Methods: Patients with a recent diagnosis of NICM (<3 months) who underwent complete clinical, echocardiographic and cMRI assessment were consecutively enrolled from 2008 to 2016. LVRR was defined as an increase = 10 points or normalization of Left Ventricular Ejection Fraction, associated with a = 10% reduction or normalization of Left Ventricular End-Diastolic Diameter at mid-term (median time 20 months) echocardiographic follow-up.
Results: Among 80 NICM patients included in the study, LVRR was observed in 43 (54%). At multivariate analysis, the clinical-echocardiographic evaluation failed to identify independent predictors of LVRR. However, absence of Late Gadolinium Enhancement (Odds Ratio [OR] 9.07; Confidence Interval [CI] 2.7-13.1; p-value 0.0003), Left Ventricular Mass (OR 1.018; CI 1.001-1.036; p-value 0.045) and Peak Circumferential Strain (OR 1.213; CI 1.011-1.470; p-value 0.049) assessed by cMRI were independently associated with LVRR. A model for LVRR prediction consisting of cMRI and clinical-echocardiographic parameters performed significantly better than the clinical-echocardiographic model alone (AUC 0.84 Vs 0.72; p-value 0.023). Conclusions. An integrated imaging approach with the addition of a structural and functional cMRI study to the standard-of-care evaluation improved the prediction of LVRR in a large cohort of patients with recently diagnosed NICM receiving evidence-based treatment.

P1027
Subclinical LV systolic dysfunction in patients with Left Bundle Branch Block and preserved ejection fraction: a 2D speckle tracking study

K Kalliopi Keramida[1]; V Kostopoulos[1]; L Markos[1]; P Kostakou[1]; CD Olympios[1]; N Kouris[1]
[1]Thriassio General Hospital, Athens, Greece

2D-speckle tracking echocardiography (2D-STE) is a method of quantitative assessment of myocardial systolic function, evaluating different pathophysiological properties of the myocardium from the ones expressed by ejection fraction (EF). 2D-STE has been used so far in patients (pts) with heart failure and Left Bundle Branch Block (LBBB), who are candidates for CRT. The aim of this study is to assess deformation mechanics in pts with LBBB and normal EF.
Our study population comprised of 62 consecutive pts with LBBB without history of heart disease. Of them we excluded 12 pts due to the presence of valvular disease and CAD proven from the diagnostic work up, so finally we included 50 pts with LBBB (39% men, with mean age 68 ± 10 years) and normal LVEF and 50 healthy controls (54% men with mean age 65 ± 10 years). All pts underwent a full echocardiographic study and additionally, global longitudinal and circumferential strain of the LV (LVGLS and LVGCS) were estimated off-line from the three apical views and from the parasternal short axis mid-LV view (at the papillary muscles level) using EchoPac 110 workstation (GE Vingmed Ultrasound).
There was no statistical difference between the two groups neither in EF (58.85 ± 3.48 vs 60.69 ± 5.47%), nor in LV end-diastolic diameter (46.84 ± 2.57 vs 48.15 ± 3.87mm). However, pts with LBBB had significantly impaired LVGLS (-12.7 ± 3.6 vs -19.6 ± 1.33%, p < 0.001) and LVGCS (-11.38 ± 4.11 vs -22 ± 2%, p < 0.001) compared to controls. The controls and 29 of pts with LBBB (58%) demonstrated normal diastolic function, while 21 pts had grade 1 diastolic dysfunction (DD), according to the latest ASE/EACVI criteria (2016). The presence of DD in pts with LBBB was not correlated to LVGLS (- 11.4 ± 4.4% in pts with DD vs -13.5 ± 3.2% in pts without DD, p = 0.22).
Consequently, the presence of LBBB, even without or before affecting EF, is not benign, as it impairs longitudinal and circumferential deformation of the left ventricle, independently of DD.

P1028
Iron deposition in the heart does not completely predict cardiac structural or fuctional impairement in patients with beta-thalassemia major

MD Maria Dimova-Mileva[1]; BK Kanazirev[1]; VK Kaleva[1]; KP Petrova[1]; VZ Zlateva[1]; SN Nikolova[1]; YB Bocheva[1]
[1]Medical University of Varna, Varna, Bulgaria

Cardiovascular complications and especially the heart failure are the leading cause of morbidity and mortality in transfusion dependent Thalassemia Major. The main pathophysiological mechanism is considered to be iron deposition in the myocardium.
Aim: to investigate the impact of cardiac iron load in transfusion dependent thalassemia on structural and functional cardiac parameters as early signs of heart failure.
Patients and Methods: we studied 37 thalassemic patients, mean age 32,35 ± 10,93 yrs, 54% female, with echocardiography, CMR (T2*) and NT-proBNP
Results: Mean value of T2* is 24,7 ± 11,8, median 27,17; 6 pts have T2* < 10, 3 pts 10-20, and 24 pts>20. There is a correlation between iron deposition and E/e' ratio: T2* value decreases in the upper tertile of E/e' while its maximum is in the middle range. In multifactor linear regression analysis with stepwise selection of the variables we find that the only significant echocardiographic predictor of myocardial iron load is E/e'. Increase of E/e' with 1 unit is related to decrease of the value of T2* with 3,46 (95% CI= -6,45 -0,465, p = 0,026), after adjusting for sex, lnBNP, age, EF, LAVi, LVMMi, TDISm, strain, and mean SBP. We find no other significant correlations between T2* and other cardiac and hemodynamic parameters and NT-proBNP.
Conclusions: The relation between iron deposition and E/e' shows early deterioration of diastolic function. Myocardial iron overload is not the only cause of cardiac complication and fibrosis and chronic ischemic condition are also important pathogenethic factors for the development of heart failure in patients with thalassemia major.

P1029
Right ventricular outflow tract tissue doppler in congestive heart failure

M Mikheil Tsverava[1]
[1]Tbilisi Medical Academy, Tbilisi, Georgia Republic of

Right ventricle (RV) plays important role in Heart Failure. Inflow and outflow tracts of this chamber are functionally and morphologically different. The inflow tract of RV (RV in) was actively studied by different EchoCG methods in normal and pathologic state, but there is little information about RV outflow tract.
Aim: To investigate RV outflow tract (RVout) pulsed wave TDI qualitative and quantitative parameters in patients with congestive heart failure (HF).
Material and Methods: We studied 125 healthy volunteers and 100 patients with HF. RVout pulsed wave TDI was registered from subcostal position with sample volume on RV lateral wall, near the pulmonary valve. RVin TDI was registered in apical 4 camber view with the sample volume positioned at lateral wall near the tricuspid valve.
Results: The pattern of TDI from RVout was quite different from pattern of TDI of RVin. It was characterized by prominent positive wave in isovolumic contraction period (Sict), high positive wave et the beginning of systole (S) with sharp decrease of velocity, prominent negative and positive waves during isovolumic relaxation period (Eict1 and Eict2) and two negative waves in diastole (E and A). The TDI waves of RVin where significantly greater and isovolumic relaxation time shorter then corresponding waves on RVout TDI. The Sict (4.0 ± 1.4 versus 6.4 ± 1.9 cm/sec), S (7.9 ± 1.8 versus 9.2 ± 2.4 cm/sec), Eist1 (-3.9 ± 1.9 versus -9.2 ± 2.4 cm/sec) and E (4.4 ± 1.3 versus 7.4 ± 1.8 cm/sec) on TDI from RVout where significantly slower in HF group compared with normal persons (p < 0.001).

Conclusion: In normal persons the TDI pattern of RV inflow and outflow tract is qualitatively and quantitatively different. In patients with HF the systolic and diastolic wave velocities where significantly lower compared to the normal persons.

P1030

Myocardial fibrosis assessment in left bundle branch block patients for prediction of response to cardiac resynchronization therapy

M Madina Utsumueva[1]; S Kashtanova[1]; O Stukalova[1]; V Shitov[1]; E Gupalo[1]; G Tarasovsky[1]; V Kiktev[1]; N Mironova[1]; S Golitsyn[1]
[1]National medical research center of cardiology, Moscow, Russian Federation

Introduction: Cardiac resynchronization therapy (CRT) is an established treatment for symptomatic patients with heart failure, severe left ventricular (LV) systolic dysfunction and prolonged QRS duration, preferably with left bundle branch (LBBB) morphology. However, up to 30% of patients do not benefit from this invasive and costly intervention. Presence, location and extent of myocardial fibrosis may influence the effects of CRT.
Purpose: To assess the impact of replacement myocardial fibrosis on the response to CRT in patients with LBBB.
Methods. The study included 25 patients with heart failure (mean age 61,6 years (SD = 8,3), 48% females and 52% males) due to ischemic (36%) or non-ischemic cardiomyopathy (64%), LV ejection fraction < 35%, QRS = 130 ms, LBBB and sinus rhythm. Late-gadolinium enhancement-cardiovascular magnetic resonance (LGE-CMR) was used to evaluate myocardial fibrosis prior to CRT devices implantation. Transmurality and location of fibrosis were estimated by LGE images using a 17-segment model, according to American Heart Assossiation. The semiquantitative analysis was performed using the fibrosis index (FI), which was calculated by the formula: FI = (1x?n1) + (2x?n2) + (3x?n3) + (4x?n4), where 1, 2, 3, 4 - fibrosis transmurality coefficient (1 - 0-25% wall thickness, 2 - 26-50%, 3 - 51-75%, 4 - 76-100%), ?n1-n4 - the number of segments affected by fibrosis. Response was defined as decrease in LV end-systolic volume by > 15% during 6 months follow-up period.
Results: Myocardial fibrosis was not found in 10 of 25 patients (40%), 7 of whom (70%) were responders to CRT. The presence of myocardial fibrosis was detected in 15 patients, 7 of whom (46,7%) responded to CRT. The average number of segments affected by fibrosis was greater in responders than in non-responders (4,1 vs 7, p < 0,05). The mean FI was significantly lower in responders than in non-responders (11 vs 23, p < 0,05).
Conclusions. The myocardial fibrosis extent was significantly greater in non-responders to CRT. The semiquantitative assessment of myocardial fibrosis is a perspective technique to improve selection of candidates for CRT. These **Conclusions:** need to be further tested in large studies.

Pharmacological stress echocardiogram: a predictor of prognosis in patients with dilated cardiomyopathy?

B Bebiana Faria[1]; M Oliveira[1]; L Calvo[1]; V Hafe[1]; O Azevedo[1]; S Ribeiro[1]; M Fernandes[1]; G Dias[1]; A Lourenco[1]
[1]Hospital Guimaraes, Guimaraes, Portugal

Introduction: The importance of pharmacological stress echocardiography (SE) has been widely documented, especially in patients with ischemic heart disease, both in the evaluation of ischemia and in the detection of viability. In recent years, there have been studies on the use of this technique in patients with dilated cardiomyopathy (DCM) based mainly on the evaluation of left ventricular inotropic reserve.
Objective: Evaluate in patients with MCD the ejection fraction and volume in SE, at baseline and peak stress, and its relation to the occurrence of cardiovascular events and the degree of recovery of left ventricular systolic function (LVSF).
Methods: A retrospective, unicentric study, included 34 consecutive patients diagnosed with MDC undergoing SE. The parameters of systolic and diastolic function were evaluated in the basal state and the ejection fraction and volume also at the peak of stress. The presence of death, dysrhythmias, hospitalizations, and emergency room visits for heart failure was determined as a combined endpoint of events.
Results: A total of 34 patients (P) with DCM were included, 55.9% of the male gender, with a mean age of 61.4 +/- 12.9 years. About 30% had a history of atrial fibrillation. Of the total of P 93.8% were medicated with ACE inhibitors, 84.4% with beta-blocker and 78.1% with aldosterone antagonist. They had cardiac resynchronization system (CRT) 17.6% of the P and 38.2% had cardioverter defibrillator (ICD). The SE was performed with dipyridamole in 82.4% of the P. At the time of the examination, 32.4% of the P had LVSF slightly depressed, 29.4% had moderate dysfunction and 38.2% had severe dysfunction, and the mean ejection fraction (EF) at baseline was 35.7 +/- 11%. At the peak of stress, there was a significant improvement of the LVSF with an increase in ejection volume (EV) of more than 20% in 50% of the P and an average value of EF at the peak of 45.8 +/- 12%.
The mean follow-up time was 25.8 +/- 27 months, with events occurring in 17.6% of the P, and in 18% of the cases there was an improvement in the LVSF from the SE until the last echocardiographic evaluation.
There was an association between the improvement of the LVSF and the presence of CRT (p = 0.022), lower baseline ejection fraction (p = 0.029) and lower s' septal value (p = 0.014). Increased age, increased QRS interval on ECG (p = 0.019), increased mean E/e' value (p = 0.002), a lower ejection fraction at peak stress (p = 0.009), increased baseline LV end-diastolic volume (p = 0.05), and a lower ejection volume in SE (p = 0.048) were associated with the presence of events.
Conclusion: SE in patients with DCM can stratify the prognosis, we observed that a lower value of EF in the peak of stress and a smaller increase in ejection volume in the subgroup of patients with events compared to the subgroup of patients with no events.

P1032

The real-world need for magnetic resonance imaging in patients with implanted pacemaker

N Radovanovic[1]; B Kircanski[1]; SU Pavlovic[1]; G Nikcevic[1]; M Zivkovic[1]; V Jovanovic[1]; A Milasinovic[1]; G Milasinovic[1]
[1]Clinical center of Serbia, Pacemaker Center, Belgrade, Serbia

Introduction: During the lifetime 50-75% of patients with cardiac implantable electronic devices are predicted to have an indication for a magnetic resonance imaging (MRI). The question is whether this assessment coincides with data from practice in all geographies.
Purpose: We aimed to assess the need for MRI in unselected patients with implanted MRI protected pacemakers in our institution in four year follow-up period.
Methods: We included patients in whom magnetic resonance-conditional pacemaker system was implanted during multicentre clinical study (CapSureFix® Novus Model 5076 Lead MRI Study, 2013.). In all, the CapSureFix® Novus Model 5076 leads were used for atrial and/ or ventricular stimulation. Four year follow-up was done in order to determine how many patients underwent MRI scan for any indication during that period.
Results: We included 27 patients. One patient was lost to follow-up. At implantation, mean age was 68.4 ± 9.3 years and 19 (70.4%) were male. The test-MRI was performed 9-12 weeks after pacemaker implantation in all patients from MRI group according to the study protocol. From that point to next 4 years follow up period only 2 (7.7%) patients required MRI (in first one MRI of abdomen due to colon cancer, and in second one MRI of lumbar spine due to herniated disc). In both, there were no MRI-related complications during and after the scans.
Conclusion: In this relatively small but typical anti-bradycardia pacemaker population sample, we have observed the sharp difference between literature and our real-world data in need for MRI in unselected patients.

P1033

Diagnostic role of cardiopulmonary exercise testing for detecting pulmonary hypertension in patients with heart failure due to Chagas disease

P Pedro Schwartzmann[1]; HT Moreira[1]; D Mayumi[1]; JC Crescencio[1]; LFL Oliveira[1]; EEV Carvalho[2]; R Arena[3]; A Schmidt[1]; L Gallo-Junior[1]; MV Simoes[1]
[1]Medical School of Ribeirao Preto, University of Sao Paulo, Internal Medicine, Ribeirao Preto, Brazil; [2]Uberaba's University, Uberaba, Brazil; [3]University of Illinois at Chicago, Physical Therapy, Chicago, United States of America

Introduction: Pulmonary hypertension (PH) is an ominous manifestation in patients with heart failure (HF). Previous research has demonstrated that cardiopulmonary exercise testing (CPX), particularly variables reflecting ventilatory efficiency, is able to accurately diagnose secondary PH in patients with HF secondary to ischemic as well as in non-ischemic etiologies. However, assessment of the diagnostic ability of CPX for detecting PH in patients with Chagas heart disease is lacking.
Purpose: We sought to evaluate the ability of CPX-derived parameters to detect elevated pulmonary pressures in Chagas HF cohort.
Methods: This retrospective study included 44 patients with HF due to Chagas disease that underwent both symptom-limited CPX and echocardiography. PH was defined as echocardiographic-derived pulmonary systolic arterial pressure (PSAP) > 40 mmHg. CPX parameters studied were minute ventilation/carbon dioxide production (VE/VCO2) slope, partial pressure of end-tidal carbon dioxide (PETCO2), and peak oxygen consumption (VO2). Correlation between CPX-derived variables and PSAP was evaluated by Pearson's correlation coefficient (r), while diagnostic value for identifying patients with PH was assessed by ROC curves. P < 0.05 was considered significant.
Results: Mean age was 57 ± 13 years, 27 (61%) were men, with mean left ventricular ejection fraction of 38 ± 19%. NYHA functional class I, II, III and IV were found in 27%, 30%, 39%, and 5% of the participants, respectively. Mean PSAP was 37 ± 13 mmHg, while PH was identified in 13 (30%) patients. Mean VE/VCO2 slope, VO2 and

peak PETCO2 were 36.6 ± 11.8, 15.5 ± 6.3mlO2.kg-1.min-1 and 35.7 ± 8.8 mmHg, respectively. Significant moderate correlations between CPX-derived variables and PSAP were found: VE/VCO2 slope (r = 0.46, p = 0.006), PETCO2peak (r=-0.44, p = 0.002) and VO2 (r=-0.41, p = 0.003). VE/VCO2 slope showed the greatest area under the curve (AUC) = 0.800, confidence interval of 95% (95%CI = 0.664-0.936], followed by PETCO2peak (AUC = 0.777, 95% 95%CI = 0.638-0.916), and VO2 (AUC = 0.737, 95%CI = 0.565-0.909). There was no statistical difference between the AUCs.
Conclusion: In patients with HF due to Chagas disease, CPX-derived variables related to ventilatory efficiency were correlated to PSAP. Our results suggest that, similar to patients with HF of other etiologies, CPX may play a diagnostic role in identifying PH in patients with HF caused by Chagas cardiomyopathy.

Third heart sound during atrial fibrillation? Confirming the existence of cardiac vibrations during deceleration phase of early diastolic filling while in atrial fibrillation

J Boehmer[1]; P Thakur[2]; Q An[2]; V Averina[2]; G Mark[3]
[1]Penn State Hershey Medical Center, Hershey, United States of America; *[2]Boston Scientific, St. Paul, United States of America*; *[3]Cooper University Hospital, Camden, United States of America*

Funding Acknowledgements: Boston Scientific

Introduction: The third heart sound (S3), caused by rapid deceleration of the blood against a stiff ventricle during early diastolic filling, is an early and specific sign of heart failure and elevated filling pressure. Studies have shown S3 to be coincident with deceleration phase of E-wave and associated with a steeper E-wave. Atrial fibrillation (AF) is a common comorbidity in HF, however questions have arisen regarding the ability to reliably detect S3 during AF as typically it is difficult to auscultate an S3 during AF. Here we present a case of simultaneous implanted device measured heart sound and echo data while the patient was in AF.
Methods: MultiSENSE enrolled patients implanted with COGNIS CRT-D devices and followed for up to a year. At enrollment CRT-Ds were converted to enable collection of heart sound data using device based accelerometer. Heart sound data was periodically collected as ensemble averaged (EA) waveforms of multiple neighboring beats that closely matched in RR interval. An optional echo was conducted if the patient was hospitalized for worsening HF. An independent core laboratory measured parameters from the echo images, including E-wave timing within the cardiac cycle (Q-E interval and E-wave deceleration time or EDT). EA waveforms over multiple days around the day of echo that matched the average heart rate (HR) around the echo exam to within 10 beats per min were identified and compared against E-wave timing.
Results: The patient, enrolled in November 2011 and reported to have a history of AF, was hospitalized for worsening HF on day 38 post enrollment. Device interrogation revealed ongoing AF burden of 24 hours since enrollment which transiently terminated on day 41 for several days before reverting to 24 hour AF burden. Patient underwent an echocardiogram starting at 9:22AM on day 39, which showed a Q-E interval of 562msec and EDT of 169msec. Figure shows one heart sound EA recorded at 10:49AM and clearly shows cardiac vibrations during the deceleration phase of the E-wave as deduced from Q-E interval and EDT (horizontal line). This observation is consistent across all EAs collected over 5 days around the day of the echo with matched HR.
Conclusion: Consistent with its known physiologic genesis, S3 measured using an implanted device occurred during the deceleration phase of early diastolic filling even when the patient was in AF. A device based objective measure may provide more consistent assessment of S3 than auscultation in the midst of an arrhythmic rumble of AF.

Funding Acknowledgements: Boston Scientific

Background: An implantable device based multi-sensor algorithm was recently shown to detect impending worsening Heart Failure (HF) events with high sensitivity. The objective of this analysis was to characterize the relationship between sensor measurements and ethnicity of HF patients.
Methods: In the MultiSENSE trial, 792 patients implanted with a COGNIS CRT-D were enrolled in the United States, and followed up to 1 year. Device software was modified to permit collection of chronic diagnostic sensor data including heart sounds, respiration, thoracic impedance, heart rate and activity. Sensor data were combined into a multi-sensor alert algorithm (HeartLogic). Patients (N = 791) were classified into four ethnic groups: Caucasian (N = 602), Black or African American (N = 127), Hispanic or Latino (N = 50) and Others (N = 12). Average sensor data from patients in different ethnic groups were compared using a one-way ANOVA.
Results: At enrollment, Black/African group had significantly lower LVEF (25.89 ± 10.63) as compared to Caucasian (30.65 ± 6.62) or Hispanic group (29.85 ± 7.36), whereas Hispanic group had a greater prevalence of NYHA Class III/IV (53%) as compared to Caucasian (26%) or Black/African group (32%). On average, patients in the Black/African group had higher Day-time Rapid Shallow Breathing Index (RSBI) (Table), whereas, Caucasian group had lower activity. No statistical differences were detected in the other five sensor trends, and the resulting HeartLogic Index. With Bonferroni correction for multiple comparisons, none of the sensor trends were statistically different across the ethnic groups.
Conclusion: There are differences in physiologic parameters associated with heart failure between groups based on ethnicity including differences in day-time RSBI and activity despite no difference in the overall predictive score of the HeartLogic Index.

HF Sensor Measurements Across Ethnicity

Daily Trend	Caucasian	Black/African	Hispanic/Latino	p value
S1 (mG)	2.57±0.94	2.60±0.97	2.39±0.93	0.388
S3 (mG)	0.97±0.33	0.96±0.31	1.00±0.39	0.688
Thoracic Impedance (Ohm)	49.69±8.73	48.56±8.30	48.00±11.21	0.217
Daytime RSBI (br/min/Ohm)	8.35±2.55	9.08±2.85	8.53±2.52	0.017
Night Heart Rate (bpm)	71.16±7.88	72.48±8.14	72.06±8.01	0.199
Respiratory Rate (median, br/min)	17.74±2.41	17.68±2.39	18.17±2.70	0.45
Activity (hours)	2.02±1.90	2.36±1.83	2.56±2.20	0.045

Association neurohumoral indicators with parameters remodeling left ventricular in patients with chronic heart failure in the relationship with dysfunction of kidney

ZD Rasulova[1]; UK Kamilova[1]
[1]*Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Cardiology, Tashkent, Uzbekistan*

Purpose: Examine the relationship levels of brain natriuretic peptide (BNP), aldosterone (Al) and norepinephrine (NE) in the serum with parameters remodeling the left ventricle (LV) and functional status of kidneys in patients with II and III functional class (FC) chronic heart failure (CHF).
Material and methods. Were examined 46 patients with coronary heart disease (CHD) with CHF with II ((24) and III (22) FC, according to the classification of the New York Association of cardiologists. All patients were carried out echocardiography, was determined creatinine of serum, calculated method determined the rate of glomerular filtration (cGFR) according to the formula MDRD, the level of Al, BNP and NE was determined by immunosorbent assay.
Results: In CHF there was a significant increase the level of BNP, NE and Al in the blood plasma, correlative with a degree of disease progression, at the same time in patients with II FC is dominated by medium-high levels neurohormones, and in patients with III FC higher levels of these indicators. In patients with CHF II FC there was an increase in the content of BNP, NE and Al to 187%, 30% and 36% ($p < 0,001$) and in patients III FC to 330%, 56% and 66.3% ($p < 0,001$), respectively, in comparison with the control group.
Installed the dependence of the degree of dysfunction kidney and processes remodeling of the level of neurohumoral factors (BNP, Al, and NE) in patients with CHF. Revealed association of the level of neurohormones BNP, Al and NE with the indicators remodeling heart: high inverse correlation with ejection fraction (EF) of LV ($r = 0.76$, $r = 0.70$ and $r = 0.72$, respectively), the average contact with cGFR with the coefficient of correlation $r = 0.45$, $r = 0.35$ and $r = 0.38$, respectively, and direct correlation with the final diastolic volume of LV ($r = 0.75$, $r = 0.78$ and $r = 0.70$, respectively).
Conclusion: Thus, in patients with CHF significant increase in neurohumoral factors (NE, BNP and Al) associated with FC CHF, the degree of systolic dysfunction LV and dysfunction kidney. In patients with II FC CHF prevailed medium-high values neurohormones, with III FC CHF - high level of improving neurohormones NE, BNP and Al.

Introduction: Loop diuretics are the mainstay of treatment in heart failure(HF) patients with congestion. However, there are concerns over deleterious neurohormonal effects and associations with reduced survival. Guidelines recommend that diuretics should be used in the lowest effective dose. We investigated a) loop diuretics dose adjustment at outpatient visits, b) associations between dose adjustment and outcomes and c) factors associated with appropriate dose decrease, in the ESC HF Long-Term Registry.
Methods: Of 9,749 outpatients we included the 8,130 (83.4%) CHF patients who received diuretics both prior to and at end of outpatient index visit. Loop diuretics were converted to furosemide equivalents based on: 1 mg bumetanide = 20 mg torsemide = 40mg furosemide. Patients were considered as clinically stable if they were in NYHA class I-II, had no history of HF hospitalization during the past 6 months and had no signs of congestion or hypoperfusion. Appropriate dose decrease was defined as a decrease in diuretics dose during index visit and no death, HF hospitalization or increase in NYHA class or diuretics dose during the 12-month period after the dose decrease.
Results: Mean age was 66 ± 13 years, 71% men. Mean left ventricular ejection fraction was 37 ± 14% (62% HFrEF, 19% HFmrEF, 19% HFpEF). Median [IQR] daily dose of diuretics was 40 [25,80] mg. During index visit, diuretic dose was increased in 1,279 patients (15.7%), decreased in 671 (8.3%) and unchanged in 6,180 (76.0%). Among 3,168 patients (39.8%) who were stable at index visit, 270 patients (8.5%) had diuretic dose increased, 284 (9.0%) had diuretic dose decreased, and 2,614 (82.5%) had diuretic dose unchanged.
During 12-month follow-up and with censoring at non-CV death, 385 cardiovascular (CV) deaths occurred (4.7%). Diuretics dose increase (vs. decrease) during index visit was associated with the risk of CV death (adj. HR: 2.01;95%CI: 1.19-3.39, $P = 0.009$), while maintenance of stable diuretic dose (vs. decrease) was also associated with a trend towards higher 1-year CV mortality (adj. HR: 1.61;95% CI: 1.00-2.61, $P = 0.052$).
Baseline variables independently associated with appropriate diuretic dose decrease was systolic blood pressure (adj. HR: 1.01 per mm Hg;95% CI: 1.00-1.02, $P = 0.032$), and with unsuccessful dose decrease the presence of sleep apnea (adj. HR: 0.24;95% CI: 0.09-0.69, $P = 0.008$), peripheral congestion (adj. HR: 0.48;95% CI: 0.29-0.80, $P = 0.005$) and moderate-severe mitral valve regurgitation (adj. HR: 0.57;95% CI: 0.37-0.87, $P = 0.008$).
Conclusion: Diuretic dose was unchanged in 76% of outpatients with CHF overall and in 82% even among stable patients. No dose reduction was associated with increased risk for 1-year CV death, independently of HF severity and other variables. Higher baseline systolic blood pressure and absence of sleep apnea, peripheral congestion and moderate-severe mitral valve regurgitation were independently associated with appropriate diuretic dose decrease.

P1038

Acute kidney failure and hyperkalaemia in patients with chronic hearth failure treated with aldosterone antagonists- a risk-benefit network meta-analysis

M Seiz[1]; H Froehlich[1]; T Taeger[1]; L Frankenstein[1]
[1]*University Hospital of Heidelberg, Heidelberg, Germany*

Background: Aldosterone antagonists (AAs) improve mortality in patients with chronic heart failure (CHF). However, they may also cause acute renal failure and hyperkalaemia. The relative risk-benefit ratio of the available AAs spironolactone, eplerenone and canrenone with respect to acute renal failure and hyperkalaemia is unclear.
Methods: We conducted a systematic review and network meta-analysis following PRISMA-P and PRISMA-NMA guidelines. 7 individual databases, 6 individual clinical trial registries, and 3 individual grey literature databases were searched up to January 2017 for randomized controlled trials with an active treatment of either spironolactone, eplerenone, or canrenone/potassium-canreonate in adults with symptomatic CHF due to systolic dysfunction (left ventricular ejection fraction < 40%) reporting on acute renal failure or hyperkalaemia. The pooled effect estimates were ranked by the surface under the cumulative ranking curve (SUCRA).
Results: We identified 5 trials including 4,923 CHF patients informing on acute kidney failure and hyperkaliaemia as safety endpoints. The relevant network plot is shown in figure 1. The analyzed results were under the influence of Beta-blocker treatment. They appear to favour spironolactone over eplerenone (OR: 3.47 [1.44-8.37]; spironolactone as reference) for acute kidney failure but did not reach significance for hyperkalaemia (OR: 18.51 [0.98-350.44]).
Conclusion: The risk-benefit ratio of spironolactone with respect to acute renal failure and hyperkalaemia appears favourable as compared to eplerenone. These results, presenting in this study could be a further evidence in the treatment of patient with CHF.

Intermittent administration of levosimendan ambulatory in patients with advanced chronic heart failure: experience in our center.

P Arenas Martin[1]; IJ Sanchez Lazaro[1]; R Lopez Vilella[1]; I Husillos Tamarit[1]; C Borras Almenar[1]; M Ezzitouny[1]; V Donoso Trenado[1]; J Sanz Sanchez[1]; L Martinez Dolz[1]; L Almenar Bonet[1]
[1]Hospital Universitario y Politécnico La Fe, Valencia, Spain

Introduction: Chronic heart failure has a high morbidity and mortality, so new therapeutic strategies should be considered. In recent years there has been a growing interest in levosimendan for this type of patients. Levosimendan is an arterial and venous vasodilator drug with a positive ionotropic effect, since it increases the sensitivity to calcium of troponin c, increasing cardiac contractility.
Purpose: Our purpose was to assess the effectiveness of ambulatory levosimendan in advanced heart failure.
Methods: We have used the Lion Heart protocol (NCT01536132) of six cycles of levosimendan (0.2 µg/Kg/min) in 6 hours every 14 days. The number of admissions caused by heart failure decompensation in the year prior to entering into the program and in the year after the end of the program, PRO-BNP and renal function were computed, as well if the patients reached heart transplantation. 30 patients were included.
Results: Of the 30 patients, 93.3% were male, with a mean of 60 years. The etiology of heart failure was 50% ischemic, 26.7% corresponded to idiopathic dilated cardiomyopathies, 3.3% were valvular, and 13.3% were congenital heart diseases.
Of the 30 patients included in the program, 9 did not complete the 6 treatment cycles. The reasons for not completing the cycles were heart transplantation (5 patients), poor tolerance (3 patients) or due to the appearance of intercurrent processes such as myocardial infarction (1 patient).
The mean admissions in the year previous to treatment with levosimendan was 2 (SD 1,6), reducing to 0.14 (SD 0.44) after the same (p: 0.001).
The average levels of PRO-BNP before starting the program were 7132 pg / ml (SD 6525) and at the end of the month it was reduced to 5447 pg / ml (SD 5335) (p: 0.25).
The mean of the GFR before the start of the cycles was 47,16 ml / min (SD 17,7), and at the end of the cycle it remained stable (mean of 50,33 ml / min, SD 16,64) (p: 0.5).
Of the 8 patients included in the transplant list before starting treatment, 6 arrived at the transplant. The 2 patients who did not receive a transplant were due to a bad baseline situation and hematologic disease.
Conclusions: The intermittent use of levosimendan ambulatory significantly reduces the number of admissions, decreases PRO-BNP and does not affect renal function. In addition, it allows patients waiting for a transplant to reach it without decompensation.

Sildenafil for chronic heart failure : a meta-analysis

C Ariano[1]; R De Vecchis[2]
[1]Division of Geriatrics, " Casa Sollievo della Sofferenza" Hospital, S. Giovanni Rotondo, Italy; *[2]Preventive Cardiology and Rehabilitation Unit, DSB 29 "S. Gennaro dei Poveri Hospital", Napoli, Italy*

Introduction: According to 2015 ESC/ERS guidelines for the diagnosis and treatment of pulmonary hypertension(PH), no specific drug is currently indicated for PH related to left heart disease(PH-LHD), i.e., the one secondary to left chronic heart failure (CHF), which coincides with the group 2 of the PH classification endorsed by the above-mentioned guidelines. In fact, adoption of therapies that specifically apply for so-called pulmonary arterial hypertension (group 1 of the PH classification) has been regarded as substantially contraindicated in patients with PH-LHD. Nevertheless, based on some previous studies, sildenafil would seem to exert a beneficial effect in CHF patients , although the comparison between these studies shows quite inconsistent or heterogeneous findings. Thus, in order to better evaluate the effects of sildenafil therapy in CHF patients, we performed a meta-analysis of randomized controlled trials (RCTs).
Methods: We searched PubMed and EMBASE electronic archives for RCTs that compared sildenafil with placebo in CHF with reduced (HFREF) or preserved (HFpEF) left ventricular ejection fraction. The endpoints of interest were: a composite of all-cause death or hospitalization, adverse events, peak VO2, 6-minute walk test(6MWT), left ventricular ejection fraction (LVEF), E/e' ratio, mean pulmonary arterial pressure (mPAP), pulmonary arterial systolic pressure (PASP) and pulmonary vascular resistance (PVR).
Results: 14 studies, enrolling a total of 928 patients, were comprised in the meta-analysis. Among these, 13 were RCTs and one was a subgroup analysis. Among patients with HFREF(no.555), a significant benefit was conferred by sildenafil against the risk of the composite endpoint of death and hospitalization (OR= 0.28; 95% CI: 0.10 to 0.74; p = 0.03) . Furthermore, among HFREF patients, therapy with sildenafil ameliorated peak VO2 (difference in means [MD] = 3.76 ml/min/kg; 95% CI: 3.27 to 4.25) as well as 6MWT (MD= 22.7 meters ; 95% CI: 8.19 to 37.21). For patients with HFREF, sildenafil therapy yielded a nonsignificant decrease in mPAP, while PASP was significantly reduced (MD: -11.52 mmHg; 95% CI: -15.56 to -7.49 mmHg; p <0.001). By contrast, in the RCTs of patients with HFpEF(no.373), no benefit ensued from sildenafil use regarding all of the investigated clinical, ergospirometric or hemodynamic endpoints.
Conclusions: Therapy with sildenafil caused a statistically significant improvement of clinical outcomes, exercise capacity and pulmonary hemodynamics in patients with HFREF, but not in HFpEF. However, in view of the relatively small sample size of the HFpEF population recruited so far in the RCTs that investigated the effects of sildenafil treatment, further research in this field is required to clarify whether sildenafil is really beneficial even in this subset.

The dilemma of recurrent hyperkalaemia and use of renin-angiotensin-aldosterone system inhibitors in heart failure with reduced ejection fraction: a European multi-national targeted chart review

P Rossignol[1]; M Pignot[2]; G Georgiana Cornea[3]; L Zakin[3]; T Schulmann[3]
[1]Institut lorrain du coeur et des vaisseaux Louis Mathieu, Centre d'Investigations Cliniques-Plurithématique Pierre Drouin - INSERM - CHRU de Nancy, Nancy, France; *[2]Kantar Health GmbH, Real World Research & Value, Munich, Germany*; *[3]Vifor Pharma Group, Glattbrugg, Switzerland*

Funding Acknowledgements: This study was funded by Vifor Pharma Group, Switzerland

Background/Introduction: ESC and ACCF/AHA guidelines recommend the use of renin-angiotensin-aldosterone system inhibitors (RAASi) at the highest tolerated targeted doses to reduce the risk of morbidity and mortality in patients with heart failure with reduced ejection fraction (HFrEF). RAASi increase the risk of hyperkalaemia (HK), especially with advancement of chronic kidney disease (CKD), and therefore are often underused, reduced or discontinued in patients with HFrEF.
Purpose: To describe the contemporary multidimensional management of recurrent HK (defined as = 2 episodes per year) and count hospitalisations in patients with HFrEF in routine clinical practice across Europe.
Methods: A targeted retrospective chart review was conducted in France, Germany, Italy, Spain and the UK. Patients with HFrEF not on dialysis with recurrent HK (serum K+ = 5.5 mEq/L) within a 12-month observational period starting with the first HK episode (HK1) were included. Demographic and clinical characteristics were documented at HK1. HK treatment and RAASi medications were recorded at each visit. If the regimen changed during a visit, the new prescription was recorded. HK treatment and RAASi use were compared between the first and second HK episode (HK1, HK2) and among countries. Hospitalisations were documented.
Results: Data collected between June and September 2016 included 333 patients with HFrEF [left ventricular ejection fraction (LVEF) = 40%]. Their mean (SD) age was 68.5 (11.11) years and 67.0% were men. At HK1, 77.8% had an LVEF of 30-40%, the mean estimated glomerular filtration rate was 43.4 (23.5) mL/min/1.73 m^2, and 70.8% had CKD. Of these patients, 82.6% had 2 documented HK and 17.4% had 3 or more episodes.
During the observational period, 116 hospitalisations were documented for 108 patients (1.2 [0.6] hospitalisations per patient). This included 41 hospitalisations (36 patients) related to HK and 54 hospitalisations (53 patients) for cardiovascular reasons.

The proportion of patients receiving RAASi was significantly lower in HK2 than in HK1, especially for angiotensin-converting enzyme inhibitors (ACEi) and mineralocorticoid receptor antagonists (MRA) (Figure 1). In HK2, the proportion of patients receiving the full target dose for the most used ACEi Ramipril was significantly lower than in HK1 (35.1% vs 50.9% of those receiving Ramipril; p < 0.001). HK treatment options used similarly in HK1 and HK2 encompassed a low potassium diet, sodium/calcium polystyrene sulfonate (SPS/CPS) and bicarbonate. Loop diuretic use was lower in HK2 than in HK1 (Figure 1).
Conclusion(s): In this population with HFrEF, ACEi and MRA discontinuation was observed between the two HK episodes. One-third of the hospitalisations were due to HK. Thus, more effective HK mitigation strategies are needed.

Gender differences in heart failure treatment in the Netherlands: a subgroup analysis of the CHECK-HF registry

J F Jesse Feiko Veenis[1]; HP Brunner-La Rocca[2]; AW Hoes[3]; GCM Linssen[4]; JJ Brugts[1]
[1]Erasmus Medical Center, Cardiology, Rotterdam, Netherlands; *[2]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands*; *[3]University Medical Center Utrecht, Utrecht, Netherlands*; *[4]Hospital Group Twente, Cardiology, Twente, Netherlands*

On behalf of: CHECK-HF investigators
Funding Acknowledgements: Servier, the Netherlands, funded data inclusion and software programme. Analysis was conducted, interpreted, and reported independently of the sponsor

Background/introduction: The poor prognosis of chronic heart failure (HF) can be optimized by adherence of medical therapy according to the guidelines. The rate of drug prescription and dosage are often used as benchmark of quality of care. Data on gender differences in HF treatment are scarce.
Purpose: Evaluation of gender differences in HF treatment in the Netherlands.
Methods: The current analysis is part of a cross-sectional registry of 10,910 chronic HF patients at 34 Dutch outpatient clinics in the period of 2013 until 2016 (CHECK-HF). Demographic parameters, laboratory and echocardiographic values as well as medication use (type, dosage and frequency and total daily dose) were recorded.
Results: We studied 8,360 patients with HF with reduced ejection fraction (HFrEF; 78.7%), of which 63.9% were male and 36,1% were female. Females were slightly older (71.6 vs. 73.4 years, male vs. female resp., p < 0.01), had more often a non-ischemic cause of HF (58.5% vs. 39.6%, p < 0.01) and hypertension (37.9% vs. 43.2%, p < 0.01), and eGFR was lower (61.4 vs. 56.6 ml/min/1.73 m2, p < 0.01). Diabetes rates were equal between men and women (25.3% vs. 25.7%, p = 0.72). Current HF medication use is presented in Table 1. Females received less RAS-inhibitors and more beta-blocker, ivabradine and diuretics, independently of other factors. We observed a lower percentage of ICD and CRT-D in females. Lifestyle interventions were more often observed in females as compared to males.
Conclusion: In this large registry, we observed a lower prescription of RAS-inhibitors, and implantation of ICD and CRT-D, but a higher prescription of beta-blocker, ivabradine and lifestyle therapy in females with HFrEF, as compared to males.

48.2 ml/min/1.73 m2, p < 0.01) between groups. Current HF medication use is described in Table 1. Elderly patients received less beta-blocker, RAS-inhibitors, MRA and ivabradine, but more diuretics (all p < 0.01). Furthermore, we observed less ICD and CRT, but more pacemaker therapy in elderly (p < 0.01). Elderly were more often treated with lifestyle treatment (p < 0.01).

Conclusion: In this large registry of HFrEF patients, we observed significant differences in medical, device and lifestyle therapy between age-groups.

P1044

Comparative efficacy of long-term digoxin and ivabradine therapy on prognosis, left and right heart functional parameters in patients with chronic heart failure and mid-ranged ejection fraction

LR Liana Tumasyan[1]; KG Adamyan[1]
[1]*Institute of Cardiology, Yerevan, Armenia*

The aim of study was to assess the comparative efficacy of digoxin (D, 0.25 mg) and ivabradine (I, 15 mg) therapy on prognosis, left (LV) and right ventricular (RV), left (LA) and right (RA) atrial parameters, NT-pro-BNP and hsCRP levels in III-IV NYHA functional class chronic heart failure with mid-ranged ejection fraction (HFmEF).

Methods: 135 pts (age 60.1) with symptomatic HFmEF in sinus rhythm with HR>70 bpm were randomly assigned to groups A (n = 44, receiving D), B (n = 46, receiving I) and C (n = 45, non-receiving both drugs) in addition to ACEI, beta-blockers and diuretics. Tricuspid annulus plane systolic excursion (TAPSE), tissue Doppler-derived tricuspid lateral annular systolic velocity (s'), LV mean e' septal and lateral wall, pulmonary artery (PA) ejection time (ET), RA and LA functional index (RAFI and (LAFI), pulmonary vein (PV) systolic contribution (SC), difference between duration of reversal atrial flow (Ar) and late (A) transtmitral filling, NT-pro-BNP and hsCRP levels were assessed at baseline, 12, 24 and 36 months.

Results: 1-, 2- and 3-year mortality were (%) 29.5, 38.6 and 45.5; 28.3, 37.0 and 41.5; 40, 53.3 and 62.2 in groups A, B and C, respectively. 1-, 2- and 3-year hospitalization rates were (%) 43.2, 52.2 and 60.9; 43.5, 50 and 60, 75.6 and 84.4 in groups A, B and C, respectively. Event-free analysis showed lower probability [relative risk (RR) reduction, (%) p < 0.05] of 1-year at 26.3 and 29.3, 2-year at 27.6 and 30.6 and 3-year mortality at 26.8 and 30.1 and 1-year at 32.5 and 32.9; 2-year at 31 and 33.9; and 3-year hospitalization at 27.8 and 28.9, respectively, in groups A and B compared to group C. 1-year I treatment significantly (%, p < 0.05 for all) improved only HR at 21.2, levels of NT-pro-BNP at 40.2. and RV functional parameters (TAPSE at 51.2, s' at 35.2, PA ET at 18.8) . 1-year D treatment significantly (%, p < 0.05 for all) decreased HR at 20.2, levels of NT-pro-BNP at 38.9, hsCRP at 44.6, e' at 39.2, Ar-A at 72.1, increased PV SC at 57.1, RAFI at 50.9 and LAFI at 43.9 Reduction of e' = 50%, NT-pro-BNP, hsCRP = 40%, HR = 25%, Ar-A = 70% , increase of RAFI and LAFI, PV SC, s" = 50%, PAET at = 25% was associated with significant improvement of prognosis compared to decrease of e' < 30%, NT-pro-BNP, hsCRP < 25%, HR < 15%, Ar-A < 50% , increase of RAFI and LAFI, PV SC, s' < 30%, PAET < 15% (RR 0.35, 0.33, 0.34,0.32, 0.37, 0.36, 0.35, 0.34, 0.32 and 0.33, p < 0.05, respectively).

Conclusions: 1) Changes of Ar-A = 50%, RAFI and LAFI, s', e' = 50%, NT-pro-BNP, hsCRP = 40%; PAET and HR = 25% identified pts with cardiovascular risk reduction. 2) I and D use associated with almost similar significant reduction of morbidity and mortality. 3) Prognostic Improvement, associated with I use, was due to significant decrease of HR and NT-pro-BNP level, and RV functional parameters improvement, while D treatment resulted to HR reduction, improvement of LA and RA functional, LV diastolic parameters, neurohormonal and inflammation status.

P1045

The reverse remodeling response to sacubitril/valsartan therapy in heart failure with reduced ejection fraction.

P Pieter Martens[1]; H Belien[1]; M Dupont[1]; W Mullens[1]
[1]*Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium*

Background: Major classes of medical therapy for heart failure with reduced ejection fraction (HFrEF) induce left ventricular reverse remodeling. The revere remodeling response to sacubitril/valsartan remains unstudied.

Methods: We performed a single center, prospective assessor-blinded study to assess the reverse remodeling response of sacubitril/valsartan-therapy in HFrEF-patients with a class I-indication (New York heart Association [NYHA]-class II-IV, Left ventricular ejection fraction [LVEF] <35%, optimal dose with Renin-Angiotensin-System Blocker [RAS-blocker]). Doses of sacubitril/valsartan were optimized to individual tolerance. Images were assessed offline by an investigator blinded to clinical data and timing of echocardiograms.

Results: Sixty HFrEF-patients (68 ± 11years) were prospectively included between October 2016 and May 2017. Over a median(IQR) follow-up of 104 (77-150) days, LVEF improved (26 ± 6 vs. 30 ± 6; p <0.001) and Left ventricular systolic volume (LVESV) dropped (165 ± 55ml vs. 149 ± 55ml; p = 0.003), paralleled by an improvement in stroke volume (58 ± 23 ml vs. 71 ± 30ml; p = 0.002) and cardiac output (3.94 ± 1.6 L/min vs. 4.53 ± 2.0; p = 0.032). Volumetric remodeling associated with a reduction in the amount of mitral regurgitation (1.59 ± 1.0 vs. 1.11 ± 0.8; p <0.001; graded on a 0-4 scale). Metrics of diastolic function improved; including a drop in the E/A-wave ratio (1.9 ± 1.3 vs. 1.4 ± 0.9; p = 0.008) and diastolic-filling time prolonged (expressed as % of cycle-length, 47 ± 9% vs. 53 ± 1%; p = 0.002). The percent of patients with a restrictive mitral filling pattern, defined as an E/A-ratio>2 or E/A-ratio>1 with deceleration time of the E-wave <140 msec, dropped from 51% to 29% (p = 0.010). A dose-dependent effect was noted for reverse remodeling changes in LVEF (p <0.001) and LVESV (p = 0.026), with higher doses of sacubitril/valsartan leading to more reverse remodeling. Furthermore, both metrics of improved systolic (?LVEF, ?LVESV) and diastolic function (?E and ?A-wave velocity) correlated with functional improvement (reduction in NYHA-class, p-value all <0.05). The amount of RAS-blocker before (56 ± 32% of target dose) and after (58 ± 32% of target dose) switch to sacubitril/valsartan was similar (p = 0.820), indicating individual optimal dosing of sacubitril/valsartan. Furthermore, indicating that the incremental reverse remodeling was a resultant of the additive neprilysin inhibition.

Conclusion: Switching therapy in eligible HFrEF-patients from a RAS-blocker to sacubitril/valsartan induces dose-dependent beneficial reverse remodeling of both metrics of systolic and diastolic function.

P1046

Assessment of safe prescribing of common cardiac medications in final year undergraduate medical students.

SELINA Jarvis[1]; SHEBA Jarvis[2]
[1]*St Thomas' Hospital, Acute Medicine , London, United Kingdom*; [2]*Imperial College London, London, United Kingdom*

Background: Medication errors are a major concern with ˜50,000 medication related incidents reported by the National patient safety agency annually.1 The General

Medical Council has highlighted the urgent need for testing prescribing skills during medical school training.2 In hospital, poor prescribing will have not only safety implications but can affect time spent with patients since 19% of nursing time is already spent on medication tasks with increasing frequency of repeated interruptions such as clarification of prescriptions.3 Recently, it has been shown that medication errors pertaining to cardiac and diabetes medications are the most common.4

Purpose: To assess safe prescribing behaviours in final year medical students using clinical case examples after a pharmacist-led teaching session focused on cardiac and diabetes medications.

Methods: A senior pharmacist delivered a 1-hr teaching session with notes provided to final year medical students (1 month from sitting final medical examinations) with specific emphasis on cardiac medications followed by a safe prescribing test 24hrs later where students had full access to the British National Formulary.

Results: 188 students attended the course and sat the safe prescribing test utilising real hospital drug charts. The majority of students correctly documented allergy status with type of reaction and 80% prescribed drugs were transcribed into the correct sections. Common prescribing errors pertained to antocoagulation with low molecular weight heparin written incorrectly by 35.3% (e.g. wrong route, incorrect preparation or dose) as well as difficulties with prescribing warfarin. 48% of students inappropriately prescribed ACE inhibitors in patient scenarios involving renal dysfunction, dehydration or hypotension. Prescription of calcium channel blockers and diuretics were correct in 90% and 75% of students respectively. Finally, although there were no major issues with the prescription of oral antidiabetic agents, insulin errors were more common with incorrect spelling of insulin (6.8%), route of administration (8.7%) or timing i.e. with meals/bedtime (18.6%) were observed.

Conclusions: Despite a structured teaching session, senior medical students still struggle with commonly prescribing medications used in patients with common cardiac conditions such as heart failure with often coexist with diabetes. Safe prescribing at undergraduate level requires urgent attention. Intensive integration of safe prescribing at the earliest stage of medical training is essential and national standardised drug charts may help reduce error

P1047

Retroespective analysis of sildenafil/bosentan in type ii pulmonary hypertension (ph)

JM Jose Maria Vietez Florez[1]; S Del Prado[1]; G Alonso[1]; M Abellas-Sequeiros[1]; A Lorente[1]; S Hernandez[1]; M Castillo[1]; E Gonzalez[1]; JL Zamorano[1]
[1]*University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain*

Background: Pulmonary hypertension (PH) is a common complication of left heart disease (LHD), however there are no evidence to support the use of specific treatment due in part to the lack of studies. Up to the present, controversy exists over the benefit of pulmonary artery vasodilators, but recently, SIOVAC trial showed negative

Purpose: To analyse the clinical benefit of pulmonary artery vasodilators in PH-LHD a consecutive series of patients diagnosed of severe PH by echocardiogram in a tertiary hospital was evaluated.

Results: 50 PH-LHD patients were retrospectively compared: 20 patients were treated with arterial vasodilators, 17 were on sildenafil and 3 on bosentan treatment; 30 patients were treated with standard treatment. The follow up was 39 months ($\pm$21,57). 64% were women, median age was 73.9 $\pm$ 7.37 .

Only two etiologies of PH-LHD were included: it was valve disease in 65% in treatment group vs 60% in control group, without significant differences (p = 0. 8). Heart failure with depressed ejection fraction was other etiology.

The systolic pulmonary artery pressure was similar in two groups (69.01 $\pm$ 14.2 vs 62.7 $\pm$ 13.3, p = 0.133). There were no differences in E/e' index, EF nor auricular volume. Pulmonary artery vasodilators group had worst renal function (42,6 $\pm$ 15,6 vs 61,9 $\pm$ 21,2, p = 0,001).

Eleven patients died (55%) in the group of sildenafil/bosentan compared with three (10%) in the control group (p= 0,001). Cardiovascular mortality was significantly higher in the treatment group compared with control group (35% 6.7%, p= 0.011). Median hospitalization days due to worsening of heart failure was 4 (range 0-10) and 0,5 (0-7) for the groups of treatment and control respectively (p= 0,004).

Conclusions: Treatment with pulmonary vasodilator (sildenafilo/bosentan) in PH-LHD was associated with all mortality causes, including cardiovascular mortality, and hospitalizations.

These results are consistent with recently presented SIOVAC trial who shows the increasing mortality PH-LHD treated with pulmonary artery vasodilators. More studies in order to define appropriate treatment are needed.

P1048

Sacubitril-Valsartan: real-world single-centre experience.

HMC Herminio Morillas Climent[1]; AVL Alvaro Vicedo Lopez[1]; JSM Julia Seller Moya[1]; EAT Edgard Alania Torres[1]; EGJ Emilio Galcera Jornet[1]; ALR Ainhoa Larumbe Rodriguez[1]; CNP Carlos Nunez Piles[2]; AVM Alfonso Valle Munoz[1]
[1]*Denia Marina Salud Hospital, Alicante, Spain*; [2]*University Hospital Doctor Peset, Valencia, Spain*

Background: Sacubitril-Valsartan clinical trials results are remarkable. However, real world data are scarce, mainly due to a short postcommercialization observation period.

Purpose: The aim of our study is to describe clinical use of Sacubitril-Valsartan in real world practice, taking into account its efficacy, tolerance, dose used and impact on different imaging and laboratory markers.

Methods: We performed a retrospective evaluation of Sacubitril-Valsartan prescriptions from the first drug prescription until the 10th January 2018. Inclusion criteria was any sustained prescription of the drug by Cardiology and/or General Practitioners. Patients were excluded if no data were available, prescription had an inadequate indication or if the drug was stopped before 2 months of follow-up without a clear reason.

We collected baseline characteristics of the patients, major adverse cardiovascular events, data of tolerance and information regarding imaging parameters and laboratory markers.

Statistical analysis was performed using SPSS Software for MAC, 20.0 version. Cualitative and cuantitative values were described as percentage and median +/- standard deviation. Changes in cuantitative values over time were analyzed using T-Test for paired samples.

Results: From the 19th October 2016 to the 8th January 2018, 114 patients were included. 18 patients were excluded from final analysis (3 no data available, 2 inadequate indication for prescription, 13 premature interruption).

96 patients remained. 60% of them were men. Mean age was 69 years. 25% were diabetic, 41% hypertensive and 52% received lipid lowering drugs. Ischaemic heart disease was the main cause of heart failure (59%). 60% of the patients reported NYHA functional class II symptoms, 33% NYHA III and 7% NYHA I. Baseline treatment was optimal.

During a medium follow-up of 203 +/- 101 days, 8 patients (8,4%) were admitted to the hospital due to heart failure and 4 patients died (all cardiovascular deaths). Sacubitril-Valsartan was withdrawn in 8 patients (8,4%) because of symptomatic hypotension. 3 patients complained about headache (2 possibly related to hypotension). Only 1 case of hyperkaliemia and no acute renal failure was reported. 3 patients referred economic issues and stopped medication. At the end of the follow-up, 87,5% of the patients continued taking the treatment, the majority of them at low doses (24/26 mg, 58%).

Pretreatment LVEF was 30,37%. During follow-up, LVEF increased to 34,47% (p 0,001). NTproBNP decreased from 3557 to 3019 pg/ml, with a trend towards significant reduction in idiopathic dilated cardiomyopathy subgroup (3787 vs 2099 pg/ml, p = 0,08). Ca125 levels decreased non-significantly over time (42,96 vs 29,17 pg/ml, p = 0,098).

Conclusion: Sacubitril-Valsartan prescription for heart failure with reduced ejection fraction is increasing in real world practice. Although tolerance is good, it is difficult to reach high dose prescriptions, mainly due to low blood pressure.

P1049

Association of body surface area with target dose guideline-directed therapy in an international cohort of patients with heart failure

T-H K Tiew-Hwa Katherine Teng[1]; W T Tay[2]; N Luo[3]; L B Cooper[4]; J Tromp[5]; W Kraus[3]; D Whellan[3]; C Chandramouli[2]; I Pina[6]; J J L Yap[7]; C M O'connor[4]; I Anand[8]; R Mentz[3]; C S P Lam[9]

On behalf of: ASIAN-HF and HF-ACTION

Funding Acknowledgements: ASIAN-HF:National Medical Research Council(Singapore); A*STAR Biomedical Research Council;Boston Scientific & Bayer; HF-ACTION:National Health Inst.

Background: For patients with heart failure and reduced ejection fraction (HFrEF), practice guidelines advocate for evidence-based HF medications at optimal

doses(GDD). In clinical practice, many physicians may believe that Asian patients need reduced dosages of medications studied in clinical trials due to their smaller body size and possible heightened sensitivity to cardiovascular drugs.
Aims: (1) To describe the usage patterns of ACE-inhibitor (ACEi) or angiotensin-receptor blockers (ARB) and ß-blockers in Asia vs. U.S./Canada/France; (2) to evaluate the association of body surface area (BSA) with prescribed doses of ACEi and ß-blockers; (3) to examine if the association is mediated by country of origin or ethnicity.
Methods: We compared patients with chronic HFrEF (EF = 35%) from the ASIAN-HF and HF-ACTION multinational studies for differences in dosing patterns of ACEi and ß-blockers. Drug doses at baseline were standardized by using lisinopril equivalents for ACEi and carvedilol equivalents for ß-blockers. Regression models were used to examine the association of BSA with maximum prescribed doses (as a continuous variable) and attainment of GDD (Yes/No) for ACEi (defined as = 20mg lisinopril equivalents) and ß-blockers (= 50mg carvedilol equivalents), adjusting for differences in baseline characteristics.
Results: Among a combined cohort of 6,683 patients with HFrEF (mean age 59 ± 13 years, 23% women), two-thirds (4,543) were Asian and one-third (2,140) were non-Asian from North America/Europe. Asian (vs. non-Asian) patients had a lower BSA (1.74 ± 0.22 vs. 2.11 ± 0.29 m2). Usage patterns of HF medications varied considerably across geographical regions. Compared to North America/Europe, patients in Asia were less likely to be prescribed ACEi/ARBs (76% vs 94%) and ß-blockers (78% vs 95%). Median lisinopril and carvedilol equivalents in Asians were half of those in non-Asians: 10 (IQR 5-20) mg vs. 20 (10-40) mg and 12.5 (6.25-25) mg vs. 25 (13-50) mg, respectively.
BSA was associated with crude beta-coefficients of 14.43 (SE 0.89) for maximum prescribed doses for ACEi and 21.51 (SE 0.90) for ß-blockers ($p < 0.001$), respectively. Adjusted for age, sex and NYHA class, BSA (per unit increment) was associated with OR 5.12 (95% CI 4.09-6.41) and OR 9.92 (95% CI 7.90-12.47) for attainment of GDD for ACEi and ß-blockers. The association of BSA with attainment of GDD for ACEi and ß-blockers persisted on additional multivariable adjustment ($p = 0.016$). Notably, geographic region modified the association of BSA ($p_{interaction} = 0.006$) with attainment of GDD for ACEi (but not ß-blockers), such that patients in US, Canada, South Asia had higher odds of attaining GDD (2.3-3.8) but not France, East Asia and Southeast Asia.
Conclusions: Our multinational data suggest that both geographic region and body size are related to dosing patterns of ACEi and ß-blockers in HFrEF. Larger body size is associated with higher doses of ACEi in some regions, but not all.

P1050

What are the predictors of positive response to trimetazidine in patients with severe chronic heart failure with reduced left ventricular ejection fraction?

M Michal Bohdan[1]; I Stopczynska[1]; P Wisniewski[2]; A Kowalczys[1]; J Morys[1]; A Frankiewicz[1]; P Niedoszytko[3]; W Sobiczewski[1]; M Rafalowska[1]; M Gruchala[1]
[1]Medical University of Gdansk, 1st Dept of Cardiology, Gdansk, Poland; *[2]Medical University of Gdansk, Department of Endocrinology and Internal Diseases, Gdansk, Poland*; *[3]Medical University of Gdansk, Department of Rehabilitation Medicine, Gdansk, Poland*

Background: Trimetazidine (TMZ) is an anti-anginal agent that modulates cardiac metabolism but its use in heart failure still remains controversial. The data concerning the effects of TMZ in heart failure with reduced ejection fraction (HFrEF) were derived mainly from retrospective studies. The aim of the study was to evaluate the effects of TMZ on exercise capacity, left ventricular ejection fraction (LVEF), NYHA class, mortality and quality of life in stable patients with severe HFrEF.
Methods: Forty-five patients aged 58.2 ± 10.6 years with stable severe HFrEF treated with optimal medical therapy were randomised in a prospective, single-centre, open-label, cross-over study to trimetazidine (35 mg b.i.d.) on top of standard medical therapy or standard pharmacotherapy for two periods of 30 days and one period of 6 months. Patients were randomised to two groups: Group I - standard pharmacotherapy and additionally TMZ 35mg b.i.d. for 1 month, then standard pharmacotherapy without TMZ for the following 1 month and once again TMZ 35mg b.i.d. for 6 months; Group II - standard pharmacotherapy without TMZ for 1 month, then standard pharmacotherapy and additionally TMZ 35mg b.i.d. for the following 1 month and once again standard pharmacotherapy without TMZ for 6 months. Initially and at the end of each period all patients underwent: cardiopulmonary stress testing, six-minute walk test (6MWT), 2D-echocardiography, symptom severity in NYHA class and quality of life assessment.
Results: Etiology of HFrEF was ischaemic in 66.6% of patients. There were 20% of responders to TMZ treatment (n = 9) in terms of LVEF improvement of = 5%. We found that patients who had a rise in LVEF = 5% during TMZ treatment had significantly lower initial BNP (262.3 ± 282.7 pg/ml vs. 714.1 ± 653.9 pg/ml, $p < 0.05$), lower 1-year and 2-year risk of death (3.6 ± 4.5% vs. 6.9 ± 5.3%; $p < 0.05$ and 6.9 ± 7.9% vs. 13.2 ± 9.7%, $p < 0.05$, respectively) and higher predicted life expectancy assessed in Seattle Heart Failure Model (15.5 ± 7.3 years vs. 10.7 ± 6.0 years, $p < 0.05$) in comparison to the patients without significant rise in LVEF during TMZ treatment (n = 36). Both after 1 month and 6 month of TMZ treatment, however, no significant changes were observed in both groups with regards to peak VO2 uptake, 6MWT, left ventricular ejection fraction or quality of life. In addition, TMZ had no effect on mortality or cardiovascular events (odds ratio: 0.5, 95% CI 0.2-1.2, NS).
Conclusions: Patients with less advanced HFrEF may have a better response to TMZ treatment with regards to left ventricular systolic function.

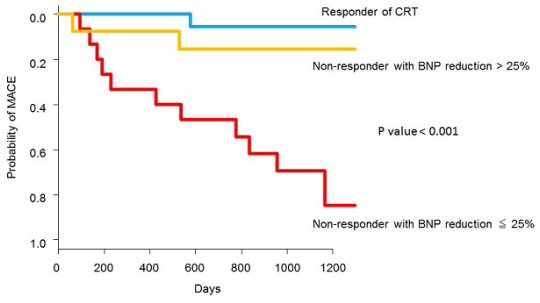
P1051

Lack of brain natriuretic peptide reduction at 30-day significantly predicts worse clinical outcomes in non-responders of cardiac resynchronization therapy

S Matsumoto[1]; YI Ikari[1]
[1]Tokai University School of Medicine, Cardiology department, Kanagawa, Japan

Backgrounds: Cardiac resynchronization therapy (CRT) is beneficial for heart failure with reduced ejection fraction accompanied by severe dyssynchrony, and responders of CRT obtain improved clinical outcomes. However, approximately 60% of patients who undergo CRT do not obtain left ventricular reverse remodeling, i.e. non-responder of CRT, and further decision criteria for additional interventions are needed. Brain natriuretic peptide (BNP) is a useful marker for management of heart failure, while associations between BNP transition and clinical outcomes after CRT were not well-known.
Purpose: We investigated long-term clinical outcomes of CRT and evaluated whether short-term BNP transition was available for the management of non-responders.
Methods: Between 2011 and 2015, we enrolled consecutive 80 patients who underwent CRT and evaluated transition of BNP levels from baseline to 30-day after implantation. In the present study, responder was defined as a reduction of left ventricular systolic volume > 10% after 6-month, and major adverse cardiac events (MACE) was all-cause death, hospitalization of heart failure, and ventricular tachycardia or fibrillation.
Results: Of consecutive 80 CRT implantations, non-responders were 35 (43.8%). During mean 3.1-year follow up, although the incidence of MACE in responders was only 2.2%, the incidence in non-responders achieved 54.3%. When focusing on the 35 non-responders, lack of BNP reduction above 25% from baseline to 30-day was significantly associated with frequent occurrence of MACE (Figure), whereas baseline BNP levels were not significantly associated with clinical outcomes after CRT. Lack of BNP reduction at 30-day was significantly associated with the presence of moderate-severe mitral regurgitation after CRT (P value = 0.02).
Conclusions: Lack of BNP reduction at 30-day significantly predicts worse clinical outcomes in non-responders of CRT and significantly associated with remaining mitral regurgitation. Early next treatment step should be considered in these patients.

Figure. Logrank test about MACE



Clinical outcomes after CRT

P1053

PR-prolongation and long-term mortality in patients with congestive heart failure treated with cardiac resynchronization therapy

AM Soldatova[1]; VA Kuznetsov[1]; VA Kuznetsov[1]; TN Enina[1]; TN Enina[1]; SM Dyachkov[1]; SM Dyachkov[1]
[1]Tyumen Cardiology Research center, Tyumen, Russian Federation

Background: Female gender, left bundle branch block (LBBB), QRS width were good predictors of cardiac resynchronization therapy (CRT) response and outcome.

Recent data indicate that PR prolongation was associated with increased risk for mortality in general population.
Aim: To analyze the relationship between clinical, functional parameters, PR-prolongation and long-term mortality in patients with congestive heart failure (CHF) treated with CRT.
Methods: 85 CRT patients (mean age 55.1 ± 9.9 years, 81.2% men) with CHF (53% ischemic and 47% non-ischemic etiology) II-IV NYHA functional class were enrolled. At baseline, 1month, 3 months and each 6 months after implantation we evaluated clinical and echocardiographic parameters. Median of follow-up period was 21.0[5.5;44.0] months. Patients were stratified according to PR width: I group - normal PR (<200 ms; n = 52) and II group - prolonged PR (= 200 ms; n = 33).
Results: At baseline groups didn't differ in main clinical and functional characteristics. In the II group history of myocardial infarction (MI) was observed more frequently (p = 0.005), left ventricular ejection fraction (LVEF) was lower (p = 0.032). Also in the II group there was a tendency to higher percentage of male gender patients (p = 0.058) and higher left ventricular end-systolic volume (LVESV) (p = 0.076). Presence of LBBB and width of QRS complex didn't differ between groups. The survival rates were 76.1% in the I group and 26.9% in the II group (Log-rank test p <0.001). Cox regression showed that LVESV (HR 1.012; 95% CI 1.006-1.018; p <0.001), PR interval (HR 1.012; 95% CI 1.005-1.020; p = 0.001) and presence of MI (HR 1.116; 95% CI 3.190-6.520; p = 0.001) were associated with long-term mortality. In ROC-analysis PR interval >197.5 ms with sensivity 63.2% and specificity 80.9% predicted long-term mortality, for LVESV - >168.4 ml with 73.7% and 74.5% respectively.
Conclusion: In patients with CHF treated with CRT LVESV, PR interval and history of MI can be used as independent predictors of long-term mortality but not LBBB and QRS width.

P1054
Increasing exercise capacity in the first year after implantation of a cf- left ventricular assist device

SEA Felix[1]; MIF Oerlemans[1]; LW Van Laake[1]; FZ Ramjankhan[2]; MP Buijsrogge[2]; JH Kirkels[1]; FW Asselbergs[1]; N De Jonge[1]
[1]University Medical Center Utrecht, Cardiology, Utrecht, Netherlands; [2]University Medical Center Utrecht, Cardiothoracic surgery, Utrecht, Netherlands

Background: Mechanical circulatory support (MCS) by a continuous flow left ventricular assist device (cf-LVAD) has shown to improve survival and quality of life in selected patients with end-stage heart failure, as a bridge to transplantation or as destination therapy. Furthermore, in previously performed studies in small numbers of patients, exercise tolerance of patients on cf-LVAD support was increased after cf-LVAD implantation, as compared to the pre-operative situation, though did not increase after the first few months after the implantation. Because of shortage of donor hearts, the number of patients on a cf-LVAD as destination therapy is increasing, thereby having MCS for a longer term. Especially in this category of patients, where functional capacity and reintegration into the society is of importance, insight into the exercise tolerance is essential.
Purpose: To give insight in the sequential exercise tolerance of patients in the first year after cf-LVAD implantation in a large cohort of patients.
Methods: 99 cf-LVAD-patients (69% male, mean age 49.5 ± 5,0 years) underwent a cardiopulmonary exercise test (CPET) at 3-6 and 12 months after implantation. In all patients a respiratory exchange ratio (RER) > 1,05 was seen, indicating satisfactory effort during the test.
The results of both moments of CPET were analyzed in SPSS ® with two-tailed paired test or non-parametric test if not normally distributed. Percentage of predicted values was calculated according to Jones.
Results: Power increased from 105 ± 36 W to 115 ± 41 W (p = 0.000), peak VO2 significantly improved both uncorrected and corrected for weight from 1.27 ± 0.43 L/min (53 ± 12% predicted) to 1.36 ± 0.47 L/min (57 ± 13% predicted) (p = 0.000) and 16.5 ± 5.0 ml/kg/min (52 ± 12% predicted) to 17.3 ± 5.6 ml/kg/min (55 ± 13% predicted) (p = 0.004) respectively, where respiratory quotient, heart rate and EqCO2 did not differ.
Conclusion: In this large cohort of patients, a further improvement in peak-VO2 levels at 12 months was seen compared to 3-6 months after cf-LVAD implantation. This is important information for the growing group of patients on long term cf-LVAD support.

P1055
Comparison of Echocardiographic Parameters influenced by

B Bernd Schulze[1]; B Fujita[1]; KT Puhlmann[1]; U Schulz[1]; J Gummert[1]; L Paluszkiewicz[1]
[1]Heart and Diabetes Center NRW, Clinic for Thoracic and Cardiovascular Surgery, Bad Oeynhausen, Germany

Background: Detection of Acute cellular rejection (ACR) still remains a challenge for clinical echocardiography. Our objective was to evaluate and compare various echocardio-graphic parameters identifying patients with biopsy-proven ACR after heart transplantation.
Methods: 204 consecutive transplant recipients were prospectively examined shortly after endomyocardial biopsy (EMB) blinded to the Results. Various conventional and deformation derived parameters of the left and right ventricle were analysed.
Results: ACR-Grade 0R was found in 135 (67%), grade 1R in 52 (26%) and grade 2R in 15 (7%) patients. Comparing group G0R with G1/2 significant differencies were increase of septal (GOR 12 (11-13) vs. G1/2R 13 (11-14), p < 0,01) and posterior wall thickness ((11 (11-12) vs. 12 (12-13), p < 0,001) , tricuspid regurgitation equal or greater than mild (25,5% vs. 41,8%, p = 0,02), presence of pericardial effusion (54% vs. 68,7%, p = 0,046), higher E/e' at the lateral mitral annulus (8 (6-10) vs. 9 (7-12), p = 0,03) , decrease of the TDI systolic velocities at the lateral mitral (10 (8,8-11,2) vs. 9,7 (8,1-10,7), p = 0,049) and tricuspid annuli (10,5 (9,3-11,8) vs. 10 (8,3-11,2), p = 0,02), increase of RV-Tei index (0,23 (0,15-0,31) vs. 0,28 (0,12-0,44), p = 0,047) and decrease of GLS-LV (-20,8 (17,6-24) vs. -19,5 (15,9-23,2), p = 0,01 and LS-RV (-22,9 (20-26,8) vs. -21,3 (16-26,6), p = 0,03. Combined cut-off analysis of the GLS-LV, LS-RV, twist, apical rotation and rotation rate resulted in a negative predictive value (NPV) of 83.3% and positive predictive value (PPV) of 79.3%. Combined analysis of GLS-LV and LS-RV resulted in a high NPV of 97%, but a low PPV of 11.7% for detection of G2 rejection.
Conclusion: Speckle-tracking of LV/RV had the highest NPV/PPV of all significant parameters for ACR enabling clinical decision making to reduce routinely performed EMB.

P1056
Heart failure patients with sleep-disordered breathing: dynamics of this highly common comorbidty before and after heart transplantation

H Fox[1]; T Bitter[1]; D Horstkotte[1]; O Oldenburg[1]
[1]Herz- und Diabeteszentrum NRW, Ruhr-Universität Bochum, Clinic for Cardiology, Bad Oeynhausen, Germany

Background: The comorbidity of sleep-disordered breathing (SDB) is known to be highly common in heart failure (HF) patents and SDB is associated with deterioration of quality of life as well as with increased morbidity and mortality in HF. Details on SDB interactions with HF and vice versa are widely unknown, because SDB and HF share many symptoms and measureable parameters. Therefore the rationale of our study was to investigate the interplay of SDB and HF in patients listed for heart transplantation (HTx) to analyze SDB characteristics in the same subject initially presenting with end-stage HF and subsequently with normal cardiac function after HTx.
Methods and Results: We included 80 HF patients listed for HTx for this study (left ventricular systolic ejection fraction 20 ± 19.5 %, 83 % male, BNP 420 ± 755 pg/ml), who were examined with cardiorespiratory polygraphy, revealing a SDB prevalence of 94.6 % (AHI > 5/h). In addition, 83.3 % of the patients had moderate to severe SDB (AHI = 15/h), mean apnea hypopnea index (AHI) before HTx was 29.6 ± 18.8 /h which decreased to 12.7 ± 13.1 /h after HTx (p < 0.05).
Conclusion: The model of HTx demonstrates the close and tight interplay of HF and SDB, with SDB representing a very common comorbidity in end-stage HF patients listed for HTx. Further studies are needed to elucidate the interdependent interaction of HF and SDB to allow successful therapy approaches for the future.

P1057
Heart transplantation in patients with restrictive cardiomyopathy: a single center experience.

A Antonio Grande-Trillo[1]; L Perez-Gomez[1]; D Rangel-Sousa[1]; JM Sobrino-Marquez[1]; E Lage-Galle[1]
[1]University Hospital of Virgen del Rocio, Seville, Spain

Introduction: Restrictive Cardiomyopathy (RCM), formed by a group of heterogeneous pathologies, is poorly represented in heart transplantation (HT) series and has been related to worse prognosis.
Methods: Retrospective study that includes patients with RCM who underwent to HT in our center (1992-2017). We analyzed RCM etiology and prognosis in comparison with the rest of our series.
Results: 11 patients (42 ± 16 years old; 82% women) with RCM were evaluated (2.5 % of our HT series). The RCM etiology was classified as follows: light chain amyloidosis (AL) (28%, 3 patients), transthyretin related amyloidosis (ATTR) (9%, 1 patient), polyglucosan storage disease (9%, 1 patient) and idiopathic RCM (64%, 7 patients). There were no significant differences in pre-transplant hemodynamic study (right heart catheterism) or liver test parameters (bilirubin, AST and ALT) between RCM group and the rest of the HT series. Primary graft failure was more frequent in RCM group without statistical signification (36% vs 16% respectively; p = 0.09). 5 RCM patients (45%) died during post-HT hospitalization: 4 due to primary graft

failure and 1 due to sepsis. The rest of the sample (n = 6) also died during the follow up: 4 deaths were related to progression of the underlying disease (AL or ATTR) at 5, 16, 18 and 72 months after HT; one patient voluntary interrupted immunosuppressive treatment, dying 14 months after HT. Last patient died due to graft vascular disease at 60 months after HT. The comparative survival curve is shown in the graph.
Conclusions: RCM has worse prognosis in our study. These results, which are comparable to others series, are mainly related to a high in-hospital mortality. In addition, those cases due to amyloidosis have unfavorable evolution because of the underlying disease itself. These data highlight that a careful selection of patients is mandatory for HT evaluation in patients with RCM.

P1058

Frailty prevalence in patients listed for heart transplantation

A Ayesta Lopez[1]; MJ Valero Masa[1]; MT Vidan Astiz[1]; I Martin De Miguel[1]; I Sousa Casasnovas[1]; E Zatarain Nicolas[1]; P Navas Tejedor[1]; C Ortiz Bautista[1]; J Yanez[1]; A Villa Arranz[1]; F Fernandez- Aviles[1]; M Martinez- Selles[1]
[1]University Hospital Gregorio Maranon, Madrid, Spain

Background and Aim: Frailty (F) reflects a state of decreased physiological reserve. Its prevalence among patients with heart failure (HF) is 20-50%. Frailty assesment is recommended before listing for heart transplantatio (HT). Our aim was to analyze the prevalence of F, depression (D), and cognitive impairment (CI) in a consecutive cohort of younger patients with advanced HF listed for HT.
Methods: The FELICITAR registry is a prospective observational study that includes adults listed for HT in Madrid since January 2017. In the present analysis we include patients from our center. Data were collected when listed. F was assessed using the Fried Frailty Phenotype (FFP) (frail = 3/5); to assess D we used the PHQ9 scale (= 5); and Montreal Cognitive Assessment (MoCA) test was used to assess CI (CI < 26).
Results: A total of 22 patients were listed for HT in our center during 2017, 15 (68.2 %) were included in the FELICITAR. 1 patient (6.67 %) was included in emergency list 1, and the rest in elective list.
Most of the patients were men (60%), were 50 ± 17 years old and had a low rate of comorbidities (Charlson score 2.2 ± 0.6). Most of them were in NYHA class III (60.7%) with a LVEF of 31 ± 15 and generally well treated (Beta blockers 60%, ACEI/ARA2/ARNI 66.7%, Ivabradine 13.7%, ICD 66.7%, CRT 26.7%). There were several causes for HF (ischemic 6.7%, valvular 20%, dilated 20%, congenital 13.3% and other 40%). 4 patients (26.7%) were frail (FPP score of 1.5 ± 1.5) , 6 (40%) had any degree of D (PHQ-9 score 7 ± 6.9) and 3 (20%) had CI (MoCA 26.9 ± 2.5).
Conclusions: The prevalence of F in patients listed for HT is relatively high. The study of its influence before and after HT could contribute to a better understanding of the characteristics of the optimal candidate for HT.

P1059

Neurohormonal blockage score - the higher the better?

D David Cabrita Roque[1]; M Santos[1]; J Augusto[1]; J Baltazar Ferreira[1]; D Candeias Faria[1]; J Simoes[1]; A Oliveira Soares[1]; C Morais[1]
[1]Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal

Background: Current treatment of HF is based on the blockage of the named neuro-hormonal response, and guidelines recommend up-titration of this drugs to its maximum dose whenever possible according to patient tolerance: angiotensin-converting-enzyme inhibitors/angiotensin II receptor blockers (ACEi/ARB), beta-blockers (BB), mineralocorticoid receptor antagonist (MRA).
Purpose: We aim to evaluate, in patients admitted for acute heart failure, the relation between a neuro-hormonal blockage score (NHB) with in-hospital outcomes and the same neuro-hormonal blockage score at discharge with outcomes at 1 year follow-up.
Methods: Retrospective study of 258 consecutive patients admitted in the emergency department for ADHF, defined by the presence of = 2 signs or symptons of heart Failure. The HF profile was assessed as according to the ESC guidelines. We evaluate the drug therapy patients had before admission, during hospitalization and at discharge, and developed a NHB (ACEIs/ARB, BB and MRA) score, based on the percentage of their maximum dose; the higher the value, in theory, the greater the blockage power in the patient.
Results: We evaluated 258 patients with ADHF (45.7% male, mean age of 74.6 ± 16.6 years). Mean NHB score at admission according to the drugs and their doses was 61.1 ± 3.2%. Patients who died in-hospital had significantly lower NHB scores at admission (mean 38.7 vs 63.1%, p = 0.019) and during hospitalization (mean 45.3 vs 76.3%, p = 0.003). NHB scores at admission and during hospitalization were not significantly associated with length of stay (p = 0.802 and p = 0.884, respectively), hyperkaliemia (p = 0.780 and p = 0.390, respectively), peak heart rate during hospitalization (p = 0.204 and p = 0.731, respectively), peak systolic blood pressure (p = 0.141 and p = 0.487, respectively) and nadir systolic blood pressure during hospitalization (p = 0.113 and p = 0.277, respectively). NHB at admission was not significantly associated with nadir eGFR during hospitalization (p = 0.944), but higher NHB during hospitalization correlated with higher eGFR (r = 0.370, p = 0.001).
At discharge, mean NHB score was 66.6 ± 3.2%. Discharge NHB score was not significantly associated with readmissions at 6-month (p = 0.969), 9-month (p = 0.574) or 12-month follow-up (p = 0.117) or all-cause mortality at 12 months after discharge (p = 0.222).
Conclusion: Calculate the NHB score at hospital admission and during hospitalization can be a useful tool to predict intra-hospital mortality in patients admitted for acute decompensated heart failure, and is a wake up call for the importance of progressing, whenever possible, in the dose of heart failure drugs until the maximum dose tolerated by the patient.

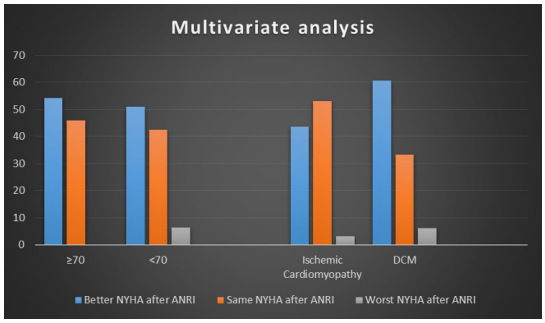
P1060

Sacubitril/valsartan treatment and its impact over functional class: does the age and the heart failure aetiology matter?

M Singh[1]; M Fernandez-De-Sanmamed-Giron[1]; M Galvan Ruiz[1]; R Montiel Quintero[1]; M Groba-Marco[1]; E Perez-Nogales[2]; JM Medina Gil[2]; E Caballero Dorta[1]; V Quevedo Nelson[1]; M Lopez Perez[1]; A Antonio Garcia Quintana[1]
[1]University Hospital De Gran Canaria "Dr. Negrin", Las Palmas de Gran Canaria, Spain; [2]University Hospital Insular of Gran Canaria, Las Palmas De Gran Canaria, Spain

Background: Despite the advances in optimal medical treatment, Heart Failure with reduced Ejection Fraction (HFrEF) is an important cause of cardiovascular death. Sacubitril/ Valsartan (SV), as an Angiotensin Neprilysin Receptor Inhibitor (ANRI), has been a milestone in HFrEF management, and has shown improved cardiovascular outcomes (PARADIGM-HF), but further real-life data is necessary in order to evaluate its role in daily clinical practice.
Purpose: To analyse the evolution of the HFrEF symptoms, according to the New York Heart Association (NYHA) classification, and its relation with the age and HFrEF aetiology, in patients with HFrEF after ANRI treatment in a real-life study.
Methods: Ambispective registry of consecutive 106 patients with HFrEF, from two hospitals, under treatment with ANRI initiated during a period of 14 months, from October 2016 to December 2017, was performed. After initiating the ANRI at dose of 24/26mg or 49/51mg, the patients were followed-up with clinical and analytical assessment with an interval of 1-3 months. Titration to the maximum dose, 97/103mg, was performed if it was feasible. The symptoms were evaluated using NYHA classification by the treating physician. Multivariate statistical analysis was later performed.
Results: Our population (n = 106) had a mean age of 63.5 ± 11.68 years, 69% were men and 31% were women. Baseline NYHA functional class was 49.1% NYHA II, 44.3% NYHA III and 6% without NYHA evaluation. HFrEF aetiology was classified in 4 groups: 49,1% had Ischemic Cardiomyopathy (ICM), 39,65% had idiopathic Dilated Myocardiopathy (DCM), 3,8% had Chemotherapy related HFrEF, 7.45% miscellaneous (genetics, valvular). 23.07% of the cohort was on 24/26mg dose, 34.6% on 49/51mg dose, 27.88% had the maximum dose and the rest had intermediate doses. After ANRI treatment the clinical assessment showed a symptomatic evolution to 22% of NYHA I, 66% of NYHA II, 12% NYHA III. In patients with < 70 years after ANRI 27% had NYHA I functional class, in front of only 12% of = 70 years aged. In patients with = 70 years, 54.17% improve their NYHA class, 45.83% maintain the same NYHA, and none of them worsened. Whereas in patients

with < 70 years 51.06% improve the NYHA, 42.55% maintain the same one and 6.38% worsened their NYHA. Related to the HFrEF aetiology, 43.75% patients with ICM had a better NYHA after treatment, 53.13% maintain the same one and 3.13% worsen their NYHA, while in patients with DCM up to 60.61% of the patients improve their NYHA class, only 33.33% maintain the same and 6.06% had a worse NYHA.
Conclusions: Sacubitril/Valsartan has shown a significant improvement in the functional class of our patients. Aged patients seem to have better symptomatic evolution when compared to the younger ones, same as patients with DCM when compared to ICM as the cause of HFrEF. Younger patients achieve NYHA class I more frequently than older patients.



Change of NYHA for age and aetiology

Background: Endothelial inflammation plays a key role in the development and progression of heart failure (HF) regardless of ejection fraction (EF), in part by suppressing downstream cyclic guanosine monophosphate (cGMP) signalling. Stimulation of guanylate cyclase (GC) may restore cGMP signalling, even in the presence of inflammation. We examined the effect of vericiguat, a soluble GC stimulator in development for HF, on high-sensitivity C-reactive protein (hsCRP), an established marker of inflammation, and prognosis in cardiovascular disease.
Methods: Circulating hsCRP was measured in the SOCRATES-REDUCED trial (NCT01951625), a 12-week, randomised, placebo-controlled, double-blind, dose-finding phase 2 study of vericiguat 1.25, 2.5, 5 and 10 mg once daily in patients with HF with reduced EF (HFrEF). Changes from baseline within each treatment arm were used to generate a linear mixed model and were adjusted for baseline hsCRP.
Results: In total, 328 of 456 randomised patients with available hsCRP values at baseline and week 12 were included (placebo [n = 65], vericiguat 1.25 mg [n = 65], 2.5 mg [n = 68], 2.5-5 mg [n = 64], and 2.5-10 mg [n = 66]). Exclusions were mainly due to protocol deviations. Overall median hsCRP was 3.68 mg/L (interquartile range: 1.41-8.41 mg/L) at baseline. Observed mean %-changes (geometric SD) from baseline were −0.5 (3.8), −26.7 (3.3), −23.2 (3.8), −26.7 (3.0) and −28.0 (3.1) for placebo, vericiguat 1.25, 2.5, 2.5-5 and 2.5-10 mg, respectively. After adjusting for baseline hsCRP, a dose-dependent treatment effect was revealed with a mean %-change in hsCRP of 0.2 for placebo, and −19.6, −24.3, −25.7, and −31.9 for increasing vericiguat doses [Figure]. This model indicated a significantly greater reduction in hsCRP in the highest vericiguat dose group of 2.5-10 mg relative to placebo (−31.9% vs 0.2%, respectively; p = 0.016). The model also demonstrated that vericiguat-treated patients in the 2.5-10 mg group were on average about 13 percentage points more likely to achieve a clinically meaningful hsCRP cut-off value of < 3.0 mg/L (e.g. 55% vs 40.6% in placebo for a baseline hsCRP of 4 mg/L and 33.4% vs 21.3% in placebo for a baseline hsCRP of 10 mg/L).
Conclusion: Vericiguat was associated with greater reductions in hsCRP levels at higher doses of the drug in patients with HFrEF.

Figure. Baseline adjusted mean hsCRP changes (%) from baseline to end of treatment across the vericiguat dose groups.

Single or combined cardiac transplantation for Cardiac Amyloidosis. A report from the French National Referral Center for Cardiac Amyloidosis

S Guendouz[1]; D Bodez[1]; A Galat[1]; M Kharoubi[1]; F Lebras[1]; K Belhadj[1]; JP Couetil[1]; JL Dubois Rande[1]; G D'honneur[1]; D Azoulay[1]; C Duvoux[1]; V Audard[1]; C Feray[1]; V Plante Bordeneuve[1]; T Damy[1]
[1]University Hospital Henri Mondor, cardiologie, Creteil, France

Cardiac Amyloidosis (CA) is caused by the extracellular accumulation of insoluble fibrillar proteins. Depending on the type of protein, disease history, localization to other organs, prognosis and treatment vary. The most common types of CA are AL amyloidosis (immunoglobulins), transthyretin amyloidosis: hereditary (hTTR) or senile (wTTR). In the absence of treatment and adequate care management, the prognosis for CA is poor. Heart transplantation is remains the final cardiac therapeutic option. Few centers offer this therapy, especially for AL CA. We report our experience of the French National Referral Center for CA.
Materials & Methods: This is a retrospective study that included all patients who had a heart transplant for CA from 2005 to 2017 (n = 15). We report the baseline and post-transplant data follow-up. Post-transplant immunosuppressive therapy included for all corticosteroids, tacrolimus, and MMF and for few anti-lymphocyte serum or basiliximab.
Results: Fifteen patients had a heart transplant, 11 (73%) had AL amyloidosis and 4 had hTTR (27%). None of them were wTTR. The average age was 56 years (43 to 66), the majority of patients were men (60%). Three patients had combined heart and liver transplant and all of them were hTTR. Three patients had combined heart and kidney transplant and all of them were AL. All AL patients received at least one cycle of chemotherapy before the surgery and 7 (82%) were in partial remission. Six patients (40%) were urgently transplanted (national priority list) of whom 5 were in cardiogenic shock treated by intravenous inotrope (n = 3) and/or extracorporeal life support-assisted patients (n = 2) and 1 had incessant ventricular arrhythmias. Prior to transplantation, 4 patients (27%) had severe ventricular arrhythmias or cardiorespiratory arrest (electromechanical dissociation). The 30-day survival is 100%, the one-year survival was 74% (n = 4). Three died from infection and 1 from severe hemorrhage due to scarpa rupture (vascular amyloidosis and vascular mycotic infection). The deaths occurred only in AL. 3 with single heart transplant and one with heart and kidney. No deaths at 1 year were associated with a recurrence of amyloidosis or graft rejection. In most AL with partial remission before the surgery, a slight decrease of light chains under immunosuppressive treatments was observed, allowing avoiding immediate postoperative chemotherapy for several months.
Discussion & Conclusions: Heart transplant is a therapeutic option for selected CA in AL and hTTR and can be combined with kidney or liver transplant. In severe AL CA cardiac transplant need to perform before expecting the complete remission as immunosuppressive therapy may stabilize or decrease the light chain after the

transplant. The survival of heart failure patients with CA treated by heart transplant is comparable to those without CA and patients with combined transplant might have a better survival than those with only heart transplant.

On behalf of: ASIAN-HF investigators
Funding Acknowledgements: National Medical Research Council (Singapore), A*STAR Biomedical Research Council, Boston Scientific and Bayer.

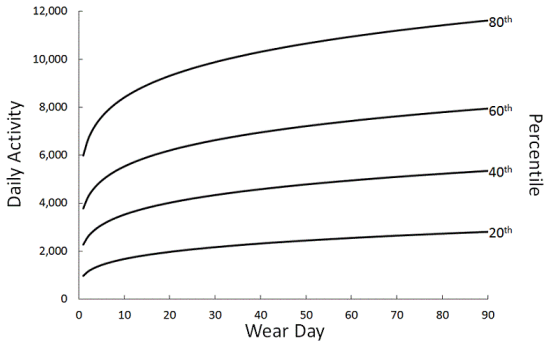
Background: It is a common perception that Asian patients with heart failure and reduced ejection fraction (HFrEF) are treated with lower doses of guideline-directed medical therapies (GDMT) such as angiotensin-converting enzyme inhibitors or angiotensin receptor blockers (ACEi/ARBs), ß-blockers and mineralocorticoid receptor antagonists (MRAs). However prospective multinational data from Asia on prescribing patterns of GDMT and its impact on outcomes have thus far been lacking.
Methods: In the prospective multinational ASIAN-HF registry, we examined GDMT uptake, achieved doses as proportions of guideline-recommended doses (GRD), and its association with 1-year composite outcome of all-cause death or HF hospitalization.
Results: Among 5,276 patients with HFrEF [mean age: 59.6 (SD13.2) y, 77.3% men, body mass index: 24.9 (5.1) kg/m2, 33.4% NYHA class III/IV], ACEi/ARBs were prescribed in 76%, ß-blockers in 78% and MRAs in 57%, with significant regional variation. GRD was achieved in only 17% of cases for ACEi/ARB, 12.5% for ß-blockers and 29.2% for MRAs. Factors associated with attainment of GRD included country (all 3 drug classes), increasing body mass index (ACEi/ARBs, MRAs), and in-patient recruitment (ACEi/ARBs, ß-blockers) (all p <0.05). Adjusted for indication bias, higher doses [including low doses (1- <25% GRD)] were associated with lower hazards of a 1-year composite outcome for ACEi/ARBs and ß-blockers compared to non-users. The lowest adjusted hazards were observed in the group that attained the GRD (HR 0.54 [95% CI 0.50-0.58] for ACEi/ARBs, HR = 0.47 [0.46-0.50] for ß-blockers, and HR = 0.77 [0.72-0.81] for MRAs). Low dosages (<50% GRD) of MRAs were associated with no better, or worse, outcomes vs non-users.
Conclusions: These first prospective multinational data from Asia demonstrate under-utilization of GDMT at recommended doses in patients with HFrEF, and suggest that effort to improve uptake and up-titration of GDMT is warranted for better patient outcomes.

P1064

Activity trends in patients recovering from acute myocardial infarction: recordings from a wearable cardioverter defibrillator

C Connor Tripp[1]; A Burch[1]; A Hain[2]; JW Erath[3]; S Sears[1]
[1]East Carolina Heart Institute, Psychology , Greenville, United States of America; *[2]Kerckhoff Heart and Thorax Center, Department of Cardiology, Bad Nauheim, Germany*; *[3]JW Goethe University, Department of Cardiology, Frankfurt am Main, Germany*

Background: Normative data for patient activity levels post-myocardial infarction (MI) does not exist. Wearable Cardioverter Defibrillators (WCDs) are equipped with accelerometers to provide information about patient activity levels. Patient management could benefit by establishing norms for objective physical activity assessment in post MI patients.
Purpose: To describe the activity level and trends in activity change after the diagnosis of acute MI.
Methods. Retrospective analysis of 480 WCD patients, 40 per month from the year 2016. Included were adult patients diagnosed with acute MI and LVEF = 35% who wore the WCD for 90 days with >100 hours of use during days 1-7 and 84-90. Age, daily wear time, and daily activity (measured by device accelerometer as steps divided by time worn) were examined. Descriptive analyses and relationship between activity levels and days of wear were examined to provide normative data during post MI recovery.
Results: Patients were mostly male (342, 71%) with a median age and 25th to 75th percentile range of 64 [56, 71]. Step count increased during the first weeks of post-MI recovery, nearly doubling before plateauing after 30 days. Median and percentile range of steps was 3100 [1300, 5700], 5600 [2700, 9100] and 6100 [3500, 9900] on days 1, 30 and 90, respectively. Patients who recorded a high number of steps at day 1, those above the 75th percentile of 5700 steps, maintained a high level of steps throughout the entire 90 day observation period: 8900 [6900, 11400], 10000 [6800, 13900] and 9200 [5500, 12000] on days 1, 30 and 90, respectively. Analysis of patients by age cohort < 65 (241, 50%), = 65 to < 75 (163, 34%) and = 75 (76, 16%) was performed. Although each age cohort increased steps during the first 30 days, age inversely correlated with median steps with age < 65 having the most and >75 the fewest: 6800 [3800, 10400] versus 3700 [1700, 5100], respectively. The figure summarizes daily activity for all post MI patients during the first 90 days of recovery.
Conclusions. Benefits associated with WCD wear include objective assessment of physical activity, thus enabling feedback and coaching in post MI patients at risk for ventricular arrhythmias.



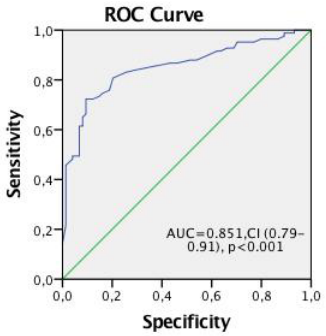
P1065

How to predict diuretic resistance in acutely decompensated heart failure patients

F Francisco Gama[1]; A Felix Oliveira[1]; P Freitas[1]; A Tralhao[1]; J Ferreira[1]; I Araujo[2]; F Marques[2]; C Fonseca[2]
[1]Hospital de Santa Cruz, Lisbon, Portugal; *[2]Hospital de Sao Francisco Xavier, Lisbon, Portugal*

Background and aim: diuretic resistance is common in heart failure (HF) patients and is associated with poorer functional capacity, recurrent hospital admissions and increased mortality. However, the clinical and pathophysiologic characteristics associated with this phenomenon remain incompletely understood. We aimed to identify predictors of diuretic resistance (DR) in HF patients across the ejection fraction range.
Methods: single-center retrospective cohort study of consecutive patients admitted to a dedicated heart failure inpatient unit between January 2013 and December 2014 with a diagnosis of decompensated HF showing clinical signs of congestion requiring intravenous furosemide. DR was defined as urine output below 20 milliliters per milligram of furosemide in the first 24 hours after loop diuretic initiation. A multivariate regression logistic model was used to determine independent predictors of diuretic resistance. A ROC curve was used to determine model's discriminative power.
Results: in a population of 159 patients, mean age was 79 years (IQR 14), 46% (n = 79) were male and 42% had resting symptoms. 39% (n = 62) had reduced ejection fraction (defined has lower than 40%) and 46% (n = 73) had ischemic etiology. Median pre-admission clearance and serum B-type NT-terminal natriuretic peptide level were 56 (Q25-75: 39.15-78.64) mL/min/1.73 m2 and 8260 (P25-75: 3160-9800) pg/ml, respectively. 53% (n = 84) of patients had diuretic resistance according to study definition. DR was significantly associated with cardiovascular death at 30 months median follow-up (HR 3.066 (1.21-7.79; p-value = 0.019). After multivariate analysis, higher serum chloride (OR 1.18 [1.02- 1.20], p = 0.015), previously on oral different diuretic classes (OR 2.74 [1.04-7.27], p = 0.03) and NYHA IV (OR 20.78

[8.04-53.71], p <0.001) emerged as independent predictors of DR. This 3-variable model had good discriminative power (c-statistic = 0.85, [0.79-0.91], p <0.001) as shown in graphic.
Conclusions: in a population of patients requiring hospital admission for decompensated HF, diuretic resistance was common. NYHA IV, previous oral diuretic association and hyperchloremia were independent predictors of DR. A simple model including two clinical variables and a single laboratory value presented a good predictive accuracy of diuretic resistance and may anticipate appropriate therapies.



Graphic 1: discriminative power of the 3-variable model on predicting diuretic resistance

P1066
Predictors of efficiency of long aerobic training for reverse myocardial remodeling in heart failure patients

T Tatiana Lelyavina[1]; VL Galenko[1]; PS Kozlov[1]; MA Bortzova[1]; MYU Sitnikova[1]
[1]*Almazov Federal Center of Heart Blood & Endocrinology, Saint Petersburg, Russian Federation*

To evaluate the effects of long-term aerobic training, designed with individualized method based on lactate threshold definition, on myocardial remodeling in heart failure patients and to detect its predictors.
Methods: We evaluated 197 HF patients, mean age 52+/-3.3, 116 men, with NYHA class III, LVEF 37,6+/-2,1%. CPET performed on a treadmill ("Oxycon Pro") at baseline, in every 8 weeks and after 9 months. All patients were randomized into following groups: 137 patients of study group (SG), who underwent physical rehabilitation program (PRP), calculated due to lactate threshold; and 60 HF patients control group (CG), who underwent physical training, calculated based on VO2 percentage.
Results: At baseline CPET results in both groups did not significantly differ. V?2 at lactate threshold and V?2peak were 8.8+/-0,5; 13,5+/-0,9 ml/min/kg and 9.0+/-0.9; 13,6+/-1,2 ml/min/kg in study group and control group, respectively (p1 = 0,08, p2 = 0,07, respectively). After 9 months of training V?2LT and V?2peak were better in the study group than in control group: the increase was 16% and 24% in the main group, and 4% and 7% in the control group, respectively (p1 < 0,01, p2 < 0,01). 54 pts from study group have trained every day more than 1,5 hour on their own. After 9 months of aerobic training it was significant improvement of myocardial contractile function in this 54 patients: LA, at baseline and after training were 5,5 ± 0,1 and 5,1 ± 0,6 sm; , LVEDD 6,4 ± 0,4 and 5,9 ± 0,2sm; LVESD 5,9 ± 0,3 and 5,3 ± 0,3 sm, LVEF 33 ± 3,7 and 46 ± 5,5%, p < 0,001. In control group patients and other 83 pts SG the improvement of myocardial contractile function was not observed: LA, at baseline and after training were 5,4 ± 0,3 and 5,4 ± 0,3 sm; , LVEDD 6,3 ± 0,5 and 6,3 ± 0,2 sm; LVESD 5,9 ± 0,5 and 5,8 ± 0,3sm, LVEF 36 ± 5,3 and 40,2 ± 4,7%, p>0,05. We found correlation between LVEDD changes and duration of training (r = 0,9, p < 0,05), LVEDD changes and BMI (r= 0,7, p < 0,05), LVEDD changes and b-blockers dose (r = 0,4, p,0,05), LVSED changes and blood creatinine (r=-0,4, p < 0,05). Conclusions. Aerobic exercise, designed with individualized method based on lactate threshold definition, increase exercise tolerance, improves myocardial contractile function more than aerobic training, calculated based on VO2peak percentage. There are correlation between LVEDD changes and duration of training (r = 0,9, p < 0,05), LVEDD changes and BMI (r= 7, p < 0,05), LVEDD changes and b-blockers dose (r = 4, p,0,05), LVSED changes and blood creatinine (r = 4, p < 0,05).

P1067
An economic analysis of an outpatient intravenous diuretic service for the delivery of therapy to ambulant patients with advanced heart failure

A Abdallah Al-Mohammad[1]; J Gosai[2]; A Birchall[1]; M Warriner[1]; K Morton[1]; NT Lewis[1]; D Rogers[1]
[1]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*; [2]*Bradford Royal Infirmary, Cardiology, Bradford, United Kingdom*

Introduction and Purpose: Services established for the administration of high dose intravenous diuretic therapy to ambulant patients with heart failure have been reported and demonstrated clinically effective, acceptable to patients, safe and feasible. They are associated with a reduction in unplanned hospital admissions. We report on the cost analysis of setting up one such service in a single cardiothoracic unit in Sheffield, United Kingdom, serving a population of approximately 500,000.
Methods: The service was set up as a multi-disciplinary service to run within an existing day case unit. Patients selected were ambulant, haemodynamically stable, and fit to transfer daily by taxi to the hospital from home. Initially, the selected patients were existing inpatients to shorten the length of stay, and later this was extended to outpatients as an admission avoidance strategy. Both those with reduced and preserved left ventricular ejection fraction were included. Dedicated support from heart failure cardiologists, heart failure specialist nurses, ward nurses, domestic and administrative staff was included in the cost calculations. Patients attended daily Monday to Friday for intravenous therapy and were given equivalent doses of oral therapy to maintain weight over the weekend. Renal function was monitored closely during therapy. Patients were discharged from the service when clinically euvolaemic or at target weight. Data from the electronic records of all patients using the service between January 2015 and September 2017 were used to calculate the costs and duration of therapy for patients. Hospital administrative and national tariff data were used to calculate potential cost and admission savings.
Results: In 32 months, 133 patients were treated for a total of 1613 sessions across 186 spells of treatment. The mean number of treatments per spell was 8.67 (minimum 2, maximum 52). 100 patients had one spell of treatment during the period studied, 33 had more than one spell of treatment. 27 patients were readmitted to hospital within 30 days of their last intravenous therapy. The cost of running the service was £302.28 per day with a capacity for six patients. This suggested an estimated cost saving of between £264,989 and £392,416, and up to 3878 bed days which would have been incurred had this cohort of patients been admitted to hospital instead.
Conclusions: Setting up and running a service to deliver intravenous diuretic therapy to ambulant patients within a cardiothoracic centre in the UK is feasible. The service was well-used and associated with considerable potential cost savings. 24% of patients required more than one spell of therapy, and 20% were readmitted to hospital within 30 days of finishing therapy. The service was not associated with a reduction in heart failure admission numbers to our hospital, and many patients who require intravenous diuretic are not fit to attend a daily outpatient service.

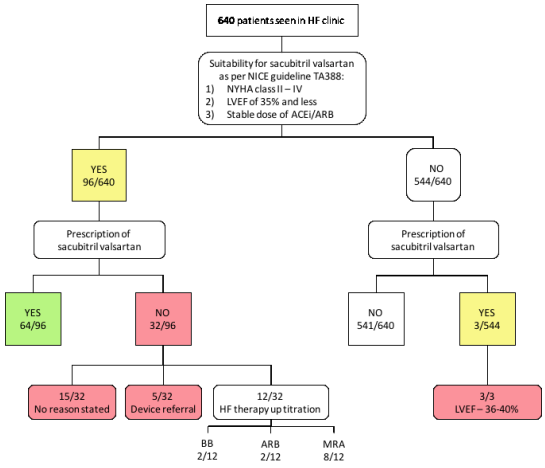
Does prior MRA use limit eligibility for sacubitril valsartan in a heart failure clinic? Insights from real world experience and implications for ESC and NICE guidelines

L Myslivecek[1]; E Sammut[2]; Y Ismail[2]; H Lightfoot[2]; H Donaldson[2]; B Pearson[2]; M Williams[2]; R Baker[2]; A K Angus K Nightingale[2]
[1]*University of Bristol, Bristol Medical School, Bristol, United Kingdom*; [2]*Bristol Heart Institute, Department of Cardiology, Bristol, United Kingdom*

Background: The 2016 ESC Guidelines on the pharmacological treatment of heart failure with reduced ejection fraction (HFrEF) recommend consideration of angiotensin receptor neprolysin inhibitors (ARNI) if a patient remains symptomatic with an ejection fraction (EF) of = 35% after maximal treatment, including a mineralocorticoid receptor antagonist (MRA). In contrast, the NICE 2016 updated guidelines for management of chronic heart failure in England suggest that ARNI is second line treatment after ACEi/ARB and B-blocker (BB) and could be initiated either before or after MRA therapy.
Purpose: Sacubitril valsartan (ARNI) was approved by NICE in April 2016 (TA388). We wanted to investigate the proportion of patients suitable for ARNI therapy in an general HF clinic. In addition, we speculated that a high rate of MRA use, as recommended by the ESC, might reduce the number of ARNI eligible patients, due to either low BP or severe chronic kidney disease (CKD).
Method: Retrospective audit of stable outpatients seen in a secondary care heart failure clinic in England between May 2016 and April 2017. Data was collected on inclusion criteria for ARNI (EF = 35%, NYHA class 2-4 and stable dose of ACEi/ARB), and exclusion criteria (systolic BP < 100mmHg, pregnancy/breast feeding, hepatic impairment and severe renal impairment) as well as use of devices and MRA prescription rates.
Results: 640 patients were seen in the clinic in the 12-month period after sacubitril valsartan was licensed. 96 (15%) met the ARNI inclusion criteria and 64 (69%) of

these were prescribed sacubitril valsartan. 3 patients did not meet the inclusion criteria but were prescribed sacubitril valsartan; all of these had EF 36-40%. 32/96 were suitable for ARNI but NOT prescribed; 5 were waiting for device implantation and in 15 no reason was given. 8 patients were initiating MRA and 4 were up-titrating ACEi/ARB or BB prior to re-evaluation of suitability for ARNI.
There was a high rate of MRA prescription (72%, 69/96) and device use (54%, 52/96) in those eligible for ARNI treatment, suggesting this clinic population was well treated according to ESC and NICE guidelines.
Only 2/96 patients otherwise suitable for ARNI had BP = 100mmHg. 6/96 had eGFR < 30 mL/min/1.73m2 (needing the lowest starting dose of sacubitril valsartan). All patients had potassium in the normal range.
Conclusion
In a large general heart failure clinic, 15% of patients were suitable for prescription of ARNI therapy.
Of these two thirds were actually on this therapy in the first year after it was approved by NICE in England.
Despite a high rate of MRA use in the group who were suitable for ARNI, there was a very low rate of exclusion due to low BP or CKD.
Optimising heart failure treatment according to the ESC guidelines, including MRA first, does not reduce eligibility for ARNI therapy in a real world heart failure clinic environment.



Patient flow chart

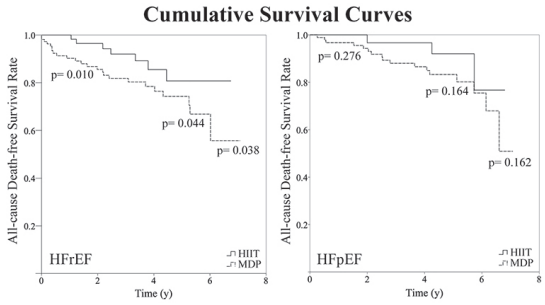
Effects of high-intensity interval exercise training on survival of heart failure patients

C-C Hsu[1]; T-C Fu[1]; J-S Wang[2]; C-H Wang[3]
[1]Keelung Chang Gung Memorial Hospital, Physical Medicine and Rehabilitation, Keelung, Taiwan ROC; *[2]Chang Gung University, Institute of Rehabilitation Science, Taoyuan, Taiwan ROC*; *[3]Keelung Chang Gung Memorial Hospital, Cardiology, Keelung, Taiwan ROC*

On behalf of: Heart Failure Research Center, Keelung Chang Gung Memorial Hospital
Funding Acknowledgements: Keelung Chang Gung Medical Research Program and the Taiwan Ministry of Science and Technology

Background: High-intensity interval training (HIIT) increases peak oxygen consumption (VO2peak) and alters cardiac geometry. However, no studies have reported effects of HIIT on survival of HF patients.



Survival curves of heart failure patient

Purpose: The cohort study aimed to determine effects of HIIT on long-term survival of heart failure (HF) patients.
Methods: HF patients, enrolled between 2009 and 2016, received multidisciplinary disease management program (MDP) and serial assessments of VO2peak, echocardiography, b-type natriuretic peptide, and quality of life questionnaire. 181 participants with left ventricular ejection fraction (LVEF)= 40% and 133 with LVEF> 40% were classified as having HF with reduced EF (HFrEF) and preserved EF (HFpEF), respectively. 72 HFrEF and 38 HFpEF patients who underwent= 36 times of HIIT were classified as the HIIT group. The remaining HF patients were classified as the MDP group. Generalized estimating equation (GEE) and survival analysis were used to assess clinical presentations during follow-up.
Results: In HFrEF patients, GEE model estimated that VO2peak increased significantly by 0.519 MET/year associated with decreases of LV end-diastolic diameter by -2.6 mm/year, LV end-systolic diameter by -5.2 mm/year, and BNP by -377 pg/mL/year during HIIT as compared with MDP subjects. In HIIT subjects with HFrEF, the 1-year (100% vs 90.9%), 5-year (80.8% vs 74.3%), and 7-year (80.8% vs 55.7%) survivals were significantly greater than the MDP subject(Figure 1). The survival was similar between the two groups in HFpEF patients.
Conclusions: HIIT increases VO2peak, reverses cardiac remodeling, and finally improves long-term survival of HFrEF patients. HIIT cannot provide cardiac protection and improve survival for HFpEF patients.

P1070

Effect of vitamin D on endothelial function in patients with chronic heart failure

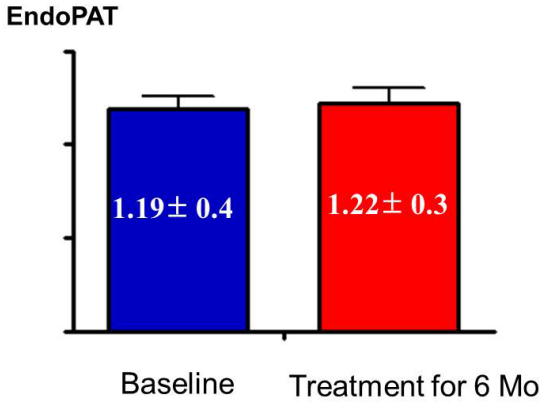
S J Ha[1]; DG Shin[1]; YM Woo[1]; YJ Song[2]; WD Bang[1]; SY Yoo[1]; SS Cheong[1]
[1]GangNeung Asan Hospital, Cardiology, GangNeung, Korea Republic of; *[2]Haeundae Paik Hospital, Cardiology, Busan, Korea Republic of*

Background: In patients with heart failure (HF), low levels of 25-hydroxyvitamin D (25OHD) are common and are associated with increased mortality risk.
Objectives: The VIVID-HF (Ventricular and Vascular function of Vitamin D in Patient with Heart Failure) study was an investigator-initiated, multicenter, prospective, randomized, placebo-controlled trial to establish safety and efficacy of oral vitamin D3 (cholecalciferol) supplementation in stable HF patients.

P1070 Mean weight and BMI of LVAD recipients

	Baseline	6 months	12 months	18 months	24 months	36 months	48 months
Weight (kg)	75.0 (±14.2)	80.8 (±14.8)	85.0 (±15.1)	85.8 (±15.3)	87.1 (±19.1)	103.4 (±9.9)	112.0 (±4.1)
BMI	25.1 (±4.4)	27.0 (±4.4)	28.5 (±4.4)	28.6 (±4.9)	29.4 (±6.8)	34.1 (±7.6)	40.3 (±8.8)

Mean weight and BMI (±standard deviation) of LVAD recipients during follow up (p<.001 for all mean values compared to baseline value)



Endo PAT

Methods: Seventy three HF patients with 25OHD level <75 nmol/L (30 ng/mL) were randomized to receive 4000 IU vitamin D daily or matching placebo for 6 months. The primary endpoint was the change of endothelial function assessed by EndoPAT between baseline and 6 months. Secondary endpoints included the change in echocardiographic parameters and differences of quality of life (6 minute walk test and New York Heart Association functional status: NYHA status) at 6 month.

Results : During study periods, there was no adverse event in both groups. Vitamin D supplementation did not improve endothelial dysfunction (Figure, EndoPAT: baseline, 1.19 ± 0.4 vs 6 month later, 1.22 ± 0.3, p = 0.65). In addition, 6-minute walking distance (baseline, 292.9 ± 120.35 vs 6 month later, 283.7 ± 116.84 m, p= 0.125), and NYHA status also did not improve. In this period, there was no significant change in echocardiographic parameters.

Conclusions: : A daily vitamin D dose of 4000 IU would be safe but did not improve endothelial function, echocardiographic parameters, 6-minute walking distance, and NYHA status.

P1071

A retrospective study of metabolic dysfunction in left ventricular assist device recipients indicating these patients are at excessive risk of cardiac transplant ineligibility

W Wasim Javed[1]; P Chaggar[1]; T Entwistle[1]; R Venkateswaran[1]; S Shaw[1]
[1]*University Hospital of South Manchester NHS Foundation Trust, Manchester, United Kingdom*

Background: LVADs are increasingly utilised in advanced heart failure. Whilst improved nutritional status has been observed following implantation, excess weight gain has also. This may impact on cardiac transplantation eligibility.

Purpose: To confirm observational claims of excess weight gain with prolonged LVAD use and define any impact on transplant eligibility.

Methods: Case records of consecutive bridge-to-transplant (BTT) patients implanted with LVAD over 6 years were reviewed retrospectively. Baseline data collection included demographics, aetiology, co-morbidity and LVAD type. Height, weight and metabolic parameters were examined 6-monthly during LVAD support for up to 2-years. Statistical analyses were performed using paired t-test.

Results: 53 patients received an LVAD as BTT. The mean age was 48.5 years and ischaemic cardiomyopathy was the commonest heart failure aetiology (67.9%). The majority were white British ethnicity (92.5%) and male (73.6%). Pre-LVAD diabetes incidence was low (7.6%).

Weight gain was observed in 86.8% of LVAD recipients. LVAD recipients who received cardiac transplantation gained significantly less weight over 12 months (mean 5.2kg) than those who did not (10.4kg). 21.7% of those with pre-LVAD body mass index (BMI (kg/m2)) under 30 experienced a rise in BMI to 30 or above during LVAD support. Table 1 displays mean weight and BMI of LVAD recipients during follow up.

Cholesterol increased significantly from a median baseline value of 3.0 to 4.5mmol/L (p= .004) at final follow up.

Conclusion: Excess weight gain was frequently observed in LVAD recipients in a time-dependent manner. Other indices of obesity-related metabolic dysfunction were observed including increased cholesterol. These patients are more likely to become ineligible for cardiac transplantation due to raised BMI or complications of metabolic syndrome. In our study, over 20% exceeded a BMI over 30, classifying them as obese. As expected, patients receiving cardiac transplant experienced less weight gain.

Active weight management is required for LVAD recipients due to an increased risk of obesity. This is vital for BTT patients to avoid cardiac transplantation ineligibility. This may be achieved with a MDT approach including a dietitian or metabolic physician. Clearly, LVADs should not be utilised for weight loss in patients already transplant ineligible due to obesity.

P1072

Clinical experience of using cardiac contractility modulation devices in patients with heart failure:the true or wrong way to success?

M Trukshina[1]; E Lyasnikova[1]; V Galenko[1]; T Lelyavina[1]; M Sitnikova[1]; I Kim[1]; Z Abakarov[1]; M Abramov[1]; E Mikhaylov[1]; E Zubarev[1]; M Vander[1]; K Simonova[1]; D Lebedev[1]; O Stovpyuk[1]; E Shlyakhto[1]
[1]*Almazov National Medical Research Centre, Heart Failure, St.Petersburg, Russian Federation*

Funding Acknowledgements: Clinical approbation programme "Cardiomodulation" Russian Federation Ministry of Healthcare

Introduction: Cardiac Contractility Modulation (CCM) is an original approach in new device therapy to improve contractility in patients with heart failure with reduced ejection fraction (HFrEF), on OMT, with sinus rhythm (SR) and narrow QRS complex.

Purpose: To assess the dynamics of the CHF, adverse events rate, structural and functional parameters of the heart in patients with implanted CCM devices during follow-up period.

Methods: From 20 Oct 2016 till 12 Sep 2017 CCM devices n = 55 (50 - Optimizer IVs, 5 - Optimizer Smart) were implanted to the patients with CHF I-IV fc NYHA, > 18 y.o. (55,0 ± 10,6), SR, QRS < 120 ms. 46 male,9 female, 36 - CAD, DCM - 19, fc NYHA I/II/III/IV- 1/37/12/5; 10 patients were with ICD. Patients were followed-up by CHF cardiologists every 3 months in outpatient HF clinic with physical examination, device programming, assessment of the life quality, cardiopulmonary exercise test, ECG, Holter Monitoring (HM), Echocardiography(Echo) and NT-proBNP level.

Results: Patients had good compliance and tolerance of CCM stimulation. No hospitalizations due to CHF or outpatient decompensation occurred among 43 patients who passed 6 month follow-up control visit. 11 of them felt clinical improvement, 4 - worsening, 28 –without any changes; fc NYHA I/ II/ III/IV- 3/33/7/0. The positive trend in Echo and NT-proBNP data was observed: LVEF increased 26.0 ± 5.4 (15-38%) vs 30.5.0 ± 7.95% (17-41), p = 0,08; LVEDV and LVESV decreased accordingly: 244.0 ± 59.8 ml (145-360) vs 233.5 ± 59.6 ml (116-380), 185.0 ± 50.9 ml (85-273) vs 163.0 ± 51.0 ml (70-290). NT-proBNP level - 1049.5pg/ml (241-20 198) vs 771pg/ml (42-3 962). ECG and HM data did not reveal any PQ, QRS, QT interval prolongation and significant rhythm and conduction disorders. Within 6 months, the following adverse events occured: 2 patients were hospitalized with unstable angina (conservative treatment), 2 died suddenly. In 12 patients stimulation of the CCM pocket was due to dislocation of the ventricular leads, in 14 patients 1 lead was disconnected because of technical problems, replacement of 2 leads was planned for 3 patients, in 1 patient CCM was deimplanted in early postoperative period time due to the device pocket infection.

Conclusions: First clinical experience in 6-month follow-up of patients with CCM devices showed the stability of clinical status, decrease in CHF fc, good patients tolerance of stimulation, absense of arrhythmogenic effects, in some patients, mostly with DCM, tendency to improve cardiac remodeling. Ventricular lead insulation failure complications and pocket device stimulation which required switching off one of the ventricle leads present the most common negative aspects of a new method and may diminish the potential treatment effect. Long-term follow-up will help to identify the subgroup of patients to get the true way and maximum benefit.

P1073

Specialised heart failure clinics are more needed in rural regions

A Klabnik[1]; J Murin[2]
[1]*Outpatient cardiology clinic, Namestovo, Slovak Republic*; [2]*1st Department of Internal Medicine , University Hospital Bratislava, Slovak Republic*

Purpose: Only 3 heart failure (HF) clinics are active in metropolitan areas of Slovakia. No organised HF disease management programme exists in rural region.

Methods: We compared clinical characteristics, evidence-based medications and outcomes in 134 patients (pts) from one regional center with others centres in Slovakia (n = 354) participated in the Heart Failure Long-Term registry. We statistically analysed the reasons for differences in benchmark report, separately for outpatients and hospitalized pts.

Results: In regional centre were as outpatients recruited significantly ($p < 0.05$) more older pts than 65 years (73.9 % vs 33.9 %, odds ratio, OR > 5), with non-ischemic etiology (68.1 % vs 41.7 %, OR 2.99, predominantly valvular etiology), more advanced HF (in NYHA class III-IV: 62.3 % vs 31 %, OR 3.69) and fewer males (62.3 % vs 70.2 %, OR 0.57). Common comorbidities were in outpatients significantly ($p < 0.05$) more often present in regional center: diabetes (44.9 % vs

25.6 %, OR 2.37), chronic renal dysfunction (31.9 % vs 11.9 %, OR 3.46), current malignant cancer (17.4 % vs 1.2 %, OR > 5), permanent atrial fibrillation (44.9 % vs 10.7 %, OR > 5).
At a glance it seemed that in regional center are in outpatients resp. hospitalized pts significantly ($p < 0.05$) underused ACE-inhibitors/sartans (72.5 % vs 90.5 %, OR 0.28, resp. 50.8 % vs 81.7 %, OR 0.23), beta-blockers (78.3 % vs 90.5 %, OR 0.38, resp. 66.2 % vs 86.6 %, OR 0.30) and mineralocorticoid receptor antagonists (31.9 % vs 63.1 %, OR 0.27, resp. 27.7 % vs 66.1 %, OR 0.20). But after accounting objective reasons for non-using these medications in regional center these differences were disappeared.
In regional center significantly ($p < 0.05$) more outpatients, respectively hospitalized pts have a history of previous hospitalisation (69.6 % vs 30.1 %, OR > 5, resp. 70.8 % vs 33.3 %, OR 4.84). During 12 month follow-up significantly ($p < 0.05$) more outpatients, resp. hospitalized pts in regional center died (20.3 % vs 9.3 %, OR 2.5, resp. 39.7 % vs 20.9 %, OR 2.48) and were more often re-hospitalisated: 1st re-hospitalisation (66.1 % vs 20.5 %, OR > 5, resp. 77.6 % vs 45.1 %, OR 4.21), 2nd re-hospitalisation (48.7 % vs 25 %, OR 2.85, resp. 48.9 % vs 38.3 %, OR 1.54, not significant). The hazard of death and re-hospitalisation increased with higher age, multiple comorbidities.
Conclusion: In Slovakia are HF clinics urgently needed in regional settings to achieve better quality of HF care and optimized outcomes.

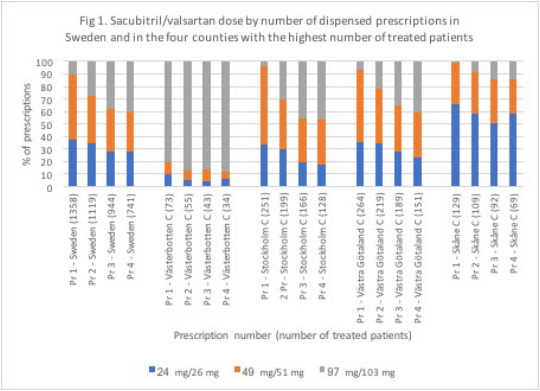
P1074

Early real-world implementation of sacubitril/valsartan in Sweden

O Ola Vedin[1]; P Vasko[2]; E Bachus[3]; U Dahlstrom[4]; M Fu[5]; K Lindmark[6]; B Svennblad[7]; D Johansson[8]; F Calado[9]; LH Lund[10]
[1]Uppsala University Hospital, Department of Medical Sciences, Cardiology, Uppsala, Sweden; *[2]Central Hospital, Vaxjo, Sweden*; *[3]Lund University, Malmo, Sweden*; *[4]Linkoping University Hospital, Linkoping, Sweden*; *[5]Sahlgrenska Academy, Gothenburg, Sweden*; *[6]Umea University, Umea, Sweden*; *[7]Uppsala Clinical Research Center, Uppsala, Sweden*; *[8]Novartis Sweden AB, Stockholm, Sweden*; *[9]Novartis Pharma AG, Basel, Switzerland*; *[10]Karolinska Institute, Stockholm, Sweden*

Funding Acknowledgements: Novartis

Introduction: Sacubitril/valsartan (s/v) improves outcomes in heart failure (HF) with reduced ejection fraction, is recommended in international guidelines, and reimbursed in Sweden since April 2016. However, information on its real-world use is scarce.
Purpose: To assess temporal trends in s/v use, dose titration strategies, background medications and demographic factors in the Swedish population who were prescribed s/v.
Methods: The Swedish Prescribed Drug Register covers all drug dispensations in Sweden. In patients with = 1 dispensation of s/v, we collected data on demographics, prior HF medications, and dose trends for consecutive dispensations on a national level and for the four (out of 21 in total) geographic regions with the highest dispensation numbers.
Results: Between January 2016 and August 2017, there were 1358 patients with = 1; 1119 patients with = 2; 944 patients with = 3; and 741 patients with = 4 s/v dispensations. Mean age of all patients was 68.0 years, 30.3% were = 75 years, 3.3% were = 85 years, and 19.1% were female. Prior to the first s/v prescription 92.9% had a RAAS inhibitor (ACE inhibitor/ARB), 93.9% a beta-blocker and 75.4% a mineralocorticoid receptor antagonist. The majority of the first dispensations were 24/26 and 49/51 mg doses but also a large proportion of subsequent dispensations were at low doses. Some regions started s/v and continued it at lower doses whereas others generally initiated treatment at the highest dose (Figure 1).
Conclusions: In this nationwide study with complete coverage of actual dispensations, a majority of patients were treated with guideline recommended HF medications prior to the first s/v dispensation. The following trends were observed: (1) lower use of HF medication in women and elderly; (2) insufficient s/v dose uptitration; and (3) highly variable s/v dosing between regions.



Figure

P1075

Iron in heart failure: time to practise what is preached

S Ng[1]; J Pan[1]
[1]St Thomas' Hospital, London, United Kingdom

Background: Iron-deficiency, present in 30-50% of patients with chronic heart failure is associated with increased morbidity and mortality. Intravenous iron supplementation has been shown to improve functional capacity, quality of life and reduce hospitalisation in patients with heart failure with reduced ejection fraction (HFrEF) who have iron deficiency (irrespective of the presence of anaemia).
Purpose: Despite guidelines recommending routine testing for iron deficiency (ID), this practice is inconsistent. This study investigates the practice of screening for ID in HFrEF patients seen in general cardiology and heart failure clinics at a teaching hospital in the United Kingdom.
Methods: A cross-section analysis was performed on patients seen in the heart failure clinic throughout October 2017. Outcomes measured were the presence of iron studies within 6 months of the clinic appointment, aetiology of HFrEF, presence of ID or anaemia and oral iron supplementation. Patients with symptomatic HFrEF defined as ejection fraction (EF) < 45% with a New York Heart Association (NYHA) functional classification = 2 were included.
Results: A total of 106 patients met inclusion criteria. Of these, 75% were male, age ranged from 33 to 90 years (median age 68). A majority of 71% of patients were classified as NYHA class II. The mean EF was 31.5% and the major aetiology of HF is ischaemic cardiomyopathy (59.4%). A biventricular pacing device was present in 25% of patients. Iron studies were completed in 28% of the cohort and only 60% of these iron studies included both ferritin and transferrin saturation. Iron deficiency was present in 50% of patients who had iron studies. Anaemia was present in 37% of the cohort. Less than 4% of the cohort was on oral iron replacement therapy.
Discussion and Conclusion: In the present study centre, iron deficiency remains underdiagnosed and undertreated in HFrEF patients, while pharmacological and device therapy are optimised. A significant proportion of iron studies in HFrEF patients were performed by other specialities (e.g. renal and haematology). When performed, essential components of iron studies were neglected, complicating the diagnosis of iron-deficiency in the context of heart failure.
To encourage screening for iron deficiency in HFrEF, a multi-discplinary and systematic approach is required. Crucial to this is also the setup of an outpatient or ambulatory system for administration of intravenous iron to treat patients identified with iron-deficiency. Further effort is required to raise awareness of accurate diagnosis of ID in HFrEF patients and optimising systems to translate trial data to clinical practice.

P1076

Acceleration training improves sarcopenia and frail factors in elderly outpatients with chronic heart failure

K Keisuke Kida[1]; S Doi[1]; C Ito[1]; N Suzuki[1]; Y Sato[1]; K Ashikaga[1]; S Kou[1]; T Harada[1]; YJ Akashi[1]
[1]*St.Marianna University School of Medicine, Department of Internal Medicine, Division of Cardiology, Kawasaki, Japan*

Background: The prevention strategies for sarcopenia and frail in cardiac rehabilitation are a future challenge. Nowadays, newly developed muscle training, such as Kaatsu training and electrical nerve stimulation, has become a focus of attention. Our previous studies have reported the safety and effectiveness of acceleration training using Power Plate®, although, no studies focusing on sarcopenia and frail have not been published in outpatients with chronic heart failure (HF).
Aims: This study aimed to assess the effect of acceleration training on sarcopenia and frail in outpatients with chronic HF.
Methods: This study conducted on 27 elderly outpatients with chronic HF undergoing acceleration training once in a week for 24 weeks. Grip strength, 10-meter walking speed, muscle volume, knee extension muscle strength and the Kihon checklist scores were assessed.
Results: After the 12-week training, grip strength (21.5 ± 4.4 to 22.7 ± 4.9kg, p = 0.0005), walking speed (1.37 ± 0.24 to 1.72 ± 0.32sec/m, p < 0.0001), knee extension muscle strength (20.9 ± 5.3 to 24.1 ± 6.2kgf, p = 0.0006) and the Kihon checklist scores (7.2 ± 4.8 to 5.1 ± 3.7, p = 0.0039) were significantly improved, whereas no significant improvement in muscle volume was found.
Conclusions: The result of this study demonstrated the usefulness of acceleration training for improving sarcopenia outcome measure, including grip strength and walking speed, in elderly outpatients with chronic HF. Although no increases in muscle volume were found, the patients could walk faster after 24-week training, suggesting that lower-limb muscle strength should be improved. Since the scores in the Kihon checklist were also improved, acceleration training might probably prevent sarcopenia and frail in elderly outpatients with chronic HF.

P1077

ARNI use leads to improved NYHA class and NT-proBNP levels in a Singaporean cohort

VJL Vera Goh[1]; N Koh[1]; CK Teoh[2]; JS Hon[1]; LLY Teo[1]; CP Lim[1]; DKL Sim[1]
[1]*National Heart Centre Singapore, Singapore, Singapore*; [2]*National Heart Institute, Kuala Lumpur, Malaysia*

Background/Introduction: LCZ696, the first-in-class Angiotensin Receptor-Neprilysin Inhibitor (ARNI), has been shown to improve outcomes in symptomatic HF with reduced ejection fraction (HFrEF). The effects of ARNI use in our local multi-ethnic Singaporean HFrEF population remain to be studied.
Purpose: We aimed to evaluate the short-term effects of ARNI use on New York Heart Association (NYHA) class and N-terminal pro B-type Natriuretic Peptide (NT-proBNP) levels in a multi-ethnic Singaporean HFrEF population.
Methods: 274 patients who initiated ARNI use between November 2015 and December 2016 were retrospectively followed up until they reached one of the following end points of death or LVAD implantation. An intention to treat analysis was performed on the data collected.
Results: Our cohort had a mean age of 61 ± 1 years and were 77% male. 92% of the cohort were either on an angiotensin converting enzyme inhibitor or an angiotensin receptor blocker prior to starting an ARNI. Over a median follow-up period of 4.2 [2.6, 6.0] months, the mortality rate due to cardiovascular causes was 2.2% and the rate of heart failure hospitalisations was 17.2%. The rate of discontinuation of ARNI due to adverse events was 15%. There was a significant decrease in NT-proBNP observed at three months compared to baseline (3041 [1570, 7095] vs 1284 [574, 3506] pg/mL, P < 0.001) (Figure 1A). Furthermore, there was also a significant decrease in NYHA class three months after starting ARNI (2.3 ± 0.6 vs 1.8 ± 0.6, P < 0.001) (Figure 1B). Conversely, there was no significant difference in serum creatinine (107 ± 36 vs 112 ± 43 μmol/L, P = 0.2) (Figure 1C) or serum potassium (4.3 ± 0.4 vs 4.3 ± 0.5 mEq/L, P = 0.7) (Figure 1D) at baseline and at three months respectively.
Conclusions: ARNI use in our multi-ethnic Singaporean HFrEF population was associated with decreased NT-proBNP levels and improvement in NYHA class, but no difference in serum creatinine or potassium at three months compared to at baseline.

Figure 1

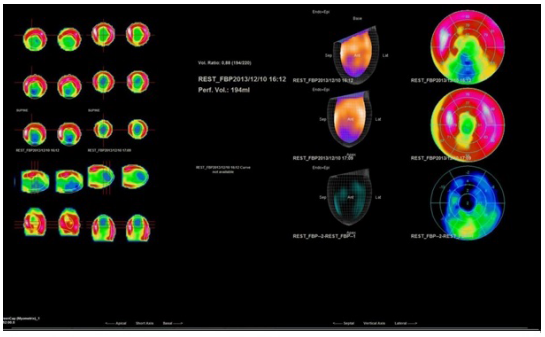
Iodine-123 Metiodobenzylguanidine (MIBG) imaging for selection heart failure patients eligible to an implantable automatic defibrillator (ICD) in primary prevention

C Chahinez Ketfi[1]
[1]*Hospital Bichat-Claude Bernard, Paris, France*

Objectives: to assess the prognostic value of cardiac iodine-123 metaiodobenzylguanidine (123)I- MIBG) scintigraphy to predict ventricular arrhythmias in patients with heart failure (HF) listed for implantable cardioverter-defibrillator (ICD) devices as primary prevention.
Methods: a prospective cohort study in 51 patients with HF referred for ICD (123) I-MIBG scintigraphy was performed with calculation of early and late heart to mediastinum (H/M) ratios washout rate and a summed score calculated innervation-perfusion mismatch was evaluated by comparing SPECT scores



results 10 patients (19.6%) experienced a significant arrhythmic event(AE) Compared with patients who suffered no event the early H / M ratio was 1.5 +/- 0.1 and the late H / M was 1.40 + / 0.2 with no significant difference between the two groups there was no significant difference for wash out (49.3 +/- 12.1 vs 55.5 +/- 17.37) there was no significant difference for the 123-I MIBG SPECT defect score (31.3 +/- 9.5 versus 37.3 +/-11.8) the rest perfusion defect score was also (16.6 +/-8.2 vs 22.1 +/-10.9) with 123-I MIBG / infusion mismatch higher score (8.2 + _4.2 vs 6.4 + - 3.7) twenty-five patients (50%) had cardiac events with a significant difference in the late H / M ratio of 1.3 ± 0.1 versus 1.4 ± 0.1 (p < 0.05).
Conclusion: the 123I-MIBG scintigraphy may be a useful examination to evaluate HF patients eligible for primary ICD imaging to predict the risk of arrhythmic events occurrence

P1079

Adherence to the pharmacotherapy in patients with cardiac resynchronisation therapy

M Brozova[1]; V Vorisek[2]; P Parizek[1]; J Ceral[1]; R Praus[1]; M Solar[1]
[1]University Hospital Hradec Kralove, 1st Department of Internal Medicine - Cardioangiology , Hradec Kralove, Czech Republic; *[2]University Hospital Hradec Kralove, Institute of Clinical Biochemistry and Diagnostics,, Hradec Kralove, Czech Republic*

Funding Acknowledgements: Supported by research project PRVOUK P037/03

Background: The cardiac resynchronisation therapy (CRT) is very effective in selected heart failure (HF) patients. However, the pharmacotherapy still remains a cornerstone of HF treatment.
Aim of the study: The aims of the study were: 1) to assess the occurrence of medication non-adherence in patients referred for the CRT and those already treated by the CRT; 2) to estimate the cost effectiveness of the medication adherence testing in routine clinical practice.
Subjects and Methods: Enrolled to the study were both the patients who were referred for the implantation of biventricular pacemaker and those who were chronically treated by the CRT.
The adherence to the medication therapy was evaluated by the estimation of the serum drug levels (SDL). Serum drug concentrations were measured by using high pressure liquid chromatography combined with mass spectrometry (beta blockers, ACE-inhibitors, angiotensin receptor blockers, diuretics and calcium antagonists) and immunoanalysis (amiodarone, digoxin). The non-adherence was diagnosed when the given drug was not detected in the serum.
Results: The study enrolled 55 patients. Twenty patients (group A) were examined before the initiation and 35 (group B) were tested during the chronic CRT.
The estimation of SDL confirmed full medication adherence in 15 (75 %) patients in group A and 25 (71.4 %) patients in group B. The partial non-adherence was diagnosed in 5 (25%) patients in group A and 10 (28.6 %) patients in group B, when some of the recommended medications were not found in the serum. No case of complete non-adherence was identified. The average cost of diagnosing one case of partial non-adherence was estimated to be 1000 €.
Conclusions: The medication non-adherence in CRT patients is not a rare problem. Although the costs of the SDL testing are not low, they are not un-proportional to the costs related to the CRT. Routine medication adherence testing can help to identify uncooperative patients who require focused counselling. The efficacy of CRT may be augmented by this approach.

P1080

Heart transplantation in Korea: 24 years of experience

M S Min Seok Oh[1]; J O Choi[1]; G Y Lee[1]; E S Jeon[1]
[1]Samsung Medical Center, Division of Cardiology, Department of Medicine, Seoul, Korea Republic of

Background: Heart transplantation has become the gold standard treatment option for end-stage heart failure. We report 24-years of experience in Korea.

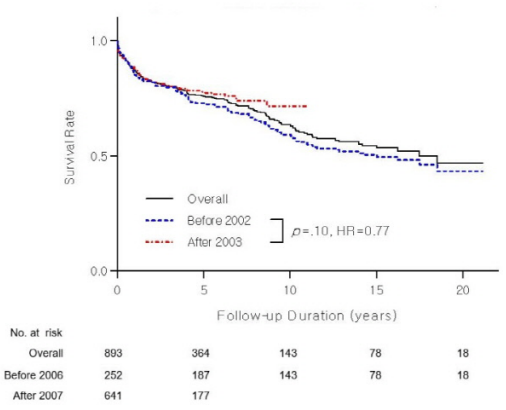


Figure 1

Methods: From January 1992 to December 2015, 1,163 patients were undergone orthotropic heart transplantation. We retrospectively reviewed the available medical records of 1,028 subjects. Patients with multi-organ transplantation (n = 33), and pediatric recipients (18 years old or younger, n = 96) were excluded for analysis of survival rate.
Results: Heart transplantation had been performed in 18 institutes. Mean age of recipients was 47.6 ± 13.6 years and 71.3% were men. Gender-matched transplantation was proceeded in 71.3%. Leading primary diagnosis for heart transplantation was dilated cardiomyopathy (59.3%). Perioperative mortality (within 1 month) was 3.3% (n = 30) and infection was the most common cause of death (43.3% of all-cause death, n = 13). After 1-, 5-, 10- years of follow-up, overall survival rates were 88.8%, 78.0%, and 67.0%, respectively (Figure 1). Malignancy-free survival rates were 98.8%, 95.1%, and 87.9%. Chronic allograft vasculopathy was occurred in 9 patients. After 2007, all-cause mortality rate (p = .060, hazard ratio = 0.78, 95% confidence interval; 0.56 -1.01) and malignancy-free survival rate (p = .31, hazard ratio = 1.42, 95% confidence interval; 0.72 - 2.79) was not statistically remarkable compared to before 2006.
Conclusion: In Korea, actuarial survival after heart transplantation were similar to those reported by the International Society of Heart and Lung Transplantation (ISHLT).

P1081

Transition from a cardiology hospitalization ward to heart failure units. Profile of the patient referred for the first time.

CN Carlos Nicolas Perez Garcia[1]; D Enriquez-Vazquez[1]; TS Luque-Diaz[1]; A Travieso-Gonzalez[1]; C Olmos-Blanco[1]; D Vivas-Balcones[1]; R Bover-Freire[1]; P Martinez- Santos[1]; M Perez-Serrano[1]; I Vilacosta[1]; C Macaya-Miguel[1]
[1]Hospital Clinic San Carlos, Instituto Cardiovascular Clínico San Carlos, Madrid, Spain

Background: ambulatory follow-up of patients with HF has been favored after the development of Heart Failure Units (HFU) that coordinate after discharge the role of nursing, primary and specialized care, achieving a multidisciplinary management.
Purpose: to describe the features of referred patients, comparing with those not referred, in order to better recognize the profile who benefits the most of this alternative.
Methods: all patients admitted to our Cardiology ward during 12 months diagnosed of HF were prospectively collected. We compared the subgroup referred to a HFU with those with the same diagnosis, not derived during the same period.

Table 1

N = 336	NON-REFERRED HFU (N = 246)	REFERRED HFU (N = 90)	P-VALUE
BETA-BLOCKERS	67,2%	81,1%	0,013
ACEI/ARB	59,8%	63,3%	NS
MRA	31,6%	61,1%	<0,001
DIURETIC	71,7%	86,7%	0,005
IVABRADINE	1,6%	7,8%	0,010
DIGOXIN	7%	15,6%	0,016
ICD/CRT	4,5% /5%	21,1%/15,6%	<0,001 /0,001

TABLE 1. Prescribed treatments at discharge of non-referred and referred patients to a HFU.

Results: from 336 patients, 90 (27%) were referred to a HFU. There were significant differences in sex (males 74% vs 44%, p <0.001) and age (72 vs 77 years, p 0.001), without differences in terms of dependency or frailty. Enolism was significantly more frequent in the first group (14% vs 6%, p 0.03) with no differences in other CVRF or comorbidities, as well as a greater proportion of patients with HF without known trigger (36 vs 9.3 %, p <0.001), more readmissions (31% vs 5%, p <0.001) and a longer average stay (5.1 vs 4.6 days, p <0.001). There was a greater referral of patients with reduced LVEF (71.6% vs 42.8%, p <0.001) and right ventricular dysfunction (47.1 vs 22.2, p <0.001). Regarding treatment at discharge, the prescription of beta-blockers, MRA, ivabradine, digoxin, diuretics and devices was higher in referred patients (table 1).
Conclusions: the referred patient to a HFU tends to be younger, more frequently male and with more risk factors. This, together with the greater proportion of left and right ventricular dysfunction and the frequent readmissions for HF, make necessary more aggressive therapeutic strategies for an optimal management.

P1082

Is acute renal failure associated to worse prognosis after a cardiac device implant?

LCSP Luiz Carlos Passos[1]; WN De Carvalho[2]; AGQ De Jesus[2]; VRS Souza[3]; AA Fagundes[2]; AMP De Lima[2]; YM Lira[4]; EL Garrido[3]; EOM Andrade[3]; NFC De Oliveira[4]; AMAF De Jesus[2]; TM Trindade[2]

On behalf of: EPICO
Funding Acknowledgements: EPICO

Background: Controversial results have been published concerning to the involvement of acute renal failure over the outcomes of heart failure patients underwent to electronic cardiac device implants (resynchronization therapy and implantable cardioverter defibrillator). Renal function has been told to be a factor for worse prognosis among these patients.
Purpose: The aim of this study was to describe the clinical differences concerning clinical profile, in-hospital and post-discharge outcomes of patients submitted to electronic cardiac device implant according to the presence of renal failure during in-hospital stay.
Methods: Cohort data from 212 patients admitted in a tertiary cardiac referral centre for cardiac electronic device implant (resynchronization therapy and implantable cardioverter defibrillator) between march 2015 and december 2017. All the data was collected from medical records. Heart failure was defined according to the European Society of Cardiology (ESC) guidelines. Renal failure was defined as a creatinine clearance level < 30mL/min.
Results: A sum of 212 patients was assessed and 17.5% (23) showed a creatinine clearance level <30mL/min during hospital stay. Renal failure patients were older (62.5 ± 10.1 vs 57.3 ± 12.9; $P = 0.02$) and had higher lethality during hospital phase (8.6% vs 1.1%; $P = 0.03$). The need of intensive unit care support was higher among renal failure patients (32.4% vs 9.1%; $P = 0.001$) and this group had also a greater lenght of hospital stay (medians of 12 vs 3.0; $P < 0.001$). Post-discharge mortality (1 to 6 months) was higher among renal failure patients (17.4% vs 3.8%; $p < 0.02$).
Conclusion: Patients who had renal failure at the time for electronic device implant were older and showed a higher amount of unfavorable clinical outcomes during hospital stay and after hospital discharge, as well. This finds suggest that the electronic cardiac device implant should be avoided or employed more judiciously among these patients.

P1083

Comparing physical,cognitive and psychological aspects of frailty before and after LVAD implantation-a retrospective study

EL E-Lynn Sng[1]; H Chen[1]; CP Lim[1]
[1]National Heart Centre Singapore, Singapore, Singapore

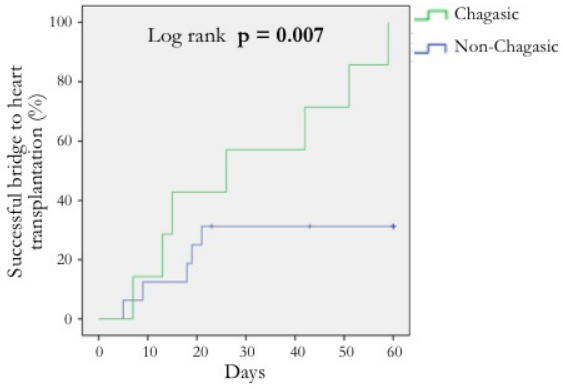
Background: Frailty is a biological syndrome characterized by weakness, fatigue and increased vulnerability to physiologic stressors. In patients with heart failure, the presence of frailty is associated with significantly worse outcomes due to the lack of physiologic reserve which may cause rapid functional deterioration and debility.
Purpose: To describe the prevalence of pre-operative physical frailty, cognitive impairment and depressive symptoms in patients referred for left ventricular assist device (LVAD) implantation and their impact on post-operative outcomes.
Methods: This is a retrospective review of patients referred for frailty assessment from January 2015 to August 2017. Frailty assessment was conducted at baseline and 3-months post-LVAD implantation. Physical frailty was assessed using the Fried Frailty Phenotype. Cognitive impairment was assessed using the Montreal Cognitive Assessment (MoCA) questionnaire. Screening for depression was done using the Center for Epidemiologic Studies Depression Scale-Revised (CESD-R). Post-LVAD implantation, all patients received multidisciplinary care, including inpatient physiotherapy rehabilitation.
Results: 22 patients (mean age of 56 years; 86% male and 14% female) had frailty assessment prior to their LVAD implantation. Of these patients, 50% were implanted as destination therapy and the other 50% as bridge to transplantation. 6 patients died before post-implantation assessment, 2 patients were lost to follow up, and 3 patients were awaiting frailty reassessment. 11 patients had both baseline and 3-months frailty reassessments performed. Prior to LVAD implantation, 6 out of 11 patient (54.5%) were considered extremely frail. 54.5% had cognitive impairment and 45.5% had possible depressive symptoms. At 3-months post-LVAD implantation, there were significant improvements in physical frailty, cognitive and psychological domains. None were considered extremely frail and 54.5% were non-frail. Only 9% still present with impaired cognition and 18.2% had possible depressive symptoms. Extremely frail patients were associated with a greater average length of stay (LOS = 34.8 days) as compared to intermediate frail patients (LOS = 26.0 days) and non-frail patients (LOS = 14.0 days). Extreme frailty was present in 54.5% of survivors versus 66.7% of patients who died within 3-months after LVAD implantation.
Conclusion: There was an improvement in the physical frailty, cognitive function and depression score after LVAD implantation. Extreme physical frailty was associated with prolonged hospitalization, but did not preclude a successful outcome after surgery.

P1084

Mechanical circulatory support as bridge to heart transplantation in Chagas cardiomyopathy: A single-centre 10-year experience.

JLV Vieira[1]; MGVS Sobral[1]; GGV Vasconcelos[1]; GPLA Almeida[1]; JRF Fernandes[1]; VLMPP Pessoa[1]; LCS Souza[1]; VRFC Cestari[1]; DLS Salles[1]; RSF Florencio[1]; DFMT Trompieri[1]; JDSN Souza Neto[1]; JACM Mejia[1]
[1]Hospital de Messejana Dr Carlos Alberto Studart Gomes, Division of Advanced Heart Failure and Transplant Cardiology, Fortaleza, Brazil

Background: Chagas cardiomyopathy (CC) is a major public health disease in Latin America and, due to migration, is becoming a worldwide health burden. Although heart transplantation (HT) was formerly contraindicated for CC, it is currently established as an important therapeutic option in patients with refractory heart failure (HF) due to CC. Considering the worse prognosis of CC patients listed as UNOS 1 as compared to non-chagasic patients (NCP) in the same condition, the use of inotropes, vasopressors and mechanical circulatory devices (MCS) should be valued in that etiology. However, the published data on MCS in patients with CC is scarce.
Purpose: We sought to determine the safety and feasibility of the implantation of MCS as a bridge to HT in patients with refractory HF due to CC.
Methods: We retrospectively assessed our experience with MCS in refractory HF over a 10-year period. We included any adult patients mechanically bridged to HT from January 2008 to December 2017. Information regarding the follow-up status was obtained from in-patient and outpatient clinical charts and telephone contact.
Results: Since 2008, we mechanically bridged 23 adults with refractory HF to HT. Seven of these patients had end-stage HF due to CC. Bridged CC patients were all male ($p = 0.21$ vs. NCP), with a mean age of 44.6 ± 13.8 years ($p = 0.31$ vs. NCP). We used the Abiomed AB500™ (n = 5) and the CentriMag™ (n = 2) (p = NS vs. NCP for both). Mean MCS support time was 26 days [range 7-58] ($p = 0.39$ vs. NCP). All CC patients were successfully bridged to HT in less than 60 days (log rank $p = 0.007$ vs. NCP, graphic).



Conclusion: Our experience shows that MCS in chagasic patients is associated with higher successful bridging when compared to non-chagasic patients. The favourable characteristics of chagasic patients, such as fewer comorbidities and lower pulmonary pressures, could be an advantage for a MCS indication in advanced HF. The major limitation to its applicability is its high cost.

P1085

Effect of sildenafil on hemodynamic parameters measured by right heart catheterisation in pts with end-stage chronic heart failure

K Krisztina Heltai[1]; L Vandor[1]; A Boros[1]; B Merkely[1]
[1]Semmelweis University Heart Center, Budapest, Hungary

Background: Sildenafil has been used in primary pulmonary hypertension (PH), however it is also has empirically administered to end-stage chronic heart failure

patients (CHF) with secondary PH being eligible for heart transplantation (HTX). Here, we aimed to test the effect of sildenafil on the hemodynamic parameters of right heart catheterisation (RHC) in this patient population.
Methods: In this single-centre, retrospective study a total of 34 CHF pts (7 woman, 27 men, age 53 ± 11 years) were admitted to the Heart and Vascular Center of Semmelweis University between 2013-2017 for eligibility check-up of HTX with increased pulmonary vascular resistance (PVR) (measured by right heart catheterisation: 5,9 ± 1,79 Wood unit). All patients underwent RHC at baseline and after 3 months sildenafil treatment (20 mg t.i.d., orally administered). 12 pts went through HTX or ventricular assist device implantation within 3 months, so there was no control measurement in them. Complete data was available in 22 cases.
Results: The cardiac output improved (3.2 ± 0.9 vs 3.7 ± 0.8 L/min, p = 0.06), the pulmonary capillary wedge pressure remained unaltered (25 ± 5 vs. 25 ± 7 mmHg, p = 0.71), both pulmonary artery pressure (43 ± 6 vs. 39 ± 10 mmHg, p = 0.05) and PVR decreased (5.6 ± 1.7 vs. 4.2 ± 1.4 Wood, p = 0.008). The clinical status of patients improved during the observational period and no adverse event occurred related to sildenafil.
Conclusions: We found that sildenafil treatment is safe and effective in CHF patients for reducing pulmonary vascular resistance and therefore it could be an optimal therapeutic choice in patients with secondary PH and helps to maintain the clinical status of pts waiting for HTX.

P1086
The influence of personalized program of physical trainings on tolerance to physical loading, aerobic physical capacity and character of myocardial vascularization in patients with terminal heart fail

V Volha Sujayeva[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Purpose: to develop personalized program of cardiac rehabilitation of patients with terminal heart failure before and after heart transplantation based on pathophysiological mechanisms of tolerance to physical loading decreasing and to estimate its efficiency.
Methods: 32 patients with terminal heart failure before heart transplantation (age 46.4 ± 12.1 y.o.) and 81 pts after heart transplantation (age 45.2 ± 12.1 y.o.). We defined both tolerance to physical loading (TPL) and aerobic physical capacity in condition of Spiro Bicycle Ergometry Test (spiroBET) before heart transplantation (I test), in 6 and 12 month after heart transplantation (II and III test, correspondingly). In the same times we also performed echocardiography (EcoCG) and endomyocardial biopsy (EMB) to study both myocardial rejection and character of myocardial vascularization.
Results: Before heart transplantation al pts had low TPL - 62.9 ± 4.4 Wt (33.9 ± 2.3% of age-appropriate level). Patients were randomized in to 2 Groups: Group 1 received individual controlled bicycle physical trainings, pts in Group 2 didn't have bicycle physical trainings. Type of the training load depended on individual character of blood circulatory system reaction on spiroBET. The main principle of the training loading selection - taking into the account individual level of power when anaerobic threshold was reached. In Group 1 we established more pronounced improvement of TPL than in Group 2. TPL in Group 1 increased from 62.9 ± 4.4 Et - at I test to 118.8 ± 23.9 Wt - at III test ($p < 0.05$), in Group 2 - to 87.5 ± 17.7Wt, $p < 0.05$. We estimated aerobic physical capacity according to maximal oxygen uptake (VO2max) level. It was 19.9 ± 4.0 ml/kg/min in Group 1 and only 15.4 ± 6.2 ml/kg/min - in Group 2 at III test ($p < 0.05$). In Group 1 we also revealed more pronounced than in Group 2 improvement of systolic and diastolic function of a left ventricle according to EcoCG within 12 months after heart transplantation ($p < 0.05$).
The average number of vessels on 10 fields of vision haven't changed significantly during all period of study: it was 69.5 ± 17.4 in Group 1 and 68.0 ± 13.3 - in Group 2 at the I test, 63,7 ± 12.4 and 70.8 ± 15.6 - at II, and 65.2 ± 3.3, 77.9 ± 7.0 - at III test, correspondingly (?>0,05). The sum of vessels on 10 fields of vision also haven't changed: it was 694.6 ± 173.8 and 679.7 ± 132.5 - in Group 1 and 2 at the I test, 637.4 ± 123.8 and 708.3 ± 155.9 - at the II test, 588,8 ± 117.2 and 779.0 - at III test, accordingly (?>0,05).
Thus, the cardiac rehabilitation improves TPL and aerobic physical capacity without significant influence on character of microvasculature in patients with heart failure after heart transplantation.

P1087
Treatment with ivabradine at the start of multidisciplinary care in an Advanced Heart Failure Unit

G L Alonso Salinas[1]; S Del Prado Diaz[2]; M Pascual Izco[2]; JM Vieitez Florez[2]; A Lorente[2]; M Abellas[2]; S Hernandez Jimenez[2]; M Plaza Martin[2]; E Gonzalez Ferrer[2]; JL Zamorano[1]
[1]*Health Institute Carlos III, CIBERCV, Madrid, Spain*; [2]*Hospital Universitario Ramón y Cajal, Cardiology, Madrid, Spain*

Background: Heart failure (HF) is the commonest reason for hospital admission in > 65 years patients, and is the first in-hospital cause of health expenditure in Spain. Maintaining heart rate (HR) below 70 bpm in these patients improves functional class and prognosis. Ivabradine is a negative chronotropic drug that, in patients in sinus rhythm treated with beta-blockers, has been shown to improve HR control and functional class. The aim of this study is to analyze the population that start a multidisciplinary care program in an Advanced Heart Failure Unit (AHFU) and receive ivabradine at the first visit.
Methods: All patients treated in the AHFU were analyzed. Only those in sinus rhythm were selected and data were collected from the physical examination, echocardiogram, treatment and blood samples. In addition, 6-minute walking test was performed to evaluate the functional class and hospital admissions during the follow-up were collected.
Results: From May'16 to March'17, 200 patients were evaluated, 87 (43.5%) of them were in sinus rhythm. Of these 87 patients, 17 (19.5%) were treated with ivabradine. Baseline characteristics of this sample is summarized in Table 1.
Patients on ivabradine had a lower LVEF than patients without ivabradine. In the first visit the patients were treated equally with ACEIs/ARBs and Beta-blockers. Patient treated with ivabradine tended to have a lower HR. There were no differences in functional class or admissions during the follow-up.
Conclusions:
Treatment with ivabradine at discharge can help to control the HR in patients with HF. Larger studies are needed to correlate it with prognosis or functional class during follow-up.

	Ivabradine (n = 17)	No ivabradine (n = 70)	p
Age (years)	69.7 ± 15.5	70.7 ± 16.4	0.83
Female sex	5 (29.4%)	21 (38.2%)	0.51
LVEF (%)	29.9 ± 7.9	36.5 ± 12.7	0.05
BNP (pg/ml)	700.9 ± 439.2	611.7 ± 644.4	0.68
Beta-blockers	14 (82.4%)	45 (81.8%)	0.96
ACEIs/ARBs	11 (64.7%)	37 (67.3%)	0.84
HR in visit 1 (bpm)	67.6 ± 9.4	73 ± 14.2	0.08
6-minutes walking test (m)	288.7 ± 53.4	257.4 ± 129.5	0.69
Admission rate	4 (23.5%)	10 (18.2%)	0.63

Low-intensity dynamic and isometric exercises are safe and well tolerated in an early phase of ADHF

K Kinga Wegrzynowska-Teodorczyk[1]
[1]*University School of Physical Education of Wroclaw, Physiotherapy, Wroclaw, Poland*

Funding Acknowledgements: Grant from the National Science Centre (Cracow, Poland), No.:UMO-2013/11/D/NZ7/00922

Physical training is recommended for stable HF patients, in accordance with class A recommendations of the ESC. Experts point out the need for early patient activation after the episode of AHF decompensation, which may prevent disability but there are no reports on the safety and effectiveness of the exercises in this phase.
The aim of the study was to assess the safety of early isometric and dynamic exercises in ADHF.
A study group comprised 18 patients admitted to our centre due to acute decompensated HF (100% male, median age 60 years, median NT-proBNP 5286 pg/mL, 15 with HFrEF - median LVEF 25%, 7 ischemic; 5 with HFpEF median LVEF 55%).
The haemodynamic parameters (CI, HR, BP, SVR) were monitored during 2 exercise tasks: isometric and dynamic. Isometric exercise included 45 repetitions of isometric contractions (1-2 seconds of contractions of the quadriceps thigh muscle with 50% MVC, followed by relaxation lasting two seconds). Dynamic exercise comprised 45 extensions of the lower limb in the knee joint (from the 45-degree bending position in the joint).
During dynamic and isometric exercises neither serious cardiac arrhythmias nor any signs of myocardial ischemia were observed (See: Table 1).
Supervised low intensity dynamic and isometric exercises performed in the early phase of AHF are safe and well tolerated by patients. The presented results may constitute to the basis for further research to develop cardiac rehabilitation specific for AHF.

P1088 Table 1

Variables	Median at Rest	Isometric Exercise (Median)	Dynamic Exercise (Median)	Rest vs. Isometric (p value)	Rest vs. Dynamic (p value)
HR (bpm)	84	81	90	0,72	0,58
SBP (mmHg)	120	125	116	0,89	0,34
DBP (mmHg)	78	78	77	0,62	0,71
CI [l/ min./ m2]	2,5	2,8	2,7	0,09	0,11
SVRI (dyn.s/cm5.m^2)	2698	2490	2628	0,08	0,61

HR - Heart Rate, SBP - Systolic Blood Pressure, DBP - Diastolic Blood Pressure, CI - Cardiac Index, SVRI - Systemic Vascular Resistance Index; p value was calculated using the Sign Test.

Comparison of the resting haemodynamic parameters with parameters obtained during dynamic and isometric exercises

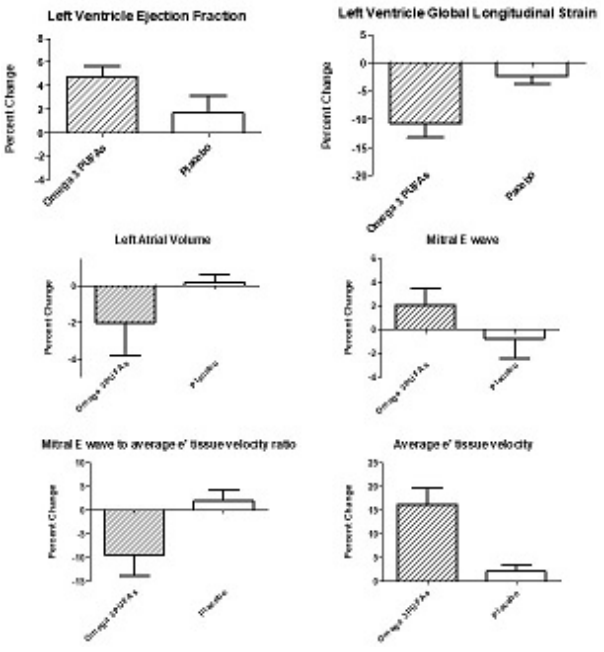
Effects of Omega 3 polyunsaturated fatty acids on fibrosis, endothelial function and myocardial performance, in ischemic heart failure patients

E Evagelos Oikonomou[1]; G Vogiatzi[1]; D Karlis[1]; G Siasos[1]; C Chrysohoou[1]; T Zografos[1]; G Lazaros[1]; S Tsalamandris[1]; K Mourouzis[1]; G Georgiopoulos[1]; M Toutouza[1]; D Tousoulis[1]
[1]*Hippokration Hospital, University of Athens, 1st Department of Cardiology, Athens, Greece*

Background: Polyunsaturated fatty acids (PUFAs) may affect the cardiovascular system with a multiplicity of mechanisms. However, the exact mechanisms of action in patients with heart failure (HF) is unknown.
Purpose: To assessed the effects of Omega-3 PUFAs supplements on inflammation, fibrosis, left ventricle performance and endothelial function of ischemic HF patients.
Methods: In this double-blind, placebo controlled, cross-over trial we enrolled 31 patients with ischemic HF. Omega-3 PUFAs (2g daily, 8 weeks) were administered PO in the intervention arm. Left ventricle ejection fraction (EF), global longitudinal strain and the ratio E/e' (early ventricular filling to early mitral annulus velocities) were measured. Endothelial function was evaluated by flow mediated dilation and myocardial fibrosis by soluble ST2.



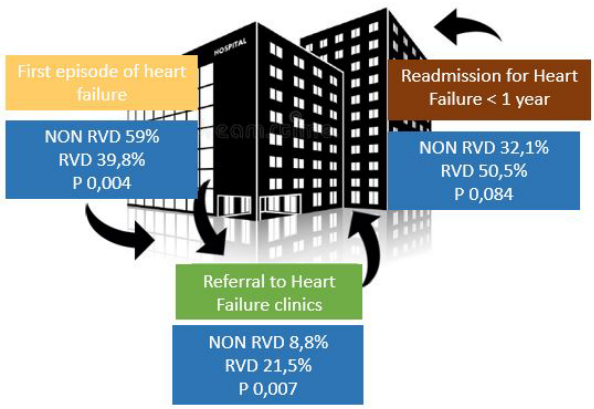
Results: At baseline there was no difference in the examined values (left ventricle EF, global longitudinal strain, and the ratio E/e') between the two treatment arms. Treatment with omega-3 PUFA, compared to placebo, improved: left ventricle EF (percent increased by 4.7% vs 1.7%, $p < 0.001$); global longitudinal strain (decreased by -10.6% vs -2.3%, $p < 0.001$); the E/e' ratio (decreased by -9.47% vs -2.1%, $p = 0.005$); ST2 levels (decreased by -4.53% vs -2.37%, 0.02); and flow mediated dilation (percent increased by 44% vs. 11%, $p = 0.003$). Interestingly, in the Omega-3 PUFAs treatment arm the improvement in FMD was associated with the improvement in the E/e' ratio ($r=-0.48$, $p = 0.005$)
Conclusion: Short term treatment with Omega-3 PUFAs in subjects with stable ischemic HF improved inflammatory and fibrotic status as well as endothelial function in parallel with systolic and diastolic performance of left ventricle. These findings emphasize the various beneficial mechanisms of Omega 3 PUFAs in patients with ischemic HF.

P1090

Patients with heart failure and right ventricular dysfunction: characterization and differential management

TS Tania Sonia Luque Diaz[1]; A Travieso Gozalez[1]; CN Perez Garcia[1]; D Enriquez Vazquez[1]; C Olmos Blanco[1]; J Higueras Nafria[1]; D Vivas Balcones[1]; I Vilacosta[1]
[1]*Hospital Clinic San Carlos, CARDIOLOGY, Madrid, Spain*

Introduction: Right ventricular dysfunction (RVD), traditionally little studied, is a prognostic marker and has important implications in different clinical conditions, such as heart failure (HF). The present study describes the clinical characteristics of patients with HF and RVD, defined with a TAPSE value of less than 17mm, as well as the main differences in the management of these with respect to patients with preserved right systolic function.
Methods: For one year, the clinical histories of patients admitted to the Cardiology service of a tertiary hospital with a diagnosis of HF have been evaluated prospectively, recording their baseline characteristics and their treatment during admission and discharge.



Results: The baseline characteristics of the patients are shown in table 1. Of the 321 patients included in total, 93 patients presented RVD. These patients were men in greater frequency and had a worse cardiovascular risk profile, although fewer patients had COPD among their antecedents. More cases were associated with depressed LVEF, especially if it was less than 40%. Analyzing the triggers of heart failure, in more cases in the RVD group it was not known and to a lesser extent it was the first episode. We also found difference in hospitalization time and NTproBNP at discharge.
Regarding treatment, patients with a lower TAPSE took more diuretic at admission (71% vs 48%, p = 0.001) as well as MRA (33% vs 18%, p = 0.014) and digoxin (18% vs 6%; p = 0.002). At discharge, more beta-blocker (77.4 vs 69.8), diuretic (82% vs 69.4), MRA (40.7 vs 24.5) and digoxin (16.1 vs 7.1) were used, although only the latter was statistically significant (p = 0.045). The use of ACEI or ARB was similar. Finally, more patients in the RVD group received an implantable automatic defibrillator (18.3% vs. 5.4%, p = 0.001), and they were referred to heart failure clinic visit at discharge (44.1% vs 19.8% ; p = 0.000)
Conclusion: The presence of RVD was not infrequent in patients admitted for HF, and was associated with a worse cardiovascular risk profile and lower LVEF. A shorter hospital stay and a higher value of NTproBNP at discharge were observed in these patients, and it was related to a greater use of diuretics, MRA and digoxin, more placement of an automatic defibrillator and greater referral to the HF clinical visit at discharge.

P1091

The effect of allopurinol on all-cause mortality and hospitalization in heart failure with reduced ejection fraction: a propensity-matched analysis

D Ural[1]; K Karauzum[2]; A Kandemir[3]; O Argan[4]; I Yilmaz Karauzum[2]; G Kozdag[2]; A Agir[2]
[1]Koc University, Istanbul, Turkey; *[2]Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey*; *[3]Kocaeli University, Hereke Vocational School, Kocaeli, Turkey*; *[4]Kocaeli State Hospital, Department of Cardiology, Kocaeli, Turkey*

Background and Purpose: Hyperuricaemia is common in heart failure (HF) and may be caused or worsened by renal dysfunction and diuretic treatment. Although hyperuricaemia is associated with a poorer prognosis in HF with reduced ejection fraction (HFrEF), the effect of urate-lowering therapy with xanthine oxidase inhibitors is uncertain. This study aims to evaluate the association of allopurinol usage with all-cause mortality and hospitalization risk in HFrEF patients.
Methods and Results: This study was a retrospective propensity-matched analysis of HFrEF patients attending a HF clinic between years 2003 and 2016. Allopurinol prescription at discharge and its association with all-cause mortality and HF hospitalization was examined in median 55 ± 33 months follow-up. Of 629 patients (mean age 65 ± 12 years; 66% men), 112 (17.8%) were prescribed allopurinol due to hyperuricemia (uric acid level >8.5 mg/dl). Patients prescribed allopurinol had more frequent right-sided HF, lower haemoglobin, lower estimated glomerular filtration rate and albumin levels than the patients without allopurinol prescription. After propensity-matching, 108 couples were established according to presence and absence of baseline allopurinol usage. A total of 107 (49%) patients died during the follow-up period. In Cox regression analysis, allopurinol use was associated with a significantly increased mortality risk compared to not using allopurinol (HR = 1.38; 95% CI 1.18-1.53; p = 0.001), but this was not statistically confirmed by the propensity-matched analysis (HR = 1.06; 95% CI 0.65-1.35; p = 0.738). In both prematch and propensity matched analysis, allopurinol use was not associated with risk of hospitalization.
Conclusions: In this study, allopurinol therapy in HFrEF patients did not affect all-cause mortality and hospitalization risk during a long-term follow-up. These results suggest decision to use allopurinol in HFrEF should not be based on uric acid level alone, but also on the associated conditions like risk of developing gut and arthritis.

P1092

Like a bridge over troubled waters: VA-ECMO as a bridge to transplantation INTERMACS 1 to 3

V Vera Marinho[1]; S Costa[1]; F Franco[1]; R Baptista[1]; P Alves[1]; J Milner[1]; C Domingues[1]; J Ferreira[1]; D Prieto[1]; F Goncalves[1]; M Pego[1]; M Antunes[1]
[1]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal

Introduction: Veno-Arterial Extracorporeal Membrane Oxygenation (VA ECMO) is an effective and increasingly used therapy in patients with advanced heart failure (HF) in severe INTERMACS strata as a bridge to high-urgency heart transplantation (BTT). We analyzed the use and outcomes of VA-ECMO for BTT in our cohort of advanced HF patients.
Methods: We conducted an observational, retrospective study including all patients admitted to our HF unit and described the clinical characteristics and outcomes of patients who received VA-ECMO as BTT. The primary endpoint was heart transplantation (HTx) and the secondary endpoint 30-day all-cause mortality.
Results: A total of 12 patients received VA-ECMO as a BTT. The median age was 50 [36-64] years and 50% were female. Familiar dilated cardiomyopathy (33%), coronary artery disease (25%) and post–inflammatory cardiomyopathy (25%) were the most common causes for HF. The mean LVEF was 22[20-25]% and the median cardiac index was 1.7[1.3-2.2] L min-1. Most patients had pulmonary hypertension (75%). Before insertion, 58% were under inotropic support with two drugs and 17% with 3 drugs; one patient was in electrical storm without inotropic support. In 36% of patients, acute kidney injury with need of continuous hemofiltration was present and 64% were mechanically ventilated. Accordingly, regarding the INTERMACS classification, 58% were in profile 1, 25% were in profile 2 and 1 patient in profile 3. The median time in VA-ECMO was 7(2-12) days. The major complications due to VA-ECMO included thrombocytopenia (64%), bleeding (55%) and nosocomial infection (45%). Pericardial tamponade and femoral artery dissection occurred each in 1 patient. Regarding the primary outcome (heart transplantation), all patients were successfully transplanted. VA-ECMO was used in period post-transplant in 3 patients. At follow up, the 30 days all-cause mortality was 18%; in long term follow up the global mortality was 64%. Of these, 6 patients died during the immediate post-transplant period. The main causes of death were septic shock in 3 patients, primary graft dysfunction in 2 patients and acute humoral rejection in 1 patient. One patient died during the long term follow-up.
Conclusions: All patients in cardiogenic shock that received VA-ECMO were successfully transplanted. The post-transplant all-cause mortality is higher than for patients transplanted electively but in line with the published results from other centers.

P1093

Risks of therapeutic interchange in HFrEF

G Marazzi[1]; G Caminiti[1]; F Pelliccia[2]; L Iaia[3]; L Cacciotti[4]; G Cice[5]; R Massaro[1]; B Sposato[1]; M Volterrani[1]; G M C Giuseppe M C Rosano[1]
[1]San Raffaele Pisana Hospital IRCCS, Rome, Italy; *[2]Umberto I Polyclinic of Rome, Cardiology, Rome, Italy*; *[3]Giovanni Calibita Fatebenefratelli Hospital, Rome, Italy*; *[4]Ospedale Vannini, Rome, Italy*; *[5]Second University of Naples, Naples, Italy*

Therapeutic interchange or substitution of an originator cardiovascular drug with a generic drugs or drugs that are similar, albeit not identical, has raised several safety. Generic drugs are believed to be therapeutically similar. However, the interchangeability between generic drugs and the bio-creep that reduces their therapeutic equivalence to the originator may pose efficacy and safety issues in patients where a narrow therapeutic interval should be sought.
We assessed the pharmacodynamics equivalence of branded and generic beta-blockers in 612 patients with heart failure and reduced ejection fraction (HFrEF). Patients were started and up-titrated on branded bisoprolol/carvedilol/nebivolol/metoprolol and referred to their general practitioner for continuation of their prescriptions. Heart rate and blood pressure were assessed at discharge and at 1 and 3 months. At discharge heart rate was 62+7 bpm and blood pressure was 118+12 mmHg.Patients who remained on branded beta-blockers at 3 months showed no significant change in either heart rate or blood pressure while patients switched to generic beta-blockers showed a significant variability in heart rate and blood pressure values at 3 months compared to end of up-titration (Table 1). Patients switched to generic beta-blockers showed a greater need of dose adjustment and augmentation of diuretic therapy. No difference between branded beta-blockers and branded generics was detected.
These findings suggest that in patients with HFrEF therapeutic interchange should be practiced with caution. Originator and branded generics have similar pharmacodynamics while non-branded generics do not guarantee adequate safety and efficacy, thereby suggesting that drugs to be used in HFrEF should be classified as drugs with narrow therapeutic interval.

Table 1

	Branded beta-blockers (pooled)	Generic beta-blockers (pooled)
Mean age Male Diabetics Hypertensives NYHA III NYHA II	67+8 72% 23% 45% 38% 62%	67+8 74% 25% 41% 32% 68%

Initial experience with sirolimus in cardiac transplant patients with graft vasculopathy

L Lavanya Saiva[1]; S Murphy[1]; N Boyle[1]; C Halley[1]; N Mahon[1]; J O'neill[1]
[1]*Mater Misericordiae University Hospital, Heart and Lung Transplant Unit, Dublin, Ireland*

Background: Cardiac allograft vasculopathy (CAV) is the leading cause of graft loss in heart transplant recipients. Sirolimus is an immunosuppressant drug with potent anti-proliferative and anti-migratory effects and is used to reduce progression of CAV. We present our initial experience with sirolimus in patients with CAV.
Methods and Results: We retrospectively analyzed all our patients in whom sirolimus was commenced for CAV. Baseline characteristics of patients, indications for sirolimus, benefits and adverse effects of sirolimus were studied.
At our center total 9 patients with CAV (diagnosed by coronary angiogram) were commenced on sirolimus. The mean age of the patients was 48.8 years ± 11.8 years (range 28-62 years), 44% (n= 4) of patients were female, and 55% (n= 5) were male. The median time from heart transplant to diagnosis of CAV was 10.9 years ± 1.77 years (range 9-14 years).
All patients on sirolimus were also on tacrolimus for maintenance immunosuppression. Mycophenolate mofetil or Azathioprine was discontinued prior to starting sirolimus. The average combined tacrolimus and sirolimus levels in our patients was 11.4 ± 2.0 and median time to achieve target levels was 44.8 ± 28.7 days. The average duration of therapy on combined sirolimus and Tacrolimus was 52.8 ± 12.6 weeks.
Sirolimus was well tolerated by all 9 patients. Repeat coronary arteriography was performed in 6 patients. There was no progression of CAV in 5 patients and in 1 patient there was marked regression of CAV. No Rejection episodes (ISHLT2R or 3R) were reported during sirolimus therapy.
With regards to side-effect profile, Peripheral odema (n = 1), herpes zoster (n = 1) and oral ulcers (n = 1) were reported. No patient had to discontinue sirolimus due to side-effects.
Conclusion: We conclude that sirolimus is a safe and well-tolerated, viable treatment option for patients affected by CAV, with disease stabilization in all patients and significant regression in one patient

Left anterior descending artery (LAD) disease prior to sirolimus

LAD disease regression post sirolimus

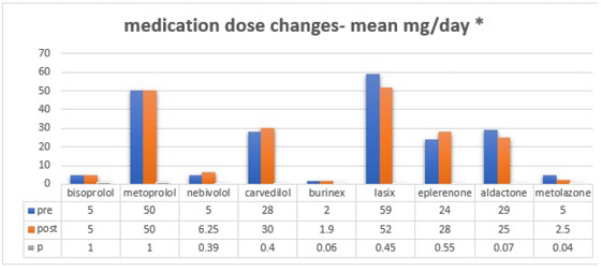
P1095

Reduced thiazide diuretic use in hfref patients taking sacubitril/valsartan (arni)

T Mannion[1]; L O Connor[1]; B Mcadam[1]; S James[1]; J Kelly O Haire[1]; G O Gara[1]
[1]*Beaumont Hospital, Supportive Heart Service, Dublin, Ireland*

Background: Post-hoc analyses from PARADIGM-HF have shown treatment with ARNI was associated with dose reductions in diuretics compared to Enalapril. Purpose To examine clinical & medication changes in HFrEF patients following treatment with ARNI.
Methods: Using a Pre-Test Post-Test Design data was collected on 43 HFrEF patients prior to initiating ARNI & post achieving max tolerated dose (mean 18 months range 2 -36). Indices of cardiac function were recorded including Left Ventricular Ejection Fraction (LVEF) vital signs (Systolic & Diastolic Blood Pressure) biochemical measures (BNP NT pro BNP renal function & electrolytes), functional capacity (NYHA Class) & changes in cardiac medications. Paired sample t-test was used to assess for statistically significant changes.
Results: Use of metolazone reduced by 12.6% (p0.04), but no significant dose changes were found in other cardiac medications (figure 1). A statistically significant change was found in LVEF with a mean increase of 7.5% (±10.5% p0.00) but there was no significant change in NYHA Class (p0.32) or QRS Duration (p0.07). Systolic BP reduced by mean 5.7mmHg (±17.6mmHg p0.04). NT pro BNP levels reduced from mean 2900pg/mL to 1662pg/mL (mean reduction of 1238pg/mL p0.04) but no significant change was found in BNP levels. Sodium levels increased by a mean of 0.9mEq/L (±2.4mEq/L p0.02) but no significant changes were found in other electrolytes/renal function (table 1)
Conclusion(s): In this small study use of ARNI was associated with more thiazide diuretic dose reduction & cessation (n = 4) but no change in loop diuretic use. There was a non-significant increase in serum sodium levels & renal function remained stable. This data suggests that treatment with ARNI results in reduced use of thiazide diuretics but does not appear to affect doses of loop diuretic/MRA in this cohort despite a modest increased in LVEF.

*note metolazone dose mg/week



Dose changes post ARNI fig 1

Disease management programs in austian heart failure patients

CM Brandstetter[1]; C Claudia Stoellberger[1]
[1]*Rudolfstiftung Hospital, Department of Internal Medicine II, Vienna, Austria*

Background: Nowadays there are multiple ways to improve the prognosis of heart failure including pharmaco- and device therapy. Nevertheless, decompensated heart failure is still common and hospitalization rates in patients with heart failure are high. To better control patients' well-being as well as their daily drug intake, Disease Management Programs (DMPs) have been developed and are recommended as class IA in the European Society of Cardiology heart failure guidelines. In Austria, discrepancies in the acceptance of DMPs have been observed which are, so far, not clarified. We hypothesized that patients in rural and urban regions may have different attitudes toward DMPs.
Methods: In a prospective study, patients hospitalized because of heart failure were asked by using a preset questionnaire comprising 40 questions about their opinion on DMPs and about their knowledge and attitude about heart failure management. Two different groups were defined: one consisted of patients hospitalized in a rural area, the other comprised patients living in a big city. The survey results between the rural and urban patients were compared.
Results: Sixty patients (females n = 26, mean age 76, range 40-94 years) were included, 30 each in a hospital in a rural area and in a big city. Significant differences between rural and urban patients were found regarding the acceptance of nurse-based DMPs (p= 0.029) which was higher among rural patients. The level of willingness to be included into a telenursing-based program was the same for both groups (p = 0.441). Patients from rural areas tend to accept nurses more likely in their private surroundings than patients living in an urban environment (p = 0.114). While the patients' knowledge of heart failure is similar in both population groups and overall adequate, their views on the current medical treatment vary: According to 50% of the rural patients the primary care physician is responsible for the follow-ups, whereas urban patients would rather go see a specialist for their follow-ups; 36,7% of urban patients chose that option.
Conclusion: Nurse-based DMPs seem to be more accepted by patients from rural areas than by patients living in big cities. DMPs for urban patients have to be developed according to their special needs.

P1097

Tolerability of sacubitril/valsartan when initiating/uptitrating in real-life patients. Initial experience in two centres.

C Goena Vives[1]; C Gomez Ramirez[2]; L Quintas Ovejero[1]; R Garcia Martin[1]; I Luis Serret[1]; R Natividad Andres[2]; I Sagasti Aboitiz[2]; M Campana Lazaro[2]
[1]*Mendaro's Hospital, Cardiology, Mendaro, Spain*; [2]*Cruces University Hospital, Cardiology, Barakaldo, Spain*

Introduction: PARADIGM-HF demonstrated the benefits of sacubitril/valsartan (SV) in patients with heart failure and reduced ejection fraction.

Purpose: Assess the tolerability of initiating/uptitrating SV and causes of no achieving the target dose in a real world registry.
Methods: Retrospective, non-protocolized study in non-selected outpatient patients with LVEF = 40% which start SV between october 2016-august 2017.We evaluated:clinical profile, tolerability, adverse effects (death, hospitalization, cardiovascular event or ventricular arrhythmias),the cause of treatment disruption or not achieving de 200mg b.i.d. dose.
Results: SV was initiated in 90 patients with mean age:66 years (43-92), 71 male (78.8%).The mean follow up time was 204 days (minimum 30 days).In our cohort the percentage of ischaemic disease was 48.8%.The mean LVEF was 27.8% (10%-40%).42.2% had LBBB with QRS duration >130 ms and 56,6% were carriers of devices:ICD, CRT-D or CRT-P.The mean basal NT-proBNP level was 2055 pg/mL (186-10989) with mean GFR of 69.44 (34 -133), mean Creatinine 1.10 mgr/dL (0.47-1.96) and mean potassium levels of 4.62 mEq/L (3.2-5.6).68.8% of patients were NYHA II/II-III, 13.3% III/IV and there is no patient NYHA I/I-II before treatment was started.Despite not achieving target SV dose there was a significant improvement in the NYHA situation when the trial stopped:12.2% NYHA I/I-II and 86.6%NYHA II/II-III.In most of the cases de initial SV dose was 50mgr b.i.d.The low dose of 50 mgr b.i.d. was the one selected for starting in most of the cases (just 13.3% (N = 12) started directly 100 mg b.i.d.).93.3% (N = 84) of patients continue with the treatment. 34.5% (N= 29) achieved and maintained the SV 200 mg b.i.d. dose and 28,6% (N= 24) the SV 100 mg b.i.d. without dose interruption/down-titration. 23.8% (N= 20) were treated with low-dose SV 50 mg b.i.d. and 13.1% (N= 11) underwent a SV dose not described in the pivotal study (1 patient with 24/26 + 49/51 and 10 with 49/51+ 97/103 mg).The treatment was discontinued in 6 patients. The main causes of not achieving the target dose were: symptomatic SBP <95 mmHg (34%, N = 19) and still titration (32.1%, N = 18).Significant renal impairment and hyperkalemia were documented in 9 and 4 patients respectively. Adverse events are infrequent.There are no angioedema, VT/FV or cardiovascular events. There are 8 cases of decompensation requiring hospital admission (1 patient was included in a palliative care home hospitalization program) and 2 died (a sudden death and a cardiogenic shock with contraindication for cardiac transplantation).
Conclusions: Initiation/uptitration of SV had a tolerability profile in line with other treatments. However, not all patients are able to tolerate the doses recommended due to dose-related adverse effects. In our initial experience with real-life patients (more symptomatic and more users of devices comparing to Paradigm),SV has an accurate security profile and improves quality of life and exercise tolerance.

P1098

ARNI treatment in hfref patients with and without pre-existing renal dysfunction-results from initial experience in single centre.

T Mannion[1]; L O Connor[1]; B Mcadam[1]; S James[1]; J Kelly O Haire[1]; G O Gara[1]
[1]*Beaumont Hospital, Supportive Heart Service, Dublin, Ireland*

Background: PARADIGM HF demonstrated the favorable cardio-renal profile in patients with HF with ARNI when compared to Enalapril with and without renal dysfunction.
Purpose: To examine clinical & biochemical changes in HFrEF patients, with & without pre-existing renal dysfunction after initiation of ARNI.
Methods Using a Pre-Test Post-Test Design data was collected on 43 Heart failure with reduced ejection fraction (HFrEF) (35 male 8 female mean LVEF 24.5% ± 6.7% & mean NYHA Class II) prior to initiating ARNI & following max tolerated dose (mean 18 months range 2-36). 66.7% had a cardiac device insitu (35.4% CRTD 29.2% ICD 2.1% PPM). Indices of cardiac function were recorded including LVEF, vital signs, biochemical measures (BNP NTproBNP renal function & electrolytes) while functional capacity was determined based on NYHA Class. Changes in cardiac medications over time were recorded. Patients were then categorized based on degree of renal dysfunction at baseline prior to initiating ARNI (Normal GFR >90, mild renal dysfunction GFR = 60-89 & moderate renal dysfunction GFR = 30-59).
Results For all patients assessed, mean baseline eGFR was 69.3 with no significant change in mean eGFR (2, p0.51) after 18 months therapy. Maximum tolerated dose of ARNI achieved, categorized by renal dysfunction is presented in figure 1. All patients were maintained on treatment for the duration of review with 1 patient requiring down titration of ARNI due to hypotension. There were no significant changes in creatinine/ eGFR in the patients between the different categories of renal function. Nor was there any significant change in plasma electrolytes between groups. Interestingly there was statistically significant change in LVEF with a mean increase of 7.5% (over the 18-month period). This finding remained statistically significant among groups categorized based on renal dysfunction. There was no appreciable changes in vital signs (see table 1) but there was an increase in BNP from baseline (from mean of 393pg/mL to 570, mean increase of 177pg/mL ± 189 pg/mL) in patients with moderate renal dysfunction following max titration of ARNI. No significant change was found in NTproBNP levels in this cohort. There was no change in mean doses of concomitant HF treatments.
Conclusion(s): Overall these findings indicate that ARNI does not compromise renal function in HFrEF patients even in those with pre-existing renal dysfunction. Pre-existing renal dysfunction at baseline did not preclude titration of ARNI to maximal dose. These findings confirm that ARNI can be safely used in HFrEF patients with mild-moderate renal dysfunction & there was no adverse impact on hemodynamics. The observed significant increase in BNP in HFrEF patients with moderate renal dysfunction, is a known pharmacological effect of ARNI but there was no change in NTproBNP levels in this cohort. In this small observational study we observed a small increase in LVEF following treatment with ARNI.

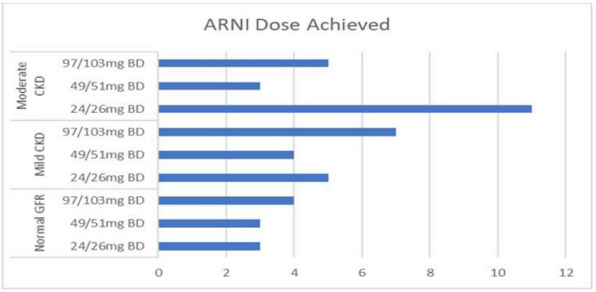

Figure 1

P1099

Effect of combination therapy of azilsartan and metoxipoliethylenglicol epoietin beta two-year survival of patients CHF with anaemia hospitalized because decompensated heart failure

K Kamala Zahidova[1]; FA Guliyev[1]
[1]*The Azerbaijan State Advanced Training Institute for Doctors , Baku, Azerbaijan*

On behalf of: Heart Failure and anaemia

Backround: The implementation into clinical of new therapeutic strategies that could improve the prognosis of patients with heart failure(HF) with reduced EF (HFrEF) with anemia remains relevant. Innovative approach is to restore imbalances of neurohumoral systems by inhibiting angiotensin II receptor.
Purpose: To asses the impact of combination therapy by angiotensin-II reseptor blockers azilsartan and Metoxipolyethylenglicolepoitin beta (MEB) of prognosis of patients CHF with anemia of hospitalized decompensated HF.
Methods. We analyzed data of hospital register of decompensated HF which comprised information on 840 patients with HFrEF ishemic aethyologi and anemia consecutively admitted in 2016-2017 years. Median follow-up was 1970 days. The level of Hb was Hb < 10 g/dl. It should be noted that in patients decompensated HF with anemia hypoerythropoietinemia was noted up to 2,3 ± 1.1 IU/ml. The 390 (46,4%) patients from them have received treatment by azilsartan in dose 20-40 mg in day and MEB in dose 50 IU in day in one months. The remaining 450 (53,6%) patients of decompensated HF combination by azilsartan and MEB did not receive. The register included cases of hospitalization in association with symptoms of HF whose severity corresponded to NYHA III-IV class and also patients in CHF with NYHA II class only in the presence of a clinical picture of acute pulmonary edema following ingestion.In the multivariate analysis of the prognosis and survival, the logistic regression method and the Cox model were used, the data are presented in the form of odds ratio (OR) and 95% confidence intervals (95%CI).
Results: The absence of combination treatment by azilsartan and MEB in 450 (53,6%) patients of decompensated HF with anemia was associated with increased risk of death: during the index hospitalization due to acute decompensated HF (HR 1.6, 95%CI 1,2-2.9), within 12 months (HR 1.3, 95%CI 1,2-1.9).The present of treatment by azilsartan in dose 20-40 mg in day and MEB in dose 50 IU in day in one months by 390 (46,4%) patients of acute decompensated HF with anemia, was associated with decreased risk of death.The mortality in it investigation was above 8,2 % -(68 patients died), which corresponds to the level of mortality in acute decompensated HF accordance with the European registers.The mortality in the group of patients in acute decompensated HF with anemia who did not receive combination therapy was above 6,4 % -(54 patients died). The mortality in the group of patients in acute decompensated HF with anemia, who receive combination therapy by azilsartan in dose 20-40 mg in day and MEB in dose 50 IU in day in one months was above 1,6 % -(14 patients died).
Conclusion: According to the Cox model, a decrease in Hb < 10 g/dl is a predictor of death.The absence of correction of anemic syndrome and appropriate therapy of angiotensin-II reseptor blockers azilsartan in patients in CHF increases risk of death of acute decompensated HF.

P1100

A retrospective observational study assessing the utilisation of sacubitril-valsartan in a single centre in the Eastern Province in Saudi Arabia

MM Alqaseer[1]; D Abdulhadi[1]; H Alrammah[1]; M Ibrahim[1]; U Ismail[1]; VJ Nambiar[1]; M Kharasani[1]; B Mushannen[1]
[1]*King Fahad Specialist Hospital, Cardiology Department, Dammam, Saudi Arabia*

Background: The landmark PARADIGM-HF trial had rapidly shifted our therapeutic approach to patients with heart failure with reduced ejection fraction (HFrEF). Within a year of the release of the trial, sacubitril-valsartan had become a cornerstone therapy in patients with symptomatic HFrEF who had not shown a marked improvement with angiotensin converting enzyme inhibitors (ACE-i) in the absence of any major contraindications to sacubitril-valsartan. In this paper, we will describe a single center's experience of utilizing this agent, highlighting its impact on our patients.
Methods: This is a retrospective observational study looking at consecutive patients that have received sacubitril-valsartan in a single center in the Eastern Province of Saudi Arabia between February 26th, 2017 and December 1st, 2017. Basic demographic data was gathered of the patients including their comorbidities and their renal function and ejection fraction prior to initiating therapies and compared against their follow up echocardiographic and laboratory studies.
Results: 34 patients were initiated on sacubitril valsartan in the hospital. Out of these patients, 19 were male, constituting 55.9% of the patient population at hand. 56% of the patient's were diabetic, 47% were hypertensive, 65% had ischemic heart disease, 38% were dyslipidemic and 9% had atrial fibrillation. The average ejection fraction of those patients prior to initiating the therapy was 27% with an average functional class of predominantly III. The average dose administered for these patients is 200mg daily. The two main causes of inability to uptitrate to the maximum dose include are slow uptitration strategy preference by the end user and hypotension. The average eGFR prior to initiation of therapy was normal at 83. 100% of the patients were on beta blockers and had received and ACE-I or ARB prior to switching. Only a third of the patients were on MRA at baseline. At follow up, the average ejection fraction had improved to 34% with improvement of functional class by an average of I class and maintenance of the eGFR with an average value of 86.
Conclusion: The utilization of sacubitril-valsartan in our patient setting was done in keeping with the PARADIGM-HF criteria. It showed a beneficial improvement of ejection fraction with an absolute improvement of 7%, and an improvement of functional class by one level, yet maintaining adequate renal function.

The limited triple therapy prescription does not depend on clinical features of heart failure patients discharged from Internal Medicine

V Verdiani[1]; A Fortini[2]; L Masotti[3]; M Alessandri[4]; G Cati[4]; C Belcari[5]; P Fabiani[6]; S Spolveri[2]; FA Tarmum[2]
[1]*Internal Medicine, Grosseto, Italy*; [2]*Internal Medicine, Florence, Italy*; [3]*Internal Medicine, Empoli, Italy*; [4]*Internal Medicine, Massa Marittima, Italy*; [5]*Internal Medicine, Pontedera, Italy*; [6]*Internal Medicine, Viareggio, Italy*

On behalf of: SMIT Study Group

Introduction: Guidelines (GL) recommend triple therapy with angiotensin-converting enzyme inhibitor (ACEI), beta-blocker (BB) and aldosterone antagonist (AA) in symptomatic heart failure (HF) patients with ejection fraction (EF) < 35 %. Nevertheless, many patients remain untreated.
Methods and Purpose: We analyzed database of a multicenter observational study (published SMIT study) on 770 patients consecutively hospitalised for HF in 32 Internal Medicine Units of Tuscany (Italian region with 3.7 million inhabitants). We selected HF patients with EF < 35% and compared features of patients treated with triple therapy (TT) respect ones untreated to identify if there were patient-dependent obstacles to follow GL recommendations in this subset of real world HF patients.
Results: The HF patients with EF < 35% was 117. At only 46 (39,3%) had been prescribed TT at discharge. TT untreated patients were mainly women (78% vs 61.9% P = 0.06) and older (mean age 78.4 vs 77.5 years, P = 0.07). In this group there was a greater number of patients with hypertension (61.9% vs 58.6% P = 0.50), Diabetes mellitus (43.6% vs 36.9% P = 0.47), Clearence Creatinine < 60 ml/min (74.6% vs 67.3% P = 0.39), Anemia (52.1% vs 45.6% P = 0.46), Atrial fibrillation (40.8% vs 34.7% P = 0.51), although none of these differences reached statistical significance. None difference about COPD. TT untreated group had a significantly greater number of patients with deficit cognitive (25.3% vs 10.8%, P = 0.04) and a major mean length of hospital stay (10.1 vs 8.4 days, P = 0.01).
Conclusions: only at a minority of HF patients discharged from Internal Medicine units had been prescribed TT. The results of our research indicate that, compared with treated patients, untreated patients were probably sicker and more complex, but, except for deficit cognitive, none singular feature was significantly prevalent. We conclude that there is space to implement guidelines recommendation also in this group of patients.

Chronic Heart Failure - Clinical

P1102

The relation between beta-adrenergic blockade and weight changes in patients with chronic heart failure

S Shirley Sze[1]; P Pellicori[2]; S Kamzi[1]; A Anton[1]; AL Clark[1]
[1]*Castle Hill Hospital, Hull, United Kingdom*; [2]*University of Glasgow, Glasgow, United Kingdom*

Background: Weight loss is common in patients with chronic heart failure (CHF) and is associated with adverse outcome. Activation of the sympathetic nervous system has been implicated in weight loss, wasting and cachexia. However, the effect of sympathetic antagonism on weight change in patients with CHF is not well defined.
Methods: We evaluated changes in body weight, the incidence of cachexia (weight loss > 6%) and significant weight gain (<5%) in unselected patients with CHF due to left ventricular systolic dysfunction (LVSD) (LV ejection fraction (LVEF) < 40%) and studied the effect of beta-blockade on weight change.
Results: Of the 1480 patients enrolled (median NTproBNP:1651ng/L, median LVEF:31%), 86% received beta-blocker, 11% never had beta-blocker and 3% discontinued beta-blocker between baseline and 1 year.
Patients who did not have or tolerate beta-blocker were more likely to develop cachexia (23% vs 10%, p < 0.001) and less likely to have significant weight gain (22% vs 24%, p < 0.001) than patient who had beta-blocker.
During a median follow up of 1876 days (IQR: 993-3052 days), 894 (60%) patients died. Higher body mass index (BMI) at baseline, weight gain and beta-blocker therapy were associated with better outcome. Patients who had all 3 features: beta-blocker therapy, baseline BMI = 25 and significant weight gain had the best outcome (22% mortality at 5 years) (Table 1).
Conclusion: Patients with CHF due to LVSD who receive beta-blocker were less likely to develop cachexia and more likely to have significant weight gain and better outcome compared to patients who did not receive or tolerate beta-blocker.

UTILITY OF BIOIMPEDANCE IN THE MONITORING OF PATIENTS WITH CONGESTIVE HEART FAILURE

A M Ana Maria Campos Pareja[1]; E Gutierrez Carretero[1]; J Rosell Ferrer[2]; A Ordonez Fernandez[1]
[1]University Hospital of Virgen del Rocio, Cardiology, Seville, Spain; *[2]Polytechnic University of Catalonia, Barcelona, Spain*

Funding Acknowledgements: Talemnology

Introduction: In the management of Congestive Heart Failure (CHF), an unmet need is to detect, for at-risk patients, at an early stage, fluid retention in order to avoid the high number of hospitalizations that for this reason they generate. For this reason different mechanisms are being developed that help patients to be able to detect early decompensations of their heart disease.
Objective: and justification: Our objective is the clinical validation of a medical wearable device based on measurement of localiced bioimpedances. This device would allow an early recongnition of fluid retention
Material and Methods: Material and methods Patients admitted to the Heart Area with signs suggestive of systemic congestion have been prospectively included. They were given an "Information Sheet", and the "Informed Consent" was obtained. The measurements of localized bioimpedance were performed on a daily basis with a experimental non invasive wearable device. During patients admission, impedance were obtained daily putting a experimental device with four electrodes that are attached to skin four finger cross above the ankle. Obtained values were correlated with analytical, clinical and echocardiographic parameters associated with decompensation of chronic congestive heart failure.
Results: Eighty patients were selected (66,3 ± 12 years. 76,3 % males). 28,6% patients had impaired renal function. Mean NT-ProBNP was 5978 pg /ml at admission. 45,6% patients had edemas at admission classified as grades 2 and 3.34,6% patients had a reduced left ventricular systolic function,52,9% patients had right ventricular systolic disfunction and 41,8% patients had pulmonary hypertension. Percentiles of the bioimpedance measurements obtained at 50 Hertz were 17.6, 22, 27.1 and 45.9 ohmios. This measures were statistically correlated with right and left ventricular function (p = 0,015) pulmonary hypertension (p = 0,000), use and doses of furosemide (p = 0,000), sodium levels and lower limbs edemas grades (p = 0,000). There was no association with ages, hypertension, diabetes or obesity.
Conclusions: Bioimpedance measurement is correlated with exploratory, analytical and echocardiographyc data related to fluid retention. This preliminary results are promising in that the device could be useful as an alert to about fluid retention, allowing an earlier consultation and treatment.

P1104

Reduced muscle-derived irisin reflects low muscles mass and impaired functioning of skeletal muscles in men with heart failure with reduced ejection fraction

M Kasztura[1]; M Dziegala[1]; KA Kobak[1]; M Tkaczyszyn[1]; M Drozd[1]; K Wegrzynowska-Teodorczyk[2]; K Josiak[3]; J Bania[4]; L Kiczak[5]; W Banasiak[6]; P Ponikowski[3]; EA Jankowska[1]

Funding Acknowledgements: Financially supported by National Science Centre (Poland) grant no. 2012/05/E/NZ5/00590

Background: Irisin is a circulating hormone-like myokine which regulates energy metabolism in several tissues, including adipose, bone and muscle ones. Adequately high production of irisin is related to optimal exercise capacity and metabolic homeostasis.
Purpose: We assessed the production of irisin in peripheral blood and in the blood draining exercising forearm muscles in relation to the mass and functioning of skeletal muscles in men with heart failure and healthy men.
Methods: Study population comprised of 53 men with stable heart failure with reduced ejection fraction (HFrEF) (LVEF = 40%); mean age: ± 64 years; NYHA class I-II: 87%) and 15 middle-aged healthy men. Lean mass of upper extremities were determined by DEXA (dual-energy X-ray absorptiometry). We analysed the levels of irisin in plasma samples from peripheral blood from all patients by ELISA. Further, we analyzed samples taken from antecubital veins which drain the forearm muscle before and after local physical exercise (standardized 5-minute handgrip exercise) for the aforementioned myokine.
Results: There were no differences in irisin levels measured in peripheral blood samples between HF patients and healthy controls. The levels of irisin in peripheral blood were not associated with NTproBNP, eGFR or CRP in both men with HF and healthy controls. There was a relationship between reduced irisin concentrations in peripheral samples and both decreased fat content in the four extremities (R = 0.35, p < 0.05) and low lean tissue mass of the upper extremities (R = 0.37, p < 0.05). Elevated irisin level was associated with longer distance in 6-minut walking test in HF patients (R = 0.37, p < 0.05). There was a correlation between concentrations of irisin in peripheral blood and in the forearm samples in HF patients (R = 0.54, p < 0.001) whereas it is not observed in healthy controls. HF progression expressed as NYHA class was associated with decreased level of irisin measured in forearm samples (R= -0.28, p < 0.05). Lower concentrations of irisin assessed both before and after exercise in forearm samples of men with HF were associated with lower lean tissue mass of the upper extremities (R = 0.47, p < 0.001; R = 0.39, p < 0.01). Reduced irisin was related to lower fat content both in upper extremities (R = 0.37, p < 0.01) and in all 4 extremities (R= 0.32, p < 0.05). There was no correlation between irisin and inflammatory marker IL 6 in the forearm samples in HF patients.
Conclusions: Reduced circulating irisin from the blood draining exercising muscles reflects decreased skeletal mass in patient with HF.

P1105

Reduced muscle strength and quality of life in patients with heart failure with preserved ejection fraction compared to healthy controls and patients with heart failure and reduced ejection fraction

T Bekfani[1]; S Derlien[2]; A Hamadanchi[1]; J Nisser[2]; E Froeb[1]; UC Smolenski[2]; G Lehmann[3]; G Wolf[3]; S Moebius-Winkler[1]; PC Schulze[1]
[1]University Hospital of Jena, Department of Cardiology, Jena, Germany; *[2]University Hospital of Jena, Institute of Physiotherapy, Jena, Germany*; *[3]University Hospital of Jena, Department of Endocrinology, Nephrology and Rheumatology, Jena, Germany*

Purpose: To compare skeletal muscle function, body composition and quality of life (QoL) among symptomatic and clinically stable outpatients with heart failure (HF) with both preserved (HFpEF) and reduced ejection fraction (HFrEF) and age-matching healthy controls (HC).
Methods: 55 participants were recruited prospectively at the University Hospital Jena: 19 HFpEF, 18 HFrEF, 18 HC (Age: 71 ± 6 vs. 68 ± 9 vs. 66 ± 7 years; sex (m/f): 8/11 vs. 15/3 vs. 7/11; BMI: 28.5 ± 4.6 vs. 27.9 ± 5.3 vs. 26.1 ± 4.3 kg/m2, respectively). All participants underwent standardized tests including echocardiography, cardiopulmonary exercise test (CPET), 6-minute walk test (6MWT), muscle function tests, balance tests, blood tests, QoL assessment as well as muscle biopsies from the vastus lateralis.
Results: HFpEF patients had worse bone mineral contents in both arms and legs (p < 0.05), reduced muscle mass in the trunk (muscle mass in the trunk/BMI 0.8 ± 0.2 vs. 1.0 ± 0.3, p = 0.02) and worse muscle strength both in arms (Peak torque internal rotation of the right shoulder 150° 24.4 ± 11.9 vs. 34.6 ± 14.0 Nm, p = 0.02) and legs (Peak torque knee eccentric extension 30°/right leg lean: 12.9 ± 5.0 vs. 18.0 ± 5.9 Nm/kg, p = 0.02). Patients with HFpEF scored worse in HADS-Questionnaire (Anxiety: 5.8 ± 3.6 vs. 2.8 ± 2.8, p = 0.02). Compared to HC, skeletal muscle dysfunction in patients with both HFpEF and HFrEF develops independently of age (p = 0.1). Patients with HFpEF and HFrEF showed worse exercise capacity both in 6MWT (495.6 ± 82.7 vs. 466.8 ± 131.8 vs. 600.7 ± 59.5 m, p = 0.001) as well as in the CPET (Peak VO2: 17.1 ± 4 vs. 14.9 ± 3.7 vs. 22.5 ± 3.1 ml/min/kg, p = 0.0001), reduced walking speed (10 m walking test: HFpEF vs. HFrEF vs. HC: 6.3 ± 1.6 vs. 6.8 ± 2.7 vs. 4.9 ± 0.8 sec. p = 0.01), worse balance capacity in walking forward and backward (p = 0.02) and worse muscle function in both extremities (Peak torque internal rotation dominant shoulder 150°/body weight%: 30.0 ± 12.9 vs. 37.5 ± 12.3 vs. 41.3 ± 11.4, p = 0.02; peak torque knee eccentric extension 30°/ body weight%: 139.5 ± 55.3 vs. 181.4 ± 40.2 vs. 202.9 ± 56.0, p = 0.004). Furthermore, patients with HF reported worse QoL (VAS: HFpEF vs. HFrEF vs. HC: 67.8 ± 19.2 vs. 62.7 ± 15.6 vs. 83.4 ± 10.1; P = 0.003). Interestingly, comparing HFpEF and HFrEF patients showed no significant difference in the reported daily physical activity in spite of the reduced muscle strength in patients with HFpEF (94.4 ± 53.1 vs. 74.2 ± 42.7 MET, p = 0.2). Peak torque internal rotation of the dominant shoulder 150°/body weight % correlated stronger with Peak VO2 in HFrEF than HFpEF (p = 0.001 r= 0.69 vs. p < 0.05, r = 0.46).
Conclusion: Patients with heart failure with preserved ejection fraction have worse muscle strength and quality of life compared to both healthy controls and patients with heart failure and reduced ejection fraction. Skeletal muscle dysfunction in patients with both HFpEF and HFrEF occurs independently of age and physical activity.

P1106

Cross talk between arterial stiffening and myocardial fibrosis in patients with heart failure: The role of galectin-3

E Evagelos Oikonomou[1]; D Karlis[2]; S Tsalamandris[2]; G Siasos[2]; C Chrysohoou[2]; G Vogiatzi[2]; S Dimitropoulos[2]; G Marinos[2]; G Charalambous[2]; E Kouskouni[2]; D Tousoulis[2]
[1]*Hippokration Hospital, University of Athens, 1st Department of Cardiology, Athens, Greece*; [2]*University of Athens Medical School, 1st Cardiology Department, "Hippokration" Hospital, Athens, Greece*

Background: Cardiac performance depends on optimum ventriculoarterial coupling which is impaired in patients with heart failure (HF). Galectin-3 is a mediator of myocardial fibrosis and remodeling, and is associated with clinical status in patients with chronic HF.
Purpose: To examine the association of arterial stiffness with galectin-3 levels in patients with HF of ischemic etiology.
Methods: We consecutive enrolled 40 subjects with stable ischemic HF and reduce ejection fraction. Central aortic stiffness was evaluated non-invasively by measurement of arotid femoral pulse wave velocity (PWV). Among other factors serum levels of galectin-3 and b-type natriuretic peptide (BNP) were measured in blood samples.
Results: The median values of galectin-3 in our study population was 12.9 (10.8-18.7) ng/ml and the mean value of PWV in our study population was 9.31 ± 2.79 m/sec. There was significant association of Galectin-3 levels with age (r = 0.48, p = 0.003) with creatine clearance (r=-0.66, p < 0.001) and with BNP levels (r = 0.36, p = 0.05). Importantly there was a significant association of Galectin-3 levels with pulse wave velocity (r = 0.37, p = 0.03) and patients with PWV above median had also significant increase levels of galectin-3 compare to patients with lower values of PWV [16.1(11.8-25.2) ng/ml vs. 12.1(10.5-14) ng/ml, p = 0.03] (Figure).
Conclusions: In the present study we found that there is association of arterial stiffness and PWV with galectin-3 levels in patients with chronic HF of ischemic etiology. These findings imply an additive alternative pathway driving arterial stiffening and myocardial remodeling in HF which give insight in the mechanism determining prognosis and clinical status of patients with HF.

Relationship between body composition characteristics and endothelial dysfunction according to heart failure types

A Orea-Tejeda[1]; R Sanchez-Santillan[1]; D Gonzalez-Islas[1]; L Castillo-Aguilar[1]; C Chavez-Mendez[1]; R Olivo-Villalobos[1]; G Davila-Said[1]; V Pelaez-Hernandez[1]; A Figueroa-Herrera[1]; M Rivera-Rodriguez[1]; K Balderas-Munoz[1]
[1]*Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico*

Introduction: Body composition has been identified as a risk predictor morbidity and mortality in heart failure (HF) patients. However, is unknown what differences are on body changes according to heart failure type
Purpose: To evaluate the relationship between endothelial dysfunction (ED) and body composition in patients according to heart failure type.
Methods: A total of 776 outpatients older than 18 years with chronic and stable HF, from our Heart Failure Clinic, were including in a cross-sectional study. We emphasized the roll of ED in the observed changes. Body composition was evaluated by bioelectrical impedance vector analysis (BIVA). Patients were divided in 3 groups: left heart failure reduced (HFrEP) or preserved ejection fraction (HFpEF), or right heart failure (RHF). Endothelial function was assessed by photoplestimography.
ED was considered in those with a maximum amplitude / over total time of the pulse wave (MAT / TT index) > 0.30 at rest and after post ischemia period.
Results: Of the total the 53% were male with a mean age 61.34 ± 17.15 years), in HFpEF and RHF predominating females 52.15 % and 37.04 %, p = 002, respectively. Weigth: 65.95 ± 16.77, 73.01 ± 21.46, 71.98 ± 21.81, p = 0.0007; Mid-Upper Arm Circumference: 28.37 ± 4.44, 29.81 ± 5.14, 29.31 ± 6.67, p = 0.051; Total Body Water (%) 56.30 ± 35.89, 52.09 ± 7.90,51.02 ± 7.21, p = 0.003; Extracellular water (%): 24.28 ± 3.10, 23.64 ± 3.58, 23.41 ± 3.06 P = 0.06; Phase Angle: 5.26 ± 1.40, 5.02 ± 1.28, 4.95 ± 1.05, p = 0.09; MAT / TT: 0.23 ± 0.18, 0.29 ± 0.09, 0.35 ± 0.06, p = 0.013, for HFrEP, HFpEF, RHF, respectively.
Conclusions: Muscle mass strength, and membrane cell integrity were worse in RHF, suggesting a most active inflammatory process.

P1108

The relationship between malnutrition and congestion in chronic heart failure

S Shirley Sze[1]; P Pellicori[2]; J Zhang[3]; AL Clark[1]
[1]*Castle Hill Hospital, Hull, United Kingdom*; [2]*University of Glasgow, Glasgow, United Kingdom*; [3]*Anglia Ruskin University, Cambridge, United Kingdom*

On behalf of: n/a
Funding Acknowledgements: n/a

Background: Mechanisms leading to malnutrition in chronic heart failure (CHF) are not fully understood. CHF is a condition characterised by systemic venous congestion. We hypothesized that malnutrition in CHF is related to right heart dysfunction and congestion which predispose to bowel oedema and malabsorption, thereby leading to malnutrition.
Methods: We assessed malnutrition using the geriatric nutritional risk index (GNRI) and studied its association with congestion, assessed either clinically or by echocardiography, in a large cohort of patients referred to a community CHF clinic.
Results: Of the 1058 patients enrolled, CHF was confirmed in 952 (69% males, median age 75(interquartile range (IQR):67-81) years, median NTproBNP 1141 (IQR: 465-2562) ng/L). 39% had HF with reduced (HeFREF, LVEF < 40%) and 61% had HF with normal (HeFNEF, LVEF = 40% and NTproBNP>125 ng/l) left ventricular ejection fraction.
Overall, 14% of patients were malnourished (GNRI = 98). Clinical evidence of congestion, increasing right atrial pressure (RAP) and pulmonary artery pressure and right ventricular systolic dysfunction (RVSD) on echocardiography were associated with malnutrition. Addition of congestion variables to a model comprising of age and NTproBNP did not improve discrimination between malnourished and non-malnourished patients.
During a median follow-up of 1683 days (IQR: 1096-2230 days), 461 (44%) patients died. Malnutrition was an independent predictor of mortality. Patients who were malnourished with both RVSD and increased RAP had 6-fold increased risk of mortality compared to non-malnourished patients without RVSD and had normal RAP. (Figure)
Conclusion: Malnutrition and congestion are modestly correlated and each is independently associated with increased mortality in patients with CHF.

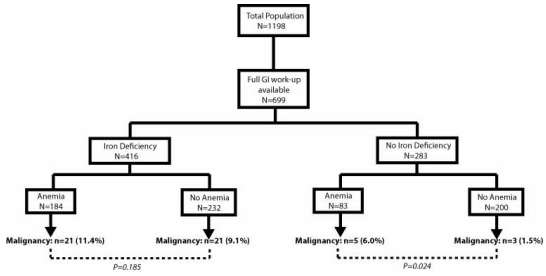
P1109

Prevalence of underlying gastro-intestinal malignancies in iron deficient heart failure.

P Pieter Martens[1]; L Minten[1]; M Dupont[1]; W Mullens[1]
[1]*Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium*

Funding Acknowledgements: FWO, grant-number: 1127917N

Background: Anemia and iron deficiency (ferritin < 100μg/l or 100-300μg/l with transferrin saturation < 20%) is prevalent in heart failure. Mechanistically, iron deficiency is linked to poor intestinal uptake, increased intestinal loss and chronic inflammation. However, the prevalence of underlying gastro-intestinal malignancies are not established in iron deficient heart failure with or without anemia.
Methods: Patients followed in a single-center, heart failure database with baseline registration of hemoglobin and iron-status were retrospectively evaluated. The proportion of patients undergoing upper and lower gastro-intestinal endoscopy between inclusion and censoring was determined. Afterwards the prevalence of biopsy confirmed intestinal malignancies in relation to baseline iron and hemoglobin status was determined. Anemia was defined according to WHO-criteria (hemoglobin < 12g/dl in females or < 13g/dl in males) and iron deficiency according to aforementioned criteria.
Results: Of the 1197 patients in the database, 699 (59%) patients underwent full endoscopic work-up over a mean follow-up of 50 ± 27 months. A total of 50 intestinal malignancies were identified (n = 42 [84%] in iron deficient vs n = 8 [16%] in non-iron deficient patients; p < 0.001). The prevalence of intestinal malignancies was highest in patients with iron deficient anemia (n = 21/184, 11%), however was not statically different from patients with iron deficiency without anemia (n = 21/232, 9%; p = 0.185). The prevalence was much lower in patients without iron deficiency, with (n = 5/83, 6%) or without anemia (n = 3/200, 1.5%). In patients with iron deficiency but without anemia (a group in which the role of endoscopic work-up is less established), a ferritin above 100 μg/L had a negative predictive value of 98.4% of excluding an underlying gastro-intestinal malignancies.
Conclusions: Endoscopic evaluation is warranted in heart failure patients with iron deficient anemia given the high prevalence of underlying intestinal malignancies. In patients with iron deficiency without anemia, an endoscopic workup might be reserved for patients with a ferritin bellow 100 μg/l, as a ferritin above this value carries a high negative predictive value to exclude the contribution of an underlying intestinal malignancy to the state of iron deficiency.



P1110

Hypovitaminozis d is related with inflammatory parameters in patients with heart failure

A Celik[1]; O Orscelik[1]; IT Ozcan[1]
[1]*Mersin University, Cardiology, Mersin, Turkey*

Introduction: Hypovitaminosis D has been observed to be highly prevalent in HF patients. Some data suggest that vitamin D deficiency is associated with the progression of HF and may be an independent predictor of mortality in patients with HF. Low vitamin D levels may contribute to the pro-inflammatory status present in HF, and may therefore play an important role in the development and progression of HF. Neutrophil lymphocyte ratio (NLR) is an accepted marker reflecting inflammatory status of body. In this study, we investigated the relationship between the level of vitamin D and NLR in patients with HF.
Methods: This is a single center observational study included the consecutive 57 HF patients (HFpEF, HFmrEF, HFrEF). Patients were divided into two groups according to vitamin D levels as < 20 ng/ml and = 20 ng/ml.
Results: The mean vitamin D level was 19.1 ± 12.4 ng/mL. There was no significant difference between HF types in terms of vitamin D levels (p = 0.53). Similarly, compared patients with lower and normal vitamin D levels, the properties of patients were similar (Table 1). Patients with lower vitamin D levels had significantly higher NLR and CRP value (Table 1). Vitamin D levels were significantly negative correlated with NLR levels (Figure 1).

Table 1

	Vitamin D <20 ng/mL (n = 34)	Vitamin D ≥20 ng/mL (n = 23)	p
Age, year	64.5 ± 11.8	65.9 ± 11.7	0.67
Gender, f/m	15/19	8/15	0.43

NLR	3.7 (0.22-19)	2.7 (0.24-6.48)	0.03

The demographic and biochemical properties of patients

Conclusion: Hypovitaminosis D is associated with inflammatory status in HF patients. Vitamin D substitution may reduce pro-inflammatory parameters in HF. Further studies are needed to confirm the use of vitamin D for regression of inflammatory parameters in patients with HF.

MIA syndrome - malnutrition, inflammation and atherosclerosis - in acute decompensated heart failure, prognosis and prevalence.

L Luisa Malvar Goncalves[1]; INÊS Pires[1]; LUÍS Abreu[1]; JULIO Pereira[1]; HUGO Antunes[1]; DAVIDE Moreira[1]; INÊS Almeida[1]; COSTA Cabral[1]
[1]*Hospital Sao Teotonio, Department of Cardiology, Viseu, Portugal*

Introduction: A strong association between malnutrition (M), inflammation (I) and atherosclerosis (A) suggests the presence of MIA syndrome, which is associated with high mortality (D). Cardiovascular disease is already associated with the 3 components (C) of MIA syndrome (MIAs). The concomitant presence of Heart Failure (HF) and MIAs should be a factor of poor prognosis.
Objective: The aim of this study was to evaluate the prevalence and prognosis of MIAs in Acute decompensated HF (ADHF).
Methods: We selected patients (P) admitted in a Cardiology ward by ADHF between 2007 and 2013. Follow-up of 24 months (m). The levels of PCR (< 0.50mg/ dL), albumin (< 3.5g/ dL), and the presence of dyslipidemia served as markers of I, M and A, respectively. The presence of MIAs was validated by the concomitant presence of 3 C (3-MIA), but the additive value of the C were also verified. Division into groups: 3-MIA, two C (2-MIA), one C (1-MIA) and zero C (0-MIA).

Results: Sample of 793 P, 50.7% male, mean age of 77.1 ± 10.2 years. 1-MIA in 42.4% (n = 336), 2-MIA in 39.3% (n = 312), 0-MIA in 11.7% (n = 93) and 3-MIA in 6.6% (n = 52). I in 78.7% (n = 624), A in 40.7% (n = 232) and M in 21.3% (n = 160). No differences in gender or age between P with 3-MIA and P without MIAs (0, 1 or 2 C). The P with 0 or 1-MIA had greater predominance of hypertension (HTA), whereas P with 2 or 3-MIA had a greater predominance of HTA and Diabetes (X2 = 17.7, p = 0.04). The higher the number of C, the more likely the P were medicated with loop diuretic (X2 = 10.3, p = 0.016) and statin (X2 = 95.3, p = 0.0001). P with 3-MIA had the lowest probability of HF diagnosis before hospitalization (X2 = 6.4, (p = 0.01), lower systolic and diastolic BP on admission (130.1 ± 26.0 vs 139.1 ± 30.9 mmHg, p = 0.02 and 76.5 ± 12.9 vs 81.3 ± 43.9 mmHg, p = 0.05, respectively), and higher mean GGT (243.9 ± 316.9 vs 95.3 ± 110.7 UI/L, p = 0.005), AST (292.3 ± 859.3 vs 49.1 ± 76.3 UI/L, p = 0.011) and ALT values (227.4 ± 597.4 vs 53.8 ± 144.5 IU/L, p = 0.023).
The presence of 3-MIA correlated with a greater interventricular septum thickness (11.7 ± 3.2 vs 13.0 ± 6.6 mm, p = 0.018) and greater number of days of hospitalization (11.3 ± 6.9 vs. 8.7 ± 6.7 days, p = 0.012). The MIAs did not correlated with rehospitalization for HF. The highest mortality rate at 3 and 6 months was found in P with 3-MIA, followed by 2-MIA, and finally the P with 0 or 1-MIA (Kaplan-Meier: X2 = 9.99, p = 0.019 and X2 = 9.52, p = 0.023, respectively). The multivariate analysis verified that the mortality was independent of the differentiating characteristics between the groups.
Conclusion: The presence of MIAs is common in HF and it is an independent factor of poor prognosis. An assessment of the presence of MIAs in practice will allow a more individualized approach, more rigorous follow-up and research of new therapeutic targets.

P1112

Chronic heart failure in liver transplant recipients: etiology, frequency, management.

A Babich[1]; H Kosmacheva[1]
[1]*the Scientific Research Institute-Regional Clinical Hospital 1 , Krasnodar, Russian Federation*

Background: Cardiovascular diseases are among the most frequent causes of patient death after liver transplantation. Due to recent improvements in survival of liver transplant, there is only few data available analyzing the prevalence and management of chronic heart failure (CHF) in liver recipients.
Purpose: The aim of this retrospective clinical study was to estimate the etiology, frequency and management of chronic heart failure before and after liver transplantation. A total of 115 patients who had undergone successful liver transplantation between 2010 and 2016 at the Scientific Research Institute-Regional Clinical Hospital ?1 were studied.
Results: Mean age was 53 ± 13 years and 66 (57.4 %) were men. Chronic heart failure was verified in 20.9% of patients before liver transplantation, among them NYHA class I - 37.5%, NYHA class II- 50%, NYHA class III - 12.5%. Chronic heart failure was considered to develop due to arterial hypertension in 58.3% of patients, due to coronary heart disease (CHD) in 37.5%, among them six patients had a combination of CHD and arterial hypertension. One case of anteroseptal myocardial infarction (CHF - NYHA class II), 3 new cases of CHF were registered as a complication of arterial hypertension 6 months after liver transplantation. Over 1 year, we observed elevation of new-onset CHF (13%) compared with preoperative, among them NYHA class I had 63.3%, NYHA class II - 36.4% (arterial hypertension and CHF - 90.9%, coronary heart disease and CHF - 9.1%).
Beta-blockers were administrated in 75%, among them 88.9% received nonselective agents - propranolol, 11.1% - bisoprolol before liver transplantation. 24 patients without cardiac pathology and CHF were assigned to propranolol, which is probably associated with portal hypertension in patients before liver transplantation. Retrospective analysis revealed that only 7.1% of recipients with CHF received beta-blockers after 6 months and 7.7% after one year transplantation. ACE inhibitors were received in 16.7% of patients before surgery, after 6 months and after one year - 3.6% and 10.3%, respectively.
Conclusions. The development of chronic heart failure arises after transplantation. We suggest that it is vitally important to manage transplant-related CHF effectively by paying our physicians' attention to administration of ACE inhibitors and beta-blockers.

P1113

Chronic kidney disease in diabetic chronic heart failure patients

EV Reznik[1]; VA Lazarev[1]; MS Komissarova[1]; ED Presnova[1]; IG Nikitin[1]; AV Salikov[2]
[1]*Russian National Research Medical University, Internal Disease 2 Department, Moscow, Russian Federation*; [2]*12 Moscow's Clinical Hospital, Moscow, Russian Federation*

Introduction and Purpose: ?omorbidities are common in chronic heart failure (CHF) and associated with increased mortality and morbidity risk, increased complexity of clinical management, increased disability and poor quality of life. Our purpose was to study chronic kidney disease in patients with chronic heart failure (CHF) and type 2 diabetes mellitus (T2DM).
Methods: We analyzed 1629 CHF patients who were hospitalized in multifield Moscow's Clinical hospital during 3 years. Left ventricular ejection fraction (LVEF, Simpson) < 45% was in 20.4% of CHF patients. 23.4% of CHF patients had T2DM. 47.2% of them had permanent atrial fibrillation. We estimated renal function (glomerular filtration rate - eGFR, CKD-EPI formula) and proteinuria in 137 patients with CHF and LVEF < 45% and T2DM (CHF-T2DM) without primary renal and oncological diseases. Median (interquartile range) of age was 61.0 (60.0-74.0) years; LVEF - 32.5 (23.0-42.0) %; HbA1c - 7.4 (6.4-8.3) %; NT-Pro-BNP 4430 (3570-12000) ng/l; 54.7% males. All patients received medical therapy in accordance with contemporary guidelines. Oral hypoglycemic drugs were prescribed to 35.8%, insulin - 28.2%, combination of oral hypoglycemic drugs and insulin - in 6.1% of CHF-T2DM patients. Duration of hospitalization was 9 (7-11) days.
Results: 95.4% and 83.2% of patients had arterial hypertension and myocardial infarction in anamnesis respectively, 15.3% had postinfarction aneurysm with thrombus in 42.9%. I NYHA class was in 2.7%, II - in 11.1%, III - in 80.3%, IV - in 5.9% of CHF-T2DM patients. eGFR was 50.9 (38.9-64.8) ml/min/1.73m2. Proteinuria was in 38.7% and its level was 0.5 (0.3-1.0) g/l. Chronic kidney disease 2 stage was in 26.2%, 3a - in 27.7%, 3b - in 28.5%, 4 - in 9.2%, 5 - in 3.1% of CHF-T2DM patients. Hemoglobin level was 134 (119-150) g/l. The death rate during follow-up was 23.6%. Mortality was higher in patient with lower eGFR (p = 0.007) and more severe CHF (higher NYHA class, p = 0.038) but wasn't associated with LVEF, NT-Pro-BNP, HbA1c.
Conclusions: 94.6% of patients with systolic chronic heart failure and type 2 diabetes mellitus have chronic kidney disease. Clinical severity of CHF and low renal function are associated with mortality risk in these patients. Future studies of mechanisms of cardiorenal syndrome and effective treatment methods are required to improve survival of patients with chronic heart failure and type 2 diabetes mellitus.

