Background: The inverse association between obesity, traditionally classified by body mass index (BMI), and mortality among patients with heart failure (HF) is well-reported in Western nations but confined to a few small single-centre studies across Asia. Given the reservations against using BMI to measure obesity and the predisposition of Asian patients to a lean HF phenotype we assessed whether this obesity paradox exists in this region when different anthropometric measures are used.
Purpose: To examine a) the associations of BMI with clinical characteristics (b) the relationships of BMI, waist circumference (WC) and waist-to-height ratio to outcomes among Asian patients with HF.
Methods: Using the prospective multinational Asian Sudden Cardiac Death in HF (ASIAN-HF) Registry, the relationship between BMI (WHO-recommended Asian cut-offs: < 18.5, 18.5-23.0, 23.0-27.5, = 27.5 kg/m^2 for underweight, normal, overweight and obese respectively) with clinical characteristics and outcomes was assessed. In a subset of patients with available measurements of WC, the associations of BMI, WC, waist-to-height ratio with 1-year all-cause mortality and composite outcomes (HF hospitalisation or 1-year mortality) were examined.
Results: Among 5954 subjects (mean age 61.7years, 26.3% women) 6.1, 30.3, 37.5 and 26.2% were underweight, normal, overweight and obese respectively. Positive correlations were observed between increasing BMI and blood pressure, WC, prevalence of hypertension, diabetes, myocardial infarction, and peripheral oedema (p-trend < 0.001).
A linear inverse trend in crude all-cause mortality at 1-year was observed across BMI subgroups (16.5%, 11.5%, 9.5%, 6.9%, p < 0.001), with the lowest rates in the obese category. Compared to obese patients, underweight patients had the highest hazards of 1-year all-cause mortality (adjusted hazards ratio [aHR] = 2.38; 95% CI 1.64-3.44) and composite outcomes (aHR = 1.53; 95 CI 1.16-2.00), followed by patients in normal and overweight categories.
Among subjects with available WC measures (n = 2051), every 1kg/m^2 increase in BMI was associated with reduced crude and adjusted risk of mortality (5% and 8% respectively, p < 0.003). WC and waist-to-height ratio did not affect the crude hazards of death. Interestingly, BMI (per 1kg/m^2) and waist-to-height ratio (per 0.1 increment) was respectively associated with 6% lower and 55% higher adjusted risk of composite outcomes (p < 0.01).
Conclusion: Among Asian patients with HF, those with high BMI had more prevalent comorbidities yet better outcomes, compared to low BMI. This obesity paradox was observed, only when obesity was defined by BMI and not WC or waist-to-height ratio. A direct correlation was observed between central obesity and poor composite outcomes in HF. These findings carry implications for the clinical application of anthropometric parameters in risk stratification of patients with HF.

S2PLIT Score: a simple risk score predicting post-discharge 1-year mortality in patients with acutely decompensated heart failure

JA Josip Andjelo Borovac[1]; K Novak[2]; J Bozic[1]; D Glavas[2]
[1]University of Split School of Medicine, Department of Pathophysiology, Split, Croatia; *[2]University Hospital of Split, Division of Cardiology, Department of Internal Medicine, Split, Croatia*

Background: The acutely decompensated heart failure (ADHF) is a condition associated with poor outcomes, especially during the first year after hospitalization.
Purpose: To assess the performance of the S2PLIT scoring model in predicting a 1-year all-cause mortality in ADHF patients.
Methods: Clinical and laboratory data of 340 patients admitted for ADHF at a single-center ICCU were retrospectively examined. Variables that were significantly associated with 1-year mortality in multivariate regression analysis adjusted for age, sex, NYHA class, post-discharge medications, and comorbidities were included in the risk stratification model. Hosmer-Lemeshow test and C-statistic were used to determine the validity and predictive power of the model. Kaplan-Meier survival analysis was used to assess survival among risk groups.
Results: The average age of the studied population was 74 ± 9.8 years and 50.6% were women. Seventy-eight patients (22.9%) were NYHA II, 162 (47.8%) were NYHA III while 100 patients (29.5%) belonged to NYHA IV functional class. The average left-ventricular ejection fraction (LVEF) was 42.2 ± 9.5% while average systolic blood pressure (SBP) was 137.4 ± 27.4 mm Hg. Serum creatinine, uric acid, and sodium levels averaged 142.3 ± 96.2 μmol/L, 489 ± 172.9 μmol/L, and 138.2 ± 4.4 mmol/L, respectively. Significant independent predictors for 1-year all-cause mortality in our sample were LVEF, SBP, prior history of ADHF hospitalization(s) and serum creatinine, uric acid, and sodium levels. According to calculated S2PLIT score (Table 1), 153, 78 and 109 patients were stratified into a low-, intermediate- and high-risk groups with the observed mortality rates of 9.8% (15/153), 33.3% (26/78) and 91.7% (100/109), respectively. The obtained area under the curve (AUC) for the proposed score model was 0.900 (95% CI 0.864-0.937, SE 0.019, p < 0.001) (Figure 1A) with clear separation among respective risk groups in terms of cumulative survival (Figure 1B).
Conclusions: The S2PLIT scoring model performed well and demonstrated high predictive power for all-cause mortality in ADHF patients during the 1-year period following discharge.

Table 1

Variable collected at admission	Points
Left-ventricular ejection fraction ≤ 45%	1
Serum creatinine of 125-160 μmol/L (1 point) or > 160 μmol/L (2 points)	1 OR 2
Serum sodium ≤ 135 mmol/L	1
Serum uric acid > 440 μmol/L	1
Systolic blood pressure < 130 mm Hg	1
History of prior hospitalization(s) due to exacerbation of the heart failure	1

Clinical and laboratory parameters incorporated into the S2PLIT score.

Increased all-cause mortality in newly diagnosed patients with heart failure between 2006 and 2012: a retrospective, population-based study in Sweden

K Lindmark[1]; K Boman[2]; M Olofsson[2]; S Bruce Wirta[3]; CC Proenca[4]; A Levine[5]; A Castelo-Branco[5]; J Stalhammar[6]; G Wikstrom[7]

[1]Umea University Hospital, Department of Public Health and Clinical Medicine and Heart Centre, Umea, Sweden; [2]Research Unit, Medicine Geriatric, Skellefteå County Hospital, Department of Public Health and Clinical Medicine, Umea, Sweden; [3]Novartis Sweden AB, Stockholm, Sweden; [4]Wellmera AG, Basel, Switzerland; [5]IQVIA, Solna, Sweden; [6]Uppsala University, Department of Public Health and Caring Sciences, Family Medicine and Preventive Medicine, Uppsala, Sweden; [7]Uppsala University, Institute for Medical Sciences, Uppsala, Sweden

Funding Acknowledgements: This study was funded by Novartis Pharma AG.

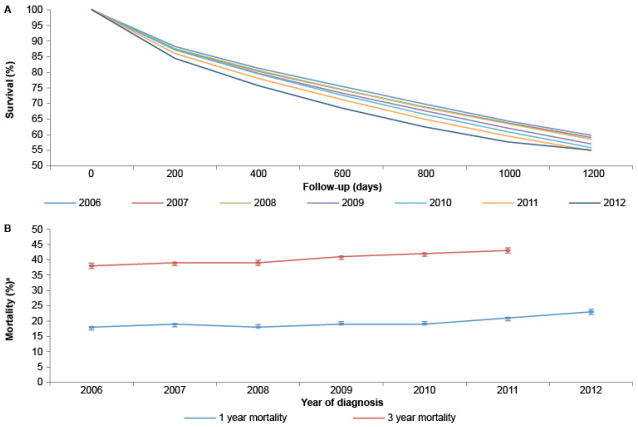
Background and Purpose: Recent analyses have shown decreasing incidence and increasing prevalence of heart failure (HF) in Sweden over time, suggesting a slowly changing composition of patients' characteristics. Factors influencing these trends in patient characteristics and mortality were studied in newly diagnosed patients.

Methods: Patients with HF were identified using secondary care data from the National Patient Register (NPR) linked via unique identifiers to data from the Cause of Death Register. Patients aged = 18 years with = 2 diagnoses of HF between 2006 and 2012, and an International Statistical Classification of Diseases and Related Health Problems, Tenth Edition (ICD-10) diagnostic code of I50 (inclusive of all granular codes), I42.0, I42.6, I42.7, I42.9, I11.0, I13.0 or I13.2 in any position were included. Date of first diagnosis was the index date. ICD-10 codes also identified comorbidities occurring in the 5 years before index. A 10-year look-back was used to exclude prevalent HF cases. Hazard ratios (HRs; adjusted for age, sex and year of diagnosis) and 95% confidence intervals (CIs) for all-cause mortality were estimated using a Cox proportional hazards model at 1 year post-index for years 2006-2012.

Results: Overall 141 607 patients were identified as newly diagnosed with HF in the NPR during 2006-2012 (median age: 80 years; 47% women; 80% first diagnosed in an inpatient setting). Patients' mean age was constant at 77 years, their Charlson comorbidity index increased significantly from 1.4 to 1.6 (P < 0.0001) and the proportion of patients with a previous myocardial infarction decreased significantly from 14% to 12% (P < 0.0001) during the study period. One-year all-cause mortality (95% CI) increased from 18% (17%, 18%) in 2006 to 23% (22%, 24%) in 2012; similar trends were seen for 3-year mortality (Figure). The risk of all-cause mortality 1 year post-index increased from 2006 to 2012 (HR [95% CI] relative to 2006: 2007, 1.06 [1.01, 1.10]; 2008, 1.04 [1.00, 1.08]; 2009, 1.07 [1.02, 1.11]; 2010, 1.08 [1.03, 1.13]; 2011, 1.18 [1.13, 1.23]; and 2012, 1.34 [1.29, 1.40]); this was significant (P < 0.0001) for the year 2007 and years 2009-2012 versus 2006.

Conclusions: These results suggest a shift in the clinical profile and HF aetiology of newly diagnosed patients with HF over time. The increasing comorbidity burden might explain the increasing mortality over time in patients with newly onset HF, and indicates the need for intense evaluation and care of these patients.

Figure. A) Survival and B) 1 and 3 year mortality over 3 years post-index in newly diagnosed patients with HF by year of diagnosis



*3 year mortality in patients diagnosed in 2012 is unavailable because NPR data collection ended in 2014, therefore none of these patients have 3 full years of follow-up on which to calculate 3 year mortality.

38

One year follow-up of heart failure patients: role of the new tnm-like classification

P Paolo Severino[1]; M Alfarano[1]; M Pucci[1]; M Straito[1]; E Pagliaroli[1]; I Ferrari[1]; S Calcagno[1]; D Alunni Fegatelli[2]; S Sciomer[1]; AR Vestri[2]; M Mancone[1]; F Fedele[1]

[1]Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrology, Anesthesiology and Geriatric Sciences, Sapien, Rome, Italy; [2]Sapienza University of Rome, Department of Public Health and Infectious Diseases, Rome, Italy

Introduction: NYHA is the most used classification for heart failure (HF), but it does not include some clinical features. We proposed a new staging system for HF, named HLM (JACC 2014;20;63(19):1959-60), which refers to heart damage (H), lung involvement (L), and malfunction (M) of peripheral organs analogous to the TNM classification used in oncology. Each parameter is allocated in four levels of severity (H1-H4, L0-L3, M0-M3).

Purpose: The aim of our study is to validate HLM as nosology for HF patients, comparing it with the classic NYHA to achieve the most accurate prognosis of these patients, in terms of rehospitalization for MACCE and mortality at 6 and 12 months follow up.

Methods: We enrolled 1064 consecutive patients with the diagnosis of, or at risk for, HF. According to HLM classification, all parameters for heart, lungs and peripheral organs function were collected and each patient was classified according to NYHA and HLM. At 6 and 12 months patients were followed up.

Results: At 6 and 12 months follow-up, comparing to NYHA, HLM showed a greater area under the ROC curve (AUC) for rehospitalization as well as for cardiac death. MACCE and cardiac death rates have been assessed for each combination of H, L and M parameters. At 1 year follow up, comparing to NYHA, each stage of HLM identifies different risk profile ranging from the initial stage of H1L0M0 with a probability of 5.25% (95% CI 3.53-7.72) of MACCE and a probability of 0.60% (95% CI 0.25-1.43) of cardiac death up to the end stage H4L3M3 that showed a probability of 67.05% (95% CI 56.67-76.0) of MACCE and a probability 35.36% (95% CI 23.37-49.53) of cardiac death. On the other hand, at 1 year follow up NYHA classes recognizes a "narrower" window of probability of events, ranging from a probability of 2.11 (95% CI 0.53 - 8.03) of MACCE and a probability of 9.47 (95% CI 5.00 - 17.21) of cardiac death for patients in class I, up to a probability of 34.54% (95% CI 28.18-41.49) of MACCE and a probability of 11.34% (95% CI 7.58-16.62) of cardiac death for subject in class IV.

Conclusions: According to these preliminary data, HLM nosology seems to be more accurate than NYHA classification to stratify risk of rehospitalization for MACCE and of cardiac death in HF patients, since the area under the ROC curve is greater for HLM in terms of rehospitalization and mortality. Moreover, within any NYHA class, HLM classification is able to better determine the prognosis at 1 year, because it evaluates both heart, lung, renal, hepatic, cerebral and hematopoietic involvement. This means that a wider and systemic approach should be used in HF patients, changing the "cardiocentric" methodology of NYHA.

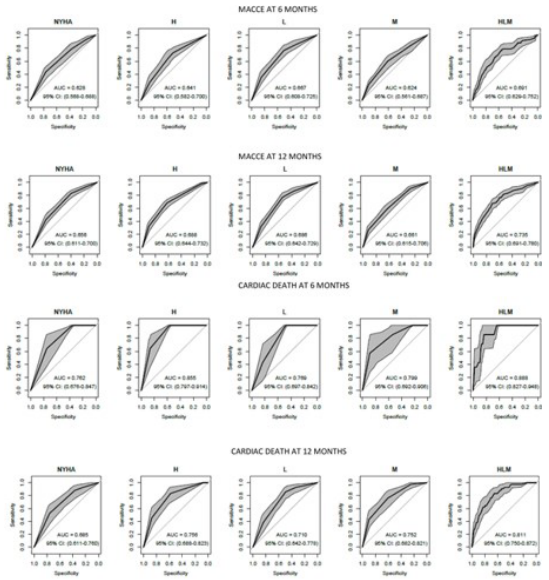


Figure 1 : ROC curve for NYHA and for HLM regarding cardiac death and major adverse cardiovascular and cerebrovascular events (MACCE) at 6 and 12 months follow up.

Funding Acknowledgements: Novartis Pharmaceuticals Corporation

Background/Introduction: The 2016 ESC Guideline on the Diagnosis and Treatment of Acute and Chronic Heart Failure endorsed sacubitril/valsartan (S/V) as class I-B treatment for heart failure with reduced ejection fraction(HFrEF) based on the PARADIGM-HF trial. Data on characteristics of S/V initiators and S/V adherence among renin-angiotensin aldosterone system inhibitor (RAASi)-naï ve patients treated in the community are limited.

Purpose: Determine associated baseline patient and healthcare facility characteristics and medication adherence of S/V vs angiotensin converting enzyme inhibitor (ACEI) or angiotensin receptor blocker (ARB) in RAASi-naïve HFrEF patients.

Methods: Retrospective cohort study of U.S. Veterans Affairs (VA) data including HFrEF (= 1 record of left ventricular ejection fraction (LVEF) = 40%) patients with = 1 in/outpatient visit for HF within 1-year pre-index (baseline period) treated with S/V, ACEI, or ARB from July 2015-June 2017. The index date was first S/V pharmacy fill and if none, first ACEI or ARB fill. RAASi-naïve defined as no S/V, ACEI, or ARB fills during the baseline period. Poisson regression models with robust errors were used to compare baseline characteristics and 4-month medication adherence (i.e. follow-up fills, proportion of days covered [PDC], and discontinuation) for S/V vs ACEI or ARB. Medication adherence comparisons were adjusted for baseline characteristics using matching weights.

Results: Among RAASi-naïve HFrEF Veterans (N = 10,743), most (97.5%) were male and 371 (3.5%) had an S/V pharmacy fill and 10,372 (96.5%) had an ACEI or ARB fill on the index date. Mean (standard deviation) baseline age, estimated glomerular filtration rate, and LVEF in S/V vs ACEI or ARB initiators were 73.6 (10.7) vs 70.3 (11.4) years, 61.3 (19.1) vs 66.4 (25.2) mL/min/1.73 m2, and 27.9% (8.3%) vs 34.4% (12.0%), respectively. History of ischemic cardiomyopathy was associated with S/V vs ACEI or ARB initiation. Veterans with lower systolic blood pressure, history of stroke, hypertension, myocardial infarction, or a visit with a Cardiologist on the index date were less likely to initiate S/V. In Veterans with a 30 day-supply index fill (N = 251 S/V and N = 3,101 ACEI or ARB) the adjusted risk ratio for 4-month PDC >80% was 0.78, 95% (confidence interval: 0.66-0.93) for S/V vs ACEI or ARB. Follow-up fills and discontinuation were similar for S/V vs ACEI or ARB. Adherence was similar for S/V vs ACEI or ARB among Veterans with a 90 day-supply.

Conclusions: In a large, integrated healthcare system, 3.5% RAASi-naïve HFrEF patients initiated S/V during the first 2-years post U.S. FDA approval. Overall, our findings suggest that S/V adherence is similar to ACEI or ARB in community-treated RAASi-naïve HFrEF patients. The low numbers of S/V initiation may reflect a lag in formulary availability; S/V was added to the VA Formulary in October 2016. The reasons for lack of guideline-directed S/V initiation needs further elucidation.

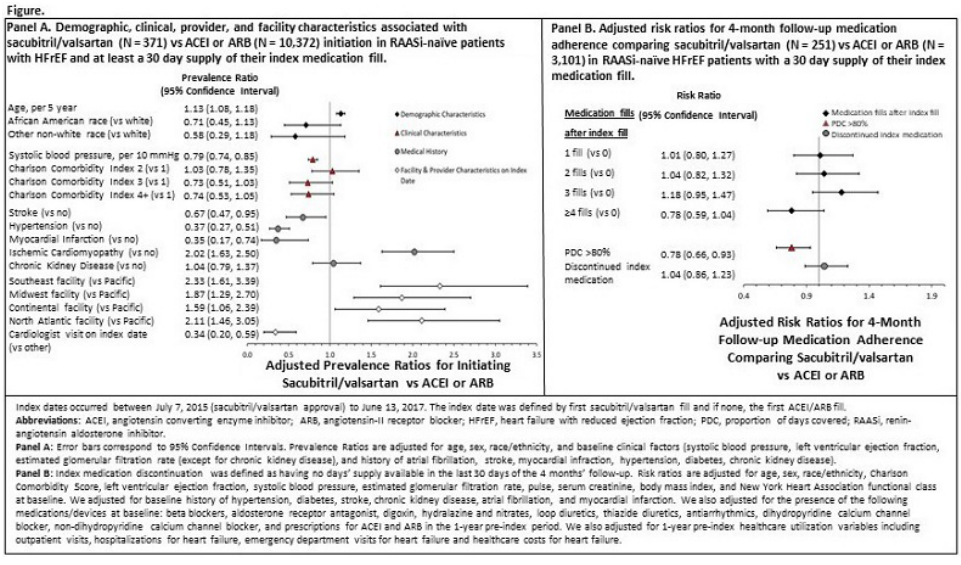
Figure.



Index dates occurred between July 7, 2015 (sacubitril/valsartan approval) to June 13, 2017. The index date was defined by first sacubitril/valsartan fill and if none, the first ACEI/ARB fill.
Abbreviations: ACEI, angiotensin converting enzyme inhibitor; ARB, angiotensin-II receptor blocker; HFrEF, heart failure with reduced ejection fraction; PDC, proportion of days covered; RAASi, renin-angiotensin aldosterone inhibitor.
Panel A: Error bars correspond to 95% Confidence Intervals. Prevalence Ratios are adjusted for age, sex, race/ethnicity, and baseline clinical factors (systolic blood pressure, left ventricular ejection fraction, estimated glomerular filtration rate (except for chronic kidney disease), and history of atrial fibrillation, stroke, myocardial infraction, hypertension, diabetes, chronic kidney disease).
Panel B: Index medication discontinuation was defined as having no days' supply available in the last 30 days of the 4 months' follow-up. Risk ratios are adjusted for age, sex, race/ethnicity, charlson comorbidity Score, left ventricular ejection fraction, systolic blood pressure, estimated glomerular filtration rate, pulse, serum creatinine, body mass index, and New York Heart Association functional class at baseline. We adjusted for baseline history of hypertension, diabetes, stroke, chronic kidney disease, atrial fibrillation, and myocardial infarction. We also adjusted for the presence of the following medications/devices at baseline: beta blockers, aldosterone receptor antagonist, digoxin, hydralazine and nitrates, loop diuretics, thiazide diuretics, antiarrhythmics, dihydropyridine calcium channel blocker, non-dihydropyridine calcium channel blocker, and prescriptions for ACEI and ARB in the 1-year pre-index period. We also adjusted for 1-year pre-index healthcare utilization variables including outpatient visits, hospitalizations for heart failure, emergency department visits for heart failure and healthcare costs for heart failure.

Figure

Introduction: High doses of loop diuretics (HDLD) have been associated with adverse outcomes in patients with chronic heart failure (CHF) and reduced ejection fraction (HFrEF). However, there are no studies to date in patients with heart failure with mid-range (HFmrEF) and preserved ejection fraction (HFpEF). We investigated whether HDLD are associated with adverse outcomes in patient with HF stratified by EF.
Methods: Of 9,749 outpatients we included the 8,130 (83.4%) CHF patients who continued diuretics after the index outpatient visit. Loop diuretics were converted to furosemide equivalents based on: 1 mg bumetanide = 20 mg torsemide = 40mg furosemide. Patients were divided based on median dose into low-dose (= 40 mg) and high-dose (< 40 mg). The association between dose and a) the composite endpoint of all-cause mortality or HF hospitalization and b) worsening renal function (WRF) at 1-year follow-up were examined, using Cox models. All covariates that were significant in the univariate analyses (P < 0.10) and those with known associations with disease severity (body mass index, history of chronic kidney disease and diabetes, systolic blood pressure, clinical stability, etc.) were entered in the final model. Clinical stability was defined as NYHA class I-II, no history of HF hospitalization during the past 6 months and absence of signs of congestion or hypoperfusion. WRF was defined as increase in serum creatinine = 0.3 mg/dl (= 26.5 μmol/L) at 12-month follow-up compared to index visit.
Results: Mean age was 66 ± 13 years, 71% men. Mean left ventricular ejection fraction was 37 ± 14% (62% HFrEF, 19% HFmrEF, 19% HFpEF). HDLD was independently associated with the composite endpoint in patients with HFrEF (adjusted HR: 1.51; 95% CI: 1.31-1.73, P < 0.001), HFmrEF (adjusted HR: 1.63; 95% CI: 1.40-2.39, P < 0.001) and HFpEF (adjusted HR: 1.84; 95% CI: 1.41-2.42, P < 0.001) at 1-year follow-up. Importantly, HDLD was also independently associated with an increased risk for WRF during 1-year follow-up in patients with HFmrEF (adjusted HR: 2.04; 95% CI: 1.33-3.12, P < 0.001) and HFpEF (adjusted HR: 2.00; 95% CI: 1.35-2.96, P < 0.001), but not in patients with HFrEF (adjusted HR: 1.19; 95% CI: 0.96-1.47, P = 0.121).
Conclusions: Use of HDLD was associated with worse outcomes, not only in HFrEF, as previously reported, but also in HFmrEF and HFpEF patients. This risk, which is proportionally higher in two latter sub-groups, seems to be paralleled by an increased risk for WRF, potentially pinpointing an underlying mechanism of the observed excess in morbidity/mortality.

41

Lung ultrasound may reduce heart failure hospitalizations: preliminary results from the LUS-HF trial.

M Rivas-Lasarte[1]; A Maestro Benedicto[1]; J Fernandez Martinez[1]; J Alvarez-Garcia[1]; E Sole Gonzalez[1]; L Lopez Lopez[1]; S Mirabet[1]; A Sionis[1]; E Roig Minguell[1]; J Cinca Cuscullola[1]

On behalf of: LUS-HF investigators
Funding Acknowledgements: Instituto de Salud Carlos III

Background: Pulmonary congestion is expressed in the form of B-lines detected by lung ultrasound (LUS), which has proven to be a potent prognostic predictor of hospitalization and mortality in HF. However, it is still unknown if a treatment strategy guided by LUS in HF patients may improve outcomes.

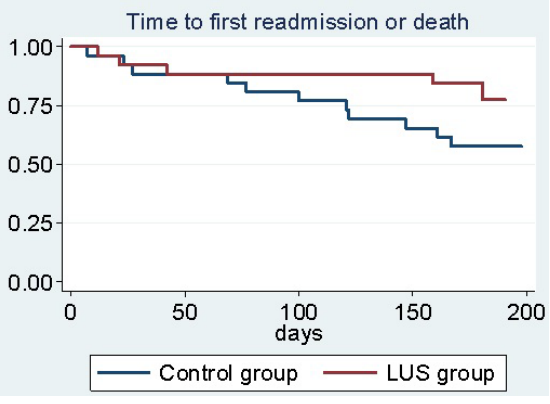

Figure. Kaplan Meier curves for first r

Purpose: The objective of our study is to analyze whether a treatment guided by LUS in patients with HF reduces the combined endpoint of readmission for HF worsening or death in a 6-month follow-up.
Methods: LUS-HF (NCT02959372 at ClinicalTrials.gov) is a randomized, single center, simple blind clinical trial that enrolls patients older than 18 years who have been hospitalized for HF. The exclusion criteria are life expectancy less than 6 months or severe lung disease. Eligible patients are randomized into either the "LUS group" or the "control group". The follow-up consists of visits in the HF clinic at periods of 15 days, 1, 3, and 6 months after discharge. Both groups are examined with LUS, but the result of the test is only provided to the treating physician in the "LUS group".
Results: Clinical characteristics of the first 52 patients included are summarized in the table. The primary endpoint occurred in the 42.3% of the "control group" versus 19.2% of the "LUS group" (log-rank test 0.077, figure).
Conclusions: According to the preliminary results of the LUS-HF trial, LUS guided treatment may reduce readmissions in HF patients.

Table. Clinical characteristics of LUS-H

	Control group (n = 26)	LUS group (n = 26)	P value

Hemodynamic evaluation as a tool for patient selection for percutaneous mitral valve repair

AJ Rieth[1]; MJ Richter[2]; E Gerhardt[1]; U Fischer-Rasokat[1]; C Liebetrau[1]; C Hamm[2]; C Walther[1]
[1]Kerckhoff Heart Center, Bad Nauheim, Germany; *[2]Justus-Liebig University of Giessen, Giessen, Germany*

Background: Percutaneous mitral valve repair (PMVR) has become a standard therapy for patients with moderate to severe mitral regurgitation (MR) and high surgical risk. Grading of MR severity by echocardiography alone may be inadequate for selection of patients. In particular, the presence of concomitant left ventricular heart failure can obscure the clinical significance of MR. In patients undergoing evaluation for PMVR, exercise hemodynamic parameters reflecting MR severity are widely unknown. Hemodynamic measurements at rest and during exercise may help to identify patients with MR who could benefit from PMVR. The objective of the present study was to explore the impact of pre-procedural hemodynamics on the benefit from PMVR.
Methods: Between Dec. 2009 and Feb. 2017, 211 patients with symptomatic MR underwent PMVR in our center. Out of these, 51 patients undergoing PMVR (CardioBand® n = 2, MitraClip® n = 49) had exercise hemodynamics taken prior to PMVR, which resulted in a reduction of MR = 1 grade in all patients. For this study, patients' benefit from PMVR was defined as sustained MR reduction = 1 grade at follow up, combined with improved (if NYHA III/IV before) or stable (if NYHA II before) symptoms.
Results: Patients had a median age of 78 years (IQR 74-83), 35,3% of the patients were female, and 72,5% presented with symptoms according to NYHA class III. 56,9% of the patients had an ejection fraction (EF) <40%. The median NT-proBNP serum level was 3131 pg/ml (IQR 1307-8250), and echocardiography revealed that 43.1% had severe MR and 56.9% moderate MR. Mean follow-up time was 7 months. The pre-specified primary outcome of benefit from PMVR was met by 30 patients (58.8%).
Compared with patients without benefit, these 30 patients had a higher V-wave in the pulmonary artery wedge pressure (PAWP) tracing at rest (p = 0.019) and a larger increase (?) in cardiac output (CO) during exercise (p = 0.036) prior to PMVR.
Prediction of improvement at follow up in univariate regression analysis was significant for PAWP V-wave, ?CO and ?PAWP/?CO (slope). Adjusted for EF, MR severity and PAWP V-wave, the PAWP/CO-slope remained an independent predictor of successful PMVR with an OR of 3.29 (95% CI 1.18-9.17, p = 0.023). ROC analysis

identified a cutoff 14.4 mmHg/l/min for the slope with an AUC of 0.67 (p = 0.08 95% CI 0.47-0.88, sensitivity 77%, specificity 73,1%).
Conclusions: In our cohort of high-risk patients with indication for PMVR, preprocedural hemodynamic parameters were associated with a sustained benefit after the procedure. A low PAWP V-wave, a low ?CO and a high PAWP/CO-slope were associated with negative outcomes. The latter two parameters are suggestive of a too advanced stage of heart failure for successful intervention, whereas the first implies a relation to MR severity. Future studies are warranted to refine the use of hemodynamic criteria as a complement to echocardiography to identify patients who may benefit from PMVR.

Funding Acknowledgements: Edwards Lifesciences

Background : The Edwards Cardioband™ Mitral Valve Reconstruction System is a CE-mark approved transcatheter implant delivered via a transseptal approach.
Purpose : The aim of this multicenter study was to evaluate the feasibility, safety and outcomes of the Edwards Cardioband™ Mitral System in the treatment of patients with secondary mitral regurgitation (MR). We report outcomes up to 2 years of patients who underwent the Cardioband Mitral System procedure which led to the CE approval of the device.
Methods : Between February 2013 and June 2016, 61 patients at high surgical risk with clinically significant secondary MR were enrolled at 11 European sites. All patients were screened by a heart team using echocardiography and cardiac CT. All echocardiography follow up assessments were performed by an independent core lab.
Results: Mean patient age was 72 ± 7 years, 44 were males (72%). Mean EuroSCORE II was 7.1%. At baseline, 52 patients (85%) were in New York Heart Association (NYHA) functional class III or IV, with a mean left ventricular ejection fraction of 33 ± 11%. The implant success rate was 98% and the device success rate 78%. After implant size adjustment, an average 28% septolateral annular reduction was observed (from 37 ± 4 mm to 26 ± 4 mm; p <0.01). At one-month follow-up, two patients had died from non-device related causes, and 87% of patients had MR = 2+. At one-year follow-up, available for 39 patients, an average 31% annular reduction was observed (from 36 ± 4 mm to 25 ± 4 mm; p <0.01), and 95% of patients demonstrated MR = 2+. Two-year follow-up is currently available for 20 patients. An average 28% annular reduction was observed (from 36 ± 4 mm to 26 ± 4 mm; p <0.0001), and 95% of patients demonstrated MR = 2+. Of the 20 patients, 89% were in NYHA class I or II. In addition, Minnesota Living with Heart Failure Questionnaire scores improved significantly by an average of 16 points (p = 0.0019).
Conclusions: : Transcatheter mitral valve repair using the Cardioband Mitral System provides clinically significant annular reduction and MR grade reduction. The favorable clinical and hemodynamic results of this customized annular reduction procedure are maintained out to two years. This novel therapy demonstrates sustained effectiveness for patients with functional mitral regurgitation while leaving options open for future interventions.

The clinical profile of a non-selected population treated with sacubitril/valsartan is different from PARADIGM-HF trial

L Lourdes Vicent Alaminos[1]; A Esteban Fernandez[2]; M Gomez Bueno[3]; J De Juan[4]; P Diez Villanueva[5]; A M Iniesta[6]; A Ayesta[1]; H Gonzalez Saldivar[1]; A Rojas[5]; R Bover Freire[2]; D Iglesias[7]; M Garcia Aguado[8]; JA Perea Egido[9]; M Martinez-Selles[1]
[1]University Hospital Gregorio Maranon, Cardiology, Madrid, Spain; [2]Hospital Clinic San Carlos, Madrid, Spain; [3]University Hospital Puerta de Hierro Majadahonda, Madrid, Spain; [4]University Hospital 12 de Octubre, Madrid, Spain; [5]University Hospital De La Princesa, Madrid, Spain; [6]University Hospital La Paz, Madrid, Spain; [7]University Hospital Infanta Sofia, Madrid, Spain; [8]Hospital de Mostoles, Madrid, Spain; [9]University Hospital of Getafe, Getafe, Spain

Introduction: Sacubitril/valsartan (SV) is a new milestone therapy in heart failure with reduced ejection fraction.
Purpose: Our aim is to describe the characteristics of the patients receiving SV in daily clinical practice.
Methods: Prospective registry in 10 hospitals including all patients who started SV in everyday clinical practice: SUMA (Sacubitril/valsartan Usado en Madrid Ambulatoriamente - sacubitril/valsartan used in Madrid in outpatients). We performed a comparative analysis with the data from the PARADIGM-HF trial.
Results: From October 2016 to March 2017, 427 patients started treatment with SV. The mean age was 68.1 ± 12.4 years and 30.5% were women (22.0% in PARADIGM-HF, p <0.001). Comparing the data from SUMA with those of PARADIGM-HF, baseline treatment was different, with a lower ratio of angiotensin converting enzyme inhibitors/angiotensin II receptor blockers (2.7 Vs. 3.5, p <0.001), and a higher proportion of patients with implantable cardioverter defibrillator (53.8 vs. 15%, p <0.001), and cardiac resynchronization therapy (25.8% vs. 5%, p <0.001). Treatment with mineralocorticoids receptor antagonists was more frequent (76.7% vs. 60.0%, p <0.001) and the use of beta-blockers was similar (94.6% vs. 93.0%, p = 0.43). We observed a lower left ventricular ejection fraction (28.8 ± 6.9% vs. 29.6 ± 6.1%, p = 0.008), more patients in functional class III-IV (30.4 vs. 24.8, P = 0.015), higher levels of Nt pro-BNP (3421 [interquartile range: 904 - 4161] vs. 1631 [interquartile range: 885 - 3154] pg/mL) and worse renal function (creatinine level 1.3 ± 0.7 vs. 1.1 ± 0.3 mg/dL, p <0.001). SV starting doses are resumed in the figure.
Conclusions: In real life patients receiving SV have a higher risk profile than in the pivotal trial, with lower left ventricular ejection fraction, poorer functional class, higher levels of natriuretic peptides, and worse renal function.

Cervicothoracic tens attenuates sympathetic cardiac overdrive in heart failure patients

ACL Antonio Claudio Lucas Nobrega[1]; MO Campos[1]; SM Miranda[1]; T Bessa[1]; CT Mesquista[1]; IA Fernandes[1]
[1]Fluminense Federal University, Department of Physiology and Pharmacology , Niteroi, Brazil

Funding Acknowledgements: FAPERJ, CNPq, CAPES and FINEP

Background: The cardiac sympathetic overdrive provides inotropic support to the failing heart. However, as myocardial insult evolves, this compensatory response impairs contractile function and constitutes an independent mortality predictor and a primary target in the treatment of heart failure (HF). We then propose cervicothoracic transcutaneous electrical nerve stimulation (TENS) as a non-pharmacological therapy to attenuate cardiac sympathetic overdrive in patients with HF. Objectives: To test whether short-term use of TENS decreases cardiac sympathetic activity in HF.
Methods: In this prospective, randomized double blind controlled crossover trial, 8 HF patients (7 men, 60 ± 5 yrs., NYHA II–III, left ventricle ejection fraction 33 ± 2%) were randomly assigned to either an in-home cervicothoracic TENS (30 min twice a day with 80 Hz frequency and pulse duration of 150μs) or a control intervention (SHAM) for 14 consecutive days. Following a 60-day washout phase, patients crossed over and underwent the opposite condition. Arterial pressure (AP), heart rate (HR), heart-to-mediastinum ratios (HMR) and washout rate (WR), indexes of sympathetic innervation density and activity from planar 123I-metaiodobenzylguanidine (123I-MIBG) myocardial scintigraphy images respectively, were quantified at the beginning and end of each condition.
Results: HMR and AP did not change throughout the study. TENS, but not SHAM, promoted a significant reduction in the WR (TENS -11 ± 11 vs. STHI + 9 ± 22%, p = 0.01) and HR (TENS -3 ± 3 vs. STHI + 3 ± 5 beats/min, p = 0.01).
Conclusion: These findings indicate that short-term cervicothoracic TENS therapy attenuates cardiac sympathetic overdrive in patients with HF with no impact on myocardial innervation density.

44
Gender differences in low-flow, low-gradient aortic stenosis

P E Philipp Emanuel Bartko[1]; MA Clavel[2]; A Dahou[2]; R Capoulade[3]; H Baumgartner[4]; I Lang[1]; G Mundigler[1]; J Bergler-Klein[1]; J Rodes-Cabau[2]; P Pibarot[2]; J Mascherbauer[1]
[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]Quebec Heart and Lung Institute, Quebec, Canada*; *[3]Massachusetts General Hospital, Institute for Heart, Vascular and Stroke Care, Boston, United States of America*; *[4]University Medical Center, Münster, Germany*

On behalf of: TOPAS Investigators

Background: Prior research is limited with regards to sex related differences in patients with Low-Flow, Low-Gradient Aortic Stenosis (LFAS). The present TOPAS sub-study sought to investigate gender related effects on anthropomorphic data, clinical presentation and outcome in patients with LFAS.
Methods: 342 Patients (263 male and 79 female) with LFAS (valve area = 1.2 cm^2, left ventricular (LV) ejection fraction (EF) = 40%, mean gradient = 40 mmHg) were prospectively enrolled. Anthropomorphic data, clinical history and symptomatic status were assessed. Dobutamine stress echocardiography was used to assess contractile reserve and stenosis severity.
Results: Size, weight and body surface area (BSA) were smaller in women than men (p <0.001, Table 1). Although women reported similar symptomatic status at study entry (p = 0.515, Table 1) females had significantly worse 6-minute walk test (6MWT) performance and a lower duke activity status index (DASI) score (both p <0.01). Echocardiography at rest revealed larger LV end-diastolic (EDD) index at rest (p = 0.028) despite similar effective orifice area (EOA) index (p = 0.995) and mean gradients (MG) (p = 0.608). At peak stress women had similar stroke volume index and ejection fraction (p = 0.776 and p = 0.242) but a larger EOA index compared to men (0.047) (Table 1).
During 4 year follow up 132 Patients died. 193 (56%; 152male and 41female) patients underwent valve intervention and 149 (44%; 111male, 38female) patients were managed medically. Kaplan-Meier and Univariate Cox regression analysis revealed a higher overall mortality in women compared to men (HR1.533, 95%CI 1.047 - 2.244, p = 0.028), Figure 1A. Sub-analysis according to treatment groups revealed that this was solely due to a higher mortality of women in the valve intervention group (HR 2.378, 95%CI 1.347 - 4.198, p = 0.003, Figure 1B) while no difference in overall survival was found between men and women in medically treated patients (HR 1.004 95% CI 0.598 - 1.685, p = 0.989, Figure 1C). In the intervention group, female gender remained independently associated with outcome even after correcting for age, BSA, stenosis severity and ejection fraction at peak stress (HR 2.672, 95%CI 1.069-6.680, p = 0.036).
Conclusion: In patients with LFAS women report similar symptoms but are at an advanced stage of the disease as assessed by more objective tests like the 6MWT and DASI. Similar stenosis severity at rest and even larger EOA at peak stress but larger LV dimensions and worse exercise capacity indicate a more pronounced impact of the valvular lesion on female hearts and a more advanced disease stage that might not be reversible and result in worse outcome after valve intervention.

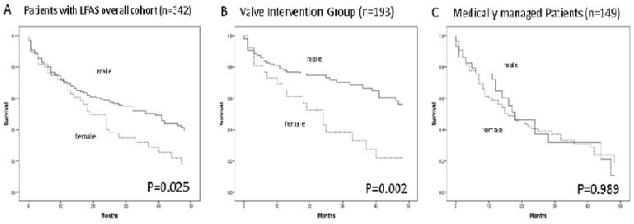

Figure 1

Patients with severe aortic valve stenosis and concomitant atrial fibrillation have an adverse clinical and hemodynamic profile

MT Micha Maeder[1]; L Weber[1]; P Ammann[1]; D Altmann[1]; R Brenner[1]; NF Ehl[1]; M Buser[1]; PK Haager[1]; H Rickli[1]
[1]Cantonal Hospital St. Gallen, St. Gallen, Switzerland

Background: In patients with aortic stenosis (AS) undergoing aortic valve replacement (AVR), the presence of atrial fibrillation (AF) is associated with increased long-term mortality. However, little is known about the detailed clinical and hemodynamic profile of patients with AS and concomitant AF. In the present study, we compared the clinical, non-invasive and invasive hemodynamic characteristics in patients with severe AS with and without AF.
Methods: We studied 486 patients (age 74 ± 10 years, 58% male) with severe AS [indexed aortic valve area (iAVA) 0.41 ± 0.13 cm2/m2, left ventricular ejection fraction (LVEF) 58 ± 12%] undergoing a detailed pre-AVR assessment including right heart catheterization. Fifty patients were in AF, and 436 patients were in sinus rhythm (SR) at the time of the assessment. All patients subsequently underwent surgical (n = 350) or transcatheter (n = 136) AVR. The median follow-up was 3.7 (interquartile range, 2.6-5.2) years.
Results: Patients with AF were older (80 ± 6 vs. 73 ± 10 years) and had higher heart rate (80 ± 19 vs. 68 ± 11 bpm) and B-type natriuretic peptide [median (interquartile range 444 (223-787) vs. 166 (67-367) ng/l] and lower estimated glomerular filtration rate (65 ± 24 vs. 75 ± 29 ml/min/1.73 m2) than patients in SR (p < 0.05 for all comparisons). Despite similar iAVA (0.41 ± 0.11 0.41 ± 0.12 cm2/m2) patients with AF had lower LVEF (51 ± 13 vs. 58 ± 12%), larger left atrial size (left atrial area: 32 ± 9 vs. 24 ± 6 cm2), and worse right ventricular function (tricuspid annular plane systolic excursion: 17 ± 4 vs. 22 ± 5 mm) than patients in SR (p < 0.05 for all comparisons). Patients with AF had higher mean pulmonary artery pressure (34 ± 13 vs. 24 ± 9 mmHg), mean pulmonary artery wedge pressure (22 ± 8 vs. 15 ± 7 mmHg), and pulmonary vascular resistance (2.8 ± 1.9 vs. 2.0 ± 1.3 Wood units) and lower cardiac index (2.0 ± 0.5 s. 2.5 ± 0.6 l/min/m2) and stroke volume index (26 ± 9 vs. 37 ± 10 ml/m2) than patients with SR. Although the number of AF patients was relatively small, there was a strong trend toward higher long-term mortality in AF compared to SR patient (log rank p = 0.05).
Conclusions: Patients with severe AS and concomitant AF represent a particularly sick subgroup of AS patients with worse biventricular function and an adverse hemodynamic profile with unfavorable outcome after AVR compared to SR patients. Thus, further studies are required to investigate the interaction between AF and valve disease with a view to develop novel treatment strategies beyond AVR for these patients.

46
Six-month outcomes from the transcatheter tricuspid valve repair multicentre TRI-REPAIR trial

A Azeem Latib[1]; G Nickenig[2]; RS Von Bardeleben[3]; J Hausleiter[4]; U Schafer[5]; KH Kuck[6]; S Baldus[7]; JM Juliard[8]; A Vahanian[8]; F Maisano[9]
[1]San Raffaele Hospital (IRCCS), Milan, Italy; *[2]University Hospital Bonn, Bonn, Germany*; *[3]University Medical Center of Mainz, Mainz, Germany*; *[4]University Hospital of Munich, Munich, Germany*; *[5]University Heart Center Hamburg, Hamburg, Germany*; *[6]Asklepios Clinic St. Georg, Hamburg, Germany*; *[7]Heart Center University of Köln, Koln, Germany*; *[8]Hospital Bichat-Claude Bernard, Paris, France*; *[9]University Hospital Zurich, Zurich, Switzerland*

Background: The Edwards Cardioband™ Valve Reconstruction System enables transcatheter repair to address patients with mitral or tricuspid regurgitation. The safety and performance in the treatment of functional mitral regurgitation have been validated in the CE mark trial.

Purpose: to report up to 6 months follow-up results from the first 30 patients included in the study designed to assess safety, feasibility and efficacy in the treatment of functional tricuspid regurgitation (FTR).
Methods: Between October 2016 and July 2017, thirty patients with severe symptomatic FTR were enrolled among 9 participating sites in Europe. All patients were screened by the heart teams of the local sites and underwent thorough pre-procedural echocardiography and cardiac computed tomography evaluation. Echocardiographic data were assessed by an independent core lab.
Results: Mean patient age was 75.2 years, 73.3% were females, 23.3% had ischemic heart disease and the mean EuroSCORE II was 4.1%. At baseline, 83.3% of patients were in NYHA functional class III-IV and LVEF was 57.5%. Successful access, deployment and positioning was achieved in 100% of the patients. There were two deaths at one month follow-up. Implant size adjustment resulted in an average reduction of septolateral tricuspid annular diameter of 16.5% (4.43 ± 0.44cm to 3.7 ± 0.45cm; $p < 0.01$) at discharge.
Thirty-day follow-up is available for 28 patients. 82.2% of patients were in NYHA class I-II. Echocardiography compared to baseline showed reduction in PISA EROA of 51% (from 0.79 ± 0.5 cm2 to 0.39 ± 0.3 cm2, $p < 0.001$) and a 28% reduction in mean vena contracta (from 1.25 ± 0.4 cm to 0.9 ± 0.4 cm, $p < 0.001$).
Six month follow-up is currently available for 22 patients. 85.7% of patients were in NYHA class I-II. Compared to baseline, there was a significant improvement in 6 minute walk test from 278.4 m to 327.4 m, ($p < 0.05$), and a decrease in the occurrence of peripheral edema from 76% to 48% ($p = 0.06$). Echocardiography showed significant reduction in PISA EROA of 48% (from 0.73 ± 0.5 cm2 to 0.38 ± 0.2 cm2, $p < 0.05$) and a 27% reduction in mean vena contracta (from 1.1 ± 0.3 cm to 0.8 ± 0.3 cm, $p < 0.001$).
Conclusions: Outcomes up to 6-months suggest feasibility and safety of transcatheter tricuspid repair with the Cardioband Tricuspid System in patients with symptomatic TR. Significant annular reduction and reduction of tricuspid regurgitation was observed despite treating a large proportion of patients with "torrential" TR at baseline. The study is ongoing and further follow-up data are warranted to validate the initial promising results.

Predictors of rehospitalization after percutaneous edge-to-edge mitral valve repair by MitraClip implantation

M Mirjam Kessler[1]; J Seeger[1]; J Woehrle[1]; W Rottbauer[1]; S Markovic[1]
[1]*University of Ulm, Department of Internal Medicine II, Ulm, Germany*

Background: In patients with prohibitive surgical risk due to concomitant comorbidities such as heart failure, transcatheter edge-to-edge mitral valve repair by MitraClip (Abbott, Abbott Park, IL, USA) implantation for severe, symptomatic mitral regurgitation (MR) has proven to relieve symptoms of MR and improve quality of life and to reduce the rate of heart failure rehospitalization.
Purpose: Rehospitalization for heart failure decompensation occurs frequently after MitraClip implantation, negatively impacting on quality of life. We aimed here to determine predictors of heart failure rehospitalization in a 1-year follow-up.
Results: 355 patients received implantation of MitraClip for severe MR at our centre. Within the 1-year follow-up period, 18.3% ($n = 65$) were readmitted to hospital for heart failure decompensation at an average of 116 days (median 76 days, interquartile range 42-153 days) after MitraClip implantation. These patients had higher levels of Troponin T (106.8 ± 321.1 vs. 43.1 ± 51.7 ng/l, $p= 0.006$), higher levels of creatinine (145.5 ± 51.0 vs. 127.3 ± 71.1 µmol/l, $p = 0.05$), a higher logistic EuroSCORE (10.5 ± 8.3 vs. 8.3 ± 7.9, $p = 0.046$) and a reduced left ventricular ejection fraction (36.6 ± 17.6% vs. 45.5 ± 17.3%, $p < 0.001$) compared to patients that were not hospitalized for heart failure within the 1-year follow-up. The etiology of mitral regurgitation was mainly functional in the rehospitalization group (73.0% vs. 49.1%, $p < 0.001$). In the 3-year follow-up, patients readmitted for heart failure decompensation after MitraClip implantation had a 2.2-fold increased risk for mortality and 3.0-fold increased risk for cardiovascular mortality. Multivariate Cox proportional-hazard regression analysis identified left ventricular ejection fraction ($p= 0.020$), Troponin T ($p= 0.003$) and NYHA class ($p= 0.020$) as independent predictors for rehospitalization within 1 year after MitraClip implantation.
Conclusion: After percutaneous edge-to-edge mitral valve repair by MitraClip implantation, rate of rehospitalization due to heart failure decompensation was 18.3% during 1-year follow up. Patients readmitted for heart failure decompensation after MitraClip implantation had a 2.2-fold increased risk for mortality and 3.0-fold increased risk for cardiovascular mortality within 3 years after MitraClip procedure in comparison to patients not requiring rehospitalization. Baseline left ventricular ejection fraction, Troponin T and NYHA functional class are independent predictors for heart failure rehospitalization within 1 year after MitraClip implantation.

Pulsatile hemodynamics in heart failure with reduced ejection fraction - role of forward wave amplitude

T Thomas Weber[1]; P Pecnik[1]; B Hametner[2]; S Wassertheurer[2]; R Binder[1]
[1]*Klinikum Wels-Grieskirchen, Wels, Austria*; [2]*AIT-Austrian Institute of Technology, Vienna, Austria*

Background: The blood pressure (BP) curve can be separated into a forward wave and a backward wave. The forward wave results from the interaction between cardiac ejection and elastic properties of the large arteries. Whereas brachial BP has no role for risk stratification in HFrEF, the the prognostic value of more advanced BP components is currently unknown.
Purpose: We aimed to clarify the determinants and prognostic value of the forward wave amplitude (Pf) in HFrEF.
Methods: We determined Pf, using radial tonometry, a transfer function and dedicated algorithms for wave separation analysis, in 81 patients (mean age 61 years, 90% men) with HFrEF (mean EF 28%, mean nt-proBNP 3851 pg/ml), and followed them for 4.1 years. Patients were divided into quartiles (Qu), according to Pf. Main outcome was all-cause mortality.
Results: As compared to Qu2+3, patients in Qu1 had lower BP, larger left atria and ventricles, lower EF, shorter ejection duration, and higher nt-proBNPs. The predominant etiology was dilated cardiomyopathy.
As compared to Qu2+3, patients in Qu4 were older, more often had hypertension and a prior myocardial infarction, had higher nt-pro-BNP, higher blood pressures, a longer ejection duration, and a higher pulse wave velocity.
In survival analysis, brachial SBP (p = 0.68) and DBP (p = 0.44) did not predict mortality.
In contrast, Pf was significantly (p = 0.029, log-rank test) related to outcome in a u-shaped fashion: 38.9, 22.5, and 56.5% of the patients died during follow-up in Qu1, Qu2+3, and Qu4, respectively. HR Qu1 vs Qu2+3 was 3.0 (95% CI 1.1-8.5); HR Qu4 vs Qu2+3 was 3.7 (95% CI 1.5 - 9.0) - Figure.
In a multivariate Cox proportional hazards model predicting all-cause mortality, Qu4 (HR 3.32 (95% CI 1.31-8.40), p = 0.01), log nt-proBNP (HR 2.72 (95% CI 1.19-6.20), p = 0.018), the presence of ischemic cardiomyopathy (HR 2.43 (95% CI 1.12-5.25), p = 0.025) and, of borderline significance, Qu1 (HR 2.63 (95% CI 0.90-7.70), p = 0.08), were the independent predictors, whereas age, gender, EF, SBP and DBP were not.
Conclusion: Lower as well as higher Pf is associated with impaired survival in HFrEF. In the first case, the lower Pf is the expression of a very poor cardiac function. In the latter case, the higher Pf suggests increased pulsatile afterload. Both conditions can be detrimental.

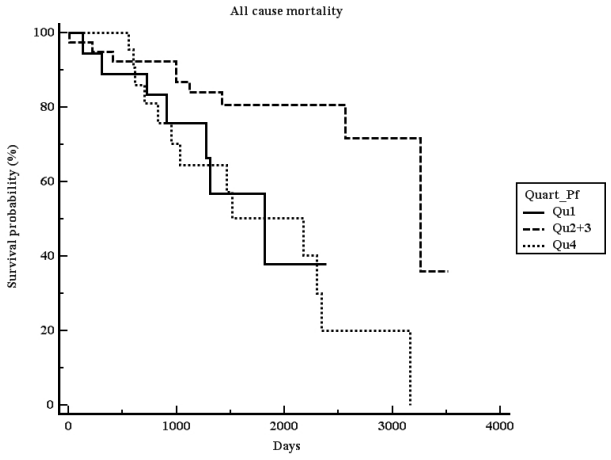

Figure: Quartiles of Pf and survival

Prognostic relevance of right ventricle global longitudinal strain in heart failure with preserved ejection fraction.

C Clotilde Roy[1]; A Slimani[1]; C De Meester[1]; M Amzulescu[1]; A Pasquet[1]; D Vancraeynest[1]; C Beauloye[1]; J-L Vanoverschelde[1]; B Gerber[1]; A-C Pouleur[1]
[1]*Cliniques Saint-Luc UCL, Cardiology, Brussels, Belgium*

Background: Right ventricle (RV) strain has emerged as an accurate and sensitive tool for RV function assessment and is a powerful predictor of survival in heart failure with reduced ejection fraction. The impact of RV strain in HFpEF is unknown.
Purpose: We sought to analyze RV strain and its prognostic value in HFpEF patients.
Methods: Between January 2015 and June 2017, we prospectively enrolled 94 consecutive patients with HFpEF (78 ± 9 years, 71% women) and 30 age and sex matched volunteers (75 ± 6 years, 60% women). All patients underwent complete 2D echo in sinus rhythm. A RV-focused four-chamber view was analyzed by 2D speckle tracking to evaluate the global longitudinal strain of RV (RV-GLS). Patients were followed up for all-cause mortality.
Results: In HFpEF patients, mean RV-GLS and TAPSE were significantly lower than controls (-23.0 ± 4.9% vs -26.3 ± 3.9%; p = 0.002 and 20 ± 5mm vs 24 ± 4mm; p < 0.001 respectively), as opposed to RV FAC (44 ± 7% vs 46 ± 7%, p = 0.22. Table). Intra observer reproducibility for RV-GLS was high (ICC 0.83 in controls and 0.89 in HFpEF). Multiple regression analysis showed that TAPSE (beta=-0.37[-0.54- -0.19], p < 0.001), RV/RA gradient (beta = 0.14[0.06- 0.22], p = 0.001) and indexed LV end-diastolic volume LV EDVi (beta = 0.12 [0.02-0.23], p = 0.025) were associated with RV strain. During a mean follow-up of 21 ± 7months, 17 patients (18%) died. In univariate analysis, RV-GLS was significantly associated with outcome (HR= 1.13 [1.03-1.24], p = 0.005). Multivariate Cox analysis identified GFR (HR= 0.97 [0.95-0.99], p = 0.040), hemoglobin (HR= 0.64 [0.47-0.87], p = 0.005) and LV EDVi (HR = 1.02 [1.00-1.04], p = 0.013) as independent predictors of prognosis ($?^2$model= 28.50). Adding RV-GLS to this preliminary model (HR = 1.10 [1.00-1.21], p = 0.050) improves $?^2$model to 34.3, demonstrating the predictive value of RV-GLS for mortality in HFpEF patients.
Conclusions: In HFpEF, RV-GLS is associated with a poorer prognosis with higher rate of mortality and added significant information compared to usual clinical and imaging variables.

	Controls (n = 30)	HFpEF (n = 94)	P value

The opioid system and pathophysiology of heart failure and renal dysfunction

J E Lisa Emmens[1]; JM Ter Maaten[1]; J Struck[2]; A Bergmann[2]; K Damman[1]; AA Voors[1]
[1]*University Medical Center Groningen, Cardiology, Groningen, Netherlands*; [2]*Sphingotec, Hennigsdorf, Germany*

Funding Acknowledgements: BIOSTAT-CHF was funded by the European Commission [FP7-242209-BIOSTAT-CHF; EudraCT 2010-020808-29].

Background: Proenkephalin (PENK) is a stable surrogate marker for enkephalins, endogenous opioid peptides, which exert important cardiovascular effects by decreasing myocardial contractility, blood pressure, and heart rate, and renal

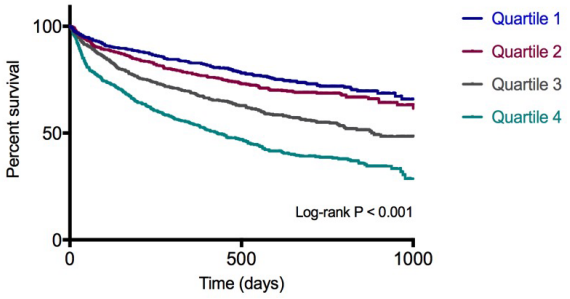
effects by increasing renal blood flow and urinary output. In heart failure (HF), PENK has been associated with renal function, heart failure severity, and clinical outcome. Yet it has only been studied to a limited extent and its exact biomarker position, additive value, and underlying pathophysiological mechanisms in HF require further investigation.

Purpose: We aim to thoroughly determine the biomarker position of PENK in HF by investigating the relationship between PENK and a wide variety of clinical variables, biomarkers, and clinical outcome.

Methods: In a large multicentre clinical cohort (BIOSTAT-CHF) consisting of 2,180 chronic HF patients, the relationship between PENK and clinical variables, biomarkers, and two clinical endpoints (mortality and a composite endpoint of death or HF hospitalisation) was established utilising several modern statistical approaches to achieve meticulous positioning.

Results: Median PENK was 86.2 (63.7 - 120.2) pmol/L. Higher levels of PENK were, among others, associated with higher age, lower systolic and diastolic blood pressure, higher BNP and NT-proBNP, higher creatinine, lower eGFR, higher NGAL, higher renin, and higher urea (all P = 0.001). The strongest predictors of log PENK were log creatinine, female sex, log NT-proBNP, log NGAL, and age (R^2 = 0.549). Using a correlation heatmap and hierarchical cluster analysis, PENK strongly clustered with renal markers such as NGAL, urea, and creatinine. PENK was a strong predictor of WRF, even after adjustment for log creatinine (OR 3.42 (2.35 - 4.96), P < 0.001). Higher levels of PENK were independently associated with an increased risk of mortality and the composite endpoint, even after correction for risk models developed for this cohort and log creatinine (HR 1.47 (1.22 - 1.78), P < 0.001 for mortality, HR 1.19 (1.01 - 1.40), P < 0.034 for the composite endpoint).

Conclusions: PENK is a novel biomarker in HF reflecting more severe heart failure, renal dysfunction, and worsening renal function beyond creatinine and therefore provides new insights into the pathophysiological role the opioid system might play in HF.



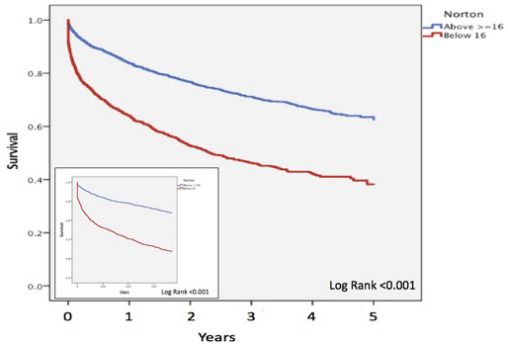
KM curve PENK for combined endpoint

53

Norton admission scale as a prognostic factor among acute heart failure patients

I Israel Mazin[1]; R Klempfner[1]; I Goldenberg[1]; E Shaviv[1]; Y Peled[1]; E Massalha[1]; N Shlomo[1]; S Natanzon[1]
[1]*Chaim Sheba Medical Center, Tel Hashomer, Israel*

Background: The Norton scale scoring system was created in 1962 assessing the frailty hospitalized patients, and is still being used nowadays by nurses evaluating patients at hospital admission. Accordingly, this scale may be an important predictor of outcome following hospitalization We hypothesized that a low Norton score is an independent predictor of long-term mortality among hospitalized acute heart failure patients.



Kaplan-Meir survival analysis

Methods: of the present study population comprised 4388 acute heart failure patients presenting to Sheba medical center between the years 2008-2016, and were followed-up for long-term mortality and HF hospitalization following discharge cohort was divided according to the Norton score, low score (<16) and high score (> = 16). Multivariate Cox proportional hazards regression modeling was used to assess the independent association between Norton score and long-term mortality.

Results: Patients with low score (n = 1611 [37%]) were older, had higher prevalence of co-morbidities such as hypertension, COPD, anemia, CVA and renal failure compared to high score (n = 3323) (p <0.05 for each). Kaplan-Meir survival analysis (Figure) showed that at 1-year of follow-up mortality rates were significantly higher among patients with a low Norton score (34%) as compared with those with a high score (15%; p <0.001 for the overall difference during follow-up). After adjustment for confounders and comorbidities, multivariate analysis showed that a low Norton score was associated with >2-fold increased risk of all-cause mortality at 1 and 5 years of follow-up following hospitalization (p <0.001 for both). The association between Norton and mortality was consistent in both the HFrEF and HFpEF subgroups (p-value for interaction < 0.10).

Conclusion: Our findings, from a large cohort of hospitalized heart failure patients, show that the Norton score at admission is powerful independent predictor of long-term mortality. These data suggest that the scale should be added as an important risk stratification parameter in this high-risk population.

54

Baseline B-type natriuretic peptide is the strongest predictor of transition to stage C heart failure in an at-risk population; Results from the STOP-HF prevention programme

S Mcclelland[1]; L Healy[1]; R Murphy[1]; S Zhou[1]; J Gallagher[2]; C Watson[3]; M Ledwidge[1]; K Mcdonald[1]
[1]*St. Vincent's University Hospital Healthcare Group, Dublin, Ireland*; [2]*University College Dublin, School of Medicine, Dublin, Ireland*; [3]*Queen's University of Belfast, Belfast, United Kingdom*

Background: Heart Failure (HF) is a global epidemic with multiple prevalent risk factors, resulting in a large at-risk population. Within this population, prevention programmes must be targeted to those at highest risk of HF development. However, the incidence of HF within a prevention service remains unknown, as does the phenotype of those at-risk patients most likely to develop HF.

Purpose: This study aimed to determine the incidence of stage C HF in an asymptomatic population with risk factors (stage A) and/or structural/functional cardiac abnormalities (stage B) in the STOP-HF prevention programme (Ledwidge et. al., 2013), and, within this population, to characterise the phenotype of patients most likely to progress to stage C (symptomatic) HF.

Methods: 2,037 patients in the STOP-HF service were characterised as stage A or stage B HF. Baseline echocardiographic parameters, BNP, blood pressure, weight and renal function, among other indices, were compared between the cohort that progressed to stage C and the population that did not.

Results: 86 patients developed Stage C HF during a median follow up of 4.8 years (overall incidence of 4.2%) with an incidence rate of 8.3 per 1000 patient years.

Strong clinical univariate predictors of progression-risk included older age (69.5 ± 8.9 vs 63.4 ± 10.6 years, p < 0.001), male gender (59.3 vs 44.9%, p = 0.012), higher body mass index (BMI) (29.8 vs 28.3, p < 0.001), higher BNP (134.6 ± 183.6 vs 39.6 ± 66pg/ml, p < 0.001) and higher creatinine (95.7 ± 34.7 vs 84.6 ± 21.3umol/L, p = 0.01) at baseline. Echocardiographic features included lower baseline EF (57.8 ± 13.9 vs 66.1 ± 7.8%, p < 0.001), higher left atrial volume index (40.6 ± 14.1 vs 28 ± 9.6, p < 0.001), left ventricular mass index (118.1 ± 27.2 vs 95 ± 46.7, p < 0.001), E/E' ratio (10.5 ± 4.1 vs 8.1 ± 3.1, p < 0.001) and left atrial diameter (44 ± 5.9 vs37.2 ± 5.7mm, p < 0.001) in patients who subsequently transitioned to stage C. The prevalence of diabetes (47.7 vs33.5%, p = 0.01), peripheral vascular disease (PVD) (9.3% vs 2.3%, p < 0.001), valvular heart disease (VHD) (4.7 vs 0.82%, p = 0.003), atrial fibrillation (17.4 vs 4%, p < 0.001) and prior myocardial infarction (36 vs 7.2%, p < 0.001) were significantly higher at baseline in patients who subsequently transitioned to stage C than in those that did not.

Multivariate analysis identified baseline BMI, BNP, reduced EF, VHD and PVD as independent predictors of the development of stage C HF. Baseline BNP level was the strongest predictor of transition to Stage C, with a value of 60.3pg/ml determined as the optimal level by which to differentiate high- and low-risk patients.

Conclusions: The incidence rate of stage C HF in the STOP-HF prevention programme is 8.3 per 1000 patient years. Among a number of independent predictors identified, the strongest indicator of transition risk is baseline BNP. These findings support the use of BNP measurement to more tightly define HF risk in an asymptomatic at-risk population.

55

Echocardiographic Killip Classification

A Milwidsky[1]; D Greidinger[2]; Y Topilsky[1]
[1]Tel Aviv Sourasky Medical Center, cardiollogy, Tel Aviv, Israel; *[2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel*

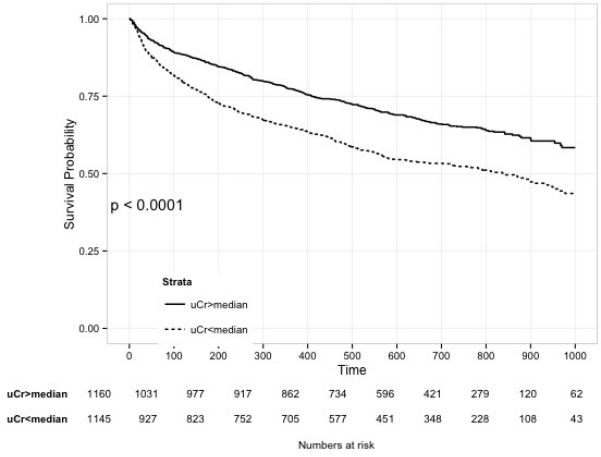
Background: The Killip classification is a well-recognized clinical assessment tool for heart failure in patients presenting with acute coronary syndromes. We hypothesized that an echocardiographic correlate of this classification, using diastolic grade and stroke volume index (SVI) as indicators of pulmonary congestion and systemic perfusion respectively, could be a useful risk stratification tool among all patients.
Methods: We included all consecutive patients in sinus rhythm evaluated by our research echo technicians and reviewed by a single senior cardiologist in Tel-Aviv Medical Center between 01/2013 to 12/2015. Echocardiographic killip (eKillip) class was defined according to diastolic grade and SVI, with levels above 35ml/m2 considered normal. Patients with a normal filling pressure (normal diastolic function or impaired relaxation) and normal SVI were defined as eKillip class-1. Patients with pseudo-normal or restrictive diastolic patterns and a normal SVI were ascribed to eKillip class-2 or 3, respectively. Those with pseudo-normal or restrictive diastolic patterns and a sub-normal SVI were defined as eKillip class-4.
Results: The study population comprised 571 patients, mean age was 65 ± 18 and 303(53%) were males. Three hundred and eighty-nine (68%) patients were at eKillip class-1, and 113 (20%), 26(5%) and 43(8%) were ascribed to eKillip classes 2, 3 and 4 respectively. In a univariate logistic regression model, e-Killip class was highly associated with all-cause mortality ($p < 0.001$). In a multivariate binary logistic regression model adjusted to age, gender, renal function, multiple cardio-vascular co-morbidities and malignancy, increasing eKillip class remained associated with all-cause mortality ($p = 0.02$). Compared to patients with eKillip class-1, those at classes 2-4 had 68%, 281% and 385% higher mortality rates, respectively (95% CI 0.80-3.50, 1.00-7.88 and 1.58-9.37, with $p = 0.17$, 0.05 and < 0.01, respectively).
Conclusion: Echocardiographic Killip class defined by combination of diastolic grade and SVI among all patients undergoing echocardiography in a tertiary hospital, was significantly associated with all-cause mortality.

56

Urinary creatinine is a marker of body composition and muscle wasting in patients with worsening heart failure

J M Jozine Ter Maaten[1]; KW Streng[1]; K Damman[1]; AA Voors[1]
[1]University Medical Center Groningen, Groningen, Netherlands

Background: Muscle wasting and unintentional weight loss has been associated with more advanced disease and poor outcome in patients with heart failure. Timely identifying muscle wasting is very difficult, yet urinary creatinine might be an easy obtainable marker to assess this.



Kaplan Meier urinary creatinine

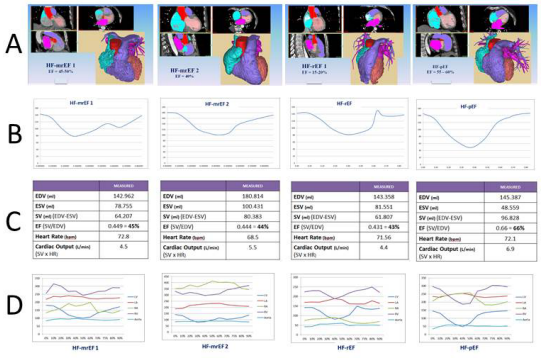
Purpose: This study aimed to identify the value of urinary creatinine in acute and worsening heart failure patients and be the first to evaluate its association with changes in body composition.
Methods: We measured spot urinary creatinine at baseline in 2,313 patients enrolled in the BIOlogy Study to Tailored Treatment in Chronic HF (BIOSTAT-CHF) trial. The association between urinary creatinine and outcome was evaluated by Cox regression analysis adjusted for potential confounders.
Results: Median spot urinary creatinine was 5.2 [2.7-9.6] mmol/L, and lower urinary creatinine was associated with older age, lower height and weight, worse renal function, and more severe heart failure. The risk of weight loss after 9 months was significantly greater in patients with lower spot urinary creatinine (OR: 1.24 [1.01-1.25] per log decrease, $P = 0.029$).
In multivariable cox regression analysis, lower spot urinary creatinine was associated with an increased risk of the combined endpoint of all-cause mortality or heart failure hospitalization (1.22 [1.14-1.30] per log decrease, $P < 0.001$), and all-cause mortality (1.27 [1.17-1.37] per log decrease, $P < 0.001$). The association remained significant after correction for body dimensions and renal function.
Conclusions: This study is the first to show that lower spot urinary creatinine is associated with smaller body dimensions, renal dysfunction and more severe heart failure in patients with acute and worsening heart failure. Additionally, lower spot urinary creatinine is associated with an increased risk of weight loss and could therefore be a novel, easy obtainable marker to assess (risk of) muscle wasting in heart failure patients.

57

3-Dimensional analysis of the haemodynamics of heart failure (HF) in mid-range- (HF-mrEF), reduced- (HF-rEF) and preserved- (HF-pEF) ejection fraction classification patients

H O' Grady[1]; H Zafar[2]; K Mostafa[3]; L Morris[1]; F Sharif[2]
[1]Galway Mayo Institute of Technology GMIT, Galway, Ireland; *[2]National University of Ireland, Cardiovascular Research Centre (CVRC), Galway, Ireland*; *[3]Galway University Hospital, Department of Cardiology, Galway, Ireland*

Background / Introduction: Heart Failure (HF) is a complex condition which may be accompanied by considerable alterations in ventricular volume depending on the particular phenotype. Analysis of 3-dimensional volume changes of the heart chambers over the cardiac cycle can provide a more global insight into HF dynamics than consideration of Ejection Fraction (EF%) alone.
Purpose: This study investigated the haemodynamics of Heart Failure using analysis of 3-dimensional volumes in patients with Heart Failure with Mid-Range- (HF-mrEF), Reduced- (HF-rEF) and Preserved- (HF-pEF) Ejection Fraction.
Methods: Cardiac-gated CT scans for 11 stages (0-90%) of the cardiac cycle were segmented using specialised software into 4 chambers and aorta. 3-dimensional models of Left Atrium (LA), Right Atrium (RA), Left Ventricle (LV) and Right Ventricle (RV) and aorta were reconstructed and exported for analysis. 3-dimensional volumes for all chambers were calculated and recorded. Cardiac cycle timings and Heart Rate (bpm) were determined from CT scan data. 3-d volumes were plotted against timings and maximum and minimum volumes measured for all chambers. LV End-Systolic Volume (ESV) and End-Diastolic Volume (EDV) of the LV were determined and clinical indices of Stroke Volume (SV), Ejection Fraction (EF %), and Cardiac Output (CO) were calculated from the results. All variables were determined for each of the 4 cases of HF EF% classification.
Results: 3-dimensional models for HF-mrEF (2), HF-rEF and HF-pEF cases were created (IMAGE A).
Values for 3-dimensional volumes for 11 stages of the cardiac cycle were tabulated and plotted against exact timings for each cycle stage (0-90%) (IMAGE B).
Values for LV volumes and clinical indices were tabulated and compared to those recorded clinically (IMAGE C).
Values for 3-dimensional volumes for 4 chambers and aorta for 11 stages of the cardiac cycle were tabulated and plotted (IMAGE D).
Conclusion(s): This study showed that the 3-dimensional analysis of volumetric changes across the cardiac cycle can provide important information regarding the haemodynamics of different classifications of Heart Failure. Further work is planned to expand this research for application in determination of clinically relevant indices representing global HF dynamics.



58

Changes in energy consumption during exercise and fatigue symptoms: a new marker of cardiac functional reserve in LVAD patients.

S Boschi[1]; M Masetti[1]; A Loforte[1]; M Bellettini[1]; E Pilato[1]; S Martin-Suarez[1]; G Marinelli[1]; F Grigioni[1]; L Potena[1]

[1]University Hospital Policlinic S. Orsola-Malpighi, Heart Failure and Heart Transplant Program, Bologna, Italy

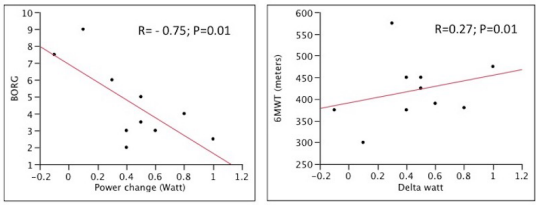
Introduction: Left ventricular assist device (LVAD) therapy may allow significant improvement of survival and quality of life in patients with advanced heart failure, in the context of a bridge to transplant or destination strategy. Tolerance to exertion is a key factor driving the perception of quality of life in these patients, and it depends upon the tailored optimization of LVAD support to cardiocirculatory function.

Objective: In this study we analyzed the variability of LVAD energy consumption and estimated flow in a group of patients undergoing six-minutes walking test (6MWT) to investigate how LVAD function may adapt to the physiological changes occurring during exercise.

Methods: We considered for inclusion all consecutive patients with Heartware LVAD presenting at our outpatient clinic for routine follow-up between May and November 2017 and with at least 2 months distance from implant. We excluded patients who had not completed rehabilitation, and with extracardiac reasons impairing ability to walk. Watt, estimated flow, and heart rate were measured before and after 6MWT. Distance walked and Borg scale represented outcome measures.

Results: Ten patients fulfilled inclusion criteria (age52 $\pm$ 14, 20 $\pm$ 18 months after implant, 2592 $\pm$ 60 rpm). Average distance walked was 420 $\pm$ 74 m, and Borg scale was 4.6 $\pm$ 2.3. Energy consumption (3.74 $\pm$ 0.41 to 4.19 $\pm$ 0.46 watt; $P < 0.01$), and estimated flow (4.17 $\pm$ 0.86 vs. 5.02 $\pm$ 0.75 l/min; $P < 0.01$) significantly increased after exercise. LVAD parameters did not predict distance walked, but changes in energy consumption and estimated flow correlated with Borg scale after exercise ($R=-0.72$; $P = 0.02$; see Figure).

Conclusions: In this pilot study we found that increase in energy consumption of LVAD during exercise is associated with lower grade of dyspnea reported by the Borg scale, but not with the distance walked. Because the function of Heartware device is highly dependent on pre-load conditions, we hypothesize that our observation reflects the ability of the LVAD to improve function in patients with left ventricle functional reserve. Further data are needed to confirm whether energy consumption variability during exercise could become a good marker to aim at in the rpm regulations and overall therapy management, to improve exercise tolerance in LVAD patients.



Clinical Case Corner 1 - Stories of women and of their broken hearts

59

An unusual case of aborted sudden cardiac death in a young woman: which is the culprit?

M Mapelli[1]; E Conte[1]; A Dello Russo[1]; G Vettor[1]; A Baggiano[1]; M Muratori[1]; L Fusini[1]; D Andreini[1]; G Pontone[1]; M Pepi[1]; PG Agostoni[1]
[1]*Cardiology Center Monzino IRCCS, Milan, Italy*

Background: Anomalous origin of a coronary artery (AAOCA) carries an associated risk of Sudden Cardiac Death (SCD) with interarterial anomalous left or right coronary artery course (ALCA and ARCA respectively). Myocarditis, especially with extensive fibrosis at MRI is also a risk factor for SCD in young population. Increasing use of cardiac imaging techniques is enhancing myocarditis and AAOCA diagnosis, previously completely skipped.
Clinical case: We present a 23y/o woman without any relevant previous disease (except for BMI 15 Kg/m2) resuscitated by a relative from SCD while she was sleeping (5 DC shocks due to ventricular fibrillation, VF), followed by uneventful course and full recover. A cardiac CT scan showed an ARCA with interarterial course (between aorta and pulmonary artery) and moderate narrowing of RCA lumen at rest (Fig.1) and she was referred at our hospital for surgical coronary artery re-implantation, asymptomatic with no further arrhythmias. Blood sample showed normal CBC, Troponin, C-reactive protein values. A cardiac MRI showed a picture consistent with a previous, subclinical, myocarditis with diffuse myocardial fibrosis (non-ischemic pattern) and mild reduction in ejection fraction (Fig.1). A right side myocardial biopsy failed to take a pathological sample due to epicardial fibrosis distribution. Both cardiac tissue PCR and serum antibodies were negative for common myocarditis viruses. Patient underwent an electrophysiological study without induced arrhythmias. A Subcutaneous Defibrillator (S-ICD) was implanted and she was discharged with no complications.
Discussion: In this peculiar case 2 diagnosis could be responsible for the aborted SCD. A recent review on AAOCA underlines the importance of ischemia in patients with ARCA where, particularly without proximal vessel narrowing, a conservative approach may be reasonable. In this woman affected both by AAOCA and myocardial fibrosis the culprit disease is debatable, but in absence of recurring events, signs of ischemia and imaging criteria for malignant pattern (acute take-off, slit-like, severe compression), eventual surgery was postpone and she was protected with a S-ICD (SCD secondary prevention). Furthermore the occurrence of VF at rest is less typical for AAOCA, mostly occurring during exercise. At 6 months she is asymptomatic without clinical events.
Conclusions: We present a case of an aborted SCD with 2 possible culprit diagnosis in which multimodality imaging is fundamental in case management and clinical decisions.

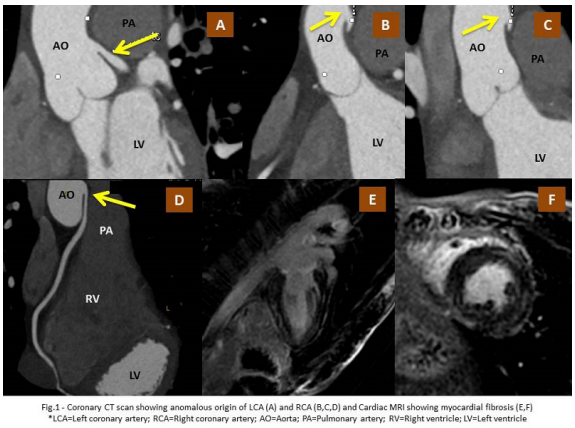


Fig.1 - Coronary CT scan showing anomalous origin of LCA (A) and RCA (B,C,D) and Cardiac MRI showing myocardial fibrosis (E,F)
*LCA=Left coronary artery; RCA=Right coronary artery; AO=Aorta; PA=Pulmonary artery; RV=Right ventricle; LV=Left ventricle

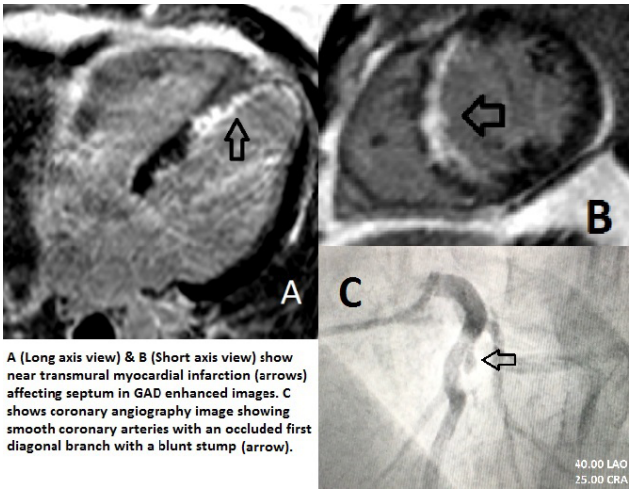
Presumed post-partum cardiomyopathy? beware of the confounder of pregnancy

CWJ Cheuk Wing Jonathan Lee[1]; A Khand[1]; R Sankaranarayanan[1]; P Kanagala[1]
[1]*Aintree University Hospital, Cardiology, Liverpool, United Kingdom*

Pregnancy is a complex process in which physiology changes significantly. The stress of pregnancy can unmask underlying heart disease or cause post-partum cardiomyopathy.
A 33 year old lady, 3 months post-partum, presented to the emergency department with 12 weeks history of breathlessness, orthopnoea, paroxysmal nocturnal dyspnoea and associated upper abdominal discomfort. She denied having any chest pain. On examination, blood pressure was 112/71 mmHg and heart rate was 90 beats per minute. There was peripheral pitting oedema, soft systolic murmur at the apex, an elevated jugular venous pressure and diminished air entry at the lung bases.



A (Long axis view) & B (Short axis view) show near transmural myocardial infarction (arrows) affecting septum in GAD enhanced images. C shows coronary angiography image showing smooth coronary arteries with an occluded first diagonal branch with a blunt stump (arrow).

GAD enhanced MRI and angiography image

Blood tests reviewed mild normocytic anaemia (Haemoglobin 109g/L) and mild transaminitis (alanine aminotransferase 143). D dimer was strongly positive. Arterial blood gas showed type 1 respiratory failure. Electrocardiogram revealed poor R wave progression from v1-v4 with accompanying 1-3mm deep T wave inversions and deep q waves (7-12mm). Chest X ray revealed raised cardiothoracic ratio with accompanying pulmonary congestion and minor blunting of the costophrenic angles consistent with small pleural effusions. CT pulmonary angiogram excluded pulmonary embolism. Echocardiogram revealed significant enlargement of all 4 cardiac chambers with severe biventricular systolic dysfunction consistent with a diagnosis of peri-partum cardiomyopathy. The patient was managed with diuretics, ACE inhibitor (subsequently switched to sacubitril/ valsartan), beta blocker and spironolactone. Follow up was arranged in the outpatient setting.
At approximately 2 year follow up, she remained symptomatic (NYHA class III). A cardiac MRI was arranged. This revealed a dilated left ventricle with moderate left ventricular systolic dysfunction. On late enhancement imaging there was extensive, near transmural infarction of the mid to distal septum involving the apex, consistent with a full-thickness proximal left anterior descending territory infarct. Coronary angiography revealed smooth coronaries except an occluded first diagonal branch with a blunt stump. There was ectasia and mild irregularity of the mid LAD at the origin of the first diagonal branch. The appearances were strongly suggestive of SCAD (spontaneous coronary artery dissection). On further questioning, patient revealed episodes of chest pain towards later stage of pregnancy.

Conclusions: and implications for clinical practice
1. Spontaneous coronary artery dissection is a known risk in pregnancy
2. Electrocardiography and troponin sampling at the time of chest pain with early access to coronary angiography and revascularisation could have ameliorated the extent of myocyte necrosis
3. Cardiac MRI provides unrivalled tissue characterisation and should be considered for all patients in heart failure post-partum
4. SCAD with infarction and other pathologies should be considered and actively sought before committing to a diagnosis of post-partum cardiomyopathy

61
Severe acute dyspnea in asthmatic patient due to secondary Takotsubo syndrome and cardiogenic shock

D Danijel Crncic[1]; D Rajtman[1]; LM Hodoscek[1]; D Kovac[1]; S Horvat[1]; UB Ferko[1]; SV Rauter[1]; J Tepes[1]; I Nikolajevic[1]; M Lainscak[1]
[1]General Hospital Murska Sobota, Department of Internal Medicine, Murska Sobota, Slovenia

Introduction: Takotsubo syndrome is an acute and usually reversible heart failure syndrome. Described triggers include asthma exacerbation but we are not aware of any reports with typical and inverted Takotsubo syndrome in a single individual.
Description: A 63-year old woman with a recent episode of primary inverted Takotsubo syndrome (3 months ago, coronary angiography without any lesions, circumferential basal hipokinesia) and history of asthma presented with severe acute dyspnea that started at 3am during sleep. After repeated rescue salbutamol inhaler dyspnea did not resolve so she was reffered to Emergency room. There was no recent history of fever, cough or chest pain. On examination she was in respiratory distress with tachypnoea (22/min), oxygen saturation on room air of 78%, peak expiratory flow of 160 L/min (steady state values of 400 L/min), used accesory respiratory muscles, and had prolonged expiratory phase with wheezing. Her blood pressure was 116/76 mmHg, chest X-ray showed lung hyperinflation and electrocardiogram (ECG) was unremarkable except sinus tachycardia. Initial management included oxygen (31% Venturi mask), intravenous methyl-prednisone and fenoterol/ipratropium inhalation. High sensitivity troponin I was 100 ng/l (reference < 15.6 ng/l), NT-proBNP was 204 ng/l, and arterial blood gas analysis showed severe combined metabolic and respiratory acidosis with pH 7.16 and elevated lactate of 3.0 mmol/l. Patient deteriorated despite supportive therapy: her blood pressure dropped to 95/55 mmHg and she presented with cardiogenic shock. Emergency transthoracic echocardiograpy showed typical apical balooning and severely depressed left ventricular ejection fraction of 30%. She was transferred to intensive care unit and was treated with levosimendan, dobutamine and furosemide. In ECG, ST segment elevation with inverted T waves in inferior, anterior and lateral leads developed but she denied any chest pain. Troponin and NT-proBNP peaked at 6057 ng/l, and 8186 ng/l, respectively. In view of recent coronary angiography we did not repeat the invasive diagnostics. After supportive measures, she recovered completely and was discharged with normal levels of cardiac biomarkers and at steady state pulmonary function tests. Echocardiography 2 weaks after discharge showed normal left ventricular ejection fraction of 65 % with no segmental wall motions abnormalities.
Conclusion: We presented a case of secondary Takotsubo syndrome with cardiogenic shock triggered by severe asthma exacerbation in a patient with history of inverted Takotsubo syndrome. In clinical practice, differentiation of dyspnea cause in patients with asthma is challenging but crucial for trigger identification and appropriate management. This case emphasizes the importance of cardiac assessment including FoCUS ultrasound and cardiac biomarkers in patients who remain symptomatic despite appropriate obstructive pulmonary disease therapy.

62
Pregnancy after cardiac transplantation: maternal and fetal outcomes in a Portuguese tertiary hospital

S Sara Nunes[1]; P Araujo[2]; AP Machado[3]; S Amorim[4]; N Montenegro[3]
[1]Hospital Center of Tras-os-Montes and Alto Douro, Obstetrics & Gynecology, Vila Real, Portugal; *[2]Sao Joao Hospital, Cardiology, Porto, Portugal*; *[3]Sao Joao Hospital, Obstetrics & Gynecology, Porto, Portugal*; *[4]Sao Joao Hospital, Cardiothoracic Surgery, Porto, Portugal*

Background: The number of pregnancies after maternal cardiac transplantation is increasing since the first report in 1988. According to current literature, cardiac function of the transplanted heart is generally adequate to pregnancy's needs, albeit the risk of hypertension and preeclampsia. Beyond these, which are associated with preterm birth and fetal growth restriction, fetal outcomes are also dependent of the maternal medication used during pregnancy.
Purpose: To evaluate maternal and fetal outcomes of pregnant women with previous cardiac transplantation.
Methods: We evaluated the clinical data of pregnant women diagnosed with previous cardiac disease, followed between 2007 and 2017, in a Portuguese tertiary hospital. From 313 pregnant women with cardiac disease, there were two with previous cardiac transplantation. Clinical information was collected from Obscare® and SClínico® databases.
Results: The first case occurred in 2008, in a 32-years-old nulliparous woman, transplanted 6 years before due to a familial dilated cardiomyopathy. The unplanned pregnancy was diagnosed at 8 weeks' gestation. By then, she was treated with cyclosporine, prednisolone, diltiazem, aspirin, lisinopril, as well as magnesium and iron supplements. Lisinopril was discontinued, but all remaining medication was maintained throughout pregnancy. This was uneventful until 35 weeks, when an increased blood pressure (systolic >140 and diastolic >90 mmHg) associated with proteinuria (2+ in test strip) was found. Patient was hospitalized with a suspected preeclampsia that was not confirmed. An elective c-section was performed at 37 weeks and a healthy male was born with 2530gr. Uterine atony during surgery was controlled with oxytocin and B-Lynch suture. Maternal echocardiography revealed a preserved biventricular function during the entire pregnancy. The second case occurred in a 28-years-old woman also transplanted due a familial dilated cardiomyopathy in 2010. She presented several rejection episodes until 2015 when she had a diagnosis of a 4 weeks' pregnancy. At that time, her medication regimen included trimethoprim/sulfamethoxazole, azathioprine, tacrolimus and furosemide. Furosemide was suspended and supplementation with magnesium was started. Cardiac function remained normal throughout all pregnancy period (left ventricular ejection fraction of 67%). She already had a healthy son from an uneventful pregnancy previous to cardiac transplantation. There were no complications during this second pregnancy and labor occurred spontaneously at 37 weeks. An urgent c-section was required because of non-reassuring fetal heart rate. A healthy female was born with 2800gr.
Conclusions: Despite the growing better outcomes presented by cardiac transplanted pregnant women, obstetrical and cardiac monitoring of these pregnancies remain a challenge. Multidisciplinary teams are crucial to deal with this particular clinical situation and improve the wellbeing of both mother and fetus.

63
A rare presentation of heart failure

A De Marvao[1]; S Hadjiphilippou[2]; A Escudier[2]; J Arnold[2]; M Sweeney[2]; C Roufosse[3]; M Pickering[4]; C Plymen[2]
[1]Imperial College London, MRC London Institute of Medical Sciences, London, United Kingdom; *[2]Imperial College Healthcare NHS Trust, Department of Cardiology, London, United Kingdom*; *[3]Imperial College Healthcare NHS Trust, Department of Histopathology, London, United Kingdom*; *[4]Imperial College Healthcare NHS Trust, Centre for Complement and Inflammation Research, Division of Immunology and Inflammation, London, United Kingdom*

A previously well 38-year-old female presented in December 2016 with abdominal pain radiating to her back. Non-contrast CT excluded renal calculi but demonstrated abnormal appearances of the renal parenchyma bilaterally. Subsequent contrast CT and MR imaging revealed widespread aortic thrombus extending into both renal arteries with bilateral renal infarction. Vasculitic and thrombophilia screen was positive for lupus anticoagulant and the patient was started on warfarin for presumed antiphospholid syndrome.
A month later she reported arthralgia. Autoimmune testing demonstrated positive antinuclear and anti-Ku antibodies. She was commenced on hydroxychloroquine. Subsequently she developed increasing breathlessness, peripheral and pulmonary oedema. Echocardiogram revealed severe biventricular systolic dysfunction (left ventricular (LV) ejection fraction ~ 15%) so prognostic medical therapy for heart failure was initiated and she was referred on to our centre. Ongoing deterioration prompted immunosuppression with mycophenolate mofetil and cyclophosphamide.
Cardiac MRI demonstrated LV hypertrophy and severely impaired biventricular systolic function. Late gadolinium enhancement pattern was unusual, with intense LV circumferential and subendocardial fibrosis with predominant nodular septal enhancement. There was patchy enhancement of the RV septum and both atria (Fig 1A and 1B). Differential included sarcoid, amyloid, vasculitis and connective tissue disease.
Renal and myocardial biopsies showed, respectively, glomerular and interstitial deposition of amorphous, congo red-positive amyloid (Fig 1C) with characteristic yellow-green appearance under polarised light (Fig 1D). Immunochemistry staining of the amyloid deposits was positive for lambda light chains, confirming diagnosis of AL amyloid.
One year following initial presentation, the patient was started on Bortezomib chemotherapy and falling lambda light chain levels indicated response to therapy. However she continued to deteriorate and was transferred to a heart transplant centre for biventricular assist device implantation. She died soon after due to pulmonary haemorrhage.
Cardiac amyloid is a rare cause of systolic heart failure in young patients and prognosis is guarded. We show that classical cardiac imaging findings are not always present. Diagnosis of amyloidosis can only be confirmed by tissue biopsy and this should be pursued early if amyloidosis is suspected.

Introduction: Heart failure (HF) related morbidity in pregnancy comprise a substantial part of maternal morbidity. The most common cause of HF in late pregnancy and postpartum without any underlying cause, is peripartum cardiomyopathy (PPCM). However, other causes of peripartum HF should be bore in mind.

CLINICAL CASE: A 22-year-old female, with smoking habits and overweight, breastfeeding her child (aged 5 months) and with a past history of not studied seizures, went to the hospital after an episode of syncope.

A few minutes after an intense discussion with her partner, the patient started a malaise, followed by syncope and masseter myoclonias and abnormal limb movements, for approximately 20 minutes. Sphincter incontinence or tongue bite were not present. Soon after, she completely recovered her consciousness and had no symptoms.

Her heart rate at admission was 105 bpm and blood pressure was 109/74 mmHg. The auscultation was normal and she denied chest pain.

An ECG was performed, revealing a discrete ST-segment elevation (<0.5 mm) in II, III, aVF and V2 to V6. The blood test revealed a maximum troponin I of 1.92 ng/mL (cut-off >0.1) and NT-proBNP 3300 pg/mL. An echocardiogram was performed, showing mid-apical dilation of the left ventricle, with hypokinesis of the middle and apical segments of all walls, resulting in a poor systolic function (Left ventricle ejection fraction (LVEF) 29%). After admission in Intensive Cardiac Care Unit, she underwent coronary angiography that revealed no significant lesions. The ventriculography, however, showed an apical ballooning ventricle.

The most likely diagnostic hypothesis at the moment were MINOCA, myocarditis, PPCM and Takotsubo syndrome. Treatment with bromocriptine, carvedilol, captopril and spironolactone was initiated.

Within a few days, the systolic function and segmental abnormalities markedly improved, as shown in the revaluation echocardiogram performed 6 days after admission (LVEF 39%).

A cardiac magnetic resonance was also performed (7 days after admission), revealing a normal systolic function (LVEF 55%) with no segmental wall motion abnormalities and absence of late myocardial enhancement, making unlikely the hypothesis of MINOCA or myocarditis sequelae.

She was discharged with beta-blocking therapy and referred to cardiology and neurology appointments.

Discussion: After detailed investigation, Takotsubo syndrome was the most likely diagnosis. The patient clearly had an emotional stress event and the maximum troponin did not correlate with the extension of affected myocardium. Also, she had rapid recovery of the systolic function and wall motion abdnormalities and absence of late myocardial enhancement. However, Takotsubo syndrome is an uncommon condition in reproductive women. Particularly, in this case of a breastfeeding woman, the high prolactin levels and decreased oestrogen levels could be implicated, as oestrogens protect the myocardium of catecholamine toxicity.

Pregnant woman with high-output heart failure related to Parkes Weber syndrome

R Mourilhe Rocha[1]; J Prezioso[1]; BB Harboe[1]; WL Agrizzi[1]; FAR Medeiros[1]; IC Furtado[1]; BR Wasjbrot[1]; DXB Setta[1]; FN Albuquerque[1]; MI Bittencourt[1]; R Esporcatte[1]; DC Albuquerque[1]

[1]State University of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil

Introduction: Parkes Weber's syndrome is a rare congenital condition characterized by a large amount of vascular abnormalities. The major signs and symptoms include capillary malformation on the skin, bone and soft tissue hypertrophy of the affected limb and multiple arteriovenous fistulas that can potentially lead to heart failure. There may also be pain in the affected limb and a size difference between limbs. Some cases of this syndrome result from mutations in the RASA1 gene and are inherited in an autosomal dominant. Physical examination is sufficient to make a diagnosis, but diagnostic imaging, including computed tomography (CT) angiography, is necessary to confirm it, to assess the extent and severity of the disease.

Case report: a first trimester pregnancy female (17 weeks), 31 years old daughter of consanguineous parents, with congenital scoliosis and glaucoma, was hospitalized after severe abdominal pain radiating to the right flank, associated with syncope. Physical examination revealed syndromic facies, marked cutaneo pallor, asymmetric bilateral lower limbs edema higher on the right side. Regular heart rhythm, with systolic murmur in tricuspid focus (3+/6+). P2 > A2 and HR = 130bpm. Digestive endoscopy showed severe peptic esophagitis with signs of recent bleeding. Echocardiography revealed severe tricuspid insufficiency with pulmonary hypertension (PASP = 76mmHg), with preserved systolic function, with increase in cardiac index (6.5L/min/m2). Venous Doppler of lower limbs and chest angiotomography confirmed the association of pulmonary thromboembolism, starting treatment with enoxaparin. Angiotomography of lower limbs showed complete deviation of large vessels, internal iliac artery fistulas with right common iliac vein, femoral vein thrombus on the same side with total occlusion of the lumen.

Patient progresses with blood dyscrasia, metabolic acidosis and acute renal failure due to renal tubular acidosis, requiring hemodialysis. At this time, it was decided for interrupting gestation (19 weeks) due to the high risk of maternal death. After the abortion, the patient developed clinical improvement and recovery of renal function as well as hemodynamic profile. Follow-up echocardiogram showing reduction of cardiac output, PASP = 40mmHg, and receiving hospital discharge, with conservative treatment of arteriovenous fistulas, using bisoprolol, furosemide and warfarin.

Conclusion: gestation is a clinical condition that naturally increases the patients' volemia and in association with a rare disease like Parkes Weber's syndrome, markedly got worse the high-output heart failure. Treatment should be individualized according to the age and clinical characteristics of each patient and depends on the presence and severity of the symptoms. The goal is to prevent disease progression and heart failure. Although conservative treatment can be considered,

surgery continues to play an important role in improving the quality of life of these patients.

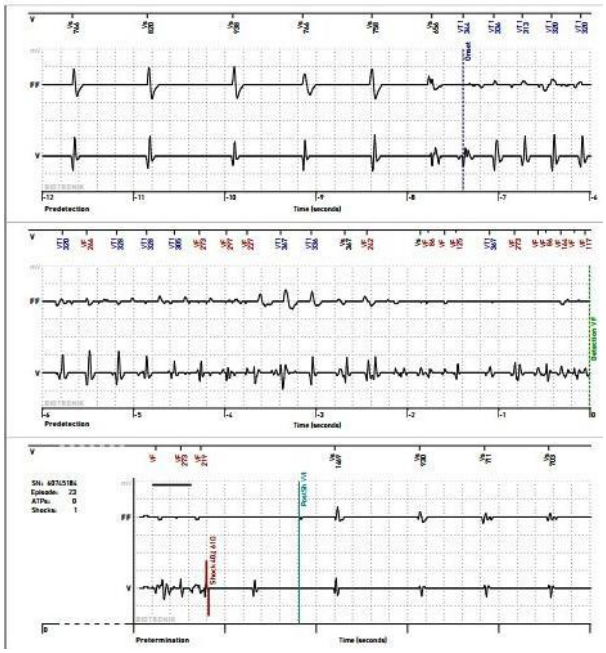
66

Pregnancy in long QT syndrome and implanted cardioverter-defibrillator for secondary prevention

S Garkina[1]; R Tatarsky[1]; T Lubimtzeva[1]; S Gureev[1]; V Lebedeva[1]; E Mikhaylov[1]; D Lebedev[1]

[1]Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation

Background: The long QT syndrome (LQTS) is associated with high risk of ventricular tachyarrhythmias mainly triggered by adrenergic activation whereas the annual rate of sudden cardiac death (SCD) is estimated up to 5% for patients with LQTS and syncope. Specialized guidelines on treatment of pregnant women with inherited arrhythmias and implanted devices are lacking and patients are usually recommended to avoid pregnancy.



VF episode terminated by shock

Case report: A 26-year-old patient with implanted ICD for secondary prevention (history of recurrent ventricular fibrillation episodes) referred for control follow up visit during pregnancy. She was previously diagnosed LQTS type 2 with verified mutation of KCNH2 gene. She experienced recurrent VT and syncopal attacks since the age of 5 years and underwent ICD implantation in 2009 and elective device replacement in 2011 and 2014. Analysis of endograms revealed regular appropriate shocks after ventricular fibrillation (VF) episodes mostly triggered by PVC during persistent bradycardia. The patient had previously taken low doses of beta-blockers daily. On admission she was pregnant at the 12th week of gestation. Since the first weeks of pregnancy she didn't present VT/VF episodes or ICD shocks and reported normal physical tolerance. She demonstrated physiological sinus tachycardia until the 38 weeks of pregnancy with subsequent planned caesarean delivery (due to obstetrics indications) and live child. Two weeks after delivery she continued to experience VF episodes terminated spontaneously or after adequate ICD shocks (9 episodes) (Figure 1). Now the patient remains on beta-blockers.
Questions, problems or possible differential diagnosis. This clinical case illustrates reduced risk of cardiac events and fatal arrhythmias in young woman with LQTS during pregnancy.
Answers and discussion: Data about potential risks and outcome in pregnant patients with implanted devices are lacking and treatment tactics remains controversial. Numerous cases of favourable course and even benefits in clinical and functional status during pregnancy in patients with LQTS are reported. The cardiac event risk can be modified using beta-blocker therapy. Patients with ICDs are considered to have a successful pregnancy with no fetal compromise but under thorough medical monitoring.
Conclusions: and implications for clinical practice. Pregnancy in patients with LQTS and implanted ICD is not contraindicated and treatment tactics depends on clinical situation while positive influence of physiological hemodynamical changes and hypersympathicotonia may contribute to temporary elimination of bradydependent ventricular life-threatening arrhytmias. Algorithms of ATP and shock therapy during pregnancy in women with ICD are corrected individually while remote monitoring is recommended to all patients.

67

Telling the story of a caucasian woman with peripartum cardiomiopathy: from cardiogenic shock to a happy-ending second pregnancy.

AB Scardovi[1]; R De Maria[2]; A Cortellesi[1]; L Luca Arcari[1]; R Ricci[1]

[1]Hospital Santo Spirito, Cardiology, Rome, Italy; *[2]Niguarda Ca' Granda Hospital, Clinical Physiology Institute, Milan, Italy*

Background: Peripartum Cardiomyopathy (PPCM) is a rare disease, which affects previously healthy women toward the end of pregnancy or in the months following delivery, with no other identifiable cause of heart failure. Although the aetiology and pathogenesis of PPCM are still unknown, several hypotheses have been proposed, comprising viral myocarditis, apoptosis and prolactin toxicity, auto-immune mechanisms, malnutrition, hormonal changes, or the result of complex interactions of pregnancy-associated factors against a susceptible genetic background . PPCM is still a diagnosis of exclusion. Established recommendations for future pregnancies do not exist. Left ventricular (LV) recovery is considered the most reliable prognostic predictor of survival in subsequent pregnancies,but it does not guarantee an uncomplicated subsequent pregnancy. Although death is rare, marked decreases in LV function have been reported in approximately 20% of patients, with persisting dysfunction after pregnancy in about 50%.
Methods and Results: We report a case of PPCM in a 30 years old Caucasian woman, with no history or evidence of pre-existing structural heart disease. She developed cardiogenic shock 12 hours after delivery by caesarean section with spinal anesthesia of her first healthy child, at 38 weeks gestation. Transthoracic echocardiography showed a dilated left ventricle with severely depressed pump function (LVEF 20%). Endomyocardial biopsy excluded active myocarditis. She was treated with i.v. inotropes, invasive mechanical ventilation and insertion of an intra-aortic balloon-pump; lactation was inhibited by a single dose of cabergoline, two infusion of levosimendan were performed and ivabradine was added to control tachycardia. At three-month follow-up, echocardiography showed complete recovery of LV function (LVEF 57%). At 18-month follow-up the patient stopped medications for symptomatic hypotension. At 24 and 30 months follow-up, off drugs, she was asymptomatic, LVEF was 64% and exercise tolerance was normal both at cardiopulmonary exercise test and six-minutes-walking test.
Four years after the acute PPCM, having been warned of the 20% risk of disease relapse, the patient decided to undertake a second pregnancy. After an uncomplicated gestation and natural delivery she gave to a healthy fetus birth. Two years later LV and functional capacity are still normal.
Conclusions: Management of PPCM is still largely empirirc. The long term prognosis and the containdication to a subsequent pregnancy for the risk of PPCM relapse in a patient who experienced full recovery remain uncertain

68

Impact of cardiac resynchronization therapy in patients with peripartum cardiomyopathy

LUIZ Camanho[1]; E B Saad[2]; C Slater[2]; LUCAS Carvalho Dias[2]; LUIS Oliveira Jr[2]; R Mourilhe-Rocha[1]

[1]State University of Rio de Janeiro and Procardiaco Hospital, RIO DE JANEIRO, Brazil; *[2]Hospital Pro Cardiaco, Electrophysiology and Pacemaker, Rio de Janeiro, Brazil*

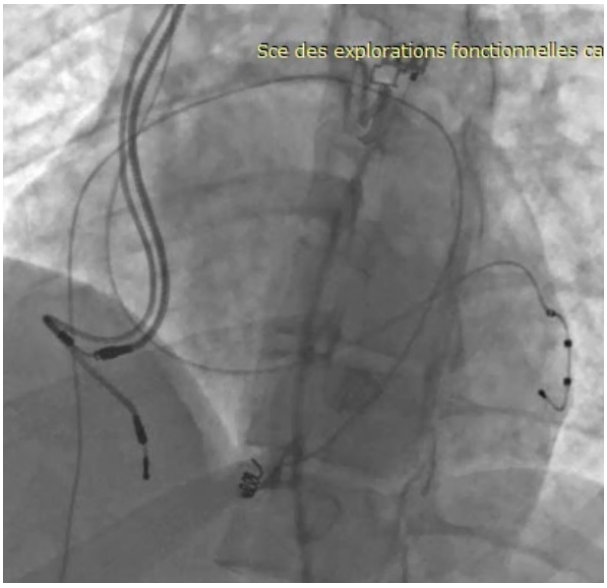
Fundamental: peripartum cardiomyophaty (PPCM) is a rare cause of dilated cardiomyophaty in pregnant women at the time of or following childbirth. Despite maximal medical treatment, 20% to 25% of patients (pt) progress to end-stage heart failure (HF) over time. There are few data on cardiac resynchronization therapy (CRT) in this population.
Objective: to describe clinical outcome in pt with PPCM and CRT.
Methods: in a cohort of 300 consecutive pt enrolled at CRT, 4 (1.3%) had the PPCM diagnosis. All pt were receiving optimal medical treatment. In all cases, the PPCM diagnosis was defined immediately after delivery. The survival and response to CRT were evaluated.
Results: the mean age was 39 years; average ejection fraction (EF): 24,5%; left bundle branch block (LBBB) and average QRS duration: 165 ms (130 to 200 ms). Average left ventricular end-diastolic diameter was 80.7 mm and left ventricular end-systolic diameter (LVESD) was 70 mm. Functional class (FC) III (NYHA) and preserved renal function were observed in all pt. BIV-ICD was also observed in 3 pt. 75% of patients progressed to end-stage HF and subsequent death. The mean survival was 16 months. Only 1 pt presented satisfactory evolution with FC and EF

improvement and left ventricular end-systolic diameter decrease. The follow-up time was 43 months. This pt had LBBB and QRS duration of 200 ms.
Conclusion: although optimal medical treatment and CRT, this population in general presents unfavorable evolution, suggesting to be an adverse model of cardiomyophaty, and that should be early evaluated for cardiac transplantation.

69
Successful pregnancy after transvenous cardiac resynchronization therapy in a woman with congenitally atrioventricular block and induced dilated cardiomyopathy

S Ouali[1]; K Sammoud[1]; M Ben Halima[1]; S Boudiche[1]; N Khedher[1]; F Meghaith[1]; MS Mourali[1]
[1]La Rabta University Hospital, Cardiology, Tunis, Tunisia

Introduction: Isolated nonimmune congenital atrioventricular (AV) block is a rare disorder, associated with a risk of sudden death in the absence of cardiac pacing. Most women with paced congenital atrioventricular block reach childbearing age. However, long term right ventricle pacing can induce dilated cardiomyopathy and pregnancy in this setting is challenging
Case: We report a case of a 31-year-old female with a history of isolated nonimmune congenital AV block and long term right ventricle pacing since 6-year old. At the age of 29, the patient achieved a non-programmed pregnancy and was admitted to our institution during the 30th week of gestation because of an exacerbation of heart failure (NYHA class III heart failure symptoms), and general physical weakness. Electrocardiogram (ECG) upon admission showed an atrial sensed and apical right ventricular-paced rhythm with QRS duration of 190 ms (Figure 1 Panel A).
Echocardiography revealed severe systolic left ventricle (LV) dysfunction, LV ejection fraction of only 35%. Significant mitral valve regurgitation was also observed. Unfortunately, a Stillbirth occurred at the 32th week of gestation despite the close monitoring. Given the underlying persistent LV dysfunction and the complete AV block requiring conventional pacemaker therapy, a biventricular pacemaker (CRT-P) was implanted, eight months later the first delivery. Postoperatively, the patient achieved total relief from her exercise tolerance and improved from New York Heart Association functional Class III to II with a QRS shortening (Figure 1 Panel B) and a significant increase of her systemic LV ejection fraction (LVEF= 47%) evaluated during a 28th week of a second gestation. The pregnancy successfully continued until term and a male infant weighting 3,200 g was born via a cesarean section.
Conclusion: A right ventricle paced induced cardiomyopathy can occurred in patients with seronegative complete AV block. These patients can be managed with cardiac resynchronization therapy and pregnancy can be achieved in this setting.



Figure

70
The clinical challenge of heart failure during the peripartum period

F Fernando Fonseca Goncalves[1]; J Pedro Guimaraes[1]; PS Mateus[1]; JI Moreira[1]
[1]Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal

A 42-year-old woman, smoker and without other known cardiovascular risk factors, with obstetric records of four gestations, three childbirths and one abortion, shows up in the emergency ward with rest dyspnea associated with orthopnea and peripheral edema with 23 days of evolution, all beginning one day after last childbirth when she had productive cough with mucopurulent sputum, being treated therefore with steroids and empirical amoxicillin/clavulanic acid without significant symptomatic improvement. On examination the patient has tachycardia, no fever, signs of central cyanosis, peripheral edema and crackles in both inferior pulmonary thirds, without heart murmurs or pericardial friction rub audible on cardiac auscultation. Analytical assay shows leukocytosis but C-reactive protein in the upper limit of normal and an elevation in D-dimers levels for what it is then carried out a computed tomography angiogram which excludes pulmonary thromboembolism. NT-proBNP levels are high without a rise in cardiac troponin T. Virus testing in bronchial aspirate reveals positivity for Coronavirus 229 E. The electrocardiogram presents a sinus rhythm with diffuse T wave inversion. The thoracic X-ray reveals alveolar congestion with bilateral small volume pleural effusion. Subsequent transthoracic echocardiogram shows a globally hypokinetic and moderately dilated left ventricle with a severe systolic dysfunction and right ventricle systolic function in the inferior limit of normal.
After institution of standard heart failure treatment, the patient is admitted to a cardiology ward for clinical stabilization and additional diagnostic investigation. Based on the records of smoking habits, symptoms and signs presented at admission and electric and echocardiographic changes, a coronary angiography is performed and excludes significant angiographic coronary disease. In order to exclude myocarditis a cardiac magnetic resonance is done and shows a nonischemic dilated cardiomyopathy with severe left ventricular systolic dysfunction, without evidence of delayed myocardial enhancement.
Therefore, a peripartum cardiomyopathy (PPCM) is assumed as the most probable diagnosis and a therapeutic scheme of bromocriptine and rivaroxaban is begun. On the sixth day of hospital stay, already with complete symptomatic resolution, improvement of left ventricular systolic function is documented on a transthoracic echocardiogram and the patient is discharged from hospital.
In conclusion, the recognition of PPCM is fundamental because its mortality rate is considerable. Besides the standard heart failure treatment, bromocriptine seems to be associated with greater survival and better left ventricular systolic function recovery.

71
Outcomes and management of arrhythmogenic right ventricular cardiomyopathy in pregnancy: a comparison of two cases.

M Marco Schiavone[1]; E Gherbesi[1]; C Gobbi[1]; M Squillace[1]; M Calcagnino[1]; M W Ossola[2]; C Bonanomi[1]; F Lombardi[1]
[1]IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Cardiovascular diseases, Milan, Italy; [2]IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Obstetrics and gynecology, Milan, Italy

Background: Arrhythmogenic right ventricular cardiomyopathy (ARVC) is an inherited cardiomyopathy with an estimated prevalence of 1:5000. Data on pregnancy in ARVC are limited. We reported two different cases of pregnant women affected by this rare cardiomyopathy that reflect the complexity and multiple clinical manifestations of the disease.
CASE 1: A 32-year-old pregnant woman was referred to our clinic during the 32th gestational week due to a family history for ARVC (brother). She was completely asymptomatic (NYHA I - WHO I).
The ECG showed sinus rhythm interrupted by premature ventricular contractions (PVCs), incomplete right bundle branch block (RBBB), epsilon wave in V2, inverted T waves in V1-V4.
An echocardiogram revealed a dilation of the right ventricle, mild tricuspid and mitral regurgitation.
A 24-hour Holter ECG monitoring showed frequent PVCs and a few runs of non-sustained ventricular tachycardia (NSVT). A therapy with Metoprolol was started.
While admitted she underwent a genetic testing, which revealed the same homozygous mutation of DSG2 gene described for her brother.
An elective caesarean section was then planned at 37 weeks; no complications occurred. After delivery, she was transferred to ICU for monitoring: Metoprolol was suspended and Sotalol was started.
To complete the assessment, she underwent a CMR which revealed fibro-fatty infiltration and reduced function of both ventricles.
At discharge the patient was asymptomatic at rest and there were no signs of heart failure (HF) during the follow-up period.
CASE 2: A 38-year-old pregnant woman was admitted to our clinic because of dyspnea (NYHA III - WHO III) and palpitations.
An ECG revealed sinus rhythm interrupted by PVCs, inverted T waves in V1-V5, but no evidence of RBBB.
An echocardiogram showed a severe dilation of both ventricles and a moderate left ventricular systolic dysfunction.

She was treated with i.v. Furosemide and a caesarean section was performed at 36 weeks due to HF.
In the early postpartum we observed a further reduction of systolic function (EF 30%) and a VT was recorded.
A CMR revealed fibrofatty infiltration, reduced function and dilation of both ventricles (RV volume > 100 ml/m^2). The patient was discharged with HF therapy.
An ICD was implanted three months later, after occurrence of a syncope (LVEF < 35% despite optimal medical therapy).
Conclusion: These cases strongly suggest that WHO and NYHA class, signs and symptoms of HF at a first evaluation play a major role to predict maternal and foetal outcome.
Neither HF nor other major cardiac complications occurred during pregnancy, delivery and puerperium of case 1 although both ventricles were involved. On the other hand, in the second case, fast hemodynamic changes and sympathetic overstimulation related to pregnancy determined a worsening of pre-existing HF signs and symptoms.

72

A case of advanced heart failure: When not everything is as it seems

A Rodriguez Chaverri[1]; I Ponz De Antonio[1]; MD Garcia-Cosio[1]; L Moran Fernandez[1]; J De Juan Baguda[1]; F Arribas Ynsaurraga[1]; JF Delgado Jimenez[1]
[1]*University Hospital 12 de Octubre, Cardiology, Madrid, Spain*

A 33 year-old woman with dyspnea and orthopnea in the last month of pregnancy that worsened in the postpartum.ECG (Image 1) showed sinus tachycardia and T-wave changes and chest x ray (Image 2) pulmonary vasculature redistribution and bilateral pleural effusion. The echocardiogram (Image 3) revealed a severe biventricular dysfunction and functional mitral regurgitation. The cardiac MRI showed LGE restricted to the posterior septum (Image 4) and the STIR sequences were negative for edema (Image 5).

Image 1

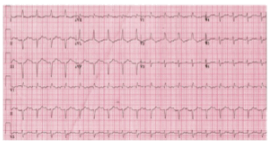


Image 2

Image 3

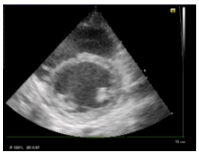

Image 4

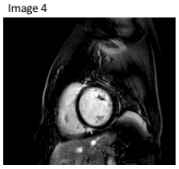

Image 5

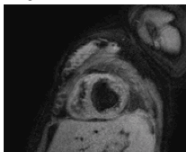

The diagnosis of a peripartum cardiomyopathy (PPCM) was posed, and once clinical stabilization was achieved, bromocriptine was tested, which had to be stopped because of skin flushing. ACE inhibitor and beta blockers were poorly tolerated due to an increasing low cardiac output profile that required inotropic support. The patient had to be transferred to the intensive care unit due to persistent clinical worsening. Invasive hemodynamic monitoring showed a RA pressure of 20 mmHg; mPAP of 35 mmHg; PWP of 29 mmHg and a CI of 1,2 l/min/m2. In this context, a VA-ECMO was implanted as a "bridge either to recovery or to decision" strategy. In the following days, in the absence of myocardial recovery, the patient was listed for cardiac transplant which was held a week later without complications.
Peripartum cardiomyopathy is a rare cause of heart failure that affects women late in pregnancy or in the early puerperium. It has been defined as an idiopathic cardiomyopathy with the following characteristics: Firstly, the development of heart failure (HF) towards the end of pregnancy or in the months following delivery. Secondly, by the absence of another identifiable cause for HF. Lastly, by LV systolic dysfunction with an LV ejection fraction nearly always less than 45 percent.
The precise mechanisms that lead to PPCM are not fully known. Several risk factors have received attention, such as abnormal autoimmune responses, myocardial inflammation and an altered prolactin processing. However, evidence from recent studies supports the hypothesis that PPCM may develop as a result of an interaction between pregnancy-related factors (eg. late pregnancy, oxidative stress) and a susceptible genetic background. The most relevant study in this field was published in the NEJM in 2016: Forty three genes were sequenced in 172 women with PPCM. Among them, twenty six distinct rare truncating variants were identified. The prevalence of this truncating variants was significantly higher that in the reference population but similar to the cohort of dilated cardiomyopathy.
This issue, bring us back to our clinical case, as the patient's mother was diagnosed in 2013 with a dilated cardiomyopathy. Genetic testing in the mother was positive for a titin-truncanting variant and so it was in both of her daughters.
Therefore , the question I pose is: Does pregnancy actually act as a second hit in a susceptible background of different etiologies in the setting of PPCM?

Enhanced activation of RSK1 in the nucleus reduces compensated hypertrophy induced by alpha1-adrenergic receptor agonist phenylephrine in mice in vivo

A Angela Clerk[1]; KA Rostron[1]; DN Meijles[2]; JJ Cull[1]; SJ Fuller[1]; PH Sugden[1]
[1]University of Reading, Reading, United Kingdom; *[2]St George's University of London, London, United Kingdom*

Funding Acknowledgements: British Heart Foundation

Background: The a1-adrenergic receptor (a1AR) agonist phenylephrine (PE), acting via ERK1/2 that phosphorylate p90 ribosomal S6 kinases (RSKs), promotes compensated hypertrophy and increases cardiomyocyte size. Both kinase families phosphorylate transcription factors producing changes in gene expression. In cardiomyocytes, potent ERK1/2 signalling causes nuclear-localisation of activated RSK1/RSK2 isoforms. This promotes cardiomyocyte growth, but hypertrophy is not sustained. Lesser ERK1/2 activation by PE causes nuclear activation of only RSK2, and this signalling is associated with a different gene expression profile.
Purpose: Our hypothesis is that activation of nuclear-localised RSK1 in addition to RSK2 promotes changes in gene expression that are not compatible with compensated hypertrophy induced by a1ARs. Our aim was to investigate if expression of nuclear-localised RSK1 is detrimental to the hypertrophic response induced in vivo by PE.
Methods/Results: Nuclear-localised (NL) RSK1 or RSK2 were expressed in cultured cells using adenoviral vectors. Immunostaining confirmed expression of NL-RSKs was confined to nuclei of HEK293, SVEC (endothelial cells) or neonatal rat cardiomyocytes. By immunoblotting with antibodies for phosphorylated (i.e. activated) RSKs, we confirmed that NL-RSKs were inactive in serum-starved cells, and activated by nuclear-localised ERK1/2 following treatment with epidermal growth factor. We generated transgenic mice for tamoxifen-inducible, cardiomyocyte-specific expression of NL-RSK1 by inserting the transgene in the ROSA26 locus, separated from the promoter by a LoxP-flanked stop cassette. NL-RSK1 mice were crossed with mice with tamoxifen (Tam) inducible CRE under control of the a myosin heavy chain promoter, producing double heterozygotes and wild-type (WT) littermates for experiments (n = 6-9 per group). Echocardiography was used to assess cardiac function/dimensions at baseline and following treatment. There was no significant difference between transgenic mice and WT litter mates up to 10 weeks of age in any of the variables studied. Tam-treatment (7 d) significantly increased diastolic (d) or systolic (s) left ventricular (LV) posterior wall (PW) thickness (16%) in transgenic, not wild-type (WT) mice indicating that enhanced NL-RSK1 alone promotes hypertrophy. PE (40 mg/kg/d, 3 d) increased LVPW ˜99% in WT or transgenic mice with corresponding decreases in LV internal diameters, but the degree of hypertrophy was significantly reduced (˜45%) in transgenic mice pretreated (4 d) with Tam.
Conclusions: Our data indicate that increased nuclear-localised RSK1 in cardiomyocytes promotes cardiac hypertrophy. However, it compromises the compensated hypertrophic response to PE. These data suggest that selective inhibition of RSK1 (rather than RSK2) may preserve the compensated hypertrophic state and, thus, reduce heart failure progression.

99

MiR-126 is involved in allograft vasculopathy

W A Heggermont[1]; L Delrue[1]; L Dierckx[1]; K Dierickx[1]; S Verstreken[1]; M Goethals[1]; J Bartunek[1]; M Vanderheyden[1]
[1]Olv Hospital Aalst, Aalst, Belgium

Background: Since cardiac allograft vasculopathy (CAV) significantly limits long-term outcome after heart transplantation, its early diagnosis is crucial. Endothelium-enriched microRNAs appear to be involved in the development of CAV. However, so far, these microRNAs were not yet measured in endomyocardial biopsies and their mechanism of action in allograft vasculopathy remains elusive.
Aims: To investigate the expression of endomyocardial microRNA-126-3p and microRNA-126-5p levels in transplant recipients with (CAV+) and without CAV (CAV-), to evaluate whether these cardiac endothelial microRNAs help to predict allograft vasculopathy, and to elaborate on the possible mechanism of action of miR-126 in CAV.
Methods: We studied 39 transplant recipients, 21 with proven allograft vasculopathy and 18 without allograft vasculopathy at serial coronary angiograms. The mRNA levels of miR-126-3p and miR-126-5p, and targets PIK3R2 and SPRED1 were determined by qRT-PCR in right ventricular endomyocardial biopsies obtained at baseline routine surveillance biopsy and at follow-up within each individual patient. Human biopsy material was extracted with the miRVANA extraction kit (Ambion); cDNA synthesis and miR-qRT-PCR was performed with specific microRNA amplification kits (Qian). Furthermore, mouse cardiac endothelial cells (MCECs) were treated with methylprednisolone, tacrolimus, cyclosporine or mycophenolate in order to determine the influence of immunosuppressive agents on miR-126 and its targets.
Results: There were no baseline differences in endomyocardial miR-126-3p and -5p between CAV- and CAV+ patients. After CAV developed however, miR-126-3p levels were significantly lower in the CAV+ group, compared to their non-CAV counterparts ($p < 0.01$). Lower miR-126-3p levels were consistent with the incidence of CAV as evidenced by the ROC curve (AUC of 0.8040, $p = 0.0003$). Levels of miR-126-5p were not significantly different at that time point. Also, although there was a trend towards higher PIK3R2 and SPRED1 levels in the CAV patients, the difference was not statistically significant. When MCEC cells were treated with immunosuppressive agents for 24 hours, PIK3R2 levels were significantly lower in the treated cells versus control ($p < 0.05$). Regarding SPRED1, levels only decreased in the methylprednisolone-treated cells. Furthermore, the short treatment with immunosuppressive agents led to a significant increase in miR-126-3p (not -5p) only in the mycophenolate-treated cells.
Conclusions: Our data provide evidence that decreased microRNA-126-3p levels coincide with allograft vasculopathy. Furthermore, although further validation is paramount, the administration of immunosuppressive agents seems to influence both miR-126-3p and its targets SPRED1 and PIK3R2. Further studies are warranted to determine if serial measurement of microRNA-126-3p could help in risk assessment and early detection of post-transplant CAV.

Background and Purpose: Nrf2 is a key transcription factor that coordinates the expression of several cytoprotective gene regulatory pathways in multiple cell types and tissues. In the heart, Nrf2 has been identified to be essential in cardioprotection. Its activation is driven by NADPH oxidase 4-derived ROS, itself a cytoprotective enzyme upregulated in hypertrophic stress and which ameliorates hypertrophy and heart failure. Nrf2 is expressed in multiple cell types but it is not known if Nrf2 derived from cardiomyocytes, as opposed to other cell types, is the crucial player in mediating cardioprotection. This is the first study to investigate the role of cardiomyocyte-targeted Nrf2 in a murine model of heart failure.
Methods: Cardiomyocyte-specific deletion of Nrf2 was achieved by crossing a floxed-Nrf2 mouse line with a Cre-expressing line under the control of the ventricular-specific Mlc2v promotor. Cardiomyocyte-specific Nrf2-deficient male mice (csNrf2-/-) alongside matched littermate floxed controls (csNrf2fl/fl), underwent transverse aortic constriction (TAC) surgery to generate pressure-overload stress. At 2 weeks, echocardiography was performed and the hearts harvested for further characterisation by histology, immunoblotting and real-time qPCR.
Results: A significant reduction in basal levels of Nrf2 expression in csNrf2-/- compared to floxed controls was confirmed with RT-PCR in the left ventricle of hearts (80% reduction; $p = 0.02$, $n = 3$ per group). No change in mRNA levels was found in other organs. Basal cardiac function, organ and body weight of knock-out and floxed controls were similar. After 2 weeks of TAC, csNrf2-deficient mice developed significantly greater LV systolic impairment than floxed controls (37% reduction in EF, when comparing the knock-out hearts to the floxed control; $p < 0.001$, $n = 6$-10 per group). They also had significant LV dilatation with evidence of lung congestion as compared to floxed controls. Histological analysis showed pressure-overloaded csNrf2-deficient hearts had significantly more interstitial fibrosis compared to floxed

hearts (6% versus 2%; $p < 0.05$, $n = 3$ per group). Finally they had significantly increased transcripts of markers of cardiac stress (raised b-MHC and ANF) than controls.
Conclusion: This study demonstrates the successful generation of mice with a cardiomyocyte-targeted deletion of Nrf2, an important transcriptional regulator of diverse cytoprotective programs. The lack of Nrf2 in this cell type is sufficient to drive the global maladaptive cardiac remodelling response to haemodynamic stress, leading to an increase in interstitial fibrosis, ventricular dilatation and congestive cardiac failure. Further study is now needed to understand the mechanisms underlying this response.

Background/Introduction: Heart failure (HF) is a complex multifunctional disease. Structural cardiac remodeling induced by alterations in gene expression result in molecular, cellular, and interstitial changes. In addition, profound perturbations in cardiac metabolism affect essential cellular processes such as energy production. An improved understanding of metabolic alterations associated with other pathological processes in HF could facility the identification of novel biomarkers and effective HF-therapies.
Purpose: Aim of this study was to gain a comprehensive understanding of the holistic metabolic alterations at different stages of HF including compensated and decompensated hypertrophy, and terminal HF in a left ventricle pressure overload mouse model.
Methods: Mice were subjected to transverse aortic constriction (TAC) or sham surgery and sacrificed either 2, 4, or 6 weeks after the procedure. Metabolite profiles of cardiac tissue were investigated by broad, untargeted metabolomics including GC-MS and LC-MS/MS and compared to results of transcriptional profiling. Since HF is associated with alterations in systemic metabolism, metabolic changes in plasma, liver, and skeletal muscle of these mice were analyzed in parallel. For further mechanistic studies of a key target we used Adeno-associated virus (AAV) 9-mediated overexpression in mice subjected to TAC.
Results: Progressive alterations of key cardiac metabolic pathways and gene expression patterns indicated impaired mitochondrial function and a metabolic switch during transition to heart failure. Similar to the cardiac alterations, liver and skeletal muscle revealed significant metabolic changes such as depletion of essential fatty acids and glycerolipids in late stages of heart failure. Circulating metabolites, particularly fatty acids, reflected cardiac metabolic defects and deteriorating heart function similar as observed with a plasma-based metabolic cardiac lipid panel biomarker established for the detection of HF with reduced ejection fraction (HFrEF) in humans. Cardiac metabolic profiling further revealed decreased carnitine shuttling and transportation preceding cardiac dysfunction. Thus, we studied the therapeutic potential of Organic Cation/Carnitine Transporter 2 (OCTN2), a key factor in carnitine shuttling. Cardiac overexpression of OCTN2 significantly improved ejection fraction and reduced interstitial fibrosis in mice subjected to TAC.
Conclusions: Alterations in metabolic profiles of heart, plasma, liver, and skeletal muscle emphasizes the impact of HF as systemic disease. Overall, these systemic changes are reflected by variations in plasma metabolites that could be used as diagnosis biomarkers. In addition, our data demonstrate that metabolomics is a valuable key technology in systems biology for the identification of new drug target candidates and the elucidation of pathological HF mechanisms.

104
Human cardiomyopathy islands as a novel iPSC based strategy for modeling adult onset cardiomyopathies in-vivo

Introduction: The study of cardiomyopathies is hampered both by the inability to assess the myocardial tissue early during disease development and the lack of suitable models. The advent of human induced pluripotent stem cells (hiPSCs) technology may provide essential means for overcoming this hurdle, since it allows deriving and studying human cardiomyocytes that carry the disease-causing phenotype. However, hiPSCs based in-vitro, "disease in a dish models", are limited by the relative structural, functional and metabolic immaturity of the cardiomyocytes, the inability to assess for the effects of systemically delivered therapeutic interventions and the lack of supporting microenvironment.
Purpose: In the current study, we aimed to establish hiPSCs based in-vivo models for cardiomyopathies and assess whether such a strategy can: (1) unmask the phenotype of adult onset cardiomyopathies (e.g. arrhythmogenic right ventricular cardiomyopathy, Pompe disease); (2) obtain functional information from the engrafted hiPSCs derived cardiomyocytes (hiPSC-CMs), and; (3) assess the effect of systemically delivered therapies on hiPSC-CMs.
Methods: Heterotopic and orthotopic strategies were used to transplant hiPSCs derived cardiomyocytes (following 15-30 days of differentiation) to NOD-SCID mice. Orthotopic experiments were conducted by direct intra-myocardial delivery of the hiPSC-CMs.
Results: Orthotopic transplantation of hiPSC-CMs to the mice myocardium resulted in stable, large and discrete grafted tissue islands. The hiPSC-CMs within the islands presented both structural and molecular hallmarks of cardiomyocyte maturation following 30 days, when compared with same stage in-vitro cultured cardiomyocytes. Importantly, when hiPSC-CMs from adult onset cardiomyopathies (i.e. Arrhythmogenic right ventricular cardiomyopathy (ARVC) and Pompe disease) were transplanted, the in-vivo environment resulted in the generation of human cardiomyopathy islands (hCI) recapitulating the adult onset cardiomyopathy phenotype without the need for stressors usually required for uncovering the phenotype of these cardiomyopathies in-vitro. Additionally, The hCI strategy was used for evaluating the effect of systemic therapies on the cardiomyopathy phenotype. Heterotopic transplantation demonstrated that transplanted cells survived within the dermal thin layer of the outer ear (for up to 3 months) but was not associated with structural maturation of the hCIs nor did it promote cardiomyopathy phenotype unmasking.
Conclusions: Orthotropic hCI may serve as an attractive strategy for modeling the structural and functional alterations associated with adult onset cardiomyopathies. Apart from phenotype uncovering, this strategy may more accurately model systemic therapy effects, interaction with the immune system and adult metabolic energetics which have significant clinical importance.

105
The MiR-221/-222 cluster is elevated both in biopsies of patients with myocarditis and idiopathic non-ischemic cardiomyopathy but fails to discriminate between both pathologies

W A Heggermont[1]; L Delrue[1]; R Dierckx[1]; K Dierickx[1]; S Verstreken[1]; M Goethals[1]; J Bartunek[1]; M Vanderheyden[1]
[1]Olv Hospital Aalst, Aalst, Belgium

Background: The narrow diagnostic window due to - normally - rapid recovery, the very low sensitivity of viral serology and the potential sampling error upon endomyocardial left ventricular biopsy procurement makes the diagnosis of acute myocarditis challenging. Sometimes the disease is difficult to distinguish from a new-onset idiopathic dilated cardiomyopathy.
Aims: To investigate the expression of known microRNAs involved in myocarditis and DCM (miR-221/-222), the expression of genes involved in viral replication (MDA5, RIG1, TLR3) and the expression of heart failure biomarkers (BNP, ST2) in order to improve the differential diagnosis of acute decompensated heart failure patients.
Methods: We prospectively studied left ventricular biopsies of control ($n = 11$), myocarditis ($n = 18$), and non-ischemic dilated cardiomyopathy patients (DCM, $n = 34$). Myocarditis patients had a suspected clinical history in combination with a rise in serum inflammatory markers (C-reactive protein) and clearly positive late gadolinium enhancement (LGE) on cardiac MRI. DCM patients were characterized by the presence of normal coronary arteries in combination with a dilated left ventricle, reduced LV function and either absence of LGE or a typical midwall LGE pattern on cardiac MRI. MicroRNA and mRNA levels were determined by qRT-PCR, serum protein levels by ELISA. Human biopsy material was extracted with the miRVANA extraction kit (Ambion), cDNA synthesis and qRT-PCR was performed with specific amplification kits (Applied Biosystems).
Results: On average, left ventricular ejection fraction was slightly reduced in the myocarditis group and strongly reduced in the DCM group (LVEF upon ventriculography 51% vs. 39%, $p < 0.006$). Both myocarditis and DCM patients were characterized by higher endomyocardial miR-221/miR-222 gene expression than in control patients ($p < 0.01$), whereas no changes were noted in genes related to viral replication (MDA5, RIG1, TLR3) in all groups. Both miR-221 and miR-222 levels positively correlated with left ventricular end-diastolic volume. Furthermore, although serum sST2 and NT-pro-BNP levels were significantly elevated in both patient groups, levels were significantly higher in the DCM group compared to the myocarditis group.

The best independent discriminator between myocarditis and DCM, was elevated complement C3 - rather than C-reactive protein - in serum of myocarditis patients compared to control and DCM.
Conclusions: The inflammatory miR-221/-222 cluster is of importance both in the pathophysiology of myocarditis and DCM, and correlates with left ventricular end-diastolic volume (among other markers of LV dysfunction). Nevertheless, both the miR-cluster and markers of viral replication did not help to discriminate between myocarditis and DCM. In contrast, activated complement C3 levels in serum are significantly higher in myocarditis patients compared to DCM patients, and this parameter helps to distinguish between myocarditis and idiopathic DCM.

Background: Heart failure with preserved ejection fraction (HFpEF) is associated with high left ventricular (LV) diastolic stiffness, which can be attributed partly to elevated cardiomyocyte stiffness. The giant cytoskeletal protein, titin, is central to high cardiomyocyte stiffness and thus LV diastolic stiffness in HFpEF. Small heat shock proteins (sHSPs), such as aB-crystallin and HSP27, function to protect titin and consequently, prevent elevations in cardiomyocyte passive stiffness. Recently, we reported that high stiffness in isolated cardiomyoctes from patients with aortic stenosis can be lowered with the administration of exogenous aB-crystallin. This suggests that boosting sHSPs may be a viable therapeutic strategy in alleviating titin-based cardiomyocte stiffness and thus LV diastolic stiffness in HFpEF.
Aims: To examine the therapeutic effect of the HSP-inducing drug, geranylgeranylacetone (GGA) in HFpEF.
Methods: 20-week old male obese ZSF1 hybrid rats, a validated model of HFpEF, were randomised to receive GGA (200mg/kg/day) or vehicle by oral gavage for 4 weeks. At the end of the treatment period, rats were subjected to echocardiography and cardiac catheterisation to assess global LV diastolic function. Titin-based cardiomyocyte stiffness was evaluated in single Triton-permeabilised cardiomyoctes at sarcomere lengths (SLs) ranging from 1.8μm to 2.4μm.
Results: When compared to the lean control rats, obese ZSF1 rats demonstrated evidence of global LV diastolic dysfunction such as increased deceleration time (47 ± 1 vs. 57 ± 3ms, $P < 0.05$), prolonged isovolumetric relaxation time (45 ± 3 vs. 52 ± 2ms) and elevated end-diastolic pressures (5.0 ± 0.3 vs. 7.0 ± 1.8mmHg). Such abnormalities in diastolic function were not observed in GGA-treated obese ZSF1 rats. Passive force (Fpassive) was significantly higher ($P < 0.01$) at all SLs in obese ZSF1 rats compared to the lean controls, suggesting diastolic dysfunction may have arisen from elevated titin-based cardiomyocyte stiffness. Four weeks of GGA treatment in obese ZSF1 rats significantly lowered Fpassive at the physiological SLs 1.8μm (0.45 ± 0.09 vs. 0.26 ± 0.04kN/m^2, $P = 0.05$), 2.0μm (0.91 ± 0.13 vs. 0.49 ± 0.1kN/m^2 $P < 0.01$) and 2.2μm (1.45 ± 0.17 vs. 1.04 ± 0.12kN/m^2, $P = 0.05$), although no difference was observed at 2.4μm (2.14 ± 0.25 vs. 1.77 ± 0.23kN/m^2, NS) compared to untreated obese ZSF1 rats. Importantly, we found a ~2 to 3-fold greater aB-crystallin and HSP27 expression in the myofilament fraction of LV samples of GGA-treated obese ZSF1 rats, when compared to the vehicle-treated obese ZSF1 rats.
Conclusion: Four weeks of GGA treatment increased sHSPs surrounding the myofilament proteins, such as titin, likely explaining the lower cardiomyocyte passive stiffness observed in these obese ZSF1 rats. These data suggest that GGA may be a viable therapeutic strategy in alleviating high cardiomyocyte stiffness and thus LV diastolic dysfunction in HFpEF.

Funding Acknowledgements: MFF Tyrol

Background: Adjuvant thoracic radiation has significantly improved the survival of patients with breast cancer, Hodgkin's disease and thoracic malignancies. However, cardiovascular disease after thoracic radiation has become the leading nonmalignant cause of death in cancer survivors. Radiation causes microvascular endothelial injury resulting in impaired cardiac function. The molecular mechanism of radiation induced microvascular damage remains unknown.
Purpose: Danger associated molecular patterns (DAMPs) are released from stressed cells and are known to activate Toll-like receptor 3 (TLR3), a receptor of the innate immune system. We hypothesized that radiation leads to release of DAMPs with subsequent activation of TLR3. Concomitant inflammation causes endothelial injury resulting in impaired myocardial function.
Methods: Endothelial cells were isolated from healthy donors undergoing heart transplantation and treated with radiation therapy (10Gy). Expression levels of TLR3 and inflammatory cytokines were compared with cells treated either with TLR3 agonist poly (I:C) or a TLR3/dsRNA complex inhibitor. Cell cycle analysis via flow cytometry was performed after radiation. To investigate in vivo effects, ApoE-/- and ApoE-/-/TLR3-/- mice underwent thoracic radiation (15Gy). Heart function and morphology was analyzed via transthoracic echocardiography, microCT and histological evaluation.
Results: Radiation resulted in activation of the TLR3 pathway with upregulation of downstream proteins TIR-domain-containing adapter-inducing interferon-ß (TRIF) and transcription factor Interferon regulatory factor 3 (IRF3). Expression of the inflammatory cytokines TNF-a, IL-6, IFN-y and IL-10 was increased after radiation. TLR3 inhibition abrogated radiation-dependent inflammatory response of endothelial cells resulting in reduced endothelial apoptosis. In vivo, thoracic radiation resulted in impairment of left ventricular function with reduced ejection fraction in ApoE-/- mice (LVEF %: 44.96 ± 1.70). However, left ventricular ejection fraction of ApoE-/-/TLR3-/- mice was clearly less affected by radiation (LVEF %: 50.08 ± 1.48, $p = 0.0401$). In addition, we found decreased vascular and valvular calcifications in ApoE-/-/TLR3-/- mice.
Conclusion: Radiation leads to endothelial injury and activation of TLR3. Inhibition of TLR3 prevents from inflammation and endothelial apoptosis. ApoE-/-/TLR3-/- show superior left ventricular function after thoracic radiation compared to ApoE-/- mice. We show major involvement of TLR3 in the pathogenesis of radiation induced heart failure. TLR3 could become an effective therapeutic target for the prevention of heart disease after radiation.

microRNAs and serum markers of fibrosis in dilated cardiomyopathy (DCM) are unknown.
Methods: Seventy DCM patients (48 ± 12 years, NYHA 2.6 ± 0.7, EF 24.4 ± 7.4%) underwent right ventricular biopsy. Markers of collagen type I and III synthesis - procollagen type I and III carboxy- and amino-terminal peptides (PICP, PIIICP, PINP, and PIIINP), fibrosis controlling factors - transforming growth factor (TGF1-ß), connective tissue growth factor (CTGF), osteopontin (OPN) and galectin-3 (Gal-3), and degradation enzymes - matrix metalloproteinases (MMP-2, MMP-9) and their tissue inhibitor (TIMP-1) were measured in serum. MiR-21, miR-26, miR-29, miR-30 and miR-133a were measured in myocardial tissue, sampled during biopsy, via qPCR.
Results: Only fibroblast-enriched microRNAs: miR-21, -26, and -29 correlated with PICP, TGF1-ß, MMP-2, and TIMP-1. None of cardiomyocyte-enriched microRNAs: miR-30 and -133a correlated with any serum marker of fibrosis (Table 1).
Conclusions: Associations between myocardial fibrosis-linked microRNAs and markers of fibrosis are lower than expected. Only fibroblast-enriched microRNAs weakly correlate with some parameters, whereas cardiomyocyte-enriched microRNAs did not correlate with any serum markers of fibrosis.

Funding Acknowledgements: Bristol-Myers Squibb Company

Background/Introduction: Dysregulated inflammation following myocardial infarction (MI) can lead to myocardial damage and inadequate infarct healing. Formyl peptide receptors play an important role in the ligand-dependent regulation of inflammation resolution. Stimulation of the resolution process via formyl peptide receptor activation is predicted to improve left ventricular (LV) structure/function relationships and prevent downstream pathological cardiac remodeling, which can lead to heart failure.
Purpose: We evaluated the capacity of Compound 43 (Cmpd43, 1-(4-chlorophenyl)-3-(5-isopropyl-1-methyl-3-oxo-2-phenyl-2,3-dihydro-1H-pyrazol-4-yl)urea), a small molecule dual agonist of formyl peptide receptor 1 (FPR1) and 2 (FPR2), to improve long-term LV and infarct scar remodeling following coronary artery occlusion in rodent MI models.
Methods: Cmpd43 was evaluated in phagocytosis, chemotaxis, signaling and cytokine response cell-based assays. In vivo, following occlusion of the left anterior descending (LAD) artery, C57BL/6 mice were treated with Cmpd43 (1 and 10 mg/kg or vehicle; PO gavage, QD). Treatment was started 24 h after occlusion and continued for 3 days to assess early inflammation or 4 weeks to evaluate passive LV mechanics and myocardial morphology. Structure/function studies in rats occurred following 60 min ischemia and reperfusion (I/R) at the LAD artery. Treatment (10 mg/kg Cmpd43 or vehicle, PO gavage, QD) was started 48 h post I/R and continued for 6 weeks.
Results: In vitro, Cmpd43 enhanced cellular phagocytosis and chemotaxis, exhibited dual agonist G-protein signaling and induced FPR2-dependent IL-10 secretion. In mice, Cmpd43 reduced LV chamber area and infarct size (30% and 49% 10 mg/kg vs. vehicle; respectively, $P < 0.05$) and preserved infarcted wall thickness (1 mg/kg, +1.6 fold vs. vehicle, $P < 0.05$). Passive LV mechanics and epicardial scar strains were improved as evidenced by ex vivo pressure-volume (PV) and pressure-strain analysis. Cmpd43 treatment yielded dose-dependent left shifts in PV curves and smaller scar strains in the circumferential (E11) and longitudinal (E22) direction. Increased arginase 1 levels were detected by in situ hybridization 3 days post-MI in the infarct border zone of Cmpd43-treated mice, suggesting a shift towards a pro-resolution phenotype in macrophages. In rats, Cmpd43 reduced LV end diastolic volume (17% vs vehicle, $P < 0.05$), preserved viable myocardium across the infarct wall (+1.4 fold vs. vehicle, $P < 0.01$) and improved LV ejection fraction (+12% vs. vehicle, $P < 0.05$).
Conclusion(s): These findings suggest that Cmpd43 treatment can limit adverse post-MI LV remodeling. Improvements in cardiac structure/function support the concept that agonism of formyl peptide receptors improves post-MI wound healing. Activation of the pro-resolution mechanism presents an innovative approach towards development of potentially effective drug therapies to prevent heart failure post-MI.

Left main coronary artery compression by a dilated pulmonary artery in a patient with pulmonary arterial hypertension

J Juan Farina[1]; A Lescano[1]; M Sztejfman[1]; M Gonzalez[1]; H Grancelli[1]; D Crippa[1]; G Romero[1]; V Daru[1]
[1]*Finochietto Clinic, Buenos Aires, Argentina*

A 56-year-old female patient diagnosed with idiopathic pulmonary hypertension (PH) with three years of follow-up presented dyspnea and chest pain in functional class III for 15 days, with two syncopal episodes not related to stress. Upon admission no evidence of heart failure was observed.
The ECG showed right ventricle (RV) hypertrophy and complete right bundle branch block. Echocardiography showed dilation of right chambers with mild depression of RV systolic function. The trunk of the pulmonary artery (PA) was severely dilated (55 mm), as well as its branches. Angiotomography of the chest confirmed the marked dilatation of the PA up to 54 mm. The course of the left main coronary artery (LMCA) was abnormal, with marked reduction of its lumen. The distance between the PA and the LMCA was narrow (3.6 mm) and the LMCA lumen was severely reduced. The calcium score was 0, not identifying atheroma plaques (Picture 1).

The case was assumed to be a LMCA compression syndrome by dilated PA. A coronary angiography (CAG) was performed, which showed the severe obstruction of the LMCA, with an almost parallel path to the wall of the left sinus of Valsalva due to the displacement generated by the PA. During the procedure the absence of plaques by intravascular ultrasound (IVUS) was registered. A stent of 4.5 mm x 20 mm was implanted with adequate result. The patient was discharged on treatment with sildenafil, macitentan, clopidogrel and acetylsalicylic acid. Six months after, there were no symptoms and new CAG was performed with no signs of complications.
Myocardial ischemia and its most frequent clinical manifestation (angina pectoris) may occur in patients diagnosed with PH with a prevalence ranging from 20-40%. Its physiopathology may involve different mechanisms:
1. Subendocardial ischemia due to RV hypertrophy.
2. Subendocardial ischemia due to an alteration of the coronary perfusion gradient.
3. Secondary mechanisms related to tachyarrhythmias and/or anemia, among others.
4. Presence of significant atherosclerotic coronary disease.
5. Extrinsic compression of the LMCA by dilation of the PA.
This last entity is an increasingly recognized cause of angina or other more serious complications (myocardial infarction, sudden death) in patients with PH. It should be suspected in all patients with PH who have a significant increase in the diameter of the main PA or in patients that presents angina or equivalent symptoms. The diagnostic confirmation is provided by angio-CT along with the CAG with IVUS, the latter procedure also allows the endovascular resolution of this intercurrence with the stent placement in the LMCA, todays therapeutic of choice over the revascularization surgery.
Considering the potential serious effects of this complication, suspicion, research and resolution of this entity are fundamental to improve the survival and prognosis of these patients.

Acute celular rejection after heart transplant: correlation of endomyocardial biopsy with significant elevation of circulating cell-free donor-derived DNA

T Kafunkova[1]; J Krejci[1]; M Pesl[1]; P Hude[1]; E Ozabalova[1]; J Godava[1]; V Zampachova[1]; D Nikulenkov Grochova[2]; L Spinarova[1]
[1]*St. Anne's University Hospital, Brno, Czech Republic*; [2]*Cytogenetic Lab, Brno, Czech Republic*

Introduction and Background: accurate and timely diagnosis of allograft rejection is essential for long-time survival of heart transplant recipients. The endomyocardial biopsy (EMB), currently the "gold standard" for diagnostics of acute allograft rejection, is an invasive procedure with some risks of periprocedural complications and a large interobserver variability by different pathologists.
Circulating cell-free donor-derived DNA (cfdDNA) can be detected in a blood and urine of heart transplant recipients. A few days after a heart transplant cfdDNA fraction decreases to a very low level in the absence of acute celular or antibody-mediated rejection. Significant elevation of cfdDNA fraction can be detected in the blood of recipients even several months before the appearance of graft damage on EMB.
Clinical case description: 56-years-old woman 4 months after heart transplant because of dilatative cardiomyopathy was admitted for routine EMB. All of previosly performed EMBs were without any rejection (ISHLT AR grade 0). Nowdays she suffered from mild dyspnea on exertion and cought. Echocardiography didn't show any new pathology compared to previous findings (no left ventricular (LV) hyperthrophy, normal systolic and diastolic LV function, old non significant pericardial effusion). There was a new finding of 11-times elevation of cfdDNA fraction compared to baseline level (2,26% vs. 0,21%). EMB showed a new finding of mild allograft rejection (ISHLT AR grade IB). Dose of tacrolimus was lightly increased with a tight serum concentration controls and dose od prednison was increased from 10 mg OD to 20mg OD. Dose of mycophenolate mofetil was not changed. 2 weeks later she was without any complaints and control EMB showed no rejection and also cfdDNA fraction decreased to baseline level.
Conclusions: and implications for clinical practice: changes of cfdDNA fraction in the blood or urine of heart transplant recipients could serve as non invasive diagnostics of acute allograft rejection. Further research studies with large amount of patients are needed to reduce the number or even replace routine invasive EMBs with non invasive diagnostics.

182

Recurrence of Takotsubo syndrome: one clinical presentation/trigger, but two different anatomical variants in the same patient. A case to reflect.

G Giulio Binaghi[1]; D Congia[1]; S Cossa[2]; R Ganga[3]; G Giardina[1]; M Melis[4]; G Matta[2]; A Pani[1]; D Pasqualucci[1]; E Serra[1]; M Porcu[1]
[1]*G. Brotzu Hospital, Department of Cardiology, Cagliari, Italy*; [2]*G. Brotzu Hospital, Department of Radiology, Cagliari, Italy*; [3]*G. Brotzu Hospital, Department of Interne Medicine, Cagliari, Italy*; [4]*G. Brotzu Hospital, Department of Neurology, Cagliari, Italy*

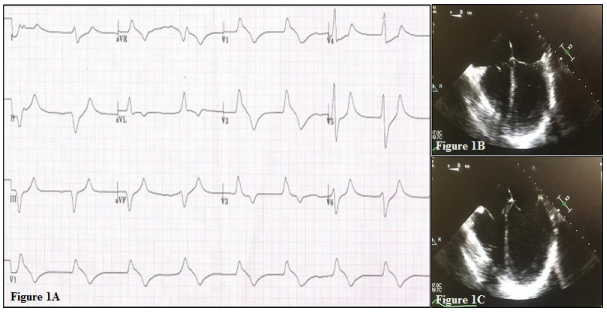
A 67-year-old woman access to our ED complaining diarrhea from one week and in the last hours also palpitations and dyspnea. She was an ex-alcoholic and had an history of breast cancer underwent surgical and radio therapy 18 years ago, but with subsequent pelvic bone metastasis treated with multiples orthopedic interventions. At hospitalization, ECG showed an atrial fibrillation and echocardiography (TTE) was normal. Laboratory tests evidenced hypo-K+ and Mg2+. Few hours after, spontaneous restoration of sinus rhythm occurred, but she suddenly became confused and developed seizures. A cerebral CT scan excluded an acute cerebral event. At the same time patient developed hypotension and a positive value of troponin I was detected in absence of ECG alterations, while TTE showed a severe left ventricular dysfunction (EF: 25%) due to akinesia of all basal segment with hyperkinesia of apex.

After adequate refilling, the hemodynamic status improved, but seizures persisted confirmed by EEG. Despite different intravenous neurologic therapies, she developed a refractory status epilepticus (SE) needing deep sedation and mechanical ventilation assistance. In following days SE resolved and TTE showed the recovery of left ventricle function; hemodynamic also improved, so it was possible to proceed to extubation. Cardiac MRI and coronary angiography were performed resulting normal and confirming our first diagnostic hypothesis of inverted Tako-Tsubo syndrome (TTS). A cerebral MRI showed a diffuse demyelination compatible with the history of alcoholism.
Discharged in therapy with bblocker and ACE-inhibitor; one week later the patient was re-hospitalized because of clonic seizures associated with hypo-K+ and Mg2+. ETT showed a picture like classical TTS (apical ballooning). Because of clinic scenario, the recent exams performed and the absence of ECG modification, we decided to support the patient and do not perform other invasive tests. Few days later the neurological and cardiac state resolved.
Acute neurological diseases are well-reported to be associated with TTS, however is rarer in case of SE. Probably TTS is unrecognized in this critical neurological state, a condition that need high therapeutic effort and resources. However, in literature it is emerging the idea that TTS could be the cause of Sudden Unexpected Death in Epilepsy (SUDEP).
Our patient had a recurrence of TTS onset with the same clinical presentation (seizures), but with two different anatomical forms: first, a reverse TTS, then a classical one. No similar cases are reported in literature, in fact usually the order of presentation of anatomical variants is inverted.
This can be justified by the hypothesis that previously affected ventricular regions are relatively protected from further injury during recurrent stress episodes.
This case highlights the need to better understand the physiopathology of TTS and the need to assess always cardiac function in case of epilepticus status.

179
Cardiogenic shock with normal ejection fraction?

A Taher[1]; H S Lim[2]
[1]Glenfield Hospital, Cardiology, Leicester, United Kingdom; *[2]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom*

A 17 year old man presented to his hospital with a 4 day history of diarrhoea & vomiting after returning from Dubai. He had no co-morbidities & did not smoke, drink alcohol or use illicit drugs. On presentation, he was self-ventilating but



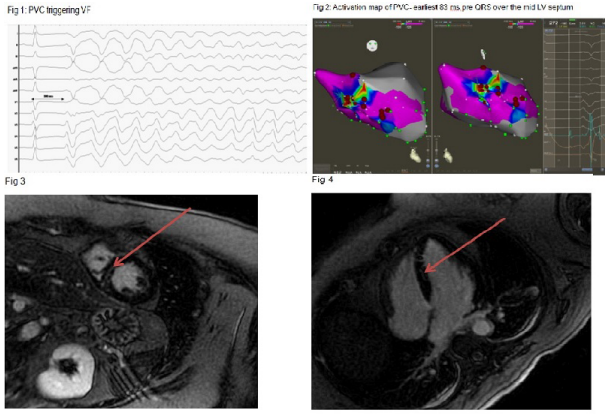
ECG and Echocardiogram

hypotensive (sBP 60). ECG on admission showed junctional rhythm at a rate of 45-50/min of RBBB morphology [Fig 1A]. Arterial blood gas showed pH 7.28, pCO2 3.9, pO2 17.5, HCO3 13.6, BE -11.7, lactate 7.8. Echo showed preserved RV & LV systolic function with normal sizes [Fig 1 B&C]. Despite high doses of noradrenaline, vasopressin, dobutamine, adrenaline & hydrocortisone, his MAP remained between 40-50, & he became anuric. Blood tests showed Alb 32, Bil 9, Ca 2.19, Cr 368, U 11.4 CRP 38, WCC 30 with Neutrophilia of 23 & left shift on blood film. Troponin increased from 43 to 249. He was started on antibiotics & antiviral therapy, & referred to our institution for mechanical circulatory support with a presumptive diagnosis of myocarditis. On arrival, a pulmonary artery catheter was inserted & showed PASP 25, PADP 10, CO of 5L/min, index of 2.8, with BP of 90/21 & HR of 50/min. The low diastolic BP, indicative of vasoplegia did not respond to high dose vasopressors. The bradycardia failed to respond to isoprenaline. We proceeded with VA-ECMO, as he continued to deteriorate with a number of brief asystolic arrests. He became persistently asystolic following VA-ECMO support & temporary pacing was inserted. However, there was failure to capture, as he was profoundly hyperkalaemic (10mmol/l). The LV was vented via thoracotomy & a cardiac biopsy was performed. This did not show evidence of myocarditis. He was commenced on CVVH & a toxicology profile was sent. Further discussions with the patient's parents revealed a history of previous self-harm & depression. The family on this occasion found several empty boxes of verapamil 240mg. Serum levels confirmed massive verapamil overdose (OD). He was treated with IV CaCl2, high dose insulin euglycaemic infusion, glucagon and 20% lipid rescue infusion. There was return of sinus rhythm after 24h and prompt & successful weaning of vasopressors & inotropes over the following 48h. The VA-ECMO was explanted after 5 days. The patient was discharged later. Problems:1)Cardiovascular manifestation of drug OD can be difficult to recognise. 2)Mechanical circulatory support can be useful as a bridge to diagnosis and recovery. Discussion:1)Atypical presentation (brady-arrhythmia in the face of shock in a young man) should prompt a search for other possible causes of shock, including drug toxicity. 2)Verapamil OD can cause bradycardia and hypotension that is refractory to inotropes & vasopressors. Treatment of verapamil OD is complex. 3)VA-ECMO support can be used successfully for hemodynamic support in OD. Conclusions:Verapamil OD can present with a combination of cardiogenic & vasoplegic shock. This atypical shock phenotype should prompt a search for other causes, including drug toxicity.

180
Extracorporeal membrane oxygenation supported ablation: unique management of fulminant myocarditis using a multidisciplinary and collaborative approach

V Val Rakita[1]; V Reddy[1]; W Whang[1]; G Dangas[1]; A Pawale[1]; S Pinney[1]; P Pirlamarla[1]; A Anywanwu[1]; A Lala[1]
[1]Mount Sinai Medical Center, New York, United States of America

A 55 year old female with 3 days of a viral prodrome suffered cardiac arrest at home due to refractory polymorphic ventricular tachycardia (PMVT) and ventricular fibrillation (VF). Initial work up included an elevated cardiac troponin-I of 1.2 ng/ml (normal range 0.00 - 0.40 ng/ml) and severely reduced ejection fraction on transthoracic echocardiography. Cardiac catheterization revealed normal coronary anatomy without evidence of obstructive coronary artery disease, but severely elevated filling pressures and a cardiac index of 1.7 L/min/m2. An endomyocardial biopsy was obtained and an intra-aortic balloon pump was placed to provide hemodynamic support. High dose steroids were administered in suspicion of giant cell myocarditis. She remained in refractory PMVT/VF storm sustaining innumerable defibrillatory shocks and as such the decision was made to place her on veno-arterial extracorporeal membrane oxygenation (VA-ECMO). After reviewing her electrocardiogram in consultation with our electrophysiology colleagues, it was discovered that she



Figures

had a focus of recurrent premature ventricular contractions (PVCs) triggering VF arrest. Despite full hemodynamic support with VA-ECMO, she continued to sustain shocks for VT/VF, and so decision was made to proceed to high-risk PVC ablation. During voltage mapping of the LV, PVC 1 (fig 1-2) was noted to frequently trigger VF. Activation mapping of PVC 1 (fig 3) demonstrated earliest activation over the mid-septum. Several foci were successfully ablated and she remained electrically quiescent and clinically stable post procedure. She was de-cannulated on post op day 2. RV biopsy did not show evidence of granulomas or giant cell. Serologic analysis was positive for Coxsackie virus. Cardiac magnetic resonance imaging was done on admission day 6, three days after ECMO was removed, revealing normal LV size with recovered LVEF of 48% and mild hypokinesis of the mid-inferoseptal and apical septal wall segments. On delayed enhancement imaging, there was intramyocardial scar in the mid inferoseptal, apical anterior, and apical septal walls (Fig 4-6) consistent with focal myocarditis. She received a single chamber implantable cardioverter defibrillator for secondary prevention on hospital day 8. She was discharged to home on hospital day 11.

This case highlights the importance of a multidisciplinary collaborative approach to management of a unique presentation of fulminant myocarditis. Complete mechanical hemodynamic support permitted the safe and successful ablation of PVC-inducing VF storm. Restoration of electric stability ultimately led to decannulation and myocardial recovery in the setting of fulminant myocarditis.

Right and left heart failure due to carcinoid heart disease complicated by a PFO with right-to-left shunt: a case report

M Lichtenauer[1]; M Mirna[1]; S Eder[2]; B Wernly[1]; V Paar[1]; E Prinz[1]; UC Hoppe[1]
[1]Paracelsus Private Medical University, Internal Medicine II, Cardiology, Salzburg, Austria; *[2]Oberndorf Hospital, Department of Internal Medicine, Oberndorf, Austria*

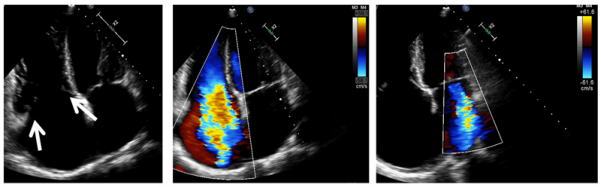
Carcinoid syndrome is a rare cause for acquired valvular heart failure. Carcinoid heart disease (CHD) occurs in 20-70% of the patients with carcinoid tumors leading to fibrotic remodeling of valvular structures, however due to degradation of serotonin in the pulmonary circulation usually only the right heart is involved. Here, we report the case of a 57 year old woman presenting with heart failure due to carcinoid syndrome. The patient was admitted to our clinic because of dyspnea and edema of the lower extremities. Transthoracic and transesophageal echocardiography showed severe tricuspid and moderate to severe mitral regurgitation. The leaflets of the tricuspid valve almost showed no motion at all. This pattern is typical for carcinoid heart disease caused by direct negative effects of serotonin in the right heart circulation leading to fibrosis of the leaflets. Furthermore, a small PFO with right to left shunt was found. We performed urine analysis screening for 5-hydroxyindoleacetic acid excretion, which proved to be severely elevated. Also serotonin (596U/l) and chromogranin A (1248µg/l) levels were elevated more than ten-fold. Next, we conducted a PET-CT scan which revealed a tumorous mass within in the liver. The primary tumor was thought to be located in the in the terminal ileum. Based on these results we hypothesized that the cause for the described symptoms was heart failure due to carcinoid heart disease. A medical therapy with the somatostatin analogue Lanreotide together with heart failure treatment was started.

During open heart surgery, it was also found that also the mitral valve was severely affected by fibrosis. We think that this was caused by direct serotonin-related effects due to the right to left shunt through the PFO leading to fibrosis of the mitral valve leaflets. A tricuspid replacement (Edwards St. Jude Epic, 33mm bioprostesis) and mitral valve repair (Edwards Physio Ring, 30 mm) was conducted successfully together with closure of the PFO and the patient showed good convalescence. This was also documented with decreasing levels of pro-BNP over the follow-up period (from 7830pg/ml to 982pg/ml).

Two months later, a hemicolectomy and liver segment resection (segment VI/VII and III) was performed. The tumor metastasis in the liver was extirpated and the (immuno-)histological analysis confirmed the diagnosis (neuroendocrine tumor of the terminal ileum).

The patient was followed-up for further 2 years and presented herself in good health without signs of recurring heart failure. At the recent follow-up exam including MRI of the abdomen new metastases were found in the liver and the patient is scheduled to undergo another liver segment resection.

This case is unique since the patient developed both right and left ventricular dysfunction due to fibrotic remodeling of not just the tricuspid valve as usually seen in carcinoid heart disease but also fibrosis of the mitral valve because of right to left shunt through a PFO.



Diagnostics - From epicardial fatty tissue to biomarkers and echocardiography

Background: A proinflammatory state and the epicardial adipose tissue (EAT) have been suggested to play a role in impaired myocardial mechanics. This epidemiological study investigates their role for impaired relaxation in a population-based adult cohort without clinically overt heart failure or coronary artery disease.
Methods: This epidemiological study tested circulatory cytokines, EAT thickness, traditional risk factors, and multiple anthropometric measurements for prediction of impaired relaxation. EAT thickness was measured by transthoracic echocardiography using published protocols.
Results: Transthoracic echocardiography was performed in 520 participants; 14 participants were excluded for atrial fibrillation (n = 6), left ventricular ejection fraction < 50% (n = 5), or = moderate mitral regurgitation (n = 3). Mean age of included participants was 51 ± 17y; 55% were females; BMI was 25.6 ± 4.6 kg/m2. The prevalence of traditional cardiovascular risk factors corresponded to other European cohorts. Diastolic dysfunction pursuant to current guidelines was present in 4%; the prevalence of early mitral annulus e' velocity < 9 cm/s and mitral E-wave/e' ratio >8.5 was 29% and 14%, respectively. Participants with EAT thickness >median EAT value (4.5 mm) were older (57 vs 34y) and more often female (56 vs 52%); traditional risk factors were more prevalent while creatinine, smoking habits, and hemoglobin level were not significantly different. The echocardiographic parameters in this group (n = 246) were compatible with a concentric cardiac phenotype. Multivariate analysis adjusted for age, gender, and body height showed that both EAT and e' velocity share prediction by blood pressure, dyslipidemia, and anthropometric measurements of obesity. However, HbA1c, and circulatory levels of C-reactive protein or interferon y exclusively correlated with EAT whereas e' velocity was associated with circulatory levels of interleukin-6 or TNFa, and EAT thickness. Despite of the fact that EAT and e' velocity have common predictors, EAT remained an independent predictor of e' velocity in a multivariate model adjusted with measured cytokines in addition.
Conclusions: This epidemiologic study shows that both interleukin-6 and EAT thickness independently predict impaired relaxation in asymptomatic participants of a population-based cohort.

The BNP genetic variant rs198389: cardiovascular phenotype and risk in stage A/B heart failure subjects from the STOP-HF Trial

V Cannone[1]; C Watson[2]; M Ledwidge[2]; JC Burnett Jr[1]; K Mc Donald[2]
[1]Mayo Clinic, Department of Cardiovascular Disease, Rochester, United States of America; *[2]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland*

Funding Acknowledgements: This study was supported by the Mayo Clinic Cardiovascular Circulatory Program Award

Background: B-type natriuretic peptide (BNP) is a cardiac hormone secreted by the heart in response to myocardial stretch and volume overload. BNP possesses blood pressure lowering, natriuretic, antifibrotic and aldosterone suppressing properties. In the general population, the minor G allele of the BNP genetic variant rs198389 is associated with higher circulating values of BNP, lower blood pressure and odds of hypertension, lower cardiovascular mortality and increased lifespan.
Purpose: We aimed to investigate the clinical phenotype and cardiovascular risk associated with rs198389 genotypes in subjects at risk for heart failure (HF).
Methods: We genotyped 971 subjects with stage A/B HF from the cohort of the STOP-HF Trial.
Results: The frequencies of the rs198389 genotypes were AA: 38% (n= 367), AG: 47% (n= 455), GG: 15% (n= 149). All subsequent analyses are AA vs GG. The two genotypes did not differ in terms of age and sex. In the multivariate adjusted analysis, the GG genotype had significantly higher circulating levels of BNP (36.3 vs 50.7 pg/mL, p value < 0.001). Prevalence of hypertension was significantly lower among the homozygotes for the G allele (77.7% vs 67.1%, p value: 0.014). In the 4.95 (IQR 3.26-6.61) years follow-up analysis, the carriers of the GG genotype had lower risk of new onset left ventricular systolic dysfunction with ejection fraction < 50% and more than 5% decrease (4.4% vs 0.67%, p value: 0.032). When we evaluated the change in BNP levels over the same time period, the two groups increased by similar amount (around 5 pg/mL per annum) maintaining their significantly different set point over time. The two genotypes did not differ in terms of blood pressure, body mass index, creatinine levels, new onset of major adverse cardiovascular events and mortality.
Conclusion: In the STOP-HF Trial cohort including subjects with stage A/B HF failure, the GG genotype of the BNP genetic variant rs198389 is associated with higher BNP circulating levels, lower prevalence of hypertension and lower risk of incident left ventricular systolic dysfunction over time. Our findings suggest a cardiovascular protective role exerted by the cardiac hormone BNP in the clinical context of stage A/B heart failure and may support the concept of a natriuretic peptide-based therapy for prevention of HF.

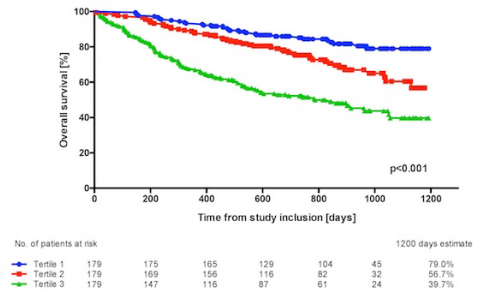
213

Cardiac fibrosis marker GDF-15 is associated with prognosis in treatment naive cancer patients

H Arfsten[1]; A Cho[1]; C Mayrhofer[1]; M Raderer[2]; G Goliasch[1]; R Wurm[1]; G Strunk[3]; C Zielinski[2]; M Huelsmann[1]; N Pavo[1]
[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]Medical University of Vienna, Department of Internal Medicine I, Division of Oncology and Hematology, Vienna, Austria*; *[3]Complexity Research, Vienna, Austria*

Background: The prognostic importance of growth differentiating factor-15 (GDF-15) has been investigated in numerous pathologic cardiac processes as myocardial infarction or heart failure. Elevated levels of GDF-15, which is equally implicated in cell growth and survival, have also been observed in distinct tumor entities. However, its general impact on prognosis in cancer has not been investigated yet. This study aimed to explore whether cardiac fibrosis marker GDF-15 has ability to predict long-term mortality also in an unselected cohort of cancer patients without prior anti-cancer therapy.
Methods. We prospectively enrolled 555 consecutive treatment naïve patients with primary diagnosis of cancer. GDF-15 as well as other cardiac and routine laboratory markers were determined. All-cause mortality was defined as the primary endpoint.

Figure 1. Overall survival rates for treatment-naïve cancer patients (n=555) according to tertiles of GDF-15 (p<0.001 between all groups, log-rank test).



Results: GDF-15 levels were 338pg/ml (IQR 205-534) for the total cohort and values were comparable in different tumor entities except for lower concentrations in breast cancer patients (Figure 1). Metastatic disease was characterized by higher circulating GDF-15 [266 (IQR 175-427) vs 435 (IQR 279-614), $p < 0.001$]. GDF-15 was significantly associated with all-cause mortality in the univariate analysis [crude HR for ln(GDF-15) 2.08, 95%CI:1.77-2.43, $p < 0.001$] and this effect was persistent after multivariate adjustment. Kaplan-Meier analysis revealed the high discriminatory power of GDF-15 ($p < 0.001$ between all groups according to tertiles) (Figure 2). There was a significant interaction of solid and liquid malignancies with loss of association of GDF-15 with outcome in myelodysplastic and myeloproliferative disease. GDF-15 correlated positively with the inflammatory status reflected by CRP, SAA and IL-6 ($r = 0.31$, $p < 0.001$, $r = 0.23$, $p < 0.001$ and $r = 0.14$, $p = 0.002$) and cardiac biomarkers as NT-proBNP, hsTnT or MR-proADM and CT-proET1 ($r = 0.46$; $r = 0.46$; $r = 0.59$; $r = 0.50$, $p < 0.001$ for all).
Conclusions: Increased plasma GDF-15 levels are associated with disease severity and all-cause mortality in solid tumors of treatment-naïve cancer patients. This association accompanies progressing systemic inflammation with subclinical involvement of other organ systems including the heart. GDF-15 represents a further molecule in the field of cardiooncology linking pathophysiologic conditions of both cardiac and neoplastic disease.

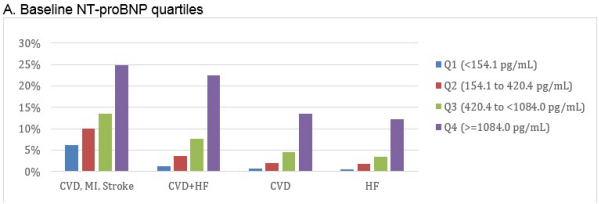
Serial monitoring of NT-proBNP predicts heart failure in patients with type 2 diabetes mellitus

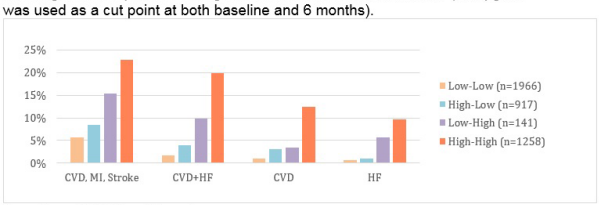
P Petr Jarolim[1]; WB White[2]; CP Cannon[3]; Q Gao[3]; DA Morrow[1]
[1]Brigham and Women's Hospital, Harvard Medical School, Boston, United States of America; *[2]University of Connecticut School of Medicine, Calhoun Cardiology Center, Farmington, United States of America*; *[3]Baim Institute for Clinical Research, Boston, United States of America*

Background: Diabetes mellitus (DM) is associated with an increased risk of microvascular and macrovascular disease. In addition, heart failure (HF) has emerged as an increasingly important complication of DM. Patients with type 2 DM (T2DM) are almost twice as likely to develop HF as patients without DM and, eventually, almost half of patients with T2DM are diagnosed with HF. In addition, some oral hypoglycemic agents increase the likelihood of developing HF, and HF itself has become a target for preventive pharmacotherapies in T2DM. Therefore, enhanced recognition of patients at risk for or who are early in the development of HF is needed to potentially guide therapeutic decision-making.

Figure: Kaplan-Meier rates for outcomes at 24 months stratified by
A. Baseline NT-proBNP quartiles



B. Categorical NT-proBNP change between baseline and 6 months (400 pg/mL was used as a cut point at both baseline and 6 months).



* p-value <0.001 for all trends

Purpose: To investigate the prognostic implications of changes in N-terminal B-type natriuretic peptide (NT-proBNP) concentration over time in patients with T2DM and ischemic heart disease enrolled in the EXAMINE trial.
Methods: EXAMINE was a phase IIIb clinical outcomes trial of alogliptin, a nonselective dipeptidyl peptidase 4 (DPP-4) inhibitor. 5380 patients with T2DM and a recent acute coronary syndrome were enrolled in the trial. NT-proBNP was measured in 5224 patients at baseline and in 4367 patients at 6 months. Cardiovascular (CV) death or hospitalization for heart failure (HF) was the endpoint of principal interest for this analysis.
Results: We observed a strong graded relationship between increasing baseline (Figure A) and 6-month NT-proBNP concentration and the incidence of major cardiovascular events. After adjusting for potential confounders, concentrations of NT-proBNP at baseline were independently associated with the development of major CV events, particularly hospitalization for heart failure. Patients who were persistently or became high at 6 months were at a significantly higher risk of adverse outcomes than those who remained low at both time points or who had a high NT-proBNP at baseline but subsequently declined to the low category (Figure B). The absolute changes in NT-proBNP by 6 months were also strongly associated with subsequent outcomes.
Conclusions: Serial monitoring of NT-proBNP in patients with T2DM and ischemic heart disease may be useful for identifying patients with T2DM at highest risk for HF. Treatment with a DPP-4 inhibitor did not meaningfully alter NT-proBNP concentration.

216

Real-World application of guideline adherence score in ambulatory systolic heart failure patients, attending a dedicated heart failure clinic

A Ali[1]; N Lagzouli[1]; US Siddique[1]; P Cliffe[1]; C Zerafa[1]; P Phen[1]; J Dungu[1]; R Barbagallo[1]; HO Savage[1]
[1]Basildon and Thurrock University Hospitals NHS Foundation Trust, The Essex Cardiothoracic Centre, Basildon, United Kingdom

Introduction: Adherence to guideline recommended therapy for the treatment of chronic heart failure is associated with improved cardiovascular outcomes. The Qualify International Registry developed a global adherence score based on the prescription of ACEIs, ARBs, Beta-blockers, MRAs and Ivabradine in order to determine the outcomes in patients recently hospitalised for heart failure.
Purpose: We aimed to assess the adherence to guideline recommended pharmacotherapy for the treatment of heart failure with a reduced ejection fraction, using this global adherence score, in new attendees of a rapid access heart failure clinic (RAHFC) at a secondary care hospital and its impact on outcomes.
Methods: We implemented this score: good (1), moderate (<0.5 to < 1) and poor (= 0.5), to a cohort of 106 new patients attending a RAHFC at a secondary care hospital over a one year period. Individual medications were also recorded as having been prescribed at recommended target doses (TD), = 50% of TD and < 50% of TD and we observed the impact on readmissions for heart failure, progression to device therapy and mortality.
Results: Of the 106 attendees, 15 were diagnosed with HFpEF and excluded from the analysis. In the 91 eligible patients, 63% were men and 27% women, with mean ages of 64 ± 12 years for men and 69 ± 11 years for women. Mean ejection fraction was 28 ± 10%. Adherence was "good" in 63% of patients, "moderate" in 33% of patients and "poor" in 4% of patients. Average time to maximum tolerated doses was 70 ± 65 days. Mean NTProBNP values were 2148 ± 1623ng/L.
Overall, 94% were prescribed an ACEI or ARB, 88% prescribed a beta-blocker, 85% prescribed an MRA, and 44% were prescribed ivabradine. With the exception of ACEi (58%), less than half of patients achieved = 50% of the target dose (TD) for all classes of drugs, 44%, 49%, 31% and 8% for ARB, BB, MRA and Ivabradine respectively.
However at 12 months follow up, more frequent reviews in the RAHFC was associated with a better adherence score; 3.3 visits (good) 2.9 (moderate), 2.2 (poor). There was a significant association between the score and readmissions for heart failure; (0.4% (good), 0.5% (moderate) and 1.2% (poor)($p = 0.019$). In addition, there was an inverse correlation between the frequency of review in the RAHFC and readmissions for heart failure ($r = -0.968$). Over the period of follow up, 5 patients progressed to device therapy, 4(good), 1(moderate) and 1 patient died in the moderate adherence group.
Conclusion: Compared with heterogeneous registry data, we have shown that a higher proportion of real world heart failure patients, managed in a specialised heart failure service, had better adherence to disease modifying therapy for heart failure with a reduced ejection fraction, with a trend to better outcomes. Our data suggests more work needs to be done to ensure timely up titration to target doses, which have been shown in randomised trials, to have the most benefit for patients.

210

Neurohormonal function across categories of systolic dysfunction in chronic heart failure

A Alberto Aimo[1]; G Vergaro[2]; N Ghionzoli[2]; C Prontera[2]; A Gabutti[2]; R Poletti[2]; A Giannoni[2]; C Mammini[2]; C Passino[1]; M Emdin[1]
[1]Sant'Anna School of Advanced Studies, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*

Background: Latest European Society of Cardiology guidelines introduced a new categorization of heart failure (HF) patients based on left ventricular ejection fraction (LVEF): HF with reduced EF (HFrEF; LVEF <40%), HF with mid-range EF (HFmrEF; LVEF 40-49%), and HF with preserved EF (HFpEF; LVEF = 50%). No treatment has demonstrated prognostic benefit in HFpEF, and there are no clear recommendations for HFmrEF.

Methods: Patients with stable HF evaluated at a tertiary referral centre from 1999 to 2017 were considered. Circulating biomarkers (plasma renin activity - PRA, aldosterone, norepinephrine, N-terminal fraction of pro- B-type natriuretic peptide), and time-domain measures of heart rate variability (HRV; standard deviation of NN intervals - SDNN, standard deviation of the average NN intervals for each 5 min segments - SDANN, percentage of successive RR intervals that differ by more than 50 ms - pNN50, root mean square of successive RR interval differences - rMSSD) were evaluated as part of baseline assessment.
Results: Out of the entire population (n = 2791), 1000 patients (36%) had information on biomarkers and HRV (HFrEF, n = 684; HFmrEF, n = 203; HFpEF, n = 113). Samples of 113 patients, matched based on age and gender to the original populations, were derived from the HFrEF and HFmrEF groups. Median ages were 68 years (62-75), 68 (57-76), and 71 (61-79) in the HFrEF, HFmrEF, and HFpEF groups; men were 75%, 71%, and 59% in the three subsets.
All indices except for aldosterone, pNN50, and rMSSD differed significantly across LVEF categories. The neurohormonal profile in HFmrEF was better than in HFrEF, and similar to HFpEF except for lower SDNN. There was a trend towards higher aldosterone levels in HFpEF than in HFmrEF and even HFrEF.
When considering two HFrEF subgroups based on the severity of systolic dysfunction (LVEF <25% vs. = 25%, n = 113 in both cases), all parameters except for aldosterone, pNN50 and rMSSD were significantly more altered in those with LVEF <25%. By contrast, patients with LVEF = 25% resembled those with LVEF = 40% except for higher PRA and NT-proBNP.
Conclusions: The degree of neurohormonal activation is similar between HFpEF and HFmrEF, and lower than in HFrEF (especially the subgroup with more severe systolic dysfunction). By contrast, aldosterone tends to increase from HFrEF to HFpEF. These findings may help explain the systematic failure of trials on neurohormonal antagonism in HFpEF, with borderline survival benefit from spironolactone. Further assessment of aldosterone antagonists and therapeutic strategies targeting the mechanisms of HFpEF onset and progression are then warranted.

211

BNP in patients with severe aortic valve stenosis undergoing valve replacement: pathophysiological determinants and long-term impact on mortality

MT Micha Maeder[1]; L Weber[1]; P Ammann[1]; M Buser[1]; NF Ehl[1]; M Gerhard[1]; PK Haager[1]; F Maisano[2]; H Rickli[1]
[1]Cantonal Hospital St. Gallen, St. Gallen, Switzerland; *[2]University Hospital, Zürich, Switzerland*

Background: In patients with aortic stenosis (AS), B-type natriuretic peptide (BNP) is a marker of disease severity and prognosis. Therefore, BNP is used as a tool for decision making regarding aortic valve replacement (AVR) in ambiguous situations. However, little is known about the pathophysiological correlates and the long-term prognostic value of high BNP in severe AS.
Methods: We measured BNP in 252 patients (age 74 ± 10 years, 58% males) with severe AS [indexed aortic valve area (iAVA) 0.4 ± 0.1 cm2/m2, left ventricular ejection fraction (LVEF) 57 ± 12%] the day before pre-AVR right heart catheterization. All patients subsequently underwent surgical (n = 157) or transcatheter (n = 95) AVR. The median follow-up was 3.1 (interquartile range, 2.3-4.3) years.
Results: The median BNP plasma concentration in the entire cohort was 188 (78-452) ng/l. Patients with supramedian BNP (BNP = 188 ng/l) were older (78 ± 9 vs. 72 ± 10 years), more symptomatic (44 vs. 20% in NYHA class III/IV), more likely to be on loop diuretics (62 vs. 39%), spironolactone (2 vs. 8%), and digoxin (16 vs. 1%), had lower body mass index (BMI; 27 ± 5 vs. 29 ± 5 kg/m2), estimated glomerular filtration rate (66 ± 29 vs. 80 ± 26 ml/min/1.73 m2), hemoglobin (130 ± 19 vs. 138 ± 15 g/l), forced expiratory volume within the first second (81 ± 21 vs. 91 ± 21 %predicted), and LVEF (53 ± 14 vs. 61 ± 10%), and had higher mean pulmonary artery pressure (mPAP; 31 ± 11 vs. 20 ± 6 mmHg), and mean pulmonary artery wedge pressure (20 ± 8 vs. 12 ± 5 mmHg; p < 0.05 for all comparisons). There was a trend toward a lower iAVA in patients with supramedian versus inframedian BNP (0.40 ± 0.12 vs. 0.43 ± 0.12 cm2/m2; p = 0.051). Parameters independently associated with higher BNP (ln-transformed values) included higher age, lower BMI, lower hemoglobin, lower LVEF, and higher mPAP (r2 for the entire model: 0.59), the strongest correlation being that with mPAP (r = 0.66). Patients with supramedian BNP had both higher 30 day mortality post AVR (p = 0.03) and higher long-term mortality (log rank p = 0.001).
Conclusions: In patients with severe AS, BNP is a marker of more advanced disease in terms of both hemodynamics and non-cardiac co-morbidities, and thereby a predictor of long-term post-AVR mortality. Importantly, non-cardiac factors known to be associated with higher BNP including older age, lower BMI and lower hemoglobin have significant impact on BNP also in the setting of severe AS which has to be taken into account when using BNP for decision making regarding AVR.

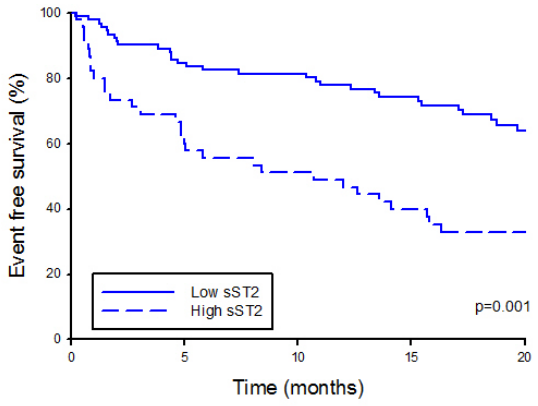
212

Elevated suppression of tumorigenicity 2 associated with poor outcome in heart failure with preserved ejection fraction

C Clotilde Roy[1]; A Slimani[1]; C De Meester[1]; M Amzulescu[1]; A Pasquet[1]; D Vancraeynest[1]; C Beauloye[1]; J-L Vanoverschelde[1]; B Gerber[1]; A-C Pouleur[1]
[1]Cliniques Saint-Luc UCL, Cardiology, Brussels, Belgium

Introduction: Soluble suppression of tumorigenicity 2(sST2) receptor is a well known biomarker implicated in inflammatory diseases. It has already been shown that sST2 is associated with worse outcome in HFrEF. In HFpEF, data are rather limited.
Purpose: We sought to evaluate the association of sST2 with clinical, laboratory and imaging findings and its prognostic value in HFpEF patients.
Methods: Between January 2015 and June 2017, we prospectively enrolled 137 consecutive patients with HFpEF (79 ± 8 years, 61% women). Elevated sST2 was determined by an age and sex-adjusted cutoff value (cutoff 55 ng/ml) corresponding to mean + 2 standard deviations in 31 controls (75 ± 6years, 61% women). All patients underwent complete 2D echo and cMR. Patients were followed up for a composite outcome of all-cause mortality and first HF hospitalization.
Results: In HFpEF patients, median sST2 level was 44.5 ng/ml (IQR: 31.6-62.2 ng/ml). Elevated sST2 (n = 46) had an impaired right ventricular function (FAC 39 ± 10% vs 43 ± 8%, p = 0.017; TAPSE 17.4 ± 5.6mm vs 19.2 ± 5.2mm, p = 0.067; RVEF by cMR 53.5 ± 9.8% vs 58.1 ± 7.8%, p = 0.008) and higher proportion with pathologic RV/RA gradient (n = 20 (40%) vs n = 23 (26%), p = 0.034). They were similar for other clinical, laboratory and imaging characteristics. Multivariate analysis showed that only RVEF by cMR was associated with high sST2 level (OR: 0.94 [0.89-0.99] p = 0.010).
During a mean follow-up of 20 ± 8months, seventy one patients (52%) reached the combined end point. Cox analysis identified GFR, hemoglobin, sST2 , use of loop diuretic and E/e' ratio as significant predictors of outcome. GFR (HR= 0.98 [0.96-0.99], p < 0.001) and sST2 (HR= 3.64 [1.37-9.65], p = 0.009) were significantly associated with the composite outcome even after adjusting for important clinical and imaging covariables.
Kaplan Meier event free survival curve showed that HFpEF patients with high sST2 had poorer 20months prognosis than those with low sST2 (p = 0.001, Figure)
Conclusions: In HFpEF, sST2 is associated with impaired right ventricular function and with a poorer prognosis with higher rate of all cause mortality and first HF hospitalization.

Event free survival Kaplan Meier curve according to sST2 level



Low sST2	91	77	72	59	35
High sST2	46	27	23	17	12

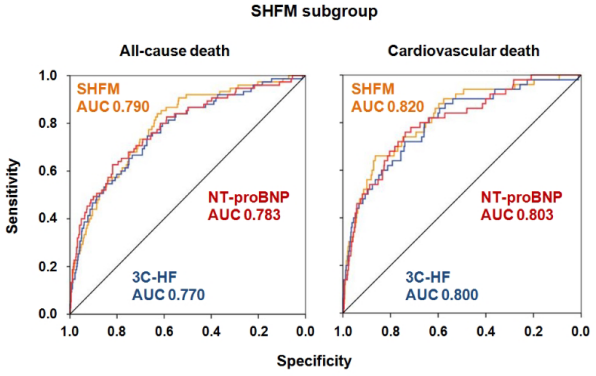
214

N-terminal fraction of pro-B-type natriuretic peptide vs. clinical risk scores for prognostic stratification in chronic systolic heart failure

A Alberto Aimo[1]; C Arzilli[2]; G Vergaro[2]; A Ripoli[2]; M Senni[3]; M Emdin[1]; C Passino[1]
[1]Sant'Anna School of Advanced Studies, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*; *[3]Ospedale Papa Giovanni XXIII, Bergamo, Italy*

Background: The Seattle Heart Failure Model (SHFM) or the Cardiac and Comorbid Conditions (3C-HF) scores may help define patient risk in heart failure (HF). Direct

comparisons between them or versus N-terminal fraction of pro-B-type natriuretic peptide (NT-proBNP) have never been performed.
Methods: Data from consecutive patients with stable systolic HF (left ventricular ejection fraction < 50%), and 3C-HF data were examined. A subgroup of patients had SHFM data available. The endpoints were 1-year all-cause or cardiovascular death.
Results: The whole population included 2023 patients, 798 (39%) with SHFM data. Mean age was 71 years, 75% were men, and 47% had ischaemic HF. At 1 year time-point, 198 deaths were recorded (10%), 124 of them (63%) from cardiovascular causes. While areas under the curve (AUC) were not significantly different, NT-proBNP displayed better reclassification capability than the 3C-HF score for the prediction of 1-year all-cause death, and (at least for net reclassification improvement) cardiovascular death. Adding NT-proBNP to the 3C-HF score resulted in a significant improvement in risk prediction.
Among patients with SHFM data available (n = 798), the AUC values for all-cause death were higher for the SHFM score (0.790) and NT-proBNP (0.783), and lower for the 3C-HF score (0.770). For cardiovascular death, the prognostic performances were slightly better, AUC values being 0.820 for the SHFM score, 0.803 for NT-proBNP, and 0.800 for the 3C-HF score. The combination of 3C-HF score and NT-proBNP displayed a similar prognostic performance than the SHFM score for both endpoints. Adding NT-proBNP to the SHFM score performed better than the SHFM alone in terms of reclassification, but not discrimination.
Conclusions: Among patients with chronic systolic HF, NT-proBNP levels had better reclassification capability for all-cause and cardiovascular death than the 3C-HF score. The inclusion of NT-proBNP to the 3C-HF score resulted in significantly better risk stratification. In a subgroup with SHFM data, the SHFM and 3C-HF scores and NT-proBNP yielded similar AUC values. The combination of the 3C-HF score and NT-proBNP had a similar prognostic performance than the SHFM score, while adding NT-proBNP to the SHFM improved reclassification over the SHFM score.



217
Prevalence and prognostic implications of longitudinal ejection fraction change in heart failure

O Ola Vedin[1]; G Savarese[2]; U Dahlstrom[3]; CSP Lam[4]; LH Lund[2]
[1]Uppsala University Hospital, Department of Medical Sciences, Cardiology, Uppsala, Sweden; [2]Karolinska Institute, Stockholm, Sweden; [3]Linkoping University Hospital, Linkoping, Sweden; [4]National Heart Centre Singapore, Singapore, Singapore

Background: In addition to the use of ejection fraction (EF) as a mere categorization tool in heart failure the clinical significance of EF change over time is becoming increasingly recognized but remains poorly described.
Purpose: We evaluated incidence and predictors of EF change and its associations with outcomes in a large cohort of patients with HF with reduced (HFrEF), mid-range (HFmrEF), and preserved EF (HFpEF).
Methods: Patients in the Swedish Heart Failure Registry with at least two EF assessments were categorized as having EF increase (transition from a lower to a higher EF category), stable EF, or EF decrease (transition from a higher to a lower EF category). Multivariable logistic regression models assessed predictors of EF increase and decrease. Multivariable Cox regression models evaluated associations between EF change and all-cause mortality and the composite of all-cause mortality and HF hospitalization.
Results: Of 4,957 patients at baseline, 63% had HFrEF, 19% HFmrEF and 18% HFpEF. Over a median follow-up of 1.4 years (interquartile range 0.5-3.0 years), 1,030 patients (21%) had an EF increase (10% HFrEF to HFmrEF, 6% HFrEF to HF with improved EF and 5% HFmrEF to HF with improved EF), 3,235 patients (65%) stable EF, and 692 patients (14%) an EF decrease (4% HFpEF to HFmrEF, 3% HFpEF to HFrEF and 7% HFmrEF to HFrEF). After adjustments, predictors of EF increase included shorter HF duration (< 6 vs = 6 months), female sex, higher eGFR (= 60 vs < 60 ml/min), no diabetes, no ischemic heart disease, higher mean arterial pressure (= 90 vs < 90 mmHg) and planned follow-up in HF nurse-led clinic. Predictors of EF decrease included atrial fibrillation, diabetes, history of stroke, higher mean arterial pressure (= 90 vs < 90 mmHg), no ACE-i/ARB, no ICD/CRT and no planned follow-up in HF nurse-led clinic. Cumulative crude incidence of all-cause mortality and the composite outcome are depicted in Figure 1. After adjustment, as compared with stable EF, increased EF was associated with lower all-cause mortality (HR 0.69; [95% CI 0.59-0.80]) and decreased EF with higher all-cause mortality (HR 1.15, [1.01-1.31]). Increased EF was also associated with lower risk of the composite outcome (HR 0.66 [0.58-0.75]) and decreased EF with higher risk (HR 1.14 [1.02-1.28]).
Conclusion: In this large nationwide contemporary heart failure cohort EF change occurred in over one third of all patients. Important predictors of change included demographic, clinical, co-morbidity and treatment factors. An increase in EF over time was associated with improved outcomes. A decrease in EF portended a poor prognosis but may be preventable by optimal HF therapy.

Poster Session 1

Atrial Fibrillation - Pathophysiology and Mechanisms

P218

Predictive value of interatrial block for atrial fibrillation in old subjects enrolled in the PREDICTOR study at 5 years follow up. A population-based study in central Italy .

A Cortellesi[1]; A Boccanelli[2]; G Mureddu[3]; G Cesaroni[4]; N Agabiti[4]; L Arcari[1]; AB Scardovi[1]
[1]*Hospital Santo Spirito, Cardiology, Rome, Italy*; [2]*Quisisana clinic, Rome, Italy*; [3]*Hospital San Giovanni Addolorata, Rome, Italy*; [4]*Epidemiology Department, Lazio region, Rome, Italy*

Background: Bayés and other authors found interatrial block (IAB) to be a substrate for the development of supraventricular arrhythmias [mostly atrial fibrillation (AF)]; a condition that was subsequently referred to as Bayés syndrome. IAB is associated with AF in multiple clinical scenarios. However, the role of IAB as predictor of arrhythmias in many other situations has not yet been evaluated. Large and comprehensive studies exploring this connection in specific subsets of individuals are still lacking.
Methods and Results: The PREDICTOR study is a population-based cross-sectional study that aimed to assess the prevalence of both preclinical and clinical heart failure (HF) in the elderly. A sample of 2001 randomly selected subjects, 65- to 84-year-old residents in the Lazio Region (Italy), underwent physical examination, biochemistry/N-terminal pro brain natriuretic peptide (NT-proBNP) assessment, electrocardiography, and echocardiography. We performed a retrospective analysis on 1489 elderly patients enrolled in the PREDICTOR study in sinus rhythm that had a baseline electrocardiogram and echocardiographic exam available for interpretation. IAB was defined as a P wave duration >120 m/sec with or without biphasic morphology in the inferior leads (II,III and aVF). Among the study population, at a administrative 5 years follow-up 90 patients were admitted to the emergency department or hospital ward due to a new occurrence of AF. The presence of IAB at the baseline ECG was associated to a higher probability of developing AF (HR = 1,71 (95%CI:1,10-1,66) p = 0.017).
Conclusions: in a large sample from an elderly general population the presence of IAB is associated to the development of AF.

P219

Clinical prognostic values of left atrial dysfunction after catheter ablation for atrial fibrillation

K Masai[1]; A Goda[1]; M Sugahara[1]; T Oshita[1]; Y Ohta[1]; A Daimon[1]; T Mine[1]; M Asakura[1]; M Ishihara[1]; T Masuyama[1]
[1]*Hyogo College of Medicine, cardiovascular, Nishinomiya, Japan*

Background: Left atrial (LA) function is important factor in atrial fibrillation (AF). We investigated whether several LA functions predict recurrent AF after catheter ablation (CA).
Methods: We studied 64 patients (39 males, age 65 ± 8 yrs) who underwent CA for AF. Transthoracic echocardiography (TTE) was performed after the CA, and all patients had sinus rhythm. LA functions were calculated using the following formula; (1) Reservoir function = {[maximum LA volume (LAVmax) - minimum LA volume (LAVmin)] / LAVmin} × 100, (2) Booster function = {[Pre-A volume (LAVpre-A) - LAVmin] / LAVpre-A} × 100, LAVpre-A was defined as LA volume at the onset of the P-wave on electrocardiogram. (3) Conduit function = [(LAVmax - LAVpre-A) / LAVmax] × 100.
Results: Recurrent AF was detected in 24/64 (38%) during the follow-up period (11.5 ± 7.0-month). Univariate analysis revealed lower reservoir function, decreased booster function, larger LA diameter, elevated E wave, and higher prevalence of persistent AF as significant variables. On multivariate analysis, booster function was only independently associated with recurrent AF (p = 0.037, OR 1.141 for each 1% decrease in AEF index, 95%CI 1.019-1.313). Moreover, patients with decreased LA booster function (<10.6%) had a higher risk of recurrent AF (log-rank p = 0.0009).
Conclusion: LA booster dysfunction after sinus rhythm conversion might predict a recurrence after CA for AF.

Atrial Fibrillation - Epidemiology, Prognosis, Outcome

P220

Is dietary salt intake a predictor of future development of atrial fibrillation in the general population?

H Hiroyuki Takase[1]; M Machii[1]; D Nonaka[1]; K Ohno[1]; T Sugiura[2]; N Ohte[2]; Y Dohi[3]
[1]*Enshu Hospital, Hamamatsu, Japan*; [2]*Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*; [3]*Nagoya Gakuin University, Seto, Japan*

Background: Atrial fibrillation (AF) is a common arrhythmia and several conditions have been proposed as risk factors contributing to the onset of AF. Dietary salt consumption, which is a modifiable factor in our life style, is associated with hypertension and cardiovascular diseases independently of its effects on blood pressure.
Purpose: We tested the hypothesis that dietary salt intake predicts new onset of AF in the general population.
Methods: Consecutive 12,769 subjects without AF (male = 7,749, 52.8 ± 12.2 year-old) who visited our hospital for a physical check-up were enrolled in this study. After baseline examination, subjects were followed up for 1,821 days (median) with the endpoint being the new onset of AF. Individual salt intake was estimated using a spot urine by a previously reported method.
Results: Salt intake was 12.1 ± 3.1 g/day in male and 8.3 ± 2.2 g/day in female subjects at baseline. During the follow-up period, 87 subjects developed AF (1.44 per 1000 person-year) with the incidence being more frequent in male than female subjects (2.10 vs. 0.39 per 1000 person-year). Non-adjusted hazard ratio (HR) (95% confidence interval [CI]) of salt intake for the new AF was 1.169 (1.108-1.234). In analysis where subjects were divided into gender-specific quartiles according to the baseline salt intake (salt intake; 7.4 ± 1.7, 9.5 ± 1.8, 11.3 ± 2.0 and 14.3 ± 3.0 g/day in the first, second, third, and fourth quartiles, respectively), the incidence of AF were increased across the quartiles (0.73, 1.31, 1.72, and 1.99 per 1000 person-years). However, multivariate Cox proportional hazard analysis adjusted for age, gender, body mass index, systolic blood pressure, heart rate, serum creatinine, uric acid, fasting plasma glucose, low-density lipoprotein cholesterol, triglyceride, haemoglobin, B-type natriuretic peptide and current smoking habit at baseline revealed that salt intake did not predict the new AF (HR:0.970, 95%CI:0.906-1.039).
Conclusions: Although salt intake is associated with the development of AF in the general population, other factors rather than salt intake have much more prominent impact on the development of AF, suggesting the complementary role of salt intake for the prediction of AF.

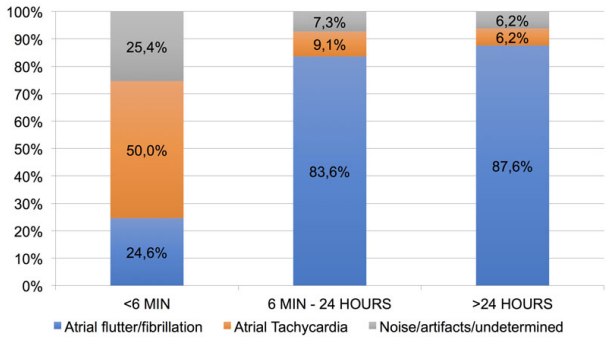
P221

Diagnostic yield and clinical implications of atrial high-rate episodes detection in patients with a cardiac implantable device

F Davi[1]; M Moretti[1]; S Agosti[1]; PF Vianello[1]; P Ameri[1]; C Brunelli[1]; G Bertero[1]; M Canepa[1]
[1]*University of Genoa, Genoa, Italy*

Background: The detection of AHREs (atrial high rate episodes) in patients with cardiac implanted electronic devices (CIEDs) and no history of atrial fibrillation has been associated with increased thromboembolic risk. The aim of this study was to analyze the prevalence and clinical predictors of AHREs and occult atrial fibrillation (AF) in an unselected population with the aforementioned characteristics.
Methods: This prospective study included all consecutive patients referred at two outpatient clinics (Ospedale Policinico San Martino Genova, Mon-Wed-Thurs; Ospedale di Novi Ligure, Wed) undergoing a routine interrogation of a CIED with an atrial lead. Clinical characteristics were collected using a structured questionnaire and the devices of patients with no history of AF and/or anticoagulant therapy were interrogated for the presence of AHREs. If AHREs were detected, EGMs (electrograms) were analyzed to further characterize the arrhythmia detected by the CIED.

Results: In a 6-month period (Jan 2017-May 2017) 1189 patients were screened and 322 were included in the final population. The mean age was 76.6 ± 9.7 years and the mean CHA2DS2-VASc score was 4.1 ± 1.8. The majority of these patients (81.4%) had a bicameral pacemaker. A total of 133 patients (41.3%) had no AHREs; 118 (36.6%) had at least one AHRE < 6 min; 55 (17.1%) had at least one AHRE >6 min and < 24 hours; 16 (5.0%) had at least one AHRE >24 hours. At EGM analysis, AF was detected in 29 patients (24.6%) in the first group (< 6min); in 46 patients (83.6%) in the second group (<6min < 24hours) and in 14 patients (87.6%) in the third group (<24hours, p < 0.0001, see Figure). At univariate analysis of clinical predictors, only age was significantly related to the occurrence of clinically significant AHREs (<6min) (p < 0.02).
Conclusions: This study demonstrates a significantly high prevalence of clinically relevant AHREs and occult AF in an unselected outpatient population with CIEDs. Further studies are warranted for ensuring systematic AHREs assessment at CIED interrogation, whose therapeutic management remains a matter of debate.



P222

Subclinical systolic dysfunction of the left ventricle in patients with chronic atrial fibrillation and preserved ejection fraction

K Kalliopi Keramida[1]; P Kostakou[1]; A Michalopoulos[1]; V Giannaris[1]; E Tryfou[1]; V Kostopoulos[1]; CD Olympios[1]; N Kouris[1]
[1]Thriassio General Hospital, Athens, Greece

2D speckle tracking echocardiography can assess subclinical myocardial dysfunction by strain at the longitudinal, circumferential and radial level, even when classical echocardiographic parameters, like ejection fraction (EF) are within the normal limits. The aim of this study was to test the hypothesis that chronic atrial fibrillation (AF), apart from the diastolic function impairs systolic deformation of the left ventricle (LV), even if it is not apparent from the reduction of EF.
Patients and Methods: 40 consecutive patients (29 males and 11 females) with chronic AF and preserved EF (58 ± 4%) and 20 healthy controls (9 males and 11 females) underwent a comprehensive 2D echocardiographic study, while strain analysis was performed off-line by GE EchoPac software version 110. Global longitudinal strain of the LV (LVGLS) was assessed from the standard three apical views, while circumferential strain (LVCS) from the parasternal short axis view at the level of papillary muscles. Exclusion criteria were presence of moderate/severe valvular disease, coronary artery disease and LV hypertrophy.
Results: Patients with chronic AF revealed significantly impaired LVGLS (-13.6 ± 3.5% vs -21.2 ± 1.3%, p < 0.0001) and LVCS (-15 ± 4.8 vs -22.5 ± 2.2, p < 0.0001). LVEF and LV end-diastolic diameter (LVEDD) did not differ between the two groups, while left atrial dimensions [left atrial diameter (LAD) and left atrial volume indexed (LAVi)] were significantly larger in patients with AF, as expected (Table 1).
Conclusion: Chronic AF impairs the deformation properties of LV despite the preserved EF. This observation is in line with the diastolic dysfunction of this group of patients that is almost always present, proving the interaction and the probable common pathophysiologic mechanism of systolic and diastolic dysfunction.

	Chronic AF	Controls	p value
LVEDD (mm)	48.8±4.5	47.5±3.4	0.29
LVEF (%)	58±4	60±3	0.20
LAD (mm)	43±5.5	35±2.4	<0.0001
LAVi (ml/m^2)	43.4±10.6	23.5±4.2	<0.0001
LVGLS (%)	-13.6±3.5	-21.2±1.3	<0.0001
LVCS (%)	-15±4.8	-22.5±2.2	<0.0001

Table 1. Echocardiographic LV parameters of patients with chronic AF and healthy controls.

Implantable Cardioverter / Defibrillator

P223

Indications and clinical outcome of subcutaneous ICD therapy in patients with heart failure

C Christoph Schukro[1]; M Sponder[1]
[1]Medical University of Vienna, Vienna, Austria

Background: Subcutaneous implantable cardioverter-defibrillators (S-ICD) are an innovative and less invasive alternative to transvenous ICD (TV-ICD) in selected patients. We aimed to investigate the indications for implanting S-ICD in clinical practice, as well as the prevalence of shock delivery and complications in patients with heart failure.
Methods and Results: From December 2012, data of 236 patients (30.5% female; age 48.6 ± 16.8 years) were gathered from 12 centres in Austria. Follow-up data over a period of 1.7 ± 1.1 years were available for 231 patients (in total 359.2 patient-years). Predominant underlying diseases were ischemic cardiomyopathy (iCMP; 32.0%), whereas dilated cardiomyopathy (dCMP) was found in 17.3%. The most frequent indications for implantation were sudden cardiac death survival (27.4%, of which only 1.3% had iCMP and dCMP, respectively), as well as primary prevention for iCMP (23.9%) and primary prevention for dCMP (12.8%). Appropriate shocks were documented in 16 patients (6.9%), iCMP being the predominant underlying disease in 8 patients. Arrhythmia conversion was successful in all patients, efficacy of the first shock was 96% in 48 of 50 episodes (both unsuccessful first shocks were found in patients with iCMP). Inappropriate shock were found in 12 patients (5.2%), of which 3 patients had iCMP and dCMP, respectively. Clinical complications needing surgical revision occurred in 8 patients (3.5%), of which 1 patient with surgical pocket revision had iCMP.
Conclusions: Overall, S-ICD were mostly implanted for primary prevention in patients with heart failure (36.7%). Clinical and functional complication rate was comparably low in this collective. In conclusion, S-ICD is a safe and efficient alternative in ICD candidates with heart failure, when no cardiac pacing is needed.

Cardiac Resynchronization Therapy

Introduction: The presence and extent of ventricular dyssynchrony is currently estimated from the morphology and width of the QRS complex. However, similar ECG pattern may be caused by various ventricular activation sequences. This may then contribute to interindividualy different response to cardiac resynchronization therapy (CRT).
Methods: Electroanatomical (CARTO) mapping and MRI scan during spontanous rhythm was performed in 11 patients with typical left bundle branch block (LBBB, QRS 170 ± 14ms) and heart failure of ischemic (CAD, n = 2) and nonischemic (DCM, n = 9) etiology. Local activation time was set for each of 17-segment model of the left ventricle (LV). Presence and extent of scarring was analysed in the same 17-segment LV model using software Segment (Medviso).
Results: Regardless of the etiology, presence of typical LBBB was associated with diffuse prolongation of impulse conduction over the ventricles with right-to-left activation sequence (Fig.1). Basal lateral wall was a constant site of late activation. Heart was always abnormally rotated with its apex pointing towards the axila. In patients with DCM, focal scarring was either not present or in form of mid/ epicardial deposits only and generally didn't exceed >6% of the LV myocardial mass. Only individuals with CAD displayed focal scar (nontransmural anteroapically in one case, transmural inferiorly in the other one). Similar finding of subendocardial scarring was also present in 1 patient with DCM (Fig.2). Despite that all 3 patients presented with typical LBBB and CARTO mapping demonstrated activation sequence and site of late activation similar to the other individuals with LBBB. Reverse remodeling (?LVESV>15% and/or ?LVEF>5%) was evident in 10 patients. Only the one man with DCM and subendocardial scarring was CRT nonresponder.

Conclusion: It seems that typical LBBB is associated with a constant activation ventricular sequence regardless of the etiology and scar localization.

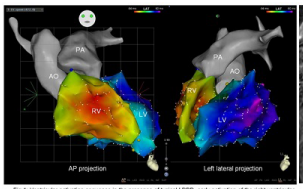

Fig.1: Ventricular activation sequence in the presence of typical LBBB- early activation of the right-ventricular free wall (red), interventricular delay 38ø18ms followed by interventricular septum activation. Site of the latest activation is located always in the basal or midventricular third of the LV lateral wall (violet).

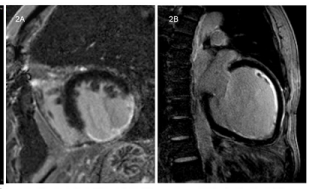

Fig.2: Scar localization in CAD patient with old transmural myocardial infarction inferolaterally (2A) and extent of subendocardial scarring in the only CRT nonresponder with idiopatic DCM (2B)

QRS width can predict outcomes in cardiac resynchronization therapy: the size really matters.

J Juan Martinez Milla[1]; AM Romero-Daza[2]; C Garcia-Talavera[1]; B Arroyo[1]; A Garcia-Ropero[2]; A Miracle[1]; J Benezet-Mazuecos[1]; M Cortes-Garcia[1]; JM Rubio Campal[1]
[1]Foundation Jimenez Diaz, Madrid, Spain; [2]Mount Sinai Medical Center, Cardiology, New York, United States of America

Background: Cardiac Resynchronization Therapy with Defibrillator (CRT-D) has proven to reduce major adverse cardiac events (MACE) in patients with reduced LVEF, impaired New York Heart Association (NYHA) class and wide QRS complex. It has not been widely studied the width of the paced QRS (pQRS) in the patients outcomes. Our objective is to determine if there is any relationship between the pQRS duration and cardiovascular events.
Methods: All consecutive patients with CRT-D implant from January 2010 to June 2016 in our center were included. Electrocardiograms before and after CRT-D implantation were analyzed. Demographic data, incidence of appropriate ICD shocks, heart failure (HF) admissions and MACE were collected.
Results: We studied 100 patients (median age 73 years ± 10 years, 82% males). Baseline QRS duration was 162 ms (± 31 ms), pQRS mean duration was 142 ms (± 25ms). The mean follow-up was 34 ± 22 months and 17 patients (17%) had a MACE. After a multivariate analysis there was a significant relationship between the QRS duration and the risk of MACE (Hazard Ratio 1.02, 95% confidence interval, 1.00 to 1.03; P = 0.048). During follow-up there were no significant associations between the QRS duration, mortality, ICD shocks or NYHA class.
Conclusions: Paced QRS width is associated with negative outcomes in CRT-D patients. We estimate that for every millisecond the QRS is wider the probability of having a MACE is increased by 2%. Narrower paced QRS may represent a novel target during follow up of these patients.

Baseline characteristics	
Baseline Characteristics	
Age (y)	71 ± 10
Males	82 (82%)
Ischemic Cardiomyopathy	50 (50%)
Baseline QRS duration (ms)	162 ms ± 31 ms
Baseline LVEF (%)	23 ± 7

Response to cardiac resynchronization therapy in heart failure patients with mitral regurgitation

A Anna Vachulova[1]; M Sasov[1]; P Margitfalvi[1]; B Liska[1]; R Hatala[1]
[1]Clinic of Cardiology SZU and NUSCH a.s., Bratislava, Slovak Republic

Cardiac resynchronization therapy (CRT) is widely acknowledged as effective device therapy for patients with failing hearts with complete left bundle branch block. However, at least 30% of patients with CRT do not benefit from it. Definition for these "non-responders" (NR) includes absence of functional improvement (NYHA) and insufficient increase in ejection fraction of LV (<5%). Functional mitral regurgitation (MR) is a common finding in HF patients and is strongly associated with a poor prognosis.
The aim of this study was to analyse CRT response in patients with moderate to severe MR.
Patients and Methods: We retrospective screened all consecutive CRT recipients from our center with moderate to severe MR who were implanted during a 2-year period (01/2015-12/2016). We used univariant statistical analysis by Fisher test.
Results: Overall, 192 patients received CRT devices in our institution during the analyzed period. At the time of implantation, moderate to severe MR was present in 53 pts (27%). Complete follow-up data for 17.5 ± 5.4 months were available in 23 pts: 15 with CRT-D and 8 with CRT-P (20 men, mean age 65 ± 13.4 years). Ischemic etiology of HF was diagnosed in 13 pts (57%), in 9 pts (39.1%) permanent atrial fibrillation was present.
At the time of implantation following parameters were observed: mean NYHA functional class 2.7 ± 0.5, mean LVEF 26 ± 7%, severe MR was present in u 3 pts (13%), the 73 ± 0,5,
typical LBBB (strict Strauss criteria) was present in 13 pts (56.5%), mean QRS duration was 165 ± 32ms. 8 pts (7 men) were NR (35%). In 4-16 months after CRT implantation 5 (22%) pts died. Mean MR stage was in responders 3.2 ± 0.1 and in NR 3.1 ± 0. Following risk factors for becoming NR were: serum creatinine >140 μmol/l (p = 0.001), any kidney disease (p = 0.040) and AF presence (p = 0.049), Most importantly, pts implanted as class I indication (ESC) were NR in 37%, pts indicated as class IIa indication were NR in 62%.
Conclusion: Hemodynamically significant MR is common (27%) in pts undergoing CRT devices implantation. Kidney disease, atrial fibrillation and class II indication for CRT are associated with increase of non-response (up to 60%). Thus, strict adherence to class I indication (ESC) for CRT is crucial in HF pts with MR for minimizing non-response to CRT.

P227

Prognosis and predictor of CRT Hyper-responder

Y Yoshifumi Ikeda[1]; K Kato[1]; K Goto[1]; T Nagase[1]; Y Shiki[1]; S Tanaka[1]; S Asano[1]; H Mori[1]; M Tawara[1]; K Matsumoto[1]
[1]Saitama International Medical Center, Cardiology, Hidaka, Japan

Background: Cardiac resynchronization therapy (CRT) is effective treatment for drug-resistant severe heart failure patients with left ventricular dyssynchrony.Some of CRT patients will become hyper responders, but the long-term effects and predictors of hyper responder are still unknown.
Methods: We performed this retrospective analysis of 167 patients underwent CRT at our institute between April 2007 and December 2016. Normal responder and hyper responder were defined as more than 15-29% and 30% reduction of left ventricular end systolic volume using ultra sonic cardiography.
Results: The mean age was 65.9 ± 19.3 years (36-86 years old). The average period of postoperative monitoring was 34.6 ± 22.7months (mean 32 months).Number of responder and non responder was 96 (57.4%) and 71 (42.6%), In those, normal responder and hyper responder was 32 and 64 cases. Normal responder group and hyper responder group did not differed significantly according to patients characteristics for example, age, percentage of sex, category of NYHA, Body size, LVEF and LVESV. Overall mortality using kaplan-meier survival curve was 27.1% during follow-up time. There was significantly difference in mortality between responder and non responder (log rank test p = 0.001). Hyper responder tended to have a better survival rate than normal responder without significantly difference(P = 0.064). In univariate analysis, CLBBB, QRS over 150ms, optimal LV lead posision and continuously optimized AV delay have tendency of predictors of hyper responder (CLBBB, optimal LV lead position and continuously optimized AV delay with significantly difference). According to multivariate analysis using cox proportional hazard models, to continuously optimized AV deplay was an only significantly independent factor to detect hyper responder (HR 1.7:p = 0.006)
Conclusion: The long-term prognosis of hyper responders of CRT is good, and it is desired that all CRT patients become hyper responders. Therefore, continuous AV delay adjustment is an important factor.

P228

Relationship between width and fragmentation of QRS stimulated in ICD-CRT in primary prevention and ventricular arrhythmia

N G Uribe Heredia[1]; R Peinado Peinado[2]; J Balaguer Recena[1]; LG Piccone Saponara[3]; R Arroyo Espliguero[4]; S Moreno Reviriego[1]; ME Jimenez Martinez[4]; E Novo Garcia[4]; JL Garcia Gonzalez[4]; B Garcia Magallon[4]; MA San Martin Gomez[4]; C Toran Martinez[4]; E Diaz Caraballo[4]; S Garcia Ortego[4]; I Rodriguez Guinea[4]
[1]University Hospital of Guadalajara, Arrhythmia unit, Guadalajara, Spain; *[2]University Hospital La Paz, Arrhythmia unit, Madrid, Spain*; *[3]Hospital General de Ciudad Real, Nefrology, Ciudad Real, Spain*; *[4]Guadalajara University General Hospital, Cardiology Department, Guadalajara, Spain*

Introduction: In view of the limited published evidence of the determinants of future major ventricular arrhythmia events in patients with implantable cardioverter defibrillator implantation with cardiac resynchronization therapy in primary prevention (ICD-CRT), we developed this study in order to identify those patients with a higher probability of VT/VF, performing in them a closer follow-up and reinforcing the treatment in an early manner.
Methods: Retrospective descriptive study. A total of 43 patients who received an ICD-CRT according to the European Guidelines from January 2010 to December 2013 were evaluated. was programmed according to the narrowest paced QRS measured by the polygraph in the time of implantation. The presence of QRS fragmentation in at least 2 contiguous leads (notching in the ascending branch of the R wave, nadir of the S wave and/or presence of more than one R wave). Follow-up up to 3 years. Variables are compared using Chi2 test and Student's T test. SPSS 20.0. Statistical significance p <0.05, 95% IC.
Results: A total of 43 patients, mean age was 71.2 ± 9.9 years, 9.1% women, the mean ejection fraction was 31.7 ± 9.1% at the time of device implantation. 48.8% ischemic. 62.8% were in advanced stages of heart failure (NYHA III-IV) and 34.9% permanent atrial fibrillation. The mean baseline QRS was 164.1 ± 29.4ms and the biventricular pacing was 128.1 ± 21.9ms. At a mean follow-up of 33.3 ± 7.8 months, 11.6% (5 patients) had at least one VT/VF. The mean time from device implantation to the first episode of VT/VF was 20.2 ± 9.9 months, all of them male, of which 80% were ischemic, the mean QRS stimulated in these patients was higher than those who did not have TV/VF (147 ± 38.9ms Vs 125.6 ± 18.1ms) although no statistically significant differences were obtained (Graph1). Stimulated QRS fragmentation was more frequent among patients who had VT/VF, 80% Vs 13.2% p = 0.001 (Graph 2).
Conclusions: In our study, the measurement of the width of the QRS stimulated in patients with ICD-CRT implanted in primary prevention was not related to the occurrence of VT/VF. In contrast, the presence of fragmentation in the stimulated QRS was related to the increased probability of this type of arrhythmia.

VARIABLES	TV/FV	P

Comparsion of clinical response to de novo vs. upgrade cardiac resynchrinzation therapy: results from a long-term, high-volume, single-center registry

W Walter Richard Schwertner[1]; A Kosztin[1]; A Kovacs[1]; E Zima[1]; L Geller[1]; V Kutyifa[2]; B Merkely[1]
[1]Semmelweis University Heart Center, Budapest, Hungary; *[2]University of Rochester, Rochester, United States of America*

Background: Approximately 10-20% of patients with previously implanted cardiac defibrillator (ICD) or conventional pacemaker (PM) develops heart failure and becomes CRT candidates due to the chronic right ventricular pacing. However recent guidelines do not provide a comprehensive recommendation for CRT upgrade.
Purpose: We assessed the long-term clinical benefits who were upgraded to CRT from a conventional PM or ICD and compared to de novo implantations in our high-volume, single-center experience.
Methods: In our retrospective registry participants underwent CRT implantation according to the current guidelines. Patients registered from 2004 to 2017, with decreased ejection fraction (EF= 35%) wide QRS (= 120 ms) and symptomatic (NYHA II-IV class) heart failure. Primary endpoint was all-cause mortality, secondary endpoint was echocardiographic response. We performed Kaplan-Meier, Cox regressional analyses and propensity score matching by baseline ejection fraction (EF = 30% vs. <30%) and NYHA class (NYHA II vs. III-IV).
Results: From 1336 (288 upgraded vs. 1048 de novo CRT implanted) patients 701 reached (176 CRT-upgrade, 525 de novo CRT) the primary endpoint during the mean follow up time of 5.8 years. Patients in the upgrade group were older (71 vs. 67 years; p <0.01), had higher serum creatinine level (116 vs. 99 µmol/l; p <0.01), prior myocardial infarction (47% vs. 40%; p = 0.03) and atrial fibrillation (48% vs. 34%; p <0.001). By univariate analysis all-cause mortality was 46% higher in the Upgrade CRT group compared to De Novo CRT group (HR 1.46; 95% CI: 1.23-1.73; p <0.001). However multivariate analysis did not show a significant difference between the upgrade vs. de novo CRT groups (HR 1.17; 95% CI: 0.96-1.13; p = 0.13), after adjusting for relevant clinical covariates. We found similar improvements 12 months after the procedure, (?LVEF de novo 6.8% vs. upgrade 4.8%; p = 0.25) when echocardiographic response was evaluated. Based on propensity score matching, selecting 214-214 pair of patients confirmed our results independently from baseline EF and NYHA parameters.
Conclusions: CRT upgrade patients show higher risk of all-cause mortality compared to de novo CRT group, it is derived from co-morbidities. After adjusting relevant parameters they show similar long-term clinical response.

Chronic Heart Failure - Pathophysiology and Mechanisms

REMODEL: Demonstration of REverse ReMODELing Effects of sacubitril/valsartan

S Kalantari[1]; DM Medvedofsky[2]; JG Grinstein[2]; ST Tayazime[1]; GK Kim[1]; NS Sarswat[1]; JR Raikelkhar[1]; BS Smith[1]; FM Maffessanti[1]; DB Beiser[1]; PW Ward[1]; GS Sayer[1]; RL Lang[1]; NU Uriel[1]
[1]University of Chicago Medicine, Chicago, United States of America; *[2]MedStar Hospital, Cardiology, Washington DC, United States of America*

Funding Acknowledgements: Novartis

Background: Sacubitril/valsartan, an angiotensin receptor-neprilysin inhibitor, significantly reduced cardiovascular mortality and heart failure hospitalizations as compared to a target-dose enalapril-based regimen for patients with heart failure reduced ejection fraction. The pathophysiology underlying the benefit of sacubitril/valsartan and its effects on remodeling remain unknown. Here we seek to further elucidate the benefits of sacubitril/valsartan on ventricular remodeling, functional status, and quality of life.
Methods: In this prospective, single-arm longitudinal study, 40 patients who were on optimal guideline directed medical therapy were initiated on sacubitril/valsartan after an appropriate wash-out period from prior ACEI or ARB therapy. The primary end-point was the degree of reverse remodeling (change in LV and RV size, volume, shape, and function) as assessed by 2D and 3D-TTE with surface analysis at 3 months compared to baseline using paired t-tests. Secondary endpoints were peak VO2, 6-minute walk distance, and quality of life parameters.
Results: There was significant reduction in left ventricular and left atrial volumes with an increase in left ventricular ejection fraction as well as improvement in LV conicity index at 3 months (Table 1). Interim analysis revealed improved 6-minute walk distance (428 ± 105 vs 451 ± 115 m; p = 0.006) and a trend towards improvement in peak VO2 (18.5 ± 5.7 vs 19.2 ± 5.6; p = 0.19) at 3 months.

Conclusion: Compared to a background of historical guideline directed medical therapy, transition to sacubitril/valsartan led to significant reverse remodeling and improved functional status.

Table 1.

Evaluation of left intraventricular synchrony in asymptomatic left bundle branch block patients by non-invasive parameters obtained from radionuclide ventriculography

A Agustin Pastor Fuentes[1]; R Mata[1]; J Perea[1]; A Nunez Angulo[1]; J Pais[1]
[1]*Hospital Universitario Getafe, Getafe (Madrid), Spain*

Background: Radionuclide ventriculography (RNV) has been used to assess left ventricular ejection fraction (LVEF) and ventricular synchrony by means of phase and amplitude parametric images and their quantitative-derived parameters, where mean phase angle (PA) represents mean time of ventricular contraction onset and the standard deviation (SD) of the PA relates to synchrony of ventricular contraction. Objective: To study global and regional LVEF data and LV synchrony parameters obtained by a RNV in patients (P) with an asymptomatic left bundle branch block (LBBB)
Methods: LVEF and LV synchrony data obtained from a RNV in 18 normal ECG P were compared with the same parameters in 45 asymptomatic LBBB P with no previous cardiac history, who were referred for evaluation because of the abnormal ECG finding. SD of PA was derived from the phase histogram obtained in the best left anterior oblique view, and expressed both in grades (°) or milliseconds (ms). Regional LVEF was derived from each of the four segments that ventricular blood pool was divided (Septal, Apex, Inferior-Lat, Post-Lat) in the same left anterior oblique view.
Results: In 18 LBBB P, mean LVEF was < 50% and > 50% in the remaining 27 P (40 ± 7% vs 60 ± 6%p<.001). Other results are expressed in the table below. In the whole LBBB group, a weak but good and inverse correlation between SD of PA and LVEF was found (r= - 0.53, p < 0.001), so the greater SD of PA, the less LVEF.
Conclusions: Abnormal LV systolic function is encountered in 40% of asymptomatic ambulatory P with LBBB. All LBBB P, show left intraventricular mechanical asynchrony data estimated by RNV parameters, although higher in P with depressed LVEF. We may speculate that abnormal LVEF in 40% of LBBB group is due to an undiagnosed primary cardiomyopathy since regional wall motion is globally affected in this group compared with control P and those LBBB P with preserved EF or due to a LV remodeling because of LBBB-dependent electrical asynchrony itself

RESULTS

Skeletal muscle metabolism characteristics of HFpEF and HFrEF patients

N Scherbakov[1]; L Klug[2]; S Von Haehling[3]; HD Duengen[4]; M Boschmann[2]; W Doehner[1]
[1]*German Center for Cardiovascular Research, partner site Berlin, Berlin, Germany*; [2]*Charité - Campus Berlin Buch (CBB), Experimental & Clinical Research Center, ECRC, Berlin, Germany*; [3]*University Medical Centre Göttingen, Innovative Clinical Trials, Department of Cardiology and Pneumology , Göttingen, Germany*; [4]*Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany*

Funding Acknowledgements: DZHK (German Centre for Cardiovascular Research), partner site Berlin

Background: Heart failure (HF) is associated with insulin resistance (IR) and there is a clear difference between the HF with reduced ejection fraction (HFrEF) and preserved ejection fraction (HFpEF). However, tissue metabolism is still not well characterized in these patients.
Purpose In this pilot study we investigated in situ skeletal muscle glucose metabolism in HFpEF and HFrEF vs. healthy controls.
Methods: Vastus lateralis muscle tissue perfusion and glucose metabolism were studied using the microdialysis technique at fasting condition and during an oral glucose challenge. Interstitial fluid energy substrate metabolites as well as tissue perfusion were assessed using ethanol dilution method. Eight men with HFrEF (age 59 ± 14 yrs, BMI 26.5 ± 3.5 kg/m^2, NYHA I-III, LVEF 32 ± 9%) and six men with HFpEF (age 65 ± 10 yrs, BMI 26.8 ± 5.8 kg/m^2, NYHA I-II, LVEF 54 ± 2) participated in this cross-sectional study after a 12h overnight fasting. Nine healthy men of similar age and BMI served as controls.
Results: In fasting condition there were no significant differences in tissue perfusion and marker metabolite levels. However, after the glucose load, tissue perfusion and glucose supply tended to be lower in HFrEF, not in HFpEF vs. controls (Fig. A, B). Furthermore, tissue lactate (indicator for anaerobic glycolysis) tended to be higher in HFrEF vs. HFpEF and controls (Fig. C). Postprandial tissue pyruvate (indicator for aerobic glycolysis) did not differ significantly between the groups (Fig. D,E). Finally, tissue glycerol (indicator for lipid mobilization) decreased similarly in all groups after the glucose load (Fig. F).
Conclusions: Postprandial muscle tissue perfusion and glucose supply might be reduced in HFrEF but not HFpEF patients that is in line with differences in insulin resistance observed in patients with HFrEF and HFpEF. However, this finding is not associated with an impaired aerobic glucose metabolism in HFrEF patients at resting.

P233

Morphological structure of diaphragm in patients with different class of heart failure

GP Arutyunov[1]; KV Ilina[2]; EA Kolesnikova[1]; AG Arutyunov[1]; EV Tulyakova[2]
[1]*The Russian National Research Medical University named after N.I. Pirogov , Moscow, Russian Federation*; [2]*Moscow City Hospital No 4, Moscow, Russian Federation*

Patients with heart failure (HF) have respiratory muscles disorders and as a result high risk of pneumonias, poor prognosis and lethal outcomes. The purpose: To study the morphological features of diaphragm and its role in ventilation disorders in patients with HF. Materials: 32 diaphragm autoptat (14 male, 16 female) with different lethal outcomes (8 myocardial infarction, 9 stroke, 5 pulmonary embolism, 10 pneumonia) were taken in 1 hour after death. Pats were selected from research data base of patients with NYHA I-IV class HF. Inclusion criteria: patients with CAD, arterial hypertension and NYHA I-IV class HF with stable standard doses of drug therapy.Exclusion criteria: patients = 75 years, with COPD, obesity, diabetes mellitus, alcohol abuse.
Methods: percentage composition of muscle, connective, adipose tissue, collagen and number of fibroblasts were studied in diaphragm autoptat. Results of functional status (vital capacity, forced vital capacity were taken from research data base. Test were done during dynamic examination no longer then within 3 months of lethal outcome date.
Results: Pats with NYHA I HF had 90% of muscle tissue, 6% connective tissues, 4 % adipose tissue, 5 fibroblasts. Pats with NYHA II HF had 80% of muscle tissue, 15% connective tissues, 8 % adipose tissue, 25 fibroblasts. Pats with NYHA III HF had 70% of muscle tissue, 20% connective tissues, 11 % adipose tissue, 23 fibroblasts. Pats with NYHA IV HF had 60% of muscle tissue, 35% connective tissues, 18 % adipose tissue, 10 fibroblasts. Collagen content in connective tissue - 2% in pats with NYHA I, 5% in pats with NYHA II, 8% in pats with NYHA III, 15% in pats with NYHA IV.Conclusion: The diaphragm undergoes structural changes with the increase in functional class of HF - connective tissue, collagen and adipose tissue is growing while muscle tissue is decreasing. Respiratory functional disorders directly correlate with the products of inflammation process - the high content of collagen and connective tissue. At the same time the other members of inflammatory

process - fibroblasts grow from I to III NYHA class and tend to decline in patients with IV class HF.

P234
Clinical phenotypes and prognosis of patients with chronic heart failure with mid-range ejection fraction

AA Nasybullina[1]; OV Bulashova[1]
[1]*Kazan State Medical University, Kazan, Russian Federation*

The European Society of Cardiologists of 2016 proposed the allocation of patients with heart failure (HF) with mid-range ejection fraction (HFmrEF). As studies have shown, patients with different ranges of ejection fraction differ in a number of clinical signs and prognosis.
Goal: Study of clinical variants and outcomes of patients with chronic heart failure (CHF) with mid-range left ventricular ejection fraction.
Material and methods. The study included 76 patients without acute decompensation of CHF I-IV functional class NYHA, 66.1 ± 10.4 years, with a duration of CHF of 8.5 years. The causes of CHF were ischemic heart disease in 89.5% and hypertension in 10.5%. Heart failure with preserved ejection fraction (HFpEF) was observed in 55.3%, HFmrEF - 23.7%, reduced EF (HFrEF) - 21,1%. The results of a walking test, a scale for evaluating the clinical status, and quality of life were evaluated. Fatal and non-fatal cardiovascular events (CVE) were analyzed during the first year: cardiovascular mortality, myocardial infarction, cerebral stroke, acute decompensation of CHF, thrombotic complications.
Results: Comparative analysis, depending on the range left ventricular ejection fraction, showed that HFmrEF occupies an intermediate position between HFpEF and HFrEF for a number of clinical characteristics (sex, scale for evaluating the clinical status, quality of life were evaluated, weighed heredity, duration of CHF). However, patients with HFmrEF, in contrast to HFpEF, were older in age (p = 0.04), with a predominance of III-IV NYHA stage, which was confirmed by comparing the results of the walking test (182.5 [110, 272], m 350 [250, 400], p <0.001).
Analysis of the structure of the CCC showed that the HFmrEF also occupies an intermediate position between the HFpEF and HFrEF in the frequency of all CVE (17.6%, 10.8%, 18.8%, respectively), myocardial infarction (5.9%, 0%, 6.2%), thrombotic complications (5.9%, 5.4%, 6.2%). However, cardiovascular mortality in HFmrEF was significantly lower than with HFpEF and HFrEF (0%, 2.7%, 12.5%), as well as the incidence of acute decompensation of CHF (0%, 2 , 7%, 6.2%).
Conclusion: Despite the similarity of some clinical characteristics, patients with HFmrEF have a special clinical profile and a prognosis for cardiovascular mortality and the incidence of acute decompensation of heart failure.

