in 7 patients:lethal outcome because of the CHF progression to "terminal stage" in 6(1,7%) out of 345 patients,acute disturbance of cerebral circulation with lethal outcome in 1 patient.Event-free median of survivability was 4,3 years.Symptoms progression to III-IV functional class (NYHA) happened in 9 (2,6%) out of 345 patients for the observation period.Genotyping was carried out in all patients with lethal outcome and in 8 patients with "terminal stage".Mutations which are the cause of HCM:Glu924Lys in MYH7 gene; Arg346His, Gln1233*(in 2 patients) in MYBPC3 gene and combination of two mutations

Glu1265Val+Cys1266Arg in MYBPC3 gene - were identified in 5 out of 8 patients with lethal outcome.Next mutations:Val186Leu, Arg663His,Glu930del,Glu1356Lys in MYH7 gene;Gln1233*(in 2 patients) and rp1007fs in MYBPC3 gene;combination of two mutations Glu1265Val + Cys1266Arg (1 patient) in MYBPC3 gene - were identified in 8 patients with CHF-progression to "terminal stage".Trp1007fs mutation leading to reading frame shift in MYBPC3 gene and forming of premature stop codon was detected for the first time.Mutation search among near relatives identified both genotype-positive/phenotype positive and genotype-positive/phenotype-negative family members.Female patient with Trp1007fs mutation in MYBPC3 gene had sudden cardiac death (SCD) in family anamnesis(son with the same replacement); male patient with Val186Leu mutation also had SCD in family anamnesis (daughter).Mother of male patient with Glu1356Lys mutation in MYH7 gene had the same mutation and died in 59-year age from CHF-progression.It should be noted that Gln1233* mutation was identified in 4 patients which indicates on it association with CHF development.Combination of two mutations Glu1265Val + Cys1266Arg in MYBPC3 gene was identified in 2 patients with this pathology one of which had died in 48-year age.There were no mutations in analyzed genes in 3 out of 15 patients.
Conclusion: genetic features along with clinical factors are markers of high risk CHF-progression and can be used for adverse outcomes prognostication in patients with HCM and for early diagnostics of the disease in their near relatives.

P2253

Nosologic spectrum and differential diagnosis in primary left ventriculare hyperthrophy syndrome: results of clinic, genetic and morphological studies

O V Olga Blagova[1]; AV Nedostup[1]; EA Kogan[1]; VP Sedov[1]; YV Frolova[2]; SL Dzemeshkevich[2]; ME Polyak[2]; EV Zaklyazminskaya[2]
[1]*I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation*; [2]*Russian Research Center of Surgery, Moscow, Russian Federation*

Purpose: to study the nosological variety of primary left ventricular hyperthrophy syndrome (LVHS) and the spectrum of morphological changes during its various forms.
Methods: in this register were included 46 adult patients (25 men, 45.8 ± 15.6 years) with primary LVHS (more than 12 mm). The exclusion criteria were athletic heart, hypertensive heart disease, severe valvular disease and other causes of secondary LVHS. We performed 11 endomyocardial biopsy, 8 intraoperative biopsy, 1 study of explanted heart, 1 autopsy with virus investigation (real-time PCR) of the blood and myocardium. Mutational screening had included NGS (Ion Torrent) simultaneous sequencing of the MYBPC3, TAZ, TPM1, LDB3, MYL2, ACTC1, MYL3, MYH7, TNNI3 ? TNNT2 genes and direct Sanger sequencing of target genes. Clinical examination had included ECG, Holter monitoring, EchoCG, coronary angiography, CT / MRI (by indication).
Results: In 20 patients was diagnosis of isolated hyperthrophic cardiomyopathy (HCM) established, another 10 have a combination of HCM and noncompaction myocardium (NCM). Mutations in MYH7 and MYBPC3 genes in six cases were detected. In 13 cases (28.3%) were non-sarcomeric causes of LVHS detected. In 3 patients was Fabry disease diagnosed, in 2 - Danon disease, in 6 - amyloidosis (AL and mutant in 1), in 1 - Friedreich ataxia, in 1 - syndrome LEOPARD (mutations in X-GAL, LAMP, TTR, FXN, PTPN11 genes were detected). In 2 patients the etiology of LVHS remains unclear (HCM? amyloidosis?). The nosological diagnosis is in 28.3% of patients genetically verified. In patients with HCM were significantly more frequent asymmetric septal hypertrophy with obstruction and muscle bridges, in other forms of primary hypertrophy - right ventricular hypertrophy, low QRS voltage, QS complexes and increasing of EF (54.1 ± 13.8% vs 63.6. ± 9.1% in HCM, $p < 0.05$). The morphologic signs of myocarditis were in 36.4% of biopsy detected: in 3 patients with NCM and in 4 patients with HCM. In two cases were identified lymphocytic infiltration in the endocardium (one patient developed thrombotic endocarditis after the myotomy). The viral genome in the myocardium was in 8 patients (72.6%) detected, previously human herpes virus type 6 (it was correlation with myocarditis in 75.0%), and also parvovirus B19 (without myocarditis in 71.4%). It was not myocarditis and virus in patients with storage disease. The patients with myocarditis had the higher NYHA class (3 [1; 3] vs 2 [1; 2]), left ventricular diastolic size (5.2 ± 1.3 vs 4.8 ± 0.3 cm) and lower EF (53.0 ± 22.4 vs 58.0 ± 13.8%), $p > 0.05$. In a follow-up of 12 months 11 patients with LVHS died due to a stroke / heart hailure.
Conclusion: The spectrum of causes of the primary syndrome of myocardial hypertrophy is very wide. The frequency of associated myocarditis was 36.4%. When lower EF and heart failure in patients with HCM can be result of myocarditis, in patients with storage disease they are the result of disease itself.

P2254

Multi-parameter approach to risk stratification of sudden cardiac death for family dilated cardiomyopathy

TG Vaikhanskaya[1]; TV Kurushka[1]; LN Sivitskaya[2]; NG Danilenko[2]; OG Levdanskiy[2]; OG Davydenko[2]
[1]*Republican Scientific and Practical Center "Cardiology", Minsk, Belarus*; [2]*Institute of Genetics and Cytology, National Academy of Science, Minsk, Belarus*

Background: Risk stratification for sudden cardiac death (SCD) in family dilated cardiomyopathy (fmDCM) remains a difficult and controversial issue. The primary prevention of SCD with ICD-device therapy is effective but it is challenging to ?nd optimal candidates - patients who can benefit from it.
The aim of this research was to study the multi-parameter data in patients with fmDCM for optimization of the SCD risk stratification to accordance identified predictors of life-threatening ventricular tachyarrhythmic events.
Materials and methods. The study included 60 unrelated patients with fmDCM (aged 37.4 ± 15.9 years, 37/61.6 % male, NYHA 2.27 ± 0.75, LVEF 31.6 ± 9.12 %, follow-up 38.4 ± 7.14 months). All patients underwent dynamic studies (Intecard-7 ECG, HM, Echo, LGE-CMR). The NGS method using the Nextera XT for searching of mutations in the genes of the cardiopanel Illumina Inc (USA) was performed.
Results: Pathogen mutations were detected in 27 (45 %) patients: 6 (10%) had non-synonymous nucleotide substitutions in the LMNA gene; in 21 pts mutations identified in other genes such as a TTN (3\5 %), MYH 6 (3\5 %), MYH7 (2\3.3 %), SCN5A (2\3.3 %); and by one mutation (1.6 %) in genes DES, ACTN2, BAG3, LDB3, LAMP2, MYBPC3, NEXN, TRPM4, ACTC1, MYPN. In the three-year follow-up period, 13 (22.03 %) patients had documented episodes of stable VT/VF (including 6\10 % carriers of LMNA mutations). The following events were accepted as primary endpoints: SCD, successful resuscitation, stable VT/FF, appropriated ICD\CRT-D shock. As a result of the Spearman correlation analysis, a positive correlation revealed with carrier LMNA mutations ($p = 0.0015$), septal ECG criteria (V1-V3: Q or QS, poor R wave progression, QRS fragmentation) and interventricular septal or ventricular ?brosis by LGE-CMR ($p = 0.0025$), myocardial global longitudinal strain deformation (GLS LV average: $p = 0.003$) and unstable fast-VT (= 5 ventricular complexes with HR = 150 bpm: $p = 0.003$); a negative correlation was detected with the LV ejection fraction ($p = 0.002$). The results of ROC analysis confirmed the significance of unstable fast-VT (AUC 0.771, $p = 0.001$), LGE-CMR ventricular ?brosis (AUC 0.775, $p = 0.001$) and LMNA mutations (AUC 0.716, $p = 0.002$).
Conclusion: Family DCM patients with LMNA mutations have poor prognosis. The obtained data confirm the strategic importance of genetic research of fmDCM pts to searching LMNA mutations for early prognosis of adverse outcomes. Risk strati?cation should include the assessment of ventricular ?brosis by LGE-CMR, in addition to GLS LV or EF LV, HM ECG and the genetic pro?le of the fmDCM pts when available. This could signi?cantly improve the appropriateness of ICD therapy for fmDCM pts to the direction of personalized and precision medicine.

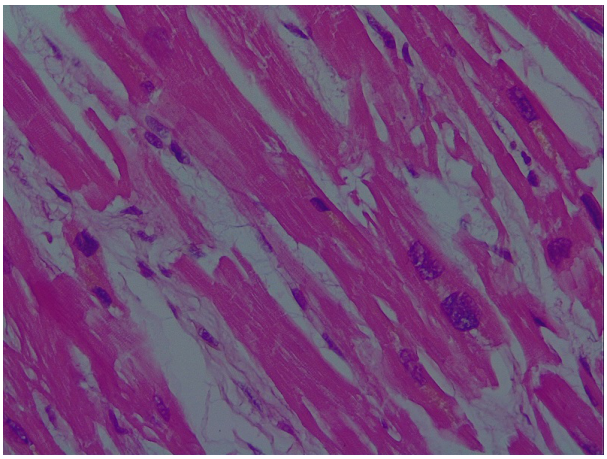
P2255

Dilated cardiomyopathy - from clinic to pathology

O Ovidiu Tica[1]; M I Popescu[2]; O A Tica[2]
[1]*University of Medicine of Oradea, Morphological Department, Oradea, Romania*; [2]*University of Medicine of Oradea, Cardiology Department, Oradea, Romania*

Introduction: Dilated cardiomyopathy (DCM) is characterized by a global heart dilation which leads to systolic impairment. More than half of primary DCM are familial in nature. Classic symptoms include paroxysmal nocturnal dyspnea, orthopnea, leg swelling, and shortness of breath. The diagnosis of DCM has been difficult to standardize given the influence of body size, athletic training, and biological heterogeneity on measurements of left ventricular volume and contractile function.
Aim: DCM is one of the most common causes of congestive heart failure with an ominous prognosis.
Methods: We performed a retrospective study were we included all deceased patients in our department with diagnosis of DCM (128 patients) during a period of 1 year (2016), excluding trauma related deaths. We examined medical charts, death certificates, autopsy reports and histopathological reports. Cardiac fragments are harvested, kept in formalin solution for minimum 24 hours, after trimming and orientation, tissue fragments undergoes processing for paraffin embedding and sectioned at a thickness of 3 to 5 μm manual microtome. The slides are stained using classical Hematoxylin-Eosin and Masson's trichrome stain.
Results: From the whole cohort (128 patients with DCM), 63 corpses were autopsied and all the organs were examined. More than 70 bodies had pulmonary complication (the most frequent was pulmonary edema) and 40 patients presented hepatic comorbidities. Generalized atherosclerosis was documented in 57 patients but the real number is consistently bigger (no documentation of atherosclerosis was made in patients who were exempt of the autopsy). Macroscopy examination reveals increased heart volume with a globular shape and a reduced tonus. In microscopy

we notice myocyte hypertrophy (enlarged, muscle fibres with hyperchromatic nuclei) and collagenous fibrosis (diffuse or extend into sub-endocardium). Interstitial cellularity is represented by scattered lymphocytes, fibrous cells, fibroblasts. Some myocardial fibres may exhibit degenerative changes and a perinuclear yellow - brown attrition pigment (lipofuscin).
Discussions: Pulmonary and systemic embolism can occur as blood stasis in dilated and hypocontractile cardiac chambers lead to activation of the coagulation cascade. Although the onset of the disease occurs with a mean age at presentation at about 50 years, in our study the main age group affected was from 61 to 80 y.o.
Conclusion: Early detection and proper treatment may improve the quality of life in these patients. When there is progressive end-stage heart failure despite maximal medical therapy and the prognosis is deemed poor, one may consider a heart transplant.



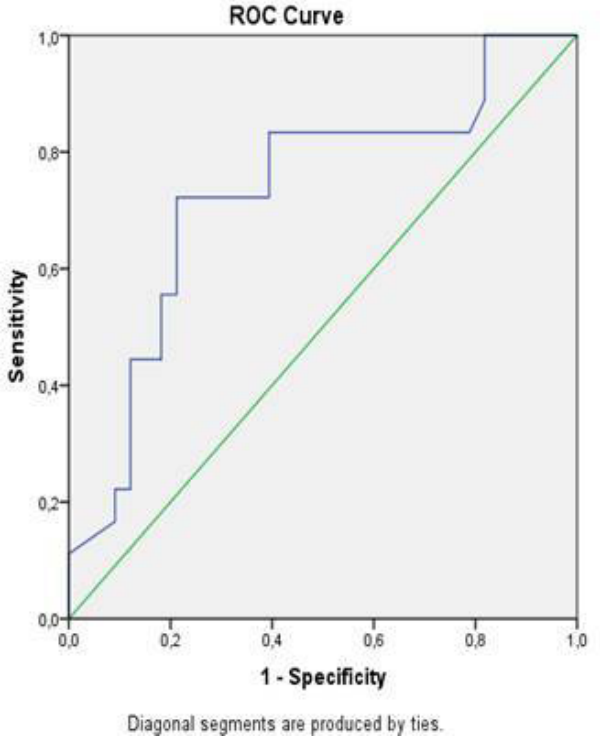
Myocite hypertrophy

P2256

Systemic ventricular longitudinal strain and NTproBNP independently predict major cardiovascular events in adult patients with congenital heart disease

A Alexandra Frogoudaki[1]; V Bistola[1]; I Pantelakis[1]; I Ikonomidis[1]; D Alexopoulos[1]; J Parissis[1]; G Filippatos[1]
[1]Second Cardiology Department, Athens University, ATTIKON University Hospital, Athens, Greece

Introduction: Global longitudinal strain (GLS) of the systemic ventricle predicts functional capacity, but its prognostic value is not established for all groups of adult patients with congenital heart disease .
Purpose: To examine the predictive value of GLS in adult patients with congenital heart disease .
Methods: We studied 57 clinically stable patients (31 men, mean age 37.1 ± 16.9) with congenital heart disease. Fourty-nine had systemic left ventricle, 5 systemic right ventricle and 3 single ventricle physiology. All patients underwent echocardiogram while NTproBNP was measured in a week interval from the echocardiogram. Off line GLS measurement of the systemic ventricle (SV) was performed (ECHOPAC GE).
All patients were followed-up by clinical visit or phone call for 782 ± 240 days and major cardiovascular events (MACE) were recorded. Death, hospitalization for heart failure, worsening functional class or cardiac intervention was defined as MACE.
Results: SVGLS significantly differed between systemic right, left and single ventricle patients
(-11.42 ± 3.37% vs -15.83 ± 4.03% vs -11.53 ± 6.13%, respectively, p = 0.025).
Median NTproBNP value was 118pg/ml (min18.7 pg/ml- max3788pg/ml).
SV GLS correlated with LogNTproBNP (r = 0.46, p < 0.001).
MACE occurred in 18 patients (30%).
NTproBNP and SVGLS independently predicted MACE (p = 0.006 and p = 0.007 respectively).
A cut-off value of NTproBNP 112pg/ml predicted MACE with a sensitivity 72% and a specificity 61%.
A cut off value of SVGLS - 14.45% predicted MACE with sensitivity 72% and specificity 79% (figure). SVGLS maintained its predictive value when adjusted for NTproBNP (HR: 1.189, 95% CI:1.047-1.349, p = 0.007)
Conclusion: Global longitudinal strain of the systemic ventricle predicted MACE in adult patients with congenital heart disease. Its predictive ability was maintained after adjustment for NTproBNP



ROC SVGLS

Does gender matter in patients with Takotsubo cardiomyopathy?

PM Pedro Azevedo[1]; B Faria[2]; R Pontes Santos[3]; N Craveiro[4]; A Marques[5]; H Antunes[6]; L Reis[7]; F Sa[8]; R Guerreiro[9]; O Azevedo[2]
[1]Faro Hospital, Cardiology, Faro, Portugal; *[2]Hospital Guimaraes, Cardiology, Guimaraes, Portugal*; *[3]Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*; *[4]Hospital of Santarem, Cardiology, Santarem, Portugal*; *[5]Hospital Garcia de Orta, Cardiology, Almada, Portugal*; *[6]Hospital Sao Teotonio, Cardiology, Viseu, Portugal*; *[7]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*; *[8]Hospital Santo Andre, Cardiology, Leiria, Portugal*; *[9]Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal*

On behalf of: SUNSHINE

Introduction: Takotsubo cardiomyopathy (TC) affects primarily female patients. Some studies reported a higher mortality rate in male patients with TC, but the impact of gender in the characteristics and outcome of these patients is inconsistent throughout the literature.
Purpose: Assess the impact of gender in patients with TC.
Methods: Portuguese multicenter, prospective, descriptive and correlational study, involving 12 hospitals, in which all patients diagnosed with TC from 2004 to 2017 were included. Patients were divided in two groups based on gender: female (F) or male (M). Clinical data was compared between the groups. The primary endpoint was in-hospital mortality and the secondary endpoints were: 1) composite endpoint of in-hospital mortality, cardiogenic shock and malignant arrhythmias; 2) all-cause mortality during follow-up; 3) TC recurrence during follow-up.
Results: 240 patients were included, 24 (10%) were male with a mean age of 67.5 ± 15 years (versus 67.8 ± 11 years for females). Men were more frequently smokers (33.3% vs 11.6%, p = 0,003) and were more likely to have a previous history of myocardial infarction (8.3% s1.4%, p = 0.02). There were no differences regarding other cardiovascular risk factors and major comorbidities.
Regarding the presentation, male patients had more frequently syncope (25%vs3.2%, p < 0,001) and physical stress as a precipitant (54.2%vs14.4%, p < 0,001), while females reported more chest pain (90.7%vs58.3%, p < 0,001) and an emotional trigger (50%vs16.7%, p = 0,002).
There were no differences regarding the type of TC, Killip class and left ventricular ejection fraction (LVEF) at admission, and electrocardiographic changes, except for complete right bundle brunch block (RBBB), which was more frequent in men (23.5%vs1.2%, p < 0,001). Men were more likely to have significant coronary artery disease (CAD) (26.1%vs11.2%, p = 0,04) and stroke during hospitalization (8,3%vs0.9%, p = 0,007). There were no differences regarding LVEF recovery and LVEF at discharge.

Concerning outcome, men had higher in-hospital mortality (12.5%vs0.9%, p = 0,008) and a tendency for higher rates of the composite endpoint of death, cardiogenic shock and malignant arrhythmias (16.7%vs8.8%, p = 0.21). After adjusting for covariates in a logistic regression model, gender had no impact in in-hospital mortality. With a medium follow-up of 35.8 months, there were no differences regarding all-cause mortality and TC recurrence.
Conclusion: Men comprise 10% of patients with TC, have more frequently significant CAD, syncope, physical stress as a precipitant and RBBB at admission. In this study, in univariate analysis, men had higher in-hospital mortality and a tendency for the higher rates of the composite endpoint of death, cardiogenic shock and malignant arrhythmias. Nevertheless, in multivariate analysis, male gender was not associated with a worse outcome.

Ventricular Arrhythmias and SCD - Pathophysiology and Mechanisms

Screening for mutations in patients with arrythmogenic right ventricular cardiomyopathy using next-generation sequencing

L Hategan[1]; J Borbas[1]; A Tringer[1]; B Csanyi[1]; V Nagy[1]; T Forster[1]; Z Hegedus[2]; I Nagy[3]; R Sepp[1]
[1]2nd Department of Internal Medicine and Cardiology Center, University of Szeged, Szeged, Hungary; *[2]Institute of Biophysics, Bioinformatics Group, Biological Research Center, Szeged, Hungary*; *[3]Seqomics Biotechnology Ltd, Morahalom, Hungary*

Funding Acknowledgements: Supported by GINOP-2.3.2-15-2016-00039.

Background: Arrythmogenic right ventricular cardiomyopathy/dysplasia (ARVC/D) is an inherited cardiac disorder caused by mutations in the genes encoding for desmosomal cell adhesion proteins or even non-desmosomal ones. Since the right ventricular myocardium is being progressively replaced by fibrofatty tissue, patients present with severe ventricular arrhythmia and an increased risk of sudden cardiac death.
Purpose: We aimed to screen for genetic variants in ARVC causative genes in patients with definite or suspected diagnoses of ARVC.
Patients and Methods: We screened 10 patients with 'definite' ARVC (6 males, average age 46 ± 10 yrs), 1 with 'borderline' ARVC (female, aged 64 yrs) and 4 with 'possible' ARVC (2 males, average age 43 ± 15 yrs). Genotyping was performed by next-generation sequencing and validated by capillary sequencing. ARVC-related genes were targeted for sequencing.
Results: Altogether 38 rare (minor allele frequency < 1%) genetic variants, leading to amino acid or 'splice-site' change have been identified in our patients. Out of the 15 patients, 3 carried a definite pathogenic gene variant (PKP2: p.Arg79*, p.Trp123* and DSC2 p.Ser645fs). Other 5 patients carried variants of unknown significance in desmosomal genes (PKP2 p.Asn512Lys, DSG2 p.Arg292Cys, DSP p.Asp2070Asn and p.Gln1670Pro, DSC2 p.Cys559Tyr). In other 4 distinct clinically confirmed patients, putative disease-causing non-desmosomal gene variants were found: p.Ala134Val in membrane-related CAV3 gene, p.Arg343Gln in AGL gene involved in glycogen degradation, p.Glu11099del in TTN gene, and p.Ser52Leu in CTNNA3 gene, already reported to be a candidate gene for ARVC. Single mutations were detected in 3 patients, whereas the others were identified as one of multiple variants.
Conclusion: Despite the high genetic heterogeneity, desmosonal genes remain the main causative genes in ARVC. Several non-desmosomal candidate genes like ACADVL, CAV3, AGL and TTN may contribute to the phenotype.

Immunosuppression in lymphocytic myocarditis with parvovirus B19 presence

C Tschoepe[1]; S Sophie Van Linthout[2]; B Pieske[1]; U Kuehl[1]
[1]Charité - Universitätsmedizin Berlin, Campus Virchow-Klinikum (CVK) Kardiologie, Berlin, Germany; *[2]Berlin-Brandenburg Center for Regenerative Therapies, Berlin, Germany*

Results from the "Cortisone in parvovirus inflammatory cardiomyopathy (CaPACITY) - observational trial"
Background: Parvovirus B19 (B19V) is generally acquired in childhood and persists lifelong in 60 to 70% of the adult population The current scientific statement of the ESC recommends avoidance of the use of immunosuppression in entero- and adenoviral genome-positive patients with lymphocytic myocarditis (MC). Whether this precaution holds true for patients with B19V persistence is unknown.
Aim: We aimed to get insights in the effects of immunosuppressive treatment of B19V-positive (+) and –negative (-) patients with endomyocardial biopsy-proven MC.
Methods and Results: B19V+ (n = 43) and B19V- (n = 17) MC patients were treated with prednisolone and azathioprine in addition to standard heart failure medication. Six months after treatment, inflammatory infiltrates had resolved in all B19V- and 36 (83.7%) of B19V+ patients, by which mean viral DNA copy numbers declined. At baseline, VP1/VP2 mRNA was present in eight patients (13.3%), of which half resolved or persisted, respectively. LV-EF improved similarly in both B19V+ and B19V- groups upon treatment and stayed for at least 13 months.
Conclusion and translation: Ongoing cardiac inflammation is the most important risk factor for impaired outcome in MC. The finding that B19V replication is not aggravated under immunosuppression and patients gain a benefit from immunosuppression as do B19V- individuals is important to reduce inflammation in B19V+ MC patients. Further significance of these findings needs be proven in a phase II trial.

Pulmonary Circulation, Pulmonary Embolism, Right Heart Failure - Clinical

A propose management model of ambulatory patients recovered by acute pulmonary embolism

AB Scardovi[1]; P Petti[1]; P Coletta[2]; T Di Giacomo[1]; A Totteri[1]; G Vitaliani[1]; S Iosi[1]; R De Maria[3]; L Luca Arcari[1]; R Ricci[1]
[1]Hospital Santo Spirito, Cardiology, Rome, Italy; *[2]Hospital Santo Spirito, Medical, Rome, Italy*; *[3]CNR Institute of Clinical Physiology, Milan, Italy*

Background: Deep vein thrombosis (DVT) and pulmonary embolism (PE) are leading causes of preventable morbidity and mortality among hospitalized patients (pts). Pts who recover from acute PE are at risk of recurrent PE, chronic thromboembolic pulmonary hypertension (CHEPT) and right heart failure. Moreover DVT/PE may represent the first clinical manifestation of hidden neoplastic or autoimmune diseases. The early diagnosis of complications and sequelae of PE remains a challenge. For the delivery of quality care in the post-acute phase a dedicated cardiology clinic may be pivotal for structured ambulatory follow-up (FU) and the organization of a medical network with community cardiologists and general practitioners may be worthwile.
Methods and Results: At the Cardiology Department of our institution we have built a model of FU of pts with previous PE (shared between the Cardiology, the Medical Department and the Hospital Health Department) for risk assessment and management of anticoagulantion within 3/6 months of discharge and referral of pts with CHEPT to invasive therapies (pulmonary endarterectomy, pulmonary artery angioplasty).
Between 2014 and 2017 we enrolled 150 pts (aged 69+12 years, median 73, 59% female) in a follow-up pathway that included at entry a cardiology visit, 2nd level echocardiogram with detailed evaluation of the size and pressure of the right sections, functional capacity assessment through six-minutes walking test , cardiopulmonary test , complete blood tests including BNP and troponin assay and, in selected cases, genetic tests for thrombophilia, doppler of lower limbs veins, multidisciplinary specialist consultations. In pts at low risk of recurrent PE and/or development of CHEPT, anticoagulant therapy was withdrawn and the FU was carried on by the community medical network. In pts at intermediate risk, anticoagulation was continued, cardiological therapy was optimized and prognosis was reassessed based on the presence of perfusion deficits. High-risk pts were referred for 2nd level procedures. When anticoagulant therapy was withdrawn, the risk of relapse was monitored through serial measurement of D-dimer for the first 3 months, and long-term anticoagulation was recommended in pts with persistently high D-dimer.
We report our preliminary findings. In 40 pts (27%) early FU is still ongoing; of the remaining 110, 60 (54%) were low risk, 35 (32 %) intermediate risk, 15 (14%) were high risk; 8 (5%) pts died during FU. Outcomes were periodically reassessed by audits within the network to verify the effectiveness and efficiency of FU strategies.
Conclusions: Although crucial from the prognostic point of view, FU of pts with previous PE is not codified by the international guidelines and very little widespread in clinical daily practice. Our goal is to spread this virtuous management model.

Prevalence and clinical characteristics of adverse prognostic factors in pulmonary hipertension

A Ferro[1]; A Lescano[1]; G Damianich[1]; D Crippa[1]; HG Santa Maria[1]; A Lavalle Cobo[1]; N Gonzalez[1]; M Gonzalez[1]; H Grancelli[1]
[1]Finochietto Clinic, Buenos Aires, Argentina

Pulmonary hypertension (PH) is a multi-factorial condition associated with high morbidity and mortality. It requires for its diagnosis and treatment a multidisciplinary approach. In the past decades there have been many advances in the epidemiological, pathophysiological and therapeutic knowledge of the disease. However, there is little information available regarding clinical and prognostic factors in patients diagnosed with PH in Latin America.
Pourpose: Determine the prevalence and clinical characteristics of adverse prognostic factors in a population with recent diagnosis of PH.
Methods: Patients with recent diagnosis of PH (< 7 days) confirmed by right heart catheterization, with a mean pulmonary-artery pressure (MPAP) = 25 mm Hg (using a Swan Ganz Catheter) from three heart failure and pulmonary hypertension services were analyzed between March 2012 and December 2017. According to the recommendations of international guidelines, the following data were recorded: Personal data, PH group (G), clinical features: symptoms, functional class FC. Direct hemodynamic parameters: pulmonary pressures (PP), wedge pressure (WP), right atrium pressure (RA) and cardiac index (CI). Functional: 6 minute walk (6MW) test distance. Echocardiographic variables: right ventricle systolic function (RVSF), systolic pulmonary pressure and presence of pericardial effusion (PE). Data obtained were analyzed with BioEstat 5.3 program. Adverse prognosis factors identified were: history of heart failure (HF), syncope, advance functional class (III-IV), performance in the 6MW test < 350 m, presence of PE, RA = 12 e CI = 2,2.
Results: Multicenter, observational, descriptive, consecutive and prospective study. 131 patients where included. 73% women. Mean age was 59.8 (±19) years, 30% = 70. The mean delay in diagnosis was 22 months after the first sign or symptom recorded. PH group distribution: GI 65%, GII14%, GIII9%, GIV5% and GV6%. FC of presentation: I4%, II 40%, III35% and IV21%. History of HF in 76%, syncope in 24%. 6MW mean distance walked was 317 (±144) meters, 49 % performed = 350 meters. RHC: MPAP 48.9 (±16) mmHg, RAP 9.9 mmHG (±5,1) and = 12 mmHg 34%; CI 2,72 litres/min/mt2 (= 2,2 24%). Ecocardiographic data show: 80 % impaired FSVD (40% slight, 19% moderate and 21% severe) and PE in 25%.
Conclusions: In our population with confirmed pulmonary hypertension, with a predominance of group I, we had a high presentation in over 70 years of age. At diagnosis time a high number of patients present adverse prognosis factors. This findings remark the need to use early diagnosis and therapeutic strategies.