P1114

Persistence of periodic breathing/Cheyne-Stokes respiration after tilt table test during short term respiratory monitoring in patients with systolic heart failure

C Chiara Borrelli[1]; F Gentile[2]; F Rossari[1]; P Sciarrone[2]; C Passino[3]; G Mirizzi[3]; F Bramanti[3]; G Iudice[3]; M Emdin[3]; A Giannoni[3]
[1]*Sant'Anna School of Advanced Studies, Pisa, Italy*; [2]*University of Pisa, Pisa, Italy*; [3]*Gabriele Monasterio Foundation, Pisa, Italy*

Background: Although periodic breathing (PB: hyperventilation/hypopneas) and Cheyne-Stokes respiration (CSR: hyperventilation/apneas) are usually considered to occur in lying and sleeping conditions in patients with heart failure (HF), there are recent evidences that both phenomena may spread throughout the 24-hour.
Purpose: We aim to evaluate whether PB/CSR may be observed in awake and orthostatic conditions in patients with systolic HF.
Methods: A total of 202 chronic systolic HF patients on optimal guideline-recommended treatment (left ventricular ejection fraction of 33 ± 9%; 66 ± 12 years of age; 79% males) underwent beyond echocardiography, pulmonary function test, 24-h electrocardiographic and respiratory recording and neurohormonal evaluation (natriuretic peptides, plasma norepinephrine, renin activity and aldosterone levels), a short term attended respiratory monitoring during tilt table testing (10 minutes in clinostatism and 10 minutes in orthostatism). A short term scoring from 0 to 3 was created, with 0 being normal respiration, 1 and 2 being respectively PB and CSR disappearing in orthostatism and 3 being PB/CSR persisting in orthostatism.
Results: The prevalence of scores 0-1-2-3 were 54%, 12%, 22% and 11%, respectively. The score was predictive of apnea-hypopnea index severity at the 24-h recording (all p <0.001), both during daytime (from 0 to 3: 7 IR 2-15, 10 IR 3-15, 16 IR 8-25, 26 IR 12-33 events/h), nighttime (20 IR 6-29, 19 IR 13-31, 25 IR 18-36, 37 IR 25-48 events/h) and the 24-hour (13 IR 5-21, 13 IR 9-20, 21 IR 12-29, 32 IR 20-36 events/h). At univariate, logistic multinomial analysis predictors of persistence of PB/CSR in orthostatism were moderate to severe mitral regurgitation (MR), left atrial volume and baseline atrial fibrillation (AF), while at multivariate analysis only MR (OR 3.5, CI 1.04-11.8, p = 0,043) and AF (OR 4.4; CI 1.3-14.7; p = 0.017) resulted as independent predictors.
Conclusions: In HF patients, a short term recording performed during tilt testing is able to stratify the severity of PB/CSR both during daytime, nighttime and the 24-hour, with MR and AF being independently associated with persistence of PB/CSR in awake/orthostatic conditions.

P1115

Cognitively impaired versus cognitively non-impaired chronic heart failure patients: which distinctions?

A Anastasiia Solonovych[1]
[1]*NSC Institute of Cardiology M.D. Strazhesko, Heart Failure Department, Kiev, Ukraine*

Background: Cognitive dysfunction (CD) is one of the most common disorders in cardiovascular patients (pts). In chronic heart failure (CHF) CD is observed in more than half of pts and closely correlates with age, severity of disease and quality of life. Nevertheless, evidence of association between cognitive function (CF) and other clinical characteristics in CHF patients is still lacking.
Purpose: To compare the spectrum of clinical variables in CHF patients in relation to presence of CD.
Methods: 94 stable CHF pts, NYHA II-IV with left ventricular ejection fraction (LVEF) < 40% were examined. CF was evaluated by using standard MMSE and Shulte tests. Cognitive dysfunction was defined as MMSE= 26 points. Besides routine examination, the 6-minute walk test, quality of life evaluation by The Minnesota Living with Heart Failure Questionnaire (MLHFQ), interview by HADS questionnaire and flow-mediated vasodilatory response (FMVR) examination by standard cuff test were performed.
Results: CD (abnormal MMSE and Shulte tests) was observed in 60 (63.8 %) patients. There was no impact of gender, LVEF, hemoglobin level, diabetes on the results of CF tests. Simultaneously, CD in patients with CHF was associated with higher NYHA class (p = 0.0001), history of hypertension and coronary heart disease (CHD) (p = 0.004 and p = 0.001 respectively). Patients with cognitive impairment were significantly older (p = 0.0001), had worse MLHFQ score (p = 0.018), higher HADS depression score (p = 0.001), lower glomerular filtration rate (GFR) (P = 0.001), lower plasma iron (p = 0.046) and worse FMVR (p = 0.013) compared to non-CD patients.
Both MMSE score and results of Shulte test significantly correlated with the 6-minute walk test (r = - 0.492, p = 0.0001 and r = 0.464, p= 0.0001, respectively), with MLHFQ (r = -0.268, p = 0.018 and r = 0.327, p = 0.001, respectively), age (r = -0.492, p = 0.0001 and r = 0.464, p = 0.0001, respectively), GFR (r = 0.325, p = 0.001 and r = -0.221, p = 0.033, respectively) and with HADS depression score (r = -0.256, p = 0.013 and r = 0.262, p = 0.011, respectively). Both groups showed no difference in 1-year survival rate (p= 0.219) but hospitalization rate was higher in CD-group (p = 0.026).
Conclusion: CD was observed in almost 2/3 of stable CHF patients; it associates with higher NYHA class, history of hypertension and CHD, with worse quality of life, lower GFR and plasma iron, worse FMVR, higher depression score and higher 12-month hospitalization rate.

P1116

FAR NHL FARmacology and NeuroHumoraL activation in chronic heart failure - one year prognosis

J Spinar[1]; L Spinarova[2]; J Parenica[2]; M Spinarova[2]; K Labr[2]; F Malek[3]; P Ostadal[3]; J Jarkovsky[4]; O Ludka[1]
[1]*University hospital Brno and Masaryk university, Brno, Czech Republic*; [2]*University hospital, Brno, Czech Republic*; [3]*University Hospital, Prague, Czech Republic*; [4]*Masaryk University, Brno, Czech Republic*

On behalf of: FAR NHL investzigators
Funding Acknowledgements: University hospital Brno

The FAR NHL (FARmacology and NeuroHumoraL activation) registry is a database of patients treated in 3 departments with specialized heart failure care in one country. Anamnestic data, physical examination and blood samples were collected from November 2014 till November 2015. One year prognosis - mortality and hospitalisation was evaluated till November 2016. The aim of the study is to evaluate the one year prognosis and factors influencing neurohumoral activity of Nt-proBNP and the role of disease severity and comorbidities in patients with stable systolic chronic heart failure with reduced or mid range ejection fraction. The patients should be treated for systolic heart failure (EF < 50%) and stable for at least one month. Parameters of the AHEAD prognostic score (0 = no comorbidity, 5 = five comorbidities) were used to reflect the impact of comorbidities on neurohumoral activation and prognosis.
Results: 1050 patients were included, mean age 65 years, 889 (80,8%) were male. 146 (13,3%) were classified as NYHA I, 663 (60,3%) NYHA II and 285 (25,9%) as NYHA III and 6 (0,5%) NYHA IV. The Nt-proBNP levels for the different NYHA classes were 150 resp. 489 resp. 1 085 pg/ml (p <0,001) and there where no sex differences 494 vs 456 pg/ml (for different NYHA: 153 vs 489 vs 1142 for male and 108 resp. 461 resp. 907 for female; p <0,001 for NYHA, but NS for gender).
Patients with AHEAD score 0 had Nt-proBNP 228pg/ml, AHEAD 1-2 369 pg/ml and AHEAD 3-5 654 pg/ml (p <0,001) and these differences were highly significant for all separate comorbidties. There was a highly significant difference in patients with and without atrial fibrillation 432 vs 1035 pg/ml (p <0,001) and these differences were significant in all NYHA classes (142 vs 432 vs 1126 without AF and 890 vs 1043 vs 1058 with AF, all p < 0,001 for NYHA as well as for presence of AF). There was statistically significant difference according to age 416 pg/ml (<65 years) and 623 pg/ml (above 65 years; p <0,001).There was a close correlation between Nt-proBNP and renal functions; CrCl < 50 ml/min 1153pg/ml, 50-70 764 pg/ml and > 70 365 pg/ml and this difference was partly independent on NYHA class.
The general pharmacotherapy was qood 93,% of the patients received beta blockers and 88,4% druggy blocking renin angiotensin system (ACE-I and/or ARB). But the doses of the drugs were frequently not sufficient. The main predictor for no dose or low dose for bose RAAS inhibitor and betablockers was high NYHA class, high NT-proBNP level and low creatinin celearance.
The one year mortality according to AHEAD score (p < 0,001), NYHA classification (p <0,001) and Nt-pro BNP levels (< 0,001) showed high statisticaly significant differences.
Summary: Nt-proBNP levels reflect the severity of heart failure, but are strongly dependent on the presence of comorbidities. All markers of desease severity, especially NT-proBNP levels, AHEAD score and NYHA classifications are strong predictors of one year mortality.

P1117

Heart remodeling and its prevention in patients with chronic heart failure due to coronary artery disease combined with chronic obstructive pulmonary disease

V Vladimir Evdokimov[1]; E Kovalenko[1]; E Zolotareva[1]; A Evdokimova[1]; G Voronina[1]; K Tebloev[1]
[1]*State University of Medicine & Dentistry, Moscow, Russian Federation*

Purpose: to determine structural and functional changes in the heart in patients with chronic heart failure (CHF) due to coronary artery disease (CAD) combined with chronic obstructive pulmonary disease (COPD) and the possibility of their correction with nebivolol and enalapril or losartan administration.
Methods: 158 patients (128 men and 30 women), aged 63.5 ± 4.8 years, with CHF classes II to III (New York Heart Association) combined with moderate and severe COPD (GOLD-2015) and with initial ejection fraction of the left ventricle (LVEF) less than 45%, were randomized to three groups - enalapril/nebivolol (60 patients), nebivolol/losartan (40 patients) and enalapril (58 patients) group. Patients of all groups received complex CHF treatment comprising diuretics, cardiac glycosides (subject to indications) and basic COPD therapy (long acting m-anticholinergic, inhalation corticosteroids). Patients were evaluated through echocardiography (including wide spectrum of right and left side parameters), exercise tests, 24-hour electrocardiography, respiratory function at baseline and after 6 months of treatment. The quality of life was evaluated by MYHFQ and SGRQ.
Results: At baseline of the study in all patient were established progressive changes in the processes of LV and RV remodeling with increasing of their sizes, wall thickness and myocardial mass index (MMI), with a decrease of ejection fraction and progression of diastolic dysfunction. After 6 months of therapy the improvement of clinical condition and quality of life were marked in all groups. In 1st, 2nd and 3rd group LVEF was increased by 21.5%, 19.6% and 15.2%, RVEF was increased by 6%, 6.4% and 5.2%, pulmonary hypertension decreased by 23%, 25.2% and 16.4%, MMI decreased by 15.5%, 14.8% and 8.2%, left ventricular end diastolic volume index decreased by 16.5%, 14.4% and 10.4% respectively. Patients showed statistically significant and clinically meaningful reduction of SGRQ score (8.8%, 12.2% and 11.8%) and MYHFQ score (39.8%, 44.2% and 31.6%), significant improvements in MMRC dyspnea grade (21.3%, 23.5% and 15.3% respectively). Episodes of silent myocardial ischemia decreased by 45.2%, 46.9% and 29.9%, respectively. Respiratory function tests after 6 months did not show any negative changes in all groups.
Conclusions: The nebivolol and enalapril or nebivolol and losartan inclusion in the structure of complex therapy in patients with CHF combined with COPD raises efficiency of treatment, improves quality of life, basic parameters of central hemodynamics and prevent further heart remodeling. Efficacy and safety of nebivolol/enalapril and nebivolol/losartan combinations in patients with CHF due to CAD combined with COPD are similar.

P1118

Discrepancy in prevalence of impaired glucose regulation and diabetes according to screening method in outpatients with chronic heart failure

SL Kristensen[1]; M Egstrup[1]; C Tuxen[2]; P Hildebrandt[3]; C Kistorp[4]; JJV Mcmurray[5]; L Kober[1]; M Schou[6]; I Gustafsson[7]
[1]*Rigshospitalet - Copenhagen University Hospital, Cardiology, Copenhagen, Denmark*; [2]*Bispebjerg University Hospital, Department of Cardiology, Copenhagen, Denmark*; [3]*Frederiksberg Heart Clinic, Copenhagen, Denmark*; [4]*Herlev Hospital - Copenhagen University Hospital, Department of Endocrinology, Copenhagen,*

Denmark; [5]*Cardiovascular Research Centre of Glasgow, Cardiology, Glasgow, United Kingdom*; [6]*Herlev Hospital - Copenhagen University Hospital, Department of Cardiology, Copenhagen, Denmark*; [7]*Hvidovre UniversityHospital, Department of Cardiology, Copenhagen, Denmark*

Background: Diabetes and impaired glucose regulation (IGR) are frequent among patients with heart failure (HF). Both are believed to be most accurately diagnosed by measuring fasting plasma glucose (FPG), and performing a 2-hour oral glucose tolerance test (OGTT) why we considered combining these tests as the golden standard. We analysed how measurement of glycated hemoglobin (HbA1c) compares to FPG/OGTT in estimating the prevalence of diabetes and IGR.
Methods: In a cohort of 254 outpatients with chronic HF (LVEF < 45%), mean age 69 years, 67% men and no history of diabetes, FPG and HbA1c were measured in all patients and 252 patients completed an OGTT. IGR was defined by an impaired FPG (6.1-6.9 mmol/l) and/or impaired OGTT (2hPG 7.8-11.0 mmol/l), and diabetes by a FPG = 7 mmol/l and/or 2hPG = 11.1 mmol/l. For HbA1c, IGR was defined by a measurement of 6.0-6.4% and diabetes = 6.5%.
Results: A total of 51 (20%) patients had diabetes of which 17 (33%) had an HbA1c indicating diabetes, 17 (33%) an HbA1c indicating IGR and 17 (33%) a normoglycemic HbA1c (Table 1). IGR was found in 82 (32%) patients of whom 13 (16%) had diabetes, 20 (24%) IGR and 49 (60%) normoglycemia, according to HbA1c. Finally among 121 (48%) patients with normoglycemia, HbA1c measurement indicated diabetes in 5(4%) patients, IGR in 24 (20%) and normoglycemia in 92 (76%) patients (Table 1).
Conclusion: In a cohort of outpatients with chronic HF, measurement of HbA1c only detected 1 out of 3 patients with diabetes as diagnosed by FPG/OGTT (although 2 out of 3 had either diabetes or IGR as assessed by HbA1c). Only 1 out of 4 patients with IGR were correctely identified by HbA1c although 40% had either diabetes or IGR by HbA1c criteria. Normoglycemia was more accurately identified by HbA1c measurement, although still only in 76% of patients. The estimated prevalence of diabetes and IGR is lower when using HbA1c than FPG/OGTT. It should be noted, however, that most guidelines recommend a repeated measurement, regardless of screening method, which was not performed in the current study.

HbA1c vs OGTT in screening for diabetes

		HbA1c		
OGTT (FPG + 2-h value)	Subjects	Normoglycemia (%)	Impaired glucose regulation (%)	Diabetes (%)
Total	254	158 (62%)	61 (24%)	35 (14%)
Normoglycemia	121 (48%)	92 (36%)	24 (9%)	5 (2%)
Impaired glucose regulation	82 (32%)	49 (19%)	20 (8%)	13 (5%)
Diabetes	51 (20%)	17 (7%)	17 (7%)	17 (7%)

HbA1c - Glycated hemoglobin A1c, OGTT - oral glucose tolerance test, FPG - fasting plasma glucose

P1119
Bronchial obstruction contribution to chronic heart failure in patients with permanent atrial fibrillation along with coronary artery disease and arterial hypertension

N Natalia Koziolova[1]; E Polyanskaya[1]; S Berestneva[1]; O Masalkina[1]
[1]*Medical Academy, Perm, Russian Federation*

Aim: to evaluate COPD contribution to chronic heart failure(CHF) in patients with permanent atrial fibrillation (AF) along with coronary artery disease (CAD) and arterial hypertension depending on forced expiratory volume (FEV1) after bronchodilation test in spirometry.
Methods and materials: 41 patients with COPD and CHF along with arterial hypertension and CAD were examined. Average age 60,1+9,3. FEV1 was evaluated in all the patients after bronchodilation test, as well as NT-proBNP, left ventricle ejection fraction (LV EF), E/e' (via echo). Patients were divided into 3 groups depending on FEV1 after bronchodilation test according GOLD Guidelines.
The 1st group included patients with slight COPD (FEV1>80%, n = 6, 14,6%). The 2nd group - moderate COPD (FEV1 = 50-80%, n = 29, 70,7%). The 3rd group consisted of severe COPD FEV1 = 30-50%, n = 5, 12,2%). Patients with terminal COPD excluded from the study.
Results: NT-proBNP was significantly higher in group 3, than in group 1 and group 2 (pmg < 0,001) (958,8+101,2 ng/mL, 634,7+88,1 ng/mL, 498,5+62,8 ng/mL (p1-2, p1-3, p2-3 < 0,001) respectively). LV EF presented as moderately reduced in all the groups and did not differ between of them: group 1 - 48,6+6,1%, group 2 - 45,9+7,6%, group 3 - 44,2+7,8%. Reliable difference was found in average transmitral flow velocity E/e': group 1 - 14,7+1,8, group 2 - 15,8+1,5, group 3 - 17,0+1,9 (pmg= 0,002; p1-2 = 0,033, p1-3 = 0,0008, p2-3 = 0,0002). Correlation analysis showed indirect moderate interconnection between NT-proBNP and FEV1 (r=-0,48, p = 0,010), and indirect severe interconnection between E/e' and FEV1 (r=-0,69, p = 0,008).
Conclusion: in patients with COPD and permanent AF (in presence of arterial hypertension and CAD), there was indicated a progressive increase of HF severity (estimated by NT-proBNP and E/e') along with decreasing of post-dilation FEV1.

P1120
Iron deficient versus iron non-deficient chronic heart failure patients: which distinctions?

VG Vera Gorbachova[1]; A Liashenko[1]; T Gavrilenko[1]; L Voronkov[1]
[1]*NSC Institute of Cardiology M.D. Strazhesko, Heart failure, Kiev, Ukraine*

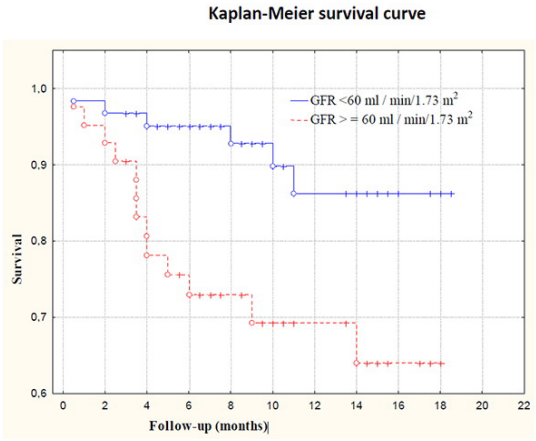
Background: According to FAIR-HF and CONFIRM-HF approach, both plasma ferritin (F) and transferrin saturation (TSAT) are considered to be an iron deficiency (ID) criteria in chronic heart failure (CHF). Nevertheless, it is still a question whether the obligate measurement of both F and TSAT is necessary in detection of ID in CHF.
Purpose: To compare clinical variables of CHF patients (pts) with ID and without ID; to evaluate the clinical significance of plasma F and TSAT in CHF patients with reduced left ventricular ejection fraction (LVEF).
Methods. 104 stable CHF patients (NYHA class II-IV, LVEF < 40%) were examined. Plasma F, IL6 and NTproBNP were determined by immunoassay, TSAT - by colorimetric assay. Beside routine clinical and laboratory examination, 6 min walk test (6MWT), standardized endurance leg extensor test and flow-mediated vasodilation (FMD) of the brachial artery were performed. Quality of life was measured with The Minnesota Living With Heart Failure Questionnaire (MLHFQ). Statistical calculations were made by Spearman's rank correlation coefficient, Student's t-criteria, Pearson's chi-squared test and Kaplan-Meyer estimator.
Results: ID was observed in 65 pts (62.5%).
No differences were observed between groups in regard to age, systolic blood pressure, heart rate, myocardium mass index, LVEF. Nevertheless, pts with ID are characterized by significantly higher NYHA class (p = 0.003), NTproBNP (p = 0.016) and IL6 levels (p = 0.040), lower Hb level (p = 0.004), lower glomerular filtration rate (p = 0.043), worse MLHFQ score (p = 0.031) and leg extensor endurance test (p = 0.024), reduced functional capacity (p = 0.007).
No correlations were found between plasma F and any main clinical variables, except Hb level. In contrast, TSAT significantly (p < 0,05) correlated with Hb (r = 0,40, p = 0,0003) and NTproBNP levels (r=-0,29, p = 0,050), 6MWT (r = 0,36, p = 0,0002), leg extensor test (r = 0,38, p= < 0,0001), MLHFQ (r=-0,27, p = 0,005) and the Duke University questionnaire (r = 0,23, p = 0,019).
All-cause mortality and combined point of mortality and hospitalization in a follow-up period of 9.5 month was significantly higher in ID group 26.1% vs 10.2% p = 0.050 and 55.4% vs 30.8%, p = 0.014 respectively.
Conclusions: Only 1/3 CHF patients do not have an ID; they are characterized by the better functional capacity, lower NTproBNP levels and better FMD response in comparison to the ID patients. Patients with ID are characterized by the lower Hb level and lower GFR, and by the higher value of IL6 and NTproBNP, higher mortality and hospitalization rate. Unlike F concentration, TSAT shows statistically significant correlations with the main parameters that represent the quality of life, patient's functional capacity and the NTproBNP level.

P1121
Renal dysfunction versus preserved renal function in chronic systolic heart failure: which patients?

A V Liashenko[1]; A E Dudnik[1]; T I Gavrilenko[1]; G V Ponomareva[1]; L G Voronkov[1]
[1]*NSC Institute of Cardiology M.D. Strazhesko, Heart failure, Kiev, Ukraine*

Background: It is known that prognosis of ?hronic heart failure (?HF) with renal dysfunction (RD) is associated with worse outcome. Finding out clinical features of patients (pts) with denoted combined pathology suggests to be useful in further understanding of the way to improve the prognosis CHF.
Purpose: To create comparative characteristics between two groups of CHF pts: with RD and preserved renal function.
Methods. 104 stable CHF pts (NYHA ??-?V, left ventricular ejection fraction (LV EF) < 40 %) were examined. According to the status of renal function, pts were divided in 2 groups: with glomerular filtration rate (GFR) <60 ml / min / 1.73 m2, and with GFR = 60 ml / min / 1.73 m2. GFR was calculated by CKD EPI formula. Daily microalbuminuria (MAU) was detected by immunoturbidimetric method. NTproBNP and interleukin-6 (IL-6) levels in plasma were determined by the immunoassay method. Plasma levels of citruline and myeloperoxidase activity were studied by spectrophotometry. Survival was analysed by the Kaplan-Meier method.
Results: Clinically relevant RD was observed in 42 pts (40,3%). There were no significant differences in both groups by: LVEF (p = 0,443), atrial fibrillation rate (p = 0,054), anemia rate (p = 0,158), heart rate (p = 0,357), systolic blood pressure (p = 0,286), NT proBNP level (p = 0,124) and activity of myeloperoxidase (p = 0,958).

Supr?s?ngly, there were no differences in MAU level (p = 0,45). At the same time, RD group demonstrate higer levels of blood urea nitrogen (BUN) (p = 0,0001), uric acid (UA) level (p = 0,0003), serum IL-6 (p = 0,0142) and serum citrulin levels (p = 0,0001). RD group was characterized by age older and higher NYHA class (p = 0,009). Pts with preserved renal function had lower rate of co-morbidities: diabetes (14% vs 43% in RD, p = 0,0012) and arterial hypertension (60% vs 86% in RD, p = 0,004). In pts with RD 1 year cumulative mortality was 30.9%, which was significantly higher than in the group without RD (11.3%) (p = 0.0125). However, there was no difference in hospitalization rate (p = 0,125).
Conclusion: Pts with CHF and reduced LVEF RD group characterized by higher rate of co-morbidities (hypertension, diabetes), higher age and NYHA class, higher UA, IL-6, BUN and citrulin levels, and demonstrate worse survival. RD was not associated with LVEF, anemia, MAU and NTproBNP levels.



Kaplan-Meier survival curve

On behalf of: HARVEST
Funding Acknowledgements: The Swedish Heart and Lung foundation [2015-0322] and Wallenberg Center for Molecular Medicine, Lund University.

Background/Purpose: We aimed to assess the predictive role of four cognitive tests in regard to risk of rehospitalization in a Swedish prospective heart failure (HF) patient cohort.
Methods: 156 patients hospitalized for HF (mean age: 75 years; 29% women) had complete data on cognitive tests assessing global cognition (Montreal Cognitive Assessment (MoCA)), cognitive speed (Quick Test of Cognitive speed (AQT)), visual attention and task switching (Trailmaking A) and information processing (the digit symbol coding test (SDC)), as well as on all covariates used in the multivariate analysis. Relations between baseline cognitive test results and rehospitalization risk were assessed using multivariable Cox regression analysis adjusting for age, sex, body-mass index, systolic blood pressure, NYHA-class at hospitalization, diabetes, total cholesterol, prevalent atrial fibrillation, educational level and smoking. A two-sided p-value of 0.05 was considered statistically significant.
Results: Among the 156 HF-patients, 38 (24%) had cognitive impairment according to MoCA-score < 23 points. In the fully adjusted Cox regression analysis, readmission (n = 84, 54%, mean follow-up time 9.0 ± 8.9 months) was more likely to occur among patients with MoCA < 23 points (hazard ratio (HR) per 1SD: 1.82, 95% confidence interval (CI), 1.08-3.05; p = 0.025), AQT > 90 seconds (HR, 1.65; CI, 1.02-2.67; p = 0.041), SDC < 39 points (HR, 3.68; CI, 1.18-3.68; p = 0.025) and Trailmaking A > 70 seconds (HR, 1.88; CI, 1.15-3.06; p = 0.012). In the multivariate Cox regression analysis of continuous values of each cognitive test the MOCA-score (HR, 0.93; CI, 0.87-0.98; p = 0.014), SDC-score (HR, 0.96; CI, 0.93-0.98; p = 0.002) and Trailmaking A-time (HR, 1.01; CI, 1.00-1.01; p = 0.024) showed significant associations with risk of readmission, whereas no such association was seen for AQT-time (HR, 1.00; CI, 1.00-1.01; p = 0.231)
Conclusion: Four cognitive tests assessing global cognition, cognitive speed, visual attention and task switching as well as information processing predict rehospitalization in HF, independent of clinical and non-clinical factors.

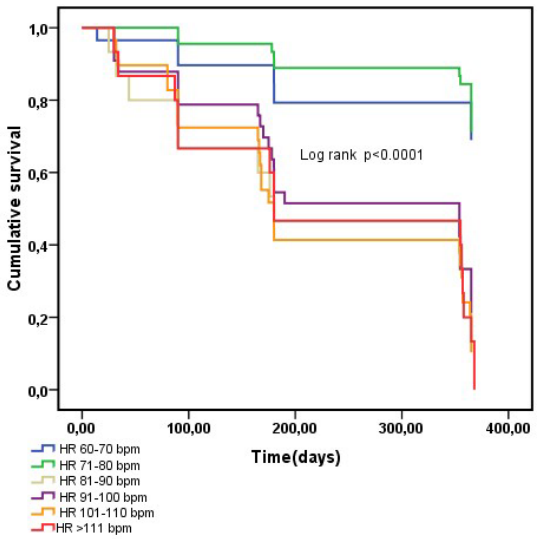
Background: Optimal heart rate (HR) in patients with heart failure (HF) and atrial fibrillation (AF) is still being under discussion. The aim of our study was to investigate clinical outcomes (overall mortality and HF hospitalization) in patients with permanent atrial fibrillation (AF) and decompensated HF depending on their discharge HR. Methods. This analysis included data from the Optimize Heart Failure Care program collected over 12 months from 740 patients, of whom 170 patients (22.9%) were with HF and AF (mean age 63.7 ± 10.9 years, 70% male), NYHA II-IV (mean 2.85 ± 0.58), left ventricular ejection fraction < 40% (mean 34.1 ± 8.8%), mean heart rate 93 ± 23.8 bpm. Patients were divided into six groups depending on their discharge HR: 60-70 bpm (29 patients), 71-80 bpm (44 patients), 81-90 bpm (18 patients), 91-100 bpm (32 patients), 101-110 bpm (29 patients) and = 111 bpm (18 patients).
Results: There were no differences in demographic and clinical characteristics between groups. The prescription rates of angiotensin-converting enzyme inhibitors/angiotensin receptor blockers, beta-blockers, mineralocorticoid receptor antagonists before discharge from hospital varied from 85% to 89% in all groups, 80% of patients received digoxin. However, the proportion of patients, who received more than 50% of recommended doses of beta-blockers (BBs) was significantly lower in groups with HR 101-110 bpm and = 111 bmp (20% for BBs, p < 0.0001), compared with other groups of patients (this proportion varied from 56% to 68% for BBs in other groups). The rate of all-cause mortality and HF hospitalization was significantly higher in the groups of patients with HR 101-110 bmp and more than 111 bmp (HR 2.1, 95% CI 1.56-2.86, p = 0.0001) than in groups with HR 60-70 bmp and 71-80 bmp.
Conclusion: Despite the lack of differences in demographic and clinical characteristics between groups, patients with HR 101-110 bpm and more than 111 bmp received significantly lower doses of BBs, which was associated with significantly higher rates of all-cause mortality and HF hospitalization compared with other groups. So, some actions are needed to optimize rate control therapy and to prescribe evidence-based doses of medications in clinical practice.



Curves for overall mortality, HF hospit.

On behalf of: the CHART-2 Investigators

Funding Acknowledgements: This study was supported in part by the Grants-in Aid from the Ministry of Health, Labour, and Welfare, the Ministry of Education, Culture, Sports, Sc

Background: We have recently reported that left ventricular ejection fraction (LVEF) dynamically changes in patients with haet failure (HF). However, sex differences in the transition of LVEF among HF with preserved LVEF (HFpEF), HF with mid-range LVEF (HFmrEF) and HF with reduced LVEF (HFrEF) remains to be fully examined.
Methods: In our Chronic Heart Failure Analysis and Registry in the Tohoku District-2 (CHART-2) Study (N = 10,219), we examined sex differences in the transition of LVEF in 3,480 consecutive HF patients. Those included 2,154 with HFpEF (LVEF = 50%, mean 71.7 yrs., male 60.8%), 596 with HFmrEF (LVEF 40-49%, mean 69.1 yrs., male 71.8%), and 730 with HFrEF (LVEF <40%, mean 66.8 yrs., male 76.7%), defined according to the 2016 ESC Guidelines.
Results: From baseline to 1-year, only a small proportion of HFpEF transitioned to HFmrEF or HFrEF in both sexes (female, 5.0% and 2.1%, respectively; male, 8.7% and 2.8%, respectively). In contrast, HFmrEF dynamically transitioned to HFpEF and HFrEF from baseline to 1-year (female, 51% and 9.7%, respectively; male, 34% and 17%, respectively), whereas HFrEF moderately transitioned to HFpEF and HFmrEF from baseline to 1-year (female, 20% and 17%, respectively; male, 14% and 21%, respectively).
In the overall population, history of ischemic heart disease (IHD) was negatively and female sex was positively associated with an increase in LVEF from baseline to 1-year (r=-0.063, P = 0.003 and r = 0.051, P = 0.014, respectively). It was noted that, regardless of HF groups at baseline, HFrEF at 1-year had increased mortality at 3-year (14.3%), as compared with HFpEF at 1-year (10.3%) and HFmrEF at 1-year (9.4%) (P for trend = 0.016). The multivariable linear regression analysis showed that HFpEF, HFmrEF, and HFrEF patients had different sets of factors associated with LVEF changes from baseline to 1-year by sex. History of IHD (r=-0.066, P = 0.002) was significantly associated with changes of LVEF only in male, while history of cancer (r=-0.018, P = 0.011) and serum albumin level (r=-0.029, P = 0.016) were significantly associated with LVEF changes only in female.
Conclusions: Sex differences were noted in the transitions among HFpEF, HFmrEF and HFrEF, where female sex, but not male sex, is associated with an increase in LVEF, which may be influenced by cancer and undernutrition.

P1125

Tachycardia-induced cardiomyopathy in children

Y Yakovleva Elena[1]; TS Loevets[1]; TL Vershinina[1]; L Butish[1]; KI Ivanova[1]; TM Pervunina[2]; DS Lebedev[3]; ES Vasichkina[1]
[1]Almazov National Medical Research Centre, Pediatric cardiovascular diseases research department, Saint Petersburg, Russian Federation; [2]Almazov National Medical Research Centre, Institute of Perinatology and Pediatrics, Saint Petersburg, Russian Federation; [3]Almazov National Medical Research Centre, Research Department of Arrhythmology, Saint Petersburg, Russian Federation

Objective: to present our clinical experience of diagnosis and treatment of the tachycardia-induced cardiomyopathy (TIC) in pediatric patients.
Methods: We enrolled 33 consecutive patients with TIC (11 girls and 22 boys). We formed 2 groups: 1st - 18 (54,5%) - frequent premature ventricular complexes (PVCs) and/or nonsustained ventricular tachycardia; 2nd - 15 (45,5%), included 13 (39,4%) had atrial ectopic tachycardia (AET), atrial fibrillation - 2 (6,1%).
Inclusion criteria were children < 18 years with idiopathic tachyarrhythmias, cardiac dysfunction (left ventricular ejection fraction < 50%), and left ventricular dilation (left ventricular end-diastolic dimension z-score = 2). Exclusion criteria were structural heart abnormalities, current inflammatory process in the myocardium.
Patients underwent a complete history, physical examination, laboratory studies (including thyroid function, CK, CK-MB, LDG, Troponin I, proBNP), echocardiography (ECHO), ECG, Treadmill test and Holter monitoring (HM). Cardiac MRI were performed according to indications and physician's decision.
The age, gender, tachycardia type, ventricular rate during tachycardia, frequency of tachycardia episodes and duration of tachycardia were studied.
All children with TIC underwent antiarrhythmic therapy (including combined treatment) and/or radiofrequency catheter ablation (RFA) of tachycardia. 1, 3 and 6 months after effective treatment of tachycardia ECHO control was performed.
Results: The mean age of diagnosis of arrhythmia was 6,78 + 6,48 (from 0 to 15) years.
The duration of tachycardia before diagnosed TIC was 32,11 + 20,48 months (range 6 to 180 months).
More often the patients complained of fatigue - 12 (36,4%), exercise intolerance - 12 (36,4%), palpitation - 11 (33,3%), shortness of breath - 6 (18,2%), dizziness - 7 (21,2%), syncope - 2 patients (6,1%).
Class of chronic heart failure was: I in 18 patients (54,5%); II - 13 patients (39,4%); III - 2 patients (6%)
NT-proBNP level was investigated in 12 children, and in 9 cases (75%) was high.
27 of 33 patients (81,8%) were obtained an antiarrhythmic therapy, 5 of them received a combination of drugs. 22 patients (66,7%) underwent RFA of tachycardia.
Long-term follow up of patients was 20,38 ± 19,14 months (range 1 to 60).
Most patients had disappeared complaints of fatigue and reduced exercise tolerance.
Heart failure resolution after effective treatment was observed in 81,8% cases (27 patients).
In all cases when the RFA was performed, follow-up with ECHO documented normalization of the heart chambers size and total recovery of ventricular function.
There were no difference between age of debut of arrhythmias, gender and duration of arrhythmias before TIC in 2 groups.
Conclusions: tachycardia-induced cardiomyopathy in children without structural myocardial defects is reversible, which underlines the importance of prompt diagnostics and control of hemodynamically significant cardiac arrhythmias.

P1126

The place of outpatient intervention program to prevent the readmissions of patients hospitalized for chronic heart failure

LG Mircheva[1]; M Rushid[1]; T Chalakova[1]; Y Yotov[1]
[1]University Hospital St. Marina, Varna, Bulgaria

Introduction: Heart failure (HF) is the leading cause of hospitalization among adults 65 years. The majority of the early readmissions could be prevented by developing disease-managing programs after discharge.
Aim: To assess the effect on rehospitalization rate of strict - ambulatory monitoring among patients with HF in out-patient HF program.
Material and subjects: We followed 198 patients with HF II-IV NYHA functional class (156 in active group and 42 in control group) for 6 months in HF out-patient program. Analysis of frequency and causes for rehospitalizations in studied patients in comparisons of control group of similar patients is made.
Results: Overall 52 patients (26,3%) have been rehospitalized. In the active group there were 33 (21,6%) events, while in the control group were 19 (42,2%), ? = 0,011. Most of them has only one rehospitalisation during follow-up. The curves' divergence starts after 30 days of follow-up. In Cox proportional regression analysis, the patients in the control group have twice higher probability to be rehospitalized during the 6-months follow-up - HR = 2,55, 95%CI = 1,44-4,53 (p = 0,001).

Conclusion: The majority of the early readmissions are prevented by developing disease-managing programs which focus on strict follow-up of the patients after discharge.

P1127

Predictors of short form-36 physical activity variables in heart failure with reduced ejection fraction

I Alexanian[1]; I Parisis[2]; V Bistola[2]; G Bakosis[2]; M Thodi[2]; F Tzifi[1]; N Karamichalakis[1]; E Rizou[1]; S Xydonas[1]; L Pappas[1]; K Letsas[1]; M Efremidis[1]; A Sideris[1]; G Filippatos[2]

[1]Evangelismos General Hospital of Athens, 2nd Department of Cardiology, Athens, Greece; *[2]Attikon University Hospital, Department of Cardiology, Athens, Greece*

Background: Quality of life reflects the multidimensional impact of a clinical condition and its treatment on patients' daily lives. It is markedly impaired in heart failure and adversely affects prognosis. Short Form -36 (SF-36) is a generic quality of life measure containing eight dimensions.
Purpose: We aimed to investigate SF-36 physical activity variables (physical function, role physical, bodily pain and general health perceptions) in patients with heart failure and reduced ejection fraction (left ventricular ejection fraction < 40%) (HFREF).
Methods: Clinical, echocardiographic and laboratory parameters were determined in 87 patients with HFREF (age: 64.81 ± 12.05, 90% male, Ischemic: 84%) visiting our outpatient clinic. Furthermore, assessment of functional capacity, quality of life and screening for depressive symptoms was performed using Duke Activity Status Index (DASI), the Kansas City Cardiomyopathy Questionnaire (KCCQ), the Minnesota Living With Heart Failure Questionnaire (MLHFQ) and the Zung self-rating depression scale (SDS). Statistical analysis was performed using SPSS 19.
Results: Median Physical function was 35.00(25.00, 70.00), median role physical was 0(0.0, 0.0), median bodily pain was 67.00(33.00,100.00) and median general health perceptions was 25.00(15.00, 42.00). Role physical correlated positively with Hgb (r = 0.363, p = 0.003), whereas it correlated negatively with NYHA (r= -0.360, p = 0.002), RV diameter (r= -0.286, p = 0.046) and logNT-proBNP (r= -0.318, p = 0.040). Bodily pain was positively associated with LVEF (r= 0.241, p = 0.046), with Hgb (r= 0.300, p = 0.014) and Na (r= 0.383, p = 0.001). General health perceptions correlated positively with LVEF (r = 0.274, p = 0.023) and Na (r= 0.288, p = 0.016) and correlated negatively with NYHA (r= -0.279, p = 0.020). Physical function was negatively associated with total score MLHFQ (r= -0.305, p = 0.008). Role physical, bodily pain and general health perceptions showed a positive association with DASI (r= 0.337, p = 0.002), (r= 0.319, p = 0.003), (r= 0.414, p < 0.001) respectively, with KCCQ overall summary (r= 0.384, p < 0.001), (r= 0.470, p < 0.001), (r= 0.406, p < 0.001) respectively and a negative association with total score MLHFQ (r= -0.319, p = 0.006), (r= -0.526, p < 0.001), (r= -0.509, p < 0.001) respectively. Physical function, bodily pain and general health perception correlated negatively with Self-rated raw score Zung (r= -0.281, p = 0.012), (r= -0.247, p = 0.027), (r= -0.493, p < 0.001), respectively.
Conclusion: NYHA, echocardiographic and laboratory parameters are significantly associated with SF-36 physical activity variables. SF-36 physical activity variables significantly correlate positively with DASI, KCCQ and negatively with MLHFQ and Self-rated raw score Zung.

Targeted DNA methylation profiling of human cardiac tissue reveals novel epigenetic traits and gene deregulation across different heart failure cohorts

N Nadezhda Glezeva[1]; B Moran[1]; P Collier[2]; C Moravec[2]; A Russell-Hallinan[1]; K Mcdonald[3]; M Ledwidge[3]; J Baugh[1]; S Das[1]; C Watson[4]

[1]University College Dublin, Conway Institute, Dublin, Ireland; *[2]Cleveland Clinic Foundation, Department of Cardiovascular Medicine, Cleveland, United States of America*; *[3]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland*; *[4]Queen's University of Belfast, Wellcome-Wolfson Institute for Experimental Medicine, Belfast, United Kingdom*

Purpose: Heart failure (HF) is a global health problem with ever increasing prevalence. Efforts to find more effective means to screen, diagnose, and treat HF must take into account the multiple aetiologies and facets that make up the complexity of the syndrome. Correct gene expression programming of the cells that form the architecture of the myocardium underlies the normal functioning of the heart. DNA methylation is a physiological process and a powerful tool for fine-tuning of gene expression in line with the needs of the body. Aberrant DNA methylation can therefore contribute to pathological cardiac remodelling. To identify novel gene-specific DNA methylation changes that may occur in different HF aetiologies, we used a focused methylation loci targeting approach to profile left ventricular myocardial tissue from patients with Left Ventricular Hypertrophy (LVH), Hypertrophic Obstructive Cardiomyopathy (HOCM), Dilated Cardiomyopathy (DCM), Ischemic Cardiomyopathy (ISCM), and age/sex-matched no HF controls.
Methods: A custom-designed SeqCap Epi Choice M kit was developed for this project to assess 18582 putative promoter and enhancer regions of coding and non-coding (nc) RNA, and 17929 CpG islands in fresh-frozen cardiac interventricular septal (IVS) tissue from 48 patients with LVH (9), HOCM (12), DCM (9), ISCM (9), and normal function controls (NF, 9). Differential methylation analysis, non-negative matrix factorisation (NMF) clustering (R software, MethylKit), and gene network analysis (Enrichr) were performed to determine methylation changes relative to gene/microRNA/long non-coding (lnc) RNA expression. Quantitative real-time PCR was carried out on a subset of methylation-sensitive genes/microRNA/lncRNA to determine changes in transcript levels.
Results: Using a 500 bp tiled approach, false discovery rate (FDR) of >0.05, and a difference in methylation of >10%, we detected 61,151 tiles with divergent methylation in the studied cohort. By comparing each HF patient group to the NF control group we identified 7 differentially methylated tiles in LVH, 5 in HOCM, 151 in DCM, and 55 in ISCM. These translated to 7 genes in LVH, 4 genes/1 ncRNA in HOCM, 131 genes/17 ncRNA in DCM, and 51 genes/5 ncRNA in ISCM. Gene ontology revealed relevance to processes and pathways implicated in HF pathogenesis. Subsequent QPCR analysis identified 10 genes (4 hyper-, 6 hypo-methylated) and 5 microRNA (3 hyper-, 2 hypo-methylated) with significantly up/down-regulated transcript levels consistent with the direction of methylation identified in the particular HF patient group.
Conclusions: Our study is the first to use a cardiovascular-specific targeted capture approach to define epigenetic signatures in HF patients with different aetiologies. We identified methylated CpG sites which affect gene expression and may contribute to disease pathophysiology. We also highlighted disease-associated genes which could be assessed as novel diagnostic or therapeutic targets.

Chronic Heart Failure - Other

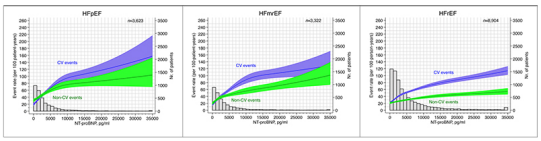
Funding Acknowledgements: Swedish Research Council [grants 2013-23897-104604-23 and 523-2014-2336], the Swedish Heart Lung Foundation [grants 20120321 and 20150557],and Relypsa

Objective: To assess the association between N-terminal pro-B-type natriuretic peptide (NT-proBNP) and cardiovascular (CV) vs. non-CV events, and between NT-proBNP and potential treatment effects, in heart failure (HF) with preserved, mid-range and reduced ejection fraction (HFpEF, HFmrEF, HFrEF) and clinically relevant sub-groups.
Background: Optimizing patient eligibility criteria in HF trials requires biomarkers that enrich for CV but not non-CV events, and select patients most likely to respond to the tested intervention.
Methods: In the Swedish HF Registry population stratified by EF category, we used: Kaplan Meier curves to estimate unadjusted CV and non-CV risk (mortality or hospitalization); Poisson regressions to calculate crude event rates of CV and non-CV events according to NT-proBNP levels; Cox regressions to calculate the adjusted hazard ratios for HF therapies according to NT-proBNP = or >median.
Results: Among 15,849 patients (23% HFpEF, 21% HFmrEF, 56% HFrEF), median NT-proBNP was 2,037, 2,192 and 3,141 pg/ml, respectively. With increasing NT-proBNP, CV event rates increased more steeply than non-CV (ranging 20-160 and 30-100 per 100 patient-years in HFpEF, 20-130 and 20-100 in HFmrEF, 20-110 and 20-50 in HFrEF, respectively). CV to non-CV ratio increased with increasing NT-proBNP in HFpEF and HFrEF, but only in the lower range in HFmrEF. The association between treatments (ACE-I /ARB and beta-blockers) and outcomes was consistent in NT-proBNP = and >median.
Conclusions: In HF trial design in different EF categories, NT-proBNP may be a useful tool for eligibility and enrichment for CV events, but its role in treatment response remains unclear. When designing HF trials, it is important to recognize that non-CV events will be higher with higher EF and potential CV treatment effect will be lower with higher EF, even if the pathophysiological treatment target is appropriate; and that higher NT-proBNP criteria will enrich for CV events but also CV to non-CV event ratios. However, it remains unknown which NT-proBNP range may have the greatest HF treatment response.



P1129

Association of phase angle and hypoxemia in patients with Heart Failure and chronic obstructive pulmonary disease

C Olivo-Villalobos[1]; D Gonzalez[1]; A Orea-Tejeda[1]; G Davila-Said[1]; C Chavez-Mendez[1]; R Sanchez-Santillan[1]; V Pelaez-Hernandez[1]; M Rivera-Rodriguez[1]; L Castillo-Aguilar[1]; K Balderas-Munoz[1]; A Figueroa-Herrera[1]
[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico

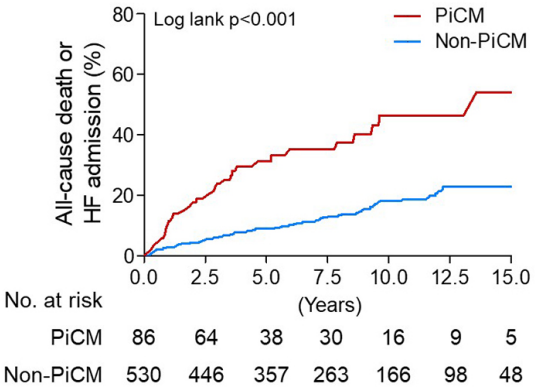
Background: Heart failure (HF) and chronic obstructive pulmonary disease (COPD) have high rates of morbidity and mortality. There is water alteration and cell damage in both pathologies and these aggravates the prognosis. The phase angle (PA), which is an indicator of the integrity of the cellular membrane and a good method of prognosis in these populations, diminished with: decrease in tissue oxygenation, in hypoxia state, which increases oxidative stress, the overproduction of peroxides and free radicals. However, there aren't studies that evaluate the relationship between hypoxia and PA in HF and COPD patients.
Purpose: To determine the relationship between hypoxia and PA in patients with HF and COPD.
Materials and Methods: Cross-sectional study was performed in 159 patients, subjects > 40 years with a diagnosis of HF and COPD were included. Those with asthma and cancer were excluded. Body composition and PA were evaluated by bioelectrical impedance vector analysis (BIVA) and hypoxia was confirmed by arterial oxygen saturation < 80%.
Results: The mean age was 67.4 ± 12 years, 58.1% were women, and 61.8% had cachexia. Subjects with hypoxia had lower PA (4.3 ± 0.84 vs 4.94 ± 0.93, p = 0.046), as well as, greater edema (89.89% vs 58.8%, p = 0.203) compared with those without hypoxia, respectively. No difference was shown between the groups in: strength, impedance index and skeletal muscle mass.
Conclusion: Subjects with HF and COPD with hypoxemia have a lower PA than the non hypoxemic group.

P1130

Clinical features, predictors, and long-term prognosis of pacing-induced cardiomyopathy

S W Cho[1]; SY Sohn[2]; KM Park[3]; YK On[3]; JS Kim[3]; SJ Park[3]
[1]Inje University, Seoul Paik Hospital, Division of Cardiology, Department of Internal Medicine, Seoul, Korea Republic of; *[2]Hospital Myongji, Division of Endocrinology, Department of Internal Medicine, Goyang, Korea Republic of*; *[3]Samsung Medical Center, Cardiology, Seoul, Korea Republic of*

Background: Right ventricular pacing sometimes have adverse effects on left ventricular (LV) structure and function. However, little is known about the clinical features, predictors, and long-term prognosis of pacing-induced cardiomyopathy (PiCM).
Methods: We reviewed 1418 patients undergoing permanent pacemaker implantation and having follow-up transthoracic echocardiography (TTE) data. PiCM was defined as less than 50% of LV ejection fraction (EF) in follow-up with = 10% decrease of EF, newly appeared regional wall motion abnormality irrelevant coronary artery disease, LV dyssynchrony, or paradoxical septal motion. The primary outcome was composite of all-cause death or admission due to heart failure (HF).
Results: Total 671 patients were enrolled and 87 (13.0%) developed PiCM, with a decrease in mean EF from 60.5% to 40.1% over a mean duration of 5.4 years. In multivariate logistic regression analysis, independent predictors of PiCM were left bundle branch block at baseline electrocardiography, wider paced QRS duration, and ventricular pacing frequencies. During the follow-up duration (mean 7.7 years), the risk of all-cause death or HF admission was significantly higher in patients with PiCM compared with non-PiCM patients (38.3% versus 54.0%, adjusted hazard ratio, 3.07; 95% confidence interval 1.90-4.94; p < 0.001).
Conclusion: PiCM showed the worse long-term prognosis compared with non-PiCM. Therefore, the patients with risk factors of PiCM should be monitored carefully and considered the biventricular pacing.



All-cause death or HF in PiCM

P1131

Differences in psychological and physical state between informal primary caregivers of patients with cardiorespiratory failure with emotional suppression or reappraising. preliminary results.

F A Figueroa Herrera[1]; V Pelaez-Hernandez[1]; B Robles-Uribe[1]; SC Torres-Montiel[1]; M Rivera-Rodriguez[1]; A Orea-Tejeda[1]; D Gonzalez-Islas[1]; G Davila-Said[1]; C Chavez-Mendez[1]; C Olivo-Villalobos[1]; L Castillo-Aguilar[1]; RN Sanchez-Santillan[1]; GK Perez-Cortes[1]; AG Navarrete-Penaloza[1]
[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosio Villegas", Heart Failure and Respiratory Distress Clinic, Mexico City, Mexico

Background: Emotional suppression (ES) reduces health, while reappraising (RE) favours it. Patients who suppress their anger increase their physiological activity and generate hostile behaviours that hinder the relationship with their informal primary caregiver (IPC), and vice versa. In addition, the ES of a person during a social interaction increases blood pressure in both individuals. However, the impact of the ES of patients with cardiorespiratory failure (CRF) on their IPCs is unknown.
Objective: To compare psychological and physical state of IPCs of patients with CRF with ES or RE emotional regulation type.
Method: A cross-sectional study was conducted involving 12 CPIs of patients with a clinical diagnosis of cardiorespiratory failure. The patients were evaluated with the Emotional Regulation Questionnaire, according to the results their IPCs were divided in two groups: 1) IPCs of patients with ES (G1, n = 8 age: 57.75 ± 12.56, 75% women) and 2) IPC of patients with RE (G2, n = 4 age: 57 ± 9.62, 75% women).
To assess psychological state of the CPIs, the Beck Anxiety Inventory (BAI), the SF-12 health questionnaire and the Perceived Stress Scale (PSS) were used. To evaluate the physical state, the 6-minute walking test (6MWT) was performed, recording distance travelled (DIST), systolic blood pressure (SBP), diastolic blood pressure (DBP) and pulse in each of the following phases. 1) Base Line (BL), 2) Final (F) and 3) Recovery (REC).
The data was analysed with SPSS for Windows version 22 using a Mann Whitney U test.
Results: No statistically significant differences were found (p> 0.05), but clinically significant differences were found in SBP and DBP.
Psychometrics
BAI (G1 / G2): 11 ± 11.40 / 7.75 ± 6.29 (z=-.171)
SF-12 (G1 / G2): 59.68 ± 18.02 / 73.95 ± 8.03 (z=-1.191)
PSS (G1 / G2): 24.50 ± 5.73 / 30.75 ± 14.17 (z=-.937)
6MWT (BL|F|REC)
SBP (mmHg, G1 / G2): 134.75 ± 20.25 / 122 ± 14.76 (z=-1.191) | 140.38 ± 21.79 / 123.50 ± 11.81 (z=-1.531) | 133.50 ± 28.48 / 120 ± 13.44 (z=-.510)
DBP (mmHg, G1 / G2): 81.38 ± 10.87 / 80.50 ± 9.57 (z=-0.85) | 87.38 ± 15.55 / 78.75 ± 6.39 (z=-1.534) | 85 ± 13.72 / 80.25 ± 10.07 (z=-.340)
Pulse (p/min, G1 / G2): 65.25 ± 11.56 / 73.50 ± 3.69 (z=-1.281) | 68.13 ± 14.10 / 74.50 ± 10.78 (z=-.778) | 64.63 ± 13.02 / 71 ± 9.27 (z=-1.023)
Distance (meters, G1 / G2): 370.50 ± 57.25; 393.75 ± 48.03 (z=-.679)
Conclusions: The clinical differences between both groups show that the IPCs of patients with ES present an alteration of the emotional state and a diminished quality of life. They also showed a deteriorated cardiovascular response, being more reactive, presented hypertensive levels of SBP and a lower performance. This translates into greater vulnerability. An interdisciplinary health team is needed to attend to the state of health of the IPCs.

P1132

Company animals, the best friends for heart failure patients?

N G H M Nick Marcks[1]; JJJ Boyne[2]; W Robaeys[1]; MA Barandiaran Aizpurua[2]; J Merken[1]; FPH Beckers-Wesche[2]; HP Brunner-La Rocca[2]
[1]Cardiovascular Research Institute Maastricht (CARIM), Cardiology, Maastricht, Netherlands; *[2]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands*

Purpose/Aims: Therapy adherence, physical activity, quality of life, hospitalisation and mortality are important regarding care in heart failure (HF) patients. Various means aim to improve these aspects, however little is known about the effects of pet ownership.
Methods and Results: We retrospectively investigated the Trial of Intensified vs Standard Medical Therapy in Elderly Patients with Congestive Heart Failure (TIME-CHF) population. Among the 622 HF patients, 154 owned a company animal. Pet owners were younger, more frequently men and were more often married or lived with a partner. Patients owning pets had more frequently chronic obstructive pulmonary disease (COPD) and were more frequently smokers. Systolic blood pressure and ejection fraction (EF) were lower in these patients. No significant differences were observed concerning quality of life measured by the Minnesota questionnaire (29 (± 19) vs 27 (± 19), p 0.456). Although univariate analysis demonstrated a better event free survival in HF patients with pet (HR 1.460, 95% CI 1.105-1.928, p = 0.008), adjusting for gender, age, arterial hypertension, current smoking status, history of COPD, social status, and EF unmaked this significant difference (HR 1.260, 95% CI 0.943-1.685, p = 0.119). Therapy adherence, defined as non-compliance without particular reason, showed no significant difference between groups (p = 0.209). Physical activity improved slightly in both groups over time, however without significant difference between groups (p = 0.336).
Conclusions: With this retrospective research, we could not find relevant differences in any of the investigated aspects between pet owners and non-owners.

Heart involvement in AA amyloidosis a prospective study on 38 patients

D Bodez[1]; S Guendouz[1]; G Grateau[2]; A Galat[1]; V Avellino[2]; M Kharoubi[1]; A Guellich[1]; E Itti[3]; JF Deux[4]; T Damy[1]; S Georgin-Lavialle[2]
[1]University Hospital Henri Mondor, Cardiology & Amyloid Research Institute, Creteil, France; *[2]Hospital Tenon, Internal medicine & CEREMAIA (national french ref center of autoinflammatory diseases and AA amyloid, Paris, France*; *[3]University Hospital Henri Mondor, Nuclear medicine & Amyloid Research Institute, Creteil, France*; *[4]University Hospital Henri Mondor, Radiology & Amyloid research institute, Creteil, France*

Funding Acknowledgements: AREMCAR, APHP

Context: AA Amyloidosis is unusually associated with cardiac amyloidosis. No systematic cardiac screening has been performed in the last decade, since new noninvasive diagnostic tools have been developed.
Aim: To determine whether AA amyloidosis is associated with a specific cardiac injury.
Methods: Thirty-eight consecutive patients with proven AA amyloidosis has been included for a systematic cardiac work-up with clinical evaluation, biomarkers, transthoracic echocardiography (TTE), cardiac MRI and bone scintigraphy.
Results: Among 38 AA patients, 11 had an inflammatory disease, 10 had an infectious disease, 10 an auto-inflammatory disease, 4 were obese, and origin of amyloidosis was unknown in 3 cases. Eleven patients were on dialysis, and 3 were already renal transplant recipients. Median age was 58.6 (51.1;67.4) years, 50% were males, 78% were in NYHA class I or II, and all presented sinus rhythm. Median troponin T us was 19 ng/l, and NT-proBNP was 382 ng/l. Median LVEF was 61%, interventricular septum thickness was 9mm, global longitudinal strain was -18%. One patient presented late gadolinium enhancement on cardiac MRI, and none patient presented myocardial bone maker fixation. Seven patients died during the study, all on dialysis with several cardiovascular risk factors.
Conclusion: None of the patients presented classical criteria of cardiac amyloidosis. A specific vascular location has to be explored with further studies.

Acute Heart Failure - Pathophysiology and Mechanisms

P1134

Orthostatic hypotension is associated with volume status changes and intensive diuretic therapy in patients with decompensated heart failure

A Soloveva[1]; M Bayarsaikhan[1]; O Lukina[1]; F Cabello Montoya[1]; S Villevalde[1]; Z Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), Department of Internal Diseases, Moscow, Russian Federation

Objective: Orthostatic hypotension (OH) is common among patients with heart failure (HF) and may have an adverse impact on the outcomes. Presently little is known about orthostatic reactions during hospitalisation and their associations in decompensated HF (DHF).
Methods: Systolic and diastolic blood pressure (SBP and DBP) were measured in recumbent and standing position within 3 min of assuming upright posture on admission and discharge in 72 patients with DHF (47 male, 68 ± 12 years (M ± SD), arterial hypertension 96%, myocardial infarction 46%, atrial fibrillation 65%, diabetes mellitus 40%, chronic kidney disease 32%, ejection fraction (EF) 40 ± 14%, EF < 40% 51%, NT-proBNP 3488(1359;7185)pg/ml). OH was defined as decrease of SBP = 20 mmHg and/or DBP = 10 mmHg within 3 min of active standing. The same increase of SBP and/or DPB was considered as orthostatic hypertension (OHtn). Hydration status was assessed by BIVA on admission and discharge, using resistance (R) and reactance (Xc) standardized by height (h). Mann-Whitney, McNemar tests were performed, p < 0.05 was considered significant.
Results: On admission OH and OHtn occurred in 17(23.6%) and 2(2.8%) of patients respectively. OH on admission occured in 1 min in 88% cases and was presented as isolated decrease of SBP, DBP or both in 8, 5 and 4 patients. OH and OHtn occured in 27(37.5%) and 17(23.6%) patients at discharge respectively.
OH at discharge occured in 1 min in 55.5% cases and was presented as isolated decrease of SBP, DBP and both in 15, 9 and 3 patients. In 1 patient DBP decrease was associated with postural tachycardia.
10(13.9%) patients had OH both on admission and discharge. Symptomatic OH was rare (in 12 and 7.4% cases on admission and discharge).
Patients with vs without OH at discharge received higher total dose of iv furosemide therapy during hospitalisation (500(240;860) vs 480(300;740) mg,p = 0.042) and had lower rate of hyperhydration by BIVA (29.6 vs 60%,p = 0.012) and higher R/h (308 ± 61 vs 278 ± 52 Om/m,p = 0.046) and Xc/h (31 ± 8 vs 25 ± 7 Om/m,p = 0.005) at discharge (meaning less hydration), absolute ?R/h (53 (7;69) vs 29(11;62)Om/m,p = 0.048) and ?Xc/h (6.3(1.8;10.5) vs 4.6(1.2;9.3)Om/m,p = 0.046), relative ?R/h(21.3 (2.7;30) vs 13 (2.7;17.8)%,p = 0.045) and ?Xc/h (33(8;64) vs 26(4.4;58)%, p = 0.038). Groups did not differ by baseline BIVA parameters.
OH on admission was associated with higher rate of rehospitalisation in 6 month (29.4 vs 9.1%,p = 0.034).OH at discharge had no negative impact on 6-month outcomes.
Conclusions: Orthostatic reactions in patients with DHF were diverse. OH was more frequent than OHtn both on admission and discharge.From admission to discharge incidence of OH and OHtn increase from 23.6 to 37.5% and from 2.8 to 23.6% respectively.Patients with OH at discharge had more intensive iv diuretic therapy and more pronounced decongestion by BIVA.OH on admission was associated with higher rate of 6-month rehospitalisation. OH at discharge had no impact on outcomes.

P1135

Takotsubo syndrome and hypersensitivity reaction to metals of environmental burden

M Marie Pavlusova[1]; J Manousek[1]; P Kubena[1]; P Kala[1]; J Jarkovsky[2]; L Dostalova[1]; A Zadakova[1]; J Spinar[1]; J Parenica[1]
[1]University Hospital Brno, Department of Cardiology and Internal Medicine, Brno, Czech Republic; *[2]Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic*

Background: Takotsubo syndrome (TS) is a rare heart pathology characterized by a sudden transient dysfunction most often of left ventricle mimicking acute myocardial infarction. The etiology is not known as yet. According to the literature and clinical observations, it appears that TS affects persons with various comorbidities.
Purpose: Our pilot project aims to determine the prevalence of comorbidities with potential pathological immune reactivity, and to evaluate the possible association between TS and delayed type hypersensitivity (type IV) reactions to metals of environmental burden assessed by lymphocyte transformation test (LTT).
Methods: A total 24 patients (23 females, 1 male, median age 65,6 years) with a history of TS acute attack and 27 healthy controls were evaluated. Hypersensitivity to metals was tested by a LTT. A questionnaire of environmental burden was used to select evaluated metals.
Results: 19 patients (79 %) had at least one condition that might potentially be associated with pathological immune reactivity (autoimmune thyroid disease, drug allergy, bronchial asthma, cancer, contact dermatitis, rheumatoid arthritis). Hypersensitivity to metals of environmental burden was identified significantly more frequently in TS patients than in healthy controls (positive reaction to at least one metal was identified in 95,8 % of TS patients and in 59,3 % of controls; p = 0,003); the difference was statistically significant particularly for mercury (45,8 % and 14,8 %, respectivelly; p = 0,029).
Conclusion: This pilot work shows that conditions with pathological immune reactivity occur frequently in TS patients, and that there in an association between TS and delayed type hypersensitivity to metals of environmental burden (mercury in particular) evaluated by LTT. Our results also suggest that apart from triggering stress factor, potential existence of other serious conditions should be considered when taking medical history of TS patients.

P1136
Right ventricular function is a strong predictor of outcome in acute heart failure

J Jack Stewart[1]; O Lazariashvili[1]; A Baltabaeva[1]
[1]*Ashford and St Peter's Hospitals NHS Trust, Cardiology, Chertsey, United Kingdom*

Funding Acknowledgements: Abbott Vascular ltd

Introduction: Acute Heart Failure (AHF) is well recognised as a growing healthcare problem with one-year mortality typically reported around 30%. Treatment strategies and prognostic markers have long been focused on the left ventricular (LV) function, despite recognition that right heart (RV) failure carries a significant mortality burden.
Purpose: In a single-centre, prospective, cross-section study, we have aimed to assess the prognostic impact of RV function markers in patients admitted with AHF or exacerbation of chronic HF (ECHF).
Methods: All consecutive patients admitted to a large district general hospital with AHF and/or ECHF over the period of 1 year had standard clinical assessment, bio-chemistry and bedside transthoracic echocardiography within 48h of recruitment. Geometric and functional parameters of cardiac function were assessed according to international guidelines. All-cause mortality was documented at 6 months post discharge.
We assessed left ventricular ejection fraction (LVEF), systolic pulmonary artery pressure (SPAP), tricuspid annular plane systolic excursion (TAPSE) and right ventricular fractional area change (RVFAC) as prognostic markers. These markers were categorised using the following cut-off values: LVEF 40%, TAPSE 1.5cm, RVFAC 32% and SPAP 45mmHg, in line with international guidelines.
Chi-square testing was used to demonstrate or refute statistical excess of mortality. Kaplan-Meier survival plots were created to demonstrate differences in survival. Individual Cox regressions were performed to obtain hazard ratios (HR).
Results: 617 patients met the inclusion criteria of whom 500 were consented and 448 were included in the study. 6-month mortality is currently available for 356 patients. 6-month mortality was 29.1%, higher than typically reported.
As expected, patients with reduced LV function (LVEF < 40%) demonstrated increased mortality compared to those with LVEF = 40% (p= < 0.05) with a HR of 1.5, (95% CI 1.0-2.2, P < 0.05).

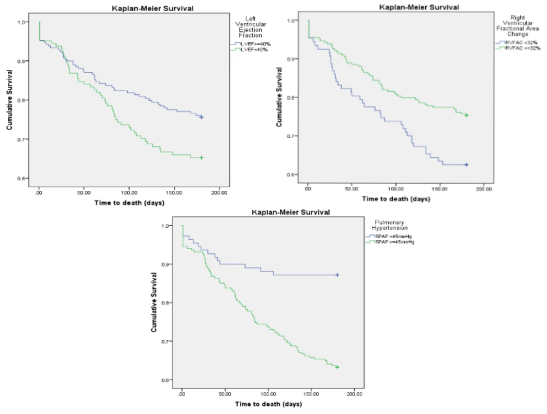

Figure 1. Kaplan-Meier survival curves

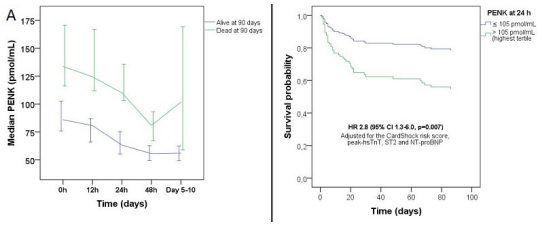
Severity of pulmonary hypertension was a strong predictor of all-cause mortality: SPAP = 45mmHg was associated with a significant increase in mortality compared to those with < 45mmHg (p= < 0.00001) with a HR of 3.2 (95% CI 1.8-5.5, p < 0.00001).
Patients with RV dysfunction as assessed by RVFAC (< 32%) showed a significant excess of mortality (p= < 0.01), with a HR of 1.9 (95% CI 1.3-2.7, p < 0.01).
TAPSE was not a significant predictor of mortality (p>0.1)
Conclusion: This study demonstrates the significance of RV failure in AHF. RVFAC is a powerful predictor of all-cause mortality in patients with AHF, as is SPAP. TAPSE is not a sensitive prognostic marker likely due to the fact that this measures longitudinal displacement not global function. Complex RV geometry should be assessed using at least 2D echo parameters. Further assessment of the right ventricle in AHF is needed, ideally using emerging and novel methods of investigating right heart function.

P1137
Prognostic value of proenkephalin in mortality prediction in cardiogenic shock

T Tarvasmaki[1]; T Jantti[1]; VP Harjola[2]; A Sionis[3]; S Di Somma[4]; A Mebazaa[5]; J Lassus[1]
[1]*Hospital District of Helsinki and Uusimaa, Heart and Lung Center, Helsinki, Finland*; [2]*Hospital District of Helsinki and Uusimaa, Department of Emergency Medicine and Services, Helsinki, Finland*; [3]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*; [4]*Sant' Andrea Hospital, Rome, Italy*; [5]*Hospital Lariboisiere, Paris, France*

Purpose: Proenkephalin (PENK) is a small endogenous opioid peptide, which has depressive effects on cardiac and renal function. High PENK levels have been associated with worsening renal function and poor outcome in heart failure. We investigated the relationship between PENK with renal function and patient outcome in cardiogenic shock (CS).
Methods: CS patients with serial plasma samples (n = 154) from the prospective CardShock study were included. PENK along with other biomarkers, such as creatinine, hsTnT, NT-proBNP and soluble ST2, were analyzed from plasma samples at baseline (0 h), 12 h, 24 h, 48 h, and the last day in cardiac or intensive care unit between day 5 and 10. Discriminative capability was evaluated by the area under the receiver operating curve (AUROC) and optimal cutoff values for biomarkers in relation to mortality were evaluated with the Youden index. The independent association of PENK with 90-day mortality was analyzed with regression analyses adjusting for the CardShock risk score, and levels of hsTnT, ST2 and NT-proBNP.



Results: The mean age was 66 (12) years, 74% were men, and 81% had acute coronary syndrome as CS etiology. Median baseline PENK was 105 (71-167) pmol/mL and creatinine was 1.11 (0.87-1.54) mg/dl. PENK levels were highest at baseline and declined thereafter; those dead at 90 days had higher PENK levels than those alive (figure 1A). PENK was highly correlated with creatinine, eGFR and Cystatin C levels at all time points with highest correlations at 24 h (Spearman ? = 0.705, ? = 0.740 and 0.745, respectively; $p < 0.001$ for all). PENK categorized according to optimal cutoff by Youden index (low/high) was independently associated with increased 90-day mortality at 12 h and thereafter. In particular, categorized PENK at 24 h predicted dismal prognosis: 90-day mortality was 66% for high vs 18% for low PENK (see also figure 1B); the same 24-h cutoff (<105 pmol/mL) was also optimal for mortality prediction by the Youden index. Categorized PENK at 24h (below/above 105 pmol/mL) provided additive value for the CardShock risk score, peak-hsTnT, ST2 and NT-proBNP in mortality prediction ($p < 0.05$ for all comparisons of nested models). Combination of categorized PENK, ST2 (below/above 480 ng/mL) and NT-proBNP (below/above 4840 ng/L) at 24 h showed good discrimination in 90-day mortality prediction with AUROC 0.855 (95% CI 0.789-0.921, $p < 0.001$).
Conclusions: In CS, PENK is highly correlated with renal function. Its level has also a positive correlation with increased mortality and PENK at 24 h can provide additive value in risk stratification.

P1138

Predictors of long lenght of stay in elderly patients with acute heart failure: realworld evidence from the ATHENA registry

A Pratesi[1]; F Orso[1]; AC Baroncini[1]; G Biagioni[2]; F Fedeli[2]; S Parlapiano[2]; A Herbst[2]; A Lo Forte[1]; C Ghiara[1]; E Giuliani[1]; F Caramelli[1]; N Marchionni[1]; M Di Bari[1]; A Ungar[1]; S Baldasseroni[1]
[1]Careggi University Hospital (AOUC), Department of Experimental and Clinical Medicine, Florence, Italy; [2]University of Florence, Florence, Italy

Backword: Clinical registries represent the so-called "real world" in contrast to clinical trials that are known to have a selection bias. However, heart failure (HF) registries may maintain a certain level of selection bias by including only patients hospitalized in cardiology wards. "Real world" administrative data show that only few patients (about a quarter) are hospitalized in cardiology units, while most of them are admitted to internal medicine and geriatrics wards.
Purpose: to identify the independent predictors of long length of stay of elderly patients hospitalized for acute HF in different clinical settings of care: cardiology, internal medicine and geriatrics.
Methods: data derived from the ATHENA retrospective observational study which included elderly patients (= 65 years) admitted with diagnosis of AHF (worsening or de novo) to the Emergency department (ED) of a tertiary University teaching-hospital and then transferred to the above described settings of care between 01-Dec-2014 and 01-Dec-2015.
Results: 401 patients were enrolled, 15.2% hospitalized in cardiology, 14.7% in geriatrics and 70.1% in internal medicine. Mean age was 83.5 years, and was higher in geriatrics (86.9 years) than in internal medicine (83.4 years) and in cardiology (81.0 years), $p = 0.001$. Females were 52.6%: 55.7% in cardiology, 52.7% in internal medicine and 49.2% in geriatrics ($p = 0.770$). Of those alive at discharge, mean length of stay was 9.0 days; then, we considered long length of stay (LLS) a bed rest >9 days. LLS occurred in 108 (29,6%) participants, and was longer in geriatrics (13.7 days) than in cardiology (9.9 days) and internal medicine (8.0 days), $p < 0.001$. In univariate analysis, variables related with LLS were: Charlson Comorbidity score, setting of care, NT-proBNP measured in ED, history of severe chronic kidney disease, eGFR and hematocrit in ED, cognitive impairment and Barthel index. In multivariate analysis, adjusted for age and sex, resulted independent predictors of LLS: NT -proBNP in ED - subsequently expressed as logarithm with base 10 (OR 4.12, 95%CI 2.08-8.14, $p < 0.001$), Barthel Index (OR 0.98, CI = 0.97-0.99, $p = 0.017$) and cognitive impairment (OR 3.17; 95% CI 1.40-7.18; $p = 0.006$).
Conclusion: NT-proBNP in ED, Barthel Index and cognitive impairment are independent predictors of long length of stay in a large cohort of elderly patients hospitalized for acute heart failure in different clinical setting of care.

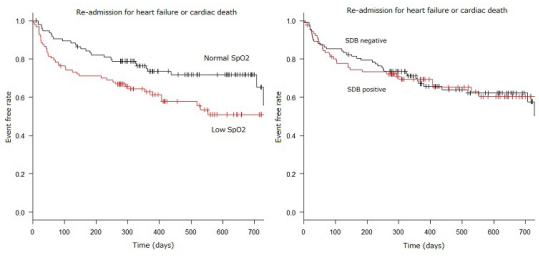
Prognostic impact of sleep disordered breathing and nocturnal hypoxemia in patients with acute decompensated heart failure

H Hirokazu Kondo[1]; Y Obayashi[1]; M Fuki[1]; M Imanaka[1]; S Nishimura[1]; M Kuroda[1]; M Amano[1]; S Nishiuchi[1]; T Harita[1]; J Sakamoto[1]; Y Tamaki[1]; S Enomoto[1]; M Miyake[1]; T Tamura[1]; Y Nakagawa[1]
[1]Tenri Hospital, Tenri, Japan

Background: It has been reported that heart failure is frequently concomitant with sleep disordered breathing (SDB) and nocturnal hypoxemia is a worsening factor of heart failure. The purpose of this study is to evaluate prognostic impact of SDB and nocturnal hypoxemia in patients with acute decompensated heart failure (ADHF).
Methods: Consecutive 193 patients (76.9 ± 11.7 years, males, 50.2%) with ADHF emergently admitted to our hospital from September 2015 to March 2017 were enrolled and performed overnight oximetry with PULSOX®-Me300 before discharge. We examined and calculated 3% oxygen desaturated index (ODI), mean oxygen saturation (SpO2) and time with oxygen saturation <90% (T90), and defined SDB positive as 3%ODI >15, low SpO2 as mean SpO2 <95, and high T90 as T90 >6 minutes, and investigated prognosis as re-admission of heart failure and cardiac death.
Results: 3%ODI was 16.7 ± 12.5 and SDB positive were 91 patients. Median of mean SpO2 was 94.9% (93.8-96.1) and low SpO2 were 97 patients and high T90 were 100 patients. 73 patients were re-admitted for heart failure or cardiac death, and Kaplan-Meier analysis revealed that low SpO2 group and high T90 group had worse prognosis than normal SpO2 group and low T90 group, on the other hand, SDB positive was not significant (log-rank P = 0.019, P = 0.011, and P = 0.88, respectively).
Conclusions: Nocturnal hypoxemia was associated with increasing risk for re-admission and cardiac death in patients with ADHF.

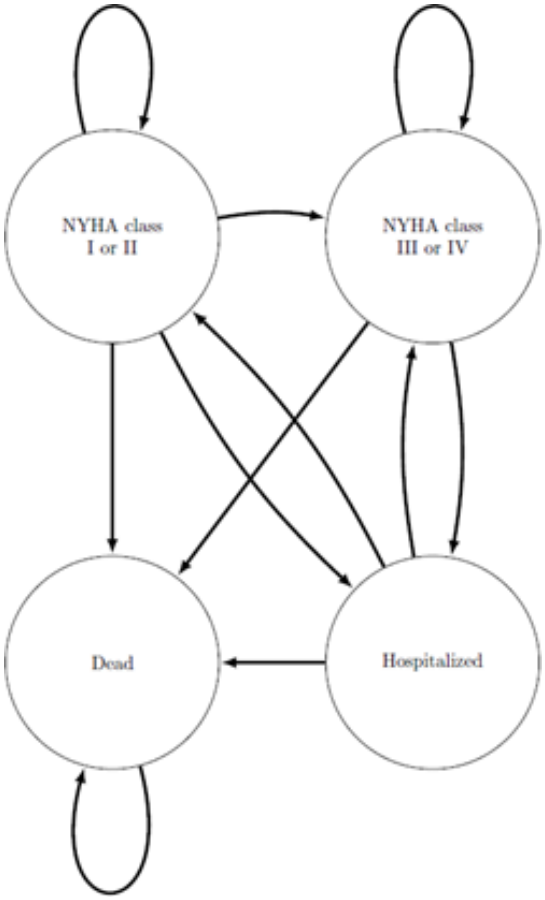


P1140

Effectiveness of heart failure care management by primary versus secondary care providers; a health state transition model.

H Henk Van Voorst[1]; AER Arnold[1]
[1]Medical Center Alkmaar, Cardiology, Alkmaar, Netherlands

Background: Heart failure reduces quality of life and life expectancy, hospital admissions are frequent and create a burden on public resources.
Purpose: The aim of this study is to quantify the differences in costs and Quality Adjusted Life Years (QALYs) of primary compared to secondary care lead heart failure follow up after an acute heart failure admission.
Methods: A health state transition (Markov) model was written with the states New York Health Association functional classification (NYHA) class I or II, NYHA class III or IV, hospitalized and dead. Transition probabilities between states were derived retrospectively from a single centre cohort of patients admitted for acute heart failure between 01-01-2013 and 31-12-2015 and available literature. 12 months of follow up data after the initial hospital admission was included in this study. QALYs in the health states were extracted from the literature. Quantity and costs of care were provided by the hospitals financial department and was only with respect to in hospital care. The treatment effect, primary versus secondary care lead follow up, was extracted from the literature. Monthly simulation steps were repeated 60 times to generate 5 years of virtual follow up data. Baseline willingness to pay was assumed € 50,000 per QALY.
Results: Primary care lead follow up decreased the costs by €137.89 and increased the QALYs by 0.22 in the baseline simulation, this resulted in a Net Monetary Benefit of € 11,227.46. Probabilistic sensitivity analysis using uniform and the most plausible distributions of parameters resulted in 86.1 % and 89.1% of the simulations favouring primary care lead heart failure follow up.
Conclusion: Involving primary care physicians in heart failure care will likely decrease costs and increase QALYs, this result was reached through a decrease of the mortality and hospitalization rate in the model.



Health state transition (Markov) diagram

Effects of beta blocker use prior to admission in patients with acute decompensated heart failure

Y Tamaki[1]; H Yaku[2]; E Yamamoto[3]; N Ozasa[2]; Y Inuzuka[4]; T Morimoto[5]; Y Nakagawa[1]; T Kato[2]; T Kimura[2]
[1]Tenri Hospital, Department of Cardiology, Tenri, Japan; *[2]Kyoto University Graduate School of Medicine, Department of Cardiovascular Medicine, Kyoto, Japan*; *[3]Massachusetts General Hospital, Cardiology Division, Boston, United States of America*; *[4]Shiga General Hospital, Department of Cardiology, Moriyama, Japan*; *[5]Hyogo College of Medicine, Department of Clinical Epidemiology, Nishinomiya, Japan*

Background: Beta blockers are guideline-recommended therapy and improve long-term prognosis in heart failure patients with reduced ejection fraction. However, whether beta blocker use before admission is beneficial in patients with acute decompensated heart failure (ADHF) remains unclear.
Purpose: The purpose of this study is to clarify the effects of beta blocker use before admission on in-hospital mortality in patients with ADHF.
Methods: This study is a physician-initiated, prospective, observational cohort study enrolling the consecutive patients who had hospital admission due to ADHF during the period between October 2014 and March 2016 in the 19 participating hospitals in Japan. After excluding 239 patients with acute coronary syndrome, 3817 patients were included in this analysis. Primary outcome measure was all cause death during hospitalization.
Results: Mean age was 78.1 years and 54.7% were male. Ischemic etiology was 28.5%. Mean left ventricular ejection fraction (LVEF) was 46.3% and 37.9% of patients showed LVEF less than 40%. Intravenous inotropes were used in 19.5%. Patients taking beta blockers before admission were 39.6%. Patients on beta blockers were significantly younger (77.6 years vs. 78.4 years, p <0.001) and had more frequently history of heart failure hospitalization (55.2% vs. 26.1%, p <0.001). Ischemic etiology was more prevalent in patients on beta blockers (36.3% vs. 23.4%, p <0.001). There was no difference in sex, prevalence of LVEF less than 40%, and use of intravenous inotropes between patients with and without beta blockers. Systolic blood pressure at presentation was lower in patients on beta blockers (143 ± 35 mmHg vs. 151 ± 35 mmHg, p <0.001). Heart rate was also lower in patients on beta blockers (92 ± 25 bpm vs. 98 ± 29 bpm, p <0.001). Patients on beta blockers showed significantly lower in-hospital mortality (4.4% vs. 7.6%, p <0.001). After adjusting for confounders, beta blocker use before admission was significantly associated with lower in-hospital mortality (hazard ratio 0.39; 95% confidence interval 0.26-0.58, p <0.001).
Conclusion: Beta blocker use prior to admission was associated with lower in-hospital mortality in patients with ADHF.

P1142

Not all acute heart failure syndromes are the same: De novo acute heart failure vs. Acutely decompensated chronic heart failure.

J-H Ju-Hee Lee[1]; WS Yoon[1]; DH Bae[1]; M Kim[1]; KK Hwang[1]; MC Cho[1]
[1]Chungbuk National University Hospital, Cardiology, Cheongju, Korea Republic of

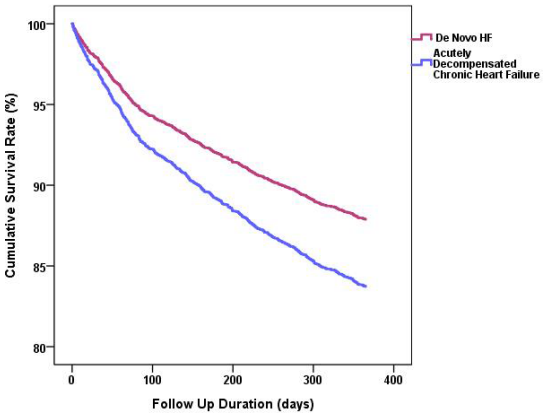
Funding Acknowledgements: This work was supported by Research of Korea Centers for Disease Control and Prevention.

Background: Acute heart failure syndromes (AHFS) can be classified into heart failure (HF) which presenting for the first time (de novo) or acutely decompensated chronic HF (AD-CHF). We compared the differences between de novo HF and AD-CHF regarding their clinical features and prognosis.
Method
We evaluated the AHFS patients hospitalized in ten regionally-representative tertiary university hospitals who registered in the Korean Acute Heart Failure (KorAHF) Registry from March 2011 to February 2014.
Results: Among the 5,625 patients who were registered at KorAHF Registry, 2,944 patients (52.3%) were classified as de novo HF and 2,681 patients (47.7%) were classified as AD-CHF. AD-CHF patients were older, more often women, and more likely to have hypertension, diabetes, ischemic heart disease, chronic kidney disease and atrial fibrillation. Regarding precipitating factors, infection, renal failure, anemia or bleeding, noncompliance and recent addition of negative inotropic drugs were predominant in AD-CHF, whereas ischemic event, severe hypertension, excessive alcohol or illicit drug use and endocrine abnormalities were predominant in de novo HF. AD-CHF patients showed lower serum sodium and hemoglobin, higher blood urea nitrogen and serum creatinine, and higher B-type natriuretic peptide level. De novo HF patients showed higher LV EF, smaller LV end-diastolic dimension and LA size, and lower RV systolic pressure. Although the use of renal replacement therapy was comparable, de novo HF patients were more frequently supported by mechanical ventilator and mechanical assisting device including IABP, PCPS and AD-CHF patients used inotropes more frequently. While in-hospital mortality was comparable between two groups (5.0% in AD-CHF vs 4.6% in de novo HF, P = 0.396), 1-year mortality was significantly higher in AD-CHF patients (22.9% vs 13.9%, P < 0.001). In multivariate analysis adjustment for 13 risk variables including age, sex, and brain natriuretic peptide, the hazard ratio for the mortality was increased in patients with AD-CHF. (Figure)
Conclusion: Independent of other key prognostic variables, AD-CHF had significantly worse prognosis than de novo HF. They also showed many differences in clinical presentation, risk factors and laboratory values. Better understanding on these differences between de novo HF and AD-CHF is needed to improve outcomes for AHFS.



P1143

Ischemic origin of heart failure is associated with worse prognosis in 3 and 12 months after acute episode

A Vinikovas[1]; R Zeimaite[2]; K Navardauskaite[2]; D Verikas[3]; D Kablucko[4]; K Stasaitis[5]; A Mebazaa[6]; A Kavoliuniene[5]; J Celutkiene[4]

On behalf of: GREAT network

Introduction: Ischemic origin of heart failure is associated with higher mortality rates for heart failure (HF) patients. However, the prognostic relevance of ischemic heart disease and prior coronary artery revascularization is not entirely clear.
Purpose: We aimed to analyse the impact of ischemic heart disease and history of revascularization on mortality (M) and rehospitalization (R) rates due to cardiovascular (CVR) and non-cardiovascular reasons (NCVR) in 1, 3, and 12 months (mo) in AHF patients.
Methods: A prospective two-centre observational cohort study enrolled 726 (mean age 72 years, 43% female) AHF patients admitted to an emergency department. Data, including patient history, R and M rates were grouped into non - ischemic HF (Non–Isch-HF) and an ischemic HF (Isch-HF) group, the latter was divided into 2 subgroups: with and without revascularization - (Revasc+) and non-revascularization (Revasc-) groups. Data was analyzed with binary logistic regression, SPSS v.20. Non-IscHF and Revasc- groups were used as references. Odds ratio (OR) were also adjusted to age, gender, LVEF, anemia and systolic blood pressure.
Results: 310 (42.6%) patients represented Isch-HF group, of them - 155 (50%) represented Revasc+ group. The results are presented in table below ($p < 0.05$ are marked with an asterisk *). After adjustment, only composite endpoint (M+R) due to cardiovascular reasons showed significant increase in Isch-HF group.
The history of coronary artery revascularization showed no statistically significant association.
Conclusion: Ischemic HF patients demonstrate significantly higher morbidity and mortality in 3 and 12 months after hospitalization compared to non-ischemic HF patients. On the other hand, ischemic HF patients are much less affected by non-cardiovascular rehospitalizations and mortality.

P1144

Characteristics of heart failure with preserved, mid-range, and reduced ejection fraction in patients admitted with dyspnea - impact of comorbidity

OW Nielsen[1]; N Valeur[1]; A Sajadieh[1]; A Andreas Fabricius-Bjerre[1]; CM Carlsen[1]; L Kober[2]
[1]Bispebjerg University Hospital, Copenhagen, Denmark; *[2]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*

Background: The distribution of subtypes of cardiac dysfunction in heart failure (HF) including preserved ejection fraction (HFpEF), mid-range EF (HFpEF), and reduced EF (HFrEF) remains elusive, probably due to unclear diagnostic criteria, patient selection, and non-cardiac comorbidity. We studied consecutively admitted patients with dyspnea. The aim was to apply novel guidelines to describe the type of cardiac dysfunction in relation to presumed cardiac or non-cardiac cause of dyspnea.
Method: All patients with dyspnea as a main reason for hospitalization were eligible; we excluded patients with acute coronary syndrome, eGFR < 30 ml/min/1.73 m^2, and low NT-proBNP (< 35 pmol/l, i.e 296 ng/l). Patients with presumptive non-cardiac dyspnea were only included if NT-proBNP exceeded 423, 845 and 1691 ng/l, for age 40-49, 50-74 and 75+ years respectively. Novel ESC criteria for HFpEF and diastolic dysfunction were assessed in every patient with LVEF of 40% or more. Cardiac dysfunction was ranked according to the first matching abnormality: valvular heart disease (HFvhd), HFrEF, HFmrEF, HFpEF, and no cardiac dysfunction. We also adjudicated whether acute decompensated HF (ADHF) had been the primary diagnosis during admission.
Results: We included 370 patients of whom 75 had presumptive non-cardiac dyspnea. Overall, 10% (38/370) had no cardiac dysfunction. Cardiac dysfunction consisted of 18.4 % HFvhd (61/332), 30.1 % HFrEF (100/332), 10.2% HFmrEF (34/332), and 41.3% HFpEF (137/332). HFpEF was twice as common in presumptive non-cardiac dyspnea vs cardiac dyspnea (71 % vs 34%, $p < 0.0001$). HFmrEF matched HFrEF, but HFrEF was associated with higher Charlson Comorbidity index than HFmrEF and HFpEF (3.2 vs 2.3 vs 2.5, $p = 0.021$) despite lower mean age (73.2 vs 77.2 vs 77.1 years, $p = 0.011$). Adjudicated ADHF was the primary diagnosis in 80% of HFrEF, 62% of HFmrEF and 28 % of HFpEF.
Conclusion: HF according to contemporary criteria applied to 90% of patients admitted with dyspnea and elevated NT-proBNP irrespective of presumptive cause of dyspnea, of these 10% had HFmrEF and 41% HFpEF. A diagnostic and therapeutic dilemma arises for the many patients who fulfill criteria for HFpEF albeit ADHF was not adjudicated as the primary diagnosis.

Funding Acknowledgements: This survey was funded by the ESC. Each participating national cardiology society was given a grant of €10 000 to help with the organizational needs o

Background: Women with cardiovascular disease have distinct clinical manifestations and outcome compared with males. Knowledge on relevant gender specific risk factors for HF can assist with appropriate targeted preventative interventions, diagnosis and therapeutics for each gender.
Aims: This analysis evaluates the gender differences in the Egyptian cohort of patients hospitalised for acute heart failure (AHF) in the ESC-Heart Failure long-term registry.
Methods and Results: From April 2011 to September 2014, 1634 patients hospitalised with AHF were enrolled by 20 hospitals all over Egypt. Of these patients, 1112 (68%) patients were men, mean age 60.5 ± 11.9 years, and 522 (32%) were women, mean age 60.3 ± 13.3 ($p = 0.80$). Women presented with a higher admission systolic blood pressure and resting heart rate. Compared to men, women had a higher body mass index (32.5 ± 9.0 vs 29.3 ± 4.9, $p < 0.001$), more frequent atrial fibrillation (35%vs 22%, $p < 0.001$) and anaemia defined by a haemoglobin <12 g/dl (83% vs 58%, $p < 0.001$). Women were more likely to present with heart failure with preserved ejection fraction than men (30% vs 11%, $p < 0.001$). Women had more frequent diabetes mellitus (48% vs 42%, $p < 0.05$) and hypertension (49% vs 39%, $p < 0.001$) than men whereas smoking was rare (9% vs 83%, $p < 0.005$). There was no significant difference in the primary etiology of heart failure between both sexes. ACE-inhibitors, MRA's, antiplatelets, statins and nitrates were less frequently prescribed to women, whereas they more often received digoxin, amiodarone, anticoagulants and calcium channel blockers. There was no significant difference in in-hospital (6% vs 5%, $p = 0.39$) and one- year mortality (28% vs 26%, $p = 0.48$) between both sexes. SBP (<100mmHg) and renal dysfunction (serum

creatinine=1.5 mg/dl) were significant predictors of in-hospital mortality. For 1-year mortality, age (one year increase in age), hemoglobin <12gm/dl, SBP <100mmHg and renal dysfunction were significant predictors.
Conclusion: Men and women with AHF differ significantly in baseline clinical characteristics, cardiovascular risk factors and management but not in adverse outcomes. These findings emphasize the importance of individualized management and need for more comprehensive recruitment of women in clinical trials.

P1146

Does the cause really matters? analysis of heart failure decompensation with or without an etiologic factor

A Alejandro Travieso Gonzalez[1]; TS Luque Diaz[1]; CN Perez Garcia[1]; D Enriquez Vazquez[1]; D Vivas Balcones[1]; C Olmos Blanco[1]; J Higueras Nafria[1]; R Bover Freire[1]; I Vilacosta[1]; C Macaya Miguel[1]
[1]*Hospital Clinic San Carlos, Madrid, Spain*

Introduction: In some acute heart failure (HF) episodes, the trigger of the event remains elusive despite a thorough investigation. Our aim is to establish if there are any differences in the clinical profile between patients with an attributable cause of the decompensation and those without it.
Methods: From July 2015 to April 2017, 336 consecutive patients were admitted to a tertiary hospital in Spain, with the diagnosis of acute heart failure. The healthcare professionals further classified them according to the presence or absence of a trigger of the event.
Results: From the 336 patients analyzed, in 281 of them a trigger for the episode was found, and in 55 it was not. Mean age was 76,2 for the first group, 73,8 for the second (p = 0,133). Slight differences in gender were seen (72,7% men without it, 51,6% women with it, p = 0,001). No significant differences were reported in other cardiovascular risk factors (Table 1).
In the complementary explorations, patients without a cause of the episode had lower values of left ventricular ejection fraction (LVEF) (38% vs 48%, p = 0,003), and lower levels of serum ferritine (111 vs 202 ng/mL, p = 0,002).
Patients without a trigger of the episode had a trend towards longer in-hospital stay (5,05 [SD 0,89] vs 4,72 [SD 0,95] days), without statistical signification. Levels of NTproBNP were higher in the group without a cause (27.141 vs 8511 pg/mL, p = 0,01). They were also characterized by a greater use of implanted cardioverter defibrillators (ICD) (16,4% vs 5,3%, p = 0,004) and cardiac resynchronization therapy (CRT) (12,7% vs 3,2%, p = 0,002). They were more commonly derived to HF specialized units at discharge (58,2% vs 20,6%, p < 0,001).

Table 1

N = 336	Without trigger (n = 55)	With trigger (n = 281)	p
Arterial Hypertension	81,8%	81,9%	0,995
Diabetes Mellitus	41,8%	47,3%	0,453
Dyslipidemia	61,8%	63,3%	0,830
Smoking habit	7,3%	10,3%	0,487
Atrial fibrillation	52,7%	55,2%	0,740
Chronic kidney disease	32,7%	28,5%	0,525

Cardiovascular risk factors.

Conclusions: Patients with an acute heart failure without a trigger of the decompensation have a different profile from those with a recognizable one. They have lower LVEF, higher levels of serum natriuretic peptides and prevalence of iron deficiency, with a broader use of device therapies for advance HF (ICD and CRT) and referral to heart failure specialized units. No significant differences were seen in the length of in-hospital stay.

P1147

Hyponatremia is associated with worse clinical markers of congestion, anemia, renal impairment, myocardial damage, neurohormonal and inflammatory activations

Y Yuksel Cavusoglu[1]; ME Altinbas[1]; S Eraslan[1]
[1]*Eskisehir Osmangazi University, Eskisehir, Turkey*

Purpose: Hyponatremia has been established as a strong predictor for worse clinical outcomes in heart failure (HF). N-terminal pro B-type natriuretic peptide (NT-proBNP), cardiac troponin, high sensitive C-reactive protein (hsCRP), hemoglobin (Hb) or estimated glomerular filtration rate (eGFR) are also known to be of prognostic significance in HF. We aim to assess possible associations between hyponatremia and other well-established clinical markers in patients with HF.
Methods: This study included 418 patients admitted to hospital with the diagnosis of acute decompensated HF, NYHA II-IV, LVEF < 40% and >18 years of age. NT-proBNP, high sensitive cardiac troponin T (hs-cTnT), carbohydrate antigen 125 (CA-125), hsCRP, eGFR, creatinine, Hb and sodium levels have been analyzed for the assessment of possible correlations and associations. Patients were classified into two groups: patients with hyponatremia (sodium < 135 mEq/L, n = 80, 19.1%) and patients with normonatremia (sodium = 135 mEq/L, n = 338, 80.9%).
Results: Mean age of study population was 67 ± 12 years. Mean EF was 25.4 ± 7.9%, NT-proBNP was 7667 ± 9876 pg/mL, CA-125 was 86.2 ± 125.5 U/mL, hs-cTnT was 0.22 ± 0.86 ng/mL, creatinine level was 1.41 ± 0.88 mg/dL, eGFR was 62.9 ± 32.4 mL/min/1.73 m2, hsCRP was 27.4 ± 39.1 mg/dL, sodium was 138.2 ± 4.7 mEq/L and hemoglobin level was 12.4 ± 2 g/dL. When compared to patients with normonatremia, patients with hyponatremia have had higher median NT-proBNP (3197 [1093-8391] vs 6964 [2647-19902] pg/mL, p < 0.001, respectively), higher CA-125 (33.33 [15.8-96.8] vs 61.04 [25.3-172.0] U/mL, p < 0.011, respectively), higher hsCRP (10.9 [3.8-24.8] vs 27.2 [10.1-67.6] mg/L, p < 0.001, respectively), higher hs-cTnT (0.033 [0.016-0.064] vs 0.044 [0.021-0.086] ng/mL, p < 0.05, respectively), higher creatinine (1.12 [0.9-1.4] vs 1.33 [1.0-1.9] mg/dL, p < 0.005, respectively), lower eGFR (59.7 [41.1-83.5] vs 48.2 [35.1-68.9] mg/L, p < 0.001, respectively) and lower Hb (12.8 [11.1-13.9] vs 11.3 [10-12.8] g/dL, p < 0.001, respectively). There were a significant negative correlation between sodium and NT-proBNP levels (r=-,232, p < 0.001), CA-125 levels (r=-,136, p = 0.01), hsCRP levels (r=-,267, p < 0.001), hs-cTnT levels (r=-,134, p = 0.008), creatinine levels (r=-,185, p = 0.001) and positive correlation between sodium and Hb levels (r=,255, p = 0.001) and eGFR (r=,173, p = 0.001). Hyponatremia was present in 26% of patients with anemia and in 11.8% of patients without anemia (p < 0.001), 22.4% of patients with an eGFR < 60 mL/min/1.73 m2 and in 14.3% of patients with an eGFR >60 mL/min/1.73 m2 (p = 0.036), in 21.2% of patients with high hsCRP and in 10.3% of patients with normal hsCRP levels (p < 0.05).
Conclusions: The results of this study showed that in decompensated HF patients, hyponatremia is associated with higher NT-proBNP, hs-cTnT, CA-125, hsCRP, creatinine levels and lower eGFR and hemoglobin levels, reflecting more severe clinical status of the disease in patients with hyponatremia.

P1148

Abnormal potassium level predicts long-term outcomes in patients with acute dyspnea

A Vinikovas[1]; R Zeimaite[2]; K Navardauskaite[2]; G Ziubryte[3]; S Tribusauskaite[3]; D Rimkeviciute-Vaiciuliene[4]; D Kablucko[5]; K Stasaitis[4]; A Mebazaa[6]; A Kavoliuniene[4]; J Celutkiene[5]

On behalf of: GREAT network

Introduction: As plasma potassium (K) level imbalance is associated with higher mortality risk, K is included in some clinical risk scores to assess the prognosis of acute heart failure (AHF) patients. The importance of hypo-/hyperkalemia in prediction of outcomes in a wide population of dyspneic patients is less clear.
Purpose: We aimed to evaluate the prognostic value of abnormal blood K levels in prediction of long-term mortality (M) and readmissions (R) in dyspneic patients.
Methods: Prospective observational cohort study enrolled consecutive patients admitted to the emergency department (ED) with acute dyspnea due to AHF and other reasons. Blood K levels at the time of admission and number of M and R due to cardiovascular (CVR) and non-cardiovascular (NCVR) reasons in 12 months of follow up were collected. Data of 1414 study patients (mean age 72 years) were included in the analysis. Patients were divided into 3 groups by plasma K level: group 1 consisted of 1243 (87.9%) patients with normal plasma K level (3,8-5,2 mmol/L); hypokalemia group - 98 (6.9%) patients with plasma K level up to 3,8 mmol/L; 73 (5.2%) patients with plasma K level higher than 5,2 mmol/L were included into hyperkalemia group. Data were analyzed using SPSS v23 with binary and multivariable regression.
Results: With binary logistic regresion, long term M and R due to CVR showed statistically significant results in hyperkalemia group: R due to CVR - OR = 1.548, C.I. 0.9; 2.4, p = 0.007; M due to CVR - OR = 2.159, C.I. 1.2; 3.8, p = 0.009. Multivariable regression's results are presented in the table below. Univariate predictors included hyperkalemia, blood urea level, chronic kidney disease (CKD), non-usage of ACE inhibitors and aldosterone inhibitors. In a multivariate analysis hyperkalemia was found as the most critical prognostic factor (adjusted OR 6,49, 95% CI 1,23-34,33; p = 0,028).
Conclusion: Patients with hyperkalemia at the time of admission have greater chances of death and readmissions due to cardiovascular reasons in a 12-month

period, compared to patients who arrived at the ED with normal blood K levels or hypokalemia.

Multivariate analysis results

Variable	Univariate analysis		Multivariate analysis	
	OR	C.I. 95%	OR	C. I. 95%
Plasma potassium level: elevated vs normal[a]	1,04	0,88-1,25	6,49*	1,23-34,33
Angiotensin-converting enzyme inhibitor: : non-use vs use[a]	0,24	0,98-1,56	1,57*	1,09-2,25
Plasma urea level: increased vs normal[a]	1,02*	1,01-1,04	1,03*	1,00-1,06

ESC guidelines for management of acute heart failure: fact vs reality, one year later

N Sahdev[1]; A Pulikal[1]; R Rajay Narain[1]; A Saidmeerasah[1]; L Ruscoe-Price[1]; N Soni[1]; J Kathirgamachelvam[1]; R Ray[1]; N Shanmugam[1]; L Anderson[1]
[1]St George's University of London, Cardiac and Vascular Sciences Research Centre, London, United Kingdom

Background/Introduction: In 1997 heart failure (HF) was said to be an emerging epidemic and twenty years on, it is at the forefront of global disease with a world prevalence of more than 23 million. Under new European Society of Cardiology (ESC) guidelines in 2016, patients with AHF with pulmonary oedema with respiratory failure should be referred to coronary care/intensive care unit within 120 minutes.
Purpose: This study aims to observe the implementation of the new ESC pathway for management of acute heart failure in a busy tertiary hospital. The study observes time periods before and after the ESC 2016 guidelines were incorporated into the hospital ED guidelines to observe if the new pathway was being competently followed.
Methods: In September 2016, we met with the ED team to draw up a pulmonary oedema pathway in line with the new ESC guidelines for AHF (referral to cardiology andtransfer of patients with pulmonary oedema and respiratory failure to CCU/HDU within 120 minutes. Patients presenting to ED and admitted to the hospital with AHF from February-June 2016 and October 2016-December 2016 who were detected by the heart failure team were extracted from the National Heart failure audit. To ensure validity in both data sets, the x-ray of each patient was reviewed by two independent cardiologists and corroborated with radiology report for pulmonary oedema. The patients that were agreed to have AHF with CXR evidence of frank pulmonary oedema were extracted. The patient notes were searched for details including: A&E diagnosis, referral pathway, final admitted ward, discharge date, HR, BP and co-morbidities.
Results: Prior to the ESC guidelines being implemented within the hospital (Feb 2016-June 2016), 26 patients admitted with AHF with pulmonary oedema were identified (11% of the total admitted AHF patients). Of these 26 patients, 9 (35%) were referred to cardiology immediately in A&E. Of these 9, 7 were transferred onto a cardiology ward [LA1] and 2 were treated on a medical ward.
Following the introduction of the ESC guidelines into hospital guidelines (Oct-Dec 2016) of the 27 patients who were admitted with AHF and frank pulmonary oedema on CXR (18% of the total admitted AHF), 13 were referred to cardiology (48%). 100% of these patients were transferred to CCU within 120 minutes.
Therefore, following the implementation of the new guidelines the percentage of patients directly referred to cardiology increased from 35% to 48%.
Conclusion(s): Following ESC 2016 guidelines more AHF patients with pulmonary oedema presenting to A&E are being referred directly to cardiology. Once referred they were transferred to a level 2 (CCU) bed within the suggested timeframe. The new guidelines allow clinicians to make more clear decisions. Although an increase in patients referred to cardiology is encouraging, further work is needed on this pathway to ensure the percentage of pulmonary oedema patients transferred to cardiology improves further.

P1150

The examination of clinical features about congestive heart failure with ischemic heart disease in cases used original clinical pathway.

Y Kato[1]; K Hayashi[1]; M Hasegawa[1]; N Matsuo[1]; T Fujiwara[1]; M Tanimoto[1]; K Kagawa[1]; Y Nakano[2]; N Onishi[1]; A Atsushi Takaishi[1]; M Ueeda[1]; S Hirohata[2]
[1]Mitoyo General Hospital, Kanonji, Japan; *[2]Okayama University, Graduate School of Health Sciences, Okayama, Japan*

Background: We introduced the clinical pathway(CP) for congestive heart failure(CHF) cases required admission from August 2015, and reported its usefulness previously. From past epidemiologic point of view, there seems to be the clinical features about age range, left ventricular function or various data of lipid and fatty acid in CHF cases with ischemic heart disease(IHD) compared in CHF cases with other underlying disease.
Purpose: We investigated the clinical features about CHF cases with IHD who ware introduced our original CP.
Method: We enrolled 197 CHF cases admitted in our hospital and introduced CP for the first time from August 2015 to July 2017(mean age 81+/-11 years old, male/female 112/85). We divided them into two groups, IHD-group(CHF with any IHD required any treatment: 62cases) and NIHD-group(CHF without IHD: 135cases), and investigated their various factors about clinical course and blood data on admission about lipid and polyunsaturated fatty acid(PUFA). Between two groups we examined the difference about each factor.
Results: In IHD-group compared in NIHD-group mean age was higher(78+/-11 vs 82+/-10 years old; $p < 0.05$), the man ratio was higher(69 vs 51%; $p < 0.05$) and the prevalence of dementia was lower(21 vs 42% $p < 0.01$). About left ventricular function the ejection fraction by echocardiography was lower(44+/-19 vs 54+/-19%; $p < 0.05$) and the value of Brain Natrium Peptide in blood on admission was higher(962+/-710 vs 734+/-645 pg/mL; $p < 0.05$) in IHD-group. The various lipid data(blood concentration of triglyceride, high density lipoprotein, low density lipoprotein or oxidized low density lipoprotein) was not different between two groups. About PUFA, in comparison except all cases administered EPA preparation, although the blood concentration of arachidonic acid(AA) and docosahexaenoic acid(DHA) on admission ware not different between two groups, the value of eicosapentaenoic acid(EPA) tended to be higher (61+/-27 vs 53+/-34 mg/dl; NS) and the ratio of cases with high EPA/AA value(= 0.3) was higher(63 vs 47%; $p < 0.05$) even in IHD-group. Although the mean hospitalization period was shorter in IHD-group(14+/-11 vs 18+/-13 days; $p < 0.05$), the ratio of cases with the history of CHF admission within past 3 years before admission was higher(37 vs 21%; $p < 0.05$) and the ratio of re-admission cases with CHF within 1 year after discharge was higher(33 vs 20%; NS) in IHD-group.
Conclusion: About clinical features in CHF cases with IHD, the result about patient characteristics or cardiac function was predictable. But we found that their hospitalization period was shorter and they tended to admit repeatedly. And we found that the EPA concentration of blood on admission among PUFA in IHD-group was higher rather than that in NIHD-group. It seemed that there was another imvolvement of influence to metabolism of PUFA in CHF cases compared in general ischemic heart disease cases.

P1151

Causes of death after hospital discharge are similar between heart failure patients with and without worsening renal function

P P M Spineti[1]; L A Feijo[2]; M I Garcia[2]; S S Xavier[2]; A S Sousa[2]
[1]Rio de Janeiro State University (UERJ), Cardiology, Rio de Janeiro, Brazil; *[2]Federal University of Rio de Janeiro (UFRJ), Cardiology, Rio de Janeiro, Brazil*

Background: Worsening renal function (WRF) is associated with higher mortality after hospital discharge in patients with decompensated heart failure (DHF).
Objectives: To describe the causes of death after discharge from patients with a previous admission for DHF. To compare the causes of death between patients with and without WRF.
Methods: Patients admitted for DHF in our university hospital, between 01/01/06 and 12/31/11, were included in a cohort study. Deaths after discharge were identified through record linkage with the state mortality database. ACRS was defined as an absolute increase in serum creatinine = 0.3mg/dL anytime during hospitalization. Causes of death were coded and grouped according the 10th International Disease Classification (IDC).
Results: 394 patients were admitted for DHF; 53.3% were men, with mean age of 64 +/- 14 years, 83.15% had systolic dysfunction and 37.6% ischemic aetiology. The incidence of WRF was 43.3. 29 patients died during the hospitalization and 248 after discharge. The accuracy of deaths search was 99.44%. The main group of death causes was diseases of the circulatory system, accounting for 58.5% of deaths. Among the diseases of the circulatory system, 45% of deaths were due to other forms of heart disease (IDCs I30 to I52), 29% to ischemic heart diseases, 12% to hypertensive diseases and 6% to rheumatic diseases. The codes referring

to heart failure (I11, I50.0 - I50.9) were cited as the underlying cause of death in 48 patients (19.35%). When all lines of the death certificate were analyzed, the codes referring to HF were cited in 99 of the 248 deaths (39.92%). If the codes referring to myocardiopathies and cardiomegaly were associated with HF codes, HF would be identified as the basic cause of 63 deaths (25.4%). Genitourinary tract disorders accounted for only 4% of deaths. The distribution of death causes was similar between groups, with the exception of death from cardiovascular causes that was higher in the ACRS group.
Conclusion: The main cause of death between DHF patients are the circulatory system diseases. The distribution of death causes was similar between patients with and without WRF.

P1152
Heart failure diagnostic after evaluation of more than surgical 1700 patients

P Losada Mora[1]; A M Alfonso Miguel Garrido Castro[1]; JL Carrillo Linares[1]; L Morcillo[1]
[1]*University Hospital Virgen de la Victoria, Cardiology, Internal Medicine, Malaga, Spain*

Introduction: Consultation are a widely used resource among the different units of a hospital. Specifically, those from Orthopedic Surgery and Traumatology (OST) and Vascular Surgery (VS) are the most frequent.
Objectives: Analyze the most frequent consultations on patients admitted to OST and VS to a team (T) assigned to the control of medical pathologies, composed of medical professionals form Internal Medicine and Cardiology.
Material and Methods: Descriptive analysis of consultations on patients admitted to OST and VS who suffered some type of medical decompensation that required to be notified to T.
Results: From June 2008 to November 2014, the following consultations were sent:
- 1486 from the OST. The most frequent consultation was "dyspnea" in 371 cases (25%), followed by "control of pluripathology" in 163 (11%), "control of diabetes" and "blood pressure" both with 124 (8.3%) and 123 (8.3%) consultations. The digestive pathology was 10.5%. 4% of the consultations were due to "analytical alterations". 48.7% of the dyspnea were of respiratory origin. 41% of the dyspnea were of cardiological origin, being the most frequent cause without evident trigger (66%, most developed an accompanying respiratory picture), while 13.6% corresponded to volume overload, 11.3% to anemia secondary to the intervention and another 11.3% to uncontrolled atrial fibrillation. The rest of dyspnea were mainly due to anxiety (4.7%). In 3.7% of the cases, dyspnea was not observed.
- 173 from the VS. The most frequent consultation was "dyspnea" in 62 cases (35.8%), followed by "control of pluripathology" in 18 (10.4%), "decrease in the level of consciousness" in 13 (7.5%), fever 13 (7.5%) renal failure 7 (4%) and "control of blood pressure" 7 (4%). 43.5% of the dyspnea were of respiratory origin. 33.8% of the dyspnea were of cardiological origin, being the most frequent cause without evident trigger (28.6%, most of them developed an accompanying respiratory picture), along with 28.6% due to volume overload, 19% to uncontrolled atrial fibrillation, 14% valvulopathy and 9.5% to hypertensive crisis. In 11.3% of cases, a specific diagnosis of dyspnea was not established.
Conclusions: Dyspnea is the most frequent consultation by these two surgical services. A quarter of the consultations for medical decompensation in patients admitted to OST and more than a third in patients admitted to VS also correspond to dyspnea correspond to dyspnea, of which almost half are respiratory and somewhat less of cardiological origin. A significant percentage of these are due to intrahospital processes like volume overload. An early evaluation of these patients could be beneficial in terms of decrease morbidity.

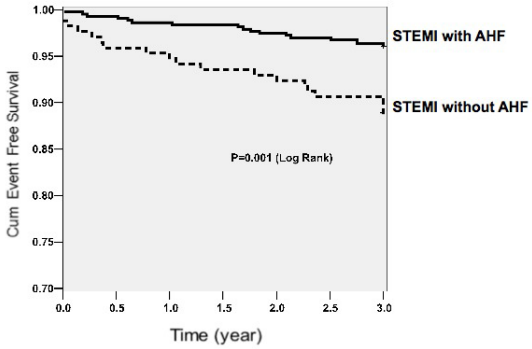
P1153
Acute heart failure in patients with ST-segment elevation myocardial infarction: prognostic significance of mid-range left ventricular ejection fraction

S Sergey Kozhukhov[1]; A Parkhomenko[1]; N Dovganych[1]
[1]*NSC "Institute of Cardiology", Kiev, Ukraine*

Background: The prevalence and clinical outcomes of acute heart failure (AHF) with mid-range left ventricular ejection fraction (mrEF) after ST-elevation myocardial infarction (STEMI) have not been well elucidated. According to the new European Society of Cardiology guidelines we allocated AHF patients (mrEF; 40% to 49%) as a distinct group.
Objective: To analyze the prevalence of AHF, clinical profile, in-hospital outcomes and and long-term survival of STEMI patients with mrEF.
Methods: We conducted a retrospective study of 606 consecutive patients with STEMI (age 54.1 ± 0.4 years) hospitalized within 12 hours of symptoms onset (4.1 ± 0.2 hours), who had echocardiographic examination performed on admission. Based on sign and symptoms of AHF (Killip II-III) within 24 hours patients were divided into two groups: with AHF - 171 and without AHF - 435 patients. Main outcome was cardiovascular mortality with a median follow-up of 3 years.
Results: Patients with AHF were likely to be older, have history of ischaemic heart disease and previous MI. On admission AHF patients presented higher level of glycemia and C-reactive protein, lower glomerular filtration rate in compare to patients without AHF. During in-hospital stay AHF patients had significantly higher rate of ventricular fibrillation/tachicardia and early left ventricle aneurism. Kaplan-Meier survival curves demonstrated that incidence of cardiovascular death in AHF patients was higher in comparison with those without AHF at long-term follow-up (Figure 1).
Conclusions: AHF is a frequent complication in STEMI even in patients with mrEF and is a powerful and independent predictor of 3-year's survival. AHF patients had higher long-term risk, required special attention and monitoring during follow-up.

Event free survival in STEMI patients with mrEF and AHF

Kaplan-Meier



Acute Heart Failure - Diagnostic Methods

P1154
Relationship between brain natriuretic peptide, high-sensitivity cardiac troponin I and kidney function in predicting worsening renal function and prognosis in acute heart failure

Y Horiuchi[1]; N Wettersten[1]; P Murray[2]; A Maisel[1]
[1]*University of California San Diego, Division of Cardiovascular Medicine, San Diego, United States of America*; [2]*University College Dublin, Department of Nephrology, Dublin, Ireland*

Funding Acknowledgements: Abbott Laboratories and Alere, Inc.

Background: In acute heart failure (AHF), relationships between brain natriuretic peptide (BNP), high-sensitivity cardiac troponin I (hscTnI) and renal function have not been fully elucidated, especially in terms of worsening renal function (WRF).
Purpose: We aimed to investigate relationships between BNP, hscTnI and creatinine and its predictive values for in-hospital mortality and WRF.
Methods: The Acute Kidney Injury NGAL Evaluation of Symptomatic heart fallure Study (AKINESIS) was a prospective, international, multicenter study of AHF. We retrospectively analyzed 886 patients for the relationships between admission BNP, hscTnI and creatinine and in-hospital death, severe WRF (sWRF), non-severe WRF (nsWRF) and WRF with clinical deterioration. sWRF was a sustained increase of = 0.5 mg/dl or 50% in creatinine and nsWRF was non-sustained increase of = 0.3 mg/dl or 50% in creatinine. WRF with clinical deterioration means nsWRF with in-hospital death, renal replacement therapy, inotrope use or mechanical ventilation.
Results: BNP, hscTnI and creatinine had significant but weak to moderate correlations ($r < 0.400$). Increased mortality was associated with both higher BNP and hscTnI (Figure 1A). WRF correlated better with hscTnI than BNP (Figure 1B, 1C and 1D). hscTnI predicted each definition of WRF after adjustment for creatinine and other confounders, while these relationships were not observed with BNP (log hscTnI; sWRF, adjusted OR 1.75, 95% CI 1.12-2.71, $p = 0.013$, nsWRF, adjusted OR 1.43, 95% CI 1.07-1.91, $p = 0.017$, WRF with clinical deterioration, adjusted OR 2.21, 95% CI 1.42-3.45, $p < 0.001$).
Conclusions: hscTnI was a significant predictor for worse in-hospital outcomes including sWRF, nsWRF and WRF with clinical deterioration.

Figure 1. Rates of clinical endpoints stratified by BNP and hscTnI above and below the median

How to predict Heart Failure readmission

M Michael Kleiner Shochat[1]; A Shotan[1]; I Kleiner[2]; JM Weinstein[2]; M Kazatsker[1]; A Asif[1]; I Dahan[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; [2]Saroka Medical Center, Cardiology, Beer Sheva, Israel

Background: Readmission for heart failure (HF) are a major burden. We aimed to assess whether the extent of improvement in pulmonary fluid content (?PC) during HF-hospitalization evaluated by lung impedance (LI), or indirectly by other clinical and laboratory parameters, predicts readmission.
Methods: The present study is based on predefined secondary analysis of the IMPEDANCE-HF extended trial comprising 266 HF patients at NYHA class II-IV and LVEF = 35% randomized to LI-guided or conventional therapy during long-term follow-up.
Results: LI-guided patients were followed for 58 ± 36 months and the control patients for 46 ± 34 months (p <0.01) accounting for 253 and 478 HF hospitalizations, respectively (p <0.01). LI, NT-proBNP, weight, radiological score, NYHA class, lung rales, leg edema or jugular venous pressure were measured at admission and discharge on each hospitalization in both groups with the difference defined as ?PC. Average LI-assessed by ?PC was 12.1% vs. 9.2% and time to HF-readmission was 659 vs. 306 days in the LI-guided and control groups, respectively (p <0.01). LI-based ?PC predicted 30 and 90-day HF readmission better than ?PC assessed by the other variables (p <0.01). The readmission rate for HF was lower if ?PC> median compared with ?PC= median for all parameters evaluated in both study groups with the most pronounced difference predicted by LI (p <0.01). Net reclassification Improvement analysis showed that adding LI to the traditional clinical and laboratory parameters improved the predictive power significantly.
Conclusion: The extent of ?PC improvement, primarily the LI-based, during HF-hospitalization, and study group allocation strongly predicted readmission and event-free survival time.

P1156

CA-125, a biomarker in acute-decompensated heart failure. Preliminary study.

M Ababei[1]; A Campeanu[1]; D Nistorescu[1]; O Zaharia[1]; T Nanea[1]
[1]University of Medicine and Pharmacy Carol Davila, Internal Medicine "Prof. Th. Burghele" Hospital, Bucharest, Romania

Background: CA-125 is a tumor antigen expressed on the surface of ovarian cells, used to monitor treatment of ovarian cancer (with normal upper limit of 35U/mL), but that also seems to have a role as a biomarker in heart failure (HF). CA-125 is secreted secondary to stimuli as mechanical stress, oxidative stress or inflammation, pathophysiological mechanisms well known in heart failure decompensation (ADHF).
Aim: To determine CA-125 changes in ADHF patients.
Method: The study group included 110 patients (mean age 72 ± 10 years, 63% men) with ADHF caused by ischemic cardiomyopathy. The subjects were clinically, ecocardiographically and biologically (NT-proBNP, CRP, serum uric acid (sUA), CA-125) evaluated.
Results: CA-125 level at admission was 53 ± 33 U/mL and decreased at discharge to 34 ± 17U/mL. The table below shows the significant differences in the CA-125 level (U/mL) depending on the followed parameters.

The CA-125 level correlated with LVEF (R = -0.221, p = 0.02), with myocardial strech marker -NT-proBNP (R = 0.371, p < 0.001), with the inflammation marker - CRP (R = 0.284, p = 0.003) and oxidative stress marker - sUA (R = 0.234, p = 0.015).
There was a significant difference between NT-proBNP at admission in obese versus normoponderal patients, which was maintained at discharge. The CA-125 level did not have the same dynamics.
Conclusions: The wide availability of this biomarker, the relatively low cost, the unchanging level with age, weight or renal function, the correlation with known prognostic factors in HF and the additional information brought outside the classical biomarkers make CA-125 a biomarker that can be used in monitoring ADHF patients.

Followed parameters

Followed parameters	YES	NO	p
Male	55±34	51±32	0.69

Reduced LVEF heart failure	57±21	35±20	0.013
Increased LV filling pressures	61±24	37±18	0.005

P1157

Combination of ST2 and BNP in diabetic patients with acute heart failure: relation with ventricular stiffness and outcome

A Alberto Palazzuoli[1]; G Ruocco[2]; I Evangelista[2]; R Nuti[2]
[1]Santa Maria Alle Scotte Polyclinic, Siena, Italy; [2]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy

Background: Diabetes is a common complication of HF and its relationship to this syndrome is bimodal: diabetes has a causative role in systolic and diastolic dysfunction, and diabetic patients have a worse outcome compared to non-diabetic patients. Moreover, diabetes is simultaneously a causal factor and a comorbidity. Recently, a novel biomarker, soluble ST-2, a member of interleukin-1 receptor family formally known as interleukin-1 receptor like 1 (IL1RL-1), demonstrated greater prognostic power with respect to traditional biomarkers in patients with HF
Purpose: In this study we sought to: 1- evaluate levels of ST-2 and B-type natriuretic peptide (BNP) in groups with HF with reduced ejection fraction (HFrEF) and HF with preserved ejection fraction (HFpEF) and in those with/without diabetes; 2- analyze the prognostic impact of ST-2 in terms of death and re-hospitalization for cardiovascular causes during a 6-month follow-up period.
Methods: we performed an echocardiographic examination and measured ST-2 and BNP within 12 hours of hospital admission. Patients were classified as HFrEF [LVEF < 50%] or HFpEF [LVEF = 50%]. We defined diastolic function according to recent guidelines, and we calculated LV Stiffness with the following formula: ratio E/e' (index of LV filling pressure) and left ventricular end diastolic diameter (LVEDD) (index of left ventricular volume). Patients were followed up for 6 months after discharge. Composite outcome was considered the sum of death and re-hospitalization for cardiovascular causes.
Results: Of 121 patients enrolled, 60 patients showed HFrEF and 61 HFpEF. We found a significant correlation between ST-2 and BNP; in particular, this relationship was more significant in patients with HFpEF with respect to patients with HFrEF (r = 0.50; p < 0.001 vs. r = 0.42; p = 0.001). We found a significant correlation between ST-2 and BNP, greater in diabetic patients (r = 0.50; p < 0.001) with respect to non-diabetic patients (r = 0.40; p = 0.001). ST-2 showed also a more significant correlation with LV stiffness in patients with diabetes (r = 0.56; p < 0.001) with respect to patients without (r = 0.29; p = 0.04). Univariate analysis demonstrated that both ST-2 and BNP were associated with adverse events occurring within 6 months (respectively: HR 2,73[1,46-5,09], p = 0.002; 2,48[1,49-4,74], p = 0.006.). After adjustment for potential confounding factors, multivariable analysis showed that only ST-2 levels greater than 50 pg/mL were correlated with a poor prognosis (2,15[1,10-4,19]; p = 0.02).
Conclusions: ST-2 confirmed its prognostic power in patients with diabetes as well as those with HFpEF. However the mechanism related to ST-2 increase remains to be completely understood, although increased cardiovascular stiffness and impaired filling of the left ventricle seem to be the most important causative factors. Its prognostic role appears to be additional to BNP.

P1158

Prognostic value of hyponatremia, hypochloremia and hypokalemia in patients with dyspnea admitted to the emergency department

A Arnas Rimkus[1]; I-M Saule[1]; A Mebazaa[2]; J Celutkiene[3]
[1]*Vilnius University, Faculty Of Medicine, Vilnius, Lithuania*; [2]*University Paris Diderot , U942 Inserm, Hospital Lariboisiére, Paris, France*; [3]*Vilnius University, Clinic of Cardiac and Vascular diseases, Center of Cardiology and Angiology, Vilnius, Lithuania*

On behalf of: GREAT network
Funding Acknowledgements: The work was supported by the Research Council of Lithuania, grant Nr. MIP049/ 2015 and approved by Lithuanian Bioethics Committee, Nr. L1501.

Introduction: The prognostic value of hyponatremia, hypochloremia and hypokalemia in a wider population of patients with acute dyspnea (AD) is unknown. Aim: To assess if low serum sodium, chloride and potassium levels had a significant value in predicting short and long-term rehospitalizations (RH) and mortality of patients with AD admitted to the emergency department (ED).
Methods: Prospective observational cohort study enrolled consecutive patients admitted to the ED with AD due to decompensated heart failure, pneumonia, pulmonary embolism and other reasons. Concentration of blood electrolytes on admission, mortality rates, RH at 1, 3 months, 1 year were collected. Hyponatremia was defined as a sodium level < 134 mmol/l, hypochloremia - chloride level < 98 mmol/l, hypokalemia - potassium level < 3.8 mmol/l. Data was analyzed using SPSS v23 and Cox proportional-hazards regression analysis.
Results: The study group consisted of 699 patients, 44.2% women, 55.8% men, mean age 68.60 ± 12.32 years. On admission 7.6% of patients had hyponatremia, 12.2% - hypochloremia, 8.7% - hypokalemia. Hyponatremic and hypochloremic patients results are summarized in the table. Hypokalemic patients were RH more times during 3 months due to cardiovascular (CV) causes (HR = 1.86 (1.11-3.11),p = 0.018), during 1 year due to all and CV causes (HR = 2.03 (1.15-3.59),p = 0.014; HR = 2.16 (1.10-4.25),p = 0.025).
Conclusion: Hyponatremia, hypochloremia are significant short and long-term predictors of outcomes in AD patients admitted to the ED. Hypokalemia had no prognostic value of mortality, but it was related with higher short and long-term RH rates.

	Hyponatremia HR (95% CI)	P-value	Hypochloremia HR (95% CI)	P-value

Neutrophil gelatinase-associated lipocalin is an early biomarker of acute kidney injury in acute decompensated heart failure

MV Lediakhova[1]; IV Zhirov[1]; SN Nasonova[1]; TM Uskach[1]; VP Masenko[1]; SN Tereshchenko[1]
[1]*National Medical Research Center for Cardiology, Moscow, Russian Federation*

Background: the incidence of acute kidney injury (AKI) is high in patients with acute decompensated heart failure (ADHF) and is linked to worse prognosis and quality of life. Early predictive biomarkers of AKI could allow early intervention and improve outcomes in AKI.
Purpose: to evaluate the value of serum neutrophil gelatinase-associated lipocalin (NGAL) concentrations for early diagnosis of AKI in patients with acute decompensated heart failure with reduced systolic function.
Methods: the study was a prospective, single-centre, randomized trial. We enrolled 60 patients hospitalized with ADHF. The patients had reduced systolic function (left ventricular ejection fraction (LVEF) <40%), increased levels of brain natriuretic peptide > 500 pg/mL and systolic blood pressure >125 mmHg. The exclusion criteria were: acute coronary syndrome; sustained ventricular tachycardia or ventricular fibrillation; severe aortic or mitral regurgitation; uncorrected obstructive valvular disease; hypertrophic obstructive cardiomyopathy; restrictive cardiomyopathy; estimated glomerular filtration rate (eGFR) < 30 mL/min/1.73m2. AKI was defined according to Kidney Disease: Improving Global Outcomes (KDIGO) Clinical Practice Guidelines. We measured of serum NGAL concentrations by a quantitative sandwich enzyme immunoassay technique (RD systems, DLCN20, USA). Statistical significance was defined as P <0.05.
Results: a total of 60 men hospitalized with ADHF were included. Average age was 62.0 ± 11.1 years and mean LVEF was 27.97 ± 6.57%. Serum NGAL concentrations were significantly higher in patients with AKI 171.2 (159.0-241.2) ng/mL compared without AKI 136.8 (108.2-163.0)ng/mL P < 0.001. For predicting AKI, the area under the receiver-operating characteristic (ROC) curve (AUC) of serum NGAL on admission for all participants in the test set was 0.83 (95% confidence interval: 0.73 to 0.93; P <0.001). A cutoff of 157.35 ng/mL yielded good sensitivity (0.83) and specificity (0.74).
Conclusion: serum neutrophil gelatinase-associated lipocalin can serve as an early biomarker for diagnosis of acute kidney injury in patients with acute decompensated heart failure with reduced systolic function.

P1160

ST-segment elevation in ECG combined with elevated high sensitive troponin-I is associated with worse long-term prognosis in ICU patients

T Javanainen[1]; R Cinotti[1]; K Cerlinskaite[1]; S Ishihara[1]; E Akiyama[1]; N Vodovar[1]; E Gayat[1]; A Mebazaa[1]
[1]*Hospital Lariboisiere, Inserm UMR-S 942 and Anesthesia and Critical Care Department, Paris, France*

Background: In critically ill patients, ST-segment elevation (STE) in ECG has been poorly described and its association with long-term outcome is unknown.
Purpose: The aim was to investigate the incidence of STE and its association with 1-year mortality in Intensive Care Unit (ICU) patients.
Methods: The FROG-ICU (NCT 01367093) is a prospective, observational study in 2087 patients, conducted in 21 ICUs in 14 European hospitals. In this sub-study, patients with at least one ECG available during the first 3 days after ICU admission were included. ECGs were analysed digitally and STE was defined according to the Third Universal Definition (1). High sensitive troponin-I (hs-TnI) was measured at inclusion. Three groups of patients were created: 1) No STE and normal hs-TnI. 2) Either STE or elevated hs-TnI. 3) Both STE and elevated hs-TnI.
Cox multivariate regression analysis for 1-year mortality was conducted and the final adjusted model included Simplified Acute Physiology Score II (SAPS II), Charlson Comorbidity Index, gender, hs-TnI at inclusion and cardiac arrest as cause for ICU admission.

Results: In the 738 included patients, 93 (13%) displayed STE. Patients with STE were older (64 years (±18) vs. 59 years (±17), p = 0.009), more often male (n = 72 (77%) vs. n = 425 (66%), p = 0.036) and had more comorbidities. Cardiac arrest or cardiogenic shock as cause for ICU admission was more common in STE and hs-TnI was higher (64 ng/l (14-348) vs. 26 ng/l (8-177) p = 0.023) (Table). One-year mortality was higher in patients with STE (n = 45 (49%) vs. n = 206 (32%), p < 0.001, Figure A) and STE was associated with mortality in the adjusted cox model (HR 1.52-IC95% (1.09-2.11), p = 0.013). Patients with both STE and elevated hs-TnI had two-fold mortality in comparison with no STE and normal hs-TnI (n = 25 (49%) vs. n = 98 (27%), p < 0.001, Figure B).
Conclusions: STE is associated with increased long-term mortality in ICU patients. Combined STE and elevated hs-TnI define patients with the highest mortality risk.

The predictive value of plasma biomarkers in heart failure patients: do they maintain their value in elderly population?

M Mauro Feola[1]; M Testa[2]; C Ferreri[3]; GL Rosso[4]
[1]Cardiovascular Rehabilitation-Heart Failure Unit, Fossano, Italy; *[2]Cardiology Division, Mondoví, Italy*; *[3]School of Geriatry University of Turin, Turin, Italy*; *[4]Emergency 118 ASLCN1, cuneo, Italy*

Galectin-3 demonstrated to be a robust independent marker of cardiovascular mid-term (18-month) outcome in heart failure (HF) patients. The objective of this study was to analyse the value of a pre-discharged determination of plasma galectin-3 alone and with plasma BNP in predicting mid-term outcome in elderly (<70 yers old) patients discharged after an acute decompensated HF (ADHF) episode.
Methods: all elderly HF subjects discharged alive after an ADHF were enrolled. All patients underwent a determination of BNP and galectin-3, a 6-minute walk test (6MWT) and an echocardiogram within 48 hours upon hospital discharge. Death by any cause, cardiac transplantation and worsening heart failure requiring readmission to hospital were considered cardiovascular events.
Results: patients (males, age 77.5 ± 5.9 ys old) were analyzed (mean follow-up 16.2 months; range months). During the follow-up events (53.6%) were scheduled (18 cardiac deaths, 27 re-hospitalizations for ADHF). HF patients who suffered an event demonstrated more impaired ventricular function (p = 0.04), higher plasma BNP (p = 0.02) and Gal-3 at pre-discharge evaluation (p = 0.05). Choosing adequate cut-off points (BNP = 500 pg/ml and Gal-3 = 17.6 ng/ml), the Kaplan-Meier curves depicted the powerful stratification using Galectin-3>17.6 ng/ml alone (log-rank 13.22; p = 0.0003) and adding BNP+Gal-3 the result was even better (log-rank 17.96; p < 0.00001).
Conclusion: in elderly population, adding Gal-3 to BNP, a single pre-discharge strategy testing seemed to obtain a satisfactorily predictive value in alive HF patients discharged after an ADHF episode.

Introduction: Early identification of patients with Acute Heart Failure Syndrome (AHFS) among patients admitted to the emergency department for dyspnea can quickly help implement the appropriate treatments. At a time when diagnostic tools (clinical ultrasound, biomarkers) are developing, knowing the performance of clinical and anamnestic data would make it possible to propose diagnostic strategies. The objective is to evaluate the diagnostic predictive value of various anamnestic and clinical signs for the diagnosis of AHFS in emergencies.
Method: PREDICA is an observational, prospective, multicentre study for construction of a diagnostic model. Inclusion of patients admitted to emergency department for non-traumatic acute dyspnea and data collection at admission were recorded by the patient's emergency physician. Criteria for judgment was assessed for AHFS after double expertise by pairs of cardiologists and emergency physicians. Construction of a model of prediction by logistic regression step by step. Sensitivity, specificity and area under the ROC curve of the model.
Results: Among 341 patients consecutively included in 3 centres, 149 (44 %) presented AHFS. The predictive factors of AHFS are shown in Table 1. The area under the ROC curve of the model is 0, 86. The sensitivity is 73% and the specificity is 81%.
Conclusion: The performance of clinical and anamnestic signs is high and should contribute to the development of diagnostic strategies in emergency departments.

Relationship between pulmonary pressures and right ventricular mechanics in patients undergoing mitral valve surgery: initial results of the PREPARE-MVR study

B K Lakatos[1]; M Tokodi[1]; Z Toser[2]; AA Molnar[1]; S Szigeti[3]; KB Koritsanszky[3]; V Berzsenyi[3]; E Kispal[1]; K Racz[3]; AV Soltesz[3]; B Merkely[1]; E Nemeth[3]; A Kovacs[1]
[1]Semmelweis University Heart Center, Budapest, Hungary; [2]Argus Cognitive Inc., Dover, DE, United States of America; [3]Semmelweis University, Department of Anaesthesiology and Intensive Therapy, Budapest, Hungary

Severe mitral regurgitation is associated with significant changes not only in left ventricular, but also in right ventricular (RV) morphology and function. One of the major cause of RV remodelling is pulmonary hypertension, which could be reversible by mitral valve repair (MVR). Following MVR, characteristic and instant alterations in RV mechanics can be established, which may be related to the hemodynamic changes in the pulmonary vasculature. The PREPARE-MVR study (PRediction of Early PostoperAtive Right vEntricular failure in Mitral Valve Replacement/Repair patients) aims to determine parameters with added value in perioperative risk stratification to predict acute RV failure.

In this preliminary analysis, we sought to investigate the relationship between pulmonary pressures and resistance, and pre- and postoperative RV mechanics in patients undergoing MVR.

Our study group consisted of 22 MVR patients (mean age: 64 ± 10 years, m/f: 14/8). Transthoracic 3D echocardiography was performed before the operation, and at intensive care unit discharge. 3D beutel model of the RV was created and RV end-diastolic volume (EDV) along with RV ejection fraction (RVEF) were calculated using commercially available software. For in-depth analysis of RV mechanics, we have decomposed the motion of the RV using the ReVISION method to determine longitudinal (LEF) and radial ejection fraction (REF). The ratio of LEF or REF to RVEF quantifies the relative contribution of longitudinal or radial (bellows effect) wall motions to global function. Right heart catheterization measurements were performed preoperatively and 24 hours after the procedure to determine mean pulmonary artery pressure (mPAP), pulmonary arterial wedge pressure (PAWP) and pulmonary vascular resistance (PVR).

Based on EDV, RV morphology was similar after the surgery (pre- vs. postoperative; 160 ± 42 vs. 155 ± 50 mL, p = NS). RVEF decreased slightly after the MVR (48 ± 8 vs. 43 ± 8%, $p < 0.05$), however, RV motion pattern has markedly changed. Before the surgery a higher LEF/RVEF ratio was seen compared to lower REF/RVEF (0.48 ± 0.11 vs. 0.37 ± 0.10, $p < 0.001$), while after MVR, the radial motion became the dominant component of RV mechanics (0.35 ± 0.07 vs. 0.54 ± 0.07, $p < 0.0001$). Preoperative mPAP and PAWP inversely correlated with preoperative LEF ($r=-0.67$, $p < 0.01$; $r=-0.52$, $p < 0.05$). Preoperative REF/RVEF ratio showed relationship with the postoperative decrease in PVR ($r=-0.49$, $p < 0.05$). Moreover, patients with elevated preoperative PVR (72%) had significantly lower REF compared to those who had normal resistance (14 ± 6 vs. 21 ± 5, $p < 0.05$).

MVR results in complex hemodynamic changes in the pulmonary vascular bed which may have significant role in the development of postoperative alterations in RV mechanics and subsequent RV failure. Novel parameters of RV mechanics show relationship with invasively measured pulmonary pressures and resistance and may predict postoperative complications and outcome.

Simplified pulmonary ultrasound in heart failure

M Tsverava[1]; D Tsverava[2]
[1]Tbilisi State Medical University Iv.Javakhishvili (TSU), Internal Medicine, Tbilisi, Georgia Republic of; [2]MediClubGeorgia Tbilisi Clinic, Medicime, Tbilisi, Georgia Republic of

Pulmonary oedema (PE), due to fluid retention and redistribution is the cardinal manifestations of acute and exacerbation of heart failure (HF). The aim of this investigation was to study the effectiveness of simplified thoracic sonography in diagnosis of PE

Material and Methods: 420 patients with acute or exacerbated chronic HF (115 patients with diastolic and 305 with systolic HF). The control group consisted of 170 patients with different heart diseases (CHD, Hypertension, Aortic valve diseases),but without HF. Sonographic examination of a lung was done with 3,0-4,0 MgHz convex or sector probe, from 10 points on thoracic wall (cross points of midclavicular line with II, IV and V intercostal spaces and anterior axilar line with IV and V intercostal spaces), which corresponded to the projection of lower, middle and upper lobes of right lung and upper and lower lobes of left lung.

Results: During ultrasound examination 94.5% of patients with HF had "Comet tail phenomenon" (CTPh), which was registered only in 35,5% patients without HF ($p>0,001$). In DHF group CTPh was registered in 90,5% and in systolic HF group in 95,9% patients. In 91% of patients with HF CTPh was registered from 3 and more registration points. In control group CTPh was registered from more than 3 points only in 2 (1,3%) patients. The best results in diagnosis of DHF can be achieved if we take "3 and more registration points" as a reference point for diagnosis of pulmonary congestion (sensitivity - 0,911, specificity - 0,942, positive predictive value 0,975). The time of examination by simplified method for evaluation of CTPh and pleural space took 3-4 minutes.

Conclusion: In patients with HF during pulmonary ultrasound examination significantly often was registered CTPh. The count of registration points from the thoracic wall of CTPh 3 and > is sensitive and specific sign of HF. The simplified thoracic ultrasound is highly effective in diagnosis of PE in patients with HF

P1165

Right ventricle free wall strain predicts post-surgical low cardiac output syndrome in patients undergoing aortic valve replacement surgery.

K Karla Balderas-Munoz[1]; H Rodriguez Zanella Hugo[1]; JF Fritche Salazar[1]; A Jordan[1]; JA Arias Godinez[1]; MBA Gaxiola Macias[1]; A Orea Tejeda[1]
[1]National Institute of Cardiology Ignacio Chavez, Echocardiography, Mexico City, Mexico

Background: Severe aortic stenosis (AoS) represents a common entity for which surgical aortic valve (SAVR) replacement remains the treatment of choice. Low cardiac output syndrome after SAVR is related with increased mortality and treatment related costs. Recently strain imaging has been shown to be useful for prognosis in AoS, and its value remains beyond left ventricular ejection fraction. However its role for predicting low cardiac output syndrome (LCOS) has not been previously assessed.

Purpose: The aim of the present study was to evaluate whether echocardiography-derived right ventricle free wall strain (RVFWS) predicts the occurrence of postoperative LCOS in patients undergoing SAVR.

Methods: We prospectively enrolled patients with symptomatic severe aortic stenosis with LVEF > 30%, NYHA Class I and II, without other significant valvular lesion. A complete echocardiographic examination was perfomed before SAVR. Right ventricle free wall strain was measured in all patients before surgery. Patients were followed up during hospital stay. The main outcome was the occurrence of LCOS.

Results: A total 32 patients were included. Baseline clinical characteristics were similar between groups.

RVFWS was significantly lower in patients with LCOS than in patients without LCOS (12.8 ± 4.3 vs. -17.1 ± 3.9) before surgery and it was independently associated to the occurrence of low cardiac output [$p = 0.005$]. ROC curves to evaluate the utility of RV free wall strain to predict LCOS occurrence yielded a sensitivity of 81.2% and specificity of 71.4% , +LR of 2.86 of and −LR of 0.25 for a cut-off point of -15.

Conclusion: Right ventricle free wall strain is a useful parameter for risk stratification in patients with Sever AoS without severely depressed LVEF, and is independently associated with LCOS occurrence. The role of right ventricle in the genesis of LCOS is never contemplated and could explain its development in patients with preserved LVEF. This is an open field to extend research.

Right ventricle free wall strain

Variable	Without Low output	With low output	p

PAAT-pulmonary acceleration timeCOV-cut off valueNS-non statistically significant

Introduction: Modified peripheral systemic vascular resistance as etiopathogeny of APE is a theory that has already been accepted. Can be non-invasive echocardiographic assessment of high pulmonary vascular resistance (PVR) helpful in understanding the pathophysiology as well as in establishing the prognosis?
Purpose: Identifying the prognostic value of pulmonary acceleration time in pulmonary artery(PAT) in Acute Pulmonary Edema outside of an acute coronary syndrome (non ACS APE) of diversified ethiologies.
Methods: 92 patients with non-ACS APE consecutively hospitalized in our clinic between 01.01-31.12.2015, distributed and analyzed according to three etiologies, based on anamnesis, clinical and paraclinical data: ischemic, primary valvular and hypertensive (with preserved LVEF, without significant valvular or documented coronary artery disease). An echocardiography was performed on admission. We assessed also PAT. We assumed that this echo parameter when has semnificative decresed values, can express high pulmonary vascular resistance and does not depend on RV systolic function. We correlated this parameter, when pathological modified, with short, medium and long-term prognosis for entire group and according with ethiology. We identified cut-off values with prognostic value using a ROC curve analysis.
Results: In the entire group 63% patients have PAT < 105 ms. PAT has been statistically significant (SS) associated with short, medium and long term prognosis in the whole group($p < 0.01$)with cut off value(COV) 92ms, 95ms and respectivly, 98ms. The prognostic value changes depending on substrate and on the end-point term:SS for in hospital mortality($p < 0.01$) for ischemic and hypertensive substrate; for 30 days mortality for ischemic($p = 0.02$) and for valvular ethiology ($p = 0.04$) for 1 year mortality.
Conclusions: A decreased PAT was present in more than 50% of pts with non ACS APE and has proven an important prognostic value for short($p < 0.01$), medium($p < 0.01$) and long- term mortality($p < 0.01$) in entire group with COV of 92ms, 95ms and 98 ms. The prognostic role changed according with etiology and endpoint term. High pulmonary vascular resistance play an important in role in APE patophysiology and PAT can be an usefull echo-parameter with diagnostic and prognostic value.

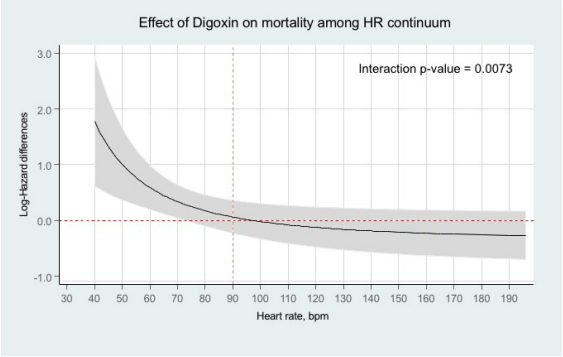
On behalf of: RICA register. SEMI

Background: The value of digoxin in heart failure (HF) remains controversial, particularly in patients with preserved ejection fraction (HFpEF). This study evaluated the 1-year risk of events after digoxin treatment for acute heart failure (AHF) in patients >70 years old with HFpEF.



Digoxin and mortality across heart rate

Methods: 1883 patients were included in this analysis (mean age, 82 years). The main endpoints were all-cause death and the composite of death and/or HF re-admission within 1 year. Cox regression analysis was used to evaluate the association between digoxin treatment and prognosis.
Results: 401 patients received digoxin treatment; of these, 86% had atrial fibrillation. The mean baseline heart rate was 86 ± 22 bpm. At the 1-year follow-up, 375 patients (20.5%) died and 684 (37.3%) had composite endpoints. Patients treated with digoxin showed higher rates of death (3.21 vs. 2.44 per 10 person-years, $p = 0.019$) and composite endpoint (6.72 vs. 5.18 per 10 person-years, $p = 0.003$). After multivariate adjustment, digoxin treatment remained associated with increased risks of death (HR = 1.46, 95% CI: 1.16-1.85, $p = 0.001$) and the composite endpoint (HR = 1.35, 95% CI: 1.13-1.61, $p = 0.001$). A distinctive prognostic effect of digoxin was found across the heart rate continuum; the risks for both endpoints were higher at lower heart rates and neutral at higher heart rates (p of the interactions = 0.014 and 0.028, respectively).
Conclusions: In older patients with HFpEF discharged after AHF, digoxin treatment was associated with increased mortality and/or re-admission, particularly in patients with lower heart rates.

On behalf of: EPICO

Background: Sacubitril/Valsartan represents a major breakthrough in the set of heart failure treatment, since it has improved risk of death and re-hospitalization after more than a decade without new perspectives. Despite of this, PARADIGM-HF trial has not investigated benefits of utilization among acute decompensated patients during their hospital phase.
Purpose: We sought to investigate and describe the proportion of elegible patients and reasons for non-elegibility for sacubitril/valsartan utilization among patients admitted for acute decompensated heart failure.
Methods: Cohort data from 543 patients admitted in a tertiary cardiac referral centre for acute systolic heart failure compensation (left ventricular ejection fraction <50%). All the data was collected from medical records. Heart failure was defined according the European Society of Cardiology (ESC) guidelines.
Results: The main reason for non-elegibility was left ventricular ejection fraction = 35% (34%; 171 individuals). 31.1% (155) of the patients had previous intolerance to angiotensin converting enzyme inhibitors or angiotensin receptor blockers and 7% (37) had hypotension during hospital stay (systolic blood pressure <90mmHg). Likewise, 37 patients (7%) had need for dialysis. At the end of the analysis, 36.5% (198) of the patients remained elegible for sacubitril/valsartan initiation during hospital phase.

Conclusion: Although there is no evidence for sacubitril/valsartan implementation during hospital phase of acute heart failure, our data suggest that more than one third of the patients could be elegible for such implementation even before of the hospital discharge.

P1169

Efficacy of Tolvaptan for the first hospitalized patients with acute decompensated heart failure

Y Yoriyasu Suzuki[1]; A Murata[1]; S Tsujimoto[1]; Y Ochiumi[1]; M Ehara[1]; T Ito[1]
[1]*Nagoya Heart Center, Nagoya, Japan*

Aim: the purpose of this study is to evaluate the efficacy of tolvaptan (TLV) for the initially hospitalized patients with acute decompensated heart failure (ADHF).
Methods: From 2015 to 2017, consecutive 124 patients initially hospitalized with a diagnosis of ADHF (clinical scenario 2/5) at Nagoya Heart Center. They were treated with or without TLV (TLV (-); n = 81, TLV (+); n = 43). We retrospectively analyzed the clinical outcome of these patients.
Results; the results are shown in the table and figure. 39.5% of cases were re-hospitalized and In the group treated with TLV, there was significantly fewer re-hospitalization (TLV(+) vs. TLV(-); 23.3% vs. 48.1%, Log rank p = 0.029). In the re-hospitalized cases, the incidence of WRF was significantly higher (TLV(+) vs. TLV(-); 0% vs. 14.8%, p = 0.004).
Conclusion: the treatment with TLV could shortened the duration of bed-rest and prevent WRF and re-hospitalization. The results of this study suggest tolvaptan initiated for acute treatment of patients initially hospitalized with ADHF had effect outcome in daily clinical practice.

Table

	TLV(+), N = 43	TLV(-), N = 81	p-value

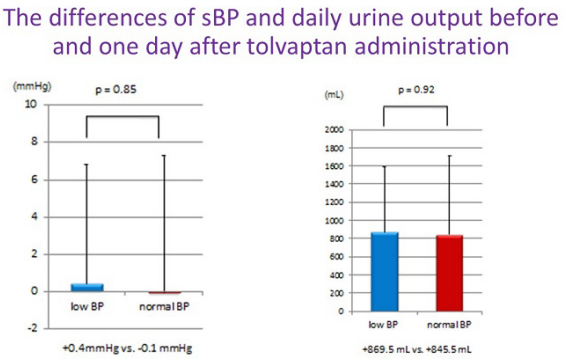
Safety and efficacy of tolvaptan administration in patients hospitalised for acute decompensated heart failure due to moderate or severe aortic stenosis

R Reo Hata[1]; Y Kawase[1]; T Tada[1]; K Kadota[1]
[1]*Kurashiki Central Hospital, Cardiology, Kurashiki, Japan*

Background: The administration of loop diuretics for the treatment of acute decompensated heart failure (ADHF) due to moderate or severe aortic stenosis has been reported to decrease blood pressure. Recently, tolvaptan, a selective vasopressin V2 receptor antagonist, has been reported to stabilise haemodynamics in patients with heart failure.
Purpose: We evaluated the short-term safety and efficacy of tolvaptan administration in patients hospitalised for ADHF due to moderate or severe aortic stenosis.
Methods: We analysed consecutive patients who had been hospitalised for ADHF due to moderate or severe aortic stenosis and treated with tolvaptan because of inadequate urine output response to loop diuretics between December 2011 and December 2014. The major outcome measures were defined as blood pressure and daily urine output before tolvaptan administration and one day after tolvaptan administration. The patients were classified into two groups on the basis of a systolic blood pressure (sBP) before tolvaptan administration: sBP <110 mmHg (low sBP group) and sBP = 110 mmHg (normal sBP group).
Results: Data on 44 patients were available for final analysis. The average age was 85.2 ± 6.3 years, the mean left ventricular ejection fraction was 49.5 ± 11.1%, and the mean estimated glomerular filtration rate on admission was 37.7 ± 21.5 ml/min/1.73m2. The average maximal aortic peak velocity was 3.48 ± 1.11 m/s, and the mean aortic valve area was 0.82 ± 0.28 cm2. Although the average daily urine output one day after tolvaptan administration was significantly increased compared with that before tolvaptan administration (1249.0 ± 627.5 ml vs. 2106.5 ± 1118.5 ml, p <0.01), the average sBP and diastolic blood pressure remained unchanged before and one day after tolvaptan administration (114.4 ± 17.5 mmHg vs. 114.6 ± 18.4 mmHg, p = 0.88 and 60.0 ± 12.7 mmHg vs. 59.1.6 ± 14.9 mmHg, p = 0.59, respectively). There were 22 patients in the low sBP group and 22 patients in the normal sBP group. Between the low and normal sBP groups, no significant differences were observed in the differences of sBP and daily urine output before and one day after tolvaptan administration (0.4 ± 6.4 mmHg vs. -0.1 ± 7.4 mmHg, p = 0.85 and 869.5 ± 723.1 ml vs. 845.5 ± 870.7 ml, p = 0.92, respectively) (Figure).
Conclusion: Tolvaptan administration to patients hospitalised for ADHF due to moderate or severe aortic stenosis may not affect their haemodynamics and is likely to be effective in obtaining adequate urine output.



Figure

P1171

Effects of low dose levosimendan on renal function in patients with advanced heart failure

R Riet Dierckx[1]; W Heggermont[1]; S Verstreken[1]; M Goethals[1]; M Vanderheyden[1]
[1]*OLV Hospital Aalst, Cardiovascular Center, Aalst, Belgium*

Background: The cardiorenal syndrome is a common problem in patients with advanced heart failure (AdHF) and is linked to poor prognosis. Levosimendan is an inodilator that improves hemodynamics and has a beneficial effect on neurohormone levels. Hypotension is a common side effect and can limit the use of higher doses in patients with AdHF.
Aims: To evaluate if administration of low dose Levosimendan in patients with decompensated AdHF can improve renal function.

Methods and Results: Between March 2016 and January 2017, 29 patients hospitalized with decompensated AdHF were treated with Levosimendan. Six patients received repetitive infusions, yielding a total of 41 Levosimendan treatments (12-hours intravenous infusion of 0.05 ug/kg/min, without bolus). Renal function was assessed before and after administration.
Most patients had ischemic cardiomyopathy (62%) and were severely symptomatic (10% New York Heart Association (NYHA) class II, 55% NYHA class III, 34% NYHA class IV). Medical treatment was often suboptimal because of history of hypotension and/or renal dysfunction: only 34% of patients were treated with ACE-inhibitors/angiotensin II-receptor blockers, 83% with beta-blockers, 93% with mineralocorticoid receptor antagonists and 3% with sacubitril/valsartan. Mean age was 68 ± 11 years, median N-terminal pro brain natriuretic peptide (NTproBNP) 6977 ng/L (IQR 4007 -16757), mean left ventricular ejection fraction (LVEF) 22 ± 8% and mean glomerular filtration rate (GFR) 38 ± 18 ml/min. All patients had pulmonary hypertension with a mean systolic pulmonary arterial pressure (sPAP) - measured by echocardiography - of 60 ± 21 mmHg.
Evaluating all 41 treatment episodes, mean pre-treatment GFR was 35 ± 17 ml/min and rose to 38 ± 18 ml/min after administration of low dose Levosimendan (p 0.03) . In 21 cases, NTproBNP levels pre-and post-treatment were available. Levosimendan infusion significantly reduced NTproBNP from 9356 ± 7547 ng/L to 6542 ± 6238 ng/L (p 0.02).
Conclusions: In patients admitted with decompensated AdHF, low dose Levosimendan significantly improves renal function.

P1172

Using Levosimanden in place for unresponsive acute decompensated heart failure to dobutamine

M-T Ming-Ting Chou[1]; CY Chiang[1]
[1]*Chi-Mei Medical Center, section of Cardiology, Tainan, Taiwan ROC*

Background: Levosimanden improves hemodynamics and symptom in acute decompensated heart failure(ADHF) at a much higher cost than dobutamine use
Purpose: To evaluate a cost-effective use of Levosimanden in ADHF unresponsive to dobutamine
Methods: Twenty-five consecutive patients admitted through emergency room due to ADHF and remained dyspnea at rest despite treatment with intravenous diuretic and /or intravenous vasodilator. They all had reduced ejection less than 35% evaluated by echocardiography. These patients first received intravenous dobutamine for 24 to 48 hours, if the symptom is not improved then they will shift to 24-hour levosimanden infusion. At 24h and after 2,3 and 5 days after infusion, patients were asked to evaluate in overall clinical status and in dyspnea. Also NT-pro-BNP level were measured at ER and after 24h and 5 days.
Results: 23 patients improved after levosimanden infusion, in which 15 patients felt markedly improved. The improvement persisted for 5 days and only 2 patients got worse.
The NT-proBNP level decreased significantly(- 30.2 ± 15.3%, $P < 0.01$).
Conclusion: In patients with ADHF unresponsive to dobutamine treatment, levosimanden provides rapid and durable symptomatic relief. This may be a more cost-effective use of this costly medication.

P1173

Outcome of temporary mechanical circulatory support bridging to left ventricular assist device

H S Hoong Sern Lim[1]; H Ahmed[1]; A Ranasinghe[1]; J Mascaro[1]; N Howell[1]
[1]*Queen Elizabeth Hospital, Birmingham, United Kingdom*

Background: Temporary mechanical circulatory support (tMCS) is increasingly used to bridge patients with severe heart failure (HF) and cardiogenic shock (CS) to durable left ventricular assist devices (LVAD).
Purpose: To compare the 1-year survival of patients with LVAD with and without bridging with tMCS.
Methods: Single-centre study of 105 consecutive patients (25 with and 80 without tMCS bridging) with advanced HF and CS who underwent LVAD implant.
Results: Patients bridged with tMCS had more severe HF and more likely to require multi organ support (Table). Acute myocardial infarction was the cause of HF in 14 (56%) vs 4 (5%) of cases with tMCS vs no tMCS. The 25 tMCS were: 10 intra-aortic ballon pumps, 5 Impella CP, 3 veno-arterial extracorporeal membrane oxygenation (VA ECMO), 4 surgical temporary VADs and 3 patients had multiple modalities with Impella, VA ECMO and surgical VADs. LVADs included Heartmate 2 in 10 (40%) vs 40 (50%) and Heartmate 3 devices in 15 (60%) vs 40 (50%) in patients with and without tMCS respectively (p = 0.382). 7 (28%) and 9 (11%) patients required right ventricular assist device or VA ECMO support post-LVAD implant (p = 0.046). 6 and 12-month survival for patients with and without tMCS were 84% vs 83% and 84% vs 79%, respectively (log rank test, p = 0.603).

Table (mean ± SD or median (IQR)

	tMCS (n = 25)	notMCS(n = 80)	p
Age (years)	50.5±5.3	54.8±2.3	0.095
Males	21 (88%)	70 (84%)	0.653
LVEF (%)	15 (10-20)	10 (10-15)	0.362
TAPSE (mm)	14.9±2.2	15.3±1.6	0.805
MAP (mmHg)	74±5	82±2	0.001
RAP (mmHg)	10 (8-20)	11 (8-14)	0.919
CI (L/min/m2)	1.5 ± 0.3	1.7±0.1	0.059
INTERMACS 1	10 (40%)	2 (2.5%)	<0.001
Pre-op ventilation	11 (44%)	3 (4%)	<0.001
Pre-op CVVH	7 (28%)	3 (4%)	<0.001

LVEF: left ventricular ejection fraction; TAPSE: tricuspid annular systolic excursion; MAP: mean arterial pressure; RAP: right atrial pressure; CVVH: continuous veno-venous hemofiltration; CI: cardiac index

Conclusion: Despite more severe HF and CS pre-operatively, and greater need for post-operative support, 1-year survival in patients with LVAD bridged with tMCS were comparable to patients without tMCS.

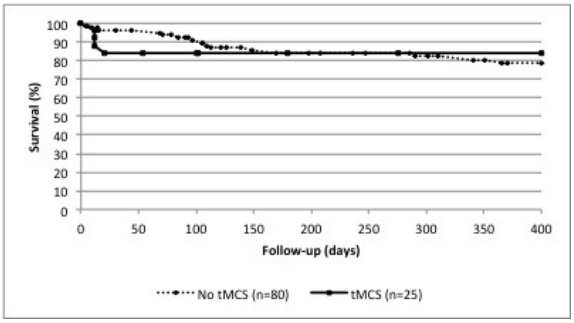


Figure: Kaplan Meier survival curves

P1174

Percutaneous implantation of extracorporeal life support for refractory cardiac arrest or cardiogenic shock complicating acute coronary syndrome: the CareGem registry.

D Domenico D'amario[1]; C Sorini Dini[2]; I Porto[1]; A Mattesini[1]; R Vergallo[1]; R Della Bona[1]; C Trani[1]; F Burzotta[1]; PG Bruno[1]; C Di Mario[2]; M Massetti[1]; S Valente[2]
[1]*Catholic University of the Sacred Heart, Institute of Cardiology, Rome, Italy*;
[2]*Careggi University Hospital (AOUC), Florence, Italy*

Background: Refractory cardiogenic shock (RCS) or refractory cardiac arrest (RCA) complicating acute coronary syndrome (ACS) is associated with extremely high mortality rate. Veno-arterial extracorporeal life support (VA-ECLS) represents a therapeutic option to stabilize patients' condition before or at the time of emergency revascularization.
Methods: We analyzed 29 consecutive patients with RCS or RCA complicating ACS, and implanted with VA-ECLS in two centers who have adopted a similar, structured approach to ECLS implantation. Data were collected from January 2010 to Dicember 2015 and ECLS had to be percutaneously implanted either before (within 48 hours) or at the time of attempted percutaneous coronary revascularization (PCI). We investigated in-hospital outcome and factors associated with survival.
Results: Twenty-one (72%) were implanted for RCA, whereas 8 (28%) were implanted on ECLS for RCS. All RCA were witnessed and no-flow time was shorter than 5 minutes in all cases but one. All patients underwent attempted emergency PCI, using radial access in 10 cases (34.5%), whereas in 3 patients a subsequent CABG was performed. Overall, 10 patients (34.5%) survived, 9 of them with a good neurological outcome. Life threatening complications, including stroke (4 pts), leg ischemia (4 pts), intestinal ischemia (5 pts), and deep vein thrombosis 2 pts), occurred frequently, but were not associated with in-hospital death. Main cause of death was multi-organ failure. PCI variables did not predict survival. Survivors were younger, with shorter low-flow time, and with ECLS mainly implanted for RCS, as opposed to RCA. At multivariate analysis, levels of lactate at ECLS implantation

(OR 4.32, 95%CI:1.01-18.51, p = 0.049) emerged as the only significant variable to predict survival.
Conclusion: In patients with RCA or RCS complicating ACS, who are percutaneously implanted with ECLS before or at the time of coronary revascularization, in hospital survival rate is higher than 30 %, generally with good neurological outcome. Level of lactate at ECLS implantation seems to be the most important factor to predict survival.

P1175
Investigating the relationship between heart failure clinical nurse specialist input and readmissions in patients hospitalised for heart failure: is there evidence of a recency effect?

M Nandakumar[1]; RR Shah[1]; T Godec[2]; J De Courcey[1]; S Piper[1]; T Mcdonagh[1]; D Bromage[1]
[1]King's College Hospital, London, United Kingdom; *[2]London School of Hygiene and Tropical Medicine, London, United Kingdom*

Background: Heart failure (HF) Clinical Nurse Specialist (CNS) intervention is known to reduce HF readmissions. However, the impact of the timing of inpatient HF CNS input is unknown.
Purpose: We aimed to analyse whether the interval between patients' last HF CNS review and their discharge date affects readmission. We hypothesised that there is a recency effect; that is, that patients reviewed closer to discharge would have reduced readmissions.
Methods: This was a retrospective observational study of 243 patients in a tertiary HF Unit, from October 2015 to March 2016. Patient data was collected into the National HF Audit database. HF CNS Review data was collected by 2 authors and a random selection checked by a third. A review was eligible if it was face-to-face and included an educational component. The primary endpoints were readmission within 12 months, mortality and admission duration.
Results: 53 patients (22.2% of the study population) had an educational review during admission (per protocol). Compared to patients without a review, the study group were older, more female, more commonly managed on general medicine wards, had less device therapy, more hypertension, higher brain-type natriuretic peptide, lower ferritin, and more atrial fibrillation (Table 1). There was no significant association with mortality. Likewise, there was no significant association between HF CNS review or its timing and rates of readmission after adjustment for other variables significantly associated with the outcome (P = 0.096). HF CNS review was significantly associated with admission duration (P = 0.019), which is likely to be a function of reverse causality.
Conclusion: HF CNS review did not significantly reduce readmissions up to 1 year and no recency effect was evident.

P1176
Improving outcomes in patients with heart failure; reduction in mortality and readmissions achieved with reduction in length of stay

C Chokanan Thaitirarot[1]; Z Vali[1]; L Clayton[1]; I Loke[1]
[1]Glenfield Hospital, Cardiology Department, Leicester, United Kingdom

Heart failure (HF) poses a staggering clinical and public health problem associated with significant morbidity and mortality. Glenfield Hospital (GH) is one of the UK's largest tertiary cardiology centres. Over the last 5 years, our HF service has been transformed. Recent studies have raised concern that shorter length of stay (LOS) in hospital is associated with increased rates of readmission and worse outcome. We carried out detailed audits to assess the impact of the improvements made, and assessed if this trend is observed in our locally collected data.
For our initial audit, electronic discharge letters of all patients admitted to GH between 30th March and 13th April 2012 were retrospectively reviewed. Patients treated for acute HF were identified, and data was then collected for these patients. We re-audited the same period in 2017. Chi-square was used to assess statistical correlation between LOS and 6 month readmissions.
The second audit does not only show significant improvement in LOS (11 to 7 days), 30 day readmissions (29% to 17%) and inpatient mortality (14.3% to 5.5%), but also the number of acute HF admissions as a proportion of all admissions has fallen from 11.4% to 7.8% (see table 1). Furthermore, we found no statistical correlation between LOS and medical readmissions at 6 months.
Since the initial audit in 2012, several changes have been implemented to improve the inpatient HF service. These include an inpatient HF nurse team, nurse led follow-up clinics with ability to see patients urgently, creation of a dedicated HF unit with beds for direct admission from the community, weekly HF MDT meetings, regular educational sessions for junior doctors and nursing staff, and expansion of consultant cover with rapid access one-stop HF clinics. Our data found improvement in prescription of evidence based medical therapy and better patient follow up. We show that reduction in readmissions can be achieved even with lower LOS.

Patient preferences for heart failure information delivery and perceptions of patient-provider communication

SE Serra Ivynian[1]; PJ Newton[2]; M Digiacomo[1]
[1]University of Technology, Sydney, Sydney, Australia; *[2]University of Western Sydney, Sydney, Australia*

Funding Acknowledgements: Australian Government Research Training Program (RTP) Scholarship

Background: Improving health literacy is a global health goal. For people managing chronic illness such as heart failure (HF), adequate health literacy is crucial to effectively self-manage on a daily basis.
Purpose: 1) To identify HF patients' preferred sources of HF information, perceived gaps in HF knowledge, and ascertain unmet educational needs from the perspective of the HF patient; and 2) to explore perceptions of patient-provider communication, highlighting barriers and facilitators of effective health information delivery, to improve health literacy in HF.
Methods: Semi-structured in-depth interviews were conducted with 15 symptomatic HF patients at a teaching hospital. Transcripts were analysed using interpretative phenomenological analysis (IPA).
Results: Participants relied heavily on providers for HF information and support, expressed numerous unmet educational needs, and had mixed feelings about quality of communication. Credibility of information was most important and participants avoided the internet to prevent misinformation. Participants expressed the need for tailored HF information, accounting for comorbid conditions, and a preference for face-to-face information delivery. Knowledge gaps included HF pharmacotherapy, symptom appraisal and management, the cause and chronicity of HF, and a specific action plan for HF symptom exacerbation. Barriers to effective patient-provider communication included participants' memory problems, providers using complex medical terminology, lack of adequately detailed information, perceived deliberate concealment of information, and relationships that did not allow for open communication. Facilitators included patient note-taking during consultations, delivery of consistent health information, and positive patient-provider relationships.
Conclusion: Suggested topics of education and communication strategies aligned with national guideline recommendations for HF education. Gaps in knowledge and poor communication may point to inadequate availability of multidisciplinary HF management programs, and/or their fidelity to guideline recommendations.

Acute heart failure in the emergency department: current trends in management

P Patricia Alves[1]; AV Marinho[1]; JP Almeida[1]; R Baptista[1]; S Costa[1]; F Franco[1]; M Pego[1]
[1]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal

Background: Although acute heart failure (AHF) remains an important public health issue, management has not changed significantly in the past decades. The initial approach in the emergency department (ED) is being increasingly emphasized.
Purpose : We studied the association of early ED management and prognosis in patients with AHF.
Methods: We retrospectively included all 870 patients admitted in our ED with AHF from November 2016 to October 2017. Baseline clinical and analytical data were collected. Outcomes regarding overall mortality, in-hospital mortality, admission and readmissions were determined. Patients were followed-up over a median period of 7 [IQR 2.8-9.9] months (all patients had a minimum follow up of one month).
Results: The mean age was 78 ± 10.5 years and 51% were male. The prevalence of valvular heart disease was 38%, coronary artery disease was 27% and atrial fibrillation 69%. Mean left ventricular ejection fraction (LVEF) was 42.5 ± 12.6% and median BNP was 500 [IQR 275-1014] pg.ml-1. At admission, 92% presented with a B profile (wet and warm), 2.4% a C profile and 1.15% a L profile, whereas 7% in acute pulmonary edema (APE). The median door-to-furosemide time was 90 [IQR 50-240] minutes; 5% received intravenous nitrates and 6% noninvasive ventilation. About 45% were discharged from the ED. Overall mortality was 21%, in-hospital mortality 13% and the all-cause readmission rates were 32% (10.5% at 30 days). BNP emerged as the best predictor of outcome (readmission and mortality) (HR 1.6, 95%CI 1.4-1.8, p <0.001). Age (OR 1.06, 95%CI 1.02-1.09, p = 0.001), BNP (OR 1.4, 95%CI 1.06-1.97, p = 0.021), creatinine (OR 1.4, 95%CI 1.07-1.9, p = 0.018), LVEF (OR 0.96, 95%CI 0.94-0.98, p = 0.002) and APE at admission (OR 2.8, 95%1.2-6.6, p = 0.028) were predictors of in-hospital mortality. No significant predictors were found for readmission. However, patients that received furosemide within the first 60 minutes of admission had a lower readmission rate than those with latter administration timings (10 vs 20%; OR 0.7, 95% 0.54-0.82, p = 0.04).
Conclusions: : In-hospital mortality and readmission rates were considerable in this cohort of elderly patients with AHF. Clinical and analytical status at admission in the ED were important predictors of poor prognosis. Rapid administration of loop diuretics was associated with smaller readmission rates.

Acute Heart Failure - Prevention

P1179

Risks of functional decline during hospitalization in patients with acute heart failure

H Hidenori Yaku[1]; T Kato[1]; Y Yoshikawa[1]; Y Inuzuka[2]; Y Tamaki[3]; T Kimura[1]
[1]Kyoto University Graduate School of Medicine, Department of Cardiovascular Medicine, Kyoto, Japan; *[2]Shiga Medical Center for Adults, Department of Cardiovascular Medicine, Moriyama, Japan*; *[3]Tenri Hospital, Department of Cardiovascular Medicine, Tenri, Japan*

Background: Previous registry data has provided limited information about the functional status of very elderly patients with acute heart failure (AHF).
Purpose: The current study sought to clarify risks for functional decline during hospitalization in patients with acute heart failure.
Methods: Using data from the Kyoto Congestive Heart Failure registry, which enrolled prospectively 4056 consecutive hospitalized patients from October 2014 to March 2016, we classified patients hospitalized for AHF into 2 groups by the change in functional status during hospitalization: those with functional decline during hospitalization (Group A) and those not with functional decline during hospitalization (Group B). Physical activity before admission and at discharge was classified as ambulatory, use of wheelchair outdoor only, and use of wheelchair indoor and outdoor. Functional decline was defined as the decline of more than one step in physical activity during hospitalization, and clinical predictors of functional decline during hospitalization were identified using multivariate logistic regression analysis.
Results: After excluding those who died in hospital (N = 271), bedridden at admission (N = 127), and missing data (N = 103), Group A and B included 528 patients and 3027 patients, respectively. Regarding the baseline clinical characteristics, Group A had significantly greater prevalence of patients with advanced age (84 ± 9 vs. 76 ± 12 years, P < 0.001), female gender (56 vs. 42%, P < 0.001), hypertension (77 vs. 72%, P = 0.02), prior stroke (24 vs. 14%, P < 0.001), chronic kidney disease (53% vs. 43%, P < 0.001), malignancy (18% vs. 14%, P = 0.006), and dementia (33% vs. 14%, P < 0.001). Regarding the clinical presentations, systolic blood pressure and heart rate was higher in Group A than in Group B [144 ± 32 vs. 149 ± 35 mmHg (P = 0.003), and 93 ± 27 vs. 96 ± 28 beat/min (P = 0.001), respectively], while left ventricular ejection fraction was higher in Group A than in Group B (48 ± 16 vs. 46 ± 16 %, P = 0.02). The median length of hospital stay was longer in Group A than in Group B (21 versus 15 days, P < 0.001). After adjusting for potential confounders, independent risk factors for the functional decline during hospitalization included age = 80 years (OR = 2.46, 95%CI 1.91-3.17), female (OR = 1.30, 95%CI 1.03-1.63), past history of stroke (OR = 1.65, 95%CI 1.27-2.14) and malignancy (OR = 1.40, 95%CI 1.06-1.84), dementia (OR = 1.97, 95%CI 1.53-2.52), hyponatremia (OR = 1.45, 95%CI 1.07-1.96), hypoalbuminemia (OR= 1.77, 95%CI 1.34-2.32), renal dysfunction (OR = 1.59, 95%CI 1.26-2.02), and New York Heart Association (NYHA) class IV at admission (OR= 1.25, 95%CI 1.01-1.55). Consequently, the proportion of patients in Group A discharged to their homes was also lower (47%), as compared with 90% of those in Group B.

Conclusions: Risk stratification for the decline in physical activity is important for the discharge to their homes in very elderly patients with AHF.

Effect of the optimize heart failure care program on clinical outcomes of HF patients at ho chi minh city heart institute in vietnam.

PHUONG Do[1]; BAN Ha[1]; DUNG Do[1]; HUAN Do[1]; MARTIN Cowie[2]
[1]Heart Institute, Ho Chi Minh city, Vietnam; [2]Royal Brompton Hospital, London, United Kingdom

On behalf of: HCMC Heart Institute OHF

Heart failure (HF) is a common public health in Europe and US but also in Asia. The HF prevalence is increasing in LMI countries with a big annual burden. The OHF program was developed in HCMcity Heart Institute to improve HF patient's awareness, to optimize HF treatment in order to improve clinical outcome.
Since October 2016, we included all of HF patients with ejection fraction (EF) <50% hospitalized . The patients received education for "HF diet", "appropriate HF exercise", "weight control", "detection of worsening HF symptoms", and optimized HF treatments. The data was collected at 2 and 6 months (M2,M6) for clinical signs, treatments and outcomes (readmission and death). We conducted a call survey at M6 to check patient's knowledge and practice.
From October 2016 to October 2017, we recruited 257 HF patients with EF <50% hospitalized. Among them, 58% are male, the mean age is 64.4 ± 15 and BMI is 22.2 ± 3.5 kg/m2. The 3 principal etiologic HF disease is IHD (64.2%), cardiomyopathy (21.8%) and valvular HD (9.3%). The key comorbidities are hypertension (48.2%), valvular HD (40.5%), dyslipidemia (33%), arrhythmia or atrial fibrillation (AF) (31%), diabetes (25.7%) and renal failure (21%).
There is a significant improvement in mean heart rate between admission (M0) vs. discharge (97.8 ± 22.2 vs 78.5 ± 11.7, p <0.001), and M0 vs. M6 (97.8 ± 22.2 vs 78.9 ± 13.6, p <0.001). The clinical signs have been improved: M0 vs. M2 and M2 vs. M6: for dyspnea (79.8% vs. 36.3%, p <0.001 and 36.3% vs. 22.2%, p = 0.002); for orthopnea (39.7% vs. 1.2%, p <0.001 and 1.2% vs. 0%, p = 0.25); and for sign of pulmonary congestion (27.3% vs. 0.6%, p <0.001 and 0.6% vs. 0%, p = 0.65). The percentage of patients with NYHA class I&II increased at M2 and M6 vs. M0 (96.8%, 99% vs. 45.3%, p <0.001 for both). The EF was also improved at M6 compared to M0 (36.5 ± 9 vs. 33.4 ± 9.3, p = 0.005).
In terms of education, 98.8% of patients were educated for "HF diet" (72.2% acquired the knowledge and 77.8% practice it); 84.8% were educated for "appropriate HF exercise" (66.7% acquired the knowledge and 62.5% practice it); 89.5% were educated for "weight control" (54.3% acquired the knowledge and 44.1% practice it) and 91.8% were educated for "detection of worsening HF symptoms", while only 55.9% remembered this education.
For HF treatment, we followed European guidelines, including at discharge: 91.4% of RAAS inhibitors, 33% of beta-blockers (but 50.3% at M6), 77% of MRA, 85.2% of others diuretics, 8.9% of ivabradine (but 18.1% at M6), 33.3% digoxin (noted 21.8% treated for AF) and 16.3% of isosorbide dinitrate.
The rate of readmission after discharge at <30 days was 8.3% and at <60 days was 12.5%. There was no in-hospital death. The mortality of 30-day was 1.2%, 60-days was 2.5% and 6-months was 10.4%.
The OHFCare Program demonstrated the benefits on clinical outcomes of HF patients after discharge. A new analysis based on dosage of HF treatment is needed to determine the target dose in Asian HF patients.

P1180

The prognostic value of B-type natriuretic peptide verus SUPER score for the onset of acute heart failure in acute heart failure unit

Y Yuan Bian[1]; FENG Xu[1]; LI-JUN Cao[1]; JIAN Zhang[1]; DAN-YU Yu[1]; RJ Lv[1]; YU-GUO Chen[1]
[1]Qi-Lu Hospital of Shandong University School of Medicine, Emergency Department, Jinan, China People's Republic of

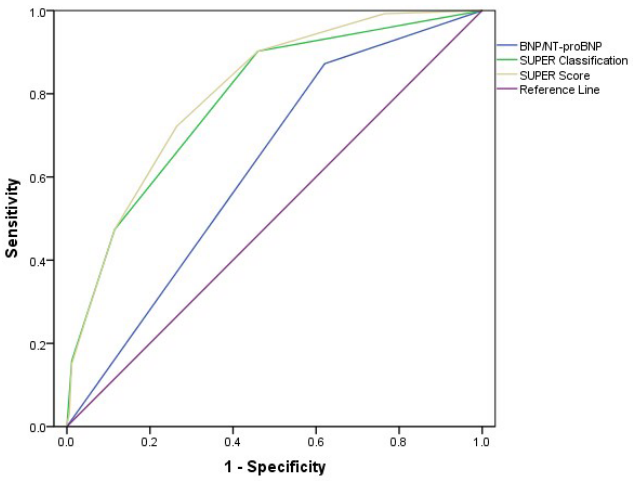
Background: Early identification of the potential risk of acute heart failure (AHF) among high-risk patients would contribute to 'time to therapy' in Acute Heart Failure Unit (AHFU). The SUPER score was an early warning scoring system for the onset of AHF, comprised of five factors: SpO2, urine volume, pulse, emotional state, and respiratory rate.

Baseline characteristics

	Negative group (n = 86)	Positive group (n = 221)	p-value
Male (n, %)	62(71.1)	118(53.3)	0.003
Age (years)	56.2±15.2	66.3±14.3	<0.001
hospitalization time (days)	6.4±8.9	8.2±7.8	0.115
ACS (n, %)	54(6208)	144(65.2)	0.693
PPCI (n, %)	44(51.2)	60(27.1)	<0.001
CAD (n, %)	58(67.4)	182(82.4)	0.006
Hypertension (n, %)	19(22.1)	56(25.3)	0.658
Diabetes (n, %)	5(5.8)	25(11.3)	0.199
Positive cTn (n, %)	55(64.0)	174(78.7)	0.009
SUPER score	1.8±1.7	2.8±1.8	<0.001
AHF onset (n, %)	17(19.8)	116(52.5)	<0.001
In-hospital Mortality (n, %)	7(8.1)	57(25.8)	<0.001

Abbreviations: ACS, acute coronary syndrome; PPCI, Primary Percutaneous Coronary Intervention; CAD, coronary artery disease; cTn, cardiac troponin; AHF, Acute Heart Failure.

Purpose: We aimed to investigate whether the predictive value for AHF of SUPER score was superior to the B-type natriuretic peptide (BNP) or N-terminal pro-BNP (NT-proBNP).
Methods: A total of 307 patients admitted in the AHFU were divided into two groups according to the level of BNP/NT-proBNP on admission: negative group (n = 86) and positive group (n = 221). The primary endpoint was the onset of AHF during hospitalization. The secondary endpoint was in-hospital all-cause mortality.



Receiver operating characteristic curve

Results: The mean SUPER score (1.8 ± 1.7 vs. 2.8 ± 1.8, p <0.001), AHF onset (19.8% vs. 52.5%, p <0.001) and in-hospital mortality (8.1% vs. 25.8%, p <0.001) was significant lower in the negative group. A binary logistic regression analysis showed the BNP/NT-proBNP (OR: 2.178, 95%CI = 1.031˜4.598, p = 0.041) and SUPER score (OR: 2.061, 95%CI = 1.695˜2.505, p <0.001) were independent risk factor for the onset of AHF. The AUC for the BNP/NT-proBNP, SUPER classification and SUPER score were 0.634, 0.785 and 0.804, respectively.
Conclusion: The SUPER score is independent predictor superiority in predicting the onset of AHF in AHFU.

P1181

Angioplasty with stenting in acute myocardial infarctions and acute coronary syndromes with 30ml contrast using cordis 6F diagnostic coronary catheters with bench testing in radial and femoral routes

MC Mark Christopher Arokiaraj[1]
[1]Pondicherry Institute of Medical Sciences, Pondicherry, India

Aims and objectives: To safely perform angioplasties in acute coronary syndromes and acute myocardial infarctions with low contrast volume using cordis infiniti 6F diagnostic catheters. To perform pushability and trackability tests on the diagnostic and guide catheters in radial and femoral paths.
Purpose: To perform safely angioplasty with low contrast volume and prevent congestive heart failure.
Methods and Results: In 327 patients (416 lesions/ 451 stents) with acute coronary syndromes angioplasty were performed with cordis 6F diagnostic catheters. 108 out of 327 patients underwent primary angioplasty. The lesions included left anterior descending (221), Left main (6), left circumflex (88), ramus (5) and right coronary artery (96) lesions, and in total 451 stents were used by this method. In 65% of cases Iodixanol was used. All contrast injections were given by hand. Regular follow-up of the patients was performed at 30 days. The patient population had 79% diabetes. All the procedures were performed in femoral route only. Pre-dilatation was performed in 83 lesions. In rest of the lesions direct stenting was used to deploy the stents. Successful revascularization of the target lesion was achieved in all cases. The mean contrast volume used per patient was 28 ml (±8 ml). Mild reversible contrast induced nephropathy was observed in three patients and no patients required dialysis. A variety of commercially available standard stents were used in the procedures. Cardiogenic shock was seen in 12 cases, and three mortality in total was observed. Of these 3 cases who expired, one patient had a large left ventricular clot, one patient had acute ventricular septal defect and the other patient presented with hypotension and severe congestive heart failure. Mild congestive heart failure was seen in 14 cases who were managed with diuretics and non-invasive ventilation. Buddy wire technique was used in 5 patients, and tirofiban was used in 99% cases in adjusted dosages. Proximal to the stent mild dissection was seen in one patient, and mild dissection distal to the stent in two patients. Coronary perforations or ruptures were not seen. Acute stent thrombosis was seen in 1 patient, who was treated with an additional stent and balloon dilatation. None of the patients required re-intervention in one month period. Bench evaluation showed balanced force transmission and flexibility parameters with diagnostic catheters compared to the guide catheters in both femoral and radial paths. There was restriction in trackability in the radial path at 81 cm which correlates wtih aorto-brachiocephalic junction. Force displacement curves showed favourable parameters with diagnostic catheters compared to guide catheters.
Conclusions: Emergency angioplasty could be performed safely in patients using Cordis 6F diagnostic catheters using low volume of contrast. Low contrast volume usage would result in lower incidence of contrast induced nephropathy and cardiac failures.

P1182
Evaluating the patient and carers perspective of the heart failure pathway following an admission with an acute decompensation of heart failure

R Ronan Kernan[1]; E Lennon[1]; J Gallagher[2]; M Walshe[2]; JP Riley[3]; C Keane[2]; PR Kalra[4]; MR Cowie[3]; K Mcdonald[2]
[1]University College Dublin, Dublin, Ireland; *[2]Heart Failure Unit, Dublin, Ireland*; *[3]Imperial College London, London, United Kingdom*; *[4]Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*

Funding Acknowledgements: Enterprise Ireland

Heart Failure (HF) is an increasingly prevalent chronic condition accounting for a substantial proportion of hospitalisations, particularly in those > 65. This study sought to evaluate the perspective of both patients and their carers with respect to symptom recognition and management of HF pre and post admission with Acute Decompensation of Heart Failure (ADHF). In order to do so we administered a validated questionnaire to patients (n = 70) admitted to a large teaching hospital with ADHF and their carers (n = 40), prior to discharge. At three months, following an intensive disease management programme (DMP), a follow-up questionnaire was also administered to patients (n = 57) and carers (n = 22).
Of the 70 patients surveyed, 66% (46) were male. The average age was 72.9 ± 12.8. The average number of co-morbidities was 3.8 ± 2.0. Patients were divided into those presenting for the first time with HF (De Novo, DN, 56% (39)) and those with an existing diagnosis of HF in their medical records (Known, K, 44% (31)).
In the baseline patient questionnaire, breathlessness was noted as the most dominant presentation with 62% (24) DN and 81% (25) K affected, however, 70% (21) DN and 42% (11) K did not associate it with HF. Furthermore, 65% (25) DN and 68% (21) K waited >7 days before seeking help with 18% (7) DN and 15% (3) K stating they would not have sought help earlier had they had thought it was HF related.
In the 3-month questionnaire, 82% (23) DN and 71% (17) K strongly agreed with calling the doctor if their limbs swell or when short of breath, however, 30% (8) DN and 25% (6) K patients still stated that they did not recognise breathlessness as a symptom of HF. While 36% (10) DN and 33% (8) K patients disagreed/strongly disagreed with calling their doctor if they experienced fatigue.
In the carer questionnaires at baseline, 92% (22) DN and 88% (14) K had daily contact with their patient. However, 63% (15) DN and 75% (12) K carers stated that their patient was suffering for >7 days before seeking help and 30% (3) DN and 25% (4) K carers were unfamiliar with their patient's medication list.
At 3-months, 76% (10) DN and 89% (8) K recognised breathlessness as a symptom of HF and 84% (11) DN and 67% (6) K felt their relative's ability to carry out routine daily activities had improved. However, despite 92% (12) DN and 78% (7) stating that their understanding of HF is of benefit to caring for their patient, 31% (4) DN and 56% (5) K stated that they were not involved in their patient's self-care management of HF.
Conclusion: Early symptom recognition and adequate management of HF in the community is vital if early intervention is to be triggered in an attempt to prevent Emergency Department visits and hospital admissions. Our results show knowledge of HF symptoms is poor even following an intensive HF DMP. Improvement and modification in the methods of delivering impactful patient and carer education are required.

Acute Heart Failure - Clinical

P1183
Epidemiology of heart failure following ST-segment elevation myocardial infarction treated with primary percutaneous coronary intervention.

N Farre[1]; A Fort[1]; H Tizon-Marcos[1]; L Recasens[1]; B Vaquerizo[1]; R Serrat[1]; M Grau[2]; J Comin-Colet[3]; J Marti-Almor[1]
[1]Hospital del Mar, Department of Cardiology, Municipal Institute for Medical Research (IMIM), Barcelona, Spain; *[2]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain*; *[3]University Hospital of Bellvitge, Barcelona, Spain*

On behalf of: Codi IAM Investigators

Introduction and objectives: To analyse the epidemiology and 30-day and 1-year mortality of heart failure (HF) that complicates ST-segment elevation myocardial infarction (STEMI) treated with primary percutaneous coronary intervention (PCI).
Methods: Multicentre registry of 14070 patients with STEMI treated with primary PCI from January 2010 to December 2015.
Results: Patients with HF were older, more frequently female, and diabetic and had higher prevalence of chronic ischemic heart disease. Only 10.3% of patients with STEMI treated with primary PCI had HF on admission and the majority of them had the mildest form (Killip-Kimball II 77.8%). The presence of HF was associated with high mortality (30-day mortality was 2.9% of patients in Killip-Kimball I, 9.5% of Killip-Kimball II and 17.4% in Killip-Kimball III, p <0.005, and 1-year mortality in patients who survived 30 days was 2.9%, 9.3% and 14.3%, p <0.005, respectively). Both the presence of Killip-Kimball class II and III were independently associated with 30-day and 1-year mortality in 30-day survivors. Up to 6% and 15% of patients in Killip-Kimball II and III on admission worsened to cardiogenic shock, and the onset of cardiogenic shock during hospitalization was independently associated with mortality at 30-day and 1-year follow-up.
Conclusion: Only 10.3% of patients with STEMI treated with primary PCI had HF on admission but it was associated with a higher risk of developing cardiogenic shock during hospitalization and with 30-day and 1-year mortality in 30-day survivors. In this high risk population, primary PCI and posterior medical treatment should be prioritized to avoid worsening of HF.

P1184
Cardiac troponin release is associated with higher CA 125, NT-proBNP and hsCRP levels in patients with acute decompensated heart failure

Y Yuksel Cavusoglu[1]; ME Altinbas[1]; S Eraslan[1]
[1]Eskisehir Osmangazi University, Eskisehir, Turkey

Purpose: High sensitive cardiac troponin (hs-cTn) has been proven to increase in majority of patients hospitalized with acute decompensated heart failure (HF), and referred as a potent predictor of poor prognosis. Plasma levels of carbohydrate antigen 125 (CA-125) have been shown to correlate with clinical, hemodynamic, and echocardiographic parameters in HF. Higher level of hsCRP is known to be present in the inflammatory process of HF. NT-proBNP is also a well-known biomarker of neurohormonal activation in HF. In this study, we aimed to evaluate the relationship between hs-cTn release and plasma levels of CA-125, NT-proBNP or hsCRP levels.
Methods: A total 425 patients admitted to the hospital with the diagnosis of decompensated HF, NYHA II-IV, LVEF < 40% and >18 years of age were included in this study. Plasma levels of hs-cTnT, CA-125, hsCRP or NT-proBNP levels have been measured from the blood samples at admission. hs-cTnT was considered to be abnormal if hs-cTnT was detected >0.014 ng/mL according to the assay used in this study. Patients were classified into two groups: patients with high hs-cTnT levels (n = 342, 80.5%) and patients with normal hs-cTnT levels (n = 83, 19.5%).
Results: Mean age of study population was 67 ± 12 years. Mean EF was 25.4 ± 7.9%, hs-cTnT was 0.22 ± 0.86 ng/mL, CA-125 was 86.2 ± 125.5 U/mL, NT-proBNP was 7667 ± 9876 pg/mL, and hsCRP was 27.4 ± 39.1 mg/dL. Plasma levels of CA-125 were found to be significantly higher in patients with high hs-cTnT as compared to those with normal hs-cTnT level (47.01 [18.8-130.3] U/mL vs 15.02 [11.3-30.9] U/mL, p < 0.001, respectively). NT-proBNP and hsCRP levels were also found to be significantly higher in patients with high hs-cTnT as compared to those

with normal hs-cTnT (4531 [1716-12047] pg/mL vs 651 [327-1768] pg/mL, p < 0.001 for NT-proBNP and 15.8 [6.05-35.43] mg/L vs 5.02 [3.44-12.51] mg/L, p < 0.001 for hsCRP, respectively). Furthermore, a significant positive correlation was found between hs-cTnT levels and CA-125 (r=.261, p < 0.001), NT-proBNP (r=.252, p < 0.001), or hsCRP levels (r=.326, p < 0.001).

Conclusions: The results of this study showed that majority of patients with acute decompensated HF have abnormal hs-cTn levels at admission and hs-cTn release in this group of patients is associated with higher CA-125, NT-proBNP and hsCRP levels, suggesting more severe clinical status of the disease in patients with cardiac troponin release.

Fig. 1 Impact of cardiorenal anemia syndrome (CRAS) status on mortality (at in-hospital, at 3-month, and at 12-month) of the Gulf CARE cohort.

Mortality	Pearson's chi-squared test				Multivariate logistic regression			
	All	No CRAS	CRAS	*p*-value	Adj. OR [95% CI]	Adj. *p*-value	HL	ROC
In-hospital	308 (3.2%)	189 (5.2%)	119 (9.0%)	<0.001	1.71 [1.03-2.81]	0.036	0.341	0.91
3-month	620 (12.6%)	390 (10.8%)	230 (17.4%)	<0.001	1.36 [1.03-1.79]	0.030	0.358	0.76
12-month	998 (20.2%)	630 (17.4%)	368 (27.9%)	<0.001	1.39 [1.13-1.71]	0.002	0.695	0.73

Impact of cardiorenal anemia syndrome

Methods: We analyzed the data of patients with CRAS and divided into patients without CRAS and patients with CRAS. Multivariate logistic regression and pearson's chi-square test were utilized.

Results: In-hospital, 3 month and 12 month mortality were significantly higher higher (adjusted odds ratio (aOR), 1.71; 95% confidence interval (CI): 1.03 to 2.81; p = 0.036), 3-month (aOR = 1.36; 95% CI: 1.03 to 1.79; p = 0.030) and at 12-month (aOR, 1.39; 95% CI: 1.13 to 1.71; p = 0.002).

Conclusions: CRAS AHF patients were associated with worse mortality at not only in-hospital but at 3-month and 12-month.

P1186

Clinical characteristics of atrial fibrillation in patients with acute heart failure; insights from The Kyoto Congestive Heart Failure (KCHF) registry

K Hotta[1]; R Taniguchi[1]; Y Sato[1]; E Yamamoto[2]; H Yaku[2]; N Ozasa[2]; T Kato[2]; T Morimoto[2]; T Kimura[2]

[1]Hyogo Prefectural Amagasaki Hospital, Cardiology, Hyogo, Japan; *[2]Kyoto University, Cardiology, Kyoto, Japan*

Background: Patients with acute heart failure (AHF) frequently have atrial fibrillation (AF), but characteristics of AF in patients with AHF are unclear.

Methods and Results: The study included patients from The Kyoto Congestive Herat Failure (KCHF) registry, prospective, observational, multicenter cohort study enrolling 4,065 consecutive patients who had hospital admission due to AHF for the first time during the period between November 2014 and March 2016 in the 19 participating hospitals in Japan. AF at presentation was detected in 1,455 (35.9%) patients. Patients with AF at presentation were older than those with Sinus Rhythm (SR) at presentation (79.5 vs. 76.6, P < 0.001), had higher left ventricular ejection fraction (48.7% vs. 44.2%, P < 0.001), lower systolic blood pressure (140 vs. 153 mmHg, P < 0.001), higher ventricular rate (103 vs 93 bpm, P < 0.001). There was no difference in-hospital mortality between patients with AF at presentation and patients with SR at presentation (3.92% vs. 4.78%). All patients were divided into four groups based on rhythm at presentation and at discharge (SR-SR 56.7%, AF-AF 32.7%, AF-SR 6.3%, SR-AF 4.3%). An admission-to-discharge percentage BNP reduction of SR-SR group was greater than other groups. There was no difference in-hospital mortality and worsening heart failure during hospitalization between four groups.

Conclusions: We elucidated clinical characteristics of atrial fibrillation in patients with acute heart failure. There was no difference in-hospital mortality between patients with AF at presentation and patients with SR at presentation.

Coronary Artery Disease - Pathophysiology and Mechanisms

Clinical outcomes of early well-developed coronary collateral circulation in patients with late presentation myocardial infarction

C Carmen Collado Moreno[1]; A Gutierrez-Barrios[2]; D Canadas-Pruano[3]; T Bretones-Del Pino[2]; A Giraldez-Valpuesta[3]; M Alba-Sanchez[3]; S Gamaza-Chulian[3]; D Ruiz-Fernandez[3]; G Calle-Perez[2]; R Zayas-Rueda[2]; E Marante-Fuertes[2]; J Oneto-Otero[3]; R Vazquez-Garcia[2]

[1]Puerto Real Hospital, Department of Cardiology, Puerto Real, Spain; *[2]University Hospital Puerta del Mar, Cardiology, Cadiz, Spain*; *[3]General Hospital of Jerez, Cardiology, Cadiz, Spain*

Background: The aim of the study was to evaluate if early well-developed coronary collateral circulation (CCC) and clinical outcomes in patients with late presentation (>24 hours) myocardial infarction (MI).

Methods: Retrospective multicenter longitudinal study on 164 patients with a late presentation MI and angiographic evidence of a thrombotic occlusion (TIMI 0) of a major coronary artery from 2009 to 2016. The Rentrop and Werner score were used for the angiographic categorization of CCC.

The primary aim of the study was to assess the impact of CCC on major adverse cardiac events (MACE) at 12 months defined as cardiovascular mortality (CVM),

transplant or heart failure hospitalization. The secondary aim was to evaluate the cardiogenic shock rate at presentation and CVM on 12 months follow up.
Results: Poor CCC was detected in 46% of the patients. Patients with good CCC more commonly had a right coronary (RC) occlusion but less often had a left anterior descending occlusion (p <0.05 for both). There were no significant differences between both groups neither in baseline characteristics nor in medical treatment at discharge.
The median follow up was 3.4 years (interquartile range 1.1-5.5 years). 3 patients lost to follow up.
Patients with good CC were less often rated as Killip class III or IV at presentation (3% vs 15%, p = 0.03) and were less often presented in cardiogenic shock (9.2% vs 1.1%, p = 0.02) and consequently the systolic blood pressure (SBP) was lower and the heart rate (HR) was higher among these patients
At one-year follow-up, patients with evidence of angiographic collaterals had statistically significant lower unadjusted rates of the combined endpoint of MACE (p <0.01); CVM (p <0.01) and were less often rated at NYHA III/IV at 12 month follow-up (p = 0.02) The independent effect of CCC on 1-year MACE was confirmed by a multiple logistic regression analysis. Significant predictors on univariable analysis were: absent or poor collateral flow (Rentrop grade 0 or 1), lower Killip class at presentation, left anterior descending (LAD) culprit vessel, decreased LVEF after MI. After adjustment the absence of CCC remained an independent predictor of 1-year MACE (p <0.01).
Logistic regression analysis shows that absence of early collateralization is an independent determinant of 1-year CV mortality (p <0.01). Using the Cox proportional hazard model, the HR for the occurrence of 1-year MACE in patients who had good CC was 8.05 (95% CI, 1.73 - 37.4; P <0.01) and 1-year CVM was 6.92 (95% CI, 1.37 - 34.7, p = 0.019) compared to patients with poor collateralization at baseline. Kaplan-meier curves showed that MACE and CVM were significantly higher (p <0.01) in poor compared to early developed CCC group according to log rank.
Conclusion: An early well-developed coronary collateral circulation in patients with late presentation MI improved one-year clinical outcome rates and exerted a protective effect against cardiogenic shock at presentation.

P1188
Relationship between Monocyte Subsets, IL-6 and hs-CRP with the Severity of Coronary Artery Disease in Stable Angina Pectoris Patients

A M Abdelmohsen Moustafa Abdou Aboualia[1]; E Mokhtar[2]; B Saleh[2]; H Nageb[3]
[1]Al-Azhar University, cardiology department, cairo, Egypt; *[2]Al-Azhar University, clinical pathology, Cairo, Egypt*; *[3]Al-Azhar University, internal medicine, Cairo, Egypt*

Background: Monocytes are crucially involved in all stages of atherogenesis as cellular drivers of vascular inflammation hallmarking atherosclerotic disease. CD16+monocytes are proinflammatory cells, whose proportion is related to the occurrence of coronary artery disease (CAD), intma-media thickness and plaque stability. Interleukin-6 (IL-6) and highly sensitive C reactive protein (hs-CRP) were also closely related to atherosclerotic disease.
Objective: We investigated the relationship between the monocyte subsets, IL-6, and hs-CRP with the severity of CAD assessed by coronary angiography (CAG) in patients with stable angina pectoris (SAP) through their correlation with Gensini score.
Methods: Our study included 45 SAP patients who underwent diagnostic CAG. Thirty two patients of them who diagnosed as CAD were subdivided into 2 groups: 17 patients with multiple-vessel disease (MVD) and 15 patients with single-vessel disease (SVD). The rest thirteen SAP patients without CAD (non-CAD) were considered as a comparative group. Gensini score was used to assess the severity of CAD. Monocyte subsets were analysed by flow cytometry and serum levels of IL-6 and hs-CRP were measured by ELISA.
Results: The relative proportion of CD14+ CD16+ and CD14bright CD16+ was significantly higher in CAD patients, MVD and SVD as compared with non-CAD patients and in MVD more than SVD. Serum levels of IL-6 and hs-CRP were significantly increased in CAD patients, MVD and SVD when compared with non-CAD patients, but no significant difference between MVD and SVD. The proportion of CD14+ CD16+ and CD14bright CD16+ monocytes was positively correlated with Gensini score (r = 0.667, P = 0.000, r = 0.695, P = 0.000).
Conclusions: Elevated proportion of CD14+ CD16+ monocytes subsets was associated with the severity of CAD in patients with SAP.

P1189
Global myocardial strain of left ventricle depending on segmentary stenosis of left anterior descending artery in STEMI patients

V Valentin Oleinikov[1]; V Galimskaya[1]; A Golubeva[1]; S Kupriyanova[1]; S Skvortcov[1]
[1]Penza State University, Penza, Russian Federation

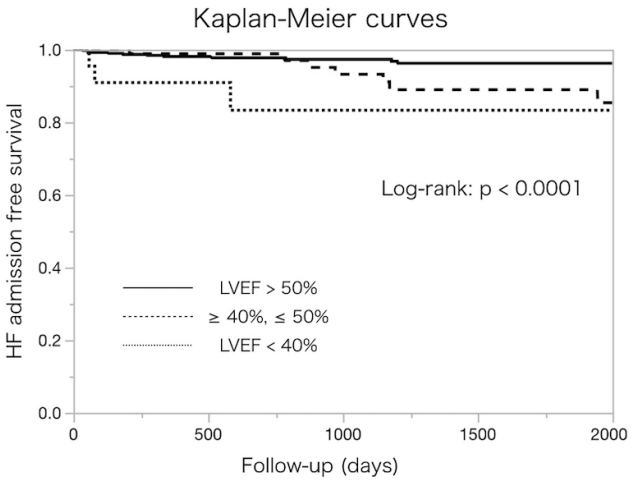
Aim: Determine the dependence of different global strain types of the left ventricle (LV) from stenosis of the left anterior descending artery (LAD) specific segments in STEMI patients.
Methods: The study included 60 patients with STEMI (51.8 ± 8.2 years), confirmed by ECG, coronary angiography (CAG), troponin I level, CK-MB. Inclusion criteria: age 35-65 years, significant stenosis only LAD (infarct-related artery), revascularized within the first hours from the cardiac pain onset, stenosis of other arteries less than 50%, the trunk of LA - less than 30%. Exclusion criterion - history of previous myocardial infarctions and other cardiovascular diseases. All patients underwent echocardiography (MyLab, Esaote, Italy) at the 6th-7th day after the disease onset. Using the X-Strain™ software, the following peak global strain parameters were determined: longitudinal (GLS), circumferential (GCS) and radial strain (GRS), as the average of 18 LV myocardium segments. The hypothesis of normality of each sample distribution is verified using the non-parametric Kolmogorov-Smirnov criterion.
Results: Taking into account the segmental location of the infarct-related LAD stenosis, patients were divided into two groups: 1 - 33 people with stenosis in the middle segment, 2 - 27 subjects with proximal segment stenosis. GLS in the 1st group was 13.8% (95% CI 11.8, 15.7), in the 2nd - 12.9% (95% CI 10.8, 14.9), (p>0.05); GCS-18.4% (95% CI 15.4, 21.3) and 15.4% (95% CI 12.2, 18.6), (p>0.05), respectively. GRS values in group 1 were 27.8% (95% CI 22.9, 32.7), in the 2nd group 24.3% (95% CI 18.9, 29.6), p>0,05).
Conclusion: Global longitudinal, circumferential and radial LV strain in STEMI patients does not depend on stenosis location in the proximal or middle LAD segment.

Coronary Artery Disease - Treatment

P1190
The influence on the onset of heart failure in patients with preserved, mid-range and reduced ejection fraction after first-time acute myocardial infarction.

R Ushigome[1]; S Namiuchi[1]
[1]Sendai Open Hospital, Sendai, Japan

Background: Left ventricular ejection fraction (LVEF) after acute myocardial infarction (AMI) is well established as an important predictor of clinical outcome. The new category of heart failure (HF), HF with mid-range LVEF (HFmrEF), has recently been propounded. The influence on the onset of HF of patients with mrEF after AMI remain unclear.
Purpose: The study sought to assess the clinical characteristics and influence on the onset of HF after primary percutaneous coronary intervention (PCI) for first-time AMI, classified by ejection fraction.
Methods: We evaluated 632 consecutive patients admitted with first-time AMI due to plaque rupture, visiting hospital within 24 hours of onset, and without a history of HF. All patients were treated with primary PCI. Patients were divided into three groups by LVEF after AMI, reduced EF (rEF): < 40%, mrEF: 40-50%, and preserved EF (pEF): >50%, and were evaluated for clinical characteristics management and onset of HF after first-time AMI.
Results: Those with rEF, mrEF, and pEF comprised 41, 126 and 465 patients, respectively. There are no significant differences in age (rEF 69yrs., mrEF 68yrs., pEF 66yrs., p = 0.07), gender distributions (Male; 88%, 72%, 76%, p = 0.11) and discharge medication, between 3 groups. In patients with mrEF, hemoglobin (13.3g/dL, 13.7g/dL, 14.3g/dL, p < 0.01), creatinine (1.1mg/dL, 0.83mg/dL, 0.80mg/dL, p < 0.01), peak creatine kinase (3964U/L, 2981U/L, 1309U/L, p < 0.01) and B-type natriuretic peptide (647pg/mL, 228pg/mL, 69pg/mL, p < 0.01) of mrEF were intermediate between pEF and rEF. Kaplan-Meier analysis revealed that the rate of onset of HF differed significantly between rEF and pEF; mrEF patients experienced intermediate rates (Figure). After adjustment with patient background, the rate of onset of HF of mrEF was significantly lower than that of rEF (adjusted HR, 6.65; 95% CI: 1.82 to 22.6, p = 0.046), while there was no significantly between mrEF and pEF (adjusted HR, 0.51; 95% CI: 0.21-1.31, p = 0.15).
Conclusion: We found that the patients with mrEF after first-time AMI represent clinically diverse group with many intermediate features compared to rEF and pEF, while mrEF patients carry a lower risk of onset of HF after MI than rEF but a similar risk with pEF.



Kaplan-Meier Curves

P1191

Predictors of hospital mortality in patients with acute myocardial infarction and reduced left ventricular systolic function

T Tanja Popov[1]; I Ivanov[1]; S Bjelic[1]; M Jarakovic[1]; M Cankovic[1]; M Petrovic[1]; I Srdanovic[1]
[1]*Institute of Cardiovascular Diseases Vojvodina, Novi Sad, Serbia*

Introduction: Modern treatment of myocardial infarction tends to faster and efficient opening of the infarct-related artery, shorter length of stay in the coronary care unit and shorten hospitalization. However, aging of the population, previous cardiovascular diseases, contribute to a growing number of patients with numerous comorbidities, reinfarction, heart failure. Mortality in these groups of patients is high, and special care must be taken to treat them. The aim of this study was to determine the predictors of in-hospital mortality in patients with acute myocardial infarction and reduced left ventricular systolic function.
Methods: This is single center, retrospective study, that includes patients who were treated in 2014/15. because of acute myocardial infarction.
Results: The study included 2665 patients (64.9% men, 35.1% women). Preserved left ventricular systolic function, EF = 50% had 1413 (53%) subjects. Hospital mortality in the group with EF < 50% was 8.6%, while in the group EF = 50% was 1.2%, p < 0.0005. Patients with EF < 50% were older (66.1 ± 11.7 vs. 61.9 ± 11.6 years, p < 0.0005), had a lower body mass index (BMI) (27.4 ± 4 , 6 vs 27.8 ± 4.4, p < 0,018), lower Jung variable (systolic blood pressure/(heart rate x age)) (0.026 ± 0.008 vs. 0.031 ± 0.009), higher dimensions of the heart chambers and regurgitation rates on the valves, p < 0.005, a higher serum glucose (10.1 ± 4.6 vs. 8.7 ± 3.9 mmol / l, p < 0.0005), creatinine (128.2 ± 80.7 vs 110.06 ± 63.38 mmol / l, p < 0.0005), lower triglycerides (1.76 ± 1.1 vs 1.92 ± 1.6 mmol / l), higher C reactive protein (66.44 ± 85.65 vs 32.41 ± 56.47 mg / dl, p < 0.0005), higher markers of myocardial necrosis and NT-pro-BNP, p < 0.0005, more frequent left anterior descending coronary artery stenosis (LAD)(53.8% vs 25.1%, p < 0.0005), fewer implanted stents during treatment (1.09 ± 0.95 vs 1.20 ± 1.0, p = 0.003), lower TIMI flows before and after intervention. The predictors of hospital mortality in the group of patients with reduced left ventricular systolic function are age, BMI, Jung variable, valvular regurgitation degree, left atrial size, serum glucose, creatinine, triglyceride, CRP, troponin, NT-pro-BNP, TIMI flow after intervention, LAD stenosis, a fewer implanted stents.
Conclusion: Ejection fraction of the left ventricle is an independent predictor of hospital mortality.

P1192

The effect of the invasive cardiology on sudden cardiac death, caused by acute heart failure

B Boris Slavchev[1]; R Ilieva[2]; T Donova[1]
[1]*University Hospital "Lozenets", Cardiology Department, Sofia, Bulgaria*;
[2]*University Hospital Tsaritsa Yoanna, Cardiology Department, Sofia, Bulgaria*

Background: Sudden cardiac death (SCD) is the third most frequent cause of death in Europe. Despite the clear reduction in the rates of SCD in the recent years through better revascularization and prevention of coronary artery disease the effect of the invasive coronary angiography on the SCD, caused by acute heart failure remains unknown.
Purpose: The aim of the study was to investigate the effect of the invasive cardiology on SCD, caused by acute heart failure.
Methods: We reviewed retrospectively the forensic department autopsy files of 1971 cases of sudden death (SD) for the period 2000-2016 in a region with population of 350 000 inhabitants. The cardiac catheterization laboratory in the region was opened in 2012 and therefore the study was divided into two periods 2000-2012 and 2013-2016.
Results: From 1971 cases of sudden death for the whole period we found 1358 cases of SCD (69%) (71 % males; mean age 64 ± 16.4 years). The SCD cases for the period 2000-2012 were 72% of all SD cases and for the period 2013-2016 were 63%. The most common reason for SCD for both periods was acute heart failure (caused by cardiomyopathy, coronary artery disease, myocarditis, valvular disease and arterial hypertension). The diagnosis was made according to the autopsy findings of acutely dilated heart, pulmonary oedema, and organ congestion and was proven histologically. The share of acute heart failure was 52.9 % of all cases of SCD for the period before the invasive cardiology introduction and 25.3% after it (p < 0.001). The significant reduction in the SCD due to acute heart failure is mainly caused by increased revascularization and decreased prevalence of chronic coronary artery disease. Better awareness of the signs and symptoms of heart failure, and the improved medical care might also have played a role.
Conclusion: SCD is the main cause of SD, with acute heart failure still comprising a huge proportion of it. In the recent years we found significant decrease in the acute heart failure SCD cases mainly due to revascularization.

P1193

Clinical, angiographic characteristics and 2-year outcome of acute coronary syndrome presenting with cardiogenic shock

A Antonio Valentim Goncalves[1]; AT Timoteo[1]; T Pereira-Da-Silva[1]; S Aguiar Rosa[1]; L Ferreira[1]; R Carvalho[1]; T Mendonca[1]; R Ilhao Moreira[1]; M Coutinho Cruz[1]; P Modas Daniel[1]; L Morais[1]; I Rodrigues[1]; R Cruz Ferreira[1]
[1]*Hospital de Santa Marta, Lisbon, Portugal*

Introduction: Among patients admitted to a catheterization laboratory with acute coronary syndrome (ACS), a minority present with cardiogenic shock (CS). Evidence for the best way to manage these patients are needed.
Aims: We aimed to assess patients' characteristics and short and long-term outcomes of CS due to ACS.
Methods: We analysed all ACS cases with CS admitted during a ten-year period in a tertiary care centre. We defined CS as systolic blood pressure <90mmHg and signs of impaired organ perfusion with need for catecholamine therapy or presenting with cardiac arrest.
At discharge, a standardized registry was performed in all cases. All patients were followed-up for two years and potencial predictors were analysed (Cox regression) for the occurrence of mortality (total and cardiovascular (CV)), CV hospitalizations and revascularization procedures.
Results: From 3283 patients admitted with ACS, 92 (2.8%) presented with CS. Mean age was 66.0 ± 12.8 years, with 64 (69.6%) males, and 60 (65.2%) presenting with STEMI. These patients presented previous ACS in 12.0%, were smokers in 28.3% and had diabetes, dyslipidemia and hypertension in 23.9%, 37.0% and 45.7%, respectively.
Angiographic characteristics are described in the table. Index-PCI was successful in 83.7% cases. Multivessel CAD was presented in 56 patients (60.9%), with complete revascularization in the index-PCI attempted in 11 patients (19.6%) and staged revascularization performed in 7 patients (12.5%). No statistical differences regarding outcomes were found between these two groups.
Mean hospitalization duration of 16.4 ± 9.5 days with in-hospital mortality of 50.0%. Unsuccessful index-PCI (p = 0.002), culprit left main coronary artery (LMCA) (p = 0.044) and reduced LVEF (p <0,001) were significant in-hospital mortality predictors. At 24 months, survival after hospital release was 91.3%, with 40.0% having at least one CV hospitalization requiring PCI in 13.0% and CABG in 4.4%.
Conclusion: CS was uncommon among ACS patients. Unsuccessful PCI, culprit LMCA and reduced LVEF were independent predictors of in-hospital mortality. Despite a very high in-hospital mortality, long-term outcome was favourable.

Coronary anatomy	Culprit vessel	CAD: Stenosis ≥70% (≥50% LMCA) Culprit or not		
n (%)	In-hospital mortality (%)	n (%)	In-hospital mortality (%)	
left main coronary artery	10 (10.9%)	80.0%	15 (16.3%)	73.3%
Left anterior descending artery	36 (39.1%)	52.8%	59 (64.1%)	47.4%
Left circumflex artery	8 (8.7%)	42.1%	42 (45.7%)	40.5%
Right coronary artery	38 (41.3%)	37.5%	57 (62.0%)	47.4%

P1194

Echocardiographic parametters of myocardial mechanic as potentially predictors of worse prognosis during one year follow up in STEMI patients

G Krljanac[1]; D Trifunovic[1]; M Asanin[1]; L Savic Spasic[1]; M Vukicevic[2]; I Mrdovic[1]
[1]*Clinical Centre of Serbia, Cardiology Clinic, Medical Faculty, Belgrade, Serbia*; [2]*Clinical center of Serbia, Cardiology Clinic, Belgrade, Serbia*

Parameters of left atrial (LA) mechanic as well as left ventricle (LV) could be substrate of worse prognosis and incidence of major cardiac events (MACE) defined as death, re-infarction, emergency revascularization, ventricular arrhythmias (VT and/or VF) and heart failure which need emergency re-hospitalization in STEMI patients (pts) treated with primary percutaneous interventions (PPCI). Aim: To determine mechanic parameters as predictors of MACE during 12 month follow up (FU). We studded conventional echo parameters, parameters of LV mechanics: global longitudinal strain (GLS) and LA mechanics: peack sistolic strain (S LAs) and strain rate (Sr LA).
Method: 120 consecutive STEMI pts treated with PPCI were prospectively included. Echo examination performed on day 4 ± 2 (VIVID 9GE, Echo PAC Ver 113).
Results: 15/95 (15.8%) of all pts had MACE during one year FU. Parameters of EF, LA vol and vol index, GLS and S LA were significant predictors of MACE. (table 1). The largest area under the ROC had GLS (area 0.815, cut off -11.53, Sn 66.7%, Sp 73.2%).
Conclusion: During after PPCI period the left atrial mechanic parameters could be important to predict of MACE. However, global longitudinal strain is the best prognostic parameter in PPCI STEMI patients.

Table 1. Predictors of MACE

	Pts without MACE (n = 95)	Pts with MACE (n = 15)	p
LVEF (%)	51.2±9.4	37.0±12.1	<0.001
LA vol (ml)	35.4±9.9	46.9±14.5	0.001
LA vol index (ml/m^2)	18.4±5.6	24.1±7.3	0.002
GLS	-14.6±4.3	-10.1±3.9	<0.001
S LAs (%)	20.9±8.1	16.0±7.1	0.030

Effect of atorvastiatin therapy on lipid profile and carotid intima-media thickness in patients with STEMI

I Matrosova[1]; E Melnikova[1]; N Burko[1]; V Valentin Oleinikov[1]
[1]*Penza State University, Penza, Russian Federation*

Aim: to analyze the lipid profile and carotid intima-media thickness (CIMT) in patients with ST segment elevation myocardial infarction (STEMI).
Methods: the study included 100 patients with STEMI: 90 men and 10 women; the average age is 52 ± 8.9 years. Patients were randomized into two groups. The main group received atorvastatin 80 mg/day, the comparison group was prescribed atorvastatin 20 mg/day. 51 patients (46 men and 5 women) were included in the 1st group, the average age was 51.4 ± 8.5 years. The second group consisted of 49 people (43 men and 6 women), aged 51.5 ± 9.5 years. The groups were matched by age, sex, height, BMI, office BP. All patients received atorvastatin for 48 weeks. The levels of total cholesterol (TC), high density lipoprotein (HDL), low density lipoprotein (LDL), triglycerides (TG) were evaluated.
The carotid artery structural and functional properties were evaluated by ultrasonic scanner MyLab 90 ("Esaote", Italy). The measurements were carried out using the radiofrequency (RF) analysis technology with RF-QIMT software. QIMT (μm) was evaluated at 7-9th days and after 48 weeks of therapy.
Results: Initial values of lipid profile in the 1st group were: TC - 6 ± 1,2 mmol/l; LDL - 4.1 ± 1.2 mmol/l; HDL - 1,2 ± 0,3 mmol/l; TG -1.3 (0.7, 2.2) mmol/l. After 48 weeks of treatment, there was a significant decrease in TC to 3.6 ± 0.7 mmol/l (by 43%, $p < 0.05$); LDL to 2.1 (1.8, 2.8) mmol/l (50%, $p < 0.05$);
In the comparison group, the baseline lipid profile values were: TC 5.6 (5.05, 6.40) mmol/l; LDL - 3.9 (3.3, 4.5) mmol/l; HDL -1,1 (0,9, 1,4) mmol/l; TG -1.3 (0.8, 1.7) mmol/l. At the end of therapy, there was a significant decrease in TC to 4.1 (3.7, 4.9) mmol/l (by 28%, $p < 0.05$); LDL to 2.6 (2.2, 3.2) mmol/l (by 24.5%, $p < 0.05$). The values of HDL and TG in both groups have not changed significantly.
Initially, the CIMT value in the first group was 739.9 ± 154.2 μm, in the second group - 711.1 ± 141.7 μm. After 48 weeks of therapy, there was a significant decrease of CIMT to 639 (541, 743) μm (by 14%, $p < 0.05$) only in patients receiving high doses of atorvastatin.
Conclusion: atorvastatin therapy 80 mg per day reduces the total cholesterol and low-density lipoprotein more effectively in patients with STEMI. In addition, this approach allows to improve the condition of carotid arteries significantly reducing the intima-media thickness according to the radio-frequency analysis of the ultrasonic signal.

P1196

Left ventricular diastolic function changes in patients with chronic stable angina pectoris in using ranolazine

A Alexey Kuchmin[1]; YV Epelshtein[1]; DY Epelshtein[1]; AA Shevelev[1]; SN Shulenin[1]
[1]*The Kirov Military Academy, St-Petersburg, Russian Federation*

Background: Elevated intracellular Na+ levels and Ca2+ overload result in diastolic dysfunction and microvascular compression that can worsen LV function in patients with chronic stable angina pectoris.
Purpose: The purpose of this study was to investigate whether inhibiting late Na+ current by using ranolazine improved diastolic function in patients with stable ischemic heart disease.
Methods: 21 patients with stable ischemic heart disease were examined using complex of cardiac assessments, including 2D and 3D echocardiography. All of them treated with 1 or 2 antianginal medications were assigned to ranolazine extended-release 1000 mg BID for 4 weeks. Echocardiograms were performed at baseline and after treatment with ranolazine for 4 weeks. Two patients failed to complete the trial.
Results: American and European guidelines recommend the use of ranolazine in the setting of chronic stable angina pectoris (CSAP) in patients who have not derived sufficient benefit from first-line agents chronic stable angina pectoris. There is data than ranolazine may improve diastolic function in some groups of patients. All patients that we enrolled in our study had signs of diastolic dysfunction. After 4 weeks of therapy with ranolazine there were a significant increase in E/A ratio (0.71 ± 0.22 and 0.85 ± 0.18, $P < 0,05$) and reduction in DT (261.6 ± 51.3 ms and 235 ± 47.3 ms, $P < 0,05$) and IVRT (114.3 ± 11.9 ms and 105.4 ± 9.8 ms, $P < 0,05$) values. Ema (TDI-derived lateral mitral annular E wave) was also decreased after treatment with ranolazine (9.11 ± 1.64 cm/s and 7.96 ± 1.89 cm/s). There was a statistically significant decrease in angina frequency ($P < 0.01$), and in doses of weekly sublingual nitroglycerin use ($P < 0.01$) in patients treated with ranolazine.
Conclusions-Results of this study revealed that ranolazine improved relaxation parameters of left ventricle in patients with chronic stable angina pectoris and diastolic dysfunction. It can be explained that impairment of diastolic function in this category of patients may be caused by ischemia of myocardium and is reversible.

P1197

Non-ST-segment elevation of acute coronary syndrome. The factors that influence the revascularization strategy.

SV Malchikova[1]; AN Kolupaev[1]
[1]*Federal State Budgetary Educational Institution of Higher Education "Kirov State Medical University", Internal medicine department, Kirov, Russian Federation*

Introduction: Non-ST-segment elevation of acute coronary syndrome (NSTE-ACS) is the most common form of acute coronary syndrome. Patients with NSTE-ACS with proximal left anterior descending (LAD) coronary artery disease (isolated and multi-vessels diseases) are the most complicated for choice of method of revascularization. There are no clear algorithm of optimal invasive strategy for this category of patients currently.

Purpose: to evaluate factors influencing the strategy of myocardial revascularization in patients with NSTE-ACS with proximal LAD coronary artery disease
Materials and methods.
103 patients with NSTE-ACS with proximal LAD coronary artery disease (hemodynamically significant stenosis) were included in the study on a prospective basis. They were divided into two groups: coronary artery bypass grafting (CABG) group - 63 patients (61.2%) and percutaneous coronary intervention (PCI) group - 40 patients (38.8%). Intervention therapy was performed in Kirov Regional Teaching Hospital, The city of Kirov.
The estimation of clinical features of the disease, the structure of comorbidity, estimation of indexes of scales: EuroScore II, SYNTAX, estimation of indexes of echocardiography were performed.
Results: There were no differences by sex and age between the groups. Statistically significant differences were observed in the structure of comorbidity: presence of hemodynamically significant atherosclerosis of peripheral arteries (4.8% and 17.5% for CABG and PCI group's, respectively, ? < 0.05). Index of Euroscore 2 scale was 1.25 ± 0.58% on average, the mortality rate was 1,6% in reality in the CABG group. The periods of operative treatment were 18.0 ± 7.8 days and 7,2 ± 7,9 days for CABG and PCI group's, respectively, ? < 0.01. Special attention was paid to the scale of angiography status. SYNTAX scores were 18.6 ± 7.0 and 9.9 ± 3.9 for CABG and PCI group's, respectively, ? < 0.05. CABG was perfomed in patients with ostial lesion of LAD, hemodynamically significant multivessels defeat, stenosis of trunk of left coronary artery more than 50%, extended stenosis of LAD (? < 0.01). There have been powerful flows between the left and right coronary artery systems in the CABG group, in comparison with the PCI group. (p < 0.01). Preference is given to PCI with technical feasibility in patients with isolated proximal LAD stenosis from 50% to 80%. The clinical status of the patient played a key role in PCI ad hoc the LAD (isolated proximal stenosis 90% or more): recurrent angina (repeated recurrence of the pain syndrome), refractory to adequate drug treatment, unstable hemodynamic parameters.
Conclusion: Thus, the choice of an optimal strategy for invasive treatment in this category of patients should be guided by the following factors: stratification of patients with NSTE-ACS risk based on the presence of clinical risk factors, evaluation of SYNTAX scale, EuroScore II scale, discussion of the findings by a heart team.

P1198
In-hospital prognostic value of plasma brain natriuretic peptide (BNP) after acute myocardial infarction

R Raymond[1]; T Zaki[1]; I Nour Eldeen[1]
[1]*Ain Shams University, cairo, Egypt*

Background: Acute myocardial infarction is a major mortality cause and in spite of diagnostic and therapeutic improvements, mortality and morbidity rate of this condition remained high. B-type natriuretic peptide (BNP) has been recognized as a useful marker for predicting acute and chronic left ventricular dysfunction. Although BNP plasma level is measured routinely in many centers in acute myocardial infarction, but it is not full determined how it is useful for estimation of left ventricular ejection fraction (LVEF) and other acute complications.
Objective: To investigate the prognostic value of B type natriuretic peptide (BNP) in acute myocardial infarction (AMI) and its correlation with in-hospital left ventricular systolic function and post-myocardial infarction complications.
Methods & Results: We enrolled 90 consecutive patients admitted to coronary care units of Ain Shams University hospitals with acute ST segment elevation myocardial infarction who were successfully reperfused by primary PCI [57 patients (63.3 %)] or thrombolysis [33 patients (36.7%)] in the period from September 2014 to April 2015. Seventy five patients (83.3%) were male, mean age 55.58 ± 8.73 years. Sixty three patients (70.0%) were smoker, 48 (53.3%) diabetic, 41 (45.6%) hypertensive and 45 (50 %) dyslipidemic. Sixty two patients (68.9%) presented with anterior MI & 28 (31.1%) with inferior MI. BNP was immediately assessed after successful reperfusion.Trans-thoracic echocardiography was done on third day of admission. ECG , cardiac enzymes & in hospital clinical follow up were done on daily basis.There was no statistically significant correlation between BNP levels and site of infarction (P-value = 0.141) , timing of symptoms onset (p- value = 0.431), nor type of reperfusion therapy (P-value = 0.744). However, a significant negative correlation was found between BNP levels and ejection fraction (P-value = 0.033) with a cut off value of BNP <1170 pg/ml. Patients with BNP level (= 1238.7 pg/ml) were significantly more likely to experience new or worsening clinical heart failure during their hospital stay (P-value = 0.035).Also, a statistically significant positive correlation was found between BNP levels and mechanical complications in the form of acute mitral regurgitation (P-value = 0.050) with a cut off value of BNP >1116 pg/ml as well as arrhythmias (ventricular tachycardia, complete heart block and atrial fibrillation) (P-value = 0.002) with cut off value of BNP >1418 pg/ml.
Conclusion: Baseline BNP level measured on admission in acute ST segment elevation myocardial infarction could be used as a predictor for the development of acute mitral regurgitation, arrhythmias, impairement of LV systolic function and new or worsening of clinical heart failure.