P235
Predictors of non-recovery of left ventricular systolic function in breast cancer patients with chemotherapy induced left ventricular dysfunction

HJ Hyun Ju Yoon[1]; KH Kim[1]; JY Cho[1]; HJ Park[1]; JC Park[1]
[1]*The Heart center of Chonnam National University Hospital, Gwangju, Korea Republic of*

Background and objectives: Non-recovery of left ventricular (LV) function is known to be a predictor of poor prognosis in patients with chemotherapy induced LV dysfunction (LVD). Although the incidence or natural history of chemotherapy induced LVD in patients with breast cancer has been changed after the introduction of target therapy with trastuzumab, the predictors of LV functional non-recovery in patients with breast cancer that developed LVD in association with trastuzumab use after conventional chemotherapy has been poorly studied. Therefore, the aim of the present study was to investigate the predictors of LV functional non-recovery in breast cancer patients with LVD in association with trastuzumab use after conventional chemotherapy.
Methods: Among 826 patients treated with trastuzmab after chemotherapy for breast cancer, a total of 243 patients with chemotherapy induced LVD were divided into 2 groups; recovery group (n = 195, 51.4 ± 10 years) vs non-recovery group (n = 48, 49.6 ± 10 years). Chemotherapy induced LVD was defined as LV ejection fraction (EF) of < 55% or the decrease in LVEF >10% from the baseline LVEF on follow-up echocardiography after chemotherapy. LV functional recovery was defined as the improvement of LVEF > 10% on follow up echocardiography as compared to the LVEF measured at the time of diagnosis of chemotherapy induced LVD. Clinical, laboratory, and echocardiographic findings were compared.
Results: On follow up echocardiography, chemotherapy and trastuzumab induced LVD was improved in 195 patients (80.2%), whereas LVD was persisted in 48 patients (19.8%). In univariate analysis, low levels of hemoglobin and albumin, larger LV end-diastolic and end-systolic dimension, lower LVEF and global longitudinal strain, and higher pulmonary artery systolic pressure were significantly associated with non-recovery of LVD. In multivariate regression analysis, severe LV dysfunction (HR10.09, CI = 4.232-24.05, p < 0.001), pulmonary hypertension (HR 2.783, CI = 1.277-6.065, p = 0.010), and anemia (HR 2.149, CI = 1.091-4.232, p = 0.027) were independent predictors of non-recovery of LV function in breast cancer patients with chemotherapy and trastuzuamb induced LVD.
Conclusion: Non-recovery of LV function in breast cancer patients with chemotherapy and trastuzumab induced LVD was not uncommon (19.8%), and severe LV dysfunction, pulmonary hypertension and anemia were independent predictors of sustained LV dysfunction. Therefore, careful monitoring and intensive medical management for LV dysfunction in breast cancer patients with these characteristics should be considered.

No short-term cardiac toxicity of novel biological therapies for advanced non-small cell lung cancer in routine clinical practice

L Loredana Mrak[1]; R Marcun[2]; T Cufer[1]; M Podbregar[3]
[1]*University Clinic of Respiratory and Allergic Diseases Golnik, Department of Medical Oncology, Golnik, Slovenia*; [2]*University Clinic of Respiratory and Allergic Diseases Golnik, Department of Cardiology, Golnik, Slovenia*; [3]*University Medical Centre of Ljubljana, Cardiovascular Intensive Care Unit, Department for Anesthesiology and Surgical Intensive Care, Ljubljana, Slovenia*

Funding Acknowledgements: University Clinic of Respiratory and Allergic Diseases Golnik

Background and Purpose: New biological therapies significantly improved overall survival rates for patients with advanced non-small cell lung cancer (NSCLC). The effects of such treatment on heart function in routine clinical practice are currently poorly known. The aim of the study was to evaluate short-term effects of biological therapies for advanced NSCLC on heart function among patients treated in our routine clinical practice.
Methods: This was a single center, prospective, observational pilot study which included 17 consecutive patients (10 female, 64 ± 9 years) with advanced NSCLC treated with biological therapy at one academic center. Patients received a clinical evaluation before, after two and after four months of treatment, at that time points also NT-proBNP, troponin T and echocardiographic examination were performed.
Results: 8 patients were treated with programmed cell death 1 receptor blocking antibodies (6 with pembrolizumab, 2 with nivolumab), 9 with a tyrosine kinase inhibitor (1 with gefitinib, 2 with erlotinib, 1 with afatinib, 5 with osimertinib). Normal cardiac function was required at baseline. After two and four months of treatment no patient developed symptoms of heart failure, body weight was stable, troponin T and NT-proBNP (248 ± 116 ng/L, 289 ± 117 ng/L, 242 ± 81 ng/L, respectively, p = 0.9) remained within normal range Dimensions of heart cavities remained normal. Left ventricular ejection fraction remained normal (69.6 ± 1.6%, 70.3 ± 1.8%, 72.2 ± 1.2%, respectively, p = 0.8) as did diastolic left ventricular function. Left ventricular filling pressure (E/e': 10.5 ± 0.8, 10.3 ± 0.9, 10.0 ± 0.7, respectively, p = 0.9) and right ventricular pressure remained unchanged.
Conclusion: This pilot study showed no short-term cardiac toxicity of novel biological therapies for advanced NSCLC in routine clinical practice. Further studies are necessary to confirm short and long-term cardiac safety of novel biological therapies.

P237
Cardiovascular risk profiles in cardio-oncology - time matters.

J Ferreira-Martins[1]; L Tan[1]; L Venneri[1]; J Cevallos[1]; N Pareek[1]; E Ciburiene[1]; P Moliner-Borja[1]; V Chambers[1]; RS Khattar[1]; AJ Baksi[1]; SD Rosen[1]; AR Lyon[1]
[1]*Royal Brompton Hospital, London, United Kingdom*

Introduction: Referrals to Cardio-Oncology services occur before, during and after cancer treatment. It is not known whether patients referred prior to cancer therapy have a different cardiovascular risk profile to those referred with late cardiovascular complications after cancer treatment.
Purpose: To determine whether patients referred before and after cancer treatment differ with regards to 1) the burden of cardiovascular comorbidities; 2) cardiac biomarker profile; 3) left ventricular ejection fraction (LVEF) and tissue characteristics assessed by cardiac magnetic resonance (CMR); as well as 4) their pharmacologic cardiac treatment.
Methods: First appointments in a Cardio-Oncology service were categorized either as "Pre-treatment" (Pre), during treatment (excluded) or "Post-treatment" (Post) if the purpose was an assessment before initiation of cancer treatment or an evaluation of cardiovascular complications after cancer therapy, respectively. A retrospective analysis of clinical, biomarker, CMR and treatment information from a specifically designed database of patients referred between February 2011 and October 2017 was included.
Results: 384 patients were referred during the study period (Pre n = 214; Post n = 170). The commonest primary neoplasia was breast cancer (Pre n = 42, 19.6%; Post n = 75, 48.4%). Pre-existing cardiovascular co-morbidities were significantly more

prevalent in the Pre- than in the Post-treatment group (61.2% vs 26.5%, p < 0.0001): arterial hypertension (Pre 47.2% vs Post 22.4%, p < 0.0001), ischaemic heart disease (Pre 16.8% vs Post 0.6%, p < 0.0001) and valvular heart disease (Pre 6.5% vs Post 1.2%, p < 0.001). Despite this, a significantly higher proportion of patients in the Post-treatment group had Troponin T >15ng/L (Pre 3.6% vs Post 11.7%, p < 0.01) and higher BNP levels (Pre 107 ± 115ng/L vs Post 164 ± 243ng/L, p < 0.01). LVEF was significantly lower in the Post-treatment group (Pre 65.1 ± 11.8% vs Post 54.5 ± 12.4%, p < 0.0001). However, the presence of late gadolinium enhancement was more common in the Pre treatment group (Pre 39.3% vs Post 26.2%, p = 0.016) possibly reflecting a higher prevalence of pre-existing cardiovascular comorbidities. More patients in the Post-treatment group were on beta-blockers (Pre 39.9% vs 54.2%, p < 0.01) and angiotensin-converting enzyme inhibitors/angiotensin receptor blockers (Pre 48.3% vs Post 71.7%, p < 0.0001).
Conclusion: Cardio-Oncology services offer care to distinct cancer populations - those at risk and those who have developed cardiovascular complications. Patients referred after cancer treatment have evidence of cancer therapy-related cardiotoxicity with an unfavorable biomarker and cardiac function profile. This is despite a lower prevalence of pre-existing cardiovascular comorbidities and higher use of cardiac medication. Personalised care is advised to improve outcomes in cancer survivors and populations before and after treatment have different requirements.

P238
Cardiotoxicity of treatment hepatitis C by triple combination of antiviral drugs

J Jakub Simka[1]; R Pudil[1]; S Plisek[2]
[1]*Faculty of Medicine in Hradec Kralove, Charles University, 1st Department of Medicine, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic*; [2]*Faculty of Medicine in Hradec Kralove, Charles University, Department of Infectious Diseases, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic*

Background: Antiviral drugs are considered as drugs that may be potentially cardiotoxic. Due to prolongation of the QTc interval may affect the incidence of severe ventricular arrhythmias.
Purpose: The aim of the retrospective study was to assess the effect of three antiviral drugs on the QTc interval and find patients who are at increased risk of developing malignant ventricular tachyarrhythmias.
Methods: The study includes 23 patients (14 men, 9 women, 46 ± 18 years) treated by combination of three antiviral drugs: interferon alpha, ribavirin, and NS3/4A protease inhibitor. We evaluated 12 leads electrocardiogram (ECG) before treatment, 3 ± 1 months after treatment and 6 ± 1 months after treatment. Bazett's formula was chosen to calculate QTc interval. ECGs assessment was digitized by the program ImageJ.
Results: Before initiation of therapy, the following mean parameters were obtained: Heart rate (HR): 69 ± 12 / min, QTc: 412 ± 35 ms. After 3 months: HR: 72 ± 11 / min, QTc: 412 ± 33 ms. After 6 months: HR: 64 ± 12 / min., QTc: 405 ± 28 ms. In the follow-up population, the QTc interval was prolonged after 3 months of treatment in 53 % of patients and after 6 months of treatment in 43% of patients. QTc prolongation over 450 ms was noted in 1 (4 %) patient. New treatment-related repolarization changes were detected in 1 (4 %) patient.
Conclusion: The study shows that combination therapy of 3 antiviral drugs significantly does not prolong the QTc interval and does not cause severe pathological changes on ECG. Patients undergoing this treatment are not endangered by the development of heart disease as an undesirable side effect. ImageJ was first used to evaluate ECGs in this study and has proved to be an appropriate and very accurate interval-measuring program.
The study was supported by project Progres Q40/03.

P239
Right ventricular to arterial elastance ratio, internal work, and late gadolinium enhancement as prognostic markers in pulmonary hypertension.

H Hamdy Shams Eddin[1]; KH Elmaghraby[1]; S Demitry[1]; A Aboelnour[1]
[1]*Assiut University, Assiut, Egypt*

Background: External cardiac work i.e. the P-V loop area, correlates poorly with heart's energy demands until IW component is added. Ea/Emax measures ventriculo-arterial coupling. LGE is known to be present within RVIPs in PH, but its prognostic role is insufficiently explored.
Purpose: To investigate the impact of right ventricular internal work (RVIW), arterial to ventricular end-systolic elastance ratio (Ea/Emax), RV insertion point (IP) late gadolinium enhancement (LGE); and its temporal change on outcome in pulmonary hypertension (PH).
Methods: Cardiac magnetic resonance (CMR) of 124 PH patients (aged 60 ± 13, 85 Females) was retrospectively examined for RV volumetric and functional indices and RVIP LGE %. Right heart catheterization (RHC) performed within 2 ± 1 months of CMR was reviewed. Ea/Emax was derived as RV end-systolic volume (ESV)/RVSV. Internal work was estimated as RVESV × (RV end-systolic pressure-RV diastolic pressure).Patients were followed from date of CMR for up to 5 years for MACE (death, hospitalized RV failure, initiation of parenteral prostacyclin, sustained ventricular arrhythmia, or referral for lung transplantation). Follow-up CMRs for 44 patients were examined for temporal change of LGE (? LGE).
Results: 48/124 (39%) patients had MACE. The strongest predictor of MACE was Ea/Emax (OR = 1.46, P = 0.01), followed by RVIW, versus mPAP, RV mass, RVEF, and IP LGE. Similar results were obtained for time-to-MACE (Ea/Emax HR = 1.44, p <0.001). Using Vanderpool et al.'s proposed Ea/Emax cut-off of 1.94 produced an early split in time-to-MACE (Log rank = 5.31, p = 0.02). ? LGE (median=-1.97, range=-25.87 to 16.48) predicted time to MACE.
Conclusions: Higher Ea/Emax and RVIW herald worse prognosis in PH. Not only is RVIP LGE static, but also it can decrease over time in PH. This is the 1st study addressing this concept. Failure to reduce RVIP LGE % (? >1.97) predicts worse prognosis.

P240
Could inferior vena cava diameter replace the central venous catheter to estimate central venous pressure?

R Mosaddegh[1]; M Chardoli[1]; M Ahmadi[1]
[1]*Iran University of Medical Sciences & Health Services, Emergency Medicine Management Research Center, Firoozgar Hospital, Tehran, Iran (Islamic Republic of)*

Introduction: It is important to know hemodynamic status of the patient when we need to resuscitate the patient whose heart condition is unknown. Bedside ultrasound is a quick and noninvasive method of hemodynamic monitoring. The researcher wants to compare the accuracy of inferior vena cava (IVC) ultrasound with central venous catheter (CVC) in estimating the Central Venous Pressure (CVP).
Methods: Adult patients who need to insert a CVC enrolled in the study. The CVP was measured used the CVC in place. The diameter of the IVC was measured in the expiration with a portable two-dimensional ultrasound and the Caval index was calculated. The cut of point, sensitivity, specificity, positive predictive value and negative predictive value of Caval index was calculated to estimate central venous pressure then.
Results: Ninety-nine patients with median age of 69 years old was enrolled in the study. The mean of CVP and IVC diameter before and after fluid challenge was 5.25 ± 3.59 vs 6.68 ± 3.43 (P value: 0.003) for CVP and 7.44 ± 5.13 vs 9.84 ± 5.29 (P value: 0.002) for IVC diameter. There is no significant difference between area under receiver operating characteristic curve of CVP vs IVC diameter (AUC 0.973 vs 0.974 P value: 0.78). The best cut off point to estimate CVP off less than 8 cm H20 was IVC diameter of less than 10.9 mm with sensitivity and specificity of 90.79 and 100 percent respectively.
Conclusion: Measuring the IVC diameter with bedside ultrasound in emergency department could estimate the CVP of the patients with good correlation and good sensitivity and specificity with CVC measuring of CVP. This method is fast, non-invasive and accurate and could replace the invasive method of CVC measuring the CVP.

P241
N-terminal prohormone brain natriuretic peptide is a weak indicator of cardiac function and haemodynamic response to exercise in chronic heart failure

M Parovic[1]; NC Okwose[1]; SJ Charman[1]; S Cassidy[1]; P Doherty[2]; K Bailey[3]; J Skinner[3]; PM Seferovic[4]; GA Macgowan[5]; D Djordje Jakovljevic[6]
[1]*Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom*; [2]*University Of York, Department of Health Sciences, York, United Kingdom*; [3]*Royal Victoria Infirmary, Cardiology, Newcastle upon Tyne, United Kingdom*; [4]*Clinical center of Serbia, Cardiology, Belgrade, Serbia*; [5]*Freeman Hospital, The Cardiothoracic Centre, Newcastle upon Tyne, United Kingdom*; [6]*Buckinghamshire New University, Research Centre for Society and Health, Chalfont St Giles, United Kingdom*

Funding Acknowledgements: National Institute for Health Research Newcastle Biomedical Research Centre

Background/Aim: Heart failure is associated with high mortality and poor quality of life. N-terminal prohormone brain natriuretic peptide (NTproBNP) plays a critical role in the diagnosis and management of patients with chronic heart failure. There is no evidence that NTproBNP can predict overall cardiac function and haemodynamic response to exercise in heart failure. Cardiac power output is a unique haemodynamic measure of overall cardiac function and is one of the strongest predictors of mortality in chronic heart failure. The aim of the present study was to assess the relationship between NTproBNP, rest and exercise haemodynamics and quality of life.

Methods: A single-centre pilot study recruited 20 patients (mean age 68 ± 7 years) with stable chronic heart failure due to left ventricular systolic dysfunction (LVEF = 31 ± 8%). Blood samples for NTproBNP were taken and all patients completed a maximal graded cardiopulmonary exercise stress testing using cycle ergometer with non-invasive gas exchange and haemodynamic (Bioreactance, Cheetah Medical, USA) monitoring. Quality of life was assessed using Minnesota Living with Heart Failure Questionnaire. Cardiac power output, expressed in watts, was calculated as the product of mean arterial blood pressure and cardiac output.
Results: The average value (± SD) for NTproBNP was 820 ± 1056 ng/L. Rest and peak exercise values for haemodynamic variables were: cardiac power output, 1.19 ± 0.21 vs. 2.93 ± 0.75 watts; cardiac index 3.1 ± 0.4 vs. 6.7 ± 1.1 L/min/m2; stroke volume index 48 ± 8.8 vs 63.1 ± 14.1 ml/beat/m2; heart rate 67 ± 7 vs. 111 ± 21 beats/min; peak oxygen consumption 1423 ± 353 ml/min; peak work rate 82 ± 20 watts; and quality of life score 27 ± 18. The NTproBNP was not significantly correlated with measures of cardiac function at rest i.e. cardiac power output (r= -0.04, p = 0.87), cardiac index (r= -0.02, p = 0.95), stroke volume index (r= -0.17, p = 0.48), mean arterial blood pressure (r= 0.14, p = 0.55), and heart rate (r= 0.22, p = 0.34). There was a weak to moderate negative relationship between NTproBNP and peak exercise haemodynamic function i.e. cardiac power output (r= -0.51, p = 0.02), cardiac index (r= -0.50, p = 0.02), stroke volume index (r= -0.04, p = 0.86), mean arterial blood pressure (r= -0.30, p = 0.20), and heart rate (r= -0.26, p = 0.27). In contrast, the NTproBNP correlated well with exercise tolerance i.e. peak oxygen consumption (r= -0.60, p = 0.01), and work rate (r= -0.62, p < 0.01), but not with quality of life (r= -0.03, p = 0.92).
Conclusion: Present findings demonstrate only weak to moderate strength relationship between N-terminal prohormone brain natriuretic peptide and measures of cardiac function at rest and in response to exercise. The NTproBNP should not be considered as an indicator of cardiac function and haemodynamic response to exercise in chronic heart failure.

P242

Role of NT-proBNP and sST2 meanings in the acute myocardial infarction in the development of left ventricle systolic dysfunction in the post-infarction period.

F Fatima Akhmatova[1]; Il Chukaeva[1]; VN Larina[1]
[1]*Russian National Research Medical University, Moscow, Russian Federation*

Introduction: One of the adverse effects of myocardial infarction (MI) is heart failure (HF), it is developed under the influence of several factors. The study of the multicomponent nature of cardiac function disorders in the acute period of MI can contribute to predicting left ventricular (LV) dysfunction in the post-infarction period.
Purpose: to study the role of changes in the acute MI period of natriuretic peptide (NT-proBNP) and stimulating growth factor (sST2) in the development of systolic LV dysfunction in the early and late post-infarction period.
Methods: 27 patients with MI were included into the study, the age was 52 [44;64] years, the criteria for exclusion were the occurrence of complications in the acute period of myocardial infarction and chronic heart failure. The study groups were formed on the first day of MI according to the change of the level HF markers in serum: the group 1 - an increase in NTproBNP concentration of more than 300 pmol/l and sST2 - more than 35 ng/ml were registered in14 patients; the group 2 - NTproBNP of less than 300 pmol/l and sST2 of less than 35 ng/ml were registered in 13 patients. The groups differed significantly in the median concentration of NTproBNP and sST2], ? = 0,006. The median age in the groups did not differ significantly. The LV function of patients was assessed according to the results of echocardiography on the 1st day, 14th day of MI (early post-infarction period) and in 6 months (late post-infarction period). The LV ejection fraction (LVEF %), LV end-diastolic dimension (LV EDD, mm) and LV end-systolic dimension (LV ESD, mm), left atrial dimension (LAD, mm) were determined. Statistical analysis was performed using Mann-Whitney U Test.
Results: There was no signs of LV dysfunction in the groups in the first day MI: in the group 1 LVEF - 52,5 [44,0; 68,0]%, LV EDD - 47,0 [42,0; 56,0] mm, LV ESD - 33 [30,0; 44,0] mm, LAD - 36,5 [35,0; 38,0] mm; in the group 2 LV EF - 56,0 [55,0; 68,0]%, LV EDD - 45,0 [40,0; 50,0] mm, LV ESD - 31 [26,0; 36,0] mm, LAD - 36,0 [34,0; 41,0] mm, p>0,05. As of for the14th day of MI the group 1 showed signs of LV systolic dysfunction - reduction of LVEF, however, the differences were unreliable: LVEF in the group 1 - 47,9 [34,5; 60,0]%, in the group 2 - 57,0 [55,0; 59,7]%, p>0,05. The remaining echocardiographic parameters also did not differ statistically. After 6 months MI in the group 1 the significant systolic LV dysfunction was determined in comparison with the group 2: LVEF in the group 1 - 48,4 [35,0; 53,6]%, in the group 2- 60,5 [52,0; 64,0]%, ? = 0,03. The remaining echocardiographic indicators were of no statistically significant differences.
Conclusion: The change in two markers of heart failure - the natriuretic peptide NT-proBNP and stimulating growth factor sST2 - in first day of myocardial infarction is associated with the development of left ventricular systolic dysfunction in the late post-infarction period.

P243

QRS duration impact on recovery of left ventricular ejection fraction in patients with Heart Failure

A Ana Neto[1]; D Seabra[1]; L Marques[1]; H Guedes[1]; A Andrade[1]; P Pinto[1]
[1]*Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*

Introduction: Heart failure (HF) is the end-stage of several cardiac diseases. The recovery of left ventricular ejection fraction (rLVEF) is an important prognostic factor in these patients (pts). A majority of pts with HF have ECG disturbances, some with delayed intraventricular conduction (DIVC). Delayed activation of the lateral wall of the left ventricle can produce dyssynchronous contraction, which impairs ventricular pump efficacy. Mechanical desynchrony is usually associated with abnormalities of intraventricular conduction (IVC), particularly left bundle branch block (LBBB).
Aims: Evaluate the presence of DIVC in pts followed in a HF clinic (HFC) and their correlation with recovery of LVEF, after at least 3 months of optimal medical therapy (OMT).
Methods: Unicentric and retrospective study; included pts with reduced ejection fraction (EF) and admitted in the HFC with a previous diagnosis of HF for at least 6 months or had prior hospitalization for acute HF. Assessed QRS duration (QRSd) after OMT, HF etiology (ischemic and non-ischemic), EF (before and after OMT). rLVEF was defined as an increase = 10% in LVEF assessed by echocardiography. Pts were divided in two groups: rLVEF (G1) and non-rLVEF (G2). Excluded pts who already had definitive pacemaker at HFC admission. CRT pts data was evaluated before the device implantation.
Results: Included 276 pts, with mean age of 60.5 ± 13.1 years. 24.6% were female. Mean QRSd was 129.6 ± 30.8 milliseconds (ms). 42.0% had ischemic etiology, with no significant differences between HF etiology and QRSd. 27.9% had LBBB and 44.2% non-LBBB delayed IVC. 30.1% had rLVEF after OMT. In univariate analysis, there were an inverse correlation between QRSd and EF at admission and this correlation remained after OMT (p < 0.001). Mean QRSd was inferior in rLVEF pts (p = 0.004). Conclusion: In this cohort of HF pts, a majority of pts showed delayed intraventricular conduction. An inverse correlation was showed between mean QRSd and admission EF, and this correlation remained after OMT. rLVEF was associated with shorter QRSd. These results highlight the importance of electrical desynchrony in myocardial contraction efficacy and, therefore, in prognosis of HF pts.

P244

Global strain of left ventricular myocardium and ejection fraction in STEMI patients

V Valentin Oleinikov[1]; V Galimskaya[1]; A Golubeva[1]; S Kupriyanova[1]
[1]*Penza State University, Penza, Russian Federation*

Aim: to compare different types of global strain of left ventricular (LV) myocardium in patients with ejection fraction (EF) more than 50%, and EF less than 50% 24 weeks after STEMI.
Methods: the study included 99 patients with STEMI (51.3 ± 8.6 years), confirmed by ECG, coronary angiography (CAG), troponin I level, CK-MB. The control group consisted of 50 healthy volunteers (52.2 ± 9.4 years). Echocardiography was performed on the MyLab device (Esaote, Italy) with ejection fraction (EF) determination by Simpson method at 7-9th days from the disease onset and 24 weeks after. The global longitudinal (GLS), circumferential (GCS) and the radial (GRS) strain (-%) were determined using X-Strain ™ software.
Results: Patients were divided into two groups 24 weeks after STEMI: the first group - 76 patients with LVEF > 50%, the second - 23 patients with EF < 50%. GLS values were 17.42 (95% CI 7.96, 26.88) in the 1st group, in the 2nd group - 13.45 (95% CI 3.17, 23.73) (p < 0.01); GCS - 20.07 (95% CI 6.51, 33.63) and 15.07 (95% CI 0.59, 29.55) (p < 0.01), respectively. GRS values in groups 1 and 2 were 32.69 (95% CI 12.75, 52.63) and 25.8 (95% CI 3.0, 48.6) (p < 0.01). GLS was 21.56 (95% CI 20.75, 22.38) in the control group, and differed from group 1 and group 2 by 18% (p < 0.01) and 37% (p < 0.01); GCS - 26.05 (95% CI 24.84, 27.27), 23% (p < 0.01), 42% (p < 0.01), respectively; GRS - 37.65 (95% CI 34.82, 40.48) differed from the strain values by 13% (p < 0.01), and 32% (p < 0.01), respectively, in groups 1 and 2.
Conclusion: EF decrease is accompanied by a reliable reduction in deformation parameters. The global strain parameters differed in patients with preserved EF from those of healthy individuals to a lesser extent.

P245

The usefulness of pulse oximetry for the evaluation of left ventricle ejection fraction in patients with heart failure

A Alexey Naimushin[1]; R Beigel[1]; S Matetzky[1]
[1]*Sheba Medical Center, Ramat Gan, Israel*

Background: The rapid determination of cardiac output (CO) is important for the evaluation of patients presenting to the emergency room, outpatient clinic or during hospitalization. The most accepted technique for CO measurement in the clinical setting is the thermodilution method. Yet, this method requires the use of sophisticated invasive equipment, time consuming measurements and experienced personnel. Pulse oxymetry is a useful method for monitoring patients in different clinical scenario yet it use for CO evaluation had yet to be studied. We sought to evaluate the use of pulse oxymetry for evaluation of CO.
Methods: We evaluated 32 consecutive patients with systolic heart failure (ejection fraction < 40%) and without know lung disease, during their treatment in our day care congestive heart failure unit. Oxygen saturation was measured at admission and if it was less then 95% at room air the second test was done after nasal oxygen supplementation of 3 l/min. The time to correction of basal saturation to +3% after oxygen supplementation was measured.
Results: Average LVEF was 30.25 ± 5.32% with an average basic saturation of 91.9 ± 1.53% without any correlation (r=-0.05). The average time for saturation correction to +3% was 38.5 ± 6.45 seconds and demonstrated a good correlation with systolic function (r=-0.9).
Conclusion: Pulse oxymetry can be a useful parameter for the quick evaluation of patients with known heart failure in regard to left ventricular ejection fraction.

P246

Left ventricular remodeling and endothelial dysfunction in postmenopausal women

N Natalia Lareva[1]; A Govorin[1]; E Luzina[1]
[1]*Chita State Medical Academy, Chita, Russian Federation*

Purpose: To assess the relationship of endothelial dysfunction and left ventricular remodeling in postmenopausal women.
Methods: 203 postmenopausal women were included in the study: 142 with surgical menopause (44,3 ± 5,4 years, menopause duration 3,8 ± 2,4 years); and 61 with natural menopause (46,2 ± 4,7 years, menopause duration 4,3 ± 2,1 years). All patients underwent general clinical examination, ambulatory blood pressure monitoring (Cardiotens-01, Meditech, Hungary), echocardiographic examination with systolic and diastolic left ventricular function assessment. Endothelial function was assessed by the level of metabolites of nitric oxide and the number of desquamated endotheliocytes. Statistical methods such as Cruskell-Walles criteria and chi-square test were used.
Results: Only 39 postmenopausal women (19,2%) had normal LV geometry; 89 pts (43,8%) demonstrated LV concentric hypertrophy, 57 pts (28,1%) - concentric remodeling and 18 women (8,9%) - eccentric hypertrophy. Nobody of included postmenopausal women had LV systolic function failure. Patients with LV concentric hypertrophy had LV diastolic dysfunction in 84,3% cases (75 pts); with LV concentric remodeling - in 52,6% cases (30 pts), with LV eccentric hypertrophy - in 31,6% cases (6 pts), this difference was statistically significant. Nitroxide-producing endothelial function was inhibited in all women included in the study, with a minimum level of nitric oxide metabolites recorded in patients with concentric LV hypertrophy; in the same group the maximum number of desquamated endotheliocytes was recorded (by 40-60% more than in patients with other types of LV remodeling, $p < 0.05$). The functional state of the endothelium in patients with LV diastolic dysfunction was changed to a greater degree than in those who had no diastolic filling disorders (the total number of nitric oxide metabolites was 12-17% lower in comparison with those patients who did not have disturbed LV relaxation processes). Significantly more pronounced in patients with impaired diastolic filling were the processes of desquamation of endotheliocytes: their number was 3.1 times higher than in healthy individuals, which was 148% of the level of this indicator in the group of women with normal parameters of diastolic function. Conclusions. Thus, violations of LV structure and function in postmenopausal women are interrelated with changes in the functional state of the endothelium. Most endothelial dysfunction is expressed in patients with concentric LV hypertrophy, as well as with its diastolic dysfunction. This relationship, perhaps, causes the rapid progression of cardiovascular complications in patients with violations of LV geometry that occur with an increase in the LV myocardial mass and changes in the characteristics of its cavity, as well as in patients with worsened diastolic filling of the LV.

P247

Evaluation of right ventricular diastolic function in patients with coronary artery disease: gender differences

A N Alexey Sumin[1]; EV Korok[1]; OG Arhipov[2]
[1]*RAMS Scientific-Research Institute for Complex Studying of Cardiovascular Diseases, Kemerovo, Russian Federation*; [2]*Sanatorium Topaz, Mysky, Russian Federation*

Background: Right ventricular dysfunction is an independent predictor of cardiovascular mortality after coronary artery bypass grafting. Early diagnosis of right ventricular (RV) dysfunction is important for an accurate assessment of the patient's prognosis. There are few studies focused on the gender differences in the evaluation of RV diastolic function in patients with coronary artery disease (CAD).
Purpose: To assess the detection rate of RV diastolic dysfunction in men and women with CAD.
Methods: 719 patients with CAD who underwent outpatient examination were included in the study. All patients were assigned to two groups according to their gender: Group 1 - men (n = 432, 61 [55, 67] years), and Group 2 - women (n = 287, 62 [56, 67] years), and echocardiography (ECHO-CG) was performed. Preserved RV diastolic function was considered with the Em / Am ratio in the range of 0.8-2.1, the Em / e't ratio < 6, and the deceleration time of early diastolic mitral and tricuspidal flows >120 msec. Alterations in the above set ranges and reduced distribution velocity of early tricuspid flow (DVETF) < 35 cm/s were defined as RV diastolic dysfunction.
Results: DVETF was higher in women compared with men. There were no differences found in the other ECHO-CG parameters in both groups (Table). RV diastolic dysfunction was commonly found in both groups, compared to RV systolic dysfunction (50.5% and 45.6% vs. 17.6% and 15%, respectively). There were no significant differences between the study groups (p>0.05).
Conclusion: There were no gender differences in the detection rate of RV diastolic dysfunction in CAD patients. However, RV diastolic dysfunction was more common than RV systolic dysfunction.

Right ventricular diastolic indexes

Parameters	Group 1 men (n = 432)	Group 2 women (n = 287)	?
$?_m/?_m$	1.2 [1.0;1.5]	1.2 [1.0;1.4]	0.536
DTE_t, ME [LQ, UQ] msec	177 [155;207]	170 [148;200]	0.100
DVTF, ME [LQ, UQ] cm/sec	38 [33;43]	39 [34;45]	0.001
$?'_t$, ME [LQ, UQ] cm/sec	13 [10;16]	13 [11;16]	0.513
$?'_t$, ME [LQ, UQ] cm/sec	15.4 [12.2;19.6]	16.1 [12.9;19.6]	0.238
$?'_t/?'_t$, ME [LQ, UQ]	0.8 [0.7;1.0]	0.8 [0.7;1.0]	0.819
$?_t/?'_t$, ME [LQ, UQ]	4.0 [3.2;4.9]	3.9 [3.2;4.9	0.416

Em / Am - the ratio of early and late diastolic transmitral flows; DT?t, - deceleration time of early diastolic tricuspidal flows; DVTF - distribution velocity of early tricuspidal flow; et, - early diastolic tricuspid annular velocity; a't - late diastolic tricuspid annular velocity; e't / a't, Et / e't is the ratio of the early filling velocity of the right ventricle to the early diastolic tricuspid annular velocity.

P248

Longitudinal strain abnormalities predict worse outcome in patients with recovered ejection fraction

J J Jort Merken[1]; HP Brunner-La Rocca[1]; J Weerts[1]; J Verdonschot[1]; J Schroder[1]; M Hazebroek[1]; V Van Empel[1]; SRB Heymans[1]; C Knackstedt[1]
[1]*Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands*

Funding Acknowledgements: TOMTEC Imaging Systems GmbH, Unterschleissheim, Germany

Background: Due to modern heart failure (HF) therapy, some patients show normalization of left ventricular ejection fraction (LVEF), classified as patients with heart failure with recovered LVEF (HFrecovEF). Still, the question remains whether this means full recovery of left ventricular systolic function or just normalization of LVEF. Global longitudinal strain (GLS) analysis at echocardiography may provide additional insight to study systolic function.
Purpose: Here, we determined the percentage of persistent GLS abnormalities in patients with HFrecovEF, and determined its prognostic value.
Methods: A total of 212 patients with HFrecovEF were included in one center. HFrecovEF was defined as an initial LVEF <35% and improvement to 55% or higher. GLS was determined on routine echocardiography using a dedicated software. GLS was considered normal <-21.5% and abnormal >-21.5%. Patient characteristics and adverse events during follow-up were taken from the medical records. All

etiologies (diseased myocardium, abnormal loading conditions, and arrhythmias) for an initial decreased LVEF were included. The primary endpoint was death or HF hospitalization.
Results: Despite normalization of LVEF after a follow-up of 56 ± 21 months (range 12-90 months), 168 (79%) of patients with HFrecovEF displayed a pathologic GLS. These patients showed a significant worse outcome of all cause death and HF hospitalization (p-value = 0.039) as compared to patients with normal GLS (Figure 1).
Conclusions: In conclusion, the majority of patients with HFrecovEF still have an abnormal systolic function of the LV, measured by GLS. Patients with HFrecovEF and an abnormal GLS exhibit a significantly worse outcome. Whether these patients would benefit from continuation of HF therapy, requires further investigation.

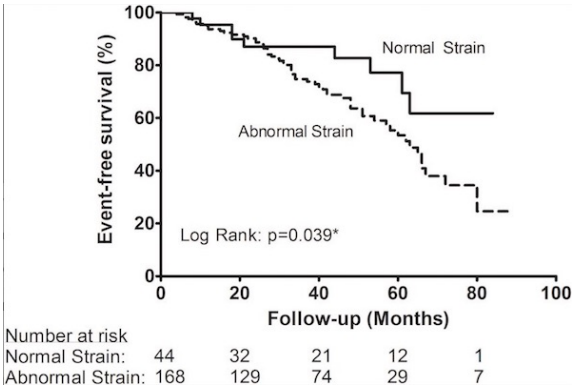

Figure 1

P249

Left ventricular remodelling and prognosis of patients with de novo heart failure: differences between ischaemic and non-ischaemic aetiology

J C Van Den Berge[1]; JF Veenis[1]; JJ Brugts[1]; K Caliskan[1]; OC Manintveld[1]; KM Akkerhuis[1]; JW Deckers[1]; AA Constantinescu[1]
[1]*Erasmus Medical Center, Department of Cardiology, Rotterdam, Netherlands*

Background: As a result of optimal medical heart failure (HF) therapy, left ventricular (LV) function may improve in HF patients. However, studies on LV remodelling were mostly performed in outpatients with chronic HF, and rarely in patients admitted with de novo HF. Moreover, there are no studies investigating LV remodelling in relation to ischaemic or non-ischaemic aetiology.
Purpose: Therefore, we studied the LV remodelling and prognosis of patients admitted with acute decompensated de novo HF. Furthermore, we investigated whether there was a difference in LV remodelling and prognosis between patients with ischaemic and those with non-ischaemic HF.
Methods: We included all consecutive patients admitted with de novo HF in the period 2008 through 2016. Patients with a history of any cardiac disease or a left ventricular ejection fraction (LVEF) at admission above 40% were excluded. LV remodelling was assessed by serial measurement of LV end diastolic (LVED) diameter, LV end systolic (LVES) diameter and LVEF by echocardiography.

	Baseline	6 months	12 months	24 months	36 months
Non-ischaemic HF	24 (17-31)	40 (32-50)	44 (38-55)	45 (36-55)	50 (38-62)
Ischaemic HF	30 (24-37)	28 (23-35)	33 (26-43)	33 (29-37)	32 (27-44)

Figure.

Results: We included 123 patients (mean age 49 ± 14 years, 57% male, 42% ischemic HF) with acute decompensated de novo HF. At discharge, the median LVED and LVES diameter were 58 mm (IQR 53-65) and 47 mm (IQR 39-55), respectively, whereas the mean LVEF was 28% (IQR 22-36). In the total population, the LVED, LVES and LVEF improved over time, especially in the first six months (LVED -4 mm [p < 0.001], LVES -6 mm [p < 0.001] and mean LVEF +6% [p = 0.01]). In patients with ischaemic HF, we could not observe an improvement in LVED (p = 0.28), LVES (p = 0.58) and LVEF (p = 0.19) during the first six months (Figure). In contrast, in the first half year after discharge, patients with non-ischaemic HF had significant remodelling with improved LVED (p < 0.001), LVES (p < 0.001) and LVEF (p < 0.001; Figure). A total of 30 patients (24%) reached the composite end-point during 3 years of follow-up. In patients with non-ischaemic HF only 17% reached the composite end-point of death, HF rehospitalisation, left ventricular assist device (LVAD) implantation or heart transplantation during 3 years of follow-up , compared to 35% of the patients with ischaemic HF (p = 0.02).
Conclusions: In patients admitted with de novo HF, we found improving left ventricular diameters (both LVED and LVES) and increasing LVEF over time, with the most improvement in the first 6 months after discharge. This LV remodelling was observed in patients with non-ischaemic HF but not in those with ischaemic HF. The prognosis of patients with non-ischaemic aetiology of de novo HF was more favourable than the prognosis of their counterparts with ischaemic HF.

P250

Myocardial deformation in STEMI patients with different types of left ventricle remodelling

V Galimskaya[1]; A Golubeva[1]; S Kupriyanova[1]; V Valentin Oleinikov[1]
[1]*Penza State University, Penza, Russian Federation*

Aim: to compare the deformation characteristics of left ventricle myocardium, determined using the speckle tracking technique, 3 months after STEMI in patients with different types of cardiac remodeling.
Methods: 74 patients (51.3 ± 8.6 years) with STEMI confirmed by ECG, coronary angiography (CAG), troponin I, and CK-MB were included in the study. Inclusion criteria: significant stenoses of one infarct-related coronary artery, PCI for the first hours after the pain onset. Exclucion criteria: history of myocardial infarction and other cardiovascular diseases. All patients underwent echocardiography on the MyLab device (Esaote, Italy) at the 7th day and 3 months later. End-diastolic volume index (EDVi) was evaluated. Using the X-Strain™ software, the Global longitudinal (GLS), circumferential (GCS) and radial (GRS) strain (-%) were determined. The criterion for pathological remodeling was considered to be an EDVi increase of more than 20% on the following measurement 3 months after the STEMI.
Results: After 3 months, the patients were separated onto two groups depending on the EDVi increase: one group included 43 (58%) people without echocardiographic signs of LV remodeling; group 2 comprised 31 (42%) patients. In the 1 and 2 group GLS had the following values: 17.71 (95%CI 16.23, 19.18) and 14.39 (95%CI 12.66, 16.13) (p <0.01), respectively; GCS - 20.84 (95%CI 18.97, 22.69) and 15.57 (95%CI 13.38, 17.76) (p <0.01). The GRS values in group 1 were 33.95 (95%CI 30.99, 36.91), in the 2nd group 28.79 (95%CI 25.31, 32.28) (p <0.05). Conclusion: the global longitudinal, circumferential and radial strain were significantly less in patients with rapidly progressive LV remodeling after STEMI, than in the group without pathological remodeling.

P251

Heart rate variability and left ventricle ejection fraction in patients after the acute Q-wave myocardial infarction

NU Zakirov[1]; YG Kevorkova[1]; A Amayak Kevorkov[1]; Z Fazylbekova[2]
[1]*Republican Specialized Center of Cardiology, Tashkent, Uzbekistan*; [2]*Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan*

Purpose: to estimate interrelations between heart rate variability (HRV) and left ventricle ejection fraction (LVEF) in patients after the acute Q-wave myocardial infarction (Q-AMI).
Materials and Methods: Study included 96 male patients (average age of 52.78 ± 9.05 y. o.) survived after the primary Q-AMI. The diagnosis of Q-AMI was established in accordance with the ESC criteria (2012). All patients underwent Holter ECG monitoring (HMECG) with the estimation of HRV and transthoracic echocardiography. HMECG performed on standard therapy on 10-14 day of the Q-AMI and after the 6 month of follow up. Standard therapy included antiplatelet agents, beta-blockers, ACE inhibitors or ARB, statins and amiodarone (if necessary). Interpretation of HRV parameters was made with estimation of SDNN, SDANN, RMSSD and pNN50. As a decrease in the total HRV, a reduction of SDNN = 100 ms was assumed. Statistical analysis was performed using nonparametric ANOVA ?2 test. Differences were considered significant for p <0.05.

Results: It was noted that afer the 6 month level of the SDNN, SDANN and pNN50 values increased on therapy by more than 20%, and the rMSSD - more than 12%. In patients with reduced HRV at 6 months of follow-up, were noted significantly lower initial values of the LVEF (49.28 ± 11.89% vs. 51.98 ± 10.39%; p = 0.038), compared with patients with normal HRV. There was also a significant positive correlation between baseline LVEF values and SDNN (R = 0.21, p = 0.041) and SDANN (R = 0.22, p = 0.034) after the 6th month follow-up. Also, group of patients with a significant baseline decrease in EF <40% compared with patients with baseline EF>40% were further analyzed. It was noted that patients with significantly reduced EF, at baseline, had reliably lower rates as SDNN (84.8 ± 25.9 ms vs. 103.5 ± 28.9 ms, p = 0.035) and SDANN (75.3 ± 21.9 ms vs. 92.9 ± 26.9 ms, p = 0.038).
Conclusions: Group of patients with reduced total HRV at 6 months of follow-up demonstrates significantly lower initial values of the LVEF and there is a significant positive correlation between baseline LVEF values and total HRV level on 6th month of follow-up. Low level of LVEF on 10-14 day of Q-AMI may be consider as a 6-month predictor of decreasing of HRV which in combination points to worsening of prognosis for such category of patients.

6 month dynamics of HRV indicators

	Initial	6 month	ANOVA χ^2	p
SDNN, ms	102.7±32.5	124.0±34.4	30.556	0.000
SDANN, ms	91.2±29.6	110.1±30.0	25.043	0.000
rMSSD, ms	23.4±12.7	26.3±12.2	12.517	0.000
pNN50, %	5.0±7.2	6.0±6.9	9.000	0.003

P252

Effect of high beta-blocker dose on the long term prognosis of patients with heart failure with reduced ejection fraction

M Marie Lazarova[1]; FM Malek[2]; MT Taborsky[1]; AI Ignaszewski[3]
[1]University Hospital Olomouc, cardiology, Olomouc, Czech Republic; *[2]Na Homolce Hospital, Cardiology, Prague, Czech Republic*; *[3]St Paul's Hospital, Cardiology, Vancouver, Canada*

Background/Introduction: Pharmacotherapy of patients with HFREF with reaching target medication doses is one of the key factors contributing to better prognosis, especially concerning beta-blockers. Despite this fact, the general HF patient population reach target medication doses only in a small percentage according to clinical practice data and registries.
Purpose: We aimed to evaluate the effect of target and more than target beta-blocker dose on a long term prognosis of HFREF patients.
Methods: We analyzed data of 739 HFREF patients who were followed during years 1975-2011 and achieved long-term clinical stabilization and reverse left ventricle remodeling. We analyzed the established pharmacotherapy of this patient group, especially concerning beta-blocker doses.
Results: 739 HFREF patients who stabilized their disease in long term period and reached LV reverse remodeling were followed for 6.4 (median) years. 65.9% of patients had non-ischemic cardiomyopathy (NICMP). Their median LV ejection fraction (LVEF) improved from 25.0% at baseline to 50.0% at the time of the latest data collection. 79.7% of patients survived 18.1 years after diagnosis of HF according to Caplan-Meier survival analysis, that is much better long term prognosis than general HF patient population. 78.1% of the patients were receiving recommended target or higher than target doses of beta-blockers. The most frequently used beta-blocker was carvedilol, target dose of 50 mg daily and more had 40.6% of beta-blocker patients. Target daily bisoprolol dose of 10 mg and more and metoprolol dose of 200 mg and more had 27.0% and 10.5% of beta-blocker patients, respectively.
Conclusion: The prognosis of patients with HFREF who developed LV reverse remodeling was much more favorable than in the general population of HF patients. Optimal pharmacotherapy, especially reaching of target beta-blocker doses might have significantly contributed to this.

P253

Clinical and humoral determinants of congestion in HFrEF patients

I Ivana Jurcova[1]; J Benes[1]; M Kotrc[1]; A Jabor[1]; J Kautzner[1]; J Kovar[1]; P Jarolim[2]; V Melenovsky[1]
[1]Institute for Clinical and Experimental Medicine (IKEM), Cardiology, Prague, Czech Republic; *[2]Brigham and Women's Hospital, Boston, United States of America*

Funding Acknowledgements: This study is supported by Ministry of Health of the Czech Republic, grant AZV 17-28784A

Purpose: Congestion is a classical feature of heart failure (HF) that is present in some but not all HF patients. The goal was to identify clinical and humoral factors associated with congestion and its impact on prognosis.
Methods: 371 stable HFrEF patients underwent clinical examination, echocardiography, blood sampling, Minnesota Living with HF Questionnaire (MLHFQ) and were longitudinally followed. Death, LVAD implantation or heart transplantation were considered as an adverse outcome. Patients scoring between 3-5 in question 1 of MLHFQ were considered congestion-positive.
Results: Congestion was present in 31% of patients. After a median follow-up of 521 days, 37% of all patients had an event. In Cox analysis, the presence of congestion was associated with 68% higher risk of an adverse outcome (p = 0.003). Patients with congestion were more symptomatic (NYHA 2.9 ± 0.5 vs 2.7 ± 0.6, MLHFQ sum: 61 ± 18vs 41 ± 21) and had more often edema at the time of the examination (50% vs 17%) than those that were congestion-free (all p?0.001). Presence of congestion was strongly (?0.001) associated with RV dysfunction, tricuspid regurgitation, dilated inferior vena cava, cardiac cachexia (15 vs 31%), furosemide daily dose, hyponatremia, hypoalbuminemia, but unrelated to age, HF duration and etiology, sex, systolic blood pressure, body mass index, left ventricular function, cardiac output, hemoglobin, eGFR and MRA or ACEi/ARB dose. The levels of mid-regional pro-adrenomedullin (MR-proADM), BNP, copeptin, endothelin-1, GDF-15, FGF-13 and adiponectin were significantly (p < 0.05) associated with congestion; on the contrary no relation between congestion and the level of insulin, cortisol and troponin was found.
Conclusion: Congestion is associated with distinct set of humoral factors and predominantly with the RV but not LV function. Congested patients suffer with more pronouced HF symptoms and have shorter survival.

P254

Left atrial dysfunction as a pathophysiological determinant of clinical status, right ventricular dysfunction and pulmonary hypertension in HFrEF patients with significant mitral regurgitation

G Palmiero[1]; L Ascione[1]; A Ferro[1]; E Melillo[1]; R Ascione[1]; S Severino[1]; P Caso[1]; V Monda[1]
[1] AO dei Colli-Monaldi Hospital, Department of Cardiology, Naples, Italy

B: Functional mitral regurgitation (FMR) and left atrial function (LAF) are determinants of clinical status but little is known about the effects of FMR on LAF in HFrEF patients.

Table 1

	FMR (n = 38)	SFMR (n = 59)	P
Age (yrs)	62,5±14,9	66,0±9,7	ns
Men (%)	5 (13,1%)	9 (15,2%)	ns
Ischaemic aetiology (%)	24 (63,1%)	46 (79,6%)	ns
NYHA Class	2,0±0,8	2,7±0,8	0,0001
LVEDV (ml)	174,3±52,9	256,3±72,1	0,0001
LVEF (%)	30,1±3,5	28,4±5,6	ns
LAVI (ml/m^2)	46,3±17,3	67,9±23,2	0,0001
E/E'	17,4±6,9	27,7±10,5	0,0001
sPAP (mmHg)	34,3±7,4	50,6±13,3	0,004
TAPSE (mm)	19,6±2,9	16,5±4,2	0,02
EROA (mm^2)	0,11±0,4	0,23±0,8	0,0001
LAAEF (%)	28,0±9,4	19,1±8,9	0,0001
LAPEF (%)	25,1±8,1	18,1±7,5	0,0001
TLAEF (%)	45,8±10,4	33,5±11,0	0,0001
LAEI (%)	92,7±44,8	54,7±26,4	0,0001

P: To assess the effects of significant FMR (SFMR) on LAF and their consequences on RV function and pulmonary pressures.
M: 97 patients with HFrEF in sinus rhythm with mild-to-severe FMR were enrolled. MR severity was assessed and patients dichotomized based on the presence of SFMR (3-4+) at TTE. LAF was evaluated using the phasic method. LA volumes were measured at 3 time-points (before mitral valve opening, at P-wave onset and at MV closure) and LAF parameters thus calculated: reservoir as LAEI, conduit as LAPEF, pump as LAAEF and total emptying function as TLAEF. LA dysfunction (LA-Dys) was defined for TLAEF values below the median and the 2 gruops subdivided on its presence.
R: The groups were well matched (Table 1). Pts with SFMR displayed higher larger LV and LA volumes, higher LV filling and pulmonary pressures and lower TAPSE and LAF values compared to those in FMR group. SFMR/LA-Dys+ group showed a worse clinical status and higher incidence of pulmonary hypertension (PH) and right ventricular dysfunction (RV-Dys) (Fig. 1)

C: SFMR seems to affect LAF in HFrEF patients and SFMR and LA-Dys to play a complimentary role in determining clinical status, RV-Dys and PH in HFrEF patients.

Initial experience of pharmacological treatment with sacubitril-valsartan: baseline clinical characteristics and follow-up at one year of clinical use

RA Montiel Quintero[1]; I Irene Menduina Gallego[1]; M Grova Marco[1]; E Perez Nogales[2]; JM Medina Gil[2]; M Galvan Ruiz[1]; M Singh[1]; M Fernandez De Sanmamed Giron[1]; A Garcia Quintana[1]
[1]*University Hospital Dr Negrin, Cardiology, Las Palmas De Gran Canaria, Spain*; [2]*University Hospital Insular of Gran Canaria, Las Palmas De Gran Canaria, Spain*

Introduction: An important novelty, with incorporation in the current guidelines of heart failure(HF) is sacubitril/valsartan. This has shown reduced risk of death and hospitalization in patients with chronic HF and reduced left ventricular ejection fraction (LVEF).Propouse: To describe the baseline demographic and clinical characteristics, in addition to the one-year follow-up of patients who were prescribed sacubitril/valsartan. Method: We analyzed 106 patients with HF and reduced LVEF assessed in the cardiology outpatient clinic of two universitary hospitals between October 2016 and October 2017, who were treated with sacubitril/valsartan.
Results: an average age of 63.56 years (+/-11.68), being 68.87% (n = 73) men. 51.52% (n = 51) were in NYHA II and 47.47% (n = 47) remaining in NYHA III. 74.53% (n = 79) were hypertensive, 49.06% (n = 52) diabetic and 51.89% (n = 55) dyslipemic. 30.19% (n = 32) had atrial fibrillation, 38.46% (n = 40) complete block of the left branch of Has of His and of these 55 %% (n = 22) received resynchronization therapy. 49.52% (n = 52) was ischemic heart disease and 40% (n = 42) idiopathic dilated cardiomyopathy. 75.47% (n = 80) of the subjects had the LVEF severely depressed (< 35%). The average LVEF was 30.4% (+/-6.94). The mean value of serum creatinine was 1.11 mg/dL (+/-0.33), serum potassium 4.48 mEq/L (+/-0.52) and NTproBNP 4072 pg/mL. The mean systolic blood pressure at the start of treatment was 127.14 mmHg (+/-21.69). 95.19% (n = 99) received betablockers, 44.23% (n = 46) spironolactone, 39.05% (n = 41) eplerenone, 80.58% (n = 83) loop diuretics and 24.27% (n = 25) ivabradine. In the majority (59.43%; n = 63), sacubitril / valsartan was started with the low dose (24/26 mg). With respect to follow-up, the mean time was 198.24 days (+/-137.6). At the end of the follow-up only 27.35% (n = 29) of the patients had achieved the target dose. The majority (35.84%, n = 38) received intermediate doses and 27.35% (n = 29) received low doses. Mean serum creatinine at follow-up was 1.16 mg/dl (+/-0.38) and only 17.07% (n = 14) reported values above 1.5 mg/dL. The mean NTproBNP at follow-up was 2323.01, with a reduction of 42.95% with respect to the baseline. 20.75% (n = 22) went to the emergency room or was admitted due to decompensation of the HF. The mortality was 4.71% (n = 5). Conclusion: When compared to the profile of patients in the Paradigm HF clinical trial, the subjects in our series were in worse functional class, had higher levels of pro-BNP and lower LVEF. In addition, a significant percentage of the patients who started with this treatment had resynchronization therapy, which is why we conclude that our patients are in more advanced stages of the ICC, which is why we should emphasize the beginning of this innovative and effective treatment in more early stages of the disease in order to improve the prognosis and quality of life.

P256

The role of sacubitril-valsartan treatment on right ventricular function and cardiorespiratory response in patients with chronic heart failure. Single-centre experience from Myltiple patient program o

C Christina Chrysohoou[1]; E Oikonomou[1]; G Vogiatzi[1]; E Paschalidis[1]; N Maggas[1]; V Katsi[1]; A Avgeropoulou[1]; I Kallikazaros[1]; D Tousoulis[1]
[1]*University of Athens, Athens, Greece*

Introduction: Cardiorespiratory response, right ventricular and global diastolic function is known to deteriorate the clinical course of patients with chronic compensated systolic heart failure, even under optimal treatment. In this work we sought to evaluate the role of sacubitrrl/valsartan initiation in patients with chronic heart failure showing clinical deterioration under optimal medical treatment in NYHA clinical status II-III.
Methods: 46 patients consecutive patients (90% male, mean age 55+/-8 years old, 60% ischemic heart failure) with chronic compensated heart failure, due to ischemic (IHF) or dilated cardiomyopathy (DCM)-NYHA classification II-III-, who were enrolled in the Sacubitril-Valsartan multiple patient program were evaluated. Cardiorespiratory exercise response and bi-ventricular Doppler indices were evaluated at first visit and 6 months after. The pulsed tissue Doppler imaging of the systolic and diastolic function of mitral and tricuspid annulus was characterized by the systolic waves Smv and Stv, and the diastolic waves: Emv and Amv; E was the early filling wave in transmitral velocity. Left atrial maximal volume and global longitudinal strain of the left ventricle (GLPS) were measured. Serum urine, creatinine levels, potassium and sodium were also measured. All of them received b-blockers, 90% eplerenone or spironolactone, 25% ivabradine and 90% diuretic treatment. Sixty six percent of them started with the dose of 50mg of sacubitrl/valdartan; while 80% finally received the full dose of 200 mg bid. One third of them were on clinical status NYHA III.
Results: Four of the patients discontinued the program due to hypotension or renal function worsening. All patients expressed improvement in clinical status; while diuretic therapy was down titrated in all of them and discontinued in 30%. As compared with the initial examination, tricuspid annulus systolic wave velocity increased by 6.6% (p = 0.04); maximum volume of left atrium was decreased by 8.4% (p = 0.004); GLPS average was improved by 50% (p = 0.001) and E/Emv ratio was decreased by 22% (p = 0.04). Moreover, improvement in Stv was more prominent in DCM as compared to IHF patients; while no such difference was detected in average GLPS. In cardio respiratory exercise VE/VCO2 and VO2 max showed a trend in improvement (p = 0.1), with no difference detected between DCM and ICM patients; although there was a significant increase in METS achieved (p = 0.04).
Conclusion: Sacubitril/valsartan initiaition was associated with improved left diastolic function and right ventricular function, along with functional status improvement in patients with chronic heart failure. These finding underline the beneficial role of sacubitril/valsartan initiation on the hemodynamic course of patients with systolic heart failure and clinical status deterioration.

P257

Sacubitril/valsartan (SV) in chronic symptomatic heart failure with reduced ejection fraction; early clinical experience from a large UK tertiary centre.

D Ali[1]; J Hyland[1]; F Riley[1]; S Kirkland[1]; L Hinitt[1]; S Al Bared[2]; R Parekh[1]; C Watson[1]; H Nicholson[1]; J Mccann[1]; F Umar[1]; P Banerjee[1]
[1]*University Hospitals of Coventry and Warwickshire NHS Trust, Cardiology, Coventry, United Kingdom*; [2]*University of Medicine Victor Babes, Timisoara, Romania*

Objective: Sacubitril valsartan (SV) is now approved to be used as an alternative to ACE-inhibitors (ACE-i)/Angiotensin Receptor Blockers (ARB) in patients with symptomatic chronic heart failure with reduced ejection fraction (HFrEF). We report our clinical experience of SV use in HF patients at a large UK cardiac centre, using dedicated nurse-led , cardiologist supported, SV clinic.
Methods: HFrEF patients seen in the HF clinic and started on SV from April 2016 till July 2017, were retrospectively evaluated. Change in New York Heart Association (NYHA) class, eGFR, up-titration to target dose and tolerability to SV were assessed. Six month and 1-year outcomes, in term of death and HF hospitalisation were evaluated. Patients were seen in nurse-led HF clinic at 4 weekly intervals until up-titration to maximum tolerated dose.
Results: A total of 140 patients were included and in 77 patients (55%) up-titration to the target dose was achieved. In 43 patients (31%) and in 23 patients, an improvement of NYHA class and LVEF respectively, was seen. Fourty four patients (31%) had symptomatic systolic blood pressure drop of >10mmHg at follow-up preventing target dose up-titration. At 6 months there were 8 (6%) HF admissions and 5 in hospital deaths. One year outcome was observed in 68 patients with a mortality of 7% (n = 5) and HF admission of 6% (n = 4). Fifteen patients (10%) had a worsening of the eGFR >10 and in 11 patients (8%) SV was stopped to due intolerability.
Conclusion: The clinical use of SV in our centre has a high rate of tolerability with significant improvement in NYHA class (31%) and low HF hospitalization and mortality rate. However, in a large proportion of patients, the target dose was not achieved (45%), mainly due to reported dizziness and postural blood pressure drop.

Outcome measures	
Outcome measures (N = 140)	
Up-titration achieved (target dose 97/103mg BD)	77 (55%)
Reduction in Loop Diuretic dosage	30 (27%)
SV intolerability and stopped	11 (8%)
Mineralocorticoid receptor antagonist (MRA) dose reduced due to hyperkalemia	2 (2%)
MRA dose stopped due to hyperkalemia	1 (1%)
Postural hypotension with drop of systolic blood pressure at (>10mmHg)	44 (31%)
Mortality (6 months n = 140) Mortality (1-year n = 68) HF admission (6 months n = 140) HF admission (1 year n = 68)	5* (4%) 5 (7%) 8 (6%) 4 (6%) *(2 HF related, 3 non-HF related death)
Hyperkalaemia (>6.0 mmol/L) Deterioration in eGFR>10	4* (3%) 15 (10%) *(2 patients admitted to hospital)
NYHA class improvement (by 1 class) Improvement in LVEF Mean EF (pre-entresto) Mean EF (post-entresto)	43 (31%) 23* out of total 34 patients (66%) *(7 patients from LVEF <35 to >55%) 23% 30%

Atrial deformation imaging predicts invasively measured pulmonary vascular resistance in advanced heart failure patients

V Marinho[1]; J Moura Ferreira[1]; P Alves[1]; C Domingues[1]; J Milner[1]; J Ferreira[1]; S Costa[1]; R Baptista[1]; F Franco[1]; MJ Ferreira[1]; R Martins[1]; F Goncalves[1]; M Pego[1]
[1]*University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*

Introduction: Advanced heart failure (HF) patients often have high pulmonary vascular resistance (PVR) which prevents candidacy to heart transplantation. Atrial myocardial deformation analysis assessed by speckle tracking echocardiography is a research imaging technique that provides information about all the components of atrial function: reservoir, conduit and booster pump.
We aimed to evaluate atrial myocardial deformation analysis as predictors of invasively measured PVR in advanced HF patients.
Methods: Retrospective, observational study that included 15 advanced HF patients that performed echocardiography and hemodynamic assessment in the same week. Atrial myocardial deformation was evaluated by speckle tracking imaging from acquired apical 4 chambers and two chambers cine loops, using EchoPAC workstation. Strain and strain rate addressing reservoir (S), conduit (E) and booster pump (A) functions were determined. Invasive hemodynamic pressure curves were reviewed, and relevant hemodynamic data was collected.
Results: Scatter plots and Pearson correlations were computed to examine the intercorrelations of the variables. PVR was significantly correlated with strain-S (4C) r(12)= -0,706, p = 0,01, strain-S (2C) r(10)= - 0,767, p= 0,01, strain-E (2C) r(9)=-0,754, p = 0,019, strain-A (4C) r(10)=-0,772, p = 0,009, strain rate -A (4C) r(11)= 0,616, p = 0,044. A regression model to predict PVR including strain-A (4C) was statistically significant F (1,8)= 11,764, p= 0,009. The adjusted R2 value was 0,55, meaning that 55% of the variance in PVR was explained by the model.
Conclusion: All the components of atrial function - reservoir, conduct and booster pump - evaluated by atrial myocardial deformation speckle tracking analysis are correlated with invasively assessed PVR in advanced HF patients.

Cardio-renal syndrome type 2: a retrospective study.

S Antit[1]; B Ben Kaab[2]; MB Menjour[2]; I Slama[1]; S Belakhel[2]; I Boussabeh[1]; M Thameur[1]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*; [2]*Interior Security Forces Hospital, Department of medicine interne, Marsa, Tunisia*

Background: Chronic heart failure (CHF) is a serious disease, and its prevalence is steadily increasing. Among patients with CHF, 30-60% have chronic renal impairment, defining cardio-renal syndrome (CRS) type 2. Patients with CRS type 2 have a higher morbidity and mortality and have a therapeutic problem. The objective of our study was to evaluate the therapeutic and prognostic impact of CKD in CHF patients.
Methods: This was a retrospective study involving 70 patients with CHF (LVEF = 50%) divided into two groups: Type 2 cardio-renal syndrome (SCR) group: patients with creatinine clearance < 60ml / min, a control group: patients with creatinine clearance = 60 ml / min
Results: Patients with CRS type 2 were older (66 years versus 54 years, p = 0.001). The risk of developing CRS type 2 was correlated with the female genus and the presence of high blood pressure. The presence of a CRS type 2 worsens the clinical picture of the CHF, as dyspnea stage IV was more severe (68% versus 38%, p = 0.03) and blood pressure was higher for Systolic (141 versus 122, p = 0.002) and diastolic (86 versus 75 p = 0.01) in the CRS type 2 group.
Biologically, patients with CRS type 2 had more anemia with lower average hemoglobin. (12.9 versus 13.9, p = 0.01).
Therapeutically, nitrates were used more often in patients with CRS type 2 (20% versus 5%, p = 0.05).
As for the evolution of our patients, the occurrence of outbreaks of heart failure and mortality were significantly higher in the SCR group type 2.
Conclusion: The occurrence of a SCR worsens the initial picture of heart failure, exposes it to more cardiovascular events, and aggravates the patient's prognosis. Management must be early and prevention of cardiovascular risk factors remains the most effective way to limit the incidence of CHF and CRS.

P260

Sacubitril/Valsartan in systolic heart failure: a short term follow up.

VIPIN Mughilassery Thomas[1]; AHMED Siddiqui[1]; SWAPNA Thomas[2]; NAWAS Mohammed[1]; TAHA El Shafie[1]
[1]*Al Ain Hospital, Cardiology, Al Ain, United Arab Emirates*; [2]*Amrita Institute of Medical Sciences, Kochi, India*

Background: Angiotensin Receptor/Neprilysin Inhibitor(ARNI),Sacubitril/Valsartan has been shown superior to Enalapril in reducing the risk of cardiovascular deaths & hospitalisation in heart failure patients with Reduced Ejection Fraction (HFrEF).
Objectives & Methods: To analyse the efficacy,tolerability,adverse effects and clinical outcome in patients treated with ARNI in our hospital population.Patients were in NYHA II-IV with LVEF < 40%.Followed up to twelve months for heart failure rehospitalisation,improvement in NYHA functional class,adverse effects and total mortality.
Results: A total of 30patients were treated with ARNI(mean age 66.6 ± 13.5 years; 63.3% male,36.7% female).
Of these,17(56.7%)had Ischemic cardiomyopathy and 13(43.3%) had non-ischemic cardiomyopathy.

14(46.7%) had GFR < 60mL/min/1.73m2. Worsening of renal function occurred in 23.3%.Asymptomatic hypotension occurred in 6.7%.Progressive elevation of BNP in 43.3% of patients.Improvement in functional class by one class, occurred in 56.7% of patients and partial improvement in 30%.There were a total of 37 rehospitalisation among the 30patients up to 9months prior to commencement of ARNI and 17 rehospitalisation with heart failure after starting ARNI. Total mortality during the follow up was 10%.

Conclusion: This short term clinical study data show that ARNI is well tolerated in our cohort population of HFrEF with improvement in functional class and reduction in hospitalisation rate.

Age	66.6±13.46yrs
Sex	male 69.5% , female 30.5%
Ischemic v/s non-ischemic	56.7% v/s 43.3%
CKD	46.7%
Worsening renal function	23.3%
Asymptomatic hypotension	6.7%
Symptomatic hypotension	nil
history of CRT-D	30%
worsening BNP	43.3%
NYHA class improvement by 1 class	56.6%
Total re-hospitalization : before ARNI	44 events
Total re-hospitalization: after ARNI	17 events
Total mortality	10%

P261

Characteristics and long-term prognosis of patients with heart failure and mid-range

J Abdulla[1]; J Lauritsen[1]; F Gustafsson[2]
[1]*Glostrup hospital, Division of cardiology, Department of medicine, Copenhagen, Denmark*; [2]*Rigshospitalet - Copenhagen University Hospital, Department of Cardiology B, The Heart Centre, Copenhagen, Denmark*

Background: The European and American societies of cardiology have introduced a new category of CHF with borderline reduced LVEF of 40-49%, called HF with mid-range EF (HFmrEF). Despite publication of a considerable number of epidemiological studies, the clinical characteristics and long-term prognosis of patients with HFmrEF are still inadequately addressed and the results concerning mortality and hospitalization have varied considerably across the published studies.
Purpose: To assess by a meta-analysis the clinical characteristics, all-cause and cardiovascular mortality and hospitalization of patients with HFmrEF compared with HF reduced EF (HFrEF) and HF preserved EF (HFpEF).
Methods: Data from twelve eligible observational studies including 109,257 patients were pooled using fixed effects model.
Results: HFmrEF patients were significantly different and occupied a mid-position between HFrEF and HFpEF: mean age 73.6 ± 9.8 vs. 72.6 ± 9.8 and 77.6 ± 7.2 years, male gender 59% vs. 68.5% and 40%, ischemic heart disease 49% vs. 52.6% and 39.4%, hypertension 67.3% vs. 61.5% and 76.5%, atrial fibrillation 45.2% vs. 39.6% and 46%, chronic obstructive pulmonary disease 26.4% vs. 24.9% and 30.5%, estimated glomerular filtration rate 62 ± 30 vs. 63.3 ± 23 and 59 ± 22.5, use of renin-angiotensin system inhibitors 79.6% vs. 90.1% and 68.7%, beta-blockers 82% vs. 89% and 73.5% and aldosterone antagonists 20.3 vs. 31.5% and 26%, p-values <0.05 (Fig.1). After a mean follow-up of 31 ± 5 months, all-cause mortality was significantly lower in HFmrEF compared with HFrEF and HFpEF (26.8% vs. 29.5% and 31%), risk ratio (RR) 0.95 [0.93-0.98; 95% confidence interval (CI)] p <0.001 and 0.97(0.94-0.99; 95% CI) p = 0.014, respectively. Cardiovascular mortality was lowest in HFmrEF (9.7% vs. 13% and 12.8%) RR = 0.81(0.73-0.91) p <0.001 and 1.10(0.97-1.24;95%CI) p = 0.13, respectively. HF hospitalization in HFmrEF compared to HFrEF and HFpEF was 23.9% vs. 27.6% and 23.3% with RR = 0.89(0.85-0.93) p <0.001 and RR = 1.12(1.07-1.17) p <0.001, respectively (Fig.2).
Conclusion: The results of this study support that HFmrEF is a distinct category characterized by a mid-position between HFrEF and HFpEF and with lowest all-cause and cardiovascular mortality.

P262

Temporal trends in clinical characteristics, management of heart failure patients with mid-range ejection fraction in Japan: from the HIJ-HF studies

K Kei Tsukamoto[1]; Y Matsui[1]; K Nagara[1]; S Haruki[1]; T Kogure[1]; N Kikuchi[1]; H Hattori[1]; A Suzuki[1]; E Kawada[1]; T Suzuki[1]; T Shiga[1]; N Hagiwara[1]
[1]*Tokyo Women's Medical University, Department of Cardiology, Tokyo, Japan*

Introduction: Temporal trends in clinical characteristics and management of heart failure (HF) patients with mid-range ejection fraction (HFmrEF) remain to be elucidated in Japan.
Methods: From a multicenter hospital-based cohort consisted of hospitalized HF patients between 2001 and 2002 (HIJ-HF 1 study), and between 2013 and 2014 (HIJ-HF 2 study), we studied HFmrEF patients. The baseline characteristics and details of medical treatment are compared between HIJ-HF 1 study and HIJ-HF 2 study. Mid-range left ventricular ejection fraction (LVEF) was defined 40% or more and 49% or less.
Methods and Results: From the HIJ-HF 1 (2001-2002, n = 2,808) and HIJ-HF 2 (2013-2014, n = 1,245) studies, we enrolled 517 and 234 consecutive HFmrEF patients, respectively. As compared with the patients in the HIJ-HF 1 study, those in the HIJ-HF 2 study had similar sex prevalence, and were characterized by higher age, lower body mass index (BMI), higher brain natriuretic peptide, higher prevalence of ischemic heart disease (IHD) and dyslipidemia. From HIJ-HF 1 study to HIJ-HF 2 study, use of renin-angiotensin system inhibitors, ß-blockers was significantly increased, while that of digitalis was decreased. The use of Aldosterone antagonists and loop diuretics was similar.
Conclusions: Comparing the HFmrEF patients 10 years ago, age was higher, BMI was decreased, and the rate of IHD was increased. Along with implementation of evidence-based medications for the treatment of heart failure, it was suggested that systemic management is necessary.

Purpose: We aimed to characterise a population with HFmrEF in a tertiary Heart Failure unit in London.

Methods: This was an observational study of 467 consecutive patients, admitted between February 2015 and March 2016. Data was collected at the time of admission into the National Heart Failure Audit database. The co-primary endpoints were in-hospital mortality, admission duration and time to readmission, within 12 months.

Results: 95 patients (20.3% of the study population) had HFmrEF. Unsurprisingly, when compared to patients with preserved or reduced ejection fraction (pEF or rEF, respectively), patients with HFmrEF had intermediate values for most parameters. However, patients with HFmrEF were more likely to be male and managed on cardiology wards than patients with HFpEF (Table 1). They were less likely to have a device, hypertension or high body mass index, and likely to have higher haemoglobin than patients with HFrEF. There was no association between EF group and in-hospital mortality after adjustment for other predictors of mortality (P = 0.890). Furthermore, there was no association with admission duration or 1 year readmission rate using Cox Proportional Hazards modelling (P = 0.318 and P = 0.213, respectively).

Conclusion: HFmrEF is a new category of HF. This observational data shows this cohort to have intermediate values for most parameters. However HFmrEF patients had similar in-hospital mortality and 1 year readmission rates to HFrEF and HFpEF patients.

P264

Differences in biomarkers and biochemical parameters between heart failure with severely depressed and mid range ejection fraction

S Del Prado Diaz[1]; G Alonso Salinas[1]; A Lorente[1]; M Abellas[1]; JM Vieitez[1]; A Pardo Sanz[1]; M Plaza Martin[1]; E Gonzalez[1]; S Fernandez Santos[1]; M Castillo Orive[1]; JL Zamorano[1]

Introduction: The European Society of Cardiology guidelines recently published, defined a new heart failure classification based on left ventricular ejection fraction, including a new group, mid-range ejection fraction (40-49%).

Methods: In order to define the biochemical and biomarkers profile in heart failure with mid-range ejection fraction (HFmrEF), a consecutive series of heart failure patients followed in a Heart Failure Unit were evaluated.

Results: A total of 151 patients were included, 115 had severely reduced ejection fraction (76,2%) and 36 HFmrEF (23,8%). Analytic parameters were evaluated showing haemoglobin and haematocrit slightly higher in HFrEF. However creatinine was similar in both groups, urea was higher in HFrEF, as well as liver enzymes and bilirubin. Sodium and chloride values were lower in HFrEF. Osmolarity and uric acid was lower in HFmrEF. No one of parameters evaluated achieved statistically significant differences. BNP was lower in HFmrEF but this date did not achieve statistical significant.

Conclusion: HFmrEF group was related with lower BNP and liver parameters, as well as higher levels of chlorine and sodium. More studies are needed about this subgroup in order to confirm these differences.

Biochemical Parameterl

Biochemical Parameters	HFmrEF (40-49%)	HFrEF (<40%)
Haemoglobin	12.6	13.3
Creatinine	1.2	1.2
Urea	62.2	66.4
AST	23.7	25.1
ALT	21.7	22.1
GGT/Bilirubin	67.9/1.43	78.6/1.45
BNP	543	777
Sodium	139.6	138.8
Potassium	4.2	4.4
Chloride	102.6	99.1
Acid uric	7.7	7.8

P265

Right ventricular outflow tract fractional shortening in mid-range EF heart failure

M Tsverava[1]

[1]*Tbilisi State Medical University Iv.Javakhishvili (TSU), Internal Medicine, Tbilisi, Georgia Republic of*

According to 2016 ESCARDIO Guideline, Heart Failure was divided into 3 types: heart failure with reduced (HFrEF, EF <40%), with preserved (HFpEF,EF> = 50%) and middle range (HFmrEF, EF = 40-50%) ejection fraction. The last is less studied. Right ventricle (RV) plays important role in Heart Failure. Inflow and outflow tracts of this chamber are functionally and morphologically different. The inflow tract of RV was actively studied by different EchoCG methods in normal and pathologic state, but there is little information about RV outflow tract.

Aim: To investigate RV outflow tract with M-mode EchCG fractional shortening (FS%) in patients with HFmrEF.

Material and Methods: We studied 210 patients with HF, from which 47 had a HFmrEF (study group), and 190 healthy persons (control group). RVout M-mode EchCG was registered from parasternal short axis view. It was measured RV outflow diastolic (RVd) and systolic (RVs) diameters. RVout FS% was calculated by formula (RVd-RVs)/RVd)%.

Results: The RVd and RVs was significantly greater (30.6 ± 4.5mm versus 34.2 ± 5.5mm and 13.2 ± 2.9mm versus 21.5 ± 4.1mm respectively, p <0.001) and RV FS% was significantly lower (56.9 ± 5.8% versus 37.2 ± 7.0%, p <0.001) in patients with HFmfEF compared to normal persons. If we take for RV FS% <50% as reference point the sensitivity and specifity of this parameter in diagnosis of heart failure is 0.96 and 0.96 respectively.

Conclusion: There are prominent changes of systolic function of RV outflow tract in patients with HFmrEF. In patients with HFmrEF the RV outflow tract systolic, diastolic diameters and FS% was significantly different compared to normal persons, RV outflow tract FS <50% is sensitive and specific sign of heart failure.

P266

Screening of prespecified comorbidities in patients enrolled in Optimizing the Management of Heart Failure with Preserved Ejection Fraction in the Elderly by Targeting Comorbidities (OPTIMIZE-HFPEF)

V Goloskokova[1]; E Thunstrom[1]; C Ergatoudes[1]; D Morales[1]; K Makvandi[1]; M Fu[1]

[1]*Sahlgrenska Academy, Department of Molecular and Clinical Medicine, Gothenburg, Sweden*

On behalf of: OPTIMIZE-HFPEF study group

Background: Despite growing recognition of the importance of comorbidities in heart failure with preserved ejection fraction (HFPEF) identification of comorbidities are often challenging due to overlapping of symptoms. Therefore, it is difficult to obtain a complete picture of the comorbidities without screening. The aim of our study was to screen prespecified comorbidities in HFPEF.

Methods: OPTIMIZE-HFPEF is a pilot prospective, randomized intervention trial. Patients with HFPEF aged >60 years were randomized 1:1 to usual care or intervention arm. Patients must meet the following diagnostic criteria for HFPEF based

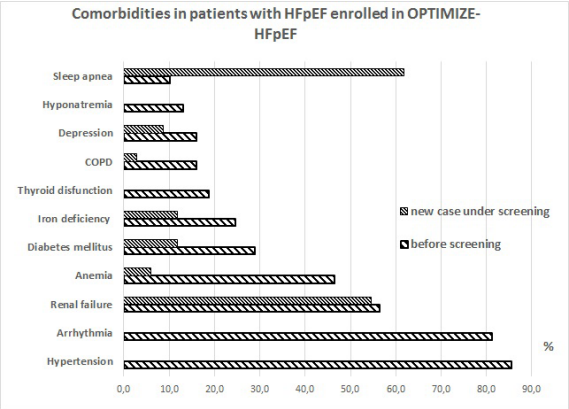

Figure 1

on the Guidelines of the European Society of Cardiology 2016 and N-terminal prohormone brain natriuretic peptide (NT-proBNP) >500 pg/ml (sinus rhythm) or >1000 pg/ml (atrial fibrillation). Comorbidity screening was based on a specified protocol including chronic obstructive pulmonary disease (COPD), Sleep disordered breathing (SDB), hypertension, diabetes mellitus, arrhythmia, hyponatremia, iron deficiency, anemia, thyroid disorders, renal dysfunction and depression.

Results: Up to now 69 consecutive patients have been enrolled in the study. Before screening, hypertension occurred in 85,5%, arrhythmia in 81,2%, renal failure in 56,5 %, anemia in 46,4%, diabetes mellitus in 29%, COPD in 15,9%, sleep apnea in 10,1%, iron deficiency in 24,6%, thyroid dysfunction in 18,8%, depression in 15,9%, hyponatremia in 13,0%. 36 patients were randomized to the intervention group e.g. screen for comorbidity according to the study protocol. Some comorbidities were completely identified before: hyponatremia, thyroid dysfunction, arrhythmia and hypertension. Other comorbidities were found to be more prevalent when screening was applied. New cases of renal failure (54,5%), diabetes mellitus (11,8%), iron deficiency (11,8%), depression (8,8%), anemia (5,9%) and COPD (2,9%) were identified. The striking finding relates to sleep apnea, where as many as 61,8% new cases were detected during the screening.

Conclusion: Screening of prespecified comorbidities is proven to be effective to identify comorbidities. Hypertension, arrhythmia, sleep apnea, renal failure and anemia are among five most common.

Body mass index and all-cause mortality in heart failure patients with normal and reduced ventricular ejection fraction - a dose-response meta-analysis

J Zhang[1]; A Begley[1]; R Jackson[1]; M Harrison[1]; P Pellicori[2]; AL Clark[3]; JGF Cleland[2]

[1]Anglia Ruskin University, Faculty of Medical Science, Chelmsford, United Kingdom; *[2]University of Glasgow, Institute of Health & Wellbeing, Glasgow, United Kingdom*; *[3]University of Hull, Hull York Medical School, Hull, United Kingdom*

Background: Many reports suggest that patients with heart failure and a lower body mass index (BMI) have higher mortality rates compared to those with a higher BMI (obesity paradox) but this relationship may be U- or J-shaped both for patients with reduced (HFrEF) or preserved left ventricular ejection fraction (HFpEF). We sought to investigate this further in a dose-response meta-analysis.

Methods: PubMed and Embase were searched between June 1980 to April 2017 for prospective cohort studies evaluating associations between BMI and all-cause mortality in patients with HFrEF (LVEF < 45%) or HFpEF (LVEF >= 50%). Summary estimated effect sizes were obtained by using random effects models. Potential non-linear relationships were evaluated by using random effects restricted cubic spline models.

Results: Ten studies were identified including 96,424 patients of whom 59,263 had HFpEF (mean age 68 years of whom 50% were women) and 37,161 had HFrEF (mean age 60 years of whom 34% were women). For patients with HFpEF, the summary hazard ratio (HR) for all-cause mortality was: 0.93 (95%CI: 0.89-0.97) per 5 unit increase in BMI (I-squared = 75.8%, P-heterogeneity = 0.01; Begg's test, p = 1.0 and Egger's test, p = 0.29) but the association was U-shaped (p_nonlinearity < 0.01) with the nadir of risk at a BMI of 32-33 kg/m^2. For patients with HFrEF, the summary HR for all-cause mortality was: 0.96 (95%CI: 0.92-0.99) (I-squared = 95%, P-heterogeneity < 0.001 and Egger's test, p = 0.01, Begg's test, p = 0.45). The relationship was also U-shaped (p < 0.01), although 'flatter' than for HFpEF, with the nadir at a BMI of 33 kg/m^2.

Conclusions: For patients with heart failure, the relationships between BMI and mortality are U-shaped with a similar nadir of risk for HFpEF and HFrEF at a BMI of 32-33 kg/m^2. Beta-blockers increase BMI and reduce risk. Whether interventions to reduce high BMI reduce risk is unknown.

P268

The role of metabolically active obesity in chronic heart failure with preserved ejection fraction

Y Vasyuk[1]; E Shupenina[1]; E Nesterova[1]; E Golubkova[1]; V Nesvetov[1]

[1]Moscow State University of Medicine and Dentistry, Clinical Functional Diagnostics, Moscow, Russian Federation

The role of metabolically active obesity in chronic heart failure with preserved ejection fraction.

Background: Heart failure with preserved ejection fraction (HFpEF) currently accounts for more than 50% of all heart failure cases and its prevalence continues to rise at 1% per year. Large outcome trials revealed that HFpEF patients suffer from multiple comorbidities, mostly from obesity (84%). Metabolically active obesity (MAO) is characterized by visceral fat accumulation, presence of associated diseases and metabolic disorders. Visceral fat, such as epicardial, is the cause of systemic and local inflammation that can lead to endothelial dysfunction, myocardial fibrosis, decreased production and increased clearance of natriuretic peptides.

Purpose: The aim of the study was to reveal early signs of HFpEF in middle-aged patients with MAO.

Methods: We investigated 43 patients with MAO aged 35-55. All patients underwent physical examination, 12-lead electrocardiography, laboratory assessment, transthoracic echocardiography with speckle tracking technology, diastolic stress testing and cardiopulmonary exercise testing.

Results: All included patients were diagnosed with MAO based on increased waist circumference (117,5 ± 16,1 and 103,8 ± 13,1 cm), waist to hip ratio (0,99 ± 0,08 and 0,92 ± 0,08 in men and women, respectively). All patients had arterial hypertension 1-3 grade and metabolic disorders with increased total cholesterol (6,4 ± 0,7 mmol/l), triglycerides (2,1 ± 0,4 mmol/l) or high level of insulin resistance (3,4 ± 0,8). Most of patients (n = 32, 74%) had one symptom or sign of HF: dyspnea, fatigue or ankle oedema. But only 17 (40%) had several symptoms of HF and were diagnosed with diastolic dysfunction 1-2 grade by echocardiography at rest and during stress test. Patients with signs of HFpEF were older compared to others (52,9 ± 3,5 versus 46,3 ± 4,6). Degree of obesity determined by body mass index (BMI) didn't affect the presence of diastolic dysfunction, but patients with HFpEF had significantly more severe visceral adiposity determined by WC and epicardial fat (EF) thickness (0,87 ± 0,4 versus 0,66 ± 0,3 cm). Patients with HFpEF had early signs of systolic dysfunction determined by speckle tracking technology. Global longitudinal strain of left ventricle (LV) was significantly decreased in patients with HFpEF (-15,1 ± 1,1 versus -17,8 ± 1,7%). All included patients had reduced exercise capacity more severe in group with HFpEF, only 6 patients (35%) with HFpEF reached submaximal heart rate during the test. The main causes for end of test were dyspnea and exaggerated hypertensive response. Conclusion: MAO is one of the most common comorbidity of HFpEF. Visceral adipose tissue, including epicardial fat, can be the cause of systemic and local inflammation leading to myocardial fibrosis and diastolic dysfunction. EF thickness, not BMI, can be used as early biomarker of HFpEF in middle-aged patients.

Design of the EMPERIAL-preserved trial of empagliflozin in patients with chronic heart failure with preserved ejection fraction

P Ponikowski[1]; W T Abraham[2]; J Lindenfeld[3]; C Zeller[4]; H Macesic[5]; M Brueckmann[6]; A Salsali[7]; S D Anker[8]

[1]Wroclaw Medical University, Wroclaw, Poland; *[2]The Ohio State University, Columbus, United States of America*; *[3]Vanderbilt University Medical Center, Nashville, Tennessee, United States of America*; *[4]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany*; *[5]Boehringer Ingelheim (Canada) Ltd, Burlington, Ontario, Canada*; *[6]Boehringer Ingelheim GmbH & Co. KG, Ingelheim am Rhein, Germany*; *[7]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, Connecticut, United States of America*; *[8]Charité University, Berlin, Germany*

Background and Purpose: In addition to increasing the risks of cardiovascular death and hospitalisation, chronic heart failure with preserved ejection fraction (HFpEF) is associated with considerable symptom burden and impaired physical functioning. Empagliflozin is a sodium-glucose cotransporter-2 inhibitor that was shown in the EMPA-REG OUTCOME trial to reduce the risk of cardiovascular events, hospitalisations and mortality in patients with type 2 diabetes and established cardiovascular disease. A Phase III trial, EMPERIAL–preserved, has been initiated to investigate the effects of empagliflozin on functional outcomes in patients with HFpEF.

Methods: EMPERIAL–preserved (Effect of EMPaglifozin on ExeRcise ability and heart failure symptoms, In patients with chronic heArt faiLure with preserved ejection

fraction) is a randomised, double-blind, placebo-controlled trial designed to evaluate the effect of empagliflozin on exercise capacity and HF symptoms in patients with HFpEF (left ventricular ejection fraction >40%). Inclusion criteria include 6-minute walk test (6MWT) distance of 100m to = 350 m, elevated N-terminal pro-brain natriuretic peptide (NT-proBNP) (>300 pg/mL or >600 pg/mL or for patients without or with atrial fibrillation, respectively) and the presence of structural heart disease (left atrial enlargement and/or left ventricular hypertrophy) documented by echocardiogram at screening and/or hospitalisation for heart failure within the previous 12 months. Patients must be on stable dose of diuretics for = 2 weeks prior to study entry. Approximately 300 patients will be randomised 1:1 to receive empagliflozin 10 mg or placebo once daily for 12 weeks. The primary endpoint is the change from baseline in 6MWT distance at week 12. Key secondary endpoints are changes from baseline in Kansas City Cardiomyopathy Questionnaire total symptom score and Chronic Heart Failure Questionnaire Self-Administered Standardised format dyspnoea score at week 12. Patient Global Impression of Change questionnaires and change from baseline in NT-proBNP at week 12 are other secondary endpoints.
Results: Recruitment for this trial will begin in 2018.
Conclusion: The findings of the EMPERIAL–preserved trial, together with those of the EMPERIAL–reduced trial that will be conducted in patients with chronic heart failure with reduced ejection fraction (HFrEF), will determine the effects of empagliflozin on symptoms, exercise capacity and patient reported outcome in patients with heart failure. The effects of empagliflozin on cardiovascular death and hospitalisation for heart failure in patients with chronic heart failure are being investigated in the EMPEROR–preserved and EMPEROR–reduced trials.

P270
Difference in effect of statin on prognosis in heart failure with preserved and reduced ejection fraction

SY Se Yong Jang[1]; DH Yang[1]; SC Chae[1]; BH Oh[2]; ES Jeon[3]; JJ Kim[4]; MC Cho[5]; SC Baek[6]; DJ Choi[7]; SM Kang[8]; BS Yoo[9]; KH Kim[10]
[1]Kyungpook National University Hospital, Daegu, Korea Republic of; *[2]Seoul National University Hospital, Seoul, Korea Republic of*; *[3]Samsung Medical Center, Seoul, Korea Republic of*; *[4]Asan Medical Center, Seoul, Korea Republic of*; *[5]Chungbuk National University Hospital, Cheongju, Korea Republic of*; *[6]The Catholic University of Korea, Seoul, Korea Republic of*; *[7]Seoul National University Bundang Hospital, Seongnam, Korea Republic of*; *[8]Severance Hospital, Seoul, Korea Republic of*; *[9]Wonju Christian Hospital, Wonju, Korea Republic of*; *[10]Chonnam National University Hospital, Gwangju, Korea Republic of*

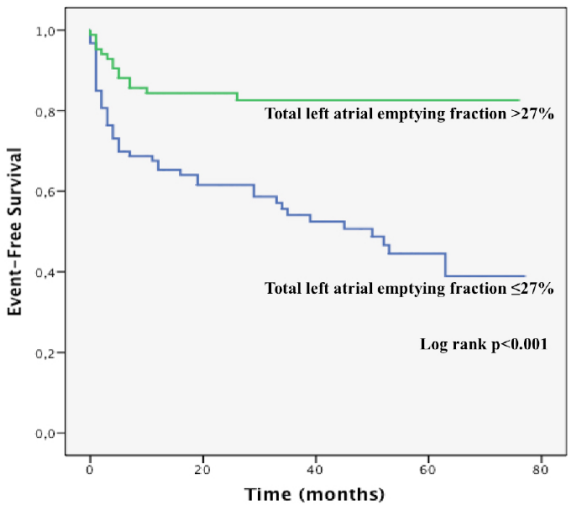
On behalf of: KorAHF study investigators
Funding Acknowledgements: National Institute of Health, Korea

Background: Statin treatment in patients with reduced ejection fraction (HFrEF) has little evidence. Meanwhile, growing evidences are suggesting the benefit of statin in heart failure with preserved ejection fraction (HFpEF). We aimed to assess the effect of statin in HFpEF and compare them with that in HFrEF.
Methods: From Korean acute heart failure registry, 1085 patients with HFpEF and 2801 patients with HFrEF were included. A propensity-matched analysis was performed between the patients treated with and without statin in both groups of HFpEF and HFrEF.
Results: During 1-year follow-up, composite event of all-cause mortality and re-admission for heart failure was observed in 30.0% and 35.0% for HFpEF and HFrEF respectively. In HFpEF, the patients treated with statin was related to lower event rate than those without statin (24.7% vs 33.1%, log rank p = 0.006). Matched-population analysis also showed lower event rate in those with statin (28.1% vs 37.6%, log rank p = 0.026). There was no significant interaction between statin treatment and ischemic etiology of heart failure (p for interaction = 0.799). Matched analysis in HFrEF showed that statin treatment was also related to better outcomes; 31.3% vs 39.4% for those with and without statin (long rank p = 0.001). However, there was a significant interaction between statin treatment and ischemic etiology in HFrEF (p for interaction = 0.04); Hazard ratios of statin treatment in patients ischemic and non-ischemic etiology are 0.633 (0.502-0.798, p < 0.001) and 0.904 (0.707-1.156, p 0.422), respectively.
Conclusion: Statin treatment was related to better prognosis in patients with HFrEF. The effect of statin was not related to ischemic etiology, Whereas the benefit of statin treatment was markedly limited to ischemic etiology in patients with HFrEF. The results are suggesting that pathophysiology of benefit from statin in patients with HFpEF might beyond the anti-atherosclerosis effect.

P271
Left atrial function and atrial fibrillation in heart failure with preserved ejection fraction

R Schoenbauer[1]; AA Kammerlander[2]; F Duca[2]; S Aschauer[2]; C Binder[2]; C Zotter-Tufaro[2]; L Fiedler[1]; FX Roithinger[1]; C Loewe[3]; C Hengstenberg[2]; D Bondermann[2]; J Mascherbauer[2]
[1]Landesklinikum Wiener Neustadt, Cardiology, Wiener Neustadt, Austria; *[2]Medical University of Vienna, AKH - Vienna, Cardiology Clinic, Vienna, Austria*; *[3]Medical University of Vienna, Department of Bioimiging and Image-Guided Therapy, Vienna, Austria*

Background: Left atrial (LA) size and function have been shown to be associated with adverse events in heart failure with preserved ejection fraction (HFpEF).
Objectives: To study LA size and function and its impact on outcome in HFpEF patients in sinus rhythm versus atrial fibrillation (AF).
Methods and Results: 189 HFpEF patients were prospectively enrolled and underwent baseline clinical and echocardiographic assessment, cardiac magnetic resonance imaging (CMR) and invasive hemodynamic assessment. Coronary artery disease was ruled out by coronary angiography. 90 patients were in persistent AF, 24 in paroxysmal AF and 71 in sinus rhythm. LA size and function were assessed by CMR.
Patients in AF had significantly larger endsystolic LA volume indices (LAVI) (81 ± 27 vs. 55 ± 18ml/m2, p < 0.001), larger enddiastolic LAVI (68 ± 25 vs. 35 ± 17ml/m2, p < 0.001), lower total LA emptying volume (24 ± 11vs. 41 ± 14ml, p < 0.001) and fraction (16 ± 7 vs. 39 ± 11%, p < 0.001) as well as lower fraction of longitudinal shortening (5 ± 4 vs. 14 ± 7%, p < 0.001). Among patients in sinus rhythm passive LA emptying volume and fraction were 21 ± 10ml and 20 ± 7%. Active LA emptying volume and fraction were 21 ± 13ml and 20 ± 11%, respectively.
After 31 ± 24 months, 64 patients reached the combined endpoint defined as hospitalization for heart failure or cardiac death. By multivariate cox regression analysis including all LA parameters, only total reduced LA emptying fraction was significantly associated with adverse outcome (p < 0.001, HR 0.962, 95% CI 0.944-0.981). After adjustment for sex, age, presence of persistent AF, NTproBNP, right ventricular ejection fraction by CMR and pulmonary capillary wedge only elevated NTproBNP (p = 0.022, HR 1.078, 95% CI 1.011-1.150) and reduced total LA emptying fraction (p = 0.004, HR 0.969, 95% CI 0.949-0.990) were predictive for adverse events.
Conclusion: Impaired LA function plays a key role in HFpEF. Reduced total LA emptying fraction outperforms LA size and presence of persistent AF in prediction of adverse events in HFpEF.



Kaplan-Meier plot

Potassium in heart failure with preserved ejection fraction - association with outcome and clinical parameters

B Begum Ozturk[1]; F Duca[1]; C Binder[1]; C Zotter-Tufaro[1]; C Nitsche[1]; AA Kammerlander[1]; S Aschauer[1]; L Schachner[1]; CDJ Capelle[1]; C Dona[1]; J Mascherbauer[1]; D Bonderman[1]
[1]*Medical University of Vienna, Internal Medicine II, Division of Cardiology, Vienna, Austria*

Background: Previous studies could demonstrate the prognostic significance of serum potassium levels in heart failure (HF) patients. However, studies investigating the association of serum potassium levels with prognosis or clinical parameters in patients with HF and preserved ejection fraction (HFpEF) have not been examined thus far.
Purpose: In the present study, we aimed to investigate the prognostic significance of baseline potassium levels and its correlation with clinical parameters in patients with HFpEF.
Methods: Consequtive HFpEF patients from a prospective registry were included into our study. Patients underwent clinical as well as laboratory assessment, 6-minute walk test, right heart catheterization, and cardiac magnetic resonance imaging. Patients were prospectively followed in 6-month invervals. The primary endpoint was a composite of cardiac death or HF hospitalization.
Results: Between December 2010 and May 2017, 263 HFpEF patients were included into our study. Median age of the study population was 72.0 years [Interquartile range (IQR): 67.0 - 77.0] , 185 (70.9%) were female, median N-terminal prohormone of brain natriuretic peptide levels were 1121 pg/mL (IQR: 455 - 2062) and 178 (68.0%) were in New York Heart Association class = III. Median level potassium was 4.2 mmol/L (IQR: 3.9 - 4.5). 13 (4.9%) patients had hypokalemia (< 3.5mmol/L), 24 (9.1%) had hyperkalemia (= 5.0 mmol/L) and 226 (86.0%) were normokalemic (= 3.5 - < 5.0 mmol/L). 97 (36.9%) patients experienced the combined endpoint.
Patients were grouped according to potassium tertiles (< 4.0 mmol/L, = 4.0 mmol/L - < 4.4 mmol/L and, = 4.4 mmol/L). Significant differences between the groups were detected with regards to estimated glomerular filtration rate [62.2 ml/min/1.73m2 (IQR: 49.2 - 74.2) versus 60.8 ml/min/1.73m2 (IQR: 45.1 - 79.3) versus 54.5 ml/min/1.73m2 (IQR: 40.5 - 66.8), p = 0.036], the combined endpoint [n = 42 (49.4%) versus n = 25 (28.4%) versus n = 30 (34.1%) p = 0.013)] and right ventricular EF (RVEF) [48.9% (IQR: 44.0 - 55.5) versus 56.5% (IQR: 44.8 - 64.0) versus 52.0% (IQR: 45.5 - 61.0), (p = 0.031)]. No differences with regards to concomitant medication were found between the groups.
The lowest potassium tertile was significantly associated with adverse outcome in univariable [hazard ratio (HR): 1.705, 95% confidence interval (CI): 1.137 – 2.555, p = 0.010] (Figure 1) as well as multivariable analyses (HR: 1.674, 95% CI: 1.089 - 2.574, p = 0.019).
Furthermore, a significant correlation between potassium and RVEF was found (R = 0.198, p = 0.016).
Conclusion: Low potassium levels (< 4.0mmol/L) are indenpendently associated with adverse outcome in HFpEF patients

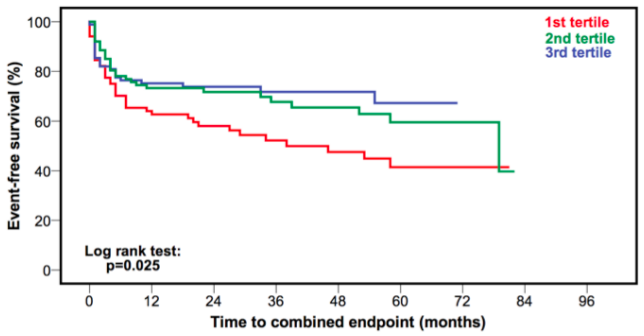

Figure 1

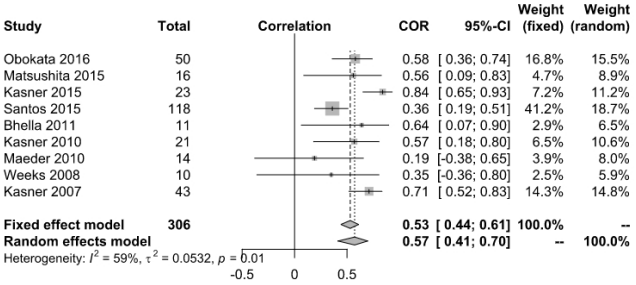
P273

What are the best echo parameters to diagnose HFpEF?

J F Jan Focko Nauta[1]; YM Hummel[1]; P Van Der Meer[1]; CSP Lam[1]; AA Voors[1]; JP Van Melle[1]
[1]*University Medical Center Groningen, Groningen, Netherlands*

Aims: Five echocardiographic parameters - left atrial volume index (LAVI), left ventricular mass index (LVMI), tricuspid regurgitation velocity (TRV), myocardial tissue velocity (e') and the ratio of early mitral inflow to tissue velocity of the mitral annulus (E/e') - are recommended in both the current ESC Heart Failure Guidelines and the ASE/EACVI recommendations for the evaluation of left ventricular diastolic function. We performed a systematic review of these echocardiographic parameters for their correlation with elevated left ventricular filling pressures and prognosis.
Methods and results: Nine studies reported the correlation between echocardiography and invasive hemodynamics, and 14 papers reported on the prognostic value of echocardiography in HFpEF. Among the parameters, the most data were reported for E/e'. The pooled correlation coefficient r was 0.57 for the relation between E/e' and invasively measured filling pressures. Higher E/e' resulted in increased hazard ratios for composite outcomes and mortality. In the largest study of 935 patients, E/e' >10 was associated with a hazard ratio of 2.36 for a composite outcome during median follow-up of 35 months. Other echo parameters were less strongly correlated with outcome. Diagnostic algorithms do increase the sensitivity and specificity of diagnosis of HFpEF over clinical examination and biomarkers alone.
Conclusion: Only a small number of studies provide rationale for the use of echocardiographic parameters in the diagnosis of HFpEF. The best established parameter appears to be E/e', but the existing data only show modest correlations of E/e' with invasive filling pressures and outcomes in HFpEF. More robust imaging techniques for diagnosing HFpEF and validation of current algorithms are therefore much needed.



P274

Renal oxygen consumption in chronic heart failure

J D Parker[1]; A Al-Hesayen[1]
[1]*University of Toronto, Toronto, Canada*

Background: The cardiorenal syndrome continues to be a major clinical problem for patients with both acute and chronic heart failure (CHF). The etiology of this syndrome remains unclear and is almost certainly multifactorial. The purpose of this study was to measure renal oxygen consumption in a group of patients with chronic CHF and reduced systolic function as compred to a group with normal ventruicular function and no history of heart failure.
Methods: We measured renal blood flow with para-aminohippurate and obtained samples of arterial and renal venous blood to measure oxygen saturatiions. Using standard calculations the oxygen content of arterial and renal venous blood was determined and renal oxygen consumption was calculated as (arterial O2 content - renal vein O2 content) x renal plasma flow. GFR was measured with inulin. Hemodynamics were asessed invasively with an arterial line and a right heart catherization using standard methodology. Renal blood was obtained using a Left Judkins catheter from the right femoral vein.
Results: The patients with CHF had a mean ejection fraction of 23 ± 2 percent and manifest lower systemic arterial pressure, higher cardiac filling pressures with relatively well preserved cardiac output. Those with normal ventricular function had normal hemodynamic parameters. Renal plasma flow was lower in patients with CHF than in those with normal ventricular function (447 ± 29 vs 585 ± 38 mls/min; P = 0.01). GFR was also lower in the CHF group (92 ± 6 mls/min vs 115 ± 10 mls/min). There was greater oxygen extraction across the kidney in patients with CHF. The AV difference of blood O2 content was 2.97 ± 0.25 vs 1.66 ± 0.91 mls; P < 0.002). Renal oxygen consumption was greater in those with CHF than in the group with normal ventricular function (1268 ± 79 vs 986 ± 78 mls/min; P < 0.03).

Conclusions: Therefore, despite lower filtration rates, patients with chronic heart fialure have increased renal oxygen consumption as compared to those with normal ventricular function. This may lead to relative renal ischemia and may contribute to the pathophysiology of the cardiorenal syndrome in chronic heart failure. Further, the response of renal oxygen consumption to therapy in the setting of heart failure should be explored.

Funding Acknowledgements: Intramural research grant from the Institue of Cardiology

Introduction: Endothelium undergoes dynamic processes of degeneration and regeneration. Endothelial progenitor cells (EPC), have endothelial reparative properties and play an important role in this mechanism. In non-transplant settings high levels of EPC are associated with better cardiovascular outcomes. However in transplant physiology, due to persistent allograft antigenicity, this EPC homeostatic mechanism may become uncontrolled and pathological.Thus allograft rejection may be a consequence of defective EPC repair mechanisms. There is no data regarding prospective EPC changes in heart failure patients (pts) undergoing HT, which might influence their prognosis.

EPC changes in HT recipients

Data in medians; paired wilcoxon test

Purpose: Prospective evaluation of EPC in heart failure patients undergoing HT.

Methods: Study comprised 27 of pts undergoing HT due to severe heart failure (HF), 12 participants included into the study before HT and 15 included within 24 hours post HT. The circulating EPC count was detected by multicolor flow cytometry (FCM) in a single-tube panel as CD34+CD45dimVEGFR+. Subjects included before HT, had their first blood samples taken before operation. Testing for all subjects were done within 12-24 hours post HT, at 1 month post HT, at 3 and 6 months post HT.

Results: Majority of participants were males 77.7% and mean age was 50.1 ± 14.3 yrs.Nonischemic etiology was a dominant cause of HF (59.6%).Table and figure present data regarding EPC per 1 million living cells. Lowest values of EPC were recorded before HT. There was a noteworthy increase in EPC within 12-24 hours post HT, with subsequent drop at 1 month post HT. At 3 and 6 months post HT, we observed steady and mild increase in EPC levels. EPC levels, at different time-points differed significantly from the preceding test.

Conclusions: Within a few hours post HT, a significant increase in EPC levels is observed. At further observation, there is subsequent drop in EPC levels, with mild increase therafter. The significance of these findings needs further evaulation.

Lack of improvement in autonomic cardiac tone after sacubitril/valsartan at lower than target doses

J Perez Copete[1]; M Navarro Penalver[1]; D Fernandez Vazquez[1]; DJ Vazquez Andres[1]; E Cabrera Romero[1]; A Martinez Lopez[1]; IP Garrido Bravo[1]; DA Pascual Figal[1]; A Garcia Arberola[1]; FJ Pastor Perez[1]

[1]Hospital Clínico Univeristario Virgen de la Arrixaca, Murcia, Spain

Background: Autonomic regulation plays a role in the progression of heart failure (HF) and is related with sudden death. Pharmacological and cardiac resynchronization therapy can improve this sympathovagal balance. The aim of the study was to evaluate the effect of Angiotensin-neprylisin inhibition (ARNI) compared to angiotensin inhibitors in the modulation of the autonomic tone in patients with HF in a RW population.

$\alpha 1$	1.20± 0.2	1.16±0.2	n.s
$\alpha 2$	1.09±0.1	1.10±0.1	n.s.
Heart rate turbulence			
TO, %	-0.67 [-1.08-0.01]	-0.16 [-1.30-0.57]	n.s.
TS, ms/RR	3.36 [2.01-5.75]	2.89 [1.54-4.90]	n.s.
Ventricular extrasystoles/24h	449 [199-1502]	586 [51-2854]	n.s.

Methods: A 24-hour ambulatory ECG was performed at baseline (under angiotensin inhibitors) and after 3 months of maximum tolerated dose of ARNI to evaluate changes in autonomic tone using hear rate variability and heart rate turbulence parameters.

Results: We enrolled 21 HF patients in sinus rhythm (60.8 ± 13.1 years; LVEF 27 ± 4%). Angiotensin inhibitors dose was 70% of the target dose and it was changed to ARNI, to a maximum tolerated daily dose of 190 ± 102mg, representing 47.5% of the recommended dose. After 3 months of ARNI, no significant differences were found in NT-proBNP levels: 912 [643-1225] vs 845 [610-1200] pg/dl, p = 0.32. Mean blood pressure dropped from 107 ± 14 mmHg at baseline to 105 ± 14 mmHg after 3 months (p = 0.21). No significant differences were found the parameters after 3 months of ARNI (table 1).

Conclusions: ARNI use at lower than target doses did not improve autonomic cardiac tone evaluated with 24-hour holter monitoring.

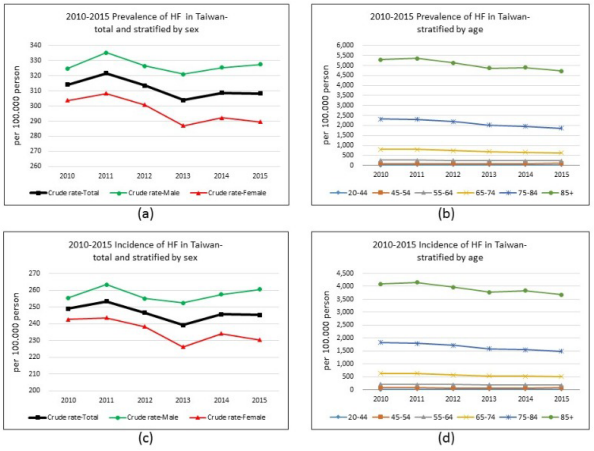
P277

Nationwide trends in prevalence and incidence of and 3-year mortality in hospitalized heart failure patients in Taiwan (2010-2015): lingering hazards remain

TD Wang[1]; ST Huang[2]; CY Wang[3]; FJ Lin[2]; SR Chen[4]; TH Ho[4]; FY Hsiao[2]
[1]National Taiwan University Hospital, Cardiovascular Center and Division of Cardiology, Department of Internal Medicine, Taipei, Taiwan ROC; *[2]National Taiwan University, Graduate Institute of Clinical Pharmacy, College of Medicine, Taipei, Taiwan ROC*; *[3]National Taiwan University, School of Pharmacy, College of Medicine, Taipei, Taiwan ROC*; *[4]Novartis (Taiwan) Co., Ltd, Taipei, Taiwan ROC*

Funding Acknowledgements: Novartis (Taiwan) Co., Ltd

Introduction: "Real-world" data on the secular trends and long-term outcomes of heart failure (HF) are scarce, especially in Asian populations. The objectives of this study were to estimate the annual prevalence, incidence, and mortality among patients hospitalized with HF in Taiwan from 2010 to 2015 using the National Health Insurance Research Database (NHIRD).



2010-2015 prevalence and incidence of HF

Methods: Patients aged 20 years or older and having been admitted for HF, defined as a hospitalization with a primary or first two secondary diagnosis of HF [ICD-9-CM codes: 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13, 404.91, 404.93, 428,428.0, 428.1 and 428.9], between 2010 and 2015 were identified from Taiwan's NHIRD. Annual prevalence and incidence of HF hospitalization were reported as estimates per 100,000 person-years at risk. Sex- and age-stratified estimates of annual prevalence and incidence were also reported. For all identified incident hospitalized HF cases between 2010 and 2012, we further estimated their 30-day, 90-day, 180-day, 1-year, 2-year and 3-year mortality rates.

Results: The overall annual prevalence (ranged from 304 to 322 per 100,000 people) and incidence (ranged from 240 to 254 per 100,000 people) remained stable during the study period (Figure). Both the prevalence and incidence of HF were ~10% higher in men as compared to women. Between 2010 and 2015, age-stratified estimates showed that among patients over 55 years, the prevalence and incidence rates declined by between 10 and 20%.

For all identified incident hospitalized HF cases between 2010 and 2012 (n = 124,816; age 74.0 ± 13.9 years, 51.2% male, 33.7% ischemic heart disease, 37.1% diabetes mellitus, and 65.5% hypertension), the 30-day, 90-day, 180-day, 1-year, 2-year and 3-year all-cause mortality were 8.1, 14.5, 20.3, 28.4, 39.0 and 47.4%, respectively. The annual mortality remained ~10% in the 2nd and 3rd year irrespective of sex. Cardiovascular disease-related deaths accounted for nearly 40% of all-cause death among these patients.

Conclusion: Our study provides population-based "real-world" estimates regarding the annual prevalence, incidence, and mortality of hospitalized HF patients in Taiwan, which could serve as a reference for HF management in Asian populations. The remaining ~10% annual mortality following the first year of hospitalization in HF patients highlights the importance of optimized long-term medical care.

P278

Modes of death in cardiac amyloidosis

C Binder[1]; S Aschauer[1]; F Duca[1]; PD Stelzer[1]; H Agis[2]; R Kain[1]; AA Kammerlander[1]; C Hengstenberg[1]; J Mascherbauer[1]; D Bonderman[1]
[1]Medical University of Vienna, AKH - Vienna, Cardiology Clinic, Vienna, Austria; *[2]Medical University of Vienna, Oncology, Vienna, Austria*

Background: Cardiac Amyloidosis (CA) used to be seen as a very rare disease, however, it may not be as uncommon as previously perceived. With the help of modern imaging techniques and a rising awareness of this disease, cases of amyloidosis with cardiac involvement are being recognized more frequently. However, little is known about the clinical course of the disease, especially in the end-stages of this condition. Our aim was to characterize patients with CA and achieve a better understanding of the modes of death in this highly malignant condition.

Methods: Between March 2012 and September 2017 we included patients with light-chain amyloidosis (AL) or transthyretin amyloidosis (ATTR) into our prospective registry at the Vienna General Hospital, a university-affiliated tertiary care center. The diagnosis of CA was made by myocardial biopsy in most cases, or by the diagnostic algorithm recently proposed by Gillmore et al. for patients with ATTR. Cases of death were evaluated thoroughly and reviewed by at least two specialized physicians. Patient records, imaging modalities including echocardiography and cardiac magnetic resonance imaging, as well as N-terminal pro-brain natriuretic peptide levels were reviewed to understand the mode of death in each given patient.

Results: In total, 101 patients were enrolled in our registry. Fifty-five patients (54.4%) were diagnosed with AL- amyloidosis and 46 (45.5%) with either wild-type or familial ATTR. During a mean follow-up time of 57.03 ± 50.91 weeks, 29 patients (28.7%) reached the primary composite endpoint of death or heart-transplantation, Of the patients who passed away or received a new heart, 25 (86.2%) had been diagnosed with AL-amyloidosis and 4 with ATTR (13.8%). In most cases, patients died from cardiac causes (80.8%). Seventeen patients (65.4%) died from pump failure and 4 (15.4%) of sudden cardiac death. Other modes of death were myocardial infarction in 1 patient and failure of another involved organ or infection in 2 further patients. In the remaining subject, mode of death was primarily unrelated to amyloidosis or could not be evaluated due to a lack of documentation.

Conclusion: In our cohort, subjects with AL-amyloidosis had a worse prognosis than patients with ATTR. When cardiac involvement is present, more than half of patients die from heart failure.

Liver-specific microRNA-122 as a prognostic biomarker in patients with chronic heart failure

S Stefan Stojkovic[1]; L Koller[1]; P Sulzgruber[1]; M Huelsmann[1]; J Wojta[1]; A Niessner[1]
[1]*Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria*

Funding Acknowledgements: Anniversary Fund of Austrian National Bank grant to Johann Wojta, OeNB grant number: AP15688ONB

Background. Several circulating microRNAs (miRs) have been proposed as potential diagnostic biomarkers in heart failure. However, studies investigating the prognostic value of circulating miRs in patients with chronic heart failure (CHF) are scarce.
Purpose: The aim of this study was to investigate the potential role of circulating miRs as prognostic biomarkers in patients with CHF.
Methods: A pathway-focused microRNA array was performed in pooled plasma samples of 40 patients with CHF who died during the follow-up and 40 age- and sex-matched survivors to screen for potential prognostic miR-candidates. In a second validation step, circulating levels of differentially expressed miRs were assessed using quantitative polymerase chain reaction in 234 patients with CHF admitted to our outpatient department for heart failure. Primary study endpoints were defined as all-cause and cardiovascular mortality.
Results: In the first phase, pathway-focused array analysis revealed differential expression of miR-122, miR-126 and miR-423 between CHF survivors and non-survivors. Circulating levels of these 3 miRs were then assessed in a large validation cohort of 234 patients. During a median follow-up time of 3.2 years, 76 patients (32.5%) died. miR-122 and miR-423 were strong, independent predictors of the primary endpoint even after comprehensive multivariable adjustment for age, sex, LVEF, NYHA class, renal function, CRP and BNP with respective HR per 1 increase of standard deviation (1-SD) of 1.16 (95% CI: 1.05-1.29, p = 0.005) and 1.24 (95% CI: 1.09-1.41, p = 0.001). In contrast, miR-126 showed no association with primary endpoint in univariate cox regression analysis (HR per 1-SD 1.01, 95% CI: 0.84-1.21, p = 0.915). Interestingly, adding miR-122 to multivariable model improved Harrell's C index from 0.78 (95% CI: 0.73-0.83) to 0.81 (95% CI: 0.76-0.86, p = 0.030), whereas no improvement was observed after adding miR-423 to the same model (C-index 0.79, 95% CI: 0.76-0.85, p = 0.259).
Conclusion: Circulating miR-122 and miR-423 are independent predictors of all-cause and cardiovascular mortality in CHF patients. Furthermore, miR-122 improves risk stratification in this vulnerable group of patients. Thus, miR-122 might be a new, valuable and easily accessible biomarker for enhanced risk assessment in CHF.

P280

Genetics in heart failure prognosis: does it make a difference?

A Ulitin[1]; V Tishkova[1]; A Kuular[1]; A Muraviev[1]; A Kozyreva[1]; E Lyasnikova[1]; A Kostareva[1]; M Sitnikova[1]
[1]*Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation*

Introduction: Heart failure (HF) is a multifactorial disease, which is the leading cause of morbidity and mortality worldwide. Severity, therapeutic response of HF and expectancy of life are variable among individuals, which may be related to genetic variation. The study of the genetic mechanisms of HF is important.
Purpose: The aim of this study to analyze relation between clinical and genetic markers including HSPB7 (rs1739843), FRMD4B (rs6787362), locus 15q22 (rs10519210) (genes associated with the HF syndrome as had been demonstrated by GWAS on a large sample of EU residents); MADD (rs10838692, rs2290149) polymorphisms (gene is participating in expression sarcomeric proteins) and 3-year follow-up in patients with ischemic HF.
Methods and Results: 506 men aged 30-65, who had MI more than 3 months ago, were evaluated. The index group consists of 260 patients with HFrEF (I - IV NYHA) LV EF (Sim) < 40% (?1 group). The reference group included 246 patients with no clinical signs of HF and LVEF (Sim)>55% (?2 group). The groups were comparable in the duration of AH (11.4 vs. 11.2 years) but different in the AH prevalence (68.5 and 83.3%; ? < 0.01) in the groups ? 1,2, respectively. Standard clinical, laboratory and instrumental, including ECHO with defining signs of the LV hypertrophy and dilatation, were performed. Investigation of gene polymorphisms was made using the real-time-PCR method. Control group consists of 257 healthy donors comparable in age. Prospective attendance was performed by phone calls. Intermediate FU was 3.3 years (3 to 5 yrs). After 3 yrs the survival of patients was 69.3% and 96.0%, contact was lost with 28% and 19% patients in the groups ? 1 and ? 2, respectively. CC genotype of gene polymorphism HSPB7 was detected more often in surviving patients compared to deceased patients both in the whole post-MI group and in the group ?2: 66% vs 39% (p = 0,002), 83% vs 50% (p = 0,037), respectively. CC genotypes of MADD polymorphisms (rs10838692) and (rs2290149) were more rarely seen, while TT genotype of MADD polymorphism (rs2290149) appeared more frequently seen in the post-MI group compared to healthy subjects: 9%vs18%(p = 0.0001); 1%vs7% (p = 0.03); 82%vs73% (p = 0.0001), respectively. Statistically significant associations with the prognosis and other polymorphic alleles of the studied genes during the 3-yrs FU were not obtained.
Conclusion: The contribution of genetic factors to the development of HF is unquestionable. On the other hand, remains still unclear, what makes a contribution more: genetic or another factor especially in ischemic HF. Investigation of candidate genes and genome-wide associations, including presented gene polymorphisms, their role in LV post-MI remodelling, development HF and prognosis may be interesting for further research.

P281

Economic impact of ivabradine use in the vulnerable phase: results from the ROCI registry

C I Clara Ines Saldarriaga[1]; G Gonzalez[2]; S Navarrete[3]; LE Echeverria[4]; M Novoa[5]; N Murrillo[6]; A Rivera[7]; MJ Rodriguez[4]; B Rolong[8]; G Trout[9]; C Martinez[1]; CV Arguello[10]; L Semanche[8]; E Contreras[8]; J Vanegas[8]

On behalf of: Optimize Colombia Program
Funding Acknowledgements: This study was supported by Servier

Introduction: The ROCI registry included patients in the vulnerable phase of heart failure, who were treated according to the recommendations of the Optimize Colombia Program in order to reduce early outcomes, such as hospitalization and death. The patients were educated and involved in self-care and treated with all pharmacological treatments that provide benefits before hospital discharge: beta-blockers, ACEI or ARB, diuretic, ivabradine. This strategy reduced the 30-day readmission rate.
Objective: To simulate the economic impact and cost savings driven by the decrease in 30-day readmissions by the implementation of a strategy recommended by the Optimize Colombia Program and to compare the cost of patients treated with and without ivabradine.
Methods: Based on the results of ROCI registry, local epidemiological data, and Colombian hospitalization costs published in the scientific literature, we simulated the potential economic impact and cost savings of the widespread use of ivabradine in heart failure patients with reduced ejection fraction in the Colombian healthcare system for a 1-year period.
Results: In the ROCI registry, 436 patients were included, the mean ejection fraction was 32%, 94% of the population was on beta-blockers, and additionally 42% received ivabradine. The 30-day readmission rate was 8.6% in patients without ivabradine and 1.5% in those with ivabradine. The 30-day readmission rate reported in international registries is around 25%. The cost of a heart failure hospitalization in Colombia is €2062, and an estimated 647 853 patients have this diagnosis. The annual estimated cost of 30-day readmission in Colombia is therefore €134 090 337. With the implementation of the Optimize Colombia Program without ivabradine (58% of patients), this cost could be reduced to €42 908 908, and if 42% have an indication for ivabradine and are treated with it, the cost of hospitalization would be €3 218 168.
Conclusion: Our results suggest that the use of ivabradine from hospital discharge, as per the recommendations of the Optimize Colombia Program, will reduce the 30-day readmission rate and hence the cost to the health care system.

P282

What is the meaning of pericardial effusion in the general population? Results from the STAAB cohort study

M Breunig[1]; C Morbach[1]; G Gelbrich[2]; T Tiffe[2]; FA Eichner[2]; M Wagner[2]; PU Heuschmann[2]; S Stoerk[1]
[1]*University Hospital of Würzburg, Comprehensive Heart Failure Center and Dept. of Medicine I, Würzburg, Germany*; [2]*Insitute of Clinical Epidemiology and Biometry and Comprehensive Heart Failure Center, University Würzburg, Würzburg, Germany*

Funding Acknowledgements: BMBF 01EO1004 and 01EO1504

Background: Pericardial effusion (PE) is usually attributed to advanced cardiac disease, inflammation, or malignancy. Knowledge on prevalence and relevance of PE in the general population is scarce.

Purpose: To determine prevalence and determinants of PE in a population-based cohort.
Methods: We present data from the first planned interim analysis of the ongoing STAAB Cohort Study (Characteristics and Course of Heart Failure STAges A/B and Determinants of Progression), which recruits participants (30-79 years) free of symptomatic heart failure from a representative sample of the population of Würzburg. Participants undergo detailed clinical evaluation and transthoracic echocardiography including a dedicated evaluation of the prevalence of PE. Echocardiographic quality is closely monitored by the EchoCoreLab Würzburg.
Results: 2440 out of 2473 participants (98.7%) had valid information on PE. Of those, PE was prevalent in n = 66 (2.7%; 95%CI 2.0-3.5%). Individuals with PE were more often female (68% vs. 51%, p = 0.008), had higher NTproBNP values (75 [42-115] ng/L vs. 53 [26-99] ng/L, p = 0.016), and their body mass index was lower (23.5 ± 3.7 kg/m2 vs. 26.6 ± 5.1 kg/m2, sex-adjusted p < 0.001). There was no significant difference regarding age (55 ± 10 years vs. 54 ± 12 years, p = 0.88), C-reactive protein (0.8 [0.4-1.5] mg/dL vs. 0.9 [0.5-2.1] mg/dL, p = 0.26), leucocytes (5.6 ± 1.4 109/L vs. 5.9 ± 1.7 109/L, p = 0.14), glomerular filtration rate (85 ± 12 mL/min/1.73 m2 vs. 86 ± 15 mL/min/1.73 m2, p = 0.44), rheumatoid disease (2% vs. 4%, p = 0.52), malignoma (ever; 11% vs. 10%, p = 0.83), atherosclerotic disease (coronary disease, peripheral artery disease, stroke; 5% vs. 7%, p = 0.62), and left ventricular ejection fraction (LVEF; 60 ± 6% vs. 60 ± 5%, p = 0.91).
Conclusions: In a population-based cohort, about 3% of individuals exhibit a subclinical PE. These subjects are characterized by higher values of NTproBNP as a potential surrogate of incipient myocardial impairment. However, presence of PE was not associated with inflammation, malignancy, atherosclerotic disease, or LVEF. It remains unclear why particularly women with lower BMI were prone to PE; this aspect deserves further research.

P283

Outcomes are equally poor for patients with suspected heart failure and raised natriuretic peptides, regardless of whether heart failure is confirmed or excluded by a specialist

A Alice Zheng[1]; K Guha[1]; P Kalra[1]; G Morton[1]
[1]*Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*

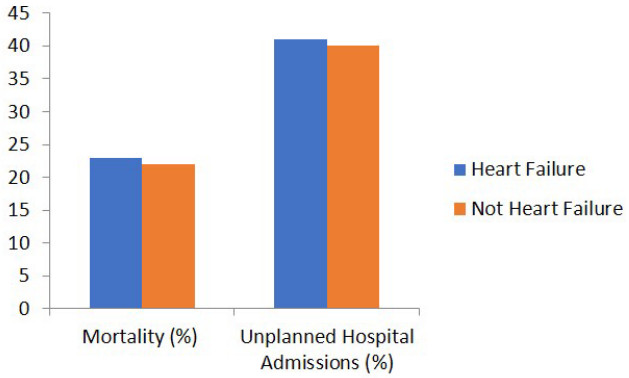
Introduction: Elevated natriuretic peptides in symptomatic patients identifies those with possible heart failure (HF) and predict prognosis. They are however non-specific, and there are few data on how prognosis compares based on whether HF is finally confirmed or excluded.

Table 1

	Heart Failure (n = 133)	Not Heart Failure (n = 102)	p value
Mean Age ±SD (Years)	79±10	80±9	0.37
Mean NTproBNP ±SD (pg/mL)	3749±4343	1542±2034	<0.0001
Male (%)	71 (53)	45 (44)	0.15
Atrial Fibrillation (AF) (%)	79 (59)	47 (46)	0.04
Hypertension (%)	93 (70)	65 (64)	0.32
Diabetes (%)	35 (26)	13 (13)	0.01

Table 1 - Baseline characteristics of patients.

Purpose: Compare outcomes in patients with suspected HF and raised natriuretic peptides, based on whether HF is confirmed or not after specialist assessment.
Evaluate the incidence of subsequent HF in the same population, where the diagnosis of HF is initially rejected.
Methods: All patients with suspected HF and raised NTproBNP (>400 pg/mL) referred to a single centre from March 2014-15 were included. Following echo and specialist assessment they were designated as HF or Not Heart Failure (NHF). All-cause unplanned hospitalisation and mortality data over a minimum follow up of 2 years were obtained from electronic records. Event rates were compared between HF and NHF groups. NHF patients who subsequently developed HF were also noted.
Results: 235 patients were included. Mean follow up was 29 ± 4 months. 133 (57%) were diagnosed with HF; 102 (43%) as NHF.
HF patients had much higher NTproBNP levels and higher rates of AF and diabetes (table 1). Despite this, there were no differences in either mortality (HF 23% [n = 31], NHF 22% [n = 22]; p = 0.75) or hospitalisations (HF 41% [n = 54], NHF 40% [n = 41]; p = 0.95) between the groups; figure 1.
7 (7%) of NHF patients were subsequently diagnosed with HF. Negative predictive value of a NHF diagnosis was 93%.
Conclusions: Patients with suspected HF and raised natriuretic peptides are at high risk of adverse outcomes regardless of their diagnosis after specialist evaluation. Prognosis in the HF group was no worse despite higher NTproBNP levels and rates of diabetes and AF. This may be due to the use of disease modifying therapies improving HF prognosis. The adverse outcome in NHF group is not explained by unrecognised HF at assessment as subsequent presentations with HF were uncommon. These findings should be taken into consideration when discussing prognosis with patients, regardless of their diagnosis.



Event rates between HF and NHF groups

P284

Heart failure with recovered ejection fraction in a colombian heart failure clinic

C I Clara Ines Saldarriaga[1]; QI Santana Fontalvo[1]; CV Gallego[1]; LA Fajardo[1]; AM Agudelo[1]
[1]*Cardiovascular Clinic Santa Maria, Universityof Antioquia cardiology department, Medellin, Colombia*

Background: Little is known about the characteristics, and outcomes of Heart failure recovered patients. Previous reports suggest that these patients might have a different clinical although this is not well understood.
Purpose: To identify the incidence of heart failure with recovered ejection fraction, in a structured Colombian heart failure clinic. The primary endpoint was the recovery of the ejection fraction (EF) to more than 40% after 1 year of follow up. The clinical variables were analysed in order to identify the predictors of the recovery
Methods: A retrospective cohort study was performed. Comprehensive multivariable analyses were performed including the covariates.
Results: 343 patients were included, the mean age was 67 +/- 13.3 years, ischaemic heart disease was the cause of heart failure in 49,3%, and diabetes was the most frequent comorbidity in 24,2% of the population. The initial EF was 25% , optimal medical therapy that included a beta blocker, ACE/ ARB and MRA was prescribed in 89.2% of the patients. After one year of follow up, 28.6% of the population presented a recovery in the EF (to more than 40%). The multivariable analysis is showed in table 1. Younger age OR: 0,97 (0,95-0,99) p = 0,038 and the use of optimal medical therapy OR 0,02 (0,004-0,09) p < 0,0001 were the best predictors of the recovery in the ejection fraction.
Conclusion: This retrospective cohort study showed that 1 of every 3 patients followed in a heart failure clinic can improve the ejection fraction after 1 year of follow up, younger patients treated with optimal medical therapy have the best chance to improve.

Predictors of recovery

characteristic	OR (CI 95%)	p value
Age	0,97 (0,95-0,99)	0,038
Male sex	1,53 (0,72-3,24)	0,264
Optimal medical therapy	0,02 (0,004-0,09)	<0,0001
CRT	0,89 (0,45-1,74)	0,732
Creatinine clearance	0,67 (0,28-1,61)	0,376
End sistolic left ventricular diameter cm/m2	0,75 (0,34-1,69)	0,496
End diastolic left vemtricular diameter cm/m2	0,63 (0,22-1,79)	0,392
Left ventricular mass index. g/m2	0,98 (0,97-1,003)	0,123

Sub-maximal cardiopulmonary exercise test in heart failure: which parameters should we trust?

A Valentim Goncalves[1]; R M Soares[1]; T Pereira-Da-Silva[1]; R Ilhao Moreira[1]; J Feliciano[1]; P Rio[1]; A Abreu[1]; T Mendonca[1]; M Coutinho Cruz[1]; S Aguiar Rosa[1]; R Cruz Ferreira[1]

[1]Hospital de Santa Marta, Lisbon, Portugal

Aims: Peak oxygen consumption (pVO2) is a major criterion for listing patients for heart transplantation but requires a maximal cardiopulmonary exercise test (CPET). In the event of a sub-maximal CPET (respiratory exchange ratio (RER) < 1.05), a ventilation equivalent of carbon dioxide (VE/VCO2) slope may be considered for risk stratification according to current guidelines, despite a low level of evidence.
Purpose: We aimed to evaluate the power of different CPET parameters to predict adverse events in patients achieving maximal and sub-maximal CPETs.
Methods: Ambulatory patients followed in our institution in NYHA class II-III with LVEF = 40%, underwent a prospective evaluation including a CPET. All patients were followed for 60 months and the combined endpoint was cardiac death and urgent heart transplantation.
The pVO2, pVO2(%) predicted, VE/VCO2 slope, oxygen uptake efficiency slope (OUES) and heart rate recovery in the first minute (HHR1) were analysed as potential predictors of the combined endpoint (Cox regression) and their predictive power was compared (area under the curve (AUC) analysis), in the subgroups of patients with achievement of RER <1.05 (G1) or = 1.05 (G2).
Results: In the 274 enrolled patients (98 in G1 and 176 in G2) the combined event rates were 27,6% and 35,8%, respectively (p = 0.164).
Age (p = 0.007) and body mass index (p = 0.003) were higher and diabetes mellitus (p = 0.01) and cardiac resynchronization therapy (p = 0.008) were more common in G1.
The discriminative power of each CPET parameter is presented in the Table. The VE/VCO2 slope was the most accurate parameter for risk stratification in both groups. No significant differences were found in the predictive power of pVO2, pVO2(%) predicted or VE/VCO2 slope between the 2 groups, despite a numerically lower AUC in G1. The HHR1 and OUES significantly lost discriminative power in G1.
Conclusions: VE/VCO2 slope seems to provide a discriminative power at least as good as pVO2 for predicting adverse events in both submaximal and maximal CPET. The discriminative power of HHR1 and OUES was lower in submaximal compared to maximal CPET.

	RER < 1,05	RER ≥ 1,05	Comparison of AUCs (p-value)
pVO_2	0,751	0,813	0,410
pVO_2 (%) predicted	0,762	0,818	0,440
V_E/V_{CO2} slope	0,767	0,860	0,161
OUES	0,654	0,829	0,017
HHR1	0,651	0,845	0,008
pV_{O2} vs V_E/V_{CO2} slope (RER < 1,05)			0,890

Discriminative power of CPET parameters

P286

Glycemic status in non diabetic elderly hypertensives with heart failure with preserved ejection fraction

L Livia Popescu[1]; H Balan[1]

[1]University of Medicine and Pharmacy Carol Davila , Bucharest, Romania

Background: Epidemiological evidence suggests increasing proportion of elderly people. Hypertension, which is worldwide spread and represents the leading cause of death and of heart failure with preserved ejection fraction (HFpEF), occurs in one half/two thirds of them. HFpEF is an important cause of disability and hospitalization and, unfortunately, until now, despite multiple randomized controlled trials, no disease-specific therapy exists to improve prognosis. The prevalence of glycemic disturbances increases with age.
Purpose: The aim of our study was to assess glycemic status in non diabetic elderly patients hospitalized with arterial hypertension and HFpEF in an Internal Medicine Department.
Methods: 168 consecutive elderly patients, 65-94 years old, with arterial hypertension and HFpEF with unknown diabetes were enrolled into the study. For each patient we recorded demographic and anthropometric data, blood pressure measurements, BMI, complete lipid profile, and cardiovascular complications (ischemic heart disease, MI, stroke, angina pectoris). Glycemic status was defined by standard oral glucose tolerance test in all non diabetic patients. Patients were divided into 4 groups: 1) normal glucose tolerance (n = 31), 2) impaired fasting glucose (IFG) (n = 60), 3) impaired glucose tolerance (IGT) (n = 32), 4) newly diagnosed diabetes mellitus (n = 45).
Results: Glucose intolerance was observed in 81.54% (n = 137) elderly with HFpEF previously non diabetic hypertensive patients. 35.71% of them had impaired fasting glucose, 19.05% had impaired glucose tolerance, and 26.78% had newly diagnosed diabetes mellitus. Newly diagnosed diabetes mellitus in elderly patients with hypertension, HFpEF, and cardiovascular complications was observed in 35%. In patients without cardiovascular complication only 14.7% had newly diagnosed diabetes mellitus. The difference was statistically significant (p <0,001). There were no statistically significant differences between groups with/without cardiovascular complications in impaired fasting glucose and impaired glucose tolerance.
Conclusions: Elderly hypertensive patients with HFpEF without previously diabetes mellitus had a high prevalence of glucose intolerance, with newly diagnosed diabetes mellitus affecting more than a fourth of them. Frequency of newly diagnosed diabetes mellitus was twice high in elderly hypertensive with cardiovascular complications than in those with uncomplicated arterial hypertension. Special attention should be given to this group of patients.

Assessment of liver and cardiac iron overload using MRI in patients with chronic anemias in Latin American countries: Results from ASIMILA study

F Manzur[1]; R Cancado[2]; N Watman[3]; C Lobo[4]; Z Chona[5]; F Traina[6]; M Park[7]; G Drelichman[8]; J Zarate[9]; L Marfil[9]

[1]Centro de Investigaciones Biomédicas - Universidad de Cartagena, Facultad de Medicina, Cartagena, Colombia; *[2]Sao Paulo University Medical School, Department of Hematology/Oncology, Santa Casa of Sao Paulo Medical School, Sao Paulo, Brazil,, Sao Paulo, Brazil*; *[3]2Hospital General de Agudos Dr. Ramos Mejía, Buenos Aires, Argentina, Buenos Aires, Argentina*; *[4]Instituto Estadual de Hematologia Arthur de Siqueira Cavalcanti, Rio de Janeiro, Brazil*; *[5]Hospital Universitario de Caracas, Caracas, Venezuela*; *[6]6Haematology and Hemotherapy Center, University of Campinas/Hemocentro-Unicamp, Instituto Nacional d, Cartagena, Brazil*; *[7]Sao Paulo Hematology Center, Sao Paulo, Brazil*; *[8]Hospital de Niños Dr. R Gutierrez, Buenos Aires, Argentina*; *[9]9Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, United States of America*

Objectives: A multicenter, noninterventional, observational study was conducted in the Latin American countries including Argentina, Brazil, Colombia, Mexico, and Venezuela to assess the prevalence of liver and cardiac iron overload using magnetic resonance imaging (MRI) in patients with chronic anemias except thalassemia.
Methods: Patients aged >10 years with transfusion-dependent anemias, except thalassemia, either with < 20 units of red blood cell (RBC) transfusions with serum ferritin (SF) levels >2000 ng/mL or with = 20 units of RBC transfusions regardless of SF level in their lifetime, were enrolled. Iron overload was assessed using MRI.
Results: Among 175 patients included, majority had sickle cell disease (SCD; 52%), followed by aplastic anemia (AA; 17.7%), myelodysplastic syndrome (MDS; 8.6%), Diamond-Blackfan anemia (DBA; 4%), pure red cell aplasia (1.1%), and others (16.6%). Liver iron overload was observed in 76.4% of patients, while cardiac iron overload was seen in only 19.2% when assessed by MRI. The prevalence of iron overload was 80.2% in patients with SCD, 73.3% in MDS, 77.4% in AA, 100% in pure red cell aplasia, 71.4% in DBA, and 68.9% in other transfusion-related disorders. A moderate correlation between liver iron concentration (LIC) and SF was observed in patients with SCD and MDS (r = 0.47 and r = 0.61, respectively). All adverse events reported were consistent with the published data for deferasirox or underlying disease.
Conclusion: A high prevalence of iron overload in this patient population seen in Latin American countries indicates that a better diagnosis and management of iron overload is required in these countries.

P288

Serial biomarkers activity determination during NT-proBNP-guided treatment and its association with long-term clinical outcomes in patients after heart failure decompensation

OY Narusov[1]; AA Skvortsov[1]; DE Protasova[2]; VN Protasov[1]; SN Nasonova[1]; TV Kuznetcova[1]; MD Muksinova[1]; VP Masenko[1]; SN Tereshchenko[1]

[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation; *[2]National Research Center for Preventive Medicine, Moscow, Russian Federation*

Purpose: To evaluate biomarkers activity changes during NT-proBNP-guided treatment and its association with clinical outcomes in pts after ADHF.Materials and methods. The study included 100 pts with ADHF III-IV FC NYHA due to CAD, arterial hypertension and dilated cardiomyopathy and LV EF < 40 %. After HF symptoms compensation, at discharge, high risk pts (discharge NT-proBNP?1400 pg/ml) were

randomized into group of therapy guided by NT-proBNP (NBGT - group1) and standard HF therapy (group2). Mean follow-up period was 10,5 ± 2,1 mts. At the end of study, an additional group 3 of high-risk pts who were noncompliant with the protocol was formed out of pts from these two groups (n = 10).Blood sampling to determine the biomarkers concentrations (sST2, copeptin, galektin-3, hsTrT,NGAL) were collected at discharge, 3,6 mts after. At discharge, median NT-proBNP was 3750.0 (2 224.0;6613.0) pg/ml in the NBGT group, 2 783.0 (2021.5;4827.5) pg/ml in the group 2, and 2162.0 (1684.5;5750.0)pg/ml in the group 3 (? = 0.315).
Results: All pts in study received the triple combination of iACE/ARB+bb+MRA (100%). Over the treatment period, NT-proBNP decreased by 53.0 % (? = 0.001) in the NBGT group and by 10.2%(p = 0.024) in the standard therapy group (? = 0.001). More pronounced biomarkers activity reduction at the end of the follow-up were also found in group 1 pts, especially for sST2 (?% =-37,1%) and copeptin (?% =-29,9%) concentration. ?% NT-proBNP, ?% sST2 and ?% copeptin closely and significantly correlated with ?% E/E' (relatively r = 0,67; r = 0,63 and r = 0,7, p < 0.01 for all). At the end of the study CV mortality rate in group 2 was significantly higher than in NBGT group 1 (34% vs 13%, p = 0.025), as well as the rate of the first and total HF hospitalization (34% vs 13%, p = 0.028 and 54%vs13%,p = 0.02,respectively). Instead of revealed lowest NT-proBNP discharge values at randomization, the highest rate of CV mortality and HF hospitalization was found in group 3 pts (20% and 80% , respectively), witch correlated with increased activity of all investigated biomarkers at the end of the protocol. This fact may be explained by pts noncompliance protocol demands (pts missed>20% of planned visits and had lowest doses of iACE/ARB+bb+MRA in our study). But, this group of pts also had significantly highest admission, discharge and follow-up median sST2 values - another powerful prognostic factor for worse outcomes. sST2 in group 1 vs group 2 vs group 3: 37,7(23,9;58,2) vs 39,7(28,7;51,3) vs 54,8(35,8;68,2)ng/ml at discharge and 22,9(12,7;30,4)vs30,9(30,2;47,3) vs 70,8(48,3;82,2)ng/ml at 6 mts of follow-up (p < 0.05 between groups 1-2 and 3).
Conclusion: The NT-proBNP-guided therapy of high-risk pts after ADHF associates with significantly more pronounced reduction of biomarkers activity during long-term follow-up compared with the standard therapy. sST2 increases opportunities additionally to NT-proBNP in pts long-term risk stratification after ADHF.

P289

Albumin as a prognostic marker in patients with chronic heart failure and reduced ejection fraction

M Marta Ferreira Fonseca[1]; J Farinha[1]; S Goncalves[1]; C Sa[1]; T Duarte[1]; R Marinheiro[1]; R Rodrigues[1]; R Caria[1]
[1]Hospital Center of Setubal, Cardiology, Setubal, Portugal

Introduction: Hypoalbuminemia is common in the presence of certain chronic diseases, usually associated with a worse prognosis. Although low levels of albumin are commonly found in patients with heart failure (HF), the relationship between them isn't totally defined.
Purpose: To determine the prognostic value of hypoalbuminemia in patients with heart failure and reduced ejection fraction (HFrEF).
Methods: We evaluated 167 patients with HFrEF, followed in a heart failure centre. The level of albumin was determined in the beginning of follow-up. Patients whose value of albumin was not determined initially were excluded. The population was characterized according to their clinical, laboratorial and echocardiographic characteristics. Patients were divided in two groups, based on the presence (or not) of hypoalbuminemia (= 3,4g/dL). The adverse events considered were the occurrence of hospitalizations (total or caused by HF) or death.
Results: We studied 167 patients (61% were males) with a mean age of 68 ± 11 years and a median left ventricle ejection fraction (LVEF) of 31 ± 8%. The mean value of albumin was 3,5 ± 0,6g/dL and 41% of the patients presented with hypoalbuminemia. Body mass index (BMI) was lower in patients with lower values of albumin (19kg/m2 vs 24kg/m2). The group of patients with hypoalbuminemia had more hospitalizations (total or caused by HF) and death (see table). Hypoalbuminemia was a predictor of total and HF hospitalizations, in multivariate analysis, independently of BMI (OR: 2,37 CI 95% 1,1-5,0; OR: 2,4 CI 95% 1,1-5,0, respectively). It was a predictor as well of death by any cause (OR: 9,5 CI 95% 1,9-47,8).
Conclusion: Hypoalbuminemia is common in HFrEF and is a marker of worse prognosis, independently of BMI. Additional investigation is needed to enhance our comprehension of the mechanism by which hypoalbuminemia correlates with the prognosis of these patients.

	Albumin≤3,4g/dL (n = 68)	Albumin>3,4g/dL (n = 99)	p
Total hospitalizations	39 (57%)	41 (41%)	0,03
HF hospitalizations	34 (50%)	36 (36%)	0,05
Death	14 (21%)	4 (4%)	0,001

Hypoalbuminemia and clinical outcomes

The target degree of sST2 and NT-proBNP values decrease during biomarker-guided treatment for long-term patients outcomes improvement after heart failure decompensation

AA Skvortsov[1]; VN Protasov[1]; OY Narusov[1]; DE Protasova[2]; MD Muksinova[3]; AV Sychev[3]; VP Masenko[3]; SN Tereshchenko[3]
[1]Russian Cardiology Research Center, Moscow, Russian Federation; *[2]National Research Center for Preventive Medicine, Moscow, Russian Federation*; *[3]Russian Cardiology Research and Production Complex, Moscow, Russian Federation*

Purpose: To evaluate target degree of sST2 and NT-proBNP values decrease during biomarker-guided treatment for long-term patients outcomes improvement after heart failure decompensation (ADHF).Materials and methods. The study included 100 patients with ADHF III-IV FC NYHA and LV systolic dysfunction due to coronary artery disease, arterial hypertension and dilated cardiomyopathy and LV EF < 40 %. After HF symptoms compensation, at discharge, high risk pts (discharge NT-proBNP ? 1400 pg/ml) were randomized into group of therapy guided by NT-proBNP (monthly) (NBGT - group 1) and standard HF therapy (group 2). The goal of treatment was to reduce NT-proBNP concentration < 1000 pg/ml, or at least 50% of the initial. Mean follow-up period was 10,5 ± 2,1 months. Blood sampling to determine the biomarkers concentrations (sST2, copeptin, galektin-3, highly sensitive Troponin T and NGAL) were collected at discharge from the hospital, 3 and 6 months after. At the time of discharge from the hospital, median NT-proBNP concentration was 3750.0 (2 224.0; 6 613.0) pg / ml in the NBGT group and 2 783.0 (2021.5; 4 827.5) pg/ml in the group 2 (? = 0.315).
Results: All patients in our study received the triple combination of iACE/ARB+beta-blocker+MRA (100%). Over the treatment period, NT-proBNP concentration decreased by 53.0 % (? = 0.001) in the NBGT group and by 10.2 % (p = 0.024) in the standard therapy group (? = 0.001 between groups). The goal of treatment (decreasing the NT-proBNP concentration to below 1000 pg / ml and / or = 50 % from baseline) achieved by 74% of pts in NBGT group. More pronounced biomarkers activity reduction at the end of the follow-up were also found in group 1 pts, especially for sST2 (?% =-37,1%) and copeptin (?% =-29,9%) concentration. ?% NT-proBNP, ?% sST2 and ?% copeptin closely and significantly correlated with ?% E/E' (relatively r = 0,67; r = 0,63 and r = 0,7, p < 0.01 for all).At the end of the study CV mortality rate in group 2 was significantly higher than in NBGT group 1 (34% vs 13%, p = 0.025), as well as the rate of the first and total HF hospitalization (34% vs 13%, p = 0.028 and 54% vs 13%, p = 0.02, respectively).Pts risk for CVevents (CV death, repeated decompensation, and hospitalization for CHF) during long-term follow-up decreased only when we achieved NT-proBNP or sST2 concentration reduction more than = 40,0% or = 24,9% from discharge values respectively [OR at 95 % CI = 0.08 (0.02-0.36), p < 0.0001 for NT-proBNP and = 0.1(0.02-0.5), p = 0.004) for sST2].
Conclusion: During NTproBNP-guided therapy high-risk patients after ADHF, reduction of CV death, repeated decompensation and hospitalization for HF may be achieved only in pts with NT-proBNP or sST2 concentration reduction more than = 40,0% or = 24,9% from discharge values

On behalf of: HEFESTOS GROUP
Funding Acknowledgements: "The project received a research grant from the Carlos III Institute of Health, Ministry of Economy and Competitiveness (Spain), awarded on the 20XX c

Background: Information about factors that contribute to decompensation of the heart failure patients attended in primary care is scarce.
Purpose: To determine the distribution and importance of factors, especially the preventable ones, that contribute to heart failure decompensation in patients attended in primary care
Methodology: HEFESTOS is a cohort study aimed at knowing the main triggers and the prognosis of some factors related with the heart failure decompensations attended in primary care setting.
The following variables were collected: age, sex, heart rate, blood pressure, NYHA class, days since the onset of symptoms, oxygen saturation, diuretic dose, crackles

, ankle oedemas, paroxistic dispnea, pathological weight gain, orthopnea, hospital admission in the last year, causative factor of decompensation, comorbidity and ejection fraction. The main outcome was hospitalization or death in the month following the inclusion.
Results: Consecutive sample of 425 patients attended in primary care for decompensation of pre-existing heart failure (from 1st, March 2015 to 31st December 2017) were included. Women were 55.8%. Mean (SD) age was 81.5 (9.1) years. Hospitalization or death in the month following the inclusion occurred in 133 (31.3%) patients. Potential causative factors for decompensated heart failure were identified in 83.1% of patients. More than one factor was identified in 34.9% of patients. Non compliance with fluid or salt restriction was the most commonly identified factor (30.3%), followed by respiratory infection (30.2%),non-compliance with drugs treatment (21.4%), worsening of atrial fibrillation(12.2%),contraindicated drugs (9.7%), worsening of renal function (4.7%), anemia(4.5%) and coronary ischaemia (3.8). Respiratory infection, worsening of atrial fibrillation, worsening of renal function and coronary isquaemia were related with more probability of hospitalizacion or dead.
Conclusions: Non compliance with fluid or salt restriction and respiratory infection Were the most frequent causes of decompensation of HF in patients attended in primary care. More than half of the causes could have been prevented

P292

One-year prognosis of patients with chronic heart failure, depending on AHEAD score and renal function (creatinine and NGAL).

K Karel Labr[1]; J Spinar[2]; J Parenica[2]; L Spinarova[1]; F Malek[3]; M Spinarova[1]; O Ludka[2]; J Jarkovsky[4]; K Benesova[4]; J Tomandl[5]; M Tomandlova[5]; R Labrova[2]
[1]St. Ann university hospital and Masaryk university, Brno, Czech Republic; *[2]University hospital Brno and Masaryk university, Brno, Czech Republic*; *[3]Na Homolce Hospital, Prague, Czech Republic*; *[4]Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic*; *[5]Masaryk University, Department of Biochemistry, Brno, Czech Republic*

Background and Purpose: The incidence of renal insufficiency is increasing with an increasing number of patients with heart failure. Therefore, it is important to detect and predict renal failure. Neutrophil gelatinase-associated lipocalin (NGAL) is an early marker of renal impairment and is associated with the prognosis of heart failure patients.
Methods and Results: 547 patients from the multicenter registry of FARmacology and NeuroHumoraL activation (FAR NHL) were included, who had available data on follow-up hospitalizations, mortality, and biomarker levels. Patients with heart failure with a lower left ventricular ejection fraction below 50% who were at least one month stable (80.3% of men, median age 66 years). The etiology of heart failure was 54% ischemic heart disease, in 40% dilatated cardiomyopathy. 69% of patients were in New York Heart Associaton (NYHA) functional class II. In the first year of follow-up, 76 events (13.9%) occurred, including all-cause deaths (3.8%), hospitalization for acute heart failure (10.1%), and left ventricle assist device (LVAD) implantation or orthotopic heart transplantation (OHT, 2.0%). In patients with AHEAD score (atrial fibrillation, anemia, old age, renal insufficiency, diabetes mellitus; 1 point for each), 0-1, the incidence of events was 11.9%, AHEAD 2-3 in 16.2%, and AHEAD 4-5 in 18.0% of patients. The best predictive power of NGAL and creatinine was in patients with AHEAD score 2-3, when NGAL at a cut-off value of 61.3 ng / mL (according to ROC analysis) has a sensitivity of 73.3% and a specificity of 50.6% (p = 0.032). For creatinine at 119.5 µmol / L, the sensitivity was 52.6% and the specificity was 65.3% (p = 0.035).
Conclusion: According to FAR NHL registry, renal functions expressed by creatinine and NGAL have the best ability to predict occurrence of events in moderately ill patients.

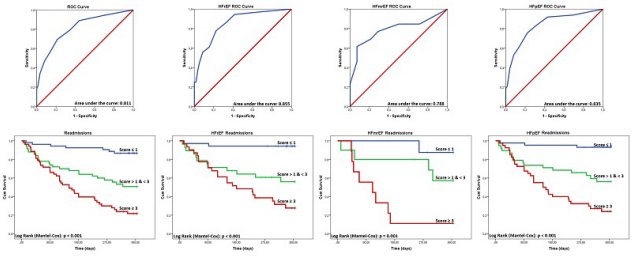
P293

Predicting readmissions in patients with heart failure: a novel and easy-to-apply scoring model

J Ribeiro Agostinho[1]; J Rigueira[1]; A Nunes-Ferreira[1]; I Aguiar-Ricardo[1]; T Guimaraes[1]; I Goncalves[1]; R Pires[2]; F Veiga[1]; M Mendes Pedro[1]; FJ Pinto[1]; D Brito[1]
[1]Cardiology Department, Santa Maria Hospital, CHLN, CCUL, Lisbon University, Lisbon, Portugal; *[2]Faculty of Psychology, CINEICC, University of Coimbra, Coimbra, Portugal*

On behalf of: RICA-HFTeam

Introduction: Readmission (reH) rates are particularly high in patients (pts) admitted for acute/decompensated chronic heart failure, being a relevant cause of impaired quality of life, and a main negative prognostic determinant. Therefore, the identification of pts at a higher risk of reH is at utmost relevance.
Objective: Development of an easy-to-apply score, useful for prediction of all-cause reH during the first year after discharge.
Methods: Retrospective study with prospective data registry of consecutive pts discharged after an index-hospitalization due to acute HF. All pts were submitted to clinical, laboratorial, electrocardiographic and echocardiographic evaluations. Cox Regression was used to ascertain predictors of readmission; ROC curve method, and Kaplan-Meier survival analysis were used to evaluate score efficacy.
Results: 156 pts were included (mean age:68.1 ± 12.4years, 60.1% males). The mean left ventricular ejection fraction (LVEF) was 36.4 ± 15.9% (LVEF < 40% in 60.3%). Seventy (44.8%) pts were discharged in NYHA I functional class, 51.9% in class II and 3.2% in class III. Mean follow-up time was 11.1 ± 2.6 months. The reH rate during follow-up was 46.2% and the mortality rate was 10.3%. Previous ischemic stroke (iS) (HR = 2.3, CI = 1.3-4.1, p = 0.004), history of malignancy (hNeo) (HR = 2.6, CI = 1.4-4.9, p = 0.025), on-admission values of hemoglobin (Hb) < 12g/dL (HR = 2.3, CI = 1.4-3.6, p = 0.001), total bilirubin (TBil) >1.2mg/dL (HR = 2.1, CI = 1.2-3.5, p = 0.007), alkaline phosphatase (ALP) >105U/L (HR = 2.0, CI = 1.2-3.3, p = 0.027) and thyroid-stimulating hormone (TSH) >4.1uU/mL (HR = 2.3, CI = 1.4-3.6, p = 0.003) and a length of stay (LOS) > 17days (HR = 2.1, CI = 1.2-3.4, p = 0.028) and NTproBNP>4250pg/mL (HR = 2.1, CI = 1.1-4.1, p = 0.011) and blood nitrogen urea (BUN) >67mg/dL (HR = 3.3, CI = 2.0-5.6, p = 0.004) at-discharge were independent predictors of reH. According to the Hazar Ratio, was attributed 1 point to iS, Hb < 12g/dL, TBil>1.2mg/dL, ALP>105U/L, TSH>4.1uU/mL, NTproBNP>4250pg/mL and LOS>17days; and 1.5 points to BUN>67mg/dL and hNeo, with a maximum score of 10 points in total. This model showed a good accuracy to predict reH during the first year after discharge [area under de ROC curve (AUC) = 0.81]. Based on tercile distribution the population was classified as low-risk (score = 1; reH rate:13.2%), intermediate-risk (score>1 and < 3; reH rate:48%) and high-risk (score = 3; reH rate:77.4%). The model showed the best accuracy for pts with either a reduced LVEF (AUC = 0.86), or a preserved LVEF (AUC = 0.84), and showed fair accuracy when applied to pts with HF and LVEF in the midrange (AUC = 0.79).
Conclusion: This new scoring model showed good accuracy in predicting all-cause readmissions during the first year after discharge when applied to patients hospitalized for acute HF. As it is based on clinical and laboratorial standard parameters, it may be a useful and easy-to-apply tool for the identification of HF patients requiring a closer follow-up after discharge.



P294

Long-term clinical outcome in patients with heart failure and pacemakers: a single-center cohort study

M Martin Riesenhuber[1]; A Spannbauer[1]; F Rauscha[1]; H Schmidinger[1]; T Pezawas[1]; C Schukro[1]; M Gwechenberger[1]; C Khazen[2]; G Stix[1]; T Wrba[3]; C Hengstenberg[1]; D Traxler[1]; C Muller[1]; M Gyongyosi[1]
[1]Medical University of Vienna, Department of Cardiology, Vienna, Austria; *[2]Medical University of Vienna, Department of Cardiac Surgery, Vienna, Austria*; *[3]Medical University of Vienna, Center for Medical Statistics, Informatics and Intelligent Systems, Vienna, Austria*

Background: Clinical and pacemaker (PM) data were retrospectively analyzed and combined with survival in a 10-year follow-up.
Purpose: Aim was to identify differences in patients with/without heart failure (HF).
Methods: Patients with all available clinical (age at the time of first implantation, diagnosis of heart disease, survival data) and PM data were included (N = 1969 women, N = 3129 men). Survival was retrieved from the Federal Institute "Statistics Austria".
Results: HF was diagnosed in 2149 of 5098 PM patients (42.2%): less female (N = 671/34.1%) than male (N = 1478/47.2%) had HF (P < 0.001). Patients with HF had similar age at the first PM implantation as compared to patients without HF (73.2years ± 16 IQR vs 72.5 ± 15 with HF, n.s.). Equal implantation rates of dual-chamber PM were found in HF/non-HF-patients (Table). Patients with HF had significant worse 10-years survival than patients without HF (Figure), with

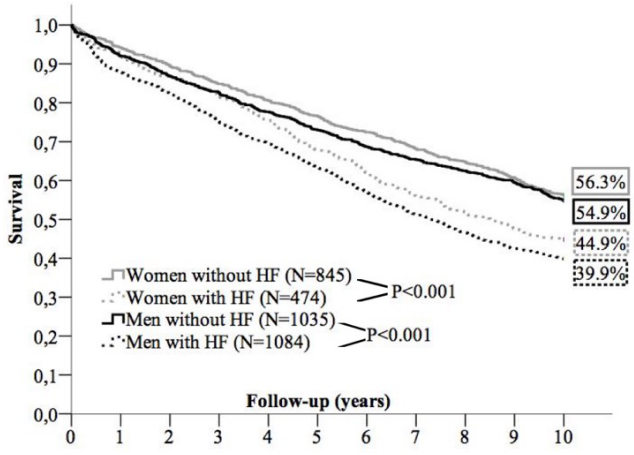
more cardiovascular deaths. Lead impedance of the PM was significantly lower in HF-patients, while pacing thresholds was not different.

Outcome parameters.

	HF N = 2149	Non-HF N = 2949	P Value
Device type			
— Single-chamber PM	624 (31.8%)	867 (31.9%)	n.s.
— Dual-chamber PM	1340 (68.2%)	1848 (68.1%)	n.s.
10-year survival N = 3438	41.4%	55.5%	<0.001
Cause of death			
— Total deaths	1209 (56.3%)	1221 (41.4%)	<0.001
— Cardiovascular death	668 (31.1%)	613 (20.8%)	<0.001
— Malign death	149 (6.9%)	194 (6.6%)	n.s.
— Other death	392 (18.2%)	414 (14.0%)	<0.001
Parameters			
— Atrial PT (V)	0.6±0.5	0.7±0.5	n.s.
— Ventricular PT (V)	0.5±0.4	0.5±0.3	n.s.
— Atrial LI (Ohm)	495±139	507±150	0.007
— Ventricular LI (Ohm)	650±210	671±194	<0.001

PT: Pacing threshold; LI: Lead impedance

Conclusion: PM-patients with HF had worse clinical outcome and higher cardiovascular mortality. Lead impedance was decreased in HF and might be a predictor of fluid overload.



Kaplan-Meier: 10-year survival

P295

QRS duration is associated with outcome in symptomatic HF patients. What about ACCF/AHA stages A and B? Data from the DAVID-Berg study

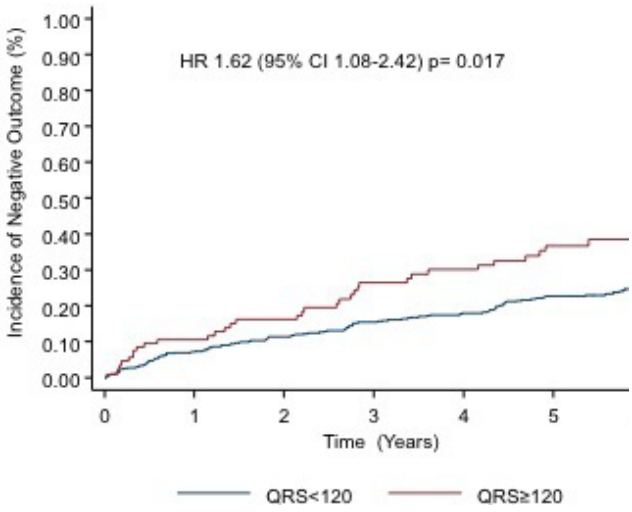
A Andrea Pozzi[1]; M Gori[2]; A Iorio[2]; A Iacovoni[2]; A Grosu[2]; A Fontana[2]; P Canova[2]; A Calabrese[2]; P Ferrari[2]; A Gavazzi[3]; M Senni[2]

[1]Cardiovascular Research Centre of Glasgow, Glasgow, United Kingdom; [2]Ospedale Papa Giovanni XXIII, Cardiology, Bergamo, Italy; [3]Ospedale Papa Giovanni XXIII, FROM Fondazione per la Ricerca, Bergamo, Italy

On behalf of: DAVID-Berg

Background: QRS duration is associated with poor outcome in symptomatic heart failure (HF), irrespective of ventricular function. However, no data are available in asymptomatic patients with HF ACCF/AHA classes A and B. Our aim was to assess whether QRS duration may predict outcome in a HF preclinical setting.

Methods: The DAVID-Berg study prospectively enrolled 614 outpatients at increased risk for HF, but asymptomatic. All patients underwent a protocol consisting of history, physical examination, blood chemistry, NT-proBNP testing, 12-lead ECG, and echocardiogram. ECGs were coded according to Minnesota coding system blinded to clinical information. QRS duration was considered both as continuous and as cathegorical variable (cut-off= 120 ms). The endpoint of interest was a composite of HF onset, cardiovascular (CV) hospitalization (stroke, TIA, myocardial infarction, and myocardial revascularization), and all cause death.



KM cumulative incidence of outcome

Results: Mean age of the population was 69 ± 7, 56% were male, mean LV ejection fraction (LVEF) was 58%, mean QRS duration was 97 ± 21 ms, and 18% (n = 109) had QRS duration = 120 ms. During a median follow-up of 5.7 years, there were 149 adverse events. At Cox regression analysis QRS duration was associated with increased risk of the composite outcome, even accounting for demographics, CV risk factors, LVEF, diastolic function, NT-proBNP, and other ECG abnormalities (HR 1.01, 95% CI 1.00-1.02, adjusted p = 0.038). Considering QRS as categorical variable, patients with wider QRS (= 120 ms) were more likely to have worst outcome (HR 1.62, 95% CI 1.09-2.42, adjusted p = 0.017; Fig 1).

Conclusions: In patients with HF ACCF/AHA stages A and B, QRS duration is related with increased risk of HF onset, CV hospitalization and all cause of death.

P296

A method for predicting the survival of patients with heart failure

LV Prokopova[1]; MYU Sitnikova[1]; EV Shlyakhto[1]

[1]Almazov National Medical Research Centre, Department for Heart Failure, Saint Petersburg, Russian Federation

To determine the tactics of management in a patient with heart failure, it is important to accurately qualitatively evaluate the patient's survival within 1 year.

Goal. Creation of a method for qualitative assessment of the survival prognosis of a patient with systolic heart failure.

Materials and methods: A prospective study of 212 II-IVF patients with "non-valvular etiology" of HF with an LV ejection fraction (Simpson) = 35% at the age of 18-70 years. Of these, 176 men (83%) and 36 women (17%). Design work: hospitalization of patients in the department, specialized in the treatment of heart failure; selection of therapy and stabilization of patients; assessment of status, performance of laboratory and instrumental studies; observation, telephone contacts, correction of therapy and hospitalization during decompensation; filling the database of 200 indicators. After 12 months, the endpoints were recorded.

Results: Within 12 months, 64% of patients (135 people) survived, 2% (5 people) had an implant system EXCOR, 10% (21 people) had cardiac transplantation, 24% of cases (51 people) were lethal. The end points reached 77 people. Later, a multiple logistic regression analysis was carried out. A method for qualitative assessment of the survival prognosis was obtained, which includes the following predictors: the age of debut of heart failure, the frequency of respiratory movements, systolic blood pressure, orthostasis measured at 3-5 minutes, lymphocyte count and erythrocytes distribution by volume in serum ($p < 0.05$). Survival is calculated by the formula including these predictors with the corresponding coefficients. If a patient with a survival prediction is less than 1 year old, he should be sent to the selection committee at a major cardiac center in the shortest time to resolve the issue of heart transplantation or mechanical support of blood circulation. With the expected prognosis of survival over 1 year, further outpatient monitoring and the resolution of the ICD question are indicated.

Conclusions: 1. The method of qualitative assessment of the prognosis of survival of a patient with systolic heart failure allows one to evaluate the patient's survival in the coming year using simple indicators.

3. Using the method of qualitative assessment of the patient's survival forecast, the doctor can adjust the tactics of the patient's management and determine the indications for high-tech medical care.

P297
Predictors of mid-term rehospitalization and mortality rates in Bulgarian patients with heart failure and mid-range ejection fraction: a single-center study

R Pancheva[1]; N Runev[1]; E Manov[1]; B Stoimenov[1]; E Dimchovski[2]; D Vassilev[3]
[1]University Hospital Alexandrovska, Cardiology Clinic, Department of Propaedeutics of Internal Diseases , Sofia, Bulgaria; *[2]Medical Institute of Ministry of Interior, Department Cardiology, Sofia, Bulgaria*; *[3]University Hospital Alexandrovska, Department Cardiology, Sofia, Bulgaria*

Background: Chronic heart failure (CHF) is a major cause of death and recurrent rehospitalization. Heart failure with midrange ejection fraction (HFmrEF) is a new category of heart failure (HF), inbetween HF with reduced ejection fraction (HFrEF) and HF with preserved ejection fraction (HFpEF). Limited data exist on the epidemiology, treatment and short or longterm prognosis of patients with HFmrEF.
Purpose: The aim of this study was to analyse baseline characteristics and outcome of patients with HFmrEF.
Methods: An observational study of patients with decompensated HFmrEF, admitted at our Department between January 2012 and June 2013, was conducted. Among the risk factors, co-morbidities, clinical, echocardiographic and hemodynamic indicators, predictors of their mortality and rehospitalization rates were investigated.
Results: A total of 135 patients, mean age 68.6 ± 11.1 years, were studied. The demographic characteristics were as follows: 89.6% had arterial hypertension (AH) (1.5% stage I; 47.4% stage II; 40.7% stage III); 33% type 2 diabetes mellitus (DM); 32.6% suffered from coronary artery disease (CAD), of whom 13.3% with previous myocardial infarction (MI); 49.5% had valvular heart disease (VHD) (of whom 21.5% with mitral valve disease (MVD); 4.4% with aortic valve disease (AVD); 8.9% with combined mitral and aortic valve disease (MVD+AVD) and 11.1% with prostetic heart valve/s); 75.6% had atrial fibrillation (AF) (of whom 2.2% with de novo AF; 11.9% with paroxysmal AF; 3,0% with persistent AF and 58,5% with permanent AF); and 51.1% elevated pulmonary artery systolic pressure (PASP) (<40 mmHg). In the follow-up period with average duration of 5 years, 68 patients (50.4%) died. For independent predictors of the 5-year mortality in our HFmrEF group, the following were found: age>67 years (OR 2.42; 95% CI, 1.19-4.92; $p < 0.05$), mitral valve disease (MVD) and combined mitral and aortic valve disease (AVD) (OR 3.29; 95% CI, 1.49-7.26; $p < 0.01$), PASP >44 mmHg (OR 4.79; 95% CI, 1.92-11.98; $p < 0.01$), CHA2DS2VASc >4 points (OR 2.80; 95% CI, 1.29-6.10; $p < 0.01$).
In the clinical follow-up period with average duration of 1 year, 19 patients (14.1%) experienced rehospitalization because of an exacerbation of congestive HF. Using a multivariate logistic regression analysis, the following independent predictors of rehospitalization were found: AH stage III (OR 3.76; 95% CI, 1.33-10.65; $p < 0.05$) and permanent AF (OR 3.38; 95% CI, 1.95-5.86; $p < 0.01$).
Conclusion: Because of the lack of data regarding patients with HFmrEF in Bulgaria, we performed this single-center study. The analysis has revealed that the 5 year mortality rate is predicted mainly by the advanced age (<67 years), presence of MVD and combined MVD + AVD, pulmonary hypertension and high CHA2DS2VASc score. The 1 year rehospitalization rate has been found to be highly dependent on AH stage III and permanent AF.

P298
Clinical presentation of heart failure in female patients-results from CRO-HF Registry

D Glavas[1]; K Novak[1]; D Milicic[2]; J Borovac[1]; B Jurcevic Zidar[1]
[1]Split University Hospital, Split, Croatia; *[2]University of Zagreb-School of Medicine, Zagreb, Croatia*

Introduction: Heart failure (HF) could be different in specific population. The aim of the study was to analyse clinical presentation of HF in female patients according to results from CRO-HF Registry.
Methods and Results: We analysed 2203 hospital HF patients (data based on CRO-HF Registry): 1175 (53.3%) males (m) and 1028 (46.7%) females (f); median age 76 y. One third patients suffered of acute HF. Preserved left ventricular function (LVEF = 50%) was recorded in 37.8% patients. Females had frequently preserved LVEF (= 50%) (f-49.3%, m-29.3%, $p < 0.001$) and males reduced LVEF (< 50%) (m-70.7%, f-50.7%).
History of hypertension (AH) had 67.5% patients, diabetes 34.4%, myocardial infarction 22.7%, renal failure 19.2%, COPD 17.3%, stroke 16.5% and atrial fibrillation 53.7% patients. In males, comparative to females, important disease was COPD (m-19.7%, f-14.7%, $p = 0.009$), renal failure (m-23%, f-14.8%, $p < 0.001$), diabetes (m-36.1%, 32.6%, $P = 0.08$), stroke (m-17.1%, f-15.9%, $P = 0.547$) and smoking habit (m-14.8%, f-6.4%, p= < 0.001).
The frequently precipitating factors of HF were: arrhytmiae (m-56.1, f-58.3), valvular diseses (m-67.3%, f-67%) and infections (m-18.7, f-20.4%). Important "trigger" in females was hypertension (f-58.7%, m-52.7%, $P = 0.009$), arrhytmiae (f-58.3%, m-56.1%), infections (f-20.4%, m-18.7%), and acute coronary syndrome (ACS) in males (m-22.1%, f-17%, $P = 0.010$). Females had often atrial arrhytmiae (f-92.2%, m-87.6, $P = 0.010$)
Lower values of haemoglobin was recorded in 51.9% patients, higher creatinine had 46.8%, ALT 29.8%, cholesterol 32.7%, triglycerides 31.9%, uric acid 79.3%, and hyperglycaemia 99.8% patients. In females, we recorded higher values of ALT (f-33%, m-27%, $P = 0.012$, $C = 0.066$), cholesterol (f-36.8%, m-29.1%, $P = 0.009$), triglycerides (f-36.1%, m-28.3%, $P = 0.014$), uric acid (f-82.9%, m-76.4%, $P = 0.007$), and males lower haemoglobin levels (m-58%, f-44.8%, $p = 0.001$)
Hospital mortality was lower in males than in females (m-12.6%, f-14.4%).
There were no significant differences in HF treatment according to gender.
Conclusion: Clinical presentation of HF could be different in female patients, according to CRO-HF Registry
Results: Females have frequently preserved LVEF, higher values of ALT, cholesterol, tryglicerides and uric acid, and males have lower values of LVEF and haemoglobin. Hypertension is important "trigger" of HF in females and ACS in males. HF treatment should be adapted to clinical presentations of HF according to gender.

P299
Heart failure and chronic obstructive pulmonary disease: outcome predictors

VM Violetta Gazizianova[1]; OV Bulashova[1]; EV Khazova[1]
[1]Kazan State Medical University, Kazan, Russian Federation

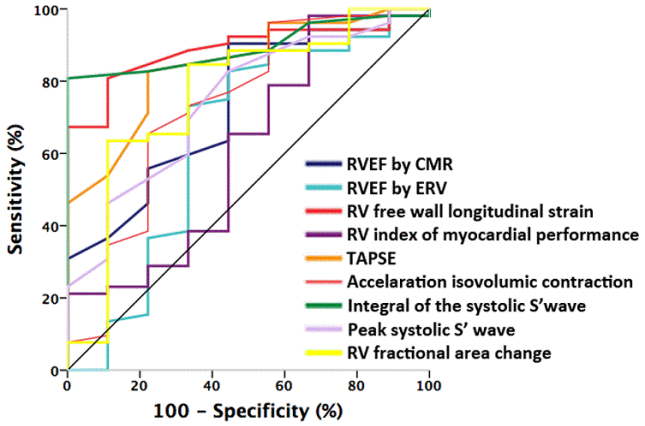
Introduction: It is well known that coexistence of heart failure (HF) and chronic obstructive pulmonary disease (COPD) increases amount of cardiovascular and pulmonary events. There is information about prognostic factors in HF and COPD, however there is little data about prognostic factors in HF associated with COPD.
Purpose of the study was to analyze the one year outcomes in HF patients concominant COPD and to indicate prognostic factors of cardiovascular and pulmonary events.
Methods: Clinical assessment, spirometry, echocardiography were performed in 105 patients with stable HF concominant COPD (mean age 65,09 ± 10,74 years, ischaemic aetiology 92,3%, NYHA class I-II 42%, III-IV 58%). Forced expiratory volume in 1 s (FEV1) and forced vital capacity (FVC) were assessed according to American Thoracic Society/European respiratory society Guidelines. All cardiovascular events (cardiovascular death, non-fatal myocardial infarction and stroke, tromboemboli complications, acute heart failure decompensation) were assessed as combine outcome. Amount of cardiopulmonary events (summary of all cardiovascular and pulmonary events) was assessed independently. The median follow up time was 1 year. Cox logistic regression was performed with using Statistica 10.0 software for analysis, p value of < 0,05 was taken as significant.
Results: The 98 patients were followed up for a period one year which included cardiovascular and pulmonary outcomes. After one year follow up the cardiovascular events structure was following: cardiovascular death was found in 6,1%, non-fatal myocardial infarction in 9,2%, non-fatal stroke in 6,1%, acute decompensation of chronic heart failure in 38,8%, tromboemboli complication in 5,1%. Combine outcome (cardiovascular events) was noted in 62,2%, cardiopulmonary outcomes in 98,0%. The combine outcome was associated with 6 minute walking distance < 300 meters (OR = 2,832; 95% CI 1.97-4.06, $p < 0,001$), FEV1 < 50% (OR = 2,155; 95% CI 1.569-2.959, $p < 0,001$), FVC < 70% (OR = 2,074; 1.496-2.876, $p = 0,004$). Cardiopulmonary outcome predictors were the same: walking test less than 300 meters (OR = 2,063; 95% CI 1.596-2.665, $p < 0,001$), FEV1 < 50% (OR = 1,875; 95% CI 1,477-2,381, $p < 0,001$), FVC < 70% (OR = 1,442; 1,158-1,797, $p = 0,049$). Conclusion. Our study showed a strong association of 6 minute walking distance < 300 meters, FEV < 50%, FVC < 70% with combine outcome (cardiovascular events) and cardiopulmonary outcome in HF patients concominant with COPD.

Chronic Heart Failure - Diagnostic Methods

P300
What is the best imaging technique to explore right ventricular function at the time of multimodality cardiovascular imaging?

S Stephanie Cazalbou[1]; V Chong Fah Shen[1]; A Petermann[2]; D Eyharts[1]; P Fournier[1]; E Cariou[1]; Y Lavie-Badie[1]; D Carrie[1]; M Galinier[1]; I Berry[3]; O Lairez[1]
[1]Toulouse Rangueil University Hospital (CHU), Department of Cardiology, Toulouse, France; *[2]Toulouse Rangueil University Hospital (CHU), Department of Radiology, Toulouse, France*; *[3]Toulouse Rangueil University Hospital (CHU), Department of Nuclear Medicine, Toulouse, France*

Background: - Right ventricular (RV) function is a powerful independent predictor of adverse heart failure outcomes. Several RV imaging parameters have been



ROC curves for the prediction of MACE

proposed to detect patients at risk new-onset acute heart failure. The objective our study was to compare the predictive value of main RV systolic parameters for outcomes.

Methods: One hundred and one patients underwent comprehensive cardiovascular imaging modalities including transthoracic echocardiography (TTE), cardiac magnetic resonance imaging (CMR) and tomographic equilibrium radionuclide ventriculography (ERV) for the assessment of RV function. The composite primary endpoint was the occurrence of a major adverse cardiac event (MACE), i.e., death, heart transplantation, or new-onset acute heart failure defined as hospital admission for diuretic treatment optimization.

Results: Mean NYHA class and left ventricular ejection fraction were 1.7 ± 0.9 and 46 ± 18%, respectively. During a mean follow-up of 10 ± 9 months, 16 (16%) patients reached the composite primary endpoint. The areas under the receiver operator characteristic curves for the prediction of MACE were 0.894 (P < 0.001), 0.890 (P < 0.001), 0.844 (P = 0.001), 0.765 (P = 0.012), 0.745 (P = 0.020), 0,735 (P = 0.025), 0.734 (P = 0.026), 0.643 (P = 0.173) and 0.613 (P = 0.281) for integral of the systolic S' wave of tricuspid annulus, RV free wall longitudinal strain, tricuspid annular plane systolic excursion, RV fractional area change, peak systolic S' wave velocity of tricuspid annulus, RV ejection fraction by CMR, RV index of myocardial performance, RV ejection fraction by ERV and acceleration of the RV myocardium during isovolumic contraction, respectively (Figure).

Conclusion: Among comprehensive cardiovascular imaging modalities allowing the assessment of RV function, echocardiographic parameters, and particularly integral of the systolic S' wave of tricuspid annulus and RV free wall longitudinal strain, have the best prognostic performance.

P301

The assessment of myocardial deformation in patients with acute decompensation of ischemic heart failure with reduced ejection fraction by 2d-speckle tracking technology

EV Kruchinkina[1]; TR Ryabova[1]; VV Ryabov[2]
[1]Cardiology Research Institute, Tomsk National Research Medical Center, Tomsk, Russian Federation; *[2]National Research Tomsk State University, Tomsk, Russian Federation*

Background: Ischemic heart disease is a common cause of chronic heart failure (CHF). Despite significant advances in study of the pathogenesis of CHF and the introduction of effective medical therapy for CHF patients, the incidence of hospitalizations for acute decompensated heart failure (ADHF) remains high. An important component in the pathogenesis of CHF and ADHF is myocardial inflammation. A left ventricular (LV) remodeling causes the development of heart failure, and directly correlates with the left ventricular ejection fraction (LVEF), but does not represent the myocardial contractility. 2D-speckle tracking echocardiography allows determining the deformation of the LV and the prognosis of CHF, in contrast to standard echocardiography.

The purpose of study was to assess the deformation of the LV in patients with ADHF of ischemic etiology depending on the presence or absence of diagnosed myocardial inflammation.

Materials and Methods: The analysis included 25 patients (84% men, LVEF 29.17 ± 9.4%) with ADHF of ischemic etiology. Patients were divided into groups according to the classification of ADHF: warm-dry (58%), warm-wet (4%), cold-dry (8%), cold-wet (30%). The average age of the patients was 60.12 ± 9.3years. All the patients underwent an echocardiography including 2D-speckle tracking technique to assess LV deformation. A coronary angiography was performed to exclude ischemic etiology of ADHF. An endomyocardial biopsy with following immunohistological examination was performed to diagnose the presence of myocardial inflammation. Patients were divided into 2 groups depending on the presence or absence of myocardial inflammation.

Results: We have revealed a statistically significant decrease in apical rotation by 49% (p = 0.0286) and apical rotation rate (S) by 44% (p = 0.0382) in the group with diagnosed myocardial inflammation upon admission. We did not notice the difference in apical rotation between 2 groups of patients in a year. However, we have observed the increase of global longitudinal strain in the group of patients with the presence of myocardial inflammation (p = 0.0431).

Conclusion: We observed significant decrease in apical rotation in the group of patients with diagnosed myocardial inflammation, while there were not statistically significant differences in basal rotation characteristics between 2 groups. This fact could be the marker of the presence of inflammatory, not the ischemic, myocardial damage. Thus, 2D-speckle tracking is a promising non-invasive method for diagnostics of myocardial inflammation.

P302

Low Levels of CA125 and Risk of Short-term Events after an Episode of Acute Heart Failure

M Amiguet Comins[1]; G Minana[1]; E Santas[1]; E Valero[1]; R De La Espriella[1]; FJ Chorro[1]; I Cardells[1]; J Gonzalez D'gregorio[1]; A Mollar[2]; J Sanchis[1]; R Heredia[1]; A Paya[1]; A Bayes-Genis[3]; J Lupon[3]; J Nunez[1]
[1]University Hospital Clinic of Valencia, Cardiology, Valencia, Spain; *[2]Research Foundation Hospital of Valencia (INCLIVA), Valencia, Spain*; *[3]Germans Trias i Pujol University Hospital, Badalona, Spain*

Funding Acknowledgements: CIBER CV 16/11/00420, 16/11/00403; FEDER and PIE15/00013.

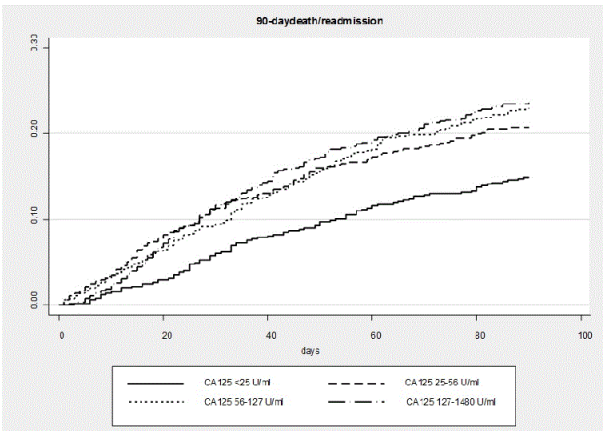
Backgroud: After an episode of acute heart failure (AHF) the risk of early adverse events, specially readmission, remains very high. Unfortunately, there are not well-established risk factors to tailor this risk. Plasma levels of Antigen Carbohydrate 125 (CA125) have emerged as a reliable biomarker of congestion and higher values have been consistently related with higher risk of mortality in AHF. In this work, we sought to evaluate the relationship between this biomarker and the composite of 90-day death and/or HF-readmission.

Methods: We included 2244 patients consecutively with AHF. CA125 was measured during early admission. The association between the composite of 90-day death and/or HF-readmission was assessed using COX regression analysis.

Results: Mean age was 73 ± 11years, 711 (31.7%), 336 (15%) and 1197 (53.3%) patients displayed reduced, intermediate and preserved ejection fraction, respectively. Median CA125 plasma levels were 56 U/ml (25-127). At 90 days, 439 events (19.6%) were registered.

Patients in the inferior quartile (Q1 < 25 U/ml) showed the lowest cumulative risk of events, as it is depicted in the figure below (p < 0.01).

After multivariable adjustment this association persisted. Compared to patients in the upper quartile (Q4), patients belonging to Q1 exhibited a significant decrease of risk (HR = 0.63; CI95: 0.47-0.84, p = 0.002). Conversely, patients in the medium quartiles (Q2, Q3) showed similar risk.



90-day death and/or readmission

Conclusion: In patients admitted with AHF, low plasma levels of CA125 identify a subset of patients at lower risk of the composite of 90-day death and/or readmission.

P303
Incremental value of intact fibroblast Growth factor 23 to natriuretic peptides for long-term risk estimation of heart failure patientsg

D Damien Gruson[1]; S Ahn[1]; MF Rousseau[1]
[1]*Saint-Luc University Clinics, Brussels, Belgium*

Background: Fibroblast growth factor 23 (FGF-23), a key hormone for the regulation of the phosphorus homeostasis, has also several direct effects on cardiac function. In heart failure (HF), the increase of FGF-23 could stimulate cardiac hypertrophy and remodeling.
Purpose: To determine intact FGF-23, the biologically active hormone, in HF patients with reduced ejection fraction (HFrEF) and assess its prognosis value for cardiovascular death over a long-term follow-up.
Methods: One hundred twenty chronic HF patients (females n = 25; males n = 95; NYHA II-IV; mean age: 66 years; etiology: ischemic n = 83, dilated cardiomyopathy n = 37; mean EF: 23 %) were included. The primary outcome was cardiovascular death. Levels of iFGF-23 and N-terminal proBNP (NT proBNP) were measured with fully automated and sensitive immunoassays.
Results: Median levels of iFGF-23 were equivalent in women (78.2 pg/mL) and men (75.1 pg/mL; p = 0.81). The concentrations of iFGF-23 were not statistically different between ischemic cardiomyopathies (79.4 pg/mL) and dilated cardiomyopathies (68.0 pg/mL; p = 0.29). As for NT proBNP, iFGF-23 levels were significantly related to New York Heart Association (NYHA) functional classes (p < 0.001). Intact FGF-23 levels were significantly correlated to age (? = 0.17, p = 0.04), eGFR (? = -0.64, p < 0.001) and NT-proBNP (? = 0.20, p = 0.03). Over a mean time of follow-up of 4.2 years, the primary outcome was reported in 76 HF patients. In univariate COX survival analysis, FGF-23 levels were significantly related to long-term cardiovascular death (p < 0.01). The area under the receiver operating characteristic curve, criteria defined as cardiovascular death at the end of the follow-up, was 0.66 (95% confident interval (CI): 0.57 to 0.75) for iFGF-23 and 0.73 (0.64 to 0.80) for NT-proBNP. When iFGF-23 and NT-proBNP were integrated in multimarker strategy, the rate of CV death at the end of the follow-up was 41% in HF patients with both biomarkers below than the median values (n = 34), 65% in HF patients with only one of the biomarker higher than their median value (n = 52); and raise to 82% in HF patients with both iFGF-23 and BNP higher than their median values (n = 34).
Conclusions: Circulating concentrations of intact FGF-23 are related to mortality in patients with HFrEF. Furthermore, measurement of iFGF-23 could provide added value to NT-proBNP for the prognostication of HFrEF.

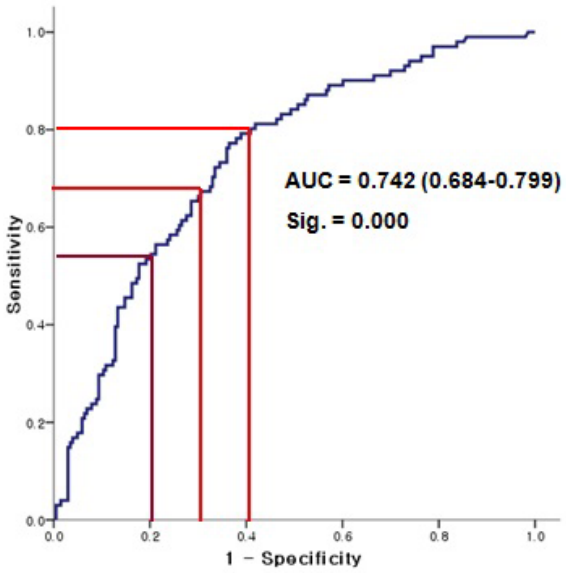
P304
N-terminal pro-B type natriuretic peptide imply left ventricular diastolic function but is a low sensitivity marker

H Hanul Choi[1]; M Shin[1]; W Chung[1]
[1]*Gil Hospital, Department of Cardiology, Gachon University, Gil Medical center, Incheon, Korea Republic of*

Background: Correlations between NT-proBNP with diastolic echocardiographic parameters were not analyzed precisely. We sought to evaluate the clinical implication of NT-proBNP on the LV diastolic function in large scale databases.

Multivariate analysis predictingNTproBNP

Variables	B-Coefficient	P-Value
Age	0.015	0.119
LVEF (vol)	-0.035	0.004
LVmi	0.004	0.229
LAVi	0.042	0.000
RVsP	0.027	0.306
E/E' ratio	0.042	0.000
BSA	-0.198	0.778



ROC curves of NT-proBNP predicting E/E'

Methods: NT-proBNP(n = 23,029) and echocardiography databases(n = 48,750) were collected. Cases measured within 24 hours were enrolled and increased serum creatinine level(>2.0 pg/ml) or acute coronary syndrome were excluded. Finally, echocardiographic parameters were compared with serum NT-proBNP levels in 1,852 patients.
Results: Among patients (54% female, mean age 63.0 ± 0.3), 460 patients (24.8%) showed preserved LV systolic functions (LVEF = 40%, 53.5 ± 0.4%). NT-proBNP levels were significantly correlated with LVEF(r=-0.52, p = 0.01), LA volume index(r = 0.50, p = 0.01), E/E'(r = 0.44, p = 0.01), RV systolic pressure (r = 0.43, p = 0.01) and LV mass index(r = 0.40, p = 0.01). NT-proBNP showed low sensitivities to determine E/E' ratio above 15 and LAVI above 27 on cut-off values of the ROC curve with specificity of 80% (51.7% at 686.6 ng/L, 58.7% at 643.1 ng/L). Interestingly, in patients with preserved systolic function (55.9% male, mean age 61.2 ± 0.7), NT-proBNP showed slightly high sensitivity than in total study group (53.5% at 717.0 ng/L, 60.9% at 443.3 ng/L).
Conclusions: Although NT-proBNP was proved as a useful parameter for assessing LV diastolic function as well as systolic function, it showed relatively low sensitivity to determining LV diastolic function. Therefore, NT-proBNP may imply LV diastolic function but should be interpreted with combining clinical informations.

P305
Increase of high molecular weight adiponectin in heart failure patients with reduced ejection fraction.

D Damien Gruson[1]; B Ferracin[1]; S Ahn[1]; MF Rousseau[1]
[1]*Saint-Luc University Clinics, Brussels, Belgium*

Background: Adiponectin is secreted by the adipose tissue and is an important regulator of insulin sensitivity, lipid metabolism and inflammation. Adiponectin has also complex roles in cardiovascular diseases and is considered cardioprotective by reducing oxidative stress, hypertrophy, and inflammation. In heart failure (HF), the increase of circulating adiponectin has been observed. However, several circulating forms of adiponectin exist and a comprehensive evaluation of high-molecular-weight (HMW), the active form of the hormone, remains to be performed in HF.
Purpose: To determine circulating levels of HMW adiponectin in HF patients with reduced ejection fraction (HFrEF) and assess the relationships with other cardiac biomarkers.
Methods: Forty four chronic HF patients (females n = 11; males n = 33; NYHA II-IV; mean age: 71 years; etiology: ischemic n = 32, dilated cardiomyopathy n = 12; mean EF: 23 %) were included. Twenty healthy volunteers were also included in our study. Levels HMW adiponectin was quantified on a fully-automated chemiluminescence-based enzyme immunoanalyzer (Lumipulse, Fujirebio). Circulating levels of other biomarkers, B-type natriuretic peptide (BNP), N-terminal pro-B-type natriuretic peptide (NT-proBNP), Galectin-3 and soluble ST2 (sST2) were also measured.
Results: The mean level of HMW adiponectin in healthy volunteers was 4.32 µg/mL and the reference interval was 1.2 to 7.4 µg/mL. The circulating HMW adiponectin levels were significantly increased in HFrEF (mean: 7.8 µg/mL; p = 0.03). As for

natriuretic peptides, HMW adiponectin levels were significantly related to New York Heart Association (NYHA) functional classes (p = 0.03). The concentrations of HMW adiponectin were not statistically different between ischemic cardiomyopathies (7.4 μg/mL) and dilated cardiomyopathies (8.8 μg/mL; p = 0.38). HMW adiponectin levels were significantly correlated to eGFR (? = -0.37, p = 0.02), NT-proBNP (? = 0.34, p = 0.05), BNP (? = 0.50, p <0.01), Galectin-3 (? = 0.36, p = 0.02) and sST2 (? = 0.45, p <0.01). Over a mean time of follow-up of 4.2 years, 35 HF patients died of a cardiovascular event. Concentration of HMW adiponectin was significantly higher in HF patients who died in comparison to survivors (8.3 vs 5.9 μg/mL).
Conclusions: Our results demonstrate that circulating HMW adiponectin, the active form of the hormone, is significantly increased in HFrEF patients and correlates with biomarkers related to HF severity.

P306

High-sensitivity cardiac troponin I in heart failure patients with preserved ejection fraction

E Eiji Miyajima[1]; N Fujii[1]; C Yajima[1]; K Hashiguchi[1]; Y Tashiro[1]; Y Takanami[1]; H Hirose[1]; H Yonezawa[1]
[1]*Yokohama City University Medical Center, Yokohama, Japan*

Objectives: High-sensitivity cardiac troponin I (hs-cTnI) is known to be increased in heart failure (HF) patients with decreased ejection fraction (EF), but for HF patients with preserved EF, less is known. Therefore, we examined serum concentrations of hs-cTnI and the relationship between serum concentrations of hs-cTnI and echocardiographic indexes in patients with preserved EF.
Methods: Echocardiography was performed on patients at HF clinic, and 144 patients with preserved EF were enrolled for this study (67 ± 14 years old, 52% male). Mean EF was 70 ± 9% (6 HFmrEF, 138 HFpEF). The 99th percentile cut-off value of the hs-cTnI assay used was 18.3 ng/L, total imprecision was 4.4 % at 18.3 ng/L, and LoD was 0.7 ng/L. During echocardiography, brachial blood pressures (BPs) were measured and echocardiographic indicators, such as left ventricular mass index (LVMI, g/m^2) and E/e' as an indicator of LV diastolic function, were also calculated. Estimated glomerular filtration rate (eGFR (mL/min/1.73 m^2)) was also calculated by converting serum creatinine value.
Results: In all patients, hs-cTnI was detected, in other words greater than LOD, and in 13 % of these patients, the level of hs-cTnI was greater than the 99th percentile value; mean hs-cTnI was 11.6 ± 10.0 (2.2 - 65.2) ng/L. hs-cTnI was significantly correlated with left atrial dimension (LAD), mean E/e', LVMI, and eGFR, but not with BPs, EF. We also applied stepwise regression for multivariate analysis of data for hs-cTnI and for echocardiographic indicators, BP, and eGFR, and found both E/e' and LVMI to be significant (p less than 0.001) variables to predict levels of hs-cTnI, but not eGFR nor EF.
Conclusion: hs-cTnI was detected in HF patients with preserved EF, and correlated with both E/e' and LVMI. Because HF with preserved EF has a poor prognosis, comparable with that of reduced EF, hs-cTnI may be a good clinical indicator for the assessment of treatment, which could improve LV diastolic function and regress LV hypertrophy.

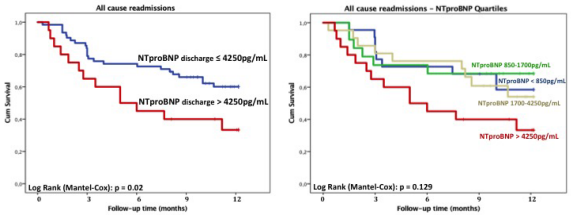
P307

NTproBNP in acute heart failure: which values to rely on to estimate long-term prognosis?

A Nunes-Ferreira[1]; JR Agostinho[1]; J Rigueira[1]; I Aguiar-Ricardo[1]; R Santos[1]; I Santos Goncalves[1]; T Guimaraes[1]; R Placido[1]; T Rodrigues[1]; N Cunha[1]; M Mendes-Pedro[1]; F Veiga[1]; FJ Pinto[1]; D Brito[1]
[1]*Cardiology Department, Santa Maria Hospital, CHLN, CCUL, Lisbon University, Lisbon, Portugal*

On behalf of: RICA-HFTeam

Background: Hospitalizations remain a main cause of morbidity and mortality in heart failure (HF) patients (pts), and readmission rate is still unacceptably high. NTproBNP is widely used as a tool in establishing the diagnosis of HF and as a marker of decompensation. However its efficacy in predicting readmissions is not well established.
Aim: To evaluate the efficacy of NTproBNP in predicting all-cause hospital readmissions during the first year after discharge (index-hospitalization for acute HF).
Methods: Retrospective study with prospective data registry of consecutive pts discharged after hospitalization for acute HF. All pts were submitted to clinical, laboratorial, electrocardiographic and echocardiographic evaluations, including NTproBNP on admission and at discharge. Multivariate Cox regression and Kaplan-Meier survival analysis were used to evaluate NTproBNP utility as a predictor of readmissions.
Results: One hundred and fifty six pts were included (mean age: 68.1 ± 12.4 years, 60.1% males). The mean left ventricular ejection fraction (LVEF) was 36.4 ± 15.9% (LVEF < 40% in 60.3%). Patients were discharged in NYHA functional class I (44.8%), in class II (51.9%), and in class III (3.2%). During a mean follow-up time of 11.1 ± 2.6 months, the readmission rate was 46.2%, and the mortality rate was 10.3%.
The median NTproBNP values were 4222 (IQ: 1981-9715) pg/mL on admission, and 1717 (IQ: 858-4249) pg/mL at discharge. In 92.5% of pts there was a decrease of NTproBNP during hospitalization, and the average descent rate was 48.1 ± 31.9%.
The presence of preserved LVEF (p = 0.011) and worse functional class at discharge (p = 0.005) were associated with readmissions during follow up. NTproBNP at discharge (p = 0.036), particularly if values > 4250pg/mL (4th quartile) were also linked to higher probability of readmission (p = 0.024).
By multivariate analysis (age-adjusted) discharge NTproBNP > 4250pg/mL was established as an independent factor to predict readmissions (HR = 2.6, CI = 1.2-6.0, p = 0.022).
There was no association between admission NTproBNP or the magnitude of decrease during hospitalization and the rate of readmission during follow up (p = NS). Additionally, an increase of NTproBNP during hospitalization did not predicted readmissions as well (p = NS).
Conclusions: NTproBNP at discharge is an important biomarker to predict one-year hospital readmissions. However, contrary to expectations, the absolute value of NTproBNP at discharge, mainly in the presence of higher biomarker levels, seems to be more important than its variation (decrease or increase) during hospitalization for acute HF.



NTproBNP values at discharge

P308

ST2 at time of hospitalisation for heart failure-considerable prognostic value over time

J J Dalal[1]; A Digrajkar[1]; B Das[1]
[1]*Kokilaben Dhirubhai Ambani Hospital, cardiology, Mumbai, India*

Aim: Ability to judge prognosis in patients with heart failure would be of considerable benefit, and the aim of the study was to evaluate the role of ST2 biomarker to predict prognosis in patients hospitalised for chronic heart failure.
Method: 150 patients hospitalised for heart failure and confirmed by NTProBNP had an ST2 measurement during their hospitalisation. All patients were followed for period of two years. They were divided into two groups (1) Normal ST2 (2) Elevated ST2 (above 35 ng/mL)
Result: There were 48 patients in the Normal Group (mean age 65 years, 58% diabetics and 71% hypertensives) and 102 in the Elevated Group (mean age 69 years, 56% diabetics and 79% hypertensives)
At the end of two years there were 2 deaths in the Normal Group and 22 deaths in the Elevated Group.
Conclusion: An elevated ST2 at time of hospitalisation for heart failure was associated with a ten fold increase in mortality over a two year period. This is of considerable clinical value in terms of patient and family understanding of the problem. It will also allow cardiologists to pay greater attention to maximise guideline therapy, and early consideration for devises and cardiac transplantation. We suggest that all patients hospitalised with heart failure should have at least one measurement of ST2 biomarker to separate patients at high or low risk of death.

HEART FAILURE	NUMBER OF PATIENTS	DEATHS AT TWO YEARS
NORMAL ST2	48	2
ELEVATED ST2	102	22

Ten fold higher mortality at two years with elevated ST2

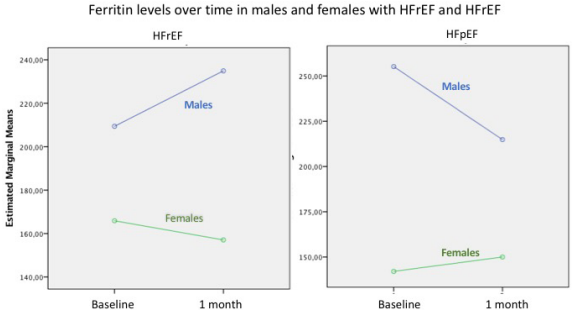
P309

Sex differences in biomarkers over time - covering the HFrEF, HFmrEF and HFpEF spectrum

S Sandra Van Wijk[1]; AMA Barandiaran Aizpurua[1]; M Maeder[2]; V Van Empel[1]; HP Brunner-La Rocca[1]
[1]*Maastricht University Medical Center, Department of Cardiology, Maastricht, Netherlands*; [2]*Kantonsspital St. Gallen, Department of Cardiology, St. Gallen, Switzerland*

On behalf of: TIME-CHF investigators
Funding Acknowledgements: Horten Research Foundation, Roche diagnostics

Background: Despite known sex differences in disease presentation and in biomarkers in heart failure (HF), it is unknown if biomarker sex differences have a similar fashion in HFpEF, HFrEF and HFmREF. Nor is it known how biomarkers change over time in males vs females.



Ferritin levels over time by sex

Purpose: investigate biomarkers over time in males vs females covering the spectrum of HFrEF, HFmrEF and HFpEF.
Methods: Biomarker levels and their changes from baseline to 1 month were compared between males and females in 622 HF patients in TIME-CHF, aged> = 65 years, included as outpatients. 459 had HFrEF (LVEF < = 40; 67% male), 52 HFmrEF (LVEF41-49; 46% male) and 112 HFpEF (LVEF > = 50; 36% male). Investigated biomarkers are NT-proBNP, hsTnT, hsCRP, Hb, creatinine, urea, cystatin-C, ferritin, sTFR, IL-6, GDF-15, Gal-3, ST2, tP1NP, PLGF, sFlt.
Results: In HFrEF, females had lower Hb, lower creatinine, higher tP1NP, lower ferritin, higher sTFR, lower hsTnT, lower GDF-15, and lower ST2. In HFpEF, females had lower creatinine, lower urea, lower ferritin, lower hsTnT. In HFmrEF, females had lower Hb and higher PLGF. The other biomarkers did not differ between males and females in neither of the HF-subtypes.
In the first month, ferritin increased in HFrEF-males but decreased in HFrEF-females (P-interaction = 0.02, figure). In HFpEF, ferritin decreased in males and slightly increased in females (P-int = 0.15). Hs-CRP and hsTnT decreased equally in males and females of all HF-subtypes. NT-proBNP decreased in HFrEF females but remained stable in HFrEF-males (P-int < 0.001). In HFpEF, NT-proBNP decreased in both sexes equally.
Conclusion: Sex-differences in changes over time of ferritin and NT-proBNP are dependent on the HF-subtype, whereas hsTnT and hsCRP decrease over time in males and females of all HF-subtypes equally. This proposes a potential for differential therapeutic strategies in males vs females in different subtypes of HF.

P310

Dynamic changes of sST2 and NT-proBNP levels in responders and non-responders to cardiac resynchronization and cardiac contractility modulation therapies

A Armenui Gasparyan[1]; NB Shlevkov[1]; TV Sharf[1]; VN Shitov[1]; SYU Kashtanova[1]; MD Utsumueva[1]; NA Mironova[1]; VP Masenko[1]; AA Skvortsov[1]
[1]*Cardiology Research and Production Center, department of heart rhythm disturbances, Moscow, Russian Federation*

On behalf of: Gasparyan AZh, Shlevkov NB, Sharf TV, Shitov VN, Kashtanova SYu, Utsumueva MD, Mironova NA, Masenko VP, Skvortsov AA

Background: Use of cardiac contractility modulators (CCM) and cardiac resynchronization therapy (CRT) known to improve clinical course of chronic heart failure (CHF). The influence of these devices on the levels of neurohormonal markers sST2 and NT-proBNP is poorly studied.
Aim: To investigate the changes in the sST2 and NT-proBNP levels in CHF patients in relation to efficacy of cardiac contractility modulaton and cardiac resynchronization therapies.

Methods: Twenty three consecutive patients (16 males / 7 females, mean age = 59 ± 9 years) with medically resistant NYHA class II-III CHF were prospectively studied after CRT (n = 11) and CCM (n = 12) implantation. Six-minute walk test distance (6MWD), echocardiography (ECHO) parameters and levels of neurohormonal markers were evaluated initially and also 6 and 12 months after implantation of the devices. Patients were considered responders to device therapy if end-systolic volume of left ventricle decreases by at least 15% according to repeated ECHO.
Results: Based on the results of observation, signs of a positive response to device therapy ('Responders' group) were registered in 6 of 12 (50%) patients with CCM and in 7 of 11 (64%) with CRT devices, the remaining patients (n = 10) were grouped together as "Non-responders". Initially the groups did not differ significantly according to 6MWD, ECHO parameters, sST2 and NT-proBNP levels. Marked differences between groups were identified after device therapy (see table) with highest relative diagnostic value for sST2 by ROC-analysis.
?onclusion: Dynamic changes in sST2 level are at greatest diagnostic value for the detection of CHF patients with clinical response of either CRT or CCM therapies.

Results of the study by groups

Parameters	'Responders' (n = 13)	'Non-responders' (n = 10)
The level of sST2 ng/ml The area under the ROC-curve = 0,806	21 (19,3-26,3)	40,4 (25,2-40,9)
The level of NT-proBNP, pg/ml The area under the ROC-curve =0,759	362 (71-867)	895 (609-1486)
6-minute walk test distance, m The area under the ROC-curve =0,704	500 (480-540)	464 (340-498)
The LVEF, % (by ECHO)	45 (42-48)	29 (25-34)

Circulating miR-489 as a useful biomarker for DCM

T Tomoya Ishiguro[1]; M Hayashi[1]; W Fujiwara[1]; H Izawa[1]; S Okumura[1]; Y Sugishita[1]; M Yoshinaga[1]; R Yamada[1]
[1]*Fujita Health University Second Hospital, Nagoya, Japan*

Background: : MicroRNAs (miRNA) are functional RNAs that have emerged as pivotal gene expression regulators in any cardiac disease. Although several cardiomyocyte miRNAs have been proven to play roles in the progression of heart failure among patients with idiopathic dilated cardiomyopathy (DCM), the role of circulating miRNAs has not been well-examined.
Methods and Results: After total RNA extraction from peripheral blood samples of three controls and six patients with DCM, miRNA profiling was performed using miRNA arrays. Based on the results of an initial screening, a quantitative analysis of blood samples from an increased number of matched patients (DCM, n = 20; controls, n = 5) was performed using RT-PCR. Finally, the correlation between specific miRNA expression levels and hemodynamic parameters was analyzed.
A primary screening of 2325 miRNAs resulted in the identification of 12 miRNA candidates. Quantitative RT-PCR results revealed significantly increased miR-489 expression levels in the DCM group. Moreover, a significant positive correlation was observed between miR-489 expression level and left ventricular ejection fraction. [Conclusions] Our results suggest that circulating miR-489 could be a potential noninvasive diagnostic biomarker for DCM. Moreover, quantification of circulating miR-489 could have potential prognostic value for patients with DCM, given its positive correlation with left ventricular ejection fraction.

Funding Acknowledgements: "Supported by MH CZ - DRO (Nemocnice Na Homolce - NNH, 00023884), IG160502"

Background: Novel CHF biomarkers have additive role in prognostic stratification, their role in the assessment of disease severity has not been established.

Study objective: to assess the role of single value of novel CHF biomarkers in the evaluation of the severity of cardiac dysfunction and other organs dysfunction in patients with stable CHF

Patients and method: NT-pro BNP together with galectin-3, sST2, GDF-15, cystatin C, TIMP-1 and ceruloplasmin were analysed together with other laboratory parameters and parameters of systolic and diastolic cardiac function in 160 consecutive stable CHF patients of a tertiary care CHF clinic. Patients cohort comprised od 123 males and 37 females with mean age 65 years, ischemic etiology had 47 % subjects, of 39% had ICD and 36% CRT-D, patients were on optimal medical therapy including BB 98%, ACEI/ARB 84%, MRA 69%. Median NYHA was 2.

Results: median NT-proBNP was 121 pmol/l (1023 pg/ml), mean LV EF 32%, E/A ratio was 1,3 and E/E ' ratio 11. NT-proBNP correlated with novel biomarkers except of galectin-3 (correlation coeficient r from 0,281 to 0,514, p < 0,001). NT-proBNP corellated signficantly with: Na, urea, creatinine, bilirubin, hemoglobin and eGFR and with LV EF, LV EDD, ESD, LA, RV, E/A, E/E'ratios, and estimated pulmonary artery pressure PAP (r from -0,259 to 0,392, p value from < 0,001 to < 0,05). Significant correlation of NT-proBNP and novel biomarkers with laboratory a echocardiografic parameters shown in tabel.

Conclusion: NT-proBNP remains golden standard in the assessment of disease severity in patients with stable chronic heart failure. Role of other biomarkers is limited.

Significant correlation of NT-proBNP and

Biomarker	Laboratory parametr	Echocardiografic parameter	Level of signifikance p
NT-proBNP	Na, urea, creatinine, bilirubin, hemoglobin, eGFR	LV EF, EDD, ESD, LA,RV, E/A, E/E´,PAP	from < 0,001 to < 0,05
Galectin 3	Na, K, urea, creatinine, eGFR		from < 0,001 to < 0,05

A comparative analysis of novel cardiac biomarkers (sST2, GDF-15, Galectin-3, suPAR, H-FABP and Fetuin-A) in patients with heart failure, STEMI and controls without cardiovascular disease

P Jirak[1]; M Lichtenauer[1]; B Wernly[1]; V Paar[1]; I Rohm[2]; C Jung[3]; A Yilmaz[4]; UC Hoppe[1]; PC Schulze[2]; R Pistulli[2]; D Kretzschmar[2]

[1]Paracelsus Private Medical University, Internal Medicine II, Cardiology, Salzburg, Austria; *[2]University Hospital of Jena, Clinic of Internal Medicine I, Jena, Germany*; *[3]Medical Faculty, University Duesseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Duesseldorf, Germany*; *[4]Elisabeth Klinikum Schmalkalden, Clinic of Internal Medicine II, Schmalkalden, Germany*

Background: Heart failure and myocardial infarction constitute a major therapeutic challenge in cardiology, leading to a considerable impact on morbidity, hospitalisation rates and health-care costs. Cardiac biomarkers represent an important tool for diagnosis, risk stratification and monitoring in these disease entities, with gaining clinical significance over the last years.

Purpose: The aim of this analysis was to investigate the role of six novel cardiovascular biomarkers, namely sST2, GDF15, Galectin-3, suPAR, H-FABP and Fetuin-A in patients suffering from heart failure (ICM and DCM) and ST-elevation myocardial infarction (STEMI)

Methods: A total of 260 patients were enrolled in this current study. 123 patients were diagnosed with ischaemic or dilative cardiomyopathy and 61 patients were diagnosed with STEMI. 76 patients without coronary artery disease (excluded by coronary angiography) or signs of acute or chronic heart failure were enrolled as control group. Plasma samples were drawn within the first hours of presentation (STEMI patients) or follow-up visits (controls, HF patients) and analyzed for sST2 (hemodynamics and inflammation), GDF-15 (injury, remodelling), Galectin-3 (fibrosis, remodelling), suPAR (inflammation), H-FABP (ischemia) and Fetuin-A (vascular calcification) by using ELISA.

Results: Levels of sST2, GDF-15, suPAR and H-FABP were significantly higher in HF and also STEMI patients compared to the control group (p < 0.0001). Galectin-3 (1792 vs. 2795 pg/ml, p < 0.0001) and Fetuin-A levels (76.8 vs. 116.6 ng/ml, p = 0.001) evidenced lower levels in HF patients compared to controls. Significantly higher levels of sST2 (13211 vs. 8169 pg/ml, p < 0.0001), GDF-15 (818.8 vs. 666.9 pg/ml, p = 0.004) and H-FABP (5.78 vs. 1.89 ng/ml, p < 0.0001) were found in STEMI patients compared to HF patients. suPAR levels showed comparable levels in HF patients and those presenting with STEMI (3614 vs. 3461 pg/ml, p = 0.6). Galactin-3 levels showed lower levels in HF patients compared to control and STEMI patients (HF: 1792 pg/ml vs. 2795 in controls and 2626 pg/ml in STEMI, p= 0.004 and < 0.0001).

Conclusion: By combining the information of different pathophysiological processes, novel cardiac biomarkers represent a promising tool for a more precise diagnosis, risk stratification and therapy monitoring. Furthermore, multimarker analysis could facilitate an easier discrimination of different cardiovascular disease entities.

Role of global longitudinal strain in cardiotoxicity monitoring of breast cancer patients initially assessed with MUGA

O Oscar Calvillo Arguelles[1]; JF Fritche Salazar[1]; HG Rodriguez Zanella[1]; JD Sierra-Lara Martinez[1]; DF Flores Diaz[2]; CH Arce Salinas[2]; LA Cota Apodaca[3]; M Herrera[3]; BE Dominguez Mendez[1]; K Balderas Munoz[1]; G Melendez[1]; LL Rodriguez Chavez[1]; J Cossio Aranda[1]; JA Arias Godinez[1]

[1]National Institute of Cardiology Ignacio Chavez, Mexico City, Mexico; *[2]National Cancer Institute (INCAN), Mexico City, Mexico*; *[3]Breast Cancer Foundation (FUCAM, A.C.), Mexico City, Mexico*

Background: Different imaging modalities can be used for cardiotoxicity monitoring of breast cancer patients receiving anthracyclines (AC) or trastuzumab (T). Although guidelines recommend using the same imaging technique for each assessment, patients who are found to have a drop in LVEF when initially assessed with MUGA are sometimes referred for an echocardiographic evaluation. The prognostic role of global longitudinal strain (GLS) in this setting is unknown.

Purpose: The aim of this study was to assess whether GLS measurements after initial MUGA assessment can predict clinical events related to cardiotoxicity

Methods: This is a prospective longitudinal pilot study including breast cancer patients who received AC within 12 months of enrollment and/or were receiving T at the time of initial assessment. Patients who had at least 2 LVEF measurements with MUGA before referral were eligible. Standard 2- dimensional echocardiography measurements, 3D LVEF, and speckle-tracking GLS from 3-, 4-, and 2- chamber views were obtained. Patients were followed up for the occurrence of a combined outcome (CO) of development of HF symptoms (= NYHA 2), HF admission, or T interruption. The clinical and echocardiographic characteristics of patients who developed the CO and patients without an event where compared. ROC curves were generated to determine the optimal GLS value to discriminate between the occurrence of the CO and no events.
Results: Between January and October, 2017, 30 eligible patients with a mean age of 48 ± 11 years and mean baseline LVEF 62.9% ± 4.1 were referred to the echocardiography laboratory of a tertiary care center. The main reason for referral was a = 5% LVEF drop in a subsequent MUGA in 18 (60%) patients. In total, 28 patients were receiving T (18 had previously received AC), and 2 patients received AC without T. Within a mean follow up of 6.7 ± 3.1 months, 13 (43%) patients reached the CO (8 had HF symptoms and 2 had HF admissions). Between patients who developed the CO and those who did not, no significant difference was observed regarding radiotherapy, mean AC dose, exposure to T (months), BMI, smoking history and dyslipidemia. The prevalence of diabetes (38.4% vs 5.8%, p = 0.027) and hypertension (61.5 vs 23.5, p = 0.035) was higher in patients with a CO. The mean change in LVEF (MUGA) was 14.7% (11.9-21) in the CO patients, and 3.1% (1.3-5) in patients without events (p < 0.001). Three- dimensional LVEF was higher in patients who did not had an event (58.7% ± 6.2 vs 45.6% ± 7.8, p < 0.001). Lower absolute measurements of GLS were observed in patients with a CO (-13.6 ± 3 vs -20.5 ± 2.3). A GLS value of -16.8%, yielded the highest accuracy with a sensitivity of 92.3% and specificity of 94.1% for a CO prediction.
Conclusions: The sequential use of different imaging modalities for cardiotoxicity monitoring can be feasible. GLS appears to have a prognostic role in this setting, which needs to be tested in a larger population.

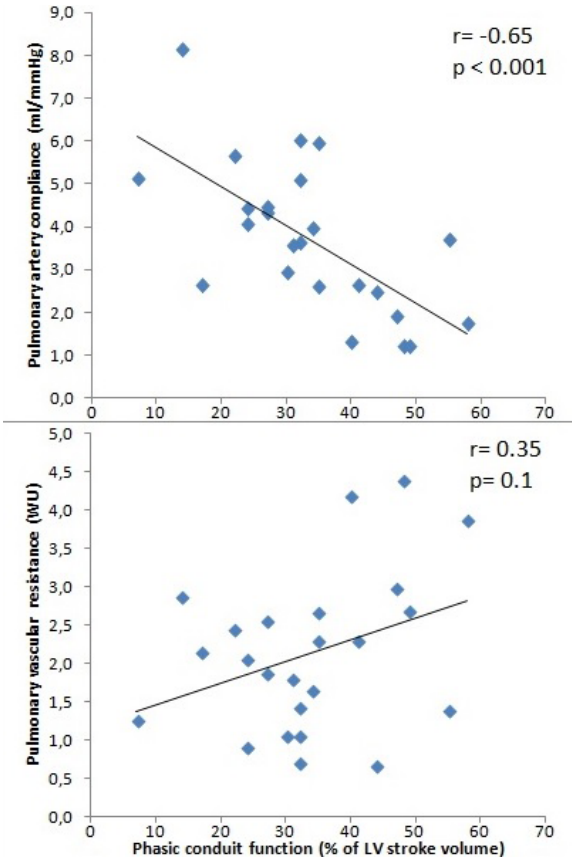
P315

The pulsatile component of right ventricular afterload is modulated by left atrial conduit function in heart failure patients

J Jacopo Zanaboni[1]; G Binda[1]; A Giubertoni[1]; C Piccinino[1]; P Marino[1]
[1]*University of Eastern Piedmont, Cardiology, Novara, Italy*

Background: Right ventricular (RV) dysfunction is an important cause of death in heart failure patients, with RV afterload contributed by a steady component (indexed by pulmonary vascular resistances [PVRs]) and a pulsatile component, assumed to be represented by pulmonary artery compliance (PAC). Left atrial (LA) properties should contribute to the pulsatile component given that atrial pulsatility is directly related to LA stiffness.
Purpose: Aim of the study was to assess if and to what extent the LA phasic conduit function (PCF), a surrogate of LA stiffness, can describe the pulsatile component of RV afterload.
Methods: 24 heart failure patients (16 males, mean age 69 ± 11 years, ejection fraction 46 ± 12%) underwent routine transthoracic echocardiographic evaluation plus real time 3D acquisitions analyzed with a dedicated echo software package. Computation of PCF was made by simultaneous gathering of real time 3D multibeat (6 cycles) LA and left ventricular (LV) volumes, using the formula proposed by Bauman & Kovacs (2004), with PCF as: PCF(time) = [LV(time)-LV minimum] - [LAmaximum - LA(time)] and expressed as % of LV stroke volume. PAC was assessed as the ratio between right ventricular stroke volume (computed as pulmonary velocity time integral*pulmonary valve annulus area measured by 3D echo) and noninvasively estimated pulse pressure, as obtained from pulmonary and tricuspid regurgitant envelopes. PVRs were obtained by the pulmonary velocity time integral using the formula: -0.156+1.154*[(pre ejection period / acceleration time) / total systolic time] as proposed by the group of Giannuzzi (2001). PAC and PVRs measures were validated invasively in 3 patients. LA stiffness was computed as the ratio between E/E' and LA integral strain.
Results: All patients were in sinus rhythm. Diastolic LV volumes averaged 135 ± 48 ml, while LA maximal and minimal volumes were 67 ± 24 ml and 40 ± 24 ml, respectively. PCF ranged from 7% to 58%, exhibiting a significant direct relation with LA stiffness (? = 0.7, p = 0.05). We found a significant reverse relationship (r = -0.65; p < 0.001) between PCF (mean 34 ± 13%) and PAC (mean 3.7 ± 1.8 ml/mmHg). On the contrary, there was no relation (r = 0.35; p = 0.1) between PCF and PVRs (mean 2.1 ± 1.0 WU).
Conclusion: The reverse relationship that we found between PCF and PAC suggests that conduit reflects the oscillatory component, but not the steady component of RV afterload. Given that PAC is a strong prognostic indicator in heart failure patients, even when PVRs are normal, our results suggest that PCF is an important parameter to be generated and taken into account in order to better stratify the early risk and to throughly quantify the global hemodynamic burden in heart failure patients.



Phasic conduit function vs PAC and PVR

P316

Ultrasound parameters associated with lower systolic blood pressure in patients with acute dyspnea

Introduction: The association of echocardiography parameters and systolic blood pressure (SBP) in acute settings is not well characterized.
Purpose: To determine the association between SBP and echocardiographic parameters in acute dyspneapatients.
Methods: Prospective multicentre observational cohort study enrolled consecutive patients with acute dyspnea due to acute heart failure (AHF) and other conditions. Conventional and right ventricle (RV) focused echocardiography was performed in 482 patients in the first 48 hours of admission and included, among others, the following parameters: tricuspid annular plane systolic excursion (TAPSE), velocity of the tricuspid annular systolic motion (RV S'), fractional area change (FAC), RV basal diameter and global longitudinal strain, left atrium volume index (LAVI), left ventricle (LV) end diastolic diameter (LVEDD), interventricular septum (IVS) and LV ejection fraction (LVEF).The current study included 446 (92.5%) patients (mean age 68.5 ± 12.9) whose clinical and echocardiographic parameters were available. Measurements of SBP were divided into two groups at the threshold of 140 mmHg. For statistical analysis univariate and multivariate logistic regressions were used.
Results: 56.9% of patients had AHF. The multivariate regression model is given in Table 1. When analysing echocardiographic parameters in univariate logistic regression, both LV and RV echocardiographic parameters had predictive value for SBP. In the multivariate stepwise regression model, TAPSE, LVEDD and IVS were significantly associated with higher SBP.
Conclusions: Progressing LV dilatation, thinner LV walls and impaired longitudinal RV function are independently associated with lower SBP in patients with acute dyspnea.

Predictors for SBP

Variable	Univariate analysis for lower SBP	Multivariate stepwise analysis for lower SBP		
	OR	95% CI	OR	95% CI
IVS, per 1 mm.	0.87*	0.79;0.96	0.87*	0.78;0.99
LVEDD, per 1 mm.	1.02*	1.00;1.04	1.03*	1.01;1.06
LAVI, per 1 mL/m^2	1.02*	1.01;1.03		
RV basal diameter, per 1 mm.	1.04*	1.01;1.06

P317
Left atrial volume and left ventricular mass index - do they associate with established heart failure related parameters in HFpEF?

C Gehlken[1]; EM Screever[1]; MHL Van Der Wal[1]; A Koops[1]; KS Dijk[1]; J Warink-Riemersma[1]; P Van Der Meer[1]; JE Coster[1]; DJ Van Veldhuisen[1]; RA De Boer[1]; WC Meijers[1]
[1]*University Medical Center Groningen, Cardiology, Groningen, Netherlands*

Introduction: Heart failure with preserved ejection fraction (HFpEF) is currently a condition that is difficult to define. Key echocardiographic parameters mentioned in the guidelines are Left Atrial Volume index (LAVi) and Left Ventricular (LV) Mass Index (LVMi). We investigated whether patients' characteristics, biomarkers or comorbidities are associated with these parameters and whether this differs in HFpEF or heart failure with reduced ejection fraction (HFrEF).
Methods: In a tertiary referral academic hospital, we consecutively enrolled 842 outpatients with a diagnosis of heart failure (HF). As part of the standardized work-up, all patients underwent baseline characterization, laboratory measurements, as well as echocardiography to assess LV function. Several co-morbidities were recorded, such as coronary artery disease, arterial hypertension, diabetes mellitus, obesity (expressed as Body Mass Index, BMI), renal disease (eGFR < 60 ml/min), and atrial fibrillation (AF). Galectin-3 and NT-proBNP were measured. Patients were optimally treated according to ESC guidelines, with ACE-inhibitors or ARBs, ß-blockers, mineralocorticoid receptor antagonists (MRAs), unless not tolerated, and implantable defibrillators when indicated. We categorized patients based upon LV Ejection Fraction (LVEF), LVEF < 40% and LVEF>50% were defined as either HFrEF and HFpEF.
Results: Mean age was 68 years (+/- 14), 63% of the patients were male, and mean BMI was 28 kg/m2, mean blood pressure was 120/72 mm Hg. Of the 842 patients, 517 had HFrEF and 183 HFpEF. In HFrEF, both LVMi and LAVi were significantly associated with age (LV: ß 0.100; P = 0.030/ LA: ß 0.295; P < 0.001), diastolic blood pressure (LV: ß -0.114; P = 0.015/ LA: ß -0.136; P = 0.006), galectin-3 (LV: ß 0.102; P = 0.028/ LA: ß 0.247; P < 0.001), NT-proBNP (LV: ß 0.183; P < 0.001/ LA: ß 0.371; P < 0.001) and renal disease (LV: ß 0.120; P = 0.009/ LA: ß 0.189; P < 0.001). LVMi was more associated with CAD, HT and male gender, whereas LAVi was more stronger associated with BMI, systolic blood pressure, and AF. In HFpEF patients however, only AF (LV: ß -0.178; P = 0.025/ LA: ß 0.373; P < 0.001) was associated with both LVMi and LAVi. LVMi was only associated with BMI and sysolic blood pressure, and LAVi only with age and NT-proBNP.
Conclusions: Although LVMi and LAVi are primarily suggested as diagnostic parameters for HFpEF, they do not correlate with multiple established HF parameters. In contrast, in HFrEF patients, LVMi and LAVi relate strongly to several other HF parameters. These findings underscore the complex pathophysiology of HFpEF.

P318
Subclinical heart failure with right ventricular apical pacing assessed by speckle tracking echocardiography

N Nikolay Poroyliev[1]; D Markov[1]; E Kinova[1]; A Goudev[1]
[1]*University Hospital Tsaritsa Yoanna, Cardiology, Sofia, Bulgaria*

Introduction: Permanent pacing is the only effective treatment for patients with symptomatic sinus node disease (SND) and atrioventricular block (AVB). Speckle tracking echocardiography (STE) provides direct information on LV (left ventricle) and RV (right ventricle) contractile performance, which may serve as a more sensitive measurement of ventricular systolic function than LVEF.
Purpose: Assess ventricular function during short term RV apical pacing.
Methods: We included 53 consecutive patients. LV and RV function were assessed with 2D echocardiography, TDI and STE. The patients were divided according to the percentage of cumulative ventricular pacing < 40% (Group 1) n = 20 (38%) or >40% (Group 2) n = 33 (62%).
Results: In Group 1 patients there was decline in RV global -22.00% to -18.58% (p = .009) and RV free wall strain -21.66% to -19.11% (p = .034) but no significant change in GLS LV and LVEF. In Group 2 we observed significant decline in GLS LV strain -20.37% to -17.49% (p = .027), RV global -20.01% to -18.34% (p = .048) and RV free wall strain -22.73% to -19.04% (p = .049), without worsening of LVEF (p=.104). In Group1 the ratio of E/e'm increased from 10.68 to 14.31 (p=.002) and in Group2 increased from 13.5 to 16.6 (p=.014), without significant increase of the RV filling pressures. There was a significant decline in TAPSE (21.65mm to 19.12mm, p=.001) and S' (17.88cm/s to 12.33cm/s, p=.007) in patients from Group 1. The results in Group 2 were similar. We found significant decrease in TAPSE (21.7mm to 19.5mm, p=.004) and S' (13.6cm/s to 12.1cm/s, p=.029). There was no significant correlation between parameters at baseline and follow-up in Group 1 except for a negative correlation between LVEF and GLS LV in Group 2 patients (r=-.767; p=.000).
Conclusion: Permanent pacing caused subclinical worsening of LV and RV during short-term follow-up.

P319
Prognostic value of right ventricular speckle tracking imaging in patients with heart failure with preserved left ejection fraction evaluated with echocardiography

J Jean-Jacques Von Hunolstein[1]; A Lawson[1]; T Caspar[1]; B Marchandot[1]; H Petit-Eisenmann[1]; A Trinh[1]; S Hess[1]; N Messas[1]; U Crimizade[1]; G Roul[1]; O Morel[1]; P Olmhann[1]
[1]*University Hospital of Strasbourg, Cardiology Departement, Strasbourg, France*

Introduction: Heart failure with preserved ejection fraction (HFpEF) is a major cause of disability and represents an important cause of cardiovascular morbidity and mortality. We investigated the prognostic value of RV strain in patients admitted for HFpEF.
Methods: we prospectively included between April 2015 and April 2017, 62 HFpEF patients. Standard echocardiographic variables of the left and right ventricles were acquired. RV strain parameters were calculated off-line: RV-global longitudinal strain (RV-GLS) and RV-free wall longitudinal strain (RV-fwLS). Clinical follow-up for mortality and readmission for heart failure was conducted at one year.
Results: HFpEF patients were 83.2 ± 6.6 years old, 63% were female and 84% have a history of hypertension. During a mean follow-up of 392 ± 39 days, 21 patients died (34%). Clinical characteristics and left ventricular echocardiographic parameters were not statistically different between survivors and non-survivors. However, RVfw-LS and RV-GLS were significantly altered in non-survivors (-17,8% ± 7.8 vs. -23,1% ± 6,1; p 0.005) and (-14,9% ± 6.1 vs. -19,2% ± 4,6; p 0.003) respectively as well as TAPSE and S'DTI (14,5 ± 5.8 vs. 19,1 ± 5,2; p 0.003 and 10,2 ± 4,1 vs. 12,8 ± 2,6; p 0.004 respectively). RVfw-LS and RV-GLS were associated with all-cause mortality: RV-GLS (OR 2.97, CI 1.08-8.2; p 0.035), RVfw-LS (OR 2.53, CI 1.03-6.2; p 0.043). The optimal threshold for RV-GLS was -17.5% (sensitivity 71,4%:

specificity 61,5%) and for RVfw-LS was -20% (sensitivity 67%, specificity 72%). Of note, the RV systolic parameters TAPSE and SDTi were also related to mortality (OR 4.6 ,CI 1.69-12.6; p = 0.003) and 5.79 ,CI 2.3-14.4; p = 0.0001 respectively). No relationship could be shown between RV strain and the rate of readmission at follow-up.
Conclusion: our results show that RV-GLS and RV-fwLS are significantly associated with mortality in patients presenting with HFpEF. RV strain parameters provide an additional tool to identify higher risk patients.

P320
Presence and evolution of multiple pulmonary nodules with halo sign detected by computerized tomography in advanced heart failure.

R Raquel Lopez Vilella[1]; C Munoz Nunez[2]; I Sanchez Lazaro[1]; L Almenar Bonet[1]
[1]Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit. Cardiology Department, Valencia, Spain; *[2]Hospital Universitario y Politécnico La Fe, Radiology Department, Valencia, Spain*

Background and obkective: A radiographic finding not described in heart failure (HF) is the presence of pulmonary nodules with halo sign. The objective of this article is to describe and analyze the evolution of a series of cases of patients with advanced HF and multiple pulmonary nodules with halo sign identified by thoracic computerized tomography (CT).
Material and methods: We enrolled patients with advanced HF who underwent thoracic CT as part of the study for heart transplantation or ventricular assistant device implantation, in which pulmonary nodules with halo sign were found. The study was performed using high resolution multidetector CT with iodinated contrast, with 1 mm transverse reconstructions with mediastinal and lung filter. A nodule was defined as a rounded or irregular opacity = 3 cm in diameter. Two CTs were performed for diagnosis and follow-up (around 3 months). The patients gave their informed consent.
Results: The total number of patients with the radiological image described was 3. All males, mean age 59 years. All the patients were in an advanced functional situation (INTERMACS 4), with repeated admissions due to decompensation. Table 1 describes the characteristics of the 3 patients.
Conclusions: Nodules with a halo sign may correspond to a finding related to advanced HF that has not yet been described. Arriving at the definitive diagnosis or, at least, excluding the infectious and neoplastic cause is especially important in these patients in whom the option of performing a heart transplant is evaluated.

	Patient 1	Patient 2	Patient 3
Sex / Age (years)	Male / 53	Male / 58	Male / 58
Basal cardiopathy	DCM	Ischemic DCM	Ischemic DCM
Initial CT	Two nodules: 7 mm (in RUL) and 4 mm (in RLL)	Multiple nodules of 10-18 mm	Multiple nodules of 10-20 mm
Follow up CT (3 months)	Disappearance of all pulmonary nodules	Disappearance of all pulmonary nodules	Disappearance of all pulmonary nodules
Follow up	Urgent heart transplant with left ventricular assist device (Levitronix Centrimag®). No incidents.	Urgent heart transplant with biventricular assist device (ECMO). PGF, ECMO had to be manteined for 4 days.	Elective heart transplant. No incidents.

DCM: Dilated cardiomyopathy ; RUL: Right upper lobe; RLL: Right lower lob; ECMO: ExtraCorporeal Membrane Oxygenation; PGF: Primary graft failure.