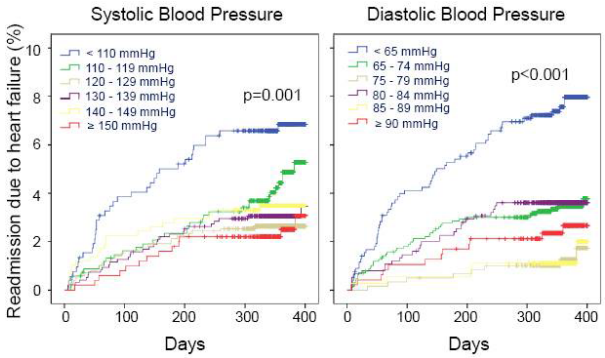
Association between six-month blood pressure level and 1-year heart failure in hypertensive patients with acute myocardial infarction

S-J Joo[1]; J-G Lee[1]; K-Y Boo[1]; J-H Choi[1]; S-Y Kim[1]; K-S Kim[1]; M-H Jeong[2]
[1]Jeju National University Hospital, Cardiology, Jeju, Korea Republic of; [2]Chonnam National University Hospital, Cardilogy, Gwangju, Korea Republic of

On behalf of: KAMIR-NIH investigators
Funding Acknowledgements: Research Fund of Korea Center for Disease Control and Prevention

Background and purposes; There has been a long debate about "J-curve phenomenon" in the management of patients with hypertension, especially who have cardiovascular diseases. The blood pressure (BP) lower or higher than optimal level may be harmful in hypertensive patients with acute myocardial infarction (AMI). This study aimed to investigate the association between 6-month BP level and 1-year readmission due to heart failure (re-HF) in hypertensive patients with AMI.
Methods:; Among 13,104 patients who enrolled in nationwide AMI database of South Korea, the KAMIR-NIH Registry, 4,216 hypertensive patients, who survived the initial attack and had 6-month BP data, were selected in this study. They were divided into six systolic or diastolic BP groups according to BP levels (Table).
Results: Lowest 6-month systolic BP group of < 110 mmHg or lowest 6-month diastolic BP group of < 65 mmHg showed the highest re-HF at 1-year (6.9±1.1% and 8.0±1.0%, respectively) (Figure). On multivariate Cox-proportional hazard analysis, patients with lowest systolic BP (OR; 2.01, 95% CI; 1.17-3.44, p = 0.011) or lowest diastolic BP (OR; 4.04, 95% CI; 1.84-8.97, p = 0.001) had the highest re-HF at 1-year compared with optimal level of BP. Higher diastolic BP than optimal level also increased re-HF. Even after excluding patients with re-HF before 6 months, patients with lowest systolic BP (OR; 2.09, 95% CI; 1.19-3.67, p = 0.010) or lowest diastolic BP (OR; 3.98, 95% CI; 1.80-8.79, p = 0.001) at 6- month showed the greatest risk for re-HF at 1-year.
Conclusions: Systolic BP lower than optimal level, and diastolic BP lower or higher than that at 6-month, increased re-HF at 1-year in hypertensive patients with AMI.



Kaplan-Meier survival curve of HF

Features of early-diagnosed preeclampsia versus non-proteinuric gestational hypertension: a clinical and echocardiographic longitudinal study

N Patrascu[1]; LF Trasca[1]; DJ Mihalcea[1]; L Lungeanu Juravle[1]; MS Neagu[1]; M Cirstoiu[1]; D Vinereanu[1]
[1]University of Bucharest Carol Davila, Bucharest, Romania

Background: Hypertensive diseases of pregnancy are important causes of both maternal and fetal morbidity and mortality worldwide. Preeclampsia (PE) has the poorest prognosis by multiple organ damage and some data show a particular worse outcome for early-diagnosed preeclampsia (before 34 weeks). It is not known the cardiovascular evolution in these particular cases of pregnancy-induced hypertension long time after delivery.
Objectives. A clinical and echocardiographic 2 years follow-up after delivery in women diagnosed with early-diagnosed preeclampsia by comparison to non-proteinuric gestational hypertension (GHT).
Methods: 41 pregnancy-induced hypertensive women were enrolled, 18 with PE diagnosed before 34 weeks of pregnancy and 23 non-proteinuric GHT, no other cardiac disease, non-smokers and non-diabetics. We assessed by 2 D, tissue Doppler, speckle tracking and 4D echocardiography left ventricle (LV) structural parameters (wall thickness, sphericity and mass indexes); systolic global and regional function: 4D ejection fraction (LVEF), TDI S wave, radial, circumferential and global longitudinal (GL) strain and strain rate; and diastolic function by a set of spectral and TDI parameters. 19 subjects (9 former early PE) were re-examined 2 years after enrollment.

P2262 Risks of re-admission due to HF at 1-yr

SBP (mmHg)	No.	HR	95% CI	p value	DBP (mmHg)	No.	HR	95% CI	p value
<110	521	2.01	1.17-3.44	0.011	<65	779	4.07	1.84-8.97	0.001

140-149	576	1.37	0.75-2.49	0.307	85-89	360	1.58	0.50-5.00	0.435
≥150	499	0.91	0.46-1.80	0.792	≥90	472	3.07	1.20-7.84	0.019

Multivariate Cox-proportional hazard analysis including age, sex, body mass index, diabetes, prior angina, prior myocardial infarction, prior heart failure, Killip class, smoking, chronic kidney disease, beta-blockers, inhibitors of renin-angiotensin system, statins, left ventricular ejection fraction, and ST-elevation myocardial infarction
DBP; diastolic blood pressure, CI; confidence interval, HR; hazard ratio, SBP; systolic blood pressure

Results: Groups were similar in terms of age (33 ± 4 vs 31 ± 6), pregnancy weeks, primi-/multiparity, systolic and diastolic blood pressure (150.3 ± 23/92.8 ± 22 vs. 157.6 ± 25/97.1 ± 24) and heart rate (90 ± 10 vs. 89.5 ± 12 bpm). At baseline, early PE group had significant lower pre-pregnancy weight (65.7 ± 11 vs 74.9 ± 15,p = 0.03), weight (76.2 ± 10 vs 85.9 ± 14 kg) and body surface area at enrollment (1.83 ± 0.1 vs 1.95 ± 0.1, both p = 0.01). No differences between all echocardiographic parameters were found. At 2 years follow up, 11 subjects (47%, 7 former early PE) were still hypertensive and treated. For all subjects, an improvement from baseline was noted only for radial strain (42.8 ± 15 vs 31.2 ± 7, p = 0.008), strain rate (2.6 ± 0.7 vs 2.1 ± 0.4, p = 0.04), GL strain (22.1 ± 2 vs 17.4 ± 3, p = 0.000) and GL strain rate (1.3 ± 0.1 vs 1.1 ± 0.2, p = 0.03) and LV sphericity index decreased (0.3 ± 0.05 vs 0.3 ± 0.1, p = 0.03). No significant changes in LV mass, LV wall thickness, S wave, LVEF or diastolic parameters were registered and there were no differences between former early PE or non-proteinuric GHT.
Conclusions: Our study showed that early-diagnosed preeclampsia women had, at baseline, a similar left cardiac systolic and diastolic function despite a significant lower weight pre-pregnancy and at enrollment time, by comparison to women with non-proteinuric gestational hypertension. However, 2 years after delivery, a significant number of women with history of early preeclampsia were still hypertensive requiring treatment. This underlines the importance of closer monitoring and management after delivery in these cases for preventing long term cardiovascular events.

P2264
Atrial electro-mechanical delay in hypertensive patients.

S Antit[1]; I Slama[1]; A Bleouer[1]; I Boussabeh[1]; M Thameur[1]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*

Background: hypertension is the first cause of atrial fibrillation. Its onset is explained by intricate mechanisms such as atrial conduction impairment.
The aim of our study was to evaluate atrial conduction by tissue Doppler imaging in hypertensive patients compared to a control group.
Methods: This is a comparative prospective study performed in the cardiology department of the FSI hospital enrolling 55 patients with hypertension and 55 controls. All of them underwent a complete echocardiography exam with Doppler tissue imaging. We measures inter-atrial and intra-atrial electromechanical delay by Pulsed Tissue Doppler.
Results: Left ventricular mass and septal thickness were more important in the hypertensive group. Mitral A wave was greater in hypertensive group compared to controls (7.1 cm/s vs 5.6cm/s; p < 0.001; respectively). Left atrial volume was of 32.7ml ± 6.8ml/m^2 in hypertensive vs 29.5 ± 4.3ml/m^2 in controls (p = 0.006). Doppler Tissue study showed homogeneous statistically significant elongation of atrial conduction times in hypertensive patients compared to controls: inter-atrial time (16.8 ± 7.8ms vs 12.7 ± 4.2ms, p < 0.0003) and left intra-atrial (27.6 ± 8.6ms vs 19.0 ± 4.3ms, p < 0.0001) and right intra-atrial time (10.6 ± 6ms vs 6.6 ± 2.9ms, p < 0.0001) respectively for hypertensive and control subjects. There was a significant correlation between measured intra-atrial and inter-atrial electromechanical delays and duration of hypertension, indexed left atrial volume and indexed left ventricular mass (r: 0.27-0.47, p < 0.001). Conclusion: Atrial conduction time is significantly longer in hypertensive patients. Impairment of atrial conduction may be predictive of atrial fibrillation and should prompt closer follow-up to detect this arrhythmia in these patients.

Renal Failure and Cardiovascular Disease

P2265
Does right ventricle function and mechanics change in patients with end stage renal disease undergoing hemodialysis?

E Egle Tamulenaite[1]; R Zvirblyte[2]; R Ereminiene[3]; E Ziginskiene[3]; E Ereminiene[2]
[1]*Lithuanian University of Health Sciences, Kaunas, Lithuania*; [2]*Hospital of Lithuanian University of Health Sciences, Department of Cardiology , Kaunas, Lithuania*; [3]*Hospital of Lithuanian University of Health Sciences, Department of Nephrology , Kaunas, Lithuania*

Background: Right ventricle (RV) systolic dysfunction has been recognized as a predictor of cardiovascular death in many cardiovascular diseases (CVD), however the impact of end stage renal disease (ESRD) and hemodialysis (HD) on RV systolic function is still unclear.
Purpose: The aim of our study was to evaluate changes of RV systolic function and mechanics and to define predictors of RV dysfunction in patients with ESRD, undergoing HD.
Methods: 38 patients undergoing HD without known clinically significant CVD (HD group) and 32 age-matched persons with normal kidney function (GFR >90mL/min/1.73m2) (control group) were included into the study. Conventional 2D echocardiography and 2D STE offline analysis was performed and parameters of RV and LV geometry, function and myocardial deformation were evaluated. Statistical analysis was performed using SPSS version 24.0, p value < 0.05 has been considered statistically significant. Logistic regression analysis was performed to evaluate predictors of RV dysfunction (GLS>-20%) in ESRD.
Results: The groups were of the same age, gender, and body surface area. Basal diameter of RV did not differ between groups. Parameters of RV free wall longitudinal function were reduced in HD group, as well, as indices of global longitudinal RV strain, while RV fractional area change (FAC) didn't differ between groups (Table 1). PH was diagnosed in 6 (15.8%) of HD group patients. Univariate analysis showed that indices of LV geometry and function (LV myocardial mass index (OR 1.028, p = 0.031), E/e' ratio (OR 1.181, p = 0.039), LV GLS (OR 1.553, p = 0.004)) and PH (OR 15.750, p = 0.024) were associated with RV dysfunction. On multivariate analysis PH was found to be an independent predictor of RV dysfunction. (OR 24.826, p = 0.040) in HD group.
Conclusion: RV longitudinal function and deformation indices are reduced in ESRD patients undergoing HD. PH was found to be an independent predictor of RV dysfunction (GLS >-20%) in this group of patients.
Conflict of interest. None.

Table1.

Characteristic	Control group N = 32	HD group N = 38	p value
RVD1 (mm)	32.4±5.7	33.2±3.9	0.490
TAPSE (mm)	26.7±5.1	22.4±5.8	0.001
RV S' (cm/s)	15.6±1.6	12.4±3.1	<0.001

P2266
Applying of combined biomarker test in early diagnosis of acute kidney injury in patients with acute cardiac diseases

M Efremovtseva[1]; S Avdoshina[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Introduction: The role of markers of structural kidney damage in diagnosis and prognosis of acute kidney injury (AKI) is widely discussed but still is unclear. Early diagnosis of AKI is especially important in acute cardiovascular diseases due to increased risk of severe adverse events associated with development of cardiorenal syndrome.
Purpose: To explore the role of biomarkers in early diagnosis of AKI and their prognostic values in patients with acute cardiac diseases.
Methods: 109 patients (51 with acute decompensated heart failure (ADHF), 58 with non-ST-elevation acute coronary syndrome (NSTE-ACS) were examined. Biomarkers of HF (NT-pro BNP in serum) and kidney damage (cystatin C in serum; neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1) and interleukine-18 (IL-18) in the urine) were estimated. Mann-Whitney test and multivariate logistic regression analysis were performed, p <0.05 was considered statistically significant.
Results: Patients with vs without AKI had higher levels of NGAL (344 ± 308.8 vs 37.9 ± 65.1 ng/ml, p <0.001) and KIM-1 (0.774 ± 0.36 vs 0.402 ± 0.59 ng/ml, p <0.01) in all groups. Patients with NSTE-ACS with vs without AKI had higher level of NT-proBNP (12857.1 ± 3108.8 vs 10134 ± 2479,μmol/ml, p <0.001), no difference was detected in ADHF group. In course of ROC analyses NGAL and KIM-1 showed the best prognostic values (AUC value 0.948 and 0.760). The ?ut points for NGAL >60.1 ng/ml (sensitivity 87%, specificity 92%) and KIM-1 > 0.519 ng/ml (sensitivity 87%, specificity 67%) were detected, coefficient of association f was 0,781 and 0,555 respectively. Simultaneous detection of two markers of structural kidney damage (increase of NGAL and/or KIM-1) in high-risk patients permits to diagnose 95% of AKI cases at admission. Patients with AKI and diagnostically significant levels of biomarkers had higher prevalence of CKD (p <0.01), acute heart failure, ADHF (p <0.05) vs those without increase of biomarkers, in-hospital mortality in this group was 29,8%.
Conclusions: Positive combined biomarker test is an independent and strong predictor of AKI in patients with acute cardiac diseases, and its implementation in

clinical practice may improve the early diagnostics of AKI when markers of kidney function are still at normal levels.

P2267

Risk assessment scale for detection of community-acquired acute kidney injury in patients admitted with cardiac diseases

S Avdoshina[1]; B Lobzhanidze[1]; M Efremovtseva[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Introduction: Acute kidney injury (AKI) is a common and serious problem associated with poor prognosis.
Purpose: To reveal the prevalence and predictors of community-acquired AKI in patients with acute cardiac diseases.
Methods: 566 patients (278 with acute decompensated heart failure (ADHF), 288 with non-ST-elevation acute coronary syndrome (NSTE-ACS), 46% male, 71 ± 11 years (M ± SD), smokers 26%, arterial hypertension 91%, previous myocardial infarction (MI) 45%, diabetes mellitus (DM) 28%, atrial fibrillation 35%, chronic kidney disease (CKD) 46%, previous hospitalization with ADHF 36%, ejection fraction (EF) <35% 15%, blood pressure (BP) 142 ± 30/83 ± 16 mmHg were examined. AKI was diagnosed according 2012 KDIGO Guidelines. Community of hospital-acquired AKI was identified depending on time of development.
Results: Incidence of AKI in all patients, patients with ADHF and NSTE-ACS was 40, 43.5 and 37.2%. In-hospital mortality in patients with AKI was higher than in those with stable kidney function (14.9 vs 3.6%, p <0.001). Community-acquired AKI was present in 18% of patients (20.5 and 15.6% in ADHF and NSTE-ACS patients), in-hospital mortality was 16.7% (10.5 and 24.4% respectively). The risk assessment scale for community-acquired AKI was developed based on independent predictors of AKI, using binary logistic regression and ROC analysis (AUC 0.860, 95% CI 0.821-0.898).
Independent variables included in the model, and the corresponding points (pts) are listed below: clinical and demographic characteristics (male gender - 6 pts, alcohol abuse - 7 pts, DM - 1 pt), present on admission (MI - 5 pts, AHF/ADHF - 9 pts, systolic BP <120 - 10 pts, <110 - 15 pts, <90 mmHg - 27 pts; state of kidney function on admission: serum creatinine >98 and >128 mkmol/L - 14 and 22 pts, GFRCKD-EPI <45 and <15 ml/min/1.73 m2 - 7 and 14 pts; glucose level >7 mmol/L - 4 pts), outpatient intake of ACE inhibitors - 4 pts, absence of spironolactone in outpatient therapy - 1 pt. Diagnostically significant risk score for predicting AKI was >30 pts, the risk prediction model showed sensitivity 89%, specificity 66%.
Conclusions: Community-acquired AKI is common in patients in acute cardiovascular events, is associated with high mortality, and often is underdiagnosed. Usage of risk assessment scale in clinical practice may help to detect patients with high-risk of AKI on admission. Baseline kidney function and blood pressure level are main predictors of AKI in patients admitted with cardiac diseases.

P2268

Cardiorenal interrelations in patients with acute cardiac diseases: prevalence and prognosis

S Avdoshina[1]; M Efremovtseva[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Introduction: Impaired renal function is a common finding in patients with cardiac diseases and confers an adverse prognosis in this population.
Purpose: to evaluate the incidence, phenotypes and prognostic value of cardiorenal interrelations in patients with acute decompensated heart failure (ADHF) and non-ST-elevation acute coronary syndrome (NSTE-ACS).
Methods: we examined 278 patients with ADHF (85.3% had anamnesis of symptomatic HF with frequent hospitalizations, 20.1% had ejection fraction <35%) and 288 with NSTE-ACS (64.9% developed myocardial infarction (MI)). In ADHF group in comparison with NSTE-ACS the patients were younger (69.7 ± 10.2 vs 72 ± 12.1 years, p <0.01), there were more men (55.4 vs 36.5%, p <0.001), smokers and alcohol abusers (47.8 and 30.6% vs 8 and 5.6%, p <0.001). The comorbidities were more typical for ADHF group: atrial fibrillation 46 vs 24% (p <0.001), obesity 55.8 vs 30.9% (p <0.001), anemia 40.6 vs 25.3% (p <0.001), diabetes mellitus 33.1 vs 23.3% (p <0.01).
Chronic kidney disease (CKD) and acute kidney injury (AKI) were diagnosed according to KDIGO 2012 Guidelines. AKI phenotypes were identified depending on time of development (community- or hospital-acquired), persistency (transient or persistent), history of CKD (AKI de novo or AKI on CKD).
Results: Incidence of CKD in patients with ADHF and NSTE-ACS was 45 and 46.5%, CKD was first diagnosed on admission in 57.6 and 64.2% of patients respectively. In 7.6% cases of ADHF and 14.2% of NSTE-ACS groups the duration of impaired kidney function was unknown. No associations of existing CKD and in-hospital mortality were detected.
Incidence of AKI in ADHF and NSTE-ACS groups was 43.5 and 37.2%. The hospital-acquired AKI, AKI on CKD and persistent AKI were found in 52.9, 47.9 and 46.3% of ADHF patients with AKI, and in 57.9, 58.9 and 50.5% in NSTE-ACS with AKI group respectively. In-hospital mortality was higher in patients with AKI in ADHF and NSTE-ACS groups (12.4 vs 5%, p <0.01 and 17.8 vs 3.3%, p <0.001). Mortality in patients with ADHF and hospital-acquired persistent AKI de novo and community-acquired persistent AKI on CKD was 41 and 29%, and in community-acquired transient AKI on CKD in the NSTE-ACS group - 29%.
Conclusions: Different cardiorenal interrelations were revealed in 75.2% of patients with ADHF and in 61.8% with NSTE-ACS. In patients with acute cardiac diseases high in-hospital mortality is tightly associated with phenotypes of hospital-acquired persistent AKI de novo and community-acquired persistent AKI on CKD in ADHF, and in community-acquired transient AKI on CKD in the NSTE-ACS.

P2269

Predictors of acute heart failure in patients with ST-segment elevation myocardial infarction of the electrocardiogram after PCI

E Mezhonov[1]; Y Vyalkina[2]; K Vakulchik[2]; S Shalaev[1]
[1]*GBUZ TO "Regional clinical hospital", Tyumen, Russian Federation*; [2]*Tyumen State Medical University, Tyumen, Russian Federation*

Background: Despite the PCI in patients with ST-segment elevation myocardial infarction (STEMI) the development of acute heart failure (AHF) Killip = II is associated with a poor prognosis.
Purpose: To identify predictors of the development of AHF and the prognostic value of AHF in patients with STEMI after PCI. Methods. In a prospective study, which lasted 6 months, included 233 patients (average age of 62.1 ± 10.89 years, 73.4% of men) admitted to the hospital due to the development of STEMI who underwent PCI. The endpoint was defined as the death from cardiovascular causes. Statistical processing of the results was carried out using the statistical packages of the programs "SPSS Statistics 17.0".
Results: During the follow-up observation from 1 day to 6 months (median follow-up of 5.2 months), 25 patients (10.7%) reported the onset of the endpoint, including 20 cases during the index hospitalization. AHF Killip = II during indexed hospitalization developed in 25 patients (10.7%). Independent predictors of Killip = II were: GFR < 60 ml/min initially on admission to hospital (OR 95% 5.690 (2.082-15.551), p = 0.001), anemia (OR 95% 5.317 (1.957-14.448), p = 0.001), EF < 40% (OR 95% 6.686 (1.291-34.628), p = 0.024). OR of the development of Killip = II increased with a decrease in GFR initially when admitted to the hospital: GFR 45-59 ml/min (OR 95% 6.167 (1.432-26.563), p = 0.015), GFR 30-44 ml/min (OR 95% 13.704 (2.795-67.187), p = 0.001), GFR 15-29 ml/min (OR 95% 32.889 (4.967-217.770), p < 0.001). The development of AHF Killip = II was associated with an increase in the frequency of the onset of the endpoint (7.2% and 40%, respectively, p < 0.001), increasing with the increase in the class Killip (I 7.2%, II 0%, III 55.6%, IV 83.3%, p < 0.001). In patients with AHF Killip = II, the incidence of acute kidney injury (AKI) increased (20.2% and 40%, respectively, p = 0.025). Killip = II increases the OR of development of AKI by 2.6 times (OR 95% 2.635 (1.105-6.282), p = 0.029). In the case of the development of both the AHF Killip = II and AKI, the OR of the onset of the endpoint increased many times (OR 95% 40.704 (8.990-184.283), p < 0.001), while the AHF Killip = II without AKI increased the OR fourfold (OR 95 % 4.361 (1.041-18.268), p = 0.044). Conclusion. In patients with STEMI the development of the AHF Killip = II is associated with a poor prognosis, the development of AKI in patients with AHF Killip = II aggravates this prognosis.

P2270

Combination of extracorporeal membrane oxygenation and continuous renal replacement therapy

R G Yarosh[1]; N S Piatrovich[1]; L G Shestakova[1]; Y P Ostrovsky[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Department of extracorporeal blood circulation, Minsk, Belarus*

Objective: Acute renal injury is observed in 60-85% of patients within 48 hours after the beginning of ECMO. The main mechanisms of kidney damage on ECMO are related to the development of a systemic inflammatory response, the extent of the renal failure is determined by the duration of the procedure.
Purpose: To analyze the combined usage of extracorporeal membrane oxygenation (ECMO) and continuous renal replacement therapy (CRRT) in cardiac surgery.
Methods: A retrospective single-center analysis of 14 patients who who recieved combined treatment(ECMO and CRRT) during the period 2010-2017. The criteria for inclusion were: 1) Patients older than 18 years, 2) The combination of the use of ECMO and CRRT. The exclusion criteria was a duration of CRRT the background of ECMO less than 24 hours. Medical protocols of cardiovascular interventions, anesthetic management, conducting of CPB, ECMO and CRRT corresponds to all standards which are accepted for our centre.

Results: The duration of CRRT ranged from 3 to 15 days. By the second day of the combined treatment (CRRT and ECMO)we observed a significant decrease in urea and creatinine serum 2-fold to 9.1 mmol / l (p = 0,034) and 133.5 mmol / l (p = 0,007) respectively, as well as the restoration of acid-base status (p = 0.004).
Conclusions: The combination of two extracorporeal methods ECMO and CRRT is an effective combination. Integration of two physiological circuits ECMO and CRRT avoids cannulation of central or peripheral veins, thus provide an opportunity to avoid additional risks and complications associated with this type of intervention.

Autoimmune/Chronic Inflammatory Disorders and Heart Disease

Prevalence, factors associated and prognostic effects of preoperative anemia on short-and long-term mortality in patients undergoing Transcatheter Aortic Valve Replacement

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; JM Garcia-Pinilla[1]; F Carrasco-Chinchilla[1]; AJ Dominguez-Franco[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; E De Teresa-Galvan[1]
[1]*University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

There is little information on the prevalence and factors associated with preoperative anemia in patients undergoing Transcatheter Aortic Valve Replacement (TAVR).
The aim of study was to analyze the prevalence and factors associated with preoperative anemia and the prognostic effects in mortality in patients with aortic stenosis undergoing TAVR.
Methods: 553 patients with aortic stenosis who underwent TAVR were included. Anemia was defined by the World Health Organization criteria (hemoglobin < 12.0 g/dl in women and < 13.0 g/dl in men).
Results: Before TAVR procedure, 367 patients (66.4%) were classified as anemic with a mean hemoglobin of 10.7 ± 1.1 g/dl vs. 13.3 ± 1.05 g/dl in the non-anemia group, p <0.001.Anemic patients were required more frequently blood transfusion (41.3% vs. 8.7%,p <0.001) after procedure. At discharge, the value mean of hemoglobin levels was 10.6 ± 1.5 g/dl in group anemic vs. 11.5 ± 1.3 g/dl, p = 0.015 in the non-anemia group.
The patients with anemia had more comorbidities compared with non-anemia group: Charlson index 3.5 ± 1.8 vs. 2.9 ± 1.4, p < 0.001; Karnosfky index 59 ± 18 vs. 66 ± 15, p < 0.001), Logistic EuroSCORE 18.4 ± 13 vs. 15.5 ± 9, p <0.001 and lower left ventricular ejection fraction 58.7 ± 15 vs. 62.8 ± 15%, p = 0.02.
Preoperative anemia was associated with total mortality 36.5% vs. 27.6% [OR= 1.511 (95% CI 1.027-2.223) p= 0.036] but not associated with 30-days mortality, 3% vs. 1.1%, p = 0.161. The predictors of anaemia were: chronic kidney injury (adjusted Odds ratio [OR]: 2.829 (95% CI: 1.680 to 4.764), p = 0.001, treatment with diuretics [OR= 3.104 (95% CI 1.676-5.749), p = 0.001] and anticoagulant treatment [OR= 1.989 (95% CI 1.006-3.936), p = 0.048].
Conclusions: the presence of anaemia is a frequent co-morbidity in patients with aortic stenosis who underwent TAVR, and it was associated with increase in overall death.

P2272
Insulin resistance, adiponectin level, endothelial function in rheumatoid arthritis females with heart failure with preserved ejection fraction

O Oksana Sirenko[1]; O Kuryata[1]; T Lysunets[2]
[1]*Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine*;
[2]*Dnipropetrovsk Regional Clinical Hospital, Dnipropetrovsk, Ukraine*

Rheumatoid arthritis (RA) are associated with higher risk for cardiovascular mortality and developing of heart failure with preserved ejection fraction (HFpEF). Endothelial dysfunction, insulin resistance, adipose tissue exchange disorders may play important role in RA females with HFpEF.
We aimed to evaluate insulin resistance, adiponectin level, endothelial function in RA females with HFpEF.
44 females with HFpEF and low disease activity (DAS28 <3.2) comorbid RA (mean age - 55,7 [51,3; 60,5] years) were enrolled. Control subgroup made HFpEF females without RA (n = 29). All patients received stable therapy more than 6 months. ?atients with verified diagnosis of ischemic heart disease and diabetes haven't included in the study. The levels of adiponectin, insulin were measured using ELISA kit test, insulin resistance (IR) was estimated using HOMA2 index. Endothelial-dependent flow mediated vasodilatation (EDVD) by D. Celermajer method was performed. Statistical analysis included non-parametric methods with p value < 0.05.
Endothelial dysfunction was established in the majority of HFpEF females with RA - 32 (72.7%). The level of EDVD was significantly lower in this pts compare to controls - 4.5 [2.6; 6.4] % and 7.3 [5.3; 8.8] % respectively (p < 0.05). In multivariate analysis remaining factors for endothelial dysfunction in HFpEF females with RA were RA disease duration>10years (OR 3.4, 95%CI 1.4-8.8), ESR>16mm/h (OR 2.3, 95%CI 1.1-5.3), GFR < 90ml/min/1.73m2 (OR 2.8, 95%CI 1.1-6.1) and seropositive RA (OR 4.2 95%CI 2.1-7.7). Insulin resistance was estimated in 35 (79.5%) main group pts, elevated serum adiponectin level - in 17 (38.6%). HFpEF females with RA had significantly higher adiponectin, insulin, insulin resistance levels compare to control (p <0.05). Risk factors for IR in RA females with HFpEF were BMI = 30 kg/m2 (OR 7.4, 95%CI 4.3-15.8), RA-duration>10years (OR 2.6, 95%CI 1.2-5.8), EDVD <10% (OR 4.8, 95%CI 1.1-18), glucocorticoid therapy > 3 months (OR 6.4, 95%CI 2.1-16) and increased serum adiponectin level (OR 5.9, 95%CI 2.8-14.7).
HFpEF females with comorbid RA are characterized by significantly higher frequency of endothelial dysfunction, insulin resistance, adipose tissue disorders that should be taken in account in management of this group of pts.