Valvular Heart Disease - Epidemiology, Prognosis, Outcome

MR indicates mitral regurgitation; NYHA, New York Heart Association functional class; PAP, pulmonary artery pressure; PAWP, pulmonary artery wedge pressure; RV, right ventricular; RVEF, right ventricular ejection fraction

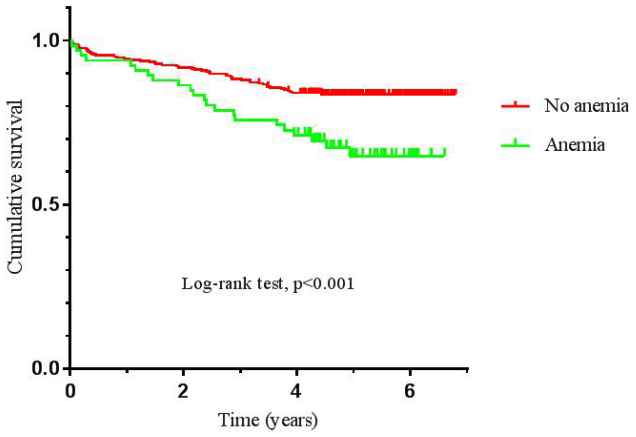
(HFrEF), mitra-clip has emerged as therapeutic opportunity and has been shown to improve functional status. By contrast, the role of secondary MR in HFpEF is fairly unknown. The aim of the present study was to determine the impact of FMR on functional status, haemodynamics and prognosis in HFpEF.
Methods and Results: 261 consecutive patients with HFpEF were screened for the presence of a FMR and were classified into 3 groups: no or mild, moderate and greater than moderate FMR. Patients were followed for a mean of 24 ± 17 months. Between groups, patient with increasing FMR severity were older, had higher rates of atrial fibrillation, higher filling pressures and worse right ventricular function (Table1). Besides, significant FMR was associated with increased mortality risk.
Conclusions: This is the first study that evaluated the role of FMR in a pure HFpEF population. FMR had a negative impact on ventricular filling pressures, right ventricular function and survival. In this light we conclude that further studies are needed to confirm current results and to evaluate interventional therapies that target FMR.

P1200
Prevalence and prognostic implication of iron deficiency in patients with severe aortic stenosis

A B Kvaslerud[1]; A Auensen[1]; A Hussain[1]; T Ueland[2]; K I Pettersen[3]; L Morkrid[4]; L Gullestad[1]; K Broch[3]
[1]Oslo University Hospital, Department of Cardiology, Rikshospitalet and Faculty of Medicine, University of Oslo, Oslo, Norway; *[2]Oslo University Hospital, Research Institute of Internal Medicine and Institute for Clinical Medicine, University of Oslo, Oslo, Norway*; *[3]Oslo University Hospital, Department of Cardiology, Oslo, Norway*; *[4]Oslo University Hospital, Department of Medical Biochemistry and Institute for Clinical Medicine, University of Oslo, Oslo, Norway*

Objectives: The clinical importance of iron deficiency (ID) in patients with heart failure (HF) is well established, but the prognostic implications of ID in patients with other chronic cardiovascular diseases are less studied. By employing the definition of ID frequently used in patients with HF (ferritin < 100 μg/L or ferritin 100-299 μg/L with a transferrin saturation < 20%), this study investigates the prevalence, predictors and prognostic value of ID in patients with severe aortic stenosis (AS).
Methods: In a prospective study of 464 patients (age 75 ± 11 years, 56% men) with severe AS who were evaluated for aortic valve replacement (AVR), iron stores were assessed at presentation.
Results: ID was detected in 246 patients (53%). 94 patients (20%) had anemia (Hgb < 13.0 g/dL for men, < 12.0 g/dL for women). Anemic patients were more often iron deficient than non-anemic patients (63% vs 51%, p = 0.03). Other independent predictors of ID were female sex, use of antacids/proton-pump inhibitors and smaller aortic valve area (all p < 0.05). 373 patients (80%) were offered surgical (337) or transcatheter (36) AVR and 91 (20%) received conservative, medical treatment (MT). During follow-up (median 4.7 years, IQR 3.8-5.5 years), 129 patients (28%) died, of whom 57 (63%) was in the MT group and 72 (19%) in the AVR group. 69 died of cardiac causes. There was no significant difference in all-cause or cardiac mortality between patients with and without ID in neither the AVR nor the MT group. Anemia, on the other hand, was associated with increased all-cause (p < 0.001) (Figure 1), but not cardiac, mortality in patients referred to AVR. Neither anemia nor ID were independent predictors of all-cause or cardiac mortality in multiple analyses adjusted for predetermined clinical, biochemical and echocardiographic predictors in either the AVR or MT groups. The composite of major adverse cardiovascular events (MACE), defined as all-cause death, myocardial infarction, stroke or transient ischemic attack, occurred in 73 of 464 patients (16%) within the first year after inclusion (21 (23%) in the MT group and 52 (14%) in the AVR group). There was no significant difference in the event rate between patients with and without ID or anemia in the MT or the AVR group. Neither anemia nor ID were independent predictors of MACE.
Conclusions: Our results indicate that ID is common in patients with severe AS. Neither anemia nor ID provided independent prognostic information on top of conventional risk factors. More studies are required to evaluate whether the definition of ID used in patients with HF is useful in other chronic cardiac diseases, such as aortic stenosis.

Figure 1. Survival analysis. Kaplan-Meyer curve reflecting overall survival in patients with severe aortic stenosis referred to operation with and without anemia



P1201
Clinical outcomes of Transcatheter Aortic Valve Implantion in patients with degenerated bioprosthetic surgical valves versus aortic stenosis

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; F Carrasco-Chinchilla[1]; AJ Dominguez-Franco[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; E De Teresa Galvan[1]
[1]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Most surgical heart valves currently implanted are bioprosthetic tissue valves but such valves deteriorate with time and re-operation carries significant risk. Implantation of a transcatheter valve inside a failed surgical valve (valve-in-valve) has recently emerged as an alternative, less-invasive option. The aim this study was to evaluate the clinical results of this technique using autoexpandible prosthesis in patients with degenerated bioprosthesis surgical valves and comparing them with patients with aortic stenosis.
Methods: The CoreValve prosthesis (Medtronic, Minneapolis, MN, USA) was implanted in 19 patients with symptomatic degenerated surgical aortic valves (SAV) and in 596 patients with aortic stenosis (AS).
Results: The mean age was lower in SAV compared with AS 74.2 vs. 79.6 ± 6.3 years, p = 0.001 and logistic EuroSCORE was higher by SAV 27.6 ± 16% vs. 17 ± 11, p= 0.001. TAVI procedure was successful in all patients with degenerated bioprosthesis. In two patients required to implant a second valve prosthesis and there were not complications after procedure including mortality at 30 days. After procedure and 1-year, the mean gradient was higher in patients with SAV than AS, 19.7 ± 13 mmHg vs. 8.8 ± 3 mmHg, and 15.1 ± 9 vs. 9 ± 4 mmHg, p < 0.001, respectively. The aortic regurgitation grade post-procedure in patients with SAV compared wit AS were: none (63.2% vs 40.1%); mild (26.3% vs. 33.8%), moderate (10.5% vs. 23.5%) and severe (0% vs. 0.9%), p= 0.045. There were more moderate and severe prosthesis-patient mismatch when compare with the rest of patients treated (75% vs. 36%, p = 0.09 and 43.8% vs. 8.2%, p = 0.001, respectively). There were tend to lower requiring pacemaker after procedure (12.5% vs. 26.1%, p = 0.175). In the follow-up, after 41.4 ± 27 months, the total mortality was similar in both groups, 42.1% vs. 34.9%, p = 0.238 and 80 % of patients was at an Association functional class I-II.
Conclusions: The valve-in-valve procedure is clinically effective in patients with degenerated bioprosthesis aortic valves. The procedure and outcomes are similar in some aspects to TAVI in the setting of native aortic valve stenosis

P1202

Mitral Valve Prolapse - a single-centre study of outcomes

R Rita Carvalheira Dos Santos[1]; A Marques[2]; S Alegria[2]; AR Pereira[2]; D Sebaiti[2]; I Cruz[2]; AR Almeida[2]; P Fazendas[2]; I Joao[2]; H Pereira[2]
[1]Hospital de Vila Franca de Xira, Vila Franca de Xira, Portugal; *[2]Hospital Garcia de Orta, Almada, Portugal*

Backgound: Mitral Valve Prolapse (MVP) is a common condition, with a wide clinical range.
Objective: Description of a MVP population and analysis of the clinical and echocardiographic relevant prognostic parameters.
Methods: Retrospective unicentric study based on electronic patient records and echocardiogram review, between 01/2012 and 12/2016. Occurrence predictors of ventricular tachycardia (VT), stroke, acute myocardial infarction (AMI), infective endocarditis (IE) and overall mortality (OM) were considered.
Results: 106 patients were included: 55.7% male with mean age of diagnosis 60 ± 14 years. In initial evaluation 36.8% of patients were asymptomatic; among the symptomatic patients, 34.9% presented NYHA class = II. Most of them had moderate mitral regurgitation (MR), 23.6% severe MR; 69,8% with posterior leaflet prolapse and 19.8% with involvement of both leaflets; mean telediastolic e telesystolic volumes of 110.6 ± 38mL and 42 ± 20mL respectively, mean left ventricle ejection fraction (LVEF) of 62 ± 7%. With a 39.4 months median follow up, the overall incidence of events was 38.7%. The stroke incidence was 8.5%, mainly in males (p = 0.036), asymptomatic (p = 0.006) or with palpitations (p = 0.007); 12.3% of patients had AMI, most diabetics (p = 0.023) with anterior leaflet prolapse (p = 0.038). The incidence of VT and IE was 5.7%, with no significant impact factors identified. The OM was 8.5%, all male, mostly symptomatic (p = 0.005). The mean age of deceased patients was significantly higher (mean 70 ± 8.6 vs 59.6 ± 14 years, p = 0.006). As expected, patients with severe MR were more submitted to surgery (p < 0.001), although they didn't have a significantly higher OM (16 vs 5.1%, p = 0.077). Of the remaining echocardiographic parameters analyzed, none showed statistically significant association with the events, even though a greater tendency for the occurrence of VT with a lower mean ejection fraction (56.7% ± 3 vs 62.8% ± 7, p = 0.058) and a greater OM with a higher LV telesystolic volume mean (51 ± 23 vs 39 ± 19mL, p = 0.068) was verified.
Conclusion: The overall incidence of events, in this population, was 38.7%, being sex, age and symptoms the main factor for their occurrence. The echocardiographic parameters analyzed may provide information regarding the severity of these patients, particularly LVEF and VTSVE.

P1203

Predictors of embolism in Infective Endocarditis

AC Ana Catarina Gomes[1]; I Cruz[1]; AI Marques[1]; S Alegria[1]; AR Pereira[1]; D Sebaiti[1]; I Rangel[1]; I Joao[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal

Background: Infective endocarditis (IE) still represents a major cause of morbimortality in patients with valvular heart disease. Among the morbidity causes, embolism burden is responsible for major disability in this patients.
Methods: We studied the endocarditis population in our hospital, from 2006-2016. The clinical and imaging data were collected as well as the complication rates, particularly the embolic-related data.
Purpose: To determine the predictors of embolism in IE.
Results: 148 patients, 75% males, 61.5 ± 15.9 years. 51.4% with hypertension (HTN), 18.9% with diabetes mellitus. Comorbidities: heart failure (HF) in 27% (6.8% with HF device), pulmonary disease (PD) in 14%, chronic renal disease (CRD) in 14.9%, 3.4% on hemodialysis (HD), chronic hepatic disease (CHD) in 22.3%.
Signs at presentation: fever 67.1%, murmur 53.3%, anemia 39.5%. Native valve disease in 72.3%.
Echocardiographic identified lesions: vegetation in 80.4%, abscess in 13.5%, pseudoaneurysm in 4.7%, valve obstruction in 6.1%, aneurysm in 3.4% and fistula in 4.1%. Global embolism occurred in 33.6% of our patients, being in 19.1% to the cerebral territory.
Embolism was directly associated IV drug use (r = 0.241, p = 0.003), septic shock (r = 0.275, p = 0.001) and lack of favorable operative condition (r = 0.286, p = 0.004). Although, it is inversely associated with Streptococcus IE (r=-0.17, p = 0.039), local complications (r=-0.268, p = 0.001), presence of abcess (r=-0.185, p = 0.032), age (r=-0.194, p = 0.018), HTN (r=-0.202, p = 0.014), HF (r=-0.20, p = 0.015) and CRD (-0.175, p = 0.034).
Conclusion: Embolism was associated with IV drug use, septic shock and non-surgical approach. It was inversely associated with Streptococcal IE, HF and local complications, including abscess.

P1204

Predictors of relapse in Infective Endocarditis

AC Ana Catarina Gomes[1]; I Cruz[1]; AI Marques[1]; S Alegria[1]; AR Pereira[1]; D Sebaiti[1]; I Rangel[1]; I Joao[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal

Background: Infective endocarditis (IE) still represents a major cause of morbimortality in patients with valvular heart disease. Apart from causes of morbimortality related to the index episode, recurrence/relapse is one of the long-term complications, particularly related to non-effective clearance of microorganisms from tissues.
Methods: We studied the endocarditis population in our hospital in the last 10 years. The clinical and imaging data was collected as well as the complication rates and rate of relapse.
Purpose: To establish the predictors of relapse in IE, particularly related to IE risk factors and associated complications.
Results: 148 patients, 75% males, 61.5 ± 15.9 years. 51.4% with hypertension, 18.9% with diabetes. Comorbidities: heart failure (HF) in 27% (6.8% with HF device), pulmonary disease (PD) in 14%, chronic renal disease (CRD) in 14.9%, 3.4% on haemodyalisis (HD), chronic hepatic disease (CHD) in 22.3%, HIV seropositive 13.5%, cancer in 9.5%, 98.6% on imunossupression (medical cause or drug-related).
Echocardiographic lesions: vegetation in 80.4%, abscess in 13.5%, pseudoaneurysm in 4.7%, valve obstruction in 6.1%, aneurysm in 3.4% and fistula in 4.1%.
Rate of relapse: 2.6%
Relapse was associated with local complications (100% vs 43.6%, p = 0.040) and local destructive lesions (75.0 vs 22.1, p = 0.043). It was not associated with specific microorganisms, type of valve and patient comorbidities.
Conclusion: Relapse was associated with endocarditis-related local complications, although not related to specific etiology, microorganisms or comorbidities.

Valvular Heart Disease - Treatment

P1205

Retrospective evaluation of the predictive value of neutrophil lymphocyte ratio (NLR) on 30-day mortality after transcatheter aortic valve implantation (TAVI)

E Emre Yilmaz[1]; S Turen[2]; B Uygur[2]; A R Demir[2]; C Z C Gevher[1]; S T Karakurt[1]
[1]Kanuni Sultan Süleyman Education and Research Hospital , Cardiology, Istanbul, Turkey; *[2]Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery Training and Research Hospital, Cardiology, Istanbul, Turkey*

Introduction: Neutrophil lymphocyte ratio (NLR) has been found to be an independent predictor of prognosis in coronary artery disease and valvular diseases. Current knowledge about the relation of NLR with prognosis after transcatheter aortic valve implantation (TAVI) is not sufficient.
Purpose: The aim of this study is to investigate if neutrophil lymphocyte ratio (NLR) is an independent predictor of 30-day mortality after TAVI.
Methods: A total of 196 patients who underwent TAVI between October 2010 and December 2016 were screened and 184 patients were included in the study. The cut off value for NLR was determined by ROC analysis. The cut off value for postoperative 3rd day NLR (NLR3) was defined as 7.93. The study population was divided into two groups: those who have higher and lower than this cut off value as "high NLR" and "low NLR" respectively. Baseline, peroperative, and postoperative clinical features, echocardiographic and laboratory findings of high and low NLR groups were analyzed by univariable and multivariable analyses.
Results: One hundred thirteen (61.4%) of the patients were female and mean age was 79,41 ± 7,88. Sixteen patients died within 30 days follow up after the TAVI. Three patients died within 24-72 hours. Mortality was found to be significantly higher in the high NLR group [12 (22.2%) versus 1 (0.8%), p <0.001]. In Kaplan-Meier survival analysis, 30-day survival was lower in the high NLR group (Log-rank, p <0.001). In multivariable Cox regression analyses, NLR3 [Odds Ratio (OR): 30,98, 95% Confidence Interval (GA): 2,4-399,48 p: 0,008], acute renal damage [OR: 6.58, 95% GA: 1,360-31,875 p = 0,019] and preoperative peak gradient [OR: 1,045, 95% GA: 1,008-1,084 p = 0,018] were found to be as independent predictors of 30-day mortality after TAVI.
Conclusion: In this study, NLR3 was found to be an independent predictor of 30-day mortality after TAVI.

P1205 NLR cut off values by ROC analysis

	Cut Off Value	Area Under the Curve (AUC)	%95 CI	Sensitivity, %	Specificity, %	p value

Transcatheter aortic valve implantation without balloon valvuloplasty is not associated with transient left ventricular dysfunction

M Mirna[1]; B Wernly[1]; S Eder[2]; M Lichtenauer[1]; C Jung[3]; C Reiter[4]; A Kypta[4]; UC Hoppe[1]; M Hammerer[1]

[1]Paracelsus Private Medical University, Internal Medicine II, Cardiology, Salzburg, Austria; *[2]Oberndorf Hospital, Department of Internal Medicine, Oberndorf, Austria*; *[3]Medical Faculty, University Duesseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Duesseldorf, Germany*; *[4]Kepler University, Department of Cardiology, Linz, Austria*

Background: Transcatheter aortic valve implantation (TAVI) is a therapeutic alternative to conventional heart surgery in patients with high-grade aortic valve stenosis. Balloon aortic valvuloplasty (BAV) under rapid ventricular pacing (RVP) has been a routine part of TAVI. However, it carries substantial risks and therefore an increasing number of interventionists have started to refrain from it. In our study, we investigated if TAVI without prior balloon valvuloplasty ("direct TAVI") was associated with a similar increase in cardiac biomarkers and decrease in ejection fraction as reported previously.
Methods: A total of 164 consecutive patients undergoing "direct-TAVI" were followed up for one year and were retrospectively analyzed regarding mortality, safety and efficacy endpoints as well as common laboratory and echocardiographic values.
Results: According to the VARC2 (Valve Academic Research Consortium) 89.1% of patients remained free of a combined safety endpoint and technical success rate was 96.3%. Mortality rates at 30 days and 1 year were 3.0% (n= 5) and 10.4% (n= 17), respectively.
TAVI without rapid ventricular pacing was highly effective in lowering aortic valve peak velocity from 4.36 ± 0.63 m/s before to 1.7 ± 0.45 m/s post intervention, resulting in a significant decrease of mean aortic valve peak velocity ($p < 0.01$). Left ventricular function remained unaltered (50,64 ± 10% prior to TAVI and 50,86 ± 8,99% post TAVI) after the intervention, whereas high sensitive troponin T, a well-established marker for myocardial injury, increased significantly from 26 ng/L (IQR= 18.00-44.00) to 119 ng/L (IQR= 73.25-166.00, $p < 0.001$) during this time. Myocardial injury (<15 ULN) was associated with mortality at one month (10% vs 2%; $p = 0.04$) and one year (8% vs 23%; HR 4.28; 95%CI 1.63-11.28; $p = 0.003$).
Conclusion: "Direct TAVI" is feasible, safe and effective. Mortality and safety resulted in similar outcomes as the frequently used approach with rapid ventricular pacing and balloon valvuloplasty. In contrast to a cohort of patients who underwent TAVI with BAV and RVP previously published by another center, our cohort did not suffer from transient impairment of left ventricular function. Furthermore, hs-troponin showed a less pronounced increase than reported previously. We therefore conclude that "direct TAVI" is a less invasive option involving less myocardial stress and is therefore be better suited for the elderly and multimorbid.

P1207

Single center initial experience with mitral annuloplasty using Carillon device for patients with significant functional mitral regurgitation and left ventricular disfunction

S Mazzetti[1]; G Singh[1]; J Rossi[1]; R Abete[1]; A De Marchi[1]; G Valenti[1]; CA Santambrogio[1]; G Sorropago[1]; F Scalise[1]; A Andrea Mortara[1]

[1]Dipartment of Cardiology Policlinico di Monza, Monza, Italy

Aims and Objectives: Presence of significative functional mitral regurgitation in patients with left ventricular dysfunction adds to worsening hemodynamics of already decompensating myocardium. Surgical annuloplasty results have shown to reduce regurgitation thus improve functional status, however data is scant to prove a survival benefit after surgical correction in these high-risk patients. Hence, different percutaneous technique have been proposed with promising Results: Aim of the present study was to assess procedural feasibility, safety, efficacy of Carillon device and intermediate term clinical and hemodynamic outcomes both by invasive (catheterization) and non-invasive (Echocardiography) evaluation in patients with secondary mitral regurgitation and left ventricular dysfunction.
Methods and Results: We performed Carillon device implantation in 6 patients from Jun'2016- May'2017. We included patients with left ventricular dysfunction and annular dilatation having moderate-to-severe mitral regurgitation, III NYHA, minimum length > 9cm of coronary sinus. We excluded patients with significant coronary artery disease (SYNTAX > 32), candidates for resynchronization therapy and renal dysfunction. Mean age was 79 ± 4 years, with mean NYHA class 3.16 ± 0.4. Mean annular dimensions (AP) by ECHO were 39.33mm and mean coronary sinus length was 11.5 ± 1.04 and diameter 9.15 ± 2.03mm. Mean device size was 10 ± 1.60 for distal anchor and 18 ± 1.78 for distal anchor with a mean length of 60mm. In one patient left circumflex occlusion was observed after releasing of distal anchor and was redeployed after stenting LCX; however no myocardial infarction was seen in any patient. Mean contrast volume used for procedure was 121.33 ml with implantation time of 35 ± 22.1 minutes. At follow up of 6 months NYHA class changed to a mean of 2.16 ± 0.40, effective orifice area reduced from 0.33 to 0.12(p value- 0.014) Vena contracta from 6.33mm to 2.33 (p value 0.03), annular dimensions from 39.67 mm to 37.50 (p value 0.086) and with MR severity 3.14 to 2 (p-value-NS). There was a reduction in left ventricular volumes as seen by ECHO (end dysatolic volume from 200.50ml to 190.40 ml (p value0.59) and end-systolic volume from 142.83ml to 129ml (p value0.79)). Right catheterization showed reduction, although not significant of PCWP(m) from 28.33(basal) to 19 (3 months) and to 20.40 (6 months) (p value NS). Similarly, RA(m) reduced from 18.67 to 13.40(p-NS), PAP(m) from 54 to 40.60(p value - NS). PVR from 1.92 to 1.68 WU (p value NS). There was no mortality at 6 months, but one patient required re-hospitalization for heart failure and renal failure.
Conclusion: Mitral annuloplasty using Carillon is safe, technically simple and fast in terms of time taken to deploy the device. Echocardiographic as well as hemodynamic data are promising. We expect further improvements in the parameters at 12 months follow-up. However, further large multi-center trials with longer follow up are needed.

P1208

Impact of TAVI referral reasons on morbimortality during hospitalization and follow-up

S Torres[1]; A Nunes[1]; P Araujo[1]; M Braga[1]; R Pinto[1]; J Rodrigues[1]; R Rodrigues[1]; JC Silva[1]; D Magalhaes[1]; M Vasconcelos[1]; PB Almeida[1]; MJ Maciel[1]

[1]Sao Joao Hospital, Porto, Portugal

Introduction: Transcatheter aortic valve implantation (TAVI) has emerged as a safe alternative to surgical aortic valve replacement (SAVR) for prohibitive or high-risk surgical patients (pts) with severe aortic stenosis. There are several reasons for referring patients for TAVI, which are often interconnected and related to the advance aged group of patients in which this valvulopathy is commonly diagnosed.
Purpose: To describe the main reasons for referring a patient for TAVI instead of conventional surgery, and to assess their impact on morbimortality during hospitalization and follow-up.
Methods: We retrospectively evaluated pts who were submitted to TAVI in our tertiary care center between October 2014 and December 2016. Clinical and laboratorial data were evaluated.
Results: A total of 89 pts, of whom 51.7% (n = 46) were female, with a mean age of 80.2 ± 7.1 years were included. All pts had symptomatic severe aortic stenosis prior to TAVI. The median EuroSCORE II was 4,5% (0.8-25.9). The main reasons for referral for TAVI were: porcelain aorta (PA) (n= 47; 52.8%); severe pulmonary disease (PD) (n= 6; 6.7%); frailty (Fr) (n= 5; 5.6%); prior cardiac surgery (CS) (n= 4; 4.5%); high surgical risk based on other major comorbidities (HSR) (n = 27; 30.3%).
During hospitalization, the median stay was similar (PA - 8 days; HSR - 12; PD - 10; Fr - 14; CS - 11; p= 0.60). The incidence of complications was higher in the Fr group (100%), compared to the remain (PA - 63.8%; HSR - 74.1%; PD - 33.3%; CS - 50%), although not significant (p = 0.10). Only one patient had in-hospital mortality (HSR).
Pts were followed up in cardiology appointments during a mean time of 386 ± 93 days. During this period, pts with PD had significantly higher rates of NYHA class = II: 100% (PA - 34.9%; HSR - 40.9%; Fr - 25.0%; CS –25.0%) (p < 0.01).
Hospitalization rates were similar between groups (PA - 23.9%; HSR - 30.8%; PD - 33.3%; Fr - 20%; CS - 75%; p = 0.29). All-cause mortality was higher in the PD (16.7%) and HSR (15.4%) groups (PA - 2.2%; Fr - 0%; CS - 0%), but cardiovascular deaths occurred only in the HSR group (11.5%).
Conclusion: Based on our results, the presence of severe pulmonary disease has a negative impact on patient outcome after TAVI, as seen by the higher rates of NYHA class = II on follow-up and higher all-cause mortality. On the other hand, cardiovascular mortality was verified in pts referred for TAVI due to high surgical risk based on other major comorbidities.

Myocardial Disease - Clinical

P1209
S100A8/S100A9 alarmin as a potential biomarker in patients with active myocarditis

I Mueller[1]; U Kuehl[2]; T Vogl[3]; B Pieske[2]; S Van Linthout[1]; C Tschoepe[2]
[1]Berlin-Brandenburg Center for Regenerative Therapies, Charite - Campus Virchow Klinikum, Berlin, Germany; *[2]Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology and Pulmonology, Berlin, Germany*; *[3]University of Muenster, Department of Immunology, Munster, Germany*

Background: S100A8/S100A9 is a damage-associated molecular pattern molecule and has been shown to be important under inflammatory conditions including arteriosclerosis and coronary heart disease. Clinical evidence highlights that high plasma levels of S100A8/S100A9 are a risk factor for future cardiovascular events.
Purpose: We aimed to evaluate the potential of serum S100A8/S100A9 levels as a prognostic biomarker in patients with endomyocardial biopsy (EMB)-proven active myocarditis (A-MC) vs non-ischemic dilative cardiomyopathy (DCM) and controls.
Methods: S100A8/S100A9, high sensitivity C-reactive protein (hsCRP) and n-terminal (NT) pro-brain natriuretic protein (BNP) levels were analyzed in serum and plasma of A-MC (n = 27; ejection fraction (EF): 38.8% ± 14%) and DCM patients (n = 16; EF: 22.5% ± 4.7%), and controls (n = 51; EF: 60% ± 5%) by specific ELISAs. Patients serum and plasma were collected at time point (T) 1, where also EMBs were collected. EMB S100A8, S100A9, and NLRP3 mRNA levels and the number of invaded inflammatory cells in EMBs were determined by real-time PCR and immunohistology stainings, respectively. Ejection fraction (EF) was determined at T1 and T2 by echocardiography and the improvement/deterioration in EF between T1 and T2 was calculated.
Results: Serum S100A8/S100A9 did not differ between controls and DCM. In contrast, serum S100A8/S100A9 levels were 3.7-fold (p <0.0001) higher in A-MC patients vs controls. Using a cut-off of 570 ng/ml, S100A8/S100A9 levels showed a diagnostic specificity and sensitivity of 77% and 89%, respectively, vs controls. Alarmin levels correlated with hsCRP (r = 0.588, p <0.012), but not with plasma NT pro-BNP levels (r =-0.210, p = 0.3013). The increase of peripheral alarmins correlated strongly with the mRNA expression of S100A8 (r = 0.731, p = 0.0006) and S100A9 (r = 0.702, p = 0.0011) and moderately with lymphocyte function-associated antigen 1 presence (LFA1; r = 0.435, p = 0.0233) in EMBs of A-MC patients. In A-MC patients, EMB mRNA levels of inflammasome 3 (NLPR3), known to belong to the intracellular signaling of alarmins, correlated with EMB S100A8 (r = 0.6, p = 0.024) and S100A9 (r = 0.66, p = 0.012) mRNA expression. Clinically, alarmin serum levels correlated with the EF T1 (r = 0.6032, p = 0.0011) and moderately with the EF improvement/deterioration (EF T2 - EF T1 7.8% ± 6.5%) over time (r = 0.498, p = 0.0415) in A-MC patients. A correlation with the EF over time did not exist for hsCRP (r = 0.363, p = 0.151) or NT pro-BNP (r=-0.180, p = 0.5046) levels.
Conclusions: The S100A8/A9-NPLR3 axis is activated in human A-MC, but not in DCM patients, and reflected by increased serum S1008/S100A9 levels. S1008/S100A9 serum levels are increased under these conditions like some other inflammatory tissue and plasma markers such as hsCRP, but correlated best with the change in LV function. We conclude that the measurement of S100A8/S100A9 serum levels can provide an additional value for the diagnosis and monitoring of A-MC.

P1210
Viral genome changes and the impact of viral genome persistence in myocardium of patients with inflammatory cardiomyopathy

D Dalibor Mlejnek[1]; JK Krejci[1]; PH Hude[1]; LS Spinarova[1]; EO Ozabalova[1]; VZ Zampachova[2]; IS Svobodova[2]; RS Stepanova[3]
[1]St. Anne's University Hospital, First Department of Internal Medicine - Cardioangiology, Brno, Czech Republic; *[2]St. Anne's University Hospital, First Department of Pathological Anatomy, Brno, Czech Republic*; *[3]Masaryk University, Brno, Czech Republic*

Funding Acknowledgements: This study was supported by Specific University Research Grant MUNI/A/0996/2017.

Introduction: Viral infections are considered the most frequent cause of myocarditis and dilated cardiomyopathy (DCM).
Material and Methods: We investigated the changes in viral presence and the impact of viral genome persistence in myocardium on echocardiographic parameters, functional status and some laboratory parameters in a 6-month follow-up. Fifty-four patients with a recent onset DCM, left ventricular ejection fraction < 40% and biopsy-proven myocarditis (<14 mononuclear leukocytes/mm2 and/or >7 T-lymphocytes/mm2) were enrolled. Polymerase chain reaction was performed to detect pathogens in myocardium. Patients were divided according to the administered therapy: standard heart failure medication (46 patients) and immunosuppressive therapy (8 patients).
Results: In the standard heart failure medication group viral clearance was observed in 13 patients and viral persistence in 24 patients in the follow-up period. Comparing both groups, there was no statistically significant difference - LVEF improvement of 12.0 ± 11.4% vs. 18.3 ± 12.6%, decrease in NYHA class of 0.7 ± 0.7 vs. 1.0 ± 0.7, decline in NT-proBNP of 1335 ± 1933ng/l vs. 1942 ± 3242ng/l and decrease in infiltrating leukocytes of 11.1 ± 15.8 vs. 6.7 ± 23.0 cells/mm2 and T-lymphocytes of 5.8 ± 15.1 vs. 1.8 ± 10.9 cells/mm2 (all p = n.s.). A decrease in PCR positive patients from 37 to 29 was observed. The number of PVB19 positive PCR findings decreased from 5 to 4 in patients with immunosuppressive therapy.
Conclusions: A decrease in the number of positive PCR findings in control EMB was observed. Viral genome persistence was not associated with worse outcome in short-term follow-up.

P1211
THE CLINICAL, MORPHOLOGICAL DIAGNOSIS AND PROGNOSTIC VALUE OF THE MYOCARDITIS IN THE LEFT VENTRICULAR NONCOMPATION SYNDROME

O V Olga Blagova[1]; EV Pavlenko[1]; NV Varionchik[1]; AV Nedostup[1]; EA Kogan[1]; AE Donnikov[2]; VV Kadochnikova[2]
[1]I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation; *[2]DNA technology, Moscow, Russian Federation*

Purpose: to study the prevalence and prognostic value of the myocarditis in the left ventricular noncompation syndrome (LVNC).
Methods: we studied 103 adult patients with LVNS (61 males, 45.6 ± 14.9 years). The average EDD LV was 6.0 ± 0.8 cm, LV EF 38.8 ± 14.5. To diagnose LVNC were performed Echo-CG, CT (n = 81) and MRI (n = 39). DNA-daignostic had included NGS (Ion Torrent) simultaneous sequencing of gene panel (12 genes), followed by Sanger sequencing of detected variants. The pathogenic mutations were detected in 9% of patients in the following genes: MYH7, MyBPC3, LAMP2, DES, DSP, TTN. We also investigated anti-heart antibodies and viruses by PCR. The morphological study was performed in 19 patients (endomyocardial biopsy in 14, intraoperative biopsy in 1, explanted heart study in 1 and autopsy in 3). The mean follow-up was 12 [2; 32] months.
Results: Acute/chronic heart failure was in 79.6% of patients diagnosed. In other cases, the main symptom of LVNC were arrhythmias, ischemia and/or thromboembolism. The average LV diastolic size was 6.0 ± 0.8 cm, LV ejection fraction 38.8 ± 14.5%. The myocarditis was diagnosed in 55 (53.4%) patients with LVNC: in 19 patients by morphological study (active in 10 and borderline in 9 patients) and in 36 patients on the basis of a complex examination (the relationship with a respiratory infection, a 3-4-fold increase in the anti-heart antibodies, the viral genome

in the blood, pericardial effusion, subepicardial LGE). The sarcoidosis was detected in one case by biopsy of lymph nodes. The myocarditis was virus-positive in 17 patients (36.1%). The parvovirus B19, human herpes virus type 6, cytomegalovirus, herpes simplex virus and Epstein-Barr virus were detected in 8 patients in the myocardium (42.1%), and in 14 patients (25.5%) in the blood. The myocarditis was associated with arrhythmic form of LVNC (in 44.4% of this patients), ischemic form (12.5%), dilated pattern (57.5%) and other cardiomyopathies (myopathies, arrhytmogenic right ventricular cardiomyopathy, hypertrophic or restrictive cardiomyopathy, 50.0%). In 10% of all patients with LVNC, acute / subacute myocarditis became the first manifestation of the disease.The association of LVNC with myocarditis led to more severe myocardial dysfunction with a more severe heart failure (NYHA class 2 [1;3] v 1.75 [0;2], $p < 0.01$), lower EF (33.8 ± 13.5 v $44.7 \pm 13.6\%$, $p < 0.001$), higher rate of the nonsustained ventricular tachycardia (67.3% v 29.3%, $p < 0.01$), appropriate defibrillators shocks (38.9% v 0, $p < 0.05$), death (16.4 ? 4.2%, OR 5.75, 95%CI 1.21-27.43, $p < 0.05$), and heart transplantation (7.3% v 2.1%, $p>0.05$). The causes of death were myocardial infarction, arrhythmias, heart failure.

Conclusion: LVNC is a favorable platform for the myocarditis (including viral), which is diagnosed in half of patients. The myocarditis is one of the leading causes of increased heart failure and ventricular arrhythmias, appropriate shocks of defibrillators and lethality in LVNC.

P1212

Cardiac involvement in the full cohort of Romanian Fabry disease patients

S Militaru[1]; R Adam[1]; A Mursa[1]; E Rusu[2]; BA Popescu[1]; C Ginghina[1]; A Saftoiu[3]; R Jurcut[1]

[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; *[2]Fundeni Clinical Institute, Bucharest, Romania*; *[3]Craiova Univeristy of Medicine and Pharmacy, Craiova, Romania*

Background: Fabry disease is a rare X-linked genetic disorder, in which alpha-galasidase deficiency leads to lysosomal accumulation of globotryaosilceramide, affecting most organs and tissues. Cardiac, renal and neurologic involvement influence prognosis. The aim of this study is to describe the particularities of cardiovascular involvement in the full cohort of Romanian Fabry disease patients (pts).

Methods: We evaluated cardiovascular parameters in all consecutive pts diagnosed with Fabry disease in Romania. Obtained data included clinical, biologic (cardiac and renal markers), ECG, ECG holter and echocardiographic (conventional measurements and myocardial Doppler velocities and Speckle tracking based deformation study). Patient files included complete data on renal and neurologic involvement.

Results: The database included 39 pts consecutively diagnosed with Fabry disease, with an average age of 47 ± 15 years, 22 women (56.4%). Women were older than men (52 ± 15 vs 40 ± 12.5 years, $p < 0.05$). More than half had been diagnosed through family screening and 8 pts were first diagnosed because of cardiovascular symptoms or signs. Patient symptomatology included: dyspnea in 19 pts, angina, palpitations and syncope. Permanent pacemakers were present in 7 pts, of which 5 were women. Lab work-up showed high levels of BNP (211 ± 378pg/ml), Troponin I (0.034 ± 0.05 ng/ml) at baseline. ECG analysis showed 16 pts with LVH criteria, while short PR interval (< 120 ms) was present in 11 pts. Holter ECG study showed supraventricular arrhythmias in 2 pts and nonsustained ventricular tachycardia in 2 pts. Cardiac ultrasonography findings included: normal global systolic LV function (LVEF: $63.3 \pm 6.5\%$), but abnormal LV longitudinal function (mean GLS $-15.6 \pm 4.4\%$); LV hypertrophy (LVH) was present in 24 pts, of which 21 pts also had RV hypertrophy and 12 pts had papillary muscle hypertrophy. Analysis showed a correlation between age and cardiac dysfunction parameters (mainly in the absence of treatment), with more severe disease in men at similar ages. Initiation of enzyme replacement therapy at an early age (< 25 yo) led to absence of significant cardiovascular changes.

Conclusions: Fabry disease pts in Romania have important cardiovascular involvement, this being the diagnostic modality in 20.5% of cases. Most frequent cardiovascular abnormalities were LVH, LV longitudinal dysfunction with normal LVEF, indication for pacemaker implant. This data reflects the importance of expert centers for the diagnosis, cardiac evaluation and family screening.

P1213

Long-term follow-up after reconstructive surgery of hypertrophic cardiomyopathy with multi-level obstruction.

YF Yulia Frolova[1]

[1]Petrovsky National Russian Research Center of Surgery, Cardio Surgery of Heart Failure, Moscow, Russian Federation

Aim: To study morphofunctional changes of the heart, genetic testing, the indications and long-term results of surgical treatment of patients with hypertrophic cardiomyopathy (HCM) with multilevel obstruction.

Material and methods: : From 2009 to 2017 a total of 124 patients (pts) with HCM (63 women, 61 men) were analyzed. The mean age was $53 \pm 2,8$ years. 79 (64%) pts had III - IV FC NYHA (functional class, New York Heart Association). According to ECHO, there was found a significant increase of the thickness of interventricular septum (IVS) ($2,24 \pm 0,03$ sm,$p < 0.05$), increase of the gradient at left ventricle (LV) outflow tract (OP) ($71,5 \pm 6.9$ mm hg,$p < 0.05$) and unreliable decrease in end-systolic volume (ESVLV) ($31,3 \pm 2.6$ ml). According to MRI/MCT of the heart in 77pts there was registered increased volume of the anterior and posterior papillary muscles, to their dystopia with reduction of ESVLV and significantly increased myocardial mass of LV in diastole (311 ± 45gr;$p < 0.05$), which we determined as a diffuse-generalized form of HCM; in 22 pts - asymmetric form of HCM. 63 pts with the obstructive form of HCM underwent operation of the extended myectomy with parietal resection of the papillary muscles in conditions of open heart surgery (included 42 pts with replacement of the mitral valve), 5 - endovascular ablation of septal perforator, 27 - implantation of cardioverter defibrillator (ICD), 39 - conservative therapy.

Results: In pts after open heart surgery found a significant improvement in a 1, 3, 5 and 7 years after surgery: I FC (NYHA) - 34 (57%) patients, of FC II (NYHA) - in 25 (53%) patients. Triggering ICD was observed in 5 (19%) pts in the postoperative period. 4 patients (6,3%) died due to life-threatening arrhythmias. ECHO revealed a significant decrease in thickness of IVS (from 2.27 ± 0.02 to 1.5 ± 0.02 cm, $p < 0.05$) and the gradient at OPLV ($71,38 \pm 6.7$ to $4,75 \pm 1.3$ mm hg, $p < 0.05$), the false increase of ESVLV ($28,31 \pm 2.8$ ml to $34.4 \pm 2,9$ml $p>0.05$). Classic "sarcomeric" genetic mutations were surprisingly only found in 14% pts, in86% pts were found other genetic disorders.

Conclusion: Reconstructive extended myectomy with the parietal resection of papillary muscle and mitral valve replacement with chordal preservation provides several long-term benefits in pts with HCM. Many questions remain unanswered about the phenotype-genotype correlations and the prognostic value of particular mutations in different genes.

P1214

Cardiac amyloidosis: a five-year series

A Vigario[1]; M Cravo[1]; I Marques[1]; C Gomes[2]; C Mendonca[1]

[1]Hospital Center of Porto, Internal Medicine, Porto, Portugal; *[2]Hospital Center of Porto, Cardiology, Porto, Portugal*

On behalf of: GEstIC

Background: Amyloidosis is a group of systemic diseases of protein-folding disorders. Prognosis is determined both by type of amyloid and involved organs, in which the cardiac involvement carries the worst one. Achieving an early diagnosis is essential for a better outcome.

Purpose: This study aims to characterize a group of patients with diagnosed cardiac amyloidosis in a tertiary university hospital, to identify the timing of diagnosis and its impact on survival.

Methods: Retrospective observational study recruiting patients from January 2013 to December 2017. All patients with cardiac amyloidosis from our heart failure clinic were enrolled and also those admitted in the Cardiology, Internal Medicine or other wards with diagnosis of amyloidosis and heart failure (HF) stated in discharge summaries. Electronic medical records, procedures and other exams were reviewed. From a total of 29 patients, 10 were excluded because they didn't have imagiological or histological evidence of infiltrative myocardial disease.

Results: These 19 patients with diagnosed cardiac amyloidosis had moderate to severe left ventricular hypertrophy associated with: 1) cardiac Magnetic Resonance Imaging (MRI) reporting typical features of amyloidosis, 9 patients; 2) histologic evidence of amyloid deposition in noncardiac tissue, 12 patients; 3) 99mTc-DPD radionuclide cardiac uptake suggesting TTR amyloid deposition, 3 patients; and/or TTR genetic mutation, 1 patient. One patient refused MRI and tissue biopsy but had plasma cell dyscrasia with free light chain and serum monoclonal gammopathy IgG lambda.

The median age of patients at diagnosis was 71 years, with a ratio of male to female of 12:7. The median time from HF symptoms to diagnosis was 10 months. At diagnosis, New York Heart Association functional class II was the most common (n = 14; 73.7%), followed by class III (n = 3; 15.8%); median NT-ProBNP was 7115 pg/mL; and high sensitive troponin T was elevated in 14 (73.7%) patients. The median ventricular septum thickness was 18.5 mm.

Immunological studies showed plasma cell dyscrasia in 13 (68.4%) patients; tissue biopsy was performed in 15 (78.9%) patients, revealing amyloid deposition in 12 (63.2%), all AL amyloid type. Seven AL amyloid patients received treatment for their haematological disease. The global mortality rate was 68.4%; the AL amyloid patients' mortality was 75%. The median time from HF symptoms to death was 16 months and from diagnosis of cardiac amyloidosis to death was 5 months.

Conclusions: This five-year series reports 19 patients with cardiac amyloidosis, a single centre population with a rare and deadly disease, as described in the literature. Although it was not possible to obtain a histological diagnosis in all the cases, the clinical scenario and imaging results ensured the diagnosis. Establishing this

diagnosis can be challenging but awareness of the early manifestations is crucial to anticipate treatment and modify prognosis.

P1215

The hypertrophic cardiomyopathy - a particular cause of the heart failure with preserved ejection fraction

A Alicja Nowak[1]; Z Oko-Sarnowska[1]; M Kaluzna-Oleksy[1]; M Lesiak[1]
[1]*Poznan University of Medical Sciences, 1st Department of Cardiology, Poznan, Poland*

Introduction: Hypertrophic cardiomyopathy is a recognized, although a particular cause of the chronic heart failure with preserved ejection fraction. Elevated BNP level, as well as diastolic dysfunction occur in both: HFpEF and HCM, however most of the HCM-patients remain asymptomatic. The specific pattern of heart failure in this group require further studies.
Purpose: the aim of the study was to determine the relationships between BNP level and diastolic dysfunction in patients with HCM, according to NYHA functional classification degree.
Material and Methods: We evaluated 145 patients (49% men) diagnosed with HCM aged 19-82 years (mean 49,6 ± 15,9 years) with preserved ejection fraction (EF = 50%). 96 (67,6%) of patient were NYHA class I, 41 (28,3%) NYHA class II and 6 (4,1%) class III. Every patient underwent echocardiographic examination (2 D as well as TDI) with evaluation of left ventricular diastolic function (E/E'av). Additionally, plasma BNP levels were measured. We classified patients into two group according to the occurred HF symptoms (NYHA I vs NYHA II/III).
Results: The significant differences between two groups of patients in BNP levels (249,2 in NYHA II/III vs 151,0 in NYHA I, p = 0,004) were proved. However, 121 patients (83,4%) had BNP level = 35 pg/ml (including 78 (79,8%) of asymptomatic patients). Patients in NYHA II/III class had higher E/E'av ratio when compared to patients in NYHA I class (13,9 vs 9,8; p = 0,00008). Moreover, the correlation between BNP level and E/E'av ratio was proved ($p < 0,05$, r = 0,54) and was higher in NYHA II/III patients (r = 0,63 vs r = 0,44). The predictors of symptomatic HF in ROC curves analysis were: BNP = 245 pg/ml (45% sensibility, 85% specificity, AUC 0,66; p = 0,002) and E/E'av = 16,4 (34% sensibility, 93% specificity, AUC 0,68; p = 0,0006).
Conclusions: Patients with HCM characterize with high BNP levels and impaired diastolic function depending on heart failure functional degree (NYHA class). There are the correlations between BNP level and E/E'av ratio in patients with HCM (more significant in symptomatic patients).

P1216

Results and clinical consequences of endomyocardial biopsy diagnostics over 12 years in a tertiary center

M Noutsias[1]; SE Ludwig[2]; G Mall[3]; K Haentze[2]
[1]*University Clinic Halle (Saale), Mid-German Heart Center, Department of Internal Medicine III (KIM-III), Division of Cardiology, Halle, Germany*; [2]*University Hospital of Jena, Jena, Germany*; [3]*Darmstadt Clinic , Pathology, Darmstadt, Germany*

Background: Diagnostics of endomyocardial biopsies (EMB) is an important cornerstone for the management of cardiomyopathy patients. However, the value of EMB diagnostics in routine settings outside of clinical trials is not well defined.
Purpose: Analysis of consecutive EMB-diagnostics in adult cardiomyopathy patients and the clinical consequences over 12 years.
Results: Between 2004 and 2016, EMB procedures were performed in n = 463 cardiomyopathy patients (mean age: 49.3+13.2 years; males: 72%; LVEF: 33.3+14%) presenting with either dilated cardiomyopathy, clinically suspected myocarditis with left ventricular dilatation, or clinically myocardial storage disease at our tertiary center. Based on the Dallas criteria, myocarditis was confirmed by histology in n = 24 (5.2%) of the patients, whereas the positivity rate of immunohistological confirmation of inflammatory cardiomyopathy (DCMi) was significantly ($p < 0.01$) higher (n = 79/16.7%). All investigated infiltrate phenotypes (lymphocytes: CD3, CD4, CD8; Kp1 macrophages; HLA class II) were significantly associated with the immunohistological diagnosis of DCMi, and were statistically interrelated ($p < 0.01$). Viral genomes were detected by polymerase chain reaction (PCR) in 40% of the EMB, with parvovirus B19 (B19V) being the leading viral genome (89%). There was no statistical significance in the comparison of PCR proof of viral genomes and the histological or immunohistological proof of intramyocardial inflammation. A cardiac amyloidosis was confirmed by histological means in 4.4% of the EMB, and a Fabry's disease was diagnosed in one male patient. These histological diagnoses led to specific treatment strategies. However, no specific therapeutic consequences were drawn by the histological proof of myocarditis, the immunohistological proof of DCMi, and the PCR proof of viral genomes.
Conclusions: Our EMB data on 463 consecutive cardiomyopathy patients with impaired LVEF confirmed the higher sensitivity of immunohistological versus histological EMB diagnostics for the detection of intramyocardial inflammation, which however are both not statistically associated with the PCR proof of viral genomes. Specific therapeutic consequences of EMB diagnostics were, however, drawn from rare histological diagnoses (cardiac amyloidosis and Fabry's disease). Immunomodulatory treatment in DCMi with or without proof of viral genomes in the clinical routine setting needs still to be established.

P1217

The dilated phenotype in left ventricular non-compactation cardiomyopathy

N Craveiro[1]; H Antunes[2]; N Marques[3]; L Reis[4]; R Santos[5]; AR Almeida[6]; O Azevedo[7]
[1]*Hospital of Santarem, Cardiology, Santarem, Portugal*; [2]*Hospital Sao Teotonio, Viseu, Portugal*; [3]*Algarve Biomedical Center, Centro hospitalar do Algarve, Department of Cardiology, Faro, Portugal*; [4]*University Hospitals of Coimbra, Coimbra, Portugal*; [5]*Hospital Espirito Santo de Evora, Evora, Portugal*; [6]*Hospital Centre do Tamega e Sousa, Penafiel, Portugal*; [7]*Hospital Guimaraes, Department of Cardiology, Guimaraes, Portugal*

On behalf of: Sunshine

Introduction: Patients with left ventricular non-compaction cardiomyopathy (LVNC) have a higher prevalence of heart failure, ventricular arrhythmias and thromboembolic events leading to increased mortality and morbidity. The clinical presentation varies widely and it's often difficult to differentiate LVNC from other severe forms of hypertrophic or dilated cardiomyopathy.
Aim: To evaluate and characterize a population of patients with LVNC comparing the dilated phenotype with the non dilated.
Methods: Multicenter retrospective study involving 12 hospital centers including 119 patients diagnosed with LVNC. Two groups were formed: Group DL (n = 66; 55,5%) with a left ventricle end-diastolic diameter (LVED) >58mm (men) or >52mm (women), and a group NDL (n = 53; 44,5%) with LVED in the normal range. We evaluated demographic, clinical, electrocardiographic, echocardiographic, cardiac magnetic resonance imaging, and follow-up data.
Results: The patients of DL group were predominantly of the male gender (74,2%, $p < 0,001$) with less family history of LVNC (p = 0,013) and presented with more symptomatic (NYHA class III/IV p = 0,005) heart failure symptoms ($p < 0,001$), mainly dyspnea ($p < 0,04$). The echocardiogram showed depressed left ventricular function as assessed by ejection fraction (EF) ($p < 0,001$) and mitral S wave velocity (septal p = 0,005; lateral $p < 0,001$) as well as more diffuse wall motion abnormalities ($p < 0,003$) and more diastolic dysfunction (Diastolic E wave velocity (p = 0,017) with elevated left atrial volume (p = 0,07)). In this population cardiac MRI was consistent with a bigger (Mass p = 0,04) LV with reduced EF ($p < 0,001$) and with the presence of late gadolinium enhancement at the LV apex (p = 0,033) when compared with the NDL group. LBBB was more frequent as assessed by ECG (p = 0,01) as well as non-sustained ventricular tachycardia assessed by Holter (p = 0,05). There were no differences related to thromboembolic events or prognostic variables between groups.
Conclusion: LVNC patients with the dilated phenotype are a particular population: more symptomatic and with worst LV function, however, prognosis seems not be different when compared to LVNC patients with non-dilated left ventricle as assessed by LVED. More studies are needed for better stratification of LVNC patients.

P1218

The role of Left Bundle Branch in patients with dilated cardiomyopathy and mildly to moderately reduced Left Ventricular Function

P Gentile[1]; A Paldino[1]; A Cannata'[1]; G Barbati[1]; F Ramani[1]; E Fabris[1]; A Aleskova[1]; D Stolfo[1]; M Zecchin[1]; M Merlo[1]; G Sinagra[1]
[1]*University Hospital Riuniti, Cardiovascular Department, Trieste, Italy*

Background: Left bundle branch block (LBBB) is a known prognostic feature in heart failure (HF) patients with a reduced ejection fraction (EF). Little is known about the prognostic role of LBBB in the setting of dilated cardiomyopathy (DCM) presenting a mildly to moderate reduced EF under optimal medical treatment.
Purpose: To assess the prognostic role of LBBB in patients with DCM without severely reduced EF after adequate period of optimal medical treatment.
Methods: We analyzed all patients with DCM consecutively enrolled in the Trieste Heart Muscle Disease Registry with available 6 (3 to 9) months follow-up evaluation under optimal medical treatment. The primary study end-point was a composite of death/heart transplantation (D/HT). CRT implantation or EF worsening below 36% during follow-up was considered as secondary end-point.
Results: The study population included 348 DCM patients (46% of initially enrolled patients) that showed mild to moderate reduced EF (35% to 49%) after 6 months

of optimal medical therapy. LBBB was present in 75 (22%) of them and it did not significantly correlate with worse long-term D/HT rates. During a mean follow-up of 177 months, 52 out of 75 (72%) patients experienced CRT implantation or LVEF worsening. At multivariate analysis moderate-severe mitral regurgitation (MR) [hazard ratio (HR) 1.228; 95% confidence interval (CI) 1.038-1.454, p= 0.017] and indexed left atrium atrial [HR 3.117; 95% CI 1.097-8.859, p= 0.01] emerged as independent predictors of secondary end-point.
Conclusions: LBBB did not emerge as a prognostic predictor in DCM patients with no-severely reduced EF after an adequate period of optimal medical therapy. However CRT could be considered in this setting of patients in case of persistence of moderate-severe MR and dilated left atrium.

P1219
Anemia and gender characteristics of DCM patients with decompensated CHF

I A Igor Tsoy[1]; TA Abdullaev[1]
[1]Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

The aim: To detect the incidence of anemia in pts with decompensated CHF due to DCM, depending on gender characteristics
Material and Methods: We performed the analysis of 300 pts data with DCM (42.1 ± 18,6 years), admitted to the hospital due to decompensation of HF. DCM pts with different degrees of anemia (with a hemoglobin level below 13 g / dL for men and < 12 g / dL for women) were evaluated for clinical data, 6MWT, and EchoCG. The arithmetic mean and standard deviation (M ± d) were calculated. In order to identify the relationship between different indicators, the method of linear regression and correlation was used.
Results: The analysis showed that among pts with DCM, anemia of varying degrees was detected in 15.3% of pts (28 women and 18 men), with an average Hb level of 11.15 ± 1.6 g / dl. The correlation analysis revealed a reliable inverse relationship between the level of Hb and 6MWT, which was 205 ± 48.4 m (r = -0.3438; p = 0.05). The study of cardiac function showed that the mean LVEF of pts with anemia was 34.97 ± 12.7% also had an indirect correlation with the severity of anemia (r = -0.37, p = 0.03). The mean values of EDD and ESD without having a reliable association with the level of hemoglobin (r = -0.1443, p = 0.4), respectively, were 71.2 ± 15mm and 58.5 ± 11mm.The study of gender characteristics showed that anemia in women with DCM was more pronounced (hemoglobin deficiency was 15%), compared to men (11% deficiency). However representatives of the male were characterized by lower values of LVEF (30.65 ± 12.2 vs. 40.4 ± 8.9, p = 0.04), with prevalence of EDD values (77.4 ± 2.5 versus 64.53 ± 4.3, p = 0.04) and ESD (61.5 ± 13 versus 51.33 ± 7.26, p = 0.05).
Thus, anemia of varying severity was found in almost 1/5 of DCM pts. It is noted that anemia is more common in female pts, however, in men such association is accompanied by a greater LV dilatation and worse contractility

P1220
Aetiology-driven diagnoses based on endomyocardial-biopsy results in a large cohort of 3072 consecutive patients with unexplained heart failure

F Felicitas Escher[1]; DL Lassner[2]; UK Kuehl[1]; BP Pieske[1]; HP Schultheiss[2]
[1]Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; *[2]Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany*

Background: The diagnosis of unexplained heart failure is challenging. The current expert consensus statement of the European Society of Cardiology (ESC) maintains that endomyocardial biopsies (EMBs) remain the gold standard for definitive diagnosis of unexplained heart muscle diseases. However, EMB is used infrequently, although histology, immunohistochemical, and molecularbiological analysis of EMB is a prerequisite to make an etiology-driven diagnosis with the aim to identify those patients in whom specific therapy would be appropriate.
Methods and results: We enrolled n = 3072 consecutive patients with unexplained heart failure (2034 men/ 788 women, mean age 51.44 ± 16.04 years) from January 2014 to March 2017, who underwent EMB. The suspected diagnosis had been made by clinicians. EMBs were send to a FDA-proved laboratory (Institute for Cardiac Diagnostic and Therapy Berlin, Germany). Analysis included histology, immunohistochemistry, molecular virology, and gene profiling.
In n = 810 patients the suspected diagnosis was acute myocarditis, in 1772 patients myocarditis or inflammatory/dilated cardiomyopathy was suspected. In n = 240 patients a storage disorder was suspected.
Based on EMB-results in 58.9% (n = 1664 patients) a specific heart muscle disease could be diagnosed.
In particular, Coxsackie-Adenovirus genomes were present in n = 44, Ebstein-Barr-Virus in n = 77, Human-herpesvirus 6 (HHV6) in n = 426 (including 21 patients with chromosomal integrated (ci) HHV6), and erythrovirus with active viral replication (positive mRNA) in n = 649 patients.
Virus-negative intramyocardial inflammation was present in n = 810 patients, including a histologically-proven active myocarditis in n = 64. Histological proof of giant cells was present in n = 20 patients. However, in n = 133 patients idiopathic giant cell myocarditis or eosinophilic myocarditis was diagnosed by analysis of myocardial gene expression profile. 116 patients showed evidence of cardiac storage disease.
Conclusions: Based on EMB-results in 58.9% of this large cohort of patients a specific heart muscle disease could be diagnosed. These aetiology-driven diagnoses implicate a specific, causal therapy.
Our data clearly show the necessity of an EMB-based diagnosis, which has a direct clinical consequence regarding a specific therapy in a notable high percentage of patients with unexplained heart failure.

P1221
The effectiveness of bromocriptine in the therapy of patients with chronic heart failure (CHF) due to peripartal cardiomyopathy

ST Mirzarakhimova[1]; TA Abdullaev[1]; I A Igor Tsoy[1]; RSH Bekbulatova[1]
[1]Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

Aim: To study the effectiveness of additive therapy with bromocriptine on the clinical and functional indices of pts with peripartal dilated cardiomyopathy (PDCM) against the background of basic treatment following the results of 1 month observation.
Materials and methods. Included 60 pts aged from 20 to 41 (an average 28,2 ± 0,8 years). The pts was divided into grs: I included pts with clinical symptomatology of CHF, who were on therapy (n = 31). In addition to standard therapy, II gr received bromocriptine (n = 29). Clinical and functional status was assessed using ECG, Echo-CG, a 6-minute walk test (6MWT). The duration of the observation was 1 month. Initially and after 1 month of observation, the concentration of prolactin and testosterone in the blood was determined.
Results: All grs were equivalent: 6MWT-155.56 ± 62.61 and 147.12 ± 82.5 m, EDD-7.12 ± 0.1 and 6.9 ± 2.3 cm, LA -3.95 ± 3.1 and 40.1 ± 2.6 cm, EF-32 ± 9.1 and 34.9 ± 12.3, the RV - 3.82 ± 4.6 cm and 3.62 ± 5.78, prolactin concentration158.4 ± 7.4 mkg / ml and 160.4 ± 4.4 mkg / ml and testosterone 7.7 ± 1.05mIU / l and 7 , 4 ± 2.05mIU / l in the I and II grs, respectively.
During the observation period, a decrease in the level of prolactin and testosterone in the bromocriptine application gr was observed up to 76.4 ± 7.4 mkg / ml and prolactin-up to 3.7 ± 2.05 mIU / l, p < 0.05. In gr 1, the decrease in both indicators was unreliable. The functional status in the dynamics has significantly improved, however, without significant differences between the grs: CAS - 2,3 ± 1,1 and 2,4 ± 1,6 points. SMWT-247.3 ± 79.1 and 241.3 ± 83.4 meters (p> 0.05).
The parameters of intracardiac hemodynamics endured the following changes: mean LV ejection fraction (EF) increased significantly in grs 1 ± 2 and 2 grs 38 ± 6.1% and 39 ± 9.6% (? < 0.05), which was accompanied by a decrease in cardiac dilatation , moreover, more pronounced in gr 2; a decrease in the CBD to 6.9.12 ± 5.1 and 6.3 ± 5.3 cm, respectively (p < 0.05). On the right ventricle side, there was also a greater regression in gr 2, up to 3.2 ± 4.1 cm, (in gr 1, 3.4 ± 6.6, respectively (p> 0.05)).
Conclusion: The addition of bromocriptine in women with PDCM to the standard therapy of CHF, improves the clinical status and stabilizes hemodynamic parameters.

P1222
Clinical forms of arrhythmogenic right ventricular dysplasia/cardiomyopathy with high risk of sudden cardiac death and chronic heart failure: factors of progression and prognosis.

Y A Yulia Alexandrovna Lutokhina[1]; O V Blagova[1]; A V Nedostup[1]; S A Alexandrova[2]; E A Mershina[3]; A G Shestak[4]; E V Zaklyazminskaya[4]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; *[2]Bakoulev Center for Cardiovascular Surgery RAMS, Moscow, Russian Federation*; *[3]Roszdrav Medical Rehabilitation Center, Moscow, Russian Federation*; *[4]Russian Research Center of Surgery, Petrovsky, Moscow, Russian Federation*

Purpose: to distinguish the clinical forms of ARVD with a high risk of sudden cardiac death/ chronic heart failure (CHF) and to identify the predictors of adverse events (AE).
Methods: 50 patients (38.1 ± 14.6 y; 20 males) with ARVD according to Revised Task Force Criteria 2010 were evaluated (26 patients with definite, 13 - with borderline, 11 with possible diagnosis). Follow-up period: 13.5 [4; 34] months. All patients underwent ECG, 24h-Holter monitoring, echocardiography, blood tests for detection of anti-heart antibodies and DNA of viruses. Also were performed DNA-diagnostic

(n = 46, detected mutations were reaffirmed by Sanger sequencing), cardiac MRI (n = 44), signal-averaged ECG (n = 16), morphological study of the myocardium (endomyocardial biopsy - 2; autopsy - 2).
Results: According to the features of clinical course of ARVD, we identified 4 clinical forms of the disease. I. Latent arrhythmic form (n = 25) - frequent premature ventricular contractions and/or nonsustained ventricular tachycardia (VT) in the absence of sustained VT (SVT) and syncope. II. Manifested arrhythmic form (n = 10) - SVT /ventricular fibrillation (VF). III. ARVD with progressive chronic heart failure (CHF) as the main manifestation of the disease (n = 8). IV. Combination of ARVD with left ventricular (LV) noncompaction (n = 7). Mutations were identified in 13 patients in the following genes: PKP2, DSG2, DSP, DES, TMEM43, FLNC, SCN5A, MYH7, MYBPC3. Associated myocarditis was diagnosed in 35 (70%) patients (viral in 7). The presence of mutations and myocarditis did not significantly affected outcomes. AE (death, syncope, appropriate ICD therapy, SVT, VF) occurred in 16.7%, 100%, 62.5% and 57.1% of patients in the I, II, III and IV forms, respectively. Determinants of AE were ?HF (odds ratio (OR) 4,3 [1.3-14.8], p = 0.014), atrial fibrillation (AF, OR 11.7 [1.3-104.3], p = 0.01), tricuspid regurgitation (TR, OR 6.3 [1.6-24.4], p = 0.01), mid right ventricle diameter (RVD2) = 2.3 cm (OR 23.8 [2.7-210], p <0.001). Cardiac death was associated with LVEF <35% (OR 623 [10.7-36658.2], p <0.001), CHF, NYHA class = 3 (OR 623 [10.7-36658.2], p = 0.001), severe TR (OR 67.7 [3-1536.7], p = 0.002), complete right bundle branch block (RBBB, OR 26.7 [1.8-387.2], p = 0.028). Appropriate ICD therapy was predicted by syncope (OR 45 [1.5-1364], p = 0.01), male sex (OR 24.2 [0.93-632], p = 0.027), low QRS voltage (OR 24.2 [0.93-632], p = 0.027), CHF (OR 21 [0.8-566.4], p = 0.045), TR (OR 21 [0.8-566.4], p = 0.045), RVD2 = 2.85 cm (OR 33 [1.06-1028.1], p = 0.024). Development of CHF was associated with low QRS voltage (OR 6.5 [1.6-27], p = 0.009), AF (OR 16.9 [1.9-153.3], p = 0.004), 1-st degree AV block (OR 7.8 [1.3-48.5], p = 0.027) and disease duration = 5,5 years (OR 10.6 [2.6-43.7], p = 0.001).
Conclusions: the highest risk of AE was observed in patients with manifested arrhythmic form and with progressive CHF. AE in ARVD patients were associated with RV enlargement, the development of CHF, complete RBBB block, AF and low QRS voltage.

P1223
Clinical profile and prognosis of senile cardiac amyloidosis

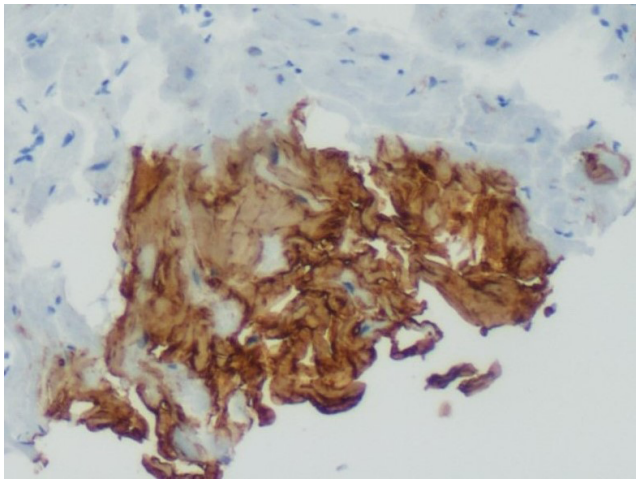
M Margarida Oliveira[1]; O Azevedo[1]; B Faria[1]; P Von Hafe[1]; G Dias[1]; M Lourenco[1]; A Lourenco[1]
[1]*Alto Ave Hospital Center, Guimaraes, Portugal*

Introduction: Cardiac amyloidosis has different clinical profile, evolution and prognosis depending on the type of amyloidosis. Senile amyloidosis is frequently underdiagnosed mainly because it affects people in advanced age and it has limited systemic involvement. The development of new therapeutic option for amyloidosis patients with wild type transtirretin deposition makes it very important to improve our knowledge about the natural history of this disease.
Aim: Describe clinical profile and prognosis of patients with senile cardiac amyloidosis.
Methods: We included all patients with clinical diagnosis of senile cardiac amyloidosis and performed a retrospective analysis of clinical, scintigraphy, electro and echocardiographic variables.
Results: We included 23 patients (18 men and 5 women). Age at diagnosis was 83 years old (SD = 3,93). 53% of patients were referred from general doctors because of left ventricular hypertrophy finding in transthoracic eco and the rest of the patients were referred after being admitted at cardiology award for decompensated heart failure (21,7%), rapid atrial fibrillation (21,7%) and complete atrioventricular block (4,3%). At the time of diagnosis, 17,4% of patients were asymptomatic, and in the symptomatic group, 73,9% of patients complain about effort dyspnoea. 26,1% have atrial fibrillation at diagnosis and 34,8% had previous diagnosis of tunnel carpal syndrome. 48,8% of patients had depressed left ventricular ejection fraction, from mild to severely depressed. Every patient had some grade of diastolic dysfunction, mostly (56%) grade II. Left ventricular mass was 314,49g (SD = 69,43) e de 178,60g/m2 (SD = 41,88). We performed cardiac scintigraphy Tc99m-DPD suggesting transthyretin amyloidosis in every patient.
Mean follow-up was 34,5 months (SD = 32,95). Incidence of complication in follow-up period was 74%: 21,7% developed atrial fibrillation, 65,2% heart failure, 21,7% needed a pacemaker implantation and 4,3% had a stroke. Number of admissions because of decompensated heart failure was 1,26 (DP = 2,00) with an annual rate of 0,8 admissions/year (DP= 1,35). Mortality was 34,8% with an annual rate of 11,9% mainly due to infection (85.7%) and occurred about 14 months (DP = 9,99) after diagnosis.
Conclusion: Cardiac amyloidosis has high mortality and complication rate. In senile amyloidosis, due to advanced age and lack of therapeutic options, mortality is reported between 70% in older studies and 40% in more recent ones. In our study mortality was a little lower - 35%. It should also be noticed that the most frequent cause of dead was infection, which was expected regarding age, comorbidity and fragility of this patients.

P1224
TTR-amyloidosis. Not so rare as we thought?

R Renata Aiglova[1]; M Taborsky[1]; M Lazarova[1]; L Pavlu[1]; P Flodrova[2]; P Flodr[2]
[1]*University Hospital Olomouc, Department of Internal Medicine I - Cardiology, Olomouc, Czech Republic*; [2]*Palacky University, Faculty of Medicine and Dentistry, Department of Clinical and Molecular Pathology, Olomouc, Czech Republic*

Introduction: Amyloidosis is a rare systemic disease caused by build-up of amyloid deposits within the tissues. For TTR amyloidosis are typical deposits of wild-type transthyretin. This disease is described in people aged over 70 years, more often in men. Restrictive cardiomyopathy and carpal tunnel syndrome are included to the clinical picture of TTR-amyloidosis.
Purpose: To improve, that cardiac TTR-amyloidosis is in our population more common, than we thought. To assess the significance of endomyocardial biopsy in differential diagnosis of amyloidosis.



TTR-amyloidosis
Methods: Patients with recently diagnosed restrictive filling failure, who were examined in years 2016-2017 in our University Hospital. Within the differential diagnosis endomyocardial biopsy and cardiac MRI are usually performed. All patients with confirmed diagnosis of TTR-amyloidosis are referred to haematologist.
Results: For suspicion of TTR-amyloidosis were in years 2016-2017 in our University Hospital examined 10 patients. All patients underwent endomyocardial biopsy. Cardiac MRI couldn't be performed by 1 patient with MRI-incompatible pacemaker. TTR-amyloidosis (Fig. 1) was immunohistochemically confirmed in 5 patients - 3 men, 2 women. Mean age of our patients was 79,6 years. AL-amyloidosis was immunohistochemically confirmed in 2 patients, both were men, mean age 55,4 years.
Conclusion: TTR-amyloidosis is described as rare disease. It is a relatively common, but very poorly diagnosed disease. Golden standard in differential diagnosis is endomyocardial biopsy with following immunohistochemically examination. In these patients is very important to provide multidisciplinary care with cooperation of cardiologist and haematologist.

P1225
Added value of genetics on top of clinics in predicting treatability of dilated cardiomyopathy patients

J A J Job Antonius Jozef Verdonschot[1]; MR Hazebroek[1]; S Sanders - Van Wijk[1]; JJ Merken[1]; YA Adriaansen[2]; A Van Den Wijngaard[2]; IPC Krapels[2]; HP Brunner-La Rocca[1]; HG Brunner-La Rocca[2]; SRB Heymans[1]
[1]*Cardiovascular Research Institute Maastricht (CARIM), Cardiology, Maastricht, Netherlands*; [2]*Maastricht University Medical Centre (MUMC), Clinical Genetics, Maastricht, Netherlands*

Background/Introduction: Predicting improvement of left ventricular (LV) function (reverse remodeling (LVRR)) in patients with dilated cardiomyopathy (DCM) remains

difficult. The added value of gene mutations on top of clinical parameters for predicting LVRR remains largely unknown.
Purpose: To determine if adding mutation status to clinical parameters improves prediction of LVRR in DCM patients.
Methods. DCM patients (n = 346; mean ejection fraction (LVEF) 30%) underwent genotyping for 47 DCM-associated genes on top of extensive phenotyping. LVRR was defined as improvement of LVEF >50% or = 10% increase, with cardiac dimensions (LV end-diastolic diameter) £33mm/m2 or = 10% decrease. After testing the predictive value of clinical variables for LVRR in univariable and multivariable logistic regression, the added value of gene mutations was tested for discrimination, calibration, and reclassification.
Results: LVRR occurred in 180 (52%) patients after a median follow-up of 12 months upon conventional treatment. LVEF, familial DCM, female gender, AV-block and treatment with beta-blockers or ACE-I/ARB, were independent clinical predictors of LVRR. Genetic mutations –with exclusion of TTN mutation- were strongly associated with a lower rate of LVRR (OR: 0.22 [0.10 to 0.47]; p < 0.001). Addition of specific gene mutations such as TTN and miscellaneous gene mutations (eg. PLN, RBM20) to the clinical prediction model was significantly associated to LVRR (OR: 3.06 [1.27-6.62]; p = 0.01 and OR: 0.1 [0.01-0.85]; p = 0.04 respectively). Adding mutation status significantly improved calibration and reclassification of the clinical model predicting LVRR (IDI 8.2% and NRI 48%, both p < 0.001), with a trend for improved discrimination (C-statistic: 0.69 versus 0.75, p = 0.059).
Conclusions: Addition of mutation status to clinical parameters in DCM improves patient stratification in terms of LVRR.

Functional class and prognosis in advanced pulmonary arterial hypertension

A Lescano[1]; A Ferro[1]; E Barimboim[1]; ML Coronel[1]; D Garcia Brasca[1]; C Huerta[1]; C Stepffer[1]; G Svetliza[1]; L Lobo Marquez[1]; C Manfredi[1]; M Villar[1]; N Naval[1]; M Diez[1]; D Echazarreta[1]; ER Perna[1]
[1]Finochietto Clinic, Buenos Aires, Argentina

Introduction: Pulmonary arterial hypertension (PAH) is a multifactorial disease associated with high morbidity and mortality. However, the diagnosis and therapeutics strategies used in most of the Argentinean regions are poorly known. The advanced functional class (FC) is an indicator of poor prognosis and one of the therapeutic goals.
Aims: 1-To determine the impact of advanced FC in patients with PAH on established markers of poor
prognosis, such as clinical, biomarker, hemodynamic, and echocardiographic parameter 2-To compare treatment strategies between an advanced and non advanced FC
Method: Between July 2014 and May 2015, 322 patients with confirmed PAH were prospectively included in a multicenter, collaborative, observational registry by 62 investigators from 22 provinces in Argentina. Inclusion criteria were as follows: 1-patients over three months of age; 2- mean pulmonary arterial pressure (mPAP) at rest = 25 mmHg by right heart catheterization (RHC) and 3-clinical stability in the absence of hospitalization in last month. WHO FC III or IV at diagnosis was defined as advanced (AFC) whereas WHO FC I or II were considered as non advanced (NAFC)
Results: Mean age was 47 years (SD 17) and 77% were female. According with the Nice classification, the distribution was: idiopathic 51.6%, inherited 1,6%, drugs 2.4%, connective tissue disease 15.3%, portal hypertension 1.6% and congenital heart disease 27.4%. WHO FC at initial diagnosis was: I: 3%; II: 27%; III: 43% and IV: 22% and during followup was: I: 19%, II 54%, III 22% and IV 6% (p < 0.001). AFC at initial diagnosis was 65% and during follow up 28% (p < 0.001). Clinical manifestations in AFC compared with NAFC was: syncope 11 vs 13% (NS); heart failure 55 vs 38% (p < 0.001); BNP 552 vs 158 pg/ml (0.02), NtproBNP 1918 vs 668 pg/ml (0.01), TAPSE 17 vs 18.8 mm (0.01), pericardial effusion 18 vs 10% (p = 0.020); 6MWT 367 vs 373 (NS); CI 2.6 vs 2.9 (0.03); RAP 11 vs 12 mm Hg (NS);. PAH targeted drugs in AFC was = None in 11%, monotherapy in 29.7% and combined therapy in 67%.
Conclusion: In our registry of PAH, we observed a high percentage of patients with AFC (65 %) at initial diagnosis and a significant decrease during followup (28%). Advanced FC at initial diagnosis was significantly associated with other variables of poor prognosis and combined therapy in 67%. These findings emphasize the need for strategies for early detection and therapy.

P1228
The prognostic role of right ventricular dysfunction decreases with an increase in pulmonary hypertension

J Julija Bugaite[1]; D Gabartaite[1]; E Paleviciute[2]; K Cerlinskaite[2]; R Norvilaite[3]; D Verikas[3]; G Ziubryte[3]; G Balciunaite[2]; A Krivickiene[3]; J Motiejunaite[3]; D Zaliaduonyte-Peksiene[3]; D Zakarkaite[2]; A Mebazaa[4]; A Kavoliuniene[3]; J Celutkiene[2]

Introduction: Right ventricular dysfunction (RVD) alone or together with pulmonary hypertension (PH) is associated with severity of symptoms and poor prognosis.
Objective: To evaluate the prognostic significance of right ventricular function assessed by echocardiography at follow up of 3 months and 1 year for rehospitalizations (RH) and mortality in patients with acute dyspnea depending on the level of PH.
Design and Methods: 1482 acutely dyspneic patients were prospectively enrolled in the observational cohort study in two university hospitals. Echocardiography was performed during the first 48 hours after admission. The RVD was defined by reduced FAC < 35%, TAPSE < 1.7 cm and RV S' < 9.5 cm/s. Patients were distributed in 2 groups - PASP < 40 (no and mild PH) and = 40 mmHg (moderate and severe PH). Hazard ratio was adjusted to gender, age and left ventricular ejection fraction.
Results: Of 482 (32.5%) examined patients (mean age 68.6 ± 12.9 years) 193 (40.0%) were female. Mean PASP was 46.54 ± 16.19 mmHg. Right ventricular

P1228 Table.1

	PASP <40mmHg	PASP≥40mmHg		
Outcomes	Hazard ratio	Confidence interval	Hazard ratio	Confidence interval
Cardiac deaths in 3-months	3.19*	1.01;10.04	1.41	0.57;3.5
Cardiac deaths in 3 months (adjusted)	4.1*	1.02;16.45	1.14	0.42;3.12
Deaths due to all causes in 3-months	1.4	0.62;3.2	1.51	0.72;3.21
Cardiac RH in 3-months	1.15	0.63;2.09	1.32	0.63;2.77
RH due to all causes in 3-months	1.35	0.76;2.41	1.05	0.58;1.9

Severe pulmonary hypertension during pregnancy: a specialist center experience

E Karelkina[1]; O Irtyuga[1]; Y Kokonina[2]; O Li[2]; A Yakubov[3]; V Mazurok[3]; I Zazerskaya[2]; A Bautin[3]; O Moiseeva[1]
[1]Almazov National Medical Research Centre, Department of Noncoronary Diseases, Saint Petersburg, Russian Federation; *[2]Almazov National Medical Research Centre, Perinatal Centre, Saint Petersburg, Russian Federation*; *[3]Almazov National Medical Research Centre, Department of Anesthesiology, Saint Petersburg, Russian Federation*

Background: Pulmonary hypertension (PH) in pregnancy is associated with a high mortality rates (30-50%) with most of the deaths occurring in the 3rd trimester and within the first 10 postdelivery days. Despite risks, patients may actively plan pregnancy. Patients may also present whilst pregnant with previously undiagnosed PH.
Methods: We report the outcomes of 18 pregnancy in women with PH associated with congenital heart disease at a specialist center between 2010 and 2017. The criteria for inclusion were the presence of CHD and pulmonary artery systolic pressure more than 60 mm Hg. Two women were after cardiac surgery. In 12 of 18 cases (66,7%) patients developed Eisenmenger syndrome.
Results: 18 pregnancies in 18 women resulted in 16 live births, 1 miscarriages and 1 terminations (range 90 - 134 days gestation). All patients were supervised by a multi-professional team. Sixteen deliveries were by Caesarean section with 1 vaginal delivery and planned between 28 to 34 weeks. Patients underwent epidural or combined spinal/epidural regional anaesthesia and were monitored peri-delivery in an intensive care environment with arterial and central venous access. In all patients after delivery had decompensation of the state with the increase of pulmonary hypertension, progression of right ventricular failure, an increase in shunting from right to left. In 4 cases, a transfer to mechanical ventilation was required, intensive therapy included a combined use of vasodilators, the use of inotropes, the prevention of thromboembolic complications. Of 18 pregnancies, 3 women died within 6 months of delivery (9, 14 and 15 days post-delivery) and none during pregnancy (16,7%). Mortality in the subgroup of Eisenmenger syndrome was 25% (3/12). 15 (83,3%) children were discharged from the hospital in a satisfactory condition.
Conclusion: Mortality of PH in pregnancy in a setting of experienced and coordinated care is less than historical series but remains significant. Counselling women with PH of these risks remains an essential part of disease management. In the event of pregnancy, patients should be managed by a multiprofessional team.

P1230

Potential role of Interleukin-18 in Pulmonary Arterial Hypertension in Systemic Sclerosis Patients

Y Yoshiyuki Orihara[1]; M Asakura[1]; A Eguchi[1]; T Ando[1]; Y Okuhara[1]; M Ishihara[1]; T Masuyama[1]
[1]Hyogo College of Medicine, Cardiovascular Division, Nishinomiya, Japan

Background: Systemic sclerosis (SSc) is a clinically heterogeneous disorder affecting the connective tissue of the skin, the wall of blood vessels, and internal organs such as the gastrointestinal tract, lungs, heart, and kidneys. SSc can develop pulmonary arterial hypertension (PAH) caused by fibrosis of pulmonary arteries. Three-year survival for SSc patients with PAH has been estimated to be 56% compared with 94% in those without PAH. Early detection of PAH in SSc patients is important for improvement in prognosis. However, there exists no useful biomarker for detecting PAH in SSc patients. Previous study reported the association of endothelin-1 (ET-1) with the development of PAH. Moreover, we revealed that the disruption of murine interleukin-18 (IL-18) gene suppressed PAH induced by hypoxia. These results suggest that ET-1 and IL-18 are potential biomarkers for early detection of PAH in SSc patients.
Purpose: The purpose of this study was to examine roles of IL-18 and ET-1 for PAH in SSc patients.
Methods: Twenty SSc patients who visited our hospital between January 2014 and June 2016 and presented tricuspid regurgitation jet velocity = 2.5 m/s were enrolled in this single-center retrospective observational study. We performed right heart catheterizations (RHC) and measured the serum levels of IL-18 and ET-1 as well as periostin as a marker of fibrosis. One patient who had WHO-FC IV and one patient with >20 mmHg of pulmonary artery wedge pressure were excluded. Finally 18 patients were assessed in this study.
Results: Mean age was 65.1 years old and 16 patients were female. Echocardiographical data showed that mean left ventricular ejection fraction was 69.9 % and mean tricupcid regurgitation (TR) velocity was 2.81 m/s. RHC showed average mean pulmonary artery pressure (PAP) and pulmonary vascular resistance index (PVRI) were 24.0 mmHg and 4.6 wood, respectively. Mean serum levels of IL-18, ET-1 and periostin were 288.4 pg/ml, 2.27 pg/ml, and 864 pg/ml, respectively. TR velocity was correlated with neither PAP nor PVRI (mPAP; R = 0.343, p = 0.178, PVRI; R = 0.327, p = 0.200). Whereas, both of IL-18 and ET-1 levels showed significant correlations with PVRI (IL-18; R = 0.674, p = 0.002, ET-1; R = 0.639, p = 0.004). ROC analysis to predict PVRI = 3 wood units showed that area under the curve (AUC) of IL-18 was higher than AUC of ET-1. (IL-18; 0.802, ET-1; 0.778). Moreover, we found a significant association between IL-18 and periostin (R = 0.498, p = 0.042). It is a possible mechanism that the elevation of IL-18 may induce expression of periostin resulting in the fibrosis of pulmonary arteries in SSc patients.
Conclusion: We revealed that both serum levels of IL-18 and ET-1 were significantly associated with the elevation of PVRI in SSc patients. IL-18 and ET-1 are potential biomarkers for early detection of PAH in SSc patients.

On behalf of: RECOPILAR

Pulmonary arterial hypertension (PAH) has been poorly characterized in Latin America. The aim of this report was to describe the clinical-epidemiological profile and management of PAH in Argentina.
Method: From Jul-14 to Oct-16, 399 incident and prevalent patients with PAH were prospectively included by 62 investigators from 22 provinces of Argentina in a collaborative registry involving 5 societies of different specialties: cardiologist, rheumatologist, pulmonologist and pediatricians. Patients must fullfill all the following inclusion criteria: 1-Age over three months; 2 - mean pulmonary arterial pressure (mPAP) at rest = 25 mmHg by right heart catheterization (RHC) and 3 - clinical stability in the absence of hospitalization in last month.
Results: Mean age was 47 ± 18 years and 79% were women. They were classified as idiopathic 160 (40.1%), heritable 5 (1,3%), drugs 2 (0.5%), connective tissue disease 95 (23.8%); portal hypertension 16 (4%); HIV 20 (5%) and congenital heart disease 101 (25.3%) and 49.4% were incident cases. RHC showed systolic/diastolic/mean PAP: 82 ± 25/36 ± 15/52 ± 17 mmHg; with pulmonary vascular resistance 9.9 ± 6.1 WU, right atrial pressure 12 ± 11 mmHg and cardiac index 2.8 ± 1 l/min/m2. Pulmonary vasorreactivity test was performed in 305 patients (76.4%) and was positive in 12.7%. 21). Baseline WHO functional class was I: 4.3%; II: 30.7%; III: 48.4% and IV: 16.5%; 27% have been previously hospitalized, half of them due to heart failure. Non specific treatment included diuretics 47%; aldosterone antagonists 43%; digoxin 18%; anticoagulants 37%, calcium channel blockers 11%; and specific therapy included prostanoids 14.3% , half of them subcutaneous; phosphodiesterase-5 inhibitors 70.7%, endothelin receptor antagonists 54.4%. Prescription of none, one

o combined specific drugs was used in 19.5, 30.1 and 50.4%. The follow up was obtained in 65% of cases, and the survival at 1, 2 and 3 years was 92, 82 and 74%.
Conclusion: The contemporary population with PAH in Argentina is comparable to other series: late diagnosis and severe profile. There was a high use of specific drugs, with combined therapy in two thirds, according with recommendation of guidelines. These results demonstrated the crucial role of specialist in the management of PAH in developing countries.

P1232
In patients with Pulmonary Hypertension, does the podometria provide anything?

V Gregorietti[1]; MF Acosta[1]; R Coronel[1]; M Muzzio[1]; PA Fernnadez[2]
[1]Sanatorio Sagrado Corazon, Cardiologia, Buenos Aires, Argentina; *[2]Hospital El Cruce, Trasplante Cardiaco, Hipertension Pulmonar, Florencio Varela, Buenos Aires, Argentina*

Objective: To assess the relationship of the steps taken during the 6-minute walk test with other parameters obtained from it and clinical parameters of prognosis and evolution.
Material and Methods: We prospectively analyzed 318 walk test studies of 6 minutes, which were performed consecutively to 318 patients
carriers of pulmonary hypertension of various etiologies according to the NICE 2013 classification.
From March / 2016 to December / 2017.
They were used:
• Pulse Saturometer, for oximetry and heart rate control,
• Sphygmomanometer for baseline blood pressure control and at the end of the study.
• Digital pedometer
• Borg scale.
• Clinical history of the patient
• Routine Laboratory, with dosing of ProBNP.
The statistical analysis was carried out through the Epi.info program
Results: Data were obtained from 318 studies in 318 patients with pulmonary hypertension, 56% of the population corresponds to the female sex.
The average age of the population is 51 ± 17 years.
The average distance traveled was 340 meters (range = 510-40), the number of steps was 526 (range = 1150-47)
The mean BNP pro levels were 270 pg / ml (14-1110).
The proBNP correlation was analyzed with the number of steps and the distance traveled, Functional Class at the time of the study, and statistical significance was observed between the proBNP levels and the number of steps walked (p: 0.001) and the functional Class at the time of the study (p: 0.003).
Conclusions: The number of steps taken in the 6-minute walk test is correlated with clinical and laboratory parameters, which make the prognosis of patients with pulmonary hypertension.
The control of the number of steps with a simple pedometer during the performance of the walk test of 6 minutes adds a useful data for the evaluation and monitoring of patients with pulmonary hypertension.

Idarucizumab for urgent dabigatran reversal at the heart transplantation surgery. Multicenter experience from Spain

M G Maria G Crespo-Leiro[1]; F Carrasco-Avalos[2]; S Mirabet-Perez[3]; T Blasco-Peiro[4]; D Rangel-Sousa[5]; F Gonzalez-Vilchez[6]; E Barge-Caballero[1]; A Lopez-Granados[2]; E Roig[3]; A Portoles-Ocampo[4]; A Grande-Trillo[5]; JA Vazquez-De-Prada[6]; V Brossa[3]; JM Arizon-Del-Prado[2]
[1]Hospital Universitario A Coruña, La Coruña, Spain; *[2]University Hospital Reina Sofia, Cordoba, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*; *[4]University Hospital Miguel Servet, Zaragoza, Spain*; *[5]University Hospital of Virgen del Rocio, Seville, Spain*; *[6]University Hospital Marques de Valdecilla, Santander, Spain*

Anticoagulation in heart transplant (HT) recipients increases the risk of serious hemorrhagic complications during the perioperative period therefore urgent anticoagulation reversion is a challenge. Dabigatran is a direct thrombin inhibitor incresingly used for anticoagulation in patients with heart failure and atrial fibrilation. Idarucizumab is the first targeted reversal agent available and is specific for dabigatran. In emergency situations like threatening bleeding or urgent surgery, idarucizumab promptly, durably, and safely reversed the anticoagulant effect of dabigatran. The usefulness of idarucizumab for dabigatran reversal at the HT surgery is not well known.
Aim: To present preliminary experience of idarucizumab use for dabigatran reveral in patients undergoing HT.
Methods: Observational multicenter study of using idarucizumab for urgent dabigatran reversal at the HT surgery in 6 HT Spanish centres from August 2016 to November 2017. The following variables were collected to assess effectiveness and safety: recipient's characteristics, Idarucizumab dose, need for redo in the immediate postoperative period to control bleeding, blood products transfusions, intensive care unit (ICU) and total hospitalization stay and survival.
Results: 11 patients from 6 centers, mean age 54.6 years, 7 males (63.6%) were treated with idarucizumab for dabigatran reversal at HT surgery. Etiology of heart disease: 7 non-ischemic dilated cardiomyopathy (63.6%), 3 hypertrophic cardiomyopathy (27.2%) and 1 other (9.1%). None of the cases had a prior sternotomy. Idarucizumab dose was 5 mg (2,5 mg x 2) in all cases and none of the patients needed rescue doses for bleeding control. Redo for bleeding control was needed in 3 (27.2%) patients. 7 (63.6%) patients required blood products transfusions: plasma 4 patients (mean 1312,5 cc), packed red blood cells 6 patients (mean 4.5 units) and platelets 4 patients (mean 2.25 platelets pools. Mean ICU stay was 10.5 days and mean hospital stay was 33.9 days. There was only one intrahospital death at 47th day after HT due to multiorgan failure and infectious complications but not considered related to bleeding.
Conclusions: This preliminary experience with the use of idarucizumab (5 mg) for urgent reversion of dabigatran at HT surgery is encouraging. Although one third of patients required early redo due to bleeding complications and 2/3 transfusions, no perioperative early mortality was appreciated. These results may support the use of dabigatran as an alternative to vitamin K antagonists in HT candidates that require anticoagulation. More studies are needed to corroborate these observations.

P1234
The influence of LVAD on mitral regurgitation and pulmonary system

M Cottini[1]; AC Aldo Cannata[1]; DB Dario Brenna[1]; AC Alessandro Costetti[1]; ML Marco Lanfranconi[1]; MPG Maria Pia Gagliardone[1]; MF Maria Frigerio[1]; CFR Claudio Francesco Russo[1]
[1]Niguarda Ca' Granda Hospital, Cardiovascular Department, Milan, Italy

Purpose: The Left Ventricle Assist Devices (LVADs) become more and more standard therapeutic choice for patients with advance heart failure. Most of the LVAD patients have mitral regurgitation (MR) due to functional mechanism: the tethering of mitral valve leaflets secondary to left ventricle (LV) dilatation and geometry/shape LV modifications. We investigated the perioperative and postoperative hemodynamic and echocardiographic parameters of LVAD patients to monitor the MR, pulmonary system parameters and the device function.
Methods: We retrospectively reviewed 85 patients undergoing continuous-flow LVAD implantation between 2007 and 2017, 62% Thoratec HMII (n = 54) and 38% Heartware (n = 31). 50.5% of them were affected by ischemic cardiomyopathy (ICM) and 49.5% by idiopathic dilated cardiomyopathy (IDCM). All included patients had done preoperative transthoracic echo (TTE), were undergone only to LVAD surgery. Study follow-up ended at 1 year after implantation.
Results: MR was at least moderate to severe in 54.1% of patients before LVAD implantation, 54.7% in ICM patients and 53.5% in IDCM patients. The statistical analysis revealed the IDCM patients had significantly preoperative larger LVEDD (74.3 ± 9.2 mm vs 66.4 ± 8.6 mm, p 0.0001) and lower sPAP (49.115.6 vs 61.6 ± 17.5 mmHg, p 0.002) as compared to ICM patients. After LVAD implantation, the prevalence of MR was 8.3% at 1 year (significantly lower than preoperative general value, 54.1%, p 0.0001). Among the ICM patients the MR and LVEDD decreased more than among IDCM patients (MR prevalence 4.7% vs 11.9%, p 0.19; LVEDD 61 vs 70.6 mm, p 0.18). In both groups the sPAP and the mean PAP decreased postoperatively (p 0.0001). The sPAP were lower in HMII than in HW patients (mean sPAP 31.0 vs 38.2 mmHg respectively, p 0.01). Postoperatively the devices performed well without significant complications during the first year.
Conclusion: According to our experience, the patient with moderate to severe MR after the only LVAD implantation had a significant reduction of MR (prevalence from 54.1 to 8.3% at 1 year, p 0.0001) with an improvement of hemodynamic and great pulmonary parameters due to a mechanism of ventricular reverse remodeling supported by unloading of LV due to LVAD. The decrease of MR degree was greater in ICM than ICDM group.

Cardiology Department, Valencia, Spain*

P1235	Case 1	Case 2	Case 3	Case 4
Gender	Male	Male	Male	Male
Age (years)	33	51	49	51
Basal cardiopathy	ccTGA + IVC (Eisenmenger syndrome)	HCM in dilated-phase	IDC	Laminopathy
Combined transplantation	Yes, heart and lung transplantation	No	No	No
Dabigatran dose	75 mg/12 hours (low weight)	150 mg/12 hours	150 mg/12 hours	150 mg/12 hours
VHA2DS2VASc-Score	1	2	4	2
HASBLED-Score	2	2	3	2

ccTGA: Congenitally corrected transposition of great arteries; HCM: Hypertrophic cardiomyopathy; IDC: Idiopathic dilated cardiomyopathy; IVC: intraventricular communication; CHA2DS2-VASc Score for Atrial Fibrillation Stroke RisK: congestive heart failure, hypertension, age, diabetes, stroke, vascular disease history and sex; HASBLED Score for Major Bleeding Risk: hypertension uncontrolled, renal disease, liver disease, stroke history, prior major bleeding or predisposition to bleeding, labile INR, age, medication usage predisposing to bleeding, alcohol use.

Introduction and purpose: Idarucizumab is a recently approved drug to reverse the anticoagulant effect of dabigatran, although the clinical experience in heart transplantation (HT) is scarce. We present a series of cases of patients undergoing HT and heart and lung transplantation (HLT) in whom anticoagulation with idarucizumab was reversed.
Methods: All patients undergoing HT or HLT and anticoagulated with dabigatran, in which anticoagulation with idarucizumab was reversed for the transplant, were selected from January 2016 to December 2017.
Results : 4 patients underwent elective HT (table 1). Anticoagulation was indicated because of atrial fibrillation or atrial flutter. Idarucizumab was administered in a dose of 5 mg, in two doses of 2.5 mg each. The drug was administered when the donor was confirmed to be valid, just before going to the operating room. No intraoperative or postoperative hemorrhagic complications were reported.
Conclusions: : This is the largest series of cases in Spain about reversal of anticoagulation with idarucizumab in HT. Our series of cases demonstrates a rapid and safe reversal of the anticoagulant effect in situations requiring a rapid reversal of the effect of dabigatran.

P1236
Preoperative levosimendan improves outcomes of coronary artery bypass grafting in patients with poor left ventricular function: cardiologist's opinion

E Vlasova[1]; V Gazizova[1]; E Dzybinskaya[1]; G Kheymets[1]; R Akchurin[1]
[1]National medical research center of cardiology of the Ministry of healthcare of the Russian Federati, Cardiac surgery, Moscow, Russian Federation

Background: We suggested that in patients with coronary heart disease (CHD) and low left ventricle ejection fraction (LVEF) scheduled for coronary artery bypass grafting (CABG), levosimendan (L) when administered preoperatively would effect the outcomes of operation and early postoperative period.
Purpose: to determine the benefit of preoperative levosimendan administration in patients with low LVEF underwent CABG.
Methods: The design of investigation was non-randomised study with retrospective control; 46 patients with multivessel coronary disease and LVEF = 35%, subjected to on-pump CABG in 2014-2017 were included. All pts received standart therapy for congestive heart failure (ACE-inhibitor, ß-blocker, spironolactone, diuretic, statin, aspirin) and were not taken to surgery until maximal possible compensation. 17 pts (mean age 64 ± 5 years, 82.7% male), received L, administered by a cardiologist, as infusion of 12.5mg for 24 h, without a bolus, 2 days before surgery (group L). 29 pts (mean age 60 ± 6 years, 82.3% male) made up the retrospective control group (group C).
Results: One patient in the group C but none in the group L died within 30 days of surgery. Need for inotropic support in preperfusion period was 12% in group L and 48% in group C, p = 0,023. Failure to wean developed in 12% vs 48% in groups L and C resp., p = 0,023. In group L the incidence of preperfusion atrial fibrillation and re-cardiopulmonary bypass (CPB) were lower. Doses of dopmin, epinephrine and norepinephrine at the end of the operation were lower in group L. CPB duration, tracheal intubation time, length of inotropic support, length of Intensive Care Unit stay and postoperative length of stay were shorter in group L. Those differences did not reach statistical significance probably due to the small number of pts in the group L.
Conclusion: In CHD-patients with low LVEF a preoperative levosimendan definitely shows cardioprotective effects that could provide better results of CABG and benefits in the postoperative period.

P1237
concurrent implantation of intra-aortic balloon pumping with extracorporeal membrane oxygenation improved survival of patients with postcardiotomy cardiogenic shock

K Kai Chen[1]; HW Tang[1]; JF Hou[1]; SS Hu[1]
[1]Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, department of cardiac surgeon, Beijing, China People's Republic of

Funding Acknowledgements: This work was supported by the 13th Five-year National Science and Technology Major Projectof China (2016YFC1300900).

Background: Extra-corporeal membranous oxygenation (ECMO) and intra-aortic balloon pumping (IABP) are widely used in patients with severe circulatory failure. The decision to initiate ECMO and IABP on optimal occasion in postcardiotomy cardiogenic shock (PCS) remains controversial in the absence of guidelines.
Objectives: The aim of this study is to report the combining application of ECMO with IABP in PCS in Fuwai Hospital.
Methods: A total of 60 consecutive patients who received both ECMO (<24 hours) and IABP for PCS between February 2006 to March 2017 in Fuwai Hospital were included in our study. Clinical characteristics of the patients were collected retrospectively and compared between survivors and non-survivors. Logistic regression analysis was used for predictors for survival of discharge.
Results: The study cohort had mean age of 51.4 ± 12.7 years in which 75% were males. ECMO was implanted intraoperatively in 38 (63%) patients and post-operatively in 22 (37%) patients. IABP was implanted concurrently with ECMO in 38 (63%) patients. Heart transplantation (38%) and coronary artery bypass graft (33%) was the main surgical procedure. ECMO was weaned successfully in 48% patients, and the survival to discharge was 43%. Survivors showed a lower rate of bedside ECMO implantation (12% vs. 41%, P = 0.012) and higher rate of concurrent implantation of IABP with ECMO (81% vs. 50%, P = 0.014). Concurrent implantation of IABP with ECMO (OR = 0.013, P = 0.017, 95% CI: 0-0.457) was an independent predictor for survival to discharge. As for complications, the rate of renal failure (59% vs. 15%, P = 0.001) and multiple organ dysfunction syndrome (29% vs. 0, P = 0.003) was higher in patients who failed to survive to discharge.
Conclusions: Although remaining unresolved problems, combined use of ECMO with IABP is recommendable as the short-term circulatory assistfor rescuing the patient with PCS. Concurrent implantation of IABP with ECMO provides better outcome for PCS.

Hypertension - Other

Subendocardial systolic dysfunction in hypertensive patients with strain st-t changes on electrocardiogram by 2-d speckle tracking

G Gerges Thabet[1]; MA Soliman[1]; MB Mena[1]
[1]Faculty of Medicine, Menoufia University , Department of cardiovascular diseases, Shebin El Kom,Menoufia, Egypt

Background: Hypertension can cause ST-T changes on ECG which may predict sub clinical left ventricular systolic dysfunction detected by 2D speckle tracking. Objective: the aim of this study was to evaluate left ventricular longitudinal strain by speckle tracking in hypertensive patients with strain ST-T on ECG.
Patients and Methods: left ventricular longitudinal strain analysis in 61 hypertensive patients with Echocardiographic evidence of left ventricular hypertrophy divided into two subgroups the 1st include 30 hypertensive patients with strain ST-T changes on ECG (G1) and 2nd include 31 hypertensive patients without changes on ECG (G2) and control group include 21 hypertensive patients without Echocardiographic evidence of left ventricular hypertrophy (G3).

P1238 Speckle tracking data

Speckle tracking data Mean ±SD	G1 (N = 30) Mean ±SD	G2 (N = 31) Mean ±SD	G3 (N = 21)	F Test	P value	Post hoc test
Average global longitudinal strain	-14.24±1.71	-18.05±1.99	-19.21±1.39	59.27	<0.001*	1 vs. 2 <0.001* 1vs.3 <0.001* 2vs.3 = 0.022*
Apical 4 longitudinal strain	-14.22±2.40	-18.43±2.16	-19.02±1.69	41.17	<0.001*	1 vs. 2 <0.001* 1vs.3 <0.001* 2vs.3 = 0.339
Apical 3 longitudinal strain	-13.90±2.13	-17.52±3.75	-18.72±2.68	19.14	<0.001*	1 vs. 2 <0.001* 1vs.3 <0.001* 2vs.3 = 0.155
Apical 2 longitudinal strain	-14.20±3.20	-18.17±2.83	-19.46±1.88	26.19	<0.001*	1 vs. 2 <0.001* 1vs.3 <0.001* 2vs.3 = 0.103

Table (1): Speckle tracking data of the studied groups:

Results: A high significant difference was detected in relation to Hypertension duration which divided into two categories (>10yrs and = 10yrs) which is the median of patients duration of hypertension (P-value <0.001). A high significant increase was present as regard to conventional echocardiography data on Left ventricular mass (P-value <0.001), Left ventricular mass index (P-value <0.001), Inter ventricular septum Diameter (P-value <0.001), Posterior wall Diameter (P-value <0.001), Left Atrium Diameter (P-value <0.001), Aortic root Diameter (P-value 0.002) and Relative wall thickness (P-value <0.001) between G1 compared to G2 and between G1& G2 compared to G3.also significant decrease was found on Doppler data as regard to E/A ratio between G1 compared to G2 and G1&G2 compared to G3. There was a high significant reduction between G1 compared to G2 and G1&G2 compared to G3 as regard mean value of longitudinal systolic strain of walls in apical 2 view, apical 3 view, apical 4 view and global left ventricular strain (P-value <0.001).
Conclusions: Subtle left ventricular systolic dysfunction evident by speckle tracking (systolic longitudinal strain) was present in hypertensive patient with ST-T changes on ECG and patients with uncontrolled BP (>140\90) independent on Left ventricular ejection fraction.

P1239

Arterial stiffening is associated with adverse cardiovascular outcome in patients without high blood pressure

S Satoru Sakuragi[1]; M Nakashima[1]
[1]Iwakuni Clinical Center, Department of cardiology, Iwakuni, Japan

Objective: Although blood pressure (BP) is a major determinant of arterial stiffness, whether high pulse wave velocity (PWV) adversely influences cardiac parameters and cardiovascular (CV) outcome in patients without high BP remains unclear.
Methods: Outpatients without high BP (n = 320), defined as systolic BP = 140 mm Hg, were enrolled in this retrospective study. At baseline, all patients underwent echocardiography and multidetector CT to determine the coronary artery calcification (CAC) score. Arterial stiffness was assessed based on brachial-ankle PWV (baPWV), from which patients were classified into two groups: those with high (= 18 m/s, n = 89) and low baPWV (< 18 m/s, n = 231). Cardiac parameters and CV event incidence during the follow-up period were compared between these groups.
Results: In multivariable linear regression analysis, baPWV was significantly associated with CAC score and serum N-terminal pro-brain natriuretic peptide hormone level, after adjustment for confounding factors. In multivariable logistic regression analysis, baPWV = 18 m/s was significantly associated with CAC score = 400 (OR 2.466, 95% CI 1.012 to 6.009, p = 0.0471). Kaplan-Meier analysis showed that the high-baPWV group experienced more CV events during the 575 days of follow-up (20% vs 6%, p = 0.0003).
Conclusions: High baPWV was associated with greater CAC and a high risk of a future CV event, especially coronary artery disease, even in patients without high BP.

P1240

NT-proBNP and metabolic risk factors in two ethnic groups - The SABPA cohort study

A Amra Jujic[1]; O Melander[1]; PM Nilsson[1]; L Malan[2]; A Fedorowski[1]; M Magnusson[3]
[1]Lund University, Malmo University Hospital, Department of Clinical Sciences, Lund, Sweden; *[2]North-West University, Hypertension in Africa Research Team (HART), Potchefstroom, South Africa*; *[3]Malmo University Hospital, Department of Cardiology, Malmo, Sweden*

Funding Acknowledgements: South African Medical Research Council; Department of Education North-West Province; ROCHE diagnostics; Metabolic Syndrome Institute, France

Background: Natriuretic peptides are vasoactive peptides with several metabolic actions.
Purpose: We aimed to explore associations of N-terminal pro-brain natriuretic peptide (NT-proBNP) with metabolic traits in a mixed ethnic African-Caucasian cohort.
Methods: Within the Sympathetic activity and Ambulatory Blood Pressure in African Prospective cohort study (SABPA), baseline examination was performed between 2008 and 2009, and re-examination after a 3-year follow-up in 397 South African teachers (African n = 194; Caucasian n = 203).
Results: In cross-sectional linear regression analyses, each 1SD increment of age and sex adjusted NT-proBNP was inversely associated with body weight (ß = -2.23; p = 0.042), body mass index (ß = -1.01; p = 0.007), waist circumference (ß = -1.82; p = 0.033), HbA1c (ß = -0.14 %; p = 0.009), insulin (ß = -1.66; p = 0.002), homeostatic model assessment of insulin resistance (ß = -0.47; p = 0.006) and triglyceride levels (ß = -0.04; p = 0.002). Intra-ethnic differences were observed, where lower NT-proBNP levels affected glucometabolic status stronger among Africans. Each 1SD increment of age, sex, waist circumference and follow-up time adjusted NT-proBNP was associated with reduced odds of incident diabetes, and subjects within the highest quartile of NT-proBNP were at lowest risk compared with the lowest quartile (OR 0.24; CI95% 0.06-0.96; p = 0.041).
Conclusions: In a cohort consisting of two ethnic groups, NT-proBNP in the high normal range is associated with lower prevalence of metabolic risk factors such as high BMI, increased waist circumference, impaired glucose tolerance, high insulin levels and hypertriglyceridemia, with strongest associations for Africans. Inspite of similar NT-proBNP concentrations, BNP may affect the propensity for metabolic disturbances differently in Africans and Caucasians.

P1241

On-treatment decreases in aortic pulse pressure induced by antihypertensive therapy are accounted by reductions in backward wave in mild hypertensive patients

EN Libhaber[1]; GR Norton[2]; G Tade[2]; I Ballim[2]; CD Libhaber[2]; P Sareli[2]; AJ Woodiwiss[2]
[1]University of the Witwatersrand, School of Clinical Medicine, , Johannesburg, South Africa; *[2]University of the Witwatersrand, Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, Johannesburg, South Africa*

Funding Acknowledgements: This work was supported by the Medical Research Council of South Africa, the Circulatory Disorders Research Trust, the University Research Council

Background: Aortic haemodinamics are predictors of heart failure. Brachial pulse pressure may not accurately reflect aortic pulse pressure measurements. Numerous factors contribute towards central pulse pressure and these may influence aortic pulse pressure by modifying either aortic backward (reflected) or forward wave pressures. Several studies suggest a more important role of the backward wave than the forward wave in contributing to variations in central pulse pressure, cardiovascular end-organ measures and outcomes than forward wave pressures at mediating cardiovascular damage. Prior studies reporting on antihypertensive drug effects on aortic blood pressure have not compared the contribution of forward and reflected wave pressures to decreases in central pulse pressure.
Purpose: We aimed to determine the relative contribution of decreases in forward vs backward wave pressures to antihypertensive treatment-induced decreases in aortic pulse pressure.
Methods: We randomized 54 mild hypertensives of black African ancestry to receive indapamide (2.5mg) (n = 27) or amlodipine (CCB) (10mg) (n = 27) daily for a month and then to receive the angiotensin-converting enzyme inhibitor, perindopril (4mg) as add-on therapy if target office pressures were not achieved, for a further 5 months. Aortic haemodynamics were determined using applanation tonometry, ShygmoCor software and echocardiography.
Results: Mean age in both groups was similar (60 ± 14 and 57 ± 14 years), the majority were females (79-85%) and obese (BMI ˜32 kg/m^2) and 19-33% had left ventricular hypertrophy. Backward and forward wave pressures were reduced to a similar degree in both the CCB (-3.6 ± 1.2 and -3.3 ± 8.9 mmHg, p < 0.01) and indapamide (-4.8 ± 1.0 and -4.6 ± 1.2 mmHg, p < 0.01) treated groups. However, in both treatment groups, with backward and forward waves in the same multivariate model

the slope of the relationship between decreases in aortic pulse pressure and backward wave pressure (indapamide: ß-coefficients: 0-1 month = 1.145 ± 0.085, 0-6 months = 1.183 ± 0.131,p < 0.0001; CCB: ß-coefficients 0-1 month = 1.192 ± 0.105, 0-6 months = 1.493 ± 0.160, p < 0.0001) was much higher than between aortic pulse pressure and forward wave (indapamide: ß-coefficients: 0-1 month = 0.611 ± 0.075, 0-6 months: 0.513 ± 0.118, p < 0.0001: CCB: ß-coefficients: 0-1 month = 0.516 ± 0.086, 0-6 months= 0.243 ± 0.148, p < 0.0001).
Conclusions: The benefit of reductions in pulse pressure mediated by major classes of antihypertensive agents are accounted more by decreases in backward than forward wave pressures .

Diabetes and the Heart

P1242
Skin autofluorescence as a measure of advanced glycation end product levels is associated with plaque burden in subjects free from diabetes

A Amra Jujic[1]; G Ostling[1]; M Persson[1]; G Engstrom[1]; PM Nilsson[1]; O Melander[1]; M Magnusson[2]
[1]Lund University, Malmo University Hospital, Department of Clinical Sciences, Lund, Sweden; *[2]Malmo University Hospital, Department of Cardiology, Malmo, Sweden*

Funding Acknowledgements: Swedish Medical Research Council. the Swedish Heart and Lung Foundation, the Medical Faculty of Lund University, Skane University Hospital

Background: Advanced glycation end products (AGEs) is an established risk factor in diabetic vascular disease, but possible associations between atherosclerosis and AGE in a population free from diabetes are yet to be investigated. Skin autofluorescence is a novel marker of AGE-levels in long-lived tissue.
Purpose: We studied the degree of atherosclerosis in an elderly population free from diabetes and its association with skin autofluorescence.
Methods: Carotid ultrasound and skin autofluorescence measurements was performed in a subpopulation within "Malmö Diet and Cancer Cardiovascular Cohort" (n = 523). Total plaque area including all prevalent plaques in the right carotid artery, was calculated. Subjects with diabetes were excluded. Complete data on all variables was available for 375 subjects.
Each 1 standard deviation (SD) increment of skin autofluorescence was associated with increased total plaque area in the right carotid artery (ß = 2.88, p = 0.018) independently of metabolic and cardiovascular risk factors. Similarly, each 1 SD increase of skin autofluorescence was associated with an approximately 1.4-fold increased risk of large total plaque area (= 34mm2) (OR 1.39; 95% CI 1.07 - 1.80; p = 0.015). The top versus bottom quartile of the skin autofluorescence was associated with an approximately 2.5-fold increased risk of total plaque area = 34mm2 (OR 2.56; 95% CI 1.22 - 5.39; p = 0.010) in fully adjusted analysis.
Conclusions: In a population free from diabetes, skin autofluorescence was independently associated with increasing degree of atherosclerosis measured as total plaque area, implicating a role of advanced glycation end products in the development of atherosclerosis even in a non-diabetic population.

P1243
The significance of diabetes mellitus on left ventricular function, heart rate variability and frequency of supraventricular arrhythmias in patients after myocardial infarction

V Stoickov[1]; M Deljanin Ilic[1]; M Stoickov[2]; S Saric[2]; S Andonov[2]; D Marinkovic[2]; I Tasic[1]; D Simonovic[2]; S Mitic[2]
[1]University of Nis, Medical Faculty, Institute of Cardiology Niska Banja, Nis, Serbia; *[2]Institute of Cardiology, Niska Banja, Serbia*

Background/Introduction: Coronary patients with diabetes are at high risk of cardiovascular events. Coronary disease in diabetic patients has speed up, progressive course because of the synergic work of hyperglycemia and other risk factors of the coronary disease, as well as dyslipidemia, hypertension, obesity and smoking too.
Purpose: The aim of this study was to establish the significance of diabetes mellitus on left ventricular function, heart rate variability and freqency of supraventricular arrhythmias in patients after myocardial infarction (MI).
Methods: We studied 337 patients after MI, in the sinus rhythm without AV blocks or branch blocks. 112 patients were with diabetes mellitus, and 225 were without diabetes. Patients were of similar age, site of infarction and baseline stress test duration. In all subjects 24-hour ECG recording and echocardiographic examination were performed. From the holter record, the analysis of the heart rate variability was performed by software. Four parameters of the time domain heart rate variability were assessed: SDNN, SDANN, RMS-SD and NN>50 ms.
Results: Patients with diabetes had a higher percentage of frequent (<10 supraventricular premature complexes / hour) and complex supraventricular arrhythmias (38.5 vs 19.2%, p < 0.001) and supraventricular tachycardias (28.8 vs 6.1%, p < 0.001) than in those without diabetes. Patients with diabetes also had significantly lower values of followed parameters of the heart rate variability (78.6 ± 20.1 vs 102.1 ± 28.7 ms, p < 0.001 for SDNN; 66.9 ± 18.7 vs 85.6 ± 29.7 ms, p < 0.001 for SDANN; 24.7 ± 10.6 vs 35.4 ± 14.9 ms, p < 0.001 for RMS-SD and 5.8 ± 5.6 vs 12.2 ± 10.3, p < 0.001 for NN>50ms) in comparison to those without diabetes. Patients with diabetes also had significantly lower values of left ventricular ejection fraction (45.0 ± 9.6 vs 54.3 ± 13.8 %, p < 0.001) and significantly higher values of left ventricular end-systolic diameter (39.5 ± 5.6 vs 35.6 ± 6.8 mm, p < 0.001), left ventricular end-diastolic diameter (55.8 ± 5.4 vs 53.1 ± 5.6 mm, p < 0.001) and left atrium (43.2 ± 5.6 vs 39.2 ± 4.7 mm, p < 0.001), in comparison to those without diabetes.
Conclusions: The study showed that in patients after MI, diabetes mellitus have a significant impact on left ventricular function, heart rate variability and supraventricular arrhythmias. The reason for that is more severe degree of the left ventricle dysfunction, diabetic neuropathy and greater inhomogeneous repolarization of myocardium.

P1244
Beneficial effect of short-term dapagliflozin therapy on arterial stiffness assessed by cardio-ankle vascular index in type 2 diabetic patients

K Takagi[1]; N Sato[1]; S Ishihara[1]; W Shimizu[2]
[1]Nippon Medical School Musashi-Kosugi Hospital, Department of Cardiology and Intensive Care Unit, Kanagawa, Japan; *[2]Nippon Medical School, Department of Internal Medicine and Cardiology, Tokyo, Japan*

Background: In type 2 diabetes mellitus (T2DM), arterial stiffness is related to the progression of complications. However, previous studies showed no relationship between glycemic control and changes in arterial stiffness. We evaluated whether or not dapagliflozin, a SGLT2 inhibitor, therapy can improve arterial stiffness using cardio-ankle vascular index (CAVI) and HbA1c after a short-term period in T2DM patients.
Methods: Sixteen T2DM patients were treated dapagliflozin 5-10mg/day for 6 months. HbA1c and CAVI were measured before and after treatments.
Results: Significant decreases in HbA1c (7.43 ± 0.60 to 6.68 ± 0.55%, P = 0.0003) and CAVI (figure) were observed after treatment.
Conclusion: In T2DM patients, dapagliflozin had beneficial effects on arterial stiffness in addition to lowering HbA1c after a short-term period, suggesting that dapagliflozin might be useful for prevention of DM-related complications.

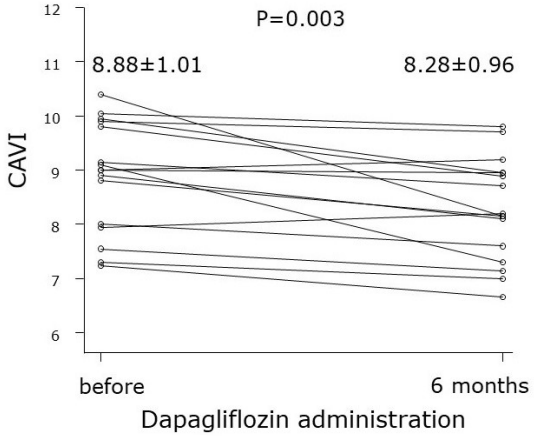

Figure. Change in CAVI after Dapagliflozin treatment for 6 months. Data are presented as mean ± SD, paired t-test.

Renal Failure and Cardiovascular Disease

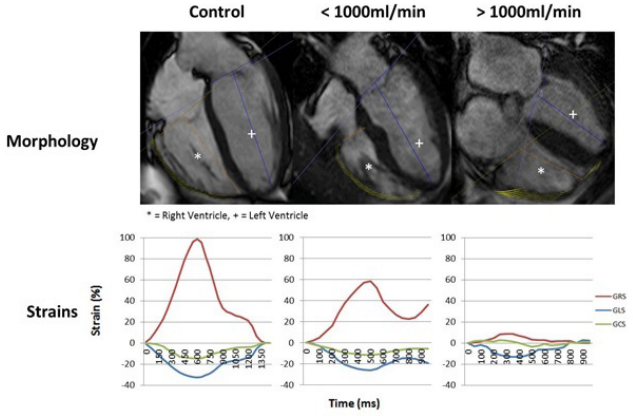
Effects of the high flow arterio-venous fistula on right ventricular contractility in hemodialysis patients

S C Bhagirath[1]; A De Vette[1]; G Karas[2]; H Suliman[2]; AWM Van Der Graaf[3]; MJW Gotte[4]; MC Weijmer[1]; P Bhagirath[1]
[1]Hospital Onze Lieve Vrouwe Gasthuis, Internal Medicine, Amsterdam, Netherlands; [2]Hospital Onze Lieve Vrouwe Gasthuis, Radiology, Amsterdam, Netherlands; [3]Sint Franciscus Gasthuis, Cardiology, Rotterdam, Netherlands; [4]VU University Medical Center, Cardiology, Amsterdam, Netherlands

Background: The presence of an arterio-venous fistula (AVF) in hemodialysis patients is a source of constant volume overload. The inability of the right ventricle (RV) to adapt to these conditions leaves it more susceptible to dysfunction as compared to the left ventricle (LV). Early recognition of RV failure in this population, especially in relation to the AVF flow, could contribute towards improved and personalized therapeutic strategies.
Purpose: In this study we utilize tissue-tracking cardiac magnetic resonance to describe the relation between AVF flow and RV contractility. It is hypothesized that the RV contractility will be decreased in patients with a high flow AVF due to volume overload related RV dysfunction.
Methods: Hemodialysis patients (n = 11) and age-matched controls (n = 5) underwent CMR. Acquisitions were obtained prior to and after dialysis to distinguish between the effects of AVF flow and volume status (fluid overload). The patients were divided in Group 1 (low flow, < 1000ml/min) and Group 2 (high flow, >1000ml/min) based on the AVF flow measured using ultrasonography. Global longitudinal (GLS), global circumferential (GCS) and global radial strain (GRS) of the RV were calculated with the tissue-tracking module of Circle Cardiovascular Imaging using short- and long-axis cine images.
Results: The contractility parameters between the groups were similar prior to dialysis. After dialysis, there were no significant changes observed between Group 1 (n = 5) and the control group (n = 5). In comparison to the control group, patients in group 2 (n = 6) had a significantly lower GLS (-16.5 ± 3.0% vs. -28.1 ± 4.4%, P < 0.05) and GRS (31.0 ± 8.5% vs. 71.7 ± 23.7%, P < 0.05) after the dialysis session. No significant change was observed for the GCS between the control group and group 2 (-3.6 ± 10.6% vs. -15.6 ± 3.5%, P = 0.06).
Conclusion: These findings suggest that patients with high AVF flow have significantly lower contractile parameters and thereby have at an increased risk for developing right ventricular failure. Tissue-tracking analysis offers the possibility to detect subtle early changes in right ventricular contractility and could have significant therapeutic consequences in this patient group.



RV Strain

P1246

Role of natriuretic peptides in renal outcomes after revascularization in patients with significant atherosclerotic renal artery stenosis

DO Geavlete[1]; C Beladan[1]; D Deleanu[1]; MR Zaharia[2]; O Tautu[3]; BA Popescu[1]; C Ginghina[1]; O Chioncel[1]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; [2]Emergency Clinical Hospital St John, Internal Medicine, Bucharest, Romania; [3]Emergency Clinical Hospital Floreasca, Cardiology, Bucharest, Romania

Introduction: Cardiac failure with preserved ejection fraction and flash pulmonary edema are cardinal manifestations of significant bilateral renal artery stenosis (RAS) and RAS in solitary kidney patients. Brain natriuretic peptide (BNP) might be a valuable predictor of clinical outcomes after renal revascularization in terms of renal function preservation.
Purpose: The present study was aimed to compare the BNP levels at admission and 12 months' after renal angioplasty with stent and to identify its' predictive value for renal outcomes (renal function and major renal events) in patients with significant RAS.
Methods: 78 hypertensive patients referred to renal angiography for suspected RAS and diagnosed with significant uni- and bilateral stenosis (<70%) were prospectively enrolled, resulting in 3 groups (34-unilateral, 28-bilateral RAS and 16-RAS in a solitary kidney). Cardiac and renal history, duration of hypertension, cardiovascular risk factors, biological profile (including BNP), extra-cardiac vascular diseases and related comorbidities were assessed. A complete echocardiography was performed in all patients. Renal function was estimated based on the serum creatinine level and glomerular filtration rate (eGFRCKD-EPI). The mean extended follow-up period was 24.27 ± 12.16 months, during which major renal events were observed (acute renal insufficiency and need for dialysis). Statistical analysis correlation followed by logistic regression analysis (stepwise Likelihood ratio method) was used.
Results: Similar baseline characteristics were found for the 3 study groups regarding age, gender, stenosis' severity, comorbidities, blood pressure values and echocardiographic parameters (p?0.05 for all). Although baseline renal dysfunction was significantly higher in patients with RAS in a solitary kidney compared to bilateral and subsequently to unilateral RAS (p = 0.001), BNP and LnBNP levels were similar between groups. The BNP and LnBNP variation percent analysis before and after revascularization showed a significant reduction in LnBNP in all patients after renal stenting (p = 0.002), with significant differences between groups (unilateral - p?0.05, bilateral - p = 0.031 and solitary kidney RAS - p = 0.007). Multivariate logistic regression analysis confirmed baseline LnBNP as an unique independent predictor for major renal events (p = 0.002). The accuracy of the emerged predictive model as quantified by the area under the receiver-operating characteristics curve was 0.95 (95% CI, 0.83-1.01, p = 0.002).
Conclusions: The study demonstrated a strong relationship between elevated BNP and major renal events after renal stenting in high-risk RAS patients, although baseline BNP levels were not predictive for renal function improvement. The present findings strengthen the current indications for renal stenting in bilateral RAS and solitary kidney RAS, groups in which BNP significantly decreased after revascularization when compared to unilateral significant RAS.

P1249

Clinical characteristics and comorbidities in very elderly patients with heart failure admitted as an emergency

A Alice Balaceanu[1]; R Staiculescu[2]; M Fronea[2]; G Dediu[2]; C Voiculet[1]; C Diaconu[3]; G Aron[1]; I Dina[1]
[1]UMF Carol Davila, Emergency Clinical Hospital Sf. Ioan, Internal Medicine Clinic, Bucharest, Romania; [2]Emergency Clinical Hospital Sf. Ioan, Bucharest, Internal Medicine Clinic, Bucharest, Romania; [3]UMF Carol Davila, Emergency Clinical Hospital Floreasca, Internal Medicine Clinic, Bucharest, Romania

Funding Acknowledgements: None

Background: It is hard to estimate the cardiovascular risk in very elderly patients.
Purpose: The aim of the study was to assess the clinical characteristics and cardiovascular risk in very elderly patients with heart failure admitted as an emergency.
Methods: The retrospective study included 84 patients with age more than 90 years old admitted to Clinical Emergency Hospital between January 2014 - May 2017. Of these patients 76.19% (64 patients) had heart failure as a diagnosis.
Results: The average age was 91 years. The maximum age was 97 for women and 98 for men. Gender distribution: 64.06% women and 35.94% men. The following NYHA class distribution in patients with heart failure was observed: class II 42.19%, class III 43.75%, class IV 14.06%.
The most common comorbidity was chronic kidney disease, encountered in 93.75% of cases. The following KDIGO staging was present: G1 3.12%, G2 23.44%, G3a 37.5%, G3b 28.12%, G4 7.82% and G5 0% (evaluated by MDRD equation). The average level of creatinine at admission was 1.46 and at discharge was 1.34. Worsening of renal function was noticed in 9.6% of patients.
Other comorbidities were: hypertension (67.18%), anemia (65.62%), respiratory insufficiency (40.62%), atrial fibrillation (32.81%), mixed dementia (31.25%), Alzheimer disease (28.12%), sequelae of stroke (23.43%), right bundle branch block (14.06%), left bundle branch block (12.50%), depression (15.62%), cancer (14.06%), cachexia (23.43%).
Urinary tract infection has been proven in 26.92% of cases. Identified germs were E. Coli in 71.42% cases of infections, Enterococcus, Klebsiella, Proteus and Pseudomonas.
The principal diagnosis on admission was acute decompensation of heart failure in 29.68%, infection in 25% and acute respiratory insufficiency in 15.62% of cases.

Conclusions: Chronic kidney disease and hypertension are the most common cardiovascular risk factors in the very elderly patients with heart failure. Anemia is an important factor in the management of heart disease in this category of patients. Nonvalvular atrial fibrillation is the most common arrhythmia in very elderly patients.

P1250

Cardiac serum biomarkers in haemodialysis patients: significance of NT-proBNP and troponin in heart failure

B Leskovar[1]; T Furlan[1]; K Vrbinc Vrtek[1]; S Poznic[1]; D Kosuta[1]; A Adamlje[2]
[1]*Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia*; [2]*Trbovlje General Hospital, Department of Hemodialyisis, Trbovlje, Slovenia*

Background/Introduction: Plasma NT-proBNP concentrations are elevated in chronic kidney disease (CKD) patients with or without clinically evident heart failure. Cardiac troponins are the preferred biomarkers for the diagnosis of myocardial injury, but stably elevated troponin concentrations are commonly observed in CKD patients in the absence of clinically evident acute myocardial damage.
Purpose: We wanted to evaluate correlations between NT-proBNP plasma levels and echocardiographic parameters that suggest heart failure. Additionally, we wanted to assess whether the plasma level of troponin in CKD patients influences the correlation of NT-proBNP with clinically significant heart failure and whether the level of troponin influences on survival of CKD patients.
Methods: We retrospectively included all CKD patients on chronic haemodialysis in our centre after January 2008. We were regularly assessing the value of troponin T and NT-proBNP every four months and we performed echocardiography in all of our patients. We calculated the average NT-proBNP and average troponin since the start of haemodialysis and divided our patients in three groups based on troponin level (group 1: TnT < 0,01, group 2: TnT 0,01-0,1, group 3: TnT>0,1 (cut-off value 0,1 ng/ml). We compared the correlation of NT-proBNP with heart failure echocardiographic parameters (LVEF, LVOT VTI, E/Em) between groups 1-3 (MANCOVA analysis). We also evaluated survival (overall survival, time to acute cardiac event and time to first heart failure hospitalization) after the start of haemodialysis (Kaplan-Meier analysis).
Results: We included 120 chronic haemodialysis patients (54% male, mean age 71 ± 12 years, mean TnT 0,2 ± 0,3 ng/ml, mean NT-proBNP 2026 ± 1364 pmol/l). None of them had negative level of troponin (TnT < 0,01), 56 were in group 2 and 46 in group 3. NT-proBNP significantly correlated with LVEF, LVOT VTI and E/Em (p = 0,001, p = 0,023 and p = 0,032, respectively), but there was no significant change between selected troponin based groups. We also assessed predicted survival between groups 2 and 3. There was no difference in estimated survival between groups (111 ± 13 vs. 93 ± 16 months, p = 0,112), no difference between predicted time to first heart failure decompensation after the start of haemodialysis (182 ± 14 vs. 191 ± 23, p = 0,43), but the group with higher troponin had shorter predicted time to acute cardiac event after the start of haemodialysis (195 ± 18 vs. 166 ± 23, p = 0,004).
Conclusion(s): Our results confirm a stably elevated troponin level and higher mean NT-proBNP in CKD patients. Nevertheless, our results indicate a positive correlation between NT-proBNP and echocardiographic markers of heart failure even in this population. We did not perform 6MWT because our study was retrospective, but this functional test should be done to confirm our findings. Also, despite persistently elevated troponin, higher troponin showed to correlate with earlier acute cardiac event.

Autoimmune/Chronic Inflammatory Disorders and Heart Disease

P1251

Inflammatory markers TNF, Il6 as predictor of outcome for Peripartum cardiomyopathy

SRS Sai Ravi Shanker[1]
[1]*CONTINENTAL HOSPITALS, CARDIOLOGY, HYDERABAD, India*

On behalf of: DR RAVI SHANKER

Aim/objective: The study aimed at correlating plasma levels of C-reactive protein TNF a and IL6 as prognostic value for major clinical in-hospital events and 6 month follow up in patients with PPCM
Material and methods: A total 86 subjects were enrolled [(patients (n-46) and controls (n-40)]. After checking for the inclusion and exclusion criteria, clinical assessment, echocardiography, and blood analysis were done at baseline and after 6 months of standard therapy. All patients received treatment Inflammatory markers (C-reactive protein, TNF a and IL 6) were measured at baseline and at 6 months.
Results: C-reactive protein (22mg/dl vs 08mg/dl) TNF alpha (9.6 vs 3.2 pg/dl, p < 001) and IL6 were (73.19 vs 8.83pg/dl, p < 0.005) which were significantly abnormal compared with study population ,and these patients showed a significant higher LV dimensions LV EDD (61.6 vs 46 p < 0.004) LV ESD (53.1 VS 32,p < 0.005) and significant lower LVEF (25.9 vs 55 P < 0.001) and well correlate with NYHA FC and death. Left ventricular ejection fraction (LVEF) improved from 25.9 to 42.9% at 6 months (P < 0.0001). Patients who completed 6 months of standard care showed a significant reduction of , LV dimensions, and NYHA FC (P < 0.001).
Conclusion: Plasma markers of inflammation were significantly elevated in PPCM patients and correlated with the pathogenesis of PPCM and its complications and predictors of mortality.

Characteristics of deceased vs.surviving

	Deceased	Survivors	P-value
Age (years)	22±1.2	28±6	0.24
No. of children (n), median (range)	2(1-4)	3(1-7)	0.14
Onset of symptoms after delivery (months), median (range)	1(1-5)	2(1-5)	0.6

Echo EF (%)	20±4	26±8	0.04
C-reactive protein (mg/L), median (range)	26	22	0.10
TNF (pg/mL)	9.6	24	<0.001
IL-6(pg/ml)	34	72	<0.001

P1252

Chronic inflammation after splenectomy is a risk factor for increased thrombotic cardiovascular events

M Mario Gerges[1]; C Gerges[1]; M Publig[1]; N Skoro-Sajer[1]; J Bergler-Klein[1]; D Bonderman[1]; M Frey[1]; I Schwarzinger[2]; MP Winter[1]; M Humenberger[3]; J Jakowitsch[1]; V Seidl[1]; B Eichelberger[4]; S Panzer[4]; IM Lang[1]
[1]*Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria*; [2]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*; [3]*Medical University of Vienna, Department of Trauma-Surgery, Vienna, Austria*; [4]*Medical University of Vienna, Department of Blood Group Serology and Transfusion Medicine, Vienna, Austria*

Purpose: Patients after splenectomy are prone to complicated thrombosis and atherosclerosis. Preclinical studies suggest that this observation may be linked to a chronic inflammatory state characterized by lymphocyte dysregulation. We tested the hypothesis that sustained inflammation and abnormal platelet function in splenectomized patients contribute to atherosclerosis and thrombosis.
Methods: In this prospective case control study, we evaluated 298 outpatients after previous splenectomy referred from 1100 primary care practitioners. 177 (89.4%) splenectomies were due to trauma. Functional asplenia was assessed by the presence of Howell-Jolly bodies (HJB) on Wright-blood smears. Platelet function was measured in a subset of 36 splenectomized patients in whom splenectomy occurred after trauma, and in 7 matched non-splenectomized controls by multiple electrode impedance aggregometry (Multiplate) and flow cytometry.
Results: Despite similar age functional asplenic patients (HJB+) were more likely to have diabetes mellitus (27.3%, p = 0.037) and stable ischemic heart disease (27.3%, p = 0.047) compared to controls (3.7%, 0%) respectively. In addition stable ischemic heart disease was more common in HJB+ patients (27.3%, p = 0.047) compared to HJB- patients (5.6%). HJB+ patients had a significantly higher number of cumulative thrombotic events (n = 70) compared to HJB- patients (n = 11, p = 0.001) and controls (n = 2, p < 0.001). Time to first thrombotic event was shorter in HJB+ patients (median, 25th and 75th percentiles: 316 months, 165-514 months) compared to HJB- patients (478 months, 466-483 months; p = 0.01) and controls (542 months, 502-581 months; p = 0.003. T cells (CD4+ and CD8+), NK cells and B cells were higher in HJB+ (1298.5 ± 532.4, 844.9 ± 638.3, 523.7 ± 395.2, 447.7 ± 328.9) than in HJB- (1138.8 ± 354.9, p = 0.299; 713.4 ± 285.0, p = 0.452; 304.2 ± 201.2, p = 0.016; 320.3 ± 114.6, p = 0.026) patients and controls (944.6 ± 328.7, 436.4 ± 189.8, 244.4 ± 132.5, 245.0 ± 86.4; all p < 0.01) respectively. Multiplate and flow cytometry analyses revealed increased platelet activatability HJB+ patients compared with HJB- patients and controls. Kaplan-Meier survival curve illustrates time to first thrombotic event or "thrombotic" death.
Event-free survival was significantly (p < 0.001) shorter in splenectomized patients compared with the general Austrian population.

Conclusions: Patients after splenectomy show sustained inflammation with higher numbers of pro-inflammatory cells and increased platelet activation. This observation may underlie the increased risk for thrombotic cardiovascular events.

Cardiovascular Nursing - Other

P1253

The long road to a care pathway

C J Caroline Wulffraat[1]
[1]*ijsselland ziekenhuis, capelle aan den ijssel, Netherlands*

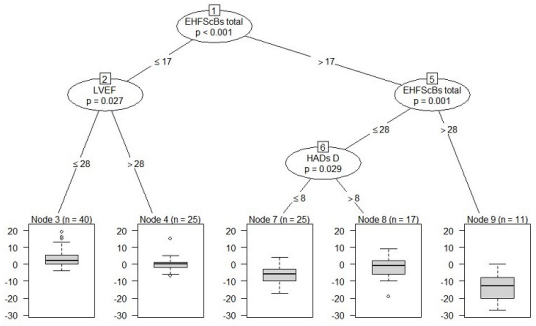
Context: Older patients have a difficult choice to make when they are confronted with a cardiac diagnosis which can be treated best with active cardiac intervention. It can technically be done in fragile, older patients, but it is difficult for the individual patient to weigh the risks and benefits. Patients are dependent on advice from their doctors at the time of decision-making. There is growing group of elderly patients with cardiac diseases who will not undergo active intervention. There is a need for a palliative care pathway that supports these patients with the adaptation to a life limiting disease from the moment of diagnosis.
Method: This study used a modified action research approach. Eleven patients, and one relative, with this specific cardiac condition were interviewed (semi structured). Two multidisciplinary heart teams gave input through patient assessments. Focus groups with local cardiologists, NP's, GP's and homecare nurses provided a multi-faceted view on the concept of the care pathway. For data analysis the approach of manifest content analysis was used.
Findings: At the time of shared decision-making patients rate honesty and expertise the highest. They expect the doctor to know best. The cardiologists used a paternalistic approach and used hard data for decision-making, however, the widely used EuroSCORE does not cover this patient category. Patients who chose for themselves not to be operated seemed to have better self-control and better adaptation to the disease. However, at discharge there was often poor communication between care professionals, particularly about symptom recognition and relief. All patients in this study used >6 medications and nearly all were dependent on homecare. They reported symptoms such as tiredness, fluid retention and weakness. They had a fear of acute, severe symptoms, such as dyspnoea, chest pain and the feeling of suffocating/ dying recurring in the night. They needed palliative care as described by WHO, but prior to this study did not receive it.
Conclusions: Inclusion of frailty scores such as ISAR, KATZ ADL and TUG can provide a better patient assessment. The cardiologists and NP demonstrated a paternalistic approach to decision-making, however, this suited the expectations of the patients in this study as "the doctor knows best". Patients who had made their own decision had more self-control and were coping better. Poor communication at discharge led to inadequate symptom recognition and relief. The unpredictability and fear of returning symptoms should be addressed by a palliative approach. There is an unclear operation of the definition of palliative care.
Recommendations Specific risk cores for frailty need to be included in risk stratification for a better patient assessment for cardiac surgery. Education for NP and homecare nurses is needed to provide palliative care for patients with cardiac diseases, which includes expert symptom recognition and relief.

P1254

Patient profile predisposing the highest potential to change self-care behaviour: data of the IN TOUCH study

E Edita Lycholip[1]; IM Aamodt[2]; I Lie[2]; T Simbelyte[3]; R Puronaite[1]; H Hillege[4]; A De Vries[4]; I Kraai[5]; A Stromberg[6]; T Jaarsma[6]; J Celutkiene[1]
[1]*Vilnius University, Clinic of Cardiac and Vascular diseases, Vilnius, Lithuania*; [2]*University of Oslo, Oslo University Hospital, Department of Cardiothoracic surgery, Oslo, Norway*; [3]*Vilnius University, Faculty of Medicine, Vilnius, Lithuania*; [4]*University of Groningen, Department of Cardiology, Groningen, Netherlands*; [5]*University of Groningen, PRA Health Sciences - Early Development Services, Groningen, Netherlands*; [6]*Linkoping University, Department of Medical and Health Sciences, Linkoping, Sweden*

Background: Self-care is an essential component of chronic heart failure (HF) management, necessary for improvement of patient's well-being, quality of life and prognosis. However, it is known that self-care is sub-optimal in HF patients worldwide and cannot always be easily improved. In attempts to design more effective interventions to improve HF management it is important to know which factors determine self-care.
Methods: The methods and design of the IN TOUCH study (INnovative ICT-guided-DMS combined with Telemonitoring in OUtpatient clinics for Chronic HF patients) were reported elsewhere. The current analysis included 118 participants (mean age 69 ± 11.5 years; 70% male) who filled PRO instruments. These included the 9 item European Heart Failure Self-care Behaviour scale (EHFScBs, range from 9 to 45 points, higher scores reflect worse self-care), Hospital Anxiety and Depression scale (HADs) and Minnesota Living with HF Questionnaire (MLHFQ). To identify subgroups with the greatest potential to improve self-care, conditional inference trees were constructed. In this case, a regression tree with a continuous target variable of change in self-care and input variables (intervention group, sex, left ventricular ejection fraction (LVEF), smoking, age, MLHFQ total scale/physical subscale/emotional subscale, EHFScBs, HADs Depression subscale, HADs Anxiety subscale, New York Heart Association (NYHA) class, N-terminal pro Brain Natriuretic Peptide [NT-proBNP]), were used. Based on the regression tree distribution, the impact of depression was separately investigated in 3 groups of different initial self-care level by univariable regression analysis.
Results: The subgroups of patients who had an initial EHFScBs total score >28 (consistent with poor self-care), or EHFScBs total score in the range from 17 to 28 (medium level) with concomitant depression subscale (HADc_D) score = 8, demonstrated the greatest potential to improve self-care during the study (see Figure: Regression tree showing variables influencing changes in self-care [decrease in EHFScBs total score means improvement in self-care]).



Regression tree of changes in self-care

Depression was significantly related to HF self-care deterioration not in the whole study group, but in the subgroup with medium range of EHFScBs score (from 17 to 28), increasing the chances of self-care worsening by 10.22 times (95% CI 1.81;57.69).
Conclusion: Depression and initial level of self-care play a major role in the change in self-care behaviour in chronic heart failure patients. Intervention aimed to improve self-care behaviour should be adapted for patients with depressive symptoms.

P1255

Cross-cultural adaptation and psychometric testing of the brazilian version of the caregiver contribution to self-care of heart failure index

C Wahast Avila[1]; D De Souza Bernardes[1]; LC Jacoby Silveira[1]; E R Eneida Rejane Rabelo-Silva[1]
[1]*Federal University of Rio Grande do Sul, Heart Failure Clinic and Transplant Group at Hospital de Clinicas de Program at the Nursing School, , Porto Alegre, Brazil*

Introduction: Caregivers make an important role in self-care of patients with heart failure (HF). Although we have validated scales to evaluate this behavior in HF patients few instruments are available to measure caregiver's contribution.
Purpose: To adapt and test the psychometrics properties of the Caregiver Contribution to Self-Care of Heart Failure Index (CC-SCHFI) into Brazilian Portuguese.
Methods: The CC-SCHFI was derived from the Self-Care of Heart Failure Index version 6.2 (SCHFI v. 6.2) and it has already been validated by Italians researches. CC-SCHFI measures the contribution of caregiver to the self-care maintenance and self-care management, as well as their ability's confidence to contribute to the HF patients' self-care. After the approval of the original author, we conducted a complete cross-cultural adaptation of the scale (translation, synthesis, back translation, synthesis of back translation, expert committee review, and pretesting). The psychometric properties assessed were face and content validity (by expert committee review), confirmatory factor analysis (CFA) and reliability.
Results: We enrolled 100 caregivers of HF patients who completed the CC-SCHFI. Most of caregivers were women (72%) with a mean age of 52 years old. The adapted version was named Brazilian version of CC-SCHFI. Face and content validity were indicative of semantic, idiomatic, experimental, and conceptual equivalence. CFA supported the original three-factor model (SCHFI v. 6.2) as having the best fit. In the present study were obtained lower fit indices compared to Italian study. The reliability of the instrument, expressed by Cronbach's alpha, was 0.78, 0.57 and 0.90 for the self-care maintenance, self-care management, and self-care confidence scales, respectively.
Conclusions: Brazilian version of CC-SCHFI was successfully adapted for its use in Brazil and can be used to measure the contribution of caregivers to self-care of HF patients. Nevertheless, further studies should be carried out to improve its psychometric properties.

Anticoagulation clinic - nursing intervention

S Susana Quintao[1]; IS Martins Sarmento[1]; JC Moreira Campos[1]; CB Girao Bastos[1]; IA Araujo[1]; FM Marques[1]; CF Fonseca[1]
[1]*Hospital de Sao Francisco Xavier, Day Hospital, Lisbon, Portugal*

Introduction: The consultation of oral anticoagulation (ACO) has undergone significant changes in recent years. This is based on referral protocols that promote accessibility and adherence to the proposed therapeutic regimen.
Objectives: To evaluate the efficiency of the method, namely the teaching performed to the user under antagonist of vitamin K (AVK) and family, through efficacy / safety and its adherence to the therapeutic regimen.
Methodology: Retrospective descriptive study, through the Gota v.8.5.0.5.6 program, of time monitoring in the therapeutic interval (TIT), by the Rosendaal method, as well as clinical events related to ACO with AVK. The consultation performed by the nurse, according to pre-defined protocol under medical supervision. INR is performed by point-of-care and drug dosage according to the INR, instructions to the user / family (feeding, drug interaction, invasive procedures, falls and warning signs), problems are identified and validated learning. Throughout the teaching, the constant availability to clarify doubts in person or via telephone is demonstrated.
Population: Patients under chronic ACO therapy, monitored in this clinic, between 2010 and 2016.
Results: We performed 73386 ACO consultations with AVK on 404 women and 410 men, mostly aged 60-89 years, and 62.8% have atrial fibrillation. We obtained a TIT greater than 60% in 89.76% and greater than 65% in 85.9% of patients. As clinical events we recorded 41 cases of major bleeding, 293 minor bleeding, 20 thromboembolic events and 58 (all causes) deaths.
Conclusion: Excellency of TIT, well above what is usually reported in the literature and the low rate of thrombotic and hemorrhagic events, attest to the efficiency and safety of the method, that includes instruction/teaching to the patient and family, reflected in the excellent adherence to the therapeutic regimen and in the low number of events related to ACO.

P1257
Low perceived social support is associated with a poorer health related quality-of-life in heart failure patients living with an implantable cardioverter defibrillator

H Hanna Allemann[1]; A Stromberg[2]; I Thylen[2]
[1]*Linkoping University, Department of Medical and Health Sciences, Linkoping, Sweden*; [2]*Linkoping University, Department of Cardiology and Department of Medical and Health Sciences, Linkoping, Sweden*

Funding Acknowledgements: Medical Research Council of Southeast Sweden (FORSS)

Introduction: The associations between cardiovascular diseases, social support and health-related quality-of-life (HRQOL) have previously been explored. To our knowledge only two small-scaled studies have focused on social support in persons with heart failure (HF) and implantable cardioverter defibrillators (ICD) with or without resynchronisation therapy (CRT-D). Furthermore, studies investigating the association between social support and self-reported HRQOL in this population are lacking. This information could be of importance when designing interventions aimed at this group.
Purpose: The aim was to study HRQOL in relation to perceived social support status in a large cohort of persons living with HF and ICD/CRT-D.
Methods: Eligible adult ICD-recipients in the Swedish Pacemaker- and ICD registry were invited to participate in a cross-sectional study. For this sub-analysis, only the ICD-recipients diagnosed with HF was included. To assess perceived social support and HRQOL, validated self-reported questionnaires were used (Multidimensional Scale of Perceived Social Support and EuroQol-5D-3L).
Results: In total, 1,515 ICD-recipients with HF (67 ± 10 years, 19% female) had complete data on the outcome variables. About half of the participants had received their ICD (52%) as secondary prevention. Time elapsed since ICD implementation varied between 1-23 years, with 57% having had their ICD < 3 years. Nearly two thirds (65%) reported slight or much discomfort from their HF symptoms. Most persons had one or more co-existing health problem (89%) and most shared a household (79%). In total, 262 (17%) described a low/medium support and 1,253 (83%) experienced a high social support.
When comparing the groups depending on their perceived social support, this indicates that persons with low/medium social support have a poorer HRQOL compared to persons with high social support (index 0.72 vs. 0.80, p<.001). Significant differences in relation to perceived social support were found in three out of five HRQOL dimensions (p<.05). For persons with low/medium social support, 48% experienced problems with mobility, compared to 39% of those with high social support. In the dimension pain/discomfort, 63% with low/medium social support reported problems, whereas 48% with high social support experienced this. Fifty percent of those with low/medium social support had problems concerning anxiety/depression, compared to 29% amongst those with high social support. No differences were found concerning self-care and usual activity in the social support groups (7% vs 4% and 29% vs 25%).
Conclusions: Nearly every fifth person with HF and ICD/CRT-D experience a low/medium social support and their HRQOL is negatively affected. This makes these persons vulnerable. Lack of social support in itself is a risk factor for poor HRQOL why it is important to put focus on patient's supportive network during follow up, and in future interventions for persons with HF and ICD/CRT-D.

SCN5A polymorphisms associated with wolff-parkinson-white syndrome

A Anna Chernova[1]; S YU Nikulina[1]; G V Matushin[1]; I I Lebedeva[1]
[1]*Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation*

Background: The aim of this study was to investigate whether polymorphisms in SCN5A is associated with family Wolff-Parkinson-White (WPW) syndrome.
Wolff-Parkinson-White (WPW) syndrome is an autosomal-dominant heart disease characterized by an accessory pathway that arises from an aberrant conduction from the atria to the ventricles. Several mutations within the SCN5A gene were shown to be responsible for WPW. The gene SCN5A encodes the main cardiac sodium channel NaV1.5. This channel predominates the cardiac sodium current, INa, which underlies the fast upstroke of the cardiac action potential. As such, it plays a crucial role in cardiac electrophysiology. The protein encoded by this gene is an integral membrane protein and tetrodotoxin-resistant voltage-gated sodium channel subunit. This protein is found primarily in cardiac muscle and is responsible for the initial upstroke of the action potential in an electrocardiogram.
Methods: This first study of WPW in a Russian population comprises the clinical and genetic investigation of 20 Russian families, including 27 affected members. This study consisted of 47 patients with symptomatic WPW syndrome and 50 healthy controls. SCN5A genotypes were determined using real-time polymerase chain reaction assay. Genotype and allele frequencies of SCN5A gene between patients with WPW syndrome and healthy controls were ascertained using chi-square test or Fisher exact test when appropriate.
Results: SCN5A were genotyped in 47 patients (23 men and 24 women; age = 34.4 ± 18.0 years) with WPW syndrome and 50 healthy controls (22 men and 28 women; age = 36.8 ± 4.2 years). There were no significant differences between the two groups in terms of age and sex. The patients with AG and AG+GG genotypes had a significantly increased risk of WPW syndrome compared with those with GG genotype [odds ratio (OR) = 1.99, 95% confidence interval (CI) = 1.01-3.89, p = 0.045; OR = 1.99, 95% CI = 1.04-3.78, p = 0.037, respectively]. The allelic types were not associated with the risk of WPW syndrome. The patients with manifest type with AG and AG+GG genotypes had a significantly increased risk of WPW syndrome compared with those with GG genotype (OR = 2.86, 95% CI = 1.16-7.05,

p = 0.022; OR = 2.84, 95% CI = 1.19-6.80, p = 0.019, respectively). The patients with right-side accessory pathways with AG and AG+GG genotypes had a significantly increased risk of WPW syndrome compared with those with GG genotype (OR = 3.07, 95% CI = 1.25-7.51, p = 0.014; OR = 2.84, 95% CI = 1.19-6.80, p = 0.019, respectively). The allelic types were not associated with the risk of WPW types and locations.
Conclusions: This study shows that SCN5A gene may be associated with family WPW syndrome among a Russian population. Further studies are provided further evidence of the genetic heterogeneity of WPW.

P1259
CNP/NPR-B/NPR-C AND miRNA TRASCRIPTOMIC EVALUATION IN BLOOD SAMPLES OF HEALTHY DONORS BEFORE AND AFTER SANGIOVESE GRAPE JUICE ADMINISTRATION

B Svezia[1]; M Cabiati[2]; C Salvadori[2]; S Masotti[1]; ME Pe'[1]; V Lionetti[3]; C Passino[3]; S Del Ry[4]
[1]Sant'Anna School of Advanced Studies, Institute of Life Science, Pisa, Italy; *[2]Institute of Clinical Physiology of CNR, Pisa, Italy*; *[3]Institute of Life Science, Scuola Superiore Sant'Anna, Fondazione Toscana "G. Monasterio", Pisa, Italy*; *[4]Institute of Clinical Physiology of CNR, Institute of Life Science, Scuola Superiore Sant'Anna , Pisa, Italy*

Funding Acknowledgements: Studio delle proprietá cardiorigenerative dei microRNA contenuti nelle bacche d'uva di sangiovese toscano nella prevenzione dello scompenso cardiaco.

Background: Nutraceutical studies suggest that a regular intake of plant food has a long-term effect in preventing many diseases and in particular the grape is known to have healthy properties. Many studies were focused on the protective effect of grape consumption on cardiovascular diseases but the modulation of natriuretic peptides (NPs) system has not yet been taken into account. Among NPs members the C-type natriuretic peptide (CNP) is one that is principally involved in regulating cardiac hypertrophy and remodeling in patients after myocardial infarction (MI). Moreover, recent studies suggest that plant food are able to provide genetic material (miRNAs) that might influence gene expression in the recipient organism.
Purpose: to evaluate the mRNA expression of CNP and its specific receptors, NPR-B and NPR-C, in whole blood of healthy donors (HD; n = 7; age34 ± 5 years) before and after Sangiovese grape juice (HD+Sgj) (Vitis vinifera L) administration. Moreover, to investigate the possible miRNA modulatory role in human physiology the transcriptomic analysis of specific miRNA was carried out in the plasma of the same subjects. This study is preliminary to the following recruitment of MI patients.
Materials & Methods: Blood samples were collected into PAXgene blood RNA system tubes for RNA expression study and in K3/EDTA tubes for routinely analyses and circulating miRNAs detection. Total RNA and miRNAs were extracted with PAXgene blood RNA kit and miRNeasy Serum/Plasma kit (Qiagen, Italy) respectively. After specific reverse transcription process, the Real-time PCR reactions were performed in duplicate using CFX-96 detection system (Bio-Rad).
Results: Routinely analyses, NT-proBNP (cardiac function) and sST2 (markers of fibrosis) resulted within the limits of normality. CNP mRNA expression resulted increased in HD+Sgj compared to HD (2253 ± 831.7 vs. 4698 ± 2177). NPR-B and NPR-C transcripts resulted counter-regulated respect to CNP. Significant correlations were observed between CNP and NPR-C (p = 0.04) and between NPR-B and NPR-C (p = 0.03). The expression levels of miR-126 and miR-210, respectively associated with coronary heart disease and cellular hypoxia, did not show significant difference after Sgj intake. A slightly decreased in transcriptional levels were observed for miR-221, miR-320 and miR-295, associated with angiogenic and metabolic processes. Interesting, both plant miRNA increased in HD+Sgj(miR-159:0.49 ± 0.13 vs. 1.21 ± 0.80; miR-166:0.11 ± 0.02 vs. 0.54 ± 0.45).
Conclusions: Our data suggest the activation of CNP/NPR-B/NPR-C pathway after grape juice supplementation. The non-invasive induction of CNP expression could be a desirable achievement for MI patients in order to reduce progression to heart failure. Moreover, in these subjects we observed a plant miRNAs absorption that could suggest a possible epigenetic action. The study could represent an important background for the development of functional foods aimed at modulating gene expression.

P1260
Induction therapy in heart transplantation: Italian single-center experience

M Cottini[1]; GP Pedrazzini Giovanna[1]; GM Gabrilella Masciocco[1]; FT Fabio Turazza[1]; BL Botta Luca[1]; SL Silvia Zannoli[1]; FC Francesco Cislaghi[1]; RN Raffaella Nardella[1]; MM Maria Minnini[1]; SGP Sara Giulia Cornero[2]; MPG Maria Pia Gagliardone[1]; MF Maria Frigerio[1]; CR Claudio Russo[1]
[1]Niguarda Ca' Granda Hospital, Cardiovascular Department, Milan, Italy; *[2]University of Milan, Faculty of Medicine, University of Milan, Milan, Italy*

Purpose: The first few days and weeks after cardiac transplantation (CT) have particularly higher risk of allograft rejection. The immunosuppressive regimens for CT recipients are designed to provide additional strenght by administering specialized antibody induction preparations or high-dose intravenous corticosteroids (or a combination of both). We reported our single center experience in the induction therapy of CT patients.
Methods: We retrospectively reviewed 283 consecutive patients undergoing heart transplantation between 2008 and 2018 (61% male, mean age 50.13 ± 18.19 years old, 28,6% Emergency). Patients were divided in two groups according to the first CD4/CD8 ratio obtained after rATG administration (1 mg/Kg in 8 hours, operative room). In addition, our protocol consists in steroid administration (metilprednisolone (MP) 500 mg, operative room) followed by MP 250 mg/three times in ICU, then prednisone 0,8 mg/Kg/die (per os) with tapering to 0,1 mg/Kg/die in the following 2-6 months. Cyclosporine and tacrolimus were usually started on first or second postoperative day, as well as mycophenolate or everolimus. Through the first year, patients were followed closely, and done endomyocardial biopsies periodically. CCA was performed yearly or according clinical/instrumental judgment.
Results: 145 patients had a CD4/CD8 ratio > 1,5 (G1) while 138 patients had ratio < 1,5 (G2). In-hospital mortality was in G1 10,9% and in G2 7,1%. The early rejection requiring iv steroid therapy were 32,5% (G1 39,8% vs G2 22,1%, p < 0,05), the early graft failure was rare (G1 1,37% vs G2 0,72, p = 0,25). In the G1 group, the first documented incidence of acute cellular rejection was at 28 ± 3 days, the G1 possibility of repeated rejection was the 19,7% (vs G2: 5,4%, p < 0,05), and the G1 incidence of short-term infection was 23,1% (vs G2: 15,7%, p < 0,05).
Conclusion: The CD4/CD8 ratio > 1,5 had an increase incidence of in-hospital mortality at 30-days. The early monitoring of Cd4/CD8 addresses us to improve the management of CT recipients with a significant decrease of early graft failure, rejection and infection in the short-term postoperative period.

P1261
LMNA splice variant progerin is upregulated in dilated cardiomyopathy

M Moritz Messner[1]; SK Ghadge[1]; V Goetsch[1]; A Wimmer[1]; J Doerler[1]; G Poelzl[1]; MM Zaruba[1]
[1]Innsbruck Medical University, Cardiology, Innsbruck, Austria

Background: Mutations in the LMNA gene are a known cause of dilated cardiomyopathy (DCM) leading to heart failure, a growing health care problem worldwide. Hutchinson-Gilford syndrome (HGPS) is a premature aging disease also caused by defined mutations in the LMNA gene. The activation of a cryptic splice donor site leads to the transcription of a defective truncated prelamin A protein called progerin. Low levels of progerin are expressed in healthy individuals associated with ageing. The intention of this work is to address the role of progerin in dilated cardiomyopathy.
Methods and Results: mRNA expression levels of progerin were analyzed in heart tissues of DCM (n = 15) and non-failing hearts (NFH) (n = 10) as control and in blood samples from patients with DCM (n = 56) and healthy controls (n = 10). The expression of progerin mRNA in the human heart was confirmed by sequencing. MRNA levels derived from DCM hearts were significantly higher compared to NFH (1.27 ± 0.42 vs. 0.81 ± 0.24; p = 0.005). In contrast, there were no significant differences of progerin mRNA levels in whole blood cells of DCM patients compared to controls. Linear regression analyses showed that progerin mRNA in the heart is significantly negatively correlated to ejection fraction (r=-0.567, p = 0.003) and positively correlated to left ventricular enddiastolic diameter (r = 0.551, p = 0.004). Increased expression of progerin protein in cell nuclei of DCM hearts were also observed in Immunohistochemistry and Immunofluorescence analysis associated with increased TUNEL+ apoptotic cells.
Conclusion: This data suggest an upregulation of progerin in human DCM hearts and a correlation with left ventricular remodeling. Progerin might be involved in progression of heart failure and myocardial aging.

Potential value of TAM receptors plasma concentrations for early detection of pulmonary vascular involvement in a cohort of systemic sclerosis patients

A Giubertoni[1]; C Piccinino[1]; M Bellan[2]; M Sguazzotti[3]; E Ubertini[1]; A Dimagli[1]; F Grimoldi[3]; J Zanaboni[1]; P Sainaghi[3]; M Pirisi[3]; PN Marino[1]
[1]Hospital Maggiore Della Carita, Cardiology, Novara, Italy; *[2]Sant'Andrea Hospital, Division of Internal Medicine, Vercelli, Italy*; *[3]Hospital Maggiore Della Carita, Division of Internal Medicine, Novara, Italy*

Background: Early identification of Systemic Sclerosis (SSc) patients at hihher risk of developing Pulmonary Arterial Hypertension (PAH) is a mainstay in the management of SSc. However, traditional first-level tests have shown low sensitivity and

right heart catheterization is an invasive procedure reserved for definite diagnosis. Novel biomarkers might improve the specificity of screening algorithms currently available.

Purpose: We aimed to test the potential diagnostic value of two promising biomarkers, the soluble receptors sMER and sAXL for early identification of vascular involvement in SSc.

Methods: We prospectively recruited 80 patients affected by SSc in our PAH outpatient clinic. All patients underwent full clinical, laboratory and echocardiographic evaluation. Right heart catheterization was performed in 12 patients.

Results: According to guidelines definitions, 12/80 patients were diagnosed with PAH. Table 1 show the differences between groups, with respect to echocardiographic, laboratory and clinical data. In particular, patients affected by PAH showed higher sMER and sAXL concentrations (Figure 1, panel A). However, the mean Pulmonary Artery Pressure (PAP), was directly related to sAXL (?= 0.732; p = 0.007), but not to sMER plasma concentration (Figure 1, panel B).

Conclusions: sAXL and sMER plasma concentration are higher in SSc patients developing PAH; sAXL seems to be a promising biomarker for early identification of pulmonary vascular involvement requiring further investigation for timely treatment.

Table 1

	General population (N. = 80)	SSc (N. = 68)	PAH-SSc (N. = 12)	P
Age, years	67 (57 - 74)	65 (55 - 74)	70 (67 - 77)	0.09

Epicardial adipose tissue proteins in heart failure patients: new predictors of long-term atrial fibrillation

RM Agra Bermejo[1]; S Eiras[2]; M Rodriguez Manero[1]; R Fandino[1]; A Fernandez Trasancos[2]; J Sierra[1]; JR Gonzalez Juanatey[1]
[1]*University Hospital of Santiago de Compostela, Santiago de Compostela, Spain*; [2]*Instituto de Investigación Sanitaria de Santiago, Santiago de Compostela, Spain*

Background: Heart failure (HF) is known as an atrial fibrillation (AF) risk factor. Recently, an animal HF model has showed the contribution of epicardial adipose tissue (EAT) to arrhythmogenesis.
Purpose: our main objective was to study if released-proteins by EAT can be predictors of atrial fibrillation in HF patients.
Methods: We obtained EAT from 42 patients undergoing heart surgery with or without HF that survive after 3 years. Patients underwent heart surgery with previous atrial fibrillation were excluded. Released proteins by EAT were collected for 6 hours after being washing overnight. Adiponectin levels in supernatants were analyzed by ELISA. During the follow up (4,74 ± 0,93 years), patients with AF were identified. Differential adiponectin levels between patients with or without HF that developed AF was determined by unpaired t-test analysis. EAT-released proteins between patients whose develop or not AF was analyzed by Liquid Chromatography-Mass Spectrometry (LC-MS/MS).
Results: Our results showed that 22% of HF patients develop AF during follow-up and 13% in those without HF. Released adiponectin levels by EAT were higher in HF with AF during the follow-up than those without AF (14.3 ± 1.5 μg/mL vs. 7.0 ± 5.2 μg/mL; p = 0.03). Moreover, mass spectrometry identified a higher level of EAT-released proteins involved in fibrinolysis pathway (a-2-antiplasmin and plasminogen), leukocytes markers (CD5 antigen-like, leukocyte elastase inhibitor, neutrophil defensin 3) and apoptotic marker (annexin V) in those patients who develop AF.
Conclusions: Epicardial adipose tissue released proteins that could be new predictors of long-term atrial fibrillation in patients with HF and may be possible new therapeutic targets.

P1264

Holter ecg parameters and cardiac fibrosis on mri are stronger predictors of malignant vt and sudden cardiac death than left ventricle ejection fraction among patients with non-ischemic cardiomyopathy

A Azamat Zhambeev[1]; N Shlevkov[1]; O Stukalova[1]; A Gasparyan[1]; KH Tengizov[1]; V Shitov[1]; S Sokolov[1]
[1]*Cardiology Research and Production Center, Department of Arrhythimas, Moscow, Russian Federation*

Background: Risk-stratification of malignant ventricular tachyarrhythmias (VT) and sudden cardiac death (SCD) is one of the unresolved issues in patients with non-ischemic cardiomyopathies (NICMP).
Aim: to identify the most powerful predictors of malignant ventricular tachyarrhythmias and sudden cardiac death in patients with non-ischemic cardiomyopathy.
Methods: Twenty patients (14 males / 6 females, mean age = 55 ± 18 years) with NICMP and LVEF < 35% with recently implanted ICD or CRTD were included into the prospective study. During 19 (18-23) months of follow-up 5(25%) patients exhibit VTs/SCD (group 1), while the remaining 15 patients survived without sustained VTs (group 2). Multiple Holter ECG, echocardiography (ECHO) and contrast magnetic resonance imaging (MRI) parameters were compared between groups.
Results: The ROC-analysis of identified predictors of VTs/SCD in study patients are presented in the table.
Conclusion: The presence of multiple forms of ventricular ectopy on Holter ECG and more substantial cardiac fibrosis by contrast MRI are the most significant predictors of malignant VTs and SCD in patients with NICMP. These parameters are superior to LVEF by ECHO in their diagnostic significance according to ROC-analysis.

Parameters	Group 1 'VT/SCD' (n = 5)	Group 2 'No VT/SCD' (n = 15)
The number of couplet ventricular extrasystoles per day (by Holter ECG) The area under the ROC curve = 0.862	83 (13-124)	2 (0-9)
The total number of ventricular extrasystoles in VTs per day (by Holter ECG) The area under the ROC curve = 0,846	9 (6-11)	0 (0-4)
Total mass of fibrosis, gr (by cardiac MRI) The area under the ROC curve = 0,80	7,3 (6,4-8,1)	4,0 (3,5-5,9)
The LVEF, % (by ECHO) The area under the ROC curve was 0,785	20 (20-23)	30 (25-32)
Determine 2 and more VT (by Holter ECG) The area under the ROC curve = 0,78	80%	20%
Maximum heart rate per day (by Holter ECG) The area under the ROC curve = 0,769	121 (109-130)	100 (97-113)
Number of segments with endomyocardial fibrosis (by cardiac MRI) The area under the ROC curve = 0,746	3 (1-3)	1 (0-2)

P1265

Increased expression of galectin-3 in the interstitium of left ventricular myocardium of dogs with chronic heart failure

V Singh-Gupta[1]; RC Gupta[1]; HN Hani Sabbah[1]
[1]*Henry Ford Hospital, Detroit, United States of America*

Background: Accumulation of collagen in the cardiac interstitium termed "reactive interstitial fibrosis (RIF)" occurs in heart failure (HF) with reduced ejection fraction (HFrEF) as well as in HF with preserved EF (HFpEF). This maladaptation leads to increased myocardial stiffness that negatively impacts ventricular filling. RIF also results in poor oxygen diffusion between capillaries and cardiomyocytes leading to cardiomyocyte hypoxia that promotes cellular contractile dysfunction and triggers programmed cell death. The protein galectin-3 (GAL-3) is a member of the lectin family. Increased expression of GAL-3 is implicated in the development of fibrosis in multiple organs including the heart. Elevated levels of GAL-3 are significantly associated with higher risk of death in patients with HF. In this study, we examined whether increased expression of GAL-3 occurs in the LV interstitium of dogs with chronic HF that also manifest increased levels of RIF.
Methods: Studies were performed in LV tissue obtained from 7 normal (NL) dogs and 7 dogs with coronary microembolization-induced HF. Frozen LV sections, 6 μm in thickness, were used for fluorescence immunostaining with antibodies against myosin heavy chain and GAL-3. DAPI (4', 6-diamidino-2-phenylindole) was used to stain nuclei. Confocal images of stained sections were obtained with an Olympus Fluoview FV1000 laser scanning biological microscope. From each section, 4-6 fields, each ~10 mm2, were randomly selected for laser scanning and subsequently used to calculate the percent area occupied by GAL-3 (%aGAL-3) from each field. The percent area occupied by RIF (%aRIF) was also calculated using frozen sections stained with fluorescein-labeled peanut agglutinin.
Results: In NL dogs, the %aRIF was 3.70 ± 0.07 and %aGAL-3 was 2.40 ± 0.45. In dogs with HF, the %aRIF increased significantly to 13.5 ± 0.57 ($p < 0.05$) and the %aGAL-3 increased significantly to 12.82 ± 1.15 ($p < 0.05$).

Conclusions: The results indicate that in dogs with HF, increased levels of RIF is associated with increased interstitial levels of GAL-3. The findings support the use of this dog model of HF to evaluate the effects of GAL-3 inhibitors for preventing or attenuating RIF that develop during HF.

Chronic Heart Failure–Pathophysiology and Mechanisms

Necroptosis in post-ischemic heart failure: causality of cardiac dysfunction and remodeling?

M Martin Lichy[1]; A Szobi[1]; J Hrdlicka[2]; M Kocmalova[3]; T Rajtik[1]; S Franova[3]; J Neckar[2]; F Kolar[2]; A Adameova[1]
[1]Comenius University, Department of Pharmacology and Toxicology, Faculty of Pharmacy, Bratislava, Slovak Republic; *[2]Academy of Sciences of the Czech Republic, Institute of Physiology, Prague, Czech Republic*; *[3]Comenius University, Jessenius Faculty of Medicine in Martin, Bratislava, Slovak Republic*

Funding Acknowledgements: APVV15-607, VEGA 1/0271/16, UK/68/2017

Background: Although failing hearts of ischemic etiology have been associated with progressive cell death, it is still unknown which particular cell death mode is responsible for the phenotypes of this cardiac syndrome. In addition, underlying molecular pathways of this cell death remain to be elucidated.
Purpose: The purpose of this study was to investigate the executive mechanisms of necroptosis in heart failure (HF) involving the canonical necroptotic pathway (RIP1-RIP3-MLKL) and the translocation of the terminal execution protein into the plasma membrane, a cytotoxic event understood to induce cell lysis during necroptosis. By this approach, we intended to determine whether these mechanisms can underlie cardiac dysfunction and remodeling of non-ischemic tissue.
Methods: In male Wistar rats, ligation of the left anterior descending artery was used to induce myocardial infarction progressing to chronic HF of ischemic etiology. 42 days after surgery, echocardiography was performed along with collagen content measurement. Non-ischemic left ventricular tissue was subjected to subcellular fractionation and immunoblotting analysis. To get a more comprehensive view on investigated mechanisms, tissue inflammatory response (cytokines) and oxidative stress (MDA) were assessed.
Results: In post-ischemic failing hearts, which exhibited adverse remodeling and contractile dysfunction as assessed by LVDd, LVDs and a decrease in FS, collagen content and pro-inflammatory cytokine levels were increased. Preliminary analysis showed, that p-MLKL as well as both phosphorylated and nonphosphorylated RIP3 levels were increased in whole cell lysates of HF indicating necroptosis execution. Supportive to these findings, detailed analysis of the membrane fraction of diseased hearts has also revealed the increased expression of pSer232-RIP3. In addition, in this particular fraction, increased extent of oxidative stress was evidenced by higher MDA and NOX2 levels. On the other hand, we were unable to detect any significant apoptosis activation in HF group. Neither active csp-8, a crucial negative regulator of necroptosis and an apoptotic initiator, nor other apoptotic markers such as p17/p19 csp-3, p25 PARP1 and Bcl2/Bax ratio were increased in failing hearts.
Conclusions: This study has indicated that the alterations in pro-necroptotic proteins and their membrane relocalization rather than apoptosis activation, might, at least in part, contribute to decreased adaptation against ischemic injury and thereby promote the phenotypes of HF.

P1267

Genetic diagnosis in transthyretin cardiac amyloidosis - a single Polish centre experience

M Monika Gawor[1]; A Sioma[1]; L Mazurkiewicz[1]; M Franaszczyk[2]; J Szczygiel[1]; M Spiewak[3]; B Milosz-Wieczorek[3]; M Marczak[3]; Z Bilinska[4]; J Grzybowski[1]
[1]Institute of Cardiology, Department of Cardiomyopathies, Warsaw, Poland; *[2]Institute of Cardiology, Department of Medical Biology, Warsaw, Poland*; *[3]Institute of Cardiology, CMR Unit, Warsaw, Poland*; *[4]Institute of Cardiology, Unit for Screening Studies in Inherited Cardiovascular Diseases, Warsaw, Poland*

Background: Transthyretin (TTR) cardiac amyloidosis is an underdiagnosed but increasingly recognized cause of heart failure and may result from the aggregation of mutant or wild-type TTR protein in the heart. More than 100 different disease-causing mutation of the TTR gene have been reported. Countries such as Portugal, Japan and Sweden have certain high frequency mutations. Common mutations in Poland have yet to be identified.
Purpose: This is the first study of the mutational pattern of patients with TTR cardiac amyloidosis in Poland.
Methods: We performed clinical and genetic testing of patients with TTR cardiac amyloidosis, who were hospitalised in our centre in 2014-2017.
Results: Three unrelated male patients have been diagnosed with hereditary TTR cardiac amyloidosis. All of them had the same rare TTR mutation - Phe33Leu. Age of onset differed among the patients. Two patients had first symptoms in their late fifties. One patient had first symptoms in his late forties. Characteristic clinical features included cardiomyopathy with increased left and right ventricular wall thickness, sparkling echoes and decreased function of left ventricle. Cardiac Magnetic Resonance (CMR) scan revealed the presence of late-gadolinium-enhancement (LGE) in subendocardial part of left ventricular segments. The standard 12-lead electrocardiogram demonstrated low QRS voltage in the limb leads and nonspecific ST-T wave changes. One patient had persistent atrial fibrillation. Laboratory examination revealed significantly increased level of troponin T and NT- proBNP. Two patients suffered from painful peripheral polyneuropathy. One patient had carpal tunnel syndrome.
Conclusions: Here we report Polish patients with a rare TTR mutation Phe33Leu. To date, the TTR Phe33Leu mutation has only been reported in two unrelated American families with Polish descent, one Polish-Lithuanian family, one Swedish family and one Taiwanese family. Previous literature data about Polish background in families with Phe33Leu mutation, and our experiences, suggest that this TTR mutation may be frequent in Polish population.

P1268

Differential endomyocardial expression of SGLT1 in idiopathic dilated cardiomyopathy patients with and without diabetes mellitus.

M Marc Vanderheyden[1]; W Heggermont[1]; S Verstreken[1]; R Dierckx[1]; M Goethals[1]; J Bartunek[1]
[1]OLV Hospital Aalst, Cardiovascular Center, Aalst, Belgium

Introduction: Sodium-Glucose cotransporter(SGLT) is thought to be expressed in the heart although more information is required to delineate the exact subtypes expressd in human heart. We herein investigated whether apart from the common glucose transporter 1(Glut1) and 4(Glut4), SGLT1 and 2 are expressed in human heart. In addition to test for differences related to diabetes mellitus we analyzed SGLT mRNA expression in idiopathic dilated cardiomyopathy(CMP) pts with diabetes mellitus (DM+) and without diabetes mellitus(DM-) .
Methods and results : LV endomyocardial biopsies obtained from 76 patients with heart failure due to idiopathic dilated cardiomyopathy (ejection fraction $44 \pm 3\%$; LVEDVI: 115 ± 7 ml/m2 and PCWP 20 ± 1 mm Hg) were analyzed for SGLT1, SGLT2, Glucose transporter 1(Glut1) and glucose transporter 4(Glut4) mRNA gene expression using quantitative RT-PCR.
Results: Baseline hemodynamic characteristics were similar between DM+ and DM- pts(EF: 43 ± 6 vs $43 \pm 3\%$, p = ns; PCWP 20 ± 2 vs 20 ± 1 mm Hg, p = ns). Whereas no difference in Glut1 and Glut4 mRNA gene expression was observed between both groups(p = ns), DM+ pts were characterized by significantly higher SGLT1 expression compared to DM-pts($0{,}2391 \pm 0{,}0280$ vs $0{,}1597 \pm 0{,}0125$ rel units; p = 0.007). In both groups SGLT2 endomyocardial mRNA was not detected. A significant correlation was noted between SGLT1 and Glut4 in DM-pts ($p < 0{,}0001$) which was not the case for DM+ pts (p = 0.07).
Conclusion: Besides the common Glut1 and Glut4, SGLT1 not SGLT2 plays a role in glucose transport in CMP. The identification of higher SGLT1 gene expression in DM+ CMP and the lack of any relationship between SGLT1 and Glut4 might suggest that glucose uptake is differentially regulated in DM+ pts compared to DM-pts.

Decreased longitudinal left ventricular contraction after acute myocardial infarction in a porcine model revealing the opportunity for new treatments with mechanical circulatory support devices

J Karlsson[1]; K Solem[2]; E Heiberg[1]; M Kanski[1]; D Nordlund[1]; R Jablonowski[1]; S Kopic[1]; C Xanthis[1]; S Bidhult[1]; H Engblom[1]; D Erlinge[3]; H Arheden[1]; M Carlsson[1]
[1]Lund University, Department of Clinical Sciences Lund, Clinical Physiology, Lund, Sweden; *[2]Syntach AB, Lund, Sweden*; *[3]Lund University, Department of Clinical Sciences Lund, Cardiology, Sweden, Lund, Sweden*

Funding Acknowledgements: Swedish foundation for strategic research, Swedish research council, The Swedish Heart-lung foundation

Introduction: Decreased systolic atrio-ventricular plane displacement (AVPD) towards the apex independently predicts mortality. In humans, 60% of left ventricular (LV) stroke volume (SV) is generated by the AVPD and longitudinal displacement is decreased after an acute myocardial infarct (AMI). How an AMI changes AVPD and LVSV at the individual level is not known from patient studies. Such information could motivate the design of future treatments and devices aiming to improve the AVPD.
Purpose: To investigate the relationship between the AVPD and LVSV in an experimental AMI model.

Methods: Nine pigs (landrace, circa 40 kg) were studied with cardiac MRI before AMI (baseline) and 2 hours after AMI reperfusion. AMI was induced by a selective coronary occlusion with a PCI-balloon under fluoroscopy guidance for 40 minutes in the left anterior descending artery (LAD) with varied distances distal to the first diagonal branch (D1). Cardiac MRI at baseline and 2 hours post-AMI included short axis and long axis cine images for function and volumes. Late gadolinium enhancement (LGE) were acquired post-AMI in the same image planes for infarct size. MR images were analysed using the post-processing software Segment v2.1 (http://segment.heiberg.se). The AVPD was measured in the 2-chamber, 3-chamber and 4-chamber cine images. Values are given as mean ± SD, results were compared using Pearson correlation and paired t-test.
Results: LAD occlusion caused an infarct size of 30.0 ± 9.8% (range 19.5-45.0%) and significant decrease in ejection fraction (EF) from 46.0 ± 6.4% to 33.0 ± 7.3% ($p < 0.001$). LV end-diastolic volume decreased (95.1 ± 12.2ml to 83.9 ± 17.1 ml) and end-systolic volume increased (51.1 ± 7.2ml to 56.3 ± 13.5 ml) 2 hours post-AMI. AVPD was significantly correlated to LVSV ($p < 0.0001$, $R = 0.82$) (Fig 1) and cardiac output ($p = 0.038$, $R = 0.49$). AMI caused decreased AVPD (9.3 ± 1.4mm to 6.0 ± 1.5mm) and LVSV (43.9 ± 9.6ml to 27.6 ± 7.8ml) in all pigs compared to baseline ($p < 0.001$ for both) (Fig 2 & 3). The correlation between relative decrease in AVPD and infarct size did not reach statistical significance ($p = 0.09$, $R = 0.59$).
Conclusions: This study has shown that AMI causes concomitant decrease in LVSV and AVPD and a strong correlation between LVSV and AVPD within the same population. The coefficient of determination ($R^2 = 0.67$) is similar to the 60% contribution of AVPD to LVSV found in humans. The relationship between decreased AVPD and LVSV after AMI in this porcine model enabels testing of future treatment options with mechanical circulatory support devices designed to improve AV-plane motion.

P1270

Enhancing fatty acid utilization ameliorates mitochondrial fragmentation and cardiac dysfunction via rebalancing OPA1 processing in the failing heart

X Xing Zhang[1]; Y Guo[1]; F Gao[1]
[1]*Fourth Military Medical University, Xi'an, China People's Republic of*

Background: Heart failure is characterized by reduced fatty acid (FA) utilization associated with mitochondrial dysfunction. Recent evidence has shown that enhancing FA utilization may provide cardioprotection against heart failure. However, the underlying mechanism of lipoprotection in the failing heart is poorly understood.
Purpose: Our aim was to investigate the effects and the underlying mechanisms of cardiac FA utilization on cardiac function in response to pressure overload.
Methods: Transverse aortic constriction (TAC) was used in C57 mice to establish pressure overload-induced heart failure.
Results: TAC mice fed on a high fat diet (HFD) exhibited increased cardiac FA utilization and improved cardiac function and survival compared with those on control diet. Such cardioprotection could also be provided by cardiac-specific overexpression of CD36. Notably, both HFD and CD36 overexpression attenuated mitochondrial fragmentation and improved mitochondrial function in the failing heart. Pressure overload decreased i-AAA protease YME1L expression and induced the proteolytic cleavage of the dynamin-like guanosine triphosphatase OPA1 as a result of suppressed FA utilization. Enhancing FA utilization upregulated YME1L expression and subsequently rebalanced OPA1 processing, resulting in restoration of mitochondrial morphology in the failing heart. In addition, cardiac-specific overexpression of YME1L exerted similar cardioprotective effects against heart failure to those provided by HFD or CD36 overexpression.
Conclusions: These findings demonstrate that enhancing FA utilization ameliorates mitochondrial fragmentation and cardiac dysfunction via rebalancing OPA1 processing in pressure overload-induced heart failure, suggesting a unique metabolic intervention approach to improving cardiac functions in heart failure.

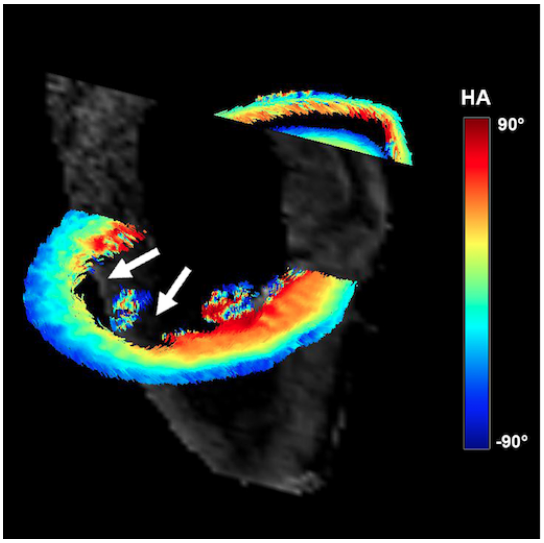
The role of subendocardial form and function in heart failure with preserved ejection fraction

N Beyhoff[1]; D Lohr[2]; A Foryst-Ludwig[1]; E Smeir[1]; R Klopfleisch[3]; LM Schreiber[2]; U Kintscher[1]
[1]*Charité - Universitätsmedizin Berlin, Center for Cardiovascular Research, Berlin, Germany*; [2]*University Hospital Würzburg, Comprehensive Heart Failure Center (CHFC), Chair of Cellular and Molecular Imaging, Würzburg, Germany*; [3]*Free University, Department of Veterinary Pathology, Berlin, Germany*

Funding Acknowledgements: Supported by the DZHK (German Centre for Cardiovascular Research) and by the BMBF (German Ministry of Education and Research)

Background: The subendocardium is highly susceptible to injury and is therefore considered to be the earliest myocardial layer affected during cardiovascular disease



Diffusion tensor imaging analysis.

development. Several studies have postulated the involvement of subendocardial damage in heart failure with preserved ejection fraction (HFpEF), especially at subclinical state. However, morphologic-functional studies regarding the impact of subendocardial status in HFpEF are currently lacking.
Purpose: To identify the role of subendocardial damage in HFpEF.
Methods: 129/Sv mice were injected with a high-dose of Isoproterenol (ISO) to induce isolated subendocardial damage, or saline as appropriate control. Animals were challenged with a graded exercise test protocol to determine exercise capacity. Two weeks after final treatment with ISO/saline, comprehensive echocardiographic examinations and gene expression analyses were performed. Myocardial microstructure was assessed by histologic analyses and diffusion tensor magnetic resonance imaging (Picture).
Results: ISO-treatment led to pronounced fibrotic lesions, predominantly in the subendocardial layer, which was accompanied by increased atrial natriuretic peptide

levels ($p < 0.05$ vs. control). Left-ventricular ejection fraction and fractional shortening were comparable among both groups. Global Longitudinal Strain and -Strain Rate were markedly impaired due to ISO-treatment, whereas radial and circumferential strain values remained unaffected. Subendocardial fibrosis induced a moderate diastolic dysfunction and increased estimated filling pressures in the absence of lung congestion or reduced exercise capacity.
Conclusion(s): Isolated subendocardial fibrosis alone is able to induce several characteristics of HFpEF, however, does not lead to heart failure symptoms or signs under experimental conditions. Diagnostic assessment of subendocardial form and function may contribute to early assessment of cardiac damages in subclinical patients at risk to develop HFpEF, and may consequently improve prevention of functional impairment.

P1272

Impact of aging and obesity on cardiac function in female mice

C Aad Withaar[1]; C Gehlken[1]; HHW Sillje[1]; SPC Lam[1]; RA De Boer[1]
[1]*University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands*

Background/Introduction: Advancing age, female gender, and obesity are well-recognized as key risk factors in heart failure. Aging and co-morbidities are believed to drive cardiac dysfunction, by impacting the loading conditions and by inducing systemic inflammation, which may partly explain why elderly obese woman are at higher risk. Despite this knowledge, female sex is largely neglected in pre-clinical research. We aimed to develop a murine model of heart failure based on the co-existence of these 3 risk factors
Purpose: To study the effects of aging and diet on cardiac function in female mice, and to determine the morphology and cardiac function assessed by echocardiography.
Methods: 4 and 18 months old female C57BL/6 WT mice were fed a low fat diet (LFD) or high fat diet (HFD) for 12 weeks. Cardiac function where determined before sacrifice by echocardiography and strain analysis where performed offline. Body mass composition and oral glucose tolerance were determined.
Results: Mice maintained on a HFD develop obesity and body mass exceeded LFD-fed control mice by 25% after 8 weeks ($p < 0.01$). HFD further significantly increased total fat mass compared to LFD-fed animals ($9{,}0 \pm 1{,}0$ vs $25{,}5 \pm 1{,}4$ g $p < 0.01$). HFD-fed mice had a significantly impaired glucose handling after oral glucose tolerance test (area under the curve, $p < 0.01$). Total heart weight to tibia length ratio (8.3 ± 0.5 vs $11{,}5 \pm 0.8$ $p = 0.018$) was increased in 18 month mice on HFD compared to LFD. Normal left ventricular ejection fraction and fractional shortening was observed in HFD and LFD-fed animals. Strain analysis shows myocardial alterations suggesting contractile dysfunction. This is associated with the development of heart failure, as evidenced by decreased effort tolerance on treadmill running between young and old animals, and further decreased by HFD.
Conclusion We conclude that a 'multiple hit' model in female mice exposed to long term HFD results in a phenotype that resembles heart failure as commonly observed in elderly human female patients.

P1273

Functional state of the rats myocardium in postinfarction and diabetic remodeling

D Dina Kondrat'eva[1]; SA Afanasiev[1]; SV Popov[1]
[1]*Research Institute of Cardiology, Tomsk Scientific Center, Tomsk, Russian Federation*

Background/Introduction: Diabetes mellitus aggravates of the cardiovascular diseases progression with a deterioration of the contractile function of the heart and serious violations of intracellular metabolism. This is determined by changes in energy metabolism, which is a trigger of functional and structural changes in the cardiomyocytes, including the alteration of the intracellular calcium handling proteins and, consequently, excitation-contraction uncoupling of cardiomyocytes.
Purpose: Aim of study is evaluate the relation between level of calcium handling proteins and energetic metabolism in contractile dysfunction of rat myocardium in postinfarction and diabetic damage.
Methods: Study was performed on adult Wistar rats with postinfarction lesion and diabetes mellitus alone and combined. The postinfarction lesion developed after 6 weeks of coronary artery occlusion. Diabetes mellitus was induced by single injection streptosotozine (60 mg/kg i.p.). Inotropic reaction on rest period (4 - 60 sec) were studied on papillary muscles, bathed at 37 C in oxygenated Krebs-Henzelait solution and stimulated at 0.5 Hz. The protein levels of SERCA2a and RyR2 in myocardium were determined by Western blotting. Oxygen consumption by mitochondria was measured using a Clark-type oxygen electrode. The activity of lactate dehydrogenase and succinate dehydrogenase were determined by histochemical method.
Results: Development of postinfarction damage alone in experimental animals led to depression of post-rest contraction. The force of post-rest twitches was better preserved in diabetic rats and postinfarction rats with diabetes mellitus. This post-rest behavior corresponded with alteration of calcium handling proteins level (RyR2, SERCA2a). The most decrease of RyR2 and SERCA2a levels were obtained in postinfarction rats. In rats with combined pathology preserving levels of calcium handling proteins were found. The development of monopathologies resulted in a significant decrease in the intensity of energy production. The energy production activity in diabetic rats was more significant decrease in compare with postinfarction rats, despite the fact that contractile disturbance of postinfarction rats was more severe. However, the development of the combined pathology resulted in the preservation of the energy production near the control level. The activity of succinate dehydrogenase (Krebs cycle key enzyme) and lactate dehydrogenase (glycolysis key enzyme), and mitochondrial respiration were most preserved in postinfarction rats with diabetes mellitus.
Conclusion: Development of diabetes mellitus in postinfarction rats facilitate preservation of inotropic reserve of myocardium, expressed by post-rest reaction, and expression of Ca2+-ATPase and ryanodine receptors and activity of key enzymes of glycolysis, Krebs cycle, and oxidative phosphorylation in comparison with postinfarction rat without diabetes mellitus.

P1274

Expression profile of the natriuretic peptide system in the heart of mice with myocardial infarction exposed to sangiovese grape juice.

B Svezia[1]; M Cabiati[2]; M Matteucci[1]; C Passino[3]; ME Pe'[1]; V Lionetti[1]; S Del Ry[4]

Monasterio", Pisa, Italy*; [4]*Institute of Clinical Physiology of CNR, Institute of Life Science, Scuola Superiore Sant'Anna , Pisa, Italy*

Funding Acknowledgements: Studio delle proprietá cardiorigenerative dei microRNA contenuti nelle bacche d'uva di sangiovese toscano nella prevenzione dello scompenso cardiaco

Background: Despite many studies were focused on the protective effect of grape and wine consumption on cardiovascular diseases, to the best of our knowledge the modulation of natriuretic peptides (NPs) system was not taken into account.
Purpose: to investigate the impact of grape juice (Vitis vinifera L., cv. Sangiovese) administration on the NPs system in a murine model of myocardial infarction.
Materials & Methods: Male and female C57BL/6J mice (n = 33) 10-12 weeks' old were randomly subdivided into 3 groups: 1) Sham (n = 7); 2) Mice with myocardial infarction (MI, n = 15); 3) MI fed for 4 weeks with a standard diet supplemented with 200 µl/die of Sangiovese juice25% vol/vol concentrated (MI+Sj, n = 11). Two-dimensional (2-D) echocardiography was performed on mice at baseline and 4 weeks after surgical procedures (MyLab 25, EsaoteSpA Genova, Italy). Cardiac function was evaluated by measuring left ventricle ejection fraction (LVEF). At the end of the protocol, the animals were sacrificed by isoflurane overdose and cardiac tissue collected for biomolecular and histological analysis. The transcriptomic profile of the NPs system in cardiac tissue of all animals was investigated by Real-Time PCR; histological analyses were also performed to assess myocardial fibrosis.
Results: The 2D- echocardiographic studies showed that infarcted animals developed progressive cardiac remodelling over 4 weeks from left anterior descending coronary artery ligation. LVEF% was significantly decreased in MI when compared to sham ($p < 0.01$). MI+Sj showed a partial recovery of LVEF. MI showed a higher expression level of ANP and BNP ($p = 0.0002$) compared to the sham. After Sangiovese grape juice administration to mice with myocardial infarction, ANP mRNA cardiac level decreased whereas BNP expression did not show any significant difference and CNP was significantly higher compared to sham ($p = 0.007$) and MI ($p = 0.03$). The mRNA cardiac expression of NPR resulted higher in MI than in the sham also if only NPR-B mRNA level was statistically significant ($p = 0.02$). In MI+Sj the mRNA expression of NPR-B ($p = 0.002$) and NPR-C showed a lower level with respect to MI, whereas NPR-A gene expression increased compared to MI. Masson's trichrome stain on infarcted heart tissue revealed a decrease in infarct size in MI+Sj as compared with MI ($p = 0.08$). In the MI+Sj, the fibrotic tissue was decreased compared to vital myocardium thereby indicating a reduction in cardiomyocytes death.
Conclusions: The data obtained suggest that in ischemic condition Sangiovese grape juice is able to modulate NPs system. In particular, CNP plays a direct cardioprotective effect through the activation of its specific receptor NPR-B but also acting as an EDHF by binding NPR-C. The data obtained suggest that in ischemic condition Sangiovese grape juice is able to mitigate fibrosis and to modulate NPs system.

P1275

Characterisation of a novel mouse-pacemaker model for mechanistic studies of dyssynchrony in heart failure

M Stahlberg[1]; R Nakagawa[2]; DI Lee[2]; B Lin[2]; DI Bedja[2]; G Zhu[2]; DA Kass[2]
[1]Karolinska Institutet, Stockholm, Sweden; [2]Johns Hopkins University of Baltimore, Department of Cardiology, Baltimore, United States of America

Funding Acknowledgements: National Institute of Health; American Heart Association; Swedish Research Council; Swedish Society of Medicine; Swedish Society of Cardiology

Purpose: Cardiac dyssynchrony plays an important role in clinical heart failure. However, the biological mechanisms underlying its detrimental effects are not well defined and have only been studied in larger mammals where genetic manipulation is not feasible. The purpose of this study was to develop a model of dyssynchronous heart failure in the mouse, a genetically modifiable animal, and to use this model to characterize the effect of dyssynchrony on phospho-kinase activation in failing hearts.
Methods: Moderate heart failure was induced in wild type (C57/Bl6) mice by ischemia-reperfusion (I/R). After recovery, an ECG-lead and a right ventricular pacing (RVP) lead was implanted Mice were then divided into two groups: (i) Dyssynchronous heart failure (DysHF - four weeks of continuous RVP) and (ii) Synchronous heart failure (SyncHF - no pacing). Nonfailing/instrumented wild type mice served as additional control (WT-CON). Fractional shortening (FS) and left ventricular end-systolic diameter (LVESD) were measured using echocardiography after pacemaker surgery and after four weeks. Mice hearts (DysHF, n = 8; SyncHF, n = 8; WT-CON, n = 5) were analyzed for relative levels of phosphorylation/activation of 46 kinase phosphorylationsites using a phospho-kinase array kit.
Results: QRS duration increased from 10 ± 1 ms in sinus rhythm to 15 ± 2 ms with RVP ($p = 0.002$). The septum-to-posterior wall motion delayed was prolonged with RVP (22 ± 6 ms) compared to sinus rhythm (3 ± 3 ms, $p < 0.001$). After four weeks FS was unchanged in the SyncHF group ($36 \pm 6\%$) but decreased in the DysHF group (24 ± 6, $p < 0.01$ vs. both others). LVESD was unchanged after four weeks in SyncHF mice (2.4 ± 0.4 mm) but was significantly increased in DysHF mice (3.1 ± 0.6 mm, $p < 0.01$). Eleven of 46 kinase phosphorylation sites had significantly higher level of phosphorylation/activation in the DysHF compared to SyncHF groups (Figure 1).
Conclusion: RVP induces left ventricular dyssynchrony in mice that when applied for four weeks accelerates heart failure remodeling in infarcted hearts. This is associated with phosphorylation/activation of kinases that regulate a range of cellular processes including cell survival, energy homeostasis and hypertrophy. This novel model can now be used to study the effect dyssynchrony on cellular signaling pathways in a genetically modifiable animal for the first time.

MIF deletion prevents heart failure after acute myocardial infarction by controlling macrophage polarization

PL Luedike[1]; MH Heisler[1]; U Hendgen-Cotta[1]; UF Floegel[2]; IH Hilgendorf[3]; JB Bernhagen[4]; TR Rassaf[1]
[1]University of Duisburg-Essen, West German Heart Center, Department of Cardiology and Vascular Medicine, Essen, Germany; [2]University Hospital Duesseldorf, Department of Cardiology, Pulmonology and Vascular Medicine, Duesseldorf, Germany; [3]University of Freiburg, Department of Cardiology and Vascular Medicine, Freiburg, Germany; [4]Ludwig-Maximilians University, Institute for Stroke and Dementia Research (ISD), Munich, Germany

Funding Acknowledgements: Deutsche Forschungsgemeinschaft DFG

Objectives: This experimental study aimed to investigate whether genetic deletion of MIF influences the inflammatory healing and consecutive cardiac function after myocardial infarction.
Background: The fine-tuned recruitment of monocytes to the myocardium represents the first step of healing after myocardial ischemia. Damage-associated pattern molecules (DAMPs) are the first to initiate the sterile immune response via toll like receptors (TLR) like TLR4. MIF controls TLR4 expression in leukemia macrophages and is also released during myocardial I/R and exhibits
auto- and intracrine cardioprotective activities. However, MIF's role in cardiovascular disease is dual, as it also has a clear-cut cardioprotective role in the setting of myocardial I/R injury contrasting the bonafide negative function in the promotion of arteriosclerosis development. Whether MIF-mediated regulation of TLR4 expression in myocardial tissue might influence the inflammatory environment after myocardial ischemia is unknown.
Methods: Wild type (WT) and MIF-KO mice underwent myocardial ischemia (50min) and subsequent reperfusion in vivo. Functional magnetic resonance imaging (MRI) was performed before and after I/R (d0,d1,d3,d5,d7,d28). Detection of late gadolinium enhancement (LGE) was applied for infarct size quantification. MIF-dependent TLR4 expression was analyzed in bone-marrow derived monocytes (BMDM) in vitro and in Ly6Chi monocytes after myocardial I/R in vivo. Polarization behavior of WT and MIF-KO macrophages was analyzed after M-CSF-mediated differentiation of BMDM.
Results: Infarct sizes (LGE) were similar in MIF-KO and WT mice at d1 after I/R ($n = 9$; $p = ns$). Ejection Fraction (EF) of MIF-KO and WT mice did not alter before and at d1 after I/R, however at d7 MIF-KO mice showed an improved recovery of heart function that persisted until d28 after I/R ($n = 9$; $*p < 0.05$). Furthermore, pharmacological inhibition of MIF by MIF-antibody led to a decreased expression of TLR4 in BMDM in vitro. Moreover, pharmacological MIF inhibition through intravenous application of MIF-antibodies attenuated TLR4 expression measured by FACS analysis on immigrated Ly6Chi-monocytes at d1 after myocardial I/R injury in vivo demonstrated. In vitro experiments revealed that stimulation with IL-4 and DAMPs showed a distinctly attenuated polarization of MIF-KO macrophages into inflammatory subtypes with decreased iNOS and increased arginase 1 expression.
Conclusion: MIF deficiency promotes polarization of functionally beneficial macrophages after myocardial I/R injury, thus improves healing and prevents development of ischemic heart failure. These date give first insights into a potential cardioprotective role of MIF inhibition after prolonged ischemia and reperfusion injury.

Funding Acknowledgements: GINOP-2.3.2-15-2016-00040, NKFIH K115990, UNKP-17-4-I-SZTE-43 (M. Sarkozy) and UNKP-17-2-I-SZTE-30 (M.G. Kovacs)

Background: A deleterious, late-onset side effect of thoracic radiotherapy is the development of radiation-induced heart disease (RIHD). It is characterized by left ventricular hypertrophy and diastolic dysfunction and often manifests as heart failure with preserved ejection fraction. The miR-212/132 family is a crucial regulator of pathologic cardiac hypertrophy and miR-132 has been proposed as a therapeutic target for heart failure.
PurposeTherefore, our aim was to investigate whether the miR-212/132 cluster and its hypertrophy associated targets play a role in the development of RIHD.
Methods RIHD was induced in a clinically relevant chronic rat model. A single dose of 50 Gy was delivered to the whole heart of the animals and 19 weeks later, cardiac function was assessed by transthoracic echocardiography and tissue samples collected for histology and molecular analysis.
Results: Echocardiography and histology revealed left ventricular hypertrophy with preserved ejection fraction, diastolic dysfunction and interstitial fibrosis in the irradiated group. The miR-212/132 cluster was overexpressed and FOXO3 mRNA was repressed in the irradiated hearts. In contrast, total FOXO3 protein level failed to decrease in response to heart irradiation. However, cardiac phospho-FOXO3 level and phospho-FOXO3/total FOXO3 ratio showed a non-significant increase in irradiated hearts. Cardiac total AKT level and the phospho-AKT/total AKT ratio failed to change in the irradiated hearts as compared to controls.
Conclusions: Cardiac overexpression of the miR-212/132 cluster might play a role in the development of cardiac hypertrophy in RIHD. The development of cardiac hypertrophy seems to be independent of the AKT/FOXO3 mediated pathways in RIHD.

Funding Acknowledgements: Funding was provided by Bayer AG

Background/Introduction: Elevated levels of arginine-vasopressin (AVP) may mediate deleterious effects via renal V2 and vascular V1a AVP receptors. While the only outcome trial in HF with a selective V2 receptor antagonist (EVEREST-trial) showed no mortality benefit, a respective trial in HF patients with a dual V1a/V2 receptor antagonist has not been conducted so far. Preclinical studies suggest beneficial aquaretic and hemodynamic effects of a dual acting V1a/V2 antagonist. However, there is a lack of predictive diagnostic readouts used in experimental models in view of transferability in a clinical scenario.
Purpose: Noninvasive cardiac output monitoring with bioreactance can be used to identify and differentiate the hemodynamic effects of a dual acting V1a/V2 antagonist compared to a selective V2 antagonism avoiding hemodynamic changes induced by anesthesia which would be required for invasive assessment.
Methods: Healthy beagle dogs (n = 9) were instrumented with telemetric sensors for hemodynamics assessment. Additional surface sensors were attached for noninvasive cardiac output monitoring (CHEETAH NICOM™, USA) and bladder catheter were placed for investigations diuretic effects. We compared the hemodynamic effects of a novel, dual acting V1a/V2 vasopressin receptor antagonist, BR-6819 with the selective V2 antagonist tolvaptan during intravenous AVP challenge in conscious animals.
Results: BR-6819 (3 mg/kg) induced a significant increase of 0.26 l/min ($p = 0.029$ vs. placebo) in cardiac output (CO) and 0.58 (l/min)/m2 ($p = 0.018$ vs. placebo) in cardiac index (CI) during vasopressin challenge, whereas tolvaptan was without any significant effect, respectively. In addition, BR-6819 treatment significantly reduced (-36.4%, $p = 0.015$) total peripheral resistance vs. placebo. BR-6819 and tolvaptan significantly ($p < 0.05$) increased urinary volume.
Conclusion: This is the first study demonstrating the feasibility of noninvasive cardiac output monitoring to differentiate between V1a/V2 and selective V2 antagonism. Use of the dual V1a/V2 antagonist BR-6819 significantly improved CO and CI while tolvaptan was without any effect here. Noninvasive cardiac output monitoring has the potential to improve the transferability of preclinical findings to the clinics.

P1279

Enzyme activity evaluation and tissue distribution of Neprilysin in heart failure

MC Asensio Lopez[1]; MC Sanchez Perez[1]; A Hernandez Vicente[1]; E Cabrero Romero[2]; D Fernandez Vazquez[2]; DJ Vazquez Andres[2]; MT Perez Martinez[1]; E Fernandez[1]; DA Pascual Figal[2]; AM Lax[1]
[1]Biosanitary Research Institute of Murcia (IMIB-Arrixaca)., Cardiology, Murcia, Spain; *[2]University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain*

Background: Neprilysin is a ubiquitous enzyme involved in degradation of numerous vasoactive peptides, notably including natriuretic peptides (NP). Despite recent data indicate a substantial mortality reduction associated with use of neprilysin inhibition in patients with reduced ejection fraction, had no data about enzymatic activity and tissue distribution.
Purpose: To evaluated the enzymatic activity and tissue distribution of neprilysin in presence of myocardial infarction and heart failure.
Methods. Wistar rats underwent MI by left coronary artery ligation were sacrificed at 4 weeks after surgery (n = 5 per group). Sham-operated animals were also included. Frozen tissue (100 mg) was homogenized using N2 liquid in adequate buffer. Neprilysin enzyme activity was measured with a fluorometric assay for the generation of free dansyl-D-Ala-Gly (DAG) from N-dansyl-Ala-Gly-D-nitro-Phe-Gly (DAGNPG)., using 562 and 342 nm as wavelengths of emission and excitation, respectively. Unpaired t-test was used to compare neprisilin activity respect sham in each tissue and, for multiple comparisons between tissues, paired t-test with Holm-Bonferroni correction was used.
Results: Neprylisin activity exhibited a gradient between tissues, with the highest level in lungs ($p < 0.01$ for all comparisons) followed by liver ($p < 0.01$) compared with kidney and heart); whereas, kidney and myocardial tissues showed similar levels. This gradient was observed in both sham animals and infarcted animals after 4 weeks (Figure 1). Of interest, animals with myocardial infarction and heart failure showed higher levels in all non-cardiac tissues as compared with sham animals: lung (1375.8 ± 166.0 vs. 152.8 ± 15.6, $p = 0.0017$), liver (68.55 ± 2.49 vs. 12.66 ± 0.76, $p < 0.0001$), and kidney (16.23 ± 3.96 vs. 2.29 ± 0.79, $p = 0.023$). In myocardium, neprylisin activity was observed at higher levels than sham (1.61 ± 0.22) in both infarcted (29.85 ± 1.84, $p < 0.0001$) and ischemic border of left ventricle (29.0 ± 4.73, $p = 0.0044$); however no differences were observed in remote myocardium compared with sham (2.59 ± 0.76, $p = 0.28$) (Figure 1).
Conclusion: Neprilysin activity has a gradient of levels from lung, to liver and kidney/heart. In the presence of myocardial infarction and heart failure, an increase of neprylisin activity was observed in non-cardiac tissues, as well as infarcted and ischemic myocardium, but not in remote non-ischemic myocardium.

Different pathophysiological mechanisms for heart failure progressions in male and female mRen2 rats

N Nikolett Olah[1]; T Csipo[1]; A Kovacs[1]; GA Fulop[1]; I Edes[1]; Z Papp[1]; A Toth[1]
[1]University of Debrecen, Division of Clinical Physiology, Institute of Cardiology, Debrecen, Hungary

Funding Acknowledgements: The work is supported by the UNKP-17-2-I and the GINOP-2.3.2-15-2016-00043 project

Introduction: In view of the effectiveness of renin-angiotensin-aldosteron system (RAAS) inhibitors in heart failure (HF) therapy RAAS appears to play a crucial role in the pathomechanism of HF. Transgenic rats (mREN2) harboring an extra copy of renin gene develop fulminant hypertension at an early age which progresses into HF.
Purpose: Here we studied hypothetical gender dependent differences in the pathomechanisms in the mREN2 model of HF.
Methods: Mean arterial pressure (MAP) of transgenic renin overexpressing rats (mRen2) were high in both females (138.5 ± 11.7 mmHg) and males (168 ± 5.8). Internal non-transgenic wild type rats (WT) served as controls. To reveal the mechanisms contributing to HF progression, levels of RAAS activity in isolated tissues were studied in vitro.
Results: Male rats had higher mortality till 1 year of age (survival rate: males: 23% versus females: 75%). At 1 year rats exhibited signs of mixed systolic and diastolic cardiac dysfunctions, indicating the progression of hypertension to HF (EF in females: WT: 68.28 ± 2.1 versus mRen2: 68.26 ± 2.3; males: WT: 74.7 ± 6.1 versus mRen2: 60.2 ± 4.9; E/A: in females: WT: 1.74 ± 0.03 versus mRen2 1.47 ± 0.052; males: WT: 1.56 ± 0.01 versus mRen2: 1.06 ± 0.038). In parallel, a dysregulation of the tissue RAAS was observed. In particular angiotensin converting enzyme (ACE) activity was higher in male mREN2 left ventricles (9.5 ± 0.8 U/mg) than in those of their WT littermates (5.5 ± 0.2 U/mg), while no similar differences were observed in the lungs (71 ± 21 versus 76 ± 9 U/mg) and in any of the above parameters in females. Activities of angiotensin 2 eliminating ACE2 enzymes were similar in the left ventricles, lung, kidney of WT and mRen2 animals irrespectively of gender.
Conclusions: Our work illuminated important gender differences in the progression of hypertension to HF. In particular, our data implicate that left ventricular ACE activities increase in males more than in females. This is in accordance with the higher clinical effectiveness of ACE inhibitors and the higher HF risks in males than those in females.

P1281

Vanhoutte and Bowditch phenomena in heart failure: their relation to ischemia-reperfusion impact

L Tacu[1]; M Ivanov[2]; E Cobet[3]; A Rotaru[4]; L Ciobanu[2]; V Rotaru[1]; V Lutan[1]; IU Feghiu[1]; V Cobet[1]; M Popovici[2]
[1]State University of Medicine and Pharmacy, Chisinau, Moldova Republic of; *[2]Institute of cardiology , Chisinau, Moldova Republic of*; *[3]State University of Moldova , Biopharmaceutical chemistry , Chisinau, Moldova Republic of*; *[4]Harvard Medical School, Cambridge, United States of America*

Aim: Evaluation of both 15,16-epoxyeicosatrien (15,16-EET) induced coronarodilation and Bowditch's staircase in experimental heart failure (HF) as well as their

influence on ischemic contracture and functional recovery of isolated heart during repefusion.
Material and methods: HF was reproduced by doxorubicin administration in rat (16 mg/kg in 2 weeks). Vanhoutte's phenomenon was estimated by coronary flow raising rate in izovolumic isolated heart perfused by Langendorff method during action of 15,16-EET (10-4 M). Bowditch's staircase was assayed by electrically induced heart rate (HR) rise till maximal level suitable to left ventricle (LV) systolic pressure elevation (LVSP). Ischemic contracture was appreciated by LV end-diastolic pressure (LVEDP) at the end of global 20 min ischemia period followed by 30 min period of reperfusion when LVSP dynamics has been recorded. Likewise, ischemia-reperfusion impact was attested in condition of 15,16-EET action during pre-ischemia (20 min) and reperfusion as well as after maximal HR reaching.
Results: Coronarodilation effect of 15,16-EET has not been compromised in HF, because the coronary flow increased like in control comparatively to basal value (13,2 ± 1,2% vs 13,9 ± 1,1%). However, Bowditch's staircase was earlier interrupted in comparison to control according to maximal HR matching to positive slope of LVSD: 285 ± 22,6 vs 372 ± 29,4 1/min ($p < 0,05$). Maximal ischemic LVEDP was significantly higher in HR: 47,6 ± 3,3 vs 24,9 ± 1,8 mmHg ($p < 0,001$). On the other hand LVSP was at the end of reperfusion lower than control: 72,4 ± 6,5 vs 112,3 ± 7,5 mmHg ($p < 0,01$). Remarkably, 15,16-EET action before ischemia and during reperfusion notably improved dynamics of LVEDP and LVEDP in both control and HF (in the last even more evidently). Relative diminution of LVEDP measured 14,3 ± 1,4% in HF and 12,5 ± 1,2% in control, and LVESP increment: 15,1 ± 1,5% vs 13,7 ± 1,3%. If the ischemia-reperfusion onset started after frequency pacing ischemic contracture and functional LV recovery worsened similarly in both control and HF series: LVEDP increased by 19-20% while LVSP decreased by 17-18%.
Conclusions: 1. Derived (in cytochrome P450 biochemical way) from arachidonic acid 15,16-EET increases coronary flow in HF similarly to control and could be an important factor of coronary regulation by hyperpolarization mechanism in cases of endothelium dependent compromised coronary reactivity.
2. 15,16-EET mitigates ischemia-reperfusion impact in HF while HR elevation worsens ischemic contracture and LV contraction recovery in reperfusion.

P1282
A link between oxidative stress and CaMKII activity in post-ischemic failing hearts: a subcellular analysis with pathophysiological implications

T Tomas Rajtik[1]; A Szobi[1]; M Lichy[1]; J Hrdlicka[2]; P Galis[1]; J Neckar[2]; F Kolar[2]; A Adameova[1]
[1]Comenius University, Faculty of Pharmacy, Department of Pharmacology and Toxicology, Bratislava, Slovak Republic; *[2]Academy of Sciences of the Czech Republic, Institute of Physiology, Prague, Czech Republic*

On behalf of: Laboratory of Experimental Cardiology
Funding Acknowledgements: APVV-15-607, VEGA-1/0271/16 and VEGA-2/0151/17.

Background: Heart failure (HF) is generally associated with increased oxidative stress (OS) which has been suggested to be linked with detrimental activity of Ca2+/calmodulin-dependent protein kinase II (CaMKII) and thereby dysregulation of Ca2+-homeostasis. As CaMKII is widely localized in various cellular compartments throughout the cell, oxidative damage of these particular cellular fractions can underlie the increase in kinase activity observed in HF and thereby its influence on cellular function such as excitation-contraction coupling.
Purpose: To test this hypothesis, we measured the activity of CaMKII and various forms of oxidative stress in whole cell lysates, and subcellular fractions, such as cytoplasmic (Cy), membrane (Me) and mitochondrial (Mi) in left ventricles of failing hearts and sham operated hearts.
Methods: In male Wistar rats, a ligation of left descending coronary artery was performed to induce post-ischemic HF. Immunoblot analysis was used to assess the levels and activity of CaMKII (evidenced as p-Thr286-CaMKII). Lipoprotein oxidation, protein S-glutathionylation (PSSG) and protein carbonylation (PC) were evaluated by measuring the levels of TBARS, formation of glutathionylated proteins in non-reduced samples and carbonylated proteins detected in DNPH-derivatized lysates, respectively.
Results: In the whole cell lysates of failing hearts, oxidative stress evidenced itself as higher levels of PSSG and slightly increased carbonylated proteins. In the Me fraction of HF, only TBARS were increased. Despite the unchanged levels of PSSG in Me fraction in HF, there was a positive correlation with p-Thr286-CaMKII indicating a novel link between glutathione homeostasis and the kinase activity. In addition, a negative correlation of p-Thr286-CaMKII with PC was found in this fraction suggesting the abolishment of its activity under such conditions. In the mitochondria of diseased hearts, TBARS and PC were higher and were not in line with the active form of CaMKII.
Conclusions: This study has shown that the various types of OS are selectively upregulated in particular cellular compartments of failing hearts. Moreover, we have indicated for the first time that contractile dysfunction of post-ischemic HF might be, at least in part, linked with the activity of the membrane-bound CaMKII being dependent on protein S-glutationylation and carbonylation.

P1283
Lung diffusion capacity is positively correlated to pulmonary capillary wedge pressure in heart failure: a capillary volume effect?

T Tania Deis[1]; L Balling[1]; K Rossing[1]; E Wolsk[1]; F Gustafsson[1]
[1]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark

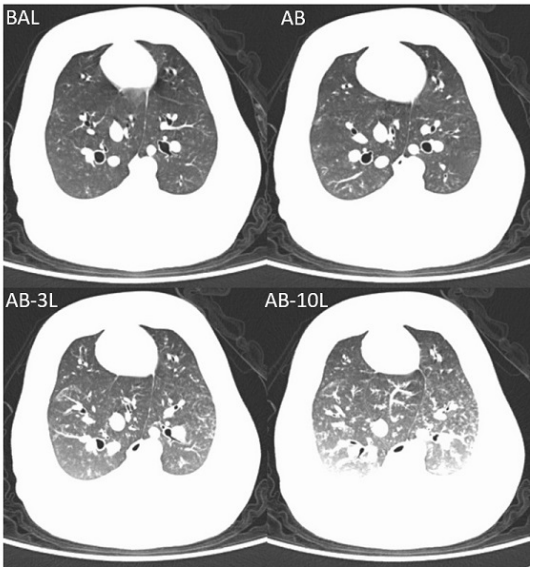
Background: Patients with heart failure (HF) are known to have a reduced pulmonary diffusion capacity for carbon monoxide (DLCO) but little is known about how hemodynamics relate to lung function. This study tested the hypothesis that pulmonary capillary wedge pressure (PCWP) is associated with alveolar volume adjusted pulmonary diffusion capacity (DLCO/VA) in patients with advanced chronic HF.
Methods: We retrospectively studied the data on 262 HF patients (mean age 51 ± 13) with a LVEF < 45 % referred non-urgently for evaluation for heart transplantation or LVAD, who underwent right heart catheterization and lung function testing. Univariate and multivariate linear regression models were constructed to examine the associations between DLCO/VA, FVC, FEV1 and hemodynamic parameters (PCWP, central venous pressure (CVP), cardiac index (CI), mean pulmonary artery pressure (MPAP) and mean arterial pressure (MAP)) as well as other factors known to affect lung function in HF.
Results: There was no significant correlation between hemodynamics and FVC or FEV1. DLCO/VA correlated positively with PCWP in both univariate ($p < 0,001$) and multivariate ($p = 0,012$) regression analysis but did not correlate to other hemodynamic factors. DLCO/VA was not a significant predictor of mortality. FVC and FEV1 were found to be significant predictors of mortality (HR for lower versus highest FEV1 and FVC tertiles 2,0 (1,4-2,9) and 1,9 (1,3-2,6)).
Conclusions: Surprisingly, PCWP was positively associated with DLCO/VA. This relation might be driven by increased lung capillary volume (Vc) in patients with lung congestion. Unlike dynamic lung parameters, DLCO did not predict mortality.

P1284
Quantitative estimation of extravascular lung water volume and preload by dynamic 15O-H2O positron emission tomography

R Roni Nielsen[1]; J Sorensen[2]; L Tolbod[2]; AKO Alstrup[2]; P Iversen[2]; CA Fredriksen[1]; J Frokiaer[2]; HJ Harms[2]
[1]Aarhus University Hospital, Skejby, Department of Cardiology, Aarhus, Denmark; *[2]Aarhus University Hospital, Department of Nuclear Medicine & PET center, Aarhus, Denmark*

Funding Acknowledgements: Lundbeck Foundation, Denmark

Background: Pulmonary congestion is an important finding in heart failure. It can be assessed invasively by the PICCO method using transpulmonary thermodilution to measure extravascular lung water content (EVLW) and preload by global



CT during the study of a pig

end-diastolic volume (GEDV) and pulmonary wedge pressure (PCWP) by pulmonary catheterization. However, at present, no reliable non-invasive methods are available for quantitatively measuring EVLW and preload.
Purpose: The present study was undertaken to evaluate whether measures derived from positron emission tomography (PET) performed to measure myocardial perfusion can be used to estimate EVLW and preload in a porcine model of pulmonary congestion.
Methods: Eight anesthetized and ventilated pigs were studied. Pulmonary congestion was induced by a combination of beta-blockers (BB), angiotensin-2 agonist (AT-2a) and saline infusion. Right heart catheterization, PICCO, computerized tomography (CT) and dynamic 15O-H2O-PET was performed. Transcardiac and transpulmonary transit times were measured by PET to calculate EVLW and GEDV.
Results: PCWP increased from 8 ± 2 mmHg at baseline to 29 ± 5 mmHg during intervention ($p < 0.001$). EVLW increased from 521 ± 76 mL to 973 ± 325 ml ($p < 0.001$) and GEDV from 1068 ± 170 ml to 1254 ± 85 ml ($p < 0.001$). 15O-H2O PET measures of EVLW increased from 566 ± 151 ml to 797 ± 231 ml ($p < 0.001$) whereas GEDV was lower than by PICCO but increased from 364 ± 60 ml to 524 ± 92 ml ($p < 0.001$). Both EVLW and GEDV measured with PICCO and 15O-H2O-PET correlated ($r2 = 0.40$, $p < 0.001$; $r2 = 0.40$, $p < 0.001$, respectively). EVLW correlated positively with Hounsfield units by CT (PICCO: $r2 = 0.36$ $p < 0.001$, PET: $r2 = 0.46$ $p < 0.001$) and GEDV with PCWP (PICCO: $r2 = 0.20$ $p = 0.01$, PET: $r2 = 0.29$ $p = 0.002$).
Conclusion: Here we demonstrate that preload and extravascular lung water content can be measured simultaneously and quantitatively during myocardial perfusions assessment using 15O-H2O-PET. Importantly, these parameters are spin-off during myocardial perfusion imaging and do not presuppose additional PET examinations. The prognostic implications of these quantitative measures can now be assessed non-invasively in outpatient settings.

P1285

Risk score for heart failure with reduced ejection fraction

R Rajesh[1]; M Al Jarallah[1]
[1]*Sabah Al Ahmad Cardiac Center, Al Amiri Hospital, Cardiology , Kuwait, Kuwait*

Today in our day to day practice there are many such calculators available and we know very few physicians adhere to them during their practice. Its mainly due to time consuming and a number of variables that they have to enter into an app from the available risk score calculators. In such scenarios, we need a simple tool which is handy to all such physicians which can be easily used while seeing your ambulatory heart failure patients. Its important to decide in which category the subject belongs to and when to give them follow-up appointment. Such an easy systematic approach can help reduce frequent hospitalisations in such patients.
We are suggesting a new prognostic risk calculator for heart failure patients with reduced ejection fraction. The treating physicians should need to take only 3 variables for getting the prognostic score which is possible during the busy schedule. As we all know the vicious cycle where heart failure is linked to kidney diseases and anemia. Hence we developed a simple tool by encorporating the values which is more relevant to all three systems above mentioned. Here we need to find ejection fraction (EF,%), estimated glomerular filtration rate (e-GFR, ml/min) and haemoglobin levels (Hb, g/dL). (Table 1)
However, the above suggested HF risk model is yet to be validated in large clinical trials in its prediction of mortality in HF patients.
Seattle heart failure model (SHFM) is one among the available risk predicting calculator in heart failure. Here again the number of variables to be entered is more compared to ours. Our RHF score equation was derived while investigating the association of heart failure with various risk factors and its relevance to mortality. Anticipated population where this score is applicable is all patients with HFrEF. At present the cut off value is derived by calculating the severity of heart failure with other variables. It is too early to comment on the expected impact of treatment on this score. More details regarding cut off value and its impact on treatment will be published soon with the results after applying this score in a large cohort of heart failure patients.

Table 1 Rajan's HF risk score

	Rajan's HF risk score (R^{HF}Score) = (EF xe-GFR)/Hb	
#	Category	R^{HF}Score
1.	High Risk	0 - 50
2.	Moderate Risk	50 - 125
3.	Low Risk	125 - 250
4.	Minimal Risk	>250

EF = ejection fraction , e-GFR = estimated glomerular filtration rate, Hb = haemoglobin

P1286

Age-related abnormalities in myocardial connexin43 expression, intercellular coupling and ultrastructure may facilitate heart dysfunction.

N Tribulova[1]; J Kohutova[2]; B Szeiffova Bacova[1]; T Egan Benova[1]; M Sykora[1]; P Weismann[3]; J Zurmanova[2]; E Goncalvesova[4]; M Barancik[1]
[1]*Slovak Academy of Sciences, Institute for Heart Research , Bratislava, Slovak Republic*; [2]*Charles University of Prague , Department of Physiology, Faculty of Science, Prague, Czech Republic,, Prague, Czech Republic*; [3]*Comenius University, Institute of Anatomy, Faculty of Medicine, Bratislava, Slovak Republic*; [4]*The National Institute of Cardiovascular Diseases, Department of Failing Heart, Bratislava, Slovak Republic*

Rationale: Heart failure is at the highest incidence in the elderly and often associated with atrial or ventricular rhythm disturbances. Myocardial gap junction (GJ) connexin (Cx) channels ensure action potential propagation and coordinated contraction. Age-related decline in Cx43 contribute to sinoatrial node dysfunction and ocurrence of atrial fibrillation. However, the role of Cx43 in deterioration of left ventricular function by ageing is poorly elucidated.
Objective: We aimed to explore whether ageing itself may facilitate heart dysfunction and increase a risk of malignant ventricular arrhythmias due to abnormal expression and/or distribution of Cx43 and alterations of the myocardial ultrastructure.
Methods: Analysis were carried out on left ventricle of the hearts of young 4-weeks-old and aged, 24-weeks-old, male and female guinea pigs. Cx43 expression, its phosphorylation and expression of PKCe were quantified using Western blot. Cryostat sections were processed for 'in situ' Cx43 immunofluorescence labeling and quantitative evaluation. Ultrathin sections of the left ventricle were examined in transmission electron microscope to reveal subcellular alterations of the cardiomyocytes and their junctions.
Key Results: The apparent differences in the distribution of Cx43 between young and old guinea pig heart were detected in males and females left ventricles. Besides intercalated disc-related 'end-to-end' type of Cx43-positive GJ, the abundant 'side-to-side' type on lateral cardiac cell membranes were observed in young animals. Lateral distribution was much less pronounced in old guinea pig heart ventricles. Both, quantitative image and western blot analysis revealed significantly lower expression of Cx43 in aging hearts of males (by 45%) and females (by 25%) guinea pigs. Likewise, functional phosphorylated forms of Cx43 were significantly decreased in old versus young male and female animals. In parallel, expression of PKCe was lower in old comparing to young guinea pigs ventricle. Ultrastructure examination revealed that enhanced extracellular collagen deposition in elder hearts is accompanied by shorter GJ profiles in comparison to young animals and also extracellular space between fascia adherens junctions increased from about 20 nm to more than 30 nm by aging. In addition, mostly electron-lucent mitochondria suggesting low energetic state were found in old hearts whereas electron-dense mitochondria reflecting high energetic state were observed in young male and female guinea pigs.
Conclusions: Unlike young guinea pig heart exhibiting high level of cell-to-cell coupling and mitochondria energetic state the old guinea pig heart are characterized by decline of Cx43 expression, impairment in intercellular coupling and reduced energetic state that likely contributes to increased propensity to ventricular arrhythmias and heart dysfunction.