P321
Caval index derived parameters and inspiratory IVC diameter are strictly related to non invasive estimation of right atrial pressure by semi-automated tracking of IVC in resting respiration patients

S Stefano Albani[1]; L Mesin[2]; M De Scordilli[1]; B Pinamonti[1]; C Gregorio[3]; G Barbati[3]; P Geri[4]; A Perkan[1]; C Daneluzzi[1]; G Sinagra[1]
[1]Postgraduate School in Cardiovascular Sciences, Cardiovascular Department, University Hospital of Trieste, Trieste, Italy; *[2]Politecnico di Torino, Mathematical Biology and Physiology - Department of Electronics and Telecommunications, Turin, Italy*; *[3]University of Trieste, Department of Medical Science, Surgery and Health (DCSMCS), Trieste, Italy*; *[4]University of Trieste, Department of Pneumology and Respiratory Intermediate Care Unit, ASUITS, Trieste, Italy*

Background: Inspiratory collapse of the inferior vena cava (IVC) and the measurement of its diameters are validated as indirect indexes for the non invasive estimation of the right atrial pressure (RAP). However, there are some critical issues about the actual reliability and reproducibility of the measurement, especially of those with intermediate values of RAP. At this regard, the use of a software able to highlight in semi-automatic mode the edges of the vessel and measure the diameter in each site could help to standardize the measurement of the IVC accurately documenting even slight variations in the caliber of the vein.
Objective of the study:
The aim of this study is to assess the usefulness and the performance in term of precision of the estimation of RAP of the semi-automated tracking technique previous

	Low-RAP group	Intermediate-RAP group	High-RAP group
N° of patients	7	11	15
Mean age	56.14 (± 15.08)	62.45 (± 15.44)	67.80 (± 13.87)
Mean weight (kg)	77.43 (± 12.93)	71.45 (± 15.31)	73.60 (± 15.66)
Mean BSA (m^2)	1.89 (± 0.19)	1.81 (± 0.22)	1.85 (± 0.22)

Mean estimated RAP (automated algorithm) (mmHg)	6,93 (± 2.37)	8,84 (± 2.92)	12,71 (± 3.62)

RHC and echo parameters

described against the standard estimation of RAP in 2 D mode echocardiography by measuring IVC diameters variations. We used RAP measurement obtained by human right heart catheterization (RHC) as gold standard technique.
Materials and Methods: We prospectively enrolled from 1/12/2015 to 1/9/2017 a total on number of 88 patients undergoing RHC catheterization for all clinical indications Subsequently all patients underwent complete echocardiographic assessment in the next 6 hours after the invasive assessment. All the echocardiographic video clip used to estimate non invasively the RAP were analyzed by L. M using the tracking software that can highlight in semi- automatic mode the vein's edges, measure the diameters at different sites in a wide IVC region and then define a multiparameter algorithm to predict with high accuracy even small changes of the diameters of the vessel to predict RAP. In addition to standard IVC parameters (such as expiratory and inspiratory diameters and caval index) other parameters were obtained: caval index max (CImax) was obtained averaging the pulsatility in the 3 distal diameters and respiratory caval index (RCI) was obtained using dedicated filters.
Results: 88 patients were enrolled, 53 patients were excluded for technical reason mainly to low quality post processing imaging. 33 patients were finally included in the study (19 males and 15 females; mean ± std: age 63.2 ± 15.2 years, weight 71.5 ± 14.6 kg, height 168.0 ± 9.1 cm). The mean estimation error of the best model when using the automated approach is 2,11 mmHg from data collected by RHC and the final algorithm included CImax, RCI and IVC inspiratory diameter.
Conclusions: The semi-automated tracking of the IVC in resting respiration is a promising technique able to correctly estimate RAP with high precision degree (mean error +/-2,11mmHg). The stronger parameters associated to RAP are the inspiratory IVC diameter and derived collapsibility indexes.

P322

Right ventricular versus left ventricular systolic and diastolic parameters using tissue Doppler echocardiography in hypertensive patients

ALI Hasan Ali Farhan Al Alfarhan[1]; M A Zahid[1]
[1]*Baghdad Medical City, Cardiology, Baghdad, Iraq*

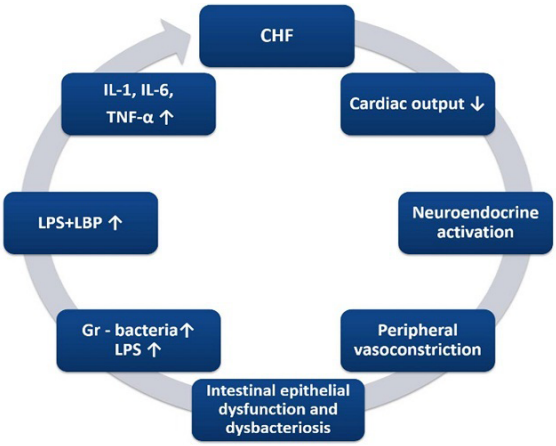
Background: Hypertension (HT) may determine impairment of both left ventricular (LV) diastolic and systolic function, due to increased afterload and changes of LV geometry and structure producing LV remodelling and hypertrophy (LVH). Also the right ventricle (RV) might be involved in this process by structural and functional abnormalities. RV chamber diastolic dysfunction has been shown in uncomplicated HT. To date, little information is available about functional changes of RV walls in HT. This issue is crucial to better understanding of the mechanisms underlying RV involvement in the hypertensive heart. Pulsed tissue Doppler has been used to analyze myocardial LV wall motion abnormalities in several cardiac pathologies and also appears suitable for assessing changes of RV longitudinal function due to HT
Purpose: To evaluate RV and LV functional and morphological changes in treated hypertensive patients using selected conventional and tissue Doppler echocardiographic methods, and to study the relationship between changes in both right and left ventricles of heart
Methods: One hundred and two treated hypertensive patients were selected in this study (group 1) in addition to 100 healthy age- and gender- matched patients for control (group 2), both study groups underwent echocardiographic examination using 2D, M Mode, Pulsed Doppler and Tissue Doppler imaging. Examination involved LV septal and posterior wall thicknesses, internal dimensions, left atrial area, ejection fraction (EF) and LV mass, also Tissue Doppler derived waves' velocities S', e', a' and e'\a' ratio. RV internal basal diastolic dimension, free wall thickness in diastole, right atrial area, TAPSE, PASP, fractional area change (FAC), PW tricuspid inflow waves' velocities e, a, and e\a ratio, Tissue Doppler derived myocardial performance index (MPI), S', e', a', and e'\a' ratio
Results: Hypertensive patients had higher measurements than control patients in: LV walls' thicknesses, end diastolic dimension, LV mass, left atrial area, peak velocity S', a', RV free wall thickness, Tricuspid inflow TV a wave velocity, right atrial area, PASP, TDI S' and a' waves velocities. Lower values than control patients in LV TDI peak velocity of e' wave and e'\a' ratio. Systolic function of both ventricles was not reduced. Diastolic function of both left and right ventricles were impaired, the Tissue Doppler derived e'\a' ratios were strongly correlated in both ventricles. There was a strong correlation between LVH and both Tissue Doppler derived RV & LV diastolic dysfunction.
Conclusions: HT causes morphological and functional changes in both ventricles, initially systolic function of LV and RV are not affected; diastolic dysfunction in LV is considered as one of the earliest functional changes, studying RV revealed diastolic dysfunction which was strongly correlated with LV diastolic dysfunction by using Tissue Doppler imaging, also with LVH were highly correlated with disease duration

P323

Intestinal dysbiosis-induced systemic inflammation in heart failure

BI Narziev[1]; AG Gadaev[1]; ME Rakhimova[1]; AA Razikov[1]
[1]*Tashkent Medical Academy, Cardiology, Tashkent, Uzbekistan*

Background: Intestinal dysbiosis plays a crucial role in the progression of chronic heart failure (CHF) and together with other pathologic processes demonstrates a vicious cycle of chronic heart failure progression (Figure 1).
Purpose: Evaluate the relationship between markers of inflammation and altered intestinal microbiome in patients with CHF.
Methods: In total 38 CHF patients with were examined. 11 patients (29%) were in functional classes III-IV (NYHA) and others 27 (71%) were in functional classes I-II (NYHA). The following laboratory test methods conducted: TNF-alpha in the blood and IL-6 in the blood by using ELISA (enzyme-linked immunosorbent assay). All patients were tested on bacteria in stool. Microbiological study of feces was carried out on the crop nutrient in the dilutions -1, -3, -5, and -7. After 48-hour incubation at 370C, estimate
Results: Microorganisms were identified by enzyme activity, as well as by microscopic examination of smears stained by Gram.
Results: There was correlation between levels of TNF-alpha and IL-6 and E. coli ($p < 0.01$), due to the growth of pathologic bacteria marked mainly by E. coli - 106 CFU / g (I-II FC HF), against 109 CFU / g (III-IV CHF FC) ($p < 0.0005$). In patients with chronic heart failure FC III-IV by NYHA, the level of IL-6 was 11.5 ± 0.3 U/L, where in FC I-II, it was 4.6 ± 0.3 IU / L. TNF-alpha in FC III-IV was 6.6 ± 0.4 U/L against 3.7 ± 0.4 IU / L in patients with FC I-II.
Conclusion: Altered intestinal function creates a condition to growing Gramm negative bacteria. Organism is contaminated either bacteria or bacteria's vital products as lipopolysaccharide (also known as endotoxin), and immune cells produce pro-inflammatory cytokines. Systemic inflammation worsens clinical course of CHF.



Cardio-intestinal syndrome

Impact of body mass index on device measured diagnostic sensor measurements in ambulatory heart failure patients

J Boehmer[1]; G Mark[2]; G Wen[3]; P Thakur[3]; GZ Duray[4]
[1]*Penn State Hershey Medical Center, Hershey, United States of America*; [2]*Cooper University Hospital, Camden, United States of America*; [3]*Boston Scientific, St. Paul, United States of America*; [4]*Military Hospital, Budapest, Hungary*

Funding Acknowledgements: Boston Scientific

Background: Prior studies have reported a link between obesity and the development and progression of heart failure (HF). A device based multi-sensor algorithm was recently shown to detect impending worsening HF events with high sensitivity. The objective of this analysis was to characterize the relationship between sensor measurements and body mass index (BMI) of HF patients.
Methods: The MultiSENSE trial followed 900 patients implanted with a COGNIS CRT-D for 1 year. Device software was modified to permit collection of sensor data: heart sounds (S1 and S3), respiration, thoracic impedance (TI), heart rate (HR) and activity. Sensor data were combined into a multi-sensor alert algorithm (HeartLogic). Patients (N = 892) were classified into four categories of BMI (kg/m2): Underweight/Normal (BMI < 25, N = 193), Overweight (25 = BMI < 30, N = 285), Obesity I (30 = BMI < 35, N = 229) and Obesity II/III (BMI>35, N = 185). Correlations between sensor data and patients' BMI were computed, and average sensor data across BMI categories were compared using a one-way ANOVA.

Sensor Values across BMI categories

Daily Trend	Underweight/ Normal	Overweight	Obesity I	Obesity II/III	p value
S1 (mG)	2.68±1.01	2.53±0.85	2.53±0.93	2.48±0.97	0.172
S3 (mG)	0.98±0.34	0.98±0.34	0.93±0.28	0.98±0.33	0.350
Thoracic Impedance (Ohm)	48.20±9.15	49.37±8.40	50.35±8.71	50.25±8.24	0.046
Daytime RSBI (br/min/Ohm)	8.31±2.87	8.10±2.40	8.60±2.56	8.77±2.59	0.029
Night Heart Rate (bpm)	70.12±7.89	70.11±7.51	70.91±8.54	72.19±8.40	0.030
Respiratory Rate (median, br/min)	18.09±2.50	17.67±2.40	17.78±2.35	17.88±2.53	0.311
Activity (hours)	2.22±2.14	2.26±2.05	2.27±2.01	2.14±1.93	0.917
HeartLogic Index	6.53±5.33	6.99±5.46	6.60±4.92	6.66±4.94	0.759

BMI = Body Mass Index, RSBI = Rapid Shallow Breathing Index, S1, S3 = 1st, 3rd heart sound, Day = 6am to 12am, Night = 12am to 6am

Results: Poor correlations between sensor measurements and BMI were observed (|r| < 0.4) for all the sensor trends. On average, obese patients had higher TI, higher day-time Rapid Shallow Breathing Index (RSBI), and higher night HR than the other patients (Table). No statistical differences across the four BMI categories were detected in the other four sensor trends (S1, S3, Respiratory Rate, Activity), and the resulting HeartLogic index. With Bonferroni correction for multiple comparisons, none of the sensor trends were statistically different across the BMI categories.
Conclusion: There are significant differences across patients in different BMI categories in TI, day-time RSBI and night HR, although the overall predictive HeartLogic Index did not vary across these groups.

P325

Indicators of humoral regulation of the circulatory system in obese patients.

T Zaletova[1]; A Bogdanov[1]; I Shevchenko[2]; T Feofanova[1]; S Derbeneva[1]; A Bogdanova[3]
[1]Research Institute of Nutrition of Russian Academy of Medical Sciences, Moscow, Russian Federation; *[2]Gazprom Transgas Diagnostic and Rehabilitation Center, Internal Medicine, Moscow, Russian Federation*; *[3]N.I. Pirogov City Clinical Hospital No.1, Moscow, Russian Federation*

Introduction: The leading cause of CHF development is an excessive activation of neurohormonal systems, primarily renin-angiotensin-aldosterone (RAAS) and sympathoadrenal ones.
Objective: To study indicators of humoral regulation of circulatory system in obese patients as predictors of CHF development.
Methods: In the studied population of obese patients two groups of 40 patients were formed: the first group consisted of patients with initial obesity (grades 1 or 2) with BMI of up to 40 kg/m2, the second group included patients with severe obesity (grade 3 obesity) with BMI of over 40 kg/m2. None of the selected patients had a history of cardiovascular events (myocardial infarction or acute cerebrovascular event). The concentration value of renin-angiotensin-aldosterone system components was determined (renin, results expressed in pg/ml, angiotensin II, results expressed in ng/ml), aldosterone, the result expressed in pg/ml). The level of N-terminal pro B-type natriuretic peptide (NT-pro-BNP) was determined by immunoassay analysis.
Results: Studying aldosterone plasma level showed that for most obese patients, it is hyperaldosteronism that can induce heart failure. It was shown that a higher obesity grade is associated with higher aldosterone level. Aldosterone level in grade 1-2 obese patients was close to normal upper border, which was 58.9 [54.9; 73.8] pg/ml (normal range is 10-60 pg/ml), while in patients with grade 3 obesity it was 79.5 [64.5; 90.1], which is 25.9% higher than in patients of the first group and 24.5% higher above the normal level (for p <0.05). Detailed data analysis showed that these two groups are significantly different not only in average plasma aldosterone level, but in absolute number of patients with hyperaldosteronism, whose number increases from 46,2% in grades 1 or 2 obese patients to 85.7% among patients with grade 3 obesity. Plasma renin level in both groups was within the normal range. The median value in patients with obesity grades 1 or 2 was 23.2 [10.9; 51.8] pg/ml, in patients with grade 3 - 22.4 [11.2; 39.8] pg/ml (lab reference values 4.0 - 37.5 pg / ml). The differences between these values were insignificant (p> 0.05). No significant differences in angiotensin II levels were demonstrated in patients of the compared groups: the average value in grades 1 or 2 obesity patients 17.95 [1.58; 18,53] pg/ml, and in patients with grade 3 obesity - 18,54 [18,25, 18,83] pg/ml. NT-proBNP level in the first group was 23.7 [10.6; 23,6] pg/ml, in the second group - 138,0 [121,5; 145.9] pg/ml, which is 5.8 times higher (p = 0.001). Correlation analysis showed that aldosterone and NT-proBNP levels are closely related (r = 0.74, p <0.05).
Conclusions: This study shows that aldosterone level can be used as a predictor of HF. An increase in aldosterone activity may cause lung congestion and peripheral edema, which together with left ventricular dysfunction make up a clinical syndrome of CHF in obese patients.

P326

Using ballistocardiography measurements to assess diuretic effects in patients with heart failure

MMH Shandhi[1]; J Fan[2]; S Dowling[2]; OT Inan[1]; LIVIU Klein[2]
[1]Georgia Institute of Technology , School of Electric and Computer Engineering, Atlanta, United States of America; *[2]University of California San Francisco, Cardiology, San Francisco, United States of America*

Funding Acknowledgements: National Institutes of Health, USA

Background: Measuring hemodynamic responses to medications in heart failure (HF) patients can potentially enable caregivers and physicians a means of ensuring that patients are correctly following the prescribed dosage and timing of medication delivery (e.g. diuretics or vasodilators). In our previous studies, we have shown that weighing-scale-based measurements of ballistocardiogram (BCG) signals - the measurement of body vibrations in response to cardiac ejection - can accurately quantify cardiac contractility changes [pre-ejection period (PEP)/ Heart Beat Period (RR interval)]. This non-invasive measure can track hemodynamics in the hospital and at home for patients with HF.
Purpose: In this study, we quantified the impact of diuretic use on patients' BCG signals and associated cardiac parameters, paving the way for future studies aimed at assessing medication usage based on BCG measurements at home.
Methods: We enrolled 12 patients with HF and reduced ejection fraction (HFrEF). BCG and electrocardiogram (ECG) signals were simultaneously recorded using a previously validated modified weighing scale (Fig. 1A) at, or close to, the day of hospital admission, daily during the hospitalization, at hospital discharge, and then daily at home for 30 days following discharge. For the current analysis, we focused on the specific recording days when diuretic dosages were changed while all other medications (neurohormonal antagonists and vasodilators) were unchanged for at least two days. The BCG features were averaged for two days before and after a change in diuretics. For one subject, we have compared these features with changes in thoracic impedance, obtained from the commercially available SensiVest device.
Results: For 89% of readings, PEP/RR increases with increase in diuretic dose and vice versa (Fig. 1B). Within patient parameters show higher correlation for percent changes in PEP/RR with percent changes in diuretics compared to global model across all patients. Percent changes in thoracic impedance showed negative correlation with percent changes in diuretics (R2 = 0.74) as well as with percent changes in PEP/RR (R2 = 0.93).
Conclusion: Using a modified weighing scale we can monitor the effects of diuretics on cardiac hemodynamics in patients with HF. Further expanding this technology to other medications and more subjects can potentially allow for algorithms to be trained to determine whether the correct dosage of medications has been taken by patients at home.

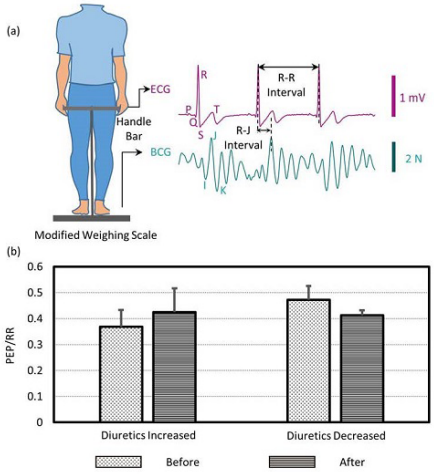

Figure 1: (a) Experimental setup with representative ECG and BCG signals. The RJ interval is a surrogate for pre-ejection period (PEP). (b) Changes in PEP/RR due to changes in diuretics doses.

P327

Structure and functional predictors of left atrial pressure in patients with end-stage heart failure

F Ferdinando Loiacono[1]; FM Righini[1]; A Dokollari[2]; CG Sassi[2]; S Bernazzali[2]; M Maccherini[2]; S Mondillo[1]; M Henein[3]; M Cameli[1]
[1]University of Siena, Department of Cardiovascular Diseases, Siena, Italy; *[2]Polyclinic Santa Maria alle Scotte, Department of Cardiac Surgery, Siena, Italy*; *[3]Umea University, Department of Public Health and Clinical Medicine, Umea, Sweden*

Background: End-stage heart failure (HF) is characterized by variable degrees of left ventricular (LV) dysfunction, myocardial fibrosis and raised filling pressures, leading to atrial enlargement and impaired function. Global peak atrial longitudinal strain (PALS) assessed through speckle tracking echocardiography (STE) is a non-invasive index of left atrial (LA) function which correlates closely with LV end-diastolic pressure. An independent but highly valuable predictor of LV dysfunction is myocardial fibrosis, which cause poor contractile and elastic properties of the myocardium, resulting in increased preload and filling pressures.

Purpose: Aim of this study was to investigate the relationship between increased filling pressure and LA function, assessed by STE and specifically global PALS, LV ejection fraction (EF) and fibrosis in patients with end-stage HF undergoing heart transplantation.
Methods: We consecutively enrolled 64 patients with end-stage HF who underwent heart transplantation into this study. Demographic, pre-transplant invasive intracardiac pressures, and echocardiographic comprehensive offline speckle tracking analysis were collected. After transplantation, specimens from explanted hearts were collected in order to quantify the degree of LV myocardial fibrosis which was defined as (fibrosis area-total area)×100. An average value of the extent of LV fibrosis was obtained from the seven samples.
Results: Patients were 56.3 ± 8.4 years old and mean NYHA class was 2.95 ± 0.7. Mean LV EF was 26.7 ± 4.3%. They presented mild LA enlargement (mean LA area 27.1 ± 9.6 cm2 and mean LA indexed volume 35.1 ± 11.1 cm2) and reduced global PALS (11.5 ± 7.5). Mean pulmonary capillary wedge pressure (PCWP) was raised (18.8 ± 7.5 mmHg) and mean pulmonary artery pressure (PAP) was 27.1 ± 9.9 mmHg, both slightly increased but not contraindicating heart transplantation. LV fibrosis was present in all specimens and 73% of the patients showed severe (i.e. >30%) LV fibrosis.
Global PALS was inversely correlated with PCWP (R -0.83; $p < 0.0001$) (figure) and with LV fibrosis (R -0.78; $p < 0.0001$), but did not correlate with LV EF (R 0.15; p= ns). Global PALS was correlated with LA diameter (R -0.35; $p = 0.05$), LA area (R -0.37; $p = 0.05$) and LA indexed volume (R -0.39; $p = 0.01$). Among the analyzed indexes, global PALS was the best index for predicting raised (<18 mmHg) PCWP (AUC 0.955).
Conclusions: In patients with end-stage HF undergoing heart transplant, abnormal LA function expressed as reduced global PALS is determined by the rise of LV filling pressure as well as by the degree of fibrosis but not by LV systolic function expressed as EF.

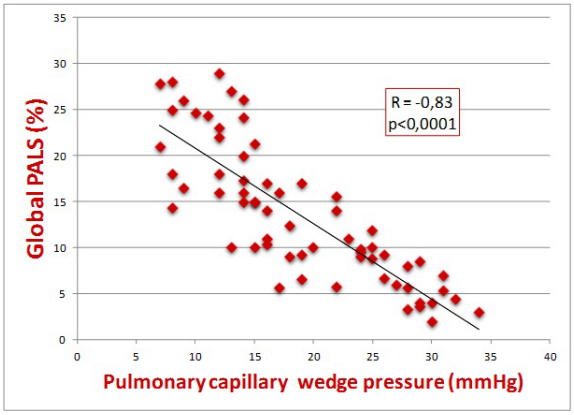

Fig 1

Chronic Heart Failure - Treatment

P328

Combined therapy with ACEI/ARB, beta-blocker, statin, antithrombotic drug and cardiovascular mortality in comorbide patients with heart failure, coronary artery disease, arterial hypertension

MM Loukianov[1]; SY Martsevich[1]; Y Mareev[1]; SS Yakushin[2]; AN Vorobyev[2]; AV Zagrebenyy[1]; RP Myasnikov[1]; AN Kozminsky[2]; EY Andreenko[1]; VG Klyashtorny[1]; EV Kudryashov[1]; KG Pereverzeva[2]; AD Deev[1]; OM Drapkina[1]; SA Boytsov[3]
[1]National Research Center for Preventive Medicine, Moscow, Russian Federation; *[2]Ryazan State Academician Medical University, Ryazan, Russian Federation*; *[3]National Research Center for Cardiology, Moscow, Russian Federation*

Aim: To evaluate prescription rate of ACE inhibitor (ACEi)/angiotensin receptor blocker (ARB), beta-blockers, statins, antithrombotic drugs (antiplatelet/anticoagulant) and cardiovascular (CV) mortality in patients with combination of heart failure (HF), coronary artery disease (CAD) and arterial hypertension, enrolled in outpatient registry RECVASA.
Methods: RECVASA registry included 3690 patients with CV diseases from 3 outpatient clinics in Ryazan region of Russia. For this analysis, we took patients with the combination of HF, CAD and arterial hypertension. CV mortality was estimated during 4-year of the follow-up period.
Results: 2303 patients were included (28.9% men, age 70.6 ± 10,7 years). 21.5% patients had atrial fibrillation (AF), 17.6% - history of myocardial infarction (MI), 11.9% - stroke in anamnesis. Accordingly, to clinical recommendations all patients have an indication for combined therapy with ACEI/ARB, beta-blockers, statins and antithrombotic (antiplatelet if the patient didn't have AF or anticoagulant in cases of AF). There were no patients with indications for double/triple antithrombotic therapy. Patients after MI had an additional indication for administration of ACEI and beta-blocker. Therapy with ACEI/ARB was administrated in 1676 (72.8%) cases, with beta-blocker - 1676 (72.8%), statins - 674 (29.3%), antithrombotic drugs in 1001 (43.5%).
Patients were divided according to the number of prescribed drugs. Therapy with all four components of drugs was administrated in 226 (9.8%) of patients, with 2-3 drugs in 1246 (54.1%) of patients and with 0-1 drugs in 831 (36%) of patients.
Mean follow-up was 3.7 ± 0.9 years. 430 (18.7%) patients died from all causes, including 297 (12.9%) from CV diseases. CV mortality was: 4.9% in patients with administration of the 4-component therapy; 12.7% and 15.4% with administration of 2-3 and 0-1 drugs, respectively. ($p = 0.0007$ and $p = 0.0001$ respectively for comparison between 4-component therapy and groups with administration of 2-3 and 0-1 drugs).
Risk ratio (RR) of CV death and 95% confidential interval (CI) were analyzed in multifactor Cox model (age, sex, administration of 0-1, 2-3 or 4 mentioned drugs, history of MI or stroke). Compared with reference group (0-1 drugs) risk of CV death was lower in patients, received 4-component therapy (RR = 0.30, 95% CI 0.16-0.55, $p = 0.0002$) and 2-3 drugs (RR = 0.70, 95% CI 0.62-0.91, $p = 0.003$).
Conclusion: Only one-tenth of patients with the combination of HF, CAD and arterial hypertension received 4-component therapy with ACEI/ARB, beta-blocker, statin, an antithrombotic drug in outpatient practice and 54.1% - 2-3 of these drugs. CV mortality and risk of CV death in patients with administration of this 4-component drug therapy were respectively 3.1 and 3.3 times less compared with cases of administration 0-1 of them.

P329

Heart failure over 19 years: are we on the right way?

N Nabil Kraiem[1]; I Fomin[1]; DS Polyakov[1]; FY Valiculova[1]
[1]Nizhny Novgorod State Medical Academy, Department of internal medicine, Nizhny Novgorod, Russian Federation

Introduction: heart failure (HF) must be treated as recommended in guidelines
Purpose: to find out how the treatment of heart failure has changed over 17 years
Methods: All medical data of the representative sample in the city of Nizhni Novgorod were analyzed to find out the prevalence of heart failure and the way this syndrome is treated. Data check and collection were started in 1998 to our days. HF therapy was analyzed depending on last HF guidelines 2017.
Results: within 17 years, 2056 people were checked for the presence of HF in 2000, 2007 and 2017. Over 17 years the prevalence of HF increased from 6.8% to 9.1% (? = 0.04), the prevalence of severe HF (NYHA III - IV classes) increased from 1.2% to 4.8% ($p < 0.001$).The averages of patients receiving drugs not considered to be disease modifying in 2000, 2007 and 2017 were 68.7%, 20.9% and 12.9% consecutively. Not depending of therapy type (mono or be or tri therapy) drug records of HF patients show that angiotensin-converting-enzyme inhibitors (ACEIs) were prescribed to 24.7% of patients in 2000 while no angiotensin II receptor blocker (ARB) was prescribed. After 7 years only 66.9% received ACEIs while ARBs prescribed only to 0.6% of patients. In 2017, 65.2% and 20.5% of patients received ACEIs and ARBs respectively. Beta Blockers (BB) prescription changed from 14.1% in 2000 to 34.3% in 2007 and 48.5% in 2017. Mineralocorticoid receptor antagonist (MRAs) were not prescribed in 2000, prescribed to 4.7% patients in 2007 and 10.6%. Considering therapy type, in 2000, 17.2% and 6.6% found to be treated in mono therapy by ACEIs and BB respectively. Important changes were identified after 7 years (40.1% and 9.9%) and in 2017 (28.0% and 3.8%). Bi therapy defined by combination of 2 recommended drugs was found in 7.6% of patients in 2000, 27.3% in 2007 and 39.5% in 2017. No patient was treated by tri therapy (ACEI or ARB, BB, MRA) in 2000, 0.6% in 2007 and 4.5% in 2017.
Conclusion: We found out a serious difference between actual guidelines on HF treatment and real therapy among ambulatory patients. We believe that inappropriate treatment choice is partially responsible for the 4 times increase of severe HF prevalence. More active work is needed to slow the development of HF.

P330

B-blockers and prognosis in cardiac amyloidosis

A Ntalianis[1]; A Koutsoukis[1]; E Tseliou[1]; E Repasos[1]; E Papadopoulou[1]; M Tselegiki[1]; D Ziogas[1]; E Kastritis[1]; K Tampakis[1]; I Stamoulopoulos[1]; A Koen[1]; S Toumanidis[1]; MA Dimopoulos[1]; I Paraskevaidis[1]
[1]*Alexandra University Hospital, Departmant of Therapeutics, Athens, Greece*

Background/Introduction: B-blockers (BB) administration in patients with light chain cardiac amyloidosis (LC-CA) might result in significant symptom deterioration. However, there are patients with LC-CA who tolerate even high BB doses without any important side effect. Theoretically, the anti-arrhythmic and cardioprotective effects of BB could improve prognosis in patients with LC-CA.
Purpose: To investigate the impact of BB treatment in patients with LC-CA
Methods: In the present retrospective study from 2002 to 2017, 85 patients with LC-CA were included. Mean age was 67 years. We investigated the impact of BB treatment, on survival rates of patients with LC-CA . All LC-CA patients received chemotherapy treatment according to previous and current guidelines
Results: Upon chemotherapy initiation, 30% of patients were under BB treatment and 7% under amiodarone or ivabradine. Fourty two percent of the patients were on furosemide (mean dose: 82 mg/d), while 4.6% was on renal replacement therapy (RRT) due to end stage renal failure. Mean survival was 24.5 ± 3 months. 5-year survival in the entire cohort was 45% and cardiovascular mortality was 70%. BB ($p = 0.033$) and lower doses of furosemide ($p = 0.011$) were associated with better survival rates.
Conclusions: The minority of patients with LC-CA either receive or tolerate BB. The prognosis of patients with LC-CA that receive BB treatment is better compared to those that do not receive BB.

P331

Safety and efficacy of valsartan-sacubitril in a cohort of patients with symptomatic heart failure receiving small doses of ACE

I Stamoulopoulos[1]; A Ntalianis[1]; E Papadopoulou[1]; E Tseliou[1]; S Sventzouri[1]; K Tampakis[1]; A Koutsoukis[1]; N Makris[1]; C Kontogiannis[1]; A Koen[1]; I Kanakakis[1]; K Stamatelopoulos[1]; I Paraskevaidis[1]
[1]*Alexandra University Hospital, Departmant of Therapeutics, Athens, Greece*

Background: Combined inhibition of the renin-angiotensin system and neprilysin (ARNI) significantly reduced mortality and morbidity in selected symptomatic patients with heart failure (HF) who could tolerate high doses of enalapril. The purpose of this study was to investigate the safety and efficacy of ARNI administration in patients with NYHA II and III receiving lower doses of ACE inhibitors (ACE-inh).
Methods: Patients with systolic HF (EF < = 35%), NYHA II-III, receiving a maximum tolerated but small dose of ACE-inh, beta-blocker and aldosterone inhibitor were prospectively included. An initial dose of ARNI 50mgX2 was administered for 1 week, up-titrated to 100mgX2 and 200mgX2 per week if tolerated. The safety and efficacy endpoints of the study at 12 months were: a) NYHA b) left ventricular ejection fraction and c) ARNI-related adverse events.
Results: A total of 27 patients were included (74% with ischemic HF, mean age: 60 ± 10 years). All patients before ARNI, they were receiving less than 50% of the maximum recommended ACE-inh dose. At 12 months, there was a statistically significant improvement in NYHA ($p = 0.01$) and a marginal statistically significant increase in EF (from 27.1 ± 3.9% to 33.6 ± 6.6%, $p = 0.08$). There was no statistically significant reduction in both SBP (from 112.3 ± 13.2 to 108.5 ± 11.8 mmHg, $p = 0.363$) and diastolic blood pressure (67.5 ± 10.4 at 62.3 ± 8 , 2mmHg, $p = 0.115$). In two cases, asymptomatic hypotension was observed with the maximum dose of ARNI for which transient discontinuation was required. No significant changes in eGFR (from 80.5 ± 23.7 to 74.9 ± 29.8 ml / min, $p = 0.507$) and K + (from 4.7 ± 0.4 to 4.6 ± 0.4 mmol / L, $p = 0.623$) were observed.
Conclusions: Administration of ARNI in patients with symptomatic systolic HF receiving low doses of ACE-inh is well tolerated and improves both symptoms and left ventricular function without significant adverse events.

P332

Barriers and motivations to physical activity in heart failure patients; is a specific approach needed for women?

E Emilie Cewers[1]; T Ben Gal[2]; A Joensson[1]; JM Weinstein[3]; T Jaarsma[1]
[1]*Linkoping University, Medical Faculty, Linkoping, Sweden*; [2]*Rabin Medical Center, Petah Tikva, Israel*; [3]*Soroka University Medical Center, Beer Sheva, Israel*

Introduction: Physical activity (PA) is an essential part of heart failure management but the adherence to exercise recommendations is low, especially in female patients. A similar sex discrepancy can be seen among healthy people, in whom research show differences in barriers and motivations. This study aimed to investigate sex differences in PA, barriers and motivations to PA and change in physical capacity. It also sought to evaluate the opinions of health care providers with regard to such differences and whether adaptations in care based on sex might be meaningful.
Methods: A mixed methodology study was conducted in two hospitals in Israel during February to May 2017. Concurrent triangulation design was used, in which interviews with health care providers were held in parallel to collection of quantitative data from heart failure patients on motivations, barriers, PA and physical capacity, measured through the Exercise Motivations Index, the Exercise Self Efficacy Scale and the 6 Minute Walk Test. Interviews were analysed through qualitative content analysis and quantitative data was studied via SPSS 24, particularly looking at differences between men and women. Quantitative and qualitative data were given equal priority and were integrated in the discussion.
Results: No sex differences in PA and capacity were found in the quantitative data, but some health care providers believed there were differences. Male patients reported higher motivations in 'I want a slower aging process and to feel younger' ($p = 0.04$) and 'Everyone else exercises, I want to do that too' ($p = 0.02$). Other items related to motivation or barriers showed no statistically significant sex differences. Qualitative data was ambivalent, and health care providers had divergent opinions regarding the existence of sex differences and the value of adapting care based on sex. 7 categories with associated subcategories were identified through qualitative content analysis. This method also revealed one pervading theme; 'Men and women; they are the same … But they are different.
Discussion: Contrasting to findings in earlier studies, no sex differences were found in PA or physical capacity although motivations were slightly different between genders. At the same time, health care providers had clear opinions about possible differences, possibly affecting their care. Given that the results pointed to potential sex differences in motivations and barriers, considering this when tailoring care might be of value.

P333

Barriers and challenges in self-care for heart failure patients with different cultural backgrounds

A Adam Joensson[1]; T Ben Gal[2]; E Cewers[1]; JM Weinstein[3]; T Jaarsma[1]
[1]*Linkoping University, Medical faculty, Linkoping, Sweden*; [2]*Rabin Medical Center, Petah Tikva, Israel*; [3]*Soroka University Medical Center, Beer Sheva, Israel*

Introduction: Heart failure (HF) is one of the most prevalent cardiovascular diseases and patients are advised to perform different self-care behaviours. Health care providers (HCPs) have an important role in providing self-care advise. The aim of this study is first, to examine if there are any specific barriers and challenges regarding the self-care of HF-patients with regard to their different cultural background and second, if the cultural background of their HCP play a part in the patients' adherence to self-care.
Methods: A qualitative study was performed with purposeful sampling method used. Data was collected through interviews focusing on cultural differences in self-care. Interviews were held with 12 HCPs of different cultural backgrounds from two different hospitals in Israel. Data was analysed with content analysis.
Results: Data on cultural issues could be summarized into 4 categories and 9 subcategories. Specific barriers in adhering to self-care depending on cultural background were identified such as cultural dietary traditions interfering with the recommended HF diet, willingness to do self-care and religious beliefs conflicting with medical treatment. It was also found that the cultural background of the HCP in some way could influence their patients' adherence to self-care. HCP also adapted their information and care, based on the cultural background of the patients. Shared backgrounds and awareness of differences were reported to positively influence self-care education while cultural differences could negatively affect this process.
During the analysis of material, information regarding other factors that indirectly might be associated with patient self-care was found.
Conclusions: Specific cultural and religious barriers in self-care for HF-patients were identified and the HCPs' cultural background also seems to influence their patients' self-care behaviour. Further research is necessary to confirm these suggested results and to assert the benefits of an adjusted care model based on cultural background.

P334

Paw prints on your heart: the influence of pets on heart failure readmission rate

L Barsky[1]; C Mcpherson[1]
[1]*Yale New Haven/Bridgeport Hospital, Cardiology, Bridgeport, United States of America*

Background/Introduction: Pet or domesticated animal ownership is an increasingly popular lifestyle trend that can have a complex impact upon the trajectory of a patient's heart failure. Indeed, while various studies support the health benefits of

having a pet, some suggest that associated stress and financial burden may promote adverse outcomes. Further, there has been no previous exploration of the specific impact of pets on heart failure readmission rate, an outcome affecting both patients and hospitals.
Purpose: This study sought to examine the effect of pet ownership on 60 day heart failure readmission rate. We hypothesized that owning a pet decreases the readmission frequency.
Methods: We queried the hospital's admission database to identify all patients admitted for a diagnosis of heart failure from January 2015 to March 2017. For those patients who consented to participate, we conducted a phone interview to inquire about pet ownership status, number and type of pets, ownership experience and outside hospital admission history. Medical chart review verified 60 day readmission status and diagnosis and provided further demographic and clinical data. Finally, we used a chi-square test to investigate correlations with readmission rates, demographic attributes and clinical attributes between the pet owner and non-pet owner populations.
Results: Of the 191 subjects in the study population, 44 owned at least one cat or dog, and 147 did not. Among pet owners, 15/44 (34%) were readmitted within 60 days, compared to 78/147 (53%) of non-pet owners (95% confidence interval, P = 0.027). There was no observed correlation between readmission rate and the variables of pet species or quantity owned, socioeconomic class, age, gender, alcohol and tobacco use, ejection fraction, coronary artery disease and clinical management. While pet owners tended to be younger, there was no significant difference in the other described attributes between the pet and non-pet owner groups. Both re-admitted and non-readmitted pet owners endorsed comparable levels of stress and happiness associated with their animals. They all identified their pets as companions.
Conclusions: Ownership of one or more cats or dogs appears to be associated with a lower 60 day heart failure readmission rate. Thus, physicians may suggest dog or cat adoption as a potentially beneficial lifestyle choice for their heart failure patients. As dog or cat ownership may require too much time or money for some individuals, further studies may explore the impact of smaller lower maintenance animals such as birds, rodents or fish on readmission rates.

P335
Comparing the effectiveness of cognitive behavioral interventions and motivational interviewing on improving self-care behaviors

H S J Han Shi Jocelyn Chew[1]; S Y Chair[1]; H Y Cheng[1]
[1]The Chinese University of Hong Kong, Nursing, Hong Kong, Hong Kong SAR People's Republic of China

Aim: To compare the effectiveness of cognitive behavioral interventions and motivational interviewing on improving self-care behaviors in patients with chronic heart failure.
Background: Chronic heart failure remains a major healthcare priority due to its high prevalence and disease burden. Although self-care has been advocated as the sustainable solution, it remains inadequate. Recent studies have shown the potential of integrating structured counseling elements into traditional educational programs to enhance self-care but the optimal counseling method remains unclear.
Design: A literature review.
Data Sources: Articles published between years of 2006 to 2016 were searched from CINAHL, MEDLINE, PubMed, ScienceDirect, PsychINFO, Cochrane Library, Scopus, ProQuest.
Review Methods: Using a systematic three-step search strategy, a literature review of self-care intervention studies that incorporated cognitive behavioural therapy and/or motivational interviewing was conducted. Quantitative and qualitative trial studies that met the inclusion criteria were appraised using the Joanna Brigg's Institute criteria.
Results: Both counselling methods produced higher yet limited significance in improving self-care, with motivational interviewing demonstrated higher potential. Sodium restriction and physical exercise seemed to be more responsive to counselling interventions, suggesting the need to develop behaviour specific strategies. Common elements included goal setting, action planning and problem solving. A striking limitation is the disproportionate number of patients who dropped-out, inconclusive results on the interventions' effectiveness and their unsustainable effects.
Conclusion: More research is needed to understand and address the motivational and operational needs of patients towards self-care instead of just applying counseling to change their outlook.

P336
Long-term tolerability of ivabradine in elderly patients with heart failure - data from oLder HF patients initiated on iVabradinE in the UK: quaLIty of liFE (LIVE:LIFE) study

S M Sarah Birkhoelzer[1]; D Stevens[2]; D Zachariah[1]; N Rowell[3]; J Taylor[4]; PR Kalra[1]
[1]Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom; *[2]Medical Affairs Department, Servier Laboratories, United Kingdom*; *[3]South Tees Hospitals NHS Foundation Trust, Middlesbrough, United Kingdom*; *[4]Glasgow Royal Infirmary, Glasgow, United Kingdom*

Funding Acknowledgements: This research was funded and supported by Servier Laboratories (UK) ltd.

Background: LIVE:LIFE study demonstrated significant improvements in health related quality of life (HRQoL) and functional status with ivabradine in patients with chronic heart failure (CHF) age = 70 yrs. Despite multiple comorbidities and polypharmacy, ivabradine was well tolerated.
Purpose: Assess long-term use and tolerability of ivabradine in older CHF patients.
Methods: LIVE:LIFE collected demographics, clinical & HRQoL (MLWHFQ, SF-12) data at baseline (V1), 2 (V2), 6 months (V3) from 240 patients across 44 UK primary & secondary care sites. Patients consented for the research team to check medical records at least 12-months after original consent (V4). Data were collected between June 2015 and April 2016 and included current medications, reasons for changes, hospitalisations and deaths. Tolerability of ivabradine was assessed where possible using a 5-point scale (very well, quite well, somewhat well, not well or not at all) by a healthcare professional.
Results: 184 patients had both V3 and V4 on the electronic case report form; 15 died prior to V4 and 6 had no data input at V4. Data were available on 163 patients at both V3 and V4 and form the current study group. Patients were elderly (mean age V4, 78 ± 6 yrs) and 61% were male. 60% had ischaemic aetiology. Co-morbidities were common: 58% hypertension, 33% diabetes and 44% asthma/COPD. The mean duration of follow-up since V1 was 456 ± 93 (± SD) days, mean interval between V3 (last direct study contact with the patient) and V4 was 267 ± 97 days. Patients were prescribed a mean of 9 daily medication at V3 and 11 at V4. At V3, the majority (143, 88%) were taking ivabradine (doses: 2.5 mg bd n = 46, 5 mg bd n = 82, 7.5 mg bd n = 15). Of 159 patients at V4 with data available regarding ivabradine use at that point 75% (119/159) remained on it (doses: 2.5 mg bd n = 29, 5 mg bd n = 76, 7.5 mg bd n = 14). Of the 40 patients who had stopped ivabradine before V4, in 18 cases recommended by the heart failure team, the remainder by primary care (n = 5), non-heart failure secondary care (n = 3), unknown (n = 14). At V4 healthcare professions felt able to comment on tolerability of ivabradine for 113 patients: "somewhat well or better" (n = 105). At V4, 58% were receiving a beta-blocker (61% at V3), 69% an angiotensin-converting-enzyme inhibitor/angiotensin receptor blocker (87% at V3), and 40% a mineralocorticoid receptor antagonist (39% at V3). Between V3 and V4 24% (39/163) patients had been hospitalized. Multiple admissions were noted for 12 patients.
Conclusion(s): In the majority of elderly patients with CHF ivabradine is well tolerated in the longer-term (around 15 months follow up), despite the presence of multiple co-morbidities and polypharmacy. These data reflect real-world practice in the UK - the final data (V4) were collected almost 9 months after the last study contact with the patient. Further evaluation is required to elucidate reasons for stopping ivabradine and neurohormonal antagonists.

P337
Effect of Carvedilol on Survival in Severe Chronic Heart Failure with reduced ejection fraction in sinus rhythm, atrial fibrillation or with a pacing device; a post-hoc analysis of COPERNICUS

Y Mareev[1]; N Ramparsad[1]; P Pellicori[1]; A Mcconnachie[1]; J JV Mcmurray[2]; M Packer[3]; JG Cleland[1]
[1]University of Glasgow, Robertson Centre for Biostatistics, Glasgow, United Kingdom; *[2]University of Glasgow, Glasgow, United Kingdom*; *[3]Baylor University Medical Center, Dallas, United States of America*

Background: An individual patient-data meta-analysis suggested that, compared to placebo, beta-blockers, reduced morbidity and mortality amongst patients with heart failure and a reduced left ventricular ejection (HFrEF) if they were in sinus rhythm but not for those in atrial fibrillation (AF). A subsequent analysis comparing carvedilol with metoprolol tartrate in COMET suggested that carvedilol reduced mortality both for patients in sinus rhythm and AF but not for patients with right ventricular pacing devices (RVPD). The reasons for the disparate trial results for AF are uncertain but could reflect longer duration of follow-up in COMET, differences in classifying patients with RVPD or deleterious effects of metoprolol tartrate (unlikely). Accordingly, we analysed data from COPERNICUS, a trial comparing carvedilol to placebo that was stopped early for overwhelming benefit but has not yet provided a definitive report on outcome by heart rhythm.

Methods & Results: Patients were classified at baseline according to the presence or absence of RVPD that could prevent heart rate reduction. Patients without RVPD were classified as sinus rhythm or AF. Access to anonymized data was provided by GSK.
Of 2,287 patients whose rhythm could be classified (<99%), 1,630 were in sinus rhythm, 414 in AF and 243 with RVPD. Of these, 1202, 268 and 184 respectively completed the titration phase. Compared to placebo, heart rates were lower at the end of titration for those assigned to carvedilol in sinus rhythm (68bpm [IQR: 62-76] vs 80bpm [72-88] or AF (68bpm [60-80] vs 80bpm [72-87]) but were similar for those with RVPD (72bpm [66-78] vs 72bpm [68-80])
In a model adjusted for sex and age, all-cause mortality was lower for patients assigned to carvedilol in sinus rhythm (HR: 0.52 [0.39-0.69], $p < 0.001$), but not in AF (HR: 0.77 [0.45-1.32], $p = 0.34$) or with RVPD (HR: 1.49 [0.87-2.56], $p = 0.114$) (interaction between treatment and rhythm: $p < 0.001$). For patients in AF, further analysis suggested a higher mortality during the titration phase for those assigned to carvedilol (HR 2.25 [0.91 - 5.57]; $p = 0.08$) but a lower mortality during the maintenance phase (HR 0.37 [0.17-0.79]; $p = 0.011$; test for time-interaction $p = 0.003$). For those in sinus rhythm, carvedilol reduced mortality during both titration (HR 0.40 [0.25-0.63]; $p < 0.01$) and maintenance phases (HR 0.60 [0.42-0.86]; $p = 0.005$). For patients with RVPD assigned to carvedilol, mortality was not reduced in either phase (HR 1.40 [0.60- 3.31] and 1.58 [0.80-3.13]).
Conclusions: This post-hoc analysis suggests that beta-blockers may not be effective and could be harmful for patients with HFrEF and RVPD. In the longer-term, carvedilol appears similarly effective for patients in sinus rhythm and AF but there may be an early excess risk for those with AF.

P338
Tolerability and safety of Sacubitril/Valsartan in real-life practice

JN Joana Neiva[1]; IGO Gomez-Otero[2]; AVR Varela-Roman[2]; MMG Moure Gonzalez[2]; ASB Seoane Blanco[2]
[1]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal; *[2]University Hospital of Santiago de Compostela, Centro de Investigación Biomédica en Red de Enfermedades Cardiovasculares (CIBERCV), Santiago de Compostela, Spain*

Introduction: After PARADIGM-HF, current ESC guidelines recommend sacubitril/valsartan (SV) for patients (P) with ongoing symptomatic chronic heart failure with reduced ejection fraction (HFrEF), despite first line medical therapy. Experience regarding tolerability and safety in real world populations is less well described.
Purpose: To assess tolerability and success in achieving maximum SV dose, as well as detailing the side effect profile, in a real world population.
Methods: Retrospective and descriptive study extended to all P initiated on SV in a specialized HF unit in a single center since October 2016. Data collected included demographics, initial dose, titration, discontinuation and adverse events. Clinical parameters were documented at each evaluation. Up-titration occurred every 2-4 weeks as per clinical judgment. Descriptive statistics were used for analysis.
Results: Within a population of 106P (79% male; 68,2+10,7years; 45,3% ischemic etiology; mean EF 29,5%; NYHA II-III 99,1%) 61,3% initiated on low doses (24/26mg) and the remaining on 49/51mg. At initiation visit 4P had systolic blood pressure (SBP) < 100mmHg, 1P serum creatinine (Cr) >2,5mg/dL and 6,6% potassium (K) >5,4mmol/L. 13P (12,3%) were still in process of up-titration. After up-titration phase (44+19days) 51,6% achieved maximum dose of 97/103mmHg; 28% were on medium dose and 11,8% remained on 24/26mg without tolerating a dose increase. The main reasons to not achieve highest dose were dizziness/hypotension (47,2%; 4P with SBP < 90mmHg) and hyperkalemia (44,4%; maximum 5,7mmol/L). After a mean follow-up time of 194 days (4-421), 45,3% remained on maximum dose; 5,9% were down titrated to a tolerable dose and 8.2% progressed in titration. The download dose occurred in all cases due to symptomatic hypotension. 11P (10,4%) discontinued SV (vs 17,8% in PARADIGM-HF), 8 of them in titration phase. The commonest reason was a composite of hypotension/dizziness (n = 5; 3P with SBP < 90mmHg); other reasons included acute renal failure (n = 1; decreasing 36% of eGFR), economic reasons (n = 2), gastrointestinal disturbance (n = 1), left ventricular assist device implantation (n = 1) and inappropriate initiation (n = 1). No episodes of angioedema.
Regarding tolerance, SBP decreased 4mmHg (122+17 vs 118+17), Cr increased 0,05mg/dL (1,11+0,34 vs 1,16+0,41) and K decreased 0,03mmol/L (4,84+0,39 vs 4,81+0,42). Of those who had worsening of renal function, 3,8% (4P) had a decrease in eGFR>35% (maximum decrease of 42,6%).
Conclusion: Our data suggests that SV is well tolerated and has good safety in real-life. True hypotension was the dominant cause for discontinuation. Caution should be taken to consider reducing or rationalize other medications with anti-hypertensive side effects to avoid it. The overall adverse reactions were lower when compared to PARADIGM-HF, however our mean follow-up period was significantly shorter.

P339
Changes in pharmacological treatment during first year of follow-up of patients included in a heart failure unit

D Iglesias Del Valle[1]; V Martinez Dosantos[1]; E Garcia Ramirez[1]; JS De Juan Baguda[2]; Z Blazquez Bermejo[3]; E De La Cruz Berlanga[1]; C Casanova Rodriguez[1]; R Cano Carrizal[1]; E Prieto Moriche[1]; A Martin Penato Molina[1]; R Cadenas Chamorro[1]; B Paredes Gonzalez[1]; A Garcia Garcia[1]; I Plaza Perez[1]
[1]University Hospital Infanta Sofia, Madrid, Spain; *[2]University Hospital 12 de Octubre, Madrid, Spain*; *[3]Hospital del Mar, Barcelona, Spain*

Introduction: Several drugs have shown prognostic benefit in heart failure with reduced ejection fraction (HFrEF). However, they cannot always be administered to all patients in whom they are recommended. In addition, in many cases the target doses of these drugs are not reached.
Purpose: To analyze how many patients are given these recommended drugs and what doses are reached during the first year of follow-up in a heart failure unit (HFU).
Methods: We collected all patients with HFrEF included in our unit from July 2014 to December 2016. We collected prospectively data of baseline characteristics as well as data related to pharmacological treatment, type of drugs and doses administered, at baseline, at 6 months and at 1 year follow-up. We calculated the percentage of patients with each type of treatment and the percentage of dose respect to target dose.
Results: We included 95 patients with a mean age of 64.5 years (±13.2), 70.5% males. 66.3% of patients had hypertension and 35.8% had diabetes. Most frequent etiologies of HFrEF were ischemic 32.6%, idiopathic 27.4%, enolic 14.7% and hypertensive 10.5%. NYHA functional class at baseline was I 6.3%, II 41.1%, III 47.4% and IV 5.3%. Mean LVEF at baseline was 25.2% (±7.6) and mean NT-proBNP levels were 5544.5 μg/L (±5511.8). Mortality rate at 1 year follow-up was 5.6%. Table shows the percentage of patients with each pharmacological type and the average percentage of dose respect to target dose at baseline, at 6 months and at 1 year of inclusion in our HFU.
Conclusions: During the first year of follow-up, the percentage of patients with ACEI decreased in favor of a higher percentage with ARB or ARNI. The percentage with beta-blocker and that of ivabradine increased and that of MRA remained stable. Regarding the percentage of dose respect to target dose, it increased in all drugs except for ivabradine.

	Baseline	6 months	1 year			
%patients	%dose	%patients	%dose	%patients	%dose	
ACEI	70.5	38.6	61.5	46.1	58.8	53.2
ARB	16.8	46.6	20.8	54.3	21.4	58.6
Beta-blocker	91.6	52.9	94.5	57.6	94.2	62.0
MRA	81.1	64.7	81.3	64.9	80.2	70.3
ARNI	0	-	5.5	55.0	10.5	52.8
Ivabradine	20.0	75.4	27.5	72.0	27.9	72.2

ACEI = angiotensin-converting enzyme inhibitor; ARB = angiotensin receptor blocker; MRA = mineralocorticoid receptor antagonist; ARNI = angiotensin receptor neprylisin inhibitor.

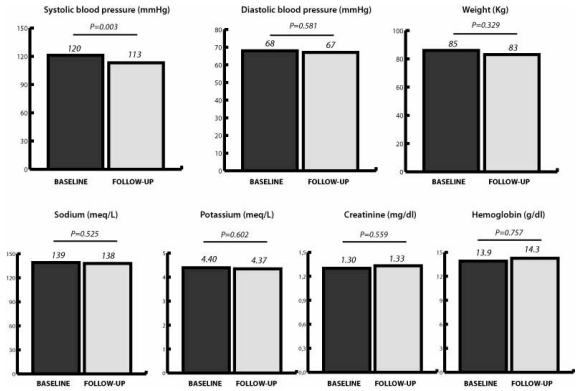
P340
The impact of baseline characteristics differences in patients treated in clinical practice with sacubitril/valsartan versus PARADIGM-HF.

P Pieter Martens[1]; H Belien[1]; M Dupont[1]; W Mullens[1]
[1]Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium

Background: Sacubitril/valsartan significantly reduced heart failure hospitalization and mortality in PARADIGM-HF. However, real world data from sacubitril/valsartan use are lacking, which might be useful to overcome hurdles in clinical practice towards its implementation.
Methods: We retrospectively assessed all baseline and follow-up data of consecutive heart failure patients receiving therapy with sacubitril/valsartan according to the Belgian reimbursement criteria, between December 2016 and July 2017 in a single center. Baseline characteristics, follow-up data and dose titration of sacubitril/valsartan were compared between patients in clinical practice and in PARADIGM-HF.

Results: A total of 120 patients (81% male) received therapy with sacubitril/valsartan. In comparison to the patients receiving sacubitril/valsartan in PARADIGM-HF, patients in clinical practice were older, had a higher serum creatinine, higher New York Heart Association (NYHA-class), lower systolic blood pressure (SBP) and a lower left ventricular ejection fraction (LVEF) (p-value all <0.05). Baseline characteristics more closely resembled the patients dropping out during the run-in faze than patients undergoing actual randomization. Even in comparison to patient experiencing dropout during the run-in phase, real world patients had a lower SBP ($p = 0.008$), lower LVEF ($p < 0.001$) and higher creatinine ($p = 0.034$). Patients were at high absolute baseline risk for adverse outcome as illustrated by the EMPHASIS-HF risk score of 6(IQR 3), in comparison to 5(IQR4) in PARADIGM-HF. After initiation of sacubitril/valsartan, NYHA-class significantly improved ($p < 0.001$). SBP dropped more than reported in PARADIGM-HF (7.1 ± 8.0mmhg vs. 3.2 ± 0.4mmHg;$p < 0.001$). Other clinical and biochemical factors did not change significantly (see figure). A total of 20.1% of patients tolerated dose uptitration during follow-up. Symptomatic hypotension (50%) and kidney insufficiency (30%) were the most common reasons for absence of uptitration. Patients received similar RAAS-inhibition before and after initiation of sacubitril/valsartan (57 ± 29 vs 55 ± 27% of target dose; p= 0.672), indicating optimal switch and uptitration of sacubitril/valsartan. However in comparison to patients enrolled in PARADIGM-HF, patients in clinical practice received a significant lower dose of sacubitril/valsartan (219 ± 122mg vs. 375 ± 75mg;$p < 0.001$).

Conclusion: Patients in clinical practice exhibit baseline characteristics that were associated with dropout during the run-in faze of PARADIGM-HF, which might lead to prescription of lower doses of sacubitril/valsartan in clinical practice. Nevertheless, patients in clinical practice are at high risk of adverse outcome, as illustrated by the EMPHASIS-HF risk score. As the relative risk reducing capacity of sacubitril/valsartan does not decreases in higher risk patients, the absolute risk reduction effect of sacubitril/valsartan might be more pronounced in patients encountered in clinical practice.



P341

Use of mineralocorticoid receptor antagonists in real-world patients with nonischemic heart failure and reduced ejection fraction: an analysis of HIJ-HF II study

Y Yuko Matsui[1]; A Suzuki[1]; K Nagara[1]; S Haruki[1]; T Kogure[1]; N Kikuchi[1]; H Hattori[1]; E Kawada[1]; T Suzuki[1]; T Shiga[1]; N Hagiwara[1]
[1]Tokyo Women's Medical University, Cardiology, Tokyo, Japan

Introduction: Mineralocorticoid receptor antagonists (MRAs) improve outcomes in heart failure with reduced ejection fraction (HFrEF), but may be under-utilized in contemporary clinical practice. The aim of this study was to assess predictors of MRAs non-use in HFrEF patients with nonischemic heart disease.

	OR	95% CI	p
Age ≥75	1.540	0.603-3.934	0.367
Men	1.415	0.600-3.335	0.428
without ICD	**6.572**	**1.138-37.959**	**0.035**
NYHA functional class III or IV	0.454	0.164-1.259	0.129
Hb <12g/dl	1.216	0.457-3.237	0.695
Albumin ≤3.0mg/dl	1.889	0.586-6.091	0.287
eGFR <60ml/min/1.73cm^2	1.599	0.654-3.907	0.304
serum potassium per 0.1mEq/ml increase	1.030	0.939-1.129	0.536
BNP <500pg/dl	**3.029**	**1.308-7.012**	**0.010**

without Nitrate	4.085	0.416-40.117	0.227

Risk factors associated with MRA non-use

Methods: We studied 214 HFrEF patients with nonischemic heart disease from a multicenter hospital-based cohort consisted of hospitalized HF patients between 2013 and 2014 (HIJ-HF II study). HIJ-HF II study was a retrospective observational study using the Japanese Diagnosis Procedure Combination (DPC) Database. Reduced left ventricular ejection fraction (LVEF) was defined less than 40%.

Results: HFrEF patients' average age was 66 +/- 17 and 138 (64%) patients were male. 145 (68%) patients were receiving MRAs. By the multivariate logistic regression analysis, there was a significant higher rates of MRAs non-use in patients without implantable cardioverter defibrillator (ICD) receiving (OR 6.572, 95% CI 1.138 to 37.959, $p < 0.05$), BNP less than 500 pg/ml (OR 3.029, 95% CI 1.308 to 7.012, $p < 0.05$). There was a trend toward higher rates of MRAs non-use in patients without angiotensin-converting-enzyme inhibitor (ACE-I) or angiotensin II receptor blocker (ARB) (OR 2.514, 95% CI 0.942 to 6.713, $p < 0.09$) (Figure).

Conclusion: MRAs remain underused in nonischemic HFrEF patients. We should understand the indications and benefits of MRAs in appropriate HFrEF patients suggested in guideline, especially with lower BNP and without ICD receiving.

Funding Acknowledgements: Unrestricted grant from Vifor Pharma and Research Projects of the Heart Failure Section 2017 from the Spanish Society of Cardiology.

Introduction: Treatment with intravenous ferric carboxymaltose (FCM) has shown to improve symptoms, functional capacity, and quality of life in patients with heart failure (HF) and iron deficiency (ID). However, the underlying mechanisms explaining these beneficial effects remains not fully understood. We hypothesize that myocardial iron changes, evaluated by cardiac magnetic resonance (CMR) after FCM would correlate with simultaneous changes in parameters of severity in HF.

Purpose: The aim of this study was to quantify CMR changes in myocardial iron content after administration of intravenous FCM in patients with HF and ID.

Methods: This is a multicentre, double-blind, randomized study. Fifty patients with stable symptomatic HF with left ventricular ejection fraction < 50% and ID will be randomly assigned 1:1 to receive CMF or placebo. Intramyocardial iron will be evaluated by T2* and T1 mapping CMR sequences before, 7 and 30 days after FCM. After 30 days, patients assigned to placebo will receive intravenous FCM in case of persistent ID. The main endpoint will be changes in myocardial iron content at 7 and 30 days. Secondary endpoints will include the correlation of these changes with the evolution of surrogate markers of disease severity: a) left ventricle ejection fraction, b) functional capacity, c) quality of life, and d) biomarkers.

Conclusions: The results of this study will add important knowledge about the effects of FCM on myocardial tissue and function.

P343

Comparative efficacy of renin-angiotensin system modulators on prognosis, right and left heart functional parameters in chronic heart failure in relation to mid-ranged or preserved ejection fraction

LR Liana Tumasyan[1]; KG Adamyan[1]
[1]*Institute of Cardiology, Yerevan, Armenia*

The aim of study was to compare efficacy of long-term therapy with ramipril (R, up to 10 mg), candesartan (C, up to 32 mg) alone and their combination with spironolacton (S, up to 50 mg) and their interaction on prognosis, left (LV) and right ventricular (RV), left (LA) and right atrial (RA) functional parameters by Doppler and tissue echocardiography, NT-pro-BNP (pg/ml) and hsCRP (ng/ml) levels in pts with III NYHA FC heart failure in relation to mid-ranged (HFmEF) or preserved (HFpEF) ejection fraction (EF).
Methods: 133 pts (age 60.1) with HFmEF (0.4 = EF <0.5) and 130 pts (age 63.2) with HFpEF (EF = 0.5) were randomly assigned to groups A and A‘ (n = 28 and 27, receiving R), B and B‘ (n = 27 and 26, receiving C), C and C‘ (n = 27 and 26, receiving R+S), D and D‘ (n = 25 and 26, receiving C+R) and E and E‘ (n = 26 and 25, receiving C+S) in addition to diuretics and beta-blockers.
Results: 1-, 2- and 3-year mortality (%) were 35.7 and 33.3, 42.9 and 40.7 and 50 and 48.1 in A and A‘; 33.3 and 30.8, 40.7 and 38.5 and 48.1 and 46.2 in B and B‘; 33.3 and 30.9; 40.7 and 38.4; 48.1 and 46.2 in C and C‘; 28 and 26.9; 32 and 30.8; 40 and 38.5 in D and D‘; and 26.9 and 24; 30.8 and 28; 38.5 and 36 in E and E‘ groups. 1-year hospitalization rates were 57.1 and 55.5 in A and A‘; 51.8 and 50 in B and B‘; 40.7 and 38.5 in C and C‘; 40 and 38.5 in D and D‘; and 34.6 and 32 in E and E‘, respectively. Survival analysis revealed relative risk (RR) reduction of 1-, 2- and 3-year mortality at 24.6 and 27.9; 28.2 and 31.2; 23 and 25.2 (p <0.05) in C+S groups with HFmEF and HFpEF, respectively, compared to group A and A‘. Significant reduction of hospitalization at 28.7 and 35.3 and 29.9 and 30.6 was depicted in groups receiving R+S and C+R (p <0.05) and at 39.4 and 42.3 in C+S group (p <0.01), in pts with HFmEF and HFpEF, respectively.1-year C+S treatment significantly (%, p <0.01 for all) decreased levels of NT-pro-BNP at 40.1.9, e‘ at 40.2, Ar-A at 74.1, increased PV SC at 62.1, RAFI at 52.9 and LAFI at 44.9 in HFmEF, and hsCRP at 44.6, TAPSE at 52.2, s‘ at 36.2, PA ET at 19.8 in HFpEF. 1-year R+S and R+C treatment, respectively, significantly (%, p <0.05 for all) improved levels of NT-pro-BNP at 35.1 and 36.6, TAPSE at 39.6 and 40.5, s‘ at 29.1 and 32.2, PA ET at 15.1 and 16.2. in HFmEF, NT-pro-BNP at 30.6 and 32.2, e‘ at 35.6 and 36.2, Ar-A at 52.2 and 54.1, RAFI at 42..8 and 43.3 in HFFpEF.
Conclusions: 1) Combined use of C+S associated with significant reduction of morbidity and mortality, while R+S and R+C treatment has resulted to significant improvement of hospitalization in pts with both HFmEF and HFpEF. 2) Changes of Ar-A = 50%, RAFI and LAFI, s‘, e‘ = 50%, NT-pro-BNP, hsCRP = 40%; PAET = 25% identified pts with cardiovascular risk reduction. 3) Prognostic improvement in pts treated by C+S was related to improvement of NT-pro-BNP level, LV diastolic functional, LA and RA functional parameters in HFmEF and to hsCRP and RV functional parameters changes in HFpEF.

P344

Prevalence of appropriate ICD shocks after primary prevention ICD implantation in chronic heart failure with reduced ejection fraction

D Denes Vagany[1]; ZS Majoros[1]; B Muk[1]; B Szabo[2]; P Bogyi[1]; M Szabo[1]; K Kosa[1]; ZS Bari[1]; B Polgar[1]; T Borsanyi[1]; M Dekany[1]; GZ Duray[1]; RG Kiss[1]; N Nyolczas[1]
[1]*Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary*;
[2]*Orebro University, Cardiology, Orebro, Sweden*

Background: According to the current ESC guidelines for the diagnosis and treatment of acute and chronic heart failure (HF) an implantable cardioverter–defibrillator (ICD) is recommended for primary prevention (PP) of sudden cardiac death (SCD) - regardless of aetiology - in patients with symptomatic HF (NYHA Class II–III), and a left ventricular ejection fraction = 35% despite = 3 months of optimal medical treatment (OMT) who are expected to survive longer than one year with good functional status. The PP ICD absolute benefit is greater in patients (pts) with ischaemic HF. The recently published DANISH study showed that ICD in non-ischemic HF does not reduce all-cause mortality. The survival benefit in association with an ICD implantation was observed only in patients below 70 years of age in that trial.
Aim: The aim of our study was to investigate the prevalence of appropriate ICD shocks in a real-life HFrEF patient cohort, who received device therapy according to the current ESC guidelines.
Methods: We analysed the data of 235 HFrEF pts referred for PP ICD implantation to our institute between 2013 and 2014 (male: 76.6%, ischemic etiology: 48.1%, mean age: 63.4 ± 10.6 years, NYHA: 2.8 ± 0.8, LVEF: 26.1 ± 6.5%, CRT-D: 57.8%), who received their devices according to the current ESC guidelines. Every pt was on OMT at least 3 months before device implantation.
Results: 113 out of the 235 pts had ischemic and 122 had non-ischemic etiology. During the 31.5 ± 12.7 months follow-up we detected 14 appropriate ICD shocks in the subgroup of pts with ischemic HF (12.4%) and 9 appropriate ICD shocks in non-ischemic pts (7.4%). In the ischemic subgroup 11 appropriate shocks (15.5%) were observed among pts < 70 years (71 pts) and 3 appropriate shocks (7.1%) in pts = 70 years of age (42 pts). In the non-ischemic patient group 9 appropriate shocks (9.1%) occurred in pts who were < 70 years old (99 pts). There was no appropriate ICD shock in patients = 70 years of age.
Conclusion: Our observation, in line with the results of the DANISH study, may indicate that elderly patients (= 70 years) with HFrEF and non-ischemic etiology benefit less from PP ICD implantation than those with ischemic etiology or those younger than 70 years.

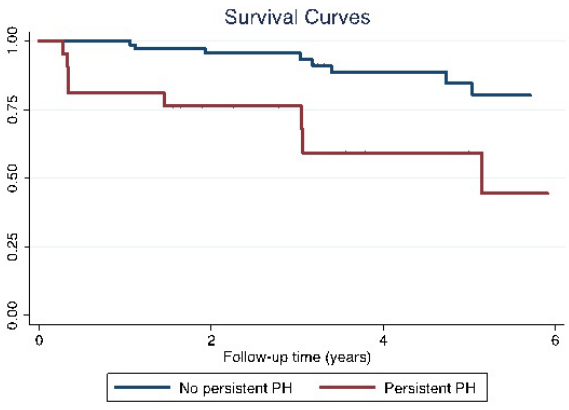
Introduction and **Purpose:** Pulmonary hypertension (PH) is a prognostic factor in patients with heart failure with reduced ejection fraction undergoing cardiac resynchronization therapy (CRT). Whether the change in pulmonary artery systolic pressure (PASP) after CRT has prognostic meaning is less established. We aimed to study the clinical correlates of persistent PH after CRT and its prognostic significance.
Methods: We retrospectively reviewed clinical and echocardiographic data of patients undergoing CRT at our center since 2012. We included those who had available echocardiographic data before and 6-12 months after CRT. Persistent PH was defined as PASP over 40mmHg before and after CRT implantation. All-cause mortality was assessed by chart review.
Results: Of the 207 patients included, 90 (43%) had available Doppler measurements on tricuspid regurgitation before and after CRT. The mean age was 69+- 10 yo with 59% of male patients and 54% of non-ischemic etiology. Most patients (79%) were in NYHA class III previous to CRT. The mean baseline PASP was 39 +- 15 mmHg with 33 patients (37%) having a baseline PASP > 40 mmHg. There were no statistically significant differences in age, sex, etiology, classic cardiovascular risk factors and current treatment strategies between patients with and without PH.
There were 21 (23%) patients who had persistent PH after CRT. These were more likely to have atrial fibrillation (44% vs 76%, p = 0.008) and non-LBBB EKG pattern (15% vs 33%, p= 0.09), lower hemoglobin level (13.2g/dL vs 12.4 g/dL, p = 0.06)) and higher NT-proBNP levels (mean: 1578pg/mL vs 4545pg/mL, p= 0.022). The cardiac phenotype of patients with persistent PH had significantly larger atrial and ventricular cavities.
Interestingly, the change in PASP did not correlate with LVEF change after device implantation (r=-0.06 ; p = 0.64).
Over a mean follow-up of 3.6 ± 1.8 years, there were 17 deaths. Persistent PH patients had a 4-fold increased risk of dying (HR 4.31; 95%CI: 1.61-11.51). It independently predicted death after adjusting for age and gender (HR 4.80; 95%CI: 1.71-13.48), the change in LVEF (HR 5.43; 95%CI: 1.19-24.69), or baseline NT-proBNP (HR 4.54; 95%CI: 1.50-13.75).
Conclusions: Persistent PH after CRT implantation is associated with a more severe clinical and echocardiographic profile. It marks patients with significantly increased risk of dying either because of the baseline severity of the disease, or the lack of response to CRT. In both cases, persistent PH after CRT powerfully signals HF patients with worse prognosis.



P346

The problem of response to cardiac resynchronization therapy: who are non-responders?

AM Soldatova[1]; VA Kuznetsov[1]; SM Dyachkov[1]; TN Enina[1]; DV Krinochkin[1]
[1]*Tyumen Cardiology Research center, Tyumen, Russian Federation*

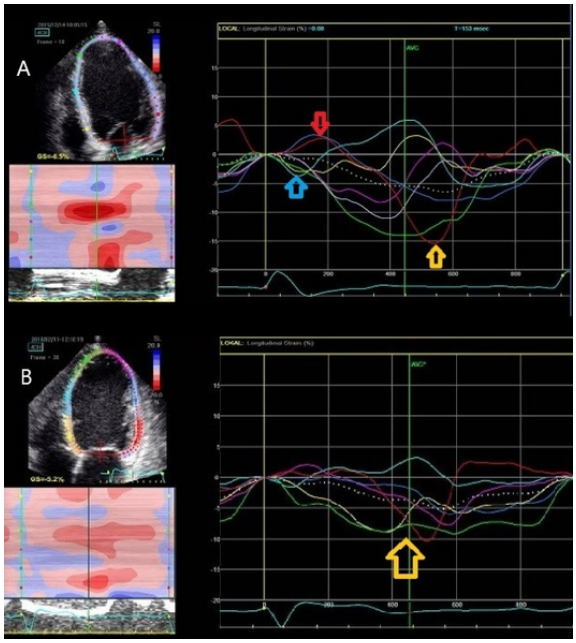
Background: In patients with congestive heart failure (CHF) treated with cardiac resynchronization therapy (CRT) a reduction of = 15% in left ventricular end-systolic volume (LVESV) is a commonly used criterion of the response. Some patients have significant clinical improvement, decrease in NYHA functional class, good long-term survival, however, they demonstrate suboptimal improvement of cardiac remodeling after CRT and they are identified as nonresponders.
Purpose: To evaluate clinical, morphological, functional features and mortality in patients with suboptimal CRT response.
Methods: The study enrolled 109 patients (mean age 54.6 ± 9.9 years, 83.5% men) with NYHA functional class II-IV. Clinical, electrocardiographic and echocardiographic parameters were evaluated at baseline, 1, 3 months and each 6 months after implantation. According to the best decrease of LVESV (mean follow-up period 34.8 ± 16.7 months) patients were classified as non-progressors (n = 18; decrease in LVESV 0-14%), responders (n = 45; decrease in LVESV 15-29%) and super-responders (SR) (n = 46; reduction in LVESV = 30%).
Results: At baseline groups were matched for main clinical characteristics, the proportion of patients with atrial fibrillation, width of the QRS complex, and the presence of left bundle-branch block (LBBB). Echocardiographic parameters didn't differ between the groups.
All groups demonstrated significant reverse remodeling, increase in left ventricular ejection fraction (LVEF), increase in 6-minute walking distance. SR demonstrated the best improvement of clinical and functional parameters after CRT. However, improvement in LVEF, LVESV, NYHA functional class between responders and non-progressors were found similar as well as in dynamics mean values of these parameters were comparable.
The survival rates were 100% in SR, 80% in responders and 88.9% in non-progressors (Log-rank test p = 0.004). Survival rates in responders and non-progressors didn't differ significantly (Log-Rank test p = 0.213) between the groups.
Conclusion: Patients with reduction in LVESV 0-14% demonstrate improvement in clinical status and LVEF and survival rates compared to subjects with reduction in LVESV 15-30%. Non-progressors demonstrate similar survival as responders in long-term period.
Taking into account the natural course of CHF we consider that functional stabilisation and absence of CHF progression in patients with LVESV reduction 0-14% is a variant of good response and these patients should not be identified as non-responders. Thus, the only use of percentage change in LVESV to define CRT response is not always correct.

P347

Role of the definition of electrocardiographic and echocardiographic variants of left bundle branch block in predicting response to cardiac resynchronization therapy.

S Svetlana Kashtanova[1]; M Utsumueva[1]; E Gupalo[1]; V Shitov[1]; G Tarasovsky[1]; V Kiktev[1]; M Saidova[1]; N Mironova[1]; S Golitsyn[1]
[1]*National medical research center of cardiology, Moscow, Russian Federation*

Introduction: Cardiac resynchronization therapy (CRT) improves prognosis in patients with heart failure (HF) and left bundle branch block (LBBB). However, a large number of patients does not benefit from CRT. The search of the reproduced markers of response on this therapy is an important problem.



Different echo contraction patterns

Purpose: To assess the value of the complex analysis of electrocardiographic (ECG) and echocardiographic (echo) variants of LBBB in predicting the success of CRT.
Methods. Our study included 17 patients (age 58,76 ± 8,16 years (mean ± SD), 65% men) with HF due to ischemic (12%) or non-ischemic (88%) cardiomyopathy, who had the left ventricular (LV) ejection fraction (LVEF) < 35% despite optimal pharmacological therapy, QRS duration = 130ms, LBBB and sinus rhythm. All patients underwent successful CRT implantation. Depending on the presence /absence of ECG-criteria, proposed by Strauss D.G. et. al, patients were divided into 2 groups: 1-strict LBBB (QRS duration = 140ms in men or = 130 ms in women, QS/rS in lead V1 and mid-QRS complex slurring/notching in >2 of leads V1,V2,V5,V6,I,aVL) and 2-other LBBB morphology. In addition to standard echocardiography, global longitudinal 2-dimensional strain (GLS) and LBBB contraction pattern were analysed. Also, patients were divided into 2 groups based on the presence of one of the echo patterns of LV dyssynchrony: "classical/typical LBBB" and "heterogeneous/atypical". (Figure. Different contraction patterns by 2-dimensional strain echocardiography. A. Classical LBBB contraction pattern, including early terminated shortening of at least 1 basal or midventricular segment in the septal wall (blue arrow), early stretching of at least 1 basal or midventricular segment in the lateral wall (red arrow), late lateral peak contraction after aortic valve closure (yellow arrow).
B. Atypical LBBB contraction pattern: segments show asynchronous peak shortening timed at aortic valve closure (yellow arrow)). Response to CRT was defined as a reduction in LV end-systolic volume (LVESV) of >15% at 6 months follow up.
Results: Within the group consisting of 17 patients, 14 patients (82%) responded to CRT. Among these 14 patients, 12 (86%) had strict LBBB criteria by ECG and "classical" LBBB contraction pattern. From the remaining 3, who did not respond to CRT, 2 patients did not have true LBBB-criteria by echo and ECG. The mean GLS was significantly worse in responders than in non-responders (364 ms ± 81ms vs 241 ms ± 50ms, $p < 0.05$).
Conclusions. Complex analysis of strict LBBB ECG criteria and echo contraction pattern in combination with GLS are promising potential parameters to predict benefit from CRT in patients with HF.

P348

Differences in VWF activity in patients with von Willebrand disease type 2A versus LVAD patients with the acquired von Willebrand syndrome.

S Deconinck[1]; L Delrue[2]; C Tersteeg[1]; E Bailleul[2]; N Vandeputte[1]; I Pareyn[1]; H Deckmijn[1]; M Goethals[2]; S Verstreken[2]; R Dierckx[2]; S De Meyer[1]; N Itzhar-Baikian[1]; K Vanhoorelbeke[1]; M Marc Vanderheyden[2]
[1]*KU Leuven, KULAK, Laboratory for Thrombosis Research, IRF Life Sciences,, Kortrijk, Belgium*; [2]*OLV Hospital Aalst, Cardiovascular Center, Aalst, Belgium*

Background: Patients suffering from von Willebrand disease (VWD) type 2A are diagnosed by an increased bleeding diathesis due to an impaired von Willebrand

factor(VWF) function with severe loss in high molecular weight (HMW) VWF multimers. Patients with implanted left ventricular assist devices (LVAD) show a moderate decrease in HMW VWF multimers and are therefore nowadays diagnosed with the acquired von Willebrand syndrome (aVWS). However, only a small portion of LVAD patients suffers from bleeding complications.
Aim: Side by side comparison of VWF function in patients with VWD type 2A and LVAD-induced aVWS to demonstrate the difference in VWF activity, and hence their different effect on bleeding, in both groups of patients.
Methods: Plasma samples from 9 known VWD type 2A and from 9 LVAD patients were analyzed for VWF:Ag, VWF:CB and VWF:RCo using ELISA and for VWF multimers using sodium dodecyl sulphate (SDS) agarose gel electrophoresis and compared to plasma of healthy donors.
Results As expected, VWF function was impaired in all VWD type 2A patients with a severe reduction in HMW VWF multimers compared to healthy individuals (0.0% (0.0-12.3) versus 34.2% (31.7-38.9) respectively, $p < 0.0001$) ensuing in decreased (< 0.7) VWF:CB/VWF:Ag and VWF:RCo/VWF:Ag ratios. In contrast, VWF function was less affected in LVAD patients where only a moderate reduction in HMW VWF multimers was noted (20.3% (15.8-21.7)) with six out of 9 LVAD patients having a VWF:CB/VWF:Ag or VWF:RCo/VWF:Ag ratio within normal range (= 0.7).
Conclusions: Whereas the decrease in HMW VWF multimers together with the depressed VWF function are responsible for the severe bleeding disorder observed in VWD type 2A pts, HMW VWF multimers and hence VWF function are only moderately impaired in LVAD-induced aVWS patients,. Accordingly, these small defects in VWF function can not alone be responsible for the bleeding diathesis in LVAD pts which might explain why only a small portion of them suffer from bleeding complications.

P349
Outcomes following electrical cardioversion for ventricular arrhythmias in patients with Left Ventricular Assist Devices (LVADs)

F Farah Al-Saffar[1]; A Naeem[2]; S Dunlay[3]; D Yip[4]; B Boilson[3]; E Steidley[1]; SK Mulpuru[1]
[1]Mayo Clinic, Cardiology, Scottsdale, United States of America; *[2]Maricopa Integrated Health System, Internal Medicine, Phoenix, United States of America*; *[3]Mayo Clinic, Cardiology, Rochester, United States of America*; *[4]Mayo Clinic, Jacksonville, United States of America*

Background: Ventricular arrhythmias (VA) are common in patients with left ventricular assist device (LVAD) either due to the underlying worsening heart failure; scar formation, LVAD suck down events, or by alteration of ion-channel dynamics.
Purpose: The characteristics of VA in LVAD patients undergoing electrical cardioversion have not been previously described. We sought to examine the success rates and outcomes following electrical cardioversion in this population.
Methods: Adult patients with LVADs obtaining health care at the Mayo Clinic enterprise practice (Minnesota, Arizona, and Florida) from January 2008 to December 2017 were included (figure). The target population was patients who have continuous-flow LVADs and had VA requiring cardioversion. We examined patient demographics were examined, type of cardiomyopathy, LVAD indication, and cardioversion success rates and subsequent outcomes. Shock strength, and the decision to shock externally or via implantable cardioverter defibrillator (ICD) was at the discretion of the supervising clinician. Therapy failure was defines as failure of the first shock to restore sinus rhythm, or recurrence of VA briefly after cardioversion.
Results: A total of 37 patients (mean age 56.55 ± 14.8 years, 25 [67.5%] were men) undergoing electrical cardioversion for VA were included (figure). 14 patients had non-ischemic cardiomyopathy and 22 had ischemic cardiomyopathy. In 18 cases the LVAD was a bridge to transplant (BTT) while in 19 cases it was a destination therapy (DT). Eleven cases (29.7%) had ventricular fibrillation. Thirteen patients in the BTT group were on amiodarone vs. 14 in the DT group. In 14 cases (38.89%) there was a failure of the first therapy or recurrence of VA. VA also tended not to respond as well to submaximal energy cardioversion. There was a higher rate of failure to convert to sinus rhythm in BTT LVAD compared to DT (47.06% vs 31.58% respectively), although not statistically significant. Patients on amiodarone had higher therapy failure (OR 2.78, [CI 0.99 - 7.76], p value 0.05).
Conclusions: Low energy shocks in LVAD patients may be associated with lower success rates. There was also a higher success rate of cardioversion in patients with DT LVAD. Patients on amiodarone were more prone to therapy failure, which could be a precursor of them having a previously-identified arrhythmogenic substrate. This suggests the need for more vigilant management when facing VA in these patients.

Novel inflammatory biomarkers after long-term ventricular assist device implantation

M Holek[1]; J Kettner[1]; A Jabor[2]; J Franekova[2]
[1]Institute for Clinical and Experimental Medicine (IKEM), Department of Cardiology, Prague, Czech Republic; *[2]Institute for Clinical and Experimental Medicine (IKEM), Department of Laboratory Methods, Prague, Czech Republic*

Introduction: Long-term left ventricular assist device (LVAD) implantation is proved treatment option for patients with end-stage heart failure. Infectious complications (IC) are one of the main causes worsening prognosis after LVAD implantation. Procalcitonin (PCT) is nowadays widely used and presepsin (PSEP) is also one of promising novel biomarkers for diagnosis of a bacterial infection. However, data about PCT and PSEP dynamics in LVAD patients are lacking.
Methods: A total of 50 consecutive patients indicated to LVAD implantation were included. PCT and PSEP levels were prospectively assessed before surgery and during 30 day follow-up - 1st, 2nd, 14th and 30th post-operative day (POD). Values were compared according to the presence of IC and are presented as median with interquartile range in μg/l (PCT) or ng/l (PSEP).
Results: In all patients PCT levels were low before surgery (0,16, 0,10-0,34). They raised significantly within 1st (5,49, 2,52-18,42; $p < 0,001$) and 2nd POD (5,65, 2,47-19,53; $p < 0,001$). Till 14th and 30th POD we observed decrease of PCT back to baseline values (0,21 /0,11-0,68/ and 0,09, /0,07-0,19/ respectively). PSEP levels were mildly elevated before LVAD implantation (543 /340-882/), raised significantly within 1st (892 /557-1362/, $p = 0,002$) and 2nd (1015 /659-1494/, $p < 0,001$) POD and decreased in 14th (838 /505-1620/) and 30th POD (566 /420-867/).
IC occurred after LVAD implantation in 11 patients (22%). Interestingly, there was no significant difference in PCT or PSEP levels between patients with or without IC during whole follow-up.
20 subjects (40%) had acute renal failure (ARF) and 17 of them needed renal replacement therapy (RRT) initiated between 1st and 7th POD. Patients with ARF had significantly higher PCT levels 2 days after surgery and further (day 2 - 24,15 /4,28-76,7/ vs. 3,3 /2,21-9,03/, $p = 0,045$, day 14 - 0,68 /0,24-2,25/ vs. 0,13 /0,09-0,28/, $p < 0,001$, day 30 - 0,21 /0,12-0,34/ vs. 0,08 /0,04-0,12/, $p = 0,005$). ARF increased PSEP levels significantly only 14 days after LVAD implantation (1926 /838-5936/ vs. 688 /430-1181/, $p = 0,005$).
Right ventricular assist device (RVAD) had to be implanted in 7 patients (14%). Also subjects with RVAD had higher PCT and PSEP values. This difference reached the significance only for PCT 14 days after surgery (8,02 /0,37-31,95/ vs. 0,17 /0,11-0,37/, $p = 0,018$).

Conclusion: Our data show that ability of PCT or PSEP to detect infectious complications in patients after LVAD implantation is limited and their concentrations more likely correlate with post-operative complications in general. Although specific mechanism is not known, explanation could possibly be activation of systemic inflammatory response syndrome (SIRS) caused by critical perioperative state including organ dysfunction, cardiopulmonary bypass during surgery and contact with non-physiological surface in LVAD/RVAD or RRT.

P351

Short-term mechanical bridge to heart transplantation

N S Piatrovich[1]; L G Shestakova[1]; Y P Ostrovsky[1]; R G Yarosh[1]
[1]Republican Scientific and Practical Centre of Cardiology, Department of extracorporeal blood circulation, Minsk, Belarus

Background: Heart transplantation (HT) is a golden standart for treating the end-stage chronic heart failure (CHF). Mono- or biventicular assist devices,extracorporeal membrane oxygenation or a total artificial heart are used in potential recipients with unstable hemodynamics, refractory to the maximum doses of cardiotonic agents during 24-48 hours and multi-organ dysfunction.Mechanical circulatory support (MCS) salvages time to complete a transplant evaluation.
Purpose: To analyze and estimate the effectiveness of pre-transplant application of temporary MCS in patients with CHF used as a bridge for heart transplantation or for putting on a waiting list.
Methods: The study conducted a retrospective analysis of 13 patients with decompensation of CHF, requiring temporary MCS. In 38,5% (n = 5) the ventricular support system Centrimag Levitronix was used (3 left- and 2 biventricular assist devices), in 61,5%(n = 8)- peripheral extracorporeal membrane oxygenation in combination with invasive methods of LV unloading: percutaneous atrioseptostomy (n = 6), drainage of LV (n = 2) and intraaortic balloon pumping (n = 1).Selective antegrade perfusion was performed in 4 cases to prevent lower limbs ischemia. 53,8% (n = 7) required renal replacement therapy, 7,7%(n = 1)- hepatic replacement therapy (albumin sorption) .
Results: In Belarus during the period 2009-2017 273 heart transplants were performed. 11,4%(n = 31) were preceded by MCS(10 short-term and 21 long-term). The main ethiology in 61,5% was dilated cardiomyopathy, in 30,8%- ischemic, in 7,7%- acute myocardial infarction. Indication for MCS was decompensation of CHF: AP 88 ± 19,5 mm Hg on the background of initropic support(100%), CI 2,13 ± 0,51 l/min/m^2, PAP 50,91 ± 11,48 mmHg, PAWP 22,5 ± 6,6 mmHg, WI 4,87 ± 1,75, LVEF 16,83 ± 5,59%, RVEF 30,55 ± 6,78%, SV 48,67 ± 22,98 ml,proBNP 9365 pg/ml, pH 7,3 ± 0,1, BE -6,23 ± 6,5 mmol/l, lactate 6,48 ± 3,1 mmol/L, AST 530U/L, ALT 771,17U/L, LDH 822,9 U/l, bilirubin 75,86 mmol/l.Mean duration of MCS was 14,8 ± 7,4 days. In 100% there was a significant positive dynamic of biochemical indices and decrease in lactate by 5,4 times. Echocardiography examination revealed reduction volume of left ventricle and increase of LVEF by 14,68%, RVEF by 23,18%, CI by 43,19%. Ten patients underwent heart transplantation. One ECMO case was converted to a long-term heart assist device. Three patients(23,1%) died due to complications(perioperative myocardial infarction, massive bleeding, irreversible multiorgan dysfunction, DIC, sepsis). Hospital survival was 76,9%.
Conclusions: Short-term MCS effectively provides maintenance of vital functions, resolution of organ disorders, normalization of biochemical indices and greatly improves survival for patients with severe refractory hemodynamic instability awaiting HT.

P352

Treatment of hypercholesterolaemia with PCSK-9 inhibitors in patients after cardiac transplantation

M Michael Kuehl[1]; J Jozwiak[2]; C Binner[3]; J Fischer[3]; J Hahn[3]; A Meyer[3]; A Addas[3]; K Jawad[3]; J Garbade[3]; M Borger[3]
[1]Heart Center of Leipzig, Rhythmology, Caridac Surgery, Leipzig, Germany; *[2]Heart Center of Leipzig, Cardiology, Leipzig, Germany*; *[3]Heart Center of Leipzig, Cardiothoracic Surgery, Leipzig, Germany*

Background: Hypercholesterolaemia is common in patients after cardiac transplantation affecting over 90% of patients 5 years post transplantation. Statin therapy after transplantation has received a class I indication irrespective of cholesterol levels. It has been shown to improve survival and has been implicated in reducing fatal rejections, decreasing terminal cancer risk and reducing the risk of cardiac allograft vasculopathy (CAV). However, some patients cannot tolerate statins because of their side effects or demonstrate residual hypercholesterolaemia. Monoclonal antibodies that inhibit proprotein convertase subtilisin-kexin type 9 (PCSK9) have been shown to reduce low-density lipoprotein (LDL) cholesterol levels and the risk of cardiovascular events in patients with dyslipidaemia. There are no published data on the effect of this medication class on cholesterol levels in patients after cardiac transplantation.
Purpose: To examine the effects of treatment with PCSK9 inhibitors on cholesterol, LDL and HDL levels, acute rejection episodes and ejection fraction in patients after cardiac transplantation.
Methods: In this retrospective study we investigated patients who were treated with Evolocumab or Alirocumab either because of intolerance of statins or residual hypercholesterolaemia with evidence of CAV. We compared the data of patients prior to the start with these medications with their most recent dataset.
Results: We identified ten patients (nine men; mean age 58 ± 6 years) who underwent cardiac transplantation 8.3 ± 4.5 (range 3-15) years ago. CAV of varying severity was present in seven patients. The reason for PCSK9 inhibitor therapy (Evolocumab: 140mg every two weeks n = 8; Alirocumab: 75mg every two weeks n = 2) was statin intolerance (n = 6) or residual hypercholesterolaemia despite statin therapy (n = 4). The treatment duration was on average 296 ± 124 days and lead to a reduction of total Cholesterol (281 ± 52 mg/dl to 197 ± 36 mg/dl; p <0.001) and LDL Cholesterol (170 ± 22 mg/dl to 100 ± 39 mg/dl; p <0.001). No significant effects on HDL Cholesterol, BNP, Creatine Kinase or hepatic enzymes were noticed. There were no unplanned hospitalisations, episodes of rejections, change of ejection fraction or opportunistic infections (CMV, aspergillosis, candidiasis). Both patients on Alirocumab developed liver pathologies: One patient died of hepatocellular carcinoma and the other developed hepatitis E.
Conclusion: Our study demonstrates that PCSK9 inhibitors lead to a significant reduction of total and LDL Cholesterol in heart transplantation recipients with hypercholesteraemia and therapeutic failure of statin regimens or statin intolerance. No effect on cardiac function or episodes of rejections were noticed. Larger and long-term studies are needed to establish the safety and efficacy of Evolocumab and Alirocumab after cardiac transplantation with a special focus on the development or progression of CAV as well as liver pathologies.

P353

Risk factors to develop new-onset diabetes mellitus after heart transplantation

A Abril Molina[1]; A Grande-Trillo[1]; D Rangel-Sousa[1]; JM Sobrino-Marquez[1]; E Lage-Galle[1]; C Gonzalez-Portilla-Concha[1]; J Rodriguez-Ortuno[1]
[1]University Hospital of Virgen del Rocio, Heart Failure and Heart Transplantation Unit, Seville, Spain

Introduction:
New-onset diabetes mellitus (DM) after heart transplantation (HT) is associated, as well as established previous DM, with worse prognosis. Our aim is to identify risk factors related to the development of DM during the first year after HT in patients with prediabetes before HT.
Methods: Retrospective analysis of HT recipients from 2007 to 2016 in our center with prediabetes status (HbA1c = 5.7%) before HT. We analyzed immunosuppressive therapy at hospital discharge and during the first year, body mass index (BMI), pre-transplant HbA1c level and the development of new-onset diabetes during first year after HT.
Results: We analyzed 106 patients (50 ± 12 years old; 73,8% male). 27,4% (n = 29) developed DM during first year after HT. Univariate and multivariate analysis are shown in the Table 1.
Conclusions: Rate of new-onset DM in the first year after HT in patients with prediabetes is high. Higher levels of tacrolimus and pre-transplant HbA1c are independent risk factors for the development of DM. To pay attention of these levels

Table 1

Univariate analysis

	No develop DM	New-onset DM	p-value
Gender (male)	75.32%	72.4%	0.47
Age (years)	50±12	50±14	0.8
BMI (kg/m^2)	24.92	26.62	0.09
HbA1c pre-transplant (%)	5.68	6.29	0.004

†Mean tacrolimus levels during first year after heart transplantation. ‡ Patients treated with everolimus (%) during first year after heart transplantation. Abbreviations: BMI: Body mass index; DM: diabetes mellitus

and establish healthy lifestyle in these patients could reduce the incidence of DM after HT.

P354

Is age of 60 reasonable refusal of heart transplantation?

V Krachak[1]; V Podpalov[2]; L Shestakova[1]; Y Ostrovsky[3]

[1]Republican Scientific and Practical Centre of Cardiology, Extracorporeal circulation, Minsk, Belarus; *[2]Republican Scientific and Practical Centre of Cardiology, Cardiac surgery #3, Minsk, Belarus*; *[3]Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Introduction: Now heart transplantation (HT) in elderly people is becoming a burning task. The age of 60 is considered to be a cutoff point after which the outcomes of HT are controversial and HT is seemed to be not always reasonable.
Purpose: To estimate outcomes after HT in people aged 60 years and older.
Methods: 260 HT operations have been conducted in our Centre during HT program developing since 2009. Among all operated patients 2 groups were selected: the 1st group - the main group with 34 patients aged 60 years and older; the 2nd group - the control group with 67 patients aged 50-59 years. The average age in the main group was 54,76 ± 2,93 years and in the control group - 63,91 ± 3,1 years (??0,0001). There were no significant differences in proportions of women and men: 2,9%(n = 1) and 97,1%(n = 33) respectively in the 1st group versus 13,4%(n = 9) and 86,6%(n = 58) in the 2nd group (p>0,05). The most wide spread etiology leading to HT was dilated cardiomyopathy which was in 50% (n = 17) in the 1st group and 53,7% (n = 36) in the 2nd group of patients; then ischemic cardiomyopathy came 35,3% (n = 12) versus and 41,8% (n = 28) respectively; other cases occupied 14,7% (n = 5) and 4,5% (n = 3) respectively. The groups of patients were similar by the following parameters: body mass index was 22 ± 9,69 in the 1st group versus 23,3 ± 10,67 in the 2nd group (p = 0,2); systolic pulmonary artery pressure - 49,82 ± 10,4 versus 50,59 ± 11,69 mm Hg respectively (p = 0,96), donor age - 35,09 ± 8,4 versus 35,93 ± 8,73 years respectively (p = 0,062), cold ischemic time - 192,83 ± 43,79 versus 203,05 ± 57,75 min respectively (p = 0,34). 30-day and 1-year survival rates were estimated as outcomes after HT.
Results: Patients from the main group treated in ICU after HT for 10,5 ± 8,36 days, the time was similar with the patients from the control group - 7,97 ± 4,61 days (p = 0,62).There were no significant differences in outcome in 2 groups: 30-day survival was 79,4% in the main group and 86,6% in the control group (p>0,05); 1-year survival was 67,6% in the 1st group and 77,6% in the 2nd group (p>0,05).
Conclusion: According to gained data age of 60 years and older doesn't seem to be a contraindication for heart transplantation.

P355

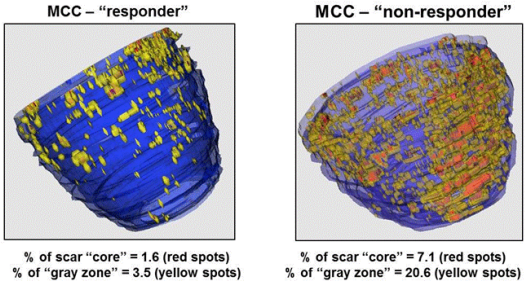
Structural changes of the left ventricular myocardium according to magnetic resonance imaging and response to cardiac contractility modulation therapy

E M Elena Gupalo[1]; NA Mironova[1]; OP Aparina[1]; OV Stukalova[1]; MD Utsumueva[1]; SP Golitsyn[1]

[1]Russian Cardiology Research Center, Moscow, Russian Federation

The novel therapeutic option in patients (pts) with chronic heart failure (CHF), low left ventricular ejection fraction (LVEF) and narrow QRS complex is cardiac contractility modulation (CCM). Pts with non-ischemic etiology of HF, LVEF of = 25% have the greater response to CCM than others. Cardiac MRI provides a noninvasive phenotyping tool for accurate and easy detection and quantification of myocardial fibrosis by probing the retention of gadolinium-contrast agent in myocardial tissue reflection the grade of myocardium structural changes. The value of LV structural changes for the response to CCM therapy is not yet known.
The aim of the study was to evaluate the value of left ventricular myocardial fibrosis according to MRI data for the response of CCM therapy.
Materials and methods: The study included 12 pts (10 male, mean age 46 ± 14 years) with chronic heart failure (CHF) NYHA functional class II-III, normal duration of the QRS complexes (96 ± 16 ms) and significantly reduced LVEF (28 ± 4% at the time of inclusion in the study) despite optimal medical. The etiology of CHF was ischemic cardiomyopathy in 2 pts and non-ischemic in 10 pts. Cardiac MRI was performed in all pts with high resolution late gadolinium enhancement (LGE) before devices' implantation. Left ventricular fibrosis quantification was performed with the original software LGE Heart Analyzer. In all pts the device for MCC (Optimizer IV or Optimizer SMART) was implanted. At 6 months follow-up the echo parameters, Nt-proBNP, a 6-minute walking test (SMWT) were assessed.
Results: According to the cardiac MRI, the volume of fibrosis was 1.6 [1.1, 5.5]% of the total volume of the myocardium. In 5 (41.6%) pts, this index exceeded 5%. In these 5 pts, the improvement of LVEF was not detected. In contrast, the rest 7 (58.3%) pts with 1.35 [0.73, 1.6]% fibrosis volume demonstrated an increase in LVEF by an average of 11 ± 5.6 after 6 months of CCM therapy. The increase in LVEF was accompanied by a decrease in the of Nt-proBNP level by an average of 479 [340, 1000] pg/ml and an increase in walking distance in SMWT at 192 ± 36 m.
Conclusions: Cardiac MRI with quantitative evaluation of scar tissue carries key information that allows to predict the increase of LVEF during CCM therapy in patients with CHF.

Three-dimensional reconstruction of MRI LGE left ventricular images obtained with the originally developed software LGE Heart Analyzer



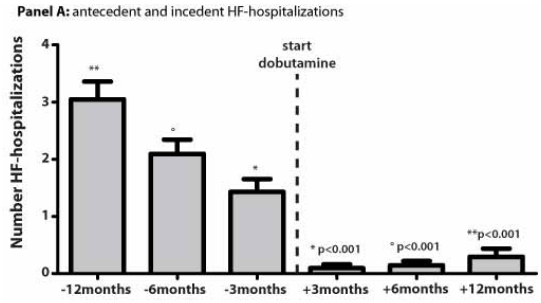
P356

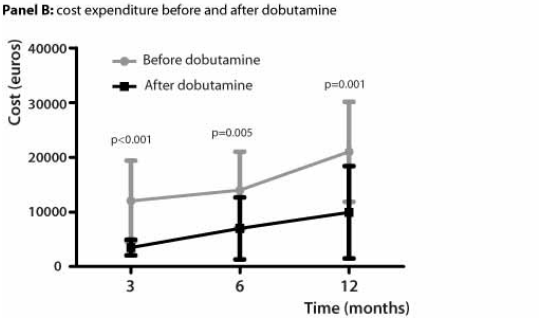
Effects of intravenous home Dobutamine in palliative end-stage heart failure on quality of life, heart failure hospitalization and cost-expenditure.

P Pieter Martens[1]; J Vercamme[1]; W Ceyssens[1]; L Jacobs[1]; M Dupont[1]; W Mullens[1]

[1]Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium

Background: In patients with palliative end-stage heart failure, interventions that could provide symptomatic relief and prevent hospital admissions are important. Intravenous inotropes have been advocated by guidelines for such a **Purpose:** We sought to determine the effect of an easy to employ continuous intravenous home dobutamine regimen on symptomatic status, hospital-stay, mortality and cost-expenditure.
Methods: All consecutive end-stage heart failure patients not eligible for advanced therapies and discharged with intravenous continuous home dobutamine from a single-tertiary center between April 2011 and January 2017, were retrospectively analyzed. Dobutamine was infused through a single-lumen central venous catheter with a small pump which was refilled by a nurse once on a daily basis. All patients received a similar dose of 2 vials (250mg/20ml) of dobutamine with 10 cc of glucose 5% in a single 50ml syringe. This 50ml volume was administered at 1.9ml/hour, which equates to approximately 4 mcg/kg/min for an 80kg patient. Symptomatic status was longitudinally assessed as the change in New York Heart association (NYHA) class and patient global assessment (PGA)-scale. Antecedent and incident heart failure hospitalizations were determined in a paired fashion and the impact cost-expenditure was assessed.





Results: A total of 21 patients (age 77 ± 9 years) were followed for 869 ± 647 days. At first follow-up (6 ± 1 weeks) after the initiation of dobutamine, patients had a significant improvement in NYHA-class (-1.29 ± 0.64; p <0.001), PGA-scale (<0.001) and NT-proBNP (6247 pg/ml vs 2543 pgml; p = 0.033). Incident heart failure hospitalizations assessed at 3, 6 and 12 months were significantly reduced (p <0.001 for all) in comparison to antecedent heart failure hospitalizations over the same time period (see figure, panel A). Cost expenditure was significantly lower after the initiation of dobutamine in comparison to the cost related to heart failure hospitalization the before initiation of dobutamine over the same timeframe. Nursing costs and medication cost formed the highest part of expenditure following initiation of IV dobutamine. Mortality rate at 1-year was 48% with 9/12 (75%) patients dying at home, most often from progressive pump failure.
Conclusion: Continuous intravenous home dobutamine in patients with palliative end-stage heart failure is feasible, and significantly improves symptomatic status, reduces heart failure hospitalizations and health-care related costs

P357

Bone marrow cell therapy in patients with chronic ischemic heart disease: a meta-analysis of randomized controlled trials

A Anweshan Samanta[1]; MR Afzal[2]; L Derbas[1]; SD Roy[1]; SS Taduru[1]; V Jeevanantham[3]; B Dawn[4]
[1]University of Missouri - Kansas City, Internal Medicine, Kansas City, United States of America; *[2]The Ohio State University, Division of Cardiovascular Medicine, Columbus, United States of America*; *[3]St. Anthony Hospital, Ohlahoma City, United States of America*; *[4]University of Kansas Medical Center, Division of Cardiovascular Diseases, Kansas City, United States of America*

Background: Although several randomized controlled trials (RCTs) have documented benefits of bone marrow cell (BMC) therapy in patients with chronic ischemic heart disease, the efficacy of this therapy still remains controversial.
Purpose: We hypothesized that BMC therapy would improve left ventricular (LV) parameters in patients with CIHD.

Table: Mean change in LV functional and structural parameters in BMC-treated CIHD patients compared with standard therapy.

Cardiac Parameter	Weighted Mean Difference	95% Confidence Interval	*P* Value
LVEF (%)	3.99	2.63 to 5.35	<0.00001
LVESV (ml)	-9.33	-16.59 to -2.06	0.01
LVEDV (ml)	1.46	-4.68 to 7.60	0.64
Infarct Size (%)	-4.92	-6.98 to -2.86	<0.00001

Methods: We performed a systemic review and meta-analysis of data from published RCTs that evaluated the efficacy of BMCs in patients with CIHD. Database searches through May 31, 2017 identified 23 studies enrolling 1026 patients. The effects of BMC therapy on LV ejection fraction (LVEF), LV end-systolic volume (LVESV), LV end-diastolic volume (LVEDV) and infarct size were analyzed. Changes in outcomes of interest were analyzed with random-effects meta-analysis.
Results: Compared with standard therapy, BMC therapy improved LVEF (3.99%; 95% confidence interval [CI]: 2.63 to 5.35; P < 0.00001) and reduced LVESV (-9.33 ml; 95% CI: -16.59 to -2.06; P = 0.01). BMC therapy reduced infarct size (-4.92%; 95% CI: -6.98 to -2.86; P < 0.00001) when compared with standard therapy in these patients with CIHD. Cell therapy did not have any significant impact on LVEDV. A separate analysis of RCTs using cardiac MRI confirmed the benefit of BMC therapy on LVEF in these patients (1.55%, 95% CI: 0.13 to 2.97; P = 0.03).
Conclusions: Results of meta-analysis of pooled data from RCTs of BMC therapy in patients with CIHD indicate a modest yet significant beneficial effect on cardiac function. The improvement in LVEF was confirmed in a separate analysis of trials using cardiac MRI.

P358

Worsening renal function and hyperkalaemia in a real-life cohort treated with sacubitril/valsartan: findings from a prospective registry

L Rodriguez Sotelo[1]; AM Iniesta[1]; A Esteban-Fernandez[2]; M Gomez-Bueno[3]; J De-Juan[4]; P Diez-Villanueva[5]; A Ayesta[6]; D Iglesias[7]; M Garcia-Aguado[8]; JA Perea-Egido[9]; L Vicent[10]; L Pena Conde[1]; SO Rosillo[1]; JL Lopez-Sendon[1]; M Martinez-Selles[10]
[1]University Hospital La Paz, Cardiology department, Madrid, Spain; *[2]Hospital Clinic San Carlos, Madrid, Spain*; *[3]University Hospital Puerta de Hierro Majadahonda, Madrid, Spain*; *[4]University Hospital 12 de Octubre, Madrid, Spain*; *[5]University Hospital De La Princesa, Madrid, Spain*; *[6]Hospital del Sureste, Arganda del Rey, Madrid, Spain*; *[7]University Hospital Infanta Sofia, Madrid, Spain*; *[8]Hospital de Mostoles, Madrid, Spain*; *[9]Hospital de Getafe, Madrid, Spain*; *[10]University Hospital Gregorio Maranon, Madrid, Spain*

Background: Since PARADIGM-HF trial various international heart failure (HF) consensus and guidelines have included the use of sacubitril/valsartan (SV) for the management of symptomatic HF with reduced ejection fraction as a class I recommendation, due to its proven benefit compared to enalapril. Despite the fact that worsening renal function (WRF) and hyperkalaemia (HK) were less frequent in the SV group, these are two undesirable adverse effects that could limit the widespread use.
Purpose: The aim of this study was to analyse the incidence of WRF and HK after introduction of SV in daily clinical practice, and to determine whether there were associated factors.
Methods: Prospective registry of outpatients from 10 hospitals receiving SV as part of their HF treatment, with at least 6-months follow-up. WRF was defined as a decrease of 50% or more in glomerular filtration rate (GFR). HK was defined as potassium level > 5.5 mmol/L.
Results: We included 427 patients (median age 68,34 ± 11,76 years; female 29,7%), 29 (6.8%) developed WRF and 21 (4.9%) HK. Table 1 shows the baseline characteristics according to WRF. Patients with WRF had prior to the beginning of therapy lower GFR (46.1 ± 16.9 vs 64.5 ± 21.2 p < 0.001), higher levels of NT-proBNP (1916, IQR 936-3917 ng/L vs 3773, IQR 2126-6454 ng/L, p = 0.024), as well as a worse functional class (NYHA III-IV: 51.7% vs 28.7% p = 0.009). The only factor related to HK during follow-up was WRF (28.6% vs 5.7%, p < 0.001). Patients with WRF received a lower SV dose at the end of follow-up (67.2 ± 55.5 vs 111.6 ± 70.6 mg b.i.d. p = 0.001), had a higher rate of SV discontinuation (24.1% vs 10.6% p = 0.027), and a higher mortality (10.3% vs 2.3% p = 0.011), readmission rate (37.9% vs 14.3%, p = 0.001), and visits to the emergency department (34.5% vs 17.1%, p = 0.019) than patients without WRF.
Conclusions: WRF and HK in the real-life scenario were less frequent than expected. When present, WRF is associated with unfavourable outcomes. Patients with a poor baseline renal function, advanced functional class, and high levels of NT-proBNP are at higher risk for WRF.

Table 1.

Variable	WRF n = 29	No WRF n = 395	p
Female sex, n (%)	10 (34.5)	116 (29.4)	0.54
Age (years) (mean ± SD)	70.5 ± 9.7	68.2 ± 11.9	0.32
Hypertension, n (%)	20 (69)	297 (74.6)	0.50
Diabetes mellitus, n (%)	16 (55.2)	154 (38.7)	0.08
Left ventricular ejection fraction (%), mean ± SD	31.27 ± 6.3	28.7 ± 6.9	0.06
Ischemic heart disease, n (%)	15 (51.7)	210 (52.9)	0.90

Background: Cardiac Resynchronization Therapy (CRT) reduces morbidity and mortality in selected patients with heart failure (HF) and electrical dyssynchrony.
Purpose/Methods: In 2016 HFA and EHRA conducted a survey of CRT implantations in 11,088 patients in 42 ESC member states. We have analysed the results, comparing patients with ischaemic vs non-ischaemic HF aetiology.
Results: Hospitalization for HF during the past year was common in both groups and use of HF medication was similar. Patients with ischaemic HF were older, more frequently men, with significantly less LBBB. They more often had a history of hypertension and non-cardiovascular co-morbidities including diabetes, anaemia and chronic kidney disease.
Conclusions: Patients in CRT Survey II with ischaemic HF aetiology were significantly older, more often male with more co-morbidity than those with non-ischaemic HF. However, they were similar in regard to clinical status.

Ischaemic vs Non-Ischaemic HF Aetiology

	Ischaemic HF (47%) n = 4875	Non-Ischaemic HF (53%) n = 5453
Age (year, median, IQR)	71 (65-77)	68 (60-75)
Men (%)	86	67
Past Medical History: (%)

Clinical impact of implantable cardioverter defibrillators in pre- and post- left ventricular assist device ventricular arrhythmias

VJL Goh[1]; CP Lim[2]; KL Kerk[2]; Y Chia[1]; TE Tan[2]; C Sivathasan[2]; JL Soon[2]; V Chao[2]; DKL Sim[2]; LLY Teo[2]
[1]Singapore General Hospital, Singapore, Singapore; *[2]National Heart Centre Singapore, Singapore, Singapore*

Background/Introduction: The significance of ventricular arrhythmias (VA) and implantable cardioverter defibrillator (ICD) therapy in patients on continuous flow LVAD (CF-LVAD) support remains controversial. Patients with pre-LVAD VA have been shown to have higher incidence of post-LVAD VA, but the utility of ICD therapy in these patients remains under studied.
Purpose: We aimed to evaluate the impact of pre-LVAD VA, post-LVAD VA, and ICD therapy on outcomes in patients with ongoing CF-LVAD support.
Methods: We performed a retrospective analysis of 87 patients receiving LVADs between May 2009 and July 2017 in a tertiary hospital in Singapore. Outcomes assessed included all-cause mortality, hospitalisation, and time to death or transplant. Pre-LVAD VA was defined as any VA occuring before LVAD implantation, and post-LVAD VA was defined as VA occurring = 30 days post-LVAD implantation. Hazard ratios were adjusted for age, sex, etiology of heart failure and INTERMACS status.
Results: Patients with pre-LVAD VA (n = 29) were younger (45 vs 53 years, $p < 0.01$), less likely to have ischemic cardiomyopathy (28% vs 59%, $p < 0.01$) and more likely to have ICDs implanted pre-LVAD (69% vs 43%, $p < 0.05$), compared to those without pre-LVAD VA. There were no differences in gender (79% vs 84% male, n = 0.5), patients with INTERMACS 1 and 2 at implantation (55% vs 43%, n = 0.4), or years on LVAD support (1.7 [1.3, 3.9] vs 2.0 [1.0, 3.6] years) between patients with and without pre-LVAD VA respectively. As expected, patients with pre-LVAD VA had higher incidence of post-LVAD VA (12.1 vs 2.3 events per patient year (EPPY), $p = 0.04$). There was no difference in mortality between patients with or without: pre-LVAD VA (24% vs 28%, $p = 0.8$), post-LVAD VA (31% vs 24%, $P = 0.6$, n= 29), or ICDs (31% vs 21%, $p = 0.3$, n = 45). Similarly, there was no difference in all-cause hospitalisations in patients with or without pre-LVAD VA (median 1.63 vs 1.22 EPPY, $p = 0.7$), post-LVAD VA (median 1.68 vs 1.22 EPPY, $p = 0.8$) or ICDs (median 1.79 vs 1.07 EPPY, $p = 0.08$). Time to death/transplant was not significantly different between patients with or without pre-LVAD VA, post-LVAD VA, and ICDs (Figure 1). In a subgroup analysis of patients with pre-LVAD VA, there was no mortality benefit for patients with concurrent ICDs (No ICDs, n = 42: 11% vs ICDs, n = 45: 30%, $P = 0.38$). Patients with ICDs experienced a mean of 6.1, 5.1 and 0.2 EPPY of ICD shocks, anti-tachycardia pacing, and ICD-related hospitalisations respectively.
Conclusions: The presence of pre-LVAD VA, post-LVAD VA, and ICDs had no significant impact on mortality or hospitalisations in our cohort, and pre-LVAD implantation of ICDs in patients with pre-LVAD VA did not improve mortality. The high rate of ICD therapy and ICD-related hospitalisations may represent unnecessary burden in patients with concurrent CF-LVAD and ICD therapy.

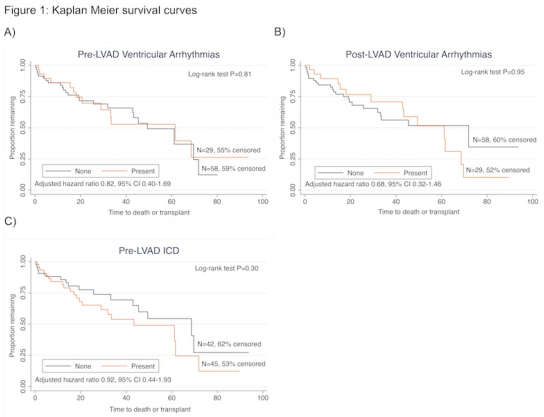

Figure 1: Kaplan Meier Survival Curves

P361

The efficiency of stem cord cells transplantation in patients with heart failure and ischemic cardiomyopathy: the emphasis on biomarkers levels

D Dina Shorikova[1]; E Shorikov[1]; A Gabrielan[2]
[1]Bucovinian State Medical University, Chernivtsy, Ukraine; *[2]National Institute of Surgery and Transplantology n. a. O. O. Shalimov, Kyiv, Ukraine*

The use of the stem cord cells may be considered as one of the perspective methods of the treatment of heart failure (HF), but we must learn the cardiac biomarkers response after this intervention.
We have learnt 86 patients with chronic HF which was developed on the basis of ischemic cardiopathy (IC) and systolic dysfunction (ejection fraction < 40,0%), which were included in the waitlist of heart transplantation. The patients treated by conservative therapy, the bypass interventions were used and transplantation of cord blood stem cell was administered to all. We have set the levels of NTproBNP,

human vascular endothelial growth factor (VEGF) ?? soluble platelet endothelial adhesion molecule-1 (sPECAM-1) in patients.

Risk factors in "good responders" and "b

Factors	"good responders"	"bad responders"	Results
Arterial hypertension	24,0%	58,0%	OR = 0,23[0,09-0,59]
Diabetes mellitus	35,0%	13,0%	OR = 3,51[1,21-10,1]
Total cholesterol	5,13±1,11	5,86±1,04	p = 0,0026
LDL-cholesterol	2,76±0,51	3,01±0,55	p = 0,036
Body mass index	29,3±2,76	29,6±3,11	p = 0,64

Results: The median of proBNP concentration in group HF before the stem cells transplantation was 499,0 (178,2 - 1404,0) p?g/ml. Six month after transplantation was set the decrease of the of proBNP: the median was 241,5 (193,0 - 892,0) pcg/ml (? < 0,05). Inverse dependence was set for the changes of biomarkers as sPECAM-1 ?? VEGF-165. The gain of sPECAM-1 after transplantation was unreliable (p>0,05) and equal to 18,8% - from 71,86 ng/ml (44,36 - 105,06) to 85,96 ng/ml (49,08 - 123,44). The VEGF increment was similar to sPECAM-1 and matched to 19,9%: from the 46,2 ng/ml (8,7-67,1) to 55,4 ng/ml (25,3-72,2) (p>0,05). However, the results of biomarkers' levels changes showed widespread sample range; using K-mean clustering we specified two groups of patients': "good responders" and "bad responders". Analysis of the influence of the occurrence of cardiovascular risk factors in both groups proved that the presence of arterial hypertension, higher levels of total cholesterol and LDL-cholesterol was associated with group of "good responders", but the group of "bad responders" has the greater rate of diabetes mellitus of type 2 (table).
Conclusion: The stem cells transplantation in six months resulted of reliable decrease of proBNP level and unreliable increase of VEGF and sPECAM-1 in HF and IC patients. The response of biomarkers' changes in patients after stem cells transplantation reliably associated with the concomitant arterial hypertension, diabetes mellitus and dyslipidemia.

Influence of the type of circulatory/ventricular assistance in the primary graft failure and heart transplantation mortality

R Raquel Lopez Vilella[1]; I Sanchez Lazaro[1]; MP Fuset Cabanes[2]; A Pajares Moncho[3]; L Donate Bertolin[4]; R Gimeno Costa[2]; I Moreno Puigdollers[3]; I Zarragoikoetxea Jauregui[3]; L Martinez Dolz[1]; A Castellanos Ortega[2]; R Vicente Guillen[3]; S Torregrosa Puerta[4]; L Almenar Bonet[1]
[1]Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit. Cardiology Department, Valencia, Spain; *[2]Hospital Universitario y Politécnico La Fe, Intensive care unit, Valencia, Spain*; *[3]Hospital Universitario y Politécnico La Fe, Anesthesiology Department, Valencia, Spain*; *[4]Hospital Universitario y Politécnico La Fe, Cardiovascular Surgery Department, Valencia, Spain*

Background and Objective: In recent years, the percentage of heart transplantation (HT) with short / medium-term assistance devices has increased. This study aims at analyzing primary graft failure and hospital mortality according to the type and duration of care.
Methods: From January 2013 to December 2017 all patients undergoing urgent HT with circulatory / ventricular assistance were retrospectively and consecutively recruited. Combined transplants, retransplantations and pediatric transplants were excluded. The sample was divided in 10 groups (table 1).
Results: A total of 53 patients were recruited, 79% men, average age 49 ± 13 years. 26 patients (51%) had mechanical ventilation at the time of the HT. Primary graft failure occurred in 20 patients (38.5%), whilst it was more frequent in patients assisted with ECMO (8 patients in group 1 (45%) and 7 in group 2 (54%), p 0.5). 14 deads (27%) were registered, whereas a higher mortality was observed in the group assisted with ECMO (6 patients in group 1 (34%) and 4 in group 2 (31%), p 0.6). Mortality was 12.5% in the group of non-urgent Levitronix.
Conclusions: Despite not showing statistical significance due to the low number of patients in some subgroups, hospital mortality was high in HT patients with circulatory assistance. A trend towards a higher incidence of primary graft failure and mortality in patients assisted with ECMO was observed. The direct implantation of a centrifugal pump as a bridge to urgent transplantation could identify a subgroup with a better prognosis.

Group	n (%)	Description	PGF (%)	HM (%)
Group 1	18 (34%)	ECMO with mechanical ventilation	45 %	34%
Group 2	14 (26.2%)	ECMO without mechanical ventilation	54%	31%
Group 3	1 (1.9%)	ECMO and, afterwards, Levitronix HT with both	0	0
Group 4	2 (3.8%)	ECMO and, afterwards, Levitronix HT with Levitronix	0	0
Group 5	7 (13.2%)	Non-urgent left Levitronix	33%	17%
Group 6	1 (1.9%)	Non-urgent right Levitronix	0	0
Group 7	1 (1.9%)	Non-urgent biventricular Levitronix	0	0
Group 8	1 (1.9%)	ECMO y Levitronix, HT with both	100%	100%
Group 9	3 (5.7%)	ECMO y Levitronix, HT with Levitronix	0	0
Group 10	5 (9.4%)	Urgent Levitronix	35%	20%

ECMO: Extracorporeal membrane oxygenation; HM: Hospital mortality; HT: Heart transplantation; PGF: Primary graft failure

P363

The influence of the level of anxiety and depression and type a personality on adherence in outpatients with chronic heart failure

SU Volkova[1]; EV Panteeva[1]
[1]Tyumen State Medical University, Tyumen, Russian Federation

Aim: to identify the level of anxiety and depression, the prevalence of personality type D (distressing) in ambulatory patients with chronic heart failure (CHF)., as well as their impact on patient adherence to prescribed therapy
Material and Methods: The study included 98 people, observed on the basis of MMAU "city polyclinic ?4" with CVD and concomitant CHF, of which 24.6% men and 75.4% women , mean age 71 ± 2.1 years. All patients initial screening, including hospital scale of anxiety and depression (HADS), the test Moriscos green to determine adherence to treatment, a test for detecting psycho (DS-14) questionnaire for measuring quality of life (SF-36). Statistical processing of research results, preparation of registers for long-term dynamic observation was carried out using the software package Microsoft Office Excel 2007.
Results: Basically, the group was represented by patients with 1-stage CHF - 78%, CHF 2A stage in 22% of subjects. The main reason for the development of CHF was a combination of CHD and hypertension - 71%, only hypertension was found in 29%. According to the questionnaire HADS subclinical anxiety was diagnosed in 25% of the observed, clinical anxiety is diagnosed in 16.5% and mainly among women (82,4% of the subgroup). Subclinical depression was diagnosed in 23.5% of patients; the clinical depression was 14.1%, also mainly women (75% of the subgroup). Psycho D was found in 17 patients (22,07%), of which 76.5% of women. Assessing adherence to therapy may be noted that in our patients is mainly observed with high - 88,2% and the average at 11.7%. Moreover, among patients with identified psycho D - high commitment to treatment and medical appointments indicated 70% of patients, 30%- medium. Among patients with an average adherence to treatment 60% had abnormalities in the HADS test, while among patients with high adherence to therapy was 55%, while the level of anxiety and depression in these groups differed.
Conclusions: Based on the results obtained, it is advisable to study the influence of the level of anxiety and depression, as well as behavioral type of the individual (psycho) on the course of CHF, and to determine the individual approach to the treatment and correction of psychological features to enhance compliance in patients with CHF, depending on individual psychological characteristics

P364

Changing of some markers of inflammation and remodeling in post-infarction patients with chronic heart failure after ubidecarenone treatment

I A Leonova[1]; S Boldueva[1]; G Kuharchik[2]; L Sichinava[1]; L Gaykovaya[1]
[1]North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation; *[2]Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation*

Objective: to evaluate the effect of ubidecharenone on the processes of inflammation in the myocardium and remodeling of the left ventricle (LV) in patients with chronic heart failure (CHF) after a previous myocardial infarction (MI).
Materials and Methods: 108 post-infarction patients with II-III functional class CHF were included in the study. Patients were randomized into 2 groups: 1 group - patients who received standard therapy and ubdecarenone 30 mg/TID within 3 months; 2 group - received only standard therapy. All patients were initially and after 3 months determined the level of bio-markers: NT-proBNP, hs-CRP, galectin-3, ST-2.

Results: the level of NT-proBNP after 3 months significantly decreased in both groups: in the 1st group from 490.70 (250.50, 752.90) pg/ml to 134.55 (80.82, 202.10) pg/ml ($p < 0.05$) and in the 2 group from 701.25 (271.40, 1385.50) pg/ml to 230.80 (178.90, 443.40) pg/ml ($p < 0$, 05). In spite of the initial values of NT-proBNP concentrations in groups 1 and 2 did not differ, after 3 months it were significantly lower in group 1 than in group 2 (p?0.05). After 3 months both groups showed a decrease in the content of hs-CRP compared to the baseline: in patients from group 1, 3.4 (1.8, 6.7) mg/l to 1.5 (0.8, 3.0 ($p < 0.05$) and in patients of the 2nd group from 3.85 (2.15, 8.70) mg/l to 1.35 (0.725, 3.4) mg/l ($p < 0$, 05). It should be noted that in some patients the values of hs-CRP were kept above 3 mg /l, which indicates that they still have a high risk of cardiovascular accidents (in group 1 -23.5% and in group 2 -28.3%). The content of galectin-3 in both groups was not initially different, it was 19.22 (10.88, 43.50) ng/ml in the 1st group and 23.31 (14.77, 31.56) ng/ml in the 2nd group (p?0.05). The results of a pairwise comparison of the content of galectin-3 in each of the groups showed that only in group 1 there was a decrease in the content of galectin-3 after 3 months compared to the baseline data (16.76 (9.92,34.50) ng/ml vs 19 , 22 (10.88, 43.50) ng/ml). After 3 months the level of galectin-3 exceeded 17.8 ng/ml in 1 group in 49% of patients (6% more than initially), and in the 2 group - in 60.4% of patients (11% more than initially). After 3 months of treatment, the content of ST-2 in patients of group 1 decreased from 75.11 (63.36, 100.43) ng/ml to 54.02 (48.84, 86.79) ng/ml ($p < 0$, 05), and in the 2 group the ST-2 content remained unchanged, reaching initially 71.42 (49.29, 98.90) ng/ml and after 3 months - 75.24 (51.74, 105.73) ng/ml (p?0.05).

Conclusion: The administration of ubedecarenone in addition to the standard treatment of post-infarction patients with chronic heart failure leads to a decrease in the activity of the inflammatory process and fibrosis in the myocardium.

P365

What do patients think about their chronic heart failure pharmacotherapy?

R Radek Pelouch[1]
[1]*University Hospital Hradec Kralove, Department of Cardiovascular Medicine I, Hradec Kralove, Czech Republic*

Funding Acknowledgements: This work was supported by the research project PRVOUK P037/03

Introduction: Although pharmacotherapy of chronic heart failure (CHF) is well established on the basis of Evidence based medicine, heart failure decompensation (HFD) rate still remains high. In accordance with literature we have proved in our previous study that adherence to CHF therapy is a real problem and significant cause of HFD. Unfortunately reasons of patient's noncompliance are mostly unclear.

Purpose: The aim of the study is to analyze CHF patient's opinions on their pharmacotherapy and to study factors influencing drug adherence

Methods: 81 stable CHF patients (mean age 64 ± 12.0 years, 67% of male, median NYHA II) were prospectively enrolled to the study examining their compliance to pharmacotherapy. Serum levels of prescribed drugs were used as an indicator of medication adherence (median of assessed drugs 4). As a part of study protocol patients filled in a questionnaire related to their drugs use habits and their opinions and feelings regarding to pharmacotherapy.

Results: Average number of used medication has been 8 drugs. 56.8% of patients knew correct number of used drugs. 46.9% were able to name complete medication, 19.8% didn't know any drug name. 92.6% were confident about flawless medication use. Questioned about skipping dose per week, 80.3% of patients denied omission of any daily dose any time, 12.3% estimated one dose skip per week, 7.4% two doses skip. More frequently they forgot midday or evening doses, comparing the morning dose (8.6% and 8.6 % to 2.5%).

Regarding side effects (SE) of the medication, 46.9% of patients denied any of them and only 1.2% had frequent SE. 27.2% suffered from occasional and 1.2% from significant lack of appetite. Only 3.7% declared influence of SE to their drug taking. On the contrary, 87.7% denied any influence of drug's size and shape.

Personality of phycian prescribing the drug was important for 75.3% of patients.

76.5% were satisfied with quality of their life. Using scale 0-100% they evaluated their health status on the average value 62.5 ± 18.64%. 19.8% of patients expected better quality of life without taking any medication. On the contrary, 98.8% considered using drugs as very important for them.

As described above, 92.6% of patients said they had used medication completely well and 80.3% of them denied omission of any daily dose any time. Actually, this is in contradiction with results of their serum drug levels - all of evaluated drugs were detected in the sera of 75.4%, one of them was missing in the sera of 12.3% and more than one in 11.1%. Finally, none of evaluated drugs was found in the sera of 1.2%.

Conclusions: Almost everybody consider regular use of medication as very important. Nevertheless, using an objective method, we demonstrated lower drug adherence than patients supposed. Neither side effects nor tablets size/shape affect significantly regular drugs use. Most of our stable chronic heart failure patients are satisfied with quality of their life.

P366

Effect of catheter denervation of renal arteries on intracardiac hemodynamics and quality of life in patients with chronic heart failure

A Kurlianskaya[1]; T Tatyana Troyanova-Shchutskaia[1]; D Goncharik[1]; T Asmalouskaya[1]; T Denisevich[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Background: Catheter denervation of renal arteries (CDRA) is an innovative method of treatment in patients with chronic heart failure (CHF), which allows controlling the effects of the sympathetic nervous system by the use of high-frequency current destroying sympathetic nerves in the adventitia of the renal arteries.

Parametr	At baseline	In 6 months after CDRA	In 12 months after CDRA	p 0-6	p 0-12
End diastolic dimension (EDD), mm	70 (64; 74)	68 (65; 77)	69 (66; 72)	0.925	0.289
End systolic dimension (ESD), mm	58 (52; 62)	55 (51; 67)	56 (51; 62)	0.547	0.535
End diastolic volume (EDV), ml	238 (205; 318)	249 (185; 292)	209 (162; 272)	0.050	0.035
End systolic volume (ESV), mm	160 (137; 224)	155 (117; 210)	126 (97; 193)	0.085	0.149
Left ventricular ejection fraction (LVEF)	31 (28; 34)	35 (29; 40)	39 (33; 41)	0.206	0.056
Mitral regurgitation (MR)	2 (2;3)	2 (2;2;)	2 (2;2)	0.753	0.638

Purpose: to investigate the effect of CDRA on intracardiac dynamics and quality of life (QOL) in patients with CHF for 12 months of follow-up.

Methods. The study included 25 patients with CHF III functional class (FC) NYHA, ejection fraction < 35%, QRS < 130ms. All patients underwent transthoracic echocardiography before and in 6 and 12 months after CDRA. The quality of life (QOL) was assessed using the Minnesota Living With Heart Failure Questionnaire.

Results: Changes in the parameters of intracardiac hemodynamics in patients before, 6 and 12 months after CDRA are demonstrated in table.

An improvement of echocardiographic parameters after the CDRA was accompanied by an improvement in the clinical status of patients: a decrease in dyspnea, an increase in exercise tolerance, an increase in the level of QOL. Initially median values of QOL were 57 (44; 61) points, in 6 months after CDRA - 47 (32; 55) points, in 12 months - 42 (24, 44).

Conclusions: The obtained data allows to provide the evidence of the positive effect of CDRA on the parameters of intracardiac hemodynamics. LVEF significantly increased, EDV significantly decreased in 12 months after CDRA. The tendency of decrease in ESV was also noted. FC of CHF decreased in 75% of patients, that was accompanied by improvement of QOL patients.

P367

Salt consumption and long term prognosis of coronary patients with heart failure; is it equally aggravating for all? Results from Hellenic Heart Failure study.

C Christina Chrysohoou[1]; M Kouvari[2]; P Aggelopoulos[2]; G Metallinos[1]; E Tsiamis[1]; C Pitsavos[1]; D Tousoulis[1]
[1]*University of Athens, Athens, Greece*; [2]*Harokopio University, Nutrition Science - Dietetics, Athens, Greece*

Background/Introduction: Dietary salt restriction is a unanimously propagated recommendation in the prevention and management of heart failure. Nonetheless, considering salt as a flavor enhancer triggering appetite, its strict restriction in the context of anorexia- and cachexia- associated disease, raises many doubts.

Purpose: the role of discretionary and hidden salt intake on 10 year prognosis of Acute Coronary Syndrome (ACS) patients was investigated.

Methods: from May 2006 to March 2009, 1,000 consecutive patients who were hospitalized at a Cardiologic Clinic in Athens with ACS diagnosis were enrolled in the study. In 2016, 10y follow-up (2006-2016) was performed in 745 participants. A validated food frequency questionnaire was used, to assess, among other dietary habits, discretionary salt intake (i.e. addition in cooking or in table) as well as consumption of major hidden-salt food sources (i.e. processed / fried meat products, canned food, feta cheese, yellow-cheese, salted nuts, bread and other bakery products).
Results: 10y fatal/non fatal ACS events were 60% in heart failure patients who reported use of salt shaker in table and 47% in patients who avoided this habit (p = 0.03). Multivariate logistic regression analysis highlighted that patients who reported use of salt shaker in table were twice as likely to develop a new cardiac episode within the decade (OR = 2.19 95% CI (1.12, 4.3), p = 0.02). Salt addition during cooking did not reach significance. Principal component analysis was performed for major hidden-salt-sources. Two out of four patterns identified, reached significance in a multivariate analysis; a pattern characterized by processed/fried meat products, fast food and salty yellow cheese was associated with unfavorable ACS prognosis (OR = 1.4 95%CI (0.97, 2.04)) whilst a pattern with healthier food choices (i.e. nuts, canned fish/vegetables, olives and feta cheese) was inversely associated with 10 year recurrent events (OR = 0.55 95%CI (0.37, 0.82)). A significant interaction was observed between age and addition of salt in table as well as the aforementioned hidden salt patterns (all ps for interaction>0.05). Stratified analysis revealed that use of salt shaker retained its significance only in younger patients (OR = 2.80 95% CI (1.18, 5.3), p = 0.02). Additionally, the potential protective effect of healthy, yet rich in salt, food choices reached significance in patients >65 years old (OR = 0.27 95% CI (0.10, 0.71), p = 0.008). Conclusion: for a more efficient treatment approach priorities should be set as regards salt restriction. Recommendations regarding salt consumption should combine the downsides attributed to excessive salt intake with the beneficial role of this flavor enhancer in appetite; with the focus oriented towards patients in advanced age threatened by a high catabolic state, which determines their prognosis.

P368

Ambulatory intravenous inotropic support and or levosimendan in failing pediatric and congenital heart disease: safety, survival, improvement or transplantation

S C Apostolopoulou[1]; GA Vagenakis[1]; A Tsoutsinos[1]; F Kakava[1]; S Rammos[1]
[1]*Onassis Cardiac Surgery Center, Athens, Greece*

Background/Introduction: End-stage heart failure (HF) frequently needs continuous inotropic support in hospital and has high morbidity and mortality. It is often treated with mechanical circulatory support or transplantation, both options associated with significant adverse events and not readily available in many countries.
Purpose: To review our experience using continuous ambulatory inotropes (AI) and/or periodic levosimendan (LS) infusions in pediatric end-stage HF patients in a tertiary care center
Methods: This is a retrospective analysis of our end-stage HF population treated with AI and LS focusing on outcome, efficacy, safety and follow up including deaths, stabilization and recovery.
Results: The study included 27 patients aged 9.3 ± 7.4 (0.1-26.1) years with severe HF (6 myocarditis, 13 dilated cardiomyopathy, 2 restrictive cardiomyopathy, 6 repaired congenital heart disease) needing continuous inotropic support. Overall, 21 patients received dobutamine and milrinone AI through a permanent central catheter for 1.1 ± 0.9 (0.3-3.7) years. Additionally, 14 AI patients and the remaining 6 study patients received periodic LS infusions for 1.4 ± 1.0 (0.1-4.2) years. Inotropes were used for 1.4-0.4 years as bridge to recovery in 6 improved myocarditis patients, who remained stable after discontinuation on follow-up. AI and or LS infusions were used as bridge to transplantation in 6 patients with only 3 survivors, in 2 of which inotropes preoperatively reversed severe combined pre and postcapillary pulmonary hypertension allowing successful heart only transplantation. Finally, inotropes were used as mainstay therapy in 15 patients for 0.3-4.2 years, mostly with good quality of life and family dynamics. Four patients died of worsening HF after 0.8-2.1 years of therapy. During 3.6 ± 5.3 (0.3-21.3) years of follow-up, we observed 4 central line infections treated with antibiotics and 4 catheter reinsertions due to dislodgement. Parenteral inotropes were also discontinued in 1 cardiomyopathy patient who received a left ventricular assist device and is still waiting for transplant 2.5 years later.
Conclusions: AI and/or LS infusions in HF is safe and beneficial for long periods even in small infants and children, allowing stabilization, discharge from hospital and cost reduction, good quality of life. It may provide precious time for heart transplantation or myocardial remodeling, improvement and possible discontinuation even after long periods of support.

P369

The use of extracorporeal photopheresis in the treatment of acute cardiac allograft rejection

T Timea Teszak[1]; A Assabiny[1]; A Kiraly[1]; Z Tarjanyi[1]; N Parazs[1]; ZS Szakal-Toth[1]; I Hartyanszky[1]; Z Szabolcs[1]; Z Farkas[2]; M Reti[2]; B Sax[1]; B Merkely[1]
[1]*Semmelweis University Heart and Vascular Center, Budapest, Hungary*; [2]*Szent Laszlo Hospital, Budapest, Hungary*

Background: Despite novel immunosuppressive agents, cardiac allograft rejection is still a major etiological factor in premature mortality after heart transplantation. Furthermore, these medications increase infectious disease mortality, too. Extracorporeal photopheresis (ECP) is an immunomodulatory therapy which was first used in the treatment of cutaneous T-cell lymphoma. Its use has now expanded to include also the treatment of cardiac allograft rejection; however, there is still no clear evidence on its exact indication.
Purpose: We aimed to evaluate the effect and efficacy of ECP in adult Hungarian heart transplant recipients.
Methods: From September 2013 to September 2017 we studied 9 patients treated with ECP who underwent heart transplantation for end-stage heart failure in our University. We characterized the duration and the side effects of ECP, the grade of rejection in transvenous endomyocardial biopsies (EMB) and the left ventricular ejection fraction (LVEF) measured by transthoracic echocardiography both before and after ECP treatment period. Data values were characterized by either mean ± standard deviation or median(min-max).
Results: The 9 patients underwent 24(2-38) ECP treatments beside standard immunosuppressive therapy. ECP treatment was initiated 186(15-3523) days after cardiac transplantation. Whereas before the ECP treatment the majority of patients (89%) were diagnosed with grade 2 acute cellular rejection in EMB according to the classification published by the International Society for Heart and Lung Transplantation, there was no rejection exceeding grade 1 acute cellular rejection post-ECP treatment. Furthermore, the average grade of rejection improved with approximately one class (grade 1.22 ± 0.67 vs. grade 0.43 ± 0.53; p = 0.038) after the ECP treatment period. LVEF discreetly increased from a baseline LVEF of 54 ± 8% to 61 ± 6% (p = 0.181) at follow-up after ECP, although it should be noted that in 6 out of 9 patients ECP treatment was initiated before any decrease in LVEF. There were no major side effects during the 208 ECP treatments. Two deaths occurred during the ECP treatment period which resulted from progression of cardiac allograft rejection; however, one of the patients refused the continuation of ECP after the second treatment.
Conclusion: We observed that ECP in cardiac transplantation is efficient: it appears to be a significant advance in reducing the severity of rejection episodes. Furthermore, it is safe and well tolerated without important side effects. Despite its promising favourable effects, further studies which focus on both the exact mechanisms of action and the standard treatment protocol are required for the maximization of its therapeutic benefit.

P370

Comprehensive heart failure self-management programme: evaluation of a pilot group intervention

I Caramlau[1]; J Gallagher[1]; B Hannon[2]; L O'connor[3]; T Mannion[3]; E Kennedy[4]; L Masterson[4]; L O'neill[5]; L Peotta[1]; S Clarke[1]; N Pender[1]; B Mcadam[6]
[1]*Beaumont Hospital, Psychology, Dublin, Ireland*; [2]*Beaumont Hospital, Cardiac Rehabilitation, Dublin, Ireland*; [3]*Beaumont Hospital, Supportive Heart Unit, Dublin, Ireland*; [4]*Beaumont Hospital, Nutrition and Dietetics, Dublin, Ireland*; [5]*Beaumont Hospital, Pharmacy, Dublin, Ireland*; [6]*Beaumont Hospital, Cardiology, Dublin, Ireland*

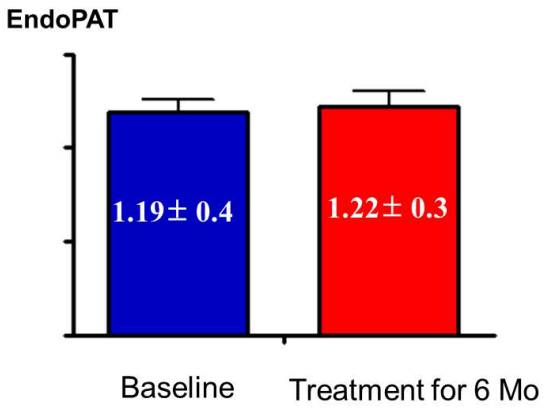
Background: Heart failure (HF) is a chronic, life-limiting condition affecting approximately 2% of people in Ireland, and is associated with frequent hospital admissions and significantly reduced quality of life. To self-manage their condition effectively, patients with HF need to engage in multiple self-care behaviours (e.g. poly-pharmacy, monitoring and responding to symptoms, maintaining a low salt diet and managing fluid intake), as well as managing the emotional impact of living with a chronic condition. Despite its importance, poor self-management remains a challenge in the treatment of HF.
Purpose: This study examined the feasibility of a comprehensive HF self-management group intervention underpinned by cognitive behavioural principles. The core components of the programme included modules on understanding HF, symptom monitoring, medication adherence, healthy eating, physical exercise, managing fatigue, managing breathlessness, managing difficult emotions, and strategies to compensate for HF-associated cognitive difficulties.
Methods: Participants were predominantly in NYHA class III, diagnosed with ischaemic cardiomyopathy and HF-preserved, had = 2 co-morbidities, and were attending a specialist HF service for >3 months. Patients were invited to participate

in a 6-week outpatient HF self-management group programme. In addition to a consultant cardiologist, this multi-disciplinary programme comprised of input from psychologists, a pharmacist, a dietician, and two Clinical Nurse Specialists (HF & Cardiac Rehabilitation). Using a pre-post design, the impact of this HF self-management intervention on patient reported outcomes was evaluated using the following measures: the Self-Care of Heart Failure Index (SCHIFI), the Medication Adherence Report Scale (MARS), and the HeartQoL.
Results: 50 eligible patients with HF were invited to participate in a screening assessment, resulting in 28 patients being referred to the HF self-management programme. Ultimately, 26 patients [88% male; mean age= 68.8 years [SD = 7.5)] attended the programme, with an overall attendance rate of 96%. Comparing Time 1 and Time 2, paired-sample T-tests showed a significant improvement in all 3 subscales of HF self-care behaviours: self-care maintenance t(25)=-3.4, p<.05, self-care management, t(25)=-2.6, p<.05, and self-care confidence, t(25)=-5.9, p<.05. An increase in medication adherence was also observed, reflected by a decrease in MARS scores [t(25) = 1.9, p<.05]. Health-related Quality of life (HeartQoL) was not significantly improved [t(25)=-2.2, p=.65]. High levels of patient satisfaction with the self-management programme were also reported.
Conclusions: A comprehensive group-based HF self-management intervention was both feasible and acceptable to patients, and improved both HF self management and medication adherence. A robust and adequately powered randomized controlled trial is warranted to evaluate the effectiveness of this intervention.

P371
Effect of vitamin D on endothelial function in Patients with chronic heart failure

S J Ha[1]; YY Choi[2]; YM Woo[1]; JY Jang[3]; JS Woo[2]
[1]GangNeung Asan Hospital, Cardiology, GangNeung, Korea Republic of; *[2]Kyunghee Medical Center, Seoul, Korea Republic of*; *[3]Gyeongsang National University Changwon Hospital, cardiology, Changwon, Korea Republic of*

Background: In patients with heart failure (HF), low levels of 25-hydroxyvitamin D (25OHD) are common and are associated with increased mortality risk.
OBJECTIVES: The VIVID-HF (Ventricular and Vascular function of Vitamin D in Patient with Heart Failure) study was an investigator-initiated, multicenter, prospective, randomized, placebo-controlled trial to establish safety and efficacy of oral vitamin D3 (cholecalciferol) supplementation in stable HF patients.
METHODS: Seventy three HF patients with 25OHD level < 75 nmol/L (30 ng/mL) were randomized to receive 4000 IU vitamin D daily or matching placebo for 6 months. The primary endpoint was the change of endothelial function assessed by EndoPAT between baseline and 6 months. Secondary endpoints included the change in echocardiographic parameters and differences of quality of life (6 minute walk test and New York Heart Association functional status: NYHA status) at 6 month.
RESULTS: During study periods, there was no adverse event in both groups. Vitamin D supplementation did not improve endothelial dysfunction (EndoPAT: baseline, 1.19 ± 0.4 vs 6 month later, 1.22 ± 0.3, p = 0.65). In addition, 6-minute walking distance (baseline, 292.9 ± 120.35 vs 6 month later, 283.7 ± 116.84 m, p= 0.125), and NYHA status also did not improve. In this period, there was no significant change in echocardiographic parameters.



Endo PAT comparison

Conclusions: A daily vitamin D dose of 4000 IU would be safe but did not improve endothelial function, echocardiographic parameters, 6-minute walking distance, and NYHA status.

P372
New onset diabetes mellitus after transplant (NODAT) in heart transplant recipients-incidence, predictors and outcomes

L Lavanya Saiva[1]; N Boyle[1]; S Murphy[1]; C Halley[1]; N Mahon[1]; J O'neill[1]
[1]Mater Misericordiae University Hospital, Heart and Lung Transplant Unit, Dublin, Ireland

Background: The success of solid organ transplantation has been increasing with advances in surgical and pharmacological techniques. With improvements in patients survival increasing attention is focussed on complications that contribute to long term morbidity and mortality post-transplant. NODAT is a common complication of solid organ transplantation. There are limited number of studies in post heart transplant patients. We sought to assess the Incidence, Predictors and Outcomes in patients with NODAT.
Methods and Results: we retrospectively analysed 100 patients transplanted from 2007 to 2017. Patients with Pre-transplant diabetes were excluded from the study. Out of 100 patients, 10% (n = 10) developed NODAT. Median time to develop NODAT was 4.3 ± 2.1 months and majority of patients (90%) developed within 6 months. More than four episodes of rejection requiring treatment were noted in 30 % (n = 3) of patients and 50% (n = 5) had at least one episode of rejection. Graft function was found to be normal in all of our patients and 30% (n = 3) of our patients had mild to moderate coronary allograft vasculopathy. The Infection rate was noted to be higher, affecting 70% (n = 7) of our patients. The Results are summarized in the pic attached.
Conclusion: NODAT is common affecting 10% of our heart transplant population. Careful screening for NODAT is important and also the frequency of screening needs to be increased during the first year of transplant as the incidence of NODAT seems to be higher during the first year after transplantation.

Endothelial function and skin temperature during psychological stress in heart and respiratory failure patients

E Elisa Perez Cabanas[1]; V Pelaez-Hernandez[1]; SC Torres-Montiel[1]; FA Figueroa-Herrera[1]; M Rivera-Rodriguez[1]; A Orea-Tejeda[1]; D Gonzalez-Islas[1]; CL Olivo-Villalobos[1]; CA Chavez- Mendez[1]; GV Davila-Said[1]
[1]National Institute of Repiratory Diseases, Heart Failure and Respiratory Distress Clinic, Ciudad de Mexico, Mexico

On behalf of: Heart Failure and Respiratory Distress Clinic

Background: Patients with cardiac and respiratory pathologies usually present endothelial dysfunction, which is responsible of the alterations in skin temperature, during physical and psychological stressors. The changes in thermoregulation response can show the endothelial function state and the emotional state of the patients when they are exposed to psychological stress.
Purpose: To describe the bilateral skin temperature response during the presentation of psychological stressor, between mild and severe endothelial dysfunction in heart and respiratory failure patients.
Method: A cross-sectional study was carried out in 40 patients with heart failure and chronic respiratory disease diagnostic (COPD, pulmonary embolism or Obstructive Sleep Apnea Syndrome). We evaluated the endothelial function with the Maximum Amplitude Time/ Total Time of the pulse wave (MAT/TT index) in five different times (baseline, at 30, 60, 90, 120 minutes after an ischemia period) by a photoplethysmography test. The patients were divided into two groups based on endothelial

dysfunction: Mild group (MG), patients who reduced the MAT/TT index in any of the five moments after ischemia; severe group (SG), patients who not reduced the MAT/TT index in any of the five moments after ischemia. Skin temperature recording was made with a temperature sensor placed on the third phalanx of the little finger of Left (LH) and Right Hand (RH), during a psychophysiological stress profile with three phases of five minutes each (baseline, arithmetic stressor, recovery). For this profile was used a biofeedback equipment. Differences between groups were determined with a Mann-Whitney U test in the SPSS 21 program for windows.

Results: Despite the fact that patients with severe endothelial dysfunction (n = 25; M. age = 69.72 ± 12.61; 52% women) show low skin temperature compared to patients with mild dysfunction (n = 15; M. age = 67.53 ± 15.54; 60% women), during the three phases of psychophysiological stress profile; baseline (LH: SG-M = 31.17 ± 3.64 |MG-M = 32.05 ± 2.87, RH: SG-M = 31.81 ± 3.77 |MG-M = 32.61 ± 2.53); stressor (LH: SG-M = 31.30 ± 3.60 |MG-M = 32.16 ± 2.76, RH: SG-M = 32.17 ± 3.76 |MG-M = 32.95 ± 2.29) and recovery (LH: SG-M = 31.68 ± 3.60 |MG-M = 32.52 ± 2.47, RH: SG-M = 32.60 ± 3.76 |MG-M = 33.41 ± 1.86). Differences in sex (p=.62); M. age (p=.76); LH temperature (p=.57); RH temperature (p=.79) during baseline; LH temperature (p=.50); RH temperature (p=.66) during stressor; LH temperature (p=.44); RH temperature (p=.62) during recovery, were not statistically significant.

Conclusion: The results indicate that the endothelial dysfunction impacts on thermoregulation. However, the endothelial dysfunction severity was not completely reflected in the skin temperature response during psychological stress in heart and respiratory failure patients. So, we suggest continuing this research line and increase the sample size.

P374

Sacubitril-valsartan: does the functional class improve objectively estimated by cardiopulmonary exercise testing?

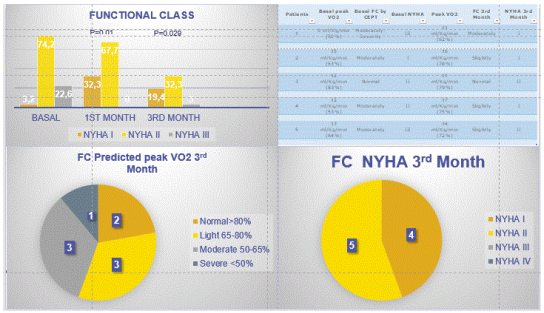
C Cristina Beltran Herrera[1]; V Suberviola[1]; S Briongos[1]; M Sarrion[1]; A Sanchez[1]; C Cortina[1]; ML Giganto[1]; E Gomez[1]; R Munoz[1]
[1]*University Hospital Infanta Leonor, Madrid, Spain*

Introduction: The new drug Sacubitril-Valsartan (ARNI) has demonstrated to improve the functional class (FC) measured by NYHA in patients (pts) with heart failure (HF) and ventricular dysfunction. The most objective method of assessing FC in HF is the peak oxygen uptake (Vo2) in a cardiopulmonary exercise testing (CPET). Our objective is to assess whether the use of ARNI in pts with HF also improves the FC measured by peakVo2.

Methods: We analyzed 31 pts with HF and left ventricular dysfunction from October 2016 to March 2017 which had been treated with Sacubitril-Valsartan evaluated in a cardiology day clinic. The FC was evaluated by NYHA before treatment, on the first and third month. CEPT was performed on the third month in 9 pts, and then compared with a baseline test before ARNI available in 5 pts. According to the % peak of Vo2 reached predicted by Wasseman values it was estimated that, the FC was: normal FC> 80% predicted, FC slightly reduced 60-79%, FC moderately reduced 59-50% and FC severely reduced < 50%.

Results: 80% males, 71 ± 10 years, LVEF 27 ± 5%, NTproBNP 3123 ± 2811, 49% ischemic C., 39% idiopathic C. 96.8% pts take beta-blockers, 58.1% MRA. The NYHA FC pretreatment, first and third month after treatment is shown in the graph, there was a significant improvement with the drug. The absolute value of peak vO2 as well as its values predicted at baseline and in the third month are shown in the table and graphs. Except in 1 patient, there was absolute improvement in the peak Vo2 measured in the third month, and in the FC estimated by CEPT. The pte that didn't show improvement maintained a normal capacity before and after treatment. If the FC is compared at third month as estimated by NYHA and Vo2, there are discrepancies, 100% in FC I-II by NYHA and 55% in FC I-II by peak vO2 (graph)

Conclusions: In our real life series, ARNI significantly improves the FC determined by NYHA. If the FC is estimated by peak Vo2, more objective, pts tend to present worse functional class than measured by NYHA. Even so, the absolute values of peak Vo2 and the FC estimated by this parameter improve after 3 months of ARNI. These are preliminary data and further studies are required in this regard but we point out that sacubitril-valsartan is an effective drug in the functional improvement of these pts.



Functional class.VO2 Pre-post Sacubitril

Efficiency and safety of physical rehabilitation in patients with chronic heart failure III-IV class NYHA candidates for heart transplantation

MA Bortsova[1]; MU Sitnikova[1]; EA Demchenko[2]; TA Lelyavina[1]; OA Babich[2]; VL Galenko[1]; PA Fedotov[1]
[1]*Federal Almazov North-West Medical Research Centre, Heart Failure, Saint-Petersburg, Russian Federation*; [2]*Federal Almazov North-West Medical Research Centre, Saint-Petersburg, Russian Federation*

Purpose: To asses the efficiency of physical rehabilitation in patients with chronic heart failure (CHF) III-IV class NYHA candidates for heart transplantation (HT).

Methods: In pilot study were included 51 men, candidates for heart transplantation, aged 20-65 years old, LVEF = 30% Simpson, ischemic etiology or dilated cardiomyopathy, stabilizated in NYHA class III-IV CHF during = 2 weeks, BP = 90/60 mm Hg, HR = 100 beats per minute, treated with standart therapy of CHF. Patients with sustained ventricular tachycardia, myocardial infarction (MI) and pulmonary embolism (PE) during the previous 3 months, unstable angina pectoris during 1 month and stroke for 6 months were not included. Safety of physical rehabilitation program (PRP) was monitored with continuous cardiomonitoring during training in the presence of a cardiologist and a physiotherapist. Patients were randomized into 2 groups: 1-st - participating in PRP (n = 26), 2-nd (control) - standard therapy of CHF (n = 25). The duration of follow-up was 6 months.

Results: Both groups were comparable in age, background cardiac and concomitant pathology. In both groups, patients received standard CHF therapy: in 1-st group and in 2-nd group: ACEI/ARA - 24 and 23 patients, ß-blockers - 23 and 21 patients, aldosterone antagonists - 24 and 16 patients, loop diuretics - 26 and 25 patients , thiazides - 8 and 4 patients, amiodarone - 14 and 10 patients, respectively. In both groups, a comparable number of patients finish the study: In 1-st group - 18 patients, early completion of 8 patients: 2 deaths, 6 - HT. In 2-nd group - 16 patients, early completion of 7 patients: 3 deaths, 4 - HT. In both groups, there were no statistically significant differences in the number of deaths. In both groups up to 6-th month, there was a comparable number of patients who switched to II NYHA class : 6 in group 1 and 5 in group 2.

In the 1-st group there were not observed life-threatening ventricular arrhythmia during exercising and within 3 hours after. After 6 months in 1-st group PE was not established while in 2-nd group were observed 4 cases, without statistical significance. In group 1, there was a statistically significant decrease in the number of the lower respiratory tract infections (LRTI): bronchitis + pneumonia compared to the 2-nd group: 5 and 18 patients, respectively (p = 0.001).

Conclusions: 1. Participation in an individually designed PRP does not increase mortality and the number of life-threatening ventricular arrhythmias in patients with stabilization of CHF in III-IV NYHA class. 2. Participation in an individually designed PRP does not cause progression of CHF in patients with stabilization of CHF in III-IV NYHA class. 3. Patients participating in an individually PRP have a lower number of LRTI compared with the control group.

P376

Prolonged use of Levitronix - right ventricular assist device (RVAD) in patients with long term left ventricular assist device (LVAD)

A Adnan Yousaf[1]; S Mihiyaddin[1]; M Aldweik[1]; S Ashraf[1]
[1]*Regional Cardiac Centre Morriston Hospital, Swansea, United Kingdom*

Aim : Severe right ventricular failure after implantation of long-term LVAD (LTLVAD) is common and occasionally requires the need for right heart support. The choices for RVAD support are limited mainly by short term devices.
Material and methods: 7 published papers were looked up reviewing data including one with multicentre trial of patients who had LTLVAD and required Centrimag RVAD implantation. There were 423 patients, 73 had Heartmate I, 20 Thoratec PVAD, 43 Jarvik 2000, 12 HeartWare and 275 HeartMate II. Mean age was 38.6 (range13-59) years. 73.9% were male, 21.7% had ICM and 78,3% DCM. 64 had preoperative mechanical ventilation, 83 had IABP and 37% had multiple inotropic support. 36.5% patients underwent early right VAD insertion (<24 hours) 26.1% delayed (>24hours) while 17.24% were moribound patients salvaged with BiVAD Centrimag as a bridge to decision and later on upgraded for a LTLVAD and required continuous support of RVAD Centrimag.
Results: Postoperative mean ventilation time 4.7 days, ICU stay of 12.3 days and hospital stay was 22.8 days. Mean duration of LTLVAD and RVAD support was 212 (range 4-619 days) and 44 (range 6 to 207) days, respectively. Operative mortality was 17.4%., 78.3% patients had their RVAD explanted, 26.1% were bridged to transplant, 8.7% had full myocardial recovery and had LTLVAD explanted. 74 patients are ongoing. There was no incidence of pump failure or thrombosis. The vast majority of patients were mobilised and exercised out of bed while on BIVAD support.
Conclusion: Prolonged use of RVAD Centrimag appears to be safe and effective for recovery or bridge to transplantation in patients with severe right ventricular failure and LTLVAD. Retrospectively it appears BiVAD devices could be used for long term in patients waiting for a transplant beyond 6 months from analysing these papers.

P377

Heart failure with mid-range ejection fraction:the effects of short-term physical training

D Dragan Marinkovic[1]; M Deljanin-Ilic[1]; V Stoickov[1]; B Ilic[1]; I Krstic[1]; S Stojanovic[1]; D Petrovic[1]
[1]*University of Nis, Medical Faculty, Institute of Cardiology Niska Banja, Nis, Serbia*

Heart failure with mid-range ejection fraction (HFmrEF), the "midlle child", as a new entity, in heart failure familly, has limited data regarding exercise tolerance and training, functional capacity and quality of life (QOL). Available data suggest that it constitutes a sizeable proportion(10-20%) of the HF population, has a unique clinical, echocardiographic, haemodynamic, and biomarker profile compared with HFrEF and HFpEF, and carries a poor prognosis.
Aim: To evaluate the effects of short-term physical training on physical exercise, tolerance and level of markers of inflammation, neuro-humoral activation and endothelial function, in patients wit HFmrEF.
Methods: The study involved 33 HF patients (21 males); mean age 60.3 ± 5.7 years, with established ischemic heart disease, mean EF 44,58 ± 5,23%, which fulfill criteria for HFmrEF. All patients were included in three-weeks rehabilitation program in the residential center, based on strictly controlled and individually prescribed physical training. Before and after rehabilitation, all patients were underwent exercise stress test, and from the veins blood samples, biochemical markers of inflammation, atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP) an endothelin (ET) were determined.
Results: At the end of the study the hs-CRP and fibrinogen level were showed a decreasing trend (p = 0.42; p = 0.68 n.s). After cardiovascular rehabilitation a significant reduction in white blood cells count was recorded (p = 0.022). Erythrocyte sedimentation rate after rehabilitation was higher, but not significant. In all pts, the concentration of ANP and BNP was lower after 3 weeks compared to baseline values (p = 0.023; p = 0.019). In contrast, the value of endothelin after rehabilitation was higher than baseline value (p = 0.112), but not significant. At end of this study, significantly higher serum HDL-cholesterol in CHF patients was found (p = 0.001). Exercise tolerance after rehabilitation was improved (55.35 ± 5,23 W vs 74.69 ± 6.13 W; p = 0.047), as well as quality of life assessed by Minnesota Living With Heart Failure Questionnaire (58,69 ± 3,69 vs 38,39 ± 2,24 p = 0.035)
Conclusion: The results of our study showed that, in patients with the midrange LVEF residential short-term training has favourable impact expressed throught decreasing of the level of inflammatory status and neuropeptids. Those positive effects are associated with significant increases of exercise tolerance and improvement of quality of life.

P378

Efficacy and safety of Urapidil and Nitroglycerin injection in acute coronary syndrome patients with acute heart failure and hypertension

J Jing Gao[1]; Q Hua[1]; JY He[1]; YL Wang[1]; J Tan[1]; ZX Fan[1]
[1]*Xuan Wu Hospital, Capital Medical University, department of cardiology, Beijing, China People's Republic of*

Background: Acute heart failure is a complex clinical syndrome responsible for high morbidity and mortality and frequently complicated by concomitant hypertension and acute coronary syndrome. Despite advances in the management of heart failure, the prognosis of these patients remains poor and there is a critical need for new treatment strategies improving the clinical outcomes.
Objective: To compare the efficacy and safety of Urapidil and nitroglycerin in acute coronary syndrome (ACS) patients with acute heart failure(AHF) and hypertension.
Methods: Thirty ACS patients with AHF and hypertension were randomly divided into Urapidil treatment group(n = 14) and nitroglycerin treatment group(n = 16).Patients in Urapidil treatment group were treated with Urapidil (50-300μg/min) and those in Nitroglycerin treatment group were treated with Nitroglycerin (5-20μg/min) for 48-140h according to their blood pressure(SBP 159.44 ± 30.95mmHg vs 146.70 ± 31.63mmHg; DBP 86.64 ± 21.00mmHg vs 82.57 ± 17.09mmHg)and cardiac function.All patients were monitored for blood pressure, heart rate, cardiac function test by echocardiography, NT-proBNP and blood biochemical index including glucose,blood lipid level, liver function, renal function, situation at the time of before treatment, 24h, 48h, 72h, 7d after treatment.
Results: The diameter of left atrium, left ventricular diastolic diameter, EDV and ESV of left ventricle were significantly lower in Urapidil treatment group than in Nitroglycerin treatment group after 48h. (37.3 ± 2.12mm vs 42.8 ± 4.87mm, p = 0.06; 51.11 ± 4.57mm vs 57.90 ± 7.44mm, p = 0.30; 124.22 ± 24.2ml vs 178.56 ± 52.98ml, p = 0.013; 52.67 ± 20.88ml vs 87.67 ± 38.13ml, p = 0.028). No significant differences between two groups in all the other parameters (P>0.05). And no significant difference between two groups in major adverse cardiovascular events on days 7 and 30(P>0.05).
Conclusion: Urapidil is a safe and effective vasculardilator for ACS patients with AHF and hypertension.

P379

6 minute walk tests performed at home are accurate and reliable

AE Burch[1]; D Scherr[2]; A Rieth[3]; JJ Griffin[4]; N Bianco[5]; T Odeneg[2]; SF Sears[1]
[1]*East Carolina Heart Institute, Psychology , Greenville, United States of America*; [2]*Medical University of Graz, Department of Medicine, Graz, Austria*; [3]*Kerckhoff Heart Center, Department of Cardiology, Bad Nauheim, Germany*; [4]*Cardiovascular Associates, Virginia Beach, United States of America*; [5]*ZOLL Medical, Pittsburgh, United States of America*

Background: Walking is fundamental to independence and cardiovascular well-being, with a 6-minute walk test (6MWT) being one of the common tools to track patients objectively. The purpose of this study was to evaluate the accuracy and reliability of the wearable cardioverter defibrillator (WCD) guided 6MWT performed at home by heart failure patients in comparison to a conventional in clinic test.
Methods: Patients (n = 198) with heart failure and a low ejection fraction prescribed a WCD were randomized to two groups. Group 1 completed a standard 6MWT while wearing the WCD. This 6MWT was performed in clinic under medical direction and the results were recorded by the clinician. Group 2 completed the WCD-guided 6MWT. This 6MWT was also performed in the clinic but without medical direction and results were recorded by the WCD accelerometer (results were also recorded by a clinician who did not interact with the patient). Over 8 weeks, both groups performed up to 8 unsupervised WCD-guided 6MWTs at home with results recorded by the WCD. Differences between group 1 and group 2, in clinic WCD-guided 6MWT and first at home WCD-guided 6MWT, and repeated at home 6MWTs were analyzed.
Results: For the initial in-clinic 6MWT there was no significant group difference in mean distance walked (group 1 = 306.3 meters, group 2 = 295.1 meters, p = 0.46). Of those who completed = one 6MWT at home, there was a 6 step difference between the in clinic WCD-guided 6MWT (group 2) and the first at home 6MWT performed (Wilcoxon signed-rank test; medians: 553 steps and 547 steps respectively, p = 0.004). For a subset of patients (n = 70) with 8 at home 6MWTs there was no significant difference over eight weeks in the number of steps walked (F(7,552) = 0.34, p = 0.93).
Conclusion: Results of the in clinic 6MWT are similar between clinician-guided and WCD-guided patients. Distances walked with a WCD-guided walk test were consistent whether conducted in the office or at home. The 6 step difference between the in clinic WCD-guided 6MWT and the first at home test is unlikely to have clinical significance. In addition, the at home WCD-guided 6MWT demonstrates good repeatability over time.

The WCD-guided 6MWT performed at home is a reliable alternative to administering the test in the clinic.

P380

Comparative effectiveness of enalapril, lisinopril and ramipril in the treatment of patients with chronic heart failure. A propensity score matched cohort study

T Tobias Taeger[1]; F Henning[1]; H Froehlich[1]; D Schellberg[1]; M Grundtvig[2]; K Goode[3]; S Kazmi[3]; T Hole[4]; HA Katus[1]; D Atar[5]; JGF Cleland[6]; S Agewall[5]; A Clark[3]; L Frankenstein[1]
[1]University Hospital of Heidelberg, Department of Cardiology, Heidelberg, Germany; *[2]Innlandet Hospital, Medical Department, Lillehammer, Norway*; *[3]Castle Hill Hospital, Hull, United Kingdom*; *[4]Norwegian University of Science and Technology, Medical Faculty, Trondheim, Norway*; *[5]Oslo University Hospital, Department of Cardiology, Oslo, Norway*; *[6]Imperial College London, London, United Kingdom*

Background: Angiotensin converting enzyme inhibitors (ACEIs) are recommended as first-line therapy in patients with heart failure with reduced ejection fraction (HFrEF). The comparative effectiveness of different ACEIs is not known.
Methods and **Results:** 4,723 out-patients with stable HFrEF prescribed either enalapril, lisinopril, or ramipril were identified from three registries in Norway, England, and Germany. In three separate matching procedures, patients were individually matched with respect to both dose equivalents and their respective propensity scores for ACEI treatment.
During a follow-up of 21,939 patient-years, 360 (49.5%), 337 (52.4%), and 1,119 (33.4%) patients died amongst those precsribed enalapril, lisinopril, and ramipril, respectively. In univariable analysis of the general sample, enalapril and lisinopril were both associated with higher mortality as compared with ramipril treatment (HR 1.46, 95% CI 1.30-1.65, $p < 0.001$, and HR 1.38, CI 1.22-1.56, $p < 0.001$, respectively). Patients prescribed enalapril or lisinopril had similar mortality (HR 1.06, 95% CI 0.92-1.24, $p = 0.41$). However, there was no significant association between ACEI choice and all-cause mortality in any of the matched samples (HR 1.07, 95% CI 0.91-1.25, $p = 0.40$; HR 1.12, 95% CI 0.96-1.32, $p = 0.16$; and HR 1.08, HR 1.10, 95% CI 0.93-1.31, $p = 0.25$ for enalapril vs. ramipril, lisinopril vs. ramipril, and enalapril vs. lisinopril, respectively). Results were confirmed in subgroup analyses with respect to age, sex, left ventricular ejection fraction, NYHA functional class, cause of HFrEF, rhythm, and systolic blood pressure.
Conclusion: Our results suggest that enalapril, lisinopril and ramipril are equally effective in the treatment of patients with HFrEF when given at equivalent doses.

P381

The clinical implication of donor-recipient mismatch in heart transplant recipients; data from the Korean Organ Transplantation Registry

J Jaewon Oh[1]; JO Choi[2]; HJ Cho[3]; HY Lee[3]; SH Jung[4]; JJ Kim[4]; ES Jeon[2]; SM Kang[1]
[1]Yonsei University College of Medicine, Cardiology Division, Seoul, Korea Republic of; *[2]Samsung Medical Center, Cardiology, Seoul, Korea Republic of*; *[3]Seoul National University College of Medicine, Cardiology, Seoul, Korea Republic of*; *[4]Asan Medical Center, Cardiovascular Surgery, Seoul, Korea Republic of*

Introduction: The International Society for Heart and Lung Transplantation (ISHLT) guidelines recommend donor-recipient matching against inappropriate weight match (IWM) for heart transplant. Few studies have explored this size matching recommendation, especially with regard to body weight and gender matching in Asian heart transplant recipients. We aimed to determine whether any difference could be observed between donor-recipient mismatching with regard to clinical outcomes in Korean heart transplant recipients.
Methods: Data from adult heart transplants (recipients = 18 years of age) between 2014 and 2017 were obtained from the Korean Organ Transplantation Registry (KOTRY). We defined IWM, defined as donor weight < 70% of recipient's weight. The clinical end-points were all-cause 30-day mortality and cumulative mortality during follow-up period.
Results: IWM was associated with increased 30-day mortality as well as cumulative mortality in Korean heart transplant recipients. Male recipients of female allografts as well as female recipients of male allografts had increased cumulative mortality compared with gender-matched transplants.
Conclusion: Our results indicate that donor weight < 70% of recipient weight increases 30 day and cumulative mortality in Korean heart transplant recipients. Gender mismatch increases mortality independently of weight match.

P382

Dynamics and prognostic value of B-type natriuretic peptide in left ventricular assist device recipients

M Papathanasiou[1]; R Sofianos[1]; L Tsourelis[2]; M Kamler[2]; N Pizanis[2]; T Rassaf[1]; P Luedike[1]
[1]University Hospital Essen, Department of Cardiology and Angiology, West German Heart and Vascular Center, Essen, Germany; *[2]University Hospital Essen, Department of Thoracic and Cardiovascular Surgery, West German Heart and Vascular Center, Essen, Germany*

Background: The prognostic utility of B-type natriuretic peptide (BNP) in heart failure is well recognized. Previous studies demonstrated that BNP levels decrease after left ventricular assist device (LVAD) implantation.
Purpose: We sought to investigate the predictive value of baseline and changes in BNP levels in LVAD recipients.
Methods: BNP was measured in baseline and follow-up plasma samples from consecutive patients receiving a continuous-flow LVAD from 2010 through 2016. Absolute values and changes from baseline were related to 180-day all-cause death or the combined end-point of all-cause death or hospitalization.
Results: Our study included 103 consecutive adult patients with a mean age of 59 years. Median BNP at baseline was 885 (Interquartile range, IQR: 450 to1624) pg/ml, significantly decreasing to 289 (IQR: 154-534) pg/ml 90 days after LVAD implantation ($p < 0.001$). Overall 63 (61%) patients survived to 90-day follow-up. In all subjects, BNP remained above the cut-off of 35 pg/ml for chronic heart failure and in 91% above 100 pg/ml. Cox proportional hazards regression analysis revealed that higher baseline and follow-up BNP levels were not associated with increased risk of death at 180 days ($p = 0.12$ and $p = 0.43$, respectively). In the univariate analysis 90-day BNP, but not baseline BNP, was significantly associated with the combined death/hospitalization outcome (HR 1.03, 95% CI 1.01-1.06; $p = 0.006$). This significance was not preserved after adjusting for multiple covariates (HR 1.01, 95% CI 0.98-1.04; $p = 0.62$). At 90 days, there was no BNP lowering in 20.6% of subjects. This was not associated with higher risk for death or the composite of death/hospitalization at 180 days ($p = 0.11$ and $p = 0.06$ respectively).
Conclusions: BNP levels significantly decrease but remain highly abnormal in the vast majority of patients following LVAD implantation. BNP absolute levels and changes from baseline are not independently associated with clinical outcome. These findings suggest an impaired prognostic performance of BNP after LVAD implantation.

P383

Remote model in the system of outpatient cardioreabilitation in subjects with chronic heart failure

N Lyamina[1]; E Kotelnikova[1]; V Senchikhin[1]; T Lipchanskaya[1]
[1]Research Institute of Cardiology Saratov State Medical University named after V.I. Razumovskiy, Saratov, Russian Federation

Background : The remote management of treatment and rehabilitation process including self-management, telemedical healthcare and remote monitoring (RM) can be executed for outpatient cardiac rehabilitation (CR) in subjects with chronic heart failure (CHF).
Purpose: Remote observational model evaluation in outpatient CR in subjects with I-III NYHA CHF after myocardial infarction (MI).
Methods: The study included 24 subjects: 22/91.7% of men, 55.3 ± 8.3 y.o.; NYHA 2.04 ± 0.25; 75% after PCI due to MI; mean GRACE scale score 92 ± 12. Home CR programs included controlled walking 5 times/week. Remote rehabilitation monitoring (3 months) included ECG autotransmitting, physical activity and physiological indicators control, asynchronous telemedicine and office counseling. ECG telemonitoring was performed by the principle of autotransmitting with mobile devices and the ECG Dongle Internet application. Physical activity (PA) was measured by Beurer AS80 digital pedometer with transmitting data to the smartphone and the mobile application Easyfit (GmbH, Germany). PA tolerance was estimated in Borg scale points. Type of attitude towards the disease was assessed by the LOBI questionnaire. Remote correction of rehabilitation assignment was carried out in the mode of asynchronous telemedicine counseling; correction of drug therapy was performed during office counseling. CR effectiveness was assessed by the results of 6-min walk distance test (WDT) and the dynamics of NYHA functional class, as well as the patients' activity indices in the RM system and dynamics of the personal response to the disease.
Results: Patients with I-III NYHA CHF were included in the RM program on 31 ± 5 days of MI. Initially disadaptive behavioral reactions prevailed (87.0%). No signs of personal disadaptation had 12.5% subjects. According to the RM parameters data transmission was stopped by 3 patients (12.5% of participants) after 4 ± 1.2 weeks of follow up. After 3 months of CR with a walking time of 37 ± 5 min/day, average number of 3223.6 ± 27.7 steps/day, total distance traveled 9.9 ± 2.7 km/week and a stable subjective reaction (0.6 ± 0.3 and 0.7 ± 0.2 Borg scale points) the dynamics

of WDT (443 ± 32 m vs. 352 ± 27, p <0.05) and NYHA CHF (1.71 vs. 2.04, p <0.05) were observed. Asymptomatic episodes of myocardial ischemia were recorded in 2 subjects (9.5%); rhythm disturbances - in 8 (38.1%). The number of patients with minimal manifestations of maladjustment increased (12.5% vs 33.3%, p <0.001). The proportion of subjects with intrapsychic orientation disorders was slightly decreased (from 66.7% to 61.9%).
Conclusions: : The RM system based on mobile communication is successful as a model of rehabilitation care for outpatient management in CHF patients. The complex predisposing factor of RM application is to increase the motivation of patients by involving them in the self-management process improving the quality of communication between the doctor and the patient and increasing patients' physical activity.

P384
Impact of introduction of a formal heart failure programme in a developing nation- a single centre study

CY Chun Yuan Khoo[1]; CT Ng[1]; TL Tran[2]; TT Pham[2]; M Le[2]; TL Le[2]; TAN Nghiem[2]; DC Truong[2]; CP Lim[1]; LY Teo[1]; LH Chan[1]; DAVID Sim[1]
[1]National Heart Centre Singapore, Singapore, Singapore; *[2]175 Military Hospital, Ho Chi Minh, Vietnam*

Background/Purpose: Formal heart failure (HF) programmes are lacking in developing countries. Prescription rates of evidence based HF medications remains suboptimal. Heart failure self-care among patients in these countries is poor. Comprehensive HF programme has been shown to result in clinical benefits in developed countries. We seek to study if similar benefits may be accrued among HF patients in a developing country in South East Asia.
Methods: This is a prospective observational study. We enrolled patients with left ventricular systolic function (LVEF) = 40% with at least 1 HF admission in the previous 12 months into a new HF programme in the 175 Military Hospital in Vietnam. The patients would have to be willing to pay medical costs at an unsubsidized fee. The HF programme was helmed by 3 local cardiologists and 3 specialist nurses trained in HF. Besides routine physical examinations, the patients were educated on their condition and medications. Advice was given for exercise and dietary restrictions. The clinical status, laboratory results and medications of the patients were reviewed 3 months later and compared to their baseline **Results: Results:** Out of the 50 patients enrolled, 34 were male (68%). Mean age was 63.9 ± 10.8 years. Mean LVEF was 35.1 ± 6.4%. At baseline, majority of the patients (62%; N = 31) were in New York Heart Association (NYHA) functional class III, while the remainder were in NYHA II.
After a duration of 3 months, mean systolic blood pressure was reduced from 122mmHg to 111mmHg (P = 0.004). Mean heart rate was reduced from 78/min to 68/min (P < 0.001). There was also a reduction in mean NT-proBNP levels from 7133pg/ml to 4563pg/ml (P = 0.007). Hospitalisation rates were reduced from 70% to 22% (P < 0.001). There was an increase in beta-blocker prescription rates (32% to 68%). Adherence to HF therapy improved from 54% to 94% (P < 0.001) at 3 months followup. Functional status of the patients also improved, with more patients in NYHA II (38% to 88%; P < 0.001).
Conclusion: The implementation of a formal HF programme improves clinical outcomes among HF patients in this single-centre study in a developing nation. Larger studies over a longer duration of time would be beneficial in studying potential cost savings translated from the health benefits.

Drug utilization in the outpatient heart failure clinic at the University hospital of Iceland- adherence to guidelines

IE Gisladottir[1]; PS Gunnarsson[1]; I Gunnthorsdottir[1]; I S Inga Sigurros Thrainsdottir[1]; A Ketilsdottir[1]; G Gudlaugsdottir[1]; K Andersen[1]
[1]University of Iceland, Cardiology, Reykjavik, Iceland

Funding Acknowledgements: none

Background: Heart failure is a common and severe type of cardiovascular disease. Four major drug classes are used in the treatment of heart failure, ACE and ARB inhibitors, beta blockers and mineralcorticoid receptor antagonists (MRAs). The objective of this study was to evaluate the drug utilization of patients in the outpatient heart failure clinic at the University hospital of Iceland and to estimate the adherence to the 2016 ESC guidelines for acute and chronic heart failure.
Methods: A retrospective and descriptive study was preformed using data collected from the electronic medical records system of the University Hospital for patients, 18 years or older, based on their last visit to the outpatient heart failure clinic in 2016. Target doses were obtained from the 2016 ESC guidelines for the diagnosis and treatment of acute and chronic heart failure.
Results: In total, 253 patients had at least one visit to the outpatient clinic for patients with heart failure in 2016. The average age of patients was 69 years and the majority of patients were men (75.5%). A total of 219 (87%) patients were treated with ACE or ARB inhibitors, 227 (90%) patients were treated with beta-blockers and 130 (51%) patients were treated with MRAs. The target dose was reached in 14% of patients receiving ACE or ARB inhibitors, 12% of patients receiving beta blockers and 16% of patients receiving MRAs. The main reasons for dose adjustments and drug selection were renal failure and hypotension. 25,4% of patients had serum creatinine higher than 150 μmol/L. 11% of patients younger than 80 years old had systolic pressure lower than 100 mmHg and 15% of patients 80 years or older had systolic pressure lower than 120 mmHg. In addition 14% of patients had other side effects as reason for lowering of dosage or discontinuation of treatment.
Conclusions: The main findings of the study are that low proportion of patients with heart failure are treated according to the ESC guidelines for acute and chronic heart failure. The main reasons that patients did not reach target dose were worsening of renal function, hypotension or patients were still in up titration phase. These results are consistent with similar studies that have been conducted in Europe.

Eplerenone titration in real-world heart failure patients: a multicenter survey

A Karavidas[1]; D Farmakis[2]; V Bistola[2]; A Kitsiou[3]; C Chatzieleftheriou[4]; C Papadopoulos[5]; J Zarifis[6]; I Styliadis[7]; S Adamopoulos[8]; J Parissis[2]
[1]General Hospital of Athens G. Gennimatas, Athens, Greece; *[2]Attikon University Hospital, Heart Failure Unit, Cardiology Department, Athens, Greece*; *[3]Sismanoglion Hospital, Athens, Greece*; *[4]Drama General Hospital, Department of Cardiology, Drama, Greece*; *[5]Hellenic Red Cross Hospital, Athens, Greece*; *[6]General Hospital G. Papanikolaou, Thessaloniki, Greece*; *[7]Hospital Papageorgiou, Thessaloniki, Greece*; *[8]Onassis Cardiac Surgery Center, Athens, Greece*

Background: Mineralocorticoid receptor antagonists (MRA) constitute a cornerstone of current therapy for heart failure with reduced ejection fraction (HFrEF). However, concerns about MRA-associated renal function worsening and hyperkalemia have been raised. In addition, prescription and particularly titration of life-saving therapies vary considerably in different HF populations.
Purpose: We sought to investigate titration rates of eplerenone in real-world HFrEF patients followed regularly in HF clinics and its effects on clinical parameters, renal function and serum potassium levels.
Methods: We enrolled a total of 413 consecutive patients on eplerenone, 79% male, 92% in NYHA class II or III, with mean left ventricular ejection fraction 30 ± 8%, from different HF clinics throughout Greece. Eplerenone dosing along with clinical parameters, renal function, serum potassium and quality of life were evaluated at baseline and at 6 months.
Results: Mean eplerenone dose increased significantly from baseline (28.5 ± 11.8 mg) to 6 months (31.8 ± 13.7 mg, p < 0.001); The target dose of 50mg was prescribed in 13% of patients at baseline and in 23% at 6 months. The corresponding prescription rates in patients with renal dysfunction were 15% and 17%, respectively. Heart rate decreased significantly from baseline to 6 months (72 ± 11 vs. 70 ± 8 bpm, p < 0.001), while systolic blood pressure remained stable (118 ± 18 vs. 118 ± 16 mmHg, p = 0.828). Creatinine clearance also remained stable throughout 6 months (73 ± 31 vs. 69 ± 48 ml/min, p = 0.146), while there was a small and marginally significant increase in serum potassium, which however remained within normal range (4.3 ± 0.5 vs. 4.4 ± 0.7 mmol/L, p = 0.047). Quality of life, as estimated by Kansas City Cardiomyopathy Questionnaire, improved from baseline to 6 months (p < 0.001).
Conclusions: Eplerenone was successfully titrated in HFrEF patients without adverse events. However, target dose prescription remains suboptimal. Efforts to increase adherence to Guideline recommendations are warranted.

P387
Oral sucrosomial iron improves quality of life in heart failure patients with iron deficiency: A preliminary proof-of-concept study

A Karavidas[1]; E Trogkanis[1]; D Farmakis[2]; G Georgios Papingiotis[2]; V Matzaraki[1]; A Perpinia[1]; D Balta[1]; J Parissis[2]
[1]General Hospital of Athens G. Gennimatas, Department of Cardiology, Athens, Greece; *[2]Attikon University Hospital, Second Cardiology Clinic, Heart Failure Unit, Athens, Greece*

Background: Iron deficiency is prevalent in 37-50% of heart failure (HF) patients and has been associated with reduced functional capacity and quality of life (QoL) and adverse prognosis. Intravenous iron supplementation improves functional capacity and QoL, but use of oral iron preparation has been limited by poor intestinal absorption.
Purpose: In this preliminary, proof-of-concept study, we evaluated the efficacy of sucrosomial iron (SSI), a new oral iron formulation that seems to overcome intestinal epithelial barriers, in HF patients with iron deficiency.
Methods: We studied 30 patients with chronic HF with reduced left ventricular ejection fraction (35% or less, HFrEF), New York Heart Association (NYHA) class

II or III, iron deficiency (ferritin level < 100 ng/mL or serum ferritin 100-299 ng/mL and transferrin saturation < 20%), and hemoglobin level 9.0-13.5 g/dL in females and 9.0-15 g/d in males. All patients had been on stable, evidence-based medical therapy for at least 1 month. Twenty patients received oral SSI, containing 28 mg of iron, once daily for 3 months and 10 served as controls. Clinical and laboratory parameters were evaluated at baseline and at 3 months.
Results: Patients in SSI group were strongly adherent to protocol and no drop-outs were noticed. At 3 months, SSI induced a significant increase in serum iron levels (from 43.7 ± 19.0 to 60.32 ± 16.23 mg/mL, adjusted p = 0.002), where hemoglobin levels remained stable. Quality of life, as expressed by Kansas City Cardiomyopathy Questionnaire, also improved significantly (from 55.7 ± 18.5 to 61.8 ± 20.81, adjusted p = 0.038) and there was also a trend towards a longer 6-min walked distance (from 318 ± 72 to 332 ± 74.63 m, adjusted p = 0.065).
Conclusion: Short-term oral SSI improved iron status and quality of life in HFrEF patients with iron deficiency, without causing any adverse event. A further evaluation of this form of iron warrants further investigation.

P388

Long-term follow-up of patients with dilated cardiomyopathy receiving cardiac resynchronization therapy: responders vs nonresponders -10 years single center trial

G Milasinovic[1]; MT Petrovic[2]; N Radovanovic[1]; SU Pavlovic[1]; G Nikcevic[1]; B Kircanski[1]; I Petrovic[2]; D Trifunovic[2]; J Petrovic[2]; MZ Petrovic[2]
[1]Clinical center of Serbia, Pacemaker Center, Belgrade, Serbia; [2]Clinical center of Serbia, Clinic of cardiology, Belgrade, Serbia

Introduction: Cardiac resynchronization therapy (CRT) is a validated therapy for patients with dilated cardiomyopathy (DCM) and impaired left ventricular systolic function, despite optimal medical therapy for heart failure.
Purpose: The aim of current study was to evaluate the outcome of patients with DCM after CRT, and to check a difference in survival between responders versus nonresponders to CRT.
Methods: This has been retrospective observational, single center study. The study population consisted of heart failure patients, who met standard inclusion criteria for resynchronization therapy, and in whom CRT was implanted in Pacemaker Center, Clinical Center of Serbia between August 2006 and March 2008. Ten years from the beginning of the trial, we did follow-up. Chart review, patient examination, device interrogation and telephone contact were assessed during long-term follow-up, after device implantation. We observed the efficacy of resynchronization therapy and survival. In terms of efficacy, patients with an increase in left ventricle ejection fraction (EF) of 5%, or decrease in end-systolic volume of 15% were considered as the echocardiographic responders and patients who improved at least one NYHA class or 6 minute walk test by 10% as the clinical responders to resynchronization therapy.
Results: In this study, 70 patients were included. At the beginning of the study, mean age was 59.2 ± 9.1 years and 53 (75.7%) patients were male. Forty-two patients (60%) were responders to CRT, and 28 (40%) patients were nonresponders. The mean age of responders was 60.2 ± 8.7, and of nonresponders 57.8 ± 9.6 (p>0.05). Also, there were no significant differences in gender and in therapy between responders and nonresponders. In group of responders EF before CRT was 25.1 ± 7.2% and on follow-up EF was 40.1 ± 12.1% (p < 0.01). In nonresponders the value of EF before CRT was 30.1 ± 7.3% and on follow-up was 31.3 ± 15.1% (p = 0.04). Responders showed significantly better survival than nonresponders. During follow-up, among responders 15 (35.7%) patients died and among nonresponders 19 (67.8%).
Conclusion: Results of our study have shown that a considerable percentage of patients do not have an appropriate response to resynchronization therapy, but those who are responders have a statistically significantly lower mortality during long follow-up. Our findings are consistent with the results of similar studies with shorter follow-up.

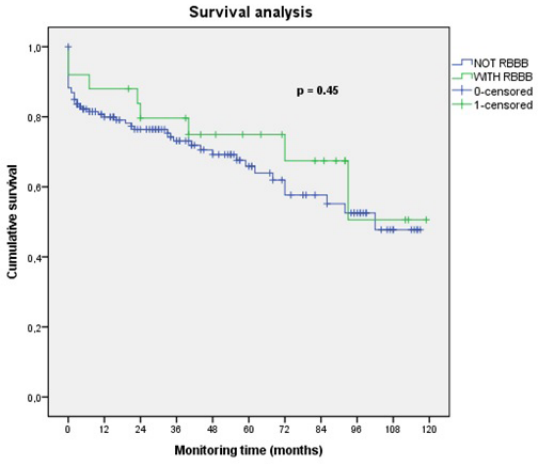
P389

Cardiac conduction system alterations in heart transplantation recipients. prognostic implications

C Gonzalez-Portilla-Concha[1]; A Antonio Grande-Trillo[1]; D Rangel-Sousa[1]; JM Sobrino-Marquez[1]; A Abril-Molina[1]; J Rodriguez-Ortuno[1]; E Lage-Galle[1]
[1]University Hospital of Virgen del Rocio, Seville, Spain

Introduction: Right bundle branch block (RBBB), the most prevalent alteration in the conduction system after heart transplantation (HT), is not related to worse prognosis in classics studies. However, several studies correlate this alteration with cellular graft rejection. Our goal is to evaluate the prevalence of conduction system abnormalities and their prognostic implications in HT recipients.
Methods: Retrospective analysis of HT recipients in our hospital since 2007. We analyse conduction system abnormalities in the discharge electrocardiogram after HT, besides donor/recipient and surgery characteristics. We evaluate the presence of cellular rejection in first endomyocardial biopsy, pacemaker implantation in the follow up and survival rates.
Results: 194 patients were analysed (median age 52 years, range 14-69 years; 75% male). The conduction system alterations were the following: 24% incomplete right bundle branch block, 14% right bundle branch block, 4% left anterior fascicular block, 3% left bundle branch block and 55% without alterations. Differences between patients with and without RBBB are described on Table 1 and compared survival curve is showed in figure 1.
Conclusions: Presence of RBBB in electrocardiogram after HT is relatively frequent (14% in our series). Although this disturbance seems not to be related to worse survival, we obtained a value near to statistical signification when we analysed cellular graft rejection in first endomyocardial biopsy and pacemaker implantation in the follow up in patients with RBBB. Therefore, we must look out RBBB find after HT and consider it as a possible sign of cellular graft rejection to dismiss it.

	Right bundle branch block	Rest of patients	Statistical signification
Recipient Age	52 (14-69)	52 (24-68)	p = 0.78
Donor Age	45 (15-66)	43 (14-65)	p = 0.97
Weight discordance donor- recipient	4.1±15.3	4.95±12.6	p = 0.79
Ischemia time (min)	218.7±47	217±55	p = 0.888
Urgent heart transplantation	16%	26%	p = 0.2
Pacemaker implantation	12%	2.6%	p = 0.06
Cellular rejection ≥ 2	17.6%	4.9%	p = 0.08



P390

Intravenous iron therapy in chronic heart failure patients with reduced and preserved ejection fraction.

S Sergio Hernandez Jimenez[1]; G Alonso Salinas[1]; S Del Prado Diaz[1]; M Pascual Izco[1]; M Plaza Martin[1]; J Ramos Jimenez[1]; JL Zamorano Gomez[1]
[1]University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain

Introduction: Intravenous iron therapy (IIT) in patients with iron deficiency and chronic heart failure (CHF) with left ventricular ejection fraction (LVEF) < 45% improves income rate due to heart failure worsening. The objective of this study is to analyse its "real life" impact, also exploring its influence in non-cardiovascular hospitalization rate and in emergency department (ED) visits.
Methods: Patients with heart failure and iron deficiency were consecutively included. Baseline characteristics, and previous-year admission rate and ED visits were retrospectively collected. During the follow-up, hospitalization rate and ED visits were registered and compared with previous-year rates according to the LVEF.

Table 1

	LVEF ≤ 45% (N = 29)	LVEF>45% (N = 27)
Age, years (m±SD)	76.1±9.5	73.4 ± 12
Female sex (n;%)	6; 20.7%	10; 37%
Chronic Kidney Disease (n;%)	15; 51.7%	10; 37%
Ischemic ethiology (n;%)	18; 62.1%	11; 40.7%

Results: 56 CHF patients with iron deficiency who were were treated with IIT, were consecutively included from August to December'17. There was a medium follow-up of 4 months. Baseline characteristics are described in table 1. Regardless LVEF, IIT reduced all-cause (0.083 (0.0 - 0.167) hospitalizations/month vs 0.0; p= 0.015) and cardiovascular (0.083 (0.0 - 0.083) Vs 0; p= 0.001) hospitalization rates. It also reduced all-cause ED visits (0.167 (0.083 - 0.333) vs 0 (0-0 - 0.143); p < 0.001) and cardiovascular ED visits (0.083 (0.0 - 0.167) Vs 0.0 (0.0 - 0.143); p < 0.001). In patients with reduced LVEF IIT improved all-cause (0.083 (0.0 - 0.167) Vs 0; p= 0.028) and cardiovascular (0.083; (0-0.083) Vs 0; p= 0.006) hospitalization rates and all-cause ED visits (0.167 (0.083 - 0.333) Vs 0 (0.0 - 0.083); p= 0.007) and cardiovascular ED visits (0.083 (0.042 - 0.167) Vs (0.0; p= 0.004). In patients with preserved LVEF, IIT reduced non-cardiovascular hospitalization rate (0.0 Vs 0.0 (0.0 - 0.04); p= 0.014) and all-cause (0.25 (0.167 - 0.417) Vs 0 (0.0 - 0.20); p= 0.005) and cardiovascular (0.167 (0.0 - 0.25) Vs (0.0; p= 0.005) ED visits. In preserved LVEF IIT did not influence cardiovascular hospitalization rate (0.083; (0-0.083) Vs 0.083; (0-0.083); p= 0.469) Conclusions. IIT improves hospitalization and ED visit rates in patients with CHF regardless LVEF. This findings are consistent with CONFIRM-HF
Conclusions: in patients with LVEF = 45%. In patients with LVEF>45% IIT reduces non-cardiovascular hospitalization rate and cardiovascular and all-cause ED visits.

P391
Hospital readmissions after left ventricular assist device implantation

P Lesny[1]; M Luknar[1]; V Simovicova[1]; M Dankova[1]; E Goncalvesova[1]
[1]*National Cardiovascular Institute, Bratislava, Slovak Republic*

Background: Left ventricular assist device (LVAD) implantation enhances survival and quality of life of end-stage heart failure patients (pts). However, unplanned readmissions are a significant cause of morbidity and reduce the potencial benefit of LVAD treatment. We analysed the causes of unplanned readmissions, their frequency, and impact on survival.
Patients and Methods: From August 2007 to June 2017, 98 pts underwent LVAD implantation (HeartMate II or III, or HearWare HVAD) at a single centre. Retrospective data analysis was performed in 81 pts, who were discharged on support. The indications were bridge to transplantation in 95% of pts and destination therapy in 5%. Mean age was 49.3 ± 10.5 years , 51% of pts were in Interagency Registry Mechanically Assisted Circulatory Support class 1 or 2. Follow-up was censored at death or transplant.
Results: Median follow-up was 11 months. Mean length of device support was 15.7 ± 11.3 months (median, 12.7 months). Fifty pts (61%) had 99 unplanned readmissions, thirty-one pts (39%) had no readmissions. Main reasons for readmission included driveline/pump-related infections (n = 25), confirmed or suspect pump thrombosis (n = 15), arrhytmias (n = 12), right heart failure (n = 11), non-device infections (n = 10), bleeding (n = 10), and neurological disorders (n = 6). Unplanned readmission predicted higher mortality (11 deaths in readmission group, vs 1 death in no-readmission group, p = 0.02).
Conclusions: Unplanned readmissions are common after LVAD implantation. The leading cause were driveline/pump-related infections. Unplanned readmission has a negative impact on survival. Multidisciplinary approach in outpatient management is required to reduce readmissions which could lead to an improved long-term survival.

P392
Decision support systems as organizing and functional part of the patient-oriented model in ambulatory stage of cardiac rehabilitation

N Nadezda Lyamina[1]; E Kotelnikova[2]; V Senchikhin[2]; T Lipchanskaya[2]
[1]*Saratov Scientific Research Institute of Cardiology, Saratov, Russian Federation*;
[2]*Research Institute of Cardiology Saratov State Medical University named after V.I. Razumovskiy, Saratov, Russian Federation*

Background: Creating of effective environment for the implementation of patient-oriented health care principles is impossible without the use of information and communications technologies (ICT). High-tech ICT devices in the format of modern communications and products of artificial intelligence are not only inferior in performance to traditional medical observation and medical mind, but in some cases surpass them, being less expensive in the future.
Purpose: User-defined reasoning about efficiency of the Decision Support System (DSS) as organizing and functional part of the patient-oriented model of cardiac rehabilitation in patients with acute myocardial infarction with ST elevation (ST-MI).
Methods: The prospective study (6 months of outpatient observation, 28 subjects with ST-MI) included use of ICT devices in the form of DSS and "Cloud" internet communications. Efficiency of DSS was assessed by the results of usability testing of 15 physicians and electronic patient reports (ePRO).
Results: Successful creation of electronic "Patient Rehabilitation Card" was demonstrated by 80% of participating physicians with an average work duration of 11 ± 4 minutes. The number of medical errors in appointing the events of cardiac rehabilitation was 4.8%. According to ePRO 53.6% of the subjects had physiological response criteria for the DSS of cardiac rehabilitation program. Remote correction of cardiac rehabilitation programs was performed in subjects with intermediate type of reaction (2.1%). Change of medical management was performed in 7 subjects (44.3%) with criteria of pathological reactions.
Conclusion: User-defined reasoning about efficiency of the DSS showed its high suitability in organizing of cardiac rehabilitation home programs. The use of ePRO in order to involve patients in treatment and rehabilitation allowed to obtain information on the safety of cardiac rehabilitation programs and to evaluate its significance for patient-oriented tactical decisions.

P393
The incidence of primary prevention ICD appropriate interventions (ATP/shock) in outpatients with severe heart failure

L Laszlo Vandor[1]; K Heltai[1]; I Osztheimer[1]; K Koltai[1]; B Merkely[1]
[1]*Semmelweis University Heart Center, Budapest, Hungary*

ICD implantation for primary prevention of sudden cardiac death is recommended in heart failure pts with >3 months optimal medical treatment (OMT) and lack of improvement of LVEF (to >35%), in ischemic heart failure with "I/A" and in non-ischemic heart failure with "I/B" level of evidence (ESC: Heart Failure Guidelines, 2016.). The role of the primary prevention ICD implantation in non-ischemic patients is also examined at the last years.
Goal: We examined the primary prevention ICD's appropriate therapy (ATP or shock) during a 4 year period. We studied the difference in ischemic and non-ischemic groups also.
Patients and Methods: Our patient are a characteristic population of heart failure, and pts on heart transplantation waiting list and pts under checkup for heart transplantation waiting list.
We retrospectively analyzed the rate of appropriate ICD therapy in 2014-2017 among our heart failure patients.
Results: 591 pts, 22% female, 78% male were observed. 62% of pts was younger than 62 y.
In 261 pts (44,2%) the underlying disease was ischemic, 92% of these patients got coronary revascularisation, 330 pts (55,8%) had non-ischemic DCM.
384 patients (65%) had EF less than 35% .
All patients received OMT before the ICD implantation.
365 patients have got ICD, of which 344 (94,2%) for primary prevention. 74 patients were observed over 4 years with appropriate ICD therapy (ATP or shock), 20,2% of the patients has got effective therapy. There was no difference between ischemic and non-ischemic pts (33 / 41 therapy).
Conclusion: Our patient population showed a higher rate of the effective primary prevention ICD therapy than the international data showes that. No difference was found between ischemic and non-ischemic patients in respect of appropriate ICD interventions. This may be partially due to the specific patient population.

P394
Usefulness of chest radiographic congestion score to predict responses to adaptive servo-ventilation

Y Nishihata[1]; N Komiyama[1]
[1]*St. Luke's International Hospital, Department of Cardiology, Tokyo, Japan*

Background: Hemodynamic effect of positive airway pressure treatment including adaptive servo-ventilation (ASV) for heart failure (HF) depends on the degree of congestion, but little has been reported on the simple marker in terms of congestion to predict efficacy of ASV.
Purpose: We assessed the usefulness of chest radiographic congestion score (CS) to predict responses to ASV.
Methods: We investigated 61 HF patients treated with ASV in our hospital between June 2009 and December 2015. We examined patient's symptoms, clinical examination, echocardiography, laboratory findings and chest roentgenogram that was blindly scored for the presence and severity of lung edema.

Results: Their mean age, LVEF, and NT-proBNP were 76 ± 13 years old, 37.3 ± 19.3% and 8666 ± 11634 pg/ml, respectively. An improvement of proportional pulse pressure and heart rate during ASV significantly correlated with patient's comfortableness in response to ASV ($p < 0.01$ and $p < 0.01$), and CS also correlated with their comfortableness at both initiation and discontinuation of ASV ($p < 0.01$ and $p < 0.05$). Among 32 patients who could continue ASV at least 1 month, there were 9 patients whose comfortableness during ASV became worse and their CS significantly decreased from initiation time of ASV (5.1 to 2.4, $p < 0.01$). Of those 9 patients, 7 stopped ASV. The other 2 patients continued ASV but they were attacked by sudden cardiac death although their NT-proBNP were improved enough. They had been enough decongested and ASV might worsened their hemodynamics.
Conclusion: Patient's comfortableness in response to ASV and lung congestion are well correlated, and they could be simple indicators about ASV therapy.

P395
Pediatric mechanical circulatory support in the presence of restrictive organ donation, single center experience.

T Tatyana Ivanova-Razumova[1]; L Mamezhanova[1]; Al Baigalkanova[1]; S Jetybaeva[2]; S Andosova[2]; GS Myrzhakmetova[2]; R Salov[3]; MS Bekbossynova[2]; S Bekbossynov[3]; Y Pya[3]
[1]National research cardiac surgery center, pediatric cardiology, Astana, Kazakhstan; *[2]National research center for cardiac surgery, cardiology, Astana, Kazakhstan*; *[3]National research center for cardiac surgery, cardiac surgery, Astana, Kazakhstan*

Objective: The objective of this study is to evaluate efficiency and safety of mechanical circulatory support (MCS) with in-core left ventricle assist devices (LVAD) using in children with end-stage heart failure.
Methods: From 2011 to 2017 year in National Research Cardiac Surgery Center (Astana, Kazakhstan) 5 MCS devices were implanted in pediatric patients. Median age - 15 years (range 9 - 17). Gender: 2 girls, 3 boys. Mean BSA was - 1,406 ± 0,5 m^2, minimal BSA was - 0,85 m^2. 4 patients were in INTERMAX II class, 1 girl - INTERMAX I. Ejection fraction of left ventricle mean - 16 ± 4,06%, mean pro-BNP level at the moment of implantation - 5967 ± 2231,6 pg/ml. Dilated cardiomyopathy were diagnosed in 4 cases, 1 boy had hypertensive cardiomyopathy, secondary to late corrected coarctation of aorta. We have evaluated basic dates, complications rate and outcomes.
Results: In 2 cases we have implanted HVAD (Heart Ware international) - 40%, in 2 cases MCS was performed with HeartMate II (Abbot) - 40% and in 1 case HeartMate III (Abbot) was implanted (20%). Driveline infection developed in 1 patient (20%), he received long-term antibiotic therapy, but 1 year late sepsis with positive blood culture was diagnosed. There were no another complications - GI bleeding, stroke, pump thrombosis, etc. One patient died after 45 days from operation due to right ventricle heart failure. 90-days survival rate was - 80%. Mean duration of mechanical circulatory support was 431,25 ± 150,13 days.4 patients, including boy with drive infection and sepsis, were successfully transplanted with adult donor hearts. 1 girl on MCS with HVAD (HeartWare international) was admitted to India (Fortis clinic) because pediatric heart transplantation is not available in Kazakhstan, and 3 weeks later she was successfully transplanted.
Conclusions: preliminary analysis of this cases revealed low rate of complications and acceptable outcomes for children with end-stage heart failure. So MCS with in-core devices is a good option for open-heart surgery center under the conditions of restrictive pediatric organ donation.

Chronic Heart Failure - Prevention

P396
Heart failure first diagnosed in the community and managed in a disease management programme (DMP) is at low risk of progression to hospitalisation

L Liam Healy[1]; R Murphy[1]; J Gallagher[1]; S Mccleland[1]; M Ledwidge[1]; S Zhou[1]; K Mcdonald[1]
[1]St Vincent's University Hospital, Cardiology, Dublin, Ireland

On behalf of: St. Vincent's University Healthcare group

Introduction: The progression of a community diagnosis of heart failure portends a poor clinical prognosis, highlighting the need to consider advanced heart failure therapies or palliative care. Defining those most at risk of syndrome progression requiring the need for hospitalisation allows heightened clinical focus on this and to focus resources on high risk patients within the framework of a disease management programme (DMP).
The purpose of this project was to define the natural history of patients diagnosed with heart failure in the outpatient setting and managed in a DMP to determine the phenotype of those most likely to progress using baseline metrics. Progression was defined as requirement of hospitalisation for acute decompensated heart failure, an accepted concerning clinical event.
Methods: A retrospective analysis of new community diagnoses of heart failure were followed over time in our heart failure unit. A rapid access clinic is provided in this centre for potentially new community diagnoses of heart failure referred in by family physicians. Subsequent confirmed cases of heart failure are followed within a cardiologist led disease management programme. Heart failure progression is defined as the need for hospital admission to manage acute decompensated heart failure.
Results: 607 patients were reviewed [age: 76.7 ± 11 years; 290 (47.8%) male; 196 (36%) heart failure with a reduced ejection fraction (HFrEF); 345 (64%) heart failure with a preserved ejection fraction (HFpEF); mean brain natriuretic peptide (BNP) 343.4 ± 465.6 pg/ml ; mean creatinine 105.7 ± 56 μmol/L].
57 (9.4%) patients demonstrated progression of HF with a mean follow up of 4.3 ± 3.3 years.
The annual incidence of progression to hospitalisation was 13 patients (2.19%).
Univariate predictors of progression included mean BNP [468.4 ± 502.2 pg/ml versus 329.7 ± 459.9 pg/ml) ($p < 0.001$)]; mean creatinine [114.2 ± 40.5 versus 104.8 ± 57.5 ($p < 0.0114$)]; E/e' [11.6 ± 4.9mmHg versus 10.1 ± 4.3mmHg ($p = 0.0467$)] in progression to hospitalisation versus non-progression respectively.
Multivariate predictors included left atrial volume index (LAVI) [66.9 ± 32.3 mL/m2 versus 47.7 ± 20.5 mL/m2 ($p < 0.001$); OR 1.03 (95%CI: 1.01, 1.05; $P = 0.014$)] in progression to hospitalisation versus non-progression respectively.
Conclusion: A Disease management programme for patients with a community diagnosis of heart failure are less likely to progress to hospitalisation affecting marginally over 2% of the population per year. The strongest indicator of risk for disease progression was left atrial size indicating that this group would likely benefit from intense follow up.

P397
Incident heart failure after myocardial infarction in regional outpatient cardiology clinic

A Klabnik[1]; J Murin[2]
[1]Outpatient cardiology clinic, Namestovo, Slovak Republic; *[2]1st Department of Internal Medicine , University Hospital Bratislava, Slovak Republic*

Funding Acknowledgements: Supported by grant from the Slovak Society of Cardiology 2015 (Selective screening of heart failure stages A- D in regional settings).

Purpose: Heart failure (HF) remains serious complication of non-ST elevation (NSTEMI) myocardial infarction (MI), even in revascularization era. Comprehensive data are lacking about long-term course beyond MI hospitalization. Previous studies focused mostly on early in-hospital phase of MI, without distinguishing between cases of HF with reduced (HFrEF), mid-range (HFmrEF) or preserved (HFpEF) ejection fraction (EF) and left ventricular systolic dysfunction (LVSD) as HF stage B equivalent.
Methods: 486 consecutive patients (pts) over 45 years (without previous HF) discharged alive after first NSTEMI from January 2015 prospectively followed by regional cardiologist. Pts without revascularization procedures were excluded (recurrent MI increased HF risk dramatically).
Results: During NSTEMI was diagnosed HF in 18.7% pts (6.3% HFrEF, 10% HFmrEF and 2.4% HFpEF). After mean 23 months follow-up additional 37.2% pts developed HF within 1 year after discharge (1.8% HFrEF, 25.6% HFmrEF and 9.8% HFpEF).
Highest HF incidence was within first 6 months after MI (33.3%) and occurrence of HF markedly increased risk of death: hazard ratio (HR) 10.2, 95% CI (confidence interval) 7.7-13.5, $p < 0.0001$.
The strongest predictors of HFpEF and HFmrEF were older age (3.1%, 15.6%, and 25.6% among men and 2.2%, 18.8%, and 30.1% among women ages 45-54, 55-74, and 75-85 years, $p < 0.001$), antecedent diabetes (HR 1.67; 1.47-1.89, $p < 0.001$) and new-onset atrial fibrillation (HR 1.20; 0.99-1.46, $p < 0.01$).
Independent risk factors for HFrEF (all $p < 0.001$) included older age (for every 1 year increase in age HR 1.03; 1.02-1.04), Killip class = III (HR 5.2; 4.1-6.4), high GRACE risk score (HR 3.3; 2.8-4.1), EF= 40% (HR 2.6; 1.9-3.3).
Global LVSD (EF= 40%) was observed in 23.6% pts at discharge and 12.1% after 12 months and significant longitudinal LVSD (S' = 6.0 cm/s) had 36.8% at index MI vs 23% after one year (all $p < 0.001$).
Conclusions: Heart failure after MI occurs in a time-dependent fashion and long-term MI survivors should be monitored closely for early signs of HF beyond acute MI period.

P398

An educational program improves knowledge and awareness of heart failure irrespective of previous professional or personal experience of disease

V Vlad Damian Vintila[1]; A Vintila[2]; S Stork[3]; R Ludwig[3]; C Malsch[3]; M Lainscak[4]; D Vinereanu[1]

[1]University of Medicine and Pharmacy Carol Davila, University and Emergency Hospital Bucharest, Cardiology Department, Bucharest, Romania; [2]University of Medicine and Pharmacy Carol Davila, Coltea Clinical Hospital, Internal Medicine Department, Bucharest, Romania; [3]Comprehensive Heart Failure Center (CHFC), University of Wurzburg, Wurzburg, Germany; [4]Faculty of Medicine, University of Ljubljana, , General Hospital Murska Sobota, Murska Sobota, Slovenia

Background: Heart failure (HF) is a common pathological condition with poor prognosis. The objective of the HF Awareness Day, which represents an European annual event, is to increase the knowledge and awareness regarding this condition, by using dedicated educational programs.
Aim: To demonstrate that exposure to an educational program improves knowledge and rises the awareness of HF, irrespective of previous medical or personal experience related to this pathological condition.
Method: We analyzed a full set of questionnaires filled in by the general population from 4 European countries, during 2013 Heart Failure Awareness Day. Awareness of HF was assessed using a score computed from the correct answers. A cut-off of 6 points was considered positive. Two specific subgroups were analyzed: one subgroup of subjects employed of former employed in the medical field (group A), and one subgroup of subjects exposed to HF (either personal or through relatives) (group B).
Results: 1777 questionnaires were analyzed. After being exposed to educational program the median score of awareness changed from 7.3 ± 4.4(4-11) to 10.7 ± 4.1(8-14) ($p < 0.001$). The evolution of the 2 subgroups is shown in tabel 1. We also analyzed the change of heart failure awareness in the two groups after being exposed to an educational program. We evaluated the change of awareness through a change of the median score = 3 points. The greatest achievement of awareness was recorded in the non-exposed population, both for the professional and personal experience subgroups.
Conclusions: Professional or personal experience in a European population gives a difference in knowledge and awareness of disease. After being exposed to an educational program the subjects show a similar level of awareness of HF. The non-exposed population benefit more from that educational exposure. Such an educational program should be considered as part of treatment in any pathological condition, including HF.

HF awareness evolution through education

	Group A scoring >6	No group A scoring >6	p	Group B scoring >6	No group B scoring >6	p

Effect of the optimize_heart failure care (ohf) program on clinic and patients outcomes at Ho Chi Minh City (HCMC) heart institute, vietnam

PHUONG Do Thi Nam[1]; BAN Ha Ngoc[1]; DUNG Do Van[2]; HUAN Do Quang[1]; MARTIN R Cowie[3]

[1]Heart Institute, Ho Chi Minh city, Vietnam; [2]Medecine and Pharmacy University, Ho Chi Minh city, Vietnam; [3]Royal Brompton Hospital, London, United Kingdom

On behalf of: OHF Ho Chi Minh City Heart Institute
Funding Acknowledgements: Servier laboratory

Heart failure (HF) is a common public health in Europe and US but also in Asia. The HF prevalence is increasing in LMI countries with a big annual burden.
HCMC Heart Institute took part in the OHF program to improve patient's outcomes by improving HF patient's awareness, and by optimizing HF treatment.

We included all of HF patients hospitalized with left-ventricular ejection-fraction(LVEF) <50%. The patients were educated about diet, exercise, weight-control and the detection of worsening HF symptoms. The data was collected at 2 and 6 months (M2, M6) for clinical signs, treatments and outcomes (readmission and death). Patient's knowledge and practice were checked at M6 by a telephone-survey.
From Oct. 2016 until Oct. 2017, we recruited 257 HF patients hospitalized with LVEF <50%, 58% male, mean age 64.4 ± 15y.o. and BMI 22.2 ± 3.5 kg/m2. The HF etiology was ischemic heart disease(64%), cardiomyopathy(22%) and valvular heart disease(9%). The principal co-morbidities were hypertension(48%), valvular heart disease(40%), dyslipidemia(33%), arrhythmia(31%), diabetes(26%), and renal failure(21%).
The mean heart rate was improved between admission(M0) vs. discharge (97.8 ± 22.2 vs. 78.5 ± 11.7, $p < 0.001$), and M0 vs. M6 (97.8 ± 22.2 vs. 78.9 ± 13.6, $p < 0.001$). The clinical signs were improved between M0 vs. M2 and M2 vs. M6 for: dyspnea (80% vs. 36%, $p < 0.001$; 36% vs. 22%, $p = 0.002$); orthopnea (40% vs. 1%, $p < 0.001$; 1% vs. 0%, $p = 0.25$); and sign of pulmonary congestion (27% vs. 0.6%, $p < 0.001$; 0.6% vs. 0%, $p = 0.65$). The patients with NYHA class I&II rising from 45% at M0 to 97% at M2 and 99% at M6, both $p < 0.001$ compared to M0). The LVEF also increased ($36.5\% \pm 9$ at M6 vs. $33.4\% \pm 9$ at M0, $p = 0.005$).
In terms of education, 99% of patients were educated about diet (72% had knowledge, 78% practice this); 85% were educated on exercise (67% had knowledge, 62% practice this); 90% were educated about weight-control (54% had knowledge, 44% practice this); and 92% were educated for "detection of worsening HF symptoms", only 56% remembered this education.
For HF pharmaceutical treatment, we followed European guidelines, including at discharge: 91% renin-angiotensin-aldosterone system inhibitors, 33% beta-blockers (but 50% at M6), 77% mineralocorticoid-receptor-antagonist, 85% diuretics, 9% ivabradine (but 18% at M6), 33% digoxin (22% treated for atrial-fibrillation) and 16% isosorbide-dinitrate.
The readmission rate at 30 and 60 day after discharge was 8.3% and 12.5%. There was no in-hospital death. The mortality rate at 30, 60 days and 6 months was 1.2%, 2.5% and 10.4%.
The OHF Care Program could be implemented in a middle-income country without difficulty. Education was provided to a high proportion, although patient did not always retain or follow the advice. The use of drug-therapy (other than for beta-blockers) is good. Clinical-control, readmission and mortality rates appear good. Further work is underway to optimize for beta-blokade usage, and how to improve patient's behavior.

P400

Microalbuminuria is an early marker of kidney damage in cardiorenal syndrome patients

A Armine Minasyan[1]

[1]Yerevan State medical university after Mkhitar Heratsi, Surb Grigor Lusavorich Medical Center, Internal Diseases, Cardiology, Yerevan, Armenia

Background: Cardiorenal syndrome (CRS) is the term used to describe a complex disorder of the heart and kidneys, in which acute or chronic dysfunction of one organ initiates and perpetuates disease in the other. CRS is recognized as an important clinical condition that is increasingly becoming a major public health problem due to the high associated morbidity and mortality rates.
Purpose: To reveal diagnostic usefulness of microalbuminuria (MA) in CRS patients.
Methods: Echocardiographic data of left ventricular remodeling, microalbuminuria level and degree of renal dysfunction in 115 patients with CRS were examined. MA was measured with diagnostic strips, contractile function of the left ventricle (LV) - by echocardiography and glomerular filtration rate was assessed by Cockroft-Gault method.
Results: The association between MA, decreased GFR, elevated creatinine level, their association with increased LV myocardial mass and LV systolic dysfunction was revealed. Direct correlation between MA and myocardial mass index and indirect - between LV ejection fraction and MA were determined. Obtained data allow to mention the level of MA ($25,4 \pm 5,8$ ng/ml), where there is more probability of LV contractile dysfunction development. This will allow early prediction and prevention of chronic kidney diseases, therefore CRS progression. Conclusion: Presented results strengthen the diagnostic usefulness of MA in CRS patients as it develops from progressive, subclinical, structural and functional changes within the kidney and represents a sensitive marker of early renal disease. MA is independently associated with numerous modifiable cardiovascular risk (CV) factors and markers of CV disease. Physicians should measure urinary albumin excretion in patients with diabetes mellitus and hypertension routinely and be as aggressive in treating this modifiable risk factor as they do in case of blood pressure, cholesterol, or blood glucose control.

Chronic Heart Failure - Clinical

P401
Clinical pathway for heart failure management in Hospital-at-Home: Better self-care?

I Isabel Fiteni Mera[1]; M Matia Sanz[1]; M Sevil Pura[1]; C Clemente Sarasa[1]; N Martin Catalan[1]; N Alcala Rivera[1]
[1]*Hospital Royo Villanova, Internal Medicine, Zaragoza, Spain*

Background: The systematic use of a clinical pathway for a medical problem allows to minimize management variability and optimize therapy. The management of heart failure (HF) with the alternative Hospital –at-home may help a closer approach to those patients, promote their medical education and empower self-care in order to improve outcomes. Using a clinical pathway in the Hospital-at-Home (HaH) could be a tool to perform this improvement.
PURPOSE: To compare early outcome after discharge in patients with heart failure assisted by internists in HaH following a clinical pathway and those assisted in a conventional Internal Medicine Ward. We focused our study on hospital stay length, mortality and readmissions rates.
MATERIAL AND Methods: Prospective study from March to November 2017: all patients admitted to HaH, and patients admitted in IM for HF decompensation were included, excluded cognitive impairment and critically ill patients. Our clinical pathway considered therapy, adverse events control and educational schedules. Group 2 in IM were treated with usual guidelines. Self-care and quality of life were measured with validated scales the first day of admission and one month after discharge. Readmissions and visits to the Emergency Departement (ED) for HF during 3 months after discharge, Hospital stay length, side-effects (wkf, hypotension, hyperkalemia) and therapy were compared.
Results: 36 patients were enrolled, 21 patients in HaH (group 1) and 15 in IM (group 2). Baseline characteristics were similar in both groups; age, sex, cardiovascular risk factors, cardiac and non-cardiac comorbidities, NYHA class, HF etiology and causes of decompensation. In group 2 we had more patients with systolic dysfunction, but similar pulmonary hypertension and atrial fibrillation in both groups. Laboratory results were similar; NT-proBNP, hyponatremia, creatinine and ferropenia. Regarding therapy, management was similar with better fluid intake control in group 1. Patients in group 1 had less hyperkalemia during treatment (p = 0,026). At inclusion self care scores were similar in both groups with better scores in group 1 at 30 days (p= 0,005). Meanwhile there was no difference between groups for quality of life before and after hospitalization. Patients in group 2 visited more often ED than group 1 (63% vs. 18,7% respectively) and had higher readmission rates at 3 months after discharge (53,8% vs 6,6%). Both rates were similar in both groups for the 3 months previous to enrollment. Mortality was similar in both groups.
Conclusion: Implementing a clinical pathway in HaH with individual targets and instructions lead to better outcomes for patients in the 3 first months after discharge, with less ED visits and readmission rates for HF. This improvement is probably due to educational aspects more easily performed in the intervention at home. We need to continue the follow-up to observe how long the effect of this intervention persists.

P402
Iron supplementation in an acute heart failure unit

R Rita Gomes[1]; J Rodrigues[1]; F Aguiar[1]; C Graca[1]; A Torres[1]; I Araujo[1]; F Marques[1]; L Campos[1]; C Fonseca[1]
[1]*Hospital São Francisco Xavier, Heart Failure Unit, Internal Medicine Department, Lisboa, Portugal*

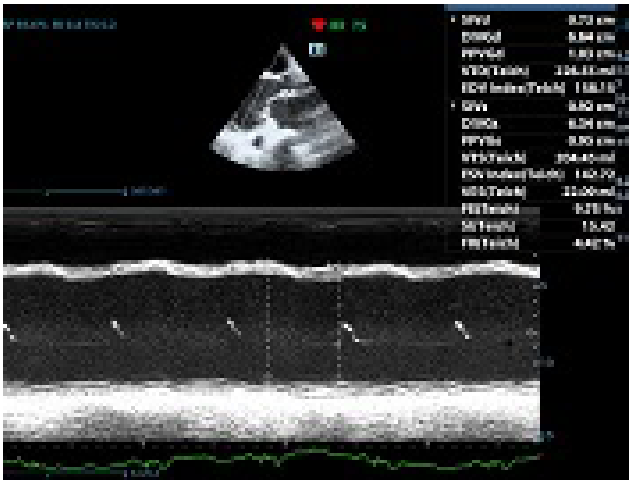
Introduction: Iron deficiency (ID) is common in heart failure (HF) and is associated with worse prognosis. Intravenous (IV) ferric carboxymaltose (FCM) is the recommended treatment. IV iron sucrose (IS) is a less expensive option. There are no published data comparing efficacy, tolerability and logistics between the administration of FCM and IS.
Purpose: to compare the burden of administration of these 2 IV iron formulations.
Methods: Consecutive patients admitted to our Heart Failure Unit (HFU) with HFpEF, HFmEF and HFrEF and ID were enrolled and randomly allocated for IV FCM or IS. Doses were determined individually according to Ganzoni's formula for IS and to the CONFIRM scheme for FCM. Follow-up was 7 months (IQR 3.5-10).
Results: 57 patients were included, 77.3 ± 9.6 years, 52.6% male. 47.4% had HFpEF, 29.8% HFrEF and 22.8% HFmEF. Hypertension (35.1%) and ischemia (26.3%) were the most prevalent etiologies. 68.4% had functional ID and 31.6% absolute ID. 59.6% had anemia (Hb 11.7 ± 2.3g/dL). 28 patients (49.1%) were given FCM and the remaining 29 (50.9%) received IS. There were no significant differences between the two treatments, except for ID type (in IS, functional ID was more prevalent (86.2%); p = 0.004) and transferrin saturation (TSat) at admission (11.8 ± 4.4% in FCM vs 15.1 ± 6.1% in IS; p = 0.024). Ferritin levels of patients with absolute ID were: at admission 53.9 ± 26.6μg/L in FCM vs 76.5 ± 30.5μg/L in IS (p = 0.163); at 6 months 493.1 ± 450μg/L in FCM vs 114.5 ± 112.4 μg/L in IS (p = 0.280). Patients with functional ID had ferritin levels: at admission of 167.2 ± 64.4μg/L in FCM vs 139.4 ± 72.4μg/L in IS (p = 0,239); at 6 month 462.3 ± 62.5μg/L in FCM vs 333.9 ± 178.9μg/L in IS (p = 0.251). TSat at admission 11.9 ± 4.9% in FCM vs 14 ± 4.7% in IS; at 6 month 24.3 ± 20.5% vs 23.6 ± 8.1% (p = 0.251). 46.4% of FCM completed the total iron dose in-hospital vs 51.7% of IS. IS had a longer hospital stay (9.4 ± 6.1days vs 8.8 ± 3.9days in FCM; p = 0.629). After 6 months, 85.4% of FCM completed the total iron dose vs 86.2% of IS. 100% in FCM vs 44.8% required only 1 or 2 administrations (p < 0.001). 7.1% in FCM and 10.3% in IS do not completed the total iron doses due to adverse reactions (p = 0.671).
Conclusions: There are no differences between the two IV iron therapies on what completing the prescribed total iron dose is concerned. At six months, all patients had ferritin and/or TSat above the normal limit, however patients who underwent FCM tended to have higher ferritin levels. FCM required a lower number of administrations and adverse events tended to be more frequent in IS. These findings suggest a reduced need for new short-term administration and related costs and a longer clinical stability with FCM, corroborating the results of the national pharmacoeconomic study recommending the use of FCM.

P403
Cardiac involvement in patients with muscular dystrophies.

N N Ali Tatar-Chentir[1]; AN Ali-Tatar Nora[1]; MT C Mt Chentir[1]; TM Tazir Meriem[1]; BY Bouhouita Yacine[1]
[1]*University Hospital Centre Mustapha, Algiers, Algeria*

On behalf of: ALI-TATAR NORA

Backround : Cardiac disease is one of the clinical manifestations of neuromuscular disorders . Heart muscle as conducting myocardial fibers may be affected in this context.



Becker dystrophy patient non responder

Purpose: To identify cardiovascular disease in patients with muscular dystrophies referred to our day hospital unit by neurologists.
Methods: We study prospectively from February 2007 to September 2017, clinical , ECG and ultrasound data according to the ESC Guidelines .
24 patients mean age 26 ± 17years (range: 6-69yrs); 22men and two women with muscular dystrophies
-9 patients were diagnosed as having Duchenne muscular dystrophy (DMD).
- 7 as having Becker muscular dystrophy (BMD) .
- 2 as having Limb-Girdle Muscular Dystrophy Type 2(LGMD2).
- 4 as having myotonic muscular dystrophy (Steinert's disease).
- One with Facioscapulohumeral muscular dystrophy (FSHD).
Results: All patients are from a first degree consanguineous marriage.
Cardiac involvement was present in 3 of 9 patients with Duchenne Muscular Dystrophy (33%) at the stage of dilated cardiomyopathy (DCM), one with left bundle brunch block (LBBB).
The occurrence of heart failure with reduced ejection fraction is observed in one of the 27-year –old brothers while his younger brother shows signs of heart failure with preserved ejection fraction (HFpEF).
Heart failure with reduced ejection fraction (HFrEF) is present in 4 of7 patients (57%) with Becker Muscular Dystrophy including two patients with cardiac resynchronization therapy (CRT) no responders. Recently one of the two CRT patients died with signs of cardio-renal syndrome.

Of the two patients with Limb-Girdle Muscular Dystrophy Type 2(LGMD2), one had premature ventricular beats that disappeared under beta-blocker treatment.
In Steiner's disease we noticed 2 LBBB, 1atrial flutter and one Left Anterior Fascicular Block (LAFB).
In Facioscapulohumeral muscular dystrophy, Echo was in the normal range.
According to the guidelines and our observations, all the patients with Duchene muscular dystrophy and Becker muscular dystrophy should began pharmacological therapy with angiotensin-converting enzyme inhibitor or angiotensin receptor blocker before the stage of DCM.
Conclusion: In addition to primary prevention aimed at discouraging consanguineous marriages, early diagnosis of myocardial involvement par strain imaging may lead to improvement of ejection fraction especially in muscular dystrophies. Further studies are needed to establish definitive occurrence of heart abnormalities in muscular dystrophies.

P404
Atrial fibrillation in heart failure with reduced versus preserved ejection fraction: Not the same thing

B T Bernadet Santema[1]; M Kloosterman[1]; IC Van Gelder[1]; I Mordi[2]; CC Lang[2]; CSP Lam[1]; JG Cleland[3]; K Dickstein[4]; H Hillege[1]; JM Ter Maaten[1]; M Metra[5]; DJ Van Veldhuisen[1]; P Van Der Meer[1]; M Rienstra[1]; AA Voors[1]
[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands; *[2]Ninewells Hospital, Dundee, United Kingdom*; *[3]University of Glasgow, Glasgow, United Kingdom*; *[4]University of Bergen, Bergen, Norway*; *[5]University of Brescia, Brescia, Italy*

Funding Acknowledgements: CVON2014-11 RECONNECT and FP7-242209-BIOSTAT-CHF

Aims: The clinical correlates and consequences of atrial fibrillation (AF) might be different between heart failure with reduced versus preserved ejection fraction (HFrEF vs. HFpEF). Biomarkers may provide insights into underlying pathophysiological mechanisms of AF in these different HF phenotypes.
Methods and Results: Among 2671 patients (2149 HFrEF [EF < 40%] and 522 HFpEF [EF = 50%]) from the BIOlogy Study to TAilored Treatment in Chronic Heart Failure (BIOSTAT-CHF), 92 cardiovascular risk markers were measured (Proseek® Olink CVD III panel). Quality of Life (QoL) was assessed by the Kansas City Cardiomyopathy Questionnaire (KCCQ). AF was associated with higher levels of 78 of 92 (85%) cardiovascular risk markers compared to sinus rhythm (SR) in HFrEF; whereas in HFpEF, many more markers were higher in SR than AF. In HFrEF, AF was associated with a poorer QoL (KCCQ score of 46 vs. 52 in SR; $p < 0.001$) whereas in HFpEF, QoL was similar between AF and SR. Over a median follow-up of 21 months, AF was associated with increased mortality risk, even after adjustment for age and sex (hazard ratio [HR] of 1.24; 95% confidence interval [CI] 1.07 - 1.43, $p = 0.004$); there was no significant interaction between heart rhythm and EF group on outcome.
Conclusion: In patients with HFrEF, the presence of AF was associated with more elevated cardiovascular risk markers and a poorer QoL. In contrast, in patients with HFpEF, the presence of AF was not associated with more elevated risk markers and/or a poorer QoL.

P405
Status of vitamin D in difficult to treat cardiorenal syndrome in heart failure patients.

N Sen[1]; SONAL Tanwar[2]; ASHOK Jain[1]
[1]Narayana Hrudayalaya, Cardiology, Jaipur, India; *[2]HG SMS Hospital, Cardiology, Jaipur, India*

Background: Decreased glomerular filtration rate(GFR) is a potent predictor of cardiovascular mortality and complications. Worsening heart failure can accelerate worsening of renal function - the so-called cardiorenal syndrome. Risk factors include hypertension, diabetes, elderly age, and prior history of heart or renal failure. Aims & Objectives: To study the correlation between serum vitamin D values in uncontrolled cardiorenal syndrome and to evidential improvement in control of cardiorenal syndrome after vitamin D supplementation and correlate it with heart & renal function.
Methods: Serum vitamin D levels were assessed in 178 patients of cardiorenal syndrome in duration of 2 years (2015-2017) and we found very low level of vitamin D (average level was 16 U ng/ml) in 108 patients of difficult to treat cardiorenal syndrome between 19 -74 years of age who were uncontrolled even after courses of Betablocker, Diuretics and ACE inhibitors or Angiotensin II Receptor Blocker Neprilysin Inhibitor (ARNI) and other optimised medical therapy . These patients were treated with calcium and Vitamin D supplementation for 12 weeks and after were re-evaluated with repeat vitamin D levels, Renal function test , GFR and Cardiac functions by 2D Echocardiography .
Results: All 108 patients showed significant improvements in B-type natriuretic peptide (BNP level), Right and Left ventricular function, LVEF incresed (14+/-4%) , decreased pulmonary capillary wedge pressure and improved class of dyspnea New York Heart Association IV to class II or III. After 3 months of vitamin D supplementation 43% patients had improved GFR and serum creatinine value as compare to placebo 16% , p value(< 0.003).
Conclusion: Study showed a strong correlation between vitamin D deficiency and difficult to manage cardiorenal syndrome and good cardiorenal outcome after supplementation.