Remote patient telemonitoring in heart failure care. Experiences and perception of nurses and physicians in the Nordic Baltic region

I T Aamodt[1]; E Lycholip[2]; J Celutkiene[2]; A Stromberg[3]; D Atar[4]; R Sorum Falk[5]; T Von Lueder[6]; R Helleso[7]; T Jaarsma[8]; I Lie[9]
[1]*Oslo University Hospital, Centre for Patient centered heart and lung research, University of Oslo, Oslo, Norway*; [2]*University Hospital Santariskiu Klinikos, Clinic of Cardiac and Vascular diseases, Centre of Cardiology and Angiology, University of Vilnius, Vilnius, Lithuania*; [3]*Linkoping University, Department of Medical and Health Sciences, Linkoping, Sweden*; [4]*Oslo University Hospital, Department of Cardiology B and University of Oslo, Faculty of Medicine, Oslo, Norway*; [5]*Oslo University Hospital, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway*; [6]*Oslo University Hospital, Department of Cardiology B, Oslo, Norway*; [7]*University of Oslo, Department of Nursing Science, Oslo, Norway*; [8]*Linkoping University, Department of Social- and Welfare studies, Linkoping, Sweden*; [9]*Oslo University Hospital, Centre for Patient centered heart and lung research, Department of Cardiothoracic surgery, Oslo, Norway*

Funding Acknowledgements: NordForsk Nordic Programme on Health and Welfare

Background: Remote patient telemonitoring (RTM) may improve heart failure patients' symptom management at home, and reduce the high rehospitalisation rate. Research reveal patients' need for knowledge on symptom monitoring, access to heart failure services and support from health care professional (HCP). HCPs experience and implementation of RTM in daily clinical practice are unknown in Norway and Lithuania.
Objective: Our aims were (1) to explore HCPs experience of and perception to use RTM in heart failure care in Norway and Lithuania, and (2) to identify characteristics of HCP considering RTM to be relevant in clinical practice.
Methods: Physicians and nurses (n = 784) working with heart failure patients either on a hospital ward or outpatient clinic at 100 hospitals, were enrolled into this cross-sectional study. Data from a 43-items questionnaire with closed and open-ended questions were collected between September and December 2016. To explore the impact on HCP considering RTM to be relevant in clinical practice, univariate logistic regression analyses with 15 variables of HCPs characteristics, including their competency with information and communication technology, was performed. Variables significant at a 5 % level were included in the multivariable analyses. Analyses of quantitative data included using SPSS. Text data from open-ended questions were qualitatively analyzed using summative content analyses.
Results: RTM is not a part of routine clinical practice in heart failure care in Norway or in Lithuania with none of the responding HCPs using telemonitoring as of today. The majority, 69% [536/784] of HCPs in Norway and in Lithuania responded to the questionnaire. The mean age of HCPs in Norway was 46 years (SD 11.2), Lithuania 48 years (SD 10.9) and the length of experience in clinical practice in Norway was 18.3 years (SD 10.5) and 24.8 years (SD 11.4) in Lithuania. The multivariable logistic regression analyses on characteristics of HCPs that found RTM relevant to implement in daily heart failure care revealed a significant interaction between country and education, and significant effect of hospital level (OR 2.6, 95 % CI 1.48-4.56). "How many years of postgraduate experience do you have" was forced to be included due to clinical relevance (OR 1.0, 95 % CI .958-1.00). As for the most challenging categories for implementing RTM in clinical practice, HCP responded (a) financing of RTM from different levels of health care authorities and (b) patients' limitations: mental and physical, knowledge and compliance issues.
Conclusion: RTM is not a part of routine heart failure care in Norway or Lithuania. Additional funding from health care authorities and targeting of heart failure patients, may improve use of RTM. Moreover, to support leaders and health care authorities

in the process of implementation of RTM at home, key HCP are characterised by level of education, working at a university hospital and their country.

P2274

Heart failure nurses education: theory and practise. implementation of the heart failure nurse curriculum in local cardiovascular education for nurses. a substudy of the interact-in-hf study

K Karolien Baldewijns[1]; HP Brunner-La-Rocca[2]; L De Maesschalck[1]; A Deville[3]; J Boyne[2]
[1]Thomas More Mobilab, Mobilab , Geel, Belgium; *[2]Maastricht University Medical Centre (MUMC), Department of Cardiology, Maastricht, Netherlands*; *[3]Thomas More Kempen, Inclusie, Geel, Belgium*

Background: According to the ESC guidelines, Heart Failure nurses (HFN) are an essential part of successful Heart Failure (HF) management programs. Due to the complexity of HF, HFN need specific competences to deliver high quality care. The heart Failure Association (HFA) of the European society of cardiology (ESC) has developed the Heart Failure nurse curriculum, yet little is known about its' implementation in additional local cardiovascular education (CE) in ESC-member states.
Purpose: To describe to which extent CE programs in Belgium, the Netherlands and Germany correspond with the HFA-curriculum.
Methods: A case study design was used to obtain an in-depth understanding of the implementation of the HFA-curriculum within three CE in three ESC-member states. Although some member states offer more than one CE, for this purpose we chose CE organised by the national cardiovascular nursing societies.
Representatives of these CE programs shared their curricula including the learning objectives, which we compared with the HFA-curriculum. This methodology corresponds with the method of structured focused comparison as defined by George (1979).
Results: All studied CE aim to provide HFN or cardiovascular nurses with essential knowledge, skills and professional behaviour to enable them implementing evidence-based and guideline derived care. It has been found that every CE has different areas of attention:
CE in Belgium discusses aspects of all core learning objectives of the HFA-curriculum. Within the HFA curriculum learning objectives consist of knowledge, skills and professional behaviour aspects necessary for competent HF-care. CE in Belgium primarily emphasizes knowledge aspects of HF-care, whereas skills and professional behaviour are less emphasized.
CE in the Netherlands concentrates on aspects of chronic diseases in general, and pays limited attention specifically to HF. Elaborate attention is paid on patient education, support in self-care and to manage the effective use of pharmacological and device therapies.
CE in Germany particularly pays attention to recognise patients with suspected HF, patient education, support in self-care, to manage the effective use of pharmacological and device therapies, palliative care and the importance of comorbidities. However, very little attention is paid to acute HF, and monitoring signs and symptoms of HF.
All studied CE pay some attention to the optional learning objectives of the HFA-curriculum i.e. management of advanced heart failure, and leadership in HF-Nursing.
Conclusion: All compared CE adopt certain aspects of the HFA- curriculum, but none of them adopts the curriculum as a whole.

P2275

Construction and validation of protocol for nursing consultation in pediatric cardiac transplantation

MGV Sobral[1]; V L Vera Lucia Pessoa[1]; RS Florencio[1]; VRF Cestari[1]; LC Souza[1]; DL Salles[1]; TMM Moreira[2]; JCS Santiago[3]; SR Braga[1]; WM Barroso[1]; KL Penaforte[1]; LR Menezes[1]; JNC Bento[1]
[1]HOSPITAL DE MESSEJANA DR CARLOS ALBERTO STUDART GOMES, Fortaleza, Brazil; *[2]State of Ceara University, Nursing Graduation, FORTALEZA, Brazil*; *[3]Federal University of Ceara, FORTALEZA, Brazil*

The pediatric heart diseases have been gaining a significant increase in society and are classified as congenital and acquired. The multidisciplinary team has a key role in the care of these heart diseases, especially the nursing professional, since it provides care to these inpatients during the whole day and in outpatient consultations. This study was intended to develop a technology to guide the outpatient follow-up consultation to the children and adolescents who underwent heart transplantation. This is a methodological study, which was developed in two steps: in the first, we drew up a protocol based on the existing literature; the second consisted of the process of validating the content and suitability of the material by expert judges. In this step, the evaluation of the quality of the protocol was performed by five judges, using the Appraisal of Guidelines for Research and Evaluation (AGREE II) instrument. This instrument is composed by 23 items divided into 6 domains, in addition to a global evaluation. In the present work, the following items 05,13, 18,21, 22 e 23 were excluded because they did not comply with the research. The scores assigned by the judges were calculated and analyzed according to the guidelines of the instrument itself and presented through tables and charts, which were produced

PROTOCOL DOC

in Microsoft Excel, version 2016. The calculation of Pearson's coefficient of variation was performed by domains; and the average by items of AGREE II. The expert judges have an average time of training of six years, four of whom have practical experience in the field of pediatric heart transplantation. Concerning the evaluation of the quality of the protocol, domain 2 (Stakeholders' engagement) received the highest score from the judges (94.3%), whilst domain 1 and domain 4 maintained a percentage equal or higher than 80%. The lowest percentage fell on domains 3 and 5, which had percentages of 76.30% and 78.60%, respectively. The analysis of PCV showed that all domains had low PCV indexes, which demonstrates the high homogeneity in the scores given by the judges to each evaluation item. When analyzing PCV, we observed that the highest degree of dispersion of the evaluation percentages was in domain 3 (8.70%), due to the greater variation of the scores assigned by the judges. The domains that presented the lowest values were domains 2 (3.00%) and 5 (5.80%), since the scores assigned to the items of these domains by the judges were mostly 6 and 7. The percentage of quality of the global evaluation of the protocol was 77.1%, and all judges pointed out the use of the protocol, but with amendments. After validation of the protocol for the nursing consultation to transplanted children and adolescents, we evaluated that its development has achieved a significant success. We hope that this protocol may subsidize the nursing practice.

Attitude toward advance directives and heart failure prognosis among patients with heart failure: a pilot study

MS Mi-Seung Shin[1]; J Kim[2]; S Heo[3]; M An[4]
[1]Gachon University Gil Medical Center, Incheon, Korea Republic of; *[2]Gachon University, College of Nursing, Incheon, Korea Republic of*; *[3]University of Arkansas for Medical Sciences, College of Nursing, Little Rock, United States of America*; *[4]Chonnam National University, College of Nursing, Gwangju, Korea Republic of*

Funding Acknowledgements: This work is supported by the Gachon University Gil Medical Center (Grant number: 2016-17).

Background: Advance directives (ADs) are initially addressed in palliative care of patients with heart failure (HF) in Korea.
Objective: The purpose of this study was to explore values, treatment wishes, and proxy of patients with HF using a Korean-Advance Directive (K-AD) model and to explore associations of AD attitude and HF prognosis.
Methods: Patients with HF participated in this pilot test and completed surveys to explore the feasibility of K-ADs, attitude toward ADs, and HF prognosis.
Results: Of 24 patients (mean age, 67 years; men, 58.3%; ejection fraction, 35.88%), 62.5% completed the K-ADs. The major reason for incomplete K-ADs was knowledge deficit. Patients valued "comfortable death" the most (45.4%), followed by "giving no burdens to their family" (13.6%). Among treatment wishes, hospice care (66.7%) was preferred by the majority, while cardiopulmonary resuscitation (CPR) (31.8%) was selected less frequently. A child (50.0%) was mostly appointed as a proxy, followed by a spouse (33.3%). Patients with HF showed moderately positive AD attitude, with their completion rate of the K-AD of 70.0%. The 5-year survival estimation was 69.2%, with patients who wished for CPR having a higher survival (70.6% vs. 68.5%) and patients who wished for hospice care having a lower survival than their counterparts (70.7% vs. 75.2%).
Conclusion: The findings support the feasibility of the K-AD model, with a high acceptance in the two-thirds of the sample. Further studies are warranted to investigate whether treatment wishes are associated with AD attitude and HF prognosis in larger samples.

*equal contribution
Background/Introduction: Depressive symptoms are highly prevalent in patients with chronic heart failure (CHF) and associated with increased morbidity and mortality. CHF events such as hospitalisations worsen depressive symptoms. Evidence-based treatment options for depression in CHF patients are scarce. However, in most telemedical studies depression is an exclusion criterion.
Purpose: We investigated the effect of telemedicine on depressive symptoms in CHF-patients.
Methods: Our investigation represents a sub-analysis of the Telemedical Interventional Monitoring in Heart Failure (TIM-HF) Study. In this randomised, controlled, interventional trial (NCT 00543881), 710 CHF-patients were randomly assigned to either a group receiving usual care (UC) or a group that received a telemedical intervention (TM) consisting of a daily remote device that monitored the electrocardiogram, blood pressure and body weight. Depressive symptoms were evaluated by the 9-item Patient Health Questionnaire (PHQ-9) every three months in the first year and every six months in the second year. The analyses included only patients, who completed every item of the PHQ-9 at baseline. The cut-off for depression was set at = 10 points. Follow-up was 24 months.
Results: 158 patients presented clinically relevant depressive symptoms with a PHQ-9 score at = 10, independently, whether all or only some items were completed (TM: 80, UC: 78). 145 patients (TM: 73, UC: 72) completed every item of the PHQ-9, of whom 28 died within the study period (TM: 17, UC: 11, p = 0,22). Baseline characteristics did not differ between TM and UC group. Functional class III, dyspnoe at exertion, hospitalisation within the last 12 months prior randomisation, living alone and a prescription of antidepressants or antiarrhythmic agents were significantly associated with higher PHQ-9 levels at baseline (p <0.05). Higher PHQ-9 scores were also correlated with higher NT-proBNP levels (r = 0,141, p <0.05). After 24 months follow-up, the survivors with depressive symptoms at baseline who received telemedical care showed clinically meaningful improvements of PHQ-9 scores compared to the UC group by 32% from 12.7 ± 3.3 to 8.7 ± 5.6, (p <0.001). The improvement was consistent over the 24-month study period. The UC group showed no changes in PHQ-9 scores over time (13.1 ± 3.1 vs. 11.8 ± 5.5, p = 0.12).
Conclusion: The results of this study suggest that a subgroup of patients with significant depression symptoms at baseline shows improvement in depressive symptoms over a period of 24 months when successfully enrolled in a long-term telemedical care programme. Further studies are needed to confirm these results.

The biomarker sst2 is an independent predictor for acute kidney injury in patients with st segment elevation myocardial infarction

IR Vyshnevska[1]; YV Hilova[1]; OV Petyunina[1]; MP Kopytsya[1]
[1]Government institution"L.T. Malaya Therapy National institute of the National academy of medical sci, Kharkiv, Ukraine

The development of acute kidney injury (AKI) in patient with ST segment elevation myocardial infarction (STEMI) significantly associated with the adverse prognosis. In order to diagnose this condition in time the search for biomarkers is going. ST-2 is a novel and promising biomarker in the evaluation prognosis for STEMI patients with AKI.
Purpose: to determine the role of various markers in the development of AKI in patients with STEMI.
Methods: 103 STEMI patients were screened (75 male and 28 female), mean age was 61,85 ± 12,23 years. All patients had to undergo baseline investigations, including the level of serum creatinine; the glomerular filtration rate (GFR) was estimated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula. Accordingly, to the result, a group of patients has been selected (n= 59), their creatinine level was determined during the first 24 hours and after 48 hours. All patients were divided into two groups according to acute kidney injury network classification (AKIN): 27 patients in the first group with negative dynamic (1st stage AKIN and higher), 32 patient in the second group without creatinine dynamic. In addition, during the first day of hospitalization the sST2 and N-terminal pro-brain natriuretic peptide (NT-pro BNP) were determined.
Results: the analyses of biomarkers interconnection (NT pro-BNP, sST2) and GFR showed significant difference of estimated parameters in both groups as well (? = 0.02; ? = 0.03, respectively). Also, correlation of high and medium strength was found between biomarkers (sST2, NT pro-BNP) and GFR (? = 0.0001, p = 0.001). For identification of the main risk factor for reduced kidney function, we have used logistic regression method and found NT-pro BNP (area under curve (AUC) 0.7; p <0.05; 95% confidence interval (CI): 0.52 - 0.8; sensitivity (Se) 63%, specificity (Spe) 71%), sST2 (AUC 0.63; p <0.02; 95% CI: 0.52 - 0.74; Se 83%, Spe 41%) were main risk factors for predicting AKI formation.
Conclusions: changes in sST2 and NT-pro BNP level independently predict development of AKI in patients with STEMI.

The effects of exercise modality on myosin heavy chain isoform remodeling in the infarcted heart

JQ Zhang[1]; JR Cruger[1]; E Chung[1]
[1]*University of Texas at San Antonio, San Antonio, United States of America*

Funding Acknowledgements: UTSA Faculty Research Grant

Following myocardial infarction (MI), myosin heavy chain (MyHC) isoform expression shifts from a-MyHC to ß-MyHC, which associates with contractile dysfunction. The purpose of this study was to evaluate the effects of resistance training (RT) and endurance training (ET) on the MyHC isoform shift in rats with MI. MI was induced via surgical ligation of the left descending anterior coronary artery (LAD) in six-week-old male rats. Sham-operated rats underwent identical surgical procedures, only without LAD ligation to serve as non-MI controls. Rats were assigned to 4 groups: Sham (no MI, no exercise; n = 7), MI-Sed (MI, no exercise; n = 7), MI-RT (MI+ resistance training; n = 7), and MI-ET (MI+ endurance training; n = 7). Exercise training began 1-week after surgery for the MI-RT and MI-ET groups and continued for 10 weeks. MI-RT training consisted of progressively weighted ladder climbs on a 1m ladder with 2cm grip steps inclined at 85°, 3 days per week. MI-ET exercise entailed 10-16m/min running on a rodent treadmill inclined to 5° for 50 minutes per day, 5 days per week. Results showed significant increases in highly contractile a-MyHC cardiac isoforms in both the MI-RT and MI-ET groups compared to MI-Sed ($P < 0.05$). Furthermore, echocardiographic assessments revealed improvements in percent fractional shortening for both exercise groups which positively correlated with increases in a- to ß-MyHC isoform ratios ($P < 0.05$, $R2 = 0.535$). These results indicate beneficial effects of both RT and ET exercise modalities on post-infarct myocardial remodeling.

The relationship between metabolic shifts and cardiomyocyte structure alterations in heart failure and ischemic heart disease

T Tatiana Kulikova[1]; O Stepanova[1]; M Valikhov[1]; A Voronova[1]; V Sirotkin[1]; V Masenko[1]; R Akchurin[1]
[1]*Russian Cardiology Research and Production Complex, cardiology department, Moscow, Russian Federation*

Introduction: It is still unknown metabolic shifts in substrate utilization in the heart may be considered a cause or consequence in the pathogenesis of contractile dysfunction and heart failure (HF). A direct causal relationship between contractile abnormalities and metabolic dysregulation remains elusive. In HF there is a decrease in fatty acid mitochondrial oxidation concomitant with an increased reliance on carbohydrates for oxidative energy metabolism. Experimental studies, in addition to the tight coupling between cardiac work and oxidative metabolism, have demonstrated a direct causal relationship between shifts in substrate utilization and contractile dysfunction. Cardiomyocytes differ from other cells in that they contain sarcomeres which are essential for the contraction of the heart. Sarcomere is a main contractile unit of the heart. We propose that metabolic dysregulation in HF is connected with contractile dysfunction and cardiac metabolic alterations may lead to cardiomyocyte structure alterations, changes in sarcomere apparatus and impaired contraction of cardiomyocytes. The aim of the work is to study the relationship between metabolic shifts in HF and cardiomyocyte structure alterations.
Methods: In our study the expression levels of PPAR alpha as main regulator of cardiac metabolism were determined in left atrial appendages from patients with ischemic heart disease (IHD, n = 10) and HF and human non-diseased myocardium autopsy specimens (n = 5) using real time qPCR. Transmission electron microscopy was used for myocardial tissue studying.
Results: PPAR alpha expression level decrease was detected in the myocardial samples of patients with HF and IHD in comparison with expression level of PPAR alpha in the myocardial samples without cardiovascular pathology. These data indicate the occurrence of metabolic disorders in IHD - an energy metabolism shifting from cardiac fatty acid mitochondrial oxidation as primary energy source to glucose oxidation. In the same samples cardiomyocytes were evaluated by electron microscopy. Revealed cardiomyocytes have such features as sarcomere disorganization, obvious disruption of the sarcomere apparatus, enhanced glycogen content, mitochondria disposition, limited perinuclear mitochondria localization. It is well noticeable that mitochondria, which produce the basic energy for cardiac contraction in the normal heart and are localized along sarcomeres, depart from the disassembled sarcomeres in HF and IHD.
Conclusions: The results of our study have shown cardiac metabolic alterations and changes in structure of mitochondria - major energy station of cardiomyocytes - such as sparse mitochondrial infrastructure with immature cristae in HF and IHD. Mitochondria depart from contractile machinery of cardiomyocytes - sarcomeres, which become disassembled that lead in turn to impaired contraction of cardiomyocytes and to the decrease in cardiac contraction in HF.

Funding Acknowledgements: GINOP-2.3.2-15-2016-00049; GINOP-2.3.2-15-2016-00048; GINOP-2.3.3-15-2016-00025; UNKP-17-4-I-PTE-209

Introduction: Oxidative stress induces imbalance in mitochondrial fusion and fission processes finally leading to cell death. Previous studies demonstrated the beneficial effect of two antioxidant molecules, BGP-15 and L2286 on mitochondrial functions and on cellular oxidative stress response. In this work, we studied the effects of these compounds on the processes of mitochondrial quality control.
Methods: We used H9c2 cardiomyoblast and isolated neonatal rat cardiomyocytes (NRCM) for the experiments. The concentration of stressors and antioxidants was determined with MTT test. We applied MNNG in 125 μM, 400 μM and 800 μM concentrations for 4 and 8 hours on H9c2 cells. H2O2 was used in 150 μM and 300μM concentration for 0.5 and 4 hours on both models. L2286 was applied in 10 μM, while BGP-15 in 50 μM doses. Cellular levels of proteins playing role in mitochondrial dynamics were measured in Western blot samples. For the analysis of mitochondrial network we applied electron microscopy and immunocytochemistry.
Results: Due to MNNG treatment the level of fusion proteins (OPA1, MFN2) decreased, while the level of fission protein DRP1 increased markedly. The levels of fusion proteins increased in L2286 and BGP-15-treated cells. During the 8 hour treatment, the level of DRP1 also increased in the treated cells ($p < 0.05$).
In H2O2 stressed cells, administration of L2286 increased the level of OPA1 in both H9c2 and NRCM cells. MFN2 levels in NRCMs raised considerably due to BGP-15 treatment ($p < 0.05$). L2286 treatment decreased the DRP1 level in H9c2 cells ($p < 0.05$). We observed that the H2O2-induced mitochondrial fragmentation could be decreased by L2286 treatment ($p < 0.05$).
Discussion: Our results indicate that the PARP-inhibitor L2286 has beneficial effect on mitochondrial dynamics during oxidative stress, and also in the case of directly induced DNA damage. We can make similar.
Conclusions: in the case of BGP-15, which, via reducing ROS accumulation, propagates fusion processes, preserving cellular viability.

Identifying the role of fat body-specific lipolysis for heart function using Drosophila melanogaster

A Blumrich[1]; A Foryst-Ludwig[1]; J Grune[1]; B Hoeft[1]; U Kintscher[1]
[1]*Charité - Universitätsmedizin Berlin, Institute of Pharmacology, CCR/German Center for Cardiovascular Research, Berlin, Germany*

Funding Acknowledgements: DZHK (German Centre for Cardiovascular Research)

Background: Adipose tissue lipolysis has recently been identified as a crucial regulator of cardiac function. To clarify the underlying mechanisms, we analyzed the

role of the ATGL (adipose triglyceride lipase) ortholog in D. melanogaster, Brummer (Bmm), which was also found to be the key enzyme for fat body lipolysis in flies.
Methods: The cardiac phenotype of male flies with fat-body specific RNAi-mediated Bmm knockdown (fbBmm-KD) was analyzed using high-speed video imaging (semi-automated optical heartbeat analysis (SOHA)).
Results: fbBmm-KD was validated by confirmation of significantly reduced Bmm mRNA expression and subsequently increased triglyceride levels due to decreased lipolytic rates. Two-week-old fbBmm-KD flies showed no changes of cardiac parameters such as fractional shortening or heart rate (HR), compared to control flies. Challenging fbBmm-KD flies with starvation (1% agar) for 48 h slightly reduced cardiac output (CO) mediated by decreased HR in the presence of preserved stroke volume. Determination of heart diameters revealed a significantly smaller diastolic and systolic diameter in fbBmm-KD flies compared to controls. Interestingly, extension of the starvation duration to 72 h led to significantly augmented decrease of CO and HR only in fbBmm-KD flies, but not in control flies. In addition, a compensatory increase of stroke volume was observed in fbBmm-KD flies compared to controls.
Conclusion: In summary, we found that fbBmm-KD affects heart function during starvation by reducing CO mediated mainly through a decrease in HR. These data suggest that adipose tissue lipolysis, which occurs not only during starvation but also during chronic heart failure, affects HR regulation. This process likely involves cardiac actions of fatty acids or glycerol released from adipose tissue during lipolysis.

P2283
Specific cleavage of cardiomyopathy associated mutant DES by CRISPR-Cas9

A Ruppenstein[1]; A Brodehl[1]; A Gaertner-Rommel[1]; J Gummert[1]; AV Marakhonov[2]; MY Skoblov[2]; H Milting[1]
[1]Heart and Diabetes Center NRW, Ruhr University Bochum, Erich & H. Klessman Institute for Cardiovasc., Bad Oeynhausen, Germany; [2]Research Centre for Medical Genetics, & Moscow Institute of Physics and Technology (Dolgoprudny), Moscow, Russian Federation

Funding Acknowledgements: Dr Brodehl is supported by the German Heart Foundation/German Foundation of Heart Research.

Background: Mutations in the gene DES, encoding the intermediate filament protein desmin, cause skeletal and cardiac myopathies. Desmin filaments are formed in a stepwise protein assembly process of dimers, tetramers and unit length filaments. Most DES mutations are small missense or in-frame deletion mutations spread over the whole sequence of the ROD domain. They are inherited in a dominant mode. At the cellular level, the majority of DES mutations cause cytoplasmic protein aggregates consisting of wild-type and mutant desmin. However, no molecular treatment is available for patients carrying DES mutations.
Purpose: Recent studies established reliable genome editing technologies used for the development of molecular therapies of different diseases in vitro and in animal models. Therefore, we tested if genome editing using Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR)-Cas9 could be applied in vitro to degrade the mutant desmin with high specificity.
Methods: We inserted two different small in-frame deletion mutations into plasmids containing the DES-cDNA via site-directed mutagenesis. Guide RNAs (sgRNAs) were generated by in-vitro transcription and the specificity of all generated sgRNAs was tested by in vitro digestion using recombinant Cas9.
Results: Confocal microscopy using transfected SW13 cells demonstrated for one DES deletion mutation a cytoplasmic protein aggregation. The cleavage assays revealed for both deletion mutations the specificity of the designed sgRNAs. Whereas the wild-type desmin plasmid could not be cleaved by Cas9 in combination with the sgRNAs, the mutant forms were efficiently recognized and digested.
Conclusion: In our study, we designed and applied sgRNAs leading in combination with Cas9 to a specific cleavage of mutant DES-cDNA without affecting the wild-type form. In future, we will apply this approach to investigate in cell culture if the expression of the mutant desmin could be inhibited which might has relevance for the development of efficient therapies for patients with DES mutations.

Background: Although a significant progress achieved by modern immunosuppressive therapy, acute coronary rejection is the important obstruction on the way to the long-term survival of heart transplant patients. Risky alleles of the first intron polymorphisms within the FTO (fat mass and obesity-related gene, OMIM acc No. 610966) are the important risk factors associated with a wide list of noncommunicable diseases.
Materials and Methods: In our study, we have genotyped a unique set of 396 adult patients (aged 55.5 ± 11.9 years, 79% of males) who underwent heart transplantation at Institute for Clinical and Experimental Medicine, Prague, between January 2005 and December 2015, together with their donors. DNA was isolated from aortic tissue samples. Genotyping was performed using TaqMan technology on an AB 7300.
Results: No significant differences in FTO genotype frequencies between donors, recipients and the general population have been detected in our study. Recipient FTO genotypes were not associated with either type of rejection, or with the presence of one or two rejections. In contrast, donor TT genotype was significantly more prevalent in subjects where both types of rejections were detected (50%), than in subjects with just one (28.8%) or in subjects without the history of rejection (28.1%). The significant difference (P = 0.02) was reached for dominant model (TT vs. G allele carriers comparison; OR, 95% CI ? 2.53; 1.16 - 5.49).
Conclusions: The results of our study suggest that a donor, but not recipient FTO genotype could be a significant predictor of acute organ rejection in heart transplant patients.

P2285
Identification of circulating microRNAs from HTG EdgeSeq sequencing to predict outcome after acute myocardial infarction

C Pedrosa Da Costa Gomes[1]; E Schordan[2]; L Zhang[1]; D Attar[3]; H Firat[2]; Y Devaux[1]
[1]Luxembourg Institute of Health, CVRU, Strassen, Luxembourg; [2]Firalis SAS, Huningue, France; [3]Oslo University Hospital, Oslo, Norway

On behalf of: Cardiolinc™ network (www.cardiolinc.org)

Background: Numerous patients develop heart failure (HF) after acute myocardial infarction (AMI), representing a leading cause of mortality worldwide. Early intervention is important to prevent left ventricular remodelling that leads to heart failure. There is an urgent need for stratification of patients since, to date, no highly reliable biomarker-based tests are available for early risk assessment.
Purpose: Identify microRNAs (miRNAs) in plasma of post-AMI patients associated with left ventricular remodelling and HF that increment the value of clinical tests.
Methods: Plasma samples were collected from 82 and 87 post-AMI patients at two-time points, 12 hours after AMI (early) and 72 hours after AMI (late), respectively. Patients were assessed by echocardiography after 1 month (early) or 4 months (late), and were classified in 3 groups according to ejection fraction (EF): reduced (HFrEF), midrange (HFmrEF) and preserved (HFpEF). Plasma samples were analysed by HTG EdgeSeq followed by a bioinformatics approach to identify miRNAs differentially expressed between EF groups ($p < 0.05$ and $|log2FC| > 0.5$). Multivariable ordinal regression analyses were conducted to generate predictive models using clinical data and miRNAs. Comparison of the Akaike information criterion (AIC) of the models with the likelihood ratio test allowed to determine the incremental predictive value provided by miRNAs. The AIC rather than the area under the curve was used to avoid model overfitting due to the multiplication of predictive variables.
Results: Two lists of candidate miRNAs were obtained, one for the early and one for the late samples, with one miRNA in common between them. Nine miRNAs were differentially expressed between HFrEF/HFpEF and HFrEF/HFmrEF groups in the early samples, and 25 miRNAs in the late samples. These miRNAs, known to be enriched in cardiomyopathy relevant pathways, were used to generate predictive models with clinical data. In both early and late samples, the models involving clinical data and miRNAs more robustly risk stratified patients compared to the model with clinical data only. In the early samples, addition of panels of 3 or 4 miRNAs to the clinical model had a significant incremental predictive value as attested by a decrease of the AIC ($p < 0.001$). The improvement of prediction provided by panels of 3 or 4 miRNAs was also highly significant in the late samples ($p < 0.001$).
Conclusion: We identified 2 panels of miRNAs that significantly increment the value of clinical parameters to risk stratify AMI patients, at an early (12h) or late (72h) stage after AMI. These findings may help moving forward personalized healthcare of AMI patients. Further independent validation in large patient groups is needed.