P1287

The role of TLR-9 in ischemia-reperfusion injury following acute myocardial infarction.

M Max Lenz[1]; A Kiss[2]; P Hohensinner[3]; K Krychtiuk[3]; J Wojta[4]; W Speidl[4]
[1]*Medical University of Vienna, Vienna, Austria*; [2]*Medical University of Vienna, Center for biomedical research, Vienna, Austria*; [3]*Medical University of Vienna, AKH - Department of internal medicine II - Cardiology, Vienna, Austria*; [4]*Medical University of Vienna, Core Facilities, Vienna, Austria*

Backround: Ischemia and subsequent reperfusion cause cell death within the reperfused tissue, followed by mitochondria leaking from the cells to the extracellular space. As recently demonstrated by experimental studies and clinical trials, circulating extracellular mitochondrial DNA (mtDNA) exhibits proinflammatory effects by binding to its corresponding receptor TLR-9. This activation causes chemotaxis and activation of neutrophils as well as monocytes which play a pivotal role in further damaging the infarcted tissue. Nonetheless, the exact role of TLR-9 in ischemia-reperfusion injury due to acute myocardial infarction remains to be unknown.
Methods: By ligation of the left coronary artery, ischemia was induced in male Wistar rats. After an ischemic period of 30 minutes, reperfusion was initiated by removal of the ligature. At this point, the animals were randomly divided into groups receiving TLR-9 antagonist ODN 2088 (bolus: 500μg and subsequently 1500μg over 24h via

subcutaneous pump) or ODN-control (bolus: 500μg and subsequently 1500μg over 24h via subcutaneous pump). Circulating neutrophil count was determined by flow cytometry 24h after the operation. Furthermore, hemodynamic measurements and histological analyses were performed 28 days thereafter.
Results: Rats receiving treatment with ODN 2088 showed significantly lower counts of circulating neutrophils after 24h compared to animals receiving ODN-control (ODN 2088: 22866 ± 7992/μl Vs. ODN-control: 35651 ± 15121/μl, p = 0.02). After 28 days, we analyzed for subsequent changes in cardiac repair in these animals. Though, hemodynamic parameters remained unchanged, left ventricular mass was significantly decreased accompanied by an enhanced aneurysm formation which was characterized by a 50% thinning of the left ventricular wall (ODN 2088: 0.93 ± 0.41mm Vs. ODN-control: 1.96 ± 0.75mm, p = 0.02).
Conclusion: We used the TLR-9 antagonist ODN 2088 to inhibit TLR-9 signaling within the first 24h following ischemia and reperfusion. This was in order to illuminate the involvement of TLR-9 in immune system activation and cardiac repair. Our presented data suggests that inhibiting TLR-9 results in a reduced activation profile of neutrophils 24h after the ischemic event. Furthermore it leads to changes in myocardial structure including a dramatic reduction of wall thickness and ventricular muscle mass. We speculate that these structural changes could cause severe defects including rupture at later stages of the healing process.

P1288

Is it possible the use of sacubitril/valsartan in HFrEF and hemodialysis?

J Jose Morgado[1]; AM Ana J Manovel Sanchez[1]; RL Raul Lopez Aguilar[1]; CCV Crecencio Camacho Vazquez[1]; FF Fernando Fernandez Giron[1]; BM Basilio Martinez Mora[1]; JF Jose Francisco Diaz Fernandez[1]
[1]Hospital Juan Ramon Jimenez, Cardiology, Huelva, Spain

Background/Introduction: Chronic heart failure (HF) is a major public health problem associated with high mortality rates.
Sacubitril/valsartan (S/V) acts by simultaneous inhibition of neprilysin (enhancement of natriuretic peptides) and inhibition of the effects of angiotensin II. It has cardiovascular and renal therapeutic effects, and has demonstrated the superiority over enalapril in reducing mortality and morbidity in patients with Heart failure with reduced ejection fraction (HFrEF) in PARADIGM-HF trial. It is unknown the use of sacubitril/valsartan in patients with end-stage kidney disease (ESKD).
Purpose: Describe our initial experience in our centre using sacubitril/valsartan in patients with HFrEF on long-term dialysis.
Methods: This study was performed as a prospective, single-center study from June 2017 to December 2017 in the University Juan Ramon Jimenez Hospital, Spain. We included three patients with this characteristics.
We describe it's safety and efficacy. Patients were verbally informed about this drug.
Results: Case 1: 68 year-old man with a medical history of hypertension, type II diabetes, end-stage renal disease (ESRD) due to diabetes, New York Heart Association (NYHA) class III-IV functional status, 34% LVEF due to ischemic heart disease. We decided to change valsartan to sacubitril/valsartan. Actually, 6 months later, he received maximum dose, and has improved his functional status (class II NYHA) with no changes in blood pressure and good hemodialysis tolerance.
Case 2: Patient 2 is a 62 year-old man with a medical history notable for systemic hypertension and ESRD due to uncertain etiology, (NYHA) class III functional status and 23% LVEF due to Non-ischemic heart disease. Because of sintomatology, losartan was changed to sacubitril/valsartan. Three months later, he received 24/26 mg with improvement in functional status and similar blood pressure and hemodinamic tolerance to dialysis.
Case 3: 53 year-old man with a medical history for systemic hypertension and diabetes, associated with ESRD due to uncertain etiology, (NYHA) class III functional status and 20% LVEF due to Non-ischemic heart disease. We added sacubitril/valsartan to his treatment, removing losartan. 1 month later, he remains asymptomatic and we have increased dose (maximum dose) with normal blood pressure
Conclusion(s): This study shows the efficacy and safety of sacubitril/valsartan in 3 patients with hemodialysis and HFrEF, with no adverse effects; although it is limited by the small number of patients.
It is necessary confirmatory studies to test this hypothesis.

P1289

How to predict thrombi formation in patients with apical aneurysms

R P Santos[1]; A Nunes Ferreira[1]; J Rigueira[1]; IS Goncalves[1]; JR Agostinho[1]; IA Ricardo[1]; T Rodrigues[1]; N Cunha[1]; R Placido[1]; C David[1]; FJ Pinto[1]; AG Almeida[1]
[1]Cardiology Department, Santa Maria Hospital, CHLN, CCUL, Lisbon University, Lisbon, Portugal

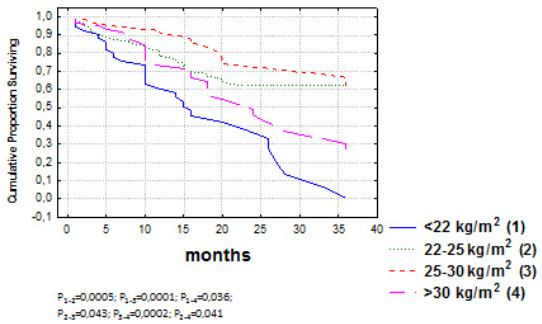
Introduction: The clinical relevance of left ventricular aneurysms (LVA) is based on the fact that they are preferred sites for arrhythmias and thrombus formation, which may secondarily imply severe thromboembolic complications. Thus, the identification of predictors of these complications may have an impact on the monitoring or therapy of patients at higher risk.
Purpose: To identify, in a population with a diagnosis of LVA, possible predictors of left ventricular thrombus (LVT) formation.
Methods: All patients diagnosed with transthoracic echocardiograms from January 2015 to December 2016 were selected. Clinical, electro / echocardiographic and therapeutic parameters prior to the echocardiogram were analysed and the relationship with the presence of LVT was evaluated through Kaplain-Meier analysis and cox regression.
Results: A total of 78 patients with LVA (80.8% males, age 63.9 ± 11.7 years) were identified. Most patients had ischemic heart disease (85%), followed by dilated cardiomyopathy (14%) and valve heart disease (1%). The left ventricular ejection fraction (LVEF) was 35.8 ± 10.8%, the left ventricular end-diastolic volume (LVEDV) was 87.7 ± 37.3 ml and the end-systolic volume (LVESV) was 58, 7 ± 31.6 ml. Regarding therapy, 19.5% of the stroke population were under anticoagulation and 39% under antiaggregation at the time of the echocardiogram, with LVT being present in 23% of the stroke population. The univariate analysis showed that the LVT formation was associated with advanced age (p = 0.006), LVEF (p = 0.013), increase in LVESV (p = 0.046), absence of anticoagulant or antiaggregation therapy (p = 0.001), dyslipidemia (p = 0.049) and coronary artery disease (p = 0.006). In the multivariate analysis of Cox regression, only therapy (anticoagulant or antiplatelet) was identified as an independent and protective factor for the formation of LVT (p = 0.001), with no difference between anticoagulation and antiaggregation therapy.
Conclusion: This study showed that the development of intraventricular thrombi is associated with older age, LVEF compromise, LVESV increase, dyslipidemia and coronary artery disease. On the other hand, chronic anticoagulation or antiaggregation therapy was the only independent and protective factor in the development of LVT.

P1290

Body Mass Index as a predictor of mortality in Chronic Heart Failure

N Nataliya Tkach[1]; L Voronkov[1]; L Voronkov[1]; L Voronkov[1]; L Voronkov[1]
[1]NSC Institute of Cardiology M.D. Strazhesko, Heart Failure department, Kiev, Ukraine

Background: Despite good knowledge about predictors of long-term mortality in Chronic Heart Failure (CHF) the influence of body mass index (BMI) on the long-term mortality of these patients is still non-well investigated.
Aim: The purpose of study was to determine the effect of BMI on the mortality of patients with CHF and with reduced left ventricular ejection fraction (LVEF)
Methods: 267 CHF patients with reduced LVEF < 40 % were analyzed. Survival analysis was performed using the "STATISTICA for Windows. Release 6.0" program (Survival Analysis section) using the Kaplan-Meier method. To assess the impact on BMI life expectancy, patients were distributed for following groups: reduced body weight - BMI < 22kg /m2, normal - BMI 22-24.99 kg/m2; overweight - BMI 25-29.99 kg/m2 and obesity - BMI = 30 kg / m2.
Results: During the 1 and 3 years of follow-up the survival rate had a lower in patients with reduced BMI (52% after 1 year, after 3 years - 0%), somewhat better in obese patients - 71% and 25%, respectively, and the best predictor was characterized by patients with overweight BMI - 90% and 60% respectively; these differences were significant (p = 0.01).
At the same time, the groups of patients did not significantly differ among themselves by age, duration of the signs of CHF and severity of reduced LVEF. The prognostic information of the BMI was greater for survival of patients over three years (OR-5,992 (CI = 1,020-114,898)) in comparison to the first year of observation (OR-3,591 (CI = 1,001-112,359)).
Conclusions: the patients with low BMI (< 22 kg / m2) in CHF patients with reduced LVEF is the worst prognostic criterion, while at the same time, patients with overweight BMI (25-29.99 kg/m2) have the best survival indices for one and three years of follow-up.



P1291

Fibroblast-mediated atrial mechanical dysfunction in HFpEF and hypertensive heart disease.

D David Bode[1]; R Doerr[1]; D Lindner[2]; M Schwarzl[2]; D Westermann[2]; U Primessnig[1]; B Pieske[1]; FR Heinzel[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Innere Klinik m.S. Kardiologie, Berlin, Germany; *[2]University Heart Center Hamburg, Hamburg, Germany*

Heart failure (HF) with preserved ejection fraction (HFpEF) is present in about 50% of HF patients and often related to metabolic syndrome. Atrial remodeling (AR) is common in HFpEF, associated with atrial mechanical stretch and increased fibrosis, leading to altered secretory activity. AR and mechanical dysfunction has been shown to independently increase patient mortality. We hypothesize that atrial cardiomyocyte function and interaction with fibroblast mediated extracellular matrix triggers is pivotal for the manifestation and progression of AR and dysfunction in heart failure.
Methods: Atrial mechanical function in-vivo was assessed using echocardiography. In-vitro, contractile function of atrial cardiomyocytes was evaluated by video edge detection in wild type (WT) and ZFS-1 rats without (Ln; hypertension) and with metabolic syndrome and AR (Ob; HFpEF, as previously shown). In addition, excitation-contraction-coupling (ECC) was examined using confocal and ratiometric Ca imaging (Ca transients; CaT) (Fluo4-AM/Fura2-AM, field stim) in atrial cardiomyocytes of Ln and Ob. CaT were recorded at 1 Hz after treatment with conditioned medium of their respective cultured unstressed or stressed (stretch-induced activation; Flexercell system) fibroblasts isolated from Ln and Ob.
Results: Under baseline-conditions at 21 weeks, Ob and Ln showed increased cell shortening compared to WT (6.449 ± 0.6761 vs. 11.46 ± 0.6247; $n = 48$ and 84 cells; $p < 0.05$; 6.449 ± 0.6761 vs. 10.84 ± 0.6144; $n = 49$ and 89 cells; $p < 0.05$) related to enhanced Ca release. In-vivo however, atrial function was impaired. Histology unveiled increased fibrosis in Ob and treatment with conditioned, activated medium vs. medium from unstressed fibroblasts was associated with increased cardiomyocyte diastolic Ca content (0.62 ± 0.02 vs. 0.068 ± 0.02; $n = 22$ and 34 cells; $p < 0.05$), prolonged cytosolic CaT time to peak (61 ± 5 vs. 77 ± 11 ms; $n = 19$ and 20 cells; $p < 0.05$) and Ca removal (209 ± 11 vs. 347 ± 52 ms; n= 19 and 20 cells; $p < 0.05$) in Ob.. In addition, while Ca spark frequency was unaltered, conditioned medium significantly increased amplitude (0.98 ± 0.03 vs. 1.1 ± 0.03; $n = 11$ cells/group; $p < 0.05$) and altered time to peak as well as duration and width. This indicates profound changes of ECC due to mechanical stress in metabolic syndrome mediated by fibroblast secretions, potentially contributing to decompensation. In Ln however, atrial in-vivo function was preserved and a shortening of Ca removal (357 ± 53 vs. 219 ± 16 ms, $n = 29$ and 18 cells: $p < 0.05$) could be observed after exposure to stressed fibroblast secretome.
Summary: During metabolic syndrome and HFpEF, impaired in-vivo atrial mechanical function might be related to adversely affected cardiomyocyte ECC due to fibroblast secretome and mechanical stress. In hypertensive AR, stressed fibroblasts enhance cardiomyocyte Ca removal and in-vivo atrial function is preserved.

P1292

Inhibition of the Na+/Ca2+ exchanger (NCX) improves cardiac remodeling and diastolic function in heart failure with preserved ejection fraction.

U Primessnig[1]; T Bracic[2]; P Pollesello[3]; B Pieske[1]; FR Heinzel[1]
[1]Charité - Universitätsmedizin Berlin, Campus Virchow-Klinikum, Department of Cardiology, Berlin, Germany; *[2]Medical University of Graz, Department of Cardiology, Graz, Austria*; *[3]Orion Pharma, Critical Care, Espoo, Finland., Espoo, Finland*

Background: Heart failure with preserved ejection fraction (HFpEF) is increasingly common but there are no therapeutic strategies available at the moment; mostly because the underlying cellular mechanisms are not well understood. Therefore, we investigated the chronical inhibition of the Na+/Ca2+ exchanger (NCX) with SEA0400 and ORM11035 in a rat model of HFpEF.
Methods: Young male Wistar rats were subjected to subtotal nephrectomy (NXT) or sham operation (SOP). Chronical treatment for 16 weeks with the NCX inhibitor SEA0400 or ORM11035 was started 8 weeks after intervention. At the end after 24 weeks the cardiac phenotype was evaluated using non-invasive blood pressure (NIBP) measurements, echocardiography and invasive pressure-volume loops (PV). Furthermore, heart morphometry as well as left ventricular (LV) cardiomyocytes were isolated and cardiomyocyte function and Ca2+ handling was measured.
Results: NXT rats (untreated) showed stable compensated renal impairment and signs and symptoms of HFpEF (hypertrophied left ventricle (LV), left- and upward shift of end diastolic pressure (EDP) volume relationship (EDPVR), increased lung weight/body weight ratio (LW/BW) indicating pulmonary congestion and preserved LV systolic function (EF, dP/dt)). In LV cardiomyocytes from untreated NXT Ca2+ transient amplitude was unchanged but time for early (50%) decay was significantly prolonged at 24 weeks and correlated with diastolic dysfunction (EDP) in vivo. In NXT treated with a NCX inhibitor cardiac remodeling and diastolic function improved. Moreover, congestion and NTproBNP was enhanced after chronic NCX modulation. Compared SEA0400 with the new, more specific NCX inhibitor, ORM11035 there were no negative inotropic effects and effects on blood pressure observed with ORM11035. Additionally, a potential antiarrhythmic effect of ORM11035 in LV cardiomyocytes was observed.
Conclusion: Chronic inhibition of the Na+/Ca2+ exchanger with ORM 11035 significantly attenuated cardiac remodeling and diastolic dysfunction without lowering systemic blood pressure in this model of HFpEF compared to SEA0400.

P1293

Aged hypertensive rats exhibit myocardial oedema: a link to HFPEF?

G Giacomo Rossitto[1]; A Harvey[1]; S Lacchini[1]; AC Montezano[1]; RM Touyz[1]; M Petrie[1]; C Delles[1]
[1]University of Glasgow, Institute of Cardiovascular and Medical Sciences, BHF Centre for Research Excellence, Glasgow, United Kingdom

Funding Acknowledgements: British Heart Foundation Glasgow Centre of Research Excellence (grant no: RE/13/5/30177)

Introduction: Salt is associated with progression of hypertensive heart disease through left ventricular hypertrophy and diastolic dysfunction, which are often precursors and/or determinants of HFpEF. Recently, Na+ was shown to accumulate in peripheral tissues with advancing age and resistant hypertension; in rodent models, glycosaminoglycans (GAGs) were identified as the putative binding site and lymphatic vessel networks have been implicated as fine-tuning buffering systems.
Purpose: This study was set out to investigate sodium accumulation and its determinants in the heart of hypertensive animals.
Methods: Heart samples from hypertensive young and old rats (SHRSP; 20 and 52 weeks old, respectively) and normotensive age-matched controls (WKY rats; n = 6-10 per group) were used for: i) chemical analysis of tissue Na+ and K+ content by flame photometry; ii) gravimetric measurement of water content, as the difference between wet (WW) and dry weight (DW); iii) histologic quantification of GAGs content by alcian blue staining (A.B., pH 2.5) of mid-myocardial tissue (A.B. positive area, %); iv) comparison of the gene expression of lymphatic-specific markers and growth factors (Lyve-1; Podoplanin; VEGFc; VEGFR3).
Results: Myocardial Na+ content and concentration were increased in SHRSP old compared to SHRSP young and age-matched WKY (0.190 ± 0.040, 0.133 ± 0.011, 0.139 ± 0.027 mmol/gDW and 54.5 ± 4.1, 45.8 ± 5.5, 46.6 ± 3.6, mmol/l, respectively), paralleled by an increase in water (76.7 ± 0.9 vs 74.4 ± 1.0 and 73.5 ± 1.5 %WW, respectively). K+ concentration showed a mirror-pattern decrease, leading to an overall similar [Na+ + K+] concentration across groups. Relative gene expression of Lyve-1 and Podoplanin or VEGFc-VEGFR3 axis was not increased in rats showing tissue Na+ accumulation. Myocardial GAGs increased with aging, but was higher in both SHRSP young and old rats compared to WKY.
Conclusion: Na+ accumulates in the heart of aged hypertensive rats and is putatively bound to the increased sulphated GAGs observed with aging, particularly in hypertension. This accumulation is overall isotonic and paralleled by water, suggestive of tissue oedema, which has been previously shown to impact on myocardial function in animal models. These processes may play a role in the development of HFpEF phenotype.

Dapagliflozin ameliorates diastolic function in an animal model of hypertensive heart disease in the absence of diabetes

K Konrad Urbanek[1]; D Cappetta[1]; A Micciche'[1]; G Esposito[1]; LP Ciuffreda[1]; A Cozzolino[1]; D D'amario[2]; F Crea[2]; S Naviglio[3]; F Rossi[1]; A De Angelis[1]; L Berrino[1]
[1]University of Campania "Luigi Vanvitelli", Department of Experimental Medicine, Naples, Italy; *[2]Catholic University of the Sacred Heart, Department of Cardiovascular and Thoracic Sciences, Rome, Italy*; *[3]University of Campania "Luigi Vanvitelli", Department of Biochemistry, Biophysics and General Pathology, Naples, Italy*

Background: The results of trial with SGLT2 inhibitors raised possibility that this class of anti-hyperglycaemic drugs may provide cardiovascular benefits independently from their anti-diabetic effects. Although it has not been specified whether patients with significantly reduced risk for HF hospitalization had any particular form of HF, it is possible that heart failure with preserved ejection fraction (HFpEF) patients were appreciably represented. HFpEF is a challenging clinical syndrome and represents yet unresolved pathophysiological continuum with a consequent perception of lack of effective treatments. Moreover, HFpEF often share co-morbidities like hypertension and diabetes.
Purpose: Following noted dissociation between control of glycaemia and cardiac outcome, we have selected a hypertensive, non-diabetic model of HFpEF.to examine

the effects of SGLT2 inhibitor dapagliflozin on the progression of experimental heart disease independently from its effects on diabetes.
Methods: Seven-week-old Dahl salt-sensitive (Dahl/SS) rats were fed a high salt diet (8% NaCl) for 5 weeks to induce hypertension. Then, rats continued with a high salt diet and were orally administered with either dapagliflozin (0.1 mg/kg/day) or vehicle for the following 6 weeks. Diastolic and systolic function were monitored by echocardiography.
Results: The animals progressively developed hypertension and after 5 weeks of high-salt diet, before initiation of pharmacotherapy, LV hypertrophy was already evident while systolic parameters were unchanged. However, diastolic function was compromised as documented by decrease of E/A ratio along with increase of E deceleration time and isovolumetric relaxation time. During 6 weeks of the treatment with dapagliflozin, blood pressure remained markedly elevated, with a slight reduction observed only during last two weeks. At completion of dapagliflozin treatment, hypertrophied LV had systolic parameters within a normal range while diastolic parameters were partially recovered. These results define an improved ventricular relaxation. Additionally, animals on high-salt diet had an increased urine albumin-to-creatinine ratio (UACR). An improved cardiovascular profile following treatment with dapagliflozin was confirmed by the reduction of UACR.
Conclusions: Dapagliflozin positively modulates diastolic compliance with cellular and molecular mechanisms yet to be identified. Although a slight reduction in blood pressure may have participated in functional and structural modifications, these changes cannot exclusively account for the beneficial effects of the drug. Because of a non-diabetic nature of our model and unaltered blood glucose levels, the protective action of dapagliflozin lays beyond its effect on glycaemia.

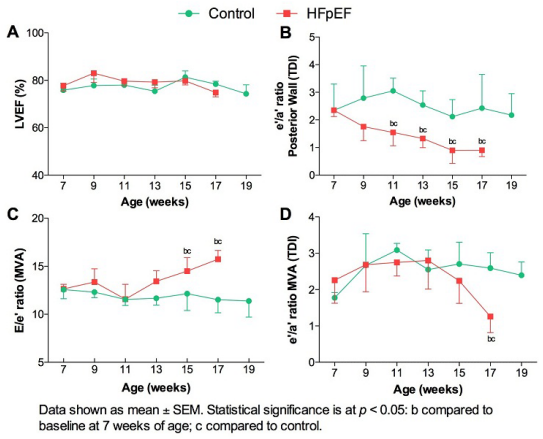
P1295

Doppler evaluation of radial myocardial tissue relaxation: an early marker of disease progression for heart failure with preserved ejection fraction

A Giraldo[1]; J Talavera[2]; MJ Fernandez-Del-Palacio[2]; G Brooks[1]
[1]University of Reading, Institute for Cardiovascular and Metabolic Research, Reading, United Kingdom; [2]University of Murcia, Department of Small Animal Medicine and Surgery, Veterinary School, Murcia, Spain

Funding Acknowledgements: University of Reading, United Kingdom.

Background: Heart failure with preserved ejection fraction (HFpEF) is highly prevalent. There are no effective therapies, and there is a lack early markers of disease progression/prognosis in populations at risk of HFpEF (e.g. hypertensive, obese, diabetic). Evaluation of diastology with tissue Doppler imaging (TDI) has mainly focused on longitudinal myocardial tissue relaxation at the mitral valve annulus (MVA).
Purpose: We hypothesized that radial motion of the myocardium using TDI in a preclinical model of HFpEF, may add valuable information to the evaluation of diastology during the progression of this condition.
Methods: Male Dahl salt sensitive hypertensive rats were fed a high salt diet (8% NaCl) from 7 weeks of age (HFpEF group). Another cohort of male Dahl rats was fed a diet containing 0.3% NaCl (Control group) throughout the study protocol until 19 weeks of age. Blood pressure was evaluated by the tail cuff method. A complete echocardiographic evaluation was performed at baseline, repeated every 2 weeks thereafter, and included amongst other parameters: mitral valve inflow velocities, longitudinal myocardial tissue relaxation via TDI with the sample volume placed at the MVA in an apical 4 chambers view, and radial myocardial tissue relaxation by placing the TDI sample volume at the posterior wall in a parasternal short axis view (papillary muscles level).
Results: Rats in the HFpEF group developed severe hypertension, whilst the control group remained normotensive. Both the HFpEF and control groups exhibited normal left ventricular ejection fraction throughout the whole study (Figure 1A). Significantly, in the HFpEF group, alterations in radial myocardial tissue relaxation velocities (reduced e', increased a' and reduced e'/a' ratio (e' reversal pattern) (Figure 1B)) occurred early, relative to commonly evaluated Doppler parameters of diastolic function (E/e' and e'/a' at MVA) (Figure 1C-D). Of note, animals that presented earlier alterations in radial myocardial tissue relaxation, also exhibited earlier development of HFpEF and deterioration of health status. No alterations in diastolic function were found in the control group.
Conclusion: Our detailed time course evaluation of myocardial tissue relaxation via TDI in the Dahl salt sensitive hypertension-induced model of HFpEF, suggests that alterations in the radial myocardial tissue relaxation pattern is an early marker of disease progression in HFpEF. Complementary studies are necessary to further validate this technique as well as to evaluate its prognostic value in patients with established or at risk of developing HFpEF.



Data shown as mean ± SEM. Statistical significance is at $p < 0.05$: b compared to baseline at 7 weeks of age; c compared to control.

P1296

Assessment of myocardial contractile function by tissue doppler echocardiography in patients with chronic heart failure with preserved systolic function

VA Barbuk[1]; MI Belskaya[1]; AN Zhuiko[1]; NV Semyonova[1]; ID Kozlov[1]
[1]Republican Scientific and Practical Centre of Cardiology, Chronic CAD Laboratory, Minsk, Belarus

Objectives: to assess myocardial contractile function in patients with chronic heart failure (CHF) of ischemic origin with preserved systolic function.
Study Methods: 65 patients with post-infarction cardiosclerosis complicated by NYHA FC II CHF aged 48 - 70 y.o. (mean-age 61.9 ± 8.09) have been examined. All patients received cardiac ultrasound examination using Vivid - 7 device (GE, USA - Belgium) in ?, ? - modes and tissue Doppler (TD) with 3.5 MHz transducer with the assessment of key structural and volumetric indices, contractility and left ventricular (LV) myocardial longitudinal deformation (strain).
Results: the results suggest that patients with post-infarction cardiosclerosis complicated by NYHA FC II CHF showed evidently reduced global longitudinal systolic left ventricular myocardial deformation (-12.3 ± 1.98%; ? <0.05) compared to normal values (-16%) secondary to preserved or slightly decreased LV ejection fraction (EF) (mean EF 50.1 ± 4.79%) suggesting the presence of chronic contractile dysfunction of heart muscle. Simultaneously, these patients showed a positive correlation between the degree of myocardial longitudinal deformation and LV EF in ? and ?-modes (r = 0.58, r = 0.74; ? <0.05, respectively). It is noteworthy, that impaired longitudinal systolic function in patients with post-infarction cardiosclerosis was discovered both in the scarring area, and in areas of preserved myocardial kinetics which some authors think is predicated by the development of subendocardial dysfunction due to fibrosis formation and microvascular disorders.
Conclusions: Thus, despite preserved LV systolic function, patients with post-infarction cardiosclerosis complicated by NYHA FC II CHF showed decreased longitudinal deformation of heart muscle suggesting the presence of ischemic contractility disorders and increased LV myocardial stiffness and may be a prognostically adverse factor in this group of patients.

P1297

Right ventricular function as a predictor of exercise tolerance in patients with chronic left ventricular failure

S M Salah Mohamed Ibrahim[1]
[1]university, cairo, Egypt

Background: Few clinical studies suggested an important role for the pulmonary circulation and right ventricular functions in determining the exercise capacity in patients with chronic left ventricular failure (CHF). No correlation has been found between resting left ventricular ejection fraction (LVEF) and exercise capacity in these patients.
Purpose: Our aim was to delineate the role of the right ventricular function in determining of the exercise capacity in such patients.
Methods: Forty subjects were included in this study; thirty male patients with CHF secondary to ischemic cardiomyopathy (16 patients) or dilated cardiomyopathy (14 patients) fulfilled the inclusion criteria for this study and ten normal subjects matched for age and weight.

Following thorough history and clinical examination; the patients underwent first pass radionuclide study for the determination of the resting right ventricular ejection fraction (RVEF), two-dimensional echocardiography and Doppler study to study both left and right ventricular systolic and diastolic function, and a progressive multi-stage breath by breath cardiopulmonary exercise test using treadmill with incremental increase in the workload to a symptom limited point, to determine the maximal exercise capacity and maximal cardiopulmonary exercise test parameters.
Results: It was found that the LVEF did not correlate at all with any of the exercise capacity predictive parameters, whereas the RVEF correlated significantly to these parameters. There were however a striking abnormalities of the ventilatory response to exercise, in the form of increased ventilation in response to given rate of CO2 production, and this excessive ventilation correlated significantly with the increase in dead space ventilation in the affected patients. While the VE/VCO2 and the VD/VT max correlated significantly with VO2max, they also correlated significantly with RVEF. The correlation between RVEF and exercise capacity may be explained by the perfusion/ ventilation mismatch resulting from chronic pulmonary changes.
Conclusion: The study showed that the exercise capacity in CHF is not related either to etiology, NYHA functional class or exercise end point.

P1298

Heart failure associated with chronic kidney disease - a reality: clinical characteristics and outcomes

T Tatiana Duarte[1]; S Goncalves[1]; M Fonseca[1]; C Sa[1]; R Marinheiro[1]; J Farinha[1]; R Rodrigues[1]; S Correia[1]; D Ferreira[1]; A Lourenco[1]; R Caria[1]
[1]Hospital Center of Setubal, Cardiology, Setubal, Portugal

Introduction: Heart failure (HF) and chronic kidney disease (CKD) share several risk factors and often coexist. Chronic kidney disease is associated with increased morbidity and mortality in heart failure and conditions use of drugs with a prognostic impact.
Treatment recommendations for patients with HF and CKD are insufficient, because the patients with severe renal impairment are excluded from most studies.
Aim: To determine the prevalence of renal dysfunction in a population with HF and to characterize these patients.
Methods: Consecutive patients from a HF clinic were evaluated. The creatinine clearance was calculated according to the Cockcroft-Gault equation.
The population was divided into 5 groups according to the degree of renal dysfunction: Group 1: GFR> 90; Group 2: < 89 and = 60; Group 3: < 59 and = 30; Group 4: < 29 and = 15; Group 5: < 15 ml / min / 1.73m2.
The population was characterized according to baseline characteristics, therapy and events - cardiovascular death and hospitalizations for HF.
Results: One hundred and seventy-eight patients were studied (male - 71% (N = 127), mean age 67 ± 11 years). Ninety-four patients (53%) had a GFR = 60.
Patients with renal dysfunction are significantly older, but without predominance of gender and ischemic etiology to HF. (Table I)
The majority of patients with renal impairment have ACE inhibitors, but not spironolactone.
Hospitalizations by HF were significantly associated with patients with renal dysfunction (GFR < 60: 34 vs 17; p = 0.019), however, the same was not found for death (10 vs 4, p = 0.146).
Conclusion: The majority of our population has associated with HF a degree of renal dysfunction.
In this sample, renal dysfunction did not affect the use of some drugs with a prognostic impact (ACEI and beta-blocker), but the same was not observed for spironolactone, which is used more cautiously in this group of patients.
More studies are needed in patients with HF and CKD for better surveillance and therapeutic orientation.

Variable	Group 1 (GFR> 90) (N=22)	Group 2 (GFR 89 - 60) (N= 69)	Group 3 (GFR 59-30) (N=58)	Group 4 (GFR 29-15) (N= 18)	Group 5 (GFR <15) (N=11)	p-value
Male (n)	19	51	38	11	8	0,3
Age (years)	54 ± 9	67 ± 11	70 ± 10	74 ± 5	65 ± 10	<0,001
Ischemic etiology (n)	7	34	26	8	6	0,65
LVEF (% median; IQ)	43(34;46)	43(35;49)	44(30;52)	40(19;55)	44(38;56)	0,001
Hospitalizations by HF (n)	4	16	14	10	7	0,006
Death (n)	2	2	4	3	3	0,146

Heart failure with "recovered function": clinical characteristics and outcomes

T Tatiana Duarte[1]; S Goncalves[1]; M Fonseca[1]; C Sa[1]; R Marinheiro[1]; J Farinha[1]; S Correia[1]; D Ferreira[1]; A Lourenco[1]; R Rodrigues[1]; R Caria[1]
[1]Hospital Center of Setubal, Cardiology, Setubal, Portugal

Introduction: Patients with systolic dysfunction that improve/recover their left ventricular systolic ejection fraction (LVEF) present a more favorable clinical profile when compared to patients that maintain dysfunction, although the therapeutic.
The characteristics and outcomes of patients with "recovered function" are not fully described, and more studies in these patients are necessary.
Aim: To determine in a population with heart failure (HF) the prevalence of patients that improved/recovered LVEF and characterize this sample according to clinical characteristics and outcomes.
Methods: Patients followed at a HF clinic with initial LVEF < 40% were retrospectively evaluated. The population was divided into 3 groups according to the LVEF:

Variable	Group 1 (LVEF < 40%) (N=89)	Group 2 (LVEF> 50%) (N=35)	Group 3 (LVEF 45-50%) (N=31)	p-value
Male (n)	73	16	23	0,034
Age (years)	67 ± 1	68 ± 2	66 ± 2	0,9
Ischemic etiology (n)	52	9	13	0,041
Death (n)	14	2	4	0,5
HF hospitalization (n)	43	16	13	0,6
Composite endpoint (n)	45	16	14	0,8
BNP pg/ml (median; IQ)	257 [93; 558]	109 [22;172]	118 [35;268]	0,032

Group I - did not recover function (LVEF < 40%); Group 2 - recovered function (LVEF> 50%); Group 3 partially improved the function (LVEF between 45-50%).
The groups were characterized according to baseline characteristics, comorbidities, therapeutics and outcomes - death for cardiovascular cause; hospitalizations for HF; composite endpoint.
The prevalence of "recovered function" and predictive factors were evaluated.
Results: One hundred fifty-five patients were studied (male 72% (n = 112), mean age 67 ± 10 years). In 43% (66) of the patients there was an improvement in systolic function: LVEF> 50%: 53% (35); LVEF between 45 and 50: 47% (31).
Patients that did not improve the systolic dysfunction are predominantly male.
The non-ischemic etiology was associated with greater ventricular remodeling with improved function. The patients that improved/recovered function had less events but non-statistically significant. Median levels of BNP were lower in the two groups that improved function. (Table I)
Conclusion: The improvement/recovery of LVEF was frequent in this sample, especially in patients with non-ischemic etiology. This group of patients keeps a reasonable number of events that suggests the persistence of a risk profile and need of surveillance.
More studies in patients with "recovered function" are necessary, to determine predictors of "improved/recovered function" and to optimize therapeutics.

P1300

Combined inhibition of the renin-angiotensin system and neprilysin enhances skeletal muscle oxidative capacity and ameliorates cachexia in tachypacing-induced heart failure

A Dietl[1]; I Winkel[1]; M Paulus[1]; R Deutzmann[2]; A Bruckmann[2]; J Schroeder[3]; A Luchner[4]; LS Maier[1]; C Birner[1]
[1]University Hospital Regensburg, Department of Internal Medicine II, Regensburg, Germany; *[2]University of Regensburg, Department of Biochemistry I, Regensburg, Germany*; *[3]University Hospital Regensburg, Electron Microscopy Core Facility, Institute for Pathology, Regensburg, Germany*; *[4]Klinikum St. Marien Amberg, Department of Internal Medicine I, Amberg, Germany*

Funding Acknowledgements: AD is supported by a research grant of the German Cardiac Society (DGK - Deutsche Gesellschaft für Kardiologie, Herz- und Kreislaufforschung).

Background: Cachexia of skeletal muscles (SKM) occurs early in heart failure. A multi-omics approach of early and advanced tachypacing-induced heart failure in rabbits was performed, revealing impaired oxidative capacity linked to natriuretic peptides. In a second step, we assumed beneficial effects of neprilysin inhibition.
Methods: Incremental tachypacing was sustained for 30 days. Left ventricular function was evaluated by echocardiography. In a first series of experiments, SKM (M. quadriceps femoris) and diaphragm tissue specimens were harvested in healthy controls (CTRL), asymptomatic left ventricular dysfunction (ALVD) and overt heart failure (CHF, n = 4 in each group) to analyse the molecular setup. In a second series of experiments, drinking water was either substituted with the RAS-/NEP-inhibitor

omapatrilat (50mg/kg/d) or placebo (n = 7 in each group). Muscle fibres were distinguished by ATPase staining. Tissue was subjected to custom-made PCR arrays and to difference in gel-electrophoresis with protein identification by tandem mass-spectrometry. In isolated mitochondria, abundance and activities of the electron transport chain complexes were assessed. The expression of natriuretic peptide receptor levels (NPR-A/B/C) and PGC1a was analysed by real-time PCR.
Results: Fractional shortening was reduced in ALVD and CHF (FS = 38.0 ± 1.4%/28.2 ± 1.9%/21.1 ± 2.2% CTRL/ALVD/CHF, $p < 0.05$ Bonferroni post-test with $p < 0.001$ for 1way ANOVA). Whereas body weight remained unchanged due to fluid retention, protein content of SKM decreased (8.7 ± 0.4% vs. 7.0 ± 0.5%, CTRL vs. CHF, $p < 0.05$) and a slow-to-fast fibre type switch occurred in CHF (slow fibres 31.9 ± 0.9% vs. 16.4 ± 1.2%, $P < 0.0001$). In ALVD and CHF, proteomic analysis revealed a dominance of catabolic pathways comprising glycolysis, the Krebs cycle, glycogenolysis and lipolysis. The diaphragm mirrored these changes. Transcriptomic analysis of SKM specimens indicated up-regulation of major mitochondrial transmembrane shuttles of fatty acids. In isolated SKM mitochondria of CHF animals, the expression levels of all complexes of the electron transport chain were reduced, which translated into diminished activities of complexes II and IV. NPR-A and B levels were reduced, whereas the clearance receptor NPR-C was increased in CHF. Albeit omapatrilat did not change systolic function, it mitigated the slow-to-fast fibre type switch, amplified the expression of enzymes involved in beta-oxidation and increased the activity of the electron transport chain. PGC-1a was on the transcriptomic and the protein level reduced in CHF animals. Omapatrilat prevented the reduction. Conclusion: For the first time we could show, that progressive tachycardia-induced heart failure entails profound and very early molecular changes of both SKM and the diaphragm muscle. Furthermore, our data provide first in vivo evidence for beneficial effects of a combined RAS-/NEP-inhibition on SKM in CHF, which is likely mediated by increased PGC-1a.

P1301

Correlation of various molecules involved in cellular traffic with the severity of heart failure in patients undergoing cardiac transplantation

M Ezzitouny[1]; I Sanchez-Lazaro[1]; M Rivera[2]; M Portoles[2]; E Rosello-Lleti[2]; L Almenar[1]; R Lopez-Vilella[1]; M Ferre-Vallverdu[1]; J Sanz-Sanchez[1]; V Donoso-Trenado[1]; P Arenas-Martin[1]; S Lozano-Edo[1]; L Martinez-Dolz[1]
[1]Hospital Universitario y Politécnico La Fe, Department of cardiology, Valencia, Spain; *[2]Hospital Universitario y Politécnico La Fe, Health Research Institute La Fe, Valencia, Spain*

On behalf of: Myocardial Dysfunction and Cardiac Transplant Unit (Research Institute La Fe)
Funding Acknowledgements: Health Institute of Carlos III

Objective: Analyze different molecules involved in cellular traffic (exportins, importins, RAN regulators and nucleoporins) to assess whether their levels are related to the severity of heart failure (HF) in patients undergoing heart transplantation.
Method: From a prospective cohort of patients with advanced HF collected between 2009 and 2015, we have analyzed 64 peripheral blood samples obtained at the time prior to the heart transplant. We compared the levels of the following molecules (determined by ELISA): IMPORTIN5 (IMP5); ATPaseCaTransp (ATPCa); NUCLEOPORIN153kDa (Nup153); RANGTPaseAP1 (RanGAP1) and EXPORTIN4 (EXP4), between two groups: urgent or elective transplant; need for ECMO or not.
Results: Of the 64 patients, 67.2% were corresponded to elective transplants and 32.8% urgent; Of the latter, 76% have undergone circulatory support (ECMO). Significantly elevated levels of IMP5 and ATPCa have been observed in patients undergoing urgent transplantation (compared to elective transplant), and have needed circulatory support with ECMO (versus patients without ECMO), also in the group with ECMO it have seen high levels of Nup153 and RanGAP1 (Table 1).
Conclusion: Patients with advanced HF in a critical situation (who have needed circulatory support or have undergone an urgent transplant) have presented a different pattern of molecular expression in the nucleic-cytoplasmic protein transport compared to those patients in a more stable clinical situation prior to transplantation. It remains to be seen whether the determination of these markers would facilitate the early identification of patients with short-term evolution to a critical situation that requires circulatory assistance, or if the alteration of these markers occurs as a consequence of circulatory support.

Table 1

	N	Mean	Std. Deviation	P	
Nup153	ECMO	16	32,905	18,053	0,032

P1302

Study of molecules involved in cellular traffic in advanced heart failure: are there differences in the nivels of these molecules between ischemic heart disease and idiopathic dilated cardiomyopathy?

M Ezzitouny[1]; I Sanchez-Lazaro[1]; M Rivera[2]; M Portoles[2]; E Rosello-Lleti[2]; L Almenar[1]; R Lopez-Vilella[1]; J Jimenez-Aguilella[1]; A Cervero-Rubio[1]; V Rosello-Perez[1]; P Pastor-Jover[1]; L Martinez-Dolz[1]
[1]Hospital Universitario y Politécnico La Fe, Department of cardiology, Valencia, Spain; *[2]Hospital Universitario y Politécnico La Fe, Health Research Institute La Fe, Valencia, Spain*

On behalf of: Myocardial Dysfunction and Cardiac Transplant Unit (Research Institute La Fe)
Funding Acknowledgements: Health Institute of Carlos III

Objective: Evaluate differences in the pattern of alterations of molecules involved in nuclear-cytoplasmic transport (exportins, importins, RAN regulators and nucleoporins) and related to ventricular function in patients with advanced heart failure with different underlying pathology (ischemic heart disease and cardiomyopathy dilated idiopathic).
Method: From a prospective cohort of patients with advanced heart failure collected between 2009 and 2015, we have analyzed 58 peripheral blood samples obtained at the time prior to heart transplantation. The levels of the following molecules were determined by means of ELISA: IMPORTIN5 (IMP5); ATPaseCaTransp (ATPCa); NUCLEOPORIN153kDa (Nup153); NUCLEOPORIN160kDa (Nup160); RANGTPaseAP1 (RanGAP1) and EXPORTIN4 (EXP4). Then, they were compared between 2 groups of pathology: Ischemic heart disease and idiopathic dilated cardiomyopathy.
Results: Of the 58 patients with advanced heart failure, 57% had ischemic heart disease and 43% had idiopathic dilated cardiomyopathy. We have observed significantly higher levels of IMP5, EXP4, RanGAP1 and Nup153 in patients with dilated idiopathic myocardiopathy compared to patients with ischemic heart disease (table 1).
Conclusion: In idiopathic dilated cardiomyopathy the alterations of nucleocytoplasmic transport are more pronounced with respect to ischemic heart disease. The usefulness and applicability of this finding remain to be determined in subsequent studies.

Differential expression of plasma microRNA fingerprint in patients with heart failure with reduced ejection fraction responding or not to exercise training

I Witvrouwen[1]; AB Gevaert[1]; N Possemiers[1]; PJ Beckers[1]; H Heidbuchel[1]; SJ Van Laere[2]; AH Van Craenenbroeck[1]; EM Van Craenenbroeck[1]
[1]University of Antwerp Hospital (Edegem), Laboratory of Cellular and Molecular Cardiology, Department of cardiology, Antwerp, Belgium; *[2]University of Antwerp, Translational Cancer Research Unit, Department of Medical Oncology, Antwerp, Belgium*

Funding Acknowledgements: This work was supported by a grant from Antwerp University (BOF DOCPRO 31495). IW holds a PhD fellowship of the Fund for Scientific Research Flanders.

Purpose: Exercise training significantly improves morbidity and mortality in patients with heart failure with reduced ejection fraction (HFrEF), but 20% of patients show non-response. Since genetic and epigenetic regulatory mechanisms are key determinants of aerobic capacity (VO2peak), we hypothesize that a circulating microRNA (miRNA) profile can distinguish exercise responders (ER) from exercise non-responders (ENR).
Methods: A miRNA microarray was performed in 18 male HFrEF patients (LVEF <40%) prior to 12-week endurance training; 9 patients were ER (?VO2peak >20%) and 9 were ENR (?VO2peak <5%). Data were normalized using geNorm. MiRNA expression was assessed with unsupervised prediction analysis (pamr package), correlation with ?VO2peak and fold change (2-?Cq). Linear regression analysis was performed to predict ?VO2peak. Statistical analysis was performed in R (v3.3.3).
Results: ER and ENR were comparable with regard to age (58.6 vs 59.9 yrs), BMI (30.5 vs 30.4 kg/m2), resting heart rate (68 vs 76 bpm) and baseline VO2peak (17.5. vs 17.2 ml/kg/min), all p>0.05. Unsupervised clustering analysis of the circulating miRNA expression profiles resulted in a distinction of the ER-group and ENR-group with 83% accuracy. A total of 57 miRNA were differentially expressed: 31 upregulated in ER, 26 upregulated in ENR. Of these, 6 miRNA correlated well with ?VO2peak (all Spearman ? abs. >0.72, p <0.001). These miRNA (miR-23a, miR-140, miR-302c, miR-551b, miR-636 and miR-346) are known to play a role in heart failure, left ventricular hypertrophy, exercise (up- or downregulation) or skeletal muscle atrophy. MiR-140 independently predicted ?VO2peak in linear regression (ß -1856 ± 384, p <0.001).
Conclusions: We found a differential expression pattern of miRNA in HFrEF patients responding or not to exercise training, which could distinguish both groups with 83% accuracy. A fingerprint of 6 miRNA could serve as biomarkers for training response and needs prospective validation in a larger cohort of HFrEF patients.

P1304

A novel method for high precision aortic banding in mice

A O Arne Olav Melleby[1]; A Romaine[1]; JM Aronsen[1]; I Veras[1]; L Zhang[1]; I Sjaastad[1]; IG Lunde[1]; G Christensen[1]
[1]Oslo University Hospital, Institute for Experimental Medical Research, Oslo, Norway

Experimental pressure overload is a commonly used model system in rodents to investigate disease mechanisms in cardiac remodeling and failure. Thoracic aortic constriction (TAC), where a suture is used to restrict blood flow through the ascending or transverse segment of the aorta, has been a valuable tool in cardiac research for three decades. However, there are limitations to TAC with regards to mortality and reproducibility. Additionally, the suture-based method has not allowed precise grading of the stenosis. Here we present a novel method for high precision aortic banding in mice, where fixed diameter micro o-rings were used to induce various degrees of reproducible cardiac remodeling and failure.
Male C57BL6/J wild-type (n = 105) and FVB/J NFAT-luciferase (n = 28) mice were subjected to mild, intermediate or severe o-ring aortic banding (ORAB) of the ascending aorta using o-rings with various inner diameters. Post-surgical assessment of cardiac structure and function was performed with MRI and echocardiography. Hearts were harvested at 2, 4 and 20 weeks post-ORAB for molecular analysis. Post-ORAB survival was 97%, i.e. only 4 technically-related deaths from 133 operations. All ORAB-operated groups developed left ventricular (LV) hypertrophy within one week of operation, assessed as increased LV mass and wall thickness by MRI and echocardiography. Hypertrophic remodeling in the severe ORAB group was more prominent. Over the 20 weeks following surgery, the severe ORAB mice gradually developed reduced cardiac contractile function and declining LV ejection fraction, followed by LV dilatation, whereas the mild and intermediate ORAB groups maintained a compensated LV function. Mice subjected to severe ORAB presented with heart failure, assessed as increased lung weight and left atrial dilatation at 20 weeks. mRNA levels of signature molecules of heart failure (NPPA, NPPB) and hypertrophy (ACTA1, MYH7) were upregulated at 2, 4 and 20 weeks in all group and with a graded response to o-ring inner diameter. Similarly, signature signaling pathways (MAPK and NFAT) associated with LV remodeling and failure were activated in a graded manner. LV fibrosis, measured by collagen mRNA (COL1A2, COL3A1) and Masson's trichrome staining, was more pronounced in mice with severe ORAB. When performed by two independent investigators, comparable structural, functional and molecular cardiac phenotypes where obtained, suggesting that ORAB surgery is inter-surgeon reproducible.
In conclusion, we have developed a novel method for experimental pressure overload in mice using fixed diameter micro o-rings. ORAB allows for inter-surgeon, inter-mouse line, graded cardiac remodeling and heart failure progression, with low mortality and post-surgical exclusion. Thus, choosing ORAB over TAC in experimental protocols is likely to increase the precision of the study and to reduce the number of mice used.

P1305

Epigallocatechin-3-gallate lowers increased calcium sensitivity in cardiac muscle strips of hypertrophic cardiomyopathy patients

F Felix Friedrich[1]; N Kresin[1]; S Stuecker[1]; E Kraemer[1]; G Mearini[1]; G Muench[1]; M Patten[1]; T Eschenhagen[1]; L Carrier[1]
[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Hypertrophic cardiomyopathy (HCM) is a primary disease of the myocardium and mainly caused by mutations in sarcomeric genes. Many forms of HCM show an increased myofilament Ca2+-sensitivity, which could account for compromised diastolic relaxation. Concerning mutations identified in HCM patients this observation has mainly been made in mouse models, reconstituted myofilament systems and isolated cells, but not multicellular tissue from patients. We therefore investigated myofilament Ca2+-sensitivity in multicellular cardiac muscle strips derived from septal myectomies or explanted heart of HCM patients. We furthermore evaluated the potential use of epigallocatechin-3-gallate (EGCg), a known Ca2+-desensitizer.
Methods: We isolated cardiac strips from cardiac tissue of nine HCM patients with either single heterozygous (MYBPC3, MYH7, ACNT2, PLN), or double heterozygous mutations (MYH7/MYBPC3, MYH7/LAMP2, MYBPC3/FLNC). After permeabilization we performed contractility measurements ± 30 μM EGCg to obtain maximal force (Fmax), force-Ca2+ curves and the Hill coefficient (nH). We furthermore evaluated gene expression with the NanoString technology using a customized heart-failure gene panel.
Results: Compared to strips from a non-failing control (NF), Fmax were not different in HCM strips except for two samples carrying MYBPC3 mutations with higher Fmax. Force-Ca2+ curves revealed a higher myofilament Ca2+-sensitivity in HCM patients' strips derived from myectomies, whereas failing explanted heart strips (PLN mutation) were not different. Strips with double heterozygous mutations showed a higher Ca2+-sensitivity than strips with single heterozygous mutations. NH as the indicator of cooperativity was different in all patients' myectomy derived strips, but not in failing explanted heart strips. 30 μM EGCg shifted the force-Ca2+curves of all strips to the right indicating myofilament Ca2+-desensitization. EGCg application induced a more pronounced shift in MYBPC3 strips than in the other genotypes and in strips from patients with truncating mutations. Compared to NF samples, gene expression analysis revealed differences in heart-failure, hypertrophy and fibrosis markers. Differences between NF and HCM samples with higher Ca2+-sensitivity were more prominent in heart-failure and hypertrophy markers, whereas fibrosis markers were more upregulated in tissue with no difference in Ca2+-sensitivity (explanted heart). NPPA and NPPB levels were markedly higher in tissue from patients with double heterozygous compared to tissue with single heterozygous mutations, and in tissue with missense vs. truncating mutations.
Conclusion: We confirmed previous results of an increased Ca2+-sensitivity in native multicellular cardiac strips of HCM patients. Findings suggest that EGCg might be useful for treatment of HCM-associated diastolic dysfunction. Moreover, EGCg could have differential effects depending on the underlying genotype and consequence of the mutation.

P1306

Yin-Yang 1 transcription factor modulates sST2 on adverse cardiac remodeling post-myocardial infarction

MC Asensio Lopez[1]; AM Antonio Manuel Lax[2]; MJ Fernandez Del Palacio[3]; Y Sassi[4]; R Hajjar[4]; DA Pascual Figal[2]
[1]Biosanitary Research Institute of Murcia (IMIB-Arrixaca)., Cardiology, Murcia, Spain; *[2]University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain*; *[3]Department of Animal Medicine and Surgery, Murcia, Spain*; *[4]Icahn School of Medicine at Mount Sinai, Cardiology, New York, United States of America*

Rationale: The cardioprotective effects of metformin in the setting of myocardial infarction remain poorly defined. IL33/ST2L signaling is a novel cardioprotective

system, which is antagonized by the soluble isoform sST2. No data exist about the regulation of ST2 expression.
Objective: To evaluate the pathophysiological implication of Yy1/HDAC4 system in the expression of soluble ST2 isoform.
Methods and Results: Myocardial infarction and left ventricular dysfunction in rats were induced by permanent ligation of the left anterior coronary artery. Animals randomly received metformin or saline (control). Our results point to improved post-infarction cardiac remodeling induced by metformin, associated with an increase in IL-33 and reduced sST2 expression. Metformin therapy modulates the activity and significantly reduces intranucleus protein levels of the transcription factor Yin-Yang 1. Moreover, metformin blocked the HDAC4 phosphorylation induced by myocardial infarction preventing its export from the nucleus to the cytosol. Dephosphorylated HDAC4 in the nucleus acts as a co-repressor of Yin-Yang-1, which leads to repress the expression of sST2.
Conclusions: Metformin prevented myocardial remodeling after MI by blocking the nuclear-cytosol shuttling of HDAC4, acting as co-repressor of Yin-Yang 1, which leads to suppresses the soluble isoform of the ST2 gene. Manipulation of this pathway might offer new therapeutic options for adverse cardiac remodeling.

P1307

Pharmacological inhibition of the mitochondrial NADPH oxidase 4/PKC/Gal-3 signaling pathway attenuates adverse cardiac fibrosis, following myocardial infarction

M C Maria Del Carmen Asensio[1]; A Lax[1]; MJ Fernandez Del Palacio[2]; MC Sanchez Perez[1]; Y Sassi[3]; R Hajjar[3]; DA Pascual Figal[4]
[1]Biomedical Research Institute Virgen de la Arrixaca (IMIB-Arrixaca), University of Murcia, Cardiology, Murcia, Spain; *[2]Veterinary Teaching Hospital, Veterinary Medicine and Surgery Department, University of Murcia, Cardiology, Murcia, Spain*; *[3]Mount Sinai School of Medicine, Cardiology, New York, United States of America*; *[4]Hospital Clínico Univeristario Virgen de la Arrixaca, Cardiology, Murcia, Spain*

Background: The antifibrotic mechanism of metformin is not completely understood. Our aim, therefore, was to characterize the possible involvement of NADPH oxidase 4 (mitoNox), PKC and Gal3 in this mechanism, given that each has been separately related with myocardial fibrosis and they could represent therapeutic targets.
Methods: Rats were subjected to MI by permanent ligation of the anterior descending coronary artery, and randomized into four experimental groups: (1) placebo-treated sham group; (2) placebo-treated MI; (3) Metformin-treated MI and (4) Metformin-treated sham group. Rats received MET (250 mg/kg/day) or normal saline for 4 weeks. An experimental model of biomechanical strain and a coculture, to allow cross talk between primary cultures of cardiomyocytes and cardiac fibroblasts (all obtained from C57BL6J mice using a Langendorff system), were established to characterize the underlying molecular mechanisms involved in the MET antifibrotic actions. The role of AMPK was determined via siRNA-mediated knockdown while those of mitoNox and PKCa were determined using the inhibitors GKT137831 and Chelerythrine, respectively. The mRNA and protein expression of different markers were measured by quantitative RT-PCR and Western blot, respectively.
Results: Long-term metformin treatment (4 weeks) following MI was associated with: i) a reduction in myocardial fibrosis, Gal3 mRNA and protein levels, as well as macrophage infiltration; ii) an increase in AMPK a1/a2 levels ($p < 0.001$), and an inhibition of both mRNA expression and enzymatic activities of mitoNox and PKCa ($p < 0.001$, in all cases). Following MI, the increase in expression and activity of both enzymes was associated with an increase in the accumulation of the superoxide anion ($p < 0.001$) which positively correlated with mitoNox and PKCa activities ($rs = 0.362$, $p = 0.018$), as well as an increase in the lipid peroxidation ($p < 0.001$) and the activation of the apoptotic death program characterized by the activation of initiatory procaspase 9 ($p < 0.001$) and effectory procaspase 3 ($p < 0.001$). MET therapy was associated with lower superoxide accumulation ($p < 0.001$), lipid peroxidation ($p < 0.001$) and caspases activation ($p < 0.001$). These findings were replicated using a biomechanical strain model. The silencing of AMPK expression (siRNA) blocked the ability of metformin to protect cardiomyocytes from biomechanical strain in terms of mitoNox and PKCa activities, Gal3 levels, cells viability and proliferation, and reactive oxygen species levels ($p < 0.001$, in all cases). The use of specific inhibitors supported the idea that PKC is downstream of mitoNox, and the activation of this pathway results in Gal-3 up-regulation. The Gal-3 secreted by cardiomyocytes has a paracrine effect on cardiac fibroblasts, inducing their activation.
Conclusion. A metformin-induced increase in AMPK improves myocardial remodeling post-MI, which is related to the inhibition of the mitoNox/ PKCa/Gal-3 pathway.

Purpose: Anthracyclines (ANTs) rank among the most effective, but also most cardiotoxic anticancer agents. The morbidity and mortality of ANT-treated cancer survivors may be affected by the irreversible damage to the heart resulting potentially into heart failure. The only cardioprotectant approved for prevention of development of ANT cardiotoxicity is dexrazoxane (DEX). It has been traditionally considered as a pro-drug of metal chelating agent ADR-925, nevertheless newer data highlight the interaction of the parent molecule with topoisomerase II beta (Top2b), which has been proposed as a key molecular target for ANTs in the heart. So far, only very few DEX derivatives have been tested for their cardioprotective effects. Furthermore, mechanisms of cardioprotection and structure-activity relationships remain unclear. Aim of this work was to study cardioprotective effects of two newly synthetized DEX derivatives very close in chemical structure to the prototype molecule (N, N‘–dimethylderivative - GK-627 and iso-methylderivative - GK-580) on a model of chronic ANT cardiotoxicity. Furthermore, the mechanisms required for effective protection were investigated.
Methods: Cardiotoxicity was induced in rabbits in a well-established schedule by daunorubicin (DAU, 3 mg/kg/week for 10 weeks) and cardioprotection was achieved by DEX (60 mg/kg before each DAU dose). New DEX derivatives were administered in the same dose and schedule as DEX. In other set of experiments, DEX and its derivatives were administered as a single dose to rabbits to study their pharmacokinetics and ability to interact with Top2b in the heart.
Results: Indeed, DEX completely protected rabbits from mortality (related to heart failure) and effectively prevented induction of the left ventricle (LV) dysfunction as assessed by both echocardiography and LV catheterization. In contrast, neither of its close derivatives was able to do the same. Mortality due to heart failure was 25% and 37.5% in GK-627 and GK-580, respectively (vs 30% in the DAU group). Furthermore, LV dysfunction and expression of natriuretic peptides in the LV were found to be similar as in the DAU group. Also biomarkers of cardiac damage (cTnT) and cardiac histopathology revealed significant damage in both groups which sharply contrasted with the DEX group. Further study confirmed that the difference between DEX and its derivatives is not due markedly altered plasma pharmacokinetics. Instead, the additional experiments revealed the striking difference is in pharmacodynamics - in particular, in ability of the studied agents to interact and deplete Top2b in the heart.

Conclusions: Interaction with Top2b seems to be essential for effective cardioprotection induced by DEX and similar compounds. Cardioprotective effects of DEX are tightly associated with the structure of piperazinedione rings and even small change to this part of molecule can completely abolish both Top2b effects in the heart and effective cardioprotection.

Funding Acknowledgements: Charles University Grand Agency (GAUK 680216)

Purpose: Chronic anthracycline (ANT) cardiotoxicity and resulting heart failure are feared complications of cancer chemotherapy. In this indication, dexrazoxane (DEX) is the only drug with well-established cardioprotective effects in both experimental and clinical settings. However, its clinical use is currently restricted because of concerns about its adverse effects. Angiotensin-converting enzyme inhibitors (ACEi) are commonly used to treat ANT-induced cardiac dysfunction and recently been suggested to possess also cardioprotective effects when used prophylactically. However, it is unclear whether ACEi can induce true and sustained cardioprotection similarly as DEX which will not diminish after the withdrawal of the protectant. Hence, the aim of this study was to evaluate cardioprotective effects of perindopril (PER) on a DEX-validated model of chronic ANT cardiotoxicity.
Methods: Chronic cardiotoxicity was induced in DEX-validated model in rabbits with daunorubicin (DAU, 3 mg/kg, weekly for 10 weeks). PER was administered in drinking water in clinically relevant doses (0.05 and 0.1 mg/kg/day) starting a week before 1st DAU dose and withdrawn 3 days after the last dose. After another 4 days when PER was largely eliminated, survivors were randomized for LV catheterization and sacrifice or for subsequent 3 weeks drug-free follow up (FU).
Results: In the treatment period, PER prevented DAU-induced mortality (0 vs. 36 %) and echo examination showed no significant decline in systolic function. LV catheterization revealed significant decline in dP/dtmax in PER co-treated animals as compared to controls, but there was found a significant improvement as compared to the animals receiving DAU alone. Histopathological examination revealed lower cardiomyocyte degeneration and fibrosis at the end of treatment period in PER co-treated animals. In the FU period, PER prevented or markedly reduced ongoing DAU-induced mortality and incidence of sings of blood congestion, but echo examination revealed significant decline in LV systolic function in both doses of the drug. While DAU-induced raise of plasma cardiac troponin T was significantly suppressed by PER in the treatment period, gradual and significant release was observed in the FU to almost match the DAU group at the end of the study. Furthermore, LV expression of ANP, BNP and collagen I was then increased in both groups similarly to the DAU group.
Conclusions: ACEi treatment showed remarkable protection against different parameters of chronic ANT cardiotoxicity during the treatment period, but the effect was found to be progressively diminishing after the withdrawal of the drug. The latter findings are strikingly different to those previously obtained with DEX on the same model and the augmentation of the dose of ACEi showed no benefit in this regard. Estimation of overall benefit of cardioprotective intervention with ACEi against chronic ANT cardiotoxicity requires further study with longer FU period.

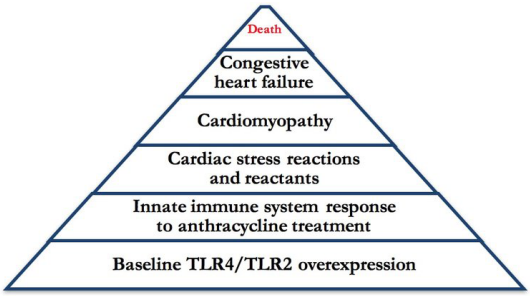
A non-biopsy genetic risk detection method from peripheral human blood for early detection of doxorubicin induced cardiotoxicity

M Trofenciuc[1]; D Darabantiu[1]; RM Christodorescu[2]; HS Branea[2]; A Pop-Moldovan[1]
[1]*Vasile Goldis Western University, Arad, Romania*; [2]*University of Medicine Victor Babes, Timisoara, Romania*

The purpose of the study was a better risk stratification and treatment management and individualization for each of the patients treated with doxorubicin without the usage of miocardial biopsy, which is (was) considered (until now) to be a “gold standard" for cardiotoxicty detection.
This was a prospective study on 25 oncological patients undergoing doxorubicin chemotherapy in which we determinated and correlated TLR2 and TLR4 (tool-like receptor) gene expression with diastolic and systolic echocardiographic parameters concerning cardiotoxicity monitoring.
Material and Methods: Our study included 25 consecutive patients who received treatment with doxorubicin for leukemia, lymphomas or multiple myeloma, aged 18-65, with a survival probability > 6 months and with left ventricular ejection fraction > 50% who expressed their informed consent. Exclusion criteria consisted of previous anthracycline therapy, previous radiotherapy, history of heart failure or chronic renal failure, atrial fibrillation, pregnancy.
Echocardiographic parameters recorded were those of left ventricular diastolic and systolic function (ventricular volumes, ejection fraction, pulsed and tissue Doppler analysis).
Results: Out of the 25 patients, 13 (52%) were males and 12 (48%) were females. Mean age was 56,9 years. The mean dose of doxorubicin administered ranged between 100 - 250 mg/m2, the doxorubicin clearance being 1443 ± 114 ml/min/m2. The average amount of gene expression units was 0.113 for TLR4 (range 0,059-0,753) and 0,218 for TLR2 (range 0,046-0,269).
After 6 months, for 4 patients (16%) left ventricular ejection fraction decreased from 64% to 45%, the other 21 patients having preserved ejection fraction. In patients with decreased of ejection fraction the mean values for TLR4 were 0,18885 and TLR2 at 0,2751 gene expression units.
Criteria for diastolic dysfunction were present after 6 months in 16 patients (64%). In these patients the mean value for TLR2 was 0,30 ± 0,19 and for TLR4 0,15 ± 0,04. Values for the patients who did not develop diastolic dysfunction were 0,16 ± 0,07 for TLR2 (p = 0.01) and 0,11 ± 0,10 for TLR4 (p = 0.2).
Mean E/e’ ratio was 15 ± 0,5 in patients with diastolic dysfunction and 7,8 ± 1,2 in those with normal diastolic function. Patients with E/e’ ratio > 15 had a mean TLR2 expression of 0,39 ± 0,2 compared with 0,23 ± 0,04 in patients with E/e’ = 15.
Conclusions: Our study suggests that TLR4 and TLR2 expression is higher in patients under doxorubicin therapy which develop diastolic dysfunction. The patients with the highest gene expression values were those with more severe diastolic dysfunction.
In all patients, in fasting state, a blood sample was drawn for the assessment of TLR2 and TLR4 gene expression. Gene expression was assessed by qRT PCR.
After 6 months of doxorubicin therapy patients were reevaluated.



Cardiotoxicity immunomodulation

Nitro oleic acids attenuated systolic heart failure in a murine model of hypertensive heart disease with reduced systolic function

D Dennis Mehrkens[1]; S Geissen[1]; M Adam[1]; M Pekarova[2]; L Kubala[2]; K Manchanda[1]; AK Schaetzle[1]; M Mollenhauer[1]; B Freeman[3]; A Klinke[1]; S Baldus[1]; V Rudolph[1]
[1]*Cologne University Hospital - Heart Center, Department of Cardiology, Cologne, Germany*; [2]*Academy of Sciences of the Czech Republic, Institute of Biophysics, Brno, Czech Republic*; [3]*University of Pittsburgh, Department of Pharmacology and Chemical Biology, Pittsburgh, United States of America*

Purpose: Hypertensive heart disease is a result of chronic arterial hypertension and ranks within the top 10 causes of death in the world, especially prevalent in industrial nations. Cardiac remodeling such as hypertrophy and fibrosis characterize its early progression. Persistent high pressure and volume overload leads to left ventricular dilatation and heart failure with reduced ejection fraction (EF). Nitro oleic acid (OA-NO2) is an endogenously produced nitroalkene which was shown to have antiinflammatory effects as a therapeutic in various animal models of cardiac disease. Recently, we reported the reduction of angiotensin II (Ang II) induced atrial fibrillation and atrial fibrosis by OA-NO2 treatment. Herein, we investigated the effects of OA-NO2 on the morphology and function of the left ventricle and underlying mechanisms in a murine model of hypertensive heart disease with impaired systolic function.
Methods and Results: Wild-type C57BL6/J mice (WT) were subjected to Ang II and additionally, to vehicle (polyethylene glycol/ethanol, AS treatment) or nitro-oleic acid (OA-NO2) via subcutaneous osmotic minipumps. All animals received a salt diet of 1% NaCl dissolved in drinking water for 28 days. Untreated WT mice of the same age were used as a control. Echocardiographic analysis showed a reduced EF in AS treated mice, an effect which was diminished in AS + OA-NO2 treated animals. Histological analyses showed a significantly larger cross-sectional area of cardiomyocytes and a higher grade of fibrosis in the left ventricle in AS

mice, as compared to AS + OA-NO2 treated mice. Of notice, heart weight was significantly increased in AS treated animals but not in the OA-NO2 group. mRNA expression analysis of left ventricular tissue showed activation of a cardiac fetal gene program in the AS treated group, primarily indicated by a shift in a-MHC/ß-MHC ratio, which was absent in OA-NO2 treated mice. Similar results were obtained in a second approach with 14 days of AS pre-treatment, which was followed either 14 days of AS or AS + OA-NO2 treatment. Mice subjected to AS + OA-NO2 showed no further decrease in EF, while AS treatment led to highly reduced EF. Invasively measured blood pressure was significantly elevated in AS and OA-NO2 treated mice compared to WT, but showed no difference between AS and OA-NO2 treatment. Mechanistically, protein and mRNA analyses of ventricular tissue and Ang II stimulated 3T3 fibroblasts indicated an OA-NO2 mediated inactivation of the STAT3 pathway and reduced expression of miR-21 in vivo and in vitro, factors which where both highly upregulated in AS treated mice.
Conclusions: The current data demonstrate that OA-NO2 reduces the cardiac effects of Ang II and high salt treatment and mitigates the progression of hypertensive heart disease due to prevention of STAT3 activation followed by reduced miRNA-21 expression.

The failing heart stimulates tumor growth by circulating factors

WC Wouter Meijers[1]; M Maglione[2]; SJL Bakker[3]; S De Jong[4]; AR Lyon[5]; DJ Van Veldhuisen[6]; BD Westenbrink[1]; P Van Der Meer[1]; HHW Sillje[1]; RA De Boer[1]
[1]University Medical Center Groningen, Department of Experimental Cardiology, Groningen, Netherlands; *[2]Innsbruck Medical University, Department of Visceral, Transplant and Thoracic Surgery, Innsbruck, Austria*; *[3]University Medical Center Groningen, Department of Internal Medicine, Groningen, Netherlands*; *[4]University Medical Center Groningen, Department of Oncology, Groningen, Netherlands*; *[5]Imperial College London, Heart and Lung Institute, London, United Kingdom*; *[6]University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands*

Purpose: Heart failure (HF) survival has improved and nowadays many patients with HF die from
non-cardiac causes, including cancer. Our aim was to investigate whether a causal relationship exists between HF and the development of cancer.
Methods: HF was induced by inflicting large anterior myocardial infarction (MI) in APCmin mice, which are prone to develop precancerous intestinal tumors, and tumor growth was measured. In addition, to rule out hemodynamic impairment as a cause for potential HF-induced effects, a heterotopic heart transplantation model was employed, where an infarcted or sham-operated heart was transplanted into the cervical area of a recipient mouse, while the native heart was left in situ. After 6 weeks, tumor number, volume, and proliferation were quantified in all mice. Candidate secreted proteins that were previously identified to be associated with (colon) tumor growth in post-MI proteomic studies and studies related to intestinal epitopes. Myocardial gene expression levels of these selected candidates were analyzed, as well as their proliferative effects on HT-29 (colon cancer) cells. We validated these candidates by measuring them in plasma of healthy subjects and HF patients. Finally, we associated the relation between the HF surrogate marker NT-proBNP and new-onset cancer in a prospective general population cohort.
Results: The presence of failing hearts, either native or heterotopically transplanted, resulted in significantly increased intestinal tumor load of 2.4 fold in both animal studies (all $P < 0.0001$). The severity of left ventricular (LV) dysfunction and fibrotic scar strongly correlated with tumor growth ($P = 0.002$ and $P = 0.016$, respectively). Identified proteins were elevated in human patients with chronic HF ($N = 101$) compared to healthy subjects ($N = 180$, $P < 0.001$). Functionally, SerpinA3 resulted in marked proliferation effects in human colon cancer (HT-29) cells. Finally, elevated NT-proBNP levels in apparently healthy humans ($N = 8319$), being a surrogate for preclinical HF, were predictive for new-onset cancer ($N = 1124$), independent of adjustment for known risk factors for cancer, including age, smoking status and body mass index.
Conclusion: We demonstrate that the presence of HF is associated with enhanced tumor growth and this is independent from hemodynamic impairment and could be due cardiac excreted factors.

Poster Session 2 - Clinical Cases

Chronic Heart Failure–Pathophysiology and Mechanisms

P1313

A patient with symptomatic heart failure with preserved left ventricular ejection fraction and right sided heart failure treated with LCZ696

M Cafka[1]; J Xhanaj[1]; E Zace[1]; A Duka[2]; J Seiti[2]; I Balla[2]; A Goda[1]
[1]University Hospital Center Mother Theresa, Department of Cardiology & Cardiac Surgery, Tirana, Albania; *[2]University Hospital Center, Intensiv Care Unit, Tirana, Albania*

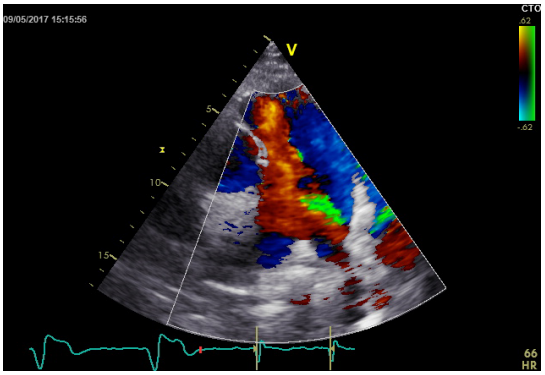
Introduction: Nowdays, where the place of LCZ696 in the treatment of heart failure with reduced systolic function is well established , there are no data about the effect of LCZ696 in patient with symptomatic heart failure with preserved ejection fraction. We present a complex case of a patient with acute cardiac decompensation, with right–sided heart failure but with preserved left ventricular ejection fraction , and chronic renal failure.
Materials : N.H 63 years old, female, presented at the hospital complaining of shortness of breath, fatigue, cough, fever. She had a history of two weeks with symptoms above, gradually worsening. The patient has a known history of repaired septal atrial defect (1990), mechanical prosthesis in aortal and mitral position (2011), a chronic atrial fibrillation, hypertension, insulin dependent diabetes mellitus, chronic renal failure. Vital signs : temperature 37.5 grade/celcius, heart rate 100-110/bpm,blood pressure 130/80 mmHg,respiratory rate 24 breaths/minute, O2 sat 90%. On cardiac examination: ortopnoe position , bibasilar pulmonary inspiratory crackles, elevated jugular venous pressure, hepatic congestion, peripheral edema. TTE revealed normal mechanical mitral and aortal prosthesis (no imaging positive for infective endocarditis). LVEDD 62 mm with LVEF 52% (evaluated by Simpson method), left atrium area 30cm2, right chamber dilated,advanced tricuspidal regurgitation, PSAP 55 mmHg. On the labs : WBC 11 200/mm3, creatininemia 1.7 mg/dl, uremia 215 mg/dl, C reaktiv protein 99 mg/dl, NT -pro BNP 1819 pg/mL, D-Dimer 583ng/ml, steril hemoculture.
Assuming that pulmonary infection and acute deterioration of chronic renal disease(Cardio-renal syndrome type 5) cause acute decompensation of heart failure in NYHA class IV, we begin the treatment with intravenous diuretics, MRA, Antibiotics .When fever is controlled (CRP 20mg/dl) and with stable with renal parameters (creatinine 1.3 mg/dl , creatinine clirence of 43 mL/min) we restart ARB and Beta blockers with minimal dose and up titrating them. Nevertheless the patient remain symptomatic, NT -pro BNP (1142 pg/mL) , so we decided to start LCZ696 50 mg 2 times a day. After 5 days the patient begin to feel better and after 2 weeks she was able to move without symptoms on normal effort; NT-pro BNP reduced to 998pg/ml.
The patient nowdays remain in NYHA Class II, tolerating 100 mg LCZ696 a day. No changes in parametres and systolic function of both ventricle, also in the LA area, was found, but a reduced of PSAP around 40 mmHg.
In Conclusion: This represent a combination of heart failure with preserved ejection fraction and right side heart failure , and chronic renal failure stade 3, where the addition of LCZ696 result in obvious clinical improvement which remain stable nowdays (for about 10 months after discharge) associated with reduction of value of BNP and reduction of pulmonary systolic pressure.

P1315

Unexpected blood flow from pulmonary veins during cardiopulmonary bypass for mitral valve surgery in a 62-year-old woman

N Nicolas Verheyen[1]; G Stoschitzky[1]; J Binder[1]; K Ablasser[1]; O Dapunt[2]; I Knez[2]; A Gamillscheg[3]; R Maier[1]
[1]Medical University of Graz, Clinical Department of Cardiology, Graz, Austria; *[2]Medical University of Graz, Department of Cardiac Surgery, Graz, Austria*; *[3]Medical University of Graz, Division of Pediatric Cardiology, Department of Pediatrics, Graz, Austria*

A 62-year-old lady was acutely referred from an external surgery department where open mitral valve annuloplasty had been cancelled directly after cardiopulmonary bypass connection and cardioplegia because the pulmonary veins had continued to deliver blood into the left atrium. At admission she reported about breathlessness on exertion equivalent to NYHA class III-IV, despite optimal medical therapy for heart failure including a loop diuretic. Auscultation revealed a grade 2/6 systolic-diastolic murmur in the aortic area. She had signs of cardiopulmonary congestion (elevated jugular venous pulse, leg edema). Further comorbidities included osteoporosis and depressive mood disorder.



Regurgitation jet in pulmonary trunk

Office blood pressure and heart rate were 160/60 mmHg and 81 bpm, respectively. An electrocardiogram showed atrial fibrillation and complete left bundle branch block and was otherwise unremarkable. Echocardiography showed a dilated and diffuse hypokinetic left ventricle (end-diastolic diameter 66mm, left-ventricular ejection-fraction 39%, global longitudinal strain –12.6 %) and severe mitral regurgitation (MR) secondary to mitral annulus dilatation. The right ventricle had normal dimension and mildly reduced function (end-diastolic diameter 35mm, TAPSE 15mm) and estimated systolic pulmonary artery pressure (sPAP) was 46 mmHg. In parasternal short axis view with focus on the RVOT, the pulmonary trunk was severely dilated (41 mm). Color Doppler revealed a massive regurgitation jet originating from the left-sided wall of the pulmonary trunk (Figure 1).
A patent ductus arteriosus Botalli (PDA) was confirmed by computed tomography. Simultaneous right and left heart catheterization revealed both post-capillary pulmonary hypertension (mean pulmonary capillary wedge pressure 22 mmHg), as a consequence of dilated cardiomyopathy and MR, and pre-capillary pulmonary hypertension (PAP 67/27 [mean 47] mmHg), due to chronic volume overload of the pulmonary arterial system. Surgical PDA closure and concomitant mitral valve annuloplasty were successfully performed. Three months after surgery the patient's symptoms were markedly improved and estimated sPAP declined to 34 mmHg.
This case illustrates congenital heart disease as a rare and potentially reversible cause of dilated cardiomyopathy and functional MR underlining the importance to perform a comprehensive echocardiographic examination in the early diagnostic work-up of heart failure.

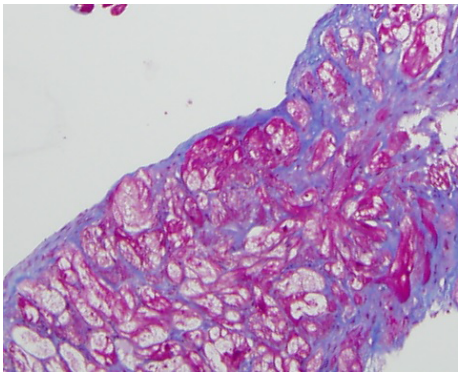
Chloroquine induced cardiomyopathy

K Krisztina Kosa[1]; B Muk[1]; D Vagany[1]; M Szabo[1]; J Papp[1]; G Bartha[1]; ZS Kiss[2]; T Borsanyi[1]; RG Kiss[1]; N Nyolczas[1]
[1]Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary; *[2]Medical Centre, Hungarian Defence Forces, Department of Pathology, Budapest, Hungary*

Introduction: Chloroquine (CQ) and hydroxychloroquine are widely used in the treatment of autoimmune diseases. Long-term use of these drugs can induce a rare, but life-threatening toxic side effect, such as cardiomyopathy with restrictive dysfunction that is associated with left ventricle hypertrophy and conduction disorders. The background of the disease is a drug-induced, acquired lysosomal storage disorder. Henceforth we present three clinical cases of CQ induced cardiomyopathy.

Clinical case: In case of pt1 (64 years old) and pt2 (71 years old) long-term (13 and 12 years, respectively) CQ treatment was given due to Sjögren's syndrome and pt3 (67 years old, 16 years CQ treatment) due to SLE. They were admitted to our Cardiology Department with severe heart failure (NTproBNP pt1: 23815 pg/ml, pt2: >35ooo pg/ml, pt3: 33342 pg/ml). Before their hospitalization permanent pacemaker was implanted in all pts because of third degree atrioventricular block (pt1: 1 year, pt2: 6 years, pt3: 1 year earlier). In all cases severe hypertrophic left ventricle and restrictive dysfunction was shown by transthoracic echocardiography. Echocardiographic results suggested cardiac amyloidosis, but further studies have excluded the possibility of it. Due to long-term CQ therapy in the patients' history drug-induced cardiomyopathy was suggested. To confirm this diagnosis endomyocardial biopsy was performed in all three cases. Histological examination showed extreme cytoplasmic vacuolisation that is typical for CQ induced cardiomyopathy. Afterwards CQ therapy was stopped in each patient. One patient showing the most severe clinical symptoms died three months after the diagnosis (pt2). The other two patients are regularly controlled in our Heart Failure Outpatient Clinic. Currently they are clinically stable, but due to the long exposure period, their status seems irreversible. In case of advanced CQ induced cardiomyopathy, heart transplantation is a therapeutic alternative, although in our two patients it is contraindicated due to comorbidities.
Conclusion: CQ induced restrictive cardiomyopathy is underdiagnosed. Early diagnosis and CQ therapy withdrawal is a key point in reversibility, before the development of severe heart failure. Therefore, cardiologic follow-up of patients receiving CQ therapy is essential.



Histology

Myocardial impairment due to cardiotoxicity after stem cell transplantation: a case report.

R Badr Eslam[1]; S Kufova[1]; B Ozturk[1]; M Krauth[2]; T Binder[1]; IM Lang[1]; J Bergler-Klein[1]
[1]Medical University of Vienna, AKH - Vienna, Cardiology Clinic, Internal Medicine II, Vienna, Austria; [2]Medical University of Vienna, Internal Medicine I, Division of Hematology and Hemostaseology, Vienna, Austria

Introduction: Cardiac toxicity is induced early or late damage to the heart frequently occurring in patients undergoing chemotherapy and oncology treatments. Early detection and treatment of cardiovascular toxicities is highly important for the further outcome. This is a case report of a 63y old female with Multiple Myeloma after receiving stem cell therapy and irradiation, referred for cardiac evaluation ongoing therapy of lenalidomid combined with dexamethasone, and previous bortezomib cancer treatment, regarding cardiotoxicity.
Purpose: Aim of the presentation is to discuss the echocardiography, spiroergometry and clinical findings in context of treatment and prognosis impact.
Methods: Transthoracic echocardiography was performed to assess of myocardial impairment. Ventilation and pulmonary gas exchange as well as cardiac parameters were measured during cardiopulmonary exercise testing (CPET) using a cycle ergometer (VYNTUSTM CPX, Carl Rainer Austria). A ramp protocol, adapted to reach maximal exercise capacity after 8-10 minutes was chosen for the test. The parameter of main interest was maximal oxygen uptake (VO2 max. ml/min.), the major factor known to limit exercise capacity in heart failure.
Results: Transthoracic echocardiography revealed a reduced left ventricular (LV) global longitudinal strain and global circumferential strain by 2D speckle-tracking (GLPS -15%; GE Vivid System) despite LV systolic ejection fraction in normal range (55%), with abnormal basal and mid- interventricular septal motion and diastolic impairment. The patient had no cardiac history and reported fatigue.
Aerobic exercise capacity was slightly reduced: VO2 max. was 16.6 ml/kg/min (= 1162 ml/ min= 83% of percent predicted). Heart rate (HR) response to exercise was slightly below reference value (resting HR 96 b/min, HR end of exercise 130 b/min = 82% of age-predicted) (Figure 1).
N-terminal pro-B-natriuretic peptide level was elevated (241.9 pg/ml).
VO2 max, global longitudinal strain and NT-proBNP have been shown to predict outcome in heart failure, and were well related in this case of cardiotoxicity after allogenic bone marrow transplantation and chemotherapy. These 3 parameters can easily be determined in the clinical setting and appear useful for the cardiac follow-up of cancer pts. Furthermore, VO2 max improvement by exercise training has been shown to improve outcome in cancer pts and heart failure.
Conclusion: Longitudinal speckle tracking strain and peak oxygen consumption are important variables identifying cardiotoxicity non-invasively. Our report should encourage health care professionals to promote exercise testing for pts undergoing chemotherapy to identify development of early myocardial impairment and start treatment as well as exercise programs.

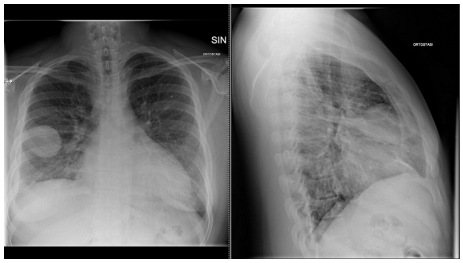
P1318

Late anthracycline - induced cardiotoxicity: a case report

M Marco Schiavone[1]; M Squillace[1]; E Gherbesi[1]; C Gobbi[1]; G Malanchini[1]; F Lombardi[1]
[1]IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Cardiovascular diseases, Milan, Italy

Background: Chemotherapy with anthracycline is a mainstay for treating Acute Promyelocytic Leukemia (APML), due to its significant survival benefit. Nevertheless, treatment with anthracycline may result in progressive myocardial dysfunction and heart failure (HF), with a pattern of dilated cardiomyopathy. Currently, three types of anthracycline-induced cardiotoxicities are described: acute, early or late (median 7 years).
Case report: A 25-year-old male with a previous history of APML, treated 5 years before with All-trans retinoic acid and Idarubicin (cumulative dose >90 mg/m2) without a subsequent cardiac follow-up, was admitted to our department due to progressive dyspnea, cough and fatigue.
Physical examination at admission revealed several signs of HF: ankle swelling, hepatojugular reflux, third heart sound with a gallop rhythm, tachycardia, pulmonary crepitations and signs of pleural effusion. NT-proBNP was 3583 pg/mL.
A chest x-ray showed right pleural effusion and an oval-shaped pulmonary opacity (8 cm) in the right middle lobe which a subsequent CT scan described as a loculated pleural effusion.
An echocardiogram revealed a dilated left ventricle, diffuse hypokinesia (EF 25%) and moderate to severe mitral regurgitation.
High doses of iv Furosemide were started, together with Bisoprolol, Ramipril (both progressively titrated to the maximum dose, 10 mg o.d.) and Spironolactone 25 mg o.d..
A CMR confirmed the left ventricular dilation and the severe biventricular dysfunction (LVEF 28%, RVEF 35%) and did not show fibrosis.
During the admission, clinical conditions progressively improved and he was discharged after ten days, asymptomatic at rest.
A cycle of cardiac rehabilitation was started. During the follow-up, a CMR showed an almost complete recovery with normal left ventricular dimensions and an improvement in left ventricular function (LVEF 41% vs 28%); right ventricular function was normal (58% vs 35%).
The patient is still in our follow-up program.
Conclusion: Anthracyclines have been shown to be associated with dose-dependent cardiotoxicity, in about 5-18% of cases when the cumulative dose exceeds 90 mg/m2. Since this percentage is not negligible, screening and risk stratification are mandatory to develop early detection strategies, considering that anthracyclines toxicity is characterized by a continuous progressive decline in LVEF, as this case suggest.
These strategies need to be standardized and widespread, as the current Guidelines underline, in order to avoid hospitalizations due to acute heart failure or late therapy. This case emphasizes the importance of a multidisciplinary team of cardiologists and hematologists with expertise in drug induced cardiotoxicity, especially in patients affected by rare subtypes of acute leukemias, who are not scheduled for a strict follow-up program, as other patients affected by more common types of cancer, who are routinely evaluated in our clinic and echocardiography labs.



Chest x-ray

P1319

Residual hemodynamic congestion is related to poorer prognosis in patients with clinically compensated heart failure.

K Kazushi Sakane[1]; R Horai[1]; D Maeda[1]; K Akamatsu[1]; M Ozeki[1]; T Fujisaka[1]; K Sohmiya[1]; N Ishizaka[1]; M Hoshiga[1]
[1]Osaka Medical College, Cardiology, Osaka, Japan

Background: Residual clinical congestion is associated with worse prognosis in patients with heart failure. In the current study, we investigated the prognostic impact of hemodynamic congestion on the prognosis of clinically compensated heart failure patients after obtaining clinical compensation.
Methods: Among 250 patients admitted with acute decompensated heart failure, 75 patients underwent right heart catheterization. After excluding 19 patients with the condition of either persistent decompensated heart failure, 56 subjects were enrolled in the current study. Residual hemodynamic congestion was considered to be present when the mean pulmonary capillary wedge pressure (PCWP) was 15 mmHg or higher, and the major adverse cardiac events (MACE) were defined as either any cause of death, hospitalization due to worsening heart failure, implantation of the left ventricular assist devices.
Results: Among the study patients, plasma BNP value was not correlated with PCWP ($r = 0.08$, $p = 0.55$). Residual hemodynamic congestion was found in 29 patients (51.7%) even though symptoms were clinically compensated. Clinical characteristics including age, sex, blood pressure, renal insufficiency and left ventricular ejection fraction were not different between two groups. During the mean follow up period of 553 ± 341 days, 55.2% of patients with residual hemodynamic congestion ($n = 29$) had experienced MACE compared with 11.1% of those without ($n = 27$, Figure A). Among patients with residual hemodynamic congestion, MACE occurred more frequently in patients who did not add on diuretics before discharge compared with whose who added on diuretics (73.3% vs. 35.7%, $p = 0.08$, Figure B).
Conclusions: Residual hemodynamic pulmonary congestion in patients whose heart failure had already been clinically compensated was associated with higher risk for MACE. Hemodynamic assessment for the pulmonary congestion even after obtaining clinical compensation may have value for the long-term management of heart failure patients.

On behalf of: Medical University of Warsaw, Institute of Cardiology, Warsaw, Poland

31y/oLS(male)presented to theInternalMedicineDept.with tachycardia & heart failure(HF)symptoms-a feeling of abdominal"fullness" & periodic chest discomfort,occurring irregardless of physical activity.For2-3wks he complained of decreased exercise tolerance & "shallow breathing."For3-4daysLS noted a wet cough.Beforehand he had considered himself to be fit,exercising regularly,and periodically taking dietary supplement & other substances intended to build muscle mass.Upon admission the physical exam showed tachycardia124bpm,BP120/80mmHg,a systolic murmur at the heart apex,with no other abnormalities.The initial work-up showed:ECG-sinus tachycardia120bpm;ECHO-enlarged heart chambers,LVEF 32%(Table1);laboratory studies-slightly increased troponin I,NTproBNP 2408pg/ml.The initial Dx was of dilated cardiomyopathy(DCM)of toxic or tachyarrhythmic etiology.Treatment(Tx)with low-doses of loop diuretic,bisoprolol & ramipril was begun.HolterECG registered sinus rhythm94bpm on avg.,with nocturnal episodes of atrio-ventricular dissociation with ventricular rate 40-60bpm.ABPM noted a tendency for hypotension.On theth day of hospitalization,LS presented motor aphasia & rt-sided neurological signs,which resolved spontaneously within25min.of onset.Based on the results of brainCT,CT-Angio & MRI,an ischaemic stroke of the lt hemisphere was diagnosed.TEEshowed no clots in the LAappendage nor signs of aPFO.No episodes of atrial fibrillation(AFib)were noted,but due to an enlarged LA & DCM,which were potential substrates forAFib,LSwas started on dabigatran.It was thought that the neurologic episode was due to a drop inBP,thusLSwas discharged 9days from admission with no diuretic.Three mo.s laterHolterECG registered nsVT of13beats with nocturnal bradycardia to37bpm,while a control ECHO showed a further fall ofLVEF to27%.Cardiac catheterization was normal.It seemed that the patient hadn't responded to initial conservativeTx,although optimalTx was limited by lowBP.ThusLS was transferred to a reference center for furtherTx & possible heart transplantation(HTx),where he was an in-patient for almost3mo.s.Initially,despite catecholamine & furosemide infusions,changing bisoprolol to carvedilol,the LVEFdecreased to16%. Pulmonary hypertension was diagnosed & sildenafil was added.The patient was qualified forICD implantation & placed on the urgent HTx list.He began to respond to conservativeTx afterICD placement,withLVEF25% at discharge(6mo.s after initial presentation [ptt]).In a control ECHOperformed 3mo.s later(9mo.s after initial ptt)theLVEF rose to36%.Four mo.s later(1yr.after initial ptt)theLVEFwas40%.The patient,following doctors' recommendations,had changed his lifestyle,stopped taking illicit substances&was able to continue daily functioning.This case illustrates the compensatory mechanisms toHF in a hitherto healthy,physically-fit young man.It also shows the dangers of using illicit substances.In addition it teaches doctors patience,in waiting for clinical improvement after optimal medicalTx.

Chronic Heart Failure–Treatment

Effectiveness of ARNI (Angiotensin II Receptor Blocker Neprilysin Inhibitor) therapy in advanced HFrEF in reduction of severe functional mitral regurgitation

J Joanna Berner[1]; M Lelonek[1]
[1]Medical University of Lodz, Department of Noninvasive Cardiology, Lodz, Poland

In 65-year old male with HFrEF, severe FMR, CAD (post CABG in 2016), arterial hypertension, DM type 2, in pursuance of HF therapy 2016 ESC guidelines, ARB was replaced with ARNI.
Patient was hospitalized due to ADHF (12/2016) - NYHA Class IV, peripheral edema, jugular veins overflow. Selected laboratory and TTE results are presented in Table. Optimal HF treatment was applied (LBA, ARB, diuretics, MRA). At discharged in 6-MWT patient covered the distance of 220m.
At ambulatory visit (02/2017) he maintained in NYHA Class III. Heart Team was performed with the decision of MitraClip procedure. ARB was replaced with sacubitryl/valsartan in start dose 49/51mg. After 1-month OMT ARNI dose was optimized to 97/103mg.
In TTE (6 months OMT with ARNI) significant reduction of FMR was observed. Heart Team re-evaluated the case and indications for MitraClip have subsided. Patient returned to work.
After 9-month OMT with ARNI (NYHA Class I), ergospirometry was performed up to the level of 150W, VO2peak:14,29ml/kg/min; VO2atAT: 11,21ml/kg/min. V02peak >14ml/kg/min and V02 at AT>11 ml/kg/min have favorable prognostic value.
This case report presents the effectiveness of optimal medical therapy with sacubitryl/valsartan in HFrEF accompanied by FMR. We documented significant reduction of FMR on ARNI.

Patient's parameters and pharmacotherapy

Successful use of ultrafiltration (UF) in patients with heart failure (HF) and diuretic resistant fluid overload - A 3 year experience in a District General Hospital

M Shanmuganathan[1]; K Saleh[2]; TP Chuah[2]
[1]Imperial College London, NHLI, London, United Kingdom; *[2]Royal Surrey County Hospital, Cardiology, Guildford, United Kingdom*

Introduction: Ultrafiltration (UF) is a non-pharmacological therapy for decompensated chronic heart failure (CHF). Its precise role in daily clinical cardiology remains undetermined. We report our experience of using UF in a district general hospital.
Method: UF treatment was delivered by the Aquadex Flexflow device via a central venous catheter. Data was prospectively collected between January 2014 to June 2017.
Results: 13 patients with decompensated CHF underwent UF. The mean age was 72 and mean LVEF was 27.5%. Median daily IV furosemide dose prior to UF was 180mg (120-240mg); 9 patients received metolazone and 2 received dobutamine infusions. Mean weight loss on IVD was 0.1kg/day over 9.67 days, indicating diuretic resistance. During UF, mean weight loss was substantially higher at 2kg/day, with a mean total weight loss of 6.75kg, over a median treatment duration of 2.4. The mean BNP level fell by 125pg/ml after UF. Mean EGFR (Renal function) was 44.21 ml/min/1.73m2. This remained stable after IVD (43.05, p = 0.48) and UF (40, (p = 0.60). There were no adverse events (bleeding or infection).
Conclusion: In our 3 year experience, UF was effective, safe in decompensated CHF with diuretic resistance. It was not associated with a deleterious effect on renal function.

Characteristics of patients		
	Mean value	Standard deviation SD)
Gender (M:F)	10:3	N/A
Mean Age (years)	72	8.24
LVEF (%)	29.29	0.12
On ARB/ACEi & Beta blocker & MRA	100%	N/A
Baseline eGFR (ml/min/1.73m2) n = 9	44.21	17.59
Post IV diuresis eGFR (ml/min/1.73m2) n= 13	43.05	12.9
Post UF eGFR (ml/min/1.73m2) n = 13	40	17.38
Post IV diuresis BNP (pg/ml)	1153	1426
Post UF BNP (pg/ml)	704	590
Pre UF Systolic Blood pressure (mmHg)	120	16
Post UF Systolic Blood pressure (mmHg)	118	15
Time on IV diuresis (days)	9.67	7.94
Time on Ultrafiltration (days)	2.4	0.49
Weight loss on IV diuresis (Kg)	1.73	3.8
Weight loss on UF (Kg)	6.75	2.16

LVEF - Left Ventricular Ejection Fraction, IV - intravenous, UF - Ultrafiltration, eGFR - estimated glomerular filtration rate, BNP - brain natriuretic peptide.

P1324

Diagnostic and therapeutic challenges limit treatment options in heart failure due to complex congenital heart disease

M Luknar[1]; M Kovacova[1]; P Lesny[1]; E Goncalvesova[1]
[1]National Cardiovascular Institute, Bratislava, Slovak Republic

Background : Number of adult complex congenital heart disease (CHD) patients with heart failure (HF) is increasing. Their management is challenging due to numerous factors and treatment options are often limited. We present a case of a patient with corrected complex CHD and late left ventricular (LV) systolic dysfunction requiring advanced treatment.
Case: A young man (b. 1991) with a family history of heart failure (HF) at a young age and sudden death was born with D-transposition of the great arteries (TGA) and patent ductus arteriosus (PDA). Early after birth, balloon atrial septostomy was performed. Anatomic correction of the TGA, PDA ligation, and atrial septal defect closure were performed at 9 months of age. Due to progressive neo-aortic regurgitation with left ventricular (LV) dysfunction, Ross surgery was done in 2002. In later course, patient's condition remained mostly stable, with persisting mild LV dysfunction (LV ejection fraction 40%) as well as recurring atrial and ventricular tachyarrhythmias. Coronary angiogram was negative. In 2016, patient's condition worsened after an episode of atrial fibrillation and thyrotoxicosis. After immediate stabilization, he was referred to an HF centre in order to consider advanced treatment options. At admission, he was in functional class IV. There was LV dilation (82 mm) and extremely severe LV systolic dysfunction (LVEF 10%). Heart transplant (HTx) was considered but severe pulmonary hypertension (PH) with a predominant pre-capillary component (pulmonary vascular resistance of 5.0 Wood units) was a contraindication for listing. Pulmonary function testing revealed a restrictive pattern, however, subsequent imaging methods did not show any relevant lung pathology. LV assist device implantation was impossible due to right ventricular dysfunction. Total heart replacement as a bridge to HTx was not available. Despite sildenafil, unacceptable PH persisted and combined heart and lung transplant was considered. Unfortunately, status of the patient further deteriorated due to recurrent atrial fibrillation resistant to all treatments and he died of end-organ failure.
Case summary : We present a case of a patient with HF due to complex CHD. The most likely cause of LV dysfunction was concomitant dilated cardiomyopathy. Treatment decision making was challenging due to several complicating factors: cardiac (modified anatomy, right ventricular dysfunction, arrhythmia), cardiac-related (multi-factorial PH, repeated surgery), and non-cardiac (thyrotoxicosis, lung disease).
Conclusion: Treatment options for patients with HF due to CHD remain limited. Decision making must be individually tailored and depends on concomitant cardiac and non-cardiac conditions, as well as non-medical factors such as availability of

HTx programme, mechanical support, and other resources. Thorough identification and optimal management of these factors is warranted.

P1325

The heart- brain connection: tracking neurocognition from cardiogenic shock to heart transplantation

M R Robinson[1]; H Khalid[1]; M Khayata[1]; L Njoroge[1]; M Zacharias[1]; M Ginwalla[1]; CA Elamm[1]; M Moghbelli[1]; R Benatti[1]; GH Oliveira[1]
[1]*University Hospitals Cleveland Medical Center, Cardiology, Division of Heart Failure and Transplantation, Cleveland, United States of America*

Our patient is a 51 year old man with prior history non-ischaemic cardiomyopathy, left ventricular ejection fraction (15%, right ventricular systolic dysfunction, polysubstance abuse in remission for 15 years, left ventricular apical thrombus maintained on systemic anticoagulation and status post CRT-D implantation. He was known to have NYHA FC 4/ACC D heart failure for the preceding 3 years and was maintained on optimal heart failure pharmacotherapy. He had had recurrent hospitalisations for decompensated heart failure and cardiogenic shock requiring inotropic use in the recent past. He was admitted with progressive dyspnea and in cardiogenic shock. On presentation, he endorsed functional debility, but felt that his mental capacity was unchanged and within normal limits for him. In addition to heamodynamic (HD) assessment, we undertook serial testing of neurocognitive function (NCF) while he was medically and surgically managed for cardiogenic shock and report our findings leading up to and following orthotopic heart transplantation (OHT). On admission HD, central venous pressure (CVP) 10 mmHg, pulmonary artery pressure (PAP) 57/30 mmHg, pulmonary capillary wedge pressure (PCWP) 30 mmHg, cardiac index (CI) 1.5 L/min/m2, systemic vascular resistance (SVR) 2400 (dynes-sec/cm5), and pulmonary arterial O2 saturation (SvO2): 54%. Testing for depression and was negative and KCCQ suggested a poor quality of life (QoL). Figure 1 details change in MoCA score and CI as he was medically managed, transplanted and post heart transplantation.

Post-OHT, there was no biopsy evidence of rejection. At his outpatient follow-up visit on Day 73, he was able to do 10 METS of activity, continued to be free of depression and QoL testing was improved by 43 points (a 10 point change is considered clinically significant). Moreover his MoCA score continued to be normal.

Implications:

NC deficits are prevalent in cardiogenic shock. Little is known of the impact of HD changes of inotropic and medical optimisation on NCF. Similarly, there is a paucity of data on the evolution of NCF in patients following OHT. Despite subjective assessments to the contrary, our patient demonstrated abnormal NCF while in cardiogenic shock. Furthermore, as he was optimized with inotropic and medial therapy there was a step wise improvement in his NCF that was sustained following OHT. Larger studies are needed to explore the prevalence of this phenomenon. Comparative studies with other methods of cardiac support, e.g. temporary and durable left ventricular assist devices, will yield novel insights that can advise treatment choices.

Acute Heart Failure–Pathophysiology and Mechanisms

P1326

A case of reverse takotsubo cardiomyopathy presenting as acute pancreatitis.

SH Shareef Mansour[1]; O Abou Hassan[1]; A Zakharia[1]; H Isma'eel[1]; H Skouri[1]
[1]*American University of Beirut Medical Center, Cardiology, Beirut, Lebanon*

Case: A 44 year old hypertensive and diabetic lady presenting to the emergency department with severe epigastric pain of 2 days with palpitation and diaphoresis. Initial vitals were a BP of 150/90 and HR of 110 bpm. Patient became drowsy with cold extremities and developed severe dyspnea, desaturation and was intubated. Initial evaluation showed a WBC count of 31300 cu.mm, a creatinine of 1,8 and an amylase level of 6438 IU/L.

A bedside echocardiogram showed severely impaired LV systolic function (EF <20%), normal functioning apical segments with akinesia of mid and basal segments, suggestive of reverse takotsubo cardiomyopathy. Urgent coronary angiography was performed revealing normal coronaries. The LVEDP was 50 mmHg. See fig. 1 LV angiogram.

A Swan ganz catheter was inserted for pressure guided therapy. Her parameters cam as follow:

SBP:150/90; HR: 150 bpm ; CVP: 9 mmHg; SVR: 1800 dyn.sec.cm-5; PVR: 21 dyn.sec.cm-5; PAP: 21/11; COP: 2.88 L; CI: 1.8 L/m2

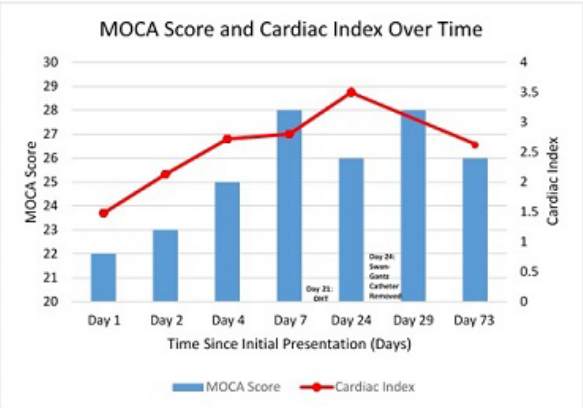

Figure 1: MOCA Total Score, pharmacotherapy, and cardiac index over time

Day 1, Prior to starting therapy

Day 2, Milrinone 0.5 mcg/kg/min, sodium nitroprusside 2.5 mcg/kg/min, spironolactone 12.5 mg QD

Day 4, Milrinone 0.5mcg/kg/min, digoxin 0.125mg QD, spironolactone 25mg QD

Day 7, Milrinone 0.5mcg/kg/min, digoxin 0.125mg QD, hydralazine 100 mg Q8H, isosorbide mononitrate 120 mg QD

Day 24, Milrinone 0.25 mcg/kg/min, hydralazine 50 mg Q8H, Prednisone, Tacrolimus, mycophenolate mofetil

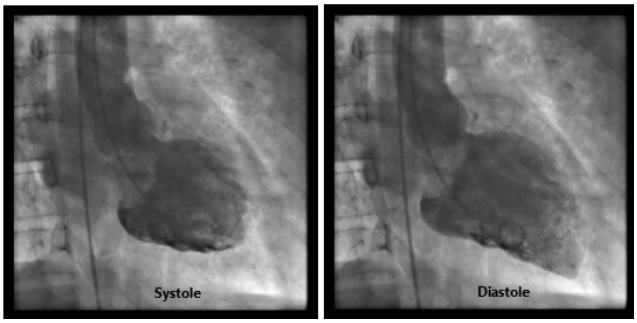
Day 29 , Hydralazine 50 mg TID, Lisinopril 10 mg QD, Nifedipine 60 mg QD, aspirin 81mg QD, Pravastatin 40mg QD, Prednisone, Tacrolimus, Mycophenolate Mofetil

Day 73, Lisinopril 10 mg QD, Nifedipine 60 mg QD, aspirin 81 mg QD, Pravastatin 40 mg QD, Prednisone, Tacrolimus, Mycophenolate Mofetil

Figure 1

Conclusion/Clinical

SBP: systolic blood pressure; CVP: central venous pressure; CO: cardiac output, PVR: pulmonary vascular resistance; SVR systemic vascular resistance, CI: cardiac index.
The patient was clinically in shock state, with evidence of organ hypoperfusion. She was comatose, cold, anuric, with severe worsening lactic acidosis and liver function. However she had a high blood pressure. She was started on nitroglycerine and



LV angiogram

furosemide drips with non adequate response. It was decided to start her on Levosimendan as inotrope. A CT abdomen showed a 5 x 6 cm left adrenal mass, suggestive of pheochromocytoma, so Doxazocin was added. However, Patient didn't show improvement, and went into multi-organ failure. Veno-arterial extracorporeal membrane oxygenator (VE-ECMO) was inserted for full hemo-dynamic support with CVVHD for acute renal failure.Patient started to show improvement until she was weaned from ECMO support after 6 days, and gradually regained her kidney function. Repeat echocardiogram showed complete recovery of LV systolic function. Pheochromocytoma was confirmed by MIBG scan and a surgical resection was performed when patient stabilized.
Discussion: The cardiovascular manifestations of pheochromocytoma can be mild as sinus tachycardia or lethal such as cardiogenic shock and Takotsubo cardiomyopathy especially the reverse type due to high level of circulating catecholamines.
Levosimendan, a calcium channel sensitizer and a vasodilator is a suitable for cardiogenic shock with systemic vasoconstriction as seen in pheochromocytoma.
Hyper-amylasemia is likely secreted by pulmonary endothelial cells under ischemic damage and hypoxia secreting the s-isoenzyme. ECMO allows a quick and full circulatory support in patients with cardiogenic shock, and is a very suitable option in phaeochromocytoma cases.

[1]St. Anne's University Hospital, Department of Cardiology, Brno, Czech Republic; *[2]St. Anne's University Hospital, Pathological –anatomical institute, Brno, Czech Republic*

Background: Myocarditis may be part of the ARVC pathophysiology, the manifestations of both diseases may also be similar. Multimodal imaging can help in differential diagnosis, but in some cases we can not do without endomyocardial biopsy.
The authors describe the story of a 47-year-old woman who has long been treated with rheumatoid arthritis, ulcerative colitis, chronic autoimmune thyroiditis and adrenal hypofunction after long-term corticotherapy. She was first hospitalized in 11/2015 at another hospital for paroxysmal atrial fibrillation. Pharmacologically restituted sinus rhythm. After 14 days she comes due to dyspnoea and fatigue, a junction rhythm is detected on the ECG. Echocardiography and laboratory are normal. After discontinuation of antiarrhythmics, no bradycardia was captured. 14 days later she was received for dyspnoea, signs of bilateral heart failure. According to ECHO, the left ventricular systolic function decreased slightly. MRI without signs of inflammation or other patology. There are large numbers of inflammatory cells present in the EMB, so the patient was treated with a pulse dose of corticoids. During the hospitalization the progression of right-heart failure was observed, temporary catecholamine support was needed. The junction rhythm is again present on the ECG. According to MRI, the most likely finding of arrhythmogenic cardiomyopathy, diagnostic kriteria were present than ICD was implanted. After improvement of the clinical condition the patient is able to dimise for oral corticotherapy, which is further reduced by the outpatient pathway. In 12 months, the patient is again admitted for total fatigue, shortness of breath, chest pain. Excluded acute coronary syndrome and pulmonary embolism. According to ECHO, signs of right heart failure with a slightly reduced systolic function of the left ventricle were present. EMB was performed again, where acute myocarditis with regressive cardiomyocyte changes and a higher proportion of eosinophils were reported. Cyclosporine and corticoid therapy was initiated with improvement in clinical status.
Conclusion: Echocardiography and especially MRI play a crucial role in the diagnosis of cardiomyopathy, in some cases, however, we can not do without invasive diagnostics. Treatment is mostly based on corticotherapy, in recurrent cases is a combination of immunosuppressant recommended. Arrhythmogenic cardiomyopathy is not available for pharmacological treatment, ICD implantation is necessary.

Acute Heart Failure–Treatment

P1328
Ivabradine in Acute Heart Failure, why not?

C Carmen Collado Moreno[1]; I Valiente-Aleman[2]; JC Rodriguez-Yanez[2]; FJ Morales-Ponce[1]
[1]Puerto Real Hospital, Department of Cardiology, Puerto Real, Spain; *[2]Puerto Real Hospital, Critical Medical Medicine, Puerto Real, Spain*

This is a 39 - year - old man patient with no personal or family history of heart disease or either cardiovascular risk factors. The patient suffered in the last 48 hours back pain, progressive dyspnea and febrile non-thermometer sensation.
At the time to hospital admission vital signs were No fever (36 °C), Blood pressure 100/65 mmHg, Heart rate 150 bpm, basal peripheral saturation of oxygen 85%, breathing frecuency 45 bpm. The patient was awake, oriented in time, space and person with Glasgow Coma Scale 15/15. Respiratory auscultation showed rales throughout the lung, cardiac auscultation was normal. No abdominal pain. No limbs abnormalities, peripheral pulses evaluated in extremities were normal.
Chest X-ray showed alveolar pattern, in transthoracic echocardiography severe left ventricular dysfunction (LVEF 30%) with akinesia in basal and mid septal segments which determined basal "ballooning" were appreciated, blood test showed elevation of ultrasensitive cardiac troponin and EKG ST-segment elevation in DI and aVL, so was firstly diagnosed of Acute Myocardial infarction with ST-segment elevation.
A coronary angiography was performed, which revealed normal arteries. The patient required admission to coronary intensive care unit (CICU) to be treated. During CICU stay sinus tachycardia (140 bpm) was treated with Ivabradine (5mg twice a day) due to low blood pressure (90/50 mmHg) so no vasoactive drugs were required. Acute pulmonary edema disappeared with Non-Invasive pulmonary ventilation, furosemide continuous intravenous infusion and heart rate control. On day 4 Ivabradine was remove due to moral opposition of physician, so the patient restarted to get on pulmonary edema although keeping the same treatment. Ivabradine was prescribed again 2 days later by all physicians agreement so the patient experimented clinical improvement that we could discharge him from the ICU in 48 hours. A cardiac MRI was performed on day 12 of hospital stay showing total normalization of LVEF and absence of late enhancements. Due to clinical evolution and complementary exams the most likely diagnosis was atypical Takotsubo Cardiomyopathy.
Conclusion: MINOCA should be considered as a working diagnosis in all patients who present myocardial infarction and normal coronary arteries. An overt cause should not exclude the physician to manage it as a MINOCA investigating the real cause although an apparent one has been presented.
Ivabradine seems to be a safe drug treatment for heart rate control in the onset of acute heart failure due to systo-diastolic disfunction.
Further clinical trials should be performed to reach best level of evidence.

P1329
A case of cardiac tumor of malignant B-cell lymphoma presented with heart failure due to cardiac tamponade

F Fumimasa Tabata[1]; T Koizumi[1]; S Taguchi[1]; I Tsutsumi[2]; C Yoshida[2]
[1]National Hospital Organaization Mito Medical Ceter, Cardiology, Ibaraki, Japan; *[2]National Hospital Organization Mito Medical Center, Hematology, Ibaraki, Japan*

Introduction: Primary cardiac tumor is only 1-2% among heart disease. 80% are benign and 20% are malignancy. Size, location, architecture of tumor are important factors for its treatment. There are many reports that could cause syncope, embolism, myocardial infraction and even sudden death so require to make early therapeutic strategies.
Case: A 80-year-old female presented heart failure. Cardiac echo revealed pericardial effusion and tamponade and pericardiocentesis was done.

Echo also pointed out 33 × 24mm mass at tricuspid valve annulus that are different from of thrombus, pedunculate tumor like myxoma or vegitation. Coronary artery CT showed no significant stenosis.
Effusion sample was bloody, cytologic diagnosis was class?b. Flow cytometry were CD45+,CD10+,CD19week, CD20-, CD79a week, that suggesting malignant B-cell lymphoma.
As get this data we thought malignant B-cell lymphoma and had started R-CHOP therapy.
This case final diagnosis is B-cell lymphoma, unclassifiable, with features intermediate between Diffuse Large B-Cell Lymphoma(DLBC) and Burkitt lymphoma, stage?B, high risk of International Prognostic Index (IPI). After chemotherapy mass vanished, no sign of refuel of pericardial effusion and his heart failure symptoms are improved.
Discussion: Cardiac tumor is rare disease in daily clinical world especially cardiac malignant B-cell lymphoma is about 1% among them and that reported rapidly progression and poor prognosis. This case cardiac tamponade is key turn for this patient's diagnosis and treatment. 6 cycle of R-CHOP has achieved complete remission now. It is difficult to diagnose DLBC accurately by Cardiologist. On the other hand Hematologist might difficult to control cardiac tamponade.

P1330
Successful extracorporeal resuscitation after intoxication with suicidal intent

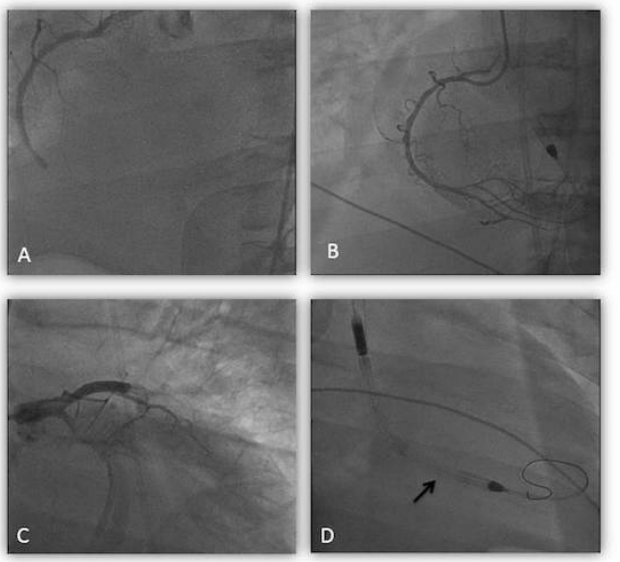
B Panholzer[1]; K Katharina Huenges[1]; M Eide[1]; G Hoffmann[1]; J Cremer[1]; A Haneya[1]
[1]University Medical Center of Schleswig-Holstein, Cardiovascular Surgery, Kiel, Germany

Background: Intoxication with suicidal intent is a possibly life threatening condition leading to a variety of symptoms with unpredictable severity. Here, we report from a case of successful extracorporeal resuscitation (eCPR) after intentional overdose of psychotropic drugs.
Methods and Results: A 24 year old female patient with a long history of depression was brought to hospital after intake of large quantities of pipamperone and citalopram. During transport and right after admission, the patient suffered from cerebral seizures, and emergency intubation had to be performed. Immediately afterwards, the patient developed ventricular fibrillation (VF), and cardiopulmonary resuscitation was inevitable. Electrocardiography revealed a pronounced long-QT- syndrome (LQTS), blood tests showed a massive metabolic disorder. Overall, the hemodynamic situation remained unstable with recurrent episodes of VF and high-dose catecholamine dependency. For immediate stabilization, veno-arterial extracorporeal membrane oxygenation (VA-ECMO) was percutaneously implanted into the femoral vessels using Seldinger's technique, and the patient was referred to our hospital. Within the following days, LQTS persisted, leading to continuous electrical storm, but under continuous VA-ECMO support, the patient remained stabile. After seven days, drug levels of pipamperone and citalopram normalized, and an additional administration of beta-blocker lead to a complete remission of VF. After eight days of support, ECMO could be explanted, and the patient was extubated two days later. Two weeks after ECMO explantation, the patient was discharged to a rehabilitation clinic.
Conclusion: eCPR using VA-ECMO is a highly effective way of achieving immediate location-independent stabilization with consecutive interhospital transfer. Our case could show that therapy with ECMO systems is a good option in unpredictable situations such as intoxication in suicidal intent.

P1331
Cardiogenic shock- bridging with multimodality short term mechanical circulatory support.

H Husnat Ahmed[1]; S Lim[1]
[1]University Hospital Birmingham, Cardiology, Birmingham, United Kingdom

A 46-year-old gentleman was transferred to our intensive care unit (ITU) for consideration of cardiac transplantation/left ventricular assist device (LVAD) due to severe left ventricular dysfunction and ongoing heart failure symptoms.
He had presented to his local hospital with left anterior descending artery (LAD) territory infarction and cardiogenic shock requiring percutaneous coronary intervention (PCI) to LAD and right coronary artery (RCA). His comorbidities included type II diabetes mellitus and hypertension.
On arrival, his observations were satisfactory.
His case was discussed at our transplant MDT and decision was made to work him up towards long term LVAD as bridge to cardiac transplant. Unfortunately, the following day he suffered further STEMI thrombosing LAD and RCA stents and a large obtuse marginal (OM) branch. Intra aortic balloon pump (IABP) was inserted and PCI to LAD initiated. Unfortunately, during PCI, he suffered cardiac arrest requiring prolonged cardiopulmonary resuscitation (CPR) with downtime of 60 minutes. Circulation was supported initially by an Impella 3.5 placed percutaneously into right common femoral artery and then laterally by peripheral veno-arterial extracorporeal membrane oxygenation (VA ECMO).



A: Occluded RCA stent; B: Restoration of RCA flow on ECMO; C: Occulded LAD stent; D: Impella (arrow)

Following ECMO, surprisingly, RCA showed spontaneous re-establishment of flow with some residual thrombus at distal end of stent. In order to preserve RV function and potentially avoid the need for biventricular assist device (BiVAD) implantation, RCA was wired and dilated using balloon with achievement of good TIMI 3 flow. As he needed an LVAD, it was felt that PCI to LAD and OM branch would not offer any additional benefit.
He was transferred back to ITU and after two days peripheral ECMO and Impella were removed and Centrimag short term LVAD was inserted. Post operatively, he was a bit slow to wake and there were concerns about his neurological prognosis. After detailed discussion with neurology colleagues, it was felt appropriate to keep supporting his cardiac care. Short term LVAD (provided support for 3 weeks) was therefore ex-planted and replaced with long term Heartmate III LVAD.
Patient made slow but steady progress post-op. He still has residual mild cognitive and mobility impairment. He has now been transferred to a neuro-rehabilitation centre and we remain hopeful that he will make enough progress to be discharged home.
Discussion: IABP, Impella and ECMO are viable short term interventions to manage cardiogenic shock secondary to severe LV dysfunction.
Uncertainty about neurological status following prolonged CPR and low flow state represents a challenging dilemma in clinical practice. Given our patient's young age and witnessed cardiac arrest we decided to support his circulation hoping that he would make meaningful neurological recovery.
Our case highlights good outcome from the use of a multimodality circulatory support in the context of severe cardiogenic shock, prolonged CPR and low flow state.

Coronary Artery Disease–Pathophysiology and Mechanisms

The role of transthoracic coronary arteries ultrasound in dyspnea differential diagnosis in a patient with chronic heart failure, atrial fibrillation and implanted permanent pacemaker

M V Agarkov[1]; O P Mamaeva[2]; S V Vlasenko[1]; D A Vorobyovskiy[1]; N E Pavlova[2]; O A Guseva[3]; A A Anton Khilchuk[1]; S V Lebedeva[2]; A M Sarana[4]; S G Scherbak[4]
[1]State City Hospital #40, Interventional Radiology, Saint-Petersburg, Russian Federation; [2]State City Hospital #40, Functional Diagnostics, Saint-Petersburg, Russian Federation; [3]North-west state medical university, Saint-Petersburg, Russian Federation; [4]Saint-Petersburg state university, Medical Faculty, Saint-Petersburg, Russian Federation

Introduction: new dyspnea onset in patients with long history of persistent atrial fibrillation and implanted permanent pacemakers is usually regarded as chronic heart failure progressing. Conducting stress-echo in order to diagnose significant stenosing atherosclerosis is difficult or impossible. We believe that transthoracic coronary arteries ultrasound is effective and specific diagnostic method to reveal hemodynamically significant coronary arteries stenoses with a further indication for coronary angiography without stress-test. Aim: to use personified approach in dyspnea differential diagnosis in a patient with multiple cardiac comorbidities. Materials: 66 years old male with rheumatic heart disease, artificial aortic and mitral valves on warfarin, implanted permanent pacemaker and persistent atrial fibrillation. Coronary angiography 5 years ago showed no stenotic lesions. Last 6 months patient has gradually worsening dyspnea after minimal exercise while on full medical therapy. We considered performing stress-echo early after transthoracic echocardiography but due to high pretest probability, high coronary diastolic flow velocity and persistent AFib with pacemaker we proceeded directly to coronary angiography.
Methods: we performed serial ECG and transthoracic echo registrations before referring the patient to the cardiac catheterization laboratory.
Results: ECG showed normo-tachisystolic persistent atrial fibrillation, TTE showed preserved systolic function with an absence of myocardium contraction abnormalities. Coronary ultrasound of middle left anterior descending artery (LAD) revealed high peak diastolic velocity (122cm/sec) which correlated with a hemodynamically significant lesion. Next day coronary angiography demonstrated hemodynamically significant critical stenosis of middle LAD, which was successfully stented in an elective way. The patient is totally fine at 90-day follow-up without dyspnea and any stable angina. Conclusion: we underscore feasibility and efficacy of hemodynamically significant stenosing atherosclerosis diagnostic with novel noninvasive ultrasound methods in patients with heart failure, persistent atrial fibrillation and implanted permanent pacemakers.

Coronary Artery Disease–Treatment

P1333
Pheochromocytoma with either myocardial infarction or myocarditis? That is the role of cardiac MRI

A Basuoni[1]; M El-Ramly[1]
[1]*Cairo University Hospitals, Cardiology , Cairo, Egypt*

Pheochromocytomas most commonly arise from the adrenal gland (90%) and are benign in 90% of cases.They produce characteristic systemic manifestations due to secretion of catecholamines, most commonly norepinephrine. Cardiac manifestations of pheochromocytoma include hypertension, myocardial hypertrophy, myocarditis, cardiomyopathy, pulmonary edema, cardiogenic shock, arrhythmias and rarely myocardial infarction. Hypertension is the most frequent cardiovascular manifestation of pheochromocytoma.
We reported a case of 31 year old female patient, was known to have hyperthyroidism, hypertension secondary to pheochromocytoma and supra-adrenalectomy 7 years ago. the patient presented with agonising chest pain. EKG showed lateral ST segment elevation with inferolateral ST segment depression. cardiac enzymes showed elevated high sensitive troponin with normal CKMB . emergency echo was normal. so cardiac MRI was recommended for suspected perimyocarditis. surprisingly, cardiac MRI showed lateral infarction so the patient underwent CA showed co-dominant LCX giving two large obtuse marginals, the second OM divided to two rami and there was a significant stenosis of one of the 2 rami most probably due to atherosclerosis. so the diagnosis was lateral MI for medical treatment, control of risk factors and searching for pheochromocytoma reactivity.
Pheochromocytomas have been rarely associated with acute myocardial infarction. Most of these cases have normal coronaries. The mechanism of myocardial infarction or segmental myocardial dysfunction associated with pheochromocytoma has been linked to coronary spasm or a direct toxic effect induced by catecholamines but in our case it could be due to acceleration of atherosclerosis. also Catecholamines increase left ventricular work by inducing left ventricular hypertrophy from hypertension and increase in heart rate. so in our case searching for activity of and recurrence of pheochromocytoma was mandatory for the diagnosis.

Myocardial Disease–Clinical

P1334
Putting the pieces together: a multimodality imaging approach to left-side pericardial agenesis diagnosis

C Catarina Ruivo[1]; R Ladeiras-Lopes[2]; R Faria[2]; N Ferreira[2]; V Gama[2]
[1]*Hospital Santo Andre, Cardiology, Leiria, Portugal*; [2]*Hospital Center of Vila Nova de Gaia/Espinho, Cardiology, Vila Nova de Gaia, Portugal*

A 56-year-old woman was referred to the Cardiology outpatient clinic complaining of atypical chest pain. Her physical examination was unremarkable. The chest radiograph (Figure 1) depicted flattening and elongation of the left heart border (Snoopy sign), right heart border superimposed on the spine and a radiolucent band. The apical four-chamber view of transthoracic echocardiogram (TTE) showed leftward position, exaggerated motion and bulbous ventricles. Suspicion of pericardial agenesis was raised.
Cardiac computed tomography (CCT) revealed extreme levoposition of the heart and interposition of lung parenchyma between the aorta and the pulmonary artery. Movement artifacts precluded accurate observation of the pericardium as well as exclusion of coronary disease. Better anatomic definition and temporal resolution were achieved with cardiac magnetic resonance (CMR). Axial T1-weighted imaging showed absence of left-side pericardium, while depicted the pericardium adjacent to right atria. Cine imaging in supine position confirmed the clockwise rotation of the heart, which assumed a near normal position (from 120° to 65°) after repositioning the patient in right lateral decubitus. Adenosine stress and late gadolinium enhancement imaging were normal. Associated non-cardiac and cardiac anomalies, including atrial septal defect, mitral valve stenosis or patent ductus arteriosus were ruled out. Given the benign prognosis, patient was managed conservatively.
This case highlights the incremental value of an integrated multimodality imaging approach. Left-side pericardial agenesis is exceedingly rare, generally found incidentally and can explain atypical symptoms1. Clinicians should be aware of the specific findings on chest radiograph and TTE. CCT aids in diagnosis and CMR stands the gold-standard. Repositioning the patient and real-time cine CMR show the hypermobility of the heart and might become part of the routine diagnostic work-up of pericardial agenesis.

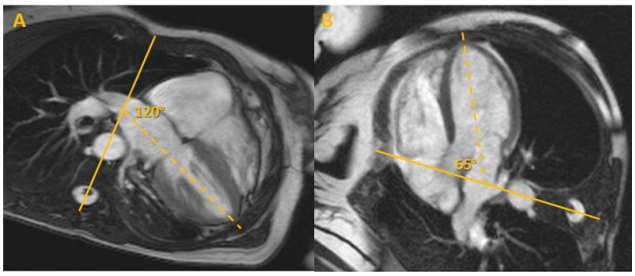

Figure 1: Cardiac magnetic resonance

P1335
A challenging case of cardiomyopathy and its clinical implications

A Antonio Xavier Fontes[1]; C Serena[1]; L Oliveira[1]; S Moura-Ferreira[1]; C Almeida[1]; C Machado[1]; R Dourado[1]; E Santos[1]; N Pelicano[1]; AM Pacheco[1]; A Tavares[1]; F Melo[1]; D Martins[1]
[1]*Hospital Divino Espirito Santo, Cardiology, Ponta Delgada, Portugal*

80-year-old female, was referred to our department in 2016 due to shortness of breath and in the last 3 months. Her past medical history included left bundle branch block (LBBB), hypertension (medicated with irbesartan 300mg and lercanidipine 20mg), diabetes, esophageal-gastric junction cancer in 2015 treated with surgery. She was considered to be cancer-free and lost 30kg (BMI = 22,2kg/m2).
She had performed an echocardiogram (ETT) in 2013 that showed calcification of aortic and mitral valves, with moderate mitral insufficiency. Patient gave birth 10 times (one daughter died suddenly at the age of 35 years old and 2 children died after delivery). Physical examination revealed a blood pressure of 126/70mHg, and systolic murmurs at the apex and left sternal edge. An electrocardiogram showed sinus rhythm and LBBB.
Patient repeated the ETT that showed dilated left ventricle with asymmetric hypertrophy of the inferior, infero-lateral and inferior septal walls (20mm), left ventricle ejection fraction (LVEF) = 25%, left atrium severely dilated, functional mild to moderate mitral regurgitation and mild pericardial effusion (PE). After the initial evaluation the main hypothesis were late-onset hypertrophic cardiomyopathy and cardiac amyloidosis. We started guideline based treatment with loop diuretic, spironolactone and beta-blocker (patient already taking irbesartan), with little improvement.
The next step considered was to perform cardiac magnetic resonance imaging. The findings in this exam were highly suggestive of amyloidosis (diffuse left ventricular wall thickening - maximum in anterior wall with 19mm, diffuse sub-endocardial and sub-epicardial heterogeneous increased signal on delayed contrast-enhanced and inability in obtaining an optimal null time on TI scout sequences).
Systemic light-chain amyloidosis has been excluded, cardiac biopsy was not performed due to the risks of the procedures and patient repeated the echocardiogram to evaluate ejection fraction 4 months after medical therapy (LVEF = 21%). We assumed senile cardiac amyloidosis.

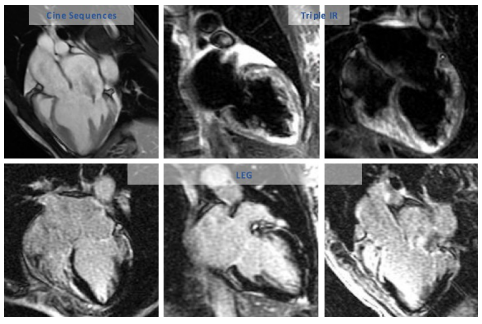
As she remained symptomatic we considered cardiac resynchronization therapy. This procedure was complicated with rupture of a great cardiac vein's collateral with consequent moderate PE. Tamponade physiology has not been developed. One month later the LVEF was 36% and the PE had mild to moderate dimension.
Cardiac amyloidosis is a clinical disorder caused by extracellular deposition of insoluble fibrils (approximately 7.5-10 nm wide) with beta-pleated sheet configuration. The cardiac involvement in the amyloidosis is, in most cases, secondary to a systemic disease. However an isolated cardiac involvement can occur. The gold standard for the diagnosis of a cardiac amyloidosis remains the endocardial biopsy, but this is an invasive procedure and is related to severe complications. A strong diagnostic suspicion can be made by identifying several specific bio-clinical and imaging findings.

P1336

An infectious cause of heart failure with increasing prevalence in Europe

AR Ana Rita Pereira[1]; AR Almeida[1]; I Cruz[1]; A Marques[1]; S Alegria[1]; AC Gomes[1]; D Sebaiti[1]; A Briosa[1]; N Marques[2]; H Pereira[1]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal; *[2]Hospital Garcia de Orta, Infectious Diseases, Almada, Portugal*

We present the case of a 49-year-old woman, coming from the countryside of Brazil and living in Europe since about 10 years ago. She had clinical history of iron-deficiency anemia caused by menometrorrhagias and an unspecified cardiac disease, diagnosed 3 years before hospital admission and characterized by left ventricular (LV) moderate systolic dysfunction [LV ejection fraction (LVEF) 32%] evaluated by a transthoracic echocardiogram (TTE) and normal coronary arteries showed by a coronary computed tomography (CT) angiography. She was admitted in our Emergency Department with complaints of oppressive chest pain, palpitations and lipothymia with 3 days of evolution. She also reported progressive worsening exertional dyspnea (at admission, triggered by mild physical activity) with 1 month of evolution. At clinical examination, she was hemodynamically stable and an apical, grade II/VI, systolic heart murmur with axillary radiation were heard. Blood tests revealed haemoglobin 7,2 g/dL, high-sensitive cardiac troponin T 153 ng/L [normal range (NR) < 13 ng/L] and NT-proBNP 948 pg/mL (NR < 153 pg/mL). A 12-lead ECG showed sinus rhythm, 63 bpm, left anterior fascicular block and complete right bundle branch block. TTE demonstrated LV dilation with reduced wall thickness, diffuse hypokinesia and moderate systolic dysfunction (LVEF 35%), moderate functional mitral regurgitation and dilated inferior vena cava with decreased respiratory size variation.
The diagnostic hypotheses of type 2 acute myocardial infarction secondary to exacerbation of chronic anaemia and reduced LVEF heart failure (HF) of unknown cause were considered. During hospitalization, transfusion support and intravenous iron therapy was given and HF disease-modifying drugs were initiated and up-titrated. The initial laboratory studies revealed no abnormalities. To better clarification of clinical case, the patient (pt) underwent a cardiac magnetic resonance imaging that was suggestive of inflammatory dilated cardiomyopathy, namely, Chagas disease (CD) or sarcoidosis. On suspicion of these diagnoses, a chest CT was performed showing no relevant findings and serological tests to detect immunoglobulin G antibodies to Trypanosoma cruzi were requested. As two different serological tests were positive, the diagnosis of chronic chagasic cardiomyopathy was established. After discharge, the pt kept under follow-up (FU) in HF and Infectious Diseases appointments, completing 60 days of antiparasitic therapy with benznidazole.
As complication during FU, the pt was readmitted, hemodynamically unstable, owing to a monomorphic ventricular tachycardia. An implantable cardioverter defibrillator for secondary prevention was placed. Currently, she is in NYHA class I-II.
This clinical case illustrates and intends to make a brief review of an increasing cause of HF and arrhythmias in Europe, which is currently hosting large populations of migrants from Central and South America where the CD is endemic.

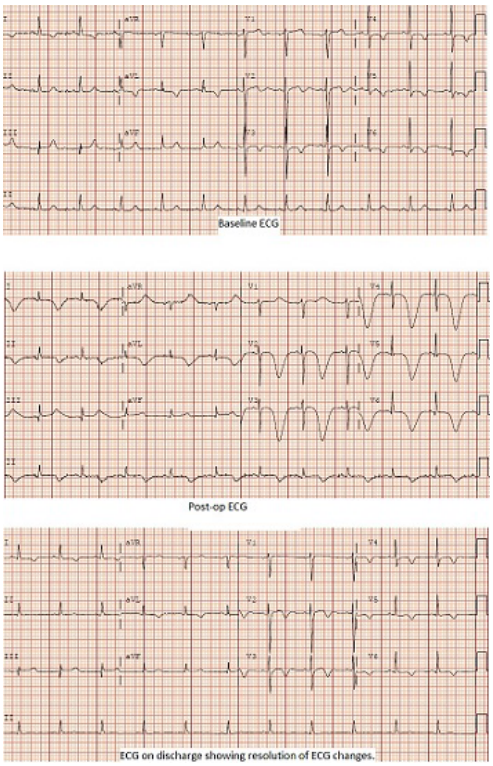


P1337

Takusubo cardiomyopathy: electrical cardiogram manifestation before myopathic changes.

C Li[1]; ZY Lim[2]
[1]Tan Tock Seng Hospital, Cardiology, Singapore, Singapore; *[2]Khoo Teck Puat Hospital, Cardiology, Singapore, Singapore*

Madam G.T is a 79-year-old Indian lady who presented with right neck swelling over the last few weeks. Her past medical history includes hypertension, hyperlipidemia,



impaired glucose tolerance and end stage renal failure on peritoneal dialysis. A transthoracic echocardiogram done a year ago showed normal left ventricular ejection fraction (LVEF), concentric left ventricular hypertrophy with no regional wall motion abnormality (RWMA). Baseline electrocardiogram (ECG) showed sinus rhythm and left ventricular strain pattern
She was admitted to Otolaryngology department for excisional biopsy of right cervical mass under general anaesthesia. Post-operatively, intravenous neostigmine and glycopyrronium bromide were given due to prolonged drowsiness but achieved only suboptimal effect and subsequently sugammadex was administered. Mrs G.T developed sinus tachycardia shortly after and was treated with intravenous beta blockers.
Serial electrocardiograms were undertaken and showed significant new T wave inversions in anterior and lateral leads which persisted despite the tachycardia settling and without any symptoms. Serial cardiac enzymes also demonstrated a dynamic rise in troponin T from 104 pg/ml to 249 pg/ml.
Based on the ECG changes and dynamic troponin rise, a provisional diagnosis of non-ST elevation myocardial infarction (NSTEMI) was made and an urgent echocardiogram was undertaken on the same day which was essentially unchanged from the previous year echo with normal LVEF and no RWMA.
Coronary angiography was also undertaken which showed normal coronary arteries and an echocardiogram was repeated. This time, it showed new apical akinesia and a depressed LVEF of 45%. The ECG changes resolved 4 days later and an echocardiogram performed 2 months later demonstrated resolution of the RWMA. These findings would fit with a diagnosis of takusubo cardiomyopathy.
Discussion: The interesting aspect of this case was the documentation of ECG changes preceding myopathic changes in keeping with Takusubo cardiomyopathy along with ECG resolution before the improvement in left ventricular function. This could have clinical implications for patients who have early investigations which could well be normal but in the presence of persistent ECG changes, a repeat left

ventricular assessment could help assist in the subsequent diagnosis of Takotsubo cardiomyopathy.

Hypertension–Other

P1338

Prognostic significance of clinical-anthropometric, biochemical, metabolic, vascular-inflammatory and molecular-genetic markers in the development of the first ischemic stroke.

V Veronika Shishkova[1]
[1]*Moscow Medical Centre Neurorehabilitation , Moscow, Russian Federation*

Aim: The study of the relationship between various parameters: clinical-anthropometric, biochemical, metabolic, vascular-inflammatory, molecular-genetic and the development of the first ischemic stroke, and the development of a prognostic model for determining the probability of its occurrence.
Material and methods. 196 patients who underwent the first ischemic stroke and 119 people who did not suffer a stroke, corresponding to age, place of residence and nationality to a group of patients, were examined. The main anthropometric, clinical, biochemical and metabolic parameters were assessed; markers of vascular inflammation and endothelial dysfunction. Genotyping of single nucleotide polymorphisms of genes: IL8, ADIPOQ, ADIROR, APOB, APOC-IV, BDNF, GRM3 using ready-made TaqMan probes was carried out.
Results: Based on the results of the correlation analysis, the following parameters were statistically significant with the first ischemic stroke: weight, BMI, WC, homocysteine, insulin, adiponectin, cystatin C, ApoA1, Apo B, OHL, XC-HDL, LDL, TG, CRB-sh , glucose, uric acid, IL-1b, IL-4, IL-6, IL-8, TNF-a, VEGF-A. The binary logistic regression method was used to construct the forecast model. The final independent model includes the following independent variables: weight, diabetes, adiponectin, Apo A1, IL-1b, IL-4, ADIPOQ (rs17366743), GRM3 (rs2228595), R2 value of Nagelkerk was 0.839. The percentage of agreement between the model and the "training sample" was 90.7%. The percentage of consent of the model with the "independent sample" was 87.1%, the overall percentage of the model's agreement for all patients was 89.8%. In accordance with the received data, the ROC-curve (Receiver Operating Characteristic) was constructed, the area under the ROC-curve was 0.92.
The conclusion: Based on the data obtained in this study, a probability model for the development of the first AI was obtained. Of all the parameters studied in the study, the largest contribution to the probability of development of the first AI, according to the model obtained, is made by the parameters: diabetes, adiponectin, Apo A1, IL-4.

P1339

Determination of knowledge levels about disease and treatment compliance in individuals with hypertension

S Oguz[1]; B Bayrak[1]; Ö Adadioglu[1]; B Akay[1]; G Camci[1]; B Kinali[1]; G Okur[1]; TE Sit[1]
[1]*Marmara University, Faculty of Health Sciences, ISTANBUL, Turkey*

Background: Hypertension is a risk factor for many chronic diseases, especially cardiovascular diseases. As individuals with hypertension become more knowledgeable about the disease, their treatment compliance increases.
Purpose: This study was planned as a cross-sectional and descriptive study to assess the level of knowledge about disease and treatment compliance in individuals with hypertension.
Materials and Methods: The study has been perfomed between January 15 and April 15, 2017 with 500 patients who were admitted to the cardiology clinic and hospitalized in cardiovascular ward of a hospital in Istanbul, were diagnosed with hypertension and had no communication problems. Data were gathered by using Questionnaire and Hypertension Knowledge Level Scale (HK-LS). The scale consists of definition, medical treatment, compliance, life style, diet, complication sub-dimensions. The highest total score of scale is 22. As the score from the scale increases, knowledge level of individuals increase. In our study, the cronbach alpha was found 0.78. Descriptive statistics, Student's T test and one-way ANOVA were used in the evaluation of research data.
Results: The mean age of the patients was 64.08 ± 12 and 56.6% of them were male, body mass index of 82.6% of them was 25 and above (BMI> 25) and %38.8 of participants were obese. 58.4% of individuals had comorbid disease and 55.8% of them had hypertension for 10 years and over. 58.8% measured blood pressure when their blood pressure was high, 40.6% drank lemon juice when their blood pressure rises, 44% did not took blood pressure medicine regularly and 43% forgotten to take their high blood pressure medication occasionally. The average score of the patients taken from the scale was 17.36 ± 3.47.
It has been found that women's medical treatment and high school graduates' definition, medical treatment, compliance, life style knowledge score was high ($p < .05$). And also it was seen total score, definition, compliance and complication knowledge score of employee and good income patients was high ($p < .05$). Total scale score, diet and complication knowledge score of patients living with family; definition, treatment, compliance, life style, diet and complication knowledge score of patients doing exercise and definition and diet knowledge score of patients without chronic disease were found to be high ($p < .05$)
Conclusion: Women, patients with good income, those living with family, those who exercise, those without chronic diseases, and those with a high education level had higher level of disease knowledge and compliance to treatment.

Cardiovascular Rehabilitation

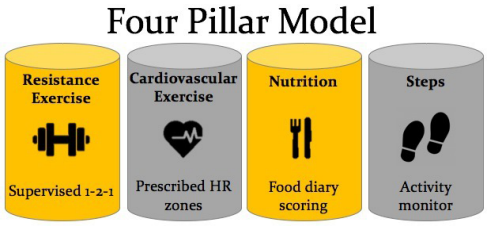
A novel '4 pillar' model of clinical exercise training in a patient with heart failure

M Thompson[1]; YLD Rumble[1]; AC Groome[1]; SD Olden[1]; MAP Fawke[1]; IR Cradock[1]
[1]*Clinical Prevention and Rehabilitation, London, United Kingdom*

Background: It's classically known that physical training improves exercise tolerance, health-related quality of life and reduces hospitalisation rates in patients with heart failure, culminating in practical recommendations being published in 2011. The current case is a modern application of these guidelines using a novel '4 Pillar' model.
Case Description: A 72 year-old male with diagnosed heart failure (NYHA III) with reduced ejection fraction (25%). History of a complex multivessel PCI and dual



Four Pillar Model

chamber-defibrillator following an episode of cardiogenic shock. Subsequent severe mitral and tricuspid regurgitation and 4 chamber dilation with dyskinesis. The patient presented with exertional breathlessness and significant limitation in day-to-day activities. He was unable to climb one flight of stairs without stopping or walk on a flat gradient for 5 minutes.
Intervention
The patient underwent a 12-week personalised and intensive exercise and nutrition programme comprising twice-weekly one-to-one resistance-based exercise sessions, twice-weekly aerobic exercise sessions, on-going targeted step-count and nutritional monitoring and prescription. Exercise was prescribed and periodised into 'training blocks'. Stage 1: interval-based work, breathing mechanics and postural correction. Stage 2: muscular endurance, using time-under-tension theory, inspiratory muscle training and step count. Stage 3: muscular strength and hypertrophy, aerobic endurance and respiratory maintenance.
The patient experienced profound improvements in activities of daily living and breathlessness, moving from NYHA III to II. Exercise capacity increased to 4 flights of stairs and 45 mins of incline walking.
Conclusions: and implications for clinical practice
Additional research is required utilising this style of training to further elucidate optimal prescription. However, the current model may offer a development to the current guidelines and provide a blueprint for optimal exercise training in heart failure within the modern healthcare system.

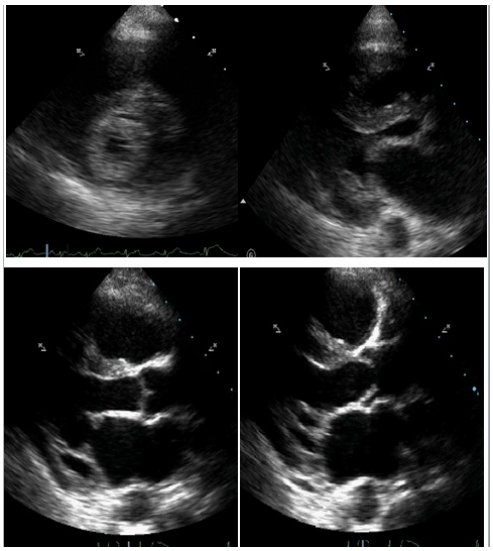
Valvular Heart Disease–Pathophysiology and Mechanisms

P1341

Non rheumatic mitral stenosis in a country with endemic rheumatic heart disease, Is it easy to judge?

AHMED Gaafar[1]; AMR Abdelaal[1]; HOSAM Magdy[1]; MAGDY Ismail[1]
[1]*Helwan University, Faculty of medicine, Cardiology department, cairo, Egypt*

Background: Mucopolysaccaridosis (MPS) is a rare inherited lysosomal storage disorder with multisystem manifestation due to systemic deposition of glycosaminoglycans (GAGs). Cardiac affection has been detected in all types of MPS syndromes and is a common cause of early mortality.
Description: young male patient from rural low socioeconomic area presented to cardiology clinic for assessment before planed surgery for inguinal hernia, he had characteristic features; He was dwarf, with coarse facies and abnormal gait. He complained from dyspnea (NYHA class III), easy fatigability and exertional palpitations with history of recurrent chest infections. No history of syncope, paroxismal nocturnal dyspnea, orthopnea or lower limb swelling.
On examination, patient was laying flat on bed, hisJugular venous pressure was



MPS syndrome

elevated , BP : 110/60, pulse: 90/min. regular. There was significant kyphoscoliosis, leading to absence of cardiac pulsations.On auscultation; cardiac sounds were distant with mid diastolic rumbling murmur hardly heard. ECG was unremarkable. X-ray revealed left atrial mitralization and deformed thoracic cage with spine deformities. Other systems revealed joint stiffness and deformities, kyphoscoliosis, large boxy skull, multiple ocular nerves paralysis with limited visual fields, large tongue, harsh voice, bilateral inguinal hernias and hepatoseplenomegaly. The lab results were within average.
Echocardiography revealed markedly thickened mitral leaflets with no evidence of calcifications and thickened sub-valvular apparatus causing severe mitral stenosis (MS), mitral valve area about 1.1cm^2 ; Bi-ventricular hypertrophy, thickened intra-atrial septum and dilated left atrium.
So the question was; Is it RHD case or these are manifestations of another systemic disease?IAS thickening, RVH in absence of significant pulmonary hypertension, LVH in absence of systemic hypertension or LVOT obstruction andwithout history of RH fever also his brother has the same manifestations in addition to valvular affection in form of grade 2 aortic regurgitation and mild AS which increased the doubt about RHD as the pathological process.So systemic storage disorder with cardiac manifestations became our main concern.The case was referred to an internist and an enzymatic assay was done for the patient, the result of which confirmed the diagnosis of MPS I Hurler-Sheie syndrome.
Management: A multidisciplinary team from cardiology, internal medicine and cardio-thoracic surgery was formed to determine and discuss the optimal line of management for the patient. Cardiac surgery in the form of mitral valve replacement was deferred by the cardio-thoracic team because of the associated risk posed by intubation and post-operative care issues.The next question was what is the appropriate management of this case? And can we apply Wilkin's score which was designed and applied for RHD in our case for suitability to perform balloon valvuloplasty?

Acute Heart Failure–Clinical

P1342
Recurrent takotsubo syndrome - case report

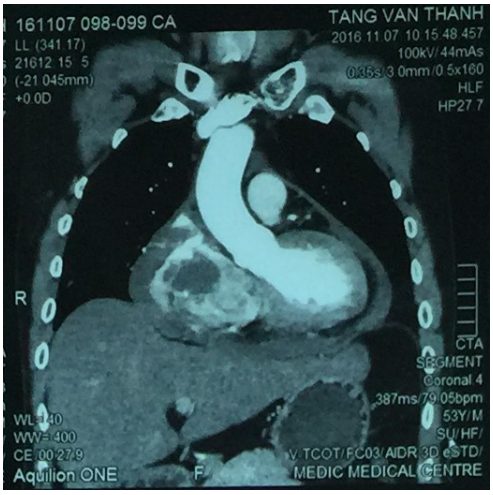
M Mariana Saraiva[1]; L Marta[1]; ML Pitta[1]; B Santos[1]; D Durao[1]; M Leal[1]
[1]*Hospital of Santarem, Cardiology, Santarem, Portugal*

Unravelling the etiology of left ventricular dysfunction is important for an appropriate therapeutic management of the patient. Many times, the differential diagnosis is challenging and meticulous. The authors present a case of Takotsubo Syndrome (TkS), peculiar for its recurrence, but also for the concomitance of coronary artery disease.
We report the case of a 67 year-old man, with arterial hypertension, anxiety and chronic obstructive pulmonary disease and active smoking. He presented to the hospital with shortness of breath and orthopnoea. Already at the hospital, he mentioned self-limited chest pain for a few minutes. On examination, he presented afebrile, with sinus tachycardia (s tach), hypoxemia and bilateral wheezing and lung rales. The most relevant findings were: s tach and nonspecific ST-T wave abnormalities in the electrocardiogram; significant elevation of myocardial necrosis biomarkers (MNB) and brain natriuretic peptide (BNP). The transthoracic echocardiogram showed severe systolic dysfunction of the left ventricle, akinesia of the anterior septum and anterior wall, hypokinesia of mid and distal segments of the other walls and hypercontractility of the basal segments of anterolateral, inferolateral and inferior walls, as well as the inferior septum. He underwent optimized treatment for acute heart failure and also antithrombotic therapy, considering the hypothesis of an acute coronary syndrome. During hospital stay, he revealed he had recently lost a family member. Coronary angiography showed a significant stenosis of the circumflex artery, where a drug-eluting stent was implanted. He evolved positively, with recuperation of left ventricular systolic function and no segmental kinetic changes at discharge. A diagnosis of TkS was considered the most likely.
Seven months later, he returned to the hospital, again with hypoxemia, acute congestive heart failure and self-limited chest pain. He mentioned the death of a previous co-worker the day before admission. For a second time, he presented a significant rise in MNB and BNP levels, and electrocardiographic and echocardiographic changes, both very similar to the ones described previously. He repeated coronary angiography which showed no relevant findings. Yet again, he had a favourable evolution and echocardiographic recovery at discharge. Pheochromocytoma and myocarditis were excluded.
Given the reversibility of these findings, the presence of a psychological stressor preceding the two episodes and the absence of other plausible causes to explain all these findings, a final diagnosis of recurrent TkS was made.

P1343
A case of hemorrhagic tamponade due to right atrium angiosarcoma

H Thai Hao Phan[1]
[1]*Pham Ngoc Thach University of Medicine, Cardiology, Ho Chi Minh, Vietnam*

Background: Primary cardiac angiosarcoma is rare. It is typically located in the right atrium and manifests as right-sided heart failure or cardiac tamponade. Most patients are symptomatic at presentation and when disease is discovered, it is often late in its course, resulting in a poor prognosis. We describe a case of hemorrhagic tamponade due to right atrium angiosarcoma.
Case presentation: A healthy 53-year-old man presented to lung diseases hosptital after one month of hemoptysis. He was started on antibiotics for suspected pneumonia. Over the next few weeks, the hemoptysis worsened and a chest computer tomography was performed.The result was a tumor in right atrium, then he was referred to our institution for further evaluation. Cardiac MS-CT showed a heterogeneous tumor in right atrium 6.5 x 8.0 x 8.0 cm in size suspected angiosarcoma, moderated pericardial effusion (Fig.) PET-CT showed hypermetabolic tumor in right atrium, paratracheal lymph nodes and intrapulmonary nodes. Over one week he suddenly developed dyspneic, hypotensive, and tachycardia. Examination revealed distended jugular veins, distant heart sounds, and diminished lung sounds at the bases. A transthoracic echocardiogram demonstrated a large circumferential pericardial effusion with evidence of cardiac tamponade. He was transfered to emergency surgery. A large amount of blood was found in the pericardial space. Direct invasion of the tumor to the pericardium detected. The tumor was located on the wall of the right atrium and extended over the epicardium. Bleeding from the tumor had ceased after sewing and blood drainage. A piece of tumor was resected and the pathological examination revealed primary cardiac angiosarcoma.
Discussion: Primary cardiac angiosarcomas are rare. Most patients present with symptoms related to heart failure and tamponade.The patient described here had numerous extensive pulmonary metastases, hemoptysis and tamponade. The majority of the primary tumor site is located in the right atrium, and the most common site for metastasis is the lung or the pericardium. Computed tomography scanning confirms the diagnosis of a cardiac mass.
Conclusion: Primary cardiac angiosarcomas-such as our patient's tumor-are highly aggressive and locally invasive. The tumor usually arises from the right atrium, with nonspecific symptoms and signs. Very rarely, the tumor presents with rupture, which leads to hemopericardium, cardiac tamponade, and a poor prognosis. In our patient, the surgery also controlled the bleeding and prevented death from cardiac tamponade; further, it provided a tissue specimen for diagnosis.



P1344

What may happen when you are expecting - a case of peripartum cardiomyopathy

T Theresa Glantschnig[1]; K Ablasser[1]; N Verheyen[1]; D Von Lewinski[1]; PP Rainer[1]
[1]Medical University of Graz, Cardiology, Graz, Austria

Introduction and description: A 29-year-old female presented with pulmonary edema and hypertension 5 days after delivering her first child and an uneventful pregnancy. Echocardiography (TTE) showed dilation of the left ventricle (LVEDD 68mm), reduced LVEF (40%) and severe mitral regurgitation. NT-proBNP was increased to 2496pg/ml and hsTnT to 27g/ml. Non-invasive positive airway pressure ventilation was administered, as well as loop diuretics and intravenous nitroglycerine. HF therapy with beta blockers, an ACE inhibitor, and aldosterone was initiated. Additionally, we gave low molecular weight heparin and bromocriptine. Cardiac MRI showed mild late gadolinium enhancement of the inferior LV wall. The patient was kept on bromocriptine for one week and symptoms improved. LVEF remained mildly impaired but recovered to near-normal values after 6 months.
Identification of the problem: Peripartum cardiomyopathy (PPCM) affects a particularly vulnerable collective. It occurs in late pregnancy or postpartally and is potentially fatal. Recovery rates are higher if LVEF is mildly reduced and response to HF therapy is present. These therapies prevent breastfeeding and may be established reluctantly. Antithrombotic prophylaxis is warranted for high risk of deep vein thrombosis (DVT). Recurrence of PPCM is possible, this necessitates prudent counseling of the patient.
Questions and differential diagnosis
1. What are important differential diagnoses and why can diagnosis be delayed?
2. How is PPCM treated?
Answers and discussion
1. DVT with pulmonary embolism is an important differential diagnosis. D-dimer levels are usually elevated after delivery, but TTE showing reduced LVEF without signs of right heart pressure overload may be helpful. Another factor delaying diagnosis is the common occurrence of dyspnea and leg swelling in pregnant patients. In such cases, risk stratification with NT-proBNP levels and, if elevated, echocardiography appears prudent. Other reasons for HF, including myocarditis, pre-existing cardiac disease, or ischemia should be excluded.
2. In addition to standard HF therapy, anti-prolactin therapy was effective in non-randomized clinical trials and case studies. Prevention of DVT is mandatory as these patients are at high risk of thromboembolic events. If PPCM occurs before birth close coordination with the obstetrician to time delivery is needed. In case of severely impaired LVEF and/or necessity of ICU treatment, we suggest referral to a center with capabilities of assist devices and heart transplantation and coordination with PPCM reference centers.
Conclusion: PPCM is a potentially fatal disease affecting young mothers. It requires early diagnosis and treatment, which is best executed in close coordination with specialized centers. Anti-prolactin therapy has been effective in small non-randomized trials and should be strongly considered in addition to standard HF therapy and antithrombotic prophylaxis.

P1345

Investigation of pulmonary edema revealed renal cell carcinoma growing into the right atrium

I Inna Rosenfeld[1]; T Levinas[1]; S Dabbah[2]; M Halabi[2]
[1]Sieff Government Hospital, Department of Cardiology, Safed, Israel; [2] Bar-Ilan University, The Faculty of Medicine in the Galilee, Safed, Israel

Background: The heart failure is a frequent morbidity in elderly age. The hypertension is a common cause for heart failure. We describe a case of heart failure due to very high blood pressure in elderly woman. Investigation of the causes showed advanced renal tumor as possible cause of hypertensive emergency.
Case report: A 84 years old woman with long history of hypertension was admitted to cardiology department complaining of severe dyspnea and weakness. Her physical examination was remarkable for signs of pulmonary edema with high blood pressure, 240/100mm Hg, HR 100/min. The patient was treated with IV diuretics , nitrates and CPAP mask with stabilization of blood pressure and resolving signs of pulmonary edema.
The diagnostic evaluation of causes for pulmonary edema was performed.
The acute coronary syndrome was excluded because absence chest pain, normal repeated troponin level and unchanged ECG.
Blood tests revealed normal for age creatinine level , normal thyroid function tests and potassium level.

Echocardiography examination showed good Left Ventricular function, EF 65%, Mild Left Ventricular Hypertrophy, Mild to moderate Mitral Regurgitation, Moderate Pulmonary systolic hypertension. An additional unexpected finding was mass in Inferior Vena Cava(IVC), suspected for thrombus .
The investigation was continued by CTA chest and abdomen that showed tumor in left kidney 4.7cm in diameter, dilated Left renal vein with tumor thrombus that continued in IVC up to entrance to the right atrium. The tumor was inoperable due to expansion . The patient declined biopsy and no chemotherapy was started.
Summary: Although acute heart failure due to hypertensive emergency is common condition, the thorough investigation of the causes may revealed uncommon finding like renal carcinoma .
The direct association between arterial hypertension and renal cell carcinoma unclear. Investigation secondary causes of hypertension recommended in patient with malignant hypertension like in our patient.

P1346

Acute heart failure and atrial fibrillation in case of myelodysplastic syndrome

S Severina Dakova[1]; K Ramshev[1]
[1]Military Medical Academy of Sofia, Cardilogy and Intensive care unit, Sofia, Bulgaria

Introduction: Cardiac involvement in patients with acute leukaemia is a well known finding, because of blast infiltration but in myelodysplastic syndroms(MDS) it is rarely reported in the literature. The symptoms may be due to presence of anaemia, iron overload or side effects of chemotherapy.
Case report: A 48-year-old male presented to intensive care unit, because of palpitations, chest discomfort, weakness, dry cough, shortness of breath, easy fatiguability and sweating started 1 day before. He described a loss of weight-20kg in one year. His vital signs were: BP 72/46, HR 153BPM- Atrial fibrilation,Temp 37,7 C and respiratory rate of 38/min, SpO2 of 77%. On examination, he was in mild respiratory distress, with signs of acute congestive heart failure, paroxysmal AF and suspected pulmonary embolism.ECG without signs of acute coronary syndrome.
He had a history of hypertension and myelodysplastic syndrome refractory anemia(MDS RARS 1) diagnosed 9 mothns ago, treated only with blood transfusions - last one 3months ago.
Laboratory tests were: HB-52 g/l, PLT-198,WBC-12,6;HCT- 0,24; RBC 2.4; TroponinI- 0.10ng/ml, NT BNP 254 pg/ml, D-Dimer slightly increased, Iron 34,1 mcmol/l, the other parameters were within normal range.
CT pulmonary angiography did not show any signs of PE, but had mild pulmonary edema.TTE showed EF 45%, with slightly increased LA volume- 33 ml/m2, diastolic disfunction type I and mild Mitral Regugitation.
He was treated with transfusion of 3U red blood cells, antibiotics, digoxin, amiodaron, diuretics,Low molecular Weight Heparins, corticosteroids. On the 5th day we performed TEE to evaluate thrombus in atrial appendage- no signs.
Conclusion: The patient was discharged on the 7th day in sinus rhythm, with normal vital signs.
We belived that cardiac problems in our patients were because of extreme anaemia and mild iron overload.
Do we need to have a long term anticoagulants in this patient?
CHA2DS2-VASc Score = 2 moderate-high risk of stroke
HAS BLED score = 2 moderate risk
ATRIA = 4 intermediate risk

According to those scores the answer is YES, but in our case we decided not to administer because of RARS 1-refractory anemia classified as a low risk MDS by WHO. It may remain stable for many years causing few symptoms, but also may progress rapidly into a different subtype of MDS or transform into an acute leukaemia. RARS is generally managed using the "watch and wait" approach with supportive care if or when required.
What would you do in your practice?
6 months later our patient is doing well, without AF, or any other cardiac problems except hypertension with excellent control.

P1347
Acute heart failure with more than one cause

N Mileva[1]; M Shumkova[1]; T Yaneva-Sirakova[1]; R Ivanova[1]; L Vladimirova[1]; D Vassilev[1]
[1]University Hospital Alexandrovska, Cardiology clinic, Sofia, Bulgaria

Case presentation: A 69-year-old man with past medical history of chronic hepatitis C infection, liver cirrhosis and esophageal varices, presented to our department with acute chest pain that started the same morning. On admission he was dyspneic and diaphoretic. Physical examination revealed bilateral jugular vein distention, tachypnea with respiratory rate of 18 breaths/min, tachycardia with heart rate of 100 beats/min, muffled heart sounds, blood pressure 90/60 mmHg and ascites. In the laboratory findings, anemia (haemoglobin 7,4 g/dl), thrombocytopaenia (85 G/l), hypoproteinemia (33 g/l), elevated spontaneous INR (2,1) were noted. Also cardiac biomarkers were elevated. The ECG was remarkable for diffuse ST-elevation V2-V6 and loss of the R-wave in the same leads. His echocardiography showed akinetic anterior wall segments, reduced left ventricular ejection fraction of 28%, pericardial effusion with interventricular interdependence with inspiration, early diastolic collapse of right ventricle, variability of left ventricular inflow (E wave) >25% and inferior vena cava dilation. Most probable diagnosis was acute coronary syndrome and coronary angiogram was performed. The examination showed thrombotic occlusion in mid-segment of left anterior descending coronary artery. We decided to perform thromboaspiration only, because of the high-bleeding risk in the patient and the unknown etiology of the pericardial effusion. The ventriculogram confirmed reduced ejection fraction with akinetic anterior wall segments. More importantly apical defect of the left-ventricle wall was noted. We proceeded with subxiphoid pericardiocentesis and evacuated 500 ml hemorrhagic fluid. It was decided to perform autohemotransfusion of the evacuated blood, considering the haemodynamic instability and the low haemoglobin of the patient. There was a significant improvement of the patients' condition, he was stabilised and promptly transferred to cardiac surgery department. The patient underwent surgery intervention and had full recovery. On follow up at 3 and 6 months he was clinically stable.
Discussion: We have described a case of a man presenting with acute heart failure due to acute myocardial infarction and cardiac tamponade in the context of apical rupture of the left ventricle at the same time. Patients with comorbid conditions can be challenging diagnostic problem and choosing the best treatment approach demands experience.
Conclusion: The presented case accentuates the importance of awareness that more than one cause for cardiogenic shock may be present at the same patient. Prompt diagnosis and decision on the right therapy approach may be challenging.

Chronic Heart Failure–Epidemiology, Prognosis, Outcome

P1348
64-Year-old man with left ventricule noncompaction cardiomyopathy

S Patino Velasquez[1]
[1]University of Puerto Rico, Hospital Cardiovascular de Puerto Rico y el Caribe , San Juan, Puerto Rico

While most cases of the patients who are recently diagnosed with heart failure develop clinical symptoms on the basis of previous known history of cardiovascular diseases, some in very unusual occasion experience new onset symptomatology without prior history or predisposing cardiovascular risk factors. Non-compaction cardiomyopathy (NCC) also called Spongy Myocardium is characterized by a prominent left ventricular trabeculae and deep intertrabecular recesses affecting majorly the left ventricular function causing clinical manifestation of heart failure.

We present the case of a 64 year old man with no past medical history who showed at our institution with 4-month history of dyspnea at mild exertion associated with recurrent heart palpitations. On physical examination, he had no significant cardiovascular finding except for an ECG with Left bundle branch block and bilateral diffuse crackles suggestive of pulmonary edema. Upon further questioning patient referred family history of non-specific cardiovascular diseases. A 2D- Echocardiogram diastolic dysfunction grade 3, moderate left ventricular dilation, LVEF of < 35% by Simpson criteria and evidence of mesh of endocardial trabeculations. Coronary angiography showing no evidences of CAD. A 24 hour holter monitor reported no arrhythmias, Cardiac MRI showed a large diastolic myocardial ratio of non-compacted to compacted thickness suggestive of NCC. In view of this findings, patient was recommended chronic anticoagulation to minimize the likelihood of cardio embolic event associated with this condition. He was started on optimal medical therapy.
This case shows an uncommon clinical manifestation of heart failure that lead to the unusual diagnosis of NCC. While the etiology in the general population is not known, it has been suggested that NCC may due to an intrauterine arrest of compaction of the loose interwoven meshwork that makes up the fetal myocardial primordium. The major clinical manifestations of NCC are heart failure, atrial fibrillation, ventricular arrhythmias, sudden cardiac arrest, and thromboembolic events, including stroke. There is a predominant genetic component among family member as evidence by our case were predominance for this cardiomyopathy was presumptively presenting among male family members.

Valvular Heart Disease–Epidemiology, Prognosis, Outcome

P1349
Heart failure and adult congenital heart disease: what's the relationship?

H Miranda[1]; I Almeida[1]; H Santos[1]; F Caetano[1]; D Mesquita[1]; J Chin[1]; C Sousa[1]; J Tavares[1]
[1]Centro Hospitalar Barreiro Montijo, Cardiology, Barreiro, Portugal

Introduction: Congenital malformations of the mitral valve (MV) can be found isolated or in association with another congenital cardiac malformation. Amongst all of the possible causes of congenital mitral stenosis (MS), parachute MV (PMV) is a very infrequent one (incidence of 0.17%). This anomaly is often associated with another obstructive lesion in the left heart - Shone Complex (SC).
Clinical case: Woman, 56 years old, obese. Complaints of palpitations and fatigue for small / medium efforts with 1.5 months of evolution. History of peripheral venous insufficiency and pulmonary thromboembolism (secondary to oral contraceptives). Admitted to our department due to onset of acute Heart Failure (HF), with progression to cardiogenic shock with severe biventricular dysfunction (Ejection Fraction (EF): 10-15%), and atrial flutter (HR 178 bpm). Inotropic, vasopressor and ventilatory support during the first 72 hours of hospitalization.
After clinical stabilization, we performed a new echocardiography that revealed reversal of biventricular dysfunction (EF 58%), the presence of MV with reduced opening (1.3 cm2 of functional area) and insertion of both primary tendinous chordae in the posterior papillary muscle. We assumed the diagnosis of PMV and, therefore, we opted for a conservative approach, with regular follow-up in our cardiology department.
1-year follow-up without intercurrences. During the follow-up, we performed a transoesophageal echocardiography to better characterize the MV and identify possible associated lesions, that showed the presence of moderate MS (area of 1.2 cm2) and mild mitral regurgitation and a fibrous membrane immediately above the MV ring. Mild tricuspid regurgitation with moderate pulmonary hypertension (PSAP 52 mmHg). We assumed the presence of two elements of the SC (PMV and supravalvular ring).
Recently, she underwent effort echocardiography that revealed mean gradient of 12mmHg and PSAP of 80mmHg. Consequently, valvular intervention was proposed.
Conclusion: The SC, whether in its complete or incomplete form, is a rare and underdiagnosed entity. Despite its low mortality in adulthood, it is associated with significant morbidity related to arrhythmias, HF and the need for valvular intervention. The recognition of this entity and associated complications is thus essential for a correct clinical orientation.

Comorbidities and cardiomyopathies: how to manage?

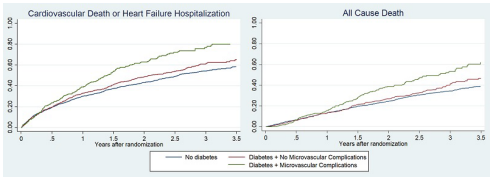
Microvascular complications in diabetes patients with heart failure and reduced ejection fraction

1387

S L Kristensen[1]; R Roerth[2]; PS Jhund[2]; L Shen[2]; M Lee[2]; MC Petrie[2]; L Kober[1]; J Mcmurray[2]
[1]*Rigshospitalet - Copenhagen University Hospital, Cardiology, Copenhagen, Denmark*; [2]*Cardiovascular Research Centre of Glasgow, Cardiology, Glasgow, United Kingdom*

On behalf of: BEST investigators

Background: The role of microvascular complications in the risk conferred by diabetes in heart failure with reduced ejection fraction (HFrEF) is unknown.
Methods: We studied 2707 HFrEF patients in the Beta-blocker Evaluation of Survival Trial (BEST), stratified into 3 groups: no diabetes and diabetes without or with microvascular complications (neuropathy, nephropathy or retinopathy). The risks of the composite of cardiovascular death or heart failure hospitalization, and all-cause death, were studied using Cox regression analyses adjusted for other prognostic variables.
Results: 964 patients had diabetes, of which 313 (32%) had microvascular complications. Patients with microvascular complications had more severe symptoms (New York Heart Association functional class IV 12% vs. 9% diabetes with no complications and 7% no diabetes), and worse quality of life (Minnesota living with HF median score 60 vs. 54 and 51 points). In patients with diabetes and complications, the rate of the composite outcome was 45 per 100 person-years of follow-up (compared with 34 and 29 in those with diabetes and no microvascular complications and participants without diabetes, respectively). Compared to patients without diabetes, the adjusted hazard ratio (HR) for the composite outcome was 1.44 (95% CI 1.22-1.70) and 1.18 (1.03-1.35) for patients with diabetes with and without complications, respectively. The risk of all-cause mortality was similarly elevated: adjusted HR 1.42 (95% CI 1.16-1.74) and 1.20 (1.01-1.42), respectively (Figure 1). Each type of microvascular complication was associated with a similar increment in risk and patients with more than one complication had an even greater elevation in risk.
Interpretation: In HFrEF, diabetes with microvascular complications is associated with worse symptoms and outcomes, than diabetes without microvascular complications. Prevention of microvascular complications has the potential to improve HFrEF outcomes.



Outcomes according to diabetes status

The importance of measuring fractional flow reserve to improve the efficiency of endovascular treatment on left main bifurcation lesions

1388

D A Daniil Maximkin[1]; Z KH Shugushev[1]; AG Chepurnoy[1]; OO Safonova[1]; AG Faibushevich[1]
[1]*Peoples Friendship University of Russia (RPFU), Moscow, Russian Federation*

Aim: to increase the effectiveness of endovascular treatment in patients with LM bifurcation lesions.
Methods: 157 patients were enrolled in the study. Inclusion criteria: true bifurcation stenosis of the LMCA according to QSA and IVUS; total risk according SYNTAX score < 32. All patients initially performed 'Provisional T' stenting of the LMCA (1stent strategy). After the procedure, a fractional flow reserve (FFR) was measured in the side branch of bifurcation (LCx or LAD)/ The main cohort of patients (n = 88) were divided into 2 groups. Group I (n = 44) included patients with FFR SB '+', and group II (n = 44) - FFR SB '-'. In the Ist group, after FFR measurement, all patients underwent complete bifurcational stenting (revers-crush, revers-culott), and in group II, implantation of the 2d stent was not performed. In retrospectively, the third (III) control group was formed (n = 69), where the 'Provisional T' stenting of the LMCA was performed without a control FFR measurement. Drug-eluting stents were implanted in all patients. At the end of the stenting procedure, all patients underwent IVUS for evaluating the optimal stent implantation. Long-term results after 48 months were followed in all patients. Primary endpoints: frequency of MACE (death, MI, repeated interventions). (death, MI, revascularizations). Secondary endpoints: frequency of restenosis and late stent thrombosis according to QSA and IVUS.
Results: survival of patients from Group I and II in the long-term period was 100%, and in the third group - 97.1% (p>0.05). Nonfatal MI was observed in 2 patients (2.9%) from group III (p < 0.05), in the Ist and IId group of cases MI was not recorded. The frequency of restenosis of and target lesion revascularization (TLR) according to QSA and IVUS was observed in 1 patient (2.3%) in group I and in 5 patients (7.2%) in group III (p < 0.05). Frequency of the target vessel revascularization (TVR) occurred in I and II group in 2.3% of patients, and in group III - in 2.9% (p>0.05). The total frequency of MACE in groups I, II and III was 4.5; 2.3 and 15.4%, respectively (p < 0.05).
Conclusion: measurement of FFR in the lateral branch of the left main bifurcation after performed PTS significantly improves the prognosis of patients with lesions of the LCA trunk and improves the efficacy and safety of PCI.

Characterization of plasmacytoid and myeloid dendritic cells in acute human and experimental myocarditis

1390

R Pistulli[1]; E Andreas[2]; S Koenig[3]; S Drobnik[4]; D Kretzschmar[1]; M Lichtenauer[5]; B Heidecker[6]; M Franz[1]; G Mall[4]; A Yilmaz[7]; P C Schulze[1]
[1]*University Hospital of Jena, Internal Medicine I, Dept. of Cardiology, Jena, Germany*; [2]*University Hospital of Jena, Department of Anesthesiology, Jena, Germany*; [3]*Heart Center of Leipzig, Cardiac Electrophysiology, Leipzig, Germany*; [4]*University Hospital of Jena, Department of Forensic Science, Jena, Germany*; [5]*Paracelsus Private Medical University, Cardiology, Salzburg, Austria*; [6]*University Heart Center, Cardiology, Zurich, Switzerland*; [7]*Elisabeth-Hospital, Clinic of Internal Medicine II, schmalkalden, Germany*

AIMS: Dendritic cells (DCs) are central mediators of adaptive immunity but their role in human myocardial inflammatory disease is still unknown. We hypothesized that plasmacytoid (p) and myeloid (m) DCs are involved in the mechanisms of myocarditis and analyzed these two main subtypes in human myocarditis subjects as well as in a murine model of experimental autoimmune myocarditis (EAM).
Methods: Circulating DCs were analyzed by flow cytometry (FACS) in patients with acute myocarditis (n = 33), dilated cardiomyopathy (DCM, n = 33) and controls (n = 33) at initial diagnosis and at follow-up at 6 and 12 months. Myocardial biopsies of acute myocarditis patients (n = 18) were immunostained for the presence of DCs and compared to non-diseased controls (n = 5). In a mouse model of acute myocarditis induced through synthetic cardiac myosine injection, effects of DC inhibition through MCS-18 treatment and placebo were tested. Histology, immunohistochemistry and echocardiography were performed at 21 days (peak myocarditis) and 28 days (recovery phase) following EAM induction.
Results: Circulatory pDCs and mDCs were significantly reduced in myocarditis patients (p < 0.01 for both), increased at 6 months follow-up, yet remained reduced compared to controls (pDCs p = 0.015, mDCs p = 0.002). Circulatory DCs of DCM patients were initially indifferent, but gradually decreased during follow-up, reaching significant reduction at 6 (mDCs, p 0.03) or at 12 months (pDCs, p < 0.01) follow-up. Human myocarditis biopsies showed accumulation of pDCs (2-fold CD304+ / 3-fold CD123+, all p < 0.01) compared to controls. Myocardial pDCs and mDCs accumulated in EAM (p for both < 0.0001). MCS-18 Inhibition reduction pDC levels (p = 0.009), reduced myocardial inflammation (myocarditis score reduction from 2.6 to 1.8, p = 0.026) and improved ejection fraction (p = 0.03) at peak myocarditis.
Conclusions: Circulating DCs are reduced in human myocarditis and accumulate in the inflamed myocardium. MCS-18 inhibits DCs in EAM leading to amelioration of inflammation and LV remodeling during the acute phase of myocarditis. Our data

further elucidate the role of DCs and their specific subsets in acute inflammatory cardiomyopathies.

Funding Acknowledgements: CVON2014-11 RECONNECT and FP7-242209-BIOSTAT-CHF

Background: A higher body mass index (BMI) is associated with better survival in heart failure (HF) patients, also known as the obesity paradox. However, BMI does not account for body composition. We therefore analysed the association between abdominal fat, measured via waist-hip ratio (WHR), BMI and all-cause mortality in patients with heart failure.
Methods: For this analysis 1738 patients from The BIOlogy Study to TAilored Treatment in Chronic Heart Failure (BIOSTAT-CHF) study were included. Patients without waist and hip measurements were excluded. WHR was defined as waist circumference/hip circumference, divided into tertiles and split for sex. A linear regression of principal components from an extensive panel of biomarkers was performed to provide insight in the pathophysiology behind a higher WHR.
Results: In total, 1479 patients with were included, of which 33% were female and mean age was 75 ± 11 years. A higher WHR was independently associated with a higher BMI, a higher prevalence of diabetes and higher functional NYHA class. There was a significant interaction between sex and WHR on its association with mortality ($P < 0.001$). In women, a higher WHR was associated with a higher mortality risk (HR 2.01; 95% confidence interval (CI) 1.33-3.02, $P = 0.001$), whereas no significant association was found in men (HR 1.21, 95% CI 0.87-1.69, $P = 0.262$). We found a strong association between a higher WHR and elevated markers of inflammation and MAPK cascade in women, while in men these associations were less profound.
Conclusions: A higher WHR was associated with a higher risk of death in female, but not in male heart failure patients. These findings challenge the obesity paradox, and suggest that fat deposition is pathophysiologically harmful and may be a target for therapy in female patients with heart failure.

Funding Acknowledgements: This study was sponsored by Ionis Pharmaceuticals (Carlsbad, CA, USA).

INTRODUCTION: Hereditary transthyretin (TTR) amyloidosis (hATTR) is a rare, progressive, and fatal disease caused by misfolded TTR that builds up as amyloid in major organ systems, especially cardiac tissue and nerves, causing cardiomyopathy (CM) and polyneuropathy (PN), respectively. hATTR causes significant morbidity and a progressive decline in patient quality of life.
Purpose: To evaluate the efficacy and safety of inotersen, an antisense oligonucleotide inhibitor of TTR protein production, in patients with hATTR with CM and PN.
Methods: NEURO-TTR (NCT01737398) is a global, randomised, double-blind, placebo-controlled phase 3 study. Adults (n = 172) with hATTR-PN (stage 1 or 2) with or without CM were randomly assigned 2:1 and received 300-mg weekly subcutaneous inotersen or placebo for 15 months. CM was defined as diagnosis of hATTR-CM or = 1.3 cm interventricular septum thickness (IVS; by echocardiography) at baseline. Primary endpoints were change from baseline to week 66 in the modified Neuropathy Impairment Score+7 (mNIS+7) and Norfolk Quality of Life−Diabetic Neuropathy (Norfolk QOL-DN) total score. Exploratory outcomes included measures of CM, including IVS, left ventricle mass (LVM), and posterior wall thickness (PWT).
Results: At baseline, 69% of patients were male, mean age was 59 years (range, 27-81 years), and 63% (108/172) had CM. Of patients given placebo and inotersen, 55% (33/60) and 67% (75/112), respectively, had CM. Inotersen treatment compared with placebo resulted in significant improvement from baseline to week 66 in mNIS+7 ($P < 0.0001$) and Norfolk QOL-DN total score ($P = 0.0006$) in all patients, irrespective of CM status. The subset of patients with CM also demonstrated significant improvement from baseline to week 66 in mNIS+7 ($P < 0.001$) and Norfolk QOL-DN total score ($P = 0.036$) with inotersen treatment compared with placebo. Patients with significant CM at baseline (IVS = 1.5 cm) treated with inotersen compared with placebo also showed significant benefit in IVS ($P = 0.0150$), LVM ($P = 0.0288$), and PWT ($P = 0.0425$). Most adverse events were mild or moderate. Key safety findings of thrombocytopenia and renal events were easily managed and monitored with routine testing.
Conclusion: Inotersen demonstrated significant benefits in quality of life and prevention of cardiac and neurological disease progression in patients with hATTR with CM and PN.

The Left atrial strain provide improved diagnostics for elevated filling pressures at rest and/or during exercise in heart failure patients

A Manouras[1]; A Lundberg[1]; M Back[1]; LA Lund[1]; A Nagy[2]
[1]Karolinska Institute, Institute of Medicine Solna, Stockholm, Sweden; *[2]Semmelweis University, Heart and Vascular Center, Budapest, Hungary*

Funding Acknowledgements: Heart Lung Fond

Background/Introduction: The non-invasive assessment of left ventricular diastolic function and filling pressures is an important clinical question. Particularly challenging is the diagnosis of those patients whose left atrial pressure (LAP) is within normal range at rest, but increases pathologically on exertion. Current recommendations on diastolic assessment are complex, have limited diagnostic accuracy and provide no guidance for that latter scenario.
Purpose: As recent data suggests that the LA constitutes an important pathophysiological substrate of diastolic heart failure we hypothesized that mechanical alteration in LA function, as expressed by reduced LA strain (LA-GS), might contribute in identification of elevated LAP and thus sought to investigate this question.
Methods: 220 patients referred for right heart catheterization (RHC) to Karolinska University Hospital for HF assessment were enrolled prospectively. Simultaneous echocardiographic examination and RHC at rest and during exercise was performed. Patients with precapillary pulmonary hypertension, constrictive pericarditis and significant valvular disease were excluded
Results: In total 164 patients were included. 56% of the patients had preserved EF. At rest, the pulmonary arterial wedge pressure (PAWP) was elevated in 97 patients and further 34 patients with normal resting PAWP values demonstrated abnormal PAWP elevation during exercise. LA-GS measurements was feasible in 97% of the patients. LA-GS showed the strongest correlation with resting PAWP (r=- 0.64 for preserved EF, and -0.46 for reduced EF, $p < 0.001$ in both cases) compared to the individual indices (E/E', LAVi, TR-Vmax) incorporated in the currently recommended diagnostic EACVI algorithm. The diagnostic performance of LA-GS for detecting elevated resting PAWP was good (AUC:0.87 and 0.74 in patients with preserved and HFrEF, respectively). More importantly, resting LA-GS values performed even better for identifying patients with pathological PAWP either at rest or on stress (AUC:0.90 and 0.80, respectively). On the other hand, the currently proposed EACVI algorithm

demonstrated a modest diagnostic ability limited in patients with preserved EF (AUC = 0.69 at rest and 0.67 for detecting patients with pathological PAWP either at rest or on exertion). Conclusion(s) - Resting LA-GS provides superior diagnostic discrimination between normal and elevated PAWP values at rest as compared to EACVI algorithm. More importantly, resting LA-GS demonstrates augmented diagnostic ability for patients with pathological elevation of PAWP during exertion.

Exercise hemodynamic profile of patients with heart failure with preserved versus mid-range ejection fraction

AJ Andreas Joachim Rieth[1]; MJ Richter[2]; K Tello[2]; W Seeger[2]; V Mitrovic[1]; C Hamm[2]

[1]Kerckhoff Heart Center, Bad Nauheim, Germany; *[2]Justus-Liebig University of Giessen, Giessen, Germany*

Background: According to the 2016 ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure, the term "HFpEF" (heart failure with preserved ejection fraction) is reserved for patients with left ventricular ejection fraction (LVEF) = 50%, and the new term "HFmrEF" denotes those with LVEF 40-49%. Possible differences in exercise hemodynamic profile between these two entities are unknown to date.
Methods: Results of exercise right-heart catheterization performed from 2009 to 2017 were screened for patients with HFpEF or HFmrEF, and 233 patients were determined to be suitable for further analysis. Differences between hemodynamic variables in the two groups were analyzed, and the ratio of tricuspid annular plane systolic excursion (TAPSE) to pulmonary artery systolic pressure estimated by Doppler echocardiography (PASP) compared for the two groups. Each group was then subdivided according to whether the TAPSE/PASP ratio was greater than or less than the median, and the hemodynamic variables were compared in the resulting four groups.
Results: The cohort of 180 patients with HFpEF and 53 with HFmrEF had the following baseline characteristics: 53% men, median age 73 years (IQR 67-77), median NTproBNP 1132 pg/ml (IQR 570-2255), 27% in NYHA class II and 69% in class III, and 66% with atrial fibrillation. Key resting hemodynamic parameters, expressed as mean mmHg (SD) or l/min/m2 (SD) for cardiac index (CI), were: mean right atrial pressure 7.55 (4.29) in HFpEF and 7.4 (5.15) in HFmrEF; mean pulmonary artery pressure (mPAP) 25.71 (7.60) in HFpEF and 25.98 (11.43) in HFmrEF; mean pulmonary artery wedge pressure (PAWP) 16.02 (5.44) in HFpEF and 15.85 (7.50) in HFmrEF; CI 2.54 (0.63) in HFpEF and 2.44 (0.60) in HFmrEF. Multiple hemodynamic exercise parameters showed no significant differences between the two groups at comparable workload, maximum heart rate, and final mixed venous oxygen saturation. However, the TAPSE/PASP ratio was significantly different (p = 0.001) between HFpEF and HFmrEF patients. Subgrouping according to median TAPSE/PASP ratio showed significant differences between the four groups: the increase in cardiac output during exercise (p = 0.001), maximum total pulmonary resistance (p = 0.000), maximum pulmonary artery compliance (p = 0.000), and maximum transpulmonary gradient (p = 0.003), whereas the rise in PAWP was not different.
Conclusions: Standard hemodynamic parameters at rest and during exercise did not differ significantly between patients with HFpEF and HFmrEF. Instead, partitioning of the two entities using an echocardiographic parameter of the right ventricular-pulmonary circulation unit showed marked differences in the exercise hemodynamic profile between the different subgroups. Thus, LVEF may be not the appropriate parameter to stratify heart failure patients with an EF >40%, but parameters of the right ventricular-pulmonary circulation unit, including exercise hemodynamics, may be helpful for profiling.

Imaging phenotypes of left-dominant arrhytmogenic cardiomyopathy and dilated cardiomyopathy - a comparative magnetic resonance study

R Rocio Eiros[1]; JB Augusto[2]; T Treibel[3]; G Captur[3]; MM Akhtar[3]; A Protonotarios[3]; T Gkosios[3]; K Savvatis[3]; S Mohiddin[3]; J Moon[3]; LR Lopes[3]

[1]University Clinic of Navarra, Cardiology, Navarra, Spain; *[2]Hospital Prof. Doutor Fernando Fonseca, Lisboa, Portugal*; *[3]Barts Health NHS Trust, London, United Kingdom*

Background: Emerging data have illustrated the diversity of genetic causes of arrhythmogenic cardiomyopathy (AC) with dominant LV involvement (ALVC).The relation between genotype and clinical phenotype is scarce and there are no systematic studies examining imaging phenotypes using cardiac magnetic resonance (CMR).
Objective: To identify phenotypic traits that distinguish ALVC from other genetic causes of dilated cardiomyopathy(DCM).
Methods: CMR data acquired for 30 patients (pts) with confirmed ALVC /DCM associated mutations in desmoplakin (DSP), filamin C (FLNC), lamin A/C (LMNA), titin (TTN) and BAG3 were retrospectively re-analysed and compared on the basis of different individual genes and when grouped as ALVC (DSP / FLNC) vs DCM (others).
Results: Causal genes included DSP (n = 11), FLNC (n = 4), lamin A/C (n = 6), BAG3 (n = 4), titin (n = 5). A comparison of clinical and imaging features is presented in Table 1. Figure 1 shows a comparison of late gadolinium enhancement patterns between different genes.
Conclusions: Patients with genetic causes of ALVC have a higher burden of myocardial scar, in a more often sub-epicardial and ring-shaped pattern, in contrast with a more discrete midwall septal late gadolinium enhancement in other genetic causes of DCM. Other imaging parameters, including LV and RV sizes and function were similar.

Pretreatment with P2Y12 Receptor Antagonists in ST-Elevation Myocardial Infarction: A Report from the Swedish Coronary Angiography and Angioplasty Registry

E Elmir Omerovic[1]

[1]Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Prehospital administration of P2Y12 receptor antagonists to patients with ST-elevation myocardial infarction (STEMI) is supported by guidelines and is a common practice despite the lack of definite evidence for its benefit.
Methods: Using data from the Swedish Coronary Angiography and Angioplasty Registry on procedures between 2005 and 2016 we stratified all patients who underwent primary PCI due to STEMI in Sweden by whether or not they were pretreated with P2Y12 receptor antagonists. We investigated associations between P2Y12 pretreatment and the risk of adverse outcomes with propensity-scores adjusted mixed-effects logistic regression, which accounted for clustering of patients within hospitals. The primary endpoint was all-cause death within 30 days. Secondary endpoints were IRA (infarct-related artery) occlusion, 30-day stent thrombosis, in-hospital bleeding, neurological complications and cardiogenic shock.
Results: In total, 44,804 patients were included. They were treated with clopidogrel (N = 26,136, 58.3%), ticagrelor (N = 15,792, 35.3%), or prasugrel (N = 2,352, 5.3%);

37,840 (84.5%) were pretreated, and 30,387 (67.8%) had IRA occlusion. At 30 days, there were 2,488 (5.6%) deaths and 267 (0.6%) stent thromboses. Pretreatment was not associated with better survival (OR 0.1.07; 95% CI 0.94-1.22; P = 0.313) at 30 days, reduced IRA occlusion (OR 1.01; 95% CI 0.95-1.08; P = 0.635), or decreased stent thrombosis (OR 0.99; 95% CI 0.69-1.41; P = 0.941), or higher risk of in-hospital bleeding (OR 1.04; 95% CI 0.89-1.23; P = 0.604), or neurological complications (OR 0.66; 95% CI 0.38-1.30; P = 0.129). We found no difference in risk of cardiogenic shock between the groups (OR 0.91; 95% CI 0.78 - 1.07; P = 0.264)
Conclusion: Pretreatment of STEMI patients with P2Y12 receptor antagonists was not associated with improved clinical outcomes.

1391

Ticagelor is not superior to clopidogrel in patients with acute coronary syndrome: A report from SCAAR

E Elmir Omerovic[1]
[1]*Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: The PLATO trial has shown that ticagrelor compared to clopidogrel improves survival and decreases risk for stent thrombosis in patients with acute coronary syndrome. The aim of this study was to investigate whether treatment with ticagrelor is superior to clopidogrel in patients with acute coronary syndrome in "real-world".
Methods: We used data from the SCAAR registry (Swedish Coronary Angiography and Angioplasty Registry) for the PCI procedures performed in Västra Götaland County in Sweden. The database contains information about all PCI procedures performed at five hospitals (˜20% of all SCAAR data). All consecutive procedures between 2005 and 2015 for UA/NSTEMI and STEMI were included. We used multilevel modeling based on complete−case mixed-effects logistic regression to adjust for hierarchical database due to clustering of observations. The following variables were used for adjustment of risk estimates: age; gender; hypertension; hyperlipidemia; smoking status; diabetes; calendar year; indication for PCI; prior MI, CABG and/or PCI; cardiogenic shock; severity of coronary artery disease; number of implanted stents; completeness of revascularization; type of stent. The primary combined endpoint was death or stent thrombosis at 30 days. The secondary end points were death at 30-days, death at one-year and cardogenic shock.
Results: The total of 12,168 patients were included in the study of which 2,929 (19%) were treated with ticagrelor. 44% had STEMI. There were 555 events at 30-days of which 53 (9.5%) were stent thromboses. 844 patients were dead at one-year. Treatment with ticagrelor was not associated with lower risk for primary endpoint (OR 0.97; 95% CI 0.66 - 1.43; P = 0.887). Estimated risk of death at 30-days (OR 1.02; 95% CI 0.59 - 1.76; P = 0.937) and one-year (OR 1.01; 95% CI 0.68 - 1.47; P = 0.992) was not different between the groups. We found no difference in risk of cardiogenic shock between the groups (OR 1.32; 95% CI 0.75 - 1.23; P = 0.330)
Conclusions: In this observational study, treatment with ticagrelor was not superior to clopidogrel in patients with acute coronary syndrome treated with PCI.

Dilated cardiomyopathy with midrange ejection fraction at diagnosis: characterization and natural history

P Gentile[1]; M Merlo[1]; A Cannata'[1]; M Gobbo[1]; M Marco Mase[1]; D Zaffalon[1]; M Gigli[1]; G Barbati[2]; F Ramani[1]; D Stolfo[1]; B Pinamonti[1]; G Sinagra[1]
[1]*Ospedale Cattinara, Cardiovascular Department, Trieste, Italy*; [2]*University of Trieste, Biostatistics Unit, Department of Medical Sciences, Trieste, Italy*

Background: Few data on the characteristics and outcomes of mid-range EF (mrEF) patients are available, mostly in the specific group of dilated cardiomyopathy (DCM).
Purpose: To define characteristics, evolution and prognosis of DCM patients with mrEF at diagnosis.
Methods: DCM patients were analyzed. mrEF and reduced EF (rEF) were defined in presence of baseline left ventricular EF between 40 and 49% and < 40% respectively. The study end-points were all-cause mortality or heart transplantation (D/HT) and sudden cardiac death or malignant ventricular arrhythmias (SD/MVA). EF worsening below 40% during follow-up was also considered.
Results: Among 812 DCM enrolled patients, 175 (22%) presented mid-range EF at baseline. Compared with rEF group, mrEF patients had smaller left ventricular end-diastolic volume, lower rates of left bundle branch block, right ventricular dysfunction, moderate−severe mitral regurgitation and restrictive filling pattern. During a mean follow−up of 135 ± 87 months, mrEF group presented a lower rate of D/HT (9.1% vs. 36%, $p < 0.001$) and SD/MVA (4.5% vs.15.2%, $p < 0.001$). Finally, 29 out of 175 mrEF patients (17%) evolved to rEF at a mean follow−up of 64 ± 40 months, showing a subsequent worsening of long−term prognosis. A restrictive filling pattern emerged as the strongest predictor of rEF development at multivariate analysis. Conclusions. mrEF identified a consistent subgroup of DCMs diagnosed in an earlier stage and presenting an apparent better long-term evolution. However, 17% of those patients evolved into rEF despite medical therapy. Baseline restrictive filling pattern was found to be independently associated with subsequent evolution in rEF.

Thromboembolic events in left ventricular non-compactation cardiomyopathy, are there any predictors?

N Nuno Craveiro[1]; H Antunes[2]; N Marques[3]; L Reis[4]; R Santos[5]; AR Almeida[6]; O Azevedo[7]
[1]*Hospital of Santarem, Cardiology, Santarem, Portugal*; [2]*Hospital Sao Teotonio, Viseu, Portugal*; [3]*Algarve Biomedical Center, Centro hospitalar do Algarve, Cardiology, Faro, Portugal*; [4]*University Hospitals of Coimbra, Coimbra, Portugal*; [5]*Hospital Espirito Santo de Evora, Evora, Portugal*; [6]*Hospital Centre do Tamega e Sousa, Penafiel, Portugal*; [7]*Hospital Guimaraes, Guimaraes, Portugal*

On behalf of: SUNSHINE

Introduction: Patients with left ventricular non-compaction cardiomyopathy (LVNC) have a higher prevalence of heart failure, ventricular arrhythmias and thromboembolic events leading to increased mortality and morbidity.
Aim: To identify predictors of thromboembolic events in patients with LVNC.
Methods: One-hundred-eleven-patients (N = 111) diagnosed with LVNC were included from a Portuguese multicenter study involving 12 hospital centers. We evaluated demographic, clinical, electrocardiographic, echocardiographic and cardiac magnetic resonance, and follow-up data. We determined the factors and conducted a multivariate analysis to establish the independent predictors that were associated with the occurrence of thromboembolic events in these patients.
Results: A thromboembolic event occurred in 10 patients (9%). In our study the factors associated with a thromboembolic event were male gender (90% p = 0,042), presence of diastolic dysfunction as evaluated by deceleration time (200 ± 81 ms vs 191 ± 44 ms, p = 0,001) and left atrium volume (40,58 ± 16,6 ml/m2 vs 30,4 ± 11,7 ml/m2 p = 0,036), as well as older age of diagnosis (60,4 ± 13,9 years vs 45,13 ± 17,7 years p = 0,010) and the presence of sustained ventricular tachycardia in Holter monitoring (p = 0,03). After multivariable analysis the only independent predictor of thromboembolic event was the presence of sustained ventricular tachycardia in Holter monitoring (Beta = 0,334; p = 0.016).
Conclusion: Thromboembolic events are frequently associated with LVNC. In our population the incidence of thromboembolism was 9%. The presence of sustained ventricular tachycardia in Holter monitoring was an independent predictor of events in our study.

De novo mutation rate in patients with hypertrophic cardiomyopathy and left ventricular non-compaction.

E Elena V Zaklyazminskaya[1]; M Polyak[1]; A Bukaeva[1]; G Radzhabova[1]; S Dzemeshkevich[1]

[1]B.V. Petrovsky Russian Scientific Center of Surgery of the Russian Academy of Medical Sciences, Moscow, Russian Federation

Funding Acknowledgements: This study was supported by Russian Research Foundation grant 16-15-10421

Introduction: Recent advances in genetic technologies provide a new insight into molecular pathogenesis of the left ventricular hypertrophy and/or non-compaction. Clinical appearance of the single mutation can vary significantly in different families and even within the same affected pedigree. Genotype-phenotype correlation is poorly understood despite extensive study worldwide.

Materials and methods: Cohort of patients. From 2009-2015 150 probands with hypertrophic cardiomyopathy (HCM) and 60 probands with LVNC had underwent genetic screening.

Genetic analysis. Study was performed in accordance with the Helsinki declaration and the local ethics committee. Genetic screening of the targeted 10 genes (MYBPC3, TAZ, TPM1, LDB3, MYL2, ACTC1, MYL3, MYH7, TNNI3, and TNNT2) was performed by next generation sequencing followed by Sanger re-sequencing. Cascade familial screening was performed when available. De novo mutational status was counted only if genetic testing reveal absence of the genetic variant in both parents.

Results: "Damaging" or "probably damaging" genetic variants were found in 39 HCM index cases (26%) what is less than expected. The vast majority of mutations were found in the MYH7 and MyBPC3 gene what fits with worldwide mutation rates. De novo origin was confirmed for 4 mutations (10% of all genotype-positive cases, and 2.6% in the whole HCM cohort). Three mutations had raised de novo in the MYH7 gene, and 1 probably damaging de novo variant was found in the TPM1 gene. Single de novo genetic variant in the MYH7 gene was found in the patient with familial HCM in addition to the known mutation in the MyBPC3 gene inherited from the affected mother. This patient had severe clinical phenotype and underwent reconstructive extended myectomy and ICD implantation at the age of 15 y.o.

"Damaging" or "probably damaging" genetic variants were found in 14 LVNC index cases (23%). Mutations in the MYH7 gene were also the most common finding. De novo status was confirmed for 4 mutations in the MYH7 gene (29% of all genotype-positive cases, and 6.6% in the whole LVNC cohort).

All carriers of de novo mutations had significantly younger age of clinical manifestation within own group.

Totally 18 mutations in the MYH7 gene were detected in this study in the whole cohort of patients (HCM and LVNC), and five of them had raised de novo.

Conclusion: Mutations de novo are responsible for a significant portion of the LVNC, and are less common but not negligible in HCM patients. Severe clinical phenotype within "mildly" affected family might be explained by additional de novo mutation (at least in some families). The MYH7 gene is an important source of de novo mutations maintaining the high prevalence of HCM and LVNC in population.

Study limitation.

We were unable to track mutation origin in half of the cases because of incomplete data from the families. So the real prevalence of de novo mutations might be underestimated.

Alpha1-adrenergic receptor agonists activate Akt signalling via insulin family receptors

A Angela Clerk[1]; KA Rostron[1]; DN Meijles[2]; S Shaw[1]; JJ Cull[1]; SJ Fuller[1]; PH Sugden[1]
[1]*University of Reading, Reading, United Kingdom*; [2]*St George's University of London, London, United Kingdom*

Funding Acknowledgements: British Heart Foundation

Background: Akt signalling (first delineated in the context of insulin receptor signalling) is cardioprotective. Akt is potently activated by insulin or insulin-like growth factor 1 (IGF1), acting through insulin or IGF1 receptors (IRs or IGF1Rs). Other receptors including a1-adrenergic receptors (a1ARs) activate Akt, but the mechanism of activation is not clear.
Purpose: Our hypothesis is that a1-ARs activate Akt via insulin family receptors (InsFRs). Our aim was to establish if this is the case, and if linsitinib [a highly selective inhibitor of insulin family receptors (InsFRs) developed for cancer] affects the functional consequences of a1-AR agonists on the heart.
Methods: Rat neonatal cardiomyocytes were exposed to or adult rat hearts perfused with a1AR agonists [50 nM A61603; 100 μM phenylephrine (PE)] in the absence/presence of 10 μM linsitinib. Effects on signalling were assessed by immunoblotting with antibodies to phosphorylated (activated) kinases. Protein synthesis was assessed by incorporation of 3H-Phe. Cardiac function in perfused hearts was measured using a Millar catheter. Effects of linsitinib (2 mg/kg/d) on cardiac function/hypertrophy induced by PE (40 mg/kg/d, 4 d) in mice (male C57Bl6; 10 wks) in vivo were by determined. Echocardiography was used to assess cardiac function. M-mode images were used for analysis of cardiac dimensions. Pulsed wave doppler was used to assess aortic and pulmonary flow.
Results: In addition to IRs/IGF1Rs, our data indicate a third InsFR is expressed in heart, the insulin receptor-related receptor (IRR). IRRs are alkali-sensitive and required for pH regulation in kidney. Alkaline pH (pH 9.0) activated IRRs and Akt, and was associated with increased protein synthesis in perfused hearts. IRRs were activated in a complex with IR/IGF1Rs. a1ARs activated Akt in cardiomyocytes and perfused hearts and increased protein synthesis. Activation of Akt and the increase in protein synthesis induced by alkaline pH or a1AR agonists was inhibited by linsitinib. Thus, a1ARs signal selectively via InsFRs to Akt and protein synthesis. Functionally, in perfused hearts, linsitinib enhanced the increase in developed pressure induced by A61603 and, in vivo, linsitinib enhanced PE-induced left ventricular (LV) hypertrophy with increased LV wall thickness and decreased internal diameter. Aortic (but not pulmonary) flow was compromised in the presence of PE/linsitinib. Therefore, there appear to be opposing effects of a1-AR signalling via InsFRs to cardiomyocyte vs cardiac hypertrophy.
Conclusions: Our data demonstrate a novel signalling paradigm in which a1-ARs signal through InsFRs in cardiomyocytes to activate Akt and increase protein synthesis although, functionally, the InsFR signal appears to mitigate some of the hypertrophic effects of a1-AR signalling in the whole heart. The data have implications for development of novel therapeutic targets for heart failure and potential cardiotoxic effects of cancer therapies.

Funding Acknowledgements: Ministry of Higher Education and Research of Luxembourg and Society for Research on Cardiovascular Diseases.

Background: According to recent estimations, heart failure (HF) is projected to rise by almost 50% by 2030. New investigation is needed to improve the current therapies in order to palliate this "epidemic". Animal models provide a valuable source of information about the mechanisms leading to disease. Beneficial remodelling in HF can be studied in zebrafish, an animal which is able to regenerate its heart after injury. Transcriptomic studies helped to decipher the mechanisms contributing to cardiac regeneration. Several families of transcription factors, such as Kruppel-like factors (KLF), are known to be associated with heart development and pathology and may play a role in cardiac regeneration. The study of these transcription factors may open new therapeutic avenues of HF.
Purpose: To characterize the regulation of KLF family members during HF development and regression in the zebrafish heart.
Methods. A HF development-regression model was developed in zebrafish using phenylhydrazine (PHZ) treatment for 5 weeks (HF development) followed by a regeneration period of 2 weeks (HF regression). Whole-genome microarray analysis was performed in heart samples at different time-points during HF development (3 and 5 weeks after PHZ treatment initiation) and during HF regression (2 and 9 days after PHZ treatment discontinuation). Gene regulation patterns were characterized using bioinformatics and validated by quantitative PCR.

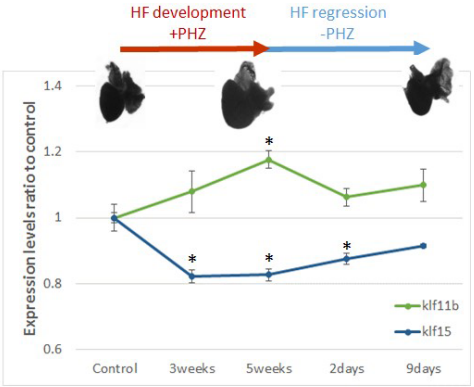

Figure: Expression of klf11b and klf15 during heart failure (HF) development and regression. Values are from microarrays normalized to control. PHZ: phenylhydrazine. * adjusted p <0.01.

Results: Microarray data analysis identified 1469 genes differentially expressed between control and PHZ-treated fish, either during HF development (1382 genes) or during HF regression (486 genes). Six KLF family members were regulated during HF development and regression: klf2a/b, klf4, klf7, klf11b and klf15. Klf2a/b, klf4, klf7 and klf15 are transcriptional activators and showed a downregulation during HF development. In addition, klf15 expression returned to baseline levels at the end of the regression period (Figure). Conversely, klf11b is known to work as a transcriptional repressor and showed an increase during HF development and a return to baseline levels during HF regression (Figure). Quantitative PCR confirmed that klf15 was significantly downregulated (3-fold, $p < 0.001$) whilst klf11b showed an increase (5-fold, $p = 0.008$) at the end of the HF development period. Furthermore, expression levels of both KLF were back to baseline at the end of the HF regression period.
Conclusion: The KLF family of transcription factors is regulated during HF development and regression in zebrafish. Whether these factors are functionally involved in these processes and constitute relevant therapeutic targets remains to be established.

Funding Acknowledgements: DFG HA7512/2-1; Bayer AG

Background: Heart failure (HF) with preserved ejection fraction (pEF) is characterized by diastolic dysfunction, increased myocardial stiffness and high oxidative stress. Here we investigated the role of enhancing the nitric oxide/soluble guanylyl cyclase/cyclic guanosine monophosphate/protein kinase G (NO/sGC/cGMP/PKG) signalling pathway in the modulation of diastolic function in a HFpEF model.
Purpose: What is the effect of sGC stimulation on 1) oxidative stress, 2) endothelial function, 3) left ventricular (LV) relaxation and filling, 4) collagen content and 5) cardiomyocyte titin-based stiffness.
Methods: Chronic sGC stimulation was studied on 15-week-old male Dahl/Salt Sensitive rats. Age-matched male SS-13BN rats served as controls (CTRL). Rats were randomized in 8 groups (n = 8-12/group): HFpEF; CTRL; and both HFpEF and CTRL treated with 0.25, 0.75 and 1.5 mg/kg/day BAY 41-8543 via drinking water for 4 weeks.
Results: LV diastolic dysfunction was found in HFpEF animals vs. CTRL (E/A: 1.17 ± 0.04 vs. 1.81 ± 0.11; IVRT: 35.4 ± 1.8 ms vs. 28.0 ± 0.9 ms; Tau: 11.8 ± 0.6 ms vs. 9.7 ± 0.4 ms, respectively), and improved upon treatment with 1.5 mg/kg (1.59 ± 0.06; 26.6 ± 1.2 ms; 9.3 ± 0.4 ms, respectively). High LV end-diastolic pressure in HFpEF rats vs. CTRL (11.9 ± 2.9 mmHg vs. 4.2 ± 0.6 mmHg, respectively) and an upwards and leftwards shift of LV end-diastolic pressure-volume relationship - as indicative of diastolic dysfunction - were improved upon treatment with 1.5 mg/kg (4.4 ± 0.6 mmHg). Arterial elastance was increased in HFpEF rats, and reduced upon treatment with 1.5 mg/kg. This result is in accordance with ex vivo vascular experiments showing arterial stiffening and endothelial dysfunction in the HFpEF group, which was corrected after 1.5 mg/kg treatment. Cardiac fibrosis and collagen gene expression were reduced in HFpEF rats after 1.5 mg/kg treatment. High oxidative stress level and inflammation were reduced after 1.5 mg/kg treatment, which corrected the low NO level observed in HFpEF rats. In addition, increased expression level of sGC in the heart after 1.5 mg/kg treatment was observed using immunohistochemistry. This improvement resulted in increased cGMP concentration and PKG activity in HFpEF rats after 0.25, 0.75 and 1.5 mg/kg treatments. Total and PKG-mediated site-specific Ser-4080 hypophosphorylation of titin in HFpEF animals (relative to CTRL:41% and 33%, respectively) were greatly improved by 1.5 mg/kg treatment (182% and 210%, respectively). Accordingly, the HFpEF group showed increased cardiomyocyte stiffness, which was reduced upon 0.25, 0.75 and 1.5 mg/kg treatments. Conclusion: Chronic stimulation of the NO/sGC/cGMP/PKG signalling pathway decreased LV passive stiffness and improved global LV performance via reduced oxidative stress and fibrosis, and restored endothelial function and titin phosphorylation. Our data suggest that chronic stimulation of sGC may be a promising treatment option for HFpEF patients.

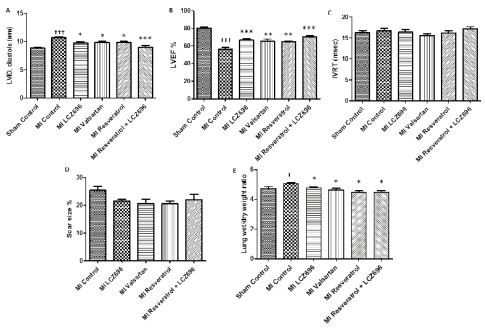
A comparative study of LCZ696, valsartan and resveratrol for the treatment of acute cardiac remodeling and dysfunction in myocardial infarction induced rats

P Pema Raj[1]; L Yu[2]; M Parikh[1]; J Wigle[1]; T Netticadan[1]; S Zieroth[1]

[1]University of Manitoba, Winnipeg, Canada; *[2] Canadian Centre for Agri-Food Research in Health and Medicine, Winnipeg, Canada*

Funding Acknowledgements: The study was funded by an unrestricted research grant from Novartis.

Background: The PARADIGM-HF trial demonstrated the first-in-class angiotensin receptor blocker–neprilysin inhibitor, LCZ696, is superior to enalapril in reducing the risk of death and hospitalization in symptomatic heart failure (HF) with reduced ejection fraction patients. Resveratrol is a promising cardioprotective plant bio-active. Our previous work demonstrated that resveratrol was comparable to perindopril in improving cardiac function and remodeling linked to HF in myocardial infarction (MI) induced rats. In the context of the above new clinical HF trial data, we developed a pre-clinical study comparing the standalone and combinatorial efficacy of LCZ696 with resveratrol in the setting of MI in a rat model.
Purpose: To evaluate the efficacy of LCZ696 as standalone and in combination treatment with resveratrol in MI rats.
Methods: The left anterior descending coronary artery was occluded to mimic MI in male Sprague Dawley rats. Sham operated rats served as controls. Sham and MI study groups received either, vehicle alone, LCZ696 alone (68mg/kg), valsartan alone (31mg/kg), resveratrol alone (2.5mg/kg) or LCZ696+resveratrol combination(68+2.5 mg/kg) daily for 8 weeks. Echocardiography was performed at 8 weeks. Left ventricular ejection fraction (LVEF), isovolumic relaxation time (IVRT) and LV internal dimension (LVID) were measured using EchoPAC. Percentage of scar and lung wet/dry weight ratio were determined. The study was approved by animal ethics board.
Results: Treatment with LCZ696, valsartan, resveratrol and LCZ696+resveratrol significantly prevented LV dilation in MI rats compared to MI control rats (Fig. 1 A: LVID diastole: 10.66 ± 0.18 vs 9.78 ± 0.20, 9.85 ± 0.23, 9.82 ± 0.21 ($p < 0.05$) and 9.01 ± 0.31 ($p < 0.001$). LVEF was significantly lower in MI control rats compared to sham control rats (Fig. 1 B: 56.60 ± 1.70 vs 80.33 ± 1.41 ($p < 0.001$)). LCZ696, valsartan, resveratrol, and LCZ696+resveratrol significantly improved LVEF in MI rats compared to MI control rats (56.60 ± 1.70 vs 66.82 ± 1.43 ($p < 0.001$), 65.45 ± 2.70, 64.82 ± 1.02 ($p < 0.01$), and 70.30 ± 1.63 ($p < 0.001$)). LCZ696+resveratrol treatment showed a trend towards an incremental benefit, but it was not statistically significant. IVRT and scar size were comparable between the groups (Fig. 1 C and D). MI control rats had significantly increased lung wet/dry weight ratio compared to sham control rats (Fig. 1 E: 5.07 ± 0.07 vs 4.73 ± 0.12 ($p < 0.05$)). LCZ696, valsartan, resveratrol and LCZ696+resveratrol significantly lowered lung wet/dry weight ratio in MI rats compared to MI control rats (5.07 ± 0.07 vs 4.77 ± 0.82, 4.62 ± 0.12 ($p < 0.05$), 4.47 ± 0.09, ($p < 0.01$) and 4.48 ± 0.10 ($p < 0.001$)).
Conclusion: Standalone treatment with LCZ696, resveratrol or valsartan significantly prevented cardiac remodeling and dysfunction in MI rats. Combination treatment with LCZ696 and resveratrol was also cardioprotective. LCZ696 and resveratrol may be further explored for their efficacy in the prevention of HF post-MI in future clinical trials.



Echocardiography ((A) LVID, (B) LVEF, (C) IVRT), scar size (D) and lung wet/dry weight ratio (E) data at 8 weeks. All values are expressed as mean±SEM. Sample size n 9 11. ***p<0.001, *p<0.05 vs Sham Control; ###p<0.001, ##p<0.01 and #p<0.05 vs MI Control.

Funding Acknowledgements: UNKP-17-4-III-DE-201 (New National Excellence Program), EFOP-3.6.2-16-2017-00006, GINOP-2.3.2-15-2016-00040

Rationale: Omecamtiv mecarbil (OM) is a myosin activator agent developed for the treatment of heart failure. OM was reported to improve left ventricular (LV) systolic function by increasing ejection fraction and systolic ejection time, but little is known about the effect of heart rate on the action of OM.
On the cellular level the present study was designed to investigate the frequency-dependent effects of OM on the elements of excitation-contraction coupling of the LV: action potential (AP) morphology, intracellular calcium transients (CaT), and unloaded cell shortening were investigated in canine cardiomyocytes. To test the in vivo effects of OM on LV function at high heart rates, rats were chosen as experimental models, having resting heart rates around 350-450 beats per minute.
Methods: During our in vitro experiments, effects of 1 μM OM were tested on isolated canine LV cardiomyocytes at pacing frequencies of 1-5 Hz. APs were recorded through an intracellular microelectrode, cell length was monitored by an optical

edge detector and CaTs were visualized using the fluorescent calcium-sensitive dye, Fura-2. In vivo effects of OM on LV function of Wistar-Kyoto rats were assessed by echocardiography and continuous LV pressure and volume monitoring. OM was administered through a jugular venous canule in increasing doses between 200-1200 μg/kg.
Results: 1 μM OM did not change the overall AP configuration or the average CaT. OM however significantly reduced both diastolic and systolic cell lengths, increased fractional cell shortening and increased the overall time of contraction. Accordingly, OM improved LV systolic function (increased ejection fraction and dP/dtmax), but impaired diastolic function (decreased E/A ratio and increased isovolumetric relaxation time).
With increasing stimulation frequency, alternating APs, CaTs and cell shortening could be seen in 1 μM OM. Such behavior could not be observed in the absence of OM at any stimulation rates, or even in the presence of OM at low pacing rates (1 Hz and 2 Hz). In line with these observations, 1200 μg/kg OM evoked alternating LV contractions in the majority of cases: every effective contraction was followed by an ineffective one. This could be seen both on echocardiography and on pressure-volume records.
Conclusion: Our results suggest that supratherapeutic concentrations of OM may impair the overall LV function especially in tachycardic patients.

Colchicine improves experimental murine Coxsackievirus B3-induced myocarditis involving the NLRP3 inflammasome

S Sophie Van Linthout[1]; K Pappritz[1]; M Sosnowski[1]; M El-Shafeey[1]; C Tschoepe[1]
[1]*Berlin-Brandenburg Center for Regenerative Therapies, Berlin, Germany*

Background: We recently demonstrated the relevance of the pattern recognition receptor Nucleotide-binding oligomerization domain-containing protein 2 (NOD2) and downstream NLRP3 inflammasome in Coxsackievirus (CVB3)-induced myocarditis. The anti-inflammatory drug Colchicine, which is traditionally used to treat gout, exerts its effects among others via reducing NLRP3 activity, and has been shown to improve several cardiac diseases including pericarditis.
Purpose: The aim of the present study was to evaluate the potential of Colchicine to improve experimental CVB3-induced myocarditis.
Methods and Results: Supplementation of 100 ng/ml Colchicine to CVB3-infected HL-1 cardiomyocytes decreased the CVB3-induced NLRP3 activity, as obviated by 1.3-fold ($p < 0.005$), 1.2-fold ($p = 0.001$), and 2.0-fold ($p < 0.0001$) lower ASC-, caspase 1-, and IL-1ß-expressing cells in CVB3+Colchicine versus CVB3-infected HL-1, respectively. In addition, Colchicine reduced the expression of the Coxsackie- and adenovirus receptor and the percentage (%) of CVB3-induced apoptotic cells by 1.7-fold ($p < 0.0005$) and 1.4-fold ($p < 0.0001$), respectively, as assessed by flow cytometry. In vivo, 5 μmol Colchicine/kg body weight per os, 1 day post CVB3 infection in C57BL/6j mice, improved left ventricular (LV) function. This was paralleled by a 1.8-fold ($p < 0.05$) reduction in LV CD68 presence, and a 1.4-fold ($p < 0.05$), 2.1-fold ($p < 0.05$), 1.7-fold ($p < 0.05$), and 4.4-fold ($p < 0.01$) decrease in LV Ly6C, TNF-a, caspase-1, and CVB3 mRNA expression versus CVB3 mice, respectively. Whereas LV NOD2, NLRP3 and ASC expression was unaltered in CVB3+Colchicine versus CVB3 mice, the % of splenic NOD2- and ASC-expressing F4/80 macrophages was 1.5-fold ($p < 0.0001$) and 1.7-fold ($p < 0.05$) lower in CVB3+Colchicine versus CVB3 mice, respectively. In addition, Colchicine decreased the CVB3-induced % of splenic pro-inflammatory Ly6Chigh monocytes and the proliferation (division index) of CD68 cells by 1.3-fold ($p < 0.0001$) and 1.3-fold ($p < 0.0001$), respectively.
Conclusion: Colchicine improves experimental murine CVB3-induced myocarditis in C57BL/6j mice involving reduction of NLRP3 activity in the spleen.

1406
Deleting cardiac GRK5 catalytic activity impairs basal cardiac function without affecting myocardial growth

A Cannavo[1]; A Elia[2]; C De Lucia[1]; D Liccardo[2]; N Ferrara[2]; N Paolocci[3]; G Rengo[2]; WJ Koch[1]
[1]*Temple University School of Medicine, Center for Translational Medicine, Philadelphia, United States of America*; [2]*Federico II University of Naples, Translational Medical Sciences, Naples, Italy*; [3]*Johns Hopkins University of Baltimore, Baltimore, United States of America*

Introduction: G protein-coupled receptor (GPCR) kinase 5 (GRK5) is a multifunctional protein. When at the plasma membrane, GRK5 exerts "canonical" effects regulating some GPCRs, such as ß-ARs, and their downstream signaling. Conversely, when in the cytosol or in the nucleus, it interacts with non-GPCRs related proteins. Interestingly, due to these multiple activities GRK5 is considered either a protective and noxious molecule. In this context, previous studies have demonstrated that cytosolic GRK5 can directly regulate p53, leading to apoptosis inhibition in several cell types, including cancer cells. While, when localized in the nucleus GRK5 can trigger pro-hypertrophic signaling in cardiomyocytes, inducing cardiac dysfunction. Surprisingly, the role played by the catalytic activity of the enzyme has not been addressed yet. Thus, it is unclear whether, and what GRK5 effects can be attributed to its catalytic domain.
Purpose: To determine whether deleting cardiac GRK5 catalytic activity impacts basal cardiac function and the heart's ability to respond to chronic stress.
Methods: Using the CRISPR/Cas9 system, a new knock-in mouse line with lysine (K) 215 replaced by arginine (R) in the GRK5 protein (K215R mice) was generated. This intervention abolishes GRK5 catalytic activity. K215R mice underwent chronic pressure overload (via transverse aortic constriction, TAC), to induce heart failure (HF) onset and progression.
Results: Compared to age-matched littermates, nine weeks-old, unstressed K215R mice exhibited larger LV chamber dimensions (LVID) and increased heart rate. Mutant mice showed higher extent of basal apoptotic rates, but no signs of maladaptive hypertrophy or fibrosis. However, TAC induced a faster progression towards HF in GRK5-K215R mice, along with markedly worsened LV function deterioration and chamber remodeling. Molecularly, after K215R mice displayed basal down-regulation of EGFR protective signaling, concomitant with a rise in p53 expression. Conclusion: Alterations in basal GRK5 catalytic activity impairs basal LV function and accelerates HF progression in mice with pressure overload due to repressed pro-survival signaling pathways. Our study suggests that rescuing GRK5 catalytic activity is a promising new avenue to prevent or reverse HF progression.

Funding Acknowledgements: Instituto de Salud Carlos III (PI15/01909, PI15/02160), European Commisision (FIBRO-TARGETS, ERA-CVD 2016 LYMIT-DIS and COST ADMIRE)

Purpose: Myocardial fibrosis is a main contributor to the development of heart failure (HF). Cardiotrophin-1 (CT-1) and galectin-3 (Gal-3) are increased in HF and associated with myocardial fibrosis. The aim of this study is to analyze whether CT-1 regulates Gal-3, and to evaluate their potential clinical impact.
Methods: Quantitative proteomics was used in human cardiac fibroblasts (HCFs) treated with CT-1. Male Wistar rats and B6CBAF1 mice were treated with CT-1 (20 μg/kg/day) for 6 and 2 weeks, respectively. Half of the mice received the Gal-3 inhibitor, modified citrus pectin (100 mg/kg/day). Dahl salt-sensitive hypertensive rats were used as a model of HF with preserved ejection fraction (HFpEF). Finally, CT-1 and Gal-3 levels were measured in plasma and myocardial biopsies from patients with HF of hypertensive etiology.
Results: Proteomic analysis revealed that Gal-3 was up-regulated by CT-1 in HCFs in parallel with other profibrotic and proinflammatory markers such as collagen type I, fibronectin, a-smooth muscle actin, vimentin, osteopontin, TGF-ß, CTGF, IL-6 and IL-1ß. CT-1 up-regulation of Gal-3 was mediated through the stimulation of ERK 1/2 and Stat-3 pathways. Rats and mice treated with CT-1 presented higher cardiac Gal-3 levels as well as perivascular fibrosis. In addition, CT-1 increased the expression of collagen type I, a-smooth muscle actin, vimentin, TGF-ß and CTGF. In CT-1-treated rats, direct correlations were found between cardiac CT-1 and Gal-3 levels, as well as between Gal-3 and perivascular fibrosis. Gal-3 genetic disruption in HCFs and pharmacological Gal-3 inhibition in mice prevented the profibrotic and proinflammatory effects of CT-1. Rats with HFpEF showed increased cardiac CT-1 and Gal-3 expression together with cardiac fibrosis. Cardiac CT-1 protein was directly associated with Gal-3 mRNA. Additionally, there was a direct correlation of CT-1 protein and Gal-3 with perivascular fibrosis. In a small cohort of 24 HF patients, myocardial CT-1 and Gal-3 were increased and directly correlated. Likewise, plasma CT-1 and Gal-3 levels were also increased and directly correlated in an independent cohort of 234 HF patients. Elevated serum CT-1 or Gal-3 levels were both significantly associated with cardiovascular death in the large cohort of HF patients. Interestingly, patients with both CT-1 and Gal-3 elevated presented a 4-fold higher risk of cardiovascular death than patients with normal values for

both parameters, after adjustment for clinically relevant risk factors and confounding factors.
Conclusions: Our data suggest that CT-1 up-regulates Gal-3 which, in turn, mediates the proinflammatory and profibrotic myocardial effects of CT-1. The elevation of both molecules in blood from HF patients identifies a subgroup of patients with high cardiovascular mortality. The CT-1/Gal-3 axis emerges as a candidate target for treating myocardial fibrosis in HF.