P406
Altered immune pattern of circulating endothelial cell-derived micro vesicles predicts chronic heart failure development in patients with metabolic syndrome

A E Alexander E Berezin[1]; A Kremzer[1]; T Samura[1]; T Berezina[2]
[1]State Medical University, Zaporozhye, Ukraine; *[2]Private medical center VitaCenter, Zaporozhye, Ukraine*

Background: Metabolic syndrome (MetS) is defined as risk factor clustering related to the premature development of type 2 diabetes mellitus (T2DM) and cardiovascular disease (CVD) in association with increased CV mortality in general population. The role of pattern of circulating endothelial cell-, platelet-, and monocyte-derived micro vesicles in chronic heart failure (CHF) patients with MetS is not still understood. The aim of the study was to investigate a pattern of circulating MVs in CHF patients with MetS in relation to neurohumoral and inflammatory activity.
Methods: The study retrospectively evolved 388 CHF (left ventricular ejection fraction = 43% [interquartile range: 35% to 48%]) patients (154 patients with MetS and 234 patients without MetS), 47 MetS patients without CHF, and 25 healthy volunteers, who were examined between February 2013 and November 2017. Serum N-terminal brain natriuretic peptide (NT-proBNP), high-sensitive C-reactive protein (hs-CRP), adiponectin (AND), and osteoprotegerin (OPG) were measured by ELISA. MVs were measured by flow citometry. CD41a+ was used as a more specific marker of platelets, and CD64+ was considered a more specific marker of monocytes. CD31 antigen was determined as essential marker for endothelial cells, platelets, and leukocytes. CD144+ was used to identify a pure population of endothelial cells. CD31+/annexin V+ was defined as apoptotic endothelial cell-derived MPs, MPs labeled for CD62E+ were determined as MPs produced due to activation of endothelial cells. Biomarkers were measured at baseline of the study.
Results: The results of the study have shown that number of circulating plateled-derived and monocyte-derived MPs in subjects with MetS (with or without CHF) insufficiently distinguished from the levels determined in healthy volunteers. We found significantly ($P = 0.001$ for all cases) elevated levels of CD31+/annexin V+ MPs and CD41a+ MVs, significantly lowered number of CD31+/CD144+ and CD62E+ MVs ($P = 0.001$ for all cases) in CHF patients with MetS compared to CHF individuals without MetS as well as non-CHF patients with MetS. In CHF population there was close inverse correlation between number of CD62E+ and levels of NT-proBNP ($r=-0.38$; $P = 0.001$), hs-CRP ($r=-0.34$; $P = 0.002$), AND ($r=-0.28$; $P = 0.001$), and OPG ($r=-0.34$; $P = 0.003$). In contrast, number of CD31+/annexin V+ positively correlated to NT-proBNP ($r=-0.36$; $P = 0.003$) and OPG ($r=-0.32$; $P = 0.001$). Additionally, we determined that biomarkers of biomechanical stress (NT-proBNP) and inflammation (hs-CRP, OPG) remain statistically significant predictors for decreased CD62E+ to CD31+/annexin V+ ratio, but not for decreased CD41a+ to CD31+/annexin V+ ratio in CHF patients with MetS. In conclusion, it has found that decreased CD62E+ to CD31+/annexin V+ ratio reflected altered immune phenotype of MVs and probably this fact may be discuss as surrogate marker of CHF development in MetS population

P407
Bone mineral density and metabolism in very elderly patients with congestive heart failure

SV Topolyanskaya[1]; IA Osipovskaya[2]; LS Lifanova[1]; TA Eliseeva[2]; ON Vakulenko[2]; LI Dvoretsky[1]
[1]I.M. Sechenov First Moscow State Medical University, Department of hospital therapy N2, Moscow, Russian Federation; *[2]War Veterans Hospital N3, Moscow, Russian Federation*

Background: There are few data available on the relationship of heart failure and osteoporosis in very elderly patients.
Purpose: The study purpose was investigation of bone mineral density (BMD) and metabolism in very elderly patients with heart failure.
Methods: The study enrolled 125 patients (38 men and 87 women, aged 75-98 years) hospitalized with coronary artery disease (CAD). Study group comprised 61 patients with clinically significant CHF (NYHA FC III-IV), control group - 64 CAD patients without CHF symptoms. Main exclusion criteria were any other diseases

that could cause osteoporosis and administration of medications reducing BMD. Lumbar spine and proximal femur BMD was measured by dual energy X-ray absorptiometry. Fracture risk was measured under FRAX model; osteoporosis standard risk factors were analyzed. Serum osteocalcin concentration was measured by immunochemiluminescent method, beta-Cross Laps level - by electrochemiluminescence.
Results: BMD in CHF patients was lower (both in absolute values and by the T-score) versus control group. Largest differences were recorded in proximal femur: BMD in CHF patients was 719.8 ± 188.2 mg/cm3 vs 797.7 ± 161.7 mg/cm3 (p = 0.02) in control group. Greater differences in BMD were detected in female patients (p = 0.007). Femoral neck BMD in CHF patients was 649.4 ± 137.1 mg/cm3 vs 696.2 ± 121.8 mg/cm3 (p = 0.03) in control group. There were no significant differences found in lumbar spine BMD (p = 0.4). Proximal femur BMD had normal values only in 5% of CHF patients, whilst normal BMD in control group was in 31% of cases (p = 0.003). Multiple regression analysis found that significant factors determining proximal femur BMD were CHF (ß = 0.375, p = 0.005) and female sex (ß = 0.698, p < 0.0001). Mean osteocalcin level in CHF patients was 1.2 ± 1.7 ng/ml vs 4.2 ± 4.1 ng/ml (? = 0.03) in control group. In 60.6% of CHF patients osteocalcin concentration was below the lower limit of normal (p = 0.02 vs control). Mean ß-Cross Laps level in CHF patients was 0.73 ± 0.4 ng/ml vs 0.4 ± 0.1 ng/ml (p = 0.003) in control group. ß-Cross Laps level was increased in 21.7% of CHF patients, but no one had high ß-Cross Laps values in control group (p = 0.03). There was negative correlation between ß-Cross Laps and BMD, especially in proximal femur (r=-0.4, p = 0.03). Negative correlation was found between tumor necrosis factor-a level with its serum concentration higher in CHF patients (p = 0.04) and BMD, especially in proximal femur (r=-0.9, p = 0.03). In patients with decreased leptin concentration (found only in CHF patients), BMD values were lower than in those with normal or increased serum leptin concentration (p = 0.006 for proximal femur).
Conclusion: These study findings suggest that bone mineral density in very elderly CHF patients is noticeably lower versus age-mathched patients with similar main diseases. This study has demonstrated significantly reduced osteoblast function in CHF patients and slight increase in bone resorption.

P408

Impact of nutritional status on heart failure hospitalization and mortality in nonischemic patients with implantable cardioverter defibrillator

K Kenjiro Oyabu[1]; A Suzuki[1]; T Shiga[1]; K Jujo[1]; S Higuchi[1]; Y Iwanami[1]; D Yagishita[1]; K Ejima[1]; M Shoda[1]; N Hagiwara[1]
[1]*Tokyo Women's Medical University, Cardiology, Tokyo, Japan*

Introduction: Malnutrition is associated with poor prognosis among heart failure (HF) patients. However, factors associated with malnutrition among HF patients received implantable cardioverter defibrillator (ICD) has not been fully elucidated. The aim of this study was to assess the predictive value of nutritional status in nonischemic HF patients with ICD.
Methods: We studied 165 nonischemic HF patients implanted ICD at Tokyo Women's Medical University from 2003 to 2015. Controlling nutritional status (CONUT) score was evaluated before ICD implantation.
Results: Average age was 56 +/- 15 and 112 (68%) patients were male. Median CONUT score was 1 (interquartile range 1 to 3). During a 39 [18-82] months of follow-up, 42 (25%) patients were hospitalized for HF exacerbation and 30 (18%) patients were died. By multivariate cox regression analysis with baseline characteristics, CONUT score was an independent risk for both HF hospitalization (HR 1.362, 95% CI 1.113 to 1.667, p < 0.05) and mortality (HR 1.432, 95% CI 1.139 to 1.800, p < 0.05) (Figure).
Conclusion: Our results suggested that malnutrition assessed by the CONUT score is an independent predictor of HF hospitalization and all-cause death in nonischemic HF patients with ICD.

	HF hospitalization			all-cause death		
	HR	95% CI	p	HR	95% CI	p
Men	0.682	0.338-1.376	0.285	0.463	0.191-1.123	0.089
Age ≥75	0.456	0.058-3.612	0.457	1.296	0.150-11.206	0.814
prior sustained VT or VF	0.960	0.463-1.991	0.913	2.054	0.927-4.552	0.076
eGFR <60mL/min/1.73m^2	2.299	1.160-4.557	0.017	1.516	0.620-3.708	0.362

CONUT score	**1.362**	**1.113-1.667**	**0.003**	**1.432**	**1.139-1.800**	**0.002**

ACEI, angiotensin-converting enzyme inhibitor; ARB, angiotensin receptor blocker; eGFR, estimated glomerular filtration; HF, heart failure; NYHA, New York Hear Association; LVEF, left ventricular ejection fraction; VT, ventricular tachycardia; VF, ventricular fibrillation.

P409

Impact of comorbidities in outpatients with chronic heart failure

D Carrillo[1]; R Lopez-Vilella[1]; I Sanchez-Lazaro[1]; E Marques[1]; L Martinez-Dolz[1]; L Almenar[1]
[1]*Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit, Valencia, Spain*

Background/introduction: The comorbidities associated with chronic heart failure (CHF) adversely affect the prognosis of the disease.
Purpose: To describe the frequency of co-morbidities and mortality in the first year follow up in outpatients with CHF.
Methods: Registry of outpatients with CHF treated between April 2010 to February 2016 with follow up of 12 months. Co-morbidities as coronary heart disease with or without myocardial revascularization, malignant disease, diseases of the central nervous system (stroke, depression), diabetes mellitus, arthritis, potassium disorders, hypertension, anemia, sleep apnea, kidney dysfunction and lung disease were included. A table of frequency of co-morbidities and a bar graph of vital status by a number of co-morbidities was made.
Results: 248 patients with CHF were included (Table). Arterial hypertension, coronary heart disease, diabetes mellitus, obesity, and hyperlipidemia were the most frequent co-morbidities present (Table). There were more deaths within the first year in patients with more than 4 comorbidities compared with none (13.05% in = 5 comorbidities vs 0 in none p = 0.041) (Figure).
Conclusions: Comorbidities are very common in patients with CHF and should be aware of them and their treatment. There is a direct relationship between the number of comorbidities and mortality.

Prevalence of comorbidities in CHF

Variable	n = 248	%
Age (y), median IQR	64	54-72
Male gender	155	62.50
LVEF (%), median IQR	30	23-56
Arterial hypertension	108	43.37
Diabetes mellitus	78	31.33
Chronic kidney disease	69	27.71
Coronary heart disease	97	38.96
Sleep disorders	14	5.69
Previous or current neoplasia	15	6.02
Anemia	45	26.01
Reumatoid arthritis	1	0.40
Potasium disorders	7	4.76
Lung disease	25	10.04
Obesity	69	34.85

P410

Iron deficiency in patients with chronic heart failure.

M Smirnova[1]; P Chizhov[1]
[1]*Yaroslavl State Medical Academy, Department of Faculty therapy, Yaroslavl, Russian Federation*

Introduction: heart failure (HF) is an important community health problem. Prevalence and incidence of heart failure have continued to rise over the years. One of the most common co-morbidities in heart failure is presence of iron deficiency (ID) and anemia. ID affects up to 50% of HF patients, and is associated with poor quality of life, impaired exercise tolerance and higher risk of death. In the 2016 ESC guidelines for the diagnosis and treatment of HF, systematic measurement of iron parameters: serum ferritin and , transferrin saturation (TSAT) is recommended in all patients suspected of having HF. In these guidelines ID is defined as follows: 1) serum ferritin <100 mg/L (absolute iron deficiency), and 2) serum ferritin 100-299 mg/L and transferrin saturation <20% (functional iron deficiency).
Methods and Results: Serum concentrations of ferrum, ferritin and TSAT were assessed as the biomarkers of iron status in 209 patients with chronic systolic HF [age: 72,35 ± 7,04 years, men: 53, New York Heart Association (NYHA) class: 0/59/110/40] at a therapeutical departmet. All standart echocardiography and tissue Doppler echocardiography (TDE) were performed with GE Vivid 7 Medical System. Conventional measurments include left ventricle (LV) cavity dimentions, wall thickness, fraction ejection and transmitral flow velosities.
Results: patients with severe NYHA more often had many signs iron limitation of erythropoiesis (reduced haemoglobin, high red blood cells distribution width) (p <0,05). 65% patients were diagnosed with iron deficiency with low ferritin and TSAT. The level of iron and TSAT in the serum of patients with severe NYHA was significantly lower (p <0,05). The number of patients with absolute or functional ID elevates with increasing HF severity.
In patients with HF and ID were increased left ventricular cavity and reduced ejection fraction with increasing NYHA. Patients with severe NYHA with ID were observed a significant decrease of contractile ability of myocardium of the LV, which characterized low transmitral flow velosities in TDE. (p <0,05).
Conclusions: frequency of anemia becomes more higer with the increase of HF and were diagnosed most frequently in patients with NYHA 4. On the background of increasing in NYHA class there is a decrease in iron levels and hemoglobin levels, suggesting a possible latent iron deficiency in these patients. Iron deficiency in patients with HF is associated with reduced myocardial contractility. Therefore, successful management of co-morbidities ID is strongly recommended in addition to conventional therapy for HF.

P411

Relation between obstructive sleep apnea and right ventricular function

L Mathe[1]
[1]*IVth Medical Hospital, Tirgu-Mures, Romania*

Study objectives: to characterise relationships between right ventricular (RV) function and geometry and the obese and non-obese patients with obstructive sleep apnea.
Methods: Obese (n = 37, BMI 38,7+/- 7,3kg/m2) and non-obese (n = 23, BMI 24,7+/- 3,1 kg/m2) participants were founded with obstructive sleep apnea (OSA) by doing overnight polysomnography. OSA was characterized by the apnea-hypopnea index (AHI, events/hour). Function and geometry of the right heart were evaluated by tricuspid annular plane systolic excursion (TAPSE), tricuspid annular systolic velocity (TDI S'), RV myocardial performance index (TEI), RV end-diastolic (RVEDD) and end-systolic diameter (RVESD), area of the right atrium (RAA) ans systolic pulmonary artery pressure (PAPs).
Results: the 60 participants were mean 49 +/- years old (27% female). AHI was associated significantly with reduced TAPSE = 15 mm. Parameters of RV function (TAPSE 24,7 +/- 3,9 vs 24,9 +/- 3,7 mm; TDI S' 13,1 +/- 2,7 vs 13,6 +/- 2,9 mm/sec; TEI 0,23 +/- 0,11 vs 0,25 +/- 0,10) as well as geometry measurements were comparable between obese and non-obese participants with obstructive sleep apnea.
Conclusions: OSA is associated with reduced RV function. Echocardiographic measures of RV function appears to be less affected by obesity.

P412

Prevalence and prognostic value of anemia in patients with heart failure in south Indian state Kerala

A Gaskina[1]; R Rajesh[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

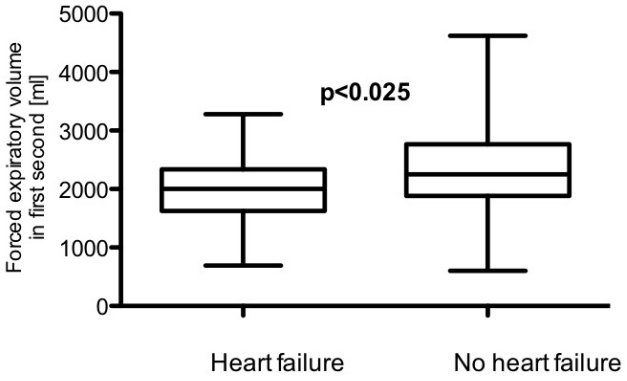
Aims: Anemia is a well-known serious comorbidity of heart failure (HF) associated with increased morbidity and mortality. The aim of the study was to evaluate the prevalence and prognostic value of anemia in patients with HF in south Indian state Kerala.
Methods: This is a single-center prospective observational study, conducted in Kerala institute of medical sciences a tertiary care hospital in the southern part of India. Patients admitted to hospital with clinical diagnosis of HF based on validated clinical criteria were included in the study. 203 patients with HF (102 male, 63,8 ± 10,1 years (M ± SD), arterial hypertension 81%, previous MI 77%, diabetes mellitus 58%, known chronic kidney disease (CKD) 28%, left ventricular ejection fraction (LV EF) (46,4 ± 14,3%) were examined. Anemia was defined as hemoglobin (Hb) < 13g/dl for males and < 12g/dl for females, based on World Health Organization definition. Mann-Whitney test and multivariate logistic regression analysis were performed. P < 0.05 was considered statistically significant.
Results: 104 (51%) patients with HF developed anemia. Patients with HF with versus without anemia were older (69 ± 13 vs 63 ± 12 years, p < 0.05), had higher baseline serum creatinine (SCr) (2,07 ± 1,15 vs 1,25 ± 0,48 mg/dl, p < 0.05), lower LV EF (37 ± 10 vs 41 ± 14%, p < 0.05). Anemia was more frequent (44.1%) in patient population with GFR = 60 ml/min/1.73 m2 (p = 0.0027). Patients with HF with versus without anemia had higher risk of 6 months rehospitalizations (59 vs 33%, p < 0.05).
Conclusions: Anemia in patients with HF and elective PCI developed in 51% of cases. Anemia in patients with HF was associated with older age, higher baseline SCr, lower LV EF. Anemia in patients with HF had negative impact on of 6 months rehospitalizations.

P413

Pulmonary function testing in heart failure patients

M Lainscak[1]; D Omersa[2]; J Farkas[1]
[1]*General Hospital Murska Sobota, Murska Sobota, Slovenia*; [2]*General Hospital Jesenice, Jesenice, Slovenia*

Background: Heart failure (HF) causes changes in pulmonary function tests that depend on volume status: restrictive pattern is observed in euvolemic patients whereas obstructive pattern is seen in volume overload. No recent studies investigated pulmonary function in HF population, characterized by echocardiography and natriuretic peptides.
Purpose: To investigate pulmonary function in HF and to evaluate influence of left ventricular function assessed by echocardiography and volume status assessed by natriuretic peptides.
Methods: The Screening Of adult urBan pOpulation To diAgnose Heart Failure (SOBOTA-HF) study is an ongoing cross sectional epidemiological study in Murska Sobota city residents aged 55 years or more. This interim report presents data for 702 participants of NT-proBNP screening; those with concentration = 125 pg/mL were invited for a detailed diagnostic visit that included echocardiography. HF diagnosis and left ventricular dysfunction were evaluated according to 2016 European Society of Cardiology guidelines. European Respiratory Society standards were used to evaluate pulmonary function.
Results: Overall, 339 participants completed diagnostic visit (age 70 ± 8 years, 35% men, NTproBNP 481 ± 936 pg/mL), 92 were diagnosed with HF and 9 had history of COPD. Average Tiffeneau index was 74 ± 9% and was < 70% in 106 participants with no higher incidence in HF patients (33% vs 31%). There was no significant correlation between Tiffeneau index and NT-proBNP, gender or age. HF and NT-proBNP significantly correlated with all other pulmonary test function parameters. Forced expiratory volume in first second was significantly lower in patients with HF (Figure).
Conclusions: In stable general population, HF and NT-proBNP are associated with lower volumes during pulmonary function testing but not with typical obstructive airway disease pattern.



P414

Utility of serum biomarkers for diagnosis of community-acquired pneumonia in patients with concomitant chronic heart failure

ZD Kobalava[1]; AA Bobylev[2]; SA Rachina[1]; SN Avdeev[3]; S Omar[1]; OT Zorya[1]
[1]RUDN University, Moscow, Russian Federation; [2]Inter-regional Association for Clinical Microbiology & Antimicrobial Chemotherapy, Smolensk, Russian Federation; [3]Sechenov University, Pulmonology Research Institute, Moscow, Russian Federation

Background: Diagnosis of community-acquired pneumonia (CAP) in patients with chronic heart failure (CHF) is associated with objective difficulties due to limited value of clinical signs/symptoms, routine laboratory and instrumental investigations.
Purpose: To assess the utility of serum biomarkers for diagnosis of CAP in patients with concomitant CHF.
Methods: Prospective observational study recruited adult hospitalized patients with suspected CAP and concomitant CHF. High-resolution chest computed tomography was used to differentiate CAP (group 1) and CHF decompensation (group 2). C-reactive protein (CRP), procalcitonin (PCT), interleukin-6 (IL-6), tumor necrosis factor a (TNFa), brain natriuretic peptide (BNP) levels were measured along with routine tests/procedures. Standard statistical tools were applied, p-value < 0.05 was considered statistically significant.
Results: Altogether 70 patients were enrolled. Groups were comparable regarding the main characteristics; only CRP, PCT and IL-6 levels were significantly higher in patients with proven CAP (table 1). AUC ROC (95% CI) was the highest for CRP - 0.91 (0.83-0.98), followed by PCT - 0.81 (0.72-0.90) and IL-6 - 0.81 (0.71-0.91). CRP value of 28.5 mg/L and IL-6 value of 27.6 pg/mL had optimal sensitivity and specificity ratio (85.7/91.4% and 82.9/71.4%, respectively). Substantial specificity reduction in sensitivity increase limited appropriate cutoff selection for PCT.
Conclusion: Serum inflammatory biomarkers such as CRP, PCT, and IL-6 can be useful to distinguish CAP and CHF worsening. It seems that CRP has the optimal diagnostic utility in this population.

Table 1. Comparison of patient groups

Characteristic	Group 1 (n = 35)	Group 2 (N = 35)	p value
Age, years/Females, %	73.9±11.4/68.6	75.1±8.7/62.9	NS

Markers of hypoxia and myocardial dysfunction and renal function in patients with acute decompensation of heart failure

EV Efremova[1]; AM Shutov[1]; ER Makeeva[1]; MV Menzorov[1]; ER Sakaeva[1]
[1]Ulyanovsk State University, Ulyanovsk, Russian Federation

Acute kidney injury (AKI) often complicates acute decompensated heart failure (ADHF). Early diagnosis AKI on the dynamics of serum creatinine and diuresis is difficult. That's why early diagnosis and predicting of AKI in patients with ADHF are relevant.
The aim of this study was to investigate factor-inducible hypoxia -1 (HIF-1) in patients with ADHF and the possibility of using it as a biomarker of AKI.
Materials and Methods: 84 patients (66 males, 18 females, mean age was 61,4 ± 7,1years) admitted to hospital with ADHF were studied. The main cause of ADHF was a combination of coronary artery disease and arterial hypertension.AKI was diagnosed according to the KDIGO Guidelines, 2012. ADHF was diagnosed and evaluated according to ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure, 2016. Comorbidity of patients with ADHF was c determined by Charlson comorbidity index (CCI). HIF-1, natriuretic peptide (NT-proBNP), erythropoietin were evaluated.
Results: The ??I was 6 (lower-upper quartiles: 4 - 8). The GFR was 59.8 ± 15.2 ml / min / 1.73 m2. AKI was diagnosed in 27 (32.1%) patients. In most cases, the first stage of AKI was observed (in 23 (27.4%) patients).HIF-1 was 1.27 ± 0.63 ng / ml, NT-proBNP was 2197.5 ± 1153.4 pg / ml, erythropoietin was 56,0 mIU / ml (lower-upper quartiles: 13,2 - 68,1) irrespective of AKI. A direct correlation was observed between the level of erythropoietin and the level of NT-proBNP (R = 0.44, p < 0.001).An inverse correlation was observed between GFR and the level of NT-proBNP (R = -0,51, ? = 0,005). However, there was no statistically significant association between the level of HIF-1 and GFR as well as the level of NT-proBNP and erythropoietin. Level of HIF-1 did not differ in patients with AKI and without AKI (1,21 ± 0,60 ng / ml vs. 1,30 ± 0,64 ng / ml, resp., p = 0.52).
Conclusion: AKI was diagnosed in every 3 patients with ADHF. Decreased kidney function is associated with the severity of heart failure (level of NT-proBNP). The factor-inducible hypoxia -1 (HIF-1) in patients with ADHF is not related to the kidney function.

Profile of the elderly patient with heart failure admitted to cardiology department

D Daniel Enriquez Vazquez[1]; C Perez Garcia[1]; TS Luque Diaz[1]; A Travieso Gonzalez[1]; V Ruiz Pizarro[1]; C Espejo Paeres[1]; C Olmos Blanco[1]; D Vivas Balcones[1]; P Martinez Santos[1]; A Esteban[1]; J Higueras[1]; M Perez Serrano[1]; R Bover Freire[1]; I Vilacosta[1]; C Macaya[1]
[1]Hospital Clinic San Carlos, Cardiovascular Institute, Madrid, Spain

Background: Prevalence of heart failure (HF) has increased, due to the increased survival of patients. Elderly patient sometimes presents multiple comorbidities that must be taken into account when managing the patient with HF.
Purpose: The objective of this study is to know in depth this subgroup of patients more and more frequent in the usual clinical practice, as well as to study the management that is carried out in them.
Methods: Patients diagnosed with heart failure who were admitted to a cardiology department between July 2016 and March 2017 were registered prospectively and consecutively for one year.
Results: Of 336 patients analyzed, 150 patients were 80 years old or older. Baseline characteristics are summarized in Table 1. Heart rate at discharge was 81.65 vs 69.85 in those under 80 years of age. (p 0.024). In those with reduced LVEF, lower percentage of beta-blockers was used in the elderly patient (70.97% vs 84.26%, p 0.039) as well as ACE inhibitors or ARA2 (56.45% vs 72, 22%; p 0.036) and MRA (38.71% vs 62.04%; p 0.003). Devices use has been significantly lower, with 0% ICD vs 4.9% in the younger age group (p 0.007). Diuretic profile used was different, with greater use of thiazide in the elderly (6.35% vs. 1.83%, p 0.014).
Conclusion: Elderly patient with HF are mostly women, predominantly the group of HFpEF and risk factors. Drugs were used in a lower percentage according to the clinical practice guidelines, and the established objectives, such as the HR, was reached to a lesser extent, and further studies are necessary to determine the reasons for these differences. It is important to know the characteristics of this subgroup due to the increasing prevalence to improve the management of the elderly patient and improve their quality of life as well as prognosis.

Table 1

Characteristics	Elderly (>80 years)	Younger patients	p value
Mean age	84,69	68,76	<0,001
Male sex	59,3%	38,2%	<0,001
Hypertension	89,3%	75,8%	0,001
Hypercholesterolemia	68%	59,1%	0,094
Smoker	4%	14,5%	0,001
Alcohol consumption	13,9%	1,3%	<0,001
Atrial fibrillation	62,7%	48,4%	0,009
Dependent	22%	10,8%	0,019

Diuretics at admission	69,84%	46,79%	0,003

P417

Comorbidity and prognosis in patients with chronic heart failure

EV Efremova[1]; AM Shutov[1]; ER Sakaeva[1]
[1]*Ulyanovsk State University, Ulyanovsk, Russian Federation*

Comorbidity determines the high mortality of patients with cardiovascular disease. The aim of this study was to investigate comorbidity, clinical and psychological characteristics and quality of life in patients with CHF and patients with CHF associated with chronic kidney disease (CKD).
Methods: 203 patients with CHF (130 males and 73 females, mean age was 61,8 ± 9,6 years) were studied. CHF was defined according to ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure, 2016. Glomerular filtration rate (GFR) was calculated using CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) formula and chronic kidney disease (CKD) was defined according to Clinical Practice Guideline for the Evaluation and Management of Chronic Kidney Disease, KDIGO 2012. Group of chronic cardiorenal syndrome (CRS) was included patients with CHF GFR < 60 mL / min / 1,73 m2 . Charlson comorbidity index was calculated. ?atients were followed up for 1 year. Psychological state, quality of life of patients with chronic cardiorenal syndrome were estimated.
Results: 89 (43,8%) patients had CKD with GFR < 60 mL / min / 1,73 m2 . CKD was the most frequent component in the structure of comorbidity of patients with CHF. Charlson comorbidity index for age was 5,0 ± 2,1 points. However, if we excluded CKD from Charlson comorbidity index. patients with CRS had a higher comorbidity (4.3 ± 1.8 vs 3.8 ± 1.7 points, resp.; p = 0.01). ?atients with CRS had a higher comorbidity. Relative risk of death of patients with high comorbidity was 1.68 (95% CI 1.35-2.09) compare with patients with low comorbidity. Patients with CRS were hospitalized due to exacerbation CHF more often than patients without CRS (1.3 ± 0.48 and 1.0 ± 0.14, resp., p = 0.01).. Patients with CRS had expressed emotional discomfort, the presence of depressive, disadaptive trends, decreased of quality of life, both in the physical and the psychological aspects.
?onclusion. CKD has a negative impact both in the clinical course and quality of life, psychological status and prognosis of patients with CHF . At the same time, patients with CRS have a high comorbidity, they are characterized by the presence of hypochondria and depression and low quality of life, which should be taken into account in the development of guidelines for the diagnosis and treatment of this group and assessment of prognosis.

P418

Heart failure and atrial fibrillation

O A Otilia Tica[1]; O Tica[2]; L Rosan[1]; MI Popescu[1]
[1]*University of Medicine of Oradea, Cardiology, Oradea, Romania*; [2]*University of Medicine of Oradea, Oradea, Romania*

Introduction: Heart failure (HF) and atrial fibrillation (AF) are two epidemics found in many patients in current daily practice. They share common risk factors and have similar pathophysiology triggers.
Purpose: The difficulty is in identifying those patients in whom AF is simply a coexisting condition and those in whom AF is an important marker in quality of life, ventricular function and long-term mortality.
Methods: A total of 318 patients admitted consecutively in our clinic were evaluated during hospitalization and after discharge periodically. Patients included had the discharge diagnosis from our clinic: heart failure and atrial fibrillation. The patients were divided into 2 groups, according their condition: if they have HF and developed AF, or have AF and developed HF. The follow-up period of 1.8 years performed included surveillance, blood test (including biomarkers) and a cardiological examination (EKG, ecocardiography and clinical examination).
Results: In our study 76 (23.89%) patients have paroxismal AF, 73 (22.95%) have persistent AF, 74 (23.27%) patients have long standing persistent and 95 (29.87%) have permanent AF. A number of 127 (39.93%) of patients developed HF first, 122 (38.36%) of patients developed AF first, and in 69 (21.69%) AF and HF occurred at the same time. The mean age is 67.4 (SD: 3.6 years; p < 0.001). Patients with higher value of NTproBNP (mean value is: 7482, SD: 3761; p>0.001) have a worse prognosis. The mean left ventricular ejection fraction is: 41, SD: 27, p < 0.02. Patients with lower ejection fraction have worse outcomes. In our study group, we had a mortality rate of 3.50% (sudden cardiac death were also included in these numbers).
Conclusion: New-onset AF in patients with established HF is proven to be an ominous sign, because it is both a sign of affected patients and because it impairs cardiac function. Patients with HF and permanent AF have a worse outcome than those in sinus rhythm, although this can be explained by age progression and HF severity.

P419

High-sensitivity cardiac troponin T and N-terminal pro-B-type natriuretic peptide in patients with hypertrophic cardiomyopathy.

M Mariusz Klopotowski[1]; K Kukula[1]; M Dabrowski[1]; A Kwapiszewska[1]; J Jamiolkowski[2]; M Spiewak[1]; Z Chmielak[1]; A Witkowski[1]
[1]*National Institute of Cardiology, Warsaw, Poland*; [2]*Medical University of Bialystok, Bialystok, Poland*

Background: High-sensitivity cardiac troponin T (hs-cTnT) and (NT-proBNP) are established biomarkers in heart failure and predict clinical outcome in patients with hypertrophic cardiomyopathy (HCM).
Aim: To assess the association between hs-cTnT or NT-proBNP and a number of demographic, clinical and echocardiographic parameters in patients with HCM.
Methods: 419 clinically stable outpatients (292 men; aged 46.7 ± 13.5 years) with HCM were included. High sensitivity troponin T and NT-proBNP measurements were performed using commercially available electro-chemiluminescence kits routinely used for diagnostic purposes during scheduled outpatient visits .
Results: The median NT-proBNP level was 659 pg/ml (IQR 288.5 - 1602.5 pg/ml). Abnormal NT-proBNP level (<125 pg/ml) was observed in 363 (86.6%) patients.
Multivariate analysis revealed an independent relationship between abnormal NT-proBNP plasma level and age (OR 1.06, 95% CI 1.02 - 1.09, p = 0.001), presence of non-sustained ventricular tachycardia (OR 3.22, 95% CI 1.51 - 6.87, p = 0.002), maximum left ventricle wall thickness (OR 1.33, 95% CI 1.21 - 1.45, p < 0.001), history or presence of atrial fibrillation (OR 3.92, 95% CI 1.22 - 12.59, p = 0.022), syncope in the past (OR 0.43, 95% CI 0.20 - 0.96, p = 0.038), and BMI > 25 kg/m2 (OR 0.28, 95% CI 0.13 - 0.63, p = 0.002)
NT-proBNP level was significantly correlated with age (r = 0.10, p = 0.038), left atrium diameter (r = 0.30, p < 0.001), maximum left ventricular wall thickness (r = 0.33, p < 0.001), maximal left ventricle outflow tract gradient (r = 0.13, p = 0.007), BMI (r = - 0.12, p = 0.016), and left ventricle ejection fraction (r = - 0.18, p < 0.001).
The median hs-cTnT level was 11 ng/ml (IQR 4 - 20 ng/ml). Abnormal hs-cTnT level (<14 ng/ml) was observed in 153 (36.5%) patients.
Multivariate analysis revealed an independent relationship between abnormal hs-cTnT level and maximum left ventricular wall thickness (OR 1.08, 95% CI 1.04 -1.12, p < 0.001), left atrium diameter (OR 1.05, 95% CI 1.02 - 1.09, p = 0.001), and left ventricle ejection fraction (OR 0.92, 95% CI 0.89 - 0.94, p < 0.001)
hs-cTnT level was significantly correlated with left atrium diameter (r = 0.22, p < 0.001), maximum left ventricular wall thickness (r = 0.24, p < 0.001), and left ventricle ejection fraction (r = - 0.19, p < 0.001).
Conclusions: Increased left ventricular wall thickness, LA diameter and lower left ventricle ejection fraction were independently associated with abnormal both NT-proBNP and hs-cTnT.

P420

Heart failure patients with depression do not only have higher symptom occurrence but also higher symptom burden

J C Van Den Berge[1]; LC Van Vark[1]; E Boersma[1]; HL Hillege[2]; I Lesman-Leegte[2]; KM Akkerhuis[1]
[1]*Erasmus Medical Center, Department of Cardiology, Rotterdam, Netherlands*; [2]*University Medical Center Groningen, Department of Epidemiology, Groningen, Netherlands*

Background: Heart failure (HF) patients with depression have higher New York Heart Association (NYHA) class than those without depression. It is unknown whether this difference might be explained by higher symptom occurrence, higher symptom burden or both.
Purpose: To compare symptom occurrence and symptom burden in HF patients with and without depression.

Methods: This Dutch multicenter study prospectively included acute HF patients. Depression was defined as = 8 points on the depression scale of the Hospital Anxiety and Depression Scale (HADS). At discharge, we asked patients to complete a questionnaire with 11 questions about HF-related symptoms. Patients were questioned on the presence (yes/no) and the burden (score 1-10) of those symptoms.
Results: We included 324 patients (72 years, 65% male, 37% depression) who completed the HADS questionnaire at discharge. Among patients with depression, NYHA class III/IV was significantly more common than in those without (57% vs. 33%, p < 0.001). Moreover, the majority of the 11 HF-related symptoms were more often present in depressive patients than in patient without depression (Table). Furthermore, patients with depression also reported higher symptom burden for most of the symptoms.
Conclusion: HF patients with depression had worse NYHA class than those without depression. Importantly, patients with depression had higher symptom occurrence and symptom burden. Therefore, both these factors may declare the difference in NYHA classification in HF patients with and without depression.

Table. Symptom occurrence and burden

	Symptom occurrence			Symptom burden		
	Depression +	Depression -	p value	Depression +	Depression -	p value
1. Ankle edema when you got out of bed	75 (69)	103 (52)	0.004	7 (6-8)	6 (4-8)	0.08
2. Ankle edema during the day	77 (71)	111 (57)	0.02	7 (6-8)	7 (5-8)	0.04
3. Troubles with falling asleep	69 (61)	112 (56)	0.41	8 (7-10)	7 (6-8)	<0.001
4. Troubles with sleeping through	95 (84)	134 (69)	0.003	8 (6-9)	7 (6-8)	<0.001
5. Decreased appetite	72 (63)	82 (43)	0.001	7 (6-8)	6 (6-8)	0.23
6. More fatigue than before	108 (95)	160 (81)	0.001	8 (7-9)	7 (6-8)	<0.001
7. Shortness of breath at rest	78 (68)	97 (50)	0.002	7 (6-9)	7 (6-8)	0.12
8. Dyspnoea d'effort	112 (97)	179 (92)	0.047	9 (8-10)	8 (6-9)	<0.001
9. Orthopnoea	82 (71)	112 (56)	0.01	8 (7-9)	7 (6-9)	0.07
10. Cough	82 (71)	127 (64)	0.21	7 (6-9)	7 (5-8)	0.01
11. Dry cough	65 (57)	89 (45)	0.04	7 (6-8)	7 (5-8)	0.01

Data on symptom occurrence reported as N (%); data on symptom burden reported as median (IQR).

P421

Role of Integrated approach of pharmacological plus non pharmacological therapy in severe chronic heart failure patients.

N Sen[1]; SONAL Tanwar[2]; ASHOK Jain[1]
[1]Narayana Hrudayalaya, Cardiology, Jaipur, India; *[2]HG SMS Hospital, Cardiology, Jaipur, India*

Background: Studies revealed non pharmacological therapy consisting of yoga, meditation ,exercise and education training, in combination with diet counselling ,stress management , Enhanced external counter pulsation machine (EECP) have good role to prevent worsening heart failure
Aim: Integrative program with focus on Integrated Medicine with life style intervention in patients with severe chronic heart failure and beneficial outcome of integrated approach.
Methods: The Observational study a 3-year outpatient : A total of 202 middle-aged men and women, chronic heart failure with Hypertension, dyslipidemia, type 2 Diabetes mellitus and obesity were enrolled. The usual care (routine allopath medicines) group A(n = 106) and the integrated approach(allopathy plus non pharmacological) with life style interventional group B (n = 96). For Group B- Education, Exercise: supervised endurance and yoga , meditation with restricted diet and aerobics: three times a week for three months with Enhanced external counter pulsation machine (EECP) four cycle weekly for 5 months.
Results: Proposed lifestyle improved after year 3 in the group A over group B. There were significant differences between groups, mean changes (and their 95% confidence intervals, CI) in waist circumference pv0.001), in waist–hip ratio p < 0.01) , decrease in HR (p < 0.01), systolic BP (p < 0.01) and diastolic BP(p < 0.05) blood cholesterol and sugar, HBA1C level . Recurrent hospitalization with congestive heart failure (CHF) in group A = 23/106, group B = 7/96(p < 0.03) . Atrial fibrillation in group A = 12/106, group B = 3/96 (p < 0.08).Ventricular tachycardia in group A = 8/106, group B = 3/96(p < 0.23). Death in group A = 18/106, group B = 6/96(p < 0.36).Post MI-CHF in group A = 9/106, group B = 3/96(p < 0.36). Post CABG-CHF in group A= 8/106, group B = 2/96.
Conclusion: Regular 3-year follow-up improvements in quality of life, decrease stress, decrease incidence of cardio-vascular events , improve Exercise Score, better reduction of heart rate, blood pressure, weight, waist circumference, three to four time decrease episodes of recurrent hospitalization , Cardiac Arrhythmias and 33% reduction of cardiovascular mortality in integrated group as compare to usual group.

P422

Comparison of depression, anxiety and perceived stress scores between patients with cardio-respiratory failure with and without cognitive impairment

M Monica Rivera Rodriguez[1]; V Pelaez-Hernandez[1]; A Orea-Tejeda[1]; A Figueroa-Herrera[1]; D Gonzalez-Islas[1]; C Chavez-Mendez[1]; C Olivo-Villalobos[1]; G Davila-Said[1]; L Castillo-Aguilar[1]; S Torres-Montiel[1]; E Perez-Cabanas[1]; R Sanchez-Santillan[1]; K Balderas-Munoz[1]
[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosio Villegas", Heart Failure and Respiratory Distress Clinic, Mexico City, Mexico

Background: Heart failure (HF) patients have high levels of anxiety, depression and perceived stress, which may be linked with cognitive impairment in many cases. However, there is no information about patients with cardio-respiratory failure, who have major oxygenation tissue problems, which affects the brain and its functions, including those cognitive and emotional.
Objective: The purpose of this study was compare anxiety, depression and perceived stress scores between patients with cardio-respiratory failure with and without cognitive impairment.
Material and Methods: A cross-sectional study was realized. Sixty-six patients with of cardio-respiratory failure were included heart failure NYHA I-III and chronic obstructive pulmonary disease (COPD), GOLD 1-3. All participants were evaluated with the following tests: a) Hospital Anxiety and Depression Scale (HADS), with 14 items to evaluate anxious and depressive symptomatology; b) Perceived stress scale in the 10 items version, and c) Montreal Cognitive Assessment (MOCA) alternate mexican version 7.2 to determine the presence of cognitive impairment if the score is less or equal to 26 points. According to the MOCA, the participants were divided into two groups: Group 1 (G1, n = 8): without cognitive impairment, and Group 2 (G2, n = 58), with cognitive impairment. The data was analyzed with SPSS v. 21 for Windows, data didn't present a normal distribution, so the U Mann Whitney test was used.
Results: Cognitive impairment was found in the 87.87%. There were no differences in the socio-demographic variables between both groups. Patients with cognitive impairment have major scores of anxiety (G1: 3.88 ± 1.959, G2: 5.47 ± 4.168, p < 0.05) and depression (G1: 4 ± 2.777, G2: 5.97 ± 4.176, p < 0.05) according to the HADS; besides of a major perceived stress (G1: 18.50 ± 5.155, G2: 23.36 ± 6.282, p < 0.05).
Conclusions: Patients with cardio-respiratory distress has a high prevalence of cognitive impairment and poor quality of life (more anxiety and depression). The interdisciplinary evaluation and intervention as part of non pharmacological treatment is necessary.

P423

Do inflammation-associated biomarkers differ between men and women in prediction of new-onset heart failure ?

L Meems[1]; N Suthahar[1]; SJ Bakker[2]; RT Gansevoort[2]; WH Van Gilst[1]; P Van Der Harst[1]; RA De Boer[1]
[1]University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands; *[2]University Medical Center Groningen, Groningen, Netherlands*

Background: Heart failure (HF) is a heterogeneous condition that may result from various etiologies. It has become apparent that the etiology of HF in men and women is different, and chronic inflammation has been suggested to be more prominent in men. We therefore evaluated the clinical and biochemical association of inflammatory biomarkers in both sexes, and studied the associationwith new-onset HF in males and females.
Purpose: Our aim is to identify and validate in a sex-specific manner if inflammatory biomarkersdiffer between men and women, and increase our knowledge and understanding of sex differences for new onset HF.

Methods: Sex-specific new-onset HF was analysed in 7954 participants (4014 females) from the Prevention of Renal and Vascular End-stage Disease (PREVEND) cohort (free of heart failure). Baseline plasma levels of biomarkers are presented as medians (IQR). To test differences at baseline, we used Wilcoxon rank sum test, as fitted for skewed variables. Predictive value of inflammatory biomarkers (copeptin (CP), procalcitonin (PCT), plasminogen activator inhibitor (PAI)-1, Galectin (Gal)-3 and C-reactive protein (CRP)) for sex-specific new onset HF was determined by Cox regression analysis, using a multivariable model that corrects for age, eGFR, BMI, smoking, systolic blood pressure, serum glucose and plasma cholesterol. P-values < 0.05 were considered significant.
Results: There were 341 cases of new-onset heart failure. At baseline, males (M) had significantly higher plasma levels of biomarkers related to endothelial vascular damage (PAI-1: 83.5 (49.7, 136,4) vs. females (F) 60.3 (34.5, 109.9), $p < 0.001$; PCT: 1.8 (1.5,2.2) vs. F 1.4 (1.2,1.7), $p < 0.001$; CP: 6.2 (4.0, 9.4) vs. F 3.6 (2.4, 5.6), $p < 0.001$). F had higher levels of biomarkers representing macrophage and T-cell activation (Gal-3: 11.0 (9.1, 13.4) vs. M 10.6 (8.9, 12.7), $p < 0.001$; CRP: 1.33 (0.56,3.27) vs. M 1.22 (0.54, 2.72), $p < 0.001$). Nevertheless, none of the biomarkers was able to predict sex-specific new onset HF: PAI-1 M HR 1.02 (0.83-1.25): vs. F 1.16 (0.89-1.52); CRP M HR 1.10 (0.92-1.32)vs. F 1.14 (0.94-1.39); Gal-3 M HR 1.38 (0.87-2.18)vs. F HR 0.94 (0.52-1.68); PCT M HR 0.91 (0.59-1.39)vs. F HR 1.19 (0.75-1.88); CP M HR 0.92 (0.66-1.27)vs. F HR: 0.88 (0.66-1.16), p = ns for all.
Conclusion: In this study, we demonstrate that levels of inflammatory markers significantly differ in males and females. Nonetheless, none of these biomarkers displayed differential utility for predicting new-onset HF in both males and females. Future studied are needed to better understand the pathophysiological meaning of this interesting finding.

P424
Impaired skeletal muscle mitochondrial and metabolic function in patients with heart failure with preserved and reduced ejection fraction compared to healthy controls and its impact on muscle function

T Bekfani[1]; M Bekhite Elsaied[2]; SD Derlien[1]; A Hamadanchi[1]; J Nisser[2]; E Froeb[1]; D Haase[1]; T Kretzschmar[1]; UC Smolenski[2]; G Lehmann[3]; G Wolf[3]; SD Moebius-Winkler[1]; PC Schulze[1]
[1]University Hospital of Jena, Department of Cardiology, Jena, Germany; *[2]University Hospital of Jena, Institute of Physiotherapy, Jena, Germany*; *[3]University Hospital of Jena, Department of Endocrinology, Nephrology and Rheumatology, Jena, Germany*

Purpose: To elucidate exercise capacity, muscle strength and Quality of life (QoL) and the associated gene expression regulating metabolic, mitochondrial and structural characteristics among symptomatic and clinically stable outpatients with heart failure (HF) with both preserved (HFpEF) and reduced ejection fraction (HFrEF) and age-matching healthy controls (HC).
Methods: 55 participants were recruited prospectively at the University Hospital Jena: 19 HFpEF, 18 HFrEF, 18 HC (Age: 71 ± 6 vs. 68 ± 9 vs. 66 ± 7 years; sex (m/f): 8/11 vs. 15/3 vs. 7/11; BMI: 28.5 ± 4.6 vs. 27.9 ± 5.3 vs. 26.1 ± 4.3 kg/m2, respectively). All participants underwent standardized tests including echocardiography, cardiopulmonary exercise test (CPET), 6-minute walk test (6MWT), muscle function tests, blood tests, QoL assessment as well as muscle biopsies from the vastus lateralis muscle. Real-time polymerase chain reaction (Real-time-PCR). Total RNA was prepared. Expression levels of genes for carnitine palmitoyl transferase IB (CPT1B), Mitofusin (Mfn2), medium-chain acyl-CoA dehydrogenase (ACADM), RAC-beta serine/threonine-protein kinase (Akt2), peroxisome proliferator-activated receptor alpha (PPARa) were measured by Real-time PCR.
Results: Markers of oxidative fatty acid metabolism (CPT1 and ACADM) were reduced in skeletal muscle of patients with HFpEF and HFrEF compared to HC ($p = 0.001$ and 0.03 respectively) suggesting impaired transport of long chain fatty acids and reduced fatty acid oxidation. Further, MFN2 decreased in HFpEF and HFrEF patients compared to HC ($p = 0.001$). The expression of Akt2 and PPARa was found to be suppressed in HFpEF patients compared to HFrEF patients and to HC ($p = 0.001$, $p = 0.0001$, respectively). Levels of PPARa and MFN2 correlate with exercise capacity assessed by peak VO2 ($p = <0.001$, $r = 0.67$, $p = 0.007$ $r = 0.46$). Higher levels of PPARa were associated with higher values of muscle strength and QoL (peak torque right leg/muscle mass right leg: $p = 0.03$, $r = 0.38$; VAS-Score: $p = 0.01$, $r = 0.5$).
Conclusion: Patients with heart failure both with preserved and ejection fraction show impaired exercise capacity, muscle strength and quality of life and evidence of distinct abnormalities of mitochondrial and metabolic function in skeletal muscle compared to HC. These changes were found more pronounced in patients with HFpEF suggesting additional impairments of muscle function and oxidative capacity.

Chronic Heart Failure - Other

P425
Long-term changes in left ventricular ejection fraction depending on the type of heart failure

R Raquel Lopez Vilella[1]; D Carrillo Gomez[1]; J Perez Gozalbo[2]; I Sanchez Lazaro[1]; L Martinez Dolz[1]; L Almenar Bonet[1]
[1]Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit. Cardiology Department, Valencia, Spain; *[2]Hospital Dr. Peset, Cardiology Department, Valencia, Spain, Valencia, Spain*

Background and objective: Left ventricular ejection fraction (LVEF) classifies the type of heart failure (HF). Three types are defined in European guidelines for HF (preserved LVEF (HFpEF) = 50%, reduced LVEF (HFrEF) < 40% and mid-range (HFmrEF) 40-49%). This classification has been shown to be non-rigid, with an exchange between the three groups. How many patients change groups during their long-term evolution is not known. The purpose of this study is to know the distribution of the type of HF and its changes in a prolonged period of time.
Methods: We recruited 249 consecutive outpatients with the clinical diagnosis of HF attended in a tertiary hospital between 2012 and 2014. We excluded patients without echocardiographic studies performed in the center and patients with poor acoustic echocardiography window, those who had less than 3 months of admission for any cause and those who suffered some degree of clinical instability. We analyzed general clinical variables and etiology of HF (ischemic, non-ischemic heart disease, hypertension, valvular heart disease and others). Information on LVEF was included at the beginning and the last echocardiographic control available.
Results: From the 249 patients of the registry, 168 had LVEF initial and follow-up by echocardiography. The median age was 64 years (interquartile range [IQR] 52.5-72), 38.69% were women. The main associated comorbidities were 41.07% hypertension, diabetes mellitus 29.17%, dyslipidemia 78.20%, and 26.79% chronic kidney disease. The mean time of follow-up until the last echocardiographic control was 3.4 years (IQR 1.86-4.61). At the beginning of the study, there were 61.90% of patients with HFrEF, 7.14% HFmrEF (12/168) and 30.95% HFpEF (Table). In the last echocardiographic control, 50.60% were HFrEF, 12.5% HFmrEF and 36.90% HFpEF. 30.09% of patients with HFrEF because of dilated cardiomyopathy changed to HFpEF, 41.03% of ischemic, and 41.03% of those of valvular etiology. The overall percentage change in the category was 60.71% (102 of 168 patients). Of the total number of patients who changed, 33% had ischemic etiology, 26% had a valvular disease, 21% had idiopathic dilated cardiomyopathy, and 1.96% had hypertensive cardiomyopathy. If we divide by subgroups according to etiology, 43% of patients with dilated cardiomyopathy changed category, 65% of patients with ischemic heart disease, 73% of patients with valvular heart disease and 67% of patients with hypertensive heart disease ($p = 0.034$). The type of HF in which the most change of category of LVEF is produced is the HFmrEF, with 92% of patients that change the category of LVEF in the follow-up.
Conclusions: The most frequent etiology of HF depends on the type of HF. Staying in a group (HFrEF, HFrEF, HFmrEF) is a variable concept. The overall percentage of exchange can be relevant. The etiology that presented the most variation was valvular and hypertensive. The type of HF that suffered the most exchange was HFmrEF.

P426
Potential substitution of chronic heart failure care according to the 'Landelijke Transmurale Afspraak' (LTA)

MPM Marijke Vester[1]; SLMA Beeres[1]; LF Tops[1]; CMHB Lucas[2]; PEJ Van Pol[2]; MJ Schalij[1]
[1]Leiden University Medical Center, Cardiology, Leiden, Netherlands; *[2]Rijnland Hospital, Cardiology, Leiderdorp, Netherlands*

Background/Introduction: The prevalence of chronic heart failure is increasing due to improved medical and invasive treatment. The Dutch "national transmural agreement" (LTA) heart failure, agreed upon in 2015, aims to optimize the organization of heart failure care in the Netherlands.
Purpose: To evaluate the proportion of patients in which heart failure care can be transferred from the cardiologist to the general practitioner (GP), based upon the LTA.
Methods: A total of 200 heart failure patients (100 from a secondary and 100 from a tertiary care hospital) were evaluated at the out-patient clinic. In line with the LTA, the following patients were considered eligible for referral to the GP: 1/ Stable heart failure patients with preserved ejection fraction (HF-pEF), 2/ Stable heart failure patients with mid-range ejection fraction (HF-mEF) and 3/ Stable heart failure patients with a recovered HF-rEF (LVEF>50%).
Results: The population consisted of 57% male and mean age was 72 ± 15 years. In total, 17% of patients were considered eligible for referral to the GP. It concerned

1.5% patients with HF-pEF, 5.0% patients with HF-mEF and 10.5% patients with recovered HF-rEF. The main indications for heart failure care by a cardiologist were: recent admission for decompensated heart failure (29.5%), recent adjustment in heart failure medication (7.5%) or active cardiac disease other than heart failure (39.5%).

Conclusion: In a substantial amount of patients heart failure care can be transferred to the GP.

Subdivision heart failure patients

	Total (n = 200)	Center A (n = 100)	Center B (n = 100)	P-value
Indications secondary care				0.068
1. Unstable heart failure	74	30	44	0.040
2. Stable heart failure, active CD, LVEF <50%	53	34	19	0.016
3. Stable heart failure, active CD, LVEF >50%	26	12	14	0.674
4. Stable heart failure, no active CD, LVEF >40% or a comorbidity	13	7	6	0.774
Potential substitution				0.559
5. Stable heart failure, no active CD, preserved LVEF	3	2	1	0.561
6. Stable heart failure, no active CD, mid-range LVEF 40-50%	10	6	4	0.516
7. Stable heart failure, no active CD, recovered LVEF	21	9	12	0.489

No significant differences were observed. Unstable heart failure was the main indication for follow up at secondary care in center B, whereas an active cardiac device was the main indication in center A. CD: Cardiac Disease; LVEF: Left Ventricular ejection Fraction

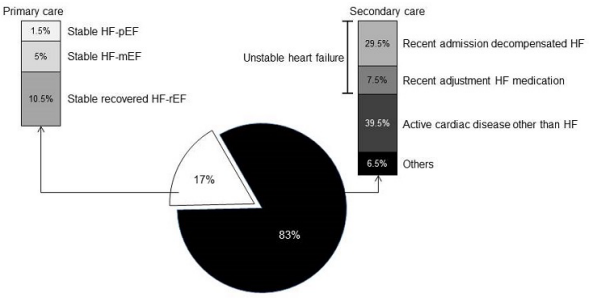

Fig. 1. Overview of patients who were eligible for referral to primary care (17%) and for who treatment by cardiologist was justified (83%) based on the 'Landelijke Transmurale Afspraak. Others includes a comorbidity or a left ventricular ejection fraction <40%. HF-pEF = Heart Failure with preserved ejection fraction; HF-mEF = Heart Failure with a mid-range ejection fraction; HF-rEF = Heart Failure with a reduced ejection fraction.

Overview of patients based on the LTA

The role of right ventricular function on peak VO2 after VAD implantation in end stage heart failure patients.

PHT Timmermans[1]; L Fresiello[2]; R Buys[3]; K Vandersmissen[2]; A Belmans[4]; W Droogne[1]; F Rega[2]

[1]University Hospitals (UZ) Leuven, Cardiology, Leuven, Belgium; [2]University Hospitals (UZ) Leuven, Cardiac surgery, Leuven, Belgium; [3]University of Leuven, Rehabilitation Sciences, Leuven, Belgium; [4]University of Leuven, Biostatistics and statistical bioinformatica, Leuven, Belgium

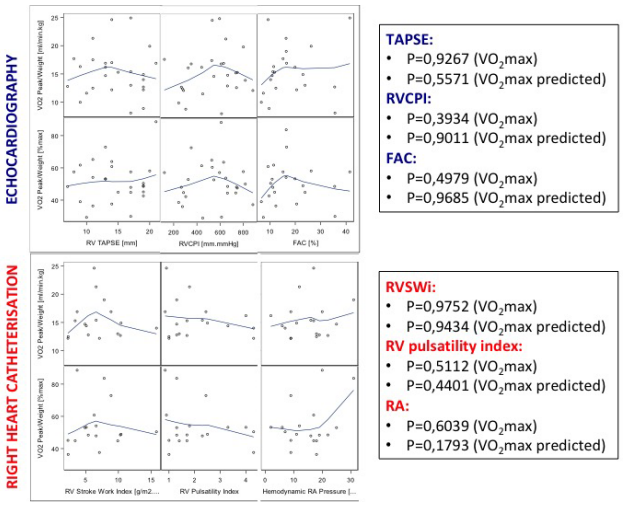
Introduction: Continuous flow LVAD therapy is not only able to improve survival in end-stage heart failure patients, but also improve excercise capacity. However, maximum excercise capacity is typically limited to around 50% of predicted VO2 max. The role of the right ventricular function on excercise capacity in VAD patients is not clear.

Purpuse: We evaluated the role of systolic RV function on excercise capacity, assessed by ergospirometry, in end-stage heart failure patients on VAD therapy.

Methods:28 patients (22 men and 6 women, mean age 54y) with end stage HF and continuous flow VAD implantation (27 HM 2, 1 HVAD) were recruted for his study, and gave written consent to participate. VAD as destination therapy and perioperative RV failure requiring temporary RV mechanical support were exclusion criteria for this analysis. All patients included underwent 3 months of ambulatory cardiac rehabilitation. All ergospirometries were conducted 4 months after device implantation. RV function was assessed pre-VAD implantation, using echocardiography parameters (TAPSE, FAC, RVCPI, PAPsystole, CVP estimations) and, if feasible, invasive measurements (full right heart catheterisation parameters and calculated vaules for right ventricular stroke work index and RV pulsatility index).

Results: Mean peak VO2 max was 15,4 ± 4,1 ml/kg.m2 or 53 ± 14% of predicted maximum, and ergospirometry parameters were compatible with cardiac limitations (mean VeVCO2 slope 42). Echocardiography was of acceptable quality to assess functional RV parameters in 26 patients (mean TAPSE 14 ± 4 mm, mean FAC 18 ± 10%, mean RVCPI 531 ± 207 mm.mmHg). Right heart catheterisation parameters were available in 18 patients (RA 15 ± 7 mmHg, mean PAP 38 ± 11 mmHg, PCWP 29 ± 9 mmHg, CI 1,7 ± 0,4 L/min.m2). Right ventricular function calculations showed a mean RV stroke work index 6,9 ± 3,5 g/m2.stroke and a mean RV pulsatily index of 2,1 ± 1,2. There was no significant correlation between any echocardiographic or invasively measured parameters of RV function (see figure).

Conclusion: There is no correlation between RV function pre-VAD implantation and VO2 max 4 months later in end-stage HF patients. Altough all patients participated in cardiac rehabilitation, mean peak VO2max was still only 53% of predicted maximum. We hypothesis that excercise capacity in patients with the of the VAD devices tested in our population is limited to the maximum output (liter per minute) these devices can generate, rather than residual right ventricular function. Further research supporting this statement is needed to further improve functional outcomes for these patients.



RV function and VO2 max correlation

P428

Differences in heart rate variability to emotional stimuli between patients with cardiorespiratory failure who suppress or reappraise their emotions

F A Figueroa Herrera[1]; V Pelaez-Hernandez[1]; M Rivera-Rodriguez[1]; SC Torres-Montiel[1]; A Orea-Tejeda[1]; D Gonzalez-Islas[1]; C Olivo-Villalobos[1]; G Davila-Said[1]; C Chavez-Mendez[1]; RN Sanchez-Santillan[1]; L Castillo-Aguilar[1]; AG Navarrete-Penaloza[1]; L Verdeja-Vendrell[1]; A Jimenez-Cepeda[1]

[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosio Villegas", Heart Failure and Respiratory Distress Clinic, Mexico City, Mexico

Background: The management of emotions modifies the autonomic activity of healthy people and patients with cardiovascular diseases. On one hand healthy people that suppress their emotions show a decrease in heart rate variability (HRV). On the other hand, expressing and reappraising emotions have positive consequences for health. However, the effects that expression and suppression have on the HRV of patients with cardiorespiratory failure (CRF) are unknown.

Objective: To compare HRV to pleasant and unpleasant emotional stimuli during processes of expression and emotional suppression between patients with CRF that suppress or reappraise their emotions.
Method: A cross-sectional study was conducted in 18 patients with CRF. They were classified according to the Emotional Regulation Questionnaire into two groups: 1) Suppressors (G1, n = 10, 75.10 ± 8.76 years, 80% women) and 2) Reappraisers (G2, n = 8, 67.25 ± 10.33, 75% men). All the participants were evaluated with two psychophysiological profiles of 20 minutes each, one showed positive emotional images and the other negative. Each profile was divided into Baseline 1 (LB1), Expression (Ex), Inhibition (In) and Baseline 2 (LB2). In LB1 and LB2 neutral images were shown, in Ex and In the emotions evoked by the stimuli were respectively experienced or inhibited. The HRV was recorded in its bands of very low (VLF), low (LF) and high (HF) frequencies. The Mann-Whitney U test was applied to determine differences in the HRV, using SPSS version 21 for Windows,
Results: There were no statistically significant differences (p> 0.05). However, clinically there is a decrease in HRV in the G1 group compared to the G2.
Negative (BL1|Ex|In|BL2)
VLF (G1/G2): 19.87 ± 17.33 / 14.80 ± 13.08 | 20.76 ± 13.88 / 12.81 ± 12.15 | 22.74 ± 15.53 / 11.76 ± 9.77 | 21.43 ± 16.64 / 16.97 ± 14.78
LF (G1/G2): 26.07 ± 14.83 / 18.67 ± 11.63 | 25.36 ± 12.51 / 20.30 ± 10.66 | 26.67 ± 14.80 / 17.29 ± 10 | 22.75 ± 10.57 / 20.59 ± 13.33
HF (G1/G2): 42.73 ± 19.85 / 47.18 ± 14.34 | 43.25 ± 17.63 / 46.38 ± 16.18 | 40.50 ± 20.48 / 52.28 ± 9.62) | 42.81 ± 18.88 / 39.30 ± 11.13
Positive (BL1|Ex|In|BL2)
VLF (G1/G2): 31.13 ± 20.28 / 22.90 ± 8.22 | 22.87 ± 14.33 / 24.83 ± 12.61 | 28.34 ± 17.10 / 30.50 ± 20.36 | 22.13 ± 19.79 / 21.95 ± 8.20
LF (G1/G2): 25.13 ± 11.37 / 25.57 ± 10.81 | 28.11 ± 9.92 / 25.78 ± 7.04 | 27.14 ± 8.14 / 20.33 ± 6.44 | 23.97 ± 12.59 / 24.10 ± 7.26
HF (G1/G2): 36.87 ± 17.57 / 41.74 ± 11.50 | 40.57 ± 17.20 / 40.04 ± 10.81 | 36.72 ± 16.96 / 38.34 ± 13.72 | 39.46 ± 18.71 / 43.57 ± 5.47
Conclusion: Emotional suppression produces diminution of HRV in both expression and emotional inhibition, with greater magnitude in suppressive patients, translating into autonomic dysregulation before emotional stimuli and a risk factor for patients. Pleasant emotional stimuli have a positive effect on HRV. An interdisciplinary treatment that promotes emotional reappraising in patients is necessary.

P429
An audit to help establish discharge criteria for the nurse-led heart failure clinic at mater dei hospital, malta

A M Alice May Moore[1]; L Buttigieg[1]; Z Gauci[1]; J Caruana[1]; RG Xuereb[1]
[1]Mater Dei Hospital, Cardiology, Msida, Malta

Background: Local audits at the Nurse-led Heart Failure Clinic (HFC) have shown that patients with heart failure with reduced ejection fraction (HFrEF) are not reaching target or maximal tolerated doses of heart failure (HF) prognostic medications. Furthermore, up-titration of these medications is taking longer than 3 months. The main reasons for this are the increasing number of referrals to this clinic and the lack of discharges being carried out.
Purpose: To determine discharge criteria for the Nurse-Led HFC in order to focus on optimal and rapid up-titration of medical treatment of patients with HFrEF.
Method: All patients that attended nurse-led HFC from January to July 2017 were analysed. Data was collected from IT systems used in the Department of Cardiology (CVIS). The definition of optimal target doses of HF prognostic medications used is according to the 2016 ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure.
Results: 563 patients were assessed. Mean age 68 years. 70.9% males; 28.9% females. Most common cause for HF were IHD (53%) and idiopathic DCM (21.8%). The ejection fraction (EF) for each patient was recorded; 280 patients (50%) had an EF>40% whilst 280 patients (50%) had EF <40%.
Of the patients with EF>40%, only 3 patients had recorded fluid overload. 1 patient required hospital admission. 7 patients (2.5%) with were discharged from HFC. There was no documentation of why the other 97.5% were being follow-up by the nurse-led HFC.
HF medications of patients with EF <40% (280 patients) were analysed. 11 (3.9%) of these patients reached target doses of HF prognostic medications. Only 1 patient was discharged from the nurse-led HFC. The other 10 (3.5%) were given routine appointments at this clinic. No clear documented reason was given for this.
23 patients (8.2%) were on maximal tolerated doses of HF prognostic medications. 2 were discharged from the nurse-led HFC. The rest, 21 patients (7.5%), were given routine follow-up appointments at this clinic. No clear documented reason was given for this.
Conclusion: Patients with EF>40% can be discharged from the nurse-led HFC safely to GP if not fluid overloaded as HF prognostic medication, and therefore up-titration, is not indicated. The mainstay of treatment is fluid management with diuretics and treatment of underlying cause. Patients with EF <40% who are on target doses or maximal tolerated dose of HF prognostic medications, and have no other pending issues, can be discharged from the nurse-led HFC. With these criteria, 270 patients (96.4%) with EF>40% can be discharged from the nurse-led HFC as well as 34 patients (12.1%) with EF <40%.
Established discharge criteria will aid the heart failure nurses with discharges and therefore decrease burden on the HFC. This will help focus on urgent follow-up of patients who need aggressive fluid management, up-titration of HF medication and education such as fluid restriction and self-management with diuretics.

Mutation spectrum of hungarian patients with hypertrophic cardiomyopathy assessed by next generation sequencing

A Tringer[1]; L Hategan[1]; V Nagy[1]; B Csanyi[1]; J Borbas[1]; Z Hegedus[2]; I Nagy[2]; T Forster[1]; R Sepp[1]
[1]University of Szeged, 2nd Department of Internal Medicine and Cardiology Centre, Szeged, Hungary; [2]Biological Research Centre of Szeged, Szeged, Hungary

Funding Acknowledgements: Supported by GINOP-2.3.2-15-2016-00039.

Background: Hypertrophic cardiomyopathy (HCM) is a primary disease of the myocardium most commonly caused by the mutations in sarcomeric genes. Due to the high degree of genetic heterogeneity the genetic screening of the disease is lengthy and laborious.
Purpose: We performed genetic analysis of Hungarian patients with HCM using next-generation sequencing.
Patient and Methods: We examined 103 patients with HCM (58 men, 45 women, average age: 45 ± 15 years). Familial disease was detected in 27 cases (26%). Maximal left ventricular (LV) wall thickness was 22 ± 6 mm and significant LV outflow tract gradient was observed in 28 cases. Using next-generation sequencing we screened 103 known causative cardiomyopathy genes.
Results: Genetic analysis identified 284 rare (< 1% minor allele frequency) potentially causative variants, causing either amino acid change of affecting the 'splice site' region. Pathogenic or likely pathogenic variants were identified in 68 patients (66%). Pathogenic variants most commonly affected the MYBPC3 gene (36/103, 35%), the MYH7 gene (16/103, 16%), and the TNNT2 and TPM1 genes (3/103, 3%). Rare sarcomeric gene variants, affecting the TNNI3 gene (2/103, 2%), the ACTC1, MYL2 and MYL3 genes (1/103, 1%) has also been detected. We observed the MYBPC3 p.Gln1233*, p.Pro955fs and p.Ser593fs variants in multiple cases (8, 5 and 6 cases, respectively) pointing out to a possible founder effect.
Discussion: Next-generation sequencing is appropriate for screening high number of patients. In accordance with literature data, the MYBPC3 gene seems to be the most commonly affected gene in Hungarian HCM patients.

Acute Heart Failure - Pathophysiology and Mechanisms

P431
Improvement of ventricular-arterial coupling was associated with changes of global longitudinal peak systolic strain and liver stiffness in patients with decompensated heart failure with reduced eject

O Lukina[1]; A Soloveva[1]; I Meray[1]; S Villevalde[1]; Z Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), moscow, Russian Federation

Objective: Ventricular-arterial coupling (VAC) represents the interaction of the heart and large arteries. VAC demonstrates mechanical efficiency in transferring the blood from the heart to the arterial system. The aim of the study was to assess correlations of dynamics of parameters of ventricular-arterial coupling and arterial stiffness in patients with decompensated heart failure (HF).
Methods: In 18 patients admitted with decompensated HFrEF (14 male, 68 ± 9 years (M ± SD), arterial hypertension 100%, previous myocardial infarction 83, diabetes 50%, NTproBNP 5462 (4219;6837) pg/ml, serum creatinine 107 (97;161) μmol/l, eGFR 59 (39;65) ± 23 ml/min/1.73m2, potassium 4.46 ± 0.59 mmol/l) arterial stiffness was assessed by applanation tonometry, parametrs of VAC by 2-dimentional echocardiography, global longitudinal peak systolic strain (GLPS) by speckle tracking echocardiography and liver stiffness (LS) by transient elastography at admission to hospital and before discharge. VAC as the ratio Ea/Ees (arterial (Ea) and end-systolic LV elastance (Ees)), optimal range was considered as 0.5-1.2. Parameters of LV efficacy were calculated. Hospital length of stay was 9.0 (7.0;10.0) days. Patients received ACEI 89%, beta-blockers 100%, aldosterone receptor antagonists 94%, iv loop diuretics 100%, iv nitrates 61%. Wilcoxon test was considered significant if $p < 0.05$.
Results: In patients with HFrEF VAC significantly decreased from 3.36 (2.98;4.00) to 2.54 (1.90;3.28) ($p < 0.05$) and Ea tended to decrease from 2.51 (1.78;3.15) to 1.63 (1.40;2.28) mmHg/ml/m2 and Ees did not change (0.63 (1.17;3.28) mmHg/ml/m2)

(p>0.05). LV efficacy (ratio stroke work/ pressure-volume area) increased from 0.49 ± 0.07 to 0.55 ± 0.10 (p < 0.05).
There were significant decrease LS from 17,6 (6,6;24,5) to 10,5 (6,3;15,7) kPa (p < 0.05). GLPS did not change significant (from -6,3 (-6,9;-3,8) to -4,8 (-8,4;-2,3)%) (p>0.05).
There was significant correlation between changes of Ea/Ees in the group of patients with HFrEF and changes of liver stiffness (R = 0.68), central pulse pressure (R=-0.64), GLPS (R=-0.82), hematocrit (R=-0.61) and hemoglobin levels (R=-0.81).
There was significant correlation between changes of LV efficacy in the group of patients with HFrEF and QRS interval duration (R = 0.79), change of hemoglobin level (R = 0.66).
Conclusion: In patients with decompensated HFrEF VAC significantly decrease due to decrease of Ea. These beneficial changes of cardiac performance was associated with changes of GLPS and liver stiffness.

P432
Beneficial changes of ventricular-arterial coupling during the treatment in patients with decompensated heart failure with reduced ejection fraction.

O Lukina[1]; A Soloveva[1]; I Meray[1]; S Villevalde[1]; Z Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), moscow, Russian Federation

Objective: The interaction of the left ventricle (LV) with the arterial system, termed ventricular-arterial coupling (VAC), is a central determinant of cardiovascular performance and cardiac energetics. Congestive heart failure (HF) modify the structure and function of both the central arteries and LV. The aim of the study was to assess dynamics of parameters of ventricular-arterial coupling and arterial stiffness in patients with decompensated HF.
Methods: In 37 patients admitted with decompensated HF (24 male, 69 ± 9 years (M ± SD), arterial hypertension 100%, previous myocardial infarction 59%, HFpEF (EF = 50%) 38%, HFrEF (EF < 40%) 49%, HFmrEF (LVEF 40-49%) 13%, diabetes 51%, NTproBNP 4219 (1402;5926) pg/ml, serum creatinine 106 (96;150) μmol/l, eGFR 52 ± 23 ml/min/1.73m2, potassium 4.56 ± 0.58 mmol/l) arterial stiffness was assessed by applanation tonometry and parametrs of VAC by 2-dimentional echocardiography at admission to hospital and before discharge. VAC as the ratio Ea/Ees (arterial (Ea) and end-systolic LV elastance (Ees)), optimal range was considered as 0.5-1.2. Parameters of LV efficacy were calculated. Hospital length of stay was 9.0 (7.0;10.0) days. Patients received ACEI 78%, BRA 11%, beta-blockers 100%, aldosterone receptor antagonists 68%, iv loop diuretics 84%, iv nitrates 46%. Wilcoxon test was considered significant if p < 0.05.
Results: Baseline Ea was 2.68 (1.89;3.14), 2.05 (1.45;2.17), 2.51 (1.78;3.15) mmHg/ml/m2, Ees 3.77 (3.06;4.69), 1.44 (1.18;1.62), 0.77 (0.51;1.01) mmHg/ml/m2 and VAC 0.78 (0.63;0.87), 1.4 (1.7;1.5) and 3.36 (2.98;4.00) in patient with HFpEF, HFmrEF and HFrEF. Changes of VAC and its components were analyzed depending EF. Dynamics of these parameters did not change significantly in all patients and in patients with HFpEF, HFmrEF. In group with HFrEF VAC significantly decreased to 2.54 (1.90;3.28) (p < 0.05) and Ea tended to decrease to 1.63 (1.40;2.28) mmHg/ml/m2 and Ees did not change (0.63 (1.17;3.28)) (p>0.05). In this group LV efficacy (ratio stroke work/ pressure-volume area) increased from 0.49 ± 0.07 to 0.55 ± 0.10 (p < 0.05). Changes of VAC were accompanied by decrease of central systolic BP from 108 ± 18 to 101 ± 13 mmHg (p < 0.05) and central diastolic BP - from 75 ± 12 to 68 ± 9 mmHg (p < 0.05).
There was a significant decrease of pulse wave velocity (PWV) (12.0 ± 3.6 vs 11.6 ± 3.7 m/s, p < 0.05), NT-proBNP level from 4219 (1402;5926) to 1924 (703;3774) pg/ml (p < 0.05), systolic and diastolic office blood pressure (130 ± 21 to 112 ± 13 mmHg (p < 0.05) and 79 ± 13 to 71 ± 6 mmHg (p < 0.05)) in all patients.
Conclusion: In patients with decompensated HFrEF VAC significantly decrease due to decrease of Ea. These changes are beneficial in this group.

Acute Heart Failure - Epidemiology, Prognosis, Outcome

P433
The inpatient costs of heart failure in Japan: evidence from the JROAD and JROAD-DPC registry

K Kanaoka[1]; S Okayama[2]; Y Saito[2]
[1]Nara City Hospital, Cardiovascular medicine, Nara, Japan; [2]Nara Medical Unibersity, First Department of Internal Medicine, Kashihara, Japan

Background: Japan is the most rapidly aging country in the world. With the aging of the population, the economic burden of heart failure is expected to increase. However, little is known about the inpatient cost of heart failure in Japan.
Purpose: Our objective was to clarify the inpatient cost of heart failure in Japan.
Methods: Using data from the Japanese Registry of All Cardiac and Vascular Diseases (JROAD) and JROAD-Diagnosis Procedure Combination (DPC) databases, we identified patients who were admitted to the hospital with common cardiovascular diseases (i.e. heart failure, acute myocardial infarction, pulmonary embolism, and acute aortic dissection) between 2012 and 2014. We evaluated the proportion of patients with heart failure out of all acute cardiovascular diseases, as well as the inpatient cost associated with heart failure. In addition, we examined how the total inpatient cost of heart failure is distributed and analysed how the cost of heart failure is distributed by age.
Results: We identified 350,636 patients with heart failure, which accounted for 61% of common cardiovascular diseases. A total of •404 billion (€3.0 billion) were spent for heart failure patients, which accounted for 49% of the cost of acute cardiovascular diseases. In heart failure patients, the median cost per patient was •775,382 (€5,730). The top 1% of spenders accounted for 8% (•33 billion [€244 million]) of all spending in heart failure, and the top 5% of spenders accounted for 25% (•99.7 billion [€736 million]) of all spending in heart failure. The cost of heart failure for patients over 70 years of age accounted for more than 75% of the total cost of heart failure.
Conclusion: The cost of heart failure is greater than the inpatient cost of any other acute cardiovascular diseases in Japan. Understanding how the total inpatient cost of heart failure is distributed may allow health providers to more effectively utilize limited resources in patients with heart failure.

On behalf of: KorAHF

Background: Clinical characteristics and outcomes of acute heart failure (AHF) according to left ventricular ejection fraction (LVEF) have not been fully elucidated. Especially, patients with borderline LVEF were not well represented in previous clinical trials and registries, and thus this is a grey zone with scarce data requiring further empirical characterization.
Purpose: We performed a comprehensive comparison of the epidemiology, pattern of in-hospital managements, and clinical outcomes with predictors in patients with AHF with different LVEF categories.
Methods and Results: The Korean Acute Heart Failure registry is a prospective multicenter cohort enrolling 5,320 hospitalized patients with AHF classified based on LVEF according to the 2016 European Society of Cardiology guidelines. We divided patients into three groups; LVEF < 40% as HF with reduced ejection fraction (HFrEF), LVEF = 50%, as HF with preserved EF (HFpEF) and borderline LVEF 40%–50%.as HF with mid-range EF (HFmrEF). Fifty-nine percent of patients had HFrEF, 16% had HFmrEF, and 25% had HFpEF. Compared to patients with HFrEF, those with HFpEF were older, more often female, and more likely to have non-ischemic aetiology. Patients with HFmrEF showed epidemiological profiles intermediate between HFrEF and HFpEF, and had a propensity to present de-novo HF with ischemic aetiology. Patients with lower LVEF had worse short-term outcomes; all-cause in-hospital mortality of HFrEF, HFmrEF, and HFpEF was 5.1%, 3.6%, and 3.0% respectively. Discharged patients with AHF showed poor 3-year all-cause mortality up to 38%, which was comparable between the LVEF subgroups (P = 0.623). Notably, ischemic aetiology was associated with the worst long-term outcome only in patients with HFrEF.
Conclusion: The LVEF subgroups in patients with AHF have diverse characteristics, which significantly impact clinical outcomes. These findings indicate that the outcomes of AHF are influenced by multiple factors beyond LVEF, and emphasize a focused phenotyping of each patient to tailor the management strategies and develop novel effective therapies for treating AHF.

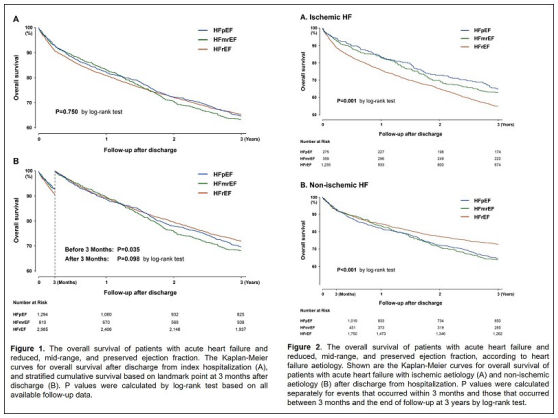

Figure 1. The overall survival of patients with acute heart failure and reduced, mid-range, and preserved ejection fraction. The Kaplan-Meier curves for overall survival after discharge from index hospitalization (A), and stratified cumulative survival based on landmark point at 3 months after discharge (B). P values were calculated by log-rank test based on all available follow-up data.

Figure 2. The overall survival of patients with acute heart failure and reduced, mid-range, and preserved ejection fraction, according to heart failure aetiology. Shown are the Kaplan-Meier curves for overall survival of patients with acute heart failure with ischemic aetiology (A) and non-ischemic aetiology (B) after discharge from hospitalization. P values were calculated separately for events that occurred within 3 months and those that occurred between 3 months and the end of follow-up at 3 years by log-rank test.

Survival

Troponin and Lung Impedance based model for prediction 30 and 90-day Heart Failure readmission

M Michael Kleiner Shochat[1]; I Kleiner[2]; JM Weinstein[2]; A Shotan[1]; M Kazatsker[1]; A Asif[1]; I Dahan[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; *[2]Saroka Medical Center, Cardiology, Beer Sheva, Israel*

The IMPEDANCE-HF trial has shown that lung impedance (LI)-guided treatment reduces hospitalizations for heart failure (HF) and decreases HF-related mortality. The aim of the current sub-analysis was to evaluate whether troponin level elevation during admission and the degree of pulmonary congestion at discharge after HF hospitalization can predict 30 and 90-day readmission rate.

Methods Study population included 266 patients with HF and LVEF = 35% in New York Heart Association class II-IV. Noninvasive LI measurements were performed with a high-sensitive device. Assessment of the degree of pulmonary congestion was assessed by the new index ?LIR= {[1-currently measured LI/ normal baseline (calculated for each patient)] ×100}. High sensitive troponin was evaluated 6-12 hours after admission for HF. LI was performed per protocol during every admission. Pulmonary congestion assessed by ?LIR at discharge was defined as mild pulmonary congestion when 0 to -20% (compared to normal baseline LI), moderate pulmonary congestion: -20.1 to -35%, and severe pulmonary congestion: -35.1 to -60%.

Results There were 155 hospitalizations due to HF with available troponin levels (median-44 ng/ml), that were divided into 3 categories: 0-13 ng/ml- normal range, 13.1-44.0 ng/ml (mildly elevated < median), and values>44.0 ng/ml (elevated>median). The 30- and 90-day readmission rate was 37 and 45%, respectively. The probability of 30-day readmission based on troponin elevation model of lower or higher than median troponin level was associated with a Hazard Ratio (HR) = 1.7 (Confidence Interval [CI]: 0.9-3.4, p = 0.09) for <median troponin and HR = 2.6, CI: 1.4-4.8 (p = 0.003 for >median troponin). The HR for 90-day re-hospitalization rate was 1.9 (CI: 0.6-5.9, p = 0.3) for <median and 5.6 (CI: 0.7-50, p = 0.1) for >median. The HR of a 30-day readmission, based on the degree of pulmonary congestion assessed by LI, was 7.4 (CI: 3.8-14, p < 0.0001) for moderate pulmonary congestion, and 27.8 (CI: 3.9-200, p < 0.0001) for severe pulmonary congestion. The HR of 90-day readmission was 6.5 (CI: 2.2-19.2, p < 0.0001) and 78 (CI: 42-370, p < 0.0001) for moderate and severe pulmonary congestion, respectively. The predictive accuracy of the 30- and 90-day HF-related mortality based on pulmonary congestion as assessed by LI at discharge was good (p < 0.0001).

Conclusion Risk stratification for the 30- and 90-day HF hospitalizations and HF mortality was accurate if based on level of pulmonary congestion on discharge, but troponin levels were not predictive for re-hospitalizations.

P436

Thirty-day readmission as an important target of quality of care after discharge due to acute heart failure. The role of a more efficient hospitalization

S Mazzetti[1]; J Rossi[1]; R Abete[1]; M Chioffi[1]; P Delfino[1]; A Andrea Mortara[1]
[1]Dipartment of Cardiology Policlinico di Monza, Monza, Italy

Readmission within 30 days (Read30) after an acute heart failure (AHF) event is a marker of quality of care and hospital efficiency. In US the Read30 rate is 22.7% (Medicare data) while in Europe nearly 12-15%; this difference has been related to length of hospitalization: 5 days in US and 8-10 days in the European countries. In Italy, the Read30 rate is 14.7% with an average hospital length of stay of 10.2 days (national data from Agenas 2015, all hospital wards). The Italian "IN-HF Outcome" register showed that in cardiology departments Ria30 drops to 6.2% (average hospitalization 12 ± 10 days) but this data was limited by the mean age of the population with less comorbidities as compared to non-cardiologic wards.

The aim of this work was to evaluate the Read30 in a cardiologic center with an Heart Failure Unit and an active program of protected discharge from hospital. Between January 2010 and December 2016, 627 patients were hospitalized for AHF (excluding AHF due to STEMI and nonSTEMI) with a mean age of 77 ± 10 years and LVEF of 36 ± 13%. Etiology of AHF was ischemic in 43.1%, hypertensive in 18.8%, valvular in 16.3%, idiopathic in 13.9%, and other in 7.9%. Because of advanced age, patients had several comorbidities including chronic renal failure (47.5%), COPD confirmed by spirometry (19.1%), Anemia (44.2%), Diabetes (33.5%), dementia (5.5%).

The average length of hospitalization was 10.3 ± 5 days and overall in-hospital mortality was low, 5.4%.

At discharge, for all patients older than 80 yrs (46.5%), a program of home support and assistance to management of therapy and personal care was planned. Accordingly, in 32 patients (5.3%) a transfer to a rehabilitation center, mid or long-care ward was organized. Only 40 patients (6.7% of patients discharged alive) were re-hospitalized up to 30 days in our or other hospital wards.

In conclusion, in a cardiology department with an HF unit and an active program for a protected discharge of more fragile patients, the rate of Read30 is low, even in a population of advanced age with several comorbidities. To reduce this important indicator of quality of care, it is therefore appropriate to think of a more efficient hospital stay rather than a shorter one.

P437

Heart Failure Registries: Worldwide comparison including Colombia

MC Montes[1]; E Rincon[1]; JE Juan Esteban Gomez[1]
[1]Valle del Lili Foundation, Cali, Colombia

On behalf of: RECOLFACA

INTRODUCTION Different Heart Failure (HF) registries describe regional characteristics and outcomes. Few publications assess differences and similarities between registries from various geographical regions. We sought to compare relevant variables of an HF Colombian Registry (RECOLFACA) with data from other registries worldwide.

Methods: We performed a literature review to identify the leading HF registries worldwilde. We compared them with RECOLFACA data. Descriptive statistics were used to present and analyze data within and among registries.

Results: Variables of those registries are presented in table 1. Latin American (LA) registries had younger population. We found male predominance (58-63%), except in the US and Brazil. The US showed the lowest percentage of reduced LVEF (47-49%). Low reported use of devices (CRT/ICD) in all registries (9-21%).

Conclusion: In these registries, population is older and mainly men. Main ethiology worldwide was ischemic. In LA registries, the high percentage of "other etiologies" could imply endemic causes. This indicates that regional differences are significant and should be considered when developing research protocols, guidelines and recommendations.

Impact of serum levels of exocrine pancreatic enzymes in patients with acute decompensated heart failure

M Masaru Hiki[1]; T Kasai[1]; S Yatsu[1]; J Shitara[1]; H Matsumoto[1]; A Murata[1]; M Shimizu[1]; T Kato[1]; S Suda[1]; H Daida[1]
[1]*Juntendo University School of Medicine, Cardiovascular Medicine, Tokyo, Japan*

Background: In heart failure (HF), multiple organ damage in association with systemic congestion and/or impaired perfusion have been focused. However, there are no data regarding interaction between HF and exocrine pancreatic insufficiency which may impair digestion and absorption.
Methods: We assessed sAmy and sLip as a suggestive of exocrine pancreatic function in patients with (N = 102) and without (N = 35) HF. In patients with HF, we performed pancreatic function diagnostic (PFD) test, direct assessment of pancreatic exocrine function to confirm exocrine pancreatic insufficiency. Furthermore, the association between sAmy or sLip and clinical outcomes including all-cause deaths and/or re-hospitalizations.
Results: HF patients had significantly lower sAmy (54IU/L versus 68IU/L, P = 0.001) and sLip (25IU/L versus 31IU/L, P = 0.018) compared with non-HF group. In multivariable regression analyses, significant correlates of sAmy were blood urea nitrogen (BUN) (coefficient, 0.552; P < 0.001), albumin (coefficient, 0.233; P = 0.020), and B-type natriuretic peptide (BNP) (coefficient, -0.227; P = 0.024). Significant correlates of sLip were BUN (coefficient, 0.377; P < 0.001) and BNP (coefficient, -0.364, P < 0.001). In patients with ADHF, PFD test showed significantly low levels of urinary para-aminobenzoic acid excretion as compared with reference lower limit (median, 50.4% versus reference lower limit, 73.4%; P = 0.027) suggesting that patients with ADHF had exocrine pancreatic insufficiency. In the multivariable Cox proportional hazard models, exocrine pancreatic insufficiency defined as low sLip (< 18IU/L) was independently associated with long-term worse outcomes (hazard ratio [HR], 1.81; P = 0.025) whereas low sAmy (< 39IU) was not (HR, 1.12; P = 0.679).
Conclusion: In patients with HF, exocrine pancreatic insufficiency can be determined by low sLip levels which were associated with congestion and possibly poor nutrition status. Such exocrine pancreatic insufficiency can be a predictor of poor clinical outcomes in patients with HF.

Long-term prognosis according to setting of care in elderly patients hospitalized for acute heart failure: data from the ATHENA registry

G Biagioni[1]; A Pratesi[1]; F Orso[1]; A Herbst[1]; F Fedeli[1]; A Berni[2]; G Ciuti[2]; F Bacci[2]; A Lo Forte[1]; AC Baroncini[1]; C Ghiara[1]; N Marchionni[3]; M Di Bari[1]; A Ungar[1]; S Baldasseroni[1]
[1]*Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy*; [2]*Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy*; [3]*Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy*

On behalf of: the ATHENA study group

Background: Acute Heart Failure (AHF) is a complex clinical syndrome, that typically affects elderly patients. Administrative registries show that in the "real world" most patients with HF are admitted to Internal Medicine and Geriatric wards with different epidemiological features, clinical profile and prognosis compared to patients admitted to Cardiology.
Aims: to evaluate the long-term prognosis and the predictors of mortality of elderly patients hospitalized for AHF in different settings of care (Cardiology, Internal Medicine and Geriatric wards).
Methods: ATHENA (AcuTe Heart failurE in advaNced Age) is a retrospective observational study which enrolled patients aged = 65 years) admitted with the diagnosis of AHF to the Emergency Departement (ED) of a tertiatry teaching Hospital and then transferred to three different settings of care: Cardiology, Internal Medicine and Geriatric wards. A telephone interview to evaluate vital status and functional level was conducted to obtain follow-up data.
Results: 401 patients were enrolled, 15.2% was admitted to Cardiology, 14.7% to Geriatrics and 70.1% to Internal Medicine. The mean age was 83.5 years, significantly higher in Geriatrics (86.9 years) and Internal Medicine (83.4 years) compared to Cardiology (81.0 years), p = 0.001. Females were 51%, with similar distribution in the three settings. Telephone interviews were conducted among patients discharged alive (365 patients, 91%); for 13 patients (3.6%) it was not possible to collect any information. One-year mortality was 33.2%, significantly higher for patients discharged from Geriatric ward (45.8%) and Internal Medicine (32.5%) compared to Cardiology (17.3%), p = 0.009. During the total median FU (¯21 months), mortality rate was 49.7% (47.4% for CV causes), significantly higher in Geriatric ward (60.4%) and Internal Medicine (52.0%) compared to Cardiology (32.7%), p = 0.013. More than half of patients (58.7%) were in a NYHA class III or IV and the disability rate was very high: in 33.3% of patients two or more functions of BADL were lost and in 65.5% of patients three or more IADL lost. By multivariable analysis, independent predictors of medium-term mortality were: NT-pro BNP level in ED (OR= 1.77, CI= 1.03-3.04, p = 0.039) and Charlson Comorbidity Index (OR=

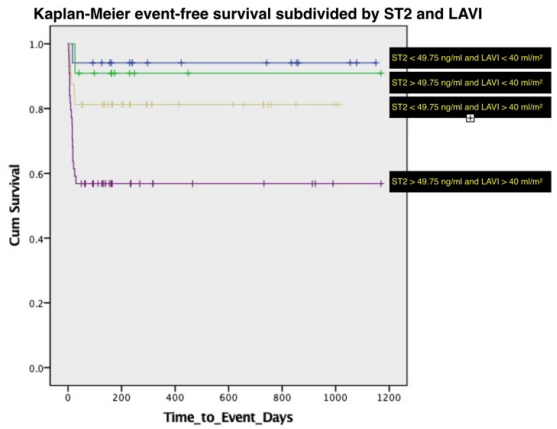
1.30, CI= 1.13-1.50, p = 0.001), with a protective effect of Beta-Blockers therapy at discharge (OR= 0.53, CI= 0.29-0.95, p = 0.033) and functional status evaluated through Barthel Index (OR= 0.99, CI= 0.98-1.0, p = 0.005). Conclusion: in elderly patients with AHF long term prognosis varies significantly according to the different setting of care. The long-term mortality is very high, influenced by geriatric variables, as disability and comorbidity, in addition to cardiological variables, as NT-pro BNP level in ED and Beta-Blockers therapy at discharge.

P440

Integrated Pre-discharge Echocardiographic Parameters and Soluble suppression of tumorigenesis 2 (sST2) level to predict Outcomes of non-ischemic acute heart failure

T Sotananusak[1]; N Suvachittanont[1]; S Wattanachai[1]; M Chandavimol[1]; P Sritara[1]; T Teerapat Yingchoncharoen[1]
[1]Faculty of Medicine Ramathibodi Hospital-Department of Medicine of Mahidol University, Bangkok, Thailand

Introduction: sST2 is the circulating form of the receptor for interleukin-33, a biomarker which associated with cardiac remodeling and fibrosis. It has been demonstrated to predict heart failure hospitalization and cardiac mortality in acute heart failure especially of ischemic origin. The data on prognostic value of sST2 in non-ischemic heart failure is limited, therefore we sought to determine this value, particularly in integration with echocardiographic parameters.
Method: We conducted a prospective cohort study of patients admitted with acute heart failure during October 2014 to December 2017. Patients with recent acute coronary syndrome or coronary revascularization were excluded. All patients received regular standard treatments and were performed echocardiogram and blood test for sST2 before discharge. The patients were followed for 30-day heart failure rehospitalization or cardiac death death. Multivariable Cox regression was used to identify events association.
Results: We enrolled 104 patients in the study, 47 were male (45%), median age was 73 years old and 33 patients (31%) had atrial fibrillation. The mean follow up duration was 18.44+12.44months. The 30-day HF rehospitalization and cardiac mortality occurred in 49 patients (47%) (42 rehospitalization, and 7 cardiac mortality) during 18-month period follow-up. sST2 was associated with 30-day outcomes (HR 1.007 [95% CI, 1.003-1.011]; P < 0.001). A sST2 cut-off value more than 49.75 ng/ml was significantly associated with 30-day outcomes (HR 2.60 [95% CI, 1.097-6.172]; P = 0.03) and remains associated with the long-term outcome (HR 2.586 [95% CI, 1.387-4.821]; P = 0.003). A left atrial volume index (LAVI) of more than 40 ml/m2 was also associated with 30 days outcomes (HR 4.84 [95% CI, 1.141-20.516]; P = 0.032) but did not associate with long term outcomes (HR 1.49 [95% CI, 0.737-3.019]; P = 0.266). A combination of sST2 more than 49.75 ng/ml and LAVI more than 40 ml/m2 are the highest risk of rehospitalization and mortality.
Conclusion: In patients with non-ischemic acute heart failure, sST2 and Left atrial volume index were associated with 30-day HF rehospitalization and cardiac mortality. However, only sST2 was associated with long-term outcome. Integrated LAVI and sST2 better stratified the risk of adverse outcome in these patients.



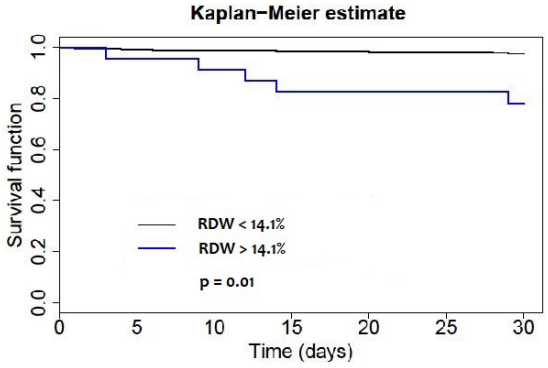
P441

Is red cell distribution width a prognostic marker of postoperative heart failure in patients undergoing valve surgery?

P Duchnowski[1]; T Hryniewiecki[1]; M Rys[1]; M Kusmierczyk[2]; P Szymanski[1]
[1]Institute of Cardiology in Anin, Department of Acquired Cardiac Defects, Warsaw, Poland; [2]Institute of Cardiology in Anin, Department of Cardiosurgery and Transplantology, Warsaw, Poland

Funding Acknowledgements: Statutory work at Institute of Cardiology, Warsaw, Poland

Introduction: Numerous studies have shown that elevated RDW is associated with poor outcomes in patients with myocardial infarction or stroke. The aim of the study was to evaluate the prognostic value of RDW for heart failure in the early postoperative period in patients undergoing valve surgery.
Methods: A prospective study was conducted on a group of 672 consecutive patients with haemodynamically significant valvular heart disease who underwent elective valvular surgery. The primary end-point at the 30-day follow-up was perioperative heart failure defined as the need for a supply of catecholamines more than 48 hours after completing the cardiopulmonary bypass surgery or the need to resupply.
Results: The perioperative heart failure occurred in 230 patients. At multivariate analysis: RDW (P = 0.0006), and hs troponin T (hs-TnT) (P = 0.01) remained independent predictors of the primary end-point.
Conclusions: Elevated RDW is associated with a higher risk of perioperative heart failure in patients with perioperative heart failure.



Kaplan−Meier event-free survival curves

P442

HFmrEF in elderly patients hospitalised for acute heart failure: data from the ATHENA registry.

S Parlapiano[1]; A Pratesi[1]; F Orso[1]; A Herbst[1]; G Biagioni[1]; F Fedeli[1]; AC Baroncini[1]; A Lo Forte[1]; C Ghiara[1]; F Bacci[2]; G Ciuti[2]; M Di Bari[1]; N Marchionni[3]; A Ungar[1]; S Baldasseroni[1]
[1]Careggi University Hospital (AOUC), Department of medicine and geriatrics, Florence, Italy; [2]Careggi University Hospital (AOUC), Department of emergency and internal medicine, Florence, Italy; [3]Careggi University Hospital (AOUC), Cardiothoracovascular Department, Florence, Italy

On behalf of: ATHENA Study group

Background: Recently, the European Society of Cardiology (ESC) has recognized the presence of a "gray area" of patients with ejection fraction (EF) between 40 and 49% defined "mid-range" (HFmrEF) and has redefined the specific cut off values for HF with preserved EF (= 50%, HFpEF) and HF with Reduced EF (< 40%, HFrEF).
Purpose: to better characterize patients with HFmrEF and to compare them to those with HFpEF and HFrEF in a real world setting of elderly patients hospitalised for acute HF.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (= 65 years) admitted with diagnosis of AHF to the Emergency department (ED) of a tertiary University teaching-hospital and transferred to cardiology, internal medicine and geriatric wards in the period 01.12.2014-01.12.2015.
Results: 291 patients with complete echocardiographic data composed the study population: patients with HFmrEF were 19.9%, 32.6% had HFrEF and 47.4% had HFpEF. HFmrEF and HFpEF had similar demographic characteristics, compared to patients with HFrEF: mean age of three group of patients was respectively 84.2, 84.3 and 80.3 years, p < 0.001; the prevalence of females was 43.1%, 66.7% and 30.5% for HFmrEF, HFpEF and HFrEF respectively, p < 0.001. Regarding cardiovascular risk factors, such as hypertension, diabetes and dyslipidaemia no significant difference

could be observed across the three groups, even if the patients with HFmrEF were more frequently smokers (p = 0.042). Furthermore, main non-cardiovascular comorbidities, did not differ significantly among the three groups, with the exception of chronic obstructive pulmonary disease which was more prevalent in patients with HFmrEF (p < 0.015). Considering CV comorbidities, however, we noticed that a history of coronary artery disease was more frequently reported in patients with HFmrEF (39.7%) and in those with HFrEF (35.8%) compared to patients with HFpEF (18.8%), p= 0.002. As could be expected, a significant difference could be observed in the prevalence of implantable biventricular pace maker and cardioverter defibrillators (CRT-D) with HFmrEF patients placed in an intermediate position (8.6%) respect to the other two groups of HF (20.2% for HFrEF and 2.9% for HFpEF; p < 0.001). No significant differences were found in the setting of care for HFmrEF patients who were equally distributed among cardiology, internal medicine and geriatric wards (p = 0.2). In-hospital mortality was not significantly different among the three groups of HF: 8.6% for HFmrEF, 8.0% for HFpEF and 7.4% for HFrEF (p = 0.961).
Conclusions: Our study shows that in real world setting of elderly admitted for AHF, HFmrEF patients are significantly represented, with clinical and demographic characteristics similar to patients with HFpEF, except for the ischemic feature that seems to bring them closer to patients with HFrEF. In-hospital mortality of patients with HFmrEF does not differ significantly to those with HFpEF and HFrEF.

P443

Acute pulmonary oedema as clinical presentation of acute heart failure is associated with better prognosis in patients with reduced ejection fraction

PSM Marques[1]; H Moreira[1]; MJ Pinto[1]; P Rodrigues[1]; P Bettencourt[1]; P Lourenco[1]
[1]*Sao Joao Hospital, Internal Medicine, Porto, Portugal*

Background: Acute pulmonary oedema (APO) is a possible presentation of acute heart failure (HF) and warrants prompt treatment. Prognostic implications of acute HF presentation have not been studied. We aimed to study the prognostic correlates of acute HF presenting with APO and to analyse if they differed according to the left ventricular systolic function.
Patients and Methods: We retrospectively analysed data concerning acute HF patients that had been previously included in an acute HF registry. Following the more recent European Society of Cardiology guidelines we have studied patients with ejection fraction <40% - HF with reduced ejection fraction (HFrEF) and patients with HF with preserved ejection fraction (HFpEF) when the ejection fraction was = 50%. Patients with acute coronary syndrome were not included in the registry. Patients with significant valvular disease were excluded from the analysis. Patients presenting in the emergency department with APO and those not presenting with APO, as considered by the attending emergency department physician, were characterized. Treatment was at the discretion of the attending physicians during hospital stay. Patients were followed for up to 2 years from hospital admission and the endpoint under analysis was all-cause mortality. The prognostic significance of being admitted in APO was studied using a Cox-regression analysis. Multivariate models were built. Analysis was stratified according to the ejection fraction (HFrEF and HFpEF).
Results: We studied 440 patients hospital-admitted due to acute HF; 154 (35.0%) had HFpEF and 268 (65.0%) had HFrEF; 48.6% were male; mean age was 75 years and 72 patients (16.4%) were admitted in APO - 16.2% in the HFpEF group and 16.4% in the HFrEF group. During the 2-year follow-up 210 patients died, 18 during the index hospitalization. Patients presenting in APO had very similar age and comorbidities when compared with their counterparts; BNP was lower in patients presenting in APO. Patients presenting in APO died significantly less at 2 years (31.9%) than those not presenting in APO (50.8%). The multivariate adjusted (age-,SBP (<90mmHg)-, ischemic aetiology-, atrial fibrillation upon admission- and admission BNP-) HR of 2-year mortality in patients presenting in APO was of 0.62 (95% CI: 0.40-0.96), p = 0.03; this beneficial effect of APO was only observed in the subgroup of HFrEF patients HR = 0.54 (0.31-0.95), p = 0.03 and no such protection was verified in HFpEF patients - HR = 0.75 (0.36-1.55), p = 0.43 **Conclusions:** Patients with HFrEF with acute HF presenting as APO have a 46% reduction in the 2-year mortality risk. The clinical presentation as APO in HFrEF patients probably reflects an ability to adapt to acute stress conditions that may not be present in other HF patients. This topic merits further investigation

P444

Common Precipitants of Initial Admission, 12-months Re-admissions and 30-days Mortality in Acute Heart Failure Patients within Northern Kuala Lumpur.

REF Bin Raja Shariff[1]; MK Borhan[1]; MR Yusoff[1]; C Lee[1]
[1]*Hospital Sungai Buloh, General Medicine, Sungai Buloh, Malaysia*

Background: A major contributor to the burden of heart failure (HF), is the cost associated with acute admissions. However, there is limited data on precipitants of acute HF in a Malaysian context.
Objective: To identify common precipitants of initial admissions and re-eadmissions, as well as 30-days mortality in acute heart failure patients in Northern Kuala Lumpur.
Materials & Methods: A retrospective, observational study was conducted on 418 patients admitted for acute HF, and subsequently re-admitted for acute HF within 12-months, to Hospital Sungai Buloh between 1st January 2012 to 31st December 2013. Case notes were analysed and likely precipitants to each admission and readmission were identified at 4 distinctive periods - one, three, six and twelve months from initial presentation within the study period.
Results: The mean age was 62.6 years (S.D. = 12.5), of which 234 (56%) were male. 261 (62.4%), 61 (14.6%), 89 (21.3%), and 7 patients (1.7%) were Malays, Chinese, Indians and of other races respectively. The three most common precipitants of acute HF on initial admission include non-compliance (to medication, diet or fluid restriction), acute coronary syndrome (ACS) and hypertensive emergencies (n = 188 (45.0%), n = 122 (29.2%) and n = 21 (5.2%) respectively). Other common precipitants identified include sepsis, cardio-renal syndrome and hospital-acquired pneumonia (n = 19 (4.6%), n = 15 (3.6%) and n = 14 (3.4%) respectively). One-month, three-months, six-months and twelve-months readmission rate were 16.0%, 24.0%, 25.6% and 28.5% respectively. 154 patients (36.9%) admitted within the study period had at least one subsequent re-admission within 12 months. Coincidentally, ACS, non-compliance and hypertensive emergencies were, again, common precipitants of readmissions. Mortality Rates were highest within the first month of admission (n = 60 (14.4%)), and the most common cause of deaths given was acute pulmonary oedema (n = 29 (48.0%) followed by ACS (n = 16 (27.0%).
Conclusion: This study reveals that in a multi-ethnic Asian population, ACS, non-compliance and hypertensive emergencies are major precipitants of both acute HF admissions, and subsequent readmission, highlighting the need for clinicians to address these 3 factors by identifying their risk factors.

P445

Baseline Characteristics & Acute Management of Patients Presenting with Acute Heart Failure Within Northern Kuala Lumpur: A Single-Centre Retrospective Analysis

REF Bin Raja Shariff[1]; MK Borhan[1]; MR Yusoff[1]; C Lee[1]
[1]*Hospital Sungai Buloh, General Medicine, Sungai Buloh, Malaysia*

Background: Heart failure (HF) contributes to a large proportion of acute hospital admission. Unfortunately the actual prevalence of acute HF is still unknown due to scarcity of local data.
Purpose: Our study aims to investigate the demographics, co-morbidities, acute clinical presentation and initial management received by patients within Northern Kuala Lumpur, presenting with acute HF.
Materials & Methods: A retrospective, observational study was conducted on 418 patients admitted for acute HF to Hospital Sungai Buloh between 1st January 2012 to 31st December 2013.
Results: The mean age was 62.6 years (S.D. = 12.5), of which 234 (56%) were male. 261 (62.4%), 61 (14.6%), 89 (21.3%), and 7 patients (1.7%) were Malays, Chinese, Indians and of other ethnicity respectively. 142 patients (34%) presented with de novo HF. Common co-morbidities include hypertension (n = 302 (72.2%)), coronary artery disease (n = 259 (62.0%)), diabetes (n = 254 (60.8%)), chronic kidney disease (n = 230 (55.0%)) and atrial fibrillation (n = 70 (16.7%)). 186 patients (44.5%) had reduced baseline left ventricular ejection fraction (40% or lower). The most common clinical symptoms on admission include dyspnoea, orthopnoea and paroxysmal nocturnal dyspnoea (323 (77.3%), 273 (65.3%) and 260 patients (62.2%) respectively). The most common clinical sign includes lung crepitations, peripheral oedema and raised jugular venous pressure (265 (63.4%), 246 (58.9%) and 189 (45.2%) patients respectively). The mean systolic blood pressure (SBP) and heart rate on admission were 142 mmHg (S.D. = 28) and 87 beats per minute (S.D. = 23) respectively. 83 patients (19.9%) had AF on electrocardiogram on admission. 7 patients (1.7%) presented with cardiogenic shock (systolic blood pressure less than 100 mmHg) and 48 patients (11.5%) required at least one form of inotrope and/or vasopressor for blood pressure support. Frusemide was prescribed in 397 (95.0%) of patients, of which 364 (87.1%), 26 (6.2%) and 7 (1.7%) were administered intravenously, as intravenous infusions and as tablets respectively. 38 (9.1%) patients had intravenous nitroglycerin prescribed on admission. 38 (9.1%) and 94 (22.5%) patients were admitted, at some point, to the Intensive Care and Coronary Care Unit respectively. 107 (25.6%) and 20 (4.8%) patients required non-invasive ventilation and invasive ventilation respectively.
Conclusion: To our knowledge, this is the first study looking at a Malaysian cohort of acute decompensated heart failure. It provides insight into the demography of such cohort, which could subsequently be compared with other established international registries, such as EHFSII and ADHERE, to analyse for heterogeneity.

Characterization of acute heart failure hospitalizations by subgroups

L Luis Oliveira[1]; L Brochado[2]; C Serena[1]; A Fontes[1]; S Ferreira[1]; C Almeida[1]; C Machado[1]; R Dourado[1]; E Santos[1]; N Pelicano[1]; A Pacheco[1]; A Tavares[1]; F Melo[1]; D Martins[1]
[1]Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal; *[2]Departamento de Ciências Biomédicas e Medicina da Universidade do Algarve, Faro, Portugal*

Introduction: Current guidelines divide heart failure (HF) in three different types according to the left ventricle ejection fraction (EF): reduced EF if < 40% (HFrEF), mid-range EF if 40-50% (HFmrEF) and preserved EF if = 50% (HFpEF). Despite the given benefits of medical treatments in patients with HF, hospitalization rates for acute HF (AHF) remain high. Also, HFpEF, with similar prognosis to HFrEF, is short on therapeutic options with proven benefit, and information on hospitalizations for AHF in this subgroup of patients is scarce.
Purpose: This study aimed to describe patients hospitalized for AHF, between types of HF and their rehospitalizations and survival rates at 5 years follow-up.
Methods: Retrospective study of patients hospitalized with AHF between June 2011 and June 2012 (index admission). All-cause mortality, HF-related mortality or rehospitalization by AHF were registered in a median follow-up time of 5.45 years (IQR 1.53-5.97).
Results: From 154 patients included, 10 were lost to follow-up and 7 died in the index admission. Of 137 patients, with a median age of 70 years (IQR 60.5-78.5), 23.4% had HFrEF, 23.3% HFmrEF and 53.3% HFpEF. On the index admission, 19.7% of patients accounted for a first episode of AHF. Main triggers were acute coronary syndrome (21.2%), arrhythmias (18.2%) and respiratory infections (18.2%). At 1 and 5 years, rehospitalization for AHF occurred in 47.4% and 77.4% of patients, all-cause mortality rates were 19.0% and 50.4% and HF-related mortality rates were 8.8% and 19.0%, accordingly.
From the readmitted patients, 55.7% had suffered at least one hospitalization apparently without any trigger. Median cumulative days of hospitalization was 23 days (IQR 10-44).
No difference in mortality, rehospitalization or cumulative days of hospitalization was found between the different types of HF. Except for gender (higher prevalence of females in HFpEF vs HFrEF - 67.1% vs 25.0%; p < 0.001), there were no statistically significant differences in the baseline characteristics of the population by subgroups.
Conclusions: Regardless of the type of HF, rehospitalizations by AHF are high. All-cause and HF-related mortality rates are high and similar between types of HF.

P447

Clinical characteristics and prognosis of patients with decompensated heart failure and preserved, mid-range and reduced ejection fraction

RM Christodorescu[1]; R Lala[2]; A Apostolescu[3]; MN Trofenciuc[4]; E Petrescu[3]; A Pop-Moldovan[2]; S Dragan[1]; D Darabantiu[2]
[1]University of Medicine Victor Babes, Cardiology, Timisoara, Romania; *[2]Vasile Goldis Western University, Cardiology, Arad, Romania*; *[3]Institute of Cardiovascular Diseases, Cardiac Rehabilitation Clinic, Timisoara, Romania*; *[4]Vasile Goldis Western University, Arad, Romania*

Background. The prognosis of patients (pts) hospitalized for decompensated heart failure(HF) regardless of ejection fraction(EF) value is poor. Recent HF guidelines introduced a new classification of HF: mid range (mrEF between 41-49%). The prognostic importance of this new classification is not clear.
Purpose: To assess the clinical profile and prognostic value of mid-range EF in patients hospitalized for decompensated HF.
Methods: This retrospective observational study included 180 consecutive HF patients admitted for decompensated HF, mean age = 67 ± 11y, female gender = 42%. The patients were divided into 3 groups according to their EF at admission: group 1 HFpEF n = 25, (13.9%), group 2 HFmEF n = 83 (46.1%), group 3 HFrEF n = 72 (40%). During follow-up at 6months all readmissions for HF aggravation and deaths were recorded. For statistical analysis we used ANOVA t test for comparison of means, Pearson x^2 test for comparison of categorical values, multivariate logistic regression for endpoint (readmission and mortality).
Results: At admission mean systolic BP was 153mmHg ± 34 in gr.1, 144mmHg ± 29 in gr.2 and 136mmHg ± 24 in gr.3, significantly higher in group 1 (p = 0.009). Mean heart rate in the 3 groups was: 82 ± 32b/min , 86 ± 20b/min and 93b ± 24/min, significanly higher in gr.3 (p = 0.049). Mean Hb was 12.3 ± 1.8g/dl, 13.7 ± 1.8g/dl and 13.5 ± 1.8g/dl , significanly lower in gr.1(p = 0.003). Mean serum creatinine was 1.34 ± 0.6mg/dl, 1.04 ± 0.3mg/dl and 1.18mg ± 0.4/dl, significanly higher in gr.1(p = 0.008). Mean serum K was 3.5 ± 1.7mEq/l, 3.8 ± 1.2mEq/l and 3.6 ± 1.5mEq/l respectively(p = 0.8). 36% pts in gr.1, 41% pts in gr.2 and 29% pts in gr.3 were readmitted. 16 deaths were recorded (20% in gr.1, 6% in gr.2 and 8% in gr.3). The predictive factors for readmission using multivariate logistic regression were hyperkalemia (p = 0.033, OR = 1.03), HFmrEF(p = 0.035, OR = 2.3) and HR (p = 0.042, OR = 1.02).
Conclusion: High heart rate at admission, hyperkaliemia and mrEF are associated with a worse outcome in patients hospitalized for decompensated heart failure. Patients with HFmrEF have a high readmission rate at 6 months and need a careful follow-up after discharge.

P448

Prognostic significance of systolic blood pressure in AHF patients

VG Samsone[1]; I Kaminskaite[2]; J Sasnauskaite[2]; V Juknevicius[3]; J Simonavicius[3]; A Mikalauskas[3]; A Mebazaa[4]; A Kavoliuniene[5]; J Celutkiene[3]

On behalf of: The GREAT network

Introduction: Acute heart failure (AHF) is continuously increasing in prevalence and is related to significant mortality and morbidity including frequent hospitalisations. Arterial blood pressure has been shown to be a prognostic factor for short-term and long-term mortality outcomes in patients with heart failure. However, there is limited information about the prognostic significance of systolic blood pressure (SBP) in AHF patients.
Purpose: We aimed to evaluate the prognostic value of SBP in prediction of short-term mortality and readmissions in patients with AHF.
Methods. A prospective study enrolled consecutive patients admitted to the emergency department with acute dyspnea. Data of 637 patients (mean age 69.7 ± 12.1 years, 58.2% men) with adjudicated diagnosis of AHF were analysed. Patients were grouped according to the SBP quartiles. Relative risk of three-month mortality and rehospitalisations was estimated by performing logistic regression on SBP quartiles and other variables. Parameters with p < 0.1 were used in the initial multivariate analysis, which was then iteratively optimised by removing statistically insignificant parameters.
Results: 11.3% (n = 72) of patients diagnosed with AHF died and 42.7% (n = 272) were repeatedly rehospitalised in 3 months. The highest SBP quartile (156-242] was associated with significantly lower mortality risk compared to normal SBP quartile (120-135], p < 0.05. Additionally, anemia was found to be a predominant factor increasing both death and rehospitalisation risk, whereas highest mortality risk (2.41; p < 0.05) was observed in patients with acute coronary syndromes.
Conclusions: Prognostic impact of SBP at admission on short-term mortality and rehospitalisation was determined. Higher SPB was found to be a prognostic factor associated with lower mortality and less frequent three-month rehospitalisation rate in patients with AHF.

Risk analysis for death in 3 months

Variable	Univariate analysis		Multivariate stepwise analysis - Primary model		Multivariate stepwise analysis - Optimised model

P449

Impact of socioeconomic deprivation on heart failure management and clinical outcomes

S Kenyon[1]; Y C Lau[1]
[1]*Monklands Hospital, Cardiology, Airdrie, United Kingdom*

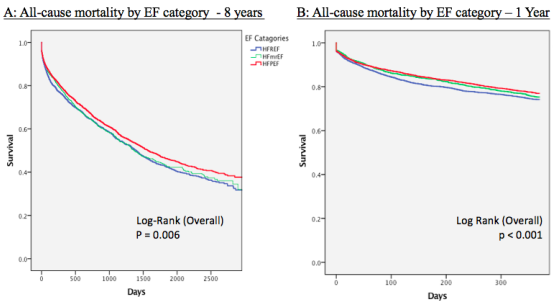
Since 1948, the NHS in UK is a publicly funded, single-payer health care system to address healthcare inequality. Heart failure results in a large healthcare burden, and is known to be more common with increased socioeconomic deprivation. Scottish Index of Multiple Deprivation (SIMD) has recently been developed to includes socioeconomic as well as other measures of deprivation (such as healthcare, education, access to housing and crime).
In this retrospective study, 96 patients admitted with Heart failure(HF) from the most deprived and least deprived tertile of Scottish Index of Multiple Deprivation (SIMD) (1 - 3, most deprived and 7 - 9, least deprived).
Between the two groups, no statistical difference exists between age, gender, haemoglobin or creatinine level; nor was there any difference in past medical history or cigarette use. Patients from the lower tertile has higher incidence of alcohol excess (16% vs 3%, p = 0.043) while higher incidence of AF for the higher tertile (55% vs 33%, p = 0.004).
Prescription of diuretics, Beta-Blocker, ACE-I or ARB were not statistically different. Patients from higher tertile is more likely to receive aldosterone antagonist (37% vs 17%, p = 0.031) and combined Beta-blocker and ACE-i/ARB treatment (42% vs 21%, p = 0.025).
6-months follow-up demonstrates composite endpoint of heart failure readmission and mortality was statistically higher among patients of lower socioeconomic tertile (p = 0.042). Stepwise multiple regression analysis also confirmed socioeconomic deprivation as an independent predictor for more adverse clinical outcome for heart failure (p = 0.003, R2 = 22%).
Summary: Despite the establishment of universal healthcare, patients from the lower socioeconomic group (based on SIMD) are still less likely to received prognostically beneficial medication and are more likely to be experience readmission for heart failure or death.

P450

Characteristics and long-term outcomes of patients with reduced, mid-range, and preserved ejection fraction following hospitalization for acute heart failure in a contemporary real world setting

I Israel Mazin[1]; D Friemark[1]; M Arad[1]; Y Peled[1]; A Gruper[1]; N Shlomo[1]; R Klempfner[1]; R Kuperstein[1]; I Goldenberg[1]
[1]*Chaim Sheba Medical Center, Tel Hashomer, Israel*

Aims: Recent ESC heart failure (HF) guidelines introduced a new mid-ranged left ventricle ejection fraction (LVEF) category. The purpose of the present study was to describe the clinical characteristics and long-term outcomes of patients hospitalized with acute HF categorized by LVEF, in large contemporary prospective tertiary center cohort.
Methods and Results: A total 7,752 patients were included in this study. Patients were divided according to the recent ESC heart failure guidelines. Patients with preserved EF (HFpEF) compared to those with mid-range EF (HFmrEF) or reduced EF (HFrEF) were older, more likely to be female, had a higher frequency of comorbidities, including hypertension, diabetes mellitus, and anemia. Kaplan-Meier survival analysis (Figure) showed increased mortality rates at 1-and 8-years of follow-up in both the HFmrEF (24% and 48%, respectively) and HFrEF (25% and 47%, respectively) groups, as compared with the HFpEF group (22% and 41%, respectively; log-rank p-value = 0.007 for the overall difference during follow-up). Consistently, multivariate analysis showed patients with HFmrEF experienced a significant higher risk for all-cause mortality (HR= 1.24, p = 0.04) and HF or death (HR= 1.2, p = 0.02) compared to the HFpEF group, and a similar risk to the HFrEF group. Systemic pulmonary artery pressure (SPAP) was an independent predictor for long-term mortality among all LVEF subgroups (HR 1.43, p <0.001).
Conclusion: Our findings suggest that acute HF patients with HFmrEF group have increased risk for long–term mortality and repeated HF hospitalization that is similar to those with HFrEF. Elevated SPAP is a powerful predictor for adverse long-term outcomes following hospitalization for acute HF.



Acute Heart Failure - Diagnostic Methods

P451

Release of mitochondrial DNA is associated with mortality in acute heart failure

KA Konstantin A Krychtiuk[1]; R Wurm[1]; S Ruhittel[1]; M Lenz[1]; K Huber[2]; J Wojta[1]; G Heinz[1]; M Huelsmann[1]; WS Speidl[1]
[1]*Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria*; [2]*Wilhelminen Hospital, 3rd Department of Internal Medicine, Cardiology and Emergency Medicine, Vienna, Austria*

Background: Inflammation is regarded as an important trigger for disease progression in heart failure (HF). Particularly in acute heart failure (AHF), tissue hypoxia may lead to cellular damage and the release of intracellular mitochondrial DNA (mtDNA), which acts as an activator of the immune system due to its resemblance to bacterial DNA. It therefore may serve as a mediator of disease progression.
Purpose: The aim of this study was to determine circulating levels of mtDNA and its association with mortality in patients with HF in different presentations.
Methods: Plasma levels of circulating mtDNA were measured in 90 consecutive patients with AHF admitted to our medical ICU as well as 109 consecutive chronic heart failure (CHF) patients.
Results: In patients admitted to our medical ICU (median age 64 (49-74) years, median NT-proBNP 4986 (1525 - 23842) pg/mL, 30-day survival 64.4%), mtDNA levels were significantly higher in patients that died within 30 days after ICU admission and patients with plasma levels of mtDNA in the highest quartile had a 3.4-fold increased risk (p = 0.002) of dying independent from age, gender, vasopressor use, NT-proBNP levels and APACHE II score. Patients with AHF showed significantly higher mtDNA levels (p <0.005) as compared to patients with CHF. In these patients, mtDNA levels were associated with NYHA functional class but were not associated with outcome.
Conclusion: mtDNA release into the circulation is associated with mortality in patients with AHF but not in patients with CHF. Release of mtDNA may therefore play a role within the pathophysiology of AHF.

P452

Decreased number of endothelial progenitor cells to apoptotic endothelial cell-derived microparticle ratio predicts atrial fibrillation in acutly decompensatede heart failure

A E Alexander E Berezin[1]; A Kremzer[1]
[1]*State Medical University, Zaporozhye, Ukraine*

Background: Acutely decompensated heart failure (ADHF) remains a leading cause of in-hospital mortality. Atrial fibrillation (AF) associated with increased premature death rate amongst in-patinets with ADHF. The aim of the study was to investigate whether the pattern of angiogenic endothelial progenitor cells (EPCs) and apoptotic endothelial cell-derived microparticles (EMPs) would be able to predict newly atrial fibrillation (AF) in ADHF with reduced (HFrEF) and preserved (HFpEF) ejection fraction.
Methods: Two hundred fifty four ADHF subjects were retrospectively enrolled in the study. ADHF patients with global left ventricular ejection fraction (LVEF) < 40% (n = 85), LVEF = 40-49% (n = 95) and LVEF = 50-59% (n = 74) were categorized. Therefore, to compare the circulating levels of biological markers 35 control subjects without HF were included in the study. All control individuals were age- and sex-matched ADHF patients. The serum level of biomarkers was measured at baseline. The flow

cytometric technique was used for predictably distinguishing circulating cell subsets depending on expression of CD45, CD34, CD14, Tie-2, and CD309 antigens and determining endothelial cell-derived microparticles. CD31+/annexin V+ was defined as apoptotic endothelial cell-derived MPs, MPs labeled for CD105+ or CD62E+ were determined as MPs produced due to activation of endothelial cells.
Results: In multivariate logistic regression model T2DM (R2 = 0.36; P = 0.001), previous MI (R2 = 0.67; P = 0.001), galectin-3 (R2 = 0.67; P = 0.003), CD31+/annexin V+ EMPs (R2 = 0.32; P = 0.001), NT-proBNP (R2 = 0.72; P = 0.046), CD14+CD309+ cells (R2 = 0.66; P = 0.001), and CD14+?D309+ Tie-2+ cells (R2 = 0.54; P = 0.001) were found as independent predictors of AF in ADHF with LVEF < 40%. In ADHF combined cohort with LVEF 40-49% and LVEF = 50-59% previous MI (R2 = 0.52; P = 0.001), hypertension (R2 = 0.14; P = 0.001), galectin-3 (R2 = 0.68; P = 0.001), CD31+/annexin V+ EMPs (R2 = 0.57; P = 0.001), NT-proBNP (R2 = 0.62; P = 0.003), CD14+CD309+ cells (R2 = 0.52; P = 0.001), and CD14+?D309+ Tie-2+ cells (R2 = 0.48; P = 0.001) predicted AF. Using multivariate Cox-regression analysis adjusted etiology (previous myocardial infarction), cardiovascular risk factors (type 2 diabetes mellitus, hypertension) we found that CD31+/annexin V+ EMPs to CD14+CD309+ cells ratio (OR 1.22; 95% CI = 1.14 - 1.36; P = 0.001) were independent predictor for newly AF in ADHF.
Conclusion: We found that CD31+/annexin V+ EMPs to CD14+CD309+ cells ratio added to NT-proBNP, clinical data, and cardiovascular risk factors has exhibited the best discriminate value and higher reliability to predict newly AF in ADHF individuals.

P453
Single high-sensitivity cardiac troponin T measurement predicts 1-year mortality and CV events in real-world patients admitted to the emergency room with acute decompensated heart failure

M Mariana Augusto Goncalves[1]; A Tralhao[1]; C Silva[1]; C Brizido[1]; F Gama[1]; G Mendes[1]; G Rodrigues[1]; P Freitas[1]; A Oliveira[1]; M Mendes[1]
[1]Hospital de Santa Cruz, Lisbon, Portugal

Background: cardiac troponin (cTn) elevation is known to influence prognosis in acute decompensated heart failure (ADHF). However, the clinical relevance of minor increases in serum cTn is still uncertain.
Purpose: to assess the prognostic role of different high-sensitivity (hs) cTnT metrics in patients admitted to the emergency room (ER) with ADHF.
Methods: single-center retrospective analysis of patients admitted consecutively to the ER during a 6-month period (March-July 2016) with an available and positive hs-cTnT (4th generation assay, 99th percentile 0.014 ng/L). ADHF adjudication was based on discharge diagnosis according to the ICD-9. A multivariate Cox proportional hazard model was used to determine independent predictors of total mortality and major adverse cardiovascular events (cardiovascular death, myocardial infarction or stroke).
Results: 1405 patients had available hs-cTnT
Results: Of these, 201 (19%) had a final diagnosis of ADHF (age 79 ± 10 years-old, 54% female). 82% of patients had known HF and 21% had prior history of coronary artery disease. In a median follow-up of 363 days [IQR 156-427], 67 patients died and 80 had a MACE. Median hs-cTnT was 44 ng/L [IQR 26-88]. Compared to other metrics of hs-cTnT (absolute 0-3 h change, peak value and percentage change), initial hs-cTnT had the best discriminative power for total mortality (c-index = 0.636 [CI 95% 0.556-0.716], p = 0.002) and MACE (c-index = 0.676 [CI 95% 0.601-0-756], p < 0.001). Cox regression using Youden's index of 109 ng/L as the cut-off yielded hs-cTnT and age (but not NT-pro-BNP) as independent predictors of total mortality (HR 4.05 [CI 95% 1.36-12.1], p = 0.012 for hs-cTnT) and MACE (HR 3.05 [CI 95% 1.17-7.99, p = 0.023] for hs-cTnT).
Conclusions: in patients presenting to the ER with ADHF, admission hs-cTnT is a powerful prognostic marker of both mortality and MACE. Further studies are warranted to determine the potential impact of therapeutic tailoring incorporating hs-cTnT on patient outcomes.

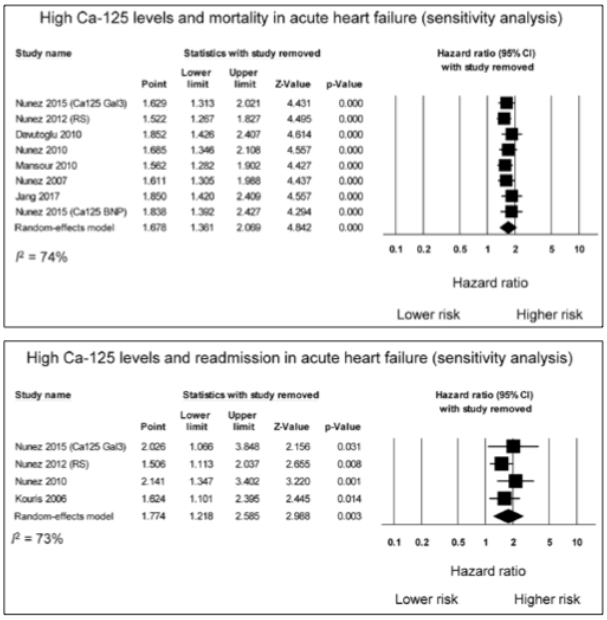
Cancer antigen-125 and hospital readmission and mortality outcomes in acute heart failure: a systematic review and meta-analysis

R E De La Espriella Juan[1]; G Tse[2]; M Gong[3]; G Li[3]; A Baranchuck[4]; T Liu[3]; MCS Wong[5]; A Beyes-Genis[6]; J Sanchis[7]; J Nunez[7]
[1]University Hospital Clinic of Valencia, Cardiology Department , Valencia, Spain; *[2]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Faculty of Medicine, Hong Kong, Hong Kong SAR People's Republic of China*; *[3]2nd Hospital of Tianjin Medical University, Tianjin Key Laboratory of Ionic-Molecular Function of Cardiovascular disease, Department of Cardiolo, Tianjin, China People's Republic of*; *[4]Queen's University, Department of Medicine, Kingston General Hospital, Kingston, Canada*; *[5]The Chinese University of Hong Kong, JC School of Public Health and Primary Care, Hong Kong, Hong Kong SAR People's Republic of China*; *[6]Germans Trias i Pujol Hospital, Heart Institute and Department of Medicine, Autonomous University of Barcelona, Badalona (Barcelona), Spain*; *[7]University Hospital Clinic of Valencia, Cardiology Department, INCLIVA, Department of Medicine, Valencia University, Valencia, Spain*

Background: Cancer antigen-125 (CA125) is an ovarian cancer marker but recent research work has focused on its role in risk stratification in heart failure. A recent meta-analysis examined its prognostic value in chronic heart failure. However, there has been no systematic evaluation of its role in acute heart failure (AHF).
Methods: PubMed and EMBASE databases were searched until 17th October 2017 for studies that evaluated the prognostic value of CA125 in AHF
Results: A total of 30 and 88 entries were retrieved from PubMed and EMBASE, of which 17 studies were included in the final meta-analysis. Sixteen studies were prospective cohort studies and one study was a randomized controlled trial. Our meta-analysis shows that high CA125 levels were associated with 68% increase in all-cause mortality (hazard ratio [HR]: 1.68, 95% CI: 1.36-2.07; P < 0.0001; I2: 74%) and 77% increase in heart-failure-related readmissions (HR: 1.77, 95% CI: 1.22-2.59; P < 0.01; I2: 73%). In patients with AHF, CA125 levels were higher in patients with fluid overload symptoms and signs compared to those without them, with a mean difference of 41.6 U/mL (standard error: 10.2 U/mL, P < 0.0001; I2: 82%).
Conclusion: CA125 is a significant predictor of hospital readmission and mortality outcomes in AHF. Therefore, CA125 emerges as a useful tool for risk stratification and monitoring following an episode of AHF.



High CA-125 Levels and Outcomes in AHF

P455

Thrombopoeitin as a biomarker and a regulatory mediator in acute heart failure

L Malinova[1]; N Furman[1]; P Dolotovskaya[1]; N Puchinyan[1]; T Denisova[2]
[1]Saratov State Medical University, Research institute of cardiology, Saratov, Russian Federation; *[2]Saratov State Medical University, Saratov, Russian Federation*

Funding Acknowledgements: The reported study was funded by RFBR according to the research project ? 17-04-00070

Background: Recently thromboeitin (TPO) has been reported as not only a stimulator of the proliferation and differentiation of megakaryocytes, but as a possible modulator of cardiac contractility, and a factor reducing myocardial necrosis, apoptosis and decline in ventricular function following ischaemia/reperfusion. However, these finding are based predominantly on animal models.
The purpose of the study was to characterize short-term profiles of thrombopoeitin in patients with acute heart failure and to assess its potential impact on clinical course and short-term prognosis.
Methods: We report the preliminary results of the ongoing study. 40 male patients (57(47;65) y.o.) admitted with ST segment elevation myocardial infarction (STEMI) were recruited into the study. According to clinical presentation and baseline level of BNP (cut off level - 100 pg/mL) patients were divided into acute heart failure (AHF) and control (C) groups. Levels of TPO, stromal cell derived factor 1 (SCD1) and myeloproliferative leukemia virus oncogene (MPL) were measured in plasma samples obtained at admission, on the 2nd and the 7th days since STEMI manifestation with commercially available ELISA Kits. Follow-up period was 12 months after admission.

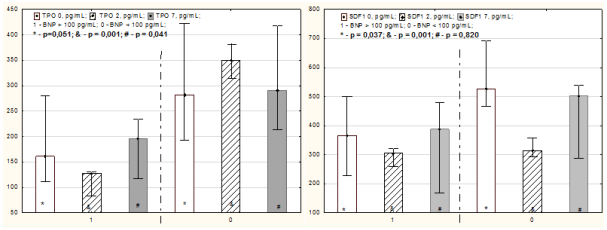


Fig.1. TPO and SDF1 dynamics

Results: Patients of both groups were comparable by age and major clinical characteristics. Symptom onset to first medical contact delay time was longer in patients with AHF: 105 (60; 180) vs 60 (30; 79) min, p = 0.018. TPO levels measured at admission, on the 2nd and the 7th days since STEMI manifestations were significantly lower in AHF patients (fig. 1). Similar situation was with SDF1 levels (fig. 1), with the only exception of the last point (7th day). MPL plasma concentrations at admission were higher in AHF patients, however this difference was non-significant. BNP and TPO levels at admission reveal negative significant correlation: Spearman R = - 0.433, p < 0.05. Early cardiovascular complications were more frequent in patients with high TPO levels at admission: 26.5% vs 8.8%, as well as incidence rate of composite endpoint (CV death + CV rehospitalisations): 25.7% vs 14.3%.
Conclusion: Received data support hypothesis of thrombopoeitin influence on cardiac function during myocardial ischaemia-reperfusion injury and acute heart failure, which may ground new diagnostic approach and pharmacological strategies in acute heart failure.

The prognostic role of different renal function phenotypes in patients Hospitalized for Acute Heart Failure

A Alberto Palazzuoli[1]; G Ruocco[2]; P Pellicori[3]; E Incampo[4]; C Di Tommaso[4]; R Favilli[4]; R Nuti[2]; JM Testani[5]
[1]Santa Maria Alle Scotte Polyclinic, Siena, Italy; *[2]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy*; *[3]University of Glasgow, Robertson Institute of Biostatistics and Clinical Trials Unit, Glasgow, United Kingdom*; *[4]Polyclinic Santa Maria alle Scotte, Cardiothoracic Department, Siena, Italy*; *[5]Yale University, Section of Cardiovascular Medicine, New Haven, United States of America*

Background: Worsening renal function (WRF) is common in patients treated for acute heart failure (AHF) and might be associated with a significant increase in blood nitrogen urea (BUN), a marker of neuro-hormonal activation.
Purpose: We aimed to evaluate the prognostic relevance of WRF according to BUN changes during hospitalisation.
Methods: We studied patients with AHF screened for Diur-HF Trial (NCT01441245). WRF was defined as an in-hospital rise in serum creatinine = 0.3 mg/dl or estimated glomerular filtration rate (GFR) reduction = 20%. BUN increase was defined as a rise in BUN = 20% during admission. Effective decongestion was defined as complete resolution of two, or more, signs of HF, or euvolemic clinical status at discharge.
Results: Of 247 patients enrolled, 59 (23%) patients experienced WRF, 107 (43%) had a BUN increase >20%, and 111 (45%) were effectively decongested during hospitalization.
During 180 days of follow-up, 136 patients died or were re-hospitalised for AHF. An increase in BUN was an independent predictor of adverse outcome, regardless of WRF (HR = 2.19 [1.35-3.54], p = 0.002 and 1.71 [1.14-2.59], p = 0.010; with and without WRF, respectively). WRF was not an independent predictor of outcome if BUN did not increase. An increase in BUN was independently associated with adverse outcome regardless of clinical congestion at discharge, whilst WRF predicted outcome only if effective decongestion was not achieved.
Conclusions: an increase in BUN>20% during hospitalization for AHF predicts a poor outcome; WRF predicts adverse outcome only if BUN increases substantially or clinical congestion persists.

P457

Carbohydrate antigen 125 and glutamic oxaloacetic transaminase as congestion markers in acute heart failure. Is there clinical association between them?

D Carrillo[1]; R Lopez-Vilella[1]; I Sanchez-Lazaro[1]; C Aguado[2]; B Laiz[2]; L Martinez-Dolz[1]; L Almenar[1]
[1]Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit, Valencia, Spain; *[2]Hospital Universitario y Politécnico La Fe, Clinical analysis service, Valencia, Spain*

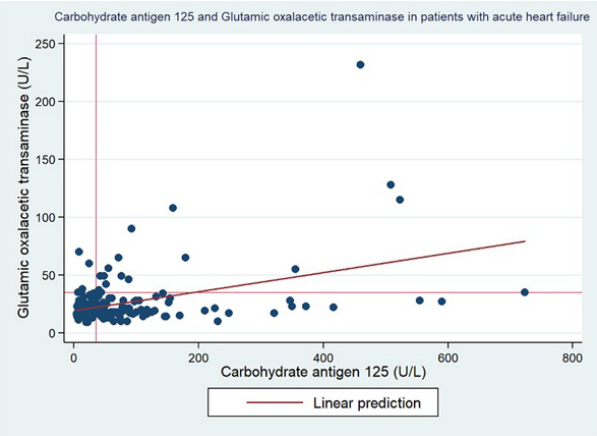
Introduction: Carbohydrate antigen 125 (CA-125) is a novel biomarker that increases when there is congestion in patients with heart failure (HF). Elevated levels require an intense diuretic treatment, while low levels are associated with acute renal failure in the case of an aggressive diuretic treatment. It might be useful to find a standardized clinical marker that correlates with CA-125 to assess the degree of congestion and help the optimization of diuretic treatment.
Purpose: To analyse the relationship between CA-125 and Glutamic oxalacetic transaminase (GOT) in patients with acute HF.
Methods: Cross-sectional study of patients admitted to hospitalization rooms of cardiology because of acute HF, between 01 august 2017 to 30 November 2017 and had, during the hospitalization, measurement of CA-125 and GOT in the same blood sample. A logistic multiple regression of GOT as dependent variable and CA-125 and BNP as independent variables were modelled.
Results: 173 patients were included. The median of age was 71 years (interquartile range IQR 61-79). 35.26% were female. Median of GOT was 19 (16-27) and 42.1 of

CA-125 (16.2-88). 10% of patients had GOT higher than 35 U/L and 3.53% more than 70 U/L. There was relation between the levels of CA-125 and GOT (Figure). Levels of CA-125 more than 35 U/L increased the probability of having increased GOT levels (OR 3.54 95% IC 1.19 to 10.54 p = 0.023) (Table).
Conclusions: There is an association between CA-125 levels and GOT values in acute heart failure. GOT could be part of the diuretic administration algorithm in AHF together with CA-125.

Logistic Regresion model of GOT

GOT elevation	Odds Ratio	95% Confidence Interval	P	
CA-125 elevation	3.54	1.91	10.54	0.023
High NTproBNP	1.01	0.34	2.89	0.99
Constant	0.068	0.02	0.19	0.00

GOT: Glutamic oxalacetic transaminase, GOT elevation >35U/L. CA-125: Carbohydrate antigen 125 35U/L. High NTproBNP >450pg/mL in < 50 years, >900pg/mL in 50-70 years, and >1800pg/mL in >70 years.



P458

Dynamics of serum lipocalin-2 concentrations in acute decompensated heart failure after levosimendan infusion

MV Lediakhova[1]; IV Zhirov[1]; SN Nasonova[1]; TM Uskach[1]; VP Masenko[1]; SN Tereshchenko[1]
[1]*National Medical Research Center for Cardiology, Moscow, Russian Federation*

Background: serum lipocalin-2 is a biomarker for early identification of acute kidney injury (AKI). Changes in serum lipocalin-2 concentrations are potentially useful for the early diagnosis of AKI in patients with acute decompensated heart failure (ADHF).
Purpose: to evaluate the value of serum lipocalin-2 concentrations in patients with acute decompensated heart failure with reduced systolic function after levosimendan infusion.
Methods: the study was a prospective, single-centre, randomized trial. We enrolled 30 patients hospitalized with ADHF. The patients had reduced systolic function (left ventricular ejection fraction (LVEF) <40%), increased levels of brain natriuretic peptide > 500 pg/mL and systolic blood pressure >125 mmHg. The exclusion criteria were: acute coronary syndrome; sustained ventricular tachycardia or ventricular fibrillation; severe aortic or mitral regurgitation; hypertrophic obstructive cardiomyopathy; restrictive cardiomyopathy; estimated glomerular filtration rate (GFR) < 30 mL/min/1.73 m2. All patients were randomized according to a 1:1 scheme to receive standard therapy or an intravenous infusion of levosimendan 0.1μg/kg/min for 24 hour added standard therapy. AKI was defined according to Kidney Disease: Improving Global Outcomes (KDIGO)
Clinical Practice Guidelines. We measured of serum lipocalin-2 concentrations by a quantitative sandwich enzyme immunoassay technique (RD systems, DLCN20, USA) at baseline, immediately after levosimendan infusion and at discharge. Statistical significance was defined as P <0.05.
Results: a total of 30 men hospitalized with ADHF were included. Average age was age 62.5 ± 9.7 years and mean LVEF was 25.0 (21.5-28.5)%. Baseline serum lipocalin-2 concentrations were similar in the two groups. We found a significant decrease of serum lipocalin-2 concentrations in the levosimendan group immediately after infusion [from 156.2 (126.4-171.2) ng/mL at baseline to 115.5 (88.9-141.5) ng/mL (P = 0.001)] and a significant increase of serum lipocalin-2 concentrations in the standard therapy group [from 164.4 (136.7-247.6) ng/mL at baseline to 185.9 (167.0-316.4) ng/mL (P = 0.047)]. At discharge, we noted a significant decrease of serum lipocalin-2 concentrations in the levosimendan group [from 156.2 (126.4-171.2) ng/mL at baseline to 128.6 (116.4-157.3) ng/mL (P = 0.041)] and a tendency to increase of serum lipocalin-2 concentrations in the standard therapy group [from 164.4 (136.7-247.6) ng/mL at baseline to 169.8 (143.4-228.1) ng/mL (P = 0.826)]. We compared the value of serum lipocalin-2 concentrations in both groups these interactions were statistically significant after infusion (P for interaction <0.001) and at discharge (P for interaction = 0.001).
Conclusion: serum lipocalin-2 concentrations are significantly reduced after infusion and at discharge in the levosimendan group in patients with acute decompensated heart failure with reduced systolic function.

P459

Endocan as a new biomarker of severity in acute heart failure

M Reina Couto[1]; JP Bessa[2]; P Serrao[2]; J Afonso[2]; R JR Roncon-Albuquerque[1]; JA Paiva[1]; A Albino-Teixeira[1]; T Sousa[1]
[1]*Sao Joao Hospital, Intensive Care Medicine, Porto, Portugal*; [2]*University of Porto, Faculty of Medicine, Porto, Portugal*

Introduction: Acute heart failure (AHF) remains a major health concern, with high mortality and re-hospitalization rates, and treatment remains largely opinion-based. Endothelial dysfunction and progression of chronic heart failure seems to be associated to increased oxidative/nitrosative stress. Although endocan is increasingly recognized as an emerging biomarker of endotelial dysfunction, it remains scarcely explored in AHF.
Purpose: To evaluate serum endocan and nitrotyrosine (a marker of redox dysfunction), and to determine the correlation between these, C-reactive protein (CRP) and high sensitivity (hs)-troponin I values in AHF.
Methods: Patients admitted to the department of intensive care medicine with the diagnosis of AHF (n = 10) and cardiogenic shock (CS) (n = 9) were included and blood samples were collected at admission and at day 3 to 5. Blood donors were used as controls (n = 10). Endocan and nitrotyrosine were measured with ELISA kits. CRP and hs-troponin I were evaluated using automated analyzers.
Results: Endocan concentration on admission was increased in patients with AHF and significantly raised in CS when compared to the values found in controls (controls: 1.9 ± 0.3; AHF: 5.2 ± 0.9 ng/mL; CS: 20.0 ± 3.8ng/mL; controls vs AHF, p = 0.0878; controls vs CS, p < 0.0001; AHF vs CS, p = 0.0441). Serum nitrotyrosine values were not significantly different between controls, AHF and CS (controls: 2.4 ± 0.4 nmol/mL; AHF: 3.4 ± 0.5 nmol/mL; CS: 3.2 ± 0.7 nmol/mL, p = 0.3623). CRP values were not different between AHF and CS groups on admission (56.8 ± 17.1 vs 116.2 ± 27.0 ng/mL, p= 0.1128). The hs-troponin I concentration was not significantly different between AHF and CS patients (19508 ± 8775 vs 67457 ± 36471 ng/mL, p= 0.356). Endocan was positively correlated with CRP (Spearman r = 0.427, p = 0.0094) but not with hs-troponin I or nitrotyrosine. Serum nitrotyrosine was positively correlated with CRP (Spearman r = 0.4101, p = 0.013) and with hs-troponin I (r Spearman = 0.6242, p < 0.0001). There were no significant differences between values of all parameters at admission and at day 3 to 5.
Conclusions: We can conclude that the extent of endothelial dysfunction is significantly higher in CS patients and is significantly associated with inflammatory status in AHF and CS. Furthermore, nitrosative/oxidative stress also seems to be associated with inflammation and myocardial damage.

Endomyocardial biopsy in paediatric myocarditis and dilated cardiomyopathy may identify infectious genome presence in myocardium and guide targeted treatment

G Kourelis[1]; S Rammos[1]; GA Vagenakis[1]; K Kyriakoulis[1]; F Kakava[1]; D Rallis[1]; S C Apostolopoulou[1]
[1]*Onassis Cardiac Surgery Center, Athens, Greece*

Background/Introduction: Myocarditis and cardiomyopathy are acquired causes of heart failure with frequently infectious aetiology, complex pathophysiology and challenging management and prognosis, especially in the paediatric population.
Purpose: This study examines the role of endomyocardial biopsy in identifying infectious genome in the myocardium of children with myocarditis and cardiomyopathy, its association with histology, and its guidance on using targeted anti-infectious agents in the therapeutic management of this population.
Methods: Retrospective data collection of paediatric patients (0-18 years old) diagnosed with myocarditis and/or cardiomyopathy between 2004 and 2017 at our

institution. Data was analyzed on the basis of demographics, diagnosis, biopsy results, therapy and outcome.
Results: 80 patients (44 boys) were included in the study with diagnoses: 39 cardiomyopathy (26 dilated; 4 hypertrophic; 5 restrictive) and 43 myocarditis. Age distribution was < 0-1 year old (n = 13), 1-5 year old (n = 25), 5-16 year old (n = 37) and 16-18 year old (n = 5). Diagnosis was based on echocardiography, myocardiac enzyme levels and biopsy findings (active inflammation; necrosis; hypertrophy; fibrosis; (near) normal; other). All patients but 3 underwent endomyocardial biopsy. Overall, 27 biopsy specimens (23 of the 'myocarditis' group and 4 of the rest) were positive for viral or bacterial genetic material through polymerase chain reaction (PCR) testing. Of the positive patients, 21 received targeted antiviral or antibiotic therapy (no specific therapy was available for the remaining patients at the time of diagnosis). Intravenous immunoglobulin was administered in 20 patients and systemic corticosteroids in 4 patients based on presence of active inflammation on biopsy and positive PCR in blood or cardiac specimen. During 7.4 ± 4.7 years follow up, 51 (63%) children improved or had full recovery, 9 (11%) required prolonged medical support for heart failure, 9 (11%) received or are waiting for transplant and 11 (15 %) died.
Conclusions: Endomyocardial biopsy and PCR testing can be useful in the management of myocarditis and dilated cardiomyopathy in children identifying infectious genome in the myocardium and guiding specific anti-infectious therapy.

P461

Guided therapy in patients with acute decompensated heart failure with dilated cardiomyopathy: left ventricular diastolic filling pattern during admission and discharge

E Ersin Saricam[1]
[1]*Medicana Hospital, cardiology, Ankara, Turkey*

Background: NT-proBNP guided therapy in acute decompensated heart failure (ADHF) has been used as in-hospital guidance. Left ventricular diastolic filling pattern in transthorasic echocardiography (TTE) might provide prognosis in the patients with ADHF.
Purpose: We investigated whether left ventricular filling pattern could be used as a criteria of discharge and the success of the therapy similar to NT-proBNP target (<30% reduction from admission to discharge).
Methods: Prospective randomized study included 31 patients admitted into emergency department between March 2017 and January 2018. All of the patients had NYHA class IV, sinus rhythm, and before diagnosed dilated cardiomyopathy. The left ventricular filling pattern in admission and discharge was evaluated in the all of them by TTE. Moreover, NT-proBNP levels were analyzed in admission and discharge.
Results: The average age of the patients had 65.80 ± 4.96 years. In admission, while left ventricular pattern of all of them was restrictive (type III) diastolic dysfunction, at discharge time, 26 patients had normal left ventricular filling pattern, and 5 patients had impaired relaxation (type I) diastolic dysfuncion (Tablo).
Conclusion: Our study demonstrated that guidance of left ventricular filling pattern was succesful in ADHF therapy, similar to NT-proBNP guided therapy.

NT-proBNP levels and echocardiography	
At presentation	
NT-proBNP levels (pg/mL)	8004.75±743

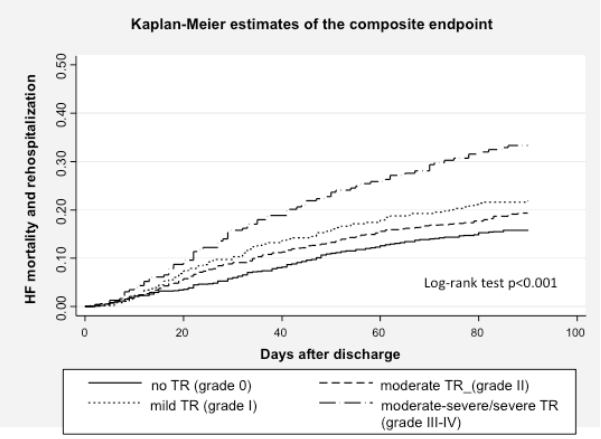
Tricuspid regurgitation predicts short-term adverse events in acute heart failure

R De La Espriella Juan[1]; E Santas[1]; G Minana[1]; A Mollar[1]; J Gonzalez[1]; M Amiguet[1]; I Cardells[1]; J Sanchis[2]; J Chorro[2]; J Nunez[2]
[1]*University Hospital Clinic of Valencia, Cardiology Department , Valencia, Spain*; [2]*University Hospital Clinic of Valencia, Cardiology Department, INCLIVA, Department of Medicine, Valencia University, Department of Medicine,, Valencia, Spain*

Background: Although tricuspid regurgitation (TR) is a common echocardiographic finding among patients with acute heart failure (AHF), its short-term prognostic impact remains unclear. We aimed to evaluate the association between the severity of TR and short-term adverse outcomes following a hospitalization for AHF.
Methods: We prospectively included 2244 consecutive patients discharged with a diagnosis of AHF. TR was assessed using an integrated multi-parametric score that combines qualitative and semi-quantitative parameters and its severity categorized as a) none (grade 0), b) mild (grade I), c) moderate (grade II), d) moderate-severe (grade III), and severe (grade IV). The primary end-point was the composite of mortality and rehospitalization for heart failure at 90 days. Multivariate analyses were performed using Cox proportional hazards models.
Results: Mean age was 73.2 +/- 11.2 years, 50.4% were male, 31.7% had a LVEF < 40% (HFrEF), 15% between 41-49% (HFmrEF) and 53.3% >50% (HFpEF). At discharge, 792 (35.2%), 843 (37.6%), 379 (16.9%), 170 (7.6%) and 60 (2.67%) patients showed none, mild, moderate, moderate-severe and severe TR. At 90-day follow-up, 439 patients either died or were readmitted due to HF. We registered a stepwise increase in the risk of the composite endpoint from grades I to IV (p < 0.001) as shown in the figure below. After multivariable adjustment, and compared to those without TR, only patients with TR III or IV showed a significantly higher risk of reaching the endpoint (HR = 1.54; 95% CI: 1.13 - 2.08; p= 0.006).
Conclusion: In AHF setting, TR grade III-IV independently predicts the risk of short-term adverse events.



P463

Impact of load variations on systolic function of failed left ventricle under extracorporeal membrane oxygenation assessed by strain and tissue doppler imaging

N Ouazani[1]; Y Shudo[1]; K Sallam[1]; A Lee[1]; J Boyd[1]; J Teuteberg[1]
[1]*Stanford University, Cardiovascular Institute, Palo Alto, United States of America*

Introduction: Load variations have been studied in a wide range of healthy and cardiac patients. Although the diastolic conventional parameters (filling pressures) showed a load dependency, the results are controversial for systolic function assessed by Tissue Doppler Imaging (TDI) and Global Longitudinal Strain (GLS) in failing hearts. Our purpose is to assess the impact of rapid variations of flow on systolic function of left ventricle (LV) of patients under veno-arterial extracorporeal membrane oxygenation (VA ECMO) by echocardiography.

Method: The data were collected from an observational prospective study conducted in Stanford Cardiovascular Intensive Care Unit since July 2017, and included all patients under VA ECMO who met the criteria to undergo a ramp study (mean arterial pressure > 60mmhg, pulsatile waveform for 24 hours at least, normal pulmonary oxygen blood flow). This study was approved by our Institutional Review Board. The baseline clinical characteristics of patients were recorded. During the ramp, the flow was decreased by 0,5 liter every 2 minutes until the minimum value, either 1 or 1,5 liter delivered by ECMO. The following echocardiographic parameters were recorded at each step of flow: LV end diastolic dimensions (LVEDD), LV end diastolic volume and LV ejection fraction in 4 cavities (LVEDV4C and LVEF4C), velocity time integral (VTI), systolic tissue Doppler on lateral (SaL) and septal (SaS) mitral annulus, global longitudinal strain on LV (GLS LV) and GLS rate on LV (GLSr LV). To homogenize and to ensure comparison between patients, the echocardiographic parameters were analyzed at baseline, 66% and 33% of initial flow.
Results: Ten patients under ECMO whom 4 myocarditis, 1 ischemic cardiomyopathy and 1 non-ischemic cardiomyopathy underwent a complete ramp study. The median age was 37,5 years (18-64), 30% were male and the median SAPS 2 score was at 24,5. The mean arterial pressure decreased but not significantly whereas the heart rate remained stable. The median LVEF4C at baseline was severely reduced at 0,2 (0,09-0,39). The LVEDD and LVEDV4C slightly increased but not significantly. The LVEF4C and VTI increased respectively, from 0,23 to 0,29 (p <0,01) and from 9,2 (InterQuartile Range IQR : 7,8-13,2) to 14cm/sec (IQR: 11,7-16,2), p <0,00001. The GLS LV and GLSr LV changed significantly, respectively from -5.3 (IQR: -2.7 to -6.1) to -8.4% (IQR: -5.84 to -9.21, p <0,01) and from -0,4 (-0.2 to -0.6) to -0.8/sec (-0.4 to -0.9, p <0,001), as TDI SaS from 5,7 (IQR: 4,1-6,5) to 6,4cm/sec (IQR: 4,9-7,6, p <0,001). The TDI SaL remained unchanged from 6,1 (IQR: 5,3-7,1) to 6,3cm/sec (5,4-8,4), p = 0,1.
Conclusion: Based on a small study, the lateral systolic TDI parameter SaL of failed LV appeared to be load independent contrary to conventional parameters (VTI, LVEF), those derived from strain (GLS and GLSr) and TDI measured on septal mitral annulus. These data need to be validated in a larger sample.

P464
Prognostic significance of in-hospital coronary angiography in patients hospitalized with acute heart failure -results from REALITY-AHF-

E Eiichi Akiyama[1]; M Konishi[1]; T Okumura[2]; K Kida[3]; S Oishi[4]; S Suzuki[5]; M Yamamoto[6]; T Kitai[7]; Y Matsue[8]
[1]Yokohama City University, Division of cardiology, Yokohama, Japan; *[2]Nagoya University , Nagoya, Japan*; *[3]St. Marianna University, Kawasaki, Japan*; *[4]Himeji Cardiovascular Center, Himeji, Japan*; *[5]Fukushima Medical University, Fukushima, Japan*; *[6]Tsukuba University, Tsukuba, Japan*; *[7]Kobe City Medical Center General Hospital, Kobe, Japan*; *[8]Kameda Medical Center, Chiba, Japan*

Funding Acknowledgements: REALITY-AHF was funded by The Cardiovascular Research Fund, Tokyo, Japan

Background: Coronary artery disease (CAD) is a major cause of heart failure (HF). Urgent coronary angiography (CAG) is recommended for patients with acute HF (AHF) complicated with acute coronary syndrome (ACS); however, clinical usefulness of in-hospital CAG in AHF patients without ACS remains unknown.
Purpose: To investigate the association between in-hospital CAG and all-cause mortality at 1-year after hospital discharge.
Methods: From the REALITY-AHF study, 1344 patients hospitalized with AHF were enrolled in this study and followed up for 1-year after hospital discharge.
Results: In our AHF cohort, 511 patients (38%) underwent in-hospital CAG. CAG group was younger, more likely to be male, had higher prevalence of HF with reduced left ventricular ejection fraction (< 40%), de novo HF, and diabetes mellitus compared with non-CAG group (all P < 0.01). The history of CAD was similarly observed in both groups. CAG group had lower creatinine levels and higher hemoglobin levels compared with non-CAG group (both P < 0.001). Unadjusted risk of death at 1 year was lower in CAG group than in non-CAG group (hazard ratio [HR] 0.30, 95%-confidence interval [CI] 0.21-0.43, P < 0.001). Likewise, CAG group was associated with lower mortality compared with non-CAG group after adjustment for MAGGIC score (HR 0.45, 95%-CI 0.29-0.70, P < 0.001) and in propensity-score matched 296 pairs (HR 0.60, 95%-CI 0.37-0.98, P = 0.04).
Conclusions: In patients hospitalized with AHF, in-hospital CAG was associated with a better long-term survival.

Acute Heart Failure - Treatment

P465
Effect of serelaxin on worsening heart failure when added to standard therapy in European patients with acute heart failure: Results from the RELAX-AHF-EU study

A P Maggioni[1]; J Lopez-Sendon[2]; M Aalamian-Mattheis[3]; J Hallen[3]; Y Wang[4]; O W Nielsen[5]; G Ertl[6]
[1]Associazione Nazionale Medici Cardiologi Ospedalieri Research Center, Florence, Italy; *[2]University Hospital La Paz, Madrid, Spain*; *[3]Novartis Pharma AG, Basel, Switzerland*; *[4]Novartis Pharmaceuticals Corporation, East Hanover, United States of America*; *[5]Bispebjerg University Hospital, Copenhagen, Denmark*; *[6]Comprehensive Heart Failure Center (CHFC), Wurzburg, Germany*

Funding Acknowledgements: Novartis pharma AG, Basel, Switzerland

Background: About 10-30% of patients with acute heart failure (AHF) develop in-hospital worsening heart failure (WHF). Serelaxin, a recombinant human relaxin-2 hormone with vasodilatory properties, improved dyspnoea and clinical outcomes in AHF patients in a phase III clinical trial. However, a larger trial, RELAX-AHF-2, reported neutral effects on WHF and 6-month cardiovascular mortality.
Purpose: RELAX-AHF-EU study (CT.gov identifier: NCT02064868) primarily assessed the effect of serelaxin added to standard of care therapy (SoC) on WHF or all-cause death through Day5 in patients hospitalised for AHF.
Methods: This prospective, randomised, open-label, blinded-endpoint evaluation study, enrolled hospitalised AHF patients at 494 sites across 26 European countries. Within 16 hours of presentation with dyspnoea, pulmonary congestion, elevated natriuretic peptide levels, mild-to-moderate renal impairment and systolic blood pressure = 125mmHg, eligible patients were randomised (2:1) to receive 48-hour intravenous infusion of 30µg/kg/day serelaxin+SoC or SoC. The primary endpoint was time to adjudicated WHF/all-cause death through Day5. Secondary endpoints included WHF/all-cause death/rehospitalisation for heart failure (HF) through Day14, persistence of HF symptoms and renal deterioration (= 0.3mg/dL increase in serum creatinine) through Day5, index length of hospital stay (LoS) and safety through Day30.
Results: Of a target of 3183 patients, 2666 were randomised when the study was terminated early by the sponsor due to the neutral RELAX-AHF-2 **Results:** Adjudicated WHF/all-cause death through Day5 was significantly reduced in the serelaxin+SoC vs SoC group (5.0%vs.6.9%; hazard ratio [HR] 0.71; 95% confidence interval [CI] 0.51-0.98; P = 0.017), but when all events reported by the investigator (not adjudicated) were considered, the difference between treatment groups was not significant. No significant difference between treatment groups was observed for the rate of WHF/all-cause death/HF rehospitalisation through Day14 (HR 0.79; 95%CI 0.61-1.02; P = 0.063) and for the LoS during index hospitalisation (P = 0.139). The rate of persistent HF signs/symptoms was significantly lower in the serelaxin+SoC vs SoC group at each visit until Day4. Fewer patients experienced renal deterioration through Day5 in the serelaxin+SoC vs SoC group (17.1%vs.23.6%; P = 0.0001). Overall incidence rates of treatment-emergent adverse events (AEs) through Day5 (serelaxin+SoC,58.1% vs SoC,56.0%), serious AEs through Day14 (12.4%vs.12.0%) and all-cause deaths through Day30 (3.3%vs.4.3%) were comparable between treatment groups. Hypotension and haemoglobin/haematocrit decreased more frequently in the serelaxin+SoC group.
Conclusion: The primary endpoint was met indicating serelaxin reduces adjudicated WHF when added to SoC, but due to early study termination and lack of power, efficacy analyses should be considered as exploratory. The incidence of AEs was comparable between groups.

Targeted interventions reducing late maternal death due to heart failure

F Feriel Azibani[1]; J Baard[1]; A Osman[2]; L Zuhlke[3]; A Lachmann[2]; E Libhaber[4]; A Chin[1]; M Ntsekhe[1]; P Soma-Pillay[5]; MR Johnson[6]; J Roos-Hesselink[7]; J Anthony[2]; K Sliwa[1]
[1]University of Cape Town, Medicine, Cape Town, South Africa; *[2]University of Cape Town, Obstetrics & Gynaecology , Cape Town, South Africa*; *[3]University of Cape Town, Paediatrics, Cape Town, South Africa*; *[4]University of the Witwatersrand, Soweto Cardiovascular Research unit, Johannesburg, South Africa*; *[5]University of Pretoria, Obstetrics & Gynaecology , Pretoria, South Africa*; *[6]Imperial College London, London, United Kingdom*; *[7]Erasmus Medical Center, CARDIOLOGY, Rotterdam, Netherlands*

Background: Late maternal mortality (up to 1 year postpartum) is poorly reported globally and is commonly due to cardiovascular disease (CVD). We reported previously on the spectrum of disease, mode of presentation, maternal and fetal outcome in patients referred to a dedicated Cardiac Disease and Maternity Clinic (CDM), identifying excellent survival outcome rates in pregnant mothers with complex diseases,

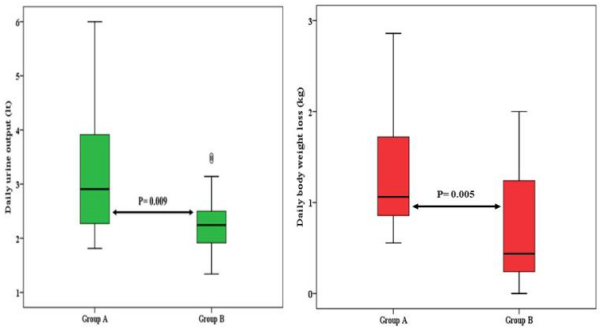
but a high 6-month postpartum mortality. The aim of this study was to investigate two targeted interventions aimed at reducing peripartum heart failure admission and late maternal death.
Methods and Results: Women presenting with CVD in pregnancy, or within 6 months postpartum, were studied in a single-centre, prospective ongoing study over a period of 6 years. Both CDM Group I (152 women assessed in 2010-2012) and Group II (117 patients assessed in 2013-2015) were attended to by a dedicated cardiac-obstetric team, with input by other specialists, at the CDM clinic while pregnant. CDM Group II patients routinely received additional targeted interventions: 1. Early (2-6 weeks) postpartum follow-up at the CDM clinic and immediate referral to dedicated CV specialist clinics, remaining under close supervision and care by the CDM team for a period of 1 year. 2. Beta-blocker therapy was continued in women with left ventricular ejection fraction <45% while pregnant, or immediately started postpartum. Follow-up data on maternal mortality and re-admission was collected over a period of 1 year post diagnosis.
Of the 269 consecutive women (mean age 28.6 ± 5.9), 213 (79%) presented prepartum, 22% in NYHA Classification group III-IV and 79% in modified World Health Organization (WHO) Group III-IV (high risk). Patients were diagnosed with congenital heart disease (30%, 25 operated previously), valvular heart disease (25%, 15 operated previously), cardiomyopathy (31%) and other (14%).
There were no significant differences between the groups in age, gravida, diagnosed condition, NYHA, modified WHO Group, blood pressure, heart rate and HIV, but patients in CDM Group II had a higher rate of previously known CVD (p <0.0001), as well as a lower rate of being nulliparous (p < 0.0005). Nine patients (6%) from CDM Group I died within the 12-month follow-up period. Eight of the 9 patients died >42 days postpartum. Group 2 had one death occurring 132 days postpartum (p = 0.029). Peripartum heart failure leading to admission was 32% (n = 48) in CDM Group I versus 14% (n = 16) in CDM Group II (p = 0.0008), with CDM Group II having a significantly higher beta-blocker use in the peripartum period (p = 0.0002). Perinatal death occurred in 1/152 in group I and 5/117 in group II (p = 0.088) - translating to a perinatal mortality rate of 22/1000 live births. Conclusion: Early follow up in a dedicated CDM clinic with targeted interventions, continuation of beta-blockers when indicated and timely referral led to a significant reduction in peripartum heart failure admission and mortality.

P467

Association between high-dose spironolactone and decongestion in patients with acute heart failure

C Chris Kapelios[1]; M Bonou[1]; P Vogiatzi[1]; P Mantzouratou[1]; S Vakrou[1]; K Malliaras[1]; D Dambasis[1]; M Chalikos[1]; LH Lund[2]; J Barbetseas[1]
[1]Laiko University General Hospital, Athens, Greece; *[2]Karolinska University Hospital, Stockholm, Sweden*

Background: Acute congestive heart failure (ACHF) is a state of severe, secondary hyperaldosteronism. Relief of congestion has prognostic implications. High doses of spironolactone have been proposed as a potential measure to increase diuresis in ACHF with diuretic resistance.
Purpose: Our aim was to assess associations between high-dose spironolactone and a) decongestion and b) safety in patients with ACHF.
Methods: Twenty patients who were hospitalized with ACHF and received high doses of spironolactone (75-300 mg daily, Group A) on top of standard of care (SOC) treatment were studied and compared with twenty matched patients who received SOC treatment alone (Group ?).
Results: The two groups were similar as per their baseline characteristics. Mean daily spironolactone dose was 143 ± 56 in group A vs. 25 ± 25 mg in group B (P < 0.001). Patients of group A demonstrated significantly greater daily urine output (2.9 [2.3, 3.9] vs. 2.2 [1.9, 2.5] L/day, P = 0.009, figure 1), daily weight loss (1.1 [0.9, 1.7] vs. 0.4 [0.2, 1.2] kg/day, P = 0.005, figure 1), total body weight loss (10.5 [7.3, 13,8] kg vs. 3.8 [3.0, 6.0] kg, P < 0.001) and percentile body weight loss (12.8 ± 4.9 % vs 5.7 ± 4.6%, P < 0.001) compared with patients of group B. The incidence of worsening renal function (15% vs. 30%, P = 0.451), hypokalemia (10% vs. 25%, P = 0.212) and hyperkalemia (5% vs. 10%, P = 0.548) were also similar among patients of group A and group B, respectively. Nineteen out of twenty patients in group A (95%) were prescribed spironolactone (50 [25, 125] mg) at discharge as compared with 14/20 (70%) in group B (25 [0, 25] mg) (P = 0.037 for comparison of prescription rates and P = 0.004 for comparison of spironolactone dose at discharge). One case of hyperkalemia (potassium levels of 6.2 mmol/L) was noted in the HPODS group. At the 3-month follow-up 1/20 (5%) patients in Group A vs 5/20 (25%) patients in Group B had been rehospitalized (P = 0.077).
Conclusions: In patients with ACHF administration of high doses of spironolactone on top of SOC treatment appears safe and is associated with greater decongestion than SOC alone.



P468

Time to Furosemide Treatment and Outcomes in patients admitted for Acute Heart Failure

D David Cabrita Roque[1]; D Candeias Faria[1]; J Augusto[1]; J Baltazar Ferreira[1]; A Sacchetti[2]; L Melo[2]; J Simoes[1]; C Morais[1]
[1]Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal; *[2]Hospital Prof Fernando da Fonseca EPE, Internal Medicine, Amadora, Portugal*

Introduction: Acute Heart Failure (AHF) is a life-threatening disease requiring urgent treatment. The most recent ESC Guidelines established the concept, previously well known for acute myocardial infarction, of time to treatment in this group of patients.
Purpose: The aim of this study is to evaluate the association between time-to-diuretic treatment and clinical outcomes in patients admitted in the Emergency Department for AHF. We also aim to evaluate if the total dose of diuretic in the first 24 hours of hospitalization has an impact on outcomes.
Methods: Retrospective study of 258 consecutive patients admitted in the emergency department for ADHF, defined by the presence of = 2 signs or symptons of heart failure. Admission, maximum and discharge values of creatinine (Cr) were collected, along with other clinical, laboratory and therapeutic variables. The HF profile was assessed as according to the ESC guidelines. Furosemide was considered as the standard diuretic since is the only endovenous diuretic in our hospital pharmacy.
Results: We evaluated 258 patients with ADHF (45.7% male, mean age of 74.6 ± 16.6 years). The median time for the administration of Furosemide was 16 (5-100) minutes. We further divided the patients in two groups: the early treatment group (= 60 minutes until the first administration of IV Furosemide, 68.6%) and the nonearly treatment group (< 60 minutes until the first administration of IV Furosemide, 31.4%). Median baseline Cr was 1.29 (0.94-1.92) mg/dl, maximum Cr was 1.49 (1.14-2.13)mg/dl and discharge Cr was 1.21 (0.96-1.71)mg/dl. The death rate during hospitalization was 8.1% (n = 21); 1-month readmission rate was 18.2%% (n = 47). The patients in the early treatment group were more likely to have na emergente admission (52.4 vs. 15.6%, p < 0.001) and to have a higher blood pressure at admission (median 150 vs 141mmHg, p = 0.042). There was a tendency to better clinical outcomes in terms of in-hospital death (7.1% in the < 60 minutes groups vs. 9.1%, p = 0.0612), but no difference in terms of nadir GFR (p = 0.823). The median diuretic dose in the first 24h was 80 (60-100mg) and patients that received > 60mg of Furosemide in the first 24h had higher systolic blood pressure at admission (median 155 vs 133mmHg, p < 0.001), were more likely to have an emergent admission (45.7 vs 33.0%, p = 0.049) and had lower peak Cr values (mean 0.95 vs 1.34mg/dL, p = 0.049)
Conclusions: This study establishes that time to treatment in patients admitted for acute heart failure should be an important parameter when evaluating the way, we treat our patients, since the time to first administration of IV furosemide (using a cut-off of 60 minutes in this study) shows a tendency to be associated with worse clinical outcomes, namely in-hospital mortality. Besides that, although it's more likely that patients admitted through the emergency room and those that have higher blood pressure to be treated early, all patients should be early evaluated and treated.

P469

Use of levosimendan in the real world over the last 10 years - what to expect?

S Sofia Alegria[1]; AC Gomes[1]; A Marques[1]; AR Pereira[1]; D Sebaiti[1]; MJ Loureiro[1]; I Rangel[1]; AR Almeida[1]; OS Simoes[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Introduction: Levosimendan is an inodilator drug that has emerged as a new cardioprotective inotropic. In addition it acts in other tissues, such as the coronary vascular endothelium, kidney and brain.
Purpose: To characterize patients treated with levosimendan, analyze its impact on kidney function, natriuretic peptides, functional class and days of hospitalization, as well as to identify predictors of mortality in this population.
Methods: Retrospective study including all patients treated with levosimendan during the last 10 years in a Cardiology Department of a tertiary center.
Results: 80 hospitalizations were identified in 61 patients, 77% male, mean age 60 years (IIQ 55-72). 72% were in NYHA class IV, LV ejection fraction (EF) was 22 ± 8% and 57% had RV systolic dysfunction.
The majority of patients were admitted from the emergency department and the outpatient clinic (50 and 44%, respectively). The main reason for initiating levosimendan was decompensated heart failure (HF) in advanced functional class and symptoms of low cardiac output (83%). It was also used in the setting of acute myocardial infarction with cardiogenic shok (11%) and previous to hemodynamic evaluation by right heart catheterization (6%). The mean blood pressure (BP) before starting levosimendan was 100/61 mmHg (minimum 74/34 mmHg), the maximum dose reached was 0.13 ± 0.06 ug/kg/min and adverse effects occurred in 5% of the cases. During hospitalization, 19% needed vasopressors and 29% dobutamine.
There was a significant improvement in kidney function (serum creatinine (Cr) 1.6 vs 1.3 mg/dl), NT-proBNP (7702 vs 3157 pg/dl), functional class (74% with improvement >= 1 class), and a reduction in the number of days of hospitalization in the subsequent 12 months compared to the previous 12 months (median 16 vs 0 days) ($p < 0.05$ in all). In the echocardiogram performed after treatment with levosimendan (median 96 days), 26% presented EF improvement (defined as >5% and final EF >30%) and 31% recovered RV function.
30-day mortality was 21%, 1-year mortality 38%, and the overall mortality at follow-up (median 575 days) was 61%. In the patients admitted for decompensated HF, the predictors of 1-year mortality were: use of metolazone before hospitalization (HR 4.54, $p = 0.018$), need for vasopressors or dobutamine (HR 2.69, $p = 0.041$, and HR 7.08, $p < 0.001$, respectively), maintenance of NYHA class IV or absence of functional class improvement (HR 78.22, $p < 0.001$, and HR 11.04, $p = 0.003$, respectively), baseline Cr >1.5 mg/dl (HR 3.06, $p = 0.034$), Cr decrease < 0.4 mg/dl (HR 3.53, $p = 0.028$) and lowest NT-proBNP after levosimendan >4500 pg/dl (HR 4, 96, $p = 0.011$).
Conclusion: The use of levosimendan in this population was well tolerated, even in patients with low BP profile, and was associated with improvement of functional class, kidney function, NT-proBNP and reduction of days of hospitalization. Despite this, the mortality rate remains very high in these patients.

P470

Impact of levosimendan in the renal function of heart failure patients: data from a 10-year cohort

S Sofia Alegria[1]; A Marques[1]; AR Pereira[1]; AC Gomes[1]; D Sebaiti[1]; A Briosa[1]; MJ Loureiro[1]; AR Almeida[1]; OS Simoes[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Background: Impairment of renal function (RF) is common in heart failure (HF) patients and is associated with high morbidity and mortality. Levosimendan (LVS) is a calcium sensitizer and ATP-dependent potassium channel opener developed for treating acute HF. Timely intervention with LVS may reverse renal dysfunction through several protective mechanisms.
Purpose: To analyze the impact of treatment with LVS in the RF of patients with HF, as well as to identify predictors of improvement in RF and its association with one-year mortality.
Methods: Retrospective study including all patients treated with LVS during the last 10 years in the Cardiology Department of a Tertiary Center. Improvement of RF was defined as decrease in serum creatinine (Cr) = 0.3 gr/dl.
Results: 80 hospitalizations were identified in 61 patients (77% male, median age 60 years (IQR 55-72). 72% were in NYHA class IV and mean EF was 22 ± 8%.
The main reasons for initiating LVS was decompensated HF in advanced functional class and with signs of low output (83%) and acute myocardial infarction with evolution in cardiogenic shock (11%). In the remaining patients, it was used previous to hemodynamic evaluation by right heart catheterization (6%). The maximum dose reached was 0.13 ± 0.06 ug/kg/min and adverse effects occurred in 5% of the cases. During hospitalization, 19% needed vasopressors and 29% dobutamine.
In 58.1% of patients RF improved after treatment with LVS (Cr 1.89 ± 1.05 vs 1.35 ± 0.55 mg/dl; $p < 0.001$), with the lowest value of Cr obtained 4 days after starting the perfusion. However, this improvement was not significant at 6 months (Cr 1.51 ± 0.66 mg/dl). Patients with CRT, AFib, adverse reaction to LVS or that required treatment with vasopressors or dobutamine were less likely to improve renal function; on the other hand, patients with diabetes or chronic kidney disease (CKD) were more likely to improve renal function ($p < 0.05$ for all). There was no difference between ischemic or non-ischemic etiology of HF regarding improvement in RF with the use of LVS.
After adjusting for confounding variables, the only predictor of improvement of RF at 6 months was the reduction of Cr in the days after treatment with LVS (OR 8.75; $p = 0.015$).
All-cause mortality was 21% at 30 days, 38% at 1 year and 61% at the end of follow-up (median 575 days). In patients admitted for decompensated HF, both the baseline RF (Cr >1.5 mg/dl) and the lowest Cr after treatment with LVS >1.05 mg/dl were predictors of 1-year mortality (HR 3.06, $p = 0.034$; and HR 6.01, $p = 0.019$, respectively).
Conclusion: This study shows that in this population the use of LVS was associated with improvement in RF, and that kidney injury is associated with higher mortality. Nevertheless, LVS seems to have less benefit in more critical patients, although it has good results in patients with previous history of CKD or risk factors for CKD, like diabetes.

P471

Value of multi-disciplinary systematic evaluation of acute mechanical circulatory support for cardiogenic shock in a regional non-transplant LVAD center

K Gobeil[1]; V Grewal[1]; F Katsikeris[1]; J Hernandez-Montfort[1]; E Lau[1]; M Slawsky[1]; G Valania[1]; D Engelman[1]; D Deaton[1]; A Haider[1]; P Robinson[1]; A Islam[1]; C Donaldson[1]
[1]*Baystate Medical Center, Springfield, United States of America*

Background: Cardiogenic shock (CS) remains a disease entity with an unacceptably high mortality. Early recognition provides the possibility of instituting therapies that can promote myocardial recovery and/or safer transition to a durable solution such as left ventricular assist device or heart transplant.
Purpose: The complexity and heterogeneity of CS patients requires expertise and longitudinal coordination of care. Early recognition and timely intervention remains paramount in this subset of patients. The aim this research is to examine the benefits of implementing a systematic approach to CS patients directed by a multidisciplinary team.
Methods: We conducted a retrospective chart review of 43 patients receiving acute mechanical circulatory support (ACMS) via Impella (CP or 5.0) with or without VA-ECMO for the indications of CS during a period from 2014 to 2016 at Baystate Medical Center. In September 2015, an AMCS/CS team initiated a systematic care program based on integration of clinical, hemodynamic and echocardiographic profiling.
Results: From January 2014 to December 2016, time to device implant went from an average of 5.4 days to 3.4 days. The number of cases performed per calendar year increased from 8 in 2014 to 21 in 2016. Patient profiling, namely echocardiographic assessment, right heart catheterization and weaning trails with hemolysis surveillance, increased from 50% to 85%; 2014 and 2016 respectively. Mortality during this time trended down from 45% in 2014 to 33% in 2016. Lastly, involvement of advanced heart failure specialist increased yearly (20% in 2014 and 85% in 2016). The purpose of the study is descriptive, additional time and patient enrollment will allow for future assessment of statistical significance.
Conclusion: We aim to highlight the importance of a multi-disciplinary systematic approach to CS patients, involving both early recognition and intervention. The importance of timely invasive strategies requires expertise and coordination of care amongst cardiovascular specialties and front-line clinicians. Implementation of a multidisciplinary AMCS/CS team resulted in streamlined care and profiling of optimal patient selection allowing earlier intervention. Through longitudinal care, we were able to drastically increase the volume of patients cared for with earlier MCS intervention, ultimately providing a trend towards mortality improvement. Multi-center prospective registry data will help define clinical and socioeconomic profiles associated with myocardial recovery.

Cardiac autonomic nerves stimulation improves hemodynamics: a pilot study in advanced heart failure patients

MPC Michael Cuchiara[1]; CM Marin Y Kall[2]; JB Boehmer[3]; MC Cowie[4]; AM Mebazaa[5]; TD Diaz[6]

[1]NeuroTronik, Clinical Research, Durham, United States of America; *[2]University of Miami, International Medicine Institute, Miami, United States of America*; *[3]Milton S. Hershey Medical Center, Hershey, United States of America*; *[4]Imperial College London, National Heart and Lung Institute, London, United Kingdom*; *[5]University Paris Diderot , Paris, France*; *[6]Hospital Punta Pacifica, Panama City, Panama*

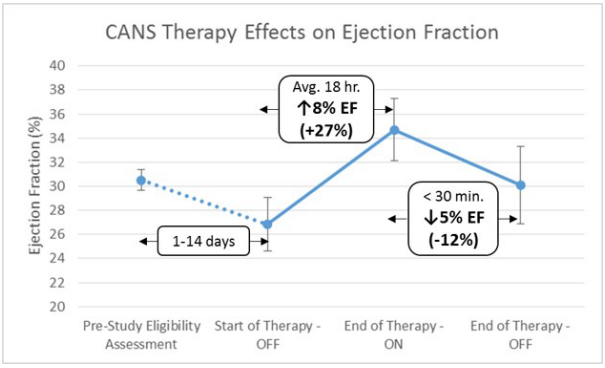
Background: Despite therapy advances in the management of heart failure, symptomatic congestion in acute heart failure is a leading cause of mortality and morbidity. An electrode catheter-based technology is being investigated to transvenously stimulate cardiac autonomic nerves to control left-ventricular contractility and heart rate (HR) in order to improve hemodynamics.

Purpose: The purpose of this study was to investigate transvenous cardiac autonomic nerve stimulation (CANS) effects on in-hospital hemodynamics and signs and symptoms of congestion.

Methods: The present study was a single-center, observational, clinical investigation of CANS. Five (5) subjects with reduced left ventricular ejection fraction (LVEF < 40%), who presented with at least two signs and symptoms of congestion were consented and enrolled. A purpose-built electrical stimulation catheter was placed percutaneously, under fluoroscopic guidance, in the left brachiocephalic vein via left subclavian vein access. A purpose-built neurostimulator was then connected to the catheter and used to deliver CANS therapy bedside, for an allowed duration up to 24 hours. Hemodynamic effects and measures of signs and symptoms of congestion were observed over the stimulation period.

Results: The majority of the subjects were male (3/5), had a mean age of 65 years, mean body mass index of 34, mean NT-proBNP of 3622 pg/mL and a mean Pulmonary Capillary Wedge Pressure (PCWP) of 30 mmHg. CANS was provided for a mean of 18 hours and was well tolerated. There were no safety concerns or adverse events reported. LVEF increased in all subjects (mean +8% from 27% to 35%) over the stimulation period. LVEF acutely decreased a mean of -5% (from a mean of 35% to 30%) in direct association with stimulation cessation. In three (3) subjects, CANS directly modulated arterial pulse pressure (12% average change) with a neutral heart rate effect (< 1% average change) over the stimulation period. PCWP decreased in all subjects (mean reduction of 10 mmHg from 30 to 20 mmHg) over the stimulation period. PCWP improvements were accompanied by improvements in dyspnea and edema from pre-study to discharge. The hemodynamic and clinical improvements occurred in the presence of minimal changes to concomitant medical therapy.

Conclusion: Alongside concomitant medical therapy, CANS directly improved hemodynamics and was associated with improved signs and symptoms of congestion in advanced symptomatic heart failure patients. These improvements, coupled with a positive safety profile, demonstrate that CANS holds promise as a tool to improve in-hospital hemodynamics and congestion. As the present study included stimulation of limited duration, in a specific patient phenotype, with a limited number of subjects, future study is warranted to investigate CANS Therapy for longer stimulation duration, in expanded patient phenotypes, in more subjects.



P473

Add-on immunoadsorption shortly-after optimal medical treatment further significantly and persistently improves cardiac function and symptoms in recent-onset heart failure

K Karolina Weinmann[1]; J Werner[1]; W Koenig[1]; W Rottbauer[1]; D Walcher[1]; M Kessler[1]

[1]University of Ulm, Department of Medicine II, Ulm, Germany

Background: Immunoadsorption and intravenous immunoglobulin administration (IVIG) can have beneficial effects in dilated cardiomyopathy patients with end-stage heart failure (HF).

Purpose: We investigated the effect of immunoadsorption with subsequent intravenous immunoglobulin (IVIG) administration on cardiac function and symptoms in patients on optimal medical heart failure treatment (OMT) with recent-onset cardiomyopathy in long-term follow-up.

Methods: Thirty-five patients with recent-onset of HF symptoms received intensive guideline-recommended medical HF therapy (OMT) for 5.2 months. Subsequently, all patients received a single cycle of immunoadsorption for five days subsequent IVIG administration. In a 28-month follow-up NYHA functional class, left ventricular ejection fraction (LVEF) and N-Terminal pro Brain Natriuretic peptide (NT-proBNP) were evaluated. Changes in quality of life (QoL) were assessed using the Minnesota Living with HF Questionnaire.

Results: During the period of 5.2 months on OMT, NYHA-class improved from median NYHA-class 3.0 to 2.0, whereas LVEF remained unchanged (LVEF 27.0%). Subsequently, all patients received immunoadsorption and subsequent IVIG administration. At first follow-up, three months after immunoadsorption treatment, NYHA-class further improved to 1.5 ($p < 0.005$) and LVEF significantly increased to from 27.0% to 39.0% ($p < 0.0001$). Long-term follow-up of 28 months showed a stable NYHA-class and a further moderate increase in LVEF from 39.0% to 42.0%

($p < 0.0001$) accompanied by a significant improvement of NT-proBNP and QoL scores.
Conclusion: Immunoadsorption and subsequent IVIG administration further enhances LVEF, HF symptoms, QoL and biomarkers in patients with recent-onset HF on optimal medical treatment.

P474
The inspection of usefulness judging from the view point of physical therapist about clinical pathway with early use of tolvaptan for congestive heart failure cases

T Teruaki Kubo[1]; K Kuroiwa[1]; H Wake[1]; J Inoue[1]; N Kajiwara[1]; K Kimura[1]; Y Kato[2]; M Hasegawa[2]; Y Nakano[2]; A Takaishi[2]
[1]Mitoyo General Hospital, Rehabilitation, Kanonji, Japan; *[2]Mitoyo General Hospital, Cardiovascular Center, Kanonji, Japan*

Background: In Japan, the patients with congestive heart failure(CHF) continue increasing rapidly in recent years. The mean age of them was usually over 80 years old, so the hospitalization period tend to be prolonged by the deterioration of dementia or lowering of activity. And they are often readmitted with exacerbation of CHF within short duration. For the resolution of these problems we introduced the original clinical pathway for CHF cases(CP) in which early use of Tolvaptan and early start of physical therapy ware provided after admission.
Purpose: We inspected the clinical usefulness about CP judging from the view point of physical therapist(PT).
Method: We enrolled 334 CHF patients admitted in our hospital between April 2011 and July 2017 who had not been admitted with CHF within past 1 year and left our hospital to own home directly(mean age 80 ± 10 years old, male/female 178/156). And we divided them to two groups, NCP-group (the cases who ware admitted before introduction of CP: 207 cases) and CP-group(the cases who ware applied CP after admission:127 cases. We investigated their characteristics and clinical course from the view point of PT and examined the difference about them between two groups.
Results: Between CP-group and NCP-group there was no difference about mean age(79.6 ± 10.2 vs 79.7 ± 10.0 years old), the ratio of male to female(95/62 vs 106/101), the prevalence of dementia(30 vs 39%) or the ejection fraction of left ventricle with echocardiography(48.3 ± 18.3 vs 50.4 ± 17.6%). In CP-group compared with NCP-group, the mean hospitalization period(15.7 ± 11.6 vs 23.8 ± 15.7 days; $p < 0.0001$) was shorter, the starting time of cardiac rehabilitation after admission was shorter(3.2 ± 1.5 vs 6.2 ± 6.1 days; $p < 0.0001$), the enforcement rate and mean duration of continuous infusion ware lower(65 vs 96%; $p < 0.0001$) and shorter(3.7 ± 2.7 vs 8.8 ± 8.6 days; $p < 0.0001$) and the enforcement rate and mean duration of urethral catheterization was also lower(41 vs 63%; $p < 0.0001$) and shorter(4.8 ± 7.6 vs 9.0 ± 8.0 days; $p < 0.0001$). In most cases of CP-group, the activities level of daily living at discharge had recovered to that before admission(99 vs 92%; $p < 0.01$). But there was not significant difference about readmission rate with CHF between CP-group and NCP-group(21 vs 31%; NS).
Conclusion: By introduction of original clinical pathway set early use of Tolvaptan and early start of rehabilitation for congestive heart failure, the enforcement of efficient medical care without waste was achieved, and this change led great shortening of their mean hospitalization period and keeping their activity level of daily living. But we could not verify the effect of prognostic improvement after discharge about this clinical pathway. We thought that the comprehensive and continuous instruction for prevention of heart failure re-exacerbation should be necessary after discharge.

P475
Multiprofessional team on acute heart failure improves short-term outcomes: results from a cohort

LCSP Luiz Carlos Passos[1]; ML Mota[2]; WN De Carvalho[2]; JCL Macedo[2]; TM Trindade[1]; VRS Souza[3]; NFC De Oliveira[4]; EOM Andrade[3]; YM Lira[4]; EL Garrido[3]; AMP De Lima[2]; AGQ De Jesus[2]; AMAF De Jesus[2]; PPC Camara[2]
[1]Federal University of Bahia, Internal Medicine, Salvador, Brazil; *[2]Ana Nery Hospital, Salvador, Brazil*; *[3]Federal University of Bahia, Faculty of Nursing, Salvador, Brazil*; *[4]Bahiana School of Medicine and Public Health, Salvador, Brazil*

Background/Introduction: Acute heart failure treatment requires specialized efforts in order to improve quality of life and reduce lethality associated to its natural prognosis. An interdisciplinary approach is one of the milestones of a high quality level of care.
Purpose: The aim of this study was to compare drug treatment and clinical outcomes before and after the initiation of a multiprofessional approach focused on acute heart failure cases in a tertiary cardiac referral centre.
Methods: Cohort data from 295 patients admitted in a tertiary cardiac referral centre for acute decompensated heart failure treatment between 2016 and 2017. Multiprofessional approach care model was defined as the initiation of a bed-to-bed clinical surveillance by a heart failure specialist staff composed by a cardiologist, a nurse and a clinical pharmacist. All the data was collected from medical records. Heart failure was defined according to the European Society of Cardiology (ESC) guidelines. All patients were submitted to a 30-day post-discharge telephone follow-up in order to investigate symptoms of decompensation, degree of drug therapy adherence and new hospitalizations or death.
Results: A sum of 295 patients was analyzed. Most of the patients were of ischaemic (34.9%) or chagasic (20.7%) etiology. Drug treatment at discharge showed significant increase over the prescription of essential heart failure pharmacologic therapy as seen by frequencies of spironolactone (56.6% vs 74.5%; $P = 0.02$), angiotensin converting enzyme inhibitor (43.4% vs 65.6; $P = 0.03$), and betablockers (77.3% vs 94.5%; $P = 0.04$). At the 30-day post-discharge telephone follow-up, patients underwent the multiprofissional approach during their hospital stay showed better therapeutic adherence (Morisky-Green scale) (75.5% vs 94.4%) and had less hospital readmissions (29.7% vs 9.4%; $P = 0.03$). Conclusion: Multiprofessional intensive surveillance significantly improved the standard of care quality as expressed by improved rates of heart failure therapy prescription and better rates of therapeutic adherence and re-hospitalizations during the shot-term post-discharge period.

P476
Clinical effectiveness and cost analysis between treatment methods of hyponatremia in acute decompensated heart failure

SP Sirait[1]; R Soerarso[1]; N Hersunarti[1]; BB Siswanto[1]
[1]National Cardiovascular Center Harapan Kita, Cardiology and Vascular Medicine, Jakarta, Indonesia

Background: Hyponatremia, defined as sodium level below 135 mEq/L, is found in 15-20% of emergency unit admissions. Hyponatremia is independently associated with adverse outcomes in patients with heart failure. High-dose diuretics for the management of congestion and edema due to heart failure may exacerbate hyponatremia caused by the loss of free water and electrolytes, including sodium and potassium. Therefore, the use of AVP receptor antagonists, which are agents that can increase free water excretion without the loss of electrolytes, may be considered in the management of heart failure. Adverse outcomes due to hyponatremia also affect health funding, and this is a potential target for intervention to decrease health costs.
Purpose: This study aims to evaluate the clinical effectiveness of treatment methods of hyponatremia in heart failure and to analyze total direct medical costs between these methods.
Methods: This is a cross sectional study in National Cardiovascular Center Harapan Kita (NCCHK) - Jakarta, Indonesia, on acute decompensated heart failure patients with hyponatremia from January 2014 until May 2017. Baseline characteristics, clinical data during hospitalization, and direct medical cost data was acquired from medical records.
Results: 128 subjects were analyzed, with 71 (55.5%) subjects treated with conventional therapy added with AVP receptor antagonist and 57 (44.5%) subjects treated with conventional therapy only. We found a significant difference ($p = 0.041$) in sodium increase after three days of therapy (median of 4 (-8 - 26) in patients receiving AVP receptor antagonist and 3 (-16 - 16) in those without), and also a significant difference ($p < 0.0001$) in length of stay (though longer in patients receiving AVP receptor antagonist, with a median of 10.50 (3-40) days, compared to 6 (3-71) days in those without). Multivariate analysis showed that day of AVP receptor antagonist initiation has the strongest correlation with length of stay ($p < 0.0001$). Partial cost analysis showed no significant difference in average daily cost with the addition of AVP receptor antagonist.
Conclusions: There is a significant difference in sodium increase after three days of therapy, yet a longer length of stay was seen in the AVP receptor antagonist group, with a strong association between length of stay and day of AVP antagonist receptor initiation. There is no significant difference in cost with the addition of AVP receptor antagonist.

P477
Shining a light on acute inpatient care experiences during an exacerbation of heart failure.

SELINA Jarvis[1]; TOM Sandford[2]; LIHUA Wu[3]; VIVEK Srivastava[1]
[1]St Thomas' Hospital, Acute Medicine , London, United Kingdom; *[2]Royal College of Nursing, London, United Kingdom*; *[3]University of Manchester, Manchester, United Kingdom*

Background: Acute Heart failure (AHF) is associated with frequent emergency hospital admissions and these may be distressing for patients. Good patient experiences have the potential to impact favourably on treatment adherence,

readmission rates and confidence after an admission. Initiatives to evaluate patient experience such as the National Patient Survey Programme (NPSP) exist but the inpatient survey asks generic questions posed which may not be relevant to patients presenting in an acute setting and are not disease tailored. Learning more about the HF patients' experience in this dynamic and acute setting may provide evidence of what is important to HF patients and help provide better care.
Purpose: (1) To understand patient experiences and care priorities during the acute inpatient stay (2) compare data acquired from qualitative interviews to a structured inpatient care experience tool, the 'AHF patient specific questionnaire (AHF-PSQ)'.

Methods: A concurrent triangulation mixed methods design was used, which included the use of qualitative semi-structured interviews to explore aspects of the acute care admission alongside data collected from the AHF-PSQ. Interviews elicited spontaneous descriptions of patient experience with AHF, which were transcribed, manually coded and a thematic analysis undertaken. In conjunction with this we compared the responses collected from the AHF-PSQ.

Results: 27 patients were interviewed with a mean (SD) age of 72.6 (12.3) yrs of age. After a thematic extraction using a hybrid method of both deductive and inductive approaches, 3 key themes that were elicited from the interviews (i) a desire to have better communication with health care staff (ii) more participation in care but through better awareness of heart failure condition and (iii) Fears about being readmitted to hospital. This data correlated with relevant items on the AHF-PSQ and also provided evidence that patients wanted more information/education about their condition and medications. 78% of patients requested more information about their 'aftercare' when leaving hospital in order to avoid readmission.
Conclusions: Qualitative approaches reveal important insight about the experiences of presenting with AHF. We also confirm that questions posed in our structured questionnaire which were deemed 'very important' to patients correlated with qualitative data. Use of a disease-focused assessment questionnaire may be a more appropriate approach to assess experience of HF patients in the acute setting which may elicit their care needs.

Acute Heart Failure - Clinical

P478
Inpatient heart failure management - cardiology participation helps improve patient care with shorter length of stay

S L Su Ling Tee[1]; GJ Ong[1]
[1]*Queen Elizabeth Hospital, Cardiology, Adelaide, Australia*

Introduction: Inpatient heart failure (HF) management is extremely complex and is often compounded by co-existing acute medical issues. Past evidence suggested that HF patients had improved outcomes when they were managed by the Cardiology team. Due to an increasing number of patients who are diagnosed with decompensated heart failure (DHF) with other acute issues in hospital, many of them are now being treated by teams other than Cardiology.
Purpose: To investigate whether admission under a different team other than cardiology would influence patient management and outcomes.
Methods: This retrospective observational study included 186 patients admitted to the local hospital over a 6-month period with a primary diagnosis of DHF under different subspecialties. Important parameters, such as length of stay, readmission rates, background medical therapy, treatment of atrial fibrillation and iron deficiency as well involvement of cardiology or heart failure nurse follow-up were obtained.
Results: Out of the 186 admissions, 133 (72%) were admitted under Cardiology. 75 (40%) of the included patients had Heart Failure with Preserved Ejection Fraction (HFpEF), 71 (38%) had Heart Failure with Reduced Ejection Fraction (HFrEF) and 24 (13%) had Heart Failure with Mid-range Ejection Fraction (HFmEF). The majority of these patients were aged 80-89 years. 127 patients (68%) had atrial fibrillation (AF), of whom 104 (82%) of them were anticoagulated. Those admitted under Cardiology had a shorter length of stay [median (interquartile range, IQR) = 5 days (IQR 3-6) vs 6 days (IQR 3-11); p = 0.02] and were more likely to receive appropriate HF therapy. In patients with HFrEF specifically, 78% (46) received cardioselective beta-blockers and 61% (35) received a mineralocorticoid receptor antagonist (MRA), compared to 58% (7) and 42% (5) (p = 0.03 and 0.01 respectively) admitted under a different team. Patients were also more likely to be followed up by HF nurse and a Cardiologist on discharge if admitted under Cardiology.
Conclusion: Inpatient HF management is challenging and optimisation of appropriate HF therapy needs further improvement. Involvement of specialist care may refine overall care with shorter length of stay and better ongoing follow up.

Medications / Follow Up	HFrEF (71)		HFmEF (24)		HFpEF (75)	
	Cardio	Others	Cardio	Others	Cardio	Others
ACE-I / ARB	49/59 (83%)	5/12 (42%)	11/20 (55%)	1/4 (25%)	28/51 (55%)	16/24 (67%)

HF Therapy - Cardiology vs Other Teams

P479
Factors influencing extended length of hospital stay in patients with heart failure with preserved ejection fraction

C Delcea[1]; CA Buzea[1]; A Dima[2]; A Tocitu[3]; A Andrus[3]; A Breha[3]; GA Dan[1]
[1]*University of Medicine and Pharmacy Carol Davila, Colentina Clinical Hospital, Bucharest, Romania*; [2]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*; [3]*Colentina University Hospital, Bucharest, Romania*

Introduction: Heart failure with preserved ejection fraction (HFpEF) is a clinical entity with increasing incidence as well as morbidity and mortality, accounting for up to 50% of patients diagnosed with heart failure. While cardiovascular mortality rates seem to be lower in this subset compared to reduced ejection fraction, the incidence and length of hospitalizations are reported to be similar.
Purpose: Our aim was to assess the clinical and biological profile of patients with HFpEF that require extended hospitalization.
Methods: We retrospectively analyzed data from HFpEF patients admitted to our clinic from January 2011 to December 2014. New patients with a cardiac ultrasound evaluation and an NTproBNP level on admission were prospectively included. We excluded patients with acute coronary syndromes, pulmonary embolism, infections. We classified patients into quartiles according to the length of stay (LOS). We defined an extended LOS a period equal to or greater than 7 days, the limit for the forth quartile.
Results: Our sample consisted of 347 HFpEF patients with a mean age of 67.1 ± 11.1 years. 219 patients (62.6%) were female. Mean length of stay was 4.78 ± 2.12 days. 59 patients (17%) had an extended LOS.
Longer LOS was observed in female compared to male patients (4.94 ± 2.27 vs 4.50 ± 1.80 days, $p = 0.05$), acute decompensated HFpEF compared to stable HFpEF (6.24 ± 2.40 vs 4.34 ± 1.83 days, $p < 0.001$), class IV HYNA compared to classes I-III (7.90 ± 2.88 vs 4.69 ± 2.03 days, $p < 0.001$), class III NYHA compared to classes I-II (5.54 ± 2.30 vs 4.43 ± 1.86 days, $p < 0.001$), atrial fibrillation (AF) compared to sinus rhythm (5.48 ± 2.37 vs 4.59 ± 2.01 days, $p = 0.001$), diabetes mellitus (DM) compared to no DM (5.36 ± 2.28 vs 4.57 ± 2.02 days, $p = 0.002$), reduced eGFR < 60ml/min compared to Egfr > 60 ml/min (5.91 ± 2.58 vs 4.55 ± 1.91 days, $p < 0.001$) and anemia vs normal hemoglobin levels (5.41 ± 2.25 vs 4.63 ± 2.07 days, $p = 0.004$).
In ROC curve analysis, NTproBNP was the best predictor for a prolonged LOS with an AUC of 0.769 (95%CI 0.729-0.809), $p < 0.001$. Other parameters with significant prognostic value were age with an AUC of 0.664 (95%CI 0.620-0.708, $p < 0.001$), hemoglobin with an AUC of 0.617 (95%CI 0.573-0.662, $p < 0.001$), and eGFR with an AUC of 0.656 (95%CI 0.614-0.698, $p < 0.001$).
In multiple logistical regression, only hemoglobin ($p = 0.023$) and NTproBNP ($p = 0.05$) were independent predictors of an extended LOS, irrespective of age, sex or NYHA class.
Conclusion: NTproBNP and hemoglobin levels on admission are independent predictors of an extended hospitalization in patients with HFpEF. Age, sex, NYHA class, AF and eGFR are also important parameters to be considered in anticipating a longer length of hospital stay.

P480

Platelet function parameters assessment by multiplate aggregometry in patients with acute coronary syndrome and heart failure

M Mirjana Isailovic-Kekovic[1]; P Kekovic[1]; S Apostolovic[2]; P Cvetkovic[2]
[1]Hospital Dr Aleksa Savic, Prokuplje, Serbia; *[2]Clinical Center of Nis, Nis, Serbia*

Background: The term acute coronary syndrome (ACS) refers to any group of clinical symptoms compatible with acute myocardial ischemia and includes unstable angina (UA), non-ST-segment elevation myocardial infarction (NSTEMI), and ST-segment elevation myocardial infarction (STEMI). Platelets play a pivotal role in atherogenesis and its thrombotic complications such as those occurring in patients with ACS which is a platelet-driven process.
Purpose: To study platelet function parameters assessment by Multplate aggregometry in patients with ACS and heart failure.
Methods: A total of 70 patients with acute coronary syndrome (ACS) (28 STEMI patients, 33 NSTEMI patients and 9 UA patients) were considered for entry into the study. Platelet function parameters-response to acetylsalicylic acid(ASPI test),clopidogrel(ADP test) and thrombin receptor activating peptide(TRAP test) were assessed by the Multiplate platelet function analyzer. We measured ratio ASPI/TRAP and ADP/TRAP (cut off value < 0.50 is for good therapy response on dual antiplatelet therapy-arachidonic acid and clopidogrel). Value of left ventricular ejection fraction (LVEF) was measured by echocardiography.
Results: 70 patients were entered into the study (45 males,25 females) .In this group were 12 patients with left ventricular ejection fraction (LVEF)= 40% and clinicaly manifest heart failure (Killip II and Killip III)-group I and 58 patients with LVEF>40%-group II.
Mean age of patients in group I was 73.00 ± 8.32,while in group II was 65.15 ± 10.26. (P < 0.05).
In I group value of ASPI test was 405.92 ± 110.75 AU*min,in II group ASPI test was 385.26 ± 210.76 AU*min. (NS). In I group value of ADP test was 641.33 ± 191.84 AU*min,in II group it was 496.22 ± 183.79 AU*min. (P < 0.05). In I group value of TRAP test was 1162.50 ± 301.55 AU*min,but in II group it was 1000.14 ± 228.96 AU*min. (P < 0.05). In I group ratio ASPI/TRAP was 0.36 ± 0.09,while in group II was 0.40 ± 0.21 (NS). In group I ratio ADP/TRAP was 0.56 ± 0.13,in group II was 0.49 ± 0.14 (P < 0.05). 53 patients have good therapy response on arachidonic acid-ASPI/TRAP < 0.5,while 35 patients have good therapy response on clopidogrel-ADP/TRAP < 0.5.
Conclusion: Patients with ACS and LVEF = 40% were oldier than patients with ACS and LVEF>40%. Patients with ACS and LVEF = 40% had higher values of ASPI,ADP and TRAP test and ratio ADP/TRAP than patients with ACS and LVEF>40%. Patients with ACS and LVEF = 40% had lower ratio ASPI/TRAP than patients with ACS and LVEF>40%.

Takotsubo syndrome as a form of an acute variant of primary microvascular angina

I A Leonova[1]; S Boldueva[1]; O Zakharova[1]; V Feoktistova[1]; A Lipunova[1]; M Kolesnichenko[1]
[1]North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation

Acute primary microvascular angina (MVA) is an unstable form, variant to acute coronary syndrome. It can occur as new-onset angina with little physical exertion or it may be characterized by recurrent attacks of pain at rest. The diagnosis is confirmed by ECG signs of myocardial ischemia appeared to regression of changes, normal coronarography (CAG) and in some cases a slight increase in cardiac enzymes. There is no doubt that in these situations should be excluded conditions such as spasm of epicardial coronary artery (CA), coronary embolism and spontaneous thrombolysis in the non-occlusive atherosclerotic plaque and other possible causes. As in the basis of acute primary MVA lies coronary microvascular dysfunction, it is needed evidence of the latter. In recent years, it expressed the view that Takotsubo (TT) cardiomyopathy refers to primary acute MVA due to generalized microvascular spasm. The proposed idea is supported by following facts: TT develops mainly in pre- and postmenopausal women, on the background of stress; patients are characterized by anxiety. Perhaps genetic polymorphisms rho-kinase are considered the causes of the general incidence of coronary vasospasm in different level of coronary vasculature. The purpose of this study to evaluate the development of various forms (acute and chronic) in patients with microvascular angina.
11192 CAG data for 2012-2017 were analyzed, of which unchanged CA were found in 12 % of cases (1343 pts.). After excluding cases of secondary MVA and type 2 myocardial infarction, 223 patients with previous diagnosis of primary MVA were selected. PET with cold test was performed to confirm the diagnosis of patients (impaired endothelium-dependent vasodilation - an increase of MBF < 25 %). Based on all diagnostic criteria in 118 patients primary MVA was diagnosed. In the analysis of the available data, it was revealed that 10 (8.5 %) patients (all women in perimenopause) were hospitalized with primary diagnosis of acute coronary syndrome. Upon further observation of patients, it was found that in 6 (5.1 %) patients myocardial infarction due to microvascular dysfunction was diagnosed, that was confirmed by the presence of hypoperfusion zones according to PET. At the same time in 4 patients (3.4%) on the basis of data of ECG, echocardiography, PET (reversible disorders of contractility and perfusion), a proved connection with severe stress situation TT syndrome was diagnosed.
Conclusion: Most patients with primary MVA have chronic form of disease, at the same time, there is less than 10 % of patients whose disease is debuted as an acute coronary event, including such variant as TT cardiomyopathy. The main pathogenetic mechanism is microvascular spasm of different severity.

P482

Inpatient management of acute decompensated heart failure (ADHF) under general medical teams remains suboptimal despite specialist input

J Mc Cambridge[1]; C Keane[1]; M Walshe[1]; P Campbell[1]; PR Kalra[2]; MR Cowie[3]; JP Riley[3]; R O' Hanlon[1]; M Ledwidge[1]; J Gallagher[1]; K Mc Donald[1]
[1]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland; *[2]Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*; *[3]Royal Brompton Hospital, London, United Kingdom*

Funding Acknowledgements: Enterprise Ireland, Boston Scientific, ResMed

Introduction: Many patients presenting with ADHF are admitted under the general medical team (GM) on call, even though it is well established that these patients have better outcomes when treated under the care of cardiologists. It is unclear if access to an inpatient HF service for GM can bridge this gap in inpatient care.
Purpose: To analyse the number of patients with ADHF admitted under GM and the differences, if any, in clinical care between these patients and those admitted under cardiology in a hospital which has a dedicated HF service.
Method: This analysis is from a single centre in an ongoing multicentre, observational study evaluating care pathways in patients admitted with ADHF. It focuses on the inpatient period; specifically, the differences in care under GM versus the cardiology/HF service. Every patient under GM had input from the HF service on a consultation basis during admission. The number and frequency of further reviews by the HF service was decided on clinical grounds. A p value < 0.05 was taken as statistically significant.
Results: A total of 114 patients were admitted with ADHF: 57 had a new diagnosis of HF (de novo, DN) and 57 had a known history of HF (recurrent admissions, RA). Of these 114 patients, 83 (73%) were admitted via the emergency department (ED). The remaining 31 (27%) were admitted directly under cardiology from the community or were transferred from another hospital/inpatient service, bypassing the ED. Of the 83 patients admitted via the ED, 60 (72%) were referred to cardiology and 23 (28%) were referred to GM. Patients referred to cardiology had an older median age (76 vs. 73, p= 0.97) and a fewer median number of comorbidities (3 vs. 4, p= 0.15) compared to patients referred to GM. Those referred to cardiology were more likely to have a background of ischaemic heart disease (50% vs. 36%, p= 0.28), whereas those referred to GM were more likely to have a background of COPD (36% vs. 13%, p= 0.02). There was no significant difference between the percentage of DN and RA admitted under GM (26% vs. 31% respectively, p= 0.62). Patients admitted under GM were more likely to spend > 24 hours in the ED (52% vs. 16%, p= 0.001), have a longer median inpatient stay (days, 8.5 vs. 6, p= 0.21) and have a time to clinical stability > 7 days (50% vs. 31%, p= 0.125) compared to those under cardiology. DN admitted medically were more likely to wait = 3 days for an echocardiogram from the time of admission compared to DN under cardiology (73% vs. 31% respectively, p= 0.012).
Conclusion: Over a quarter of patients admitted with ADHF via ED were admitted under GM in a hospital with a dedicated inpatient HF service. These patients experienced suboptimal quality of care when compared with those under cardiology, despite input from the HF service. This underlines the need for patients with ADHF to be cared for primarily under the cardiology service.

Aim: To study the impact of Cardio renal anemia syndrome (CRAS) in de novo acute heart failure (de novo-AHF) and acutely decompensated chronic heart failure (ADCHF).
Subjects & Methods: Patients were categorized into de novo-AHF patients with CRAS (A1) and ADCHF patients with CRAS (A2). Chi-square test of independence was utilized for A1 and A2.
Results: In hospital cardiogenic shock, intubation, stroke were reported almost same in both groups. In hospital major bleeding was seen more with de novo-AHF group 4.1% (25/608) p = 0.019. Mortality rate was seen slightly higher with ADCHF group 8.3% (61/735) while de novo-AHF group had 6.9% (42/608) p = 0.016.
Conclusions: In the setting of acute heart failure de novo-AHF CRAS patients were more prone towards in-hospital major bleeding compare to those ADCHF CRAS patients. Incidence of in-hospital mortality was seen higher with ADCHF CRAS patients.

Demographic and clinical characteristics

Characteristics	Cardiorenal Anemia Syndrome

Cardiogenic shock in myocardial infarction: role of beta-blocker therapy

M J Maria Joao Nobre De Matos Pereira Vieira[1]; D Durao[1]; A Belo[2]; K Domingues[1]; N Craveiro[1]; M Saraiva[1]; B Saldanha Santos[1]; M Alves[1]; M Leal[1]; RNSCA Investigadores Do Registo Nacional De Sindromes Coronarios Agudos[2]
[1]Hospital Santarém, Cardiology, Santarém, Portugal; *[2]Sociedade Portuguesa de Cardiologia, Lisboa, Portugal*

On behalf of: Registo Nacional dos Sindromes Coronarios Agudos da Sociedade Portuguesa de Cardiologia (RNSCA)

Background: Beta-blockers (BB) are one of the most widely therapy used in the context of myocardial infarction (MI). In the past its benefit was demonstrated with a significant reduction in mortality. However, in the era of percutaneous revascularization, conflicting data have emerged on the association of BB and the development of cardiogenic shock (CS).
Purpose: To evaluate the association between in-hospital BB therapy and the development of cardiogenic shock.
Methods: We performed a retrospective study including 16587 patients (age 66 ± 13 years, 74% men), from the Portuguese Registry on Acute Coronary Syndromes (RNSCA) with the diagnosis of myocardial infarction (MI) admitted between 01/10/2010 and 03/01/2018. The population was divided into two groups: Group A (A), with in-hospital oral beta-blocker therapy (n = 13635) and Group B (B), without in-hospital BB oral therapy (n = 2952). The primary outcome was the development of CS during hospital staying. Demographic, clinical, electrocardiographic, echocardiographic and angiographic data were evaluated. Multivariate analysis was conducted by logistic regression.
Results: Significant differences were observed between groups regarding age, smoking habits, previous history of diabetes mellitus, chronic kidney disease, previous myocardial infarction, type of myocardial infarction at admission, left ventricular ejection fraction, use of angiotensin-converting enzyme inhibitors (table). Cardiogenic shock was observed in 359 pts (2,2 %) with significant differences between groups (A 1,2% vs B 6,5%; OR = 0,18; P < 0,001). The use of BB therapy was also associated with lower occurrence of mechanical complications (A 0,4% vs B 1,3%; OR = 0,3; P < 0,001), lower development of congestive heart failure (A 10,7% vs B 20,1%; OR = 0,48; P < 0,001), lower need for intra-aortic balloon (A 0,3% vs B 0,9%; OR = 0,36; P < 0,001) and invasive ventilation (A 0,7% vs B 2,7%; OR:0,26; P < 0,001), lower onset of sustained ventricular arrhythmias (A 1,2 vs B 1,9%;OR = 0,41; P < 0,001), lower cardiorespiratory arrest (A 2,3 vs B 3,5%; OR = 0,63; P < 0,001) and lower all causes intra-hospital death (A1,4 vs B 7,2%; OR = 0,19; P < 0,001).
In the multivariate analysis, beta blocker was an independent predictor of CS, assuming a protective role in this setting (OR: 0,32; 95% CI: 0,23-0,45; P < 0,0001), regardless of whether the presentation was STEMI (OR: 0,18; 95% CI: 0,14-0,24; P < 0,0001) or NTEMI (OR: 0,17; 95% CI: 0,11-0,26; P < 0,0001).
Conclusions: In this study the use of BB therapy in patients with MI decrease in-hospital mortality and the incidence of CS. The benefits were observed both in STEMI and NSTEMI patients. The benefits of beta-blocker therapy were widely described in long-term follow up period studies, but its effects in in-hospital outcomes have been scarcely described.

P485
Positive stress test at myocardial scintigraphy and obstructive coronary artery disease: is associated factors match?

A N Alexey Sumin[1]; EV Korok[1]; AA Korotkevitch[1]; EN Kachurina[1]; AN Kokov[1]; OL Barbarash[1]
[1]RAMS Scientific-Research Institute for Complex Studying of Cardiovascular Diseases, Kemerovo, Russian Federation

Background: The detection rate of non-obstructive coronary arteries (CA) in patients with suspected coronary artery diseases (CAD) accounts for 58.4% according to the European registries. Recent Russian studies report the rate of 55.6%. They pay particular attention to a low performance of non-invasive stress tests before coronary angiography (CAG), while in the European and American clinical practice this figure reaches 64%. The question arises: why this does not affect the improvement of the detection of obstructive coronary artery lesions of the coronary arteries during CAG. Apparently, the relationship between the results of non-invasive tests and structural changes in the coronary arteries requires further investigations.
Purpose: To compare the factors associated with positive stress tests with single photon emission computed tomography (SPECT) and the presence of hemodynamically significant CA stenoses during invasive CAG.
Methods: The retrospective analysis included 107 patients who were examined and treated at the clinic KPSSZ Research Institute during 2012-2015 with previously diagnosed CHD or hospitalized for CHD exclusion. To identify hemodynamically significant stenoses CA all the patients underwent coronary angiography and SPECT, the time interval between the studies did not exceed 3 months.
Results: In the analysis of the studied sample observed the predominance of males, the average age of 61 year. A quarter of the patients represented by smokers, most often suffer hypertension, had angina. The typical clinical picture of angina is more common than atypical and cardialgia and angina functional class (FC) II prevailed. Myocardial infarction (MI) in history was observed in 56.1% of patients, Chronic Heart Failure - in 91.6%. Coronary revascularization in the whole group was subjected to 51.4% of patients. At the same time the average pre-test probability of the CHD presence was quite high (77 [58; 84]). Positive results of pharmacological stress testing with SPECT detected in 28% of cases, obstructive lesions of CA with invasive coronary angiography - in 56% of patients. Independent clinical predictors of a positive stress test with SPECT and significant CA stenoses were male gender and the presence of angina (with SPECT - angina FC II, and at CAG - angina IV FC). Conclusion. The results of this study it is advisable to consider when developing diagnostic approaches to identify obstructive coronary artery disease, in particular when using a stress test with SPECT.

P486
The level of C-reactive protein and major artery elasticity in patients with ischemic heart disease

O V Oleg Ilyukhin[1]; MV Ilyukhina[1]; DL Tarasov[1]; DI Dorashenko[1]; YM Lopatin[1]
[1]State Medical University, Volgograd, Russian Federation

Methods: the study included 52 patients with coronary artery disease, all men, the average age was 54 ± 1.58 years, I-III angina and functional class (FC) I-III heart failure (NYHA). Major artery elasticity was evaluated by pulse wave velocity (PWV). The reactivity of the major arteries (a. radialis) in response to increased blood flow was measured using the test with reactive hyperemia (RH). The concentration of CRP was quantified by ELISA.

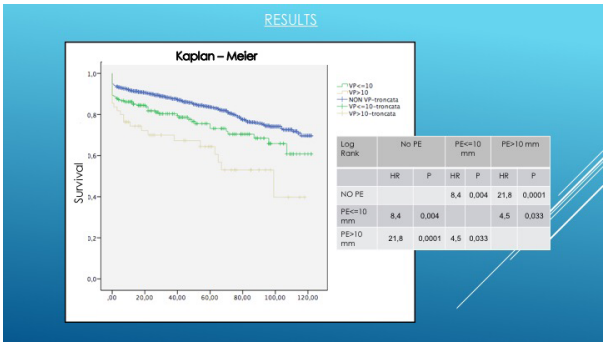
Results: the figures were compared elasticity and reactivity of the main arteries, depending on the level of CRP. A significant correlation between pulse wave velocity for elastic arteries and the concentration of CRP (r = 0.34; p = 0.018). In the study of endothelium-dependent reactivity we detected significant changes in the arteries of muscular type of reaction in response to increased blood flow in the test of the RH. See example reduction in sample, an average of CAD patients was only 12.4% in the control group and 19.7% (p < 0.05). The level of CRP was highly significant correlation with a decrease in PWV in response to increased blood flow (r = 0.49; p = 0.0005).
Conclusion: the increase in the level of CRP in blood plasma in patients with coronary artery disease may be associated with significant changes from the elasticity of the main arteries and simultaneous assessment of lipid spectrum and CRP enhances diagnostic significance of each index separately.

P487

Long term prognostic relevance of small pericardial effusion after an ST elevation myocardial infarction

S Stefano Albani[1]; L Falco[1]; D Stolfo[1]; E Fabris[1]; S Santangelo[1]; A Perkan[1]; G Sinagra[1]
[1]*Postgraduate School in Cardiovascular Sciences, Cardiovascular Department, University Hospital of Trieste, Trieste, Italy*

Background: Although the presence of moderate (<10 mm detected by echocardiography) pericardial effusion (PE) after ST elevation myocardial infarction (STEMI) increases the risk of short term mortality at 30 days, data concerning the impact on long-term prognosis of small pericardial effusion (SPE) after STEMI in the current era of primary percutaneous coronary interventions (PCI) are lacking.
Objective of the study and Methods: The aim of this study was to evaluate the potential association between different degrees of PE and long-term survival in a large cohort of STEMI patients treated with primary PCI. The presence of PE was assessed by transthoracic echocardiography within 3 days after the hospital admission.
Results: We evaluated 1728 patients affected by STEMI from 2/2007 to 3/2017, mean follow up 6,7 years. Patients were divided in 2 groups: PE group (244 patients - 14,2%) and patients without PE (NPE, 1483 patient, 85,8%). PE patients were older (67,7+/-12 vs 65 +/-12 P = 0,008), more frequent woman (31,8% vs 24% P = 0,006) more frequent they were affected by anterior MI (65,7% vs 39,8%,p = 0,0001) and less frequent inferior MI (28,5% vs 52%,p = 0,0001) compared to NPE patients. PE patients were further divided in SPE (> = 10 mm: 195 patients, 79,6%) and moderate-severe PE (MSPE) (PE > 10 mm and < = 20 mm: 43 patients, 17,6%, and PE > 20 mm: 7 patients, 2,9%). The univariate analysis showed a clear association of PE and all cause mortality (HR 1,89, IC 1,38-2,57, p < 0,0001). The only different variable between the 2 groups was the Killip class at the admission that was higher in MSPE than SPE (24,5% - 13 pts vs 10,5% - 20 pts, p < 0,008). At the multivariate analysis PE is still a risk factor for all cause mortality in patients with reduced ejection fraction (IC 95% 1,05-2,46, p < 0,027) and SPE was an independent risk factor to all cause mortality in patients with preserved ejection fraction at discharge (IC 1,20-2,51, p < 0,003). Kaplan-Meier curves for all cause mortality showed a significant worse survival for each subgroup of PE compared to NPE (log rank test, p = 0.004) and for MSPE compared to SPE (log rank test P = 0,0001)
Conclusion: The study showed that the presence of PE after primary PCI was independently associated to increase long term all cause mortality, however in a multivariate model without considering ejection fraction, also the presence of only a SMP after primary PCI was associated to increase long term mortality compared to patient without PE.



Survival Kaplan Meier curves

Coronary Artery Disease - Treatment

Frailty is associated with mortality and hemorrhagic risk in elderly patients with acute coronary syndrome

N N Nino Soseliya[1]; L Babaeva[1]; N Bagmanova[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation*

Background: Frailty is a high-priority issue in cardiovascular medicine because of the aging of patients. It reflects the complex functional disorders and is associated with high morbidity and adverse outcomes. Estimation of the risk of mortality and bleeding in patients with acute coronary syndrome (ACS) = 75 years remains ambiguous. In the widely used GRACE and TIMI scales age is one of the main factors if risk grading. The CRUSADE scale includes comorbidity, decreased glomerular filtration rate (GFR), which frequency increases with age. The aim of the study was to examination prevalence of frailty, its associations with mortality and hemorrhagic risk in elderly patients with ACS.
Methods: In 130 patients = 75 years (83 ± 5 years, arterial hypertension (AH) 92%, previous myocardial infarction (MI) 32%, atrial fibrillation 32%, diabetes mellitus 27%, chronic heart failure (HF) 77%, acute HF (Killip I - 60%, II - 29,2%, III - 10%, IV - 0,8%), left ventricular ejection fraction (LVEF) 43,1 ± 10,6%, admitted with MI (75%) or unstable angina (25%), frailty (national validated questionnaire), mortality (GRACE, TIMI scales) and hemorrhagic risk (CRUSADE scale) were assessed.
Results: Frailty was revealed in 66% of patients. 68% of patients had >140 points on GRACE scale (high mortality risk), 53% >5 points on TIMI (high mortality risk), 73% >40 points on CRUSADE (high hemorrhagic risk). Patients with frailty were more likely women (72 vs 59%; p < 0,05), had higher incidence of AH (94 vs 86%; p < 0,01), MI in this hospitalization (86 vs 55%; p < 0,05), GFR < 60 ml/min/1,73 m2 (71 vs 48%; p < 0,05). Patients with frailty had higher risk of bleeding (47 ± 10 vs 41 ± 10 points on CRUSADE scale, p < 0,001) and mortality (162 ± 36 vs 144 ± 22 points on GRACE scale, 4,9 ± 1,1vs 4,5 ± 1,1 points on TIMI scale, p < 0,001). More pronounced frailty score was revealed in patients with TIMI >5 points (3,3 ± 1,1 vs 2,5 ± 0,5 points, p < 0,001), ?RUSADE >40 points (3,1 ± 1,0 vs 2,0 ± 1,4 points, p < 0,001), ST-segment elevation MI vs unstable angina (3,5 ± 0,9 vs 2,9 ± 1,2 points, p < 0,01). Frailty score correlated with heart rate (r = 0,27), troponin (r = 0,294), GRACE score (r = 0,187), TIMI score (r = 0,216), serum creatinine (r = 0,198), urea (r = 0,194), p < 0,05 for all. Duration of hospitalization was higher in patients with frailty (9,6 ± 3,8 vs 9,1 ± 2,2 days, ?2 = 36.3, p < 0,01). In-hospital mortality occurred only in patients with frailty (1,16%), 6-month mortality was not significantly higher (24,6 vs 16,2%) in this group. Conclusion. Frailty occured in 66% of elderly patients with ACS, was associated with MI during index hospitalizathion, higher score risk of mortality and bleeding

P489

Geriatric syndromes are common and associated with ischemic and bleeding risk in elderly patients with acute coronary syndrome

N Soseliya[1]; B Lobzhanidze[1]; N Bagmanova[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation*

Background: Elderly patients with acute coronary syndrome (ACS) can experience a wide spectrum of geriatric conditions that aggravate their prognosis. Older age is universally considered as a risk factor, but geriatric conditions are not usually evaluated. The aim of the study was to assess the prevalence and associations of geriatric syndromes in elderly patients with ACS.Methods.In 130 patients = 75 years (83 ± 5 years, arterial hypertension(AH) 92%, previous myocardial infarction (MI) 32%, atrial fibrillation 32%, diabetes mellitus(DM) 27%, chronic heart failure (HF) 77%, acute HF (Killip I - 60%, II - 29,2%, III - 10%, IV - 0,8%, left ventricular ejection fraction (LVEF) 43,1 ± 10,6%, admitted with MI (75%) or unstable angina (25%) physical disability (Barthel index), functional mobility, nutritional status (Mini Nutrition Assessment), cognitive function (Mini Mental State Examination), mortality (GRACE, TIMI scales) and hemorrhagic risk (CRUSADE scale) were assessed.Results.Disorders of functional mobility were revealed in 93,1% of patients (mild 57,7%, moderate 30,8%, severe 4,6%). 13,8 and 60,8% of patients had mild and moderate physical disability of daily living. The risk of malnutrition was revealed in 53,8% of patients, two (1,5%) patients were malnourished. 31,5% of patients had cognitive dysfunction (mild 13.8%, moderate 17,7%).More pronounced cognitive dysfunction was revealed in patients with GRACE >140 points (26,6 ± 5,0 vs 29,9 ± 1,9 points, p < 0,05), with MI vs unstable angina (26,7 ± 4,9 vs 28,7 ± 3,1 points, p < 0,05), with vs without DM (25,7 ± 4,3 vs 27,7 ± 4,6 points, p 0,01). Higher physical disability of daily living was revealed in women (87,7 ± 11,1 vs 91,2 ± 11,8 points, p 0,014) patients with TIMI >5 points (86,9 ± 9,4 vs 95,2 ± 5,1, p < 0,001), ?RUSADE >40 points (89,3 ± 8,9 vs 98 ± 1,2 points, p < 0,001), MI vs unstable angina (86,8 ± 12,1

vs 95,2 ± 5 points, p < 0,001), More disorders of functional mobility had patients with GRACE >140 points (34,0 ± 3,6 vs 37,1 ± 1,2 points, p < 0,01) and ?RUSADE >40 points (34,4 ± 3,4 vs 38,2 ± 1,1 points, p < 0,01). Barthel index correlated with BMI (r = 0,19), age (r=-0,21), TIMI score (r=-0,23), troponin (r=-0,24), total cholesterol (r=-0,18), glucose (r=-0,2). There was significant correlation between cognitive function and LVEF (r = 0,31), troponin (r=-0,32), glucose (r=-0,29), total cholesterol (r = 0,2), serum creatinine (r=-0,22), hemoglobin (r=-0,2), p < 0,05 for all. Functional mobility correlated with BMI (r=-0,3), systolic blood pressure (BP) (r = 0,28), diastolic BP (r = 0,25), troponin (r=-0,29), serum creatinine (r=-0,22), hemoglobin (r=-0,2), p < 0,05 for all.Conclusion.Geriatric syndromes are common in elderly patients with ACS. Disorders of functional mobility were revealed in 93,1% of patients, physical disability of daily living in 74,6%, disorders of nutritional status in 55,1%, cognitive dysfunction in 31,5%. Geriatric syndromes were associated with MI during index hospitalization, DM, higher risk of mortality and bleeding

Impact of prior exposure to aspirin on prognosis after acute coronary syndrome: a multicenter portuguese registry

C Catarina Ruivo[1]; F Montenegro Sa[1]; L Santos[1]; J Correia[1]; J Morais[1]
[1]*Hospital Santo Andre, Cardiology, Leiria, Portugal*

On behalf of: Portuguese National Registry of Acute Coronary Syndromes

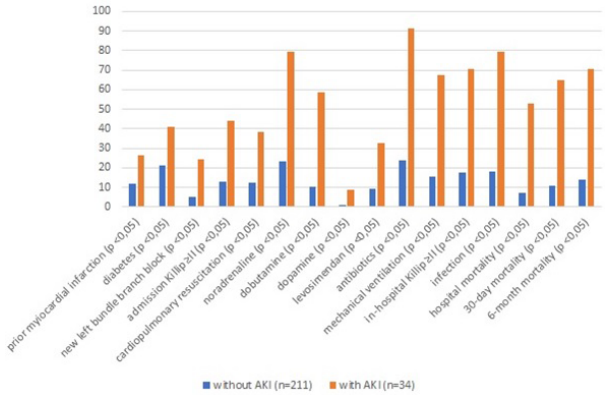
Background: Despite the known protective cardiovascular effect of aspirin, former studies identified its prior exposure to an acute coronary syndrome (ACS) as an independent risk factor for adverse events. However, those studies did not reflect contemporary approaches. In the current study, we determine whether patients exposed to aspirin before an ACS have a worse cardiovascular risk profile and if it predicts higher risk of recurrent cardiovascular events or mortality.
Methods: A cohort of patients enrolled in a national registry of ACS was analyzed according to prior exposure to aspirin. A propensity score standardized patients according to baseline comorbidities. Multivariable COX regression analysis was performed in unmatched and matched populations for a primary endpoint (composite of all-cause mortality and/or cardiovascular rehospitalization) and two secondary endpoints (all-cause mortality and cardiovascular rehospitalization, separately) at 1-year follow-up.
Results: Among 5533 ACS patients, 1763 were previously exposed to aspirin. They were older and had more comorbidities; contemporary approaches, both coronary angiography and percutaneous coronary angioplasty were less likely to be performed. Before matching the population, prior exposure to aspirin was an independent predictor of primary composite endpoint (p = 0.002) and cardiovascular rehospitalization as the secondary endpoint (p = 0.001). There were no statistically significant differences between both groups in the multivariable model for the primary or secondary endpoints after matching.
Conclusions: Previous exposure to aspirin identified ACS patients with worse baseline characteristics, establishing its role as a cardiovascular risk marker. However, our data do not support including aspirin pretreatment in risk stratification scores as an adverse prognostic variable.

P491

Acute heart failure is among significant predictors of acute kidney injury in patients with acute ST-elevation myocardial infarction

K Masnik[1]; M Mihevc[1]; A Andreja Sinkovic[2]
[1]*University of Maribor, Medical faculty, Maribor, Slovenia*; [2]*University Medical Centre Maribor, Maribor, Slovenia*

Background/introduction: Acute kidney injury (AKI) is defined as a rapid decline of renal function due to a decrease of glomerular filtration rate, followed by an increase of serum urea and creatinine. One of the most important causes of AKI in STEMI patients is myocardial necrosis, which causes systolic or diastolic dysfunction of the left ventricle leading to renal hypoperfusion and initiation of inflammation. Other risk factors for AKI are hypovolemia, dehydration, toxic effect of contrast media, nephrotoxic drugs, etc.
AKI develops in up to 30% of patients with STEMI and represents an important risk factor for complications and mortality of STEMI patients.
Purpose: The aim of our study was to evaluate the incidence of AKI in STEMI patients, its relation to the treatment outcome, and risk factors for AKI.
Methods: 245 STEMI patients (67,3% men and 32,7% women, mean age 63,9 ± 11,9 years) treated at the Department of medical ICU of University clinical centre Maribor between December 2014 and December 2015 were studied retrospectively.
AKI was defined as a 1,5-fold increase in baseline levels of serum creatinine in 24-48 hours after presentation. Heart failure was defined as Killip-Kimball classes = II. Collected data were compared using chi-squared test and t-test. Significant variables were tested in a model of binary logistic regression.
Result: Primary percutaneous coronary intervention (PPCI) was performed in 92,2% of STEMI patients. AKI developed in 13,9% of patients after PPCI.
In patients without and AKI significant difference in admission and in in-hospital acute heart failure was found. Patients with AKI had significantly more often prior myocardial infarction (MI), diabetes, new left bundle branch block, and were more likely resuscitated. They were significantly more often treated with noradrenaline, dopamine, dobutamine, levosimendan, and antibiotics. Furthermore, there was a significant difference in mechanical ventilation (MV), infection, and in-hospital, 30-day and 6-month mortality (Picture 1).
Patients with AKI in comparison to STEMI patients wihad significantly higher mean peak CRP (69,1 ± 81,8 vs. 198,9 ± 123,0 mg/L, p <0,001), mean peak NT-proBNP (881,3 ± 1186,2 vs. 2757,4 ± 1565,9 pmol/L, p <0,001), and lower ejection fraction (41,41 ± 14,9 vs. 24,34 ± 10,9%, p <0,001).
Using logistic regression, we proved prior MI (OR 8,69; 95%CI 1,82 to 41,58; p = 0,007), MV (OR 5,29; 95%CI 1,37 to 20,34; p = 0,015), infection (OR 7,15; 95%CI 2,12 to 24,05; p = 0,001), and in-hospital heart failure (OR 3,73; 95%CI 1,21 to 11,45; p = 0,021) to be the most significant independent predictors of AKI in STEMI patients.
Conclusion: AKI was observed in 13,9% of patients. Most significant independent predictors of AKI were prior MI, MV, and infection. Acute in-hospital heart failure proved to be the fourth most important predictor of AKI in STEMI patients. AKI was a significant risk factor of mortality of STEMI patients.