Funding Acknowledgements: This work was supported by a grant 2.7/II/17 from the Institute of Cardiology, Warsaw, Poland

Background: A heart transplant (OHT) is performed on patients with end-stage heart failure when other medical or surgical treatments have failed. End-stage hypertrophic cardiomyopathy (HCM) indicates progression to left ventricle remodeling and systolic dysfunction. It is associated with a poor prognosis and affects 2.4-15.7% of cases of HCM. Mortality in this group of patients reaches 11%.
Purpose: Sarcomeric mutations are found in 30-65% of patients with HCM. However, most of the studies on HCM genetic background did not take into account the end-stage form, mainly due to its low prevalence in the HCM population. On the other hand, studies conducted in groups with end-stage HCM focused mainly on sarcomeric genes. In this study patients who underwent heart transplantation in the course of end-stage HCM were investigated using next generation sequencing for genetic background of the disease.
Methods: Nineteen unrelated patients (6 male, 31.6%) who underwent heart transplantation in the course of end-stage HCM were investigated for genetic background of the disease. Two approaches of next generation sequencing were used: TruSight Cardio panel by Illumina (n = 14) that provides coverage of 174 genes with known associations to 17 inherited cardiac conditions including cardiomyopathies, or custom panel of 35 cardiomyopathies genes (n = 5). Mean age of OHT were 44.2 ± 12.2 (range 17-63), 43.8 ± 18.3 in males (range 17-58) and 44.4 ± 9.1 in females (range 32-63).
Results: Thirteen probands (68.4%) had a single mutation in one of the sarcomeric genes: MYH7 (n = 7, 36.8%), MYBPC3 (n = 3, 15.8%), TNNT2 (n = 2, 10.5%), TNNI3 (n = 1, 5.3%) and one proband (5.3%) was compound heterozygote (MYH7 + MYBPC3). In 5 patients (26.3%), genetic examination did not reveal a pathogenic mutation. All mutations in MYH7 were missense variants and all mutations in MYBPC3 were truncating variants. The youngest OHT recipient (male, OHT at 17 y) had known pathogenic mutation in TNNT2 gene. Mean age of OHT in MYH7 carriers was 44.4 ± 10.7 and in MYBPC3 was 49 ± 4.4. The carrier of double mutation had OHT at 57.
Conclusion: The high prevalence of sarcomeric mutations with majority cases of MYH7 and MYBPC3 in OHT recipients confirms that genetic background of typical HCM and end-stage HCM is similar. The finding only truncating variants in MYBPC3 gene may suggest the stronger impact on the course of the disease. Surprisingly, the double mutation carrier has undergone OHT later than the average for the study group. Despite a small study group, our results suggest that the specific gene mutation may be related to the age of receiving a heart transplant. Also, more than 1/4 unsolved cases suggests that in some cases whole exome/genome sequencing might be needed to recognize the pathogenic mutation.

P2287

The polymorphic variant rs2070744 of NOS3 gene is associated with the functional state of the myocardium in patients with coronary artery disease and type 2 diabetes mellitus

E F Muslimova[1]; T YU Rebrova[1]; T G Nonka[1]; S A Afanasiev[1]; A N Repin[1]
[1]Cardiology Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, , Tomsk, Russian Federation

Coronary artery disease (CAD) is one of the most socially significant cardiovascular diseases, commonly resulting in chronic heart failure (CHF). It is important to carry out fundamental research aimed at finding predictors of pathological changes in the myocardium. The range of candidate genes of cardiovascular pathology is large. Among them, a clinical importance is attached to the NOS3 gene, which encodes endothelial nitric oxide synthase. Polymorphism T-786C (rs2070744) of this gene is particularly distinguished.
Aim: The association of polymorphism T-786C of the endothelial NO-synthase gene NOS3 with the functional state of the left ventricle (LV) was studied among residents of the West Siberian region with CAD and CHF, including that combined with type 2 diabetes mellitus (DM2).
Methods: The work followed the ethical principles set forth in the 1975 Helsinki Declaration, revised in 1989 in Hong Kong. All patients gave their informed consent for participation in the study. The sample consisted of 198 male patients (58 (52; 63) years of age) with chronic CAD. CHF was diagnosed in 190 (96.0%) patients. DM2 was identified in 56 (28.3%) patients; their glucose level was 6.4 (5.9; 7.4) mmol/L; the level of glycated hemoglobin 6.4 (5.7; 7.2)%. Amplification was carried out by allele-specific polymerase chain reaction using the commercial kit.
Results: In the total sample of patients, the frequencies of genotypes of polymorphism T-786C of gene NOS3 were as follows: 786TT, 69 (34.8%); 786TC, 97 (49.0%); 786CC, 32 (16.2%). The distribution complied with the Hardy–Weinberg equilibrium (p = 0.830). The frequency of allele –786C was 41%. Among patients without T2DM, the carriers of genotype –786TT were characterized by the largest LV ejection fraction (p = 0.012). In a pairwise comparison, statistically significant differences were found between –786TT and –786TC groups (p = 0.024). This dependence was not revealed in the group of patients with CAD combined with DM2. In the group with genotype –786TC, the frequency of left ventricular hypertrophy was higher among patients with DM2 than patients without it (p = 0.025). But there was no association between NOS3T –786C polymorphism and the severity of functional class of heart failure in both the groups.
Conclusion: The risk of development and progression of CAD and CHF is caused by numerous factors, among which genetic predictors play a significant role and in combination with metabolic disorders and specific environmental influences form a wide clinical variability of these diseases.

P2288

THE effect of Pex14 RNA interference on cardiomyocytes under anoxia-reoxygenation

I Tetjana Drevytska[1]; E Gonchar[1]; L Tumanovska[1]; D Klionsky[2]; V Dosenko[1]
[1]Bogomoletz Institute of Physiology, Department of general and molecular pathophysiology, Kiev, Ukraine; *[2]University of Michigan, Life Sciences Institute, Michigan, United States of America*

As a step toward understanding the homeostasis of peroxisomes in mammalian cells, we investigated a role of PEX14 RNA interference on the culture of neonatal in response to anoxia-reoxygenation. Selective autophagy is the significant process in cardioprotection and has beneficial and detrimental roles to cardiomyocytes depending on the level of autophagy and another circumstance. Proteins of pexophagy, and in particular, Pex14p plays a pivotal role in pexophagy via direct interaction with LC3-II.
Ventricular myocytes were isolated from 2-days-old Wistar rats by enzymatic digestion. 2 μg of expression plasmid mixtures were electroporated into isolated neonatal cardiomyocytes with a Nucleofector™ device using a Rat Cardiomyocytes Neo Nucleofector Kit (USA). For establishing the number of living and necrotic cells after 48-hours of cultivation we used fluorescence microscopy with hoechst and propidium iodide staining of cardiomyocytes. To identify signs of autophagy cardiomyocytes were stained with dansylcadaverine. Peroxisome labelling was assessed by a SelectFX Alexa Fluor 488 Peroxisome Labeling Kit with primary antibody directed against peroxisomal membrane protein 70 (PMP 70) according to manufacturer's protocol. For monitoring autophagy degradation, we quantified the number of the p62-staining aggregates protein in each cell using ImageJ software. RNA isolation was performed using phenol-chloroform extraction with guanidine isothiocyanate. cDNA was synthesized by reverse transcription. Real-time PCR was for quantitative evaluation of PEX14 and PINK1 mRNA. Data are present as means ± SE. The analysis of variance was performed using one-way ANOVA.
We found that the application of antiPEX14 siRNA significantly decreased the level of PEX14 mRNA (4.9x compared to the scrambled group, P < 0.01) confirming the

effectiveness of PEX14 RNA-interference. It was shown that PEX14 decreased the cell viability and led to an increase in the amount of propidium-positive cells at anoxia-reoxygenation (AR) modelling compared to scrambled. The AR modelling led to a decrease in peroxisomes quantity compared to control. The PEX14 RNA interference increase of peroxisomes quantity compared to the scrambled group with anoxia-reoxygenation modelling. Level of p62 was higher in culture with antiPEX14 siRNA application in contrast with scrRNA application at AR modelling. Thus, it is shown that the interference of the PEX14 at the modelling of AR led to an increase of the number of peroxisomes, which is accompanied by the suppression of autophagy, accumulation of the protein p62, and downgrade of the survival of cells. Taken together, these results suggest that peroxisomal proteins such as PEX14 are necessary to ensure pexophagy and, as a consequence, to protect the heart in a number of pathological conditions, such as, for example, myocardial infarction. The intensity of pexophagy can be a target for the development of future cardioprotective drugs.

P2289

Pharmacological and genetic aspects of RAAS genetic polymorphisms in patients with chronic heart failure

S U Volkova[1]; KA Tomashevich[2]; MY Soloboeva[3]; EV Panteeva[1]; AU Efanov[4]
[1]Tyumen State Medical University, Tyumen, Russian Federation; *[2]"Neftyanic" hospital, Tyumen, Russian Federation*; *[3]Tyumen Regional Hospital, Tyumen, Russian Federation*; *[4]Tyumen Department of the South-Ural Scientific center RAMS, Tyumen, Russian Federation*

Aim: To estimate influence of different medicine classes intake on disease issues in patients with chronic heart failure (CHF) in dependence of RAAS genetic polymorphism.
Materials and Methods: 51 patients have been investigated (27 women, 24 men, mean age 73.1+11.3 years old) with congestive heart failure, who had been hospitalized in "Neftyanik" hospital. All patients received standard therapy according to National guidelines. Using PCR genome DNA analyses "SNP-express" followed by electrophoretic detection we estimated polymorphisms ofA1166C angiotensin II receptor type I (AGTR1),T174M and M235T angiotensinogen gene (AGT), angiotensin converting enzyme (ACE) gene. We estimated the end point (lethal issue) within 4 years of surveillance (mean period 325.8+291.5 days) in these patients and analyzed pharmacological and genetic correlation for all medicine classes, used for CHF treatment: ACE-inhibitors, beta-blockers, aldosterone antagonists, digoxin, calcium channel blockers.
Results. RAAS genotypes were matched with clinical issues in patients with CHF. Kaplan-Meier method showed no correlation of RASS genetic polymorphisms with lethal issues. Significant pharmacological and genetic correlation and their influence on survival were detected for ACE gene Del allele in patients taking ACE inhibitors (? <0,06), and for T174M –AGT polymorphisms.Kaplan-Meier method for AA showed more cumulative survival among patients, who didn't have 174?et AGT gene allele, compared to the ones, who had this allele ($p = 0.012$). Similar data were obtained for T174M –AGT polymorphisms in patients, taking beta blockers. The cumulative survival was higher in patients, who didn't have 174?et AGT gene allele compared to the ones, who had this allele ($p = 0.004$). In all the cases the survival curves diverged from the first weeks of surveillance. For diuretics, digoxin, calcium channel blockers in our research we found no pharmacological and genetic associations.
Conclusion: Results of our research (obtained even on a small population of patients) showed that it is preferable to take into account RAAS genetic polymorphism when prescribing CHF medical therapy. This would certainly have significance for long-term prognosis in these patients.

AMPK/PGC1 activation by melatonin attenuates acute doxorubicin cardiotoxicity

D Dong Liu[1]
[1]Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Cardiology, Beijing, China People's Republic of

Doxorubicin (DOX) is a highly effective antineoplastic anthracycline drug; however, the adverse effect of the cardiotoxicity has limited its widespread application. Melatonin, a highly conserved molecule that is mainly produced by the pineal gland, is well known for its free radical scavenging and anti-oxidative roles. The aim of this study was to investigate the possible protective effects of melatonin against DOX-induced cardiomyopathy. We preliminarily established DOX-induced cardiotoxicity models in H9c2 cells, and C57 mice, which clearly showed cardiac dysfunction and injury, oxidative stress, and apoptotic damage. Treatment with melatonin obviously attenuated the DOX-induced cardiac dysfunction and pathological changes. The anti-oxidative stress activity of melatonin was achieved via reduced generation of reactive oxygen species through regulation of AMPK and PGC1a signaling. Its anti-apoptotic activity was shown by reductions in the number of TUNEL-positive cells and DNA fragments along with a decreased ratio of Bax/Bcl-2 expression. In a further mechanistic study, melatonin exerted improvement on the cardiac function, oxidative stress, and apoptosis were inhibited by Compound C treatment or AMPK/PGC1a siRNA. The present work demonstrates for the first time that melatonin obviously prevented DOX-induced cardiotoxicity via the suppression of oxidative stress and apoptosis through the AMPK/PGC1a signaling pathway.

Funding Acknowledgements: National Research, Development and Innovation Office of Hungary (NKFIA; NVKP-16-1-2016- 0017)

Background: Calcium homeostasis and signaling has been object of intensive investigations in various tissues. A novel transgenic rat strain has recently been generated that stably expresses the genetically engineered calcium sensor protein GCaMP2 (containing a calmodulin-based calcium sensor and a fluorescent protein) in different cell types including cardiomyocytes (Sci Rep 2015;5:12645). This animal model offers a unique possibility to directly examine calcium signaling in cells, tissues and organs, thus it might be a useful tool for assessing the effects of drugs and pathophysiological states on cardiac calcium homeostasis. In order to investigate whether the expression of the GCaMP2 protein itself affects cardiac function, in the present work we aimed at characterizing in vivo hemodynamics by left ventricular (LV) pressure-volume analysis in the GCaMP2 transgenic rats strain.
Methods: GCaMP2 transgenic rats (GCaMP2 group, $n = 10$) and age-matched Sprague-Dawley control animals (Co group, $n = 10$) were investigated. In vivo hemodynamic characterization was performed by LV pressure-volume analysis, obtaining both conventional hemodynamic parameters as well as sensitive, load-independent functional indices.
Results: Post-mortem heart weight data showed increased heart weight in the GCaMP2 group compared to controls (heart weight to tibial length ratio: 0.26 ± 0.01 GCaMP2 vs. 0.23 ± 0.01g/cm Co, $p < 0.05$), suggesting myocardial hypertrophy. We detected elevated mean arterial pressure (MAP: 138 ± 3 GCaMP2 vs. 128 ± 3mmHg Co, $p < 0.05$) in transgenic rats. LV systolic function was not altered in transgenic rats as indicated by conventional parameters (ejection fraction, stroke volume, dP/dtmax) and load-independent, sensitive indices (end-systolic pressure-volume

relationship, preload recruitable stroke work). Regarding diastolic function we found a marked deterioration of LV active relaxation in GCaMP2 animals (Tau: 16.8 ± 0.7 GCaMP2 vs. 11.7 ± 0.6ms Co, p <0.001; dP/dtmin: -9641 ± 247 GCaMP2 vs. -10781 ± 420mmHg/s Co, p <0.05). Parameters of LV stiffness were found to be unchanged in transgenic rats.
Conclusions: Our data indicated myocardial hypertrophy, arterial hypertension and impaired LV active relaxation along with unchanged systolic performance in the heart of transgenic rats expressing the GCaMP2 fluorescent calcium sensor protein. Myocardial expression of this genetically engineered calcium sensor protein might interfere with physiological calcium handling, resulting in the observed characteristic changes in the heart. While there were no significant changes in calcium handling in primary cardiac cell cultures (Sci Rep 2015;5:12645), special caution should be taken when using this rodent model in cardiovascular pharmacological and toxicological studies. In addition, this rat may be a useful model for studying calcium handling in cardiac hypertrophy.

Totally percutaneous model with echoguidance of ischemic mitral regurgitation in the pig

OUAFA Hamza[1]; A Kiss[1]; AM Kramer[1]; K Tillmann[1]; BK Podesser[1]
[1]Ludwig Boltzmann Cluster for Cardiovascular Research, Center for Biomedical Reasearch, Vienna, Austria

Background: Development of translational animal models of cardiovascular disease is crucial to understand the disease mechanism and pathophysiology and provide a unique platform to test novel therapies and devices. The European heart survey showed that 49% of patients with severe symptomatic mitral regurgitation were denied surgery. This patient population was characterized by one particularly recurrent parameter: Secondary mitral regurgitation. Surgical treatment of secondary mitral regurgitation remains a subject of controversy and still doesn't show a clear impact on the mortality. In addition, there is unmet need to establish less invasive approaches in patients with secondary mitral regurgitation. Aims: therefore, the aim of the present study was to establish a clinically reliable large animal model of mitral valve regurgitation.
Methods: Young female domestic pigs were used for this model extablischement (n = 9). The induction of mitral valve regurgitation was performed by localized posteromedial papillary muscle (PMPM) myocardial infarction. The PMPM irrigating branches are first identified by selectively injecting contrast media in the circumflex branches while performing echocardiography. Then a 2ml of pure Ethanol are injected in the identified branches. The evaluation of the mitral valve regurgitation and cardiac function was assessed by echocardiography.
Results: 7 pigs survived during the 6 weeks follow up period. One pig was euthanized after 3 weeks and another after 2 because of refractory pulmonary edema. Ethanol injection resulted in postero-inferior wall and PMPM dyskinesia. Significant left ventricle enlargement was noticed (End diastolic diameter at baseline: 50,04 ± 4.34mm vs at 6 weeks 62,12 ± 3.92mm; p < 0.001) as well as left atrium enlargement (left atrium area at baseline: 7.75 ± 0.95 vs at 6 weeks 17.65 ± 3.2mm; p < 0.001). Mitral regurgitation jet area significantly increased over the 2 weeks follow up period (jet area at baseline 0.03 ± 0.015 cm^2 vs at 6 weeks 3.22 ± 0.53). A significant tenting area developed over the follow up period (Tenting area at baseline 0.35 ± 0.21cm^2 vs 2.17 ± 0.63cm^2 at 6weeks; p < 0.001)
Conclusion: Our results clearly provided significant evidence about a totally percutaneous clinical relevant model of ischemic mitral valve regurgitation in pigs.

P2293
Comparison of the anti-remodeling effect of pharmacological soluble guanylate cyclase activation with pressure unloading in pathological myocardial left ventricular hypertrophy

M Mihaly Ruppert[1]; T Radovits[1]; S Korkmaz-Icoz[2]; S Li[2]; P Brlecic[2]; BT Nemeth[1]; A Olah[1]; CS Matyas[1]; K Benke[1]; EM Horvath[3]; B Merkely[1]; M Karck[2]; G Szabo[2]
[1]Semmelweis University Heart Center, Budapest, Hungary; *[2]University of Heidelberg, Department of Cardiac Surgery, Heidelberg, Germany*; *[3]Semmelweis University, Department of Physiology, Budapest, Hungary*

Funding Acknowledgements: UNKP-17-3-I-SE-6; NKFIA; NVKP-16-1-2016- 0017

Background: Pressure unloading induces the regression of left ventricular myocardial hypertrophy (LVH). Recent findings indicate that pharmacological activation of the soluble guanylate cyclase (sGC) - cyclic guanosine monophosphate (cGMP) pathway may also exert anti-remodeling properties in the myocardium.
Purpose: Therefore, we aimed to investigate the effects of the sGC activator cinaciguat in a rat model of LVH and compare it to the "gold standard" pressure unloading therapy.
Methods: Abdominal aortic banding was performed for 6 or 12 weeks. Sham operated animals served as controls. Pressure unloading was induced by removing the aortic constriction after week 6. The animals were treated from week 7 to 12, with 10 mg/kg/day cinaciguat or with placebo p.o. respectively. Cardiac function and morphology were assessed by left ventricular pressure-volume analysis and echocardiography. Additionally, key markers of myocardial hypertrophy, fibrosis, nitro-oxidative stress, apoptosis and cGMP signaling were analyzed.
Results: Pressure unloading effectively reversed LVH (heart weight to tibial length ratio [HW/TL]: 0.57 ± 0.02 AB-Co vs. 0.40 ± 0.01g/cm Debanded, p < 0.05), decreased collagen accumulation and provided protection against oxidative stress and apoptosis. Regression of LVH was also associated with a full recovery of cardiac function. In contrast, chronic activation of the sGC enzyme by cinaciguat only slightly influenced the pre-established hypertrophy (HW/TL: 0.57 ± 0.02 AB-Co vs. 0.48 ± 0.03g/cm AB-Cin, n.s.). However, it led to increased PKG activity and had a significant impact on myocardial fibrosis (Masson's score: 1.71 ± 0.11 AB-Co vs. 1.12 ± 0.18 AB-Cin, p < 0.05), nitro-oxidative stress and cardiomyocyte apoptosis. The inhibition of pathological processes resulted in improved systolic (cardiac contractility, ejection fraction) and diastolic (myocardial stiffness) function.
Conclusion: Our results indicate that both cinaciguat treatment and pressure unloading evoked anti-remodeling effects and improved LV function, nevertheless in a different manner.

FGF23 induces local angiotensin II signaling in cardiomyocytes

K N Ketaki Mhatre[1]; P Wakula[1]; O Klein[1]; E Bisping[2]; J Volkl[1]; B Pieske[1]; F Heinzel[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Experimental Cardiology, Berlin, Germany; *[2]Medical University of Graz, Cardiology, Graz, Austria*

Heart failure (HF) manifestation and progression are driven by systemic activation of neuroendocrine signaling cascades, such as the renin-angiotensin aldosterone system (RAAS). Fibroblast growth factor 23 (FGF23), an endocrine hormone, is linked to HF and cardiovascular mortality. It is also a mediator of left ventricular hypertrophy (LVH). FGF23 is proposed to trigger pathological signaling by involving Ca2+-regulated transcriptional pathways. In vivo, high circulating levels of FGF23 are associated with an altered systemic RAAS response. In the present study, we investigated Ca2+-dependent signaling of FGF23 in ventricular cardiomyocytes and its association with angiotensin II (ATII).
Neonatal rat ventricular cardiomyocytes (NRVMs) were isolated and cultured for 5 days. ATII (1μM) or FGF23 (25ng/ml) were used as hypertrophy stimuli. Cell surface area and ATII levels were studied by immunostaining. Gene expression was accessed by qPCR. Ca2+ transient (CaT) amplitude (F/F0peak at 1Hz; Fluo-4 AM) and CaT area under the curve (AUC) were quantified in cytosol and nucleus. A subset of NRVMs was treated with losartan (1 μM), Aminoethoxydiphenyl borate (2-APB, 5μM) 30 min before agonist stimulation. Mass spectrometry analysis was carried out to detect secreted ATII.
In neonatal rat ventricular myocytes (NRVMs), both ATII and FGF23 induced hypertrophy as reflected by cell area and hypertrophic gene expression. In Ca2+ imaging experiments, an increase of cytoplasmic (2.4folds ± 0.3) and nuclear (1.9folds ± 0.3) CaT amplitude was observed on acute treatment with FGF23 (p < 0.01) similar to ATII. CaT AUC too was augmented significantly by both the treatments in cytoplasm and nucleus. The study with inositol 1, 4, 5-triphosphate (IP3) inhibitor 2-APB showed that FGF23– like ATII– induced IP3-dependent Ca2+ release from the nucleoplasmic Ca2+ store, associated with cellular hypertrophy.
Interestingly, ATII receptor antagonist losartan significantly attenuated FGF23-induced changes in Ca2+ homeostasis and cellular hypertrophy suggesting the involvement of ATII receptor-mediated signaling. Furthermore, FGF23 increased intracellular ATII expression (4.2folds ± 0.5) at 24h as well as on acute 90mins treatment (2.2folds ± 0.1) vs. control (p < 0.01), suggesting ATII involvement. Moreover, the mass spectra (m/z range: 1044-1054) of the supernatant collected from FGF23 treated NRVMs clearly showed the presence of a peak of ATII peptide (m/z 1046.562), confirming ATII secretion. However, the ATII peak was absent in the supernatant collected from untreated NRVMs.
In conclusion, FGF23 and ATII share a common mechanism of IP3- and Ca2+-dependent cardiomyocyte hypertrophy. FGF23-mediated cellular hypertrophy is associated with increased production and secretion of ATII by cardiomyocytes. These findings indicate a pathophysiological role of the cellular angiotensin system in FGF23-induced hypertrophy in ventricular cardiomyocytes.

Background: Autophagy is a cytoprotective process required for the maintenance of physiological homeostasis of virtually every organ, including the heart. Chronic ß-adrenergic stress causes a profound left ventricular cardiac dysfunction and increases cardiomyocyte death in autophagy-deficient hearts. We tested the hypotheses that loss of autophagy causes dysfunctional subcellular calcium homeostasis early in life and that these alterations are potentiated in response to acute ß-adrenergic activation. Such early alterations of intracellular calcium homeostasis may contribute to the development of contractile dysfunction and functional remodeling of autophagy-deficient cardiomyocytes.
Methods: Ventricular myocytes were isolated from adult (14-16 weeks old, male and female) cardiomyocyte-specific autophagy-deficient mice (Atg5-/-; N = 4) and their control littermates (Atg5+/+; N = 4). Nucleoplasmic and cytoplasmic calcium transients were recorded using line-scan confocal imaging in electrically stimulated cells (1 Hz, steady-state, room temperature) loaded with Fluo-4/AM (8 μM) and perfused with normal Tyrode solution containing 1 mM CaCl2 (control) followed by acute exposure to the ß-adrenergic agonist isoprenaline (10 nM). Sarcoplasmatic reticulum calcium content was assessed as calcium released during rapid caffeine application (30 mM) at the end of each experiment. Data were analyzed using two-way RM ANOVA and are reported as mean ± S.E.M..
Results: At baseline, Atg5-/- cardiomyocytes had significantly increased time for 50% relaxation from peak of the cytosolic calcium transient (RT50: 242 ± 17ms vs. 204 ± 10ms; n = 13-16 cells, P < 0,02), while cytosolic calcium transient amplitude, time to peak and time for 90% relaxation from peak of the cytosolic calcium transient (RT90) were not different. Autophagy-deficient cardiac myocytes also showed markedly prolonged time to peak of nucleoplasmic calcium transient compared to control cells (235 ± 14ms vs. 172 ± 14ms; P < 0,01). As expected, administration of isoprenaline profoundly increased calcium transient amplitude and reduced decay time of the calcium transient in cytosol as well as nucleus in both groups. In Atg5-/- cells, however, isoprenaline increased cytosolic calcium transient amplitude to a significantly higher level as compared to Atg5+/+ cells (by 149% vs. 74% of control, P < 0,01; respectively). In addition, RT50 and RT90 were reduced by a greater extent in Atg5-/- cells than relaxation times from Atg5+/+ cells (32% vs. 20% and 33% vs. 24% of control; P < 0,01 and P < 0,03, both respectively). Upon isoprenaline administration the sarcoplasmatic reticulum calcium load was comparable between groups.
Conclusion: Autophagy-deficient ventricular cardiomyocytes display increased susceptibility to ß-adrenergic activation underlying potentiated cytosolic and nuclear calcium cycling. Our results suggest that intact autophagy plays a protective role in the intracellular calcium handling during ß-adrenergic stress.

Introduction: Repeated remote ischemic conditioning (RIC) is considered as a potential clinical approach to improve cardiac function following myocardial infarction (MI).
Purpose: To clarify the impact of RIC on: 1) hemodynamic function following chronic MI; 2) the regulation of myocardial Ca2+-dependent force production
Methods: MI was induced by permanent ligation of the left coronary artery in male Sprague-Dawley rats (10-12 weeks old). At 4 weeks after MI, rats were allocated into the untreated control (n = 6) and RIC-treated groups (n = 6). RIC treatment was performed by 3 cycles of 5 min unilateral hindlimb ischemia and 5 min of reperfusion once a day for 2 weeks. Echocardiography was used to asses left ventricular (LV) ejection fraction (LVEF). 6 following MI, hemodynamic function was monitored by an invasive method involving the determination of LV systolic pressure (LVSP) and the rate of LV pressure development (+dP/dt). Tissue samples were collected from the remaining anterior and a remote non-infarcted inferior LV areas to: 1) assess Ca2+ regulated force production in permeabilized isolated cardiomyocytes and 2) to determine site-specific phosphorylation statuses of cardiac troponin-I (cTnI) by Western Immunoblotting and cardiac myosin-binding protein C (cMyBP-C) by a ProQ Diamond phosphoprotein staining kit.
Results: 4 weeks after MI LVEF decreased from 82 ± 1% and 81 ± 1% to 54 ± 2% and 51 ± 4% in the control and RIC groups, respectively. However, at 6 weeks after MI LVEF was markedly imporved in the RIC group (57 ± 4%; P <0.05) than that at 4 weeks, while it was unchanged in controls (50 ± 1%). These differences were accompanied by higher LVSPs (96 ± 3 vs. 87 ± 2 mmHg, P <0.05) and +dP/dt values (5226 ± 96 mmHg/s vs. 4622 ± 142 mmHg/s, P <0.05) in rats with RIC than in controls. In addition, the Ca2+ sensitivity of cardiomyocyte force production was significantly lower both at the anterior (pCa50: 5.93 ± 0.02 vs. 6.05 ± 0.03, P <0.05) and the non-infarcted LV areas (pCa50: 6.01 ± 0.03 vs. 6.10 ± 0.02, P <0.05) in the RIC groups than in controls, respectively. Furthermore, RIC enhanced cTnI phosphorylation levels at Ser(22) both in the infarcted (1.09 ± 0.04 in the RIC group; 0.78 ± 0.05 in controls, P <0.05, in relative units) and non-infarcted LV areas (1.08 ± 0.08 in the RIC group; 0.82 ± 0.02 in controls, P <0.05). cTnI phosphorylation at the Thr(143) site showed difference only in the infarcted region between the groups (1.0 ± 0.07 in the RIC group; 0.58 ± 0.06 in controls, P <0.05). Similarly, phosphorylation of cMyBP-C was enhanced by RIC in the infarcted region of LV (0.97 ± 0.06 vs. 0.65 ± 0.04 in controls, P <0.05).
Discussion: RIC limited LV hemodynamic impairment following MI via a mechanism possibly involving cTnI and cMyBP-C phosphorylations in infarcted rat hearts. These findings implicate the preservation of ß-adrenergic responsiveness during repeated RIC evoked cardioprotection, and provide support for RIC as a therapeutic approach for improve post-infarct cardiac depression.

P2297

Repeated remote ischemic conditioning enhances Neuregulin-1/ErbB2/3/4 expression following myocardial infarction in rats

P Pilz[1]; M Lang[1]; O Hamza[1]; C Kaun[2]; J Wojta[2]; BK Podesser[1]; A Kiss[1]
[1]*Medical University of Vienna, Center for Biomedical Research, Vienna, Austria*; [2]*Ludwig Boltzmann Cluster for Cardiovascular Research, Department of Internal Medicine II, Medical University of ViennaCluster for Cardiovascular Research, Vienna, Austria*

Introduction: Adverse left ventricle (LV) remodelling following myocardial infarction (MI) plays an important role in the progression of congestive heart failure (HF). Recombinant human Neuregulin-1 (rhNRG-1) has been demonstrated to improve LV ejection fraction (LVEF) and coronary microcirculation in patients with HF. Repeated remote ischemic conditioning (RIC) is considered as a potential clinically approach to improve cardiac function following MI, however the mechanisms are not fully elicited.
Purpose: The aim of the present study was to (1) clarify the effects of a brief period of RIC on LV hemodynamic function and coronary flow and (2) to assess the expression of NRG-1, ErbB2/3/4 expression following MI.
Methods: Male Sprague-Dawley rats were subjected to permanent left coronary artery (LCA) occlusion and allocated to two groups: (1) Myocardial infarction (MI; n = 7) and (2) MI+RIC; n = 5). Repeated RIC was started at the 3rd day after MI once a day for 5 days by 3 cycles of 5 min of unilateral hindlimb ischemia and 5 min of reperfusion. Cardiac functional parameters were assessed by transthoracic echocardiography at baseline and at days 3 and 8 following MI. Coronary flow (CF) and LV systolic pressure (LVSP) were evaluated on an isolated erythrocyte-perfused working heart model at day 8 following MI. The alterations in coronary flow primarily reflect alterations in coronary resistance, allowing evaluation of microvasculature function in this experimental set up. The expression of plasma level of NRG-1 was measured by ELISA and mRNA expression of ErbB2/3/4 was accessed by RT-qPCR.
Results: RIC enhanced LVEF as compared to MI group (63 ± 1% vs. 58 ± 2% on day of 8th following the induction of MI, p = 0.074). This was accompanied by preserved LV systolic function in rats with RIC as compared with MI (LVESD: 5.9 ± 0.06 mm and 6.4 ± 0.2 mm, p = 0.064). Results were obtained from the isolated working heart system showed that CF and LVSP were markedly enhanced in rats with RIC as compared to MI (CF: 4.3 ± 0.2 vs 3.1 ± 0.2 ml/g heart weight and LVSP: 109 ± 2 mm Hg vs 119 ± 4; mm Hg; p <0.01, respectively). Both plasma and tissue expressions of NRG-1 were significantly elevated by RIC in comparison to MI group (plasma: 10.6 ± 1.7 μg/ml vs 19.4 ± 3.3 μg/ml and LV tissue: 0.53 ± 0.09 vs. 3.16 ± 0.9 1/18S; p <0.05). Similarly, the mRNA expression of ErbB2/3/4 showed at least part in significant differences between the groups (ErbB2: 1.0 ± 0.2 vs. 2.08 ± 0.4 1/18S, p <0.05; ErbB3: 1.07 ± 0.3 vs. 2.4 ± 0.4 1/18S, p <0.05; ErbB4: 0.46 ± 0.12 vs. 0.64 ± 0.23 1/18S; n.s) in LV tissue samples were taken from the infarcted zone.
Discussion: RIC preserves systolic LV function and markedly enhances basal coronary flow following MI in rats. These results were accompanied by with a marked increase in NRG-1 levels in plasma and myocardial tissue samples indicating enhanced cardioprotection. Therefore, repeated remote RIC is a potential therapeutic approach for improved post-MI remodeling.