A Kinase Interacting Protein 1 (AKIP1) regulates cardiomyocyte elongation and promotes physiological cardiac remodeling by activating the AKT/CEBP-b/CITED4 pathway

K T Kirsten Nijholt[1]; HG Booij[1]; RA De Boer[1]; SU Oberdorf[1]; M Pavez[1]; WH Van Gilst[1]; HHW Sillje[1]; BD Westenbrink[1]
[1]*University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands*

Funding Acknowledgements: Heart Foundation the Netherlands project 2012T066

INTRODUCTION: A Kinase Interacting Protein 1 (AKIP1) has been proposed to serve as a nodal point for physiological cardiomyocyte hypertrophy based on studies in cultured cardiomyocytes. Whether AKIP1 regulates the cardiac adaption to physiological stress in vivo is unknown.
Purpose: To determine the effect of cardiomyocyte-specific overexpression of AKIP1 on the cardiac response to voluntary wheel running (VWR).
Methods: Adult male mice (8-12 weeks) with cardiomyocyte specific overexpression of AKIP1 (AKIP1-TG) or their wild type (WT) littermates were caged individually with or without the unlimited access to a running wheel (N = 9-20 / group). Exercise performance, heart weight/tibia length (HW/TL) , cardiac MRI, cardiac histology, and left ventricular (LV) biochemistry were evaluated. Groups were compared by Two-way ANOVA.
Results: Cardiac mass and function were comparable between sedentary WT and AKIP1-TG mice and the average running speed and distance were similar among genotypes. Cardiac hypertrophy induced by VWR was markedly augmented in AKIP1-TG vs WT mice as evidence by 57 % higher increase in HW/TL and a 27 % greater increase in LV- mass on MRI. The estimated cardiomyocyte volume was also increased by 27% in AKIP1-TG vs WT mice, which was predominately determined by an increase in cardiomyocyte length (61.94 ± 5.35 μm vs 99.48 ± 2.18 μm; $p < 0.05$). The augmentation of cardiac hypertrophy induced by VWR in AKIP1-TG mice was associated with a 6-fold increase in the phosphorylation of AKT, downregulation of C/EBPß and the subsequent upregulation of CITED4 mRNA and protein levels in LV lysates.
Conclusion: In conclusion, AKIP1 promotes cardiomyocyte elongation and physiological cardiac remodeling through activation of the AKT/C-EBPß/CITED4 pathway. These findings suggests that AKIP1 may serve as a nodal point for beneficial reprogramming of hypertrophic heart disease.

Atrial natriuretic peptide hypersecretion contributes to systemic insulin resistance in pressure overload heart failure

F Gao[1]; X Qin[1]; J Xu[1]; X Xing Zhang[1]
[1]*Fourth Military Medical University, Xi'an, China People's Republic of*

Funding Acknowledgements: This study was supported by the grants from National Natural Science Foundation of China (No. 31500928, No. 81670253)

Background: Emerging evidence has shown that heart failure (HF) may increase the risk of systemic insulin resistance (IR), resulting in a deleterious vicious cycle of cardiac dysfunction and worsening of clinical outcomes in HF patients. However, the underlying mechanism is still elusive.
Purpose: This study aims to investigate the role of HF-induced natriuretic peptides in systemic IR and the underlying mechanism.
Methods: To delineate the relationship between natriuretic peptide (NP) and IR in the context of HF, 136 HF patients and 20 age-matched healthy subjects were included in this study. We evaluated serum NP levels and systemic insulin sensitivity (HOMA-IR). A mouse model of pressure overload-induced HF and atrial natriuretic peptide (ANP) knockout mice were used to examine the role of ANP in systemic IR in HF.
Results: We found that systemic IR was prevalent in HF patients compared with age-matched healthy subjects as evidenced by HOMA-IR. A Spearman's rank correlation analysis showed that serum ANP had the highest association with systemic IR in hypertensive HF patients ($r = 0.429$, $p < 0.001$). The association between ANP and IR was further evaluated with laboratory studies of gain- and loss-of-function in mice. ANP infusion to C57BL/6J mice decreased insulin sensitivity, whereas ANP knockout mice exhibited increased insulin sensitivity. Moreover, using a mouse model of transverse aortic constriction-induced HF, impaired insulin sensitivity as well as increased serum ANP were observed in HF mice, while blocking ANP signaling with either a pharmacological inhibitor (isatin, the inhibitor of ANP receptor) or genetic manipulation (ANP knockout mice) showed ameliorated HF-induced systemic IR. Mechanistically, ANP impaired insulin-stimulated glucose uptake as evidenced by blunted insulin-stimulated Akt phosphorylation and GLUT4 translocation in skeletal-muscle C2C12 cells.
Conclusion: These results suggest that ANP suppresses skeletal muscle glucose uptake, which contributes to systemic IR in pressure overload-induced HF.

Clinical Case Corner 4 - The great fire: inflammation of the heart and beyond

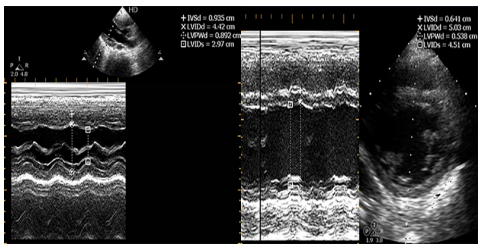
A case of lupus myocarditis presenting as acute cardiogenic shock

A Elsayed[1]; M Ali Dawood[1]; M Hassan Abada[2]; A Beltagy[3]
[1]*Alexandria University, cardiology and angiology department, Alexandria, Egypt*;
[2]*Alexandria University, Critical care medicine department, Alexandria, Egypt*;
[3]*Alexandria University, Rheumatology and Clinical Immunology Department, Alexandria, Egypt*

Introduction: Systemic lupus erythematosus (SLE) is an autoimmune disorder. Cardiac involvement may be in the form of pericarditis or myocarditis. In our case report we are reviewing the management of a case of lupus myocarditis presenting with acute cardiogenic shock.
Case report: A 20-year-old female previously diagnosed lupus nephritis class V with maintenance treatment of mycophenolate mofetil (MMF), hydroxychloroquine and low dose prednisolone presented with dyspnea. On clinical examination she was hypotensive, tachycardic, tachypneic with audible pulmonary rales, she also was oliguric and hypoxic on room air. She was mechanically ventilated and Norepinephrine infusion was added with up-titration to 10μg/Kg/min but no improvement. Chest x-ray revealed pulmonary congestion and left pleural effusion. Echocardiography revealed dilated left ventricle (LV) dimensions (end diastolic dimension(EDD)/end systolic dimension (ESD); 52/46 mm) with global severe hypokinesia sparing the apex and reduced LV systolic function (Ejection fraction (EF); 30%).
Laboratory findings were; Anemia (Hemoglobin; 8.7g/dl), Hypoalbuminemia (serum Albumin; 1.7g/dl), (Erythrocytes sedimentation rate; 44mm/h), positive cardiac enzymes (Troponin I; 25 ng/mL, normal; less than 0.01 ng/mL), consumed complement (C3-C4), positive anti-nucleic acid (ANA) and anti-dsDNA. We could make a diagnosis of acute lupus myocarditis based on the previous results Dopamine infusion and intravenous methylprednisolone (500mg/day) for 5 days were added with marvelous response. Urine output and vital signs improved within 2 days, so Dopamine and norepinephrine infusions were weaned and anti-failure measures were initiated including intravenous furosemide, spironolactone (50mg/day) and angiotensin converting enzyme inhibitors.
After 5 days of initial management an echocardiography was done revealed dramatic improvement of the LV systolic function (EDD/ESD; 44/29mm) and (EF; 55%).
Conclusion: SLE is a common multisystem autoimmune disorder with female to male ratio 9:1. Cardiac affection of SLE can be in the form of pericarditis, myocarditis, coronary arteritis and premature coronary atherosclerosis. Echocardiography helps in diagnosis of SLE-related pericardial effusion, myocardial affection, valvular involvement, and cavity thrombus formation. Other imaging modalities can be used such as cardiac computed tomography (CT) and cardiac magnetic resonance (CMR). Management of lupus myocarditis relies on previous case reports in literature due to rarity of clinical evidence.
Although our case was on immunosuppressive medications she developed lupus myocarditis and this considered inadequate control of activity. Our case responded marvelously to high dose steroids and was shifted to monthly cyclophosphamide pulse therapy. Also, medical management of heart failure including angiotensin-converting enzyme inhibitors, beta-blockers and diuresis was a cornerstone.



Echo showing EF before & after treatment

Case of massive thromboembolism in a patient with necrotic vasculitis and inherited thrombophilia

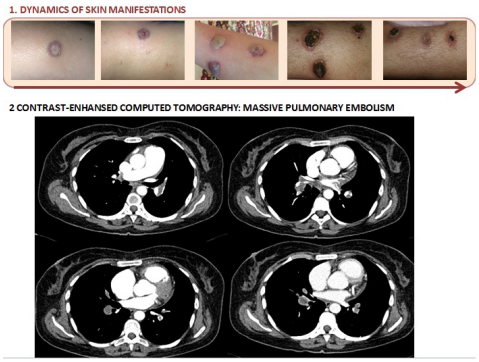
S Martirosyan[1]; H Kosmachova[1]; T Matushina[1]
[1]*Cuban Regional Clinical Hospital No 1, Krasnodar, Russian Federation*

Introduction: a 43-year-old women with preliminary diagnosis of right-heart infective endocarditis was delivered to our clinic to resolve the issue of surgery.

Clinical characteristics

	BP, mmHg	HR, bpm	SatQ2,%	D-Dimer, ng/ml	NTproBNP, pg/ml	HB, g/l	WBC
D1	100/80	140	82	3406	7318	92	10,6
D22	110/70	100	96	456	597	107	7,8

D1 - admission date, D29 - discharge date



Presenting condition: pale skin with multiple rounded wounds in the scarring stage on the legs, progressive dyspnea with wet wheezes, SpO2 82-84%, arterial BP 100/80 mmHg.
Anamnesis: patient with no history of heart or vascular diseases. Rounded bullous rashes on legs with hyperemia and edema appeared 2 months earlier. Progressive dyspnea appeared 2 weeks ago. In regional hospital was suspected right-heart infective endocarditis and the patient was sent to our clinic for surgery
Gynecological anamnesis: pregnancy - 9 miscarriage - 6
Identification of the problem: D-Dimer 3406 (N = 243) NTproBNP - 7318 (N = 110)
On ECG: sinus tachycardia HR140 Esco: MV - mid reg TV - med reg LA 22 mm LV 33 mm RA 50x55 mm RV 43 mm EF 38% Systolic Pulmonary artery pressure >100 mmHg NO EVIDENCE OF ENDOCARDITIS
Contrast-enhanced computed tomography of the chest: massive pulmonary embolism
Ultrasound of lower limbs: bilateral thrombosis of superficial femoral veins
Anticoagulation (enoxaparin 1 mg/kg each 12 h -> rivaroxaban 15 mg each 12 h) therapy, CPAP-BIPAP ventilation has been started. The patient's condition was stabilized in 2 weeks .
Questions and problems:
1. Was the diagnosis of right-heart infective endocarditis competent? Did this patient need the surgery? There were no any reasons for acquiring an infectious process on the tricuspid valve, so no need for surgery
2. What is the cause of massive thromboembolic events?
Considering gynecological anamnesis, in order to find the answer to this question, we conducted a genetic test for susceptibility to thrombophilia. The mutation in folate metabolism was found. So we added to the treatment folic acid.

3. What were the causes and nature of skin rashes?
We performed a biopsy of the skin flap with histological examination. The cutaneous form of necrotic leg ulcerative vasculitis was revealed.
This patient was discharged in a satisfactory condition with positive clinical dynamics.
Conclusions: the correct interpretation of heart failure symptoms and searching for etiological and pathogenic triggers of cardiac decompensation is the only way to successful treatment.

1412
Giant cell myocarditis: a giant challenge

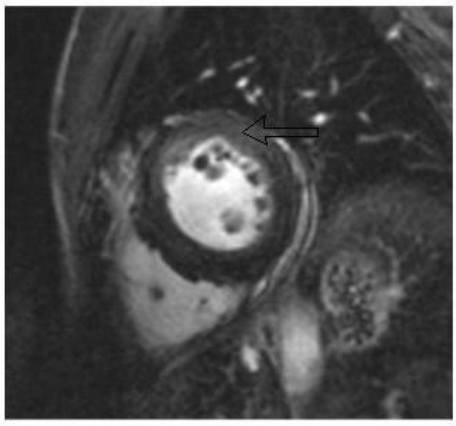
A Addas[1]; M Kuehl[2]; K Jawad[1]; S Feder[1]; J Jozwiak-Nozdrzykowska[3]; J Fischer[1]; M Nozdrzykowski[1]; A Al-Naamani[1]; M Sandri[3]; P Lurz[3]; A Arya[2]; A Meyer[1]; S Lehmann[1]; J Garbade[1]; M Borger[1]
[1]Heart Center of Leipzig, Department of cardiac surgery , Leipzig, Germany; [2]Heart Center of Leipzig, Department of Electrophysiology, Leipzig, Germany; [3]Heart Center of Leipzig, Department of cardiology, Leipzig, Germany

A 51-year-old man with no previous medical history presented with an episode of pre-syncope, orthopnea and paroxysmal nocturnal dyspnea. Echocardiography showed severely impaired left ventricular systolic function with global hypokinesia (LVEDd 59mm, LVEF: 30%), mildly reduced right ventricular systolic function, and moderate mitral and tricuspid valve regurgitation. An initial cardiac MRI scan showed signs of acute myocarditis. Coronary angiography excluded coronary artery disease. After initial stabilisation and initiation of heart failure drugs, the patient was discharged home. Two weeks later the patient was readmitted to our hospital with worsening heart failure. An endomyocardial biopsy was performed and demonstrated histological features consistent with giant cell myocarditis. Immunosuppressive therapy with Cyclosporin, Steroids and monoclonal antibodies (Rituximab) was immediately initiated. After further two weeks an intermittent AV-Block III° required the implantation of a permanent dual chamber defibrillator. A repeat cardiac MRI scan showed progressive worsening of both ventricular systolic function and still signs of active myocarditis. Beginning end-organ involvement required the initiation with Milrinon (0,5 μg/kg/min). A right heart catheterization whilst on inotropic support demonstrated a severely reduced cardiac index of 1.5 [l/min/m^2] and the patient was therefore listed for urgent heart transplantation. During the next weeks the patient suffered from recurrent sustained VT's refractory to medical therapy, DC cardioversions or overdrive pacing and therefore underwent radiofrequency ablation of the ventricular arrhythmia. Over the next weeks, the inotropic requirements increased and signs of end-organ failure and cardiogenic shock developed (INTERMACS 1). Therefore it was necessary to implant a left ventricular assist device (HeartMate III). Despite this mechanical support the patient developed progressive right heart failure, which made the implantation of an extracorporeal right ventricular assist device (Levitronix) necessary. Under the support of both devices, the patient's clinical condition stabilized, and the renal and hepatic functions improved. The further clinical course was complicated by a spontaneous haemothorax under therapeutic anticoagulation, requiring a thoracotomy. Finally, the patient underwent orthotropic heart transplantation approximately 6 months after the initial presentation and the patient was discharged home in a very good clinical condition.
Conclusion: Giant cell myocarditis can cause rapid deteriorating heart failure. For a successful management the complete armamentarium of modern heart failure therapy might become necessary. Early transfer to a specialized heart centre is the key to survival.

1413
Cardiogenic shock as first manifestation of multiple sclerosis relapse

B Barbara Hudournik[1]; G Voga[1]; N Glavnik Poznic[2]
[1]General Hopsital Celje, Medical intensive care unit, Celje, Slovenia; [2]General Hopsital Celje, Department of cardiology, Celje, Slovenia

Introduction: Multiple sclerosis (MS) is the leading cause of neurological disability in young adults. Most patients with cardiovascular involvement present with signs of autonomic dysfunction. Compromised systolic function is seldom described. We present a case of young female admitted due to cardiogenic shock, which preceded signs of MS relapse.
Case presentation: 33-year old woman with known MS experienced headache, vertigo and nausea while on the swing on a picnic. Upon arrival to the emergency room she was hypotensive and severely respiratory distressed due to pulmonary oedema. Neurological status was correct. Cardiac ultrasound (US) demonstrated severe systolic dysfunction of both ventricles. She was intubated and mechanically ventilated. Hemodynamic monitoring by transpulmonary thermodilution revealed low cardiac index (CI), low global end diastolic volume index and high extra-vascular lung water. High dose noradrenaline and dobutamine were started simultaneously with low dose of levosimendan. Despite extensive support she remained hemodynamically unstable. Intra-aortic balloon pump was inserted, which resulted in only slight increase of CI. We considered the possibility of relapse of MS to be the cause of refractory cardiogenic shock. Five hours after ICU admission she received first dose of methylprednisolone (1g/day). Approximately six hours afterwards CI improved significantly. After second dose the methylprednisolone was changed to human immunoglobulin (0,4 g/kg/day) due to evolving infection. Two days later we were able to wean the patient from inotropes, vasopressors and mechanical circulatory and respiratory support. Coronary angiography and serologic tests for cardiotropic viruses revealed no pathology. Magnetic resonance imaging (MRI) showed some myocardial oedema, described as residual after stress cardiomyopathy or myocarditis. MRI of the brain revealed significant dissemination of demyelinating lesions. Neurologic evaluation demonstrated severe gait disorder, which persisted after six months. At the same time US and MRI revealed complete restoration of cardiac function and morphology. Discussion Several case reports of acute cardiac failure in patients with MS relapse have been described in literature. Clinical trials evaluating cardiac function in patients with MS frequently showed reduced systolic function of left or both ventricles in otherwise hemodynamically stable patients. Different theories have been proposed as possible mechanism, but we still lack robust evidence. Common feature of all described cases is severe impairment of systolic function, which responds to treatment of MS relapse. Although it is impossible to exclude spontaneous and relatively rapid recovery typical for stress-induced cardiomyopathy of any cause, we believe in the light of available evidence that these patients should receive high dose corticosteroids in the absence of contraindication and in conjunction with supportive treatment.



Cardiac MRI:Anterolateral wall oedema

When an exhausted heart holds on for two: a remarkable case of fulminant myocarditis

L Luis Graca Santos[1]; F Montenegro Sa[1]; C Ruivo[1]; R Ribeiro Carvalho[1]; J Correia[1]; J Guardado[1]; S Pernencar[1]; J Morais[1]
[1]Hospital Santo Andre, Cardiology, Leiria, Portugal

We present the case of a 27-year-old black woman, 7 weeks pregnant, who was brought to the Emergency Room following a syncopal episode. She complained of a 4-day course influenza-like syndrome associated to epigastric discomfort, fatigue and dyspnea. The patient had no relevant medical history, denying drug abuse, and was taking iodine and folic acid. At admission, she was conscious and oriented, with sinus tachycardia, hypotension (90/50mmHg), fever (38,8°C), and polypnea with peripheral oxygen saturation of 95%. Cardiopulmonar auscultation was normal. The electrocardiogram revealed concave and diffuse ST segment elevation. Blood tests showed elevated C-reactive protein (15.7mg/L, normal (N) <5.0), CK-mb (87U/L, N = 5.0-24.0) and troponin I (4.37ng/mL, N <0.04). Transthoracic echocardiogram (TTE) revealed biventricular systolic dysfunction (left ventricular ejection fraction (LVEF) of 28%; systolic excursion of the tricuspid ring (TAPSE) of 13mm) and mild to moderate circumferential pericardial effusion (Panel 1.A)
The presumptive diagnosis of acute myocarditis was established and the patient admitted to the Cardiac Intensive Care Unit. Few hours later, she developed cardiogenic shock with need for high doses of dobutamine and noradrenaline. Due to refractoriness to aminergic support, the patient was transferred the next day to the nearest cardiac surgery department anticipating the need for mechanical ventricular assistance. The following days, her haemodynamic state gradually improved and

amines were totally suspended on the 7th day, initiating bisoprolol and spironolactone at low doses. The patient chose not to interrupt the pregnancy. On the 8th day, TTE revealed normalization of biventricular systolic function and important reduction of the pericardial effusion presenting, however, signs of thrombus in the right atrium (RA) adherent to the central venous catheter (Panel 1.B). Subcutaneous enoxaparin 1.5mg/Kg/day was started. She returned to the cardiology ward on the 13th day, clinically stable and asymptomatic, and was discharged two days later only on enoxaparin. The pre discharge TTE showed good biventricular function (LVEF 60% with global longitudinal strain -21.1% (Panel 1.C), TAPSE 24mm), residual pericardial effusion and >50% reduction of the RA thrombus size.
During follow-up, the patient remained asymptomatic presenting with optimal functional class. TTE performed a month after discharge showed no signs of thrombus in the RA. She was closely followed by an experienced obstetrician. The pregnancy and delivery were uneventful and the baby was born apparently healthy.
The present case of a young pregnant woman developing fulminant myocarditis represents a challenging case of acute heart failure not only due to its rarity and high mortality but also because the patient's decision not to interrupt pregnancy has conditioned the medical management, however, with no apparent impact on maternal and fetal prognosis.

Panel 1. **(A)** Mild to moderate pericardial effusion on initial transthoracic echocardiogram; **(B)** Filiform mobile echogenic structure in the right atrium suggestive of thrombus (yellow arrow); **(C)** Longitudinal global strain the day before discharge (mean value -21,1%)

Serial transthoracic echocardiograms

Mid-ventricular Takotsubo cardiomyopathy caused by myasthenic crisis

T Furlan[1]; S Poznic[1]; D Kosuta[1]; B Leskovar[1]
[1]*Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia*

Introduction: Myasthenic crisis is an autoimmune condition, characterized by muscle weakness that leads to respiratory failure. Takotsubo cardiomyopathy is a syndrome, characterized by profound but reversible left ventricular dysfunction in the absence of coronary artery disease.
Case report: We describe a case report of a 66-year-old man with arterial hypertension, COPD and myasthenia gravis treated with pyridostigmine who developed Takotsubo cardiomyopathy and concomitant myasthenic crisis that were triggered by a physically and emotionally stressful event. On admission, he presented with mid-sternal chest pain and severe shortness of breath leading to respiratory failure requiring intubation. Electrocardiogram showed ST elevation in lateral leads and echocardiography showed diffuse hypokinesia. His troponin level was elevated, while cardiac catheterization revealed no significant coronary artery disease. Left ventriculogram showed mid-ventricular akinesia with reduced overall left ventricular systolic function suggestive of Takotsubo stress cardiomyopathy. He transiently required intra-aortic balloon pump, but his condition improved quickly and was extubated on the second day. Plasmapheresis or immunoglobulin therapy were not required. Control echocardiogram seven days after acute presentation showed complete resolution of cardiac function with normal left ventricular chamber size, normal ejection fraction and no regional wall motion abnormalities.
Discussion: There are only a few case reports describing causative associations between myasthenic crisis and Takotsubo cardiomyopathy. In our case it seems that a severe physical and emotional stress triggered both myasthenic crisis and Takotsubo cardiomyopathy. Takotsubo cardiomyopathy is a clinical syndrome characterized by transient left ventricular systolic dysfunction, mimicking myocardial infarction. It is most commonly presented as apical ballooning on left ventriculogram, but our patient had a less common variant with ventricular hypokinesis restricted to the mid-ventricle and relative sparing of the apex (mid-ventricular type). It is generally a transient disorder that is managed with supportive therapy. Myasthenic crisis is a life-threatening condition with respiratory failure due to weakness of respiratory muscles. It can be precipitated by various factors, most often concurrent infection but physical and emotional stress have also been described as a trigger. General measures are supportive therapy and intravenous immunoglobulins and plasma exchange as primary pharmacologic therapies. In our case, we observed quick resolution of symptoms with supportive measures only.
Conclusions: Takotsubo cardiomyopathy can be a rare presentation of myasthenic crisis, both can be precipitated by physical or emotional stress and managed with supportive therapy only.

1416
A rare case of leptospira myocarditis

CT Ng[1]; CY Khoo[1]; L Chan[1]; D Sim[1]; LY Teo[1]
[1]*National Heart Centre Singapore (NHCS), Singapore, Singapore*

Introduction: A 60-year-old Chinese male visiting from Australia presented with syncope, cough, fever and myalgia. Past medical history included AF and hypertension. He reported contact with pond water 2 weeks ago. Vitals were stable. Labs were unremarkable except for raised troponin of 3680ng/L and transaminases. The infectious disease physician empirically started antibiotics (ceftriazone & doxycycline) after septic workup. Paired convalescent leptospiral IgM was positive, confirming acute leptospirosis.
Management: Initial transthoracic echocardiogram (TTE) showed depressed left ventricular ejection fraction (LVEF) of 42%. Overnight, he had alternating bundle branch blocks. He subsequently VT, which was terminated by lignocaine and amiodarone. Urgent coronary angiogram showed minor coronary artery disease.
On day 3, Veno-Arterial Extracorporeal membrane oxygenation (VA-ECMO) circuit was inserted for refractory cardiogenic shock despite dual inotropes. There was no pulse pressure and cardiac rhythm while on ECMO. Repeat TTE showed severely depressed LVEF of 10%. Renal replacement therapy (RRT) was initiated in view of acute renal impairment. Endomyocardial biopsy was also done on day 3.
The patient was started on pulsed methylprednisolone 1g daily for 3 days. His blood pressure and ventricular arrhythmias improved with pulsed steroids. ECMO was successfully explanted after 10 days of support. TTE performed at 3 weeks showed normalisation of the LVEF to 65%.
Etiology: Given the presentation of viral-like symptoms with rapid onset of cardiogenic shock and malignant arrhythmias, our initial diagnosis was acute viral myocarditis. Comprehensive hunt for the etiology was started after considering the travel history and exposure to pond water. Endomyocardial biopsy was consistent with myocarditis, and the positive paired convalescent leptospiral IgM pointed to leptospirosis as the most likely cause.
Diagnosing leptospira myocarditis requires high clinical suspicion as it could present with only conduction abnormalities. Our patient had malignant arrhythmias with episodes of VT, VF and AF.
Treatment: Acute fulminant leptospira myocarditis is associated with a high mortality rate. Timely recognition and initiation of antimicrobial therapy is pivotal. Management of hemodynamic instability associated with leptospira myocarditis is supportive. VA-ECMO therapy was used as a bridge to recovery. Our patient responded favourably to steroids. To our knowledge, this is the first successful reported case of fulminant leptospira myocarditis managed by using VA-ECMO and pulsed steroids.
Conclusion: Although uncommon, fulminant leptospira myocarditis should be considered in patients with risk factors. Endomyocardial biopsy and early initiation of appropriate antimicrobials and supportive treatment such as VA-ECMO support can improve survival. More studies would be required to confirm the efficacy of pulsed steroids in this group of patients.

1417
Severe cardiac dysfunction in a patient with acute myocardial infarction and multiple sclerosis-more than a coincidence?

AM Chitroceanu[1]; N Patrascu[2]; VD Vintila[2]; D Vinereanu[2]
[1]*University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania*;
[2]*University of Bucharest Carol Davila, Bucharest, Romania*

Intriduction: The increased risk of mortality in patients with multiple sclerosis (MS) may be explained by a higher cardiovascular risk and occurrence of cardiovascular disease. Although recent evidence shows controversial results, cardiac dysfunction (CD) might not be so exceptional and could be secondary to disease treatment. Herein, we wanted to draw attention to a rare togetherness by reporting a case of acute myocardial infarction in a patient with MS and interferon induced thyroiditis, in which CD seems to be prior to the acute coronary event.
Case report: A 49 year-old man presented with new onset chest pain 6 hours prior to arrival without signs of heart failure. Acute antero-lateral ST-elevation myocardial infarction, Killip I class was diagnosed. He was diagnosed for 9 years with multiple sclerosis in treatment with interferon beta-1a, without any relapse-remitting episode during this time. He admitted to smoke (40PY) and had a previous history of diabetes and interferon induced autoimmune thyroiditis. Coronary angiogram revealed only one-vessel disease with partially occlusive thrombus in proximal left anterior descending artery (LAD), TIMI 0 flow. Primary percutaneous coronary intervention was performed with successful stenting, without procedural complications, TIMI 3 flow. Transthoracic echocardiogram detected markedly reduced left ventricular (LV) ejection fraction (25%), mild mitral regurgitation, global hypokinesia with apical and inferior akinesia and increased LV sphericity. We confirmed hypothyroidism and severe dyslipidemia. Additionally to standard cardiac management, we postponed the nextscheduled interferon dose taking into consideration its immunomodulatory effects that could interfere with cardiac remodelling.
Questions, problems. In our case, echocardiogram revealed increased LV sphericity, important LV remodelling, severe global dysfunction and extensive impaired

wall motion which exceeded the LAD topography, otherwise rapidly reperfused. This finding suggests a pre-existing cardiac dysfunction which could be explained in the context of MS or, even if controversial, by its treatment. Main possible mechanisms are oxidative stress with endothelial dysfunction, inflammatory status with subclinical myocarditis, myocyte structure alteration, vascular microthrombosis, and perfusion abnormalities; also, associated secondary hypothyroidism. Moreover, cardiovascular risk factors (hypertension, diabetes, and smoking) which our patient with MS leads to an excess of cardiovascular disease.
Conclusions.To sum up, in the setting of a chronic neurological disease in which the treatment has multiple secondary effects, an acute coronary syndrome in a young patient with cardiovascular risk factors can unmask a pre-existing subclinical CD. Scarce data existing about CD in SM, we consider mandatory a rigorous imagistic follow-up plan (cardiological and neurological).

1418

Safe use of percutaneous right ventricular assist device for prevention of acute right ventricular failure during pericardiectomy for constrictive pericarditis

R Rastko Rakocevic[1]; H Singh[2]; M Shah[3]; A Lucev[3]; B Kim[2]; R Berkowitz[2]; M Anderson[4]; K Satya[2]
[1]New Jersey Medical School, Internal Medicine, Newark, United States of America; *[2]Hackensack University Medical Center , Cardiology, Hackensack, United States of America*; *[3]New Jersey Medical School, Cardiology, Newark, United States of America*; *[4]Hackensack University Medical Center , Cardiothoracic Surgery, Hackensack, United States of America*

Constrictive pericarditis (CP) causes restriction of diastolic heart filling and heart failure. Pericardiectomy is standard of treatment for CP. However, myocardial atrophy in prolonged constriction and rapid increase in venous return after pericardial decompression leads to 'low output syndrome' and right ventricular (RV) failure. Recent studies showed that percutaneous right ventricular assist device (pRVAD) is effective solution for treatment of acute RV failure. Thus, we report a first case of successful use of pRVAD for prevention of acute RV failure peri- pericardiectomy for CP.
A 57-year-old male with paroxysmal atrial fibrillation (AF) on apixaban, and CP, was transferred to our hospital for CP surgery. He had four-year history of shortness of breath (SOB), lower extremity (LE) edema, weakness and chest discomfort with establish diagnosis of CP by cardiac catheterization (CATH) in 9/2015. Physical exam was noted for JVD, regular heart rhythm, bibasilar lung crackles, abdominal distension and bilateral LE edema. Interferon-gamma release assay and A1AT were negative. Drained pleural fluid was serous without malignant cells and negative for ADA. EKG, chest XR and transthoracic echocardiography (TTE) showed typical changes for CP. Chest CT showed pericardial calcification along anterior aspect of RV and right atrium (RA) and along the inferior aspect of LV. Bilateral CATH was characteristic for CP with coronary artery changes unchanged from the CATH in 2015. pRVAD and pulmonary artery catheter were placed preoperatively. During pericardiectomy pRVAD was on RCFV 6 mode. Pre, during and after procedure transesophageal echocardiography (TEE) was obtained. During surgery, total anterior pericardiectomy was undertaken from phrenic to phrenic with excellent removal results over anterior and diaphragmatic RV surface and entire RA. The LV was not involved. Pericardial pathology result showed fibrosis with calcification. Bilateral pleural drains and mediastinal drains were placed and surgical field was closed in the usual manner. Postsurgical TEE revealed preservation of ventricular function with no new wall motion abnormalities. Eight hours after the surgery, monitored intracardiac pressures were satisfactory, with CVP of 15 mmHg, and hence pRVAD and pulmonary artery catheter were removed. Patient was discharged on sixth postoperative day.
This case demonstrates safe and effective use of pRVAD as a preventive measure in patients with anticipating acute RV failure, such as in patients with CP requiring pericardiectomy.

1419

Takayasu arteritis associated with chronic reduced heart failure. Study of a case.

EJJ Eduardo Julian Jose Chuquiure[1]; C Silva-Ruz[1]; G Gabriela Mendez[2]; M Chuquiure-Gil[3]; K Jacobo-Garcia[1]; R Hernandez-Isidro[1]; E Morales-Hinojosa[1]; O Fiscal-Lopez[1]
[1]Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico; *[2]Universidad del estado de México, Medicina, ciudad neza, Mexico*; *[3]Instituto Tecnologico de Estudios Superiores de Monterrey, Escuela de Medicina, Monterrey, Mexico*

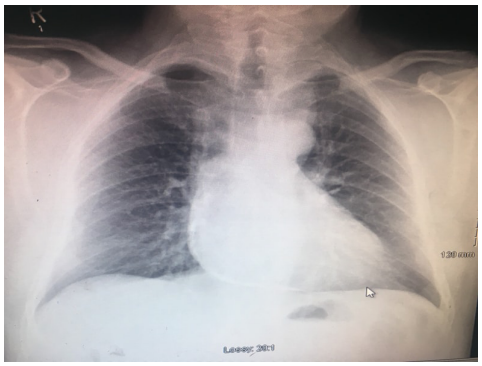
Female 29 years old.
At 7 years, the patient presented intense thoracic-abdominal pain, lasting more than 6 hours, associated with dizziness. He received symptomatic treatment.
At 15 years, she showed a two-week evolution with progressive dyspnea to small efforts, orthopnea, fever, and abdominal epigastric pain with vomit, dry cough in accesses. Irregular, characteristically nocturnal palpitations, Hypertension. ECHO LVEF: 25%. Treatment: Oral Carvedilol and Diltiazem.
At 18, she had dyspnea at rest, hydric retention. Cardiomegaly was detected.
At 28 Caesarean by pregnancy of 36 weeks.
Physical examination:
Murmur in the neck and left supraclavicular area, Blood pressure is not felt in both arms, imperceptible radial pulses, pedial pulses very reduced, both legs claudication (since four years). Abdominal murmur (left flank). Mitral and tricuspid regurgitation.
Labs and Imaging
Negative Viral and Chagas serological test. NT-pro-BNP 2240 pg/dL.
Endomyocardial biopsy: Increase in the size of myocytes and their nuclei, hyperchromatic and atypical, minimal endocardial fibrosis.
MRI: Total obliteration of the left common carotid artery, as well as ipsilateral subclavian artery. External carotid occlusion, infrarenal abdominal aorta severe stenosis. Left common iliac arterywith major stenosis.
PET/CT: Hyper-uptake at brachiocephalic trunk suggesting activity. Takayasu type V (Numano).
ECHO: Four cavities dilation, LV generalized hypokinesia, LVEF 24% TAPSE 11 mm. systolic dysfunction. Mitral and tricuspid regurgitation.
Conclusions: There are few reported cases of myocardial damage associated with acute arteritis. The present case exemplifies the association between Takayasu's Arteritis with HFrEF of long evolution as an etiological feature.

1420

A tight squeeze: constrictive pericarditis in the presence of myelodysplastic syndrome-a case report

F Fionnuala Kennedy[1]; C Kennedy[1]; A Flynn[1]
[1]HSE West, Cardiology, Galway, Ireland

Introduction: Constrictive pericarditis (CP) is a form of diastolic heart failure caused by an inelastic pericardium inhibiting ventricular filling. It must be considered in all cases of unexplained heart failure (HF). Pericardectomy is the only definitive treatment. This case highlights the importance of considering this rare cause of HF and highlights the challenge a dual diagnosis of Myelodysplastic Syndrome (MDS) presents.
A 67 y/o haulage business owner presented to the emergency department in December 2016 with exertional dyspnea, orthopnea and paroxysmal nocturnal dyspnoea for the past six weeks. He had noticed a gradual decrease in his exercise tolerance and general fatigue for the previous six months. Clinical examination revealed a raised jugular venous pressure, bilateral pitting oedema to the mid-calf and bi-basal inspiratory crackles.
His past medical history included hypertension and obesity. He was undergoing investigation for pancytopenia at the time of presentation for a subsequent diagnosis of MDS.
Historical data from old records revealed a pericardial ring on a chest X-ray from 2014. A repeat chest X-Ray done on this admission showed progression of this calcification. There was also evidence of venous pulmonary congestion.
An echocardiogram gave further supportive evidence showing a ventricular septal shift on respiration and hepatic vein flow reversal during expiration on doppler imaging. His ejection fraction was low-normal at 50-55%. Right heart catheterisation confirmed the diagnosis of CP with a Right Ventricular Diastolic Pressure of 29mmHg and Left Ventricular Diastolic Pressure of 24 mmHg. The End Diastolic Pressures in the Right and Left Ventricle were 34mmHg and 35 mmHg respectively. He was discharged on 40mg of Furosemide but re-presented twice with acute decompensated heart failure and was ultimately referred for pericardectomy. Of course other causes of HFpEF were considered, including hypertensive heart disease, hypertrophic cardiomyopathy and infiltrative disorders including hemochromatosis and amyloid. The calcification on X-Ray and echocardiogram findings, however, were most suggestive of constriction. After this diagnosis was made the biggest challenge facing us was managing his perioperative risk given his thrombocytopaenia, which increased his overall mortality significantly. CP still poses a diagnostic challenge today. This case highlights the typical clinical, radiological and echocardiographic features of this condition. In a large proportion of patients with surgically confirmed CP, the non-invasive imaging techniques, including chest x-ray, echocardiogram, computed tomography and magnetic resonance imaging, lack characteristic features; this makes CP a very difficult diagnosis to make in the early stages. Despite this, it must remain an important consideration in the differential of diastolic heart failure, a condition which has similarly poor 5 year mortality as HFrEF.



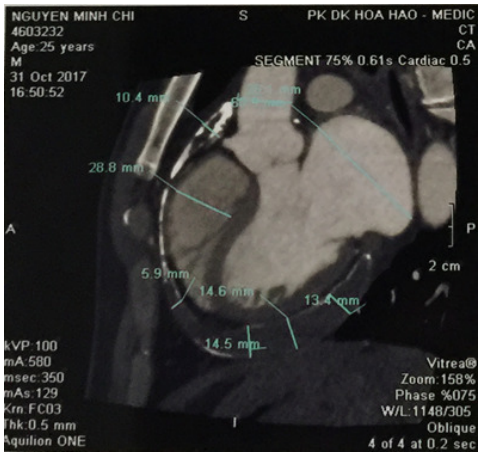
admission chest x ray

1421

A case of severe calcific chronic constrictive tuberculous pericarditis

H Thai Hao Phan[1]
[1]*Pham Ngoc Thach University of Medicine, Cardiology, Ho Chi Minh, Vietnam*

Introduction: Chronic constrictive pericarditis is a chronic inflammatory process that involves both fibrous and serous layers of the pericardium in which fibrous thickening of the pericardium occur. Many etiological factors have been identified. Among them infection, idiopathic chronic pericarditis, post cardiac surgery, mediastinal radiotherapy are important. But pericarditis caused by Mycobacterium tuberculosis is the most common cause in endemic area. We reported a case of severe calcific chronic constrictive tuberculous pericarditis.



cardiac MSCT

Case Report: A 25-year-old Vietnamese, nonsmoker, nonalcoholic, non-diabetic, normotensive salesman from a province near our city presented with dyspnea on exertion, ankle edema, puffiness of face and abdominal distension, nonproductive cough, weight loss about 14kg for two months and a half. Night sweat, slight evening fever for about a week. General examination revealed generalized pitting edema, swelling of face, elevated jugular venous pressure, Kussmaul's sign. Physical examination revealed a pericardial knock over the left sternal border, distended abdomen, liver 3 cm from right costal margin. Patient was previously healthy, referring no prior cardiac surgery, chest radiotheray or tuberculosis. His family were normal.

Results: CRP: 25.44mg/l (<5mg/l). NT-proBNP: 592pg/ml (<75y: = 125pg/ml; = 75y: = 450pg/ml). TSH: 4.76 µIU/ml (0.32-5 µIU/ml), anti ds-DNA was negative. Chest X-ray: frontal and lateral views showed calcified pericardium, cardiac shadow was within normal limits. Abdomen Ultrasonography: mild ascites and congestive hepatomegaly. Echocardiography: pericardial thickened (5mm), moderate pericardial effusion (12mm), left atrium enlargement (LA = 48mm), EF: 55%. Cardiac MSCT: Left and right atrium enlargement. Total thickened and calcified pericardium. Normal coronary arteries. After 42 days of admission, surgical procedure pericardiectomy was done. Histopathological report of removed pericardium consistent with tuberculous pericarditis. After operation patient's postoperative course was uneventful with improvement of heart function.

Discussion: This case we diagnosed of constrictive pericarditis is based on 2015 ESC Guidelines for the diagnosis and management of pericardial diseases consist of the association of signs and symptoms of right heart failure and impaired diastolic filling due to pericardial constriction by one or more imaging methods including: Chest X-ray, Echocardiography, CT. Cause of this constrictive pericarditis was tuberculous pericarditis confirmed by histopathological report.

Conclusion: Constrictive pericarditis, a disease with particularly high morbidity and mortality, remains a challenging clinical diagnosis, and one that is frequently overlooked. The commonest aetiologies are idiopathic pericarditis, prior cardiac surgery and chest radiotherapy in the developed world and Tuberculosis pericarditis in the developing world.

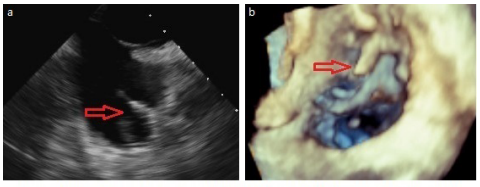
The "irritable pericardium": a rare cause of heart failure

E Piccinelli[1]; A Maloberti[1]; F Musca[1]; L D'angelo[1]; P Vallerio[1]; R Pirola[1]; N Morici[2]; A Sacco[2]; G Viola[2]; G Magenta[3]; F Oliva[2]; M Lunati[3]; A Moreo[1]; C Giannattasio[1]
[1]*Niguarda Ca' Granda Hospital, Cardiology IV Unit, Milan, Italy*; [2]*Niguarda Ca' Granda Hospital, Cardiology I Unit, Milan, Italy*; [3]*Niguarda Ca' Granda Hospital, Cardiology III Unit, Milan, Italy*

A 73 year old woman with worsening dyspnea, orthopnea and bilateral ankle swelling was referred to our hospital emergency department. Those symptoms were present for some weeks but exacerbate in the days before the admission.

She had a previous history of Hashimoto thyroiditis and leukocytosis of unknown origin. A bicameral pacemaker was implanted 40 days before the actual presentation for brady-tachy syndrome.

At admission, physical examination revealed rhythmic and paraphonic heart sounds with bilateral basal pulmonary crackles. She was hemodynamically stable with a blood pressure of 135/65 mmHg, a heart rate of 64 bpm and arterial oxygen saturation was 97% while she was breathing ambient air. A Chest x-ray showed cardiomegaly in the absence of pleural effusion or pulmonary thickening. Electrocardiogram revealed low voltages of the QRS complex while laboratory exams showed only anemia (haemoglobin 10 g/dL), leukocytosis (leukocytes 12.000/L) and renal insufficiency (creatinine 1.5 mg/dL), all stable in comparison with previous data.



Pacemaker's atrial lead in deep contact with the right atrial appendage chronically rubs and irritates the visceral pericardium (a. 2D TEE; b. 3D TEE).

Transthoracic echocardiography (TTE) revealed the presence of diffuse pericardial effusion (maximum thickness 60 mm) with signs of initial diastolic collapse of the right atrial and ventricular walls. The patient was urgently subjected to pericardiocentesis with drainage of 1200 cc of citrine liquid. The cytological examination showed an inflammatory nature of the drained fluid.

Two days later, the subsequent chest-abdominal Computed Tomography (CT) scan excluded the presence of cancer while detecting the persistence of the pericardial effusion (thickness 30 mm) with evident contrast enhancement of the pericardial layers.

A transesophageal echocardiography (TEE) confirmed the circumferential distribution of the pericardial effusion and established that the pacemaker's atrial lead was in deep contact with the right atrial appendage wall and was near to cross it. This data was also confirmed by 3D TEE.

We concluded that the etiopathogenesis of the tamponant pericardial effusion appeared to be a mechanical/irritative mechanism of the distal end of the pacemaker leads on the visceral pericardium. So a procedure of both leads removal was performed, with modest resistance in extraction of the right atrial lead.

After PM removal, ECG monitoring revealed episodes of marked sinus bradycardia and 2nd degree sinoatrial block and a bicameral pacemaker urgent reimplantation was done. At discharge, TEE showed almost complete resolution of the pericardial effusion.

This case shows an infrequent cause of a cardiac tamponade that need to be considered in clinical practice, i.e. the continuous mechanical-irritating stimulation of a badly inserted pacemaker lead even after weeks from implantation. Moreover, it is confirmed the importance of echocardiography in the first approach to the patient

in order to understand the cause of signs and symptoms of heart failure and then in establishing exactly the etiopathogenesis.

Early transition to myocardial recovery in a case of cardiogenic shock and possible myocarditis

P P Poorna Pushkala Natarajan[1]; M T Slawsky[1]; G Valania[1]; E Y Lau[1]; J Hernandez-Montfort[1]

[1]Baystate Medical Center, Cardiology - Advanced heart disease, Springfield, United States of America

Myocarditis is inflammation of the heart muscle and can lead to dilated cardiomyopathy (DCM) in up to 30% of patients. Inflammatory dilated cardiomyopathy (DCMi) is characterized by inflammation of the heart muscle in addition to dilation and impaired contraction that is not explained by abnormal loading conditions or coronary artery disease. In patients with unexplained heart failure, 9-10% of cases was reported to be due to inflammatory cardiomyopathy. DCMi is a major cause of DCM and leads to sudden cardiac death in younger patients. Long-term prognosis of DCMi is unclear, suggesting the need for markers to assess the clinical course and to identify patients at increased risk for adverse events.

A 48 year old male with history of uncontrolled diabetes, obesity, obstructive sleep apnea not on treatment, post traumatic stress disorder was transferred with progressively worsening shortness of breath over 1 month, new onset left bundle branch block on ECG and an echocardiogram showing biventricular dilatation and systolic dysfunction with an ejection fraction < 20 %. There was no family history of congestive heart failure and no ingestion of toxic substances. A right heart catheterization showed hemodynamics of left more than right elevated filling pressures with PAPi (Pulmonary artery pulsatility index) >1.0 despite a right atrial pressure of 20 cm and cardiac index of 1.4 L/min/m2. An intraaortic balloon pump (IABP) was placed. However his mental status deteriorated and respiratory distress ensued requiring mechanical ventilation. Left coronary circulation was without obstructive coronary artery disease. Since IABP alone was insufficient, a decision was made to place an Impella CP. Hemodynamics post Impella implantation improved, however with evidence of left ventricle to paortic uncoupling with a cardiac output of 3.8 L/min at maximal flow. Course was complicated by hemolysis and hence transitioned to Impella 5.0. In the interim, he developed thrombocytopenia and fever. Group A beta hemolytic streptococcus was isolated from sputum. After 10 days, he was able to be weaned off the Impella. Neurohormonal initiation was delayed due to acute tubular necrosis from cardiorenal syndrome. He underwent cardiac resynchronization therapy (CRT). Cardiac MRI showed severely dilated and thinned out LV with global hypokinesis and transmural enhancement in the inferior wall after gadolinium suggestive of small infarct vs myocarditis.

Our patient had a subacute presentation, with cardiogenic shock in the setting of an inflammatory response from streptococcal pneumonia. Underlying preexisting cardiomyopathy is not ruled out. His recovery reiterated that timely use of appropriate mechanical support device, guideline directed medical therapy, and CRT can help recover cardiac function in situations where there is a reversible cause of cardiogenic shock.

A reversible cause of heart failure: a vascular dilemma

H Miranda[1]; C Sousa[1]; G Sobrinho[2]; J Gouveia[3]
[1]*Centro Hospitalar Barreiro Montijo, Cardiology, Barreiro, Portugal*; [2]*Centro Hospitalar Lisboa Norte, Vascular Surgery, Lisboa, Portugal*; [3]*Centro Hospitalar Lisboa Norte, Intensive Care Unit, Lisboa, Portugal*

Case Report: Man, 65 years old. History of hypertension, permanent atrial fibrillation and nonmalignant intestinal polyposis. Admitted to our department due to functional incapacity for moderate efforts, abdominal volume increase and progressive lower limb edema (2 months of evolution).
The physical examination showed a non-painful hepatomegaly and edema in the lower limbs, while the auscultation revealed a cardiac ejection murmur, more audible in the precordium, and the presence of continuous murmur on the right flank.
Marked elevation of NT-proBNP (4012 pg / ml) with estimated creatinine clearance of 72 ml / min. The echocardiogram revealed a dilated left ventricle with an estimated ejection fraction of 40% and biauricular dilatation. Dilated right ventricle with decreased systolic function (TAPSE - 13mm; RV S '- 9cm / s). Moderate tricuspid regurgitation associated with tricuspid ring dilatation.
Medical therapy was optimized and a coronary angiography (which revealed occlusion of the medial anterior descending artery) and a hemodynamic study (cardiac index of 6.83 l/min/m2; pulmonary arteriolar resistance of 1.1 Uwood; PSAP 72 mmHg) were requested.
A contrast injection at the level of the abdominal aorta was performed. It showed a high-caliber, high-flow communication between this vessel and the inferior vena cava, rising the hypothesis of a high-throughput fistula.
Given this diagnostic hypothesis, an abdominal angiography was performed and the presence of a high-throughput arteriovenous fistula was confirmed.
In this context, the patient was presented to our vascular surgery team and underwent surgical intervention.
Evaluation at the 1st and 3rd month after surgery revealed progressive functional (patient currently in class I of the NYHA scale) and echocardiographic improvement (Ejection Fraction 51% and PSAP 34mmHg).
Conclusion: One possible cause of reversible heart failure is the presence of a high-throughput arteriovenous fistula. From a clinical point of view, its presentation is similar to other causes and, as such, a high degree of suspicion is needed. On the other hand, its recognition is crucial since its treatment allows the reversibility of a dramatic clinical situation.

Heritable pulmonary arterial hypertension with cardiogenic shock: venous-arterial extracorporeal membrane oxygenation (VA ECMO) as a bridge to bilateral lung transplantation

H Husnat Ahmed[1]; EP Kew[1]; S Lim[1]
[1]*University Hospital Birmingham, Cardiology, Birmingham, United Kingdom*

A 23 year-old man with end stage hereditable pulmonary arterial hypertension was assessed at our centre in August 2017 for lung transplantation. He was taking triple vasodilator therapy (Ambrisentan, Tadalafil and intravenous Iloprost).
His Echo showed severe right ventricular (RV) hypertrophy and dilatation with severely impaired systolic function. LV function was borderline reduced. Cardiac MRI confirmed the echo findings and showed no RV late gadolinium enhancement. Right heart catheter study showed mean right atrial (RA) pressure of 15 mmHg, mean pulmonary arterial pressure (PAP) of 85 mmHg, transpulmonary gradient (TPG) of 62 mmHg, cardiac index of 1.4 L/min/m2 and pulmonary vascular resistance (PVR) of 23 Woods unit. He was listed for routine bilateral lung transplantation.
He later presented to the hospital with worsening right heart failure. Repeat ECHO confirmed previously documented severe RV impairment with compression of left ventricular (LV) cavity. He was admitted to intensive care unit for invasive monitoring and commenced on Milrinone and vasopressin to support his low cardiac output state and lung transplant waiting list priority was changed from routine to urgent.
Despite above measures, he developed multi-organ failure. Venous-arterial extracorporeal membrane oxygenation (VA ECMO) support was started as a bridging strategy to lung transplantation as well as to restore perfusion to his end-organs with subsequent satisfactory haemodynamic and biochemical improvement. TOE at this point showed some improvement in RV function. After 4 days he received successful bilateral lung transplantation. TOE on day-3 post-op showed good RV function, so VA ECMO was weaned off and explanted. His post-operative recovery course was uneventful.
Discussion: 1)Given the severe pulmonary hypertension and associated RV dysfunction, our options were to offer him heart-lung transplant or bilateral lung transplant but the evidence is unclear as to which option is more superior. A recent observational study suggests both options achieved good long term survival rates. Based on the improvement seen in RV function following VA ECMO, we felt that there was enough RV contractile reserve to warrant a double lung transplantation rather than heart-lung transplantation.
2)There are a few bridging strategies to lung transplantation for pulmonary hypertension: VA ECMO, temporary right ventricular assist device (RVAD), lung assist device (LAD) and atrial septostomy. We opted for VA ECMO for a combination of factors including our institutional experience and the less invasive nature of VA ECMO.
Conclusion: We report a successful case of bilateral lung transplantation in the context of severe pulmonary hypertension and significant RV dysfunction. VA ECMO is a viable bridging strategy. It also allowed us to assess RV contractile reserve prior to transplantation and strengthened our decision on bilateral lung transplantation instead of heart- lung transplantation.

Reversal of heart failure and pulmonary hypertension by arteriovenous fistula ligation in patient with arteriovenous fistula toxicity

B Burabha Pussadhamma[1]
[1]*Srinagarind hospital, Khon Kaen University, Khonkaen, Thailand*

A 57-year-old man with history of end-stage renal disease and needed hemodialysis via arteriovenous fistula (AVF) (1997), percutaneous coronary intervention (PCI) to left anterior descending artery (LAD) (2002), kidney transplantation (KT) (2009), and arterial hypertension, presented by intractable heart failure for 2 months (Feb 2014). Initial physical examination revealed BP of 148/84 mmHg, HR of 88 bpm in sinus rhythm, puffy eyelids, jugular vein engorgement, normal heart sound without heart murmur, bilateral pulmonary crackle, pitting edema 3+ of both legs, and residual functioning AVF at left arm (figure 1), which was left unused since his successful KT. Transthoracic echocardiography (TTE) demonstrated right ventricular dilatation (figure 2), with D-shape of left ventricle and pulmonary hypertension (PH), with tricuspid regurgitation maximal velocity (TRVmax) of 3.1 m/s, and estimated right ventricular systolic pressure (RVSP) of 55 mmHg. Right heart catheterization (RHC) was further performed and confirmed the evidence of combined pre- and post-capillary PH, with mean right atrial pressure of 24 mmHg, mean pulmonary artery pressure of 59 mmHg, left ventricular end-diastolic pressure (LVEDP) of 24 mmHg, transpulmonary gradient of 35 mmHg, cardiac output (CO) of 6.3 L/min, cardiac index of 3.8 L/min/m2, and pulmonary vascular resistance (PVR) of 5.5 Wood units. The CO dropped to 5.1 L/min after occlusion of left arm AVF. Thyroid function test was normal. The diagnosis was heart failure and PH. Although the ultrasound Doppler of AVF showed no evidence of highly abnormal flow, but due to the high cardiac output detected from RHC, the AVF toxicity was then the most likely etiology. Diuretics was administered to control congestion whereas pulmonary arterial hypertension (PAH) specific drug was not given due to worrying about high LVEDP and

lacking definite evidence of benefit of PAH-specific drug use in combined pre- and post-capillary PH. AVF ligation was successfully underwent on May 2014. After the procedure, the AVF was totally absence (figure 3), and he regained his normal functional capacity with no recurrent heart failure. Oral diuretics was uneventfully discontinued and follow-up TTE on Sep 2016 showed a complete recovery of right ventricular dilatation and PH (figure 4), with TRVmax of 2.2 m/s, and estimated RVSP of 22 mmHg.

Conclusions: Long-standing high flow from AVF could lead to heart failure and PH in susceptible patient. AVF ligation, a correction of primary pathology, is an effective method that could reverse both heart failure and PH.

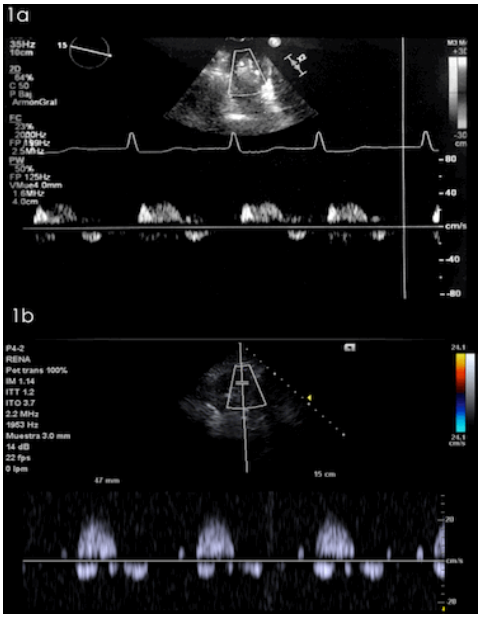
Intrarenal venous flow patterns in acute heart failure: an insight into intrarenal hemodynamics

R De La Espriella Juan[1]; J Gonzalez[1]; M Amiguet[1]; G Minana[1]; E Santas[1]; J Nunez[1]

[1]*University Hospital Clinic of Valencia, Cardiology Department , Valencia, Spain*

We report a case of an 81-year-old woman with heart failure with preserved ejection fraction and type 2 cardiorenal syndrome that presented with increased dyspnea, abdominal discomfort and 1.5 kg gain. The patient had been strictly followed-up for recurrent episodes of congestion and diuretic resistance that required intravenous diuretics repeatedly over the last two-years. The echocardiography showed a normally functioning prosthetic mechanical mitral valve, a dilated right ventricle with preserved systolic function and double tricuspid lesion: moderate-severe regurgitation and moderate stenosis. The laboratory analysis showed an NT-proBNP of 3205 pg/ml, CA-125 68 U/ml (prior determination within normal range) and serum creatinine of 1.9 mg/dL with estimated GFR 27 ml/min/1.73m2 (previously she had an estimated GFR of 39 ml/min/1.73m2). Vital signs at presentation: heart rate 69 bpm, arterial blood pressure 87/56 mmHg. The physical examination revealed abdominal distention, positive hepatojugular reflux but no peripheral edema nor signs of pulmonary congestion. Her pre-admission daily diuretic regimen was: furosemide 160 mg/d, chlorthalidone 25 mg/d, acetazolamide 125 mg/d, spironolactone 12.5 mg/d. We performed an intrarenal doppler ultrasonography using color Doppler images to determine interlobar vessels, and pulsed Doppler waveforms to record interlobar arteries and veins simultaneously. A monophasic intrarenal venous flow pattern (figure 1a) was obtained. Question: Which is the best treatment strategy to improve her clinical status? 1) intravenous diuretic intensification; 2) oral diuretic intensification; 3) intermittent inotropic therapy; 4) reduce the diuretic therapy.

Answers and Discussion: given the clinical presentation, the change in CA125 serum levels and the venous flow pattern obtained in intrarenal ultrasonography, we considered that the renal function deterioration was related to an increased in renal venous pressure. With this in mind, we administered 250 mg of intravenous furosemide diluted in 1.4% hypertonic saline solution over 3 hours. At 48 hours visit, we performed an additional intrarenal ultrasonography, and we observed a biphasic venous flow pattern (figure 1b). In parallel to those findings, there was an improvement in patient clinical status (resolution of abdominal heaviness) and renal function (GFR of 38 ml/min/1.73m2). Low intrarenal venous impedance index calculated from the renal venous waveforms has been classically linked with elevated renal interstitial pressure caused by renal obstruction. However, recent evidence suggests the potential application of this imaging modality as a surrogate of intrarenal hemodynamics in heart failure. We hypothesized that intrarenal venous flow pattern and its reversibility in response to diuretic therapy could help us to identify a potential phenotype of patients with "congestive kidney failure."



1470

An atypical case of cardiac tamponade: what should be the best approach?

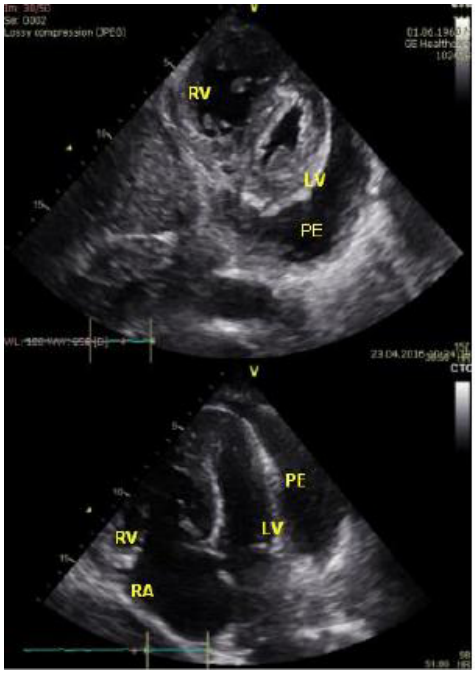
D Deniz Cadil[1]; M Stoian[1]; S Iancovici[1]; M Dorobantu[1]

[1]*Emergency Clinical Hospital Floreasca, Cardiology, Bucharest, Romania*

Systemic sclerosis (SSc) is an autoimmune disorder in which symptomatic pericarditis occurs in 7 to 20% of patients, making it the connective tissue disorder with the most cases of pericardial involvement.

A 55-year old male patient diagnosed with SSc in 2014, with pulmonary fibrosis and chronic cor pulmonale, was referred for progressive dyspnea in the last 3 months, aggravated in the last 3 days. On admission, the patient had hemodynamic compromise with a BP of 85/60 mmHg, intense dyspnea and anasarca. The ECG showed sinus tachycardia and low voltage QRS complexes. The transthoracic echocardiogram (ETT) revealed a moderate pericardial effusion (20 mm) located posterior and lateral to the left ventricle, with extremely dilated right cavities, with right ventricular dysfunction and severe pulmonary artery hypertension. The left cavities were compressed between the pericardial effusion and the right ones. There was a respiratory variation of the mitral and tricuspid inflow, with 25% relative decrease in inspiratory flow across the mitral valve and 50% relative augmentation in inspiratory flow across the tricuspid valve. The patient underwent a thoracoscopic pericardial fenestration and 200 ml of pericardial fluid were extracted. The afterwards ETT showed no pericardial effusion and an improvement in left cavities' function. Hours after the procedure the patient developed hemodynamic instability followed by cardiogenic shock that lead to cardiac arrest and death.

There are few cases of cardiac tamponade and SSc cited in literature, most of which had a poor outcome due to severe pulmonary hypertension, renal or heart failure, with infrequent exceptions. The questions that arise are firstly the aetiology - whether it is a primary pericardial involvement of SSc or, most probably, secondary to severe PAH that lead to right ventricular failure. The pathology findings support this theory, as the analysis of pericardial fragments showed a normal hystological structure and a minimal vascular congestion. Secondly, it is an atypical case of cardiac tamponade with the absence of right cavities' collapse and pulsus paradoxus and the presence of isolated left ventricle compression. In this situation there is an interventricular asynchrony that impairs the preload of the LV and leads to further decreases in cardiac output. The therapeutic challenge consists of deciding whether to drain the effusion or to stabilise the right heart function with vasoactive therapy (bosentan, sildenafil). Literature data is limited and controversial, while cardiac tamponade is a clear indication for drainage. In conclusion, pericardial tamponade is exceptional in SSc patients and the management of such clinical cases is still a challenge and also a controversy. The treatment of choice remains pericardiocentesis, while further studies are required in order to determine whether stabilisation of severe PAH and cautious drainage afterwards can be a more effective approach.



Cardiac tamponade and severe PAH

1471

Combination cisplatin and 5-fluorouracil-induced takotsubo cardiomyopathy in oropharyngeal cancer: a case report

N Nkem Okonkwo[1]; A Barron[1]
[1]*Harefield Hospital, London, United Kingdom*

Introduction: Takotsubo Cardiomyopathy (TC) is a rare yet increasingly reported syndrome described as a sudden yet temporary weakness or 'stunning' to the myocardium. There remains much intrigue in the correlation between cancer, chemotherapy and takotsubo syndrome especially in this era whereby as cardiologists we are faced with growing referrals of patients who have suffered cardiotoxic side effects from these agents.
Case presentation: We describe the case of a 52-year-old patient with T2 N2c M0 squamous cell carcinoma of the oropharynx who presented with acute heart failure, acute kidney injury and transaminitis requiring Intensive Care Unit admission within hours of receiving her first course of infusional 5-fluorouracil (5-FU) and Cisplatin. Her history included an upper GI bleed and non-alcoholic fatty liver disease, but no history of cardiac disease while being a lifelong non-smoker and was abstinent from alcohol. Additionally, there was no history of emotional or psychological factors at play that could have contributed to the patient's presentation. Within 72 hours of chemotherapeutic treatment, she developed sudden onset dyspnoea with associated chest pain. ECG displayed sinus tachycardia with lateral T-wave flattening. Subsequent CT pulmonary angiogram showed bilateral parenchymal changes and associated moderate volume bilateral pleural effusions, suggestive of fluid overload but no pulmonary embolus. An echocardiogram performed at initial presentation showed left ventricular ejection fraction of 15%. She was initially diuresed with intravenous furosemide but her worsening clinical state necessitated escalation to haemofiltration following the development of a severe AKI and symptomatic uraemia. The differential diagnoses suggested at this juncture included acute coronary vasospasm, inflammatory myocarditis or chemotherapy-induced cardiomyopathy. Consequent coronary angiogram reported unobstructed coronary arteries. A follow-up MRI scan 10 days after admission showed a return of normal LV function consistent with stress cardiomyopathy. Subsequent 5-FU treatment was discontinued and the patient went on to receive radiotherapy and cetuximab as second-line chemotherapy.
Conclusion: 5-FU is the most common chemotherapy molecule associated with TC in the literature. Cisplatin and other platinum agents have been implicated in TC both in combination with 5-FU and in isolation. A multispecialty approach is required when managing such a significant clinical phenomenon such that oncologists and cardiologists alike must remain aware of the varied cardiotoxic consequences of these frequently administered chemotherapy agents. Furthermore, clinicians may be able to stratify those patients at risk of stress cardiomyopathy, which may prompt seeking alternative agents and avoid rechallenging with the same drug

Patient management - From oral treatment to transplant

Structured follow-up program of patients with heart failure: impact on quality of life and prognosis.

J Ribeiro Agostinho[1]; J Rigueira[1]; A Nunes-Ferreira[1]; R Santos[1]; I Aguiar-Ricardo[1]; I Goncalves[1]; T Guimaraes[1]; R Pires[2]; F Veiga[1]; M Mendes Pedro[1]; FJ Pinto[1]; D Brito[1]

[1]Cardiology Department, Santa Maria Hospital, CHLN, CCUL, Lisbon University, Lisbon, Portugal; *[2]Faculty of Psychology, CINEICC, University of Coimbra, Coimbra, Portugal*

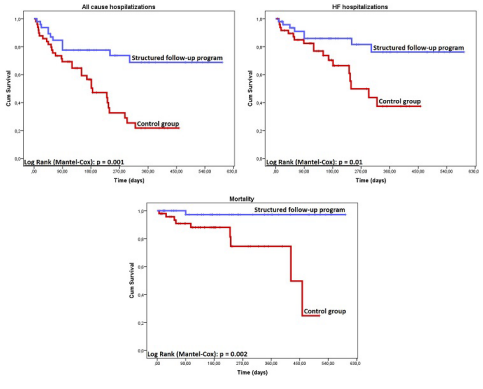
On behalf of: RICA-HFTeam

Introduction: Patients with heart failure (HF) benefit from regular clinical follow-up in order to maintain therapeutic optimization and to identify early signs of decompensation, thereby reducing readmission rates and improving prognosis. However, the magnitude of this potential benefit is seldom objectified.

Objective: To evaluate the actual impact of the implementation of a structured follow-up program in pts with HF, regarding quality of life (QoL) and hospitalization and mortality rates.

Methods: Nested-case control study, with prospective data registry of 50 consecutive pts discharged after hospitalization for acute HF (AHF). This population (study group) was followed (HF team) at 10 days, 3, 6 and 12 months after discharge, with predefined procedures (by protocol), including clinical evaluation, therapeutic optimization (according to ESC guidelines), laboratorial, electrocardiographic and echocardiographic evaluations, and QoL assessment [Kansas City Cardiomyopathy Questionnaire (KCCQ)]. The control group consisted of 100 pts hospitalized for AHF and regularly followed after discharged but prior to the implementation of the protocol. Cox Regression, Kaplan-Meier survival analysis and Wilcoxon test were the statistical methods used.

Results: The study group (mean age: 67.1 ± 11 years, 75.5% males) had a mean left ventricular ejection fraction (LVEF) of 27.6 ± 10.3% (85.7% with LVEF < 40%) at discharge. Sixteen pts (31%) were discharged in NYHA I functional class, 63.3% in class II and 6.1% in class III. Demographics and all functional cardiac variables were similar in the two. Mean follow-up time was 8.2 ± 5.3 months in the study group, and 8 ± 4.7 months in the control group (p = NS).



In the study group, there was a significant improvement in LVEF (p < 0.001), NYHA functional class (p = 0.001), and in all the parameters assessed by the KCCQ, namely in symptoms (p < 0.001) and overall QoL (p < 0.001). There was also an effective optimization of treatment during follow up, including the up-titration of recommended drugs: compared to the doses of pharmacological therapies previously used before the index-admission for AHF, a significant increase in doses of angiotensin converting enzyme inhibitor/angiotensin II receptor antagonists (p < 0.001), beta-blockers (p < 0.001) and mineralocorticoids receptor antagonists (p < 0.001), was achieved during follow up.

In comparison with the results observed in the control group, the group included in the structured follow-up program showed a significant reduction in all cause readmissions (24.5% vs 61.2%, p = 0.001), HF readmissions (16.3% vs 36.7%, p = 0.001) and total mortality (2% vs 18.4%, p = 0.001) during follow up. Conclusion: A structured follow-up program of HF patients allowed a significant reduction in readmission and mortality rates in the medium term, and was associated with a significant improvement in functional class, quality of life, and LVEF. These results support the imperative need to establish such programs.

1537

Impact of physicians' adherence to guideline-recommended therapy on heart failure re-hospitalizations: data from the Optimize Heart Failure Care Program

Y M Lopatin[1]; A Grebennikova[1]; H Sisakian[2]; H Hayrapetyan[3]; Z Pagava[4]; T Abdullaev[5]; G Dadashova[6]; S Berkinbayev[7]; A Rakisheva[7]; A Chesnikova[8]; E Tarlovskaya[9]; Z Kipiani[10]; N Koziolova[11]; V Tseluyko[12]; L Voronkov[13]

[1]Volgograd State Medical University, Volgograd Regional Cardiology Centre, Volgograd, Russian Federation; *[2]Yerevan State Medical University Hospital 1: University Cardiology Clinic, Yerevan, Armenia*; *[3]Erebouni Medical Center, Yerevan, Armenia*; *[4]Centre of Vascular and Heart Diseases, Tbilisi, Georgia Republic of*; *[5]Specialized Cardiology Center of the Republic of Uzbekistan, Tashkent, Uzbekistan*; *[6]Scientific Research Institute of Cardiology, Baku, Azerbaijan*; *[7]Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*; *[8]State Medical University of Rostov-on-Don, Rostov-on-Don, Russian Federation*; *[9]Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russian Federation*; *[10]"New Hospital", Tbilisi, Georgia Republic of*; *[11]Perm State Medical Academy, Perm, Russian Federation*; *[12]Kharkiv National Academy of Postgraduate Education, Kharkiv, Ukraine*; *[13]NSC Institute of Cardiology M.D. Strazhesko, Kiev, Ukraine*

Background: In spite of the evidence that good adherence to guidelines can improve clinical outcomes many studies demonstrate suboptimal implementation of guideline-based heart failure (HF) treatment into real clinical practice. The aim of our study was to evaluate the impact of physicians' adherence to guideline-recommended therapy on the rate of HF re-hospitalizations at 12-months of follow-up.

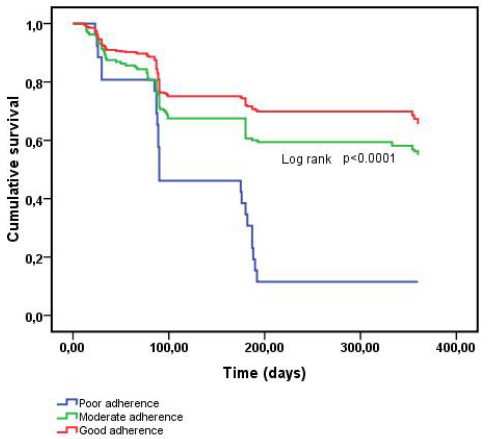
Methods: This study was part of an international multicenter Optimize Heart Failure Care Program and included 740 patients hospitalized due to worsening HF (mean age 61.9 ± 11.8 years, 70% male, 77.7% with sinus rhythm, NYHA II-IV, mean 2.7 ± 0.6, mean LVEF 35.1 ± 9.9%). To assess physicians' adherence to the medications recommended by the 2016 ESC HF guidelines, a five-class guideline adherence score for angiotensin converting enzyme inhibitors (ACEIs), beta-blockers (BBs), angiotensin receptor blockers (ARBs), mineralocorticoid receptor antagonists (MRAs), and ivabradine was used.

The score was calculated for each patient by summing the points: 0 for non-prescription of medication in the absence of contraindications and one point each for the use of ACEIs/ARBs, BBs, MRAs and ivabradine. Three types of adherence were defined: good adherence (use of all guideline-recommended medications; score = 1); moderate adherence (use of >50% recommended medications; score >0.5- <1); poor adherence (use of 50% recommended medications; score = 0.5). To analyze the adherence to the recommended doses of HF medications the score was calculated for each patient by summing the points: 0 for non-prescription of medication, 0.5 points for use of <50% of target doses and 1 point for the each prescribed medication at = 50% target dose.

Results: The score of adherence to guideline-recommended medications was good in 80%, moderate in 16%, and poor in 4% of HF patients. However, at discharge from hospital, the proportion of patients at target doses and = 50% of target doses was low (17.7% and 47% for ACEIs/ARBs, 15% and 42% for BBs, 14% and 35% for ivabradine, respectively). 70% of HF patients were at recommended doses of MRAs. The score of adherence to the recommended doses of HF medications was good in 35%, moderate in 63%, and poor in 2% of HF patients without a tendency for improvement during 12 months of follow-up. Poor adherence to guideline-recommended HF medications and to the recommended doses was associated with significantly higher HF hospitalization rates (HR 1.46, 95% CI, 1.18-1.76, p = 0.0001 and HR 1.46, 95% CI, 1.18-1.76, p = 0.0001, respectively) (Figure).

Conclusion. Regardless of the prevalence of good scores of physicians' adherence to guideline-recommended HF medications, in most cases the doses of these agents continue to be suboptimal. Poor adherence to guideline-recommended

therapy is associated with a higher rate of HF re-hospitalizations. New educational initiatives improving physicians' adherence to guidelines are required.



Event-free curves for HF hospitalization

Perceptions of heart failure treatment decision-making and side effects of heart failure treatment by patients and cardiologists: a multinational survey in the real-world cardiology setting

B Balas[1]; S Bruce Wirta[2]; CC Proenca[3]; H Bailey[4]; Z Phillips[4]; S Cotton[4]; J Jackson[4]

[1]Novartis Pharma AG, Basel, Switzerland; *[2]Novartis Sweden AB, Stockholm, Sweden*; *[3]Wellmera AG, Basel, Switzerland*; *[4]Adelphi Real World, Bollington, United Kingdom*

Funding Acknowledgements: This study was funded by Novartis Pharma AG.

Background and Purpose: This study aimed to explore how often patients with heart failure (HF) are consulted regarding their treatment decisions and also the extent to which side effects experienced by patients as a result of their HF treatment regimen are recognized by their cardiologists.

Methods: A cross-sectional survey of cardiologists and their consulting patients with HF was conducted in 10 countries (Argentina, Brazil, China, Colombia, France, Japan, Mexico, Russia, Saudi Arabia and Turkey). Patient record forms (PRFs) were completed by cardiologists for consecutively consulting patients with HF, who were then invited to complete a patient self-completion questionnaire (PSC). Only responses from PRFs with an associated PSC were analyzed. Patients and cardiologists reported the degree of patient input into treatment decisions and the side effects experienced as a result of the patient's current HF treatment regimen; these were compared, and concordance calculated. Responses were also analyzed by taking the patient perspective and evaluating how often a patient-reported side effect was not recognized in the PRF (cardiologist under-reporting) and vice versa (cardiologist over-reporting).

Results: Almost one third (30%) of patients were not consulted on their choice of therapy. For 65% of patients, a discussion occurred with the cardiologist having the final call, while for 6% of patients a discussion occurred but the patient had the final call. A high level of concordance (74%) between matched cardiologist and patient pairs (n = 2228) was observed for the degree of patient input into treatment decisions. Concordance was also high between matched cardiologist and patient pairs (n = 2385) for the occurrence of side effects, ranging from 77% (fatigue/tiredness) to 98% (gout, rash and swelling of lips, tongue, throat or face) (Figure). Individual side effects were reported by 1-22% of patients (Figure). Cardiologists more often under- than over-reported the occurrence of side effects of treatment reported by patients (Figure).

Conclusions: Shared decision-making is the pinnacle of patient-centred care whereby the physician educates the patient about treatment options, possible outcomes and side effects, in order to reach an informed treatment decision. This process could be considered fundamental to an overall improvement of patient care. In this study, we observed that almost one third of patients were not at all involved in decisions about their HF treatment, and, when they were, the ultimate decision was not made in partnership between the patient and cardiologist. Side effects experienced by patients as a result of their HF treatment regimen were more frequently under-reported than over-reported by their cardiologists. Improved communication between patients and cardiologists is essential to optimize treatment decision-making and to increase awareness of, and concordance with, the occurrence of treatment side effects.

The effect of home-based cardiac rehabilitation following coronary artery bypass graft surgery in a low income country: A controlled trial

J Jamal Uddin[1]

[1]Ibrahim Cardiac Hospital & Research Institute, Dhaka, Bangladesh

Background: CVD is the leading cause of mortality and morbidity in Lower and low to middle income countries, including Bangladesh. To date no controlled trials of cardiac rehabilitation (CR) have been conducted in low or low to middle income countries (LLMICs).

Methods: A quasi-randomised controlled trial comparing home-based CR plus usual care (CR group) to usual care alone (UC group) for patients following coronary artery bypass graft (CABG) surgery. CR consisted of an initial CR class, an educational booklet with details of a home-based exercise programme, and monthly telephone calls from a CR team member over a 12-month period. The outcomes of maximal oxygen uptake (VO2max), coronary risk factors, health-related quality of life, and mental health status were collected at baseline between at 3 and 6 months follow-up. Differences in outcomes between groups were compared in patients with complete outcome data.

Results: A total of 142 participants participated in the trial; 71 patients in each group. At 12-months follow-up, 61 (86%) patients in the CR group and 40 (56%) in the UC group provided complete outcome data.VO2maxwas higher in CR compared to UC group (mean difference: 7 ml/kg/min, 95% CI: 2 to 11, P = 0.005).In addition, greater improvements in health-related quality of life, and coronary heart disease (CHD) risk factors were seen for CR group compared to UC group.

Conclusions: In the context of a low-income country, the addition of a home-based CR programme supported by telephone calls following CABG surgery has been shown to provide important patient benefits compared to usual care alone.

The optimal plasma volume status in heart failure in relation to clinical outcome

P Pieter Martens[1]; P Nijst[1]; M Dupont[1]; W Mullens[1]
[1]*Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium*

Background: Progressive plasma volume (PV) expansion is a hallmark of chronic heart failure (HF), ultimately contributing to decompensated heart failure. Monitoring PV might offer prognostic information and might be a target for tailored therapy.
Methods: The correlation between technetium-(99Tc)-labeled red blood cell measured PV and calculated PV was first determined in a validation cohort. The relationship between PV-status (PVS; a marker how much actual PV deviated from the ideal PV; for formula see figure) and outcome was analyzed using cox-proportional modeling in a prospective CHF-population (the outcome cohort).
Results: Thirty-one HF-patients were included in the validation cohort. Calculated PV correlated well with technetium-(99Tc)-measured PV (r = 0.714; p = 0.001). A total of 1173-patients (HFrEF n = 872, HFmrEF n = 229, HFpEF n = 72) were prospectively included in the outcome cohort. The mean PVS in the outcome cohort was -6.7 ± 10%, indicating slight PV-contraction. Mean PVS was similar in HFrEF, HFmrEF and HFpEF (post-hoc ANOVA all p>0.05). A higher PVS was independently associated with an increased risk for heart failure hospitalization and all-cause mortality (HR = 1.017; CI = 1.007-1.028 per 1 % increase in PVS). ROC-curve analysis indicated that an PVS of -6.5% optimally predicted absence of adverse outcome (defined as optimal PVS). Hazard ratio analysis indicated that CHF-patients were less equipped in tolerating PV-expansion in comparison to PV-contraction (see figure). The use of ACE-I/ARBs and MRAs were independently associated with a higher odds for having an optimal PVS in HFrEF and HFmrEF (all p <0.05), but not in HFpEF.
Conclusions: Calculated PV correlates well with measured PV in HF-patients. An increase in PV is independently associated with a higher risk for adverse outcome. The optimal PV in HF is lower than what would be expected based on an ideal prediction formula. Higher dosages of Renin-Angiotensin-Aldosterone blockers are associated with a higher odds for having an optimal PV-status in HFrEF, HFmrEF but not HFpEF.

Funding Acknowledgements: Boehringer Ingelheim & Eli Lilly and Company Diabetes Alliance

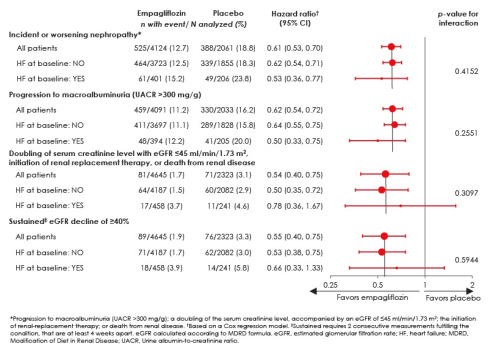
Background: Chronic kidney disease (CKD) is common and portends worse prognosis in patients with heart failure (HF), especially in the presence of type 2 diabetes (T2D). Since pathophysiologically, CKD and HF are linked, progression of CKD and its association with outcomes may not be similar among patients with or without HF. In the EMPA-REG OUTCOME trial (NCT01131676), the SGLT2 inhibitor,

empagliflozin (EMPA) on a background of standard of care significantly reduced the risk of cardiovascular (CV) death by 38% vs placebo (PBO) in patients with T2D and established CV disease (CVD). Empagliflozin also reduced the risk of incident or worsening nephropathy by 39%, and slowed progression of CKD. Here, we report post-hoc kidney outcomes in patients with or without HF at baseline from the EMPA-REG OUTCOME trial.

Methods: Patients were randomized (1:1:1) to EMPA 10 mg, 25 mg or PBO. The composite kidney outcome of incident or worsening nephropathy, defined as progression to macroalbuminuria, doubling of serum creatinine, initiation of renal replacement therapy, or death from renal disease, was analyzed in patients with or without HF at baseline. The incidence of first sustained decline in eGFR from baseline of = 40% was also evaluated. Cox proportional hazards models were used to investigate the consistency of treatment effect across subgroups.

Results: Of 7020 treated patients, 706 (10.1%) had HF at baseline. Overall, the incidence of kidney outcome events was numerically higher in patients with HF than without HF. In the HF group, EMPA reduced the risk of incident or worsening nephropathy by 47% (HR 0.53 [95% CI: 0.36-0.77]) (Figure), consistent with the effects in the overall study population (treatment interaction p-value: 0.42). EMPA reduced progression to macroalbuminuria by 50% (HR 0.50 [0.33-0.75]). The composite of hard renal endpoints (doubling of serum creatinine, initiation of renal replacement therapy, or death from renal disease) was reduced in the overall trial population, and the effect was consistent in the HF subgroup (HR 0.78 [0.36-1.67]) (Figure). The time to first sustained eGFR decline from baseline of = 40% was reduced overall with consistency of effect seen in the HF population (HR 0.66 [0.33-1.33]). All effects in patients with HF were consistent with those in the overall study population (p-values for interaction >0.05).

Conclusions: In the EMPA-REG OUTCOME trial, patients with T2D and concomitant HF at baseline were at high risk of progressive CKD. In this vulnerable population, EMPA reduced the risk of clinically relevant kidney events. The renoprotective effects were observed on a background of standard of care and were consistent with those reported for the overall study population. The potential of empagliflozin to slow CKD progression in patients with HF (with or without diabetes) is being further investigated in ongoing trials in patients with reduced (EMPEROR-Reduced) or preserved ejection fraction (EMPEROR-Preserved).



*Progression to macroalbuminuria (UACR >300 mg/g); a doubling of the serum creatinine level, accompanied by an eGFR of ≤45 ml/min/1.73 m²; the initiation of renal-replacement therapy; or death from renal disease. †Based on a Cox regression model. §Sustained requires 2 consecutive measurements fulfilling the condition, that are at least 4 weeks apart. eGFR calculated according to MDRD formula. eGFR, estimated glomerular filtration rate; HF, heart failure; MDRD, Modification of Diet in Renal Disease; UACR, Urine albumin-to-creatinine ratio.

Renal outcomes by baseline HF

The ketone body 3-hydroxybutyrate increases cardiac output and left ventricular contractile function in heart failure patients with reduced ejection fraction

R Roni Nielsen[1]; N Moller[2]; HE Botker[1]; H Eiskjaer[1]; L Gormsen[3]; H Wiggers[1]
[1]Aarhus University Hospital, Skejby, Department of Cardiology, Aarhus, Denmark; *[2]Aarhus University Hospital, Department of Endocrinology and Metabolism, Aarhus, Denmark*; *[3]Aarhus University Hospital, Department of Nuclear Medicine & PET center, Aarhus, Denmark*

Background: The ketone body 3-hydroxybutyrate (3-OHB) fuels ATP-generation in the heart during prolonged periods of fasting and metabolic stress. Patients with severe heart failure and reduced ejection fraction (HFrEF) have inherently increased utilization of 3-OHB, and it has been hypothesized, that 3-OHB may act as a "super fuel" with beneficial effects on cardiac function in HFrEF patients.

Purpose: To investigate the cardiac and hemodynamic effects of short-term 3-OHB infusion compared to placebo in patients with stable HFrEF. The primary outcome was cardiac output (CO), and secondary outcomes were stroke volume (SV), mixed venous saturation (SVO2), central venous pressure (CVP), left ventricular filling pressure (PCWP), LVEF and strain (GLS).

Methods: We studied 24 stable chronic HFrEF patients (LVEF 36 ± 4%, age 61 ± 11 years) using Swan-Ganz catheterization and echocardiography. Study 1: In a randomized, single blinded cross-over design, 16 patients received 3-OHB (0.18 g/kg/h) or saline (placebo) at an equivalent volume for 3 hours. Study 2: Eight patients were examined in a dose-response study at 3 different rates of 3-OHB infusion for 2 hours consisting of a) saline followed by b) 3-OHB 0.045g/kg/h and c) 3-OHB 0.09g/kg/min.

Results: Study 1: Compared to placebo, 3-OHB infusion increased circulating 3-OHB levels from 0.4 [0.1;0.6]mM to 3.3 [3.1;3.7]mM. (p < 0.001). This was associated with an increase in CO of 42% (p < 0.001, table 1 and figure 1A) mediated by an increase in SV (p < 0.001) and heart rate (p < 0.001). During 3-OHB infusion, SVO2 increased (p < 0.001) whereas CVP (p = 0.04) and PCWP (p = 0.04) decreased while mean arterial (p = 0.47) and pulmonary pressure (p = 0.83) remained unaffected. LVEF (p = 0.001) and GLS (p < 0.001) improved as compared with placebo. Study 2: 3-OHB increased gradually from a: < 0.1mM to b: 0.7 ± 0.1mM and c: 1.6 ± 0.3mM (p < 0.001) with an associated increase in CO (a: 5.0 ± 0.9 vs. b: 5.3 ± 1.0 vs. c: 6.2 ± 1.3 L/min; p < 0.001), which, however, was lower than in the high-dose study 1 (p = 0.007) (figure 1B).

Conclusion: The findings demonstrate dose-dependent beneficial cardiac and hemodynamic effects of 3-OHB in HFrEF patients. Thus, 3-OHB may be used for short-term treatment of heart failure.

Swan-ganz and echo parameters

	Saline (n = 16)	3-OHB (n = 16)	P-value
CO (L/min)	4.8±0.6	6.8±1.0	<0.001
SV (ml)	75±16	95±18	<0.001

Are target doses relevant for women with heart failure? - implications for sacubitril-valsartan

HM Helena Norberg[1]; V Pranic[2]; E Bergdahl[2]; K Lindmark[2]
[1]Umea University, Public Health and Clinical Medicine, Pharmacology and Clinical Neuroscience, Umea, Sweden; *[2]Umea University, Public Health and Clinical Medicine, Umea, Sweden*

Funding Acknowledgements: The Heart Foundation of Northern Sweden

Background: In the PARADIGM-HF trial sacubitril-valsartan reduced both heart failure hospitalizations and cardiovascular death by 20% compared to enalapril. The proportion of women in the study was only 21%. Previous work has shown that in a community based heart failure population the proportion of women eligible for sacubitril-valsartan is only 16%. This is surprising since the total heart failure population is evenly distributed.

Purpose: To investigate why so few women are eligible for treatment with sacubitril-valsartan.

Methods: We applied the PARADIGM-HF main inclusion and exclusion criteria to a community based heart failure population in northern Sweden and statistically compared the women and men cohort.

Results: Of the whole heart failure population of 1924 patients, 43% were women. However, in patients with ejection fraction (EF) = 35%, only 28% were women and after applying the PARADIGM-HF main inclusion and exclusion criteria, only 15 women would have been eligible for inclusion in the trial, corresponding to 16% of the eligible patients. The most common reason for not meeting the criteria was failure to reach target dose of ACE inhibitor or ARB. In patients with heart failure and reduced ejection fraction (HFrEF) women were older (81.1 ± 10.6 vs. 74.8 ± 11.5, p < 0.001) had lower body weight (69.4 ± 17.2 vs. 85.3 ± 17.5, p < 0.001), lower estimated glomerular filtration rate (48.5 ± 26.2 vs. 70.1 ± 34.5, p < 0.001), and higher systolic blood pressure (127.4 ± 19.0 vs. 122.5 ± 18.5, p = 0.018). Besides fewer women reached target dose of ACE inhibitor or ARB (26% vs. 43%, p = 0.001), heart failure therapy did not differ between the genders except that women were more often prescribed loop-diuretics and less likely to have an implantable cardioverter defibrillator or cardiac resynchronization therapy defibrillator.

Conclusions: Fewer women suffer from HFrEF and tolerate target doses of ACE inhibitor or ARB, and are consequently less eligible for sacubitril-valsartan compared to men. Women probably tolerate target doses to a lesser degree owing to being older, having lower body weight (less volume of distribution), and lower renal function. Though, we cannot exclude that women are treated differently because of gender bias. This study shows that target doses as entry criteria in clinical trials favors men, which is important to consider in future study design to gain better knowledge of how to offer women with heart failure the best available care. Since current guideline recommended target doses are mainly based on men, we suggest more individualized doses to women with heart failure.

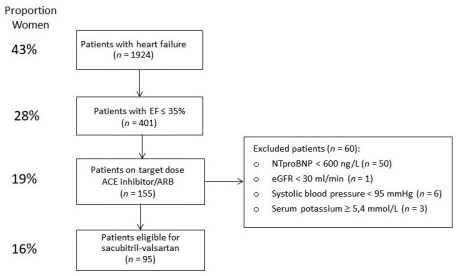

Figure 1 Selection of patients eligible for sacubitril-valsartan in a community based hospital when applying main inclusion and exclusion criteria from the PARADIGM-HF trial. The proportion of women in each selection step is shown on the left.

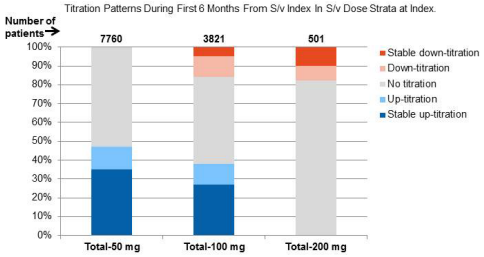
Real-world titration and treatment patterns of sacubitril/valsartan in germany, a retrospective cohort study using a longitudinal pharmacy database

R Wachter[1]; S Klebs[2]; B Balas[3]; CC Proenca[4]; M Dworak[2]; R Schlienger[3]; J Engelhard[5]; T Maier[3]; S Bruce Wirta[6]; K Kostev[5]
[1]Universitätsklinikum Leipzig, Leipzig, Germany; *[2]Novartis Pharma GmbH, Nuremberg, Germany*; *[3]Novartis Pharma AG, Basel, Switzerland*; *[4]Wellmera AG, Basel, Switzerland*; *[5]IQVIA, Frankfurt, Germany*; *[6]Novartis Sweden AB, Stockholm, Sweden*

Funding Acknowledgements: Novartis Pharma AG

Background: The angiotensin receptor neprilysin inhibitor sacubitril/valsartan (s/v) was launched in Germany in January 2016 for the treatment of symptomatic heart failure (HF) with reduced ejection fraction.
Purpose: To characterize real-world titration and treatment patterns of s/v patients in Germany.
Methods: Patients with at least one s/v prescription (Rx) between January 2016 and June 2017 were identified in the German longitudinal pharmacy database (IMS LRx), covering ~60% of all dispensed Rx from statutory insured patients. Prescriber specialty and first recorded s/v dose were analysed (date of first Rx = index date). Titration patterns were defined as "stably up-titrated" (with no subsequent down-titration), "stably down-titrated" (with no subsequent up-titration), and "up-titrated" and "down-titrated" (with a mix of up- and down-titration).
Results: A total of 26,191 patients (= 18 years) fulfilled the inclusion criteria. General practitioners (GPs) accounted for the majority (~80%) of the 127,803 s/v Rx, while cardiologists accounted for ~15% of Rx. Patients with a first s/v Rx by GPs were on average older (mean ± sd 73 ± 12 vs 69 ± 11 years) and more often female (27% vs. 20%) versus those with first s/v Rx from cardiologists. Overall, there was high usage of HF drugs prior to s/v index (angiotensin-converting enzyme inhibitor/angiotensin receptor blocker 92%, beta-blocker 89%, mineralocorticoid receptor antagonist 63%).
Of the 12,082 patients with 12 months pre-index activity (defined by any Rx every 6 months) and a minimum of 6 months follow-up, 64% had a first observed Rx of 50 mg bid, 32% had 100 mg bid and 4% had 200 mg bid. During the first 6 months, 26% of patients with a first cardiologist Rx received the target dose of 200 mg bid, compared to 19% of patients with another specialty at index ($p < 0.001$).
In patients starting on 50 mg bid, 47% were up-titrated, of which 80% maintained a stable dose of either 100 or 200 mg bid. In patients on 100 mg bid at index, 38% were up-titrated, of which 77% maintained the target dose, whereas 5% were stably down-titrated. In patients with target dose at index, 10% were down-titrated to a stable lower dose, and 8% were down-titrated at some point, but then back-titrated to the target dose. The mean (sd) time to first titration was 54 days (44) while the mean time to reach the target dose varied from 79 days (44) to 57 days (47) for patients on 50mg and 100 mg bid at index, respectively ($p < 0.05$). Results were similar across specialty at index.
Conclusion: There were no attempts to up-titrate s/v in the majority of patients, while for patients up-titrated, the overall proportion of stable up-titration was 80%. Overall, only 20% of patients received the target dose of 200 mg bid. Titration took longer than what is recommended in the EU summary of product characteristics. The barriers for up-titration must be further explored and educational efforts to promote up-titration have to be intensified.



Titration Patterns

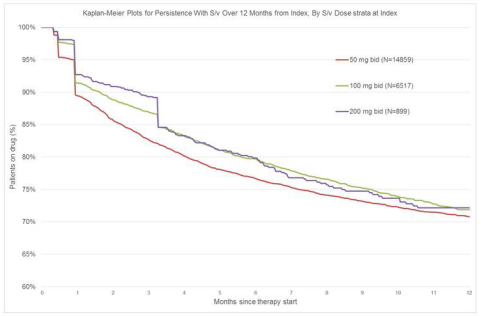
Background: The angiotensin receptor neprilysin inhibitor sacubitril/valsartan (s/v) was launched in Germany in January 2016 for the treatment of symptomatic heart failure (HF) with reduced ejection fraction.
Purpose: To characterize compliance and persistence in s/v patients in real-world clinical practice.
Methods: Patients with at least one s/v prescription (Rx) between January 2016 and June 2017 and 12 months pre-index activity (defined by any Rx every 6 months) were identified in the German longitudinal pharmacy database (IMS LRx), covering approximately 60% of all dispensed Rx from public health insured patients. The date of the first Rx was defined as index. Days' supply was defined as dispensed pack size/2, and discontinuation was defined as no new s/v Rx within 90 days after last days' supply. Compliance was calculated as the proportion of days covered (PDC). Persistence was estimated with Kaplan-Meier (KM) plots, implementing definitions as above, and additionally censoring at end of study period or after a 90 days gap of no activity in the database (any Rx). A multi-variate Cox-regression model was used to assess the association between patient characteristics and persistence.



Kaplan-Meier Plots

Results: A total of 22,275 adult patients (= 18 years) fulfilled the inclusion criteria. S/v persistence at 12 months from index was 71%. Among non-persistent patients, the majority discontinued s/v within the first 90 days. Furthermore, persistence at

12 months was similar across different s/v doses at index, while time to discontinuation was shorter for 50 mg bid at index compared to 100 and 200 mg bid at index. Multivariate analysis revealed that younger age, male sex, a higher index dose of s/v, baseline use of HF therapy, oral diuretics, novel oral anticoagulants and lipid-lowering drugs showed significant associations with higher persistence. Compliance was assessed in a subset of patients with at least 12 months follow-up data, defined as a minimum of one s/v Rx each during 6 months post-index and 7-12 months post-index (N = 8,226). High s/v compliance (PDC >80%) was observed. Compliance increased with the maximum dose reached by 6 months (PDC was 77% for 50 mg bid, 82% for 100 mg bid, and 85% for 200 mg bid). The same trend was observed for strata of s/v dose at index (PDC was 80% for 50 mg bid, 83% for 100 mg bid, and 85% for 200 mg bid).
Conclusion: Both persistence and compliance with s/v were high during the first year after index. The use of higher s/v dose was associated with increased compliance.

Funding Acknowledgements: Alnylam Pharamceuticals

Background/Introduction: Hereditary transthyretin-mediated (hATTR) amyloidosis is a rare, multi-systemic, progressive, fatal disease. Heterogeneous clinical presentation of hATTR amyloidosis includes sensory, motor and autonomic neuropathy, gastrointestinal symptoms and cardiac involvement resulting in substantial disease burden for patients impacting their quality of life (QOL). Patisiran, an investigational RNAi therapeutic, was evaluated in hATTR patients with polyneuropathy in the APOLLO study and resulted in a statistically significant improvement in the neuropathy (measured by modified neuropathy impairment, mNIS+7) and QOL (measured by Norfolk QOL-DN) scores compared to placebo and was generally well tolerated. To investigate cardiac involvement, APOLLO included a pre-defined cardiac subpopulation.
Purpose: Evaluate the impact of patisiran compared to placebo on Norfolk QOL-DN scores in the pre-defined cardiac subpopulation enrolled in the APOLLO trial.
Methods: APOLLO was a Phase 3 multi-center, international, randomized (2:1), double-blind, study of patisiran 0.3mg/kg or placebo IV q3W in patients with hATTR amyloidosis (NCT01960348). Pre-defined cardiac subpopulation included patients with baseline left ventricular (LV) wall thickness = 13mm and no medical history of aortic valve disease or hypertension. Norfolk QOL-DN, a secondary endpoint of the trial, assessed 5 domains: small fiber neuropathy, physical functioning/large fiber; autonomic neuropathy; activities of daily living; and symptoms. Scores for this QOL instrument range from -4 to 136 with a lower score indicating QOL improvement.
Results: APOLLO enrolled 225 patients, the cardiac subpopulation comprised 56% of the total population and had a mean age 61 years (54-67); 78% males; 27% V30M. Mean (95% CI) baseline Norfolk QOL-DN values for patisiran (n = 90) and placebo (n = 35) in the cardiac subpopulation were 61 (17,102) and 64 (5,119), respectively. In the cardiac subpopulation, patisiran treatment led to significant improvement relative to placebo in Norfolk QOL-DN at 18 months, with a LS mean (95% CI) decrease (improvement) compared to baseline of -3 (-7, 2) points in the patisiran group compared to an LS mean (95% CI) increase (worsening) compared to baseline of 20 (13, 28) points in placebo patients with an overall treatment difference (patisiran –placebo) LS mean (95%CI) -23 (-32, 14). Additionally, patisiran resulted in improvement across all domains relative to placebo. Detailed data will be presented.
Conclusions: These results show that treatment with patisiran improved QOL compared to placebo in hATTR amyloidosis patients with evidence of cardiac involvement. These results are consistent with the outcomes in the overall population, thereby demonstrating that patisiran provides clinical benefit to hATTR amyloidosis patients with both polyneuropathy and cardiomyopathy.

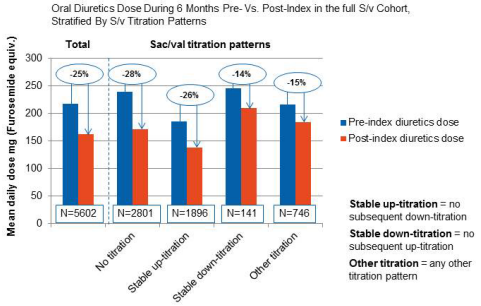
Funding Acknowledgements: Novartis Pharma AG

Background: The angiotensin receptor neprilysin inhibitor sacubitril/valsartan (s/v) was launched in Germany in January 2016 for the treatment of symptomatic heart failure with reduced ejection fraction.
Purpose: To characterize real-world concomitant use of beta-blockers (BB) and mineralocorticoid receptor antagonists (MRA) in s/v patients, and to describe the use of oral diuretics with different s/v titration patterns.
Methods: Patients with a first s/v prescription (Rx) between Jan 2016 and Dec 2016, and a minimum of 12months of pre-index data (first s/v Rx = index date), and at least one additional s/v Rx following index, were identified in the longitudinal pharmacy database (IMS LRx), covering approximately 60% of all dispensed Rx from public health insured patients. Prescriber specialty, s/v dose at index, and patient-level s/v titration patterns were analysed. The dose of the four most frequently prescribed oral diuretics (furosemide, torasemide, hydrochlorothiazide, and xipamide) was calculated and normalized per substance to the defined daily dose (DDD, WHO definition). The DDD per patient was calculated as dispensed DDD divided by the time until the next dispensation. Pre- and post-index doses were compared in patients with recorded pre-index diuretics. For calculations purposes, no post-index diuretic dispensation was defined as a dose of zero. For interpretation, DDD was transformed to the furosemide equivalent dose.
Results: A total of 10,556 adult patients (= 18 years old) fulfilled the inclusion criteria. Post-index use of BB was similar between general practitioner (GP) and cardiologist patients (84% vs 86%); while MRA use was lower in GP versus cardiologist patients (54% vs 63%).
Oral diuretics were dispensed in 77% of all s/v patients during the 6 months pre-index period compared to 73% in the 6months post-index ($p < 0.001$); 64% of all s/v patients had diuretics dispensed in both pre- and post-index, while 12% discontinued and 9% started diuretics after index. Post-index daily diuretic dose was 47% higher in GP patients compared to cardiologist patients ($p < 0.001$).
In the entire s/v cohort, the mean furosemide equivalent dose was 218mg during the 6 months pre-index and 163mg in the 6 months after index. Daily diuretic dose decreased from pre to post-index by 48mg (-26%) in patients up-titrated on s/v ($p < 0.001$), decreased by 67mg (-28%) in patients with no s/v titration ($p < 0.001$) and decreased by 35mg (-14%) in those who were down-titrated on s/v ($p = 0.003$)-Figure.
Conclusions: Concomitant use of BB and MRA remained high following s/v index. GPs generally prescribed less MRA and higher doses of oral diuretics than cardiologists. Lower diuretic doses and more frequent down-titration of diuretics after s/v index was observed in patients who were up-titrated on s/v compared with those who had s/v down-titrated. This suggests that an adjustment of oral diuretic doses may need to be considered during s/v initiation and titration.



Oral Diuretics Dose During 6 Months

On behalf of: The PCHF VAD-ICD/CRT Registry

Introduction: The role of multiple devices frequently implanted in patients with advanced heart failure requires further insight from diverse patient cohorts. We have formed a registry of ventricular assist device (VAD) carriers through a network of European heart failure centres, aiming to investigate the association between implantable defibrillator and all cause death in VAD recipients.
Methods: At current, the registry includes data on 246 patients with continuous flow LVADs (median age 56 (IQR 48-63), 83% male), 63% of which also received an ICD or CRT-D. We created a propensity score to determine the possibility of having an ICD/CRT-D. This was followed by a propensity score adjusted analysis to assess the relation of ICD or CRT-D device carrier status and the occurrence of the primary event of all-cause death. The median follow-up time was 1.3 years (IQR 0.4-2.0) from index date, defined as time of LVAD or ICD/CRT-D implant, whichever came later.
Results: The baseline characteristics varied significantly according to ICD/CRT-D carrier status (Table 1). The rate of all-cause death was significantly lower in ICD/CRT-D carriers (14.0 (9.8-19.9) vs 31.6 (22.8-43.8) per 100 patient-years) as was the crude hazard ratio for all-cause death (0.43 (0.27-0.71), p = 0.001). After propensity score adjustment for 17 baseline characteristics, the relative risk of all-cause death remained significantly reduced in ICD/CRT-D carriers (HR 0.30 (0.16-0.57), p <0.0001), even after additional adjusting for CRT-P carrier status (HR 0.27 (0.14-0.52), p <0.0001).
Conclusion: The initial results from our registry suggest that ICD/CRT-D might be associated with reduced all-cause death in VAD carriers.

Table 1.

	No ICD/CRT-D (N = 90)	ICD/CRT-D (N = 156)	Group P-value
Age at implant, years	50±13	56±10	<0.001
Male gender, n (%)	69 (76.7%)	134 (85.9%)	0.07
INTERMACS class 1, n (%)	24 (27.3%)	13 (8.4%)	<0.001
INTERMACS class 2, n (%)	24 (27.3%)	33 (21.3%)	
INTERMACS class 3, n (%)	19 (21.6%)	61 (39.4%)	
INTERMACS class 4-7, n (%)	21 (23.9%)	48 (31.0%)	
MCS prior to VAD, n (%)	40 (44.4%)	27 (17.3%)	<0.001
VAD type - HMII, n (%)	56 (62.2%)	66 (42.6%)	0.008
VAD type - HW, n (%)	16 (17.8%)	47 (30 3%)	
VAD type - HM3, n (%)	15 (16.7%)	41 (26.5%)	
VAD type - Other, n (%)	3 (3.3%)	1 (0.6%)	

Baseline characteristics of patients according to ICD/CRT-D carrier status.

Are there differences in the outcomes of ischemic and non-ischemic cardiomyopathy in the current era?

R Raed Odeh[1]; RO Odeh[1]; MK Alkhateeb[1]; MM Almallah[1]; AA Ahmad[1]; AH Ardah[1]
[1]King Abdulaziz Medical City, Riyadh, Saudi Arabia

Background: There has been conflicting evidence on whether the outcomes of ischemic (ICM) and non ischemic (NICM) exit. While older studies suggested the ICMP have worse outcomes, recent data suggest that the outcomes may be the same. The aim of this analysis is to explore the differences between ICM and NICMP in a well-treated contemporary cohort with heart failure with reduced ejection fraction (HFrEF).
Methods: A post hoc analysis of 2,805 (HFrEF) patients (Mean age 57.4, 70% females) were included. ICMP was defined HFrEF in the presence of obstructive coronary artery disease or myocardial infarction. Patients were followed up for a median duration of 4.4 years for all cause mortality.
Result: A total of 1,675 patients had ICM while 1,130 patients had NICMP. Patients with ICMP were older, more often females, with higher prevalence of hypertension, diabetes, and dyslipidemia. NICMP patient had lower ejection fraction (33.6 ± 8.7 vs. 31.5 ± 11.1, p= <0.0001). Patients with NICMP were more often treated with beta blocker and aldactone, with no differences in ACEI/ARB. After a median follow-up duration of 4.4 years, 436 patients died (147(14.7%) in the NICMP and 289 (18.86%)in the ICMP). After adjusting for confounders, including differences in medical therapy, ICMP was associated with increased risk of all-cause mortality (Hazarad ratio 1.62, 95% CI 1.32-2.04)
Conclusion: In the current era, ischemic cardiomyopathy continues to be associated with worse outcomes. This may be partially attributed to differences in medical therapies'.

1548

Noninvasive recognition of experimental cardiac allograft rejection by molecular targeting of apoptotic process with radiolabeled duramycin in vivo

M Adapoe[1]; A Petrov[1]; F Chaudhry[1]; N Narula[1]; B Gray[2]; Y Pak[2]; HW Strauss[1]; P Heeger[1]; J Narula[1]
[1]Icahn School of Medicine at Mount Sinai, New York, United States of America; *[2]Molecular Targeting Technologies Inc, West Chester, United States of America*

Background: Myocardial apoptosis, a cellular death process distinctly different from the cellular necrosis has been described as an obligatory component of moderate and severe cardiac allograft rejection (CAR) in addition to interstitial inflammation. In clinical practice, CAR is universally detected by an invasive endomyocardial biopsy repeated at least 10-12 times in the first year after heart transplantation. Therefore, the importance of a noninvasive test can hardly be overstated.
Objective: Since apoptosis almost always accompanies CAR, and offers cell membrane signatures of the death process in form of asymmetric exposure of phosphatidylserine and phosphatidylethanolamine (PE), we evaluated the usefulness of radiolabeled PE-targeting agent- Technetium-99m-labeled duramycin (D) by microSPECT/CT imaging.
Methods: 16 mice received abdominal heterotopic cardiac allografts in 4 groups of 4 animals each. Group 1: BALB/c (H-2d) donor to B6 (H-2b) recipient (allogeneic transplant, ALO). Group 2: B6 donor to B6 recipient (syngeneic control transplant, CON). Group 3: BALB/c donor to B6 recipient treated with CTLA4-IG (allogeneic transplant and immunosuppressed, IMS). Group 4: Bm12 H-2bm12) donor to B6 recipient (class II MHC disparate transplant to test for chronic CAR, CHR). ALO and CON were sacrificed 6-7 days following transplant. IMS animals were sacrificed 14-15 days following transplant. CHR animals were sacrificed 21 days following transplant (all grafts were beating at the time of harvest). MicroSPECT/CT imaging of the heterotopic transplant was performed in vivo and ex vivo after intravenous D administration. The transplant was collected for quantitative injected dose/gram uptake (%ID/g) of radiotracer. Hearts were then pathologically characterized using the ISHLT grading rubric.
Results: The in vivo and ex vivo imaging, and the quantitative uptake (expressed in mean %ID/g ± SD) of the radiotracer demonstrated the most intense uptake in ALO (5.8 ± 2.2 %ID/g), followed by CHR (1.8 ± 1.5 %ID/g), then IMS (1.2 ± 0.4 %ID/g), and finally CON (0.90 ± 0.04 %ID/g). One-way ANOVA with Tukey post-hoc test revealed ALO had significantly higher uptake than that of the CON and IMS groups ($P < 0.05$). Pathology demonstrated ISHLT Grade 3R rejection in ALO (3 out of 4 animals), no rejection in CON and Grade 1-2R in IMS and CHR groups. Chronic vasculopathy was also observed in the CHR group.
Conclusion: Noninvasive molecular imaging of apoptosis in CAR is feasible with radiolabeled D, which can identify various shades of graft rejection verified by histopathological characterization.

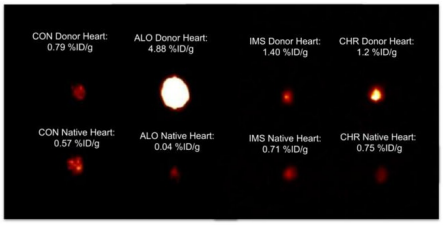

Figure 1. Ex vivo SPECT imaging of hearts are shown with their respective uptake values (%ID/g). Top row contains heterotopic donor transplanted hearts. Bottom row contain native recipient hearts

Surfactant proteins changes after acute hemodynamic improvement in patients with advanced chronic heart failure treated with levosimendan

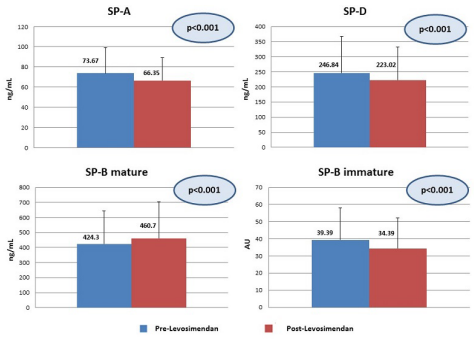
M Mapelli[1]; J Campodonico[1]; C Banfi[1]; E Spadafora[1]; E Salvioni[1]; C Vignati[1]; S Sciomer[2]; A Del Torto[1]; F Nicoli[1]; N Corrieri[1]; M Contini[1]; PG Agostoni[1]
[1]Cardiology Center Monzino IRCCS, Milan, Italy; *[2]Sapienza University of Rome, Rome, Italy*

Background: Alveolar-capillary membrane diffusion evaluated by carbon monoxide diffusion (DLCO) plays an important role in heart failure (HF). Cardiopulmonary exercise test (CPET) is a powerful diagnostic and prognostic tool in this context. Surfactant Proteins (SPs) have also been suggested as a worthwhile marker in these patients. In HF, Levosimendan improves cardiopulmonary hemodynamics and reduces lung fluids but associated SPs and DLCO changes are unknown.

Tab1

	Pre-Levosimendan	Post-Levosimendan	p value
Hemoglobin	12.91±1.93	12.44±1.77	ns
BUN (mg/dl)	78.14±36.43	75.14±34.33	ns
Creatinine (mg/dl)	1.55±0.55	1.51±0.56	ns
BNP (pg/ml)	1277.06±994.02	578.03±591.01	<0.01
Peak VO2 (ml/Kg/min)	10.07±2.36	11.50±2.30	<0.01
Watts	44.45±18.29	51.15±18.34	<0.01
VO2/work slope	8.99±1.87	9.64±1.51	<0.01
VE/VCO2	41.98±9.86	36.36±7.13	<0.01
FEV1 (L)	2.09±0.56	2.26±0.63	<0.01
DLCO (mL/mmHg/min)	18.00±4.51	17.74±4.06	ns

Laboratory, spirometry and CPET changes



SPs changes after Levosimendan infusion

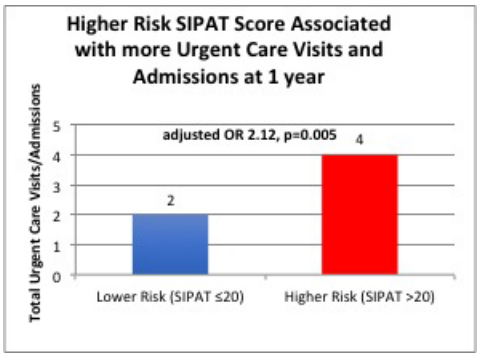
Purpose: To show changes in serum SPs values and in CPET parameters after Levosimendan administration in patients with advanced HF.
Methods: Sixty-five advanced HF patients (NYHA class III/IV, VO2 = 12 underwent complete spirometry, CPET and SPs determination before and after Levosimendan infusion.
Results: Levosimendan caused a significant natriuretic peptide-B (BNP) reduction (from 954 to 370 ng/ml*), peakVO2 increase (from 10.1 ± 2.4 to 11.5 ± 2.3 mL/kg/min*) and VE/VCO2 slope reduction (from 42 ± 10 to 36 ± 7*) (* = p < 0.01, Tab.1). FEV1, FVC and alveolar volume increased but DLCO did not. SP-A, SP-D and immature SP-B reduced while mature SP-B increased (Fig.1). Spirometry, BNP and CPET changes suggest an hemodynamic improvement and lung fluid reduction after inotropic drug infusion. In parallel SP-A, SP-D and immature SP-B reduction indicates an alveolar-capillary membrane hemodynamic and general inflammatory stress reduction. Conversely, mature SP-B increase suggests an alveolar cell function restoration.
Conclusions: Levosimendan improves VO2 peak, decreases VE/VCO2 slope and decreases plasma levels of BNP. Hemodynamic improvement and acute lung fluid reduction is associated with SPs but not DLCO changes. SPs are fast responders to alveolar-capillary membrane condition changes.

1552

Stanford integrated psychosocial assessment for transplantation scores track with intermacs profile and predict readmissions in patients undergoing left ventricular assist device implantation

M Matthew Cagliostro[1]; A Bromley[1]; P Ting[1]; J Donehey[2]; K Parks[2]; E Palumbo[2]; D Mancini[3]; A Anyanwu[1]; A Pawale[1]; S Pinney[3]; N Moss[3]; A Lala[3]
[1]Mount Sinai School of Medicine, New York, United States of America; *[2]Mount Sinai Medical Center, New York, United States of America*; *[3]The Zena and Michael A. Wiener Cardiovascular Institute, New York, United States of America*

Background: Psychosocial assessment is integral to evaluation of advanced therapies in patients with end-stage heart failure. The Stanford Integrated Psychosocial Assessment for Transplantation (SIPAT) is a standardised tool used to predict outcomes in heart transplantation but is not established for utility in patients undergoing left ventricular assist device (LVAD) implantation.
Purpose: To determine the association of SIPAT scores, demographics and INTERMACS profiles in patients undergoing LVAD implantation as well as to explore the relationship between SIPAT scores and outcomes post LVAD.
Methods: SIPAT assessments are routinely performed for patients undergoing LVAD evaluation at Mount Sinai Hospital. Data were collected for consecutive patients implanted from January 2014 through December 2016. Baseline characteristics were evaluated for all patients and compared based on SIPAT scores = 20 (excellent or good candidates) versus >20 (minimally acceptable or high-risk candidates). Outcomes included urgent visits or readmission, death, and adverse events, and were adjusted for age and INTERMACS profile.



Results: During the study period, 111 patients (26% female, 39% white, 66% INTERMACS profile = 3) were implanted with an LVAD and had SIPAT scores available for analysis. The median SIPAT score was 12 (SD 9.95, IQR 8-20), with most patients categorised as excellent or good (77%, n = 85). Higher risk (SIPAT>20) and lower risk (SIPAT = 20) patients were similar in age, gender, ethnicity and medical history, but INTERMACS profiles were significantly different. The higher risk SIPAT group had a greater proportion of INTERMACS profiles 1 and 2 (p = 0.03). At 1-year post LVAD implant, 22 patients were transplanted, and 68 patients experienced an adverse event, including 12 deaths. Higher risk patients had more urgent visits and admissions (4 vs 2, p = 0.005) with a trend towards spending a greater number of days in hospital over 1 year (27 vs 14, p = 0.08) compared to lower risk patients. This difference persisted after adjusting for INTERMACS profile and age (OR 2.12, 95% CI 1.26 - 3.6). There was no significant between group difference in adverse

events of pump thrombosis, gastrointestinal bleeding, right heart failure, arrhythmia, cerebrovascular events or survival. However a trend towards more infections in the higher risk SIPAT group was observed (52% vs 31%, p = 0.06).
Conclusions: Higher psychosocial risk as measured by SIPAT score > 20 was more frequently associated with INTERMACS profiles 1 and 2 compared to lower risk patients. High SIPAT scores were also associated with more frequent urgent visits and readmissions, with a trend towards greater number of days in hospital and more infections at 1-year post VAD implantation. SIPAT scores may help identify patients in need of additional LVAD management assistance in the outpatient setting.

1553
What happened to patients being listed for Heart Transplantation who did not arrive to Transplantation? Reasons for coming out of the waiting list and long term follow-up

M A Castel Lavilla[1]; M Farrero[1]; A Garcia[1]; E Santiago[1]; F Perez-Villa[1]
[1]*Hospital Clinic de Barcelona, Cardiology Department, Barcelona, Spain*

Introduction and Objectives: Waiting time for patients listed for Heart Transplantation (HTx) has been steadily increasing in Spain. There are registers of patients dying in the waiting list but there is little information about patients coming out of the waiting list for other reasons. The objective of this study is analyzing all patients delisted after being listed for HTx, the reason for delisting and their outcomes after long follow-up.
Methods: We investigated all patients from a single center officially listed for HTx in Spain between January 2000 and March 2017. Date entering and date leaving the waiting list were recorded. We investigated reasons for delisting, basal characteristics and mortality at long term. Data of follow-up was obtained in 99% of patients through the hospital records or by the region's shared medical history.
Results: From a total of 399 patients who were listed for Htx, 310 patients reached transplantation and 89 patients were delisted without reaching HTx. Mean age of patients was 54.6 ± 12.6 yrs (12-70 yrs), 82.2% males. Cause of exclusion was death while listed in 31 pat. (34.8%; 7.8% of total), clinical worsening in 31 (34%; 7.8% of total), clinical improvement in 26 (29%; 6.5%) and patient's wish to leave in 2 patients (2.2%; 0.5%). Mean waiting time in list was 123 ± 187 days, after a median follow up of 189 days (IQR 18, 741 days) 76% of patients who came out of list died. Total mortality of patients who were excluded because of clinical worsening was 89.6% and from patients with clinical improvement was 38.5%. From all patients excluded 60% were on elective list, 29% in Urgency status 0 and 10% in Urgency status 1. Total mortality was associated to time in waiting list (p < 0.001) but there was no relationship to urgency status, age, size or time of transplantation.
Conclusions: In our experience mortality of patients awaiting Htx is underestimated. Most patients leaving the waiting list due to clinical worsening died, also an important percentage of patients who improved and were delisted died at long term. Most of patients who left the list were on elective urgency status.

Funding Acknowledgements: Corvia Medical

Background: HFpEF is one of the most challenging disorders in contemporary cardiology. The pathophysiology is complex. Impaired LV diastolic function leading to elevated LA pressures, particularly during exertion, is a key driver of symptoms and outcomes. To date pharmacologic therapies have been primarily ineffective. A mechanical approach (interatrial shunt device, IASD) to reducing LA pressures in HFpEF patients by LA decompression has been shown to be safe and to be associated with short-term hemodynamic and symptomatic benefit. The effects of IASD placement on HFpEF survival and heart failure hospitalization (HFH) in the intermediate to longer term is unknown.
Methods: HFpEF patients (n = 64) participating the REDUCE LAP-HF trial (Corvia Medical) of an IASD were followed for up to 3 years post IASD implant (median 739 days). An invasive rest and exercise hemodynamic assessment was included in the assessment for trial eligibility. The theoretical impact of IASD implantation on HFpEF outcomes was investigated by estimating the survival probability of the study cohort at baseline using the MAGGIC score. Observed and predicted survival curves were compared over the follow-up period using a log rank test. Baseline and post IASD implant parameters associated with HFH were also investigated.
Results: Based upon the baseline clinical and demographic HF features of the cohort, the MAGGIC score predicted mortality rate of the cohort 10.2/100pt years compared with an observed rate of 3.4/100pt years, representing a 33% lower rate (p = 0.02). By Kaplan Meier analysis, observed survival in IASD patients was greater than predicted (p = 0.014). For patients experiencing a HFH event, first hospitalization events occurred at a median of 182 days post IASD. Baseline parameters were not predictive of future HFH, however post IASD a poorer exercise tolerance (6 minute walk distance: 312 ± 23 vs 375 ± 14m, p <0.05) and higher workload corrected exercise pulmonary capillary wedge pressure (94 ± 13 vs 60 ± 5 mmHg/(W/kg), p <0.05) were associated with HFH.
Conclusions: The current study suggests IASD implantation may be associated with a reduction in mortality in HFpEF. Large scale ongoing randomized studies are required to confirm this finding.

Prognosis of patients with cardiac amyloidosis referred in the French national referral Centre for Cardiac Amyloidosis

D Bodez[1]; M Kharoubi[1]; A Galat[1]; S Guendouz[1]; S Rouffiac[1]; J Badie[1]; V Plante-Bordeneuve[2]; A Amiot[3]; C Radu[4]; F Le Bras[5]; L Hittinger[1]; T Damy[1]
[1]*University Hospital Henri Mondor, Cardiology & Amyloid Research Institute, Creteil, France*; [2]*University Hospital Henri Mondor, Neurology & Amyloid Research Institute, Creteil, France*; [3]*University Hospital Henri Mondor, Gastroenterology & Amyloid Research Institute, Creteil, France*; [4]*University Hospital Henri Mondor, Cardiac Surgery & Amyloid Research Institute, Creteil, France*; [5]*University Hospital Henri Mondor, Lymphoid Malignancies unit & Amyloid Research Institute, Creteil, France*

Funding Acknowledgements: APHP & AREMCAR

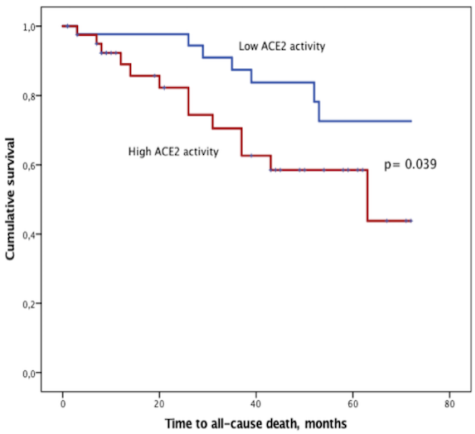
Background: Cardiac amyloidoses (CA) are distinct diseases caused by the extracellular infiltration of the myocardium by different types of amyloid proteins (immunoglulin, transthyretin...). The most frequent CA are light chain (AL) amyloidosis, hereditary transthyretin (TTR-h) and wild-type transthyretin (wt-TTR).
Aim: To describe baseline clinical, biological, echocardiographic characteristics and prognosis of patients referred for suspicion of CA in the French National Referral center for CA.
Methods: From 2010 to July 2016, all patients referred for suspicion of CA were included. Baseline demographic, clinical, laboratory and ultrasound characteristics were recorded. Patients were followed-up for major events (MACE) including death, cardiac transplantation and left ventricular assistance implant.
Results: Of the 942 patients referred for suspicion of CA, 502 had confirmed CA of whom 162 had AL amyloidosis, 203 h-TTR and 141 wt-TTR. CA were men in 60%, the median age was 69 years w-TTR amyloidosis were older (83 [79; 87], p < 0.001) and more men (86%, p < 0.001) than the two other types of CA. NYHA III-IV dyspnea was more frequent in AL amyloidosis (60%) and wt-TTR (54%, p < 0.001) compared to h-TTR, while neurological symptoms were more predominant in h-TTR (62% p < 0.001). Creatinine, NT-proBNP and troponin were higher in AL amyloidosis and w-TTR (p < 0.001) than in h-TTR. Wt-TTR amyloidosis had thicker Interventricular septum thicker, lower LVEF, higher global strain E/A and E/Ea ratios than other groups. During a median follow-up of 22 (8;36) months, 137 major events occurred. The survival without MACE was 59% for AL amyloidosis, 79% for w-TTR, 81% for h-TTR versus 88% for patients without amyloidosis (p < 0.001). In multivariate analysis (including only CA), NYHA class III-IV, hyponatremia, elevation of creatinine, troponin and NTproBNP were independent prognostic factors (p < 0.001).
Conclusion: Cardiac amyloidosis is more frequent than initially thought, with very different layouts depending on the type of amyloid protein involved, and a poor prognosis. The challenge is to achieve earlier diagnosis to improve prognosis.

1556
Angiotensin based biomarkers predict outcome in HFpEF-patients

C Binder[1]; M Poglitsch[2]; FD Duca[1]; C Zotter-Tufaro[1]; AAK Kammerlander[1]; SA Aschauer[1]; C Nitsche[1]; J Mascherbauer[1]; DB Bonderman[1]
[1]*Medical University of Vienna, AKH - Vienna, Cardiology Clinic, Vienna, Austria*; [2]*Attoquant Diagnostics, Vienna, Austria*

Background: The importance of the renin-angiotensin system (RAS) on the development and progression of heart failure (HF) has been studied extensively. In patients with HF with reduced ejection fraction (HFrEF), inhibition of angiotensin-converting enzyme (ACE) is an effective treatment strategy, not only by reducing Angiotensin II (Ang II) but also by increasing its metabolites Ang 1-7 and Ang 1-5 which are produced via ACE2 action and mediate cardio-protective effects. In contrast, studies

have failed to show benefits of RAS inhibiting (RASi) therapy in patients with HF with preserved ejection fraction (HFpEF).
Purpose: We aimed to investigate the RAS profiles of HFpEF patients to gain more insight into the
pathogenesis and to evaluate the prognostic impact of RAS metabolites in this disease.
Methods: Consecutive patients were included in a prospective registry at our dedicated HFpEF outpatient clinic at the Medical University of Vienna. Baseline parameters were assessed and serum samples analyzed by RAS-Fingerprint (Attoquant, Vienna Austria) using mass spectroscopy to quantify equilibrium angiotensin levels for each patient. The sum of Ang 1-7 and Ang 1-5 was calculated as a surrogate for ACE2 activity and patients were then stratified into tertiles. The lowest tertile was compared to the highest tertile regarding baseline characteristics and the primary outcome variable, all-cause death.
Results: RAS-Fingerprint analysis was performed in serum samples of 137 HFpEF patients. 26 patients were only on ACE inhibitors, 94 patients were treated with other RASi and 17 patients did not receive RASi. Notably, baseline parameters associated with advanced disease progression were associated with higher Ang 1-7 levels. During a mean follow- up time of 135 ± 23.6 months, 22 patients (16.1%) died. Of these, 11 (50.0%) patients died of cardiac causes. Univariate Cox regression analysis identified the ACE2 surrogate marker as a predictor for all-cause death with a hazard ratio of 1.005 (95% CI 1.002-1.008), p= 0.005), and remained predictive even after adjusting for common risk factors including age, N-terminal pro-brain natriuretic peptide and glomerular filtration rate (HR 1.005 (95% CI 1.002-1.008), p = 0.004). Furthermore, we found that higher plasma renin was associated with worse outcomes, indicating a higher RAS activity in patients with advanced HF, independent of ACEi therapy (HR 2.781 (95% CI 1.364-5.670), p= 0.005).
Conclusion: We hypothesize, that much like NT-proBNP, ACE2 activity is enhanced in progressive HF to counteract the detrimental effects of Ang II. Angiotensin based biomarkers not only serve as predictors of outcome in patients with HFpEF but also give insight into the individual state of the RAS, which in turn could potentially identify patients who would benefit from RAS inhibiting therapies. Furthermore, it could help characterize patients with respect to therapeutic response for future recombinant ACE2 treatment strategies.



All-cause death according to ACE2 activt

1557

Cardiogenic shock and acute coronary syndrome: could the vascular access influence our patients outcome?

H Miranda[1]; I Almeida[1]; C Sousa[1]; D Mesquita[1]; S Almeida[1]; J Chin[1]
[1]*Centro Hospitalar Barreiro Montijo, Cardiology, Barreiro, Portugal*

On behalf of: Portuguese National Registry of Acute Coronary Syndromes

Introduction: Cardiogenic shock (CS) is the leading cause of death in patients with acute coronary syndrome (ACS), with a 70-90% mortality rate in the absence of early intervention. It's crucial to ensure rapid revascularization, since hospital mortality increases with waiting time until reperfusion.
Objectives: To determine if vascular access (femoral versus radial) for percutaneous coronary intervention (PCI), in patients admitted with CS, had an influence on the outcome.
Material and Methods: Retrospective study, based on the Portuguese National Registry of Acute Coronary Syndrome (ACS), from 10/10/2010 to 19/09/2017. All patients admitted for CS in the context of ACS were selected. Exclusion criteria: Killip class I-III, lack of information on coronary angiography and vascular access.
Results: The initial pool was comprised of 318 patients with ACS. After applying the exclusion criteria, only 258 ended up being included. Male predominance (65.1%). Mean age 68 ± 13 years. Hypertension (69.8%), diabetes (50.2%) and dyslipidaemia (32.1%) were the most frequent comorbidities. 68.24% of the included patients had a diagnosis of ACS with elevation of the ST segment. Mean time symptoms-reperfusion and 1st medical contact-reperfusion contact of 319 and 148 minutes, respectively. PCI was performed, using the femoral access, in 62.02% of the cases.
We found out a greater use of intra-aortic balloon and temporary pacemaker in patients with femoral access (p-value of 0.039 and 0.001, respectively), as well as a higher prevalence of atrioventricular block and hospital death (p-value 0.002 and 0.001, respectively) when compared to radial access. We also found out that the main predictors of death in CS were age over 65 years, haemoglobin above or equal to 12mg / dl, cardiac arrest as the predominant symptom, right bundle branch block on admission's electrocardiogram, hospital medication performed (ACEI, statin and inotropes) and left ventricular function < 40%. There was no significant association between type of access and hospital death (OR 0.51, CI 0.16-1.68, p-value 0.270).
Conclusion: Early and definitive restoration of coronary blood flow is the standard therapy in patients admitted for CS in the context of myocardial ischemia. According to our findings, the vascular access had no impact on mortality in this type of patients.

Clinical Case Corner 5 - New treatments and interventions on the horizon

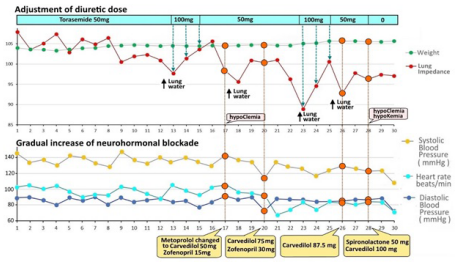
Lung impedance as a sensitive non-invasive tool for home monitoring of lung water in the vulnerable phase

E Paleviciute[1]; E Lycholip[1]; IT Aamodt[2]; I Lie[2]; J Celutkiene[1]
[1]Vilnius University Hospital Santaros Clinics, Clinic of Cardiac and Vascular Diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania; [2]Oslo University Hospital, Centre for patient centered heart and lung research, Department of Cardiothoracic surgery, Oslo, Norway

On behalf of: The Symptom Monitoring After CongeStive Heart Failure study
Funding Acknowledgements: This research was supported by NordForsk. "Nordic Programme on Health and Welfare" Project no.: 76015.

Clinical problem: A key factor in the management of heart failure (HF) patients is an accurate assessment of volume status. The sensitivity of transthoracic impedance (TI) to monitor pulmonary congestion in an individual patient was previously questioned. Recently it has been shown, that the use of a high sensitive non-invasive device measuring lung impedance (LI) reduces hospitalizations for HF and cardiovascular and all-cause mortality. We present a case 1-month follow up of the patient discharged after an episode of acute HF using home LI measurements.
Technique for patient monitoring
Edema guard monitor is based on an algorithm calculating the chest wall impedance that is a preponderant component of the total electrical TI. Subtraction of the chest wall impedance from the latter yields the net LI, which composes only a small fraction of the overall TI. Decreasing LI values represent increase of lung fluid. Measurements are done using 3 electrodes on each side of the chest wall. Before discharge the patient and his caregivers were trained to perform measurements of LI values, arterial blood pressure, heart rate and reported these data to HF nurse by a call or SMS daily.



Case description: A 62-year old man with chronic ischemic HF with reduced ejection fraction was hospitalized due to deterioration accompanied by dyspnea, fatigue, feet edema. On the electrocardiogram paroxysms of ventricular tachycardia were seen, led by cold sweat and extreme weakness. During 17 hospitalization days the patient was treated medically, a biventricular defibrillator was implanted. Medications on discharge included metoprolol 100 mg b.i.d., spironolactone 25 mg q.d., zofenopril 7,5 mg q.d., amiodarone 200 mg q.d., torasemide 50 mg q.d., anticoagulation with warfarin; discharge LI value was 107.9. During 1 month after discharge treatment has been adjusted 6 times. Decrease of LI by -9% and -18% compared with baseline LI twice was treated increasing the dose of torasemide. According to heart rate and arterial blood pressure, dosage of beta-blockers and ACE inhibitors were up-titrated 3 and 2 times, respectively. Laboratory assessment of creatinine and electrolytes was performed 3 times, twice diuretic dose was not raised as hypochloremia and hyponatremia was detected, despite decrease of LI values. In 30 days patient's weight fluctuated between 103.3-105.7 kg. In 4 days, when LI decreased most, weight increased by average 200 g (0.2%), compared with the previous day. After 30 days, patient's status improved compared with the discharge - NT-proBNP level decreased (2061 vs 3485 ng/l), left ventricular ejection fraction increased (28 vs 20%), estimated pulmonary capillary wedge pressure decreased (16.5 vs 20.6 mmHg).
Conclusion: Significant fluctuation of lung water amount is registered by high sensitive LI measurements. Non-invasive daily monitoring of lung impedance seems to be an important component of successful transition from acute to stable phase of HF.

1559

Frailty syndrome: the same age does not mean the same health status

MH Lisiak[1]; I Uchmanowicz[1]
[1]Wroclaw Medical University, Department of Clinical Nursing , Wroclaw, Poland

Introduction: Frailty syndrome (FS) is a multidimensional problem associated with high dependency and mortality rate. The evidence shows that early identification of FS can improve management and outcomes in elderly patients. The relationship between age and frailty is not completely understood. Individuals of the same chronological age vary in terms of their biological age, which depends on the stage of aging processes and the number of co-morbidities. Multiple conditions in a frail person can trigger physical, psychological or social decline.
Case report description: A multidimensional FS assessment was carried out in two women (WA and WB) of the same age (70 y/o) hospitalized in Intensive Cardiac Unit. Data (ICU) on pre-existing diseases and test results were obtained from medical records. Both of them were widows, supported by their children. WA did not work while WB was still professionally active. The women differed in the some aspects. WA had many co-morbidities, such as: chronic heart failure (HF), NYHA III/IV (with triple decompensation in 2017), hypertension, diabetes type 2, chronic kidney disease, arrhythmias, history of heart attacks (PCI treatment and ultimately CABG in 2006). On admission due to decompensation of HF and heart attack she complained of cardiac symptoms, shortness of breath, dizziness and reduced exercise tolerance. In turn, WB was admitted to the ICU due to acute coronary syndrome (ACS) STEMI (stenocardial pain lasted only for an hour) and the only with dyslipidemia and kidney stones. She did not complain of any pain but sometimes she felt anxiety associated with hospitalization. The following screening tools were used: Mini Mental State Examination (MMSE) for cognitive function (CF), Tilburg Frailty Indicator (TFI), Edmonton Frail Scale (EFS), FRAIL scale (FSc) for FS, WHOQOL-Bref for quality of life (QoL), EPWORTH scale (ES) for sleep problems and Center for Epidemiologic Studies Depression Scale (CES-D) for depressive symptoms (DS). The results obtained by the women (A and B, respectively) were as follows: MMSE (pts): 24 (cognitive impairment (CI)) vs. 28 (no CI); TFI (pts): 11 (FS) vs. 1 (no FS); EFS (pts): 10 (moderate FS) vs. 1 (no FS); FSc (pts): 4 (FS) vs. 0 (robust); ES (pts): 15 (moderate excessive) vs. 3 (lower normal) daytime sleepiness; CES-D (pts): 27 (DS) vs. 10 (no DS). In all QoL domains, WA chose the poor or neither satisfied nor dissatisfied answers, while WB always reported good or very satisfied QoL.
Conclusions: All the scores in all the measures revealed that woman A had CI with FS, poor QoL and high DS while woman B had no FS, proper CF, good QoL and no DS. The comparison confirmed that the same age does not have to mean that two different patients are at the same level of multiple biopsychosocial decline. Only a multidisciplinary approach and frailty screening tools in acute care can be useful in identifying FS, planning complex assessment, creating appropriate care plan and discharge.

Progressive heart failure in patient with ccTGA after double switch operation performed in early adulthood.

M Marketa Hegarova[1]; J Vrbska[1]; V Melenovsky[1]; I Malek[1]; J Pirk[2]
[1]Institute for Clinical and Experimental Medicine (IKEM), Department of Cardiology, Prague, Czech Republic; [2]Institute for Clinical and Experimental Medicine, Department of cardiovascular surgery, Prague, Czech Republic

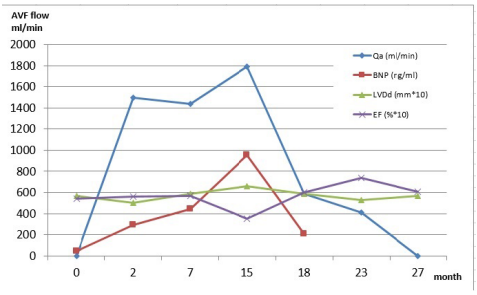
Introduction: Anatomic repair of congenitally corrected transposition of the great arteries (ccTGA) , a double switch operation (venous switch and great vessel switch wherein morphologic left ventricle (MLV) becomes the systemic ventricle) is considered to be superior procedure in order to improve patients' long term outcome. The late retraining of MLV is very controversial because of different response of an immature growing myocardium and matured myocardium to increased pressure overload. Aim: Presentation of the case with a fast progression of heart failure after double switch for ccTGA who was succesfully treated by heart transplantation.

Case report: Female 18 years old (born 1998) with ccTGA. From 2010 she was treated at a foreign heart clinic where the pulmonary artery banding was performed twice (2010, 2011, in age 12 and 13 years) for MLV retraining. She received DDD pacemaker due to complete AV block. Although the pt was doing well, in May 24, 2016 double switch operation was there performed. Immediately after the surgery, the MLV function deteriorated considerably, followed by a slight improvement after six weeks. Despite complete pharmacotherapy, chronic heart failure developed. In August 2016 she was hospitalized twice for severe decompensation with need for levosimendan treatment in the Children's Heart centre Motol university Hospital in Prague Czech Republic. In September 16, 2016 she was referred to our institution as heart transplant candidate. Upon admission she had signs of advanced heart failure, tachycardia, gallop, signs of malnutrition, BMI 14,5, severe systolic dysfunction of the MLV with mild mitral regurgitation and moderate dysfunction of right ventricle. Despite intensive pharmacotherapy she developed terminal heart failure requiring combined inotropic therapy. A successful heart transplantation (OHTx) was performed in October 7, 2016, 18 weeks after the double switch operation. Due to increased gradient on superior vena cava has been extended by CorMatrix patch two days later.
On standard immunosuppressive prophylaxis (MMF, tacrolimus, prednisone) graft function remains normal. Only one episode of cellular rejection was detected by protocolar endomyocardial biopsy without the need for antirejection therapy. Coronary angiography findings were normal one year after OHTx. Nowadays (1/2018) pt is doing well, she is in good clinical condition.
Conclusion: Despite the retrained MLV the double switch operation in ccTGA in early adulthood is very risky. We present a case of very rapid development of MLV dysfunction after the procedure with subsequent progressive deterioration, which resulted in terminal heart failure despite intensive pharmacotherapy.

1561
The role of arteriovenous fistula flow on heart failure in a dialysis patient

J Jan Malik[1]
[1]*Charles University, 1st Faculty of Medicine , Prague, Czech Republic*

Introduction: Creation of arteriovenous fistula (AVF) as the dialysis access leads to a low-resistance circuit with substantial increase in flow volume (Qa). Typical Qa values reach 500-1500 ml/min, but cases with significantly higher values are not rare and usually are well tolerated. Heart failure and pulmonary hypertension represent possible complications due to increased demands on cardiac output. Heart failure is very common in end-stage renal disease patients due to many mechanisms. Safe values of Qa are still a matter of debate.
Case: Here is presented a case of a 52-years old hemodialysis patient (due to polycystic kidney disease) with no prior cardiovascular history, who was cardiologically examined in detail repeatedly. She tolerated the creation of vascular access well. Later the increase in Qa led to the increase of BNP and to the dilatation of the left ventricle - see the Graph. Otherwise, the only echo abnormity was concentric left ventricular hypertrophy.
Graph legend: Qa = AVF flow volume; LVDd = left ventricular end-diastolic diameter (the values in mm times 10 to make them better visible); EF = left ventricular ejection fraction (% multiplied by 10 to make them better visible)
First examination was performed before AVF creation (far left). The surgery resulted in asymptomatic increase of BNP. After 15 months the patient experienced symptoms of heart failure –Qa rose to 1800 ml/min, which was mirrored by further increase of BNP, with left ventricular dilatation and decrease of its systolic function. AVF banding (arrow) reversed the signs and symptoms. AVF thrombosis developed after another 9 months. Thus, safe Qa was below 1500 ml/min in this patient.
Conclusion: This case documents individual toleration of Qa. Calculation of Qa should be a part of cardiological examination of dialysis patients with heart failure. Even usual Qa values can be too high for individual patients.



Graph

1562
MitraClip in a refractory heart failure patient: last but not the least

L Zamfir[1]; D Botezatu[1]; D Benea[1]; G Cerin[1]; M Hakimpour[1]; G Musica[1]; M Diena[1]; L Laudisa[2]
[1]*San Gaudenzio Clinic, Cardiothoracic Surgery, Novara, Italy*; [2]*San Gaudenzio Clinic, Novara, Italy*

Background: MitraClip procedure may improve clinical status in heart failure patients. Moreover, in case of recurrent hospitalization this procedure is of financial benefit.
Purpose: This is a case report of a successfully MitraClip treatment in a patient with numerous hospitalizations for heart failure and one last episode of decompensation refractory to medical treatment.
Methods: a 84 years old female patient that suffered numerous hospitalizations for heart failure. She had a history of a lateral miocardial infarction (1980) and severe residual systolic dysfunction (EFVS 30%). For the primary prophylaxis a cardiac defibrilator was implanted. The attempt to CRT upgrading was unsuccessfull because of the coronary sinus anatomy. Five years ago she had an acute pulmonary edema and was diagnosed with severe functional mitral insufficiency. Although she had frequent hospital recoveries under optimal medical therapy no additional treatment was considered so far. The patient was hospitalized in our Clinic for cardiogenic shock (NYHA IV functional class) that needed CPAP and inotropic therapy support (Levosimendan). The transthoracic echocardiogram showed dilated left ventricle (end diastolic volume 220 ml, 130 ml/m^2) with severe systolic dysfunction (FEVS 15%), severe functional mitral insufficiency and associated pulmonary hypertension (systolic pulmonary artery pressure 70mmHg). The coronarography didn't detect significant coronary artery stenosis.
Results: As the patient was unresponsive to medical therapy the MitraClip procedure was considered as a last alternative in a patient with cardiogenic shock and multiple organ failure. Because of the extension of the mitral jet insufficiency, 2 clips were implanted. The final result was good with mild residual mitral insufficiency, no mitral stenosis (medium gradient 2.46mmHg and 3.8cmq of mitral valvular area) and significant reduction of the polmonary pressure (PAPs 40 mmHg). The patient was hospitalized for 5 days after the procedure and was dicharged home with a significant improvement of the NYHA functional class (IIb). The 15 month follow-up showed stabile ecocardiographic and clinical data with no other hospitalization.
Conclusions: Traditionally, patients undergo corrective surgery. MitraClip is a less-invasive treatment for mitral regurgitation in high surgical risk patients. Our case illustrates the spectacular clinical response even when other therapies are of no significant benefit. As it is eficient in reducing simptoms and in decreasing medical costs MitraClip shouldn't be the last therapeutical alternative in heart failure patients.

1563
Diuretic resistance overcome by mannitol infusion

H Altay[1]; F Ozkalayci[1]; S Pehlivanoglu[1]
[1]*Baskent University Istanbul Hospital , Cardiology, Istanbul, Turkey*

Introduction: Case description 1: 64 years-old man admitted to our hospital with volume overload . The patient had a history of heart failure (HF), coronary artery disease(CAD), hypertension and atrial fibrillation . In the past year, he had had three hospitalization with decompansated HF. Blood pressure was 150/90mmhg, heart rate 100/minute. Bibasiller rales and severe pretibial edema was present. Notable admission labs included amino terminal pro-BNP level 4310pg/ml and creatinine (Cr) 1,26 mg/dl. Echocardiography revealed an ejection fraction (EF) of 20%. He was treated with diuretic infusion at a rate of 5mg/h. Despite stepwise increase in furosemide dose, desired diuretic response was not achieved. Then dobuatmine infusion was tried but didn't bring decongestion and renal function worsened. Before the ultimate treatment with ultrafilltration, 20% mannitol 150 ml three times a day was added in addition to furosemide. Diuresis of the patient increased. After 3 days the patient was decongested .The patient weaned off mannitol and discharged with furosemide.
Case description 2: 82 years-old male patient presented to cardiology outpatient with pretibial oedema and dyspnea. The patient had a history of CAD, anemia, diabetes , hypertension and chronic kidney disease..His blood pressure was 150/90mmhg, pulse rate 100 b.p.m. He had severe pretibial edema with clear lung sounds. Notable labs were NT-proBNP 11,321pg/ml, creatinine 2,3 mg/dl. Echocardiography revealed an EF of %55. We started diuretic infusion at a rate of 10 mg/h, low dose dopamine and perlinganit infusion. At the end of 48 hours, diuresis was 60ml/h, and Cr level increased to 3,1 mg/dl. Peripheric congestion persisted. Mannitol was added to the treatment regime . Average diuresis increased to 212ml/h. At day 3, Cr was decreased to 1.8 mg/dl , NT-proBNP was 6230 pg/ml and pretibial oedema regressed . He was discharged with furosemide 80 mg.
We reported two cases of diuretic resistance one with HF with reduced EF(HFrEF) and one with HF with preserved EF(HFpEF) both of which were overcome by mannitol treatment . Despite escalating doses of furosemide infusion and inotropic

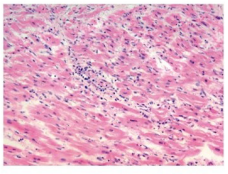
support, our attemps to decongest patient were complicated with worsening renal function. Diuretic resistance is an important clinical problem in patients with acute heart failure, particularly advanced HF and HfpEF with underlying renal disease. Mannitol is an osmotic diuretic that acts primarily on the loop of Henle and the proximal tubule where large amounts of sodium is reabsorbed by increasing the osmotic pressure of glomerular filtrate, thus inhibiting tubular reabsorption. It has the potential to increase diuresis on top of furosemide by sequential nephron blockade mechanism.
Conclusion and implications for clinical practice: Diuretic resistance is a frequent problem in acue HF. Adding mannitol on top of furosemide may be beneficial in these patients circumventing ultrafiltration.

1564

Acute heart failure due to myocarditis under mitral valve replacement in patient with active infective endocarditis

N Safarova[1]; A Pisaryuk[2]; N Povalyaev[1]; M Sorokina[1]; M Teterina[2]; A Chukalin[3]; E Kotova[4]; P Kakhktsyan[3]; I Merai[2]; J Karaulova[4]; A Safarova[2]; A Milto[2]
[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation; *[2]City Clinical Hospital No 64, cardiology department, Moscow, Russian Federation*; *[3]Bakoulev Center for Cardiovascular Surgery RAMS, Moscow, Russian Federation*; *[4]Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Introduction: Post-infectious immune-mediated myocarditis is an uncommon complication of an IE. IVIG may be used in myocarditis, both viral and autoimmune, particularly if aab-mediated.
Case description: A 69-year old white male patient with hypertension and prior stroke (1999; 2010) admitted to our hospital with fever (39-40C) for 3 months. Physical examination was notable for Lukin spots, digital clubbing and systolic murmur on the apex. TEE was performed, which showed myxomatous degeneration of the MV, vegetations and severe MR. IE was diagnosed and empiric therapy was started with oxacillin (12 g/day), ampicillin (12g/day) and gentamycin (240mg/day) end was changed on oxacillin after a positive blood culture (S. haemolyticus), then patient underwent CABG, mitral valve replacement with a mechanical prosthesis. Three weeks later he had an edema and a decrease in LVEF - 38%, GLPS -8,6% and enlarged LV (LVEDV 60 mm), NTproBNP level 3286 ng/ml. Coronarography was performed which ruled out a bypass failure. Further investigation revealed a high level of troponine I (0.9 ng/ml) and a positive IgG to Parvovirus B19. Myocardial perfusion imaging has showed LV dilatation and no signs of a focal scarring. Biopsy has showed a diffuse cellular infiltrate and a myocyte necrosis, positive viral PCR Parvovirus B19. The Patient was treated with 10 g human immunoglobulin G iv in addition to a standard therapy HF. After the therapy patient had a slight increase and a stabilization of LVEF 44%, GLPS -10.8%. Furthermore, contractility of the apical segments improved, but there still was hypokinesis in septal segments. After 3 months of follow-up after IG-therapy the patients had no clinical sings of heart failure.
Questions and issues: After a successful cardiac surgery, there are many reasons for the development of an acute heart failure, but the immune complications of endocarditis are rare. Myocarditis is the only complication for which treatment is possible with immunomodulation. The nature of the myocardial inflammation could not be clearly defined with a differential diagnosis between postviral (Parvovirus B19) and aab-mediated-myocarditis.
Answers and Discussion: The primary cause of the heart failure in this patient was myocarditis, although a coronary artery disease or a bypass failure could be excluded in a presence of multiple risk factors. Parvovirus-B19 can be a random findings in the myocardium. In our case, there was a normal IgM titer and a high IgG titer to Parvovirus-B19. Nevertheless, IVIG recommended to treat of both immune and postviral myocarditis.
Conclusion: Subacute long-term course of an infective endocarditis can lead to various immune complications, in rare cases to myocarditis that presents several diagnostic and treatment challenges, with a possibility of a favourable outcome in case of a timely treatment.



1565

Description of a clinical turning point after barostim therapy: is permanent atrial fibrillation always permanent?

G Giovanni Tilocca[1]; L Lazzari[1]; A Tordini[1]; C Marini[1]; S Donzelli[1]; G Carreras[1]; E Boschetti[1]; G Ambrosio[2]
[1]Az. Osp. "S. Maria", Cardiology Department, Terni, Italy; *[2]Hospital Santa Maria Della Misericordia, Cardiology Department, Perugia, Italy*

C.F. is a 70 years old man with an ischaemic cardiopathy resulting in ventricular dilatation and severe systolic dysfunction (FE 25%): in 2003 a coronary bypass grafting was performed (LIMA to LAD and two venous grafts, one to the posterior interventricular branch of the RCA and the other one to the first Obtuse Marginal branch), in 2014 a PTCA in proximal LAD was carried out.
The patient is suffering from chronic kidney disease (KDOQI- V stage) with severe hypertension due to a right renal artery stenosis previously treated with percutaneous transluminal angioplasty (PTA).
Because of renal disease, heart failure (HF) therapy was not optimized: being limited to a beta-blocker and a loop diuretic (furosemide), the former being directed to AF rate control as well.
As far as the atrial fibrillation was concerned, we decided to adopt a "rate control" strategy after several ineffective attempts to restore sinus rhythm.
In 2015 a CRT-D was implanted for primary prevention of sudden cardiac death.
A transthoracic echocardiogram performed in July 2015 showed severe dilatation of the LV (EDV 210 ml) with severe systolic dysfunction (Biplane EF 20%), dilatation of the left atrium (area 30 cm2), moderate secondary mitral regurgitation and systolic dysfunction of the RV (TAPSE 10 mm).
In the following months the patient was referred several times to our Unit for acutely decompensated chronic HF, he developed diuretic resistance and a progressive worsening in functional class (NYHA IV and a very poor 6 minute walking test).
The recurrence of several HF hospitalizations led us to implant an endovascular carotid baroreceptor stimulator in February 2016, that allowed to partially overcome diuretic resistance (the sequential nephron blockade therapy, that was our first strategy, was reduced to metolazone 2.5 mg once a week with stable dry weight maintenance) and to improve the functional class (NYHA III and an increase of the 6 minute walk distance) and the self-reported quality of life.
In September 2016 a spontaneous reversion to sinus rhythm from permanent atrial fibrillation (after 6 months of Barostim Therapy) was observed.
An echocardiographic follow-up showed an improvement of the echo parameters (EDV 180 ml, EF raised up to 38% and mild mitral regurgitation).
Thus, because of sinus rhythm restoration and cardiac state improvement, we decided to upgrade the device adding an atrial electrocatheter.
In conclusion this patient showed a dramatic clinical improvement after Barostim therapy with the restoration of sinus rhytm and, as a consequence, of the atrial contribution to the diastolic filling. Since the implantation of Barostim the patient has been no longer hospitalized for decompensated HF. The baroreflex activation therapy allowed the opportunity to antagonize neurohormonal activation, which could not have been persued by pharmacological therapy alone.

Remote monitoring with cardiac implantable electronic device to follow-up pharmacodynamic effects of sacubitril/valsartan treatment: a case report

U O Turk[1]; E Alioglu[1]
[1]Central Hospital, Izmir, Turkey

Introduction: Cardiac implantable electronic devices (CIEDs) collect diagnostic information from continuous monitoring of several physiological variables. The variables includes intrathoracic impedance (ITI), patient activity (PA), and heart rate variability (HRV). Sacubitril/Valsartan is recommended by current guidelines as foundational therapy for patients with symptomatic HFrEF.
However, temporal relationship between sacubitril/valsartan treatment and these variables has not yet been reported.

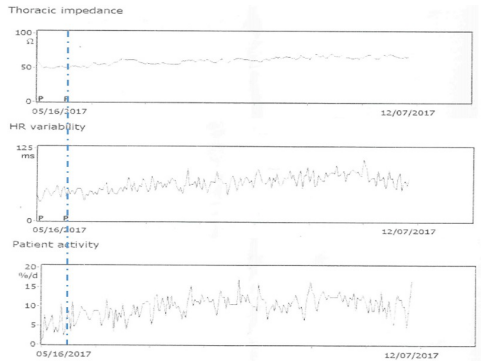

Figure.

Case Report: A 59-year-old physician with HFrEF admitted to with exertional dyspnoea. He has a past medical history of CABG operation, and a dual chamber ICD (Itrevia 5 DR-T, Biotronik, Berlin, Germany) implantation at May 2017. He was receiving Ramipril 10 mg od, atorvastatin 40 mg od, carvedilol 12.5 mg bid, furosemide 40 mg od, spironolactone 25 mg od, aspirin 100 mg od and insulin therapy. Blood pressure was 125/80 mmHg, heart rate was 88 bpm. Transthoracic echocardiography demonstrated akinetic left ventricular septum, anterior wall and apex. Left ventricular ejection fraction calculated as 32% with modified Simpson method. ICD counter revealed no any atrial or ventricular pacing. Serum B-type natriuretic peptide level was 105 pg/mL (normal <35 pg/mL). After comprehensive evaluation, ramipril 10 mg treatment was replaced with Sacubitril/Valsartan 97/103 mg twice daily. at June 2017. The patient admitted to outpatient clinic for scheduled visit six months later. Patient reported improving his symptoms of exertional dyspnoea, fatigue as well as increasing in his ordinary physical activities. ICD interrogation revealed stable increasing in ITI (from 51 to 73 ohm), HRV (from 42 to 66 millisecond) and PA values (from 5% to13%/day). (Figure)
Discussion: PARADIGM-HF trial demonstrated the superiority of sacubitril/valsartan over enalapril on physical capacity and symptoms, quality of life which measured with Kansas City Cardiomyopathy Questionnaire (KCCQ). KCCQ have limitations such as absence of appropriate reference standards for the various domains, and its patients' perspective fashion (subjectivity). Investigators and many physicians often rely on physiologic variables, such as LVEF or NT-proBNP levels to monitor therapy in HFrEF population. However, such surrogate markers may not always be useful. CIEDs include remote monitoring functions allow to monitor particular physiologic function day by day. They serve objective measurements with high temporal resolution that permitting to follow any trend. In this case, patients' self-reported improvements in symptoms and PA levels confirmed by CIED monitoring functions objectively. To the best of our knowledge, this is the first case documenting improvements in ITI, PA, and HRV levels with sacubitril/valsartan treatment. CHILISALT Study (NCT03359967) will obtain more information in these patient population.
Figure Legend: Vertical lines denotes the date of sacubitril/valsartan initiation.

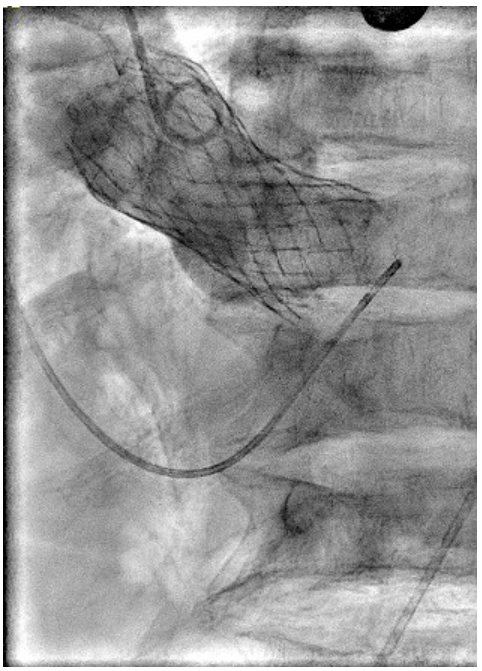
Transcatheter aortic valve implantation in a patient with sickle-cell disease

E Zhiduleva[1]; O Moiseeva[1]; D Strelkov[1]; D Zverev[1]
[1]*Almazov National Medical Research Centre, Saint Petersburg, Russian Federation*

Introduction: Heart diseases represent a significant cause of mortality and morbidity in hereditary haemoglobin disorders. Peri-operative hemolysis is the serious problem during open-heart surgery. We report a case of successful transcatheter aortic valve implantation (TAVI) in a patient with sickle-cell disease (SCD).



Description. A 64-year-old Caucasian man was hospitalized because of deterioration of congestive heart failure. Clinical sympthomps included dispnea, orthopnea, massive lower limb edema and repeated syncope associated with excercise. He had a past medical history of SCD with vaso-occlusive crises from the age of 35. Hemoglobin level was 90 g/l. Heart chambers dilation with reduced left ventricular systolic function (LVEF = 31%) was revealed by ECHO. Severe aortic valve stenosis (peak aortic jet velocity 4 m/sec, mean gradient 33 mmHg, AVA 0.9 cm2) and severe pulmonary hypertension (systolic pulmonary arterial pressure (PAP) 83 mm Hg) were also detected. The coronary angiography showed normal vessels, but the patent ductus arteriosus (PDA) was presented by aortography. The transcatheter occlusion of PDA was performed as the first step. Because of high risk of hemorrhagic complications the patient underwent TAVI (transfemoral access). Blood transfusion was performed before surgery. At the the 6th day of the postoperative period a permanent pacemaker was implanted because of the transient complete atrioventricular block. We didn't observe significant hemoglobin level decrease, major bleedings, stroke or vascular complications in postoperative period. Control ECHO after TAVI described decrease of systolic PAP (67 mm Hg). Paravalvular aortic regurgitation wasn't presented. Despite the absence of left ventricular systolic function improvement dyspnea reduced (Borg from 8 to 4), six-minute walk distance increased from 150 to 300 m.
Discussion: Acceleration of degerative aortic stenosis formation in patient with tricuspid aortic valve and SCD might be potentially associated with high output state and elastic tissue defects. Left ventricular disfunction is described in hereditary haemoglobinopathies, its pathogenetic mechanisms include high output state, iron overload, vascular disease, myocardial ischaemia, myocarditis, and valvular disease too. Pulmonary hypertension occurs in approximately one third of patients with homozygous SCA and has multifuctorial mechanisms due to haemolysis, impaired nitric oxide bioavailability, chronic hypoxaemia, thromboembolism, parenchymal and vascular injury because of sequestration of sickle erythrocytes. Additional impact to increased PAP was done by left heart disease and PDA. The preferable method of treatment in this case was TAVI. The most significant complication we observed was complete atrioventricular block that was described as one of the most common complications seen after TAVI.
Conclusion: TAVI is considered as a safely procedure in patients with SCD that could improve their life quality.

Treatment of cardiorenal syndrome with haemodialysis: a case report

B Leskovar[1]; T Furlan[1]; S Poznic[1]; D Kosuta[1]; A Adamlje[2]
[1]*Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia*;
[2]*Trbovlje General Hospital, Department of Hemodialyisis, Trbovlje, Slovenia*

Introduction: Cardiorenal syndrome (CRS) is characterised by diuretic-resistant heart failure with congestion and concomitant progressive worsening of kidney

function, even more pronounced with up-titration of heart failure therapy. Ultrafiltration has been proposed as an alternative to diuretics in severe congestion in ESC guidelines (class IIa, evidence level B). The effect of chronic haemodialysis (HD) on long-term outcome and survival in CRS has not yet been extensively evaluated.
Case report: 64-year-old patient with arterial hypertension, diabetes type 2, paroxysmal atrial fibrillation, PAD, COPD and Pickwick syndrome was admitted to our hospital in June 2015 due to first decompensation of heart failure with preserved ejection fraction and concomitant acute worsening of chronic kidney disease. We introduced heart failure therapy with beta blocker, diuretic and angiotensin receptor blocker. In the next 18 months, he was hospitalized 6 times for decompensated heart failure and required several thoracenteses and abdominal paracenteses despite maximal dose of diuretic. Due to hyperkalaemia and progressive worsening of kidney function we could not successfully titrate the dose of angiotensin receptor blocker. He was persistently NYHA class IV with poor quality of life. In March 2017, during another heart failure decompensation, we decided to start with chronic HD. We inserted a tunnelled central venous catheter through the right internal jugular vein and started with low-efficiency bicarbonate HD three times a week. Since the start of HD, he was not hospitalized for to heart failure, his weight decreased for 22 kg, we up-titrated angiotensin receptor blocker to target dose (chronic HD assured good electrolyte control), his quality of life increased significantly, he is currently NYHA II functional class (6MWT) and requires no nocturnal BiPAP support anymore. In the last months, we were able to reduce the frequency of HD to twice a week.
Discussion: Between July 2004 and January 2015, we have treated 67 heart failure patients with HD. Indications for HD were terminal, symptomatic heart failure in NYHA IV patients with uncontrollable hypervolemia and/or metabolic acidosis and/or hyperkalaemia. All patients were receiving maximally-tolerated dose of diuretics and most of them were treated with inotropes and vasopressors before starting HD. We observed a significant decrease in hospitalization rate due to heart failure after the start of HD (before HD: $0,79 \pm 1,32$; after the start of HD $0,22 \pm 0,65$, $p = 0,001$) and a significantly longer survival of NYHA IV patients (1-year survival 81%, 3-year 52%, 5-year 39%)
Conclusion: In our experience, chronic HD is a feasible, safe and effective treatment modality in NYHA IV heart failure patients with uncontrollable hypervolemia, acidosis and hyperkalaemia as a bridge to definite therapy and for patients who are not candidates for heart transplantation.

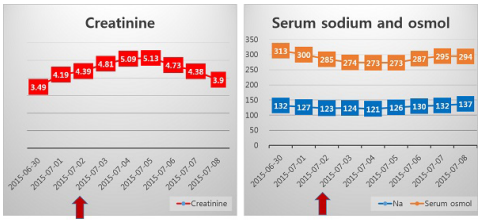
Impact of tolvaptan in acute heart failure who did not respond to loop diuretics alone

SK Lee[1]; MS Park[1]; SW Choi[1]; JC Youn[1]; SW Han[1]; EJ Kim[2]; KH Ryu[1]
[1]Hallym University, Cardiovascular center , Dongtan, Korea Republic of; *[2]Korea University Guro Hospital, Cardiovascular Center, Korea University Guro Hospital, Seoul, Korea Republic of*

Introduction: Patients with acute heart failure (AHF) and renal dysfunction have prolonged hospital admission and high mortality rates. More efficacious and safer decongestive therapy is clearly needed, but optimal treatment strategies remain unclear.
Case: A 63-year-old female with a chronic kidney disease (CKD, stage IV) visited for newly onset chest pain. She had a history of percutaneous coronary intervention (PCI) in left anterior descending (LAD) and left circumflex artery 1 year ago. On admission, her laboratory tests revealed serum creatinine of 3.46 mg/dL, serum sodium 132 mmol/L, CK-MB 7.88 ng/mL, Troponin T 0.243 ng/mL. Coronary angiography revealed multiple severe restenosis in a previous stent in the LAD. Next day, the patient underwent PCI in the LAD with two drug-eluting stents and follow-up angiogram showed good immediate results. However, her renal function worsened after PCI and urine volume reduced gradually along with progression of dyspnea regardless of incremental doses of intravenous furosemide (max: 320mg/day). At day 3 after PCI, her serum creatinine increased up to 4.81 mg/dL, and sodium level gradually decreased to 124 mmol/L. Because she had no option other than hemodialysis, we decided to start tolavaptan as the last option. After administration of tolvaptan, her urine volume started to increase eventually even in condition with increasing serum creatinine levels. At day 5 from tolvaptan administration, her congestion was successfully treated with decreased levels of serum creatinine. Serum sodium level was also restored to 137 mmol/L without any neuorologic symptoms (Figure). She recovered without any sequelae and discharged at the day 15 of admission. At 3 months follow-up, her performance status was excellent, and her creatinine level decreased to 3.12 mg/dL. Problems: Patients with diuretic resistance may require higher diuretic doses, and even more dosage is needed when renal dysfunction is combined, and this may result to worsening of renal function in the acute phase of HF. In addition, loop diuretics which are most commonly used in HF patients may increase the neuro-hormonal cascade, which is detrimental for the patients of AHF.
Discussion: Tolvaptan shows an effect by antagonizing the V2 receptors present in the collecting ducts in kidney, and produces diuresis largely by increasing free water diuresis. This may explanation for no further worsening of the renal function even in situation of increasing urine volume in our case. In contrast to loop diuretics, tolvaptan acts as a diuretic without activating the neuro-hormonal system. This may result in the improvement in pulmonary edema, and symptoms of heart failure without progressive deterioration of LV function.
Conclusions: Our present findings indicate that the administration of tolvaptan might be considered in AHF patients with renal insufficiency who show no response to loop diuretics.



Tolvaptan 15mg with IV continuous furosemide (320mg/day)

Importance of tissue characterization with cardiac magnetic resonance in diagnosis of acute myocarditis

M Shah[1]; H Singh[2]; R Rastko Rakocevic[3]; A Lucev[2]; B Kim[2]; R Berkowitz[2]; K Satya[2]
[1]New Jersey Medical School, Cardiology, Newark, United States of America; *[2]Hackensack University Medical Center , Cardiology, Hackensack, United States of America*; *[3]New Jersey Medical School, Internal Medicine, Newark, United States of America*

Acute myocarditis can progress to chronic myocarditis or dilated cardiomyopathy that has poor prognosis. Cardiac magnetic resonance CMR can delineate the severity of myocarditis for risk stratification and can help guide management with its tissue characterization properties.
A 35 year old otherwise healthy Ecuadorian soldier presented to the emergency room with sudden onset of substernal chest pain, dyspnea, rigors and chills. His ECG showed sinus tachycardia at 171 beats/min and ST segment elevation in the infero-lateral leads. Initial troponin and BNP were 117 ng/mL and 1850 pg/mL, respectively. Emergent cardiac catheterization showed no coronary artery lesions and a left ventricular ejection fraction (LVEF) < 15% by ventriculogram. Intra-aortic Balloon Pump (IABP) was placed and hemodynamics measurements by pulmonary artery catheterisation showed right atrial pressure of 12 mm Hg, mean pulmonary artery pressure 41 mm Hg, pulmonary artery wedge pressure of 33 mm Hg, systemic vascular resistance of 17 wood units and cardiac index of 2.7 L/min/m2. Mean arterial pressure was 78 mm Hg while on high dose norepinephrine and IABP support. Transthoracic echocardiogram showed LVEF of < 20% and global hypokinesis.
Further workup to determine the etiology of myocardial dysfunction was negative for rheumatoid factor, antinuclear antibody, RPR, lyme ELISA. Blood cultures and virology PCR (including for adenovirus, HHV-6, HIV, Parvovirus, CMV, Coxsackie A/B, EBV) were all negative. With mechanical ventilation, low dose norepinephrine and broad spectrum IV antibiotics patient improved clinically in 48-72 hours. Blood cultures remained sterile. Repeat transthoracic echocardiogram five days from admission revealed left ventricular ejection fraction of 40%. CMR was performed one week after presentation. There was diffuse hypokinesis of the left ventricle on cine images with LVEF of 46%. Right ventricular function and tissue characterization were normal. Short TI inversion recovery (STIR) images with triple inversion recovery showed increased intensity suggesting diffuse myocardial edema affecting all myocardial walls. On late gadolinium enhancement (LGE) images, there was diffuse hyperenhancement of all myocardial segments from base to apex. Basal to apical septum had mid myocardial hyperenhancement whereas the remaining myocardium showed subepicardial hyperenhancement with sparing of the endocardium. All these findings are suggestive of acute myocarditis.
Novel CMR techniques such as native T1 mapping, extracellular volumes (ECV) of distribution and T2 mapping have shown promising results in the assessment of myocarditis. ECV quantification and LGE imaging markedly improved diagnostic accuracy for myocarditis compared to Lake Louise criteria. This case is a perfect example of using these CMR techniques to make a definitive diagnosis of acute myocarditis in the setting of severe myocardial dysfunction with negative standard workup.

Acute heart failure: how to improve survival

1615

The usefulness of the MEESSI score for risk stratification of patients with acute heart failure at the emergency department: validation in a new Spanish cohort.

O Miro[1]; X Rossello[2]; V Gil[1]; H Bueno[2]; P Llorens[3]; FJ Martin-Sanchez[4]; J Jacob[5]; P Herrero-Puente[6]; R Escoda[1]; S Aguilo[1]; C Sanchez[1]; J Marco-Hernandez[1]; G Martinez[1]; V Rico[1]; SJ Pocock[2]

On behalf of: ICA-SEMES Research Group
Funding Acknowledgements: ISCIII (Spanish Ministry of Health) and FEDER (PI15/01019 and PI15/00773), Fundació La Marató de TV3 (2015/2510) and Calalan Govern (GRC 2014/0313)

Aims: The MEESSI (Multiple Estimation of risk based on the Emergency department Spanish Score In patients with acute heart failure –AHF-) scale is a new tool to stratify AHF patients at the emergency department (ED) according to the 30-day mortality risk. We aimed to validate the MEESSI risk score in a new cohort of Spanish patients to assess its accuracy in stratifying patients by risk and to compare its performance in different settings.
Methods: We included consecutive patients diagnosed with AHF in 30 EDs during January and February 2016 (60 fays). The MEESSI score was calculated for each patient. The area under the curve of the receiver operating characteristic (AUC ROC) measured the discriminatory capacity to predict 30-day mortality of the MEESSI full model (13 variables) and the 7 secondary models (lacking the Barthel Index, troponin or NT-ProBNP, in any combination). Further comparisons were made between subgroups of patients from university and community hospitals, EDs with high, medium or low activity and EDs that recruited or not patients in the original MEESSI derivation cohort.

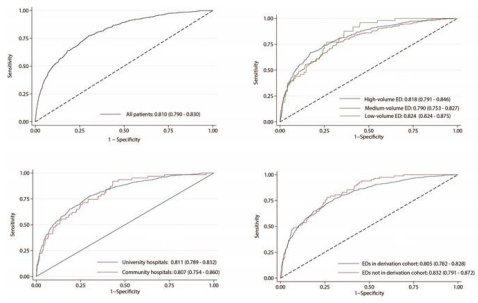

Figure 1

Results: We analyzed 4711 patients (university/community hospitals: 3811/900; high-/medium-/low-activity EDs: 2695/1479/537; EDs participating/not participating in the previous MEESSI derivation study: 3892/819). The distribution of patients according to the MEESSI risk categories was: 1673 (35.5%) low-risk, 2023 (42.9%) intermediate-risk, 530 (11.3%) high-risk and 485 (10.3%) very high-risk, with 30-day mortality of 2.0%, 7.8%, 17.9% and 41.4%, respectively. The AUC ROC for the full model was 0.810 (95% CI: 0.790-0.830), and ranged from 0.731 to 0.785 for the subsequent secondary models. The discriminatory capacity of the MEESSI risk score was similar among subgroups of hospital type, ED activity, and original recruiter EDs (Figure 1).

Conclusion: The MEESSI risk score successfully stratifies AHF patients at the ED according to the 30-day mortality risk, potentially helping clinicians in the decision-making process for hospitalizing patients.

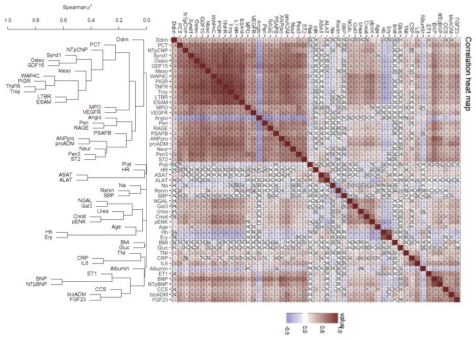
Bio-adrenomedullin is strongly related to congestion and poor outcome in patients with worsening heart failure

J M Jozine Ter Maaten[1]; D Kremer[1]; BG Demissei[1]; J Struck[2]; AA Voors[1]
[1]University Medical Center Groningen, Groningen, Netherlands; [2]Sphingotec, Hennigsdorf, Germany

Background: Adrenomedullin (ADM) is a vasodilatory hormone with natriuretic effects that has been postulated to play a role in tissue congestion. Its specific pathophysiological function however remains unclear. We therefore evaluated clinical and biological factors associated with plasma biologically active ADM (bio-ADM).
Methods: Plasma bio-ADM was measured in 2,189 patients with acute or worsening heart failure enrolled in the BIOSTAT-CHF study. We utilized regression models and network analysis tools to identify associations of bio-ADM with clinical and biological variables. Prognostic value of bio-ADM was analyzed using Cox regression.
Results: Acute or worsening heart failure patients with higher bio-ADM levels were significantly older, had a higher BMI and NYHA class and had more signs and symptoms of congestion (all $p < 0.01$). In multivariable regression analysis, higher plasma bio-ADM levels were associated with higher BMI and more severe edema, as well as higher FGF23, aldosterone, and CRP levels (all $p < 0.03$). Conversely higher plasma bio-ADM was significantly associated with lower sodium levels. Interestingly, plasma bio-ADM clustered strongly with markers of congestion, such as FGF23, (NT-pro)BNP and a clinical congestion score (CCS). Plasma bio-ADM was independently associated with an increased risk of all-cause mortality and heart failure rehospitalization (Hazard ratio: 1.18 per log increase (1.08-1.30), $p < 0.001$).
Conclusions: Bio-ADM is strongly associated with clinical variables and biomarkers related to congestion, RAAS activation and inflammation. Also, higher bio-ADM levels are associated with an increased risk of adverse outcome. As such, bio-ADM may play a significant role in heart failure pathophysiology and might be used for risk stratification and to guide treatment.



Heatmap bio-ADM in worsening HF

1619

Catherter-based enhancement of lymphatic drainage in fluid overloaded acute decompensated heart failure: First in human experience

D Dan Haberman[1]; M Jonas[1]; L Zilberman[1]; I Fungenfirov[1]; S Goland[1]; K George[1]; MR Costanzo[2]; WT Abraham[3]
[1]Kaplan Medical Center, Heart Center, Rehovot, Israel; [2]Advocate Heart Institute, Naperville, United States of America; [3]Ohio State University Hospital, Division of Cardiovascular Medicine, Ohio, United States of America

Funding Acknowledgements: WhiteSwell

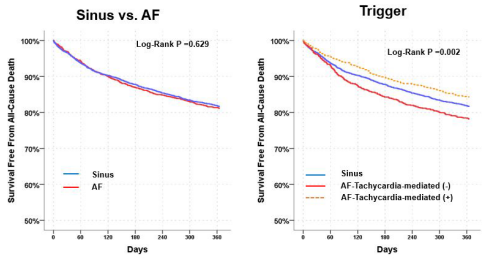
Background: Fluid overload leading to pulmonary and peripheral edema causes about 90% of all acute decompensated heart failure (ADHF) admissions. This excess in extracellular fluid volume resides in both the intravascular and interstitial spaces. Removal of fluid from the intravascular space is usually accomplished with diuretic therapy, while there is currently no direct means for enhancing fluid removal from the interstitial space, frequently resulting in intravascular volume depletion, hypotension, worsening renal function (WRF), and poor patient outcomes. We evaluated a novel catheter-based system for the enhancement of lymphatic drainage in a first-in-human proof of concept study.
Methods: The White Swell System (White Swell Medical Ltd, Herzliya, Israel) increases the movement of interstitial fluid, via enhanced lymphatic system drainage, to the intravascular space and thus enables total body fluid volume excess to be removed from the body via the kidneys. This prospective, multi-center, single arm study evaluated the safety, feasibility, and preliminary efficacy of the White Swell System in in ADHF patients. Performance measures of interest included device functioning, volume removal (diuresis), and changes in renal function, during treatment.
Results: Ten hospitalized ADHF patients with signs of fluid over load were enrolled and 8 underwent the procedure; 2 patients did not complete the procedure due to technical issues. The average age was 73 ± 6.7 years; 75% were men; 62.5% had reduced left ventricle ejection fraction (mean 29.25 ± 8.1%). On average, procedure duration was 6.4 ± 2.44 hours, reduction in CVP was 6.4 ± 4.3 mmH2O, urine output was 1.76 ± 0.45 liters, and no WRF was observed. In fact, there was a mild post procedure reduction of creatinine levels seen in 7 out of 8 patients. There were no serious adverse events related to the procedure and no readmissions at 30-day follow up.
Conclusion: In this pilot study, we found the White Swell system to be safe and feasible with initial promising results for the reduction of total body fluid overload in patients with ADHF. The combination of high volume diuresis with preservation or slight improvement in renal function supports additional clinical trials of this approach.

1620
The effect of trigger on the prognosis of patients with heart failure and atrial fibrillation: tachycardia-mediated acute decompensation

J J Jin Joo Park[1]; IY Oh[1]; DJ Choi[1]
[1]*Seoul National University Bundang Hospital, Division of Cardiology,, Seongnam, Korea Republic of*

On behalf of: Korea Acute Heart Failure (KorAHF) Registry Investigators
Funding Acknowledgements: This work was supported by Research of Korea Centers for Disease Control and Prevention [2010-E63003-00, 2011-E63002-00, 2012-E63005-00, 2013-E63003-0

Background: Atrial fibrillation (AF) is common in heart failure (HF) patients. There exists controversy on the prognostic value of AF in HF patients. Patients with AF and HF, who experience acute decompensation mediated by tachycardia may have different prognosis than those whose decompensation is triggered by other factors, because tachycardia may be an acute and reversible event.
Purpose: We investigated the effect of tachycardia-mediated acute decompensation on the clinical outcomes.
Methods: The Korea Acute Heart Failure (KorAHF) registry consecutively enrolled 5,625 patients. The trigger for acute decompensation was classified as either tachycardia-mediated (TM) or not. Atrial fibrillation was confirmed in ECG taken during hospital admission. The primary outcomes were in-hospital mortality and 1-year all cause mortality according to rhythm and trigger.



1-Year All Cause Mortality

Results: Among 5,625 patients, 3665 (65%) patients had sinus rhythm and 1961 (35%) had AF. Among patients with AF, 928 (47%) had TM acute decompensation. Patients with sinus rhythm was older than those with AF (Sinus: 67 ± 15 years, AF-TM(-): 71 ± 12 years, AF-TM (+): 70 ± 12 years, P < 0.001). Patients with AF-TM(+) had lowest NT-proBNP level (sinus: 9900 ± 11464 pg/microL, AF-TM(-): 8252 ± 9296 pg/microL AF-TM (+): 7462 ± 8945 pg/microL, P < 0.001).
Regarding the clinical outcomes, patients with AF-TM(+) had the lowest in-hospital mortality (Sinus: 5.1%, AF-TM(-): 6.5%, AF-TM (+): 1.7%, P < 0.001). In multivariable analysis, AF-TM (+) was associated with 53% reduced risk (HR, 0.47; 95% CI, 0.24-0.93).
Regarding the 1-year all-cause death, there was no difference in 1-year survival between patients with sinus and AF (P = 0.629). When stratifying the patients according to trigger, AF-TM(+) had the best prognosis, followed by those with sinus rhythm, while AF-TM(-) had the worse prognosis (P = 0.002). However, in multivariable analysis, AF-TM (+) was not associated with reduced risk for 1-year all-cause mortality (HR, 0.91; 95% CI, 0.71-1.17).
Conclusions: HF patients with AF whose acute decompensation is triggered by tachycardia have better in-hospital but similar post discharge outcomes like HF patients with sinus rhythm or those with AF who are decompensated by other factors.

Clinical manifestations and outcome of acute heart failure in Chagas cardiomyopathy patients in comparison do other etiologies: results of the I Brazilian Heart Failure Registry

MV Marcus Vinicius Simoes[1]; CH Miranda[1]; DC Albuquerque[2]; LC Danzmann[3]; S Rassi[4]; HP Guimaraes[5]; MF Canesin[6]; LEP Rohde[7]
[1]*Medical School of Ribeirão Preto - University of São Paulo, Brazil, Ribeirão Preto, Brazil*; [2]*State University of Rio de Janeiro (UFRJ), Cardiology, Rio de Janeiro, Brazil*; [3]*Lutheran University of Brazil, Cardiology, Porto Alegre, Brazil*; [4]*Federal University of Goias, Cardiology, Goiania, Brazil*; [5]*Hospital for the Heart (Hcor), Cardiology, Sao Paulo, Brazil*; [6]*University Hospital, State University of Londrina, Cardiology, Londrina, Brazil*; [7]*Federal University of Rio Grande do Sul, Cardiology, Porto Alegre, Brazil*

On behalf of: BREATHE - Brazilian Heart Failure Registry
Funding Acknowledgements: DEIC - Heart Failure Department of the Brazilian Society of Cardiology

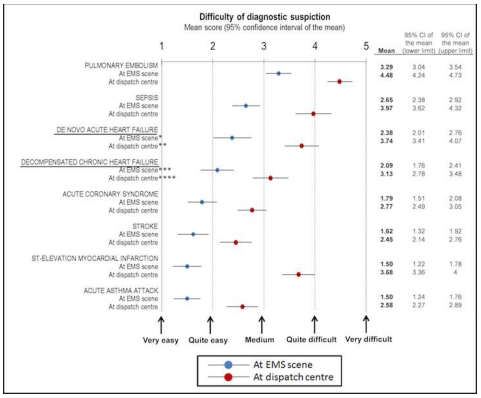
Background: Chagas cardiomyopathy (CC) is a prevalent cause of heart failure in Latin America countries and has recently been spread to Europe owing globalization and migratory waves from endemic regions. Studies describing clinical manifestations and outcomes of heart failure associated to CC are scarce and restricted to single center reports.
Purpose: Report the results of the I Brazilian Heart Failure Registry (BREATHE) addressing the clinical characteristics and outcomes of patients with acute heart failures (AHF) due to CC in comparison to other etiologies.
Methods: BREATHE was a multicenter observational nationwide prospective registry, conducted in 51 Brazilian hospitals, including private and public institutions, from different Brazilian regions. BREATHE included 1,253 patients, >18 years-old patients hospitalized with primary diagnosis of AHF. We proceeded the comparative analysis between patient group with CC etiology (n = 136, 10.9% of the sample) and patients with other etiology (n = 1,117, 89.1% of the sample), concerning demographic, physical examination changes at admission, non-invasive clinical/hemodynamic profile, LVEF on Echocardiogram, use of intravenous inotropic drugs, and death rate during hospital stay and 3, 6 and 12 months after discharge. The categorical variables were compared by using Fisher Exact test and the continuous variables were compared by using Mann-Whitney non-parametric test.
Results: CC patients, in comparison to other etiologies, were younger (62.5 ± 15.2 vs 69.9 ± 16.1 y.o., p < 0.01), presented lower systolic blood pressure (104.2 ± 24.9 vs 127.0 ± 31.4 mmHg, p < 0.001), lower heart rate (76.8 ± 23.3 vs 89.1 ± 22.3 bpm, p < 0.001), lower rate of jugular vein distension (63.2% vs 44.8%, p < 0.001) and hepatomegaly (59.6% vs 34.4%, p < 0.001), lower rate of pulmonary crackles (64.0% vs 73.7%, p = 0.022), higher rate of "cold and wet" clinical hemodynamic profile (36.0 vs 15.7%, p < 0.001), larger diastolic left ventricular diameters (68 [57.2 - 74.0] mm, p = 0.017), lower left ventricular ejection fraction (29.5 [22.2 - 35.5]% vs 37 [26.0 - 49.8]%, p < 0.001), higher rates of intravenous inotropic drugs use (31.5% vs 12.4%, p < 0.001). The CC patients in comparison to non-CC patients presented higher cumulative death rate during hospital stay (20.6% vs 11.7%, p = 0.009), and after discharge at 3-months (34.3% vs 22.1%, p = 0.002, at 6-months (41.0% vs 27.7%, p = 0.002, and at 12-months (53.4% vs 37.8%, p = 0.001).
Conclusions: Patients hospitalized with AHF with CC etiology, in comparison to other etiologies, present more prominent physical signs of systemic congestion, lower arterial blood pressure, more severe left ventricular systolic dysfunction and remodeling, more frequent low cardiac output manifestations and higher use of intravenous inotropic drugs. This higher risk profile was associated to a poorer outcome both in-hospital and after discharge.

1626

The perceived difficulty of identifying acute heart failure in dispatch centre and by emergency medical services on scene compared to other critical medical conditions

P Harjola[1]; VP Harjola[1]; M Kuisma[1]; M Christ[2]; X Escalada[3]; F Martin-Sanchez[4]; O Miro[5]
[1]Helsinki University Hospital, Emergency Care, Helsinki, Finland; *[2]Luzern Hospital, Emergency department, Luzern, Switzerland*; *[3]Hospital Clinic de Barcelona, Sistema d'Emergéncies Médiques, Catalunya, Barcelona, Spain*; *[4]Hospital Clinic San Carlos, Emergency department, Madrid, Spain*; *[5]Hospital Clinic de Barcelona, Emergency department, Barcelona, Spain*

Background: Acute heart failure (AHF) is one of the most important causes for hospital admission. The prehospital treatment of AHF is a novel topic in the recent literature. Real-life data about the readiness of dispatch centres and emergency medical services (EMS) to treat and diagnose AHF is scarce.
Purpose: Our main interest was to find out the difficulty of EMS and dispatch centre to identify AHF. Secondly, we wanted to compare the difficulty of identifying AHF to other common cardiovascular conditions taken care by EMS.
Methods: A survey was sent to EMS leaders on charge of EMS regions covering more than 20% of the countries' population. The study was designed to cover 12 different European countries (Finland, Denmark, Sweden, Norway, Germany, Poland, Czech Republic, France, Spain, Italy, Switzerland, and United Kingdom). The survey included five common conditions: decompensated chronic heart failure (CHF), de novo AHF, stroke, ST-elevation myocardial infarction (STEMI), acute coronary syndrome (ACS), pulmonary embolism (PE), acute asthma attack (AAA), and sepsis. Difficulty of identifying these conditions was graded through a 5-points qualitative scale from very easy to very difficult. Difficulty was compared between EMS and dispatching centre and among the conditions. For comparisons between decompensated CHF and de novo AHF, we used chi-square test. For comparisons between dispatch centre and EMS and between medical conditions results we transformed into quantitative variables and compared by one-way ANOVA.



Diagnostic difficulties in EMS

Results: We received 34 surveys from 3 countries fulfilling the inclusion criteria: 19 from Spain (covering 40.0 million citizens, 86.0% of the population), 9 from Switzerland (covering 2.3 million, 27.1% of population) and 6 from Finland (covering 3.5 million, 63.3% of population). The percentages of responders considering suspicion of decompensated CHF/de novo AHF at dispatch centre as very or quite easy was 29.0/6.5, medium 38.7/35.5, and quite or very difficult 32.3/58.1 ($p = 0.034$ for comparison between decompensated and de novo), while identifying these conditions by EMS was considered very or quite easy in 64.8/55.9, medium in 29.4/29.4, and quite of very difficult in 5.9/14.7 ($p = 0.471$). For all conditions surveyed, difficulty in suspecting these conditions was higher in dispatch centre than in EMS ($p < 0.001$ in all comparisons). The perceived difficulty in identifying the 8 conditions are shown in Figure .
Conclusions: Interestingly, it is considered rather easy to detect de Novo AHF and decompensated CHF in EMS. Whereas in dispatch centre it is rather difficult. Also, a surprising finding is that identifying decompensated CHF is considered easier than de novo AHF. The study also showed that it is more difficult to detect AHF than AAA, STEMI, stroke and ACS but easier than sepsis and PE. A prospective observational study is needed to confirm these findings.

1628

The relationship between peripartum cardiomyopathy with age and other risk factors

SK Lee[1]; MS Park[1]; SW Han[1]; KH Ryu[1]; EJ Kim[2]
[1]Hallym University, Cardiovascular center , Dongtan, Korea Republic of; *[2]Korea University Guro Hospital, Cardiovascular Center, Korea University Guro Hospital, Seoul, Korea Republic of*

Funding Acknowledgements: This study was funded by the Ministry of Health & Welfare, Republic of Korea (Grant Number: HI16C0483)

Background: Peripartum cardiomyopathy (PPCM) is a significant cause of maternal morbidity and mortality, yet its etiology remains unclear. No comprehensive evaluation of the relationship between age and PPCM exists. In addition, little is known regarding the implications of risk factors in PPCM patients.
Purpose: The purpose of this study was to evaluate the associations across quartiles of maternal age and the incidence of PPCM. Moreover, we sought to evaluate not only for independent risk factors of PPCM but also whether the clustering of risk factors of PPCM has a greater impact on PPCM prevalence.
Methods: A systematic search strategy was performed by using the Korea National Health Insurance Claims Database of the Health Insurance Review and Assessment Service.
Results: Patients with PPCM were older compared to control (32.1 ± 4.3 vs 30.9 ± 4.1, < 0.001). Moreover, when divided into quartiles based on age, old maternal age was linearly associated with increasing prevalence of PPCM (P for trend $<$ 0.001, Table). In multivariate analysis, Age = 35 years (OR 1.56, 95% CI 1.32 - 1.83), primiparity (OR 1.18, 95% CI 1.02 - 1.37), multiple pregnancy (OR 2.19, 95% CI 1.64 - 2.93), cesarean section (OR 2.59, 95% CI 2.15 - 3.14), preeclampsia (OR 6.02, 95% CI 4.94 - 7.34), and gestational DM (OR 1.70, 95% CI 1.26 - 2.29) were significantly correlated with PPCM. Intriguingly, the rate of PPCM was exponentially increased when clustering risk factors, and was approximately 200 times greater in patients with = 6 risk factors than in those with none.
Conclusions: The incidence of PPCM was linearly associated with mother's age at birth. PPCM patients were older, more associated with primiparity and multiple pregnancy, and had more pregnancy related complications than control. In addition, the number of risk factors amplifies the PPCM, emphasizing more intensive monitoring on those at high risk.

Table

	Age	P trend†			
	Q1	Q2	Q3	Q4	
Age	<29.9	30-34.9	35-39.9	≥40	
Total delivery number	488,135	653,890	213,164	28,465	
PPCM number	204	363	193	35	
Incidence of PPCM	1:2,393	1:1,801	1:1,104	1:813	<0.001
OR, risk factor adjusted*	1	1.25	1.78	1.96	<0.001

New renal hemodynamic indices can predict worsening of renal function in acute decompensated heart failure

M Magdy Abdelhamid[1]; K Said[1]; W Ammar[1]; A El Taweel[2]; A Mostafa[1]
[1]Cardiology Department , Cairo University, Cairo, Egypt; *[2]Cairo University, Clinical pathology, Cairo, Egypt*

Background: Combined disorders of heart and kidney are classified as cardiorenal syndromes (CRS). CRS type 1 includes acute heart disorder leading to acute kidney injury (AKI) and occurs in ˜25% of patients admitted with acute decompensated heart failure (ADHF). The development of duplex ultrasound has enabled the evaluation of changes in intra-renal blood flow.
Objectives: To evaluate the role of intra-renal duplex parameters in predicting worsening of renal functions (WRF) in hospitalized patients with ADHF.
Methods: Among 90 patients hospitalized with ADHF, intra-renal duplex parameters (resistivity index (RRI), pulsitility index (PI) and acceleration time (AT)) were assessed on admission, after 24 and 72 hours. WRF was defined as rise of the serum creatinine level = 0.3 mg/dL from the baseline. Diuretic efficiency was defined as net daily urine output normalized for the amount of Furosemide received in mg. Adverse in-hospital outcomes were defined as the composite outcome of death, use of vasopressors and need for ultrafiltration.
Results: The mean age of the patients was 57.5 ± 11.1 years with 62% of them males. WRF developed in 40% of the patients. The Mean value of RRI on admission was 0.717 ± 0.08 and it showed significant increase at 24 and 72 hours follow up

(p= 0.001 for both). The independent predictors of WRF by multivariate regression analysis were AT at 24 hours follow up, urea on admission, RRI on admission, LVEF and plasma cystatin C on admission. Patients with lower diuretic response had higher levels of admission RRI and higher levels of PASP on admission. The independent predictors of development of the composite outcome were LVESD, WRF and E/e'.
Conclusions: The intra-renal duplex parameters RRI and AT are independent predictors of WRF in hospitalized patients with ADHF on diuretic therapy. Higher admission RRI is associated with lower diuretic response. WRF is among the independent predictors of adverse outcome in hospitalized patients with ADHF.

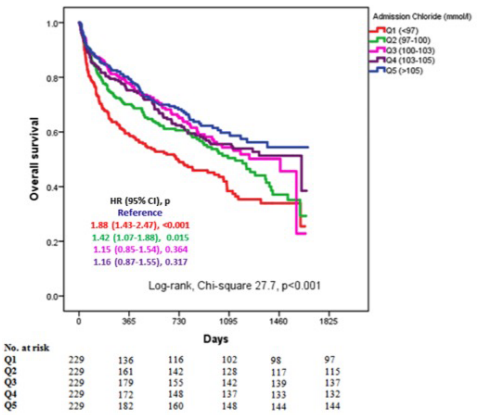
Prognostic importance of serum chloride concentration in patients hospitalized due to worsening heart failure

A Urbinati[1]; P Pellicori[2]; J Cuthbert[3]; D Pan[3]; S Kazmi[3]; F Guerra[1]; A Capucci[1]; AL Clark[3]; JG Cleland[2]
[1]Marche Polytechnic University of Ancona, Ancona, Italy; *[2]University of Glasgow, Glasgow, United Kingdom*; *[3]Castle Hill Hospital, Hull, United Kingdom*

Background: Blood electrolyte disorders are common in patients hospitalized for heart failure: serum chloride is usually measured but rarely considered.
Methods and **Results:** Between October 2012 and November 2016, patients hospitalized with worsening heart failure enrolled in the OPERA-HF, a single-centre, prospective, observational study had serum chloride measured at admission and discharge. 1145 patients (mean age 75 ± 12 years, median NTproBNP 4999 (IQR: 2331-10971) ng/l, of whom 62% had HFrEF on echocardiography, were enrolled. Hypochloraemia (serum chloride < 96 mmol/l) was present in 161 patients (14%) at admission and in 390 patients (34%) at discharge. Compared to patients in the highest quintile (median chloride 107 mmol/l; range 105-117 mmol/l), those in the lowest quintile of serum chloride at admission (median 94 mmol/l, range 76-97 mmol/l) were more likely to die (hazard ratio [HR]: 1.88; 95% confidence interval [CI]: 1.43-2.47, p < 0.001). Increasing chloride, but not sodium or potassium, levels at admission were independently associated with lower all-cause mortality (HR 0.94; 95% CI 0.89 to 0.99; p = 0.035). Compared to those who had normal chloride levels at admission and discharge, those who developed hypochloraemia during admission (HR:1.58; 95% CI 1.29-1.93, p < 0.001), or those who remained hypochloraemic (HR: 2.07; 95% CI 1.61-2.66, p < 0.001) had a higher mortality. Patients in whom hypochloraemia was corrected during hospitalisation had the same survival as those who were never hypochloraemic (HR: 1.08; 95% CI 0.65-1.79, p = 0.761).
Conclusion: Hypochloraemia is a common electrolyte disorder in patients admitted with worsening heart failure and is a powerful predictor of increasing mortality.



Quintiles of chloride and ACM

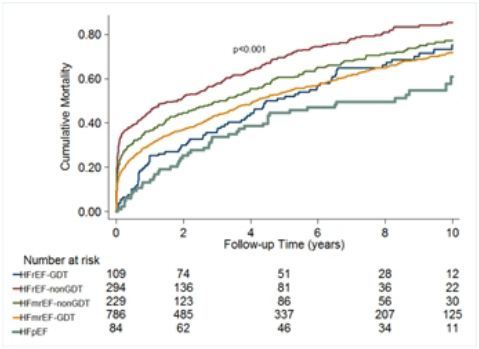
Long-term (10-year) outcomes of patients admitted with decompensated heart failure in a tertiary care centre in India.

S Sivadasanpillai Harikrishnan[1]; G Sanjay[1]; P Jeemon[1]
[1]Sree Chitra Tirunal Institute for Medical Sciences & Technology (SCTIMST), Cardiology, Trivandrum, India

Funding Acknowledgements: Indian Council for Medical Research

Introduction: Heart failure (HF) is emerging as a leading cause of hospitalization in India. There is paucity of long term outcomes of HF from India.
Objective: To assess the long-term outcome of patients admitted with acute decompensated HF(ADHF) at a tertiary care hospital in Kerala, India.
Methods: The data of consecutive patients from the state of Kerala who were admitted during 2001-2010 with a diagnosis of HF (satisfying European Society of Cardiology Criteria) at SCTIMST were retrospectively collected. Follow-up data were obtained until June 2017 and the follow-up was right censored at ten years.
Results: The data of 1502 patients were collected (mean age:51.1 years (SD = 14.3); females: 37.7%). Diabetes and hypertension was prevalent in 27.4% and 28.6% of participants at baseline, respectively. The most common etiology was ischemic heart disease (36%) followed by rheumatic heart disease (RHD) (34%), Others were non-RHD valve disease (8.2%), dilated cardiomyopathy (4.8%), other cardiomyopathies (6.4%; restrictive, hypertrophic and endomyocardial fibrosis) and grown-up congenital heart disease (4.8%). One third (33%) of patients were in atrial fibrillation or atrial flutter(AF). When the patients were classified based on ejection fraction (EF), HFpEF (57.9%) was the commonest condition followed by HFrEF (26.8%) and HFmrEF (15.3%) (p-preserved, r-reduced, mr-mid-range). We got the follow-up data in 92% of the patients at June 2017.
The total time at risk was 6248 person-years. Almost three fourths of the patients (n = 1051; 72.24%, 95% CI 0.70-0.74) died during the follow-up. The median survival time was 3.7 years and the death rate was 16.8 per 100 person years of follow-up (95% CI: 15.8 to 17.8). One of six patients with HFrEF received guideline directed therapy - GDT (combination of ACE inhibitor/ARB and beta-blocker). Those who received guideline directed therapy reported better cumulative survival rate in both HFrEF and HFmrEF groups (Figure). The survival benefit was however well established in the first three months of follow-up itself.
Conclusions: Compared to data from the west, HF patients in Kerala are relatively younger and predominantly males. Although RHD is a major contributor to HF in this region, ischemic heart disease is the most prevalent etiological condition. Median survival time of 3.7 years is comparatively lower than the Western data. Importantly, guideline directed therapy reduced the mortality in both HFrEF and HFmrEF. Additionally, HF patients with preserved ejection fraction (HFpEF) reported the lowest mortality. This is the first study from India showing long term outcomes of ADHF.



Survival analysis of long term outcome

1622
Five-year follow-up in patients with peripartum cardiomyopathy (PPCM) shows high and stable recovery rate and longterm use of cardiovascular medication

V Abou Moulig[1]; T Pfeffer[1]; M Ricke-Hoch[1]; S Schlothauer[1]; M Kasten[1]; D Berliner[1]; T Koenig[1]; J Schwab[2]; J Bauersachs[1]; D Hilfiker-Kleiner[1]
[1]Hannover Medical School, Klinik für Kardiologie und Angiologie, Hannover, Germany; *[2]Nuremberg Hospital South, Nuremberg, Germany*

Background: Peripartum cardiomyopathy (PPCM) is a rare type of heart failure, defined by reduced left ventricular ejection fraction (LVEF) occurring in previously healthy women during late pregnancy or in the months following delivery. Although many patients recover, PPCM is lethal for some women despite optimal treatment. Longterm studies are rare. Here, we present five-year follow-up data in PPCM patients.
Methods: All patients who were diagnosed with PPCM between February 2006 and May 2013 were included (n = 70). LVEF, medical treatment, adverse events and subsequent pregnancies were recorded. Follow-up data were obtained one and five years after the first diagnosis either by a subsequent visit in our clinic or by requesting the medical report from the treating cardiologist. For 14 patients who did not attend to any cardiologic follow-up, a telephone interview was performed.
Results: Of the 70 patients six were lost to follow-up. Of the remaining 64 patients (mean age 34 ± 5 y) follow-up data after one year (13 ± 2 months) were available for 42 patients and after five years (63 ± 9 months) for 50 patients.

At diagnosis LVEF was reduced (26 ± 10%). 70% of the patients received combination therapy of beta-blocker, angiotensin-converting enzyme (ACE) inhibitor/angiotensin-receptor-blockers (ARB) and mineralocorticoid receptor antagonists (MRA), 28% received two of these drugs and 2% did not get any heart failure medication. In addition 90% were treated with the dopamine agonist bromocriptine.
After one year mean LVEF had improved to 51 ± 11%. 60% of the patients had achieved full cardiac recovery with LVEF = 50%, 31% had recovered partially (LVEF 35-49%), 9% showed no recovery (LVEF < 35% or left ventricular assist device, LVAD) and no patient had died.
After five years mean LVEF had increased to 54 ± 6%. 70% of the patients showed full and 26% partial recovery. No recovery was seen in 4% (two patients needed LVAD of whom one had died). 76% of the patients still took heart failure medication (29% had three drugs, 27% had two drugs and 20% one drug). 20% needed these medications for arterial hypertension or ventricular extrasystoles. Ten patients had a subsequent pregnancy, the mean LVEF after delivery was normal.
Conclusion: Our prospective five-year follow-up study shows a high and stable longterm recovery rate of PPCM with low mortality with standard heart failure treatment combined with prolactin blockers in the acute phase, and longterm cardiovascular drug therapy during the years following the diagnosis. Our results emphasize that the recovery process continues even beyond the first year after diagnosis. Selected patients achieving good LVEF recovery when managed according to this concept seem to have a good chance for successful subsequent pregnancies without relapse. However, a high percentage of patients had developed hypertension and arrhythmias, suggesting that PPCM is associated with cardiovascular disease even in patients with recovery in LVEF.

1623
Time trends in characteristics, clinical course and outcomes of an unselected sample of 13,791 Spanish patients with acute heart failure (2007-2016)

O Miro[1]; P Javaloyes[2]; V Gil[1]; P Herrero-Puente[3]; FJ Martin-Sanchez[4]; H Bueno[5]; J Parissis[6]; CE Muller[7]; MP Lopez-Diez[8]; JM Garrido[9]; E Salvo[10]; M Fuentes[11]; F Richard[8]; FJ Lucas[12]; P Llorens[2]

On behalf of: ICA-SEMES Research Group
Funding Acknowledgements: ISCIII (Spanish Ministry of Health) and FEDER (PI15/01019 and PI15/00773), Fundació La Marató de TV3 (2015/2510) and Calalan Govern (GRC 2014/0313)

Objectives: To analyse time trends in patient characteristics, clinical course, hospitalisation rate, and outcomes in acute heart failure along a 10-year period (2007-2016).
Patients and Methods: The EAHFE registry has prospectively collected 13,971 consecutive AHF patients diagnosed in 41 Spanish emergency departments (EDs) at 5 different time points (2007/2009/2011/2014/2016). Eighty fundamental variables and patient outcomes were described and statistically significant changes along time were evaluated. We also compared our data with large ED- and hospital-based registries.
Results: Compared to other large registries, our patients were older [80 (10) years], more frequently women (55.5%) and had a higher prevalence of hypertension (83.5%) and a lower prevalence of ischaemic cardiomyopathy (29.4%). De novo AHF was observed in 39.6%. 63.6% showed some degree of functional dependence, and 56.1% had preserved left ventricular ejection fraction (LVEF). 56.8% of the patients arrived at the ED by ambulance, 4.5% arrived hypotensive, and 21.3% hypertensive. Direct discharge from the ED home was seen in 24.9%, and internal medicine (32.5%) and cardiology (15.8%) were the main hospital destinations. Triggers for decompensation were identified in 75.4%, the most being frequent infection (35.2%) and rapid atrial fibrillation (14.7%). The AHF phenotypes were: warm/wet 82.0%, warm/dry 6.2%, cold/wet 11.1%, cold/dry 0.7%. The length of hospitalisation was 9.3(8.6) days, and in-hospital, 30-day and 1-year all-cause mortality were 7.8%, 10.2% and 30.3%, respectively; and 30-day re-hospitalisation and ED revisit due to AHF were 16.9% and 24.8%. Thirty-nine of the 80 characteristics studied showed significant changes over time (Figure 1), while all outcomes remained unchanged along the 10-year period.
Conclusions: The EAHFE Registry is the first European ED-based registry describing the characteristics, clinical course and outcomes of a cohort resembling the universe of patients with AHF. Significant changes were observed over time in some aspects of AHF characteristics and management, but not in outcomes.

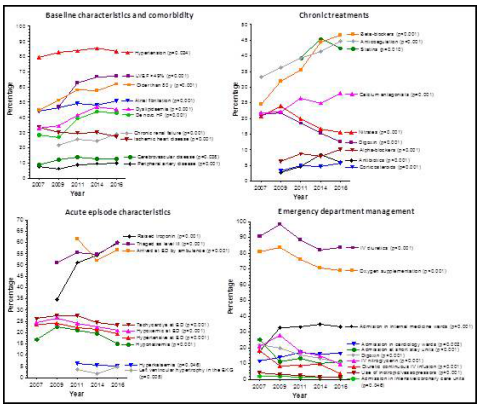

Figure 1

30-Day mortality in the takotsubo syndrome compared to acute coronary syndromes

B Bjorn Redfors[1]; S Jha[1]; O Angeras[1]; C Dworeck[1]; I Haraldsson[1]; S Volz[1]; J Odenstedt[1]; G Hirlekar[1]; P Petursson[1]; E Omerovic[1]
[1]Sahlgrenska Academy, Univ. of Gothenburg, Dept of Molecular & Clinical Medicine/Cardiology, Gothenburg, Sweden

Background: The incidence of the Takotsubo syndrome (TS) has increased over the last decade, but high-quality outcomes data from large TS cohorts are scarce and the impact of TS on prognosis is poorly understood. Whereas prognosis in TS was first believed to be excellent recent reports imply as high risk of dying as for patients with acute myocardial infarction.
Purpose: We sought to compare the 30-day prognosis of patients with TS to that of patients with ST-elevation (STE) and non ST-elevation (NSTE) acute coronary syndromes (ACS).
Methods: Using data from the Swedish Coronary Angiography and Angioplasty Registry on procedures performed between 2009 and 2016 we compared patients with TS to patients with STE and NSTE ACS in regards to 30-day mortality. We adjusted for patient characteristics (age, sex, diabetes, smoking status, hypertension, hyperlipidemia, prior myocardial infarction and prior PCI) using multivariable Cox proportional hazards regression, which accounted for clustering of patients within hospitals.
Results: We identified 1950 patients (1465 [75.0%] women) with TS, 33727 patients (10256 [30.4%] women) with STE-ACS and 88659 patients (28768 [32.5%] women) with NSTE-ACS. The average age was similar among patients with TS (67.0 ± 11.4 years) and STE-ACS (67.1 ± 12.5, p = 0.47), whereas patients with NSTE-ACS were older (67.9 ± 11.1 years, p = 0.0003). The crude 30-day rate of all-cause mortality was 2.9% among patients with TS, which was higher than patients with NSTE-ACS (1.5%, p < 0.0001) but lower than patients with STEMI (6.0%, p < 0.0001). The adjusted 30-day risk of dying associated with TS remained lower than that of STE-ACS (adjusted hazard ratio [HR] 0.45, 95% confidence interval [CI] 0.32-0.63, p < 0.0001) and similar to that of NSTE-ACS (adjusted HR 1.72, 95% CI 1.22-2.44, p < 0.0001).
Conclusion: Patients with TS have unadjusted and adjusted short-term prognosis that is intermediate between NSTE-ACS and STE-ACS.

1627
Short-term outcomes of heart failure patients with reduced and preserved ejection fraction after acute decompensation according to the final destination after emergency department care

O Miro[1]; V Gil[1]; FJ Martin-Sanchez[2]; J Jacob[3]; P Herrero-Puente[4]; S Aguilo[1]; R Escoda[1]; A Dominguez-Rodriguez[5]; J Marco-Hernandez[1]; G Martinez[1]; V Rico[1]; C Sanchez[1]; J Parissis[6]; CE Muller[7]; P Llorens[1]

University Hospital, Cardiology Department, Athens, Greece; [7]*University Hospital Basel, Cardiology Department, Basel, Switzerland*

On behalf of: ICA-SEMES Research Group
Funding Acknowledgements: ISCIII (Spanish Ministry of Health) and FEDER (PI15/01019 and PI15/00773), Fundació La Marató de TV3 (2015/2510) and Calalan Govern (GRC 2014/0313)

Aims: To compare short-term outcomes after an episode of acute heart failure (AHF) in patients with a reduced and preserved ejection fraction (HFrEF, < 40%; and HFpEF, >49%; respectively) according to their destinations after emergency department (ED) care.
Methods and Results: This secondary analysis of the EAHFE Registry (consecutive AHF patients diagnosed in 41 Spanish EDs) investigated 30-day all-cause mortality, in-hospital all-cause mortality, prolonged hospitalisation (<7 days), and 30-day post-discharge ED revisit due to AHF, all-cause death, and combined endpoint (ED revisit/death) in 5,829 patients with echocardiographically documented HFrEF and HfpEF (HFrEF/HFpEF: 1,442/4,387). Adjusted ratios were calculated for patients admitted to internal medicine (IM), short stay unit (SSU), and discharged from the ED without hospitalisation (DEDWH) compared with those admitted to cardiology. For HFrEF, the only significant differences were lower in-hospital mortality (OR = 0.26; 95%CI = 0.08-0.81; p = 0.021) and prolonged hospitalisation (OR = 0.07; 95%CI = 0.04-0.13; p < 0.001) related to SSU admission. For HFpEF, IM admission had a higher post-discharge 30-day mortality (HR = 1.85; 95%CI = 1.05-3.25; p = 0.033) and combined endpoint (HR = 1.24; 95%CI = 1.01-1.64; p = 0.044); SSU admission had a lower in-hospital mortality (OR = 0.43; 95%CI = 0.23-0.80; p = 0.008) and prolonged hospitalisation (OR = 0.17; 95%CI = 0.13-0.23; p < 0.001) but a higher post-discharge 30-day combined endpoint (HR = 1.29; 95%CI = 1.01-1.64; p = 0.041); and DEDDWH had a lower 30-day mortality (HR = 0.46; 95%CI = 0.28-0.75; p = 0.002) but higher post-discharge ED revisit (HR = 1.62; 95%CI = 1.31-2.00; p < 0.001) (Figure 1)
Conclusion: While HFrEF patients have similar short-term outcomes irrespective of the destination after ED care for an AHF episode, HFpEF patients experience worse short-term outcomes when managed by non-cardiology departments, despite adjustment for different clinical patient profiles. Reasons for this heterogeneous specialty-related performance should be investigated.

Funding Acknowledgements: Orion Spain

Background: The LION-HEART study was a multicentre, double-blind, randomised, parallel-group, placebo-controlled trial evaluating the efficacy and safety of intravenous administration of intermittent doses of levosimendan in outpatients with advanced chronic heart failure. In this study, a lower rate of hospitalization for heart failure (HF) was observed in patients treated with levosimendan (22,9%) than in untreated patients (66,7%).
Purpose: Perform a cost analysis to determine whether the lower rate of hospitalizations for HF with levosimendan could generate savings for the Spanish National Health System (NHS), compared to the option of not treating patients with advanced HF.
Methods: An economic model that included hospitalization rates from the LION-HEART study, HF hospitalization costs and acquisition and intravenous administration costs of levosimendan was performed. The time horizon of the analysis was 12 months. Two analyzes were carried out, one deterministic and the other probabilistic (second-order Monte Carlo simulation).
Results: According to the deterministic analysis, the total saving for each patient treated with levosimendan would amount to €1,093.30. The additional cost of the medication (€1,404.61) and its intravenous administration (€480.24) was more than compensated by the savings due to the lower rate of hospitalization with levosimendan (€2,978.16). In the probabilistic analysis, the saving per patient treated with levosimendan would be €1,162.43 (95% CI €286.47; €2,599.65). The probability of savings with levosimendan compared to the no treatment option would be 94.1%.
Conclusion: Intermittent outpatient treatment with levosimendan could generate savings for the Spanish NHS, compared to the option of not treating patients with advanced HF.

Atrial Fibrillation - Epidemiology, Prognosis, Outcome

P1630

Clinical characteristics of patients with heart failure with mid-range ejection fraction and atrial fibrillation

A Samaras[1]; G Fotos[1]; G Dividis[1]; E Paschou[1]; J Goulas[1]; D Vasdeki[1]; E Forozidou[1]; P Tsoukra[1]; E Kotsi[1]; A Kartas[1]; H Karvounis[1]; A Tzikas[1]; G Giannakoulas[1]
[1]*Ahepa University Hospital, 1st Cardiology department , Thessaloniki, Greece*

On behalf of: MISOAC-AF investigators

Background: Heart failure (HF) often coexists with non-valvular atrial fibrillation (AF) and this combination increases the risk for thromboembolic events. Data on the population of patients with heart failure with mid-range ejection fraction (HFmrEF) and concomitant AF are currently lacking.
Aim: To determine the clinical characteristics and treatment strategy of rate/rhythm control and anticoagulation of patients with HFmrEF and AF in a dataset of patients who were hospitalized in a tertiary University Hospital.
Methods: Patients with chronic HF were classified into three groups according to the left ventricular ejection fraction (EF) [HF with reduced EF <40% (HFrEF), HF with mid-range EF:40-49% (HFmrEF) and HF with preserved EF = 50% (HFpEF)]. All patients had coexisting AF. A multivariate model using stepwise logistic regression analysis was performed to analyze the differences among the HF subgroups.
Results: In total, 307 patients with HF and AF (mean age75 ± 9.6 years, mean CHA2DS2-VASc score 5.3 ± 1.6) were studied (HFpEF 52%, HFmrEF 19%, HFrEF29%). HFmrEF patients presented more often with palpitations as their main symptom at admission compared with HFrEF (19% vs 6%, OR 5.52, 95%CI 1.43-2.18, p = 0.013) and HFpEF patients (19% vs 11%, OR 7.33, 95%CI 1.80-29.97, p = 0.006). HFmrEF patients were more likely to be male (62% vs 39%,OR 2.23, 95%CI 1.04-4.81, p = 0.039), younger (mean age 74 ± 10 vs 77 ± 9 years, OR 1.07, 95%CI 1.02-1.11, p = 0.003), have concomitant coronary artery disease (66% vs 44%,OR 3.61, 95%CI 1.61-8.09, p = 0.002) and history of prior stroke (25% vs 19%, OR 3.75, 95%CI 1.47-9.59, p = 0.006) in comparison with HFpEF patients. The presence of diabetes mellitus was more frequent in HFmrEF patients compared with HFrEF (45% vs 33%, OR 6.13, 95%CI 1.95-19.23, p = 0.002) and HFpEF (45% vs 40%, OR 9.31, 95%CI 2.73-31.74, p <0.001). Paroxysmal AF pattern was less frequent in HFmrEF compared with HFpEF patients (22% vs 37%, OR 0.33, 95%CI 0.14-0.76, p = 0.01). There was no difference in the CHA2DS2-VASc and HAS-BLED score among the HF subtypes. HFmrEF patients received more frequently beta-blockers compared with HFpEF patients (96% vs 80%, OR 11.78, 95%CI2.41-57.58, p = 0.002) and less often amiodarone at discharge compared with HFrEF patients (7% vs 27%, OR 0.23, 95%CI 0.07-0.78, p = 0.018). There was no difference in the use of anticoagulants (novel oral anticoagulants and vitamin K antagonists) among the three groups.
Conclusions: Among the HF-AF populations, patients with HFmrEF had more frequently a history of coronary artery disease, diabetes mellitus, prior stroke and increased use of beta-blockers. Patients with HFmrEF and AF share similar clinical phenotype and comorbidities with HFrEF-AF patients and have distinct differences from HFpEF-AF patients.

P1631

Mid-term outcomes in heart failure patients treated with non-vitamin K antagonist oral anticoagulants. A real world study.

C Goena Vives[1]; L Quintas Ovejero[1]; R Garcia Martin[1]; I Luis Serret[1]; J Taboada Gomez[2]; I Rilo Miranda[3]; JR Beramendi Calero[3]; C Gomez Ramirez[4]; R Natividad Andres[4]
[1]*Mendaro's Hospital, Cardiology, Mendaro, Spain*; [2]*Mendaro's Hospital, Public Health, Mendaro, Spain*; [3]*Donostia University Hospital, Cardiology, Donostia, Spain*; [4]*Cruces University Hospital, Cardiology, Barakaldo, Spain*

Introduction: New oral anticoagulants (NOAC) have been released for prevention of thromboembolism in non-valvular atrial fibrillation (NVAF).In the general population, each of them has been proven to be at least as effective and safe as warfarin but has to be studied in a real-world setting and in special patient population.
Purpose: Evaluate the mid-term efficacy and safety of NOAC in Heart Failure (HF).
Methods:520 consecutive patients with NVAF and NOAC with HF(158 cases, 30.4 %) or without (no-HF) (362 cases, 69.6%) were retrospectively reviewed.The incidence of HF was 9.4% in 4 years (34 new cases).The efficacy outcome was stroke or systemic embolism.The safety outcome was bleeding or death.
Results: The follow-up days were 507 ± 434.The mean age (75 ± 10), prevalence of previous stroke, HTA and DM was similar in the two groups.HF patients had a higher predicted stroke, renal dysfunction and bleeding risk (see table 1).The NOAC used were Dabigatran, Apixaban, Edoxaban and Rivaroxaban. In HF patients Apixaban was the most used.Differences between groups were statistically significant(see table 1). The global incidence of death (9%), systemic embolism (2.3%:Stroke N = 10, ACS N = 1, peripheral embolism N = 1) and major(3.5%) and minor(10.3%) bleeding was higher comparing the pivotal trials due to the higher predicted risk of population in the study but there were no differences statistically significant between groups.Conclusions:The benefit of NOAC was similar in NVAF patients with and without HF, despite the HF group has an additional risk for adverse effects in our series. Individual potential risk, benefit and harness of treatment must be carefully examined before matching a NOAC to a particular patient. Further research is required concentrating NVAF and heart failure.

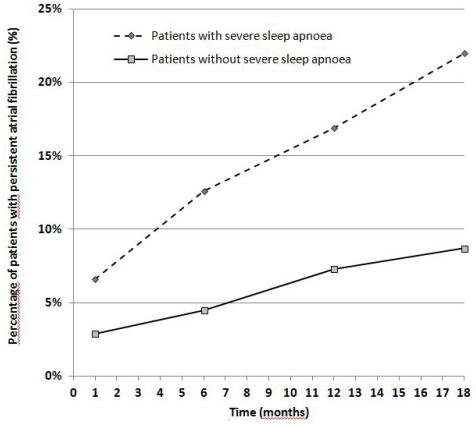
Background/Introduction: Patients with sleep apnoea (SA) often have atrial fibrillation (AF). Gold-standard diagnosis of SA with polysomnography is costly and often lengthy, making widespread use of this method impractical. The SA monitoring feature in REPLY 200 DR pacemakers analyses and records abnormal night-time breathing events, eg, apnoea and hypopnoea, allowing pre-screening of SA via the measurement of the respiratory disturbance index (RDI).
Purpose: The RESPIRE (Registry of Sleep Apnea Monitoring and Atrial Fibrillation in Pacemaker Patients) study examined the development of persistent AF in an unselected pacemaker population over 18 months, according to the severity of SA.
Methods: RESPIRE was an 18-month multicentre, international, single-arm, open-label study that observed adult patients after implant with an SA monitoring–enabled dual chamber pacemaker. SA severity during sleep was determined from device memory using RDI, the sum of abnormal respiratory events divided by sleep duration. Severe SA was defined as a mean RDI = 20. Persistent

AF was defined as an AF episode lasting for more than 7 consecutive days, based on the duration of fallback mode switch in the device memory. Endpoints included were the development of persistent AF in patients with severe SA and patients without severe SA from implant to 1, 6, 12 and 18 months. Mean intergroup differences (95% confidence intervals) were estimated in successfully implanted patients with valid SA monitoring data for = 80% of nights.
Results: In the 1147 enrolled patients, 56.3% were male and mean age was 75.7 ± 10.3 years. There were
301(36%)/525(64%) patients with severe/non-severe SA at 1 month, 230(34%)/449(66%) at 6 months, 172(31%)/381(69%) at 12 months, and 118(27%)/312(73%) at 18 months. The development of persistent AF in patients with and without severe SA is described in the Figure. Mean intergroup differences in the incidence of persistent AF at 1, 6, 12 and 18 months were 3.8% (0.2% to 7.4%), 8.2% (2.8% to 13.5%), 9.5% (2.5% to 16.6%) and 13.4% (4.1% to 22.7%).
Conclusion(s): In unselected pacemaker patients, persistent AF develops sooner and more often in patients with severe SA than in patients without severe SA.



P1633

Holter monitoring value in cardioembolic stroke: a follow up study

H Helena Nascimento[1]; C Sousa[1]; J Rema[1]; M Braga[1]; A Lebreiro[1]; D Souteiro[1]; P Chaves[1]; M Campelo[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Porto, Portugal*

Background: Cardioembolic etiology accounts for 14-30% of all cerebral infarctions. As atrial fibrillation (AF) is the most important cause, identification of paroxysmal atrial fibrillation (PAF) may have crucial prognostic impact. Holter monitoring (HM) has been increasingly used in stroke and transient ischemic attack (TIA) patients (pts) as a routine investigation to search for occult PAF. The purpose of this study was to verify the HM prognostic implications in the follow-up of cardioembolic stroke.
Methods: A group of 80 pts selected in the setting of post stroke or TIA, that were in sinus rhythm at the time of the event and performed HM between October 2009 and October 2011 were reviewed and followed up. Clinical, echocardiographic and neuro imaging data were collected an inserted in an uniform base.
Results: In our population 53% were male, with a median age of 63 (range 52-67) years at the index event. Sixty-four pts had a stroke (80%), and 17 a TIA (20%); thrombolysis was performed in 24% of the case. In the HM, PAF occurred in 5% of the pts (4). Comparing PAF and ESVEA groups of pts and sinus rhythm pts, no statistically significant differences were found, neither concerning clinical nor imaging data. During a median follow up (fup) of 82 months (range 58-98), 9 pts developed AF, 7 PAF (78%) and 2 permanent AF. During this period, 9 pts had a recurrent cerebrovascular event: 4 TIA and 5 strokes (only one hemorrhagic). From these pts, 56%were male(5), median age 69 (range 61-82) years, 44% hypertensive, 22% diabetic, 56% dyslipidemia and 33% smokers. Regarding demographic and cardiovascular risk factors, no differences were found between the group of pts with recurrent events and the other pts with no events in fup. Although not statistically significant, we found a tendency towards a higher value ofCHA2DS2-VASc in pts with recurrent cerebral ischemic events (5.4 ± 1.4 vs. 4.9 ± 1.3). Concerning the documentation ofAF, it was detected in only one of recurrent AIT/stroke pts. Still, it must be recognized that only 10 pts repeated the HM during the fup period.
Conclusions: Our study emphasizes that is of paramount importance to detect PAF after acute cerebral ischemia in order to prevent recurrence. HM is an invaluable tool in the workup of suspected cardioembolic stroke. However, new strategies like prolonged Holter monitoring and loop recorders are needed. Moreover, our investigation suggests a potential role of CHA2DS2-VASc score as a predictor of recurrent events even in patients without fibrillation.