Significant differences in parameters

Drug-eluting balloon catheters in the endovascular treatment of patients with true left main bifurcation lesions

Z KH Shugushev[1]; D A Maximkin[1]; OO Safonova[1]; AG Chepurnoy[1]
[1]*RUDN University, Moscow, Russian Federation*

Aim: to evaluate the effectiveness of drug-eluting balloons in patients with Left Main (LM) bifurcation stenosis.
Material: 128 patients with true bifurcation lesions of the LM were included in the study. All patients underwent 'Provisional T' stenting of the LM coronary artery with the final kissing-dilatation technique. Depending on the balloon catheters used for the final kissing, the patients were randomized into 2 groups. Group I (n = 64) included patients who had a kissing-dilatation performed with traditional NC balloon catheters, and group II included patients (n = 64) who had a kissing-dilatation of the main bifurcation artery with a traditional NC balloon catheters, and a side branch - with drug-eluting balloon catheters. In addition, patients from group II also underwent kissing-predilatation with drug-eluting balloon catheters. All interventions were culminated with vascular imaging using IVUS or OCT.
Results: all patients were implanted with drug-eluting stents. Survival of patients after PCI was 100% in both groups. All interventions are performed without complications. 6-month results were analyzed in all patients. After 6-months no cases of MACE were observed. In 3 patients (4.7%), group I showed signs of new-intima hyperplasia (restenosis up to 50%), repeated interventions were not performed. 12-month results were followed in 52 patients from group I and 48 patients from group II. In 1 patient (1.9%) from group I, and 1 patient (2.1%) from group II (p> 0.05) there was a recurrence of angina. Myocardial ischemia is confirmed by stress tests, coronary angiography revealed stent restenosis up to 80%. Both patients underwent repeated interventions. Restenosis of the side branch of less than 50% according to QSA was detected in 5 patients (9.6%) from group I and in 4 patients (8.3%) from group II (p>0.05). In patients from group I, the average MLA in the side branch (LCX) after 12 months was 5.58 ± 1.34 and 4.21 ± 1.21 mm, respectively (p <0.05), compared with data after PCI; in the ostium of the side branch (LAD) - 6.34 ± 1.56 and 5.28 ± 1.14, respectively (p <0.05). In patients from Group II, the average MLA at the end of PCI and after 12 months were, respectively, 5.38 ± 1.24 and 5.11 ± 1.44 mm

for the ostium of LCX (p> 0.05) and 6.68 ± 1.75 and 6.46 ± 1.22 mm for the ostium of LAD (p <0.05). All patients had complete stent endothelization, with no signs of malapposition. There were no cases of late thrombosis of the stents.
Conclusion: the use of drug-eluting balloon catheters to perform 'Provisional T' stenting of true LM bifurcation stenoses is highly effective and safe, as evidenced by a significant low incidence of restenosis of the side branch according to intravascular imaging methods without affecting the MACE frequency and can be considered as an alternative two-stent strategy of bifurcation stenting.

P493
How do we treat patients diagnosed with Myocardial Infarction with Non Obstructive Coronary Arteries?

C Carmen Collado Moreno[1]; I Valiente-Aleman[2]; RF Garcia-Gonzalez[1]; D Castro-Sanchez[3]; S Blasco-Turrion[1]; I Lobo-Torres[1]; A Gomez-Juanatey[1]; P Gonzalez-Perez[1]; FJ Morales-Ponce[1]
[1]Puerto Real Hospital, Department of Cardiology, Puerto Real, Spain; *[2]Puerto Real Hospital, Critical Medical Medicine, Puerto Real, Spain*; *[3]University of Cadiz, Cadiz, Spain*

Background: Myocardial Infarction and NonObstructive Coronary Arteries (MINOCA) is an important subtype of MI type 1 where epicardial vessel shows a stenosis < 50%. The aim of this study is to describe prevalence, clinical features, management and prognosis of patients diagnosed with MINOCA.
Methods: A prospective observational study of patients admitted to Intensive Care Unit with diagnosis of acute MI was performed between January 1st 2007 and December 31 st 2016. Data were extracted from the ARIAM Andalucia registry. All patients underwent coronary angyography. Patients with MI and no were diagnosed as MINOCA. Follow-up data were obtained from DIRAYA.
Results: A total of 1676 patients with diagnosis of acute MI were registered but only 54 patients fulfilled inclussion criteria for MINOCA disease.
The prevalence of MINOCA was 3.2 % with a mean age of 60.59. MINOCA was more frequent in women than in men. Most frequent cardiovascular risk factors were hypertension (55.6%), smoking (51.9%) and hyperlipemia(35.2%). Median risk score GRACE was 123 ± 32.68 and CRUSADE 27.4 ± 16.07. Left ventricular ejection fraction (LVEF) was preserved in 59.39%, mildly reduced in 24.1%, moderately reduced in 11.1% and severely reduced in 5.5% patients. Preferred treatments at discharge were aspirin (96%), statins (86%), ACEI/ARBs (80%), beta-blockers (70%) and DAPT (64%). One patient died at 3 month follow-up (1.85%).
Conclusions: MINOCA disease has an important prevalence and short-term mortality. Diagnostic work-up of these patients is often suboptimal so its management is not completely accurate. Therefore more studies on etiology and management of MINOCA are needed.

P494
Does intra-aortic balloon add value to cardiogenic shock therapeutics?

D Daniela Carvalho Silva[1]; D Bento[1]; J Guedes[1]; N Marques[2]; W Santos[2]; J Mimoso[1]; P Gago[1]; I Jesus[1]; A Belo[3]
[1]Faro Hospital, Cardiology, Faro, Portugal; *[2]DCBM, UAlg, Faro Hospital, Cardiology, Faro, Portugal*; *[3]Portuguese Society of Cardiology, Lisbon, Portugal*

On behalf of: ProACS

Introduction: Cardiogenic shock (CS) is a frequent complication in acute coronary syndromes (ACS). In addition to myocardial revascularization, there are few therapeutic arms with proven efficacy in reducing in-hospital mortality (IHM), which remains high.
Purpose: To characterize, in a population of patients (P) with ACS complicated by CS, the differences between P who underwent the use of intra-aortic balloon (IAB) and those who were not, as well as the predictive factors (PF) of the use of IAB. To evaluate if the use of IAB was associated to differences in complications and IHM, in univariate (UA) and multivariate (MA) analyzes.
Methods: Retrospective, descriptive and correlational study, with P included in a national registry of ACS, between October 1, 2010 and September 19, 2017, with ACS complicated by CS. They were divided into 2 groups - in group 1 (G1) were included the P not submitted to IAB and in group 2 (G2) those that were. Baseline characteristics, acute episode, therapeutic (TX), complications and IHM were assessed in UA using SPSS 19.0. In MA, PF were evaluated for the use of IAB and if it was independent predictor of IHM and other complications.
Results: 703P, 624 (88.8%) in G1 and 79 (11.2%) in G2 were included. In UA, were associated with the use of IAB (p < 0.05): younger age; absence of history of valvular disease, heart failure, peripheral arterial disease and COPD; ACS with ST segment elevation and, among them, the anterior location; lower systolic blood pressure (SBP), hemoglobin minimum level and HDL; TX in admission with acetylsalicylic acid, clopidogrel, gp IIb / IIIa inhibitors and unfractionated heparin; TX reperfusion TX, but greater door-reperfusion and door-balloon time; coronary angiography and angioplasty; common left main (CLM) significant stenosis or culprit, anterior descending occlusion, 2-3 vessels disease, indication for myocardial revascularization surgery; CLM angioplasty; use of thrombectomy devices; lower left ventricular ejection fraction and emergent transfer to another center. There were no differences in complications or IHM. In MA, the PF of IAB use were lower diastolyc and SBP. The diagnosis of non ST elevation myocardial infarction was independent predictor of non-use of IAB. There were no differences in IHM and complications.
Conclusions: The IAB was used in younger P, with more severe presentation. There were no differences in complications and mortality. In this context, the decision on the use of IAB should be individualized.

The ASSAIL-MI trial: a Norwegian multicentre, randomised controlled trial designed to assess the effect of tocilizumab on ischaemia reperfusion injury in ST-elevation myocardial infarction

AK Anstensrud[1]; S Woxholt[2]; K Sharma[3]; K Broch[4]; B Bendz[1]; JK Damaas[2]; BH Amundsen[5]; O Kleveland[2]; AK Opdahl[4]; NE Kloew[6]; I Seljeflot[7]; G Andersen[3]; R Wiseth[2]; P Aukrust[8]; L Gullestad[1]
[1]Oslo University Hospital, Department of Cardiology, Rikshospitalet and University of Oslo, Institute of Clinical Medicine, Oslo, Norway; *[2]St Olavs Hospital, Department of Cardiology and Norwegian University of Science and Technology, Trondheim, Norway*; *[3]Oslo University Hospital, Department of Cardiology, Ullevål, Oslo, Norway*; *[4]Oslo University Hospital, Department of Cardiology, Rikshospitalet, Oslo, Norway*; *[5]St Olavs Hospital, Department of Cardiology, Trondheim, Norway*; *[6]Oslo University Hospital, Department of Radiology, Ullevål and University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; *[7]Oslo University Hospital, Ullevål and University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; *[8]Oslo University Hospital, Rikshospitalet, Oslo University Hospital, Institute of Clinical Medicine, Oslo, Norway*

Background: Interleukin-6 (IL-6) may be involved in plaque destabilisation and ischaemia-reperfusion injury following revascularisation during myocardial infarction (MI). We have recently shown that IL-6 inhibition by tocilizumab attenuates systemic inflammation and troponin T-release in patients with non-ST elevation MI (NSTEMI). Experimental studies suggest that IL-6 inhibition can also limit infarct size through anti-inflammatory mechanisms. We have recently started enrolment in the ASSAIL-MI trial, designed to address this issue in ST-elevation MI (STEMI) patients.
Purpose: To examine whether a single administration of the IL-6 receptor antagonist tocilizumab can reduce myocardial injury in patients presenting with an acute STEMI.
Methods: In this three-centre, randomised, double blind, placebo-controlled trial, 200 patients with first-time STEMI scheduled for acute PCI within 6 hours from the onset of chest pain will be randomised to receive one dose of intravenous tocilizumab or matching placebo prior to PCI. The patients will be followed-up for 6 months.
The primary endpoint is the between-group difference in the myocardial salvage index measured 3-7 days post-PCI by cardiac magnetic resonance imaging (CMR). Secondary endpoints are plasma markers of myocardial necrosis (e.g., troponins), systemic inflammation and extracellular matrix remodelling, and final infarct size at 6 months assessed by CMR. Efficacy and safety assessments during follow-up include physical examination, blood sampling, cardiac imaging and recording of clinical adverse events.
Results: Trial enrolment has started at all participating sites. Demographics of the first 40 patients are presented in Table 1.
Summary: The ASSAIL-MI trial is a randomised clinical trial designed to evaluate the effect of IL-6 inhibition on myocardial injury in patients with STEMI.

Table 1 Baseline characteristics

Age (years)	58.7 ± 8.9
Male gender	32 (80.0)
Body mass index (kg/m2)	27.6 ± 4.2
Cardiovascular risk factors	
Current smoker / former smoker	19 (47.5) /9 (22.5)
Hypertension	13 (32.5)
Diabetes mellitus	5 (12.5)

Background: The COOL AMI EU Pilot trial was a multicenter, prospective, randomized, controlled pilot trial to assess the feasibility of using intravascular therapeutic hypothermia (TH) as an adjunctive therapy to primary PCI (PPCI) in patients with anterior ST-elevation myocardial infarction (STEMI). As a secondary endpoint, we reported a non-significant, 7.1% absolute and 30% relative reduction in infarct size in the TH group. However, hypothermia patients had a longer ischemic time (IT) than controls due to non-cooling related delays from symptom onset to randomization. Since IT is an established predictor of infarct size, we aimed to further evaluate its potential impact on trial
Results: Methods: Fifty conscious patients with anterior STEMI and symptom duration < 6 hours were recruited and randomized to PPCI + TH or PPCI alone. TH was induced using an intravascular temperature management system and rapid infusion of 1L of cold saline, with a target temperature of 32 degrees Celsius. Infarct size (IS, of %LV) was measured by cardiac magnetic resonance (cMR) at 4 to 6 days post-PCI. Adjusted medians for infarct size for TH and control patients were obtained from quantile regression models with ischemic time as a covariate, and compared using the Wald test.
Results: From the 50 randomized patients, 22 in the TH and 23 in the control group completed cMR follow up. At reperfusion, mean intravascular temperature in the TH group was 33.6 +/- 1 degrees Celsius. TH patients had a significantly longer IT (mean 262 ± 79 vs 200 ± 65 minutes, P = 0.01) due to a potential chanceful longer delay from symptom onset to randomization ($p < 0.01$) . After adjustment for this imbalance, we observed a significant, 37% relative risk reduction in infarct size with an absolute decrease of 9.9% in the TH group as compared to control PPCI patients ($p < 0.05$).
Conclusions: In the COOL AMI EU Pilot Trial, following adjustment for ischemic time, therapeutic hypothermia was associated with a 37% reduction in infarct size in anterior STEMI. These results hold promise for improved clinical outcomes in patients with STEMI treated with hypothermia, and warrant a large-scale trial powered for clinical efficacy, where the risk of chanceful between-group differences are minimized.

P497

Heart failure in elderly patients after acute ST-elevation myocardial infarction

U Kostomaj[1]; A Kenk[1]; A Andreja Sinkovic[2]; V Kanic[2]; F Naji[2]
[1]University of Maribor, Medical faculty, Maribor, Slovenia; *[2]University Medical Centre Maribor, Maribor, Slovenia*

Background: The incidence of acute ST-elevation myocardial infarction (STEMI) is constantly increasing in younger than in older people, in particular in younger men. The mortality in STEMI patients is influenced by many risk factors, including time delay to treatment, the use of primary percutaneous coronary intervention (PPCI), acute heart failure, assesed by Killip class and advanced age. Predictors of mortality in elderly patients are less well known.
Purpose: To evaluate 30-day and 6-month mortality, as well as predictors of 30-day and 6-month mortality in STEMI patients older than 65 years of age.
Methods. We retrospectively included 286 STEMI patients (67.1% men, mean age 64.8 ± 11.7, age span 35 - 89 years), admitted to University clinical centre Maribor in 2016. Reperfusion strategy was primary percutaneous coronary intervention (PPCI). We evaluated demographic, clinical and mortality data of STEMI patients and compared them between older (over 65 years of age) and younger (younger than 65 years) STEMI patients, as well as independent predictors of 30-day and 6-month mortality of STEMI patients older than 65 years of age.
Results: 49% (140/286) of our STEMI patients were older than 65 years and in comparison to younger ones (< 65 years) they were significantly less likely men (54.3% vs 79.5%, $p < 0.001$), with significantly increased incidence of arterial hypertension (71.4% vs 42.5%, $p < 0.001$), prior diabetes (28.6% vs 14.4%, $p < 0.05$), increased incidence of admission bundle branch block (25.7% vs 9.6%, $p < 0.05$), in-hospital Killip classes II-IV (37.9% vs 23.9%, $p < 0.05$), multivessel coronary artery disease (31.4% vs 20.5%, $p < 0.05$) and increased 30-day (18.6% vs 8.9%, $p < 0.05$) and 6-month mortality (23.6% vs 9.6%, $p < 0.05$). There were nonsignificant differences between younger and older than 65 years in time to PPCI, the use of PPCI, anterior STEMI, TIMI flow III after PPCI and in in-hospital complications such as arrhythmias, in-stent thrombosis, reinfarctions, bleedings. However, cardiogenic shock during in-hospital treatment was most significant independent predictor of 30-day (OR 88.636, 95%CI 10.532 to 745.950, $p < 0.001$), as well as of 6-month mortality (OR 25, 95% CI 7.620 to 82.025, $p < 0.001$) of STEMI patients older than 65 years.
Conclusions: Acute heart failure - in particular cardiogenic shock - is a significant and independent predictor of short and log-term mortality in STEMI patients older than 65 years of age.

P498

Right ventricular function in patients with symptomatic aortic stenosis candidate for trans-catheter aortic valve implantation (TAVI): long term results of a single center experience

M Mara Gavazzoni[1]; E Vizzardi[1]; E Sciatti[1]; A Castiello[1]; I Bonadei[1]; R Raddino[1]; C Fiorina[1]; M Adamo[1]; S Curello[1]; M Metra[1]
[1]Civil Hospital of Brescia, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health University, , Brescia, Italy

Background: Lack of knowledge does still exist about role of right ventricular function and right ventricle-arterial coupling as prognostic parameters in patients with symptomatic aortic stenosis candidate for TAVI.
Purpose To evaluate prognostic significance of right ventricular free wall deformation imaging and right ventricular arterial-coupling in a cohort of patients with heart failure due to severe aortic stenosis candidate for TAVI.
Methods: The study is a retrospective analysis of 56 patients with aortic stenosis admitted to our department with heart failure and candidate for TAVI (mean age: 81,6 ± 6,3 years) ; follow up period was 8,5 ± 0,4 years. Left ventricular ejection fraction was preserved in most patients (median value: 51% ± 14%) . Imaging of the right ventricle was performed by echocardiography; RV function was defined on the basis of tricuspid annular plane systolic excursion (TAPSE) and its normalization for pulmonary artery systolic pressure (PASP); right ventricular free wall longitudinal strain (RVFWLS%) and its normalization for PASP; fractional area changement (FAC%), peak systolic myocardial velocity by DTI (RVSm). All-cause mortality was the primary endpoint of survival analysis; composite of death and hospitalization for heart failure was the secondary end-point.
Results: Patients in our cohort were homogeneous regard to their demographic characteristics, aortic valve degree and type of degeneration (severe degenerative aortic stenosis), type of intervention (all patients had femoral access), so these parameters were not related to long-term incidence of events. Our patients had left ventricular hypertrophy and mean ejection fraction of 51% ± 14%. After a mean follow up of 8,5 ± 0,4 years, using Cox regression analysis we found that right ventricle free wall longitudinal strain was independently associated with all-cause mortality (HR: 1,5, 95% CI: ,1,1-2,1, P= 0,011); RVFWLS (-%) (HR 7.542, 95% CI 1.325-42.921, P = 0.023), PASP (HR 1.421, 95% CI 1.045-1.932, P= 0.025), TAPSE/PASP (HR 4.977, 95%CI 5.425-21,99, P = 0.044), RVFWLS/PASP (HR 2,333, 95% CI 3,96777-12,999, P = 0.046) were independently associated with composite end-point.
Conclusions: Deformation imaging of right ventricle free wall and correction of contractility parameters for PASP provide better risk stratification at long-term follow up than other echocardiographic parameters in patients with heart failure due to severe aortic stenosis.

P499

Transcatheter aortic valve replacement (TAVR) leads to an increase in the subendocardial viability index assessed by pulse wave analysis

C Claudia Mueller[1]; G Goliasch[1]; S Schachinger[1]; S Kastl[1]; G Delle-Karth[2]; J Kastner[1]; M Gyongyosi[1]; I Lang[1]; M Gottsauner-Wolf[1]; N Pavo[1]
[1]Medical University of Vienna, Department Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]Hietzing Hospital, Department of Medicine IV, Vienna, Austria*

Background: Pulse wave analysis (PWA) is a useful tool for non-invasive assessment of central cardiac measures as subendocardial perfusion (Subendocardial Viability Index, SVI) or contractility (dP/dtmax). The immediate influence of transcatheter aortic valve replacement (TAVR) on these indices has not been investigated yet.
Methods: We prospectively enrolled 40 patients presenting with severe aortic stenosis receiving TAVR. Central pressure curves were derived from radial and

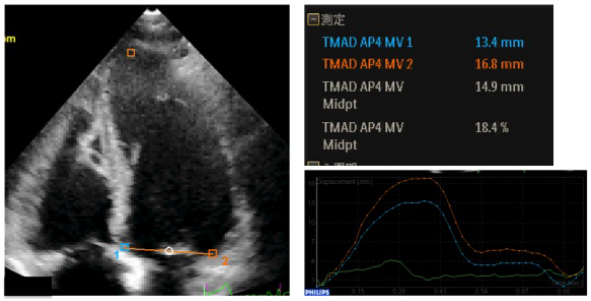
carotid sites using PWA up to 2 days before and 7 days after TAVR. Parameters were compared between peripheral measurement sites. Changes in SVI, dP/dtmax and in indices of vascular stiffness were assessed. Additionally, association of these variables with clinical outcome was evaluated during a 12-month follow-up.
Results: Central waveform parameters were comparable between measurement sites. SVI, but not dP/dtmax, augmentation Index (AIx) or augmentation pressure height (AGPH) correlated significantly with disease severity reflected by peak transvalvular velocity and mean transvalvular pressure gradient over the aortic valve (Vmax, ?Pm) [r=-0.372,p = 0.029 for Vmax and r=-0.371,p = 0.021 for ?Pm]. Vmax decreased from 4.5m/s (IQR:4.1-5.0) to 2.2m/s (IQR:1.9-2.7), (p < 0.001). This resulted in a significant increase in SVI [135.3%(IQR:115.5-150.8) vs. 140.3%(IQR:123.0-172.5),p = 0.039] and dP/dtmax [666mmHg(IQR:489-891) vs. 927mmHg(IQR:693-1092),p < 0.001], and a reduction in AIx [154.8%(IQR:138.3-171.0) vs. 133.5%(IQR:128.3-151.8),p < 0.001] and AGPH [34.1%(IQR:26.8-39.0) vs. 25.0%(IQR 21.8-33.7),p = 0.002], confirming the beneficial effects of replacing the stenotic valve. No association of these parameters could be revealed with outcome.
Conclusions: PWA is suitable for assessing coronary microcirculation and contractility mirrored by SVI and maxdP/dt in the setting of aortic stenosis. PWA parameters attributed to vascular properties should be interpreted with caution.

P500

Speckle-tracking echocardiographic mitral annular displacement can detect latent left ventricular longitudinal systolic dysfunction in patients with chronic aortic regurgitation

T Hozumi[1]; T Nishi[1]; K Terada[1]; K Takemoto[1]; S Ota[1]; M Kashiwagi[1]; K Shimamura[1]; A Kuroi[1]; T Kameyama[1]; Y Matsuo[1]; Y Ino[1]; H Kitabata[1]; T Kubo[1]; A Tanaka[1]; T Akasaka[1]
[1]Wakayama Medical University, Cardiology, Wakayama, Japan

Background: Chronic aortic regurgitation (AR) with reduced ejection fraction (EF) is one of important etiology in patients with heart failure. Previous reports using global longitudinal strain (GLS) analysis have shown left ventricular (LV) longitudinal systolic function decrease prior to reduction in EF in patients with chronic AR. Application of tissue-tracking echocardiography provides quick and easy assessment of mitral annulus displacement (TMAD) which may be used for detection of LV longitudinal systolic dysfunction alternative to GLS.
Purpose: To examine whether TMAD can be used for the detection of LV longitudinal systolic dysfunction in patients with moderate-severe chronic AR with preserved EF.
Methods: The study population consisted of 41 patients with moderate-severe AR and preserved EF (EF>50%, EF: 59±5 %, age: 61±20 years) who underwent tissue-tracking echocardiography (Philips, iE30 or EPIQ, QLAB). %TMAD from apical 4-chamber view was automatically assessed in all the study patients. GLS from apical 4-chamber, 2-chamber, and long-axis views was successfully measured in 36 of 41 patients. The final study population of the 36 patients successfully analyzed by both %TMAD and GLS was divided into two groups; 22 patients with preserved LV longitudinal systolic function (|GLS|>20%; Group-A) and 14 with more decreased LV longitudinal systolic function (|GLS| < 20%; Group-B).
Results: %TMAD was significantly lower in Group-B compared with Group-A (10.2±1.8 vs 14.5±2.1%, p < 0.01). According to ROC curve analysis, a cut-off value of %TMAD < 11.6 had a sensitivity of 100%, specificity of 77% for the presence of decreased LV longitudinal dysfunction (area under the curve: 0.94).
Conclusions: The present results showed that TMAD was useful in the assessment of LV systolic dysfunction in patients with moderate-severe AR and preserved EF. Noninvasive assessment of TMAD may be used for the detection of latent systolic dysfunction in patients with chronic AR and preserved EF.



Assessment of TMAD

P501

Left ventricular compliance and filling early after TAVI in severe aortic stenosis with marked cardiac hypertrophy

TG Thomas Gero Von Lueder[1]; P Hoffmann[2]; R Bjornerheim[1]; M Wennemo[3]; P Majak[4]; A Opdahl[2]; A Al-Ani[2]
[1]Oslo University Hospital, Department of Cardiology, Oslo, Norway; [2]Oslo University Hospital, Department of Cardiology, Division of Cardiovascular and Pulmonary Disease, Oslo, Norway, Oslo, Norway; [3]Oslo University Hospital, Department of Cardiothoracic Anesthesia, Oslo, Norway; [4]Oslo University Hospital, Department of Cardiothoracic Surgery, Oslo, Norway

Background: Left ventricular (LV) hypertrophy in aortic stenosis (AS) is associated with impaired LV relaxation, compliance and filling. While transcatheter aortic valve implantation (TAVI) unloads the LV, the effects of TAVI on these maladaptive changes is unknown.
Purpose: We studied whether TAVI would confer early improvement in LV structure, stiffness, filling pattern and relaxation.
Methods: LV dimensions, doppler velocities, and diastolic wall strain (DWS), an index of LV compliance by echocardiography in 22 patients in sinus rhythm were compared before, at day 2 after and at 3 months after TAVI using a self-expanding system.
Results: see table: Patients exhibited LV hypertrophy, low DWS and severe diastolic functional abnormalities. Three months after TAVI, E/e', an index of LV filling pressures was lower and DWS increased consistent with improved LV compliance; while no other changes in LV structure or function were observed after TAVI. LV mass index (R = 0.54), E velocity and DWS (R=-0.67; both P < 0.05) a baseline correlated with mean pressure gradient at 3 months.
Conclusions: This data in subjects with AS and a high degree of LV hypertrophy shows that cardiac unloading by TAVI improves LV filling pressures and compliance early on but does not alter other measures of LV structure, filling and relaxation. Preexisting LV hypertrophy and stiffness may be important determinants of LV diastolic function early after TAVI.

The coagulation state of patients with infective endocarditis

M Mariia Sorokina[1]; NM Povalyaev[1]; AA Andreev[1]; AS Pisaryuk[2]; JUL Karaulova[2]; EO Kotova[2]; AN Balandina[3]; DM Polokhov[3]; MA Panteleev[3]; IA Merai[4]; AS Milto[4]
[1]M.V. Lomonosov Moscow State University, Basic Medicine, Moscow, Russian Federation; [2]Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation; [3]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Laboratory of cellular hemostasis and thrombosis, Moscow, Russian Federation; [4]V.V. Vinogradov City Clinical Hospital, Moscow, Russian Federation

Background: The activity of the hemostasis system seems to be highly relevant in terms of susceptibility to progression, various complications (heart failure, embolism) and treatment of IE. The incidence of heart failure reaches 50-78% and embolic events occur in 34-56% of patients diagnosed with IE. Both of these complications are independent risk factors for mortality. The laboratory

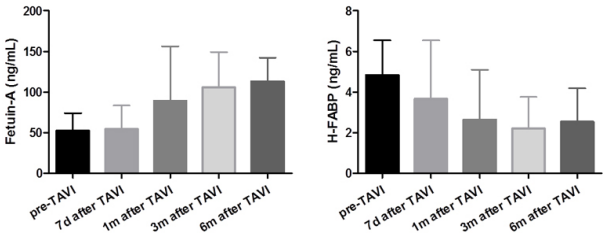
hemostasis assays are supposed to "highlight" patients shifted to hypercoagulation to prevent embolism, as a result, help clinicians to change treatment strategy in time.
Purpose: The aim of this study was to reflect the coagulation state of patients with IE via hemostasis tests in comparison with healthy individuals.
Methods: We conducted an observational study in 15 consecutive patients diagnosed with IE (patients) and in 53 healthy individuals (control group). Blood samples were collected 3-5 hours after the onset of the diagnosis. Platelet functional activity was estimated by flow cytometry, coagulation was assessed using integral assay of thrombodynamics. Mann-Whitney U-test was used for statistical analysis of the data.
Results: Platelet count in patients: median value 175*10^9/l vs 245*10^9/l in controls didn't differ significantly. Practically all platelet functions were profoundly impaired in patients diagnosed with IE according to the test of functional activity. In patients there was a significant decrease in mepacrine uptake in dense granules before activation: median value 70 vs 100 ($p < 0.001$) in healthy individuals. After inductor addition uptake was higher in patients: median 34 vs 24 ($p < 0.001$). CD62p (P-selectin) in patients with IE was significantly lower after activation: median value 82 vs 99 ($p < 0.05$). CD61 (GPIIb-IIIa) binding PAC1 antibody (possible only after platelet activation when CD61 changes its configuration) was significantly higher in endocarditis group before activation: median value 4 vs 3 ($p < 0.05$) and significantly lower after inductor addition: 51 vs 99 ($p < 0.001$) in controls. CD42b (GPIb) was significantly higher only after activation in patients: median value 69,0 vs 57,5 ($p < 0.05$). The percentage of procoagulant platelets (by detecting annexin V) was higher both before: median value 1,53 vs 0,01 ($p < 0.001$) respectively and after activation: median 13,20 vs 0,18 ($p < 0.001$) in IE patients. The granularity of platelets (SSC) before activation was significantly lower in patient: median value 72,0 vs 99,6 ($p < 0.001$). However, platelet size (FSS) in patients was similar to controls. Initial clot growth rate (Vi) in thrombodynamics was increased for patients compared to healthy individuals values: median value was 59,3 μm/min in patients with IE vs 29,0 μm/min in healthy donors ($p < 0.05$). All other parameters of thrombodynamics didn't differ.
Conclusion: Platelets functional activity in IE patients was mostly increased before activation and decreased after. Plasma coagulation reveal hypercoagulation in patients with IE via thrombodymanics.

Valvular Heart Disease - Epidemiology, Prognosis, Outcome

P503
Analysis of novel cardiovascular biomarkers in patients with severe aortic stenosis undergoing TAVI

M Mirna[1]; M Lichtenauer[1]; B Wernly[1]; V Paar[1]; C Jung[2]; UC Hoppe[1]; A Lauten[3]; PC Schulze[4]; D Kretzschmar[4]
[1]Paracelsus Private Medical University, Internal Medicine II, Cardiology, Salzburg, Austria; *[2]Medical Faculty, University Duesseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Duesseldorf, Germany*; *[3]Charite University Hospital, Cardiology, Berlin, Germany*; *[4]University Hospital of Jena, Clinic of Internal Medicine I, Jena, Germany*

Background: Novel biomarkers have recently been investigated for their use in the risk stratification of patients with heart failure and acute coronary syndrome and they show promising results in predicting patient outcome. Since transcatheter aortic valve implantation (TAVI) is associated with myocardial injury, we sought to examine wether the procedure is followed by an increase in the plasma levels of GDF-15, H-FABP, Fetuin-A, Galectin-3 and suPAR. We believe that these biomarkers might help to improve periprocedural risk stratification of patients undergoing TAVI in the future.
Methods: We collected blood samples of 79 patients with high-grade aortic valve stenosis undergoing transcatheter aortic valve implantation (TAVI) before and after the intervention (at 7 days, 1 month, 3 months and 6 months post TAVI) and analyzed the plasma concentrations of GDF-15, H-FABP, Fetuin-A, Galectin-3 and suPAR.
Results: Compared to the baseline plasma levels, there was a statistically significant increase in the median concentrations of Fetuin-A (median 53.19 ng/ml, IQR 37.38-77.11 to median 113.2 ng/ml, IQR 85.39-142.6 post TAVI, $p < 0.001$) and sUPAR (median 2758 pg/ml, IQR 2121-3665 to median 3291, IQR 2373-4177 post TAVI, $p < 0.001$). H-FABP showed a statistically significant decrease after TAVI (median 4.9 ng/ml, IQR 2.4-6.61 to median 2.21, IQR 0.76-3.8 post TAVI, $p < 0.001$). Galectin-3 and GDF-15 evidenced no significant change in serum concentration after TAVI.
Conclusion: Transcatheter aortic valve implantation was associated with a significant increase in the plasma levels of Fetuin-A and suPAR and a significant decrease in the concentration of H-FABP. In fact, it has recently been shown that the plasma levels of H-FABP and suPAR are elevated in conditions with ongoing myocardial damage and that they are associated with an increased risk for adverse events in patients with various cardiac diseases. Plasma levels of Fetuin-A have been found to be inversely associated with adverse events in coronary artery disease. The significant decrease in the concentration of H-FABP and the significant increase in the serum concentration of Fetuin-A in our cohort could be associated with a hemodynamic improvement after valve replacement. We therefore hypothesize that these novel biomarkers could add prognostic information for the individual patient and serve to improve periprocedural risk stratification of patients undergoing TAVI in the future.



P504
Echocardiography factors associated with development of late significant tricuspid regurgitation after successful left-sided valve surgery

H Ben Ayed[1]; I Zairi[1]; K Mzoughi[1]; M Jabeur[1]; W Saieb[1]; S Kraiem[1]
[1]Habib Thameur Hospital, CARDIOLOGY DEPARTEMENT, Tunis, Tunisia

Background: Persistent significant tricuspid regurgitation (TR) after successful left-sided valve surgery is frequently reported.
The aim of this study was to determine the clinical and echocardiographic factors which could impact on the development of late significant TR after successful left-sided valve surgery.
Methods: We undertook a retrospective comparative study between 1995 and 2013, including 64 patients divided in two groups, all has undergone surgery for one or double left-valve diseases with minimal TR requiring no act on it.
These patients developed during their follow-up mild to severe tricuspid insufficiency. The study group (n= 32) who developed moderate to severe TR requiring correction of valve defect were compared to a control group (n= 32) paired by the same epidemiological caracteristics but having kept a minimal and stable TR.
Results: The mean age was 48.5 ± 8.5 years with a female predominance Sex-Ratio = 0.28;
In univariate analysis, we retained as predictive preoperative factors of TR evolution, the female gender ($p = 0.002$), atrial fibrillation (AF) ($p = 0.007$), the expansion of the left atrium (LA) ($p = 0.0001$) or the Right Ventricle (RV) ($p = 0.04$) and the pulmonary arterial hypertension ($p = 0.04$). In Postoperative, in addition to precedent factors we retained the left ventricular ejection fraction ($p = 0.0001$), the tricuspid annular dilatation ($p = 0.0001$), the decrease of the TAPSE ($p = 0.0001$) and the increase of the VR Tei-index ($p = 0.0001$).
However, in multivariate analysis, we retained only 3 factors: a female gender, an AF and a LA expansion
Our study was concordant with the most published papers and meta-analysis about this subject.
Conclusion: The indication for more aggressive interventions for low-grade TR in the left valve surgery may be considered for female patients, dilated LA and AF.

P505
Impact of valve type in morbidity and mortality of a population with endocarditis

AC Ana Catarina Gomes[1]; I Cruz[1]; AI Marques[1]; S Alegria[1]; AR Pereira[1]; D Sebaiti[1]; I Rangel[1]; I Joao[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal

Background: Infective endocarditis still represents a major cause of morbimortality. The population with prosthetic valve is at increased risk of serious complications.
Methods: We analyzed the endocarditis population in our hospital in the last 10 years. The clinical and imaging data were collected as well as the complication rates and mortality data.
Purpose: To compare the clinical features and adverse outcomes of patients with native versus prosthetic endocarditis.
Results: 148 patients, 75% males, 61.5 ± 15.9 years. 51.4% with hypertension (HTN), 18.9% with diabetes mellitus (DM). The aetiology of valvular heart disease: 2 patients with previous IE (infective endocarditis), 9 with degenerative disease, 1 with congenital heart disease, 1 with rheumatic heart disease. Comorbidities:

heart failure (HF) in 27% (6.8% with HF device), pulmonary disease (PD) in 14%, chronic renal disease (CRD) in 14.9% (3.4% on haemodialysis (HD)), chronic hepatic disease (CHD) in 22.3%, HIV seropositive in 13.5%, cancer in 9.5%, 98.6% on immunosuppression (medical cause or drug-related).
76.4% with single valve endocarditis, 14.9% with double valve endocarditis. 56.8% with aortic valve disease, 39.2% with mitral valve disease and 13.5% with right valve heart disease. Native valve disease in 72.3%.
Signs at presentation: fever in 67.1%, murmur in 53.3%, anemia in 39.5%.
Echocardiographic findings: vegetation in 80.4%, abcess in 13.5%, pseudoaneurism in 4.7%, valve obstruction in 6.1%, aneurysm in 3.4%, fistula in 4.1%. Regurgitation was observed in 54.1%.
The populations were similar in terms of gender (p = 0.29), HTN (p = 0.1), DM (p = 0.16), PD (p = 0.80), CRD (p = 0.62), haemodyalisis (p = 0.32), cancer (p = 0.59), HIV infection (p = 0.06), IV drug use (p = 0.10), fever (p = 0.84) and murmur (p = 0.77) at presentation. The microrganisms were also similar between the two groups, except for Staphylococcus epidermidis infection (1.9% vs 9.8%, p = 0.05).
Although, patients with native valve disease had less HF (21.5% vs 41.5%, p = 0.02), haemorrhagic stroke (5.0% vs 44.4%, p = 0.02), aortic (49.5% vs 75.6%, p = 0.005) and right-sided valve diseases (17.8% vs 2.4%, p = 0.01), abcess (8.3% vs 30.8%, p = 0.002) and pseudoaneurism (2.1 vs 12.8%, p = 0.02).
They had more CHD (28.2% vs 7.3%, p = 0.007), vegetations (92.8 vs 74.4%, p = 0.008), regurgitation (67.7% vs 38.5%, p = 0.002) and local destructive lesions (27.1 vs 10.3%, p = 0.04).
No differences were found in survival between patients with native versus prosthetic valve endocarditis (log rank 2.5, p = 0.194).
Conclusion: Patients with native valve disease had more vegetations, local destructive lesions and regurgitation. Although, they had less HF, hemorrhagic stroke, abscess and pseudoaneurysm. Overall, the survival was similar between the two groups.

P506
Predictors of in-hospital mortality in Infective Endocarditis

AC Ana Catarina Gomes[1]; I Cruz[1]; AI Marques[1]; S Alegria[1]; AR Pereira[1]; D Sebaiti[1]; I Rangel[1]; I Joao[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Background: Infective endocarditis (IE) still represents a major cause of morbimortality in patients with valvular heart disease. The main causes of mortality are a non-controlled infection, refractory heart failure and embolic complications.
Methods: We analyzed the endocarditis population in our hospital in the last 10 years. The clinical and imaging data were collected as well as the complication rates and mortality data.
Purpose: To determine the independent predictors of hospital mortality in IE patients.
Results: 148 patients, 75% males, 61.5 ± 15.9 years. 51.4% with hypertension (HTN), 18.9% with diabetes mellitus. Aetiology of valvular heart disease: 2 patients with previous IE (infective endocarditis), 9 with degenerative disease, 1 with congenital heart disease, 1 with rheumatic heart disease. Comorbidities: heart failure (HF) in 27% (6.8% with HF device), pulmonary disease (PD) in 14%, chronic renal disease (CRD) in 14.9% (3.4% on haemodialysis (HD)), chronic hepatic disease (CHD) in 22.3%, HIV seropositive in 13.5%, cancer in 9.5%, 98.6% on immunosuppression (medical cause or drug-related).
Microorganisms identified in blood cultures: S. Aureus 23.7%, S. Epidermidis in 3.9%, Streptococcus spp in 28.3%, Enterococcus 11.8%, Gram-negative agents 3.9%, Candida spp 2.0%, others in 6.7% and no identified agent in 19.7%.
Signs at presentation: fever in 67.1%, murmur in 53.3% and anemia in 39.5%.
56.8% with aortic valve disease, 39.2% with mitral valve disease and 13.5% with right valve heart disease. Native valve disease in 72.3% and prosthetic valve disease in the remaining (6.6% with prosthetic valve less than 1 year).
Echocardiographic lesions: vegetation in 80.4%, abcess in 13.5%, pseudoaneurysm in 4.7%, valve obstruction in 6.1%, aneurysm in 3.4% and fistula in 4.1%.
The in-hospital mortality was associated with previous HF (r = 0.24, p = 0.004), HF complications (r = 0.29, p <0.001), septic shock (r = 0.428, p <0.001), S. Aureus IE (r = 0.22, p = 0.008) and abscess (r = 0.20, p = 0.018). The logistic regression showed abcess (OR 3.9, p = 0.048) and prosthetic valve implantation less than 1 year (OR 4.6, p = 0.032), as independent predictors of in-hospital mortality.
Conclusion: The main associations with in-hospital mortality were previous HF diagnosis, "de novo" HF symptoms related to IE, abscess, septic shock and S. Aureus infection. Although, after multivariate analysis, only abscess and recent prosthetic valve implantation remained as independent predictors.

P507
Significance of a new simple echocardiographic parameter for mitral regurgitation severity

A Daimon[1]; M Asakura[1]; A Goda[1]; M Sugahara[1]; K Masai[1]; T Oshita[1]; Y Ohta[1]; T Masuyama[1]
[1]*Hyogo College of Medicine, Cardiovascular Division, Nishinomiya, Japan*

Background: Generally, the severity of mitral regurgitation (MR) is evaluated with proximal isovelocity surface area (PISA) or volumetric methods. However, these methods are time consuming and there are some anatomical difficulties and limitations for the quantification of MR severity and integrated approaches using echocardiography are recommended. Recently, left ventricular early inflow-outflow index (LVEIO index), which is calculated by dividing the mitral E-wave velocity by the LV outflow velocity time integral has been proposed as a new index for evaluation of MR severity. However, its usefulness remained unclear to differentiate the severity in various etiology of MR.
Purpose: The aim of this study was to evaluate the usefulness and determine ideal threshold of LVEIO index to diagnose severe MR in different backgrounds, and we investigated whether LVEIO index can be the prognostic factor among patients with MR.
Methods and Results: We reviewed 76721 transthoracic echocardiographic reports performed at our institution from January 4, 2008 to May 15, 2015. MR severities were evaluated according to the guideline of the American Society of Echocardiography and the European Association of Cardiovascular Imaging. Cases with moderate or severe aortic valve regurgitation, any mitral stenosis, prior mitral valve surgery, congenital heart diseases, LV assist device, or any arrhythmias were excluded. Also cases with inadequate or missing LV inflow or outflow Doppler recordings were excluded. Finally we evaluated 18692 cases and classified them as 17960 of no, trivial, or mild MR (Grade 0/1), 600 of moderate MR (Grade 2), 82 of moderate to severe MR (Grade 3) and 50 of severe MR (Grade 4). The average LVEIO index of Grade 0/1, Grade 2, Grade 3 and Grade 4 were 3.6 ± 1.4, 6.0 ± 2.5, 7.4 ± 3.1 and 9.5 ± 2.8, respectively. For diagnosis of moderate to severe or severe MR, area under the curve for LVEIO was 0.93 by receiver operating characteristic analysis. The optimal threshold of LVEIO was 5.4 to distinguish moderate to severe or severe MR from non-severe MR (sensitivity 84%, specificity 91%). There were no differences in the prognostic value of LVEIO index between the cases with reduced LV ejection fraction (<50%) and preserved LV ejection fraction (= 50%), which area under the curves were 0.94 and 0.92, respectively. We checked up the etiology of MR in grade 2-4, and found that secondary MR had greater average of LVEIO than primary MR (primary MR 5.8, secondary MR 6.9, p <0.0001). In the group of LVEIO index = 5.4, the risk ratio of heart failure hospitalization was 2.7 times high compared with the group of LVEIO index < 5.4 (p = 0.009, Hazard ratio 1.75, 95%CI 1.18 to 2.58).
Conclusion: LVEIO is a simple and useful method to diagnose severe MR by using adequate thresholds regardless of LVEF and can be the predictor for heart failure hospitalization in patients with MR.

Valvular Heart Disease - Treatment

P508
The importance of heart failure with reduced ejection fraction in a cohort with infective endocarditis: a single-centre experience

CP Primus[1]; J Bragg[2]; KS Rathod[1]; K Wong[1]; R Uppal[1]; S Bhattacharyya[1]; LC Davies[1]; S Woldman[1]; MD Thomas[1]
[1]*Barts Heart Centre, London, United Kingdom*; [2]*University College London Hospitals, London, United Kingdom*

On behalf of: Barts Heart Centre Infective Endocarditis Multi-Disciplinary Team

Introduction: The 2015 ESC Guidelines on Infective Endocarditis (IE) acknowledge the importance of congestive cardiac failure (CCF) as an independent predictor of morbidity and mortality in this challenging disease. Left heart valve lesions are well known to cause CCF in IE. However, there is no published literature investigating the importance of heart failure with reduced ejection fraction (HFrEF) on outcomes in this population.
Purpose: We sought to establish the incidence of HFrEF in our IE cohort. As a cardiothoracic centre, we further sought to understand the impact of left ventricular systolic dysfunction (LVSD) on medical vs surgical management of IE and ultimately inpatient mortality.
Methods: Medical records of all patients referred to the Endocarditis Team (MDT) were reviewed (October 2015 to date). Each case was reviewed for MDT consensus of diagnosis by modified Duke's Criteria, medical vs surgical management and mortality. Echocardiographic findings were reviewed for EF in the study immediately prior to MDT decision.
Results: IE was confirmed or probable in 289 patients (male = 195) aged 56.5 years (range 16-89). Native valves were culprit in 205 patients, prosthetic in 84

patients, with concomitant device IE in 24 patients. LVEF was normal/hyperdynamic (EF>55%, range 55-81%) in 206 patients (71.3%), with LVSD (EF < 45%, range 9-45%) in 55 (19.0%) patients.
Cardiac surgery was mandated in 139 (48%) patients and device extraction in 15 (5%). The primary indication for surgery was CCF with refractory pulmonary oedema in 59 (42.4%) patients: 37 due to valvular insufficiency; 15 with decompensated LVSD; 7 in cardiogenic shock. Other important surgical indications were: a haemodynamically significant valve lesion (n = 50, 36.0%); intracardiac abscess (n = 28, 20.1%); uncontrolled infection despite appropriate antibiotics (n = 26, 18.7%).
Overall inpatient mortality was 49/289 (16.9%), of whom 19 had advanced non-cardiac medical comorbidities that precluded surgical intervention. Of the 13 surgical deaths, 6 underwent surgery for CCF. Importantly however, LVSD had no bearing on overall, nor surgical, mortality by hazard ratio (HR). There was however a trend towards increased mortality in medically managed IE with LVSD [HR 1.83 (95% CI 0.99-3.38) p = 0.053].
Discussion: Moderate to severe LVSD was seen in 19% of our large IE cohort. To our knowledge, this has not been previously reported. CCF was the primary indication for surgical intervention in 42.4% of our patients, as per published series, and is well established as an independent predictor of in-hospital and 1-year mortality. Critically however, the importance of HFrEF has not been widely discussed. Our data suggest that HFrEF does not increase mortality in those requiring surgery for IE. Further work is required to understand whether the trend in medically managed patients is a facet of HFrEF or whether aggressive HF management is required to allow early surgery in this high-risk group.

P509

Relationship among gradient and systolic function: prognosis impact after TAVR

P Pablo Meras Colunga[1]; FJ Irazusta Cordoba[1]; VA Rial Baston[1]; D Gemma[1]; R Mori Junco[1]; AM Iniesta Manjavacas[1]; O Gonzalez Fernandez[1]; A Rivas Perez[1]; A Velez Salas[1]; T Lopez Fernandez[1]; R Moreno[1]; JL Lopez Sendon[1]
[1]University Hospital La Paz, Cardiology, Madrid, Spain

Introduction: Among patients (p.) undergoing transcatheter aortic valve replacement (TAVR), some studies suggest that the presence of low gradient may associate a worse prognosis, with even more impact than the presence of ventricular dysfunction.

Table 1.

Groups	LVEF >40% Gradient >40 mmHg	LVEF >40% Gradient <40 mmHg	LVEF <40% Gradient >40 mmHg	LVEF <40% Gradient <40 mmHg
N	101	75	22	11
Age (years)	81.6 (±7.5)	81.3 (±6.2)	79.3 (±8.4)	78.4 (±9.4)
Female sex	56.4	53.3	31.8	45.5
Hypertension Diabetes Dyslipemia Chronic kidney disease / dyalisis	85.1 41.6 61.4 36 4	88 44 62.7 36.5 5.4	86.4 63.6 57.1 63.6 9.1	81.8 54.5 45.5 54.5 0
Coronary artery disease Complete revascularization	41.6 27.7	56 33.3	68.2 13.6	45.5 27.3
EuroScore II STS	3.9 ±3.3 4.4 ±3	4.4 ±3.1 4.7 ±2.6	9.9 ±7.7 5.4 ±2.1	7.8 ±4.3 6.6 ±4.1
Hospital stay (days)	13.1 ±12	15.8 ±19	13.6 ±10	17.1 ±22
Pacemaker implant Minor / major vascular complication Bleeding Heart failure	14.9 10.9 / 5 11.9 3	18.7 13.3/ 6.7 14.7 9.3	13,6 4.5 / 0 9.1 4.5	9.1 36.4 / 0 9.1 0
1-year mortality	15.8	20	18.2	0

Table 1. Baseline characteristics and main complications. Data are expressed as percentages or as mean (+/- standard deviation).

Methods: We made a retrospective analysis of 209 consecutive p. undergoing TAVR at our center, divided into 4 groups according to ventricular dysfunction (LVEF < 40%) and low mean gradients (< 40 mmHg) as measured by echocardiography.

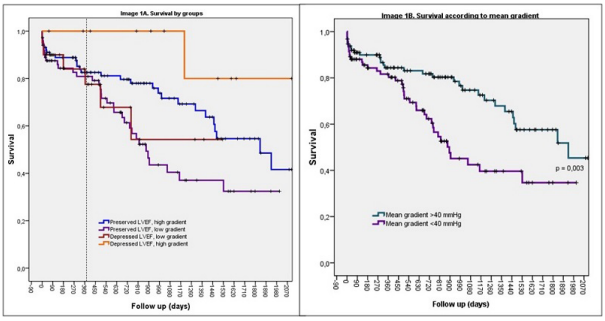


Image 1. Kaplan-Meier survival.

We analysed baseline characteristics and complications of each group, as well as survival rates with Kaplan-Meier curves.
Results: Mean age was 80,1 years, 52.2% were female, with a mean EuroScore II of 4.9% and STS of 4.8% and a mean follow up of almost two years (23.8 ± 20.3 months). Baseline characteristics and main complications are detailed in table 1.
Regarding Kaplan-Meier survival analysis (image 1), p. with low aortic gradient had a significantly higher mortality rate (p = 0.003 compared with the groups with high gradient). Importantly, this occurred both for those with preserved and depressed ejection fraction. These differences were increased after the first year of follow up.
In our series, p. with ventricular dysfunction and high aortic gradient had a good survival rate, being this finding limited by a low number of individuals in that group.
Conclusions: Our results support the presence of a worse prognosis - with higher mortality rates at follow up- in p. with aortic stenosis and low aortic gradient undergoing TAVR, and this is independent of the presence or absence of ventricular dysfunction.

P510

Do the patients with coronary artery disease have the same benefits from transcatheter aortic valve implantation?

PM Paulo Maia Araujo[1]; A Nunes[1]; S Torres[1]; M Braga[1]; R Pinto[1]; J Rodrigues[1]; RA Rodrigues[1]; PB Almeida[1]; MB Campelo[1]; JC Silva[1]; MJ Maciel[1]
[1]Sao Joao Hospital, Cardiology, Porto, Portugal

Introduction: Transcatheter aortic valve implantation (TAVI) is an effective treatment for symptomatic severe aortic stenosis, considered at high surgical risk. Coronary artery disease (CAD) is a frequent comorbidity in these patients (pts) and can influence the results of this procedure.
Purpose: To evaluate if the beneficial effects of TAVI on morbi/mortality and on the symptoms improvement are comparable in patients with or without CAD.
Methods: We retrospectively evaluated pts submitted to TAVI in our hospital between October 2014 and December 2016. All pts had symptomatic severe aortic stenosis prior to the procedure and the decision for referral for TAVI was made by a multidisciplinary Heart Team. CAD was defined as the presence of obstructive lesions (any stenosis = 70% or left main [LM] stenosis = 50%).
Results: During this period, 89 pts were submitted to TAVI, with a mean age of 80.2 ± 7.1 years, of whom 51.7% (n = 46) were female. Forty two pts (47.2%) had CAD: one vessel in 19.1%; 2 vessels in 4.5%; 3 vessels in 5.6%; involvement of LM in 33%. Of this group, 47.6% had been previously submitted to PCI and 35.7% to CABG. Additionally, in fifteen pts (35.7% of CAD group) periprocedural PCI was performed.
Baseline characteristics weren't significantly different between pts with/wihout CAD regarding to age (81.1 vs 79.5 years; p = 0.69), sex (45.2% vs 57.4% female; p = 0.25), left ventricular ejection fraction (55.0% vs 50.7%; p = 0.66), NYHA class = 2 (97.6% vs 100%; p = 0.29) or presence of angina (26.2% vs 14.9%; p = 0.19). As expected, EuroScore II was higher in CAD pts (7.8% vs 3.8%; p < 0.01).
Incidence of intra/postprocedural complications was similar between CAD pts vs no CAD: 64.3% vs 68.1% (p= 0.71). However, mean stay was higher in CAD pts (15.3 vs 12.4 days; p= 0.01). Only one patient had in-hospital mortality (no CAD).
During a mean time of follow-up of 386 ± 93 days after discharge, CAD pts had similar rates of all-causes mortality (9.8% vs 4.3%, p = 0.32), but cardiovascular mortality was tendentially higher (7.3% vs 0%), although not reaching statistical significance (p = 0.06).
CAD group had higher rates of hospitalizations: 39.0% vs 19.6% (p = 0.05).
At one year after discharge, in the CAD group, TAVI resulted in a significant reduction of angina (pre-TAVI: 26.2% vs post-TAVI 5.7%; p < 0.01) and of NYHA class = 2 (pre-TAVI: 97.6% vs post-TAVI 37.1%; p < 0.01). The proportion of pts reporting an overall improvement on functional capacity after the procedure was high, with similar rates between pts with or without CAD: 85.7% vs 76.7% (p = 0.32).

Conclusion: In this population, the presence of CAD was associated with higher morbidity and a tendency to higher cardiovascular mortality after TAVI. However, this procedure successfully improved symptoms and functional capacity in CAD group, similarly to the other pts. Therefore, TAVI has important clinical benefits even in pts with CAD.

P511

Anticoagulant strategy for prosthetic valve in patients with endocarditis does not influence anemia, preexistent heart failure and mortality

MM Monica Mariana Baluta[1]; E Panaitescu[2]; MM Vintila[3]
[1]*Carol Davila University of Medicine-St Pantelimon Clinical Emergency Hospital-Cardiology Department, bucharest, Romania*; [2]*Carol Davila University of Medicine and Pharmacy , Medical Informatics and Biostatistics, Marketing, Medical Technology , Bucharest, Romania*; [3]*St. Pantelimon Emergency Hospital, Cardiology, Bucharest, Romania*

Introduction: The type of anticoagulant therapy (ACT) used in patients with prosthetic valve endocarditis (PVE) is individualized by the endocarditis team.
Purpose: To determine the safety of anticoagulant therapy in PVE patients with anemia and prior heart failure.
Method: We analyzed 56 patients who fulfilled the modified Duke's criteria of PVE (early 29, late 27) out of which 86% with mechanical and 14% with biologic valves. At admission patients presents with anemia (Hemoglobin less than 10 g/dl) and describe various degree of dyspnea with or without congestion. PVE approach was intended to be initially conservative with surgical rescue if the patient condition requires that. We analyzed the type of ACT, clinical and paraclinical variable from patients follow up notes.
Results: Of these 56 patients, 71% were on oral anticoagulant therapy (OACT), 14% on low molecular weight heparin (LMWH), 9% were OACT-naïve during hospitalization. Aspirin was associated with OACT in 36% patients and with LMWH in 14%. The mean age of 36 men and 20 women included in this study was 54.64 ± 11.34 years (range 28-74 years) at admission. Survivors (90.4%) received antibiotics during 33.55 ± 12.8 days and 71% responds well to antibiotic therapy only. Antibiotic responders had initial Hb 9.76 ± 1.4 g/dl and deceased ones de 8.58 ± 1.38 g/dl, p = 0.07. Anticoagulant therapy was stopped in 1 case of hemorrhagic stroke and 1 episode of severe digestive bleeding. Patients that received transfusions had a higher mortality (p = 0.008). The ACT type was not related to mortality p= 0.52, neither Aspirin if associated p = 1.0 (Fisher's Exact Test). However in studied patients mortality was influenced by anemia per se at admission (p = 0.001) and further major bleeding (p = 0.007) irrespective of the ACT status. PVE type, baseline ejection fraction (EF), NYHA class or anemia, were not statistically related to hemodynamic instability. Study limitation: the sample size was small.
Conclusions: Anticoagulant therapy associated or not with aspirin was safe in patients with prosthetic valve endocarditis. Irrespective of the anticoagulant strategy type, there was no significant difference in the incidence of post admission hemorrhagic stroke and major bleeding.
Anemia degree and transfusions significantly alter the patient prognosis in term of increased mortality without a relationship with baseline EF, hemodynamic stability or NYHA class.
Anemia remains not only a marker of infection but also a strong predictor of adverse outcome without being influenced by the anticoagulant strategy.

P512

Congestive heart failure in patients with post rheumatic valvulopathies: occurrence and management in a tertiairy subsaharan centre

J C Jacques Cabral Tantchou[1]; TTJC Tantchou Tchoumi[1]; JCA Jean Claude[1]; MM Mve Mvondo[1]; GB Gianfranco[1]
[1]*St. Elizabeth Catholic General Hospital, Cardiac centre, Kumbo, Cameroon*

On behalf of: -
Funding Acknowledgements: -

The aim of the study was to investigate the occurrence, the management and challenges faced in patients with congestive heart failure in St. Elizabeth catholic general hospital Shisong, cardiac centre.
Material and Methods: Between November 2002 and November 2008, a population of 581 patients were diagnosed with congestive heart failure according to the modified Framingham criteria for the diagnosis of heart failure. Complementary investigations used to confirm and establish the aetiology of the disease were the chest X ray, electrocardiography, bi-dimensional doppler echocardiography.
Results: Congestive heart failure was diagnosed in 287 females and 294 males, aged between 9 and 76 years old (40,5 ± 15 years old). Post rheumatic valvulopathies (14,6%) and congenital heart diseases (1,9%) are the first aetiologic factor of congestive heart failure in the young, meanwhile cardiomyopathies (8,3%) in elderly followed by hypertensive cardiomyopathy (4,4%). Congestive heart failure was also seen in adults with congenital heart diseases in 0,01%. In patients with post rheumatic valvulopathies, congestive heart failure is due to left ventricular systolic dysfunction. The mean duration of hospital stay for the compensation treatment was nine days. Financial limitation is causing the exacerbation of the disease and premature death.
Conclusion: Congestive heart failure is mainly due to post rheumatic valvulopathies in young patients in our centre. National program for fight against rheumatic fever and complications are of great urgency in our country. The compensation treatment of congestive heart failure is challenging in our milieu, characterized by poor compliance and financial limitation.

Transcatheter aortic valve implantation: a real-life experience

M Marta Braga[1]; P Araujo[1]; A Nunes[1]; S Torres[1]; R Pinto[1]; J Rodrigues[1]; RA Rodrigues[1]; PB Almeida[1]; M Vasconcelos[1]; D Magalhaes[1]; JC Silva[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Background: Transcatheter aortic valve implantation (TAVI) is a therapeutic solution for patients with severe symptomatic aortic stenosis who are not candidate for conventional surgery. Despite its growth, TAVI is an invasive procedure in evolving and requires further refinement to reduce complications. The aim of this study was to describe the baseline characteristics and the short-outcomes in a cohort of patients referenced for TAVI procedure.
Methods: We retrospectively analysed data of a cohort of patients submitted a TAVI in a single centre, from October 2014 to December 2016. Data were collected from the electronic clinical process and registered in a uniform base.
Results: Of a total of 89 patients, 51.7% were female. Mean age of patients was 80.2 ± 7.1 years. The prevalence of hypertension was 82.0% and of diabetes was 34.8%. Almost half of patients had obstructive coronary artery disease and 19.1% had history of cardiac surgery. Cerebral vascular disease was present in 22.5% and peripheral artery disease was diagnosed in 21.3% of the cohort. More than half of patients met criteria of chronic kidney disease. The prevalence of chronic obstructive pulmonary disease was 11.2%. Mean euroscore II was 5.7 ± 0.5. Significant aortic calcification was present in 52.8%. Previous EKG showed first or Mobitz I second degree atrialventricular block in 74.2% of the patients and 12.3% had complete right or left branch block. Corevalve Evolute was the prothesis chosen for most patients and femoral artery was the main vascular access for the procedure. Regarding the in-hospital outcomes, 44.9% of the patients had a haemorrhagic complication peri-procedure with need of blood transfusion. Vascular complications were found in 12.4% of the patients. About 19.1% of the patients had rhythmic abnormalities requiring definite pacemaker implantation. Although 13.5% of the patients presented acute kidney failure, only 2.2% needed dialyses. Acute stroke was diagnosed in 4.5% of the patients. Moderated to severe paravalvular regurgitation was found in 2.2% of the patients. Only 1 patient died in-hospital stay.
Conclusions: Although TAVI can improve long-term outcomes of selected patients, this procedure had risks. Most TAVI complications occurred in periprocedural period and more studies are needed to understand their rate in real-world. Anticipating complications, as well as their prompt detection and management, is crucial to limiting the potential consequences of these adverse events.

P514

Evolution of Functional Mitral Regurgitation

P E Philipp Emanuel Bartko[1]; N Pavo[1]; A Perez-Serradilla[1]; H Arfsten[1]; R Wurm[1]; I Lang[1]; G Strunk[1]; J Dal-Bianco[2]; R Levine[2]; M Huelsmann[1]; G Goliasch[1]
[1]*Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria*; [2]*Massachusetts General Hospital, Institute for Heart, Vascular and Stroke Care, Boston, United States of America*

Aims:Functional mitral regurgitation (FMR) drives adverse remodeling towards late heart failure stages. Little is known about the evolution of FMR under guideline-directed therapy and its relation to cardiac remodeling and outcome. We aimed to assess incidence, impact and predictors of progressive functional mitral regurgitation in patients under guideline-directed therapy.
Methods and Results: Of 249 patients with chronic heart failure and reduced ejection fraction receiving guideline-directed therapy 81% remained stable whereas 19% had progressive FMR. Those patients were more symptomatic(P < 0.001), had higher neurohumoral activation(various neurohumoral pathways in heart failure, all P < 0.05), larger left atria(P = 0.004) and more tricuspid regurgitation(P = 0.02). During a median follow up of 61 months(IQR50-72), 61patients died. Progression of FMR conveyed an increased risk of mortality - univariately(HR 2.33; 95%CI 1.34-4.08; P = 0.003), that persisted after multivariate adjustment using a bootstrap-selected confounder model(adj.HR 2.48; 95%CI 1.40-4.39; P = 0.002). Conclusions:Every fifth patient with chronic heart failure suffers from FMR progression. This entity is associated with a more than two-fold increased risk of death even after careful multivariable

adjustment. Symptomatic status, left atrial size, tricuspid regurgitation and neurohumoral pathways help to identify patients at risk for progressive FMR in an early disease process and open the possibility for closer follow-up and timely intervention.

Funding Acknowledgements: This study was supported by Specific University Research Grant MUNI/A/0996/2017.

Introduction: Viral infections are considered the most frequent cause of myocarditis and dilated cardiomyopathy (DCM).
Material and Methods: We investigated the changes in viral presence and the impact of viral genome persistence in myocardium on echocardiographic parameters, functional status and some laboratory parameters in a 6-month follow-up. Fifty-four patients with a recent onset DCM, left ventricular ejection fraction < 40% and biopsy-proven myocarditis (<14 mononuclear leukocytes/mm2 and/or >7 T-lymphocytes/mm2) were enrolled. Polymerase chain reaction was performed to detect pathogens in myocardium. Patients were divided according to the administered therapy: standard heart failure medication (46 patients) and immunosuppressive therapy (8 patients).
Results: In the standard heart failure medication group viral clearance was observed in 13 patients and viral persistence in 24 patients in the follow-up period. Comparing both groups, there was no statistically significant difference - LVEF improvement of 12.0 ± 11.4% vs. 18.3 ± 12.6%, decrease in NYHA class of 0.7 ± 0.7 vs. 1.0 ± 0.7, decline in NT-proBNP of 1335 ± 1933ng/l vs. 1942 ± 3242ng/l and decrease in infiltrating leukocytes of 11.1 ± 15.8 vs. 6.7 ± 23.0 cells/mm2 and T-lymphocytes of 5.8 ± 15.1 vs. 1.8 ± 10.9 cells/mm2 (all p = n.s.). A decrease in PCR positive patients from 37 to 29 was observed. The number of PVB19 positive PCR findings decreased from 5 to 4 in patients with immunosuppressive therapy.
Conclusions: A decrease in the number of positive PCR findings in control EMB was observed. Viral genome persistence was not associated with worse outcome in short-term follow-up.

P516

Iron deficiency relates to neurohormonal activation in acute myocarditis

P Pawel Franczuk[1]; K Kulej-Lyko[1]; M Drozd[1]; M Tkaczyszyn[1]; N Sidorowicz[2]; I Flinta[3]; P Gac[4]; W Banasiak[2]; P Ponikowski[1]; EA Jankowska[1]

Funding Acknowledgements: This research was financially supported by the National Science Centre (Poland) grant number 2014/13/B/NZ5/03146.

INTRODUCTION: Acute myocarditis (MCD) can progress to post-myocarditis non-ischaemic cardiomyopathy (CM). Immune response is considered the major pathomechanism of progressive myocarditis. Optimal iron status is essential for the functioning of immune cells, cardiomyocytes and cardiofibroblasts. Therefore, there are premises to consider iron metabolism as a significant modulator of complex pathophysiology of MCD.
Purpose: We investigated iron status in MCD and related it to the clinical characteristics of examined patients.
Methods: We prospectively recruited consecutive patients hospitalized for MCD in a tertiary referral cardiology center in 2015-2017. According to the European Society of Cardiology position statement, all subjects had comprehensive laboratory tests, transthoracic echocardiography, cardiac magnetic resonance, and coronary angiography or coronary computed tomography angiography. Iron deficiency (ID) was defined as serum ferritin < 100 μg/l or ferritin 100-299 μg/l with transferrin saturation (TSAT) < 20%.
Results: Study group comprised of 27 patients with confirmed MCD [age: 29 (25-34) years, men: 96%, left ventricular ejection fraction (LVEF): 58 ± 7%, and left ventricular global longitudinal strain (GLS): −18% ± 2%]. First measured C-reactive protein (CRP) was 55 ± 51 mg/l, N-terminal pro-B type natriuretic peptide (NT-proBNP) - 429 (184-1130) pg/ml, high sensitivity cardiac troponin I (hs-cTnI) - 5,8 (2,2-11,7) μg/l. ID was present in 8 patients (30%), serum ferritin was 305 ± 213 μg/l, transferrin saturation - 22 ± 9%, mean soluble transferrin receptor (sTfR) - 1,2 ± 0,3 mg/l. Ferritin < 100 μg/l was present in 4% patients, ferritin 100-299 μg/l - 59%, TSAT < 20% - 48%, mean reticulocyte hemoglobin content (CHR) < 28 pg - 19%. Only 1 patient during hospitalization developed anaemia (defined as hemoglobin < 12 g/dl in women and < 13 g/dl in men). Between patients with ID and without ID there were no differences in LVEF (56 ± 8 vs. 58 ± 7%), first measured CRP 42,5 ± 30,1 vs. 59,7 ± 57,3 mg/l) and first measured hs-cTnI - [7,9 (3,5-10,3) vs. 8,3 (4,0-17,3)] μg/l. However, patients with ID had higher NT-proBNP on admission than subjects without ID [983 (278-1734) pg/ml vs. 479 (141-542) pg/ml; p = 0,04]. Patients with TSAT < 20% had higher peak NT-proBNP [1130 (371-1504) pg/ml vs. 395 (261-542) pg/ml; p = 0,02]. All patients survived hospitalization and no subject needed left ventricular assist device (LVAD).
Conclusions: ID is present in 30% patients hospitalized for MCD and relates to indices of neurohormonal activation. Follow-up of these patients is needed to compare long-term outcomes (i.a. the development of CM) according to the presence of ID during hospitalization.

Role of myocardial fibrosis in hypertrophic cardiomyopathy: A systematic review and updated meta-analysis of risk markers for sudden death

MI Marcelo Imbroinise Bittencourt[1]; SA Cader[1]; DV Araujo[1]; ALF Salles[1]; FN Albuquerque[1]; PPM Spineti[1]; DC Albuquerque[1]; R Mourilhe-Rocha[1]
[1]State University of Rio de Janeiro, Cardiology, Rio de Janeiro, Brazil

Background: Hypertrophic cardiomyopathy (HCM) is associated with sudden death (SD). Myocardial fibrosis is reportedly correlated with SD in these patients.
Purpose We performed a systematic review with meta-analysis, updating the risk markers (RMs) in HCM emphasizing myocardial fibrosis.
Methods: We reviewed HCM studies that addressed severe arrhythmic outcomes (SD, aborted SD, documented sustained ventricular tachycardia, or appropriate shock in patients with ICD) and the certain RMs: SD family history, severe ventricular hypertrophy, unexplained syncope, non-sustained ventricular tachycardia (NSVT) on 24-hour Holter monitoring, abnormal blood pressure response to exercise (ABPRE), and left ventricular outflow tract obstruction (LVOTO) in the MEDLINE, LILACS, and SciELO databases. We used relative risks (RRs) as an effect measure and random models for the analysis.
Results: Twenty-one studies were selected (14,901 patients aged 45 ± 16 years; men, 62.8%). Myocardial fibrosis was the major RM correlated with severe arrhythmic outcomes (RR, 3.43; 95% CI, 1.95-6.03). The other RMs, except for LVOTO, were also predictors: SD family history (RR, 1.75; 95% CI, 1.39-2.20), severe ventricular hypertrophy (RR, 1.86; 95% CI, 1.26-2.74), unexplained syncope (RR, 2.27; 95% CI, 1.69-3.07), NSVT (RR, 2.79; 95% CI, 2.29-3.41), and ABPRE (RR, 1.53; 95% CI, 1.12-2.08).
Conclusions: We confirmed the association of myocardial fibrosis and other RMs with severe arrhythmic outcomes in HCM and emphasize the need for new prediction models in managing these patients.

BNP in patients with hypertrophic cardiomyopathy: results of a national registry

E Elisabete Bernardes[1]; A Lebreiro[2]; A Sousa[1]; S Leite[3]; C Sousa[2]; A Belo[4]; BY Hypertrophic Cardiomyopathy Registry Investigators[4]
[1]University of Porto, Faculty of Medicine, Porto, Portugal; *[2]Sao Joao Hospital, Cardiology, Porto, Portugal*; *[3]Hospital Guimaraes, Cardiology, Guimaraes, Portugal*; *[4]Centro Nacional de Coleção de Dados, Coimbra, Portugal*

Introduction: In hypertrophic cardiomyopathy (HCM), plasma levels of B-type natriuretic peptide (BNP) have been associated with different parameters of left ventricle remodeling and clinical outcomes. A major issue is to understand if the occasional measurement of BNP in HCM is more dependent of the morpho-functional disease parameters (due to ongoing slow progressive disease mechanisms) or are mostly related with the acute condition of the patient (such as transient higher intraventricular pressure) at the time of blood collection.
Objective: In this study, we sought to determine if BNP measured in an occasional blood sample maintains any correlation with clinical parameters and if the associations are affected by the body mass index (BMI) in HCM patients.
Methods: We analyzed data from the National Registry of adults with HCM. All the included patients have BNP measurements, and the highest concentration of BNP was the value considered for the associations with clinical variables.
Results: Among 247 HCM patients, 57% males, 94% had asymmetrical LV hypertrophy, 38% intraventricular gradient, 16% moderate-severe mitral insufficiency, 68% symptoms at first consultation and 24% BMI >30. BNP correlated with age at diagnosis ($r = 0,300$; $p = 0,000$), left atrium diameter ($r = 0,292$; $p = 0,000$) and volume ($r = 0,353$, $P = 0,003$), septum ($r = 0,172$; $p = 0,008$) and posterior wall thickness ($r = 0,177$; $p = 0,007$) and the number of hypertrophied segments ($r = 0,303$; $p = 0,009$). BNP was negatively correlated with body surface area ($r=-0,273$; $p = 0,000$) but not with BMI. BNP also didn't correlate with intraventricular gradient.
Conclusion: Our results reinforce the usefulness of BNP measurement as a marker of LV remodeling in HCM, particularly the parameters related to LV hypertrophy and left atrium dilatation. BMI seems to not significantly affect these associations.

The impact of hypertension overlapping on hypertrophic cardiomyopathy

TCP Gil[1]; MB Castier[1]; AFP Gondar[1]; ALF Sales[1]; RM Rocha[1]
[1]State University of Rio de Janeiro (UERJ), FCM- Pedro Ernesto University Hospital , Rio de Janeiro, Brazil

Funding Acknowledgements: FAPERJ

Background: The differential diagnosis between hypertensive heart disease and hypertrophic cardiomyopathy (HCM) in general is not dificult. But many patients with HCM have systemic arterial hypertension associated. Assessing the magnitude of this association is fundamental to prognosis.
Objective: Compare HCM patients with and without systemic arterial hypertension associated.
Methods: In a sectional study, 45 HCM patients were consecutively recruited from Pedro Ernesto University Hospital / State University of Rio de Janeiro (22 males, mean age 45 + 14 years). 14 of these had systemic arterial hypertension. The diagnosis of HCM was confirmed by magnetic resonance imaging. The echocardiographic transthoracic studies were performed (iE-33 Matrix, Philips), using QLAB software. The main parameters related to the differential diagnosis between these diseases were evaluated. Two-dimensional echocardiography assessed left ventricular outflow tract obstruction, diastolic function and myocardial deformation through the global longitudinal strain (GLS). Left atrial volume and left ventricular mass were analyzed by three-dimensional echocardiography. The statistical software package R (version 3.2.4) was used to compare the averages (t test).
Results: No significant difference was observed between the groups concerning gender, age and body surface area. The mean systolic and diastolic pressures were higher in the group of hypertensive patients ($p < 0.05$). No differences were observed between the groups in relation to left ventricular outflow obstruction, diastolic function, left ventricular mass and left atrial volume. GLS had lower mean values in hypertensive group ($p = 0.03$).
Conclusion: Although the mean blood pressures were higher in the group of hypertensive patients, no significant difference was observed between the groups in relation to ventricular mass, left atrial volume and diastolic function, parameters directly influenced by arterial hypertension. The mean lower GLS in hypertensive patients reflects a worse systolic function and may represent a factor of poor prognosis. Prospective studies are needed for a better evaluation.

P520

Predictors of ACEI/ ARB therapy in patients with hypertrophic cardiomyopathy: results of a national registry

E Elisabete Bernardes[1]; A Lebreiro[2]; C Sousa[2]; S Leite[3]; A Sousa[1]; A Belo[4]; BY Hypertrophic Cardiomyopathy Registry Investigators[4]
[1]University of Porto, Faculty of Medicine, Porto, Portugal; *[2]Sao Joao Hospital, Cardiology, Porto, Portugal*; *[3]Hospital Guimaraes, Cardiology, Guimaraes, Portugal*; *[4]Centro Nacional de Coleção de Dados, Coimbra, Portugal*

Introduction: Angiotensin-converting enzyme inhibitors (ACEI) and angiotensin II receptor blockers (ARB) are not considered disease-modifying drugs in hypertrophic cardiomyopathy (HCM) and their use is usually dependent on other clinical indications. Few data exist about the use of ACEI/ARB in HC in the real world, particularly in patients with intraventricular obstruction.
Objective: In this study, we sought to determine the frequency of ACEI / ARB therapy in patients with HCM and the predictors for their use.
Methods: We analyzed data of patients included in a large National Registry of adults with HCM and evaluated the associations of ACEI/ARB therapy with different clinical and echocardiographic variables.
Results: Among 1021 patients with HC, 397 (39%) were medicated with ACEI and/or ARB. Of these, the majority had hypertension (85%) and asymmetric left ventricular (LV) hypertrophy (86%), 38% had an intraventricular dynamic obstruction and 10% had LV systolic dysfunction. Symptoms of heart failure at first visit were present in 67% of those under ACEI/ARB and concomitant coronary heart disease was present in 9.2%. In multivariate analysis, the use of ACEI / ARB was associated with the presence of hypertension ($b= 4,44$; $P = 0,00$) and LV systolic dysfunction ($b = 1.86$; $p = 0.04$), and negatively related with intraventricular gradient ($b=-0,95$; $p = 0,02$) and abnormal blood pressure response in treadmill test ($b=-1,09$; $p = 0,04$).
Conclusion: Even in the absence of specific recommendations, ACEI / ARB are frequently used in patients with HCM, including in the presence of an intraventricular gradient, suggesting good tolerability. The main factors favoring their use in clinical practice are the coexistence of hypertension and LV systolic dysfunction.

Beneficial effects of immunoadsorption in dilated cardiomyopathy patients revealed by meta-analysis

M Noutsias[1]; M Ali[1]; M Teren[1]; M Matiakis[1]; S Sakellaropoulos[1]; AG Rigopoulos[1]
[1]University Clinic Halle (Saale), Mid-German Heart Center, Department of Internal Medicine III (KIM-III), Division of Cardiology, Halle, Germany

Introduction: Humoral anticardiac autoimmunity is involved in the pathogenesis of dilated cardiomyopathy (DCM). Several anticardiac autoantibodies have been identified in DCM patients. Immunoadsorption (IA), aiming at elimination of autoantibodies, may be a promising immunomodulatory regimen in DCM.
Methods: Using standardized literature search modes, n = 100 publications referring to IA treatment in DCM patients were retrieved. Out of these, n = 18 publications prospective investigations with >8 DCM patients met the inclusion criteria of the meta-analysis, encompassing n = 528 DCM patients and n = 145 control patients.
Results: The demographic and clinical data of the n = 528 patients of the 18 included publications were as follows at baseline before IA: age: 51.5+3.1 years; men: n = 431 (81.6%); history of DCM: 51.4+20.8 months; LVEF: 25.6+4.6%; LVEDD: 69.8+3.2 mm. Histological analyses of endomyocardial biopsies (EMB) were available in n = 6 investigations / n = 84 patients, and were entirely negative for active myocarditis. In one study, IA was accompanied by a significant decrement of immunohistologically quantified intramyocardial infiltrates and HLA expression in DCM patients. Virological analyses of EMB were available in n = 6 publications / n = 292 patients, and viral genomes as detected by PCR were reported in n = 60 (20.5%) of these patients. After five courses of IA, the immunoglobulin levels decreased significantly from 10.7+0.8 to 1.1+0.5 g/l ($p < 0.0001$). Follow up analyses were carried out at a median of 4.5 months (interquartile range: 3-6 months). LVEF rose to 32.0+6.3% ($p = 0.0015$), and LVEDD decreased to 63.9+1.2 mm ($p = 0.0011$). NYHA functional class decreased from 2.9+0.4 to 1.9+0.2 ($p < 0.0001$). A significant decrease of indices of oxidative stress after IA was determined in DCM patients in one of the included studies. A substantial relative reduction of the 5-year mortality by 41% was reported in one prospective trial in IA treated DCM-patients compared to controls.
Conclusions: This meta-analysis on n = 528 DCM patients under IA, which reduces significantly immunoglobulin levels, summarizes several beneficial clinical effects: Significant improvement of LVEF, of NYHA functional class, and decrement of LVEDD. Further, reduction of intramyocardial inflammation and of oxidative stress, as well as reduction of mortality were published in some investigations. These results may be prone to general error sources underlying meta-analyses (e.g. publication and selection bias). A multi-center, randomized IA trial is warranted to foster the

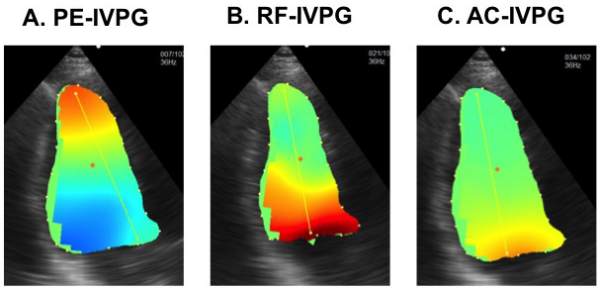
evidence on the clinical and prognostic benefits of IA in DCM, and to furthermore elucidate the profiles of "responders" versus "non-responders".

P522

Noninvasive assessment of intra-ventricular pressure gradients estimated by vector flow mapping in patients with dilated cardiomyopathy

T Hozumi[1]; Y Nozawa[1]; T Nishi[1]; K Takemoto[1]; S Ota[1]; M Kashiwagi[1]; K Shimamura[1]; A Kuroi[1]; T Kameyama[1]; Y Matsuo[1]; Y Ino[1]; H Kitabata[1]; T Kubo[1]; A Tanaka[1]; T Akasaka[1]
[1]*Wakayama Medical University, Cardiology, Wakayama, Japan*

Background: Previous studies have reported that there are intraventricular pressure gradients (IVPG) between left ventricular (LV) base and apex during diastole and between LV apex and outflow tract during systole using invasive catheter method and noninvasive color M-mode echocardiography. However, IVPG has not been widely measured in the clinical practice because it requires invasive process or non-commercially available software. Recent introduction of vector flow mapping (VFM) using combination of color Doppler and tissue Doppler echocardiography provides noninvasive assessment of IVPG which may be used as additional index for LV function in patients with dilated cardiomyopathy (DCM).
Purpose: To examine characteristics in IVPG assessed by VFM in patients with DCM compared with healthy subjects with preserved EF.
Methods: The study population consists of 45 subjects; 27 subjects with DCM (Group-D, EF: 32 ± 8%), 18 healthy subjects with preserved EF (Group-C, EF: 63 ± 3%). Patients with segmental wall motion abnormalities, significant valvular diseases, and arrhythmia were not included in this study population. Apical long-axis views were recorded by color Doppler echocardiography(Prosound F 75 and a10, Hitachi, Japan. Peak IVPG between apex and LV outflow tract during pre-ejection period (PE-IVPG, figure A), peak IVPG between mitral annulus and apex during rapid filling period (RF-IVPG, figure B), and atrial contraction period (AC-IVPG, figure C) were assessed using commercially available VFM analysis software (DAS-RS1, Hitachi).



IVPG measurement by VFM

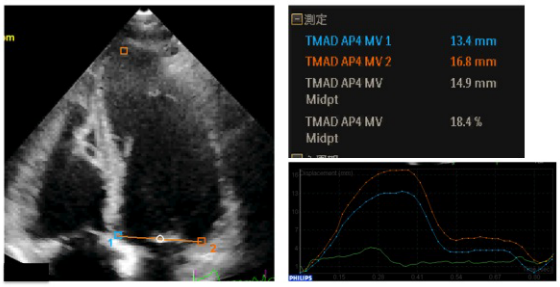
Results: 1) PE-IVPG in Group-D was significantly lower than that in Group-C (0.95 ± 0.56 vs 1.34 ± 0.48 mmHg, $p < 0.05$).
2) RF-IVPG in Group-D was significantly lower compared with that in Group-C (0.65 ± 0.37 vs 2.33 ± 1.11 mmHg, $p < 0.01$).
3) AC-IVPG in Group-D was significantly lower compared with that in Group-C (0.62 ± 0.43 vs 0.89 ± 0.30 mmHg, $p < 0.05$).
Conclusions: VFM analysis showed that IVPG during pre-ejection, rapid filling, and atrial contraction period were lower in patients with DCM compared with healthy subjects with preserved EF. The present results suggest that noninvasive IVPG estimated by VFM can be used as additional index for LV function in patients with DCM.

P523

Noninvasive assessment of left ventricular longitudinal systolic dysfunction in patients with dilated cardiomyopathy by speckle-tracking echocardiographic mitral annular displacement

T Hozumi[1]; K Terada[1]; T Nishi[1]; K Takemoto[1]; S Ota[1]; M Kashiwagi[1]; K Shimamura[1]; A Kuroi[1]; T Kameyama[1]; Y Matsuo[1]; Y Ino[1]; H Kitabata[1]; T Kubo[1]; A Tanaka[1]; T Akasaka[1]
[1]*Wakayama Medical University, Cardiology, Wakayama, Japan*

Background: Severely decreased left ventricular (LV) global longitudinal strain (GLS) obtained from 3 apical echocardiographic views has been reported to be a prognostic index in patients with reduced LV ejection fraction (EF) including dilated cardiomyopathy (DCM). Mitral annular displacement by speckle-tracking echocardiography (TMAD) from single 4-chamber view provides quick assessment of LV longitudinal systolic dysfunction in patients with preserved EF. However, it remains whether this simple index can be used as an alternative index to GLS in patients with DCM.
Purpose: To evaluate whether TMAD from single view can be used for the assessment of LV longitudinal systolic dysfunction alternative to GLS in patients with DCM.
Methods: The study population consists of 39 patients with DCM (Group-D, age: 60 ± 12 years, EF: 31 ± 5%) and 22 patients without cardiac diseases (Group-C, age: 64 ± 13 years, EF: 62 ± 3%) in whom GLS was successfully assessed from apical 4-chamber, 2-chamber, and long-axis view (EPIQ, Philips Medical systems). TMAD was quickly assessed as the base-to-apex displacement of mid-point mitral annular line in 4-chamber view by setting ROI in septal and lateral mitral annuls and apex with QLAB software (Philips Medical systems). The percentage of TMAD to LV length from the mid-point of mitral annuls to the apex at end-diastole (% TMAD) was automatically calculated.
Results: Both GLS and %TMAD in Group-D was significantly smaller than those in Group-C (|GLS|: 11.1 ± 2.7 vs 21.3 ± 2.3%, $p < 0.001$, %TMAD: 7.2 ± 2.6 vs 15.2 ± 3.3 %, $p < 0.001$). Group-D was divided into two groups; 16 patients with |GLS| < 10.0% (Group-Da) and 23 patients with |GLS|>10.0% (Group-Db). %TMAD was significantly lower in Group-Da compared with Group-Db (5.1 ± 1.1 vs 8.8 ± 2.2, $p < 0.001$). A cut-off value of %TMAD < 6.4 had a sensitivity of 94% and specificity of 91% for the presence of severely decreased LV longitudinal systolic function.
Conclusions: TMAD rapidly estimated by speckle-tracking echocardiography was useful for the assessment of severely decreased LV longitudinal systolic function in patients with DCM. TMAD can be used as the prognostic index alternative to GLS in patients with DCM.



P524

The prevalence and prognostic significance of right ventricular involvement evaluated by cardiac magnetic resonance in nonischemic dilated cardiomyopathy

AR Ana Rita Pereira[1]; AR Almeida[1]; I Cruz[1]; A Marques[1]; S Alegria[1]; AC Gomes[1]; D Sebaiti[1]; A Briosa[1]; LR Lopes[2]; M Ramalho[3]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*; [2]*Barts Health NHS Trust, Cardiology, London, United Kingdom*; [3]*Hospital Garcia de Orta, Radiology, Almada, Portugal*

Introduction: Cardiac magnetic resonance (CMR) is the gold-standard technique for the assessment of ventricular structure and function. Left ventricular (LV) volumes and ejection fraction (LVEF), as well as, late enhancement gadolinium (LGE) are strong predictors of outcome in nonischemic dilated cardiomyopathy (DCM). Nevertheless, there are limited data regarding the prognostic significance of right ventricular involvement in this patients (pts).
Purpose: To evaluate the prevalence and prognostic value of the right ventricular (RV) involvement in pts with DCM.
Methods: Retrospective unicenter study that included the pts followed for DCM with LVEF < 40% at the time of diagnosis and submitted to CMR to complete the diagnostic evaluation. The DCM diagnosis was established by the presence of LV dilation in the absence of uncontrolled arterial hypertension, hypertrophic or restrictive cardiomyopathy, significant valvular or coronary disease. The primary endpoint (PE) was a composite endpoint of all-cause mortality, ventricular arrhythmias (VA) with hemodynamic instability and unplanned heart failure (HF) admission. Secondary endpoint (SE) was LVEF recovery (= 50%).
Results: Forty-nine pts were included: 30 (61,2%) male; mean age 54 ± 12 years. At the time of diagnosis, 30 (61,2%) pts were in NYHA functional class = III with a median NT-proBNP value of 2451 pg/mL [interquartile range (IQR) 2233 pg/mL]. Initial LVEF, measured by transthoracic echocardiogram, was 25 ± 8%. The mean values of RV parameters obtained by CMR were: RV end-diastolic volume (RVEDV) 89 ± 34 ml/m^2, RV end-systolic volume (RVESV) 55 ± 36 ml/m^2 and RV ejection fraction (RVEF) 41 ± 18%. Twelve (22,2%) pts had RV dilation, 21 (38,9%) RV systolic

dysfunction (RVSD) and 2 (3,7%) LGE in the RV free wall. At a median follow-up (FU) of 26 months (IQR 51 months), there were 22 primary events: 5 deaths, 3 AV with hemodynamic instability and 14 unplanned HF admissions. Seventeen (34,7%) pts recovered LVEF. A significantly higher number of PE events were observed in pts with RVSD [4 pts (19%) with preserved RVEF vs 14 pts (50%) with depressed RVEF, p = 0,04]. As expected, pts who have experienced primary adverse events had a significantly lower mean of RVEF (34 ± 17% vs 45 ± 18%, p = 0,04). However, no significant difference was found between RVEF and time until PE occurrence (log rank 0,17; p = 0,68). We did not also found a significant correlation between RVEF and LVEF (p = 0,69), as well as, an association between primary adverse events and RVEDV (p = 0, 17), RVESV (p = 0,13) and LGE in the RV free wall (p = 0,99). No RV structural and functional parameters were associated with SE occurrence.
Conclusions: In this study, RVSD was associated with medium to long term adverse events in pts with DCM. These results support a potential role of CMR assessment of RV function in the evaluation and risk stratification of DCM pts but not as a predictor of LVEF recovery.

P525
Influence of atrial fibrillation on clinical status and parameters of hemodynamics in dilated cardiomyopathy patients

MF Salikhova[1]; TA Abdullaev[1]; I A Igor Tsoy[1]; YR Akhmatov[1]
[1]Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

The aim: Evaluation of parameters of hemodynamics in dilated cardiomyopathy (DCM) pts complicated by atrial fibrillation (AF).
Material and Methods: The study includes 35 DCM pts (27 male and 8 female) with the newly discovered AF which diagnosed during initial application to clinic. Depending on the rhythm there were formed: gr I with 16 pts (average age of 44,8 ± 2,4 years) who were treated by pharmacological (amiodarone) cardioversion with restoration of sinus rhythm (SR) with optimal background therapy of chronic heart failure. Second gr was formed by 19 pts (average age of 53,2 ± 1,8 years) whose rhythm had not restored. Evaluation of EKG and EchoCG parameters was done. Median of observation comprised 22,5 months. Average functional class of HF in 1st gr comprised 3,1 ± 0,22 and in 2nd gr– 2,9 ± 0,58 (?>0.05).
Results: Analysis of clinic status of pts revealed improvement of indices comparing to control period. Thus, average functional class of HF at 1st gr decreased up to 2,5 ± 0,11 and 2,5 ± 0,13 in 2nd gr (both ? <0,05), whereas results of 6-minute walking test (6MWT) increased on 47,8% in 1st gr and 33,4% in 2nd gr. (both ? <0,05). After SR recovering in 1st gr we observed an increase of systolic arterial pressure on 12,6 mm Hg (? <0,05), whereas 2nd gr had this parameter unchanged. As for heart rate 1st gr had positive dynamics; lowering of heart rate on 18,5 bpm (p <0,05), 2nd gr– on 5,3 bpm (p>0,05). Analysing EKG-indices there were revealed an extension of interval QTc on 13,7% at pts after SR recovering (? <0,05) with unchanged parameters of QRS duration in both grs. SR recovering at 1st gr was accompanied by decrease of volume of left atrial on 7,3%, EDV LV - on 6,8%, ESV LV – on 18,5% (all ?>0.05) with respective increase of LVEF on 9,4% (p <0,05). 2nd gr did not show significant dynamics of EchoKG-parameters (??? ?>0,05). Analysis of EchoKG-parameters of right heart departments in 1st gr revealed regression of volume of right ventricle on 6,5% (?>0,05), whereas these parameters of 2nd g remained on the same level.
Conclusion: For DCMP pts complicated by atrial fibrillation - during long-time observation the recovering of sinus rhythm contributes to improvement of general clinic status of such category of pts that shows not only as regress of heart failure appearance but also as positive dynamics from EchoKG-parameters.

P526
Dilatative cardiomyopathy and atrial fibrillation

O Ovidiu Tica[1]; OA Tica[2]
[1]University of Medicine of Oradea, Morphological Department, Oradea, Romania; *[2]University of Medicine of Oradea, Cardiology Department, Oradea, Romania*

Introduction: Atrial fibrillation(AF) is a common arrhythmia in patients with dilated cardiomyopathy(DCM). AF presence in patients with DCM influences the long term evolution
Aim: To assess and to quantify if AF is a predictive factor for DCM patients and how it influence the prognosis and mortality of these patients.
Method: We conducted a retrospective study among adult patients, who had a clinical diagnosis of DCM and AF. We included 253 patients admitted consecutively in our clinic between January 2013 and December 2014 diagnosed with dilated cardiomyopathy and atrial fibrillation divided according to etiology in non-ischemic and ischemic. Blood test, clinical examination, ECG, and echocardiography was performed. Patients were followed for 2.3 years. They were divided into 2 groups according to the DCM etiology: non-ischemic and ischemic.
Results: In our study AF was identified in the non-ischemic DCM group in 10.67% as paroxystic AF, in 11.46% as persistent AF, 13.04% as long standing persistent and in 12.25% as permanent AF. In the ischemic DCM group, 7.51% of patients have paroxystic AF, 9.48% have persistent AF; 11.06 % have long standing persistent, 10.27% have permanent AF. NYHA class >3, left ventricular ejection fraction < 35%, presence of mitral regurgitation greater than grade 2, QRS duration = 110ms, LV end-diastolic diameter >63mm were ominous signs, and patients with al lest one of these this factors have a poor prognosis. Overall mortality, was influenced by the presence of AF(p = 0.002).
Conclusions: AF turned out to be a condition that can contribute to lower quality of life and heart failure worsening, influencing the patients prognosis and mortality.

P527
Rationale and design for the Peripartum Cardiomyopathy in Nigeria (PEACE) registry, and results for cardiac function in pregnancy sub-study

KM Karaye[1]; IY Mohammed[1]; H Sa'idu[2]; NA Ishaq[3]; SA Balarabe[4]; J Tukur[1]; TA Adedeji[5]; ON Makinde[6]; RA Adebayo[7]
[1]Bayero University/Aminu Kano Teaching Hospital, Kano, Nigeria; *[2]Bayero University, Medicine, Kano, Nigeria*; *[3]Aminu Kano Teaching Hospital, Medicine, Kano, Nigeria*; *[4]Mohammed Abdullahi Wase Specialist Hospital, Medicine, Kano, Nigeria*; *[5]Obafemi Awolowo University Teaching Hospital, Chemical Pathology, Ile Ife, Nigeria*; *[6]Obafemi Awolowo University Teaching Hospital, Obstetrics and Gynaecology, Ile Ife, Nigeria*; *[7]Obafemi Awolowo University Teaching Hospital, Ile Ife, Nigeria*

Background: Nigeria probably has the highest burden of Peripartum Cardiomyopathy (PPCM) in the world. However, much of the epidemiology of the disease is yet to be described in a comprehensive national study. In addition, the relationship between selenium deficiency and PPCM seems to be relevant in the Sahel regions of Africa, and if proven, could potentially lead to a cure of the disease. Finally, the data on cardiac function in pregnancy in Nigeria is limited, and its relationship with selenium deficiency has not yet been described.
Purpose: To primarily describe the burden, ventricular remodelling and survival of PPCM in Nigeria. In the sub-studies, we aimed to describe the relationship between selenium deficiency, oxidative stress and PPCM, the impact of sodium selenite supplementation on left ventricular reverse remodelling, change in New York Heart Association functional class and survival in PPCM, and the prevalence of selenium deficiency and its relationship with cardiac function in apparently healthy pregnant women.
Methods: The main Registry and the first sub-study are prospective longitudinal studies, while the second sub-study is an open-label randomised trial. 20 study centres across Nigeria have been recruiting PPCM subjects for the main registry; from June to December 2017 in most centres, but till 31st March 2018 for the late-starters, while the sub-studies are going on in 4 centres in 2 cities. PPCM subjects will be followed up for at least 1 year. Serum selenium and glutathione peroxidise (GPO) is being assayed at recruitment for consecutive PPCM patients with left ventricular ejection fraction <45% at 6 months postpartum. 200 subjects with selenium deficiency are being randomised into treatment (Selenium Selenite 200μg tablets daily for 3 months) and control arms. In the second sub-study, 120 apparently healthy pregnant women have been recruited at 28-38 weeks of gestation and are being reviewed at 6-8 weeks postpartum, and their serum selenium and GPO levels were measured at recruitment.
Results: A total of 131 apparently healthy pregnant women with a mean age of 29.6 ± 5.3 years, and 270 PPCM patients with a mean age of 28.3 ± 7.2 years have thus far been recruited (censored on 10th January 2018). The sub-study on apparently healthy pregnant women will be completed in March 2018 and the results could be presented at the HFA Congress in May 2018.
Conclusion: This is the largest systematic evaluation of PPCM in Nigeria, and it is hoped that the information will assist in developing locally applicable treatment guidelines and policies for the disease. (ClinicalTrials.gov Identifier: NCT03081949)

P528
Characterization of a population with Left Ventricle Non Compaction - a Multicentric Study

J Joao Pedro De Sousa Bispo[1]; H Antunes[2]; N Marques[1]; N Craveiro[3]; L Reis[4]; R Guerreiro[5]; R Santos[6]; O Azevedo[7]
[1]Faro Hospital, Cardiology, Faro, Portugal; *[2]Hospital Sao Teotonio, Viseu, Portugal*; *[3]Hospital of Santarem, Cardiology, Santarem, Portugal*; *[4]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*; *[5]Hospital Espirito Santo de Evora, Evora, Portugal*; *[6]Hospital Centre do Tamega e Sousa, Penafiel, Portugal*; *[7]Alto Ave Hospital Center, Guimaraes, Portugal*

On behalf of: Grupo Sunshine

Introduction: Left Ventricle Non-Compaction (LVNC) is a cardiomyopathy in which the left ventricular walls are non-compacted with deep trabeculations. It has an

estimated prevalence of 0,014 a 1,3%. Patients can present from asymptomatic to advanced heart failure (HF), arrhythmias, and systemic embolism (SE).
Objective: To characterize a population of patients with LVNC
Methods: A data base of LVNC patients that were followed as outpatients in 12 public hospitals between January of 2007 and December of 2017 was created. We conducted a retrospective and descriptive analysis of the baseline characteristics, form of presentation, diagnostic methods and genetic testing **Results: Results:** 120 patients were included in the study, 70 (58,3%) were male, average age of 46,79 ± 18,1 years, 114 (95%) caucasians. Family history of LVNC was present in 21 (17,5%) cases. Most common form of presentation was asymptomatic in 42 (35%) cases, HF in 39 (32,5%) - with 11 (9,2%) patients in NYHA III or IV - and arrhythmia in 17 (14,2%). The diagnosis was made by echocardiogram (TTE) in 70 (58,3%) patients and by magnetic resonance imaging (MRI) in 50 (41,7%). The most frequently present TTE diagnostic criteria were the Jenni criteria, present in 85 patients (70,8%). 61 (50,8%) patients also had significant valve disease, most frequently in the mitral valve (in 57 cases) and tricuspid (in 39 cases). Average ejection fraction was 47,9 ± 15,7%. On MRI 18 (70,8%) patients had late gadolinium enhancement. On the 12 lead ECG, 106 (88,3%) patients were in sinus rhythm, 11 (9,2%) in atrial fibrillation, and 2 (1,7%) in atrial flutter. 15 (12,5%) had left bundle branch block, and 4 (3,3%) had right bundle brunch block. 24h Holter monitoring was performed in 101 (84,2%) patients, and 3 (2,5%) patients had periods with 2nd degree AV block, 3 (2,5%) had periods of 3rd degree AV block, 21 (17,5%) had periods of supraventricular tachycardia, 23 (19,2%) periods of ventricular tachycardia, but only 1 (0,8%) of these casas was sustained. Genetic study was performed in 43 (35,8%) patients, and mutations were found in the MYH7 gene in 3 (2,5%) patients, in the MYBPC3 in 6 (5,0%) and the TNNT2 in 1 (0,8%). Follow-up was 3,54 ± 2,67 years, and during that time a total of 6 (5,0%) patients died (3 for advanced HF, 1 for sudden death, 3 with non-cardiovascular causes), 9 (7,5%) had stroke, and 1 (0,8%) had MI. 55 (45,8%) had HF (16 more patients than at presentation).
Conclusion: LVNC remains a poorly understood cardiomyopathy, without specific treatment. In our population, the most frequent complications were HF, arrhythmias and SE events. In our study, we also had a relatively high prevalence of significant valve disease, mostly mitral. The genetic etiology of LVNC remains understudied. Several genes have been implicated. In our population, the number of mutated genes was relatively low, which may mean that there may be other affected genes that have yet to be identified.

P529

Myocardial infarction (necrosis) as a typical manifestation of noncompact cardiomyopathy

O V Olga Blagova[1]; NV Varionchik[1]; EV Pavlenko[1]; AV Nedostup[1]; EA Kogan[1]; VP Sedov[1]; NV Gagarina[1]; EA Mershina[2]; VE Sinitsyn[2]
[1]I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation; *[2]Roszdrav Medical Rehabilitation Center, Moscow, Russian Federation*

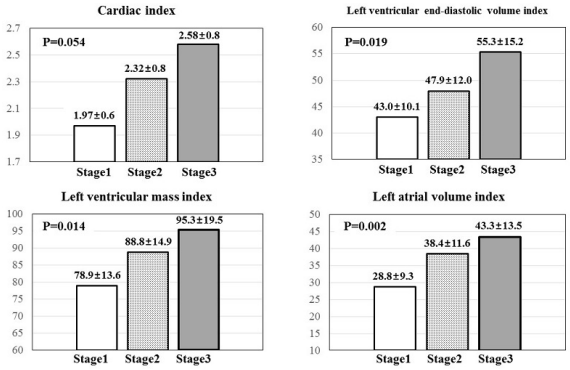
Purpose: To study the incidence of acute myocardial infarction (MI) in patients with noncompact myocardium (NCM) and its possible specific mechanisms, influence on the prognosis and means of prevention.
Methods: We observed 85 adult patients with NCM. The study included 10 patients (7 men, mean age 46.3 ± 15.8 years) who developed acute MI. The diagnosis of NCM is established according to the current visual criteria (using Eco-CG, MRI in 5 patients and cardiac CT in 7 patients). Mean follow-up was 10,5 [1,75; 32,25] months. In all patients were performed the anti-heart antibodies and virus genome investigation and coronary visualization (7 coronary angiography, 7 CT). Additionally were performed the troponin measurement (n = 7), morphological study of the myocardium (n = 6), myocardial scintigraphy with 99mTc (n = 6) and DNA diagnosis.
Results: In 4 of the 10 patients MI was the first manifestation of the NCM. The clinical picture of MI was presented typical angina with dyspnea (50%), isolated asthma (10%) and ventricular arrhythmias (sustained ventricular tachycardia, fibrillation, sudden death, 40%). Stable angina was observed in only 2 patients (with intact coronary arteries). In two patients with MI in the debut of the disease was detected pathogenic mutation in the gene MyBPC3. They were identified four mechanisms of MI, which can be combined. 1. Thromboembolism in the coronary arteries from the left chambers of the heart (verified at autopsy in one patient and can be assumed in 5 patients). 2. Accession of myocarditis with the development of vasculitis, focal necrosis in ischemic myocardium (6 patients, morphologically verified myocarditis in 2 patients, viral genome in the blood or myocardium in 3 patients). 3. Severe coronary atherosclerosis (2 patients). 4 The sharp deterioration of blood flow of a non-compact layer in the presence of low cardiac output (more than half of the patients). Risk factors for MI were intracardiac thrombosis, low ejection fraction, atrial fibrillation, the combination of NCM with hypertrophic cardiomyopathy (in two patients).
Conclusions: Myocardial infarction (necrosis) is a typical manifestation of NCM (in 11.8%). The MI with intact coronary arteries requires the exclusion of NCM. The main mechanisms of MI in NCM are thromboembolism, myocarditis, disturbances of microcirculation under the NCM, and coronary atherosclerosis. MI is a life-threatening complication of NCM leading to a severe worsening of the initial heart failure and ventricular arrhythmias. Mortality among patients with MI was 20%. As a means for MI prevention must considered the appointment of anticoagulant therapy at least in patients with atrial fibrillation and systolic dysfunction, as well as the timely diagnosis and treatment of myocarditis.

P530

Liver cirrhosis related changes in cardiac function and structure, beyond diastolic dysfunction.

MN Mi-Na Kim[1]; TH Kim[1]; YS Seo[1]; SM Park[1]; SH Um[1]; WJ Shim[1]
[1]Korea university anam hospital, Seoul, Korea Republic of

Background: Patients with liver cirrhosis (LC) could develop a progressive impairment of cardiac function and change of cardiovascular structure in their disease course. These changes are related with worsen clinical manifestation and poorer prognosis. But cirrhotic cardiomyopathy might be difficult to determine due to the complex and muddled diagnostic criteria. The aim of this study was to evaluate cardiac structural and functional changes according to disease severity in patients with LC.
Methods: 74 patients (F/M = 17/57, 54.9 ± 10.2yrs) who was newly diagnosed LC were included. In each patient, the model for end-stage liver disease (MELD)



score was calculated for assessment of severity of LC and the stage of LC was evaluated by the presence of varix or ascites (Stage1: compensated patients without varix and ascites, Stage2: Compensated patients with varix and without ascites, Stage3: Decompensated patients with ascites). Cardiac structure and function were assessed by trans-thoracic echocardiography.
Results: Among 74 patients, stage 3 was present in 39 patients (6%) and 22 patients (14.9%) were belonged to stage 2. The mean age and presences of diabetes, hypertension and coronary artery disease were not different between the groups. The MELD score was gradually increased, according to raising the stage of LC. (Stage1: 11.3 ± 6.2, Stage2: 13.9 ± 7.3 and Stage3: 16.3 ± 6.3, P = 0.05)
Cardiac index (CI) had a trend to be progressively increased from Stage1 to Stage3 (1.97 ± 0.6, 2.32 ± 0.8 and 2.58 ± 0.8, P = 0.054). Left ventricular (LV) volume and mass index were increased from Stage1 to Stage3. Left atrial volume index was also increased (Figure). But LV ejection fraction, global longitudinal strain (GLS) and diastolic functional parameters, including E of E prime, were not different between the groups. In the evaluation of relations between MELD score and cardiac functional and structural parameters, GLS as well as CI was independently related with MELD score by multivariate analysis. (OR = 2.24, P = 0.03 and OR = 3.73, P <0.001, respectively).
Conclusion: In advanced stage of cirrhotic patients, the cardiac output was increased and LV was larger and thicker. The hepatic function was independently associated with cardiac output and LV myocardial mechanics. To evaluate diastolic dysfunction might be limited in these high cardiac output stated LC patients. From these, a subtle change of ventricular tissue mechanics would be one of precursors of cirrhotic cardiomyopathy. A new definition of cirrhotic cardiomyopathy might be needed.

Pulmonary Circulation, Pulmonary Embolism, Right Heart Failure - Clinical

P531

The product of TRPG and Pulmonary artery diameter/Aortic diameter is a useful screening parameter for detecting pulmonary hypertension in systemic sclerosis patients

Y Yoshiyuki Orihara[1]; M Asakura[1]; A Eguchi[1]; T Ando[1]; Y Okuhara[1]; M Ishihara[1]; T Masuyama[1]
[1]*Hyogo College of Medicine, Cardiovascular Division, Nishinomiya, Japan*

Background: Systemic sclerosis (SSc) is a connective tissue disease characterized by inflammation and fibrosis of the skin and certain internal organs, and vascular injury due to autoimmunity. Compared with SSc patients without pulmonary arterial hypertension (PAH), poor survival rate in SSc patients with PAH was revealed. Accurate assessment of PAH is important for the management of patients with SSc. However, tricuspid regurgitate jet pressure gradient (TRPG), an echocardiographic parameter commonly used for estimating PAH, does not always reflect accurate invasive pressures in all patients. Several reports showed that a ratio of diameter of pulmonary artery to ascending aorta (rPA) calculated by computed tomography (CT) were correlated with severity of pulmonary hypertension. Neither TRPG nor rPA does not reach a satisfactory level to assess the degree of PAH in SSc patients. We hypothesized that the product of TRPG and rPA (pTRPA) would be a novel parameter to estimate the severity of PH accurately in SSc patients.
Purpose: the purpose of this study was to determine whether pTRPA was a useful parameter for detecting PH in SSc patients.
Methods: Thirty six SSc patients who visited our hospital and presented tricuspid regurgitation jet velocity = 2.5 m/s were enrolled in this study. All patients performed echocardiography, chest CT and right heart catherization. PAH was defined as mean pulmonary arterial pressure (mPAP) = 25mmHg and mean pulmonary arterial wedge pressure (mPAWP) = 15mmHg. We measured both a widest pulmonary artery diameter and an adjacent ascending aorta diameter at the same level of the bifurcation of the main pulmonary artery using CT images.
Results: Mean age was 64.2 years old and 29 patients were female. Echocardiography showed mean TRPG was 35.1 mmHg and average left ventricular ejection fraction were 71.0%. Average mPAP and mPAWP were 24.7 mmHg and 10.1 mmHg, respectively. Average pulmonary artery diameter and ascending aorta diameter were 31.6mm and 30.1mm, respectively. Mean rPA were 1.06 and mean pTRPA were 37.9. Mean PAP was well correlated with TRPG ($r = 0.734$, $p < 0.001$), rPA ($r = 0.584$, $p < 0.001$), pTRPA ($r = 0.848$, $p < 0.001$), respectively. Among three parameters, the highest area under the curve by receiver operating characteristic (ROC) analysis to predict mPAP = 25mmHg was found for pTRPA with area of 0.917. In addition, ROC in pTRPA showed sensitivity was 0.933 and best cutoff value was 33.1. When SSc patients in this cohort is divided into two groups according to this best cutoff value, positive predictive value was 0.74 and negative predictive value was 0.93.
Conclusion: The product of TRPG and pulmonary artery diameter/Aortic diameter may be a potential, useful, and nonivasive parameter for detecting the severity of PH in patients with SSc.

P532

Pulmonary Vascular Distensibility In Pulmonary Hypertension Due To Left Heart Disease

C Christian Gerges[1]; M Gerges[1]; IM Lang[1]
[1]*Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria*

Background: The diameter of healthy pulmonary vessels increases by 2% per mmHg of transmural pressure. A model of the pulmonary circulation incorporating the coefficient of distensiblity (a, percentage change in diameter per mmHg increase in distending pressure) can be used to describe this behavior. In patients with pulmonary vascular disease a is reduced to 0.25%/mmHg. We sought to describe loss vascular distensibility in patients with pulmonary hypertension (PH) due to left heart disease (LHD).
Methods: Distensibility a was estimated in 119 patients using following formula:
mPAP = [(1 + a*PAWP)5 + 5a*PVR*CO] 1/5 - 1] / a
(mPAP = mean pulmonary artery pressure; PAWP = pulmonary arterial wedge pressure; PVR = pulmonary vascular resistance; CO = cardiac output)
Distensible properties in combined pre- and post-capillary PH (Cpc-PH, n = 30) were compared with isolated post-capillary PH (Ipc-PH; n = 30) and patients with idiopathic pulmonary arterial hypertension (iPAH, n = 29). Subjects with normal pulmonary hemodynamics (n = 30) served as controls.
Results: Distensibility a was lowest in iPAH, intermediate in PH-LHD and preserved in controls (0.23 ± 0.12%/mmHg vs. 0.63 ± 0.23%/mmHg vs. 2.3 ± 1.2%/mmHg, $p < 0.001$). Despite higher mPAWP in Ipc-PH (31.2 ± 7.2mmHg) than in Cpc-PH (25.4 ± 4.9mmHg, $p = 0.001$), distensibility a was lower in Cpc-PH (0.53 ± 0.21%/mmHg) than in Ipc-PH (0.74 ± 0.20%/mmHg, $p < 0.0001$). Distensibility a was significantly correlated with DPG ($r=-0.64$; $p < 0.001$) and PVR ($r=-0.74$; $p < 0.001$) in patients with PH-LHD.
Conclusion: Distensibility of pulmonary vessels is impaired in PH-LHD, and worst in iPAH. Despite similar or even higher mPAWP in Ipc-PH, pulmonary vessels are less distensible in Cpc-PH, presumably because of pulmonary vascular remodeling.

P533

Insulin resistance in pulmonary hypertension

N Naderi[1]; S Taghavi[1]; A Amin[1]; Z Ghaemmaghami[1]; M Nouri[1]; M M Ansari-Ramandi[1]; A Zavarei[1]
[1]*Rajaie Cardiovascular Medical and Research Center,Iran University of Medical Sciences, Tehran, Iran (Islamic Republic of)*

Funding Acknowledgements: None to declare

Introduction: The relationship of glucose intolerance and insulin resistance (IR) with pulmonary hypertension (PH) has been suggested . In present study we measured insulin level in patients with pulmonary hypertension without history of diabetes mellitus(DM) or glucose intolerance.
Methods: Fifty-nine patients with Pulmonary hypertension in accordance with updated clinical classification of pulmonary hypertension were enrolled.Demographic ,functional ,laboratory and hemodynamic data were obtained. The homeostasis model assessment of insulin resistance (HOMA-IR) was used to assess IR.
Results: Regarding the PH classification 47.5% of them had class I of PH, 28.8% class II,5.1% class III,16.9% class IV and 1.7 % class V . With respect to the Iranian cut point of HOMA-IR 27% of patients had IR. IR was more common in patients with pre-capillary PH than post capillary ones. There was no difference between IR and insulin sensitive (IS) group regarding NYHA class, 6MWT, laboratory tests and hemodynamic data.
Conclusion: IR seems to be a common finding in PH. However, further studies are needed to clarify the role of IR in pathogenesis and progression of PH in particular in patients with pre capillary pulmonary hypertension.

Evaluation of breathlessness during daily living activities in patients with pulmonary arterial hypertension

RENGIN Demir[1]; RAZIYE Atar[1]; UMIT S Yasar[1]; SERDAR Kucukoglu[1]
[1]*Istanbul University Cardiology Institute, Department of Cardiology, Istanbul, Turkey*

Pulmonary arterial hypertension (PAH) is a clinical condition characterized by the presence of pre-capillary PH and pulmonary vascular resistance >3 Wood units, in the absence of other causes of pre-capillary PH such as PH due to lung diseases, chronic thromboembolic PH, or other rare diseases. Patients with PAH has symptoms of exertional dyspnea, fatique and their quality of life is reduced. The aim of this study was to evaluate breathlessness during daily living activities in patients with pulmonary arterial hypertension. Sixty one patients were included in the study (mean age 46.5, 17 men/44 women). Thirtytwo patients were in WHO Functional Class II, 29 were in WHO Functional Class III. Exercise capacity, activities of daily living, fatique and quality of life were assessed. The 6-minute walk test (6MWT) was used to evaluate exercise capacity. The London Chest Activity of Daily Living (LCADL) scale was used to measure the impact of breathlessness on activities of daily living. LCADL is divided in 4 domains: self-care (4 items), domestic (6 items) physical activity (2 items) and leisure (3 items). Each item is scored from 0 to 5 points. The total scores range from 0 to 75 with higher scores corresponding to greater limitation in activity of daily living. Fatique was assessed with the Fatique Severity Scale (FSS). Quality of life was assessed by the Nottingham Health Profile (NHP). LCADL scale total score was 25.6. Mean 6MWT distance was 427.2 m. LCADL scale total score showed positive correlation with age (r= 0.26, p = 0.004), functional class (r= 0.45, p = 0.0002), fatique (r= 0.55 p= < 0.0001) NHP total score (r= 0.61 p= < 0.0001) and negative correlation with 6MWT distance (r= -0.39, p = 0.002). Breathlessness during daily living activities in patients with PAH is correlated with fatique severity, exercise capacity and the severity of PAH and is also correlated with decrease in quality of life.

Obesity types affect development of major cardiovascular risks :Data from Korean National Health Insurance Service

EJ Cho[1]; SH Park[2]; HY Lee[3]; JH Shin[4]; HK Jeon[1]
[1]*Catholic University of Korea, Cardiology division, Seoul, Korea Republic of*; [2]*Yonsei University , Cardiology, Seoul, Korea Republic of*; [3]*Seoul National University, Cardiology, Seoul, Korea Republic of*; [4]*Hanyang University, cardiology, Seoul, Korea Republic of*

Background: Population based study demonstrated that obesity (defined as increased body mass index, BMI) is important predictor for developing hypertension and diabetes mellitus (DM), which have been well known major cardiovascular (CV) risk factors. Increased waist circumference (WC) representative of central obesity is focused as main factor for developing CV disease and its major risks.
Purpose: This study was to evaluate obesity as a predictor for new onset of hypertension and DM within 1-year in previously normotensives or normoglycemic subjects.
Methods: The Korean National Health Insurance Service - National Sample Cohort (NHIS-NSC) established data about BMI and WC with medical, social and familial histories in 2009 and have been followed up for 1 years. Among total 349,257 subjects with age more than 20 year-old, 95,124 (normotensive group: 75.2% of population were 25-55 year-old, 54121(56.9%) male) of normotensives for evaluate new hypertension and 120,501 (normoglycemic group: 83.6% of population were 25-65 year-old, 67,183 (55.8%) male) normoglycemic subjects for evaluate new DM were analyzed.
Results: During 1-year follow-up period, 3,773 (3.97%) new hypertension in normotensive group and 1,594 (1.32%) new DM in normoglycemic group were developed. Binary logistic regression analysis revealed that BMI was the predictor (Exp(B) = 1.18, Sig < 0.001) for new onset hypertension with age (Exp(B) = 1.31, Sig < 0.001), sex (Exp(B) = 0.664, Sig < 0.001), dyslipidemia and family history of hypertension. For new onset DM, WC (Exp(B) = 1.04, Sig < 0.001), age (Exp(B) = 1.26, Sig < 0.001), sex Exp(B) = 0.664, Sig < 0.001) and family history of DM (Exp(B) = 1.76, Sig < 0.001) were the independent predictors.
Conclusion: Increase of BMI is independent predictor for new onset hypertension and increase of WC is independent predictor for new onset DM within 1-year. Obesity type might affects development of different major CV risks and hence, obesity itself is the important risk factor for CV disease.

P536

Relationship of cardiac magnetic resonance-derived myocardial fibrosis and molecular biomarkers of fibrosis with cardiac geometry and strain in hypertensive heart disease

G Gernot Pichler[1]; F Martinez Garcia[2]; E Solaz[2]; O Calaforra[1]; A Ruiz[1]; B Lopez[3]; J Diez[3]; M San Andres Marco[4]; A Maceira Gonzalez[5]; J Redon[6]
[1]*Research Foundation Hospital of Valencia (INCLIVA), Cardiometabolic and Renal Risk, Valencia, Spain*; [2]*University Hospital Clinic of Valencia, Valencia, Spain*; [3]*Center for Applied Medical Research, Pamplona, Spain*; [4]*Fundación CETIR Centre Medic, Valencia, Spain*; [5]*ERESA Medical Center, Cardiac Imaging Unit, Valencia, Spain*; [6]*University of Valencia, Department of Medicine, Valencia, Spain*

Background: Hypertension is an etiologic factor for heart failure by inducing left ventricular hypertrophy (LVH). Myocardial fibrosis is a relevant component of LVH due to the impact in ventricular dysfunction. Novel cardiac magnetic resonance (CMR) imaging techniques have shown potential in quantification of diffuse cardiac fibrosis, with T1 mapping, and estimating preclinical cardiac dysfunction, with strain analysis.
Purpose: The aim was to investigate the relationship of CMR-assessed fibrosis and molecular biomarkers of fibrosis with cardiac geometry and strain in hypertensives with LVH.
Methods: CMR was performed on a 3T scanner in hypertensive individuals with positive ECG-derived criteria for LVH and free of cardiomyopathy other than LVH. Extracellular volume fraction (ECV) and the partition coefficient as measures of cardiac fibrosis were assessed using the T1 mapping technique shMOLLI. Longitudinal, circumferential and radial strain were assessed using CMR-feature tracking. Molecular biomarkers of collagen synthesis (PICP and PIIINP) and collagen degradation (CITP and MMP-1) were measured in blood using commercial kits. Pearson's correlation and multiple linear regression analysis controlling for gender, age, height, weight, heart rate and 24-h systolic BP were performed in order to assess the relationship between available variables.
Results: 36 hypertensives (83% males, mean age 50.6 ± 4.3) underwent CMR imaging, and T1 mapping was performed in 29 (79% males, mean age 50.1 ± 4.3) participants. Correlation models showed a significant relationship of ECV and the partition coefficient with left atrial (LA) diameter, LV mass, LV posterior wall thickness, LV end-diastolic volume and longitudinal strain. In fully adjusted regression models, ECV was associated with LA diameter (ß = 0.75, p = 0.005, R2 = 0.47) and longitudinal strain (ß = 0.43, p = 0.030, R2 = 0.38) (figure 1); the partition coefficient was associated with LV posterior wall thickness (ß = 0.53, p = 0.046, R2 = 0.49). Regarding molecular biomarkers of fibrosis, longitudinal strain was associated with CITP (ß = 0.46, p = 0.025, R2 = 0.25), and circumferential strain was inversely associated with MMP-1 (ß=-0.38, p = 0.047, R2 = 0.32) in fully adjusted regression models. No significant association between molecular biomarkers of fibrosis and CMR-derived cardiac geometry or fibrosis was observed.
Conclusions: CMR-assessed fibrosis showed significant associations with cardiac geometry and myocardial strain: A greater extension of cardiac fibrosis was related to an increase in cardiac dimensions (LV posterior wall thickness, LA diameter) and a reduction (i.e., "less negative" values) in longitudinal strain. Molecular biomarkers of collagen degradation were associated with myocardial strain but not with the extension of CMR-derived cardiac fibrosis.
Figure 1: Regression line, scatter plot and correlation coefficient for the association between ECV and longitudinal strain.

Arterial hypertension in heart transplanted recipients

M Simonenko[1]; P Fedotov[2]; Y Sazonova[3]; M Sitnikova[2]; M Karpenko[4]
[1]Almazov National Medical Research Centre, Cardiopulmonary Exercise Test, Saint-Petersburg, Russian Federation; *[2]Almazov National Medical Research Centre, Heart Failure Department, Saint-Petersburg, Russian Federation*; *[3]Almazov National Medical Research Centre, Thoracic Surgery and Transplantation Laboratory, Saint-Petersburg, Russian Federation*; *[4]Almazov National Medical Research Centre, Chairman of Scientific Clinical Council, Deputy Director for Science and Medical Work, Saint-Petersburg, Russian Federation*

Background: Post-transplantation arterial hypertension (AH) is a major cardiovascular problem and is present in 50-90% of patients after heart transplantation (HTx). Multiple factors are involved in generating AH after HTx; these include immunosuppression, increased sensitivity of beta-adrenergic receptors due to donor heart denervation, worsening of endothelial function and drug nephrotoxicity.
Purpose: to estimate the frequency of AH following HTx and define factors which may impact on its development.
Methods: From 2010 to 2017 we performed 96 HTx (mean age - 46,5 ± 13,9 yrs; m - 70), 38,5% (n = 37) of them coped with AH prior HTx. In fact, 83% (n = 30) of recipients with AH were smoking before HTx and had ischemic heart disease (IHD) (p <0,001). After HTx all patients were treated with triple-drug therapy (steroids, calcineurin inhibitors, mycophenolate mofetil/everolimus) and induction (basiliximab - 79% (n = 76), thymoglobulin - 21% (n = 20)). Post-HTx hypertension was defined as the need to use drugs for its control. We estimated post-transplant outcomes.
Results: During early-term follow-up (less than 1 month) 8 patients died in ICU. In fact, only 15% (n = 13 from 88) of recipients (mean age - 32 ± 15 yrs) had normal blood pressure (BP) through the whole posttransplant follow-up (30,4 ± 23,9 months). During 6 months after HTx 56% (n = 49) of patients required antihypertensive drugs, 2 drugs were prescribed 18 of them and 3 drugs - 2 of them. During this period the most often used single class of drugs were angiotensin-converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARB) (46%, n = 32), followed by calcium channel blockers (CCBs) (37%, n = 26) and beta-blockers (10%, n = 7). From 6 months to 1 yr after HTx AH was diagnosed in 68% of patients: 19 recipients were treated with 2 classes of drugs and 2 of them - with 3 drugs. During 1st yr more patients with AH prior HTx coped with post-transplant AH than those who did not have high BP before it (72% (n = 26) vs. 45% (n = 27), p <0,05). More than 1 yr after HTx AH was present in 81% of patients, 21 recipient followed by 2 classes of drugs and 4 - by 3 drugs or more. Two yrs after HTx the amount of patients with AH increased to 79%, 2 drugs were prescribed 16 of them, 3 drugs or more - 5 recipients. In long-term follow-up the most used drugs were ACE inhibitors or ARB and then CCBs. In addition, male gender (76% (n = 53) vs. 46% (n = 6), p <0,05), smoking prior HTx (70% (n = 49) vs. 15% (n = 2), p <0,001), family history of AH (40% (n = 28) vs. 8% (n = 1), p <0,05) and IHD (54% (n = 38) vs. 15% (n = 2), p <0,05) were associated with post-HTx AH. We found corellations between AH and male gender (r = 0,41; p <0,001), smoking (r = 0,35; p <0,001) and advanced age (r = 0,35; p <0,05).
Conclusion: After HTx most of patients coped with AH. In some patients it can be controlled with a single antihypertensive agent. The most important factors in the development of AH are IHD and the presence of AH prior HTx, male gender and smoking.

Longitudinal systolic strain of left ventricle in association with hypertension and its control in a population

V Guseva[1]; A Ryabikov[2]; E Voronina[1]; Y Palekhina[1]; S Shakhmatov[1]; MV Holmes[3]; M Bobak[4]; S Malyutina[1]
[1]Institute of Internal & Preventive Medicine SB RAS, Novosibirsk, Russian Federation; *[2]Novosibirsk State Medical University, Novosibirsk, Russian Federation*; *[3]University of Oxford, Oxford, United Kingdom*; *[4]University College London, London, United Kingdom*

Funding Acknowledgements: Russian Science Foundation (14-45-00030)

BACKGROUND: Ultrasound assessment of systolic myocardial strain allows non-invasive identification of early stages of heart failure with preserved ventricular ejection fraction. There is evidence of a decline of global longitudinal strain of left ventricle (LV) in hypertension (HT) with left ventricular hypertrophy (LVH); however, these findings were reported for clinical samples with overt HT. Data on the relationship between longitudinal strain and blood pressure (BP) and HT in a general population is scarce.
Purpose: We aimed to study a relationship between peak systolic global longitudinal strain (GLS) and strain rate (GSR) of (LV) and HT and BP control in a general population sample aged over 50 years.
DESIGN and METHODS. The cross-sectional study was based on a population cohort (HAPIEE, Novosibirsk). In a random sample (n = 446, aged 58-82) we conducted echocardiography and evaluated GLS and GSR of LV by speckle tracking technique. ANOVA multivariable models were applied for analysis.
Results: The prevalence of HT In studied sample was 78,9%. The mean GLS value was - 18.7% (SD3.79), it was lower in men than in women (- 18.2% vs - 19.2%, p = 0.005). The mean GSR value was - 0.84 s-1 (SD 0.17), and did not differ by sex. The absolute value of GLS in HT was lower than in normotensives: - 18.5% (SD3.73) vs - 19.9% (SD3.42), p = 0.003; this difference was independent of age, sex and LV myocardium mass index (IMM), p = 0.011; but it was attenuated in a multivariate model including BMI. In HT groups, the GLS was the lowest among those "treated ineffectively" (0.043) and significantly lower versus normotensives independently of age, sex and myocardium mass index (p = 0.008). The absolute value of GSR in HT was lower than in normotensives: - 0.83 s-1 (SD 0.17) versus - 0.90 s-1 (SD 0.17), p < 0.001; and persisted in multivariable models. GSR was the lowest among those "treated ineffectively" and significantly lower versus normotensives in multivariable models independently of age, sex, BMI and myocardium mass index (p = 0.017; 0.002).
CONCLUSION: In studied population sample, GLS and GSR of LV were associated with HT; however, the association between GLS and HT was largely explained by BMI. In hypertensives, the lowest GLS and GSR, as well as higher extent of LVH, were found among those treated ineffectively, which might reflect the initial reduction of systolic ventricular function in hypertension with inadequate control of BP.

Acute heart failure in hypertensive crisis: focus on left ventricular diastolic dysfunction

AR Aida Babaeva[1]; EA Slepukhina[1]; SI Davydov[1]; KS Solodenkova[2]; MA Osadchuk[2]
[1]Volgograd State Medical University, Volgograd, Russian Federation; *[2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Background: Acute left ventricular failure (ALVF) could occur in patients with arterial hypertension (AH) in the setting of hypertensive crisis (HC) even in the absence of systolic dysfunction. In sever HC dramatically elevated BP leading to increased peripheral resistance seems to be a crucial factor in pathogenesis of ALVF. Myocardial remodeling and hypertrophy in AH commonly is associated with diastolic dysfunction (DD), which contributes to a cardiac output reduction.
Aims. The purpose of this clinical study was to assess the frequency of ALVF due to HC in patients who were hospitalized at cardiology department and evaluate the role of LV DD in the AHF manifestation in the patients with hypertensive crisis.
Methods: We analyzed 294 medical cards of pts who were hospitalized at cardiology ward of in-patient clinic due to ALVF (pulmonary edema) during last 10-year period. Among total ALVF cohort we separated and studied the medical cards of 67 pts (27 women and 40 men, mean age 73.28 ± 9.25) with AH and HC. Clinical, laboratory and instrumental data were analyzed in term to reveal the relationship between DD and ALVF. The diagnosis of AHF and its severity was proved on the basis of indicated respiratory rate (RR), clinical and radiologic signs of the pulmonary congestion, and the brain natriuretic peptide (BNP) levels. The presence of DD was confirmed according to the recommendations of the American Society of Echocardiography in conjunction with the European Association for Cardiovascular Imaging (2016).
Results: The commonest cause of ALVF was acute coronary syndrome (ACS), which was diagnosed in 68.38% pts, the second common cause was complicated HC (in 23% pts), arrhythmias accounted for 5.5% cases and other cardiovascular diseases were diagnosed in 4.11% of pts with ALVF. Echocardiography data from 67 pts with ALVF due to HC demonstrated that 23 pts (34.33%) did not have systolic dysfunction. The mean LV ejection fraction in this subgroup accounted for 56.05% ± 2.06%. Along with this there were not significant changes in final diastolic size of LV (mean size 5.25 ± 0.39 sm). In compliance with Doppler echocardiography protocols DD was diagnosed in 18 pts (26.87%) (mean ratio E/e' was 19.45 ± 2.34): the 1st degree of DD was documented in 12 (17.91%) pts, the 2nd degree DD - in 6 (8.96%) pts. There was strong positive correlation between the clinical (RR, pulmonary rules, HR), instrumental (PAP) and laboratory (BNP) data reflecting the severity of pulmonary congestion on the one hand and DD indices on the other hand (r>0.6, p < 0.05).
Conclusion: Sever hypertensive crisis is common cause of ALVF and reason for urgent hospitalization in AH. About one third of pts presented with ALVF due to HC do not have systolic dysfunction. Determined diastolic dysfunction was in 26.87% cases. Revealed relationship between the severity of ALVF and signs of LV DD confirms the important role of LVDD in AHF manifestation.

Early beneficial effect of bariatric surgery on subclinical myocardial impairment using global LV longitudinal strain in severely obese patients: contribution of abdominal visceral fat mobilization

ME Piche[1]; M Rodriguez-Flores[2]; K O Connor[1]; P Garceau[3]; A Auclair[1]; J Martin[1]; MA Clavel[1]; P Poirier[1]
[1]*Quebec Heart and Lung Institute, Quebec, Canada*; [2]*National Institute of Medical Sciences and Nutrition Salvador Zubiran, Mexico City, Mexico*; [3]*Montreal Heart Institute, Montreal, Canada*

Background/Introduction: The effect of bariatric surgery on subclinical myocardial function assessed using global left ventricular (LV) longitudinal strain (GLS) in severely obese individuals with normal LV dimensions and function is unclear.
Purpose: We explored the early effect of bariatric surgery on subclinical obesity-related myocardial performance impairment, and its relationship with changes in body fat distribution and cardiometabolic profile following bariatric surgery.
Methods: Thirty-eight severely obese patients (age, 41 ± 11 years; BMI, 48.4 ± 7.4 kg/m2, 40% type 2 diabetes) with preserved LV ejection fraction (<50%) who underwent biliopancreatic diversion with duodenal switch (BPD-DS) bariatric surgery, and 13 age and sex-matched healthy non-obese controls were studied. Blood samples and computed tomography were performed at baseline and 6 months following surgery. Comprehensive standard LV echocardiographic evaluation as well as GLS measurements were obtained preoperatively and 6 months post-bariatric surgery.
Results: Preoperatively, severely obese patients displayed a significant impairment in GLS vs. non-obese controls (-17.3 ± 2.5 vs. -19.7 ± 1.5%, $P < 0.01$). Six months post-bariatric surgery, mean GLS was comparable between obese patients and non-obese controls (-19.2 ± 2.1 vs. -19.7 ± 1.5%, P = NS), and GLS was normalized in 82% of severely obese patients ($P < 0.001$). The mean percentage of weight loss at 6 months was 26.3 ± 5.2%. Change in GLS following bariatric surgery was significantly associated with changes in abdominal visceral fat levels ($r = 0.43$, $P < 0.05$) and hs-CRP levels ($r = 0.45$, $P < 0.01$), whereas no significant association was found with percentage of weight loss and changes in insulin sensitivity, heart rate variability parameters or NT-proBNP levels. Additional subgroup analysis showed that those who experienced improvement in GLS post-bariatric surgery ($n = 31$) showed higher reduction in abdominal visceral fat and hs-CRP levels than those who worsened GLS ($P < 0.05$).
Conclusions: Severely obese patients with preserved LV ejection fraction showed a significant subclinical myocardial impairment as assessed by GLS measurements, which normalized at 6 months following bariatric surgery. This improvement in subclinical myocardial function was related to a greater mobilization of visceral fat depot following bariatric surgery.

Food of Short supply chain impacts metabolism and cardiovascular risk. A survey in Southern Italy

M De Rosa[1]; R Giannotti[1]; AV Pascale[1]; R Finelli[1]; V Visco[1]; M Ilario[2]; M Ciccarelli[1]; G Iaccarino[1]
[1]*University of Salerno, Dept. of Medicine, Surgery and Dentistry, Salerno, Italy*; [2]*Division of Health Innovation, Campania Region Health Department, Naples, Italy*

Background: Dietary habits influence not only body weight but also cardio-metabolic risk factors, including cholesterol, blood pressure (BP), glucose homeostasis, inflammation and visceral adiposity. In the past decades, the development of big retail distribution of food has favored energy-dense and processed foods over than fresh ones, with high fat, sugar and salt content. The so called "Western-style diet" played a key role in the spreading of diet-related chronic diseases such as obesity, type II diabetes, cardiovascular diseases. Recent studies showed that specific foods and overall dietary patterns, rather than single isolated nutrient removal from diet, are more relevant for cardio-metabolic health. Several public health interventions around the word advocate for locally grown fresh foods (Short Supply Chain-SSC- Reg. (EU)1305/13) in order to improve general population dietary habits.
Purpose: To evaluate whether food from SSC can influence metabolic outcomes and cardiovascular risk.
Methods: We carried out body weight and blood pressure measurements and collected blood samples and information on dietary habits of 539 participants in the Salerno Area (Southern Italy) during the World Hypertension Day. All of them answered an 8 items-survey to calculate a dietary score (SSC-DS) that quantifies the tendency to purchase fresh and local foods rather than industrial ones. Blood glucose, insulin, HOMA-IR Index, lipid profile, markers of renal function were assessed as metabolic outcomes, while cardiovascular risk (CVR) was calculated according to the Framingham charts. Following data quality check, data from 365 subjects were analyzed. Pearson correlation and multivariate analysis were performed to explore the relationship between the SSC-DS, metabolic outcomes and cardiovascular risk.
Results: The overall population mean age was 51.95 ± 0.7 and female sex was slightly prevalent (57.8%), while mean body mass index (BMI) was 27.08 ± 0.3. SSC-DS was inversely correlated with blood glucose ($r = -0.148$, $p < 0.01$), insulin ($r = -0.291$, $p < 0.01$), HOMA-IR index ($r = -0.325$, $p < 0.01$) and CVR score ($r = -0.113$, $p < 0.05$). CVR score was correlated also with several other parameters, such as body weight, blood glucose, urea, triglycerides and diastolic blood pressure, not included in Framingham Risk Score calculation. After multivariate analysis which included all these parameters, SSC-DS confirmed its impact on CVR.
Conclusions: : These data support the hypothesis that SSC can improve cardio-metabolic health. If confirmed in larger prospective studies, these results could promote public interventions to improve people's lifestyle.

P542

Molecular genetic markers of endothelial function in obese patients with chronic heart failure

T Tatiana Zaletova[1]; A Bogdanov[1]; S Derbeneva[1]; T Feofanova[1]; I Vorojko[1]
[1]*Research Institute of Nutrition of Russian Academy of Medical Sciences, Moscow, Russian Federation*

Introduction: Nitric oxide (NO) is synthesized in the endothelium by a specific enzyme - NO synthase, which in turn is regulated by a gene of endothelial NOS-3 synthase (NOS3). A DNA sequence of NOS3 gene, in which guanine (G) is replaced by thymine (T) at position 894, is called genetic marker G894T. As a result of this substitution in the amino acid sequence of the protein, glutamate at position 298 is replaced by aspartate (Glu298Asp), which changes protein properties. A sequence in the regulatory DNA region of the NOS3 gene, in which thymine (T) is replaced by cytosine (C) at position 786, is called genetic marker T (-786) C. Possible genotypes are ?/?, ?/?, ?/?. This substitution causes a significant reduction in gene expression and NO synthesis by the endothelium.
Objectives: To study molecular genetic predictors of chronic heart failure development in obese patients with chronic heart failure (CHF).
Methods. Samples of biomaterials (whole blood) were taken from 104 obese patients, of Russian nationality, who lived in Moscow. Consequently all patients were divided into two groups: Group 1 - Grade 3 Obesity (O3) - 50 obese patients without CHF ("CHF –"); Group 2 - Grade 3 Obesity + CHF (O3+CHF) - 54 obese patients with CHF ("CHF +").
Results: No difference was shown in the incidence of T allele between "CHF +" and "CHF -" groups while studying frequency distribution of alleles of NOS3 gene polymorphic marker G894T. In males genotype frequencies in the control group and in the main group show that polymorphic marker G894T of NOS3 gene is not associated with the development of HF in obese male subjects. In female CHF patients, genotype NOS3 T / T ($p = 0.04$) and T allele incidence ($p = 0.04$) were significantly more common. At the same time, relative risk of HF development in patients with the given genotype was 2.73 times higher (RR = 2.27, 95% CI [0.31-12.18]). Distribution analysis of allele frequency and genotypes of polymorphic marker T786C of NOS3 gene did not reveal any differences between sexes in both "CHF +" and "CHF -" groups.
Conclusions: Thus, the study suggests that verifying mutations of NOS3 gene to stratify the risk of CHF development in obese patients is reasonable only in females, with G894T being informative.

P543

The effect of high plasma nesfatin-1 level on metabolic risk factors in hypertensive patients

M Maryna Vizir[1]
[1]*Kharkiv National Medical University, Kharkiv, Ukraine*

Background: Estimation of total cardiovascular risk is based on blood pressure level, risk factors and presence of organ damage. The link between such factors as hypertension, obesity, hypercholesterolemia, insulin resistance exists at the level of pathogenetic mechanisms. Nesfatin-1 was discovered as anorectic peptide secreted by hypothalamus, adipose tissue and other organs. Currently, its possible role in the development of concomitant diseases and the possibility of its use for therapeutic purposes are being studied.
Purpose: To investigate the association between the highest plasma nesfatin-1 levels and metabolic parameters in hypertensive patients.
Methods: 106 patients with essential hypertension were examined. Anthropometric data were obtained. Fasting and postprandial glucose levels were determined by the glucose oxidase method. Insulin (mkIE/ml) and nesfatin-1 (ng/ml) levels were determined by enzyme immunoassay method. Total cholesterol, triglycerides,

high-density lipoprotein cholesterol (HDLc) and low-density lipoprotein cholesterol were measured. The atherogenic coefficient was obtained as non-HDLc/HDLc. Nesfatin-1 levels were divided into quartiles, and these 4 groups (Q1-4) were used for comparing of results using the Mann-Whitney test, ANOVA rank Kruskal-Wallis test, the median test. Spearman's rank correlation coefficient was used for estimation of the relationship between two variables.
Results: The range of nesfatin-1 distribution was from 4.88 to 9.71 ng/ml. Patients of Q4 (= 8.44 ng/ml) were characterized by lower body mass index (p = 0.01), hips circumference (p = 0.002), lower levels of postprandial glucose (p = 0.03), HDLc (p = 0.01) and higher levels of triglyceride (p = 0.02).
Application of Spearman's rank correlation coefficient to Q4 parameters showed negative correlation of nesfatin-1 with weight (r= -0.356, $p < 0.01$), body mass index (r= -0.514, $p < 0.001$), waist circumference (r= -0.451, $p < 0.001$), hips circumference (r= -0.471, $p < 0.001$), levels of fasting glucose (r= -0.289, $p < 0.05$), postprandial glucose (r= -0.468, $p < 0.05$), and positive correlation of nesfatin-1 with atherogenic coefficient (r= 0.288, $p < 0.05$).
Conclusions: Higher nesfatin-1 levels in hypertensive patients were accompanied by lower anthropometric and glycemic parameters and increased atherogenic risk. These data may have important value for early diagnostics and treatment of patients in order to reduce cardiovascular risk.

Diabetes and the Heart

Association between crucial risk factors for heart failure and gut microbiota: Moscow study

DA Daria Kashtanova[1]; ON Tkacheva[2]; AS Popenko[3]; AV Tyakht[3]; EN Doudinskaya[2]; DG Alexeev[3]; YUV Kotovskaya[2]
[1]National Research Center for Preventive Medicine, "Research of Age and Age-associated Conditions" Department, Moscow, Russian Federation; *[2]Russian National Research Medical University, Russian Clinical Research Center for Gerontology, Moscow, Russian Federation*; *[3]Moscow Institute of Physics and Technology, Moscow, Russian Federation*

Funding Acknowledgements: Governmental support

Introduction: Diabetes mellitus type 2 (DM), obesity (O) and abdominal obesity (AO), arterial (AH), high fat diet (HFD) are important modifiable risk factors (RF) for heart failure. At the same time recent years have brought interesting insights into the human gut microbiota impact on cardiovascular diseases (CVD). The aim of this study was to evaluate the associations between all these factors including gut microbiota composition in apparently healthy individuals from Moscow.
Materials and Methods: The study included 98 Moscow residents, 66 women and 32 men aged 25 to 76y/o (52 ± 13y/o) carefully selected through exclusion of CVD by

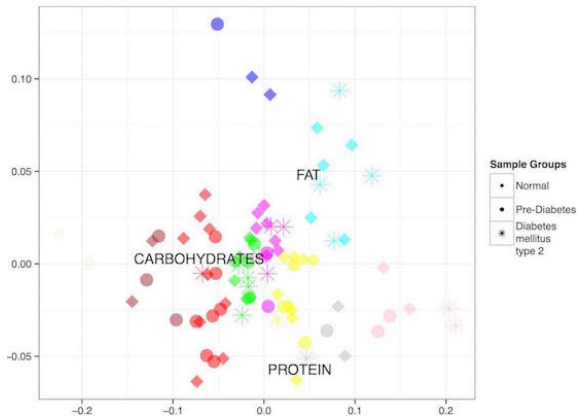

Fig. 1. Diet clusters

means of clinical and laboratory evaluation, ECG, treadmill test, ECHOCG, carotid ultrasound examination. RF were considered as follows: new onset 1st grade AH, O and AO except morbid, new onset DM, HFD. Gut microbiota was studied by 16S rRNA sequencing (V3-V4 regions). Diet - by quantitative assessment. Statistical analysis was performed using the R3.1.0., generalized linear models (FDR, age and sex adjusted) and clustering methods.
Results: 1st grade AH was detected in 37%, O in 25%, AO in 55%, DM in 23%, HFD - in 39%. Low bacterial alpha-diversity was associated with DM (FDR 0,015, k-means clustering). DM as well as O and AO were associated with high abundance of gram-negative opportunistic genera Serratia (FDR 0.003; 0.003; 0.004) and Prevotella (FDR 0.001; < 0.001; < 0.001). Low Oscillospira abundance was strongly correlated with abdominal obesity (FDR < 0.001). This genus is a "central enigmatic component" of the gut microbiome, which reduce inflammation and associated with leanness and high physical activity level. Interestingly, Blautia genus was highly abundant in patients with AH (FDR 0.002) and DM (FDR < 0.001). These bacteria induce low-grade inflammation and convert CO2 into acetate, which is an established lipids precursor. HFD was associated with low representation of Bifidobacterium (FDR 0.008). Samples were clustered by diet (protein, fat, carbohydrate consumption) with Calinski-Harabasz criterion. Cluster with very high consumption of fat contained 50/50% stool samples from donors with DM and normal glucose metabolism (Fig. 1, cian color). There were no differences between these patients in caloric consumption, age, sex and diet features. Although DM in high fat cluster was strongly correlated with Blautia representation (FDR 0.0001).
Conclusions: We concede that gut microbiota composition shifts along with classical risk factors act together to influence metabolic and CVD risk. Also we propose that combination of HFD with high Blautia abundance may lead to DM.

Exercise Testing

P545
Atrial geometrical and functional remodelling in long-term endurance training athletes

A A Molnar[1]; B Lakatos[1]; B Solymossi[1]; Z Tarcza[1]; C Bognar[1]; O Kiss[1]; A Kovacs[1]; B Merkely[1]
[1]Semmelweis University, Heart and Vascular Center, Budapest, Hungary

Purpose: Left atrial (LA) enlargement is common in master athletes. It is suggested that this represents a physiologic adaptation to long-term endurance training and not a consequence of increased left ventricular filling pressures secondary to diastolic dysfunction. The aim of our study was to investigate atrial remodelling and exercise capacity of elite athletes.
Methods: Sixty professional football male players (17.7 ± 3 years) and 20 non-sportive males (18.9 ± 1.9 years) were compared. All subjects underwent ECG, spiroergometry and two-dimensional transthoracic echocardiographic examination (Philips EPIQ7 Ultrasound) with the evaluation of left (LA), right atrial (RA) dimensions and deformation by strain and strain rate. Images were analyzed off-line with a commercially available software (TomTec 2D Cardiac Performance Analysis). LA and RA strains and strain rates were calculated with the reference point set at the onset of the P wave of the surface ECG, which allowed identifying left atrial contraction strain (LASa) and contraction strain rate (LASRa), atrial conduit strain (LASc) and conduit strain rate (LASRc), and finally atrial reserve strain (LASr) and reserve strain rate (LASRr). Maximum oxygen uptake (peak VO2) was defined as the highest value reached at the end of the exercise.
Results: LA and RA volumes were larger in athletes than in controls (52.2 ± 18.2 vs. 43.1 ± 12.4 mL, $p < 0.05$ and 56.5 ± 19.3 vs. 46.0 ± 10.4 mL, $p < 0.05$ respectively). LASa and LASRa during active atrial contraction were decreased in athletes (-8.1 ± 3.1 vs. -10.1 ± 3.5 %, p = 0.01; -0.91 ± 0.4 vs. -1.2 ± 0.4, p = 0.01). Athletes LA volumes trend to correlate with LASa (r = -0.22, p = 0.08) and show a significant correlation with peak VO2 (r= 0.33, $p < 0.01$). Furthermore, there was a significant correlation between peak VO2 and LA ejection fraction, LASc, LASRc, LASr and LASRr (r= -0.27, r= 0.38, r= 0.43, r= 0.32, r= -0.38 respectively, $p < 0.05$).
CONCLUSION: Endurance athletes showed left atrial enlargement and decreased left atrial contraction deformation as a physiologic response to long-term endurance training. Beyond, this adaptation correlates with maximum oxygen uptake reflecting physical capacity in a given athlete. The key challenge in an athlete's screening is the distinction between abnormal and normal which is hindered by the fact of the adaptation to sports activity.

P546
Detection of oscillatory ventilation in different phases of cardiopulmonary exercise testing is associated with the functional capacity of patients with chronic heart failure

N Panagopoulou[1]; L Karatzanos[1]; V Zarvalias[1]; P Ferentinos[2]; C Kapelios[3]; S Dimopoulos[1]; A Ntalianis[4]; E Repasos[4]; S Nanas[1]; A Sideris[5]
[1]Clinical Ergospirometry, Exercise & Rehabilitation Laboratory, NKUA, Athens, Greece; *[2]Carnegie Faculty , School of Sport, Leeds Beckett University, Leeds, United Kingdom*; *[3]Laiko General Hospital of Athens, Cardiology Department, Athens, Greece*; *[4]Department of Therapeutics, School of Medicine, NKUA, Athens, Greece*; *[5]Evaggelismos General Hospital of Athens, 2nd Cardiology Department, Athens, Greece*

Intoduction: Oscillatory ventilation (OV) is an abnormal breathing pattern chronic heart failure (CHF) patients present during exercise phase in cardiopulmonary exercise testing (CPET) and it is highly associated with poor prognosis.
Purpose: To seek possible associations of the OV during exercise and/or recovery phase with the functional capacity of patients with CHF.
Methods: 267 patients (age: 54 ± 13 years) with stable systolic CHF were prospectively enrolled and evaluated with maximum, symptom-limited CPET.

Criteria to determine oscillatory cycles were based on amplitude = 15% of the average resting amplitude, lasting = 60% of total CPET phase duration. These criteria were applied at both the exercise and the recovery phase (3min duration). The following 3 OV groups were identified: a) OV occuring during exercise and recovery phases (E-ROV), b) OV occuring only at exercise phase (EOV) and c) OV occuring only at the recovery phase (ROV). Groups were compared for CPET parameters, LVEF and OV specific characteristics (percentage of duration, average amplitude and average length). Values are expressed as mean ± SD.

Results: A total of 85 E-ROV, 58 EOV and 44 ROV were identified. Significant differences in VO2peak, VEpeak and VO2/t slope were found among the study groups (Table 1). EOV patients displayed broader average OV length at exercise than E-ROV (50 ± 18 sec vs 45 ± 13 sec respectively, p = 0.05). No differences were observed (p>0.05) for percentage of duration (80 ± 12% vs 77 ± 11%) and average amplitude (7.4 ± 4.0 L/min vs 7.6 ± 4.5 L/min).

Conclusions: Among patients with CHF, OV can appear in different phases of CPET. An OV pattern only during the phase of exercise associates with a worse functional capacity and consequently with a potentially higher severity in CHF patients. Broader average oscillatory length, likely reflects higher circulatory delay, could explain, up to some extent, the worse functional capacity in EOV CHF subgroup.

Table 1. Comparison of the three OV groups for CPET parameters and LVEF

	EOV	E-ROV	ROV	p
N	58	85	44	
VO_2peak (ml/kg/min)	15.8±5.8	19.4±8.1*	20.0±8.6*	0.024

Echocardiographic findings in amateur male marathon runners

Z Lewicka-Potocka[1]; A Dabrowska-Kugacka[2]; L Danilowicz-Szymanowicz[2]; R Galaska[1]; M Kubik[2]; AM Kaleta[2]; E Lewicka[2]; G Raczak[2]
[1]Medical University of Gdansk, First Department of Cardiology, Gdansk, Poland; *[2]Medical University of Gdansk, Department of Cardiology and Electrotherapy, Gdansk, Poland*

Background: Regular and moderate physical activity has a number of positive effects on human organism, however the "upper dose" of beneficial endurance exercise has not been determined yet. Long-term endurance training can lead to multiple well-described adaptations in cardiac morphology, called the "athlete's heart". Marathon running has become very popular now, however, very little is known whether any physiological remodeling appears also in amateur marathon runners. The question arises which reference values should be applied in echocardiographic assessment of amateur runners, should ranges for competitive athletes or those for general population be used?

Purpose: We analyzed heart structure of amateur marathon runners by means of echocardiography to verify whether they fulfill the current normative values criteria for adults.

Methods: We included 34 amateur male marathon runners in the mean age of 40 years (24-55). Transthoracic echocardiography included two-dimensional conventional measurements, spectral and tissue Doppler, and flow propagation velocity. The examination was performed two weeks before their attendance in the 2nd PZU Marathon in Gdansk, Poland. We compared echocardiographic results with published reference values for adults, as well as professional athletes.

Results: The comparison was made for general adult population. The mean left atrial area index was 11.2 cm2/m2 and in 22 out of 34 (65%) participants it exceeded the upper normal value for adults. The mean left atrial volume index was 35.2 ml/m2 and in 26 (76%) subjects it was greater than the upper normal value for adults. The mean interventricular septum dimension was 1.12 cm and it exceeded the normal range in 22 men (65%). The mean left ventricular mass was 94.55 g/m2 and it was increased in 10 subjects (29%). The mean proximal right ventricular outflow diameter was 2.99 cm and was beyond the norm in 16 (47%), while the mean basal right ventricular dimension was 3.75 cm and it exceeded the normal range in 5 individuals (15%).

Conclusion(s)

When compared with the reference ranges for general adult controls, amateur male marathon runners fulfilled the general criteria or presented larger dimensions. Left atrial enlargement was the most often finding. Presented results may suggest that physiological remodeling within the heart can appear also in amateur athletes, what should be taken into account when echocardiographic examination is performed in individuals with the marathon attendance history.

P548

Benefits of cardiac rehabilitation in diabetic patients after an acute coronary syndrome

M Marta Braga[1]; A Rocha[1]; H Nascimento[1]; R Pinto[1]; P Araujo[1]; S Torres[1]; A Nunes[1]; V Araujo[1]; F Parada-Pereira[1]; MJ Maciel[1]
[1]Sao Joao Hospital, Porto, Portugal

Introduction and Purpose: Diabetes mellitus is a major risk factor for cardiovascular (CV) disease. It is well known that cardiac rehabilitation program (CRP) improves outcome in patients after acute coronary syndrome (ACS). The aim of this study was to characterize the risk profile of diabetic patients and evaluate the impact of CRP in functional capacity (FC) in these patients comparing to non-diabetic patients.

Methods: We analysed data prospectively collected from patients who completed a CRP after an ACS, from 2008 and 2016. Patients were divided in two groups: Diabetic patients (G1) and non-diabetic patients (G2), according to International Diabetes Foundation criteria. FC was assessed using a standard exercise test (ET), including exercise duration and intensity in metabolic equivalents (METs).

Results: Of 734 patients, 133 patients were diabetic (18.1%). Mean age was 59.9 ± 8.9 years in G1 and 53.2 ± 9.6 years in G2, p < 0.001. In both groups, most patients were male. Only 23.5% of diabetic patients were insulin dependent and initial mean glycated haemoglobin was 7.7 ± 1.4%. Concerning to other CV risk factor, hypertension (53.4% vs 39.1%, p = 0.003), dyslipidaemia (72.2% vs 58.7%, p = 0.011) and obesity (35.4% vs 22.7%) were more frequent in G1, while smoking was more prevalent in G2 (33.1% vs 57.7%, p < 0.001). About 50.0% of patients in G1 had multivessel coronary artery disease, comparing to 24.5% in G2 (p = 0.021) and coronary artery bypass graft occurred more frequently in G1 (15.8% vs 6.3%). Mean left ventricular ejection fraction was similar in both groups (52.6 ± 12.6 vs 52.6 ± 11.4). Regarding baseline FC, ET duration was 7.3 ± 2.1 min in G1 and 8.7 ± 2.4 min in G2 (p < 0.001), and ET intensity was 7.9 ± 2.0 METs in G1 and 9.2 ± 2.3 METs (p < 0.001). In the end of CRP, both patients improved their FC, duration (increase of 18.0% in G1 and 17.3% in G2) and intensity (increase of 16.9% in G1 and 16.0 in G2) without statistically significant difference. Mean glycated haemoglobin of G1 patients after CRP was 6.2 ± 1.0%.

Conclusions: Diabetic patient had higher CV risk profile comparing to non-diabetic and even so they had lower participation in CRP. In spite of showing worse ET results at the beginning and at the end of CRP, they had improved their FC in a similar form as the non-diabetic patients. This study highlights the need to identify and correct the barriers to CRP recruitment of this higher risk group of patients.

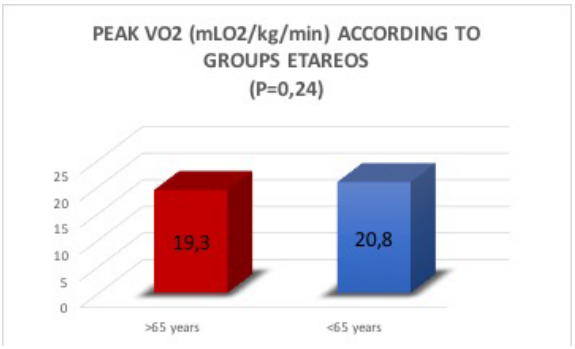
Introduction: The prevalence of coronary disease increases with age, with the cardiovascular cause being the main cause of death in people over 65 years old, up to 80% of cases according to some series.

PARAMETERS	>65 years	<65 years	P
METS	7,9 + 1,6	8,3 + 2,5	0,47
BP sistolic at maximum load (mmHg)	171,8 + 15,2	162,4 + 17,7	0,03
RER at maximum load	1,1 + 0,1	1,09 + 0,09	0,73
Peak VO_2 (mLO_2/kg/min)	19,3 + 4,2	20,8 + 6,7	0,24
Predicted percentage VO2	79,3 + 20,9	77,9 + 19,7	0,79
O_2 pulse trajectory (mL/beat)	11,6 + 2,6	14,2 + 3,8	0,001
Predicted percentage PO2 (%)	82,7 + 15,3	79,6 + 17,1	0,45
Volumen Tidal at maximum load (L/min)	1,67 + 0,5	1,96 + 0,6	0,04
$P_{ET}CO_2$ at maximum load (mmHg)	30,9 + 3,6	33,4 + 4,1	0,01
Ventilation minute (L/min)	59,8 + 17,4	67,1 + 20,4	0,12
Porcentaje predicho VE (%)	99,3 + 25,1	79,9 + 26,2	0,01
VE/VCO2 slope	33,4 + 4,3	32,1 + 6,6	0,3

Methods: Cross-sectional study. 91 patients subjected to cardiopulmonary exercise testing, with a diagnosis of ischemic heart disease who underwent cardiac catheterization and coronary revascularization for an acute coronary syndrome, between 2-3 months before the test. The patients were divided into two groups (group 1:>65 years, group 2: <65 years). We evaluated demographic variables, percutaneous angioplasty, anthropometric, echocardiographic, CVRF and comorbidities. SPSS 20. Qualitative variables were evaluated with X2. The quantitative variables are expressed as means+/-SD, being evaluated with the Student's T test. Statistical significance p <0.05.
Results: 91 patients; 21.7% (20 pctes) were >65 years old, the mean age was 56.9 ± 9.5 years, 9.8% women (9 pts). Among the baseline characteristics of both groups, we found that those >65 years had lower BMI (p = 0.04), without finding differences in other CVRF, comorbidities and echocardiographic characteristics. The parameters of oxygen consumption, in absolute value and adjusted per kilogram of weight are detailed in table 1.
Conclusions: : In our study, patients older than 65 years showed an aerobic capacity with cardiopulmonary response within normality, similar to younger patients, although with higher blood pressure at rest and at maximum load and slight tendency to hyperventilation, without showing greater alteration of the ventilation/perfusion relationship.



P550
Preliminary results in physical recovery after laparoscopic vs. open liver resection

S Stephanie Kampf[1]; C Schwarz[1]; M Sponder[2]; J Bergler-Klein[2]; C Sandurkov[3]; K Kaczirek[1]
[1]Medical University of Vienna, Department of Surgery, Vienna, Austria; *[2]Medical University of Vienna, AKH - Vienna, Cardiology Clinic, Vienna, Austria*; *[3]Medical University of Vienna, Division of Anatomy, Vienna, Austria*

Background: Minimally invasive laparoscopic surgery has proven to be equivalent in colorectal and gastric surgery. The role in liver surgery still remains controversial. This study was designed to investigate the impact of laparoscopic liver resection compared to open surgery on short- and long-term postoperative fitness and inflammatory response.
Methods: 40 Patients undergoing liver resection will be included into a laparoscopic (group 1) or open surgery group (group 2). Post-operative recovery is measured by bicycle stress testing at month 1 and 6 and compared to the preoperative performance. Standardized performance (%) for bicycle stress testing was calculated based on age, sex, height and weight. Postoperative recovery was compared between groups as mean change of performance (%).
Results: 15 patients completed the 1st month control, 9 patients the full trial. 3 of 9 patients had laparoscopic and 6 of 9 patients had open surgery. Mean arterial blood pressure was 104 ± 14 mmHg in group 1 vs. 111 ± 9 mmHg in group 2 (p = 0.51). Mean heart rate preoperative was 77 ± 12 bpm in group 1, respectively 75 ± 15 bpm in group 2 (p = 0.76). 1 month postop mean heart rate was 79 ± 19 bpm in group 1, respectively 73 ± 16 bpm in group 2 (p = 0.51).
Mean preoperative performance was 78 ± 19 % in group 1 and 80 ± 16 % in group 2 (p = 0.82). Baseline performance for both groups therefore was below average due to multimorbidity and age. One month postoperatively the relative performance changes to baseline were -3.8% in group 1 vs. -6.4% in group 2 and -7.7% in group 1 vs. -8.9% in group 2 at 6 months. Postoperative mean CRP was 3.6 vs 5.2 in group 2, postop AST (378 vs. 396U/L), ALT (335 vs. 332U/L), bilirubin (0.55 vs. 0.88mg/dL), prothrombin time (65 vs. 58%) showed no statistical difference.
Conclusion: So far, recovery after laparoscopic vs. open surgery did not show any statistical significant **Results:** However, a tendency regarding faster recovery recovery could be observed after after laparoscopic surgery, but due to the small sample size no definite conclusion can be drawn yet.

Atrial Arrhythmias and Sarcoidosis: Prevalence and clinical implications

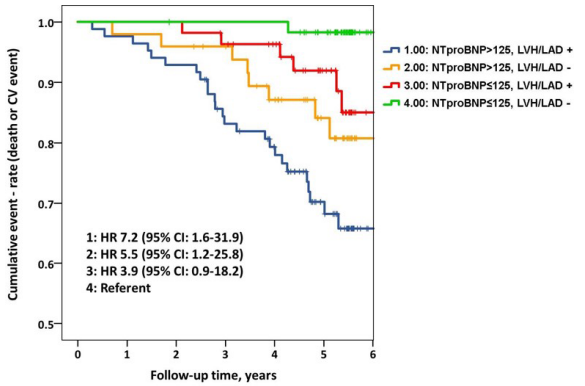
E Elias Gialafos[1]; S Katsanos[2]; L Kolilekas[3]; E Tsougos[4]; E Manali[2]; G Stratakos[1]; N Koulouris[1]; S Papiris[2]; G Filippatos[2]
[1]University of Athens, Athens, Greece; *[2]Attikon University Hospital, Athens, Greece*; *[3]Sotiria Regional Chest Diseases Hospital, 7th Department of Pulmunology, Chest Disease Hospital "Sotiria", Athens, Greece*; *[4]Errikos Dunant Hospital, 2nd Cardiac Department, Athens, Greece*

Introduction: Cardiac sarcoidosis is a major cause of morbidity and mortality in affected individuals. Ventricular arrhythmias are one of the main causes of sudden death in cardiac sarcoidosis .However, the incidence of atrial arrhythmias (AA) in sarcoidosis is not well known. Aim of this study was the assessment of the prevalence as well as the predictors of atrial arrhythmias in a large population of patients with sarcoidosis.
Methods: We included 328 patients with biopsy proven sarcoidosis (121 males, 52.78 ± 12.46 yo) who underwent a full cardiac examination included cardiac magnetic resonance (CMR) for workup of suspected cardiac sarcoid involvement. ECG, Holter monitoring or implantable cardioverter defibrillator interrogations were used to document AA. Echocardiographic data, lung function tests, demographics, and extracardiac involvement were recorded, and univariate and logistic regressions were performed to compare characteristics of patients with and without documented AA.
Results: The prevalence of AA was 30.3% with atrial fibrillation being the most common type of arrhythmias with 12,7%. Age (p = 0.002, CI:1.014-1.060), diffusing capacity for carbon monoxide (p:0.026, CI:0.968-0.998) and cardiac involvement (p = 0.0001, CI: 0.121-0.377) were independent predictors of AA on multivariate analysis. Feeling of palpitation, arterial hypertension, dyslipidemia, increased left atrial diameter, valvular dysfunction, diastolic dysfunction, total lung capacity and left anterior hemiblock on ECG were predictors of AA on univariate analysis.
Conclusion: In a large cohort of sarcoidosis patients, this study found a prevalence of AA of about 30%. AA in patients with is associated with cardiac involvent and the feeling of palpitation.

P552
Presence of echocardiographic criteria for heart failure with preserved ejection fraction multiplies the risk for death and cardiovascular events in patients with rheumatic diseases

M Breunig[1]; C Morbach[1]; S Kleinert[2]; H-P Tony[3]; CE Angermann[4]; S Stoerk[1]
[1]University Hospital of Würzburg, Comprehensive Heart Failure Center and Dept. of Medicine I, Würzburg, Germany; *[2]University Hospital of Würzburg, Dept. of Rheumatology/Clinical Immunology and Rheumatology and Nephrology Erlangen, Erlangen, Würzburg, Germany*; *[3]University Hospital of Würzburg, Dept. of Rheumatology/ Clinical Immunology, Würzburg, Germany*; *[4]University of Würzburg, Comprehensive Heart Failure Center, Würzburg, Germany*

Background: Patients with rheumatic diseases (RD) have an increased risk for cardiovascular (CV) disease and heart failure (HF). Clinical assessment of HF signs & symptoms in RD is often limited by functional impairment. We investigated the prognostic value of echocardiographic and neurohormonal criteria for HF with preserved ejection fraction (HFpEF) in patients with RD.
Methods: This prospective, single-center study included consecutive RD outpatients considered at increased risk for CV events according to ESC score (= 3%), pathological ECG, or elevated NTproBNP (<200 pg/mL) as published by this group*.



Clinical assessment and transthoracic echocardiography according to ESC criteria was performed. Presence of HFpEF was assumed positive, if patients had NTproBNP >125 pg/mL, and either left ventricular hypertrophy (LVH; averaged septal-posterior wall thickness >11 mm) or left atrial dilation (LAD; LA Diameter >43 mm), regardless of presence of dyspnea. Kaplan-Meier plots were generated, and hazard ratios (HR) with 95% confidence intervals were computed using Cox regression with adjustment for age.

Results: Out of 764 patients (mean age 51 yrs, 70% female) 46% had rheumatoid arthritis (RA), 34% systemic autoimmune diseases (SAI; connective tissue disease or vasculitis), and 20% spondylo-arthritis (SpA); 248 of these patients (mean age 61 ± 13 yrs, 62% female, RA 46%; SAI 32%; SpA 22%) had valid echocardiographic data (4 patients with LV ejection fraction < 50% were excluded; follow-up data was missing in 3 cases). After a median follow-up time of 5.4 yrs, 20.6% of patients (group 1-4: n= 19/5/8/1 respectively) had died or suffered a CV event (myocardial infarction 4.1%; stroke 1.8%; decompensated HF 1.8%; resuscitation 0.9%).

In univariable analysis NTproBNP >125 pg/ml (HR 3.6; 1.9-6.8, p = 0.0001), LAD or LVH (HR 2.3; 1.1-4.5, p = 0.02), and age per 5 years (HR 1.4, 1.2-1.6, p < 0.0001) were significant predictors for an increased risk for death or CV event.

Compared to the referent group consisting of patients with no signs of LVH or LAD in the presence of normal NTproBNP (group 4; n = 59, 23.8%), patients with echocardiographic criteria for HFpEF (group 1; n = 84, 33.9%) had a 7-fold increased risk for death or CV event: HR 7.2 (1.6-31.9; figure). The event risk for both patients with elevated NTproBNP but absent LVH or LAD (group 2; n = 49, 19.8%) as patients with normal NTproBNP but presence of LVH or LAD (group 3; n = 56, 22.6%) was also 5- to 6-fold increased: HR 5.5 (1.2-25.8) and 5.5 (0.9-18.2), respectively.

Conclusions: In patients with RD with an increased baseline CV risk, echocardiographic criteria suggestive of HFpEF are highly relevant indicators of worse outcome (7-fold increased risk for death or CVE), in particular in conjunction with an elevated NTproBNP value, irrespective of clinical presentation.

Use of standard cardio-vascular risk estimation scales may not be enough in patients with rheumatoid arthritis

E Troitskaya[1]; S Velmakin[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples'Friendship University of Russia (RUDN University), Moscow, Russian Federation*

Objective: Rheumatoid arthritis (RA) is associated with increased cardiovascular (CV) risk. Besides monitoring of the disease activity, identification of high CV risk patients is of great importance.

The aim of the study was to assess the abilities of 3 risk models (SCORE, QRisk 2 and 10-year ASCVD) in detecting high CV risk RA patients.

Materials and methods: 56 patients with RA (ACR/EULAR 2010) without known CV disease were examined (84% females, age 58.4 ± 14.1 (M ± SD) years, BMI 26.1 ± 5.4 kg/m2, smokers 9%, arterial hypertension (AH) 64%, dyslipidemia 57%, diabetes 7%). Median duration of RA was 7 years (IQR 2-14). Seropositive RA was diagnosed in 73% of patients. Median hsCRP was 7.8 mg/dl (IQR 2;21.4), rheumatoid factor (RF) - 61.2 IU/ml (IQR 18.5;179.2), mean DAS-28(CRP) - 3,7 ± 1,2. All patients received disease-modifying antirheumatic drugs. SCORE, QRisk2 and 2013 ACC/AHA 10-year ASCVD risk and EULAR recommended modified versions were calculated. Patients with SCORE = 5%, QRisk2 = 20% and ASCVD risk = 7.5% were classified as having high CV risk. Carotid intima-media thickness (CIMT) = 0,9 mm and/or carotid plaques detected by ultrasonography were used as the gold standard test for high CV risk. p < 0.05 was considered significant.

Results: The median SCORE, QRisk2 and ASCVD were 2.2% (IQR 0.6;4.9), 10.2% (3.4;19.2) and 4.9% (1.5;12.8) respectively. The proportion of high-risk patients was as follows: 14 (25%), 13 (23%), 24 (43%) for SCORE, QRisk2 and ASCVD. Mean CIMT was 0.76 ± 0.24 mm. US criteria for subclinical atherosclerosis (US+) were found in 27 (48%) pts. Discriminating capacities for the indexes were as follows: AUC 0.723 (CI 95% 0.626-0.821) for SCORE, AUC 0.705 (CI 95% 0.606-0.804) for QRisk2 and AUC 0.837 (CI 95% 0.757-0.917) for ASCVD. The percentages of high-risk patients in US+ group were as follows: 13 (48%), 12 (44%) and 21 (78%), respectively, (p < 0.05 compared to ASCVD). After multiplying by 1.5 (EULAR 2016) mASCVD reclassified 2 (7.4%) and mSCORE - 4 (14.8%) pts from moderate to high risk. Use of lower cut-off values for risk indices (SCORE = 1%, QRisk2 = 10% and ASCVD = 5%) resulted in better detection of US+ pts (100%, 85% and 85% respectively).

Conclusions: The 2013 ACC/AHA 10-year ASCVD risk estimator is better than the SCORE and QRisk2 indices for the detection of high CV risk RA patients. Adjustment of the threshold may be a better modification of risk scales than use of the EULAR multiplier factor.

P554

High prevalence of left ventricular systolic dysfunction assessed by speckle tracking in asymptomatic patients with diabetes mellitus type 1

C Chris Kapelios[1]; S Liatis[1]; M Bonou[1]; A Tentolouris[1]; I Eleftheriadou[1]; P Mantzouratou[1]; E Papachristoforou[1]; K Barmpagianni[1]; D Tsiliggiris[1]; J Barbetseas[1]
[1]*Laiko University General Hospital, Athens, Greece*

Background: Diabetes mellitus type 1 (DM1) primarily affects young, otherwise healthy, individuals. Cardiomyopathy presenting in these patients is usually the direct result of hyperglycemia and its effects. Thus, this subset of patients is of special clinical interest. Pre-symptomatic diagnosis of myocardial injury could enable prompt and potentially more effective implementation of therapeutic measures. However, the data that are available to date on the specific topic are limited.

Methods: We investigated the association between global longitudinal strain (GLS), an established index of subclinical left ventricular systolic dysfunction (SLVSD), assessed by 2-D speckle tracking and a) patient history, b) demographic and clinical baseline characteristics, c) autonomic nervous system function, measured using the battery of the 4 standardized tests proposed by Ewing, d) arterial stiffness, assessed by calculating pulse wave velocity between the carotid and common femoral arteries, e) prevalence and severity of diabetic nephropathy and f) prevalence and severity of diabetic retinopathy in patients with DM1 and no history of cardiovascular disease.

Results: We prospectively enrolled seventy-three asymptomatic patients with DM1. Thirteen (17.8%) were men, while mean age, disease duration and glycated hemoglobin were 36.8 ± 12.9 years, 19.9 ± 10.3 years and 7.2 ± 1.2%, respectively. SLVSD, defined as a value of GLS> -19.6%, was prevalent in 32/73 (43.8%) patients. GLS was significantly associated with body mass index (BMI, Pearson co-efficient, r = 0.387, P = 0.001) and glycated hemoglobin levels (r = 0.296, P = 0.015). Logistic regression analysis demonstrated a significant association between presence of SLVSD and ??? (OR: 1.232; 95% CI:1.074-1.414, P = 0.003) and glycated hemoglobin (HR: 1.699; 95%CI: 1.034-2.791, P = 0.034).

Conclusion: Our results indicate that apart from chronic hyperglycemia a dysmetabolic component, expressed by a higher BMI, may be implicated in the pathogenesis of premature myocardial injury, which leads to diabetic cardiomyopathy, in patients with DM1.

Effects of tailored telemonitoring on functional status and quality of life in patients with heart failure

J Josiane Boyne[1]; A Gingele[2]; B Ramaekers[3]; HP Brunner La Rocca[2]; GJ De Weerd[4]; J Kragten[5]; V Van Empel[2]; HJM Vrijhoef[2]; APM Gorgels[2]; G Cleuren[2]; C Knackstedt[2]
[1]*University Hospital Maastricht, Maastricht, Netherlands*; [2]*Maastricht University Medical Center, Maastricht, Netherlands*; [3]*Maastricht University Medical Center, Department of Clinical Epidemiology and Medical Technology Assessment (KEMTA), Maastricht, Netherlands*; [4]*Zuyderland Medical Center, Cardiology, Sittard, Netherlands*; [5]*Zuyderland Medical Center, Cardiology, Heerlen, Netherlands*

Aims: Functional status and quality of life (QoL) are important in patients with heart failure (HF). Little is known about the effect of telemonitoring (TM) on functional status and QoL in HF patients.

Methods/Results: 382 HF-patients (NYHA class 2-4) were included in a randomized controlled trial to compare tailored TM to usual care. At baseline (T0) and after 12 month (T12), patients' functional status was determined by Metabolic equivalent scores (METS) and Borg rating of perceived exertion scale (Borg). QoL was measured with the EuroQol five dimensions questionnaire (EQ-5D) and EQ-5D visual analogue scale (VAS). By analyzing electronic patient files, clinical data about mortality was obtained. TM was significantly related with an increase in METS after one year (Regression coefficient 0.318; p = 0.01). Telemonitoring did not have an effect on changes in Borg, EQ-5D and VAS after one year.
We found that EQ-5D (Hazard ratio (HR) 0.19, 95% Confidence interval (CI) 0.07-0.54), EQ-5D VAS (HR 0.98, 95%CI 0.96-0.99), Borg (HR 1.21, 95%CI 1.11-1.31) and METS at T0 (HR 0.73, 95%CI 0.58-0.93) were significantly associated with survival at T12.
In both groups, an increase of METS (T12-T0) was correlated with improved Utility (p <0.05) and a decrease of Borg (T12-T0) (p <0.05).
Conclusions: TM increased functional status of patients with HF, whereas no effect on QoL could be found. EQ-5D, Borg and METS can be used to predict survival in HF patients.

Mean scores of VAS, Utility, METS and Bo

Group	Score T0 (SD)	Score T12 (SD)	Δ T12-T0	Coefficient Intervention Group	p-value
	VAS	VAS			
Control (C) (n = 173)	57.82 (18.45)	63.18 (17.55)	5.36		
Intervention (I) (n = 179)	63.31 (16.84)	66.03 (15.34)	2.72	-0.081	0.95
	Utility	Utility			
C (n = 173)	0.61 (0.30)	0.63 (0.30)	0.02		
I (n = 179)	0.64 (0.30)	0.65 (0.28)	0.01	0.005	0.83
	METS	METS			
C (n = 173)	4.10 (1.79)	3.91 (1.70)	-0.19		
I (n = 179)	4.35 (1.82)	4.36 (1.86)	0.01	0.318	0.01
	Borg	Borg			
C (n = 173)	10.76 (3.76)	10.81 (3.74)	0.05		
I (n = 179)	10.25 (3.71)	10.18 (3.62)	-0.07	-0.368	0.22

Borg = Borg rating of perceived exertion scale; METS = Metabolic equivalent scores; n = numbers; P < 0,05 was considered statistical significant; SD = Standard deviation; Utility = calculated with EQ-5D scores; VAS = visual analogue scale.

Communication difficulties in the care pathway of patients admitted to hospital with acute decompensated heart failure

M Walshe[1]; C Keane[1]; M Ledwidge[1]; J Gallagher[1]; R O'hanlon[1]; K Mc Donald[1]
[1]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland

On behalf of: The Heart Failure Unit, St Vincent's Hospital
Funding Acknowledgements: Enterprise Ireland

Communication difficulties in the care pathway of patients admitted to hospital with acute decompensated heart failure.
Effective management of any chronic illness requires effective communication between all involved in delivering and receiving care. Central to this is effective inter-personnel communication and access to medical records. Heart failure (HF) care in particular demands good communication given the complexity of the illness and the tendency towards poly pharmacy.
Method: In an ongoing study defining the care pathways of patients admitted with ADHF (Acute decompensated HF) (de novo presentations, DN; and known HF patients, KHF) we assessed specific features of communication along the care pathway: availability of HF records on Emergency Department (ED) presentation and clinically stable natriuretic peptide (NP) level and weight record for KHF patients. Confirmation of self-care education of DN patients was also assessed, as was education of DN relative or carer, including frequency of sessions for both. In addition, availability of medication lists on presentation, and confirmation of discharge information communications to GP and community pharmacist for all patients, were examined.
Population: Eighty eight patients admitted to hospital with ADHF: 52.2% (46) DN, 47.7% (42) KHF, mean age 76 years, with a mean of 5 comorbidities.
Results: Of 88 patients followed 21 bypassed the ED. Of the 67 who attended the ED 43.2 % (28) were KHF. HF records were available for 39.2% (11); NP during clinical stability was available for 28.5% (8) KHF, no NP on record for DN. Weight records were available for 21.4% (6) of known patients. Medication lists were available in ED for 38.8% (26) of all patients; Eighty-eight % (37) of the DN patients received education; of these 29.7% (11) received 1 session and 70.27% (26) received 1-3 sessions. Thirty-five% (15) relatives or carers received education with 46.6% (7) receiving 1 session and 53.3% (8) receiving 1-3 sessions. No prescriptions were faxed to community pharmacists, and 73.75% (59) patients discharged had letters sent to GP.
Conclusion: This data highlights the communication difficulties present at various points in the care pathway of patients admitted to hospital with ADHF. Improved data access and inter-individual communication is necessary system-wide, to optimise management of HF patients.

P557

Palliative care in cardiac transplant: heart team perception

V L Vera Lucia Pessoa[1]; LC Souza[1]; DL Salles[1]; MGV Sobral[1]; VRF Cestari[1]; RS Florencio[1]; WM Barroso[1]; TMM Moreira[2]; JCS Santiago[3]; AACC Lima[2]
[1]HOSPITAL DE MESSEJANA DR CARLOS ALBERTO STUDART GOMES, Fortaleza, Brazil; [2]State of Ceara University, Nursing Graduation, FORTALEZA, Brazil; [3]Federal University of Ceara, FORTALEZA, Brazil

Introduction: The cardiac transplantation is the main alternative to refractory cardiac insufficiency; however, the patients need to have caring in many ways and, still, have a survival time of ten years. Thus, it is inevitable to consider the probability of death and suffering among these people, appearing the need of a caring directed to comfort, which is a scenario to palliative care. Method: It is an exploratory study with a qualitative approach, in which it was sought to know the perception of professionals who work in the cardiac transplantation area of palliative caring in their field of work. Ten professionals from the heart team were interviewed guided by a semi-structured interview, in which there were two doctors, one nutritionist, one psychologist, one social worker and five nurses. The interviews were recorded and, after transcription, organized and analyzed with the IRAMUTEQ software.
Results: The discursive corpus was presented in a dendrogram with the following analytical classes: Unsafety and uncertainty in indicating palliative care; Feelings and expectations related to palliation. The professionals' perception of palliative care is restricted to keep the comfort to the patient, but there is no clarity about how to conduct this care. There is a clear difficulty in establishing criteria to guide cardiac transplanted patients to palliative caring, it is punctuated aspects like clinical features, age, and comorbidities but there is no parameters definition. The professionals also related that an important obstacle in initiating palliation is fear, prejudice and, in many times, lack of knowledge of the team and family.

International Study on Carers of patients with heart failure

A Stromberg[1]; R Greene[2]; A Creswell[3]; C Suridjan[4]; E Holzhausen[5]; S Campbell[6]; N Nick Hartshorne-Evans[7]; G Arthur[8]
[1]Linkoping University, Department of Medical and Health Sciences, Division of Nursing Science, Linkoping, Sweden; [2]National Alliance for Caregiving, Bethesda, United States of America; [3]Carers Australia, Deakin, Australia; [4]Carers Canada, Mississauga, Canada; [5]Carers UK, London, United Kingdom; [6]WomenHeart: The National Coalition for Women with Heart Disease, Washington DC, United States of America; [7]Pumping Marvellous, Preston, United Kingdom; [8]The Heart and Stroke Foundation of Canada , Brampton, Canada

Funding Acknowledgements: The study was supported by an unrestricted grant from Novartis

Background: The impact of heart failure on carers is an under-studied area when compared to other conditions like cancer, stroke, mental illness and dementia. The aim of this international study was therefore to describe the effects of caregiving for a person with heart failure on the daily life and well-being of family carers.
Methods: This research study was initiated and implemented by the International Alliance of Carer Organizations (IACO), a coalition of 14 member nations committed to building a global understanding and respect for the vital role of family carers. The study was conducted in Australia, Canada, United Kingdom and United States and IACO collaborated with carer and patient organisations in the four countries. The design was cross-sectional. Data collection using a web-based survey format was conducted between February and March 2017.
Results: The survey included 519 carers, mean age 58 years and 79% women. Half of the carers were partners, 61% had a college or university education. 30% were retired, and 30% worked full time. Three out of four were the primary carer for the person with heart failure and the meantime of care provided was 22 hours/week. The mean age of the persons with heart failure was 69 years. It was a severely

ill group of persons with heart failure whose carers participated in the study, with only 12% not having any other co-morbidities. Carers helped with activities of daily living (ADL) i.e bathing, dressing and instrumental activities of daily living (IADL) i.e cooking, shopping, managing finances, medical and/or nursing tasks. One in five stated that they had chosen to become a carer, the rest had to take on the role (81%). There was no significant correlation between feeling prepared to be a carer and having a choice to be a carer. Half of the carers perceived no control over the heart failure condition, 27% experienced some control and the rest perceived they had good control. Less than 1/3 of the carers felt they were supported by someone to balance their own well-being. Half of the carers did not think caregiving had affected their health, the rest thought it had made it worse. The findings demonstrated tha many similarities in the experiences of carers of persons with heart failure in the four countries participating in the study.
Conclusion: Carers play a vital role in assisting with the implementation and adherence of the treatment regime and self-care for persons with heart failure. It is therefore noteworthy that this survey found that many carers felt unprepared for many of their caregiving tasks and not in control of the heart failure condition. Carers need more education and skill building training as well as psychosocial support to increase preparedness for caring and perceived control over the heart disease. That can both improve carers life situation and well-being as well as give them more tools to support their loved ones with heart failure to improve and maintain self-care behaviour.

P559
Quick screening of nutritional status in an outpatient heart failure unit using de mini nutritional assessment short form tool

B Gonzalez[1]; M Cachero[1]; C Rivas[1]; V Diaz[1]; A Ros[1]; N Benito[1]; M Puertas[1]; A Morales[1]; P Velayos[1]; J Josep Lupon[1]; M De Antonio[1]; M Domingo[1]; P Moliner[1]; E Zamora[1]; A Bayes-Genis[1]
[1]*Germans Trias i Pujol University Hospital, Badalona, Spain*

Background: Nutritional status is an important prognostic factor in patients with heart failure (HF). Malnutrition, independently of the used definition, has been shown to carry worse prognosis above and beyond body mass index in such patients. In a pilot study we observed that the Mini Nutritional Assessment Short Form tool (MNA-SF) was the best approach for the screening of nutritional status in HF outpatients over other tools such as the Malnutrition Universal Screening Tool (MUST) or the Malnutrition Screening Tool (MST).
Purpose: To implement the MNA-SF screening tool in a routine way in a multidisciplinary HF Unit in order to catch those patients with malnutrition or at risk of malnutrition for further evaluation and management by a nutritionist when appropriate.
Methods: The MNA-SF screening tool was introduced in October 2016 in the global nurse evaluation of patients and scheduled to be repeated every 6 months. The scoring ranges from 0 to 14, being considered 0 to7 as malnutrition status, 8 to 11 as being in risk of malnutrition and 12 to 14 as normal nutritional status.
Results: A total of 809 assessments have been performed until November 2017 in 557 patients (mean age 69 ± 11.6 years, 70.5% men, body mass index 28.2 ± 4.7, LVEF 45% ± 13, NYHA class I 6.1%, II 82.6%, and III 11.3%). At first evaluation 15 patients (2.7%) fulfilled the criteria of malnutrition, 88 (15.8%) where at risk of malnutrition and 454 (81.5%) were considered to have normal nutritional status. 252 patients were reassessed at 6.8 ± 1.7 months. Out of the 38 reassessed patients who had malnutrition or were at risk of malnutrition at first evaluation, only 1 fulfilled the criteria of malnutrition while 14 remained at risk of malnutrition. On the other hand, of the 214 patients with normal nutritional status at first evaluation 15 evolved to at risk of malnutrition and 1 to malnutrition. Thus, of the 252 reassessed patients only 2 (0.8%) fulfilled the criteria of malnutrition and 29 (11.5%) were at risk of malnutrition.
Conclusions: The implementation of the MNA-SF as a routine screening tool in a multidisciplinary HF Unit allowed detecting malnutrition and risk of malnutrition in almost one every five ambulatory patients. Malnutrition and risk of malnutrition decreased in reassessed patients at 6 months.

P560
Determination of activities of daily living of individuals with cardiovascular disease

B Betul Bayrak[1]; S Oguz[1]; G Camci[1]; E Beysulen[1]; N Ozturk[1]; S Balci[1]; S Kesdi[1]
[1]*Marmara University, Faculty of Health Sciences, ISTANBUL, Turkey*

Background: Cardiovascular diseases, which are among the most important causes of death in the world, affect the activities of daily living of individuals in a negative way. For this reason, patients who have cardiovascular disease are insufficient in self-care management.
Purpose: This study was conducted as a descriptive and cross-sectional to determine the activities of dailiy living of individuals with cardiovascular disease.
Methods: The study has been performed between March-April 2017 with 491 patients hospitalized in cardiology wards of two hospitals in Istanbul. Patients who had cardiovascular disease, had no communication problems and were willing to participate in the study were taken into the study. Data were collected with Questionnaire and the Katz Activities of Daily Living (ADL) Scale. The Katz ADL Scale includes washing, dressing, toilet needs, transfer, continence and nutrition sub-dimensions. In activities of daily living scale, 0-6 points dependent, 0-12 points semi independent and 12-18 points as independent are evaluated. In the analysis of data, descriptive statistics, Mann Whitney U and Kruskal Wallis Test were used. Significancy value was evaluated as $p < .05$.
Results: The mean age of the patients was 61.21 ± 14 and 60.5% were male. 88% of the patients were married, 91% were living with their family, 44.2% of their sleep was regular and 86.8% do not exercise. 85% of the patients were adversely affected by the disease. The mean Katz ADL scale of patients was 17.1 ± 2.3. The mean score of bathing and dressing activity of the patients (2,741 ± 0,582 2,794 ± 0,511, respectively) were the lowest. Male (p=.029), married (p=.029), those with regular sleep (p=.003), those without comorbid disease (p= .036) and those who were not adversely affected by disease of the mean Katz ADL score (p=.00) was found to be high.
Conclusion: Patients with cardiovascular disease were independent in their activities of daily living. They were most difficult in bathing and dressing activities.

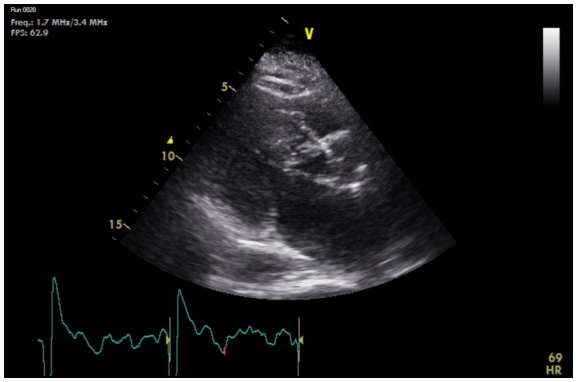
A Clinically and Echocardiographically Demonstrable Dynamic Left Ventricular Outflow Tract (LVOT) Obstruction

S Saad Ahmad[1]; W Khan[1]
[1]*Royal Preston Hospital, Cardiology, Preston, United Kingdom*

Dynamic left ventricular outflow tract (LVOT) obstruction is a distinctive finding on echocardiography and often supports a diagnosis of hypertrophic obstructive cardiomyopathy (HOCM). It is also a clinical entity in its own right and is reproducible with stress. We describe a case of dynamic outflow obstruction in an elderly man



Dynamic LVOT on Echo following exercise

with classical exertional symptoms. Echocardiography was used to demonstrate a variable gradient, with imaging performed at rest and following physical exertion. We will review the patho-physiological changes seen in this condition, both in terms of cardiac structure and the physics of fluid dynamics. Medical treatment is centered around a meaningful understanding of these changes, but there are also surgical and ablative options available. Device therapy with an implantable cardioverter-defibrillator (ICD) is the mainstay of HOCM treatment, particularly when ventricular arrhythmias are evident. A risk stratification for sudden cardiac death from hypertrophic cardiomyopathy is imperative to case by case management.

P562

The single nucleotide polymorphism Q222R in the DNase 1 gene is linked with mortality in patients after ST-elevation myocardial infarction.

A Anna Ondracek[1]; TM Hofbauer[1]; T Scherz[1]; J Mueller[1]; A Panzenboeck[1]; A Mangold[1]; IM Lang[1]
[1]*Medical University of Vienna, Vienna, Austria*

Background/Introduction: Neutrophils are able to release their nuclear content into extracellular space by formation of neutrophil extracellular traps (NETs). NETs are capable to neutralize pathogens, but have also been implicated in autoimmune and thrombotic diseases, including ST-elevation myocardial infarction (STEMI). Deoxyribonuclease (DNase) 1 degrades NETs. DNase 1 Q222R single nucleotide polymorphism (SNP), which impairs DNase 1 function, was associated with an increased incidence of MI. In STEMI, impaired DNase 1 activity was correlated with increased NET burden and infarct size. In a mouse model of coronary artery ligation, DNase 1 treatment decreased infarct size, indicating a potentially therapeutic role. We hypothesized that DNase 1 is crucial to counteract dysregulated NET formation in coronary artery disease (CAD). The Q222R SNP in the DNase 1 gene, resulting in dysfunction of the enzyme, might thereby induce chronic NET burden with influence on long-term outcome.
Methods: We enrolled CAD patients with a history of STEMI, which received primary percutaneous coronary intervention between 2006 and 2016 (n = 711). Genotyping using allelic discrimination was performed to identify DNase 1 Q222R SNP (rs1053874). Mortality data was obtained from the national registry of death. Causes of death were classified according to ICD-10. By multivariable Cox regression, we assessed the influence of DNase 1 SNP on all-cause and cardiovascular mortality, adjusting for the following established cardiovascular risk factors: age, sex, body mass index, diabetes, smoking, hyperlipidemia, renal function as measured by serum creatinine concentration at admission and arterial hypertension.
Results: Homozygous mutation of the DNase 1 SNP was present in 64 (9.0%) patients; 304 (42.8%) and 343 (48.2%) were heterozygous and homozygous for the wild-type allele, respectively. Median survival was 60.0 [interquartile range 30.3; 91.5] months. A total of 133 (18.7%) patients deceased; 78 (11.0%) died of cardiovascular causes. Homozygous mutation of DNase 1 was independently associated with all-cause mortality (hazard ratio 2.05, 95% CI 1.22-3.46, p = 0.006) and cardiovascular mortality (hazard ratio 2.02, 95% CI 1.02-4.01, p = 0.046).
Conclusion: We report a negative influence of the Q222R DNase 1 SNP on survival after STEMI. Our findings argue for a deleterious role of NETs not only in CAD.

Long-term safety follow-up of patients with advanced heart failure treated with transendocardial delivery of muscle-derived stem/progenitor cells with overexpression of connexin-43

A Adrian Gwizdala[1]; N Rozwadowska[2]; A Cieplucha[1]; A Katarzynska-Szymanska[1]; T Kolanowski[2]; A Malcher[2]; E Straburzynska-Migaj[1]; W Seniuk[1]; Z Oko-Sarnowska[1]; B Perek[3]; K Blaszyk[1]; S Grajek[1]; M Kurpisz[2]
[1]*Poznan University of Medical Sciences, 1st Department of Cardiology, Poznan, Poland*; [2]*Institute of Human Genetics, Poznan, Poland*; [3]*Poznan University of Medical Sciences, Department of Cardiac Surgery, Poznan, Poland*

Background: Patients with advanced heart failure (HF) have poor prognosis despite number of available treatments, including new drugs and devices. Regenerative therapy is continuously an interesting approach to treatment of this condition. Our recently published data demonstrated for the first time that injection of muscle-derived stem/progenitor cells with overexpression of connexin-43 (MDS/PCs-Cx43) in patients with severe HF led to significant improvement of exercise capacity and myocardial viability while inducing no significant ventricular arrhythmias. It could be due to improved electrical coupling of the injected cells and host myocardium and thus better in-situ cooperation between cells.
Objectives: To evaluate the long-term safety of transendocardial delivery (NOGA® MyoStar® intramyocardial injection catheter) of MDS/PCs-Cx43 in patients with advanced HF.
Methods: Thirteen subjects (one female) with advanced HF, NYHA class II-III, with implanted cardioverter-defibrillator, ineligible/disagreeing to other intervention, including transplantation ("no option group") that underwent transendocardial injection of MDS/PCs-Cx43 were enrolled. For safety assessments patents were followed-up for up to 36 months (medical history, physical exam and rhythm monitoring by implanted devices every 12 months).
Results: Total of 3 deaths (23%) were documented. There were 2, 0 and 1 deaths at 12, 24 and 36 months, respectively (one from pancreatic cancer and two form worsening HF). One patient (8%) suffered from sustained ventricular tachycardia (14 months of index procedure) terminated with ICD intervention (anti-tachycardia pacing, ATP) during strenuous exercise; he was further treated with oral amiodarone and no VT recurrence was observed.
Conclusions: The study demonstrated no arrhythmic deaths in patient with severe HF previously treated with injection of Cx-43+ MDS/PCs. Only episode of nonfatal ventricular tachycardia was effectively treated with ATP. These observations may support the thesis that genetic modification (Cx43) of implanted muscle-derived stem/progenitor cells may attenuate the proarrhythmic potential of unmodified skeletal myoblasts due to improved electrical coupling between the injected cells and host cardiomyocytes making the safety acceptable.

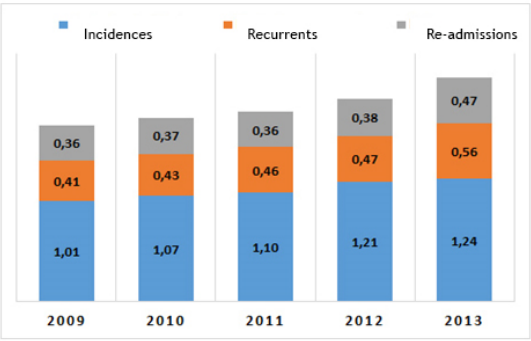
Poster session 1 - Basic Science

Chronic Heart Failure - Epidemiology, Prognosis, Outcome

P584
Long-term natural history of the Heart Failure.

M L Maria Lucia Fernandez Gasso[1]; D Pascual-Figal[2]; L Hernando-Arizaleta[3]; J Palomar-Rodriguez[3]; J Martinez-Diaz[1]; P Ramos-Ruiz[1]; I Garcia-Escribano[1]; G Clavel-Ruiperez[1]; R Soto-Ruiz[1]; J Abellan-Huerta[1]; C Fernandez-Pascual[1]; D Dau-Villareal[1]
[1]Hospital General Universitario de Santa Lucia, Cardiology, Cartagena, Spain; *[2]Hospital Clínico Univeristario Virgen de la Arrixaca, Cardiology, Murcia, Spain*; *[3]Consejería de Sanidad de la Región de Murcia, Servicio de Planificación Sanitaria, Murcia, Spain*

Background: The natural history of the first hospitalization for heart failure (HF), in particular the interaction between survival and re-hospitalizations, is not well established.
Methods: Systematic analysis of all hospitalizations in the Region of Murcia in the period 2003 to 2013. After merging the episodes corresponding to each person, 8.258 different individuals were identified with a first hospitalization due to HF in the period 2009-2013. All patients were followed at least 2 years (median 3.2 years).
Results: In the period 2009-2013, the rates of first hospitalization for HF showed an increase up to 1.24 per thousand inhabitants (2.31% annual percentage change). The first hospitalization accounted for 71% of patients and 57% of hospitalizations for HF. The incidence of readmission at 5 years was 51% for HF, 64% due to cardiovascular causes and 88% to any cause. Survival was significantly lower, 40% at 5 years, to the general population with similar age and sex ($p < 0.001$). Among the 4.368 patients who died, of those without readmissions (15.8%) 58% died in the first six months; and of 84.2% with readmissions, re-hospitalizations were accumulated mainly before death and only in those with a survival longer of two years, a bimodal phenomenon was observed due to early re-hospitalizations after discharge.
Conclusions: The first hospitalization due to HF presents increasing population rates, and its natural history shows a high mortality and re-hospitalization charge, related to time to death. These data support the importance of establishing strategies for end-of-life care with extra-hospital strategies.



P585
Trends in heart failure prevalence and expenditure in portugal

L Santos[1]; ML Lelis[1]; CF Fonseca[2]
[1]Hospital Funchal, Internal Medicine, Funchal, Portugal; *[2]Heart Failure Unit, Hospital de Sao Francisco Xavier, Lisbon, Portugal, NOVA Medical School, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal*

Background: Heart failure (HF) prevalence in the developed world continues to grow, with growing economic burden of disease. Governments and health organizations must keep track of the costs related to this public health issue. High-income countries devote 1,42% of their annual health care budget for HF direct costs and around 0.06% of their GDP for indirect costs.
Purpose: Given the percentage of annual GDP devoted to healthcare has remained relatively stable we hypothesized that there may be underbudgeting for HF in Portugal.
Methods: We estimated the annual prevalence for HF in Portugal from the age-group prevalences in the 2002 EPICA study. We applied these prevalences to the respective age groups from 2006 to 2016 in order to derive the estimated yearly HF prevalence. Annual expenditure with HF was estimated from the portuguese annual GDP and mean percentage of health budget devoted to HF in high-income countries, from the literature.
Results: Statistically significant correlation between the increase in prevalence and a lowering budget per HF patient ($r=-0,718$, $p = 0.013$) in the past decade. Table 1 shows that adequate financing for HF may be lacking. Conclusion: The ageing process of the portuguese population is determinant to HF prevalence. It is importante to further investigate the actual prevalences and institute measures for prevention of overall cardiovascular disease. Our investigation hints at an ongoing underbudgeting of HF. This must be taken into consideration by governaments and health organizations.

Table 1.

Year	GDP (€)	%GDP for health expenditure	Total health expenditure (€)	Mean % spent of HF (direct)	Estimated direct HF costs (€)	% spent on HF indirect	Estimated indirect HF costs (€)	Estimated overall HF costs (€)	HF prevalence	Mean per patient (€)

Mechanisms responsible for increased circulating levels of galectin-3 in heart disease

X-J Xiao-Jun Du[1]; MN Nguyen[1]; Y Su[1]; D Vizi[2]; AH Ellims[2]; WB Zhao[1]; H Kiriazis[1]; XM Gao[1]; J Sadoshima[3]; AJ Taylor[2]; JR Mcmullen[1]; AM Dart[2]; DM Kaye[2]
[1]Baker IDI Heart and Diabetes Institute, Experimental Cardiology, Melbourne, Australia; [2]The Alfred Hospital, Alfred Heart Centre, Melbourne, Australia; [3]New Jersey Medical School, Department of Cell Biology and Molecular Medicine Rutgers, New Jersey, United States of America

On behalf of: Experimental Cardiology Lab
Funding Acknowledgements: National Health and Medical Research Council of Australia

Background : Galectin-3 has been utilised as a biomarker for heart disease, however the mechanisms for increment of circulating galectin-3 and its dependency on aetiology or disease-associated conditions, such as inflammation or ß-adrenergic activation, are unclear.
Purpose: To study the mechanisms responsible for elevated circulating galectin-3 levels in animal models of various heart diseases and in patients with cardiomyopathies and heart failure.
Methods : We studied mouse models of dilated cardiomyopathy (cardiac Mst1 overexpression) or fibrotic cardiomyopathy (cardiac ß2-adrenergic receptor overexpression), ischemia-reperfusion (I/R) and treatment with the ß-adrenergic receptor agonist isoproterenol. Plasma and cardiac levels of galectin-3 were measured by ELISA. Myocardial inflammatory cell density was quantified by immunohistochemistry and galectin-3 expression by circulating leukocytes were determined by RT-PCR. Circulating and trans-cardiac gradient of galectin-3 levels were also determined either in mice or cardiomyopathy patients with heart failure.
Results : Relative to controls, all mouse models showed multi-fold increases in cardiac galectin-3 expression while renal function was maintained estimated by cystatin-C levels. In transgenic mouse models of fibrotic cardiomyopathy, I/R or treatment with isoproterenol, plasma levels of galectin-3 and cardiac inflammatory cell infiltration were elevated, including a 3.5-fold increase in galectin-3 gene expression by circulating leukocytes from I/R mice. These models also exhibited parallel changes in cardiac and plasma galectin-3 levels and presence of trans-cardiac galectin-3 gradient indicating cardiac release of galectin-3 into circulation. Despite a 50-fold increase in cardiac galectin-3 content, transgenic mice with dilated cardiomyopathy showed no change in circulating galectin-3 levels nor myocardial inflammatory infiltration. In patients with hypertrophic or dilated cardiomyopathy, plasma galectin-3 increased only in those with impaired renal function, and a trans-cardiac galectin-3 gradient was not present in patients with dilated cardiomyopathy and severe heart failure (NYHA Class III-IV).
Conclusions: : Increase in circulating galectin-3 is dependent on the aetiology of heart disease and occurs by diverse mechanisms. In cardiomyopathy patients, renal dysfunction is responsible for elevated circulating galectin-3 without evidence for cardiac release. In mouse models that exhibit significant cardiac and/or systemic inflammation or ß-adrenergic receptor activation, cardiac release of galectin-3 contributes to elevated circulating levels.

P587

Right ventricular and pulmonary vascular function are influenced by age and volume expansion in healthy humans

E Wolsk[1]; R Bakkestrom[2]; CB Kristensen[1]; KA Myhr[1]; JH Thomsen[1]; L Balling[1]; MJ Andersen[1]; JS Dahl[2]; SJ Shah[3]; F Gustafsson[1]; C Hassager[1]; JE Moller[2]
[1]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark; [2]Odense University Hospital, Odense, Denmark; [3]Northwestern University, Chicago, United States of America

Aims: Patients with heart failure (HF) often show signs of right ventricular (RV) dysfunction. The function of RV coupled with the pulmonary circulation (tricuspid annular plane systolic excursion [TAPSE]: pulmonary artery systolic pressure [PASP]) has been shown to divide HF patients into distinct prognostic strata, however no normative values exist limiting the clinical utility of this measure. We sought to obtain normative values and discern the individual effects of age, gender, and fluid overload on the TAPSE:PASP ratio.
Methods and Results: Sixty healthy subjects aged 20-80 years were enrolled in this prospective study. Right heart catheterization with hemodynamic measurements were performed at rest and following a rapid saline infusion (10 ml/kg, 150 ml/min). Linear regression and Spearman correlation models were used to estimate associations between TAPSE:PASP and relevant variables.
In healthy persons of all ages, the normative TASPE:PASP ratio was median (5th-95th percentile) 1.25 (0.81-1.78) mm/mmHg. The correlation between progressive age and declining TAPSE:PASP was significant (r: -0.35, p = 0.006). Gender did not influence TAPSE:PASP (p = 0.30). Rapid fluid expansion increased central venous pressure from 5 ± 2 mmHg to 11 ± 4 mmHg after fluid infusion (p <0.0001). This resulted in a 32% decrease in the TAPSE:PASP ratio after fluid infusion, compared to baseline (figure 1, p <0.0001).
Conclusion: The TAPSE:PASP ratio was affected by age, but not gender. TAPSE:PASP is not only a reflection of intrinsic RV function and pulmonary vascular coupling, but fluid status dynamically affects this index of RV function. Normative values were obtained for future assessment of HF patients.

Funding Acknowledgements: Financial support: German Ministry of Education and Research (BMBF, grants: 01EO1004, 01E1O1504).

Introduction: In vivo diffusion tensor cardiac magnetic resonance (DT-CMR) has recently been used to characterize myocardial microstructure dynamics during left ventricular wall thickening, showing distinct, abnormal sheetlet function in HCM and DCM patients. However, the necessary trade-off between the number of averages, diffusion weighted directions, and image resolution in clinically used parameter settings have been shown to lead to poor precision of sheetlet and helix angles (HA) of ± 31° and ± 14° respectively. MRI at higher field strength such as 7T may provide higher signal-to-noise ratio (SNR), allowing for improvement of spatial and angular resolution, image quality as well as consistency of diffusion metrics in clinically applied parameter settings.
Purpose: To assess feasibility of DT-CMR at 7T and compare SNR and diffusion metrics in spin echo based diffusion tensor acquisitions of the unfixed, ex vivo porcine heart at 7T and 3T.
Methods: Measurements were performed on 7T and 3T whole body MRI systems using 1Tx/32Rx head coils. Porcine hearts were imaged in physiological saline

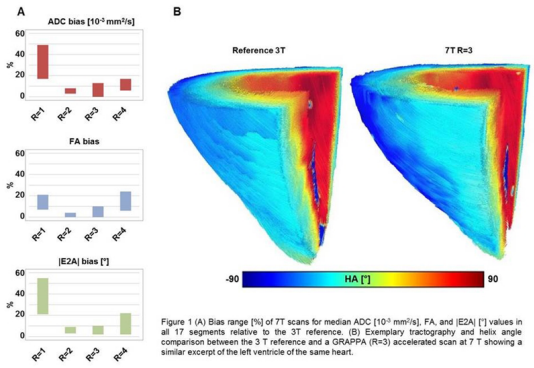

Figure 1 (A) Bias range [%] of 7T scans for median ADC [10^{-3} mm^2/s], FA, and |E2A| [°] values in all 17 segments relative to the 3T reference. (B) Exemplary tractography and helix angle comparison between the 3 T reference and a GRAPPA (R=3) accelerated scan at 7 T showing a similar excerpt of the left ventricle of the same heart.

solution, unfixed, at room temperature within 10 hours after cardiac arrest. MRI with spatial resolution of 1.3x1.3x1.3 mm^3 was performed obtaining 25 and 8 cDTI datasets at 3T and 7T as a reference. Scans at 7T were repeated using parallel imaging acceleration (GRAPPA) factors R = 2, R = 3, R = 4. Apparent diffusion coefficient (ADC), fractional anisotropy (FA), HA and secondary eigenvector angle (E2A) were compared within segmentation according to the American Heart Association (AHA).
Results: DTI data was successfully acquired for all parameter settings used. SNR values in b0 images of scans at 3T and 7T was 34 ± 3 and 45 ± 4 for identical scans. On average DTI analysis was performed for 6 ± 2 slices of apical cap, 8 ± 1 apical, 8 ± 1 mid-cavity, and 8 ± 1 basal slices. Maximal and minimal deviations of ADC [$10^{-3}mm^2/s$], FA, and |E2A| [°] within the AHA segments were used to define a bias range for 7T acquisitions relative to the 3T reference. The smallest bias was found for scans using GRAPPA factor R = 2 (Figure 1). Derived metrics from scans using GRAPPA factor R = 3 showed significant differences in FA in mid-cavity and basal parts. No significant differences were found for scans using GRAPPA factor R = 2.
Conclusion: Feasibility of DTI acquisitions of ex vivo porcine hearts was demonstrated for spin echo based acquisitions with spatial resolution of 1.3x1.3x1.3 mm^3 via comparison with a reference data set measured at 3 T. Derived metrics were statistically similar to the 3T reference data using GRAPPA factors R = 2 and R = 3. The relative SNR gain in 7T acquisitions may benefit clinically used parameter settings for DT-CMR allowing optimization of the trade-off between averages, diffusion directions, and image resolution, especially, when using stimulated echo approaches, which can utilize the increased T1 at higher field strengths.

Funding Acknowledgements: São Paulo Research Foundation (FAPESP)

Background: Myocardial perfusion defect (MPD) is a common finding in Chronic Chagas cardiomyopathy (CCC), but it is unclear if the perfusion derangement can precede the left ventricular (LV) systolic dysfunction. We investigated the time-course of myocardial perfusion changes and the correlation with the progression of LV systolic dysfunction in an experimental model of CCC.
Methods: Female Syrian hamsters (n = 40) were infected with 3.5x104 trypomastigotes forms of T. cruzi Y-strain and the surviving animals (n= 22) were submitted to in vivo imaging 2, 4, 6, 8 and 10-months afterwards. Rest high-resolution SPECT imaging using 99mTc-sestamibi was used to assess MPD extension that was analyzed by using polar maps and compared to matched control animal database. The left ventricular (LV) systolic function was assessed by using 2D-echocardiogram. The animals underwent PET imaging for assessment of myocardial inflammation using 18F-FDG under myocardial uptake suppression conditions at 10-months after infection and co-registered with SPECT images. Histological analysis included quantification of myocardial fibrosis.
Results: Compared to control animals, 7 out of 22 (32%) infected animals showed significant LV ejection fraction (LVEF) deterioration after 8-months (69 ± 2% and 61 ± 11%, respectively, p = 0.03), and after 10-months (70 ± 2% vs 54 ± 10%, respectively, p = 0.0002). Individual animals presented MPD at 2-months and progressive deterioration after 6-monts after infection. All animals that died during protocol, presented MPD in the last assessment. LVEF at 10m negatively correlated with MPD at 6m (r= -0.58, p = 0.005), 8m (r= -0.62, p = 0.002) and 10m (r= -0.7, p = 0.0001). Animals with MPD showed higher 18F-FDG uptake topographically correlated with the LV regions with MPD. Segments with MPD in comparison to segments with normal perfusion displayed higher %ID/g (0.15 ± 0.02 vs 0.13 ± 0.03, p= 0.005), SUV (g/cc, 0.28 ± 0.040 vs 0.23 ± 0.05, p < 0.0001) but similar extent of histological fibrosis (21 ± 7.6% vs 22.9 ± 7.1%, p = 0.3). Compared to controls animals, infected animals presented higher interstitial fibrosis (%, 15 ± 6 vs 9 ± 1, p = 0.002), however no transmural scar was revealed.
Conclusions: Rest MPD precedes the development and correlates with the ulterior deterioration of LV systolic dysfunction in experimental CCC. The MPD was topographically associated with elevated 18F-FDG uptake, suggesting a correlation between inflammation and the myocardial perfusion derangement. Our findings suggest that MPD may be a surrogated marker of myocardial inflammation in CCC and raise the possibility of using perfusion imaging for risk stratification and monitoring the course of this myocardial disease.

Chronic Heart Failure - Treatment

Elamipretide restores protein and mRNA expression levels of S100A1 in left ventricular myocardium of dogs with chronic heart failure

RC Gupta[1]; V Singh-Gupta[1]; HN Hani Sabbah[1]
[1]Henry Ford Hospital, Detroit, United States of America

Funding Acknowledgements: Supported by a research grant from Stealth BioTherapeutics, Inc.

Background: S100A1 is a calcium-binding protein predominantly expressed in cardiac and skeletal muscles and localizes to Z-discs and sarcoplasmic reticulum. S100A1 was shown to play a pivotal role in cardiac contractility. More recently, a novel interaction of S100A1 with mitochondrial F1-ATPase was recognized which affects F1-ATPase activity and cellular ATP production. Cardiomyocytes that overexpress S100A1 exhibit high ATP content whereas knockdown of S100A1 decreases ATP levels. Elamipretide (ELAM), a mitochondria targeting peptide, has been shown to improve cardiac contractility and increase the rate of ATP synthesis in left ventricular (LV) myocardium of dogs with advanced heart failure (HF). This study examined the effects of chronic therapy with ELAM on protein and mRNA levels of S100A1 in LV myocardium of dogs with coronary microembolizations-induced HF (LVEF ~30%).
Methods: LV tissue from 14 HF dogs randomized to 3 months therapy with subcutaneous injections of ELAM (0.5 mg/kg once daily, n = 7) or saline (control, CON, n = 7) and LV tissue from 6 normal (NL) dogs was used. Protein levels of S100A1 were determined in LV tissue extract by Western blotting coupled with chemiluminescence and band intensities expressed in densitometric units (du). mRNA expression of S100A1 normalized to GAPDH was measured in RNA from LV tissue using real-time PCR and was expressed as fold change from NL.
Results: Data are shown in the Table. Levels of GAPDH were unchanged among the 3 study groups. mRNA and protein levels of S100A1 were decreased significantly in HF-CON dogs compared to NL dogs. Treatment with ELAM (HF+ELAM) normalized S100A1 mRNA and protein expression.
Conclusions: mRNA and protein levels of S100A1 are decreased in LV of HF dogs and are normalized after chronic therapy with ELAM. The finding supports the observations of improved LV function and rate of ATP synthesis after chronic therapy with ELAM.

mRNA and Protein Expression of S100A1			
	NL	HF-CON	HF+ELAM
S100A1 protein level (du)	470 ± 0.29	2.50 ± 0.37*	3.31 ± 0.17†
S100A1 mRNA (fold change from NL)	1.00	-5.48*	-1.60†

* = p < 0.05 vs. NL; † = p < 0.05 vs. HF-CON

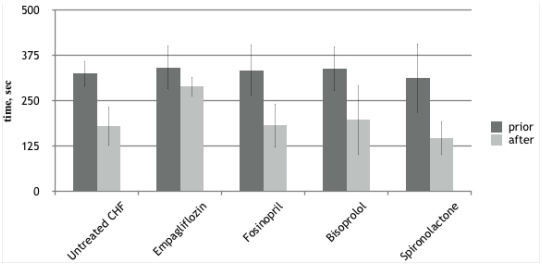
possibility of empagliflozin administration for chronic heart failure (CHF) treatment with the absence of carbohydrate metabolism disorders.

Purpose: The experimental comparative study on empagliflozin efficacy in CHF in normoglycemic settings with the drugs which are generally accepted agents for CHF treatment: angiotensin-converting enzyme inhibitor, ß-blocker and aldosterone antagonist.

Methods: CHF in 50 rats was simulated via permanent ligation of the left coronary artery. 1 month later, the operated animals were randomized under echocardiographic (echoCG) control to 5 equal groups of 10 animals: a group that did not receive any treatment, groups which took empagliflozin, fosinopril, bisoprolol and spironolactone as monotherapy, respectively. 3 months of the therapy, echoCG and treadmill exercise time were analyzed.

Results: The administration of empagliflozin resulted in the retarded progression of left ventricular dysfunction in comparison with the animals not receiving the treatment (Tabl. 1). The tolerance during the treadmill exercise was evidently decreased in 3 months in all study groups of animals. The maximum activity time was the highest in the rats taking empagliflozin (289 ± 27sec), it was significantly higher than in the animals of groups ?1 (180 ± 53sec, $p < 0.05$), ?3 (183 ± 61sec, $p < 0.05$), ?4 (197 ± 95sec, $p < 0,05$), and ?5 (147 ± 46sec, < 0.05) (Fig. 1)

Conclusions: Sodium-glucose co-transporter 2 inhibitor empagliflozin improves tolerance of physical exercise in normoglycemic rats with experimental CHF being superior in this respect to reference agents for CHF treatment.



Maximum activity time at the treadmill

[1]*Puerto Real Hospital, Cardiology, Puerto Real, Spain*; [2]*Puerto Real Hospital, Internal Medicine, Puerto Real, Spain*

INTRODUCTION: iSLGT2 have shown cardiovascular benefits due not only to a better glycemic control but to weight lo and beter blood pressure and metabolic control. Knowing the limited use of this treatment in Andalucía yet we started a registry of every diabetic patient hospitalized in the Cardiology service and modify their treatment if needed.

METHODS: Prospective and descriptive study of type 2 diabetic patients hospitalized in the Cardiology Service from June 2016 to December 2016, with clinical and laboratory 6-month follow up.

DISCUSSION Out of 750 patients hospitalized 121 were diabetic with 60% male and a mean age of 71 years old. All of them had other cardiovascular risk factors such as hypertension (82%) dyslipidemia (65%) BMI>25 (98%) or smoking history (39%). All were properly treated with beta-blockers, ACE inhibitors, high-intensity statin and antiaggregation drugs. Still 54% of the hospitalizations were due to an acute coronary syndrome, 20% to heart failure (new onset or flare-up) and 20% to arrhythmias. Regarding previous anti-diabetic drugs only 1 patient was already being treated with an iSGLT. As for the rest the majority were treated with metformin and insulin or with the combination of two other oral antidiabetic drugs (most frequently metformin and sulfonylureas).Having said the cardiovascular benefits of the iSGLT2 we started this drugs in every diabetic patient with poor metabolic control. Out of 19 patients that started an iSGLT2 only 1 had an urinary mycotic infection but discontinuation of the treatment was not necessary, 1 patient had an isolated hypoglycemic episode and none suffered from dehydration.There were 4 re-hospitalizations (1 due to hypokalemia,1 due to chest pain with negative ischemic induction test,and 2 due to myocardium infarction) with no deaths in our registry.We also detected a mean weight reduction of 1.2kg ± 2.57, as well as a mean reduction in HbA1c of 0.18 ± 1.9%. Creatinin levels got discreetly better in most of the patients. We also detected a reduction in uric acid (0.18 ± 1.6mg/dl), total cholesterol (30 ± 26mg/dl), LDL (26 ± 31mg/dl) and triglycerides (20 ± 24mg/dl) as well as higher levels of HDL (0.33 ± 20mg/dl). We did not have information about cardiac function at the moment of publication of this study.

CONCLUSION: Following clinical practice guidelines recommendations we started treating diabetic patients with poor metabolic control with SGLT inhibitors with a 6-month follow up, detecting reduction in plasma levels of total cholesterol, LDL, triglycerides and uric acid, as well as HbA1c reduction and weight loss, and also higher HDL plasmatic levels. Up to the publication of this study only 4 patients were rehospitalized with no deaths detected and no important adverse effects. Nevertheless longer tracking period and bigger sample size are needed to validate these findings and evaluate possible long-term adverse effects.

P593

Outcome evaluation of the association of sacubitril/valsartan and iSGLT2 in diabetic patients with heart failure with reduced ejection fraction.

S Blasco Turrion[1]; FJ Camacho Jurado[1]; A Gomez Lopez[1]; I Lobo Torres[1]; R Castilla Ortiz[2]; C Collado Moreno[2]; P Gonzalez Perez[2]; JA Sanchez Brotons[2]; S Casquero Dominguez[2]; M Iravedra[2]; E Martinez De Morentin[2]; M Maestre Garcia[2]; J Lozano Cid[2]; P Martinez Romero[2]; FJ Morales Ponce[2]
[1]*Puerto Real Hospital, Cardiology, Puerto Real, Spain*; [2]*Puerto Real Hospital, Internal Medicine, Puerto Real, Spain*

Introduction: The latest Heart Failure and Cardiovascular Prevention ESC Guidelines have shown the benefits of Sacubitril/Valsartan (LCZ) in reducing rehospitalizations and mortality in patients with heart failure with reduced ejection fraction (HFrEF) that are still symptomatic despite proper treatment with beta-blockers, ACE inhibitors, and MRA drugs. Likewise, these guidelines include iSGLT2, mainly

Empagliflozin, as antidiabetic treatment with important benefits in the prevention and slower progression of heart failure, as well as reducing cardiovascular mortality, due not only to glycemic control but to a better blood pressure and plasma lipid control, and weight reduction. Therefore our goal is to evaluate the progression of patients with HFrED treated with LCZ and an iSGLT2.
Methods: A prospective study of diabetic patients with HFrEF evaluated in the Heart Failure Day-Hospital from September 2016 to December 2017, treated with LCZ and either iSGLT2 or other antidiabetic drugs.
Results: Out of 107 patients evaluated in the Heart Failure Day-Hospital in that period of time, 56 are being treated with LCZ (52%), from which 21 are diabetic patients; 48% are being treated with an iSGLT2 and 52% with either other oral antidiabetic drugs or insulin. In both groups we detected an improvement of their left ventricle ejection fraction, not statistically significant (8.6% ± 10% vs 5.1% ± 8% p = 0.3847) as well as a reduction in plasma NT-proBNP levels (-2229 ± 1329ng/ml vs -2404 ± 1500ng/ml p = 0.7812). Regarding the weight reduction described in pivotal studies, we indeed detected a greater reduction in the patients treated with an iSGLT2 but it was not statistically significant (-2.3 ± 2.9kg vs -0.625 ± 4.5kg p = 0.0963). As for plasma lipid control, we found a greater reduction in total cholesterol and LDL plasma levels in patients treated with other antidiabetic drugs, that was statistically significant (total cholesterol 30 ± 20mg/dl vs -8.6 ± 32mg/dl p = 0.04, LDL 20.6 ± 8mg/dl vs -8.6 ± 24mg/dl p = 0017) while there were no big differences in the increase of HDL plasma levels (-2 ± 7 mg/dl vs 2 ± 14mg/dl p = 0.4255). Likewise, we detected a greater reduction in HbA1c in patients treated with antidiabetic drugs different to iSGL2, statistically significant (-0.15 ± 0.33% vs -0.9 ± 0.77% p = 0.0103). Finally, we did not detect statistically significant differences in complication rates, renal function, ionic or blood pressure control.
Conclusion: In our sample we have not find a statistically significant benefit of the Association of iSGLT2 and LCZ in diabetic patients with HFrEF, in fact, we have detected a worse metabolic control with a disturbing deterioration of plasma lipid control in this patients. Nevertheless, longer tracking period and bigger sample are needed to validate these findings that, at least initially, go against pivotal studies results.

P594

Outcome evaluation of Sacubitril/Valsartan in patients with Heart Failure and reduced ejection fraction with regular follow-up meetings in a Spanish heart failure day-hospital.

S Blasco Turrion[1]; FJ Camacho Jurado[1]; I Lobo Torres[1]; R Castilla Ortiz[1]; A Gomez Lopez[1]; C Collado Moreno[1]; P Gonzalez Perez[1]; JA Sanchez Brotons[1]; S Casquero Dominguez[1]; E Martinez De Morentin[1]; M Maestre Garcia[1]; M Iravedra[1]; J Lozano Cid[1]; P Martinez Romero[1]; FJ Morales Ponce[1]
[1]Puerto Real Hospital, Cardiology, Puerto Real, Spain

Introduction: The latest Heart Failure and Cardiovascular Prevention ESC Guidelines have shown the benefits of Sacubitril/Valsartan (LCZ) in reducing rehospitalizations and mortality in patients with heart failure with reduced ejection fraction (HFrEF) that are still symptomatic despite proper treatment with beta-blockers, ACE inhibitors, and MRA drugs. Therefore our goal is to evaluate the progression of patients with HFrEF treated with LCZ.
Methods: A prospective study of patients with HFrEF treated with LCZ, evaluated in the Heart Failure Day-Hospital from September 2016 to December 2017.
Results: Out of the 107 patients regularly evaluated in the Heart Failure Day-Hospital, 76.4% were male, with a mean age of 66 ± 12 years old. They all had other cardiovascularlar risk factors such as Hypertension (60%), Dyslipidemia (53%), Diabetes (45%) or active smoking (7.5%). 13% of them had had cerebrovascular disease and 54% prior coronary artery disease.
52% of these patients are being treated with Sacubitril/Valsartan, detecting an improvement of left ventricle ejection fraction (6.6 ± 9.2%) and right ventricle function measured by TAPSE (1.16 ± 3.5mm) as well as a reduction in plasma NT-proBNP levels (-3981 ± 11238ng/ml). When compared to those without LCZ we did not find statistically significant differences in weight reduction (-1.29 ± 5kg vs -1.25 ± 5kg p = 0.9671), plasma LDL levels (-20.5 ± 35mg/dl vs -9.7 ± 34mg/dl p = 0.1091) nor plasma HDL levels (4.8 ± 17mg/dl vs 4.7 ± 9.5mg/dl p = 0.97), although there were statistically significant differences in plasma total cholesterol levels, with a greater reduction in patients treated with LCZ (-17 ± 39mg/dl vs 2.6 ± 43mg/dl p = 0.015). We noticed minor hyperkaliemia in 21% of the patients treated with LCZ as well as a 25% of patients without it (p = 0.7477). Finally, regarding complications, there was just 1 death and 2 rehospitalizations due to cardiovascular causes in the group treated with LCZ, while there were 2 deaths and 3 rehospitalizations due to cardiovascular causes in the group without LCZ.
Conclusion: Following the latest Heart Failure Guidelines indications, we started treatment with Sacubitril/Valsartan in patients with reduced ejection fraction that were still symptomatic despite proper treatment with beta-blockers, ACE inhibitors, and MRA drugs, detecting an improvement in cardiac function and reduction in plasma NT-proBNP levels as expected. We also detected a greater reduction in plasma total cholesterol levels, but not in plasma LDL levels. We did not find statistically significant differences in complications or mortality rates until now. Nevertheless longer tracking period and bigger sample are needed to validate these findings.

P595

Effects of irbesartan for renal failure in the patients with chronic heart failure and preserved systolic function and atrial fibrillation

M Muhammad[1]; O Mytrokhina[1]
[1]Dnipropetrovsk medical academy, Dnipropetrovsk, Ukraine

Background: Renal failure is a common disease affecting an increasing number of patients with chronic heart failure (CHF) due to its progression and increased cardiovascular morbidity and mortality. Angiotensin II Receptor Blockers (ARBs) showed renoprotective effects, but the role of ARBs in patients with CHF and preserved systolic function and atrial fibrillation (AF) remains debatable.
Aim: We aimed to evaluate the effects of irbesartan on progression of renal failure in the patients with chronic heart failure and preserved systolic function and atrial fibrillation.
Methods: 31 pts (14 M, 17 F, mean age - 68,63 [45,00;85,00] years) with CHF NYHA I-III class and preserved ejection fraction (LVEF >45%) and AF were enrolled. Pts were divided into 2 groups: 19 (61,29%) pts (1 group) with glomerular filtration rate (GFR) <90 = 60 ml/min/1,73m2 and 12 (38,71%) pts (2 group) with GFR <60 = 30 ml/min/1,73m2. The serum creatinine (SCr) levels were determined in the blood in all pts. GFR was calculated by CKD-EPI formula. All pts received the standard treatment and irbesartan for 12 weeks.
Results: Increased blood pressure (BP) levels correlated to GFR (r=-0,34; p <0,05). After 12 weeks of treatment with irbesartan the SCr levels had been decreased by 9,78 and GFR had been increased by 12% in the 2 group versus 1 group (by 5,45% and 6,82%, respectively (p <0,05)).
Conclusions: The data show, irbesartan therapy may retard progression of CHF and preserved systolic function and AF. Its administration may provide benefits for the reduction of hospitalizations and mortality in its population.

P596

assessment of physical fitness of patients with heart failure. pilot study

M Malec[1]; M Kaluzna-Oleksy[2]; J Migaj[2]; E Straburzynska-Migaj[2]; A Straburzynska-Lupa[1]
[1]University of Physical Education , Physical Therapy and Sport Recovery, Poznan, Poland; *[2]Poznan University of Medical Sciences, Department of Cardiology, Poznan, Poland*

Background: Heart failure (HF) is a complex pathological process that leads to changes not only in cardiovascular system. Functional and structural changes affect muscular tissue resulting in impairment of functional capacity and leading to lower tolerance of exertion and disability. The Fullerton Fitness Test is a simple diagnostic tool used in rehabilitation of geriatric patients and recently also in people with heart failure, as it reflects changes in fitness and capacity caused by aging.
Aim: The aim of the study was to assess the physical fitness of patients with HF by using Fullerton Fitness Test.
Method: This was a prospective study of 20 men, including 10 with chronic HF with reduced left ventricular ejection fraction (LVEF) (= 40%) in stable clinical state (at least 4 weeks without HF decompensation, defined as no changes in diuretics use), and 10 - control group. They underwent echocardiography with LVEF assessment, laboratory tests with natriuretic peptide evaluation, six-minute walk test (6MWT), and Fullerton Fitness Test, which assessed physical fitness.
Results: Patients with HF had lower LVEF (23.5 ± 7.4 vs. 62.8 ± 4.5, p < 0.001), higher BNP (208.4 ± 201.9 vs. 25.5 ± 19.2, p = 0.0021) and NT-proBNP (1225.6 ± 1055.9 vs. 90.6 ± 139, p < 0.0008). There were no significant differences between the investigated groups as to age (50.90 ± 8.99 vs. 49 ± 9.66, NS) but there was a significant difference in BMI - HF patients had lower BMI (25.33 ± 4.25 vs. 30.96 ± 2.9, NS, p < 0.0015). HF patients showed shorter 6MWT distance (439 ± 146.93 vs. 558.10 ± 62.72, p < 0.0433), longer time of "8-FootUp&Go" (7.42 ± 1.81 vs. 5.74 ± 0.85, p < 0.0433), lower number of repetitions "Chair Stand" (14 ± 5.79 vs. 20.3 ± 5.05, p < 0.0433) and "Arm-Curl" (16.5 ± 5.14 vs. 25.7 ± 4.71, p < 0.0015). Significantly worse results were also obtained in the "BackScratch" (-25.3 ± 17.08 vs. -1.50 ± 5.81, p < 0.0005) and "Chair Sit & Reach" (-17.10 ± 11.82 vs. -4.10 ± 8.02, p < 0,0089). In addition, a positive correlation was observed between LVEF and all test of Fullerton, "6MWT" (r = 0.61,p = 0,004), "Chair Stand"(r = 0.63,p = 0.002), "Arm Curl" (r = 0.7,p = 001), "Chair Sit & Reach" (r = 0.5,p = 0.023), "Back Scratch" (r = 0.71,p < 0.001), " 8-FootUp&Go" (r=-0.59,p = 0.005).
Conclusions: Patients with HF with reduced left ventricle ejection fraction have worse physical performance compared to healthy subjects. The Fullerton Fitness

Test can therefore be used in the comprehensive assessment of patients with heart failure as a repetitive tool for assessing physical fitness.