P2298

Acute effects of palmitoleic acid, an obesity-related free fatty acid, on ventricular cardiomyocyte Ca signaling

T Tim Guthof[1]; I Betz[2]; D Bode[1]; F Hohendanner[1]; A Foryst-Ludwig[2]; U Kintscher[2]; B Pieske[1]; F Heinzel[1]
[1]*Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany*; [2]*Charite - Campus Mitte (CCM), Institute of Pharmacology, Center for Cardiovascular Research, Berlin, Germany*

Background: Obesity plays an important role in the development of heart failure and is associated with alterations of fatty acid metabolism and elevated free fatty acids. Previously, we have found palmitoleic acid (PE16:1) to be involved in heart failure with reduced ejection fraction in mouse and human.
Purpose: We tested the hypothesis that palmitoleic acid has an acute effect on the intracellular calcium (Ca2+) homeostasis in ventricular cardiomyocytes.
Methods: Freshly isolated rat ventricular cardiac myocytes were incubated with PE 16:1 and the respective BSA concentration (Control) for 30 minutes. Cells were stimulated in an electric field and confocal line scan images were recorded (Fluo-4). Ca2+ transients (CaT, 1-5 Hz) were examined by the calculation of CaT amplitude (F/F0), time to peak (TTP), the time to half maximal release (TF50) and the time constant of decay (Tau). The amplitude of the caffeine response was used to estimate the asarcoplasmic reticulum (SR) Ca2+ load and the respective time constant of Ca2+ decay was used to estimate the NCX function.
Dyssynchrony of Ca2+ release was assessed by calculating the percentage of the local early Ca2+ release (local TF50 < 5 ms) compared to the control group. To further investigate the causes of the dyssynchrony the probability of early release and the propagation velocity of spontaneous waves were calculated.
Results: Myocytes incubated with PE 16:1 (30 min) showed a normal CaT amplitude but prolongation of global TF50 (control: 5.4ms vs. PE 16:1: 9.4ms, $p < 0.05$) and global TTP (26.7ms vs. 41ms, $p < 0.05$). Cytosolic Ca2+ removal was significantly slowed (Tau: 97ms vs. 156ms, $p < 0.05$), but SR Ca content was significantly increased with PE 16:1. Slowed decay of the caffeine-induced Ca transient (Tau: 606ms vs. 1353ms, $p < 0.05$) suggested reduced forward mode Na/Ca exchanger activity.
Moreover, intracellular Ca2+ release was more dyssynchronous with significantly less early release sites (control: 50%; PE 16:1: 25%, $p < 0.05$) and increased time to half maximal release (TF50) of late release sites (9ms vs. 15ms, $p < 0.05$). The probability of local early Ca2+ release was lower (0.71 vs. 0.61, $p < 0.05$) and the propagation velocity of waves slower (150.4 μm/ms vs. 120.4 μm/ms ; $p < 0.05$). The cells incubated with PE16:1 showed more sparks (159 /100μm/ms vs. 814 /μm/ms, $p < 0.05$) but a lower wave to spark ratio (0.61 vs. 0.30, $p < 0.05$). The average wave count was higher but statistically not significant (2.1 vs. 3.5, $p = 0.08$).
Conclusion: In cardiomyocytes palmitoleic acid acutely reduces the synchrony and global kinetics of Ca homeostasis and at the same time increases arrhythmogenic Ca release. These acute changes precede and may trigger cardiomyocyte remodeling leading to adipositas-related cardiac contractile dysfunction and heart failure.

Background: Stress-regulated mitogen-activated protein kinases (SR-MAPKs; i.e. p38-MAPKs and JNKs) are activated in the heart by various stresses. They cause cardiac dysfunction and cardiomyocyte death, so pathway components are potential therapeutic targets for heart failure. Cardiac ischemia is associated with increased oxidative stress that is further enhanced on reperfusion (I/R). Oxidative stress (e.g. H2O2) activates SR-MAPKs in cardiomyocytes and perfused hearts but, while ischemia activates p38-MAPKs, JNKs are only activated by I/R. SR-MAPKs are activated by specific MAPK kinases, but the upstream MAP3Ks that initiate the signal in different conditions are not well-defined. ASK1 is an oxidative stress-responsive MAP3K for SR-MAPKs and is required for cardiac hypertrophy, but its specific role in ischemia or I/R is not clear.
Purpose: Our aims were to determine if ASK1 signals selectively to p38-MAPK in the heart, particularly during ischemia, and establish downstream consequences of ASK1 signalling in the heart.
Methods:/Results: We confirmed that H2O2 activated SR-MAPKs in rat neonatal cardiomyocytes by immunoblotting with antibodies to the phosphorylated (activated) kinases. The concentration-dependence for ASK1 phosphorylation by H2O2 was bell-shaped, with maximal activation at 1 mM and reduced activation >1 mM H2O2. Rat hearts were perfused ex vivo in the Langendorff mode and subjected to ischemia (15 min) or I/R (15/45 min). ASK1 was activated only during ischemia, consistent with moderate levels of oxidative stress being required. We did not detect activated ASK1 with I/R. Selonsertib (1 μM), a highly selective ASK1 inhibitor, suppressed p38-MAPK, but not JNK, activation by H2O2 in cardiomyocytes or perfused hearts, or hearts subjected to ischemia or I/R. Thus, ASK1 signals selectively to p38-MAPK. The effects of 4 mg/kg/d selonsertib on mouse hearts (male C57Bl6; 10 weeks) in vivo were assessed with/without 0.8 mg/kg/d angiotensin II (AngII), a hypertensive model associated with increased oxidative stress (7 d; n = 6-8). Echocardiography was used to assess cardiac function/dimensions. Selonsertib alone had no effect on any of the variables studied. AngII promoted cardiac hypertrophy with increased diastolic and systolic left ventricular posterior wall thickness. This was significantly inhibited by selonsertib indicating ASK1 is required in AngII-induced cardiac hypertrophy.
Conclusions: ASK1 is an oxidative-stress responsive MAP3K that signals selectively to p38-MAPK in cardiomyocytes in the context of moderate stress during ischaemia. High level oxidative stress as occurs on reperfusion does not activate ASK1 to a significant degree. Moreover, ASK1 activation in hypertension contributes to the hypertrophic response. By dissecting upstream activators of p38-MAPK and JNKs, it will become increasing apparent which may be targeted under specific conditions to manipulate p38-MAPK and/or JNK signalling for the management of heart failure.

Objective To investigate the effects and mechanisms of Pyridostigmine(PYR) on cell proliferation and fibrosis in human cardiac fibroblasts(HCFs). Methods The model of fibrosis in HCFs was induced by transforming growth factor beta. After the intervention of PYR, the content of collagen I(COL1) was observed by measuring the hydroxyproline concentration. The cell cycle of HCFs was screened by Flow cytometry. The mRNA levels of Connective tissue growth factor(CTGF) and Smad3 were examined by real-time PCR analysis.The relative expressions of CTGF, Smad3, pSmad3 were examined by Western blot. Results Compared with the TGF-ß group, the TGF-ß+PYR group had lower proportion of S/G2 phased cells[(30.8 ± 1.4) % vs (48.6 ± 3.5)%], less synthesis of COL1 [(0.95 ± 0.15) vs (1.25 ± 0.18)]and fewer expressions of CTGF mRNA [(1.73 ± 0.10) vs (2.92 ± 0.12)]and CTGF protein[(1.23 ± 0.42) vs (2.36 ± 0.62)], the difference was statistically significant($P < 0.05$). However, the expressions of Smad3 mRNA[(1.50 ± 0.06) vs (1.55 ± 0.08)] , Smad3 protein [(2.85 ± 0.45) vs (2.98 ± 0.47)] and pSmad3 protein[(2.39 ± 0.32) vs (2.51 ± 0.52)] between these two groups showed no significant difference($p>0.05$). Conclusion Pyridostigmine significantly alleviated cell proliferation and collagen synthesis in HCFs induced by TGF-ß, and its mechanism was related to the inhibition of CTGF expression rather than blocking the TGF-ß/Smads signaling pathway.

Real-time measurement of intraventricular ECG changes in ischemic pre- and postconditioning

A Andreas Spannbauer[1]; RM Riesenhuber[1]; TD Traxler[1]; GA Gugerell[1]; ML Mandic[1]; WJ Winkler[1]; ZK Zlabinger[1]; LD Lukovic[1]; PN Pavo[1]; GM Gyongyosi[1]
[1]*Medical University of Vienna, Internal Medicine II (Cardiology), Vienna, Austria*

Background: An important contributor to the development of heart failure is ischemia-reperfusion (I/R) injury sustained after revascularized acute myocardial infarction (AMI). A potential treatment strategy for I/R injury is ischemic conditioning. In Ischemic Preconditioning (IPC), a short period of ischemia prior to AMI can protect the heart from I/R injury. In ischemic Postconditioning (PostC) short periods of ischemia immediately after reperfusion of AMI are supposed to decrease I/R injury. The electrophysiological consequences of ischemic conditioning are scarcely understood. Here, we have used an electrophysiological mapping catheter to record intraventricular ECG changes in real-time.
Methods: Domestic pigs were split into 3 groups: IPC-AMI (n = 6), AMI-PostC (n = 4) and AMI-control (n = 5) (Fig.1). IPC was performed with 3 cycles of 5 min I/R using a balloon catheter in the mid LAD prior to infarction. Myocardial infarction was induced via inflation of a balloon in the mid LAD for 90 minutes (Fig. 2). PostC was accomplished by inflating and deflating the balloon for 6x30 second cycles of I/R immediately after infarction. A NOGA endocardial mapping catheter was positioned in the left ventricle to measure a single point of myocardium for the entire procedure. Infarct size and LV function were assessed with cardiac MRI + late enhancement at 1-month follow-up. Intraventricular R-Amplitude, ST-Elevation, QRS width, Heart Rate (HR) and QT time were measured in every minute.
Results IPC led to a significantly lower max. ST-Elevation during ischemia (at 20 minutes, Median(IQR), IPC 5.00 (3.40 - 5.10) mV vs. PostC 6.10 (4.90 - 6.30) vs. AMI 6.30 (4.70 - 6.75) mV $p < 0.001$) at 60 minutes after reperfusion, there was no significant difference between the groups. Both IPC and PostC led to higher R-Amplitudes after reperfusion (at 60 minutes, Median(IQR), IPC 0.82 (0.57-1.01) vs. AMI-PostC 0.98 (0.90-1.31) vs. AMI 0.49 (0,33-0,89), Median(IQR), mV, $p= < 0.001$) (Fig. 1). IPC reduced HR significantly throughout the entire procedure compared to AMI-PostC and AMI (Mean ± SD, IPC 89 ± 12 vs. PostC 123 ± 5 vs. AMI 129 ± 12). MRI+LE resulted in significantly better LV ejection fraction and smaller infarct size in group IPC-AMI compared to AMI-control and AMI-PostC groups.
Conclusion IPC significantly reduced maximum ST-Elevation during ischemia. At follow-up, IPC showed the smallest infarct area and best ventricular function. Both IPC and PostC led to higher R-Amplitudes after reperfusion, possibly indicating preserved electrophysiological function of myocardial cells. IPC significantly reduced HR throughout the entire procedure, possibly contributing to its protective effect.

The human H2 receptor as a possible target for treatment of acute heart failure

J Joachim Neumann[1]; M Mahnkopf[1]; N Misslinger[1]; H Wache[1]; F Bergmann[1]; U Gergs[1]
[1]*Martin Luther University of Halle-Wittenberg, Halle, Germany*

In experimental animals, anthracycline-induced heart failure also involved release of histamine and this heart failure could be attenuated by pretreatment of animal with histamine H2 receptor antagonists. This is similar to the beneficial effects of ß1-adrenoceptor blockade chronic human heart failure, because both receptors signal through Gs proteins and cAMP induced protein phosphorylation. To study the hypothesis that histamine H2 receptors might be a novel target to treat heart failure, we have generated transgenic mice (TG) which overexpress the human H2 receptor in cardiomyocytes via the alpha myosin heavy chain promoter. In isolated perfused hearts (Langendorff technique) from transgenic mice (TG) but not in hearts from wild type litter mates (WT), histamine induced positive inotropic effects, positive chronotropic effects and increased phospholamban phosphorylation in frozen hearts from these perfused hearts. This mouse model was used here to get data on the relevance of histamine in a model of cardiac failure. To this end, LPS (lipopolysaccharides) were injected intraperitoneally at 30 µg/g (or isotonic sodium chloride: NaCl) body weight in TG and WT. Thereafter, the time course (1,3,7 h) of LPS-action was followed by echocardiography in isoflurane-anaesthetized mice. LPS led to a time dependent reduction in left ventricular ejection fraction (n = 6-9). EF was less in TG than in WT at 7 h after LPS injection (n = 8 each). Finally, hearts were obtained used for Western blotting or RNA isolation and reverse transcription - quantitative polymerase reaction (RT-PCR) . A LPS- induced increase in IL-6 or IkBalpha was less pronounced in TG than in WT. Moreover, in NaCl-treated TG levels of IL-1b were much smaller than in NaCl-treated TG. Finally, LPS increased CD14-levels only in TG but not in WT. Hence, TG are more sensitive to LPS-induced acute heart failure which might suggest a possible detrimental role of H2 at least in acute heart failure.

The role of the endocardial endothelium in the inotropic effects of the histamine and metabolism modifiers of cyclic nucleotides on the contractility of rat's right heart ventricle.

S Sonja Smiljic[1]
[1]*Medical faculty, Deaprtment of Physiology, Kosovska Mitrovica, Serbia*

Background: Endocardial endothelium synthesize endothelial mediators, it has receptors, acts as blood-heart barrier and has complex influence on cardiomyocytes.
Objective. The aim of the research was to determine effect of histamine and metabolism modifiers of cyclic nucleotides to heart contractility with intact and removed endocardial endothelium.
Methods: Adult rats, of both sexes, type Wistar albino were used in this experiment. Experimental model consisting of twelve experimental groups was divided into six subgroups with endocardial endothelium and six without endocardial endothelium. During the experiment, the following inotropic effect of pharmacological substances was investigated: histamine, theophylline, imidazole, dibutiril cyclic adenosine monophosphate (dbcAMP), pyrilamine and cimetidine. The stabilization period for the isolated right ventricle in the water bath, stimulated by electrical impulses, was 30 minutes. After this time, the test substance was added and its inotropic effect was monitored over the next 60 minutes.
Results: The contractility of the right ventricle of the rat's heart with the removed endothelium was 60% lower than in the heart with the intact endocardial endothelium. Inotropic effect of the histamine (1x10-4 mol/l) is significantly larger when there is no endocardial endothelium ($p < 0.05$). Theophylline (1x10-2 mol / l) had manifested a positive inotropic effect on the heart, independently of the presence of endocardial endothelium. Modulating role of the endocardial endothelium on the inotropic effect of imidazole (1x10-4 mol/l) was significant ($p < 0.05$). A significantly higher inotropic response of cardiomyocyte to dbcAMP (1x10-6 mol/l) was obtained in the absence of endothelium. Modulating role of the EE on the effects of pyrilamine (1x10-6 mol/l) was significant and a positive inotropic effect was obtained in the absence of endothelium. Cimetidine (1x10-4 mol/l) achieved a discrete inotropic effect in the case of the preserved endocardial endothelium, and when the EE was removed, the contraction amplitude was increased by 29%.
Conclusion: Our results show the definite significance of the modulating role of the endocardial endothelium in achieving the effects of the tested substances. The influence of the endocardial endothelium is of major importance in achieving cardiac performance.

Introduction: The AXL is a membrane receptor tyrosine kinase, correlates with poor survival in patients with cancer. Also, AXL is expressed in myocardium. Hypoxia activates AXL signalling and the direct transcription of hypoxia inducible factors. The aim of the present study was to investigate the expression of AXL in myocardial infarction and the relation with apoptotic proteins.

Methods: We studied myocardial samples of hearts with histological findings of acute myocardial infarction, old myocardial infraction and normal myocardium. An immunohistochemical method was performed with the use of AXL, Bax, Bcl-2 antibodies.
Results: The immunoreactivity of AXL was low in normal myocardium and increased positive expression was noted from acute myocardial infarction (12,4%) to old myocardial infraction (62,5%). Also, AXL was associated with worse prognosis in heart failure. High concordance of AXL and Bax (pro-apoptotic protein) expression was detected in old myocardial infarction (82% of cases).
Conclusions: Increased levels of AXL were associated with intense expression of proapoptotic bax protein in old myocardial infraction. Decreased levels of AXL and intensive expression of anti-apoptotic bcl-2 were found in cases of acute myocardial infraction. The increased expression of AXL and Bax in old myocardial infraction is associated with the progressive loss of myocytes by apoptosis.

New role of Kv4.3 ion channel with HMGB1 in the the heart

V Viktoria Szuts[1]; F Otvos[2]; ZS Hamari[3]; J Jarabin[4]; JG Kiss[4]; L Rovo[4]; G Czifra[5]; CS Vagvolgyi[3]; K Halasy[6]; ZS Szegletes[2]
[1]University of Szeged, Faculty of Medicine, Department of Pharmacology & Pharmacotherapy, Szeged, Hungary; *[2]Hungarian Academy of Sciences, Center for Biological Research, Szeged, Hungary*; *[3]Department of Microbiology, Faculty of Science and Informatics, University of Szeged, Szeged, Hungary*; *[4]University of Szeged, Department of Otorhinolaryngology–Head and Neck Surgery, Szeged, Hungary*; *[5]University of Debrecen, Department of Anatomy and Histology, Debrecen, Hungary*; *[6]Szent Istvan University, Department of Anatomy and Histology, Budapest, Hungary*

The voltage-dependent transient outward currents (Ito) are major early repolarization currents and determined by Kv4.2 and Kv4.3 ion channels with synapse-associated protein 97 (Sap97) proteins. High-mobility group B1 plays a major role in the DNA replication and may be involved in the activation of proinflammatory pathways and known as a pathological factor in heart diseases. HMGB1 effects are depending of its concentration in heart. Once released into the extracellular milieu, HMGB1 activates inflammatory responses, serving as a late mediator of systemic inflammation. Contrasting actions of this cytokine are seen as it mediates both regeneration of damaged tissue. The Kv4.3 type channels associate with in the complex and maybe modulating the kinetic properties of Ito. Ophiobolins are important members of the family of phytotoxic metabolites, and they can modulate activities of kv4.x ion channels. The hypothesis was that HMGB1 is mainly localizes in the nuclear and associates with Kv4.3 ion channels but the HMGB1 cytokine effects can modulate the distribution of Kv4.x ion channels in the cardiomyocytes. In this work, we have examined the action of HMGB1 as a cytokine on the Kv4.3 channel distribution in cardiomyocytes. The microscope figures validate first the spatial difference localization of Kv4 channels. Ophiobolins A (OPA) served as an external stress agents on Kv4.x ion channels with different OPA concentrations. Our result were demonstrated that acute treatment by HMGB1 or OPA injured the structure of cells after 24 hours marking and altered the distribution of Kv4.x proteins in cell organs. Because HMGB1 is associated directly to the Kv4.3 ion channel this can be hearted directly the K+ ion homeostasis in high concentration of OPAs.

Reference values of segmental evaluation of longitudinal deformation of left ventricular myocardium in healthy individuals

A Alexey Kuchmin[1]; EP Galova[1]; DA Galaktionov[1]; AA Kazachenko[1]; AO Gergel[1]; MY Yaroslavtsev[1]; YV Epelshtein[1]; AA Shevelev[1]
[1]The Kirov Military Academy, St-Petersburg, Russian Federation

Background: Evaluation of longitudinal deformation is recognized as a reliable, reproducible and highly informative method in the diagnosis of cardiovascular diseases. However, the limiting factor for the wide use of the technique is the absence of recognized segmental norms of longitudinal deformation of the left ventricular myocardium.
Purpose: Determination ofthe level reference values of the segmental deformation of the myocardium in middle aged healthy individuals.
Methods: 56 volunteers without signs of cardiovascular pathology, 48 men and 8 women were examined. The mean age was 33.6 ± 9.3 years. All patients underwent an echocardiographic study using the GE "VividE95" device, (USA) in accordance with the recommendations of the European echocardiographic association and the American echocardiographic society. The analysis of longitudinal deformations of the myocardium was carried out, which was determined by the percentage of shortening of the fibers in each segment of the left ventricle, and was visualized on the device with the help of the "bull's eye" technique.
Results: Data of echocardiographic structures of the left and right heartsectors in all examined patients were within the limits of normal values, violations of systolic and diastolic function or valve apparatus was not detected.
In assessing the deformation of the left ventricular myocardium, it was revealed that the most values of deformations are the median anterior, lower-septal and lower (8, 9, 10 segments) and all apical segments: (13-17 segments). Based on the results obtained, the reference values for each segment are calculated: the mean plus / minus two standard deviations. Calculated reference values of LV segments: 1 - 11,3-22,9%, 2 - 12,7-21,1%, 3 - 11,6-18,8%, 4 - 12,9-20,9 %, 5 - 11,1-21,5%, 6 - 10,9-19,7%, 7 - 15,1-24,3%, 8 - 15,9-24,7%, 9 - 15,5-23,9 %, 10 - 15,6-24,0%, 11 - 12,0-23,2%, 12 - 12,7-21,1%, 13- 17,4-31,0%, 14 - 20,6-29,8%, 15 - 17,7-30,9%, 16 - 15,9-28,7% and 17 - 18,5-29,3%.
Conclusions: The obtained reference values of the segmental longitudinal deformation can be used as an approximate norm in persons of the Caucasian race when making a comparative evaluation of the changes in longitudinal deformation in different cardiovascular pathologies on GE devices "Vivid E95".

P2307

Dipeptidyl peptidase-4 activity plays a critical role in the pathogenesis of experimental autoimmune myocarditis

Y Yasuhiro Maejima[1]; Y Shiheido-Watanabe[1]; N Tamura[1]; Y Ito[1]; K Hirao[1]; M Isobe[2]
[1]Tokyo Medical And Dental University, Cardiovascular Medicine, Tokyo, Japan; *[2]Sakakibara Heart Institute, Tokyo, Japan*

Funding Acknowledgements: JSPS KAKENHI Grant-in-Aid for Scientific Research (C) (26461126); Grant for research collaboration with TMDU and Boehringer Ingelheim Japan, Inc.

Background: Autoimmune myocarditis is the most common cause of heart failure among young adults and is a major precursor of dilated cardiomyopathy. We have shown previously that dipeptidyl peptidase-4 (DPP-4) plays an important role in the development of experimental autoimmune myocarditis (EAM) in mice. However, the precise mechanism how DPP-4 aggravates EAM remains to be elucidated.
Purpose: The aim of this study is to explore the role of DPP-4 in the pathogenesis of EAM in mice.
Methods: & **Results:** Mouse EAM models were given normal diet (CONT group), or a diet mixed with linagliptin, a DPP-4 inhibitor (3mg/kg/day)(LINA group). Left ventricular ejection fraction after 21-day of EAM induction was significantly higher in LINA-group than in CONT-group (72.6 ± 6.6%* vs. 60.1 ± 9.2%, *P < 0.05). Immunohistochemical analyses demonstrated that the number of ROR?t-positive Th17 cells, a subset of T-lymphocytes expressing high level of enzymatically active DPP-4, infiltrated to EAM myocardium was significantly smaller in LINA-group than in CONT-group (46.9 ± 2.4 RFU* vs. 116.8 ± 8.6 RFU, *P < 0.05). Consistently, the DPP-4 activity in EAM myocardium was significantly lower in LINA-group than in CONT-group. Mass spectrometry analysis using lysates from EAM myocardium co-immunoprecipitated with Flag-DPP-4 recombinant protein and co-immunoprecipitation-western blot analysis demonstrated that DPP-4 bound to cathepsin-G(CTSG), a plasma membrane-bound serine protease, in the EAM heart. The activity of CTSG in EAM myocardium was significantly higher in EAM mice compared to those in untreated mice, and administration of linagliptin effectively suppressed the CTSG activity in the EAM hearts. We also found that DPP-4 significantly suppressed the activity of a1-antichymotrypsin, a protease which can catalyzes CTSG and is activated in response to EAM. Finally, we revealed that the of angiotensin II, a product catalyzed by CTSG, in the EAM heart was markedly decreased in LINA-group than in CONT-group.
Conclusion: These results suggest that DPP-4 physically interacts with CTSG, thereby enhancing CTSG activity through suppressing a1-antichymotrypsin, which, in turn, promoting angiotensin II accumulation in the EAM hearts. Thus, DPP-4 derived from Th17 cells would aggravate cardiac dysfunction during EAM.

Evaluation of PD-1 and PD-L1 expression as potential diagnostic and therapeutic targets in ischemic cardiac injury - preliminary results of a translational approach

K Hess[1]; R Rouven Berndt[2]; K Huenges[2]; R Rusch[2]; B Panholzer[2]; J Cremer[2]; M Albrecht[3]; A Haneya[2]
[1]University Medical Center, Institute of Neuropathology, Münster, Germany; *[2]University Medical Center of Schleswig-Holstein, Cardiovascular surgery, Kiel, Germany*; *[3]University Medical Center of Schleswig-Holstein, Department of Anesthesiology and Intensive Care Medicine, Kiel, Germany*

Background: Programmed cell death 1 (PD-1) and programmed cell death ligand 1 (PD-L1) are transmembrane molecules with a wide range of immunoregulative functions. Latest experimental results indicate influence of PD-1/PD-L1 expression

on the extent of cardiac ischemic injury. The aim of this study was to investigate the expression of PD-1 and PD-L1 in ischemic myocardial tissues.
Methods: Cardiac tissue samples from patients with acute myocardial infarction (n = 24), chronic ischemic cardiomyopathy (n = 18) and a control group (n = 14) were collected during cardiac surgery. Immunohistochemically staining was performed for PD-L1 and PD-1 and analyzed in a blinded manner. Clinical, demographic and echocardiography data of all patients were evaluated retrospectively and correlated with PD-L1 and PD-1 expression. Cell culture experiments with human iPSC-derived cardiomyocytes under hypoxia were performed to examine the hypoxia-depend expression of PD-L1 and PD-1.
Results: Low or absence of PD-1 and PD-L1 expression levels were detected in cardiac tissue without hypoxic injury. Acute myocardial injury was associated with a significantly increased inflammatory infiltrate, mostly consisting of PD-1 positive T-lymphocytes. In respond to chronic hypoxia in tissues from ischemic cardiomyopathy, cardiomyocytes displayed a significantly increased PD-L1 expression and showed negativity for PD-1. PD-1 expression was restricted to low levels of T-lymphocytes. Cox regression for six months follow-up after cardiac surgery demonstrated a significant higher cardiac-related morbidity and mortality in patients with enhanced PD-L1 expression. Cell culture experiments revealed a hypoxia-depend expression rate of PD-L1 in cardiomyocytes.
Conclusion: The present results demonstrated a hypoxia associated expression of PD-L1 in human cardiomyocytes whereas the expression of PD-1 was low and restricted to T-lymphocytes. Expression of PD-L1 in chronic ischemic cardiac tissue was significant correlated with higher mortality what makes PD-L1 a potential diagnostic and therapeutic target in cardiac ischemia.

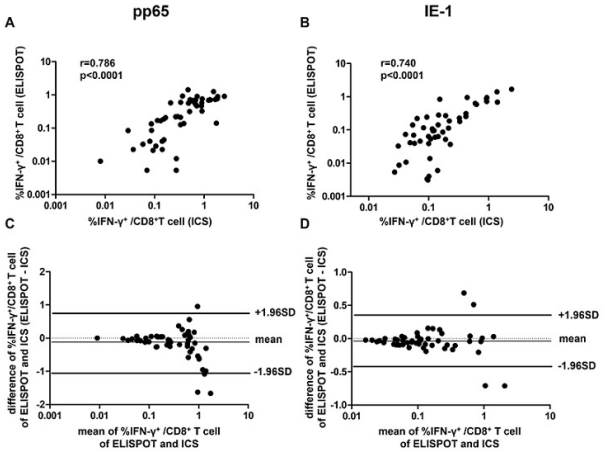
Analysis of cytomegalovirus-specific T-cell responses in patients with hypertension: comparison of assay methods and antigens

JC Youn[1]; SK Lee[1]; SW Choi[1]; S Han[1]; KH Ryu[1]; S Park[2]; EC Shin[3]
[1]Dongtan Sacred Heart Hospital, Hallym University, Division of Cardiology, Hwaseong, Korea Republic of; *[2]Yonsei University College of Medicine, Division of Cardiology, Severance Cardiovascular Hospital, Seoul, Korea Republic of*; *[3]Korea Advanced Institute of Science and Technology, Laboratory of Immunology and Infectious Diseases, GSMSE, Daejeon, Korea Republic of*

Funding Acknowledgements: National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT, & Future Planning (NRF-2015R1C1A1A02036645)

Background: Recent studies suggest an association between cytomegalovirus (CMV) infection and hypertension. In the present study, we used a variety of antigens and different assay methods to investigate the relationship between CMV-specific T-cell responses and arterial stiffness in patients with hypertension.
Methods: To evaluate arterial stiffness, pulse wave velocity (PWV) was measured in 207 hypertensive patients (average age, 63 ± 8 years). To measure CMV pp65 and IE-1-specific T-cell responses, we performed intracellular cytokine staining (ICS) and enzyme-linked immunospot (ELISPOT) assays. We also analyzed CMV-specific T-cell responses against 10 different CMV antigens using ELISPOT assays.