P1634

Development of significant atrial fibrillation over 18 months in the RESPIRE study in unselected pacemaker patients with or without severe sleep apnoea

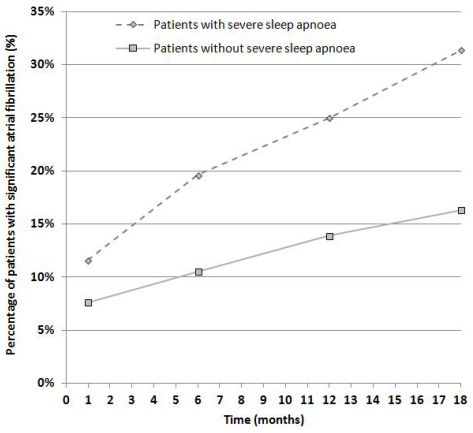
Background/Introduction: Patients with sleep apnoea (SA) often have atrial fibrillation (AF). Diagnosing SA with polysomnography is costly and often lengthy, making widespread diagnosis with this method impractical. Some pacemakers are able to pre-screen SA via the measurement of the respiratory disturbance index (RDI). One of these, the REPLY 200 DR pacemaker, has an SA monitoring feature that analyses and records abnormal night-time breathing events, eg, apnoea and hypopnoea.
Purpose: The RESPIRE (Registry of Sleep Apnea Monitoring and Atrial Fibrillation in Pacemaker Patients) study examined the development of significant AF in an unselected pacemaker population, according to the severity of SA.
Methods: RESPIRE was an 18-month multicentre, international, single-arm, open-label study that observed adult patients after implant with an SA monitoring–enabled dual chamber pacemaker. SA severity during sleep was determined from device memory using RDI, the sum of abnormal respiratory events divided by sleep duration. Severe SA was defined as a mean RDI = 20. Significant AF was defined as cumulative AF episodes lasting = 24 hours over 2 consecutive days, based on duration of fallback mode switch. Endpoints included the development of significant AF from implant to 1, 6, 12 and 18 months, according to SA severity. Mean differences and 95% confidence intervals between the two groups (with versus without severe SA) were estimated in successfully implanted patients with valid SA monitoring data for = 80% of nights.
Results: In the 1147 enrolled patients, 56.3% were male and mean age was 75.7 ± 10.3 years. There were 301(36%)/525(64%) patients with severe/non-severe SA at 1 month, 230(34%)/449(66%) at 6 months, 172(31%)/381(69%) at 12 months and 118(27%)/312(73%) at 18 months. The development of significant AF over time in severe and non-severe SA patients is described in the Figure. Mean differences in the incidence of significant AF at 1, 6, 12 and 18 months were 4.0% (-0.3% to 8.3%), 9.1% (3.2% to 15.0%), 11.1% (3.7% to 18.4%) and 15.0% (5.7% to 24.3%).
Conclusion(s): In unselected pacemaker patients, significant AF develops sooner and more often in patients with severe SA than in those without.



Ventricular Arrhythmias and SCD - Treatment

P1635
Targeted temperature management after cardiac arrest

C Catarina Ruivo[1]; C Jesus[1]; J Morais[1]; J Correia[1]; P Viana[1]
[1]*Hospital Santo Andre, Cardiology, Leiria, Portugal*

Introduction and Purpose: Targeted Temperature Management (TTM) for patients with return of spontaneous circulation (ROSC) after cardiac arrest (CA) remain a matter of debate. Doubts remain about management, target temperature and duration. In the present study we describe the experience of a non-tertiary care center with TTM after CA and seek predictors of mortality and neurological outcome.
Methods and Results: 2279 patients were hospitalized in the intensive care unit and 82 of them had diagnosis of CA with ROSC. 15 patients were submitted to TTM, 47.3 ± 14 years, 10 (67.0%) male. The CA occured out-of-hospital (n = 11; 73.3%) or in-hospital (n = 4; 26.7%), in initial shockable (n = 10; 66.7%) or nonshockable (n = 5, 33.3%) rhythm. The average time from CA to ROSC (CA-ROSC) was 44.7 ± 36.5 min. All patients met the 24 hour target temperature of 33°C. The average value of neuron specific enolase (NSE) was 93.7 ± 109.0 μg/L. Patients who survived with good cerebral performance (n = 7; 46.7%) had lower median age (38.4 ± 10.1 vs 55.1 ± 13.2 years; p = 0.032), shorter CA-ROSC (22.9 ± 12.9 vs 63.8 ± 40.4 min; p = 0.048), lower measurements of NSE (42.6 ± 35.1 vs 138.4 ± 133.4 μg/L; p = 0.020) and initial ventricular fibrillation rhythm (p = ns) than those who died (n = 8; 53.3%).
Conclusions: The effectiveness of TTM seems related with younger age, shockable initial rhythm and reduced CA-ROSC time. These results point out some lines of research that appropriate prospective studies should develop. The role of biomarkers to predict prognosis is an open issue for debate, with the NSE occupying a particular role in this field.

P1636
Role of catheter ablation in electrical storm treatment

S Garkina[1]; R Tatarsky[1]; E Mikhaylov[1]; V Lebedeva[1]; V Orshanskaya[1]; YU Miller[1]; A Kamenev[1]; S Gureev[1]; D Lebedev[1]
[1]*Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation*

Background: Electrical storm (ES) is a life threating situation that involves recurrent episodes of ventricular tachyarrhythmias (VTA). It is defined as 3 or more sustained episodes of ventricular tachycardia (VT), ventricular fibrillation (VF) or appropriate implantable cardioverter-defibrillator (ICD) shocks during 24 hours. Several clinical studies demonstrated the rate of ES about 9-12% after ICD implantation due to both primary and secondary prevention while 7% of patients developed it during first year of follow up. Radiofrequency (RF) ablation of triggering ventricular premature beats or substrate-based catheter treatment are considered to be effective in ICD patients with heart failure (HF) and drug-refractory, repetitive polymorphic ventricular tachycardias (VT) after myocardial infarction (MI).
The purpose of the study was to evaluate the effectiveness of early and delayed radiofrequency ablation (RFA) in ES patients with severe HF, implanted ICD and postinfarction ventricular arrhythmias.
Materials and methods. We enrolled 14 consecutive patients with ES (mean age 61 + 12 years, 11 male) which underwent endocardial electrophysiological (EP) study and catheter ablation using the nonfluoroscopic navigation and mapping system. Average rate of appropriate ICD shocks during ES was 12,2 ± 14,1 per day whereas ICD was implanted 3,4 ± 3,2 years before the first ES episode. Only 3 patients were treated with ICD for primary prevention while 11 patients required secondary prevention of sudden cardiac death (SCD). Chronic heart failure (CHF) with NYHA III-IV functional class and left ventricular ejection fraction of 32 ± 12% was diagnosed in 10 patients (71%) among those who underwent emergency RFA. Catheter treatment was performed in 1-3 days after admission when potential reversible causes of ES were excluded. The procedure also included mapping during hemodynamically tolerated clinically relevant VT or clinical VTA triggers with subsequent homogenization of the scar. Patients with "fast" VT underwent primary scar homogenization.
Results: Acute effectiveness of emergency RFA in patients with clinically relevant VT was 64% (9 patients). During the first year of follow-up, 6 patients experienced recurrent VT episodes (43%) in 5 ± 3 months after discharge. The overall survival rate was 25%. Long-term effectiveness of ES elimination was 100% while freedom from clinically significant VTA was up to 79% due to repeated ablation procedures. We also observed improvement of NYHA functional class in 80% of patients. Conclusion. Catheter ablation of ES may be effective treatment in patients with sustained VTA resistant to drug therapy both in acute period and long term follow up. It also may be effective in improvement of heart failure NYHA functional class in some patients.

Implantable Cardioverter / Defibrillator

P1637
Occurrence of ventricular tachyarrhythmias in left ventricular assist devices patients with implantable defibrillators

M Sasov[1]; P Lesny[1]; M Svetlosak[1]; P Margitfalvi[1]; R Hatala[1]; E Goncalvesova[1]
[1]*National Institute of Cardiovascular Diseases, Bratislava, Slovak Republic*

Background: Primary prevention of sudden death with implantable defibrillators (ICD) in patients (pts) with left ventricular assist devices (LVAD) is still studied. Information on the impact of LVAD on malignant ventricular tachyarrhythmias (VTA) - ventricular tachycardia / fibrillation (VT/VF) and inappropriate ICD therapies is limited.
Purpose: Retrospective analysis of occurrence and type of VTAs and ICD interventions prior and post LVAD implantation in a single tertiary care centre.
Patients and Methods: 33 pts with end-stage systolic heart failure with implanted LVAD and ICDs or pacemakers were included. LVADs were implanted during years 2008-2015: all were continuous flow devices. Six pts (18%) died within 30 days after LVAD implantation. From the 27 surviving pts indications for LVADs were bridge to transplant (16 pts), bridge to candidacy (10 pts), destination therapy (1 pt). The aetiology of heart failure was dilated cardiomyopathy in 17 pts, coronary heart disease in 9 pts and congenital heart disease in 1 pt. 17 pts had implanted ICD (8 pts CRT-D), 1 pt had CRT-P and 1 pt dual-chamber pacemaker. Twenty three were men, mean age of the cohort was 47.7 ± 10.7 years. At the time of LVAD implant mean INTERMACS score was 2.56 ± 1.15, mean LVEF 18.8 ± 4.7%, mean CI 1.82 ± 0.37 l/min/m2. Mean follow-up duration was 29.9 ± 34.6 months before LVAD implantation and 17.2 ± 11.9 months after LVAD implantation. At the end of follow-up 14 pts underwent heart transplantation (52%), 10 pts died (37%), 2 pts were on waiting list for transplantation (7%) and LVAD was destination therapy in 1 pts (4%).
Results: Prior to LVAD implantation 9 pts (33%) had overall 40 VT episodes and 9 VF episodes. Following LVAD implantation 5 pts (19%) had 68 VT episodes and 11 VF episodes. Seventeen pts (63%) were free of VT/VF. Total annual per patient incidence of VTA increased post LVAD implantations from 0.59 to 1.75 and from 0.13 to 0.28 (episodes/pt/year) for VT and VF, respectively. In 6 pts with pre-LVAD occurrence of VT/VF the arrhythmia burden was reduced after LVAD, in 3 pts the burden increased. New VT/VF episodes after LVAD implant was diagnosed only in 1 pt. Inappropriate ICD interventions were diagnosed in 5/25 pts (20%) and accounted for 32% of all anti-tachycardia interventions. Annual incidence of inappropriate ICD interventions post-LVAD was 0.68 episodes/pt/year.
Conclusions: In our retrospective analysis VTA episodes post LVAD implant occurred mainly in those pts who had VTA episodes already prior to LVAD. Patients without VTA prior to LVAD implantation manifested a relatively low risk of VTA post-LVAD. Number of pts with VT/VF post LVAD implantation decreased, but total burden of VT/VF episodes increased. Almost 1/3 of ICD interventions post LVAD were inappropriate. Based on our observations in pts without ICD prior to LVAD implantation we recommend ICD implantation post-LVAD only for secondary prevention of VTA.

P1638
Cardiac device-related infective endocarditis: a challenge condition

H Helena Nascimento[1]; M Braga[1]; L Flores[1]; V Ribeiro[1]; F Melao[2]; D Paula[2]; MJ Maciel[2]
[1]*Sao Joao Hospital, Porto, Portugal*; [2]*Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*

Introduction and Purpose: In the last decades, the number of cardiac devices has grown exponentially. Cardiac device-related infective endocarditis (CDRIE) is a fearful complication, accounting for 10-23% of all cardiac device infections. Diagnosis and management of this condition remains a challenge. The aim of this study was to assess clinical and prognostic profile of CDRIE patients (pts).
Methods: A retrospective study of 173 consecutive diagnosed infective endocarditis (IE),admitted to several departments in a tertiary center from 2011 to 2014. Data were collected from the electronic clinical process and registered in an uniform base.
Results: Among theIE cases studied, 16 cases were CDRIE (9%). Mean age was 62 ± 22 years-old and 63%were males. The most common comorbidity was diabetes (25%). Intracardiac device was a pacemaker in 12 cases and a implantable cardioversor-defibrillator in the other 4. Average time from device implantation/replacement procedure to diagnosis was 64 months (range 7-86). No previous cases of IE were present; 50% of the cases were health-care associated IE. Fever was the predominating signal at hospital presentation (69%). Staphylococci species were the main causative microorganisms (25% coagulase negative and 44% S.aureus) and almost one fifth of the episodes were caused by methicillin resistant strains. Most pts had isolated infection of the cardiac leads (75%), however 3 pts

had also involvement of the tricuspid valve and 1 patient had also left side involvement. Lead vegetations were identified in 44% by transthoracic echocardiography and in 56% by transesophageal approach; vegetations were multiple in 11 cases and large (<10mm) in 2 cases. Complications developed during the clinical course were renal failure (19%), persistent infection (50%), heart failure (31%), shock (25%) and systemic embolism (19%). Most of the patients underwent surgical or percutaneous removal of the infected system (88%). Three pts died during the hospital stay.
Conclusion: CDRIE is a rising problem, with major diagnostic and therapeutic barriers. The clinical evolution is characterized by serious complications. Therefore, a high level of suspicion is of paramount importance to an accurate CDRIE diagnosis and treatment.

Cardiac Resynchronization Therapy

P1639
Minute ventilation sensor driven rate response as part of resynchronization therapy optimization

C Lenz[1]; S Fischer[2]; C Hansen[3]; A Werner[4]; C Beaudoint[5]; T Kayser[5]; N Cielen[5]; RC Braun-Dullaeus[6]; S Vikman[7]; B Zrenner[8]; S Pakarinen[9]

Erxleben, Internal Medizin, Quedlinburg, Germany; [3]Herz- und Gefäßzentrum am Krankenhaus Neu-Bethlehem Göttingen, Göttingen, Germany; [4]Clinic Oldenburg, Klinik für Kardiologie, Oldenburg, Germany; [5]Boston Scientific, Clinical RM, Diegem, Belgium; [6]Otto-von-Guericke University of Magdeburg, Klinik für Kardiologie und Angiologie , Magdeburg, Germany; [7]Tampere University Hospital, Heart Center, Tampere, Finland; [8]Hospital Landshut-Achdorf, Cardiology, Landshut-Achdorf, Germany; [9]Helsinki University Central Hospital, Division of Cardiology, Helsinki, Finland

Background: With increasing life expectancy and optimized pharmacological treatment, more patients (pts) show signs of chronotropic incompetence (CI) and heart failure (HF). Currently, not much data is available on the use of minute ventilation sensor (MVs) in those pts.

Table 1

Variable	Cohort 1 (n = 35)	Cohort 2 (n = 11)					
0 to 1 Month MVs off	1 to 3 Month MVs on	P value between time MVs off/ on	0 to 1 Month MVs off	1 to 3 Month MVs off	P value within off	P value between cohorts	
Age	71	75	0.205				
80% APMHR (bpm)	120	116	0.268				
Resting Heart Rate (bpm)	72	70	0.297	74	70	0.344	0.571
Maximum Heart Rate (MHR) during 6mWT (bpm)	95	101	0.038	101	108	0.365	0.246

* between group p value from the repeated measure ANOVA model.							
* within group p value from Wilconson signed-rank test							

Objective: To assess the clinical impact of optimized rate adaptive pacing (RAP) by MVs alone in HF patients following 6 minute walking test (6mWT).
Methods: A total of 61 pts with well established indication for CRT-P were enrolled into the study; participants were implanted with a device capable of rate adaption based on a minute ventilation driven algorithm. All patients suffered from symptomatic heart failure (NYHA class II or greater).
At pre-discharge, all pts were programmed in DDD mode, unless they had a known need for RAP. At 1 Month (mo), a 6mWT was performed in a non-RAP mode and walking distance was collected. When max. HR (MHR) was < 100min-1 or < 80% Age predicted MHR (APMHR), MVs was turned ON. At 3 Mo, the 6mWT was repeated in DDDR. Demographics, resting and MHR and % atrial pacing (AP) were collected.
Results: Implanted pts (n = 61; mean age: 73.3 ± 10.1 years) had LVEF of 41.1 ± 11.6% and NYHA value of 2.6 ± 0.64. After 6mWT at 1Mo, 35 pts had MVs turned ON , 11 pts remained in DDD and 15 pts were excluded (other programming, incomplete datasets). Pts with MVs ON resulted at 3 month FU in a higher % AP, allowed an increase of the MHR similar to subjects with no CI, and improved 6mWT distance. No MVs related adverse events have been reported.
Conclusion: This study showed beneficial clinical effects of using MVs only in a CRT-P cohort who could not reach 80% APMHR at 1 mo 6mWT. Patients under optimal medical therapy have an underestimated need of sensor driven HR frequency which is supporting CRT therapy.

P1640
The change pattern of doses in loop diuretics according to cardiac resynchronization therapy response is associated with clinical outcomes in patients with heart failure and reduced left ventricular e

J Jaewon Oh[1]; JS Uhm[1]; IJ Cho[1]; TH Kim[1]; HN Pak[1]; MH Lee[1]; B Joung[1]; SM Kang[1]
[1]Yonsei University College of Medicine, Cardiology Division, Seoul, Korea Republic of

Introduction: Cardiac resynchronization therapy (CRT) improves cardiac hemodynamics. Recently, down-titration of loop diuretics was associated with improved clinical outcomes after CRT. Therefore, we evaluated the change pattern of doses in loop diuretics according to CRT response and its association with clinical outcomes in patients with heart failure with reduced ejection fraction (HFrEF).
Methods: We retrospectively investigated 76 HFrEF patients (M:F= 41:35) with CRT implantation from January 2010 to October 2015. Pre-defined echocardiographic responses 6 months after CRT implant were: 1) negative responder (increased LV end systolic volume, LVESV), 2) non-responder (decreased LVESV, 0-14%), 3) responder (decreased LVESV, 15-29%), and, 4) super-responder (decreased LVESV = 30%). Loop diuretics dose (daily furosemide equivalent) was assessed before and 6 months after CRT implant. Clinical outcomes including all-cause mortality and HF rehospitalization were assessed during follow-up period (median 555 days)
Results: Mean age, baseline LVEF and ischemic HF were 67 ± 10 years, 24.3 ± 6.1% and, 14.5%, respectively. There were 53 (69.7%) patients with down-titration or no loop diuretics (34.2%) and unchanged diuretics dose (35.5%). The prevalence of these pattern of diuretic users were 43.8% in negative responders (n = 7/16), 66.7% in non-responders (n = 18/27), 88.9% in responders (n = 8/9) and 83.3% in super-responders (n = 20/24) (p = 0.031). Up-titration of loop diuretics (30.3%) was associated with higher all-cause mortality (47.8 vs. 13.2%, p = 0.005) and HF rehospitalization (52.2 vs. 18.9%, p = 0.006) compared with other patterns of diuretic users.
Conclusion: After CRT, down-titration or no loop diuretics and unchanged diuretics dose are significantly less common in negative responder compared to other responder groups. Up-titration of loop diuretics was associated with poor clinical outcomes after CRT in HFrEF patients.

P1641
Mild to moderate functional mitral regurgitation and cardiac resynchronization therapy: Evaluation and prognosis

JL Jose Luis Martins[1]; J Milner[2]; N Antonio[2]; L Elvas[2]; J Viana[1]; M Pego[2]; J Santos[1]
[1]Centro Hospitalar do Baixo Vouga, Cardiology, Aveiro, Portugal; [2]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal

Introduction: Functional mitral regurgitation (MR) may be a consequence of systolic dysfunction, changes in geometry or occur in the presence of dyssynchrony. Degree reduction of severe functional MR after cardiac resynchronization (CRT) therapy appears to have a mortality impact. On the other hand, the long-term prognosis of mild to moderate MR changes after CRT implantation is not well established.
Methods: We retrospectively studied patients submitted to cardiac resynchronization therapy with pre-implantation MR. The patients were divided in 4 groups according to MR severity changes: grade 1 or 2 worsened MR (Group 1); improved or unchanged grade 1 or 2 MR (Group 2); worsened or unchanged grade 3 or 4 (Group 3); improved grade 3 or 4 (Group 4). Mortality and echocardiographic measurements were evaluated during mean follow-up of 1303 ± 634 days.

Results: The study included 144 patients with MR pre-CRT implantation (age 63 ± 11years, 75% male, 30% ischemic etiology). Preclinical grade 1 MR was present in 44% of patients and grade 2 in 29% of patients. Super-responders rate was 21%; 24% responders and 54% non-responders. Pré-implantation left ventricular final diastolic volume (LVEDV) was 234 ± 83 ml compared to 203 ± 96 ml LVEDV postimplantation (p = 0.001). Pré-implantation left ventricular final systolic volume (LVESV) was 174 ± 78 ml versus 142 ± 86 ml postimplantation LVESV (p < 0.001). There was no difference in mortality between group 1 and 2 (logrank, p = 0.98). There was a tendency for a better survival when there was improvement in the severity degree if the degree was moderate to severe (group 3 versus group 4, logrank, p = 0.1).
Conclusion: Among patients with mild to moderate MR at baseline, the worsening degree of MR does not appear to have a prognostic impact.

P1642
Left ventricular only pacing with dual chamber pacemaker system: Improve left ventricular function in patients with atrioventricular conduction delay and left ventricular systolic dysfunction.

HABIBA Umme Habiba Ferdaushi[1]; ATAHAR M Atahar Ali[1]; SHAILA Shaila Nabi[1]; MAINUL Mainul Islam[1]
[1]*National Institute of Cardiovascular Disease, cardiology, Dhaka, Bangladesh*

Background: In patients with atrioventricular (AV) delay and concomitant left ventricular (LV) systolic dysfunction, conventional right ventricular (RV) apical pacing may lead to further deterioration of LV function and heart failure, particularly in patients with depressed LV function at baseline. Cardiac resynchronization therapy (CRT) improves LV hemodynamics and function in this subset of patients, partially reversing the deleterious effects of RV apical pacing. However, these devices are not affordable to many patients in Bangladesh.
Objective: We aimed to assess the efficacy of LV only pacing using two leads, right atrial (RA) and LV leads with dual chamber pacemaker as a cost effective alternative to conventional CRT in patients with AV block requiring pacing, and concomitant LV systolic dysfunction.
Methods: We implanted right atrial (RA) and LV leads with dual chamber pulse generator in four patients with complete heart block and LV dysfunction with New York Heart Association (NYHA) functional class III/IV symptoms, at the National Institute of Cardiovascular Diseases (NICVD), Dhaka from December 2016 to November 2017. The sensed atrioventricular delay was programmed to pre-excite the LV and achieve fusion beat. Response to therapy was assessed six months post implantation using clinical and echocardiographic parameters.
Results: Four male patients were included. The indication for pacing in all patients was complete heart block. The mean age was 73 ± 1.2 years. Pacing was achieved in all patients. At six months follow up, no patient reported syncope or pacing failure. There was significant improvement of NYHA functional class from 3.3 ± 0.44 to 1.7 ± 0.6 (p <0.001) in all patients. On echocardiography, mean LV end-diastolic diameter (LVEDD) decreased from 65.5 ± 4.65 mm to 54.75 ± 2.21 mm (p <0.001) and mean LV end-systolic diameter (LVESD) decreased from 53.75 ± 4.78 to 43.5 ± 4.35mm (p < 0.001). The mean difference of LVEDD and LVESD pre and post-procedure was 10.25 ± 2.5mm and 9.75 ± .62mm respectively. LV ejection fraction (EF) improved significantly from 30.5 ± 5.3% to 44.25 ± 3%(p <0.001).
Conclusion: RA-LV pacing is a cost-effective alternative to CRT in patients with LV systolic dysfunction and indication for anti-bradycardia pacing. Although the study was performed on a small number of patients, it can be considered that this therapy had favorable haemodynamic effect and improved myocardial structure and function by left ventricular reverse remodeling.

P1643
The impact of left ventricular lead position on long-term clinical outcome: a high volume, single center experience

A Annamaria Kosztin[1]; W Schwertner[1]; A Kovacs[1]; E Zima[1]; L Geller[1]; V Kutyifa[1]; B Merkely[1]
[1]*Semmelweis University, Heart Center, Budapest, Hungary*

Background: There is limited data on the association of left ventricular (LV) lead location with long-term clinical outcomes in patients after cardiac resynchronization therapy (CRT).
Purpose: We evaluated the mid-term echocardiographic response and long-term survival of patients who underwent CRT implantation by LV lead non-apical positions and further characterised by right to left ventricular activation delay (RV-LV AD).
Methods: In our retrospective registry patients underwent CRT implantation according the current guidelines from 2004 to 2017 were registered. Those with non-apical LV lead location was classified into anterior (n = 30), posterior (n = 154), and lateral (n = 370) positions. Primary endpoint was all-cause mortality assessed by Kaplan-Meier and Cox regressional analyses. Secondary endpoint was echocardiographic response within 12 months.
Results: From 554 patients 291 (53%) reached the primary endpoint during the mean follow up time of 4.3 years. Univariate analysis showed patients with lateral position had significantly better outcome compared to others (HR 0.78; 95% CI: 0.61-0.98; p = 0.04), which was also confirmed by Cox analysis (HR 0.79; 95% CI: 0.62-1.01; p = 0.05) after adjusting for RV-LV AD. The mean of RV-LV AD was significantly larger in the lateral group and showed an U-shaped curve by LV lead location. When echocardiographic response was evaluated in the lateral group, ROC analysis showed 100 ms as the optimal cutoff value (AUC 060, 95% CI: 0.51-0.69; p0.03).
Conclusions: Mortality benefit derived from CRT is associated only with lateral LV lead location, moreover the most beneficial echocardiographic response could be expected in those patients where RV-LV AD is longer than 100ms in this group.

Chronic Heart Failure - Pathophysiology and Mechanisms

P1644
Relationship of circulating plasma levels of D-Dimer and outcome in patients with heart failure: findings from BIOSTAT-CHF

P Pellicori[1]; G James-Rae[1]; A Voors[2]; K Dickstein[3]; G Filippatos[4]; F Zannad[5]; S Anker[6]; P Ponikowski[7]; A Mcconnachie[1]; JGF Cleland[1]
[1]*University of Glasgow, Robertson Centre for Biostatistics, Glasgow, United Kingdom*; [2]*University Medical Center Groningen, Groningen, Netherlands*; [3]*University of Bergen, Bergen, Norway*; [4]*National & Kapodistrian University of Athens, Athens, Greece*; [5]*University Hospital of Nancy , Nancy, France*; [6]*Charité - Universitätsmedizin Berlin, Berlin, Germany*; [7]*Wroclaw Medical University, Wroclaw, Poland*

Aims: D-Dimer, is produced by fibrinolysis of cross-linked fibrin, and may be increased in heart failure, reflecting activation of both haemostatic and fibrinolytic systems. Gross elevations may occur with thrombo-embolic disease. We investigated the prognostic significance of increases in D-Dimer in patients with heart failure.
Methods and Results: D-Dimer was measured in 2,358 (94% of the entire cohort) patients enrolled in The BIOlogy Study to TAilored Treatment in Chronic Heart Failure (BIOSTAT-CHF). 1,592 patients (67%) had a D-Dimer equal to, or below, the lower limit of detection (< 102ng/mL), 611 (26%) had values between 102 and 499 ng/mL and 155 (7%) had values = 500 ng/mL (upper limit of normal); 50 (2%) had values >1,000 ng/mL. Compared to out-patients (n = 780, 33%), in-patients (N = 1,578, 67%) were more likely to have an elevated D-Dimer = 500ng/mL (7.9% v 4.0%; p < 0.001). Compared to patients with atrial fibrillation (AF; n = 1070; 45%) those without AF (N = 1288, 55%) were more likely to have an elevated D-Dimer = 500ng/mL (7.5% v 5.4%; p = 0.029). D-Dimer levels were weakly correlated with age (r = 0.076, p < 0.001), NTproBNP (r = 0.136, p < 0.001) and Troponin-I (0.134; p < 0.001) levels, but not with creatinine.
During a median FU of 559 (257-784) days, 148 out-patients (19%) and 456 in-patients (29%) died and 237 out-patients (30%) and 713 in-patients (45%) died or were re-hospitalised with HF (HFH). Overall, patients with an elevated D-Dimer did not have worse outcomes. However, amongst out-patients, risk rose progressively as plasma D-Dimer concentrations exceeded the limit of detection (HR (95% CI) for HFH/ACM; 1.47 (1.09-1.98); p = 0.01 for 102-499 ng/mL and 2.02 (1.17-3.83); p = 0.01 for = 500 ng/mL) and for ACM 1.26 (0.86-1.86); p = 0.24 and 2.41 (1.29-4.49); p = 0.006). Also, for patients without a history of AF, an increase in risk was observed (HR for HFH/ACM: 1.41 (1.15-1.72); p = 0.001 and 1.47 (1.06-2.05); p = 0.02 and for ACM 1.21 (0.93-1.57);p = 0.16 and 1.61 (1.09-2.39);p = 0.018).
Conclusions: Amongst patients with heart failure, plasma D-Dimer concentrations are lower in patients with AF, perhaps reflecting greater use of anticoagulants but higher in hospitalized patients perhaps reflecting greater severity of heart failure or a higher rate of occult venous thrombo-embolism. D-Dimer was most strongly associated with outcome amongst out-patients in sinus rhythm. The prognostic significance of D-Dimer and its modification by anticoagulants requires further investigation.

P1645
Left ventricular ejection fraction, systolic blood pressure and smoking history are good predictors of respiratory muscle weakness in systolic heart failure

NK Naomi Kondo Nakagawa[1]; MA Diz[1]; TS Kawauchi[1]; GN Andrade[1]; IIK Umeda[2]; FM Murakami[1]; JP Oliveira-Maul[1]; JA Nascimento[1]; N Nunes[3]; JY Takada[3]; AP Mansur[3]; LP Cahalin[4]
[1]*Sao Paulo University Medical School, Sao Paulo, Brazil*; [2]*Institute Dante Pazzanese of Cardiology, Sao Paulo, Brazil*; [3]*Heart Institute of the University of Sao Paulo (InCor), Cardiology Department, Sao Paulo, Brazil*; [4]*University of Miami Miller School of Medicine, Physical Therapy Department, Miami, United States of America*

Funding Acknowledgements: Research Foundation of São Paulo State (FAPESP 2017/21264-7 and 2017/01113-4)

Introduction: Inspiratory muscle weakness (IMW) has been identified in 30 to 50% of patients with systolic heart failure. However, little is known on possible risk factors for IMW.
Purpose: To assess clinical and echocardiographic characteristics, physical capacity and inflammatory and cardiovascular diseases markers in patients with systolic heart failure.
Methods: Patients with LVEF < 40% (NYHA II and III) were consecutively recruited in a cardiac ambulatory and divided in two-groups: with IMW (IMW) and without IMW (no-IMW). We assessed demographic, echocardiographic and clinical variables, smoking history, pulmonary function, peripheric and respiratory muscle strength, as well as systemic inflammation and cardiovascular diseases markers in blood samples.
Results: Patients (56 years, 46 male, BMI = 27.5 kg/m2) entered into the study and 36 patients presented IMW (55 ± 17 cmH2O) and 34 had no-IMW (88 ± 20 cmH2O). Groups were different in LVEF (27 ± 6 vs 31 ± 6%, p = 0.003), systolic blood pressure (110 ± 21 vs 126 ± 24 mmHg, p = 0.005), diastolic pressure (68 ± 12 vs 75 ± 15 mmHg, p = 0.042), smoking history (25 vs 10 pack-years, p = 0.012), BNP level (256 vs 110 pg/mL, p = 0.020), frequency of pulmonary hypertension (58 vs 34%, p = 0.029), non-dominant quadríceps strength (211 ± 77 vs 261 ± 94 N, p = 0.024), lung function (predicted vital forced capacity: 72 ± 15 vs 81 ± 13%, p = 0.006; predicted forced expiratory volume 1 s: 61 ± 17 and 75 ± 15%, p = 0.022). The other demographic and clinical variables and markers were similar between groups. Stepwise logistic regression model analysis showed that lower LVEF, lower systolic pressure and smoking history can acurately predict IMW (AUC=.79). Conclusion: IMW can be acurately predicted using a simple model that may help in clinical decision-making due treatment of patients with systolic heart failure using the following:
Probability of IMW= exp (6.0694+(0.0315 x Pack-years)-(0.1038 x LVEF)-(0.03 x SBP) [1 + exp (6.0694+ (0.0315 x Pack-years)-(0.1038 x LVEF)-(0.03 x SBP)]

P1646

Correlation between Th1, Th2, Th17, and Treg cytokines serum levels with autonomic function in patients with chronic Chagas disease and systemic arterial hypertension

RB Bestetti[1]; R Dellalibera-Joviliano[1]; G Lopes[1]; R Furlan-Daniel[1]; K Lopes[2]; CHC Domingos[1]
[1]University of Ribeirao Preto, Ribeirao Preto, Brazil; *[2]Clinica Sao Rafael, Piumhi, Brazil*

Funding Acknowledgements: Unaerp

Background: Cytokines serum levels have been associated with autonomic function in patients with different types of heart disease. In general, proinflammatory cytokines have positively been correlated with sympathetic nervous system drive, whereas anti-inflammatory cytokines have negatively been associated with parasympathetic activity. Therefore, the autonomic nervous system may influence the innate immunity system response (the so-called inflammatory reflex). In patients with chronic Chagas disease, there is a marked impairment in Parasympathetic Nervous System. No study has previously addressed the association between cytokines serum levels and autonomic function in patients with chronic Chagas heart disease and systemic arterial hypertension (CCHD-SAH).
Purpose: The aim of this study was to correlate the panel of cytokines (Th1, Th2, Th17, and T treg) serum levels with indices of autonomic function in patients with CCHD-SAH.
Methods: This study focus on eight patients with CCHD-SAH in which a 24-hour Holter monitoring was performed, and heart rate variability in the frequency domain was determined. Parasympathetic activity was evaluated by the high-frequency component (HF), whereas the sympathovagal balance was determined by means of the relation between low frequency component (LH)/ HF component of the heart rate variability in the frequency domain. Cytokines serum measurements were made through the double-ligand/sandwich enzyme-linked immunosorbent assay (ELISA). The Spearman test was used to correlate cytokine serum levels with indices of parasympathetic and sympathetic activity obtained in the power spectral analysis.
Results: There was a strong positive correlation between IL-8 serum levels and parasympathetic activity (r = 0.84; p = 0.0085). A strong negative correlation was found between IL-6 serum levels and parasympathetic activity (r= -0.81; p = 0.01), and TGF Beta serum levels and parasympathetic activity (r= -0.75; p = 0.03). A strong negative correlation between IL-6 serum levels and indices of sympathovagal balance was also observed (r= -0.80; p = 0.01). No correlation was detected between TNF alpha, IL-13, IFN gamma, IL-12, IL-17, IL-23, IL-1 Beta, IL-10, IL-2, IL-4, IL-7 serum levels and indices of parasympathetic activity or sympathovagal balance. Conclusion. Cytokines serum levels correlated with autonomic dysfunction, particularly with parasympathetic derangement, in patients with CCHD-SAH. This suggests a role for the inflammatory reflex in the pathogenesis of patients with this condition.

P1647

Impact of left ventricular assist device implantation on right and left ventricular volumes and functions

C Clement Delmas[1]; E Cariou[1]; P Fournier[1]; S Cazalbou[1]; D Carrie[1]; J Roncalli[1]; M Galinier[1]; O Lairez[1]
[1]Toulouse Rangueil University Hospital (CHU), Cardiology department, Toulouse, France

Background: Because the right ventricle is not assisted, its function is a critical determinant of the hemodynamic in patients with left ventricular (LV) assist devices (LVADs) and contributes significantly to postoperative morbidity and mortality. Right ventricular (RV) failure remains a challenge in the area of continuous-flow LVADs. The aim of this study was to evaluate the evolution of RV volumes and function before and after LVAD implantation.
Methods: Fifteen patients underwent tomographic equilibrium radionuclide ventriculography for the assessment of LV and RV volumes and functions before and after LVAD implantation. Evolution of LV and RV volumes and functions after LVAD implantation were analyzed regarding the results of right heart catheterization.
Results - Mean LV and RV ejection fractions before implantation were 18 ± 7 and 43 ± 13%, respectively. LVAD implantation had no impact on RV ejection fraction (43 ± 11% after implantation, P = 0.955) but increased LV ejection fraction (31 ± 19% after implantation, P = 0.008). LVAD led to a decrease of LV end-diastolic volume (? = -129 ± 88 after implantation, P = 0.001) and RV end-diastolic volume (? = -75 ± 49 after implantation, P = 0.001). The decrease of RV end-diastolic volume was inversely correlated with pulmonary arterial wedge pressure before implantation (R = - 0.651, P = 0.009) but not with pulmonary vasculature resistance (R = 0.018, P = 0.949).
Conclusion: In patients with preserved RV ejection fraction, LVAD implantation leads to a decrease of RV volumes without impact on RV ejection fraction. The decrease of RV end-diastolic volume after LVAD implantation could be explained by the decrease of pulmonary arterial wedge pressure. These results highlight the importance of afterload on RV volumes in patients with heart failure.

P1648

The effect of standard treatment of acute decompensation of heart failure at the concentration of omega-3 and omega-6 polyunsaturated fatty acids in whole blood

A Aleksandra Zaplatina[1]; A Vlasov[1]; S Salikova[1]; O Bystrova[2]; G Osipov[2]; V Grinevich[1]
[1]Military medical Academy, therapy of advanced medical, Saint-Petersburg, Russian Federation; *[2]The international research Centre N. D. Zelinsky Institute of Organic Chemistry, Moscow, Russian Federation*

Introduction: Blood levels of polyunsaturated fatty acids (PUFAs) may have prognostic value in chronic heart failure (?HF). Changes in PUFAs in acute decompensation of CHF and background treatment remains unclear.
Objective: To study the effect of standard treatment of acute decompensation of ?HF on the concentration of eicosapentaenoic acid (EPA), docosahexaenoic (DHA), arachidonic (AA) and linoleic (LA) fatty acids (FA), omega-3 index and the ratio of omega-3 / omega-6 polyunsaturated fatty acids (PUFAs) in whole blood.
Material and Methods: We studied the content of 22 FA in the blood of patients with CHF in stable stage (CHF, n = 12) with acute decompensation (ADHF1, n = 24) and after the standard treatment (ADHF2, n = 24). We calculated omega-3 index (the ratio of the sum of EPA and DHA to the sum of all FA) and the ratio of the sum of EPA and DHA to the sum of AK and LK.
Results: Indicators of EPA, DHA, omega-3 index in the group ADHF1 was lower than in group CHF (0.085 (0.06;0.17) vs. 0.26 (0.15;0.4) mmol/ml, p = 0.0005; 0.37 (0.16;0.62) vs 0.84 (0.55;1.10) mmol/ml, p = 0.004; 1.11 (0.65;2.11) vs 2.44 (1.80;3.71) %, p = 0.0008, respectively). After the standard treatment acute decompensation CHF the levels of EPA, DHA, omega-3 index increased and amounted in group ADHF2 to 0.16 (0.11;0.21) mmol/ml, p = 0.0016; 0.46 (0.35;0.76) mmol/ml, p = 0.045; 1.74 (1.14;2.42) %, p = 0.043 respectively.
Statistically significant differences the contents of AK and LK in the blood between patients groups ADHF1 and CHF were not revealed. The indicators of AK and LK in group ADHF1 were 2.74 (1.80;4.15) mmol/ml, p = 0.25 and 6.70 (4.92;9.44) mmol/ml, p = 0.19, respectively. On the background of treatment was observed the increase of the concentration AK in group ADHF2 (3.40 (2.56;4.91) mmol/ml, p = 0.011) and a trend of increasing LK (9.13 (5.08;11.28) mmol/ml, p = 0.09). The concentration of AK patients in group CHF was 3.42 (2.42;4.62) mmol/ml, p = 0.76; the concentration of LK was 7.27 (6.45;11.88) mmol/ml, p = 0.9.

The dynamics of the ratio omega-3 / omega-6 testified to the prevalence of a share of omega-6 in all participants, especially within the decompensated CHF. The ratio omega-3/omega-6 in patients group ADHF1 was 1/22.94 (12.87;36.32), in patient's group CHF was 1/15.63 (11.71;25.32), and patient's group ADHF2 was 1/12.25 (8.25;14.82). After reversal of the syndrome of fluid retention in patients, the ratio was changed due to the increase level of omega-3 PUFA.
Conclusion: During the acute decompensation of CHF observed a significant reduction in patients' blood omega-3 index, the concentration of EPA and DHA. Standard therapy of decompensated CHF increases content in the blood of patients with EPA, DHA, AA, omega-3 index.

P1649
Mortality from cardiovascular diseases among US cancer survivors

K Kathleen Sturgeon[1]; L Deng[2]; S Bluethmann[1]; D Trifiletti[3]; C Jiang[4]; S Kelly[5]; N Zaorsky[6]
[1]Penn State College of Medicine, Public Health Sciences, Hershey, United States of America; *[2]Albert Einstein College of Medicine, Jacobi Medical Center, New York, United States of America*; *[3]Mayo Clinic, Jacksonville, United States of America*; *[4]Mount Sinai School of Medicine, Internal Medicine, New York, United States of America*; *[5]National Institutes of Health, Bethesda, United States of America*; *[6]Penn State Cancer Institute, Radiation Oncology, Hershey, United States of America*

Introduction: Cardiotoxicities from cancer treatment have been shown to increase mortality risk in cancer survivors. But, the specific risk by cancer site and cardiovascular disease (CVD) over time is unknown.
Purpose: We conducted an epidemiological analysis to characterize death from CVDs in multiple cancer sites, with respect to the following: (1) continuous calendar years of diagnosis, (2) follow-up time after diagnosis, and (3) age at diagnosis.
Methods: We analyzed Surveillance, Epidemiology, and End Results (SEER) program data for death from CVDs among 3,234,256 U.S. cancer patients between 1973 and 2013. CVDs were defined as heart disease, hypertension, cerebrovascular disease, atherosclerosis, and aortic aneurysm/dissection. For objective 1, we characterized total deaths due to CVDs in each continuous calendar year of diagnosis in cancer patients by cancer type. For objectives 2 and 3, we calculated standardized mortality ratios (SMRs), which compare the risk of death from CVDs vs the general population; SMRs were characterized as a function of follow-up time since diagnosis (objective 2), and age at diagnosis (objective 3). Analyses were adjusted by age, race, and sex.
Results: Among 28 cancer types, from 1973-2013, 1,228,328 patients (38%) died from cancer and 365,689 patients (11.3%) died from CVDs. Among CVDs, >80% of deaths were due to heart or cerebrovascular disease. The majority of CVD deaths were in patients with cancer of the prostate (23.1%), breast (16.5%), and bladder (7.6%). For objective 1, of 564,129 cancer patients diagnosed from 1973-1982, 19.3% have died of CVDs, compared to 10.6% CVD deaths of cancer patients diagnosed from 1993-2002. In certain cancers (e.g. prostate, breast, rectal, lymphoma), there has been an upward trend in death due to CVDs; in other cancers (e.g. pancreas, lung), the rate remained relatively low. For objective 2, the highest SMR of heart disease (SMR, 3.93 [95% CI, 3.89-3.97]) was within the first year after cancer diagnosis, decreasing at 1-10 years follow-up, and climbing in years 15-20 (SMR, 2.29 [95% CI, 2.26-2.32]) and 20+ (SMR, 2.72 [95% CI, 2.69-2.76]). For objective 3, the highest SMRs of heart disease (<30) were noted in patients diagnosed at < 35 years of age. SMRs of heart disease declined with increasing age of diagnosis (40-44y: SMR, 23.16 [95%CI, 21.36-25.08]; 50-54y: SMR, 15.38 [95%CI, 14.83-15.95]; 60-64y: SMR, 7.29 [95% CI, 7.15-7.43]; 70-74y: SMR, 3.59 [95% CI, 3.55-3.64]; and 80-85y: SMR, 2.17 [95% CI, 2.15-2.19]).
Conclusions: Patients at highest risk to die of CVDs include cancers of the prostate, breast, bladder, or lymphatic system. The risk of death from CVDs (vs the general population) is highest in the first year after diagnosis; this risk declines with time but always remains elevated over the general population. Patients diagnosed with cancer at a younger age should be followed closely for potential CVDs, as they are at higher risk than older survivors.

P1650
Low body mass index and arterial hypotension as early predictors of cardiotoxicity in patients with HER2 + breast cancer

M Marina Vitsenya[1]; A Potekhina[1]; A Ovchinnikov[1]; S Gavryushina[1]; A Skorobogatova[1]; F Ageev[1]; I Chazova[1]
[1]Cardiology Research and Production Center, Outpatient care, Moscow, Russian Federation

Background: Pre-existing cardiovascular risk factors, mainly arterial hypertension (AH), or established cardiovascular disease (CVD), increase the risk for chemotherapy-induced left ventricular (LV) dysfunction and heart failure. The monitoring and management strategies for patients with low cardiovascular risk receiving cardiotoxic therapy require considerable attention.
Aim: To determine the incidence and risk factors of LV dysfunction in hypertensive and normotensive patients with HER2+ breast cancer (BC) receiving anthracycline-containing regimens with trastuzumab.
Methods: 60 women with newly diagnosed HER2+ BC, mean age 49,9 ± 11,8 years without established CVD were enrolled. 43% of patients had AH and antihypertensive therapy with ACE inhibitor or ARB was initiated / optimized. Patients had been receiving neoadjuvant cancer therapy with anthracyclines and trastuzumab with further adjuvant therapy with trastuzumab during one year. Complex cardiological examinations including echocardiography with myocardial global longitudinal strain (GLS) assessment were performed before the start of cancer treatment and every 3 months. Chemotherapy-induced LV dysfunction was considered if LVEF decrease of 10 percentage points, to a value below 50%, and early subclinical cardiotoxicity if a relative percentage reduction of GLS of 15% from baseline occurred.
Results: The hypertensive (HG) and normotensive (NG) groups at baseline demonstrated differences in mean age (58 ± 8.5 vs. 43.7 ± 10.2, p < 0.00001), BMI (28.45 [26, 31.6] vs. 23,5 [20; 28], p < 0.01), lipid and serum glucose levels, LVEF (62 [60, 65] vs. 64 [63, 67]%, p < 0.05) and GLS values (-20,2 [-18.5, -21.8] vs. -22.3 [-21, -23.2]%, p < 0.01). LVEF and GLS decreased significantly in both groups. After completion of therapy LVEF was 59[55;62]%, GLS -17,2[16;18,9]% in HG and 56[53;61]%, -19[-18,2;-20,2]% in NG (p < 0,05 vs. initial values). Chemotherapy-induced LV dysfunction was observed in 6 (10%) of patients, 5 (83,3 %) of them were from NG. 28 patients (46,6 %) developed subclinical cardiotoxisity, 20 (71,4%) of them were from NG. Initial BMI below 25 kg/m2 and arterial hypotension (SAD < 120 mmHg) demonstrated the prognostic significance for the development of early subclinical cardiotoxisity (OR 10,04 (95% CI 3,09-39,21), ? < 0,001 and OR 4,27(95%CI 1,25-14,56), ? = 0,015, respectively).
Conclusion. The incidence of chemotherapy-induced subclinical cardiotoxisity was lower in hypertensive BC patients probably due to prevalence of antihypertensive therapy with cardioprotective effect. Low body mass index and arterial hypotension showed the predictive role for subclinical cardiotoxisity development in HER2+ BC patients receiving anthracycline-containing regimens with trastuzumab.

Routine use of global longitudinal strain among active breast cancer patients: A Cardio-Oncology registry

LM Michal Laufer-Perl[1]; A Milwidsky[1]; L Mor[1]; D Ravid[1]; N Amrami[1]; M Derakhshesh[1]; J Sherez[1]; G Keren[1]; Y Arbel[1]; Y Topilsky[1]
[1]Tel Aviv Sourasky Medical Center, Cardiology, Tel Aviv, Israel

Background: Increased survival among breast cancer patients exposed a wide range of side effects, with cardiotoxicity being the most significant one. Cancer therapeutic related cardiac dysfunction (CTRCD) is defined as a left ventricular ejection fraction (LVEF) reduction of >10 % points, to a value below 50%. Unfortunately, a detectable drop in LVEF occurs only after the loss of a substantial amount of myocardial tissue, and in up to 58% of these patients the ventricular function will not recover. Therefore, according to the American and European Society of Echocardiography, global longitudinal strain (GLS) is the optimal parameter for early detection of subclinical LV dysfunction, with a relative reduction of = 15% considered to be clinically significant. However, due to the lack of studies routine use of GLS has not been fully adopted.
Objectives: Evaluating the frequency of significant GLS reduction and whether it predicts CTRCD development among active breast cancer patients.
Methods: Data was collected as part of the International Cardio-Oncology Registry (ICOR), enrolling all patients evaluating in the cardio-oncology clinic in our institution. All patients performed at least two GLS examinations by the same vendor, technician and interpreting cardiologist.
Results: Among 103 consecutive patients, 5 (5%) developed CTRCD for which lower baseline GLS (18 ± 3 vs. 21 ± 2, p = 0.016) was a significant predictor. Among 79 patients,
9 (11%) developed significant GLS reduction, of which 44% had no concomitant EF reduction. Median time for GLS reduction was 93 days. There were no significant differences in the baseline cardiac risk factors and no predictors for GLS reductions were identified, including blood tests or echocardiography parameters (diastolic function, right ventricular function or systolic pulmonary artery pressure).
Conclusions: Our study demonstrate that GLS reduction is frequent among breast cancer patients, precedes LVEF reduction and cannot be anticipated by other echocardiographic parameters. Using GLS routinely may lead to an early diagnosis and prevention of cardiotoxicity.

P1652

Dispersion of ventricular repolarization in men treated by hormone therapy for advanced prostatic cancer.

ACD Andrei Cristian Dan Gheorghe[1]; GS Gheorghe[1]; A Ciobanu[1]; AS Hodorogea[1]; IT Nanea[1]
[1]*Clinical Hospital Dr Theodor Burghele, Cardiology, Bucharest, Romania*

Aim: To evaluate the proarrhythmic effects of the treatment with luteinizing hormone-releasing hormone (LHRH) antagonists in advanced prostate cancer by determining the surface ECG parameters of electrical instability.
Method We investigated 24 men (pts) with advanced prostatic cancer treated by orchiectomy and LHRH antagonist degarelix. We noted clinical history and excluded pts with atrial fibrillation, heart failure (HF) NYHA III and IV class, acute myocardial infarction (MI) in the last 6 months, chronic renal disease stages IV-V. We performed ECG, Holter ECG, echocardiography and evaluated QT interval dispersion (QTd), Tpeak-Tend interval (Tpe, in V5), J-T peak interval (JT), Lown class ventricular premature beats (VPB) on Holter ECG, left ventricular ejection fraction (LVEF) before the beginning of the treatment (V1) and after 3 (V2) and 6 months (V3). We used paired t-test for comparing the differences.
Results: Pts were 67.5 +/-10 years old. 18 (75 %) had arterial hypertension, 13 (54.1%) stable angina, 6 (25 %) old myocardial infarction, 5 (20.8 %) diabetes mellitus, 5 (20.8%) chronic renal disease grade 1-3b. They were stable during the study. 18 (75%) pts had an statistical significant (p = 0.02) increase of the QTd (83 +/- 10 ms) and JT (78 +/- 30 ms) intervals between V1 and V3, . Tpe changes were variable. We did not note an increase in the number or severity of VPB between V1, V2 and V3. Mean LVEF was 60+/-5%, stable between V1 and V3.
Conclusion: In pts with advanced prostatic cancer receiving LHRH antagonist for 6 months the values of QTd and JT duration had a rising tendency. TPe changes were variable. No increase was noted in the number or severity of VPB during the first 6 months of treatment

P1653

The use of myocardial deformation imaging to predict cardio toxicity in breast cancer treated with trastuzumab

S Charfeddine[1]; C Yousfi[1]; L Abid[1]; D Abid[1]; S Kammoun[1]; W Ben Kridis[2]; S Sghaier[2]; M Frikha[2]
[1]*Hedi Chaker University Hospital, Cardiology department, Sfax, Tunisia*; [2]*Habib Bourguiba University Hospital, Oncology department , Sfax, Tunisia*

BACKYGROUND: Trastuzumab, a chemotherapeutic agent used in the treatment of breast cancer, could induce cardio toxicity (CT). Although left ventricular ejection fraction (LVEF) is the gold standard to monitor chemotherapy-induced CT, measurement of myocardial deformation using speckle tracking enables more detailed assessment of myocardial contractility.
Purpose: The aim of this study was to determine the value of strain imaging in the early detection and screening of Trastuzumab's cardio toxicity.
Methods: This was a prospective study of 31 breast cancer patients receiving adjuvant Trastuzumab, who underwent 2-dimensional, tissue Doppler, and strain echocardiographic examination at baseline, 4 months and 10 months after therapy. The LV global longitudinal strain (GLS), global circumferential (GCS) and radial strain (GRS), and other echocardiographic parameters were calculated.
Results: At the first follow up, The LV ejection fraction, tissue Doppler parameters, GCS and GRS values did not show any change, whereas significant decreases were observed in GLS value (-20.58+/-2.28% vs. -19.35+/-2.14, p = 0.001) and systolic annular velocity of the lateral LV wall (S' velocity) (10.83+/-2.31 vs. 9.64+/-1.72, p = 0.002). At the last follow up, patients who have presented an earlier significant decrease in GLS value, have developed subclinical LV dysfunction with a significant decrease in LVEF > 10%.
Conclusions:
The two dimensional 2D strain imaging is a new non-invasive technique that can better assess the real state of left ventricular function. Our study confirms the value of global longitudinal strain in the early detection of subclinical cardio toxicity before conventional measures in women undergoing treatment with Trastuzumab for breast cancer.

Long-term follow up of acute heart failure patients underwent levosimendan infusion: identification of responders and non responders by using hlm classification

P Paolo Severino[1]; M Pucci[1]; M Alfarano[1]; E Pagliaroli[1]; M Straito[1]; S Calcagno[1]; A Fusto[1]; M Mancone[1]; F Fedele[1]
[1]*Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrology, Anesthesiology and Geriatric Sciences, Sapien, Rome, Italy*

Introduction: Acute heart failure (AHF) still has poor long-term prognosis with high rehospitalization and mortality rates; Levosimendan (Levo) is an inodilator that seems to reduce mortality in AHF patients. AHF determines involvement of other organs beyond heart; similar to TNM used in oncology, we proposed the HLM staging system to assess prognosis of HF patients, evaluating heart damage (H), lung involvement (L) and malfunction (M) of peripheral organs (JACC 2014;20;63(19):1959-60).
Hypothesis: The aim is to evaluate the outcomes of Levo infusion in AHF patients and, by using HLM classification, to identify the predictors of increased cardiac mortality and rehospitalization for
major cardiovascular and cerebrovascular events (MACCE) risk.
Methods. AHF patients admitted to our Hospital were enrolled. All patients received 24-h Levo i.v. infusion (0.05- 0.2 mcg/kg/min, no bolus) in addition to standard therapy. Pre and post Levo
infusion, clinical, laboratory and imaging data for H, L and M were collected in according to HLM.
At 6 and 12 months all patients were followed up to check for rehospitalization for MACCE and cardiac death.
Results: We enrolled 300 AHF patients, two of which died in hospital. Levo infusion improved HLM stages with a greater impact on L and M parameters (L, M pre vs L, M post; p <0.001). About H parameter, we observed a statistical significative improvement of the left ventricular ejection fraction (p < 0.0001) pre and post Levo infusion as well as reduction of left
ventricular end-systolic volume (p < 0.0098) and pro-BNP (p < 0.338). Patients were also divided into two groups: Group A, with no improvement or only in L or M; Group B, with an improvement of L and M. At 6 and 12 months, Group B showed significant better outcomes in term of cardiac mortality and rehospitalization compared with Group A.
Conclusions: 24-h Levo infusion improves clinical status of AHF patients. HLM identifies patient responder to this inodilator, with a significant reduction of mortality and rehospitalization risk at 6 and 12 months beyond risk factors and AHF etiology. Moreover, using HLM it may be possible to
identify patients with a poorer prognosis that may need repetitive use of Levo or advanced therapy.

P1655

Haemodynamic profiles in type 2 pulmonary hypertension influence response to phosphodiesterase-5 inhibitors

P Patricia Alves[1]; AV Marinho[1]; C Domingues[1]; JA Ferreira[1]; J Milner[1]; R Baptista[1]; F Franco[1]; G Castro[1]; M Pego[1]
[1]*University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*

Background : Pulmonary hypertension (PH) is a complication of left heart disease with a small subset having elevated transpulmonary gradient (TPG), diastolic pulmonary gradient (DPG) or pulmonary vascular resistance (PVR).
Purpose: To assess the effect of phosphodiesterase-5 inhibitors (PDE5i) in type 2 PH hemodynamic profiles.
Methods: We retrospectively enrolled 195 patients with type 2 PH and created the following groups: group A with TPG = 14 mmHg and DPG = 7 mmHg; group B with TPG = 14 and DPG <7; group C with TPG <14 and DPG <7. All groups had PVR = 3.WU Parameters before and after PDE5i were collected.
Results : About 57% of patients were started on PDE5i. Prevalence of the different profiles was: 15% for group A; 39% for group B; 20% group for C. Patients that were started on PDE5i had higher values of MPAP (p <0.001), PVR (p <0.001) and TPG (p <0.001) and lower values of cardiac output (CO) (p = 0.01). No significant differences were observed in DPG values. After institution of PDEi5, there was an overall significant decrease of MPAP (44 to 39, p <0.001), PVR (6.3 to 3.4, p <0.001), capillary wedge pressure (CWP) (25 to 23mmHg, p = 0.03), while CO was significantly increased (3.2 to 3.9 L.min-1, p <0.001). This effect seemed to be driven by group B, as per subgroup analysis showed in the table. PVR reduction was seen in groups A, B and C. CO increase was notorious in group B and also in groups A and C.
Conclusions: : A high prevalence of a hemodynamic profile with high TPG and PVR and low DPG was found. Hemodynamic parameters in patients under PDE5i significantly improved, particularly in the group with isolated high TPG, but not with high DPG.

		Pre-PDE5i	Post-PDE5i	P value
MPAP	A	45.4(±13.8)	40(±12.3)	0.07
B	45.6(±9.6)	38.5(±10.5)	<0.001	
CWP	B	26.4(±7.6)	22.4(±7.8)	0.006
PVR	A	9.5(±8.9)	4.2(±2.8)	0.008
B	6.8(±6.1)	4.1(±3.4)	<0.001	
C	4.4(±1.4)	1.8(±1.9)	0.003	
TPG	A	24.8(±9.1)	17.4(±6.9)	<0.001
B	19.1(±4.6)	16.1(±7.9)	0.004	
CO	A	3.3(±0.8)	3.9(±0.8)	0.06
B	3.2(±0.9)	3.9(±1.1)	<0.001	
C	3.2(±2.5)	3.8(±1.3)	0.05

Prognostic impact of chronic kidney disease on long-term mortality in patients with preserved, moderately impared and severely impared left ventricular systolic function after myocardial infarction

L Lidija Savic[1]; I Mrdovic[2]; G Krljanac[2]; M Asanin[2]; R Lasica[2]; D Rajic[2]; D Matic[2]
[1]*Clinical Center of Serbia, Institute for Cardiovascular Disease, Belgrade, Serbia*; [2]*Clinical Center of Serbia, Institute for Cardiovascular Disease, Emergency Hospital, Belgrade, Serbia*

Background/aim: Chronic kidney disease (CKD) is associated with poor cardiovascular outcome in the general population after ST-elevation myocardial infaction (STEMI). The aim of this study was to investigate and compare the prognostic impact of preterminal CKD in patients with preserved, moderately and severely reduced left ventricular systolic function following STEMI.
Method: we included 2436 consecutive STEMI patients treated with primary percutaneous coronary intervention (pPCI). Patients presenting with cardiogenic shock and patients on hemodyalisis were excluded. Left ventricular systolic function was assesed by echocardiographic examination before discharge. According to EF, patients were divided in three groups: preserved left ventricular systolic function - EF >50%, moderately impared left ventricular systolic function - EF 40-50% and severely impared left ventricular systolic function - EF < 40%. The follow-up period was 6 years.
Results: Out of a total of 2436 patients, 1773(72.7%) were men and 663 (37.3%) were women. The average age of the examined patients was 57 (50, 63) years. Preserved, moderately and severely reduced left ventricular systolic function were registered in 741(30.5%), 1367(56.1%) and 328(13.4%) patients, respectively. Baseline CKD was registered in 472(19.3%) patients and the mean eGFR value was 88.5 (67.7, 108.8)ml/min/1.73m2. CKD was registered in 105 (14.2%) patients with preserved systolic function, in 247(18.1%) patients with moderately impared and in 120(36.5%) patients with severely impared systolic function. Over a 6-year follow-up period there were 196 (8.3%) deaths overall. Regardless of the presence of CKD, 6-year mortality rates in patients with preserved, moderately and severely impared systolic function were 2.7%, 5.2% and 31.1% respectively. Within each EF group, patients with CKD had a worse outcome, both in the short- and long term. In cox rgression model CKD remained an independent predictor of all-cause mortality during a 6-year follow-up in patients with moderately and severely reduced systolic function, but not in patients with preserved systolic function: EF >50% (HR 0,59, 95%CI 0,14-1,41, p = 0.461), EF 40-50% (HR 2.52, 95%CI 1.54-3.78, p = 0.001) and EF < 40% (HR 2.84, 95%CI 1.68-5.34, p < 0.001). Conclusion: Although patients with CKD had higher 6-year mortallity following STEMI regardless of the EF, CKD remained a strong independent predictor for 6-year mortality only in patients with moderately and severely reduced systolic function

P1657

Correlation of large arteries stiffness parameters in STEMI patients with systolic and diastolic left ventricular dysfunction

L Salyamova[1]; A Khromova[1]; A Golubeva[1]; N Burko[1]; I Matrosova[1]; V Valentin Oleinikov[1]
[1]*Penza State University, Penza, Russian Federation*

Aim: to study the correlation between central pressure parameters, arterial stiffness and echocardiographic indicis of systolic and/or diastolic left ventricular dysfunction in patients with ST segment elevation myocardial infarction (STEMI).
Methods: the study included 69 patients with STEMI. Inclusion criterion was the presence of significant stenosis of one coronary artery according to the coronary angiography results Patients underwent echocardiography using the MyLab device (Esaote, Italy) at 7-9th day from the disease onset. The end-diastolic volume index (EDVi), and ejection fraction (EF) were determined. Diastolic function was analyzed by the following parameters: E/A peak velocity ratio, deceleration time of early diastolic mitral inflow velocity (DTE), the time of isovolumetric relaxation (IVRT). The structural and functional properties of the large arteries were assessed by the applanation tonometry method using the Sphygmocor device (AtCorMedical, Australia) for the following parameters: aortic systolic (SBPao), diastolic (DBPao) and pulse (PPao) pressure, carotid-femoral pulse wave velocity (cfPWV). Ultrasound of the common carotid arteries with high-frequency RF signal technology was performed on the MyLab device ("Esaote", Italy). Local systolic (locPsys) and diastolic (locPdia) pressure, local pulse wave velocity (locPWV), stiffness index ß, coefficient of transverse distensibility (DC) were recorded. The Spearman rank correlation coefficient was used to determine the correlations.
Results: positive relationship was found between EF and SBPao (r = 0.27, p = 0.03), PPao (r = 0.26, p = 0.03), locPsys (r = 0.32, p = 0.01), negative - between EF and index ß (r=-0.28, p = 0.02). The E/A ration index correlated with DBPao (r=-0.29, p = 0.02), cfPWV (r=-0.26; p = 0.04), locPsys (r=-0.33; p = 0.01), locPdia (r=-0.41, p < 0.01), locPWV (r=-0.28, p = 0.02), the DC coefficient (r = 0.37, p < 0.01). The DTE decrease was associated with lower values of SBPao (r = 0.64, p < 0.01), DBPao (r = 0.30, p = 0.03), PPao (r = 0.45, p < 0.01), locPsys (r = 0.41, p < 0.01), locPdia (r = 0.39, p < 0.01). IVRT also correlated with BP in the aorta and common carotid arteries: SBPao (r = 0.45, p < 0.01), PPao (r = 0.29, p = 0.03), locPsys (r = 0.29, p = 0.03), locPdia (r = 0.30, p = 0.02). The relationship between EDVi and indicators reflecting the structural and functional properties of the aorta and common carotid arteries was not revealed.
Conclusion: the deterioration of systolic and diastolic left ventricular function is associated with lower values of BP in the aorta and common carotid arteries, and increased local vascular rigidity in patients with ST segment elevation myocardial infarction.

P1658

Mid-range ejection fraction: a grey zone in heart failure?

JJ Herrera Paz[1]; N Zareba[1]; CL Gonzalez[1]; CE Sandoval[1]; M Urdapilleta[1]
[1]*FLENI Institute, Cardiology, Buenos Aires, Argentina*

Background: From the use of the terms Heart failure (CHF) with preserved ejection fraction (EF) and reduced ejection fraction, a group of undefined patients remains in the middle of these values (between 40 - 49 of EF), a true grey area. Recently the European Guidelines incorporated this group as mid-range EF. Neither the behavior of this group nor the therapeutic strategy to be implemented are entirely clear.
Objectives: To evaluate in a population of patients hospitalized for HF if the patients with mid-range EF evolve as the reduced EF group or as the preserved ones. For this, we took death during hospitalization; CHF-related hospitalization and death during follow-up as end points.
Materials and methods: We retrospectively evaluated 428 patients hospitalized for CHF in a center in the city of Buenos Aires, Argentina, between 2008 and 2013. The hospitalizations were consecutive and for the first time. All the patients were followed up by telephone for at least one year. The population was divided in three groups, group A, n = 178 patients with preserved EF (< 50%), group B, n = 180 patients with reduced EF (< 39%) and group C, n = 70 patients with mid-range EF (from 40 to 49%)
The Wilcoxon test was performed for the analysis of the variables. For the comparison between EF groups, the chi2 test was carried out and later logistic regression was conducted.
Results: Mortality during hospitalization was 3.9% for group A, 6.6% for group B and 2.8% for group C. During follow up, death was 30% for A, 38% for B and 35% for C. CHF-related hospitalization were and 33% for A, 36% for B and 40% for C.
We found no significant differences between the baseline characteristics of each group. Only one statistical trend was found, the presence of coronary disease between group B and C (p = 0.054).
No statistical relationship was found between group A and C in the end points.
There was a statistically significant relationship between groups B and C in the end points of death and CHF-related hospitalization during follow-up of patients (p < 0.05)
Conclusions: Patients with intermediate EF do not relate in a statistically significant way with preserved EF.
Patients with intermediate EF have a statistically significant association with the group of reduced EF in terms of mortality and CHF-related hospitalization in the follow-up. This could suggest that the grey or mid-range EF group behaves, in this population, similarly to the reduced EF group. Considering this, we could propose a similar therapeutic strategy for this new group.

P1659

Reperfusion and reversible diastolic dysfunction of the left ventricle in patients with ST elevation myocardial infarction

D KH Rakhmanov[1]; S R Kenjaev[2]; A L Alyavi[3]; M L Kenjaev[4]; M S Mirmaksudov[1]; SH B Turg'unboyev[1]
[1]Tashkent Medical Academy, Tashkent, Uzbekistan; *[2]Republican Research Center of Emergency Medicine, Tashkent, Uzbekistan*; *[3]Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Tashkent, Uzbekistan*; *[4]Bukhara branch of Republican Research Center of Emergency Medicine, Bukhara, Uzbekistan*

Aim: To study the effect of reperfusion on the reversibility of diastolic LV myocardial dysfunction in patients with ST elevation myocardial infarction (STEMI).
Methods: 302 patients with STEMI were included in the study. All patients underwent primary PCI. Depending on the results of myocardial reperfusion, patients were divided into 3 groups. 1st group consisted of 196 patients with successful myocardial reperfusion; 2nd group was 76 patients with partial myocardial reperfusion; and 3rd group was included 30 patients without successful myocardial reperfusion. Stress echocardiography with low dose dobutamine was carried out after stabilizing condition on 3rd-5th days of the disease to evaluate reversible diastolic dysfunction.
Results: In 242 (80.0%) of 302 patients with STEMI, type I of diastolic dysfunction of left ventricle (DDLV) were identified in the first day of the disease, type II (pseudonormal type) and type III were determined in 15 (5%) and 45 (15%) patients respectively. Among patients with adequate reperfusion (1st group), 97% had DDLV as a relaxation disorder and 3% had a pseudonormal type DDLV. In this group, the restrictive type of DDLV was not detected. After injection of low doses of dobutamine in 6 patients with type 2 DDLV, a transformation to type 1 DDLV was noted, which was probably due to an improvement in diastolic properties in the zone of myocardial stunning in response to small doses of dobutamine. In the second group, the administration of low doses of dobutamine also resulted in a reduction in the number of patients with type III DDLV by 51% and type II DDLV by 66%. Consequently, the number of patients with type I DDLV increased from 63 to 83%. The introduction of low doses of dobutamine did not lead to significant changes in 3rd group patients. Restrictive type of diastolic dysfunction was often found among 3rd group patients with absence of myocardial reperfusion, which may be due to severe myocardial dysfunction. Type III of DDLV recorded also in 3rd group (with unsuccessful reperfusion) after injection of low dose dobutamine.
Conclusions: Successful myocardial reperfusion in patients with STEMI helps maintain diastolic LV function. Changes in diastolic LV function during low dose dobutamine echocardiography are associated with the presence of reversible myocardial dysfunction. Effective and early application of reperfusion methods (TLT, PCI) improves the diastolic properties of LV myocardium in the ischemic injury zone, which prevents the development of CHF. An irreversible restrictive type of diastolic dysfunction often develops after unsuccessful myocardial revascularization, which can be predictor of unfavorable post-infarction myocardial remodeling and severe form of CHF.

P1660

Ventriculoatrial remodeling in patients with recurrent atrial fibrillation and diastolic dysfunction: does gender matter?

A Shavarov[1]; E Kokhan[2]; G Kiyakbaev[1]; Z Kobalava[1]
[1]RUDN University, Moscow, Russian Federation; *[2]Lomonosov Moscow State University, Moscow, Russian Federation*

Background: Left ventricular (LV) hypertrophy and left atrial (LA) remodeling are associated with recurrence of atrial fibrillation (AF). There exists a significant gender variability in the response of the LV to increased hemodynamic load. But the data concerning the relationship between LV and LA remodeling depending on gender is scarce.
Purpose: To evaluate the impact of gender on the relationship between LV and LA remodeling in patients with AF, hypertension and diastolic dysfunction (DD).
Methods: The study included 27 men and 28 women (median age of 65 [60;72]) with recurrent non-valvular AF, hypertension, mild to moderate LV DD and preserved ejection fraction (<50%). All patients underwent conventional and speckle tracking echocardiography. Global peak LA longitudinal strain (PALS, %) in the reservoir (r) and contractile (c) phases was assessed using 6 segments in the 4-chamber and 2-chamber views. We calculated diastolic index using the ratio of E/E' to LV-end diastolic volume.
Results: There were no significant differences between men and women in most clinical characteristics including median of hypertension duration (67 vs 65 moths in men and women, respectively; $p = 0.88$) and the prevalence of paroxysmal and persistent AF (10 and 17 pts in men, respectively vs 14 and 14 pts in women, respectively; $p = 0.33$). Despite the fact that DD was more pronounced in women than in men [E/E' (13 vs 11.2; $p = 0.03$) and diastolic index (0.13 vs 0.09 ml-1; $p = 0.001$)], LA structural and functional parameters were similar between the two groups. Compared to men, women also had higher median of LV relative wall thickness (0.53 vs 0.4; $p = 0.03$). In women only the diastolic index was significantly related to LA size ($r = 0.52$; $p = 0.005$ vs $r=-0.32$; $p = 0.14$, respectively); PALSr ($r=-0.53$; $p = 0.004$ vs $r=-0.1$; $p = 0.62$, respectively) and PALSc ($r = 0.51$; $p = 0.005$ vs $r=-0.1$; $p = 0.65$, respectively); p for all interactions < 0.05. Subgroups of patients with paroxysmal and persistent AF differed by diastolic index (0.13 vs 0.16 ml-1; $p = 0.01$ and 0.1 vs 0.08 $p = 0.16$ ml-1 in women and men, respectively) and LV global longitudinal strain (-19 vs -16.5; $p = 0.04$ and -17.5 vs -17.1 $p = 0.41$, respectively for women and men) in women only.
Conclusion: Patients of both genders had similar patterns of LA remodeling. Only in women LV function was significantly related to LA remodeling and type of AF. That may be because a relation between increased afterload, LV and LA remodeling is stronger in women than in men.

P1661

How about heart failure with reduced or preserved diastolic function?

JP Jose Pedro Sousa[1]; M Madeira[1]; L Reis[1]; C Negrier[1]; L Goncalves[1]
[1]Centro Hospitalar e Universitário de Coimbra - Hospital Geral, Cardiology, Coimbra, Portugal

Introduction: Left ventricular ejection fraction (LVEF), the main parameter of systolic function, is a cornerstone for classification, management and outcome prediction in heart failure (HF). Having been more difficult to evaluate, diastolic dysfunction is less studied and the usefulness of its objective measurement in determining clinical care is controversial.
Purpose: To characterize diastolic dysfunction and determine its short term prognostic significance in the setting of acute HF.
Methods: Retrospective single-center study comprising patients consecutively admitted into a cardiac intensive care unit, during six years, presenting with de novo or decompensated acute HF. Demographic, clinical, laboratory, echocardiographic, therapeutic and prognostic data were assessed. Diastolic function was comprehensively evaluated using echocardiography and dysfunction was graded into three patterns: impaired relaxation (IR), pseudonormal (PN) and restrictive (RT). Follow-up (FU) was performed targeting hospital readmission for acute HF and all-cause mortality. All statistical analysis was performed using SPSS version 23 (IBM Corp., Armonk, NY, USA).
Results: 264 patients were included. Mean age was 70 ± 14 years and 22% were female. Median FU was 10 months. In-hospital mortality was 15%, while readmission for HF and death in FU occurred in 46.7% and 42% of patients, respectively. FEVE was 34 ± 12.9% and the distribution of diastolic function across patients was as follows: 13.8% normal, 53.2% IR, 14.7% PN and 18.3% RT. These groups were homogeneous as to sex, whereas IR patients were older than RT patients (72 vs. 64 years, p 0.013). Personal history of arterial hypertension was more common in IR and rarer in RT (p 0.001), while that of type 2 diabetes mellitus was only numerically more frequent in PN (p 0.078). PN showed itself dependent upon coronary artery disease (p 0.005) and chronic kidney disease was found to be at the verge of significance for dependency on diastolic dysfunction as a whole (p 0.068). Both serum creatinine and NT-proBNP, at admission, maximum value and discharge, exhibited no statistically significant differences between groups. LVEF was lower in RT than in all other groups (24 ± 8.7%, $p < 0.001$). Maximum daily dose of furosemide was greater in RT than in IR (202 ± 137 vs. 149 ± 100mg, p 0.011). Similarly, and in spite of independency between diastolic dysfunction and in-hospital mortality, when compared to IR, RT was associated with superior rates of readmission for acute HF (p 0.005) and death during FU (p 0.023).
Conclusions: In the setting of acute HF, diastolic dysfunction is the rule, with IR as the predominant pattern. However, only RT displays association with greater rates of hospital readmission and all-cause mortality during FU.

P1662

Abnormally elevated left-ventricular filling pressure as a prognostic factor in an Advanced Heart Failure Unit

G L Alonso Salinas[1]; S Del Prado Diaz[2]; M Pascual Izco[2]; S Hernandez Jimenez[2]; M Plaza Martin[2]; JM Vieitez Florez[2]; M Abellas[2]; A Lorente[2]; E Gonzalez Ferrer[2]; JL Zamorano[1]
[1]Health Institute Carlos III, CIBERCV, Madrid, Spain; *[2]Hospital Universitario Ramón y Cajal, Cardiology, Madrid, Spain*

Background: The relationship between E wave velocity and e 'wave velocity allow us to non-invasively estimate left ventricle (LV) filling pressure. An increase in LV filling pressure correlates, in previous studies, with the presence of exercise dyspnea, and even with an increase in readmission or mortality rates. The aim of this study is to analyze the population that presents abnormal elevated LV filling pressure in a cohort of Advanced Heart Failure Unit patients.

Methods: Patients followed in an Adavanced Heart Failure Unit were consecutively included. Baseline, analytical and echocardiographic data were collected. Therapeutic strategy was also collected. Functional class was evaluated through 6-minute walking test, and admissions and mortality rate were collected during the follow-up. Abnormal elevated LV filling pressure was defined as those patients with an E/e' ratio greater than or equal to 15.
Results: A total of 136 patients were consecutively included from May 2016 to March 2017. Of them, 60 (44.1%) had increased LV filling pressure. Baseline characteristics are defined in Table 1.
Patients with increased filling pressures were older and tended to receive less beta-blockers. This group of patients presented also a lower functional class in 6-minute walking test, a higher rate of readmissions and a higher mortality rate, although these differences did not reach statistical significance.
Conclusions:
An abnormally elevated LV filling pressure tend to decrease survival in patients with heart failure. Treatment with beta-blockers may decrease filling pressures. The findings suggested by this study should be tested in a larger cohort of patients.

	Increased filling pressures (n = 60)	Normal filling pressures (n = 76)	p
Age (years)	77.3 ± 9	71.4 ± 14.2	0.01
Female sex	23 (38.3%)	28 (36.8%)	0.86
LVEF (%)	36.4 ± 13.2	38.6 ± 11.1	0.29
BNP (pg/ml)	806.4 ± 967.2	572.7 ± 573.9	0.18
ACEIs/ARBs	34 (61.8%)	46 (63.9%)	0.81
Beta-blocker	38 (69.1%)	60 (83.3%)	0.05
Mineralocorticoid Antagonists	35 (63.6%)	42 (58.3%)	0.54
Furosemide daily dose (mg)	82.6 ± 44.3	74.5 ± 50.6	0.41
6-minute walking test (m)	256.7 ± 107.2	290.6 ± 125.2	0.87
Admissions	14 (23.3%)	12 (15.8%)	0.23
Mortality rate	4 (6.7%)	1 (1.3%)	0.10

Funding Acknowledgements: This work was funded in part by the Italian Ministry of Health

Background: After a myocardial infarction, the loss of viable tissue initiates a process of complex geometrical alterations leading to adverse remodeling and progressive heart failure (HF). Matrix myocardial proteinases (MMPs) were shown to play a key role in adverse remodeling in several preclinical models.
Purpose: To investigate the role of different myocardial tissue MMPs, i.e. MMP1, MMP2 and MMP9, and their respective inhibitors in subjects with ischemic heart failure (HF) undergoing left ventricular (LV) surgical reconstruction (SVR).
Methods: Twenty-six patients (20 male, 6 female, mean age 63 ± 9) with previous anterior myocardial infarction and HF undergoing elective SVR were recruited. LV function and geometry were evaluated by echocardiography before surgery and at follow-up. LV biopsies were obtained after the opening of the left ventricle. For each patient, two biopsies were harvested: one from the border zone (peri-infarctual area) and one from the remote myocardium. Samples were immediately treated according to the protocol in the operating theatre and stored at -80°C. Plasma samples were collected from each patient before surgery and at follow-up. We analyzed MMP1, MMP2, MMP9, TIMP4, TIMP2 and TIMP1 both in myocardial tissue samples and in plasma. All the subjects were prospectively followed for 12 months after surgery.
Results: Subjects with a more adverse geometrical remodeling, i.e. with a higher systolic sphericity index, had higher myocardial MMP9 in the remote zone (Rho = 0.5, p = 0.01). Furthermore, MMP9/TIMP1 in the remote myocardium significantly correlated with systolic sphericity index (Rho = 0.447, p = 0.03). Conversely, both MMP9 concentrations in the remote and border myocardium negatively correlated with systolic conicity index (Rho=-0.49, p = 0.02 and Rho=-0.42, p = 0.04, respectively). Remote myocardium MMP2 was significantly correlated with NTproBNP (Rho = 0.59, p = 0.003) and LV ejection fraction (EF) (Rho=-0.46, p = 0.02). The highest quartile of LV EF improvement, thereby defining optimal response to SVR, was a postoperative improvement of at least 17%. Subjects with the greatest improvement in terms of LV EF had a significantly lower MMP9 concentration in the border myocardium (9 vs 48, p = 0.006). At the same time, they had a significantly lower concentration of MMP2 both in border myocardium (8.8 vs 29.0, p = 0.006) and in the remote myocardium (7.7 vs 16.8, p = 0.005). On the other hand, MMP1 concentration in the border myocardium was higher in subjects with the greatest improvement in LVEF (3.6 vs 1.4, p = 0.001).
Furthermore, subjects in whom the target ESVi of < 60mL/m2 was obtained had a lower MMP9 concentration in border myocardium (11 vs 17, p = 0.04).
Conclusions-Different MMPs and TIMPs in myocardial tissue appear to associate differentially with diverse parameters of myocardial dysfunction and adverse remodeling. Our data support a heterogeneous role for these molecules in post-infarction remodeling.

P1664

Left ventricle remodeling, blood pressure profile and endothelial dysfunction in hypertensive patients with chronic heart failure

N Nadiia Demikhova[1]; T Rudenko[1]; S Bokova[1]
[1]Sumy State University, Medical Institute, Sumy, Ukraine

Chronic overload of the left ventricle in hypertension leads to structural and morphological reorganization of the myocardium, which combines the concept of "remodeling", which is characterized by the presence of hypertrophy, dilatation and changes in the geometry of the left vetricular (LV).
Objective: To evaluate the relationship of endothelial dysfunction with blood pressure (BP) daily profile and type of LV remodeling in hypertensive patients with chronic heart failure (CHF).
Methods: We examined 98 patients with arterial hypertension and CHF. Assessment of: systolic and diastolic LV function, condition vasomotor endothelial function (doppler brachial artery during reactive hyperemia), daily BP monitoring.
Results: Analsis of vasomotor function in patients with BP profiles showed that the diameter of the brachial artery was the greatest in patients with profile type night-peaker, and was 4.25(3.80;5.00), followed by patients with non-dipper - 4.20(3.70;4.60), dipper - 4.10(3.50;4.65) mm Hg, reduced and most patients over-dipper, while the velocity of the blood was reduced in patients with night-peaker - 0.60(0.53;0.84) m/s.
Vasodilatatory reaction during decompression was the least pronounced in night-peaker patients - 5.47 (3.04;11.72)% (p < 0.00014), in non-dipper patients - 11.63 (7.76;18.92)%, dipper - 8.94 (7.04;15.46)%, over-dipper - 7.24 (5.82;13.32)%.
Vasodilatatory response to nitroglycerin was preserved in most patients with non-dipper, accounting for 16.6(10.52;25.00)%, night-peaker - 13.67(8.01;20.24)%, over-dipper - 11.72(7.54;17.08)%, and decreased in dipper - 9.97(7.04;15.46)%.
Evaluation of correlation of endothelial dysfunction and indices of LV structural and functional properties showed that there is an inverse correlation between endothelial dysfunction in the form of reduced vasodilatatory effects on diagnostic tests and concentric hypertrophy (r=-0,32, p = 0.001), type of BP non-dipper (r=-0.27, p = 0.009), degree of night reduction in diastolic BP (r=-0.25, p = 0.014), systolic index (r=-0.25, p = 0.016), performance dilatation of brachial artery with nitroglycerin (r=-0.24, p = 0.017), normal LV geometry (r=-0.22, p = 0.026), the type of dipper (r=-0.22, p = 0.032), degree of night reduction in systolic BP (r=-0.22, p = 0.030), speed E (r=-0.21, p = 0.037). Direct correlation was between of endothelial dysfunction degree and diastolic dysfunction degree (r = 0.37, p = 0.00038), concentric remodeling (r = 0.25, 0.23), excentric hypertrophy (p = 0.015; p = 0.02), restrictive type of diastolic dysfunction (r = 0.25, p = 0.026), normal LV geometry (r = 0.21, p = 0.036), type of night-peaker (r = 0.23, p = 0.026), LV systolic dysfunction (r = 0.21, p = 0.036).
Conclusion. Endothelial dysfunction is a factor of correlation with LV myocardial remodeling by concentric type, and with the change of BP circadian rhythm as night-peaker in hypertensive patients with CHF.

P1665

Dynamics of chronic heart failure indicators in patients with rapidly progressive left ventricular remodelling after myocardial infarction

L Salyamova[1]; A Khromova[1]; O Kvasova[1]; A Golubeva[1]; V Valentin Oleinikov[1]
[1]Penza State University, Penza, Russian Federation

Aim: to study the dynamics of laboratory parameters of chronic heart failure and exercise tolerance during 48 weeks of follow-up in patients with rapidly progressive left ventricular remodeling after STEMI.

Methods: 97 patients with STEMI were included in the study. Inclusion criterion was the presence of one coronary artery significant stenosis according to the coronary angiography results At the 7-9th day and after 48 weeks of follow-up, all patients had undergone echocardiography on the MyLab apparatus ("Esaote", Italy) with the determination of the end diastolic volume index (EDVi). The patients were divided into two groups. The first group included 52 subjects without echocardiographic signs of LV remodeling: the dynamics of EDVi was < 20% at 48 weeks after STEMI. Group 2 included 45 patients with rapidly progressive LV remodeling (an EDVi increase > 20%). The groups were matched by age, sex, anthropometric data, and treatment. The brain natriuretic peptide (BNP) was determined at the 7th-9th day and at 48 weeks of follow-up using immunochemical analysis. The 6-minute walk test was performed after 12 and 48 weeks.
Results: Initial values of BNP did not differ: in the 1st group - 27.1 (18.2, 45.3) pg/ml, in group 2 - 31.6 (19.9, 52.1) pg/ml (p>0.05). After 48 weeks there was no significant BNP dynamics in patients without pathological EDVi increase (30.2 (19.7, 49.1) pg/ml, p>0.05); the values increased to 59.4 (30.1, 94.3) pg/ml in patients with rapidly progressive LV remodeling (p = 0.001). After 12 weeks of follow-up the average distance traveled during 6-minute walk test was 511.3 ± 72.4 m in group 1. At the same time, FC 0 was detected in 32% of cases, FC 1 - in 56%, FC 2 - in 12%. At 48 weeks after STEMI, the mean distance was 612.2 ± 85.6 m (p = 0.01). FC 0 was detected in 47% of cases, FC 1 - in 48%, FC 2 - in 5% (p>0.05). In group 2 the mean distance initially was 529.1 ± 76.1 m. FC 0 was detected in 35% of cases, FC 1 - in 38%, FC 2 - in 27%. After 48 weeks the indices were 527.4 ± 89.2 m (p>0.05), FC 0 - 41%, FC 1 - 24%, FC 2 - 32%, FC 3 - 3% (p>0, 05), respectively.
Conclusion: in patients with rapidly progressive LV remodeling after STEMI the BNP level increase was detected without reliable decrease in exercise tolerance after 48 weeks of follow-up. While in patients without pathological remodeling, there was an improvement in exercise tolerance without BNP changes.

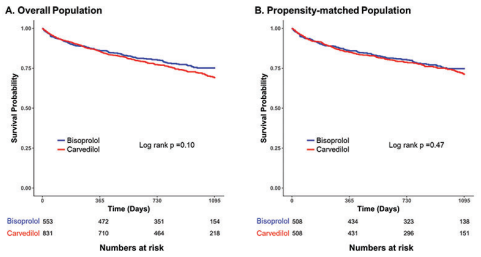
P1666

The mortality benefit of carvedilol versus bisoprolol in patients with heart failure with reduced ejection fraction : an analysis from Korean Acute Heart Failure (KorAHF) registry

KH Choi[1]; JO Choi[1]; ES Jeon[1]
[1]*Samsung Medical Center, Sungkyunkwan University, Cardiovascular Center, Seoul, Korea Republic of*

On behalf of: KorAHF investigators
Funding Acknowledgements: This work was supported by the Research of Korea Centers for Disease Control and Prevention.

Background/Aims: It is unknown whether different beta-blockers (BBs) have variable effects on the long-term survival of patients with heart failure with reduced ejection fraction (HFrEF). Therefore, this study compares the effects of carvedilol and bisoprolol on survival in patients with HFrEF.



Kaplan-Meier curves for all-cause death

Methods: The KorAHF registry is a prospective multicenter cohort that includes 5,625 patients who were hospitalized for acute heart failure (AHF). We studied 1,384 patients with HFrEF who were prescribed carvedilol or bisoprolol upon discharge. Accordingly, patients were separated into respective groups based on these prescriptions, with a carvedilol group (n = 831) and bisoprolol group (n = 553). Propensity score matching analysis was performed to reduce confounding factors.
Results: Among patients who were prescribed a BB at discharge, 60.5% received carvedilol and 32.7% received bisoprolol. There was a significant reduction in all-cause mortality in those patients with HFrEF prescribed a BB at discharge (n = 1,707) compared to those who were not (n = 1,309) (BB vs. no BB, 26.1% vs. 40.8%, hazard ratio [HR] 0.59, 95% confidence interval [CI] 0.52-0.67, p < 0.001). However, there was no significant difference in the rate of all-cause mortality between those receiving different types of BB (carvedilol vs. bisoprolol, 27.5% vs. 23.5%, HR 1.21, 95% CI 0.99-1.47, p = 0.07). Similar results were observed after propensity score matching analysis (carvedilol vs. bisoprolol, 508 pairs) (26.2% vs. 23.8%, HR 1.10, 95% CI 0.86-1.40, p = 0.47).

Conclusions: In the treatment of AHF with reduced EF after hospitalization, the mortality benefits of carvedilol and bisoprolol were comparable in acute HF patients with reduced EF.

Relationship between parathyroid hormone and cardiac function and congestion in chronic heart failure: a prospective cohort study

L Kattnig[1]; V Habenicht[1]; M Gangl[1]; E Kolesnik[1]; J Schmid[2]; M Manninger[1]; H Brussee[1]; S Pilz[3]; A Tomaschitz[1]; B Obermayer-Pietsch[3]; D Scherr[1]; F Fruhwald[1]; D Von Lewinski[1]; K Ablasser[1]; N Verheyen[1]
[1]*Medical University of Graz, Department of Cardiology, Graz, Austria*; [2]*Medical University of Graz, Department of Radiology, Graz, Austria*; [3]*Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria*

On behalf of: Role of Comorbidities in Chronic Heart Failure Study

Background: Chronic heart failure (CHF) is often accompanied by disturbed bone metabolism, but potential mechanistic links are unclear in large parts. High parathyroid hormone (PTH) levels increase the risk of CHF and hyperparathyroidism is common in CHF patients. Few clinical studies aimed to elucidate the role of PTH in CHF, but their majority was limited by the retrospective character and very low sample sizes prohibiting multivariate analyses.
Purpose: We aimed to correlate plasma PTH levels with echocardiographic and laboratory parameters reflecting both cardiac systolic or diastolic function and congestion in CHF patients.
Methods: Subjects were enrolled between September 2016 and December 2017, as part of a single-center prospective cohort study. Main inclusion criteria were age over 18 years, CHF according to the ESC CHF guidelines 2016 and left ventricular ejection fraction (LVEF) < 50%. Stable disease was defined as absence of unplanned hospitalization or change in medication or device therapy within the previous month or major surgery within the previous 3 months. Exclusion criteria were any acute illnesses or more than moderate primary valvular disease. Blood samples were taken after an overnight fast and all laboratory parameters were determined immediately.
Results: We enrolled 99 patients (mean age 64.8 ± SD 9.6 years, 79% males). Mean LVEF was 35.9 +/- 9.0 % and median NT-proBNP was 1301 [IQR 349 - 2750] pg/ml. Hyperparathyroidism was present in 50% of patients and median PTH was 65.0 [47.0 - 94.6] pg/ml.
PTH correlated significantly with NT-proBNP (Pearson r = 0.467, p < 0.001), but not with LVEF, tricuspid annular plane systolic excursion or e'. In multivariate linear regression analyses with adjustment for age, sex, estimated glomerular filtration rate, 25-hydroxyvitamin D and body mass index, PTH remained significantly associated with NT-proBNP (adjusted beta-coefficient 0.331, p = 0.004).
Conclusion: In 99 patients with CHF, PTH was significantly correlated with NT-proBNP, but not with parameters of cardiac function, independently of important potential confounding variables. This observation is in line with previous studies and suggests a mechanistic interweavement between cardiac congestion and PTH secretion. Further investigation will be necessary to elucidate the impact of this possible interaction on bone health in CHF patients.

P1668

Total Left Atrial Emptying Fraction as a novel prognostic marker in HFrEF patients with significant functional mitral regurgitation

G Palmiero[1]; L Ascione[1]; A Ferro[1]; E Melillo[1]; R Ascione[1]; S Severino[1]; P Caso[1]
[1] *AO dei Colli-Monaldi Hospital, Department of Cardiology, Naples, Italy*

Background: A comprehensive risk assessment for prediction of adverse outcomes has been proposed in HF to overwhelm LVEF limitations. LA size and MR are considered prognostically relevant parameters.
Purpose: To assess the effects of significant functional MR on LA function and its prognostic impact in HFrEF patients.
Methods: 97 patients with LVEF = 40%, sinus rhythm and with mild-to-severe FMR were enrolled and underwent a comprehensive echocardiogram. MR severity was evaluated and patients were dichotomized according to the presence of SFMR (3-4+). LAF was evaluated using the phasic method with LA volumes measured at three time-points: before mitral valve opening, at P-wave onset and at MV closure. Different components of LAF were calculated consequently (reservoir as LAEI, conduit as LAPEF, pump as LAAEF and total emptying function as TLAEF). LA dysfunction (LA-Dys) was defined by TLAEF values below the median.
Results: LAF indices were more impaired in SFMR group (Table 1) and the SFMR/LA-Dys+ group showed the worst outcome in terms of survival (Figure 1). At the ROC curve analysis the TLAEF showed the highest predictive value (AUC 0.81) and at the final backward multivariate model (R2 0,31; Beta 0.62; p<.04) it was the only independent predictor of outcome.

Conclusions: SFMR seems to affect the LAF. TLAEF proved to be an important prognostic factor and may represent a novel parameters to consider in risk assessment of HFrEF patients.

Table 1

	FMR (n = 38)	SFMR (n = 59)	P
Age (yrs)	62,5±14,9	66,0±9,7	ns
Men (%)	5 (13,1%)	9 (15,2%)	ns

Serum calcium, phosphate and parathormone homeostasis in patients with heart failure with reduced ejection fraction

E Sawicka[1]; K Ptaszynska-Kopczynska[2]; M Marcinkiewicz-Siemion[1]; E Tarasiuk[2]; A Lisowska[2]; M Witkowski[2]; WJ Musial[2]; B Sobkowicz[2]; KA Kaminski[1]
[1]Medical University of Bialystok, Department of Cardiology, Department of Population Medicine and Civilization Diseases Prevention, Bialystok, Poland; *[2]Medical University of Bialystok, Department of Cardiology, Bialystok, Poland*

Introduction: Heart failure with reduced ejection fraction (HF-REF) is one of the most severe outcomes of cardiovascular diseases. Dysregulation of calcium (Ca) and phosphate (P) homeostasis may play a potential role in the development and progression of this disease. The adverse effect of elevated levels of P and parathormone (PTH) have been described, while the role of abnormal Ca concentration remains unclear.
Purpose: To evaluate the association of Ca, P and PTH status with biochemical and functional parameters in HF-REF patients in relation to patients without HF-REF.

Comparison of HF-REF and control groups

	HF-REF group -baseline (n = 124)	Control group (n = 21)	P value HF-REF baseline vs control baseline	HF-REF group - 6 months	P value HF-REF baseline vs HF-REF 6 months	P value HF-REF 6 months vs control baseline
Calcium, mmol/l	2.3 IQR: 2.2-2.4	2.4 IQR 2.3-2.5	0.017	2.4 IQR: 2.3-2.4	0.085	0.062
Phosphorus, mmol/l	3.4 IQR: 3.1-3.6	2.9 IQR 2.7-3.4	0.018	3.3 IQR: 2.8-3.6	0.274	0.135
Parathormone, pg/ml	34.9 IQR: 14.7-44.7	44.1 IQR 35.7-79.1	0.031	46.7 IQR 34.4-64.9	0.005	0.615
Calcium-phosphate product, mmol^2/l^2	7,8 IQR: 7.1-8.6	7 IQR: 6.5-8.4	0.108	7,8 IQR: 7-8.2	0.564	0.29

Methods: The study included 124 stable HF-REF patients with optimal pharmacotherapy, aged 64 ± 10 years (107 males) and 21 volunteers without HF-REF aged 64 ± 9 years (14 males), who had assessed calcium or phosphate or both of them at baseline.
Results: The analysis showed higher serum P, lower Ca and lower PTH levels in HF-REF patients compared to controls (Table). However, in both study groups the levels of Ca and PTH remained within the normal range, while the level of P was increased. After 6 months of the treatment there was an increase in PTH in HF-REF group (Table). Calcium-phosphate product did not differ between study groups at baseline and 6 months follow-up (Table).
The analysis of correlations in HF-REF group at baseline revealed that calcium inversely correlated with BNP (r = -0.21, p = 0.029), ventricular asynchrony (r = -0.21, p = 0.049) and directly with hemoglobin (r = 0.2, p = 0.032) and ejection fraction (r = 0.26, p = 0.014).
While phosphate correlated with urea (r = 0.25, p = 0.007) and maximal ventilatory equivalents for carbon dioxide measured in cardiopulmonary exercise test (r = 0.23, p = 0.042).
Conclusions: HF-REF patients at baseline present the altered mineral element profile compared to the control group, that reflect their worse general status. After 6 month of treatment calcium and phosphate levels were similar with those observed in control group.

P1670

Design of the EMPERIAL-reduced trial of empagliflozin in patients with chronic heart failure with reduced ejection fraction

W T Abraham[1]; P Ponikowski[2]; S D Anker[3]; A Salsali[4]; B Peil[5]; M Brun[6]; M Brueckmann[7]; J Lindenfeld[8]
[1]The Ohio State University, Columbus, United States of America; *[2]Wroclaw Medical University, Wroclaw, Poland*; *[3]Charité University, Berlin, Germany*; *[4]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, Connecticut, United States of America*; *[5]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany*; *[6]Boehringer Ingelheim France, Reims cedex, France*; *[7]Boehringer Ingelheim GmbH & Co. KG, Ingelheim am Rhein, Germany*; *[8]Vanderbilt University Medical Center, Nashville, Tennessee, United States of America*

Background and Purpose: Besides increasing the risks of cardiovascular death and hospitalisation, chronic heart failure with reduced ejection fraction (HFrEF) is associated with a high symptom burden, and impaired functional capacity. Empagliflozin is a sodium-glucose cotransporter-2 inhibitor that was shown in the EMPA-REG OUTCOME trial to reduce the risk of cardiovascular events, hospitalisations and mortality in patients with type 2 diabetes and established cardiovascular disease. A Phase III trial, EMPERIAL–reduced, has been initiated to investigate the effects of empagliflozin on functional outcomes in patients with HFrEF.
Methods: EMPERIAL–reduced (Effect of EMPaglifozin on ExeRcise ability and heart failure symptoms, In patients with chronic heArt faiLure with reduced ejection fraction) is a randomised, double-blind, placebo-controlled trial designed to evaluate the effect of empagliflozin on exercise capacity and symptoms in patients with HFrEF (left ventricular ejection fraction = 40%). Inclusion criteria include 6-minute walk test (6MWT) distance of 100m to = 350 m and elevated N-terminal pro-brain natriuretic peptide (NT-proBNP) >600 pg/mL. Patients must be clinically stable and on appropriate medical therapy for heart failure consistent with current guidelines, with doses stable for = 4 weeks (or = 2 weeks for diuretics). Approximately 300 patients will be randomised 1:1 to receive empagliflozin 10 mg or placebo once daily

for 12 weeks. The primary endpoint is the change from baseline in 6MWT distance at week 12. Key secondary endpoints are changes from baseline in Kansas City Cardiomyopathy Questionnaire, total symptom score and in Chronic Heart Failure Questionnaire Self-Administered Standardized format dyspnoea score at week 12. Patient Global Impression of change questionnaires and change from baseline in NT-proBNP at week 12 are other secondary endpoints.
Results: Recruitment for this trial will begin in 2018.
Conclusion: The findings of the EMPERIAL−reduced trial, together with those of the EMPERIAL−preserved trial that will be conducted in patients with chronic heart failure with preserved ejection fraction (HFpEF), will determine the effects of empagliflozin on symptoms, exercise capacity and patient reported outcome in patients with heart failure. The effects of empagliflozin on cardiovascular death and hospitalisation for heart failure in patients with chronic heart failure are being investigated in the EMPEROR−reduced and EMPEROR−preserved trials.

Changes of arterial function in patients with reduced left ventricular systolic function

K-H Park[1]; WJ Park[1]; SJ Han[1]; HS Kim[1]; SH Jo[1]; S-A Kim[1]
[1]Hallym University Sacred Heart Hospital, Cardiology, Anyang-Si, Gyeonggi-Do, Korea Republic of

Funding Acknowledgements: This work was supported by the NRF funded by the Ministry of Science, ICT, & Future Planning (NRF-2017R1D1A3B03028830) to K.H. Park

Background: In patients with heart failure with reduced ejection fraction (HFrEF), there has been no report about serial changes of arterial function according to the changes of the left ventricular ejection fraction (LVEF).
Purpose: The current study was designed to access the association between serial changes of LVEF and changes in arterial endothelial function and arterial stiffness in patients with HFrEP (LVEF <45%).
Methods: We consecutively enrolled 50 patients with HFrEP (25 patients with non-ischemic heart failure [NIHF] and 25 with ischemic heart failure [IHF]). The echocardiography, B-type natriuretic peptide (BNP), flow-mediated dilation (FMD), and brachial ankle pulse wave velocity (baPWV) were evaluated at baseline and at 6-month follow-up, and the change values (?) were evaluated.
Results: Compared to the baseline measurements, the 6-month values were as follows: ?LVEF, 10.0 ± 11.5 (from 32.7 ± 10.7 to 42.9 ± 13.4, p <0.01); ?BNP, -178.1 ± 278.3 (from 315.7 ± 299.2 to 126.1 ± 157.7, p <0.01); FMD, 0.86 ± 1.43 (from 2.44 ± 2.27 to 3.16 ± 2.27, p <0.01); ?baPWV, -61 ± 224 (from 1545 ± 346 to 1488 ± 378, p = 0.07), respectively. There was no significant correlation between initial LVEF and initial FMD (r = 0.136, p = 0.35), but there were significant correlations between 6-month LVEF and 6-month FMD (r = 0.398, p <0.01) and ?LVEF and ?FMD (r = 0.522, p <0.01). However, there was no significant correlation between LVEF and FMD in patients with IHF during the study period. In patients with NIHF, there were significant correlations between initial EF and initial FMD, 6-month LVEF and 6-month FMD, and ?LVEF and ?FMD (r = 0.568, p <0.01; r = 0.694, p <0.01; and r = 0.787, p <0.01, respectively). In multivariate analysis, only ?FMD was significantly correlated with ?LVEF, and the association was independent of the other variables, ?BNP, ?baPWV, ?systolic blood pressure, and ?diastolic blood pressure in patients with NIHF. There was no significant correlation between LVEF and baPWV throughout the study.
Conclusions: In patients with NIHF, there was significant correlation between serial changes of endothelial function and left ventricular systolic function.

P1672

Statins in non-ischemic heart failure - friend or foe?

L Luis Puga[1]; R Teixeira[1]; L Reis[1]; J Gameiro[1]; J Sousa[1]; JM Ribeiro[1]; M Madeira[1]; P Dinis[1]; A Siserman[1]; A Goncalves[1]
[1]University Hospitals of Coimbra, Cardiology Department, Coimbra, Portugal

Background: The use of statins in patients with heart failure (HF) has generated controversy due to conflicting results of clinical trials.
Purpose: To identify the long-term prognosis associated with prescription of statins in patients with HF.
Methods: Retrospective study of 119 patients admitted to a cardiac intensive care unit due to acute HF of non-ischemic etiology. The sample was divided in two groups, A - statins prescribed at discharge from hospital (n = 59) and B - no statins prescribed at discharge from hospital (n = 60). The groups were compared for mortality, mean survival in months and readmissions for heart failure. It was performed a sub analysis dividing the groups in two subsets of age (= 75 or >75 years old).
Results: The sample had a mean age of 68 ± 15 years old and 75% of the patients were male. The prevalence of hypertension was 74% and diabetes mellitus was 31%. 56% of the patients were admitted in NYHA class IV, 40% in NYHA class III. The mean left ventricle ejection fraction was 33 ± 14%. Mean follow-up time was 17 ± 15 months.
No statistically significant differences were found between mortality rate during follow up in the groups (A 29% (17/58) vs B 41% (24/59), P = 0,198). The readmission rate and the mean survival time by the Kaplan Meier method were also similar in both groups.

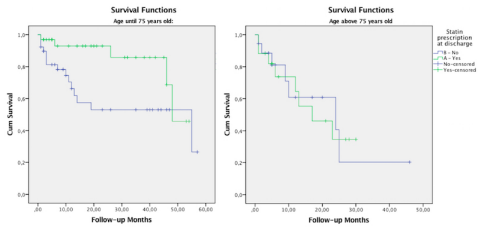

Figure 1 - Cumulative survival curves

In the sub analysis performed in two classes of age (Figure 1), group A showed a statistically significant increase in mean survival until 75 years old (A 46 months CI95%(39,6-51,8) vs B 34 months CI95%(24,7-42,6), log rank P = 0.028). This effect was not demonstrated in the subgroup of patients above 75 years old (A 18 months CI95%(11,9-23,6) vs B 22 months CI95%(11,8-31,7), log rank P = 0.955).
Conclusions: In our sample, the prescription of statins at discharge from hospital was associated with an increase in mean survival in the subgroup of patients = 75 years old. The decrease in the lipid levels associated with the progression of HF may explain the loss of the protective effect of statins in older ages.
Figure 1 - Cumulative survival curves by the Kaplan Meier method

P1673

Tolerance to the uptitration of the dose of sacubitril/valsartan is comparable to that of angiotensin converting enzyme inhibitors; single center experience

A Elasfar[1]; A Tharwat[1]; SA Elasfar[2]; I Alharbi[1]; OA Amoudi[1]
[1]Madina Cardiac Center, Madina, Saudi Arabia; *[2]CK secondary school, Chatham-kent, Canada*

Background: Sacubitril/valsartan is the first drug from a new class of angiotensin receptor neprilisin inhibitors (ARNIs) recommended to replace angiotensin converting enzyme inhibitors (ACE-Is) in heart failure with reduced ejection fraction (HFpEF).
Objective: We aimed to present our initial experience with regard to the tolerance to the uptitration to the recommended target dose of Sacubitril/ Valsartan (200 mg twice daily) to those of angiotensin converting enzyme inhibitors (ACE-Is) in a cohort of patients with HFpEF.
Methods: It's a single center cross sectional cohort study for patients with heart failure and reduced EF who were divided to 2x4 groups; group I includes patients on Sacubitril/ Valsartan and group II includes patients on ACE-Is plus standard background medical therapy. We tested both groups at 4 levels of tolerances: level 0 tolerance (patients who did not tolerate any dose); level I (patients only tolerated 25 of the target dose); level II (patients tolerated 50 % of the target dose); Level III (patients tolerated 100% of the target dose). Tolerance was mainly dependent on the assessment for symptomatic hypotension, worsening renal functions and rising serum potassium. The standard ACE-I used is enalapril with target daily dose of 20 mg. Average follow up was between 3 and 11 months. We used Chi Square software to test significance between groups with P value more than 0.05 was considered non-significant.
Results: One hundred and eighty five patients with heart failure and EF < 35, age of 48.7+/-11.9 years, 78.82% males were divided to 2 groups; group I (Sacubitril/valsartan) includes 105 patients and group II (ACE-Is) includes 80 patients. There were non-significant differences between both groups regarding the baseline demographic and clinical characteristics. The level of tolerance in group I/group II was 6.4/7.8%, 18.9/ 18.6, 57.5/ 55.8, and 17.2/17.8 for level 0, I, II, and III tolerance respectively with P value less than 0.05.
Conclusion: the level of tolerance to escalating to target doses for Sacubitril/valsartan was comparable to that of ACE-Is in ambulatory heart failure patients with reduced ejection fraction.

P1674

Effect of Low-Dose Dopamine on Depression of Patients with Heart Failure in Coronary Intensive Unit

T Kivrak[1]
[1]Firat University, Department of Cardiology, Elazig, Turkey

Objective: The aim of this trial is to assess the effects of low-dose dopamine on patients with depression in the intensive coronary unit.

Methods: Relatives of 43 ICU patients enrolled in the study. Sociodemographic characteristics of patients and their families recorded. Patients evaluated basal echocardiographic and biochemical values measured in the patient group. The Beck Anxiety and Depression Scale was used to assess anxiety and depression. The assessment performed first and the twenty-fourth hour by Beck scale.
Results: The final study population consisted of 42 patients hospitalized with heart failure. Median patient age was 67.5 ± 12.6 years. Average EF was 23.5 ± 8.7 and mean ProBNP was 6343.76 in our study population. Changes in depression score of HF patients before and after dopamine treatment was showed significantly(before value:18.95 ± 9.89; after value:17.29 ± 10.30;p <0.001) however systolic and diastolic pressure difference was not significant(Table 1).
Conclusion: We think that critical study because of low dose dopamine decreased depression degree in the intensive coronary unit, and low dose dopamine can be used for to increase renal perfusion in these patients.

TABLE 1

	Before	After	P value
Depression score	18.95±9.89	17.29±10.30	<0.001
Systolic blood pressure (mmhg)	115±20	117±17	0.342
Diastolic blood pressure mmhg)	70±11	69±10	0.279

Changes in parameters of HF patients before and after dopamine treatment

P1675

Prognostic impact of neurohormonal blockade in patients with an acute coronary syndrome and mid-range ejection fraction

PM Pedro Azevedo[1]; T Mota[1]; D Bento[1]; D Carvalho[1]; J Bispo[1]; J Guedes[1]; S Pereira[1]; W Santos[1]; J Mimoso[1]; N Marques[1]; I Jesus[1]
[1]*Faro Hospital, Cardiology, Faro, Portugal*

Introduction: In 2016, the European Society of Cardiology introduced the term heart failure (HF) with mid-range ejection fraction (HFmrEF) to represent patients with HF and left ventricular ejection fraction (LVEF) between 40% and 49%. This range of LVEF is less well studied compared with HFpEF and HFrEF. Whether these patients benefit from neurohormonal blockade, similarly to patients with HFrEF, requires further studies. After an acute coronary syndrome (ACS), beta-blockers (BB) and angiotensin-converting enzyme inhibitors (ACEi) are frequently prescribed, but their impact on long-term outcomes of patients without systolic dysfunction is controversial.
Purpose: Evaluate the impact of BB, ACEi and mineralocorticoid receptor antagonists (MRA) on long-term mortality and rehospitalization of patients with mid-range EF after an ACS.
Methods: Retrospective, descriptive and correlational study with all patients admitted to a Cardiology department with the diagnosis of ACS between the 1st of October 2010 and 31st September 2016. Patients were divided as followed: LVEF < 40% (rEF), LVEF between 40% and 49% (mrEF) and LVEF = 50% (pEF). Patients were followed for 1-year. Statistical analysis was performed in SPSS.
Results: 2860 patients were included, 309 (10.8%) had rEF, 460 (16.1%) had mrEF and 2091 (73.1%) had pEF. The mean age of patients with mrEF was 68.4 ± 13.7 years (versus 68.6 ± 13.7 in rEF and 64.6 ± 12.9 in pEF, p < 0.001). Patients with mrEF had more frequently STEMI (54.8% in mrEF, 49.8% in rEF and 45.2% in pEF, p < 0.001). Acute HF was present in 131 (28.5%) patients with mrEF (vs 49.5% in rEF and 7.2% in pEF, p < 0.001). Coronary angiography was performed in 310 (67.4%) patients with mrEF (vs 50.5% in rEF and 83.1% in pEF, p < 0.001) and PCI in 233(50.7%) (vs 41.4% in rEF and 64.7% in pEF, p < 0.001). The overall in-hospital mortality rate was 3.1% (16.5% in rEF, 3.7% in mrEF and 1.0% in pEF, p < 0.001).
After discharge, beta-blockers were prescribed to 74.3% of patients (75.6% in rEF, 71.7% in mrEF and 74.6% in pEF, p = 0.4), ACEi to 76% (82.2% in rEF, 79.3% in mrEF and 74.6% in pEF, p = 0.007) and MRA to 13.7% (60.7% in rEF, 34.8% in mrEF and 3.6% in pEF, p < 0.001).
At 1-year, mortality rate was 8.5% (26.3% in rEF, 15.8% in mrEF and 4.7% in pEF, p < 0.001) and rehospitalization rate was 21.4% (42.1% in rEF, 30.7% in mrEF and 16.8% in pEF, p < 0.001).
In patients with mrEF, after adjusting for covariates, neurohormonal blockade had no impact on 1-year mortality (BB OR 0.96, 95%CI 0.45-2.1; ACEi OR 0.36 95%CI 0.6-3.4 and MRA OR 0.74 95%CI 0.5-2.7) or 1-year rehospitalization (BB OR 1.1 95%CI 0.7-2.1; ACEi OR 0.74 95%CI 0.4-1.4 and MRA OR 0.7, 95%CI 0.4-1.4).
Conclusion: In this study, treatment with BB, ACEi or MRA had no impact on 1-year mortality or rehospitalization rate in patients with ACS a mid-range EF. Further studies, preferably randomized controlled trials, should be performed to assess the impact of neurohormonal blockage in this range of LVEF.

P1676

Urine biomarkers as determinants of poor outcomes in patients with acute kidney injury and heart failure with mid-range ejection fraction

A Klimenko[1]; S Villevalde[1]; Z Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: Decompensated heart failure (DHF) is one of the leading causes of hospitalization worldwide. The development of acute kidney injury (AKI) is associated with poor outcomes. There is a strong need to detect AKI before serum creatinine (SCr) rise. The aim of the study was to determine the AKI in patients with DHF in subpopulation with mid-range ejection fraction (DHFmrEF), to evaluate the association of urine neutrophil gelatinase associated lipocalin (uNGAL) and kidney injury molecule-1 (KIM-1) with changes in kidney function and outcomes.
Methods: In 65 patients with DHFmrFF (53 male, 69 ± 9 years (M ± SD), arterial hypertension 94%, ischemic heart disease 63%, myocardial infarction 51%, atrial fibrillation 49%, diabetes mellitus 26%, known chronic kidney disease 51%) levels of SCr, uNGAL and KIM-1 were determined on admission. AKI was defined using 2012 KDIGO Guidelines. Patients with AKI were classified into four groups on the basis of their levels of SCr, uNGAL and KIM-1. Mann-Whitney and multiple logistic regression analysis were performed. P < 0.05 was considered statistically significant.
Results: 32% of patients developed AKI. Patients with AKI compared with patients without AKI had higher SCr (227 ± 92 vs 109 ± 19 mkmol/l, p < 0.001), uNGAL (234 ± 74 vs 3,8 ± 1,5 ng/ml, p = 0.001). Levels of KIM-1 did not differ (0,48 ± 0,03 and 0,42 ± 0,03, p>0.05). Urine NGAL >184 ng/ml (odds ratio (OR) 3.85; 95% confidential interval (CI) 1.8-5.8) was determined to be significant and independent factor for development of AKI. Urine KIM-1 >0.41 ng/ml (OR 2.85; 95% 95% CI 1.4-4.6) was determined to be significant and independent factor for DHF rehospitalization after AKI. Of 21 patients with AKI 13% had two criteria of AKI [NGAL(+)/KIM-1(+)], 20% - isolated increase of SCr, 30% two criteria [Scr(+)/KIM-1(+)] and 37% - two criteria [SCr(+)/NGAL(+)]. Patients with NGAL(+)/KIM-1(+) and patients with SCr(+)/NGAL(+) compared with other groups demonstrated transient character of AKI and the higher risk of 30-days mortality: all patients with AKI and NGAL(+)/KIM-1(+), 50% of patients with AKI and NGAL(+)/SCr(+) died in 30 days. There were no deaths in 30 days in patients with AKI with isolated increase of SCr and patients with AKI and SCr(+)/KIM-1(+).
Conclusions: 32% of patients admitted to the hospital with DHFmrEF developed AKI. Elevation levels of urine biomarkers (uNGAL >184 ng/ml and KIM-1 >0.41 ng/ml) in patients with AKI is associated with persistent character of AKI and higher risk of 30-days mortality. The use of uNGAL together with KIM-1 might be useful for the clinician to suspect the subgroup with high risk of mortality in patient population with DHFmrEF and AKI.

P1677

Clinical characteristics and biomarkers in the patients with different phenotypes of heart failure

T Tatyana Kurchick[1]; S Tikhonova[1]; L Kholopov[1]
[1]*Odessa National Medical University, Internal Medicine #2, Odessa, Ukraine*

Background: The pts with mid-range ejection fraction (EF) 40-49% (HFmrEF) have a clinical profile and prognosis that are closer to those of pts with preserved EF >50% (HFpEF) than those of reduced EF < 40% (HFrEF), with certain distinctions.
Purpose: Evaluation of co-morbidities and some biomarkers that may point to a higher risk of developing HF and characterize pt's EF range.
Methods. The pts (N = 127, 54M:73F), hospitalized during 2017 to Internal Medicine Dept. with proved diagnosis of HF (NYHA I-IV) were classified according to EF by transthoracic echo (Simpson) into 3 groups: 1 (n = 12) - with HFrEF, 2 (n = 22) - HFmrEF, and 3 (n = 93) - HFpEF. Some clinical and laboratory markers and parameters as well as rate and types co-morbidities were estimated and compared between groups.
Results: The most pts (73.2%) were related to HfpEF. It was no gender differences between groups. Group 3 was significantly younger (69.3 ± 11.3 yrs) compared to group 2 (73.8 ± 10.2 yrs, p < 0.05). During analysis of comorbidity structure of groups we reveal that group 1 prevailed over the rest in the proportion of pts with stroke and/or transient ischemic attack (25.0%), arrhythmias (83.3%), c2 = 6.635, p < 0.01) and peripheral arteries disease (PAD) (33.3%, c2 = 6.422, p < 0.05). Group 2 prevailed in hypertension (45.5%), coronary artery disease (54.5%), encephalopathy (81.8%) and atrial fibrillation (AF) (63.6%, c2 = 6.635, p < 0.01). Group 3 prevailed only in diabetes mellitus rate (33.3%). We didn't find any significant difference in hypertension rate between groups, but blood pressure (BP) levels were significantly higher in groups 2 (systolic 201.0 ± 30.9 and diastolic 114.0 ± 5.5 mmHg) and group 3 (176.3 ± 18.0 and 108.8 ± 8.5) compared to group 1 (156.3 ± 9.5 and 91.3 ± 2.5 mmHg, p < 0.01 for all). These differences can be connected with more strict BP control in group 1 pts. We found increasing of uric acid levels with EF decreasing. Thus, uric acid level in group 3 (316.0 ± 132.8) was significantly lower compared to both other groups (442,3 ± 84,4 and 398.3 ± 81.0 mmol/l, p < 0.05). We noted

reducing the severity of dyslipidemia as the EF decreases. So, total and LDL cholesterol (CHL) were significantly higher in group 3 (6.5 ± 1.2 and 4.4 ± 0.6 mmol/l) versus group 1 (4.0 ± 1.0 and 2.3 ± 0.6 mmol/l, p < 0.05 for all). Moreover, there were light positive correlation for CHL and EF (r = 0.3, ? < 0.05). HDL-CHL in group 3 (1.6 ± 0.4) was higher compared to groups 1 (1.1 ± 0.2) and 2 (1.2 ± 0.4 mmol/l, p < 0.05 for all). Creatine phosphokinase levels tended to decrease with EF increasing. It can be connected with high rate of multifocal atherosclerosis clinical manifestations in groups 1 and 2.
Conclusion: Some concomitant factors of HF with different meaning of EF may be distinct. Significant difference demonstrated for BP, uric acid, CHL, HDL- and LDL-CHL levels, pts with PAD and arrhythmias, AF especially. We can characterize HFmrEF pts as separate clinical grope with specific metabolic and co-morbidity profile.

P1678
Characteristics of obese patients with heart failure with mid-range ejection fraction

Background. Despite all complex therapeutic opportunities, heart failure remains a tremendous public health burden. Moreover, the diagnosis of chronic heart failure in obese population brings unique challenges. So, a comprehensive understanding of their paradoxical particularities is desirable.
Purpose: To investigate and improve the knowledge on the profile of obese patients with heart failure with mid range ejection fraction.
Material and methods. We retrospectively enrolled 126 overweight and obese (body mass index = 25 kg/m2) patients who were hospitalized for decompensated heart failure. Baseline characteristics, clinical presentation, laboratory data, echocardiographic parameters and in-hospital therapies were compared among obese heart failure patients divided into three groups: with reduced (< 40%), mid-range (40-49%) and preserved (= 50%) ejection fraction (EF). Heart failure was defined according to 2016 ESC criteria. A multivariable analysis was performed.
Results: The mean age of the analyzed study population was 70.45 ± 9.12 years and 54.8% were men. Among the patients, 26.4% had reduced ejection fraction (HFrEF) with a mean NT-proBNP value of 4355.76 ± 4312.08 pg/ml, 28.8% mid-range ejection fraction (HFmrEF)- NT-proBNP mean value of 2257.97 ± 2507.91 pg/ml, and 44.8% preserved ejection fraction (HFpEF)- NT-proBNP value of 1921.57 ± 1824.10 pg/ml. The 3 groups were similar in terms of age, sex, BMI and renal function. Patients with HFmrEF had a mean BMI of 35 ± 4.71 kg/m2. In HFmrEF obese patients the most frequent precipitating factor for admission was atrial fibrillation with rapid ventricular response. The main etiology of HF in our patients with mid-range EF was ischaemic (50%), followed by valvular heart disease. NT-proBNP values negatively correlated with BMI in patients with HFpEF (r= -0.307, p = 0.028), in the other groups NT-proBNP was not significantly influenced by BMI. An inverse relationship was found between NT-proBNP values and creatinine clearance estimated by Cockcroft-Gault equation in patients with HFmrEF (r=-0.355, p = 0.038) and HFpEF (r= -0.279, p = 0.042). NT-proBNP levels were not significantly influenced by the presence of atrial fibrillation, diabetes mellitus, age in neither of the three groups, regardless of sex. NT-proBNP levels were not significantly influenced by the presence of echocardiographic left ventricular hypertrophy or atrial dilatation.
In conclusion, obese individuals with HFmrEF presented particular characteristics, in terms of aetiology, precipitating factors, NT-proBNP values. In this group, NT-proBNP values were not significantly influenced by BMI, age, the presence of atrial fibrillation or diabetes mellitus. Despite all controversial data regarding the NT-proBNP diagnostic and prognostic value in patients with obesity and the lack of evidence in those with obesity and HFmrEF, this study showed they remain important biomarkers in this category of patients, too.

Profile and differential management of patients with a mid-range ejection fraction compared to patients with reduced ejection fraction

D Daniel Enriquez Vazquez[1]; C Perez Garcia[1]; TS Luque Diaz[1]; A Travieso Gonzalez[1]; V Ruiz Pizarro[1]; C Olmos Blanco[1]; D Vivas Balcones[1]; P Martinez Santos[1]; M Perez Serrano[1]; R Bover Freire[1]; I Vilacosta[1]; C Macaya[1]
[1]*Hospital Clinic San Carlos, Cardiovascular Institute, Madrid, Spain*

Background: In European Society of Cardiology guidelines on the diagnosis and management of patients with heart failure (HF), a new door opens to that gray area corresponding to patients with ejection fraction (EF) between 40-49%. These are framed within a new group known as mid-range ejection fraction (HFmrEF).
Purpose: The objective of this study is to characterize this type of patients and their comparison with heart failure with reduced EF (HFrEF).
Methods: Patients diagnosed with HF admitted to a Cardiology Service of a tertiary hospital between July 2016 and March 2017 were registered prospectively and consecutively for one year.
Results: Of the total of 341 patients, 90 patients had HFmrEF and 113 patients with HFrEF. Baseline characteristics of both groups of patients are shown in Table 1. Patients with HFmrEF have a generally poorer cardiovascular risk profile, and more often tachyarrhythmias or acute ischemic heart disease as triggers.
Beta-blockers were used at discharge in higher proportion in patients with HFrEF (83.8% vs 73.5%). The percentage of use of ACE inhibitors or ARA2 is similar between the two groups (65%), but in HFmrEF, ARA2 was used in a higher percentage (20, 4% vs 8.1%, p 0.027). MRAs are used in both groups, with greater use in patients with HFrEF (65% vs 30% at discharge, p < 0.001). The use of diuretics at discharge was higher in the group of patients with HFrEF than in the mid-range group (82% vs 69.4%, p 0.07).
Conclusion: HFmrEF patient presents higher cardiovascular risk, with admissions for heart failure mainly due to tachyarrhythmias or acute ischemic heart disease. They also have less right ventricular dysfunction. Diuretics are used in smaller quantities, as well as ARMs, and to a greater extent the ARA2.

Comparison of self-reported and accelerometer-assessed physical activity and sedentary time in patients with heart failure with preserved ejection fraction

C Cristine Schmidt[1]; L Bohn[1]; M Santos[2]; D Moreira-Goncalves[1]; J Oliveira[1]
[1]*Faculty of Sport University of Porto , CIAFEL, Porto, Portugal*; [2]*Faculty of Medicine University of Porto, Surgery and Physiology Department; Centro Hospitalar do Porto, Department of Cardiology, Porto, Portugal*

Funding Acknowledgements: FCT, European Union, QREN, FEDER and COMPETE (UID/DTP/00617/2013) D.M.G and C.S: individual grant (SFRH/BPD/90010/2012 and CAPES/BEX 0554/14-6)

Introduction: Pharmacological therapies have failed to improve clinical outcomes among patients with heart failure have preserved ejection fraction (HFpEF), who represent more than half of patients with HFpEF. High levels of physical activity and low sedentary time are associated with better quality of life and reduced risk of hospitalization and mortality in HFpEF patients. In order to effectively prescribe physical activity, recommendations need to be grounded in accurate measures of physical activity.
Purpose: To compare self-reported with accelerometer-assessed physical activity levels and sedentary time in HFpEF patients.
Methods: HFpEF patients (n = 24; stable and well-medicated) were recruited and assessed for physical activity levels through the IPAQ–Short Form and with accelerometers (ActiGraph GTX3). To be considered as valid data, a minimum of 4 days recorded with at least 10 wear-time hours/day was determined. Sedentary time and time spent in moderate to vigorous activity (MVPA) were compared according to gender. Time spent in MVPA derived from IPAQ were merged with self-reported walking and MVPA to compare with objectively measured MVPA (= 2752 cpm, derived from vector magnitude). Mean differences were examined using the Mann–Whitney test (non-parametric data) or the Student t test (parametric data).
Results: Validated data was obtained from twenty-two patients (age= 76 ± 6.1; 16 females, and 6 males). Mean accelerometer wearing time was 13.16 ± 1 h/day. IPAQ

underestimated sedentary time compared with the accelerometer (253 ± 156 vs 555 ± 78 min.d-1, p = 0.002), even when adjusted for gender. According to IPAQ, 68% of the patients accumulated at least 150 minutes of MVPA, in bouts = 10 minutes, as specified by the guidelines, while none met the recommendations when PA was objectively measured. However, if remove the bout length restriction, 77% of the patients would achieve the recommendations for MVPA objectively measured.
Conclusion: The study suggests that in patients HFpEF, IPAQ–Short Form may underestimate sedentary time and overestimate physical activity MVPA levels according to the guidelines (bouts = 10 minutes). This has important clinical implications as it limits IPAQ-based decisions targeting the management of both sedentary time and MVPA in HFpEF patients.

Genetic determination of myocardial mechanics: towards a deeper understanding of heart failure with preserved ejection fraction?

A Kovacs[1]; AA Molnar[1]; M Kolossvary[1]; B Szilveszter[1]; B Lakatos[1]; AD Tarnoki[2]; DL Tarnoki[2]; G Jermendy[3]; PP Sengupta[4]; P Maurovich-Horvat[1]; B Merkely[1]
[1]Semmelweis University Heart and Vascular Center, Cardiovascular Imaging Research Group, Budapest, Hungary; *[2]Semmelweis University, Department of Radiology and Oncotherapy, Budapest, Hungary*; *[3]Bajcsy-Zsilinszky Hospital, Budapest, Hungary*; *[4]Heart and Vascular Institute, Morgantown, United States of America*

Genetic effects in the determination of left ventricular (LV) mechanics are scarcely characterized. The present study was performed to assess heritability of LV function and to reveal possible common genetic background of different LV functional phenotypes as measured by advanced echocardiographic parameters in a cohort of Caucasian twins.
Ninety-two twin pairs were recruited (54 monozygotic and 38 same-sex dizygotic twin pairs, mean age 56 ± 9 years). Siblings with obstructive coronary artery stenosis assessed by coronary CT angiography or siblings with any cardiomyopathy or severe valvular disease were excluded. Beyond conventional echocardiographic parameters, global longitudinal (GLS), circumferential strain, apical counter-clockwise, basal clockwise rotation and longitudinal early diastolic strain rate were measured by speckle-tracking echocardiography.
The univariate genetic and environmental effects model showed high genetic component in the variance of LV systolic deformation (62-77%), however, heritability of LV diastolic functional parameters was low (31-46%), whilst unique environmental effects dominated. Cholesky decomposition was carried out to calculate the magnitude of covariation between the investigated phenotypes and to estimate the proportion of shared and unique genetic factors. Despite high heritability of LV systolic deformation parameters, no shared genetic background could be revealed between these parameters (p = 0.99). Even though LV diastolic parameters showed low genetic determination, we found a significant common latent phenotype responsible for the heritability of these parameters (p < 0.001). Furthermore, GLS and LV diastolic function showed also common heritability (p < 0.001).
Our work demonstrated high heritability of LV systolic deformation in Caucasian twins. These findings support further investigation of potential candidate genes determining LV systolic function. Different directions of LV deformation are inherited independently. However, GLS shares common genetic background with diastolic function. This points at the importance of systolo-diastolic coupling of myocardial mechanics and may provide further insights into the understanding of heart failure with preserved ejection fraction.

Differences in patient reported outcome in women and men with HFpEF

U Ulrika Ljung Faxen[1]; C Hage[1]; E Donal[2]; JC Daubert[2]; C Linde[1]; LH Lund[1]
[1]Karolinska Institute, Department of Medicine, Stockholm, Sweden; *[2]University Hospital of Rennes, Département de Cardiologi & CIC-IT U 804, Rennes, France*

On behalf of: KaRen investigators
Funding Acknowledgements: The Swedish Research Council, The Swedish Heart & Lung Foundation, Stockholm Country Council, Fédération Française de Cardiologie, Medtronic Bakken Re

Aims: Heart failure with preserved ejection fraction (HFpEF) is associated with poor quality of life (QoL), or patient reported outcome (PRO). Despite female predominance in HFpEF, sex-specific differences in PROs remain poorly studied. We assessed PRO measures and their association with HF-severity and outcome in HFpEF by sex.
Methods and Results: In 387 patients with HFpEF from the KaRen study, EQ-5D-3L® and Minnesota Living with Heart Failure Questionnaire® (MLHFQ) were assessed. Characteristics and comorbidities were largely similar in women (n = 220, 57%) and men. Women expressed more problems in EQ-5D part 1 in all five dimensions, but significantly different from men regarding mobility (53 vs. 42%, p = 0.018), usual activities (47 vs. 34% p = 0.011), and anxiety and depression (51 vs. 38% p = 0.012). Women also expressed worse QoL in EQ-5D part 2 (EQ-VAS), independent of age and HF severity, mean (SD), 56(20) vs. 61(19), p = 0.010. There was no difference in MLHFQ, 31(20) vs. 29(21), p = 0.269.
Spearman's correlations with HF severity (NYHA class) were for MLHFQ in women r 0.35 vs. men 0.41, p for both < 0.001, and for EQ-VAS r -0.27, p = 0.001 vs. -0.45, p < 0.001. Correlations with natriuretic peptides were for MLHFQ r 0.22 in women vs. men 0.25, p = 0.002, and for EQ-VAS r -0.18, p = 0.012 vs. -0.26, p = 001.
Associations between PRO and the composite of HF hospitalisation or all-cause death were present in men only, adjusted HR per 5 units increase in MLHFQ 1.06, 95% confidence interval(CI) 1.01-1.11, p = 0.027 and EQ-VAS, HR 0.92, 95% CI 0.88-0.98, p = 0.010.
Conclusion: n HFpEF, women had worse general but similar disease specific QoL compared to men. QoL was more strongly associated with HF severity in men, and associated with outcomes in men only. In women with HFpEF, QoL appears less determined by HF itself and potentially more by other unknown factors. This might have implications for the magnitude of improvement of PRO in women from HF treatment.

P1683

Left atrial function, volume and compliance in patients with HFpEF

G Bajraktari[1]; I Bytyci[1]; MY Henein[2]
[1]University Clinical Centre of Kosova, Clinic of Cardiology, Pristina, Kosovo Republic of; *[2]Umea University, Department of Public Health and Clinical Medicine, Umea, Sweden*

Background and Aim: Left atrial (LA) structure and function indices; LA function index (LAFI), LA volume index, LA stroke volume and LA diameter have been shown to predict clinical outcome in patients with heart failure and preserved ejection fraction (HFpEF). The aim of this study was to assess the relationship between LAFI and LA structure and function in patients with HFpEF.

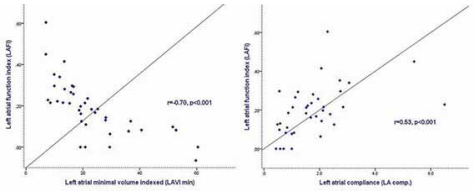

Figure 1. Correlation of LAFI with LAVI

Methods: In 53 consecutive patients with HFpEF (age 62 ± 7 years, NYHA class I - III, LV EF = 50) and 40 controls, a complete echocardiographic examination was performed. In addition to conventional volume measurements, LAFI was calculated using the formula (LAFI = LAEF x LVOT VTI/LAVI max) and LA compliance using the equation [LAV max - LAV min / LAV min x 100].
Results: Patients were older (p = 0.002), with higher LV mass index (p = 0.01), reduced septal and lateral MAPSE (p < 0.001, for both), reduced TAPSE (p = 0.01), larger LA volume (p < 0.001), raised LAVI max and LAVI min (p < 0.0001, for both) and impaired LA compliance index (p < 0.001), compared to controls. LAFI modestly correlated with LV EF (r = 0.39, p = 0.01), LA size (r=-0.47, p = 0.01), LA EF (r = 0.46, p = 0.003), LAVI max (r=-49, p = 0.01) and LA compliance (r = 0.53, p < 0.001) but correlated strongly with LAVI min (r=-0.70, p < 0.001, figure 1).
Conclusions: Patients with HFpEF have increased left atrial volume and reduced compliance. These measurements support the need for routine assessment of LA in heart failure clinics.

P1684

The dynamics of galectin-3 in patients with heart failure and preserved ejection fraction

Y Yulia Kushnir[1]
[1]Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Nowadays galectin-3 is concidered as a myocardial firosis marker and the possibility of its applying in diagnostics and prognosis of chronic heart failure (CHF) is discussed. At the same time some authors presuppose the existence of antifibrotic effect of the torasemide - one of the loop diuretics which are the major drug group to reduce liquid retention in patients with CHF.
The aim of the study was to estimate the dynamics of galectin-3 in patients with CHF with preserved left ventricular ejection fraction during loop diuretics treatment.

Materials and methods. There were examined 31 patients (male - 23, female - 8) with the age limit 51-75 years (average M ± m - 66.9 ± 1.4) who suffered from CHF II-III functional class caused by coronary heart disease (CHD) with preserved ejection fraction. The control group consisted of 15 patients in age from 46 to 73 (average M ± m - 66.2 ± 2.2) with CHD without CHF manifestation. Twenty-six examined patients who needed prescription of diuretics were randomly divided into 2 groups. The fist one – 15 CHF patients who were treated with torasemide, the second one - 11 patients who were prescribed furosemide. Before the therapy was started groups were comparable in all investigated parameters (p>0,05 in all comparisons). In addition to diuretics, all patients received standard CHF therapy. Clinical efficiency and dynamics of galectin-3 was estimated in 2-3 month.
Results: The positive dynamics of the functional class (FC) was established in both groups after treatment. In group I the average FC decreased from 2.80 ± 0.11 (Me = 3) to 2.20 ± 0.17 (Me = 2) (p = 0.008), in the II group - from 2.73 ± 0.14 (Me = 3) to 2.27 ± 0.19 (Me = 2) (p = 0.043). The positive dynamics of the FC was associated with improving the health of patients. Thus, in the first group complaints of general weakness decreased by 46.6%; shortness of breath by 60.0%; swelling of the lower extremities by 93.3%; heart pain by 20.0%; in the second group 36.3%; 54.5%; 90.9%; 18.2%, respectively. The analysis of the dynamics of the galectin-3 levels on the background of treatment with loop diuretics is presented in the table.
Conclusion. Analysing the clinical comparability of loop diuretics in patients with CHF addition of torasemide to their therapy has advantages which are expressed by positive influence on the dynamics of galectin-3 level.

Increased pulmonary capillary wedge pressure is the major hemodynamic abnormality during supine exercise in patients with heart failure with preserved ejection fraction

E Emil Wolsk[1]; D Kaye[2]; J Komtebedde[3]; SJ Shah[4]; D Burkhoff[5]; B Borlaug[6]; DW Kitzman[7]; C Lam[8]; D Van Veldhuisen[9]; P Ponikowski[10]; M Petrie[11]; C Hassager[12]; JE Moller[13]; F Gustafsson[12]
[1]Gentofte Hospital, Department of Cardiology, Copenhagen, Denmark; *[2]Baker IDI Heart and Diabetes Institute, Melbourne, Australia*; *[3]Corvia Medical, Andover, United States of America*; *[4]Northwestern University, Chicago, United States of America*; *[5]Cardiovascular Research Foundation, New York, United States of America*; *[6]Mayo Clinic, Rochester, United States of America*; *[7]Wake Forest University, Winston-Salem, United States of America*; *[8]Duke-NUS Graduate Medical School Singapore, Singapore, Singapore*; *[9]University Medical Center Groningen, Groningen, Netherlands*; *[10]4th Military Hospital, Wroclaw, Poland*; *[11]University of Glasgow, Glasgow, United Kingdom*; *[12]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*; *[13]Odense University Hospital, Odense, Denmark*

Background: Severely reduced exercise capacity is a hallmark of heart failure with preserved ejection fraction (HFpEF), but its mechanisms are not fully understood.
Methods: We examined invasive hemodynamic variables during rest and peak supine cardiopulmonary exercise testing in HFpEF patients compared with healthy controls at matched workloads utilizing data from 3 large prospective trials: 108 HFpEF patients from REDUCE LAP-HF & REDUCE LAP-HF I (LVEF:52 ± 10%) and 42 healthy controls from the HemReX study (LVEF:62 ± 7%). Student's t-test and logistic regression with stepwise selection (p < 0.05) were used to assess hemodynamic variables associated with HFpEF vs. controls. Dominance analysis was used to obtain the proportion of fit metric attributable to each independent variable. A p value of < 0.05 was considered statistically significant.
Results: At matched workloads (HFpEF - peak workload: 45 ± 13 W vs. controls - matched workload: 45 ± 23 W, p = 0.85) in HFpEF patients compared to controls, the increase in cardiac index (+1.5 ± 0.9 vs. +2.9 ± 1.1 l/min/m2, p < 0.0001) and stroke volume index (SVi; +4 ± 10 vs. +19 ± 10 ml/m2, p < 0.0001) were substantially blunted, and pulmonary capillary wedge pressure [PCWP] was increased(+17 ± 7 vs +10 ± 6 mmHg, p < 0.0001), whereas changes in heart rate (29 ± 19 vs. 29 ± 16 bpm, p = 0.94) were similar (Table). Changes in arterial-venous O2 difference, a measure of peripheral function, tended to be lower in HFpEF compared to controls (+4.8 ± 0.8 vs. +5.1 ± 1.5 ml/dl, p = 0.08). In multivariate modeling, 2 exercise hemodynamic variables independently distinguished HFpEF from healthy controls (r2:0.75); SVi (OR: 0.89 [0.82, 0.96], p = 0.002) and PCWP (OR: 1.55 [1.30, 1.86], p < 0.0001), accounting for 17% (SVi) and 57% (PCWP) of the difference between HFpEF and controls.
Conclusion: Increased PCWP and blunted SVi account for the majority of hemodynamic differences between HFpEF patients and healthy controls during supine exercise.

Hemodynamics at matched workloads

	Controls	HFpEF	p-value
Heart rate (bpm)	93±18	99±20	0.04

P1686

The level of uric acid in patients with heart failure with preserved ejection fraction depending on age

Y Kushnir[1]
[1]Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Today there is numerous evidence of the importance of hyperuricemia in the progression of chronic heart failure (HF). Hyperuricemia considered as a marker of poor prognosis in patients with HF. According to the literature hyperuricemia can be observed in 60% of patients with CHF hospitalized with decompensation.
The aim was to estimate the level of uric acid in patients with heart failure with preserved ejection fraction (EF) depending on age.

Uric acid level in patients with HF

Measurement, units	Number of patients (abs.,%) or average level (M±m, ??)		
Patients under 59 years (n = 74)	Patients from 60 to 75 years (n = 73)	Patients over 76 years (n = 51)	
Uric acid, mcmol/l	349±6,4	356±8,5	377±7,2*
Hyperuricemia	12 (16,2%)	9 (12,3%)	11 (21,6%)

Materials and Methods: A retrospective analysis of clinical records of 198 patients with HF and preserved EF (EF more than 45 %, average (M ± m) - (63,8 ± 6,3) %) was enrolled. All patients were hospitalized in 2015-2016 and were older than 40 years (average age (M ± m) of 51.7 ± 9,4). All patients were divided into three groups according to age: the first group - patients aged 40 to 59 years (n = 74), the second group - patients aged 60 to 75 years (n = 73), the third group - patients older than 75 years (n = 51). HF was diagnosed in case of presence of objective and subjective features inherent to this clinical syndrome, collected anamnesis, physical examination, laboratory and instrumental analysis. The average level of uric acid in all patients with HF and preserved EF was estimated. According normative values were adopted following indicators: men - 200-420 mmol/l; women - 140-340 mmol/l. Statistic processing of materials research conducted using the methods of biostatistics implemented in the software package STATISTICA 6.0.
Results: The increased average level of uric acid was found in all age groups. However, the frequency of hyperuricemia registration was maximum (21.6%) in patients from 75 years, which may indicate poor prognosis in this age group (Table).
Conclusion. All patients with chronic heart failure have increased average level of uric acid. Determined that the average level of hyperuricemia increases with age.

P1687

Role of vascular endothelial growth factor-A in left ventricle remodeling and diastolic dysfunction in patients with heart failure

D Dina Shorikova[1]; E Shorikov[1]
[1]Bucovinian State Medical University, Chernivtsy, Ukraine

At the last decades, the paradigm about exclusive role of renin-angiotensin-aldosterone system in target organs injuries during chronic heart failure (HF) is the basic conception in the most of clinical trials. But, it is also essential to provide

researchers about relating role of different biomarkers which could affect cardiovascular continuum. On our opinion, the superfamily of growth factors, especially vascular endothelial growth factor-A (VEGF-A), may keep definite position in the development of HF.

Material and methods: We have included 288 patients with diagnosis of non-ischemic HF with preserved ejection fraction (HFpEF) (mean of LVEF of patients was 53,8 ± 4,72%) in the study. All patients were inspected with echocardiographic and Doppler ultrasound and immunoassay detection of VEGF-165 (type ?).

Using unadjusted regression model we have analyzed interrelationship between the VEGF-165 concentration and parameters of LV remodeling in patients with HFpEF

We have set the reliable negative correlation between level of VEGF-A and LV mass (R=-0,61; ? = 0,007) and myocardium mass index (R=-0,54; ? = 0,004). Nevertheless, the observed data showed unreliable regression between the decrease of the VEGF-A level and the relative wall thickness as with VEGF-A level and index EDV/LV mass. In non-parametric ANOVA we have found the dependency of the distribution of medians of the VEGF-A level on the eccentric and concentric hypertrophy (? = 6,58; ? = 0,04).

However, we observed strong positive correlation between VEGF and ratio of early and late peak velocity (Ve/Va) and negative correlation with VEGF and isovolumetric relaxation time. The decrease of VEGF level also associated with the shortness of duration time of early peak of diastolic flow (DTe) (table).

Conclusion: in patients with HFpEF the decrease of VEGF-165 associated with the increase of left ventricle mass and the strongest link set in condition of eccentric and concentric hypertrophy. In addition, there is the direct dependency between the level of VEGF and the parameters of diastolic function of left ventricle.

Interrelationship between VEGF-A and som

Index	IVRT, ?	DT E, ?	Ve/Va
Level VEGF-165	r=-0,52 (? = 0,03)	r = 0,47 (? = 0,09)	r = 0,65 (? = 0,011)

Diastolic dysfunction grades stratify patients on chronic hemodialysis therapy

J Jan Malik[1]; A Valerianova[1]; J Lachmanova[1]; M Bartkova[1]
[1]*Charles University, 1st Faculty of Medicine , Prague, Czech Republic*

Funding Acknowledgements: Grant of the Agency of Health Research of the Czech Republic 17-31796A.

Background: Heart failure is a frequent consequence of end-stage renal disease (ESRD). Among other involved mechanisms, left ventricular (LV) diastolic dysfunction is frequent. New echocardiographic guidelines for assessing diastolic function were published recently. They help in the diagnosis and severity stratification of HFpEF and have been studied in various populations. However, data in ESRD patients, typically affected by cyclic volume overload, is sparse. In this population, the diagnosis of heart failure is tricky since both echo findings and B-type natriuretic peptide (BNP) levels are related also to the actual volume status.

Purpose: We performed a single center study aimed at assessing the role of diastolic dysfunction grading in ESRD patients treated by hemodialysis.

Methods: We included a cohort of 46 ESRD patients treated by hemodialysis in our Institution if they fulfilled the following criteria: good echo visibility, ejection fraction >45%, lack of moderate-to-severe valvular disease. The Euro-American 2016 guidelines primary criteria for assessing diastolic function (mean E/e'>14, e' septal < 7cm/s or e' lateral < 10 cm/s, peak tricuspid regurgitation velocity > 2,8m/s, left atrial volume index >34 ml/m2) were applied. Examinations and blood drawing for BNP analysis was done just before hemodialysis.

Results: Included subjects were 62 ± 15 years old, their dialysis vintage lasted for 61 ± 52 months. Diastolic dysfunction as well as left atrial dilatation was present in 64% of them. BNP rose significanty with diastolic dysfunction grade and also with left ventricular mass index. Medial e' was more robust than lateral e'.

Conclusions: Diastolic dysfunction grades further differentiate ESRD patients according to their BNP levels. High frequency of diastolic dysfunction is affected mainly by the high prevalence of LV hypertrophy. The border between heart failure and water overload is not sharp in this population.

P1689

Hepatocardiac relations in patients with heart failure and diabetes mellitus.

I Kniazkova[1]; A Bilovol[1]; V Maziy[2]
[1]*Kharkov national medical university, Kharkov, Ukraine*; [2]*Institute therapy of L.T.Malay of AMS of Ukraine, Kharkov, Ukraine*

We aimed to investigate the association between the structural and functional state of the liver and the cardiac haemodynamics in patients (pts) with ischemic heart failure (HF) and diabetes mellitus (DM).

Materials and methods. The study included 82 pts with HF NYHA II-III after myocardial infarction, 42 of which (mean age 55.8 ± 2.6 years) had DM (1 group) and the other 40 (mean age 54.3 ± 2.9 years) - had not (group 2). The groups comparable to demographic and clinical characteristics. Central haemodynamics parameters was evaluated with echocardiography. Structural state of the liver was investigate with an ultrasound scanner and included assessment of the echogenicity of hepatic parenchyma, vascular pattern, the degree of fatty change and the stage of liver fibrosis. The parameters of the liver functional status and hepatocyte damage markers were determined (serum total protein and albumin, total bilirubin, prothrombin index, alanine aminotransferase (ALT) and aspartate aminotransferase (AST) alkaline phosphatase (AP) and gamma-glutamyltransferase (GGP)). The insulin resistance index of HOMA and the QUICKI test were calculated. The hepatic steatosis index (HSI), the fatty liver index (FLI) and nonalcoholic fatty liver disease fibrosis score (NFS) were calculated.

Results: It was found that the HSI and the FLI were significantly ($p < 0.05$) higher in group 1 (39.1% and 2.3-fold respectively) than in group 2. Patients with DM also had higher values of NFS (-0.51 ± 0.7) compared with non-DM patients (-1.5 ± 0.6; $p < 0.05$). The patients of group 1 characterized by higher blood levels of bilirubin 2.2-fold, GGTT 4-fold, ALT 5.3-fold and AST 1.7-fold and lower total protein levels (67.1 ± 3.2 vs. 72.9 ± 3.6 g/l) and albumin (36.1 ± 3.1 vs. 42.1 ± 3.3 g/l) in compare with group 2. Also, under comparable NYHA classes of heart failure the left ventricular myocardial mass index (LVMI) was 12.1% ($p < 0.05$) higher in group 1 in compare with group 2. In group 1 the following left ventricle (LV) remodeling patterns were noted: concentric hypertrophy and eccentric hypertrophy (54.8% and 45.2% respectively), which significantly differed from group 2, where 15% of patients had a normal geometry of LV, in 62,5% and 22.5% of patients - concentric hypertrophy and eccentric hypertrophy, respectively. We found a correlation between LVMI and the FLI ($r = 0.31$, $p < 0.05$) and LVMI and the NFS ($r = 0.33$, $p < 0.05$) in group 1. In addition, the NFS demonstrates correlation with the six minute walk test and NYHA classes (r=-0.33 and r = 0.31 respectively, all $p < 0.05$) in group 1.

Thus, in patients with CHF and DM showed more expressed structural and functional status changes of the liver, which included formation of steatosis and initial signs of hepatic fibrosis, laboratory syndromes of cytolysis and cholestasis. This corresponds to more pronounced structural changes in the heart, manifested by increasing LVMI and development of adverse types of LV remodeling.

P1690

Single centre audit of experience in tallaght hospital among patients with chronic heart failure and iron deficiency anemia (ida).

W Ashram[1]
[1]*Beaumont Hospital, cardiology, Dublin, Ireland*

Introduction: Chronic heart failure is a common condition and is significantly projected to increase in the coming years due to increased survival of patients with coronary artery disease.

Iron deficiency anemia is a commonly present co-morbidity in patient with heart failure and it has been associated with increased mortality and a poorer quality of life. Symptoms related to iron deficiency anemia are not specific and is considered as a major contributor to exercise intolerance even in the absence of anemia.

Purpose: The main purpose of this audit is to further characterize patients with chronic heart failure with iron deficiency anemia and normal iron storage irrespective of hemoglobin level in relation to the degree of kidney function, Pro BNP level and left ventricular systolic function.

Methods and Results: We reviewed 133 patients with chronic heart failure in our Hospital, in 12 months period of time from June 2016 until July 2017. The age range was between 39 and 94 with mean of 71 years. 88 patients were males and 45 patients were females.

94 patients (70%) out of 133 patients have iron profile. Interestingly, two groups were almost equal in number (46 patients with IDA and 48 patients with normal iron storage)

Comparing 2 groups in relation to kidney function, Pro BNP level and left ventricular systolic function showed significant difference in Pro BNP level between 2 groups (Pro BNP was elevated in 84.78% in IDA while only 12.5% in patients with normal iron storage). Both groups showed > 90% of patients have stage 2 to stage 5 CKD. In relation to left ventricular systolic function, 50% in each group showed severely reduced systolic function.

Conclusion: IDA is strongly associated with high level of Pro BNP and heart failure exacerbation in 85% of HF population studied (especially when LVEF is severely reduced) when compared to patients with normal iron storage. There is no much difference in both groups regarding kidney function and left ventricular systolic function as both group almost (half of them) have severe LVEF with CKD stage 2 to 5. Therefore, checking iron storage in patients with high level of Pro BNP and heart failure exacerbation will have an excellent impact on patients' wellbeing and eventually reducing the burden on health care system. Which can be easily corrected if approached appropriately.

P1691

Paulus criteria are valuable for predicting outcome in patients with asymptomatic diastolic dysfunction

A Anna Bobenko[1]; L Schleussner[1]; A Duvinage[2]; T Trippel[1]; C Herrmann-Lingen[3]; L Binder[4]; K Nolte[5]; V Holzendorf[6]; M Mende[7]; G Hasenfuss[5]; R Wachter[5]; B Pieske[1]; F Edelmann[1]

[1]Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany; *[2]Technical University of Munich, Depatment of Prevention, Rehabilitation and Sports Medicine, Munich, Germany*; *[3]University Medical Center Gottingen (UMG), Depatment of Psychosomatic Medicine and Psychotehrapy, Gottingen, Germany*; *[4]University Medical Center Gottingen (UMG), Clinical Chemistry, Gottingen, Germany*; *[5]University Medical Center Gottingen (UMG), Department of Cardiology and Pneumology, Gottingen, Germany*; *[6]University of Leipzig, Clinical Trial Centre, Leipzig, Germany*; *[7]University of Leipzig, Department of Informatics, Statistics and Biometry, Leipzig, Germany*

Background: High prevalence and lack of pharmacological treatment are making heart failure with preserved ejection fraction (HFpEF) a growing public health problem. Therefore, prevention of onset of HFpEF has become an important issue, but no algorithm for screening asymptomatic patients with risk factors for developing HFpEF exists to date.
Purpose: We assessed whether Paulus criteria are suitable for predicting cardiovascular outcome in asymptomatic patients with preserved left ventricular ejection fraction (LVEF) and diastolic dysfunction.
Methods: We performed a post-hoc analysis of the Diagnostic Trial on Prevalence and Clinical Course of Diastolic Dysfunction and Heart Failure (DIAST-CHF) investigating patients with cardiovascular risk factors. All patients underwent a comprehensive non-invasive diagnostic workup, including ECG, blood pressure measurement, detailed echocardiography and blood analysis at baseline and within a 5-year-follow-up. Asymptomatic patients with preserved LVEF (< 50%) were selected from all DIAST-CHF patients and classified according to Paulus criteria (tissue doppler derived E/e' > 15 or E/e' > 8 and presence of either NT-proBNP > 220 ng/l, BNP > 200 ng/l or atrial fibrillation) into "Paulus positive" and "Paulus negative". Outcome was assessed for both groups after 5 years of follow-up.
Results: 851 asymptomatic patients (age 65.5 ± 7.6 years, 44% female, mean BMI 28.1 kg/m2) were included in the analysis. Paulus positive patients were significantly older ($p < 0.001$), more often women ($p = 0.003$) and more often had a history of coronary artery disease, atrial fibrillation and renal dysfunction ($p < 0.001$) compared to Paulus negative. Incidence of death, cardiovascular hospitalization and onset of heart failure signs or symptoms was significantly higher in Paulus positive group after 5 years of follow-up ($p < 0.001$).
Conclusion: Asymptomatic patients with preserved LVEF that fulfill Paulus criteria on diastolic dysfunction have a worse 5-year-outcome than those who do not fulfill Paulus criteria. Therefore, Paulus criteria may be used for outcome assessment and prevention of HFpEF in asymptomatic patients with risk factors for heart failure.

Chronic Heart Failure - Epidemiology, Prognosis, Outcome

Impact of cardiometabolic syndrome on the incidence of heart failure; a nationwide, longitudinal cohort study in South Korea

S H Sung Hea Kim[1]; KH Ryu[2]; SW Han[2]; HJ Kim[1]; HS Kim[1]; JC Youn[2]; SW Choi[2]

[1]Konkuk University Hospital, Seoul, Korea Republic of; *[2]Hallym University, Cardiology, Dongtan, Korea Republic of*

Background: Although studies on association with HF (HF) and the cardiac CMS(CMS) have been conducted in Swedish study (ULSAM cohort) and the Finnish study, these studies were conducted only in middle aged men with 50 years old or old age over 70. But there is few data on the association between HF and CMS in young age group or women, furthermore in Asian.
Methods: In this study, 7,830,602 study subjects who were aged between 30 and 70 years and had received national health checkups in 2009 were retrospectively included and followed up for 7 years. Participants excluded were those with cardiovascular disease and cancer. Based on revised National Cholesterol Education Program-Adult Treatment Panel III criteria, subjects were divided into three groups according to their number of MS factors: the control group (0), Pre-MS Group (1-2), and MS group (3-5). The occurrence of HF was defined by the ICD-10 coding system after considering medication history and admission to a tertiary hospital. The incidence of HF was presented as the rate per 100,000 person-years, and the risk of HF with respect to MS was analyzed through Cox proportional hazard regression analysis. Confounding variables were gender, age, health behavior (e.g., smoking and exercise), family history (e.g., stroke, hypertension, heart disease, and diabetes), body mass index, and blood creatinine and hemoglobin values. The results are presented as hazard ratio (HR) and 95% confidence interval (95% CI).
Results : A total of 1,251,138 (15.9%) of the 7,830,602 subjects were assessed as having MS. Of the total 57 million person-years, the incidence rate per 100,000 person-years was 27.7 for HF. The incidence of HF increased significantly in both men and women over the age of 40 with respect to the stage of MS. The risk of HF in the Pre-MS and MS groups was 1.661 and 2.456 times higher, respectively, than that in the control group, even after adjustment for all confounding variables.
Conclusion : MS was associated with a higher risk of HF in young and women group in addition to old and men in Korea.

HF incidence according to age and sex

Rate per 100,000 person-years	30's	40's	50's	60's

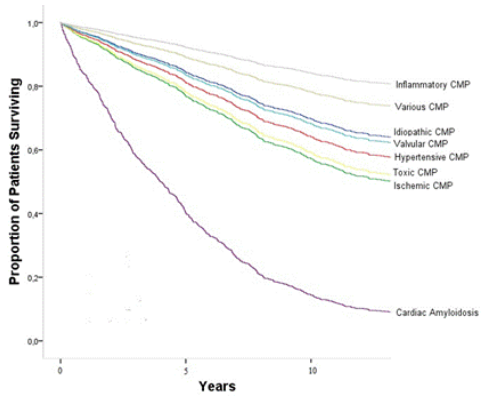
Long-term outcome in cardiomyopathies according to etiology: survival is best in inflammatory CMP and worst in cardiac amyloidosis

P Pliger[1]; F Kocher[2]; S Dobner[3]; C Ensinger[4]; J Doerler[1]; MM Zaruba[1]; G Poelzl[1]

[1]Innsbruck Medical University, Department of Internal Medicine III, Cardiology and Angiology, Innsbruck, Austria; *[2]Innsbruck Medical University, Department of Internal Medicine V, Haematology and Oncology, Innsbruck, Austria*; *[3]Bern University Hospital, Department of Cardiology, Bern, Switzerland*; *[4]Innsbruck Medical University, Institute of Pathology, Innsbruck, Austria*

Introduction: Early studies have shown that etiology of underlying cardiomyopathy (CMP) predicts prognosis in heart failure. However, diagnostic work-up and goal-directed therapy have improved substantially over time. We were interested if advancements in diagnosis and therapy have changed the impact of various etiologies on prognosis.
Methods: In this single-centre registry 2029 consecutive patients treated for heart failure according to prevailing guidelines between 2000 and 2016 were analysed. Underlying CMPs were classified into eight groups: idiopathic (25.9%), ischemic (24%), hypertensive (16.4%), inflammatory (15.0%), various (5.5%), toxic (4.5%), cardiac amyloidosis (4.4%), and valvular (2.9%). Patients were followed for a median of 80 (IQR 34-134) months. Primary endpoint was death of any cause. Kaplan-Meier estimator was used to calculate 5-year survival. A multivariate cox regression analysis was performed to compare survival between groups.
Results: Five year overall survival in the whole cohort was 81.9% (inflammatory 91.9%, various 90.4%, idiopathic 85.3%, hypertensive 81.1%, valvular 80.8%, toxic 77.7%, ischemic 76.3%, cardiac amyloidosis 48.4%). In multivariate analysis

adjusted for age, gender, LV-EF, and NYHA class, individuals with cardiac amyloidosis were 6.5 time (95% CI 3.0-14.0; p < 0.01) more likely to die of any reason than were individuals with inflammatory CMP. In this model, mortality was also higher in ischemic (HR 3.0, 95% CI 1.8-5.2; p < 0.01), valvular (HR 2.5, 95% CI 1.2- 5.4; p = 0.02) and toxic CMP (HR 2.4; 95% CI 1.3 - 4.4; p < 0.01).
Conclusion: Comparing long-term outcome according to CMP etiology survival is worst in patients with cardiac amyloidosis and best in patients with inflammatory CMP. From this perspective, thorough etiologic evaluation and targeted therapy is mandatory in the management of patients with heart failure.



Overall surivival according to etiology

P1694
Prevalence of bendopnea in elderly patients with heart failure

VN Larina[1]; Il Chukaeva[1]; DG Karpenko[1]; OM Kulbachinskaya[1]
[1]The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation

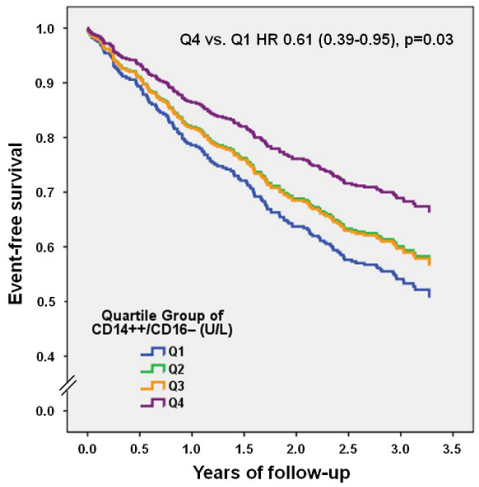
Recently, a symptom of heart failure (HF) called bendopnea or flexodyspnea was described by J. Thibodeau. We conducted the present study to evaluate the prevalence and characteristic of bendopnea in elderly ambulatory patients with heart failure. There was a a single-center prospective observational study of a convenience sample of 80 outpatients aged 60-89 years with HF, which was reviewed by the institutional review board. All patients had clinical examination, laboratory collection, ECG and echocardiography examination during the outpatient clinic visit. All patients were under optimal HF therapy. HF duration was 24 (12-48) months. To determine the presence of bendopnea, each subject sat in a chair and bent forward at the waist as if putting on their shoes or socks. The subject was classified as having bendopnea if they reported shortness of breath within 30 seconds of bending. If there was no shortness of breath at 30 seconds, the patient was classified as not having bendopnea.
Results: The prevalence of bendopnea in ambulatory elderly patients with heart failure is 39% and it increases to 90% in those with LVEF <45%. 31 (38,8%) patients (7F/24?, ? <0,001), aged 73,2 ± 6,7 years, had bendopnea. All patients had advanced NYHA functional class and 14 (45,2%) - orthopnea. In addition, bendopnea had 90% patients with LVEF <45% and 21,6% - with LVEF = 45% (? <0,001). The relationship of bendopnea with male gender (? <0,001, ?R 11,8, 95% CI 4,04 - 34,8), symptoms of advanced HF (? <0,001, ?R 1,78, 95% CI 1,29-2,38), ischemic heart disease (? = 0,002, ?R 26,6, 95% CI 3,3-21,3), LV aneurysm (? = 0,002, OR 13,3, 95% CI 2,7-65,9), LV EDDi (? = 0,008, ?R 4,9, 95% CI 1,5-15,9), LV ESDi (? = 0,004, ?R 8,2, 95% CI 1,9-34,1), left atrium (? = 0,008, ?R 4,3, 95% CI 1,4-12,5), LV EDV (? = 0,012, ?R 1,12, 95% CI 1,03-1,2), LV ESV (? = 0,010, ?R 1,32, 95% CI 1,07-1,64), systolic pulmonary pressure (? = 0,002, ?R 1,26, 95% CI 1,03-1,45), serum NT-proBNP (? = 0,055, ?R 1,0, 95% CI 1,0-1,002), creatinine (? = 0,001, ?R 1,04, 95% CI 1,02-1,07) or uric acid (? = 0,004, ?R 1,006, 95% CI 1,002 - 1,011) was confirmed. In addition, patients with bendopnea had a greater rate of all hospitalizations (? = 0,003, ?R 7,61, 95% CI 2,04-28,4) and cardiovascular hospitalizations (? = 0,003, ?R 1,4, 95% CI 1,09-1,80). Conclusion. The prevalence of bendopnea in ambulatory elderly patients with heart failure is 39% and it increases to 90% in those with LVEF <45%. Our findings indicate that this symptom of heart failure may have a great interest in ambulatory clinical practice, indicating a group of patients with worse course of disease and hospitalization risk.

P1695
Prognostic value of monocyte subsets in patients with heart failure

E Elchinova[1]; J Lupon[2]; MA Fernandez-Sanmartin[2]; M De Antonio[2]; I Teubel[2]; M Domingo[2]; S Roura[2]; P Moliner[2]; E Zamora[2]; B Gonzalez[2]; C Rivas[2]; V Diaz[2]; J Santesmases[2]; MI Troya[2]; A Bayes-Genis[2]
[1]Inselspital, Berm, Switzerland; [2]Germans Trias i Pujol University Hospital, Badalona, Spain

Background: Circulating monocytes can be distinguished by flow cytometry. Three distinct human monocyte subsets are identified. The distribution and role of these monocyte subsets in heart failure (HF) is not established.

	Total N = 404	Alive N = 295	Dead N = 109	p-value
Percentage				
CD14++/CD16-	50.0 ± 17.2	50.4 ± 16.5	48.6 ± 19.0	0.36
CD14++/CD16+	42.0 ± 17.2	41.1 ± 16.6	44.3 ± 18.7	0.10
CD14-/CD16+	8.1 ± 4.2	8.5 ± 4.2	7.1 ± 4.1	0.003
U/mL				
CD14++/CD16-	890 ± 437	916 ± 423	820 ± 468	0.05
CD14++/CD16+	732 ± 368	736 ± 362	721 ± 383	0.73
CD14-/CD16+	146 ± 89	155 ± 90	119 ± 81	<0.001



Purpose: To evaluate the prognostic role of monocyte subsets in HF outpatients.
Methods: Monocyte subsets were classified as CD14+/CD16– (classical), CD14++/CD16+ (intermediate), and non-classical CD14–/CD16+ (also described as CD14+/CD16++). We assessed the percentage of each monocyte subset and also we determined quantitatively the absolute cell count of each subset, expressed by units/mLitter (U/mL).
Results: Four-hundred four patients were consecutively included (73% male, age 69.5 ± 12.2 years, LVEF 41.6% ± 14.5). During a mean follow-up of 2.6 ± 0.9 years, 109 patients died, 101 had a HF hospitalization and 162 suffered the composite end-point of all-cause death or HF hospitalization. Table 1 shows percentage and U/mL of monocyte subsets in alive and dead patients at the end of the study. In multivariable analysis percentage of monocyte subsets did not remain related to any of the end-points. In contrast, when U/mL were considered, non-classical subset remained associated with all-cause death (p = 0.03) and classical subset whit HF-related hospitalization (p = 0.04) and the composite end-point (p = 0.01). Figure 1 shows free-event survival curves for quartiles (U/mL) of classical monocyte subset.
Conclusions: The quantitative determination of the absolute cell count of each monocyte subset was superior from the prognostic viewpoint than the percentage of these monocyte subsets in HF outpatients. Classical subset was independently associated with HF-related hospitalization and the composite end-point and non-classical subset with all-cause mortality.

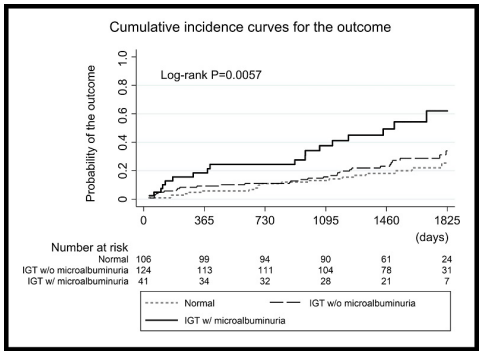
P1696

Association between impaired glucose tolerance and prognosis according to presence of microalbuminuria in patients with chronic heart failure

K Kotaro Nochioka[1]; YS Sakata[1]; RA Abe[1]; TO Oikawa[1]; SK Kasahara[1]; MS Sato[1]; HA Aoyanagi[1]; MM Miura[1]; TS Shiroto[1]; JT Takahashi[1]; MS Miyata[2]; HS Shimokawa[1]
[1]Tohoku University Graduate School of Medicine, Department of Cardiovascular Medicine, Sendai, Japan; *[2]Tohoku University Graduate School of Medicine, Departments of Evidence-based Cardiovascular Medicine, Sendai, Japan*

On behalf of: The SUPPORT Trial Investigators
Funding Acknowledgements: The Ministry of Health, Labour, and Welfare and from the Ministry of Education, Culture, Sports

Background: Previous studies have shown that diabetes mellitus (DM) is a strong predictor in patients with chronic heart failure (CHF), especially when complicated with microalbuminuria. However, it is unclear whether the association of impaired glucose tolerance (IGT), a prediabetic status and microalbuminuria also has a prognostic impact in CHF patients.
Purpose: To examine the prognostic impact of the association of IGT and microalbuminuria in CHF patients.
Methods: We studied 554 CHF patients (mean 66 yrs., women 25%, HbA1c 6.4%) from the control arm of our intervention trial, the SUPPORT (SUPPlemental benefit of an angiotensin receptor blocker in hypertensive patients with stable heart failure using OlmesaRTan), which examined whether an additive treatment with an ARB (olmesartan) reduces the mortality and morbidity in CHF patients with history of hypertension. In patients without known DM (n = 280), we performed 75g oral glucose tolerance test (OGTT). Microalbuminuria was defined as a spot urine albumin = 30 mg/L. We examined the prognostic impact of the association of IGT and microalbuminuria on the composite endpoint of all-cause death, myocardial infarction, stroke, and HF hospitalization for 5 years.



FIgure

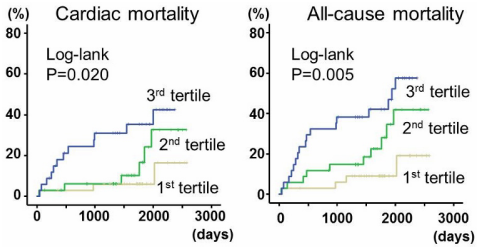
Results: We identified 158 (57.7%) normal glucose tolerance (NGT; 64 yrs., women 27%) and 113 (41.2%) IGT (mean 67 yrs., women 30%) patients, after excluding 3 newly diagnosed DM (mean 70 yrs., all men). As compared with NGT patients, IGT patients had comparable prevalence of microalbuminuria (IGT, 36% vs. NGT, 33%, P = 0.56), estimated glomerular filtration rate (75.9 ± 33.7 vs. 79.1 ± 39.2 mL/min/1.73 m^2, P = 0.48), and the use of angiotensin converting enzyme inhibitors (85 vs. 80%, P = 0.27). After adjustment for age, sex, systolic blood pressure, heart rate, body-mass index, ischemic etiology, NYHA functional class, history of HF hospitalization, left ventricular ejection fraction, and B-type natriuretic peptide levels, the multivariable Cox hazard models showed that IGT itself was not associated with increased risk of the composite endpoint (hazard ratio (HR) 1.03, 95% confidence interval (CI) 0.63-1.68, P = 0.90). However, when stratified by the presence of microalbuminuria, IGT was a risk in the presence of (HR 2.20, 95%CI 1.13-4.28, P = 0.02), but not in the absence of microalbuminuria (HR 0.77, 95%CI 0.37-1.54, P = 0.21) (P for interaction = 0.045). (Figure)
Conclusions: These results indicate that although IGT itself is not a risk factor in CHF patients, it is associated with poor prognosis when complicated by microalbuminuria. Thus, combined assessment of OGTT and urinalysis may be useful for risk stratification for CHF patients.

P1697

Urinary N-terminal fragment of titin to predict mortality in dilated cardiomyopathy

Y Yasuchika Takeishi[1]; A Yoshihisa[1]
[1]Fukushima Medical University, Fukushima, Japan

Titin is associated with myocardial stiffness and hypertrophy, and mutations in its gene have been identified in cardiac myopathies such as dilated cardiomyopathy (DC). It has recently been reported that in damaged muscle, the N-terminal fragment of titin (Titin-N) is cleaved by calpain-3, and urinary Titin-N could be a marker of sarcomere damage. We aimed to investigate the impact of urinary Titin-N on prognosis of DC. We measured urinary levels of Titin-N/creatinine ratio (U-TN/Cr; pmol/mg/dl) in 102 DC patients, and followed up all the patients (mean 1,167 days). The patients were divided into three groups based on the U-TN/Cr: 1st (U-TN/Cr < 3.35, n = 34), 2nd (3.35 = U-TN/Cr < 7.26, n = 34) and 3rd (7.26 = U-TN/Cr, n = 34) tertiles. In the Kaplan-Meier analysis, cardiac and all-cause mortality progressively increased from the 1st to 2nd and 3rd groups (P < 0.05, respectively). In the Cox proportional hazard analyses, U-TN/Cr was a predictor of cardiac and all-cause mortality in DC patients (P < 0.05, respectively). Urinary Titin-N, a novel marker of sarcomere damage, can identify high risk DC patients.



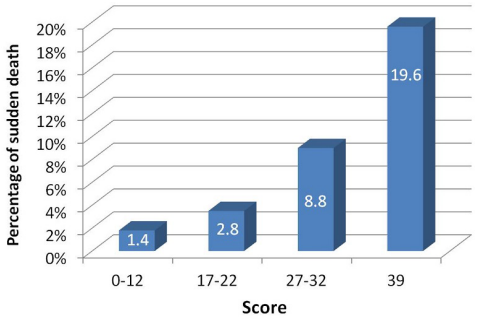
P1698

Sudden death prediction in outpatients with heart failure

P Moliner[1]; J Josep Lupon[1]; G Cediel[1]; M De Antonio[1]; M Domingo[1]; J Nunez[2]; E Zamora[1]; E Santiago[1]; B Gonzalez[1]; C Rivas[1]; V Diaz[1]; J Santesmases[1]; C Diez-Quevedo[1]; M Boldo[1]; A Bayes-Genis[1]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain; *[2]University Hospital Clinic of Valencia, Valencia, Spain*

Background: Although prevalence of sudden death (SD) has declined during last decade in patients with chronic heart failure (HF) its prediction remains a difficult challenge, not only for the diversity of parameters possibly associated with it and the difficulty of selecting the most influent but also the need of threshing from other causes of death, currently more frequent in HF patients.
Purpose: To assess the prevalence of SD at 5 years in a real-life cohort of patients managed according to international guidelines and closely followed and to find a simple prognostic predictive model of SD.
Methods: Competing risk strategy using the Gray method was adopted in Cox regressions analyses, considering non-cardiovascular and other cardiovascular causes of death as the competing event. Statistics-C were also calculated taking into account competitive risk and time-to-event outcome. SD was considered any unexpected death, witnessed or not, occurring in a previously stable patient with no evidence of worsening HF or any other cause of death. Ambulatory patients treated at a multidisciplinary HF unit were consecutively included in the study in an outpatient setting from May 2006 to July 2010. All patients have been followed until death or completion of 5 years of follow-up.
Results: After excluding 27 patients who died from unknown causes 837 consecutive outpatients (72% men, mean age 67.9 ± 12.2 years, LVEF 36% ± 14, 65.6% NYHA class II and 25.9% class III) were included. During follow-up 336 deaths occurred; causes of death were: HF 100 patients, sudden death 43, AMI 18, stroke 10, cardiovascular procedure 8, other cardiovascular 25 and non-cardiovascular 132. Variables associated with SD in univariate analyses were age (p = 0.04), hemoglobin (p = 0.02), eGFR (p = 0.001), HF duration (p = 0.02), hs-TnT (p < 0.001), NTproBNP (p = 0.004) and ST2 (p = 0.001). In a multivariable analysis (backward stepwise) that included all these variables and also other considered clinically relevant such as sex (p = 0.16), NYHA class (p = 0.06), LVEF < 45% (p = 0.07), ischemic etiology (p = 0.18), beta-blocker treatment (p = 0.28), loop diuretic dose (p = 0.08) and ICD (p = 0.38), only HF duration (p = 0.01), eGFR (p = 0.009), LVEF < 45% (p = 0.04) and ST2 (p = 0.005) remained in the model. The obtained model achieved an AUC of 0.75 (0.68-0.82) for the prediction of 5-year risk of SD. The constructed

score including such variables in a dichotomous manner (ST2 >45), LVEF < 45%, HF duration > 3 years and eGFR < 55) obtained an AUC of 0.76 (0.69-0.83).
Conclusions: In a current HF real-life cohort managed according to a structured HF clinic and international recomendations, SD accounted only for the 12% of all deaths at 5 years, affecting only to the 5.1% of the cohort. Of the 3 studied biomarkers, only ST2 remained indepenently associated with SD. A simple model containing ST2, eGFR, LVEF and HF duration allowed to predict the risk of SD at 5 years with an AUC of 0.76.



P1699

Elevated cystatin C predicts higher mortality in chronic heart failure independently of creatinine clearance based on 24h urine collection

P Lourenco[1]; J Pereira[1]; A Ribeiro[1]; P Marques[1]; S Silva[2]; JP Araujo[3]; P Bettencourt[4]
[1]Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal; [2]Hospital CUF, Department of Internal Medicine, Porto, Portugal; [3]Sao Joao Hospital, Department of Internal Medicine - University of Porto Medical School, Porto, Portugal; [4]Hospital CUF, Department of Internal Medicine - University of Porto Medical School, Porto, Portugal

Funding Acknowledgements: Project DOCnet (NORTE-01-0145-FEDER-000003), supported by NORTE 2020, under the PORTUGAL 2020 Partnership Agreement, through the ERDF

Background: Cystatin C is a biomarker mainly used to assess kidney function. It can be also used as a prognostic marker in cardiovascular diseases. Its role in acute heart failure (HF) has been widely documented. The prognostic value of cystatin C in chronic HF is less well established with some, but not all, reports suggesting added value beyond estimated glomerular filtration rate.
Purpose: We aimed to assess the prognostic value of Cystatin C in a cohort of real-world chronic stable HF patients taking into consideration the creatinine clearance based on 24h urine.
Methods: We prospectively recruited HF patients followed in a HF clinic. To be eligible patients had to have HF diagnosed for at least 6 months and be under optimized and stable evidence-based therapy. Only patients with ejection fraction < 40% were included in the analysis. Patients were excluded if they were on renal replacement therapy and if they had hospitalizations or therapeutic adjustments in the previous 2 months. Patients' comorbidities and medications in use were recorded; a venous blood sample and 24h urine were collected in all patients. Follow-up was 5 years and all-cause mortality was the outcome under analysis. Cystatin C was measured and creatinine clearance was calculated using (Urinary creatinine x Urinary volume)/(Serum creatinine x 1440). A receiver-operating characteristic curve was used to assess the association of Cystatin C with 5-year mortality. The area under the curve (AUC) was calculated and the best cut-off for death prediction chosen. The prognostic role of cystatin C was determined using a Cox-regression analysis. Multivariate model was built including creatinine clearance based on 24h urine collection.
Results: We studied 215 chronic stable HF patients with ejection fraction < 40%. Mean age was 68 years and 72.1% were male. Median cystatin C 1.15 (0.89-1.54)mg/dL, creatinine 1.20 (1.00-1.50) mg/dL, and creatinine clearance (24h urine) 63.6 (40.6-98.0) ml/min. During the 5-year follow up 103 (47.9%) patients died. The AUC under the ROC curve for cystatin C in predicting mortality was of 0.77 (0.70-0.83), p < 0.001. The best cut-off value for 5-year death prediction was approximately 1.00mg/dL with a Sensitivity of 83.5%, a specificity of 56.2% a 63.7% positive predictive value and a 78.7% negative predictive value. The multivariate-adjusted (age-, BNP-, beta blocker-, ACEi or ARB-, NYHA class- and creatinine clearance-) HR of 5-year mortality was of 2.46 (95% CI: 1.28-4.73), p = 0.007 for patients with cystatin C = 1.00mg/dL.
CONSLUSIONS: Patients with Cystatin C < 1.00mg/dL have an almost 80% probability of being alive at 5 years. Patients with Cystatin C = 1.00mg/dL have almost 2.5-fold higher death risk independently of BNP and creatinine clearance based on 24h urine collection.

On behalf of: JOURNEY HF-TR Study Investigators

Background: Atrial fibrillation (AF) is common among patients with acute decompensated heart failure (ADHF).
Purpose: The aim of this study was to determine AF prevalence and impact of AF in patients hospitalized due to ADHF.
Methods: The Journey HF-TR study is a cross-sectional, multicenter and observational trial that was conducted in 37 intensive/coronary care units and cardiology. Patient's demographic and clinical characteristics, clinical history, symptoms and signs and their journey in hospital (using diagnostic methods, laboratory findings, medications, length of stay, mortality) were evaluated. The demographic, clinical and prognostic factors were compared between the patients with and without AF.

	HF with AF	HF without AF	P – value
Age (years)	71 ± 12	65 ± 13	<0.001
Female (%)	51	37.4	<0.001
De novo presentation (%)	15.6	21.3	0.007
NYHA class III – IV (%)	83.4	70.1	<0.001
Hypertension (%)	69.9	64.8	0.048
Diabetes mellitus (%)	37.3	44.7	0.002
Ischemic heart disease (%)	49.9	65.9	<0.001
Cerebrovascular disease (%)	16.6	7.3	<0.001
HFpEF (%)	23.2	11.5	<0.001
Pulmonary hypertension (%)	66.2	47.6	<0.001
Heart rate (bpm)	102 ± 26	88 ± 20	<0.001
LVEF (%)	33.9 ± 16.1	32.0 ± 12.6	0.017
NT-proBNP (pg/ml)	7895 ± 1103	8022 ± 2021	0.918
Length of stay for ICU (days)	4	4	0.405
In-hospital mortality (%)	8.9	6.8	0.069

Table

Results: Among 1604 patients (male 57.2%, mean age 67.8 ± 13 years) with ADHF, 39% had atrial fibrillation. Patients with AF were older (71 vs. 65 years, p < 0.001) and the half of them were female (p < 0.001). The de novo clinical presentation was lower in patients with AF (p = 0.007). Patients with AF were more symptomatic and a greater proportion were NYHA III-IV (p < 0.001) than those without. The prevalence of hypertension, cerebrovascular disease, pulmonary hypertension and heart failure with preserved ejection fraction were higher in AF group (p = 0.04, p < 0.001, p < 0.001, p < 0.001 respectively). However, the ischemic heart disease was more common in patients without AF. Heart valve diseases were more prevalent in AF group (p = 0.007 and p < 0.001, respectively). The rate of the patients who have taken digoxin and diuretic was higher in AF group. Compared to those without AF, patients with AF had a higher mean ventricular rate on admission (102 vs. 88 bpm, p < 0.001). The NT-proBNP levels on admission were similar between patients with and without AF.
Conclusion: Atrial fibrillation was frequent in patients hospitalized with ADHF and they were more likely elderly and female. The concomitant diseases were higher in this group and nearly quarter of patients with AF had a preserved ejection fraction. However the length of hospitalization was similar in patients with and without AF, the in-hospital mortality rate was higher in patients with AF.

Concerns about the ESC heart failure guidelines

C Claudia Stoellberger[1]; B Schneider[2]
[1]*Rudolfstiftung Hospital, Department of Internal Medicine II, Vienna, Austria*; [2]*Sana Kliniken, Luebeck, Germany*

Background: In 2011, the Institute of Medicine (IOM) published standards for developing trustworthy clinical practice guidelines (CPGs) recommending that "Whenever possible guideline development group members should not have conflicts of interest (COIs)… Members with COIs should represent not more than a minority of the guideline development group members. The chair or cochair should not be a person with COIs."
Purpose: Aim of the study was to assess if the standards of the IOM have influenced the development of the heart failure guidelines of the European Society of Cardiology (ESC).
Methods: From the ESC homepage, the declarations of COIs of task force members (TFM) and reviewers of the 2012 and 2016 guidelines for the diagnosis and treatment of acute and chronic heart failure were retrieved. The number of COIs was assessed for each version of the guideline.
Results: Of the 2012 guidelines, 24 TFMs (92%) indicated any COI (range 1-36). The mean number of direct personal payments was 6.7 per TFM with COIs. Among the TFMs, the chairperson had the 14th most COIs (8). Among the reviewers 32 (84%) indicated any COI (range 1-29). The mean number of direct personal payments was 5.2 per reviewer with COI.
Of the 2016 guidelines, 19 TFMs (90%) indicated any COI (range 1-35). The mean number of direct personal payments was 9.3 per TFM with COI. Among the TFMs, the chairperson had the second most COIs (33) and the co-chairperson the fourth most COIs (21). Among the reviewers 67 (77%) indicated any COI (range 1-31). The mean number of direct personal payments was 5.4 per reviewer with COI.
Conclusion: Despite the recommendations from the IOM, the COIs among TFM and reviewers for heart failure guidelines, especially personal payments, have increased from 2012 to 2016. Additionally, there was an increase in COIs among the chairs and cochairs from 2012 to 2016. Since we are interested in CPGs in whom we can trust, we suggest that the ESC follows the standards of the IOM when developing guidelines including the choice for appropriate experts for the task force and as reviewers.

P1702

The economic burden of heart failure: findings from a systematic literature review

CL Freeman[1]; L Giles[1]; P Field[1]; G Osei-Assibey[2]; E Sorstadius[3]; B Kartman[3]
[1]*PharmaGenesis Oxford Central, Oxford, United Kingdom*; [2]*Oxford PharmaGenesis, Oxford, United Kingdom*; [3]*AstraZeneca Gothenburg, Mölndal, Sweden*

Funding Acknowledgements: Systematic review and medical writing support were provided by PharmaGenesis Oxford Central, Oxford, UK, and funded by AstraZeneca.

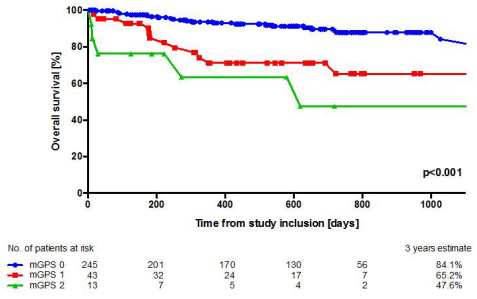
Background: Heart failure (HF) represents a growing economic burden owing to various factors, including the ageing population worldwide and the rising prevalence of cardiovascular disease, diabetes mellitus (DM) and obesity.
Purpose: To assess the impact of HF with preserved, mid-range or reduced ejection fraction on costs and resource use, using findings from a systematic literature review (SLR).
Methods: Electronic databases (Embase, MEDLINE and the Cochrane Library) were searched in May 2017 for observational studies published between 2012 and 2017 reporting costs in 100 patients or more.
Results: In total, 70 papers were identified (Europe: 15; North America: 49; rest of the world/multinational: 6). The total annual costs associated with HF varied widely across studies and geographies owing to differences in study settings and patient populations (n = 208-88 195). In Germany, Spain, and Sweden the annual cost of HF per patient was estimated at 3150 EUR, 6571 EUR and 5700 EUR, respectively. In two Italian studies this cost was 11 864 EUR and 11 100 EUR, respectively. In other countries the annual cost of HF per patient was estimated at 27 809 CAD (Canada) and 28 974 RMB (China), and in the range of 13 897-36 426 USD (USA). Hospitalization and inpatient care were identified as cost drivers in HF, accounting for 48-90% of overall spending in multiple studies. Several US studies, but none in any other region, compared costs for patients with HF with those incurred by individuals without HF, and the results indicated that HF is associated with significant additional expenditure. One of these studies reported that overall total costs were more than four times higher for individuals with HF than for those without HF. A US study compared annual healthcare costs for individuals with HF and those with DM and found that HF was associated with a comparatively higher cost. Another US study reported costs associated with various chronic conditions, and showed that annual costs were higher for HF than for asthma, coronary artery disease, chronic obstructive pulmonary disease, DM, hyperlipidaemia, and hypertension. There was a very limited evidence base for costs of HF relative to disease severity. Only one study, conducted in Japan, reported costs for patients with HF of different NYHA classes; hospitalization costs increased significantly for patients with HF at NYHA class III or IV compared with those at class II.
Conclusions: The evidence identified in this SLR indicates that patients with HF incur considerable health care costs. Inpatient care and hospitalization are key cost drivers in HF, contributing up to 90% of total costs in some studies. Furthermore, HF is associated with higher costs compared with both individuals without HF and those with other chronic diseases. Limited evidence indicates that hospitalization costs are likely to be higher in patients with more severe HF than in those at earlier disease stages.

P1703

The inflammation based prognostic score mGPS predicts survival in stable heart failure patients.

A Anna Cho[1]; N Pavo[1]; H Arfsten[1]; G Goliasch[1]; PE Bartko[1]; R Wurm[1]; G Strunk[1]; M Huelsmann[1]
[1]*Medical University of Vienna, Vienna, Austria*

Background: The progression of heart failure is presumed to be linked to inflammatory host response. The combination of the inflammatory markers albumin and C-reactive protein (CRP), termed modified Glasgow Prognostic Score (mGPS), has been derived from cancer patients and validated in multiple cohorts. This study aimed to investigate the impact of the easily available mGPS on survival of stable patients with heart failure with reduced ejection fraction (HFrEF).
Methods: HFrEF patients under routine ambulatory care at the heart failure unit of the Medical University of Vienna between January 2011 and November 2017 were retrospectively identified. Comorbidities and laboratory data at baseline were assessed. All-cause mortality was defined as the primary study endpoint. The mGPS score and its impact on overall survival were determined.
Results: Data was complete and analyzed for a total of 301 patients. The mGPS score was 0 for 245 (81%), 1 for 43 (14%) and 2 for 13 (4%) patients, respectively. The three groups showed significant differences in other routine laboratory parameters associated with survival, especially NT-proBNP [1895pg/ml (IQR 834-3462) vs. 3852pg/ml (IQR 2312-7232) vs. 9935pg/ml (IQR 4082-19821) for mGPS score 0, 1 and 2 respectively; $p < 0.001$]. In the Cox regression analysis, increasing mGPS was associated with adverse outcome in the univariate analysis [crude HR 2.43 (95%CI 1.60-3.69), $p < 0.001$] and after adjustment for age and NT-proBNP [adj. HR 1.79 (95%CI 1.02-3.12), $p = 0.042$]. Kaplan-Meier analysis confirmed the high discriminatory power of the mGPS score ($p < 0.001$) (Figure1).
Conclusions: The inflammation based score mGPS predicts survival in HFrEF patients. The association underlines the age independent impact of the inflammatory response in heart failure. Inflammatory response appears to be most relevant in patients with advanced heart failure.



P1704

Left ventricular ejection fraction and prognosis in chronic heart failure

A Alberto Aimo[1]; JL Januzzi[2]; G Vergaro[3]; V Siciliano[4]; S Molinaro[4]; C Passino[1]; M Emdin[1]
[1]*Sant'Anna School of Advanced Studies, Pisa, Italy*; [2]*Massachusetts General Hospital, Boston, United States of America*; [3]*Gabriele Monasterio Foundation, Pisa, Italy*; [4]*Institute of Clinical Physiology, CNR, Pisa, Italy*

Background: The recent introduction of a new heart failure (HF) category defined by a left ventricular ejection fraction (LVEF) interval (40-49%) has attracted great criticism, and led to a reappraisal of the meaning of LVEF in HF. The prognostic value

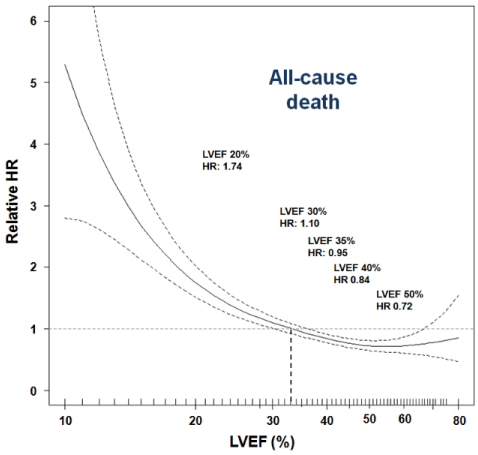
of LVEF and LVEF-based patient categorization has been basically overlooked in this debate.

Methods: Data from patients with stable chronic HF assessed at a tertiary referral center from 1999 to 2017 were analyzed. Baseline characterization and follow-up were considered. The endpoints were all-cause and cardiovascular death.

Results: 2583 patients were evaluated (69 ± 12 years, 70% men, LVEF < 50% in 84% of patients). Over 3.2 years (interquartile interval 1.3-6.7), all-cause death occurred in 872 patients (34%), and cardiovascular death in 513 (20%). Patients with LVEF < 50% had shorter survival than those with = 50% (all-cause death: log-rank 17.9, p < 0.001; cardiovascular death: log-rank 42.1, p < 0.001), because of patients with LVEF < 40% (n = 1539).

In the LVEF < 50% subgroup, LVEF retained an independent association with both all-cause and cardiovascular death. The 35% cut-off displayed a more balanced combination of sensitivity and specificity than the 40% cut-off. At spline curve analysis, considering the whole LVEF spectrum, the risk of death increased slowly with decreasing LVEF until 35%, which was very close to the inflection points of the curves (33% for all-cause death, and between 35 and 36% for cardiovascular death). Patients with very severe depression of systolic function (LVEF < 20%) had a particularly high risk for all-cause and cardiovascular death, though representing only a small minority of patients (n = 122, 5%). This accounted for the prognostic relevance of higher LVEF cut-offs, including 40%.

Conclusions: Patients with chronic HF and LVEF = 50% have worse prognosis than those with LVEF < 50%, although the risk increases gradually until LVEF values around 35%. In systolic HF, defined as LVEF < 50%, LVEF is an independent predictor of all-cause and cardiovascular mortality. The 40% LVEF cut-off has independent prognostic significance, which is driven mostly by patients with severely depressed systolic function. For this reason, lower LVEF cut-offs, such as 35%, display a better combination of sensitivity and specificity than 40% for risk stratification.



P1705

Long-term clinical impact of permanent pacemaker after Transcatheter Aortic Valve Replacement

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; A Ruiz-Salas[1]; A Barrera-Cordero[1]; JM Garcia-Pinilla[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; E De Teresa-Galvan[1]
[1]*University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

Very few data exist on the clinical impact of permanent pacemaker implantation (PPI) after Transcatheter Aortic Valve Replacement (TAVR) at the long-term follow-up. The aim of this study was to assess the impact of PPI after TAVR on late outcomes in a large cohort of patients in terms of all-cause mortality and morbidity.

Methods and Results: A total of 561 consecutive patients without prior PPI undergoing transcatheter aortic valve replacement were included. Of them, 145 patients (25.8%) required a PPI within the first 30 days after TAVR, median time 2 days (1.9-2.4 days) and 16 patients required a PPI in the follow-up. At a mean follow-up of 37 ± 25 months, there was a tend more mortality in patients with PPI (42.1% vs. 34.4% p= 0.061), but no association was observed between the need for PPI and all-cause mortality (hazard ratio, 1.385; 95% confidence interval, 0.940-2.041; P = 0.100), cardiovascular mortality (hazard ratio, 1.122; 95% confidence interval, 0.466-2.699; P = 0.797), and it was associated with more rehospitalisation for heart failure (hazard ratio, 2.352; 95% confidence interval, 1.172-4.718; P = 0.016).

There were 8 cases of unexpected (sudden or unknown) death and was observed in 7 patients without PPI. Patients with new PPI showed a poorer evolution of left ventricular ejection fraction over time. Mean left ventricular ejection fraction increased from 59.6 ± 14 % to 62.7 ± 11% after TAVI and decreased to 60.9 ± 10% at 1 years and 59.7 ± 6 at 4 years (p for post-TAVI trend 0.04).

Conclusions: The need for PPI was a frequent complication of TAVR and it was associated with increased admission for heart failure, A new PPI did have a little negative effect on left ventricular function over time. However, but not associated with any increase in overall or cardiovascular death, a mean follow-up of 3.06 years.

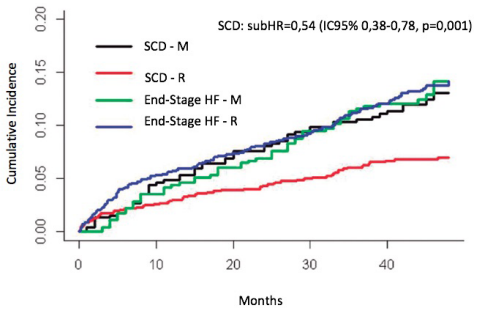
On behalf of: MUSIC and REDINSCOR I research groups

Introduction: Optimal medical therapy (OMT) and the use of implantable cardioverter-defibrillator (ICD) had improved global survival of patients with heart failure (HF) with reduced ejection fraction. Nevertheless, there are few data available regarding the evolution of mortality before and after the implementation of these therapies. MUSIC register (2004-2004) studied HF outpatients before widespread use of ICD as prevention of sudden cardiac death (SCD) and OMT. On the other hand, REDINSCOR register (2007-2011) has a OMT and ICD rate similar to nowadays.

Purpose: To describe variations in cumulative incidence of death and its causes related to implementation of ICD therapy and medical treatment.

METHODS. Retrospective study of clinical, analytical and imaging variables of 2307 patients with < 45% ejection fraction (EF) and NYHA Class II/III taken out of the MUSIC and REDINSCOR registers. Mortality and way of death analysis by using cumulative incidence curves.



Cumulative incidence function for EF < 35%

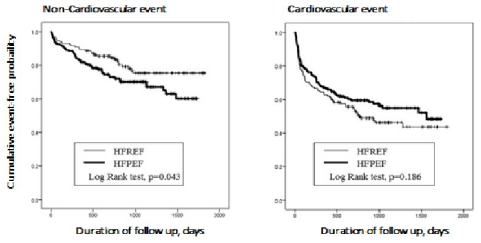
Results: There were no significant differences between both cohorts in age (64 ± 11 vs. 64 ± 12 years, p = NS), male gender (77% vs. 77%, p = NS), previous myocardial infraction (47% vs 43%; p = NS), atrial fibrillation (17% vs 18%; p = NS) or dilated cardiomyopathy (26% vs 24%; p = NS). However, patients from REDINSCOR register had a significant higher prevalence in hypertension (52% vs 63%; p < 0.001), diabetes (36% vs 42%; p = 0.012), mitral regurgitation III-IV (13% vs 20%; p < 0.001), higher levels of N-terminal pro-B type natriuretic peptide (median 921 vs. 1809 pg/mL; p < 0.001) as well as worse functional status (NYHA III) (23% vs 48%; p < 0.001). In spite of, patients from REDINSCOR register had a significant higher rate of ICD (1.6% vs 20.2%; p < 0.001) and use of angiotensin-converting enzyme inhibitors or angiotensin receptor blockers (90% vs 100%; p < 0.001), beta-blockers (71% vs 86%; p < 0.001) and mineralocorticoid receptor antagonists (43% vs 63%; p < 0.001). After 48 months follow-up, there were no significant differences in total mortality (28% vs 27 %; p = NS). We analyzed mortality causes and found a significant decrease in sudden cardiac death (SCD) in REDINSCOR cohort (10.6% vs 6.3%; p < 0.001), without significant differences in end-stage heart failure death (10.1% vs 11.5%; p = NS). Cumulative incidence curves showed a decrease in SCD

for REDINSCOR group without differences in end-stage heart failure death. In the sub-group analysis, patients with < 35% EF show a significant decrease in SCD (13.1 vs 7.0%; p < 0.001) without changes in end-stage heart failure death (14.1 vs 14.2%; p = 0.79) (Fig. 1). Besides, we found similar results in the sub-group analysis by NYHA Class.
CONCLUSIONS: Optimal medical therapy and ICD had shown a decrease in sudden cardiac death in patients with heart failure with reduced ejection fraction, while not having implication in avoiding disease progression.

P1707
Difference in pattern of mortality between heart failure with reduced ejection fraction and heart failure with preserved ejection fraction after hospitalization for acute decompensated heart failure

M Mitsutaka Nakashima[1]; S Sakuragi[1]
[1]*Iwakuni Clinical Center, Cardiology, Iwakuni, Japan*

Background/Introduction : Prevalence of heart failure (HF) is increasing rapidly in the community. HF with preserved ejection fraction (HFpEF) currently represents almost one-half of all HF patients. It is still unknown whether long term prognosis is different between HFpEF and heart failure with reduced ejection fraction (HFrEF).
Purpose: In this study, we investigated the difference in clinical features and pattern of mortality between HFpEF and HFrEF.
Methods: Two hundred and ninety-seven patients with acute decompensated HF were enrolled (158 males, 76 years). Patients were classified into two groups according to LVEF: HFrEF (LVEF <50%, n = 165) and HFpEF (LVEF ?50%, n = 132). We followed cardiovascular event, such as cardiovascular death, coronary artery disease, heart failure and stroke and non-cardiovascular event. Clinical outcomes were compared between the two groups.
Results: HEpEF had higher age, higher proportion of female. Prevalence of non-cardiac comorbidities, such as anemia and pulmonary dysfunction, were significantly higher in HEpEF. With regards to long term mortality, the incidence of non-cardiovascular events was significantly higher in HFpEF group (p = 0.043), whereas incidence of all cardiovascular event (p = 0.186) as well as heart failure admission (p = 0.234) were comparable between the two group. In Cox regression analysis, HFpEF was associated with higher incidence of non-cardiovascular event compared with HFrEF after adjustment for confounding factors, including age, gender, and cardiovascular risk factors (HR 1.648, 95%CI 1.009, 2.691, p = 0.046).
Conclusion(s): HFpEF tend to be associated with non-cardiovascular event more than HFrEF.



long term events

Disparate risk for heart failure in immigrants compared to residents Results from the STAAB cohort study

C Morbach[1]; G Gelbrich[2]; T Tiffe[2]; F Eichner[2]; M Breunig[1]; M Wagner[2]; PU Heuschmann[2]; S Stoerk[1]
[1]*University Hospital Wuerzburg, Comprehensive Heart Failure Center and Dept. of Medicine I, Wuerzburg, Germany*; [2]*University of Wuerzburg, Institute of Clinical Epidemiology and Biometry and Comprehensive Heart Failure Center, Wuerzburg, Germany*

Funding Acknowledgements: German Ministry of Education and Research (BMBF 01EO1004 and 01EO1504)

Introduction: About 20% of the German population are immigrants. Different cultural backgrounds may influence health/health behaviour, and health status can be affected by a migration background.
Purpose: We here compare the profile of risk factors for heart failure (HF) in immigrants against German residents.
Methods: We report data of a planned interim analysis of the prospective Characteristics and Course of Heart Failure Stages A-B and Determinants of Progression (STAAB) cohort study investigating a representative sample of inhabitants of the City of Würzburg, Germany, aged 30 to 79 years, free of self-reported HF. Residents: individuals speaking German as native language, who had no other native language and/or were born in Germany. Immigrants: non-residents. Risk factors for HF were hypertension, obesity, atherosclerotic disease, diabetes mellitus, and metabolic syndrome, defined according to current guidelines. Differences between groups were adjusted for age and sex, and reported as odds ratio (OR) with 95% confidence interval (CI). If p < 0.05, mean effects were displayed separately for subgroups (EU vs Russia vs other countries).
Results: Of 2,473 subjects, 291 (12%) were immigrants, 2,168 (88%) were residents, and 14 did not provide this information. The origin of 107 (37%) immigrants was from an EU country, 117 (40%) from Russia, 67 (23%) from another country. Of both immigrants and residents, 51% were female, but immigrants were younger: mean age 51 ± 11 vs. 55 ± 12 years, p < 0.001. Risk factors of residents and immigrants (table) were similar with respect to hypertension, atherosclerotic disease, and diabetes mellitus, and also smoking and alcohol consumption (data not shown). By contrast, prevalence of obesity and metabolic syndrome was significantly higher in immigrants.
Conclusion: Immigrants exhibited a higher risk factor burden predisposing to accelerated development of HF compared to residents. Differences were predominantly carried by higher frequency of obesity and metabolic syndrome with the least favourable profile apparent in immigrants from Russia. Strategies for primary prevention of HF may benefit from deliberately considering the migration background.

Risk factors for heart failure

Risk factor - n (%)	Residents	Immigrants	OR (95% CI)	EU	Russia	OC
Hypertension	995 (46)	121 (42)	1.2 (0.9-1.5)			
Atherosclerotic disease	149 (7)	19 (7)	1.3 (0.8-2.2)			
Diabetes mellitus	214 (10)	24 (8)	1.1 (0.7-1.7)			
Obesity	413 (19)	70 (24)	1.5 (1.1-2.1)	1.6	2.2*	0.6
Metabolic syndrome	401 (18)	61 (21)	1.5 (1.1-2.0)	1.2	1.7*	1.5

* p = 0.05 compared with residents. EU= European Union, OC= other country

P1709
The prognostic power of cardiopulmonary exercise testing in patients with Chagas heart disease

P Pedro Schwartzmann[1]; HT Moreira[1]; D Mayumi[1]; JC Crescencio[1]; LFL Oliveira[1]; EEV Carvalho[2]; R Arena[3]; A Schmidt[1]; LFL Gallo-Junior[1]; MV Simoes[1]
[1]*Medical School of Ribeirao Preto, University of Sao Paulo, Internal Medicine, Ribeirao Preto, Brazil*; [2]*Uberaba's University, Uberaba, Brazil*; [3]*University of Illinois at Chicago, Physical Therapy, Chicago, United States of America*

Introduction: Cardiopulmonary exercise testing (CPX) has demonstrated a strong prognostic value in patients with ischemic and non-ischemic heart failure (HF). Increased minute ventilation/carbon dioxide production (VE/VCO2) slope, presence of exercise oscillatory ventilation (EOV), and low peak oxygen consumption (VO2) are markers of adverse outcomes in patients with HF. However, the prognostic role of these CPX-derived parameters in patients with Chagas disease is unknown.
Purpose: We aimed to examine the prognostic performance of CPX in a cohort of patients with Chagas heart disease.
Methods: This longitudinal retrospective study included 93 patients with Chagas disease and HF who underwent a symptom-limited CPX. The patients were classified according to VO2: >18, between 10-18 and < 10 mlO2.kg-1.min-1; according to EOV: presence or absence; and according to VE/VCO2 slope < 35 and = 35. The primary outcome was a composite of cardiovascular death or heart transplantation. Survival analysis was performed using Kaplan-Meier curves, log-rank test, and Cox regression analysis. Age, sex and left ventricular ejection fraction (LVEF) were included in the multivariable model. Harrell's C statistics was used to verify discrimination of risk prediction models. P < 0.05 was considered significant.
Results: Mean age was 56 ± 14 years, 51 (55%) were men, with mean LVEF of 43 ± 18. NYHA functional class I, II, III and IV were detected in 39% 29% 29% and 3% of the participants, respectively. Mean VE/VCO2 slope and mean VO2 were 36 ± 11 and 16 ± 6 mlO2.kg-1.min-1, respectively. EOV was present in 11 (12%) patients. During a follow-up of 1.87 ± 1.32 years, 30 events of interest (26 cardiovascular deaths and 4 heart transplants) were recorded. In the univariate analysis, all the CPX-derived parameters studied were predictors of the combined outcome (logrank p < 0.001 for both VO2 and VE/VCO2 slope, and logrank p = 0.030 for EOV), figure 1. In the multivariable analysis, VO2 < 10 mlO2.kg-1.min-1 and presence of EOV were associated with the combined outcome independently

of age, sex and LVEF (Hazard Ratio [HR] = 5.72; 95% confidence interval [95%CI] = 1.17-27.76, p = 0.03, and HR = 3.32, 95%CI = 1.35-8.15, p = 0,009, respectively).

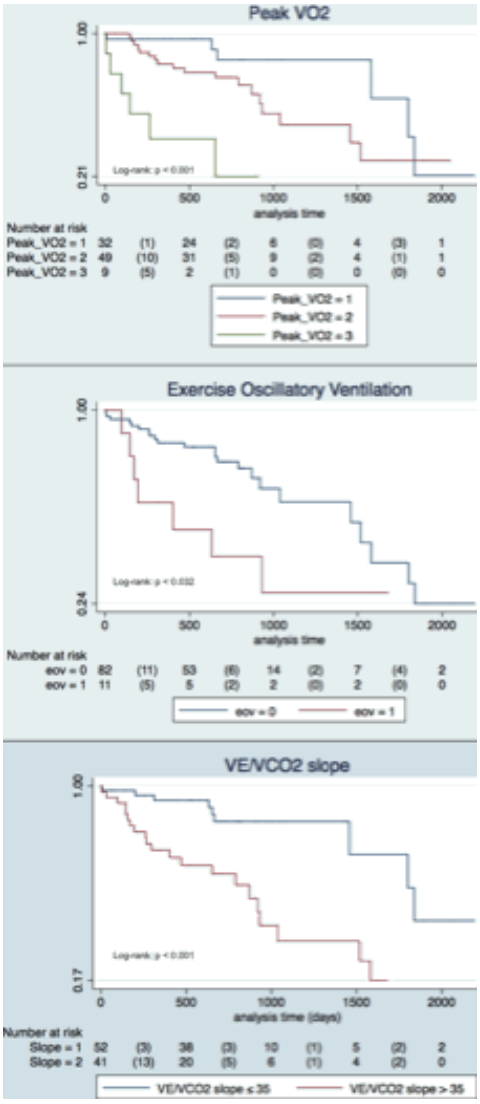

Figure 1

No association of VE/VCO2 slope and the combined outcome in the multivariable analysis was found. Harrell's C statistics of the VO2 adjusted model and of the EOV adjusted model were 0.815 and 0.819, respectively.
Conclusion: In a cohort of patients with Chagas heart disease, CPX demonstrated prognostic power for cardiovascular death and heart transplant. Lower VO2 and the presence of EOV showed prognostic value independently of sex, age or LVEF.

P1710

Clinical value of the Geriatric Nutritional Risk Index in Patients Aged >80 Years With heart failure with preserved ejection fraction

Y Mitsuke[1]; Y Suzuki[1]; N Ootsuki[1]; H Tsutani[1]
[1]NHO Awara Hospital, Fukui, Japan

Background: Malnutrition has been identified as an important predictor of poor clinical outcomes in patients with heart failure with preserved ejection fraction (HFpEF). The clinical significance of nutritional risk assessment in HFpEF patients aged >80 years is less well defined.
Methods: We studied consecutive 122 Japanese HFpEF patients (58 males, older than 80 years of age (84.1 +/- 3.2 years) who were hospitalized with HFpEF at the authors' institution. The impact of nutrition, assessed using Geriatric Nutritional Risk Index (GNRI) on admission was calculated as follows:14.89 × serum albumin (g/dl) + 41.7 × body mass index/22. None had evidence of unstable angina, chronic inflammatory disease, collagen disease, or cancer at the time of evaluation. Patients were followed up for an average of 24.1 months, and 23 of 122 patients had all death.
Results: Patients in the low-GNRI group (GNRI < 92) had higher cystatin C, interleukin-6, and B-type natriuretic peptide (BNP), noradrenalin, and uric acid compared to those in the high-GNRI (GNRI = 92) group (P < 0.05, respectively). By multivariate Cox proportional hazard analysis, GNRI, cystatin C, and IL-6 were significant predictors for all death in those patients.
Conclusions: These findings indicate that GNRI measurement provides additional prognostic information in those elderly patients with HFpEF.

P1711

The prognostic value of B-natriuretic peptide is more evident in first diagnosed Acute Coronary Syndrome patients, with heart failure and preserved ejection fraction, irrespectively of renal function;

C Christina Chrysohoou[1]; H Kosyfa[1]; M Kouvari[2]; G Georgiopoulos[1]; P Aggelopoulos[1]; G Metallinos[1]; C Pitsavos[1]; D Tousoulis[1]
[1]University of Athens, Athens, Greece; [2]Harokopio University, Nutrition Science - Dietetics, Athens, Greece

Background/Introduction: The prognosis stratification in case of heart failure management remains a challenge, despite the undeniable advances performed in the interpretation of the pathophysiology behind this chronic disease. Among the predictors of much interest renal function and B-natriuretic peptide (BNP) are on the short list.
Purpose: the role of glomerular filtration rate (GFR) and BNP on the 10y ACS mortality of coronary patients with heart failure was evaluated.
Methods: from May 2006 to March 2009, 1,000 consecutive patients who were hospitalized at a Cardiologic Clinic in Athens with ACS diagnosis were enrolled in the study. In 2016, the 10y follow-up (2006-2016) was performed in 745 participants. GFR was evaluated through the MDRD formula. Heart failure phenotype was defined according to baseline ejection fraction (EF); heart failure with reduced EF (i.e. <40%) (HFrEF), preserved EF (i.e = 50%) (HFpEF) and mid range EF (i.e. 40-49%) (HFmrEF).
Results: 10y ACS incidence was 55% with fatal events being 21%. Patients who suffered from a new fatal episode within the decade had significantly lower GFR and higher BNP values at baseline, compared with their alive counterparts (all ps <0.001). In multivariate logistic regression analysis, GFR remained an independent predictor for the 10y ACS event, after adjusting for potential confounders (OR = 0.98 95%CI (0.97, 1.00), p = 0.04). Moreover, since BNP levels were strongly associated with both the primary outcome and the GFR (p <0.001 from Spearman's correlation test), BNP was forced included in the multivariable model as a covariate with potential mediating effect. After adjusting for baseline BNP, GFR lost its significance whilst BNP levels (expressed per 2 fold increase) independently predicted ACS mortality (OR = 1.39 95%CI (1.15, 1.67), p = 0.001). What is more significant interactions of BNP with EF and baseline ACS history on the tested outcome were highlighted (p for interaction = 0.002 and p for interaction <0.001, respectively). In analysis with HF phenotype as strata, the aforementioned significant predictive value of BNP retained only in HFmrEF (OR = 1.43 95%CI (1.01, 2.03), p = 0.04) and in HFpEF (OR = 1.80 95%CI (1.15, 2.82), p = 0.01). Additionally, in case of baseline ACS history, subgroup analysis revealed a similar outcome only in first diagnosed ACS patients OR = 1.53 95%CI (1.21, 1.94), p <0.001).
Conclusion: BNP level was highlighted as a significant predictor in long term prognosis of coronary patients with heart failure, namely in case of first diagnosed ACS patients and most importantly, in those subjects with preserved performance of left ventricle.

Implementation of diagnostic strategy for heart failure in frail elderly with reduced exercise tolerance or shortness of breath

F H Frans Hendrik Rutten[1]; Y Van Mourik[1]; LCM Bertens[2]; MJM Cramer[3]; JWJ Lammers[4]; A Gohar[1]; JB Reitsma[1]; KG Moons[1]; AW Hoes[1]
[1]University Medical Center Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands; [2]Erasmus Medical Center, Rotterdam, Netherlands; [3]University Medical Center Utrecht, Cardiology, Utrecht, Netherlands; [4]University Medical Center Utrecht, Pulmonology, Utrecht, Netherlands

On behalf of: Utrecht Heart Failure Organization
Funding Acknowledgements: Research grant from the "Netherlands Organization for Health Research and Development" (ZonMw grant 311040302).

Background: Heart failure often remains undiagnosed in older individuals, while it inhibits functionality and impair health. We wanted to assess the effectiveness of a case-finding strategy.

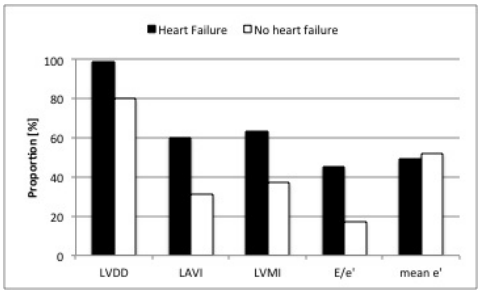
Methods: A cluster randomized trial with general practices randomly allocated to a case-finding strategy or usual care. Frail (pragmatically defined by the number of comorbidities and drugs prescribed) community-dwelling subjects aged 65 years or over with shortness of breath or reduced exercise tolerance were eligible for inclusion. The case-finding strategy consisted of history taking, physical examination, blood tests, electrocardiography, spirometry and echocardiography. Subsequent treatment decisions were at the discretion of the general practitioner. Outcomes: Changes in medication and health care use during the six months follow-up.
Results: In total, 18 general practices were randomized resulting in 829 participants; 389 in the screening strategy group (8 practices) and 440 in the usual care group (10 practices). More patients in the screening group received a new diagnosis of heart failure than the usual care group (cumulative incidence 34% vs. 2%, respectively). After six months of follow-up, the scores for health status, functionality, and health care use were similar between the two strategies.
Conclusion: A screening strategy applied in primary care to frail older people with shortness of breath or reduced exercise tolerance resulted in a number of new diagnoses of heart failure, but did not result in short-term improvement of health status compared to usual care.

P1713

Left ventricular dysfunction and heart failure in general population

M Lainscak[1]; A Zupan Meznar[2]; D Crncic[1]; I Nikolajevic[1]; D Omersa[3]; J Farkas[1]
[1]General Hospital Murska Sobota, Murska Sobota, Slovenia; *[2]General Hospital Celje, Celje, Slovenia*; *[3]General Hospital Jesenice, Jesenice, Slovenia*

Background: Heart failure (HF) prevalence in general population is estimated at 1-2% with about even distribution between reduced and preserved left ventricular systolic function. According to 2016 European Society of Cardiology guidelines, evidence of left ventricular diastolic dysfunction is needed for diagnosis of HF with mid regional or preserved ejection fraction. To best of our knowledge, there are no studies to investigate left ventricular dysfunction and heart failure in general population.



Left ventricular diastolic dysfunction

Purpose: To investigate prevalence and characteristics of left ventricular dysfunction in general population with emphasis on left ventricular diastolic dysfunction.
Methods: The Screening Of adult urBan pOpulation To diAgnose Heart Failure (SOBOTA-HF) study is an ongoing cross sectional epidemiological study in Murska Sobota city residents aged 55 years or more. This interim report presents data for 702 participants of NT-proBNP screening; those with concentration = 125 pg/mL were invited for a detailed diagnostic visit that included echocardiography. HF diagnosis and left ventricular dysfunction were evaluated according to 2016 European Society of Cardiology guidelines.
Results: Overall, 339 participants completed diagnostic visit (age 70 ± 8 years, 35% men, NTproBNP 481 ± 936 pg/mL) and 92 were diagnosed with HF. Left ventricular diastolic dysfunction was detected in 289 participants and prevalence was higher in HF (99% vs 80%). Most HF patients met two criteria (37%), followed by three (34%), single (24%) and all four criteria (4%). More patients with HF also met individual criteria for left ventricular diastolic dysfunction except for mean e' septal and lateral wall (Figure). Presence of left ventricular diastolic dysfunction did not correlate with age, gender or NT-proBNP.
Conclusions: Left ventricular diastolic dysfunction is common in general population aged 55 years or more and is present in almost all patients with HF.

P1714

Clinical PrOfile, ManagemEnt and In-Hospital Outcome of Patients AdmittEd with Acute Heart Failure Syndromes (COME HOPE HF)

N W Neil Wayne Salces[1]; A Junia[1]; E Gallardo[1]; L Noval[1]
[1]Chong Hua Hospital - Heart Institute, Section of Adult Cardiology, Department of Internal Medicine, Cebu City, Philippines

Background: Acute heart failure syndrome usually results in hospitalization and this has become a costly global health care epidemic that carries a high burden of morbidity and mortality. There is no national database on heart failure.
Purpose: This study aims to describe the heart institute's epidemiology of acute heart failure syndromes (AHFS) for a period of one year.
METHODOLOGY: This is a retrospective cross-sectional chart review study design.
Results: A total of 140 patients were identified from the hospital's database with a final diagnosis of heart failure based on the ICD 10 classification. Eighty four (84) patients with acute heart failure syndromes were included in the final analysis. The mean age of patients with AHFS was 66 years (range, 32-91 years old), and over one-half of the population were males (64%). Hypertension was most commonly seen in these patients in 70%. At presentation, 37% were hypertensive (SBP >140 mm Hg) and the mean blood pressure was 139/80 mmHg. Blood urea nitrogen, natriuretic peptides, and troponins were underutilized. Overall, 95% of patients were receiving diuretics, 56% on ACEi or ARB and 49% on beta blockers. Heart failure patients with reduced ejection fraction are seen in majority of cases (58%). There was no significant difference with the in-hospital outcome of patients in both groups in terms of the length of hospital stay and all-cause mortality. Male sex ($p = 0.011$), prior history of heart failure ($p = 0.001$) and the use of RAS inhibitors ($p = 0.034$) and aldosterone antagonists ($p = 0.002$) were associated with HFrEF while female sex ($p = 0.011$) and the use of CCBs ($p = 0.002$) were associated with HFpEF.
Conclusions: In Chong Hua Hospital, acute heart failure syndromes were commonly seen in the elderly males who are hypertensive. They were usually normotensive on clinical presentation. Diuretics, renin-angiotensin system (RAS) inhibitors and beta-blockers were most commonly used during the hospital phase. Majority of heart failure patients had reduced ejection fraction.

P1715

Quality of life and mortality on 1 year follow up in Manipal Heart Failure Registry [MHFR]

A Singh[1]; T Devasia[1]; H Kareem[1]; YR Karkala[2]; S Chauhan[2]; PN Shetty[1]; S Rao[1]
[1]Kasturba Medical College and Hospital, Cardiology, Manipal, India; *[2]Melaka Manipal Medical College, Pharmacology, Manipal, India*

Background/Introduction: Health-related quality of life in heart failure (HF) patients is an imperative indicator of mortality and re-admissions. Treatment policies are targeted to improve the quality of life. There are various parameters to know the physical and psychological condition of the HF patients.
Purpose: To assess the health-related quality of life in HF patients and to study 1-year mortality and re-admissions
Methods: The Manipal Heart Failure Registry (MHFR) study is an observational cohort study. It analyses the health-related quality of life (secondary objective) for recruited patients. The patient's data is collected on admission, discharge and at 1 month, 6 month and 12 month follow up. Mobility, self-care, routine activities, pain and anxiety, were the different parameters analysed to assess the quality of life.
Results: A total of 532 patients were studied. The mean age was 59 years and 61% were male. In-hospital mortality was 9.02% during an average of 5.2 days hospitalization. One month, 6 month and 12-month mortality were 4.9%, 13.2% and 16.9% respectively. HF with preserved ejection fraction (HFpEF), HF with mid-range ejection fraction (HFmid-rangeEF) and HF with reduced ejection fraction (HFrEF) was diagnosed in 17%, 28% and 55% patients respectively.
The incremental changes in quality related parameters after index hospitalization show the therapeutic success. Significant decrement compared to 1 month follow up was seen at 6 month and 12 month follows up. A score of wellness was calculated. There was clinical and statistical significance at admission and discharge. Mean wellness score at index admission, discharge, 1 month, 6 month and 12 month follow-up were 53.5%, 83.2%, 78.8%, 74.3% and 70.1% respectively. Wellness score < 50% at admission was significantly associated with in-hospital and 12-month mortality. Wellness score < 50% at discharge was significantly associated with 1 month and 6 month mortality and frequent re-admissions. Factors contributing to decreased mobility, self-care and barrier in usual activities were also analysed. Psychological status improved after extensive counselling and treatment; though it did not decrease at different follow up.
Conclusion(s): The decrement in wellness score is significantly associated with mortality and can be used as an indicator for aggressive HF management and frequent monitoring.

Improved heart failure awareness over a period of three years in an European population

V Vlad Damian Vintila[1]; A Vintila[2]; M Cinteza[1]; M Lainscak[3]; S Stork[4]; D Vinereanu[1]
[1]*University of Medicine and Pharmacy Carol Davila, University and Emergency Hospital Bucharest, Cardiology Department, Bucharest, Romania*; [2]*University of Medicine and Pharmacy Carol Davila, Coltea Clinical Hospital, Internal Medicine Department, Bucharest, Romania*; [3]*Faculty of Medicine, University of Ljubljana, , General Hospital Murska Sobota, Murska Sobota, Slovenia*; [4]*Comprehensive Heart Failure Center (CHFC), University of Wurzburg, Wurzburg, Germany*

Background: Heart failure (HF) is a common pathological condition with high impact on prognosis. The objective of the HF Awareness Day, which represents an European annual event, is to increase the knowledge and awareness regarding this condition, using various educational approaches.
Aim. To demonstrate that exposure to general medical information and a better access to this information over time improve awareness of HF, irrespective of specific medical or personal experience to disease.
Method: We compared two cohorts of subjects (200 and 221 respectively) who were questioned about HF using the standard awareness questionnaires approved by the specific Working group of the European Society of Cardiology. Data from 2013 & 2016 campaigns were used. A score of awareness was computed and measured for each cohort.
Results: The global awareness score between the two years improved significantly from 4.7+/- 3.9 to 6.0 +/- 3.4 ($p < 0.001$). This was achieved by similar populations in relation to professional exposure (3.6 vs.7.2%, p = NS). The clinical picture was better presented in the latter cohort, tiredness (39.0 vs 79.6%, $p < 0.001$), weight gain (6.5 vs. 18.1%, $p < 0.0001$) and shortness of breath (45.0 vs. 55.7%, $p = 0.029$)being reported as most frequent presentation for HF. Depression (13 vs 34.9% $p = 0.002$) and memory disturbances (10.5 vs. 25.8%, $p < 0.001$) were reported as worsening conditions for HF. In terms of treatment a better recognition for diet (24.0 vs. 43.4%, $p < 0.001$), sport (20.0 vs. 38.5% $p < 0.001$) and pharmacotherapy (47.0 vs. 57.0% $p = 0.004$) was noted.
Conclusions: A better exposure of general population to general medical information improves both the knowledge and treatment of heart failure. Special educational programs are needed to further improve the general awareness.

P1717

Management of heart failure patients in a Slovenian General hospital: What has changed in 15 years?

B Mahne[1]; S Kariz[1]; L Jeraj[1]
[1]*Izola General Hospital, Department of Cardiology, Izola, Slovenia*

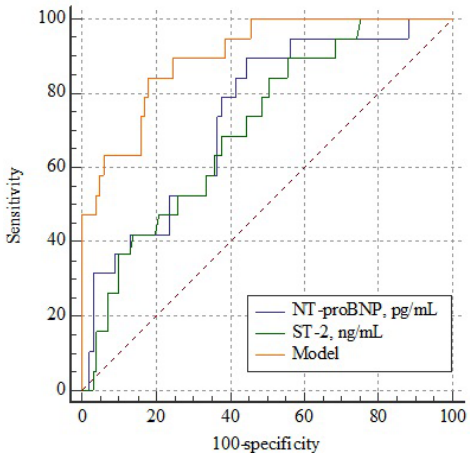
Background. Epidemiology trends in developed countries show that despite the decrease in the incidence of heart failure (HF) its prevalence is increasing. The population of HF patients is becoming older with a growing proportion of HF with preserved ejection fraction (pEF).
Purpose: The aim of the study was to investigate demographic trends, clinical characteristics and changes in management of patients hospitalized for HF in a Slovenian General Hospital in years 2001 and 2016.
Methods: We retrospectively analyzed medical records of all patients discharged from hospital with the diagnosis of HF between January and June 2016. Demographic data, clinical characteristics, comorbidities, pharmacological treatment and in-hospital mortality data were collected and analyzed. The results were compared with similar data collected in the period from January to June 2001.
Results: 198 patients in 2016 and 187 patients in 2001 were included in the study. Within a period of 15 years the median age increased from 76 to 81 years ($p < 0.001$) and the proportion of patients older than 80 years from 31% to 57% ($p < 0.001$). The median length of stay decreased from 10 to 7 days ($p < 0.001$). Patients hospitalized in 2016 had higher in-hospital mortality (18% vs 13%), however, the difference was not statistically significant. The proportion of patients with HFpEF increased from 43% to 54% ($p = 0.045$). However, no difference in etiology of heart failure was observed - ischemic heart disease was the most frequent cause of HF in both groups (33% vs 30%, $p = 0.495$), followed by hypertensive and valvular heart disease. Arterial hypertension and atrial fibrillation were more frequent in patients hospitalized in 2016 (76% vs 49%, $p < 0.001$ and 61% vs 48%, $p < 0.004$, respectively). COPD was less frequent (10% vs 27%, $p < 0.001$), while there was no significant difference in the prevalence of diabetes (32% vs 31%). More than half of patients treated in 2016 had anemia and chronic kidney disease (59% and 62 %, respectively). At hospital discharge, beta blockers were prescribed more frequently in 2016 (70% vs 16%, $p < 0.001$). On the contrary, angiotensin-converting enzyme inhibitors or angiotensin receptor blockers (61% vs 77%, $p < 0.001$) and mineralocorticoid antagonists (35% vs. 54%, $p < 0.001$) were prescribed less frequently. Several additional types of treatment were also introduced in this period.
Conclusions. Our data confirm that HF has become primarily a condition of the older population characterized by an increased prevalence of HFpEF, and a greater burden of cardiac and non-cardiac comorbidities. No pharmacological intervention has so far demonstrated any convincing benefit on the outcome of HFpEF, therefore management of HF is increasingly challenging. However, the length of stay is decreasing and several new types of HF treatment were introduced or made more easily available.