P597

Response to cardiac resynchronization therapy improves cognitive function and frailty in older heart failure patients. a prospective, controlled study

S Stefano Tolone[1]; G Pulignano[1]; MD Tinti[1]; D Del Sindaco[1]; A Avella[1]; P De Girolamo[1]; A Di Lenarda[2]; G Barbati[2]; L Tarantini[3]; M Uguccioni[1]
[1]*San Camillo Forlanini Hospital, Heart Failure Clinic, Cardiology1/CCU, Rome, Italy*; [2]*Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy*; [3]*San Martino Hospital, Belluno, Italy*

Background: Cognitive impairment (CI) and Frailty are common in older heart failure (HF) patients and are associated with higher hospitalizations rates and worse prognosis. Available evidences suggest that Cardiac Resynchronization Therapy (CRT) could improve cognitive or physical capacity as a consequence of improved cardiac function and, therefore, improved cerebral blood flow. The aim of this study was to assess the effects of CRT on cognitive function and frailty in elderly HF patients.
Material and Methods: Consecutive NYHA II-III HF patients aged >65 years, with EF < 35%, optimized medical therapy with ACE-i/ARB, Beta-blockers and MRA, and life expectancy > 1 year with an indication to electrical device (CRT or ICD) were enrolled. Patients underwent, at baseline and 6 months after device implantation with standard transvenous techniques, a single-blinded clinical, instrumental and multidimensional evaluation of Cognitive function (Folstein MMSE, Trailmaking Test A and B, WAIS Digit Symbol, Verbal Fluency) and frailty (4m gait speed and stand-up time from a chair).
Results: Twenty-nine patients were enrolled: 22 (76%) male, mean age 76 years (65-87), median NYHA class 2.6+0.5 and mean EF 30+4 (22-35). According to ESC guidelines 11 (38%) patients had indication to ICD and 18 (62%) to CRT-D. Two different statistical analysis were performed. In the former the ICD group (n = 11) was compared to the CRT group (n = 18). In the latter ICD and nonresponders to CRT (CRT-NR) patients (n = 17) were compared to CRT responders (CRT-R) (n = 12). There were no significant differences in baseline characteristics between groups, except for QRS duration in CRT and female gender among CRT-R. At 6-month follow-up, compared to ICD group, CRT patients showed a significant improvement of EF, TM-B and TM-A tests, and gait speed. Compared to CRT-NR/ICD group, CRT-R patient showed a more significant improvement of EF, NYHA Class, BNP level, TM-B and TM-A, and gait speed (Figure 1).
Conclusions: Our pilot study suggests that CRT may improve cognitive function and frailty in older HF "responders" patients, with particular regard to executive functions. Assessment of cognitive function and frailty should be recommended before and after device implantation in order to optimize management and evaluate effectiveness.

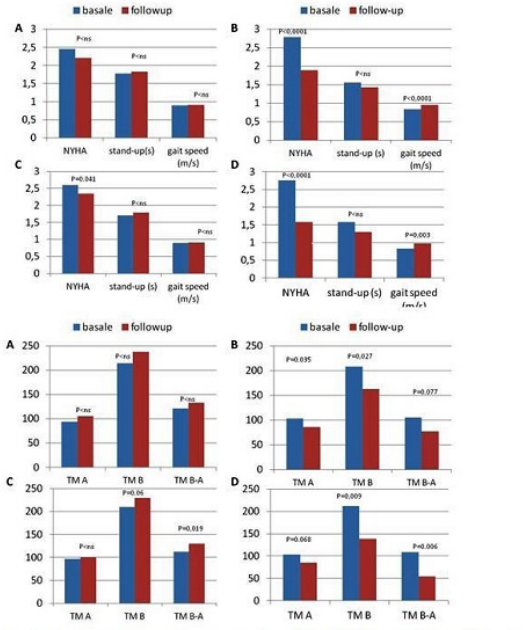

Figure 1. Baseline and follow-up functional capacity, frailty indices and Trial making test A, B and B-A in ICD (A), CRT (B), ICD/CRT-NR (C) and CRT-R patients (D)

Biventricular stimulation in patients with chronic heart failure with moderate clinical manifestations

ES Atroshchenko[1]; OV Koshlataja[1]; DV Romanovskiy[1]; VA Sujayeva[1]; YP Ostrovskiy[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

On behalf of: Atroshchenko E.S., Koshlataja O.V., Romanovskiy D.V., Sujayeva V.A., OstrovskiyY.P.

Objective: to assess the effectiveness of CRT (cardiac resynchronisation therapy) implantation in patients with chronic heart failure NYHA functional ?lass II at 12 months
Methods: 52 patients (pts) with ischemic or dilated cardiomyopathy, complicated by CHF NYHA functional ?lass II, LV EF below 35%, QRS duration 150 msec ?nd more and with ECHO confirmed mechanic myocardial dyssynchrony were examined. All patients underwent the LV end-diastolic volume (LVEDV), LV end-systolic volume (LVESV),LV end-systolic diameter (LVESD) LVEF, LV end-diastolic diameter (LVEDD), interventricular delay, dyssynchrony index , all segments max delay were estimated by ECHO. The levels of BNP, the six-minute walk test (6MWT) and life quality (LQ) were measured initially and at 12 months after CRT implantation.
Results: At 12 months LVEDV significantly decreased from 318,41 ± 15,8 ml to 229,06+23,95ml (? < 0,05), LVESV decreased from 241,41 ± 12,9 to 149,6+21,72 (? < 0,05), LVEF increased evidently from 24,17 ± 0,85% to37,81+2,57 % (? < 0,05). Intracardiac hemodynamic changes were accompanied by decreased mechanic dyssynchrony event rate - there was trend to the evident decrease of interventricular delay from 67,7 ± 4,2 to 29,3+6,8msec. (? < 0,05); improved LQ of patients: LQ evidently decreased from 59,9 ± 1,67 scores to 30,8 ± 0,75scores (? < 0,05); 6 MWT increased from 393,2 ± 15,07 m to 477,0 ± 18,43 m; NT-proBNP decreased from 1442,4 ± 277,8 to 287,16 ± 0,75 (? < 0,05).
Conclusions: At 12 months biventricular heart stimulation evidently enhances heart haemodynamic and the clinical conditions of pts, improving exercise tolerance in pts with chronic heart failure NYHA functional ?lass II.

P599

Aortic telomere length as a potential predictive factor for post transplant allograft function

J Vymetalova[1]; D Dlouha[2]; J Hubacek[2]; V Lanska[3]; I Malek[4]
[1]*Institute for Clinical and Experimental Medicine (IKEM), Cardiac Centre, Cardiovascular Surgery Department, Prague, Czech Republic*; [2]*Institute for Clinical and Experimental Medicine (IKEM), Centre for Experimental Medicine, Prague, Czech Republic*; [3]*Institute for Clinical and Experimental Medicine (IKEM), Statistical Unit, Prague, Czech Republic*; [4]*Institute for Clinical and Experimental Medicine (IKEM), Cardiac Centre, Cardiology Department, Prague, Czech Republic*

Background: Independent of the age, the telomeres may be engaged to the beginning and/or to the progression of cardiovascular diseases. The recipients of orthotopic heart transplantation (OHT) encounters a number of complications which can be connected with the activity of telomerase and length of telomeres. We analyzed how the length of telomeres in aortic DNA correlates with the subsequent post-transplantation development of the organism.
Materials and Methods: During 2005 - 2015 years, we have collected aortic samples of 376 heart recipients (age 50.8 ± 11.8 years) and 383 donors (age 38.6 ± 12.2 years). Relative telomere length in aortic tissue DNA (ArTL) was performed using a quantitative PCR - based method.
Results: Shorter ArTL was detected in heart allograft recipients in comparison to donors (P < 0.0001). Etiology of HF wasn't associated with ArTL of recipients. Patients affected by acute cellular rejection (AR) had significantly shorter ArTL (P < 0.008). Shorter ArTL was detected in patients with implanted mechanical circulatory support before OHT (P < 0.03), and also in subjects who were affected cardiac allograft vasculopathy (CAV; P < 0.05). Overall survival time after heart transplantation was associated only with donors ArTL (P < 0.004).
Conclusions: ArTL differes between donors and recipients independently on sex and age of patients. Changes in ArTL may probably reflect some important mechanisms which contribute to the development of complications after heart transplantation such as AR and CAV.

Addressing the psycho-educational needs of caregivers of patients with advanced heart failure: a systematic review

L Lorna Cassidy[1]; D Fitzsimons[1]; L Hill[1]; J Mcgaughey[1]; E Greene[1]
[1]*Queen's University of Belfast, School of Nursing and Midwifery , Belfast, United Kingdom*

On behalf of: Queen's University Belfast
Funding Acknowledgements: Northern Ireland Chest Heart & Stroke

Background: Caregivers play a significant role and contribute to the self-care of patients with heart failure. This can be at the expense of their own needs, with limited healthcare resources available to support or reduce caregiver burden. With the increased emphasis on family-centered care there is an urgent need to provide effective psycho-educational care tailored to the needs of caregivers.
Aim: To determine the effectiveness of psycho-educational resources used within published intervention studies for caregivers and thereby inform the components of an intervention.
Methods: A systematic search of PsychInfo, Medline, CINAHL Plus, EMBASE, and SCOPUS databases, citations from relevant articles and expert recommendations was undertaken in November 2017. Randomised controlled trials published in English (2007-2017) with successful psychological outcomes on caregiver burden, caregiver strain, quality of life and depression were assessed. Titles and abstracts were screened, with 39 full texts of potential studies assessed by three independent reviewers. Nine studies were selected and data was subsequently extracted using an inductive approach and methodological quality was assessed.
Results: Nine studies originating from six countries with a total sample size of 1239 participants were included. Qualitative synthesis of the findings identified four themes:
Improved communication by a multidisciplinary team: caregivers desired better communication on the patient's current health status and future treatment plan. Involvement in key discussions and clinical decisions were desired.
Education on heart failure condition and symptoms: caregivers expressed the need for concise written information on how to monitor the patient's heart failure symptoms and what to expect as the condition progresses. Timing of information was vital, with preference being prior to discharge and when the patient became palliative.
Impact of caring on everyday life: practical and problem solving skills to enable the patient to maintain self-care were desired. Communication strategies to help caregivers interact positively with the patient was also considered important.
What to do when symptoms worsen: caregivers wanted knowledge of warning signs indicating deterioration and who, how and when to contact someone in an emergency.
Conclusions: Caregivers have an important and valuable role in the self-care of patients with heart failure. Multidisciplinary teams should involve caregivers in discussions and decisions about the patient's condition. Further research is needed into an intervention amendable to everyday clinical practice.

Cardioprotective effect of sphingosine 1-phosphate receptor 1 agonist in myocardial infarction and revascularization experimental model

N Ahmed[1]; M Mansoor[2]; D Linardi[3]; M Mansoor[4]; GEBRIE Mebratu[3]; G Rungatscher[3]; G Faggian[3]
[1]University of the Punjab, , Faculty of Health Sciences, Lahore, Pakistan; *[2]King Edward Medical University, Internal Medicine, Lahore, Pakistan*; *[3]University of Verona, Cardiac Surgery Division, Verona, Italy*; *[4]Punjab Institute of Cardiology, Cardiology, Lahore, Pakistan*

Background: Myocardial Infarction is a major health issue and its survival limited by ischemia reperfusion injury leading to heart failure. The mechanism of this phenomenon is not clear because of complicated and complex phathophyiology of this model. In this study, we investigated pharmacological cardioprotective role of Sphingosine 1-Phosphate Receptor 1 agonist an in vivo model of myocardial revascularization.
Methods: We developed in vivo rat models of LAD occlusion and revascularization monitored by invasive hemodynamics measurement. At the beginning of LAD occlusion, animals randomly treated with Sphingosine 1-Phosphate Receptor 1 agonist (Group A, n = 30) or placebo (normal saline) (Group B, n = 30). Half of the animals (Group A1&B1, n = 15 each) were sacrificed after 3 hours and remaining (Group A2&B2) after 14 days of reperfusion. Blood and myocardial tissue were collected for analysis of cardiac biomarkers, inflammatory markers and cell signaling pathways.
Results: Sphingosine 1-Phosphate Receptor 1 agonist treatment activated the cardioprotective reperfusion injury salvage kinase (RISK) and survivor activating factor enhancement (SAFE) pathways leading to decreased myocardial apoptosis and oxidative stress. This improvement contributed in significant recovery of left ventricular systolic and diastolic functions.
Conclusions: Sphingosine-1-phosphate receptor activation with fingolimod increased survival, cardiac function after prolonged myocardial ischemia. Our data strongly support a cardioprotective role for Sphingosine -1–phosphate Receptor-1 agonist activation during reperfusion after myocardial revascularization.

Implantable peritoneal ultrafiltration device: A novel systemic fluid decongestion approach

Y Feld[1]; N Hanani[2]
[1]Sunnybrook Health Sciences Centre, Cardiology, Toronto, Canada; *[2]Paragate Medical LTD, Nazareth, Israel*

Funding Acknowledgements: Paragate Medical LTD

Background: Diuretic therapies aiming to enhance fluid removal in chronic HF are limited due to diuretic resistance in about 30% of the patients. Intravenous diuretics and ultrafiltration as alternatives are associated with side effects, multiple visits and cost. Based on peritoneal dialysis and peripheral ultrafiltration principles, we suggest a novel continuous peritoneal ultrafiltration approach, in which extracellular fluids are slowly prompted through the peritoneal membranes by induction of hydrostatic pressure gradient, into a fully implantable device and cleared to the urinary system. This work tested long term performance and scalability of the concept.
Methods: A flat disk shaped absorption chamber covered by semi-permeable membrane was implanted intraperitoneally in 13 healthy rats (405 ± 33 gr.). Two control rats where implanted with common peritoneal dialysis catheter for comparison of drainage performance. Extracorporeal drainage and sampling of fluids by induction of intermittent hydrostatic vacuum were conducted between 2-3 times a week for period of 4-7 weeks followed by histopathological analysis.
Large model was tested with a fully implantable device in 5 healthy pigs (68.1 ± 5.3kg) up to 6 weeks. Impact of congestion on drainage rate was assessed in another animal by induction of acute venous overload.
Results: In rats, isotonic extracellular fluid was drained at an average rate of 3.2 ± 0.5 cc/kg/hour during follow up period. Unlike designated membrane based chambers, catheters drained 25 folds less per square centimeter. In pigs, the average drainage rate after follow-up was 10 ± 4.9 ml/hr and 210 ± 109 ml/day throughout follow-up period. Overloading central venous pressure acutely from 7 to 16mmHg has doubled drainage rate (0.14 to 0.29 ml/min) despite presence of normal kidney function (increased from 0.4 to 11.7 ml/min). The drained fluid was comparable to serum's electrolytes and toxins, unlike content of secreted Albumin (1.2 ± 0.8 g/dL) that was about one third of the serum Albumin (4.1 ± 0.5 g/dL).
Conclusions: The minimally invasive implantable absorption chamber enables durable systemic extracellular fluids removal through the peritoneal membranes, suggesting of a novel non-aggressive therapy for congested HF patients.

Funding Acknowledgements: Berlin Heals

Background: The application of pulsed electrical signals from CRT or CCM devices improves cardiac function in selected patients beyond the restoration of a synchronized cardiac excitation. In recent publications we have shown that application of direct electrical microcurrent signals improves myocardial function and modifies extracellular matrix components.
Purpose: We wanted to examine whether the chronic application of a moderate microcurrent of 5μA per cm^2 impairs cardiac function to evaluate the upper safety margin for the application of direct microcurrent for the treatment of patients with heart failure.
Methods: By a small left thoracotomy, in five healthy adult sheep (mean weight / age at baseline, 70.8 kg /2.2 years) a epicardial platinum patch electrode (active surface, 36 cm^2) was fixed on the left ventricular free wall by fixation on the pericardium. A coil electrode was implanted transvenously into the right ventricle as counter electrode. Both leads were connected to a battery driven direct microcurrent generator, which supported the leads with a constant current of 180 μA over a mean period of 195 days. Besides a set of different blood chemistry and cell count parameters, left ventricular ejection fraction (LVEF; primary endpoint) and fractional shortening (FS; secondary endpoint) was serially (mean examinations per animal, 12) performed over a follow-up time of 6,5 month by echocardiography and evaluated statistically by non-inferiority testing. Data are given as mean ± SD.
Results: All animals survived the operative procedure and completed the follow-up. Over the observation period the average LVEF increased by 1.4 % from 71.4 to 72.8 % (n.s.). Therefore, the calculated probability to impair the LVEF through microcurrent application by more than 3.9% within 6 months is less than 5 %. The mean FS rose by 4.6 % from 44.8 to 49.4% (P = 0.068, n.s.). A reduction of the FS by more than 5% induced by chronic moderate microcurrent application is

very unlikely (0.05 %). Changes in ECG or signs of infection were not observed. Furthermore, constant levels of hematocrit (32,2% ± 1,8), CK (173,7 U/l ± 50,5) and LDH (415,4 U/l ± 32,5) sustained that no further tissue damage was caused by the chronic application of electrical microcurrent during follow-up compared to baseline levels.
Conclusions: The chronic application of moderate direct electrical microcurrent of 5μA per cm^2 on the hearts of healthy sheep does not compromise heart function. The authors conclude that administration of direct electrical microcurrent for the treatment of heart failure is safe up to a limit of 5μA per cm^2.

Chronic Heart Failure - Prevention

P604
Prevenction of cardiotoxicity during doxorubicin, trastuzumab or pertuzumab treatment by Icz 696 administration in our in vitro model

N Maurea[1]; R Paciello[1]; G Piscopo[1]; G Sorrentino[1]; F Maurea[1]; C Coppola[1]; C De Lorenzo[2]
[1]Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCCS, Division of Cardiology, Naples, Italy; *[2]University 'Federico II', Department of Molecular Medicine and Medical Biotechnology , Naples, Italy*

Background: Cardiotoxic effects related to anticancer drugs are among the leading causes of morbidity and mortality in cancer patients treated with Doxorubicin (DX), Trastuzumab (T) and Pertuzumab (P), antineoplastic drugs used in the treatment of breast cancer. Sacubitril-valsartan (LCZ 696), a drug used for the treatment of heart failure in patients with a reduced ejection fraction, is a combination drug, made up of neprilysin inhibitor sacubitril and angiotensin II receptor blocker valsartan.
Purpose: In this study, we aim to assess whether LCZ 696, administered during DX, T or P treatment, reduces in vitro anticancer drugs-related cardiotoxicity, compared to Valsartan (V), used as a control drug.
Methods: Our in Vitro model, the H9C2 rat cardiomyoblasts, were seeded in 96-well plates at a density of 1 x 104 cells/well and incubated at 37°C with 5% CO2 for 16 hours. After the addition of 200 nM of T, P or DX in the culture medium, cells were incubated for further 72 hours. Cells were then treated in the absence or presence of 10 μM of LCZ 696 or V for additional 3 days. Cells viability was evaluated by trypan blue exclusion test; the percentage of viable cells compared to control untreated cells express cell survival.
Results: LCZ 696 reduced significantly T, P and DX related toxicity in H9C2 cardiomyoblasts as evidenced by the higher percentage of viable cells treated with combinations of T, P or DX with LCZ 696 with respect to cells treated with T, P or DX alone ($p < 0.001$).
V reduced significantly T and DX related toxicity in H9C2 cardiomyoblasts treated with combinations of T or DX and V with respect to the cells treated with T or DX, used as single agents ($p < 0.001$). However, there was no significant reduction of toxicity when H9C2 cells were treated with P + V.
Thus, both LCZ 696 and V reduced significantly DX related toxicity when administered to H9C2 cardiomyoblasts after the antineoplastic treatment (no significant difference between LCZ 696 and V treatment, $p = 0.6$).
Moreover, LCZ 696 was significantly more effective than V ($p < 0.001$) in reducing both T and P related toxicity when administered to cultures of H9C2 cardiomyoblasts after antineoplastic treatments.
Conclusions: These results show that LCZ 696 administration, during DX, T or P treatment, significantly increases the viability of treated cells, thus reducing cardiotoxic effects of these drugs, as demonstrated by our in vitro experiments. The future purpose is to test LCZ 696 in in vivo models as well, in order to assess its capability to blunt left ventricular dysfunction after antineoplastic treatments.

Chronic Heart Failure - Clinical

P605
Prognostic role of structural changes of large arteries and peripheral blood flow in patients with chronic heart failure

I Shkurat[1]
[1]Institute of Heart, Kyiv, Ukraine

Purpose: To investigate the dependence of structure of a.femoralis (a.F) and peripheral blood flow (PBF) on severity and 12-months survival prognosis of chronic heart failure (CHF).
Methods: Ultrasonography of a.F, a.dorsalis pedis (a.DP) were performed in 129 patients (age 56.6 ± 1.2 years; 89 males) with stable CHF (NYHA II-III) and LVEF < 40% and in 40 age-matched healthy subjects. Diameter (D), intima-media thickness (IMT) of a.F, velocities (Vps and Ved) in a.DP were measured; index of relative wall thickness (RWT) of a.F: RWT = IMT/D; index of peripheral resistance (RI): RI=(Vps-Ved)/Vps. Kaplan-Meier 12-months survival analysis was performed for RWT as well as for Vps, Ved, RI in a.DP based on 'below median vs. above median' approach.
Results: In pts with CHF IMT and RWT were significantly higher (IMT: 0.99 ± 0.16 vs 0.59 ± 0.09mm, $p < 0.001$; RWT: 0.16 ± 0.03 vs 0.10 ± 0.01unit, $p < 0.001$). Vps and Ved in a.DP were significantly lower in pts with CHF (39.3 ± 2.1 vs 56.4 ± 6.6cm/s, $p < 0.01$ and 5.2 ± 0.8 vs 12.9 ± 1.7cm/s, $p < 0.01$, respectively), and RI in a.DP was significantly higher (0.83 ± 0.04 vs 0.77 ± 0.02unit, $p < 0.01$). These changes become more pronounced in pts with NYHA class III-IV than in NYHA class II (Vps 32.3 ± 1.9 vs 35.7 ± 2.1cm/s, $p = 0.03$, Ved 5.8 ± 0.7 vs 6.9 ± 1.3cm/s, $p = 0.03$ and RI 0.84 ± 0.03 vs 0.82 ± 0.02unit, $p = 0.04$, respectively). Kaplan-Meier 12-months survival analysis was performed in relation to the RWT ($p = 0.038$), Vps in a.DP ($p = 0.04$), Ved in a.DP ($p = 0.037$) and RI in a.DP ($p = 0.04$). Significantly lower survival was apparent in pts with RWT>0.16, Vps < 36?m/s, Ved < 6?m/s, RI>0.84unit.
Conclusions: The present study indicates that remodeling of peripheral blood vessels is accompanied by decrease peripheral arterial blood flow and by increase in resistance of resistive vessels in patients with CHF. RWT, Vps, Ved and RI in a.DP may be used for mortality risk stratification in patients with CHF.

P606
Reversibility of heart failure-specific changes in systemic metabolomics through mechanical cardiac unloading in end-stage HF patients

MS Marion Susanna Hilse[1]; R Pistulli[1]; T Kretzschmar[1]; M Franz[1]; T Bekfani[1]; S Moebius-Winkler[1]; M Kiehntopf[2]; S Neugebauer[2]; J Gummert[3]; H Milting[3]; PC Schulze[1]
[1]University Hospital of Jena, Internal Medicine I, Dept. of Cardiology, Jena, Germany; *[2]University Hospital of Jena, Institute of Clinical Chemistry and Laboratory, Jena, Germany*; *[3]Heart and Diabetes Center NRW, Bad Oeynhausen, Germany*

Aims: Metabolism is impaired in advanced heart failure (HF) and mechanical unloading through implantation of left ventricular assist devices (LVADs) is known to improve clinical symptoms and hemodynamics in patients with end-stage HF. The aim of this study was to systematically evaluate systemic metabolic changes in end-stage HF patients before and after LVAD therapy in comparison to non-diseased controls.
Methods: 181 serum metabolites were assessed in serum of 40 end-stage HF patients (n = 20 ICM, n = 20 DCM, mean EF 21.5 ± 6.0 %, LVEDD 69.4 ± 12.3mm) before and after LVAD implantation as well as 20 controls using liquid chromatography tandem mass spectrometry. Metabolomic measurement in HF patients were repeated at 30 days and 100 days post-LVAD implantation. Principal component analyses (PCA) with heatmapping of measured metabolites were performed in order to assess group differences in metabolites.
Results: Following LVAD implantation, echocardiographic parameters of HF patients improved (100 d post-LVAD: EF from 21.5 ± 6.0 to 26.1 ± 6.7 %, $p = 0.003$; LVEDD 69.4 ± 12.3 to 59.6 mm ± 14.5 mm, $p < 0.0001$). A clear separation of HF patients and control individuals but not between HF subgroups was evident in the PCA analyses of serum metabolites. In HF patients compared to controls, we found a significant decrease of phosphatidylcholines and sphingolipids (2.7-fold, $p < 0.0001$) as well as an increase in acylcarnitines (3.0-fold, $p < 0.0001$). There were no significant intergroup differences preceding LVAD or at 30 days following LVAD implantation. In DCM, but not ICM patients, phosphatidylcholines increased after 100 days LVAD therapy (1.6-fold, $p = 0.01$). Such partial reversibility was not observed for acylcarnitines or other metabolites.
Conclusions: In line with our previous observations, we found distinct alterations of serum metabolites in advanced HF patients. Following LVAD therapy, a partial reversibility of these metabolic alterations, in particular involved in fatty acid metabolism, occurs in patients with DCM. Further studies are needed to explore possible metabolic differences between ischemic and non-ischemic HF as well as their response to LVAD therapy.

Budget impact of IV iron therapy with ferric carboxymaltose in patients with chronic heart failure and iron deficiency in France

M Mathilde Faller[1]; FO Champs[1]; H Moutier[1]; K Levesque[2]; S Bourguignon[1]; A Cohen-Solal[3]
[1]IQVIA, Health Economics and Outcome Research, paris, France; *[2]Vifor Pharma, Health Economics and Outcome Research, paris, France*; *[3]Hospital Lariboisiere, Cardiology, Paris, France*

Funding Acknowledgements: Vifor Pharma

Introduction: Iron deficiency (ID) is highly prevalent in patients with systolic chronic heart failure (CHF). CHF with ID is a major cause of hospitalization and represents a major cost for national healthcare budgets. The ESC recommends intravenous (IV) iron therapy with ferric carboxymaltose (FCM) as the only treatment against ID for such patients.
Purpose: This analysis aims to evaluate the budget impact of IV iron therapy with FCM for patients with systolic CHF and ID, from the French public health insurance perspective.
Methods: A budget impact model was adapted to forecast the budget impact over a 5-year horizon, as the difference of costs between two scenarios: one where patients can be either treated for ID by 1000 mg of FCM annually, or not treated for it, and the other where patients are not treated for ID. Cost saving can be through NYHA class improvement, lower rate of hospitalizations, and shorter length of stay. Clinical data were extrapolated from pooled data from four randomized controlled FCM trials (FER-CARS-01, FAIR-HF, EFFICACY-HF and CONFIRM-HF) using regression models. The time horizon was extended to 5 years by applying transition probabilities estimated from CONFIRM-HF. Our model used data from the FCM arms of these trials for patients treated with FCM, and data from the placebo group for patients not treated for ID. Epidemiological parameters for France were derived from the literature. To document costs, the French Diagnostic-Related Groups and hospital activity from the national hospitalizations database (PMSI), as well as national recommendations were used. Market shares of FCM were based on forecasts. Secondary scenario and univariate sensitivity analyses assessed the influence of various factors, including FCM dose, cost of other medication, hospitalization, or outpatient visits by NHYA levels.
Results: In the primary analysis, the modelled 5-year cost difference between the scenarios with and without FCM in a population of 189 334 prevalent and incident patients with CHF+ID was −881 834€, giving a negative budget impact of increased use of FCM for health insurance. The cumulative savings resulted from lower hospitalization costs due to CHF worsening (-€35.8M€) and follow-up (-2.9 M€). These CHF cost savings outweighed costs for FCM treatment (37.7 M€). In sensitivity analyses, the budget impact varied from -16 M€ to +146 M€ if the hospitalization rate for patients not treated for ID either improved or reduced by 25%. Other factors with a budget impact were the dose used (+36 M€ with a dose of 1679 mg), the absence of hospitalization cost differentiation between NYHA classes (−12 M€ if costs are differentiated), and administration settings (-34 M€ if another administration setting is used).
Conclusion
Increased use of FCM in France is expected to meet a medical need in patients with CHF+REF and ID with a minimum economic impact on the French public healthcare system.

P609
Flow-mediated vasodilatory response in patients with chronic heart failure

I Shkurat[1]
[1]*Institute of Heart, Kyiv, Ukraine*

Purpose: To establish the dependence of endothelium-mediated vasodilatory response on severity, etiology of CHF, depending on the availability of the phenomenon of insulin resistance and 12-months survival prognosis of CHF.
Methods: We examined 106 hemodynamically stable CHF patients (pts), NYHA II-IV, LVEF < 40%. Hypertensive heart disease (HHD) was established in 66 pts and dilated cardiomyopathy (DCMP) in 40 pts. 42 pts (’40%) had IR. Diameter of a.brachialis (D) was detected ultrasonographically before (D1) and after (D2) standard forearm cuff test. Flow-mediated vasodilation (FMV) was calculated by formula: (D2-D1)/D1 × 100%. Insulin resistance index (HOMA-IR) was calculated according to the formula: fasting insulin (microU/L) x fasting glucose (nmol/L)/22,5. IR was based on the value of the index HOMA^{3}2,77. Kaplan-Meier 12-months survival analysis was performed for FMV based on ‘below-median vs above-median’ approach.
Results: In CHF pts FMV was significantly impaired in comparison to age-matched controls (6,8 ± 0,5% vs 11,04 ± 1,3%, p < 0,01). More pronounced impairment of FMD in III-IV NYHA class pts than in II NYHA class was observed (6,3 ± 0,8% vs 7,1 ± 1,1%, p = 0,03). In DCMP FMV was significantly worse than in HHD (5,5 ± 0,8% vs 7,4 ± 1,3%, p < 0,001) despite comparable LVEF (p = 0,47) and NYHA class (p = 0,62) in both groups. In IR pts FMD was significantly lower than in pts without IR (5,2 ± 0,8% vs 7,9 ± 1,3%, p < 0,03). Respectively, significant correlation relationship was found between HOMA index and FMV (rho=-310,p = 0,004). 12-months survival was significantly better in group with better (above-median) FMV (93% of pts alive vs 85% of pts alive in below-median group, p = 0,047), although LVEF in both groups were comparable (33,5 ± 8,1% vs 32,1 ± 7,3%, p = 0,32).
Conclusions: In CHF FMV is pronounsly impaired, particularly in NYHA III-IV, DCMP pts and IR pts. The better FMV responders demonstrated the better 12-months survival than worse responders despite comparable LVEF in both groups.

Acute Heart Failure - Pathophysiology and Mechanisms

Myocardial infarction is sufficient to increase GLP-1 secretion leading to improved left ventricular contractility and mitochondrial respiratory capacity

M Michael Lehrke[1]; S Diebold[1]; J Moellmann[1]; F Kahles[1]; E Haj-Yehia[1]; A Nickel[2]; C Maack[2]; N Marx[1]
[1]*RWTH University Hospital Aachen, Cardiology, Aachen, Germany*; [2]*DZHI, Cardiology, Würzburg, Germany*

Background and aims: The incretin hormone GLP-1 holds cardioprotective efficacy and was recently found to be increased by inflammatory stimuli. This study was performed to characterize the secretion of GLP-1 in response to myocardial infarction in mice and investigate its functional relevance.
Background and aims: The incretin hormone GLP-1 holds cardioprotective efficacy and was recently found to be increased by inflammatory stimuli. This study was performed to characterize the secretion of GLP-1 in response to myocardial infarction in mice and men and investigate its functional relevance.
Materials and Methods: GLP-1 plasma levels were assessed in 143 patients following myocardial infarction and 15 controls. Myocardial infarction (MI) was induced by permanent LAD ligation in 6 week old, male C57BL/6J mice, the dipeptidylpeptidase-4 (DPP-4) inhibitor linagliptin (3 mg/kg p.o., bid) was given for 3 days before to LAD ligation, GLP-1 and exendin-9 (both 100 nM/kg i.p.) were given for 1 day before LAD ligation, experiments were performed in wild type and GLP-1 Receptor KO mice.
Results: GLP-1 plasma levels were elevated in patients at days 1-3 after myocardial infarction, but not thereafter. Induction of Myocardial infarction in mice led to a significant increase of circulating GLP-1 concentrations (from 7.9 pM to a maximum of 20.8 pM after 6 hours; n = 6; p < 0.05 in comparison to baseline and sham control). Prevention of GLP-1 degradation by pretreatment with linagliptin increased left ventricular contractility (10101 ± 1690 dp/dt by Millar catheter) relative to control (7830 ± 1445 dp/dt; p < 0.05 n = 8) 6h post MI, while antagonism of the GLP-1 receptor (exendin-9; 100 nM/kg i.p., 1 day pretreatment) worsened contractility (6469 ± 944 dp/dt; p < 0.05 n = 7). Further, linagliptin failed to improve left ventricular function in GLP-1 receptor KO mice demonstrating a GLP-1 receptor-dependent effect. Mechanistically we found linagliptin or GLP-1 pretreatment to similarly increase myocardial AMPK-activation in non-infarcted tissue (1.6 fold induction by linagliptin; p < 0.01 n = 6; 1.5 fold induction by GLP-1; p < 0.04 n = 4;), which was associated with improved respiratory capacity of isolated mitochondria from non-infarcted myocardial tissue (2 fold induction by GLP-1; p < 0.04 n = 6; 1.7 fold induction by DPP-4 inhibition; p < 0.04 n = 7) detected by Clark electrode.
Conclusion: Myocardial infarction is a GLP-1 secreting stimulus, which improves left ventricular function in a GLP-1 receptor dependent manner. This is amplified by linagliptin dependent DPP-4 inhibition leading to AMPK-activation and improved mitochondrial respiration of cardiomyocytes in non-infarcted tissue.

Background: Predicting heart failure (HF) development after acute myocardial infarction (AMI) would allow tailoring healthcare to each individual. Yet, this task is still challenging due notably to limited accuracy of current biomarkers such as brain natriuretic peptides (BNP) in this setting. In our search of novel biomarkers, we previously identified a circular RNA named MICRA (Myocardial Infarction-associated Circular RnA) which was associated with HF after AMI.
Purpose: Here, we addressed the ability of MICRA to risk stratify AMI patients according to the 3-group classification of HF defined by the ESC: HF with reduced ejection fraction (HFrEF, EF < 40%), mid-range EF (HFmrEF, EF 40-49%) and preserved EF (HFpEF, EF > 50%). In addition, we addressed the function of MICRA in lymphocytes.

Methods: MICRA expression was measured by quantitative PCR using divergent primers in whole blood samples obtained at reperfusion in 472 AMI patients. Left ventricular EF was determined at 4 months using echocardiography. Multivariable analyses with ordinal regression were conducted to determine the ability of MICRA to classify patients into 3 EF groups.
Results: Eighty seven patients (18%) had HFrEF, 106 (22%) had HFmrEF and 279 (59%) had HFpEF at 4 months. Expression levels of MICRA were lower in patients with HFrEF compared to patients with HFmrEF and HFpEF ($p < 0.001$), and were comparable between patients with HFmrEF and HFpEF. MICRA classified patients into 3 EF groups with an adjusted odds ratio [95% confidence interval] of 0.78 [0.64-0.95]. Patients with low levels of MICRA were at high risk of reduced EF. Computation of the Akaike Information Criteria and bootstrap internal validation attested that MICRA improved the predictive value of a multivariable clinical model including BNP ($p = 0.012$). In AMI patients, MICRA was positively associated with lymphocytes count ($p < 0.0001$) and T cell markers CD4 and CD8. In vitro experiments in Jurkat T cells showed an overexpression of MICRA upon stimulation by anti-CD3/CD28 ($p = 0.003$), which was accompanied by a blunting of cell proliferation. These results suggest a potential implication of MICRA in T-cell proliferation/activation/differentiation.
Conclusion: These results confirm and strengthen the ability of MICRA to predict HF and improve risk stratification after AMI. MICRA is expressed by T lymphocytes and may find utility in future prognostication strategies aiming to personalize healthcare of AMI patients (Figure).

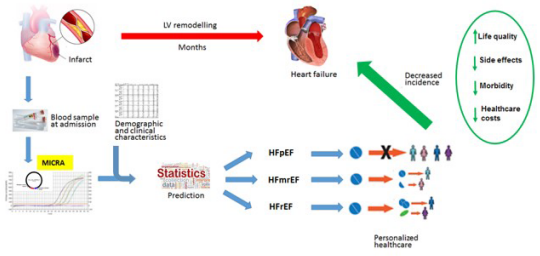

Figure: MICRA is a novel prognostic biomarker for personalized healthcare of acute myocardial infarction patients.

Background: In recent years, long non-coding RNAs (lncRNAs) have emerged as a new type of non-coding RNAs with potential as biomarkers in various cardiovascular pathologies. In contrast to other non-coding RNAs such as microRNAs, lncRNAs lack strong sequence conservation across species but can be highly tissue-specific. Cardiovascular disorders such as coronary artery disease, acute myocardial infarction (AMI) and heart failure (HF) are leading causes of mortality and morbidity in the modern World. A consensus emerged that more personalized healthcare would allow stopping the "epidemic" raise of the burden of cardiovascular disease, especially HF. However, to move forward towards personalized healthcare, novel biomarkers reflecting cardiac function and able to aid in diagnosis, prognosis, monitoring of drug effects and disease activity, are needed.
Purpose: In the present study, we aimed to identify cardiac-enriched lncRNAs associated with HF which can be used as biomarkers.
Methods: We performed deep sequencing in 26 cardiac biopsies from failing (11 end-stage ischemic cardiomyopathy and 10 end-stage non-ischemic cardiomyopathy) and non-failing (n = 5) human hearts.
Results: An average of 211 M reads of total-RNA-Seq librairies were generated. From these data, we identified a panel of 3353 lncRNAs that were either cardiac-enriched or differentially expressed between failing and non-failing hearts, including 1036 novel lncRNAs (i.e. not described in GENCODE database). To test their potential as biomarkers, we performed RNA-Sequencing in whole blood collected in PAXgene tubes in 57 AMI patients and in plasma samples collected from AMI patients and control subjects. We found that out of the 3353 lncRNAs identified in cardiac biopsies, 2171 were detectable in whole blood samples and 2669 in plasma samples. Moreover, cardiac lncRNAs were up-regulated in patients with AMI compared to controls. Interestingly, we identified 150 lncRNAs differentially expressed between patients developing HF 1 month after AMI compared to patients not developing HF.
Conclusion: These results motivate the development of a molecular diagnostic kit for the measurement of cardiac enriched lncRNA based on capture probes technology for a for high throughput targeted sequencing approach that can be applied on large cohort of patients to assess cardiac lncRNAs.

P613
Cyclin dependent kinase inhibitor 1 C is a female-specific marker of left ventricular function after acute myocardial infarction

T Lalem[1]; L Zhang[1]; M Scholz[2]; R Burkhardt[3]; V Saccheti[1]; A Teren[4]; J Thiery[3]; Y Devaux[1]

Background: A significant proportion of patients develop left ventricular (LV) remodelling leading to heart failure after acute myocardial infarction (AMI). Being able to identify these patients would represent a step forward towards personalized medicine. Since men and women with AMI have different clinical profiles, risk factors, pathophysiology and outcome, it is important to find ways to risk stratify patients in a gender-specific manner.
Purpose: To determine the ability of cyclin dependent kinase inhibitor 1C (CDKN1C) to risk stratify AMI patients, in a gender-specific manner.
Methods - CDKN1C expression was measured in blood samples obtained at admission in a test cohort of 447 AMI patients and a validation cohort of 294 patients. The study end-point was LV function assessed by the ejection fraction (EF) at 4-month follow-up. Patients were either classified as having a reduced EF (rEF, < 40%), mid-range EF (mrEF, 40-49%) or preserved EF (pEF, > = 50%).
Results - In the test cohort, CDKN1C was lower in rEF patients compared to mrEF and pEF patients. This observation was specific to women (Figure 1). Furthermore, CDKN1C was a significant univariate predictor of LV function only in women with an odds ratio (OR) [95% confidence interval (CI)] of 0.56 [0.37-0.83]. In multivariable analyses adjusted for [age, body mass index, white blood cells count, CPK, cTnT, Nt-proBNP, ischemic time (i.e. delay between chest pain onset and reperfusion), gender, history of AMI, diabetes, hypertension, hypercholesterolemia, smoking and infarct type (STEMI vs NSTEMI)], CDKN1C was a strong predictor of LV function in women (OR [95% CI] 0.44 [0.23-0.82]) but not in men (0.90 [0.70-1.16]). On the opposite, Nt-proBNP was associated with LV function in men (1.85 [1.37-2.47]) but not in women (1.06 [0.55-2.0]). CDKN1C increased the predictive value of the clinical model as attested by a decrease of the Akaike information criterion (AIC). This effect was present in women ($p = 0.006$) but not in men ($p = 0.41$). Of note, contrarily to the area under the curve, the AIC is penalized by the number of covariates, thus avoiding model overfitting. A decreased AIC indicates an improvement of prediction. The incremental predictive value of CDKN1C specifically in women was confirmed using bootstrap internal validation. The female-specific association of CDKN1C with LV function after AMI was validated in the independent cohort: OR [95% CI] 0.18 [0.04-0.90] in women and 0.67 [0.29-1.58] in men.
Conclusion: CDKN1C is a novel female-specific biomarker of LV function after AMI. If replicated in additional patient cohorts, this finding may help personalizing healthcare of AMI patients, in a gender-specific manner.

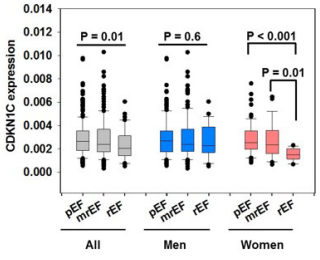

Figure 1. Expression of CDKN1C in the three EF groups, in all patients of the test cohort (n=447) and in men (n=338) and women (n=109) separately.

Funding Acknowledgements: GINOP-2.3.2-15-2016-00043

Background: The cardiac myosin activator omecamtiv mecarbil (OM) improves the contractility of the failing heart via increased number of acto-myosin interactions and prolonged systole. These promising cardiotonic effects of OM have been reported in preclinical and phase I/II clinical investigations. However, there is limited preclinical information on OM.
Purpose: Here we investigated the alternative cardiac mechanisms of action of OM beyond positive inotropy.
Methods: In vivo effects of OM were studied on Wistar-Kyoto rats by left ventricular (LV) hemodynamic analysis (n = 10), echocardiography (n = 10) and blood pressure measurement by carotid artery catheterization (n = 10). OM was administered through a jugular venous canule in increasing doses from baseline (BASE) up to 200, 600 and 1200 μg/kg cumulative doses. In vitro effects of 0.1 and 1 μM OM were tested on isolated LV myocytes. Action potential characteristics, calcium transients and unloaded cell shortening were studied on isolated canine (n = 9), and force generation was studied on human donor (n = 9) cells.
Results: LV systolic function was improved upon treatment with OM (ejection fraction, %: BASE: 70 ± 2; 200 μg/kg: 72 ± 4; 600 μg/kg: 78 ± 5; 1200 μg/kg: 82 ± 8; and dP/dtmax, mmHg/s: BASE: 9102 ± 597; 200 μg/kg: 9633 ± 533; 600 μg/kg: 10683 ± 594; 1200 μg/kg: 11055 ± 437). At the same time, we found dose-dependent deleterious effects of OM on diastolic function: decrease of E/A ratio (BASE: 2.0 ± 0.1; 200 μg/kg: 1.7 ± 0.1; 600 μg/kg: 1.4 ± 0.1; 1200 μg/kg: non measurable) and dP/dtmin (mmHg/s: BASE: -11622 ± 607; 200 μg/kg: -10548 ± 710; 600 μg/kg: -10704 ± 810; 1200 μg/kg: -9751 ± 679), and increase of isovolumetric relaxation time (ms: BASE: 22.3 ± 1.3; 200 μg/kg: 31.7 ± 2.3; 600 μg/kg: 35.1 ± 1.8; 1200 μg/kg: 50.7 ± 4.2) and tau (ms: BASE: 9.2 ± 0.4; 200 μg/kg: 10.4 ± 0.5; 600 μg/kg: 12.6 ± 0.1; 1200 μg/kg: 15.4 ± 0.7). These results are in accordance with the dose-dependent effects of OM on skinned myocytes enhancing not only Ca2+-dependent active force, but Ca2+ sensitivity (pCa50) and Ca2+-independent passive force of the contractile machinery. In vivo at 1200 μg/kg OM evoked an electromechanical dissociation in 76.6% of cases (n = 23 of total 30): with continuous ECG every effective contraction was followed by an ineffective one. In line with this phenomenon, at the myocyte level, we found alternating action potential, calcium transient and cell shortening upon administration of 1 μM OM at high pacing frequencies (4 and 5 Hz). Finally, the above mentioned cardiac alterations at high (1200 μg/kg) dose led to a significant decrease of blood pressure (vs. BASE: systolic: -59 ± 9%; diastolic: -63 ± 11%).
Conclusion: OM improves LV systolic function, but induces diastolic dysfunction even at low doses in the rat. In addition, OM can evoke periodical electromechanical dissociation beyond myosin sensitization.

P615

Predicting mortality in patients with ECMO: is the SAVE score applicable in our population?

N Nahikari Salterain Gonzalez[1]; R Manrique Anton[2]; J Ibero Valencia[1]; E Iglesias Colino[1]; JJ Gavira Gomez[1]; G Rabago Juan-Aracil[2]

[1]University of Navarra, Cardiololgy, Pamplona, Spain; *[2]University of Navarra, Cardiac Surgery, Pamplona, Spain*

Introduction and Objectives.
The newly created SAVE score has overcome previous scores in predicting survival after an urgent veno-arterial extracorporeal membrane oxygenator implantation (vaECMO).
The objective of our study was to assess the applicability of this new tool in our population.
Material and Methods.
All patients in cardiogenic shock who underwent a vaECMO implantation in our center between January 2007 and December 2017 were included. The SAVE score was calculated retrospectively for each patient. Data were collected from the hospital ventricular assist devices database.
We evaluated: 1) the total mortality of the group, 2) the classification and mortality of our series according to the SAVE score and 3) the utility of this score in our population.
Results: Thirty-two patients were included, 56% being above 63 years old. The most frequent cardiomyopathy was ischemic heart disease (47%) and the indication for ECMO implantation in 69% of them "bridge to transplant", qualified as "other" in the SAVE diagnosis variable. 56% had acute kidney injury prior to implantation and 44% liver dysfunction. In 91% of the cases, peripheral access was preferred. The Levitronix Centrimag was the most frequently used device. The majority of patients were included in the higher risk group of the score.
The in-hospital mortality was 53% (16 patients with the device in situ and one weeks after explantiation). The distribution of patients for each group of the classification and mortality is shown in Table 1.
Conclusions.
Our results are comparable to those published in international registries. Even though the profile of our patients may be different from those included in the score, both the distribution of patients per group and the mortality resembles the SAVE score. The use of this score is feasible in our setting but further experience may be needed.

Table 1. Mortality.

SAVE score	CUN		
Classification	Mortality (%)	N	Mortality n (%)
I	25	0	0
II	42	5	0
III	58	5	2(40)
IV	70	12	6 (50)
V	82	10	9 (90)

Coronary Artery Disease - Pathophysiology and Mechanisms

Measuring coronary artery calcium with high-pitch computed tomography acquisition: is it as consistent as prospective acquisition

L-L Lan-Linh Truong[1]; F Erthal[1]; O Clarkin[1]; A Hossain[2]; Y Yam[1]; J Inacio[3]; BJW Chow[1]

[1]University of Ottawa Heart Institute, Cardiac Imaging, Ottawa, Canada; *[2]University of Ottawa Heart Institute, Cardiovascular Research Methods Centre, Ottawa, Canada*; *[3]The Ottawa Hospital, Radiology, Ottawa, Canada*

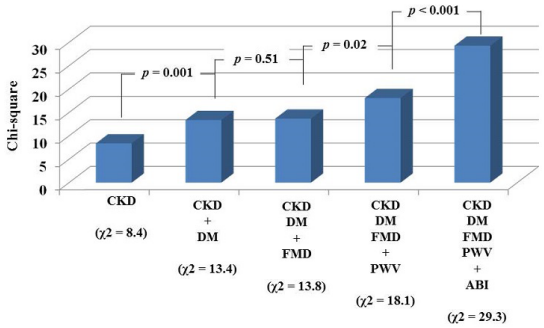
Background and Purpose: The detection of coronary artery calcification (CAC) with computed tomography (CT) is a reliable method for detecting coronary atherosclerosis. Traditional prospective ECG-triggered CAC image acquisition exposes patients to radiation doses of approximately 1-2mSv. A new technique using high-pitch ECG-triggered acquisition reduces radiation doses to approximately 0.3mSv. However, it has the detriment of increasing image noise, which may impact the reliability of CAC measurements. The purpose of this study is to understand the inter-observer variability associated with prospective and high-pitch acquisition protocols and the effect of patient habitus on CAC measurements.
Methods: 9741 patients undergoing CAC imaging a between 2006 and 2016 were screened. Readers measured CAC of these patients using the Agatston method. Readers were blinded to each other's CAC measures. Inter-observer agreement was assessed using linear-regression model and Bland-Altman plot. Inter-observer variability across different BMI groups was assessed by percentage difference.
Results: Inter-observer correlation was excellent (r = 0.999) and agreement was very good for both prospective and high-pitch acquisition methods (r = 0.999 and 0.998 respectively). Variability in CAC measurements was directly related to patient size. This finding was true for both prospective ECG-triggered and high-pitch acquisition models. The variability between readers was less in the high-pitch population.
Conclusion: Inter-observer variability of CAC measurements increased with patient body habitus. Prospective ECG-triggered acquisition, despite having a higher radiation dose, yielded the highest variability.

P617

Severity and complexity of coronary artery disease assesssed by comparison of multimodality evaluation of atherosclerosis : Pulse wave velocity ,flow-mediated dilation and ankle-brachial index

Y Y Yun Young Choi[1]; JS Woo[1]; HO Kim[1]; HM Chung[1]; JM Lee[1]; SJ Kim[1]; WS Kim[1]; KS Kim[1]; W Kim[1]; JB Kim[1]
[1]*Kyunghee University, cardiology, Seoul, Korea Republic of*

Background: Flow-mediated dilation (FMD), Ankle-brachial index (ABI) and Pulse wave velocity (PWV) have been used as noninvasive modalities for evaluating atherosclerosis. This study was revealed that which non-invasive atherosclerosis tests could predict complexity and severity of coronary artery disease (CAD).
Methods: From January 2010 to November 2013, 1,630 stable angina patients who performed non-invasive arthrosclerosis evaluation (FMD, ABI, PWV) with diagnostic Coronary angiography (CAG) were enrolled in this study. The primary end point was differences of non-invasive tests according to CAD severity (number of diseased vessel) and complexity (syntax score).



Incremental prediction of CAD complexity

Results: Patients with high syntax score (= 23) showed significantly low values of FMD and ABI and high PWV. CAD extent was significantly associated with ABI ($p < 0.001$). However, there was no significant correlation of CAD extent and FMD ($p = 0.17$), PWV ($p = 0.06$). Non-invasive tests showed incremental predictive values of CAD complexity (Figure) Conclusion: Different non-invasive tests could be useful to predict CAD severity and complexity in a complementary manner regardless of its purpose in patients with stable angina.

Psychological stress aggravates the vulnerability of atherosclerotic plaques in ApoE knockout mice via SDF-1 /CXCR4 signalling

Z-Y Huang[1]; C-L Peng[2]; Y-Y Liu[3]; X-B Wang[4]; M-P Huang[3]; L Lu[1]; D-H Liang[2]
[1]*The First Affiliated Hospital, Guangzhou University of Chinese Medicine, Guangzhou, China People's Republic of*; [2]*School of Traditional Chinese Medicine, Southern Medical University, Guangzhou, China People's Republic of*; [3]*Department of Traditional Chinese Medicine, Zhujiang Hospital, Southern Medical University, Guangzhou, China People's Republic of*; [4]*Department of Cardiology, Zhujiang Hospital, Guangzhou, China People's Republic of*

On behalf of: Psychosomatic treatment of cardiovascular disease

Background: Psychological stress has been recognized as a key risk factor for acute coronary syndrome (ACS). However, little information is available on the mechanism underlying psychological stress-induced vulnerable plaque formation. Here, we report the aggravation of vulnerable plaques via the SDF-1/CXCR4 biological axis imbalance, which is caused by psychological stress.
Purpose: Our purpose is to provide new insights for early psychological prevention and treatment of ACS.
Methods: The mice were subjected to chronic unpredictable mild stress (CUMS) or administered with AMD3100 (2.5mg/kg/day, i.p.) together for 12 weeks. Animals were evaluated for behavioral changes, such as anxiety-related behaviour by high plus maze, behavioral despair by forced swim test, and exploratory behaviors by an open field test. CRP mRNA in liver, along with lipid metabolism, NEUT%, norepinephrine (NE), IL-6, SDF-1/CXCR4 indexes in serum were investigated. The changes of atherosclerosis plaque in the aortic arch and the aorta were observed by oil red O staining and HE dying. Moreover, the expression of SDF-1 and CXCR4 in aorta was examined by immunofluorescence assay and western blotting assay.
Results: Our results showed that CUMS not only significantly increased the levels of plasma lipid, NEUT%, norepinephrine (NE), IL-6 and reduced SDF-1/CXCR4 indexes, but also accelerated depressive-and anxiety-like behaviors and vulnerable plaque formation in mice. The immunofluorescence assay results showed that SDF and CXCR4 were significantly down-regulated in the aortic arch of the stressed mice. The protein levels of SDF-1 and CXCR4 in the platelets, aorta were decreased under CUMS intervention. AMD3100 significantly aggravated the CUMS-induced changes in CUMS mice.
Conclusions: Psychological stress is a crucial factor that causes SDF-1/CXCR4 biological axis dysfunction and growing vulnerable plaque.

P619

Heart failure after acute coronary syndrome: demographic and clinical predictors.

I Ines Almeida[1]; H Miranda[1]; J Chin[1]; C Sousa[1]; S Almeida[1]; D Mesquita[1]
[1]*C.H.Barreiro-Montijo , Lisboa, Portugal*

Introduction: Heart failure (HF) is an important complication that can derive from the acute coronary syndrome (ACS), however its prevalence has been decreasing when associated with the implementation of new therapeutics.
Objective: Evaluation of predictor factors of HF in patients (P) with ACS.
Materials and Methods: Retrospective analysis of the P data admitted with ACS included in multicentric register between 2012-2017. Comparison of the implemented double antiaggregation strategy (CLOPI versus TICA) and evaluation of the endpoint HF.
Results: 10135 P with ACS were admitted, of which 15.9% developed HF during the internment. The average age was of 73 +/- 12 years, 64.4% of the P were the masculine genus. The comorbidities more prevalent were arterial hypertension (76.4%) and dyslipidemia (59.7%). 2.1% of the admitted P already had a previous diagnosis of HF. In comparison with the P that did not develop HF, the average value of the brain natriuretic peptic was superior to (844 +/- 840 vs 302 +/- 556 pg/ml, $p < 0.001$) and presented an ejection fraction inferior to (43+/-12 vs 53 +/- 11%, $p < 0.001$). 17% were medicated with CLOPI and 9.7% with TICA ($p < 0.001$). The patients treated with CLOPI presented HF with greater frequency during the internment (85.6% vs 91.9%, $p < 0.001$, OR 1.90) than those medicated with TICA (14.4% vs 8.1%, $p < 0.001$, OR 0.53). The therapeutic with TICA is associated with a lower probability of developing HF in respect to CLOPI (p 0.002, OR 0.71). Other associated factors to HF were antecedents of valvular disease, peripheral arterial disease, renal disease, the presentation in dyspnea or cardiac arrest; the presence of tachycardia or hypotension; the persistent elevation of the ST segment in the electrocardiogram; and the previous utilization of diuretic pharmacies.
Conclusion: The presence of systemic arterial vascular disease, ACS with atypical presentation and the presence of clinical and electrocardiographic markers of seriousness and therapeutic with clopidogrel, when compared with ticagrelor, looks to be predicting factors of development of HF during the internment.

P620

Prognostic impact of the antiaggregation strategy implemented in acute coronary syndrome

I Almeida[1]; H Miranda[1]; J Chin[1]; C Sousa[1]; D Mesquita[1]; S Almeida[1]
[1]*C.H.Barreiro-Montijo , Lisboa, Portugal*

Introduction: The patients (P) with acute coronary syndrome (ACS) must go through double antiaggregation therapeutic with acetylsalicylic acid (ASA) and an inhibitor PY12 (IPY12). According to the recommendations of the European Society of Cardiology of 2017, the preferable IPY12 are the ticagrelor (TICA) and the prasugrel, being the clopidogrel (CLOPI) recommended if unavailable or counter indication for the first.
Objective: Prognostic impact evaluation of the second antiaggregate pharmacies choice - CLOPI versus (vs) TICA - in the P with ACS.
Materials and Methods: Retrospective analysis of the P data admitted with ACS included in multicentric register between 2012-17. Compared intra - hospitable morbimortality and multivaried analysis accomplished for the second antiaggregate choice impact evaluation.
Results: 10157 P were admitted, having been administrated CLOPI in 75.7% of them. The P medicated with CLOPI were older (66 +/- 13 vs 62 + / - 12 years, $p < 0.001$), with predominance of the masculine genus and with more previous coronary disease. During the internment, the P under CLOPI were more medicated with antagonists of vitamin K (2.4 vs 0.6%, $p < 0.001$), however the prescription of ASA at the discharge date was inferior (94.1 vs 97.6%, $p < 0.001$). The P under TICA were more frequently submitted to reperfusion (91.4 vs 85.6%, $p < 0,001$), the majority percutaneous angioplasty (98.7 vs 93.3%, $p < 0.001$) being overlapping in

the two groups the prevalence of multivessel disease and the involvement of the left main or anterior descendant artery. Of the evaluated endpoints, the P medicated with CLOPI presented a greater ratio of heart failure (HF) (17 vs 9.7%, $p < 0.001$) and atrial fibrilation (AF) (5.5 vs 3.2%, $p < 0.001$). The major hemorrhage ratio was inferior in the patient group medicated with CLOPI (1.4 vs 1.6%, p 0.047) however the intra-hospitable mortality was superior (3.2 vs 1.5%, $p < 0,001$).

Conclusion: The P medicated with CLOPI were older and with more prevalence of important comorbidities. The utilization of TICA was associated to a greater ratio of hemorrhagic events major but a minor occurrence of complications, namely HF and AF, and intra - hospitals mortality. This data shows the real life the impact of the new IPY12 in the patients with ACS.

Cardiotoxicity versus Diastolic Dysfunction: Distinct Features in Biopsy-Proven AL and ATTR Cardiac Amyloidosis

F Felix Escher[1]; S Schneiderbauer-Porod[2]; J Doerler[1]; M Zaruba[1]; C Ensinger[3]; C Ebner[2]; G Poelzl[1]

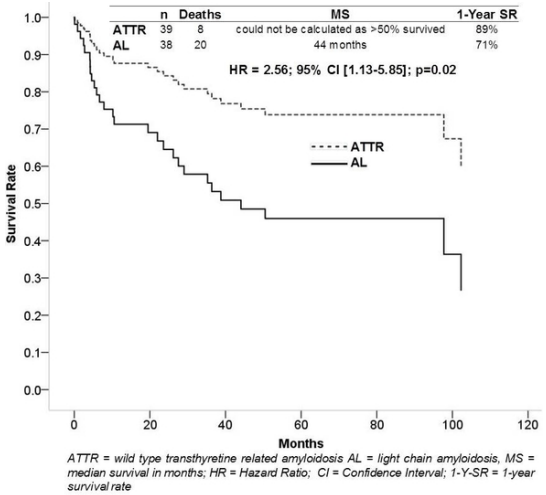
[1]Innsbruck Medical University, Department of Cardiology and Angiology, Innsbruck, Austria; *[2]Elisabethinen University Teaching Hospital, Department of Cardiology, Linz, Austria*; *[3]Innsbruck Medical University, Institute of Pathology, Innsbruck, Austria*

Introduction: Amyloidosis is a severe, systemic disease associated with poor survival. Prognosis depends primarily on cardiac involvement and the underlying amyloid subtype. Cardiac light-chain amyloidosis (AL) is associated with worse survival compared to transthyretine-related amyloidosis (ATTR). However, reasons for this difference in prognosis are still poorly understood.
Purpose: It was the aim of our study to retrospectively compare survival between patients with cardiac AL and ATTR amyloidosis and to evaluate subtype-specific characteristics that might explain differences in survival between groups.
Methods: 77 patients with biopsy-proven amyloidosis (AL: n = 38, ATTR: n = 39) diagnosed and managed in two medical centres between 03/2001 - 12/2017 were analysed. Data were obtained from health records, phone calls and public death registers. The endpoint was defined as death from any cause. Univariate cox regression analysis was used to compare survival and T-Tests and Fisher's Exact tests were used to evaluate mean values and frequencies.
Results: AL patients had a significant worse overall survival compared to ATTR patients (HR= 2.56 [95%CI = 1.13-5.85]; p = 0.02, 1-year survival-rate 71% vs. 89%, median survival time 44 months in the AL group vs. median survival could not be calculated for the ATTR group as more than 50% survived). LV-EF was still preserved and not different between groups (p = 0.34). Characteristics of diastolic dysfunction such as LV posterior wall thickness (p <0.001), LV mass (p <0.001), and percentage of patients with atrial fibrillation (p = 0.001) were significantly higher in ATTR compared to AL patients. In contrast, troponin T as a marker for cardiotoxicity from amyloid deposition was significantly higher in AL patients (p = 0.02).
Conclusions: Survival is worse in individuals with AL amyloidosis despite less cardiac amyloid deposits compared to individuals with ATTR amyloidosis. Differences in prognosis may be explained by cardiac toxicity from light chain deposition in AL rather than diastolic dysfunction in ATTR. However, extensive extra-cardiac involvement and severe infectious complications may add to higher mortality in AL and need further investigation.

Cardiac Characteristics

Variables	AL Amyloidosis (n = 38)	ATTR Amyloidosis(n = 39)	P Value
cTnT (µg/L) (mean ± SD)	0.091 ± 0.02	0.051 ± 0.03	0.02
LV Mass (g) (mean ± SD)	246.9 ± 14.8	334.1 ± 18.1	<0.001
PWD (mm) (mean ± SD)	14.7 ± 2.31	17.1 ± 2.95	<0.001
LV EF (%) (mean ± SD)	51.7% ± 12.6	49.1% ± 10.5	0.34
AF (n) (%)	5 (13.2%)	20 (51.3%)	0.001

cTnT = cardiac Troponin T, PWD = Posterior Wall Thickness; AF = Atrial Fibrillation



ATTR = wild type transthyretine related amyloidosis AL = light chain amyloidosis, MS = median survival in months; HR = Hazard Ratio; CI = Confidence Interval; 1-Y-SR = 1-year survival rate

Funding Acknowledgements: The conduct of this study was in part supported by a grant from the Austrian Science Funds (FWF SFB 54-P04).

Background: The implantation of continuous - flow ventricular assist devices (VAD) is suggested to evoke angiodysplasia contributing to adverse events like gastrointestinal bleeding.
Purpose: To investigate possible systemic microvascular changes we evaluated in vivo capillary density and glycocalyx dimensions in patients with chronic heart failure and VAD support vs. standard treatment.
Methods: Forty- two patients with VAD support were compared to fifty- three patients with ischemic and non-ischemic CHF and standard pharmacotherapy in a prospective cross- sectional study. Sublingual microcirculation was visualized using a Sidestream Darkfield videomicroscope and functional and perfused total capillary densities quantified. A reduced glycocalyx thickness was measured by an increased perfused boundary region (PBR).
Results: Mean time after VAD implantation was 20.9 ± 16.6 months; patients were treated with centrifugal-flow devices (n = 31) and axial-flow devices (n = 11). Median functional capillary density was markedly lower in patients with VAD therapy (196 vs. 245/mm2, p = 0.024); in addition total perfused capillary density was also rarefied, though not significant (19% difference). Glycocalyx dimensions were similar in both groups.

Conclusion: Improvement of hemodynamic conditions in patients with continuous-flow VAD treatment leads to an alteration of shear forces, which might contribute to capillary density rarefaction.

Chronic Heart Failure - Diagnostic Methods

P566

Klotho is induced in human cardiomyopathy independently of circulating klotho levels

S K Santhosh Kumar Ghadge[1]; G Poelzl[1]; M Messner[1]; B Haubner[1]; P Wuertinger[2]; A Griesmacher[2]; J Doerler[1]; C Ensinger[3]; H Ulmer[4]; MM Zaruba[1]
[1]Innsbruck Medical University, Department of Internal Medicine III, Innsbruck, Austria; *[2]Innsbruck University Hospital, Central Institute for Medical and Chemical laboratory Diagnosis, Innsbruck, Austria*; *[3]Innsbruck Medical University, Department of Pathology, Innsbruck, Austria*; *[4]Innsbruck Medical University, Department of Medical Statistics, Informatics and Health Economics, Innsbruck, Austria*

Funding Acknowledgements: The study was sponsored in part by Tirol Kliniken Ltd.

Introduction: Klotho is an antiaging protein which exerts cardioprotection. In the kidney, trans-membrane Klotho acts as essential co-receptor of fibroblast growth factor 23 (FGF23) which has been linked to the cardiac remodeling, advent and progression of chronic heart failure (CHF). In the heart, soluble Klotho (sKlotho) protects from stress induced hypertrophy and systolic dysfunction independently of FGF23. Since the role of sKlotho in CHF is barely understood, we aimed to analyze the association of FGF23 and sKlotho upon progression of heart failure and analyzed Klotho expression in human non-ischemic cardiomyopathy (CMP).
Methods and Results: Serum levels of sKlotho and FGF23 were measured in 287 patients with CMP. Tissue samples from CMP (n = 10) and non-failing control hearts (n = 10) were analyzed for Klotho expression using 3'RACE-PCR, qRT-PCR, immunoblotting, and immunohistochemistry. In tertile-based sex-stratified analysis, individuals in the third FGF23 tertile were 4.1 times (95%CI 1.42-12.38; p = 0.009) more likely to reach an endpoint of death, heart transplantation or assist device implantation compared to first tertile. No relationship was found between sKlotho and the combined endpoint (hazard ratio 0.76 [0.45-1.2]; p = 0.299). Instead, Klotho mRNA encoding the full-length form was upregulated in human DCM hearts. Immunoblotting and immunohistochemistry confirmed upregulation of sKlotho associated with increased expression of proteases involved in cleavage of Klotho like ADAM10, ADAM17, and BACE1 in DCM hearts suggesting local cleavage of Klotho in the heart.
Conclusions: Our data indicate that in contrast to FGF23, serum sKlotho is not associated with disease severity or progression in CHF. Instead, Klotho is expressed and upregulated in diseased hearts, suggesting local cardioprotective paracrine effects.

P567

Neprilysin (CD10) expression on peripheral leukocytes in chronic heart failure patients

J Johannes Novak[1]; H Arfsten[1]; A Cho[1]; G Goliasch[1]; PE Bartko[2]; G Strunk[3]; M Huelsmann[1]; N Pavo[1]
[1]Medical University of Vienna, AKH - Vienna, Cardiology Clinic, Cardiology, Vienna, Austria; *[2]Medical University of Vienna, Vienna, Austria*; *[3]Research Institute for Complex Systems - Complexity-Research, Vienna, Austria*

Background: Neprilysin inhibition (NEPi) has been shown to reduce hospitalization and all-cause mortality in patients with heart failure and reduced ejection fraction (HFrEF). Since then circulating NEP concentration (sNEP) has been discussed controversially as a biomarker. Neprilysin (CD10) is known to be present on the surface of monocytes and lymphocytes as well as at higher levels on neutrophils in healthy subjects and implicated in the inflammatory response. The possible impact of NEP expression on peripheral leukocytes on sNEP levels and prognostic measures in HFrEF have not been investigated yet.
Methods: We prospectively enrolled 99 consecutive patients with stable HFrEF, who were clinically followed-up routinely. Laboratory markers including NT-proBNP were assessed. sNEP and NEP (CD10) expression on peripheral blood cells were measured by FACS analysis for all patients. The association between NEP expression and laboratory parameters as well as with sNEP levels were determined.
Results: Figure1 shows characteristic FACS expression results for patients with HFrEF with high and low expression intensities of CD10. NEP was markedly expressed on granulocytes with 94.8% (IQR 90.5-97.4) and measureable on B-cells and monocytes with 8.5% (IQR 5.3-13.5) and 0.8% (IQR 0.4-1.5) of CD10+ cells of the respective leukocyte subtype. NEP expression on T-cells was not detectable. The mean fluorescence intensity (MFI) of CD10 was 5461 (IQR 4028-6904) for granulocytes, 640 (IQR 535-740) for B-cells and 1589 (IQR 1395-1975) for monocytes. An inverse correlation of NT-proBNP could be proven with the MFI of CD10+granulocytes (r=-0.46, p < 0.001) but not with the MFI of CD10+B-cells (r=-0.13, p = 0.191) or CD10+monocytes (r = 0.07, p = 0.477). Figure2 depicts differences in MFI for CD10+granulocytes according to tertiles of selected variables, i.e. NT-proBNP, albumin, hemoglobin and butyryl-cholinesterase. sNEP concentrations were 2425pg/ml (IQR 1559-3349). sNEP concentrations correlated positively with the expression of CD10 on granulocytes (r = 0.22, p = 0.030) and with the MFI of CD10+granulocytes (r = 0.306, p = 0.003).
Conclusions: CD10 expression levels on neutrophils might reflect a distinct systemic inflammatory disposition, with low expression levels accompanying a more severe disease state reflected by NT-proBNP. Granulocyte CD10 expression correlates to measurable sNEP levels.

Background: The circulating form of the membrane-bound zink-metalloendopeptidase neprilysin (cNEP) as a biomarker in heart failure has been discussed controversially in recent studies. However, evidence emerges that NEP is not only implicated in the homeostasis of vasoactive peptides, but also plays a key role in tumor biology. NEP could therefor represent another link between the heart and cancer which might be of special interest in the field of cardiooncology. Concentrations of cNEP have not yet been assessed in cancer patients.
Aim: The aim of the study was to determine cNEP levels in an unselected cohort of treatment-naïve cancer patients and to investigate the association of cNEP levels with biomarkers of the heart, other organ systems and inflammatory state as well as the effect of cNEP on prognosis.
Methods: 555 consecutive patients with primary diagnosis of cancer without prior anticancer therapy were enrolled prospectively. NEP levels were determined in venous plasma samples alongside routine laboratory parameters, a set of cardiac biomarkers, i.e. N-terminal pro-B-type natriuretic peptide (NT-proBNP), high-sensitive TroponinT (hsTnT), mid-regional pro-atrial natriuretic peptide (MR-proANP), mid-regional pro-adrenomedullin (MR-proADM), C-terminal pro-endothelin-1 (CT-proET1) or Copeptin, and inflammatory parameters, i.e. C-reactive protein (CRP), interleukin-6 (IL-6) and serum amyloid A (SAA). All-cause mortality was defined as primary endpoint.
Results: cNEP showed a wide distribution in the total cohort with a median of 276pg/ml (IQR 0-5981), displaying a weak correlation with age [r=-0.12, p = 0.023]. cNEP showed a modest but consequent inverse rank-correlation with the inflammatory status [r=-0.14, p = 0.007 for CRP; r=-0.20, p < 0.001 for IL-6 and r=-0.18, p < 0.001 for SAA], however seemed not to be related to the functional parameters of other organ systems as the heart [r=-0.05, p = 0.367 for NT-proBNP; r=-0.10, p = 0.075 for hsTnT; r=-0.03, r=-0.02, p = 0.664 for MR-proANP; r=-0.05, p = 0.387 for MR-proADM; r = 0.07, p = 0.168 for CT-proET1 and r=-0.01, p = 0.864 for Copeptin], kidney or liver. cNEP was not associated with overall survival in the total cohort [adj.HR for ln(cNEP) 1.00, 95%CI:0.94-1.06, p = 0.887], and neither in the subgoups of solid tumors nor myeloproliferative disease, but in myelodysplatic malignancies [adj.HR for ln(cNEP) 1.27, 95%CI:1.01-1.61, p = 0.044]. Figure 1 shows the Kaplan-Meier analysis according to cNEP tertiles.
Conclusions: cNEP shows a wide distribution in human plasma of cancer patients. cNEP levels are comparable between different tumor entities and stages and lack association with outcome but for myelodysplastic disease. Moreover, no association could be revealed between cNEP and other organ system, especially the heart, assessed by a set of established cardiac biomarkers.

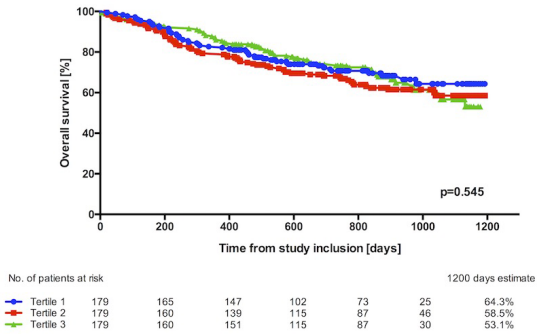

Figure 1

P569

Diagnostic accuracy of 99m-DPD SPECT scintigraphy in TTR-Amyloidosis

M Manuel Ebert[1]; F Escher[1]; J Doerler[1]; MM Zaruba[1]; C Ensinger[2]; C Uprimny[3]; AP Kroiss[3]; G Poelzl[1]
[1]Innsbruck Medical University, Department of Internal Medicine III, Cardiology and Angiology, Innsbruck, Austria; *[2]Innsbruck Medical University, Institute of Pathology, Innsbruck, Austria*; *[3]Innsbruck Medical University, Clinic for Nuclear Medicine, Innsbruck, Austria*

Introduction: Two-dimensional bone scintigraphy with 99m technetium 3,3-diphosphono-1,2-propanedicarboxylic acid (99mTc-DPD) is recommended to discriminate transthyretin amyloidosis (ATTR) from other forms of cardiac amyloidosis (CA), e.g. light chain amyloidosis (AL). Three-dimensional imaging with Single Photon Emission Computed Tomography (SPECT) may improve diagnostic accuracy in these patients. It was the aim of our study to evaluate the diagnostic accuracy of 99mTc-DPD SPECT scintigraphy in patients with CA using semi-quantitative (Perugini-Score) and quantitative measurements.
Materials and Methods: SPECT scintigraphy with 99m-DPD was performed in a total of 17 patients (m = 14 [82.4 %], f = 3 [17.6 %]). All patients underwent endomyocardial biopsy for histologic and immunohistochemical evaluation. Three groups were generated according to the final diagnosis: ATTR (n = 7), AL (n = 5), no CA (n = 5). Semi-quantitative assessment of SPECT scintigraphy was performed using the Perugini Grading System. Quantitative assessment was based on measuring intensity of tracer uptake in predefined areas of the left ventricle (LV) and right ventricle (RV). Finally, intensity of tracer uptake was correlated with serum troponin T values.
Results: Perugini-Score 0 was assigned to 10 patients (58.8 %), Perugini-Score 1 and 2 to no patient, and Perugini-Score 3 to seven patients (42.2 %) by a physician unaware of the final diagnosis. All patients with Perugini-Score 3 were finally diagnosed with ATTR by endomyocardial biopsy resulting in a positive predictive value (PPV) and negative predictive value (NPV) of 1, respectively. All patients with ATTR showed an increased tracer uptake in RV, although uptake was lower compared to LV (p = 0.001). Correlation of troponin T with intensity of tracer uptake was significant in RV (p = 0.02) and of borderline significance in LV (p = 0.073).
Conclusion: Our data indicate an exceptional high diagnostic accuracy for 99mTc-DPD SPECT scintigraphy in the diagnosis of ATTR. In addition, this technique allows for detection of amyloid deposition in the right ventricle that correlates well with troponin T levels. Further studies are needed to evaluate a possible association of RV tracer uptake with long-term prognosis in CA.

P570

Correlation of strain and strain-rate imaging and left ventricular function in ischemic and non-ischemic chronic heart failure patients

K Klemens Ablasser[1]; M Gangl[1]; E Kolesnik[1]; L Kattnig[1]; M Manninger[1]; D Scherr[1]; D Von Lewinski[1]; F Fruhwald[1]; N Verheyen[1]
[1]Medical University of Graz, Department of Cardiology, Graz, Austria

Background: Left ventricular ejection fraction (EF) is the standard method for assessing the left ventricular function in heart failure (HF) patients.

Speckle-tracking echocardiography allows to quantitative determine myocardial deformation by strain and strain-rate imaging.
Purpose: The purpose of this investigation was to analyse the relationship between global longitudinal strain (GLS), global strain rate (GSR) and ejection fraction (EF) in a prospective cohort of ischemic and non-ischemic CHF patients.
Methods: Heart failure patients with mid-range reduced EF (HFmrEF) or reduced EF(HFrEF) were enrolled in the study. They had to be in a stable disease condition, as defined by absence of unplanned hospitalization or change in medication or device therapy within the previous month or major surgery within the previous 3 months. Patients also had to be on ESC guideline conform medication. Patient history, physical examination and an extensive echocardiography exam were performed. Manual longitudinal strain was calculated using EchoPAC (General Electric Medical Systems, Horten, Norway) by a single and blinded examiner. LVEF was measured using Simpson's biplane method.
Results: Overall, 103 patients were enrolled, however 19 patients were excluded from this analysis due to inadequate echocardiography image quality. Participants were 76% male with a mean age 61.0 years. Mean EF was 35,7 % (SD +/- 9,5 %), mean GLS was -9.6 % (SD +/- 4.5 %) and mean GSR -6,67 (SD +/- 0,21). Aetiology was 70.0 % ischemic vs 30.0 % non-ischemic heart failure.

There was a significant correlation between GLS and EF (Pearson r = 0.620, p < 0.001) as well as GSR and RF (Pearson r = 0.595, p < 0.001). However in a multivariate regression analysis only GLS, but not GSR, remained significantly correlated with EF (adjusted beta-coefficient= 0.429, p = 0.043).

In the subset of patients with an ischemic cardiomyopathy both GLS (Pearson r = 0.716, p < 0.001) and GSR (Pearson r = 0.714, p < 0.001) remained highly correlated to EF. However, in patients with non-ischemic heart failure significant correlation could only be demonstrated between EF and GSR (Pearson r = 0.334, p = 0.003), but not EF and GLS (Pearson r = 0.338, p = 0.17).
Conclusion: In CHF results from speckle tracking echocardiography correlate highly with EF, which also held true for GLS in a multivariate regression analysis.

However, in a subset of patients with a non-ischemic aetiology of CHF GSR show a better correlation to EF. Therefore, different measurements of left ventricular function might be best suited for different aetiologies of heart failure.

P571

Correlation of global longitudinal strain and NT-proBNP in ischemic and non-ischemic chronic heart failure patients

M Gangl[1]; E Kolesnik[1]; L Kattnig[1]; V Habenicht[1]; M Manninger[1]; J Schmid[2]; D Scherr[1]; F Fruhwald[1]; D Von Lewinski[1]; N Verheyen[1]; K Klemens Ablasser[1]
[1]Medical University of Graz, Department of Cardiology, Graz, Austria; *[2]Medical University of Graz, Department of Radiology, Graz, Austria*

Background: In chronic heart failure (CHF) NT-proBNP and left ventricular ejection fraction (LVEF) by echocardiography are standard diagnostic as well as follow-up markers and are known to correlate with prognosis. Speckle-tracking echocardiography is a more recent technique to quantify myocardial deformation as a measurement of left ventricular function with potential benefits over LVEF.
Purpose: The purpose of this investigation was to analyse the cross-sectional relationship between 2D speckle tracking-derived global longitudinal strain (GLS) and NT-proBNP plasma levels in a prospective cohort of ischemic and non-ischemic CHF patients.
Methods: We enrolled 103 patients with chronic heart failure. Major inclusion criteria were age over 18 years, stable disease with absence of unplanned hospitalization or change in medication or device therapy in the previous month or major surgery in the previous 3 months. CHF treatment had to be according to the recommendations of the ESC CHF guidelines 2016 and LVEF had to be below 50%.
Patient history, physical examination and an extensive echocardiography exam were performed. Lab results included NT-proBNP. Manual longitudinal strain was calculated using EchoPAC (General Electric Medical Systems, Horten, Norway) by a single and blinded examiner. LVEF was measured using Simpson's biplane method.
Results: Of 103 patients included in the trial, 19 patients were excluded from the analysis due to poor echocardiography image quality or missing lab
Results: The baseline characteristics included mean age 61.0 years and 76% male. Mean GLS was -9.6 % (SD +/- 4.5 %) and median NT-proBNP 1269.5 (IQR 379.5 - 2759.5) ng/ml. The CHF aetiology was 70.0 % ischemic vs 30.0 % non-ischemic.
There was a significant negative correlation between GLS and NT-proBNP (Pearson r = 0.239, p = 0.029), this was not significant for LVEF and NT-proBNP (Pearson r = 0.149, p = 0.228).In a multivariate regression analysis adjusted for age, sex, NYHA classification and HF aetiology, GLS remained significantly correlated with NT-proBNP (adjusted beta-coefficient= 0.289, p = 0.011). Furthermore, in contrast to LVEF, GLS showed a significant correlation to NT-proBNP in patients with ischemic (Pearson r = 0.266, p = 0.049) as well as non-ischemic aetiology of heart failure (Pearson r = 0.434, p = 0.034).
Conclusion: Global longitudinal strain, not LVEF, was significantly correlated with NT-proBNP in patients with CHF, independently of age, sex, symptoms or heart

failure aetiology. This shows that speckle-tracking might be superior to LVEF for the assessment of left ventricular function in CHF.

P572

Estimation of NTproBNP and overhydration (ECF excess) during the 12-channel routine ECG

F Skrabal[1]; K Skrabal[1]; M Penatzer[2]
[1]*Institute for Cardiovascular and Metabolic Medicine, Graz, Austria*; [2]*Barmherzige Schwestern, Innere Medizin 1, Wien, Austria*

Funding Acknowledgements: This work was supported by the SFG grant Nos 1.000.034.146, 1.000.037.669 and FFG grant Nos 849750 and 855562

Background: The diagnosis of chronic heart failure (CHF) in clinical practice is no triviality. We have developed a 12 channel ECG which combines the Einthoven, Wilson and Goldberger leads with segmental impedance spectroscopy and impedance rheography in six body segments (thorax, abdomen and the four extremities) using only one additional double electrode at the neck (Combyn ECG). Using this technology it is possible to measure the acceleration of blood and also the relation of extracellular to intracellular water (ECF/ICF ratio) during the routine ECG in these 6 body segments. These two parameters combined may be used for estimation of NTproBNP levels.
Purpose: We evaluated prospectively the sensitivity of the methodology to estimate NTproBNP in unselected outpatients.
Methods: 195 patients (91 without CHF, 104 with CHF) were evaluated. The measured NTproBNP plasma levels were compared with the output of the Combyn ECG using discriminant function analysis. The following cut offs for groups 1 to 4 were used: NTproBNP (1) < 120, (2) 120-400, (3) 400-1000, (4) >1000 pg/ml.
Results: Participants of the study without CHF and with NTproBNP levels < 120 pg were allocated to group 1 and 2 (74.7 and 17.6%, respectively; total 92.3%), patients with CHF and NTproBNP >1000 pg were allocated to group 3 and 4 (20.8 and 58.3%, respectively; total 79.1%). Patients with NTproBNP levels between the above extremes were detected with lower sensitivities (table).
Conclusions: NTproBNP is an (over-)stretch release hormone, overstretch also leads to an impaired acceleration of blood which can be measured by the Combyn ECG. Based on these physical principles (i.e. an inverse correlation between NTproBNP levels and blood acceleration and a positive correlation between NTproBNP levels and ECF excess) our prospective study shows promising sensitivity for estimating NTproBNP levels solely by recording of the 12 channel Combyn ECG.

Table

Discrimination Analysis: Classification Results in %, cross validated

	Predicted Group				
Groups based on NTproBNP (pg/ml)	1	2	3	4	Sum
1: NTproBNP < 120	74.7	17.6	6.6	1.1	100
2: NTproBNP 120-400	22.4	53.1	20.4	4.1	100
3: NTproBNP 400-1000	12.9	22.5	32.3	32.3	100
4: NT proBNP > 1000	4.2	16.7	20.8	58.3	100

Chronic Heart Failure - Treatment

P573

Therapeutic response of peritoneal dialysis as a therapy for refractory heart failure and congestive right ventricular dysfunction

N Noemi Pavo[1]; R Yarragudi[1]; H Puttinger[1]; G Strunk[2]; A Bojic[1]; A Vychytil[1]; M Huelsmann[1]
[1]*Medical University of Vienna, Vienna, Austria*; [2]*Research Institute for Complex Systems - Complexity-Research, Vienna, Austria*

Background: In patients with refractory heart failure (HF) peritoneal dialysis (PD) is associated with improved functional status and decrease in hospitalization. However, previous studies did not focus on right ventricular dysfunction as important pathophysiologic component of cardiorenal syndrome.

Methods: In a prospective cohort study PD was started in 40 patients with refractory right HF (with/without left HF). Refractoriness to conservative therapy was defined as persistent right heart congestion/ascites with intensified diuretic treatment and/or = 2 hospitalizations within 6 months because of cardiac decompensation despite optimal medical treatment, and/or acute renal failure during intensified conservative treatment of cardiac decompensations.

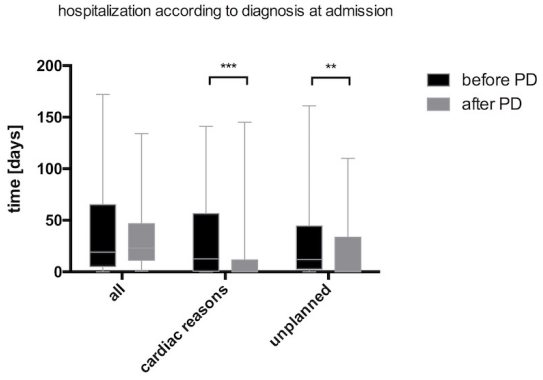

Figure 1

Results: Patient survival was 55.0% at 1 year, 35.0% at 2 years and 27.5% at 3 years. The number of hospital days declined after initiation of PD for both cardiac [13 (IQR 1-53) days before vs. 1 (IQR 0-12) days after PD-start of PD, p < 0.001] and unplanned reasons [12 (IQR 3-44) days before vs. 1 (IQR 0-33) days after PD-start, p = 0.007] (Figure 1). Using a combined endpoint including survival time of = 1 year and either improvement in quality of life or decline in hospitalizations we found that patients with extended ascites, higher systolic pulmonary artery pressure, more marked impairment of right ventricular function and tricuspid valve insufficiency, higher residual renal function as well as those who could perform PD without assistance most benefited from this therapy.
Conclusions: Patients with more pronounced backward failure, less marked residual renal functional impairment and those not depending on assistance for therapy are likely to profit most from PD.

P574

Baroreflex-activation-therapy in advanced heart failure: do patients accept an additional device-based therapy when symptomatic under optimized treatment?

D Denise Guckel[1]; KJ Gutleben[1]; D Horstkotte[1]; G Noelker[1]
[1]*Herz- und Diabeteszentrum NRW, Ruhr-Universität Bochum, Clinic for Cardiology, Bad Oeynhausen, Germany*

Background/Introduction: Baroreflex-Activation-Therapy (BAT) is a new promising treatment option for patients (pts) suffering from advanced heart failure (HF) with reduced left ventricular ejection fraction (HFrEF) to improve functional status and quality of life. Data on the acceptance of this novel therapeutic device are lacking. Comparative clinical data on outcome of pts implanted with BAT devices in comparison to control HFrEF pts are scarce as well.
Purpose: The aim of our study is to analyse the acceptance of this novel therapeutic device and to evaluate the outcome of pts implanted with a BAT device in comparison to HFrEF pts solely treated with a guideline directed medical therapy (GDMT). Beyond that we intend to examine to which extent possible factors (e.g. cardiac resynchronisation therapy (CRT), atrial fibrillation, sacubitril/valsartan or sleep apnoea) might influence the response to BAT.
Methods: In this single centre prospective study, 38 HFrEF pts (67 ± 1.8 years) (mean ± SEM) (32 males) eligible for BAT (EF 27 ± 1 %, NYHA III, NT-proBNP 2302 ± 460 pg/ml, 6-minute hall walk distances (6MWD) 281 ± 23 m) were included. Baseline pts answered a questionnaire focussing on the acceptance of BAT. Follow-up visits (FU) were scheduled after 3, 6 and 12 months. Primary efficacy endpoints will include an improvement in quality of life (EQ-5D-5L), New York Heart Association (NYHA) functional class, ejection fraction, hospitalisation rate due to recurrent heart failure symptoms, NT-proBNP levels and 6MHWD. Pts refusing BAT served as a control group.
Results: 34 pts (87%) completed the questionnaire concerning their acceptance of BAT. 32 of these pts (95%) were unaware of this novel therapeutic option and were interested in BAT, 12 of them (38 %) wanted to be implanted directly, 11 pts (34 %) expected further information before treatment. The majority of pts interested in BAT

(16 pts, 50%) wanted to make sure that no other competing therapeutic options were available. 3 pts (9%) strictly denied the option of a BAT therapy because of potentially unexpected adverse effects caused by the implantation, but none of the pts refused BAT due to other reasons. 10 pts (30%) could not yet decide and hence requested further information (6 pts, 20%) and time for consideration (4 pts, 12%). Eight pts have already been implanted with a BAT device. All pts were interested in regular visits at our centre due to their severe heart failure.

Conclusion: To the best of our knowledge, we are the first to analyse the acceptance of BAT in pts suffering from advanced HFrEF. From our limited data BAT seems to be a broadly accepted but previously unknown therapeutic tool in HFrEF pts. Details on mid-term clinical outcome will be available and presented at the meeting.

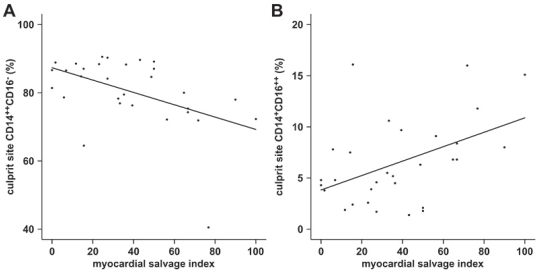
Funding Acknowledgements: Austrian Science Fund (APKLI209)

Background: Myocardial infarction (MI) is a major cause of acute and chronic heart failure. The pathomechanisms of myocardial salvage and scar formation are incompletely understood. We have previously shown that neutrophils release neutrophil extracellular traps (NETs) at the culprit lesion site (CLS). Coronary NET burden correlated significantly with increased infarct size in ST elevation MI (STEMI) patients. It was shown that macrophages are critical for the clearance of NETs. Monocytes are circulating macrophage precursors and play a critical role after myocardial ischemia/necrosis. Monocytes are sub-grouped according to their CD14/CD16 expression into classical (CD14++CD16-), intermediate (CD14++CD16+) and non-classical (CD14+CD16++) monocytes. These subsets fulfill diverging roles in inflammation; especially patrolling non-classical monocytes are important for the efficient removal of cell debris after tissue damage. The chemotactic fractalkine receptor CX3CR1 is highly expressed on non-classical monocytes. We sought to investigate monocyte subsets at the CLS of STEMI patients.



Monocyte subsets and myocardial salvage

Methods: In the course of a clinical trial, in which out of hospital-initiated therapeutic hypothermia was tested in STEMI patients (STATIM trial, n = 120, submitted), we determined monocyte subsets in thrombectomy specimens from the CLS compared to femoral blood samples (n = 30) using flow cytometry. Cardiac magnet resonance (CMR) was performed in these patients 4 ± 2 days after STEMI. The primary endpoint of this trial was myocardial salvage index (MSI). In a second STEMI population (n = 36), we performed a detailed expression marker analysis of respective subsets at the CLS compared to the femoral site. NET surrogate markers (citrullinated histone 3 [citH3], double-stranded deoxyribonucleic acid [dsDNA]) were measured in CLS and femoral plasma using immunometric assays. Enzymatic infarct size (CK-MB area under the curve [CK-MB AUC]) was determined in all patients.

Results: Therapeutic hypothermia had no effect on MSI or other outcome measures. Classical monocytes were significantly decreased at the CLS and correlated negatively with MSI, whereas non-classical monocytes where significantly increased and correlated positively with MSI. In the second STEMI population, CX3CR1 expression of non-classical monocytes correlated negatively with CK-MB AUC and with citH3 and dsDNA. These NET surrogate markers correlated positively with CK-MB AUC, as previously published.

Conclusion: These data indicate that non-classical monocytes accumulate at the CLS and contribute to myocardial salvage, potentially via effective clearance of cell debris and NETs. CX3CR1 appears to be highly important in this process.

Fibrocytes accumulate at the culprit lesion site in STEMI and are functionally impaired by neutrophil extracellular traps

A Anton Frueh[1]; T Hofbauer[1]; T Scherz[1]; A Ondracek[1]; A Panzenboeck[1]; M Schneider[1]; C Feist[1]; L Kascha[1]; A Mangold[1]; IM Lang[1]
[1]*Medical University of Vienna, AKH - Vienna, Cardiology Clinic, Vienna, Austria*

Introduction: Inflammation is important in the pathogenesis of ST-elevation myocardial infarction (STEMI). Neutrophil extracellular traps (NETs) are enriched at the culprit lesion site (CLS) of patients. Fibrocytes, mesenchymal progenitor cells with both leukocyte and fibroblast properties, accumulate in cardiac tissue of a murine ischemia/reperfusion model and contribute to tissue repair and Collagen-I deposition. In advanced atherosclerotic plaques, expression of bone morphogenic protein receptor II (BMPRII) is lost. We studied fibrocyte frequencies and their BMPRII expression at the CLS of STEMI patients.

Methods: We drew blood samples from the CLS and femoral site during primary percutaneous coronary intervention from STEMI patients (n = 50, male = 78%, mean age = 61 ± 13y). Fibrocytes were characterized using flow cytometry. Double-stranded (ds)DNA, a surrogate marker of NETosis, was measured in plasma using PicoGreen®. To assess the influence of NETs on Collagen-I and BMPRII expression, fibrocytes were stimulated in vitro with isolated NETs.

Results: Fibrocytes were increased two-fold at the CLS compared to femoral blood. No differences were found in BMPRII expression between CLS and femoral blood. dsDNA was highly increased at the CLS and negatively correlated with both Collagen-I and BMPRII expression of fibrocytes. In vitro treatment of fibrocytes with NETs induced a decrease of Collagen-I and BMPRII. DNase 1, which degrades NETs, abolished this effect.

Conclusion: We report the accumulation of fibrocytes at the CLS and STEMI. Furthermore, our data suggest a functional link between NETs and fibrocytes, leading to Collagen-I and BMPRII downregulation. NETs might thereby impair reparative functions of fibrocytes after STEMI.

Abstracts role of irisin in ischaemia reperfusion injury in isolated heart of albino rats

S M Salah Mohamed Ibrahim[1]
[1]*university, cairo, Egypt*

Background: Irisin, a newly identified myokine, is critical in modulating body metabolism, thermogenesis and reducing oxidative stresses. Lower plasma level of irisin in patients with acute myocardial infarction (AMI) was reported. Nevertheless, the significance and functional role of irisin in the modulation of myocardial ischemia and reperfusion injury are not clear.

Purpose: This study was designed to explore possible effect of irisin on ischemia-reperfusion injury in isolated heart of adult male albino rats and to explain the possible involved mechanisms, in a trial to clarify irisin expected cardioprotective effect.

Methods: This study was carried out on thirty sex adult male albino rats which were divided equally (n = 12) into 3 groups: Group I (ischemia-reperfusion I/R group); hearts were stabilized then subjected to (I/R) protocol, Group II (Irisin pre-conditioning group); Irisin was infused for 20 minutes before hearts were subjected to ischemia and Group III (Irisin post-conditioning group); Irisin was infused for 20 minutes at the beginning of 60 minutes of reperfusion. Cardiac performance indicators as left ventricular pressure (LVP), +max (LV dp/dt), -max (LVdP/dt), in addition to heart rate were recorded. Lactate dehydrogenase (LDH), creatine kinase-MB (CK-MB), superoxide dismutase (SOD) and C-reactive protein (CRP) were measured in the collected perfusate and cardiac Malondialdehyde (MDA) was measured. Finally, Nitro blue tetrazolium stain was used to detect the necrotic tissue percentage to the whole left ventricular mass.

Results: In group III (post conditioning group), there was a significant increase of the studied cardiac parameters compared to group I (I/R). Irisin significantly increased LVP, +max (dp/dt), -max (dp/dt) and HR in comparison with I/R group. This was associated with a significant decrease in LDH and CK-MB levels, a significant increase in SOD level and a significant decrease in MDA and CRP levels. Moreover, Irisin caused a significant decrease in percentage of necrotic tissue to the whole left ventricular mass. Regarding group II, no significant changes were detected in all parameters when compared to group I.

Conclusion: Irisin could protect against ischemia/ reperfusion injury in vitro through its antioxidant and anti-inflammatory properties, by limiting the infarction area, only

if given as a post conditioning factor after I/R. Those results open the way to include Irisin among the strategies for management of cardiac infarction during reperfusion.

The damage-associated molecular pattern S100A8/S100A9 as a potential biomarker in patients with active myocarditis

I Irene Mueller[1]; U Kuehl[2]; T Vogl[3]; B Pieske[2]; S Van Linthout[1]; C Tschoepe[2]
[1]Berlin-Brandenburg Center for Regenerative Therapies, Charite - Campus Virchow Klinikum, Berlin, Germany; *[2]Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology and Pulmonology, Berlin, Germany*; *[3]University of Muenster, Department of Immunology, Munster, Germany*

Background: The alarmin S100A8/S100A9 is a damage-associated molecular pattern molecule and has been shown to be of importance under inflammatory disorders such as arteriosclerosis and coronary heart disease. Clinical evidence highlights that high plasma levels of S100A8/S100A9 are a risk factor for future cardiovascular events.
Purpose: We aimed to evaluate the potential of serum S100A8/S100A9 levels as a prognostic biomarker in patients with endomyocardial biopsy (EMB)-proven active myocarditis (A-MC) vs non-ischemic dilative cardiomyopathy (DCM) and controls.
Methods: S100A8/S100A9, high sensitivity C-reactive protein (hsCRP) and n-terminal (NT) pro-brain natriuretic protein (BNP) levels were analyzed in serum and plasma of A-MC (n = 27; ejection fraction (EF): 38.8% ± 14%) and DCM patients (n = 16; EF: 22.5% ± 4.7%), and controls (n = 51; EF: 60% ± 5%) by specific ELISAs. Patients serum and plasma were collected at time point (T) 1, where also EMBs were collected. EMB S100A8, S100A9, and NLRP3 mRNA levels and the number of invaded inflammatory cells in EMBs were determined by real-time PCR and immunohistology stainings, respectively. Ejection fraction (EF) was determined at T1 and T2 by echocardiography and the improvement/deterioration in EF between T1 and T2 was calculated.
Results: Serum S100A8/S100A9 was not increased in DCM vs controls. In contrast, serum S100A8/S100A9 levels were 3.7-fold ($p < 0.0001$) higher in A-MC patients vs controls. At the cut-off of 570 ng/ml, S100A8/S100A9 levels showed a diagnostic specificity and sensitivity of 77% and 89%, respectively, vs controls. Alarmin levels correlated with hsCRP ($r = 0.588$, $p < 0.012$), but not with plasma NT pro-BNP levels ($r = -0.210$, $p = 0.3013$). The peripheral increased alarmins correlated strongly with the mRNA expression of S100A8 ($r = 0.731$, $p = 0.0006$) and S100A9 ($r = 0.702$, $p = 0.0011$) and moderately with lymphocyte function-associated antigen 1 presence (LFA1; $r = 0.435$, $p = 0.0233$) in EMBs of A-MC patients. In A-MC patients, EMB mRNA expression of inflammasome 3 (NLPR3), known to belong to the intracellular signaling of alarmins, correlated with EMB S100A8 ($r = 0.6$, $p = 0.024$) and S100A9 ($r = 0.66$, $p = 0.012$) mRNA expression. Clinically, alarmin serum levels correlated with the EF T1 ($r = 0.6032$, $p = 0.0011$) and moderately with the EF improvement/deterioration (EF T2 - EF T1 7.8% ± 6.5%) over time ($r = 0.498$, $p = 0.0415$) in A-MC patients. For hsCRP ($r = 0.363$, $p = 0.151$) and NT pro-BNP ($r = -0.180$, $p = 0.5046$) levels such latter correlation did not exist.
Conclusions: The S100A8/A9-NPLR3 axis is activated in human A-MC, but not in DCM patients, and reflected by increased serum S1008/S100A9 levels. S1008/S100A9 serum levels are increased under these conditions like some other inflammatory tissue and plasma markers such as hsCRP, but correlated best with the change in LV function. We conclude that the measurement of S100A8/S100A9 serum levels can provide an additional value for the diagnosis and monitoring of A-MC.

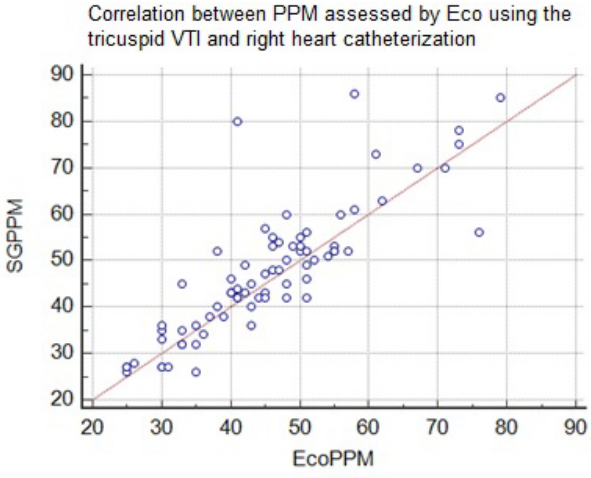
Accuracy and precision of mean pulmonary pressure assessed by echocardiography among patients with pulmonary hypertension

D A Crippa[1]; A Ferro[2]; MG Romero[1]; H Gomez Santa Maria[2]; N Gonzalez[2]; A Lavalle Cobo[2]; G Damianich[2]; F Nehme[1]; I Constatin[1]; MA Gonzalez[2]; H Grancelli[2]; V Daru[3]; M Sztejfman[4]; C Giuliani[4]; A Lescano[1]
[1]Finochietto Clinic, Cardiovascular Imaging, Buenos Aires, Argentina; *[2]Finochietto Clinic, Cardiology, Buenos Aires, Argentina*; *[3]Finochietto Clinic, Buenos Aires, Argentina*; *[4]Finochietto Clinic, Interventional cardiology, Buenos Aires, Argentina*

Background: Non-invasive estimation of pulmonary pressures by Doppler echocardiography (DE) is an important management tool for pulmonary hypertension (PH) patients. Previous reports suggested the use of the velocity-time integral (VTI) of the tricuspid jet for estimating the mean pulmonary pressure (MPP). However, there is limited information regarding precision and accuracy of the VTI tricuspid reflux in patients with HP.
Porpuse: Estimate the concordance between mean pulmonary pressures assessed by DE using the tricuspid VTI and right heart catheterization (RHC)
Material and Methods: Patients with confirmed PH diagnosis (MPP = 25mmHg) that underwent RHC between March 2012 and May 2016 from three heart failure services were included in the analysis. The echocardiographic studies were performed using two ultrasound systems (Esaote Vivid mylab 5s and 30 Gold) equipped with a 3.5MHz transducer. The MPP was obtained by adding the tricuspid jet VTI to the right atrial pressure (RAP), estimated by the inferior vena cava diameter and inspiratory collapse. Hemodynamic confirmation was obtained by a RHC with a Swan-Ganz catheter to asses pulmonary pressures. RHC and DE were performed with less than 24 hs of difference between them and the physicians performing the RHC were blind to echocardiography results. The MPP obtained by the two methods were compared using Lin's concordance correlation coefficient and Bland Altman plot. MPP was categorized in 11 groups per 10 mmHg increase and quadratic weighted kappa was performed for qualitative agreement measures.



Results: A total of 98 patients with confirmed diagnosis of PH were included. Mean age was 57.5 years (SD 19) and 73% were women. PH group (G) distribution was GI 64; GII 16%; GIII 8%; GIV 8% and GV 6%. 79% had heart failure, 26% syncope and 23% chest pain; mean distance in the 6 minute walk test was 326 meters (SD 137). Mean RHC pressures (mm Hg) were: MPP 48 (SD 15), Systolic pulmonary pressure (SPP) 76 (SD 20), Diastolic pulmonary pressure (DPP) 34 (SD12), transpulmonary gradient 35, RAP 10 (SD 5,1). Mean cardiac index was 2,7 liters/min/mts2 (= 2,2, 25%). Analysis of DE data shown: mean TAPSE 18mm (DS 4), SPP 73mmHg (DS 16) and MPP 45,6mmHg (SD 12,1). The concordance correlation coefficient resulted in 0.83 (95% CI 0.74-0.88), with a Pearson r of 0.84 (precision) and a Cb correction factor of 0.97 (accuracy). The Bland Altman plot shows a mean difference of 2mmHg and SD of 7,6mmHg. Although related to a small number of observations, DE underestimated pulmonary pressures above 70mmHg MPP. The k resulted in 0.80 (95% CI 0.70-0.90).
Conclusion: A moderate to high concordance in MPP assessment between a noninvasive technique (tricuspid VTI) and right heart catheterization was observed among patients with PH. These results supports the use of DE as a reliable diagnosis measure of MPP among patients with PH. Further research may be needed to assess accuracy in very high PH patients (MPP above 70mmHg).

Diabetes and the Heart

RAS Antagonists and beta blockers stabilize HbA1c and improve insulin resistance in patients with diabetes free from cardiac disease

R Raphael Wurm[1]; M Resl[2]; S Neuhold[3]; H Arfsten[1]; N Pavo[1]; M Clodi[2]; A Luger[4]; M Huelsmann[1]
[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]Convent of the Brothers of Mercy Hospital Linz, Department of Internal Medicine, Linz, Austria*; *[3]Medical University of Vienna, Department of Anaesthesia, General Intensive Care and Pain Control, Vienna, Austria*; *[4]Medical University of Vienna, Department of Endocrinology, Vienna, Austria*

Background: Sacubitril/Valsartan improves glycemic control in patients with diabetes and heart failure. Conversely, the translational PONTIAC trial showed that first line heart failure drugs, i.e. renin-angiotensin-system (RAS) antagonists and beta blockers, improve outcome in patients with diabetes free from cardiac disease.
Purpose: Here we sought to assess the effects of RAS antagonists and beta blockers on HbA1c and HOMA in the PONTIAC population.

Methods: The PONTIAC trial enrolled 300 patients with stable diabetes free from cardiac disease. They were randomized to either intensified treatment with RAS antagonists and beta blockers titrated to reach guideline recommended target doses, or control for one year. In this post-hoc hoc analysis, we included patients in whom complete insulin profiles were available. We compared changes in HbA1c, and in insulin resistance via the homeostatic model assessment (HOMA), between baseline and one year of follow up.
Results: We included 195 patients (100 control, 95 treatment). The mean age of the cohort was 66 ± 9 years, mean duration of diabetes was 15.4 ± 12.6 years.
After one year, HbA1c increased significantly in the control group (6.7% to 7.0%, p < 0.05) while there was no change in the treatment group (7.2% to 7.1%, p = n.s.). Correspondingly, HOMA did not change in the control group (13.2 to 13.6, p = n.s.), while it decreased significantly in the treatment group (19.1 to 14.9, p = 0.047).
Discussion: Despite treatment, diabetes tends to worsen over time. Here we show that treatment with RAS antagonists and beta blockers can halt this deterioration and improve insulin resistance in patients free from cardiac disease. Potential mechanisms include improved peripheral circulation or a positive effect on subclinical heart failure. Future trials to evaluate heart failure drugs as preventive measures in patients with diabetes appear warranted.

Baseline characteristics

	Control (n = 100)	Intervention (n = 95)	p-value
Male n (%)	64 (64.0)	64 (67.4)	0.731
Age (mean (sd))	66.22 (9.40)	67.72 (7.82)	0.230
Duration of diabetes (median [IQR])	12.50 [5.75, 20.00]	10.00 [5.00, 20.00]	0.607
BMI (median [IQR])	29.10 [25.35, 32.92]	27.70 [25.60, 33.00]	0.682
Insulins, n (%)	38 (38.0)	43 (45.3)	0.377
Oral antidiabetic therapy n (%)	70 (70.0)	69 (72.6)	0.804
eGFR (median [IQR])	81.40 [68.40, 96.20]	82.00 [72.70, 93.80]	0.757

Withaferin A attenuates inflammatory response and cardiovascular dysfunction induced by LPS

C Chintan Koyani[1]; C Trummer[2]; I Plastira[2]; M Lechleitner[2]; H Sourij[3]; S Frank[2]; W Sattler[2]; E Malle[2]; D Von Lewinski[1]
[1]Medical University of Graz, Division of Cardiology, Graz, Austria; *[2]Medical University of Graz, Institute of Molecular Biology and Biochemistry, Graz, Austria*; *[3]Medical University of Graz, Division of Endocrinology and Diabetology, Graz, Austria*

Background: Prevalence of diabetes is steeply rising in developing countries. Along with hyperglycaemia, other diabetic complications including impaired cardiovascular function, elevated inflammatory cytokines (primarily derived from monocytes/macrophages) and higher susceptibility to develop infection are detrimental and require substantial clinical attention. Withaferin A, a steroidal lactone derived from Withania somnifera belonging to Solanaceae family, has recently been identified as a potent anti-diabetic agent with positive effects against weight gain.
Purpose: In the present study we aimed to evaluate the effects of withaferin A against LPS-induced inflammation (in cardiomyocytes and macrophages) in vitro, and cardiovascular dysfunction (aortic ring contractile function and survival) and sepsis in vivo.
Methods: Murine cardiomyocyte (HL-1) and macrophage (RAW 264.7) cell lines were used to study intracellular signalling. C57BL6 mice were used to clarify the effects of withaferin A on LPS-induced cytokine release, cardiac and vascular dysfunction, and survival.
Results: Withaferin A (1 μM) impaired LPS-induced p42/44 MAPK and p65 activation in both cell lines. Inhibition of STAT1/3/6 phosphorylation was observed only in macrophages. As a consequence, LPS-induced cytokine (TNFa, IL-4/6/10) production and iNOS expression became apparent in response to LPS. Myography data revealed protective effect of withaferin A (10 mg/kg, i.p.) against LPS-impaired endothelial relaxation and significantly improved survival rate (˜40%) in septic mice. Conclusion: Our data reveval therapeutic potential of withaferin A against LPS-induced cardiovascular damage, inflammation and mortality.

Protein tyrosine phosphatase non receptor type 22 (PTPN22) function impacts neutrophil extracellular trap formation

L Lisa Kascha[1]; T Hofbauer[1]; M Winter[1]; A Panzenboeck[1]; K Distelmaier[1]; S Scherz[1]; A Ondracek[1]; C Feist[1]; A Mangold[1]; IM Lang[1]
[1]Medical University of Vienna, Department of Cardiology, Internal Medicine II, Vienna, Austria

Background: Neutrophils undergo NETosis via peptidylarginine deiminase 4 (PAD 4) activation and release extracellular traps (NETs) into the extracellular space to combat pathogens. NETs also have a significant role in thrombotic disease. Coronary NET burden correlates positively with infarct size in ST-elevation myocardial infarction (STEMI) patients. It was reported that a missense mutation (R620W) in the protein tyrosine phosphatase non receptor type 22 (PTPN22) results in abrogated PAD4 inhibition and consecutively leads to enhanced NETosis. Deoxyribonuclease (DNase) is a natural counter mechanism against NETs.
Purpose: We analyzed the effect of PTPN22 deficiency on NET formation in a murine model and studied the R620W single nucleotide polymorphism (SNP) in coronary artery disease (CAD) patients with regard to outcomes.
Methods: Blood was drawn from PTPN22 knockout (KO) mice, NETosis was induced by ionomycin and compared to wildtype (WT) mice (each n = 10). NETotic neutrophils were measured by flow cytometry. DNase activity in murine plasma samples was measured by an in-house built activity assay. Furthermore, we tested the R620W SNP in 711 CAD patients who suffered from ST elevation myocardial infarction using allelic discrimination polymerase chain reaction (PCR).
Results: PTPN22 KO mice displayed significantly reduced NETosis compared to WT. Interestingly, PTPN22 mice had a significantly increased plasmatic DNase activity, which correlated with reduced NETosis. CAD patients carrying the R620W showed no altered mortality compared to controls.
Conclusion: In contrast to present literature, we found decreased NETosis in PTPN22 KO mice. In this ongoing project, we will further evaluate NETosis and DNase in connection to PTPN22.

Cardiac Resynchronization Therapy

P583
Underuse of Cardiac resynchronization in Austria, and the role of dedicated heart failure clinics for implementation.

M Marianne Gwechenberger[1]; M Huelsmann[1]; D Moertl[2]; G Poelzl[3]; L Kaltenbach[4]; C Gangl[1]
[1]Medical University of Vienna, Vienna, Austria; *[2]University Hospital Sankt Poelten, Sankt Poelten, Austria*; *[3]Medical University of Innsbruck, Innsbruck, Austria*; *[4]Innsbruck Medical University, Innsbruck, Austria*

Background: Cardiac resynchronization therapy (CRT) is a well established therapy in patients with heart failure and has been proven to reduce morbidity and mortality. However, there is still a gap between the number of patients with an indication for a CRT (according to the guidelines) and its actual utilization, with wide variations between different countries.
Purpose: Aim of the study was to investigate the utilization of CRTs in Austria in general and in the heart failure registry which is conducted in dedicated heart failure clinics.
Methods: The calculations are based on a previously published models: Roughly 1-2% of the general population suffer from heart failure, of whom 10% have a class I indication for CRT, leading to 1000-2000 eligible patients per million inhabitants. Due to varying guideline definitions 24.5-30% if the population have a class I and IIa indication, leading to 24500-3000 eligible patients per million inhabitants. The actual number of patients treated with a CRT was calculated from the sum of CRT implantations over five years (normalized / million). Statistics Austria was used as a source. The CRT penetration was defined as CRT patients treated with a CRT divided by the prevalence of patients eligible for CRT. The normalized implant rates increased over the years. The Austrian Working Group on Heart Failure has established a registry in for all patients referred to dedicated heart failure clinics with a planned follow-up after 12 ± 3 months. For this analysis we assessed the rate of patients with a CRT at the follow up visit.
Results: In Austria the normalized implant rates increased over the years, leading to 752.2 patients normalized per million population (2012-2016) that received a CRT device. Therefore the estimated CRT penetration range was 37.6-75.2% for the class I indication and 25,1-30.7% for class I and IIa indication. In the heart failure registry 16,2% of all patients received a CRT-device at 1 year follow up. However 12.1% with an indication for a CRT remained without device.
Conclusion: Although implant rates increased over the years, the CRT penetration range is still needs optimization. The implementation of CRT recommendation seems to be higher in dedicated heart failure clinics.

Anagrelide induced cardiomyopathy: a case report

A Tsipis[1]; N Skandalakis[1]; N Kanakakis[1]; N Pilatis[1]; E Petropoulou[1]
[1]*IASO General Hospital, Department of Cardiology, ATHENS, Greece*

Introduction: Anagrelide is a synthetic quinazoline derivative that has been shown to reduce platelet production and the risk of thrombosis in patients with thrombocythaemia associated with myeloproliferative disorders. Anagrelide inhibit platelet cyclic adenosine monophosphate cyclic phosphodiesterase (cAMP) and platelet aggregation. Phosphodiesterase inhibitors are associated with positive inotropy, vasodilatation and cardiac arrhythmias. Experimental studies have shown that treatment with anagrelide produces myocardial necrosis and apoptosis.
Material and Methods: We report a case of an 80-year old woman with essential thrombocythaemia developed anagrelide induced cardiomyopathy. The patient had no cardiovascular risk factor and the cardiac function was normally prior to treatment. After anagrelide introduction, patient appears worsening dyspnoea, fatigue and palpitations.
Results: Echocardiography revealed decreased left systolic dysfunction and left ventricular enlargement. The serum levels of brain natriuretic peptide were elevated. It was decided that this condition was due to anagrelide administration and the treatment was interrupted. Three months later, following treatment for heart failure, the patient presents improved left ventricle systolic function and BNP was normalized.
Conclusions: Cardiotoxicity secondary to anegralide treatment manifests as congestive heart failure and cardiac arrhythmias. Mechanism by anegralide induced cardiotoxicity involves inhibition of cAMP, interference with mitochondrial metabolism, myocardial necrosis and apoptosis. Anagrelide should be used with caution in patients with heart disease. A pretreatment cardiovascular examination is recommended along with careful monitoring during treatment in all patients with or without heart disease.

P622
Use of sacubitril/valsartan beyond guidelines

H Altay[1]; S Pehlivanoglu[1]
[1]*Baskent University Istanbul Hospital , Cardiology, Istanbul, Turkey*

A 54 year-old-man applied to our outpatient clinic for progressive dyspnea and dizziness. He had had aortic valve replacement surgery 18 years ago. Further workup in early 2014 revealed an echocardiogram with left ventricular ejection fraction (LVEF) of 20 % and cardiac angiography with no significant coronary disease. Cardiac resynchronization therapy (CRT) device was implanted 3 years ago. He did not respond to CRT device favourably and he has been on atrial fibrillation (AF) for the last two years. He was on medical therapies that included, carvedilol, spironolactone, tolvaptan, furosemide and warfarin. He had been started ARNi one month ago but could not tolerate because of hypotension. Physical examination was notable for blood pressure 85/60 mmHg, no peripheral edema, and cool peripheral extremities. Decreased breath sounds were heard at the base of her left ungs. Notable admission labs included creatinine (cr) 1,56 mg/dl, blood urea nitrogen (BUN) 74 mg/dl, estimated glomerular filtration rate (eGFR) 59 ml/minute, sodium 130 mmol/L and amino terminal pro-brain natriuretic peptide (NT-proBNP 750 pg/mL. An echocardiogram demonstrated LVEF 15 %, severe tricuspid regurgitation, systolic pulmonary artery pressure 50 mmHg and normal aortic prosthesis function. His ECG revealed AF with left bundle branch block. A chest radiograph revealed left-sided pleural effusion. He was diagnosed with low output HF and hospitalized. The patient was transitioned to digoksin with carvedilol discontinued. She was started dobutamine infusion in addition to a thoracentesis for pleural effusion. Dobutamine was weaned off at day 4. On Day 5, sacubitril/valsartan was initiated at the dose of 24/26 mg b.i.d and followed for 2 more days in the hospital. The patient maintained adequate blood pressure and urine output meantime. He was discharged with sacubitril/valsartan and digoksin . Sacubitril/valsartan was titrated to dose of 49/51 mg b.i.d mg b.i.d. after one month postdischarge. At 6 months after discharge, on clinic visits she has been without signs of decompensated or low output HF.
In a patient with valvular cardiomyopathy, stage D HFrEF and low cardiac output profile, we describe the successful use of sacubitril/valsartan after failed attempts to use due to hypotension. The hypotensive effects of these drugs may potentially explain the lack of benefit or potential harm that may be observed in advanced HF patient who have already low blood pressure. Additional lowering of SBP in a patient with baseline hypotension may result in organ hypoperfusion, worsening renal function, cardiac ischemia, and reductions in cardiac output further.
Conclusion and implications for clinical practice
Given the long-term favourable findings of sacubitril/valsartan and our experience with this patient, sacubitril/valsartan may be a potential option for advanced HF patients with low cardiac profile after a trial of intravenous inotrop support.

P623
Questions and doubts about ARNI therapy in a patient with heart failure: a real life experience

D Kosuta[1]; T Furlan[1]; S Poznic[1]; A Adamlje[1]; B Leskovar[1]
[1]*Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia*

Introduction: ARNI (angiotensin receptor-neprilysin inhibitor) is considered a breakthrough therapy in heart failure with reduced ejection fraction since it has been shown to have a great prognostic impact. However, the administration and titration of the drug in real life carries multiple doubts that are not easy to solve.
Case presentation: We are presenting the case of a 77-year-old gentleman with ischemic heart disease, diabetes mellitus type 2, chronic kidney disease, with a pacemaker-defibrillator implanted due to intermittent 3rd degree AV block and a history of myocardial infarction. In May 2015, he was enrolled in our outpatient clinic due to heart failure with reduced ejection fraction (20 - 30%). Despite optimised medical treatment with maximum tolerated doses of standard drugs and several applications of levosimendan, he remained symptomatic, his functional status was NYHA class III, so we decided to start ARNI therapy.
Discussion: At the beginning of the therapy his pulse rate was around 100 beats/minute despite ivabradine and digoxin and his blood pressure was within normal range. After initiation with the lowest dose of sacubitril/valsartan (24/26 mg twice daily) we observed an increase in the ejection fraction by 10%, a systolic and diastolic pressure drop to 96/65 mmHg and a drop in the heart rate to 87 beats/minute. We considered stopping the drug because of hypotension however, since the patient was feeling good and did not have any symptoms of hypotension, we continued with the therapy. Moreover, the reduction of heart rate was an indicator of an improved hemodynamic status, which allowed the heart to meet the organism's needs for oxygen at a lower heat rate. When the systolic pressure reached values over 100 mmHg again, we increased the dosage. The patient would not tolerate a high dose increase at once, because his pressure was still on the lower side and his renal function was impaired, so we did it with a stepwise approach over a six months period. We increased the dose for 24/26 mg per day every month till we reached the recommended dose, with check-ups every two to four weeks. Each time we increased the dose, we noticed an initial drop in blood pressure, which increased again after a while, and a consistent lowering of the heart rate. During this period of time patient's lean body mass raised for about 12%, he was feeling increasingly better, his performance status improved to NYHA class II according to the six-minute walking test and he has maintained a good functional status ever since.
Conclusion: ARNI therapy has a great impact on the prognosis of patients with heart failure with reduced ejection fraction and its pros outweigh minor cons. Therefore patients experiencing asymptomatic hypotension should not discontinue ARNI but they should rather be thoroughly monitored and ARNI titration scheme should be individually tailored with a stepwise approach.

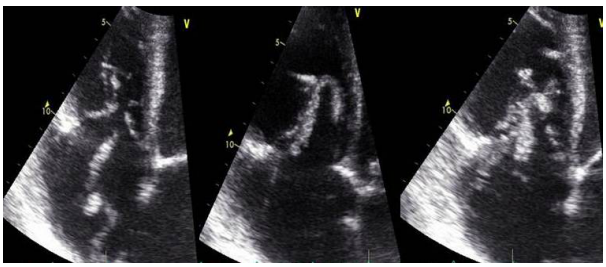
Dilated cardiomyopathy with severe left ventricular dysfunction and right atrial thrombi secondary to thyrotoxicosis.

S Antit[1]; I Slama[1]; S Chenik[1]; S Belakhel[2]; A Mestiri[2]; I Boussabeh[1]; M Thameur[1]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*; [2]*Interior Security Forces Hospital, Department of medicine interne, Marsa, Tunisia*

Introduction: Hyperthyroidism can affect variously the cardiovascular system. The cardiovascular findings range from sinus tachycardia to atrial fibrillation and from a high cardiac output state to rarely congestive heart failure due to impaired systolic left ventricular function and it is associated with a higher risk of thrombo-embolism events. Thrombosis of the right atrium is extremely rare, and to the best of our knowledge, only two cases are described in the literature. We report a rare case of right atrial thrombi in a patient with Graves'disease induced dilated cardiomyopathy with severe left ventricular systolic dysfunction.
Case report: A 45-year-old man with a past medical history of diabetes mellitus, thrombophlebitis of the right lower limb in 2011 and Graves'disease since 2008. He was admitted in our department of cardiology for acute heart failure associated to a recurrent thrombophlebitis of the right lower limb. On clinical examination, he appeared very anxious and had fine tremors in hands, exophthalmos associated with a large goiter. Cardiovascular system examination revealed left ventricular gallop, bilateral basal crackles and clinical signs of right heart failure. Electrocardiogram showed a sinus rhythm, incomplete right bundle branch block. Transthoracic echocardiography (TTE) revealed a dilated left atrium, moderately dilated left ventricle with severe global systolic dysfunction (Ejection Fraction: 20%). The right cavities were also dilated and there was severe right ventricular dysfunction and pulmonary hypertension (52mm Hg). There was significant mitral and tricuspid insufficiency. The patient was managed with intravenous diuretics, bisoprolol, spironolactone, anticoagulation therapy and anti-thyroid drugs.
One week later, a repeat TTE showed large highly mobile snake-like echogenic masses in the right atrium partially adherent to the tricuspid valve and floating in the right ventricle and the inferior vena cava. The diagnosis was between thrombi or vegetations. The patient didn't present fever (37°C) and the laboratory tests didn't show inflammatory syndrome. Despite optimal anticoagulation range, the diagnosis of atrial thrombi was made and we associated antiplatelet agent to anticoagulation therapy. A further TTE (after 7 days) showed totally regression of the atrial thrombi. The patient was discharged on optimal medical therapy, asymptomatic, with a recommendation of radioactive iodine treatment.
Conclusion: In summary, we should keep in mind the possibility of atrial thrombus with Graves'hyperthyroidism, especially patients that have heart failure or atrial fibrillation. In such case, performed echocardiography was warranted. And, if intra-cardiac mass identified, careful differential diagnosis are needed.



Snake-like thrombi in the right atrium.

P625

Case 5-Fluorouacil-Induced Myocardial Infarction and Recurrent Stent Thrombosis; An Unusual Case

B Benedicte Lefebvre[1]; S Dandona[1]; I Malcolm[1]; N Mousavi[1]
[1]*McGill University Health Centre, Cardiology, Montreal, Canada*

A 66 year-old gentleman known for diabetes mellitus and no other cardiac risk factors presented to the emergency room with retrosternal chest pain of a few days duration. He was known for stage IV colon cancer and had undergone resection of primary tumour and liver metastases. The patient had been treated with 1 cycle of 5-Fluorouacil (5-FU) 2 weeks prior to admission. Anterior ST Elevation MI was diagnosed and the patient immediately underwent an angiography, which revealed 100% occlusion of the left anterior descending artery (LAD), with patent remaining coronaries. Deployment of the stent to the LAD lesion relieved the patient's symptoms. However, 12 hours after the procedure, chest pain and anterior ST segment elevation recurred despite dual antiplatelets therapy with aspirin and Clopidogrel. The patient was emergently brought back to the cath lab. In-stent thrombosis was diagnosed and a new stent was inserted after aspiration of clots. Clopidogrel was replaced with Ticagrelor. Throughout the following days, the patient had residual chest pain and ST segments remained elevated despite the troponin level trending down. Echocardiogram showed a left ventricular ejection fraction (LVEF) of 20-25% with septal, anterior and apical akinesis. He was returned to the cath lab on day 6 as mild chest discomfort was still present. He was found to have recurrent in-stent thrombosis despite adequate treatment and well-apposed stents. The decision was made by the interventionalist not to perform another angioplasty as clot aspiration was impossible and a new stent would have to be inserted back into the left main. A cardiac MRI was done to assess for viability of the anterior wall. It showed massive haemorrhagic infarction of the entire LAD territory without viability with LVEF of 21%, right ventricular ejection fraction of 20% and apical thrombus. From these results, 2 dilemmas arose. First, should we anticoagulate for the apical clot given the haemorrhagic transformation and would we risk myocardial rupture? Second, should we insert an implantable cardioverter defibrillator (ICD) without waiting the recommended amount of time as the ejection fraction is unlikely to recover? Given that the patient was returning to a community center and had episodes of non-sustained ventricular tachycardia, we elected to insert the ICD prior to transferring the patient. The patient passed away right after the procedure of unclear circumstances.
5-FU is an antimetabolite chemotherapeutic agent with potential for cardiotoxicity. The mechanism is not well understood but is thought to be secondary to myocardial ischemia due to coronary vasospasm, thrombosis or arteritis provoked by dysregulation of endothelial nitric oxide synthase and upregulation of protein kinase C. Here we present an extreme case of 5-FU toxicity in a patient with increased prothrombotic state due to underlying malignancy and also, difficult clinical decisions for anticoagulation and early ICD insertion

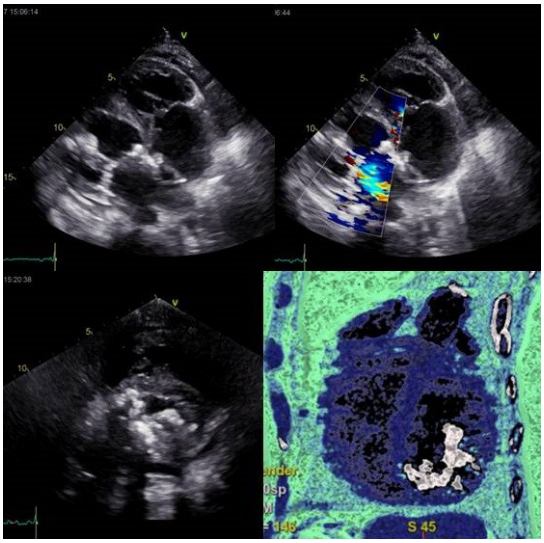
The legend of a stone heart

M Maia Rusu[1]; A Ionescu[1]; T Constantinescu[2]; T Barascu[3]; B A Popescu[1]; C Ginghina[1]; R Jurcut[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*; [2]*"Marius Nasta" Institute Of Pneumology, Bucharest, Romania*; [3]*Fundeni Clinical Institute, Bucharest, Romania*

Introduction: Exposure to radiation is associated with a risk of radiation-induced heart valve damage characterised by valve fibrosis and calcification. There is a latent interval of 10-20 years between radiation exposure and development of clinically significant heart valve disease. Risk is related to radiation dose received, younger age at the time of irradiation, interval from exposure and use of concomitant chemotherapy.



Clinical case: A 38-year-old man was admited to our clinic with moderate exertional dyspnea, fatigue and a syncope during exercise. The medical history revealed: left pulmonary sarcoma at the age of 4 years old (in 1982) treated with radiotherapy

(16 sessions of cobaltotherapy in a 6 months interval), chemotherapy (medication not known) and left total pneumonectomy. At admission, laboratory tests showed an increased BNP levels (1426 pg/ml) and mild dyslipidemia, with normal calcium and parathormon levels.The transthoracic echocardiography found a normal LV systolic function with severe calcifications of the papillary muscles, apical segments of inferior septum and inferior wall asociated with severe mitral regurgitation probably related to radiotherapy during childhood. It also revealed a severe tricuspid valve regurgitation, severe pulmonary hypertension and small amount of pericardial fluid. A thoracic computed tomography with contrast was performed to exclude pulmonary thromboembolism, which described severe cardiac calcifications, right bazal pulmonary emphysema, mediastinal adenopathies. Pneumological evaluation found a hypertrophic right lung herniated in left hemythorax, without patological changes at CT examination (fibrosis or bronchiectasis), only right bazal emphyzema. The patient had severe ventilator dysfunction with prevalence of restrictive component. In this case pulmonary hypertension the most probably is determined by the left cardiac stuctural changes (severe mitral regurgitation postradiotherapy), so it has a limited indication for pulmonary vasodilator therapy and cardiac catheterization. Cardiac reevaluation after 4 months revealed an improvement in clinical state, a decrease of BNP level to 1031pg/ml. In case of clinical worsening, the patient has an indication for valve replacement, but we should be aware about periprocedural complications in conditions of left pneumectomy and severe calcifications of mitral subvalvular apparatus.

Conclusions: Radiation exposure is a risk factor for development of clinically significant valvular heart disease. Cancer survivors who received mediastinal radiotherapy require vigilance and screening for valvular heart disease many years after curative treatment. Although the majority of patients are initially asymptomatic, a proportion of patients will require valve surgery. Physicians must be aware of post-radiation cardiac complications, recognize at-risc patients, and screen such patients for symptoms and signs of cardiac disease.

P627

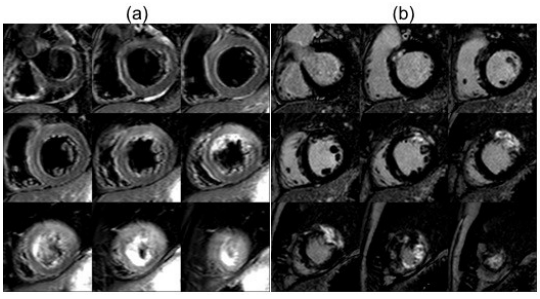
A case of bleomycin induced myocarditis

M Sweeney[1]; GD Cole[1]; CM Plymen[1]
[1]*Imperial College Healthcare NHS Trust, London, United Kingdom*

We report the case of a 26-year-old man with no preceding medical history who presented with metastatic embryonal carcinoma of the right testicle. Following orchidectomy, he commenced adjuvant combination chemotherapy with bleomycin, etoposide and cisplatin with curative intent.

On day 5 of the first cycle of chemotherapy, he experienced severe retrosternal chest pain associated with vomiting and sweating. An ECG at the time demonstrated widespread saddle-shaped ST-segment elevation in the inferior and lateral leads and serum troponin increased from 28 ng/L (Ref: = 34 ng/L) on admission to 18,520 ng/L at 12 hours. A cardiac MRI demonstrated normal overall left ventricular systolic function, however, there were regional wall motion abnormalities in the anterior and anterolateral walls and apex associated with myocardial oedema (panel a) and there was widespread late gadolinium enhancement (panel b) suggesting a diagnosis of acute myocarditis. Within 24 hours the chest pain was improving and serum troponin was downtrending. He was symptom free by day 3 of admission and was discharged on regular ibuprofen and colchicine.

The aetiology of myocarditis remained unclear. An autoimmune screen was negative, common viral markers demonstrated no acute viral infections and the temporal relationship between starting chemotherapy and onset of symptoms made a reaction to chemotherapy the most likely cause. Bleomycin was suspected as the causative agent due to a number of case reports of an acute chest pain syndrome following its administration.



Cardiac MRI at presentation

After discussion with the treating oncologist, it was felt that omitting bleomycin would not significantly reduce the efficacy of the chemotherapy. Therefore given the significant troponin rise in a young patient, this was withheld from future cycles. We did not start prognostic heart failure therapy as the overall LV function remained normal despite the wall motion abnormalities.

6 months after initial presentation, the metastatic deposits had resolved and tumour markers were negative. He remained asymptomatic from a cardiac perspective and repeat cardiac MRI demonstrated improvement of the wall motion abnormalities with only mild hypokinesia of the lateral wall and apex. The myocardial oedema had almost completely resolved and late gadolinium enhancement was markedly improved.

No conclusive diagnosis has been made in any of the previous cases of bleomycin induced chest pain and this is the first reported case to have a cardiac MRI performed following an acute reaction which may provide insight into the aetiology of previously reported cases. This case highlights the importance of multi-disciplinary team working when managing cardio-oncology patients where decisions to alter life-saving chemotherapy need to be made on a patient-by-patient basis with careful consideration of the severity of the cardiotoxicity and the anti-neoplastic benefit which would be lost by excluding a suspected cardiotoxic chemotherapy.

Chronic Heart Failure - Diagnostic Methods

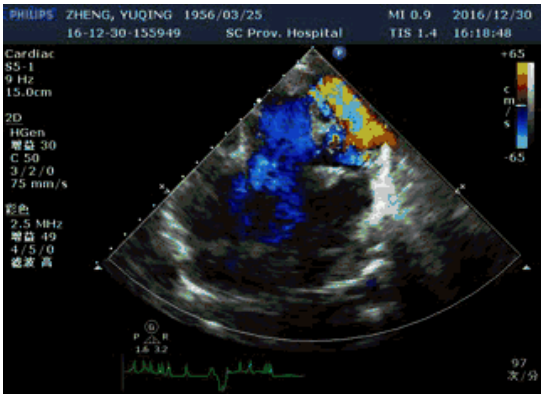
Anomalous origin of the left coronary artery from the pulmonary artery in an old female

G Geqi Ding[1]
[1]*Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Department of Cardiovascular Ultrasound and Non-invasive Cardiology, Chengdu, China People's Republic of*

A 60-year-old female referred to our center due to paroxysmal nocturnal dyspnea and orthopnoea. During the 2 days prior to admission, she had suffered progressive dyspnea with chest pain. she had suffered dyspnea on exertion from one year previously, which was in New York Heart Association (NYHA) functional class II, without any history of chest pain and syncope. At presentation, blood pressure was normal and a holosystolic murmur of grade III/VI at the left sternal border were detected. A twelve-lead electrocardiogram showed a rapid atrial fibrillation rhythm with ST-T changes. Chest X-ray showed marked cardiomegaly and pulmonary venous congestion. Lab data showed NT-proBNP was elevated (9000 pg/ml).

Transthoracic echocardiography demonstrated severe left ventricular and atrium enlargement with moderate dysfunction [LVEDD = 63mm, LA diameter = 61mm, left ventricular ejection fraction (LVEF) = 45%] and moderate to severe mitral and tricuspid insuffciency along with 36 (mmHg) increased systolic pulmonary artery pressure. There was regional wall motion abnormality in the anterior and lateral wall and multiple dilated coronary branches with abundant color doppler signals in both right and left territories through the inferior wall and apex extending by septal toward the anterior and basal. The origin of the right coronary artery from the right sinus of Valsalva was seen; however, the left coronary branches were connected to the backward of pulmonary artery and the color doppler was presence of "steal blood phenomenon".



Electrocardiographically-gated multi-detector computed tomographic (CT) angiograp-hy revealed anomalous origin of the left coronary artery from the

pulmonary artery (ALCAPA) with a retrograde ?ow from the left coronary artery to the pulmonary artery and extensive collateral vessels at the left ventricle.
Diuretic intravenous treatment for 7 days and metoprolol for ventricular rate control, trimetazidine for myocardial metabolism improvement, The patient's congestive symptoms were decreased and clinical situation improved stable, but she refused to have surgery due to the high risk. she was discharged 10 days after admission in a stale status, with all previously reported parameters within normal limits. At discharge, she was followed by cardiologist and cardiac surgeons, and her clinical situation one year later is stable without signs and symptoms of heart failure.
Possible differential diagnosis: In this case two main possibilities need to be differentiated: coronary artery fistula and ALCAPA. The origin of left coronary is correct in coronary fistula and the flow is antegrade which is no steal phenomenon.
Conclusion: This case illustrates an congenital coronary origin anomaly cause of acute heart failure (ALCAPA)that might be underdiagnosed in clinical practice (especially in patients with chronic comorbidities) and emphasizes the importance of echocardiography for management of heart failure.

Chronic Heart Failure - Treatment

P629
The case of sudden cardiac death at patient with heart failure and reduced ejection fraction in long-term period after stem cell therapy

D Dina Shorikova[1]; A Gabrielan[2]; E Shorikov[1]
[1]Bucovinian State Medical University, Chernivtsy, Ukraine; [2]National Institute of Surgery and Transplantology n. a. O. O. Shalimov, Kyiv, Ukraine

Case Summary: Patient M., 63 years old, was hospitalized in clinic with the substantial decreased tolerance to exercise stress, class NYHA IV of heart failure (HF) was diagnosed. The patient's ejection fraction was 18% and local contractility index was set at 2,63 points. The mean blood pressure during 24-hour monitoring was 124/78 mmHg. Heart rate was 68 bpm, the ECG showed normal sinoatrial rate. Plasma NT-proBNP was measured at the level of 2970 pcg/ml. Blood TORCH-infection markers were negative. On the basis of conservative medicamentous treatment, which consist of carvedilol 12,5 mg daily, ramipril - 2,5 mg daily, spironolactone 50 mg daily, the procedure of steam cells transplantation from cord blood was applied. After 6 month of controlled follow-up was reported the diminishing of clinical symptoms and signs of HF, NYHA III class was set and the EF increased up to 28%, the NT-proBNP level decreased down to 757 pcg/ml on the basis of the reaching of the maximal tolerated doses of prescribed drugs. The patients returned to the stable previous work in the office and started gradually maximize everyday physical activity.
After 6 and a half month the patient was urgently hospitalized in cardiologic department with the episode of paroxysmal ventricle monomorphic tachycardia. The episode was quickly stopped by administration of bolus dose (800 mg) of amiodarone with the continued use of 400 mg daily maintenance dose of it. The investigation of the TORCH markers became positive by finding of cytomegalovirus and Epstein-Barr infection.
After the 8 month after transplantation of steam cord blood cells the acute viral respiratory infection was diagnosed in patient, and on this background sudden cardiac death was occurred. The possible cause of lethal incident was the fatal ventricle rhythm disturbance.
Questions: 1. Is there an association between fatal rhythm occurrence and steam cord cells transplantation? 2. What is the role of TORCH infection markers in the origin of lethal rhythm disturbance? 3. Should we prevent the development of the dangerous heart rhythm disorders after transplantation of steam cells of cord blood?
Discussion: Steam cells transplantation is followed by stable level of some adverse effects. Firstly, the proarrhythmogenic activity was typical for steam cells, mostly expressed in skeletal mioblasts. Secondly, the manifestation of persistent viral infection is also characterized the live cycles of polipotent heamathopoetic cells, embryogenic cells and mesenchymal adipose tissue steam cells. The diagnosis of lethal arrhythmias and routine use of daily ECG-monitoring in patients after steem cells transplantation especially after acute viral respiratory infection now remains an open-ended question. Also the estimation of the influence of TORCH-infection on HF patients with low ejection fraction follow-up keeps actual

P630
An unusual case of explantation of a left ventricular assit device.

O Oyvind Reitan[1]; B Kornhall[1]; C Meurling[1]; E Grins[1]; B Bronden[1]
[1]Lund University Hospital, Department of Cardiology, Lund, Sweden

Case description: A 60 year old lady suddenly became ill with irradiating chest pain. ECG showed sinus tachykardia, RBBB and anterior ST-elevation. The patient was referred to our hospital for coronary angiography, which was performed 8 hours after debut.
The angiogram showed a LM stenosis, LAD and RCA ocklusion and a Cx stenosis. Ultrasound showed a normal-sized LV with contractions only in the basal segments. An acute CABG, with intra aortic balloon pump (IABP) support was done.
The postoperative stay on the thoracic intensive care unit was stormy with repetitive episodes of pulmonary edema, ventricular fibrillations, despite the continuous use of IABP, different inotropes and anti arrhytmic drugs. Ultrasound showed an ejection fraction (EF) of 15 %.
After 2 weeks it was decided to provide the patient with a left ventricular assist device (LVAD). Post
LVAD-implantation the arrythmias disappeared and the patient recovered and could be transferred to the ward for training but also be examined as a possible candidate for heart transplantation (HTx).
However, her vascular system showed extensive calcified arterial vessels especially in the pelvic arteries and she was therefore found not eligible for a HTx.
After discharge the patient did well on the pump. She was treated with RAAS blockade and betablocker to keep the mean blood pressure between 70-90mmHg. After some months, the patient started to produce pulse and the blood pressure increased. Continous examinations of the heart with ultrasound were performed showing neither dilatation of the left ventricle nor development of an aneurysm which is common in an LAD-related myocardial infarction. The native heart function was tested in a controlled manner in the echo-lab by reducing the speed of the pump gradually untill non-support. The heart thereby took over the pump work without any discomfort for the patient.
After approximately 3 years on pump, the LVAD started to give unexpected larms, which turned out to be due to cable brake. It was decided to explant the pump and replace it with a second one. The pump was explanted and the native heart function was tested during 2 hours in the operating theatre. It was concluded, that the native heart function was good enough to explant the LVAD with no replacement, but the inflow cannula in the left ventricular apex was left in and plugged, in case the patient would require a second LVAD later.
Nearly one year after, the patient is doing well and has no clinical signs of heart failure and the EF is about 30 % on common heart failure medication.
Conclusion: An LVAD provides the heart with a substantial afterload reduction. The question is if the present case indicates if a patient with a large established MI should be equipped with a mechanical support system during the time when remodeling is expected to occur in order to preserve normal geometry of the heart, prevent development of an aneurysm and preserve more pump power of the native heart.

P631
Intracoronary stem cell life saving infusion in a patient with chronic decompensated heart failure dependent on intra-aortic balloon pump

A Ntalianis[1]; A Repasos[1]; E Papadopoulou[1]; N Makris[1]; E Anninos[1]; I Stamoulopoulos[1]; N Zografos[1]; M Kondilis[1]; A Cohen[1]; A Koutsoukis[1]; A Mareti[1]; S Sventzouri[1]; K Tambakis[1]; I Kanakakis[1]; I Paraskevaidis[1]
[1]University of Athens Medical School, Dept of Clinical Therapeutics, Alexandra Hospital, Athens, Greece

A 57 year male old patient with idiopathic dilated cardforiomyopathy, CRT-D, atrial fibrillation on intermittent inotrope infusion for the last 3 months was implanted with an Intra-aortic balloon pump (IABP) because of decompensated biventricular heart failure. His heart echo parameters before IABP implantation are shown in table 1. After 3 months of support with IABP, weaning process failed and atrial fibrillation cardioversion plus continuation of IABP support for 2 additional months was decided. At the end of the two-month extended IABP support period, weaning process failed again and intracoronary peripheral stem cells infusion was proposed to the patient. An informed consent was obtained and after subcutaneous administration of filgastrim (a granulocyte colony stimulation factor) for 5 days, 20.000.000 CD34 cells were infused with a non-stop flow technique in the LAD, LCX and RCA. After an additional month of support with IABP, the patient was successfully weaned off and stayed alive and free of complications for 3 years when he deceased from septic shock.

Acute Heart Failure - Pathophysiology and Mechanisms

P632
Gravity of gravetic heart failure

HS Kemal[1]; A Gunsel[1]; S Asvaroglu[2]; B Tasel[1]; L Cerit[1]; H Duygu[1]
[1]Near East University Hospital , Cardiology , Nicosia, Cyprus; *[2]Near East University Hospital, Internal Medicine, Nicosia, Cyprus*

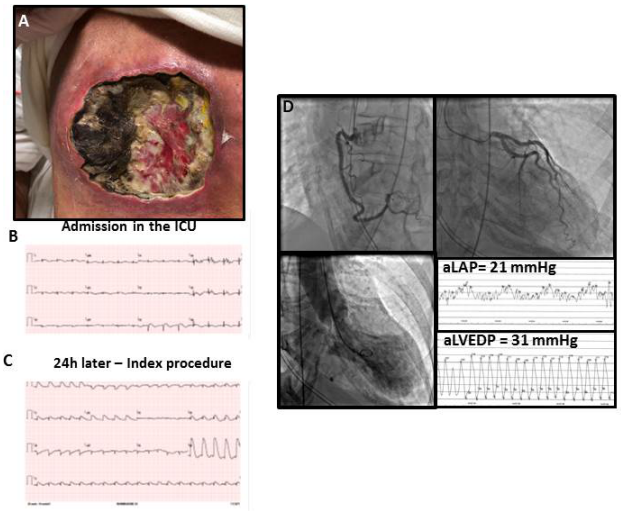
Funding Acknowledgements: No funding

Introduction: We present a case of acute heart failure as the first manifestation of Graves' disease.
Description: A 49-year old woman presented with progressive dyspnoea, swelling of legs and abdominal pain for the last 5 months. She refused treatment until this time and was in NYHA class IV. She had no prior history of chronic disease. She was nervous, emotionally depressed, tachypnoeic and tachycardic. She had bilateral lower limb oedema up to the knee, lung sounds were diminished on the left side and rales were present on the right side, JVD was visible. She had an enlarged, tender liver and massive ascites.ECG showed atrial fibrillation with high ventricular rate. She was hypotensive and hypoxic.
Identification of the problem, procedures, techniques and patient management: Diuretic and dopamin infusion was started. Pleurocentesis showed serous transudate fluid. Echocardiography revealed moderate mitral regurgitation, severe tricuspid regurgitation, and biatrial dilatation. LVEF was 48% and right ventricular systolic function was slightly depressed, TAPSE 14 cm, RVSm 8 cm/s. Systolic pulmonary artery pressure was 40 mmHg. There was interventricular septal bounce movement and mitral E was 94 cm/s, mitral septal S 7cm/s, E' 77 cm/s, lateral E' 11 cm/s and there was also respiratory change in mitral and tricuspid inflow. Right heart catheterization was performed;Pulmonary artery pressure 40/20 mmHg, RV mean pressure 14 mmHg, RA P 15 mmHg, LV P 15 mmHg and PCWP was 18 mmHg, no dip and plateau was observed. Coronary angiography revealed normal coronary arteries.
Significant blood test results were: low albumin, high bilirubin levels, high GGT, decreased TSH, increased T3 and T4. Abdominal CT scan showed cirrhosis and oesophageal varices. Thyroid ultrasound showed enlarged and heterogeneous echotexture and TSH receptor antibody was positive and thyroid scintigraphy showed homogeneously increased activity.
Questions, problems or possible differential diagnosis: What is the diagnosis? Bi-ventricular heart failure? Constrictive pericarditis? Hepatic cirrhosis? Hyperthyroidism?
Conclusion and Implications: The patient was diagnosed as Graves' disease and was started on metibasol (30 mg/day) and propranolol (40 mg/day). After six months of medical therapy, and normal thyroid function for three months the patient was NYHA class I. The ECG showed sinus rhythm, reassessment by TTE showed systolic pulmonary artery pressure of 15 mmHg, normal left and right systolic functions and mild valvular dysfunction. Heart failure is generally a rare occurrence in thyrotoxicosis patients, but requires attention because it can lead to death. The RV is expected to fail in hyperthyroid states due to the pulmonary vasculature physiology. Like in our case challenging differential diagnosis could be present and Graves' disease should be kept in mind, since it is treatable and its complications may be reversible.

P633
Might Imperial Caesar, dead and turned to clay, stop a hole to keep the wind away?

D Domenico D'amario[1]; A Buffon[1]; S D'arrigo[1]; F Lassandro Pepe[1]; F Crea[1]
[1]Catholic University of the Sacred Heart, Institute of Cardiology, Rome, Italy

A 73-year-old caucasian woman, with advanced breast cancer, who consistently refused surgical resection, was admitted in ER for an acute respiratory failure, associated with generalized muscle rigidity, trismus, hyperpyrexia, sweating which needed neuromuscular blocking agent and an early tracheostomy to avoid tube biting and obstruction. No previous cardiac history was reported.



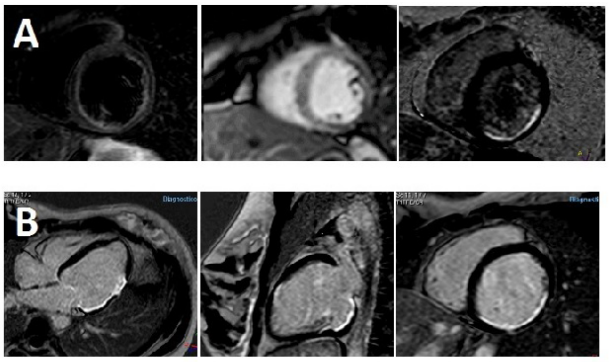
Over the last four weeks, for the occurrence of secondary skin ulceration, the patient was advised to apply clay mud over the breast. Subsequently, she developed an extensive local necrosis (Figure 1A). Microbiological results from necrosectomy revealed Clostridium tetani and Clostridium sporogenes isolation. Human tetanus globulin, intravenous cephalosporin and high dosage of benzodiazepines were admistered.
ECG on admission showed a prolonged QT interval without any evidence of ST segment depression (InterTAK Score: 56) (Figure 1B). On admission, hsTroponin was 1.46, peaking 3.95 ng/mL.
The clinical course rapidly deteriorated with vegetative crisis and hemodynamic instability associated with atrial fibrillation rhythm and significant ST segment elevation (Figure 1C).
Coronary angiography was performed: no evidence of obstructive epicardial coronary atherosclerosis was observed. Following the 2017 STEMI guidelines, LV angiography was performed showing an apical type takotsubo syndrome (TTS), with high average LVEDP and left atrial pressure (Figure 1D). Sadly, the patient died less then 48h later.
To the best of our knowledge, this is the first report documenting a TTS in a patient with a diagnosis of tetanus.
Tetanus per sé may increase the systemic concentrations of catecholamines. Moreover the tetanus toxin is involved in autonomic nervous system dysregulation, suggesting that it might accelerate catecholamine release resulting in the sympathetic nervous system hyperactivity, that is the pathophysiological substrate of TTS.
As recently demonstrated, TTS may be a life-threatening condition: early cardiac catheterization is fundamental to make a correct diagnosis, even in the acute heart failure setting.

Acute Heart Failure - Diagnostic Methods

P634
Dress syndrome and myocarditis: is the endomyocardial biopsy always necessary?

M Maria De La Cruz Mezzadra[1]; MC Carrero[1]; G Diaz Babio[1]; G Masson[1]; T Garcia Bota[1]; G Vera Janavel[1]; P Stutzbach[1]
[1]Instituto Cardiovascular de San Isidro (ICSI), Sanatorio Las Lomas, San Isidro, Argentina

Introduction: Drug Rash with Eosinophilia and Systemic Symptoms (DRESS) syndrome is a potentially life-threatening idiosyncratic drug reaction. Although liver involvement is the most common manifestation, cardiac association varies between 4 % and 21%.



CRM images. Upper panel (A) shows short axis slices during acute presentation (ischemia, edema, late gadolinium enhancement). Lower panel (B) indicates definitive myocardial involvement (late gadolinium enhancement).

Case: A 17 years old female presented in the emergency room for progressive dyspnea that started 5 days before admission. She has history of recently diagnosed minocycline-induced DRESS syndrome (severe exfoliative dermatitis, eosinophilia, liver, lung and renal involvement) with 6 months systemic steroids treatment completed 2 weeks before symptoms onset. Minocycline was given for Acne Vulgaris treatment. Physical exam at admission revealed signs of heart failure (HF). Initial electrocardiogram detected 1 mm ST-T elevation segment in DII-DIII-AVF-V5-V6 and 2 mm ST-T depression segment in V2-V3. The coronary angiography performed showed normal coronary arteries. Cardiac biomarkers were above normal range: Troponin I (TnI) 949 mg/l (normal: < 0.01 mg/L) and Pro- hormone of basic natriuretic peptide (pro-BNP) 6.388 pg/ml (normal: < 72.3 pg/ml). A transthoracic echocardiogram revealed akinesia of mid and basal segments of the inferior, inferolateral and inferoseptal walls that compromised left ventricular systolic function (LVEF: 30%) and generated a severe functional mitral regurgitation (MR). She was admitted with diagnosis of HF secondary to probable myocarditis and treatment with intravenous diuretics and vasodilators was initiated. Cardiac magnetic resonance (CMR) with gadolinium was performed to approach an etiological diagnosis. Intramyocardial edema, endocardium perfusion defect and late gadolinium endomyocardial enhancement from basal to apical segments from the inferior, inferolateral, inferoseptal walls were observed. LVEF was 25.2 %. The case was interpreted as an acute necrotizing eosinophilic myocarditis (ANEM) and immunosuppression was added to HF conventional treatment. After 2 weeks of medical treatment she was discharged with undetermined TnI and pro-BNP of 1800 pg/ml. Two months later a new CMR revealed late gadolinium endomyocardial enhancement from basal to apical segments from the inferior, inferolateral and inferoseptal walls. Some areas of transmural myocardial enhancement and mid inferolateral wall aneurism with mild MR were observed. LVEF was 46 %.
Problem: Although endomyocardial biopsy (EMB) is the gold standard for ANEM diagnosis, a sampling error due to the patchy nature of inflammation and necrosis can limit diagnosis. If we had a negative EMB, would we deny immunosuppressive treatment to this patient?
Conclusion: Unlike the rest of myocarditis, ANEM frequently involve the endomyocardium. Though not specific, CRM is very sensitive to both structural and functional changes. Considering that EMB sensitivity is not good, a CRM with late gadolinium enhancement ANEM pattern in patients with DRESS syndrome should be enough to initiate immunosuppressive treatment.

Acute Heart Failure - Treatment

Bail out strategy: sacubitril/valsartan in de novo heart failure with reduced ejection fraction

SI James[1]; B Mcadam[1]
[1]*Beaumont Hospital, Cardiology, Dublin, Ireland*

Mr PW, 52 years old, airport baggage handler, with no prior medical history presented with progressive 4 months history of shortness of breath to the emergency department. He complained of shortness of breath at rest, sleeping on 4 pillows, and had been wakening up in the middle of the night really short of breath (NYHA IV). He has no family history of heart disease. He is an ex-smoker with 10-pack year history, does not take alcohol and lives alone. Clinical examination revealed a very dyspnoeic patient with cold extremities and raised JVP. His initial assessment showed a BP of 129/86mmHg, HR 127bpm, temperature 37.1 degree Celsius, and respiratory rate of 15 breath/minute with peripheral oxygen saturation of 93% at room air. Auscultation normal heart sounds, with reduced air entry and mild crepitation at mid-basal lung field. No sacral or pedal oedema noted. ECG was normal. Chest x-ray showed cardiomegaly with vascular congestion. His initial blood panel revealed normal full blood count, inflammatory marker, renal and liver blood tests. NT-proBNP was raised at 7097pg/ml. Fasting glucose was 8.2mmol/L with Hb1AC 44mmol/mol. TTE showed severely dilated cardiomyopathy with LVIDd of 7.2cm and LVEF of 15-20%. There was a suspicious mass in the LV suggesting thrombus. He was immediately commenced on IV furosemide and milrenone for inotropic support. He was commenced on ramipril, eplerenone and bisoprolol. Day 6 into admission, he continues to be in low output state. Ivabradine was added. He was commenced on rivaroxaban upon confirmation of LV thrombus. Despite all medical therapy, he was still having symptoms of dyspnoea at minimal exertion and severe fatigue. As a last attempt, sacubitril/valsartan 24/26mg was introduced on day 13. The milrenone and furosemide infusion was successfully weaned off by day 21. He was linked in with Heart Support Unit team prior to discharge on day 28. Diagnostic angiogram showed only minor coronary artery disease. CMR was done and cine images showed global hypokinesia with severe biventricular impairment of LVEF 12%. The EGE confirmed focal distal LV thrombus and the LGE revealed septal mid-wall fibrosis. His followup CMR showing LVEF improvement to 61% and the apical thrombus has resolved. He is currently on maximum dose of sacubutril/valsartan 103/97mg. Important differential diagnoses to consider are giant-cell myocarditis, severe infective myocarditis and infiltrative cardiomyopathy. CMR helped to establish the diagnosis of non-ishaemic DCM and rule out infiltration and myocarditis. In a low output state, maximising gold standard medical therapy can be challenging. Concomittant use of ivabradine has been shown to improve heart rate and cardiac index. The authors acknowledge that the off-label use of sacubutril/valsartan in this patient was outside of the guidelines. The implication of this early use of sacubutril/valsartan is still unknown and as such this patient's case will be closely monitored.

P636
An unusual cause of hypoxemia in acute heart failure

P-H Peter-Hans Tolen[1]; L El Bouazzaoui[1]; IB Van Der Bilt[1]; JWJ Vriend[1]
[1]*Haga University Hospital, cardiology, The Hague, Netherlands*

Introduction: Hypoxemia is often encountered in acute heart failure patients due to pulmonary congestion. We report a patient with an unusual cause of hypoxemia in the setting of a (semi-)acute myocardial infarction and heart failure.
Case report: This case presents a 75-year old male with a history of an ischemic cardiomyopathy and ICD-implantation due to late ventricular tachycardia. He was presented to the emergency room with feelings of becoming unwell and chest pains. Physical examination showed normal hemodynamics except a severe desaturation, a high central venous pressure and peripheral edema. His ECG showed a sinus rhythm with pathological Q-waves inferior and ST segment changes suggestive of a semi-acute inferolateral myocardial infarction. Laboratory results at admission showed an elevated troponin T (4.220 ug/l) and CK (826 U/l). His ICD readings showed no signs of rhythm disturbances. Emergency transthoracic echocardiography revealed a reasonable left ventricular systolic function and a moderate right ventricular systolic function with dilatation. He had an unexplained hypoxemia. Chest X-ray showed no pulmonary congestion. A CT-scan was performed which was unremarkable, especially no signs of pulmonary embolism. A pulmonologist was consulted, but could not explain the hypoxemia.
He was admitted to the ICU and received intravenous diuretics and Optiflow. Despite this treatment, his clinical condition deteriorated. Additional transesophageal echocardiography with agitated saline showed a dilated right ventricle with a poor systolic function and a right to left shunt due to pulmonary hypertension with high right ventricular filling pressures, and a persistent foramen ovale creating an Eisenmenger syndrome physiology. The patient was treated with iloprost inhalations to decrease his pulmonary vascular resistance, leading to a decrease in the right ventricular afterload. He was also treated with milrinone, which is a prostaglandin phosphodiesterase-3 inhibitor, creating an increase in contractility of the ventricles and vascular dilatation, which decreases the afterload and improving cardiac output. After treatment with iloprost and milrinone, he showed a steep increase in saturation and an improvement in hemodynamics. Once hemodynamically stable, patient could be transferred to the general department of cardiology. Unfortunately he had a delirium and due to his comorbidities and a late myocardial infarction it was decided to treat him conservatively. After stabilisation, he was transferred to a rehabilitation centre.
Summary: We report a 75-year old male with a semi-acute inferolateral myocardial infarction complicated by severe hypoxemia due to acute heart failure, which could not be explained by pulmonary congestion on the chest X-ray. Once pulmonary embolism is excluded, we suggest further examination for a (intra)-cardiac shunt in which a transesophageal echocardiogram is superior to a transthoracic echocardiogram.

P637

Successful application of extracorporeal membrane oxygenation in woman after childbirth

N S Piatrovich[1]; L G Shestakova[1]; Y P Ostrovsky[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Department of extracorporeal blood circulation, Minsk, Belarus*

A 22 year-old patient(without any problems before)on ventilation with progressive cardiovascular failure,pulmonary edema in early postpartum period(cesarean section,extirpation of the uterus with fallopian tubes).Massive hemorrhage,4 episodes of ventricular fibrillation with cardiopulmonary resuscitation were observed in perioperative period.Inotropic support:dobutamine 10mcg/kg/min,epinephrine 0,3mcg/kg/min,noradrenaline 0,9mcg/kg/min). Acid-base state:pH 7,18, pO2 49,1mmHg, pCO2 31,4mmHg, SaO2 66,4%, lactate 16mmol/l, BE -15,5mmol/l.Peripheral veno-arterial extracorporeal membrane oxygenation was applied.Clinical and instrumental signs of pulmonary edema gradually increased.We carried out atrioseptotomy,intraaortic balloon pump and drainage of LV during the first day. Inotropic support was stopped on the third day but suddenly we observed neurological deterioration(lamellar dural hematoma).The patient received an adequate therapy and was extubated on the 7th day.On the 10th day ECMO was explanted because of laparotomy due to bleeding into abdominal cavity. IABP was stopped the next day.Hemodynamics remained stable, cardiac contractility significantly improved.On the 13th day the patient was transferred to the gynecological department. Problems:1)Desaturation of coronary,cerebral blood flow and aggravation myocardial insufficiency can be observed during peripheral ECMO. 2)Chronic volume LV overload can cause pulmonary edema. Discussion:1)It is important to maintain residual LV pumping function and oxygenating ability of lungs.2)ECMO management includes thorough selection of heparin dose.
Conclusions: The presented case demonstrates successful usage of extracorporeal membrane oxygenation as a component of cardiopulmonary resuscitationim catastrophic conditions.

P638

Optimization of pressure setting during adaptive servo ventilation support using overnight pulse-oximetry: case report

Y Yasushi Tanaka[1]
[1]*Yodogawa Christian Hospital, Osaka, Japan*

Background: Adaptive servo ventilation (ASV) therapy is a recently developed non-pharmacological therapy that has been reported to improve cardiac function and survival in patients with severe congestive heart failure (CHF).
However, a recent large randomized study suggested that ASV therapy at relatively higher pressure setting worsens some of patients prognosis compared with optimal medical therapy. On the other hand, It is well-known that overnight pulse-oximetry derived high oxygen desaturation index (ODI) predicted mortality in patients with CHF. Therefore, we examined optimal pressure settings of ASV therapy using overnight pulse-oximetry.
Case presentation
We present the case of a 80-year-old female with CHF, which was caused by right heart failure, who was admitted to our institution for dyspnea. The acute phase treatments according to the guideline-based standard medical therapy and Noninvasive positive pressure ventilation (NPPV) therapy resulted in improved congestive conditions. Then, we performed ASV therapy in terms of the default settings [peak end-expiratory pressure (PEEP) 5 cm H2O] instead of NPPV therapy. But we reperformed NPPV therpy, as CHF was worsened. We performed ASV support test, during which PEEP settings were set at levels ranging from 2 to 6 cm H2O using overnight pulse-oximetry for this patient's care. Considering the ODI of patient, PEEP of 4 cm H2O would be optimal pressure setting at least in this case.
Conclusions: Our case report was the first to use overnight pulse-oximetry to examine optimal pressure settings of ASV therapy in patients with CHF.

Coronary Artery Disease - Treatment

P639

Great improvement of systolic function of left ventricle in patient with chronic total occlusion of left anterior descending artery and ischaemic cardiomyopathy

MI Marta Izabela Kaluzna-Oleksy[1]; WS Skorupski[1]; ML Lesiak[1]; MJ Janus[1]; WS Skorupski[1]; ML Lesiak[1]
[1]*Poznan University of Medical Sciences, Ist Department of Cardiology , Poznan, Poland*

A 46-year-old man was admitted to our cardiology clinic with symptoms of severe chronic heart failure. The exertional dyspnea has emerged six months earlier but has been identified as associated with respiratory tract infection and treated with antibiotics without success. Over the following months, fatigue, exercise intolerance and dyspnea were increasing. On admission patient presented with NYHA class IV with tachycardia, tachypnoe and legs oedema. Blood pressure (BP) was 140/80 mmHg. In electrocardiogram sinus rhythm 150 bpm and signs of previous myocardial infarction of antero-lateral wall were observed. Laboratory tests showed elevated, but not significant for acute ischaemia, troponin level - 0,086 ng/mL, and elevated level of brain natriuretic peptide NT-proBNP - 7671,6 pg/mL. Echocardiography revealed with left ventricular end-diastolic diameter (LVEDD) enlargement - 68 mm, global hypokinesis of the left ventricle (LV) walls with left ventricular ejection fraction (LVEF) about 10%. Coronary angiography showed a chronic total occlusion (CTO) of left anterior descending coronary artery (LAD) and significant stenosis (75%) in right coronary artery (RCA). Cardiac magnetic resonance imaging (CMR) showed transmural enhancement in the apex and all apical segments, subendocardial enhancement within the medial segment of anterior wall and anterior part of intraventricular septum (IVS) > 75% of the thickness of the wall (= 3 mm viable myocardium), subendocardial enhancement within the medial segment of lateral wall and posterior part of IVS < 50% of the thickness of the wall (>5mm viable myocardium). The decision to perform in the first line the revascularization of LAD was taken. Successful PCI of CTO of LAD with bioabsorbable everolimus-eluting stent implantation was performed. Improving in the clinical symptoms was observed. Patient was discharged from hospital in stable clinical sate (NYHA II, without angina). After one month (next-step therapy) the PCI of RCA with bioabsorbable everolimus-eluting stent implantation was performed. In the following months significant reduction in the symptoms of heart failure (NYHA I/II), as well as increase of LVEF (up to 37%) were observed, what was confirmed in CMR.
Conclusion: The revascularization of CTO in the area of viable myocardium is often performed. In many patients it reduces the symptoms of ischemia. The effect on the improvement of left ventricular systolic function and survival of the patients is not objectively proven in large clinical trials. We report on the case where great clinical benefit after the full revascularization with PCI of chronic occlusion of the LAD (without clear sing of viable myocardium) was observed.

Myocardial Disease - Clinical

P640

Acute deterioration of the hypertensive heart disease in the patient with the paraganglioma of the urinary bludder

O V Olga Blagova[1]; IN Alijeva[1]; EA Bezrukov[1]; LI Ippolitov[1]; GV Polunin[1]; EA Kogan[1]; AV Nedostup[1]; EA Mershina[2]; VE Sinitsyn[2]; VV Fomin[1]
[1]*I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation*; [2]*Roszdrav Medical Rehabilitation Center, Moscow, Russian Federation*

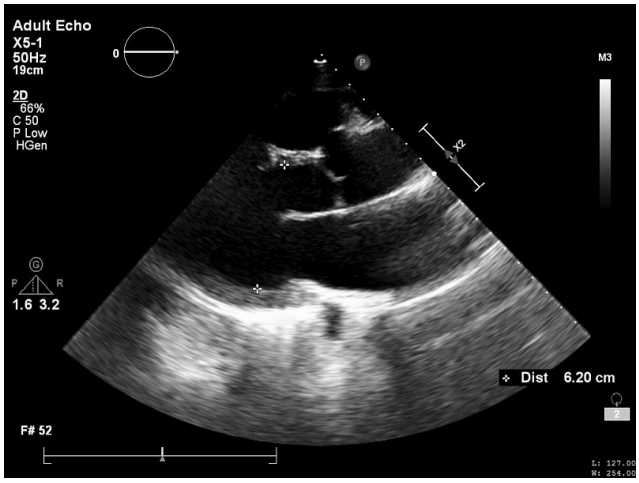
Background: Hypertensive heart disease with acute biventricular cardiac failure is not common in clinical practice. This diagnosis requires an extensive diagnostic search aimed at excluding primary myocardial diseases.
Purpose: to describe the difficulties in diagnosis of rare causes of decompensated hypertensive heart disease and results of complex treatment of this patient.
Methods: We present the clinical case of the male patient 38 years old. He comes in the clinic with acute cardiac failure 3-4 NYHA class appeared within ten days. His mother suffered from hypertension and died at the age of 70. He had no history of heart disease, except for episodic recording of high blood pressure (up to 220 and 140 mmHg) over the past two years. The complex investigation included ECG, EchoCG, thoracic radiography and computed tomography (CT), magnetic resonance imaging (MRI), scintigraphy with 131I-MIBG and also level of anti-heart antibodies and adrenal hormones detection, cutaneous test with tuberculin antigen.
Results: EchoCG revealed symmetric hypertrophy of the left ventricle to 18 mm without its dilatation, a decrease EF to 42%, restrictive hemodynamics, overload of the right chambers, severe pulmonary hypertension (60 mm Hg). The clinical status also included persistent arterial hypertension (180-220 and 120-150 mm Hg), effusion in both pleural cavities and pericardium, ascites, renal failure (creatinine at 2.0 mg / dL), microhematuria, malignant hypertensive retinopathy. During examination (CT, MRI, scintigraphy with 131I-MIBG), bladder paraganglioma was diagnosed (urine normatenafrin 1468 μg / day). No data were obtained for pulmonary embolism, hypertrophic cardiomyopathy, sarcoidosis, amyloidosis of the heart, myocarditis, takotsubo syndrome, Fabry's disease (study of the level of anti-heart antibodies, CT, cardiac MRI, subcutaneous adipose tissue biopsy, XGAL gene study), tumors of other localization. On the background of drug therapy, resection of the tumor was performed, with ismunohistochemical research - neuroendocrine carcinoma, G1. After three months of irregular drug therapy with doxazosin, beta-blockers, furosemide, calcium antagonists, a partial regression of hypertension and cardiac failure was noted with the preservation of a high level of creatinine.
Conclusions: The paraganglioma of the urinary bludder is the very rare cause of malignant arterial hypertension, that may by the sole manifestation of tumor. The differential diagnosis of the hypertensive heart disease and the syndrome of primary myocardial hypertrophy is not easy. The complex mechanisms of myocardial damage within the pheochromocytoma can lead to acute development of biventricular heart failure. The radical resection of the tumor is the main method of the treatment, which leads to lower blood pressure, however, heart failure may be irreversible.

P641

A case of late cardiac toxicity and CKD stage 4 related to chemotherapy and radiotherapy for acute leukemia treated with sacubitril/valsartan

A Alexander Valerievitch Nossikoff[1]; K Angeloff[1]; P Ilieff[1]; G Lazarova[1]; T Donova[1]
[1]*University Hospital "Lozenets", Cardiology, Sofia, Bulgaria*

A 25-year old male presented to our unit with symptoms and signs consistent with de novo NYHA III heart failure. Past medical history was remarkable for chemotherapy and total body radiation followed by allogenic bone marrow transplantation at age 16 due to T-cell leukemia. There have been no signs of disease activity since then. He was left with CKD, which is stage 4. He was followed up for cardiotoxicity until 4 years ago and his echocardiograms were normal.
The apical beat was laterally displaced, there were S3 and bibasal crackles on auscultation. Jugulars were not distended. Liver was mildly enlarged. EKG revealed NSR, QRS of 100msec, LAA, LAHB, LVH and strain.
Patient was admitted: Echocardiography revealed dilated LV with EF of 25%. The IVC was plethoric and there was small right-sided pleural effusion. The transmitral flow was restrictive. His creatinine was 320 umol/L, corresponding to eGFR of 22ml/min/1.73m2. BNP was elevated at 1165 pg/dl, hsTnI was normal, rest of labs unremarkable. We commenced torasemide with full and rapid decongestion achieved. The IVC became with normal dimensions and respiratory movement, which was against concomitant pericardial constriction. Metoprolol succinate was commenced and tolerated well. Patient was discussed on multidisciplinary meeting, diagnosis of late cardiotoxicity due to chemo- and radiotherapy was agreed. We decided to titrate very low dose ARNI under close follow up of renal function. We started with 12/13mg a day and titrated the dose every 2 weeks by another 12/13mg to our target of 2x24/26mg, which was well tolerated by the patient. We titrated the metoprolol up to 2x50mg. There was no evidence of worsening renal failure or hyperkalemia. His functional capacity improved and he is now asymptomatic during all day-to-day activities. Metoprolol will be titrated to maximum tolerated dose and LV EF will be reassessed once he has been on optimal medical therapy for 3 consecutive months. Due to high risk of contrast induced nephrotoxicity we refrained from coronary angiogram.
Conclusions: Late cardiotoxicity after chemo- and radiotherapy is a possible complication and its incidence is likely to increase with the improved survival of patients treated for malignancy. Patients with HF and concomitant severe CKD present a therapeutic challenge as the evidence on use of ACEI/ARB is unclear in this setting due to increased risk of worsening renal function and hyperkalemia. Sacubitril/valsartan is considered to have favourable cardiorenal profile compared to ACE-inhibitors, but has not been prospectively studied in eGFR < 30ml/min/1.73m2. In contrast, metoprolol succinate is safe due to its liver metabolism. EMA label allows cautious use of sacubitril/valsartan in HF patients with eGFRs of 15-30ml/min/1.73m2, which we have done in this case with a favourable clinical outcome. More data is needed on ARNI for this patient subgroup so we can be more confident in its use.



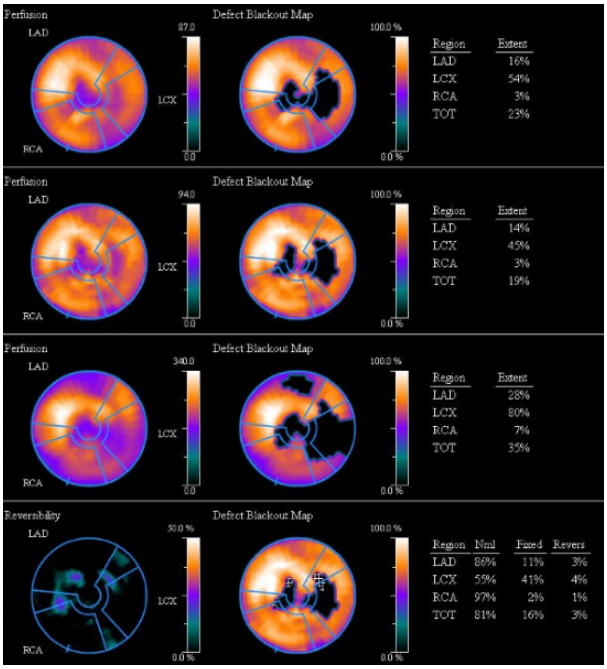
62mm LVEDD from 2D PLAX

P642

A new mutation causing arrhythmogenic right ventricular cardiomyopathy with atypical presentation

A Alberto Aimo[1]; A Barison[2]; GD Aquaro[2]; U Startari[2]; G Vergaro[2]; M Emdin[1]
[1]*Sant'Anna School of Advanced Studies, Pisa, Italy*; [2]*Gabriele Monasterio Foundation, Pisa, Italy*

A 38-years old woman with referred familiarity for myocardial infarction (MI) was admitted to an Emergency Department because of chest pain. While biomarkers of myocardial necrosis and B-type natriuretic peptide were normal, and the electrocardiogram showed only a right ventricular (RV) conduction delay, transthoracic echocardiogram revealed diffuse left ventricle (LV) wall motion abnormalities and an apical aneurism. A coronary angiography demonstrated a normal coronary tree, leading to the diagnosis of "unstable angina with normal coronary arteries, possible prior MI."



A rest and stress myocardial perfusion imaging with 99mTc-sestamibi was negative for inducible ischemia, but showed "evidence of prior myocardial infarction (MI) in the anterior and apical regions of the LV." Even the findings at cardiac magnetic resonance (CMR) were deemed "compatible with previous MI" because of late gadolinium enhancement in the apical and inferolateral LV segments, and the thinning of LV apex. The RV was overlooked.

After discharge, a re-evaluation of CMR findings at another institution raised the suspicion of arrhythmogenic right ventricular cardiomyopathy (ARVC). Gene sequencing allowed to find homozygosity for the c.428 T>A mutation in the desmoglein gene (DSG2). Although not previously reported, this was considered a pathogenic variant as it produces a stop codon, which blocks protein synthesis after inclusion of 143 amino acids instead of 1119. A definite diagnosis of ARVC was then made (two major criteria: CMR findings and a pathogenic mutation).

Considering the ventricular ectopic burden (over 6000 ectopic beats during the 24 hours, with 100 couplets), the patient underwent mapping and ablation of an arrhythmogenic focus located into the LV apex. She then repeated the CMR examination. The reader found "diffuse regional wall motion abnormalities and alterations of signal intensity within both ventricles, suggesting multiple, large areas of fibrofatty replacement." A single chamber defibrillator was eventually implanted for primary prevention. Cardiologic assessment and genetic screening of other family members is currently underway; the c.428 T>A mutation and CMR abnormalities have already been found in the patient's sister.

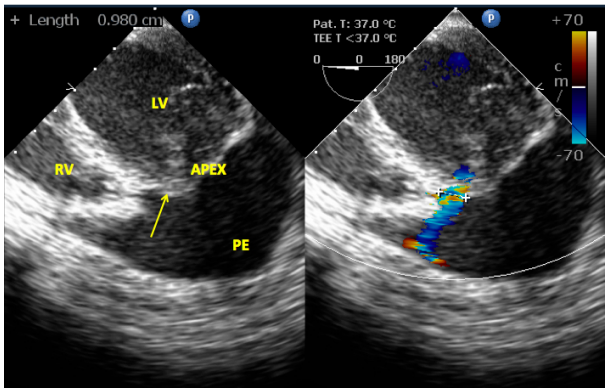
This is the first report of the c.428 T>A mutation as the cause of ARVC. It also demonstrates that the clinical and imaging presentation of ARVC may be misleading, so that a high index of suspicion is needed to come to the correct diagnosis.

P643

Left ventricular free wall rupture with pseudoaneurysm formation from penetrating cardiac injury

J P Rangel[1]
[1]*Philippine Heart Center, Adult Cardiology, Manila, Philippines*

Background: Left ventricular free wall rupture is a catastrophic complication of stabbing injuries and is associated with a high mortality rate due to pump failure. The majority of patients present with pericardial tamponade and subsequent exsanguination. Left ventricular pseudoaneurysms are uncommon but develop when cardiac rupture is contained by adherent pericardium and scar tissue. Diagnosis by chest radiograph and transthoracic echocardiogram are the most readily available imaging modalities in the emergency setting to diagnose these complications.



Intraoperative Transesophageal Echo

Presentation: A 27-year old male was admitted after sustaining a stab wound on his left anterior chest at the 4th anterior axillary line. He was rushed to a nearby hospital and managed as a case of hemothorax and pericardial effusion then underwent chest tube and pericardiostomy tube insertion. Despite twenty-three days since pericardiostomy tube, pericardial fluid drainage was still noted with febrile episodes accompanied by dyspnea, two to three pillow orthopnea and mild edema.

Imaging Findings: Chest radiograph showed moderate ascending pleural based density in the left hemithorax, true cardiac size could not be ascertained with minimal contralateral shift of mediastinal structures. Electrocardiogram initially showed sinus rhythm with anterolateral wall ischemia with episodes of ventricular tachycardia and ST segment elevation. Intraoperative transesophageal echocardiogram revealed penetrating anterior left ventricular wall injury with localized massive pericardial effusion, hematoma formation and possible pseudoaneurysm formation. Chest CT scan confirmed findings of contained rupture of the left ventricle with pseudoaneurysm. He underwent urgent primary repair of left ventricular injury and pseudoaneurysm with evacuation of hematoma.

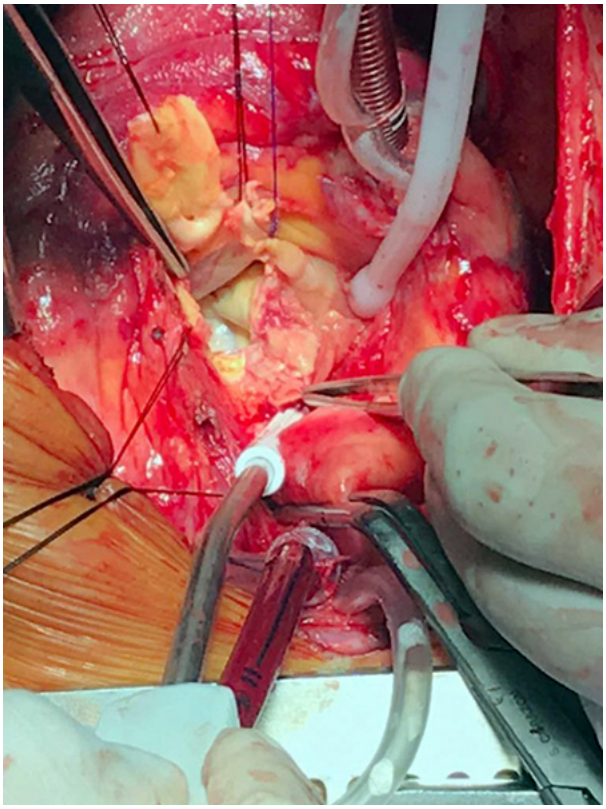
Conclusion: We presented a complicated case secondary to a stab wound injury. The patient completed antibiotics and was discharged stable. Diagnosis of left ventricular rupture and pseudoaneurysm formation is very challenging. Imaging modalities can supplement the index of suspicion and physical examination findings. The mortality rate for penetrating cardiac injuries range from 19% to 65% in several studies. Timely surgical repair therefore remains the cornerstone for management.

P644

A clinical rarity: Austrian syndrome (endocarditis, meningitis and pneumonia caused by Streptococcus pneumoniae), based on a clinical case.

CL Carlos Luis Gonzalez[1]; LN Gil[1]; MF Acosta[1]; FJ Estevez Traversi[1]; C Perea[1]; DA Pranteda[1]; LA Miserque[1]; JP Cattaneo[1]; G Di Giorno[1]; ER Catena[1]; G Vizcarra[1]; S Budelli[1]; L Saglietti[1]; CM Muzzio[1]; V Gregorietti[1]
[1]*Sanatorio Sagrado Corazón, Cardiology, Buenos Aires, Argentina*

Introduction: We present the case of a patient with endocarditis caused by Streptococcus pneumoniae. The patient also experienced meningitis and pneumonia caused by the same germ, suffering from the triad described by Robert Austrian. The syndrome generally affects the aortic valve and it is currently regarded as a clinical rarity.



Aortic annulus and abscess

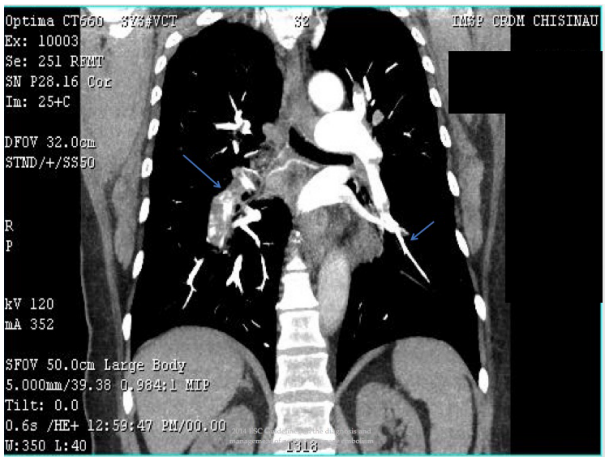
Case: 52 year old male patient, under enalapril and amlodipine treatment for hypertension. No history of cardiovascular disease. The patient was admitted to the emergency room in a state of disorientation and consciousness impairment.
The physical exam showed a blood pressure of 80/30 mmHg, heart rate of 105 bpm. Breathing rate of 20 rpm, temperature of 39.8°C. Bradypsychia, disorientated, and positive Kerning sign.
Blood test showed anemia, acid-base status reflecting metabolic acidosis with respiratory alkalosis. Blood cultures for Streptococcus pneumoniae were performed. Cerebrospinal fluid with Streptococcus pneumoniae growth was cultured. Positive latex test for the same germ.
Imaging: Chest CT showed bilateral laminar pleural effusion. Bilateral images in ground-glass, with reticular and nodular opacification. Transesophageal echocardiogram with broadly unstructured aortic valve with multiple associated masses and severe reflux. Abscess in the aortic root with discrete expansion of the left coronary sinus. Degenerative and mildly deteriorated mitral valve.
Evolution: Antibiotic treatment with ceftriaxone/vancomycin was administered. The patient evolved with signs of heart failure and subsequent tachypnea, inotropic drugs were required; poor ventilation mechanics leading to mechanical ventilation. A Swan Ganz catheter with mixed measuring pattern (distributive-cardiogenic) was placed.
The case is now diagnosed as septic shock that started in the central nervous system with lung (pneumonia) and endovascular (severely compromised aortic valve) impacts. The cardiovascular surgical team performed an emergency procedure. A No. 23 cryopreserved aortic homograft was implanted.
As a complications the patient presented cardiac tamponade that requiere surgery to remove blood clots in the mediastinum and bilateral pleural drainage due to effusion. The patient evolved favorably, was transferred to the clinical medicine service and several days later discharged from hospital.
Conclusion: Nowadays, Streptococcus pneumoniae accounts for less than 1% of endocarditis, although its mortality rate cannot be undermined. Concurrent onset of endocarditis, meningitis and pneumonia was described by Austrian proving this mortal triad in 1957. This syndrome evolution is often severe and highly aggressive, with complications such as, aortic cusps rupture and puncture and subsequent cardiac failure, myocardial abscesses, septic arthritis and glomerulonephritis. The case that we are presenting shows a clinical case with a very low incidence but increased mortality, even when fast and appropriate treatment is administered.

Autoimmune/Chronic Inflammatory Disorders and Heart Disease

P645
Upper limb vein thrombosis and pulmonary embolism in a HIV infected patient

I Irina Cabac Pogorevici[1]; V Revenco[1]
[1]*State University of Medicine and Pharmacy, Cardiology, Chisinau, Moldova Republic of*

A 32 year old caucasian male, known with congenital heart disease (i.e. biscupsid aortic valve), a positive history of HIV and drug and steroids abuse, presented to the emergency room, complaining of shortness of breath, repeated syncopes, progressive generalised oedema, oliguria for the past 2 weeks. During the 8 weeks before admission, hospitalized to a regional clinic with acute deterioration of the renal function requiring haemodyalisis. He was discharged with clinical and haemodinamical improvement, but shortly quiting the prescribed therapeutical regimen. Physical exam at admission showed hyperstenic appearance (BMI 29), audible S3 gallop, massive oedema, elavated jugular preassure, generalized cyanosis, predominantly in the upper body, multiple pulmonary crackles and abolished respiration basal bilaterally, SpO2 76 %. ECG revealed incomplete right bundle branch block, SIQIII axis, signs of right atrial and ventricular strain. The transthoracic echocardiography reported severely dilated left ventricle, with a moderately reduced ejection fraction and an apical thrombus, moderately dilated right heart with considerably elevated pulmonary artery pressure (75 mmHg). The abdominal ultrasound unveiled ascites, hepatomegaly and splenomegaly, hepatic congestion, normal looking kidneys and bilateral pleural effusion, confirmed by the chest x-ray. Doppler ultrasonographic scan of the upper limbs showed absent color flow and thrombotic masses in left basilica, subclavia and jugular veins. Thoracic CT exam found trombi in the main, segmental and sub-segmental pulmonary arteries, indicating a high probability of pulmonary embolism. Pleural liquid analysis was unremarkable.
The blood analysis showed elevated serum creatinine (147.46 mcmol/l), with a GFR 53.6 ml/min/1,73 m2, normal hepatic enzymes, positive D-dimer. General blood analysis showed anemia (hb 91 g/l), normal platelets levels and moderate lymphopenia. CD4 - 1948, ARN HIV 40 c/ml. Antiretroviral therapy with Lamivudin and Dolitegravir was initiated alongside with anticoagulation with Fondaparinux 7,5 mg od, NOAC in recommended therapeutic doses (Rivaroxaban 15mg bid). After 14 days dispneea and cyanosis subsided, and he was discharged on therapeutic doses of NOAC (Rivaroxaban 15mg bid three weeks followed by 20 mg od, indefinetely).
Conclusions: The clinicopathologic pattern related to HIV is encumbered with a spectrum of hypercoagulability states leading to thromboembolic complications.



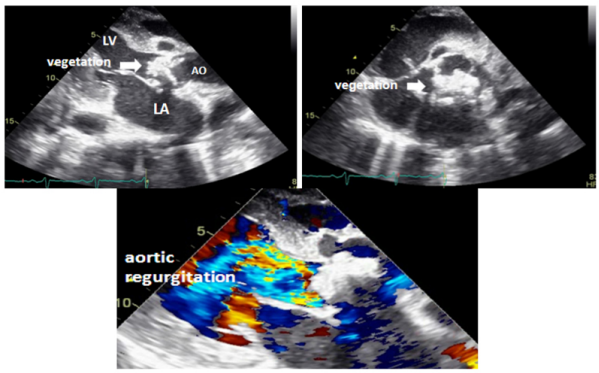
Physicians treating HIV positive patients should keep in mind that not only opportunistic infections and malignancies are following this chronic state but also less expected events such as thromboses, especially concerning younger individuals who do not meet the classical VTE risk factors. Concerning the anticoagulant treatment a special attention should be paid to potential interactions between warfarin and antiretrovirals, eventual bleeding complications could be mitigated by prescribing a NOAC regimen.

Valvular Heart Desease - Treatment

P646
Right sided heart failure in a aortic valve endocarditis caused by Campylobacter fetus

O Pachirat[1]; D Kaewkes[1]; S Pathani[1]
[1]*Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand*

Case description: A 45-year old male, poultry farmer presented with high fever, cough, chest tightness and bilateral ankle swelling for two weeks at his primary care provider with diagnosis of massive pericardial effusion impending cardiac tamponade requiring drainage and possible infective endocarditis. Pericardial fluid culture was negative. The patient had no significant medical history. He was transferred to our cardiac center for evaluation. On examination: temperature 39°C, BP 100/50 mmHg, heart rate 105 bpm. regular, a grade IV/VI diastolic blowing murmur at left lower sternal border and grade III/VI systolic ejection murmur at AVA was detected with both basal pulmonary crackles. Three sets of blood cultures were done. A transthoracic echocardiogram (TTE) revealed large vegetation on the aortic valve with severe aortic regurgitation and moderate aortic stenosis, bicuspid valve, normal left ventricular function and no evidence of pericardial effusion. Intravenous ampicillin and gentamicin were begun on admission. However, clinical of congestive heart failure worsened and the patient developed cardiogenic shock. He underwent urgent aortic valve replacement. Three sets of blood cultures were negative.



Echocardiographic features

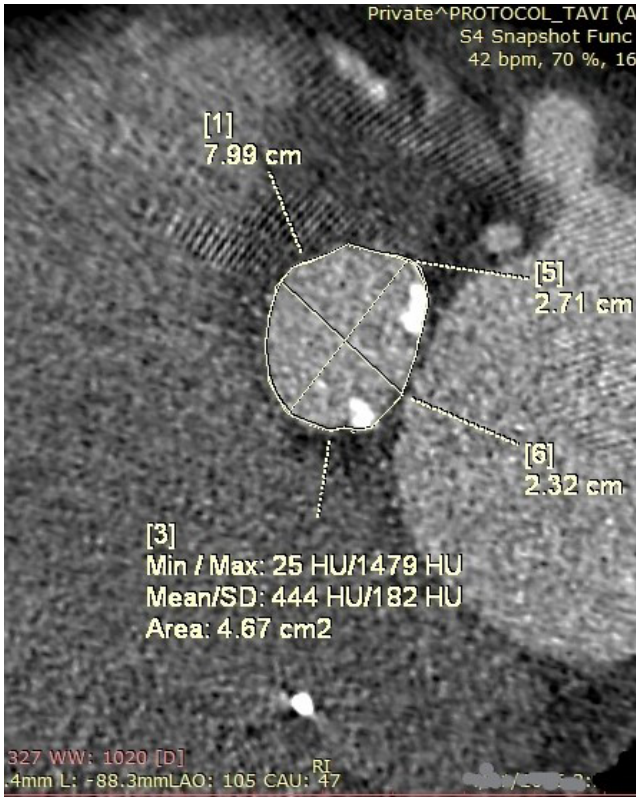
Possible differential diagnosis: In this scenario, (blood culture negative endocarditis) two main possibilities need to be differentiated: (1) the patient received antibiotics before blood was cultured (2) it was fastidious organisms such as Bartonella spp, Coxiella burnetii and Chlamydia. Campylobacter fetus was demonstrated in heart valve tissue by polymerase chain reaction(PCR). One month after surgery his cardiac condition stabilized and he was discharged from the hospital with good clinical outcome. Two years follow up he remained clinical stable.

Conclusion: C. fetus is a zoonotic and uncommon cause of human infection, mainly affect persons at higher risk and those with occupational exposure to ruminants. This case illustrates an infrequent C. fetus endocarditis associated with large pericardial effusion that might be underdiagnosed in clinical practice and emphasizes aggressive combined antibiotics treatment with early surgical intervention to prevent cardiovascular complications such as heart failure.

P647
One heart, many long-term complications of thoracic radiotherapy for Hodgkin lymphoma

S Albu[1]; A Ionescu[1]; O Mihailescu[2]; B Popescu[1]; D Deleanu[1]; C Ginghina[1]; V Iliescu[1]; O Chioncel[1]; R Jurcut[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*;
[2]*Sanador, Bucharest, Romania*

Introduction: A 60-year old patient with multiple cardiovascular risk factors complains about exertional dyspnea and angina pectoris precipitated by mild effort. At the age of 30, he was diagnosed with Hodgkin lymphoma and he received chemo- and radiotherapy, achieving remission of the neoplasia. His full history of cardiovascular events include: in 2001, persistent atrial fibrillation, which required employment of a pacemaker for antitachycardia pacing; at the age of 53, anterior myocardial infarction with angioplasty and stent implantation at the proximal segment of the left anterior descending coronary artery, at the same time his echocardiogram revealed aortic valve disease- moderate to severe stenosis.



Panel A

Patient management: The progression to severe aortic stenosis was revealed during his follow-up after a couple of years, while the patient was symptomatic by dyspnoea and angina pectoris on light exertion. Coronary angiography was repeated, but no stent restenosis or other significant atherosclerotic lesions, was revealed. His echocardiogram confirmed the aortic valve disease with severe stenosis (mean gradient 50 mmHg, indexed valve area 0.5 cm2/m2) and moderate regurgitation. The association of porcelain aorta was raised as the ascending aorta walls were thickened and calcified. Aortic valve replacement was indicated, with an EUROSCORE of 0,8%.

Questions, problems: In this case, due to the thoracic radiotherapy history and porcelain aorta, the Heart-Team decided it was best for the patient to undergo TAVR. According to angio-CT measurements (Panel A), a 26 mm Edwards Sapien XT valve was selected. He successfully underwent TAVR procedure via a left femoral artery approach.

Conclusion: Advances in radiotherapy over the past decades have improved outcomes in patients with malignancy, but increased longevity has come at the cost of late side effects - radiation-induced heart disease, which may involve any cardiac structure. The role of TAVR as an alternative to surgical aortic valve replacement (SAVR) is well established; one of the contraindications for SAVR, is the so-called hostile chest, including those with expected intrathoracic fibrosis and adhesions secondary to thoracic radiotherapy. In this setting, patients who are not ideal candidates for SAVR, TAVR is a reasonable approach, with high feasibility, acceptable risk, low mortality and high clinical effectiveness.

P648
Aortic valvular endocarditis masked by suspected Lime borreliosis

T Tanja Popov[1]; S Keca[1]; M Sladojevic[1]; M Stefanovic[1]; L Velicki[1]; S Susak[1]; I Srdanovic[1]
[1]*Institute of Cardiovascular Diseases Vojvodina, Novi Sad, Serbia*

Case Report: A 24-year-old female patient was sent to the urgent cardiological examination because of suspected Lime myocarditis. She was previously with good

health, had heart murmur in the childhood, but with no cardiological examination. During examination she said that the disease started about three months previous when she had got a few bites of ticks during picking strawberries. Bites were not accompanied by the local redness of the skin. A few weeks later, she noticed migratory arthritis, felt weakness and shiver. In laboratory analyzes inflamatory markers were elevated (CRP 175 mg/l and SE 100 mm/h), low hemoglobin (HgB 101 g/l). Serological analyzes for Borellia Burgdorferi were negative. She was treated with antibiotics. The infectologist suggests further examination for rheumatic diseases. The general condition of the patient was gradually worsening during a later period, with night sweats, significant weight loss, cough, ankle swelling. Two months later, she was again examined by the infectoligist and immunologist, reffered to repeat serological tests on Borellia B. (Western blot) and immunological tests. In laboratory analysis there was still high CRP 85 mg/l, worsened anemia HgB 86 g/l. She was treated with antibiotics because of bronchitis. Due to the deterioration of the dyspnea three days later, she was referred to the cardiologist because of suspected Lime myocarditis. During examination she was anxious, with dyspnoea, pale skin, an auscultatory rough systolic and diastolic murmur above the aorta, lung crackles, enlarged liver, swollen ankles. She was undergone urgent echocardiographic examination by which was registered bicuspid aortic valve, dilated ascending aorta, aortic cuspises were thickened, with suspected vegetations, and perianular pseudoaneurysms, there was severe aortic regurgitation. MSCT of the aorta shown no dissection. The patient was undergone to urgent surgery. The aortic valve was bicuspid, with tiny vegetations along both velums, which extend to the base of the frontal mitral cusp and subanular to the interventricular septum. There was several fibrotically altered abscesses subanular, and in the area of the interventricular septum. Aortic valve was replaced, with the closure of the abscesses. After surgery she was with complete atrio-ventricular block on the rithm of temporary pacemaker. Three weeks later, permanent pacemaker was implanted. She was discharged in good condition.

Conclusion: Infectious endocarditis can remain unknown for a long time, masked by associated diseases and conditions. When diagnosis and adequate treatment are made on time, serious complications and adverse events can be avoided.

P649

Fulminate endocarditis - complications and therapy

CD Botezatu[1]; D Benea[1]; G Martinelli[2]; G Lanzillo[2]; M Diena[2]; E Onorato[3]; F Armienti[4]; E Stelian[2]; A De Jong[2]; L Zamfir[1]; T Campesato[1]; G Cerin[1]
[1]San Gaudenzio Clinic, Cardiology, Novara, Italy; *[2]San Gaudenzio Clinic, Cardiac Surgery, Novara, Italy*; *[3]Clinical Institute Humanitas Gavazzeni, Bergamo, Italy*; *[4]San Gaudenzio Clinic, Radiology, Novara, Italy*

A 78 years old male patient recovered in cardiogenic shock and acute pulmonary edema is reported. One year ago the patient underwent aortic valve substitution with a biological prosthesis, and in the last 30 days presented non-investigated episodes of fever. A permanent peacemaker for complete atrioventricular block was implanted in another hospital. The patient was transferred to our center due to hemodynamic instability. Echocardiography revealed a periaortic abscess with a perimembranous interventricular septal communication, a vegetation on the aortic prosthesis (18mm length), a second vegetation on the septal cusp of the tricuspid valve (25mm length), small vegetations on the pacemaker's leads and severe mitral regurgitation due to posterior papillary muscle's rupture. Therefore an emergency surgical intervention was performed: aortic and mitral valves substitution with biological prosthesis, tricuspid valve repair, interventricular communication closure with autologous pericardial patch and pacemaker's leads removal. The patient had good outcome with empiric antibiotic therapy. Enterococcus faecalis, the bacteria incriminated for endocarditis, proved to be highly sensitive to the chosen therapy that was continued for 3 months. The patient remained asymptomatic and had normal echocardiographic exams. At six months follow up he complained of new onset dyspnea. Echocardiography revealed severe periaortic valvular leak. The optimized medical therapy didn't improve the clinical status. Blood laboratory exams showed hemolytic anemia with progressive reduction of the hemoglobin. Because of the high surgical risk, the leak was closed with a specific device implanted echo guided through a transfemural approach. The procedure was successful with an asymptomatic patient during follow-up, a well-positioned device and a mild residual leak and no hemolytic anemia. This case illustrates the management complexity of fulminate multiple endocarditis with aortic abscess and ventricular septal defect, associated with pacemaker's endocarditis and cardiogenic shock. Acute heart failure is an obvious indication for surgery performed on an emergency basis. A fulminate endocarditis with multiple valvular localization, periaortic abscess creates tissue fragility with potential devastating acute and late complications. Echocardiography proved to be an important tool in the diagnosis and the management of this case but other imaging techniques as angioCT are necessary. Use of non-surgical procedures may solve late complications in these high surgical risk patients. Results on short term follow-up are encouraging. Longer follow-up is needed to characterize the outcome of these patients.

P650

Cardiac MRI helped for decision making in a patient with ruptured tricuspid valve and severe right ventricular failure

M M Ansari-Ramandi[1]; N Naderi[2]; A Firouzi[2]; AA Ghavidel[2]; H Pouraliakbar[2]; N Rezaeian[2]
[1]Syed Mostafa Khomeini Hospital, Tabas city, Birjand University of Medical Sciences, Birjand, Iran (Islamic Republic of); *[2]Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, Iran (Islamic Republic of)*

A 62 years old man with a car accident history that leaded to a blunt chest trauma in 2002 underwent coronary angiography ten years later due to dyspnea and atypical chest pain. He had normal coronary arteries at that time and on ECG he had atrial fibrillation. He was discharged on digoxin and warfarin and was on medical therapy for the following 5 years until he was admitted in hospital due to anemia and anasarca. On admission he had severe edema and ascites. He was pale and had a systolic murmur at the left sternal border. The laboratory data showed normal renal function and thyroid function. Hemoglobin level was 9.2 mg/dl and there was low level of ferritin and serum Iron. Due to Iron deficiency anemia, stool examination was requested which showed positive occult blood. Before preparation for upper gastrointestinal (GI) endoscopy and colonoscopy, heart specialist consultation and echocardiography were done due to the murmur and edema. Echocardiography showed:
(1)moderate left ventricular systolic dysfunction, (2)severe right ventricular enlargement and dysfunction, (3)flail of anterior tricuspid valve {TV} leaflet and rupture of chordae and severe tricuspid regurgitation, (4)systolic flow reversal in hepatic veins. Systolic pulmonary artery pressure was estimated to be 25mmHG and the TV annulus was 5.5cm. Due to the severe anemia, GI endoscopy and colonoscopy were done which were reported as normal. Red blood cell scan was also done which showed bleeding from the small intestine; the gasteroenterologist believed it was due to the patient's RV failure. After treatment with furosemide, the patient underwent Cardiac MRI for clinical decision making about the need for surgery. Cardiac MRI reported the RV ejection fraction to be about 37% and the patient underwent TV replacement with a tissue valve. Treatment was continued with furosemide and the patient's condition improved over 6 months. His edema diminished and he did not have anemia any longer. This case describes the role of cardiac MRI in clinical decision making for the treatment of ruptured TV and RV failure.

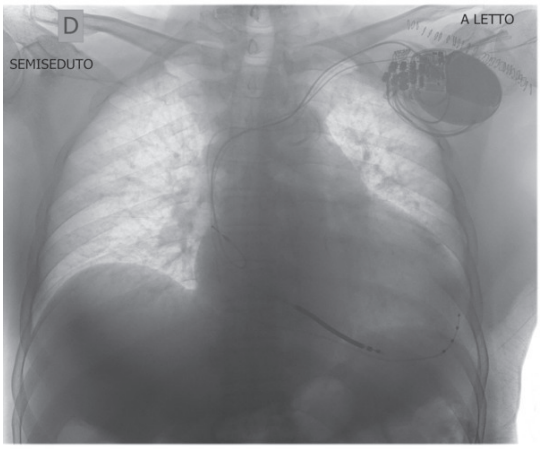
Cardiac Resynchronization Therapy

P651

Absence of the target veins during CRT-device implantation procedure: a simple approach to reduce the failures rate.

N Nikoloz Bakhtadze[1]; O Ornago[1]; C Pandini[1]; N Ashofair[1]; M Colella[1]; R Griner[1]; A Kheir[1]; M Manfredi[1]; P Peci[1]; C Piemonti[1]; S Todd[1]
[1]*San Pietro Polyclinic, Department of Cardiology, Ponte San Pietro, Italy*

CRT-device implantation is an effective and clinically proven option for some patients with HFrEF.
Optimal LV lead placement is dependent on the presence of an acceptable target vein: lateral (marginal) cardiac vein, postero-lateral cardiac vein, posterior cardiac vein. But the absence of the suitable vein/excessive venous tortuosity/unfavorable angle of the desired vein/small (atretic) vein is not a rare finding during retrograde venography.



Chest radiography AP view

A lot of studies published previously reported worse long-term outcomes in case of LV leads placed in anterior (great) cardiac vein.
The aim of our study was to verify and evaluate the possibility of the using of simple periprocedural tricks to avoid LV lead placement in anterior vein. We used the following approach in patients with no lateral vein during retrograde venography: gradual pull back displacement of delivery system with 2-3 injections of the contrast solution (to rule out the presence of postero-lateral/posterior cardiac veins) until direct cannulation of the middle cardiac vein. Using a J-tip guidewire the exploration of distal branches of the middle cardiac vein is performed in LAO (30-45°) to find anastomoses with branches of lateral/postero-lateral/posterior cardiac vein with subsequent over-the wire (OTW) LV lead placement in the target vein via distal branches connections.
Analyzing the results of CRT-device implantations (first/upgrading) performed in our centre in the period from September 2016 to October 2017 we found 5 patients (from 95 pts, 5,3%) in which above-mentioned technique was used. Mean age of these patients was 73,2 ± 4,44 yrs (range 68-79 yrs), M/F 80/20 %, ischemic vs. dilated cardiomyopathy 60/40%, 3 patients had baseline NYHA class II, 2 patients - NYHA class III. Mean EF of LV was 28% (range 25-30 %). In 4 patients (from 5 pts, 80%) our approach was successful, one patient was sent to the cardiac surgeon for epicardial LV lead placement. No major/minor complications were observed. All 4 patients were seen within 2-4 months after hospital discharges. None of them had any hospitalization for worsening of HF, 3 patients had both clinical (NYHA class, 6MWT) and echocardiographic signs of improvement (responders), one patient was sent for AV and VV intervals optimization.
Our data, even if derived from a small number of patients demonstrate simplicity, efficacy (both acute and long-term) and safety of such approach for increasing of success rate of transvenous LV lead implantation and decreasing of CRT-procedures failure.

P652

Influence of advanced age on the response and survival to cardiac resynchronization therapy

L E Camanho[1]; E B Saad[2]; C Slater[2]; LA Oliveira Jr[2]; L Carvalho Dias[2]; R Mourilhe-Rocha[1]
[1]*State University of Rio de Janeiro and Procardiaco Hospital, RIO DE JANEIRO, Brazil*; [2]*Hospital Pro Cardiaco, Electrophysiology and Pacemaker, Rio de Janeiro, Brazil*

Fundamental: cardiac resynchronization therapy (CRT) improves functional class (FC) and reduces total mortality in patients (pt) with advanced heart failure (HF) and depressed ejection fraction (EF). However, current guidelines do not suggest any upper age limit for CRT, but recommended avoidance in pt with a life expectancy less than one year.
Objective: to define the role of advanced age in the survival and response of pt undergoing CRT.
Methods: 250 pt who underwent a CRT were retrospectively evaluated. All presented in FC III/ IV (NYHA). They were divided into two groups: Group I - 92/150 pt (37%) - 75 years or older (< 75 y) and Group II - 158/250 pt (63%) - age less than 75 years. The criteria of response to CRT were: improvement of FC, increase in EF (<10%) and decrease in left ventricular end-systolic diameter (LVESD) - < 15%. The response to CRT and post-implant survival were evaluated in both groups. Statistical analysis was done through exact Fisher Test ($p < 0.05$).
Results: in group I, the mean age was 81.6 years; 73% were male; left bundle branch block (LBBB) was observed in 98% and average QRS duration was 167 ms; average EF: 28%; average LVESD and left ventricular end-diastolic diameter (LVEDD): 53 and 68 mm, respectively. BIV-ICD was observed in 72% of pt. 84% of the patients were responders to CRT and average post-implant survival was 36 months. in group II, the mean age was 61 years; 67% were male; LBBB was observed in 94% and average QRS duration was 166 ms; average EF: 26%; average LVESD and LVEDD: 58 and 72 mm, respectively. BIV-ICD was observed in 82% of pt. 85% of the patients were responders to CRT ($p = 0.13$) and average post-implant survival was 40 months.
Conclusion: despite a higher number of associated comorbidities in elderly pt, advanced age did not directly influence the response to CRT and post-implant survival, and should not be a limiting factor of this therapy.

Implantable Cardioverter / Defibrillator

P653

Possible aborted cardiac arrest in a patient with newly diagnosed non-ischemic dilated cardiomyopathy: reverse remodelling and no need for defibrillator implantation

A Alberto Aimo[1]; A Barison[2]; C Passino[1]; M Emdin[1]
[1]*Sant'Anna School of Advanced Studies, Pisa, Italy*; [2]*Gabriele Monasterio Foundation, Pisa, Italy*

A 60-year old woman with unremarkable medical history fainted while doing her housework. Her husband, a doctor, found that she did not have a carotid pulse, and did two precordial thumps. The woman regained consciousness. When the emergency medical service arrived, her electrocardiogram (ECG) showed sinus rhythm, with an heart rate of 80 beats per minute, and a left bundle branch block, not previously known. After excluding acute brain lesions, an urgent coronary angiography was performed, demonstrating normal coronary arteries. Transthoracic echocardiogram and cardiac magnetic resonance (CMR) showed severe left ventricular (LV) systolic dysfunction (LV ejection fraction - LVEF - 30%, global hypokinesis), and dilatation (LV end-diastolic volume index - LVEDVi - 128 mL/m2 at CMR, reference values 51-91 mL/m2). Non-ischemic dilated cardiomyopathy was then diagnosed. A therapy with angiotensin-converting enzyme inhibitor, beta-blocker, and aldosterone antagonist was started and uptitrated.
Since the syncopal episode was compatible with an aborted cardiac arrest, two 24-hour ECG Holter recordings were performed during the hospital stay. Only 16 ventricular ectopic beats were recorded over 48 hours, with one triplet; there were no conduction disturbances. Heart rate variability was normal, attesting a preserved autonomic balance. In addition, no area of late gadolinium enhancement (LGE) were remarked at CMR. The risk of recurrent arrhythmias was then deemed low. Moreover, a recovery from LV dysfunction and dilatation in response to treatment was expected due to a combination of established predictors of RR: female gender, non-ischemic etiology, and absence of LGE. For all these reasons, and following thorough discussion with the patient, a cardioverter defibrillator was not implanted; the patient refused even a wearable defibrillator.

After three months of clinical stability, the patient underwent a follow-up CMR examination. Her systolic function had improved (LVEF 42%), while LV dilatation persisted (LVEDVi 130 mL/m2). Four months later, her LVEF was 50%, and her LVEDVi (100 mL/m2) approached the normal range. Eight months after this last CMR, the patient feels well.

Guideline-recommended medical treatment for HF may lead to a recovery in LV geometry and function, named reverse remodelling (RR). The improvement may be substantial, as demonstrated by the 20-unit LVEF improvement over seven months in our patient. In parallel, she has been completely asymptomatic for fifteen months. Although a malignant ventricular arrhythmia may only be speculated in this case, it may be concluded that, when such arrhythmia occurs in the setting of newly diagnosed HF, defibrillator implantation may be deferred if the arrhythmic risk is low, and RR may be predicted.

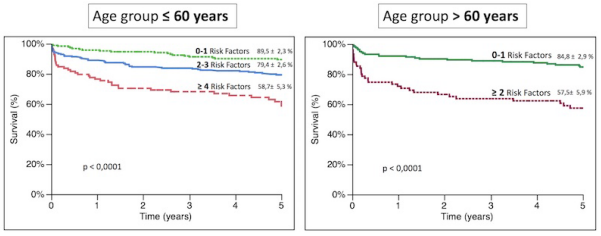
Interplay between recipient age and comorbidities in heart transplant survival: a step towards a tailored approach for advanced heart failure therapies

M Bellettini[1]; M Masetti[1]; H Luikart[2]; A Russo[1]; J Gordon[2]; N D'emilio[2]; M Gessaroli[1]; G Marinelli[1]; F Grigioni[1]; L Potena[1]; K Khush[2]
[1]University Hospital Policlinic S. Orsola-Malpighi, Heart Failure and Heart Transplant Program, Bologna, Italy; [2]Stanford University Medical Center, CV Medicine, Stanford, United States of America

Background: Heart transplantation (HT) is still the best available treatment for patients (pts) with end-stage heart failure. In context of the current donor shortage, optimal candidate selection is crucial for appropriate stewardship of this limited resource. Many risk factors are known to influence post-HT outcomes, but it remains difficult to evaluate the role of multiple comorbidities in a single patient, and their interplay with recipient age has not been adequately explored.
Purpose: We designed this study to evaluate post-transplant outcomes in recipients with multiple comorbidities, and their relevance across different recipient age strata.
Methods: Retrospective cohort study of all adult pts receiving an HT between 1999 and 2016 in two medium-large transplant centers in Europe and North America, in order to account for differences in practice between the two continents. Pts bridged to HT with an LVAD were excluded. Study population was divided into two age groups: = 60 y and > 60 y. Within each group, we examined the association between the primary endpoint (all-cause mortality at 5 years post-HT) and pre-HT clinical, laboratory and hemodynamic data. Finally, post-transplant survival was examined by the number of recipient comorbidities, stratified by age.
Results: Of the 779 pts who met inclusion criteria, 30.6% (n38) were > 60 y. There were no significant differences in 5 yr survival between the two age groups (79.3 ± 1.8 % vs 76.2 ± 2.8 % p = 0.30). Univariate analyses revealed different recipient comorbidities that are associated with survival across the two age strata: diabetes, BMI >30 kg/m2, eGFR < 60ml/min, Bilirubin > 2 mg/dl, Haemoglobin < 12 g/dl, Right atrial pressure > 8 mmHg, CHD etiology and UNOS status in those = 60 y old, and eGFR < 60ml/min, COPD, diabetes and Bilirubin > 2 mg/dl in those >60y old. Within both age groups, post-transplant survival decreased as the number of risk factors increased (Figure). Despite similar overall survival, patients >60 yrs have significantly reduced survival probability with = 2 risk factors, while the cumulative adverse effect of multiple comorbidities seems to be lower in younger patients. Similar results were obtained after adjusting for donor age.
Conclusions: Although age itself should not be considered an absolute contraindication to HT, the poor post-transplant survival seen in patients over 60 years with multiple comorbidities underscores the need to carefully select these candidates for transplantation. HT may be considered as first choice strategy in selected older pts with a low risk profile, while other treatment strategies (i.e LVAD as destination therapy) in patients with multiple comorbidities may improve allocation of a very limited resource.



5 y survival by Age and Risk Factors

708

Heart failure patients with a higher protein intake live longer

K W Koen Streng[1]; JM Ter Maaten[1]; K Damman[1]; DJ Van Veldhuisen[1]; P Van Der Meer[1]; JL Hillege[1]; AA Voors[1]
[1]University Medical Center Groningen, Groningen, Netherlands

Funding Acknowledgements: CVON2014-11 RECONNECT and FP7-242209-BIOSTAT-CHF

Background: A higher protein intake has been associated with a higher muscle mass and lower mortality rates in the general population, but data about protein intake and survival in HF patients is lacking.
Methods: We studied the association between protein intake and survival in 2516 patients from the BIOlogy Study to TAilored Treatment in Chronic Heart Failure (BIOSTAT-CHF) study were included. Protein intake was calculated using a validated formula including urea excretion in spot urine, corrected for urine creatinine and body mass index (BMI) (adjusted Maroni formula; 13.9 + 0.907 * BMI (kg/m2) + 0.0305 * urinary urea level (mg/dL)). Association with mortality was assessed using multivariable Cox regression models.
Results: We included 2281 patients with available data (mean age 68 ± 12 years and 27% female). Patients in the highest quartile of protein intake were more often male, had lower NT-proBNP levels and had a higher BMI. Mortality rate in the lowest quartile was 31%, compared to 18% in the highest quartile (P < 0.001). In a multivariable model, lower protein intake was associated with a higher risk of death (Hazard ratio (HR) 1.46; 95% confidence interval (CI) 1.01-2.12, P = 0.045 for the lowest quartile and HR 1.58; 95% CI 1.19-2.28, P = 0.015 for the 2nd quartile.
Conclusions: In patients with HF we found a higher protein intake to be independently associated with a better survival. The potential benefit of a high protein diet in patients with HF warrants further study.

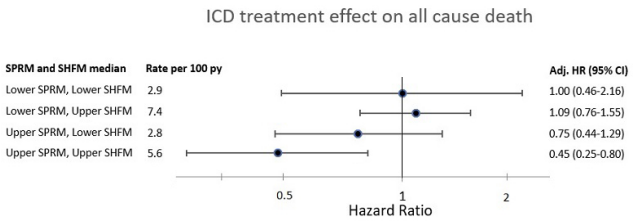
The Seattle heart failure and proportional risk model for prediction of ICD benefit in non-ischemic cardiomyopathy: A posthoc analysis of the DANISH trial

SL Kristensen[1]; WC Levy[2]; JC Nielsen[3]; J Haarbo[4]; L Videbaek[5]; E Korup[6]; NE Bruun[4]; H Eiskjaer[3]; C Hassager[1]; JH Svendsen[1]; DE Hoefsten[1]; C Torp-Pedersen[7]; S Pehrson[1]; L Koeber[1]; JJ Thune[1]
[1]Rigshospitalet - Copenhagen University Hospital, Cardiology, Copenhagen, Denmark; *[2]University of Washington, Seattle, United States of America*; *[3]Aarhus University Hospital, Department of Cardiology, Aarhus, Denmark*; *[4]Gentofte Hospital - Copenhagen University Hospital, Department of Cardiology, Hellerup, Denmark*; *[5]Odense University Hospital, Department of Cardiology, Odense, Denmark*; *[6]Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark*; *[7]Aalborg University, Aalborg, Denmark*

On behalf of: DANISH investigators

Background: No single study has demonstrated benefit of an ICD for primary prevention in patients with nonischemic cardiomyopathy (NICM). A likely explanation is that ICDs are beneficial mainly in patients at high risk of sudden cardiac death (SCD). We sought to identify a subset of NICM patients at high risk of SCD and thus more likely to benefit from ICD implantation by combining two models, one predicting overall mortality and the other the likelihood of SCD among HF patients who die.
Methods: We applied the Seattle Heart Failure (SHFM) and Seattle Proportional Risk Models (SPRM) on 1116 patients from the Danish study to Assess the Efficacy of ICDs in Patients with Non-ischemic Systolic Heart Failure on mortality (DANISH). The SHFM predicts 1-year all-cause mortality while SPRM predicts the proportion of deaths due to SCD. Both models use information on age, sex, clinical and paraclinical data and pharmacotherapy. Rates of all-cause mortality and ICD treatment effect were estimated according to median SPRM and in 4 subgroups according to a combination of median SPRM and median SHFM.
Results: In DANISH, SHFM predicted a median 1-year all-cause mortality of 4.5% (Q1-Q3 2.9%-7.5%) and SPRM estimated that 54% (Q1-Q3 45%-62%) of eventual deaths would be due to SCD. Among patients with SPRM above the median, rate of death per 100 person-years (py) was 3.6, and in these patients ICD implantation reduced all-cause mortality (hazard ratio (HR) 0.63, 95% CI 0.43-0.94) whereas patients with lower SPRM had a mortality rate of 5.8 per 100 py and no apparent effect of ICD treatment (HR 1.08, 95% CI 0.78-1.49, p = 0.04 for interaction). In four subgroups further stratified by predicted 1-year all-cause mortality, rates of death varied from 2.8 up 7.4 per 100 py, with the highest rate in those with lower SPRM/upper SHFM. ICD implantation reduced all-cause death among those with upper SPRM/upper SHFM (HR 0.45, 95% CI 0.25-0.80) with no significant benefit in the other groups, p = 0.01 for interaction (Figure).
Conclusion: NICM patients with a high relative risk of SCD, as predicted by SPRM seemed to benefit from ICD implantation. Further stratification based on overall mortality risk demonstrated the strongest effect of ICD implantation in patients with both high overall risk of death and high relative risk of SCD. Patients with low relative risk of SCD did not seem to benefit from ICD implantation, regardless of absolute mortality risk.



ICD treatment effect by SPRM and SHFM

710

INCIDENCE OF DYSKALEMIA IN HEART FAILURE WITH PRESERVED, MID-RANGE, AND REDUCED EJECTION FRACTION: AN ANALYSIS OF 6,401 PATIENTS FROM THE SWEDISH HEART FAILURE REGISTRY

Background. Heart failure with preserved (HFpEF), mid-range (HFmrEF) and reduced (HFrEF) ejection fraction are characterized by demographic and clinical characteristics and treatments that may differently impact on kidney potassium (K) excretion, and thus, on the risk of developing dyskalemias (dysK). We assessed the incidence of dysK within 1 year in HFpEF vs. HFmrEF vs. HFrEF.
Methods: We included consecutive patients from Stockholm region also enrolled in the Swedish Heart Failure Registry during 2006-10. HFpEF was defined as EF = 50%, HFmrEF as EF = 40-49%, HFrEF as EF < 40%. Kaplan-Meier curves were fitted to assess the crude incidence of hyper- (hyperK) and hypokalemia (hypoK).
Results: Of 6,401 patients, 1,555 (24%) had HFpEF, 1,430 (22%) HFmrEF and 3,416 (54%) HFrEF. Mean age was 73 ± 13 years and 37% were female. In HFpEF, HFmrEF and HFrEF, baseline K levels were 4.0 ± 0.4, 4.1 ± 0.4 and 4.1 ± 0.4 mmol/l, baseline eGFR was 57.7 ± 22.8, 61.1 ± 24.1 and 62.3 ± 24.8 ml/min/1.73m2, use of ACE/ARB was 71.1%, 78.0% and 85.8%, use of MRA was 30.9%, 31.1% and 41.4% and use of diuretics was 80.1%, 69.9% and 75.8% (p < 0.001 for all the comparisons), respectively.
1-year incidence rates for any hyperK (<5.0) were 26.4% in HFpEF, 23.1% in HFmrEF and 25.4% in HFrEF (p = 0.11), for mild hyperK (K 5.1-5.5) 22.0% in HFpEF, 19.9% in HFmrEF and 22.8% in HFrEF (p = 0.07), and for moderate/severe hyperK (K>5.5) 11.5% in HFpEF, 10.9% in HFmrEF and 10.1% in HFrEF (p = 0.32). 1-year incidence rates for any hypoK (K < 3.5) were 27.3% in HFpEF, 22.0% in HFmrEF and 19.4% in HFrEF (p < 0.001), for mild hypoK (3.0-3.4) 26.8% in HFpEF, 21.8% in HFmrEF and 18.9% in HFrEF (p < 0.001), and for moderate/severe hypoK (K < 3.0) 5.0% in HFpEF, 4.6% in HFmrEF and 3.5% in HFrEF (p = 0.03).
Conclusions: Both incident hyper- and hypokalemia was common in HF, regardless of HF type. There were no differences in risk of hyperK among HF types but 1-year incidence rates for hypoK were lower in HFrEF, intermediate in HFmrEF and higher in HFpEF, reflecting the different use of treatments affecting K excretion. These data may be helpful to tailor RAASi therapy, identify patients in need of stricter K monitoring, and to design trials of e.g. RAASi and K-binder agents in HF.

711

High prevalence of cancer in patients with peripartum cardiomyopathy: is there a pathophysiological connection between these two entities?

S Schlothauer[1]; T Pfeffer[1]; CS Falk[2]; M Ricke-Hoch[1]; E Stelling[1]; V Abou-Moulig[1]; M Kasten[1]; J Bauersachs[3]; D Hilfiker-Kleiner[1]
[1]Hannover Medical School, Molecular Cardiology, Hannover, Germany; *[2]Hannover Medical School, Institute of Transplant Immunology, Hannover, Germany*; *[3]Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany*

Background: Peripartum cardiomyopathy (PPCM) is a rare heart disease occurring in the last month of pregnancy or in the first 6 months after delivery. In our study we compared the risk for cancer in PPCM patients to the prevalence in age-matched women. Additionally, we evaluated the kinetics of several plasma markers potentially associated with cancer in PPCM patients.
Methods: Full medical records were available for 207 PPCM patients of the German PPCM registry. Cancer prevalence among PPCM patients was compared to the 10-year cancer prevalence in women aged 0-49 years using the German cancer registry.
Furthermore, we measured plasma levels of 61 markers at baseline (BL, n = 47), 6 months follow-up (FU, n = 44) and long-term follow-up (LTFU, 11 months to 7.5 years, n = 29) using a Luminex-based multiplex assay. Healthy age and postpartum matched women served as controls (n = 29). Depending on their outcome after 6 months we divided patients into subgroups (left ventricular ejection fraction, LVEF = 34%, LVEF: 35-49%, LVEF = 50%) and compared the data using Mann-Whitney test or Students t-test, if they were normally distributed.
Results: Our PPCM cohort shows a cancer point prevalence of 6.28% (13 out of 207), whereas the 10-year prevalence in women aged 0-49 years in Germany is only 0.59%. Since one patient presented with two different neoplasms there were 14 cancer diagnoses: 9 cases before PPCM (3 lymphoma, 2 breast carcinoma, 2 osteosarcoma, 1 melanoma, 1 prolactinoma) and 5 cases after PPCM (3 breast carcinoma, 1 colorectal carcinoma, 1 acute myeloid leukaemia).
Mean LVEF of PPCM patients included in the multiplex analysis was 23 ± 7% at BL, 48 ± 11% at FU and 52 ± 8% at LTFU. Mean LVEF of patients with cancer diagnosis was 29 ± 11% at BL. Some plasma markers potentially associated with cancer (Her2/neu, PAI-1, sIL-6Ra, Osteopontin) were significantly elevated at BL and FU (p < 0.05) in PPCM patients compared to healthy controls. Of note, these markers returned to a normal level at LTFU. Their kinetics showed no difference between PPCM patients with or without cancer. A comparison between the subgroups of PPCM patients revealed significantly elevated baseline levels of Her2/neu (p = 0.0024) and sIL-6Ra (p = 0.0435) in patients with persistently reduced cardiac function (LVEF = 34%) compared to patients with cardiac recovery (LVEF = 50%).
Conclusion: Our findings suggest that PPCM patients have a prevalence of cancer compared to age-matched woman in Germany. PPCM patients with a previous or follow-up cancer diagnosis displayed similar plasma levels of markers potentially

associated with malignancies as PPCM patients without cancer. However, Her2/neu and sIL-6Ra were elevated at baseline and follow-up in PPCM patients and high plasma levels of these two markers were associated with an adverse cardiac outcome.
Further studies are required to evaluate a possible pathophysiological connection of malignant growth and PPCM.

Funding Acknowledgements: British Heart Foundation Clinical Research Training Fellowship

Background: The DANISH trial highlighted that the selection of patients with dilated cardiomyopathy (DCM) for implantable cardioverter defibrillators needs to be improved. Additional features which predict sudden cardiac death (SCD) risk are required for a more personalised approach.
Purpose: To examine the association between mid-wall late gadolinium enhancement (LGE) and SCD in DCM.
Methods: We recruited consecutive patients with DCM referred between 2000 and 2011. The presence and quantity of mid-wall LGE was determined by 2 independent experts. A blinded panel adjudicated the occurrence of the primary end-point that comprised either SCD or aborted SCD. The association between the presence, extent, pattern and location of LGE and the end-point was examined using proportional hazard modelling. The Akaike information criterion was used to compare the quality of each model in predicting the outcome.
Results: Overall, 874 patients (588 men, median left ventricular ejection fraction [LVEF 39%], median age 52 years) were followed-up for a median of 4.9 years. Mid-wall LGE was present in 300 (34.3%) cases (median extent 3.8%, IQR 2.0:6.7%; septum only: 142, left ventricular free-wall only: 42, both septum and free-wall: 116). After adjusting for prognostic variables including LVEF, the presence of LGE was associated with SCD events (HR 4.12; 95%CI 2.64:6.45; p <0.001). Estimated HRs for patients with LGE extent of 0-2.5%, 2.5-5% and >5%, compared to patients without LGE were 2.92 (95% CI 1.51-5.65), 4.28 (2.38-7.68) and 5.14 (3.01-8.79). There was a marked non-linear relationship between LGE extent and outcome such that even small amounts of LGE predicted a substantial increase in risk (Figure 1). SCD events were most strongly associated with the combined presence of septal and free-wall LGE (HR 5.82; 95% CI 3.30-10.27), followed by the presence of LGE only in the septum (HR 3.13; 95% CI 1.68-5.81) and LGE only in the free-wall (HR 2.19; 95% CI 0.76-6.31). Predictive models using LGE presence and location were superior to models based on LGE extent or pattern.
Conclusions: In DCM, the presence of mid-wall LGE is associated with a large increase in the risk of SCD events, even when the extent is small. SCD risk is greatest with concomitant septal and free wall LGE.

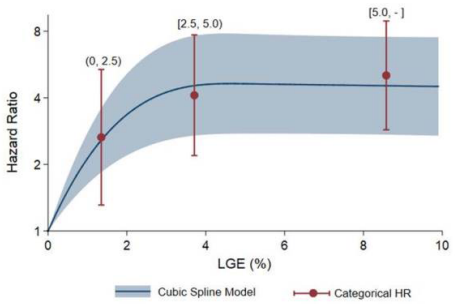

Figure 1. Estimated adjusted hazard ratios with 95% confidence intervals (red lines) for the end-point, per patient group based on increasing extent of late gadolinium enhancement (LGE) (0-2.5%, 2.5-5%, >5%). The hazard ratios are positioned at the median LGE extent within each category. A cubic spline model (blue line) has been fitted to the observed data.

Background: Recovery of left ventricular ejection fraction (LVEF) is common in patients with non-ischaemic dilated cardiomyopathy (NIDCM). Whether this represents remission or cure remains unclear.
Purpose: To characterise and phenotype patients with recovered DCM.
Methods: We evaluated 54 patients with a prior diagnosis of NIDCM and LVEF = 40%, whose LV function had recovered (improvement in LVEF to = 50% with normal left ventricular size) and HF symptoms had resolved (NYHA 1), using cardiovascular magnetic resonance (CMR), cardiopulmonary exercise testing (CPET) and biomarkers.
Results: The median age of patients was 56 years, 18 were women, 7 had left bundle branch block and all were prescribed neurohormonal heart failure therapy.
CMR: The median LVEF, indexed left ventricular end-diastolic volume and indexed left atrial volume of patients with recovered DCM was 62% (IQR 55:64%; normal range 56:78%), 83ml/m2 (IQR 75:89ml/m2; normal range 50:103ml/m2) and 41.6ml/m2 (IQR 34.1:45.4 ml/m2; normal range 27:53ml/m2) respectively.
Overall, 19 (32%) patients had late gadolinium enhancement (Figure 1a). The median native T1 value of patients was 1291ms (IQR 1271:1314ms), which was not significantly different to healthy volunteers (HVOLs) (median 1284ms; IQR 1252:1316ms; p = 0.749) (Figure 1b).

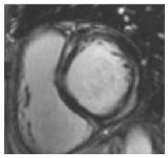

Figure 1a. Late gadolinium enhancement images of a patient with recovered dilated cardiomyopathy, demonstrating mid-wall and sub-epicardial enhancement.

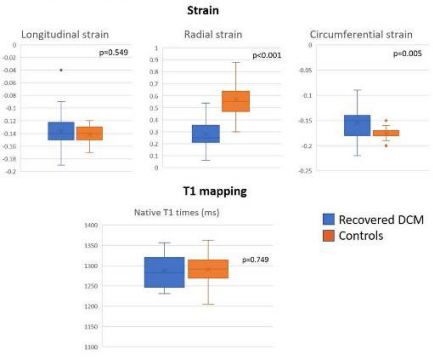

Figure 1b. Myocardial strain and native T1 times of patients with recovered dilated cardiomyopathy compared to healthy volunteers.

Figure 1

The median radial and circumferential strain of patients was 0.25 (IQR 0.21:0.35) and -0.15 (IQR -0.14:-0.18), which was significantly less than HVOLs (median radial strain 0.55, IQR 0.55:0.6, p <0.001; median circumferential strain -0.18, IQR -0.17:-0.18, p = 0.005) (Figure b). There was no difference in longitudinal strain between patients (median -0.14, IQR -0.12:-0.14) and HVOLs (median -0.14, IQR -0.14:-0.15; p = 0549).
Biomarkers: The median plasma NT-pro-BNP level was 77ng/L (IQR 43:134ng/L); 17 of 54 patients had values >125ng/L and 1 had a value >2000ng/L; 3 patients had plasma troponin I >20ng/L.
CPET: The median peak oxygen consumption of patients was 25.6ml/kg/min (IQR 22.0:31.5mlkg/min); 44 of 51(86%) patients recorded values that were >80% of the predicted peak oxygen consumption based on age, sex and height predicted normal ranges.
Conclusions: Many patients with recovered NIDCM have abnormal myocardial strain, replacement myocardial fibrosis and persistently elevated plasma NT-pro-BNP concentrations, despite normalisation of ventricular volumes and functional capacity.

714

The benefits of having a nurse fully dedicated to telemonitoring heart failure patients with an implanted cardiac device: a mixed method study

M Michela Barisone[1]; A Bagnasco[1]; M Zanini[1]; G Catania[1]; G Aleo[1]; L Sasso[1]
[1]University of Genoa, Genoa, Italy

Background/Introduction: Heart failure is often the result of the clinical progression of several common diseases, such as ischaemic heart disease, arterial hypertension, and cardiomyopathy, with an incidence of 2 million cases per year in the world, 470,000 in Europe, and 66,000 in Italy.
Heart failure is the most frequent cause of hospitalization in older people.
In the last decade, there has been a rapid increase in the use of Health Technology Assessment, pacemakers, and defibrillators, which have ensure better clinical
Results: Implanted heart devices play an important role in telemonitoring heart failure. Telemonitoring systems enable to check, at any time, current and previous data produced by the implanted device, resulting in early detection of arrhythmias or incipient anomaly of the stimulation or heart defibrillating system.
Purpose: To evaluate how remote control and monitoring by nurses with arrhythmology competences reduces hospital re-admission rates, hospitalization costs and mortality.
Methods: A study with a convergent parallel mixed method design was used with two components: a descriptive qualitative study and a retrospective observational cohort study. A sample of 849 remotely monitored patients with implanted cardiac devices was recruited from January 2011 to December 2016 from electronic records. The primary endpoint of the study is to check how this activity reduces readmissions. Qualitative data were collected through semi-structured interviews with 10 dedicated nurses, to understand what type of education and practical training they had received in relation to their current practice in the field of cardiac nursing and evaluate how nursing impacts on the organization of care in terms of nursing sensitive outcomes.
Results: We found that in the centres where there was nurse dedicated to remote monitoring, hospital readmissions decreased by almost 20%, of patients who met admission appropriateness according to their diagnosis on admission. Mortality decreased in the centres with a nurse fully dedicated to remote monitoring of HF patients compared to centres where there was no dedicated nurse. A correlation between death and baseline diagnosis is highlighted. In hospitals where the seniority of cardiac nurses was higher, there was a significant reduction of readmissions and mortality.
Conclusion(s): The benefits for the patients were found to be relevant in terms of reducing social costs: reduction of transport costs for patients by 60%, reduction of working days lost by the patient and / or carers, failure to give up personal activities (patient and family members) and greater patient satisfaction and acceptance with better follow-up adherence. From the data received through the telemonitoring systems, there was a reduction of inappropriate shocks, prevention of heart failure events, reduction of the number and duration of readmissions and improved survival.