Results: In patients with hypertension, senescent CD8+ T-cell frequencies were significantly correlated with arterial stiffness. Moreover, arterial stiffness was independently associated with CMV pp65-specific CD8+ T-cell responses as measured by ICS. CMV-specific CD8+ T-cell responses measured by ICS and ELISPOT assays showed good agreement and significant correlation with each other. ELISPOT analyses against 10 different CMV antigens revealed a consistent response pattern irrespective of age, gender, and diabetes.
Conclusions: CMV pp65-specific CD8+ T-cell responses were independently correlated with arterial stiffness in patients with hypertension. Additionally, the results of ICS and ELISPOT assays showed a significant correlation and good agreement with each other. These findings are important for guiding choices regarding the broad clinical application of CMV-specific T-cell response assays in this patient population.

P2310

The role of complement-complex (c5b-c9) expression and apoptosis in myocardial infract area and in infract border zones

A Tsipis[1]; AM Athanassiadou[2]; E Petropoulou[3]; P Athanassiadou[2]; G Athanassopoulos[1]; N Kavantzas[2]
[1]Onassis Cardiac Surgery Center, Division of Cardiology, Athens, Greece; *[2]University of Athens, Department of Pathology, Athens, Greece*; *[3]IASO General Hospital, Department of Cardiology, ATHENS, Greece*

Introduction: Although increasing experiment data suggest that necrosis and apoptosis occur in myocardial infarction, it is less clear the relation between the two conditions and the relevant pathophysiological mechanism. The terminal complement pathway (C5b-9) inserts into the cell membrane and induces cell lysis. Complement complex (C5b-9) may also play a key role in cell apoptosis, by regulating the apoptotic proteins Bax, bcl-2 and by involving the mechanism of caspase cascade.
The aim of the present study was to investigate the expression of C9 in myocardial infarction and the relation with apoptotic proteins.
Methods: We studied myocardial samples of hearts with histological findings of acute myocardial infarction (group A, n = 100), old myocardial infraction (group B, n = 100) and myocardial samples of normal heart (control group, n = 20). An immunohistochemical method was performed with the use of C9, Bax, Bcl-2 antibodies, in order to investigate the expression of C9 and apoptosis-related proteins in ischemic cardiac disorders.
Results: The immunoreactivity of complement component was intensive at infract areas and low at infract border zones of samples with acute myocardial infarction. In old myocardial infraction the complement expression was decreased. Anti-apoptotic protein Bcl-2 is high expressed in cardiomyocytes at the risk areas of acute myocardial infarction. High concordance of complement component and proapoptotic protein Bax expression was detected at infracts areas. In old myocardial infraction the bcl-2 positive samples demonstrated weak staining as in the control group.
Conclusions: Increased levels of complement component were associated with intense expression of proapoptotic bax protein at infracts areas and decreased levels of complement component were associated with intense expression of antiapoptotic bcl-2 protein at infract border zones. Apoptosis as a consequence of complement-mediated cell damage may provide an explanation for the presence of apoptotic proteins in inflammatory processes, but the increased expression of anti-apoptotic procedure represents a possible compensatory mechanism of salvaged myocytes and a defense mechanism against myocardial ischaemia.

Background: Sepsis is a systemic inflammatory response syndrome (SIRS) caused by a severe local infection, and further develops to multiple organ dysfunction syndrome (MODS). It is one of the major causes of death in clinical setting. One of the reasons of the myocardial dysfunction in sepsis is the cardiomyocytes converted to proinflammatory phenotype. Dynamin-related protein 1 (Drp1) is a regulator of mitochondrial fission.. However, little is known to date that whether inhibition of Drp1 could prevent the conversion of cardiomyocytes into a proinflammatory phenotype in sepsis.
Objective: To determine whether Drp1 plays a role in sepsis-induced conversion of cardiomyocytes into a proinflammatory phenotype.
Method: In vivo: Rat model of sepsis was induced by intraperitoneal (i.p.) injection of fecal material (180 mg/mL) at a dose of 3 g/kg body weight. Rat received normal saline (NS) served as control (sham). Some rats were pretreated with Mdivi-1 (25 mg/kg, i.p.) 1h before induction of sepsis.. Six hours after the induction of sepsis, rat plasma was isolated and hearts were harvested for myocardial myeloperoxidase

(MPO) and neutrophil infiltration assay. In vitro: Isolated rat cardiomyocytes were challenged with either septic plasma (from septic rat), or sham plasma (from sham rat), Drp1 activation was evaluated with inhibitory Drp1 S637 (serine 637) phosphorylation and mitochondria translocation. Proinflammatory phenotype of cardiomyocytes was determined by measuring chemokine (LIX and KC) expression.
Results: Rats with sepsis incurred increased myocardial MPO activity and myocardial polymorphonuclear neutrophil (PMN) accumulation as compared to control animals (P <0.05). Treatment of the septic rat with Mdivi-1(25 mg/kg) attenuated the sepsis-induced increase in myocardial MPO activity(P <0.05)and myocardial PMN accumulation(P <0.05). Challenge of cardiomyocytes with septic plasma activated Drp1 and promoted Drp1 mitochondria translocation(P <0.05), and resulted in conversion of cardiomyocytes into a proinflammatory phenotype as indicated by increase in LIX and KC expression(P <0.05). Mdivi-1(10 μmol/L) pretreatment prevented the increase in LIX and KC production in cardiomyocytes with septic plasma(P <0.05)and the dephosphoration of Drp1 at S637(P <0.05) and the Drp1 translocation to mitochondria(P <0.05).
Conclution: The activation of Drp1 plays a pivotal role in conversion of cardiomyocytes into proinflammatory phenotype in sepsis.

Fingolimod can play important role in prevention of heart failure induced by ischemia reperfusion injury during heart transplanatation

N Ahmed[1]; GEBRIE Mebratu[2]; MAHYM Mansoor[3]; M Mansoor[4]; MAHAK Mansoor[3]; A Rungatscher[2]
[1]University of the Punjab, , Faculty of Health Sciences, Lahore, Pakistan; *[2]University of Verona, Cardiac Surgery Division, Verona, Italy*; *[3]King Edward Medical University, Internal Medicine, Lahore, Pakistan*; *[4]Punjab Institute of Cardiology, Cardiology, Lahore, Pakistan*

Background: Heart failure followed by Ischemia-Reperfusion Injury is a major issue in heart transplantation. During last decade, multiple strategies have been used to control this important problem. It is well known that fingolimod, a Sphingosine 1-Phosphate receptor modulator may cause anti-inflammatory, antioxidant and T-lymphocyte depletion leading to lymphopenia. Thus, it leads to a reduction in ischemia-reperfusion injury and ultimately, prevention of heart failure
Purpose: The main purpose to investigate the preoperative effect of fingolimod was to evaluate cardioprotective role in heterotopic heart transplantation experimental model in comparison of placebo administration.
Methods: Male Sprague–Dawley (SD) rats (300-350 g) (n = 30); treated with either fingolimod (1 mg/kg total body weight) or normal saline solution. Ischemia was applied for 60 minutes and reperfusion was followed for 24 hours and 1 week. Post heterotopic heart transplantation at 24 hours and 2 weeks all surviving rats were sacrificed. Blood and myocardial tissue were collected for analysis of myocardial biomarkers, inflammatory markers, oxidative stress, and signaling pathways. Myocardial fibrosis was investigated using Masson's trichrome staining and Fluorescein-activated cell sorting (FACS) to measure T-lymphocyte.
Results: Following 60 minutes of ischemia, neither saline treated nor vehicle treatment showed significant protective effects on long-term survival after Heterotopic Heart Transplantation.In fingolimod treated group, reduction of inflammation and oxidative stress have been observed as compared to saline-treated or vehicle group. FACS analysis showed a significant T-lymphocyte depletion in peripheral blood after fingolimod treatment, which was not observed after saline or vehicle treatment.
Conclusion: The long-term survival improved in this study might be due to a cardioprotective role of fingolimod to prevent ischemia reperfusion injury in heterotopic heart transplantation model, which may be mediated by decreaed inflammation, reactive oxygen species and the lymphocyte depletion shown in the FACS analysis.

Cardiac microdomains in cyclic nucleotide signalling: role of popeye domain-containing (Popdc) proteins

N K Navneet Kaur Bhogal[1]; Z Dong[1]; A Alvarez-Laviada[1]; R F R Schindler[1]; P Sarathchandra[1]; E Ioannou[1]; A V Glukhov[2]; J Gorelik[1]; T Brand[1]

Cardiac microdomains recruit components of the various signalling pathways including cAMP signalling. cAMP is stimulated by β-adrenergic receptors (βAR) in response to catecholamines to elicit physiological and pathophysiological responses. In the heart, Popdc1 and Popdc2 are expressed highly in the cardiac conduction system and have a high affinity-binding site for cAMP localized to the cytoplasmic region of the protein. Popdc genes encode transmembrane proteins, which are localized to the plasma membrane and transverse-tubules (TT). Work in model organisms and patients have indicated an important role of Popdc for controlling expression and membrane localization of scaffolding proteins as well as membrane trafficking of Nav1.5 and TREK-1 electrogenic proteins. Therefore, Popdc could well be involved in the structural and functional applications of cardiac microdomains, where loss-of-function mutations in Popdc have been associated with cardiac arrhythmia and pacemaking abnormalities. The aim of this study is to correlate findings between single cell and tissue work, by investigating mouse atrial myocytes (AMs) to understand the way in which cAMP is modulated by cardiac microdomains, and to understand how Popdc1-/- and Popdc2-/- null mutants alter electrophysiological characteristics of the atria and the structure of AMs.
Pacemaking and atrial conduction were studied in Popdc1, Popdc2 -null and wild type mice using high spatial and temporal resolution optical mapping of the isolated atrial preparations stained with the voltage-sensitive dye di-4-ANNEPS, both, at baseline and after isoproterenol (non-selective βAR agonist; 1-300 nM) stimulation. Both premature and skipped beats were captured resulting in heart rate variability in both mutants, in response to isoproterenol. Both mutants demonstrated slower atrial conduction propagation. Popdc1-/- presented increased fibrosis levels, which is a potential substrate for re-entrant activity and AF. To determine how these responses are controlled at a cellular level left and right AMs were structurally imaged, using confocal microscopy. Three subgroups were recorded from control AMs: (a) organized, (b) disorganized, and (c) sparse TT structures. Preliminary data from Popdc1-/- AMs suggests a higher proportion of AMs with a disorganised TT structures. To understand the functional role of βARs in single AMs Förster resonance energy transfer (FRET) measured the cAMP response. So far, control AMs produced a higher cAMP response from ß1AR stimulation compared to ß2AR stimulation. However, inhibiting PDE4 during ß2AR stimulation demonstrated right AMs have a stronger cAMP response compared to left.
In conclusion, PDE4 is important for cAMP modulation in AMs and specifically in right AMs. In addition, the loss of Popdc1 proteins causes a disorganisation of the TT structure in AMs with pacemaking and atrial conduction abnormalities at a tissue level, which significantly raises the risk of developing AF.

Inflammation and cytokine production contribute to wound healing and cardiac remodeling after a myocardial infarction (MI). However, excess inflammation can lead to more injury, infarct expansion, and adverse ventricular remodeling and thereby propagate heart failure development. We have shown that the serum and heart tissue levels of pro-inflammatory cytokines are elevated in isoproterenol-induced myocardial infarction and the serum levels of TNFa are positively correlated with the degree of coronary luminal stenosis in patients with stable angina. It seems that immunosuppressant and anti-inflammatory therapeutic strategies may have potential beneficial effects in the treatment of post MI heart failure. However, several studies show that immunosuppressant and anti-inflammatory treatments after heart attack is controversial. In a rat model of isoproterenol-induced MI we demonstrated that early administration of infliximab, a TNFa monoclonal antibody,

along with the MI induction despite early protection against myocardial inflammation and tissue injury (24 and 48 hours after MI) had no protective effects against the myocardial dysfunction. Even, in the long run (after 96 hours) it exacerbated the development of tissue damage from endocardium to myocardium and led to heart failure by decreasing the left ventricular systolic pressure, contractility, and relaxation and by increasing the left ventricular diastolic pressure. Heart tissue remodeling and restoration appear to be suppressed by TNFa inhibition. It is suggested that, anti-inflammatory strategies to reduce inflammation in heart after myocardial infarction should be carefully balanced as they might interfere with the tissue repair and healing.

Iron deficiency impairs contractility of human cardiomyocytes through decreased mitochondrial function.

MF Hoes[1]; N Grote Beverborg[1]; JD Kijlstra[1]; J Kuipers[2]; DW Swinkels[3]; BNG Giepmans[2]; RJ Rodenburg[4]; DJ Van Veldhuisen[5]; RA De Boer[5]; P Van Der Meer[5]
[1]University Medical Center Groningen, Department of Experimental Cardiology, Groningen, Netherlands; *[2]University Medical Center Groningen, Department of Cell Biology, Groningen, Netherlands*; *[3]Radboud University Medical Centre, Department of Laboratory Medicine, Nijmegen, Netherlands*; *[4]Radboud University Medical Centre, Department of Pediatrics, Nijmegen, Netherlands*; *[5]University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands*

Aims: Iron deficiency is common in patients with heart failure and associated with a poor cardiac function and higher mortality. How iron deficiency impairs cardiac function on a cellular level in the human setting is unknown. This study aims to determine the direct effects of iron deficiency on mitochondrial function, contractility and morphology of human cardiomyocytes, and to assess whether repletion of iron levels restores cardiomyocyte function.
Methods and Results: Human embryonic stem cell-derived cardiomyocytes were depleted of iron by incubation with the iron chelator deferoxamine (DFO). Mitochondrial respiration was determined by Seahorse Mito Stress test, and contractility was directly quantified using video analyses according to the BASiC method. Detailed cellular morphology was studied using electron microscopy. The activity of the mitochondrial respiratory chain complexes were examined using spectrophotometric enzyme assays.
Four days of iron depletion resulted in an 84% decrease in ferritin ($p < 0.0001$) and significantly increased gene expression of transferrin receptor 1 and divalent metal transporter 1 (both $p < 0.001$). Mitochondrial function was reduced in iron deficient cardiomyocytes, in particular ATP-linked respiration and respiratory reserve were impaired (both $p < 0.0001$). Iron depletion affected mitochondrial function through reduced activity of the iron-sulfur cluster containing complexes I, II and III, but not complexes IV and V. Furthermore, mitochondria in iron-deficient cardiomyocytes appeared swollen and contained inclusion bodies. Iron deficiency reduced cellular ATP levels by 73% ($p < 0.0001$) and reduced contractile force by 43% ($p < 0.05$). The maximum velocities during both systole and diastole were reduced by 64% and 85% respectively (both $p < 0.001$). Supplementation of transferrin-bound iron recovered functional and morphological abnormalities within 3 days.
Conclusion: Iron deficiency directly affects human cardiomyocyte function, impairing mitochondrial respiration, and reducing contractility and relaxation. Restoration of intracellular iron levels can reverse these effects.

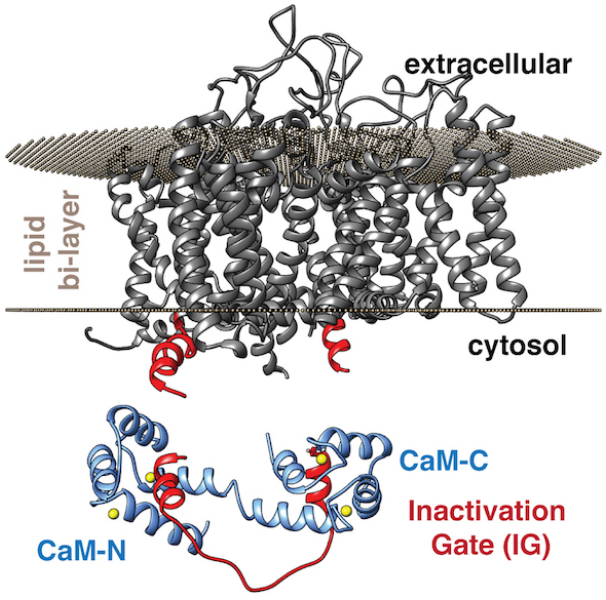
Funding Acknowledgements: C.N.J. was supported by: NRSA 2T32NS007491-11, AHA postdoctoral fellowship 13POST14380036, and NIH NSRA 5 F32 HL117612-02. This work was also supporte

Purpose: The human cardiac sodium channel (NaV1.5) is essential for the generation and propagation of action potentials in the heart. Genetic mutations in both NaV1.5 and the accessory proteins cause channel dysfunction and are associated with life threatening cardiac conditions. Despite much investigation, treatment options for patients suffering from NaV1.5 dysfunction are lacking. Identification and development of novel therapeutic targets and improvements to existing treatments are hindered by a lack of understanding the atomic underpinnings governing channel function and regulation.
Methods: The atomic structure of CaM bound to the NaV1.5 inactivation gate was determined using a unique combination of X-ray crystallography, NMR spectroscopy and small angle X-ray scattering. A homology model of the NaV1.5 alpha subunit was created based on the atomic structure of the functional CaV1.1 channel using Rosetta. The NaV1.5 model was oriented in a lipid bi-layer using the Orientations of Proteins in Membranes database. Using strategic structure guided mutations we evaluate channel function in the absence and presence of an impaired CaM-IG interaction by whole cell patch clamp electrophysiology.
Results: Here we present the structure of a Ca dependent interaction between the Ca sensing protein Calmodulin (CaM) and the NaV1.5 channel inactivation gate (IG). CaM binds to two independent sites on the channel IG in an antiparallel manner using an unanticipated structural mode. Importantly CaM engages the IG with a high affinity that has not been previously recognized. Incorporating our structure into a homology model of the full-length channel reveals a mechanism for how CaM directly modulates NaV1.5 function in response to changes in Ca. We find that in the presence of Ca, the CaM-IG interaction promotes recovery from inactivation while impeding the kinetics of inactivation. Based on our structural findings we predict the importance of disease associated mutations contained within the channel inactivation gate and we validate perturbations to CaM binding by NMR.
Conclusions: Our results identify and characterize a new high affinity CaM interaction that forms the basis of a novel mode of Ca regulation of the NaV1.5 channel, where Ca activates CaM to engage the channel IG and facilitate re-opening. Structural investigations of disease associated mutations contained in both CaM and the NaV1.5 IG suggest new potential mechanism(s) for the cause of arrhythmia.



Model of NaV1.5 CaM Interaction

Purpose: Reprogramming of the cardiac myocyte (CM) transcriptome underlies maladaptive pathological remodelling in cardiac hypertrophy and heart failure. Long non-coding RNAs (lncRNAs) are emerging as key regulators of gene expression in cellular development, homeostasis and pathology.
The lncRNA Malat-1 is of particular interest as it is involved in regulation of mRNA splicing, ERK/MAPK signalling, regulation of myogenic differentiation, histone lysine methylation and miR-133 activity - processes established as having important functions in cardiac hypertrophic remodelling.
Methods: CMs are outnumbered 1:3 by non-CMs in the adult heart. To study gene expression specifically in CMs from intact postmortem human and rodent hearts, we employed a powerful method involving fluorescence-assisted cell sorting to selectively isolate CM nuclei (based on positive labelling for PCM-1). RNA was isolated from PCM-1+ve nuclei and CM gene expression analysed by RT-qPCR or RNA-seq.
A CM-specific and inducible Malat-1 knockout mouse was created by crossing C57BL/6J Malat-1fl/fl mice with CM-restricted (Myh6 promotor) tamoxifen-inducible MerCreMer expressing mice to generate Malat-1fl/fl;Tg(Myh6-MCM) mice. Littermate Malat-1fl/fl mice were used as controls. Pathological hypertrophy was induced by transverse aortic constriction (TAC) on 8-10 week old mice (males and females). Control mice were sham operated. Tamoxifen (40 mg/kg) was administered one week pre-operative by a single intraperitoneal injection, to avoid transient cardiomyopathy by repetitive tamoxifen administration. Mice were sacrificed 4 weeks post-surgery.
Results: Profiling of the transcriptome in healthy and failing human CMs identified an increase in Malat-1 expression, which was also observed in rodent pathology. Pressure overload induced pathological remodelling invoked by TAC was attenuated with CM-specific genetic ablation of Malat-1 compared with controls. CM-specific loss of Malat-1 prevented the TAC-associated increases in left ventricular mass and posterior wall thickness and decrease in ejection fraction. Absence of reactivation of the cardiac foetal gene programme also indicated protection from pathological remodelling.
Probing the CM transcriptome revealed downregulation of pro-apoptotic genes in Malat-1 KO mice. Notably, the initiator caspases 8 and 9 were downregulated in Malat-1 KO CMs, genes which were otherwise upregulated in CMs with TAC in control mice. CM death is associated with pathological hypertrophy and heart failure, which was reflected by a drop in the fraction of CM nuclei measured during flow sorting in controls mice with TAC, that was not seen with TAC in Malat-1fl/fl;Tg(Myh6 MCM) mice. Suppression of CM apoptosis induced by TAC in Malat-1 KO mice was validated using the TUNEL assay.
Conclusion: Loss of Malat-1 in CMs protects against maladaptive cardiac hypertrophy through a mechanism that may involve attenuation of initiation of apoptosis.

P2318

A new form of inherited cardiomyopathy leads to to changes in heterochromatin structure in man and mice

B Gerull[1]; N Abdelfatah[2]; R Chen[1]; J Gross[1]; C Fielding[2]; H Duff[2]
[1]Comprehensive Heart Failure Center (CHFC), Internal Medicine , Wurzburg, Germany; *[2]Libin Cardiovascular Institute of Alberta - University of Calgary, Calgary, Canada*

Introduction: Nuclear envelope proteins have been shown to play an important role in the pathogenesis of inherited dilated cardiomyopathy (DCM). We recently discovered a novel homozygous mutation (p. L13R) in the inner nuclear membrane (INM) protein LEMD2 causing juvenile onset of arrhythmic cardiomyopathy and bilateral cataract. LEMD2 has been implicated in several important roles such as stabilization of the nuclear membrane and chromatin organization. However, its role in cardiac development and disease remains unknown.
Purpose: To determine the effects of mutant LEMD2 in human cells and heart tissue, in vitro cell culture and an in vivo knock-out mouse model.
Methods: Heart tissue of a deceased homozygous mutation carrier, affected fibroblasts as well as transfected cells expressing wildtype and mutant LEMD2 were investigated by histology, immunohistochemistry, electron microscopy (EM) and different assays regarding cell senescence and apoptosis. Additionally, a knock-out mouse model (KO) was generated by CRISPR/Cas9 technology and initially characterized.
Results: Histology of affected heart tissue showed myocyte disarray and extensive interstitial fibrosis. EM revealed extensive changes of myocyte nuclei, including extensive elongation and bizarre shapes with clumping of peripheral heterochromatin. However, immunohistochemistry demonstrated regular nuclear membrane localization of mutant LEMD2 in affected cardiac tissue as well as in dermal fibroblasts from patients and transfected C2C12 cells. Next, we investigated proliferation, apoptosis and cell senescence in age and passage matched patient fibroblasts and controls as well as transfected cell lines. Mutant cells showed decreased proliferation, increased cell senescence, but no increased apoptosis compared to controls. To unravel the role of Lemd2 in vivo a KO was created. Homozygous KO mice were not viable and died between embryonic day 9.5 and 10.5. Histology of E10.5 embryos showed ventricular wall thinning and abnormalities of the outflow tract. Furthermore, EM of hearts revealed extensive changes of myocyte nuclei, including bizarre shapes with clumping of peripheral heterochromatin as similar seen in cardiac tissue from patients. Abnormal heterochromatin formation may suggest inactivation of chromatin and DNA damage. Therefore, we looked at phosphorylated H2AX, a molecular marker for DNA-damage and premature aging and found in KO animals remarkedly reduced expressed gH2AX as well as repair foci compared with wildtype animals ($p < 0.00001$). Even heterozygous embryos showed a significant reduction of gH2AX levels.
Conclusion: Mutant LEMD2 leads to remarkable changes in nuclei with abnormal heterochromatin formation in mice and man. Disturbed H2AX phosphorylation, cellular senescence and reduced proliferation capacity may suggest an involvement of LEMD2 in chromatin remodeling processes and premature aging.

Funding Acknowledgements: Else-Kröner-Fresenius-Stiftung, ESAC Germany, Dresdener Herz-Kreislauf-Tage

Introduction:
Inflammation is recognized as a key driver for the development of cardiac remodeling and dysfunction. Chronic pressure overload increases the number of CD45+ leukocytes in the heart. Leukocyte migration and activity is closely regulated by endothelial cells. Mineralocorticoid receptor antagonists, an established therapy of chronic heart failure, have anti-inflammatory properties. The aim of this study was to investigate the impact of endothelial mineralocorticoid receptors on cardiac inflammation and remodeling.
Methods and Results: In order to assess to role of endothelial mineralocorticoid receptors on cardiac inflammation and remodeling we generated mice with endothelial cell-specific deletion of the mineralocorticoid receptor (MRCdh5Cre) using the Cre/loxP system. MRCdh5Cre and Cre-negative littermates (MRwildtype) underwent transverse aortic constriction (TAC, $n = 5$-7 per group). After pressure overload, the number of CD45+ CD11b+ leukocytes was similarly increased in the hearts of both genotypes (MRCdh5Cre 3840 ± 443 vs. MRwildtype 4051 ± 385 /mg tissue, n.s.). However, subtype analysis revealed a higher proportion of inflammatory Ly6Chigh F4/80low monocytes in the heart of MRwildtype after TAC (TAC 20 ± 6 vs. sham 4 ± 1 %, $P < 0.05$) but not of MRCdh5Cre mice (TAC 6 ± 2 vs. sham 3 ± 1 %, n.s.).
CD45+ CD11b+ F4/80high Ly6Clow macrophages from pressure overloaded vs. sham treated hearts were isolated by fluorescence-assisted cell sorting and showed marked differences in gene expression as determined by RNAseq. Expression of 185 genes was differentially regulated ($q < 0.05$) in macrophages from MRwildtype hearts after pressure overload but restored by MR deletion from endothelial cells.
Cardiac hypertrophy (ventricle weight 143.2 ± 5.2 vs. MRwildtype 167.3 ± 6.7 mg, $P < 0.001$) and interstitial fibrosis (sirius red stained area 8.2 ± 4.7 vs. MRwildtype 13.5 ± 4.5 %, $P < 0.05$) after pressure overload were attenuated in MRCdh5Cre mice. mRNA expression levels of atrial natriuretic peptide (Nppa), the pro-fibrotic molecule galectin 3 (Lgals3) and the monocyte marker C-C chemokine receptor type 2 (Ccr2) were determined by qRT-PCR and confirmed these findings. The attenuated cardiac inflammation and remodeling after TAC in MRCdh5Cre mice was paralleled by preserved diastolic function (mitral valve E acceleration time, TAC 11.2 ± 0.6 vs. sham 12.2 ± 0.9 ms, n.s.) vs. MRwildtype mice (TAC 15.7 ± 0.5 vs. sham 12.8 ± 0.4 ms, $P < 0.05$).
Conclusion: MR deletion from endothelial cells alters cardiac leukocyte subtype composition and macrophage gene expression after pressure overload. This is paralleled by improved left ventricular diastolic function and remodeling. Our findings suggest that MR modulates endothelial-macrophage interaction.

P2320

Novel insights into regulation of proarrhythmic persistent Na current by Ca2+/Calmodulin-dependent protein kinase II

P Tirilomis[1]; S Ahmad[2]; N Dybkova[1]; S Pabel[1]; P Bengel[1]; T Fischer[1]; L Maier[2]; G Hasenfuss[1]; S Sossalla[2]
[1]University Medical Center Gottingen (UMG), Department of Cardiology and Pneumology, Gottingen, Germany; *[2]University Hospital Regensburg, 2nd Department of Medicine, Regensburg, Germany*

In human heart failure (HF) and cardiac hypertrophy (Hy), persistent Na current (INaL) is enhanced leading to arrhythmias via action potential duration (APD) prolongation and increased diastolic sarcoplasmic reticulum (SR)-Ca leak. Cardiac Hy is mostly caused by chronic pressure overload and may lead to HF. In HF, Ca/Calmodulin-dependent protein kinase IId (CaMKIId) and INaL are increased in parallel. CaMKIId has been reported to enhance INaL thereby contributing substantially to arrhythmias through early- and delayed-afterdepolarizations (EADs and DADs). Increased INaL may also activate CaMKIId promoting INaL leading to a vicious cycle.
We investigated whether the neuronal Na channel isoform NaV1.8 contributes to the regulation of INaL and SR-Ca leak in a CaMKIId transgenic mouse model (CaMKIId TG), in human Hy and in HF cardiomyocytes.
We have shown that CaMKIId, which is known to regulate cardiac isoform NaV1.5, also associates with the NaV1.8 isoform. In co-immunoprecipitation experiments, we detected an increased co-expression of NaV1.8 and CaMKIId while interaction of NaV1.5 and CaMKIId was decreased in HF. To measure the contribution of NaV1.8 to INaL generation and APD, we performed whole-cell patch clamp experiments in isolated murine and human ventricular cardiomyocytes (HF & Hy). We observed a significant reduction in INaL after addition of the novel specific NaV1.8 blocker PF-01247324 (orally bioavailable; 1 μmol/L) or a CaMKIId inhibitor, autocamtide inhibitory peptide (AIP, 1 μmol/L) in human ventricular HF cardiomyocytes. Additionally, we recorded that APD was significantly abbreviated after inhibition of NaV1.8 in hypertrophied human cardiomyocytes. Inhibition of NaV1.8 lead to a decrease of 40% in SR-Ca spark frequency (CaSpF) in hypertrophied and failing human cardiomyocytes measured by confocal microscopy (Fluo-4 AM). Increased Ca-leak can be induced by INaL via Na-dependent Ca overload which may result in DADs. To further elucidate the role of CaMKIId in NaV1.8 regulation we measured INaL and CaSpF in the presence of the novel NaV1.8 blocker in CaMKIId TG mouse myocytes. The already enhanced INaL and CaSpF were significantly decreased after exposure to NaV1.8 blocker.
Furthermore, we also generated a new mouse model by crossbreeding CaMKIId TG and NaV1.8 KO (SCN10A-/-) mice hypothesizing a rescue of the arrhythmogenic phenotype. In this new mouse model (CaMKIId TG/SCN10A-/-) measurements show a 53% reduction in INaL. A survival curve is currently under investigation to test the hypothesis whether CaMKIId TG/ SCN10A-/- mice are protected against arrhythmias compared to CaMKIId TG.
Our results demonstrate the significance of both CaMKIId and NaV1.8 in INaL generation and suggest that increased CaMKIId activity plays a substantial role in the activation of NaV1.8. Therefore, NaV1.8 seems to be a promising therapeutic antiarrhythmic target and its regulation merits further investigation.