P1718

Biomarkers of myocardial stress and fibrosis in determining clinical outcomes in patients with heart failure and previous myocardial infarction

N Shilyaeva[1]; E Medvedeva[2]; A Shpigel'[1]; Y Shchukin[1]
[1]*Samara State Medical University, Cardiology, Samara, Russian Federation*; [2]*Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation*

Purpose: To evaluate the prognostic value of suppression of tumorigenicity 2 (ST2) and N-terminal prohormone of brain natriuretic peptide (NT-proBNP) levels in patients with chronic heart failure (HF) and previous myocardial infarction (MI).



ROC curves of biomarkers and model

Methods: The study included 127 patients with HF and the duration of MI with percutaneous coronary intervention (PCI) between 4 and 6 weeks (median age, 57 years; left ventricular ejection fraction (LVEF), 54%). The patients underwent clinical examination and echocardiography. Levels of biomarkers reflecting myocardial stretch (NT-proBNP) and ventricular fibrosis and remodeling (ST2) were determined by immunoassay analysis. The primary endpoint was the composite of all-cause mortality and rehospitalization due to HF and unstable angina, stroke and new MI with 9-month follow-up. Descriptive data are presented as frequencies (percent), median. Comparison between patients with adverse outcomes and without of them was performed using Mann-Whitney test. Receiver operating characteristics (ROC) curve was drawn to evaluate the potential roles of NT-proBNP and ST2 in predicting adverse clinical events. Logistic regression analysis was conducted to identify the independent risk factors for negative outcomes in this cohort. $P < 0.05$ was considered statistically significant.
Results: More than half of patients had I or II NYHA FC and cardiovascular risk factors. Most patients in both groups underwent primary PCI. During the 9-month follow-up period, communication was lost with 7 patients, adverse cardiovascular events occurred in 19 patients. Differences in age and sex between patients with adverse outcomes and without of them were not revealed. Enrolled patients were characterized by following levels of ST2 and NT-proBNP: 41,05 ng/ml and 245,99 pg/ml, respectively. Biomarkers concentrations were higher in patients with adverse outcomes compared with patients without recurrent cardiovascular events (? < 0,01, for both). Follow-up ROC analyses for outcome prediction showed similar areas under the curve (AUC) of biomarkers (? = 0,659): 0,709 for ST2 and 0,738 for NT-proBNP. Biomarkers yielded cut-off values 43,6 ng/mL for ST2 and 285 pg/mL for NT-proBNP. The odds ratio (OR) for cut-offs of the study biomarkers were 2,84 for ST2 and 2,97 for NT-proBNP. In the binary regression model, ST2, NT-proBNP and established risk factors (NYHA FC, aneurysm of the LV, a history of stroke, estimated glomerular filtration rate < 90 ml/min per 1,73m2) were statistically significant predictors for the combined endpoint. Model led to an AUC of 0.900 ($p < 0,001$), which better the AUC value for ST2 and NT-proBNP separately.

Conclusion. ST2 and NT-proBNP were independent predictors of adverse clinical outcomes in HF and previous MI patients.

P1719

Clinical and sociodemographic profile of patients with cardiac insufficiency admitted in a reference hospital in Fortaleza-Ce, Brazil

V L Vera Lucia Pessoa[1]; BJ Souza[1]; DL Salles[1]; MS Gama[1]; LC Souza[1]; MGV Sobral[1]; RS Florencio[1]; JD Souza Neto[1]; G G Vasconcelos[1]
[1]HOSPITAL DE MESSEJANA DR CARLOS ALBERTO STUDART GOMES, Fortaleza, Brazil

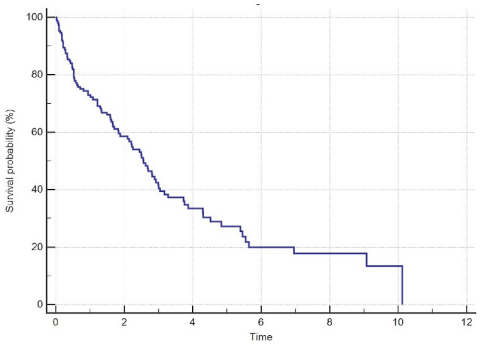
Introduction: Cardiac Insufficiency (CI) is a chronic disease considered as the final stage of most of cardiac illnesses. The causes are variable, being responsible for generating systemic impairment. It is known that socioeconomic characteristics are factors that can interfere in the prognosis as well as contribute to hospital readmission.
Objective: To describe the clinical and socioeconomic profile of patients admitted in a reference hospital.
Methods: It is a cross-sectional study with a quantitative approach conducted in adult patients, from both sexes, admitted in a hospital reference in treating cardiac illness, during April 2016 to October 2017, in Fortaleza-Ceará-Brazil. Such research is fruit of a conjunct project of Brazilian hospitals, by the Supporting Program for the Institutional Development of the Health System (from the Portuguese PROADI-SUS) of the Health Ministry, in partnership with the American Heart Association (AHA) and the Brazilian Cardiology Society. The clinical diagnosis of cardiac insufficiency was established by laboratory and echocardiographic tests as well as clinical information. It was used formularies and questionnaires to data collection. Data analysis was performed by the software SPSS 22.0 and statistic evaluation involved the calculation of frequencies and means. The results were discussed according the pertinent literature.
Results: from the 144 patients hospitalized by CI, it was verified that 59.9% were male, 95.8% considered "pardo", 35.7% did not finished elementary school and 22.5% did finished elementary school, 57.9% have a family income more than one minimal salary or less or equal to two minimal wages, 56.4% smoke, 57.4% drink alcohol and 82.9% do not exercise. Relating the clinical aspects of CI, 29.5% from the people have ischemic etiology, 17.3% idiopathic etiology, 12.7% valvar etiology, 10.1% Chagas disease etiology and 6.5% hypertensive etiology. Regarding the knowledge of CI before admission, 76.3% have already done treatment and 26.4% have been admitted in less than 6 months and 25.9% were diagnosed with NYHA of IV and had a mean ejection fraction of 37 ± 16.01.
Conclusion: cardiac insufficiency represents a challenge to health team, being configured as one of the major causes of hospitalization globally. Among them, it highlights the lack of knowledge about non-pharmacological methods, inadequate treatment adhesion and lack of capacity to identify signs and symptoms that are predictive to decompensation of the disease.

P1720

Prognosis and determinants of survival in patients with severe heart failure disqualified from heart transplantation due to contraindications

P Paula Polaska[1]; G Jerzak-Wodzynska[1]; P Leszek[1]; W Smigielski[1]; J Gajda[1]; P Rozentryt[2]; J Korewicki[1]; T Zielinski[1]; T Rywik[1]
[1]Institute of Cardiology, Warsaw, Poland; *[2]Silesian Center for Heart Diseases (SCHD), Zabrze, Poland*

Introduction: Heart failure is a common problem worldwide and despite some progress in treatment survival still leaves much to be desired. In patients with severe heart failure (SHF) the prognosis is particularly ominous. For these patients heart transplantation (HT) remains one of treatment options. However, presence of contraindications precludes acceptance for HT. There is a limited data on clinical characteristics and survival determinants of such patients.
Purpose: We intended to evaluate clinical characteristics and survival determinants of patients disqualified from HT due to contraindications.
Methods: It was a retrospective analysis, based on medical documentation of patients with SHF considered for HT, from a single transplantology center (Institute of Cardiology), between 01.2006 and 12.2016. There were 151 patients who constituted study population. All subjects were divided into two groups based on survival status: alive (AG) and deceased (DG).
Results: There were 57 in AG and 94 patients in DG. The mean age in both groups (AG/DG) was 56.3 ± 9 vs 55.7 ± 8.9 years ($p = 0,7$), percentages of males 82.4% vs 90.4% ($p = 0.2$). There was also no significant difference between groups in terms of occurrence of renal failure (RF) (33.3% vs 32.9%, $p = 1$), COPD (15.8% vs 24.5%, $p = 0.2$). The predominant etiology of SHF was ischaemic (61.4% vs 69.1% $p = 0.08$). There were borderline differences between groups in: EF (25.7% vs 22.4% $p = 0.06$), percentage of pts with liver failure (3.5% vs 7% $p = 0.08$), right ventricle failure (56.1% vs 47.3% $p = 0.09$), pulmonary hypertension (PH) (42.1% vs 50% $p = 0.08$), stroke (17.5% vs 10.6% $p = 0.098$), peripheral atherosclerosis (8.8% vs 11.7% $p = 0.05$), diabetes (40.4% vs 32.98% $p = 0.07$) and staying under the ambulatory care from specialist cardiological center (33.3% vs 26.6% $p = 0.07$). Median FU time for this population was 1.67 yrs. 2.1 yrs in AG group and 1.34 yrs in DG ($p = 0.0009$). At 1 year, there were 72% of subjects alive, whereas at 5 years only 25%. After excluding first 30 days of FU (to eliminate in-hospital mortality) in Cox regression model, supervision by specialist ambulatory cardiological center (HR 0.6, $p = 0.05$) was a negative predictor of death, whereas RF (HR 1.59; $p = 0.05$), PH (HR 1.5; $p = 0.06$) were positively associated with unfavorable prognosis.
Conclusions: The prognosis of patients with SHF disqualified from HT due to contraindications is poor. The ambulatory supervision by cardiology specialist center is beneficial in this population.



Survival probability

Prognostic evaluation of HF-rEF using the MECKI score can be improved by adding natriuretic peptide levels

F Francisco Gama[1]; P Freitas[1]; C Aguiar[1]; D Matos[1]; A Tralhao[1]; J Ferreira[1]; A Ventosa[1]; MJ Rebocho[1]; M Mendes[1]
[1]Hospital de Santa Cruz, Lisbon, Portugal

Background: Heart transplantation guidelines recommend the Seattle Heart Failure Model and the Heart Failure Survival Score when deciding on the timing of listing for transplantation, but recent studies have shown that the Metabolic Exercise Cardiac Kidney Index (MECKI) score has superior predictive accuracy. The aim of this study was to determine whether the NT-proBNP level adds prognostic value to the MECKI score.
Methods: Retrospective analysis of 129 patients with HF-rEF who underwent cardiopulmonary exercise test (CPET). The MECKI score was calculated for each patient using data at the time of the CPET, and NT-proBNP levels were measured before the test. The study endpoint was heart transplantation or death (any cause), whichever occurred first within 2 years after the CPET. ROC curve analyses were performed to determine the best discriminatory level of NT-proBNP.
Results: Mean age was 55 ± 11 years and 80% were male. The most common heart failure etiology was ischemic (50%). Peak VO2 was £14 mL/kg/min in 34 patients (26.4%). Over the 2-year follow-up period, 7 patients died and 8 underwent heart transplantation (study endpoint rate 10.9%). The MECKI showed good discrimination ability (c-statistic 0.85; 95% CI, 0.74-0.95). A NT-proBNP level >1404 pg/mL showed the best discriminatory accuracy (26% positive predictive value, 98% negative predictive value), and predicted the study endpoint independently of the MECKI score in Cox regression analyses (adjusted HR 5.9; 95% CI, 1.2-29) (see figure).
Conclusion: In patients with HF-rEF, the level of NT-proBNP added significant prognostic information to the MECKI score.

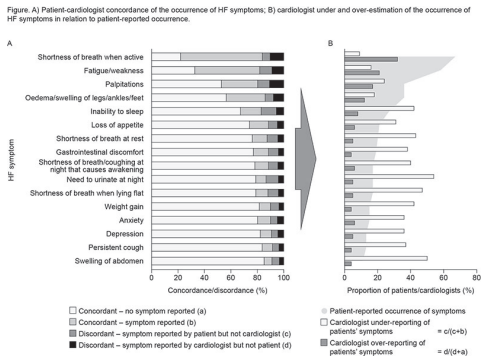
Funding Acknowledgements: This study was funded by Novartis Pharma AG.

Background and Purpose: This study aimed to explore the extent to which symptoms experienced by patients with heart failure (HF) are recognized by their cardiologist and the level of concordance between patient and cardiologist perceptions of associated severity of HF.
Methods: A cross-sectional survey of cardiologists and their consulting patients with HF was conducted in 10 countries (Argentina, Brazil, China, Colombia, France, Japan, Mexico, Russia, Saudi Arabia and Turkey). Patient record forms (PRFs) were completed by cardiologists for consecutively consulting patients with HF, who were then invited to complete a patient self-completion questionnaire (PSC). Only responses from PRFs with an associated PSC were analyzed. Patient- and cardiologist-reported occurrences of individual HF symptoms were compared, and concordance was calculated as the number of response agreements by PSC and PRF for the total number of matched pairs. The over- or under-reporting of symptom occurrence by cardiologists relative to patient-reported occurrence was also calculated by taking the patient perspective and evaluating how often a patient-reported symptom was not recognized in the PRF (cardiologist under-reporting) and vice versa (cardiologist over-reporting). Patients' perceived severity of HF was also compared to their cardiologists' perceived risk of death within 12 months.



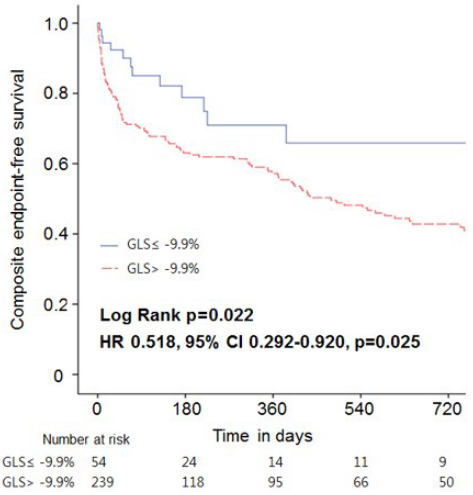
Results: Overall, a very high level of concordance was reported for the occurrence of symptoms experienced between matched patient and cardiologist pairs (n = 2379); 93% of matched cardiologists and patients described similar occurrences of any HF symptom. High concordance was also observed for the occurrence of individual HF symptoms reported by patients with HF and their cardiologists (range 80-92%) (Figure). For symptoms reported by >50% of patients, cardiologists more frequently over- than under-reported their occurrence, whereas for symptoms reported by < 50% of patients, it was more common for cardiologists to under-report than over-report their occurrence (Figure). The overall concordance of patient- and cardiologist-perceived severity of HF was 54% (n = 2260). Of the patients reporting their HF as mild, 28% were perceived by their cardiologist to have a moderate to high or very high risk of death within 12 months, which increased to 50% in patients that reported their HF as moderate and 75% in patients reporting their HF as severe.
Conclusions: This study shows that cardiologists are aware of the most common HF symptoms, but have a tendency to under-report less common HF symptoms. Results also show that patients often underestimate the severity of their HF. A better dialogue between cardiologists and patients may result in increased awareness of HF-associated risks and lead to improved treatment and outcomes.

P1723

The association of global longitudinal strain with clinical outcomes in heart failure patients with severe left ventricular systolic dysfunction

H W Lee[1]; JC Choi[1]; JY Shin[1]; SH Lee[1]; JH Ahn[1]; JS Park[1]; JH Oh[1]; JH Choi[1]; HC Lee[1]; KS Cha[1]; TJ Hong[1]
[1]Pusan National University Hospital, Department of Cardiology, Busan, Korea Republic of

Purpose: The heart failure (HF) patients with severe left ventricular (LV) systolic dysfunction still have unfavorable prognosis.We aimed to investigate if better global longitudinal strain (GLS) predicts improved clinical outcomes in these patients.



Severe LV dysfunction and GLS

Methods: Among 293 consecutive HF patients with severe LV systolic dysfunction, defined as LV ejection fraction (LVEF) = 30% at baseline echocardiogram, in an urban tertiary center (October 2013-September 2017), the predictive ability of GLS by speckle-tracking echocardiography for the subsequent occurrence of clinical outcomes was evaluated. The primary outcome was composite endpoint of cardiac death and HF readmission.
Results: Composite endpoint occurred in 140 patients (47.8%) during a mean 367 days of follow-up. GLS was independently predictive of composite endpoint, but LVEF was not. In the receiver operating characteristic curve analyses of GLS, the cutoff values for predicting composite endpoint were -9.9 % (sensitivity: 0.90; specificity: 0.28; area under the curve: 0.598). Better GLS group (defined as GLS =-9.9%, n = 54), compared to worse GLS group (defined as GLS >-9.9%, n = 239), had significantly lower rate of composite endpoint (24.1% vs. 53.1%, p < 0.001). Composite endpoint-free survival rate was significantly higher in better GLS group than worse GLS group (75.9% vs. 46.9%, log rank p = 0.022).Conclusion: GLS may provide the additive information for clinical outcomes in patient with severe LV systolic dysfunction.

Who will progress to advanced heart failure? Predictors from within a multidisciplinary disease management program.

RM Murphy[1]; LH Healy[1]; JG Gallagher[1]; S MCC Mc Cleland[1]; ML Ledwidge[1]; SZ Zhou[1]; K MCD Mc Donald[1]
[1]*St Vincent's University Hospital, Cardiology, Dublin, Ireland*

Background: Recurrent hospitalisation for acute decompensated heart failure (ADHF) is a concerning prognostic sign and usually underlines the need to consider advanced heart failure (HF) therapy or palliative care. Multidisciplinary disease management programs (DMP) are now recognised as the optimal method to deliver state of art HF care to those surviving an ADHF admission. What is unclear are the characteristics of those managed in a DMP likely to display a downward course in disease trajectory and thereby in need of a change in management strategy.
Methods: We recruited patients entering our DMP following an admission for ADHF. Patients were followed over time to determine what percentage of them defined features of disease progression (defined as 2 subsequent ADHF admission within a 6-month period) compared with those demonstrating a more stable course.
Results: 1984 patients were followed for an average of 3.6 years in our DMP post admission with ADHF. Mean age was 73 years old. 58% were male. Of these 493 had heart failure with a preserved ejection fraction (HFpEF) and 1239 had heart failure with a reduced ejection fraction (HFrEF). 264 patients demonstrated heart failure disease progression at an annual incidence of 3.7% per year.
On multivariate analysis the strongest indicators of progression to refractory heart failure were B-type natriuretic peptide (BNP) and renal function as estimated by creatinine, with stable raised BNP being the strongest predictor of disease progression. The optimal stable BNP to differentiate high and low risks was approximately 440 pg/ml.
Conclusion: Patients managed in a multidisciplinary disease management program showed a low rate of annual progression of HF syndrome as defined by recurrent hospitalisations. This highlights the importance of referring patients at risk of recurrent hospitalizations to a DMP to help improve patient outcomes. Persistently high stable BNP and impaired renal function were the strongest predictors of disease progression.

Chronic Heart Failure - Diagnostic Methods

Lung ultrasound in the diagnosis of cardiogenic dyspnea

T Valova[1]; ID Daskalov[1]
[1]*Military Medical Academy of Sofia, Cardiology and intensive therapy, Sofia, Bulgaria*

Introduction: Dyspnea is a common challenge in the routine clinical practice, especially arising in intensive care units, where the therapeutic modality has to be approved upon medical examination.
Objectives: Verifying the subtype of cardiogenic or non-cardiogenic dyspnea with reliable, safe, time-saving and non-expensive diagnostic method that can be performed anytime, at the patient's bench.
Method: Lung ultrasound differentiating B-lines score in 51 patients with non-cardiogenic dyspnea, 52 - with cardiogenic dyspnea and 49 - healthy controls was tested against conventional X-ray and FOCUS.
Results: All patients with cardiogenic dyspnea (class III-IV NYHA) showed B-lines score over 15 (16,85). The result from the performed lung ultrasound in this group strongly correlated with the chest X-ray (r- 0,86, $p < 0,001$). A moderate correlation with FOCUS (r- 0,68, $p < 0,001$) was also detected. No B-lines were shown in patients with non-cardiogenic dyspnea. A moderate correlation between the presented diagnostic modalities was found in the non-cardiogenic group (r-o,567, $p < 0,0001$). The estimated single B-lines in a definite lung zone was not a sign of cardiogenic dyspnea. It was accepted as an indirect criterion for inflammation or vessel damage in the observed lung zone. The absence of B-lines detected with lung ultrasound supposed non-cardiogenic cause for dyspnea such as chronic obstructive pulmonary disease, bronchial asthma, pneumothorax, pulmonary fibrosis or hysteria. It correlated with negative for pulmonary congestion chest X-ray and normal or low left ventricle filling pressure. No typical B-lines were identified in healthy controls.
Conclusions: B-lines seem to be an easy-to-perform and reliable non-invasive diagnostic tool for dyspnea pathogenetic differentiation. The method advantages include safe and bed lung ultrasound application, multiple use and precise control of the administrated therapy.

P1726

Changes in circulating miRNAs as a prognostic tool for heart failure related morbidity and mortality in patients suffering from stable HFpEF: A subgroup analysis of the ALDO-DHF trial

J Johannes Petutschnigg[1]; MWJ De Ronde[2]; TD Trippel[1]; L Schleussner[1]; F Baehr[1]; D Hashemi[1]; V Holzendorf[3]; JJ Leenders[4]; YM Pinto[5]; R Wachter[6]; G Hasenfuss[7]; C Hermann-Lingen[8]; B Pieske[1]; F Edelmann[1]
[1]*Charite - Campus Virchow-Klinikum (CVK), Department of Medicine and Cardiology, Berlin, Germany*; [2]*Academic Medical Center of Amsterdam, Amsterdam, Netherlands*; [3]*University of Leipzig, Faculty of Medicine, Leipzig, Germany*; [4]*Academic Medical Center of Amsterdam, ACS Biomarker BV, Amsterdam, Netherlands*; [5]*Academic Medical Center of Amsterdam, Heart Failure Research Center, Amsterdam, Netherlands*; [6]*Leipzig University Hospital, Department of Cardiology, Leipzig, Germany*; [7]*University Medical Center Gottingen (UMG), Department of Cardiology, Gottingen, Germany*; [8]*University Medical Center Gottingen (UMG), Department of Psychosomatic Medicine and Psychotherapy, Gottingen, Germany*

Background/ Introduction: Heart failure with preserved ejection fraction (HFpEF) is increasingly common as a major health burden in the western world. The underlying cellular mechanisms remain hardly explored and solid treatment opportunities as well as tools for risk prediction are desperately needed. Therefore, we investigated 14 selected microRNAs (miRNAs) regarding their potential to add prognostic information in patients with HFpEF.
Methods: We examined 14 miRNAs in the ALDO-DHF cohort in which the benefit of spironolactone 25 mg once daily vs. placebo for 12 months in 422 HFpEF patients with NYHA class II–III, LVEF = 50%, and peakVO2 = 25 mL/kg/min was investigated. MiRNA levels together with one technical normalization miRNA (cel-miR-39) were measured in plasma samples by standard Q-PCR at baseline, and after 6 and 12 months follow-up. Multivariable Cox proportional hazard regression analyses were performed to assess the association of the miRNAs with cardiovascular (CV) death and hospitalization rate during follow-up in comparison to established risk factors (in this case: age, sex, diabetes, creatinine, hemoglobin and sodium) with and without miRNAs and in conjunction with NT-proBNP.
Results: The panel that turned out to be predictive for worsening of the HFpEF related disorder (expressed by CV death and hospitalization rate) comprises the following 7 miRNAs: miR-22-3p, miR-142-5p, miR-320a, miR-378a-3p, miR-423-5p, miR-499 and miR-1254. We compared c-stats (Table 1) of established risk factors alone [0.54 (95% CI 0.48-0.61)] and in conjunction with NT-proBNP [0.60 (95% CI 0.54-0.66)] or the panel of miRNAs [0.66 (95% CI 0.60-0.72)]. Finally, we also used all of them [0.68 (95% CI 0.63-0.74)] and compared it with the prognostic value for HFpEF patients of solely this panel of miRNAs [0.67 (95% CI 0.60-0.74)].
Conclusion: Our findings suggest that a baseline model for risk prediction, using only established risk factors, performs poorly in the prediction of CV death and hospitalization rate. Adding NT-pro-BNP to this model increases the capacity of the model to predict risk, but the strongest contributor to the prediction model appeared to be the panel of 7 miRNAs.

Table 1

Analyzed models	c-stat (95% CI)
Established rik factors	0.54 (95% CI 0.48-0.61)
+ NT-proBNP	0.60 (95% CI 0.54-0.66)
+ panel of 7 miRNAs	0.66 (95% CI 0.60-0.72)
+ NT-proBNP and panel of 7 miRNAs	0.68 (95% CI 0.63-0.74)
panel of 7 miRNAs only	0.67 (95% CI 0.60-0.74)

P1727

Biomarker role of relaxins in myocardial fibrosis and left ventricular diastolic function in ischemic heart failure with reduced ejection fraction

E Edit Gara[1]; J Simon[1]; GY Csiko[1]; J Skopal[1]; T Radovits[1]; G Foldes[1]; B Merkely[1]
[1]*Semmelweis University, Heart Center, Budapest, Hungary*

Funding Acknowledgements: National Research, Development and Innovation Office of Hungary (NKFIA; NVKP-16-1-2016-0017)

Background and Purpose: Relaxin is a pleiotropic hormone with well characterised effects in pregnancy and labor. Furthermore, preclinical and clinical studies are evaluating its possible therapeutic role in decompensated heart failure. Relaxin may also act as a novel biomarker in chronic heart failure. Here we aimed at investigating the value of endogenous, circulating relaxins (RLX-1 and RLX-2) in cardiac remodelling and fibrosis, as well as on left and right ventricular function.

Methods: Human myocardial samples were collected from consented patients with ischemic end-stage heart failure (HF) (n = 55). Serum and explanted myocardial tissue were biobanked during heart transplantation surgery. Medical history, laboratory findings, hemodynamical (cardiac output, PVR, PCWP) and echocardiographic measurements were assessed. Circulating RLX-1 and RLX-2 was measured by ELISA from serum. To assess collagen and connective tissue left and right ventricular wall segments were stained for Picrosirius red and Massons' trichrome. The amount of myocardial fibrosis was quantified with Image J density analyses. For statistical analyses, t-tests and Spearman's correlation tests were used.
Results: Mean levels of RLX-1 from end-stage HF were comparable with those measured in pregnant women (702 ± 283 pg/ml in vs. 560-1060 pg/ml, respectively). RLX-1 proved to be independent from age, gender, hypertension, diabetes mellitus, BMI or BSA. We found a moderate inverse correlation between serum RLX-1 levels and the extent of ventricular fibrosis (r=-0.493, p = 0.0005 in the right ventricle and r=-0.487, p = 0.0006 in the left ventricle). In parallel with this, a moderate correlation was found in left ventricular diastolic function parameters (E/A r = 0.456, p = 0.0025, n = 55). There were no significant differences in the laboratory results, hemodynamics, and other echocardiography parameters. RLX-1 levels showed moderate correlation with RLX-2 levels (r = 0.453, p = 0.0003).
Conclusion: In this population of end-stage heart failure patients with ischemic etiology higher endogenous RLX-1 levels were accompanied by significantly lower extent of myocardial fibrosis. This finding suggests the specified biomarker role for RLX-1 and emphasizes its therapeutic use of RLX-1 as an anti-fibrotic drug. Further studies are warranted to fully understand its role in myocardial function and detailed intracellular mechanisms of action.

Eyes on amyloidosis: Severe microvascular retinal dysfunction in cardiac amyloidosis.

E Zampiccoli[1]; J Barthelmes[1]; M Naegele[1]; R Schwotzer[1]; I Sudano[1]; F Ruschitzka[1]; AJ Flammer[1]
[1]University Heart Center, Cardiology, Zurich, Switzerland

Funding Acknowledgements: Swiss Heart Foundation, LHW Foundation, University Hospital Zurich

INTRODUCTION: Endothelial dysfunction is crucial in the development, progression, and prognosis of cardiovascular diseases. Cardiac amyloidosis is a particular form of heart failure with typical sings and symptoms and a devastating prognosis. Amyloid deposits are found both in the heart muscle as well as in the vasculature, limiting the ability of the vessel to adapt blood flow according to the need of the organs. Whether retinal endothelial function is impaired in these patients is still unclear. Therefore, it was the aim of this study to evaluate retinal vessel endothelial function - an easily assessable vasculature - in patients with amyloidosis.
OBJECTIVE: To investigate vascular function in chronic heart failure patients with cardiac amyloidosis.
MATERIALS & **Methods:** 22 patients with amyloidosis (15 AL, 7 TTR mean age 64 ± 9.2 years) were included. 82 healthy individuals (HC) without any cardiovascular risk factors served as controls (mean age 54.2 ± 15.8 years). Microvascular retinal endothelial function was measured via dynamic retinal vessel analysis (RVA). This non-invasive technique measures mainly NO-dependenr flicker light-induced dilatation of retinal arteries (FIDart). Other vascular measures included flow-mediated dilatation (FMD), retinal arteriovenous ratio (AVR) and pulse-wave velocity (PWV). To account for imbalanced possible confounders (age, sex, BMI, blood pressure, glucose and cholesterol levels), an inverse probability weighted analysis (propensity score) was employed.
Results: Arterial retinal vascular function (FIDart) was significantly impaired in patients with amyloidosis compared to HC (mean FIDart 3.7 ± 1.9 % vs. 1.0 ± 1.3 %, p < 0.001). CHF patients with AL (n = 15) and TTR (n = 7) amyloidosis both showed significantly impaired vascular function (mean FIDart = 1.5 ± 2.1 % for AL and mean FIDart = 0.5 ± 1.4 % for TTR) to a similar degree (p = 0.33). PWV was significantly faster in patients with amyloidosis than in HC (mean PWV 9.1 ± 2.6 ms-1 vs. 7.5 ± 1.3 ms-1, p = 0.005). There was no significant difference in FMD between the two groups (HC vs. amyloidosis; mean FMD 6.6 ± 3.4 % vs. 6.1 ± 3.4 %, p = 0.11). Balance for potential confounders was achieved.
Conclusions: Our results demonstrate profound alterations in microvascular function of patients with cardiac amyloidosis. Whether these results have clinical or prognostic impact needs to be carefully evaluated in further clinical studies.

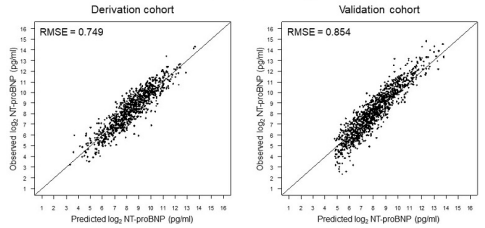
Derivation and validation of a conversion equation between B-type natriuretic peptide and N-terminal pro BNP levels

S Kasahara[1]; Y Sakata[1]; K Nochioka[1]; R Abe[1]; T Oikawa[1]; M Sato[1]; H Aoyanagi[1]; M Miura[1]; T Shiroto[1]; J Takahashi[1]; S Miyata[2]; H Shimokawa[3]
[1]Tohoku University Graduate School of Medicine, Department of Cardiovascular Medicine, Sendai, Japan; [2]Tohoku University Graduate School of Medicine, Department of Evidence-based Cardiovascular Medicine, Sendai, Japan; [3]Tohoku University Graduate School of Medicine, Department of Cardiovascular Medicine and Department of Evidence-based Cardiovascular Medicine, Sendai, Japan

Funding Acknowledgements: This study was supported in part by the Grants-in Aid from the MHLW, MEXT and AMED (No. 17ek0210081h0001), Tokyo, Japan.

Background: The ESC guidelines recommend measurement of natriuretic peptides for diagnosis of Heart Failure (HF) as a Class I indication. Among natriuretic peptides, biologically active B-type natriuretic peptide (BNP) and inactive N-terminal pro B-type natriuretic peptide (NT-proBNP) are the most widely used diagnostic tools for HF. Although both molecules are released in equimolar proportions, their levels differ depending on clinical conditions, such as age, sex, body weight, renal function, anemia and so on. However, a reliable conversion equation between BNP and NT-proBNP remains to be developed in the daily clinical practice.
Purpose: To develop a conversion equation between BNP and NT-proBNP.
Methods: The derivation cohort included 928 patients (mean 66 yrs., female 26%) from our Supplemental Benefit of Angiotensin Receptor Blocker in Hypertensive Patients with Stable Heart Failure using Olmesartan (SUPPORT) Trial, in which we examined whether an additive treatment with olmesartan reduces the mortality and morbidity in hypertensive HF patients treated with evidence-based medications. The validation cohort included 1,163 consecutive cardiovascular patients aged = 20 yrs., in whom both BNP and NT-proBNP levels were measured simultaneously at a university hospital between April 2017 and October 2017 (mean 66 yrs., female 41%). To develop the conversion equation, we regressed log2 NT-proBNP onto log2 BNP and other covariates. In the multivariable models, all possible combinations of log2 BNP and the variables including age, sex, creatinine, hemoglobin, body weight, and height were examined as independent variables. For the best conversion equation, we selected the set of the covariates that maximized the adjusted R^2 in the derivation cohort first. Then, the root mean squared error (RMSE) was obtained in the validation cohort to examine the predictive accuracy of the selected model.
Results: Mean log2 BNP and log2 NT-proBNP levels were 6.2 pg/ml and 8.4 pg/ml, respectively, in the derivation cohort, while they were 5.8 pg/ml and 8.1 pg/ml, respectively, in the validation cohort. In the derivation cohort, the model with the highest adjusted R^2 consisted of log2 BNP, age, creatinine, hemoglobin, body weight, height, and sex. We developed the conversion equation as follows; log2 NT-proBNP (pg/ml) = 0.957*log2 BNP(pg/ml) - 0.00655*age(yrs.) + 0.731*creatinine(mg/dl) - 0.0184*hemoglobin(g/dl) - 0.00554*weight(kg) + 0.00880*height(cm) + 0.238(if female sex) + 1.34 (Figure). In the validation cohort, RMSE of this conversion equation was 0.854, which was smaller than that of previously reported conversion equations, demonstrating that this equation excellently converts BNP levels to NT-proBNP levels.
Conclusion: An excellent and reliable conversion equation between BNP and NT-proBNP levels has been developed with age, creatinine, hemoglobin, body weight, height and sex.

Figure. Predicted vs. Observed NT-proBNP levels



P1730

Prevalence of heart failure with preserved and reduced left ventricular ejection fraction and diagnostic value of MR-proANP in 803 outpatients with type 2 diabetes

J Jensen[1]; M Schou[1]; C Kistorp[2]; J Faber[2]; TW Hansen[3]; MT Jensen[4]; HU Andersen[3]; P Rossing[5]; T Vilsboll[5]; JS Jensen[1]; PG Jorgensen[4]
[1]Herlev and Gentofte Hospital, Faculty of Health and Medical Sciences, Copenhagen University, Department of Cardiology, Copenhagen, Denmark; [2]Herlev and Gentofte Hospital, Faculty of Health and Medical Sciences, Copenhagen University, Department of Endocrinology, Copenhagen, Denmark; [3]Steno Diabetes Center Copenhagen, Copenhagen, Denmark; [4]Herlev and Gentofte Hospital, Department of Cardiology, Copenhagen, Denmark; [5]Steno Diabetes Center Copenhagen, Faculty of Health and Medical Sciences, Copenhagen University, Copenhagen, Denmark

Background/Introduction: Type 2 diabetes (T2D) is associated with diastolic dysfunction and an increased risk of heart failure (HF). Overt HF may be difficult to acknowledge in T2D patients due to coexisting factors such as obesity. Also, the prevalence of HF with preserved (HFpEF) and reduced (HFrEF) left ventricular ejection fraction (LVEF) in T2D patients is debatable due to several ways of defining diastolic dysfunction. Further, in the outpatient setting, no data exist on the diagnostic value of the new natriuretic peptide, mid-region pro-atrial natriuretic peptide (MR-proANP), to rule out HFrEF or to diagnose HFpEF and HFrEF in T2D patients.
Purpose: To identify the prevalence of HFpEF and HFrEF and evaluate the diagnostic value of MR-proANP in a cohort of patients with T2D, consecutively followed in two specialized diabetes outpatient clinics.
Methods: The MR-proANP level was measured and a comprehensive echocardiography was performed in N = 803 T2D patients with sinus rhythm followed in two specialized diabetes outpatient clinics. HFrEF was defined regardless of presence of dyspnea as a LVEF = 40% and HFpEF defined as presence of dyspnea and at least one of the following present: LVEF > 40% and = 50%, E/e'medial = 15, increased LV mass or a left atrial volume index >34 ml/m2. Univariate and multivariate logistic regression analyses were applied.
Results: Of the patients (median [interquartile range] age of 65 [58, 71] years, 35% female), 38% complained of dyspnea, 17% had HFpEF and 2% had HFrEF. MR-proANP levels were respectively 61 [40, 88], 105 [68, 190] and 125 [95, 208] pmol/l in patients with normal echocardiography, in HFpEF and in HFrEF patients. Receiver operating characteristic (ROC) curves showed an optimal cut-off level for MR-proANP of 60 pmol/l to rule out HFrEF (N = 19) in all patients (sensitivity 94.7%, specificity 39.4%, negative predictive value (NPV) 99.7%, positive predictive value (PPV) 3.7%) (Figure A) and in patients with dyspnea (N = 309) (sensitivity 87.5%, specificity 32.9%, NPV 99.0%, PPV 3.3%) (Figure B). Adding MR-proANP to a multivariate model (including age, sex, T2D duration, albuminuria, systolic blood pressure above 170 mmHg, abnormal ECG and ischemic heart disease) in order to identify either HFpEF or HFrEF patients as a group, increased area under the curve (AUC) from 0.689 to 0.784 ($p < 0.001$) in patients with dyspnea (Figure C).
Conclusion(s): HFpEF (17%) is frequent and HFrEF (2%) is rare in outpatients with T2D. An MR-proANP level of less than 60 pmol/l effectively rules out HFrEF in T2D outpatients regardless of the presence of dyspnea and adds independent information in diagnosing either HFpEF or HFrEF in patients with dyspnea. Since HFpEF is frequent in T2D, a diagnostic rather than a rule out strategy is preferable in a specialized diabetes clinic setting.

Prognostic impact of copeptin and mid-regional pro-adrenomedullin in chronic heart failure with regard to comorbidities

L Lenka Spinarova[1]; J Parenica[2]; J Spinar[2]; M Spinarova[1]; K Labr[1]; F Malek[3]; P Ostadal[3]; O Ludka[2]; M Goldbergova-Pavkova[4]; J Tomandl[5]; K Benesova[6]; J Jarkovsky[6]
[1]Masaryk University,St. Anne's Faculty Hospital,1st Department of Internal Medicine-Cardioangiology, Brno, Czech Republic; [2]University Hospital and Masaryk university, Internal Cardiologic Dpt, Brno, Czech Republic; [3]Homolka Hospital, Cardiologic Dpt, Praha, Czech Republic; [4]Medical Faculty of Masaryk University, Pathophysiologic Dept, Brno, Czech Republic; [5]Masaryk University, Biochemistry Dept, Medical Faculty of Masaryk University, Brno, Czech Republic; [6]Masaryk University, Faculty of Medicine, Institute for Biostatistics and Analysis, Brno, Czech Republic

The aim of the study is to evaluate the impact of new humoral substances: copeptin and mid- regional pro-adrenomedullin (MR-proADM) on one year survival of patients with stable systolic chronic heart failure (CHF) and to compare them with AHEAD score assessing the comorbidities. The FAR NHL (FARmacology and NeuroHumoraL activation) registry is a database of patients treated in departments with specialized HF care in three University hospitals. The patients should have been treated for systolic HF: EF < 50% and stable for at least 1 month, follow up was 1 year. Primary endpoint after 1 year follow-up was: death or hospitalization for decompensation of HF or heart transplantation (HTX) or LVAD implantation. This endpoint was related to the levels of copeptin and MR-proADM and was caluculated for separate AHEAD scores. AHEAD score is a simple bed-side mortality predictive model for a wide population of AHF patients based on age and basic comorbidities. To whole FAR NHL registry a total amount of 1076 patients were included, in 552 of them the levels of copeptin and MR-proADM were available. Mean age was 65 +12 years, the etiology of CHF was ischemic heart disease in 53.5%, dilated CMP in 40.2% and 6.3% were classified as other. Mean EF was 31+9%. Patients without primary endpoint were assigned as group A (469 pts), those with the primary endpoint group B (83 pts). There were statistically significant differences between the groups in the levels of copeptin: group A median 15.9 pmol/l(3.4-50.9) vs group B 23.7 pmol/l(5.0-89.44) ($p < 0.001$),MR-proADM: group A median 0.63 nmol/l(0.32-1.34) vs group B 0.74 nmol/l(0.4-1.94) ($p < 0.001$)
Patients were then divided according the AHEAD score into three groups: AHEAD score 0-1, AHEAD score 2-3, AHEAD score 4-5. Relationship of AHEAD score to primary endpoint in the first year of follow-up was not significant, but within 24th month it reached statistical significance: p= 0.017. Patients with higher AHEAD score (more comorbidities) reached more often the primary end-point
The cutt-off value = 23.7 for copeptin had 50.6% sensitivity and 73.3% specificity to predict primary outcome at the first year of follow -up, $p < 0.001$. The cut –off value for MR-proADM= 0.58 had higher sensitivity 79.5% and lower specificity 42.0% for one year follow- up with $p < 0.001$. For both humoral substances there was statistical significant difference for discrimination of patients with primary endpoint in lower AHEAD score groups: copeptin ($p < 0.006$ and $p < 0.004$), MR-proADM ($p < 0.008$ and $p < 0.002$). However, in the highest AHEAD score the level of these substances lost their predictive value. Higher levels of copeptin, MR-proADM might identify HF patients with higher risk of adverse outcome. Our study is the first which evaluates the predictive value of copeptin and MR-proADM over the comorbidities of patients with HF assessed by AHEAD score.

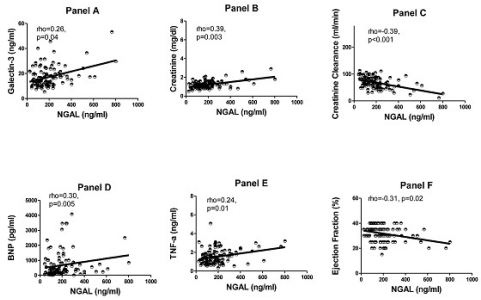
Interaction between renal and heart function in patients with heart failure: The role of NGAL

E Evagelos Oikonomou[1]; D Karlis[1]; S Tsalamandris[1]; G Siasos[1]; C Chrysohoou[1]; G Vogiatzi[1]; S Dimitropoulos[1]; G Charalambous[1]; E Kouskouni[1]; D Tousoulis[1]
[1]Hippokration Hospital, University of Athens, 1st Department of Cardiology, Athens, Greece

Background: Neutrophil gelatinase-associated lipocalin (NGAL) is a biomarker of renal injury associated with the progression of heart failure (HF). Galectin-3 is expressed in several tissues by inflammatory cells and may be used as an additive diagnostic and prognostic biomarker in patients with HF.
Purpose: To examine how NGAL levels are interrelated to Galectin-3 levels in patients with chronc HF of ischemic etiology.
Methods: We consecutive enrolled 115 subjects with stable ischemic HF of reduce ejection fraction. Serum levels of Galectin-3, b-type natriuretic peptide (BNP), NGAL and tumor necrosis factor alpha (TNFa) were measured.
Results: NGAL levels were positive correlated with Galectin-3 levels (rho = 0.26, p = 0.04), with BNP levels (rho = 0.30, p = 0.005), with TNF-a levels (rho = 0.24, p = 0.01) and inversely correlated with left ventricle ejection fraction (rho=-0.31, p = 0.02). NGAL levels were also positively correlated with Creatinine levels (rho = 0.39, p = 0.003) and inversely associated with CrCl (rho=-0.39, $p < 0.001$). After adjustment

for many confounders including age, gender, diabetes mellitus, hypertension, CrCl and BNP; logNGAL was independently associated with Galectin-3 levels [b = 0.05 95%CI (0.001 = 0.36), p = 0.04].



Figure

Conclusions: In the present study we found a positive correlation between NGAL and Galectin-3 in patients with heart failure. These findings reveal the potential association between renal injury and myocardial fibrosis and remodeling in heart failure and highlight a potential role of NGAL in the crosstalk between kidney and heart.

P1733

The importance of the NTproBNP rule-in criteria in the early diagnosis of HFmrEF and HFpEF

M Marta Szabo[1]; B Muk[1]; ZS Majoros[1]; D Vagany[1]; K Kosa[1]; T Borsanyi[1]; M Dekany[1]; RG Kiss[1]; N Nyolczas[1]
[1]*Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary*

Background: In patients with acute dyspnoea, early diagnosis may reduce the duration of hospitalization, the probability of rehospitalization, and costs. In patients with left ventricular ejection fraction (LVEF) < 40% the diagnosis of heart failure (HF) can be accepted as proven. In case of LVEF = 40%, further examinations are necessary to confirm or exclude HF. In the current ESC guideline for HF, diagnostic criteria for HF with mid-range EF (HFmrEF; 40% = EF < 50%) and HF with preserved EF (HFpEF; EF = 50%) are the typical clinical signs and symptoms, specific values of LVEF, elevated natriuretic peptide levels, and structural heart disease (left ventricular hypertrophy and/or left atrial enlargement) and/or diastolic dysfunction (SHD/DD). In the ESC guideline the 300 pg/ml value of NTproBNP is the diagnostic cut-off value for rule-out in acute HF. The guideline of the Canadian Cardiovascular Society for HF determines age specific diagnostic rule-in NTproBNP criteria, according to the results of the ICON study (under 50 years >450 pg/ml, between 50 and 75 years >900 pg/ml, over 75 years >1800 pg/ml).
Purpose: The aim of the study was to evaluate the diagnostic importance, sensitivity, specificity, negative and positive predictive value of the NTproBNP rule-in criteria in the early diagnosis of HFmrEF and HFpEF.
Patients and **Methods:** We assessed the data of 207 patients (mean age: 76.5 ± 0.7 years, men: 61.4%, NYHA: 3.25 ± 0.35, ischemic etiology: 48.6%) with signs and symptoms of HF who had not been treated for HF previously and were referred to our hospital between 01.12.2015. and 30.11.2017. Echocardiography and NTproBNP measurement were performed in every case. Patients with atrial fibrillation, renal failure (GFR < 60 ml/min/1,73m2) and obesity (BMI>30 kg/m2) were excluded.
Results: By using the ESC rule-out criteria, HF was excluded in 56 cases. In the remaining 151 patients (72.9%) SHD/DD could be proved in 131 patients and HF was excluded in 20 patients. NTproBNP rule-in criteria were not met in any of these 20 patients. In the 131 patients with SHD/DD, rule-in criteria were met in 75 patients. In the HFmrEF and HFpEF patients diagnosed by the ESC criteria, the sensitivity of the NTproBNP rule-in criteria was 57.3%, specificity was 100%, negative predictive value was 26.3% and positive predictive value was 100%. When using both rule-in and rule-out NTproBNP criteria, HF could be excluded in 27.1%, the diagnosis could be confirmed in 36.2% with an easy laboratory examination, and time-consuming echocardiography for SHD/DD assessment is needed only in 36.7% of the patients.
Conclusion: Based on our findings, it appears that NTproBNP rule-in criteria reliably select HF patients in the LVEF = 40% patient population. In addition to the NTproBNP rule-out criteria, the use of rule-in criteria can significantly reduce the need for time-consuming SHD/DD assessment and thus shorten the time until the appropriate diagnosis is established.

P1734

Biological markers of endothelial dysfunction in patients with heart failure.

G A Gayane Shakaryants[1]; MV Kozhevnikova[1]; VY Kaplunova[1]; IS Ilgisonis[1]; AO Iusupova[1]; EA Zheleznikh[1]; JA Danilogorskaya[1]; EV Babayan[1]; ES Koniaeva[1]; VA Shakaryants[1]; EV Privalova[1]; YUN Belenkov[1]; NV Khabarova[1]
[1]*I.M. Sechenov First Moscow Medical State University, Moscow, Russian Federation*

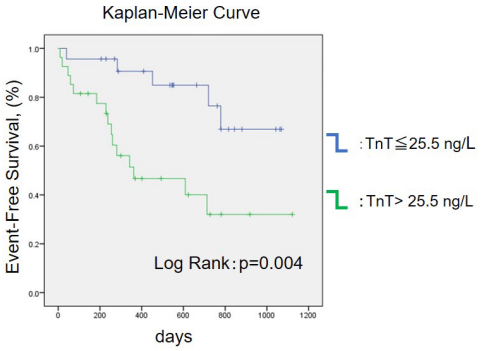
Background: the study was aimed to compare the level of biomarkers of endothelial dysfunction (endothelin-1 and E-selectin) in patients with heart failure (HF) as a result of ischemic heart disease and patients with coronary artery disease (CAD).
Patients and methods : We included 90 patients with CAD: 1) 40 patients with HF (the average 65,78 ± 8.79 years, women 16,EF 47,9 ± 7,16) 2) 50 patients without signs of HF (the average 65.31 ± 7.22 years, women 10, EF 59.23 ± 5.06). Among patients of the first group 17 persons (42,5%) have preserved ejection fraction (HFpEF), 16 persons (40%) with mid-range (HFmrEF) and 7 (17,5 %) - reduced ejection fraction (HFrEF). Diabetes mellitus type 2 (DM) was in 43 examined. The markers of endothelial dysfunction were assessed: E-selectin and endothelin-1 - by ELISA. We assessed endothelial function of large vessels (phase shear (PS, ms) and microcirculation (occlusion index (IO)).
Results: In patients with HF, the level of endothelin-1 was 0.86 fmol/L [0.41;1.3] significantly higher compared to the control group 0.87 [0.47; 1.28] p = 0.07. The same results were obtained for E-selectin: the level of the marker in the HF group was 48.37 ng/ml [40.77; 55.97] compared with the level 33.07 ng/ml [26.07, 40.06], p = 0.001 in the group with only CAD. There was a tendency for differences in the levels of E-selectin in subgroups of patients with HF (HFpEF 60.4 ng/ml [47.29, 73.51] HFmrEF 40.21 ng/ml [27.1, 53.32], HFrEF 39.51 ng/ml [19.69, 59.33] p = 0.066). Differences in endothelin-1 levels in patients with different variants of HF were not detected. There were not differences in levels of biomarkers in patients with and without DM. Strong positive correlation was revealed between the E-selectin level and the EF (r = 0.16, p <0.012), the negative correlation - endothelin-1 and EF (r = -0.35, p = 0.000). IO was decreased in both groups, perhaps in HF group it was significantly lower (1,45 ± 0,08) than in controls (1,6 ± 0.07) p = 0,003. Negative correlation was revealed between the E-selectin level and the IO (r = -0.4, p <0.05), and positive correlation between endothelin-1 and PS (r = 0.48, p = 0.05).
Conclusions: : 1) Significant increase in the levels of endothelin-1 and E-selectin in patients with CHF compared with the control group, which indicates an endothelial dysfunction, were found. 2) We obtained significant differences in the level of E-selectin in patients with HFpEF and HFrEF. 3) The levels of the endothelial dysfunction markers are interrelated with the ejection fraction.4) There was no significant difference in biological markers parameters between groups of patients with HF associated with diabetes mellitus type 2 and in patients with isolated HF

P1735

Prognostic significance of troponin t in patients with heart failure with preserved ejection fraction

S Suzuki[1]; H Motoki[1]; M Minamisawa[1]; Y Okuma[1]; W Shoin[1]; T Okano[1]; K Kimura[1]; S Ebisawa[1]; A Okada[1]; K Kuwahara[1]
[1]*Shinshu University Hospital, Matsumoto, Japan*

Background: Although several studies have demonstrated an association between elevated Troponin T (TnT) levels and risks of adverse clinical outcomes among patients with Heart Faliure with reduced Ejection Fraction (HFrEF), prognostic significance of TnT in Heart Failure with preserved Ejection Fraction (HFpEF) is not well established.
Purpose: To investigate the prognostic significance of TnT in patients hospitalized for decompensated HFpEF.
Methods: In consecutive 155 patients hospitalized for Heart Failure (HF), we evaluated TnT levels at discharge. All cause Death, non-fatal myocardial infarction, stroke, and HF hospitalization were prospectively followed up for median 449 [260-780] days.
Results: In our study cohort (age 76 [67-84] years, EF 45 ± 16%), major adverse cardiac events (MACE) were observed in 63 patients. TnT was significantly higher in patients with MACE in both HFpEF (36 [22, 66] ng/L vs 21 [14, 32] ng/L, p = 0.002, n = 64) and HFrEF (40 [29, 71] ng/L vs 27 [15, 56] ng/L, p = 0.021, n = 91) subgroups. TnT correlated with age, estimated glomerular filtration rate (eGFR), and B-type natriuretic peptide (BNP) levels. In Kaplan-Meier analysis, higher TnT group showed worse prognosis in both HFpEF (Figure, p = 0.004) and HFrEF (p = 0.010). In multiple Cox regression analysis, TnT level was an independent predictor for MACE (p = 0.004) after adjusting for age and eGFR (HR 1.018 [95% CI 1.005-1.032], p = 0.006), and age and BNP (HR 1.022 [95% CI 1.008-1.035], p = 0.001) in HFpEF population.
Conclusions: Elevated TnT levels were associated with MACE in patients not only with HFrEF but also HFpEF.



Kaplan Meier Curve (HFpEF)

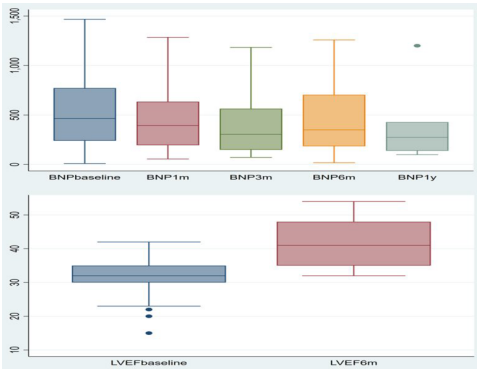
Sacubitril-valsartan and BNP: Will they live happily ever after?

M Abellas-Sequeiros[1]; J M Vieitez Florez[1]; A Lorente[1]; G Alonso[1]; S Del Prado[1]; J M Del Rey[1]; J L Zamorano[1]
[1]*University Hospital Ramon y Cajal de Madrid, Madrid, Spain*

Introduction: After publication of the PARADIGM-HF trial, sacubitril/valsartan has been included in ESC Guidelines for the treatment of chronic heart failure. It is thought that sacubitril inhibits neprilysin, slowing down BNP degradation and rising its levels, but not NT-proBNP levels. That is the reason to recommend an NT-proBNP based monitoring. However, does this mean BNP is no longer useful during the follow-up of patients? Is it trustworthy in the acute setting?
Methods: To describe the evolution of BNP in that context, a series of patients with HFrEF who initiated LCZ696 was prospectively assessed. Clinical characteristics, aetiology, functional class and admissions were evaluated. BNP was analysed before treatment, in the first, third, sixth month and 1 year after treatment, just like in-hospital admission.
Results: Fifty-one patients with HFrEF receiving sacubitril/valsartan were included; mean age was 73 years old; 45 (88%) patients were men and 49% had ischaemic etiology. Mean LVEF was 32% and median estimated glomerular filtration rate was 60 ml/min. Regarding to OMT: 100% were on ACE-I, 89% beta-blocker and 81% MR antagonist; 33% had CRT and 35% an ICD. LCZ696 was discontinued in 9 patients (4 of them because of renal dysfunction; 1 hyperkalemia; 2 hypotension and the others because of economic trouble). One patient died during the follow up.
BNP levels were compared before and after the initiation of treatment with LCZ696 using nonparametric Wilcoxon signed-rank test. LCZ696 does not significantly rise BNP levels, as opposite, there was a tendency to lower levels in the long-term follow-up.
In acute decompensation BNP rises significantly in patients treated with a neprilysin inhibitor (p = 0,01), decreasing afterwards, resembling the biological response in the context of decompensation without sacubitril/valsartan.
Conclusions:
BNP could be still an applicable biomarker, not only in the acute setting, but also in clinically stable patients. We hypothesized that this tendency to lower BNP blood level, as NT-proBNP does, might be related to a decreased of parietal stress in context of heart failure improvement, as we described in that cohort, but more studies are needed to confirm it.

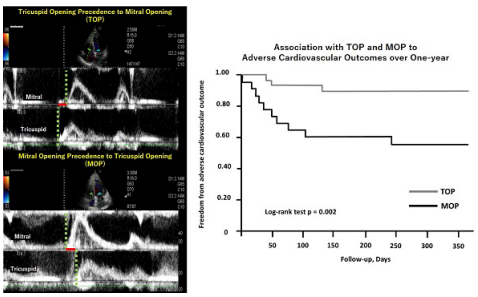


P1737

Time interval between mitral and tricuspid opening has prognostic value in patients with heart failure

M Sugahara[1]; M Asakura[1]; A Goda[1]; K Masai[1]; A Daimon[1]; T Masuyama[1]
[1]*Hyogo College of Medicine, Nishinomiya, Japan*

Background: There are no doubts about the values of comprehensive noninvasive assessment of LV and RV hemodynamics in the management of patients with heart failure (HF), the values have been hampered by methodological limitations. Dual Doppler echocardiography was used to overcome the limitations by measuring time interval between the mitral and tricuspid valve opening (MO-TO time) in a real-time fashion.
Purpose: We assessed hemodynamic correlates and prognostic value of MO-TO time in patients with HF.
Methods: We prospectively enrolled 60 patients with HF and sinus rhythm. MO-TO time was measured in addition to routine echo parameters, invasive hemodynamic parameters and plasma BNP level in all patients. Patients were divided into either of two groups based on the MO-TO time: MOP (MO precedence to TO), and TOP (TO precedence to MO) groups. We followed up the predefined adverse outcome, cardiovascular death and hospitalization due to worsening HF in all patients for a year.
Results: Pulmonary artery wedge pressure (PAWP) was higher in the MOP group than in the TOP group (21 ± 8.5 vs. 11 ± 4.5 mmHg, $p < 0.001$). PAWP correlated with MO-TO time ($r = -0.74$, $p < 0.001$). MOP had a high probability of adverse cardiovascular outcome (Log-rank test; $p = 0.002$). In univariate Cox analysis, mitral E/A ratio, BNP, and MO-TO time were significant predictors ($p = 0.044$, $p = 0.019$, and $p = 0.012$), respectively. An addition of MOP improved the predictive power of univariate predictors (mitral E/A ratio, BNP) in the bivariate Cox analysis.
Conclusions: MOP reflects pulmonary hypertension due to left heart disease and has a prognostic value in predicting adverse cardiovascular events in patients with HF.



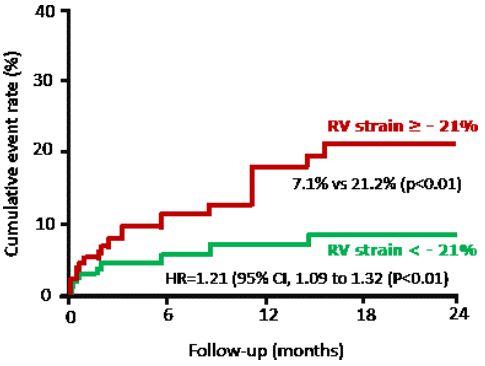
P1738

Right ventricular-2 dimensional strain as a prognostic factor in patients with dilated cardiomyopathy

IH Jung[1]; JH Park[1]; KS Kim[1]
[1]*Inje University, Seoul, Korea Republic of*

Funding Acknowledgements: Hanmi Pharm.Co.,Ltd.

Background: Several studies reported that systolic function of right ventricle (RV) influence the prognosis of patients with heart failure (HF). The aim of this study is to investigate the role of RV-2D strain as a prognostic factor for adverse events in patients with dilated cardiomyopathy (DCMP).



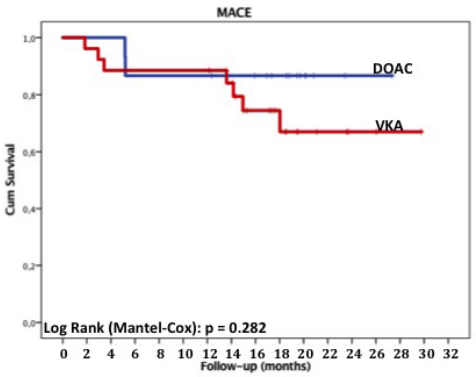
Cumulative incidence of adverse event

Methods: We reviewed medical records and analyzed echocardiographic data of 89 patients who had been newly diagnosed and registered the list of dilated cardiomyopathy at our institute from January 2015 to March 2016. Enrolled patients had been performed echocardiography annually according to our study protocol and the occurrence of adverse events including death, hospitalization, atrial fibrillation and fatal arrhythmia were noticed.
Results: The mean age of study population was 53 ± 17 years including 68 male patients (76.4%) and they have LVEF of 26 ± 10%. There was none of death during the follow-up period (mean 19 ± 7 months). Eleven patients (12.3%) presented with hospitalization for worsening HF. Atrial fibrillation newly occurred in 4 patients (4.5%) but fatal arrhythmia was none. Tricuspid annular plane systolic excursion (TAPSE), fractional area change of RV (FAC) and RV strain were related to adverse prognosis by Cox univariate analysis. However, mulivariate analysis showed that FAC and RV strain were independent predictors. FAC and RV strain demonstrated HRs of 0.92 (95% CI, 0.89 to 0.96; p < 0.01) and 1.21 (95% CI, 1.09 to 1.32; p < 0.01). Patients divided in RV strain < - 21% (n = 56) and -21% (n = 33) demonstrated a 2-year event rate at of 7.1% and 21.2% (p < 0.01).
Conclusion: This study demonstrated that RV strain would be a strong prognostic factor with other representing values of RV function including TAPSE and FAC in patients with DCMP.

P1739
The clinical impact of intraventricular thrombi

A Nunes-Ferreira[1]; R Santos[1]; JR Agostinho[1]; T Rodrigues[1]; N Cunha[1]; J Rigueira[1]; I Santos Goncalves[1]; I Aguiar-Ricardo[1]; T Guimaraes[1]; R Placido[1]; C David[1]; FJ Pinto[1]; AG Almeida[1]
[1]*Cardiology Department, Santa Maria Hospital, CHLN, CCUL, Lisbon University, Lisbon, Portugal*

Introduction: The occurrence of intracardiac thrombi is a condition of increasing clinical significance due to its frequency, potential embolic complications and scarce clinical evidence regarding optimal therapy. The impact on cardiovascular prognosis also remains uncertain.
Objective: Evaluate the impact of the presence of left intraventricular thrombus (LVT) on cardiovascular prognosis.
Methods: Retrospective unicentric study with the inclusion of all patients with echocardiographic diagnosis of LVT during 2016. Clinical, echocardiographic, therapeutic and follow-up data were collected. Predictors of major cardiovascular events (MACE) - acute myocardial infarction (AMI), stroke/transient ischemic attack (TIA), peripheral embolism and death were determined through multivariate Cox regression and Kaplan-Meier survival analysis.



Anticoagulation regimen in LVT

Results: We identified 48 patients (85% men, age 63 ± 13 years) with the diagnosis of LVT; 77% with ischemic heart disease. The mean left ventricular ejection fraction (LVEF) was 32.5 ± 9.2%; LV telediastolic volume 94 ± 41.4 mL; presence of apical aneurysm in 58% and segmental alterations in another location in 27%. 85% of patients had apical thrombus and 15% had another LV location. In 29% the thrombus was diagnosed during an episode of AMI. Mortality during follow-up was 14.6% (7.1 + 5.5 months). There was an association of MACE with age > 65 years (p = 0.01), presence of apical aneurysm (p = 0.02), creatinine > 1.9 (p = 0.004) and previous stroke / TIA (p = 0.024). In the multivariate analysis, age > 65 (p = 0.011, HR = 11.97 CI 95% 1.77-80.16) was the only independent predictor of MACE. On the other hand, the absence of previous stroke / TIA was a protective factor of MACE (p = 0.006, HR 0.16 95% CI 0.015-0.487). Regarding the anticoagulation strategy, direct oral anticoagulant (DOAC) therapy was not associated with an increased incidence of MACE (p = NS), with no difference between this strategy and vitamin K antagonists (VKA, p = NS).
Conclusion: In this study, in which the majority of the sample was anticoagulated, the independent predictors of the occurrence of MACE identified were age > 65 years and history of stroke / TIA. Although there is no evidence to support the safety of anticoagulation strategy with DOAC in the context of LVT, this strategy was not associated with a higher incidence of MACE when compared to vitamin K antagonists. Large randomized clinical trials are necessary to confirm these results.

P1740
Appearance of L wave Predicts the change of Left Ventricular and the Poor Outcome

K Kumiko Masai[1]; A Goda[1]; M Sugahara[1]; A Daimon[1]; M Asakura[1]; T Masuyama[1]
[1]*Hyogo College of Medicine, cardiovascular, Nishinomiya, Japan*

Background: L wave is easily recorded as mid-diastolic mitral forward flow with conventional Doppler echocardiography. L wave is occasionally detected in heart failure (HF) patients but its mechanism to produce L wave and the prognostic value is still unknown.
The aim of this study is to clarify the related factors of L wave in patients of HF with preserved ejection fraction (HFPEF) and reduced ejection fraction (HFREF) and the prognostic impacts of L wave in HF patients.
Methods and **Results:** One hundred fifty one HF patients were enrolled (HFREF: 82, HFPEF: 69). Both in HFPEF and HEREF, transmitral E velocity (E), E to mitral annulus velocity ratio and Left atrial volume index were higher with L wave than in those without L wave. Relative wall thickness (RWT) was lower in HFREF with L wave than those without L wave (0.26 ± 0.07 vs 0.30 ± 08). Meanwhile, in HFPEF patients, RWT was higher in patients with L wave than those without L wave (0.42 ± 0.07 vs 0.39 ± 0.07). Kaplan-Meier survival curve revealed that the patients with L wave demonstrated significant poorer prognosis compared those without L wave in HF patients (P < 0.05).
Conclusion: L wave is associated with LV diastolic dysfunction and LV geometry. Also L wave has potentially predicting value for the prognosis in patients of HF.

Echocardiographic characteristics

	ALL	HFpEF	HFrEF

Background: beta-thalassemia major is a genetic disease that makes the patient dependent to blood transfusion so iron overload is common in these patients. Defining a reliable and feasible modality to assess iron overload in initial steps

can lower the chance of cardiomyopathy.In this study we tried to to find a reliable echocardiography index and cut of point to assess iron overload.
Methods:A cross sectional study was conducted from June 2016 to May 2017. Demographic features physical findings and Para clinic tests including CBC test and serum ferritin were gathered. All the patients underwent standard T2* CMR and Tissue Doppler Imaging (TDI) echocardiography. We used inter-evaluator agreement method to omit the biases .Patients were categorized in three classifications: Those with T2*>20ms as negative iron overload, 20ms>T2*>10ms as moderate and T2* < 10ms as sever iron overload. Echocardiography findings were compared in groups. Result:44 patients enrolled , 23 (52.35%) were male and 21 (47.7%) were female. Patients with hypertension, Rheumatic heart disease and cardiac disorders were excluded. Only one patient was diabetic. All the patients received chelator drugs. There was a significant difference in left ventricular global longitudinal strain average in positive or negative iron overload groups.(LV GLS average, p = 0.012).The cutoff point of -17.5 in LV GLS had a specificity of 100% and sensitivity of 43.8% in defining iron overload. Also in case of detecting severity between moderate and sever iron overload, LV GLS average (p < 0.001), left ventricular end diastolic volume index (LVEDI, p = 0.016), left ventricular end systolic index (LVESI, p = 0.016), and S velocity of tricuspid valve (p = 0.32) showed significant difference between the two groups.
Conclusion: LV GLS average may be used as a specific and somehow sensitive echocardiography parameter for detection of iron overload.
Keywords: left ventricular global longitudinal strain, major thalassemia, CMR T*, Iron overload

Table 1

Specificity	Sensitivity	Cut point
32%	68.8%	-20.5
40.5%	62.5%	-19.5
100%	43.8%	-17.5
100%	25%	-16.5
100%	6.2%	-15

specificity, sensitivity, and cut point of GLS echocardiography

Introduction: Due to its high potential there is growing demand for the application of ultra-high field (B0 = 7T) scanners in cardiovascular magnetic resonance (CMR) imaging, although technical challenges increase significantly with the static magnetic field strength. For evaluation and follow-up of patients with cardiovascular disease, ventricular morphology and function are important clinical parameters, which can be assessed non-invasively and comprehensively using CMR. First studies have shown a high level of agreement for ventricular volumetric parameters measured at 7T and routine clinical field strengths. Another fast way of obtaining basic hemodynamic parameters is 2D phase contrast CMR, which can be used to measure blood flow in the ascending aorta. In the absence of valve disease, the aortic forward flow should resemble the left ventricular stroke volume. However, to date flow parameters in the ascending aorta based on 2D phase contrast measurements at 7T have not yet been validated.

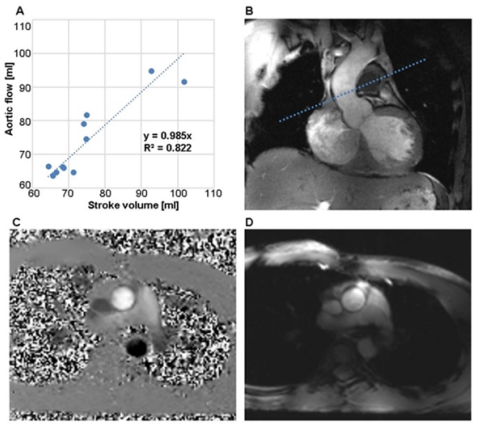

Figure 1 (A) Positive correlation between aortic forward flow determined by phase contrast imaging and stroke volume derived from CINE images. (B) Exemplary plane used for acquisition of phase contrast measurements at 7T (dotted blue line). (C) and (D) Phase contrast velocity and magnitude images at 7T, respectively.

Purpose: To assess the agreement between parameters of cardiac function derived from 2D phase contrast measurements in the ascending aorta and left ventricular short axis gradient-echo (GRE) CINE pulse sequences at 7T in healthy subjects.
Methods: 11 healthy volunteers (6 female, 5 male) were scanned using a 1TX/16RX thorax coil. Mean subject age was 27.3 years (range 22-39), and body weight 67.6 kg (range 52-92 kg). For triggering both the integrated ECG (n = 6) and an external acoustic triggering (n = 5) system were used. Sequence parameters for the short axis GRE CINE stack were TE = 3.57 ms, TR = 30.6-88.3 ms, voxel size 0.6x0.6x6.0 mm, segments 6-11, phases 20-35, slices 14-17. The parameters for the phase contrast sequence were TE = 98.9 ms, TR = 3.2 ms, voxel size 1.5x1.5x6.0 mm, segments 7-9, phases 20-25, VENC = 150 m/s. Volumetric and flow analyses were performed on an integrated scanner-side software. Agreement between stroke volume und aortic forward flow was analysed using the Pearson correlation coefficient and a two-sided t-test.
Results: Mean left ventricular stroke volume determined by CINE sequences was 74.9 ml (standard deviation (SD) 11.3 ml) and mean forward flow in the ascending aorta based on phase contrast imaging was 73.9 ml (SD 10.8 ml), showing no significant difference (p = 0.52) and a strong positive correlation (r = 0.91) (Figure 1).
Conclusion: We found a high level of agreement between stroke volume based on short axis GRE CINE sequences and aortic forward flow derived from 2D phase contrast imaging at 7T. This suggests that phase contrast CMR at 7T can correctly quantify ascending aortic flow and thus may play an important role in potential future clinical assessment of valve disease and cardiac function at 7T. However, a larger patient sample, in particular of patients with cardiac disease is essential for improving clinical acceptance. Moreover, validation against flow parameters acquired at routine clinical field strengths is necessary.

P1743

Relationship between myocardial viability and development of chronic heart failure in patients after ST elevation myocardial infarction

M Mirmaksudov[1]; S Kenjaev[2]; A Alyavi[1]; SH Turg'unboyev[1]; ML Kenjayev[3]; R Saydaliyev[1]
[1]Tashkent Medical Academy, 2nd department of hospital and facultative therapy, Tashkent, Uzbekistan; *[2]Republican Research Center of Emergency Medicine, Tashkent, Uzbekistan*; *[3]Bukhara branch of Republican Research Center of Emergency Medicine, Bukhara, Uzbekistan*

Background: Myocardial infarction (MI) is remaining the most common cause of heart failure (HF) worldwide. The presence of a viable myocardium in the damage area after adequate reperfusion prevents development of severe LV dysfunction and chronic heart failure(CHF).
Purpose: to study the relationship between identifying the myocardial viability of the left ventricle and the development of heart failure in patients after ST segment elevation myocardial infarction(STEMI).
Methods. 134 patients with STEMI of anterior wall were examined. The average age is 61 ± 5,3 year. Successful PCI was performed in all patients within maximum 12 hours. All patients initially underwent transthoracic echocardiography. In all patients, average LVEF was 45 ± 4,2%. All patients underwent low dose dobutamine stress echocardiography for verifying the myocardial viability (in 2-3th days). Depending on the results of low dose dobutamine stress echocardiography, the patients were divided into 2 groups. The 1st group comprised 78 patients (58,2%) with viable myocardium, the 2nd group of 56 patients (41,8%) without viable myocardium. A follow-up examination of the patients was carried out after 3 months.
Results: In our study, low dose dobutamine stress echocardiography didn't cause any complication in acute period of disease. The average value of LVEF in the first group with the introduction of low dose of dobutamine significantly increased to 52 ± 4,3%, while in the second group it practically did not change. After 3 months, as suggested by the results of low dose dobutamine stress echocardiography in the first group, LVEF was improved to 51+3,9% and in the second group LVEF decreased to 42 ± 2,3%. Among the patients of the first group, in the third month, Class I HF (NYHA) was observed in 67 patients (85,9%) and Class II HF in 11 patients (14,1%). Among patients of the second group, Class I HF developed in 19 patients (33,9%), Class II HF in 21 patients (37,5%), Class III HF in 10 patients (17,8%). In 2 patients (3,6%) developed Class IV HF. In the 2nd group, 1 (1,8%) fatal outcome was identified.
Conclusions: Thus, the presence of myocardial viability after MI, determines the improvement of global contractile function of the left ventricle after 3 months. The

absence of myocardial viability in patients after STEMI is an important predictor of the development of severe HF classes and death in our followed-up patients.

Funding Acknowledgements: Grant of the President of the Russia Federation

Background: Cardiac sympathetic activity dysfunction has a huge impact on the development of dilated cardiomyopathy. Radionuclide assessment of cardiac sympathetic activity and ventricular dyssynchrony may help to develop new predictors of dilated cardiomyopathy treatment efficacy.
Purpose: Aim of this study was to evaluate the relationship between cardiac sympathetic activity and global contractile function in patients with dilated cardiomyopathy before cardiac resynchronization therapy.
Methods: The study comprised 32 patients (mean age of 66 ± 11 years) with chronic heart failure (NYHA III) due to dilated cardiomyopathy. All patients underwent 123I-MIBG imaging and gated blood-pool SPECT (GBPS). Systolic and diastolic functions (EDV, ESV, and EF) as well as mechanical intraventricular dyssynchrony both for the left (LV) and the right ventricles (RV) were analyzed. Late Heart to mediastinum ratio (H/M) as well as 123I-MIBG washout rate (WR) were calculated. All examinations were performed using GE Discovery NM/CT 570C with cadmium-zinc-telluride detectors.
Results: According to GBPS data in all patients the LV and RV dilatation and contractility impairment were revealed. The main parameters of cardiac volumes were the following: LV_EDV 291 ml (237-388 ml); LV_EF 24% (20-32%); LV peak ejection rate (PER) 0,89 EDV/s (0,75-1,39 EDV/s); RV_EDV 176 ml (132-217 ml); RV_EF 39% (19-54%); RV_PER 1,81 EDV/s (0,75-1,38 EDV/s). Moreover, severe mechanical dyssynchrony of both ventricles was detected: LV intraventricular dyssynchrony - 119 ms (91-161 ms); RV intraventricular dyssynchrony - 102 ms (77-161ms); interventricular dyssynchrony - 66 ms (37-92 ms). According to 123I-MIBG imaging median values of late H/M was 1,6 (1,43-2,13), median value of 123I-MIBG WR was 24% (18-29%).
The correlation between the cardiac sympathetic activity and contractile indexes of both ventricles was found out: H/M and LV_EDV (r=-0,54; p = 0,05), H/M and LV_ESV (r=-0,49; p = 0,05), H/M and RV_EDV (r = 0,39; p = 0,05), H/M and LV intraventricular dyssynchrony (r = 0,39; p = 0,05). The 123I-MIBG washout rate correlated with: LV_EDV (r = 0,47; p = 0,05), LV_ESV (r = 0,41; p = 0,05), RV_EF (r = 0,40; p = 0,05), RV PER (r=-0,42; p = 0,05).
Conclusion: In patients with dilated cardiomyopathy the relationship between cardiac sympathetic activity and contractile function was found out. These data may be used in the follow-up study after CRT device implantation in order to develop new predictors of CRT outcomes.

P1745

The first and last echocardiographic examination in patients with chronic heart failure; experience from a single outpatient clinic

V Arva[1]; I Krajnc[2]; FH Naji[2]
[1]Faculty of Medicine, University of Maribor, Maribor, Slovenia; *[2]University Medical Centre Maribor, Department of Cardiology and Angiology, Maribor, Slovenia*

Background: In patients with chronic heart failure echocardiographic examinations are routine procedures used to confirm the diagnosis of heart failure (HF) and to evaluate heart function. Left ventricular ejection fraction (EF) is one of the most basic echocardiographic parameters measured in patients with HF and clinicians rely on it heavily. The course of HF may be very heterogeneous. It is often nonlinear, with many fluctuations. It is probable that different pathophysiological processes play a different role in HF subgroups.
Purpose: Aim of this study was to examine the possible connection between basic echocardiographic measurements and the duration of HF in patients with chronic HF, managed in an outpatient clinic. We used data from the first echocardiographic examination at the beginning of HF, and their last examination before their death.
Methods: This is a retrospective study from a single outpatient clinic for chronic HF. Inclusion criteria were clinically confirmed diagnosis of HF, and a known cause of death. Due to a small number of patients with HFpEF only HFrEF and HFmrEF patients were included. Patients were treated according to the current standard guidelines. Ultrasound measurements included LVEDD, RVEDD, LA, mitral and tricuspid regurgitation grade, diastolic dysfunction, tricuspid gradient, EF, and a composite parameter of LVEDD and EF. We also analysed the differences between the first and the last measurement and the association between different measurements and the duration of heart failure.
Results: The study included 97 patients with HF. The average age was 67.5 ± 12.1 years and 81 (83.5%) patients were male. The average duration of heart failure was 7.1 ± 4.5 years. Ischemic aetiology was found in 52 patients (53.6%). Cardiovascular cause of death was found in 72 patients (74.2%). On the initial ultrasound, the mean LVEDD was 60.5 ± 9.2 mm, LA 45.4 ± 8.0 mm, and EF 29.7 ± 10.5 %. On their last examination mean LVEDD was 60.5 ± 10.6 mm, LA 48.7 ± 9.4 mm and EF 26.8 ± 12.3 %. The composite parameter (LVEDD x EF) in the initial measurement was 17.5 ± 6.1 mm, and 15.4 ± 5.7 on the last.
There was a correlation between the duration of HF and the initial EF (0.26 p = 0.017) and while the correlation was not significant with LVEDD, we observed a significant correlation for the composite parameter LVEDD x EF (0.35 p = 0.001). In the group of patients that died from cardiovascular causes, the correlation was accentuated (EF: 0.39 p = 0.002; composite parameter: 0.41 p = 0.001). There was no significant association between the measurements from the last examination and the duration of HF.
Conclusion: Our study shows that the initial, but not the last echocardiographic measurements can provide important prognostic factors for the duration of HF. EF, while important, can be overemphasised, and even the simple composite parameter of LVEDD and EF showed a better fit, suggesting that a more complex picture must be taken into account.

P1746

The prognostic significance of the 12-lead ECG in peripartum cardiomyopathy

J Hoevelmann[1]; CA Viljoen[2]; J Baard[1]; K Manning[3]; J Bauersachs[4]; K Sliwa[1]
[1]University of Cape Town, Hatter Institute for Cardiovascular Research in Africa, Cape Town, South Africa; *[2]University of Cape Town, Division of Cardiology, Cape Town, South Africa*; *[3]University of Cape Town, Department of Medicine, Cape Town, South Africa*; *[4]Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany*

Background: Peripartum cardiomyopathy (PPCM) is defined as heart failure secondary to left ventricular (LV) systolic dysfunction, which develops in previously healthy women towards the end of pregnancy or up to five months following delivery. PPCM contributes significantly to maternal morbidity and mortality, with only 23 to 54% of patients having full LV recovery at 6 months. The degree of systolic dysfunction and ventricular dilatation on echocardiography have previously been reported as predictors of poor outcome in PPCM. However, it remains elusive whether any features on the electrocardiogram (ECG) have a prognostic value in this condition.
Purpose: We aimed to assess the predictive utility of the ECG in the long-term outcome of PPCM.
Methods: 12-lead ECGs of women with PPCM were analysed at index presentation, and at 6 and 12 months follow-up. Poor outcome was determined by the combined endpoint of death, rehospitalisation, NYHA class III/IV or left ventricular ejection fraction (LVEF) < 35% at follow up.
Results: This cohort of 59 patients with PPCM (median age 28.68, IQR 25.69-31.71) presented with a median LVEF of 33% (IQR 25-40), which improved to 46% at 6 months (P < 0.001) and 54% at 1 year (P = 0.001). 30.77% and 37.93% of patients had a poor outcome at 6 and 12 months respectively. The median heart rate was 87bpm (IQR 71-102) at baseline. Initial sinus tachycardia (<100bpm) was associated with poor outcome at 6 months (OR 7, 95% CI 1.55-31.52, P = 0.011) and 1 year (OR 9.33, 95% CI 1.65-52.68, P = 0.011). The median QRS width was 82ms (IQR 78-88). Only 3 patients presented with left bundle branch block. Fragmented QRS and pathological Q waves did not predict poor outcome. Poor R wave progression (R/S ratio < 1 in V4), which declined from 46.2% at baseline to 26.9% after 1 year (P = 0.019), had no prognostic value. While 17 patients met Sokolow-Lyon criteria for left ventricular hypertrophy (LVH) on ECG, echocardiography showed LVH in only 1 patient (PPV 0, NPV 97%). T wave inversion was often encountered at baseline (69%), but tended to resolve with time (56% at 6 months, P = 0.527; 44% at 12 months, P = 0.02). T wave inversion in any lead was associated with LVEF < 35% at presentation (OR 5.45, 95% CI 1.64-18.09, P = 0.006), but did not predict poor long-term outcome. The baseline median QTc interval (454ms, IQR 427-471) reduced significantly within 1 year (426ms, IQR 411-454, P = 0.001). An initial prolonged QTc interval (<460ms) predicted poor outcome at 6 months (OR 10, 95% CI 1.8-55.63, P = 0.009). On multivariate logistic regression analysis, prolonged QTc and sinus tachycardia at baseline were independent predictors of poor outcome at 6 months (OR 14.58, 95% CI 1.41-150.74, P = 0.025) and 1 year (OR 24.38, 95% CI 1.44-410.43, P = 0.028) respectively.
Conclusions: Sinus tachycardia and prolonged QTc at baseline are predictors of poor long-term outcome in PPCM. T wave inversion is associated with an initial LVEF < 35%, but does not predict long-term outcome.

P1747

Plasma clusterin but not neprilysin levels are associated with ischemic acute myocardial injury

D Traxler-Weidenauer[1]; M Gyongyosi[1]; J Winkler[1]; K Zlabinger[1]; A Gugerell[1]; M Riesenhuber[1]; C Mueller[1]; D Lukovic[1]; N Pavo[1]
[1]*Medical University of Vienna, Division of Cardiology, Vienna, Austria*

Background: Currently a variety of biomarkers, e.g. plasma neprilysin (NEP), clusterin (CLU), neutrophil gelatinase-associated lipocalin (NGAL), endothelin-1 (ET1) and osteopontin, are under thorough investigation as cardiac biomarkers for prognosis and diagnosis in the setting of ischemic myocardial infarction (MI) and cardiac remodeling as a consequence of MI.
Purpose: The aim of this study was to assess suitability of the above-mentioned biomarkers in a porcine model of acute MI and correlate them with cardiac magnetic resonance imaging (cMRI) parameters.
Methods: A total of 24 pigs underwent MI induced by 90min percutaneous balloon occlusion of the mid left anterior descending coronary artery (LAD). cMRI was performed at day 3 and after 6 weeks to assess infarction size, left ventricular end-systolic volume (LVESV), left ventricular end-diastolic volume (LVEDV) and left ventricular ejection fraction (LVEF). NEP and CLU concentrations as well as other cardiac biomarkers (NT-proBNP, NGAL, ET1, osteopontin, troponin I) were measured by ELISA and miRNA21 and miRNA29 through rtPCR during the acute and subacute phase of MI. Troponin I and cMRI were used to validate our porcine MI model. Furthermore NT-proBNP was assessed as a heart failure marker. The course of biomarkers and correlations with cMRI parameters were investigated.
Results: The area at risk was 16.4% of LV at day 3 after acute MI and was accompanied by a depressed LV function (LVEF = 36.1%). LVEF remained depressed (39.5%) with signs of adverse remodeling reflected by increased LVESV (93.9ml) and LVEDV (153.5ml) during the 6-week follow-up period. Further NT-proBNP levels were significantly increased after 3 weeks (pre vs. 3 weeks: 112.3 vs. 189.9 pg/ml, $p = 0.03$). Plasma levels of NGAL (pre vs. 3 weeks: 122.7 vs. 224.1 pg/ml, $p < 0.05$), miRNA21 (pre vs. 3 weeks: 1.0 vs. 7.6 fold increase, $p < 0.0001$) and miRNA29 (pre vs. 3 weeks: 0.6 vs. 14.3 fold increase, $p < 0.0001$) were significantly elevated at 3 weeks post MI. CLU levels were significantly decreased (post vs. 3 weeks: 8276 vs. 5250 pg/ml, $p < 0.001$). However, a correlation with troponin I levels was not observed. Changes in plasma NEP concentrations could not be observed ($p = 0.59$).
No correlations of cMRI parameters with CLU were identified, however, NEP levels post MI correlated with LVEDV ($r = 0.424$, $p = 0.049$) and LVESV ($r = 0.470$, $p = 0.027$) at day 3.
Conclusions: As opposed to recent data on NEP in chronic heart failure, plasma NEP levels were not associated with acute ischemic injury in a porcine model of reperfused myocardial infarction. However, CLU, NGAL, miR21 and miR29 were significantly associated with acute myocardial injury.

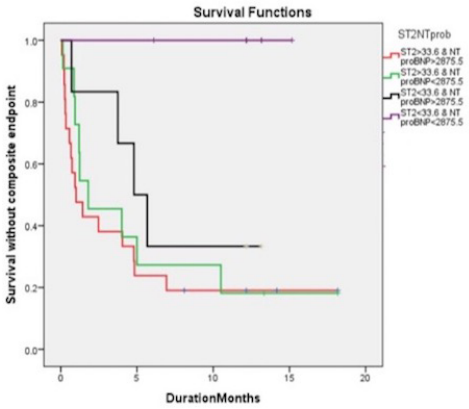
P1748

Comparing sST2 with the classical biomarkers (Troponin T and NTproBNP) in the prognostication of patients with heart failure with reduced ejection fraction

M N Dilip[1]; A G Koshy[1]; K S Viswanathan[1]; P N Gupta[1]; K Sivaprasad[2]; V V Radhakrishnan[1]; M Iype[1]
[1]*Government Medical College, Cardiology, Trivandrum, India*; [2]*Government T D Medical College, Cardiology, Alappuzha, India*

Funding Acknowledgements: Kerala Heart Foundation

Introduction: Suppressor of Tumorgenicity 2 (ST2) is a member of the IL-1 receptor family. Its soluble form (sST2) has been implicated as a marker of poor outcome in patients with heart failure.
Purpose: The aim of the study was to find out the prognostic value of serum levels of sST2 biomarker and compare it with NT-proBNP and Troponin T in patients presenting with Heart failure with reduced ejection fraction (HFrEF) for predicting composite endpoint of cardiac death and need for re-hospitalisation for worsening HF.
Methods: We prospectively recruited 51 patients admitted with HFrEF and followed them up for 1 year. Patient with recent(<2months) ACS or revascularisation, severe valvular heart disease, end-stage renal disease, cardiogenic shock or heart failure due to acute myocarditis, anemia, thyrotoxicosis or hypocalcemia were excluded.
Clinical evaluation, echocardiography along with serial measurements of biomarkers were done at admission, discharge, 1 month, 6 months and at the end of 1 year. Patients were categorised in to Group A - who did not meet endpoint and group B who met the composite endpoint.



Biomarkers and Survival analysis

Results: Ischemic heart disease (48%) followed by dilated cardiomyopathy (43.8%) were the most common cause for heart failure in the study cohort. Baseline characteristics were fairly similar in both the goups (mean age 57 years) except for total leucocyte counts (group B = 14437 vs group A = 8331/mm3, $p = 0.043$) and LV volumes, both end diastolic (group B = 165.9ml vs group A = 134.2ml, $p = 0.012$) and end systolic volumes (group B = 124.5ml vs group A = 99.6ml, $p = 0.031$). Receiver Operating Characteristic (ROC) analysis of % change in sST2 was strongly reflective of cardiac decompensation with area under the curve (AUC) of 0.746 which was better than NTproBNP (AUC 0.737; $p = 0.006$) and ST2 on admission alone (AUC 0.696, $p = 0.024$). Cut off values of sST2 = 33.6ng/ml (sensitivity = 70%, specificity = 66.7%, $p = 0.0001$), NT-proBNP = 2875.5 pg/ml (sensitivity = 86.7%, specificity = 66.7%, $p = 0.013$) was associated with worse outcomes while Troponin T was not found to be significant in predicting prognosis($p = 0.253$). A percentage reduction in sST2 levels of less than 24.76% from baseline value was associated with unfavourable future course (sensitivity = 90%, specificity = 66.7%, $p = 0.013$). Age >60 years, atrial fibrillation, baseline sST2 >33.6ng/ml and reduction in sST2 levels of <24.76% were found to be independent predictors of outcome on multivariate analysis. Patients with both sST2 and NTproBNP levels exceeding 33.6ng/ml and 2875.5 pg/ml respectively had an event free survival of less than 20% at the end of 1 year.
Conclusion: We concluded that serial measurement of sST2 is a useful tool to predict future course of the disease. sST2 = 33.6ng/ml is an independent predictor and has a 3.25 fold higher risk of cardiac death or heart failure re-hospitalisation. Combining sST2 and NT-proBNP has an incremental value in prognostication in patient presenting with HFrEF.

Chronic Heart Failure - Treatment

Tertiary heart failure care in the netherlands: what is the added value

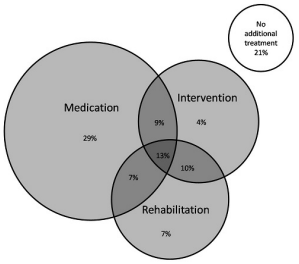
MPM Marijke Vester[1]; LF Tops[1]; ML Antoni[1]; J Braun[2]; RJM Klautz[2]; HF Verwey[1]; R Wolterbeek[3]; MJ Schalij[1]; SLMA Beeres[1]
[1]*Leiden University Medical Center, Cardiology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Cardiothoracic Surgery, Leiden, Netherlands*; [3]*Leiden University Medical Center, Department of Statistics, Leiden, Netherlands*

Background/introduction: Ideally, heart failure care is provided in a multi-professional manner with a seamless transition across primary, secondary and tertiary care. For this to succeed, it is essential that the added value of each part in the chain of the heart failure care is clear.
Aim :The aim of the current study was to evaluate the added value of a dedicated heart failure management program in a tertiary referral hospital.
Methods : Heart failure patients with a reduced left ventricular ejection fraction (LVEF) referred by a cardiologist between 2011 and 2015 to our tertiary heart failure outpatient clinic to assess their additional heart failure treatment options were included. Treatment options were identified systematically and the effect on clinical outcome and hospital admissions were evaluated.

Clinical outcome							
	Baseline	6 months	12 months	P - value*			
NYHA functional class	2.4	(95% CI 2.3 - 2.5)	1.9	(95% CI 1.9-2.0)	1.9	(95% CI 1.8-2.0)	P <0.001
LVEF (%)	29	(95% CI 29 - 30)	33	(95% CI 32 - 36)	34	(95% CI 33 - 35)	P <0.001
NT-pro BNP (ng/L)**	7.6	(95% CI 7.4 - 7.7)	7.1	(95% CI 6.9 - 7.2)	7.0	(95% CI 6.9 - 7.2)	P <0.001
Heart rate (/min)	75	(95% CI 74 - 77)	72	(95% CI 71 - 73)	70	(95% CI 68 - 72)	P <0.001
Systolic blood pressure (mmHg)	115	(95% CI 113 - 116)	113	(95% CI 111 - 115)	114	(95% CI 112 - 116)	P = 0.540
Diastolic blood pressure (mmHg)	70	(95% CI 69 - 71)	70	(95% CI 68 - 71)	70	(95% CI 68 - 71)	P = 0.970
	-6 months - baseline	Baseline - 6 months	6 months - 12 months				
Admission (%)	33		25		11	P <0.001	

* P value compared with baseline** Estimated using log transform.Clinical outcome at baseline and 6- and 12 months follow up. Continuous data are presented as mean (SD). Categorical data are presented as numbers (%). NYHA, New York Heart Association; N-terminal pro B type natriuretic peptide.

Results: 454 patients (62 ± 12 year, 69% male) were included. Additional treatment options were identified in 79% of patients comprising optimisation of medication in 58%, invasive treatment in 41% and cardiac rehabilitation in 40%. At 1 year, NYHA class improved from 2.4 (95% CI 2.3-2.5) to 1.9 (95% CI 1.8-2.0;P <0.01) and LVEF increased from 29% (95% CI 29-30%) to 34% (CI 33-35%;P <0.01). Moreover, the percentage of patients admitted for decompensated heart failure declined from 33% before referral to 25% (P <0.01) in the first 6 months and 11% (P <0.01) in the 6-12 months after referral.
Conclusion : A dedicated heart failure management program in a tertiary referral hospital is of added value since additional treatment options can be identified in the majority of patients yielding improved clinical outcome and a reduction in hospital admissions for decompensated heart failure.



The additional treatment options

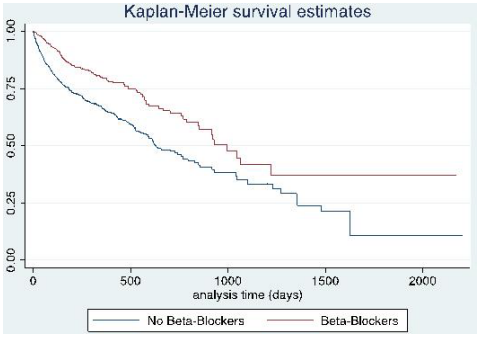
The protective effect of beta-blockers in 3,278 advanced heart failure patients treated with continuous inotropes

O Havakuk[1]; M Wilson[2]; T Artig-Brown[3]; S Savel[3]; N Meux[3]; LP Grazette[4]
[1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; *[2]University of Southern California, Preventive Medicine, Los Angeles, United States of America*; *[3]Option Care, Chicago, United States of America*; *[4]University of Southern California, Cardiology, Los Angeles, United States of America*

Funding Acknowledgements: None

Background: Continuous inotropic therapy is considered deleterious in the management of advanced heart failure (HF) patients. Nevertheless, data supporting this deleterious effect were drawn from studies in which the utilization of ß-blockers therapy was scarce.
In the present study we sought to examine the potential protective effect of additive ß-blockers therapy in a large cohort of advanced HF patients treated with continuous inotropic therapy.



Beta-blockers effect on survival

Methods and Results: Data were prospectively drawn from a US nationwide home infusion company. The cohort included 3,278 advanced HF patients treated with inotropes between May 2009 and June 2016. Mean age was 60.8 ± 16.1 years and 74% were male. Median time on inotrope therapy was 121 days (IQR 35-207), 2,289 patients were treated with milrinone, 935 with dobutamine and 54 with dopamine. ß-blockers therapy was applied in 799 (24.2%) patients and reduced mortality rates considerably (HR1.8, CI 95%:1.6-2.0, p <.001). Additionally, the use of ß-blockers therapy eliminated survival advantages in milrinone-treated compared with dobutamine-treated patients (HR 1.12, CI 95% 0.92-1.27, p = 0.19 and HR 1.65, CI 95%1.4-1.95, p = 0.001 with and without ß-blockers therapy respectively) and was shown to further improve survival rates with patients' advancing age (HR 0.76, CI 95%: 0.51-1.13, p = 0.178; HR 0.49, CI 95%: 0.31-0.79, p = 0.003; HR 0.46, CI 95%: 0.31-0.68, p <0.001; HR 0.42, CI 95%: 0.3-0.59, p <0.001 for age groups <53, 54-63, 64-73 and 73> years respectively).
Conclusion: Our results suggest that additive ß-blocker therapy can significantly improve survival rates in advanced HF patients treated with continuous inotropic therapy.

P1751
The benefits of ivabradine in the management of angina pectoris and heart failure.

Z Zainab Raissuni[1]
[1]Ibn Sina University Hospital, Cardiology B, Rabat, Morocco

On behalf of: ESSENTIEL Study group

Introduction: Several studies have shown the benefit of Ivabradine, in the management of both angina and heart failure.
Purpose: The study ESSENTIEL 2 aims to observe in the real clinical practice conditions in Morocco, over a 4-month follow up period, the effects of an exclusive HR reduction with Ivabradine in stable coronary angina and chronic heart failure patients. Methodology: Non-interventional, observational study conducted on an open cohort in Morocco, in patients with stable angina or chronic heart failure. Heart rate, Ejection Fraction, functional classification of NYHA for heart failure patients as well as SEATTLE self-assessment quality of life questionnaire for angina patients, were documented at baseline and after 1 and 4 months. The results were analyzed using descriptive statistical methods, by the SPSS version 20.
Results: 420 patients were included in 39 cardiology centers over the country. The global population mean age was 65,61 ± 11,02 years and 67,1% of them were men. 92,8% were receiving beta-blockers, 49,4% of which were carvedilol and 24,5%

Bisoprolol. The HF group represent 54,8% (n = 230) of the global population. Its mean HR was 90,73 ± 15,45bpm, with a LVEF of 39,35 ± 11,47. The NYHA classification at baseline was 16,6% NYHA II, 63,3% NYHA III and 20,1% NYHA IV. After 1 and 4 months of prescribing Ivabradine the HR was reduced to 71,65 ± 12,21 bpm and 64,21 ± 9,59 bpm, respectively. A 8,21% improvement of the LVEF was observed after 1 month, and reached 13,7% (p < 0,0001) after 4 months . It was accompanied by a shift in NYHA classification towards better functional class: 35,2% in NYHA I, 50% NYHA II, 14,3% NYHA III and only 0,5% remained NYHA IV after 4 month follow up.The angina group represents 45,2% (n = 190), the mean HR was 85,41 ± 13,99bpm with a LVEF 52,32 ± 11,91. After 1 and 4 months of prescribing Ivabradine the HR was reduced to 67,99 ± 9,80bpm and 62,14 ± 8,15 bpm, respectively. The evolution of the five SAQ domains are resumed in the table. The rate of adverse events was 3,1%, the main adverse events reported with Ivabradine are those related to its mechanism of action namely bradycardia.Conclusion: over 4 months of treatment, using Ivabradine is associated with a significant reduction in HR, an improvement in LVEF and symptoms of heart failure and stable angina; these benefits were accompanied with an improved QoL and good tolerability.

	Baseline (V0)			4-months follow up (V2)

Anti diabetic therapy in patients with heart failure and type 2 diabetes mellitus in general population.

N Nabil Kraiem[1]; I Fomin[1]; NG Vinogradova[1]; DS Polyakov[1]; M Zhirkova[1]; M Farzaliev[2]; A Azariashvili[2]; N Anyutochkina[2]; E Farafonova[2]
[1]Nizhny Novgorod State Medical Academy, Department of internal medicine, Nizhny Novgorod, Russian Federation; *[2]Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russian Federation*

Introduction: The prevalence of type 2 diabetes mellitus (T2DM) in heart failure (HF) patients ranges from 24% to 40%, coexistence of HF and T2DM needs an appropriate management.
Purpose: To analyze the use of anti diabetic drugs in real clinical practice among patients after acute heart failure decompensation.
Methods: 700 patients with HF decompensation were studied, all patients were 18 years old or older. At the moment of hospitalization 35.7% patients had T2DM, of them 9.7% patients were diagnosed of T2DM for the first time (group1; G1), 26% were diabetic before decompensation (group2; G2).
Results: Before hospitalization, Hb1ac was not checked in G1, in G2 only 8,2% patients had checked their Hb1ac the last year, mean Hb1ac was 7.0 ± 0.9%. Patients in G1 were never treated with anti diabetics whereas 59.9% patients in G2 were treated. DM treatment was present as mono-therapy (48.6%), bi-therapy (45%) and tri-therapy (6.4%). Anti diabetics were Metformin (41.2%), sulfonylurea (32.7%), DPP4 inhibitors (1.2%), SGLT2 inhibitors (6.1%) and different types of insulin (19%). Conclusion: In real clinical practice, one of ten decompensated HF patients is diagnosed with T2DM for the first time. DM treatment control was only in 8.2% patients. The majority of diabetic patients needs more than one anti diabetic drug for glucose control. Most popular anti diabetics are Metformin, sulfonylureas and insulin with a low compliance to treatment.

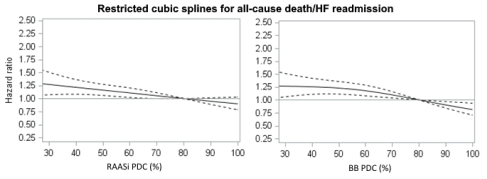
P1753

The association between adherence to evidence-based medicines and outcomes in seniors with heart failure: a landmark analysis

XW Qin[1]; J Hung[2]; M Knuiman[1]; T Briffa[1]; THK Teng[3]; FM Sanfilippo[1]
[1]The University of Western Australia, School of Population and Global Health, Perth, Australia; *[2]The University of Western Australia, Medical School, Sir Charles Gairdner Hospital Unit, Perth, Australia*; *[3]National Heart Centre Singapore, Singapore, Singapore*

On behalf of: Cardiovascular Research Group
Funding Acknowledgements: National Health and Medical Research Council (NHMRC) of Australia

Background: Sub-optimal adherence to evidence-based medicines (EBM), renin-angiotensin aldosterone system inhibitors (RAASis) and beta-blockers (BBs), in patients with heart failure (HF) is associated with adverse outcomes.
Purpose: To determine the association between adherence to EBM and subsequent HF rehospitalisations and/or death in a landmark analysis of patients who survived to 1-year after the index HF hospitalisation.
Methods: Patients aged 65-84 years and alive at 1 year post hospitalisation with non-valvular HF between 2003 and 2008 were identified from linked morbidity and mortality data in Western Australia. National pharmaceutical dispensing records for RAASis and BBs were identified within 1 year post-HF discharge. Medication adherence was measured by proportion of days covered (PDC). Outcomes during 12-months follow-up from the 1-year landmark were: (i) all-cause death, and (ii) all-cause death/HF readmission. Adjusted restricted cubic splines (RCS) were used to determine the adherence-response cutoff (see Figures). Cox regression models were used to calculate adjusted hazard ratios (HR).
Results: At the 1-year landmark, there were 4234 patients with heart failure: mean age 76 +/- 5.5 years, 56% male. Among these, 3668 (87%) and 2822 (67%) were dispensed a RAASi and BB, respectively, in the preceding year. Good adherence (PDC = 80%) was seen in 74% and 52% of patients dispensed a RAASi and BB respectively. Sub-optimal adherence (PDC < 80%) to RAASi was associated with an increased risk of all-cause death (adjusted HR 1.38, 95% CI 1.14-1.67) and all-cause death/HF readmission (HR 1.24, 95% CI 1.07-1.44). The corresponding HRs for BB were 1.30, 95% CI 1.05-1.62 and 1.31, 95% CI 1.12-1.54, respectively. The Figures (HR = solid lines; 95% CIs = dotted lines) confirm that a PDC adherence threshold < 80% for either RAASi or BB had significantly higher risk for both non-fatal and fatal events, although lower thresholds may exist for HF readmissions.
Conclusion: In seniors with HF, adherence to RAASi and BB are sub-optimal, and PDC below 80% was associated with higher risks of subsequent HF readmissions and/or death. Adherence-response curves for EBM will help to determine thresholds for adherence that clinicians should target to improve major HF outcomes.



P1754

Sacubitril/valsartan improves functional class and objective parameters in heart failure patients with reduced ejection fraction and its discontinuation is associated with a poor prognosis.

L Vicent Alaminos[1]; A Esteban-Fernandez[2]; M Gomez-Bueno[3]; J De Juan[4]; P Diez-Villanueva[5]; A Manuel Iniesta[6]; A Ayesta[1]; H Gonzalez Saldivar[1]; A Rojas[5]; R Bover Freire[2]; D Iglesias[7]; M Garcia Aguado[8]; J Perea Egido[9]; M Martinez-Selles[1]
[1]University Hospital Gregorio Maranon, Cardiology, Madrid, Spain; *[2]Hospital Clinic San Carlos, Madrid, Spain*; *[3]University Hospital Puerta de Hierro Majadahonda, Madrid, Spain*; *[4]University Hospital 12 de Octubre, Madrid, Spain*; *[5]University Hospital De La Princesa, Madrid, Spain*; *[6]University Hospital La Paz, Madrid, Spain*; *[7]University Hospital Infanta Sofia, Madrid, Spain*; *[8]Hospital de Mostoles, Madrid, Spain*; *[9]Hospital de Getafe, Madrid, Spain*

Background: Sacubitril/valsartan (SV) is a new milestone therapy in heart failure with reduced ejection fraction.
Purpose: Our aim was to ascertain the efficacy and safety of this drug in a real-world setting.
Methods. Prospective registry in 10 hospitals including all outpatients who started SV in everyday clinical practice.
Results: From October 2016 to March 2017, 427 patients started treatment with SV. During a mean follow-up of 7.0 ± 0.1 months, 49 (11.5%) discontinued SV and 12 (2.8%) died. SV discontinuation was associated with cardiovascular (hazard ratio [HR] 13.22, 95% confidence interval [CI]: 6.71 - 15.73, P <0.001) and all-cause mortality (HR 13.51, 95% CI 3.22 - 56.13, p <0.001). Figure shows Kaplan-Meier curves according to sacubitril/valsartan (SV) treatment. [Death from cardiovascular causes (A), and all-cause death (B)]. Symptomatic hypotension was documented in 71 patients (16.6%). Baseline parameters improved at the end of follow-up in patients that continued with SV, including median N-terminal pro–B-type natriuretic peptide (Nt Pro-BNP) levels 1879.0 (Interquartile Range [IQR] 904-3816) ng/L to 1326.0 (IQR: 618-2673) ng/L, rate of functional class >II 29.8% to 5.6%, and left ventricular ejection fraction (LVEF) 28.7 ± 6.8% to 32.3 ± 9.3%; all p values = 0.001. This improvement was not significant in patients with SV discontinuation: median Nt Pro-BNP 3052.5 (IQR 1844.1-6178.5) ng/L to 2237.5 (IQR 1267.5-5393.0) ng/L, rate of functional class >II 42.9% vs. 32.7%, and LVEF 27.8 ± 7.0% vs. 30.0 ± 11.2%; all p values = 0.21.
Conclusions: SV withdrawal in a real-world cohort of heart failure with reduced ejection fraction is independently associated with all-cause mortality. Patients that continued with SV at the end of follow-up showed an improvement in functional class and objective parameters.

Funding Acknowledgements: The trial is sponsored by Boehringer Ingelheim

Background and aims: Despite available therapies for heart failure with reduced ejection fraction (HFrEF), rates of hospitalization and mortality remain high. With an aging population and high prevalence of diabetes and obesity, there is an unmet medical need for additional treatments on top of guideline-directed medical therapy for HFrEF. In the EMPA-REG OUTCOME trial in patients with type 2 diabetes mellitus (T2DM) and established cardiovascular disease, the sodium-glucose co-transporter-2 (SGLT-2) empagliflozin reduced the risk of cardiovascular (CV) mortality by 38% and the risk of HF hospitalizations by 35%. Several mechanisms have been put forward to explain these benefits, which may go beyond the blood glucose lowering effect of empagliflozin. This raises the possibility of using empagliflozin as treatment for patients with established HF regardless of the presence or absence of T2DM.

Methods: The phase III randomized, double-blind EMPEROR-Reduced trial will explore the efficacy and safety of once daily empagliflozin 10 mg compared with placebo, in patients with chronic HFrEF on top of guideline-directed medical therapy. The trial includes patients with left ventricular ejection fraction (EF) = 40% and elevated NT-proBNP levels (NT-proBNP cut-offs for patients without/with atrial fibrillation are: NT-proBNP = 2500 / 5000 pg/ml with EF 36-40%, = 1000 / 2000 pg/ml with EF 31-35%, = 600 / 1200 pg/ml with EF = 30%). Alternatively, patients with EF = 40% qualify, if they had a hospitalization for HF within 12 months and present with NT-proBNP levels of = 600 pg/ml (without AF) or = 1200 pg/ml (with AF). The composite primary endpoint for this trial is the time to first adjudicated CV death or HHF. Approximately 2850 patients are planned to be randomized. The number of patients in this event-driven trial may be increased based on a blinded assessment of the primary event rate. The incidence of adjudicated HHF (first and recurrent) and the renal outcome of eGFR slope of change from baseline are key secondary endpoints.
Perspectives: The EMPEROR-Reduced study evaluates empagliflozin in patients with chronic heart failure with reduced ejection fraction. Together with the EMPEROR-Preserved study, which is evaluating empagliflozin in patients with preserved ejection fraction (EF > 40%), these trials are expected to deliver conclusive insights regarding the value of empagliflozin treatment for patients with heart failure.

Funding Acknowledgements: None to report

Background Recently, the PARADIGM-HF (Prospective comparison of ARNI with ACEI to Determine Impact on Global Mortality and morbidity in Heart Failure) trial demonstrated the superiority of sacubitril/valsartan over enalapril on the composite of death from cardiovascular causes or hospitalization for heart failure (HF).
Purpose The present study assessed the effect of sacubitril/valsartan on circulating catecholamine levels in patients with HF in an observational cohort study.
Methods We included 54 consecutive HF patients attending our HF outpatients clinic who were eligible for sacubitril/valsartan according to the PARADIGM-HF inclusion and exclusion criteria. Norepinephrine and epinephrine were measured with immunoradiometric assays at baseline and at 3 and 6 month time follow-up.
Results Compared with baseline levels, there was no change at 3 months in epinephrine (P = 0.177) or norepinephrine (P = 0.815) concentrations. At 6 months, norepinephrine remained unchanged (P = 0.359). However, at 6 months, we observed a significant increase in epinephrine levels compared with baseline [66 pg/mL (37-93) vs. 38 pg/mL (18-74), P < 0.001] (Table).
Conclusions: This study is the first to report on the effect of the new drug sacubitril/valsartan on circulating catecholamine levels in HF patients. Our data show a significant increase in epinephrine levels during a 6 month follow-up in stable HF patients.

Measured change in catecholamine levels

Laboratory Data

	Baseline (n = 48)	3 months (n = 46)	6 months (n = 34)
NT-proBNP, pg/mL	388 (196 - 944)	361 (140-727)	149 (61 - 373)
Epinephrine, pg/mL	38 (18-74)	31 (23-81)	66 (37 - 93)
Norepinephrine, pg/mL	563 (419-762)	522 (324-833)	364 (300 -829)
Creatinine, mg/dL	1.2±0.2	1.2±0.2	1.1±0.2
eGFR, mL/min/m^2	68.1±14.7	67.8±17.7	71.9±17.3

Values are expressed as mean (standard deviation) or median (interquartitile range)eGFR; estimated glomerular filtration rate, NT-proBNP; N-terminal pro-brain natriuretic peptide

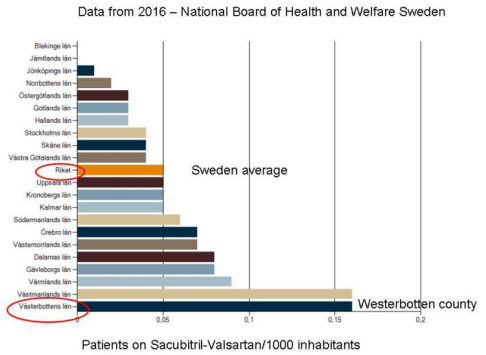
Population wide introduction of novel heart failure treatments
–Experience with Sacubitril-Valsartan in a community based heart failure population in northern Sweden

Background: Heart failure is a chronic disease where many patients do not have regular contact with heart failure cardiologists but are instead taken care of by primary care physicians or general cardiologists. When novel heart failure treatments arrive the introduction phase often takes several years before all eligible patients have been considered. With the computerization of medical records and emergence of quality registries we wanted to investigate the feasibility of using local registries for mass screening of patients eligible for Sacubitril-Valsartan and introducing treatment on all appropriate patients.

Methods: All patients with a main or side diagnosis of heart failure that had had at least one contact with the dept of cardiology or internal medicine at Umeå University Hospital between 2010-2016 were identified in the hospital records. The PARADIGM-HF criteria were applied and all patients who would have been eligible for the study were identified and were summoned to an out patient visit. If the latest echocardiography was older than 18 months a new echo was performed.

Results: Out of 2029 patients with heart failure, 622 had ejection fraction (EF) = 40%, 250 of these tolerated at least half dose ACE-inhibitor/ARB and fulfilled other formal criteria for inclusion in the PARADIGM-HF study. After discussion with the local pharmaceutical committee, for budget reasons we decided to summon all patients who were on maximum dose ACE-inhibitor/ARB and had EF = 35%, a total of 95 patients. After manually checking medical records on these patients and excluding patients with other terminal illness, whose condition had changed, a total of 76 patients were summoned to the out patient clinic.

Conclusion: Using a local registry for mass screening was feasible and helped identify patients in need for treatment. Even with a strict interpretation of the study criteria, Westerbotten county had the fastest introduction of Sacubitril-Valsartan in Sweden. Using this method patients receive the benefit of novel treatments considerably faster than the conventional way of identifying patients when they present themselves in the clinic. It is also likely that this approach helps with the cost effectiveness of new treatments guaranteeing that strict criteria is used in the selection process. It remains to be seen if larger scale registries are useful for this purpose.



Patients on Sacubitril-Valsartan

P1758

Relative efficacy of spironolactone, eplerenone, and canrenone in patients with chronic systolic heart failure - a systematic review and network meta-analysis of randomized controlled trials

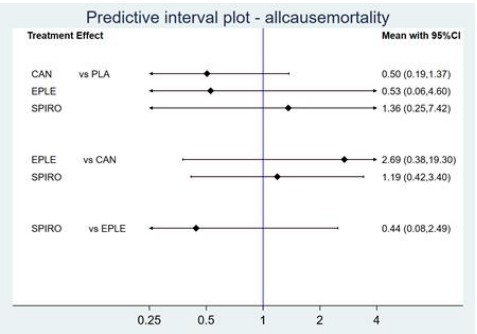
L Lutz Frankenstein[1]; T Taeger[1]; H Froehlich[1]; JGF Cleland[2]; M Grundtvig[3]; T Hole[4]; H Katus[1]; S Agewall[5]; A Clark[6]; D Atar[5]
[1]The Medical Faculty of Heidelberg, Heidelberg, Germany; *[2]Robertson Centre for Biostatistics & Clinical Trials, Glasgow, United Kingdom*; *[3]Innlandet Hospital, Lillehammer, Norway*; *[4]Norwegian University of Science and Technology, Trondheim, Norway*; *[5]University of Oslo, Oslo, Norway*; *[6]Castle Hill Hospital, Hull, United Kingdom*

Objectives: To assess the comparative benefit and risk profile of treatment with spironolactone, canrenone, or eplerenone with regards to all-cause mortality (primary endpoint), cardiovascular mortality, or heart failure related hospitalisation (secondary endpoints) and the safety endpoints hyperkalaemia, acute renal failure, and gynaecomastia.

Design: Systematic review and network meta-analysis following PRISMA-P and PRISMA-NMA guidelines.

Data sources: search in seven individual databases, six individual clinical trial registries, and three individual grey literature databases, no time-restrictions for start date, up to January 2017, cross-checking of reference lists of retrieved publications.

Eligibility criteria for selecting studies: Randomized controlled trials with an active treatment of either spironolactone, eplerenone, or canrenone/potassium-canreonate in adults (age >18 years) with symptomatic heart failure (NYHA II - IV) due to systolic dysfunction (left ventricular ejection fraction < 40%) reporting any of the above endpoints were included - the availability of full reports being the only restriction.



adjusted predictive interval plot

Results: Pairwise meta-analysis confirmed efficacy for all MRAs for the primary endpoint. Uncorrected network meta-analysis favoured spironolactone over eplerenone (OR: 0.74 [0.60-0.93]) but not canrenone (OR: 1.21 [0.44-3.35]). Beta-blocker adjustment did not confirm superiority of spironolactone (OR: 0.44 [0.08-2.49]). Sensitivity analysis excluding either trials with < 30 patients per arm or < 12 months of follow-up confirmed the base case. Cumulative probability ranking plots of benefit vs. safety favoured spironolactone for acute renal failure and hyperkalaemia but eplerenone for gynaecomastia. Results for the secondary endpoints essentially mirrored these findings.

Conclusion: In head-to-head comparisons, spironolactone, eplerenone, and canrenone show comparable efficacy with respect to all-cause mortality, cardiovascular mortality, heart failure related hospitalisations, acute kidney failure, hyperkalaemia, and gynaecomastia.

P1759

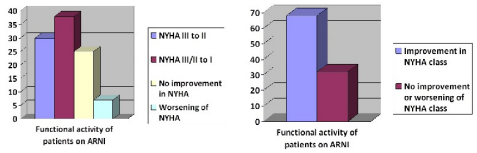
Impact of ARNI (Angiotensin Receptor Neprilysin Inhibitor) on functional status of patients with heart failure and reduced ejection fraction (HFrEF).

M A Muhammad Adil Soofi[1]; F Alsamadi[1]
[1]King Fahad Medical City, Prince Salman Heart Center, Riyadh, Saudi Arabia

Introduction: Pharmacological measures have improved the survival and functional class among patients with heart failure. ARNI is the newest medication approved for patients with HFrEF and associated with significant improvement in survival and hospital readmissions. Functional activity can be assessed by NYHA class.

Method: Retrospective analysis of the patients switched from ACEI/ARB to ARNI at out patient clinic of our hospital. Patients were regularly seen at the clinic after the initiation of ARNI. Symptoms, clinical examination and demographic and hemodynamic data were recorded at each visit along with modification and

adjustment of medications. Their NYHA class were assessed before the initiation and recorded at each visit.
Result: 82 patients were switched from ACEI/ARB to ARNI in last 1 year. 62% of patients were in NYHA class II and 38% of patients in NYHA III/IV. ARNI was stopped in 10 patients (7 patients due to kidney injury, hypotension and non-compliance and 3 patients expired with 15-20 days of initiation).
Baseline characteristics were studied in 72 patients. Renal dysfunction was present at baseline in 35% of patients. Beta blockers were prescribed in 100% of patients (optimum dosage: 40%, 50% - < 100% of optimum dosage: 44%, < 50% of optimum dosage: 15%). MRA was prescribed in 54% of patients.
Follow up completed for 60 patients. ARNI was titrated to optimum dosage in 58% of patients. No mortality recorded in the long term follow up. Drop in systolic BP were recorded in 58% of patients (maximum drop was of 42 mmHg and average was 19 mmHg). No worsening of renal function was noted in 42% of patients. NYHA class improved in 68% of patients (NYHA III to II: 30%, NYHA II/III to I: 38%).
Conclusion: ARNI was tolerated in 88% of patients when switched from ACEI/ARB and was associated with significant improvement in NYHA class in 68% of patients.



Functional activity of patients on ARNI

P1760

Differences in patient characteristics and cardiovascular events between low dose and medium-high dose of Sacubitril-Valsartan

JSM Seller Moya[1]; CNP Nunez Piles[2]; HMC Morillas Climent[1]; AVD Vicedo Lopez[1]; EMJ Galcera Jornet[1]; EAT Alania Torres[1]; LRA Larumbe Rodriguez[1]; AVM Valle Munoz[1]
[1]Hospital Marina Salud, Cardiology, Denia, Spain; *[2]University Hospital Doctor Peset, Cardiology, Valencia, Spain*

Sacubitril-Valsartan (SV) is the most recent drug approved for the treatment of heart failure (HF) with depressed ejection fraction. Results in clinical trials are remarkable. Introduction of SV into daily practice should aim to achieve maximum tolerated dose. However, real world data are limited, mainly due to a short postcommercialization period.
Purpose: The primary objective of our study is to describe, in real word practice, basal patient (p) characteristics together with imaging and laboratory markers related to the used SV dose. We also analyze cardiovascular events during follow-up.
Methods: We performed a retrospective evaluation of SV prescriptions from the first drug prescription until 10th January 2018. P were excluded if no data were available, drug indication was inadequate or if the drug was stopped before 2 months of follow-up
We divided p into 2 groups: low dose (24/26 mg, LD) and medium-high dose (49/51 and 97/102 mg, MHD) of SV. We collected data regarding baseline characteristics, imaging parameters, laboratory markers and major adverse cardiovascular events.
Results: From the 19th of October 2016 to the 10th of January 2018, 114 p were included. Eighteen patients were excluded from final analysis (3 had no data available, 2 had a inadequate indication for prescription, 13 stopped the drug prematurely without a reason). Ninety-six p remained. 72,3% of them were men, 31.7% were diabetic, 83,4% hypertensive and 52% receive lipid lowering drugs. Mean age was 69,9 years. Baseline treatment was optimal: 95% of patients were treated with angiotensin-converting enzyme inhibitors, 90% with beta-blockers and 75% with mineralcorticoid receptor antagonists.
The percentage of low, medium and high dose at the end of the study was 58,33, 37,50 and 4,16% respectively. 60% of the p reported NYHA functional class II symptoms, 33% NYHA III and 7% NYHA I (no significant differences were found between groups). Ischaemic heart disease was the main etiology of heart failure (51,8%)
Mean LVEF was 30,37%, with no differences between groups (29,89 vs 30,95, p = 0,559). Lower pretratment levels of NTproBNP were significantly associated with MHD (3405,63 vs 1609,78 p = 0,014). Ca125 presented a non-significant trend towards higher values in LD (39,11 vs 21,11, p = 0,076). Medium and median dose of furosemide were 60 and 65.54 mg per day (54,91 vs 49,55, p = 0,623).
During a medium follow-up of 203 +/- 101 days, 8 p (8,4%) were admitted to the hospital due to HF and 4 p died (all cardiovascular deaths). We did not find any significant differences, maybe due to the low event rate.
Conclusion: 58% of p remained with LD of SV during follow-up. This dose was associated with higher initial values of NTproBNP and a non-significant trend towards higher levels of Ca125. No differences were identified in NHYA class, LVEF and dose of furosemide.

P1761

Safety of ambulatory intermittent cycles of levosimendan in patients with advanced heart failure listed for heart transplant

I Ponz De Antonio[1]; J De Juan Baguda[1]; A Rodriguez Chaverri[1]; L Moran Fernandez[1]; C Ortiz Bautista[1]; MD Garcia Cosio[1]; R Gutierrez Garcia[1]; C Munera Jimenez[1]; N Tejada Hernandez[1]; R Salguero Bodes[1]; F Arribas Ynsaurriaga[1]; JF Delgado Jimenez[1]
[1]University Hospital 12 de Octubre, Cardiology, Madrid, Spain

Introduction: Intermittent use of inotropes for the long-term treatment of advanced HF (AdHF) remains controversial.
Methods: Observational, prospective study of patients with AdHF awaiting heart transplant (HTx), who received ambulatory intermittent cycles of levosimendan (ICL) between January 2016 and November 2017. All patients received a previous cycle in hospital for 24 hours. Levosimendan was administered every 2 weeks, initiated at 0.1 μg/kg/min and increased to 0.2 μg/kg/min for 6 hours. Implantable cardioverter defibrillators (ICD) were periodically interrogated.

Baseline characteristics	% (n = 11)
Age (years)	53.0 (IQR 41-63)
Male	63.6% (7)
Arterial hypertension	36.4% (4)
Dyslipidaemia	27.3% (3)
Diabetes mellitus	18.2% (2)
Aetiology - Ischaemic disease - Hypertrophic cardiomyopathy - Dilated cardiomyopathy	- 45.5% (5) - 9.1% (1) - 45.5% (5)
LVEF (%)	28 (IQR 19-30)
ICD	100% (11)
CRT	27.3% (3)
INTERMACS Stage 3	100% (11)
Creatinine (mg/dl)	1.5 (IQR 1.3-1.9)
Creatinine clearance (ml/min/1.73m^2)	45.9 (IQR 36.9-59.7)
NTproBNP (pg/dl)	4858.0 (IQR 3047.0-5801.0)
Treatment - ACEI - ARB - Betablockers - MRAs - Ivabradine - Hidralazine + Nitrates	- 54.5% (6) - 9.1% (1) - 90.9% (10) - 100% (11) - 36.4% (4) - 18.2% (2)

IQR: 25% to 75% interquartile range

Results: 11 patients (baseline characteristics in table) received 12.0 ICL (3-49), median follow up was 6.0 months (1.5-12). One patient (9.1%) suffered a symptomatic hypotension during treatment infusion, which forced a reduction of the infusion velocity, remaining afterwards asymptomatic. No patient suffered ventricular tachycardia during infusions, and no significant arrhythmia was detected means ICD interrogations.
In 2 patients (18.2%) ventricular assist devices were implanted as bridge to transplant, 1 (9.1%) experienced clinical improvement and 8 (72.7%) underwent HTx, 25% of them (2) in urgent circumstances. One patient (9.1%) continues with ICL.
Conclusions: : Levosimendan administration was safe in all patients, without significant arrhythmia during treatment infusions nor between cycles. ICL may contribute in reducing the emergency transplantation rate.

P1762

In HFrEF patients, reduced doses of sacubitril / valsartan do not result in increased mortality or heart failure hospitalizations compared to target dose. A retrospective cohort study

R De Vecchis[1]; C Ariano[2]; G Di Biase[3]; M Noutsias[4]
[1]Preventive Cardiology and Rehabilitation Unit, DSB 29 " S. Gennaro dei Poveri Hospital", Napoli, Italy; *[2]Division of Geriatrics, " Casa Sollievo della Sofferenza" Hospital, S.Giovanni Rotondo, Italy*; *[3]Division of Geriatrics, Clinic "S. Maria del Pozzo", Somma Vesuviana, Italy*; *[4]Division of Cardiology, Angiology and Intensive Medical Care, University Hospital Halle, Martin-Luther-University Halle, Halle, Germany*

Introduction: In HFrEF patients, the dosage of sacubitril/−valsartan is modulated according to a gradual increase scheme adjusting to arterial blood pressure tolerance. Nevertheless, if candidate patients exhibit tolerability problems, a provisional reduction of the dose of sacubitril−valsartan or even its interruption are suggested.

Methods: This study provides estimates of respective proportions of HFrEF patients receiving minimum or intermediate dose of sacubitril /valsartan. In addition, a comparison was made to detect possible differences regarding all–cause mortality and heart failure hospitalizations in patients treated with the recommended optimal dose compared to those receiving submaximal maintenance doses of sacubitril/valsartan.
Results: N = 68 HFrEF patients were treated with sacubitril –valsartan in addition to beta–blocker and mineralocorticoid receptor antagonists. Among them, 20 patients (29.4%), were identified as having clinical features that were contra–indicating the administration of sacubitril– valsartan at target doses. The cause eliciting or propitiating the interruption or missing achievement of maximal drug dosage was annotated: symptomatic hypotension (11 cases / 16%), worsening renal function (3 cases), systolic blood pressure = 95 mmHg (3cases), palpebral angioedema (1 case), paradoxical worsening heart failure(1 case), hyperkalemia(1 case). The subsequent decision was to maintain an intermediate dose in 11 patients and to reduce the dose at the minimum allowed level, i.e., 24 mg/26 mg twice daily in 9 patients. After a median follow–up of 5.25 months, no differences were found concerning the risk of all–cause death in the comparison between patients treated with different dosages of sacubitril valsartan. Likewise, patients subjected to submaximal doses of sacubitril–valsartan had similar risk of heart failure hospitalization when compared to patients treated with full dosages of the drug (odds ratio: 1.7083 ; 95% CI: 0.4887- 5. 9718 ; p = 0.5011).
Conclusions: During a median follow–up of 5.25 months. in HFrEF patients who had been proven to be intolerant to the maximum dose of sacubitril/ valsartan, the use of reduced doses of the drug did not result in increased mortality or hospitalization for heart failure compared to patients who tolerated the target dose of sacubitril/valsartan.

Oral diuretics in very intensive treatment, an early intervention in outpatients with heart failure. DIVINE STUDY

EJJ Eduardo Julian Jose Chuquiure[1]; C Silva-Ruz[1]; K Jacobo-Garcia[1]; G Gabriela Mendez[2]; M Chuquiure-Gil[1]; R Hernandez-Isidro[1]; E Morales-Hinojosa[1]; O Fiscal-Lopez[1]
[1]Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico; *[2]Universidad del estado de México, Medicina, ciudad neza, Mexico*

Background: In patients with heart failure (HF), majority of hospital admissions at emergency room are caused by hydric retention, with increase in: Mortality and hospital costs. The purpose of the present investigation is to apply high doses of oral diuretics in patients with HF clinical deterioration.
Material and Method: In the present pilot study, consecutive patients, older than 18 years, of both genders were included. The diagnosis of reduced Heart Failure (HfrEF) according to: Clinical pattern, laboratories and Cardiac imaging (ESC criteria). Treatment was assigned in two groups: Bumetamide and the other group received Indapamide. Each groups received maximum tolerated dose for fourteen days with Clinical evaluations every 48 hrs. (Face-to-face and/or telephone). Serum labs (Sodium, Potassium, NT-PRO-BNP and Creatinine) were evaluated. Daily in-home register were made. Final points were: Mortality, Urinary failure, Clinical Impairment, Hospital admissions, Oedema. (MUCHO). They were followed for 30 days.
Results: We evaluated 14 HfrEF patients with LVEF mean 23.4 ± 9.43%, age: 48.8 ± 12.13 years, 53% with ischemic etiology, Mean Risk Scores: MAGGIC (20.13 ± 4.47) and EMPHASIS (3.74 ± 1.13), only three were female. Nine Patients were assigned in the Bumetamide Group and five in the Indapamide Group.
At Basal: Main signs were worsening dyspnea at rest and Hydric retention.
Intensive pharmacological Stage (1-14 day): Oral average doses were: Bumetamide 7 mg/day and Indapamine 5 mg/day. During the follow-up, dose titration was assessed clinically, every 48 hrs. Orthopnea was the first symptom to be controlled (86%, 24-48 hrs.), followed by Elevated jugular venous pressure, Oedema and Hepatomegaly (in the first 48-72 hrs. in 84%, 79%, 53%, respectively). In the first 48 hours, there was no greater difference in abdominal perimeter and weight. After 72 hours, the reduction began. At 7-10 days there was a mean reduction of 5.7 ± 0.9Kg, and Abdominal perimeter of 2.3 ± 0.2cm. Without modification in creatinine levels. Two patient had cramps, corrected with an oral potassium supplement. Decreases in blood pressure levels were observed, without significant hypotension. In this period, Hospital readmission and Mortality were not observed.
At the 30-day follow-up: No mortality was reported, only two patients attended at emergency room (diarrhea and flu).
Conclusions: Diuretic maximum tolerated doses were safe in both groups. In the present study there was no 30 days mortality.

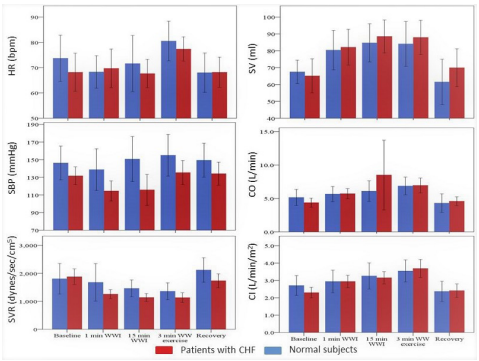
P1764

Warm water immersion in patients with chronic heart failure: A pilot study

P Parin Shah[1]; P Pellicori[1]; A Kallvikbacka-Bennett[1]; D Pan[1]; A Clark[1]
[1]Castle Hill Hospital, Academic Cardiology, Hull, United Kingdom

Funding Acknowledgements: Hull & East Riding Cardiac Trust Fund (Registered with the Charity Commission No. 252918)

Background: Little is known about the acute effects of warm water immersion (WWI) in patients with chronic heart failure (CHF).
Methods: Seventeen patients with clinically euvolaemic CHF (mean age 67 years, 88% male, mean left ventricular ejection fraction 33%) and 10 normal subjects were immersed up to the neck in a pool (33-35°C). Cardiac haemodynamics were measured non-invasively, and echocardiography was performed at baseline, during WWI, 3 minutes after kicking in the supine position and after emerging.
Results: In patients with CHF, compared to baseline, WWI immediately increased stroke volume (SV, mean ± standard deviation; from 65 ± 21 to 82 ± 22 ml, P = 0.01), cardiac output (from 4.4 ± 1.4 to 5.7 ± 1.6 L/min, P < 0.001) and cardiac index (from 2.3 ± 0.6 to 2.9 ± 0.70 L/min/m^2, P < 0.001) with decreased systemic vascular resistance (from 1881 ± 582 to 1258 ± 332 dynes/sec/cm5, P < 0.001) and systolic blood pressure (132 ± 21 to 115 ± 23 mmHg, P < 0.001). The haemodynamic changes persisted for 15 minutes of WWI. In normal subjects, compared to baseline, WWI increased SV (from 68 ± 11 to 80 ± 18 ml, P = 0.03). In patients with CHF, compared to baseline, WWI caused an increase in left atrial volume (from 57 ± 44 to 72 ± 46 ml, p < 0.05) and tricuspid annular plane systolic excursion (from 1.9 (0.6) to 2.1 (0.5) cm, p < 0.05), without any changes in left ventricular size or function or amino terminal pro B-type natriuretic peptide.
Conclusions: In patients with CHF, WWI causes an acute increase in cardiac output and a fall in systemic vascular resistance. The changes were well-tolerated.



haemodynamic changes during immersion

P1765

Identifying accelerometers to measure physical activity in patients with heart failure

L Klompstra[1]; M Kyriakou[2]; T Jaarsma[1]; A Stromberg[3]; M Piepoli[4]; E Lambrinou[2]
[1]Linkoping University, Department of Social and Welfare studies, Linkoping, Sweden; *[2]Cyprus University of Technology, Department of Nursing, Cyprus, Greece*; *[3]Linkoping University, Department of Medical and Health Science, Linkoping, Sweden*; *[4]Guglielmo da Saliceto Hospital, Heart Failure Unit, Piacenza, Italy*

Introduction: Physical activity limitation is a major problem in patients with heart failure (HF) and needs to be accurately measured if therapies aiming to improve this are to be properly evaluated. A range of devices is available for this purpose but most of them have been validated in young, healthy subjects. Their applicability to the HF populations, where movements tend to be slower, is not well established. The number of activity monitors available to measure physical activity is growing, but it remains a challenge to assess physical activity in patients with HF.
Purpose: The aim of this research was to identify activity monitors used to measure physical activity in patients with HF and give an overview of the characteristics of these devices with focus on costs, size, placement, data storage time, outcomes, validity and reliability.
Method: An extensive search of online electronic databases (PubMed, Scopus, CINAHL, Web of Science) was conducted in October 2017. Search words were: ("accelerometer" OR accelerometry OR "motion sensor" OR "activity monitor") AND ("heart failure"). Two reviewers independently reviewed the results and third reviewer adjudicated.

Results: Overall, 27 publication were identified as relevant studies, 6 uniaxial activity monitors, 4 triaxial and 1 multisensor were identified. Most activity monitors placement was on the hip, ankle or wrist (n = 5), two on the thigh, one on the waist and one on the upper arm. Data storage was between no data storage at all and 378 days. Most of the activity monitors measured steps (n = 8) and/or activity counts (n = 6), and some also calculated activity (intensity) level (n = 2) and/or the mean vector magnitude unit (n = 2). Results show that most of the activity monitors (n = 8) were field validated in healthy adults with the total energy expenditure calculated from the activity monitor compared to the total energy expenditure measured with doubly labelled water (r = 0.18 - 0.83). Two activity monitors were also field validated in people with chronic disease (r = 0.33-0.83). Additionally 8 activity monitors were validated in healthy adults with laboratory validation where the total energy expenditure with indirect calometry was compared to the activity monitor outcomes (r = 0.46-0.93). Two activity monitors were also laboratory validated in people with chronic disease (r = 0.72-0.93). Additional data will be presented on costs and reliability of the activity monitors.
Conclusion: The results of this study gives an overview of the devices which measures physical activity in patients with HF in order to help researchers and clinicians in identifying the appropriate accelerometer to measure physical activity in their HF population.

P1766
Assesment of symptom limited stair climbing test efficacy in patients with chronic heart failure

B Busra Alkan[1]; S Ozalevli[2]; N Gullu[3]
[1]KTO Karatay University, Physical Therapy and Rehabilitation, Konya, Turkey; *[2]Dokuz Eylul University, Physical Therapy and Rehabilitation, Izmir, Turkey*; *[3]Konya Kizilay Hospital, Cardiology, Konya, Turkey*

Introduction: To assess the efficacy of symptom-limited stair climbing test (SLSCT), in determining exercise capacities of patients with chronic heart failure (CHF) by comparing cardiopulmonary exercise test (CPET) and 6-minute walk test (6 MWT) and to interpret the results according to clinical characteristics of patients.
Methods: The study included 31 patients aged 50-75 years with stage II-III according to the NYHA (Newyork Heart Association) classification, diagnosed with CHF, with a left ventricular ejection fraction (LVEF) of 45% or less. Demographic and clinical characteristics of the patients were questioned. Exercise capacity was assessed by SLSCT, 6 MWT, CPET. Patients dyspnea and effort perception were assessed by Modified Borg Scale (MBS), pulmonary functions by spirometric measurements, health-related quality of life (HRQOL) by Chronic Heart Failure Questionnaire (CHFQ).
Results: It was determined that the test with the highest VO2 max value among the tests was SLSCT. A significant difference was noted between the other tests ($p < 0.05$). In heart rate changes before and after the tests, SLSCT was found to increase heart rate more than 6MWT and less than CPET. A significant correlation was found between the predicted VO2max values of CPET and SLSCT (r = 0.52, p = 0.003). It was also found that SLSCT was more related to clinical characteristics of patients.
Conclusion: SLSCT is effective in evaluating exercise capacity and easy to use in CHF patients. Compared with the 6MWT, it gives better results in determining the clinical characteristics and hemodynamic responses of the patients. It is an alternative to assessing exercise capacity in the absence of CPET.

P1767
Functional evaluation of resynchronization therapy by means of non invasive cardiac output measurement during cardiopulmonary exercise test

C Carlo Vignati[1]; A Scoccia[1]; G Cattadori[2]; E Salvioni[1]; S Farina[1]; P Agostoni[1]
[1]Cardiology Center Monzino IRCCS, Heart Failure Unit, Milan, Italy; *[2]IRCCS Multimedica of Milan, Milan, Italy*

Background: More than one third of patients with heart failure (HF) shows an LBBB. This is associated to a mechanical dyssynchrony, which cause a suboptimal left ventricular filling and consequently a decrease in cardiac performance. These patients show more severe symptoms, worse prognosis, and an increase risk of death. Cardiac resynchronization therapy (CRT), stimulating properly the right and left ventricles, restores the coordination of contraction. Multiple studies have shown the benefits of CRT, in patients with enlarged QRS complex and optimized medical therapy. However, the wider diffusion of CRT, has shown that ˜30% of candidates don't benefit from the treatment. Little is known about prediction of the non responders.
Aim of the study: to assess the effects of CRT, through the evaluation of oxygen consumption (VO2) and the measurement of cardiac output (CO) by means of inert gas rebreathing technique.
Results: We have enrolled 81 patients who had a standard indication for an CRT (NYHA class = II, LBBB brunch block, optimized medical therapy, LVEF = 35%) and peak VO2 = 16 ml/kg/min. In the overall population we observed an improvement of NYHA class (from 2.6 ± 0.5 to 1.9 ± 0.4), an increase of LVEF (from 29.3 ± 7.4 to 34.1 ± 9.5), a reduction of telediastolic (EDV from 212.6 ± 71.9 to 188 ± 71.1 ml) and telesystolic volume (from 151.1 ± 62.9 to 127.7 ± 60.4) and a improvement of mitral regurgitation. Also peak VO2 improved (from 1094 ± 345 to 1199 ± 376 ml/min). This was related to an increase of CO (from 6.15 ± 1.86 L/min to 7.05 ± 2.2 L/min), whereas the arteriovenous oxygen difference (Ca-vO2) was unchanged. We have then compared the CRT-responder (reduction of EDV >10% or increase of LVEF>10%) and CRT-non responder from a clinical, functional and echocardiographic point of view.
Using the reduction of EDV as criterion the two groups differ at baseline for heart rate, and rest VO2, while using the increase of LVEF CRT responder patients have a lower LVEF than non responders.
During CPET we assessed differences in peak VO2 (from 1153.5 ± 339.5 to 1280.6 ± 369.8 in CRT-responder vs from 1050.4 ± 289.3 to 1147 ± 335.2 in CRT-non responder), O2 pulse (from 10.8 ± 2.9 to 12.5 ± 2.9 in CRT-responder vs from 10.3 ± 2.6 to 11.1 ± 3.34 in CRT-non responder) and CO (from 6.4 ± 2.1 to 7.7 ± 2.3 in CRT-responder vs from 5.8 ± 1.3 to 6.4 ± 1.8 in CRT-non responder) but no differences in baseline functional characteristics.
Conclusion: We can assess the benefits of CRT through the increase of peak VO2. Through the simultaneous measurement of CO, we could assess that the increase of peak VO2 was related to an increase of CO, whereas the (Ca-vO2) difference was unchanged. In both groups we observed an increase in CO, but in CRT-responder this was related exclusively to the increase of stroke volume whereas (Ca-vO2) difference and heart rate were unchanged.
After CRT implantation we have assessed an improvement of LVEF, but in CRT Non Responder we have not observed a reverse remodeling.

P1768
Role of fibrosis detected by cardiac magnetic resonance in predicting the response to cardiac resynchronization therapy in ischemic heart failure.

P Manca[1]; S Cossa[2]; GF Tola[1]; A Scalone[1]; B Schintu[1]; A Setzu[1]; S Mameli[1]; N Sanna[1]; A Giardina[1]; L Minerba[3]; G Matta[2]; M Porcu[1]
[1]G. Brotzu Hospital, cardiology, Cagliari, Italy; *[2]G. Brotzu Hospital, radiology, Cagliari, Italy*; *[3]University of Cagliari, Public health, Cagliari, Italy*

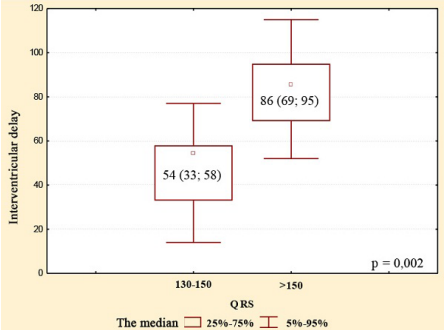
Background. Cardiac resynchronization therapy (CRT) can reduce mortality and morbidity in selected patients with ischemic heart failure (IHF). However, the indication to this treatment is still based mainly on electric parameters and the role of myocardial scar is not completely defined.
Purpose: To evaluate the significance of the extension and localization of left ventricle fibrosis, assessed by cardiac magnetic resonance (CMR), in the response to CRT in patients with IHF. Methods. We retrospectively enrolled 36 symptomatic IHF patients (30 M, 6 F, mean age 68 ± 8 years), who had a complete cardiovascular evaluation, including clinical examination, blood parameters, ECG, echocardiography and cardiac magnetic resonance (CMR). The diagnosis was supported by a definite clinical history of coronary artery disease and at least one stenosis = 50% in one epicardial artery at coronary angiography. At baseline, the ejection fraction (EF) was $27 \pm 5\%$, NYHA class $2,7 \pm 0,6$ and QRS 150 ± 17 msec. Thirty patients (83%) were in sinus rhythm and 6 (17%) in atrial fibrillation. All patients were treated with optimal medical therapy for at least 3 months before the implant (ßb 86%, ACEI/ATIIA 88%, furosemide 100%, AA 50%). The effectiveness of CRT was defined according to the following criteria: 1) Responders: improvement = 1 NYHA functional class and/or improvement = 15% in the EF; 2) Non-Responders: no improvement or even worsening of NYHA class and improvement < 15% in the EF.
Results: At a mean follow up of 36 ± 12 months, 20 patients (55%) were considered responders, while 16 (45%) did not show any benefit. Responders had a baseline higher NYHA class (3,1 vs 2,2, p= < 0,0001). No other factors, including baseline QRS length and its shortening after CRT, showed a prognostic value. Four patients did not show a significant myocardial scar and all of them were responders. The percentage of left ventricle fibrosis (23.2% vs 14.5%), the number of transmural fibrotic segments (4.8 vs 2.6) and the number of lateral fibrotic segments (1.6 vs 0.8) were higher in non-responders. However, these differences were not statistically relevant, probably for the limited sample size. Conclusions. These data support the hypothesis that in IHF the extension and the localization of myocardial fibrosis documented by CMR can influence the response to CRT. Larger studies are needed to confirm it.

P1769

Effect of cardiac resynchronization therapy on parameters of myocardial dissynchrony in patients with chronic heart failure and atrial fibrillation

T Tatyana Troyanova-Shchutskaia[1]; A Kurlianskaya[1]; D Goncharik[1]; A Chasnoyt[1]; T Denisevich[1]; O Shatova[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Background: Myocardial dissynchrony is one of the most important causes of chronic heart failure (CHF). The matters of the effect of cardiac resynchronization therapy (CRT) on myocardial dissynchrony has not been studied in patients with permanent atrial fibrillation (AF).
Purpose: to study the effect of CRT on myocardial dissynchrony in patients with chronic heart failure complicated by PAF.
Methods. The study included 50 patients with CHF III NYHA, PAF, ejection fraction < 35%, QRS >130ms. Patients were divided into 2 groups (1 - QRS 130-150ms, 2 - QRS >150ms) and underwent CRT with ablation of atrioventricular node. Echocardiography with determination of myocardial dissynchrony was performed at baseline and in 12 months after CRT.
Results: At baseline presystolic aortic delay was higher in group 2 (p = 0.001). Association of presystolic aortic delay and QRS-duration was confirmed by a significant correlation (rs = 0.51 at p < 0.001). In group 1 interventricular dyssynchrony was also significantly higher than in group 2 (p = 0.002) (Picture). The correlation coefficient indicated a moderate correlation of interventricular delay and QRS-duration (rs = 0.38 at p = 0.018).
Analyzing presystolic aortic delay the difference in the frequency of effects of CRT was statistically significant only in group I (p = 0.010). In 12 months after CRT the presystolic aortic delay disappeared in 23% of patients, remained in 57% and appeared in 8%. No presystolic aortic delay was observed before or after CRT in 12% of patients. In 12 months after CRT presystolic aortic delay decreased significantly from 161 (140, 168) ms to 147 (133, 155) ms (p = 0.014) despite a rather large percentage of the absence of positive dynamics (57%). In group 2 there was no statistically significant positive effect of CRT on the incidence of presystolic aortic, but it decreased from 211 (183; 223)ms to 172 (155; 179)ms (? = 0,028). In both groups interventricular delays decreased significantly (p < 0,001). Parameters of intraventricular dyssynchrony decreased insignificantly. Perhaps these changes are caused by different coefficients of variability.
Conclusions: The positive dynamics of parameters of interventricular and intraventricular dyssynchrony was revealed in 12 months after CRT. The severity of mechanical dissynchrony depends on the width of the QRS complex. Presystolic aortic delay, interventricular delay and all segments maximum delay were higher in patients with QRS > 150 ms.



P1770

The prognostic value of age in patients with continuous flow left ventricular assist devices and association with ICD/CRT-D treatment

N Jakus[1]; M Cikes[1]; JJ Brugts[2]; K Holcman[3]; E Gaizauskas[4]; A Gigase[5]; LM Jacquet[6]; E Barge-Caballero[7]; S Adamopoulos[8]; D D'amario[9]; I Planinc[1]; LH Lund[10]; A Flammer[11]; F Ruschitzka[11]; D Milicic[1]

On behalf of: The PCHF VAD-ICD/CRT Registry

Introduction: There is an increasing interest in exploring the association between implantable defibrillators (ICD and CRT-D) and outcomes in ventricular assist device (VAD) carriers. Through a VAD registry formed by 10 European heart failure centres, we aimed to investigate the baseline differences among VAD carriers subgrouped by age quartiles, the prognostic role of age and its association with ICD/CRT-D treatment.
Methods: At current, the registry includes data on 246 patients with continuous flow LVADs (median age 56 (IQR 48-63), 83% male), 63% of which are also ICD or CRT-D carriers. For this subanalysis, patients were subgrouped in quartiles according to age (Table 1). Median follow-up time was 1.3 years (IQR 0.4-2.0) from index date, defined as time of LVAD or ICD/CRT-D implant, whichever came later.
Results: The baseline patient characteristics are presented in Table 1. The crude event rates for the primary outcome (all-cause mortality) increased with age (event rates per 100 person-years: Q1: 9.8 [5.1-18.8], Q2: 11.3 [6.3-20.5], Q3: 27.1 [17.5-42.0], Q4: 36.2 [24.8-52.8]). In unadjusted analysis, the hazard ratio for all-cause death was significantly higher in Q3 and Q4 compared to Q1 (HR [95% CI] for Q2, Q3 and Q4 was 1.15 [0.48-2.79], p = 0.8, 2.48 [1.13-5.45], p = 0.024 and 3.31 [1.55-7.06], p = 0.002, respectively), remaining significant after adjusting for HF aetiology, INTERMACS class and prior cardiac surgery. ICD use was associated with reduced mortality, and age strata at LVAD implantation did not modify the association between ICD/CRT-D therapy and reduced mortality (interaction p = NS for all age quartiles).
Conclusion: Although increasing age at LVAD implantation is associated with a higher risk of all-cause death, it does not appear to modify the treatment effect of ICD/CRT-D therapy in cf-LVAD carriers.

Table 1.

	Q1 (16-48 y) (N = 62)	Q2 (48-56 y) (N = 61)	Q3 (56-63 y) (N = 62)	Q4 (63-75 y) (N = 61)	P value
Male gender, n (%)	47 (75.8%)	52 (85.2%)	52 (83.9%)	52 (85.2%)	0.45
Dilated cardiomyopathy, n (%)	39 (62.9%)	28 (45.9%)	14 (22.6%)	20 (32.8%)	<0.001
Ischemic cardiomyopathy, n (%)	15 (24.2%)	28 (45.2%)	43 (69.4%)	32 (52.5%)	
Other cause of HF, n (%)	8 (12.9%)	5 (8.1%)	5 (8.1%)	9 (14.8%)	
INTERMACS class 1, n (%)	18 (29.0%)	9 (14.5%)	8 (13.1%)	2 (3.4%)	0.006
INTERMACS class 2, n (%)	14 (22.6%)	16 (25.8%)	15 (24.6%)	13 (22.0%)	
INTERMACS class 3, n (%)	21 (33.9%)	21 (34.4%)	18 (29.5%)	19 (32.2%)	
INTERMACS class 4-7, n (%)	9 (14.5%)	15 (24.2%)	20 (32.8%)	25 (42.4%)	
ICD and CRT-D therapy during VAD support, n (%)	30 (48%)	38 (62%)	44 (71%)	43 (72%)	0.022

Haemodynamic parameter analysis during impella-protected pci in high risk patients with reduced ejection fraction

D Domenico D'amario[1]; F Burzotta[1]; G Russo[1]; F Ribichini[2]; A Piccoli[2]; L Paraggio[1]; L Previ[1]; C Aurigemma[1]; C Trani[1]; F Crea[1]
[1]*Catholic University of the Sacred Heart, Institute of Cardiology, Rome, Italy*; [2]*University of Verona, Verona, Italy*

Background: The use of cardiac assistance devices represents a promising strategy to facilitate percutaneous coronary intervention (PCI) in high risk patients. The haemodynamic response to Impella-protected PCI (pIMP) in real-world patients has not been systematically investigated.
Purpose: To assess the haemodynamic response to pIMP in patients with heart failure with reduced ejection fraction undergoing high risk PCI.
Methods: We extracted and analyzed the device console data continuously recorded during assistance in consecutive patients who underwent elective pIMP-protected PCI in two high volume centers. Patients with established cardiogenic shock before intervention were excluded. Coronary artery disease burden was graded using the British-Cardiovascular-Intervention-Society jeopardy-score (BCIS-JS) score. pIMP motor speed and pressure signals (systolic blood pressure, SBP, and mean blood pressure, MBP) recorded during pIMP

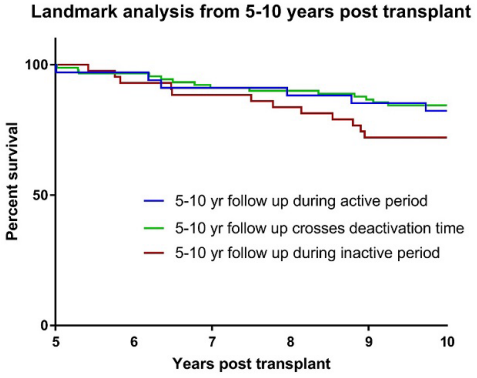
assistance were analyzed to evaluate the occurrence of device malfunctions and arterial pressure drops. Primary haemodynamic pre-determined end-points were "major systolic blood pressure (SBP) drop" (SBP decrease = 20 mmHg reaching = 90 mmHg values) and "major mean blood pressure (MBP) drop" (MBP decrease reaching = 60 mmHg).
Results: The study population comprised 37 patients who underwent pIMP-protected PCI. All patients enrolled in the study had severe left ventricular dysfunction (EF 31 ± 10%) and 86% had a New-York-Heart-Association class III or IV. Pre-PCI BCIS-JS was 11 ± 2 and more than a half underwent left main PCI. Mean assistance duration was 254 ± 549 minutes and no device malfunction occurred. SBP and MBP significantly decreased during PCI , but all patients had SBP values >78 mmHg. Major SBP and MBP drops occurred in 10.8% of patients in both cases. BCIS-JS was the only significant predictor of both SBP (p = 0.001) and MBP drop (p = 0.001). No correlations were found between lactate levels and haemodynamic pre-determined end-points.
Conclusions: PCI is becoming the treatment of choice for complex, fragile patients that are considered to be not amenable to surgical revascularization at reasonable risk. Unfortunately, there is an ever-enlarging gap between the supply and the demand for such complex procedure, a gap which is made more severe by the expanding indications and less conservative criteria widely used for candidacy.
In patients with reduced ejection fraction, undergoing pIMP-protected PCI, a significant pressure decrease occurs during PCI but pressure is systematically maintained at levels warranting vital organ perfusion. Pressure drops during PCI may occur in patients with higher jeopardized myocardium. Therefore, as patients' selection is a crucial moment, a major effort has to be performed in order to have every single candidate undergoing a comprehensive evaluation, during Heart Team discussion and before pIMP planning.

P1772

Does deactivation of a site's surgical cardiac transplant program affect the long-term survival of its recipients?

WA Parker[1]; HJ Ramshaw[1]; EK D'arcy[1]; J Pickering[1]; RR Burger[2]; K Adatia[2]; O Ogunleye[2]; KW Ow[2]; SJ Armour[2]; AA Girach[2]; PC Braidley[1]; A Al-Mohammad[1]
[1]Northern General Hospital, The Heart & Lung Transplant Unit, Sheffield, United Kingdom; *[2]University of Sheffield, The Medical School, Sheffield, United Kingdom*

Background: When a cardiac transplant centre permanently ceases its surgical programme, it may continue ongoing follow-up of its recipients. The effects of this transition on the long-term survival of the recipients have not been well studied. It remains unclear whether follow-up should continue at such a site or be transferred to a surgically active centre.
Purpose: We explored factors, including site deactivation, affecting mortality before and after our centre's surgical programme was deactivated.
Methods: Baseline and mortality data were collected on the 215 patients who underwent orthotopic cardiac transplantation over a 13 year period at a single centre that voluntarily ceased its programme in September 2002 but continued a dedicated service for follow-up of the surviving recipients, now all at least 15 years post-transplant. Kaplan-Meier curves were constructed and relationships assessed using log-rank testing and a 17-factor Cox proportional hazards model. To compare long-term mortality during similar periods of follow-up before and after site deactivation, patients were divided into those undergoing 5-10 year follow up before, through and after deactivation and a landmark analysis performed to compare mortality outcomes during these periods. Statistical analyses were performed using IBM SPSS v23.



p=0.21 between groups (Cox regression)

Summary figures

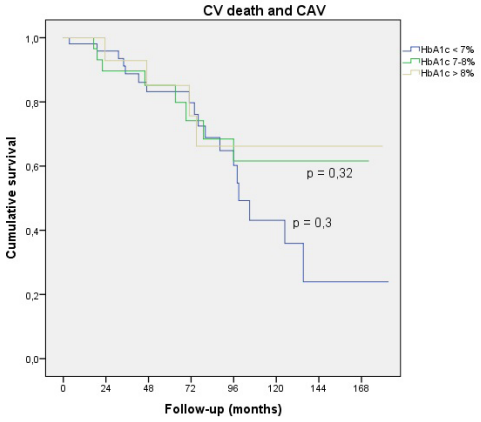
Results: Overall 1, 5, 10 and 15-year survival rates were 88%, 77%, 62% and 37% respectively. Non-ischaemic indication for transplant (hazard ratio [HR] 0.63 [95% CI 0.40-0.99], p = 0.046) and lower pre-transplant pulmonary vascular resistance (exp[B] = 0.71 [95% CI 0.57-0.89], p = 0.004) were identified as significant independent predictors of lower long-term mortality in this cohort. Survival curves did not significantly differ between chronological quartiles (chi square 3.24, p = 0.36) and a landmark analysis performed from 5-10 years post-transplant showed no significant difference in survival curves between the 3 analysis groups (log-rank chi square 1.54, p = 0.21). There was no relationship between date of transplant and risk-adjusted 15-year survival (p = 0.89 by Cox regression).
Conclusion: Based on these data, cessation of cardiac transplant activity at a centre does not appear to significantly affect long-term outcomes of its recipients and follow-up can safely continue there, with advantages of continuity and geographical convenience.

P1773

Is glycated hemoglobin a prognosis factor in Heart Transplant Recipients with diabetes?

A Antonio Grande-Trillo[1]; JM Sobrino-Marquez[1]; D Rangel-Sousa[1]; E Lage-Galle[1]
[1]University Hospital of Virgen del Rocio, Seville, Spain

Introduction: Diabetes mellitus (DM) is associated with poor survival after heart transplant (HT). However, the significance of glycemic control in diabetic HT recipients have not been studied yet. Our aim is to establish if poor glycemic control evaluated by glycated hemoglobin (HbA1c) is related with a poor prognosis.
Methods: We analyzed prospectively all HT recipients in our center from 2002. Those with pre-existing DM before HT and those who developed DM after HT attending on DM diagnostic criteria from American Diabetes Association were included as diabetic patients. In-hospital mortality cases were excluded. We evaluated survival free of cardiovascular (CV) death and cardiac allograph vasculopathy (CAV) in diabetic and non-diabetic patients. Finally, we assessed influence of glycemic control using average HbA1c in their follow-up after HT.
Results: 209 patients were included in the analysis (figure 1). Univariate analyses reveals an increase of combined endpoint (CV death and CAV) in DM patients (pre-existing and new onset) with an OR of 2,5 (p = 0,04; IC 95% 1,29 - 5,02). However, diabetic patients subgroups attending on HbA1c did not show differences in combined endpoint (figure 1).
Conclusions: DM is associated with poor prognosis after HT as happen in another series, including both pre-existing and new onset DM. However, specifically in DM patients, mean HbA1c is not related with a worse outcome. It may means that HbA1c is not a good marker for HT patients or we don't know nowadays optimal target HbA1 for HbA1c recipients.



P1774

Predisposing factors for development of acute right ventricular failure after heart transplantation

J Ljubas Macek[1]; D Fabijanovic[1]; B Skoric[2]; M Cikes[2]; J Samardzic[2]; D Lovric[1]; H Jurin[1]; H Gasparovic[3]; N Jakus[1]; I Planinc[1]; M Pasalic[1]; D Milicic[2]
[1]University Hospital Centre Zagreb, Department of cardiovascular diseases, Zagreb, Croatia; *[2]University of Zagreb School of Medicine, and University Hospital Centre Zagreb, Dpt. of cardiovascular diseases, Zagreb, Croatia*; *[3]University Hospital Centre Zagreb, Dept of Cardiac surgery, Zagreb, Croatia*

Introduction: Isolated acute right ventricular failure (ARVF) is one of the most common haemodynamic complications after heart transplantation (HTx), often requiring

mechanical circulatory support (MCS) as the only possible treatment option. Irreversibly elevated pulmonary vascular resistance (PVR) despite vasodilators (= 4 Wood units) is a major risk factor for ARVF and presents contraindication for HTx, but other contributing factors could also be recognized.
Purpose: The aim of our study was to detect other less known predisposing conditions for the development of ARVF, including patient (PT) comorbidites and peritransplant injury as well as early postHTx PT clinical characteristics. Clinical intention was to better prepare the PT before the transplant procedure and more precisely stratify PT's risk factors for postHTx ARVF.
Methods: 145 HTx PTs, mean age 51 ± 12 years, were included in the study. ARVF was treated medicamentously or in combination with MCS. We analyzed potential predisposing conditions for ARVF, such as preHTx comorbidities: chronic obstructive pulmonary disease, diabetes mellitus type II, chronic renal failure (CRF) and INTERMACS score. Donor age, ischemic time and cardiopulmonary bypass time (CPB) were also considered. Early postHTx clinical parameters such as acute renal failure with the use of perioperative hemodialysis (pHD), average heart rate (HR) during 1st month, high-sensitivity troponine T (hsTnT) and NT-proBNP levels and liver enzymes (alanin-aminotransferase - ALT and gamma-glutamyl transferase - GGT) were also collected.
Results: 16% of PTs developed ARVF (N = 23), among who 60% were treated with short-term MCS. PTs with ARVF have significantly increased mortality (p = 0,005). From preHTx comorbidites, only CRF significantly predisposes to ARVF (p = 0,009, creatinine clearance: ARVF vs normal RV, 50 vs 62 ml/min). INTERMACS score has no impact (p = 0,112) as well as donor age (p = 0,215), ischemic time (p = 0,225) and CPB (p = 0.272). Lower HR is a significant predisposing condition (p = 0,028, ARVF vs normal RV: 80 vs 90 /min) and preHTx use of amiodarone could be the cause of lower HR early postHTx (p = 0,026). Development of ARVF is marked with significantly higher levels of early hsTnT (2nd postHTx day: ARVF vs normal RV: 1520 vs 800 ng/L, during the 1st week 1230 vs 533 ng/L), ALT (p = 0,003), GGT (p = 0,005) and expectedly NT-proBNP (10207 vs 2211 pg/ml).
Conclusion: ARVF developed in 16% of PTs and MCS was required in majority cases. CRF predisposes to development of ARVF potentially through more pronounced volume overload and further on, perioperative deterioration with use of pHD is a significant contributor. Peritransplant graft ischemic-reperfusion injury does not seem to be relevant, as well as donor age. PTs with lower HR early posttransplant are at higher risk to develop ARVF and those PTs were often more pretreated with amiodarone. ARVF significantly elevates early hsTnT, NT-proBNP and liver enzymes.

P1775

Assessing and comparing the need for palliative care in different advanced HF cohorts

F Strangl[1]; J Ehlert[2]; A Ullrich[2]; S Vehling[2]; S Blankenberg[1]; C Bokemeyer[2]; K Oechsle[2]; M Rybczynski[1]
[1]University Heart Center Hamburg, Klinik für Allgemeine und Interventionelle Kardiologie, Hamburg, Germany; *[2]University Medical Center Hamburg Eppendorf, II. Medizinische Klinik, Hamburg, Germany*

Objective: The psycho-social burden of cardiovasvular disease is vast and frequently under-estimated. Within a multi-modal and interdisciplinary treatment approach to advanced chronic heart-failure (CHF), palliative treatment has gained rising attention. While psychological treatment has been well implemented in the treatment of VAD and HTX patients, the role of palliative care (PC) in advanced CHF patients is unclear.
Methods: In a cross-sectional single-center pilot study, we evaluated 243 CHF patients regarding a need for palliative care. Both inpatients from the heart-failure unit (HFU, n = 148) and outpatients from the heart transplantation (HTX, n = 69), ventricular assisted device (VAD, n = 21) and CHF department (CHF, n = 5) were included.
The feasibility of the tools used had been demonstrated earlier (Oechsle et al. 2017). The "Minimal Documentation System For Palliative Medicine" (MIDOS) and "Distress-Thermometer" (DT) were used for self-assessment of symptom burden and distress, and a modified version of the "Five-Item-Palliative-Care-Screening-Tool" (Glare et al. 2011) served as screening-tool by treating cardiologists.
Results: Patient-reported outcomes showed a significantly higher symptom burden (as assessed by MIDOS and DT) among hospitalized HFU patients than HTX outpatients. Two thirds (66%) of patients scored above the cut-off (DT = 5) for "clinically relevant" distress, and HFU patients were more likely to do so when compared to HTX outpatients (74% vs. 57%, p = 0.018). "Fatigue" (45%), "weakness" (42%), "dyspnea" (38%), "lack of appetite" (19%), and "pain" (17%) were the most frequent symptoms with moderate or severe intensity.
While the highest mean symptom-score was encountered among VAD outpatients, MIDOS and DT score did not differ significantly between the VAD and HTX outpatient group (p = 0.21).
The Glare-Screening revealed a need for PC support (Score = 5) in more than two thirds (68%) of all patients. The need was significantly higher among HFU than HTX patients (84% vs. 32% above cut-off, each p < 0.001), mirroring the increased symptom burden among hospitalized patients.
Among outpatients, the Glare-Score was significantly higher in the VAD than the HTX group (p < 0.001), as was the concluded need for PC support (67% vs. 32%, p = 0.006).
Discussion: Data suggest a distinctive need for PC within a multi-modal treatment approach for advanced CHF. Hospitalized patients with a significant symptom burden and, in outpatient care, especially VAD patients may benefit from integrating interdisciplinary PC into standard CHF care.
Psychological treatment may already be well implemented among HTX and VAD patients - However, enhancing therapy with additional PC approaches and expanding it to other advanced CHF patients seems advisable.

P1776

Usefulness of hypertonic saline solution plus intravenous furosemide as treatment for acute heart failure in patients with refractory congestion

C Aguilera Agudo[1]; J Baena Herrera[1]; M Torres Sanabria[1]; A Restrepo Cordoba[1]; P Garcia Pavia[1]; I Zegri Reiriz[1]; M Marta Cobo Marcos[1]
[1]University Hospital Puerta de Hierro Majadahonda, Department of Cardiology, Madrid, Spain

Background: Refractory congestion in heart failure (HF) is related with a poor prognosis. Treatment with saline hypertonic solution (HSS) in combination with intravenous furosemide has shown promising results.
Aim: Analyze the safety and effectiveness of HSS together with furosemide in patients with HF and persistent congestion.

Results

	24 h before HSS (mean and standard deviation)	24 h after HSS (mean and standard deviation)	Difference	p
Diuresis (ml)	1375 (733)	2146 (971)	+ 771	0,000
Weight (kg)	80,2 (21)	79,3 (20)	-0,95	0,000
Systolic arterial pressure (mmHg)	112 (16)	107 (18)	-5	0,02
Cr (mg/dl)	1,7 (0,9)	1,7 (0,9)	0	0,75
Na (mEq/L)	137,2 (4,6)	137,6 (4,1)	0,37	0,258
K (mEq/L)	4,2 (0,4)	4,1 (0,6)	-0,1	0,144
NTproBNP (pg/ml)	15222 (18482)	9675 (8079)	-5546	0,056

Cr: creatinine, Na: sodium, K: potassium, NTproBNP: N-terminal pro b-type natriuretic peptide

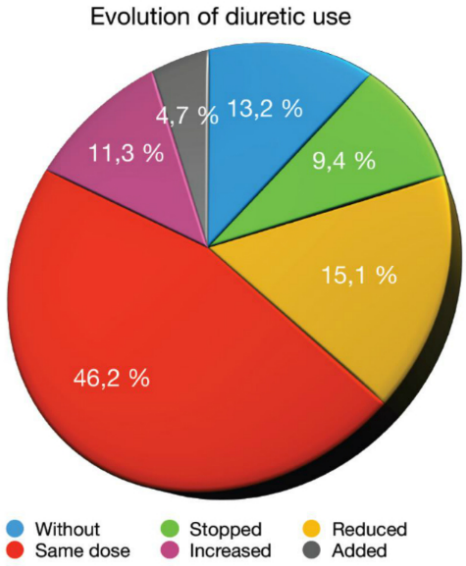
Methods: Retrospective analysis of patients admitted in our hospital during 2016 and 2017 in which we used this strategy. The infusion consisted on 100 mL of 2,9% NaCl saline solution with 125 mg of furosemide, once a day, for 30 minutes. We compared diuresis, weight, serum sodium, potassium, creatinine and systolic blood pressure 24 hours before and after the infusion. We evaluated intra-hospital mortality and readmissions for decompensated HF within the first 30 days.
Results: 341 patients were admitted for HF. 51 (15%) had persistent congestion and received HSS + intravenous furosemide (median: 2, rank 1-13). The mean age was 73 years old , 67% were men, and there were a high prevalence of comorbilities (80% AHT, 45% DM, 65% chronic kidney disease) and advanced cardiopathy (50% with LVEF < 35%, mean NTProBNP 15222 pg/mL). 24 hours after the treatment the diuresis had a mean increase of 771 mL and the weight had a mean decrease of 1 kg, with a slight decrease of systolic blood pressure (- 5mmHg). There were no differences in serum sodium, potassium and creatinine levels. 80% of the patients had a favourable response in terms of diuresis or weight. At discharge, the weight had a mean decrease of 6 kg and the NTproBNP decreased in 36%. Intra-hospital mortality was 19%, with a 10% of early hospital readmissions. None of the deaths were related to the treatment.
Conclusions: In our experience, intravenous furosemide together with HSS is an effective, cheap, easy and safe strategy and should be considered in the patientes with HF and persistent congestion.

P1777

Clinical impact of Sacubitril/valsartan in patients with heart failure with reduced ejection fraction and management of loop diuretic during follow up

M Fernandez-De-Sanmamed-Giron[1]; M Galvan Ruiz[1]; M Blanco-Nuez[1]; M Singh[1]; M Groba-Marco[1]; R Montiel Quintero[1]; E Perez-Nogales[2]; JM Medina Gil[2]; E Caballero Dorta[1]; H Mendoza Lemes[1]; M Lopez Perez[1]; A Antonio Garcia Quintana[1]
[1]University Hospital De Gran Canaria "Dr. Negrin", Las Palmas de Gran Canaria, Spain; [2]University Hospital Insular of Gran Canaria, Las Palmas De Gran Canaria, Spain

Background: Diuretic therapy in heart failure with reduced ejection fraction (HFrEF) is recommended to reduce signs and symptoms of congestion. Sacubitril/valsartan, an angiotensin receptor-neprilysin inhibitor (ARNI), is a novel treatment of HFrEF that has shown to reduce symptoms and improve survival. No real world data is available to study the association between clinical response to ARNI and loop diuretic management over time.



Diuretic use after ANRI treatment

Purpose: The aim of our study is to assess the clinical impact of ARNI treatment in patients with HFrEF and evaluate diuretic treatment patterns in these patients.
Methods: Overall, 106 patients with HFrEF started on ANRI during September 2016 to December 2017 in two university hospitals were analysed in an ambispective, multicentre study. Baseline characteristics, clinical response using the NYHA class and assessment of the dosage of loop diuretics during the follow up was carried out.
Results: The cohort included 68.9% men and 31.1% women, with a mean age of 63.5 ± 11.6 years. Regarding comorbidities, 74.5% had hypertension, 51.9% dyslipidaemias, 49.1% diabetics and 30.2% had AF. 37.7% had a LBBB, 20.8% had a CRT and 28.3 had an ICD. 44.3% were on NYHA class III, 49.1% NYHA class II, and 6.6% had no detailed NYHA class. At the baseline, treatment included: 63.2% ACEIs, 33% ARBs, 94.3% betablockers, 82% had antialdosterone drugs and 24.5% had ivabradine.
Of the total cohort, 82% of the patients were treated with oral diuretic (94% furosemide or 6% torasemide) before the start of INRA. In a mean follow up of 219 (51-304) days, 13,2% was maintained without loop diuretic, in 9,4% was discontinued, in 15,1% reduced, 46,2% continued with the same dose, 11,3% needed to be increased and 4,7% (n 5) loop diuretics were newly introduced. In those patients who required an increase in diuretic treatment, 25% presented hospitalization after INRA initiation and 2 patients worsened their functional class.
A further analysis of the loop diuretic patters of those patients during follow-up in NYHA class I was performed (n = 16, 15%), concluding that 37.5% had no diuretic at the end of the follow-up, 6% decreased the diuretic dosage, 25% increased dosage, and in 31.5% the same dose was continued despite clinical improvement and no symptoms of heart failure. Interestingly, the average dosage in these patients was of 35 mg/day. No worsening of the renal function, no increase of NT-proBNP or secondary effects were related to maintained diuretics on these patients.
Conclusion: INRA treatment usually allows to stop or decrease diuretic dose. Nevertheless, in our serie no significant dosage reduction of loop diuretics was observed despite improvement in the symptomatology of patients with HFrEF under treatment with INRA. Efforts should be made to adjust diuretic dosage according to individual needs over time, achieving the lowest needed dose (including discontinuation) to maintain euvolemia and therefore avoid possible adverse effects.

P1778

Elevated pulmonary vascular resistance is superior to mean transpulmonary gradient in predicting right heart failure after heart transplantation: a 12-year single center analysis

CMF Christopher Strong[1]; A Tralhao[1]; C Aguiar[1]; MJ Rebocho[1]; T Nolasco[2]; M Marques[2]; A Ventosa[1]; M Mendes[1]; M Abecasis[2]; JP Neves[2]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; [2]Hospital de Santa Cruz, Lisbon, Portugal

Background: Right heart failure (RHF) after heart transplantation (HTx) may adversely affect prognosis. Risk prediction is mostly based on invasive hemodynamic data but there is no consensus about the single best parameter to aid in risk stratification.
Purpose: We sought to compare the ability of usual right heart catheterization (RHC) derived parameters in predicting RHF after HTx.
Methods: Single-center retrospective study of all adult patients undergoing orthotopic bicaval HTx between January 2006 and November 2017 in a single-center. Pulmonary artery (PA) pressures (mean [mPAP], diastolic [dPAP]), transpulmonary gradients (mean [mTPG], diastolic [dTPG]) and pulmonary vascular resistance (PVR) were obtained from each patient's last RHC before HTx. RHF after HTx was defined as right ventricular dilatation (right ventricle/left ventricle basal diameter > 1) and dysfunction (tricuspid annular systolic plane excursion < 12 mm) on transthoracic echocardiography plus signs of end-organ dysfunction (creatinin increase > 0.5 mg/dL from baseline or spontaneous prothrombin time > 14 s), without a plausible alternative cause. Univariate and multivariate analysis were performed to find independent predictors of RHF and receiver operating curve (ROC) analysis was used to assess discriminative power.
Results: Fifty-eight heart transplant patients were identified and analyzed (mean age 51 ± 11 years, 58 % male). The most frequent etiologies were ischemic heart disease (n = 21) and dilated idiopathic cardiomyopathy (n = 16). Pre-operative PVR was 3.3 ± 2.1 Wood units, mean PAP was 38 ± 10 mmHg, dPAP was 27 ± 7 mmHg and mTPG and dTPG were 10 ± 5.3 and 3.5 ± 2.7 mmHg, respectively. 14% of patients (n = 8) were on inotropic support and 10% (n = 6) required pre-HTx mechanical circulatory support (MCS). After HTx, RHF incidence was 5.2 % (n = 3) and one patient required temporary right ventricular MCS. In univariate analysis, elevated PVR, mTPG, mPAP and dPAP were associated with increased incidence of RHF. After multivariate logistic regression modelling, only PVR remained significantly associated with post-HTx RHF (OR 1.6 [CI 95%, 1.1-2.6], p = 0.03). ROC curve analysis using PVR as the discriminator yielded a C-statistic of 0.8 [CI 95%, 0.7-1.0, p = 0.03) for RHF occurrence after HTx. In a mean follow-up of 4.2 years, overall mortality was not different between those with RHF and those without (p = 1.0).
Conclusions: In our population, RHF after HTx was an uncommon finding. Elevated PVR seems to be superior to other RHC derived parameters in predicting RHF following HTx.

P1779

Effectiveness of cardiac resynchronization therapy in heart failure patients with valvular heart disease: comparison with patients with dilated cardiomyopathy

V Vera Marinho[1]; J Milner[1]; P Alves[1]; C Domingues[1]; F Ferreira[1]; N Antonio[1]; L Elvas[1]; F Goncalves[1]; M Pego[1]
[1]University Hospitals of Coimbra, Cardiology, Coimbra, Portugal

Introduction: Heart failure (HF) may occur in the presence of a wide range of underlying heart diseases, including valvular heart disease (VHD). In the majority of randomized clinical trials that validated the clinical use of cardiac resynchronization therapy (CRT), the presence of a clinically significant valvular heart disease were exclusion criteria. The aim of this study was to analyze the effectiveness of CRT in patients with VHD in comparison with dilated cardiomyopathy patients.
Methods: Retrospective single-centre study that included all patients submitted to CRT therapy between January 2006 and December 2015. For the aims of current analysis, the following groups were considered: 1) patients with valvular heart disease (evidence of clinically significant primary valvular disease or previous valve replacement or repair; 2) patients with dilated cardiomyopathy (presence of a typical pattern of this heart disease, without ischaemic or organic VHD). The response to CRT was evaluated comparing the baseline with 6 month follow-up echo data. In long term follow-up we evaluated all-cause mortality, transplantation rate and admissions for HF.

	Chi square	df	Sig.
Log Rank (Mantel-Cox)	4,337	1	,037

Results: A total of 431 patients submitted to resynchronization therapy in our centre were included. Of these, 199 patients (46%) had dilated cardiomyopathy and 26(6.0%) had valvular heart disease. Age did not differ between groups [65 (+11) vs 69 (+9) years, p = 0.253)]. There were no differences between the distribution of Diabetes Mellitus (29% vs 24%, p = 0.574), hypertension (51% vs 42%, p = 0.531), dyslipidemia (62% vs 75%, p = 0.331) and chronic kidney disease (29%vs53%, p = 0.07). The distribution of LBBB (82% vs 89%, p = 0.402), and basal LV end diastolic volume [219(104) vs 210(110), p = 0.867] was similar between groups. At 6 months echo, there was a trend to a more positive response to CRT in group of patients with dilated cardiomyopathy (55% vs 49%, p = 0.06). Interestingly, group 1 patients were more frequently super responders (29 vs 6.3%, p = 0.04). The mean follow up was 42(+33) months. Mortality (18% vs 35%, p = 0.04) was significantly lower in dilated cardiomyopathy. Both groups did not differ in transplantation rate (6.1 vs 3.8, p = 0.538) and admissions for acute HF (29% vs 35%,p = 0.33). The survival curves for all-cause mortality obtained by Kaplan–Meier analysis are shown in Figure 1 and revealed a worse prognosis of patients with VHD (Log-rank test, p = 0,037). In multivariate logistic regression analysis, the presence of Diabetes Mellitus [4.0 (1.1-16), p = 0.04] and the VHD etiology [6.1(1.1-33), p = 0.03] significantly increased the risk, while responsiveness to CRT proved to have a significant protective role in the whole patient population [0.13(0.03-0.4), p = 0.02].
Conclusions: No randomized controlled trial has specifically evaluated the effects of CRT in patients affected by a VHD, but on the basis of 'real world' clinical practice, CRT appears more effective in dilated cardiomyopathy than VHD.

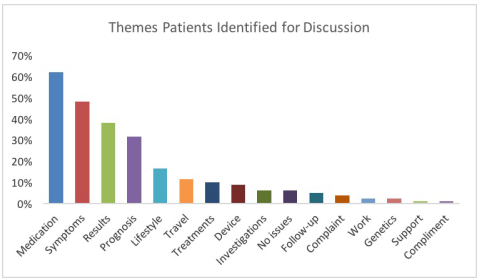
"The patient will see you now". Use of a clinic proforma to help clinicians identify the heart failure patients' agenda

MG Williams[1]; R Baker[1]; B Pearson[1]; H Lightfoot[1]; H Donaldson[1]; AK Nightingale[1]; Y Ismail[1]
[1]Bristol Heart Institute, Department of Cardiology, Bristol, United Kingdom

Background: Heart failure patients have significant comorbidities and present complex decision-making issues in clinic. As a result, issues that are important to patients and their carers can easily be overlooked. Often this can mean that clinicians do not give sufficient time to identify the issues of most importance to a patient. Shared decision-making helps to improve patient quality of life and outcomes.
Purpose: We wanted to identify if a proforma given to patients and their carers to complete prior to their clinic appointment would help identify the patients' agenda for the appointment.
Methods: We designed a proforma for patients to complete while they were waiting to be called in for their clinic appointment. We asked them to record any topics or specific questions they would like to discuss in the clinic. We collected this data from our doctor or nurse led outpatient specialist heart failure clinics between August and December 2017. Individual responses were then thematically analysed and divided into 16 broad categories. Patients were asked after the clinic to rate how useful they found the form on a scale of 1 to 5.
Results: We received completed forms from 79 patients with a total of 202 questions or themes to be discussed. The main topics to discuss were medication (62%), symptoms (48%) and test results (38%). In addition to these subjects, almost one third of patients wanted to discuss the future and a significant proportion asked about lifestyle and travel. Other themes are shown in figure 1.
Patients found the survey useful with an average rating of 3.9 out of 5. All clinicians found the proforma helpful.
Conclusions: The use of a proforma to identify topics that patients wanted to discuss in their heart failure clinic appointment was helpful to clinicians and valued by patients. This may give further opportunities to increase shared decision-making and provide opportunities to discuss complex issues such as planning for the future and prognosis. These results would also suggest a beneficial role for cardiac pharmacists and palliative care specialists within our heart failure clinic to help meet patient and carers' needs.



P1781

Incidence and factors related to vasoplegia in the early postoperatory period of orthotopic heart transplantation

R Raquel Lopez Vilella[1]; I Sanchez Lazaro[1]; MJ Paniagua Martin[2]; G Barge Caballero[2]; E Marques-Sule[3]; E Barge Caballero[2]; M Crespo Leiro[2]; L Almenar Bonet[1]
[1]Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit. Cardiology Department, Valencia, Spain; [2]University Hospital Complex A Coruña, Cardiology Department, A Coruña, Spain; [3]University of Valencia, Physiotherapy Department. , Valencia, Spain

Background and objective: The vasoplegia syndrome is a serious complication that may occur after any surgery with extracorporeal circulation. It is defined as hypotension, acidosis and vasodilation with normal or increased cardiac output. Our purpose was to describe the incidence of vasoplegia after heart transplantation (HT), the factors related to the presence of vasoplegia, and its repercussion on mortality in the early postoperatory period of heart transplantation
Methods: All HT performed between June 2010 and December 2016 were consecutively recruited in two Spanish centres. Combined transplants, pediatric transplants and retransplants were excluded. Definition of vasoplegia: mean arterial pressure < 50 mmHg, serum bicarbonate < 19 mE / L and lactic acid > 2.
Results: 100 patients, 78% males, average age 52 ± 15 years. 39% of HT (37) were urgent, 98% of them (38) with circulatory / ventricular assistance. 16 patients presented post-transplant vasoplegia (16.8%). The development of post-transplant vasoplegia was related to: elevation of GOT before HT (30% vs 11%, p 0.022), previous mechanical ventilation (33% vs 13%, p 0.041), perioperative bleeding (31% vs 6%, p 0.02) and number of previous sternotomies (p 0.01). In the multivariate analysis, only perioperative bleeding was independently associated to the presence of post-transplant vasoplegia. The presence of vasoplegia was associated to an increase of mortality at one month (50% vs 11%, p < 0.01) and at 6 months after HT (31% vs 6%, p 0.003).
Conclusions: The incidence of vasoplegia after heart transplantation may reach high values 16.8% . The presence of vasoplegia is independently related to perioperative bleeding, whilst it is associated to an increase in early mortality and mortality at 6 months after HT.

P1782

Effects of a home-based nurse monitoring program on treatment compliance, quality of life, and hospitalizations of patients with chronic heart failure

V Bistola[1]; M Thodi[1]; E Lambrinou[2]; G Bakosis[1]; S Katsanos[1]; K Toli[1]; J Parissis[1]; G Filippatos[1]
[1]Attikon University Hospital, Athens, Greece; [2]Cyprus University of Technology, Nicosia, Cyprus

Background: Home-based nurse monitoring programs have been shown to reduce unplanned readmissions of patients hospitalized due to decompensated heart failure.

Purpose: To investigate whether a home-based nurse-provided monitoring program, combined with standard multidisciplinary outpatient heart failure clinic care improves treatment compliance, quality of life and reduces risk of unplanned HF-related hospitalization in patients with chronic heart failure (CHF).
Methods: Eighty patients with CHF were randomized by a 1:1 ratio to either standard heart failure clinic care alone (Group ?, n = 40) or to standard care combined with a home-based nurse-provided monitoring program (Group B, n = 40). Home-based monitoring was delivered through regular home visits or telephone contacts by a heart failure nurse. Monitoring included recording of vital signs, HF symptoms and assessment of treatment compliance by Morisky scale and quality of life by Kansas City Cardiomyopathy Questionnaire (KCCQ). Data collected were communicated to the heart failure physician who made drug changes or advised further specific monitoring according to standard protocols. We compared changes in treatment compliance and quality of life between Groups A and B as well as the effect of home monitoring program on rates of HF hospitalizations during a 6-month follow up.
Results: At baseline, Groups A and B did not differ with respect to gender (male: 67.5% vs 77.5%, respectively, p = 0.317), HF etiology (ischemic: 40% vs 55%, p = 0.467), NYHA class (I/II: 65% vs 60%, p = 0.255), LVEF (35 ± 10% vs 33 ± 10%, p = 0.299), treatment compliance (High compliance: 37.5% vs 20%, p = 0.192), and the overall summary (OS) (59.9 ± 24.4 vs 55.1 ± 23.2, p = 0.366) and clinical summary (CS) KCCQ score (68.7 ± 24.6 vs 60.9 ± 26, p = 0.174). At follow up, Group B patients showed better treatment compliance compared to Group A (High compliance: Group B 82.5% vs Group A 32.5%, p < 0.001), and improved both OS and CS KCCQ score, as compared to Group A patients whose KCCQ scores deteriorated (d(KCCQ-Overall): Group B, 17.3 ± 17.7 vs Group ?, -7.9 ± 17.7, p < 0.0001; d(KCCQ-Clinical): 20.8 ± 23.6 vs Group A, -8.5 ± 19.7, p < 0.0001). During a median follow up of 178 days (min 27-max 250 days), 8 patients in Group A compared to 3 in Group B were hospitalized due to HF. Age-adjusted Cox regression analysis showed that randomization to Group B was associated with lower risk of HF hospitalization (HR, 95%CI: 0.217, 0.054-0.865, p = 0.03).
Conclusions: Enrolment of CHF patients to a home-base nurse-provided monitoring program combined with standard multidisciplinary heart failure clinic care may improve treatment compliance, quality of life and reduces risk of unplanned HF hospitalizations.

P1783

Early effects of empagliflozin on exercise tolerance in patients with heart failure: a pilot study

A Anna Mollar Fernandez[1]; P Palau[2]; E Dominguez[2]; E Nunez[1]; JM Ramon[1]; G Minana[1]; E Santas[1]; L Facila[1]; JL Gorriz[3]; J Sanchis[1]; A Bayes-Genis[4]; J Nunez[4]

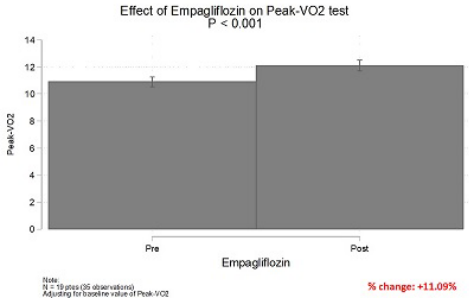
Funding Acknowledgements: CIBER CV 16/11/00420, 16/11/00403; FEDER and PIE15/00013

Background: Sodium-glucose transporter 2 (SLGT2) inhibition recently emerged as a promising therapy for reducing the risk of heart failure (HF) in patients with type 2 diabetes. However, there is a lack of data endorsing its role in symptomatic HF patients. We sought to evaluate the short-term effects of empagliflozin on maximal exercise capacity in these patients.
Methods and Results: Nineteen type 2 diabetes patients with symptomatic HF were prospectively included and underwent a cardiopulmonary exercise testing before and 30 days after initiation of empagliflozin therapy. A mixed-effects model for repeated-measures was used. Median (IQR) age was 72 years (60-79) and 42.1% were on New York Heart Association class III. Baseline mean (SD) peak oxygen consumption (peak VO2) was 10.9 ± 4.0 ml/min/kg. Peak VO2 increased significantly at 30-day (?=+1.21 (0.66-1.76); p <0.001). A significant improvement in ventilatory efficiency during exercise, distance walked in 6-minute, quality of life, and a reduction in plasma levels of antigen carbohydrate 125 were also found. Estimated glomerular filtration rate and natriuretic peptides did not significantly change.
Conclusions: In this pilot study, empagliflozin was associated with 1-month improvement in exercise capacity in type 2 diabetic patients with symptomatic HF. This beneficial effect was also found for other surrogates of severity.



Effect of Emplaglifozin on Peak-VO2 test

P1784

Possibilities of differentiated immunosuppressive therapy in patients after orthotopic heart transplantation

A Kurlianskaya[1]; YU Ostrovkiy[1]; T Troyanova-Shchutskaia[1]; O Shatova[1]; T Denisevich[1]; T Dubovik[1]
[1]Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

Backgroud: Coronary artery disease of the transplanted heart is one of the serious problems reducing patients' life expectancy, despite the successful clinical experience of orthotopic heart transplantation.
Purpose: to evaluate the effectiveness of various schemes of immunosuppressive therapy in patients after orthotopic heart transplantation
Methods. After the initial intravascular ultrasound (IVUS) all patients were randomized according to different immunosuppressive therapy: tacrolimus+mycophenolate mofetil (group 1, n = 60) and tacrolimus+everolimus (group 2, n = 17). The next IVUS was performed in 24 months after surgery.

Tge degree of affection of coronary arteries	tacrolimus + mycopheno-late mofetil (n = 60)	p	tacrolimus + everolimus (n = 17)	p		
Intravascular ultrasound 1	Intravascular ultrasound 2	Intravascilar ultrasound 1	Intravascular ultrasound 2			
Moderate	0.40 (0.37; 0.43)	0.60 (0.53; 0.65)	0.031	0.43 (0,40; 0.58)	0.39 (0.36: 0.43)	0.851
Severe subclinical	0.68 (0.59; 0.82)	0.60 (0.50; 0.79)	0.835	0.76 (0.56; 0.90)	0.66 (0.61; 0.74)	0.046

Results: Some differences between analizing groups were noted from the primary to the second IVUS. The body mass index significantly increased from 26.0 (26.0, 30.0) to 28.0 (25.0, 31.5) in group 1 (p = 0.002) vs. no significant changes in group 2 (p = 0.500). Statistically significant differences were revealed between groups before recurrent IVUS by the following echocardiographic indices: myocardial contractility, estimated by the index of local contractility (ILC) and global peak strain. The ILC was 1.10 (0.96, 1.49) in group 1 and 1.00 (1.00, 1.13) group 2, p < 0.001. The average global peak strain was lower in group 1 (-16.95 (-16.10, -18.70) vs. -18.60 (-13.10, -22.30), p = 0.012. In both groups a significant increase in VO2 and VO2AT was revealed. However in the group 2 the growth of these indicators was greater. The VO2 index increased by 84.00% (p = 0.018), the VO2AT index by 48.70% (p = 0.002). In group 1 these indicators increased by 12.4% (p = 0.001) and by 16.7% (p < 0.001), respectively.
The regression of intima thickness was observed in patients of the group 2 and with severe subclinical coronary arthery lesions. Intimal thickness changed from 0.76 mm to 0.66 mm (p = 0.046) in 24 ± 3 months after the start of treatment. In group 1 there was no statistically significant decrease in intimal thickness (table).
Conclusion. The regression of intimal thickness was observed in patients with severe subclinical coronary artery lesions, diagnosed 24 ± 3 months after heart transplantation. Everolimus needs to be included into the scheme of immunosuppressive therapy.

P1785

Meldonium and gamma-butyrobetaine combination improves cognitive function and flow-mediated vasodilatory response in chronic systolic heart failure: the results of open-label pilot study.

L Voronkov[1]; A Anastasiia Solonovych[1]; A Liashenko[1]; A Dudnik[1]
[1]*NSC Institute of Cardiology M.D. Strazhesko, Heart Failure Department, Kiev, Ukraine*

Background: Cognitive impairment and endothelial dysfunction are observed in majority of chronic heart failure (CHF) patients (pts). There is evidence that new formulation - meldonium (M) and gamma-butyrobetaine (GGB) combination - improves cognitive function (CF) in patients with neurological disorders. M partially blocks fatty acid transport to mitochondria through inhibition of carnitine synthesis that results in elevation of gamma-butyrobetaine GBB tissue content. It was shown that through its muscarinic receptor agonism, GBB ethyl- and methyl ethers stimulate endothelial nitric oxide synthesis and, therefore, cause improvement of endothelium-mediated vasodilator response.
Purpose: to evaluate the dynamics of CF, quality of life and flow-mediated vasodilatory response (FMVR) in pts with systolic CHF under M+GGB administration.
Methods: 22 cognitively impaired pts with stable CHF, NYHA II-IV and left ventricular ejection fraction (LVEF) < 40% were examined. Informed consent was mandatory. CF was evaluated by standard MMSE and Shulte tests, anxiety/depression score - by HADS scale. Quality of live was evaluated by The Minnesota Living with Heart Failure Questionnaire (MLHFQ). FMVR of the brachial artery was detected ultrasonically by the standard cuff test. M 360 mg + GBB 120 mg combination was prescribed t.i.d. (every 8 hours) for four weeks. Statistic methods descriptive statistics, Wilcoxon signed-rank test.
Results: after 4-week M + GBB administration pts demonstrated significant improvement of MMSE score (p = 0.001), Schulte score (p = 0.002) and MLHFQ score (p = 0.029). M + GBB combination also demonstrated pronounced improvement of FMVR (p = 0.0001). However, there were no significant changes of anxiety and depression levels by HADS score (p = 0.16 and p= 0.09, respectively).
Conclusion: our pilot study demonstrates that 4-week M + GBB administration improves CF and quality of life in pts with CHF associated with significant FMVR improvement.

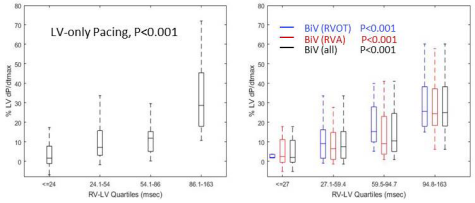
P1786

The Effect of Interventricular Delay on Acute Hemodynamic Response with Cardiac Resynchronization Therapy

A Auricchio[1]; K Siejko[2]; Y Nancy Yu[2]
[1]*Cardiocentro Ticino, Lugano, Switzerland*; [2]*Boston Scientific Corporation, St. Paul, United States of America*

Funding Acknowledgements: Boston Scientific

Background: Despite the benefits of CRT, the non-responder rate still remains challenging. Measurement of electrical interventricular delay (i.e. RV-LV delay) has been shown as a strong determinant of clinical outcomes. Thus, pacing at site of longest RV-LV delay shall increase LV contractility. Moreover it is unknown whether LV pacing alone or biventricular pacing determines the same increase in LV contractility.
Methods: This study included 88 patients (65% male, mean age 60 ± 9 years, LV ejection fraction (LVEF): 23% ± 7%, QRS duration 156 ± 21 ms, 87% LBBB) undergoing CRT implants. At implant, invasive left ventricular (LV) dP/dtmax was measured by a micromanometer catheter during biventricular (BiV) or LV-only pacing at different LV sites while the right atrium was in sense mode. During BiV pacing, different RV sites (i.e. RV apex (RVA) and RV outflow tract (RVOT)) were also tested in combination with different LV sites. For each pacing configuration, 4 different AV delays were tested in randomized order. The intrinsic RV-LV duration was defined as the time interval from the peak of the RV electrogram (EGM) to the peak of the LV EGM. The maximum LV dP/dtmax responses were calculated for BiV and LV-only mode per LV pacing site in each patient.
Results: The RV-LV delay for this cohort ranged from -68 to 163 ms. The improvement in the LV dP/dtmax response increased progressively as RV-LV increased for both LV-only and BiV pacing, as well as for BiV pacing with RV pacing at RVA and RVOT (see figure).
Conclusions: Longer RV-LV delay was associated with larger acute hemodynamic response during both LV-only and BiV pacing regardless of the RV lead location. The RV-LV delay can be easily measured at implant and by CRT devices and may provide a simple means of selecting/optimizing LV stimulation site and possibly maximizing CRT response.



P1787

Evaluation of the optimal energy, protein, fat and carbohydrate needs in obese patients with chronic heart failure.

T Tatiana Zaletova[1]; A Bogdanov[1]; T Feofanova[1]; S Derbeneva[1]; I Shevchenko[2]
[1]*Research Institute of Nutrition of Russian Academy of Medical Sciences, Moscow, Russian Federation*; [2]*Gazprom Transgas Diagnostic and Rehabilitation Center, Internal Medicine, Moscow, Russian Federation*

Introduction: Obesity in chronic heart failure (CHF) patients is a new clinically significant factor. Previously, suboptimal food intake or even a strict caloric restriction used to be widespread in treating obesity, which significantly deteriorated comorbidities. The need for energy, necessary to prevent malnutrition of obese patients with heart failure is not still completely determined. Objective. To evaluate resting energy expenditure in obese patients with chronic heart failure. Methods. A total of 392 obese people were examined. According to the results of echocardiography and 6 minute walk test (SMWT), 152 people were included in the group with confirmed CHF. Assessment of basal metabolic rate was performed in all patients using indirect calorimetry with a stationary metabolograph.
Results: We demonstrated lower basal metabolic rate in patients with CHF compared to patients without CHF: in grade 1 obesity: 1687 ± 148 kcal/day vs. 1715.5 ± 63 kcal/day, p> 0.05, in grade 2 obesity: 1635 ± 164 kcal/day vs 1843 ± 52 kcal/day, p>0.05, in grade 3 obesity 2072 ± 51 kcal/day vs 2334 ± 110 kcal/day, p < 0.05, respectively. Also patients with CHF had a significantly (p < 0.01) lower carbohydrate oxidation rate compared with patients without CHF. The study showed that protein oxidation rate increased in CHF patients with progressive obesity; while in patients without CHF this tendency was not observed. Thus, depending on the presence or absence of CHF, in grade 1 obesity patients protein oxidation rate was 79 ± 11 g/day and 55 ± 3.2 g/dayin grade 2 - 88 ± 6 g/day and 69.4 ± 3.94 g/day, with grade 3 - 92 ± 4 g/day for and 73.75 ± 3.98 g/day, respectively. Conclusions. Thus, obesity along with CHF compared with obesity without it is accompanied by significant changes in the nutritional metabolic status of patients, in particular a lower basal metabolic rate, lower carbohydrate oxidation rate and a higher protein oxidation rate, which can be caused by such pathogenetic processes as decreased energy consumption in the mitochondrial system, by insulin resistance and muscular tissue catabolism. The revealed data confirm the need to optimize diets for this category of patients.

Distribution of subjects by group

Value	Obesity Grade 1 with CHF (n = 18)	Obesity Grade 2 without CHF (n = 78)	Obesity Grade 3 with CHF (n = 23)	without CHF (n=81)	with CHF (n = 111)	without CHF (n=81)

Chronic Heart Failure - Clinical

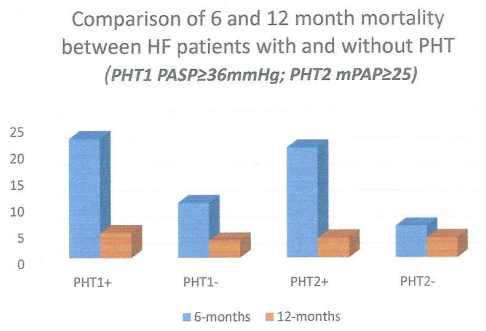
P1788

Influence of pulmonary hypertension on the 6 and 12 months outcome in acutely decompensated heart failure patients.

A Amam Chinyere Mbakwem[1]; O Kushimo[2]; JNA Ajuluchukwu[1]
[1]*University of Lagos, Lagos, Nigeria*; [2]*Lagos University Teaching Hospital, Lagos, Nigeria*

Background: Pulmonary hypertension (PHT) is highly prevalent amongst heart failure (HF) patients and now recognized as an independent predictor of poor prognosis. There is paucity of data on the frequency and correlates of PHT in HF in our environment, effect on management and its impact on outcomes. We therefore evaluated the 6 and 12 months influence of PHT on HF outcomes in our environment.

Purpose: To Evaluate effect of PHT on the 6 and 12 months outcomes in acutely decompensated HF patients seen at a West African academic hospital.
Methods This was a prospective study of 219 HF patients in NYHA II-IV with acute decompensation, consecutively recruited from the emergency room and the cardiology out-patient clinic. HF patients with other co-morbidities that can cause PHT were excluded. Data on demographic parameters, clinical features and echo parameters were collected with a CRF. Correlation between elevated PASP / mPAP and selected clinical parameters were further interrogated. Patients were followed up for 6 and 12 months post discharge for death or rehospitalisation.
Results The frequency of PHT was determined by two criteria. PHT using a PASP cut off of = 36mmHg was present in 85 (38.8%) of subjects and 136(61.6%) of subjects using the mPAP criteria of = 25mmHG. HF subjects with PHT were more likely to be male, p = 0.001, with a lower BMI, p < 0.001, lower systolic blood pressure, p < 0.001 and a worse NYHA functional class, p < 0.001 compared with subjects without PHT. The PHT subjects also had significantly higher LV filling pressures, p = 0.001), severe mitral regurgitation (higher mitral regurtitant volume, p = 0.001), poorer LV systolic function, and worse RV structure and function compared with those without PH.
Echocardiographic variables that correlated significantly with PASP include parameters of LV filling pressures (p < 0.001 for all), mitral regurgitant volume (r = 0.269, p < 0.001) LV and ejection fraction (r = -0.239, p > 0.001). Similar correlations were obtained with mPAP. On multivariate analyses, the left atrial volume index and E/e' ratio were independently associated with PASP, while the LV ejection fraction, E/e' ratio and the left atrial volume index were independently associated with mPAP.
At 6-months, 33(15%) of the patients had died; higher in the PHT group, 19(22.4%) vs 14(10.4%), p 0.02 using PASP and 28(20.7%) vs 5(6.0%), p = 0.003 using mPAP. There were 7(3.8%) more deaths at 12-months but there was no difference between the patients with or without PHT using both criteria. About 5 people were rehospitalised over the 12 month period, 3(1.4%) within 6 months and 2(0.9%) by the end of 12 months with no differences seen between the PHT groups
Conclusion: PH is common amongst HF in our environment with a variable frequency depending on the assessment method employed. It is associated with a worse 6-month mortality but no effect on 12-month mortality.



6 and 12 month mortality of HF with PHT.

P1789

Prognostic impact of serum metabolomic profiling of patients with heart failure with reduced ejection fraction

R Pistulli[1]; S Neugebauer[2]; T Kretzschmar[1]; D Kretzschmar[1]; B Heidecker[3]; M Franz[1]; M Kiehntopf[2]; P C Schulze[1]
[1]University Hospital of Jena, Internal Medicine I, Dept. of Cardiology, Jena, Germany; *[2]University Hospital of Jena, Institute for Clinical Chemistry and Laboratory Medicine, Jena, Germany*; *[3]University Heart Center, Cardiology, Zurich, Switzerland*

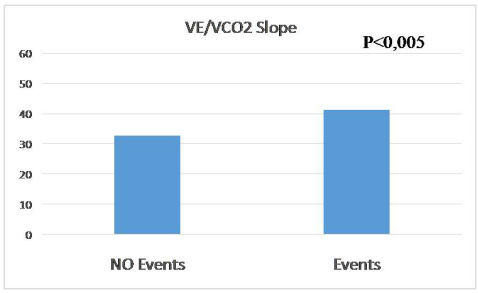
Aims: Recent studies on metabolomics of patients with heart failure with reduced or preserved ejection fraction have shown several alterations of metabolites. Systematic screening allows the characterization of new pathways for the discovery of prognostic markers or therapeutic targets in heart failure. We used this novel technique in order to characterize metabolic changes in heart failure patients, as well as asses their prognostic potential.
Methods: 181 serum metabolites of 40 chronic severe heart failure patients (n = 20 ICM, n = 20 DCM, mean EF 28.3%, 65% NYHA III/IV), as well as 10 control individuals were quantified by liquid chromatography tandem mass spectrometry. Significantly altered metabolites (using a predefined Bonferroni corrected level of significance) were then correlated to an extensive patient database of clinical parameters at the time of the measurement, as well as after a 12 months follow-up period. Altered metabolites were analyzed for their specificity of the severity of HF, as well as their correlation to dEF (calculated EF difference during the follow-up period).
Results: In HF patients compared to controls, we found a significant decrease of phosphatidylcholines and sphingolipids, as well as an increase of acylcarnitines, the aminoacids aspartate, methionine and phenylalanine. The specificity of long-chain acylcarnitines for the severity of HF was similar to BNP (ROC for NYHA III/IV, AUC 0.796 and 0.761 respectively), while both were better than EF (AUC 0.343). Such was also observed for phosphatidylcholines (AUC: 0.8, vs. BNP 0.86 vs EF 0.73). Correlation statistics between altered metabolites and follow-up parameters revealed a significant inverse correlation between acylcarnitines and dEF (r -0.681, p < 0.01).
Conclusions: We observed significant alterations of serum metabolites in severe HF patients. Phosphatidylcholines and acylcarnitines were strongly related to heart failure severity, while acylcarnitines also correlated with disease progression in terms of LV function. This novel technique could possibly identify prognostic markers of HF and lead to a better understanding of metabolic abnormalities of HF.

P1790

Left ventricular ejection fraction is unable to prognostic stratification in patients with chronic heart failure. the role of cardiopulmonary exercise test and right ventricular evaluation

A Antonio Pagliaro[1]; R Molle[2]; E Iardino[3]; M Cameli[1]; S Bernazzali[4]; M Iacoviello[5]
[1]University Hospital AOUS, Department of Heart,Thorax and Vessels, Cardiology Division, Siena, Italy; *[2]Misericordia Hospital, Cardiology, Grosseto, Italy*; *[3]University of Siena, Cardiology, Siena, Italy*; *[4]Polyclinic Santa Maria alle Scotte, Cardiothoracic Surgery, Siena, Italy*; *[5]Policlinic University Hospital, Cardiothoracic, Bari, Italy*

Background: It is well know how hard is the prognostic stratification in patients with chronic
heart failure reduced ejection fraction (CHFrEF). At the same time it is well know how is important this information to optimize resources. Many different parameters, including left ventricular ejection fraction (LVEF), right ventricular (RV) function, cardiopulmonary exercise test (CPET) data, are available in literature for this goal. LVEF is current used to assemble patients in consistent groups, to justify many therapeutic decisions and it is also the most noted and cited heart failure indicator but it is an inadequate parameter to achieve a correct prognostic stratification.
Aim: we analyzed CPET and echocardiographic data collected in our center during outpatients visits for heart transplantation screening to understand which parameters had correlation to hard cardiac events (heart failure hospitalization, cardiac death, heart transplantation -HTx, left ventricular assist device -LVAD- implantation).



VE/VCO2 Slope and events

Methods and Results: 410 patients with CHFrEF underwent incremental CPET and echocardiographic evaluation from January 2012 to October 2016; of these patients we analyzed data from 170 (mean ± SD age: 55,09 ± 9,94; 88% male; non-ischemic: 63%; LVEF: 30,44 ± 7,61 %; end-diastolic diameter EDD: 66,53 ± 9,36 mm; end-systolic diameter ESD: 53,71 ± 11,5 mm; RV EDD 35,26 ± 6,95 mm; tricuspid annular plane systolic excursion TAPSE 18,55 ± 3,98; peak oxigen uptake VO2: 17,08 ± 4,6 mL/Kg/min; % predicted Peak Oxigen uptake %pVO2: 61,07 ± 13,95; minute ventilation VE/carbon dioxide production VCO2 relationship VE/VCO2 Slope: 34,81 ± 8,7) and collected prognostic information of 133 (follow up from January 2012 to October 2017, total events 60, of these 37 hospitalizations, 4 deaths, 14 HTx 5 LVAD implantation). Patients who have been affected by events showed a statistically significant (p < 0,005) lower VO2 value (< 15 ml/Kg/min; %pVO2 < 55%), higher VE/VCO2 slope (<41), higher LV ESD (<52 mm) and higher RV EDD (<39 mm) than patients without events. Contrarily LVEF was not statistically significant different between patients with and without events. We have also found a statistically significant correlation between VE/VCO2 slope and RV EDD (R 0,35; p 0,0005).
Conclusion: outpatients CHFrEF prognostic stratification is still an hard challenge for cardiologist. The LVEF alone, moreover cornerstone of many different therapeutic choices, is lacking. Useful are those parameters that identify an advanced stage of the disease (extreme adverse LV remodelling, right ventricular involvement)

or provide a quantification of the system reserve (VO2 peak; VE/VCO2 slope). Also the correlation between VE/VCO2 slope and RV EDD supports the role of ventriculo-arterial unit in the clinical history of CHFrEF

Iron status and muscle-derived secretion of regenerative and pro-hypertrophic myokines (follistatin and decorin) in men with heart failure with reduced ejection fraction

MM Dziegala[1]; M Kasztura[1]; KA Kobak[1]; M Tkaczyszyn[1]; M Drozd[1]; K Wegrzynowska-Teodorczyk[2]; K Josiak[3]; J Bania[4]; L Kiczak[5]; W Banasiak[6]; P Ponikowski[3]; EA Jankowska[1]

Funding Acknowledgements: This research was financially supported by National Science Centre (Poland) grant no. 2012/05/E/NZ5/00590

Background: Disturbed iron status impairs the functioning of skeletal muscle in patients with heart failure (HF). Skeletal muscle has recently emerged as an important secretory organ producing various, mainly contraction-induced proteins (myokines). These bioactive factors trigger local responses and influence energy metabolism, hypertrophy and regeneration of the muscle.
Purpose: The aim of the study was to determine whether patients with HF and iron deficiency (ID) had the altered the secretion of follistatin, a myokine enhancing muscle regenerative potential, and decorin which exerts pro-hypertrophic effect. Further, we investigated whether the intravenous iron repletion influenced the exercise-induced production of these myokines.
Methods: Study population comprised of 53 men with heart failure with reduced ejection fraction (LVEF = 40%; mean age: ± 64 years; NYHA class I-II: 87%) and of 15 middle-aged healthy men. We assessed follistatin and decorin levels in plasma samples from peripheral blood from all patients by ELISA. Further, we analyzed samples taken from antecubital veins draining the forearm muscle before and after physical local exercise (standardized 5-minute handgrip exercise) for the myokines. Additionaly iron-deficient HF patients (serum ferritin < 100μg/L or serum ferritin = 100 μg/L and = 300 μg/L with Tsat < 20%) and were randomized in a 1:1 fashion (double-blind scheme) to receive either intravenous ferric carboxymaltose (FCM) or saline (comparator) (24-week dosing protocol according to CONFIRM-HF trial).
Results: There were no differences in both myokine levels measured in peripheral samples between HF patients with and without ID, and between HF patients and controls. There were no correlations between myokine concentrations in peripheral and forearm samples. Levels of follistatin and decorin assessed in the forearm samples both before and after handgrip were significantly lower in HF patients with ID as compared to those with preserved iron status (all $p < 0.001$). Further, lower levels of decorin in forearm samples of men with HF were associated both before and after exercise with lower mean handgrip strength ($R = 0.45$, $p < 0.01$; $R = 0.46$, $p < 0.01$). In HF patients during exercise a reduced netto decorin production correlated with higher netto lactate formation in forearm samples ($R = -0.38$, $p < 0.01$). Importantly, after FCM therapy the netto muscle production of follistatin in forearm samples were significantly increased in men with HF and ID treated with FCM as compared to those who received saline ($p < 0.01$).
Conclusions: Reduced follistatin and decorin secretion assessed in forearm blood, but not in peripheral blood, reflects the lower regenerative and pro-hypertrophic potential of muscle from patients with HF and ID. In patients with HF lower secretion of decorin during exercise is associated with altered muscle metabolic activity. Iron repletion therapy in patients with HF and ID partially restores the follistatin production during exercise.

Body composition and hydratation status in Heart Failure types

D Gonzalez[1]; A Orea-Tejeda[1]; R Sanchez-Santillan[1]; C Olivo-Villalobos[1]; G Davila-Said[1]; C Chavez-Mendez[1]; V Pelaez-Hernandez[1]; M Rivera-Rodriguez[1]; L Castillo-Aguilar[1]; K Balderas-Munoz[1]; A Figueroa-Herrera[1]
[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico

Introduction : Patients with Heart Failure (HF) present different alterations in hydration status as well as a dismish of protein reserves wich increase the mortality and the hospitalization risk. However, the protein reserve has been unusually studied by the heart failure types.
Purpuse: To evaluate the hydration status and the protein reserve by heart failure type.
Materials and Methods: Cross-sectional study. 776 subjects older than 18 years old with a diagnosis of stable HF were included. The HF type was classified in: Heart Failure with reduced ejection fraction (HFrEF), Heart Failure with mid-range Ejection Fraction (HFmrEF), Heart Failure preserved Ejection Fraction (HFpEF). Patients with cancer diagnosis were excluded.
Results: Mean age 63.56, the 51.93% were men. Significant differences were observed between HErEF, HFpEF and HFpEF groups: sex (57.8 % vs. 59.2% vs. 43.6%, $p < 0.001$), body weight (66.3 ± 17.2 kg vs. 68.9 ± 17.6 kg vs 74.7 ± 23.8 kg, $p < 0.001$), mid upper arm circumference (28.1 ± 4.2 cm vs. 28.9 ± 4.6 cm vs. 29.8 ± 6.2 cm), total body water (56 ± 33.8% vs. 53.9 ± 8 % vs. 51.2 ± 8.7%, $p = 0.036$), third space (0.4 lt [-0.4 to 1] vs -0.3 lt [-0.8 to 0.8] vs 0.005 lt [-0.8 to 0.71], $p = 0.027$), lean body mass (8.6 ± 1.9 vs 9.2 ± 2.2 vs 9 ± 3.4, p= 0.106) and cachexia (65.9 % vs 55.6 % vs 49.5 %, $p = 0.003$).
Conclusions: Besides, subjects with HErEF have higher hydration status alterations and muscle depletion, those with HFmrEF present a similar and middle behaviour between HFrEF and HfpEF, wich disclose the degradation and poor prognosis.

P1793

Abdominal obesity as risk factor for endothelial dysfunction in heart failure and chronic obstructive pulmonary disease

C Chavez-Mendez[1]; A Orea-Tejeda[1]; R Sanchez-Santillan[1]; D Gonzalez-Islas[1]; L Castillo-Aguilar[1]; C Olivo-Villalobos[1]; G Davila-Said[1]; V Pelaez-Hernandez[1]; M Rivera-Rodriguez[1]; K Balderas-Munoz[1]
[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico

Introduction: The prevalence of obesity in heart failure (HF) and Chronic Obstructive Pulmonary Disease (COPD) is high. Obesity affects the structure and endothelial function increasing the risk of cardiovascular events. Endothelial dysfunction (ED) is the imbalance between vasodilator and proinflammatory mediators and this one lead to atherogenesis. Waist circumference (WC) is a practical and non-invasive method that evaluates abdominal obesity (AO). Nevertheless, there is not enough evidence between the impact of AO on endothelial dysfunction.
Purpose: To determine if AO is a risk factor for ED in patients with HF and COPD.
Materials and methods: A cross-sectional study of 173 patients with HF and COPD diagnosis. The patients were divided into to groups; those with ED and those without. It was excluded patients with asthma, cancer and pulmonary fibrosis. Endothelial dysfunction was evaluated by photoplethysmography. Abdominal obesity was defined as waist circumference > 90 cm in males and > 80 cm in females.
Results: The mean age was 70.53 ± 12.02 years, 41.04% were men and 64.14% had cachexia. Patients with ED has lower arm circumference (27.91 ± 5.19 vs 30.89 ± 14.36, $p = 0.090$), compared with subject without ED. There was no difference in: fat mass, muscle mass, body fluids, impedance index, phase angle and force. Subjects with AO have 3 times the risk of developing ED compared to subjects without AO [RR 3.11, IC 95%; 1.07- 9.03, $p = 0.037$].
Conclusions: AO is a risk factor for ED in patients with HF and COPD.

P1794

Heart failure with atrial fibrillation: are greater elevations in natriuretic peptide levels temporary or permanent?

B T Santema[1]; CSP Lam[1]; AA Voors[1]
[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands

Funding Acknowledgements: CVON2014-11 RECONNECT and FP7-242209-BIOSTAT-CHF

Background: Natriuretic peptides (NP) are elevated in heart failure (HF), but patients with atrial fibrillation (AF) and HF have even higher NP levels. These elevated NP levels in patient with concomitant AF could either be directly related to the hemodynamic changes during an episode of AF, to structural or functional cardiac remodeling due to sustained episodes of AF, or they could reflect that patients with AF have more advanced HF. In a post-hoc analysis of The BIOlogy Study to Tailored Treatment in Chronic Heart Failure (BIOSTAT-CHF) trial, we evaluated these three explanations.
Methods: Patients were categorized based on history and baseline electrocardiogram into three groups: (1) AF at time of NP measurement, (2) history of AF but in sinus rhythm (SR) at time of NP measurement and (3) SR at time of NP measurement and no previous documented episode of AF. The levels of N-terminal pro-B-type natriuretic peptide (NT-proBNP) were compared between the three rhythm groups. These levels were compared to the levels of growth differentiation

factor 15 (GDF-15); a biomarker that is well-established to reflect HF severity but is not known to be influenced by AF.
Results: A total of 1230 patients with HF with reduced ejection fraction (HFrEF) and 583 patients with HF with preserved ejection fraction (HFpEF) were studied. Similar trends were observed across the three rhythm groups, with stepwise increase in median NT-proBNP: lowest in the group with SR at baseline without a history of AF, intermediate in those with SR at baseline with a history of AF, and highest in those with AF at baseline (Figure 1). In contrast, the levels of GDF-15 were similar in patients with AF at baseline and those who only had a history of AF and were in SR at baseline.
Conclusion: These data suggest that the greater elevation in NP levels in HF patients with concomitant AF seem to be mainly caused by the immediate hemodynamic alterations during the actual episode of AF, and to a lesser extent to the chronic structural or functional cardiac remodeling as a result of sustained episodes of AF.

The cholesterol paradox may only be valid for heart failure patients without diabetes

FM Cunha[1]; J Pereira[2]; A Ribeiro[2]; S Silva[3]; JP Araujo[4]; A Leite-Moreira[5]; P Bettencourt[6]; P Lourenco[2]
[1]Hospital Center of Tras-os-Montes and Alto Douro, Department of Endocrinology, Vila Real, Portugal; *[2]Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal*; *[3]Hospital CUF, Department of Internal Medicine, Porto, Portugal*; *[4]Sao Joao Hospital, Department of Internal Medicine - University of Porto Medical School, Porto, Portugal*; *[5]Sao Joao Hospital, Department of Cardiothoracic Surgery - University of Porto Medical School, Porto, Portugal*; *[6]Hospital CUF, Department of Internal Medicine - University of Porto Medical School, Porto, Portugal*

Funding Acknowledgements: Project DOCnet (NORTE-01-0145-FEDER-000003), NORTE 2020 under the PORTUGAL 2020 Partnership Agreement, European Regional Development Fund

Background: In heart failure (HF) patients, several paradoxes have been reported concerning traditional cardiovascular risk factors. In patients with diabetes mellitus (DM), a frequently encountered comorbidity in HF, such paradoxes not always hold true. This appears to occur with the blood pressure and the obesity paradoxes. The cholesterol paradox consists in HF patients with lower total cholesterol (TC) having a more ominous outcome than the ones with higher values. A differential prognostic impact of TC in HF patients according to DM has never been addressed.
Purpose: We aimed to study if the prognostic impact of TC was different according to DM status in a chronic HF population.
Methods: We prospectively recruited HF patients followed in a HF clinic. Patients with systolic HF diagnosed for at least 6 months, under optimized and stable evidence-based therapy were consecutively recruited. Patients were excluded if they were on renal replacement therapy, if they had hospitalizations or therapeutic adjustments in the previous 2 months and if the left ventricular ejection fraction was = 50%. Patients' comorbidities and medications in use were recorded, a complete physical examination was performed and a venous blood sample was collected in all patients. Patients were followed for up to 5 years and all-cause mortality was the endpoint under analysis. The prognostic impact of TC was analysed using the Kaplan-Meier method. Analysis was then stratified according to coexistence of DM. Multivariate models were built.
Results: We studied 262 chronic stable HF patients, 182 (72.1%) males, mean age 69 years, 98 (37.4%) were diabetic and 62.2% had severe left ventricular systolic dysfunction. Median BNP was 237.8pg/mL and median (interquartile range) TC was 162 (135-200)mg/dL); 96.9% of the patients were taking beta blockers and 93.5% were on an angiotensin converting enzyme inhibitor or an angiotensin II receptor blocker. Sixty-nine percent of the patients were taking statins. During the 5-year follow-up 121 (46.2%) patients died. Patients with TC>200mg/dL had better survival than those with lower TC (p log rank < 0.001); however this protective effect was only reproduced in the group of non-diabetic HF patients. In non-diabetic HF patients the multivariate (age-, haemoglobin-, creatinine-, BNP-, body mass index-, coronary artery disease- and statin use-) adjusted 5-year mortality HR was 0.34 (95% CI: 0.16-0.74) for those with TC>200mg/dL. In the group of HF patients with DM no significant survival benefit of TC>200mg/dL was reported [HR = 0.72 (95%CI: 0.31-1.66)].
Conclusions: Non-diabetic chronic HF patients with TC>200mg/dL have a 66% lower risk of dying in the upcoming 5 years. In chronic HF patients with DM, no protective effect of elevated TC appears to exist. The cholesterol paradox may not be valid in diabetic HF patients.

P1796

Fibroblast growth factor 21 is markedly elevated in patients with chronic heart failure and cardiac cachexia - a possible role of increased inflammation is suggested

M Refsgaard Holm[1]; HM Christensen[1]; J Rasmussen[1]; ML Johansen[1]; M Schou[2]; J Faber[1]; C Kistorp[1]
[1]Herlev Hospital - Copenhagen University Hospital, Department of Internal Medicine, Copenhagen, Denmark; *[2]Herlev Hospital - Copenhagen University Hospital, Department of Cardiology, Copenhagen, Denmark*

Funding Acknowledgements: Research council, Copenhagen University Hospital, Herlev/Gentofte; A.P. Moeller Foundation

Background/Introduction: Fibroblast growth factor 21 (FGF-21) is a novel regulator in glucose and lipid metabolism. Cardiac cachexia is a wasting syndrome with poor prognosis, which is prevalent 10-15 % of patients with heart failure with reduced ejection fraction (HFrEF). Cardiac cachexia is characterized by insulin resistance, increased systemic inflammation and wasting of muscle and fat mass. As elevated FGF-21 levels have been reported in patients with insulin resistance and systemic inflammation further research of the clinical significance of FGF-21 in cardiac cachexia is warranted.
Purpose: To assess circulating FGF-21 levels in relation to cardiac function, inflammation and wasting in patients with ischemic heart disease, HFrEF and cardiac cachexia.
Methods: We included 57 patients in a cross-sectional study among three groups. One group with HFrEF and cardiac cachexia (HF+cachexia, n = 19); a second group with HFrEF but without cachexia (HF%cachexia, n = 19); and a third group with prior myocardial infarction and left ventricle ejection fraction > 45 % (IHD, n = 19). The three study groups were matched by age and sex. Cardiac cachexia was defined as unintentional non-oedematous weight loss of > 5 % within the last 6 months. FGF-21 was measured in EDTA-plasma using a validated ELISA assay.
Results: Mean (±SD) age was 78.0 (±7.1) years with a male/female ratio of 15/4 in all groups. Patients with HFrEF and cardiac cachexia displayed markedly higher FGF-21 levels, NT-proBNP levels and systemic inflammation, as assessed by IL-6, compared with the two other groups: FGF-21 (median (IQR): HF+cachexia: 381 (232-577) pg/mL, HF%cachexia: 224 (179-309), IHD: 221 (156-308), p = 0.050; NT-proBNP (median (IQR): HF+cachexia: 2310 (1430-3860) ng/L, HF%cachexia: 1090 (508-2110), IHD: 423 (140-1100), p = 0.001; IL-6 (median (IQR): HF+cachexia: 5.3 (2.8-6.8) pg/mL, HF%cachexia: 2.8 (2.0-6.9), IHD: 2.6 (1.7-3.6), p = 0.042. Notably, FGF-21 showed no association to NT-proBNP (Ln) (ß = 0.128, p = 0.087). In multivariate linear regression analysis, adjusted for sex and age, FGF-21 (Ln) was independently associated with IL-6 and total cholesterol and inversely associated with muscle mass and HbA1c (IL-6 (Ln): ß = 0.304, p = 0.026; total cholesterol: ß = 0.270, p = 0.009; muscle mass: ß= -0.038, p = 0.024; HbA1c:ß= -0.426, p = 0.044).
Conclusions: We demonstrated markedly increased FGF-21 levels in patients with HFrEF and cardiac cachexia. Our data suggest that the elevated FGF-21 levels in cardiac cachexia are mediated by increased inflammation and wasting of muscle mass rather than impaired cardiac function. FGF-21 could, therefore, bear clinical implications in predicting cardiac cachexia.

P1797

Lower heart rate predicts spontaneous echo contrast presence in left heart chambers in patients with dilated cardiomyopathy

A Aurora Bakalli[1]; LG Ismail[2]; D Kocinaj[1]; X Krasniqi[1]
[1]University Clinical Center of Kosova, Prishtina, Kosovo Republic of; *[2]University Clinic of Cardiology, Skopje, Macedonia The Former Yugoslav Republic of*

Introduction: Spontaneous echo contrast (SEC) is "smoke-like" echo detected in heart chambers and is highly associated with embolic events.

Purpose: We aimed to determine predictors of left heart chamber SEC presence in sinus rhythm patients with dilated cardiomyopathy of mild to moderate systolic dysfunction.
Material and Methods: This was a prospective cross-sectional transesophageal echocardiography study which included 101 patients (70 m, 31 f, age 58.1 ± 12.7). Patients with atrial fibrillation, anticoagulation therapy, valvular heart disease, prosthetic valves, severe systolic dysfunction, acute myocardial infarction were excluded.
Results: SEC in left ventricle (LV) was significantly related to older age (r = 0.2), history of coronary artery disease (CAD) (r = 0.2), more advanced NYHA class (r = 0.289), lower heart rate (HR) (r=-0.237), larger LV inner dimensions (LVID) in diastole (r = 0.324) and systole (r = 0.44), lower LVEF (r=-0.443), higher wall motion score index (WMSI) (r = 0.295), lower average MAPSE value (r=-0.33). The overall logistic regression model revealed that lower HR (OR = 0.909; 95%CI 0.845-0.978; p = 0.011) and larger LVIDs (OR = 1.200; 95%CI 1.034-1.394; p = 0.017) were independent predictors for LV SEC presence.
SEC in left atrium (LA) was significantly related to male gender (r = 0.211), more advanced NYHA class (r = 0.276), lower HR (r=-0.2), higher packed cell volume (r = 0.332), higher count of red blood cells (r = 0.268), larger LVID in diastole (r = 0.398) and systole (r = 0.425), lower LVEF (r=-0.494), higher WMSI (r = 0.468), lower average MAPSE value (r=-0.305), larger LA diameter (r = 0.258) and it's normalized value for BSA (r = 0.256), larger LA area (r = 0.255), greater LAV/BSA (r = 0.210). Prediction model for LA SEC revealed that only lower LVEF was an independent predictor (95%CI (-0.079)-(-0.037)) (p = 0.0001).
SEC in left atrial appendage (LAA) was significantly related to longer duration of diabetes mellitus (r = 0.404), history of CAD (r = 0.284), lower HR (r=-0.238), high C-reactive protein (CRP) (r = 0.2), greater LV length in diastole (r = 0.238; p = 0.016), greater LA diameter (r = 0.252; p = 0.011) and it's normalized dimension for BSA (r = 0.284), greater LAA maximal area (r = 0.196), greater LAA dysfunction (r = 0.354). In a prediction model for SEC in LAA, lower HR (95%CI, (-0.030)-(-0.003); p = 0.018), greater LA dimension normalized for BSA (95%CI, 0.016-0.116; p = 0.010) and higher value of CRP (95%CI, 0.0026-0.031; p = 0.027) were responsible for LAA SEC presence.
Conclusion: Lower HR is an important predictor of SEC presence in left heart chambers. Additionally, lower LVEF, larger LVIDs and LA, and CRP predict SEC in left heart chambers in patients with dilated cardiomyopathy. This study calls for future research to determine the optimal heart rate in heart failure patients.