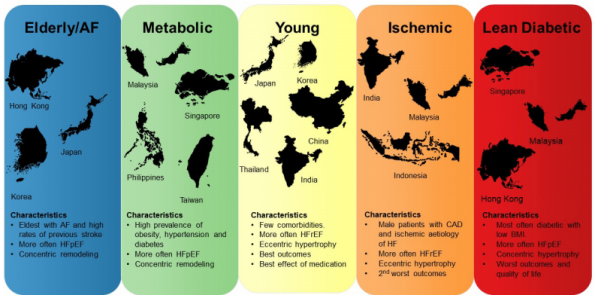
715

Multimorbidity in asian patients with heart failure: data from ASIAN-HF.

J Jasper Tromp[1]; WT Tay[1]; W Ouwerkerk[2]; THK Teng[1]; J Yap[1]; M Macdonald[3]; K Leineweber[4]; JJV Mcmurray[5]; MR Zile[6]; IS Anand[7]; CS Lam[1]
[1]National Heart Centre Singapore, Cardiology, Singapore, Singapore; [2]Academic Medical Center of Amsterdam, Amsterdam, Netherlands; [3]Changi General Hospital, Singapore, Singapore; [4]Bayer AG, Wuppertal, Germany; [5]University of Glasgow, Glasgow, United Kingdom; [6]Medical University of South Carolina, Charleston, United States of America; [7]Veterans affairs Medical Center, Minneapolis, United States of America

Funding Acknowledgements: Boston Scientific Investigator Sponsored Research Program, National Medical Research Council of Singapore, A*STAR Biomedical Research Council ATTRaCT

Background: Comorbidities are common in patients with heart failure (HF) and complicates their treatment and outcomes. Prior studies have focused mainly on individual comorbidities in isolation, underestimating the total burden of multimorbidity in HF.
Purpose: We sought to identify the pattern of multimorbidity in Asian patients with HF and their association with patients' quality of life, cardiac remodeling, outcomes and treatment response to HF medications.
Methods: We performed latent class analysis (LCA) using comorbidities including: atrial fibrillation (AF), CAD, stroke, CKD, obesity, hypertension, chronic obstructive pulmonary disease (COPD), peptic ulcer disease, renal artery stenosis, cancer, liver disease, dementia, anemia, depression, diabetes and peripheral arterial disease, to identify patterns of multimorbidity. Analyses were performed using 6479 prospectively enrolled patients with HF from the ASIAN-HF registry (1204 HF with a preserved ejection fraction [HFpEF]) from 11 Asian regions. Following, we investigated the associations of multimorbidity patterns with geographical distribution, patients' quality of life, cardiac structure and function, outcomes and treatment response to HF medications.
Results: We identified 5 distinct multimorbidity groups (N = 1048-1759 in each group): Elderly/atrial fibrillation (AF) (oldest, more AF), Metabolic (Obesity, diabetes, hypertension), Young (youngest, low comorbidity rates, non-ischemic etiology), Ischemic (Ischemic etiology) and Lean Diabetic (diabetic, hypertensive, low prevalence of obesity and high prevalence of chronic kidney disease). The Metabolic and Lean Diabetic groups had the highest proportions of concentric left ventricular hypertrophy (LVH) and the Young group had the highest proportion of eccentric LVH. Patients in the Lean Diabetic group had the worst quality of life, more severe signs and symptoms of HF and the worst outcomes, independent of confounders (P for all <0.001). Multimorbidity groups modified the association of guideline directed dosages of beta-blockers and mineralocorticoid receptor antagonists with outcomes (all-cause mortality and HF hospitalizations), such that patients in the Young group appeared to derive the most survival benefit with these drugs (Pinteraction <0.05 for both).



Conclusion: Among Asian patients with HF comorbidities naturally clustered in 5 distinct patterns, each associated with specific underlying patterns of cardiac remodeling, and differentially impacting patients' quality of life, outcomes and treatment response to some HF medications. These data underscore the importance of studying multimorbidity in HF and the need for more comprehensive approaches in phenotyping patients with HF and multimorbidity.

716

Cognitive impairment and the level of self-care behaviors among elderly patients with heart failure

I Uchmanowicz[1]; B Prochota[2]; K Katarzyna Lomper[1]; M Lisiak[1]; A Chudiak[1]; M Wleklik[1]
[1]*Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland*; [2]*Health Facility , Olesno, Poland*

Introduction: Heart failure (HF) is diagnosed in 1-2% of the general population. HF is the most common cause of hospitalization among cardiovascular diseases. HF is a leading cause of hospitalizations among cardiovascular diseases. Over 80% of the HF population are patients over 65 years of age. Aging together with reduced perfusion in the cerebral blood flow in HF may be the reason for the development of cognitive impairment (CI). Cognitive impairment is one of the key barriers to achieving the satisfactory level of self-care affecting the final therapeutic effect.
Purpose: To investigate the influence of CI on the level of self-care behaviors among elderly patients with HF.Methods. The study included 100 patients (mean age of 73.78 years) with diagnosed HF hospitalized in the Public Health Care. The cognitive functions were evaluated using the Mini-Mental State Examination (MMSE) questionnaire and the level of self-care was assessed with the European Heart Failure Self-care Behavior Scale (EHBScB). In the statistical analysis, the significance level was assumed for p> 0.05.
Results: Analysis of the MMSE questionnaire showed the presence of CI without dementia in 29% of patients, CI with mild degree dementia has been reported in 24% of respondents and CI with moderate dementia in 27%. In turn, CI was not observed in the remaining group (20%). The average score in EHBScB questionnaire for the studied population was 61.78 (SD = 23.59). Post-hoc analysis showed a significant relationship between CI and the level of self-care. People with CI without dementia and without recognized CI had significantly higher levels of self-care than those with CI and moderate dementia (p = 0.001).Conclusion.Cognitive impairment significantly and negatively influences the level of self-care behaviors in elderly patients with HF.

717

Increased risk of cancer death in patients with chronic heart failure with a special reference to inflammation and diabetes mellitus -A report from the CHART-2 Study-

Y Sakata[1]; T Takuya Oikawa[1]; K Nochioka[1]; M Miura[1]; R Abe[1]; S Kasahara[1]; M Sato[1]; H Aoyanagi[1]; T Shiroto[1]; K Sugimura[1]; J Takahashi[1]; S Miyata[2]; H Shimokawa[3]

On behalf of: The CHART-2 Investigators
Funding Acknowledgements: This study was supported in part by the Grants-in Aid from the MHLW, MEXT and AMED (No. 17ek0210081h0001), Tokyo, Japan.

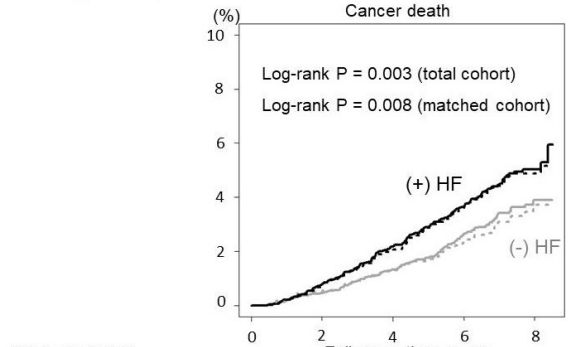
Background: It has been reported that several factors, including heart failure (HF), diabetes mellitus (DM) and inflammation, affect the incidence of cancer. However, it remains to be examined whether HF is a risk of cancer death, particularly with a reference to inflammation and DM.

Table. Impact of Temporal Changes of CRP Levels on Cancer Death in HF Patients

Changes in CRP levels from baseline to 1-year	HR	95%CI	P value
From < 2.0 mg/L to < 2.0 mg/L (N = 918)	1.00	reference	NA
From < 2.0 mg/L to ≥ 2.0 mg/L (N = 286)	1.09	0.48-2.46	0.83
From ≥ 2.0 mg/L to < 2.0 mg/L (N = 456)	1.42	0.74-2.71	0.29
From ≥ 2.0 mg/L & ≥ 2.0 mg/L (N = 569)	1.84	1.05-3.24	0.03
Variables: age, sex, heart rate, dyslipidemia, heart failure admission, NYHA Class, antiplatelet			

Purpose: To examine the relationship between HF and risk of cancer death.

Figure. Kaplan-Meier Curves for Cancer Death



Number at Risk							
Total	——	(-) HF	4,622	4,405	3,980	2,975	599
Cohort	——	(+) HF	4,221	3,817	3,242	2,474	359
Matched	– – –	(-) HF	2,895	2,793	2,495	1,888	391
Cohort	– – –	(+) HF	2,895	2,657	2,307	1,851	331

Methods: Our Chronic Heart Failure Registry and Analysis in the Tohoku district-2 (CHART-2) Study (N = 10,219) is a multicenter, prospective, observational cohort study, designed to identify the characteristics, mortality and prognostic risks of cardiovascular patients with and without HF in Japan. We examined 8,843 consecutive patients without a prior history of cancer in the CHART-2 Study (mean 68 yrs., female 30.9%).
Results: During the median 6.5-year follow-up (52,675 person-years), 282 cancer deaths occurred. HF patients had significantly higher cancer mortality than those without HF in both the overall (3.6 vs, 2.8%, hazard ratio (HR) 1.42, 95% confidence interval (CI) 1.12-1.79, P = 0.004) and the propensity score-matched cohorts (HR 1.49, 95%CI 1.08-2.05, P = 0.016) (Figure), which was confirmed in the competing risk models. Subgroup analysis showed that HF was associated with increased incidence of cancer death in patients with C-reactive protein (CRP) = 2.0mg/L (HR 2.26, 95%CI 1.34-3.79, P = 0.002) but not in those with CRP <2.0mg/L (HR 0.92, 95%CI 0.56-1.50, P = 0.728) (P for interaction = 0.014), and in patients without DM (HR 1.98, 95%CI 1.33-2.94, P <0.001) but not in those with DM (HR 1.01, 95%CI 0.64-1.59, P = 0.972) (P for interaction = 0.030). The multivariable Cox proportional hazard model showed that temporal changes in CRP levels were associated with cancer death: HF patients with CRP = 2.0mg/L at both baseline and 1-year had significantly increased mortality of cancer (Table), particularly that of lung cancer.
Conclusions: These results provide the first evidence that HF is associated with increased cancer death in the presence of prolonged inflammation, but not DM.

718

Acute coronary syndrome in-hospital mortality: role of beta-blocker therapy.

M J Maria Joao Nobre De Matos Pereira Vieira[1]; D Durao[1]; A Belo[2]; K Kevin Domingues[1]; C Craveiro[1]; M Saraiva[1]; B Saldanha Santos[1]; M Alves[1]; M Leal[1]; RNSCA Investigadores Do Registo Nacional De Sindromes Coronarios Agudos[2]
[1]Hospital Santarém, Cardiology, Santarém, Portugal; *[2]Sociedade Portuguesa de Cardiologia, Lisboa, Portugal*

On behalf of: Registo Nacional dos Sindromes Coronarios Agudos da Sociedade Portuguesa de Cardiologia (RNSCA)

Background: Beta-blockers (BB) are one of the most widely used therapeutic options in the context of acute coronary syndrome (ACS). Although the long-term survival benefit from chronic BB has been proven in clinical trials, the short-term benefits of early beta-blockade in the setting of ACS are less well-established. The aim of this study was to evaluate the effects of BB therapy in early survival of patients with ACS
Methods: We performed a retrospective study including 17148 patients (age 66 ± 13 years,74,3% men), from the Portuguese Registry on Acute Coronary Syndromes (RNSCA) with the diagnosis of Acute Coronary Syndrome (STEMI n = 7284; NSTEMI n= 8670; Unstable Angina n= 1194) admitted between 01/10/2010 and 03/01/2018. The population was divided into two groups: Group A (A), with in-hospital oral BB therapy (n = 13902) and Group B (B), without in-hospital BB oral therapy (n = 3246). The primary outcome was in-hospital mortality. Demographic, clinical, electrocardiographic, echocardiographic and angiographic data were evaluated. Multivariate analysis was conducted by logistic regression.
Results: Significant differences were observed between groups regarding age, smoking habits, previous history of diabetes mellitus, chronic kidney disease, previous myocardial infarction, type of myocardial infarction at admission, left ventricular ejection fraction, use of angiotensin-converting enzyme inhibitors. Overall in-hospital mortality rate was 3,4% (n = 581), with significant differences between groups (A 1,6 % vs B 10,9 %; OR = 0,14; P < 0,001). The use of BB therapy was also associated with lower occurrence of mechanical complications (A 0,4% vs B 1,9%; OR = 0,22; P < 0,001), lower development of congestive heart failure (A 12,7% vs B 26,4%; OR = 0,4; P < 0,001), lower need for intra-aortic balloon (A 0,5% vs B 1,8%; OR = 0,25; P < 0,001) and invasive ventilation (A 1,4% vs B 4,6%; OR:0,3; P < 0,001). In the multivariate analysis, BB therapy was an independent predictor of in-hospital mortality, assuming a protective role in this setting (OR: 0,33; 95% CI: 0,24-0,46; P < 0,0001). The effect of BB therapy in in-hospital mortality was dependent of the subtype of ACS. In STEMI and NSTEMI patients the beta-blocker therapy was associated with a lower in-hospital mortality (OR = 0,30; P < 0,0001 and OR = 0,68; P = 0,039, respectively). This association was not observed in unstable angina patients with no benefits of beta-blocker therapy in early survival (P = 0,34).
Conclusions: In this study the use of BB therapy in patients with ACS decreased not only in-hospital mortality, but also the development of congestive heart failure and cardiogenic shock, mechanical complications, need for mechanical support and need for invasive ventilation. The benefits on survival were observed in both STEMI and NSTEMI patients, but in patients with unstable angina no benefits were observed.

719

Care-seeking decisions in patients with heart failure: a matter of identity and previous healthcare experience

SE Serra Ivynian[1]; PJ Newton[2]; M Digiacomo[1]
[1]University of Technology, Sydney, Sydney, Australia; *[2]University of Western Sydney, Sydney, Australia*

Background: Responding to symptom exacerbation in a timely manner is paramount to effective heart failure (HF) self-management, yet, little is known about what drives patients to seek or avoid professional care for HF symptoms.
Purpose: To extend beyond what is known to impact self-management behaviours by exploring patients' perspectives of factors that influence their decisions to seek professional care for worsening HF symptoms.
Methods: Semi-structured in-depth interviews were conducted with 15 symptomatic HF patients at a teaching hospital. Transcripts were analysed using interpretative phenomenological analysis (IPA) to illuminate participants' experience of events to gain an in depth understanding of factors that led to avoidance of professional care.
Results: Participants described delayed care-seeking due to values and beliefs associated with healthcare use, and desire to avoid hospitalisation. The experience of being hospitalised represented a loss of freedom and control and served as a reminder of being ill. Perception of illness as a threat to identity led to rejection of treatment, whilst fear of being a burden to others also led to avoidance behaviours. Uncertainty about the cause and likely trajectory of symptoms often led to a 'wait and see' response, as symptoms were not perceived as serious. Professional care was often viewed as a last resort, when all alternative coping strategies were exhausted, and participants could no longer cope with the physical and emotional impact of symptoms. Patient-provider interpersonal relationships and preferences for continuity also impacted care-seeking.
Conclusion: Whilst various patient-related factors influenced care-seeking decisions, previous healthcare experiences and interactions with providers largely informed subsequent decisions to interact with health services. Positive patient-provider relationships are key in encouraging timely care-seeking in HF.

720

The increased level of GRK2 correlates with preserved exercise capacity in patients with HF.

G Iaccarino[1]; G Vitulano[1]; F D'auria[1]; M Polito[1]; D Bonadies[2]; A Gigantino[2]; F Piscione[1]; M Ciccarelli[1]
[1]University of Salerno, Salerno, Italy; *[2]AOU S. Giovanni e Ruggi, Salerno, Italy*

Background: G protein-coupled receptor kinase 2 (GRK2) activates mechanisms of desensitization and downregulation of b adrenergic receptors (bAR) during chronic heart failure (HF) Previous work has proposed GRK2 as a possible biomarker for human heart failure (hHF). In this study, we evaluate the physiopathology of stress tolerance underlying the role of GRK2 levels in hHF.

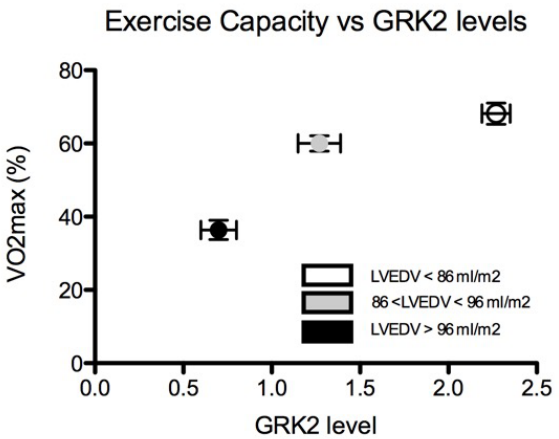


Figure 1

Methods: hHF patients (N = 31; NYHA I: 22,6%, NYHA II:58%, NYHA III:19,3%) were subjected to echocardiographic evaluation of cardiac function (Ejection Fraction, EF%; Left Ventricular End Diastolic Volume, LVEDV, ml) and cardiopulmonary test (CPET) for exercise capacity. Levels of GRK2 were evaluated in peripheral blood mononuclear cells (PBMC) by western blot (WB), on blood samples taken after CPET.
Results: As expected, LVEDV negatively correlates with %VO2 max ($R2 = 0.64$, $p < 0.01$) indicating the association of reduced exercise capacity in HF patients with dilated cardiomiopathy. GRK2 levels negatively correlate with LVEDV ($R2 = 0.53$, $p < 0.01$), but not with EF ($R2 = 0.008$, ns). Instead, GRK2 levels positively correlate with the exercise capacity, estimated as oxygen consumption (%V02 max, $R2 = 0.78$, $p < 0.01$). To confirm that level of GRK2 correlates with exercise capacity, we grouped our population by LVEDV. As shown in figure 1, patients with relatively low LVEDV and increased GRK2 level after exercise display a better exercise capacity respect to patients with increased LVEDV and reduced levels of GRK2.
Conclusions: Our data demonstrate that increased level of GRK2 correlates with exercise capacity in patients with HF.

721

Prevalence and determinants of heart failure stage A and B in a population-based sample Results from the STAAB cohort study

C Morbach[1]; M Breunig[1]; G Gelbrich[2]; T Tiffe[2]; F Eichner[2]; M Wagner[2]; PU Heuschmann[2]; S Stoerk[1]
[1]University Hospital Wuerzburg, Comprehensive Heart Failure Center and Dept. of Medicine I, Wuerzburg, Germany; *[2]University of Wuerzburg, Institute of Clinical Epidemiology and Biometry and Comprehensive Heart Failure Center, Wuerzburg, Germany*

Funding Acknowledgements: German Ministry of Education and Research (BMBF 01EO1004 and 01EO1504)

Background: Heart failure (HF) is considered a progressively aggravating continuum ranging from subjects with risk factors for HF (stage A) to asymptomatic cardiac dysfunction (stage B) and symptomatic HF (stages C and D). To derive the population at risk for developing HF, we aimed to assess prevalence and characteristics of early stages of HF in a population-based cohort.
Methods: We report a planned interim analysis of the prospective Characteristics and Course of Heart Failure Stages A-B and Determinants of Progression (STAAB) cohort study investigating a representative sample of residents of the City of Würzburg, Germany, aged 30 to 79 years and reporting no previously diagnosed HF. Participants underwent detailed cardiac phenotyping and standardized echocardiography. Categorization of HF was performed according to AHA/ACC guidelines. A: = 1 risk factor for HF (hypertension, arteriosclerotic disease, diabetes mellitus, obesity, metabolic syndrome), but absence of structural heart disease (SHD); B: asymptomatic but SHD (reduced left ventricular (LV) ejection fraction, LV hypertrophy, LV dilation, stenosis or more than mild regurgitation of aortic or mitral valve, worse than mild diastolic dysfunction) or prior myocardial infarction; C: SHD and signs and symptoms of HF (Framingham criteria);
Results: We analyzed 2473 participants (54 ± 12 years, 51% female): stage A, 42% (58 ± 11 years, 42% female); stage B, 18% (58 ± 12 years, 63% female). 31% of stage B subjects had no risk factor that would qualify for A (B-not-A). Compared to individuals in stage B with present A criteria, B-not-A were significantly younger (47 ± 10 vs. 63 ± 10 years, $p < 0.001$), more often female (78% vs. 56%, $p < 0.001$), and had LV dilation as predominant B-qualifying criterion ($p < 0.001$).
Conclusion: In this population-based cohort, prevalence of both stage A and B was high and increased with advancing age. Unexpectedly, about one third of individuals in stage B showed no risk factors qualifying for stage A thus challenging the conventional conception of the HF disease continuum. Future research should aim to further characterize this pathophysiologically interesting subgroup, investigate the factors driving its natural course, and possibly adjust risk modifying strategies.

722

Prevalence of early stages of heart failure in an elderly high risk population: the copenhagen heart failure risk study

F Gaborit[1]; C Kistorp[2]; T Kumler[1]; C Hassager[3]; N Toender[4]; L Kober[3]; P Hansen[5]; P Kamstrup[6]; J Faber[2]; K Iversen[1]; M Schou[1]

Funding Acknowledgements: The Danish Heart Foundation; Herlev Gentofte University Hospital Research Council; Toyota-Fonden, Denmark

Background: Early stages of heart failure (HF) are overlooked in the community, nevertheless, associated with increased risk of hospitalization with congestion and increased risk of death. Prevalence and clinical presentation of HF stages in an elderly high risk population is unknown.
Purpose: To describe the prevalence of HF stage B and C in a cohort of elderly patients with apparently HF stage A. Furthermore, to characterize clinical, biochemical and echocardiographic findings in each stage.
Methods: A prospective cohort study. Patients who fulfilled in- and exclusion criteria were recruited consecutively from the Department of Cardiology, the Diabetes Clinic and the Nephrology Clinic, Herlev Gentofte University Hospital, Denmark. We included 400 patients, >60 years old, with one or more risk factor of HF (diabetes, chronic kidney disease, cardiovascular disease, atrial fibrillation (AF), hypertension) and without history of HF. Patients underwent physical examination, echocardiogram, HF questionnaire and blood samples. HF stages were defined as: stage A (normal echocardiogram), stage B (abnormal echocardiogram but no symptoms of HF), stage C (abnormal echocardiogram and symptoms of HF combined with clinical signs and/or increased plasma concentrations of NT-proBNP (sinus rhythm>125pg/mL, AF>524pg/mL)). Abnormal echocardiogram was pre-defined by gender specific reference values of left ventricle systolic and diastolic function, left ventricle mass and left atrial volume, according to current guidelines.
Results: Before examination all patients were considered to be stage A (median age 72 years; 48.5% female); after thorough evaluation 45% remained in stage A, whereas 37% were stage B, 18% stage C (figure 1). In total 128 patients (32%) reported HF symptoms; 30% in stage A, 1.4% in stage B, 100% in stage C. Higher stages of HF were older; stage A median 69, stage B 74.5, stage C 74($p < 0.0001$); and more frequently had AF; stage A 22.2%, stage B 31.8%, stage C 43.1%($p = 0.0035$). Higher stages of HF had lower median estimated glomerular filtration rate (mL/min/1.73m2); stage A 76.0, stage B 65.5, Stage C 65.0($p = 0.0059$) and lower median hemoglobin (mmol/L); stage A 8.7, stage B 8.5, stage C 8.3($p = 0.0285$). Median plasma concentrations of NT-proBNP (pg/mL) increased with higher stages of HF; stage A 133.0, stage B 275.5, stage C 397.5($p < 0.0001$). Plasma concentrations of TroponinI were more frequently increased in patients with abnormal echocardiogram; 10.1% in stage A, 27.0% in stage B, 30.6% in stage C($p < 0.0001$). Minnesota Living with HF score was higher in patients with stage C, reflecting reduced quality of life; score in stage A 11, stage B 8, stage C 24($p < 0.0001$).
Conclusion: In an elderly high risk population HF stage B and C is frequent. Higher stages of HF had increased plasma concentrations of NT-proBNP and TroponinI, as well as reduced quality of life. Focus on HF symptoms and referral for an echocardiogram in this population is warranted.

[1]*National research center for cardiac surgery, Astana, Kazakhstan*

Objective: We report the successful heart transplantation following an ex-vivo allograft perfusion time of 960 minutes into a recipient with dilated cardiomyopathy and left ventricular assist device implant.
Patients: The patient was on LVAD support as a bridge to transplantation. Drive line infection influenced his clinical status necessitating heart transplantation.
Results: The patient underwent successful heart transplantation, requiring central veno-arterial ECMO support for the first 44 hours. In 13 days he was undergoing early rehabilitation with normal cardiac function.
Conclusion: We report the longest out-of-body time for a successful cardiac transplant to be added to a global learning curve of long runs using TransMedics Organ Care System.

724

Regression of severe aortic regurgitation in LVAD patient

K Poopong[1]; PS Sakiyalak[2]; SJ Janwanishstaporn[3]
[1]*Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand*; [2]*Faculty of Medicine Siriraj Hospital, Mahidol University, Division of Cardiothoracic surgery, Department of Surgery, Bangkok, Thailand*; [3]*Faculty of Medicine Siriraj Hospital, Mahidol University, Division of Cardiology, Department of Medicine, Bangkok, Thailand*

Introduction: Aortic regurgitation (AR) is a significant complication in patients with continuous flow left ventricular assist device (LVAD). Severe AR can cause refractory heart failure (HF) usually requiring intervention. We present a patient with regression of severe AR associated with LVAD without aortic valve (AV) intervention.
Description: A 59-year-old Thai male with history of dilated cardiomyopathy for 10 years progressed to advanced HF with LVEF of 16%. He underwent a LVAD implantation, Heartmate II, as a bridge-to-transplantation. AR was not present in both pre- and post-operative period. After 4 months of uneventful follow-up and improved HF symptoms, TTE showed a well-decompressed left ventricle (LV) with LVEF of 42% and mild AR with intermittent AV opening.
After 1 year of implantation, his HF symptoms worsened. TTE revealed an enlarged LV with a worsening LVEF of 18% and continuous severe AR without AV opening despite optimization of pump speed by ramp study.
The patient was planned for urgent heart transplantation due to symptomatic severe AR. Unfortunately, his panel-reactive HLA antibody was extremely high, contraindicating heart transplantation. After discussing with the patient, we decided to closely observe and planned an AV intervention if his HF worsened. The heart failure medications were continued as shown in the Table. However, his HF symptoms gradually improved. Serial TTE study revealed progressive decline in AR severity to mild diastolic AR with minimal AV opening and improved LV contraction at 3 years after implantation.
Questions: What is the explanation and underlying mechanism behind the regression of severe AR in LVAD patient?
Implications: We propose the improved LV function possibly from HF medication may have contributed to AR regression in this patient. As lacking of AV opening is a key mechanism for AR in the LVAD patient. If the recovered LV can generate greater pressure to reopen the AV, this should reduce AR severity. The putative role of HF medications in LV reverse remodeling and prevention of AR in LVAD patients warrants further research.

Timeline

Timing (mo. after LVAD)	Pre-LVAD (0 mo.)	Mild AR (4 mo.)	Severe AR (15mo.)	Mild AR (42 mo.)
LVIDd (mm)	74.6	46.0	67.4	47.0
LVEF (%)	16.1	41.6	20.6	36.1
Carvedilol (mg/d)	50	12.5	12.5	25
Enalapril (mg/d)	0	40	10	15
Spironolactone (mg/d)	25	0	0	37.5

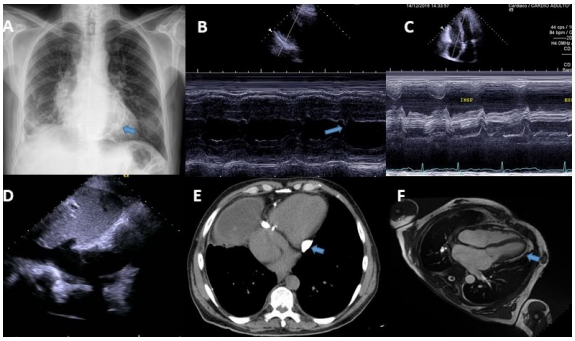
A rare cause of heart transplant

A Ainhoa Perez Guerrero[1]; C Lopez Perales[1]; A Portoles Ocampo[1]; T Blasco Peiro[1]; C Aured Guallar[1]; JM Vallejo Gil[1]; M Lasala Alastuey[1]; A Juez Jimenez[1]; P Auquilla Esteban[1]; I Caballero Jambrina[1]; A Ruiz Aranjuelo[1]; E Gambo Ruberte[1]; J Jimeno Sanchez[1]; M Sanz Julve[1]
[1]*University Hospital Miguel Servet, Zaragoza, Spain*

Introduction: Constrictive pericarditis (CP) is a potentially reversible cause of heart failure. Pericardiectomy is the treatment of choice for chronic constrictive with persistent clinical.
Case Presentation: A 57-year-old male non-immunocompromised patient with past medical history of Tuberculous pericarditis. He was readmitted due to dyspnoea, ortopnea and anasarca. Exploration revealed bilateral jugular vein dissension and hepatojugular reflux, hepatomegaly, ascites and bilateral lower leg pitting edema.
Chest X-ray revealed extensive pericardial calcifications (Figure 1A). Echocardiography showed a small left ventricle (LV) with normal systolic function. 2D and M mode demonstrated ventricular interdependence with an early diastolic notch and a dilated inferior vena cava without respiratory variability (Figures 1B, 1C, 1D). The peak early mitral annular velocities (e') assessed by pulsed wave tissue Doppler at the septal and lateral mitral annulus were 0,1 m/sg and 0,08 m/s, and the ratio of the peak early transmitral velocity (E) to e' (E/e'), was only 5 ("annulus paradoxus"). Right cardiac catheterization confirmed the presence of a constrictive physiology and assisted in discriminating between CP and restrictive cardiomyopathy (RC). Computed tomography (CT) and magnetic resonance imaging (MRI) confirmed extensive pericardial calcification and thickening mostly involving the lateral wall of LV and the atrioventricular grooves (Figures 1E, 1F).
Despite adequate diuretic therapy, the patient was readmitted with the same symptoms. Pericardiectomy was recommended to control the disease. However, due to the location of the pericardial calcification, with a high risk of perforation;

the heart team decided to perform an elective heart transplant that it resulted in a success.

Conclusion: This case illustrates an infrequent cause of CP in industrialized countries, and even more rare cause of heart transplant. Orthotopic transplantation may be considered in highly select patients with CP.



726

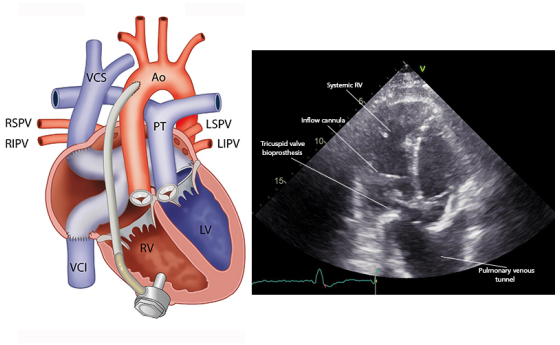
Ventricular assist device implantation in a patient after mustard correction for transposition of the great arteries

T E Zandstra[1]; M Palmen[2]; MG Hazekamp[2]; B Meyns[3]; SMLA Beeres[1]; ER Holman[1]; P Kies[1]; MRM Jongbloed[1]; HW Vliegen[1]; MJ Schalij[1]; LF Tops[1]
[1]Leiden University Medical Center, Cardiology, Leiden, Netherlands; *[2]Leiden University Medical Center, Cardiothoracic surgery, Leiden, Netherlands*; *[3]University Hospitals (UZ) Leuven, Cardiothoracic surgery, Leuven, Belgium*

We present the case of a 47-year-old man with transposition of the great arteries (TGA), for which he underwent atrial switch procedure according to Mustard at 3 years of age. He had received a pacemaker for sick sinus syndrome and later he was ablated for a supraventricular tachycardia. Because of progressive systemic right ventricular (s-RV) failure and important tricuspid valve regurgitation, he received a biological tricuspid valve prosthesis in 2016.

Because of failure of clinical improvement (NYHA class IIIb, INTERMACS level 5), he was screened for cardiac transplant and eventually accepted for ventricular assist device (VAD) implantation in his s-RV, intended as destination therapy (DT). During preoperative admission, his circulatory status was optimized with inotropic support and intravenous diuretics. Sternotomy was performed after cardiopulmonary bypass was started via the femoral vessels. Multiple trabeculations were removed from the s-RV to prevent obstruction of the inflow cannula. Because of lack of space between the sternum and the s-RV, the inflow cannula was placed mid-basally in the ventricle instead of in the apical position that is usual for VAD implantation in the left ventricle. After implantation, stable VAD inflow and outflow cannula flow patterns and normal interventricular septum position were observed with transoesophageal echocardiography. Re-operation was necessary 13 days later because of a tamponade. After that, the patient remained stable and was discharged 1 month after VAD implantation. In the outpatient setting, a ventricular tachycardia (VT) of 185 beats per minute occurred, which was hemodynamically well tolerated. Most likely it originated from the site of the inflow cannula, The VT was successfully terminated with intravenous procainamide, and treatment with sotalol was initiated to prevent recurrent VT. There have been no recurrent VTs and the patient is currently doing well 6 weeks after hospital discharge.

This case illustrates that VAD implantation as DT is a challenging but feasible treatment option for patients after atrial switch correction for TGA and failure of the s-RV.



Schematic and echocardiographic anatomy

Use of Therapeutic Plasma Exchange (PLEX) for Treatment of Vasodilatory Shock Post Heartmate-2 LVAD

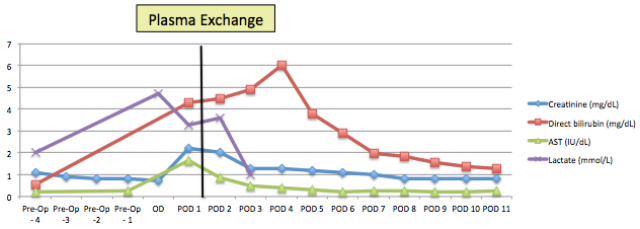
R Raymond Lee[1]; O Gilbert[1]; D Smull[1]; G Marler[1]; S Satko[1]; E Tatum[1]; P Keith[1]
[1]Novant Forsyth Medical Center, Cardiothoracic Surgery, Winston-Salem, United States of America

Objetive: Vasodilatory shock post left ventricular assist device implantation can occur in up to 50% of cases. For cases with refractory vasodilatory shock with signs of multi-system organ failure, morbidity and mortality remain high. We present a case of severe vasodilatory shock post LVAD insertion, treated with therapeutic plasma exchange.

Methods: This is a retrospective case review of a 56 year-old male with non-ischemic cardiomyopathy with New York Heart Classification Class 4 heart failure and severe mitral regurgitation. The patient underwent Heartmate 2 insertion as destination therapy and beating mitral valve repair.

Results: The patient was extubated postoperative day 1 with vasodilatory shock successfully managed by epinephrine and vasopressin pharmacotherapy. Post operative day 2, the patient began to show signs of worsening vasodilatory shock unresponsive to vasopressin, cathecholamines, methylene blue, empiric steroids, and broad spectrum antibiotics. The patient began experiencing multi-system organ failure with liver dysfunction, renal dysfunction, and lactic acidosis. We hypothesized the patient was experiencing refractory vasodilatory shock as a result of an inflammatory cytokine storm. The patient underwent two cycles of plasma exchange with 3.5 liters of FFP each. Within 24 hours, the patient was off all vasopressors with resolution of end organ ischemia and lactic acidosis. All cultures and infectious workup were negative.The patient had an uneventful post operative course and was discharged home.

Conclusions: Vasodilatory shock without an infectious source continues to be a common problem after LVAD insertion. We hypothesize this cytokine storm may be a result of reperfusion injury in a chronically hypoperfused patients and also the inflammatory mediated response to cardiopulmonary bypass. Plasma exchange can reduce TNF alpha, IL-1, IL6, and other inflammatory cytokines, which may contribute to refractory vasodilatory shock. Further studies need to be conducted to elucidate which inflammatory mediators are associated with refractory vasodilatory shock post LVAD insertion.



Laboratory Parameters with PLEX

An unexpected cause of abrupt dyspnea and peripheral edema in heart transplantation recipient.

MN Mi-Na Kim[1]; JS Jung[1]; SM Park[1]; HS Son[1]; WJ Shim[1]
[1]*Korea university anam hospital, Seoul, Korea Republic of*

61 years old women who had underwent orthotopic heart transplantation(OHT) 32 month ago visited to emergency department due to abrupt New York Heart Association grade IV dyspnea and generalized edema. She had been diagnosed with multiple myeloma(MM, ?-type light chain) with amyloid cardiomyopathy(ACM) 5 years ago and undertaken chemotherapy. At 1 year after chemotherapy, bone marrow biopsy revealed total remission of MM but heart failure became progressively worse. Therefore she underwent OHT and did not have any symptoms and signs which were suspicious for ACM, as well as MM during follow-up. Subsequent routine endomyocardial biopsy(EMB) did not show deposition of amyloid in myocardium.
On admission, she looked puffy and her jugular vein was distended. The breathing sound was diminished in both lower lung field. Bilateral lower extremity pitting edema was observed to groin area. Chest radiography showed newly developed cardiomegaly and bilateral pleural effusion. There was no significant changes on electrocardiogram, compared with previous examinations.
Under suspicion of allograft rejection, echocardiography and EMB were conducted. Echocardiography showed thickened pericardium and increased echogenicity within pericardial space with loculated pericardial effusion(Figure1A). Left ventricular size and function were normal(LVEF = 63%) but septal bouncing motion, respiratory variation of mitral inflow and plethora of inferior vena cava were observed. Cardiac computed tomography revealed thickened pericardium(thickness = 7.8mm) with localized pericardial effusion(Figure1B). There was no evidences of allograft rejection nor amyloid deposit on EMB.
From these findings, constrictive pericarditis was diagnosed. We suspected atypical infection like tuberculosis or recurred amyloidosis as cause of constrictive pericarditis. She had heavy proteinuria (9.8 g/24h) and hypoalbuminemia(2.2g/dL). Recurrence of amyloidosis was strongly suspicious. For confirmation, minimal open pericardial biopsy was performed. Perivascular and interstitial amyloid deposits were detected on Congo-red stain(Figure1C) and polorized light microscopy(Figure1D). Electron microscopic examination showed aggregate of non-branching filaments amyloid fibrils in the interstitial tissue of pericardium(Figure1E). BM biopsy showed a 15% monoclonal plasma cell(?-type) infiltration. She began to recieve chemotherapy with lenalidomide and dexamethasone.
OTH for with cardiac amyloidosis remains controversial because of concerns about recurrent amyloid deposition in allograft heart and insufficiency of donor. Nevertheless OHT has been considered as a therapeutic option for an untreatable ACM. Recurrence of ACM in transplanted heart mostly occurs in myocardium. The amyloid involvement only in pericardium is extremely rare. To the best of our knowledge, herein we present the first case of recurred amyloidosis in pericardium without evidence of myocardial involvement in transplanted heart.

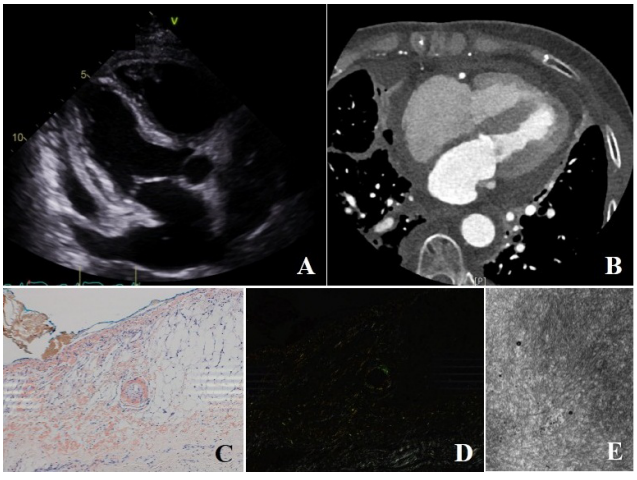

Figure 1

729

Sudden death after cardiac transplantation.

I Malek[1]; M Podzimkova[1]; M Hegarova[1]; V Melenovsky[1]
[1]*Institute for Clinical and Experimental Medicine, Cardiology, Prague, Czech Republic*

Introduction: Sudden death after cardiac transplantation is relative frequent complication contributing to 10-58 % of deaths. The most frequent finding on postmorten examination is coronary vasculopathy, but in one third of deceased patients (pts) no coronary pathology has been detected. Ventricular fibrillation is suspected as a mechanism of death, but doccumented cases are rare.
Aim: Presentation of the case of the patient, who was succesfully resuscitated for sudden circulatory standstill due to electromechanical dissociation.
Case report: Male 37 years old with dilated cardiomyopathy developed terminal heart failure and in Aug. 2012 orthotopic cardiac transplantation (CTX) was performed with uncomplicated course in subsequent 16 months. Unfortunately, he interrupted immunosupressive therapy and appeared with severe graft failure due to combined cellular and antibody mediated rejection. After intensive therapy including plasmapheresis, rituximab and bortezomib graft function and clinical status improved, but donor specific antibodies (DSA) class II were present in blood (SAB Luminex method). Consecutive 3 years were uneventful, except of one episode of bradycardic syncope, solved by 2D pacemaker implantation. In 1/2017 the patientt was succesfuly resuscitated for sudden circulatory standstill and cardioverter-defibrillator (ICD) was implanted. Graft function was normal, as well as coronary angiography findings. High amounts of DSA class II were found in blood, with only partial effect of therapy including immunoadsorbtion. Three month later circulatory standstill recurred, the pt was once more resuscitaded with normal findings afterwards. No tachyarythmia or cardiac standstil was documented on ICD record. Electromechanical dissociation due to diffuse coronary spasm was suspected as the primary cause. Nowadays (11/2017) pt is in good clinical condition, medical therapy is directed on coronary artery disease prevention, including m-TOR inhibitor added to immunossuppressive prophylaxis. Unfortunately, DSA are still present, with only modest derease in spite of repeated attempts of elimination.
Conclusion: Circulatory standstill after CTX is not always sequelae of ventricular tachyarrythmia or conduction disturbance. Here we documented electromechanical dissociation, probably due to diffuse spasm of coronary vasculature. Elimination of DSA is mandatory as these antibodies contribute to the development of coronary vasculopathy.

730

Ventricular assist device support for failing systemic ventricle in adult patient with congenitally corrected transposition of the great arteries and dextrocardia

S Sandra Jaksic Jurinjak[1]; M Udovicic[1]; B Starcevic[1]; M Stipcevic[1]; V Ivanovic[1]; D Susnjar[2]; H Falak[1]; J Vincelj[1]; M Planinc[2]; R Blazekovic[2]; N Bradic[3]; Z Sutlic[2]
[1]*University Hospital Dubrava, Institute of Cardiovascular Diseases, Department of Cardiology, Zagreb, Croatia*; [2]*University Hospital Dubrava, Department of Cardiac surgery, Zagreb, Croatia*; [3]*University Hospital Dubrava, Department of Cardiac Anesthesiology, Zagreb, Croatia, Zagreb, Croatia*

Patients with congenitally corrected transposition of great arteries (ccTGA) present with heart failure commonly in the fourth or fifth decade of life. Prevalence of ccTGA is < 0.5%, with dextrocardia reported among 20% of these patients. We present a 52-year old female patient with ccTGA and dextrocardia. In 2008, she was first admitted to our institution because of heart failure and diagnosed with ccTGA combined with dextrocardia. She was treated with heart failure medications for approximately ten years which improved her condition. In the January 2017, despite optimal medication, she developed congestive heart failure and required additional rehospitalization with symptoms of congestion and low cardiac output with elevated NT-pro-BNP levels up to 10752 pg/mL. Her cardiac functional status decreased to NYHA (New York Heart Association) class IV. She was treated with inotropic support and careful volume management. Echocardiography confirmed the presence of ccTGA and dextrocardia with situs solitus, with ejection fraction of dilated systemic right ventricle less than 20%. Patient also had severe tricuspid regurgitation and mild mitral regurgitation, mild pulmonic regurgitation with mild subpulmonic obstruction due to accessory fibrous tissue of basal part of interventricular septum. She was at that time evaluated for heart transplantation and placed on the cardiac transplant waiting list. Despite medication her condition deteriorated, so invasive haemodynamics measurements were repeated revealing RVP 71/6/19mmHg, PCWP 29mmHg, CI 1,39 L/min/m2, MPAP 45mmHg, PVR 6,24WU. Pulmonary hypertension may have induced right heart failure in the transplanted heart, so multidisciplinary heart transplant team decided for long term unloading with ventricular assist device (VAD) as a bridge to heart transplant candidacy. In September 2017 intrapericardial VAD (centrifugal continuous flow, fully magnetically-levitated technology) was implanted at midline position, guided by transoesophageal echocardiography for

positioning the inflow cannula in the systemic ventricle, assessment of an outflow cannula in the lateral right side of ascending aorta, in setting of dextrocardia present in our patient. Post procedural hospital course was complicated by mild subpulmonic ventricle failure managed by inotropic support and pump adjustment. Patient was discharged four weeks after implantation of VAD, taking pharmacological treatment of warfarin, acetylsalicylic acid and heart failure medication, currently in NYHA class I-II. Implantation of VAD in systemic ventricle in ccTGA has been described in small groups of patients, and to our knowledge in a single patient with ccTGA combined with dextrocardia. Accurate imaging (transthoracic echocardiography with contrast, transoesophagic echocardiography, cardiac MSCT) and multidisciplinary heart team is pivotal in successful implantation of small size intrapericardial VAD in patient with complex anatomy as ccTGA and dextrocardia.

731

Bridging a knife's edge with a percutaneous left ventricular assist device: a patient with few options to optimise, but many ways to decompensate.

J Jiliu Pan[1]; SM Ng[1]
[1]*St Thomas' Hospital, London, United Kingdom*

Case presentation: A 78 year old man presented with a one day history of chest pain and shortness of breath on a background of hypertension, previous episodes of atrial fibrillation, COPD, bipolar disorder.
The patient was peripherally shut down and a lactic acidosis suggested an element of cardiogenic shock. There was clinical and radiological evidence of pulmonary oedema. Electrocardiograms (ECG) revealed atrial flutter with ventricular rates up to 150 bpm with inferior Q-waves and lateral ST depression. A CT pulmonary angiogram (CTPA) provisionally suggested a pulmonary embolus (PE). Initial Troponin-T was 236 ng/L and peaked 2 days later at 584 ng/L.
Problems and management: It was thought that a PE drove the tachyarrhythmia which then caused the low cardiac output and subsequent coronary ischaemia. However, an effort to rate-control with beta-blocker and verapamil resulted in a bradycardic and hypotensive decompensation requiring atropine and adrenaline to resuscitate. An acute screening echo suggested severe left ventricular (LV) dysfunction, thin akinetic inferior wall and moderate mitral regurgitation. A senior radiological review of the CTPA the next day refuted the diagnosis of PE. Subsequent management involved a period of continuous positive end-expiratory pressure and diuresis. Tachycardia and hypotension was a recurrent problem but was eventually controlled on amiodarone.
Coronary angiography revealed a chronically occluded right coronary artery and severe left main stem stenosis. A multidisciplinary meeting decided that the patient was too high risk for cardiac surgery.
The patient subsequently underwent coronary intervention with the support of a percutaneous left ventricular assist device (PLVAD). Left main stem stenting achieved good angiographic result but following the procedure the patient lost intrinsic cardiac output, relying solely on the PLVAD for cardiac output and to stay awake and asymptomatic. He then improved with fluid resuscitation.
The patient later declined further treatment and discharged himself.
Discussion: This patient's cardiac output did not need much of a push to fall off the edge. Underlying it was severe coronary disease, ventricular dysfunction, tachyarrhythmia and possible PE. The cause-effect relationship between these was unclear and initial treatments were met by further compromise. A PLVAD supported him through another decompensation following coronary intervention.
Lessons learnt and future implications: This case serves as a reminder that cause and effect (especially when unclear) should not always dictate acute management while stabilisation is key. In our efforts to achieve the optimum, we must not forget the dangers of overstepping the mark with an ever-expanding therapeutic repertoire at our fingertips.
Will future technology play greater roles in mitigating our human limitations and shortcomings?

732

Bortezomib-related acute cardiogenic shock in multiple myeloma patient with perivascular cardiac and renal amyloidosis. A clinical report.

A Greco[1]; C Ranieri[1]; I Raso[1]; M Wu[1]; T Spezzano[1]; B Matrone[1]; R Camporotondo[1]; R Totaro[1]; G Tavazzi[2]; E Arbustini[3]; GM De Ferrari[1]; L Oltrona Visconti[1]
[1]*Policlinic Foundation San Matteo IRCCS, Cardiology, Pavia, Italy*; [2]*Policlinic Foundation San Matteo IRCCS, General Intensive Care, Pavia, Italy*; [3]*Policlinic Foundation San Matteo IRCCS, Pathology, Pavia, Italy*

Background: Amyloidosis is a rare systemic disease in which insoluble amyloid proteins are deposited in body organs with the extent of cardiac involvement acting as the major determinant of a poor prognosis.
Case Report: A 61-year old man with kappa chain multiple myeloma complicated by perivascular cardiac and renal amyloidosis started treatment with bortezomib and dexamethasone. The day after the second cycle, he developed acute dyspnoea and was found to be in cardiogenic shock with multiple organ failure. B-type natriuretic peptide was 34308 pg/mL (nv < 210) and troponin T 3112 ng/mL (nv < 14). In comparison with recent echocardiographic evaluation (see Table 1) left ventricular ejection fraction (LVEF) dramatically dropped to 10%, with associated advanced right ventricular dysfunction. Urgent venoarterial extracorporeal membrane oxygenation (ECMO) with intra-aortic balloon pump (IABP) were required. Endomyocardial biopsy showed acute and spread myocyte damage, with some ongoing reparative processes. LVEF slowly but progressively improved allowing ECMO and IABP removal after three weeks, and discharge three weeks later. The overall behaviour was indicative of bortezomib toxicity.
Conclusions: Although proteasomes inhibition by bortezomib is known to rarely induce cardiac dysfunction, the occurrence of severe refractory cardiogenic shock has never been described. Perivascular amyloidosis has possibly contributed to the severity of the effect. Immediate advanced circulatory support and prompt diagnosis with endomyocardial biopsy have allowed a favourable outcome.

Table 1: Echocardiographic evaluation

	December 2016	February 2017 (acute onset)	November 2017

Continuous Intravenous Inotropes as a Bridge to Myocardial Recovery

O Ofer Havakuk[1]; LP Grazette[2]
[1]*Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*; [2]*University of Southern California, Cardiology, Los Angeles, United States of America*

Background: Chronic inotrope therapy in advanced heart failure (HF) patients is generally considered palliative and contemporary guidelines recommend low dose and early discontinuation of inotropic therapy due to concerns for an increased arrhythmia-related mortality. However, data on the use of parental inotropes are scant and mostly predates the current treatment era in HF. Here we

732 Table 1

Age	Sex	Initial EF/EDD	Etiology	Onset of HF	Inotrope type	Inotrope duration	HF Tx	Indication	Final EF/EDD
66	F	10%/6.6cm	ChemoTx	12/2014	Milrinone	11 m	Bisoprolol 5, spironolactone 25, digoxin 0.125, ivabradine 2.5 bid	Palliation	55%/4.3cm

Baseline demographics, therapies and outcomes of 3 advanced HF patients on chronic milrinone therapy

present a case-series of 3 advanced HF patients for whom advanced intervention was either undesirable or not feasible, who showed remarkable myocardial recovery after a prolonged parental inotropic support combined with aggressive guideline-recommended, disease modifying therapy.

Methods and **Results:** Retrospective case review of 3 subjects presenting for evaluation of advanced HF who were discharged on IV milrinone for palliation or bridge to candidacy. Baseline demographics, therapies and outcomes are presented in table 1 and show a dramatic improvement in systolic function.

Conclusion: In select patients unsuitable or reluctant to undergo advanced interventions, extended use of inotropic therapy may facilitate application of disease modifying therapy and represent a bridge to recovery. Prospective investigations are needed.

734
The power of the kidney

P Pablo Meras Colunga[1]; V Rial Baston[1]; FJ Irazusta Cordoba[1]; O Gonzalez Fernandez[1]; A Rivas Perez[1]; A Velez Salas[1]; S Rosillo[1]; AM Iniesta Manjavacas[1]; G Veiga Fernandez[2]; V Fradejas Sastre[2]; L Gayo[3]; M Moreno Yanguela[1]; JL Lopez Sendon[1]
[1]University Hospital La Paz, Cardiology, Madrid, Spain; *[2]University Hospital Marques de Valdecilla, Santander, Spain*; *[3]University Hospital La Paz, Nephrology, Madrid, Spain*

Case description: We present the case of a 31-year-old woman with VACTERL syndrome, expressed as a severe urogenital malformation, esophageal atresia and limb abnormalities. She underwent a nephrectomy when she was 2 years old and at the age of 18 she had to start hemodialysis (HD). A few months later she received a renal transplant (Tx), with good function until 2012, when she suffered an allograft rejection and was obliged to re-start HD.
Until this moment, routine transthoracic echocardiograms (TTE) had shown no abnormalities. In 2013, she was admitted to the hospital for an acute pulmonary edema requiring urgent HD. A new TTE revealed moderate left ventricular (LV) dysfunction and secondary moderate mitral regurgitation (MR). Despite the initiation of treatment with ACEI and beta-blockers, ventricular function deteriorated. In next TTE the LV was markedly dilated, ejection fraction (EF) was 19%, with a restrictive pattern and severe MR, and there was right ventricular dysfunction and mild pericardial effusion. A cardiac magnetic resonance did not show intramyocardial edema or late gadolinium enhancement. Treatment was optimized by adding ivabradine. More important, HD sessions were intensified from three days per week to daily sessions, with strict weight and volume overload control. In addition, she was proposed for a heart-kidney Tx.
Progressively, cardiac function began to recover and one year after starting daily HD, TTE was completely normalized. LV telediastolic diameter was 39 mm with EF 63%, TAPSE 20 mm, and disappearance of MR and pericardial effusion. She was clinically better with NYHA functional class I/IV. The patient underwent a second renal Tx in 2016 and she has been stable and asymptomatic since then.
Discussion: Heart and kidney have close and bidirectional interactions, which has led to the description of cardiorenal syndrome (CRS). Traditionally, this term was used to describe a decline in renal function due to heart failure progression or to the use of therapies to relieve congestive symptoms. The mechanisms by which renal failure may lead to cardiac damage are multiple but have been worse described. Volume overload and a pro-inflammatory status have been suggested to play a role. This case represents an extreme example of CRS. The patient had a small body size (152 cm, 43 kg), so small changes in weight (for example 4 kg between HD sessions) were really important for her (10% relative gain). Volume overload with increased ventricular filling pressures could explain most of myocardial wall stress and progressive deterioration. Absence of other findings suggesting different etiologies and complete recovery with daily sessions support this explanation. Curiously, HF drugs seem to have had a minor effect in the evolution.
Conclusions: This case illustrates a pure type 4 CRS with extremely severe cardiac damage that was solved with complete recovery by means of optimal dialysis management in addition to medical treatment.

735
Cardiogenic shock in an adult patient with severe haemolytic uraemic syndrome supported with veno-arterial ECMO as a bridge to recovery

M Kelham[1]; L Gleeson[1]; I Alcalde[1]; R Spiritoso[1]; J Cordingley[1]; S Woldman[2]; J Down[3]; M Scully[4]; A Proudfoot[1]
[1]Barts Health NHS Trust, Department of Perioperative Medicine, Barts Heart Centre, London, United Kingdom; *[2]Barts Health NHS Trust, Cardiology, Barts Heart Centre, London, United Kingdom*; *[3]University College Hospital, Critical Care, London, United Kingdom*; *[4]University College Hospital, Haematology, London, United Kingdom*

A 19 year old female with no past medical history presented with bloody diarrhoea. Investigations revealed acute kidney injury, thrombocytopenia and microangiopathic haemolysis. Stool sample confirmed E. coli 055 and a diagnosis of haemolytic uraemic syndrome (HUS). CT abdomen demonstrated severe pancolitis and normal sized kidneys with multiple renal infarcts. She was commenced on antibiotics, haemofiltration and daily plasma exchange. Transthoracic echocardiogram (TTE) performed on day 10, in response to a serum troponin T of >500ng/L, revealed normal biventricular function and a small pericardial effusion with no haemodynamic compromise.
On day 11 she rapidly deteriorated with tachycardia, drowsiness and a serum lactate of >8mmol/L. Bedside TTE supported a diagnosis of tamponade. Drainage of 180ml of straw-coloured pericardial fluid failed to improve her haemodynamic status. Repeat TTE (figure 1) demonstrated severe biventricular impairment with an EF of < 15%. Pulmonary artery catheter data demonstrated a cardiac index of 1.9 L/min/m2 and pulmonary capillary wedge pressure of 20mmHg. Despite moderate doses of adrenaline and milrinone her lactate remained elevated at >5mmol/L with clinical evidence of hypoperfusion. CT brain showed symmetrical changes in the basal ganglia likely secondary to microvascular thrombosis.
In view of her refractory cardiogenic shock, a multi-disciplinary conference call (SHOCK call) with heart failure cardiology, critical care and mechanical support specialists was undertaken through an app based mobile teleconference. Despite a high predicted mortality, the prognostic uncertainty merited a trial of veno-arterial extracorporeal membrane oxygenation (VA-ECMO). Plasma exchange was continued and treatment with Eculizumab, a complement inhibitor normally reserved for atypical HUS, was initiated on day 2 of ECMO in view of the evidence of significant complement over activation with likely microangiopathic injury in the coronary microvasculature, myopericarditis, and renal and central nervous system infarction. She was stabilised with an ECMO flow of 3.4L/min with pulsatility throughout. After 72 hours her physiology and cardiac imaging (TTE) supported cardiac recovery and she was decannulated from ECMO after 96 hours. She was discharged home after 13 weeks with an ejection fraction of 60%, NYHA Class I symptoms, normalisation of her renal function and resolution of the basal ganglia changes on MRI. She suffered bilateral visual loss, which is expected to persist.
We present the first adult case, to our knowledge, of HUS induced cardiogenic shock supported with VA-ECMO as a bridge to cardiac recovery. We highlight the role of the multidisciplinary team as well as the SHOCK call system to optimise decision-making and outcomes in cardiogenic shock. We also raise the potential role of Eculizumab for infection related HUS if there is evidence of complement over activation.

Low socioeconomic status is associated with higher risk of readmission among patients with heart failure with reduced ejection fraction: a population-based cohort study

I Inge Schjoedt[1]; SP Johnsen[2]; A Stromberg[3]; NK Kristensen[4]; BB Loegstrup[1]
[1]Aarhus University Hospital, Department of Cardiology, Aarhus, Denmark; *[2]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*; *[3]Linkoping University, Department of Medical and Health Sciences, Linkoping, Sweden*; *[4]Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark*

Funding Acknowledgements: The Danish Nurses Organization Research Foundation and PROCRIN established by the Lundbeck Foundation and the Novo Nordisk Foundation

Introduction: Low socioeconomic status is associated with higher incidence of heart failure (HF) and mortality following HF diagnosis. However, the role of low socioeconomic status on risk of unplanned hospital readmission in patients with HF remains unclear.
Purpose: To investigate the association between socioeconomic status and unplanned hospital readmission following HF diagnosis.
Methods: A population-based cohort study based on data from Danish nationwide public registries. We identified patients with incident HF with reduced ejection fraction (= 40%, HFrEF) between January 2008 and October 2015 in a national heart failure registry. Socioeconomic status was assessed based on three variables; cohabiting status, highest education attained, and mean family income. Outcomes included all-cause hospital readmission, HF readmission and non-HF readmission within days 1-30, 31-90 and 91-365 following HF diagnosis. We used Cox regression to estimate hazard ratios (HR) of readmission, controlling for potential confounders.
Results: We identified 17,214 patients with HFrEF. Mean age was 70.0 ± 12.8 years, 68.6% men, 25.4 % left ventricular ejection fraction < 25% and 27.2% NYHA (New York Heart Association) functional class III-IV. A total of 8,341 patients (48%) were readmitted at least once within the first year after the HF diagnosis. Patients with a low socioeconomic status (living alone, low educational level and a low family income) had a higher risk of all-cause readmission (adjusted HR 1.42; CI 95% 1.14-1.78) and a higher risk of non-HF readmission (adjusted HR 1.35; CI 95% 1.06-1.71) within days 31-90 compared to patients with a high socioeconomic status (cohabiting, high educational level and a high family income). However, low socioeconomic status was not associated with any type of readmission within days 1-30 and days 91-365 in the adjusted analysis. Regarding the individual socioeconomic variables, neither cohabiting status nor educational level were associated with readmission within days 1-30, 31-90 and 91-365 in the adjusted analysis. However, low family income was associated with higher all-cause readmission (adjusted HR 1.20; CI 95% 1.04-1.38) and non-HF readmission risk (adjusted HR 1.31; CI 95% 1.13-1.52) within days 31-90. In addition, low family income was associated with higher risk of all-cause readmission (adjusted HR 1.27; CI 1.14-1.41, HF readmission (adjusted HR 1.26; CI 1.02-1.54) and non-HF readmission (adjusted HR 1.24; CI 1.11-1.38) within days 91-365. The same pattern was seen for medium compared to highest family income.
Conclusion: Low socioeconomic status was associated with higher risk of all-cause readmission and non-HF readmission within days 31-90 following HF diagnosis in patients with HFrEF, but not with very early or late readmissions.

781

Person-centred telephone-support is effective in patients with chronic obstructive pulmonary disease and/or chronic heart failure - six-month follow-up of a randomized controlled trial

A Fors[1]; E Blanck[1]; L Ali[1]; K Swedberg[2]; I Ekman[1]
[1]University of Gothenburg, Sahlgrenska Academy, Centre for Person-Centred Care (GPCC), Institute of Health and Care Sciences, Gothenburg, Sweden; *[2]University of Gothenburg, Sahlgrenska Academy, Centre for Person-Centred Care (GPCC), Department of Molecular and Clinical Medicine, Gothenburg, Sweden*

Funding Acknowledgements: Swedish Research Council; ALFGBG; Research and Development Unit, Primary Health Care, Region Västra Götaland

Background: Long term health conditions, including chronic heart failure (CHF) and chronic obstructive pulmonary disease (COPD), are one of the major challenges facing healthcare systems worldwide; and telehealth has been suggested as a safe option to promote self-management. The effectiveness of person-centred care as a tool to improve health care has been demonstrated in several conditions and contexts but there are few existing telehealth interventions that fully address person-centred care.
Purpose: To evaluate the effects of person-centred support at distance via telephone for patients with CHF and/or COPD.
Method: 221 patients = 50 years with CHF and/or COPD were randomized to usual care or a person-centred telephone-support intervention in addition to usual care and followed during six months. In the intervention group patients where phone called by a registered nurse and a person-centred health plan reflecting both perspectives was co-created, which was further discussed and evaluated during additional follow-ups by telephone. A composite score of changes that included changes in general self-efficacy = 5 units, re-hospitalization and death was used as primary outcome measure.
Results: At the six-month follow-up no difference in the composite score was found between the two study groups (57.6%, n = 68 vs. 46.6%, n = 48; OR = 1.6, 95 % CI: 0.9 - 2.7; P = 0.102). Significantly more patients in the control group decreased = 5 units in general self-efficacy (22.9%, n = 27 vs. 9.7%, n = 10; OR = 2.8, 95% CI: 1.3 - 6.0; P = 0.011). There were no differences between groups on re-hospitalization or death. In the per-protocol analysis of the composite score more patients in the control group deteriorated compared with the intervention group (57.6%, n = 68 vs. 42.9%, n = 36; OR = 1.8, 95% CI 1.0 - 3.2; P = 0.039).
Conclusion: A person-centred support at distance via telephone mitigates worsened self-efficacy without increasing the risk of clinical events in patients with CHF and/or COPD. This highlights the possibility to establish a patient-health care professional partnership, which is not dependent on face-to-face consultations, not the least in vulnerable patient groups.

782

Objectively measured frailty score and mortality in elderly patients hospitalized for heart failure

K Kamiya[1]; S Tanaka[2]; N Hamazaki[2]; R Matsuzawa[3]; K Nozaki[3]; E Maekawa[4]; A Matsunaga[1]; T Masuda[1]; J Ako[4]
[1]Department of Rehabilitation, School of Allied Health Sciences, Sagamihara, Japan; *[2]Department of Cardiovascular Medicine, Kitasato University Graduate School of Medical Sciences, Sagamihara, Japan*; *[3]Kitasato University Hospital, Sagamihara, Japan*; *[4]Department of Cardiovascular Medicine, Kitasato University School of Medicine, Sagamihara, Japan*

Background: Frailty in geriatric patients is defined as a syndrome of decreased physiological reserve and vulnerability to stressors, broadly classified as acute or chronic illnesses. Due to a lack of a simple and objective tool for its assessment, the impact of frailty on the prognosis of elderly patients hospitalized for heart failure (HF) remains unclear.
Objectives: This study was performed to examine the prognostic utility of frailty score in elderly patients hospitalized for HF.
Methods: A retrospective cohort study was performed in 603 consecutive HF patients with a mean age of 75 ± 6 years (378 men). Frailty was measured by a composite of four markers combined into a frailty score (possible range 0 - 12): gait speed, handgrip strength, serum albumin, and activities of daily living status (Green et al.JACC Cardiovasc Interv 2012). The Meta-Analysis Global Group in Chronic Heart Failure (MAGGIC) risk score was calculated for each participant to assess prognosis on the basis of clinical parameters. The endpoint was all cause mortality. Survival was evaluated using the Kaplan–Meier method and compared by the log-rank test. The relations between each component of the frailty score and mortality were evaluated by Cox regression analyses. The prognostic ability of frailty score was also examined by Cox regression analysis constructing two predictive models as follows: Model 1: MAGGIC risk score, Model 2: Model 1 + comorbidity score + BNP.
We calculated the incremental information added by frailty score over MAGGIC risk score using the continuous net reclassification improvement and integrated discrimination improvement, developed as more sensitive statistical methods to quantify model improvement with the addition of a new variable to an existing clinical model.

Results: Over a mean follow-up period of 1.7 ± 0.5 years, 89 patients died. Following adjustment for several preexisting factors associated with prognosis, i.e., MAGGIC risk score and comorbidities, the frailty score (hazard ratio [HR]: 1.11; P = 0.014) and frailty (HR: 1.75; P = 0.036) were independently associated with all-cause mortality. Including frailty score in the MAGGIC risk score significantly increased continuous net reclassification improvement (0.396; P < 0.001) and integrated discrimination improvement (0.017; P = 0.030) for all-cause mortality.
Conclusions: Frailty score provides accurate prognostic information in elderly patients hospitalized for HF.

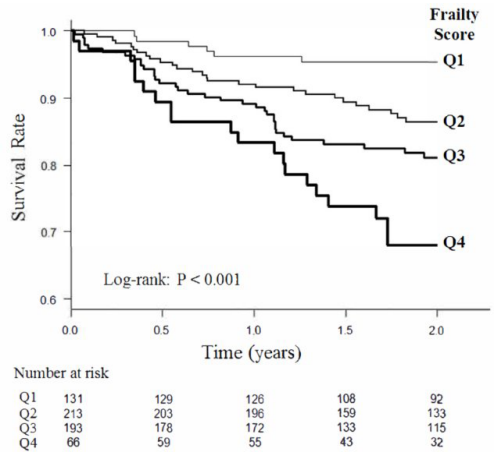

Fig. Frailty Score and Mortality

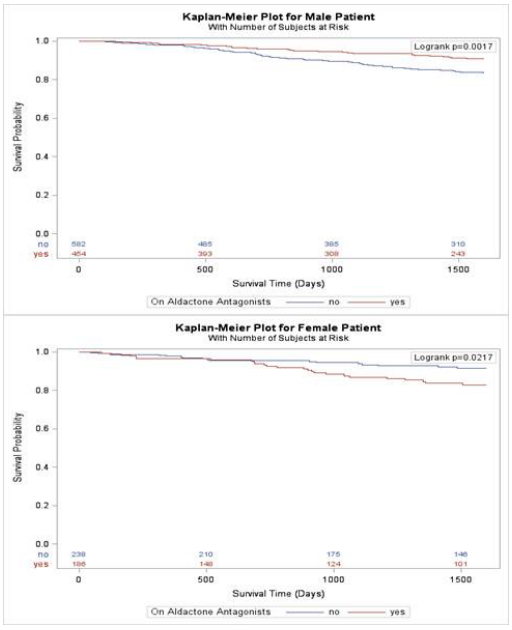
783

gender differences in the response to spironolactone in patients with chronic heart failure : a propensity matched analysis

M May Khateeb[1]; R Odeh[2]; HA Ardah[2]; AM Ahmed[2]; AA Alanazi[2]; MH Al-Mallah[2]
[1]King Abdulaziz Medical City, Riyadh, Saudi Arabia; [2]King Abdulaziz Medical City, King Abdulaziz Cardiac Center, Riyadh, Saudi Arabia

Background: The current ACC guidelines recommend using spironolactone in patients with advanced heart failure reduced left ventricular systolic function (HFrEF). The aim of this analysis is to determine whether gender differences exist in the response to spironolactone use in a contemporary HFrEF cohort.



Methods: We included 2,805 (Mean age of 57.8, 28.34 % females) consecutive HFrEF patients treated in dedicated heart failure clinic. Patients were divided into 2 groups depending on whether they received spironolactone. Propensity matching was used to match the groups in a 1:1-2 fashion. The primary outcome was all-cause mortality (ACM)
Results: Of the initial 2,805 patients, 692 spironolactone users were matched with 917 non users. The matched cohort did not have differences among demographics and clinical variables. Overall, the prevalence of the use of guideline suggested therapies was 96%. After a median follow-up duration of 4.4 years, 231 patients died. Overall, spironolactone use was associated with decreased ACM (14.2% vs. 19.7%; P = 0.006). In multivariate adjusted analysis, there was a significant interaction between gender, spironolactone use and ACM. A significant reduction in ACM was observed among male patients (HR 0.700; 95% CI 0.493t o 0.993), while there was a trend towards increased mortality among females (HR 1.311; 95% CI 0.804to 2.139).Result
Conclusion: In this analysis of well treated HFrEF patients, spironolactone was associated with improved survival, primarily in male patients.

784

App based remote monitoring of cardiac implantable device:patients' expectation

A Zanni[1]; C Sticozzi[1]; M Pessina[1]; A Villani[1]; MF Piepoli[1]; GQ Villani[1]
[1]Guglielmo da Saliceto Hospital, Cardiology, Piacenza, Italy

Background: Remote monitoring (RM) of cardiac implantable electronic devices (CIEDs) is an established technology integrated into clinical practice, which allows data exchange, doctor–doctor and doctor–patient communication, and remote vital sign monitoring. Recent developments in smartphone technology and the introduction of smartphone-compatible devices that can measure various health parameters and able to automatic transferring of generated data, have increased the possibilities for remote monitoring and the interest in Mobile health (mHealth).
Objective: The patients' interests in the possibility of receiving directly RM data from their CIED, clinical and health advices on their smartphones were investigated.

Which data related to device mode of operation are you interested to receive on your smartphone?	
1	Device function alert
2	Heart rate changes
3	Device battery life
4	Lead integrity
5	Stimulation percentage
Which clinical data are you interested to know?	
6	ECG tracing
7	Physical activity level
8	Heart failure severity
9	R-R interval variability
10	Atrial fibrillation occurrence
11	Severe arrhythmias occurrence
12	Silent device intervention
Which healthy lifestyle promotion alerts are you interested to receive?	
13	Have you performed at least 30' physical activity daily?
14	Did you check your weight?
15	Did you check your daily liquid intake?
16	Did you take your pills?
17	Have you been careful in your diet?
18	Have you reduced your salt intake?
19	Stop smoking alert
In addition are you interested in	
20	Regular remind for your pill intake
21	The possibility to have direct contact with your GP and/or medical center

Figure 1

Methods: A questionnaire entitled "Expectations for future possibility of self-management of device data" (Figure 1) (Likert scale scored) was submitted to 300 consecutive patients attending the outpatient clinic. The questionnaire was focused to collect patients' expectations in receiving direct information regarding their CIED status (item 1, five questions), their own clinical status (item 2, seven questions) and advices on healthy lifestyle promotion (item 3, nine questions). Individual patient characteristics associated with higher interest were also investigated.
Results: Complete questionnaires were available from 268 patients (221 males, 69 ± 14years). The Cronbach test reported an alpha value of 0.98 for the item 1, 0.94 for the item 2 and 0.97 for the item 3. Patients declared to be mainly interested in the device interventions (62%) and in the severe arrhythmias occurrence (61%), followed by data on heart failure severity (54%) and their performed physical activity (48%). Patients showed very little interest on ECG tracing (37%). The lowest interest was expressed towards healthy lifestyle promotion advices (< 40%). An high educational degree and the presence of caregiver positively affected the interest in receiving RM information (p < 0.001).

Conclusions: The patients' interests were mainly directed in receiving information related to technical data of the CIED and not to the overall management of the disease, underlying the need to increase patients' awareness on the importance of self-control health status.

785

Healthcare professionals and engineers can work together? development and testing of a text messaging monitoring software for patients with acute decompensated heart failure

L Lopez Pedraza[1]; JR Wagner De Moraes[2]; E R Eneida Rejane Rabelo-Silva[1]
[1]*Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Program at the Nursing School, , Porto Alegre, Brazil*;
[2]*Federal University of Rio Grande do Sul, Porto Alegre, Brazil*

Introduction: Strategies and new approaches are necessary in the current scenario and worldwide panorama of HF epidemiology, in order to prevent both hospital readmissions and morbidities caused by this clinical syndrome. In this perspective, there is an opportunity to boost the increasing accessibility of mobile technologies to enable patients to monitor their own health outside the hospital especially in developing countries. Short Message Service (SMS), which has high utilization rates among less favored socioeconomic groups, is a promising platform for the management of chronic diseases in low-income populations.
Purpose: To develop and test of a text messaging monitoring software for patients with acute decompensated heart failure (ADHF).
Methods: The elaboration of the prototype was developed in three stages: definition of all the expected functionalities, codification of the program modules and tests. The program sends two types of messages: questions that should be answered by the patients, and educational reinforcements that don't require answers. In addition, the system generates alarms in case of no response or according to a flow chart to detect congestion in the patient previously created by the team. For the test we included 10 patients admitted to the hospital for ADHF. After discharge, the system asked about weight, shortness of breath, fatigue and medications so as to detect congestion. Messages that required responses were sent for one week (two in the morning and two in the evening). Educational SMS was sent once every two days.
Results: All the functionalities were defined in several meetings with the researchers of the study, software modules were encoded and several tests were performed. Ten patients participated in the prototype test. The mean age was 67 ± 13 years old. The patients were predominantly males and lived with relatives. The ejection fraction was $35 \pm 7\%$. Of the 264 SMS sent, 247 were answered. The alarm was triggered seven times: three patients woke up with shortness of breath for two consecutive nights and four patients felt more fatigued for two consecutive days. All patients took the prescribed medications during follow-up. The study nurse guided the patients who generated alarm in the system.
Conclusions: SMS software was successfully developed and during the test was possible to visualize some limitations that were corrected. We observed a high response rate and preliminary evidence of improvements in self-management of HF.

Generation and validation of a mouse model of the phospholamban p.Arg14del mutation

T R Eijgenraam[1]; HHW Sillje[1]; RA De Boer[1]
[1]*University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands*

Funding Acknowledgements: CVON-DOSIS grant 2014-40; NWO VIDI grant 917.13.350 and a PLN patient foundation grant

Background: The phospholamban p.Arg14del (PLN-R14del) mutation is the most frequently identified mutation in cardiomyopathy patients in the Netherlands. Human carriers of the PLN-R14del mutation have a high risk of developing heart failure with a phenotype of arrhythmogenic cardiomyopathy (ACM) or dilated cardiomyopathy (DCM). Cardiomyopathy patients with the PLN-R14del mutation show more appropriate implantable cardioverter-defibrillator (ICD) discharges and greater family history of sudden cardiac death (SCD). So far, no established therapeutic treatment exists for these patients.
Purpose: In order to investigate the underlying pathology of this disease, we aimed to develop a mouse model that exactly resembles the situation of human PLN-R14del carriers.
Methods: The PLN-R14del mutation was introduced into the genome of C57BL/6N mice and backcrossed into C57BL/6J mice. Presence of the mutation was confirmed by genomic sequencing and RNA expression of the mutant form was confirmed by cDNA sequencing. We performed cardiac phenotyping on these mice including cardiac MRI, ECG and histological analysis (n = 3-8).
Results: Homozygous PLN-R14del mice showed increased left ventricular (LV) volume in diastole (42.91 ± 0.20µl vs. 58.31 ± 4.68µl, $p < 0.05$) and systole (16.40 ± 1.23µl vs. 39.93 ± 4.83µl, $p < 0.001$) with a decreased LVEF ($61.85 \pm 1.92\%$ vs. $31.96 \pm 2.89\%$, $p < 0.001$) and limited life span as compared to control mice. We also demonstrated other findings compatible with DCM, including decreased wall thickness in diastole (0.70 ± 0.01mm vs. 0.64 ± 0.01mm, $p < 0.05$) and systole (1.07 ± 0.07mm vs. 0.86 ± 0.04mm, $p < 0.05$). Furthermore, decreased QRS-complex voltage (1.18 ± 0.13mV vs. 0.55 ± 0.06 mV, $p < 0.01$) was observed. Finally, histological analysis demonstrated a strong increase in cardiac fibrosis ($1.07 \pm 0.11\%$ vs. $14.31 \pm 2.42\%$, $p < 0.05$).
Conclusions: We have generated a representative mouse model of PLN-R14del-induced cardiomyopathy that develops a similar cardiac phenotype as seen in human mutation carriers and thus properly mimics the human situation. This model will be useful in better understanding of cardiomyopathies that are primarily caused by PLN mutations or with secondary PLN abnormalities. At a later stage, we will study potential therapeutic treatment strategies.

HDAC inhibitors repress cardiac hypertrophy through hyperacetylation of 14-3-3 chaperones and nuclear accumulation of class II HDACs

D Daniel Finke[1]; LH Lehmann[1]; L Frischbier[1]; S Wieber[1]; HA Katus[1]; J Backs[1]
[1]*University Hospital of Heidelberg, Heidelberg, Germany*

Histone deacetylase inhibitors (HDACi) are new anti cancer drugs. It has also been suggested that HDACi inhibit cardiac hypertrophy, but the critical downstream targets remained unclear.
Here we show that superoylanilide hydroxamic acid (SAHA) treatment reduced the activity of the transcription factor myosin enhancer factor 2 (MEF2) in neonatal rat ventricular cardiomyocytes (NRVMs). Additionally, the prohypertrophic effects of endothelin (ET-1), phenylephrine (PE) or serum (FCS) on NRVMs were blunted. (FCS: 177% vs. 115%**; PE: 163% vs. 106%**, ET-1: 164% vs. 115%**; ** = $p < 0.05$). Gene silencing of HDAC1 to HDAC11 by siRNA unmasked that HDAC4 and HDAC5 act as the main repressors of MEF2. Likewise, HDAC4/HDAC5 double knockout mice displayed reduced fractional shortening and cardiac hypertrophy at an age of 18 weeks, whereas single HDAC deletion did not lead to an obvious cardiac phenotype, pointing to redundant roles of HDAC4 and HDAC5 in the regulation of cardiac function and hypertrophy. Treatment with SAHA led to hyperacetylation of the chaperone 14-3-3, which resulted in a lower binding affinity of 14-3-3 to HDAC4 and HDAC5. Accordingly, mimicking 14-3-3 acetylation by replacing specific lysines with glutamines at the predicted acetylation sites led to reduced HDAC-14-3-3 binding. SAHA also inhibited nuclear export of class IIa HDACs upon ET-1, FCS or PE treatment. The critical histone deacetylases that act enzymatically on 14-3-3 were further identified by the siRNA approach, leading to the identification of distinct HDACs that do not inhibit but promote MEF2 activity.
We conclude that HDACis might act as antihypertrophic agents by promoting nuclear accumulation of the class IIa HDACs HDAC4 and HDAC5 with subsequent MEF2 inhibition. This effect might be explained by a loss of binding of HDAC4 and HDAC5 to the hyperacetylated chaperone 14-3-3.

Changes in titin phosphorylation and PKG activity underlie diastolic dysfunction at the cross-bridge level in the early stages of type 2 diabetes

MT Waddingham[1]; N Hamdani[2]; AJ Edgley[3]; H Tsuchimochi[4]; T Sonobe[4]; DJ Kelly[3]; N Yagi[5]; WJ Paulus[1]; M Shirai[4]; JT Pearson[4]
[1]*VU University Medical Center, Amsterdam, Netherlands*; [2]*Ruhr University Bochum (RUB), Bochum, Germany*; [3]*University of Melbourne, Melbourne, Australia*; [4]*National Cerebral and Cardiovascular Center, Osaka, Japan*; [5]*Japan Synchrotron Radiation Research Institute , Harima, Japan*

Background: Patients with insulin resistance (IR) and type-2 diabetes mellitus (T2DM) are at a significantly increased risk of developing heart failure with preserved ejection fraction (HFpEF). The pathological changes to the myocardium that drive the evolution of diabetic cardiomyopathy (DCM) and eventually HFpEF, are still largely unknown. Using synchrotron radiation as a source for small angle x-ray scattering (SAXS) in the in situ beating heart and simultaneous left ventricular (LV) pressure-volumetry, we have shown a clear correlation between diastolic myosin head displacement and declining LV function in a rat model of early type-1 diabetes (T1DM). These data suggest that the actin-myosin cross-bridges and the myofilament/sarcomeric regulatory proteins play a role in the development of DCM in early T1DM.
Purpose: To examine if pathological changes at the level of the cross-bridge and the myofilament/sarcomeric regulatory proteins contribute to myocardial dysfunction in the early stages of T2DM.
Methods: Male Goto-Kakizaki (GK) rats, a non-obese model of IR and T2DM (10-12 weeks old, n = 7) and age-matched Wistar control rats (n = 9) were surgically anaesthetised, thoracotomised and cardiac catheterisation was performed. Myocardial SAXS patterns showing myosin mass transfer within in situ cardiomyocytes were then digitally recorded in different layers of the LV free-wall. Western blotting and SDS-PAGE were used to determine total and phosphoprotein levels of sarcomeric proteins and protein kinase activity in the myocardium.
Results: In comparison to the Wistar rats, GK rats exhibited mild hyperglycaemia ($P < 0.05$) and greater cardiomyocyte cross-sectional area ($P < 0.01$). Early diastolic dysfunction was demonstrated in GK rats as evidenced by a significantly prolonged Tau relaxation constant (12 ± 1 vs. 9 ± 1msec, $P < 0.05$) and a slight elevation in LV end diastolic pressure (11.9 ± 2.2 vs. 8.3 ± 1.2 mm Hg, NS). Myosin head displacement from actin in the subendocardium was increased ($P < 0.05$) in GK rats compared to Wistar rats. No differences in the relative phosphorylation of the small myofilament proteins cMyBP-C, cTnI or MLC-2 were found between the two groups, however titin phosphorylation was significantly lower in GK rats ($P < 0.05$) when compared to Wistar. Importantly, site-specific titin phosphorylation was significantly lower at the PKG site S4080, which was associated with reduced myocardial PKG activity in GK rats (both $P < 0.05$ vs. Wistar rats). These changes occurred largely independent of indices of oxidative stress.
Conclusion: Early diastolic dysfunction may be attributed to myosin head displacement from actin in sarcomeres of the subendocardium in young IR GK rats. Given that the phosphorylation state of titin is an important regulator of myocardial relaxation and cross-bridge kinetics, a reduction in myocardial PKG activity may be an underlying cause of early DCM and its progression to HFpEF.

857

Myocyte BDNF generation prevents chronic post-ischemic decompensation via cardiac reinnervation: the role of beta-AR and GRK2 signals.

A Cannavo[1]; G Rengo[2]; ML D'amico[2]; A Elia[2]; J Agrimi[3]; G Gambino[2]; D Liccardo[2]; N Ferrara[2]; WJ Koch[1]; N Paolocci[4]
[1]Temple University School of Medicine, Center for Translational Medicine, Philadelphia, United States of America; *[2]Federico II University of Naples, Translational Medical Sciences, Naples, Italy*; *[3]Sant'Anna School of Advanced Studies, Pisa, Italy*; *[4]Johns Hopkins University of Baltimore, Baltimore, United States of America*

Introduction: In the heart, Brain-derived neurotrophic factor (BDNF) sustains contraction and relaxation and confers protection against ischemia. However, the mechanisms of such protective actions remain elusive. Moreover, neuronal but not myocardial BDNF has been deemed important in preventing post-myocardial infarction (MI) heart failure (HF). Yet deleting myocardial bdnf enlarges the heart at baseline, suggesting a role for autologous BDNF. In the brain, adrenergic signaling promotes BDNF production in the target cell but whether, and under which conditions, szligßAR stimulation accounts for BDNF genesis in the heart is currently unknown.
Purpose: In post-ischemic HF mice, we tested the effect of ßAR dysfunction induced by the up-regulation of G protein-coupled receptor (GPCR) kinase 2 (GRK2) on myocyte-borne BDNF. We also determined if limiting GRK2 activity (thus enhancing myocardial BDNF signal) promotes cardiac re-innervation that is a major protective mechanism.
Methods: Isolated neonatal rat ventricular myocytes (NRVMs) were used to directly measure myocardial BDNF production while modifying myocyte GRK2 levels. Wild-type (WT, male C57BL/6J) and cardiac GRK2 over-expressing (BK12) mice were employed to correlate BDNF levels with LV function and extent of cardiac innervation after MI in vivo.
Results: Stimulating NRVMs with the ß1/2AR agonist, isoproterenol (ISO), augmented myocyte BDNF content. This effect was prevented in NRVMs infected with an Adenovirus (Ad) encoding for GRK2 to induce chronic ßAR desensitization. In vivo, we observed that WT mice exhibited a marked rise in cardiac BDNF levels immediately after MI (up to 24 hrs) when GRK2 expression was still unchanged. Whereas, with ensuing HF (i.e., 4 weeks after MI) and in presence of significantly augmented cardiac GRK2 content, cardiac BDNF protein abundance declined below values found under control (non-ischemic) conditions. Of relevance, the latter change was accompanied by a marked impairment of cardiac sympathetic innervation measured via tyrosine hydroxylase (TH) staining. To establish a direct in vivo link between GRK2/BDNF levels with the extent of post-MI cardiac innervation, we subjected GRK2 (BK12) cardiac over-expressing and non-transgenic control (NLC) mice to MI. We found that when HF is overt (i.e, 4 weeks after MI), BK12 mice had more severe LV dysfunction and remodeling than infarcted NLC mice, and exhibited markedly reduced cardiac BNDF content. Consistently, the amount of cardiac TH positive fibers was substantially reduced in infarcted BK12 mice as compared to the NLC counterpart.
Conclusion: ßAR dysfunction due to GRK2 up-regulation contributes to chronic post-MI HF, at least in part, by reducing myocardial BDNF generation. Preserving or enhancing this autologous production could represent a new avenue to arrest HF progression. Our data suggests that the communication between the heart and the autonomic nervous system is bidirectional.

Funding Acknowledgements: HFSP-Young Investigator's grant

Background: Desmosomes are transmembrane cell-cell connecting organelles providing resilience against tissue strain, mostly in the heart and skin. Patients with desmosomal mutations are prone to develop arrhythmogenic cardiomyopathy and skin fragility. Exercise is believed to accelerate disease progression, however this is mostly based on epidemiological data. It is unknown whether strain (as a proxy for exercise) accelerates the loss of desmosomal integrity.
Purpose: Investigate the direct effect of strain on the integrity of desmosomes from cells compromised by a pathogenic desmosomal mutation.
Methods: Four patients from one family, presenting with mild and severe forms of cardiomyopathy, and a control were included in the present study. We identified the genetic cause and evaluated desmosomal integrity on ex vivo explanted heart and skin material. Induced pluripotent stem cells (iPSC) were generated, and differentiated into cardiomyocytes (CMs), these were investigated under static and low intensity strain conditions (15% cyclic strain induced at 60 strains/minute).
Results: Two compound heterozygous patients, carrying a splice mutation (c.273+5G>A) and a novel truncating mutation (c.6687delA; p.(Arg2229Serfs*32) in desmoplakin (DSP), had end-stage HF due to fat deposition in the right and a non-compacted left ventricle (LV). In addition, palmoplantar keratoderma (PPK) and woolly hair were observed. In one of them, the explanted heart showed reduced and aberrant desmosomes in the RV, but not in the LV. Heterozygous patients, only carrying the truncating mutation, had LV non-compaction and PPK. Skin biopsy staining of compound heterozygous and heterozygous patients showed no desmosomal aberrations under non-stressed conditions.
In vitro iPSC-CMs from compound heterozygous and heterozygous carriers showed a two-fold reduction in DSP mRNA compared to control($P < 0.005$). The truncating product undergoes nonsense mediated RNA decay (NMD), because NMD inhibition resulted in a truncated protein product not otherwise observed(Fig.1B). Furthermore, static CMs from compound heterozygous carriers had significantly lower DSP levels compared to heterozygous carriers and control($P < 0.05$)(Fig.1A). Low intensity strain did not reduce already low DSP levels in CMs derived from compound heterozygous carriers, but did significantly reduce DSP levels in heterozygous carriers($P < 0.05$), something not observed in control CMs (Fig.1C).
Conclusion: We show that in vitro iPSC culture provides the platform to investigate the plastic nature of desmosomal integrity under static and strained conditions. Our study demonstrates that the integrity of desmosomes from control CMs are not challenged by low intensity strain. When desmosomes are compromised due to a DSP mutation, their integrity is challenged, supporting the concept that exercise indeed may lead to disease progression.

Recent studies revealed that myocardial infarction (MI) triggers the activation of CD4+T-cells in mice, which in turn modulate myocardial inflammation, healing, and remodeling. In the present study, we sought to assess whether antigen specificity is crucially involved in these circumstances, and how T-cell responses are fine-tuned in the injured myocardium milieu. Thus, cardiac-myosin-specific Thy1.1+ CD4+ T-cells (TCR-M) were adoptively transferred into Thy1.2+ WT recipients prior to MI induction. Flow cytometry and light-sheet microscopy analyses showed that TCR-M cells accumulate in the heart and mediastinal lymph nodes of infarcted, but not of sham-operated animals, at the peak of healing process (day 7), whereas no TCR-M accumulation was observed in other irrelevant sites (spleen, subiliacal

lymph node). Notably, these cells vanished at later chronic remodeling phase, indicating that post-MI T-cell auto-reactivity is self-limiting. Most strikingly, TCR-M cells, which are pathogenic and drive lethal myocarditis in their donors, differentiate into Foxp3+ cells, acquire a unique pro-healing gene expression profile and promote cardioprotection when transferred into MI-recipients, leading to preserved functional parametres. Our results provide definitive evidence that post-MI T-cell responses are largely driven by heart-specific antigens. Furthermore, beyond specificity, our data reveal that the unique MI-milieu dictates the phenotypic polarization of specific CD4+ T-cells favoring the development of autoimmune responses that benefit self-maintenance.

Prophylactic use of carvedilol to prevent ventricular dysfunction in patients with cancer treated with doxorubicin

A J Abuosa[1]; A J Elshaikh[1]; A J Kinsara[1]
[1]*King Saud bin Abdulaziz University for Health Sciences, COM-J. King Abdul Aziz Medical City -WR, King Faisal cardiac center , Jeddah, Saudi Arabia*

Objective: Deterioration in ventricular function is often observed in patients treated with anthracyclines for cancer. There is a paucity of evidence on interventions that might provide cardio-protection. We investigated whether carvedilol can prevent doxorubicin-induced cardiotoxicity and whether any observed effect is dose related.
Methods: A prospective, randomized, double-blind study in patients treated with doxorubicin, comparing placebo (n = 38) with different doses of carvedilol [6.25 mg/day (n = 41), 12.5 mg/day (n = 38) or 25 mg/day (n = 37)].
Results: The primary endpoint was the measured change in left ventricular ejection fraction (LVEF) from baseline to 6 months. LVEF decreased from 62% ± 5% at baseline to 58% ± 7% at 6-months (p = 0.002) in patients assigned to placebo but no statistically significant changes were observed in any of the 3 carvedilol groups. At 6 months, only one of 116 patients (1%) assigned to carvedilol had an LVEF < 50% compared to four of the 38 assigned to placebo (11%), (p = 0.013). No significant differences were noted between carvedilol and placebo in terms of the development of diastolic dysfunction, clinically overt heart failure or death.
Conclusions: Carvedilol might prevent deterioration in LVEF in cancer patients treated with doxorubicin. This effect may not be dose related within the studied range.

What proportion of patients with HFrEF might be candidates for Sacubitril-Valsartan?

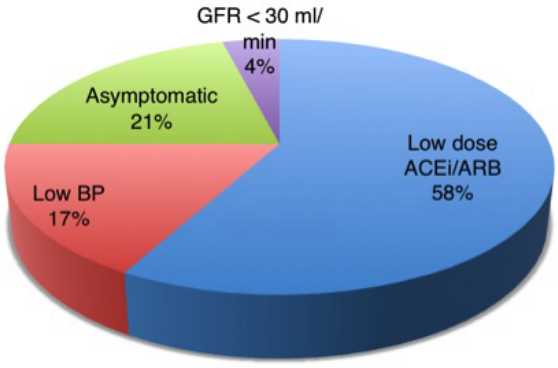
M Montoro Lopez[1]; T O'connor[1]; T Ibrahim[1]; E Sweeney[1]; F Bakcsi[1]; M Islam[1]; N Stakelum[1]; N Carter[1]; C Gray[1]; C Halley[1]; P Keelan[1]; NF Murphy[1]
[1]*Our Lady of Lourdes Hospital, Cardiology, Drogheda, Ireland*

Background: After the landmark PARADIGM-HF trial, the 2016 ESC HF guidelines included Sacubitril-Valsartan (SV) in the HFrEF management algorithm. Nevertheless, unlike the inclusion criteria of the PARADIGM trial, ESC guidelines recommend mineralocorticoid receptor antagonists (MRA) as a previous step before considering SV (Table). This difference may cause that a lower number of patients than expected are eligible for SV and, thus, benefit from it. The aim of our study was to retrospectively determine what proportion of patients would meet the criteria for SV according to the ESC algorithm in a chronic HF outpatient clinic.

Criteria to be eligible for SV

	PARADIGM-Trial	ESC HFrEF algorithm
Echocardiography	EF ≤ 35%	
Optimal medical treatment	ACEi or ARB equivalent to Enalapril 10 mg BID + Beta-blocker	ACEi or ARB equivalent to Enalapril 10 mg BID + Beta-blocker + MR antagonist
Laboratory	BNP ≥ 150 or NT-proBNP≥ 600 pg/mL BNP ≥ 100 or NT-proBNP ≥ 400 pg/mL if recent hospitalization (<12m) GFR > 30 ml per minute per 1.73 m2 of body-surface Potassium < 5.4 mmol per liter	
Clinical status	NYHA II,III or IV	
Blood pressure	SBP < 95 mmHg	

Methods: We conducted an observational and retrospective study in the specialized HF clinic of our institution (Ireland). From January 2015 to December 2016, all patients referred to the clinic were included in the analysis. Clinical, echocardiographic and analytic variables were collected from medical records in order to select the population eligible for SV.
Results: Over a 2 year period, 434 new patients were referred to the HF clinic. Out of them, 116 patients had EF = 35%. From this group, 51 patients (44%) were eventually prescribed a MRA in addition to ACEi/ARB and betablockers. From this group, after taking into account NYHA class, blood pressure, ACEi/ARB dose and GFR, 27 patients would have been eligible for SV (23% of all referrals with HFrEF). The main cause to be excluded for SV was intolerance to high dose of ACEi/ARB (figure).
Conclusion: In our HF clinic, less than a quarter of patients with HFrEF met the criteria for SV according to the ESC-HFrEF algorithm. More flexibility in these criteria may increase the potential number of eligible patients for this life-saving drug.



Causes for not being eligible for SV

862

Heart failure patients with reduced left ventricular ejection fraction, who reached 100% target dose of beta-blockers in randomized and observational studies

Introduction: It is recommended to take beta-blockers (BB) for patients with heart failure (HF) and reduced left ventricular ejection fraction (LVEF) to decrease hospitalizations, mortality and improve symptoms. To achieve maximum clinical benefit 100% target dose (ESC Guidelines) or maximum tolerated dose are advised. The n (%) patients who reached target dose in randomized trials (RCT) and observational studies (OS) has not been studied enough. Its evaluation can guide quality indicators in clinical practice
Objective: To evaluate n (%) of patients with HF and reduced LVEF, who reached 100% target dose of BB in RCT and OS
Methods: Systematic review of bibliography (PUBMED, EMBASE, CINHAL, COCHRANE Library) and manual search in relevant journals. 2 independent reviewers. Inclusion criteria: RCT, drug vs. placebo or drug vs. drug, (1994-2017) and multi-center OS (2007-2017) of BB, carvedilol, bisoprolol and nevibolol, which evaluated n (%) of patients in target dose. Categorical variable described as n%. (95% CI). We performed a random-effects meta-analysis with the Stata metaprop program (Stata v10). For the extraction of RCT results the Analysis by intention to treat has been considered.
Results: 242 articles were reviewed and 16 RCTs were selected (7,830 patients) 3 of them with 2 intervention arms, not considering data from the placebo arm and 18 OS (27,645 patients), 3 of them with 2 arms. Subtotal RCT 58.68% (95% CI: 50.1-66.97) Subtotal OS: 29.03 % (95% CI: 23.36-35.05) (Figure).
Conclusions: Significant RCT / OS differences were observed in the proportion of patients achieving BB target doses. New studies are needed on the possible conditions associated, clinical and sociodemographic characteristics of the patients and the organization of the intervention, in order to establish improvement programs.

Metabolic response to exercise training in heart failure with preserved ejection fraction

M Bahls[1]; N Friedrich[1]; M Pietzner[1]; F Edelmann[2]; G Hasenfuss[3]; R Wachter[4]; M Nauck[1]; SB Felix[1]; S Schwarz[5]; M Halle[5]; M Dorr[1]
[1]University Medicine of Greifswald, Greifswald, Germany; *[2]Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany*; *[3]Ernst Moritz Arndt University of Greifswald, Department of Internal Medicine B, Greifswald, Germany*; *[4]Heart Center of Leipzig, Leipzig, Germany*; *[5]Technical University of Munich, Munich, Germany*

On behalf of: DZHK (German Centre for Cardiovascular Research), partner sites Greifswald, Munich, Göttingen and Berlin, Germany

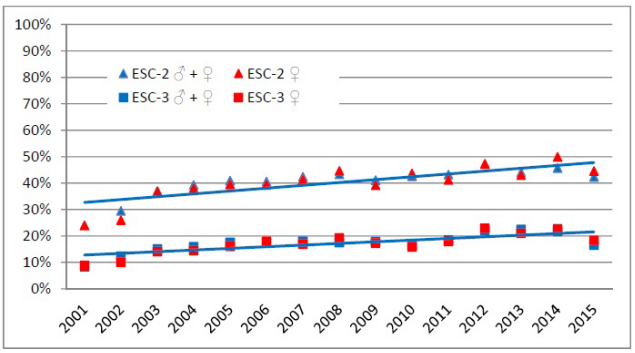
Background: Heart failure (HF) with preserved ejection fraction (HFpEF) accounts for more than 50% of all HF cases with rising prevalence. No evidence-based pharmacological treatment options exist to reduce disease burden. Exercise training (ET) has been shown to partly reverse diastolic dysfunction and improve exercise capacity. However, the biological mechanisms underlying these observations are not completely understood.
Purpose: We aimed to improve our understanding of exercise induced cardiac and cardiopulmonary improvements in HFpEF by analyzing metabolic changes related to a 12-week ET utilizing a targeted plasma metabolomics approach in patients of the EX-DHF-P trial.
Methods: The EX-DHF-P trial was a multi-center, prospective, randomized, controlled parallel group study exploring the impact of structured ET on cardiac function and exercise capacity in patients with HFpEF. We used the Biocrates AbsoluteIDQ® p180 Kit to quantitatively measure the concentration of 188 endogenous plasma metabolites in 44 patients who participated in ET (EX) and 20 controls (CON). Generalized estimating equation and linear regression models were used to assess differences in changes in metabolite concentrations over time between responder and non-responder as well as the relation between alterations in cardiac outcomes and metabolites, respectively. Further, responders to ET were defined based on whether the change in outcome of interest (i.e. VO2peak, E/e', LAVI, VE/VCO2 slope) was above the median.
Results: Overall, 70 metabolites significantly changed from baseline to follow-up in both groups. In EX a total of 51 metabolites were reduced and only one was increased. In the CON, 11 metabolites were decreased and 10 were increased. There was an overlap between the groups of 12 metabolites with decreased concentrations. Ten metabolites showed a significant time*group interaction. Specifically, in EX glutamine concentration increased while three sphingolipids (i.e. SM(OH) C16:1, SM C18:0 and SM C24:0) decreased. In CON circulating carnitine as well as four phosphotidycholines (i.e. PC aa C28:1, PC aa C34:2, PC ae C44:4 and PC aa C36:2) increased while acetylornithine decreased. A total of 39, 12, 6, and 36 metabolites were related to changes in VO2peak, E/e', LAVI and VE/VCO2 slope, respectively. The abundance of 14, 15, and 15 metabolites were different between VO2peak, E/e' and LAVI, respectively, when responders and non-responders were compared.
Conclusions: Twelve weeks of exercise training in HFpEF patients resulted in a large number of metabolites being decreased compared to control. Interestingly, metabolic changes vary vastly according to the investigated outcome parameter. Overall, plasma metabolomics may be a useful technology to identify biomarkers and mechanisms of metabolic changes in HFpEF and response to therapy. Further, this method allows monitoring metabolic changes that have previously been reported only by invasive skeletal muscle.

864

Adherence to ESC guidelines after hospital admission for heart failure in 22500 Dutch patients: 2001-2015

WJ Kruik-Kolloffel[1]; HJ Kruik[2]; KLL Movig[3]; GCM Linssen[2]; J Van Der Palen[3]
[1]Röpcke-Zweers Hospital, Clinical Pharmacy, Hardenberg, Netherlands; *[2]Hospital Group Twente, Cardiology, Hengelo, Netherlands*; *[3]Medical Spectrum Twente, Clinical Pharmacy, Enschede, Netherlands*

Introduction: Adherence to guideline-recommended medication in patients with chronic heart failure (HF) improves clinical outcomes. In the past two decades, specific disease-modifying HF drugs have been incorporated into the European (ESC) practice guidelines. However, use of advocated medication in real-world clinical practice is still suboptimal.
Purpose: To analyse how evolving guideline-directed recommendations influenced the medication profile at discharge after a first hospital admission for HF. We focussed on diuretics, angiotensin-converting-enzyme inhibitors (ACEI)/angiotensin-receptor blockers (ARB), beta-blockers (BB) and mineralocorticoid-receptor antagonists (MRA).
Methods: We extracted from the PHARMO Database Network 22500 patients in the Hospitalisation Database with a diagnosis of HF or hypertensive heart disease with (congestive) HF at hospital discharge, in the Netherlands, between 2001 and 2015. Patients were unselected. Drug dispensings from primary and secondary care prescriptions were extracted from the Out-Patient Pharmacy Database.
Results: The prescription of ACEI/ARB and diuretics was stable at about 63% and 82%, respectively. The proportion of ARB increased, without foundation in the guidelines. The percentage of patients on combined ACEI and ARB was less than 3% and declined till less than 1% after the formal warning of the regulatory authorities. Despite the substantially enhanced recommendation in ESC guideline 2012 of MRA to NYHA class II, the percentage of patients in which MRA was prescribed remained approximately 40%. A rise in the prescription rate of BB was a result of the distinct recommendation since the guideline of 2001, mostly BB with a market authorisation for HF. Subsequently, the percentage of patients prescribed ACEI/ARB and beta-blocker almost doubled to about 50%; the percentage of patients prescribed ACEI/ARB, BB and MRA reached almost 20%. See the Figure. There were no differences between males and females. Each year of higher age was associated with 2% decrease in dual therapy (ACEI/ARB and beta-blocker) and 1.5% of triple therapy (ACEI/ARB and BB and an MRA).
Conclusion: The adherence with the European (ESC) HF guidelines influenced prescription behaviour at discharge after a first hospitalisation for HF. However, adherence with the guidelines varied for the individual recommendations. At the same time some developments were demonstrated, which were not covered by the guidelines. Although the exact HF classification of the patients was unknown, our large and representative database provided insights in real-world HF medical therapy from 2001 till 2015.



ESC-2: Beta-blocker + (angiotensin-converting-enzyme inhibitor or angiotensin-receptor blocker)
ESC-3: Beta-blocker + (angiotensin-converting-enzyme inhibitor or angiotensin-receptor blocker) + mineralocorticoid-receptor antagonist

Prescribed medications in HF: 2001-2015

Cardiovascular outcomes with the incretin-based therapies GLP-1 agonists and DPP-4 inhibitors in type 2 diabetes participants with and without heart failure

SL Zheng[1]; P Collins[1]
[1]Royal Brompton Hospital, London, United Kingdom

Background: Incretin-based therapies (GLP-1 agonists and DPP-4 inhibitors) are frequently used in patients with type 2 diabetes. Incident heart failure is associated with poor outcomes in these patients. The overall effect of incretin-based therapies from pooled cardiovascular outcome trials in patients with and without heart failure has not been tested.
Aim: To investigate the effect of GLP-1 agonists and DPP-4 inhibitors on the primary outcome in cardiovascular outcome trials in patients stratified by baseline heart failure status.
Methods: Meta-analysis was used to pool primary endpoint data for GLP-1 agonist and DPP-4 inhibitor cardiovascular (CV) outcome trials. The primary outcome in these trials was pooled CV mortality, non-fatal stroke and non-fatal myocardial infarction (MI). Effects were analysed in participants with and without heart failure. Required data was available from study publications in all cases except for EMPA-REG OUTCOME, where data was provided by the study sponsor. Results were analysed as pooled HR format, with 95% CI. Random-effects meta-analysis model was used. Statistical analysis done on Review Manager 5.3.
Results: There were five CV outcome trials enrolling a total of 58,551 participants (Drug: 29,283, Placebo: 29,268). Three trials enrolling 27,388 participants tested GLP-1 agonists: EXSCEL (Exenatide), LEADER (Liraglutide), and SUSTAIN-6 (Semaglutide). Two trials enrolling 31,163 participants tested DPP-4 inhibitors:

SAVOR-TIMI 53 (Saxagliptin) and TECOS (Sitagliptin). There were 9015 participants with heart failure (15.4% of participants). GLP-1 agonists reduced the primary outcome in participants without heart failure (HR 0.84, 95% CI 0.73 to 0.95, P = 0.007), but had no effect in those with heart failure (HR 0.97, 95% CI 0.84 to 1.11, P = 0.62). DPP-4 inhibitors had no effect, regardless of baseline heart failure status. Incretin-based therapies combined reduced the outcome in participants without heart failure (HR 0.90, 95% CI 0.82 to 0.99, P = 0.03) but not in those with heart failure (HR 1.00, 95% CI 0.90 to 1.10, P = 0.93).

Post-hoc inclusion of studies enrolling post-MI participants (ELIXA and EXAMINE) did not affect the Results: GLP-1 agonist (without heart failure: HR 0.88, 95% CI 0.77 to 1.00, P = 0.04; and with heart failure: HR 0.96, 95% CI 0.85 to 1.08, P = 0.50), DPP-4 inhibitor (without heart failure: HR 0.99, 95% CI 0.91 to 1.06, P = 0.72; and with heart failure: HR 0.98, 95% CI 0.84 to 1.15, P = 0.82).

Conclusion: Incretin-based therapies reduce the CV endpoint in patients without heart failure, but not in those with heart failure. This was effect was driven by the differential effect of GLP-1 agonists by baseline heart failure. While there was no reduction in the primary endpoint in patients with heart failure, there was no evidence of harm. Incretin-based therapies may be used in patients with heart failure for glycaemic control, but did not reduce the CV outcome.

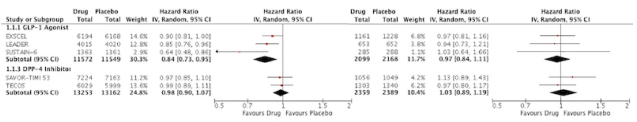

Figure: Forest plot of CV outcomes

866

Functional and anatomical pulmonary arterial disease in patients with persistent pulmonary hypertension after left valve replacement according to the hemodynamic phenotype

E Domingo[1]; J Grignola Rial[2]; P Trujillo[3]; B Janssen[3]; R Aguilar[4]; A Roman[5]
[1]University Hospital Vall d'Hebron, Cardiology, Barcelona, Spain; *[2]Hospital de Clinicas Dr. Manuel Quintela, Pathophysiology, Montevideo, Uruguay*; *[3]Hospital de Clinicas Dr. Manuel Quintela, Cardiology, Centro Cardiovascular Universitario, Montevideo, Uruguay*; *[4]University Hospital De La Princesa, Cardiology, Madrid, Spain*; *[5]University Hospital Vall d'Hebron, Clinic de Pneumologia, Barcelona, Spain*

Background: The prediction of pulmonary vasculopathy severity in patients (p) with pulmonary hypertension associated with left heart disease (PH-LHD) based on hemodynamic phenotype is a matter of debate.

Purpose: To assess pulmonary arterial stiffness (PAS) and area wall thickness (AWT) and their role on the right ventricular-arterial coupling (RVAC) according to the hemodynamic phenotype in p with persistent-PH after mitral (MVR) and aortic (AVR) valve replacement.

Methods: 15 p (72 ± 7 y, 13 F) underwent successful MVR (6 with concomitant AVR) at least one year ago presenting PH by echo (<50 mmHg). Prosthesis-p mismatch and LV dysfunction were discarded. All p were submitted to RHC and intravascular ultrasound in medium-sized PAs at rest and during iNO (20 ppm). We assessed mean PA pressure (mPAP), PA wedge pressure (PAWP), cardiac index (CI), peripheral and total pulmonary vascular resistance (PVR, TPR), PA capacitance (PAC), PAS (elastic modulus -EM-), and the relative AWT. We obtained the ratio TAPSE/sPAP. Data were compared with a historical cohort of control subjects.

Results: 5 p had combined post and pre-capillary PH (Cpc-PH, diastolic pressure gradient-DPG- = 7 mmHg and PVR > 3WU), 5 p had isolated post-capillary PH (Ipc-PH, DPG < 7 mmHg and PVR = 3 WU) and 5 p presented indeterminate phenotype (Indet-PH, DPG = 7 mmHg or PVR >3 WU). All p showed significant pulmonary vasculopathy (Table). Transpulmonary gradient, DPG, PVR, and PAC were correlated with EM (r>0.6, p < 0.05). RVAC was significantly correlated with PAC (r = 0.63) and EM (r=-0.59), which is worst in Cpc-PH p (0.16 ± 0.02, p < 0.05). During iNO, p with the highest rest EM showed the most significant change in TPR, mPAP, pulse PAP, EM, stroke volume (SV), and PAC (Figure).

Conclusions: Persistent-PH after MVR/AVR shows different hemodynamic phenotypes which cannot be identified by echo-doppler. The worse pulmonary vasculopathy, the worse RVAC, and the higher vasoreactivity response to iNO.

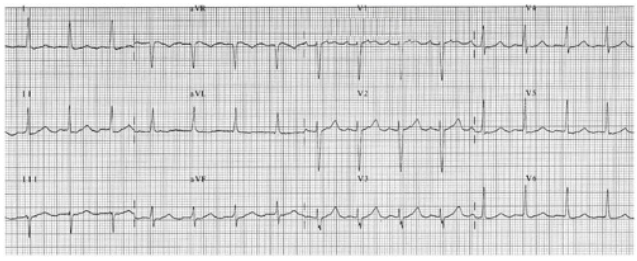
Effective catheter treatment of atrial tachyarrhythmias in non-responder to cardiac resynchronization therapy

S Garkina[1]; R Tatarsky[1]; D Lebedev[1]; V Lebedeva[1]; T Lubimtzeva[1]; V Orshanskaya[1]; A Kamenev[1]; YU Miller[1]; E Mikhaylov[1]; S Gureev[1]
[1]*Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation*

Background: Candidates for cardiac resynchronization therapy (CRT) often experience atrial tachyarrhythmias that may reduce the probability of positive response after resynchronization due to different reasons, including rapid and irregular ventricular rhythm inconsistent with a permanent LV capture when compared to patients in sinus rhythm.



ECG with atypical atrial flutter

Case presentation: We report a clinical case of a 46-year-old male who was a candidate for cardiac resynchronization due to congestive heart failure symptoms including dyspnea and massive edema and also demonstrated LBBB pattern (QRS duration of 182 msec) on ECG. He experienced frequent hemodynamically significant atrial fibrillation episodes with rapid ventricular response and maximum ventricular rate up to 170 bpm. Physical examination and instrumental data confirmed diagnosis of dilated cardiomyopathy with significant impairment of left ventricle systolic function (ejection fraction level (EF) of 28 %). Coronary angiography didn't reveal any abnormalities. The patient was implanted CRT-D system for primary prevention. However, he didn't respond well to cardiac resynchronization therapy and decompensated during 2 years due to heart failure progression. Control echocardiography revealed severe systolic disfunction (EF level of 20%). Considering longstanding atrial fibrillation patient was planned to catheter treatment and underwent three subsequent radiofrequency ablation procedures. During endocardial electrophysiological study different types of arrhythmias were demonstrated: typical atrial flutter, atrial fibrillation and right atrial tachycardia. Three months later the patient developed atypical left-side atrial flutter with rapid ventricular response (Figure 1). Repeated radiofrequency ablation procedure with sinus rhythm restoration contributed to clinical improvement. Persistent conduction block was shown on the mitral isthmus, and the patient remained free of atrial tachyarrhythmia during 16 months of follow-up using device telemetry. Now patient is stable and demonstrates good physical tolerance along with improvement in the global systolic function of the LV (EF level of 48%).

Answers and discussion: Sinus rhythm restoration is especially important in CRT candidates because failure of biventricular capture may contribute to the lack of benefit of resynchronization in patients with persistent or permanent atrial fibrillation. This clinical case illustrates role of effective catheter treatment of atrial arrhythmias in patients with implanted CRT devices.

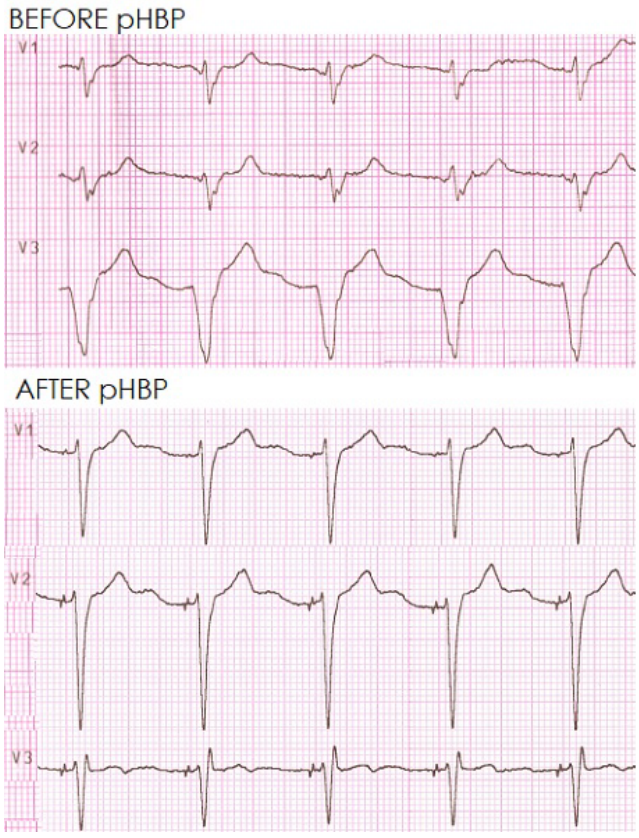
Conclusions: and implications for clinical practice. All patients who meet the current criteria for CRT, despite their atrial arrhythmias burden, should be recommended to receive this therapy. Early catheter ablation is indicated with continuous monitoring of cardiac arrhythmias and clinical re-evaluation of current treatment to optimize rhythm or rate control in CRT patients.

868

Permanent his-bundle pacing for cardiac resynchronization therapy in a patient with an imlantable cardioverter-defibrillator.

B Skonieczny[1]; A Gajek[1]; J Adamowicz[1]; J Gajek[1]; A Slawuta[2]
[1]*Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland*;
[2]*Klodzko County Hospital, Department of Cardiology, Klodzko, Poland*

69 years old male with ischemic cardiomyopathy, diabetes mellitus type 2 [DMT2] and permanent atrial fibrillation [pAF] had a sudden cardiac arrest [SCA] in 2007 due to ventricular fibrillation [VF]. As prevention of subsequent episodes of the arrhythmia an implantable cardioverter-defibrillator [ICD] was implemented. Unfortunately a disease course was further complicated by an adequate as well as inadequate ICD therapies treated successfully with increased dose of beta blocker. This medication resulted in slowing of atrioventricular conduction. Since that time the dominant ventricular rhythm was right ventricular pacing. The obvious effect of this was prolonged QRS duration (200 ms). Echocardiography revealed left ventricular ejection fraction (LVEF) decrease and the patient developed symptoms of heart failure New York Heart Association [NYHA] functional class III with seriously impaired quality of life. Upgrade from conventional ICD to cardiac resynchronization therapy [CRT] was implemented – patient underwent an implantation of pacing lead in His bundle area with selective capture and satisfactory pacing threshold. Procedure resulted in restoring of native QRS complexes which were narrow (118 ms), increase in LVEF (+7%) and improvement in NYHA class (for now on functional class I).



Biventricular pacing [BiV] is a well established method for CRT, although permanent His bundle pacing (pHBP) seems to be more physiologic way of pacing and as such it is promising alternative for BiV, either as a rescue strategy or as a first line treatment. Case of our patient shows that pHBP could be successfully used as primary strategy for CRT in patients with high percentage of ventricular pacing with both echocardiographic and clinical improvement. However, there is still a strong need for high quality randomized clinical trials to legitimate efficiency of pHBP in particular indications for CRT and establish its position.

869

A case of reversible dilated cardiomyopathy caused by atrial fibrillation

G Gulnoza Dussekeyeva[1]; AB Isakhanova[1]; GS Bimagambetova[1]
[1]*Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*

On behalf of: Issakhanova Ainur, Bimagambetova Gulnaz

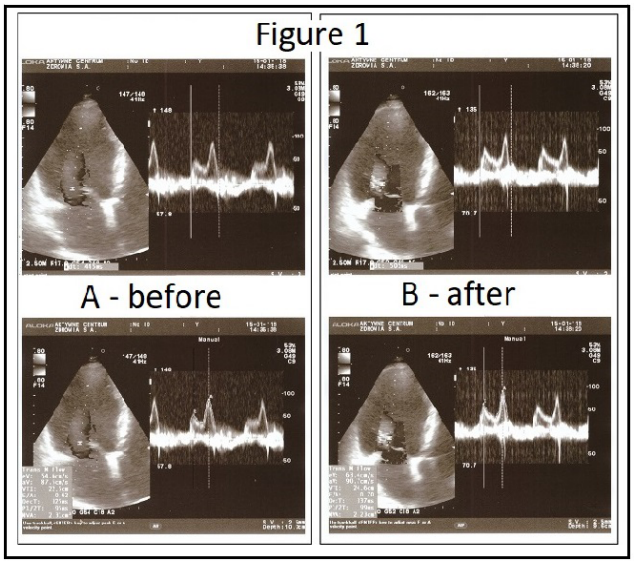
37-year-old male was consulted to the cardiology because of clinics of heart failure (edema, dyspnea). Heart failure symptoms firstly appeared 2 years ago. He had no history of hypertension or recently infectious process. Electrocardiography (ECG) finding was atrial fibrillation with average ventricular rate of 150-178 per minute. Transthoracic echocardiography showed all heart cameras dilated, reduced ejection fraction: left atrium-5,1 centimeters (cm), right ventricular 4,6 cm, end diastolic size-7,2cm, end systolic size -6,5?m, end diastolic volume -274 milliliters (ml), end systolic volume -209ml, impact volume -65 ml , ejection fraction by Simpson - 35%, ?S-11%, intraventricular wall thickness-1,0 ?m, left ventricular posterior wall thickness -1,0 ?m. Coronary angiography showed no significant stenosis of coronary artery. 24-hour Holter Monitoring showed atrial fibrillation with average ventricular rate of 148-170 per minute, one episode of wide-complex tachycardia longing 30 seconds. The short wide-complex tachycardia episode was then registered on ECG and identified as ventricular tachycardia. He was admitted optimal heart failure therapy (beta-blockers, angiotensin-converting enzyme (ACE)-inhibitors, diuretics) and anticoagulant therapy. Transesophageal echocardiography showed no thrombosis signs in heart cameras. Heart team diagnosed Dilative Cardiomyopathy and made a decision to implant this patient Implantable Cardioverter Defibrillator (ICD) for the prevention of sudden cardiac death. By the end of hospitalization, clinical signs of heart failure had regressed. Patient adhered prescribed treatment strictly 6 months, on time he sensed ICD shock. ICD checking confirmed one ICD shock because of ventricular tachycardia. On control clinical examination patient had no signs of heart failure. On ECG is sinus rhythm 67 beats per minute. After 6 months, follow-up echocardiography showed that LV function markedly improved with decreased LV size.
Transthoracic echocardiography showed: left atrium-3,1 cm, right ventricular 3,6 cm, end diastolic size-4,7 cm, end systolic size -3,4?m, end diastolic volume -103 ml, end systolic volume -48 ml, impact volume -55 ml , ejection fraction by Simpson - 54%, ?S-28%, intraventricular wall thickness-1,1 ?m, left ventricular posterior wall thickness -1,2 ?m.

870

Left ventricle filling improvement by permanent his bundle pacing treatment in patient with atrial fibrillation, first-degree atrioventricular block and impaired left ventricle systolic function.

P Piotr Strozik[1]; J Zawadzki[1]; A Gajek[1]; J Adamowicz[2]; J Gajek[2]; A Slawuta[3]
[1]*Wroclaw Medical University, Students Scientific Association, Wroclaw, Poland*;
[2]*Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland*;
[3]*Klodzko County Hospital, Department of Cardiology, Klodzko, Poland*

Introduction: A 72-year-old male presented with ischemic cardiomyopathy. The LV ejection fraction decrease to 42% was the cause of coronary angiography, which revealed satisfactory effect of previous angioplasty of Cx. The sinus bradycardia resulted in a low dose of metoprolol. In 2015 the first atrial fibrillation (AF) episode was confirmed with the heart rate 100 bpm and spontaneous sinus rhythm return was observed. The next year one more oligosymptomatic incident of arrhythmia was diagnosed. In 2017 during several hospitalizations, because of non-cardiac reasons, observed AF was considered to be permanent. Several months later in the cardiology ward the echocardiography showed enlargement of the left ventricle with significant deterioration of its function (LVEDD 70mm, EF 33%). The patient was qualified for ICD (Implantable Cardioverter Defibrillator) with possible upgrade to the CRT-D system due to the slow AF. After 2 weeks, the patient came again due to symptomatic dizziness. ECG revealed sinus bradycardia (44 bpm) with first degree atrioventricular block (PQ 240ms). The patient was consulted by a specialist who, recognizing the risk of pacing-induced deterioration after implantation of dual chamber ICD, qualified the patient for implantation of the CRT-D system with direct His bundle pacing (DHBP).
Procedures, techniques
The patient underwent CRT-D device implantation with the use of LV-channel electrode for permanent His-bundle pacing. Selective DHBP was achieved with satisfactory pacing threshold. The atrial lead was placed in the Bachmann's bundle. The basic rate was set to 65 bpm, with rate response up to 80 bpm. The av and vv delay programming (A-LVonly) of the device resulted in PR interval of 170 ms.
First-degree atrioventricular block (AV block) is a disorder of the electrical conduction system of the heart. The prolongation of PR interval is a known reason of increased mortality and the risk of atrial fibrillation. The first-degree AV block is usually a result of proximal disorder in atrioventricular node conduction. The possible shortening of the conduction by ablation is more speculative than clinical. Another approach to reduce the PR interval is the DHBP procedure. This method of treating first-degree AV block seems to be very promising, yet frequently ignored.
Conclusions: This case illustrates the potential of improving EF by integrating electrical and mechanical function of atrium by mean of DHBP and by preserving narrow QRS with A-V interval shortening. The P-R interval with DHBP and delay programming was reduced from 240ms to 170ms. Those settings gave benefit of the increase in mitral filling time by 60 ms and mitral VTI increase by 2 cm (Figure 1). The rough estimation of the cardiac output change indicates the increase of approximately 300 ml/min. The use of existing CRT device not only makes this approach widely available but also makes it possible to treat patients with already implemented pacemakers.



871

Recurrent syncopes in a patient on androgen deprivation therapy for prostate cancer: a clinical case presentation

I Ilir Sharka[1]; S Myftiu[1]; B Dita[1]; J Rustemaj[1]; D Malaveci[1]
[1]*University Hospital Center Mother Theresa, Department of Cardiology & Cardiac Surgery, Tirana, Albania*

Introduction: Androgen deprivation therapy (ADT) is considered an important treatment in patients (pts) with prostate cancer. Concerns about adverse cardiovascular effects have been raised, although no reports on its potential proarrhythmic effects in previously healthy pts. This is a case of a prostate cancer patient with recurrent syncopes due to very frequent Torsades de Pointes (TdP) under ADT.
Case presentation: A 70 years old prostate cancer male treated surgically 6 month before with a recent history of syncope was admitted to ICCU due to a wide QRS tachycardia associated loss of conscience. Resting ECG showed mild bradycardia, a borderline QTc, inverted U wave & good hemodynamic conditions. He was on Bicalutamide 50 mg/d for 3 months and Goserelin injection a month to referral. He had no chest angina history. Several patterns of extrasystoles, atrial and junctional tachycardia were seen and lab tests revealed blood electrolytes abnormalities (low K, Ca, Mg), normal cardiac echo, troponin & other tests. The 1° day of admission, besides the correcting doses of electrolytes the patient experienced two self-limited episodes of TdP, which were treated with 1 gr iv Mg. QTc interval kept increasing, despite normalizing blood electrolyte levels from the preliminary clinical workup. We didn't find any other relevant causes of this phenomenon and concluded

that a potential complication of ADT should be considered. We decided to stop Bicalutamide. The 2° day appeared with worse clinical scenario; nausea, vertigo, agitation and ECG parameters (Tab 1). Continuous Mg infusion & Dobutamine to maintain a heart rate round 90bpm improved clinical symptomatology, a stable heart rhythm and normalization of QTc, without complex arrhythmias. The patient was referred to oncology follow up.

Conclusion: ADT may lead to severe electrolyte imbalances and life-threatening cardiac arrhythmias. It should be considered an important cause of QT prolongation. Further studies are necessary to investigate its effects in several cardiac populations.

Disease development of arrhythmogenic cardiomyopathy: a case report.

E Eszter Fodi[1]; R Faludi[1]; T Simor[1]
[1]*University of Pecs, Heart Institute, Pecs, Hungary*

The diagnostics of arrhythmogenic cardiomyopathy (AC) has been facilitated by a complex criteria system that is continuously improving to increase sensitivity. Due to the great differences in the clinical picture, decision making is challenging even with the use of recently available imaging techniques.

We report a case of a 29-year-old male patient, whose cardiac evaluation started 10 years ago because of pre-syncopal episodes during driving. Based on the initial echocardiographic and cardiac MRI examinations in NYHA I, a primary dilated cardiomyopathy (DCM) was diagnosed (36 % EF, slightly dilated left and right ventricle with diffuse hypokinesis). His treatment and follow-up were set up according to DCM. But recently, based on the appearance of an epsilon wave in lead V1 on a follow-up 12 lead surface ECG, cardiac MRI was repeated with the indication of AC. The cardiac MRI confirmed AC, as it showed the previously known reduced left (41%) and novel low right ventricular EF (35%) and proved both right ventricular and left ventricular delayed enhancement (Figure 1). According to the analysis of the 20 ECGs collected during the 10 years, we found only minor ECG criteria for AC. The epsilon wave appeared only recently for the first time. Therefore, the risk of sudden cardiac death was re-evaluated and based on the heart failure, the documented novel non-sustained right ventricular outflow tract ventricular tachycardias and still present pre-syncopal episodes, implantable defibrillator therapy was suggested. Unfortunately, the patient declined the intervention.

Our case draws attention to the diverse presentation of AC (both right and left ventricular involvement). Furthermore, our case shows the progressive nature of the AC disease development. We emphasize the fact that besides the regular clinical follow-up visits the disease progression should be estimated paying close attention to the changes both on the surface ECG and cardiac MRI.

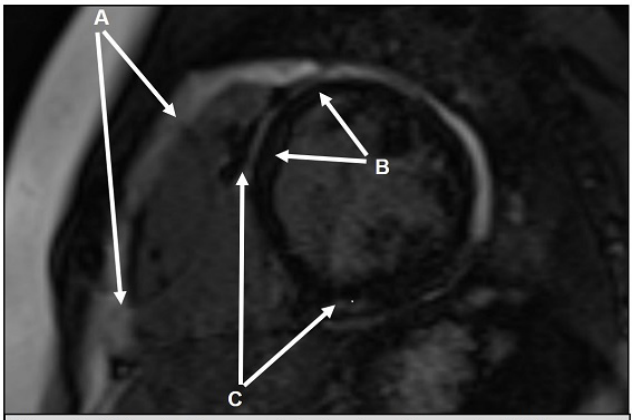

Figure 1. Delayed-enhancement short axis cardiovascular MRI image of the patient showing delayed enhancement in the right ventricular free wall (A), mid-myocardial (dilated cardiomyopathy pattern) (B) and subepicardial delayed enhancement (myocarditis pattern) (C) in the left ventricular wall.

Figure 1. Short axis cardiac MRI image

873

Iatrogenic cardiac arrest and cardiogenic shock

M Carrington[1]; AR Santos[1]; J Pais[1]; B Picarra[1]; D Bras[1]; R Azevedo-Guerreiro[1]; K Hyde-Congo[1]; J Carvalho[1]; J Aguiar[1]
[1]*Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal*

A 61-year-old woman with previous history of severe hypertension presented with a rapid deterioration of mental state and was assisted by a pre-hospital emergency team. An extreme bradycardia was detected, with no response to atropine, and a transcutaneous pacemaker stimulation was applied. During hospital transport, she had a cardiac arrest in asystole, with return to spontaneous circulation after five cardiopulmonary resuscitation cycles. She was intubated and mechanically ventilated and carried to our emergency department. On examination, she was hemodynamically instable with hypotension and a deficient external pacemaker stimulation causing an extreme bradycardia of 20 bpm, and had discrete inferior limbs oedema. The electrocardiogram showed sinus arrest with escape beats. A cardiogenic shock secondary to extreme bradycardia was assumed and she was immediately admitted at the coronary intensive care unit for urgent stabilization.

She had previous history of a severe hypertension and dyslipidaemia. She was being treated with diltiazem 300mg od, carvedilol 25mg twice a day, rilmenidine, spirono-lactone, torasemide and simvastatin. She was being treated for her hypertension by her general practitioner and two different specialists.

A transvenous pacemaker was immediately implanted and vasopressor support was initiated with need for noradrenaline dose titration. On echocardiogram, she had a non-dilated left ventricle (LV), with concentric hypertrophy and a moderately

depressed global LV ejection fraction (EF). Right ventricle was normal and both mitral and tricuspid moderate insufficiencies were present. Biochemical and hematologic investigations revealed renal dysfunction with severe hyperkalaemia (7,5mmol/L), hepatic dysfunction and normal c-reactive protein and troponin I.
She had a rapid recovery and in the thirty-six hours following admission, she was extubated and vasopressor support was gradually weaned. The electrocardiogram revealed sinusal rhythm at 80 bpm, with normal AV and interventricular conduction and no ST-T segment changes. Coronary angiography showed no angiographic significant lesions and echocardiographic re-evaluation showed a preserved global LVEF and no significant functional valvular alterations.
Beta-blockers therapy is the most common cause of drug-induced bradycardia. The addition of non-dihydropyridine calcium channel blockers augments the effects of beta-blockade, as both drugs depress cardiac electrical and mechanical activity. They interfere with slow action potential generation and atrioventricular conduction and both have negative chronotropic and inotropic effects. Non-coordinated treatment of severe hypertension by different doctors is potentially fatal, as demonstrated by this clinical case. All patients should be advised to carry a personal medication and dosage chart, which should be revised for potential drug-interactions by treating doctors each visit.

874

Reversal of systolic dysfunction in a male adolescent with left ventricular hypertrabeculation/noncompaction and Wolff-Parkinson-White syndrome after accessory pathway ablation

K Rezkalla[1]; E Gatterer[1]; JO Huber[1]; C Neuhold[1]; C Claudia Stoellberger[1]
[1]*Rudolfstiftung Hospital, Department of Internal Medicine II, Vienna, Austria*

Introduction: Recurrent or incessant tachycardia may occur in symptomatic Wolff-Parkinson-White (WPW) syndrome, leading to ventricular dysfunction, tachycardia-induced cardiomyopathy (TIC). Asymptomatic WPW syndrome-induced TIC has rarely been reported, with incidence rates higher in pediatric patients than in adults. Left ventricular hypertrabeculation/noncompaction (LVHT) is a cardiac abnormality of unknown etiology and is found in normally sized, well contracting left ventricles as well as in dilated ventricles with systolic dysfunction. LVHT associated with WPW has been reported several times, however reversal of systolic dysfunction after ablation has not been described so far.
Description of the patient: A previously healthy 17-years old male underwent the first electrocardiogram (ECG) of his life at the conscription for military service. ECG showed WPW-syndrome with overt pre-excitation, and he was referred for cardiological investigation. He reported no cardiac symptoms and was an active soccer player. Clinical investigation was normal. Echocardiography revealed an enlarged left ventricle (enddiastolic diameter 59mm), a reduced ejection fraction (14%) and LVHT of the apex and lateral wall. Resting ECG and 24-hour Holter monitoring disclosed multiple episodes of atrial tachycardias with a heart rate of 110/min. After repeated inquiries the patient admitted that he felt frequently "rapid heart beats", but this was so normal that it did not bother him.
Patient management: Cardiac magnetic resonance (CMRI) imaging was planned but could not be carried out because of atrial arrhythmias. Electrophysiological examination disclosed an epicardial left posteroseptal accessory pathway with ante- and retrograde conduction. Radiofrequency ablation was carried out in October 2017. After 16 radiofrequency deliveries in the left atrium and in the coronary sinus, the retrograde conduction was completely blocked and the anterograde conduction was blocked intermittently. The postinterventional ECG did not show Delta waves any more. Two months later, in December 2017, echocardiography showed a normally sized left ventricle (enddiastolic diameter 56 mm) with normal systolic function (EF 60%) and unchanged LVHT. The patient did not receive any pharmacotherapy except acetylsalicylic acid 100 mg/d for 4 weeks after ablation. The patient is continuously in NYHA I class of heart failure and reports that he feels no "rapid heart beats" any more. CMRI is scheduled for February 2018. Genetic testing is under way.
Conclusions: and implications for clinical practice: WPW-induced TIC may even occur in asymptomatic patients, who are so adapted to their arrhythmias that they do not recognize them. Ablation of the accessory pathway leads to reversal of systolic dysfunction without necessity for neurohumoral therapy. Since the further course of the cardiac situation including LVHT is uncertain, the patient remains under cardiologic observation.

875

Cardiac thromboembolic stroke due to inappropriate implantable cardioverter defibrillator shock

D Zizek[1]; B Antolic[1]; M Jan[2]; L Notar[3]
[1]*University Medical Centre Ljubljana, Department of Cardiology, Ljubljana, Slovenia*; [2]*University Medical Centre Ljubljana, Department of Cardiovascular Surgery, Ljubljana, Slovenia*; [3]*University Medical Centre of Ljubljana, Department of Neurology, Ljubljana, Slovenia*

Introduction: Device detected atrial tachyarrhythmias, especially subclinical atrial fibrillation (AF) episodes, are associated with an increased risk of stroke. However, the precise threshold of AF episode duration and daily burden that justifies initiation of oral anticoagulation is still controversial. Additionally, in spite of tachyarrhythmia discrimination advances implemented in implantable defibrillators devices the incidence of inappropriate therapy remains relatively high.
Case report: A 57-year-old male with recently implanted cardiac resynchronization therapy device with a defibrillator (CRT-D) due to nonischaemic heart failure (HF), no history of AF and receiving contemporary HF medication was admitted to the Neurology department due to symptoms of stroke and impaired consciousness. Computed tomography angiography scan, performed 2 hours after the onset of stroke symptoms, demonstrated an occlusion of the left middle cerebral artery (MCA) (Figure 1A - arrow) and the treatment with intravenous tissue plasminogen activator (tPA) was initiated according to the guidelines. In addition, before stroke symptoms, the patient reported a defibrillator shock. CRT-D device interrogation revealed an inappropriate device-related shock due to short AF episode (< 3 minutes) with rapid ventricular response (Figure 1B) approximately 1 hour before the onset of stroke symptoms. There were no additional atrial tachyarrhythmia episodes registered since the device was implanted. As cardiogenic thromboembolism was suspected transoesophageal echocardiography was performed which revealed a thrombus in the left atrial appendage (Figure 1C - arrow).
Clinical question: Could abrupt device-related sinus restoration in an inadequately anticoagulated patient present an additional thromboembolic risk irrespective of subclinical AF duration?
Conclusion: In HF patients with implantable CRT-D or defibrillator devices detection of new subclinical AF requires appropriate clinical management and decisions (oral anticoagulant treatment, antiarrhythmics, device programming etc.) not only because device-detected AF is a determinant of stroke but also due to possible risk of inappropriate shock related thromboembolism.

Catecholaminergic polymorphic ventricular tachycardia with ventricular dysfunction: a new reality?

T Tatiana Duarte[1]; S Goncalves[1]; C Sa[1]; R Marinheiro[1]; M Fonseca[1]; J Farinha[1]; F Seixo[1]; L Parreira[1]; R Caria[1]
[1]*Hospital Center of Setubal, Cardiology, Setubal, Portugal*

Introduction: Catecholaminergic polymorphic ventricular tachycardia (CPVT) is a highly malignant inheritable cardiac channelopathy, the most common genetic mutations responsible for CPVT occur in the gene that encodes the cardiac ryanodine receptor (RyR2).
CPVT is characterized by episodic syncope occurring during exercise or acute emotion in individuals without structural cardiac abnormalities. In the literature has been reported the association with takotsubo cardiomyopathy in scarce cases.

Considering all cardiac events (syncope, aborted cardiac arrest, sudden death), the rate of occurrence is 54-58% in untreated individuals, according some data 33-38% of patients presented with cardiac arrest.
Case report: An 52 year-old female patients was admitted in emergent department (ED) by episodic syncope without prodromes and no previous history similar. Patient with history of intermittent left bundle branch block (LBBB), arterial hypertension and profound venous thrombosis and family history of sudden death.
In ED, hemodynamically stable without precordial pain. ECG with intermittent LBBB and negative troponin. She realized CT angiography that excluded pulmonary thromboembolism but CT cranioencephalic with subarachnoid hemorrhage without need for invasive therapy.
Coronary angiography excluded coronary disease and echocardiography transthoracic with evidence of moderate-severe left ventricular dysfunction. The cardiac NMR showed moderate left ventricular dysfunction (LVEF 40%) by diffuse hypokinesia without ventricular dilation and no ischemia pattern. The electrophysiological study was normal.
During hospitalization without evidence of dysrhythmic episodes and evolution in NYHA class II. At the 25th day, there was discharge after implantation of cardioverter-defibrillator.
After one year, she is followed in a Heart failure (HF) outpatient clinic, actually in NYHA class I and recovered ventricular function and no dysrhythmic events. The genetic study evidenced a new variant of mutations in gene of RyR2 (Ala4860 Val), potentially pathogenic, however without record any other case in the literature.
Conclusion: The association between CPVT and takotsubo syndrome has been a reality, although the cases described are scarce and the mechanics not yet cleared as well as the prognostic impact.
In our case, the segmental alterations are not compatible with takotsubo, but eventually the transient dysfunction may be explained by similar mechanisms: effect of catecholamines, effect of intracellular calcium and its role in HF.
Our knowledge about CPVT continues to grow and new genetic mutations are found, more studies are important to help shape newer diagnostic and treatment strategies.

877

A rare combination of two genetic cardiomyopathy (arrhythmogenic right ventricular dysplasia and left ventricular noncompaction) and the role of myocarditis in disease progression

O V Olga Blagova[1]; AV Nedostup[1]; EA Kogan[1]; YA Lutochina[1]; NV Varionchik[1]; EV Pavlenko[1]; SA Alexandrova[2]; AG Shestak[3]; EV Zaklyazminskaya[3]
[1]*I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation*; [2]*Bakoulev Center for Cardiovascular Surgery RAMS, Moscow, Russian Federation*; [3]*Russian Research Center of Surgery, Moscow, Russian Federation*

Background: First identified the phenotype of dilated cardiomyopathy (DCM) should be considered as a syndrome that requires expanded nosological diagnosis. Simultaneous presence of sustained ventricular tachycardia (SVT) increases the probability of the genetic nature of the disease.
Purpose: to evaluate the features of the clinical picture, laboratory and instrumental diagnostics and the effectiveness of complex treatment in a patient with a high risk of sudden cardiac death.
Methods: There was a female patient 34 years. From 23 years (after a respiratory infection) - chest pains, shortness of breath. Coronary arteries are intact. In 2013 she survived syncope, in Holter-ECG she had 2048 PVBs / day, episode of SVT (1 minute). MRI was performed, and a cardioverter-defibrillator (ISD) was implanted. Follow up is 50 months.
Results: ECG showed the low QRS voltage and negative T waves in leads V2-V6. EchoCG revealed LV EDD 6.2 cm, RV EDD 4.0 cm, LVEF 35%, LV myocardial noncompaction (NCM). Late ventricular potentials were detected. MRI sowed NCM of LV, thickening of the epicardial fat on the anterior wall of the right ventricle (RV), RV EDV 133 ml/m2, EF 41%, LV EDV 115 ml/m2, EF 25%, hypo / dyskinesia of the anterior wall, subepicardial gadolinium enhancement in the early and late phase in the LV, intraventricular septum and the free walls of the RV. The level of all anti-heart antibodies was high (1:160-1:320). The reasons for statement of a possible diagnosis of myocarditis in this case were the connection the onset of symptoms with viral infection, high titers of anti-heart antibodies, early and late subepicardial gadolinium enhancement by MRI. The endomyocardial biopsy of RV was performed: subendocardial lipomatosis (about 10%), separation of myocardium by fibrous septa, lymphocytic infiltrates (more than 14 cells), vasculitis without viral genome. DNA diagnosis revealed a splicing mutation in the gene desmoplakin (DSP). Arrithmogenic right ventricular dysplasia (ARVD), LV NCM and myocarditis were diagnosed. Immunosuppressive therapy (hydroxychloroquine, prednisone, azathioprine) was prescribed, LV EF stabilized at 40%. The appropriate shock of the ICD for VT (HR of 210 / min.) with transformation in ventricular fibrillation was recorded twice. For this reason, sotalol was replaced with amiodarone.
Conclusion: In a young patient with arrhythmogenic syncope and DCM syndrome was diagnosed combination of ARVD (3 major and 2 minor criteria, definite diagnosis) and NCM with the biopsy proved virus-negative chronic myocarditis. The DCM as a syndrome can have multiple causes, and the combination of myocarditis and primary cardiomyopathy is not rare. NCM can be observed in patients with typical desmosome proteins mutations. The use of immunosuppressive therapy led to the stabilization of heart failure, however, recurrent ventricular arrhythmias a greater degree determined by the presence of primary cardiomyopathy.

878

A comparison between strain echocardiography and quantitative gated myocardial perfusion scintigraphy in patients with low ejection fraction of left ventricle prior to implantation of CRT-D

A Alexander Kazakov[1]
[1]*Saint Petersburg Pavlov State Medical University, Hospital surgery ? 2, Saint Petersburg, Russian Federation*

Objective: The objective of this study is to compare the strain echocardiographic and scintigraphic parameters for evaluating of the left ventricular (LV) functions in patients prior to implantation of CRT-D.
Methods: Fifteen our patients (male/female: 10/5) were included in this study. All patients underwent gated myocardial perfusion scintigraphy gated single-photon emission computed tomography (GSPECT) and echocardiography (EC). LV was divided into 17 segments. The echocardiographic strain (S) and strain rate (SR) values were calculated by using speckle tracking method. The results obtained by these techniques were compared to each other. Also global strain of LV were measured using speckle tracking echocardiography (STE) and ejection fraction of LV using GSPECT.
Results: A total of 255 (17x15) segments of LV wall were evaluated. In all patients, 94 segments were scored as normokinetic, 65 as hypokinetic, 96 as akinetic or dyskinetic using echocardiographic strain method; and 89 as normal thickening, 105 as decrease thickening and 61 as no thickening using GSPECT. All patients had decreased global strain (<12%) and low ejection fraction (<35%).
Conclusion: GSPECT and STE allow to evaluate regional and global myocardial contractility in patients prior to implantation of CRT-D. We showed that GSPECT and STE were in agreement with each other. Also, STE method could be used in order to choose optimal localization of LV electrode as a non-invasive alternative of other methods.

879

Right-sided subcutaneous ICD in a patient with congenitally corrected transposition of the great arteries with situs inversus and dextrocardia

I Igor Zupan[1]; K Prokselj[1]; M Kozelj[1]; J Tasic[1]; D Zizek[1]; J Winter[2]
[1]*University Medical Centre of Ljubljana, Department of Cardiology, Ljubljana, Slovenia*; [2]*University of Dusseldorf, Division of Cardiac Surgery, Dusseldorf, Germany*

Introduction: Subcutaneous implantable defibrillator (S-ICD) may require nonstandard placement because of anatomic abnormalities in patients with complex congenital heart disease. We describe the placement of an S-ICD on the right side of the thorax in a patient with congenitally corrected transposition of the great arteries with situs inversus and dextrocardia.
56 years old woman with complex congenital heart disease presented with presyncope and dizzines. Holter monitoring revealed episodes of non-sustained ventricular tachycardia. Treatment with amiodarone was contraindicated due to Wegener disease and thyroid dysfunction. Implantation of a conventional ICD in a subpulmonary ventricle was questionable because of the presence of a small atrial septal defect and further need for an anticoagulation treatment. Besides, she had a hystory of bleeding from an aneurism of left segmental pulmonary artery, probably caused by endocarditis of the pulmonary valve seven years ago.
Echocardiography revealed slightly dilated subpulmonary ventricle with 50% ejection fraction, enlarged both atria, small atrial septal defect, moderate pulmonary hypertension and moderate pulmonary stenosis.
She received a S-ICD (Boston Scientific, Model SQRX) implanted intermuscularly between the anterior surface of serratus anterior and the posterior surface of latissimus dorsi on the right side. The pulse generator pocket incision overlied the fifth to sixth intercostal space 3-4 cm lateral to the mid-clavicular line towards the mid-axillary line. The distal tip of the electrode was tunnelled from the pocket above the fascial layer and fixed at the xyphoid with the suture sleeve. We opted for a third incision, so that the distal tip could be visualized and fixed.
A 50-Hz burst induced VF with adequate sensing and termination of VF with restoration of sinus rhythm after 17 seconds from a single 65-J shock. After a few seconds atrial fibrilation appeard which used to be her basic rhythm over past years. At 2 months follow-up, the patient has presented no complications and no significant events have been recorded.

The S-ICD system can be used effectively in the right thorax in patients with complex heart disease and dextrocardia. We are not aware of any case of particular congenital disease with right-sided S-ICD implantation.

880

His-bundle-pacing-based ICD as an innovative approach in decompensated chronic heart failure and concomittant permanent atrial fibrillation.

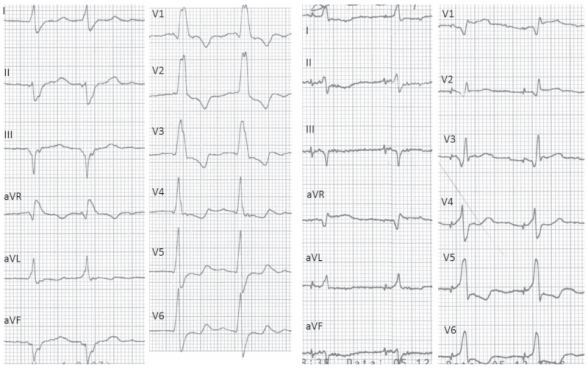
J Adamowicz[1]; A Slawuta[1]; M Sokolowska[2]; J Adamowicz[2]; J Moszczynska-Stulin[3]; J Gajek[4]; D Zysko[5]

[1]Klodzko County Hospital, Department of Cardiology, Klodzko, Poland; *[2]Wroclaw Medical University, Students' Scientific Association, Department of Cardiology, University Hospital, Wroclaw, Poland*; *[3]Wroclaw Medical University, Department of Cardiology, University Hospital,, Wroclaw, Poland*; *[4]Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland*; *[5]Wroclaw Medical University, Department of Emergency Medicine, Wroclaw, Poland*

Introduction: Patients with atrial fibrillation and congestive heart failure decompensation prove to be a troublesome population. AF often recurs after an electric cardioversion, requiring a strict rhythm control approach. According to recent reports index population may not benefit from ß-blocker therapy, due to insufficient blockage of adrenergic stimulation, limited by impaired AV conduction and depletion of cardiac output. Ambiguous reports about intravenous digoxin were noted. Inotropic agents may be useful as heart failure symptoms aggravate, however sympathetic activation promotes higher ventricular response in AF, impeding haemodynamic benefit.

Case description: 68-year male with a history of chronic heart failure with permanent AF after inferior myocardial infarction with partially ischaemic mitral regurgitation was admitted with a consecutive episode of decompensation. Patient presented with dyspnoea, ortopnoea, peripheral oedema and right sided pleural effusion. Echocardiography revealed enlarged LVEDD (72mm) with EF = 28%. A severe MR with jet area estimated at 11 cm^2 was a significant finding was as well. Carefully dosed catecholamines caused tachycardia with exacerbation of heart failure. Digoxin administered intravenously resulted in only moderate negative chronotropic effect. As a detrimental influence of atrial fibrillation proceeded, we decided to regularize the rhythm with pacing. Because of ECG pattern of RBBB patient was not a target candidate for conventional resynchronization. In these circumstances the direct His bundle pacing (DHBP) seemed to be a more appropriate alternative. We achieved a broad zone of selective His Bundle pacing with additional RBBB abolition. The His bundle electrode was connected with atrial port of the dual ICD and ICD electrode was placed in RV apex. The heart rate regularization enabled to stop i.v. drugs administration, up-titrate digoxin and start beta-blocker. The oral loop diuretic doses were gradually reduced. The initial pacing rate of 80 bpm was lowered to 70 bpm. After the procedure echocardiography showed immediate LVEDD reduction to 69mm and EF increase to 35%. During 12-month follow up the patient required few modifications of pharmacotherapy according to renal status, blood pressure and AV conduction, but there was no episode of heart failure decompensation.

Conclusions: 1. Standard pharmacological treatment of decompensated heart failure with AF may lead to a detrimental effect on patient's haemodynamics. 2. Direct His-bundle pacing in patients with non-LBBB QRS morphology is an attractive treatment option to regularize the heart rate without harmful right ventricular pacing. 3. In presented case the innovative His-ICD implantation during episode of acute heart failure enabled better patient's treatment with immediate and subsequent clinical and echocardiographic improvement.



12-lead ECG; pre- and postprocedural.

Multifocal ectopic Purkinje-related premature contractions caused by mutation in SCN5A gene may result in arrhythmia induced cardiomyopathy

T Tereza Nedvedova[1]; M Kubanek[1]; A Krebsova[1]; L Piherova[2]; M Blaha[1]; J Vrbska[1]; V Melenovsky[1]; P Peichl[1]; S Kmoch[2]; J Kautzner[1]

Funding Acknowledgements: research grant of the Ministry of Health, Czech Republic [MZ 15-27682A]

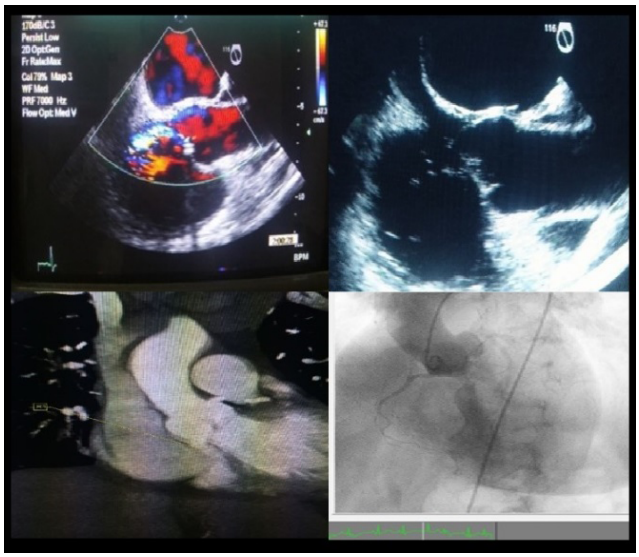
Background: The SCN5A gene encodes the subunit of voltage-gated sodium channel which is responsible for rapid electrical transmission through cardiac conduction system and for myocardial excitability. Mutations of SCN5A have been associated with a broad spectrum of hereditary arrhythmias and/or cardiomyopathies. Multifocal ectopic Purkinje-related premature contractions (MEPPC) have been recognized as a cause of arrhythmia induced reversible systolic dysfunction which can be sometimes reversed by class I antiarrhythmic drugs. These drugs are known to decrease the rapid depolarizing sodium influx, thereby slowing depolarization and reducing the amplitude of the action potential. This results in slower conduction and reduced automaticity.
Methods: We present a patient with non-ischemic, severe left ventricular systolic dysfunction due to frequent multifocal ectopy originating from the conduction system with a verified - likely pathogenic - mutation in SCN5A gene. Molecular diagnostics were performed by whole exome sequencing.
Clinical case: A 38-year-old female was examined due to palpitations and dyspnea at mild exertion. Her ECG showed junctional rhythm with MEPPC, which constituted 44% of the 24h ECG recording. Echocardiography revealed severe systolic dysfunction of non-enlarged left ventricle (LVEF 20-25%), while MRI did not show late gadolinium enhancement. Quinidine sulfate 800 mg daily suppressed MEPPC and resulted in rapid improvement of LVEF to 35-40% during the initial hospitalization. At 12 months of follow-up, MEPPC were reduced to 3% of beats and LVEF normalized (60%). An attempt to replace quinidine with flecainide 100 mg daily resulted in reappearance of MEPPC. After re-administration of quinidine sulfate 600 mg daily, the patient remains clinically stable with preserved LVEF and significant suppression of MEPPC. Genetic testing confirmed a pathogenic SCN5A gene mutation (c.68635 C>T, p. R814W). Cascade screening in the family revealed the same mutation in the patient's father, which was characterized by very frequent MEPPC and normal LV function.
Conclusions: Frequent MEPPC due to mutations in SCN5A gene may cause arrhythmia-induced cardiomyopathy. Targeted antiarrhythmic therapy may lead to normalization of LV systolic function. However, there is an uncertainty about the optimal prevention of sudden cardiac death of patients with this condition.

910

Acute right heart failure presented as acute abdomen

I Ina Refatllari[1]; A Banushi[1]; V Beqiraj[2]; H Gjergo[1]; A Demiraj[1]; A Goda[1]
[1]University Hospital Center Mother Theresa, Cardiology, Tirana, Albania; *[2]Polyclinic Ambulatory Service, Cardiology, Tirana, Albania*

Introduction: Acute heart failure has a poor prognosis. Early identification and correction of its cause is crucial in order to increase the chances of survival. Spontaneous rupture of a Sinus of Valsalva may lead to serious hemodynamic instability and death if left untreated.Case report: A 67 y.o female patient presented in the ER as acute cholecystitis complaining of strong epigastric pain irradiating in the right hypochondrium and shortness of breath. The pain started a week ago spontaneously and at first it was succeeded by a syncope. Moreover, she had an isolated fever episode of 38.5 °C and persistent diarrhea. Otherwise than hypertension and blood pressure lowering therapy, her past medical history was unremarkable. She underwent a transthoracic echocardiography examination three years earlier with no significant findings.An abdominal ultrasound was performed and it showed dilated suprahepatic veins, vena porta of 14 mm, gallbladder with thickened walls, sludge and pericholecystic fluid. On initial assessment the patient was pale, diaphoretic, tachycardic (115/min) and orthopneic. She had irregular heartbeats, an ejection systolic murmur (5/6 in intensity) all over the precordium, diminished breathing sounds at the lung bases and dilated jugular veins. BP was 140/80 mmHg. She was admitted for further evaluation. Transthoracic echocardiography revealed a possible aorta to right atrium fistula in a tricuspid aortic valve with right chambers dilation, mild tricuspid regurgitation, severe pulmonary hypertension (PAP 79 mmHg) and normal left ventricular function. Subsequently, a transesophageal echocardiography and an aortic angio CT confirmed the diagnosis and showed a communication between the noncoronary cusp and right atrium. She was immediately started on diuretics i/v and referred to the angiography cath lab to confirm the fistula and exclude the presence of coronary artery disease considering the patient's age and risk factors. The patient was transferred to the cardiac surgery department and underwent reconstructive surgery of the aorta. Endocarditis was excluded as a possible cause. The patient was discharged in good condition a week later.Discussion: Aorto-atrial fistulas (AAF) are rare but important pathophysiologic conditions of the aorta and have varied presentations such as acute pulmonary edema, chronic heart failure and incidental detection. A variety of mechanisms such as aortic dissection, endocarditis with pseudoaneurysm formation, post surgical scenarios or trauma may precipitate the fistula formation. Prompt surgical repair is usually helpful in relieving symptoms and decreasing mortality.
Conclusion: Spontaneous rupture of a nondilated Sinus of Valsalva is rare. Was angiography really necessary to confirm the fistula presence considering the patient's condition and imminent cardiac surgery? Non-invasive imaging techniques play an important role for making the correct diagnosis without needing further invasive examination.



Aorto-Atrial fistula images

Fecal microbiota transplantation in a heart transplant recipient

Z Zoltan Tarjanyi[1]; G Prinz[2]; A Kiraly[1]; A Assabiny[1]; N Parazs[1]; ZS Szakal-Toth[1]; T Teszak[1]; B Sax[1]; B Merkely[1]
[1]Semmelweis University Heart Center, Budapest, Hungary; *[2]Szent Laszlo Hospital, Budapest, Hungary*

We report a case of a 64 years old patient who received heart (HTX) in March 2016 due to end stage ischemic cardiomyopathy. Postoperative period was uneventful. One month after HTX repeated Weber tests were positive for occult blood in stool. A

colonoscopy was performed, which showed sessile polyps in the colon confirmed as high grade dysplasia with histopathological examination.
As removal with endoscope was not feasible, we decided to closely follow the lesion, because surgical removal would have carried high infectious risk because of the high immunosuppression (IS) level due to the very early stage after HTX. The controls showed no progression. At the one year checkup a PET-CT was performed showing fluorodeoxyglucose uptake in the dysplastic region. Oncology multidisciplinary team recommended right hemicolectomy, which was performed in May 2017.
In the next three months after the surgery patient was admitted to hospital several times due to Gram negative sepsis, gastrointestinal (GI) infections and weight loss. Despite to various antimicrobial therapy we were not able to stop the recurrence of the GI infections caused by Clostridium difficile and multi-resistant Gram negative bacterium species. Reducing IS was not an option due to a constant low-to-mid grade allograft rejection. With the failure of conventional treatments we decided to perform fecal transplantation. The procedure was performed in August 2017 for the first time in Hungary for a HTX recipient. The donor was the healthy daughter of the patient.
In the 5 months after the fecal transplantation the patient was free of GI infections and gained 12 kilograms. With this case we would like to draw attention to an effective treatment option for immunosuppressed patients with recurrent gastrointestinal infections.

912

Cardiomyopathy due to severe malnutrition reversed after total parentral nutrition

M Noshi[1]; AT Mahdi[1]
[1]*Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates*

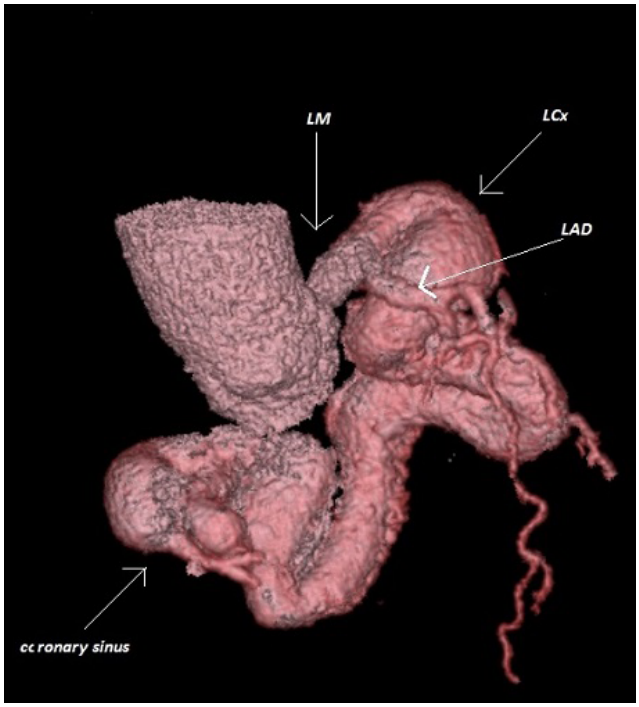
Background: Cardiomyopathy has been linked to nutritional status in conditions such as Beriberi, kwashiorkor, and Keshan disease. Micronutrients deficiency such as selenium has been reported to cause cardiomyopathy. In this case study we present reversal of Cardiomyopathy after treating malnutrition with total parenteral nutrition (TPN).
Case: Our patient is a 19 years old male who was diagnosed with severe Crohn's disease at the age of 8 years. The patient suffered from extensive intestinal strictures that eventually lead to ileocecal resection. Malabsorption and poor oral intake lead to severe malnutrition and growth impairment. At the age of 15 years his creatinine level was less than 15 mmol/L (Normal range 24-77mmol/L), albumin level was 21 mmol/L (normal range 35-52 mmol/L), His hemoglobin was 75 g/L, and His Body mass index (BMI) reached 14 kg/m2. Multiple attempts to enhance enteral feeding have failed. The patient was complaining of chronic fatigue, dyspnea and exertion intolerance. He was diagnosed with Heart failure with reduced ejection fraction of 25 %,gradual TPN refeeding program was started, the patient's nutritional status improved dramatically in the following 2 years ,Hemoglobin reached 105 G/L with normalized MCV of 84, BMI at the age of 19 years reached 23 kg/m2. His Heart failure symptoms improved, Follow up echocardiogram revealed reversal of cardiac impairment with left ventricular ejection fraction of 55%.
In Conclusion We believe that TPN (with proper portions of macronutrients, and micronutrients with trace elements) played a major role in the reversal of cardiomyopathy due to severe malnutrition in a patient with Crohn's disease, We strongly recommend aggressive and early nutritional management in patients suffering from malnutrition to avoid cardiac impairment. In addition, we believe that trace elements status should be monitored in these patients with adequate supplementation to avoid deficiencies.

913

NYHA class III chronic heart failure in 76-year old female with huge coronary fistula from LCx to coronary sinus and arterial pulmonary hipertension

S Nowak[1]; W Wojciech Kula[1]; G Sobieszek[1]; B Olajossy[1]
[1]*1st Military Hospital in Lublin, Cardiology, Lublin, Poland*

A 76-year-old female patient with history of hypertension and hypercholesterolemia, worsening symptoms of NYHA class III chronic heart failure, systolic heart murmur, with echocardiographic features of probable pulmonary hypertension, was referred to the Cardiology Department for diagnosis. The ECG recording revealed sinus rhythm, a dextrogram, an extension of the P-Q interval, and the right bundle branch block. The chest X-ray showed an enlarged heart profile and increased vascular drawing of the lungs. Transthoracic and transesophageal echocardiography reveals enlargement of the right heart cavity, normal left ventricle ejection fraction, moderate aortic and tricuspid regurgitation and the presence of arterial flow from the widened coronary sinus to the right atrium with a maximum speed of 3.1 m/s. Imaging diagnostics were supplemented with a computer tomography and coronary angiography, in which the presence of coronary anomaly was confirmed - widening of the pulmonary trunk to 42mm, dilatation of the left main up to 11 mm, dividing into the correct LAD and significantly widened (up to 22mm) and very twisted LCx, extending into the widened coronary sinus; right coronary artery without significant atherosclerotic lesions with a typical departure and course. In addition, right heart catheterization was performed, which showed pre-capillary pulmonary hypertension - mean pulmonary artery pressure 55 mmHg, total lung gradient 44mmHg, total pulmonary resistance 6.4 WU, heart index 3.8l / min * m2. In the six-minute walk test, the patient overcame a distance of 400m, fatigue assessed 8 points in the 10-point Borg scale. After consultation by the CardioGroup, the patient was qualified for conservative treatment due to the inability to undergo surgical and percutaneous treatment. At the moment, he is awaiting evaluation in the reference center of treatment of pulmonary hypertension against possible anti-proliferative pharmacotherapy.
Fistulas of the coronary arteries are a very rare anomaly observed in 0.05-0.25% of patients undergoing coronarography, the majority of which than the connections of the right coronary artery to the right ventricular cavity. The clinical case presented by us is an example of an extremely rare cause of pulmonary arterial hypertension and chronic heart failure, for which there are no unambiguous therapeutic recommendations



Fistula from LCx to coronary sinus

Iatrogenic pulmonary hypertension: a strange cause of heart failure.

J Ramos Jimenez[1]; M Maria Plaza Martin[1]; D Del Val Martin[1]; R Hernandez Antolin[1]; L Salido Tahoces[1]; R Rodriguez Olivares[1]; S Del Prado Diaz[1]; GL Alonso Salinas[1]; S Hernandez Jimenez[1]; JL Zamorano Gomez[1]
[1]*University Hospital Ramon y Cajal de Madrid, Madrid, Spain*

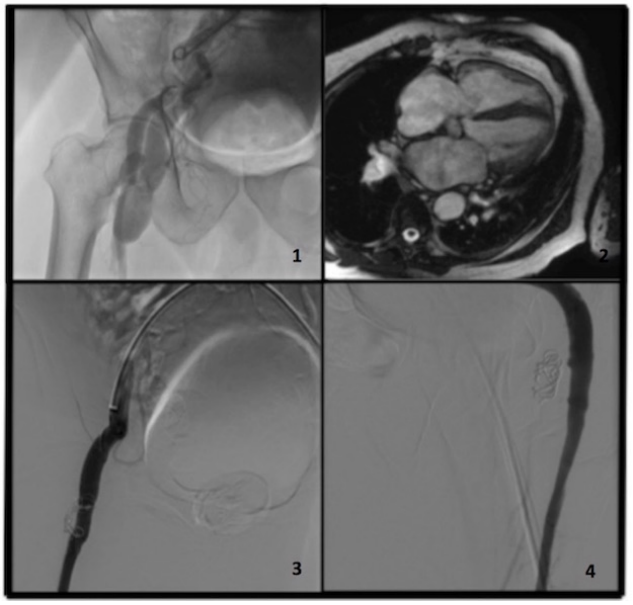
A 67-year-old man was admitted to our hospital in April 2017 due to shortness of breath and functional deterioration to NYHA class III. The patient had a first heart failure episode in January 2017 which was managed in a district hospital.
Respecting previous history, coronary artery disease was known since 2006, when he suffered a first myocardial infarction which was fibrinolysed. In 2014 the patient presented an episode of unstable angina and coronariography was performed by femoral approach. It revealed a total occlusion of right coronary artery, and severe stenosis in circumflex and first marginal arteries, with percutaneous revascularization of these last two. Besides, the patient was hypertensive, former smoker with COPD stage I (GOLD) and had moderate sleep apnea-hypopnea syndrome.

Physical exam showed jugular vein distension, loud second sound and light oedema lower limbs. Resting oxygen saturation was 85%. EKG consist of atrial fibrillation with controlled heart rate and right bundle branch block. Chest X-ray and blood test showed no relevant abnormalities. BNP was 389 pg/mL. Hypoxemic respiratory failure (pH 7,40, pO2 57, pCO2 43) was encountered in resting arterial blood gases. Infectious and autoimmune analysis were negative. Transthoracic echocardiography described preserved LVEF with impaired relaxation, whereas right ventricle was severely dilated with mild systolic dysfunction (TAPSE 15 mm) and PSAP was estimated in 67 mmHg. Right ventricle impairment was confirmed by cardiac-MRI, which also revealed inferior late gadolinium enhancement in relation to ancient myocardial infarction.

As a part of pulmonary hypertension study protocol, thorax-CT was demanded showing signs of mild centroacinar emphysema, dilatation of pulmonary artery trunk and both pulmonary branches. Pulmonary function was tested, with moderate obstruction to air flow (FEV1/FVC 0,67; FEV1 76%) and severely reduced DLCO (34%). That severe reduction and the severity of symptoms was not in concordance with mild imaging alterations. In this sense, a V/Q scintigraphy was performed with no signs of pulmonary embolism, and left-right heart catheterization was demanded with the following findings: PASP 74 mmHg, PADP 31 mmHg, PAMP 45, PWP 15 mmHg, CO 3,9 L/min and no changes in coronary anatomy. At the time of femoral puncture, thrilling was perceived by palpation. Selective iliac arteriography was done, showing arteriovenous fistula with important left to right shunt. Findings were confirmed by aortic-CT.

The patient was submited to percutaneous closure of the fistula with a remarkable improvement in his functional class and hemodinamics a few months after the procedure.

Arteriovenous fistula is responsible for a high output state which is identified as a cause of pulmonary hypertension included in the clinical group 5 of the recent classification. In this case, catheterization was the origin and the solution of this reversible ethiology of heart failure.



1AV fistula. 2RV dilatation. 3-4 result

Poster Session 2

Atrial Fibrillation - Epidemiology, Prognosis, Outcome

P915
Heart rate control in atrial fibrillation and outcomes in acute heart failure patients: the lower the best.

RM Agra Bermejo[1]; A Varela Roman[1]; I Gomez Otero[1]; A Ferrero-Gregori[2]; D Pascual Figal[3]; J Delgado Jimenez[4]; J Alvarez Garcia[4]; F Fernandez Aviles[5]; F Worner Diz[6]; L Alonso Pulpon[7]; J Cinca[2]; JR Gonzalez Juanatey[8]

On behalf of: Red Española de Insuficiencia Cardiaca researchers (REDINSCOR II).

Introduction: The optimal resting ventricular rate in patients with AF and HF is uncertai. The ESC HF guidelines recommend that the target for rate control therapyshould be between 60-100 bpm.
Ventricular rates < 70 bpm are associated with a worse outcome.This may explain why betablockers titrated to guideline-target doses failed to reduce morbidity or mortality in patients with HFrEF and AF, and might also explain the association between digoxin and adverse outcomes reported in some observational studies of AF.

Purpose: The aim of the study was to evaluate the impact of the more strict rate control(< 60 bpm) in acute HF patients with atrial fibrillation on short and long- term mortality.
Methods: The analysis included acute heart failure and atrial fibrillation patients enrolled in the REDINSCOR Registry. Patients with sinus rhythm and/or paced rhythm presented during index hospitalization were excluded from the study. Patients were divided into two subgroups according to heart rate at discharge: < 60 bpm or > 60 bpm . The primary endpoint was 30- day and 1- year mortality.
Results: The final analysis included 653 patients; 128 with HR < 60 bpm (18.3%) and 535 with HR >60 bpm (75.1%). There were no differences in age, sex, cardiovascular risk factors, NT-proBNP levels or left ventricular ejection fraction. There were no differences in the use of betablockers but the use of digoxin was higher in the HR > 60 bpm group (36,7% vs 21,4%, p < 0,001). The heart rate at discharge was 54,9 ± 5 bpm in the HR < 60 bpm and 79,2 ± 13 in the HR > 60 bpm group (p < 0,001). There were no differences in the use of betablockers but the use of digoxin was higher in the HR > 60 bpm group (36,7% vs 21,4%, p < 0,001).
The 30 -day mortality was 1,6% in HR < 60 bpm group vs 6,5% in HR >60 bpm group (p = 0,029) and the 1- year mortality was 14,1% in HR < 60 bpm group vs 21.1% in HR >60 bpm group. The Kaplan Meier Curves showed that these differences were statistically significant (FIGURE1). In the multivariate analysis HR>60 bpm (HR 1.70, CI 95% 1.02-2,83, p 0.042), betablockers (HR 0.65, CI 95% 0.45-0.95, p 0.025) and digoxin HR 1.56, CI 95% 1.04-2.32, p 0.030) were predictors of mortality.
Conclusions: In acute heart failure patients with AF HR < 60 bpm is associated with better short and long term prognosis. The use of betablockers not digoxin in this population remains beneficial.

Personalized left atrial substrate modification in patients with long-standing persistent atrial fibrillation and chronic heart failure.

VS Orshanskaya[1]; AV Kamenev[1]; MA Naimushin[1]; LA Belyakova[1]; EN Mikhailov[1]; DS Lebedev[1]
[1]Almazov Federal Heart Centre, Electrophysiology , Saint Petersburg, Russian Federation

Background: Emerging evidence suggests that left atrial (LA) electroanatomic substrate (EAS) outside the pulmonary veins (PV) plays a crucial role in the maintenance of persistent atrial fibrillation (PsAF) and chronic heart failure (CHF). Whether personalized LA EAS modification in addition to circular pulmonary vein isolation (PVI) improves the long-term procedure outcome and heart function in patients with long-standing persistent atrial fibrillation (PAF) and CHF with left ventricular (LV) systolic dysfunction (SD) is unknown.
Method: We prospectively analyzed electroanatomical high density bipolar maps (HDBM) in 125 subjects with long-persistent AF and chronic HF (group I with LVEF < 45%, n = 43 and group II with LVEF = 45 %, n= 82), who underwent circular PVI. Bipolar signals = 0.75mV outside PV, associated with local conduction velocity delay were tagged on LA maps, considered as EAS and measured. Patients in groups I and II were further divided according to whether LA EAS modification to addition to circular PVI was performed (group IA, n= 22; group IIA, n = 36) or not (group IB, n = 21, group II B, n = 46). Patients were followed up with implanted electrocardiographic monitors when possible (63%). Long-term ablation success and LV EF dynamics after procedure were analyzed.
Results: EAS areas were identified in 93 % and 57 % of patients in groups I and II respectively and a mean relative EAS area was 16.8 ± 10.3% and 32.6 ± 18.5% in groups I and II respectively(P = 0,003). The LA roof and the posterior, anterior and septal wall LA were most often affected. During a mean follow-up of 21 ± 8 months, long-term ablation success was higher in group IA than in group IB (64 % vs 38 %; P 0.025) as well as in group II A was higher than in group II B (67.0 % vs 40 %; P 0.03). The mean increase in LVEF following AF ablation was higher in IA group, than IB group (19 ± 9 % vs 8,4 ± 6 %, p = 0,001 respectively) and higher in IIA group than IIB group (11 ± 7 % vs 5,6 ± 5 %, p = 0.04 respectively).
Conclusion: In patients with long-standing persistent atrial fibrillation and heart failure, personalized LA EAS modification in addition to circular pulmonary vein isolation significantly improves their long-term procedure outcome and heart function.

P917

Maze III procedure in patients with heart failure, atrial fibrillation and valve disease

A A Kulikov[1]

[1]*Cardiology Research and Production Center, Moscow, Russian Federation*

Research objective: To estimate effectiveness of Maze III procedure combined with a mitral valve operation in patients with heart failure and long-standing atrial fibrillation.

Methods: In the study were included 100 adult patients (48 men) with heart failure, persistent and longstanding persistent forms of AF and valvular pathologies. Average age of patients was 59 years. Average AF duration was 4 years.

Functional class of heart failure on NYHA 2,7 ± 0,75. The size of the left atrium 5,1 ± 1,5 cm, average left ventricular ejection fraction 61 ± 8,6%.

Antiarrhythmic therapy was tried to all patients, however it was inefficient.

All patients had mitral valve pathology. Also 80% of patients had the tricuspid valve insufficiency.

To all patients the electric cardioversion was made. After restoration of a sinus rhythm, the EP was executed. Then, on the first or second day after EP, correction of valve pathologies combined with "Maze III" procedure was carried out.

Results: Following the results of Maze III procedure combined with correction of valve disease, disposal of AF was observed in 95% of patients. 46% of patients had stable sinus rhythm to the moment of discharge from the hospital. 24% of patients had atrial rhythm with the maximum heart rate of 80-110 bpm (according to results of 24-hour Holter monitoring). For 25% of patients, it was necessary to implant a pacemaker. According to results of EP study, 13% of these patients suffered from sick sinus syndrome before operation. For 9% of the remaining 12% of patients, the indications for pacemaker implantation were atrioventricular nodal rhythm with low heart rate and pauses more than 3 sec long. For 1% of patients the indication was second degree AV block (type 2) and second degree SA block (type 2); for 1% the indication was complete heart block, and for 1% it was atrial rhythm and pauses more than 3 sec long.

13% of patients with an atrial rhythm and normal heart rate developed typical atrial flutter (AFL) in the early postoperative period. For all of them the RF catheter ablation with linear ablation of the right atrial isthmus and creation of isthmus block was effective, and further recurrence of AFL was not observed.

Conclusions: In the early postoperative period Maze III procedure combined with a mitral valve operation proved to be an effective surgical technique of treatment of persistent and long-standing persistent forms of AF in patients with heart failure. NYHA class II heart failure was not an obstacle for surgical treatment of AF.

Ventricular Arrhythmias and SCD - Pathophysiology and Mechanisms

P918

Last but not least: second half of the QRS complex is more important for differential diagnosis between ventricular tachycardias and various aberrant supraventricular tachycardias.

HF Salami[1]; AA Zhambeev[1]; AGH Gasparyan[1]; PS Novikov[1]; NYU Mironov[1]; NB Shlevkov[1]

[1]*Research Institute of Cardiology, violation of rhythm and conductivity, Moscow, Russian Federation*

Background: Majority of known ECG criteria for differential diagnosis between various wide QRS complexes tachycardias (WCT) rely on either initial components of the QRS or the general polarity. The diagnostic significance of the components of the "second half" of the QRS is poorly understood. Aim: to compare the importance of initial and the late components of the QRS for differential diagnosis between various WCT.

Methods: 120 patients (83 M, 37 F, age 47 ± 19) with RBBB tachycardias (n = 60) or LBBB tachycardias (n = 60) were included into the study. All patients underwent EPS resulting in diagnoses of VT (n = 40), SVT with aberrant conduction (n= 40) or SVT with preexcitation (n = 40). Multifactorial and ROC-analyzes of the 240 ECG parameters were performed to compare the diagnostic value of initial (q-beginning to R-peak) and late (R-peak to S-end) components of QRS.

Results: identified 66 significant differences between LBBB groups as well as 140 differences between RBBB groups.

Conclusion: The final components of the QRS are at least highly underestimated for the differential diagnosis between various WCT.

Heart rate variability in patients with refractory epilepsy

T Faria[1]; M Campelo[2]; H Rocha[3]; R Rego[3]; P Barata[4]; G Pestana[5]; R Pinto[5]; M Silva[5]; D Souteiro[5]; D Alves[3]; JG Pereira[1]; F Rocha Goncalves[4]; E Elisabete Bernardes[4]

[1]*Sao Joao Hospital, Nuclear Medicine, Porto, Portugal*; [2]*Faculty of Medicine University of Porto, Cardiology, Porto, Portugal*; [3]*Sao Joao Hospital, Neurology, Porto, Portugal*; [4]*University of Porto, Faculty of Medicine, Porto, Portugal*; [5]*Sao Joao Hospital, Cardiology, Porto, Portugal*

Introduction: Autonomic heart function is impaired in patients with epilepsy (mainly drug-resistant).Their resting sympathetic tone is increased and their parasympathetic tone (vagus-mediated) is decreased. These conditions lead to diminished protection from the sympathetic stress occurring during seizures which can increase the risk of myocardial lesions and arrhythmias that can cause sudden unexplained death in epilepsy (SUDEP). In other cardiac pathologies, a decrease in heart rate variability (HRV) is associated with worse prognosis.

Objective: To evaluate basal HRV parameters in patients with drug-resistant epilepsy, trying to identify groups with increased risk, more likely to suffer SUDEP.

Material and Methods: From 25th April 2016 to 18th December 2017, we prospectively evaluated patients without known cardiac pathology, hospitalized in our Video-EEG Monitoring Unit, as part of their pre-surgical evaluation of drug-resistant epilepsy. We excluded patients with only psychogenic nonepileptic seizures and those with very frequent seizures which precluded 1-hour basal ECG recording.

All patients underwent a 48 hour single-lead ECG recording from which we evaluated 1 hour while awake and at rest. We included for analysis time and frequency dependent measures of HRV as recommended by the European Society of Cardiology.

Statistical analysis by SPSS version 24.

Results: 47 patients (28?), median age 41 (16-73) years, 51% with Temporal Lobe Epilepsy (TLE), 55.3% with right epilepsies (25.5% left and 19.1% bilateral), 36.2% with cardiovascular risk factors and median epilepsy duration 14 (1-67) years. The most frequent etiology was hippocampal sclerosis (23.4%), but in 34% the etiology remained undetermined.

We did not find any statistical difference in any of HRV parameters between TLE vs non-TLE patients or between right vs left epilepsy patients.
We found negative correlations between SDNN and the duration of the epilepsy (r=-0,458; p = 0,001), and between RMSSD and the duration of epilepsy (r=-0,327; p = 0,025).
Conclusion: In this specific population, there is lower HRV in patients with longer epilepsies, evaluated by the SDNN and the RMSSD parameters, which may point to a higher cardiac risk in those patients. Since the duration of the epilepsy is included in SUDEP risk scores, SDNN and RMSSD may present as biomarkers of that risk.

P920
Relationship between polymorphism of ADRA2B gene and primary cardiac conduction disorders

A Anna Chernova[1]; S YU Nikulina[1]
[1]*Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation*

Background: Cardiac conduction system (CCS) disease, which results in disrupted conduction and impaired cardiac rhythm, is common with significant morbidity and mortality. Current treatment options are limited, and rational efforts to develop cell-based and regenerative therapies require knowledge of the molecular networks that establish and maintain CCS function. Recent genome-wide association studies (GWAS) have identified numerous loci associated with adult human CCS function, including ADRA2B.
Materials and Methods: A family examination was performed in 71 patients with atrioventricular block (AVB). The control group consisted of 657 patients without clinical ECG manifestations of cardiac diseases. All the examinees have undergone ECG, echocardioscopy, electrophysiological examination of the heart.
Results: by results of research it is established that the frequency of carriers of a homozygous genotype on rare allel (DD) among patients with AVB (43,7% ± 5,9) was higher in comparison with control selection (16% ± 1,4). The obvious tendency to decrease in carriers of a heterozygous genotype (ID) among patients with AVB (23,9% ± 5,1) in comparison with group of control (51,1% ± 2,0) is also noted.
Conclusions: In this work we for the first time revealed on clinical - genetic material association between hereditary disturbances of cardiac conduction and polymorphism of 2-adrenergic receptor gene.

P922
The study of the relationship between C reactive protein and the severity of ventricular arrhythmia of non-coronary etiology

H Husniddin Kuchkarov[1]; G Mullabayeva[1]
[1]*Cardiology Center of Uzbekistan, Tashkent, Uzbekistan*

Purpose: The study of the relationship between C - reactive protein (CRP) and the severity of ventricular arrhythmia.
Materials and Methods: 43 patients (18 women, 25 men) with ventricular arrhythmias (VA) were included to the study. The mean age of the patients was 35,8 ± 8 years. All patients had a history of myocarditis, confirmed by extracts from the case histories, outpatient cards. The duration of the anamnesis for myocarditis was 3,2 ± 1,1 years. All patients underwent a 24 hour Holter ECG monitoring in outpatient conditions. The conventional classification of VA by Lown was used for separating of VA. VA of III and and upper classes (IV a and IV b) was assigned as high grades. The level of CRP was determined by using Dayton biochemical analyzer. Patients were divided according to the level of CRP into 2 groups: 1 group (n = 21) patients with CRP level of 6,7 ± 1,9 mg/dl, 2 group (n = 22) patients with CRP less than 5 mg/dl.
Results: as the comparative analysis showed, the groups did not differ in age and gender. But it should be noted that in the 1 group the number of men (16 men in the 1 group against 9 in the 2 group, p > 0,05) was unreliably more. The total number of

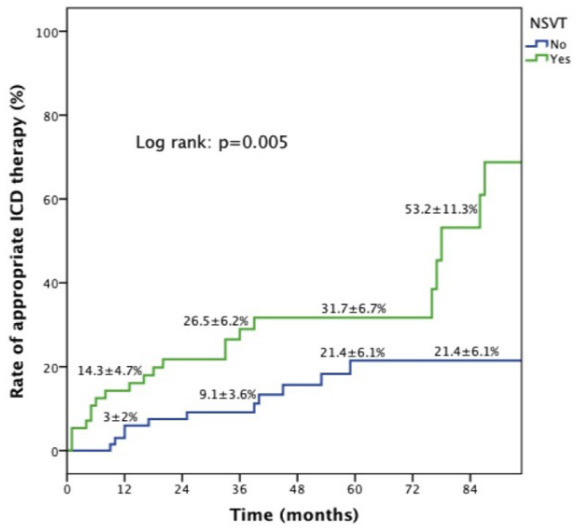
VA in the compared groups was almost similar and amounted to 6368 ± 956 per day and 6920 ± 1000 per day, respectively, in 1 and 2 groups (?>0,05). Structural analysis of VA showed that, the high grade VA prevailed in the 1 group. So VA of II class was observed in 2 (9,5%) and 9 (40,9%) patients, of III class in 3(14,3%) and 6 (27,3%) patients, VI a and IV b in 16 (76,2%) and 7 patients (31,8%) respectively in both groups. Statistical nonparametric analysis demonstrated a significant prevalence of patients with high - grade VA in a group with high level of CRP (?2= 6,8; ? = 0,009). In case of VA with different origins, there were no significant differences (?2 = 0,45; ? = 0,51). It should be noted that in the 2 group there were significantly more frequent cases of VA of II class according to Lown (?2 = 4,0; ? = 0,04).
Conclusion: thus, we identified an association of high levels of CRP with high - grade VA.

Implantable Cardioverter / Defibrillator

P923
Is there a role to implantable cardioverter defibrillator for primary prevention in non-ischemic dilated cardiomiopathy?

JN Neiva[1]; IR Rodrigues[2]; PSC Cunha[2]; BV Valente[2]; NS Nogueira Da Silva[2]; RP Pimenta[2]; ASD Delgado[2]; MB Bras[2]; RCF Ferreira[2]; MO Oliveira[2]
[1]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal; *[2]Hospital de Santa Marta, Lisbon, Portugal*

During the last decade implantable cardioverter defibrillator (ICD) became the mainstay of sudden cardiac death (SCD) prevention, resulting in a marked increase of ICD implantation for primary prevention. Despite the proven survival benefit of ICD in patients (P) with severe left ventricular systolic dysfunction, there is much more robust evidence in ischemic cardiomyopathy (ICM). Recent evidence has questioned the benefit of ICD implantation in nonischemic dilated cardiomyopathy (NICM). The aim of this study was to evaluate the long-term clinical impact of ICD in P with NICM for SCD primary prevention, and to investigate the predictors of ventricular tachyarrhythmic events (VTE) in this population.
Methods: Retrospective, descriptive and correlation study extended to P with ICD for primary prevention in NICM. P with hypertrophic cardiomyopathy, right ventricular arrhythmogenic cardiomyopathy, left ventricle noncompaction and inherited channelopathies were excluded. Baseline clinical characteristics were analysed. Uni and multivariate analysis of markers for the occurrence of VTE with appropriate therapy (antitachycardia pacing and shock) via ICD and of overall mortality was performed. The statistical methods used were Mann-Whitney's U test, Chi-squared test and Cox regression.



Survival curve

Results: Within a population of 126P with NICM (69% male; age 60,8+11,2 years; NYHA class II/III; 69% with a cardiac resynchronization therapy system - CRT -), 28,8% had diabetes mellitus (DM); 38,4% dyslipidemia; 60,8% hypertension (HT) and 25% permanent atrial fibrillation (AF). The mean ejection fraction (EF) was 25%. Natriuretic peptides were high in 78,4% of the P, 29,8% had creatinine clearance <60mL/min and 45,5% had nonsustained ventricular tachycardia (NSVT) on 24h Holter recording before ICD implantation. After a median follow-up time of 61months (6-139), the mortality rate was 14,3% and 2P underwent heart transplantation. Appropriate therapies occurred in 27% of the cases. The first appropriate intervention occurred after a median of 49,2 months. P with NSVT had more appropriate therapy (12 months: 14,3 ± 4,7% vs. 3 ± 2%; 36 months: 26,5 ± 6,2% vs. 9,1 ± 3,6%; 84 months: 53,2 ± 11,3% vs. 21,4 ± 6,1%; p= 0,005). The occurrence of NSVT before implantation was a strong predictor of appropriate ICD therapy (HR 2,59, 95% CI 1.29-5.19; p = 0,008). Gender, age, EF, NYHA class, AF, DM, HT, dyslipidemia, CRT, renal dysfunction and elevation of natriuretic peptides were not predictors of therapy via ICD.
Conclusions: In a long-term follow-up period, 27% of NICM P received appropriate therapies after ICD implantation for primary prevention. NSVT seems to be a strong predictor of appropriate therapy delivered.

P924
Right ventricular septal pacing with narrow QRS less than 125ms is beneficial for preventing pacing induced cardiomyopathy

DH Kim[1]; SY Lee[1]; SW Park[1]
[1]Sejong General Hospital, Arrhythmia division, Cardiology department, Bucheon, Korea Republic of

Background: When ventricular pacing more than 40% is expected for patients with complete AV block, current guideline demonstrates that bi-ventricular pacing is recommended for preventing pacing-induced cardiomyopathy. However, it is not clear that right ventricular (RV) septal pacing is more beneficial than RV apical pacing.
Objective: Narrow QRS after pacing is more important factor than pacing site. We hypothesize that RV septal pacing with narrow QRS is beneficial for preventing pacing-induced cardiomyopathy.
Methods: Total 117 consecutive patients with complete AV block and pacemaker implantation were studied from 2014 to 2016. RV septal pacing was performed in 66 patients and RV apical pacing was performed in 51 patients. Pacing induced cardiomyopathy was defined as reduced left ventricular ejection fraction (LVEF) after pacing compared to baseline LVEF before pacing. We evaluated LVEF, aggravation of tricuspid regurgitation (TR), ventricular diastolic dimension (LVDD), and left ventricular systolic dimension (LVSD).
Results: QRS width after septal pacing is less than QRS width after apical pacing (122 ± 28ms vs. 137 ± 33ms, p = 0.007). During the mean 20.9 ± 17.7 months, there is no significant differences of change of LVEF between septal pacing and apical pacing (-5.57% vs. -3.94%, p = 0.292). Aggravation of TR is not different (12.1% vs. 23.5%, p = 0.138). The change of LVDD is not different (-1.8mm vs. -0.7mm, p = 0.614). The change of LVSD is not different (1.2mm vs. 1.5mm, p = 0.158). However, patients with narrow QRS less than 125ms after RV septal pacing have experienced less reduced LVEF than those with wide QRS more than 125ms after pacing (-2.56% vs. -6.35%, p = 0.040). Aggravation of TR is not different (15.2% vs. 18.3%, p = 0.803) after pacing. The change of LVDD (-1.9mm vs. -0.4mm, p = 0.348) and LVSD (1.8mm vs. 0.6mm, p = 0.827) is not different.
Conclusion: This study showed that RV septal pacing with narrow QRS less than 125ms is beneficial for preventing pacing-induced cardiomyopathy

Cardiac Resynchronization Therapy

P925
The significance of NT-proBNP plasma concentration at baseline for predicting outcomes after CRT-D implantation in heart failure patients

M Michal Kerekanic[1]; M Hudak[1]; S Misikova[1]; E Komanova[1]; A Boho[1]; B Stancak[1]
[1]East-Slovak Institute of Cardiovascular Diseases, Department of Arrhythmias, Kosice, Slovak Republic

Introduction: The efficacy of cardiac resynchronization therapy (CRT) in patients with heart failure (HF) in ambulatory class NYHA III or IV and wide QRS complex has been established in numerous clinical trials. N-terminal fragment produced from the cleavage of proBNP (NT-proBNP) is commonly used and well established in daily clinical practice in diagnostic and monitoring of treatment of HF. The importance of baseline levels of NT-proBNP in HF patients before CRT implantation and its impact on survival and mortality has not been enough evaluated until now. Aim of our study was evaluated whether it is possible to determine cutoff value of NT-proBNP level at baseline that can predict all-cause mortality after CRT implantation.
Methods: We realized prospective study and enrolled patients during the time period from May 2011 to April 2013. Eligible patients had advanced HF regardless of etiology, severe systolic dysfunction of left ventricle with ejection fraction (EF) = 35%, native QRS complex duration = 120 ms and optimal medical therapy. The primary endpoint was death from any cause. Serum concentrations of NT-proBNP levels at

baseline were analyzed by ROC analysis, and the cut-off value was calculated for primary endpoint. Patients were divided into two groups according to the cut-off value of serum concentration of NT-proBNP.
Results: We enrolled 90 patients. The primary endpoint occurred in 22 patients (24,4%). Cut-off concentration of NT-proBNP for primary endpoint was 1401 ng/ml at comparable values of sensitivity and specificity (AUC 0,8; p = 0,001). The primary endpoint was reached by 5 patients in group with NT-proBNT level less than 1401 ng/ml (entitled group A) and by 17 patients (51,5%) in group with level of NT-proBNP equal or more than 1401 ng/ml (entitled group B). Survival of patients in both groups was calculated using Kaplan-Meier analysis. Patients in group B had statistically significant survival, p <0,001 according to log-rang test. Impaired renal function (HR 1.04, p = 0.001) and elevated level of NT-proBNP (equal or more than 1401 ng/ml) (HR 5.26, p = 0.002) were independent predictors of increasing risk of all-cause mortality after adjusting using multivariable analysis.
Conclusion: The baseline NT-proBNP level is independent predictor of all-cause mortality of HF patients who undergoing CRT implantation. It can be used for selection high risk patients before CRT implantation. The choice of specialized treatment (assist devices, heart transplantation) in first line for high risk patients (elevated NT-proBNT level = 1401 ng/ml) could be potential possibility how to decrease high amount of nonresponders to CRT.

P926
Cardiac resynchronization therapy in the elderly

A Lorente Ros[1]; S Del Prado Diaz[1]; JM Vieitez Florez[1]; M Abellas Sequeiros[1]; J Moreno Planas[1]; E Franco Diez[1]; GL Alonso Salinas[1]; JL Zamorano[1]
[1]University Hospital Ramon y Cajal de Madrid, Cardiology Department, Madrid, Spain

Introduction: Chronic heart failure is a common and prevalent entity in elderly patients. However, the benefit and safety of cardiac resynchronization therapy (CRT) in this patient population are not well defined. The objective of this study was to analyse the safety and outcomes after CRT in elderly patients.
Methods: Patients aged = 80 years referred to CRT in 2015 and 2016 in a tertiary care hospital were consecutively included. Baseline demographics, complications and outcomes were retrospectively analysed. Functional class, left ventricle ejection fraction (LVEF) and number of hospitalizations over a one-year period were registered and compared before and after the procedure.

Figure 1.

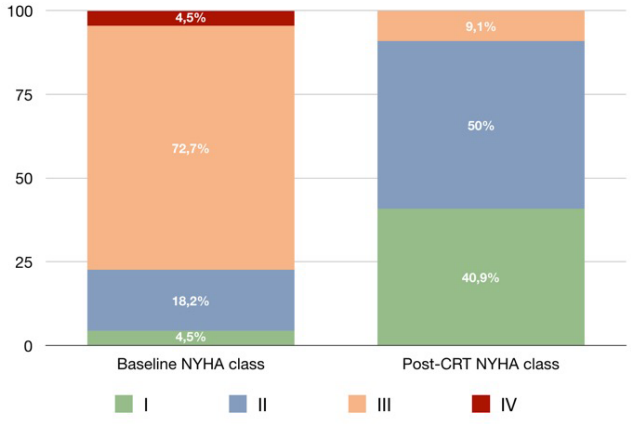


Figure 1

Results: Patient characteristics: A total of 22 consecutive elderly patients were included with a median follow-up of 383.0 (329.5-620.0) days. Age at implantation was 83.6 ± 2.5 years and 14 (63.6%) were male. Cardiovascular risk factors were prevalent: 18 (81.8%) patients suffered hypertension, 11 (50%) diabetes, and 13 (59.1%) dyslipidaemia. 11 (50%) patients presented atrial fibrillation, ischemic aetiology was present in 9 (19.1%) patients and 16 (72.7%) were in NYHA functional class III at baseline. 6 cases (27.3%) were upgrades from previously implanted pacemakers. No defibrillator therapy was implanted. Atrioventricular node ablation was performed in 5 (22.7%) patients. Median serum creatinine and BNP were 1.1 (0.9-1.3) mg/dl and 574 (216-1281) pg/dl, respectively.
Outcomes: Improvement in functional class was observed in 16 patients (72.7%) and was significant (Figure 1). The number of heart failure admissions over the first year of follow-up decreased compared with the year before implantation (0.6 ± 0.7 vs 0.2 ± 0.4; p = 0.021). LVEF significantly improved (34.9% ± 7.7 vs 43.8% ± 9.4, p = 0.021). There was only one complication (4.5%) reported that required medical assistance: a device infection requiring explant and surgical re-implantation. Two deaths were reported, both after the first year of follow-up: a sudden death and a non-cardiovascular death.
Conclusions: In the subgroup of patients aged = 80 years, CRT is safe and effective. It improves functional class and decreases the number of hospital admissions due to heart failure on the first year of follow-up.

P927
Correlation between change in QRS duration and responsiveness in patients with heart failure and CRT device.

J Joao Pedro De Sousa Bispo[1]; D Carvalho[1]; P Azevedo[1]; J Guedes[1]; T Mota[1]; R Fernandes[1]; D Bento[1]; R Candeias[1]; A Camacho[1]; I Jesus[1]
[1]Faro Hospital, Cardiology, Faro, Portugal

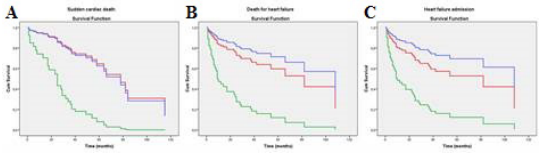
Introduction: Prediction of responsiveness to cardiac resynchronization therapy (CRT) in heart failure patients remains a challenge. This study intends to determine whether the degree of change in QRS duration is a good predictor of responsiveness and lower mortality.
Methods: Retrospective study of a group of patients with heart failure that have CRT device. QRS duration change was calculated from pre- and post-implantation 12-lead ECG, and correlated with LVEF and symptom improvement, all-cause mortality and all-cause hospitalization.
Results: A total of 55 patients were included, 38 (69,1%) were male, and average age was 67,0 ± 15,5 years. Follow-up was 25,1 ± 17,8 months. Most common diagnosis were dilated cardiomyopathy in 28 (50,9%) patients and ischemic cardiopathy in 20 (36,4%). Previously to implantation, QRS duration was 170,5 ± 24,2 msec, 23 (42,9%) patients were in NYHA classification of 3 or 4, and average LVEF was 27,5% ± 6,2. The device implanted was a CRT-D in 44 (80,0%) cases. After implantation, there was a significant decrease in QRS duration (170,5 ± 24,2 vs 139,2 ± 24,3 msec, p-value <0,001), in NYHA classification (42,9% in NYHA III or IV vs 18%, p-value <0,001) and a significant increase in LVEF (27,5 ± 6,2 vs 42,6 ± 14,2, p-value < 0,001). There was no direct correlation between degree in decrease of QRS duration and increase in LVEF (Pearson correlation = 0,072, p-value = 0,63).
A total of 13 (23,6%) patients were hospitalized and 10 (18,2%) patients died during follow-up. There was a non-significant trend towards lower QRS duration change among patients that died (16,9 ± 28,8 vs 35,3 ± 27,4, p-value = 0,051). There was no difference between hospitalization status (23,1 ± 28,7 vs 34,5 ± 28,1, p-value = 0,71). In the composite end-point of hospitalization and mortality, there was a significantly lower QRS duration change in patients that had an event (19,3 ± 29,9 vs 36,5 ± 26,8, p-value = 0,045).
Conclusion: Change in QRS duration had no correlation with less symptoms and higher LVEF after device implantation. A higher QRS duration change showed a non-significant trend towards lower all-cause mortality, and a significant reduction in a composite end-point of all-cause mortality and hospitalization.

P928
Electrophysiological parameters predictive of clinical response to cardiac resynchronization therapy.

M Matteo Casale[1]; M Mezzetti[2]; M Gigliotti De Fazio[1]; M Morelli[2]; L Caccamo[2]; P Busacca[2]; G Dattilo[1]
[1]University of Messina, Messina, Italy; *[2]Hospital S. Maria della Misericordia, Operative Unit of UTIC and Cardiology, Urbino, Italy*

Background: Left ventricular lead implantation in maximally electrically delayed site recently allowed optimal results in patients undergoing to CRT. However most of the studies had small follow up periods without prospective evaluation.
Purpose: We assessed in a prospective way the long term clinical response to CRT in patients undergoing to left ventricular stimulation in sites of maximum delay.
Methods. 130 consecutive patients underwent to CRT. In 86 the maximum local delay (QLV) was electrophysiologically assessed and the remaining 44 underwent to a standard implantation technique of the left ventricular lead. Clinical status was evaluated within a median period of 25 (IQR = 13-47) months. The presence of heart failure (HF) rehospitalizations, HF death or sudden cardiac death (SCD) identified the nonresponders.
Results: Receiver operating characteristic (ROC) curve analyzes for QLV were significant for all the study endpoints: p= 0.015 for SCD; p= 0.015 for death due to HF; p= 0.035 for HF re-hospitalizations. A cutoff of 25 msec had a sensibility of 12.5% and a specificity of 100% for SCD and HF death, a specificity of 100% and a sensibility of 11.8% for HF re-hospitalizations. Survival analysis by Cox proportional hazards regression showed a significantly worse clinical outcome for patients with a QLV = 25 msec (Figure - green line) in comparison to patients with QLV>25 msec

(blue line) and to patients with standard implantation technique (red line). SCD was significantly higher (p = 0,024; HR= 5,74) compared to patients with a QLV>25 msec (Figure - Panel A). There was a significant (p = 0,015; HR= 6,3) better long-term survival free from HF death in patients with a QLV>25 msec in comparison to those ones with QLV = 25msec (Figure - Panel B). HF re-hospitalizations were significantly (p = 0,021; HR= 5,76) less for patients with a QLV>25 msec compared to those ones with QLV = 25 msec (Figure - Panel C).
Conclusion: Targeting sites with a QLV < 25 msec is associated with a long term poor prognosis due to sudden cardiac death, heart failure death and heart failure re-hospitalizations. This intraoperative assessment is easy and cost effective, being feasible also by standard programmer. Clinical response to CRT is improved by this simple assessment.



Home and Remote Patient Monitoring

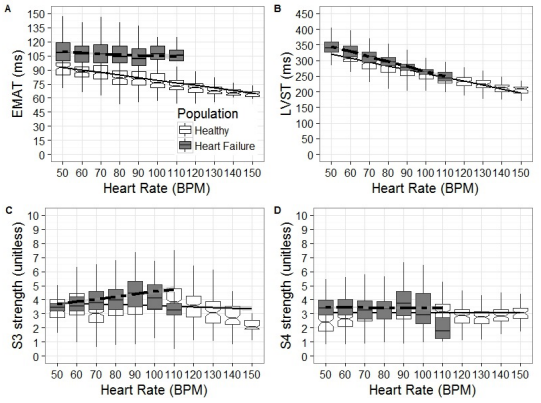
Heart rate affects cardiac acoustic biomarkers: implications for ambulatory management of heart failure patients

R Perumal[1]; T Masuda[1]; M Shozakai[2]
[1]*ZOLL, Pittsburgh, United States of America*; [2]*Asahi Kasei Corporation, Kanagawa, Japan*

Purpose: Ambulatory management of heart failure (HF) is challenging. Cardiac acoustic biomarkers (CABs) can be recorded noninvasively using an accelerometer on the chest and timing these heart sounds to ECG signals, thus enabling remote monitoring. CABs are related to both systolic and diastolic function. However, it has not been determined that CABs can be used independent of heart rate. The purpose of this study is to define the relationship of CABs and heart rate in healthy and HF subjects.
Methods: CABs were collected from 15 healthy volunteers (87% male, age: 33 ± 15 years), wearing an acoustic cardiography enabled accelerometer with ECG electrodes during graded exercise. CAB and heart rate data were also accumulated from 1433 acute HF patients with EF = 35% (78% male, age: 58 ± 13 years), who wore an acoustic cardiography enabled wearable cardioverter defibrillator. The following systolic and diastolic CABs were calculated from the recorded heart sounds and ECG signals: electromechanical activation time (EMAT) measured from the onset of the Q wave to 1st heart sound; left ventricular systolic time (LVST) measured from 1st heart sound to 2nd heart sound; S3 and S4 "strengths" (calculated based on the third and fourth heart sounds intensity and persistence, and expressed as a continuous variable on a scale of 0 to 10). Analysis of variance were used examine the impact of heart rate changes on CABs in both healthy and acute HF groups.



Box-plot with linear trend line

Results: For healthy subjects, both EMAT and LVST showed a significant (p <0.05) decrease with increased heart rate (Figure). For acute HF patients, EMAT did not significantly change with increased heart rate whereas LVST showed a significant decrease as heart rate increased. S3 strength did not change with heart rate in healthy subjects, but showed a significant though modest increase with heart rate in the HF group. S4 strength did not change significantly with heart rate in either group.

Conclusions: In contrast to healthy subjects, EMAT did not change with heart rate in the HF group, implying an inability to increase contractility with demand. S3 strength showed an increase with heart rate in the HF group suggesting reduced ventricular compliance in early diastole. EMAT, S4, and possibly S3 could be used independent of, or in conjunction with, heart rate for ambulatory monitoring of HF. Ongoing evaluations will determine if changes in CABs are associated with outcomes, thereby providing a useful signal by which to guide therapy.

Therapeutic approach to implantable haemodynamic monitoring: a strategy based on timing of haemodynamic recordings

S Shankho Ganguli[1]; C Sauld[1]; O Cheema[1]; TE Hastings[1]; E Roberts[1]; A Ghafoor[1]; DL Zwicke[1]; V Thohan[1]; N Sulemanjee[1]
[1]*Aurora Sinai/Aurora St. Luke's Medical Centers, Aurora Cardiovascular Services, Milwaukee, United States of America*

Funding Acknowledgements: Sullivan Grant

Background: Despite significant advancements in management, heart failure (HF) exacerbation is still the leading cause of hospitalisation in the western world. Until recently, there was no definitive way to predict those who are on the precipice of another exacerbation. Now, with remote implantable haemodynamic monitoring (RIHM) devices assessing pulmonary artery (PA) pressures, heart failure (HF) patients can be diagnosed prior to another heart failure exacerbation and prevent hospitalisation with appropriate titration of medications. We propose that optimising the timing of PA pressure measurements will lead to a more accurate reflection of haemodynamics and thus better treatment.
Purpose: RIHM device has been growing as an effective strategy to manage HF and reduce hospitalisations. Unlike standard drug regimen, current practice leaves the timing of these haemodynamic measurements to the patients, leading to large variances in observations. We hypothesize that standardising the timing of these measurements will lead to an accurate reflection of response to therapy and effective utilisation of this technology.
Methods: This is a prospective randomised study. We included all patients in the Advanced Heart Failure Clinic implanted with RIHM in 2015. Out of 27 patients, 12 met the inclusion criteria. First, everyone underwent a 3-day period of checking PA measurements twice a day, once before and then 1 hour after taking their morning meds. Next, the patients were randomised in a 1:1 manner into two groups. Group 1 took all measurements per patient preference and Group 2 took all their measurements 1 hour after. We collected PA pressure trends, medication adjustments and HF hospitalisations at baseline, 1 and 4 months. We also collected additional information on 6-minute walk test (6MWT) and heart failure QoL questionnaire.
Results: There was no statistically significant difference in PA systolic pressure (PASP), pulmonary artery diastolic pressure (PADP) and mean pulmonary artery pressure (PAP) obtained pre- and post-medication during the initial 3 days prior to randomisation. Timing of the readings had no statistically significant effect on change in PASP (p = 0.683), PADP (p = 0.485), or mean PAP (p = 0.254) from baseline to 4 months, and had no statistically significant effect on change in creatinine from baseline to 4 months (p = 0.320). Repeated measure ANOVA showed no statistically significant effect of timing of readings on HF QoL (p = 0.445) and 6MWT (p = 0.146) Results: There was no statistically significant difference in number of medication adjustments between the groups.
Conclusion: Our pilot study tried to answer the clinically relevant question of whether timing of haemodynamic (PA pressure) measurements affects observations and clinical outcome. We did not find any statistical difference in the PAPs or clinical outcomes in pre- vs post-medications groups; however, a larger sample size may be required to be conclusive.

Chronic Heart Failure - Pathophysiology and Mechanisms

Cardiopulmonary exercise testing in pulmonary hypertension associated with congenital heart disease vs. other forms of pulmonary hypertension: physiological insights

FM Righini[1]; A Apostolo[1]; C Carlo Vignati[1]; P Bambul Heck[2]; S Farina[1]; A Hager[2]; M Correale[3]; R Badagliacca[4]; S Sciomer[4]; P Agostoni[1]

[1]Cardiology Center Monzino IRCCS, Heart Failure Unit, Milan, Italy; [2]Deutsches Herzzentrum Technische Universitat, Department of Pediatric Cardiology and Congenital Heart Disease, Munich, Germany; [3]UTIC Universitaria Ospedali Riuniti OO.RR , Cardiologia-UTIC Universitaria, Foggia, Italy; [4]Sapienza University of Rome, Dipartimento di Scienze Cardiovascolari, Respiratorie, Nefrologiche, Anestesiologiche e Geriatriche, Rome, Italy

Background: Cardiopulmonary exercise testing (CPET) allows the assessment of integrative cardiopulmonary response to exercise.
Objectives: To evaluate CPET parameters behaviour in adult pulmonary hypertension (PH) patients with congenital heart disease (CHD) and without CHD.
Methods: The present is a multicenter retrospective study which includes PH Group 1 and 4 patients. All subjects underwent full clinical and instrumental evaluation, including CPET and right heart catheterization.
Results: 166 PH patients (92 women and 74 men, 56 CHD and 110 non-CHD) were enrolled. CHD patients had higher pulmonary pressure (mPAP: 60.1 ± 19 mmHg vs 43.1 ± 16.2 mmHg, p<.0001) and lower systemic cardiac output (3.8 (3.1;4.4) L/min vs 4.5 (3.9;5.4) L/min, p = 0.0094). At CPET they had lower peakVO2/kg (13 ± 3.6 ml/kg/min vs 15.5 ± 4.2 ml/kg/min, p = 0.0002) and higher VE/VCO2 slope (54.6 ± 15.9 vs 45.6 ± 14.3, p = 0.0003). Moreover patients were paired for gender and peakVO2 (± 1 ml/min/kg), obtaining 47 pairs and even so CHD patients had higher pulmonary pressure (mPAP: 58.7 ± 19.9 mmHg vs 43.9 ± 17 mmHg, p = 0.0004) and VE/VCO2 slope (54.2 ± 15.3 vs 47 ± 15.1, p= 0.0248). VE/VCO2 slope correlated with SpO2 at peak exercise only in CHD patients.
Conclusions: In PH CHD patients, pulmonary pressure and VE/VCO2 are higher compared to non-CHD PH patients, while CO and peakVO2 are lower. After matching patients for peakVO2, pulmonary pressure and VE/VCO2 remains higher in ACHD patients suggesting that the long term adaptation to high pulmonary pressure, hypoxia and low systemic cardiac output, as well as a persisting shunt has, at least partially, preserved exercise performance of PH-ACHD patients.

P932

The occurence of Heart failure result in low weight at birth in woman with congenital heart disease

S Sonila Bele[1]; A Rrugia[2]; E Petrela[3]
[1]University Hospital"Queen Geraldine" Tirana, Tirana, Albania; [2]University Hospital"Koco Glozheni" , Tirana, Albania; [3]University Hospital Centre "Mother Theresa",Tirana, Tirana, Albania

Background: Obsetric and neonatal complications are common during pregnancy and delivery in woman with congenital heart disease. Heart failure can cause premature labor or arrhythmias Risk of maternal or fetal death correlates with NYHA functional classification.
Objective: To evaluate the course of pregnancy in patients with Congenital Heart Disease in severale cases that referred to our clinic.
The Material and Methods: This study was monitored in a single-centre cohort between Janary 2000 and December 2016 The data and information have been collected through clinical record sheets. Patients with valvular heart disease were excluded and only patients with documented unrepaired or repaired Congenital Heart Disease(CHD) entered the study.
Results: Pregnancy outcomes were analyzed in 352 consecutive women aged 29.8 ± 5.5 years with heart disease. The patients with corrected CHD including 19 % of all cases and patients with uncorrected CHD including 19,3 % of all cases .These including Atrial Septal Defect, Ventricular Septal Defect, Tetralogy of Fallot ,Coarctation of the Aorta, The ductus Botalli, Pulmonary Stenosis, Transposition of the Great Arteries,Ebstein 'Anomaly,Eisenmenger Syndrome.There was no maternal mortality. Primipare were 47,6% of women.
Average birth number is 1,71 ± 0.89.Average baby weight is 2829.4 ± 629 gr. The occurrence of Heart failure were 18.7% of all cases. Preeclampsia (28.4 %% of all cases with corrected CHD and 36.6%% of all cases with uncorrected CHD) may be modifiers of the risk of CV complications. By looking through correlation Kendal's coeficient, a relation was found between weight at birth and Heart failure (p <0.001), uncorrected CHD(p = 0.017), weight and Tetralogy of Fallot(p = 0.029), weight and Coarctation of the Aorta(p = 0.018). As well as weight and Pulmonary Hypertension at birth (p = 0.003). The occurence of such pathologies result in low weight at birth.
Conclusion: Most women with successful repair CHD can have a successful pregnancy Risk is increased even such women have symptoms. Women with class III or IV heart failure or may be advised to obtain an early therapeutic abortion

P933

Relationship between serotonergic-modulating psycoactive treatments and 24-hour Cheyne-Stokes respiration occurrence in systolic heart failure.

G Gianluca Mirizzi[1]; C Borrelli[1]; A Giannoni[2]; F Bramanti[2]; G Iudice[2]; M Emdin[1]; C Passino[1]
[1]Sant'Anna School of Advanced Studies, Pisa, Italy; [2]Gabriele Monasterio Foundation, Department of Cardiovascular Medicine, Pisa, Italy

Background: central apneas (CA) in the form of Cheyne-Stokes respiration in systolic heart failure (HF) occur frequently during the 24-hour and are associated with excess mortality. In animal models, enhanced brainstem serotoninergic neurotransmission has been linked to central apneas development via enhancement of central chemoreflex sensitivity. Psychiatric comorbidities are frequently diagnosed in HF and often treated with central serotonergic-modulating drugs.
Purpose: to evaluate the relationship between serotonergic-modulating treatments and CA occurrence in systolic HF.
Methods: among 667 patients with systolic HF (mean left ventricular ejection fraction -LVEF- 32 ± 9, age 67 ± 12 years, 75% males, BMI 27.5 ± 5.4 kg/m2, N-terminal fragment of pro-brain natriuretic peptide, NT-proBNP, 1435 ng/L, interquartile range -IR- 585-3615), 438 (65.7%) showed CA, expressed by an apnea/hypopnea index (AHI) = 5 and CA/total apnea = 50% (mean AHI 18/h, IR 9-27). Psychoactive treatment was prescribed in 25% of patients, with 11% taking benzodiazepines, 17% serotonergic modulating drugs (selective serotonin or serotonin/norepinephrine reuptake inhibitors, SSRI/SNRI in 11% of patients, trazodone in 9.8%). Patients on psycoactive treatment showed similar levels of 24-h AHI (17.0/h, interquartile range -IR- 8.0-28.0 vs. 18.0 ev/h, IR 9.0-27.0 p = ns) and 24-h central apnea index (CAI; 6.1 ev/h, IR 1.2-17.7 vs. 5.8 ev/h, IR 1.6-15.6, p = ns); similar results were observed for nighttime and daytime AHI and CAI and in specific therapeutic subgroups of patients. Among patients with the highest risk of having CA (expressed by levels of NT-proBNP = 1680 ng/l), psycoactive treatment was not associated with differences in AHI or CAI. Treatment with SSRI/SNRI was associated with a trend towards increased levels of 24-h CAI (14.2 ev/h, IR 9.5-20.9 vs. 12.1 ev/h, IR 3.6-28.4, p = 0.08).
Conclusion: among systolic HF patients and CA/CSR, psychoactive treatments modulating serotonergic neurotransmission are very often prescribed; CA occurrence, albeit significant, is however not influenced by serotonergic drugs.

P934

The association between markers of fibrosis and myocardial dyssynchrony in patients with CHF

OV Bilchenko[1]; TA Rudenko[1]
[1]Kharkiv Medical Academy for Postgraduate Education , Internal medicine and Nephrology, Kharkiv, Ukraine

Background: Pathological activation of fibroblasts and collagen synthesis contributes to increased reactive interstitial myocardial and substitutional fibrosis, which leads to myocardial dyssynchrony and the progression of CHF.
Purpose: To study the association between markers of fibrosis and myocardial dyssynchrony in patients with CHF and DM type 2.
Methods: 106 patients (63 women and 43 men) with CHF of ischemic origin examined. The mean age of patients was (67.45 + 10.32) years; age (65 + 10.62) years. All patients divided into two groups depending on the presence of DM. The first group consisted of patients with DM (83 persons - 78.3%). The second group - patients without DM (23 - 21.7%). All patients were subjected to a standard 12 leads electrocardiography (ECG) according to the generally accepted method. To detect electrical dyssynchrony, the criteria of a narrow QRS complex <120ms and an extended QRS complex = 120ms were used. Myocardial dyssynchrony was divided into intraventricular, interventricular, atrial-ventricular (atrioventricular) and combined. The presence of myocardial fibrosis was assessed by the content of galectin (Gal) -3 in the blood serum by an enzyme immunoassay (EIA) and the content of matrix metalloproteinase (MMP) 1. The interstitial collagen volume fraction (ICVF) was calculated using the J. Shirani method.
Results: In patients with myocardial dyssynchrony on the background of DM type 2, compared with the group without DM, there was an increase in Gal-3 (7.49 + 0.6) ng/ml and ICVF (7.6 ± 4.03%) and a decrease in MMP-1 (0.46 + 0.2) ng/ml (p <0.05). Gal-3 increased in the presence of combined forms of mechanical dyssynchrony. Thus, with simultaneous combination of intra-ventricular and interventricular or Atrioventricular myocardial dyssynchrony, the level of Gal-3 was the highest (9.03 + 4.63) ng/ml against a background of a decrease in MMP-1 (0.2 ± 1.7) ng/ml. In patients with the presence of one of the forms of myocardial dyssynchrony, Gal-3 was lower (6.67 + 5.14) ng / ml, but the level of MMP-1 (0.78 + 1.55) ng/ml increased (p <0, 05). In patients with CHF of ischemic genesis without DM type 2 and myocardial dyssynchrony, the level of Gal-3 was the lowest (5.13 ± 0.37) ng/ml. A high content of Gal-3 was observed in patients without DM type 2 with manifestations of myocardial dyssynchrony (7.92 ± 0.95) ng/ml.

Conclusions: when there is a combination between CHF of ischemic genesis and DM type 2, there is an increase in the serum level of Gal-3, which correlates with the progression of mechanical dyssynchrony, an increased Functional class (FC) of CHF, development of systolic and diastolic failure. The content of MMP-1 depends on the form of mechanical myocardial dyssynchrony - decreases in combined forms.

P935

Circulating biomarkers of inflammation and left ventricular hypertrophy in patients with heart failure with preserved ejection fraction

A V Alexandr Bilchenko[1]; AA Bilchenko[2]; MA Khvysiuk[1]
[1]Kharkiv Medical Academy for Postgraduate Education , Internal medicine and Nephrology, Kharkiv, Ukraine; *[2]Kharkiv National Medical University, Internal medicine, Kharkiv, Ukraine*

Background: The association between left ventricular hypertrophy (LVH) and high sensitivity CRP values has recently been investigated. Little is known, however, about the association between LVH and the new biomarkers of inflammation P-selectin and galectin-3 in patients with HFpEF.
Purpose: The goal of our study was to investigate the relations between several inflammatory markers (P-selectin and galectin-3) and LV geometry in patients with HFpEF.
Methods: 73 patients with HFpEF NYHA II-III (28 men and 44 women; mean age 72.2+5.1 years) were included in the study. All subjects underwent routine laboratory tests, as well as specific biomarkers assessment (P-selectin, galectin-3) by using standard kits. Left ventricular mass index (LVMI) was measured. LV geometry was divided into four categories: normal LV geometry, concentric LVH, eccentric LVH and concentric remodeling.
Results: In patients with concentric left ventricular hypertrophy P-selectin level was significantly higher as compared with patients without left ventricular hypertrophy (98,1+4,3 vs 86,3+3,2 ng/ml) ($p < 0.05$). In patients with eccentric LVH and concentric remodeling P-selectin levels were not increased as compared with patients without left ventricular hypertrophy (88,1+3,3 ng/ml and 84,9+2,6 ng/ml, respectively, ($p > 0.05$). There was no significant difference in galectin-3 levels in four groups (10,2+3,4 ng/ml; 9,8+2,5 ng/ml; 9,7+4,1 ng/ml and 10,5+3,7 ng/ml, respectively, ($p > 0.05$).
Conclusions: P-selectin was increased significantly in HFpEF patients with concentric left ventricular hypertrophy but did not in patients with eccentric LVH and concentric remodeling. There was no difference of galectin-3 levels in HFpEF patients with all types of LVH as compared with patients without left ventricular hypertrophy.

Radiation induced valve disease and cardiotoxicity induced heart failure is frequent

J Bergler-Klein[1]; M Schneider[1]; M Frey[1]; M Gyongyosi[1]; T Binder[1]
[1]Medical University of Vienna, Dept. of Cardiology, Vienna, Austria

Radiation of the mediastinum causes direct linear damage of the myocardium. Additional chemotherapy and oncologic therapies may cause cardiotoxicity of the left and right ventricular systolic and diastolic function. This study aims to demonstrate typical findings of radiation induced valve disease (RIVD) in the long term follow up. Considering the relatively younger age of e.g. lymphoma or breast cancer patients, cardiovascular disease after 10-20 years is clinically demanding.
Methods: 25 Pts with breast cancer, lymphoma, gastric cancer, or survivors of childhood cancer, after chemotherapy and/ or radiation were examined by echo and underwent coronary angiography or valve interventions as clinically indicated. Appropriate heart failure medication was initiated and pts followed up accordingly.
Results: In 4 survivors of Hodgkin's lymphoma, radiation induced valve disease was prominent of the aortic valve and rigid anterior mitral valve leaflet, causing low flow aortic stenosis leading to valve replacement in 2 pts. In contrary 1 pt showed only highly reduced LV function with typical thinned myocardium. Pericardial constriction was observed in a lymphoma pt after 15 y. In a pt with breast cancer irradiation left side additionally to aortic stenosis and basal anterior mitral leaflet calcification, severe stenosis of the left subclavian artery and carotids were observed at 20 y FU. After right side radiation the tricuspid valve and RV were dilated in another breast cancer pt. Another pt underwent TAVR due to low flow AS after radiation. Aortic regurgitation due to sclerosis after radiation of metastatic gastric cancer was observed with additional LV systolic impairment by previous multiple chemotherapy cycles including anthracyclines and cisplatin. Additional chronic thromboembolism and pulmonary hypertension complicated a case of breast cancer with aortic stenosis undergoing TAVR and balloon pulmonary angioplasty. Subclinical forms with only mild valvular thickening or reduced LV strain were frequently observed in the breast cancer pts.
Conclusion: Patients with radiation especially in left, but also right breast cancer or mediastinal radiation demonstrate typical premature calcifications and thickening of the aortic valve and the mid to basal part of the anterior mitral leaflet and mitral ring. Patients should be followed closely and cardiac treatment initiated early. Studies to prevent further sclerosis progression e.g. with statins should be performed in the future.

P937

Dual cardioprotection improves right and left ventricular systolic function in patients receiving cardiotoxic chemotherapy

AGF Ana Ferreira[1]; G Lloyd[1]; S Woldman[1]; M Westwood[1]; T Crake[1]; M Maxwell[1]; LR Lopes[1]; C Manisty[1]; AK Ghosh[1]
[1]Barts Health NHS Trust, Barts Heart Centre, London, United Kingdom

Introduction: Cardiotoxicity is a side effect of many chemotherapeutic agents. Cardioprotective therapy (CP) [Angiotensin Converting Enzyme Inhibitors (ACEi) or Angiotensin Receptor Blockers (ARB) and/or beta blockers (BB)] may prevent chemotherapy-related left ventricular (LV) dysfunction. Advanced echocardiographic measurements of cardiac function may help guide CP.
Methods: We retrospectively reviewed patients (pts) seen in the Cardio-Oncology service over a 28-month period. 46 pts [57.6 ± 10.9ys, 35 (76.1%) females] had received potentially cardiotoxic chemotherapy [20 (43.5%) also had radiotherapy] and at least one echocardiographic evaluation before and another after CP.
Results: 24 pts had breast cancer (52%), 7 lymphoma (15%), 7 myeloma (15%), 4 other haematological (9%) and 4 gastrointestinal malignancies (9%). 15 pts received anthracyclines, 9 trastuzumab, 13 anthracyclines and trastuzumab, 9 other chemotherapy. 34 pts (73.9%) received dual CP (BB and ACEI/ARB), 8 (17.4%) ACEI/ARB, and 4 (8.7%) BB only. Baseline and follow-up echocardiographic values shown in table 1. Time interval between assessments was 130 ± 100 days. GLS, LVEF, e' septal, e' average and TAPSE improved with dual CP.

P937 Table 1

	FIRST ECHO	SECOND ECHO							
	All	Dual therapy	ACEI/ARB only	All	P value vs 1st echo	Dual therapy	P value vs 1st echo	ACEI/ARB only	P value vs 1st echo
GLS (%)	-13.7±3.3	-13.9±3.3	-14.0±3.0	-16.4±3.1	<0.0005	- 16.4±3.3	<0.0005	-16.5 ± 3.1	0.127
LVEF Biplane (%)	46.3±8.3	46.0±8.6	49.9±4.7	50.2±13.4	0.049	50.4±12.7	0.031	48.4 ± 21.5	0.960

S' RV (cm/s)	12.4±3.0	12.4 ± 3.1	14.0±2.8	12.1 ± 3.2	0.679	12.0 ± 3.4	0.672	12.5 ± 7.1	0.500

Measurements of systolic and diastolic function at first and second echocardiography. GLS - Global longitudinal strain, LVEF - Left ventricular ejection fraction, avg - average, cm/s - centimetres/second, TAPSE - Tricuspid annular plane systolic excursion, RV - Right ventricle.

Conclusions: Early effects of CP in left and right ventricular function are identifiable by GLS, LVEF, e' and TAPSE, with dual CP demonstrating an early beneficial effect.

P938

Cancer therapeutic related cardiac dysfunction among active breast cancer patients: A Cardio-Oncology registry

M Laufer Perl[1]; A Milwidsky[1]; L Mor[1]; D Ravid[1]; N Amrami[1]; M Derakhshesh[1]; J Sherez[1]; G Keren[1]; Y Arbel[1]; Y Topilsky[1]
[1]*Tel Aviv Sourasky Medical Center, Cardiology, Tel Aviv, Israel*

Background: Progress in the treatment of breast cancer during the past two decades has led to substantial improvement in survival but at the cost of increased side effects, with cardio-toxicity being the most significant one with a mortality rate reaching as high as 60% in two years. The most commonly used definition is cancer therapeutic related cardiac dysfunction (CTRCD), defined as a left ventricular ejection fraction (LVEF) reduction of >10 %, to a value below 50%. Latest studies have implied that the incidence of CTRCD among breast cancer patients is decreasing resulting from the lower doses of anthracyclines and lower correlation for Trantszumab and Pertuzumab treatment.
Objectives: Evaluating the incidence of CTRCD among breast cancer patients and identifying significant predictors for its development.
Methods: Data was collected as part of the International Cardio-Oncology Registry (ICOR), enrolling all patients evaluating in the cardio-oncology clinic in our institution. All patients performed at least two echocardiograms.
Results: Among 103 consecutive patients, 5 (5%) developed CTRCD and 10 (10%) developed LVEF reduction of 5% and above. Mean time for CTRCD development was 171days (range 66 to 231). There were no significant differences in the baseline cardiac risk factors (hypertension, diabetes, hyperlipidemia or smoking) between the groups. Significant predictors for developing CTRCD were treatment with Trantszumab (80% vs. 18%, p = 0.001) or Pertuzumab (80% vs. 14%, p <0.001) and low systolic blood pressure (100 ± 13 vs. 132 ± 22, p = 0.006). Interestingly, Doxorubicin was not. Significant predicting echocardiography parameters included lower baseline global longitudinal strain (GLS) (18 ± 3 vs. 21 ± 2, p = 0.016), increased left ventricular end systolic diameter (LVESD) (35 ± 6 vs. 25 ± 4, p <0.001) and low e' septal (5.2 ± 0.5 vs. 7.4 ± 2.6, p <0.001).
Conclusions: CTRCD is frequent among active cancer patients and relates to Trantszumab and Pertuzumab treatment. Early GLS evaluation may identify it and allow cardio-protective treatment in order to prevent it.

P939

Mesalazine-induced cardiotoxicity: a retrospective study initial results

C Goena Vives[1]; L Quintas Ovejero[1]; R Garcia Martin[1]; I Luis Serret[1]; E Zapata Morcillo[2]; A Castiella Eguskiza[2]; L Zubiaurre Lizarralde[2]; A Iribarren Etxeberria[2]; JI Emparanza Knorr[3]; I Urreta Barallobre[3]
[1]*Mendaro's Hospital, Cardiology, Mendaro, Spain*; [2]*Mendaro's Hospital, Gastroenterology, Mendaro, Spain*; [3]*Donostia University Hospital, Clinical epidemiology, Donostia, Spain*

Introduction: Cardiac complications in inflammatory bowel disease (IBD) may be associated with the disease or due to Mesalazine (M) used in the treatment.The cardiac toxicity may appear after 2-4 weeks and as infrequent,its diagnosis is difficult in daily practice.Early drug cessation is enough to achieve improvement with no apparent long-term sequelae.
Purpose: Estimate the prevalence of M-related cardiomyopathy in IBD, asses feasibility of a simple screening protocol and present its initial results.
Methods: Observational retrospective cohort study EPA-SP (CGV-EII-2015-01). Inclusion criteria: ambulatory patients>16 years with >30 days of treatment at the moment of the evaluation and prior signed informed consent.Exclusion criteria: < 16 years and previous cardiopathy.Collected data:age, gender,type of IBD,NYHA,M dose and time of treatment.Every patient underwent a physical examination, ECG and transthoratic echocardiogram (TTE).If anomalies were detected, M was stopped, the patient underwent a CMR and NTproBNP and medical treatment and follow-up.

Table 1

	Case 1	Case 1
Age/Gender	17/Male	67/Female
IBD	Non controlled	Controlled
M treatment duration (months)	3	20
Basal ECG and 6 months after cessation	Sinus rythm	Sinus rythm+ LBBB
TTE	Dilated LV. LVEF 45%. RV affected.Pericardial effusion.	Dilated LV. LVEF 30%, RV affected. Paradoxical septal movement.
CMR/CMR 6 months after cessation	No late enhancement/=	No late enhancement/=
NYHA/NYHA 6 months after cessation	I/I	IIb/I
TTE 6 months after cessation	Non dilated LV.LVEF 60%.RV ok.	Non dilated LV.LVEF 47%.RV ok.

Results:84 patients (86 screened) between December 2015 and December 2016.83 were NYHA I/IV and one NYHA II/IV.42.86%women.The average time of treatment was 102 month(3-360). 2 patients had AF without structural cardiac disease.TTE evaluation revealed that the great majority of patients had good biventricular function.6 patients had reduced LVEF (1 alcoholic myocardiopathy and 3 coronary multivessel disease) and among these patients 2 cases of toxicity were reported (see table 1). Biventricular function normalized in less than 6 months after treatment disruption.
Conclusion: M is a frequent treatment in IBD with infrequent severe paucysintomatic cardiac adverse effect, potentially reversible with the drug withdrawal.Conventional TTE provides enough information for the initial screening.

P940

Haemodynamic changes associated with Cheyne-Stokes respiration in patients with heart failure: an echocardiographic study

A Giannoni[1]; V Raglianti[1]; C Taddei[1]; C Chiara Borrelli[2]; V Chubuchny[1]; A Valleggi[1]; C Passino[1]; E Pasanisi[1]; G Mirizzi[1]; M Cameli[3]; M Emdin[1]
[1]*Gabriele Monasterio Foundation, Pisa, Italy*; [2]*Sant'Anna School of Advanced Studies, Pisa, Italy*; [3]*University of Siena, Siena, Italy*

Background: Although Cheyne-Stokes respiration (CSR) is an oscillatory phenomenon, the effects of CSR phases (hyperventilation and apnea) on cardiopulmonary hemodynamics have never been investigated.
Purpose: The aim of the study is to examine the echocardiographic changes associated with CSR in a group of patients with systolic heart failure (HF).
Methods: 12 HF patients (age 69.7 ± 9.1 years, LVEF 24.1 ± 5.5%) underwent, beyond 24-hour polysomnography, chemoreflex tests by rebreathing technique, neuro-hormonal assessment and simultaneous echocardiographic and respiratory monitoring by inductance plethysmography.
Results: All patients had 24-hour CSR (24-hour apnea-hypopnea index, AHI: 25.0 IR 18.0-39.0). During CSR, systolic pulmonary artery pressure increased from hyperventilation (H) to apnea (A) (H 48.0 ± 9.6 versus A 53.5 ± 14.6 mmHg, p = 0.002), acceleration time of the pulmonary artery decreased (H 110.3 ± 20.9 versus A 92.1 ± 21.6 ms, p = 0.009) and pulmonary vascular resistances increased (PVR: H 3.8 ± 2.7 versus A 5.5 ± 3.5 wood units, p = 0.005) (Figure 1). During apnea a reduction of right and left ventricular outflow tract VTI (right VTI: H 12.5 ± 5.2 versus A 10.1 ± 3.3, p = 0.015; left VTI: H 30.1 ± 15.9 versus A 25.9 ± 13.2 mm, p = 0.009) and a reduction in tricuspid annular plane systolic excursion (H 15.8 ± 4.6 versus A 14.5 ± 4.2 mm, p = 0.03) was also observed, while no significant change in left ventricular systolic and diastolic function was found. Notably, PVR variation strongly correlated with norepinephrine levels (Rho = 0.93, p = 0.001), and chemosensitivity to hypercapnia (n = 7; Rho = 0.82, p = 0.023).
Conclusions: In HF patients with CSR, recurrent chemoreflex-mediated adrenergic discharge may cause pulmonary vasoconstriction and increase in pulmonary arterial pressure during apnea, with undesirable changes in right and left ventricular hemodynamics.