P2321

Differential sodium channel regulation as a novel proarrhythmic mechanism in the human failing heart

P Philipp Richard Felix Bengel[1]; N Dybkova[1]; S Ahmad[1]; S Pabel[1]; P Tirilomis[1]; N Hartmann[1]; LS Maier[2]; K Streckfuss-Boemeke[1]; G Hasenfuss[1]; S Sossalla[2]

Funding Acknowledgements: Ministery of Culture and Science, State of Lower Saxony; Marga and Walter Boll Foundation; German Center for Cardiovascular Research

Heart failure (HF) is known to be associated with pathological electrical remodeling involving prolongation of the action potential (AP) and occurrence of early- (EADs) and delayed afterdepolarizations (DADs). An important role in these proarrhythmogenic changes is attributed to a pathological enhancement of the late sodium current (INaL). However, the underlying mechanisms are not entirely understood. It is suspected that other sodium channel isoforms than the cardiac isoform NaV1.5 could contribute to INaL. Therefore, we investigated the role of sodium channel isoform NaV1.8 in the human failing heart.
Using Co-immunocytochemistry, we could detect expression of NaV1.8 in t-tubules and at intercalated discs. Western Blots interestingly revealed NaV1.8 to be significantly upregulated in tissue homogenates from patients with end-stage HF compared to non-failing (NF), while expression of the NaV1.5 was decreased. We further measured INaL and action potential duration (ADP) in isolated cardiomyocytes from failing hearts in absence or presence of the selective NaV1.8-blockers either A-803467 (30nmol/L) or PF-01247324 (1 μmol/L). Both reduced INaL and APD significantly. Additionally, we measured proarrhythmic Ca2+-spark-frequency (CaSpF) using confocal microscopy (Fluo4-AM). Both, A-803467 and PF-01247324 reduced CaSpF significantly (˜58%). Moreover, the occurrence of DADs and spontaneous action potentials (sp. APs) as a parameter for cellular proarrhythmic events in the presence of low dose isoproterenol (ISO, 30 nmol/L) were potently suppressed by addition of PF-01247324.
To confirm our inhibitor-derived findings, we measured INaL, APD and CaSpF in isolated cardiomyocytes from NaV1.8-knock-out (SCN10A-/-) and wild-type (WT) mice. Application of ISO significantly increased INaL and CaSpF in both SCN10A-/- and WT myocytes, but significantly less in SCN10A-/- compared to WT. Pre-treatment with A-803467 and PF-01247324 also resulted in a small, but significant reduction of INaL and CaSpF in ISO treated myocytes. Since NaV1.8-channels are resistant to low concentrations of tetrodotoxin (TTX), we measured INaL in presence of 2 μmol/L TTX to inhibit NaV1.5-mediated INaL. ISO-induced INaL in SCN10A-/- and WT myocytes was clearly reduced by TTX, but significantly more in SCN10A-/-.
Additionally, APD was significantly shorter in ISO-treated cardiomyocytes from SCN10A-/–mice compared to WT. Also, frequency of DADs and sp.APs were lower in SCN10A-/- cardiomyocytes.
In summary, our results provide first evidence of an upregulation of NaV1.8 in human heart failure, that contributes to arrhythmogenesis by enhancing INaL. Major issues of electrical remodeling in HF like AP-prolongation, occurrence of EADs and DADs and increased CaSpF as triggers for cellular proarrhythmogenic events could be ameliorated by inhibiting NaV1.8. Therefore, inhibiton of NaV1.8 constitutes a novel specific antiarrhythmic approach in HF that needs further investigation.

Introduction: Inflammatory activation and metabolic impairment are becoming the focus of research as novel therapeutic targets in heart failure. We recently demonstrated in a genetic model of arrhythmogenic cardiomyopathy (desmin-deficient mice, Des-/-) that modulation of innate immunity through elimination of complement C5a receptor (C5aR) resulted in impressive improvement of cardiac function.
Aim: To analyze the role of the second C5a receptor (C5L2) that has been linked to energy metabolism and inflammation as a novel therapeutic target in desmin deficient cardiomyopathy.
Materials/Methods: We generated C5L2-/-Des+/- mice by crossing C5L2-/- with Des-/- mice. Histology, electron microscopy, echocardiography, RNAseq and 18F-FDG microPET/CT were performed in 12 months old animals (n = 10) and parameters related to cardiac structure, function and myocardial glucose consumption were compared with those of wild type (WT) controls of similar age.
Results: C5L2-/-Des+/- mice developed severe cardiac dysfunction compared to WT controls (Fractional shortening 22.89 ± 2.52 vs. 46.94 ± 0.67, $p < 0.0001$). Histology revealed increased fibrosis in C5L2-/-Des+/- compared to WT (Fibrosis index, 1.5 ± 0.21, vs. 0.4 ± 0.34, $p < 0.01$). Electron microscopy showed severe mitochondrial and T-tubules abnormalities in C5L2-/-Des+/- compared to WT. Additionally, cardiac tissue RNAseq analysis demonstrated altered expression of several genes involved in metabolic pathways, indicating a "metabolic switch" in C5L2-/-Des+/- from fatty acid to glucose oxidation compared to WT. This was also confirmed by the higher myocardial metabolic rate of glucose values in C5L2-/-Des+/- compared to WT animals (168.6 ± 55.2 vs. 39.8 ± 3.3μmol/min/100g, $p < 0.05$).
Conclusions: Our results highlight the detrimental consequences on cardiac structure and function of C5L2 receptor elimination in arrhythmogenic cardiomyopathy and support the hypothesis of its implication in the metabolic impairment, which occurs in this pathological entity.

P2323

Pretreatment with propargylglycine and L-cysteine improves diastolic heart function and decreases arterial stiffness in aging

N A Natali Dorofeyeva[1]; KO Drachuk[1]; VF Sagach[1]
[1]Bogomoletz Institute of Physiology, Kiev, Ukraine

Background and aims: Aging is accompanied by diastolic dysfunction and increased arterial stiffness. Hydrogen sulfide (H2S) is a gas transmitter that has an important role in the regulation of cardiovascular function. We have recently

shown that exogenous H2S (NaHS) improves diastolic heart function in hypertension and aging. The aim of work is to investigate the effect of combination DL-propargylglycine (PAG) and L-cysteine on heart function in old rats.
Materials and Methods: The study was conducted on adult (6 months old) and old (24 months old) male Wistar rats. The functional cardiohemodynamic indicators registered via microcatheter and Pressure-Volume System. The DL-propargylglycine (11,31 mg/kg) and L-cysteine (121 mg/kg) were administered intraperitoneally with 30 min intervals between injections.
Results: We demonstrate that combination PAG+ L-cysteine c improves diastolic heart function in old rats. We found, that End-diastolic pressure decreases by 22,6% ($P < 0,05$), the end-diastolic myocardial stiffness decreases by 27,7% ($P < 0,05$) in old rats. The arterial stiffness decreased by 25,4%, that indicates an improvement the ventriculoarterial coupling. Also, we found that the parameters of pumping function increase after injections. Stroke volume increases by 12,3% ($p < 0,05$), cardiac output increases by 12 % ($p < 0,05$). We demonstrate that pretreatment with PAG and L-cysteine increases H2S levels and decreases the markers of oxidative and nitrosative stress that accompanied by increases coupling ?NOS.
Conclusion: Pretreatment with PAG and L-cysteine improved diastolic heart function and decreased arterial stiffness that may be the result of alternative ways of increasing the synthesis of hydrogen sulfide and recovery coupling of cNOS in old rats.

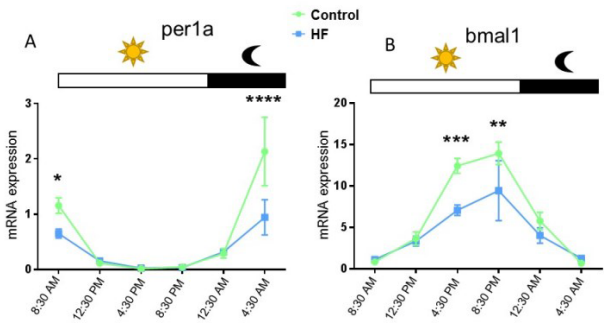
Background: Circadian rhythms are biological oscillations regulated by molecular clocks. Whether they are affected by heart failure (HF) remains poorly characterized. Also, the pathophysiological mechanisms remain unidentified.
Purpose: We aimed to assess whether zebrafish and mouse hearts display circadian gene expression patterns, so that they can serve as models for mechanistic studies into the circadian clock in HF. We hypothesized that circadian gene expression may be altered in the failing heart, and that nocturnal (mice) and diurnal (zebrafish) animals have different expression patterns.
Methods: Zebrafish and mice were housed on 14/10 and 12/12 light/dark schedules, respectively. HF was induced in adult zebrafish by phenylhydrazine hydrochloride (n = 108). After 5 weeks of treatment, 9 hearts from control and HF groups were isolated every 4 hours in a 24-hour period and pooled by 3. In mice, myocardial infarction followed by HF was induced by permanent ligation of the left anterior descending coronary artery or sham operation (n = 56). After 4 weeks, 4 hearts per group were isolated every 3.5 hours in a 24-hour period. Expression of core clock genes was analysed using qPCR and oscillations confirmed with cosinar analysis in R statistics. Differences between groups were assessed with 2-way analysis of variance (ANOVA) with Sidak post hoc test or with Mann-Whitney U test, as appropriate.



Clock gene expression in zebrafish heart

Results: Gene expression of core clock genes, namely per1a/2/3, bmal1, clock and cry1ba for zebrafish, and Per1 and Bmal1 for mice, showed clear circadian rhythmicity in both control and HF groups. In zebrafish, per1a of the control group raised during the rest phase (lights off) and reached a maximum at 04:30 AM before the start of the animal's active phase (lights on) (Figure A). Expression of per3 reached a maximum when the light comes on (08:30 AM), followed by per2 peak a couple of hours later (12:30 PM). However, in HF, per1a (Figure A) and per3 were significantly lower expressed during these peak phases ($p < 0.00001$) while per2 was significantly higher expressed in the control group ($p < 0.01$). Clock, bmal1 (Figure B) and cry1ba reached their maximum just before the onset of the dark phase (08:30 PM) for the control group, whereas in HF their expression was significantly down-regulated. Clock, bmal1 and cry1ba mRNA levels were in counter phase with members of Per gene family. Similarly, in mice, Per1 peak times were shifted (01:30 PM for HF and 05:00 PM for sham) and peak time of Cry2 (08:30 PM) was higher in sham animals compared to HF animals at the same time point ($p = 0.016$).
Conclusions: Failing hearts of zebrafish and mice display circadian expression patterns of clock genes. While peak and trough times of the clock genes are largely unchanged, the amplitude of the oscillations differ between healthy and failing hearts. We conclude that both zebrafish and mice represent appropriate models for future mechanistic studies into the circadian clock in HF.

P2325

Acute administration of high levels of spermidine and spermine impair ryanodine receptor type 2-dependent contractility in human atrial tissue

Background: The polyamines spermidine, spermine and putrescine affect membrane excitability and cell contractility in experimental animal models. Binding of polyamines to several types of membrane ion channels alters ion homeostasis and may cause arrhythmias. Yet, the effect of polyamines on force development and arrhythmias in intact human cardiac tissue remain unknown.
Purpose: To assess acute functional effects and underlying mechanisms of the polyamines spermidine, spermine, and putrescine on human atrial tissue.
Methods: We used isolated muscle strips (trabeculae) of human atrial tissue from 35 patients undergoing cardiac surgery (coronary artery bypass graft and/or aortic valve replacement). Trabeculae were electrically stimulated at 1 Hz and perfused with modified Tyrode's solution supplemented with increasing concentrations of spermidine, spermine, or putrescine (100 nM, 1 mM, 10 mM, 100 mM and 1 mM; 20 min each concentration at 37°C). Developed force of trabeculae was measured using a force transducer. Untreated muscle strips served as controls. To elucidate underlying mechanisms of spermidine-induced changes in the force development (1 mM), trabeculae were pre-incubated with ryanodine (1 μM) and phosphoinositol 3-kinase (PI3K) inhibitors LY 294002 (5 μM) and A-66 (1 μM). Mixed ANOVA was used to test for differences within groups (time/concentration) and between groups (treatment). Data are shown as mean ± SEM. Values of $P < 0.05$ were considered statistically significant.
Results: Low concentrations (100 nM - 100 μM) of spermidine (n= 14 trabeculae), spermine (n= 10 trabeculae), and putrescine (n= 7 trabeculae) did not reduce force development (control n= 9 trabeculae). However, supraphysiological level of spermidine or spermine (1 mM) exerted significant negative inotropic effects (A). In addition, high concentrations (1 mM) of spermidine and spermine evoked arrhythmic events (spermidine: 25% of trabeculae, spermine: 50% of trabeculae, control: 0% of trabeculae) that were accompanied by impaired force development (B). Two spermidine-treated trabeculae developed sustained arrhythmias. In contrast, putrescine-treated trabeculae did not show any arrhythmic events and force development was comparable to control. The negative inotropic effect of spermidine was significantly blunted by ryanodine (n = 7 trabeculae) but not by the PI3K inhibitors LY 294002 (n = 10 trabeculae) and A-66 (n = 9 trabeculae; C).
Conclusions: Pharmacological inhibition of cardiac ryanodine receptor attenuated spermidine-induced negative inotropic effect and may be due to decreased myocardial calcium transients. Our results suggest that ryanodine receptor - dependent mechanisms are responsible for the acute negative inotropic effects of high-dose polyamines in human cardiac tissue.

Introduction: Pulmonary arterial hypertension (PAH) directly affects the right ventricle but left ventricle dysfunction (LVD) can also be present, which is associated with left ventricle (LV) atrophy and/or neurohumoral activation.

Purpose: Analyse the hypothetical cardioprotective effects of exercise preconditioning on LV in a rat model of PAH induced by monocrotaline (MCT).

Methods: Male Wistar rats were randomly separated in sedentary (SED; 4 weeks sedentary) and trained groups (EX; running sessions of 60 mim/day, 5 days/week, at 25 m/min, during 4 weeks). After 4 weeks, animals were injected with MCT (60mg/kg; SED+MCT, n = 15 and EX+MCT, n = 15) or the same volume of vehicle (SED+V, n = 10). Afterwards, all animals remained sedentary for additional 4 weeks. Next, animals were submitted to LV hemodynamic evaluation in baseline and isovolumic conditions, and LV samples were prepared for light microscopy analysis (cardiomyocyte cross sectional area and collagen deposition) and endothelin (ET-1) mRNA analysis.

Results: in baseline conditions, systolic (peak systolic pressure, dP/dtmax, cardiac output and stroke volume) and diastolic function (dP/dtmin, Tau and end-diastolic volume) were compromised in SED+MCT but not in EX+MCT ($P < 0.05$ vs. SED+MCT). Under isovolumic conditions, SED+MCT showed additional deterioration in diastolic function (dP/dtmin and end-diastolic pressure) and prevented in EX+MCT ($P < 0.05$ vs. SED-MCT). This improved hemodynamic profile was paralleled with prevention of cardiomyocytes atrophy and fibrosis, and with normalization of ET-1 mRNA levels ($P < 0.05$ vs. SED.MCT). Exercise preconditioning also enhanced exercise tolerance and positively impacted survival. Of note, these improvements were observed 4 weeks after the cessation of exercise training, highlighting that the protective phenotype promoted by exercise training is maintained for several days.

Conclusion: Our findings suggest that exercise preconditioning can prevent LV dysfunction secondary to MCT-induced PAH, a protective effect that was observed several weeks after the end of the last training session. Mechanisms underlying exercise-induced protection can be related to the prevention of LV atrophy, fibrosis and neurohumoral activation.

Chronic Heart Failure - Pathophysiology and Mechanisms

P2327
Severe myocardial dysfunction: a rare side effect of bevacizumab and 5 fluorouracil

PM Paula Maria Mendoza Cuartero[1]; A Elorriaga Madariaga[1]; M Codina Prat[1]; A Arregui Lopez[1]; A Andres Morist[1]; C Asla Ormaza[1]; I Bravo Martinez[1]; G Aurrekoetxea Bajeneta[1]; L Ruiz Gomez[1]; R Saez Moreno[1]
[1]Hospital de Basurto, Bilbao, Spain

We present the case of a 60 year old male, active smoker with known arterial hypertension (HTN) without medical treatment. He was diagnosed of an irresecable rectosigmoid advance staged adenocarcinoma in May 2017 and underwent 6 cycles of FOLFOX (oxaliplatin + 5-fluorouracil bolus + 5FU by continous infusion) + Bevacizumab (BVZ). Due to inadequate blood pressure controls, antihypertensive treatment with manidipine was started. Following chemotherapy, he underwent external radiation therapy and surgical resection in september 2017. Adjuvant therapy with FOLFOX-BVZ in the 6th week after the procedure was planned.
October 2017, he is derived to the emergency room because of severe diarrhoea. Blood tests showed slightly elevated troponine T levels (seriated 19-20 ng/L; normal < 14) and hemoglobin 9,3g/dL as the only abnormal findings. On the 12 lead EKG negative, symmetric T waves in precordial leads with a long corrected QT Interval were registered. Cardiological evaluation was asked for. The patient was sweaty, slightly hypotensive (100/60 mmHg) and tachyicardic with no congestive signs. Echocardiography revealed a dilated left ventricle (LV) with severe impairment of left ventricular ejection fraction (LVEF) due to diffuse hypokinesia, moderate mitral regurgitation and minimal pericardial effusion.
The patient was admitted to the cardiology station and monitored. Medical treatment of heart failure with reduced ejection fraction according to current guidelines was started. A coronariography excluded arterial coronary disease. The cardiac MRI showed a mild to severe dilated LV with a moderate to severe impaired LVEF (29%). Right ventricle was normal. No early nor late enhancements were observed. The potential cardiovascular (CV) side effects of 5FU and BVZ were assumed to be responsible for the LV dysfunction. After hospital discharge he is being followed up by the cardiooncologist. The echocardiogram performed two months later showed a non dilated LV with partial recovery of the LVEF (42%). The adjuvant therapy is on stand by waiting for the cardiovascular evolution.
LV dysfunction is not known to be a frequent side effect of BVZ nor 5FU. 5FU‘s most common CV side effects are angina, arrhytmias or EKG changes. In rare cases heart faliure (HF) has been reported. BVZ has been associated with many CV events mainly high grade HTN, arterial and venous thromboembolic events. In contrast, LV dysfunction and HF have rarely been reported. Rather than direct cardiotoxicity, the main mechanism responsible for BVZ-associated HF is suggested to be uncontrolled HTN, which could have been the mechanism responsible for LV dysfunction in our patient. This case highlights the importance of an adequate screening and baseline assesment of patients prior to initiating chemotherapy and an adequate control of CV risk factors. Periodic controls with EKG, cardiac biomarkers and echocardiogram are necessary in order to detect CV complications.

P2328
First case of successful treatment with an interatrial shunt device after market authorisation

FX Kleber[1]; PJ Koeln[1]
[1]Charité - Universitätsmedizin Berlin, Berlin, Germany

Aim: Heart Failure with preserved ejection fraction (HFpEF) has been a therapeutic dilemma for many years. Recently reports emphasise the importance of a sharp rise in left ventricular filling pressures under exercise. A device has been developed to induce a right to left shunt at the atrial level and favourable results on its efficacy in improving hemodynamics and exercise capacity as well as reducing hospital readmissions have been reported in two small clinical trials. One device has gained CE mark. We report the first patient who has been treated using this interatrial shunt device after market authorisation.
Methods and Results: This 74 years old female patient has had aortic valve replacement for severe aortic stenosis 5 years ago but has not had any relieve of symptoms thereafter. Her NYHA class was III. Systolic left ventricular function was normal. She presented with severe diastolic dysfunction: Her echocardiographic E/e' was 24, her mean resting pulmonary capillary wedge pressure (PCWP) was 20 mmHg and her right atrial (RA) pressure was 6 mmHg under optimal medical treatment with Valsartan, Torasemid and Digitoxin for rate control of atrial fibrillation. Her heart rate was optimally controlled and a further increase of diuretics seemed to be impossible. She had only mild pulmonary hypertension at rest with a mean pulmonary artery pressure of 23 mmHg. Her 6 min walk test distance was 240 m.
An interatrial shunt device was inserted in July 2017. After six months her symptomatology was greatly improved. She was able to go shopping again and to climb up one floor of stairs. Her 6 min walk test distance was 360 m. The shunt was open and the calculated orifice area using the PISA formula from an echocardiographic subxiphoid view did not reveal any narrowing of the 8 mm diameter shunt within the device.
Conclusion: This patients shows exemplarily which patients might benefit most from such a therapy: Patients with severe HFpEF and high gradient between PCWP and RA pressure, whose filling pressure cannot be further reduced by medical therapy without decreasing forward right ventricular output.

P2329
Effect of ivabradine on heart rate reduction, change of QRS width and change of LV EF and NT-proBNP in patients with non-ischemic cardiomyopathy and LBBB pattern at baseline

F Malek[1]; L Dujka[1]; A Kucerova[1]; V Lekesova[1]; P Volf[1]; K Koscova[1]; P Neuzil[1]
[1]Na Homolce Hospital, Department of Cardiology, Prague, Czech Republic

Funding Acknowledgements: “Supported by grant MH CZ - DRO (Nemocnice Na Homolce - NNH, 00023884), IG170501”

Background: the SHIFT study showed that LBBB increased risk in the patients with chronic heart rate and heart rates = 70 bpm in sinus rhythm. Ivabradine was safe in LBBB and its effect was similar to that in patients without LBBB. We report four clinical cases of patients with non-ischemic cardiomyopathy, sinus rhythm and LBBB at baseline when adding ivabradine to optimal medical therapy was associated with heart rate reduction, narrowing of QRS complex duration and loss of LBBB pattern on ECG.
Patients: Four patients, one male and three females, with age range 28-76 years, were followed at a tertiary care heart failure clinic after diagnosis of heart failure with reduced EF caused by non-ischemic cardiomyopathy, three with idiopatic CMP and one patient post myocarditis. Patients were on optimal medical therapy including BB, ACEI/ARB and MRA.
Ivabradin was started in all subjects at dose from 5 mg to 7.5 mg twice daily when heart reates remained > 75 bpm despite maximal tolerated betablocker dose.
Observation: After mean 866 days (538-1211) days of follow-up, heart rate reduction after ivabradine was associated with clinical improvement, increase of LV EF and decrease of LV enddiastolic diameter (EDD) and reduction of NT-proBNP level. We observed reduction of QRS duration with loss of LBBB pattern on ECG too. The change of parameters after ivabradine is shown in the table.
Conclusion: Heart rated redution after ivabradine was associated with decrease of duration and change of morphology of QRS complex in patients with CHF and non-ischemic cardiomyopathy. This phenomenon might be explained by effect of ivabradine on reverse remodelling of left ventricle with improvement of intraventricular conduction.

Change of parameters after ivabradine

Case number Gender, age	Follow-up days	HR bpm	QRS width ms	LV EF %	LV EDD mm	NT-proBNP pmol/l
M 76 y	924	-28	-30	+ 20	-11	-203
F 45 y	1211	-17	-48	+18	-12	-415
F 28 y	791	-14	-54	+19	-6	-92
F 44 y	538	-17	-36	+12	-8	-65

M-male, F - female, y - years, HR - heart rate, bpm - beats per minute, LV EF, left ventricle ejection fraction, EDD - enddiastolic diameter, NT-proBNP - N-terminal B-natriuretic peptide

The Marfan syndrome case as a successful treatment of severe heart failure.

YULIYA Yuliya Martyanova[1]; DA Kondratev[1]; AV Kadykova[1]; DG Tarasov[1]; YV Frolova[1]; SL Dzemeshcevich[1]
[1]*Federal Center of Cardiovascular Surgery, Astrakhan, Russian Federation*

Patient - 29 - year man.
Symptoms: dyspnea, weakness, palpitation.
Dissecting aneurysm of ascending aorta diagnosed on TTE, CT scan.
He had high growth (1.90 m), the total length of his hands was 1.10 m.
Hypermobility and deformation of joints, chest deformation. Rude diastolic aortic murmur. BP - 110/30 mmHg.
Life history: Marfan Syndrome confirmed by genetic and dilatation of ascending aorta (44 mm) identified when the patient was 16 years old.
Also he had kidney malformation (dystopia of right kidney, dysfunctional left kidney).
In 2013 he was hospitalized with respiratory insufficiency because of Bullous lung disease. He was operated - right lobectomy. Dyspnea and weakness appeared in 2014. TTE (2014): aneurysm of ascending aorta 55 mm and AR 2. He had family history of aortic dissection (his mother was successfully operated on aorta at age of 50). He had a normal pressure, his brother was healthy.
TTE in this hospitalization (2015): aortic diameters: aortic annulus 40 mm, valsalva sinuses 100 mm, tubular ascending aorta 63 mm, aortic arch 46 mm. Dissecting aneurysm of ascending aorta from aortic valve to brachiocephalic trunk. Mean aortic gradient 17 mm Hg, total aortic regurgitation, non-calcified tricuspid aortic valve. Left ventricle volume (LVV) 176/99 ml, EF 52%.
CT scan (2015): ascending aorta (aortic annulus - 40 mm, valsalva sinuses - 94 mm, sino-tubular junction - 94 mm, tubular ascending aorta - 75 mm), aortic arch (proximal diameter - 27 mm, isthmus - 20 mm), thoracic descending aorta (maximum diameter - 19 mm), abdominal aorta (infra-renal segment - 18 mm). Detachment intimal flap - a projection ascending aorta, aortic arch and brachiocephalic trunk had not dissection.
Serum creatinine – 118 mmol/l. PRO BNP - 12000. Multidisciplinary decision and the
patient was operated - Total aortic root replacement with reimplantation of coronary arteries and prosthetic valve replacement '??? ??? 29'(Bental operation). Post Operative Outcome - uneventful postoperative course, no neurological symptoms, no simptoms of heart failure, no severe renal and respiratory failure and good surgical correction. PRO BNP - 425. Two years later: good quality of life, LVV - 115/40 ml, mean prosthetic valve gradient - 12 mm Hg, INR - 2,5.
Results: only surgery in such case of aorta pathology is effective method of treatment severe heart failure.

P2331

An unexpected cause of acute kidney injury in a patient with ischemic cardiomyopathy treated with sacubitril/valsartan

R Abete[1]; S Mazzetti[1]; J Rossi[1]; P Delfino[1]; M Chioffi[1]; A Andrea Mortara[1]
[1]*Dipartment of Cardiology Policlinico di Monza, Monza, Italy*

We report a clinical case of a 70-year-old man evaluated in May 2017 for chronic heart failure (NYHA class III) and LV ejection fraction of 20%. In 2001, the patient underwent coronary artery bypass grafting and implantation of a bicameral ICD for primary prevention. Co-morbidities included type 2 diabetes, peripheral vascular disease, chronic kidney disease G3 and systemic arterial hypertension treated with multiple antihypertensive drugs. In 2015, a CT angiography of the renal arteries showed no critical stenosis. In last May, sacubitril/valsartan (ARNI) was started at dosage of 49/51 mg BID, and titrated to 97/103 mg BID after one month of therapy. In July, an increase in serum creatinine from 1.9 to 3.7 mg/dL was documented. Diuretics were reduced and appropriate volume of liquids restored. In August, creatinine was still 3.5 mg/dL, therefore ARNI was replaced with captopril 75 mg/die (previous therapy). A week later, the patient reported oliguria associated with acute onset of dyspnea at rest and weight gain and was admitted to our ICU. Physical examination showed bilateral peripheral edema and pulmonary rales, with right pleural effusion on the chest X-ray. Blood pressure was 120/80 mmHg, body temperature 36°C and oxygen saturation 95% at room air. Serum creatinine was 4.4 mg/dL, NT-pro-BNP 34100 ng/L. ECG and echocardiogram were unchanged compared to previous exams, except for an increase in pulmonary artery pressure (80 mmHg) and IVC diameter (20 mm). Urine cultures and urinary tract echography were negative. High-dose intravenous furosemide (40mg/hr) failed to reduce the pulmonary congestion. Diuresis increased to >200/hour and clinical conditions improved after association of metolazone 10mg and canrenone 200mg to furosemide; nevertheless, creatinine remained high (3.7 mg/dL). Nephrologists were consulted and, despite the high risk of contrast-induced nephropathy, a renal angiogram was performed. It showed a marked progression of atherosclerosis with a thrombotic occlusion of the right renal artery and a 60% ostial stenosis of the left renal artery. The stenoses were not susceptible to angioplasty, because of thrombus anatomic features and a high risk of embolization. In the next days, renal function was stable with a satisfactory diuresis on oral furosemide 500mg/die. The patient was discharged on oral anticoagulant therapy with warfarin and a program of short-term evaluation of the clinical status and renal function. In conclusion, worsening of renal function may, in some patients, be interpreted as the consequence of the unfavorable effects of pharmacologic therapy, including, as in this case, a shift from ACE-I to ARNI. However, all possible causes of renal dysfunction must firstly be ruled out, including a rapid progression of renovascular disease. If, in this patient, anticoagulant treatment will improve renal perfusion, ARNI could be gradually restarted with a potentially important impact on the subsequent clinical course.

Chronic Heart Failure - Treatment

P2332

Successful wound management with vacuum-assisted-therapy

J Jamila Kremer[1]; M Farag[1]; R Arif[1]; B Schmack[1]; A Heininger[2]; A Ruhparwar[1]
[1]*University Hospital of Heidelberg, Cardiac Surgery, Heidelberg, Germany*;
[2]*University Hospital of Heidelberg, Department of Infectious Diseases, Medical Microbiology and Hospital Hygiene, Heidelberg, Germany*

Introduction:
Wound infections in patients on left assist device (LVAD) support are an imminent threat to survival and outcome after orthotopic heart transplantation (OHT). Hospitalization is prolonged and mortality rates are increased with wound infections prior to OHT. Here we present a rare case of hazardous wound infection on LVAD support with major skin lesions and vacuum-assisted-therapy.
Case Report:
A 47-year-old male patient suffering dilated cardiomyopathy after chronic myocarditis underwent LVAD implantation as bridge to transplantation in 2014 in an external hospital. Further diagnoses were severe mitral regurgitation, partial lung resection due to aspergilloma and combined restrictive and obstructive ventilation disorder. He initially developed deep wound healing disorder around the LVAD driveline in 2016. Colleagues in the referring transplantation centre treated the wound with vacuum-assisted therapy and intravenous antibiotics. However, the wound situation aggravated and the patient was removed from the transplantation waiting list due to multiresistant Pseudomonas aeruginosa infection in 2017. Upon admission at our centre the patient presented multiple wound blisters and open skin lesions along the driveline course. We did an extensive wound debridement and started another cycle of vacuum-assisted-therapy. The patient received dressing changes in the operating theatre every 48-76 hours until the wound site showed improvement.
During the last 6 months, after 47 surgical dressing changes, we observed immense amelioration under vacuum-assisted-therapy and could stop the vacuum-assisted treatment. Nonetheless, the wound is still infected by a multiresistant Pseudomonas aeruginosa, which will not be eradicated by intravenous antibiotic treatment. The patient was placed on high urgency transplantation waiting list due to LVAD-related wound infection.
Antibiotic treatment will be continued for at least 6 weeks after successful transplantation and regular blood cultures and wound swabs will monitor the actual infective status of the patient.
Summary:
With sufficient care and dedication, severe multiresistant Pseudomonas aeruginosa infection of biomaterial surfaces could be sustained by high frequent dressing changes. Wound infection in patients with a ventricular assist device, whether univentricular or biventricular, still represent the major criteria for emergent OHT. Wound care of driveline infections can be guaranteed with vacuum-assisted therapy.

Treating diuretic resistance in non-adherent 'Big Baby'

VKP Putri[1]; IW Anwar[2]; DA Sinaga[1]; A Arles[2]
[1]*Awal Bros Hospital Pekanbaru, Department of Cardiology, Pekanbaru, Indonesia*; [2]*Awal Bros Hospital Pekanbaru, Department of Internal Medicine, Pekanbaru, Indonesia*

The 57-year-old man came to the emergency department with progressive breathlessness and edema of the limbs since 10 days before admission. He also complained of an abdominal discomfort and a swollen scrotum. The patient seemed congested. There is edema in both limbs, scrotum, and abdominal ascites are also present. The patient's weight was 105 kg. On chest auscultation found crackles at the base of the lung during inspiration. Electrocardiogram results show atrial fibrillation with normal ventricular response. In laboratory tests, the serum creatinine values were increased (1.72 mg/dL), hyponatremia (128 mmol/L), and mild hyperkalemia (5.4 mmol/L). Echocardiography showed dilatation of the entire heart chambers, left ventricular ejection fraction 20%, decreased right ventricular function.
The patient with a history of CABG in 2014, after surgery he did not take regular medication. Within one year the patient is hospitalized 6 times due to heart failure. He also had a history of diabetes melitus with poor blood sugar control.
Management of heart failure was done by giving intravenous bolus Furosemide as much as 120 mg followed by intermittent bolus 100 mg 4 times per day. We also give him Ramipril 5 mg o.d and fluid restriction. On the first day of treatment, urine output is only 1000 cc per 24 hours. Edema and ascites have not diminished, the body weight is 102 kg. An additional Tolvaptan therapy is given 15 mg o.d. Tolvaptan is given within two days, without increasing urine production per day. Renal and electrolyte function evaluations were performed, no significant differences were found. Tolvaptan was discontinued, replaced with hydrochlorthiazide 50 mg o.d. Frequency of Furosemide is increased to 100 mg five times per day. After administration of HCT, urine production increased slightly to 1500 cc per 24 hours, but the edema persisted. An abdominal ultrasound examination was performed with dilated findings in the intrabdominal vein and ascites. It was decided to perform ascites puncture which drains serous fluid as much as 650 cc. Immediately after ascites puncture, urine production increased to 4000 cc per 24 hours without increased diuretic dose. Within two days, the patient's weight to 90 kg with improvement on the examination of kidney and electrolyte function. He was discharged with Furosemide 80 mg t.i.d, Ramipril 5 mg o.d, Spirolactone 50 mg o.d, Bisoprolol 1.25 mg o.d, and diabetes medication.
Diuretic resistance is common in patients with advanced heart failure, the handling becomes very difficult in patients who are not adherent to treatment. All efforts should be attempted to achieve decongestion and should be done in a short time. In this case, if no increase in urine production after ascites puncture, we have been considered for hemodialysis. A good and clear education to the patient should be done repeatedly to improve medication adherence, in order to avoid re-hospitalization due to heart failure in the future.

P2334

A young patient with heart failure and malnutrition - a holistic approach. which is the chicken and which is the egg?

E Edit Floderer[1]; R Luostarinen[1]
[1]*Karlstad Hospital, Department of Heart- and Acute Medicine, Karlstad, Sweden*

Introduction: Malnutrition and anxiety are seen in heart failure at the end stage disease. However, malnutrition as a possible underlying cause of heart failure is rarely seen in developed countries and therefore both evidence and recommendations are lacking.
Case presentation:
A 42 year old man, smoker, admitted to hospital with a feeling of malaise, chest pain, fatigue, dyspnea, dysphagia. Historically HLA-B27 positivity and idiopathic, recurrent hydrothorax were known. Also suffered from gastroesophageal reflux disease, certain grade of anxiety. No hypertension or diabetes were found. The physical examination showed tachypnea, cachexia with BMI 18 kg/m2, poor physical condition and severe panic attacks. Investigations revealed a severely dilated cardiomyopathy (with ejection fraction 10-15 %) without presentation of coronary artery disease, myocarditis, arrhythmias or myocardial infiltrative disease. Standard medical therapy failed to improve physical performance and ejection fraction. Transplantation was denied because of the poor performance status (NYHA IV) and mental health issues (severe anxiety and panic syndrome). Complementary therapy with enteral nutrition (tube feeding), treatment of anxiety and the addition of angiotensin receptor blocking neprilysin inhibitor (ARNI) improved the patient's overall health, functional capacity and fully reversed the heart failure.
Conclusions: Conventional treatment of heart failure often leads to improved cardiac status in most cases. However, it is important to recognize complicating conditions like malnutrition and severe anxiety (reason for the dysphagia) which may impede recovery. By complementing traditional heart failure treatment with additional therapies (as above) and by using a new medical therapy (ARNI) the patient's severe heart failure was fully reversed in this case and heart transplantation was no longer needed.

Acute Heart Failure - Pathophysiology and Mechanisms

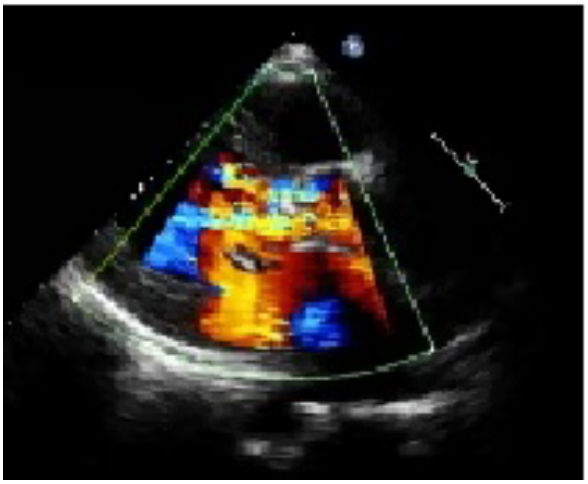
Acute heart failure in a preterm pregnant with infective endocarditis

M J Jhessica Pecson[1]; JR Bacani[1]
[1]*Philippine Heart Center, Adult Cardiology, Quezon City, Philippines*

Infective endocarditis during pregnancy is a rare but serious condition with significant fetal and maternal morbidity and mortality.
We report a 39 year old female, Filipino, known Rheumatic Heart Disease, G8P7 on her 29 weeks AOG who was admitted for worsening heart failure symptoms with history of chronic fever. She arrived at the emergency room awake in respiratory distress hence immediately intubated. Cardiovascular examination revealed dynamic precordium, displaced PMI, (+) diastolic murmur at the 2nd right intercostal space and (+) systolic murmur at the apex. Abdominal examination revealed positive for fetal heart tone. Diuretics and vasodilator given. Complete left bundle branch block seen in ECG and pulmonary edema in chest X-ray. Empiric antibiotic therapy was initiated. Transthoracic echocardiography revealed infective endocarditis of the aortic valve – a vegetation on the right coronary cusp with severe aortic regurgitation. She was referred then to surgery, infectious disease and Obstetric services. OB started patient on Dexamethasone for lung maturity. Patient was stabilized hence medical therapy continued to optimize fetal viability. However, on the 12th hospital day, Biophysical score revealed fetal distress hence patient underwent emergency cesarean section followed by valve surgery. Intraoperatively, there was perforation at right and left coronary cusps with vegetations. On the 3rd post-operative day, she was extubated, transferred to the ward and discharged on the 25th hospital day. Repeat transthoracic echocardiography 6 months post-operatively showed normally functioning metallic aortic and mitral valve with no paravalvular leak.



Aortic valve vegetation with severe AR

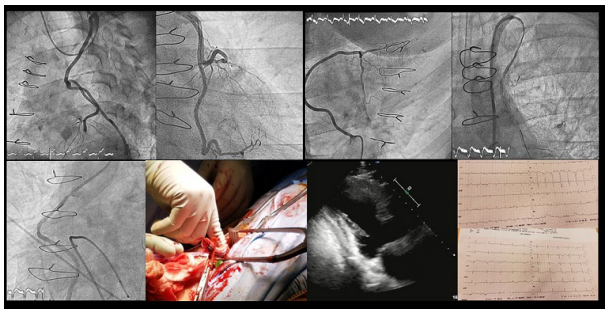
Unusual vascular access for ECMO implantation after a complication during PCI.

MG Ascencio Lemus[1]; P Maiorano[2]; C Minguito Carazo[1]; L Castillo Pardo[2]; S Prieto Gonzalez[1]; C Palacios Echavarren[1]; S Del Castillo Garcia[1]; JC Morales Echarte[1]; P Menendez Suarez[1]; J Borrego Rodriguez[1]; A Perez De Prado[1]; M Castano Ruiz[2]; F Fernandez Vazquez[1]
[1]Hospital of Leon, Cardiology department, Leon, Spain; *[2]Hospital of Leon, Cardiac surgery department, Leon, Spain*

A 60 year-old man was admitted due to recurrent syncope. Medical background includes cerebrovascular disease: right internal carotid endarterectomy,1998. Severe left internal carotid stenosis. Peripheral vascular disease (aortic bifemoral bypass, 2010) and coronary artery disease (CABG in 2006: LIMA to LAD. RIMA to OM [T-graft to LIMA]. RA to PDA). 3 months prior to admission he began to experience syncopes, non-related to efforts and no chest pain.
No relevant data at physical examination. ECG at admission was a sinus rhythm with T wave inversion in leads I, AVL, V1-V2. No evidence of arrhythmias. An angio-CT was requested, reporting a moderate stenosis in right carotid territory, occlusion of left internal carotid artery and moderate stenosis in both subclavian arteries. Basal echocardiogram reported a LVEF of 55%, and apical hipokinesis. ECG exhibited new T-wave inversion in leads V2-V6. A stress echocardiography confirmed ischemia in the LAD territory; therefore he underwent an angiography that evidenced severe stenosis in the LAD, distal to the anastomosis of the LIMA graft, being permeable all of the grafts and no new stenosis in the other native coronary arteries. It was decided to perform a PCI on the LAD through the LIMA graft. After guidewire introduction to distal LAD, the patient experienced hemodynamic instability with severe hypotension and bradycardia and then cardiac arrest.
Advanced life support was initiated (orotracheal intubation, transfemoral pacemaker and intra-aortic ballon pump implantation) obtaining a pulse recovery in less than 10 minutes, high doses of amines were required. The angiogram exhibited severe spasm of the RA graft and loss of caliber in the proximal segment of LIMA, hence it was performed a DES implantation 3/48 mm into the LIMA graft; a flow recovery was proved. An echocardiogram at the bedside of the patient revealed a LVEF of 10%, no pericardial effusion, and due to the refractory cardiogenic shock, the patient was intended for ECMO placing, as a bridge to recovery.
Given the severe atherosclerotic disease the artery cannulation was a total challenge. It was planned an approach through the previous aortofemoral graft: by placing an end-to-side Dacron graft sewn into the right branch of the previous Dacron graft to insert the arterial cannula. Femoral venous cannulation was carried out by dissection and the implantation guided by TOE was successfully achieved.
Sufficient flow, adequate gas exchange and ventricular unloading were confirmed. A remarkable improvement on clinical, hemodynamics and echocardiographic findings were proved (LVEF 35 %, Simpson biplane). And thus, ECMO weaning was accomplished being possible its removal on the 6th postoperative day.
This case illustrates how this unusual approach by might be a safe and feasibly procedure for those patients with severe generalized atherosclerosis requiring mechanical support with no other alternative options for arterial cannulation.



Complicated PCI resulting in ECMO.

Coronary Artery Disease - Treatment

A case report of ischemic cardiomyopathy and purulent pericarditis

Y Niu[1]; CC Pai[2]
[1]Chang Bing Show Chwan Memorial Hospital, Cardiology, Chang Hwa, Taiwan ROC; *[2]Show Chwan Memorial Hospital, Surgery, Chang Hwa, Taiwan ROC*

Introduction: We report a case of a drug abuser with purulent pericarditis, accidentally found at bypass surgery for his severe ischemic cardiomyopathy.
Case Report: A 57-year-old male patient had presented with exacerbated dyspnea and intolerable chest pain since one week before admission. He has type II diabetes mellitus, hypertension, hepatitis B and hepatitis C, and a history of heroin dependence under methadone treatment. The patient also has peripheral artery occlusive disease with chronic ulcer over bilateral lower legs. Wound culture of the ulcer lesions was Klebsiella Pneumonia. When he visited emergency room, physical examination revealed blood pressure of 137/94 mmHg, heart rate of 82 beats/min., respiratory rate of 17/min and body temperature of 37°C. Laboratory data showed leukocytosis, significant elevated C reactive protein (CRP): 23.07 mg/dL, and mild elevated troponin I: 0.87 ng/mL. EKG showed abnormal Q wave over inferior and anterior leads, showing non-ST-elevation myocardial infarction. A chest X-ray demonstrated cardiomegaly. Coronary angiogram revealed 3-vessel-disease with left main lesion. His right coronary artery (RCA) showed chronic totally occluded (CTO, Figure 1, Panel A). The left main showed 50% stenosis, left anterior descending artery (LAD) showed CTO, and the proximal segment of left circumflex artery (LCX) showed 70% stenosis (Figure 1, Panel B). Echocardiogram revealed mild pericardial effusion (PE) and inferior-lateral wall hypokinesia (Figure 1, Panel C). Bypass surgery was performed. However, severe adhesion over mediastinum, thickened pericardium, moderate amount of yellowish fluid in the pericardium was noted during operation. There was fibrin peeling over pericardium and abscess rupture over posterior wall of pericardium (Figure 1, Panel D). Left internal mammary artery (LIMA) was connected to LAD, and left radial artery was used to connect aorta and LCX. The symptom of chest pain subsided and his infectious signs were improved soon after surgery.

Conclusion: We report a drug abuser of severe ischemic cardiomyopathy with purulent pericarditis. The implication of the case is to notify the possible existence of multiple etiologies of acute chest pain. Acute chest pain should be differentiated from aortic dissection, myocardial infarction, myocarditis, pneumonia / pleuritis, pulmonary embolism, pneumothorax and pericarditis. The preliminary diagnosis of myocardial infarction was not complete until the abscess was found during surgery.

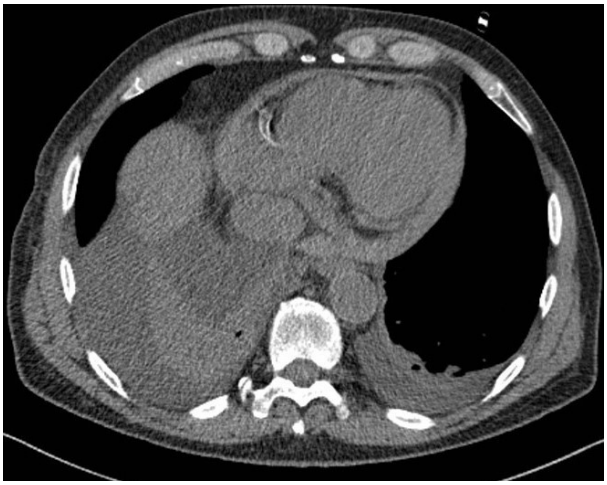
Autoimmune pericarditis after device implantation and atrial lead reposition

S Garkina[1]; S Nemtzov[1]; V Lebedeva[1]; R Konoshkova[1]; S Gureev[1]; R Tatarsky[1]; D Lebedev[1]; G Nikolaev[1]
[1]*Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation*

We present case report of a 71-year-old male who underwent uncomplicated dual chamber pacemaker implantation due to binodal disease (transient 2 degree SA block, transient 2 degree AV block). His clinical status was stable, except moderate thrombocytopenia (platelets count was 93*10 9/l. During in-hospital follow up high atrial lead threshold was registered (up to transient loss of capture). Despite chest X-ray results without lead dislocating the revision of pacemaker system revision was performed. During the procedure massive subcutaneous hematoma near subclavian vein punction points was noted. Atrial lead was repositioned in right atrial appendage with acceptable parameters (2 mV endocardiogram amplitude, pacing threshold of 0.8 mA/0.4 ms , impedance of 700 Oms). During postoperative period patient was stable. In a week after implantation the patient developed retrosternal chest pain, hypotension (systolic BP was 60/40 mm Hg), severe hiccough and pain in the back during deep breath, low grade fever (37,5 - 38 C). X-ray showed right-sided hydrothorax. Blood test showed hemoglobin level lowering to 92 g/l, erythrocytes - 3,06*1012 /l, C-reactive protein level was 12,5 g/l. Chest CT-scan demonstrated the liquid content of the layer thickness in the posterior sections up to 6-7 cm (figure 1), hemorrhagic pericardial effusion (up to 14 mm). The patient received symptomatic therapy and hemotransfusion of 2 doses of red blood cells. Right pleural cavity drainage was performed with evacuation of 1000 ml of slightly turbid liquid. The pleural fluid analysis revealed lymphocytosis (no erythrocytes), single mesothelium cells with reactive changes, indicating reactive emptying with a lymphoid response involving an autoimmune response. Drainage of the pericardial cavity was not recommended. Further therapy with NSAIDs promoted regression of symptoms. Control chest X-ray showed no air or fluid in pleural cavities.

This case illustrates typical signs of post-pericardiotomy syndrome including fever, pleuritis and pericardial effusion with underlying autoimmune mechanism. It is observed rather rarely after interventional procedures and device implantation but should be always considered by clinicians especially in early post-operative period.



Chest CT scan

Pulmonary Circulation, Pulmonary Embolism, Right Heart Failure - Clinical

The difficult diagnosis of dyspnoea - PH due to HFpEF

M Magdalena Dudek[1]; M Kaluzna-Oleksy[1]; J Migaj[1]; M Lesiak[1]; E Straburzynska-Migaj[1]
[1]*Poznan University of Medical Sciences, 1st Cardiology Department, Poznan, Poland*

70-year-old male presented to our hospital because of progressive dyspnoea and massive oedema of lower limbs. His medical history was significant for hypertension, diabetes mellitus type 2, persistent atrial fibrillation, chronic renal failure - stable for many years (CKD G3a), and obesity (BMI 35,3 kg/m2). On admission, physical examination revealed, legs oedemas, unregularly heart rhythm with HR about 120 bpm, BP 140/80 mmHg, no abnormalities in pulmonary auscultation. Laboratory tests showed elevated levels of NT-proBNP (2552 pg/ml). Transthoracic echocardiography showed enlarged right ventricle (RV 36 mm - parasternal long axis view; 52 mm 4-chamber-view (4CHV)) with normal size of the rest chambers of the heart - left ventricle (LV 44 mm, 4CHV 25mm), posterior wall of the left ventricle (11 mm), interventricular septum (12 mm), left atrium (LA 35 mm) and preserved ejection fraction (LVEF 50%), as well as shortness of pulmonary artery acceleration time (ACT 59 ms), elevated right ventricular systolic pressure (RVSP 70 mmHg), s' wave 5 cm/s and paradoxical movement of interventricular septum. Coronary angiography revealed with severe stenosis of distal left main (LM)-70% and left circumflex artery (LCx) - 50% proximally and 90% distally. Percutaneous coronary intervention (PCI) of LM with DES implantation was successfully performed. Despite successful coronary angioplasty, dyspnoea was increasing, so computed tomography angiography (CTA) of the chest was performed. It revealed no features of pulmonary embolism and significant amount of fluid in right pleural cavity. Lung scintigraphy showed low probability of pulmonary embolism. Due to suspicion of pulmonary hypertension (PH) based on clinical symptoms and echocardiography the right heart catheterization was performed. Results of catheterization showed mean pulmonary artery pressure (PAP) 42mmHg, pulmonary capillary wedge pressure (PCWP) 24 mmHg, pulmonary vascular resistance (PVR) 3 Wood Unit, diastolic pulmonary gradient (DPG) 3 mmHg. Based on the carried out diagnostics isolated post-capillary pulmonary hypertension was diagnosed. The patient was treated with optimal pharmacotherapy in accordance to guidelines. Currently, the patient is treated optimally, in a stable clinical condition (NYHA II), and is under constant medical supervision.

Assessment of the polymorphic genes variants of the lipid and carbohydrate metabolism, vascular inflammation and neurotransmitter system in the first ischemic stroke

V Veronika Shishkova[1]
[1]*Moscow Medical Centre Neurorehabilitation , Moscow, Russian Federation*

Aim: To study the relations of polymorphic variants of the genes: ????, MTHFR, IL8, IL6, TNF-?, VEGFA, ADIPOQ, ADIROR, APOB, APO?-V,
APOC-IV, LPL, LP(a), BDNF, GRM1, GRM3 and development of the first ischemic stroke (IS).

Material and methods: The alleles frequencies and genotypes assessed for 20 mono-nucleotide polymorphic gene variants in 435 patients, who had first IS, and 229 persons with no stroke, comparable with age, gender, place of living and ethnicity. Genotyping of polymorphisms was done with the prepared TaqMan probes.
Results: For polymorphisms ???? (rs676210) and IL8 (rs1803205) there was significant difference between groups in the variety of minor alleles and genotypes.
Conclusion: There is significant relation of mononucleotide polymorphisms of the genes ???? (rs676210) and IL8 (rs1803205) with the development of first IS in the studied groups.

Chronic Heart Failure - Other

P2341
A fatal case of the Barth Syndrome in 1-year-old boy

TS Loevets[1]; NM Boldina[1]; EV Yakovleva[1]; TL Vershinina[1]; AA Kostareva[2]; ES Vasichkina[1]
[1]National Almazov Medical Research Centre, Pediatric Cardiovascular Diseases Research Department, Saint Petersburg, Russian Federation; *[2]National Almazov Medical Research Centre, Institute of Molecular Biology and Genetics, Saint Petersburg, Russian Federation*

Barth syndrome is a rare condition characterized by cardiomyopathy, skeletal myopathy, neutropenia, growth delay, exercise intolerance, distinctive facial features and 3-methylglutaconic aciduria. Barth syndrome occurs almost exclusively in males. Mutations in the tafazzin gene (TAZ) which is located at the long arm of the X chromosome are associated with Barth syndrome.
Objective: To present a rare clinical case.
Methods: Complex inpatient examination.
History of the disease: At the age of 3 months patient was hospitalized to intensive care unit with severe heart failure (HF) and high temperature. After the first examination enlarged LVEDD (45 mm), decreased EF (25%), hypertrophy of interventricular septum (IVS, 10 mm), mitral insufficiency 2-3 were diagnosed by echocardiography (ECHO), bilateral pneumonia and right-sided hydrothorax was established by chest X-ray. The disease was regarded as acute myocarditis. The early management included mechanical ventilation, tube feeding, intravenous inotropes, loop diuretics and immunoglobulin G. After the stabilization ACEi, diuretics and Digoxin per os were prescribed with positive result by ECHO (LVEDD 38,5 mm. EF 40-45%).
Results: Patient was admitted in our clinic at the age of 8 months with such complaints as excessive sweating, dyspnea, poor growth, poor weight gain, delay of motor skills. He had no syncope. No family history of cardiac disease.
Laboratory findings: intermittent neutropenia (2,53-0.85x109/L), high level of NT-proBNP (11927.00 pg/ml), Troponin I (0.0655 ng/ml). No data for infection agents by PCR and bacteriological methods and lysosomal storage diseases.
ECG and Holter ECG monitoring were demonstrated characteristic "sagging" ST segments and T waves, short QT interval without heart rhythm disturbances.
ECHO: enlarged LV (LVED 32-35 mm), low EF 37%, hypertrophy of IVS 9 mm.
Anomalies of the coronary arteries were excluded.
Neurological examination with conducting of electroneuromyography and skeletal muscle biopsy showed nonspecific signs of myopathy.
Research of 108 genes associating with different variants of cardiomyopathy using Illumina MiSeq system and Sanger's method sequencing was conducted. The pathogenic mutation in TAZ chr X153648583 which associated with Barth Syndrome was found.
Therapy of chronic HF was corrected: dose of digoxin was reduced, furosemide - increased, ß-blocker (Carvedilol) - added.
At the age of 12 months child fell ill with acute urinary tract infection, which led to cardiac decompensation, and eventually to a fatal outcome.
Conclusions: The highlights of the reported case that it is difficult to differentiate the etiology of cardiomyopathies in infants because of its similar clinical course in the debut. Combination of cardiac pathology with involvement of other systems occurs, complete clinical examination including genetic testing is necessary. It could be useful for determining the tactics of further management and prognosis for patient and his family.

P2342
Heart failure in patient with hypothyroidism

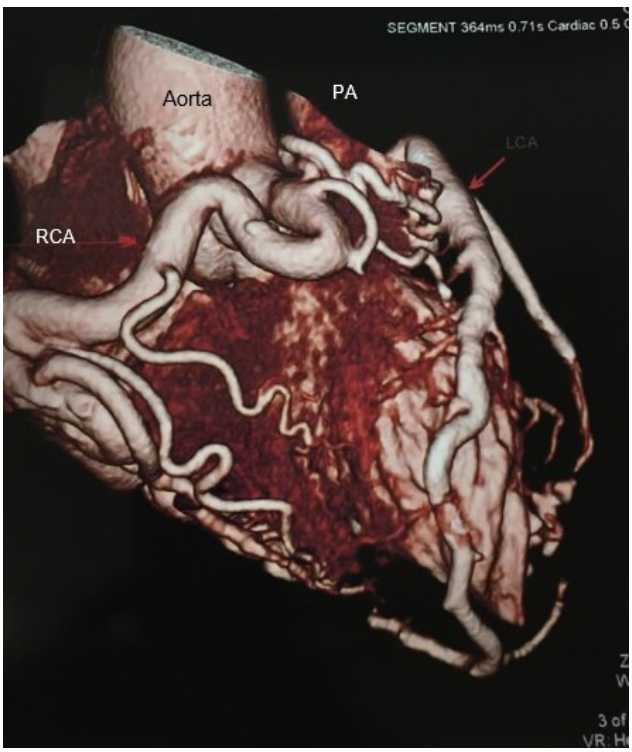
L Levan Gugushvili[1]
[1]LTD MKL, ER, Batumi, Georgia Republic of

The cardiovascular system is the main target organ of thyroid hormone. Overt hypothyroidism decreases myocardial contractility, and diminished myocardial contractility reduces thyroid hormone metabolism. 32 years old woman comes for consultation to cardiologist with complaints: swelling mainly of the face and upper extremity, difficulty breathing and dysritmia, dry skin. These changes started about 2 weeks ago. By anamnesis shown that about 2 years ago conducted a tonsillectomy, preoperative examinations with any pathological changes. Is not married, never been pregnant and does not take any contraceptives. Cardiologist did the ECG and echocardiography, they were found impaired left ventricular ejection fraction, the negative T wave in I, II, aVF, V4-6. A small amount of free fluid in the both pleural, C-reactive protein in normal, by blood chemistry hypo chromic anemia, blood plasma BNP(B-type natriuretic peptide) - 225pg/ml (N - <130ng/ml), Troponin I <0.1ng/dl (N- <0.1ng/dl).
Suspected that patient has hypothyroidism, by ultrasound research main volume - 39.9 ml, thyrotrophic hormone (TSH) - 63.3 (N-0.27-4.2mIU/L) and FT4 - 0.1 (N-1.0 - 1.6 ng/dl) they was diagnosed primary hypothyroidism. We start replacement therapy with increasing doses of levothyroxine to 100mkg. After compensation of hypothyroidism left ventricular ejection fraction returned to normal levels, ECG changes are corrected, free fluid in the pleural not observed all complaints disappeared. Patient continues treatment with levothyroxine. We will look after in dynamic. In conclusion, as seen cardiovascular changes are reversible when the underlying thyroid disorder is recognized and treated.

P2343
A rare case of Bland-White-Garland syndrome in a 60-year-old woman

H Thai Hao Phan[1]
[1]Pham Ngoc Thach University of Medicine, Cardiology, Ho Chi Minh, Vietnam

Background: Bland-White-Garland syndrome or Anomalous origin of the left coronary artery from the pulmonary artery (ALCAPA) is a rare congenital anomaly. The usual clinical course is severe left sided heart failure and mitral valve insufficiency presenting during the first months of life. However, in some cases collateral blood supply from the right coronary artery is sufficient and symptoms may be subtle or even absent. We report A Rare Case of Bland-White-Garland Syndrome in a 60-Year-Old Woman.
Case presentation: A 60-year-old female patient presented with a 10-day history of shortness of breath and exertional angina, with ischemic heart disease, mitral regurgitation, heart failure 5 years ago. Her physical examination revealed a grade III/VI systolic murmur over the apex. Electrocardiogram showed normal sinus rhythm with left ventricular enlargement, poor R wave progression in the precordial leads.



Cardiac MS-CT 640 Slices

The patient's echocardiographic imaging revealed dilated left-sided heart chambers, as well as reduced left ventricular ejection fraction (43%), severe mitral valve insufficiency and elevated systolic pulmonary artery pressure (60 mmHg). Multislice computed tomography with three dimensional reconstruction showed that the left main coronary artery originated from posterior side of the main pulmonary artery, confirming the diagnosis of ALCAPA (Figure). The patient was treated by ligation of the left coronary artery from the pulmonary artery combined with coronary artery bypass grafting and mitral valve repair.

Discussion: 85% of all cases of ALCAPA present within the first two months of life. However, symptoms may be misinterpreted (as in our case) or even be absent. In adult life patients with ALCAPA could present with symptoms of heart failure, mitral valve insufficiency, angina or arrhythmias. Objective findings include cardiomegaly on chest X-ray, and ECG may display an anterolateral infarct pattern. The diagnosis can often be made by two-dimensional echocardiography with direct visualization of the abnormal origin of the left coronary artery and retrograde flow into the pulmonary artery. In cases where the clinical suspicion is strong, a coronary angiography or CT-angiography should be performed.

Conclusion: the diagnosis of ALCAPA should be considered in adults without evidence of ischemic heart disease presenting with arrhythmias, left sided heart failure with or without mitral valve dysfunction, since an early diagnosis and surgical treatment generally results in an excellent prognosis.