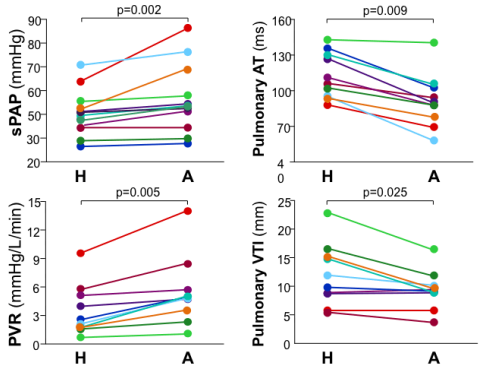

Figure 1. Haemodynamic changes from hyperventilation (H) to apnea (A) in patients with HF and CSR
AT: acceleration time, CSR: Cheyne-Stokes respiration, HF: heart failure, PVR: pulmonary vascular resistances, sPAP: systolic pulmonary arterial pressure, VTI: velocity-time integral

P941

Combined post- and pre-capillary pulmonary hypertension in heart transplant candidates with ischemic versus nonischemic etiology

Z Bayram[1]; C Dogan[1]; RD Acar[1]; B Guvendi[1]; A Karaduman[1]; T Unkun[1]; OY Akbal[1]; A Hakgor[1]; S Uysal[1]; C Kaymaz[1]; N Ozdemir[1]
[1]Kartal Kosuyolu Heart Education and Research Hospital, Department of Cardiology, Istanbul, Turkey

Background: A pulmonary hypertension (PH) is relevant complication of left ventricular heart failure. We aimed to investigate the effect of heart failure etiology (ischemic or non-ischemic) on the presence of isolated postcapillary PH (Ipc-PH) or combined pre-and postcapillary PH (Cpc-PH) or no-PH.
Methods and Results: A total of 210 patients with end-stage heart failure undergoing evaluation for heart transplantation were stratified into two groups; namely, those with ischemic cardiomyopathy (ICMP) and nonischemic cardiomyopathy (NICMP). The patients with left ventricle ejection fraction (LVEF) = 25%, NYHA class III or IV and INTERMACS III and VII levels were included to study.Ninety seven patients had ICMPand 113 patients had NICMP. There were no differences in terms of left ventricular ejection fraction, NYHA, INTERMACS grades, presence of severe mitral regurgitation, left ventricular diastolic dysfunction and duration of heart failure betweengroups. The systolic pulmonary pressures, PAPm and PVR were higher in ICMP group compared to NICMP group [57 ± 18 vs. 47.2 ± 15.1, p < 0.001; 35.8 ± 11.5 vs. 30.6 ± 10.7 p = 0.001 and 3.4 (1.7-6.5) vs. 2.4 (1.0-4.4); p = 0.007]. Although more Cpc-PH was found in ICMP it didn't reached statistically significance (55.6% vs. 40.7%, p = 0.07). The patients with ICMP and NICMP had similar rate of Ipc-PH and no-PH (25.7% vs. 33.6%, p= 0.216; and 19.5% vs. 28.3%, p = 0.150; respectively).The patients with ICMP had a similar rate of PVR= 3 but significantly increased rate of PVR = 5 WU compared to NICMP (56.7% vs. 44.2%, p = 0.05 and 32.9% vs. 17.6%, p = 0.008). In subgroup analysis of patients who don't require inotropic treatment (170 patients), patients with ICMP had higher rate of Cpc-PH compared to NICMP (55.8% vs. 337.7%,p = 0.043).
Conclusions: It seems that heart failure etiology, ischemic or nonischemic, didn't affect the rate of Ipc-PH, Cpc-PH and No-PH. However, more Cpc-PH was determined in patients with ICM who didn't require inotropic treatment.

P942

Effect of ischemic versus nonischemic cardiomyopathy on invasive hemodynamic findings in heart transplant candidates

Z Zubeyde Bayram[1]; C Dogan[1]; RD Acar[1]; B Guvendi[1]; A Karaduman[1]; OY Akbal[1]; T Unkun[1]; A Hakgor[1]; S Uysal[1]; C Kaymaz[1]; N Ozdemir[1]
[1]Kartal Kosuyolu Heart Education and Research Hospital, Department of Cardiology, Istanbul, Turkey

Background: Results of studies evaluating the effect of heart failure (HF) etiology (ischemic or nonischemic) on invasive hemodynamic measurements are inconsistent because of heterogeneities of studies and relatively small number of patients in those studies. We aimed to investigate how does etiology of HF affects the invasive hemodynamic findings about right ventricular function, including novel parameters such as pulmonary artery pulsality index (PAPi), pulmonary arterial capacitance (PAC) and pulmonary arterial elastance (PAE).
Methods and Results: A total of 215 patients with end-stage heart failure undergoing evaluation for heart transplantation were stratified into two groups; namely, those with ischemic cardiomyopathy (ICMP) and nonischemic cardiomyopathy (NICMP) and all of the patients underwent right heart catheterization. One hundred and one patients had ICM and 114 patients had NICM. Patients with left ventricle ejection fraction (LVEF) = 25%, NYHA class III or IV and INTERMACS IV and VII levels were included to study. There was no difference in terms of LVEF, duration of HF,NYHA and INTERMACS grades between ICMP and NICMP (p>0.05). The patients with ICMP had higher pulmonary artery systolic and mean pressures, pulmonary vascular resistance (PVR) compared to NICMP [59.0 (42.0-73.0) vs. 46.0 (37.0-59.0), p < 0.001; 35.0 (27.0-46.0) vs. 31.0 (23.0-39.0), p = 0.002 and 3.5 (1.8-6.6) vs. 2.4 (1.0-4.4), p = 0.007; respectively]. The cardiac output, cardiac index, stroke volume, right atrial pressure, pulmonary wedge pressure and pulmonary artery diastolic pressure were similar between group [3.3 ± 0.81 vs.3.4 ± 0.96, 1.7 ± 0.45 vs. 1.8 ± 0.5, 41.6 ± 12.9 vs. 41.4 ± 15.1, 10.0 (5.0-15.0) vs. 11.0 (6.0-16.0), 23.7 ± 7.8 vs. 22.0 ± 7.3 and 24.0 (16.0-30.0) vs.31.0 (23.0-39.0); p>0.05 in all]. While the right ventricular stroke work index (RVSWI) and PAPi were higher and PAC was lower in patients with ICMP compared to NICM [6.5 (4.8-8.2) vs. 5.4 (3.7-7.7), p = 0.007; 3.4 (2.2-5.2) vs. 2.5 (1.7-4.0) p = 0.004 and 1.2 (0.8-1.8) vs. 1.5 (1.0-2.2), p = 0.002; respectively], the PAE was similar between groups [1.3 (0.92-2.0) vs. 1.2 (0.81-1.6), p = 0.638]. Among to PVR= 3 WU, higher PAPi and lower PAC was determined among to ICM group compared to NICMP group (3.8 ± 2.1 vs. 2.9 ± 1.5, p = 0.026 and 1.1 ± 0.55 vs. 1.4 ± 0.79, p = 0.017), and RVSWI and PAE were similar between groups (7.6 ± 3.1 vs. 6.6 ± 2.7, p = 0.122; 1.89 ± 0.78 vs. 1.69 ± 0.58, p = 0.317).Among to PVR < 3 WU, PAC and PAE were similar between in ICM and NICMP (p = 0.243 and p = 0.662). While patients with ICMP had higher RVSWI and PAPi, it didn't reach statistically significance in patients with PVR < 3 WU (6.2 ± 3.2 vs. 4.9 ± 2.9, p = 0.051; 4.4 ± 3.2 vs. 3.3 ± 2.4, p = 0.05).
Conclusions: The patients with ICM had higher RVSWI, PAPI and PAC than patients with NICM.It seems that the ischemic cardiomyopathy is better than nonischemic cardiomyopathy in terms of RVSWI, PAPiand PAC of which are invasively determined risk factors for RVF.

P943

Experience using sacubitril/valsartan in real life: tolerability and clinical evolution in a long term

R Rafael Bravo Marques[1]; E Timonet Andreu[1]; JL Rodriguez Martinez[1]; S Lopez Tejero[1]; PA Chinchurreta Capote[1]; C Corona Barrio[1]; JR Siles Rubio[1]; A Valle Alberca[1]; FE Mesa Prado[1]; C Martin Dominguez[1]; F Ruiz Mateas[1]; FJ Torres Calvo[1]
[1]Hospital Costa del Sol, Cardiology, Marbella, Spain

Introduction: The prevalence of chronic heart failure (HF) has been increased, due to the improvement in the management and treatment of most of heart diseases and the longer life expectancy of the population, becoming an important public health problem. The clinical practice guidelines of HF have aproved using Sacubitril/Valsartan in patients with HF with reduced eyection fraction (HfrEF) and functional class (FC) = II.
Material and Methods: We conducted a prospective observational study of patients with HfrEF assessed in our outpatient clinic, who started treatment with Sacubitril/Valsartan between October 2016-Febrery 2017. We analyzed their baseline characteristics and the one year evolution in functional class, analytical parameters and drug tolerance.
Results: We analyzed 57 patients, with a mean age of 69.1 ± 10,1 years, being 80.7% male. 57,9 were hypertensive, 33.3% diabetic and 45.6% dyslipemic. The mean FG of 65.2ml/min (CKD-EPI). The cause of heart failure was dilated cardiomyopathy in 68.4% and in ischemic heart disease in 29.8%. The mean telediastolic diameter of left ventricle was 63.8 ± 6.6mm, with an average LV ejection fraction of 33.6 ± 6.4%. Atrial fibrillation was present in 31.6%.
At the beginning, the majority were in FC II (43.9%), 43.9% in FC III/IV. Mean baseline systolic blood pressure was 117.2 ± 20.4mmHg and diastolic 69.7 ± 12.4mmHg and mean heart rate was 69.4 ± 14.1bpm. Pretreatment was optimal in all cases (maximum tolerated doses of ACEI, ARB II, BB, mineralcorticoids). ARNI was started (after stopping ACE inhibitors in 56.2% and the rest ARI II), at low doses in 57.9%, at medium doses 29.8% and the rest at high doses. In a review at 7 months follow-up, 18 patients improved functional class (3 patients from IV to III, 10 patients from III to II and 5 patients to FC I). Concerning analytical parameters, we observed a reduction of NT-ProBNP (from 1813 to 813µg/L; this parameter was measured one month after initiating ARNI and after 6 months) and uric acid (from 10.9 to 6.9mg/dL). We found a significant decrease in blood pressure at month and the six months (115.2/67.8mmHg and 109.8/65mmHg respectively; p = 0,034 and 0,005) but allowed us to optimize the treatment with LCZ696, being at medium dose 40.5%, at high dose 38.1% and the rest at low doses. We did not find significant differences in renal function or in potassium levels during follow-up. The LV ejection fraction improved significantly to 37.3 ± 10.2% (p = 0,034) on echocardiogram 7 months after starting treatment with ARNI. Only one patient stopped taking medication due to pruritus.
Conclusions: The treatment with LCZ696 in a group of patients in real-life was well tolerated in all cases, with a significant decrease in blood pressure, being able to

optimize the dose of LCZ696. It was related to improvement in the functional class, LV ejection fraction and in analytical parameters, even with a long follow-up.

P944

What is the significance of right ventricular dysfunction in patients with preserve, mid-range and depressed LVEF?

M Plaza Martin[1]; S Del Prado Diaz[1]; G Alonso Salinas[1]; J Ramos Jimenez[1]; S Hernandez Jimenez[1]; A Pardo Sanz[1]; M Valverde Gomez[1]; VC Lozano Granero[1]; M Pascual Izco[1]; JL Zamorano Gomez[1]
[1]*University Hospital Ramon y Cajal de Madrid, Madrid, Spain*

Introduction: European Society of Cardiology (ESC) guidelines establish three categories of heart failure (HF) based on left ventricular ejection fraction (LVEF). Meanwhile the presence of right ventricular (RV) dysfunction is not considered.
Methods: An observational study was designed in order to evaluate differences in baseline characteristics and functional class between consecutive patients with and without RV dysfunction followed in HF Unit.
Results: A total of 200 patients were included. Mean age was 74.5 ± 12.5 years, 60% were men, 62% hypertensive, 17% diabetic, 43% dyslipidemic and 56% were on atrial fibrillation or flutter. There was RV dysfunction in nearly 30% of patients. According to ESC recent classification, the majority of patients (58%) had depressed LVEF, 18% mid-range and 24% preserved LVEF. There was no difference in baseline characteristics between patients with and without RV dysfunction except higher rate of atrial arrhythmias in the group with RV dysfunction (69% vs 51%, p = 0,020). The proportion of patients in the three cathegories based on LVEF was similar in both groups. However, irrespective of left ventricular function, patients with RV dysfunction showed worse functional class (p = 0,041) and higher natriuretic peptides levels (829 ± 623 vs 656 ± 558, p = 0,021).
Conclusions: In this cohort, RV dysfunction was related with worse functional class and higher natriuretic peptides regardless of left ventricular dysfunction degree. As a result, it would be reasonable performing studies focused on the analysis of RV dysfunction to evaluate its role in the follow up of patients with HF.

Baseline characteristics

	Right ventricular function preserved	Right ventricular dysfunction	p
Age (X ± SD)	75,09 ± 11,7	74,0 ± 12,8	0,572
Hypertension	63%	61%	0,086
Diabetes mellitus	38%	42%	0,069
Dyslipidemia	41%	49%	0,302
Smoking	12%	5%	0,148
COPD	23%	20%	0,624
Atrial arrhythmias	51%	69%	0,020
Depressed LVEF	55%	63%	0,510
Mid-range LVEF	20%	14%	0,510
Preserved LVEF	25%	24%	0,510

Echocardiographic evaluation of left ventricular filling pressures in patients with pulmonary hypertension

M Matthias Schneider[1]; H Ran[2]; A Pistritto[3]; C Gerges[1]; I Lang[1]; T Binder[1]; G Goliasch[1]
[1]*Medical University of Vienna, AKH - Vienna, Cardiology Clinic, Vienna, Austria*; [2]*Nanjing 1st Hospital, Department of Echocardiography, Nanjing, China People's Republic of*; [3]*San Paolo Hospital, Emergency Department, Division of Cardiology, Savona, Italy*

Background: Echocardiographic estimation of diastolic function is an essential part of every comprehensive transthoracic echocardiographic examination. The 2009 recommendations for the evaluation of left ventricular (LV) diastolic function combined a series of parameters to a diagnostic algorithm for the echocardiographic diagnosis of LV diastolic dysfunction. In 2016, an updated version was published, proposing a more simplified approach. Both recommendations primarily rely on the secondary findings left atrial dilatation, tricuspid regurgitation velocity, and the Doppler criteria E/A, e' and E/e'. Tricuspid regurgitation velocity plays a major role in this algorithm. This can lead to false interpretation of LV diastolic function in patients with pulmonary hypertension.
Purpose: We aimed to compare the accuracy of the 2009 and the 2016 recommendations in patients with pulmonary hypertension.
Methods: We prospectively evaluated all adult patients with clinically indicated right heart catheterization between July 2015 and July 2016. For the final analysis, only patients with pulmonary hypertension were included. All patients had a complete transthoracic echocardiographic examination shortly before right heart catheterization. In a subgroup of patients LV end-diastolic pressure was measured via left heart catheterization when clinically indicated.
Results: A total of 63 patients were included in the final analysis, 35 patients (56%) were female. Mean age was 68 years (range 21-91). All patients had pulmonary hypertension (mean pulmonary artery pressure = 25 mmHg). A total of 27 patients (43%) had elevated left ventricular filling pressures (defined as mPCWP >12 mmHg and/or LVEDP >16 mmHg). Left ventricular systolic function was normal in all patients. Right ventricular systolic function was graded normal in 40% of the patients. Mean TAPSE was 17 ± 4 mm, and mean longitudinal strain of the free lateral wall of the right ventricle was -18 ± 6 %. At least moderate tricuspid regurgitation was present in 27 patients (43%), at least moderate mitral regurgitation was present in 11 patients (17%). Sensitivity for correct echocardiographic classification of diastolic function was 67% and 84%, specificity was 82% and 80%, in the 2009 and 2016 recommendations, respectively. The area under the curve (AUC) for the 2016 guidelines with 0.82 was significantly better compared to the AUC of 0.74 for the 2009 guidelines (P = 0.0427)
Conclusion: Our study demonstrates that the 2016 recommendations for echocardiographic evaluation of diastolic function are superior to the 2009 recommendations in estimating left ventricular filling pressures in patients with pulmonary hypertension.

P946

Metabolic syndrome phenotypes have different effects on the diastolic function of the left ventricle and arterial ageing

AM Jakstaite[1]; J Celutkiene[2]; S Solovjova[2]; J Badariene[2]
[1]*Vilnius University, Medical faculty, Vilnius, Lithuania*; [2]*University Hospital Santariskiu Klinikos, Clinic of Cardiac and Vascular Diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania*

Background: It was shown that some metabolic syndrome (MetS) clusters are associated with significantly stiffer arteries.
Purpose: We aimed to investigate the association between MetS phenotypes, left ventricle diastolic function [LVDF] and arterial markers.
Methods: 357 high cardiovascular risk patients were recruited prospectively. Inclusion criteria: defined MetS, echocardiographic LVDF evaluation, arterial markers (pulse wave velocity [PWV], augmentation index [AI], common carotid artery intima-media thickness [IMT], common carotid artery stiffness [CAS], cardio-ankle vascular index [CAVI]). According to the combination of MetS components (increased waist circumference [W], increased triglyceride [T], increased plasma glucose [G], low high-density lipoprotein [H], arterial hypertension [B]) subjects were divided into MetS phenotypes. Impaired relaxation was described as E/A < 1.0 and E/e'mean < 13. Pseudonormal or restrictive diastolic dysfunction- as E/e'mean = 13. In case of E/A>1.0, e'septal = 8 cm/s and e'lateral = 10 cm/s- as normal diastolic function.
Results: Subjects composed 15 phenotypes, the most common being WTGHB (n = 72), WGB(n = 66), WTGB(n = 58), WTB(n = 48), WTHB(n = 33), WGHB(n = 26). All MetS phenotypes mostly presented with impaired relaxation. About ? of WGHB and WTHB subjects had pseudonormal or restrictive diastolic dysfunction. Furthermore, the majority of WGHB subjects had impaired diastolic function. Significant differences of arterial markers (PWV, AI, CAVI, IMT) were found between MetS phenotypes (Table 1.).
Conclusion: Specific MetS phenotype is associated with particular stage of diastolic dysfunction and arterial ageing, being WGHB type the strongest predictor of high impairment degree.

P947

Diastolic dysfunction of the right ventricle as an early diagnostic marker of heart failure

V Kirillova[1]; E YU Prosviryakov[2]

* p value < 0.05

The study included 152 hypertensive patients (61.4 ± 1.4 years, 74.7% women). The control group was 55 people without cardiovascular disease (37.1 ± 1.3 years, 66.6% women). RV and LV diastolic function was assessed using early (E) and late (A) transtricuspid and transmitral flow velocities, E/A ratio, and e' and a' tissue Doppler velocities.

The hypertensive patients had right ventricular diastolic dysfunction with left ventricular diastolic dysfunction with and without pulmonary hypertension (mean systolic pressure of pulmonary artery in the patients was 23.9 ± 1.2 Hg vs 15.8 ± 0.59 Hg in the control group, p < 0.05). The hypertensive patients had different types of right and left ventricular diastolic dysfunction. 55 patients had early diastolic dysfunction of the right and left ventricles (LV: E/A = 0.7 ± 0.02, e' = 7.9 ± 0.3 m/s, a' = 12.8 ± 0.5 m/s; RV: E/A = 0.76 ± 0.01, e' = 8.2 ± 0.29 m/s, a' = 14.8 ± 0.54 m/s vs control LV: E/A = 1.65 ± 0.05, interventricular septum: e' = 12.4 ± 0.33 m/s, a' = 8.9 ± 0.17 m/s, lateral wall: e' = 16.2 ± 0.48 m/s, a' = 10.1 ± 0.33 m/s; RV: E/A = 1.4 ± 0.02, e' = 14.3 ± 0.36 m/s, a' = 10.4 ± 0.36 m/s). 27 patients had early diastolic dysfunction of the left ventricle and pseudonormal diastolic dysfunction of the right ventricle (LV: E/A = 0.76 ± 0.03, e' = 9.2 ± 0.37 m/s, a' = 14.4 ± 0.5 m/s; RV: E/A = 1.26 ± 0.04, e' = 9.1 ± 0.5 m/s, a' = 15.6 ± 0.7 m/s). 20 patients had pseudonormal diastolic dysfunction of the right and left ventricles (LV: E/A = 1.17 ± 0.03, e' = 8.7 ± 0.29 m/s, a' = 11.4 ± 0.49 m/s; RV: E/A = 1.25 ± 0.02, e' = 8.8 ± 0.24 m/s, a' = 14.1 ± 0.38 m/s). 50 patients had normal diastolic function of the left lateral ventricular wall and pseudonormal diastolic dysfunction of the right ventricle; the interventricular septum, which is shared by both ventricles, had early diastolic dysfunction (LV: E/A = 1.29 ± 0.05, interventricular septum: e' = 11.0 ± 1.64 m/s, a' = 12.4 ± 1.89 m/s, lateral wall: e' = 13.7 ± 0.29 m/s, a' = 9.8 ± 0.29 m/s; RV: E/A = 1.38 ± 0.03, e' = 9.4 ± 0.37 m/s, a' = 13.8 ± 0.47 m/s). The last group with right ventricular diastolic dysfunction and normal left ventricular diastolic function had a short duration of disease (less than 7 years) versus the other groups having more than 10 years of hypertension.

This study has demonstrated that, in hypertensive patients, the right ventricular diastolic dysfunction accompanies the left ventricular diastolic dysfunction. The right ventricular diastolic dysfunction has been demonstrated in cases without pulmonary hypertension. The patients with a short period of hypertensive disease have only pseudonormal right ventricular diastolic dysfunction, which can be an early diagnostic marker of heart failure.

P948

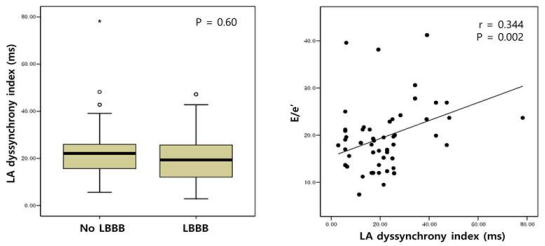
Impact of left bundle branch block on left atrial dyssynchrony and its relationship to left ventricular diastolic function in dilated cardiomyopathy

SM Seong-Mi Park[1]; DH Cho[1]; MN Kim[1]; WJ Shim[1]
[1]*Korea University College of Medicine, Seoul, Korea Republic of*

Background: The impact of left bundle branch block (LBBB) on left atrial (LA) dyssynchrony in heart failure (HF) patients with non-ischemic dilated cardiomyopathy (DCM) has not been clearly elucidated.

Methods: Eighty consecutive symptomatic HF patients with non-ischemic DCM (left ventricular ejection fraction, LVEF < 35%) were included. LBBB was defined according to standard electrocardiographic criteria on a 12-lead electrocardiogram. LV systolic and diastolic dyssynchrony index and LA dyssynchrony index were obtained by color-coded tissue Doppler imaging.

Results: There was no significant difference in LV size, LVEF, and LA volume between patients with LBBB (n = 38) and no LBBB (n = 42). NT-pro BNP level was similar between two groups. There was a significant difference in LV systolic dyssynchrony index (P = 0.014) and there was a mild difference in LV diastolic synchronicity index between patients with LBBB and no LBBB (P = 0.045). However, there was no difference in LA dyssynchrony index between the two groups (P = 0.60). LA dyssynchrony index was not related to LV systolic and diastolic dyssynchrony indexes, but it was related to the deceleration time of mitral early diastolic velocity



LA dyssynchrony index (E) (r = -0.249, P = 0.029), the ratio of E to mitral annular early diastolic velocity (E/e', r = 0.344, P = 0.002) and LA volume (r = 0.242, P = 0.031). E/e' was most related to LA dyssynchrony index (r^2 = 0.325, P = 0.002).

Conclusion: LBBB influences both LV systolic and diastolic dyssynchrony, but not LA dyssynchrony. LA dyssynchrony was related to LV diastolic function and the improvement of LV diastolic function by HF therapy may improve LA mechanical dysfunction regardless of the presence of LBBB in in patients with non-ischemic DCM.

P949

Early circulating predictors of post-infarction myocardial remodeling pattern

M Ivanov[1]; I Popovici[1]; V Ivanov[1]; D Dragoi[1]; V Cobet[2]; M Popovici[1]
[1]*Institute of cardiology , Chisinau, Moldova Republic of*; [2]*State University of Medicine and Pharmacy, Chisinau, Moldova Republic of*

Aim: Daily assaying of serum level of pro- and anti-inflammatory cytokines during first 7 days of post-infarction evolution in patients with STEMI exposed to angioplasty as well as MMP-8 in correlation to installed myocardial remodeling pattern estimated echocardiography at 4-6 month period after revascularization.

Material and methods. From a big group (n = 238) of patients with STEMI exposed to angioplasty in first 12 hours since infarction onset have been selected 56 pts who developed adaptive (AMR) myocardial remodeling and 57 pts who developed pathological (PMR) myocardial remodeling according to geometric (concentric or eccentric remodeling) and functional (end diastolic volume rise more than 20%) criteria. Using ELISA method daily serum concentrations of pro-inflammatory ((high sensitive C reactive protein, interleukins (IL) 1, 6, tumor necrosis factor alpha and monocyte chemoattractant protein 1)), anti-inflammatory biomarkers (IL-4, IL-10, IL-33, IL-1 receptor antagonist and heregulin-1beta) ?s well as ???-8 have been determined in the first 7 days after myocardium revascularization.

Results: Initial serum content of the explored pro-inflammatory biomarkers was in both groups significantly bigger than control value. Their dynamics did not differ in patients with AMR and PMR after revascularization. It was characterized by a significant biomarker increase at 3-rd day followed by a decline toward 7-th day up to initial level. Among anti-inflammatory biomarkers IL-4 and IL-10 have manifested by a distinct dynamics in concern to myocardial remodeling pattern. In both groups these interleukins decreased after angioplasty, reaching a minimal level at 3-rd day.

However, in patients with AMR since 4-th day has been established an increase of serum content of IL-4 and IL-10, their increment being at 7-th day in a range of 52-55% ($p < 0,05$). In patients with PMR the interleukins rise was negligible: 5,7-5,8%. MMP-8 dynamics also has been different in groups and was correlated with dynamics of IL-4 and IL-10. Thus, in patients with AMR its level has fallen since 3-rd day up to 7-th day by 46,6%, while in group with PMR metalloproteinase level in this period practically did not change, remaining significantly higher than control by 45-53%.

Conclusion: In patients with STEMI determining of serum content of IL-4 and IL-10 in the first 7 days after angioplasty is important in regard to myocardial remodeling pattern prediction in post-infarction period. Their rise more than 50% since 4-th day up to 7-th day (period of anti-inflammatory macrophages, M2, activation) testifies priority of AMR developing, while a negligible increment (up to 6%) is a predictor of PMR. The MMP-8 dynamics correlated with dynamics of IL-4 and IL-10.

P950

Early left ventricular reverse remodelling after sacubitril/valsartan treatment in clinical practice

M Groba-Marco[1]; M Singh[1]; M Galvan Ruiz[1]; M Fernandez-De-Sanmamed-Giron[1]; R Montiel Quintero[1]; E Perez-Nogales[2]; JM Medina Gil[2]; M Blanco-Nuez[1]; E Caballero Dorta[1]; JR Ortega Trujillo[1]; I Menduina Gallego[1]; J Morales Gonzalez[1]; V Quevedo Nelson[1]; H Mendoza Lemes[1]; A Antonio Garcia Quintana[1]
[1]University Hospital De Gran Canaria "Dr. Negrin", Las Palmas de Gran Canaria, Spain; *[2]University Hospital Insular of Gran Canaria, Las Palmas De Gran Canaria, Spain*

Background: Sacubitril/Valsartan is an angiotensin receptor-neprilysin inhibitor (ARNI), recommended to further reduce morbidity and mortality in ambulatory patients with heart failure with reduced ejection fraction (HFrEF) symptomatic despite optimal treatment. Few data on echocardiographic parameters of remodelling has been published after ARNI treatment.

Purpose: To analyse the evolution of left ventricle ejection fraction (LVEF) and end diastolic diameter (LVEDD) in patients with stable symptomatic HFrEF and optimized treatment after ANRI, and study whether aetiology of HF and early initiation of this drug after diagnoses of HFrEF is associated with better outcomes.

Methods: We performed a retrospective study of 17 patients with ARNI treatment. Clinical characteristics, date of HFrEF diagnoses and ARNI treatment initiation, LVEF and LVED were collected. Follow-up transthoracic echocardiography was performed after mean time of 4.91 ± 3.05 months of treatment with ANRI.

Results: Mean age was 60.6 ± 10.93 years, 13 patients (76%) men and 4 (24%) women. Aetiology of HFrEF was 41.2 ischemic and 58.8 non-ischemic. Along with ANRI treatment, 88.2% of patients received beta-blocker, 56.2% mineralocorticoid receptor antagonist and 29.2% Ivabradine. 3 patients (17%) had cardiac resynchronization therapy before ANRI. ARNI dose was 24/26mg 3 patients (17,6%), 49/51mg 9 patients (52,9%) and target dose 97/103mg 5 patients (29,5).

Mean LVEF before and after ANRI was $30 \pm 7.9\%$ and $35.47 \pm 10.3\%$ respectively, with mean improvement $5.47 \pm 9.5\%$ (p value = 0,031). Mean LVED before and after ANRI was 66.42 ± 6.74mm and $62,42 \pm 7,5$mm respectively, with mean reduction $4 \pm 5,3$mm (p-value = 0,025). Baseline LVEF in ischemic and non-ischemic HF was 29.14% and 31.14% and after ARNI 20,60% and 38.50% respectively ($p = ns$).

Mean improvement of LVEF and LVED with ARNI initiation before 12months of HFrEF diagnoses was $14,0 \pm 17,5\%$ and 2.2 ± 4mm respectively and in patients with ARNI initiation after 12months of HFrEF diagnoses $2,8 \pm 3,6$ % ($p = 0,036$) and 4.9 ± 5.8mm respectively ($p = ns$).

Conclusions: A statistically significant improvement in LVEF and LVED is observed in patients with ARNI and optimal heart failure treatment. A more significant increase in LVEF is observed in patients with non-ischemic HFrEF and in patients with earlier ARNI treatment initiation. However, extended data with larger cohort size is needed to confirm these results and enlighten the role of ARNI in ventricular reverse remodelling process.

P951

Pathological left ventricle remodelling and electric instability in patients with myocardial infarction

E Dushina[1]; Y Barmenkova[1]; V Galimskaya[1]; N Burko[1]; V Valentin Oleinikov[1]
[1]Penza State University, Penza, Russian Federation

Aim: analysis of the effect of left ventricle pathological remodeling in patients in the postinfarction period on the detecting of late ventricular potentials (LVP), pathological turbulence of the heart rhythm (HRT), and the development of ventricular arrhythmias (VA).

Methods: 100 subjects aged from 35 to 65 years were examined at the 7th-9th day, and 24 weeks after STEMI. Daily 12 leads ECG monitoring with the analysis of LVP and HRT was performed using the Holter Analysis-Astrocard complex (Meditek, Russia). The presence of LVP was established if at least two of the following conditions existed: QRSf = 120 ms, HFLA = 39 ms, RMS = 25 μV. The normal ranges of the parameters were used in HRT assessing: TO less than 0% and TS more than 2.5 ms/RR. The pathological HRT was determined in deviation of any of these parameters. The Lown and Wolf classification was used for the VA evaluation. Echocardiography was performed on MyLab 90 scanner (Esaote, Italy), end-diastolic volume index (EDVi) was determined. The patients were separated onto two groups depending on the EDVi increase: one group included 43 (58%) people without echocardiographic signs of LV remodeling; group 2 comprised 31 (42%) patients with an EDVi increase by 20% or more.

Results: the frequency of impaired HRT registration in group 1 decreased significantly from 31% (18 patients) to 12.1% (7 patients) ($p = 0.02$), this positive intra-group dynamics was accompanied by a marked decrease in absolute values of TO with -0,42% (95% CI -2.22, 1.38%) at 7-9th days to -2.47 ms/RR (95%CI -3.58, -1.35 ms/RR) at the 24-week ($p = 0.007$). In the compared group, the incidence of pathological baroreflex sensitivity was not significantly changed and was 23.8% (10 subjects) at the 7-9th days, and 11.9% (5 patients) at the end of follow-up. VA of high grades (gradation 3 and above on Lown and Wolf) was more often in group 2 (45.2%), compared to group 1 (22.4%) ($p = 0.02$). There was no significant change in the LVP registration in both groups.

Conclusion: pathological remodeling of the left ventricle in the post-infarction period adversely affects the baroreflex sensitivity, and also promotes the life-threatening arrhythmias development.

P952

Dynamical 3D modeling possibilities in the left ventricle reconstructions Personalized surgical approach in cardiac surgery

J Imre Barabas[1]; Z Szabolcs[1]; F Horkay[1]; T Huttl[1]; L Fazekas[1]; M Polos[1]; L Daroczi[1]; K Benke[1]; P Kovacs[1]; A Koszegi[1]; R Toth[1]; B Gasz[2]; B Merkely[1]; I Hartyanszky[1]
[1]Semmelweis University Heart Center, Budapest, Hungary; *[2]University of Pecs, Department of Surgical Research and Techniques, Pecs, Hungary*

Development of computer science, more accurate planning and simulation spread into the medical patient care. Although the surgical specialties utilized static model but by the evolution of dynamical planning method and practical usage of computer simulations created the possibility of introduction of dynamical parameters in cardiac surgery.

Our aim was the amelioration and application of 3D models in cardiac surgical practice wherewith the prediction of fluid dynamical variables and remaining ventricle shape, volume and function in surgical ventricle restoration cases.

Using own developed script, the raw Dicom files were imported, the dilated left ventricle was modeled and fluid dynamical parameters simulated, such as flow kinematic and profile analysis, turbulence calculation and myocardial response to shear stress.

Then step-by-step simulation of the surgical ventricle restoration procedure was accomplished and the calculated variables were imbedded in silico model of the left ventricle reconstruction. The extension and length of resection lines were modified based on the previous computer simulation. Optimal resection of the myocardium was applied during the operation, considering the all feasibility. The sphericity and conicity indexes were improved significantly in postoperative period (0,42vs. 0,67 és 0,36vs. 0,72, $p < 0,05$, Student t-test). The occurred shear stress at endocardium decreased 83% due to the normalization of flow kinematic pattern of the ventricle in postoperative period (54 ± 12vs. 32 ± 9 $p < 0,02$, Student t-test). The postoperative turbulent flow pattern - based on Reynolds number - significantly decreased, according to our computational method (2712vs. 1823, $p < 0,0001$, Student t-test). With our method, the standardization of the surgical ventricle reconstruction was achievable and the surgical steps were predictable. Therefore, a new decision making support system was established in cardiac surgery for high risk patients. Consequently, a personalized surgical technique was offered our patients, improving their life expectancy and quality of life.

P953

Corrected QT interval and right shifted association with mortality in acute heart failure patients

HY Hae-Young Lee[1]; HJ Cho[1]; BH Oh[1]
[1]Seoul National University Hospital, Seoul, Korea Republic of

On behalf of: KorAHF registry
Funding Acknowledgements: Korea CDC

This study sought to investigate the predictive power of corrected QT (QTc) interval in acute heart failure patients. In this prospective cohort study, we analyzed 4,990 patients who were followed up to 5 years. They had QTc interval of = 350 msec and did not have pacing rhythm, and history of malignant neoplasm. Patients were

grouped according to QTc intervals as follows: normal QTc (350-439 msec, n = 1,022), prolonged QTc (440-479 msec, n = 1,849), and longest QTc (= 480 msec, n = 2,119) groups. Kaplan-Meier survival analysis showed that the longest QTc group had significantly higher 30-day and 5-year mortalities than the prolonged QTc group (P = 0.018 and P = 0.037). Cox regression analysis showed that all-cause death was more frequent within the longest QTc group than the prolonged QTc group in both univariate analysis [Hazard ratio (HR) 1.105; 95% confidence interval (CI) 1.006-1.213; P = 0.037] and multivariate analysis (HR 1.153; 95% CI 1.042-1.276; P = 0.006]. Interestingly, there was no significant difference in clinical outcomes between the normal QTc and prolonged QTc groups. Modeling with multivariable fractional polynomials showed a J-shaped association between QTc interval and 5-year all-cause mortality. In patients with AHF, QTc interval was an independent predictor of overall death. Patients with QTc interval up to 440-479 msec had a neutral prognosis, while patients whose QTc intervals were longer had higher risk of mortality.

P954

Long term outcome and factors associated with reduced systolic ventricular function in survivors of sudden cardiac arrest

H Helle Soeholm[1]; JK Kjaergaard[1]; JHT Hartvig Thomsen[1]; EH Hadziselimovic[1]; FKL Lippert[2]; LK Kober[1]; CH Hassager[1]
[1]Rigshospitalet - Copenhagen University Hospital, Heart Centre, Department of Cardiology, Copenhagen, Denmark; [2]Emergency Medicine and EMS, Head Office, Copenhagen, Denmark

Funding Acknowledgements: The Danish Foundation Trygfonden

Background: Outcome after sudden cardiac arrest (SCA) outside hospital has increased in recent years but is still only 10%. Nearly 50% of successfully resuscitated patients survive to discharge, however little is known about the association between post-SCA comorbidity, systolic LV function and long-term survival.
Purpose: In SCA survivors we aimed to describe long-term outcome and predictors of discharge with reduced systolic ventricular function defined by left ventricular ejection fraction (LVEF) < 40% at hospital discharge.
Methods: From a consecutive cohort in 2002 to 2011 of SCA-patients with cardiac cause in the Copenhagen area we report long-term outcome up to 11 years (median 3.6 years) presented as Kaplan-Meier curves. Logistic regression analyses were used to assess factors associated with discharge with LVEF = 40% vs. < 40% in patients without pre-SCA congestive heart failure according to the Danish National Patient Registry.
Results: A total of 497 SCA survivors with a mean age of 61 years were discharged alive from hospital (44% of patients admitted with successful resuscitation). Patients with LVEF = 40% had higher survival rates with 78% being alive at follow-up compared to 70% in patients with LVEF < 40%. (p logrank = 0.02). The difference in survival rates according to LVEF at discharge was primarily noted in patients with other causes than Acute Coronary Syndrome (ACS) as cause of SCA (Figure 1). Independent factors associated with LVEF < 40% at discharge were older age (odds ratio (OR) pr 5 years = 1.14 (95% CI: 1.03 - 1.26) and ACS (OR = 1.90 (1.01 - 3.50), whereas gender, time to return of spontaneous circulation (ROSC), bystander cardiopulmonary resuscitation (CPR), shockable initial rhythm nor being conscious at hospital arrival were not.
Conclusion: SCA survivors discharged alive with LVEF < 40% had significantly lower long-term survival rate compared to patients with preserved LVEF. Independent factors associated with reduced EF at discharge were older age and ACS as cause of SCA.

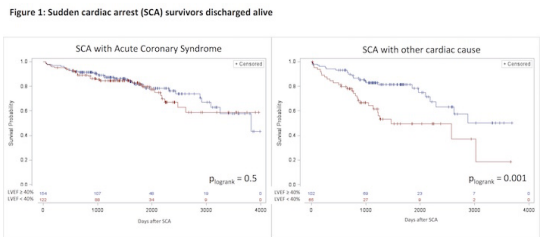


Figure 1

P955

Ivabradine in the treatment of heart failure with reduced ejection fraction

GM Dadashova[1]; NZ Farajova[1]
[1]Scientific Research Institute of Cardiology, Heart Failure, Baku, Azerbaijan

Background: Elevated heart rate represents an important risk factor for adverse outcomes in patients with heart failure. As heart rate is associated with hospital admissions and mortality, the open question is whether early treatment to achieve heart rate reduction with an If-channel inhibitor - ivabradine could reduce the high readmission rate and mortality.
Objectives: We aimed to assess the effect of heart-rate reduction by the selective sinus-node inhibitor ivabradine on outcomes in heart failure.
Material and methods - A prospective observational study that included 50 consecutive patients with hospitalized systolic heart failure, sinus rhythm and heart rate >70 b/min in whom ivabradine was administered during hospitalization or early after discharge. Clinical data, echocardiography, follow-up events were recorded at baseline and after 6 months, 12 months of follow-up; 1 year mortalty and rehospitalization rates for heart failure were compared with ivabradine and placebo groups. Patients were randomly assigned by computer-generated allocation schedule to ivabradine titrated to a maximum of 7·5 mg twice daily or matching placebo.
Results: 50 patients were randomly assigned to treatment groups (26 ivabradine, 24 placebo). Ivabradine was administered in 52,1%. Median follow-up was 12 months. 11 (42%) patients in the ivabradine group and 16 (66%) of those taking placebo had a hospitalization in one year period. The hospitalization rate (number of hospitalization) in the placebo group was much higher than in the ivabradine group (9 [37,5%] vs 3 [11%]; p < 0,001), and the deaths due to heart failure (14 [58%] vs 1 [3,8%]. One year all cause mortality was 30%. Fewer serious adverse events occurred in the ivabradine group (3 events) than in the placebo group (8 events, p < 0,001).
Conclusion: Ivabradine therapy in patients hospitalized for decompensated heart failure improve of clinical outcomes,well tolerated, reduce mortality and rehospitalizations.

P956

Endocrine hormonal imbalance in heart failure with reduced ejection fraction

M Matthias Naegele[1]; J Barthelmes[1]; S Cantatore[1]; F Ruschitzka[1]; I Sudano[1]; AJ Flammer[1]
[1]University Heart Center, Cardiology, Zurich, Switzerland

Funding Acknowledgements: LHW Foundation, Swiss Heart Foundation, University Hospital Zurich, Zurich Heart House

Background: Neurohormonal activation is an important pathophysiologic component of heart failure with reduced ejection fraction (HFrEF). Alterations in thyroid, parathyroid, sex and glucocorticoid hormones have also been described in isolated studies. A systemic analysis of these hormones in a contemporary cohort of well-treated patients is lacking.
Objective: Study the difference in thyroid hormone status (TSH, fT3/fT4 ratio), parathyroid hormone (PTH), estradiol, progesterone, prolactin, testosterone and cortisol in compensated patients with HFrEF compared to a cohort of healthy controls (HC).
Methods: In this prospective observational study, patients with compensated HFrEF with a last known LVEF of <40% and healthy controls, = 40 years of age, free of cardiovascular disease and major risk factors (smoking, hypertension, dyslipidemia or diabetes), were included. Exclusion criteria were use of hormone supplements, anti-thyroid therapy or amiodarone. Fasting morning blood samples were obtained and analyzed using established methods. All patients signed informed consent.
Results: We included 38 patients with HFrEF (mean age 62 ± 10 years, 29% female, mean LVEF 28 ± 7%, median NT-pro BNP 824 ng/L, 61% ischemic cardiomyopathy, 29% dilated cardiomyopathy) and 52 healthy controls (mean age 62 ± 12 years, 29% female). The majority of patients were on guideline-recommended therapies (ACE-inhibitor or angiotensin receptor blocker 95%, beta-blocker 95%, mineralocorticoid antagonist [MRA] 74%, diuretic 71% and CRT 32% of patients respectively). While there were no significant differences in TSH (2.1 ± 0.9 vs. 2.8 ± 2.5 mU/l, p = 0.15), HFrEF patients had a significantly lower fT3/fT4 ratio compared to controls (0.29 ± 0.06 vs 0.33 ± 0.05, p <0.01). PTH was significantly elevated in HFrEF patients vs. controls (74 ± 45 vs. 47 ± 12 p <0.01). Regarding steroid hormones, HFrEF patients had significantly elevated cortisol levels vs. controls (521 ± 155 vs. 418 ± 114 nmol/l, p <0.001). The difference in cortisol was observed in patients both with and without MRA therapy as well as with and without diabetes. Male HFrEF patients had lower testosterone levels than male controls (14 ± 6 vs. 19 ± 5 nmol/l, p <0.01). Estradiol, progesterone and prolactin levels were not different between both groups stratified by gender. The fT3/fT4 ratio correlated inversely with Log(NT-pro BNP) and high-sensitivity troponin T in HFrEF patients (r2 = 0.21, p <0.01 and r2 = 0.3, p <0.001). A significant positive association between PTH and Log(NT-pro BNP) was found (r2 = 0.36, p <0.001) which was stronger than the inverse correlation between PTH and eGFR (r2 = 0.16, p = 0.01). Cortisol correlated inversely with eGFR (r2 = 0.25, p = 0.001).

Conclusions: There is evidence of significant endocrine hormonal imbalance in HFrEF despite use of guideline-recommended therapies. A lower fT3/fT4 ratio, elevated PTH and elevated cortisol are associated with important prognostic biomarkers of HFrEF patients.

Reduction in the number of heart failure hospitalizations in patients included in a heart failure unit.

V Victor Martinez Dosantos[1]; D Iglesias Del Valle[1]; E Garcia Ramirez[1]; Z Blazquez Bermejo[2]; J De Juan Baguda[3]; E De La Cruz Berlanga[1]; C Casanova Rodriguez[1]; R Cadenas Chamorro[1]; B Paredes Gonzalez[1]; A Martin-Penato Molina[1]; E Prieto Moriche[1]; R Cano Carrizal[1]; I Plaza Perez[1]
[1]University Hospital Infanta Sofia, Madrid, Spain; *[2]Hospital del Mar, Barcelona, Spain*; *[3]University Hospital 12 de Octubre, Madrid, Spain*

Background and objectives: The prevalence of heart failure (HF) is approximately 1-2% of the adult population in developed countries, and is increased in/to 10% of the population over 70 years old. The mortality rates for any cause at 12 months in hospitalized and ambulatory patients with HF are 17% and 7% respectively, as well as hospitalization rates at 12 months are 44% and 32% respectively in both groups. The main causes of deaths are related to cardiovascular disease.
The objectives of this study were to demonstrate the reduction of admissions for HF at 12 months after the inclusion of patients diagnosed with HF in our heart failure unit (HFU) and identify their causes.
Methods: We studied all patients included in our HFU between July 2014 and December 2016. All patients received an education focused on self-care behaviors and a contact telephone. A structured follow-up was carried out within the unit. Demographic and clinical data were collected per protocol. All relevant clinical changes, emergency visits, hospital admissions and deaths were documented. We counted all HF admissions in the year before and in the year after inclusion.
Results: We collected 137 patients with a mean age at inclusion of 65.1 years (±12.7), 73.7% men. They had a mean left ventricular eyection fraction of 28.1% (±9.7) and a baseline NT-proBNP levels of 5403.8 µg/L (±5162.3). Regarding the cardiovascular risk factors, 69.3% had hypertension, 35.0% had diabetes mellitus, 51.8 had dyslipidemia and 23.4% were smokers. The most frequent etiologies of HF were ischemic 35.8%, idiopathic 23.4, enolic 11.7% and hypertensive 10.2%. 47.4% were in functional class NYHA III, 39.4% in NYHA II, 9.5% in NYHA I and 3.6% in NYHA IV. 48.9% of patients were included after a first episode of HF, the rest was diagnosed with chronic HF. The mean number of admissions in the year prior to inclusion in the specific HF program was 1.04 admissions per patient, compared to 0.31 admissions in the following year. This implies a relative reduction of 69,9% (95% CI 51,6%-88.3%, $P < 0.0001$). In the year following the inclusion there were 43 hospitalizations in 24 patients. In 5 of them the patient died. 113 patients (82,5%) did not need any hospital admission in the following year. The most frequent causes of hospitalization in the following year were infection (34.9%), acute kidney injury (7.0%), arrhythmia (4.7%), anemia (4.7%) and therapeutic noncompliance (4.7%) The mortality rate at one year of follow-up was 9.7%.
Conclusion: In view of these results, there is evidence of the need for specific HFU for the management of this type of patients in order to reduce the number of HF admissions. HF hospitalizations were due to non-preventable causes in most cases, such as infection, acute renal failure, anemia and arrhythmic events.

P958
Predictors of recovery of left ventricular ejection fraction in patients included in a heart failure unit

D Iglesias Del Valle[1]; V Martinez Dosantos[1]; E Garcia Ramirez[1]; JS De Juan Baguda[2]; Z Blazquez Bermejo[3]; E De La Cruz Berlanga[1]; R Cano Carrizal[1]; C Casanova Rodriguez[1]; E Prieto Moriche[1]; A Martin Penato Molina[1]; R Cadenas Chamorro[1]; A Garcia Garcia[1]; MB Paredes Gonzalez[1]; I Plaza Perez[1]
[1]University Hospital Infanta Sofia, Madrid, Spain; *[2]University Hospital 12 de Octubre, Madrid, Spain*; *[3]Hospital del Mar, Barcelona, Spain*

Introduction: Left ventricular ejection fraction (LVEF) is the main parameter for measurement of left ventricular systolic function. It also allows us to differentiate between heart failure (HF) with preserved, mid-range or reduced ejection fraction. In case of reduced LVEF, it can remain stable or variate over time. It would be interesting to know what factors can predict a recovery of LVEF.
Purpose: To analyze predictors of recovery of LVEF in patients with heart failure with reduced ejection fraction (HFrEF) included in a heart failure unit (HFU).
Methods: We collected all patients with HFrEF included in our unit from July 2014 to December 2016. We collected prospectively data of baseline characteristics as well as LVEF measurements at baseline and at 1 year follow-up. For each patient, we calculated variation between LVEF at baseline and at 1 year. We analyzed predictors of variation in LVEF by simple and multiple linear regression. We obtained standardized regression coefficient (Beta) and statistical significance (P) for each possible predictor.
Results: We included a total of 112 patients. Mortality rate at 1 year was 7.6%. In 97 patients (86.6%) we were able to measure LVEF at 1 year. Mean age was 65.0 years (±12.7) and 70.1% were male. Considering the time course, 18.6% had chronic stable HF, 28.9% had chronic decompensated HF and 52.6% had new-onset HF. As cardiovascular risk factors, 70.1% had hypertension, 36.1% had diabetes, 49.5% had dyslipidemia and 22.7% were smokers. The most frequent etiologies of HFrEF were ischemic 35.1%, idiopathic 26.8%, hypertensive 11.3% and enolic 8.2%. As comorbidities, 39.2% had coronary artery disease, 14.4% had previous stroke, 16.5% had chronic obstructive pulmonary disease, 27.8% had anemia and 25.8% had chronic kidney disease. NYHA functional class at baseline was I 9.3%, II 41.2%, III 46.4% and IV 3.1%. Mean NT-proBNP levels at baseline were 5577.5 µg/L (±5558.2). Mean LVEF at baseline was 25.6% (±7.3) and at 1 year was 39.5% (±14.2), which means an average change of 14.0 (95% confidence interval 11.2-16.8, $P < 0,0001$). 48.5% of patients had LVEF = 40% at one year. In univariate linear regression analysis the variables age (Beta=-0.218, $P = 0.032$), new-onset versus chronic HF (Beta = 0.544, $P < 0.0001$), ischemic etiology (Beta=-0.347, $P = 0.0005$), coronary artery disease (Beta=-0.386, $P = 0.0001$), chronic kidney disease (Beta=-0.213, $P = 0.036$) and narrow QRS (Beta = 0.369, $P = 0.0002$) were associated with LVEF variation. In multivariate linear regression analysis only the variables new-onset HF (Beta = 0.428, $P < 0.0001$), coronary artery disease (Beta=-0.267, $P = 0.001$) and narrow QRS (Beta = 0.219, $P = 0.009$) remained as independent predictors of LVEF variation.
Conclusions: HFU represent the appropriate scenario for implementation of measures that can lead to a recovery in LVEF. New-onset versus chronic HF, absence of coronary artery disease and presence of narrow QRS are variables capable of predicting this recovery.

P959
Reduction of the need for diuretic treatment in patients included in a heart failure unit

V Victor Martinez Dosantos[1]; D Iglesias Del Valle[1]; E Garcia Ramirez[1]; Z Blazquez Bermejo[2]; J De Juan Baguda[3]; E De La Cruz Berlanga[1]; C Casanova Rodriguez[1]; A Martin-Penato Molina[1]; R Cadenas Chamorro[1]; B Paredes Gonzalez[1]; R Cano Carrizal[1]; E Prieto Moriche[1]; A Garcia Garcia[1]; I Plaza Perez[1]
[1]University Hospital Infanta Sofia, Madrid, Spain; *[2]Hospital del Mar, Barcelona, Spain*; *[3]University Hospital 12 de Octubre, Madrid, Spain*

Background and objectives: The prevalence of heart failure (HF) is approximately 1-2% of the adult population in developed countries, and is increased in/to 10% of the population over 70 years old. Most of these patients needs loop diuretic to reduce congestive symptoms. The objective of this study was to demonstrate the reduction of the need for diuretic treatment in patients diagnosed with HF during the first 12 months after inclusion in our heart failure unit (HFU).
Methods: We studied all patients included in our HFU between July 2014 and December 2016. Demographic and clinical data were collected per protocol. We measured the daily dose of loop diuretics at baseline, at 6 months and at 1 year of follow-up.
Results: We collected 114 patients with a mean age at inclusion of 64.9 years (±13.1). 70.2% of them were men. According to time course, 29.8% were included with chronic decompensated HF, 21.1% with chronic stable HF and 49.1% with new-onset HF. The mean left ventricular eyection fraction was 28.4% (±10.2) and mean baseline NT-proBNP levels were 5408.2 µg/L (±5292.6). Regarding the cardiovascular risk factors, 66,7% had hypertension, 36.8% had diabetes mellitus, 51.8 had dyslipidemia and 22.8% were smokers. The most frequent etiologies of HF were ischemic 33.3%, idiopathic 24.6, enolic 13.2% and hypertensive 10.5%. In terms of functional class, 49.1% had NYHA III and 39.5% NYHA II. The mortality rate during the first year was 7.4%. At inclusion, 64.9% of the patients were treated with furosemide, 9.6% with torasemide and the remaining 25.4% were not taking loop diuretics. At 6 months the percentages were 44.4%, 9.3% and 46.3% and at 1 year 40.6%, 8.9% and 50.5%, respectively. The mean daily dose of furosemide or equivalent (torasemide, assuming a 2:1 ratio) taken by the patients was 38.8, 25.7 and 24.8 mg at baseline, 6 months and 1 year after inclusion. There was an average reduction of 12.3 mg of the furosemide daily dose (95% CI 7.2-17.4, $p < 0.001$) in patients with treatment at baseline and at 6 months (108) and 12.2 mg (95% CI 6,1-18.1, $p < 0.001$) in those with treatment at the baseline and at 1 year (101). According to the time course of HF, the mean daily doses of furosemide are shown in the table 1.
Conclusion: The inclusion in our HFU meant a significant reduction in the doses of loop diuretics, mainly in the new-onset HF group.

1

	Baseline	6 months	1 year
Chronic decompensated HF	57,9	44,7	45.3
Chronic stable HF	23,8	24,8	19,5
New-onset HF	33,7	15,3	14,7

Table 1. Daily dose of furosemide (mg) according to the time course.

Ejection fraction monitoring in patients with heart failure: the improved ejection fraction as a prognostic marker

ML Maria Lorena Coronel[1]; JP Cimbaro Canella[1]; MJ Blanchet[1]; SM Macin[1]; JI Parras[1]; BN Gonzalez Arjol[1]; L Borgo[1]; ER Perna[1]
[1]*J.F. Cabral Cardiology Institute, Corrientes, Argentina*

In patients with heart failure, ejection fraction (EF) was historically associated with prognosis. The "improved" ejection fraction has emerged in recent years, with diverse implicancy on prognosis. Data in our country about the role of this condition is limited.
Objective: Characterize the long-term outcome of patients with heart failure according to the EF at baseline and at follow-up.
Methods: Between January and August 2011, 79 patients with chronic heart failure (CHF) and 98 with acute heart failure (AHF) who survive at discharge, were prospectively included. At the moment of enrollment, an echocardiogram was performed (baseline-B) and it was repeated during follow up (S). A final follow up was done in August 2016, where we evaluated survival (SUR) and survival without hospitalization due to AHF (SURH). Cox proportional hazard model was built, which included significant variables in the univariate analysis. Patients were classified according to baseline EF in B1 = 40%, B2 41-49% and B3 = 50%; and according with EF during follow up in S1 = 40%; S2 >41% current and previous and improved EF (iEF) with previous EF = 40 and current >40%).
Results: Of the cohort of 177 patients; the mean age was 65 ± 12 years, male 66%, 39% with ischemic heart disease, 28% with diabetes; 68% with previous hospitalization due to AHF and 46% were in functional class III-IV. According to the baseline EF, the distribution was B1 = 58; B2 = 12 and B3 = 30%; and according to EF during follow up was S1 = 51; S2 = 34; iEF = 15%. From 102 patients with EF-B = 40%, 27 (26.5%) improved the EF; 11 of 21 with EF-B 41-49%, deteriorated the EF (52.4%) and only 4 of 54 patients with EF-B = 50%, deteriorated the EF during follow up.
The survival at five years in groups B1, B2 and B3 was 53; 55 and 50% (p = 0.586), while in S1, S2 and iEF was 52; 51 and 61% (p = 0.04). The survival free of hospitalization in B1, B2 and B3 was 35; 39 and 37% (p = 0.669) and in S1, S2 and iEF was 33; 37 and 44% (p = 0.043). In the Cox proportional hazard model, only the improved EF was associated with better survival free of hospitalization (HR = 0.44, 95%CI = 0.24-0.83, p = 0.01) and better survival at 5 years of follow up (HR = 0.47, 95%CI = 0.25-0.89, p = 0.0019).
Conclusion: One out four subjects with reduced EF improved the EF during follow up; and this group presented a better clinical course than those who maintain the EF reduced or preserved

P961

Efficacy of heart failure reversal treatment followed by 90 days follow up in chronic heart failure patients with low ejection fraction

RM Sane[1]; R Mandole[2]; D Amin[3]; G Amin[3]; R Singh[4]

Funding Acknowledgements: Vaidya Sane Ayurvedic Education and Agricultural Trust

Objectives: The present study was designed to evaluate efficacy of heart failure reversal therapy (HFRT) that uses herbal procedure (panchakarma) and allied therapies, in chronic heart failure (CHF) patients with low ejection fraction.
Methods: This efficacy study was conducted in CHF patients (aged: 25-65 years, ejection fraction (EF) < 30%) wherein HFRT (60-75 minutes) consisting of snehana (external oleation), swedana (passive heat therapy), hrudaydhara (concoction dripping treatment) and basti (enema) was administered twice daily for 7 days. During this therapy and next 30 days, patients followed the study dinarcharya and were prescribed ARJ kadha in addition to their conventional treatment. The primary endpoint of this study was evaluation of maximum aerobic capacity uptake (MAC) as assessed by 6 minute walk distance (6MWD) using Cahalins equation from baseline, at end of 7 day treatment, follow-up after 30 days and 90 days. EF was assessed by 2D Echo at baseline and after 30 days of follow-up.
Results: CHF patients with < 30% EF (N = 52, mean [SD] age: 58.8 [10.8], 85% men) were enrolled in the study. There was a 100% compliance to study therapy. A significant improvement was observed in MAC levels (7.11%, p = 0.029), at end of 7 day therapy as compared to baseline. This improvement was maintained at two follow-up visits. Moreover ejection fraction was observed to be increased by 6.38%, p = 0,012 as compared to baseline at day 7 of the therapy
Conclusion: This 90 day follow up study highlights benefit of HFRT, as a part of maintenance treatment for CHF patients with reduced ejection fraction.

P962

The impact of coronary artery disease on clinical outcomes in heart failure with mid-range ejection fraction patients

JC Choe[1]; JH Choi[1]; SH Lee[1]; J Ahn[1]; JP Park[1]; HW Lee[1]; JH Oh[1]; HC Lee[1]; KS Cha[1]; TJ Hong[1]
[1]*Pusan National University Hospital, Department of Cardiology, Pusan, Korea Republic of*

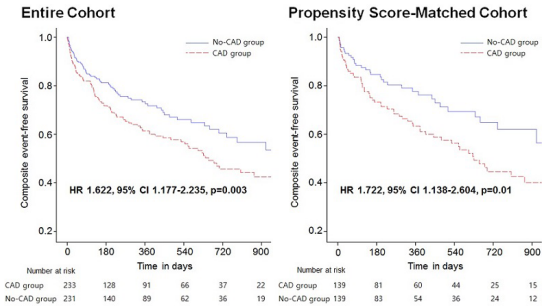
Background: Limited data are available on the role of coronary artery disease (CAD) in heart failure with mid-range ejection fraction (EF) (HFmrEF).
Purpose: We evaluated the association of CAD with outcomes and prognostic impact of revascularization in HFmrEF patients.
Methods: Among 464 consecutive patients with primary diagnosis of HFmrEF (EF 40-49%) in an urban tertiary referral center from October 2013 to March 2017, 233 (50.2%) were in CAD group and 231 (49.8%) were in no-CAD group. We compared the characteristics and composite event (all-cause death and cardiovascular readmission) in the entire and propensity score (PS)-matched cohorts.
Results: HFmrEF patients with CAD vs. no-CAD had higher incidence of hypertension, diabetes mellitus, peripheral artery disease, and right ventricular dysfunction and increased value of B-type natriuretic peptides and troponin I. Composite event occurred in 169 patients (36.4%), with a significantly higher rate in CAD group. After risk adjustment, the presence of CAD (entire: hazard ratio [HR] 1.622, 95%

P962 Clinical Outcomes

	Entire Cohort (n = 464)		Propensity Score-Matched Cohort (n = 278)		
CAD group (n = 233)	No-CAD group (n = 231)	p	CAD group (n = 139)	No-CAD group (n = 139)	p
All-cause death	28 (12.0%)	18 (7.8%)	0.048	16 (11.5%)	10 (7.2%)	0.047
CV death	15 (6.4%)	6 (2.6%)	0.017	9 (6.5%)	2 (1.4%)	0.049
CV readmission	73 (31.3%)	50 (21.6%)	0.031	49 (35.3%)	25 (18.0%)	0.016
CV death and CV readmission	88 (37.8%)	56 (24.0%)	0.004	58 (41.7%)	27 (19.4%)	0.006
All-cause death and CV readmission	101 (43.3%)	68 (29.4%)	0.003	65 (46.8%)	35 (25.2%)	0.01

confidence interval [CI] 1.177-2.235, p = 0.003; PS-matched: HR 1.722, 95% CI 1.138-2.604, p = 0.01) and age (entire: HR 1.028, 95% CI 1.013-1.043, p <0.001; PS-matched: HR 1.058, 95% CI 1.032-1.085, p <0.001) were predictive for the increased risk of composite event. In CAD group, coronary revascularization (n = 212) were associated with the improved risk of composite event (entire: HR 2.368, 95% CI 1.541-3.640, p <0.001; PS-matched: HR 3.631, 95% CI 2.018-6.531, p <0.001), with a similar composite event rate of no-CAD group (HR 0.942, 95% CI 0.669-1.326, p = 0.731). Additionally, the prescription of beta-blocker (HR 0.556, 95% CI 0.333-0.929, p = 0.025) and inhibitor of renin angiotensin system (HR 0.482, 95% CI 0.290-0.801, p = 0.005) were predictors of lower risk of composite event in CAD group.

Conclusions: CAD presented in approximately one-half of patients with HFmrEF and was associated with the unfavorable outcomes. However, coronary revascularization and optimal medical treatment could contribute to better outcomes in HFmrEF patients with CAD.



KM curve for composite event

The value of bioimpedance vector analysis in decompensated heart failure patients with mid-range ejection fraction

A Klimenko[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: Volume overload is the known main driver for morbidity, mortality and hospital readmission in patients with decompensation of heart failure (DHF). Acute kidney injury (AKI) occurs up to 70% in DHF. But the prevalence remains unclear in DHF patients with mid-range ejection fraction (DHFmrEF). Bioimpedance vector analysis (BIVA) is a non-invasive accurate technique for hydration status (HS) evaluation. The aim of the study was to evaluate HS in DHFmrEF patients by BIVA and clinical/ radiographic criteria and to determine the diagnostic and prognostic value of these methods.

Methods: in 65 patients admitted with DHFmrEF (53 male, 69 ± 9 years (M ± SD), arterial hypertension 94%, ischemic heart disease 63%, myocardial infarction 51%, atrial fibrillation 49%, diabetes mellitus 26%, known chronic kidney disease 51%, ejection fraction (EF) 44.7 ± 3.0%) HS was assessed by BIVA and clinical/ radiographic criteria. AKI was defined using 2012 KDIGO Guidelines. Mann-Whitney test was performed. P < 0.05 was considered statistically significant.

Results: In 88% overhydrated patients clinical evaluation corresponded to BIVA results (G1), 12% patients were overhydrated only by BIVA (G2). Patients G1 compared with patients G2 had more marked clinically presentation of systemic congestion: ascites (22 vs 0%, p < 0.01), Rg-hydrothorax 49 vs 0%, p < 0.001), echo-hydropericardium (28 vs 0%, p < 0.05), oedema (93 vs 50%, p < 0.01), bilateral crackels (79 vs 50%, p < 0.05). Patients G1 compared with patients G2 were older (71 ± 7 vs 57 ± 7 years, p < 0.01), lower EF (44 ± 2.0 vs 47 ± 0.5 %, p < 0.01), higher level of NT-proBNP (12515 ± 3319 vs 9145 ± 2618 fmol/ml, p < 0.05) and tendence to higher rate of prior HF hospitalizations (57 vs 50%,p>0.05). There was lower frequency of AKI in G1 (29 vs 50% in G2, p < 0.05), but all AKI in G2 was transient (100 vs 41%, p < 0.01). Patients G1 compared with patients G2 had higher rate of HF rehospitalization (14 vs 0%, p < 0.001) and 30-days mortality (9 vs 0%, p < 0.01).

Conclusions: In 88% of patients with DHFmrHF and overhydration clinical/ radiographic criteria corresponded to BIVA results, 12% patients were overhydrated by BIVA only. Patients with overhydration by BIVA only had less evident systemic congestion; AKI was more frequent but transient and was not associated with poor short-term and long-term outcomes. Hydration status evaluation by BIVA has no independent prognostic value in patients with DHFmrHF.

Left ventricular systolic dysfunction before planned surgical revascularization: "grey area" features

P964

O Yepanchintseva[1]; K Mikhaliev[2]; O Zharinov[3]
[1]*Heart Institute of the Ministry of Healthcare of Ukraine, Kiev, Ukraine*; [2]*State Scientific Institution "Scientific and Practical Center of Preventive and Clinical Medicine", Kiev, Ukraine*; [3]*National Medical Academy of Postgraduate Education, Kiev, Ukraine*

Background: Left ventricular (LV) ejection fraction (EF) is a key parameter for risk stratification and decision-making in the management of patients with coronary heart disease (CHD) and heart failure (HF), including myocardial revascularization. The heterogeneity of HF with mid-range LV EF (HFmrEF) determines the need to study the clinical profile of these patients, compared to patients with preserved and reduced LV EF.

Purpose: to study the clinical characteristics of patients with stable CHD and HFmrEF (LV EF 40-49%), selected for the planned coronary artery bypass grafting (CABG) in the real-life settings.

Methods. A cross-sectional one-center study included 622 consecutive patients with stable CHD (mean age [61 ± 9] yr, 526 [84,6%] males and 96 [15,4%] females), selected for planned CABG. We analyzed demographic, clinical, laboratory, echocardiographic and coronary angiographic data. The population of enrolled patients was stratified into three groups according to LVEF: group 1 (G1; LVEF = 50%, n = 350 [56,3%]); group 2 (G2; LVEF 40-49%, n = 115 [18,5%]); and group 3 (G3; LVEF < 40%, n = 157 [25,2%]).

Results: The G2 profile was similar to G1 by parameters, such as frequency of functional class IV angina and mild tricuspid regurgitation, the severity of heart failure and mitral regurgitation. At the same time, G2 and G3 were comparable by gender; the frequency of earlier ST-elevation myocardial infarction; baseline diuretics use; serum potassium and estimated glomerular filtration rate; the frequency of moderate-to-severe tricuspid regurgitation; the frequency of significant left anterior descendent artery stenosis. Parameters in G2, having intermediate values compared to G1 and G3, were (shown as G1 vs. G2. vs. G3): the frequency of baseline aldosterone antagonists administration (8,3%; 24,3% and 41,4%, respectively; pG1-G2 < 0,001; pG1-G3 < 0,001; pG2-G3 = 0,017); the frequency of patients without mitral (71,2%; 36,5% and 18,4%, respectively; p < 0,001) and tricuspid regurgitation (87,1%; 70,5% and 41,4% in , respectively; p < 0,001); the frequency of moderate-to-severe mitral regurgitation (4,5%; 13,0%; and 38,9%, respectively; p < 0,001); mean systolic pulmonary artery pressure (30 [28-36]; 35 [30-40]; and 43 [35-62] mm Hg, respectively; pG1-G2 = 0,003; pG1-G3 < 0,001; pG2-G3 < 0,001); the frequency of LV aneurysm at coronary ventriculography (4,6%; 27,8%; and 47,1%, respectively; pG1-G2 < 0,001; pG1-G3 < 0,001; pG2-G3 = 0,007).

Conclusion: The population of patients with CHD and HFmrEF, undergoing CABG in the real-life clinical practice settings, is associated with clinical heterogeneity by vast majority of parameters, which influence the decision to perform CABG. Further studies are needed to determine LVEF changes after CABG in these patients.

P965

Heart failure with mid-range ejection fraction: characteristics and outcome in patients with and without acute kidney injury

IR Lala[1]; DA Darabantiu[1]; A Pop-Moldovan[1]; RM Christodorescu[2]; M Puschita[1]
[1]*Vasile Goldis Western University, Cardiology, Arad, Romania*; [2]*University of Medicine Victor Babes, Timisoara, Romania*

Background: Worsening renal function during hospitalization is associated with increased mortality among patients with heart failure and reduced ejection fraction (HFrEF) however in patients with HF and mid range ejection fraction (HFmrEF) such information is lacking.

Purpose: To evaluate incidence and prognostic implications of acute kidney injury (AKI) during hospitalization in HFmrEF patients.

Methods: Of 556 consecutive patients with a primary diagnosis of acute heart failure included in our regional heart failure registry 2014-2016, we identified 144 with HFmrEF (EF 40-49%). Patients were divided into two groups: with or without AKI (defined as an increase of serum creatinine by = 0.3 mg/dl within 48 hours from admission). For statistical analysis we used independent t test for comparison of continuous values, Pearson x^2 test for comparison of categorical values, multivariate logistic regression, survival curves and Cox regression for predictors of in-hospital mortality.

Results: Mean age was 68 ± 11 years and 42% were female regardless of AKI development. The percentage of patients with AKI was 27%. The AKI group presented higher systolic blood pressures compared to the non-AKI group (161 ± 41mmHg vs 146 ± 32mmHg p = 0.038). Previous history of chronic kidney disease was more often described among patients with AKI (64% vs. 31% p = 0.001). Hyperglycemia and QRS length were predictive factors for AKI development during hospitalization (OR = 1.05, p = 0.009; OR = 1.01, p = 0.01). Patients with AKI had a significantly

worse survival profile during hospitalization (log-rank test, p = 0.014) and Cox proportional hazards modelling showed a crude HR = 4.7 (95%CI [1.5.-14], p < 0.007) for in-hospital mortality.
Conclusion: Within the current group of HFmrEF, AKI is quite often and these patients are more likely to have a history of Chronic Kidney Disease and Hypertension. Hyperglycemia is of predictive value for AKI development during hospitalization. AKI was linked with worse in-hospital survival rates, thus this information might be important for future HFmEF outcome studies.

P966
Mortality in patients with heart failure and midrange ejection fraction

A Antonio Xavier Fontes[1]; C Serena[1]; L Oliveira[1]; S Moura-Ferreira[1]; C Almeida[1]; C Machado[1]; R Dourado[1]; E Santos[1]; N Pelicano[1]; AM Pacheco[1]; A Tavares[1]; F Melo[1]; D Martins[1]
[1]Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal

Introduction: In 2016 the recommendations of the European Society of Cardiology introduced the concept of heart failure (HF) with mid-range leff ventricle ejection fraction (MREF) and suggested research by the scientific community around this concept, once patients (pts) shared characteristics of populations with reduced and preserved ejection fraction (EF). There is little data regarding mortality predictors in this population.
Objective: To identify predictors of mortality in patients with HF and MREF.
Methods: Retrospective study, which included 255 pts consecutively admitted to a center from January to December 2011, with the main diagnosis of decompensated HF. We performed 5 years follow-up. Clinical characteristics and exams results were evaluated. The binary logistic regression model was used to identify independent predictors of mortality.
Results: Of the 255 pts included, 87 (34.8%) presented MREF and 40 (45.9%) male gender. A complete follow-up time of 5 years was obtained in 98% of the cases, with a cumulative mortality of 50.0% in men and 55.3% in women (p = 0.620). Pts who died were an older population (73.6 ± 12.2 VS 63.5 ± 3.7 years old, p = 0.001), more cases of chronic kidney disease (69.7 VS 32.1%, p = 0.014), EF between 40-44% (67.4 VS 32.6%, p = 0.007) and with usual NYHA functional classes 2 or 3 (67.9% VS 32.1%, p < 0.001). They had higher levels of creatinine (1.41 (1.10-1.99) VS 1.04 (0.91-1.22 mg/dL, p < 0.001) and urea (60.5 (41.75-114.0) VS 45 (30.5-56.5) mg/dL, p = 0.001) and lower levels of hemoglobin (11.5 ± 2.0 VS 13.7 ± 1.8 g/dL, p = 0.001), hematocrit (35.2 ± 7.6 VS 42.2 ± 6.0%, p < 0.001) and sodium (135.7 ± 3.7 VS 137.7 ± 3.7mEq/L, p = 0.017). In terms of multivariate analysis the only independent predictor of mortality was the ejection fraction between 40-44% (OR = 4.5, 95% CI 1.31-15.53 p = 0.017).
Conclusion: Patients with HF and an episode of hospitalization due to decompensation present high mortality at 5 years. An EF between 40-44% was the independent predictor of mortality in pts at a 5-year follow-up.

P967
Impact of hypoalbuminemia in heart failure with preserved ejection fraction: a future therapeutic target?

M I Maria Ines Pires[1]; L Goncalves[1]; H Antunes[1]; J Gil[1]; L Abreu[1]; I Almeida[1]; J Costa Cabral[1]
[1]Hospital Sao Teotonio, Cardiology, Viseu, Portugal

Background: Hypoalbuminemia is common in heart failure (HF), particularly in elderly patients with multiple comorbidities, and is associated with a negative prognosis. This study aims to evaluate the impact of hypoalbuminemia in the prognosis of patients with heart failure with preserved ejection fraction (HFpEF).
Methods: All patients admitted for acute HFpEF between 2009 and 2015 in a Cardiology Department were enrolled in this study. Patients with cardiogenic shock were excluded from the analysis. Hypoalbuminemia was defined by serum albumin concentration < 3.5 g/dL. In-hospital mortality and mortality at 3, 6, 12, 18 and 24 months after discharge were assessed. Chi-square and Mann-Whitney U tests were used for group comparisons; survival analysis used Kaplan-Meier curves and log-rank tests; and predictors of mortality were assessed with logistic regression analysis.
Results: 473 patients were included in the study. Mean patient age was 79.4 ± 8.3 years, and 38.7% were male. Hypoalbuminemia occurred in 102 (21.6%) patients, and was associated with greater in-hospital mortality (53.3% vs. 46.7%; ?2 = 9.24; p = 0.002). In survival analysis, there was greater mortality in hypoalbuminemic patients in the follow up at 3 months (9.3% vs. 2.4%; ?2 = 8.10; p = 0.004), 6 months (14.9% vs. 6.6%; ?2 = 5.37; p = 0.020), 12 months (19.2% vs. 10.1%; ?2 = 4.03; p = 0.045), 18 months (21.1% vs. 11.1%; ?2 = 4.33; p = 0.037) and 24 months (23.2% vs. 11.5%; ?2 = 5.96; p = 0.015) after discharge. Univariate logistic regression identified the following predictors of in-hospital mortality: hypoalbuminemia (OR 4.426; 95% CI 1.565-12.513; p = 0.005), female gender (OR 9.232; 95% CI 1.204-70.812; p = 0.032), hemoglobin (OR 0.765; 95% CI 0.586-0.998; p = 0.048), urea (OR 1.013; 95% CI 1.001-1.026; p = 0.029), and B-type blood natriuretic peptide (OR 1.000; 95% CI 1.000-1.001; p = 0.035). At multivariate analysis hypoalbuminemia (OR 5.098; 95% CI 1.518-17.128; p = 0.008) and female gender (OR 11.396; 95% CI 1.352-96.031; p = 0.025) were the only independent predictors of in-hospital mortality. Hypoalbuminemia was also a predictor of 24 month-mortality (OR 2.314; 95% CI 1.189-4.507; p = 0.014), and in multivariate analysis was an independent predictor of worse survival at 24 months (OR 3.439; 95% CI 0.981-12.049; p = 0.05).
Conclusion: In this study, hypoalbuminemia was associated with greater in-hospital mortality as well as worse prognosis in the 24-month follow up, in patients with acute HFpEF. It was also an independent predictor of in-hospital and 24-month mortality. Since there are no disease-modifying therapies available for HFpEF and treatment of comorbidities has an important role in the management of these patients, in the future, albumin replacement treatment may arise as an option to reduce mortality in this subgroup of HF patients.

P968
Improvement in quality of life in patients with hereditary transthyretin amyloidosis with polyneuropathy and cardiomyopathy treated with inotersen in the phase 3 study NEURO-TTR

T Thibaud Damy[1]; M Maurer[2]; S Heitner[3]; B Drachman[4]; C Whelan[5]; D Judge[6]; S Guthrie[7]; L Tai[7]; S Hughes[7]; B Monia[7]; E Ackermann[7]; M Benson[8]

Funding Acknowledgements: Ionis Pharmaceuticals, Carlsbad, CA

Introduction: Hereditary transthyretin (TTR) amyloidosis (hATTR) is a rare, progressive, and fatal disease. The disease is caused by misfolded TTR that builds up as amyloid in major organ systems, especially cardiac tissue and nerves, causing cardiomyopathy (CM) and polyneuropathy (PN), respectively. hATTR causes significant morbidity and a progressive decline in patient quality of life (QOL), severely limiting activities of daily living.
Purpose: To evaluate the effect of inotersen, an antisense oligonucleotide inhibitor of TTR protein production, on QOL of patients with hATTR with CM and PN.
Methods: NEURO-TTR (NCT01737398) is a global, randomised, double-blind, placebo-controlled phase 3 study. Adults (n = 172) with hATTR-PN (stage 1 or 2) with or without CM were randomly assigned 2:1 and received 300-mg weekly subcutaneous inotersen or placebo for 15 months. CM was defined as diagnosis of hATTR-CM or = 1.3 cm interventricular septum thickness (by echocardiography) at baseline. Primary endpoints were change from baseline to week 66 in Norfolk Quality of Life–Diabetic Neuropathy (Norfolk QOL-DN) total score and the modified Neuropathy Impairment Score+7 (mNIS+7). The Optum SF-36v2 Health Survey (SF-36v2) score was an exploratory outcome.
Results: At baseline, 69% of patients were male, mean age was 59 years (range, 27-81 years) and 63% (108/172) had CM. Of patients given placebo and inotersen, 55% (33/60) and 67% (75/112), respectively, had CM. Patients with CM had higher baseline mNIS+7 scores (higher scores indicate worse neuropathy), higher Norfolk QOL-DN total scores (higher scores indicate worse QOL) and lower SF-36v2 physical component summary scores (lower scores indicate worse QOL) than patients without CM. Inotersen-treated patients achieved highly statistically significant benefit compared with placebo in Norfolk QOL-DN total score (P = 0.0006) and mNIS+7 (P < 0.0001), irrespective of CM status. In patients with CM, inotersen treatment demonstrated significant improvement compared with placebo in Norfolk QOL-DN total score (P = 0.036) and the physical component summary score of SF-36v2 (P = 0.025). Most adverse events were mild or moderate. Key safety findings of thrombocytopenia and renal events were monitorable and manageable.
Conclusion: Significant improvement in Norfolk QOL-DN and SF-36v2 scores, which include several domains related to patient well-being and activities of daily living, suggest that inotersen improves the QOL of patients with hATTR-PN with CM, the hATTR population with the greatest disease burden.

P969
Impact of gender on the association between diastolic function and left atrial strain in atrial fibrillation patients with preserved ejection fraction

A Shavarov[1]; E Kokhan[2]; G Kiyakbaev[1]; Z Kobalava[1]
[1]RUDN University, Moscow, Russian Federation; *[2]Lomonosov Moscow State University, Moscow, Russian Federation*

Background: Diastolic dysfunction (DD) is one of the main causes of structural and functional changes of the left atrium (LA) that are substrate for atrial fibrillation (AF). Some studies have found that the rate of DD is higher in women compared to men. However, the influence of gender on the association between diastolic function and LA remodeling is yet to be established.
Purpose: We aimed to investigate the influence of gender on the relationship between left ventricle (LV) diastolic function parameters and LA strain in patients with AF and preserved ejection fraction.
Methods: Twenty seven men and 28 women (median age of 65 [60;72]) with recurrent non-valvular AF and mild to moderate DD were enrolled in the study. All patients had preserved LV ejection fraction (<50%). Beyond conventional echocardiographic protocol, global peak LA longitudinal strain (PALS, %) in the reservoir (r) and contractile (c) phases was measured using two-dimensional speckle tracking echocardiography. We used the diastolic index [(E/E')/LV-end diastolic volume] as a measure for LV stiffness.
Results: There were no significant differences in LA structural and functional parameters between men and women. However, despite the similar number of patients with E/E'>14 in both groups (9 vs 10 pts in men and women, respectively; p = 0.99), the medians of LV diastolic function parameters were worse in women than in men: E/E' (13 vs 11.2; p = 0.03) and diastolic index (0.13 vs 0.09 ml-1; p = 0.001). Women, but not men, had significant association between diastolic index and LA size (r = 0.52; p = 0.005 vs r=-0.32; p = 0.14, respectively); PALSr (r=-0.53; p = 0.004 vs r=-0.1; p = 0.62, respectively); PALSc (r = 0.51; p = 0.005 vs r=-0.1; p = 0.65, respectively); p for all interactions < 0.05.
Conclusion: A greater impairment of LV diastolic function was significantly associated with worsening of LA strain in the reservoir and contractile phases in women only. It could indicate a higher susceptibility of the women's LA to increased hemodynamic overload caused by DD.

P970

Effect of inspiratory muscle training on functional capacity in patients with heart failure with preserved ejection fraction: does baseline inspiratory muscle function matters?

P Palau Sampio[1]; E Dominguez[1]; JM Ramon[2]; L Lopez[2]; E Santas[2]; A Mollar[2]; E Valero[2]; J Melero[1]; JP Tormo[1]; A Briatore[1]; A Bellver[1]; FJ Chorro[2]; J Sanchis[2]; J Nunez[2]
[1]Hospital General de Castellón. Universitat Jaume I, Cardiology Department, Castellón, Spain; [2]Cardiology Departament, Hospital Clínic Universitari de Valencia, Valencia, Spain

Background: Heart failure with preserved ejection fraction (HFpEF) is a clinical syndrome characterized by severely impaired exercise capacity. Some evidence has shown that simple and home-based program of inspiratory muscle training (IMT) offers promising results in terms of functional capacity improvement. However, whether this effect is only limited to patients with inspiratory muscle weakness it is a matter of debate.
Purpose: We sought to evaluate whether the baseline inspiratory muscle function predicts the changes in peak oxygen uptake (peakVO2) after a program of IMT in HFpEF.
Methods and Results: A total of 45 stable symptomatic patients with HFpEF and NYHA II-III receive a 12-week home-based program of IMT between June 2012 and May 2016. They underwent a cardiopulmonary exercise test pre- and post-training and serial measurements of maximum inspiratory pressure (MIP) and peakVO2 were registered. Inspiratory muscle weakness (IMW) was defined as maximum inspiratory pressure (MIP) < 70% of normal predicted values. Multivariate linear regression analysis was used to assess the association between changes in peakVO2 (?-peakVO2) and baseline predicted MIP (pp-MIP).

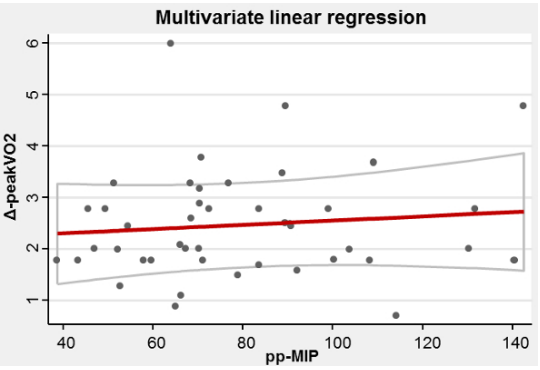

Figure 1

Mean (SD) age was 71.4 ± 9.7 years, 53.3% were women, and 35.1% displayed NYHA III. The mean peakVO2 and pp-?-peak VO2 were 10.4 ± 2.8 ml/min/kg and +2.2 ± 1.3 ml/min/kg (+21.3%), respectively. The median (IQR) of pp-MIP and ?-MIP were 71% (64-92) and 39.2 (26.7-80.4) cmH2O, respectively. After a multivariate analysis, baseline pp-MIP remained not associated with ?-peakVO2 (ß coefficient = 0.004, CI 95%: -0.009-0.017, p = 0.529) and is shown in figure 1.
Conclusions: In symptomatic and de-conditioned elderly patients with HFpEF, IMT offers an alternative to exercise training that improves maximal functional capacity regardless of baseline MIP.

Potential usefulness of diastolic stress-test echocardiography in patients with suspicion of heart failure with preserved ejection fraction - a pilot study

E Belyavskiy[1]; DA Morris[1]; M Url-Michitsch[2]; N Verheyen[2]; AK Radha Krishnan[1]; A Frydas[1]; F Huang[1]; M Kropf[1]; R Lindhorst[1]; A Bobenko[1]; M Tadic[1]; C Tschoepe[1]; F Edelmann[1]; E Pieske-Kraigher[1]; B Pieske[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Department of Internal Medicine and Cardiology, Charité - Universitätsmedizin Berlin, Berlin, Germany; [2]Medical University of Graz, Department of Cardiology, Graz, Austria

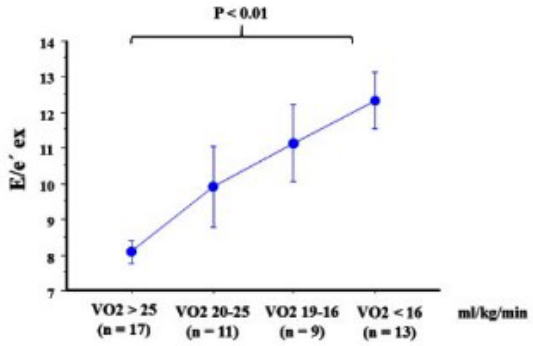
Funding Acknowledgements: Evgeny Belyavskiy received the HFA/ESC Grant

Aim: The purpose of this pilot study was to assess the potential usefulness of diastolic stress test echocardiography (DST) in patients with suspicion of heart failure with preserved ejection fraction (HFpEF).
Methods: Patients with suspicion of HFpEF (undetermined dyspnea NYHA class I-II, septal E/e' at rest 9 - 14, and NT-proBNP at rest < 220 pg/ml; n = 13) and a control group constituted by asymptomatic patients with arterial hypertension (HT) (n = 19) and healthy subjects (n = 18) were included. All patients were analyzed by 2D and Doppler echocardiography at rest and during exercise (DST) and underwent cardiopulmonary exercise test and NT-proBNP analysis during exercise. HFpEF during exercise was defined as exertional dyspnea and peak VO2 = 20.0 ml/kg/min.
Results: In patients with suspicion of HFpEF at rest, 84.6% of these patients developed HFpEF during exercise, whereas in the group of asymptomatic patients with HT and healthy subjects the rate of developed of HFpEF during exercise was 0%. Regarding the diagnostic performance of DST to detect HFpEF during exercise, an E/e' ratio > 15 during exercise was the most accurate parameter to detect HFpEF (accuracy 86%), albeit a low sensitivity (45.5%). Nonetheless, combining E/e' with tricuspid regurgitation (TR) velocity during exercise provided a significant increase in the sensitivity to detect patients with HFpEF during exercise (sensitivity 72.7%,

Diagnostic Performance of DST

Variable	Sensitivity	Specificity	VPP	VPN	Accuracy
E/e´> 15 or TR > 2.8 m/s during exercis	72.7%	79.5%	50%	91.2%	78%
E/e´> 15 during exercise alone	45.5%	97.4%	83.3%	86.3%	86%
TR > 2.8 m/s during exercise alone	36.4%	79.5%	33.3%	81.6%	70%
No increase of SV during exercise	9.1%	97.4%	50%	79.1%	78%
NT-proBNP during exercise > 125 pg/ml	36.4%	89.7%	50%	83.3%	78%
NT-proBNP during exercise > 220 pg/ml	18.2%	97.4%	66.7%	80.8%	80%

DST - diastolic stress test; VPP - positive predictive value, VPN - negative predictive value, TR-tricuspid regurgitation velocity, SV-stroke volume



Association of E/e' with peak VO2

specificity 79.5%, and accuracy 78%).In line with these findings, an increase of E/e' was significantly linked to worse peak VO2 and the combination of an increase of E/e' and TR velocity with elevated NT-proBNP values during exercise

Conclusion: The findings of this pilot study suggest that diastolic stress test using E/e' ratio and TR velocity could be of great usefulness to diagnose HFpEF during exercise in patients with suspicion of HFpEF at rest.

P972

Design and rationale of the EMPagliflozin outcomE tRial in patients with chrOnic heaRt failure (EMPEROR-Preserved)

J Butler[1]; M Packer[2]; G Filippatos[3]; F Zannad[4]; A Salsali[5]; K Kimura[6]; J Schnee[5]; C Zeller[7]; S Pocock[8]; J George[9]; M Brueckmann[9]; S D Anker[10]

[1]Stony Brook University Medical Center, Medicine, Stony Brook, United States of America; *[2]Baylor Heart and Vascular Institute, Dallas, United States of America*; *[3]University of Athens, Athens, Greece*; *[4]Institut Lorrain du Coeur et des Vaisseaux, Nancy, France*; *[5]Boehringer Ingelheim Pharmaceuticals, Ridgefield, United States of America*; *[6]Boehringer Ingelheim Canada Ltd., Burlington, Canada*; *[7]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany*; *[8]London School of Hygiene and Tropical Medicine, London, United Kingdom*; *[9]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany*; *[10]Charité - Universitätsmedizin Berlin, Berlin, Germany*

Background and aims: Heart Failure with preserved ejection fraction (HFpEF) increasingly contributes to heart failure (HF) hospitalizations with outcomes as poor as in patients with HF and reduced ejection fraction (HFrEF), and there is no evidence-based therapy for HFpEF patients. In the EMPA-REG OUTCOME trial, the sodium-glucose co-transporter-2 (SGLT-2) empaglifozin reduced the risk of cardiovascular (CV) mortality by 38% and the risk of HF hospitalizations by 35% in patients with type 2 diabetes mellitus (T2DM) and established cardiovascular disease. Several mechanisms have been put forward to explain these benefits, which may go beyond the blood glucose lowering effect of empaglifozin. This raises the possibility of using empagliflozin as treatment for patients with established HF regardless of the presence or absence of diabetes.

Methods: The phase III randomized, double-blind EMPEROR-Preserved trial will explore the efficacy and safety of once daily empagliflozin 10 mg compared to placebo, in patients with chronic HFpEF with left ventricular ejection fraction (EF) > 40%. Patients are required to have elevated NT-proBNP levels (< 300 pg/ml for patients without atrial fibrillation (AF), or > 900 pg/ml for patients with AF), and structural heart disease or documented hospitalisation for HF within 12 months. The composite primary endpoint for this trial is the time to first adjudicated CV death or HHF. Approximately 4130 patients are planned to be randomized. The number of patients in this event-driven trial may be increased based on a blinded assessment of the primary event rate. The incidence of adjudicated HHF (first and recurrent) and the renal outcome of eGFR slope of change from baseline are key secondary endpoints.

Perspectives: As yet, EMPEROR-Preserved is the only phase III outcome study to evaluate an SGLT-2 inhibitor in patients with chronic HFpEF. Together with the EMPEROR-Reduced study, which is evaluating empaglifozin in patients with reduced ejection fraction (EF= 40%), these trials are expected to deliver conclusive insights regarding the value of empagliflozin treatment for patients with HF.

P973

Independent predictors of sudden cardiac death in patients with ischemic chronic heart failure with preserved ejection fraction and renal dysfunction

D Dmytro Lashkul[1]

[1]Zaporizhzhya State Medical University, Zaporizhzhya, Ukraine

The aim of the study was to determine the independent predictors of sudden cardiac death in patients with ischemic chronic heart failure (CHF) with preserved ejection fraction (EF) and renal dysfunction.

Materials and methods: The study included 243 patients (200 (80.3%) men) with (CHF), with an average age of 58.7 ± 9.3 years. CHF was diagnosed according to the Recommendations (2012) of the Association of Cardiologists of Ukraine, preserved EF were determined at EF>45%. The etiology of CHF: in 221 (90.9%) patients was a combination of coronary heart disease (CHD) and arterial hypertension, in 22 (9.1%) - CHD. II functional class (FC) was diagnosed in 112 (46.1%), III FC - 126 (51.8%), IV FC - 5 (2.1%), prior myocardial infarction in 165 (67.9%) patients. The glomerular filtration rate (GFR) was calculated according to the MDRD formula. Echocardiography was performed on ultrasound scanner GE VIVID 3 PRO EXPERT (USA). Primary endpoint: events of sudden cardiac death registered within 3 years after the signing of informed consent. To study the predictive value of the indicators the Receiver operating characteristic analysis, univariate and multivariate Cox's regression analysis was performed. The log rank test was used to compare different strata in Kaplan-Meier analyses of survival.

Results: As a result of the univariate analysis of Cox proportional risks, there are associated risk factors that have a reliable prognostic value for the risk of developing a three-year mortality in patients with ischemic CHF with preserved EF and renal dysfunction: matrix metalloproteinase-9 (odds ratio [OR] 12.66; 95% confidence interval [95% CI] 1.32-120.7; p = 0.02), age (OR 13.32; 95% CI 4.79-37.01; p < 0.0001), LV mass index (OR 5.61; 95% CI 1.79-17.54; p = 0.003), right ventricular pressure (RVPs) (OR 10.4; 95% CI 1.29-83.9; p = 0.02); Borg scale (OR 7.64; 95% CI 2.16-26.94, p = 0.001), GFR (OR 8.09; 95% CI 2.29-28.55, p = 0.001), creatinine (OR 6.38; 95% CI 1.81-22.50, p = 0.004), heart rate (OR 3,8; 95% CI, 1.38-10.43, p = 0.009), NTproBNP (OR 26.9; 95% CI 2.38-305.9; p = 0.008), LV end-diastolic size (OR 10,24; 95% CI 1.36-77.14; p = 0.02), LV end-diastolic volume (OR 3.71; 95% CI 1.34-10.23; p = 0.01). According to the results of the multivariate Cox regression analysis it was found that with the excess of the optimal distribution point for MMP-9 (<11.19 ng/ml), the risk of developing a three-year mortality in ischemic CHF patients with preserved EF and renal dysfunction significantly increases (hazard ratio [HR] 11.58; 95% CI 21-110.39; p = 0.03), age>72 years (HR 4.55; 95% CI 1.02-20.21; p = 0.04), LV mass index > 144 g/m2 (HR 5.18; 95% CI 0.99-27.07; p = 0.05), RVPs >27.3 mm Hg (HR 7,82; 95% CI 0.91-67.9; p = 0.05).

Conclusions: The level of MMP-9, age, LV mass index and RVPs in patients with ischemic chronic heart failure with preserved EF and renal dysfunction are independent predictors of the risk of sudden cardiac death during long-term follow-up.

P974

Rationale, design and methodology of the APOLLON trial: A population-based, observational registry of heart failure with mid-range and preserved ejection fraction

B Bulent Ozlek[1]; E Ozlek[1]; M Biteker[1]

[1] Sitki Koçman Universty, School of Medicine, Cardiology, Mugla, Turkey

On behalf of: APOLLON investigators

Objective: Although almost half of patients with chronic heart failure (HF) have mid-range (HFmrEF) and preserved left-ventricular ejection fraction (HFpEF), there have been no studies carried out with these patients in our country. This study aims to determine the demographic characteristics and current status of the clinical background of HFmrEF and HFpEF patients in a large, multicenter nationwide trial.

Methods: The APOLLON trial (A POpuLation-based, ObservationaL Registry Of Heart Failure with Mid-range and Preserved EjectioN Fraction) will be an observational, multicenter, and non-interventional study conducted in Turkey. The study population will include 1065 patients from 10 sites in Turkey. All the data will be collected at one point in time and current clinical practice will be evaluated (ClinicalTrials.gov number NCT03026114).

Results: We will enroll all consecutive patients admitted to the cardiology clinics from January 30, 2018, through April 31, 2018, who were at least 18 years of age and had New York Heart Association class II, III, or IV HF, elevated natriuretic peptides within last 30 days, and an left ventricular ejection fraction (LVEF) of at least 40%. Patients will be stratified into two categories according to LVEF: mid-range EF (HFmrEF, LVEF 40-49%), and preserved EF (HFpEF, LVEF = 50%). Exclusion criteria included; an alternative probable cause of the patient's symptoms (e.g., significant pulmonary disease), any LVEF below 40%, a history of acute coronary syndrome, coronary revascularization, or stroke within the previous 3 months, primary hemodynamically significant uncorrected valvular heart disease,

percutaneous or surgically corrected valvular disease (e.g., mechanical or biological prosthetic valves), hypertrophic or restrictive cardiomyopathy, pericardial disease; cor pulmonale or other cause of isolated right heart failure, pregnancy, patients with congenital heart diseases and heart transplant recipients. Regional quota sampling will be performed to ensure that the sample was representative of the Turkish population. Demographic, lifestyle, medical and therapeutic data will be collected by this specific survey.
Conclusions: APOLLON registry will be the largest and most comprehensive study in Turkey evaluating HF patients with a LVEF= 40%, and also will be the first study specifically analysing recently designated HFmrEF category.

P975
What influences exercise capacity in male and female with heart failure and preserved ejection fraction of left ventricle?

KI Cherniaieva[1]
[1]*National O.O. Bohomolets Medical University, Department Internal Medicine, Kiev, Ukraine*

The evaluation of the ability of an individual to perform exercise appears to be one of the strongest criteria of patient's subjective and objective well-being. However, factors observed in patients with HFpEF that alter exercise capacity are not unified and can be different dependently on gender.
Purpose: To reveal the link between echocardiographic parameters or laboratory tests and the results of 6-minute walk test n male and female with HFpEF, paying the most attention at diastolic function of left ventricle (LV).
Materials and methods. We consequently enrolled 54 patients with signs and symptoms of chronic HF II and III class NYHA at the moment of admission. Transthoracic 2D Echocardiography and tissue Doppler were performed to confirm LV diastolic dysfunction (criteria: LV ejection fraction (LVEF)>45%, left atrium diameter (dLA)>40 mm, LVMI >115 g/m^2 , E/e'>13). Plasma NT-proBNP level was evaluated to establish HFpEF; arterial elastance (Ea) and ventricular elastance (Ees) were calculated. 6-minute walk test was performed according to "ATS Statement: Guidelines for the Six-Minute Walk Test". Patients with proven coronary artery diseases were not included.
Results: 28 women and 26 men were examined. Groups didn't differ in age (f-71 ± 7,6 vs m-67,3 ± 12,1) and body mass index (BMI) (f-31,5 ± 4,9 vs m-29,9 ± 5,4), all p>0,05. The correlation analysis revealed an inverse correlation between the LA volume index (LAVI) (f-40,9 ± 6,3; m-42,7 ± 6,9), E/e' (f-15,1 ± 2,4; m-14,9 ± 1,5), mean pulmonary artery pressure (MPAP) (f-44,6 ± 13,3; m-38,2 ± 11,7), plasma NT-proBNP (f-595,5 ± 430,6; m-673,9 ± 428,3) level and distance of 6MW (f-362,5 ± 65,2; m-433,1 ± 102,3) in both groups of patients; between the right ventricle diameter (dRV) (2,9 ± 0,6), Ea (2,1 ± 0,5) and the distance of 6MW in women; between the age and the distance of 6MW in male. Results are shown in the table.
Conclusions: Such parameters as LAVI, MPAP, E/e', NT-proBNP correlates significantly with the results of 6MW test independently on gender. Correlation between age and 6MW distance in men can probably be associated with multiple comorbidities that are added with age. In women, correlation between dRV and Ea can be determined by mechanisms that provide a female-specific cardiovascular aetiology in HFpEF, but still it has to be clarified.

Correlation with 6MW test results

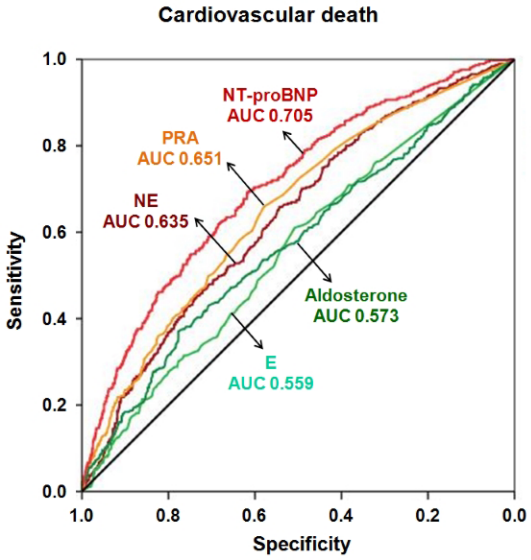
Groups	Parameters						
LAVI	E/e'	MPAP	NT-proBNP	dRV	Ea	Age	
Female (n = 28)	R=-0,541	R=-0,471	R=-0,684	R=-0,719	N/C	N/C	R=-0,479
Male (n = 26)	R=-0,687	R=-0,677	R=-0,637	R=-0,768	R=-0,524	R= -0,512	N/C

N/C - no correlation; in all cases p < 0,005

P976
Norepinephrine, plasma renin activity and prognosis in chronic systolic heart failure

A Alberto Aimo[1]; G Vergaro[2]; C Passino[1]; M Emdin[1]
[1]*Sant'Anna School of Advanced Studies, Pisa, Italy*; [2]*Gabriele Monasterio Foundation, Pisa, Italy*

Background: The demonstration of sympathetic and renin-angiotensin-aldosterone system activation in systolic heart failure (HF), and its negative prognostic impact, changed our understanding of HF pathophysiology and our therapeutic approach. Little is known on neurohormonal function in contemporary cohorts of HF patients.
Methods: Data from 1477 consecutive outpatients with systolic HF (LVEF < 50%) assessed from 1999 to 2016 were retrieved. Norepinephrine (NE), epinephrine (E), plasma renin activity (PRA), aldosterone, and N-terminal fraction of pro-B-type natriuretic peptide (NT-proBNP) were evaluated as predictors of cardiovascular death.
Results: Patients were aged 66 ± 13 years, 75% were men, and 44% had non-ischemic HF. Median
left ventricular ejection fraction (LVEF) was 32% (interquartile interval 25-38%). At the time of sampling, 69% of patients were on BB, 75% on ACEi/ARB, and 48% on MRA, versus 88%, 87%, and 66%, respectively, after therapy optimization during the same visit. Median values of NE, E, PRA, aldosterone, and NT-proBNP were 494 ng/L, 30 ng/L, 1.2 ng/mL/h, 130 ng/dL, and 1441 ng/L, respectively.
Over a median 4.8-year follow-up (2.4-8.2 years), 376 patients (26%) experienced cardiovascular death. The best cut-offs were 487 ng/L NE, 29 ng/L E, 1.2 ng/mL/h PRA, 200 ng/dL aldosterone, and 1645 ng/L NT-proBNP. The risk of cardiovascular death increased almost exponentially with the number of neurohormones equal or above cut-offs. All the neurohormones were univariate predictors of cardiovascular death. In prognostic model including age, ischemic etiology, estimated glomerular filtration rate (eGFR), LVEF, diabetes and chronic obstructive pulmonary disease, both NT-proBNP (hazard ratio - HR 1.36, 95% confidence interval - CI 1.25-1.49) and PRA (HR 1.22, 95% CI 1.14-1.31) were independent predictors of cardiovascular death. Also the 1.2 ng/mL/h PRA cut-off held independent prognostic value. Adding either absolute PRA levels or the PRA cut-off to a prognostic model including age, ischemic etiology, eGFR, LVEF, diabetes, chronic obstructive pulmonary disease, and NT-proBNP improved both discrimination and reclassification.
Conclusions: Circulating PRA and NE hold prognostic significance for cardiovascular death, although only PRA is independent predictor in a model including NT-proBNP. These assays deserve consideration as further tools for risk stratification in this patient population.



P977
Clinical outcome and prognosis in patient with acute heart failure

A Ashok Tahilyani[1]
[1]*Tan Tock Seng hospital, Cardiology , Singapore, Singapore*

Introduction: Acute pulmonary oedema (APO) is a potentially life-threatening condition, characterized by dyspnoea and is a frequent cause for recurrent hospitalisation. Many of the published series of patients with APO are historical and offer only descriptive data on highly selected patients following presentation with acute myocardial infarction. There is therefore an important paucity of data indicating the prognosis of this condition and limited data describing the spectrum of APO in the broader population. Moreover, little is known about the functional status of such patients and even less about their potential for rehabilitation.
Objective: To provide a description of clinical factors and outcomes in an unselected series of patients presenting with APO
Methods: A total of 921 patients were selected who were admitted under heart failure services in 2015 at Tan Tock Seng hospital, Singapore. All admissions with

primary cause of dyspnoea had their case records and chest radiograph/ TTE, and are identify as appropriate patients and were chosen for study.
Approval for this study was sought from our national health group domain specific review board Singapore.
Result: We followed these patient for 14 months +/- 8 months. The total mortality was 194 patients (21.06%) during the study period. Predictors for mortality were low EF (<35%) with high pulmonary artery systolic pressure (> 40mmHg) in the setting of AMI, sepsis and out of hospital collapse. Out of 921 patients enrolled in study, 38 died in 1 yr. Patient with EF of <25% have high mortality rate in year time. The commonest cause of admission for patient with pre-existing poor EF is non-compliance to fluid restriction and medication, Followed by Atrial fibrillation, IHD, Hypertensive urgency, and others.
Conclusion: The outlook of APO in the present era remains substantial but may have improved from historical series. According to previous studies published in acute medicine journal and EHJ on long term survival of acute of acute pulmonary oedema, the mortality rate has noted to be significantly lower in our study group. It is unclear as of now the exact cause of significantly improved mortality over period of time. However, its presumed to be the early revascularisation, increase awareness of fluid restriction and life style modification.

P978

Difference in n-terminal pro-b-type natriuretic peptide (NT-proBNP) levels in patients with heart failure with preserved ejection fraction (HFpEF) and non-cardiac comorbidity

KI Cherniaieva[1]
[1]*National O.O. Bohomolets Medical University, Department Internal Medicine, Kiev, Ukraine*

Multiple studies have already revealed a direct link between non-cardiac comorbidities and the development of HFpEF, emphasizing that it is challenging to assess how significant is a role of the comorbidities and their combinations in elevation of plasma NT-proBNP levels.
Purpose: To estimate the difference between NT-proBNP values in patients with HFpEF, who have one or more concomitant non-cardiac diseases diagnosed prior or during hospitalization, or doesn't have any of them.
Materials and methods. We enrolled 80 hemodynamically stable patients with HFpEF, confirmed clinically (signs and symptoms), instrumentally (echocardiography with careful evaluation of left ventricle diastolic function) and laboratory (elevated plasma NT-proBNP level). After additional examination (plasma levels of glucose and HbAc1, hemoglobin, ferritin, GFR, calculated by CKD-EPI and spirometry) patients were divided into 4 groups: with 1, 2 or 3 and more concomitant non-cardiac diseases, or without them.
Results: Non-cardiac comorbidity was present in 57 (71,25%) patients. Group 1 included 22 patients (27,5%), Group 2 - 12 (15%), Group 3 - 23 (28,75%) and Group 4 - 13 (16,25%). They didn't differ in age (63,2 ± 10,9 vs 63 ± 6,9 vs 69,9 ± 6,6 and 65 ± 7,7 years), gender (12 (54,5%) vs 7 (58,3%) vs 10 (43,5%) and 8 (61,5%) males) and body mass index (30,9 ± 4,3 vs 28,1 ± 1,9 vs 30,9 ± 4,1 and 28,8 ± 2,7); all p>0,05. Plasma NT-pro-BNP levels are demonstrated in the table. The revealed comorbidities distributed following way: type 1 diabetes mellitus – 23 (28,75%) patients, anemia - 16 (20%) patients, chronic renal impairment - 34 (42,5%), ventilation disorders (obstructive, restrictive and combined) - 29 (36,25%).
Conclusions: Benefits of using comorbidity-oriented approach to assessment of patients with HFpEF can be proven by statistically important difference in mean NT-proBNP levels between groups of patients with concomitant non-cardiac diseases and a group with none of them. Combination of non-cardiac comorbidities, when 3 or more are present, can cause higher levels of NT-proBNP.

NT-proBNP levels in groups of patients

	Gr1 (n = 22) M±m	Gr2 (n = 12) M±m	Gr3 (n = 23) M±m	Gr4 (n = 13) M±m
NT-proBNP	420,6±231,6*	615,4±323**	947,4±402,9***	287,4±132,2

*p < 0,001 compared to group 3; **p = 0,012 compared to group 4; ***p < 0,001 compared to group 4.

Chronic Heart Failure - Epidemiology, Prognosis, Outcome

On behalf of: ASIAN-HF Investigators
Funding Acknowledgements: National Medical Research Council (Singapore); A*STAR Biomedical Research Council; Boston Scientific; Bayer

Background: Resting heart rate (HR) is an important prognostic marker for patients with heart failure (HF) and reduced ejection fraction (HFrEF) who are in sinus rhythm (SR). However, survival benefits in patients with preserved ejection fraction (HFpEF) or atrial fibrillation (AF) remain unclear.
Purpose: To determine if low resting HR reduced mortality or HF hospitalisations for patients with HF; and if ejection fraction (EF) or rhythm status modified this relationship.
Methods: We included patients with HFrEF (EF < 40%) or HFpEF (EF = 50%) from 11 Asian regions in the prospective multi-national ASIAN-HF study. Baseline clinical characteristics including resting HR (measured in beats per minute, bpm), comorbidities and usage of guideline recommended pharmacological agents were obtained. HR control was categorised into low (< 80 bpm) versus high (= 80 bpm). Patients with AF were identified from either a history of AF or baseline electrocardiography (ECG) showing AF rhythm. Patients in SR were defined as those without a history of AF and who were in SR on baseline ECG. Patients were followed for the primary composite outcome of all-cause mortality or first HF hospitalisation.
Results: A total of 6405 patients (mean age 62 ± 13 years, 73% male, 82% HFrEF) were studied. Majority had ischaemic aetiology of HF (54%) and were in New York Heart Association (NYHA) classes I-II (60%). Mean baseline HR was 79 ± 16 bpm, with 3542 (55%) and 2863 (45%) patients having low and high resting HR respectively. A total of 4076 (64%) patients were in SR while 1370 (21%) had AF; with similar HR control between both groups (SR vs AF, 79 ± 15 bpm vs 79 ± 18 bpm, p = 0.431). Patients with low resting HR were more likely to be older (63 vs 60 years, p < 0.001), have HFpEF (vs HFrEF, 21% vs 15%, p < 0.001), lower NYHA class (I-II vs III-IV, 72% vs 60%, p < 0.001) and on beta-blockers (80% vs 70%, p < 0.001). The primary outcome occurred in 1613 (25%) patients over a median follow-up period of 392 days. When adjusted for baseline clinical characteristics, comorbidities and HF medication (including beta-blocker) usage, a high (vs low) resting HR was associated with worse outcomes (adjusted HR = 1.18, 95% CI 1.06-1.31). This was irrespective of aetiology of HR (ischemic vs non-ischemic, p-interaction = 0.937), EF (reduced vs preserved, p-interaction = 0.107) or beta-blocker usage (p-interaction = 0.515). However, low (vs high) resting HR control conferred survival benefits mainly for patients in SR (adjusted HR = 0.78, 98% CI 0.68-0.90) but not for patients in AF (adjusted HR = 1.10, 95% CI 0.88 - 1.37) (p-interaction = 0.001) (Figure 1). Beta-blockers reduced the primary outcome (adjusted HR = 0.83, 95% CI 0.72-0.95) regardless of rhythm status (AF vs SR, p-interaction = 0.617).
Conclusions: Low resting HR reduced mortality or HF hospitalisation in patients with HF regardless of EF or beta-blocker usage. However, it was associated with better prognosis only for patients in SR and not for patients with AF.

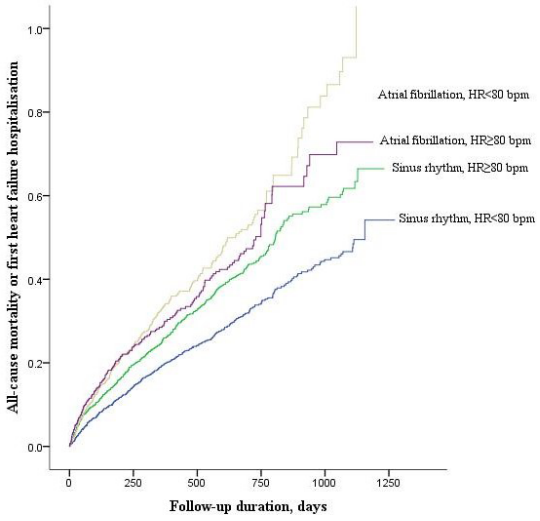

Figure 1

P980

Long-term and clinical profile of patients with heart failure with recovered ejection fraction followed in a non-tertiary hospital heart failure unit.

V Martinez Mateo[1]; MJ Fernandez Anguita[1]; L Cejudo Del Campo[1]; AJ Paule[1]
[1]Hospital Mancha Centro, Cardiology, Alcázar De San Juan, Ciudad Real, Spain, Spain

Introduction and objetives: Recovered heart failure (HF) with reduced ejection fraction (EF) is emerging as a different HF subtype. Information about his clinical profile and evolution in hospitals that are not reference in advanced HF is not described.
Purpose/Methods: We analyzed characteristics and prognosis of patients with recovered HF followed prospectively in the HF Unit of a non-tertiary hospital.
Results: Since the begin of Unit in 2010 until 2017, 431 patients with HF with reduced EF have been followed (median 50 months, 79.3% men, mean age 70.3 ± 12.2 years [median 73]). 26,9% patients (N 116) recovered EF, mainly in the first year of follow-up (76.7%). Compared with patients that did not recovered EF in the follow-up, they are younger (64.,3 vs 68,0 years, p 0.006), rate of ischemic origin of cardiomyopathy is less frequent (31.3% vs 51.4%, p 0.000) and presented less comorbidity (chronic renal failure 19.0 vs 27.9%, p 0.05; peripheral arterial disease 15.1 vs 26.1%, p 0.07; and chronic obstructive pulmonary disease 23 vs 33.7%, p 0.04). Rate of treatment with beta blockers/ivabradine, angiotensin converting enzyme inhibitors/angiotensin receptor blockers/sacubitril-valsartan and aldosterone antagonists were 93.1%, 95.7% and 57.1% respectively without significant differences between both groups. Implantable electronic devices (ICD/CRT) were more frequently used in patients without recovered EF (23.8 vs 10.4%, p 0.000). Younger age of 68 years (odds ratio [OR] 0.98, 95% confidence interval [CI] 0,96-0,99; p 0,025), ischemic origin (OR 1,12, CI 1,01-1,21; p 0,003) and use of aldosterone antagonists (OR 1,89, CI 1,09-3,26; p 0,023) were the variables independently associated to normalization of EF. Regarding the prognosis, mortality was lower in patients with recovered HF (survival median of 85,2 +/- 2,1 vs 74,2 +/- 1,9 months respectively; Logrank 11.5, p 0.001) with etiology of deaths mainly not secondary to HF (73.4 vs 46.0%, p 0.000). Chronic renal failure was the only variable independently associated to higher mortality (hazard ratio [HR] 0.42, CI 022-0.79; p 0.008) while age less than 68 years (HR 1,03, CI 95% 1,01-1,10; p 0,018) and treatment with beta blokers (HR 2,74, CC 95% 1,34-5.58; p 0,005) and sacubitril/valsartan (HR 11,97, CI 95% 3,26-43.9; p 0,000) with lower mortality.
Conclusion: Recovered HF is a frequent phenomenon in patients with HF with reduced EF. It has a more favorable clinical course, prognosis and basal characteristics than HF with persistent reduced EF. Further studies are needed to identify natural history and optimal medications for HF-recovered patients.

P981

Gender differences in the characteristics and outcomes of heart failure: the israel heart failure disease management study (IHF-DMS)

A Avishay Grupper[1]; D Freimark[1]; H Murad[2]; L Olmer[2]; M Benderly[2]; LS Freedman[2]; A Ziv[2]; N Friedman[3]; G Kaufman[3]; H Silver[3]; O Kalter-Leibovici[2]
[1]Sheba Medical Center, Leviev Heart Center, Ramat Gan, Israel; [2]The Gertner Institute for Epidemiology & Health Policy Research, Ramat Gan, Israel; [3]Maccabi Health Services, Tel Aviv, Israel

Background: Heart failure (HF) incidence is increasing in both men and women, and becoming a major and growing problem globally. Approximately half of all HF patients are women, and there are significant sex related differences in disease etiology, expression, patient's characteristics, outcomes and response to therapy.
Purpose: To study the effect of sex on HF characteristics and outcomes.
Methods: This is a sub-analysis of a randomized controlled prospective trial on HF disease management (DM) in which patients with HF (N = 1,360; 27.5% women) were randomly assigned to DM (N = 682) or usual care (UC) (N = 678). The study intervention did not significantly affect the rate of hospital admissions or mortality. The association between sex and hospital admissions and mortality during follow-up was tested in multivariable models adjusted for the patients' baseline characteristics.
Results: Compared to men, women recruited in this study were, on average, 3 years older and presented with worse functional capacity, quality of life and depression symptoms (p <0.001). Women were more likely than men to have HF with preserved EF (LVEF = 50%) and less likely to have HF due to ischemic heart disease (p <0.001). At recruitment, there were no sex-related differences with respect to treatment with HF medications (ACE-I/ARBs, beta adrenergic blockers, aldosterone antagonists and loop diuretics), but women were less likely than men to be treated with statins and anti-aggregates. During a median follow-up of 2.7 years (range: 0-5), 557 (56.5%) men and 218 (58.3%) women had a primary composite endpoint event (HF hospitalization or death from any cause). In multivariable analysis adjusted for study group, baseline demographic, EF, morbidity-related characteristics and medical treatment during follow-up, women were significantly less likely than men to experience the primary outcome [adjusted hazard ratio (HR) = 0.835, 95% confidence interval (CI): 0.699, 0.998)] or to die from any cause [adjusted HR = 0.712; 95%CI: 0.560, 0.901]. Women also had lower rates of all-cause hospital admissions and in-hospital days during follow-up compared to men [rate ratio (95%CI): 0.798; (0.705, 0.904), and 0.801 (0.661, 0.970), respectively].
Conclusions: Women with HF have 30% lower risk of all caused mortality as well as lower rates of all-cause hospital admissions and in-hospital stay compared to men. These sex differences were not explained by HF characteristics, comorbidities or medical treatment.

Funding Acknowledgements: This work was supported by the Jaap Schouten Foundation and the Foreest Medical School.

Background: Single, 'baseline' measurements of systolic and diastolic left ventricular function are predictive of adverse clinical outcomes in patient with chronic heart failure (CHF). However, the temporal evolution of these measurements preceding adverse outcomes has not yet been investigated in detail.
Purpose: To investigate temporal evolution of echocardiographic measurements and their associations with adverse clinical outcomes in CHF patients with reduced ejection fraction.
Methods: This prospective, observational study comprised of 106 CHF patients, in whom repeated, 6-monthly echocardiographs were performed. The following parameters with known high feasibility and reproducibility, were assessed using TOMTEC software: ejection fraction, end-diastolic and end-systolic left ventricle diameter, end-systolic left atrium diameter and Doppler E, e' and A wave velocities. The endpoint was a composite of HF hospitalization, cardiovascular death, left-ventricular assist device or heart transplantation, whichever occurred first. Data were analyzed using joint models, which combine mixed models for subject-specific evolution of the echocardiographic measurements and Cox regression for occurrence of the composite endpoint.
Results: Mean age was 58 years, 78% were man and 13 were in a NYHA-class >II at baseline. During a median (IQR) follow-up of 2.3 (1.7-2.7) years, a total 331

echocardiographs were made (median (IQR) per patient 3 (2-4)); 25 patients had the study endpoint. Overall, in endpoint cases, dimensions and diastolic ratios were larger and ejection fraction was lower(Table). None of the parameters revealed significant worsening on the echocardiographs before the study endpoint(Figure).
Conclusion: Although the echo measurements were associated with adverse cardiovascular outcomes, serial measurements during a 2.3 year time window did not capture echocardiographic worsening prior to the outcomes. It thus seems that regular monitoring of the systolic or diastolic function with echocardiography within the short time frame of several years does not carry incremental prognostic information over a single measurement.

Results joint models

On behalf of: REDINSCOR II research groups

Background: Heart failure (HF) re-hospitalizations remain as an unsolved problem in the management of the disease. The transition after discharge represents a relevant intervention in order to prevent re-hospitalizations. We aimed to study the impact in clinical practice of a specialized follow-up in the transition period after discharge.
Methods. The study population consisted of 1,831 patients hospitalized with acute HF from a national multicenter prospective registry (REDINSCOR II), which included data from 18 Spanish hospitals of varying complexity. Patients were consecutively recruited between October 2013 and December 2014. Data were collected using specifically designed web forms (http://www.redinscor2.org/), and quality controls were undertaken periodically. Patients were included in the analysis only if they had available data on "long term control after discharge", resulting in a study population of 1530 patients (83.6% of the total). Only 30 patients (1.6%) were lost to follow-up. Patients were classified according to the presence of a structured follow-up in a HF unit or not. Readmission was defined as any hospital readmission within the first year after discharge due to HF causes, or readmission due to any cause. Due to the nonrandomized nature of the study we performed a propensity score matching (statistical package "MatchIt" from the R project) analysis aimed to minimize potential biases that might influence the prognosis.
Results: Of 1500 patients, a total of 439 (29.3%) had access to a structured follow-up in a HF clinic. Among other characteristics, these patients had a higher rate of prior HF admissions (1.06 ± 1.50 vs. 0.74 ± 1.38, p <0.001) and lower left ventricular ejection fraction (44.5 ± 17.4 vs. 49.1 ± 18.1%, p <0.001). At 1 year, a structured transition in a HF clinic was associated with lower rate of HF readmissions (26.2% vs. 32.0%, p = 0.027) and all-cause readmissions (51.3% vs. 57.0%, p = 0.041), as well as lower number of HF readmissions (0.38 ± 0.78, p = 0.017) and all-cause readmissions (0.96 ± 1.46 vs. 1.25 ± 1.66, p = 0.003). After propensity score matching, a balanced population without differences in clinical characteristics was obtained (415 vs. 415); the transition in a HF unit had a significant effect on reducing the number of HF readmissions (RR 0.71 (CI95 0.54-0.93, p = 0.0136) and all-cause readmissions (RR 0.83 CI95% 0.68-0.99, 0.0487). No interactions were observed regarding clinical characteristics.
Conclusions. In the transition of care after a HF hospitalization, a structured follow-up in a HF clinic was associated with a lower risk of readmissions at 1-year, which was driven by a reduction in the risk of HF readmissions.

P984

What main concerns do patients with chronic heart failure report? A textual analysis of the opening question of the (Integrated) Palliative care Outcome Scale POS and IPOS

A Anna Oriani[1]; P Guo[2]; A Gadoud[3]; L Dunleavy[3]; M Brice[4]; P Kane[2]; FEM Murtagh[5]
[1]Hospital of San Giovanni, Oncological Institute of Southern Switzerland, Bellinzona, Switzerland; *[2]King's College London, Cicely Saunders Institute , London, United Kingdom*; *[3]Lancaster University, International Observatory on End of Life Care, Lancaster, United Kingdom*; *[4]St Christopher's Hospice, London, United Kingdom*; *[5]Hull York Medical School, Wolfson Palliative Care Research Centre, York, United Kingdom*

Background: Chronic heart failure has a significant impact on physical, psychological and social wellbeing. The Palliative care Outcome Scale and Integrated Palliative care Outcome Scale (POS and IPOS) are part of a family of tools specifically designed to measure physical symptoms, psychosocial, spiritual, and information and support needs of people severely affected by advanced chronic disease. POS and IPOS start with an open question for patients to report their main concerns, with subsequent closed questions about multi-dimensional needs.
Purpose: To explore the main concerns self-reported by patients with chronic heart failure in the open question of POS and IPOS.
Methods: A secondary textual analysis of the opening question of the POS and IPOS collected in three previous longitudinal studies with patients with chronic heart failure. Each participant contributed only one survey to this secondary analysis. Thematic analysis is used to search for and identify themes which are then used to compare with the subsequent closed questions.
Results: Data came from 102 participants in three studies: i) 40 participants with advanced heart failure, receiving a palliative care intervention, ii) 37 participants with end-stage kidney and chronic heart disease managed conservatively, and iii) 25 participants with advanced heart failure. The participants' mean age was 80 years (range 52-98), 62% male and 87% white. The baseline NYHA score was available for only 65 patients: 19 patients were classified NYHA I, 37 patients were classified NYHA II, and nine patients were classified NYHA III. 88/102 (86%) completed the IPOS or POS questionnaire, with 19 patients providing three responses to the open question, 18 providing two, 26 providing one and 25 patients providing no concerns. Of those 88 participants, 21 (24%, 95%C.I. 16%-32%) reported poor mobility, 14 (16%, 95% C.I. 10%-22%) breathlessness, 12 (14%) fatigue, 9 (10%, 95%C.I. 8%-20%) general concerns caused by co-morbidities , 9 (10%, 95% C.I. 4%-16%) pain, 8 (9%, 95% C.I. 4%-15%) practical problems not addressed, and 7 (8%, 95%C.I. 3%-11%) anxiety. There were other self-reported concerns including decrease of quality of life, fluid retention, depression, bowel problems, drowsiness, itch, cough, and insomnia. A total of 107 concerns were reported in the open questions problems. Of these 83 (77%) were reflected in the subsequent IPOS/POS closed questions.The high correspondence between the free-text responses and the

closed questions, indicates that most issues are included in the closed POS/IPOS items.
Conclusion: Patients affected by chronic heart failure are characterised by high symptom burden. IPOS and POS questionnaires reflect comprehensively main problems and concerns of these patients and the open question is able to capture the remaining unique concerns. IPOS and POS are useful questionnaires for advanced CHF, but further psychometric validation is needed in this population.

P985
Beta blocker doses and heart rate in patients with heart failure

M Grundtvig[1]; T Eriksen-Volnes[1]; LL Gullestad[2]
[1]St Olavs Hospital, Fagenheten, Trondheim, Norway; [2]Oslo University Hospital, Department of Cardiology and University of Oslo, Oslo, Norway

Background: It is an IA recommendation by the European Society of Cardiology to treat patients with heart failure (HF) and reduced left ventricular ejection fraction (HFrEF) with the highest tolerated dose of a beta blocker. The ESC Guidelines for HF recommend (IIa) additional treatment to reduce heart rate (HR) in patients with HFrEF and sinus rhythm and HR above 70 bpm. Our aim of the present study was to examine HR in relation to the use of beta blockers in these patients.
Method All the patients (N = 1762) with sinus rhythm at stable follow-up who had left ventricular ejection fraction (EF) < 40% at the first visit to the specialised heart failure hospital outpatient clinics and recorded in our registry were included.
Results: Two thirds of the patients had a resting HR < 70 bpm. Of those, 19.9 % used = 100 % of the target beta blocker dose, while 32.3 % of those with HR = 70 bpm used = 100 % of the dose . One third of the patients had a HR = 70bpm (Table 1) and these patients were younger, had higher NYHA functional class, higher NT-proBNP, lower blood pressure, lower serum sodium, lower eGFR, more obstructive lung disease and used much more diuretics than patients with HR < 70/min. One year mortality for the 1011 patients who were observed for a minimum of 365 days after stable follow-up were 5.8, 7.5, 11.0 and 14.7 % among the patients with a HR < 70, 70-79, 80-89 and > 89 bpm, respectively. Ivabradine was only used in one patient.
Conclusions: A high HR in patients with sinus rhythm and EF < 40 % is associated with worse clinical variables and worse outcome. A very high proportion of the patients with a HR = 70 bpm were not treated with/do not tolerate the target dose of a beta blocker suggesting increased effort to increase the beta blocker dose should be done or treatment with ivabradine should be considered. However, more studies to examine actions to reduce HR in these patients are in great need.

Table 1

Heart ratebpm	Beta blocker in % of target dose	Total N

P986
Prevalence of iron studies during admission of heart failure patients to leeds teaching hospitals

R Khatib[1]; S Winsor[1]
[1]Leeds Teaching Hospitals NHS Trust, Department of Cardiology, Leeds, United Kingdom

Funding Acknowledgements: Vifor Pharma

Background and Aim: Around 900,000 people in the United Kingdom are living with heart failure (HF), a life-limiting condition marked by frequent hospital admissions. Iron Deficiency (ID) and Iron Deficiency Anaemia (IDA) are known co-morbidities of HF, with research consistently showing an overall prevalence of around 50%. ESC guidelines recommend that patients with HF should be screened for ID and the simple treatment, iron therapy, be prescribed where appropriate. We audited the prevalence of iron studies during the admission of patients with HF to our hospital (LTHT) to inform practice.
Methodology: We reviewed the records of 1,000 patients to assess how many of those patients in a one year period anaemia had and how many had any iron studies done during their acute admission with HF. We assessed findings against the following standards:
- All patients admitted with HF need to have their haemoglobin levels measured
- All patients admitted with HF should have iron studies carried out during admission
- All patients admitted with HF and identified to have anaemia need iron studies
Results: From April 2016 - February 2017, 1,000 patients were admitted to LTHT, of whom 527 (53%) were men and 473 (47%) were women, with an average age of 77 (minimum 22 - maximum 101).
- Almost all patients (99.7%) had their haemoglobin (Hb) measured during admission, consequently 60% were found to be anaemic (n = 601).
- Only 12.9% of patients received a Hospital Episode Statistics (HES) code for secondary anaemia or ID suggesting the condition is under-reported.
- Only 18.5% of the overall sample and 24% of the anaemic patients received Ferritin testing.
- When iron studies were conducted, Ferritin was the predominant test requested, with only 1.1% and 0.4% of patients undergoing serum iron and transferrin saturations (TSAT) measurements, respectively.
Conclusion: Whilst standards for Hb testing are well adhered to, iron studies are not conducted as frequently as advised by guidance. Despite ESC and other international guidelines, clinicians are not screening enough for ID in both anaemic and non-anaemic patients admitted with HF. We need to raise awareness about the growing evidence in this area and improve protocols.

P987
Improvement of pulmonary hypertension is significantly correlated with better long-term prognosis in patients with pulmonary hypertension associated with heart failure with reduced ejection fraction

HJ Heejin Kwon[1]; JH Park[1]; SW Seong[1]; BJ Sun[1]; JH Lee[1]; IW Seong[1]
[1]Chungnam National University Hospital, cardiology, Daejeon, Korea Republic of

Background: The presence of pulmonary hypertension (PH) was associated with increased mortality and morbidity in heart failure with reduced ejection fraction (HFrEF) patients. However, there is little data on prognosis about the changes of LVEF and/or improvement of PH in these patients. We evaluated long-term survival of patients with PH associated with left ventricular systolic dysfunction (LVSD), especially according to the improvement of PH and/or LVSD.
Methods: We screened all consecutive patients with PH with HFrEF from September 2011 to March 2017. PH was defined maximal tricuspid regurgitation velocity (TR Vmax) more than 3.0m/sec and the presence of HFrEF was decided LVEF less than 45% with reasonable symptoms. We included only patients with follow-up echocardiographic study within 12 months.
Results: We screened total 1237 consecutive patients with PH and LVSD. Of them, 271 patients (167 males, mean 65 ± 14 years old) were enrolled in this analysis. In the baseline echocardiography, LVEF was 28 ± 8% and TR Vmax was 3.4 ± 0.4m/sec. In the follow-up echocardiography, 183 (68%) showed improvement of LVEF more than 15% and 165 (61%) demonstrated disappearance of PH (TR Vmax < 3.0m/s). According to the improvement of PH and/or LVSD, we classified the study group into 4 groups; group 1 with both improvement (134 patients), group 2 with PH and improvement of LVEF (49 patients), group 3 with disappearance of PH and LVSD (31 patients) and group 4 with sustained PH and LVSD (57 patients). Group 4 had older age and higher incidence of MI and aggravation of pre-existing HF. Study patients were followed total 31 ± 20 months. During the period, 97 patients had more than 1 episode of major cardiocerebrovascular accidents (MACCE, 52 deaths, 65 admissions for HF, and 17 strokes). The 5-year survival rate was 72.3% and MACCE-free survival rate was 50.2%. Group 4 showed worst survival rate and MACCE-free survival rate. Group 3 showed better MACCE-free survival rate than group 2 after the adjustment of age and gender (Figure 1, P = 0.001).
Conclusion: In patients with PH associated with HFrEF, the improvement of PH was associated with more favorable MACCE-free survival.

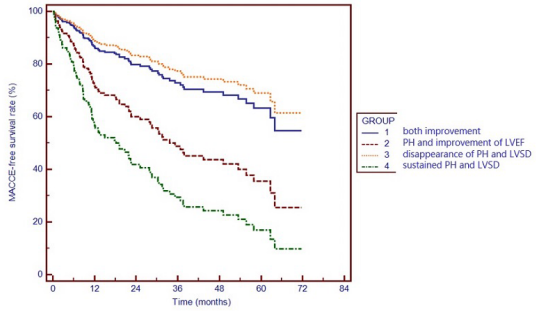

Figure 1. MACCE-free survival rate

Health-related quality of life in heart failure: findings from a systematic literature review

L Giles[1]; CL Freeman[1]; P Field[1]; G Osei-Assibey[2]; E Sorstadius[3]; B Kartman[3]
[1]PharmaGenesis Oxford Central, Oxford, United Kingdom; *[2]Oxford PharmaGenesis, Oxford, United Kingdom*; *[3]AstraZeneca Gothenburg, Mölndal, Sweden*

Funding Acknowledgements: Systematic review and medical writing support were provided by PharmaGenesis Oxford Central, Oxford, UK, and funded by AstraZeneca.

Background: The physical and mental limitations of heart failure (HF) may have a significant effect on the health-related quality of life (HRQoL) of patients with the condition.
Purpose: To assess the impact of HF on HRQoL, using findings from a systematic literature review (SLR).
Methods: Electronic databases (Embase, MEDLINE and the Cochrane Library) were searched in May 2017 for observational studies reporting HRQoL in 200 patients or more, published between 2007 and 2017. The search was focused by HRQoL as measured using the 12- or 36-item Short Form Health Surveys (SF-12/36), the EuroQol Group 5-dimensions measure of health status (EQ-5D), Minnesota Living with Heart Failure Questionnaire (MLHFQ) and Kansas City Cardiomyopathy Questionnaire (KCCQ).
Results: In total, 54 studies were identified (Europe: 25; North America: 24; rest of the world/multinational: 5). Relatively few of these studies examined HRQoL in patients with HF in comparison with individuals without HF or patients with other chronic diseases. In a Dutch study, patients with HF (New York Heart Association [NYHA] class II–IV) reported worse scores across all individual domains of the SF-36 instrument compared with a population of age- and sex-matched community controls. In a cohort survey conducted in the UK, patients with HF reported lower baseline EQ-5D scores (both index value and visual analogue scale [VAS]) than patients with asthma, chronic obstructive pulmonary disease, diabetes mellitus, epilepsy or stroke. In this survey, the only significant change found for EQ-5D between baseline and 1-year follow-up was for VAS scores in HF. A total of four studies across the three geographical regions assessed HRQoL by NYHA class, all of which reported worse HRQoL (measured by MLHFQ and KCCQ) as NYHA class increased; in particular between NYHA class I and II, and between class II and III, with a smaller HRQoL reduction between class III and IV. An additional study reported that HRQoL declined with increasing disease severity, but did not report data for separate NYHA classes.
Conclusions: The evidence identified in this SLR indicates that HF is associated with worse HRQoL compared with both the general population and patients with other chronic diseases. Furthermore, there is evidence that HRQoL deteriorates as disease severity increases, in particular between NYHA class I and II, and between class II and III.

P989

30-days hospital readmission does not depend solely on clinical features of elderly heart failure patients discharged from Internal Medicine Units

V Verdiani[1]; P Francesconi[2]; F Profili[2]; G Panigada[3]; I Chiti[3]; R Laureano[4]; C Lusini[4]; F Bacci[4]; A Fortini[4]; G Landini[4]; L Masotti[5]
[1]Internal Medicine, Grosseto, Italy; *[2]Tuscany Regional Agency of Health, Florence, Italy*; *[3]Internal Medicine, Pescia, Italy*; *[4]Internal Medicine, Florence, Italy*; *[5]Internal Medicine, Empoli, Italy*

On behalf of: POST-SMIT Study Group

Background: Approximately 20% of Heart Failure (HF) patients who have been hospitalized are readmitted within 30 days. Although some different models have been studied, the preventability of readmission remains unclear, particularly in real world of Internal Medicine.
Methods: We enrolled patients who were discharged by 23 Internal Medical Units of Tuscany, an Italian region of 3,7 million inhabitants, in a period of 30 days with the main diagnosis of HF. We recorded epidemiological, instrumental and clinical data and patients were followed over a 1 month period. We considered 6 comorbidities: diabetes mellitus, hypertension, chronic renal failure (CRF), chronic obstructive pulmonary disease (COPD), atrial fibrillation (AF), anemia, NYHA class, LVEF during hospitalization. We compared 30-days readmission group respect not 30-days readmission group to identify potential correlations between features of patients and early rehospitalisation.
Results: We recruited 451 patients (M= 44.3%) with a mean age of 83 + 8.4 years. In 1 month follow-up 83 patients (18.4%) were readmissed for medical causes. In multivariate analysis, early readmission were not significantly correlated with: age (RR 0.99; P = 0.50), sex (F vs M RR 0.87; P = 0.54), diabetes (RR 1.11; P = 0.65), hypertension (RR 1.04; P = 0.88), CRF (RR 1.23; P = 0.11), COPD (RR1.38; P = 0.16), AF (RR 0.93; P = 0.76), anemia (RR 1.40; P = 0.15), NYHA class (RR 1.19; P = 0.46), LVEF < 40% (RR 1.20; P = 0.51), number of comorbidity (RR 1.01; P = 0.93). Only previous hospitalization (< 1 year) was significantly correlated with 30-days readmission (RR 1.38, P = 0.02).
Conclusions: The only clinical features are not able to indicate which of HF patients discharged from Internal medicine units are at major risk of early readmission, but patients with previous hospitalization are more likely to be readmissed. Particularly for elderly patients, future study should assess the relative contributions of different data (eg. caregiver presence, disability, psychological, environmental, social factors) to early readmission risk prediction.

P990

Overweight/obesity paradox in coronary patients with heart failure; the sociodemographic hypothesis. Hellenic Heart Failure study.

C Christina Chrysohoou[1]; M Kouvari[2]; M Kouvari[2]; P Aggelopoulos[1]; P Aggelopoulos[1]; C Pitsavos[1]; I Haritou Kotsopoulou[1]; D Tousoulis[1]; C Pitsavos[1]; D Tousoulis[1]
[1]University of Athens, Athens, Greece; *[2]Harokopio University, Nutrition Science - Dietetics, Athens, Greece*

Background/Introduction: Overweight/obese patients are to have a survival advantage in a wide range of chronic diseases during the rehabilitation procedure. This is also the case in established acute coronary syndrome (ACS) with major complications (i.e. heart failure), yet to what extend this is irrespective to other characteristics, remains inconclusive.
Purpose: to evaluate the role of body mass index (BMI) in ACS prognosis and to investigate potential interactions with patients' age and gender.
Methods: in 2006-2009, 1,000 consecutive patients, hospitalized at a Cardiologic Clinic in Athens with ACS diagnosis were enrolled in the study. In 2016, 10y follow-up was performed (75% participation rate). Overweight was defined as 25 = BMI = 29.9 kg/m2 while obesity as BMI>29.9 kg/m2.
Results: BMI status and 10y ACS prognosis followed a J-shape association (p = 0.009). In multivariate logistic regression analysis, overweight patients had significantly better ACS prognosis compared with their normalweight counterparts (OR = 0.45, 95%CI (0.23, 0.90)), whilst obese patients did not have significant differences compared with the reference group. Significant interactions were observed between sociodemographic parameters (i.e. age, gender) and BMI on 10y ACS prognosis (all ps for interaction = 5%). Stratified analysis was performed using gender (males vs. females) and age (= 65 vs. >65 years) as strata. In this context, the aforementioned paradoxical association was retained only in patients being females (OR = 0.37, 95%CI (0.16, 0.82)) and = 65 years (OR = 0.25, 95%CI (0.09, 0.69)).
Conclusions: overweight paradox was highlighted in 10 year ACS prognosis of heart failure patients. Nonetheless, certain prerequisites were indicatively stated, implying that this paradoxical association is not a case for all; with this relation being more evident in females and younger patients.

P991

Prognostic value of right and left heart functional parameters and levels of biomarkers in chronic heart failure patients with preserved, mid-ranged and reduced ejection fraction

LR Liana Tumasyan[1]; KG Adamyan[1]
[1]Institute of Cardiology, Yerevan, Armenia

The aim of study was to assess predictive power of right and left heart functional parameters and levels of NT-pro-BNP and high sensitivity C-reactive protein (hsCRP)

in prediction of survival in patients (pts) with chronic heart failure in relation to reduced (HFrEF), mid-ranged (HFmEF) or preserved (HFpEF) ejection fraction (EF).
Methods. Left (LV) and right ventricular (RV), left (LA) and right atrial (RA) functional parameters by Doppler and tissue echocardiography, NT-pro-BNP (pg/ml) and hsCRP (ng/ml) levels were prospectively studied in 186 pts (age 59.8) with HFrEF (EF < 0.4), 133 pts (age 60.1) with HFmEF (0.4 = EF < 0.5) and 128 pts (age 63.2) with HFpEF (EF = 0.5) in III-IV NYHA functional class CHF.
Results: During 37 ± 0.7 months from cardiac causes died total 157 (35.1%) pts, 68 (36.6%) with HFrEF, 46 (34.6%) with HFmEF and 43 (33.6%) with PEP. In HFpEF probability of death was predicted (p < 0.01 for all) by levels of hsCRP, tricuspid annulus plane systolic excursion (TAPSE), tissue Doppler-derived tricuspid lateral annular systolic velocity (s') and a mean e' septal and lateral wall and level of NT-proBNP (p < 0.05). Kaplan-Mayer analysis survival rate (%) was 62 in pts with CRP = 15, 61 with TAPSE < 15, 63 with s' < 8.5 and e' = 16 (63), 65 with NT-pro-BNP = 1500, and 86 with CRP < 15, 87 with TAPSE = 15, 86 with s' = 8.5, and 87 with e' < 16 and 80 with NT-pro-BNP < 1500. In HFrEF Kaplan-Mayer analysis (p < 0.01 for all) revealed survival of 62 for NT-proBNP = 3500, 62 with RA functional index (RA FI < 0.18) and 64 with LA FI < 0.19, 65.5 with pulmonary vein (PV) systolic contribution (SC) < 30, 62.5 with PV S/D < 0.25, and 88 with NT-pro-BNP < 3500, 86 with RA FI = 0.18 and 87 with LA FI = 0.19, 82 with PVSC = 30 and 87 with S/D = 0.25. In HFmEF independent prognosticators of death (p < 0.05) were levels of parameters with survival rate of 62 for NT-pro-BNP = 2500, 60 for hsCRP = 25, 64 for TAPSE < 14, and 62 for s' < 7, 63 and 66 for RAFI and LAFI < 0.3, and 88 in pts with NT-pro-BNP < 2500, 85 with CRP < 25, 83 for TAPSE = 14 and 87 for s' = 7, 86 and 85 with RAFI and LAFI = 0.3, respectively. Distribution of pts with HFrEF, HFmEF and HFrEF according to cut-off values NT-pro-BNP < 3500, 2500, 1500 and NT-pro-BNP = 3500, = 2500, = 1500 respectively, allowed to identify low (20.5, 19.6 and 18.7) and high risk (49.1, 46.1 and 42.7) of cardiac death (p < 0.01 for HFrEF, p < 0.05 for HFmEF and HFpEF).
Conclusions: 1) In pts with severe HFrEF, HFmEF and HFpEF revealed almost similar mortality. 2) NT-pro-BNP levels were the strong prognosticators in CHF, irrespective of LV EF, but with different threshold and significance. 3) Levels of hsCRP, RV systolic and LV diastolic dysfunction were the most powerful predictor of death in HFpEF. 4) LA and RA functional parameters were the strong prognosticators in HFrEF. 5) RV systolic and LV diastolic dysfunction, LA and RA parameters were strong predictor of death in HFmEF, but with low significance (p < 0.05) of parameters compare to HFpEF and HFrEF.

P992

Prevalence, incidence and long-term prognosis of patients with heart failure in the Czech Republic: data from national health registers 2012-2016

J Jiri Parenica[1]; JJ Jarkovsky[2]; JS Spinar[1]; MP Pavlusova[1]; RM Miklik[1]; SL Littnerova[2]; K Benesova[2]; J Belohlavek[3]; F Malek[4]; V Melenovsky[5]
[1]Faculty Hospital, Brno, Czech Republic; [2]Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic; [3]General University Hospital, Prague, Czech Republic; [4]Na Homolce Hospital, Prague, Czech Republic; [5]Institute for Clinical and Experimental Medicine (IKEM), Prague, Czech Republic

Data about the prevalence/incidence and prognosis of patients with heart failure are based on relatively small studies/registries. The aim of the work is to provide this important information on the basis of extensive data from Czech National Register of Hospitalizations and the Database of Deaths. Patients with heart failure were identified on the basis of the international classification of disease, used data were mainly from the period 2012-2016. Data since 1994 were used to estimate the number of surviving heart failure patients.
In total, 36-40 thousand patients with newly dignosed heart failure (as a first or other diagnosis according to DRG coding) are hospitalized annualy in the Czech Republic. In total, 60-65 thousand of the patients with diagnosis of heart failure (600 patients/100 thousand inhabitantts/year) are hospitalized annualy. The total number of hospitalizations for heart failure is 95-98 thousand /year (920 hospitalizations/100 thousand inhabitants/year). The average age of admitted men is 71 years, women 74 years. There is 52% of men. Hospitalization mortality is 16,2%. 5-year standardized survival is only 36.8%.
There are about 216,000 patients in the Czech Republic with a history of heart failure, which represents 2.7% of the adult population.

P993

What is the prevalence of heart failure with preserved ejection fraction (HFpEF) in patients referred for sleep apnoea assessment?

A Gallagher[1]; A Simonds[2]; MR Cowie[1]
[1]Imperial College London, London, United Kingdom; [2]Royal Brompton Hospital, London, United Kingdom

Background: Breathlessness and fatigue are common, but non-specific, presenting symptoms. Hence different diagnostic pathways can be followed, including testing for sleep apnoea. Patients diagnosed with obstructive sleep apnoea typically share similar phenotypic characteristics with heart failure patients with preserved ejection fraction (HFpEF). Current guidelines indicate the use of natriuretic peptide measurements and echocardiography, in symptomatic patients, for diagnostic work-up of heart failure.
Purpose: We aimed to determine the prevalence of HFpEF in patients with suspected sleep apnoea.
Methods: Patients scheduled for a diagnostic respiratory polygraphy were recruited as part of an ongoing observational study. Exclusion criteria included age < 40 years, previous heart failure diagnosis or treated sleep apnoea. Each patient was assessed with a cardiovascular examination, electrocardiogram, N-terminal-pro B-type natriuretic peptide (NT-proBNP) measurement and transthoracic echocardiogram.
Results: Preliminary data for 45 patients are presented. Hypertension (56%), diabetes (20%) and obesity (67%) were highly prevalent. Sleep apnoea was identified (apnoea-hypopnoea index >5) in 30 patients (67%). 64% were breathless and 34% reported peripheral oedema. All were in sinus rhythm. NT-proBNP levels ranged between 5-609pg/ml. 11 patients (24%) had NT-proBNP levels above 125pg/ml, the ESC recommended threshold for echocardiography referral. Of these 11 patients, all had normal left ventricular ejection fraction and one patient had definite diastolic dysfunction, but no associated heart failure symptoms or signs. Another patient had severe septal left ventricular hypertrophy. No significant correlation between NT-proBNP and sleep apnoea severity was seen (r = -0.39, p = 0.81).
Conclusion: Cardiovascular risk factors are highly prevalent in patients referred for sleep apnoea assessment. However, in this population HFpEF appears uncommon, with no cases identified according to standard criteria. Given the considerable proportion of false positive NT-proBNP levels, biomarker screening in these patients may be of limited benefit. The value of echocardiography, however, remains to be determined.

Patients (n = 45)	
Age (Mean ± SD)	59 ± 10.5
Male	23 (51%)
Body Mass Index (Mean ± SD)	32.8 ± 3.5
NT-proBNP (Median (IQR))	60 (32-119)
LVEF (Mean ± SD)	61.8 ± 3.6
Epworth Sleepiness Score (Median (IQR))	10 (6-14)

Table 1: Baseline Characteristics

Figure 1: NT-proBNP levels in patients tested for Sleep Apnoea

Background: Heart failure (HF) is a leading epidemic problem worldwide. The data on the outcomes including mortality rates in patients with HF is of great epidemic and clinical importance.
Purpose: The purpose of the study was to analyse the secular trends in one-year mortality in patients hospitalized for the first time with principal diagnosis of HF in Silesia, Poland between 2010 and 2015.
Methods: Data on the patients hospitalized each year for the first time with the primary HF diagnosis, and their one-year mortality was obtained from National Health Fund in Katowice. One-year mortality from the hospital admission was presented as crude, by sex and age groups (< 65 and = 65 years old) and after adjustment for age and sex. The trends were analysed using Mann Kendall trend test. P-value of < 0.05 was considered significant.
Results: The study included 61,496 patients admitted to hospital for the first time with principal diagnosis of HF between 2010 and 2015. There was no significant trend in crude one-year all-cause mortality. After adjustment for age and sex, the decreasing trend became significant. Similar trend was found among patients < 65 years old.
Conclusion: In large population of patients hospitalized for the first time with principal diagnosis of HF, decreasing trend in one-year mortality adjusted for age and sex was found between 2010 and 2015.

Echo-derived peak cardiac power output-to-left ventricular mass with cardiopulmonary exercise testing predicts outcome in patients with heart failure and depressed systolic function

N Pugliese[1]; I Fabiani[1]; G Galeotti[1]; G Mandoli[1]; L Conte[1]; A Lombardo[1]; A Simioniuc[1]; G Bigalli[1]; V Di Bello[1]; F Dini[1]
[1]*Azienda Ospedaliero-Universitaria Pisana, Cardiothoracic Department, Pisa, Italy*

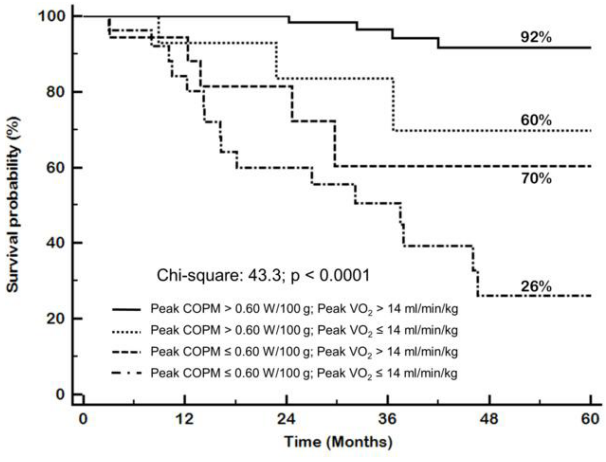

Fig.1

Background: Peak cardiac power output-to-mass (CPOM) represents a measure of the rate at which cardiac work is delivered with respect to the potential energy stored in left ventricle (LV) mass.
Aim: To investigate the value of peak CPOM and cardiopulmonary exercise test (CPET) in risk stratification of patients with chronic heart failure (HF).
Materials and methods. We studied 137 patients with chronic HF (mean LV ejection fraction 30%) undergoing CPET and exercise stress echocardiography. CPOM was calculated as the product of a constant (K = 2.22 × 10-1) with cardiac output (CO) and the mean arterial pressure (MAP), divided by LV mass (M), and expressed in the unit of W/100 g: CPOM = [K × CO (l/min) × MAP (mmHg)] / M(g). Patients were followed-up for the primary end-point, that included all-cause death and VAD implantation and the composite end-point that comprised hospitalization for HF.
Results: In multivariate Cox regression analyses, peak COPM was selected as the most powerful independent predictor of the end points (HR: 0.043, 95% CI: 0.004-0.044, p = 0.008; HR: 0.011, 95% CI: 0.02-0.66, p = 0.016). 5-year survival free from all-cause death or VAD implantation was 92% in those exhibiting VO2 >14 ml/min/kg and peak COPM >0.6 W/100 g. Peak VO2 = 14 ml/min/kg provided incremental prognostic value over demographic and clinical variables, BNP and resting echocardiographic parameters (chi-square: from 34.2 to 46.1; p = 0.005), that was further increased by peak COPM = 0.6 W/100 g (chi square: 52.2; p = 0.026).
Conclusion: Peak COPM and peak VO2 showed independent and incremental prognostic values in patients with chronic HF.

P996

Low T3, it is not the same.

SM Mettini[1]; DA Fernandez[1]; CA Biglia[1]; C Cejas[1]; M Taboada[1]; IL Ramella[1]; L Secco[1]; SM Pereiro Gonzalez[1]
[1]*Hospital Center Churruca-Visca, Buenos Aires, Argentina*

Objective: To establish the difference between patients (p) hospitalized with decompensating heart failure (DHF) according to T3 values (normal or diminished).
Method: It is a retrospective analysis of 524 patients admitted for decompensated heart failure, consecutively, in our Cardiology Department, from June 2012 to November 2017. Median follows up: 39 months (Q1 24 - Q3 54). We divided 2 groups (G) according to admission T3 values: G1: normal T3 (260 p) and G2: low T3 (173 p). Quantitative variables were expressed with median (m) and quartiles (analyzed by Mann Whitney's Test). Dichotomous variables were analyzed by Chi^2. It had been made a survival curve (Kaplan-Meier and Cox-Mantel test) for mortality and rehospitalization. It had been evaluated variables'impact on endpoints for uni and multivariable analysis.
Results: Median age was G1 69 years old (yo) (Q1 61-Q3 78) vs 79 yo (Q1 68-Q3 85), with differences statistically significant (DSS). There were less p older than 75 yo at G1 (46.2 vs 65.3% p < 0.001), and shorter stay (4 vs 5 days, p = 0.011), but more smokers (49 vs 34.7%, p = 0.003). Prevalent etiology was coronary disease but the DSS were of unknown etiology and valvular at G2 (p < 0,05 and p = 0.009 respectively). Inadequate treatment and arrhythmias were the 2 more prevalent decompensating cause, without DDS, but diet was higher at G1 (p < 0.001). G1 p had wider intraventricular diameters with DSS and lower ejection fraction (EF). Both G had predominantly p with EF < 40%. Presence of HFpEF was bigger at G2, also the number of p with a pacemaker (p = 0.001). At admission, G2 had DSS in higher values of BNP, BUN, creatinine and glomerular filtration rate (GFR), and lower values of proteins and albumin, and at hospital discharge, as higher values of creatinine and BUN. Normal T3 was associated with higher diminished in the GFR during the stay. Low T3 had more atrial fibrillation (p < 0.05). More patients in G2 needed non-invasive ventilation and inotropic agents (p = 0.005 and p = 0.02, respectively).

The multivariate analysis showed that age, albumin, GFR, cardiac rhythm and elderly patients were independent predictors to low T3 ($p < 0.001$, OR 1.08; $p < 0.001$, OR 0.3; $p < 0.05$, OR 0.98; $p < 0.05$, OR 0.55 y $p < 0.05$, OR 0.43 respectively). Patients with low T3 had higher hospital mortality (5.8 vs 1.5% $p = 0.01$) but not at the follow up (40.3% vs 64% $p < 0.001$). In the multivariate analysis, T3 value, maximum furosemide dose, patients older than 75 yo, cardiac rhythm and inotropic use, were hospital mortality independent predictors. T3 values were associated with rehospitalization (OR 0.99).
Conclusions: Patients with low T3 showed a subgroup with more serious heart failure. T3 values also were associated with worst hospital evolution and rehospitalization. We believe it is very important to detect this sort of patients in admission to adjust treatment. Hormonal replace treatment is still controversial.

P997
Is there a real difference in age between patients with heart failure with reduced or preserved left ventricular ejection fraction?

A Abdallah Al-Mohammad[1]; D Rogers[1]; NT Lewis[1]; A Charalampopoulos[1]
[1]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*

Introduction and Purpose: The majority of those with Heart failure (HF) are old people. Patients with HF associated with reduced left ventricular ejection fraction (HFREF) are believed to be younger than those with other types of HF. We investigated whether age varies according to the type of HF diagnosed in an incident HF clinic.
Methods: Patients in our city suspected of having new onset HF are referred to our incident HF clinic if their NTproBNP is > 400 ng/l. Our clinic is the only provider of the service for a population of 550,000 people. All patients undergo detailed echocardiography and are assessed by a HF consultant cardiologist. We collected data on consecutive patients between 13th of April 2012 and 31st of December 2016. The age, the NTproBNP levels and the type of HF were recorded. Comparisons were made between those with HFREF and those with heart failure with preserved left ventricular ejection fraction (HFPEF), using independent t test statistics, with significance at $p < 0.05$.
Results: A total of 3939 patients were seen in this period with a median age of 80 years. HFREF was diagnosed in 1209 patients (30.7%), with median age of 80 years and mean NTproBNP of 3243 ng/L. The patients with HFPEF were 1354 patients (34%) with a median age of 81 years and a mean NTproBNP of 1684 ng/L ($p < 0.0002$). The remaining patients were 846 patients with HF related to pulmonary hypertension [median age of 82 years and a mean NTproBNP of 2004 ng/L (p NS)]; and 950 patients (24%) who did not have HF. Those latter group had a median age of 78 years and a mean NTproBNP level of 969 ng/L. The NTproBNP ranges were overlapping.
Conclusions: Patients with HFREF and HF due to pulmonary hypertension tend to have similar mean NTproBNP levels, that are significantly higher than those with HFPEF. Contrary to common assertions, the median age for patients with different types of heart failure appear to be similar, and thus can not help differentiating HFREF from HFPEF.

P998
Lower left ventricular ejection fraction can independently predict the poor response to immunosuppressive treatment in patients with cardiac sarcoidosis

K Kisho Ohtani[1]; K Takesue[1]; K Hiasa[1]; T Fujino[1]; T Higo[1]; T Ide[1]; H Tsutsui[1]
[1]*Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan*

Immunosuppressive agents including corticosteroid are mainstay of initial treatment for cardiac sarcoidosis (CS), however, a subset of patients with CS fail to respond to these treatments. This study aimed to identify the predictors for non-responders to immunosuppressive treatments. Non-responders were defined as those in whom cardiac death, hospitalization due to worsening heart failure, marked decrease in left ventricular ejection fraction (< 15%), life-threatening ventricular arrhythmias occurred within 5 years after immunosuppressive treatments. We analyzed 39 consecutive patients (58 ± 14 years, 27 women) who were definitely diagnosed as CS and treated with immunosuppressive agents. Eight patients received a single second-line immunosuppressive agent such as methotrexate or a combination of this agent and corticosteroid. During a mean follow-up of 7.4 years, 12 patients (30.8%) were identified as non-responders. The estimated 10-year survival from cardiovascular death was 28.8% in non-responders, as compared with 77.4% in responders (hazard ratio [HR] for cardiovascular death as compared with responders, 9.8; 95% confidence interval [CI], 2.4 to 40.2; $P = 0.0015$). Univariate analysis showed presence of basal thinning in interventricular septum (100% vs 63%, $P = 0.017$), lower left ventricular ejection fraction (LVEF, 34.9 ± 15.2% vs 48.9 ± 19.0%, $P = 0.03$), and higher BNP (543 ± 368pg/ml vs 233 ± 308pg/ml, $P = 0.023$) before the immunosuppressive treatments were associated with non-responders. Multivariate Cox hazard analysis showed lower LVEF (HR, 1.08; 95% confidence interval, 1.02-1.16; $P = 0.0062$) was the only independent predictors of the non-responders. In conclusion, lower LVEF is a predictor of poor response to immunosuppressive therapy in patients with CS.

P999
The rehospitalisation rates among patients with preserved, mid-range and reduced ejection fraction: databased analysis

R Pancheva[1]; N Runev[1]; E Manov[1]; E Dimchovski[2]; D Vassilev[3]
[1]*University Hospital Alexandrovska, Cardiology Clinic, Department of Propaedeutics of Internal Diseases, Sofia, Bulgaria*; [2]*Medical Institute of Ministry of Interior, Department Cardiology, Sofia, Bulgaria*; [3]*University Hospital Alexandrovska, Department Cardiology, Sofia, Bulgaria*

Background: The hospital readmissions due to worsening of heart failure (HF) remain huge medical, social and financial burden.
Purpose: The aim of this study was to compare the frequency of rehospitalization rates among patients with preserved, mid-range and reduced ejection fraction (EF).
Methods: An observational analysis of patients, hospitalized due to congestive HF from our department between January 2012 and June 2013, was conducted to assess readmission rates for decompensated HF.
Results: A total of 1028 patients were included with an age of 67.5 ± 11.3 years; 49.8% were women, the mean EF was 57 ± 11.2% (66.1% with preserved EF (<50%), 13% with mid-range EF (40-50%) and 7.6% with reduced EF (< 50%)). A total of 290 patients (28.2%) were aged = 75 years, and 737 (71.7%) were aged < 75 years. The demographic characteristics of our population are as follows: 94.8% of HF patients had hypertension (HT) (1.8% I stage; 64.1% II stage; 28.9% III stage); 26.97% diabetics (DM); 47.2% had coronary artery disease (CAD) and 32.6% of whom experienced myocardial infarction; 32% had valvular heart disease (VHD), 15.5% had thyroid gland disorders (3.4% hyperthyroidism vs. 12.1% hypothyroidism). Atrial fibrillation (AF) was present in 61.7% of the patients with HF; 29.8% had elevated pulmonary artery systolic pressure (PASP) (<40 mmHg). The length of hospitalization for HF was typically between 5 and 10 days, mean 6 days. All patients received guideline-directed medical therapy for HF. During the 3-year follow-up 14% experienced hospital readmissions because of an exacerbation of congestive HF. The patients with EF < 50% had more frequent readmissions due to increasing severity HF than those with preserved EF (2.5% of the patients with more than two hospitalizations had preserved EF, 5.2% had mid-range EF and 6.4% had reduced EF) ($p < 0.05$).
Conclusions: Our data showed that EF predict the frequency of rehospitalization for HF. The patients with mid-range and reduced EF experienced significantly high readmission rates, then those with preserved EF.

P1000
sST2 adds to the prognostic value of Gal-3 and BNP in chronic heart failure, independent of Mineralocorticoid Receptor Antagonists treatment.

M Barutaut[1]; P Fournier[1]; WF Peacock[2]; C Dambrin[1]; C Caubere[1]; C Servoz[1]; F Koukoui[1]; M Galinier[1]; F Smih[1]; P Rouet[1]
[1]*UMR UT3 CNRS 5288, Evol. Medicine, Obesity and heart failure: molecular and clinical investigations, Toulouse, France*; [2]*Baylor College of Medicine, Emargency Medicine, Houston, United States of America*

Funding Acknowledgements: We are grateful to Eurobio and BioMérieux for the support of this study, the supply of reagents for measurements and lending us a VIDAS automat for Ga

Aims: The soluble form of the IL-33 receptor (sST2) and Galectin-3 (Gal-3) are fibrosis biomarkers with prognostic value in heart failure (HF). We investigated the prognostic capacity of sST2 when combined with Gal-3, and determined if the prognostic utility of sST2 is affected by mineral corticoid receptor antagonist (MRA) therapy.
Methods and Results: sST-2 and Gal-3 were measured in 100 stable chronic HF (CHF) patients receiving MRA therapy and compared to 97 BNP and cardiovascular risk factor matched patients not treated with MRA. sST2 and Gal-3 levels were measured to determine the relationship with all-cause mortality at 6 year follow up. ROC curve cut-off points were defined as sST2 = 36.3 ng/ml, Gal-3 = 17.8 ng/ml, and BNP = 500 pg/ml, and had 6-years mortality hazard ratios (HR) of 7.3, 6.6 and 4.4, respectively. The combination of an elevated sST2 and Gal-3 had a HR = 4.4 [95% CI 1.9-8.9]. Adding BNP decreased the HR to 2.1 [95% CI 1.2-4.8]. Combining sST2 and Gal-3 to a clinical model relevant for CHF prognosis allowed a significant reclassification of 1-year adverse outcome risk, even when BNP was included. Finally, prognostic prediction by sST2 was unaffected by MRA treatment.

Conclusion: Simultaneous sST2 and Galectin-3 elevation is associated with poorer prognosis compared to either alone, regardless of BNP levels, and the prognostic capacity of sST2 is independent of MRA therapy.

P1001

Managements and outcomes of heart failure patients with paroxysmal vs. non-paroxysmal atrial fibrillation in Taiwan: Data from Taiwan Society of Cardiology-Heart Failure with reduced Ejection Fraction

H-Y Hung-Yu Chang[1]; M-C Fong[1]; A-N Feng[1]; W-T Lai[1]; C-W Hsueh[1]; Z-C Chiang[1]; W-H Yin[1]
[1]*Cheng-Hsin General Hospital, Taipei, Taiwan ROC*

Background: The prognostic significance and treatment strategy of atrial fibrillation (AF) in patients with heart failure remains controversial. We aimed to evaluate the characteristics, managements and outcomes of AF patients in the Taiwan Society of Cardiology-Heart Failure with reduced Ejection Fraction (HFrEF) registry.
Methods: We collected the clinical data of 1509 patients hospitalized for acute heart failure with left ventricular ejection fraction less than 40% from 21 hospitals between 2013 and 2014 in Taiwan. Baseline characteristics, AF status, medications, and one-year outcomes were analyzed.
Results: At baseline, 393 (26%) patients had AF, including 117 (29.8%) patients with paroxysmal AF (PAF) and 276 (70.2%) with non-paroxysmal AF (N-PAF). Age, gender, CHADS2-VASc score, and history of stroke were similar in both groups. PAF patients more frequently had ischemic cardiomyopathy (47.3% vs. 29.7%, p = 0.021) compared with N-PAF patients, while N-PAF patients had larger left atrial diameter (50.5mm vs. 47.3mm, p = 0.004) compared with PAF patients.
PAF patients were more likely to receive amiodarone (31.6% vs. 13.8%, p <0.001) and anti-platelet agents (54.1% vs. 42.5%, p = 0.041) but less likely to received renin-angiotensin system blockers (52.3% vs. 64.9%, p = 0.021), digoxin (26.1% vs. 46.6%, p <0.001), diuretics (80.6% vs. 88.4%, p = 0.058) and anti-coagulants (33.3% vs. 50%, p = 0.003) compared with N-PAF patients at discharge. Discharge heart rate, systolic blood pressure, and beta-blocker prescription rates were similar in both groups. One-year mortality (25.9% vs. 16.5%, p = 0.038) and non-cardiovascular death rates (13% vs. 5%, p = 0.008) were significantly higher in PAF patients.
Conclusions: In this observational, real-world registry, patients with PAF and HFrEF were less likely to receive guideline-recommended therapy, more likely to receive anti-arrhythmic agents and had worse one-year outcome. Our findings further emphasize the importance of optimized medication in HFrEF patients.

P1002

The time of presentation to the emergency department defines two different phenotypes of acute heart failure

C Lombardi[1]; A Ravera[1]; A Roncolato[1]; V Carubelli[1]; Al Castrini[1]; E Sciatti[1]; I Bonadei[1]; E Gorga[1]; E Vizzardi[1]; M Metra[1]
[1]*University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health, Brescia, Italy*

Background: Acute Heart Failure (AHF) is a potentially life-threatening condition characterized by different clinical presentations.
Purpose: The aim of the study is to evaluate if the time of presentation to the Emergency Room can influence different clinical characteristics and treatments of patients (pts) with AHF.
Methods: we retrospective analysed 426 pts admitted to the Emergency and Urgency Department and hospitalized for clinical and instrumental evidence of AHF. Pts admitted to the Emergency Department were divided in two groups according to the time of presentations: daytime pts from 8 am to 20 pm, and night-time pts from 20 pm to 8 am. Medical and clinical data at time to presentation were collected. We have also analysed the echocardiographic parameters obtained at the Emergency Department. The therapeutic pathway during hospitalization has been analysed according to the time of presentation.
Results: 329 pts arrived at the hospital during the day (8 am - 20 pm), 97 pts during the night (20 pm - 8 am). No differences were found in age, sex, weight, comorbidities and baseline therapies between the two groups. Pts admitted during the night were characterized by significantly higher systolic and diastolic blood pressure compared with pts admitted during the day (systolic blood pressure 142 ± 34 mmHg vs 127 ± 28 mmHg, p < 0.0001; diastolic blood pressure 82 ± 19 mmHg vs 73 ± 15 mmHg p < 0.001). Peripheral oxygen saturation was significantly worse in pts hospitalized during the night (92 ± 7% vs 94 ± 5%, p 0.03). Echocardiographic parameters showed an increase of vena cava congestion in daytime pts (87% vs 76%, p < 0.01). Pts admitted during the night required higher use of vasodilators (15% vs 6%, p 0.005) and higher average doses of furosemide (125 ± 118, p.0.04 vs 100 ± 11 mg, p < 0.01) compared with daytime pts. NT-proBNP and Troponin values were inferior in patients admitted during the night without statistical significance. During hospitalization death for cardiovascular causes occurred in 5% of daytime pts and in 6% of night-time pts (ns).
Conclusion: the time of presentation to the Emergency Department characterizes a specific phenothipe of Acute Heart Failure. During the night patients with elevated blood pressure, desaturation and no congestion of vena cava are significantly more frequent. This clinical picture, typically characterized by acute pulmonary edema, required higher doses of vasodilators and diuretics compared with daytime patients.

P1003

Predictors of cardiac death due to progression of chronic heart failure in patients after myocardial infarction

I A Leonova[1]; S Boldueva[1]; E Bykova[1]
[1]*North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation*

Despite the achievements of recent years in the management of patients with myocardial infarction (MI), patients continue to die from progression of chronic heart failure (CHF).
Objective: to identify predictors of cardiac death due to the progression of CHF in patients after MI.
Methods: 772 patients with acute MI were examined, prospective follow-up was carried out at the time from 1 to 7 years. The average age of patients was 58.2 ± 8.9 years.
Results: One of the leading causes of death of patients was the progression of CHF (in 26% of all cases
of death). Based on the results of multifactorial regression Cox analysis among independent risk factors of development of non-sudden cardiac death were age, aneurysm and left ventricular ejection fraction (LVEF).
With augment of age, every year increased the risk is of cardiac death due to the progression of CHF almost in 2.5 (RR = 2.46, p = 0.01). It seems interesting the fact that the average age of survivors and suddenly patients did not differ, while patients who died as a result of progression of CHF, were older than survivors: 63.8 ± 9.0 years vs 57.9 ± 9.5 years, p = 0.002. The results of most of the studies conducted also consider age as an independent prognostic factor affecting the mortality of patients with CHF for 5 years. In 21.9% of all cases MI was complicated by the development of aneurysm of LV, however among patients, who died due to progression of CHF, LV aneurysm was noted in 50% of cases.
Based on the results of multivariate regression analysis of Cox the absence of LV aneurysm resulted in a reduction in the risk of non-sudden cardiac death by 4.3 times (RR = 4.32, p = 0.003). Average LV EF among patients who died due to the progression of CHF was authentically (p = 0.000004) lower (45.59% ± 11.27%) than in survivors (56.51% ± 10.67%). It should be noted that the number of person with LVEF less than 40% in the group of CHF died patients was significantly more (22,7% p = 0.001) then among the survivors (5.6% of cases). As a results of multivariate regression analysis Cox increase of EF LV for each unit of measurement made it possible to reduce the risk of death in 2.4 (RR = 2.43, p = 0.006).
Conclusion: the main risk factors of cardiac death after MI were age, systolic dysfunction and LV aneurism

P1004

Training general practitioners to improve treatment of patients with heart failure: a cluster randomized trial

F H Frans Hendrik Rutten[1]; MJM Valk[1]; AW Mosterd[1]; MA Landman[1]; DDL Broekhuizen[1]; NPA Zuithoff[1]; AW Hoes[1]
[1]*University Medical Center Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands*

Funding Acknowledgements: Health Insurance Company Achmea, the Netherlands

Background: Drug treatment of patients with heart failure (HF) can be improved and we wanted to assess whether a single training session of general practitioners improved evidence-based drug treatment of heart failure patients.
Methods: A cluster randomized controlled trial in established heart failure patients. Primary care practices (PCPs) were randomized to care-as-usual (control) group, or to the intervention group in which GPs received a half-day training on HF management, and a leaflet on HF drug uptitration. Changes in HF medication, health status, hospitalization, and survival were compared between the two groups.
Results: 15 PCPs with 200 HF patients were randomized to the intervention group, and 15 PCPs with 198 HF patients to the control group. Mean age was 76.9 (SD 10.8) years, 52.5% were female. On average the patients were diagnosed with HF 3.0 (SD 3.0) years ago. In total, 204 had HFrEF and 194 HF with preserved ejection fraction (HFpEF). In participants with HFrEF, the use of angiotensin converting enzyme inhibitors/angiotensin receptor blockers (ACEI/ARB) decreased in six months in both groups (5.2% (95% confidence interval (CI) 2.0-10.0) and 5.6% (95%CI 2.8-13.4)),

respectively (baseline-corrected odds ratio (OR) 1.07 (95%CI 0.55-2.08), while beta-blocker use increased in both groups with 5.2% (95%CI 2.0-10.0) and 1.1% (95%CI 0.2-6.3), respectively (baseline-corrected OR 0.82 (95%CI 0.42-1.61). Also for health status, hospitalizations, or survival after 12 to 28 months there were no significant differences between the two groups, also not when separately analysed for HFrEF and HFpEF.
Conclusion: A half-day training of GPs does not improve HF drug treatment of patients with established HF.

P1005
Clinical profile and management of octogenarian patients admitted for acute heart failure

EK Egle Kavaliunaite[1]; I Navickaite[1]; I Kaminskaite[1]; R Salkevic[2]; J Motiejunaite[3]; I Jonauskiene[3]; V Juknevicius[4]; D Rimkeviciute[3]; A Mebazaa[5]; A Kavoliuniene[3]; J Celutkiene[4]

Introduction: Acute heart failure (AHF) is the most common cause of hospitalization in elderly patients. (1) More than 25% of AHF patients are octogenarians. (2) Previous studies have demonstrated substantial differences in presentation and management of AHF according to age. (3, 4) Therefore, the aim of our study was to describe the clinical profile and management of elderly AHF patients presenting to emergency department.
Purpose: We aimed to evaluate whether the clinical profile and management of octogenarian patients admitted for AHF differ from their younger counterparts.
Design and Methods: A prospective two-centre observational cohort study enrolled 1433 dyspnoeic patients consecutively admitted to the emergency department. AHF was the cause of acute dyspnoea in 725 patients (50%). Patients were classified as octogenarians when being = 80 years old. Data were analyzed with One-way ANOVA.
Results: 171 (24%) of all AHF patients were octogenarians. The more common comorbidities in the octogenarian patient group differ (see table). Clinical signs at admission were similar in both patient groups. Diuretics and beta-blockers were more often prescribed to younger patients compared to octogenarians, while other medical treatment at discharge did not differ between the two groups.
Conclusions: Octogenarians presented with more comorbidities than younger AHF patients. Clinical profile at admission was similar in octogenarians compared to younger AHF patients. Basic medical treatment at discharge did not differ between octogenarians and younger AHF patients, except diuretics and beta-blockers

>= 80 vs. < 80 year old AHF patients

	≥80 years old	<80 years old	p value

P1006
A gradient of frequency of rehospitalization of heart failure patients between different types atrial fibrillation and correlation with left atrial diameter

R Pancheva[1]; N Runev[1]; E Manov[1]; B Stoimenov[1]; E Dimchovski[2]; D Vassilev[3]
[1]University Hospital Alexandrovska, Cardiology Clinic, Department of Propaedeutics of Internal Diseases , Sofia, Bulgaria; *[2]Medical Institute of Ministry of Interior, Department Cardiology, Sofia, Bulgaria*; *[3]University Hospital Alexandrovska, Department Cardiology, Sofia, Bulgaria*

Background: The atrial fibrillation (AF) and heart failure (HF) have emerged as new cardiovascular epidemics over the last decade. The fact that either AF or HF alone can predispose a patient to repeated hospitalization, and that prognosis of both together is worse than either alone, makes this interplay even more interesting.
Purpose: To assess the frequency of rehospitalization of HF patients with the different types AF.
Methods: An observational analysis of patients hospitalized due to congestive HF (with preserved EF (<50%), mid-range EF (40-50%) and reduced EF (< 50%)) from our depatment, between January 2012 and June 2013, was conducted to assess the gradient of frequency of rehospitalization between the different types AF and correlation with left atrial (LA) diameter.
Results: A total of 1029 patients were included with an age of 67.5 ± 11.3 years; 49.8% were women, mean EF was 57 ± 11%, 634 of whom had AF (61.7%) (3.9% new onset AF; paroxysmal 20%; persistent 5.6%; permanent 31.6%). The demographic characteristics of our population are as follows: 94.8% had arterial hypertension (HT) (1.8% I stage; 64.1% II stage; 28.9% III stage); 26.97% had diabetes mellitus (DM); 47.2% had coronary artery disease (CAD) and 32.6% of whom had previous myocardial infarction (MI); 32% had valvular heart disease (VHD), 15.5% had thyroid gland disorders (3.4% hyperthyroidism; 12.1% hypothyroidism). The patients with AF had greater risk of rehospitalization due to more severe congestive HF than those without AF (1.3% vs. 11.4%, respectively; $p < 0.01$). The different types AF were associated with difference in the readmission rates (5.0% had new onset AF, 20.3% had paroxysmal AF, 15.8% had persistent AF and 17.8% had permanent AF ($p < 0.01$). The patients with LA diameter >55mm experienced more frequent rehospitalization (8.6% vs. 2.8%, respectively; $p < 0.01$). The readmission rates were not influenced by management of AF - 27.2% had rhythm control strategy and 72.8% had rate control strategy ($p = 0.671$). Anticoagulation therapy didn't affect the rehospitalization rates, but antiplatelet therapy was associated with increased readmission rates: 1% for monotherapy and 6,8% for dual antiplatelet therapy ($p < 0.01$). On multivariate logistic regression analysis the independent predictors of readmissions due to decompensated HF were: de novo AF (OR 0.298; 95% CI, 0.146-0.605; $p < 0.01$), LA diameter > 55 mm (OR 0.457; 95% CI, 0.233-0.897; $p < 0.05$), rate control strategy ($p < 0.05$) with digoxin (OR 0.205; 95% CI, 0.053-0.794; $p < 0.05$), beta blocker (OR 0.099; 95% CI, 0.020-0.560; $p < 0.01$) and Ca-antagonist (OR 0.298; 95% CI, 0.146-0.605; $p < 0.01$).
Conclusions: Our data showed that the different types AF are associated with difference in readmission rates due to decompensated HF and LA diameter more than 55 mm is independently associated with higher readmission rates.

P1007
Prognostic role of myocardial SERPINA3 and ST2 transcripts in predicting mortality in patients with heart failure due to idiopathic cardiomyopathy

L Delrue[1]; K Dierickx[1]; W Heggermont[1]; R Dierckx[1]; S Verstreken[1]; M Goethals[1]; M Marc Vanderheyden[1]; J Bartunek[1]
[1]OLV Hospital Aalst, Cardiovascular Center, Aalst, Belgium

Background: Prognostic stratification in heart failure (HF) remains challenging. Myocardial serine peptidase inhibitor class 3A gene expression has recently been shown to be upregulated in pts with non-ischemic cardiomyopathy and a significant positive correlation between myocardial LV SERPINA3 and length of hospitalization was found in LVAD patients. Similarly, clinical trials revealed that serum sST2 levels predict outcome in pts with chronic heart failure and that ablation of ST2 causes exaggerated cardiac remodelling in non-ischemic HF.
Aim: To evaluate the prognostic role of myocardial LV SERPINA3 and ST2 transcripts as markers of remodeling/inflammation with respect to mortality in patients with CCMP.
Methods: LV message levels (qRT-PCR, rel units) were investigated in non-surviving HF patients due to CCMP with LV ejection fraction (EF) < 45% and < 75 years (n = 35). All patients died within 5 years after LV biopsy procurement taken at the time of routine cardiac catheterization. LV message levels were compared to those in CCMP survivors (n = 39) matched for age and hemodynamic phenotype including volumes, filling pressure and ejection fraction. The impact of myocardial expression on survival was analyzed by Kaplan-Meier curves dichotomized according to the median value of the transcripts levels.
Results: Significant up-regulation of LV ST2 (10.99 ± 24.22, $p < 0.01$) and SERPINA3 (2.44 ± 3.80, $p < 0.001$) transcripts was seen in non-survivors vs survivors

(0.72 ± 0.81 and 0.36 ± 0.22, resp.). CCMP patients with a higher than median expression of one of the 2 factors showed survival rates of resp 39 and 43 % at 5 years vs 71-63% in patients with a low expression. When combining both factors, survival rate dropped to 11% in HF patients with both high SERPINA3 and ST2 expression or 50% survival at 10 months (log-rank test, p = 0.0103)(Fig.1). Note, no significant difference was seen in the mean proBNP and ST2 serum levels in the four groups.

Conclusion: Combined myocardial upregulation of SERPINA3 and ST2 is associated with poor survival in CCMP patients irrespective of circulating BNP and ST2 serum levels. Further prospective studies should determine whether tissue myocardial profiling may be of added value in prognostic stratification in heart failure in addition to conventional analysis of circulating biomarkers.

Clinical outcomes at 5 to 9 years following Transcatheter Aortic Valve Replacement

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; JM Garcia-Pinilla[1]; F Carrasco-Chinchilla[1]; AJ Dominguez-Franco[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; E De Teresa-Galvan[1]

[1]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

The durability of transcatheter heart valves and long-term clinical outcomes are unknown. The aim of this study was to evaluate clinical and hemodynamic outcomes between 5 to 9 years after Transcatheter Aortic Valve Replacement (TAVR).

Methods: Between April 2008 and December 2012, 305 patients underwent TAVR for the treatment of severe symptomatic aortic stenosis with the auto-expandable prosthesis

Results: the mean age, logistic EuroSCORE and STS score were 79.3 ± 6.5 years, 19.4 ± 12% and 6.6 ± 4% respectively. Mean aortic valve gradient decreased from 48.7 ± 15 mm Hg to 8.9 ± 4.3 mmHg after TAVI, to 11.1 ± 9 mm Hg at 4 years, and 22.7 ± 12 mmHg at 5 years (p for post-TAVI trend 0.03). Mean aortic valve area increased from 0.63 ± 0.16 cm2 to 1.57 ± 0.3cm2 after TAVI to 1.48 ± 0.2 at 4 years and 0.97 ± 0.3 cm2 at 5 years (p for post-TAVI trend 0.01). Mean left ventricular ejection fraction increased from 61.1 ± 15 % to 65.5 ± 11% after TAVI, to 58.2 ± 17% at 4 years and 60.7 ± 8% at 5 years (p for post-TAVI trend 0.001) Late mortality after a mean of 4.15 ± 2.4 years 58% and in only 34.1% patients was cardiovascular mortality. Survival rates at 1 to 9 years were at 87.5%, 79%, 73.1%, 65.6%, 55.4%, 48.2%, 41.9%, 37.3% and 35.1% respectively. At 5 years, 3 patients had severe prosthetic valve dysfunction (severe stenosis and moderate transvalvular regurgitation). Median survival time after TAVI was 6 years (95% confidence interval [CI]: 5.89 to 6.28), and the risk of death was significantly increased in patients with frailty (adjusted hazard ratio [HR]: 1.864; 95% CI: 1.204 to 2.886),p = 0.001, Charlson index [HR= 1.243 (95% CI 1.148-1.346), p < 0.001], and left ventricular ejection fraction [HR= 1.012;(95% CI 1.001-1.024)p = 0.044].

Conclusions: Our study demonstrated favorable long-term outcomes after TAVR. Signs of prosthetic valve failure were observed in 0.97% of patients.

P1009

Role of emergency medical system and early intervention by specialist cardiologist/heart failure expert in influencing the clinical outcomes in Manipal Heart Failure Registry [MHFR] patients

A Ajit Singh[1]; T Devasia[1]; H Kareem[1]; YR Karkala[2]; S Chauhan[2]; PN Shetty[1]; S Rao[1]; P Ganesh[1]; D Uppunda[1]; KK Shetty[3]

[1]Kasturba Medical College and Hospital, Cardiology, Manipal, India; *[2]Melaka Manipal Medical College, Pharmacology, Manipal, India*; *[3]Vinaya Hospital, Medicine/Cardiology, Kundapur, India*

On behalf of: MHFR

Background/Introduction: Optimal utilization of emergency services in emergency department (ED) is necessary/ important for better patient outcome and cost-effectiveness. Visit by an HF specialist delineates further treatment plans who decide on admission to ward/ICCU or discharge.

Purpose: To evaluate the time consumption of emergency medical facilities for HF care and to assess the impact of factors on patient outcome

Method: Manipal heart failure registry is an observational cohort study conducted in a tertiary care referral hospital in South India. The study recruited all patients who came to the emergency department with acute HF or exacerbation of chronic HF from September 2015 to December 2016. Arriving modalities and exercises including first evaluation by ED physician, admission, assessment by HF expert at ED, and shifting to HF special care unit were analysed. Clinical outcomes upto one year were evaluated.

Results: A total of 764 patients were included in this study. Mean age was 59 ± 10.7 years. 527 (69%) patients were males. 397 (52%) patients arrived by public transport, and 92 (12%) patients came by ambulance. After the initial evaluation, 99 (13%) patients were found to have only mild symptoms, these were managed with IV diuretics and sent back. 665 (87%) patients were admitted to HF special care unit from ED.

Preliminary tests including ECG, ECHO, troponin T and NT- proBNP were done at ED to confirm HF. Majority of the patients (n = 636; 83.2%) were diagnosed to have HF with reduced ejection fraction and remaining 128 (16.8%) had HF with preserved EF.

In-hospital mortality was 9.02% during an average stay of 5.2 ± 2.9 days. Post-discharge cumulative one month, 6 month and 12-month mortality were 4.9%, 13.2% and 16.9% respectively.

Arrival by ambulance was significantly associated with in-hospital mortality, whereas arrival by public transport was positively associated with 6-month mortality (p < 0.05).

First evaluation by HF expert in ED was done 41 minutes (average gap) after patient's arrival to ED. The average time between arrival at ED to admission, first evaluation by HF expert in ED to transfer to HF care unit and emergency arrival to HF care unit were 85 minutes, 102 minutes and 121 minutes respectively.

Time from patient's emergency arrival to reach HF care unit is statistically associated (p < 0.01) with in-hospital mortality. Delayed first evaluation by HF expert at ED to HF care unit transfer is associated (p < 0.05) with higher in-hospital mortality. Increased time delay between patient's emergency arrival and first evaluation by HF expert at ED is associated (p < 0.05) with 1 month mortality.

Conclusion(s): HF patient may present to ED with acute decompensation. Early evaluation by HF expert with ECG, ECHO, troponin T and NT-proBNP play a vital role in both short and long-term mortality and morbidity. Emergency management of acute decompensation play a pivotal role in the management of HF patients.

Chronic Heart Failure - Diagnostic Methods

P1010

Diastolic dysfunction as a prognosticator in patients with heart failure with preserved ejection fraction

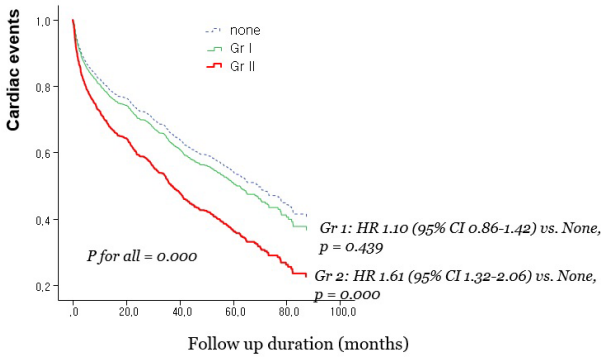
GY Goo-Yeong Cho[1]; JJ Park[1]; JB Park[2]; JH Park[3]

[1]Seoul National University Bundang Hospital, Seongnam, Korea Republic of; *[2]Seoul National University Hospital, Seoul, Korea Republic of*; *[3]Chungnam National University Hospital, Cardiolgoy, Daejon, Korea Republic of*

Background: Echocardiographic Doppler parameters were used for assessment of diastolic dysfunction. Heart failure with preserved ejection fraction (HFpEF) is usually associated with diastolic dysfunction. However, not all patients had diastolic dysfunction in HFpEF.

Purpose: We evaluated whether how many patients had diastolic dysfunction and whether this dysfunction was associated with adverse cardiac outcome.

Methods. Total 1,132 consecutive patients (age 73, female 61%) were admitted for acute decompensated heart failure. All patients had EF = 50%. Diastolic dysfunction was graded based on diastolic annular tissue velocity (e') and E/e' (Non: E/e' = 14 and e' = 7 cm/sec, Gr I: E/e' > 14 or e' < 7, Gr II: E/e' > 14 and e' < 7). Cardiac events were defined as all-cause death and heart failure admission.



diastolic grading for events

Results: Diastolic dysfunction was detected in 78% (grade 1: 31%, grade 2: 47%). During a median follow-up of 28.6 months (IQR 8.9-52.1), 569 patients (50.3%) were developed cardiac events. Patients with cardiac events showed older age, higher incidence of atrial fibrillation, lower EF, higher E/e', and lower e' than patients without events. By cox-regression survival analysis, progression of diastolic dysfunction was associated with higher cardiac events in both univariate and multivariate analysis. However, event free survival between Non and Gr I dysfunction was not statistically significant (HR 0.91, p = 0.439) (Figure).
Conclusions: Among patients with HFpEF, 22% of patients did not have a diastolic dysfunction. Although the degree of diastolic dysfunction was closely related with cardiac events, patients with Gr I dysfunction were not different from Non.

P1011

Prognostic value of NT-ProBNP/BNP ratio in patients with heart failure and reduced ejection fraction using sacubitril-valsartan: systematic review and post hoc analysis of PARADIGM-HF Trial

E Eduardo Pitthan[1]; VN Hirakata[1]; JN Barbisan[1]; CG Rodrigues[1]
[1]*Institute of Cardiology of Rio Grande do Sul, Porto Alegre, Brazil*

Background: The PARADIGM-HF trial showed that Sacubitril–Valsartan (SV) was superior to Enalapril in reducing the rates of morbimortality among patients with heart failure and reduced ejection fraction (HFrEF). SV increases B-type natriuretic peptide (BNP) and decreases NT-proBNP levels. The NT-proBNP/BNP ratio might be a valuable prognostic biomarker in HFrEF patients in treatment with SV and indirectly discriminated "responder" and "no responder" patients.
Purpose: To assess the relationship between NT-proBNP/BNP ratio and clinical outcomes in patients with HFrEF undergoing treatment with SV.
Methods: A systematic review (SR) was conducted in accordance with PRISMA. We included studies evolving HFrEF patients undergoing treatment with SV which had the levels of NT-proBNP and BNP and morbimortality outcomes measured. We reviewed PubMed, EMBASE and Web of Science. Data from PARADIGM-HF trial publications was extracted and reanalyzed for the purpose of this study. Associations between NT-proBNP/BNP ratio and cardiovascular death (SD) or HF hospitalization (HFH) were examined, among others, as was the effect of SV vs Enalapril on the NT-proBNP/BNP ratio.
Results: 180 publications were screened and 8 included. Decreased NT-proBNP/BNP ratio when compared to baseline before randomization (6.39) was associated with good prognosis: patients alive (6.33) and event-free (6,14) at the end of the study. In contrast, increased NT-proBNP/BNP ratio when compared to baseline was associated with poor prognosis: sudden death (6.49), death due to progression of HF (7.35), cardiovascular death (CD) (6.65), non-CD (6.62), HF hospitalization (6.48), emergency visits (6.53) and worsening of cardiac function (6.72). In the Enalapril arm, the NT-proBNP/BNP ratio was not associated with good or poor prognosis outcomes. The ratio was indirectly associated with the efficacy of SV in the treatment of HFrEF. The MAGGIC Score predicts mortality in HF, the applicability of the NT-proBNP / BNP rate was linearly associated with risk of HFrFE mortality. The Score EMPHASIS was linearly associated with worsening of quality of life and the applicability of the index can be a predictor or guide for quality of life evaluation.
Conclusions: When compared to baseline, reduced NT-proBNP/BNP ratio is associated with better outcomes and increased ratio with worse outcomes. More studies will be conducted to clarify the prognostic value of NT-proBNP/BNP ratio in HFrEF patients in treatment with SV.

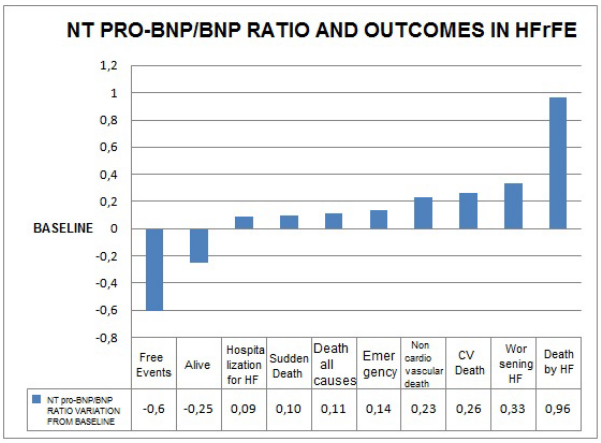


Figure 1

P1012

Relationship between aldosterone level and comorbidities in chronic heart failure with preserved ejection fraction

A Shevelyok[1]; N Vatutin[2]; N Vatutin[3]; V Venzheha[1]; V Venzheha[2]
[1]*Donetsk national medical university, Donetsk, Ukraine*; [2]*M. Gorkiy Donetsk national medical university, V. K. Gusak Institute of Urgent and Recovery Surgery, Donetsk, Ukraine*; [3]*V. K. Gusak Institute of Urgent and Recovery Surgery, Donetsk, Ukraine*

Background: Plasma aldosterone level has been shown to be an independent determinant of cardiovascular complication in chronic heart failure (CHF), but whether it's associated with comorbidities is unknown.
Purpose: The study aims to investigate the relationship between plasma aldosterone level and comorbidities in CHF with preserved ejection fraction (CHFpEF).
Methods: The study included 158 patients (58 men and 100 women, mean age 62.3 ± 7.4 years) with CHFpEF (< 50%). All patients had no history of primary aldosteronism and did not use the mineralocorticoid receptor antagonists during the last 6 weeks. Aldosterone plasma level was measured and comorbidities were assessed. For statistical purpose, patients were divided into two groups according to whether their median value of plasma aldosterone was high (< 160 pg/ml) or normal (< 160 pg/ml). The predictive capacity of comorbid burden for explaining variance in aldosterone level was assessed after standardization for any other differences.
Results: According to laboratory results 99 patients (67.1%, 95% confidence interval (CI) 59.6-74.2%) had normal aldosterone level (nAld) and 59 patients (37.3%, 95% CI 30.0-45.0%) had high aldosterone level (hAld). hAld patients were significantly younger (57.75 ± 7.5 vs. 65.02 ± 7.1 years, p < 0.001), severe (NYHA III-IV) CHF majority (62.7% vs. 33.3%, p < 0.001) compared with nAld patients. They more often had a history of myocardial infarction (59.3% vs. 41.4%, p = 0.044), atrial fibrillation (33.9% vs. 17.2%, p = 0.027), long-term (<10 years) history of arterial hypertension (57.6% vs. 25.3%, p < 0.001), chronic obstructive pulmonary disease (COPD) (27.1% vs. 7.1%, p = 0.001), diabetes mellitus (39.0% vs. 19.2%, p = 0.011), obesity (64.4% vs. 29.3%, p < 0.001) and renal dysfunction (88.1% vs. 50.5%, p < 0.001). Multiple regression analysis showed that after standartization for age and severity of CHF only long-term arterial hypertension (odds ratio (OR) 2.67, 95% CI 1.58-5.59), COPD (OR 4.62, 95% CI 2.00-8.53), obesity (OR 3.15, 95% CI 1.96-6.24) and renal dysfunction (OR 4.82, 95% CI 2.12-10.61) remained the independent risk factors of high aldosterone level.
Conclusion: In patients with CHFpEF plasma aldosterone level is closely associated with comorbidities. Long-term history of arterial hypertension, COPD, obesity and renal dysfunction are the independent risk factors of secondary hyperaldosteronemism.

P1013

Predictive models of mortality and readmission in patients with chronic heart failure and preserved ejection fraction

A Ana Belen Mendez Fernandez[1]; A Ferrero Gregori[1]; J Ordonez Llanos[2]; MJ Pirla Buxo[1]; A Garcia Osuna[2]; M Grau Agramunt[2]; S Mirabet Perez[1]; J Alvarez Garcia[1]; J Cinca Cuscullola[1]; E Roig Minguell[1]
[1]*Hospital de la Santa Creu i Sant Pau, Department of Cardiology , Barcelona, Spain*; [2]*Hospital de la Santa Creu i Sant Pau, Department of Biochemistry, Barcelona, Spain*

Introduction: Heart failure with preserved ejection fraction (HFpEF) is an increasingly common diagnosis and responsible for a high number of consultations as well as hospital admissions and readmissions. The pathophysiological pathways leading to the disease are not clear, which makes it difficult to find specific treatments.
The knowledge of predictors of mortality and re-entry would allow early identification of higher risk patients. Different metabolic markers have been introduced in the usual clinical practice, being undoubtedly the natriuretic peptides the reference ones.
Objective: The aim of the study was to evaluate the value of new biomarkers, which involve different pathophysiological pathways, to assess the prognosis of patients with HFpEF or mid-range ejection fraction (HFmrEF).
Methods: From May 2009 to May 2015,HFpEF and HFmrEF patients assessed for the first time in the Heart Failure Unit were included in the study.
Blood samples were taken by peripheral venipuncture and frozen, for later evaluation of a multi-marker panel with NTproBNP, GDF15, hs-TnT and Galectina 3.
Results: A total of 315 patients were included. 70% had LVEF> 50%, and 30% had LVEF between 40-49%. Mean age was 68 years (32% were women). The ethiology was ischemic (34%), followed by idiopathic (24%).
The values of the biomarkers were: Galectin 326 ± 20 ng/ml; hs-TnT 61 ± 405 ng/L; GDF-15 3809 ± 3521 pg/ml; NTproBNP 2867 ± 4909 pg/ml. There were no significant differences in the mean value of the biomarkers under study (GDF15, Galectina 3, hsTnT, NTproBNP) between patients with HFpEF and HFmrEF. The mean follow-up in the HFpEF group was 24 ± 20.6 months and in the HFmrEF group 21.6 ± 19.8 months (no significant differences). There were also no differences in the re-admission rate in both groups, which was 10.9% during the first month and 48.9% during the follow-up in the HFpEF group, and 10% during the first month and 43.3% during the follow-up of HFmrEF
Mortality during follow-up was 35% in the HFpEF group and 22% (p 0.02) in the HFmrEF group.
Multivariate analysis identified NYHA FC 3-4 (p 0.04); Systolic blood pressure (p 0.01); Left atrium size (p 0.03) and Age (p 0.0001) as independent predictors of mortality. When the biomarkers were added to the model, only GDF15 was statistically significant (p 0.01).
The IDI after the inclusion of GDF15 in the model with established mortality risk factors was 0.0279, which increases the ability to precede death by 2.8% (p 0.0118). The NRI, which represents the quantification of the improvement in the classification for events (mortality), discounting what worsens for non-events, was 0.271, which means a 27.1% improvement in the reclassification (p 0.024).
Conclusions: In patients with HFpEF and HFmrEF, the addition of GDF-15 values to the current clinical model could add prognostic information beyond that of current methods.

P1014

Cardiovascular biomarkers predict post-discharge rehospitalization risk and mortality among swedish heart failure patients

J Molvin[1]; E Bachus[2]; W Gallo[2]; G Tasevska-Dinevska[1]; H Holm[2]; A Jujic[2]; O Melander[2]; A Fedorowski[2]; M Magnusson[1]
[1]Lund University, Department of Cardiology, Skåne University Hospital, Malmö, Lund, Sweden; *[2]Department of Clinical Sciences, Lund University, Skåne University Hospital, Malmö, Sweden*

On behalf of: HARVEST
Funding Acknowledgements: The Swedish Heart and Lung foundation [2015-0322] and Wallenberg Center for Molecular Medicine, Lund University.

Background/Purpose: Here we aimed to analyse biomarkers related with neuroendocrine responses and cardiovascular stress (mid-regional pro-adrenomedullin (MR-proADM), copeptin, C-terminal pro-endothelin-1 (CT-pro-ET1) and N-terminal pro-brain natriuretic peptide (NT-proBNP)) and renal function (cystatin C) to test their predictive role in regard to mortality and risk of rehospitalization in a Swedish prospective heart failure (HF) patient cohort.
Methods: Two-hundred-and-sixty-eight patients hospitalized for HF (mean age: 75 years; 29% women) had complete data on all variables used in the analyses. Relations between baseline biomarker plasma concentrations and death as well as rehospitalization risk due to cardiac causes were assessed using multivariable Cox regression analysis adjusting for age, sex, body-mass index, systolic blood pressure, NYHA-class at hospitalisation, diabetes, total cholesterol, high-density lipoprotein, prevalent atrial fibrillation and smoking. A two-sided Bonferroni-corrected p-value of 0.05/5 = 0.010 was considered statistically significant;
Results: During follow-up period (mean time, 17 ± 12 months), a total of 57 patients died. In the multivariable-adjusted Cox regression analysis, all the biomarkers except CT-pro-ET1 (hazard ratio (HR) per 1SD: 1.42, 95% confidence interval (CI), 1.03-1.95; p = 0.034) were significantly associated with increased risk of death; NT-proBNP (HR, 1.85; CI, 1.17-2.17; p = 4.0x10-4), MR-proADM (HR, 1.72; CI, 1.22-2.41; p = 2.2x10-4), copeptin (HR, 1.70; CI, 1.22-2.36; p = 0.0002), and cystatin C (HR, 2.11; CI, 1.56-2.86; p = 1.0x10-6). A total of 178 patients were rehospitalized (mean follow-up time, 9 ± 8 months) due to cardiac causes. NT-proBNP was the only biomarker that showed significant association with risk of 1st rehospitalization due to cardiac causes ((HR, 1.47; CI, 1.13-1.91; p = 0.005).
Conclusion: Among patients hospitalised for HF, elevated plasma levels of NT-proBNP, MR-proADM, copeptin and cystatin C are significantly associated with increased risk of death after discharge, whereas NT-proBNP is the only biomarker that independently predicts the risk of rehospitalization.

Exhaled acetone in the differential diagnostics of heart failure

A A Alexandra Bykova[1]; L K Malinovskaya[1]; PH YU Kopylov[1]; P SH Chomahidze[1]; V B Betelin[2]; A L Syrkin[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; *[2]Scientific Research Institute for System Analysis of the Russian Academy of Science, Moskow, Russian Federation*

Background: Heart failure (HF) had certain symptoms, most of them has high sensitivity and low specificity. To verify the diagnosis of HF various laboratory and instrumental testing had to be done. According a few recent studies exhaled acetone increase in patients (pts) with HF.
Purpose: The aim of this study was to evaluate exhaled acetone in the differential diagnostics of HF.
Methods: From October 2014 to April 2016 78 pts with symptoms of HF such as breathlessness, fatigue, reduced exercise tolerance and ankle swelling was enrolled. Fasting exhaled breath samples were collected during the first 24h of hospitalization in 1L Tedlar bags. Exhaled breath was analyzed using PTR-MS (Compact PTR-MS, Ionicon, Austria). Diagnosis of HF was confirmed by echocardiography (in all pts) and NTproBNP (in pts with left ventricle ejection fraction (LV EF) more than 40%).
Results: The baseline characteristics of pts are in the Table 1. Exhaled acetone was significantly higher in pts with HF (916 [433; 2474] vs 383 [313; 665] ppb, p = 0,012). Receiver operator characteristic (ROC) analyses was performed to assess optimal cutoff points for this biomarker and to calculate sensitivity and specificity. The area under the ROC curve for acetone was 0,722 (95% CI 0,603 - 0,842, p = 0,012). The optimal cutoff concentration for acetone was 340 ppb, corresponding to sensitivity of 84% and specificity of 61%. The positive predictive value of the elevated exhaled acetone was 81%. The negative predictive value of the elevated exhaled acetone was 33%.
Some significant correlation of exhaled acetone also has been found with LV EF (r= - 0,244, p = 0,009), mean pulmonary artery pressure (r = 0,649, p < 0,0001), NTproBNP (r = 0,546, p < 0,0001).
Conclusion: Exhaled breath analysis is a novel non-invasive method of diagnostic of HF. It could be performed in real-time manner and detection of exhaled acetone might be used in the differential diagnostics of pts with symptoms of HF. The relatively few participants is the main limitation of this study.

P1016

Measurement of multiple cytokines for discrimination and risk stratification in patients with chagas disease and idiopathic dilated cardiomyopathy

A Adnan Khan[1]; Y Wang[1]; N Wessel[2]; HP Schultheiss[3]; MDA C Moreira[4]; T Walther[5]
[1]Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany; *[2]Humboldt University Berlin, Department of Physics, Berlin, Germany*; *[3]Charite - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany*; *[4]Federal University of Minas Gerais, Department of Internal Medicine, Belo Horizonte, Brazil*; *[5]School of Medicine and School of Pharmacy, University College Cork, Department of Pharmacology and Therapeutics, Cork, Ireland*

On behalf of: Excellence Cluster Cardio-Pulmonary System (ECCPS)
Funding Acknowledgements: DAAD and CAPES Grant (415-br-probral/po-D/08/11632)

Introduction: Chagas' disease (CD), caused by the hemoflagellate protozoan, Trypanosoma cruzi, is endemic in most countries of South and Central America, where it continues to be a major source of social, health, and financial burden. Heart failure (HF) is often a late manifestation of chronic CD, and is associated with high morbidity and mortality. Early identification of patients with CD, therefore, would be desirable as early intervention may help to improve the prognosis.
Purpose: Keeping in view the inflammatory nature of CD, this study investigated the possible role of 21 different inflammatory cytokines as biomarkers for prediction and prognosis of CD.
Methods: The plasma concentration of each of these cytokines was measured in a group of patients with CD (n = 94), and then compared with those measured in patients with dilated cardiomyopathy (DCM) from idiopathic causes (n = 48), and with control subjects (n = 25).
Results: Using monovariate analysis, plasma levels of cytokines such as stem cell growth factor beta (SCGF beta), hepatocyte growth factor (HGF), monokine induced by interferon gamma (MIG), and macrophage inhibitory factor (MIF) were significantly increased in CD patients with advanced HF compared to control group. Although, none of the cytokines could demonstrate any prognostic potency in patients with

CD, MIG was however, able to show a clear trend in predicting mortality and necessity for heart transplant in patients with DCM. Further, multivariate analysis was able to prognosticate a large proportion of CD and DCM patients, but it could not discriminate CD from idiopathic DCM. In CD patients, HGF and Interleukin-12p40 (IL-12p40) together were able to separate 81.9% of 3-year survivors from the deceased, while in DCM, stromal derived factor-1 alpha (SDF-1alpha), stem cell factor (SCF), and MIG together discriminated 77.1% of survivors from the deceased.

Fig 1

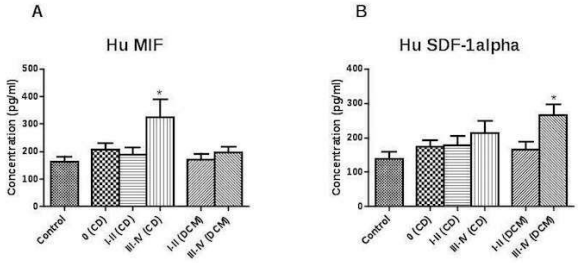

Fig 1A. Plasma concentration of MIF in controls (n = 25); in patients with CD distributed in asymptomatic (0) (n = 46), NYHA classes I-II (n = 24), and NYHA classes III-IV (n = 23); and in patients with DCM divided in NYHA classes I-II (n = 22) and NYHA classes III-IV (n = 26). Data is given as mean ± SEM. * $p < 0.05$ vs control.

Fig 1B. Plasma concentration of SDF-1alpha in controls (n = 21); in patients with CD distributed in asymptomatic (0) (n = 44), NYHA classes I-II (n = 25), and NYHA classes III-IV (n = 23); and in patients with DCM divided in NYHA classes I-II (n = 22) and NYHA classes III-IV (n = 26). Data is given as mean ± SEM. * $p < 0.05$ vs control.

Plasma concentration of MIF & SDF-1alpha

Conclusion: The significant increase in plasma concentrations of cytokines such as HGF and MIG in CD patients with advanced heart failure compared to controls, and the ability of these cytokines to prognosticate a large proportion of patients with CD and DCM using multivariate analysis, encourages further studies to clarify the diagnostic and prognostic potential of cytokines in these patients.

P1017

How much does right ventricular dysfunction influence the elevation of NT-proBNP in patients with acute heart failure?

R Raquel Lopez Vilella[1]; I Sanchez Lazaro[1]; I Husillos Tamarit[1]; L Martinez Dolz[1]; L Almenar Bonet[1]
[1]*Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit. Cardiology Department, Valencia, Spain*

Background and Objective: Acute heart failure (AHF) is associated with an elevation of brain natriuretic peptides due to myocardial stress caused by ventricular wall tension. If right ventricular dysfunction (RVD) would significantly increase peptide values is not clear. Our purpose was to analyze whether in patients with left-sided heart failure (HF) with preserved ejection fraction (HFpEF) and reduced ejection fraction (HFrEF) right dysfunction increases NT-ProBNP levels.
Methods: We included 1140 consecutive patients admitted for AHF in a cardiac acute hospitalization area of a reference hospital. We excluded patients with a poor acoustic window in the echocardiographic study, lack of determination of NT-ProBNP at admission, values of this peptide below 1,000 pg / mL and severe renal dysfunction (creatinine clearance < 30 ml/min). The total number of patients recruited was 602. Patients were classified into 6 groups depending on the left ventricular ejection fraction (LVEF) in good (LVEF > 45% (G)) and poor (LVEF < 45% (P)) ejection fraction, and right ventricular function (good > 50% (G), intermediate 40-50% (I) and poor < 40%(P)).
Results: The majority of patients were male (54%), age 73 ± 12 years. Etiology: Hypertension: 11%, Ischemic heart disease: 28%, Idiopathic dilated cardiomyopathy: 11%, Valvular: 17%, other: 33%. The values of NT-ProBNP were increasing as the degree of dysfunction increased (p: 0.0001). In patients with HFpEF and good right ventricular function, the NT-ProBNP value was 6477 ± 7382 pg / mL. In patients with HFpEF and poor right ventricular function, the NT-ProBNP value was 8946 ± 7730 (p: 0.9). Similarly, the levels of NT-ProBNP in patients with HFrEF was 10119 ± 9417 pg / mL, and 11954 ± 10236 when RVD was associated (p: 0.85).
Conclusions: In patients with AHF, NT-ProBNP values are higher when right ventricular dysfunction is associated. This occurs in both HFpEF and HFrEF. In our study, these differences were not statistically significant because of the large dispersion of NT-ProBNP levels.

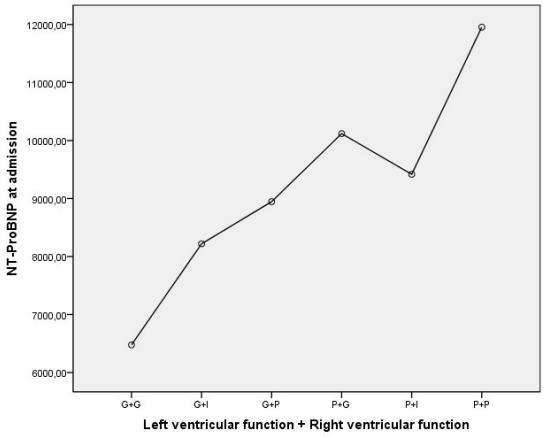

Image 1

P1018

The level of natriuretic peptide at the diagnosis of heart failure in comorbidal patients with thyrotoxicosis

Al Chesnikova[1]; EV Pashchenko[1]; VI Kudinov[1]; VP Terentev[1]; O Olga Kolomatskaya[1]; VA Safronenko[1]; NS Skarzhinskaya[1]
[1]*State Medical University of Rostov-on-Don, Rostov-on-Don, Russian Federation*

Background: It's necessary to take into account a frequent combination of ischemic heart disease (IHD) with thyroid pathology, as well as their combined effect on CHF markers level (such as brain natriuretic peptide (BNP) and N-terminal pro-B-type natriuretic peptide (NT-proBNP).
Purpose: To estimate the clinical significance of NT-proBNP level analysis for the diagnosis of CHF in patients with IHD and thyrotoxicosis, to determine the cut-off index for a combination of these diseases.
Methods: 111 patients were divided into 4 groups. Mean age was 58,3 ± 5,6 years. The main group consisted of 25 patients with IHD, CHF II-III FC and thyrotoxicosis; the 1st group of comparison - 30 patients with IHD and CHF II-III FC, normal finding of thyroid gland; the 2nd group - 30 patients with thyrotoxicosis without IHD, the 3rd group - 26 patients with thyrotoxicosis and IHD, with no signs of CHF. The levels of free triiodothyronine (fT3), free tetraiodothyronine (fT4), thyroid-stimulating hormone (TSH) were determined. The level of NT-proBNP was evaluated by the method of enzyme immunoassay. A new cut-off NT-proBNP for the diagnosis of CHF in comorbid patients was calculated by using ROC analysis and ROC-curve making (Receiver Operator Characteristic Curve).
Results: In all patients the concentration of NT-proBNP exceeded the set level of 125 pg/ml. The lowest index was obtained in the 2nd group - 225.5 (180.1, 376.1) pg/ml. The NT-proBNP values in the patients of the 1st and 3rd groups did not differ significantly (326.6 (253.7, 456.7) pg/ml and 345.3 (263.8, 420.6) pg/ml; p = 0.88), but exceeded the result in patients of the 2nd group by 27.8% and 35.2% respectively (p <0.05). The highest level of NT-proBNP was detected in the main group - 712.1 (434.3, 893.9) pg/ml. Accounting for the initial elevated level of NT-proBNP in patients with thyrotoxicosis, a cut-off of this marker for screening CHF in comorbid patients with IHD and thyrotoxicosis was calculated by using ROC analysis - 556.4 pg/ml. Thus, in our study, NT-proBNP values below 556.4 pg/ml make it possible to exclude CHF in this group of patients with a sensitivity of 72%, a specificity of 100%, an accuracy of 87.2% (p <0.001). The Area Under Curve (AUC) was 0.942 ± 0.0298 (p <0.001), which indicates an excellent quality of the model and the possibility of its application in clinical practice.
Conclusions: The highest level of NT-proBNP was observed in the group of patients with CHF by IHD and thyrotoxicosis, which is probably due to the combined influence of the volume load on the heart and thyroid hyperfunction. There were no significant differences in the concentration of NT-proBNP in patients with IHD and CHF without thyrotoxicosis and in patients with thyrotoxicosis and IHD without CHF. Consequently, a new cut-off of this biochemical marker is to be calculated for the diagnosis of heart failure in comorbid patients with thyrotoxicosis.

P1019

Serum N-terminal pro-BNP levels predicts the progression of arterial stiffness in Japanese healthy men

H Hirofumi Tomiyama[1]; KT Shiina[1]; T Chikamori[1]; A Yamashina[1]
[1]*Tokyo Medical University, Tokyo, Japan*

Funding Acknowledgements: Omron Health Care company

Backgrounds: Although several prospective observational studies have demonstrated that the serum N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels is a marker for future cardiovascular events including heart failure, the underlying mechanisms of this association has not been fully clarified. On the other hand, arterial stiffness and abnormal central hemodynamics have been much focused as independent risks for cardiovascular disease.
Purpose: The present prospective study was conducted to examine whether the serum NT-proBNP levels predict the progression of arterial stiffness and/or worsening central hemodynamics in healthy Japanese men.
Methods: In 1972 Japanese healthy men (43 ± 8 years old; the subjects with cardiovascular disease and/or whose serum NT-proBNP levels >100 pg/mL were excluded), serum NT-proBNT levels, radial augmentation index (rAI) and brachial-ankle pulse wave velocity (baPWV) were measured at the baseline of study period, and 6 years later baPWV and rAI were measured again.
Results: During the study period, baPWV was increased significantly (from 1278 ± 170 to 1333 ± 197 cm/sec) and rAI was also increased (from 69 ± 12 to 72 ± 12 %)($p < 0.01$). The delta change of baPWV, but not rAI, during the study period was higher in subjects whose NT-proBNP >10 pg/mL (n = 628, 62 ± 128 cm/sec) than in those whose NT-proBNP < 10 pg/mL (n = 1344, 41 ± 112 cm/sec), even after the adjustment of covariates ($p < 0.05$).
Conclusion: In Japanese healthy men, mild elevation of serum NT-proBNP levels is a risk for the progression of arterial stiffness rather than worsening central hemodynamics. Thus, increased arterial stiffness may be one of underlying mechanisms of increased cardiovascular risk related with elevated serum NT-proBNP levels.

P1020

Association of plasma Fischer ratio (FR) and atrial fibrillation (AF) in Patients with Idiopathic Dilated Cardiomyopathy (DCM)

M Wakasa[1]; H Aoki[1]; K Hujibayashi[1]; H Akao[1]; Y Kawai[1]; K Kajinami[1]
[1]*Kanazawa Medical University, Ishikawa, Japan*

Backgrounds: FR is the molar ratio of branched-chain AAs (BCAAs: leucine, valine, isoleucine) to aromatic AAs (phenylalanine, tyrosine) and
Decreased level of BCAA has been reported in AF rats. However, the relation between its levels and AF remains unclear in human. To explore potential role of FR or BCAA in AF of human failing heart, we measured plasma FR in patients with biopsy-proven DCM and evaluated association between its levels and the clinical parameters.
Methods: Consecutive 70 patients with DCM (M/F: 54/16, mean age: 62 years) were enrolled. Subjects showing abnormal liver enzyme level or chronic hepatitis viral infection were excluded. We measured plasma FR in peripheral blood samples, washout rate of Tc-99m Sestamibi (WOR) as function of mitochondria and LVEF as LV function parameters. The planer imaging was obtained 30 min and 180 min after injection of MIBI and WOR was calculated.
Results: Mean plasma FR of AF group (n = 14) were significantly lower than those of without AF (n = 56) (2.87 ± 0.40 vs 3.28 ± 0.55, $p < 0.05$). In AF group, plasma FR showed a significant and positive association with LVEF ($r = 0.658$, $p < 0.05$). Furthermore the WOR showed significant negative association with FR (r=-0.749, $p < 0.05$).
Conclusions: BCAA might have a protective role in AF development in DCM patients through maintain mitochondrial function.

P1021

Association of heart and vessels remodeling with biological markers level: transforming growth factor and e-selectin, in patients with heart failure.

M Maria Kozhevnikova[1]; GA Shakaryants[1]; VYU Kaplunova[1]; AA Shchendrygina[1]; EV Babayan[1]; EA Zheleznykh[1]; YUA Danilogorskaya[1]; FM Bogatyreva[1]; IS Ilgisonis[1]; AO Iusupova[1]; EV Privalova[1]; YUN Belenkov[1]; YUF Shumskaya[1]; LD Morozova[1]; VYU Zektser[1]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Purpose: to reveal association between hemodynamic parameters estimated by using echocardiography (ECO) and remodeling of large and small vessels measured by photoplethysmography (PPG) and nail fold computer videocapillaroscopy (VC) and transforming growth factor ß2 (TGF-ß2) level in patients with heart failure (HF).
Methods: 34 patients (18 men, average age 65,82 ± 10) with HF: fifteen patients (44,1%) with preserved ejection fraction (HFpEF) and 19 (55,9%) patients with mid-range ejection fraction (HFmrEF) comparable to age, sex, presence of diabetes mellitus type 2 (DM) and hyperlipidemia were included in the study. All patients underwent ECO (ejection fraction (EF), interceptall wall thickness (IWT), left ventricle posteriori wall (LVPW). Remodeling of small vessels was assessed by VC (capillary densities (CD, cap/sq.mm), CD after reactive hyperemia test (CDrh, cap/sq.mm) and CD after venous occlusion (CDvo, cap/sq.mm)) and by PPG (index of refractionRI). Remodeling of large vessels (stiffness index-aSI, in\s) were evaluated by PPG. TGF-ß2 level was measured by IFA.
Results: It was found that TGF-ß2 level was increased (23305 pg/ml [1259; 65087] (reference level = 5222 - 13731 pg/ml)) in patients with HF. The E-selectin level was higher (39,4 ng/ml [27,62;51,17]) in patients with HFpEF than in patients with HFmrEF (56,53 ng/ml [43,63;69,43]), ? < 0,076. There was not significant differences of E-selectin level in patients with and without DM. LVPW was significantly thicker ($p < 0.028$) in patients with HFpEF (1,04 sm. [0,96;1,12]) compared to the patients with HFmrEF (1,18 sm. [1,10;1,27]), as well as IWT 1,04 [0,94;1,16]; 1,2 [1,08;1,31] respectively $p < 0.03$). Significant negative correlation was found in both groups between CD($r=-0.51$; $p < 0.05$), CDrh ($r=-0.55$; $p < 0.05$), CDvo ($r=-0.59$; $p < 0.05$) and E-selectin level. TGF-ß2 has been correlated with CD. There was not any correlation between E-selectin level and RI, aSI.
Conclusion: 1. This data revealed, that patients with HF had high levels of TGF-ß2. There was no significant difference in TGF-ß2 and E-selectin parameters between groups of patients with HF associated with diabetes mellitus type 2 and in patients with isolated HF. 2. Significant negative correlation was found in both groups between TGF-ß2 level and parameters of microvascular remodeling. 3. Patients with HFpEF and HFmrEF had different levels of E-selectin. 4. The negative correlation of E-selectin level with capillary densities after reactive hyperemia test and after venous occlusion was revealed.

P1022

Cardiorenal relationships in patients with heart failure of ischemic etiology

N Shilyaeva[1]; ? Ryabov[1]; A Germanov[1]; Y Shchukin[1]
[1]*Samara State Medical University, Cardiology, Samara, Russian Federation*

Purpose: To investigate the association of biomarkers of renal dysfunction with other biochemical and instrumental indicators in patients with CHF of ischemic etiology.
Methods. 133 patients (the average age of 55.3 ± 7.7 years) with chronic heart failure (CHF), previous myocardial infarction (MI) and percutaneous intervention were enrolled in the study. Patients grouped by type of MI: Q-wave and non-Q wave. NGAL, cystatin C, galectin-3 and NT-proBNP were measured by immunoassay analysis. eGFR was calculated using the CKD-EPI equation. Descriptive data are presented as frequencies (percent), median (25th-75th percentile). Comparison between two groups was made using Mann-Whitney test. Rank correlation coefficients were calculated according to Spearman (r). $P < 0.05$ was considered statistically significant.
Results: Patients with MI with Q-wave had lower LVEF and higher levels of NT-proBNP, but there had not differences in levels of biomarkers of renal dysfunction and Syntax score between groups (table). Correlation analysis revealed the weak and moderate positive correlations in pairs: NGAL-galectin-3 ($r = 0,210$, $p < 0,05$), NGAL-NT-proBNP ($r = 0,314$, $p < 0,01$), NT-proBNP-index of violation of local LV contractility ($r = 0.404$, $p < 0.01$) and NT-proBNP-Syntax score ($r = 0.324$, $p < 0.01$) for 1 group; cystatin C-pulmonary artery pressure (PAP) ($r = 0,402$, $p < 0,05$), cystatin C-Syntax score ($r = 0,413$, $p < 0,05$) for 2 group. eGFR decreased significantly with increasing levels of NT-proBNP and PAP (r=-0,210, -0,219, accordingly, for all $p < 0,05$) in 1 group and with decreasing LVEF ($r = 0,330$, $p < 0,05$) in 2 group.
Conclusion: Biomarkers of renal dysfunction are significantly correlated with echocardiographic and coronary angiographic measures in CHF patients with previous MI. Cystatin C, NGAL and eGFR are associated with biomarkers of myocardial stress and fibrosis in patients with MI with Q-wave.

Baseline characteristics of CHF patients

Characteristics	1 group (n = 94)	2 group (n = 39)	p
Male, n (%)	86 (91,5)	29 (74,4)	0,009

Introduction: Right ventricular (RV) systolic dysfunction (RVSD) can clinically manifest as dyspnoea. Echocardiography may provide information about the mechanisms of RVSD. However, knowledge on RV dysfunction is scarce.
Purpose: To characterize echocardiographic parameters of RVSD in patients presenting with acute dyspnea to the emergency department (ED).
Methods: Prospective observational cohort study enrolled consecutive patients admitted to the EDs of two university hospitals with acute dyspnea due to various causes. Echocardiography was performed in 482 patients during the first 48 hours of admission. It included the following parameters: RV basal diameter, tricuspid annular plane systolic excursion (TAPSE), velocity of the tricuspid annular systolic motion (RV S'), fractional area change (FAC), pulmonary artery systolic pressure (PASP) and RV longitudinal strain of free wall and entire RV. The current study included 347 (72%) patients with demographic, clinical and RV echocardiographic parameters. All patients were divided into five groups: acute heart failure (AHF), n = 206 (60%); pulmonary embolism (PE); n = 42 (12%); pulmonary disease (pneumonia and COPD) n = 26 (8%); acute coronary syndromes (ACS) n = 30 (9%); and other diagnoses, n = 43 (13%). Data were analyzed using One-way ANOVA.
Results: The distribution of RV echocardiographic parameters is presented in Table 1. Parameters of prominent RV dysfunction were comparable in AHF and PE groups: only RV S' was significantly lower in AHF group (p = 0.02). Dilatation and impaired RV deformation was observed in pulmonary diseases. Both AHF and PE showed significantly reduced longitudinal strain of free wall and entire RV compared to ACS and other diagnoses (p = 0.02). PASP was significantly increased in PE compared to other diagnoses (p = 0.04). Normal RV free wall strain was found only in ACS and other diagnoses.
Conclusions: RV function was much more impaired in AHF and PE than other causes of dyspnea. Reduced RV deformation was found in the majority of acute dyspnea patients.

ECHO parameters of RV in acute dyspnea

	AHF	PE	Pulmonary disease	ACS	Other diagnoses
RV basal diameter (mm)	46.8±9.7[a]	46.5±9.3[b]	42.2±7.2	38.0±7.3*§	38.8±9.2*§
TAPSE (mm)	15.5±5.4[a]	16.8±4.9[b]	18.7±6.2*	18.0±4.8*	19.3±5.9*§
RV S' (cm/s)	9.6±3.4[a]	11.1±3.5*	11.9±3.6*	10.7±2.7	12.6±4.2 *
FAC (%)	34.5±13.6[a]	35.6±11.7[b]	41.1±10.6	43.2±10.6*	43.6±13.2*§
Strain ofRV free wall	-15±6[a]	-12±6[b]	-16±7	-22±7*§	-19±7*§
Strain of entire RV	-11±5[a]	-10±5[b]	-13±6	-16±5*§	-15±6*§
PASP (mmHg)	42.1±14.9[a]	46.2±13.3[b]	38.2±14.4	37.6±13.8	36.3±13.7§

Lessons learned during an echo certification process in heart failure trials

A K Radha Krishnan[1]; DA Morris[1]; E Belyavskiy[1]; A Frydas[1]; F Huang[1]; M Kropf[1]; S Marandi[1]; B Pieske[1]; E Pieske-Kraigher[1]

[1]*Charité - Universitätsmedizin Berlin, Department of Internal Medicine and Cardiology, Berlin, Germany*

Background: Echo certification process is designed to improve the standard echo image quality in clinical trials.
Aim: The aim of the present study was to analyze the prevalence and reasons of echocardiograms with poor imaging quality in heart failure (HF) clinical trials.
Methods: We evaluated the quality of the echo acquisitions for three contemporaneous HF clinical trials that used echocardiographic parameters as clinical end-point. We analyzed 428 echocardiograms from 214 different centers from Australia, America, Canada, Europe, Japan, Singapore, South Korea, and Taiwan in an Echo Core Lab. The optimal echo acquisitions were determined according to the recommendations for chamber quantification and diastolic function of the European Association of Cardiovascular Imaging.
Results: Seventy-seven (18%) out of 428 echocardiograms did not pass the certification process. The reasons of the echocardiograms that did not pass the certification process were: poor endocardial border definition or dropout in > 2 LV segments (30%); poor imaging quality of mitral spectral Doppler measurements (15%); poor imaging quality of mitral tissue Doppler measurements (18%); incorrect number of cardiac cycles [< 3 in sinus rhythm or < 10 in atrial fibrillation] (25%); and technical or incorrect saved format (12%) see Figure 1.

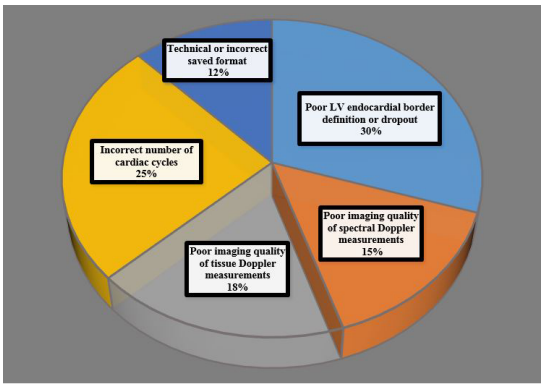

Figure 1.Reasons for failing

Conclusion: In spite of the advances in modern echocardiographic technologies, echocardiograms remain operators' and patients' dependent, which could represent up to 18% of dropout in HF clinical trials. In addition, the findings from this study suggest that a certification process before the initiation of a trial could reduce the dropout due to operators' mistakes and thereby, improve significantly the quality of the echocardiograms in clinical trials.

Multiparametric evaluation of the right ventricle systolic function after cardiac surgery

G Giovanni Tilocca[1]; L Lazzari[1]; A Crocetti[1]; G Khoury[1]; D Bovelli[1]; E Boschetti[1]; G Ambrosio[1]

[1]*Az. Osp. "S. Maria", Cardiology Department, Terni, Italy*

Background: the evaluation of right ventricular systolic function (RVSF) is essential to the management of patients undergoing cardiac surgery (CS) as it is a strong prognostic predictor in follow-up. Nevertheless, correct assessment of RVSF is challenging, as tricuspid annular plane systolic excursion (TAPSE) is often reduced despite normal value of other parameters.
Purpose: different echocardiographic indices express different characteristics of RVSF; so a correct evaluation requires a multiparametric assessment. We evaluate diagnostic power and correlation among parameters of three different echocardiographic indices in evaluation of RVSF after CS.
Methods: 265 consecutive patients (70.56% males, age 69.89 ± 9.87 years) with normal RVSF, undergoing CS, were re-evaluated before discharge using three echocardiographic parameters: TAPSE, Fractional Area Change (FAC) and the Tissue Doppler TEI index. The cut-off reported by the ESC position paper on the evaluation of cardiac chambers (European Heart Journal - Cardiovascular Imaging 2015 16; 233-271), were used for definition of right ventricular systolic dysfunction (RVSD): TAPSE < 17 mm, FAC < 35%, TEI index > 0.54.
Results: incidence of RVSD was 30.93% according to TEI index and 23.02% according to FAC, while it raises up to 84.89% using TAPSE. We also evaluated whether two of the three different methods, alternately, were in agreement or not expressing normal right ventricular function or dysfunction: TAPSE showed poor results, with an assessment agreement of only 36.95% compared to FAC (absence

of correlation: r = 0.164; = 0.059) and 42.02% compared to TEI (mild correlation: r = -0.180; p = 0.036). On the other hand, FAC and TEI agreed in 74.64% (moderate correlation r = -0.356; p = 0.000). Compared to post-CS RVSD identified by the TEI (assumed as the most reliable parameter), TAPSE was very sensitive (92.9%) but poorly specific (16.8%), p NS, - AUC 0.653, p < 0.05 - while FAC was not very sensitive (44.2%) but very specific (86.3%), p 0.000, - AUC 0.723, p 0.000 - . Different types of CS did not show different incidences of RVSD.
Conclusion: if used alone, TAPSE is an unreliable parameter in the detection of post-CS RVSD: it is not specific and has little correlation with other evaluation parameters. This study strengthen the recommendation of a multiparametric evaluation using FAC and, where possible, TEI index.

Comprehensive structural and functional integrated imaging for prediction of left ventricular reverse remodeling in non-ischemic cardiomyopathy

M Merlo[1]; M Mase[1]; G Vitrella[1]; M Belgrano[2]; G Faganello[1]; M Gobbo[1]; M Gigli[1]; A Altinier[1]; G Barbati[3]; F Ramani[1]; A De Luca[1]; G Morea[1]; MA Cova[2]; D Stolfo[1]; G Sinagra[1]
[1]Ospedale Cattinara, Cardiovascular Department, Trieste, Italy; *[2]Ospedale Cattinara, Radiological Department, Trieste, Italy*; *[3]University of Trieste, Biostatistics Unit, Department of Medical Sciences, Trieste, Italy*

Background: Defining short-term prognosis in NICM is challenging in clinical practice. Even though Left Ventricular Reverse Remodeling (LVRR) is a key prognostic marker in NICM there are few parameters able to predict it.
Purpose: To investigate whether a complete structural and functional Cardiac Magnetic Resonance Imaging (cMRI) evaluation is incremental to the classic clinical-echocardiographic approach in predicting Left Ventricular Reverse Remodeling (LVRR) in a large cohort of Non-Ischemic Dilated Cardiomyopathy (NICM) receiving evidence-based treatment.