P1798

Thyroid hormones levels and their circadian changes in patients with persistent atrial fibrillation and chronic heart failure

YO Tsareva[1]; EA Mayskova[1]; YG Shwartz[1]
[1]*Saratov State Medical University, Saratov, Russian Federation*

Aim of study. We had been studied circadian changes in the levels of secretion of thyrotropin (TSH) and free triiodothyronine (T3) in patients with stable coronary heart disease (CHD) complicated by persistent atrial fibrillation (AF) and chronic heart failure (HF).
Materials. 133 patients with stable ?HD and HF (I-III classes by NYHA) were included. Persistent AF was detected in 79 patients. Persons with hypo - or hyperthyroidism were excluded. The average age of subjects was 64,1 ± 5,4 years. The serum levels of TSH and free T3 were determined twice a day (at 7 a.m. and 8 p.m.). Changes in the diurnal levels of hormones were defined as the difference between the morning and the evening concentrations, and also were calculated in percent (%).
Results: Most of included patients (89 persons - 66,9%) had a certain diurnal rhythm of TSH secretion, which had high values in the morning and low in the evening within the reference range. A part of the examined patients (33,3%) had the opposite tendency, and higher values of TSH were recorded in the evening. This phenomenon was called 'the inversion of TSH variation'.
In patients with inversion of TSH diurnal changes there was noticed a predominance of III-IV classes of angina pectoris on I-II classes (45% versus 22.3%), p < 0.04. Age differences in the two groups were not significant. There was tended to shorter duration of chronic heart failure in the group with the inversion of TSH in comparison with persons with "normal" direction of TSH biorhythm (3 years (1,0;5,0) vs 5 years (2,0;5,0), p < 0,05). In the group with inversion of TSH variation patients with non-congestive heart failure (NYHA I-II) prevailed over persons with NYHA III (42,4% vs 28.5%), p < 0.03.
In patients without rhythm disturbances the range of TSH circadian changes was wider than in patients with AF (18% vs 6.3%, p < 0.05). In the presence of NYHA III the range of TSH variation had tendency to be more widely (13%) than in patients with non-congestive HF NYHA I-II (8%), p < 0.05. Among patients with AF a certain narrowing of TSH diurnal changes was revealed in case of NYHA III opposite to the subgroup NYHA I-II (3% vs 6.7%, p < 0.05). Amplitude of variation of T3 had a narrower range in the subgroup NYHA III as well. The most significant differences in the changes of thyroid hormones levels were identified in patients with a recent episode of arrhythmia (less than 7 days before enrollment). In this group in case of combination with NYHA III the narrowest interval of variation of T3 was detected.
Conclusions: A part of patients with stable ?HD had the inversion of the circadian changes in TSH which combined with the clinical features of cardiovascular pathology. Significant narrowing of the range of circadian variation of TSH and T3 was observed in patients with ischemic heart disease and atrial fibrillation. Changes in the levels of TSH and T3 in chronic heart failure depended on the severity of HF and the presence of a rhythm disorder.

On behalf of: RICA-HFTeam

Introduction: Erectile dysfunction (ED) is a common comorbidity in patients (pts) with cardiovascular disease, with major impact on their quality of life (QoL). Given the association between ED and the pharmacological therapy commonly used in heart failure (HF) with reduced left ventricular ejection fraction (LVEF), the management of ED in these pts may be challenging.
Objective: To evaluate the erectile function (EF) in pts with chronic HF and reduced LVEF, and its possible potential relation with the clinical severity, QoL and pharmacological therapy used to treat the syndrome.
Methods: Single centre prospective study that included men aged 18 to 70 years hospitalized for decompensate chronic HF. EF was assessed at discharge and at 9 ± 3 months of follow-up, using the validated Portuguese Version of the International Index of Erectile Function. ED is considered to be present when the test value is < 26, and can be classified as mild (25-17), moderate (16-11) and severe (10-6).
The relationship of EF with clinical features, medical therapy and QoL [(validated Portuguese Version of the Kansas City Cardiomyopathy Questionnaire (KCCQ)] was established by Spearman correlation, Mann-Whitney, Wilcoxon and Chi-square tests.
Results: 24 pts, 62.8 + 7.5 years, were included. The prevalence of hypertension (HTN), diabetes and ischemic heart disease, was 71%, 50%, and 38%, respectively. The median LVEF was 26.5%.
The prevalence of ED at the initial evaluation was 92% (mild in 3 pts, moderate in 6 and severe in 13), and 71% at the follow-up (mild in 2 pts, moderate in 3 and severe in 12) - P= N.S.
The EF evaluated in the follow-up associated with age (p < 0.01; r= -0.767), HTN (p= 0.30), maximum and minimum NTproBNP values recorded during hospitalization (p= 0.11, r= -0.54 and p= 0.38, r= -0.048, respectively), serum creatinine (p= 0.06, r= -0.416) and urea (p= 0.025, r= -0.488).
During the follow-up it was possible to increase significantly beta-blocker (p < 0.001) and ACEI/ARB doses (p= 0.006) - compared to pre-admission ones - and a significant improvement in LVEF (p= 0.001) and NYHA functional class (p= 0.002) was also observed. Erectile dysfunction had no relationship with these parameters, but it correlated with physical limitation (p= 0.022, r= 0.509) and frequency of symptoms (p= 0.024, r= 0.502) assessed by KCCQ.
Conclusions: Erectile function in patients with chronic HF correlated with NTproBNP values and erectile dysfunction showed impact on QoL. The progressive increase in doses of neurohormonal antagonists was not associated with a significant change in erectile function, suggesting that the beneficial effects of recommended HFrEF therapies prevail in this population. This should motivate medical therapy uptitration, regardless of the presence of erectile dysfunction.

P1800

Gender-specific differences of anxiety and depressive disorders in chronic heart failure

S Sviatlana Matskevitch[1]; ES Atroschenko[1]; MI Belskaya[1]; OG Shatova[1]; TA Troyanova-Shchutskaia[1]
[1]*Scientific and Practical Center "Cardiology" , Minsk, Belarus*

Purpose: To assess gender-specific differences of anxiety and depressive disorders in chronic heart failure (CHF).
Materials and Methods: A total of 102 men and 102 women (mean-age 59.9 ± 5.25 y.o.) with functional class (FC) II and III CHF of ischemic origin were examined. Both groups included 59.8% patients with FC II CHF (LVEF 51.9 ± 5.11%) and 40.2% patients with FC III CHF (LVEF 47.1 ± 6.58%). The assessment of the presence and severity of anxiety and depressive disorders was made using Scale HADS while CES-D questionnaire was used as a screening tool to establish depression. Life quality (LQ) was measured using MLHFO.

Results: Psychological testing (CES-D) showed that 70.6% of patients had signs of depression. Therefore, the presence and severity of depressive experience was also defined using HADS questionnaire and based on gender-specific differences. The signs of depression were shown in 22.5% of men (CES-D). As evidenced by HADS, anxiety and depressive experience was demonstrated in 30.4% of men, whereas isolated anxiety was seen only in 23.5% of cases, and depression in 17.6% of cases. 14.7% of men had both depression and anxiety, and LQ was 1.5 time poorer compared to those having no comorbidities. Thirty percent of men with FC II CHF showed anxiety and depressive experience (HADS), while 25% and 16.6% showed signs of isolated anxiety and depression, respectively. In FC III CHF, anxiety and depressive experience (HADS) were shown in 31% men, while isolated anxiety and depression was seen in 19% of cases. As for the women's group, 48% (CES-D) showed signs of depression. Based on HADS, anxiety and depressive experience was evident in 63.7% of women; signs of isolated anxiety were seen in 39.2% of cases and depression was noted in 41.2%. In addition, 21.6% of women had both depression and anxiety; in this group, LQ was 1.5 times poorer compared to those with no comorbidities. Some positive associations were established between LQ and depression (r = 0.59, ? <0.01) and anxiety (r = 0.54, ? <0.01) level. As for women with FC II CHF, anxiety and depressive experience (HADS) were seen in 56.7%, whereas the signs of isolated anxiety and depression were noted in 36.7% and 28.4% of cases, respectively. In FC III CHF, anxiety and depressive experience (HADS) were shown in 76.1%, and the signs of isolated anxiety and depression were seen in 45.2% and 61.9%, respectively. This group showed a correlation between LQ and depression (r = 0.56, ? <0.01) and anxiety severity (r = 0.40, ? <0.05). Signs of anxiety and depression were noted in 38.1% of FC III CHF women, and the life quality was poorer compared to isolated anxiety and depression (? <0.01).
Conclusion: In this regard, women showed anxiety and depressive disorders 2 times more frequently compared to men in CHF. In women's group, unlike men, the more aggravated CHF became, the more evident were the signs of anxiety and depressive disorders. In addition, women were shown to be more prone to depression.

P1801

Association of depression and inflammatory markers in patients with congestive heart failure after cardiac resynchronization therapy

GS Pushkarev[1]; YA Fisher[1]; AD Sapozhnikova[1]; AM Soldatova[1]; TN Enina[1]; VA Kuznetsov[1]
[1]Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Russian Academy of Scienc, Tomsk, Russian Federation

Background: Depression is a severe mental illness associated with significant morbidity and mortality. More recently, inflammation has been implicated in the patho-etiology of depression. It is also known that inflammatory syndrome is of major importance in the pathogenesis of congestive heart failure (CHF) because of the activation of pro-inflammatory cytokines. Thus, the study of markers of inflammation in patients with CHF according to depressive symptoms (DS) is a pressing issue.
Purpose: To reveal the association between the severity of depression with inflammatory markers in patients with CHF after cardiac resynchronization therapy (CRT). Methods. The study included 54 patients (46 males and 8 females, mean age 55.3 ± 8.6 years) who underwent CRT. The Beck Depression Inventory was used to measure DS. DS was considered mild for a score between 10 and 18, significant - if more 19 and absent for a score less than 9. Plasma levels of interleukin (IL)-1ß, IL -6, IL -10, tumor necrosis factor a (TNF -a), C-reactive protein (CRP), myeloperoxidase were measured.
Results: The mean Beck Depression Inventory score was 12.3 ± 7.5. The absence of DS was detected in 24 (44.4%), mild DS in 20 (37.0%) and significant DS in 10 (18.5%) patients. CRP level was significantly higher in the group with significant DS (9.4 ± 3.3 mg/L vs 5.2 ± 3.6 mg/L in the group with mild DS, p = 0.02 and vs 4.5 ± 3.5 mg/L in the group without DS, p = 0.008). Significantly higher myeloperoxidase level was in the group of patients with significant DS compared to patients without DS (170.9 ± 248.5 pg/mL vs 47.4 ± 11.4 pg/mL, p = 0.03). No significant differences were found in IL-1ß, IL -6, IL -10 and TNF –a in the groups.
Conclusion: Patients with significant DS had higher levels of CRP and myeloperoxidase.

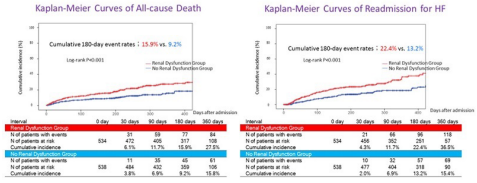
P1802

Relationship of renal dysfunction with prognosis of acute decompensated heart failure

R Reo Hata[1]; Y Kawase[1]; T Tada[1]; K Kadota[1]
[1]Kurashiki Central Hospital, Cardiology, Kurashiki, Japan

Purpose: The prevalence of renal dysfunction (RD) in patients hospitalized for acute decompensated heart failure (ADHF) is high, which seems to be related to their high in-hospital mortality; the purpose is to investigate the relationship of RD with prognosis of ADHF

Methods: We retrospectively analyzed 1072 consecutive patients hospitalized for ADHF and divided them into two groups based on levels of estimated glomerular filtration rate (eGFR): 578 patients with eGFR <45 ml/min/1.73m2 (RD group) and 593 patients with eGFR = 45 ml/min/1.73m2 (non-RD group). The clinical outcome measures were defined as all-cause death and readmission for heart failure. Subgroup analysis of the RD group was performed to further stratify the risk of all-cause death.
Results: The 180-day cumulative rates of all-cause death and readmission for heart failure were significantly higher in the RD group than in the non-RD group (15.9% vs. 9.2%, p <0.01; 22.4% vs. 13.2%, p <0.01). Multivariate Cox proportional hazards model showed that over 80 years of age (hazard ratio [HR], 1.66; 95% confidence interval [CI], 1.08 to 2.56; p = 0.02), hyponatremia (<135 mEq/L) (HR, 1.71; 95% CI, 1.08 to 2.71; p = 0.02), and prior ischemic heart disease (HR, 1.53; 95% CI, 1.02 to 2.29; p = 0.04) were independent predictors of all-cause death.
Conclusion: Our findings suggest that RD is strongly related to poor prognosis of ADHF. Elderly, hyponatremia, and a history of ischemic heart disease were negative predictors of all-cause death in ADHF patients with RD.



Cumulative incidence of event rate

P1803

Potassium value in heart failure and atrial fibrillation patients

O A Otilia Tica[1]; O Tica[2]; MI Popescu[1]
[1]University of Medicine of Oradea, Cardiology, Oradea, Romania; [2]University of Medicine of Oradea, Oradea, Romania

Introduction: Hyperkalemia is a common electrolyte disorder among patients with heart failure (HF) and atrial fibrillation (AF). Hyperkalemia is associated with poor clinical outcomes.
Aim: To prove the prevalence and clinical outcomes in hyperkalemia compared to hypokalemia in patients with heart failure and atrial fibrillation.
Methods - A total of 374 patients admitted consecutively in our clinic were evaluated at admission, during hospitalization and after discharge periodically. Patients included had the discharge diagnosis from our clinic: atrial fibrillation and heart failure. The patients were divided into 2 groups, depending on whether they have atrial fibrillation, heart failure and hyperkalemia(serum potassium >5.1 mEq/l) or hypokalemia (potassium serum < 3.5 mEq/l). The follow-up period of 1.8 years performed included surveillance, blood test (potassium level and creatinine value) and a cardiology examination (EKG, echocardiography, and clinical examination). Furthermore, hyperkalemia group was classified into mild, moderate and severe for better analyze outcomes based on severity of hyperkalemia.
Results: In our study, hyperkalemia was present in 173 patients (46.25%) with mean admissions serum sodium 5.8 ± 3.4 mg/dl. Hypokalemia was found in 89 (23.79%) patients, and 117 (31.28%) have normal potassium value. Patients with hyperkalemia had significantly higher in-hospital mortality (p = 0.027) and longer hospital stays (p = 0.002) compared to hypokalemia, but no difference in readmission rate was observed between groups (p = 0.502). Among hyperkalemia groups, severe hyperkalemia had worse clinical outcomes, with highest in-hospital mortality (17.11%) and longest length of stays (9.6 ± 4.1 days).
Conclusions: - Hyperkalemia was a relatively common condition found in patients hospitalized for HF and AF. It was associated with higher in-hospital mortality and longer hospital stays. Hyperkalemia has poorer clinical outcomes and is proven to be an ominous sign in patients with HF and AF.

P1804

Mini mental state exam for evaluation of cognitive function in patients with CHF treated with sacubitril / valsartan compared with controls taking conventional therapy: a retrospective cohort study.

R De Vecchis[1]; C Ariano[2]; G Di Biase[3]; M Noutsias[4]
[1]Preventive Cardiology and Rehabilitation Unit, DSB 29 " S. Gennaro dei Poveri Hospital", Napoli, Italy; [2]Division of Geriatrics, "Casa Sollievo della Sofferenza" Hospital, S.Giovanni Rotondo, Italy; [3]Division of Geriatrics, Clinic "S. Maria del Pozzo", Somma Vesuviana, Italy; [4]Division of Cardiology, Angiology and Intensive Medical Care, University Hospital Halle, Martin-Luther-University Halle, Halle, Germany

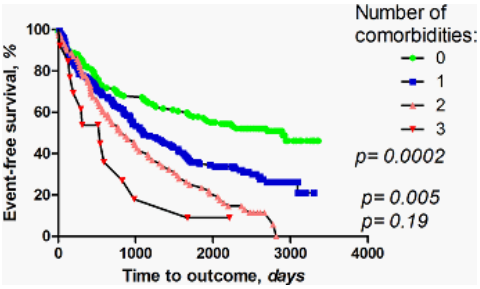
Introduction: Sacubitril, a neprilysin inhibitor, is present in the combination molecule called sacubitril / valsartan, used for therapeutic purposes as an agent able to slow down degradation of endogenous natriuretic peptides, thereby achieving an enhancement of their beneficial cardiovascular effects. However, sacubitril might also favor, through neprilysin inhibition at the level of central nervous system, missing degradation and consequent intracerebral accumulation of beta-amyloid, thus promoting neuronal dysfunction and cognitive impairment in patients with chronic heart failure(CHF) treated with sacubitril/valsartan.
Methods: A retrospective cohort study was undertaken to detect the effects on cognitive function exerted by sacubitril / valsartan in CHF patients. The clinical sheets of these patients were examined as regards the information provided in the specific questionnaire (Mini Mental State exam, MMSE), routinely administered during clinical visits carried out in the Heart Failure Units at two centers from May 15 to November 30,2017. The cases, i.e., CHF patients in the sacubitril/ valsartan group, had to have a clinical history of at least three continuous months of administration of sacubitril/valsartan. Control group, i.e. the group of CHF patients free from sacubitril/valsartan therapy, had to be composed of patients with similar mean age, educational level and percentage distribution of male sex compared to cases, as well as similar severity of clinical picture, that is CHF patients had to belong to NYHA classes II-III in both groups, and their comorbidities had to show a substantial overlap as regards nosographic type and clinical severity in the betwen-group comparison.
Results Mean MMSE score in sacubitril /valsartan group (no.51 patients) was 21.70 ± 3.33(mean $\pm$ SD) , whereas mean MMSE score in control group (no.51 patients) was 20.60 ± 3.77(mean $\pm$ SD) ($p = 0.1215$ using independent samples t-test). Thus, according to usual criteria, a similar mild-to moderate impairment in cognitive performance was found in the comparison of the two groups.
Conclusions: The alleged harmful influence of sacubitril/ valsartan on cognitive function has not been proven in our retrospective study. Indeed, patients taking therapy with sacubitril /valsartan for at least three months have shown a mean MMSE score not significantly different from that exhibited by controls.

P1805

The impact of comorbidities in heart failure patients

J Jan Benes[1]; M Kotrc[1]; P Jarolim[2]; J Kautzner[1]; V Melenovsky[1]
[1]IKEM, Prague, Czech Republic; [2]Brigham and Women's Hospital, Department of Pathology and TIMI-group, Boston, United States of America

Background: Diabetes mellitus (DM), chronic obstructive pulmonary disease (COPD) and chronic kidney disease (CKD) are prevalent in heart failure (HF) patients. The goal of the study was to determine the impact of DM, COPD and CKD on quality of life and outcome of a well-treated cohort of HF patients.
Methods: A total of 397 patients with stable systolic HF were followed for 1135 (IQRs 379-2005) days. Clinical, laboratory and echocardiographic evaluations were performed at study entry. During follow-up, 250 pts (62.9%) experienced an adverse outcome (death, urgent heart transplantation, implantation of mechanical circulatory support).



Event-free survival

Results: 16.4% of patients had COPD, 33.4% DM and 34.5% CKD. 40.3% of patients had no comorbidity, 38.0% were diagnosed with one, 18.4% with two and 3.2% with three comorbidities. Patient with more comorbidities were older, had longer HF history and more often CAD as the underlying HF etiology ($p < 0.0001$). They were using larger diuretic dose ($p = 0.0003$) and were less likely treated with ACE-inhibitors/angiotensin receptor blockers ($p = 0.003$). No difference in LV ejection fraction, LV end-diastolic diameter, blood pressure and heart rate was observed. Patients with more comorbidities reported similar quality of life assessed by MLHFQ ($p = 0.48$). With increasing comorbidities, no significant difference in BNP ($p = 0.06$), but sharp increase in GDF-15 ($p < 0.0001$) was observed. All three comorbidities were associated with impaired survival (Fig.1), the effect of comorbidities on outcome was independent and additive ($p < 0.0001$).

Conclusion: Comorbidities in HF patients are unrelated to cardiac function and are not associated with impaired quality of life, but they additively portend a poor prognosis.

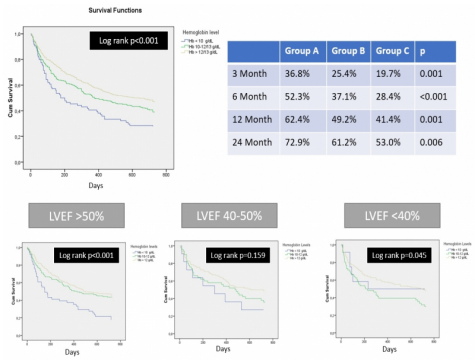
P1806

Heart Failure and Anemia: importance of hemoglobin in prognosis

J G Julio Gil Goncalves Pereira[1]; I Pires[1]; L Abreu[1]; H Antunes[1]; ML Goncalves[1]; B Marmelo[1]; JM Santos[1]; D Moreira[1]; R Silverio[2]; LF Santos[1]; J Costa Cabral[1]
[1]Hospital Sao Teotonio, Cardiology, Viseu, Portugal; [2]Hospital Sao Teotonio, Internal Medicine, Viseu, Portugal

Introduction: Reduced hemoglobin (HB) has been shown to be associated with a worse overall outcome in patients with heart failure (HF).
Purpose: The objective of this study is to evaluate which patients hospitalized for HF present with anemia. Assessment of the impact of anemia in the outcome is evaluated, namely the mortality/hospital readmission rate (M/Ra) at 3, 6, 12 and 24 months (M).
Methods: A retrospective study was performed on all patients admitted for HF. Clinical data, blood work and echocardiogram imaging were evaluated. Patient follow-up was maintained for 24 months. The study population was divided into 3 groups: Group A with HB < 10g/dL; Group B with HB 10-12 g/dL (in women) and 1013g/dL (in men); Group C with HB > 12g/dL (in women) and >13 g/dL (in men).
Results: The study population included 1052 patients.
When evaluating in-hospital mortality, there was no statistical difference (7.0% vs 8.8% vs 6.0%, p = 0.187). However, when evaluating the occurrence of the combined endpoint, there is a significant difference, already detected at 3-month follow-up. That difference was especially evident in the group with preserved ejection fraction. The image contains the survival curve and M/Ra rates as well as the survival curves for each specific group of patients depending on left ventricular ejection fraction (LVEF).
Conclusion: In this population, it is confirmed that anemia is particular frequent in older patients with chronic kidney disease. Anemia does not seem to affect in-hospital mortality. However, there was a higher mortality and readmission rate in the group with lower hemoglobin levels throughout follow-up. Anemia also seems to play a particularly more important role in prognosis in patients with preserved ejection fraction.

	Group A	Group B	Group C	p
Male	46.5%	43.8%	55.1%	0.004
Age	80±7 yo	78±9 yo	76±10 yo	<0.001
Diabetes	42.6%	37.7%	33.3%	0.131
Hypertension	69.3%	64.6%	68.3%	0.490
Dyslipidemia	26.7%	30.3%	30.0%	0.778
Coronary disease	12.9%	13.8%	15.0%	0.798
Cerebrovascular disease	11.9%	5.4%	7.5%	0.092
Chronic Kidney disease	40.0%	31.3%	17.3%	0.029
Chronic Obstructive Pulmonary disease	19.3%	18.3%	14.8%	0.472
Atrial Fibrillation	48.0%	49.3%	55.7%	0.115

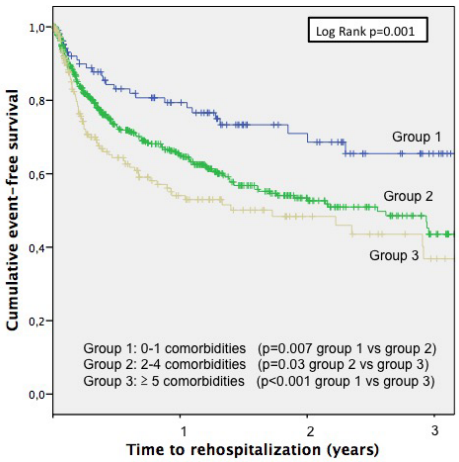


P1807

Can the number of Comorbidities predict readmissions for Heart Failure patients?

MF Maria Ferre[1]; R Lopez-Vilella[1]; I Sanchez-Lazaro[1]; I Husillos[1]; L Martinez-Dolz[1]; L Almenar[1]
[1]*Hospital Universitario y Politécnico La Fe, Valencia, Spain*

The aim of this study was to evaluate whether the comorbidities in patients hospitalized for acute heart failure predicts readmission rates for heart failure (HF).
Methods: A prospective cohort study of 901 consecutive patients admitted to our centre for acute heart failure was conducted. All hospital readmissions within 3 years of discharge were reviewed.
We collected different comorbidities such as: diabetes mellitus, hyperlipidaemia, hypertension, kidney disease, atrial fibrillation and anaemia.
We divided the study population in three groups: 1) patients with 0 or 1 comorbidities, 2) patients with 2, 3 or 4 comorbidities and 3) patients with 5 or more comorbidities.
Kaplan-Meier was used to analyse readmission rates for HF.
Results: The study population had a mean age of 74 ± 11 years. 53% of the patients were men. More than half of the population (53%) had HF with preserved ejection fraction (EF).
The majority of the patients (66%) were in group 2, followed by 22% of patients in group 3 and 12% of patients in group 1.
During the 3-years follow-up, the readmission rate for all the population was 32%. According to the subgroups, the readmission rate was 25% in group 1, 32% in group 2 and 38% in group 3 (p = 0.06).
The median time period to readmission was higher in the group with less comorbidities, being 927 days compared to 764 days in group 2 and 631 days in group 3.
The readmission rate was lower in group 1 being 17% at 6 months, 21% at 12 months and 29% at 24 months compared with group 2 (26%, 33% and 47% at 6, 12 and 24 months respectively) and group 3 (36%, 46% and 52% at 6, 12 and 24 months respectively) (p = 0.001).
Conclusions: Presence of comorbidities in heart failure patients is associated with a high readmission rate for heart failure. Thus, we recommend closer monitoring in these patients in order to avoid readmissions.



Time to rehospitalization.

P1808

Diabetes mellitus type 2 contribution to chronic heart failure in patients with permanent atrial fibrillation along with coronary artery disease

N Natalia Koziolova[1]; E Polyanskaya[1]; S Berestneva[1]; P Karavaev[1]
[1]*Medical Academy, Perm, Russian Federation*

Aim: to evaluate diabetes mellitus type2 (DM2T) contribution to chronic heart failure (CHF) in patients with permanent atrial fibrillation (AF) along with coronary artery disease (CAD) and arterial hypertension depending on glycated hemoglobin (HbA1c) Methods and materials: 48 patients with CHF, and ischemic permanent AF, and DM2T were examined. Average age was 64,2+8,9 years. HbA1c was evaluated in all the patients, as well as NT-proBNP, left ventricle ejection fraction (LV EF), E/e' (via echo). Patients were divided into 3 groups depending on HbA1c. The 1st group included patients with HbA1c 6-7,9%, (n = 13, 27,1%). The 2nd group - HbA1c = 8-10% (n = 21, 43,8%). The 3rd group consisted of patients with HbA1c >10% (n = 14, 29,1%).
Results: NT-proBNP was significantly higher in group 3, than in group 1 and group 2 (pmg < 0,001); it consisted of 846,8+74,1 ng/mL, 489,6+54,8 ng/mL, 421,4+32,7 ng/mL, respectively (p1-2, p1-3, p2-3 < 0,001). LV EF presented as moderately reduced in all the groups and did not differ between of them: group 1 - 54,8+6,7%, group 2 - 53,7+6,1%, group 3 - 49,5+7,2%. Reliable difference was found in diastolic dysfunction by average transmitral flow velocity E/e': group 1 - 13,9+2,0, group 2 - 15,3+1,6, group 3 - 16,2+1,8 (pmg= 0,0001; p1-2 = 0,0005, p1-3 < 0,001, p2-3 = 0,007).
Correlation analysis showed direct moderate interconnection between NT-proBNP and HbA1c (r = 0,53, p = 0,007), and direct severe interconnection between E/e' and HbA1c (r = 0,73, p < 0,001).
Conclusion: in patients with DM2T and permanent AF, there was indicated a progressive increase of HF severity (estimated by NT-proBNP and E/e' in echo with moderately decreased LV EF) along with increase of HbA1c

P1809

Novel truncating titin gene variants in hungarian patients with cardiomyopathies identified by next-generation sequencing

B Csanyi[1]; V Nagy[1]; L Hategan[1]; J Borbas[1]; A Tringer[1]; I Nagy[2]; Z Hegedus[3]; T Forster[1]; R Sepp[1]

Funding Acknowledgements: Supported by GINOP-2.3.2-15-2016-00039

Background: The sarcomere protein titin, encoded by the TTN gene, is responsible for the passive elastic properties of cardiac muscle. Mutations affecting the TTN gene may play a role in the development of various cardiomyopathies.
Aim: The aim of our study was to screen for genetic variants in TTN gene using Next- Generation Sequencing (NGS) in a cohort of Hungarian patients with cardiomyopathy.
Patients and Methods: A total of 148 patients with proven diagnosis of a cardiomyopathy were screened. The patient cohort included 103 patients with hypertrophic cardiomyopathy (HCM, 58 males, avg. age 50 ± 17 years), 21 patients with dilated cardiomyopathy (DCM, 10 males, avg. age 43 ± 21 years), 9 patients with left ventricular non-compaction cardiomyopathy (LVNC, 3 males, avg. age 58 ± 20 years) and 15 patients with arrhythmogenic right ventricular cardiomyopathy (ARVC, 8 males, avg. age 48 ± 10 years). Genotyping was performed by NGS and validated by capillary sequencing.
Results: Genetic screening detected 143 TTN non-common (minor allele frequency <1%), possibly disease causing variants that led to amino acid change or 'splice site' variation. Out of these, there were 8 (5%) variants which had truncation effect (all novel). In 6 cases frameshift (p.Glu13828fs, p.Glu16261fs, p.Glu19847fs, p.Lys22311fs, p.Thr18527fs, p.Val18616fs) and in further 2 cases nonsense variants (p.Gln34219 *, p.Ser8519 *) were identified. These potentially pathogenic variants occurred primarily in patients with DCM (4/21, 19%) and LVNC (4/9, 44%). The further 135 variants were predominantly likely benign or variants of uncertain significance (VUS).
Summary: Our results suggest that due to the size of the TTN gene, many variants can be detected, which can often be classified as VUS or benign. The identification of novel truncating pathological variants in DCM and LVNC patients, further strengthen the predominant role of titin in the pathogenesis of DCM and LVNC.

P1810

The prominent Y descent of right atrial pressure waveform was related to poor outcome in heart failure patients

K Kazushi Sakane[1]; R Horai[1]; D Maeda[1]; K Akamatsu[1]; M Ozeki[1]; T Fujisaka[1]; K Sohmiya[1]; N Ishizaka[1]; M Hoshiga[1]
[1]*Osaka Medical College, Cardiology, Osaka, Japan*

Background: The 'Y' descent of right atrial (RA) pressure occurs at the beginning of right ventricle (RV) diastolic phase following the 'V' wave. The presence of prominent 'Y' descent is known to represent poor RV compliance and volume overload. However its prognostic importance remains uncertain.
Methods: Among 250 patients who were admitted with acute decompensated heart failure, 56 patients underwent right heart catheterization (RHC) under clinically compensated status after conventional heart failure treatment. We defined prominent 'Y' descent of RA waveform that 'Y' descent was deeper than 'X' descent, and investigated its related clinical factors and prognostic importance.

Results: Among 56 patients, 15 patients (26.8%) were observed prominent 'Y' descent of RA pressure waveform. In patients with prominent 'Y' descent, the prevalence of atrial fibrillation (AF) was higher (92.3% vs. 34.8%, p = 0.001), plasma BNP levels were higher (274.3 ± 254.3pg/mL vs. 163.2 ± 102.3, p = 0.006), and the history of previous cardiac surgery were more frequent (46.7% vs. 18.8%, p = 0.05) compared to patients without prominent 'Y' descent. During the mean follow up period of 553 ± 341 days, patients with prominent 'Y' descent were more likely to have experienced major adverse cardiac events (MACE; death, heart failure re-hospitalization, LVAD implantation) than those without prominent 'Y' descent (80.0% vs. 18.9%, p <0.001, Figure).
Conclusion: The presence of prominent 'Y' descent as assessed by RHC was associated with AF prevalence, BNP and poor prognosis in patients with heart failure even in clinically compensated status. To evaluate the RA pressure waveform is useful to identify the high risk group of heart failure patients and it is hopefully applicable by less invasive method such as monitoring of jugular pulse waveform.

Defining heart failure with mid-range ejection fraction

S Del Prado Diaz[1]; G Alonso Salinas[1]; AM Martin Acuna[1]; JM Vieitez[1]; M Abellas[1]; A Lorente[1]; A Pardo Sanz[1]; M Plaza Martin[1]; M Pascual Izco[1]; E Gonzalez[1]; M Castillo Orive[1]; I Rayo[1]; S Fernandez Santos[1]; JL Zamorano[1]
[1]*University Hospital Ramon y Cajal de Madrid, Department of Cardiology, Madrid, Spain*

Introduction: European Heart Failure Guidelines published in 2016, defined a new classification based on left ventricular ejection fraction (LVEF).

Clinical characteristics

Characteristic	HFrEF	HFmrEF	HFpEF	P value
No of patients (%)	115 (57.5%)	36 (18%)	49 (24,5%)	
Age	73.8	72.5	77.9	NS
Male sex -no (%)	72.20 %	69.40 %	24.5 %	<0,05
Hypertension	60 %	58.30 %	71.4 %	NS
Dyslipemia	40 %	47.2 %	49 %	NS
Diabetes (non-insulin-depent)	28.7 %	13.9 %	6.1 %	<0,001
Diabetes (insulin-dependent)	10.4 %	22.2 %	30.6 %	<0,001
COPD	20.9 %	25.5 %	26.5 %	NS
Peripheral artery disease	7 %	13.9 %	8.3%	NS
Stroke	11.3 %	13.8 %	12.2 %	NS
Atrial fibrilation/Flutter	50.4 %	52.8 %	73.5 %	NS
Mitral regurgitation III_IV	20%	22%	10%	<0,05

Methods: A series of 200 patients followed at Heart Failure Unit was analysed with the aim of defining characteristic of mid-range group (40-49%), and comparing with preserved (= 50%) and reduced (< 40%) LVEF.
Results: In the series, only 18% of patients was in mid range group, facing 57,5% with severely depressed EF and 24,5% with preserved EF. HFmrEF was the younger group, and similarly to HFrEF, masculine sex was more frequently (69,4 and 72,5%), opposite to HFpEF group where 75% were women.
Regarding risk factors, there were no differences in hypertension and dyslipemia, however there were significant predominance of non-insulin-dependence diabetic patient in HFrEF and insulin-dependence diabetic patients in HFpEF group. Relative to prevalence of atrial fibrillation/flutter it was significantly higher in HFpEF (73,5%). The presence of significative mitral regurgitation was predominant in reduced and mild-range EF above preserved EF (20% vs 22% vs 10%), and the prevalence of RVdysfunction was higher in HFrEF than HFmrEF (9% vs 4%).
There were no differences related to renal function, BNP, all causes admissions nor exitus in this series.
Conclusions: In the subgroup HFmrEF it was remarkable the prevalence of males and younger age, higher prevalence of mitral regurgitation and fewer right ventricle dysfunction. Nowadays, mild range ejection fraction represents a grey area as far as characteristics, etiology and prognostic, to be researched next years.

P1812

Clinical profile and prognosis in a spanish cohort of elderly patients with mid range ejection fraction managed in a hospital-based heart failure care program

A Olmo Sanchez[1]; J A Jose Satue[1]; J Belinchon Paraiso[1]; S Gonzalo Pascua[1]; J Marrero Frances[1]; A De La Rosa[1]; A San Martin Prado[1]; A Zapatero Gaviria[1]
[1]*University Hospital of Fuenlabrada , Fuenlabrada, Spain*

Objective : The aim of this study is to compare clinical profile and prognosis of Mid Range Ejection Fraction Heart Failure (MREF- HF) patients managed in our Internal Medicine Hospital Based HF Care Program with reduced and preserved ejection fraction Heart Failure patients.
Patients and methods : 323 consecutive patients with heart failure admitted into our internal medicine ward between june 2011 and may 2017 were prospectively recruited. Demographic data, cardiovascular risk factors, clinical, biochemical and echocardiography findings, Barthel and Charlson scores, and treatments at discharge were registered in our electronic health records (EHR). Follow up was performed after discharge through ambulatory consult and telephonic interview Patients were classified as MREF-EF when ejection fraction (EF) was 40-49%, reduced EF (HFrEF) when EF <40% and preserved EF (HF-PEF), when EF was = 50%.Statistical análisis was performed with IBM SPSS statistics version 20.
Results : 34/323 patients had MREF-HF (10,5% of all). Male sex percentage is greater in MREF-HF (50%) than in HF-PEF (32,3, p 0,041%) and HFrEF (34,2%, no statistically significant). Mean age and Body Mass Index (BMI) are similar in MREF-HF and HF-PEF(78,47 years (SD 8,43) vs 79,77 years (SD 8,33) , and 31,56 kg/m2 (SD 6,43) vs 30,9 kg/m2(SD 5,95) respectively. Hypertension (91,2%), dyslipidemia (76,5%), diabetes (55,9%) and atrial fibrillation (64,7%) are found in similar percentages in MREF-HF and HF-PEF. There are more tobacco users (47,1%) and Chronic Obstructive Pulmonary Disease (COPD, 26,5%) in MREF-HF than in HF-PEF patients (p 0,034 and 0,048 respectively), also with a greater percentage of patients with pulmonary hypertension (73,5%), but not significantly. Mean NT-pro BNP is greater in MREF-HF patients (1907,5 pg/mL) than in HF-PEF (1679 pg/mL) and lower than HF-rEF (3150 pg/mL), with statistical significance (p 0,043 in Kruskal-Wallis test). Patients with MREF-HF had a similar prognosis to HF-rEF patients, with a follow-up mortality of 41,2 % and 42,1% respectively, greater than HF-PEF patients (35,1%), but without reaching statistical significance.
Conclusions: : 10% of Elderly patients managed in our Internal Medicine Hospital-based heart failure care program had Mid Range Ejection fraction (MREF-HF). They are usually hypertensive and obese patients in atrial fibrillation, with many other comorbidities as patients with HF-PEF, but there are more frequently tobacco users, with COPD and Pulmonary Hypertension; they also have a higher mean NT-pro BNP and a worse prognosis after discharge than patients with HF-PEF. More studies are needed to better determine clinical phenotype and prognosis in MREF-HF elderly patients

[1]*American University of Beirut AUB, School of Nursing, Beirut, Lebanon*;
[2]*University of Colorado Denver, College of Nursing, Denver, United States of America*

Funding Acknowledgements: University Research Board grant from the American University of Beirut

Background: Self-care is recognized as a common means for improving outcomes of heart failure (HF); yet failed self-care remains common and more prevalent in developing countries like Lebanon and the Middle East and North Africa (MENA) region. Studies to date have not addressed what predicts successful self-care in

Lebanon and the MENA region. Until we understand self-care behaviors from a cultural perspective, failed self-care will remain common, with tremendous socioeconomic costs and burdens to the individual, family, and society. Knowledge from this study will facilitate clinician understanding of what factors affect the performance or lack thereof of self-care in Lebanon and the MENA region and aid in designing tailored behavioral modification interventions targeting improved HF self-care.
Purpose: The primary purpose of this study was to describe self-care behaviors and the relationships among clinical and sociodemographic characteristics, functional ability, and psychological status and self-care in a sample of Lebanese patients with HF.
Methods: Self-care was measured in a sample of 100 participants with confirmed HF (76% males; mean age of 67.59 years) recruited from a major tertiary medical center in Lebanon. Self-care was measured using the Arabic translated version of the Self-Care of HF Index (A-ScHFI), which provides scores on self-care maintenance, management, and confidence.
Results: Provider-directed self-maintenance behaviors were expectedly high in this sample and included compliance with medication and appointment keeping. Abiding by physician directives is a characteristic of collectivist cultures like Lebanon. Behaviors low in this population were symptom monitoring and exercising. Taking an extra water pill had one of the lowest scores and this is attributed to either providers not prescribing diuretics to use as necessary or not educating patients on how to adjust their diuretic dose. About a quarter of the participants were unable to detect changes in their symptoms. Lebanese HF patients participated in self-care behaviors mainly in response to an acute deterioration. This indicates an acute model of HF self-care, where participants are unable to connect chronic symptoms with their HF and hence do not perform routine self-care.
Higher HF knowledge, higher confidence, and lower New York Heart Association class predicted better self-care maintenance. Higher HF knowledge score, higher maintenance, no recent hospitalization, and being unemployed predicted better self-care confidence. Self-care management was predicted by confidence alone.
Conclusion: HF self-care in Lebanon is suboptimal. To effectively address HF self-care practices, healthcare professionals need to understand facilitators and barriers to self-care identified in this study. Higher HF knowledge, self-care confidence, and social support were consistently associated with better self-care in this population.

P1814
Role of right ventricle in heart failure

S Del Prado Diaz[1]; G Alonso Salinas[1]; AM Martin Acuna[1]; M Plaza Martin[1]; M Abellas[1]; A Lorente[1]; JM Vieitez[1]; E Gonzalez[1]; S Fernandez Santos[1]; M Castillo Orive[1]; I Rayo[1]; JL Zamorano[1]
[1]*University Hospital Ramon y Cajal de Madrid, Department of Cardiology, Madrid, Spain*

Introduction: Heart failure traditionally has been classified according to left ventricle ejection fraction (LVEF), in fact, in the last European heart failure guidelines, it was reclassified in three types; however, the great forgotten in this issue has been the right ventricle (RV).
Methods: It was designed a registry to evaluate RV impact in heart failure. For this aim it was recorded echocardiographic data, laboratory analysis, functional class and symptoms, and related with RV function.
RV dysfunction was assessed according to ESC recommendation for chamber quantification by echocardiogram.
Results: A series of 198 patients followed in a tertiary Hospital Heart Failure Unit was included. 28% of patients presented some degree of RV dysfunction: 9.1% mild, 13.6% moderate and 7.1% severe dysfunction.
NYHA functional class was directly related to RV dysfunction ($p = 0.016$), just like the RV dysfunction degree and regardless of left ventricle function. The presence of RV dysfunction was associated with pulmonary hypertension. Nevertheless, it was not statistically significant related to LVEF, nor different types of LV dysfunction.
Patients with RV dysfunction showed tendency to more deteriorated glomerular filtration ($p = 0.06$) and higher urea levels ($p = 0.06$), without significant differences in creatinine levels. Regarding liver values, transaminases were higher (AST 23,9 vs 24,8; ALT 22,8 vs 26,1) but it has no achieved significant statistical difference. BNP presented clear tendency to be lower in normofunctional right ventricles (608 vs 839, $p = 0.09$).
It was remarkable the large prevalence of atrial fibrillation or flutter in RV dysfunction and it increased with RV dysfunction severity ($p < 0.05$).
Regarding symptoms, in RV dysfunction paroxysmal nocturnal dyspnea was more frequent ($p = 0.035$), however it was not related with orthopnea.
Relative to treatment, diuretic dose needed was higher in RV dysfuncion (95.2 mg vs 76.3 mg, $p < 0.05$)
Conclusion: RV plays and important role in heart failure, both in functional class, as in symptoms and treatment.

P1815
Heart failure associated to the hemoglobinopathy

K Khadija Khay[1]; Z Qechchar[1]; H Mechal[1]; A Kone[1]; H Bendahou[1]; A Quessar[1]; K Hachim[1]; R Habbal[1]
[1]*Ibn Rochd University Hospital, cardiology, Casablanca, Morocco*

Introduction: Due to the increased longevity of patients with hemoglobinopathy, cardio-vascular complications are more and more evident, such as rhythm and conduction disorders, heart failure, vascular involvement and pulmonary artery hypertension.
The aim of our work is to detect the repercussions of these hemoglobinopathies on the cardiovascular system.
Material and Methods: Prospective study including patients with sickle cell anemia and thalassemia followed in adult and pediatric hematology department at Ibn Rochd University Hospital in Casablanca and whose age is greater than 14 years. This is a study conducted between May and October 2017. All patients had a complete clinical examination with electrocardiogram and echocardiography.
Results: A total of 46 patients were included, with predominantly younger patients, the mean age is 23 years. 63% of our patients had thalassemia (55% homozygous thalassemia), 30.5% had sickle cell disease and 6.5% had sickle-thalassemia.
Only one patient was hypertensive and 4 smokers.
In our series, one patient had left ventricular systolic dysfunction with 48% of LVEF and a longitudinal strain at -16.
Diastolic heart failure was present in one case with elevated LV filling pressures. Three patients were in right heart failure with pulmonary arterial hypertension, one with homozygous sickle cell disease, one with heterozygous sickle cell disease and the other with sickle-thalassemia.
The right ventricle was dilated in 2 cases with impaired function in a case of homozygous sickle cell disease. Left ventricular was dilated in 14 cases, or 30% of cases.
The longitudinal global strain was altered in 2 cases, one of which had a LVEF lowered.
Conclusion: Heart failure in hemoglobinopathy remains a common complication that is a prognostic factor in this type of patients.

Chronic Heart Failure - Other

P1816
Riociguat in transthyretin cardiac amyloidosis - experiences from a prospective heart failure registry

F Franz Duca[1]; C Zotter-Tufaro[1]; C Binder[1]; AA Kammerlander[1]; B Boerries[1]; H Agis[2]; R Kain[3]; J Mascherbauer[1]; D Bonderman[1]
[1]*Medical University of Vienna, Cardiology, Vienna, Austria*; [2]*Medical University of Vienna, Oncology, Vienna, Austria*; [3]*Medical University of Vienna, Pathology, Vienna, Austria*

Background: Transthyretin cardiac amyloidosis (TTR CA) is a rare disease and represents the prototype of a restrictive cardiomyopathy. A vast majority of affected patients present with advanced heart failure and face significant morbidity and mortality. However, an effective therapy is still lacking and a diagnosis of CA precludes patients from participation in standard heart failure clinical trials.

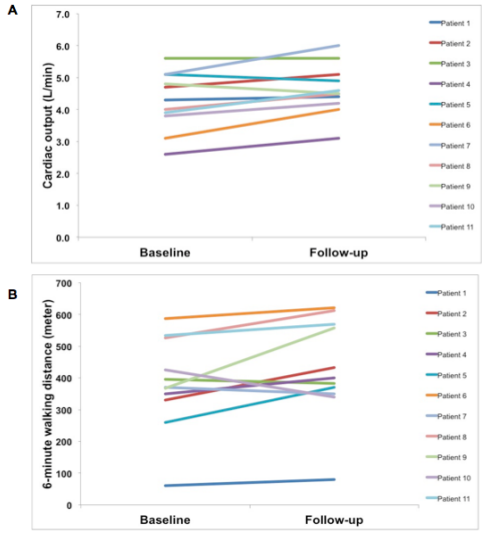

Figure 1

The soluble guanylate cyclase - stimulator riociguat, already approved for the treatment of pre-capillary pulmonary hypertension, has also been shown to have favorable hemodynamic effects in heart failure.

Purpose: We aimed to test the safety and efficacy of riociguat in a case-series of patients with TTR CA.

Methods: TTR CA was diagnosed either by histological assessment of endomyocardial biopsy samples with Congo red staining and subsequent immunohistochemical typing or non-invasively in accordance with current recommendations.

Parameters of interest were change in invasively measured hemodynamics, exercise capacity, quality of life as well as safety and tolerability.

Results: Between August 2014 and June 2017, 11 patients with wild-type TTR CA and 2 patients with mutations of the TTR gene (His108Arg) were included into our study. 2 patients discontinued with the study and the remaining 11 patients completed all procedures.

Median age of the study population was 75.0 years (IQR: 69.0 - 83.0) and 9 (81.8%) were male. The majority of the patients were in New York Heart Association (NYHA) class = III (n = 6, 54.6%), and NT-proBNP values were markedly elevated with a median of 2923pg/mL (IQR: 1773 - 7912). Median 6-MWD was 370m (IQR: 330 - 526).

Cardiac output improved significantly from 4.3L/min (IQR: 3.8 - 5.1) to 4.5L/min (IQR: 4.2 - 5.1) (p = 0.022, Figure 1) whereas diastolic pressure gradient decreased (baseline: 0.0mmHg, IQR: -2.0 - 3.0; follow-up: -1.0mmHg, IQR: -3.0 - 1.0; p = 0.049).

6-MWD increased from 370m (IQR: 330 - 526) at baseline to 400m (IQR: 350 - 570) at follow-up (p = 0.045, Figure 1B) Correspondingly, NYHA class improved significantly (baseline: NYHA class = III: n = 6, 54.6%; follow-up: n = 0, 0.0%; p = 0.031). However, NT-proBNP did not change from baseline 2923pg/mL (IQR: 1773 - 7912) to follow-up: 2584pg/mL (IQR: 1804 - 7255) (p = 0.929). Overall health status improved significantly from 50% (IQR: 40.0 - 50.0) at baseline to 60% (IQR: 50.0 - 75.0) at follow-up (p = 0.021).

Conclusion: The present case series of TTR CA patients suggests beneficial effects of riociguat administration in this patient population. However, further studies of stronger design are warranted to explore the therapeutic potential of riociguat in TTR CA.

P1817

Impact of hyperkalaemia on managing patients with cardiorenal disease; a healthcare professional perspective

N Navneet Kalsi[1]; H Purcell[2]; P Kalra[3]; P R Kalra[1]
[1]Portsmouth Hospitals NHS Trust, Cardiology, Portsmouth, United Kingdom; *[2]Cardiorenal Forum, London, United Kingdom*; *[3]Salford Royal Hospital, Renal Medicine, Manchester, United Kingdom*

Funding Acknowledgements: This survey was supported by an educational grant from Vifor Pharma UK Ltd.

Background: Renin-angiotensin-aldosterone system (RAAS) antagonism is of prognostic benefit in cardiac and renal disease. The incidence of associated hyperkalaemia (potassium >5.5mmol/L) is unknown. Guidelines advocate target doses of RAAS inhibitors in heart failure, but concerns about hyperkalaemia may limit their use. Little data exists documenting potassium levels clinicians treat and how this impacts on RAAS blockers.

Purpose: This survey describes how healthcare professionals' perceive the burden of hyperkalaemia and the impact on RAAS blockade.

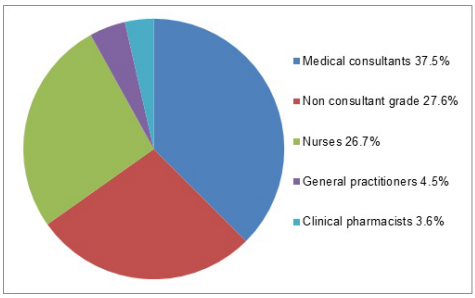
Methods: Healthcare practitioners from the British Journal of Cardiology and UK Cardiorenal Forum databases participated in an anonymised online survey.

Results: 112 complete responses were received (37% attended the Cardiorenal Forum). UK respondents totalled 81%. 74% work in hospitals: cardiac care 55.4%, renal medicine 24.1%, or other clinical domains.

Table 1.

	Number of respondents	Average potassium level (mmol/L) necessitating action	Mode of response range
Cardiology all grades Consultant only	62 18	5.7 5.7	5.5 (SD 0.4) 6.0 (SD 0.3)
Nephrology all grades Consultant only	27 15	5.8 5.7	6.0 (SD 0.4) 6.0 (SD 0.3)
Other practitioners	23	5.7	6.0 (SD 0.5)

Respondent cited values of hyperkalaemia prompting treatment.



Respondent characteristics by profession

Across all respondents, the serum potassium cited as requiring treatment ranged from = 4.8 to 6.6mmol/L (mean 5.7mmol/L). Little difference in opinion existed between those in cardiology and nephrology (Table 1). Higher values of hyperkalaemia were cited by nephrologists. Reasons given for consideration of intervention included concerns regarding cardiac stability (31.5%) and deterioration in renal function (15.7%).

70% of professionals felt hyperkalaemia would affect use of RAAS blockers in up to 25% of patients, with 10% having this concern for over half of their patients. Respondents ranked the European Society of Cardiology Heart Failure Guidelines as most influential when prescribing neurohormonal blockade. When considering which factors influence the initiation and choice of RAAS inhibitor, the priority was renal over cardiac function.

Long-term benefits are proven for RAAS blockers, but it's recognised that hyperkalaemia limits their use and impacts on prognosis. Successful interventions to manage hyperkalaemia, rather than avoidance of the drugs is perceived as beneficial in cardiorenal patients. Respondents identified the need for newer agents, such as orally active potassium binders.

Conclusions: Minimal differences between cardiologists and other prescribers exist when managing hyperkalaemia in cardiorenal patients. Healthcare professionals identify a need for alternatives in therapies that will facilitate RAAS blockade to maximal prognostic benefit.

P1818

Starting with the patient: designing an electronic application with patient and caregiver feedback to promote heart failure self-care in the home setting

C Catherine Demers[1]; S Wali[1]; L Nguyen[1]; G Mulvale[1]; E Mckay[2]; L Mbuagbaw[1]; K Keshavjee[3]
[1]*McMaster University, Medicine, Hamilton, Canada*; [2]*Ux Design Edge, Burlington, United States of America*; [3]*InfoClin, Toronto, Canada*

Background: Heart failure (HF) affects over 1% of Canadians and is associated with growing healthcare costs. Readmission rates represent 70% of these costs. Despite an overall decline in HF-related hospitalizations, up to 50% of patients are readmitted within 3 months. Self-care is key to HF management and potentially leads to improved clinical outcomes. Self-care includes daily weight and symptom monitoring, as well as adjusting diuretics according to their current weight. Less than 50% of patients regularly weigh themselves, as they view HF self-care as both challenging and intimidating.
Purpose: Mobile health (mHealth) applications (apps) can support self-care. However, technology is often poorly adopted due to factors such as literacy, numeracy, and mild cognitive impairment. To optimize the potential of a mHealth app we must ensure these barriers are addressed in its design. Our pilot study supports the use of a paper-based standardized diuretic decision tool (SDDST) to promote self-care in older individuals with HF. The purpose of this study is to convert our paper-based SDDST into a user-centered mHealth app by using participant (HF patients, informal caregivers/CPs) input throughout its design process.
Methodology: We recruited patients with a confirmed diagnosis of HF (male and female, age > 60), and their CPs. HF patients were categorized according to their self-care adequacy measured with the Self-Care Heart Failure Index (SCHFI) (score < 70 suggests poor self-care). Patients were separated into three groups, 1) Patients with adequate self-care, 2) Patients with inadequate self-care without a CP or 3) Patients with inadequate self-care with a CP. We completed standardized, semi-structured interviews with patients and CPs using a Persona-Scenarios methodology. Thematic data analysis was conducted following verbatim transcription and using NVivo, version 10. This study has received ethics approval.
Results: We have interviewed 9 patients (5 male, 4 female, mean age: 74) and 5 CPs. Six themes were identified: 1) Challenges with technology, 2) Communication and assistance with circle of care, 3) App customization, 4) Complexity of self-care, 5) Usefulness of HF information and 6) Cost and long-term use. These themes were a reflection of the challenges patients and their CPs face and how they felt the tool would either help or hinder them with self-care. We found participants were supportive in using the HFApp when the inclusion of volunteers and nurse assistance was mentioned.
Conclusion: Our solution proposes to engage patients and CPs in the design process. Patient and CP feedback will lead to the development of a simple, cost-effective and user-centered mobile application that will promote self-care in the home setting following hospital discharge.

P1819

Identification of preclinical predictors of systolic dysfunction in an elderly outpatient population without a diagnosis of heart failure: rationale and design of PULSE-HF study

ME Esquerro[1]; R Zamora[2]; ER Perna[3]; G Cursack[4]; D Caruso[5]; FP Manghi[6]; C Majul[7]; C Engel[8]; S Volman[1]; L Pereyra[1]
[1]*Novartis Argentina S.A., Buenos Aires, Argentina*; [2]*Hospital de Clinicas Jose de San Martin, Department of Internal Medicine, Buenos Aires, Argentina*; [3]*J.F. Cabral Cardiology Institute, Heart Failure Clinic, Coronary Intensive Care Unit, Corrientes, Argentina*; [4]*Sanatorio Esperanza, Santa Fe, Argentina*; [5]*MClin Res, Head of the Clinical Research Department, U.A. Dr. César Milstein, Buenos Aires, Argentina*; [6]*Centro de Investigaciones Metabólicas (CINME), Buenos Aires, Argentina*; [7]*Centro de Especialidades Médicas (CEMEDIC), Buenos Aires, Argentina*; [8]*Centro Cardiovascular, Salta, Argentina*

Background: Heart failure (HF), especially in the elderly population, poses diagnostic challenges due to its overlap with other co-morbidities and lack of direct access to echocardiography. The signs and symptoms of HF in the elderly are characterized by poor sensitivity and specificity, and the classical signs of HF are not present in approximately 30-40% of patients, which makes an early detection of HF difficult in this population. To our knowledge, no clinical score exists to screen systolic dysfunction in an elderly outpatient population.
Purpose: PULSE-HF, aims to develop a simple predictive score for systolic dysfunction and HF in an outpatient elderly at-risk population, suitable for the everyday clinical setting. The primary objective is to develop a clinical score to predict systolic dysfunction (left ventricular ejection fraction [LVEF] = 40%) and evaluate its diagnostic precision compared with echocardiogram. The secondary objectives include assessment of prevalence of reduced and preserved ejection fraction (EF) (LVEF = 40% and = 50%, respectively); identification of independent predictors for preserved EF and eventually a score derivation; and assessment of the association between N-terminal pro B-type natriuretic peptide (NT-proBNP) and reduced EF.
Methods: PULSE-HF, a cross-sectional, phase IV study that will enrol 800 elderly (aged = 70 years) at-risk outpatients without a diagnosis of HF, at 15 centres in Argentina. No study drug will be administered to patients during the study. The study will consist of two visits. At Visit 1, information on demographics, comorbidities, concomitant medications and disease characteristics will be collected. In addition, at Visit 1, patients will undergo a physical examination and cognitive (Mini-Cog test), functional (VIDA questionnaire and Edmonton scale) and emotional (geriatric depression scale) assessments, along with an evaluation of falls, incontinence and other geriatric parameters. Patients will receive recommendations for any outstanding assessments that cannot be performed at Visit 1 and the reports of such assessments will be collected at Visit 2, which will be within 3 months of Visit 1. No further assessments will be performed at Visit 2.
The primary analyses will be based on multivariate logistic regression model. Any adverse events occurring during the course of the study will be reported to the local health authority.
The study has enrolled 583 patients until Dec 2017 and the interim analysis results of the first 400 patients are expected in May 2018.
Conclusion: This study aims to develop a clinical score to predict systolic dysfunction and HF in an elderly at-risk outpatient population without a diagnosis of HF to assist screening programmes for HF. This clinical score may also assist clinicians in the early recognition of HF in the elderly, and can help to optimize treatment and lead to an improved prognosis.

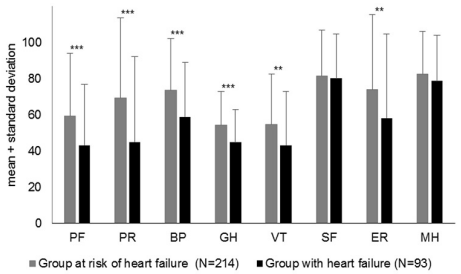
P1820

Health-related quality of life, depressive symptoms and satisfaction with life in population with and at risk of heart failure

N Natasa Sedlar[1]; M Lainscak[2]; D Omersa[3]; J Farkas[4]
[1]*National Institute of Public Health, Ljubljana, Slovenia*; [2]*General Hospital Murska Sobota, Department of Internal Medicine, Murska Sobota, Slovenia*; [3]*General Hospital Jesenice, Jesenice, Slovenia*; [4]*General Hospital Murska Sobota, Department of Research, Murska Sobota, Slovenia*

Funding Acknowledgements: Heart failure epidemiology in Slovenia: prevalence, hospitalizations and mortality, J3-7405 - financially supported by the Slovenian Research Agency

Background: Measuring health-related quality of life (HRQOL), depression and satisfaction with life is important to understand the impact of heart failure (HF) on patients' lives. Despite the numerous studies evaluating HRQOL and subjective well-being in patients with HF, little is known about subjective experiences among people at risk of HF.



PF: physical functioning; PR: physical role functioning; BP: bodily pain; GH: general health perception; VT: vitality; SF: social functioning; ER: emotional role functioning; MH: mental health;
** p<0.01 and *** p<0.001

SF-12 scales in both groups.

Purpose: The aim of our study was to compare levels of health-related quality of life, depressive syptoms and satisfaction with life in population with and at risk of heart failure.
Methods: A cross-sectional study assessing the prevalence of HF in general population aged 55 years or more has been conducted in city of Murska Sobota. Overall, 702 persons were screened with NT-proBNP and 307 had concentration = 125 pg/mL; they underwent detailed diagnostic visit with echocardiography, history and physical examination and electrocardiogram. HF diagnosis was based on 2016 European Society of Cardiology guidelines. We also assessed HRQOL (the Short-Form 12 Health Survey, SF-12), depressive symptoms (Patient Health Questionnaire, PHQ-9) and satisfaction with life (Satisfaction With Life Scale, SWLS). Differences on the subscales were assessed with the Mann–Whitney U-test.
Results: HF was confirmed in 93 persons and 214 were at risk of HF. Compared to the group at risk of HF, the group with HF reported significantly (p <0.001) lower scores on all four SF-12 physical health domains (physical functioning, role

limitations due to physical problems, bodily pain, general health) and two SF-12 mental health domains: vitality (p = 0.002) and role limitations due to emotional problems (p = 0.004). They also reported significantly more depressive symptoms (p <0.001), while there were no significant differences between the groups with respect to social functioning, experienced psychological distress and self-rated satisfaction with life. In both groups, depressive symptoms and satisfaction with life were significantly (moderately) negativelly associated with all HRQOL domains.
Conclusions: HRQOL is generally worse in patients with HF than in those at risk of HF, while its association with depressive symptoms was found for both groups. Longitudinal studies assessing trajectories of change in HRQOL and subjective well-being in patients developing HF are needed.

Acute Heart Failure - Pathophysiology and Mechanisms

P1821
Different outcome and fibrosis marker profiles suggest different pathomechanisms for peripartum cardiomyopathy in German and South African patients

F Feriel Azibani[1]; TJ Pfeffer[2]; M Ricke-Hoch[2]; W Dowling[1]; O Briton[1]; J Baard[1]; J Anthony[3]; S Stella[2]; D Hilfiker-Kleiner[2]; K Sliwa[1]
[1]University of Cape Town, Medicine, Cape Town, South Africa; *[2]Hannover Medical School, Cardiology and Angiology, Hannover, Germany*; *[3]University of Cape Town, Obstetrics & Gynaecology , Cape Town, South Africa*

Background Peripartum cardiomyopathy (PPCM) is heart failure with reduced systolic LV function in the last month of pregnancy or in the first 6 postpartal months in previously healthy women. Multiple pathomechanism trigger the disease suggesting different disease entities in Caucasian and African patients
Purpose We compared collagen metabolism related blood markers in PPCM cohortes from Germany (G) and South Africa (SA)
Methods and Results German (G-PPCM, n = 80) and South African (SA-PPCM, n = 74) PPCM patients were divided according to their LVEF at 6-months follow-up: poor outcome: < 35%, partial recovery: 35%-50%, full recovery: >50%. We observed lower mean baseline LVEF but a higher 6 months recovery rate and lower mortality rate in the G-PPCM (LVEF 24 ± 9%, recovery rate: 71%, mortality rate: 0) compared to the SA-PPCM (LVEF 30 ± 9%, full recovery rate: 36%, mortality rate: 11%). Age and parity were similar in both collectives. Healthy pregnancy state matched women from Germany (G-controls, n = 60) and South Africa (SA-controls, n = 28) served as controls.
Serum levels of type I (PINP) and type III (PIIINP) N-terminal procollagen propeptide, soluble ST-2 (sST-2) and plasma levels of Galectin 3 (Gal3) were measured by ELISA at diagnosis (baseline) and after 6 months follow up (FU). Gal3 was elevated in G- and SA-PPCM patients at baseline compared to controls ($p < 0.001$) and were normalised after 6 months, with no differences between the two cohorts. SST2 was elevated significantly in G-PPCM patients ($p < 0.01$), and tended to be higher in SA-PPCM patients compared to their respective controls. In patients with poor outcome from both collectives Gal3 levels were significantly higher at baseline compared to patients with total recovery ($p < 0.01$). Furthermore Gal3 ($p < 0.001$) and sST2 ($p < 0.01$) levels at baseline were significantly higher in non-survivors compared to survivors of the SA-PPCM cohort.
PINP and PIIINP differed between G- and SA controls and the kinetics of both markers differed between SA- and G-PPCM patients. In SA-PPCM, baseline PINP and PIIINP levels were similar to SA-controls, whereas 6 months FU PINP and PIIINP levels were significantly reduced. The PINP/PIIINP ratio was lower in non-recovered compared to recovered SA-PPCM patients ($p < 0.01$) and baseline PINP/PIIINP ratio was significantly decreased in the non-survivors versus survivors ($p < 0.05$).
In G-PPCM baseline PINP levels were higher compared to G-controls ($p < 0.01$), whereas PIIINP levels were not elevated. At 6 months FU both markers were similar to controls and no correlation was seen between the ratio of PINP/PIIINP with regard to the recovery status in the G-PPCM cohort.
Conclusion: Baseline cardiac function was lower in the G-PPCM patients compared to the SA-PPCM patients but the outcome in the G-PPCM was better. In addition, fibrosis related biomarkers differ substantially between the two cohorts supporting the hypothesis of different pathomechanisms of PPCM in G and SA-PPCM patients

P1822
Change of iron status and its association with prognosis in patients with acutely decompensated heart failure

K Kenji Kajitani[1]; K Nagao[1]; A Tamura[1]; T Kobayashi[1]; H Yukawa[1]; K Aida[1]; T Kanazawa[1]; Y Kobayashi[1]; N Takahashi[1]; E Nakagawa[1]; H Ito[1]; F Hayashi[1]; T Makita[1]; I Tsukasa[1]; M Tanaka[1]
[1]Osaka Red Cross Hospital, Department of Cardiovascular Center, Osaka, Japan

Background: Iron deficiency (ID) in chronic heart failure (HF) is common and infusion iron therapy has been proved to improve functional capacity in patients with reduced ejection fraction (EF). However, change of iron status in the acute phase of HF and its association with prognosis remain unclear. The purpose of this study is to analyze the change of iron status and its association with prognosis in the patients with acutely decompensated heart failure (ADHF).
Methods: We prospectively evaluated iron parameters on admission and at discharge among 201 ADHF patients without iron therapy. ID was defined as ferritin < 100 μg/L or ferritin 100-299 μg/L with transferrin saturation < 20%.
Results: Proportion of ID on admission was 73 %, which was decreased to 55% at discharge (P = 0.01). Factors independently associated with ID on admission were gender female and reduced EF. During the hospitalization, 13 patients died. ID on admission was not related to in-hospital death (P = 0.7). During the median follow-up of 320 days, 21 cardiac death and 52 readmission for HF occurred. Cumulative 1-year incidence of composite endpoint of cardiac death and admission for HF was 33% in the patients with ID at discharge and 31% in the patients without ID at discharge (log-rank P = 0.9). During the hospitalization, ferritin level was increased in the 75% of patients, whereas it was decreased in the remaining 25% of patients. Patients with decreased ferritin level were associated with worse prognosis as compared with those with increased ferritin level (log-rank P = 0.02). Decrease in ferritin level during the hospitalization was independently associated with poor prognosis (adjusted hazard ratio: 2.8, 95% confidence interval: 1.5-5.4, P = 0.003)
Conclusion: ID is very common and iron status dynamically changes in the patients with ADHF. Not only temporal iron status, but also its transition should be evaluated during the acute phase of HF.

Acute Heart Failure - Epidemiology, Prognosis, Outcome

P1824
Performance measurement has a different prognostic implication in de novo vs. acute decompensated heart failure

MS Ahn[1]; BS Byungsu Yoo[1]; JW Son[1]; JY Kim[1]; SW Park[1]; SH Baek[2]; ES Jeon[3]; MC Cho[4]; DJ Choi[5]; SC Chae[6]
[1]Wonju College of Medicine, Yonsei University, Division of Cardiology, Department of Internal Medicin, Wonju, Korea Republic of; *[2]The Catholic University of Korea, Cardiology, Seoul, Korea Republic of*; *[3]Samsung Medical Center, Seoul, Korea Republic of*; *[4]Chungbuk National University Hospital, Cheongju, Korea Republic of*; *[5]Seoul National University Bundang Hospital, Seongnam, Korea Republic of*; *[6]Kyungpook National University Hospital, cardiology, Daegu, Korea Republic of*

Background: Guideline driven therapy (GDT)can reduce morbidity and mortality in patients with HF and treatment guideline adherence is an important predictor of clinical deterioration. There is a paucity of data on the differential effects of adherence to treatment on outcomes according to acute HF classification such as de novo or acute decompensated HF. This study assessed the differential relationship according to heart failure classification between performance measures at hospital discharge and relevant patient clinical outcomes, including 60day and 1 year heart failure hospitalization, all-cause mortality and a composite end point of both.
Method and Results: Korean Heart failure registry (KorAHF) is a prospective observational multicentre cohort study, which have been consecutively enrolled since March 2011. Among 5,625 patients in the KorAHF, 2,769 patients with left ventricular systolic dysfunction who survived hospitalization and were not candidate for heart transplantation were separately analyzed as de novo HF and acute decompensated HF. Modified validated performance measures were defined as follows: use at discharge of ACEI, ARB or ß-blocker. An additional performance measure for MRA and anticoagulation were developed using a population definition similar to that used for ACE inhibitor/ARB. In de novo heart failure, adherence to ACEI or ARB was significantly associated with 60days rehospitalization (odds ratio (OR), 0.54; 95% confidence interval (CI), 0.31-0.93), mortality (OR, 0.37; 95% CI, 0.21-0.65) and composite end point (OR, 0.48; 95% CI, 0.31-0.73). That was not associated with 1 year rehopitalization (OR, 0.75; 95% CI, 0.49-1.15) but with 1 year mortality(OR, 0.58; 95% CI, 0.38-0.87) and composite end point (OR, 0.61; 95% CI, 0.43-0.87). The adherence to beta blocker was associated with all outcomes except 60day mortality. In acute decompensated heart failure, adherence to ACEI or ARB did not influence to all 60 day rehospitalization(OR, 1.08; 95% CI, 0.73-1.59), composite end point (OR, 0.83; 95% CI, 0.60-1.15), 1 year rehospitalization (OR, 1.31; 95% CI, 0.97-1.78), death (OR, 0.81; 95% CI, 0.59-1.11) and composite end point (OR, 1.07; 95% CI, 0.81-1.42). That was only associated with 60 day mortality (OR, 0.57; 95% CI, 0.36-0.90). Adherence to beta blocker had a constant significant effect on the outcome except 60 day rehospitalization. The adherence to MRA and anticoagulation had no effect on clinical outcomes in both group.
Conclusion: The adherence to treatment performance measures has a difference effect on the prognosis according to the heart failure classification. ACEI or ARB at discharge has a prognostic implication in de novo heart failure but its effect is weak in acute decompensated heart failure. Beta blocker has a constant effect on the prognosis regardless of heart failure classification.

P1825

Inequalities in mortality due to heart failure in chile: a gender-based analysis

J Martinez[1]; F Diaz[2]; H Verdejo[3]; M Sanhueza[1]
[1]Catholic University Clinical Hospital, Santiago, Chile; *[2]Universidad Andres Bello, Faculty of Nursing, Santiago, Chile*; *[3]Pontifical Catholic University of Chile, Faculty of Medicine, Santiago, Chile*

Background: Heart Failure (HF) is one of the leading cause of death and re-hospitalization in older people worldwide. Several studies had shown that gender inequality increases mortality rates in HF patients. However, there is limited evidence of its impact in Latin American countries.
Aim: To assess the impact of gender inequality in mortality due to HF in Chilean patients.
Methods: Cross-sectional study. We reviewed all country-wide deaths during 2015 of subjects 20 years and older using the national mortality database. Mortality due to HF was identified by the following ICD-10 codes: I500 (congestive heart failure), I501 (left ventricular heart failure), and I509 (non-specified heart failure). We analyzed sociodemographic and clinical variables stratified by gender. We assessed the prevalence of deaths due to HF by age, educational level, and rural/urban area of living. Odds ratios (OR) and 95% confidence intervals were calculated through multivariate logistic models.
Results: During the study period, there were 103,327 deaths in people older than 20 years in Chile. From those, 1,156 (1.12%) had HF as the primary cause of death. The number of women who died due to HF was higher than men (55.5% vs. 44.6%; p <0.002). Women were older (83.2 vs. 76.2 years; p <0.001), had less education (less than 8 years of schooling 88.5% vs. 77.4% p <0.001), and a larger percentage died in rural areas (16.2% vs. 10.9%; p <0.01) when compared with their male counterparts. Factors associated with mortality by HF in multiple logistic regression analysis were: women older than 80 years old (OR 2.81 IC95%; 2.19-3.61; p <0.001), women with less than 8 years of education (OR 1.99 IC95%; 1.43-2.78; p = 0.005) and living in rural areas (OR 1.72 IC95%; 1.21-2.47; p = 0.003).
Conclusion: Older and less educated women are features associated with higher mortality due to HF. While the reported mortality of HF is probably underestimated, this research is the first approach to assess the epidemiologic impact of inequalities in the Chilean population with HF.

P1826

Predictors of high killip class on admission in st-segment elevation myocardial infarction

K Kevin Domingues[1]; MJ Vieira[1]; D Durao[1]; M Leal[1]
[1]Hospital of Santarem, Cardiology, Santarem, Portugal

On behalf of: Investigators of the National Registry of Acute Coronary Syndrome of the Portuguese Society of Cardiology

Introduction: Heart failure (HF) is a common complication of ST-segment elevation myocardial infarction (STEMI). The Killip-Kimball classification (KK) is a system used in this setting, which takes into account physical examination and the development of heart failure in order to predict and stratify the risk of mortality. KK class is expectedly dependent on several factors, however, it is unknown which are the predictors of an elevated KK class on admission.
Aim: To determine predictors of high KK class on admission in STEMI patients.
Methods: A retrospective study of patients inserted the National Registry of ACS of the Portuguese Society of Cardiology was performed. The sample was divided in two groups: patients with KK class = 1 (KK = 1) and patients with KK class >1 (KK>1). Demographic and clinical data were analysed.
Results: A total of 7274 patients were included, predominantly men (75.4%), with a mean age of 64 ± 14 years. Most patients (85.5%) presented in KK = 1 (II 8.6%; III 2.3%; IV 3.6%).
There was a higher incidence of KK>1 in the female gender (36.3% vs 22.6%, p < 0.001), older patients (71 vs 63 years old, p < 0.001), patients with longer time from the beginning of symptoms to the first medical contact (median 143 vs 128 minutes, p = 0.008), anterior infarcts (59.6% vs 46.5%, p < 0.001) and in patients with atrial fibrillation (13.4% vs 4.0%, p < 0.001). Higher creatinine and glycaemia were both associated with a higher incidence of KK>1, as well as previous medication with commonly used cardiovascular drugs (including aspirin, clopidogrel, beta-blockers, ACE-inhibitors, statins, diuretics) and antidiabetic drugs (both oral and insulin).
In the multivariate analysis, including sex, age, comorbidities, time from the beginning of symptoms to the first medical contact, previous medication, blood tests and haemodynamic parameters on admission as variates, age >75 years old (p < 0.001; OR 1.82, CI95 1.46-2.27), prior heart failure (p < 0.001, OR 2.91, CI 1.75-4.85), previous medication with statins (p = 0.018; OR 1.29, CI 1.05-1.60), creatinine >2 mg/dL (p < 0.001; OR 2.25, CI95 1.44-3.52) and glycaemia >200 mg/dL (p < 0.001; OR 2.16, CI95 1.74-2.68) were independent predictors of KK>1 on admission.
On the contrary, sinus rhythm on admission (p < 0.001; OR 0.45, CI95 0.33-0.60) and right coronary artery as culprit (p = 0.010; OR 0.66, CI95 0.48-0.91) were independently associated with a lower incidence of KK>1.
Conclusion: In this study of STEMI patients, age >75 years old, previous medication with statins, creatinine >2 mg/dL and glycaemia >200 mg/dL were independent predictors of KK>1 on admission. On the contrary, sinus rhythm on admission and right coronary artery as culprit were independently associated with a lower incidence of KK>1.

P1827

Frequency and prognostic significance of hypoalbuminemia in cardiogenic shock

T A J Toni Antti Juhani Jantti[1]; T Tarvasmaki[1]; V-P Harjola[1]; J Parissis[2]; K Pulkki[3]; A Sionis[4]; J Silva-Cardoso[5]; L Kober[6]; M Banaszewski[7]; J Spinar[8]; V Carubelli[9]; S Disomma[10]; A Mebazaa[11]; JP Lassus[1]

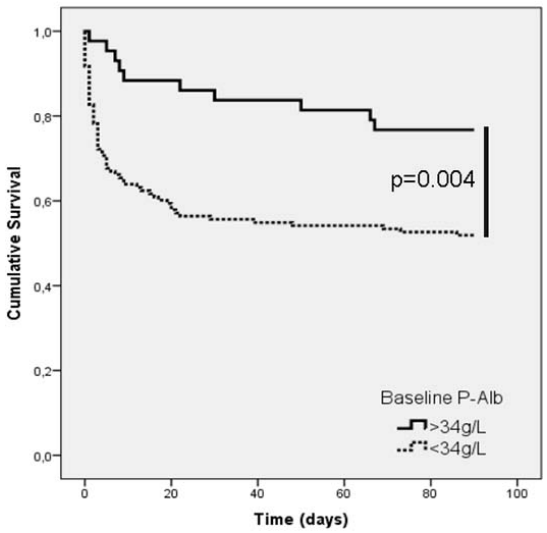
On behalf of: CardShock study group
Funding Acknowledgements: This study was supported by grants from the Finnish Foundation for Cardiovascular Research and Aarne Koskelo Foundation.

Background: The prevalence of hypoalbuminemia, early changes of plasma albumin levels and their effects on mortality in cardiogenic shock are unknown.
Methods: Prospective multinational observational study enrolling consecutive patients in cardiogenic shock. Plasma albumin was measured from serial blood samples in 178 patients. Clinical characteristics, course of hospital stay including treatment and procedures were registered. The main outcome was all-cause 90-day mortality.
Results: Hypoalbuminemia (plasma albumin < 34g/L) was very frequent (75%) at baseline in patients with cardiogenic shock. Patients with hypoalbuminemia had higher mortality than patients with normal albumin levels (48% vs. 23%, p = 0.004). Odds ratio for death was 2.4 [95% CI 1.5-4.1] per 10 g/L decrease in baseline plasma albumin. The association remained independent in regression models adjusted for risk prediction scores developed for cardiogenic shock (CardShock score, IABP-SHOCK II score) and variables associated with hypoalbuminemia at baseline in this study.
In serial measurements, albumin levels declined at a similar rate between 0h and 72h in both survivors and nonsurvivors. In contrast, the rate of albumin decline was greater for patients with normal plasma albumin at baseline (p < 0.001). The rate of albumin decline was not associated with outcome.
Conclusion: Hypoalbuminemia is a frequent finding early in cardiogenic shock, and plasma albumin levels decline during hospital stay. Low plasma albumin at baseline, but not change in albumin, is associated with mortality independently of other previously described risk factors. Thus, plasma albumin should be part of the initial evaluation in patients with cardiogenic shock.



Kaplan-Meier curves of 90-day mortality

P1828

C-terminal fragment of IGFBP-4 is independently associated with mortality in patients hospitalized due to acute heart failure

AB Postnikov[1]; AA Konev[1]; AV Kharitonov[2]; PN Datskevich[2]; FN Rozov[2]; J Lassus[3]; VP Harjola[3]; AG Katrukha[1]
[1]HyTest Ltd, Turku, Finland; *[2]Moscow State University, Faculty of Biology, Moscow, Russian Federation*; *[3]Helsinki University Central Hospital, Heart and Lung Center, Helsinki, Finland*

Background: Insulin-like growth factor binding protein-4 (IGFBP-4) fragments are products of proteolytic cleavage mediated by pregnancy-associated plasma protein A (PAPP-A). IGFBP-4 fragments have been proposed as biomarkers of major adverse cardiovascular events risk in patients with acute coronary syndrome. In addition, IGFBP-4 fragments have been shown to predict cardiac and all-cause mortality in patients with type 1 diabetes. Recently carboxy-terminal fragment of IGFBP-4 (CT-IGFBP-4) was shown to provide incremental prognostic information on cardiovascular events and mortality in patients with ST-elevation myocardial infarction. As progressive heart failure (HF) is a major cause of morbidity and mortality following acute myocardial infarction, we suggest that CT-IGFBP-4 could also be utilized as a biomarker for prognosis of HF outcomes.
Purpose: In this study the prognostic value of CT-IGFBP-4 for all-cause mortality was evaluated in emergency patients with acute HF.
Methods: CT-IGFBP-4 was measured at admission in Li-heparin plasma samples of 156 emergency patients with acute HF. A specific immunoassay utilizing monoclonal antibodies recognizing proteolytic neo-epitopes of CT-IGFBP-4 was used. Cross-reaction of the immunoassay with intact IGFBP-4 was less than 2%. One year all-cause mortality was recorded. ROC curve and Cox proportional hazard ratio analysis were performed to evaluate prognostic value of CT-IGFBP-4.
Results: During one year of follow-up 52 (33.3%) patients died. 52% of deaths (27 of 52 cases) occurred during the first month of observation. The concentration range of CT-IGFBP-4 of the study cohort was 9.4-1121 ng/mL. CT-IGFBP-4 was significantly elevated in non-survivors at both one month ($p = 0.0003$) and one year ($p = 0.0018$) periods. CT-IGFBP-4 predicted all-cause mortality at one month and one year follow-up periods: the areas under the ROC curves were 0.753 and 0.727, respectively. The optimal cut-off value of CT-IGFBP-4 for predicting all-cause mortality was 92.5 ng/mL that corresponded to 81% sensitivity and 58% specificity. Also the Cox hazard analysis revealed CT-IGFBP-4 as a predictive factor of one month and one year mortality. The unadjusted hazard ratio (HR) for CT-IGFBP-4 = 92.5 ng/mL was 6.15 (95% confidence interval [CI]: 2.12-17.79, $p = 0.0008$) for one month and 4.20 (95% CI: 2.11-8.39; $p < 0.0001$) for one year of follow-up. After adjustment for multiple clinical and echocardiographic variables CT-IGFBP-4 was an independent risk biomarker (HR 5.39 [95% CI: 2.11-13.76, $p = 0.0004$] and HR 3.26 [95% CI: 1.63-6.51, $p = 0.0008$] for one month and one year mortality, respectively).
Conclusion: CT-IGFBP-4 independently predicted all-cause mortality in patients with acute HF, suggesting that PAPP-A/IGFBP-4 might be involved in the pathogenesis of HF.

P1829

Risk factors for 30-day all-cause readmissions in patients with acute dyspnoea

K Cerlinskaite[1]; T Javanainen[2]; R Cinotti[2]; R Visinskiene[3]; A Kavoliuniene[4]; J Celutkiene[1]; A Mebazaa[2]
[1]Vilnius University, Clinic of Cardiac and Vascular diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania; *[2]Hospital Lariboisiere, Inserm UMR-S 942 and Anesthesia and Critical Care Department, Paris, France*; *[3]National Health Insurance Fund Under the Ministry of Health, Vilnius, Lithuania*; *[4]Department of Cardiology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania*

On behalf of: GREAT (Global Research on Acute Conditions Team) Network
Funding Acknowledgements: The work was supported by the Research Council of Lithuania, grant Nr. MIP-049/2015 and approved by Lithuanian Bioethics Committee, Nr. L-15- 01.

Introduction: Patients with acute dyspnoea are at high risk of vulnerable phase readmission after initial episode, but the risk factors for early readmissions have yet to be established.
Purpose: To determine predictors of 30-day all cause readmissions in both acute heart failure (AHF) and non-AHF patients with acute dyspnoea.
Methods: Prospective multicentre observational cohort study enrolled 1404 consecutive patients admitted with acute dyspnoea due to AHF and non-AHF. Present analysis included 30-day survivors who were divided into AHF and non-AHF groups. Cox regression analysis was used to determine independent predictors for 1 month all-cause readmissions.
Results: Of 1284 patients (median age 70 (62-78) years) included, 707 (55%) patients had AHF, and 577 (45%) had non-AHF (pneumonia 95(16%), pulmonary embolism 82(14%), etc.) dyspnoea. In AHF group 169 patients (24%) were readmitted in 1 month, in non-AHF group - 147 (25%) ($p < 0.05$). Median time to first 30-day readmission was 6 (1-16) and 6 (1-16.5) in AHF and non AHF groups, respectively ($p < 0.05$). In AHF group 30-day all-cause readmissions were mainly caused by impaired renal function and inadequate HF treatment, while in non-AHF group acute myocardial infarction (27 (5%) and pleural effusion (18 (3%) were the most important factors (Table 1). 19 readmitted patients (11%) died in 3 months vs 25 non-readmitted patients (5%) in the AHF group ($p = 0.004$); 23 readmitted patients (16%) died in 3 months vs 21 non-readmitted patients (5%) in the non-AHF group ($p < 0.001$).
Conclusions: Main predictors of readmission appear to be different in patients with acute dyspnoea due to AHF and non-AHF. Targeting the potential risk factors of readmissions in both groups could improve long-term outcome.

Predictors of 30-day readmissions

	Variable	HR (95% CI)	p value
Non-AHF group	Age per 1 year	1.02 (1.01-1.04)	0.000486
Dyslipidemia	0.45 (0.27-0.75)	0.002367	
Heart rate at admission > 90 b.p.m.	1.63 (1.16-2.28)	0.004714	
Psychotropic drugs at discharge	2.63 (1.42-4.9)	0.002225	
Acute myocardial infarction	2.71 (1.44-5.09)	0.001959	
Pleural effusion	2.66 (1.33-5.29)	0.005399	
AHF group	ACE inhibitors or ARBs at admission	0.65 (0.47-0.89)	0.00666
Creatinine at admission > 130 μmol/l	1.55 (1.12-2.15)	0.00817	
Beta blockers at discharge	0.71 (0.51-0.99)	0.0494	

HR - hazard ratio, CI - confidence interval

Background: Multifactorial pathways are implicated in heart failure (HF) and chronic kidney disease (CKD), complicating the pathogenic features of cardiorenal syndrome. Consequently, the pathophysiology and treatment of acute decompensated HF with CKD remain ill defined.
Purpose: Here we compared the prognostic factors for one-year mortality in patients with acute decompensated HF with and without CKD.
Methods: We retrospectively studied 392 consecutive patients with acute decompensated HF. CKD was defined as an estimated glomerular filtration rate of < 60 mL/min/1.73 m2. Potential risk factors for one-year mortality were selected using univariate analyses; subsequently, multivariate Cox regression analysis with forward stepwise selection was performed with variables showing a statistical value of $P < 0.10$ in the univariate analyses to identify significant factors. Kaplan-Meier survival curves and log-rank testing were used to compare one-year mortality between groups.
Results: Across the study cohort, 65% of patients had CKD, and the one-year mortality rate was 9.2%. There were no significant differences between patients with and without CKD with respect to left ventricular ejection fraction, ratio of early transmitral velocity to tissue Doppler mitral annular early diastolic velocity, and discharge prescription rates of renin–angiotensin–aldosterone system inhibitors, beta blockers, calcium channel blockers, and diuretics. In the HF with CKD group, older age, lower systolic blood pressure at admission, discharge medications without beta-blockers, and discharge medications without diuretics were independent risk factors for one-year mortality. In contrast, coexisting chronic obstructive pulmonary disease and higher C-reactive protein levels were independent risk factors for one-year mortality in the HF without CKD group. Kaplan-Meier survival curves

showed that discharge medications with no beta-blockers or diuretics correlated with significantly lower survival rates in patients with CKD (P < 0.001 in both groups, log-rank test), but not in patients without CKD (P = 0.822 and P = 0.374, respectively, log-rank test).
Conclusions: There were significant differences in the prognostic factors for one-year mortality between patients with acute HF with and without CKD. In particular, differential prognostic impacts of beta-blocker and diuretic treatments were demonstrated. Elucidation of the mechanisms underlying these findings could lead to more effective individualized therapeutic strategies for patients with HF.

Acute decompensated heart failure- predictive factors for all-cause in-hospital mortality

H B Hui Beng Koh[1]; SS Lim[1]; J Jaafar[1]; MA Sulong[1]; IS Sabian[1]; N Jaafar[1]; AA Abdul Rahim[1]; A Mohd Ghazi[1]; CK Teoh[1]; D Chew[1]
[1]National Heart Institute, Cardiology, Kuala Lumpur, Malaysia

Background: Heart failure is an important cause of morbidity and mortality. Its prevalence is on the rise not only due to increasing average life expectancy but also higher survival from cardiac events.
Purpose: Risk stratification, by identifying predictive factors for in-hospital mortality in patients presented with acute decompensated heart failure (ADHF), is vital so that prudent treatment can be instituted early.
Methods: A retrospective observational cohort study based on patient first admission to National Heart Institute from 2009 to 2015, using descriptive, cross tabulation, univariate and multivariate logistic regression analysis.
Results: 2,785 patients were admitted for ADHF. 124 had in-hospital mortality. Independent predictors for in-hospital mortality were background atrial fibrillation (OR 1.857, p = 0.021), stroke (OR 2.762, p = 0.009), elevated NT-Pro BNP (OR 3.534, p = 0.005), hyponatraemia (OR 1.962, p = 0.006), raised urea (OR 2.713, p = 0.001) and impaired LVEF <40% (OR 1.997, p = 0.045). Other non-independent predictors for in-hospital mortality were SBP = 100mmHg, HR >100, Stage 4 CKD and hyperuricaemia. Medications independently reduced in-hospital mortality- beta blocker (BB) (OR 0.299, p = 0.011), Angiotensin Converting Enzyme inhibitor (ACEI)+BB (OR 0.212, p = 0.007), Angiotensin Receptor Blocker (ARB)+BB (OR 0.274, p = 0.038), BB + Mineralocorticoid Receptor Antagonist (MRA) (OR 0.185, p <0.001), ACEI+BB+MRA (OR 0.149, p <0.001), ARB+BB+MRA (OR 0.048, p <0.001). Background hypertension showed an independent predictor for reduced in-hospital mortality (OR 0.506, p = 0.009). Initial SBP = 140mmHg upon admission was associated with lowered in-hospital mortality (OR 0.322, p <0.001), whereas SBP = 100mmHg was associated with increased in-hospital mortality. However, this was non-independent after adjusted for multivariate analysis. At presentation, patients with background hypertension had significantly more disease-modifying heart failure medications, less atrial fibrillation, less hyponatraemia, less SBP presentation of = 100mmHg. They however, had more pre morbid history of stroke and had more patients with Urea > 7. There were numerically more patients with LVEF <40% in the non hypertensive group versus hypertensive group, however it was not significant.
Conclusions:
Identification of predictors will help risk stratify ADHF patients to reduce in-hospital mortality. Background hypertension was found to independently reduce in-hospital mortality. It could be due to the presence of more disease-modifying heart failure medications already prescribed to hypertensive patients, thus lowering their in-hospital mortality. Other factors may have played some roles in explaining why background hypertension was associated with reduced in-hospital mortality. Prompt initiation of oral disease-modifying heart failure medications are crucial to reduce in-hospital mortality amongst patients presenting with acute decompensated heart failure.

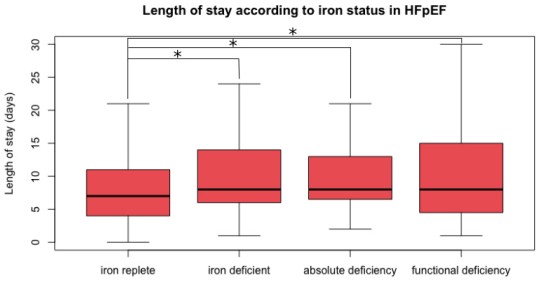
Iron deficiency predicts longer hospital stay in patients with heart failure and preserved ejection fraction, but not in those with reduced ejection fraction

A L Anna Louise Beale[1]; J Stirnemann[2]; N Garin[2]; D Carballo[2]; D M Kaye[3]; P Meyer[2]; S Carballo[2]
[1]Monash University, Melbourne, Australia; *[2]Geneva University Hospitals, Geneva, Switzerland*; *[3]The Alfred Hospital, Melbourne, Australia*

Funding Acknowledgements: No sources of funding to declare.

Background: Iron deficiency (ID) is gathering recognition as an important determinant of outcomes in heart failure, with evidence suggestive of a pathophysiological role in myocardial remodelling. Existing data on the prognostic and therapeutic use of iron predominantly relates to heart failure with reduced ejection fraction (HFrEF).
Purpose: This study investigated the associations between ID and length of hospital stay, dyspnoea class, biomarker levels, and echocardiographic indices of diastolic function in patients with HFrEF and heart failure with preserved ejection fraction (HFpEF).
Methods: Consecutive patients admitted with acute decompensated heart failure were included between December 2014 and August 2017 at a single Swiss tertiary centre. Demographic information, blood tests, echocardiography results and metrics regarding hospital stay and readmission were extracted from the patients' hospital record. Patients were classified as having 'absolute' ID if they had a ferritin level <100ng/mL; or 'functional ID' if they had a ferritin 100-200ng/mL in conjunction with a transferrin saturation <20%.



Length of stay in HFpEF

Results: Of the 503 patients recruited with ejection fraction data available, 160 (33%) had HFrEF, 270 (55%) had HFpEF, and 57 (12%) had HFmrEF. Reflecting other reported heart failure cohorts, HFpEF patients were older, female predominant, had a higher prevalence of hypertension and atrial fibrillation, and lower levels of natriuretic peptides than those with HFrEF. Other key comorbidities did not differ between groups. The prevalence of ID was 58% in HFpEF, 60% in HFmrEF, and 55% in HFrEF patients with iron results available. HFmrEF patients were excluded from further analyses due to a low number with iron studies. Haemoglobin level was significantly higher in HFrEF at 129 ± 20g/mL, compared to 121 ± 23g/mL in HFpEF. In patients with HFpEF, ID was significantly associated with female sex and a longer length of hospital stay of approximately 2 days (9 ± 6 vs. 11 ± 7.7 days, depicted below). HFpEF patients with functional ID had a higher C-reactive protein (CRP), and were older than those without ID or with absolute ID. No such associations were seen in the HFrEF cohort. No association was found between ID and dyspnoea class or diastolic function in either group.
Conclusions: This study highlights a high prevalence of ID in all heart failure phenotypes, along with an increased length of stay of 2 days in ID HFpEF patients compared to iron replete HFpEF patients. This may indicate an enhanced role for ID in HFpEF, which could be due to the detrimental effects of ID on exercise tolerance and myocardial remodelling in HFpEF. Furthermore, inflammation plays an important role in both HFpEF and ID, and may mediate the link between the two, as suggested by the elevated CRP in HFpEF patients with functional ID. Further studies in larger cohorts of patients from diverse ethnic backgrounds are warranted to increase the generalisability of these results.

On behalf of: The GREAT network

Introduction: Observational studies related treatment with high loop diuretic (LD) dose to worse long-term prognosis in chronic heart failure (HF); prognostic significance of LD dose in acute HF (AHF) is less certain.
Purpose: This study was designed to investigate the relation between LD dose administered to AHF patients in an emergency department (ED) and composite end-point of 1 year rehospitalisation and mortality.
Methods A prospective two-centre observational cohort study consecutively enrolled dyspnoeic patients admitted to an ED. Single centre data were included in the present analysis because medical records regarding LD doses were not available in the collaborating institution. 414 subjects were diagnosed with AHF; 1 year follow-up of mortality and rehospitalisation was available in 230 subjects that underwent outcome analysis. Patients were divided into quartiles (Q) based on LD dose administered at an ED (70% intravenous (IV), 26% oral (PO), 4% IV and PO

administration): Q1 (mg of furosemide) (= 60 mg) was compared with Q2 (61-80 mg), Q3 (81-100 mg) and Q4 (<100 mg).
Results: Patients treated with the highest LD dose were younger (mean age Q1 vs Q4 was 70 vs 65 years [p < 0.05]) and predominantly male (83%), their systolic (SBP) and diastolic (DBP) blood pressure at admission was lower (SBP Q1 vs Q4 was 139 vs 127 mmHg; DBP Q1 vs Q4 was 82 vs 74 mmHg [p < 0.05]). 21.7% of patients died; 51.4% were rehospitalised in 1 year. In an univariate analysis Q4 was identified as a predictor of 1-year rehospitalisation and mortality (Q1 vs Q4 unadjusted odds ratio (OR) 2.44, 95% confidence interval (CI) 1.06-5.64 [p < 0.05]) (Table). Other univariate predictors were included in a multivariate analysis, where furosemide dose >100 mg retained its predictive value (adjusted OR 2.98, 95% CI 1.01-8.80; p < 0.05) along with anaemia (Table).
Conclusion. Higher loop diuretic dose administered at admission for AHF is an independent predictor of 1-year rehospitalisation and mortality in AHF patients.

Mitral regurgitation worsens prognosis in acute heart failure

J Jack Stewart[1]; A Baltabaeva[1]; O Lazariashvili[1]
[1]*Ashford and St Peter's Hospitals NHS Trust, Cardiology, Chertsey, United Kingdom*

Funding Acknowledgements: Metanoic Health Ltd.

Introduction
Acute Heart Failure (AHF) is a well recognised and growing healthcare problem with 1 year mortality typically reported around 30%. Mitral regurgitation (MR) is a highly prevalent valvular disease, but it's impact on heart failure and the potential benefits of intervention are currently unclear.
Purpose: We have aimed to assess the prognostic impact of MR in patients admitted with AHF or exacerbation of chronic HF (ECHF) in a single-centre, prospective, cross-sectional study.
Methods: All patients admitted to a large district general hospital with AHF and/or ECHF over the period of 1 year were assessed and approached for recruitment to the study. Those recruited had standard clinical assessment, biochemistry including bedside B-type natriuretic peptide levels and bedside transthoracic echocardiography within 48 hours of recruitment. Demographic and comorbidity data was also recorded including history of heart failure and MR. Geometric and functional parameters of cardiac function were assessed according to international guidelines with a specific focus on valvular disease characteristics. All-cause mortality was documented at 6 months post discharge.
MR was categorised as mild, moderate, moderate-severe and severe according to international guidelines.
Subsequent recategorisation was performed with patients divided into Mild MR and Significant MR (moderate severity MR and above).
For statistical comparison values were categorised and analysed using Chi-square testing. Kaplan-Meier survival plots were created to demonstrate differences in survival.
Results: 617 patients met the inclusion criteria of whom 500 were consented and 448 patients were included in the study. 6 month mortality is currently available for 356 patients. Of these patients, 151 (42%) had known MR at admission. MR of at least trace severity was found in all patients (100%). Clinicians felt that worsening of MR was the likely cause of decompensation of HF in only 15 patients (4.2%).
6 month mortality was higher than previously reported data at 29%.
Patients with significant MR demonstrated significantly increased 6-month mortality when compared to mild MR (p < 0.05).
Additionally, patients with known MR prior to admission demonstrated significantly increased mortality at 6 months compared to those without (p < 0.05).
Conclusion: Significant MR is associated with reduced 6 month survival in acute heart failure. Known MR is also a predictor of impaired long term survival, irrespective of whether or not this is the cause of acute decompensation.

Precipitant of hospitalisation predicts mortality in acute heart failure

J Jack Stewart[1]; O Lazariashvili[1]; A Baltabaeva[1]
[1]*Ashford and St Peter's Hospitals NHS Trust, Cardiology, Chertsey, United Kingdom*

Funding Acknowledgements: Abbott Vascular ltd

Introduction: Acute Heart failure (AHF) has a poor prognosis with mortality similar to or worse than 5 of the most common cancers. The ability to prognosticate for individual patients is of significant benefit and clear understanding of precipitants of hospitalisation may provide useful information for targeted treatment.
Purpose: We aimed to assess how precipitants of hospitalisation in acute heart failure (AHF) can predict of outcome in patients with AHF presenting to the emergency room of a large district general hospital in a single-centre prospective cross-sectional study.
Methods: All patients admitted to a large district general hospital with AHF over 1 year underwent standard clinical assessment, biochemistry and transthoracic echocardiography. Patients admitted with AHF as a non primary driver of admission were excluded from the study. Parameters of cardiac function were assessed according to international guidelines. Precipitants of AHF were recorded according to the CHAMP classification as outlined in the ESC guidelines, with additional categories for 'Medication withdrawal' (MW) and 'Unclear precipitant' (U). All-cause mortality was documented at 6 months post discharge. Chi-square analysis was used to demonstrate or refute statistical excess in mortality.
Results: 617 patients met the inclusion criteria of whom 500 were consented and 448 were included in the study. 6-month mortality is currently available for 356 patients. 49 (14.6%) had acute ischaemia (C) as precipitant of HF admission, 5 (1.5%) - hypertensive crisis (H), 94 (28%) - arrhythmias (A), 41 (12.2%) - mechanical cause (M), 6 (1.8%) - lung disease (P), 18 (5.3%) - MW and 123 (36.6%) had U.
Overall 6-month mortality was 29.1%.
Patients with hospitalisation precipitated by medication withdrawal had significantly increased mortality at 6 months (p < 0.05). Patients in whom precipitant was unclear had significantly increased mortality at 6 months (p < 0.05).
Patients with AHF precipitated by pulmonary disease had significantly increased mortality at 6 months compared to the rest of the cohort (p < 0.05).
Patients with an arrhythmogenic precipitant of AHF had the best outcome, with significantly reduced mortality at 6 months compared to the rest of the cohort (p < 0.0001).
6-month mortality in AHF precipitated by acute ischaemia, hypertensive crisis or mechanical disease was not statistically significantly different from the rest of the cohort.
Conclusions: Aetiology of decompensation offers significant prognostic information to clinicians and patients. The prevalence of non-compliance and physician led withdrawal is relatively high and associated with poor 6-month prognosis, as is worsening of HF with no clear precipitant. Arrhythmias are significant contributors to HF admissions but demonstrate good 6-month survival. Inpatient treatment could be focussed on patients with greater risk, with the outpatient setting reserved for those with better prognosis.

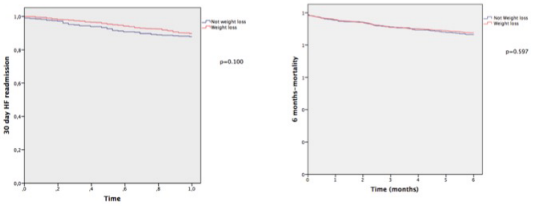
On behalf of: REDINSCOR II
Funding Acknowledgements: Centro de Investigación Biomédica en Red de Enfermedades Cardiovasculares (CIBERCV)

Introduction: Congestion is recognized as the major cause for hospitalization in the vast majority of patients with heart failure (HF) and contributes to adverse outcomes. Nevertheless, a significant proportion of the patients admitted to the hospital for acute decompensated heart failure (ADHF) is discharged with unresolved congestion. Despite the fundamental role congestion plays in AHF limited data exist regarding the association between changes in weight and outcomes following a hospitalization for AHF



outcomes

Purpose: The aim of the study was to evaluate the relationship between body weight change during HF hospitalización and outcomes.
Methods: The analysis included patients admitted for acute heart failure regardless of ejection fraction enrolled in the REDINSCOR II Registry, in whom body weight was avalaible at baseline and discharge. The primary endpoint was all-cause mortality or heart failure readmission at 30- day, 6 months and 1- year.
Results: The final analysis included 1391 patients; 981 with weight loss (71.1%) and 402 with no weight loss (28,9%). The median change in body weight during hospitalization was -2,74 ± 4,9 Kg in weight loss group and 1,2 ± 4,2 kg in no weight loss group. There were no differences between groups in age, sex, cardiovascular risk factors, NT-proBNP levels , renal disfunction , left ventricular ejection fraction or in utilization of guideline-directed medical therapies. The 30 -day mortality was 4,2% in weight loss group vs 4,5% in no weight loss group (p = 0,818), the 6 month mortality was 12,1% vs 13,3% (p = 0,544) and 1 year mortality was 18,6% vs 20,3% (p = 0,479) respectively. The Kaplan Meier Curves showed that these differences were not statistically significant. There was no statistically significant association between inhospital body weight loss and 30-day, 6 month and 1 year heart failure readmission
Conclusions: Only about 70% of patients admitted for acute heart failure experience weight loss during index hospitalization. Weight loss was no associated with a better post-discharge and one year prognosis.

P1837

Impact of end-stage chronic kidney disease on short- and long-term outcomes of acute heart failure patients

A Vinikovas[1]; R Rasa Zeimaite[2]; D Verikas[3]; D Kablucko[4]; K Stasaitis[5]; A Mebazaa[6]; A Kavoliuniene[5]; J Celutkiene[4]
[1]University Hospital Santariskiu Klinikos, Vilnius, Lithuania; *[2]Vilnius University, Vilnius, Lithuania*; *[3]Lithuanian University of Health Sciences, Faculty of Medicine, Kaunas, Lithuania*; *[4]Vilnius University, Clinic of Cardiac and Vascular diseases, Center of Cardiology and Angiology, Vilnius, Lithuania*; *[5]Lithuanian University of Health Sciences, Department of Cardiology, Kaunas, Lithuania*; *[6]University Paris Diderot , U942 Inserm, Hospital Lariboisiére, Paris, France*

On behalf of: GREAT network

Introduction: Chronic kidney disease (CKD) is the most frequent comorbidity in heart failure patients. However, importance of end-stage CKD in acute heart failure (AHF) is not entirely clear.
Aim: We aimed to evaluate the impact of end stage CKD (eGFR < 30 ml/min) on mortality (M) and rehospitalization (R) rates due to cardiovascular (CVR) and non-cardiovascular reasons (NCVR) in 1, 3, and 12 months in AHF patients.
Methods: A prospective two-centre observational cohort study enrolled 726 (mean age 72 years, 43% female) AHF patients admitted to an emergency department. Data of 679 patients (those without eGFR data were excluded from the study), including patient history, follow-up data and glomerular filtration rate (eGFR) was grouped into normal eGFR group (<90 ml/min), end-stage eGFR (< 30 ml/min) and analysed using binary logistic regression, SPSS v.20. Normal eGFR group was used as a reference. Odds ratio (OR) were also adjusted to age, gender, LVEF, anemia and systolic blood pressure.
Results: 96 patients (14.1%) represented normal eGFR group, 82 (12.1%) - end-stage eGFR group, 501 patient had eGFR between 30 and 90 ml/min. The results are presented in the table below (p < 0.05 are marked with an asterisk *). End-stage renal disease increases the chance to die due to cardiovascular reasons in 3 and 12 months after discharge by 3.5 times for acute heart failure patients. The chance of being rehospitalized due to the cardiovascular reasons increases twice in the long-term period - 12 months. Adjusted OR did not show independent association.
Conclusion: Acute heart failure patients with end-stage renal disease die and are readmitted due to cardiovascular reasons more frequently in 3 and 12 months after hospitaliazation. However, no independent association could be demonstrated.

Different characteristics and treatments of patients hospitalized to acute heart failure in the department of cardiology or medicine

C Lombardi[1]; A Roncolato[1]; A Ravera[1]; E Sciatti[1]; V Carubelli[1]; I Bonadei[1]; AI Castrini[1]; E Gorga[1]; E Vizzardi[1]; M Metra[1]
[1]University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health, Brescia, Italy

Background: pts may have a different diagnostic and therapeutic patway depending on the hospitalization department.
Purpose: analyse the different characteristics of pts admitted to the ED for AHF and to describe the differences in treatment and outcome according to the hospitalization department.
Methods: we retrospective analysed 426 pts admitted to the ED. We evaluated the characteristics and therapeutic management compared Cardiology (CD) vs Medicine (MD) departments. Results (table 1): 134 pts were admitted in CD, 276 in MD. Pts in CD were more male and younger with lower EF and higher NT-pro BNP. Previous history of MI or devices was higher in CD. More than 80% of pts had iv furosemide in both departments. Inotropes and vasodilators were more given in CD. The average duration of the hospitalization in MD was 13 days vs 11 in CD. Death for CV occurred in 7% in CD and in 5% in MD. Conclusion: The results demonstrate

different characteristics and treatment strategies between pts hospitalized for AHF Medicine or Cardiology

Age and gender-related differences in clinical presentations, managements, and outcomes in taiwanese patients with acute decompensated heart failure

H-Y Hung-Yu Chang[1]; M-C Fong[1]; A-N Feng[1]; Z-C Chiang[1]; C-W Hsueh[1]; W-T Lai[1]; W-H Yin[1]
[1]*Cheng-Hsin General Hospital, Taipei, Taiwan ROC*

Introduction: Data of the Taiwan Society of Cardiology-Heart Failure with reduced Ejection Fraction (TSOC-HFrEF) registry had provided insights into the characteristics and management of hospitalized decompensated systolic HF patients in Taiwan. We aimed to evaluate the age and gender-related differences in the TSOC-HFrEF registry patients.
Methods: A total of 1509 patients hospitalized for acute decompensated HFrEF were recruited in 21 hospitals in Taiwan between 2013 and 2014. Baseline characteristics, medical history, presenting symptoms, medications, and one-year outcomes were collected and analyzed. Patients were divided by age and by gender for analysis.
Results: Of the 1509 patients included in this registry, 416 (27.6%) were women, mean age 70.1 years; 1093 (72.4%) were men, mean age 61.7 years; 271 (18.0%) were older than 80 years and 300 (19.9%) were younger than 50 years. Older patients more frequently had atherosclerotic cardiovascular disease, valvular heart disease, diabetes, atrial fibrillation, chronic kidney disease, hypothyroidism, cardiac implantable electronic device compared with younger patients. Women more frequently had valvular heart disease, diabetes, cancer with history of chemotherapy, hyperthyroidism, and less frequently coronary heart disease, dilated cardiomyopathy, obstructive lung disease, or sleep apnea compared with men.
Older patients and women were unlikely to received guideline-directed medical therapy at discharge. One-year re-hospitalization rates (38.5%) were similar in both genders and age groups. One-year morality rates were higher in older patients but similar in both gender groups. Non-cardiovascular death was significantly higher in women compared with men (7.9% vs. 4.5%, p = 0.042).
Conclusion: Significant age and gender differences exist in etiology and co-morbidities. Individual factors should be considered for setting personalized and patient-centered HF management.

P1840

Acute renal failure as a predictor for in-hospital death in acute heart failure patients

LCSP Luiz Carlos Passos[1]; TM Trindade[2]; WN De Carvalho[2]; AGQ De Jesus[2]; EL Garrido[3]; NFC De Oliveira[4]; EOM Andrade[3]; YM Lira[4]; AMP De Lima[2]; VRS Souza[3]
[1]*Federal University of Bahia, Internal Medicine, Salvador, Brazil*; [2]*Ana Nery Hospital, Salvador, Brazil*; [3]*Federal University of Bahia, Faculty of Nursing, Salvador, Brazil*; [4]*Bahiana School of Medicine and Public Health, Salvador, Brazil*

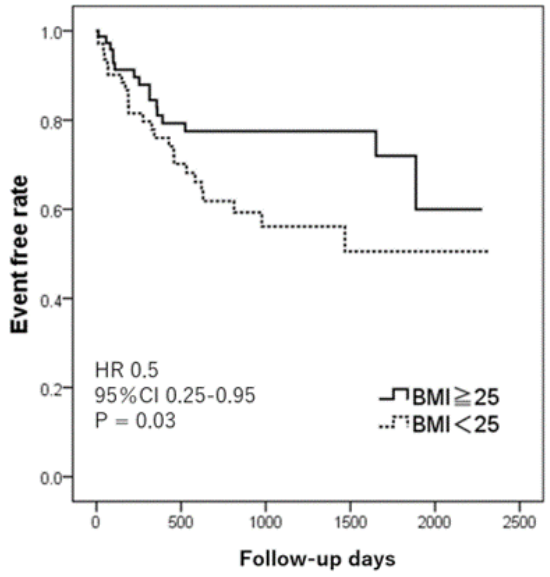
Background/Introduction: The development of acute heart failure involves complex features and worsening renal function has been reported as a factor for longterm poor prognosis. Cardiorenal syndrome has been reported as a panel in which both cardiac and renal dysfunction coexist.
Purpose: The aim of this study was to investigate if acute renal failure developed during hospital stay was a predictor for worse prognosis among acute heart failure patients.
Methods: Cohort data from 295 patients admitted in a tertiary cardiac referral centre for acute decompensated heart failure treatment between 2016 and 2017. All the data were collected from medical records. Heart failure was defined according the European Society of Cardiology guidelines.
Results: The mean of age was 55.2 years among non-acute renal failure patients and 57.4 among its acute renal failure counterparts (P = 0.3). The mean of Left Ventricular Ejection Fraction (%) (31.8% vs 30.5%) and the prevalence of previous comorbidities such as hypertension (60% vs 65%; P = 0.3), diabetes mellitus (28.3 vs 29.7; P = 0.8) and coronary artery diease (11% vs 16%; P = 0,3) showed no diferences between the groups. On the other hand, acute renal failure patients had higher incidences of infection (12% vs 38.9%; P < 0.001), hyperkalemia (30% vs 71.4%; P= < 0.001), intensive care unit admission (34 vs 61.1%; P= < 0.001) and sudden cardiac arrest, (1% vs 12.6%; P= < 0.001) during hospital stay. Moreover, acute renal faliure patients had a longer average length of hospital stay (10.5 vs 20 days; P < 0.001) and higher in-hospital lethality (8% vs 23.4%; P < 0;001). Conclusion: Acute renal failure was a predictor for worse outcomes such as intensive care unit, sudeen cardiac arrest, length of hospital stay and in-hospital lethality.

P1841

Clinical characteristics and mid-term outcomes of non-elderly obese patients with acute decompensated heart failure in Japan

M Ito[1]; H Wada[1]; K Sakakura[1]; T Ibe[1]; Y Ugata[1]; S Momomura[1]; H Fujita[1]
[1]*Jichi Medical University Saitama Medical Center, Cardiology, Saitama, Japan*

Background/Introduction: Obesity is the well-known risk factor for cardiovascular diseases including heart failure (HF). However, previous reports suggested better clinical outcomes in obese patients with HF and higher body mass index (BMI) levels of HF patients were significantly associated with younger age. The impact of obesity on clinical outcomes in non-elderly HF patients should be elucidated.
Purpose: The purpose of this study was to investigate the clinical characteristics and the mid-term outcomes of the obesity patients with HF among Japanese non-elderly population.
Methods: Consecutive 155 non-elderly acute decompensated HF patients (< 60-year-old) who admitted to our institution between 2009 and 2013 were included. Those patients were divided into the two groups according to the BMI: the obesity group (BMI = 25 kg/m2, n = 81) and the non-obesity group (BMI < 25 kg/m2, n = 74). The primary composite outcome of this study was defined as re-admission due to HF and all-cause death.
Results: The prevalence of hypertension was significantly greater in the obesity group (87.7%) than in the non-obesity group (63.5%) (P < 0.001). The levels of plasma B-type natriuretic peptide (BNP) were significantly lower in the obesity group (758.4 ± 765.8 pg/ml) than in the non-obesity group (1099.2 ± 968.0 pg/ml) (P = 0.03). The apnea-hypopnea index (AHI) was greater in the obesity group (25.5 ± 19.2 /hour) than in non-obesity group (14.0 ± 13.1 /hour) (P < 0.01). The primary composite outcome (re-admission due to HF and all-cause death) was less frequently observed in the obesity group as compared to the non-obesity group (Hazard ratio [HR] 0.50, 95% confidence interval [CI] 0.26-0.95, P = 0.03).
Conclusions: The mid-term outcomes in non-elderly HF patients with obesity were better as compared to non-elderly HF patients without obesity which supports obesity paradox in this specific population.



Kaplan-meier event-free curve

Acute Heart Failure - Diagnostic Methods

P1842

Prediction of all cause death in patients with acute decompensated heart failure using the combination of the fibrosis-4 index and geriatric nutritional risk index.

Y Sato[1]; O Nakagawa[1]; M Kumada[1]; M Tsukiyama[1]; Y Okazaki[1]; Y Koh[1]; T Iida[1]; N Fukushima[1]; A Miyaoka[1]
[1]*Toyonaka Municipal Hospital, Cardiology, Toyonaka, Japan*

Background: Malnutrition is associated with poor outcome in acute decompensated heart failure(ADHF)patients. Liver stiffness(LS), assessed by Fibrosis-4 index(FIB4), is known as indication of liver congestion in patients with HF. Aim of this study was to investigate the prognostic value of combining objective nutritional index and LS for long-term mortality prediction in ADHF patients.
Methods: We retrospectively enrolled 165 ADHF patients between 2012 and 2015. Objective nutritional indexes were evaluated by Geriatric Nutritional Risk Index(GNRI), Controlling Nutrition Status(CONUT)and prognostic nutritional index(PNI). LS was also valuated by FIB4. The primary outcome was all cause death(ACD).
Results: During a follow-up period of 2.5 ± 1.2 years ,35 patients had ACD. At multivariate Cox analysis, GNRI(p = 0.0001) and FIB4(p = 0.0012)were independently associated with ACD. Kaplan-Meier analysis revealed that patients with both positive lower GNRI (< 90: determined by ROC analysis)and higher FIB4(>2.22: determined by ROC analysis) had a significantly greater risk of ACD than those with either positive the lower GNRI or higher FIB4 (38% vs 20% p = 0.0005, adjusted HR 3.1126 [1.5092 to 6.4196]). Furthermore, patients with either positive the lower GNRI or higher FIB4 also had a significantly greater risk of ACD than those with neither positive the lower GNRI nor higher FIB4 (20% vs 2% p= 0.0113, adjusted HR 8.7554 [3.0942 to 24.7745]).
Conclusion: The combination of GNRI and FIB4 index would be useful for the prediction of ACD in HF patients.

Neutrophil gelatinase-associated lipocalin predicts long-term outcomes of worsening renal function in patients with acute heart failure

Y Horiuchi[1]; N Wettersten[1]; P Murray[2]; A Maisel[1]
[1]*University of California San Diego, Division of Cardiovascular Medicine, San Diego, United States of America*; [2]*University College Dublin, Department of Nephrology, Dublin, Ireland*

Funding Acknowledgements: Abbott Laboratories and Alere, Inc.

Background: Neutrophil gelatinase-associated lipocalin (NGAL) is a marker of renal tubular damage. Prognostic values of NGAL have not been fully elucidated in patients with acute heart failure (AHF).
Purpose: We aimed to investigate prognostic values of NGAL in relation to renal glomerular function in AHF.
Methods: We retrospectively analyzed 927 patients enrolled in the prospective, international, multicenter Acute Kidney Injury NGAL Evaluation of Symptomatic heart Fallure Study (AKINESIS). The endpoint of this analysis was a composite of death, HF hospitalization or emergent visit requiring intravenous diuretic therapy within one year. Worsening renal function (WRF) was defined as an increase in creatinine = 0.3 mg/dl or 50% of the first creatinine during the first 5 days.
Results: Sixteen patients lacking admission NGAL values were excluded leaving 911 patients for analysis. The composite endpoint occurred in 45% of patients with admission NGAL = 150 ng/dl versus 34% in those with NGAL < 150 ng/dl (p < 0.001). Patients with an NGAL < 150 ng/dl had better outcomes regardless of eGFR < or = 60 ml/min/1.73m2 (Figure 1). The composite endpoint correlated better with NGAL values than developing WRF (31% in low NGAL with WRF, 35% in low NGAL without WRF, 44% in high NGAL with WRF and 45% in high NGAL without WRF, p = 0.005, Figure 2). In multivariate Cox regression analysis, a high level of NGAL predicted one-year adverse outcomes.
Conclusions: In patients with AHF, admission NGAL has long-term prognostic utility beyond renal function and the development of WRF during hospitalization.

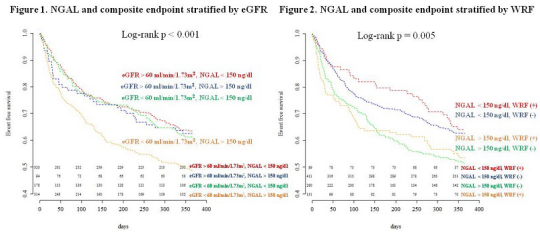

Figure 1 and 2

Serial high sensitivity cardiac troponin I measurements in acute heart failure patients

Y Horiuchi[1]; N Wettersten[1]; P Murray[2]; A Maisel[1]
[1]*University of California San Diego, Division of Cardiovascular Medicine, San Diego, United States of America*; [2]*University College Dublin, Department of Nephrology, Dublin, Ireland*

Funding Acknowledgements: Abbott Laboratories and Alere, Inc.

Background: Troponin elevation is common in acute heart failure (AHF) and is associated with worse outcomes. However, previous studies mainly used older-generation less sensitive assays and conflicting results exist, especially in terms of long-term outcomes.
Purpose: We aimed to investigate the association between serial measurements of high-sensitivity cardiac troponin I (hs-cTnI) and outcomes in AHF.

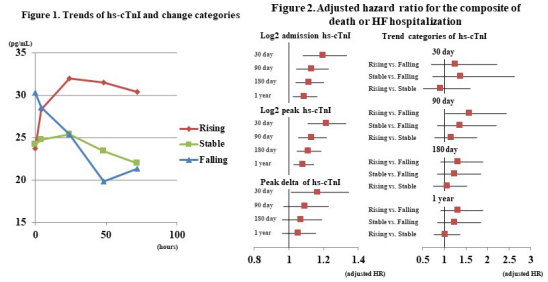

Figure 1 and 2

Method: The Acute Kidney Injury NGAL Evaluation of Symptomatic heart fallure Study (AKINESIS) was a prospective, international, multicenter study of AHF. hs-cTnI was measured at admission, 4-hours, day 1, 2, 3 and discharge. We retrospectively analyzed 849 patients for the relationships between admission, peak, peak delta and trend categories of hs-cTnI and a composite endpoint of death or HF hospitalization within 30, 90, 180 days and 1 year. Peak delta was the absolute change from log2-transformed admission to peak values of hs-cTnI. Trend categories included rising, falling and stable patterns. Rising was at least one value = 20% higher than admission hs-cTnI. Falling was at least one value = 20% lower than admission hs-cTnI with the last measured value less than admission. Stable was all values within 20% of admission value.

Results: The mean age was 68 ± 14 years, 62% were male and 47% had a history of coronary artery disease (CAD). Patients with hs-cTnI = median (25.6 pg/mL) were more likely to be male with CAD and impaired renal function. Rising, falling and stable trends occurred in 42%, 31% and 25% of patients, respectively (Figure 1). Higher admission and peak hs-cTnI were associated with worse short and long-term outcomes independent of confounding factors, although their risk ratios declined at long-term follow-up (Figure 2). Similar findings were observed with peak delta and trend categories, which were not statistically significant at long-term follow-up.

Conclusion: Higher admission and peak hs-cTnI were associated with short- and long-term worse outcomes. Changes of hs-cTnI may have short-term prognostic implications.

P1845 Prolonged QTc interval in ECG predicts long-term mortality in ICU patients

T Javanainen[1]; R Cinotti[1]; K Cerlinskaite[1]; S Ishihara[1]; E Akiyama[1]; N Vodovar[1]; E Gayat[1]; A Mebazaa[1]

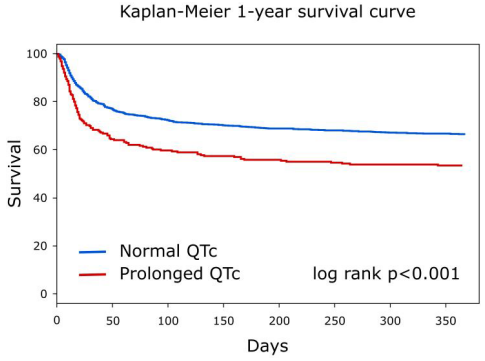
[1]*Hospital Lariboisiere, Inserm UMR-S 942 and Anesthesia and Critical Care Department, Paris, France*

Background: Prolonged QTc interval in ECG is a common finding in Intensive Care Unit (ICU). It has been associated with higher mortality in population based studies, but there is little information about the association with long-term mortality in critically ill patients.

Table

	Normal QTc (n = 1176)	Prolonged QTc (n = 421)	p-values
Age, years (SD)	59 (17)	63 (15)	<0.001
Male gender, n (%)	700 (60)	312 (74)	<0.001
Charlson Comorbidity index, n (%)	2.9 (2.3)	3.5 (2.4)	<0.001
SAPS II, n (%)	48 (19)	52 (19)	0.003
Cardiogenic shock, n (%)	63 (5)	34 (8)	0.059
Acute cardiac arrest, n (%)	80 (7)	52 (12)	0.001
Amiodarone treatment, n (%)	196 (17)	121 (29)	<0.001
Neuroleptic administration, n (%)	133 (11)	40 (10)	0.351
hs-TnI, ng/L (IQR)	30 (7-199)	60 (16-340)	<0.001

Baseline characteristics.



Figure

Purpose: The aim was to investigate the association between prolonged QTc and long-term prognosis in ICU patients.

Methods: FROG-ICU (NCT 01367093) is a prospective, observational study conducted in 21 ICUs in 14 European hospitals. In this sub-study, patients with at least one ECG available during the first 3 days after ICU admission were included. QT was measured digitally on standard 12-lead ECG, and it was corrected with Bazett's formula. Prolonged QTc was defined as QTc = 450ms in male and QTc = 460ms in female patients. For 1-year mortality analysis, adjusted cox model was formed including Simplified Acute Physiology Score II (SAPS II), Charlson Comorbidity Index, gender, amiodarone treatment, hs-TnI at inclusion and acute cardiac arrest or cardiogenic shock as cause for ICU admission.

Results: Of the 2087 FROG-ICU patients, 1597 (77%) were included in this study. 421 (26%) patients displayed with prolonged QTc. These patients were older (63 (± 15) vs. 59 years (± 17), p < 0.001), more often male (312 (74%) vs. 700 (60%), p < 0.001) and had more comorbidities. Amiodarone administration and acute cardiac arrest as cause for ICU admission were more common in prolonged QTc patients (Table) and hs-TnI was higher (60 ng/l (16-340) vs. 30 ng/l (7-199), p < 0.001). 1-year mortality was higher in patients with prolonged QTc (182 (43%) vs. 373 (32%), p < 0.001, Figure). In adjusted mortality analysis, prolonged QTc remained predictor of 1-year mortality (HR 1.29-IC95% (1.08-1.55), p = 0.006).

Conclusions:

Prolonged QTc during the first 3 days after ICU admission is a marker of long-term mortality in ICU patients.

P1846 Multiple soluble neprilysin concentration testing and its prognostic value in patients with at least moderate functional mitral regurgitation and hospitalized for acute decompensated heart failure.

K Kamil Janikowski[1]; A Sakowicz[2]; T Pietrucha[2]; M Lelonek[1]

[1]*Medical University of Lodz, Department of Noninvasive Cardiology, Lodz, Poland*; [2]*Medical University of Lodz, Department of Medical Biotechnology, Lodz, Poland*

Funding Acknowledgements: The study was carried due to research funding young scientists and doctoral students of the Faculty of Medicine of Medical University of Lodz

Background: The prognosis of patients (pts) hospitalized due to acute decompensated heart failure (ADHF) is still poor. One of the independent factors that worsen the prognosis of ADHF population is functional mitral regurgitation (FMR), regardless of the left ventricular ejection fraction (LVEF). The predictive value of soluble neprilysin concentration (sNEP) is unclear in this population.

Purpose: Evaluation of the prognostic value of sNEP in pts hospitalized for ADHF, related to FMR, in 6-month follow-up.

Methods: In a single-centre, prospective, non-interventional study we analyzed 55 pts hospitalized for ADHF (73% male, mean age 72 ± 12 yrs, median LVEF: 30% and ischemic etiology in 44%). All of them were referred due to exacerbation to III-IV NYHA class of previously confirmed chronic heart failure with peripherial oedema and required administration of intravenous diuretics. During hospitalization blood samples were collected at three time points: on admission, in the second day and at discharge. The population was divided into 2 groups related to FMR:

- with at least moderate FMR (30 pts, 73% men, mean age 73 ± 11 yrs, median LVEF: 30%, 53% of ischemic etiology, 55% of HFrEF);
- and non-FMR group (25 pts, 33% men, mean age 71 ± 12 yrs, median LVEF: 30%, 32% of ischemic etiology).

FMR was diagnosed based on transthoracic and/or transesophageal echocardiography and 2017 ACC expert consensus concerning management of mitral regurgitation. All FMR pts were disqualified by the Heart Team from invasive treatment of FMR. During 6-month follow-up all pts were treated with OMT for the heart failure.

Telephone calls concerning HF hospitalizations (HFh) and/or death were conducted 7 days, 1 month, 3 (3M) and 6 months (6M) after discharge.
Results: Of all 36% (n = 19) pts were rehospitalized for HF and 12 pts died (2 during the initial hospitalization) within 6M observation.
FMR subpopulation: HFh concerned 39% (n = 11) in 3M and 43% (n = 12) of pts in 6M. After 3M and 6M the mortality rate was 18% (n = 5) and 25% (n = 9), respectively. ROC-analysis showed the best significant predictive value of sNEP on admission for HFh in two time points - 3M and 6M (in both cases: AUC>0.7, p < 0.05). There were no significant predictive values for the results performed in the second day of hospitalization and at discharge.
non-FMR subpopulation: HFh were observed in 20% pts (n = 5) during 3M and in 28% (n = 7) during 6M. No one died in 3M and 3 pts died in 6M. ROC analysis revealed that sNEP results for HFh in 3M were statistically significant only at discharge (AUC>0.7, p < 0.05). sNEP peak results demonstrated a significant predictive value only for HFh during 6M (AUC>0.7, p < 0.05).
In each analysis NT-proBNP revealed no significant predictive value.
Conclusions: In the studied population hospitalized for ADHF, in contrast to NT-proBNP, sNEP has a good predictive power for HF hospitalizations, it seems that better for FMR pts than for non-FMR ones.

P1847
Higher natriuretic peptide levels is associated with higher hs-cTnT, CA-125, hsCRP and lower eGFR, hemoglobin and sodium levels in patients with acute decompensated heart failure

Y Yuksel Cavusoglu[1]; ME Altinbas[1]; S Eraslan[1]
[1]*Eskisehir Osmangazi University, Eskisehir, Turkey*

Purpose: Plasma levels of natriuretic peptide have been shown to correlate with clinical and hemodynamic parameters in heart failure (HF), and referred as a potent predictor of poor prognosis. A variety of clinical parameters such as cardiac troponin, high sensitive C-reactive protein (hsCRP), hemoglobin or sodium levels are also known to be of prognostic significance in patients with HF. The aim of this study was to assess possible associations between natriuretic peptide levels and other well-established clinical markers in patients with HF.
Methods: A total 446 patients admitted to hospital with the diagnosis of acute decompensated HF, NYHA II-IV, LVEF < 40% and >18 years of age were included in this study. N-terminal pro B-type natriuretic peptide (NT-proBNP), high sensitive cardiac troponin T (hs-cTnT), carbohydrate antigen 125 (CA-125), hsCRP, estimated glomerular filtration rate (eGFR), hemoglobin and sodium levels have been analyzed for the assessment of possible correlations and associations.
Results: Mean age of study population was 67 ± 12 years. Mean EF was 25.4 ± 7.9%, NT-proBNP was 7667 ± 9876 pg/mL, CA-125 was 86.2 ± 125.5 U/mL, hs-cTnT was 0.22 ± 0.86 ng/mL, creatinine level was 1.41 ± 0.88 mg/dL, eGFR was 62.9 ± 32.4 mL/min/1.73 m2, hsCRP was 27.4 ± 39.1 mg/dL, sodium was 138.2 ± 4.7 mEq/L and hemoglobin level was 12.4 ± 2 gr/dL. There were a significant positive correlation between NTproBNP and hs-cTnT levels (r=,252, p < 0.001), CA-125 levels (r=,303, p < 0.001), or hsCRP levels (r=,261, p < 0.001). Also significant negative correlations were found between NTproBNP and eGFR levels (r=-,451, p < 0.001), hemoglobin levels (r=-,453, p < 0.001) or sodium levels (r=-,219, p < 0.001). Furthermore, median NTproBNP levels were found to be significantly higher in patients with high hs-cTnT (<0.014 ng/mL) as compared to those with normal hs-cTnT levels (4531 [1716-12047] pg/mL vs 651 [327-1768] pg/mL, p < 0.001, respectively), in patients with anemia as compared to those without anemia (6594 [2535-19250] pg/mL vs 1740 [581-4397] pg/mL, p < 0.001, respectively), in patients with hyponatremia (sodium < 135 mEq/L) as compared to those with normonatremia (6779 [2650-19513] pg/mL vs 2986 [976-7966] pg/mL, p < 0.001, respectively), in patients with high hsCRP (<3.5 mg/dL) as compared to those with normal hsCRP levels (3800 [1254-11250] pg/mL vs 1841 [588-3732] pg/mL, p < 0.001, respectively), and as expected, significantly higher in patients with an eGFR < 60 mL/min/1.73 m2 as compared to those with an eGFR >60 mL/min/1.73 m2 (6654 [2723-15898] pg/mL vs 1482 [554-3665] pg/mL, p < 0.001, respectively).
Conclusions: The results of this study showed that in decompensated HF patients, higher NTproBNP level as a marker of nörohormonal activation is associated and correlated with higher hs-cTnT, CA-125, hsCRP levels and lower eGFR, hemoglobin and sodium levels.

P1848
Soluble ST2 Levels Predicts Length of Stay in Patients with Acute Heart Failure

H Gunes[1]; H Kaya[2]; E Aksu[1]; H Nacar[1]; M Kerkutluoglu[1]; MA Tatlisu[3]
[1]*Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey*; [2]*Cumhuriyet University, Cardiology, Sivas, Turkey*; [3]*Numune Hospital, Cardiology, Sivas, Turkey*

Introduction: The increased length of stay of patients with acute heart failure increases costs and morbidity. The association of ST2 levels with mortality and morbidity in patients with heart failure has been established.

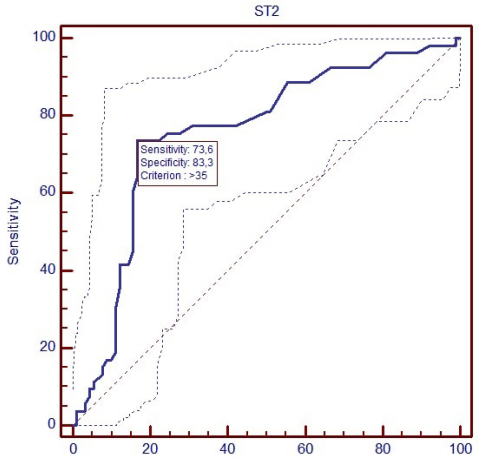


Figure 1
Purpose: We aimed to investigated the relationship between ST2 levels in patients with acute decompensated heart failure and the length of stay.
Methods: This study included 143 patients who were hospitalized for acute decompensated heart failure. The average length of stay was 4 days. Patients were divided into 2 groups: group 1 consisted of patients who stayed 4 days or less; group 2 consisted of patients who stayed more than 4 days.
Results: The serum ST2 levels were greater in the group 2 as compared to the group 1 (32 (3-68) versus 47 (9-298)) (P < 0.001). The optimal cutoff level of ST2 in the prediction of length of stay was >39 U/mL, with a specificity of 95.8% and a sensitivity of 96% (area under the curve, 0.979; 95% confidence interval [CI], 0.953-0.992). In the multivariate logistic regression model, ST2 levels of >35 U/mL on admission (OR = 10.750, 95% CI: 4.218-27.395 , p < 0.001), were also associated with a longer length of stay after adjustment for variables was found to be statistically significant in univariate analysis and correlated with ST2 levels.
Conclusion: In our study, the ST2 levels were found to be an independent marker for the length of stay in patients with acute decompensated heart failure.

P1849
Heart rate reduction and galectin 3 levels in patients with decompensated heart failure

D Darabantiu[1]; R Lala[1]; A Pop Moldovan[1]; L Pilat[1]; RM Christodorescu[2]
[1]*Vasile Goldis Western University, Arad, Romania*; [2]*University of Medicine & Pharmacy Victor Babes, Timisoara, Romania*

Premises and Purpose: In patients with heart failure and low ejection fraction heart rate and galectin 3 levels have an important prognostic value. The objective of this study was to assess the influence of heart rate reduction with ivabradine on galectin 3 levels in patients with decompensated systolic heart failure.
Material and Methods: This prospective study included 35 consecutive patients (P) (28 males, 7 females) (group 1), with LV systolic dysfunction (LVEF < 40%), hospitalized for heart failure decompensation, in whom heart rate reduction therapy with ivabradine was initiated. The control group (group 2), consisted of 29 hospitalized heart failure patients (18 males, 11 females) treated with guideline-recommended therapy but without ivabradine. At baseline and after 6 months of follow-up clinical and echocardiographic parameters (systolic and diastolic function) were collected. Also, both at baseline and after 6 months, galectin-3 levels were determined (Novus Biologicals assay-ELISA method). Data were expressed as mean ± standard deviation or percentages, comparisons between baseline and follow-up data were done with Student's paired t test, differences between groups with Fisher's exact test.
Results: Mean age was 60 ± 12 years in group 1 and 69 ± 10 years in group 2 , heart failure etiology was ischemic in 19 group 1 P (54 %) vs 16 group 2 P (55%). Diastolic function improved in group 1, E/e' ratio decreased significantly in group 1 (from 14.7 ± 5 to 11 ± 4) and remained stable in group 2 (11.5 ± 3 to 11.6 ± 4), while e' velocity increased in group 1 (from 5.5 ± 1.7 to 7.2 ± 1.6) and did not change in group 2 (from 7.3 ± 1.6 to 6.8 ± 1.3). At baseline left ventricular ejection fraction was 26 ± 8% in group 1 and 34 ± 10% in group 2, while after 6 months it increased in group 1 (31 ± 8%) and remained stable in group 2 (34 ± 9%). At 6 months as compared to baseline heart rate decreased from 96 ± 12 b/min to 72 ± 13 b/min

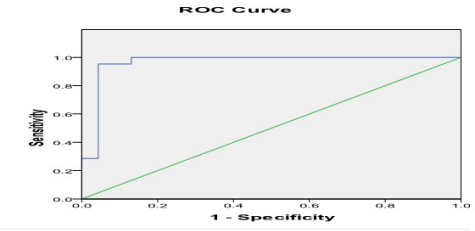
in group 1 and from 91 ± 20 b/min to 76 ± 26 b/min in group 2 ($p < 0.001$ for both differences). Betablocker therapy was given in 94% of group 1 P and 96% of group 2 P, and there were no differences regarding to ACE-inhibitor/ARB or spironolactone administration between the 2 groups. In group 1 galectin 3 levels changed nonsignificantly after 6 months (from 9.7 ± 7 ng/ml to 10.8 ± 3 ng/ml) ($p = 0.3$), and increased significantly in group 2 (from 8.5 ± 6 ng/ml to 11 ± 3 ng/ml) ($p = 0.03$). A decrease in galectin-3 level was observed in 11 P from group 1 (31%) and 8 P from group 2 (27%), while an increase more than 100% from baseline level was noted in 12 P from group 1 (34%) and 12 P from group 2 (41%).
Conclusions: In patients with systolic heart failure heart rate reduction with ivabradine does not decrease significantly galectin 3 levels at 6 months despite an improvement in systolic and diastolic LV function.

P1850

What is the importance of serum free testosterone in prediction of heart failure in patients with acute myocardial infarction?

M Mohammad El Tahlawi[1]; A Al Alfi[1]; M Alzaki[1]; M Aboueleinein[1]
[1]*Zagazig University Hospitals, Cardiology, Zagazig, Egypt*

Background: Testosterone is a potent coronary vasodilator; an effect mediated by a calcium channel antagonist action
The pro-fibrinolytic activity of testosterone was noted and confirmed by several subsequent studies.
The serum testosterone levels were found to be decreased significantly In early hours of MI.
Aim of work: This study is conducted to find out if serum testosterone can help in prediction of heart failurein patients with myocardial infarction.
Patients & Methods: This is an observational prospective case control study.
Inclusion criteria:
Male patients presenting with ST elevation myocardial infarction.
Presentation during the first 24 hours of onset of the chest pain.
Exclusion criteria:
Female patients.
Patients with non S-T segment elevation myocardial infarction
Patients on renal dialysis as serum testosterone levels flactuating before, during and after dialysis.
Patients with previous history of CABG.
Patients on anti-androgenic agents for prostrate and testicular cancer.
Patients on prolonged use of anabolic steroids.
Patients not willing for informed consent.
The included patients were subjected to:
Detailed history taking.
Thorough physical examination.
12 leasds ECG.
Measuring Serum free testosterone (between 6-9 AM) next to admission).
Echocardiography.
Assessment of patients' height & weight to calculate their BMI.
The studied patients have been divided into two groups (based on their ejection fraction):
Group I: this group included patients with ejection fraction (EF) < 50%.
Group II: this group included patients with ejection fraction = 50%.
Statistical analysis:
Data from the patients was collected and subjected to statistical analysis using test of significance.
Results: The studied included 44 patients with 21 patients in group I and 23 patients in group II.
There was high significant difference between both groups regarding testosterone level (10.58 ± 4.82 vs. 24.62 ± 4.51 " P value= 0.001").
There was significant positive correlation between testosterone level and EF with P value = 0.001.
With ROC curve data of free testosterone level in this study, the optimal cutoff of free testosterone level was 17.6. Area under the curve is 0.965, the sensitivity is 95.2% and the specificity is 95.7%.
Conclusion: free testosterone is considered a good predictor biomarker of heart failure after ST elevation myocardial infarction.



ROC curve of free testosterone level

Readmissions or death are more likely when device-derived rapid shallow breathing index worsens during heart failure hospitalization

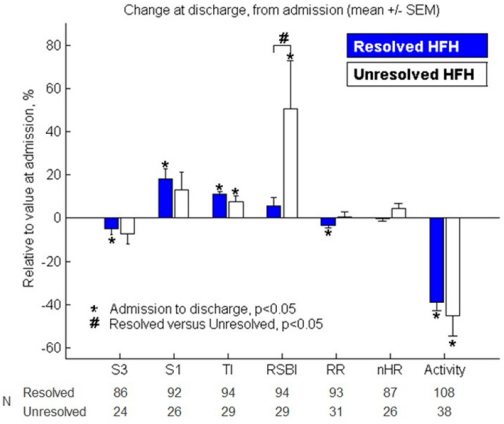
Background: A multisensor algorithm has been demonstrated to predict heart failure (HF) events in patients with implanted devices with high sensitivity and low false positive rate. However, it is not known how the individual sensors change from hospital admission to discharge and whether it can be indicative of readmissions or death within 30 days.
Methods: The MultiSENSE study followed 900 HF patients with CRT-D for up to 1 year. Devices were modified to enable the collection of first (S1) and third (S3) heart sounds, thoracic impedance (TI), respiratory rate (RR), rapid shallow breathing index (RSBI), night heart rate (nHR), and activity. All hospitalizations were adjudicated by an independent committee. Hospitalizations with HF as a primary cause (HFH) were identified. HFH with an admission outside of the customized data collection were excluded due to lack of sensor data. Each HFH was classified as unresolved if it was followed by all-cause hospitalization or death within 30 days of discharge; otherwise, it was classified as resolved. For each type of HFH, daily sensor values on the day before admission and the day before discharge were compared with a pairwise t-test. The changes in each sensor were compared between the resolved and the unresolved group via t-test. Significant difference in comparisons was defined as that with $p < 0.05$.
Results: Out of 149 HFHs, 109 were determined as resolved and 40 as unresolved. Additional HFHs were excluded if sensor data at admission or discharge was not available. Admission-to-discharge differences for resolved HFHs showed improvement in S3, S1, TI, and RR, and reduction in activity (see Figure). Admission-to-discharge differences for unresolved HFHs showed improvement in TI, worsening in RSBI, and reduction in activity. Changes in RSBI were significantly different between the two groups of HFHs.
Conclusions: Worsening in RSBI during hospitalization identified a group of patients with either early HF readmissions or death.



P1852

Echocardiographic predictors of early in-hospital heart failure during first ST segment elevation myocardial infarction

KM Elmaghraby[1]; H Shamseddin[1]; YT Kishk[1]; MM Reda Abdel Aziz[1]
[1]*Assiut University, Cardiology department, Assiut, Egypt*

Introduction: Acute heart failure complicates acute myocardial infarction as a result of complex interaction of structural, hemodynamic, neurohormonal, and genetic mal-adaptations. Left ventricular systolic function has been extensively studied in relation to development of HF, however left ventriuclar diastolic function contributes to symptoms and signs of clinical HF.

Purpose: To analyze the role of left atrial volume index (LAVI) compared to other conventional parameters of systolic and diastolic left ventricular function in patients with first time STEMI, in predicting in-hospital heart failure & mortality and development of HF and mortality over a follow up period of 6 months.

Methods: The present study is a prospective observational study done on 70 STEMI patients. Left ventricular EF, LV wall dimensions, left atrial volume (LAV), left atrial volume index (LAVI), Pulsed Doppler mitral flow velocity (E, A, E/A ratio, and deceleration time of early filling (DT), E/e' ratio and systolic parameters were measured within 24 hours after admission and then 6 months later. These variables were correlated with development of in hospital heart failure according to Killip classification and 6 months later by NYHA classification.

Results: 23 patients developed in hospital HF with Killip class>II, 20 of them being in class III (28.6%) and 3(4%) patients in class IV. A total of 4 patients died during admission (in-hospital mortality 5.7%). On follow up 6 months later, further seven patients died (10%) due to cardiac causes and twenty patients were readmitted either due to development of heart failure or new ischemic insult. Estimated LAV (mean ± SD) on admission was 47.7 ± 13.4, 60.8 ± 25.4, 77.9 ± 16.4 &78.2 ± 13.4 ml in patients with Killip class I, II, III & IV respectively (P.value0.000). LAVI (mean ± SD) on admission was 24.6 ± 7.3, 26.9 ± 10.3, 36.2 ± 3.9&38.9 ± 4.9 ml/m2 in patients with killip class I, II, III & IV respectively (P.value 0.000). Also DT decreased significantly from 209.3 ± 25.7 in Killip class I to 166.7 ± 23.1 in killip class IV patients (P.value0.000). E/e'increased significantly from 7.9 ± 2 in killip class I to 14.9 ± 4.5 in killip class IV patients (P.value0.000). LAVI (mean ± SD) in inhospital mortality cases was 37.9 ± 1.9 versus 28.4 ± 8.8 ml/m2 in survivors (P.value0.000) & it was 38 ± 3 in the follow up mortality cases versus 27.1 ± 8.4 ml/m2 in survivor follow up cases (P.value 0.000). On 6 months follow up measured LAVI was 24.44 ± 7.78, 28.61 ± 8.18 & 34.35 ± 6.49 ml/m2 in NYHA class I, II & III patients respectively (P.value0.001) .

Conclusions: LAVI and other determinants of systolic and diastolic functions have significant role in prediction of heart failure and mortality both in the in-hospital setting and after a follow up period of 6 months.LAVI, E/e'ratio & EF are the most significant predictors of in hospital heart failure. LAVI and E/e' were the most powerful predictors of mortality and heart failure during a follow up period of 6 months.

P1853

Value of natriuretic peptides and tissue doppler imaging in the estimation of intracardiac filling pressure in patients with cardiac amyloidosis

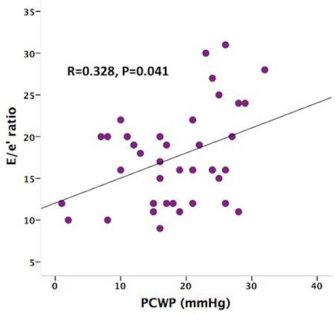
S Stephanie Brun[1]; E Cariou[1]; P Fournier[1]; D Ribes[1]; S Faguer[1]; D Carrie[1]; M Galinier[1]; O Lairez[1]
[1]*Toulouse Rangueil University Hospital (CHU), 31, Toulouse, France*

Background: - Estimation of ventricular filling pressures (VFP) is a determining factor in the follow-up of patients with cardiac amyloidosis (CA). Low VFP can lead to decreased cardiac output and symptoms of fatigue, with signs of hypotension and hypoperfusion. High VFP lead to shortness of breath and cardiac decompensation. Natriuretic peptides (NPs) and tissue Doppler imaging are daily used to monitor VFP in patients with CA. The aim of this study was to evaluate the value of NPs and Doppler parameters in estimating left VFP in patients with CA.

Methods: - Forty-six patients with biopsy verified light chain (29), AA (1), Apoliporotein A2 (1) or bone scintigraphy proven transthyretin (15) CA were retrospectively included. All patients underwent transthoracic echocardiography, BNP (20) or NT-proBNP (26) measurement and right heart catheterization (RHC).

Results - Median BNP and NT-proBNP levels were 786 [from 37 to 3798] and 3796 [from 1178 to 49402] ng/L, respectively. Echocardiography demonstrated left atrial enlargement with a mean volume of 44 ± 14 mL and low tissue Doppler lateral e' of 5 ± 1 cm.s-1. Median E/e' ratio was 18 ± 8 and pulmonary capillary wedge pressure (PCWP) by RHC was 18 ± 7 mmHg. There was no correlation between BNP (R = 0.308, P = 0187) or NT-proBNP (R=-0.095, P = 0.646) levels and PCWP. There was a slight correlation between E/e' ratio and PCWP (R = 0.341, P = 0.041; Figure).

Conclusion: In patients with CA, NPs do not accurately estimate PCWP. Tissue Doppler– derived mitral E/e' ratio is correlated with PCWP but the slight correlation requires to consider it carefully and to integrate others parameters to estimate intracardiac filling pressures.



P1854

Semi-automated detection of pulmonary congestion in patients with non-ST acute coronary syndrome by using of quantitative chest cardiac-CT analysis: analysis of methodological aspects

A Andreas Fabricius-Bjerre[1]; J Petersen[2]; M Heitmann[1]; H Elming[3]; H Ashraf[4]; KF Kofoed[5]; JT Kuhl[5]; L Kober[5]; OW Nielsen[1]
[1]*Bispebjerg University Hospital, Copenhagen, Denmark*; [2]*University of Copenhagen, Department of Computer Science , Copenhagen, Denmark*; [3]*University Hospital, Roskilde, Denmark*; [4]*Akershus University Hospital, Oslo, Norway*; [5]*Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*

Background: Quantitative assessment of pulmonary water content based on cardiac-CT could add objective information about pulmonary congestion to an already accurate method of diagnosing coronary artery disease. However, methodological problems related to semi-automated software, CT settings, and contrast enhancement remains to be examined.

Purpose: The objective was to identify the best imaging-biomarkers of pulmonary congestion, and to analyze the impact of various methodological effect modifiers.

Method: We identified patients with and without heart failure from a retrospective database with non-ST acute coronary syndrome patients who underwent cardiac-CT prior to invasive treatment. We defined HF cases as patients with Killip class > 1 and loop diuretic administered. Controls subjects had Killip class = 1, no loop diuretic administered, matched cases in regards to sex, age and smoking history.

From the contrast based cardiac-CT protocol and the non-contrast calciumscore protocol the scans were reconstructed with full view in 0.5, 1 and 3 mm slice thickness using standard medium soft and hard kernel. We used in-house developed software to segment the lungs and extract the relative attenuation distribution histograms of from cases and control.

Results: 40 patients were included (10 cases, 30 controls). Manual and automated segmentation agreed perfectly (mean diff; 12ml, limits of agreement; -67ml to 89 ml). The attenuation distribution (in Hounsfield Units) for cases was skewed more to the right and flatter than for control subjects (see table). Slice thickness or softer reconstruction kernel did not significantly influence the segmented lung volume or the median lung density.

Conclusion: All the mathematical parameters of the histogram discriminated cases and control subjects, but the median was numerically best. The methods works in both cardiac-CT and calciumscore protocols and are robust to changes in voxel size and reconstruction kernel. Based on these result we propose this method is being further investigated in consecutive patients with all degrees of pulmonary congestion.

	Cardiac-CT Protocol	Calcium-score Protocol								
	Control	Cases	p	t-score	AUC	Control	Cases	p	t-score	AUC
Mean	-753 (20)	-647 (44)	<0.001	-11,50	1.00 (1.00 to 1.00)	-802 (31)	-705 (57)	<0.001	-7.76	0.95 (0.88 to 1.00)

Background/Introduction: Lung ultrasound (LUS) has been proposed as a point-of-care examination where B-lines are markers of pulmonary congestion. Most previous studies examined patients with existing signs of heart failure (HF), but there is lack of studies to examine its diagnostic value in unselected consecutive patients with dyspnoea and comorbidity.

Purpose: To examine the diagnostic value of B-Lines by LUS to a final diagnosis of acute HF (AHF) and the association to other signs of congestion by lung auscultation, and chest X-ray (CXR).

Methods: We included patients with acute dyspnoea admitted to Bispebjerg Hospital EDs over a 3 month-period. Inclusion criteria were all adults (<50 years) with acute dyspnoea (sudden onset or worsening of chronic dyspnoea within 14 days). We excluded patients who were respiratory unstable (a need for mechanic/non-mechanic ventilation), circulatory unstable (need inotropes), acute coronary syndrome, life expectancy < 3 months, not able to give consent. CT-examinations were only available daytime, why patients admitted 15 pm-02 am were excluded.

All patients were examined with physical examination, CXR, LUS, low-dose CT and echocardiography (Echo) within 12 hours of admittance. The maximum time between LUS, CT and Echo was 5 hours. A 14 zone LUS protocol with a cardiac probe and 18-20 cm of depth was used. Congestion on LUS was defined as at least one zone on each lung with 3 or more B-lines (vertical lines extending the whole field of view). AHF was defined as abnormal echocardiography (HfpEF, HfmrEF, HFrEF, tachyarythmia or severe valve disease) combined with increased left ventricular filling pressure on Echo-doppler and pulmonary congestion on CT.

Results: 40 consecutive patients were examined on January 2018, 22 females and 18 males, with a mean age of 74 years for females and 78 years for males. One third (37,5%) had chronic heart failure, 70% were active/past smokers, 25% had diabetes, 45% had copd, 5% had kidney disease, 20% had atrial fibrillation and 27,5% IHD.

Abnormal echo was found in 16 patients, while 10 patients had AHF (25%) and just 6 patients (15%) had a positive LUS for congestion (see Table). Congestion on LUS was significantly associated with AHF with a specificity of 93% and a sensitivity of 40 %, but it was not significantly associated to congestion on CXR or lung auscultation. Pleural effusion on LUS measured against CT was significant with a 98% specificity and a 77% sensitivity.

Conclusion: Our preliminary results suggest that bilateral B-Lines on LUS has a high specificity for pulmonary congestion and pleural effusion in consecutive breathless patients in the ED. But the sensitivity for cardiac abnormality and AHF seem low in these consecutive patents, meaning that absence of bilateral B-lines cannot rule out cardiac dysfunction or AHF. However, a firm conclusion must await larger studies, and updated data will be presented during the congress.

Comparisons of B-lines on lung ultrasound with other modalities in 40 patients

Association of impaired strain and development of in-hospital heart failure after acute myocardial infarction

S Torres[1]; PM Araujo[1]; A Nunes[1]; C Sousa[1]; PB Almeida[1]; V Ribeiro[1]; R Almeida[1]; J Rodrigues[1]; S Costa[1]; G Ferreira[1]; S Maia[1]; MB Campelo[1]; F Macedo[1]; MJ Maciel[1]

[1]Sao Joao Hospital, Porto, Portugal

Introduction: Strain imaging by speckle tracking echocardiography (STE) has been shown to provide important information on regional and global ventricular function and is therefore a helpful tool in risk assessment of patients with acute myocardial infarction (AMI).

Purpose: Since Killip classification is a powerful predictor of prognosis in AMI, we aimed to assess its relationship with myocardial strain imaging parameters.

Methods: We retrospectively evaluated patients (pts) who were admitted to our center due to AMI during a six-month period and who had strain evaluation done by two-dimensional (2D) speckle tracking echocardiography (STE). Global longitudinal strain and global circumferential strain of the left ventricle (LV) were assessed by 2D STE with layer-specific myocardial deformation quantitative analysis. Clinical, laboratorial and coronary anatomy data were also evaluated.

Results: A total of 76 pts, of whom 75% (n = 57) were male, with a mean age of 63.4 ± 12.0 years were included. The diagnosis was STEMI in 52.6% (n = 40) and NSTEMI in 47.4 % (n = 36). All pts were submitted to coronariography: 7.9% had left main significant disease, 40.8% had one-vessel disease, 27,6% had two-vessel disease, 17.1% had three-vessel disease and 6.6% had no significant coronary disease. In-hospital heart failure (HF) was defined by Killip class > I, thus dividing pts in two groups: group A [Killip I (KI); n = 50; 65.8%] vs group B [Killip >I (K>I); n = 26; 34.2%]. Pts in group B had significantly lower endocardial (-12.68 vs -15.53; p = 0.01), epicardial (-10.07 vs -12.52; p = 0.01) and mid-layer longitudinal strain (-11.33 vs -13.88; p = 0.01); lower LV ejection fraction (42.2 vs 49.8%; p = 0.03); higher left atrial volume (40.24 vs 28.66 ml/m2; p < 0.01) and higher BNP (856 vs 250 pg/ml; p < 0.01). There weren't significant differences concerning layer-specific circumferential strain, as well as other echocardiographic parameters (E, A, E', E/A, E/E', right ventricular function) and maximum troponin values.

Conclusion: In our study, pts with K>I had more impaired layer-specific longitudinal strain and therefore this parameter may also be a valuable tool for identification of pts with higher risk of in-hospital HF post-AMI, besides classic echocardiographic and laboratorial parameters.

Acute Heart Failure - Treatment

P1857

Clinical impact of temporal diuretic efficiency, in-hospital diuretic infusion and diuretic amount at discharge in acute heart failure

A Alberto Palazzuoli[1]; G Ruocco[2]; L Luschi[2]; I Evangelista[2]; R Nuti[2]

[1]Santa Maria Alle Scotte Polyclinic, Siena, Italy; *[2]University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine , Siena, Italy*

Background: Several studies showed the importance of adequate response to loop diuretics administration in acute heart failure (AHF) patients. Nevertheless, no data are currently available about the oral loop diuretic dose regimen after infusion and the risk assessment after discharge.
Purpose: To elucidate these aspects we sought to evaluate: 1-the most reliable diuretic efficiency (DE) formula over timing infusional period for outcome prediction; 2-the relationship among intravenous and oral loop diuretic administration and outcome.
Methods This is a single-center prospective randomized study in which we compared Low (LD) vs High (HD) dose of loop diuretic infusion and oral amount either during hospitalization and before discharge compared to outcome.DE formula was defined as weight loss/40 mg daily of furosemide and it was examined at day 1, day 3 and during the whole infusion period.
Results A total of 121 patients consecutively admitted for AHF were evaluated. A lower DE measured during the entire infusion period (AUC 0.69 [CI 0.60-0.79];$p < 0.001$) was able to predict outcome with greater significance than DE measured at day 3 and day 1 (AUC 0.64;$p = 0.007$ and AUC 0.56;$p = 0.229$ respectively). Both infusional and oral diuretic amount at discharge were able to predict poor prognosis (AUC 0.82;$p < 0.001$).HD group showed an higher rate of 180 days adverse events with respect to LD group (86% vs 22%; $p < 0.001$).
Conclusions: Low DE measured during the whole infusion period appears to be the best predictor for poor outcome.Therefore, the diuretic amount at discharge is much more related to an adverse outcome compared to low DE during hospitalization.

P1858

Prescription rate of beta-blockers and factors of its use or nonuse in patients hospitalized for acute heart failure (from the KCHF Registry)

Y Yoshikawa[1]; Y Tamaki[2]; H Yaku[1]; N Ozasa[1]; Y Inuzuka[3]; T Kato[1]; T Kimura[1]
[1]Kyoto University Graduate School of Medicine, Department of Cardiovascular Medicine, Kyoto, Japan; *[2]Tenri Hospital, Department of Cardiovascular Medicine, Tenri, Japan*; *[3]Shiga Medical Center for Adults, Department of Cardiology, Moriyama, Japan*

Background: The current guidelines recommend beta-blockers for reduction of morbidity and mortality in patients with heart failure with reduced ejection fraction (HFrEF).
Purpose: The current study sought to clarify the relationship between use or nonuse of beta-blockers in patients with acute heart failure and their clinical characteristics.
Methods: The Kyoto Congestive Heart Failure (KCHF) registry is a cohort without any exclusion criteria of patients hospitalized for acute heart failure in Japan. We classified patients with HFrEF into 2 groups by medication status at discharge: those on beta-blockers at discharge (Group A) and those not on beta-blockers at discharge (Group B). We compared the clinical characteristics between Group A and B.
Results: A total of 4056 patients were enrolled, including 1551 patients with HFrEF. After excluding those who died in hospital (N = 142), Group A included 1093 patients and Group B 316 patients. As shown in the table, there were significant differences not only in medical characteristics (such as age, history of hypertension and heart rate) but also in reduced physical and social function, including the presence of dementia and activities of daily living. A significantly higher proportion of patients in Group B suffered worsening heart failure during hospitalization than those in Group A. A multivariable logistic regression model assessed the odds for prescription of beta-blockers at discharge. As shown in the table, age = 80, dementia and ambulatory status remained as independent factors associated with prescription of beta-blockers at discharge.
Conclusion: Poorer social and physical functioning were independently associated with prescription of beta-blockers at discharge in patients with HFrEF. Further studies would be warranted to examine the effectiveness of beta-blockers for these frail patients.

Patient characteristics by beta-blockers

	Group A (N = 1093)	Group B (N = 316)	P value	Multi-variable Odds for prescription of beta-blockers	95% CI	P Value
Age≥80	387 (35%)	171 (54%)	<0.001	0.62	[0.45-0.86]	0.004
Male	755 (69%)	187 (59%)	0.001	1.26	[0.91-1.74]	0.16
Hypertension	699 (64%)	230 (73%)	0.004	0.73	[0.54-1.01]	0.057
Asthma	58 (5.3%)	22 (7.0%)	0.26	0.85	[0.47-1.53]	0.59
Dementia	128 (12%)	83 (26%)	<0.001	0.57	[0.38-0.85]	0.006
Heart rate <80/min	185 (17%)	78 (25%)	0.002	0.52	[0.36-0.75]	<0.001
Ambulatory status	940 (87%)	225 (72%)	<0.001	1.81	[1.23-2.68]	0.003
Worsening heart failure	228 (21%)	83 (26%)	0.041	NA	NA	NA

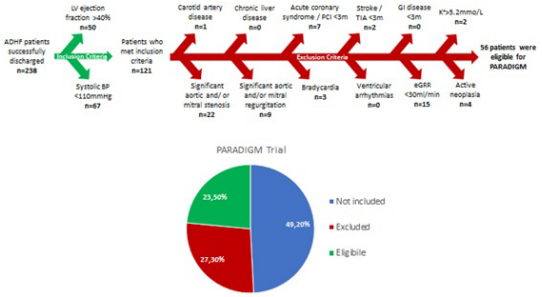
The multivariable model assessed 12 potential factors for prescription of beta-blockers at discharge, including the characteristics listed in the table.

P1859

Eligibility criteria for Sacubitril-Valsartan in patients admitted for heart failure: the real world ?

D David Cabrita Roque[1]; J Augusto[1]; M Santos[1]; D Candeias Faria[1]; J Baltazar Ferreira[1]; A Sacchetti[2]; L Melo[2]; A Oliveira Soares[1]; C Morais[1]
[1]Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal; *[2]Hospital Prof Fernando da Fonseca EPE, Internal Medicine, Amadora, Portugal*

Background: Heart failure is the CV clinical condition with the biggest and most rapid growth in the world and the morbi-mortality associated with this disease is still in an epidemic scale.
Purpose: To evaluate the eligibility at hospital discharge for Sacubitril-Valsartan (SB) according to the inclusion and exclusion criteria of the Paradigm trial.



Methods: Paradigm main inclusion criteria was HFrEF NYHA II-IV, NT-proBNP = 600 pg/mL or = 400 pg/mL if hospitalized for ADHF in the previous 12 months and on a stable treatment for = 4 weeks with ACEI/ARB and BB. The main exclusion criteria were and eGFR <30 mL/min/1.73 m2, K+>5.2 mmol/L, symptomatic hypotension or SBP <100 mmHg, among others. ADHF was defined by the presence of = 2 signs or symptoms of HF.
Results: A total of 238 patients with ADHF were successfully discharged from our hospital in the período evaluated (8.4% of patients, n = 20, were excluded because of in-hospital death). Mean age of our population was 77.4 ± 0.7 years; 45.8% male). One hundred and twenty-one patients (56.7%) met the inclusion criterias of the Paradigm trial. Inclusion criteria were not met in 50 patients (21%) because of LVEF > 40% and in 67 patients (28.2%) because of low systolic blood pressure (SBP < 100mmHg at discharge). Among the patients who met the inclusion criteria, a total of 65 patients (53.7%) have been excluded according to the exclusion criteria in Paradigm protocol; the main exclusion criteria were the presence of a significant valvular stenosis (18.1%), followed by an eGFR <30ml/min/m2 (14%). Figure 1 summarizes our findings. Of the 238 patients, only 56 patients were eligible to initiate the treatment with Sacubitril-Valsartan.
Conclusions: Sacubitril-Valsartan is a new treatment for patients with HFrEF, who remain symptomatic after otimized treatment with ACEI and beta-blocker. However the study protocol excluded patients with severe comorbidities, often present in

patients with HF. We concluded that in a "real world" population of HF patients, at hospital discharge, only one-quarter of the patients were eligible for this new drug.

P1860

Effects of acetazolamide (Diamox) on plasma volume, serum electrolytes and renal function in comparison with conventional diuretics

H Hajime Kataoka[1]
[1]*Nishida Hospital, Oita, Japan*

Background: According to the "chloride theory" for heart failure (HF) pathophysiology (AHA2015/ACC2016/ESC2016), changes in the serum chloride concentration are the primary determinant of changes in plasma volume, suggesting that manipulation of the serum chloride concentration could be a central therapeutic target for controlling body fluid in HF patients.
Purpose: The present study examined the effects of the chloride-regaining diuretic acetazolamide on plasma volume, serum electrolytes and renal function in comparison with conventional chloride-depletion diuretics.
Methods: I retrospectively analysed 13 data from treated with acetazolamide (Diamox treatment; group A, n = 13) or conventional diuretic treatment with a combination of loop diuretics, aldosterone blockade, and thiazide diuretics (group B, n = 13), which were matched based on diuresis-induced weight reduction (= 1kg) during resolution of worsening HF. Changes in plasma volume (Strauss method), renal function, and serum electrolytes under treatment were determined by peripheral blood tests.
Results: Treatment duration and body weight reduction by treatment did not differ between the A and B groups (27.6 ± 12.7 vs. 26.7 ± 15.8 days; -2.23 ± 1.11 vs -2.22 ± 1.06 kg). After each treatment, the serum chloride concentration markedly increased in group A, but decreased in group B (+5.31 ± 4.91 vs. -4.54 ± 4.68 mEq/L, $p < 0.0001$). Plasma volume (0.63 ± 13.1 vs. -12.1 ± 10.5%, $p < 0.01$) and renal function based on changes in the serum creatinine (0.048 ± 0.12 vs. 0.21 ± 0.24, $p < 0.047$) were better preserved in group A than in group B.
Conclusions: Under achievement of the same body weight reduction by diuresis, plasma volume and renal function were better preserved by diuretic treatment with acetazolamide than with conventional diuretic treatment. These differential effects are in accordance with my "chloride theory" for HF pathophysiology (Figure).

Hypertonic saline solution with furosemide for the treatment of congestive symptoms of acute heart failure

D Carrillo[1]; R Lopez-Vilella[1]; I Sanchez-Lazaro[1]; L Martinez-Dolz[1]; L Almenar[1]
[1]*Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit, Valencia, Spain*

Introduction: Hypertonic saline solution (HSS) favors the mobilization of extravascular fluid to the intravascular space and the excretion of this volume by the action of furosemide improving the congestive symptoms of acute heart failure (AHF).
Purpose: To describe the diuretic response after continuous infusion of 3% HSS with furosemide in patients with AHF.
Methods: A retrospective study of patients admitted to the hospital due to AHF, received a continuous infusion of 3% HSS 500ml with 200mg of furosemide for 24 hours each cycle. A box plot of the diuresis per day and a random-effects model of diuretic response over the time adjusted for glomerular filtrate rate, age and hours of HSS infusion.
Results: 38 patients were included. Only 6 patients didn't have more than 500 mL of diuresis compared to the previous 24 hours, these patients had lower baseline sodium and received more frequently thiazides (Table). After 24-hour HSS infusion, the diuresis increased 430mL, 1034mL after 48 hours (Figure). Elevation of creatinine in time affected de diuretic response to HSS with furosemide (-502.09mL 95% IC -979 to -25mL) (Table).
Conclusion: The infusion of SSH together with furosemide increased the diuretic response in patients with AHF. However, a combination of diuretics and several HSS infusion cycles in some patients were required to achieve the observed response.

P1862

Correlation between degree of pulmonary congestion and rate of heart failure hospitalization in Heart Failure patients with reduced Left Ventricle Ejection Fraction. : Results from extended IMPEDANCE-

M Michael Kleiner Shochat[1]; A Shotan[1]; I Kleiner[2]; JM Weinstein[2]; I Dahan[1]; M Kazatsker[1]; A Asif[1]; S Meisel[1]
[1]*Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel*; [2]*Saroka Medical Center, Cardiology, Beer Sheva, Israel*

Results of the IMPEDANCE-HF trial have shown that lung impedance (LI)-guided treatment reduces hospitalizations for heart failure (HF) and decreases HF-related mortality. The main trial was extended for an additional year to accrue more data on predictors of hospitalizations due to HF. The main aim of the study was to prove that HF patients with higher degree of long-standing pulmonary congestion are hospitalized more often.
Methods: Study population included 266 patients, with HF and LVEF = 35% in New York Heart Association class II-IV. Patients were randomized (1:1) to a control group treated by clinical assessment and a LI-guided group whose therapy was also assisted by LI. Patients were examined and LI measured monthly in our outpatient clinics. Noninvasive LI measurements were performed with the

high-sensitive device. Assessment of the degree of pulmonary congestion was by the new index ?LIR, measured at each visit and calculated as ?LIR = [currently measured LI/ normal baseline (calculated for each patient) -1] × 100 expressed as percentage. The annual average ?LIR for each patient was calculated as the mean of all ?LIR measurements at each consecutive year of follow-up (FU).
Results The cumulative FU period was 642 patient × years in the LI-guided group and 510 patient × years in the control group ($p = 0.001$). Groups were similar with respect to baseline characteristics. There were 249 HF hospitalizations in the LI-guided group (mean 0.38 per year) and 475 HF hospitalizations in the control group (0.93 per year, $p < 0.001$). Rate of HF hospitalization was divided into 4 categories as follows: Q1: 0.00-0.1; Q2: 0.11-0.32; Q3: 0.33-1.07, and Q4 >1.07 HF hospitalizations/ per year of FU. Number of patients in Q1:Q2:Q3:Q4 were 68 (51%), 39 (29%), 16 (12%) and 10 (8%) in the LI-guided group and 48 (36%), 29 (22%), 21 (16%) and 33 (25%) in the control group, respectively ($p < 0.01$). Results show that the level of congestion according to ?LIR during FU period increased progressively from Q1 to Q4 in both groups ($p < 0.001$).
Conclusions: LI-guided treatment of HF patients significantly reduces the incidence of HF hospitalizations.
Preemptive LI-guided treatment cases a shift of patients from Q3-4 to Q1-2 in the LI-guided group in comparison with the control group.
As a result of the above, the main predictor for HF hospitalizations is the degree of pulmonary congestion during the FU period.

P1863
Cardiogenic shock complicating peripartum cardiomyopathy: importance of early left ventricular unloading in combination with bromocriptine therapy

T J Pfeffer[1]; J-T Sieweke[1]; D Berliner[1]; T Koenig[1]; CN Napp[1]; J Tongers[1]; C Kuehn[2]; JD Schmitto[2]; D Hilfiker-Kleiner[1]; A Schaefer[1]; J Bauersachs[1]
[1]Hannover Medical School, Cardiology, Hannover, Germany; [2] Department of Cardiac, Thoracic, Transplantation and Vascular Surgery, Hannover, Germany

Background: Peripartum cardiomyopathy (PPCM), a rare heart disease with an onset during the last month of pregnancy or within the months postpartum, is characterized by heart failure with reduced ejection fraction in previously healthy women. A prolactin fragment is considered causal for the pathogenesis of PPCM. Treatment with the prolactin inhibitor bromocriptine in addition to heart failure therapy is associated with improved LV function and outcome. Nevertheless, in some cases PPCM is complicated by cardiogenic shock, representing a life-threatening situation. Catecholamine treatment in PPCM has been associated with adverse outcomes in animal models and patients. Mechanical circulatory support (MCS) with micro-axial flow-pumps and extracorporeal membrane oxygenation (ECMO) are increasingly used in the treatment of refractory cardiogenic shock. This study sought to investigate the role of early percutaneous MCS in combination with the prolactin inhibitor bromocriptine in cardiogenic shock complicating PPCM.
Methods and Results: Five PPCM patients with cardiogenic shock received MCS with either ImpellaCP microaxial pump only (n = 2) or in combination with veno-arterial ECMO (n = 3) in the setting of biventricular failure. In all cases MCS was combined with bromocriptine therapy and early administration of levosimendan. All patients survived the acute phase of cardiogenic shock, three patients were bridged to left ventricular assist device (LVAD). In our cohort MCS led to a significant reduction of catecholamine dosage while maintenance of blood pressure was achieved. In particular, early left ventricular unloading with ImpellaCP (= 24 hours) resulted in myocardial recovery, whereas a prolonged conservative management with catecholamines was associated with poor recovery. All three patients that could not be weaned from MCS and required permanent LVAD implantation had undergone prolonged conservative treatment with high dosages of dobutamine at secondary hospitals before transfer to our department (8 (IQR 7-8) days vs 1 (IQR 1-1) day, p = 0.2). Safety outcome was reasonable, as no major bleeding, no limb ischemia and no thromb-embolic event occurred during MCS.
Conclusion: MCS in PPCM patients with cardiogenic shock was associated with a 30-day survival of 100% and a favorable outcome. Remarkably, early left ventricular unloading combined with bromocriptine therapy was associated with left ventricular recovery. In contrast, patients treated with high catecholamine dosages for several days did not recover. Therefore, an immediate transfer to a tertiary hospital with experience in MCS for left ventricular unloading in combination with bromocriptine treatment seems to be crucial for treatment of cardiogenic shock complicating PPCM.

P1864
Non-invasive lung ventilation in patients with acute heart failure

K Akmal Koyirov[1]; S R Kenjaev[1]; U SH Ganiev[1]; S SH Khaitov[1]; Z A Kambarova[2]; M S Mirmaksudov[3]
[1]Republican Research Center of Emergency Medicine, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [3]Tashkent Medical Academy, Tashkent, Uzbekistan

Background: It is known that unreasonable carrying out of artificial ventilation of lungs has undesirable consequences, the risk of development of infectious complications (primarily tracheobronchitis, sinusitis and ventilator-associated pneumonia) increases. In this regard, the use of noninvasive ventilation in patients with cardiogenic respiratory insufficiency is fully justified.
Aim: To study the effect of noninvasive ventilation on acid base balance, hemodynamics, external respiration in patients with acute heart failure.
Material and Methods: 31 patients with acute heart failure were treated, against standard treatment, noninvasive ventilation in BiPAP mode. The exclusion criteria included respiratory arrest and the need for immediate intubation, hypotension, upper airway obstruction, the inability to remove sputum or use of a facial mask.
Non-invasive ventilation with positive pressure was carried out with a face mask using IVL apparatus. In the non-invasive ventilation of the lungs in the BiPAP 10/5 cm H2O mode, a significant decrease in respiratory rate by 29.1% and a heart rate of 13.4% was observed through the face mask for 1 hour. Moreover, an improvement of ejection fraction of left ventricle (by 17,4%), the parameters of acid base balance and blood gases (PaO2 increased by 37.8%, PaCO2 decreased by 36.4%, SpO2 increased by 15.9%) also observed in our study.
Non-invasive ventilation can increase the vital capacity of the lungs, improve gas exchange and quickly restore the function of the respiratory system. Advantages of non-invasive ventilation are clinical efficacy, physiology of the method, comfort for the patient.
Conclusions: Non-invasive ventilation allowed to normalize the gas composition of blood, parameters of hemodynamics and external respiration in patients with cardiogenic respiratory failure avoiding intubation of the trachea. Control of the adequacy of ongoing respiratory support can be carried out on the basis of SpO2 monitoring and hemodynamic parameters, acid base balance and venous blood gasometry.

P1865
Trends in the performance measures of drug therapy for heart failure with reduced ejection fraction under the optimize heart failure care program

E Eugenio Reyes[1]; FER Punzalan[1]; PFM Reganit[1]; MJF Agbayani[1]
[1]Philippine General Hospital, Section of Cardiology, Department of Internal Medicine, Manila, Philippines

Trends in the performance measures of drug therapy for Heart Failure with reduced Ejection Fraction under the Optimize Heart Failure Care Program
In 2013, the Optimize Heart Failure Care Program was introduced in the Philippines. The major components of the program are education, the use of checklist, and monitoring of performance through a disease registry. We report here performance measures in the use of Class IA drugs for HFrEF on a yearly interval to establish trends. The utilization rates of Class IA drugs for HErEF before and after the introduction of the Optimize Heart Failure Care Program were measured through review of data in the Heart Failure Registry in the Philippines. Data from 2004 was used as the baseline parameter. The percentage of patients who were prescribed ACE-Inhibitors or ARB, Beta-blockers, Spironolactone, and Ivabradine before discharge were measured. The baseline Utilization rate of drugs were 72% for ACE-I/ARB, 34% for Beta-blockers, and 14% for MRA. When optimize was initiated, the utilization rates were 74.8% for ACE-I/ARB, 50% for Beta-blockers, 21% for MRA, and 15% for Ivabradine. When analysis was done on a yearly basis, the utilization rates for ACE-I/ARB were 73%, 75%, and 32%; for Beta-blockers 51%, 47%, and 23%; for MRA 2%, 24%, and 18%, and for Ivabradine 13%, 7%, and 16%. Utilization rates of Class IA drugs for heart failure with reduced ejection fraction improved with the introduction of the Optimize Heart Failure Care Program. However, it deteriorates overtime and it was associated with higher mortality. We recommend the continuous monitoring of performance measures on a yearly interval and establish trends, run the program continuously and repeatedly since new doctors get in and new patients come in, incorporate the program in the Heart failure pathways, and establish heart failure clinics so the unit can take over the continual improvement process.

Performance measures for HFrEF by year

Year	2004 n= 1078	2014 n = 86	2015 n = 319	2016 n = 125
ACE-I/ARB	776 (72%)	63 (73%)	240 (75%)	41 (32%)
Beta-blockers	366 (34%)	44 (51%)	151 (43%)	29 (23%)
MRA	150 (14%)	2 (2%)	77 (24%)	22 (18%)
Ivabradine	na	8/60 (13%)	16/239 (7%)	12/76 (16%)
Mortality Rate	10%	2.3%	3.2%	4.8%

The utilization rates of Class IA drugs and ivabradine for HFrEF by year of enrollment. There is sudden drop in the performance measures after 2 years.

P1866

Intra-aortic balloon counterpulsation pump in heart failure patients during MitraClip implantation

M Mirjam Kessler[1]; J Seeger[1]; J Woehrle[1]; W Rottbauer[1]; S Markovic[1]
[1]*University of Ulm, Department of Internal Medicine II, Ulm, Germany*

Background: MitraClip implantation emerged as a treatment option especially for patients with prohibitive surgical risk due to severe impairment of left ventricular function. The use of intra-aortic balloon counterpulsation pump extended the spectrum of percutaneous cardiac interventions, to complex high-risk procedures with acceptable outcome.
Purpose: To analyse immediate and 30-day results after percutaneous mitral valve repair using an IABP as circulatory support during MitraClip implantation
Methods: Since 2012 17 patients of 557 patients (3%) at our centre received an IABP during MitraClip implantation procedure. The indication for prophylactic IABP implantation was a severely reduced left ventricular function (22.8 ± 8.3%) and haemodynamic impairment (cardiac index 1.9 ± 0.4 l/min/m^2).
Results: The mean age of the predominantly male population was 66.8 ± 12.1 years, mean Logistic EuroSCORE was 6.8 ± 5.6 and mean ASA Score was 3.8 ± 0.4. The mean NT-pro BNP at baseline was 6616.1 ± 4748 pg/ml, and the mean New York Heart Association (NYHA) functional class was 3.5 ± 0.5. Grade of MR before Clip procedure was 3.4 ± 0.5. All procedures were carried out successfully, with 1.2 ± 0.4 implanted clips and achieving a sufficient MR reduction (grade of MR after Clip 1.5 ± 0.5). Length of in-hospital stay was 11.7 ± 14 (3-48) days. No peri- or postprocedural death and no periprocedural resuscitation were observed. All 17 patients had an event-free 30-day follow-up. One patient remained hospitalized due to refractory heart failure until the end of follow-up and died after 48 days.
Conclusion: Implantation of an IABP during MitraClip procedure may provide additional safety and improve procedural outcomes in the setting of high-risk percutaneous mitral valve repair in heart failure patients.

P1867

Is there changes in the diuretic response to hypertonic saline plus furosemide depending on the type of heart failure?

D Carrillo[1]; R Lopez-Vilella[1]; I Sanchez-Lazaro[1]; L Martinez-Dolz[1]; L Almenar[1]
[1]*Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit, Valencia, Spain*

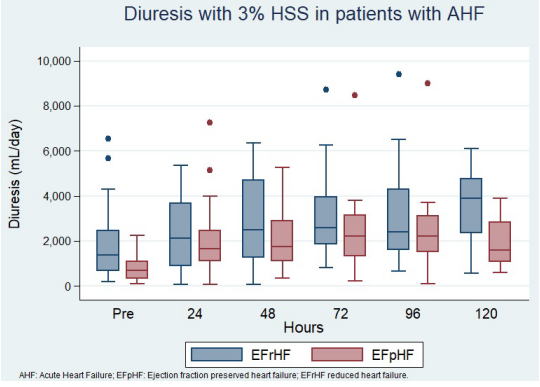
Background and Purpose: Hypertonic saline solution (HSS) in patients with heart failure (HF) may improve diuresis due to an increase in renal blood flow and may facilitate the action of diuretics. Our purpose was to describe the diuretic response to HSS in patients with acute HF according to the left ventricular ejection fraction (LVEF).

Characteristic of patients.

Variable	Left Ventricular Ejection Fraction				
	<45% (n = 24), n %	≥45% (n = 18), n %	p		
Age (y)*	65.83	13.8	68.55	12.09	0.46
Male gender	18	75.00	11	61.11	0.50
Ischemic aetiology of heart disease	6	25.00	1	5.56	0.10
Hospital admissions due to HF*	17	70.83	9	64.29	0.72
Previous furosemide dose (mg/d)**	60	60-150	80	60-120	0.91
Initial laboratory					
Sodium*	135.58	4.28	135.92	6.35	0.86
Creatinina*	2.08	0.82	1.71	0.95	0.26
Hours of 3%HSS**	60	24-120	48	24-48	0.32
In-hospital mortality	5	20.83	7	38.89	0.30

* Media, standar deviation, ** Median, interquartile range. HF: Heart failure, HSS: Hypertonic Saline Solution

Methods: Retrospective study of patients admitted because of acute HF, and received continuous infusion of 500mL of 3% HSS plus furosemide, as a treatment of congestive symptoms of HF. Variables was described and classified according to the presence of ejection fraction = 45% as preserved (EFpHF), otherwise as reduced (EFrHF). The diuresis in the 0, 24, 48, 72 and 120 hours after de initiation of HSS was graphed by LVEF categories. A regression model of random effects of diuresis conditioned by time between 0 and 120 hours of SSH infusion were made.
Results: Forty-two patients. Median age was 67 years (Table). After the infusion of HSS with furosemide, compared to the diuresis of the previous 24 hours, on average the diuresis increased 483mL in the first 24 hours (p = 0.22), 1080 in the 48 hours (p = 0.005), 1728 in the 72 hours (p = 0.00), EFpHF was not related to greater diuresis with respect to EFrHF (-436mL 95% CI -1268 to 394 p = 0.30) (Figure). However, the older age and the lower glomerular filtration rate were related to changes in the diuretic response (-49mL 95% CI -80 to -18 p = 0.002 and 16mL 95% 0.90 to 31 p = 0.038 respectively).
Conclusion: The infusion of HSS with furosemide increased the diuretic response without differences between EFpHF and EFrHF



P1868

Intravenous fluids in patients admitted with acute heart failure

D David Cabrita Roque[1]; D Candeias Faria[1]; J Augusto[1]; J Baltazar Ferreira[1]; J Simoes[1]; A Sacchetti[2]; L Melo[2]; A Oliveira Soares[1]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal*;
[2]*Hospital Prof Fernando da Fonseca EPE, Internal Medicine, Amadora, Portugal*

Introduction: Acute Heart Failure (AHF) is a life-threatening disease requiring urgent treatment. Most of patients present with signs and symptoms of volume overload. However, in clinical practice, in addition to diuretic therapy many hospitalized patients receive intravenous fluids, which is counterintuitive.
Purpose: The aim of this study is to evaluate the association between the institution of fluid therapy and clinical outcomes in patients admitted in the Emergency Department for AHF.
Methods: Retrospective study of 258 consecutive patients admitted in the emergency department for ADHF, defined by the presence of = 2 signs or symptons of heart failure. Admission, maximum and discharge values of creatinine (Cr) were collected, along with other clinical, laboratory and therapeutic variables. The HF profile was assessed as according to the ESC guidelines. We focused on early treatment with fluids to avoid treatments performed in response to over-intensive diuretic treatment. We defined intravenous fluid therapy as any use of = 500ml of normal saline or half-saline in the first 24 hours of admission, and did not include administration of dextrose 5% solution because it would not enhance intravascular volume significantly.
Results: We evaluated 258 patients with ADHF (45.7% male, mean age of 74.6 ± 16.6 years). received intravenous fluid therapy: < 500ml (71.2%, n = 183) and = 500ml (28.8%, n = 74). The mean IV fluid volume was 195 ± 394ml. The median dose of Furosemide administered in the first 24 hours was 80 (60-100) mg. Mean baseline Cr was 1.29 (0.94-1.72) mg/dl, peak Cr was 1.49 (1.14-2.13) mg/dl and discharge Cr was 1.18 (0.95-1.60) mg/dl. The death rate during hospitalization was 8.1% (n = 21); 1-month readmission rate was 18.2%% (n = 47). The mean in-hospital length of stay was 12.5 ± 10.8 days, with no significant differences found between those who received (= 500ml) and those that didn't received fluids (< 500ml) (13.3 ± 10.3 vs. 12.1 ± 11.0 days, respectively, p = 0.118). We also found no association between in-hospital mortality and fluid therapy in this group of patients (10.8 vs 7.1%, respectively, p = 0.324)
Conclusions: Although some studies have suggested that fluid therapy in combination with diuretics provide hemodynamic and clinical improvements, in those studies

the volume used was very small. We demonstrated that the use of fluid therapy (= 500ml of normal saline or half-saline) in the first 24 hours of admission for acute heart failure as no impact on hospital outcomes or in-hospital mortality.

Acute Heart Failure - Clinical

Comparative analysis of short term outcomes of patients with heart failure with mid-range ejection fraction after acute decompensation

O Miro[1]; P Javaloyes[2]; V Gil[1]; FJ Martin-Sanchez[1]; J Jacob[1]; P Herrero-Puente[3]; J Marco-Hernandez[1]; V Rico[1]; G Martinez[1]; S Aguilo[1]; R Escoda[1]; VP Harjola[3]; J Parissis[4]; CE Muller[5]; P Llorens[2]
[1]Hospital Clinic de Barcelona, Emergency Department, Barcelona, Spain; [2]General University Hospital of Alicante, Emergency Department, Alicante, Spain; [3]Helsinki University Central Hospital, Emergency Department, Helsinki, Finland; [4]Attikon University Hospital, Cardiology Department, Athens, Greece; [5]University Hospital Basel, Cardiology Department, Basel, Switzerland

On behalf of: ICA-SEMES Research Group
Funding Acknowledgements: ISCIII (Spanish Ministry of Health) and FEDER (PI15/01019 and PI15/00773), Fundació La Marató de TV3 (2015/2510) and Calalan Govern (GRC 2014/0313)

Aims: To investigate short-term outcomes after an episode of acute heart failure (AHF) of patients with mid-range ejection fraction (between 40%-49%; HFmrEF) compared with patients with reduced (< 40%) and preserved (<49%) ejection fraction (HFrEF and HFpEF, respectively), and according to their final destination after emergency department (ED) health care.
Methods: This is an exploratory, secondary analysis of the EAHFE Registry, which includes consecutive AHF patients diagnosed in 41 Spanish EDs. Patients with echocardiography data were included and divided in HFrEF, HFmrEF and HFpEF. Primary outcome was 30-day all-cause mortality, and secondary outcomes were in-hospital all-cause mortality, hospital length of stay (LOS) longer than 10 days, and 30-day post-discharge ED revisit due to AHF and combined endpoint (ED revisit/death). Adjusted ratios were calculated for patients with HFmrEF compared with HFrEF and HFpEF; and for patients with HFmrEF admitted to internal medicine and not hospitalized compared with those admitted to cardiology.
Results: We included 6,856 patients (age 79 (10); 52.1% women): 21.6% had HFrEF, 14.3% HFmrEF, and 64.1% HFpEF. Main destinations after ED management for HFmrEF patients were internal medicine (293, 29.8%), cardiology (194, 19.9%) and not hospitalized (241, 24.5%). Outcomes for HFmrEF did not differ respect to either HFrEF or HFpEF (Figure 1). Compared with HFmrEF admitted to cardiology, internal medicine admission increased the 30-day post-discharge combined endpoint (HR = 1.598, 95%CI = 1.012-2.524, p = 0.044), and patients not hospitalized increased the 30-day post-discharge ED revisit (HR = 1.779, 95%CI = 1.114-2.829, p = 0.011) and combined endpoint (HR = 1.818, 95%CI = 1.165-2.836, p = 0.008).
Conclusion: Short-term outcomes of HFmrEF patients do not differ from those of the HFrEF and HFpEF patients, but patients admitted to internal medicine and not being hospitalized after the ED management of an AHF episode have increased risks after being discharged from hospital or ED in comparison with those admitted to cardiology.

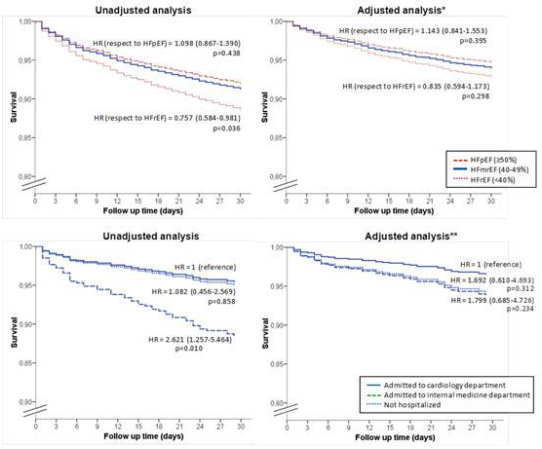

Figure 1

P1870

Non-alcoholic fatty liver disease and increased risk of all-cause mortality in elderly patients admitted for acute heart failure

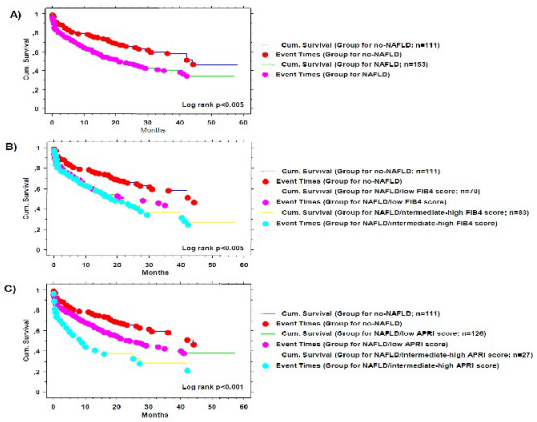
F Filippo Valbusa[1]; D Agnoletti[1]; G Scaturro[1]; L Scala[1]; S Calabria[1]; E Turcato[2]; P Arduini[2]; S Bonapace[3]; G Targher[4]; G Arcaro[1]
[1]Sacro Cuore - Don Calabria Hospital, Internal Medicine, Negrar-Verona, Italy; [2]Sacro Cuore - Don Calabria Hospital, Division of Geriatry, Negrar-Verona, Italy; [3]Sacro Cuore - Don Calabria Hospital, Division of Cardiology, Negrar-Verona, Italy; [4]University and Azienda Ospedaliera Universitaria Integrata of Verona, Section of Endocrinology, Diabetes and Metabolism, Verona, Italy

Introduction: Non-alcoholic fatty liver disease (NAFLD) is an emerging risk factor for incident heart failure (HF). It is currently unknown whether NAFLD predicts all-cause mortality in patients admitted for acute HF. We sought to determine whether NAFLD and its severity (diagnosed by ultrasonography and non-invasive fibrosis markers) were associated with the risk of in-hospital and post-discharge all-cause mortality in this particularly high-risk patient population.

Table 1

Cox Hazard Models	Hazard ratio(s)	95% CI	p value
Inadjusted model	1.70	1.20-2.39	<0.005
Adjusted model 1	1.86	1.30-2.66	<0.001
Adjusted model 2	1.61	1.11-2.35	<0.01
Adjusted model 3 (n = 223)	1.82	1.22-2.81	<0.005

Sample size, n = 264 unless noted otherwise. Other covariates included in the three multivariable regression models, together with NAFLD, were as follows: model 1: age and sex; model 2: age, sex, past history of HF, diabetes, CHD, CKD (i.e. eGFRMDRD < 60 ml/min/1.73 m2), COPD and pacemaker; model 3: adjustment for the same variables included in model 2 plus body weight, systolic blood pressure, LV-ejection fraction, use of ACE-I/ARBs, daily furosemide dosage, plasma albumin, NT-proBNP and GGT levels.



Methods: We studied 264 elderly patients, who were consecutively admitted for acute HF to our hospital between years 2013 and 2015, after excluding those with acute myocardial infarction, severe valvular heart diseases, kidney failure, cancer, cirrhosis of any etiology or known chronic liver diseases.
Results: Over a mean follow-up period of 23.2 months (range: 3 days-58 months), there were 140 (53%) total deaths. Of these, 24 deaths occurred during the first hospital admission (in-hospital death) and 116 deaths occurred after the hospital discharge over the follow-up period. Patients with NAFLD at hospital admission had significantly higher cumulative incidence rates of in-hospital and post-discharge all-cause mortality (singly or in combination) compared with those without NAFLD. This mortality risk was particularly increased among patients with advanced NAFLD fibrosis (Fig.1). In Cox regression analysis, NAFLD was associated with an increased risk of all-cause mortality (adjusted-hazard ratio 1.82, 95% confidence intervals 1.22-2.81, p < 0.005) even after adjustment for established risk factors and potential confounding variables (Table 1). Conclusion: NAFLD and its severity were independently associated with an increase risk of

in-hospital and post-discharge all-cause mortality in elderly patients admitted for acute HF.

P1871

Contemporary cardiovascular management in pre-hospital emergency medical services- comparison of acute heart failure, dyspnoea, chest pain, and ST-elevation myocardial infarction protocols

P Harjola[1]; VP Harjola[1]; M Kuisma[1]; M Christ[2]; X Escalada[3]; F Martin-Sanchez[4]; O Miro[5]

[1]Helsinki University Hospital, Emergency Care, Helsinki, Finland; *[2]Luzern Hospital, Emergency department, Luzern, Switzerland*; *[3]Hospital Clinic de Barcelona, Sistema d'Emergéncies Médiques, Catalunya, Barcelona, Spain*; *[4]Hospital Clinic San Carlos, Emergency department, Madrid, Spain*; *[5]Hospital Clinic de Barcelona, Emergency department, Barcelona, Spain*

Background: Acute heart failure (AHF) is one of the most important causes for hospital admission. Ca. 10 -20 % of AHF patients are first treated by pre-hospital emergency medical services (EMS). Whereas e.g. ST-elevation myocardial infarction (STEMI) protocols are well defined and adopted, there are no uniform protocols for AHF.
Purpose: Our aim was to find out the prevalence and contents of EMS protocols and compare those to other existing cardiovascular protocols in different European countries.
Methods: A survey was sent to 12 European countries. The study was designed to cover Finland, Denmark, Sweden, Norway, Germany, Poland, Czech Republic, France, Spain, Italy, Switzerland, and United Kingdom. The study cites reported data regarding different EMS units ranging from basic to advanced life support units as well as helicopter EMS. This analysis includes data from those EMS regions covering more than 20% of the countries' population.
Data on the prevalence of protocols for AHF, dyspnoea, chest pain STEMI as well as the diagnostic and therapeutic options of these protocols were collected. The prevalence of different protocols was compared by Fisher exact test.
Results: We received 34 surveys from 3 countries fulfilling the inclusion criteria: 19 from Spain (covering 40.0 million citizens, 86.0% of the Spanish population), 9 from Switzerland (covering 2.3 million, 27.1% of the population) and 6 from Finland (covering 3.5 million, 63.3% of the population). Twenty-seven (79.4%) of these EMS regions had a specific protocol for AHF, 29 (85.3%) for dyspnoea, 30 (88.2%) for chest pain and STEMI (p = NS for all comparisons). Spanish EMS had less frequently AHF protocols (73.7% compared to 100% in Switzerland and Finland, p = 0.1). The following diagnostic and therapeutic options were included in the EMS protocols (% of EMS by permanent standing order/ % of EMS after EMS physician's consultation): i.v. line (72.4/17.2), ECG (65.5/17.2), troponin point-of-care test (POCT) (3.6/0) or BNP POCT (3.6/0), ultrasound assessment (3.6/0), oxygen supplementation (72.2/20.7), non-invasive ventilation (51.7/24.1), invasive mechanical ventilation (37.9/27.6), i.v. diuretic (55.6/25.9), i.v. nitrates (34.6/30.8), and i.v./s.c. opiates (70.4/18.5)
Conclusions: Current data suggests that pre-hospital EMS protocols for suspected AHF are common. I.v. line, ECG and ventilatory support are fairly common interventions whereas the use of troponin and BNP POCT and ultrasound are very rarely available.

Aim: To study the impact of digoxin in acutely decompensated chronic heart failure (ADCHF).
Subjects & Methods: Data was analyzed from 5005 consecutive patients admitted to 47 hospitals in 7 Middle Eastern countries with AHF from February to November, 2012. Patients were categorized into ADCHF patients off digoxin therapy (A1) and ADCHF patients on digoxin therapy (A2). Chi-square test of independence was utilized for A1 and A2.
Results: In Gulf-CARE registry 45.56 % (2280/5005) were identified as ADCHF patients where 28.6% (652/2280) patients were already on digoxin therapy. Patients on NYHA IV were seen more with digoxin group 35.6% (232/652) while non-digoxin group had 29.5% (480/2280) p = 0.001. CAD, hypertension and dyslipidemia were seen more with non-digoxin group and was statistically significant p = 0.001. In hospital major bleeding, cardiogenic shock, intubation, stroke and mortality were reported almost same in both groups with no statistical significance.
Conclusions: In ADCHF patients digoxin has no impact on in-hospital major bleeding, cardiogenic shock, intubation, stroke and mortality.

Role of digoxin in ADCHF

Characteristics	Acute Decompensated Chronic Heart Failure		
Without Digoxin n = 1628 A1	With Digoxin n = 652 A2	P-Value

On behalf of: Gulf CARE
Funding Acknowledgements: Funded by Servier, Paris, France; and (for centers in Saudi Arabia) by the Saudi Heart Association

Background: Cardio renal anemia syndrome (CRAS) in acute heart failure (AHF) is considered to be a high risk condition.
Subjects and **Methods:** Patients were categorized into group of AHF patients without CRAS and group of AHF patients with CRAS. Chi-square test of independence was utilized for A1 and A2.
Results: In Gulf-CARE registry 26.8% (1343/5005) patients were identified as CRAS patients, where anemia was observed in 54.5% (2728/5005) and

chronic kidney disease (CKD) in 45.1% (2257/5005) patients. In-hospital cardiogenic shock, intubation, stroke was reported almost similar in both groups. In-hospital major bleeding was seen more with A2 1.4% (19/1343) when compared to A1 0.6% (21/3662) with a statistical significance p = 0.003. The mortality rate was almost similar in both groups 6.2% (228/3662) in A1 and 6.3% (85/1343) in A2.

Conclusion: In the setting of acute heart failure, CRAS is not considered to be an independent predictor of in-hospital cardiogenic shock, stroke and mortality.

Relationship between on-treament blood pressure and outcomes in patients with heart failure

D David Cabrita Roque[1]; M Santos[1]; J Augusto[1]; J Baltazar Ferreira[1]; D Candeias Faria[1]; J Simoes[1]; P Magno[1]; A Oliveira Soares[1]; C Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal*

Background: Blood pressure (BP) is a well known and studied CV risk factor. However, when CV disease is established, the optimal level of BP is not well defined, and some studies had shown that lower BP is related to increased mortality.

Purpose: We aim to evaluate the relationship between BP at admission, during hospitalization and at hospital discharge, with clinical outcomes.

Methods: Retrospective study of 258 consecutive patients admitted in the ER for HF, defined by the presence of = 2 signs or symptoms of HF. Admission and discharge values of systolic blood pressure (SBP) were recorded. We further divided our population according to the first SBP registered at hospital admission and at discharge: group 1 <130mmHg (31.8 and 64.3%, respectively); group 2 130-160mmHg (37.2 and 28.7%, respectively) and group 3 >160mmHg (31 and 3.9%, respectively). The HF profile was assessed according to the ESC guidelines. We also evaluated patients' medication before admission, during hospitalization and at discharge.

Results: We included 258 patients with ADHF (45.7% male, mean age of 74.6 ± 16.6 years). Emergent hospital admission was more frequent in admission group 3 (61.3% vs 28.1% in group 2 and 28.1% in group 1, p <0.001). Admission group 3 also presented more frequently with acute pulmonary oedema (66.3% vs 17.7% in group 2 and 13.4% in group 1, p <0.001). Chronic renal disease was less frequent in admission group 3 (20% vs 37.5% in group 2 and 31.7% in group 1, p = 0.040); previous acute coronary syndrome was more frequent in admission group 1 (45.1% vs 29.2% in group 2 and 25% in group 3, p = 0.015). Ejection fraction was significantly lower for patients in both admission and discharge group 3 (admission: mean 42% group 3 vs 58.8% group 1 vs 74.4% for group 2), p = 0.019; discharge: mean 26% group 3 vs 65.7% group 1 vs 47.2% group 2, p = 0.004). There were no significant differences in hospital mortality between admission SBP groups (7.3% group 1, 9.4% group 2, 7.5% group 3, p = 0.855). Interestingly, patients in admission group 3 had shorter lengths of stay (mean 9.4 vs 13.5 for group 2 and 14.2 days for group 3, p <0.001). Of note, prior prescription of ACEIs/ARB and beta blockers was unrelated to admission SBP categories. There were no differences in readmission rates for ADHF at 1, 3, 6, 9 and 12 months after discharge, according to SBP categories. There was a trend for patients in groups 1 and 3 to have higher mortality rates after discharge (14.5% for group 1 and 10% for group 3 vs 5.4% for group 2, p = 0.128), suggesting a J-shaped curve for mortality according to SBP.

Conclusions: During hospitalization, SBP does not seem to have an association with mortality; however, according to the SBP values at discharge, those patients with the highest and the lowest values are those with higher risk of mortality at 1 year FUP, suggesting that in HF SBP has a J-shaped curve, and that the least possible BP may not be an adequate treatment target.

Heart and mind interaction in heart failure

I Aguiar Ricardo[1]; J Ribeiro Agostinho[1]; ISS Goncalves[1]; J Rigueira[1]; A Ferreira-Nunes[1]; R Santos[1]; N Andre[1]; T Guimaraes[1]; N Cunha[1]; R Pires[2]; FJ Pinto[1]; D Brito[1]
[1]*Cardiology Department, Santa Maria Hospital, CHLN, CCUL, Lisbon University, Cardiology, Lisbon, Portugal*; [2]*Faculty of Psichology and Educational Sciences, CINEICC, University of Coimbra, Lisbon, Portugal*

On behalf of: RICA-HFTeam

Introduction and aim: Anxiety and depression appear to contribute to morbidity in heart failure (HF). However they are rarely evaluated. Our aim was to characterize these aspects in HF patients (pts), and to evaluate their potential impact on prognosis.

Methods: Single center prospective study including pts admitted for acute or chronic decompensate HF (index admission) who gave written informed consent for inclusion in a post-discharge follow-up program (by protocol).

The Hospital Anxiety and Depression Scale (HADS) - validated Portuguese version - was used for anxiety and depression screening. We defined for each condition: abnormal value - HADS>11; normal - HADS < 7; and borderline - HADS= 8-10. The test was performed the first time at discharge, and repeated at 9+3 months during follow-up (Fup). Cox regression, Kaplan-Meier survival analysis, Spearman, Mann-Whitney and Wilcoxon correlation analysis were used.

Results: 40 pts (66.5 ± 11.4 years, 75% men, 67.5% with hypertension, and 32.5% with diabetes) were included. At the time of first HADS application, 85% had left ventricle ejection fraction < 40%, and 95% were in NYHA functional class I-II; for 40% of patients, it was the first hospitalization due to HF.

At the first evaluation:

1)Depression - 15% of pts were classified with abnormal HADS, and 27.5% with borderline HADS; the value of HADS was associated with weight (p = 0,026, r= -0,352), blood pressure (p = 0,038, r= -0,329) and anxiety (p < 0,001, r= 0,625); 2) Anxiety - 20% had abnormal HADS, and 25% had a borderline value.

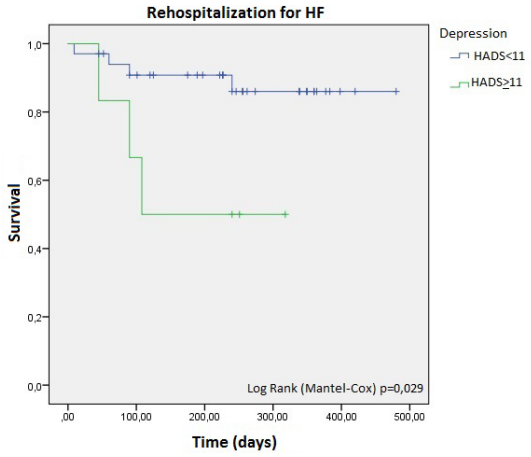
The presence of altered HADS correlated with female gender (p = 0,028; Z= 2,196), first HF hospitalization (p = 0,035, Z= -2,107) and depression.

Anxiety and/or depression were associated with a negative impact on general symptoms (p = 0,023, r= -0,377 and p = 0,002, r= -0,494, respectively) and overall quality of life (p = 0,005, r= -0,459 and p= 0,0001, r= -0,591, respectively), evaluated by the Kansas City Cardiomyopathy Questionnaire.

During Fup, all cause and HF rehospitalization rates were 25%, and 17.5%, respectively.

There was no improvement in anxiety or depression scores during Fup. HADS >11 for depression was a predictor of HF rehospitalization (p= 0,048); anxiety did not predict events.

Conclusion: Anxiety and/or depression have impact on the quality of life of HF pts. The presence of depression predicts rehospitalization for HF, which can be attributed, at least in part, to the difficulty in self-management of the syndrome, contributing to a vicious cycle deserving attention and preventive management in the follow-up of these patients.



Rehospitalization and depression in HF

Coronary Artery Disease - Pathophysiology and Mechanisms

Diagnostic value of ZNF606 expression from monocytes in coronary artery disease

L Lu Lu[1]; ZY Huang[1]; JB Guo[2]; AH Chen[2]
[1]The First Affiliated Hospital, Guangzhou University of Chinese Medicine, Department of Cardiology, Guangzhou, China People's Republic of; *[2]Southern Medical University,, Department of Cardiology, Heart Center, , Guangdong, China People's Republic of*

Funding Acknowledgements: This work was supported by grants from the National Natural Science Foundation of China (grant numbers: 81270218)

Background: Although coronary artery angiography (CAG) shows high degree of specificity in coronary artery disease (CAD) diagnosis, it is an invasive procedure that causes discomfort to patients and may lead to various complications. Early atherogenesis is characterized by the adherence of blood circulating monocytes. hence, this study hypothesized monocyte gene expression changes in patients with CAD may have diagnostic value.
Purpose: We aimed to evaluate the increase in related mRNAs from monocytes may become a new non-invasive means for diagnosing CAD in the early stage,
Methods : Chip data (GSE9820) retrieved from Gene Expression Omnibus (GEO) was reanalyzed, and the selected candidate genes meeting specific conditions were upregulated and verified for diagnostic values for CAD in the prospective cohort study that recruited 194 individuals: group Non-CAD (GN), n = 68; group CAD (GC), n = 126. The GC patients of 53, 50, and 23 were categorized as having 1 (GC1), 2 (GC2) or = 3 (GC3) coronary arterial stenosis, respectively. All candidate mRNA expressions were analyzed from patients' monocytes with quantitative PCR (q-PCR). Receiver-operating characteristic (ROC) curves and the area under the ROC curves (AUCs) were used to evaluate the mRNAs' feasibility for CAD diagnosis. AUCs = 0.8 were accounted as high diagnostic efficiency for CAD.
Results: GBA2, CSTF3, ZNF606 and MPP5 were selected as candidate mRNAs from chip data reanalysis. GBA2 ($P = 0.002$) and ZNF606 ($P < 0.001$) expressions were significantly increased in GC. ZNF606 showed significant increase by adjusting the risk factors with logistic regression analysis (OR = 3.624, 95% CI: 1.815, 7.491, $P < 0.001$), and its expression level was positively correlated with age ($\beta = 0.04 \times 10\text{-}3$, $P < 0.001$). The AUCs (and 95% CI) of ZNF606 expression in GC2 and GC3 are = 0.8 showing high diagnostic efficiency in CAD.
Conclusions: These findings suggest that ZNF606 expression from monocytes may be a novel and specific diagnostic means of CAD, especially in multiple coronary artery stenosis.

P1877

Single nuclear polymorphism a1166c of agtiir1 gene and cardiac remodeling after st segment elevation myocardial infarction

OV Petyunina[1]; MP Kopytsya[1]; IR Vyshnevska[1]
[1]Government institution"L.T. Malaya Therapy National institute of the National academy of medical sci, Kharkiv, Ukraine

Purpose: To perform medical-genetic analysis of dynamic of structural and functional myocardial parameters, heart rate variability data depending on polymorphism ?1166? of R1 receptor of angiotensin II (AGTIIR1) gene in patients with myocardial infarction with ST segment elevation - STEMI.
Matherials and methods: 87 patients with STEMI, 70 (80%) male and 17 (20%) female at average age ($58{,}94 \pm 10{,}16$) years were examined. Patients were hospitalized during first three days after selective coronary angiography and infarct-related artery stenting were performed. After 6-month observation period patients were reexamined. Allele polymorphism A1166C of AGTIIR1 gene was determined by polymerase chain reaction in real time, heart rate variability (HRV) - Cholter 24-hour monitoring, morpho-functional data - ultrasound research.
Results and discussion. In patients with ??+??-genotypes compared with ?? on 1-3 day of STEMI higher level of left ventricular (LV) end diastolic diameter (EDD) (? = 0,004), LV end systolic diameter (ESD) (? = 0,043), LV myocardial mass (MM) (? = 0,041), frequency of mitral regurgitation (? = 0,028), the tendency to higher LV end diastolic volume (EDV) (? = 0,089) were revealed. These means unfavorable structure of early after infarction myocardial remodeling (RM). After 6 month patients with ??+??- genotypes compared with ?? demonstrated higher LVEDD (? = 0,083), left atrium (? = 0,091), LVMM (? = 0,081). When analysed echocardiographic data in acute period of STEMI and after 6-month observation, groups with ?? and ??+??-genotypes demonstrated significant or tendency to higher level of LVEDV (? = 0,06, ? = 0,034), LVEDD (? = 0,057, ? = 0,01), LV ejection fraction (EF) (? = 0,037, ? = 0,07) respectevly. In patients with AC+CC-genotypes compared with AA were lower level of SDNN ($P = 0{,}049$), HF (? = 0,053), higher level of LF ($P = 0{,}069$) and LF/HF-index ($P = 0{,}046$).
Conclusions: Polymorphic ??+??-genotype cariers compared with ??-genotype of AGTIIR1 gene demonstrated more relevant increase of left ventricular diameters and volume, left atrium and LV myocardial mass in acute period of STEMI. After 6-month period in both groups LV dilatation and LVEF were observed. These data refer to the similar with Frank-Starling law dynamic of compensation. Patients with ??+??-genotypes compared with A? demonstrated unfavorable structure of LV CR and associates with more expressed sympathic-vagous dysbalance.

P1878

Artificial neural network for prediction of coronary artery disease in patients with abnormal myocardial perfusion

VA Kuznetsov[1]; EI Yaroslavskaya[1]; DV Krinochkin[1]; DV Teffenberg[1]; SM Dyachkov[1]
[1]Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Tyumen, Russian Federation

Introduction: It is challenging often to detect coronary artery disease (CAD) without coronary angiography (CAG) in atypical patients with myocardial perfusion abnormalities by single photon emission computed tomography (SPECT) data. The purpose of the study was to reveal predictors of significant coronary lesions in patients with myocardial perfusion abnormalities by SPECT using artificial neural network.
Methods: From 13,283 consecutive patients with suspected CAD we selected patients after (99)Tc(m)-methoxyisobutylisonitrile (MIBI) gated SPECT and CAG who had no more than 3 months between the tests. There were 47 patients among them who had abnormal SPECT. We divided these patients in two groups: with significant coronary lesions (= 50% of lumen) by CAG and without.
Results: In 15 patients with abnormal SPECT and CAD compared to patients without CAD (n = 32) we observed more often acute myocardial infarction (37.1 vs 6.5%, $p = 0.005$) and higher level of serum glucose (6.9 ± 2.5 vs 5.3 ± 0.8 mmol/l, $p = 0.007$). Reduced left ventricular (LV) systolic function (LV ejection fraction < 50%) was more frequent in these patients (17.4 vs 7.4%, $p < 0.001$), as well as mild, moderate or severe mitral regurgitation (81.3 vs 59.4%, $p = 0.026$). They had higher index of LV wall motion abnormalities (1.4 ± 0.3 vs 1.0 ± 0.1), and only patients of this group had signs of myocardial scars detected by echocardiography (31.3%, all $p < 0.001$). According to the results of discriminant analysis, CAD was associated with index of LV wall motion abnormalities and mitral regurgitation. The obtained sensitivity, specificity and positive predictivity were 81%, 82%, and 81%, respectively. Then, artificial neural network was used to improve the diagnostic accuracy of the method. Application of multilayer perceptron allowed obtaining sensitivity, specificity and positive predictivity as 69%, 94%, and 85%, respectively.
Conclusion: Application of artificial neural network allowed to improve diagnostic accuracy of CAD detection in patients with abnormal SPECT.

P1879

Dynamics of the left ventricle remodeling in patients with Q- wave myocardial infarction

G U Guzal Mullabayeva[1]; RD Kurbanov[1]
[1]*The Republican Specialized Center of Cardiology, Tashkent, Uzbekistan*

Funding Acknowledgements: governmental grants

Purpose of the study: a comparative study of the dynamics of postinfarction remodeling of the left ventricle (LV), in patients with Q- wave myocardial infarction (MI) in a high-risk group.
Materials and Methods: The study included 294 male patients (mean age 52.6 ± 9.1 years) with primary Q- wave IM. Patients were included on the 10-14th day of the disease. Patients were referred to clinical and instrumental examinations for 6 months, 1st and 2 years of follow-up. All patients echocardioscopy (ECHO) were carried out. The following parameters were measured and calculated: end diastolic LV size (EDS), end systolic size of the LV (ESS), LV ejection fraction (LV EF). To quantify the geometric shape of the LV, the sphericity index (SI) = d 1/ d 2 was determined , where d1 is the longitudinal end-diastolic dimension of the LV, d2 is the transverse end-diastolic LV dimension. Results of the study: In two years of follow-up, the total mortality was 11.9% (35 patients). From non-cardiac causes 3 patients (1%) died, total cardiac mortality occurred in 32 (10.8%) patients, including sudden coronary death - in 24 (8.1%) patients. For the comparative analysis, the patients were divided into 2 groups: 1 group of surviving patients (n = 259), 2 group of the poor prognosis (n = 32). On 6 months Group 2 patients treated more often for progressive angina, the cases of hospitalization for the destabilization of the state and reinfarction. Thus, at the end of the follow-up period, reinfarction cases were registered in 40 patients (13.6%), 15 (46.8%) of them were observed in patients with group 2. On the 10-14th day, the SI index (normally tending to 2) in both compared groups was comparatively the same. Later in the group with an unfavorable prognosis there was a decrease in SI from 1.64 to 1.45($p < 0.05$), whereas in the group 1 the negative dynamics is not traced. Moreover, by the end of the second year of observation, the index of SI in the first group is close to 2. A summary of linear LV indices showed that already on the 14th day of the disease the group 2 had higher rates of EDS and ESS. By the 6th month in the 2 group there ESS was an increase of 8,2% ($p < 0,05$) and end EDS by 14% , while in the group 2 this trend is unreliable. By the end of the 1-year follow-up, the increase in EDS in 2 group relative to the initial values were already 14% and 19% ($p < 0.05$).In the same period, in the 1 st group, there was a significant reduction in the EDS by 5.2% ($p = 0.004$). It should be noted that by the end of the second year of follow-up, the first group showed a favorable dynamics in relation to these indicators. Conclusion: The progression of remodeling after MI is determined not only due early pathological remodeling. An important contribution is made by repeated MI, persistent angina pectoris.

Coronary Artery Disease - Treatment

Effect of intra-coronary (IC) Tirofiban following aspiration thrombectomy on infarct size, in patients with large anterior ST-segment elevation myocardial infarction (STEMI) undergoing primary PCI

A Basuoni[1]; WAEL El-Naggar[1]; M Mahdy[1]; S Al-Kaffas[1]
[1]*Cairo University Hospitals, Cardiology , Cairo, Egypt*

Background: Thrombus embolization during percutaneous coronary intervention (PCI) in ST-segment elevation myocardial infarction (STEMI) is common and results in sub-optimal myocardial perfusion and increased infarct size. Two strategies were proposed to reduce distal embolization and improve outcomes after primary PCI are bolus intra-coronary (IC) Tirofiban and manual Aspiration Thrombectomy.
Objective: To evaluate effect of Intra-coronary delivery of bolus Tirofiban following Aspiration Thrombectomy on reduction of infarct size using cardiac magnetic resonance imaging (cMRI) in patients with large anterior STEMI undergoing primary PCI.
Methods: A Prospective single-blind randomized controlled trial was conducted between August, 2014 and November, 2015. 50 patients with large anterior STEMI were screened at 2 sites in one country (Egypt). Aspiration Thrombectomy was performed in all patients using a 6 F aspiration catheter. Patients were randomized to IC Tirofiban (Study group) and no IC Tirofiban (control group). To ensure high intra-thrombus drug concentrations, a 25 mcg/kg bolus of Tirofiban was administered locally at the site of the infarct lesion via the aspiration catheter after flushing of the aspiration catheter well.
Primary end point was infarct Size at 30 Days measured by cMRI. Secondary end point was myocardial blush grade at the end of the PCI procedure. Major Adverse Cardiac and Cerebrovascular events (MACCE) at 30 days defined as re-infarction, stroke, severe heart failure and death.
Results: Evaluable MRI results at 30 days were present in only 40 of 50 patients (80%), with the most common reasons for missing data being patient re-infarction prior to 30 days and inability to tolerate the procedure. Patients randomized to IC Tirofiban compared with no IC Tirofiban had a significant reduction at 30 days infarct size (median, 15451 mm3 - IQR, 17404 mm3 - n = 20) vs (median, 43828 mm3 - IQR, 49599 mm3 - n = 20) P value= 0.002. myocardial blush grade results at the end of the PCI where present in 50 patients, randomized to IC Tirofiban compared with no IC Tirofiban had no significant difference (P value= 0.67). There is no significant difference in MACCE at 30 days between patients received bolus IC Tirofiban and patients who did not receive (P value= 0.723).
Conclusions: In patients with large anterior STEMI presenting early after symptom onset and undergoing primary PCI, infarct size at 30 days was significantly reduced by bolus IC Tirofiban delivered to the infarct lesion site following manual Aspiration Thrombectomy. There is no significant difference in MACCE at 30 days between patients received bolus IC Tirofiban and patients who did not receive.

Single centre experience with Impella CP in different clinical settings

I Sousa Casasnovas[1]; J Jorge Garcia Carreno[1]; M Juarez Fernandez[1]; C Devesa Cordero[1]; V Bruna Fernandez[1]; F Diez Delhoyo[1]; R Sanz Ruiz[1]; F Fernandez Aviles[1]; M Martinez Selles[1]
[1]*University Hospital Gregorio Maranon, Madrid, Spain*

Introduction: Impella CP is an intravascular microaxial blood pump that can support the circulatory system during a maximum of 5-7 days. The use of this short duration mechanical assist device in cardiogenic shock has significantly increased in the last few years.
Purpose: Our aim is to summarize our first experience using the Impella CP system in patients with refractory cardiogenic shock or undergoing high risk percutaneous coronary interventions.
Methods: We present a retrospective registry, conducted in a tertiary center, which shows our initial experience using Impella CP in different clinical situations. The device was cannulated percutaneously, by the interventional cardiologist at the hemodynamic lab, using the Seldinger technique under fluoroscopy guidance. The usual approach consisted in advancing the Impella Catheter to the ascending aorta and placing the pigtail at the left ventricle, 3 cm beyond the aortic annulus.
Results: From August 2017 to January 2018, Impella CP was initiated in ten cases, six were male (60%) and the mean age was 64.8 ± 17.9 years. Every patient had severe left ventricle dysfunction at admission (26.5 ± 9.14%) and the overall survival rate at hospitalization discharge was 70%.
Eight patients were assisted with the Impella System due to refractory cardiogenic shock despite high dose of inotrope drugs. Mean left ventricle function at admission was 26.9 ± 9.9%. Mean serum lactate before placing the device was 6.4 ± 4.5 mmol/L and two patients had cardiac arrest. The most frequent etiology was acute myocardial infarction that occured in five patients, followed by fulminant myocarditis in two cases and advanced heart failure due to restrictive cardiomyopathy in the remaining patient. The only major complication referred in these patients was the perforation of the left ventricle wall which was solved by cardiac surgery.
In three patients, Impella CP was successfully placed together with a veno-arterial extracorporeal membrane oxygenation, in order to unload the left ventricle.
On the other hand, the Impella device was used to support percutaneous coronary intervention in two patients with multivessel coronary disease and left ventricle dysfunction. It was placed before the procedure and removed after achieving revascularization without complications.
Conclusion: In our experience, the Impella CP System seems to be an effective and safe hemodynamic support therapy, with a low complications rate. Interestingly, it allows unloading the left ventricle in those patients being assisted with veno-arterial extracorporeal membrane oxygenation who develop ventricle distension.

P1882

Role of coronary collateral circulation in late presenter myocardial infarction

C Carmen Collado Moreno[1]; A Gutierrez-Barrios[2]; D Canadas-Pruano[3]; A Giraldez-Valpuesta[3]; M Alba-Sanchez[3]; S Gamaza-Chulian[3]; E Diaz-Retamino[3]; D Ruiz-Fernandez[3]; J Oneto-Otero[3]; G Calle-Perez[2]; R Zayas-Rueda[2]; E Marante-Fuertes[2]; R Vazquez-Garcia[2]
[1]*Puerto Real Hospital, Department of Cardiology, Puerto Real, Spain*; [2]*University Hospital Puerta del Mar, Cardiology, Cadiz, Spain*; [3]*General Hospital of Jerez, Cardiology, Cadiz, Spain*

Aim: Demonstrate if good coronary collateral circulation(CCC) may be related to myocardial viability and left ventricular ejection fraction (LVEF) in late presenter myocardial infarction (MI) patients (>24h).

Methods: Ambispective multicenter study on 164 patients with a late presentation MI and angiographic evidence of a thrombotic occlusion (TIMI 0) of a major coronary artery from 2009 to 2016.
The Rentrop and Werner score were used for the angiographic categorization of CCC. Two experienced cardiologists retrospectively evaluated the angiographies in a blinded manner to classify the CCC into grades.
12 patients were prospectively followed up and left ventricular(LV) wall motion score(WMS) was assessed for each of the 17 segments of the LV with a visual scoring system in which 1 = normal, 2 = hypokinetic, 3 = akinetic, and 4 = dyskinetic.
Results: The median follow up was 3.4 years(IR 1.1-5.5 years). Culprit vessel revascularization was attempted in 83% of the patient (129/155) and successfully recanalized in 84% of them (108/129). Successful PCI of culprit vessel was not associated neither with LVEF at baseline (46 ± 13vs50 ± 10 p = 0.06) nor with increase in LVEF, WMS at baseline and at follow up (p>0.1 for all).
LVEF was significantly higher in patients with good CCC at baseline (53 ± 8 vs 45 ± 12, p <0.001) and at follow-up (56.7 ± 11vs 44 ± 11,p = 0.01). Qualitative assessment of culprit vessel territory motion showed significant differences between patients with poor and good CCC(p = 0.019): dyskinesia (15%vs3%); akynesia (41%vs12%), Hipokynesia (22%vs59%) and normokynesia (22%vs25%) respectively.
Myocardial viability in the culprit vessel territory was confirmed in 56.6% of patients (90/159), 4.5% of them had akinesia and viability was assessed by a stress echocardiogram. Viability was significantly higher in good compare to poor CCC patients (76.5%vs33.8%, p <0.001).
Rentrop and Werner classification were respectively correlated to: LVEF (r = 0.38, p = 0.001 and r = 0.32, p = 0.005);WMS at baseline (r=-0.605, p0.049 and r=-0.55, p = 0.07) and WMS at follow-up (r=-0.66 p = 0.01 and r=-0.47, p = 0.11) and both classifications were significantly higher in patients with myocardial viability: 1.77 ± 0.9vs0.9 ± 0.9 p <0.001 for Rentrop and 1 ± 0.6vs0.49 ± 0.5, p <0.001 for Werner.
Rentrop and Werner were also correlated with follow-up EKG: Number of leads with persistent ST segment elevation (r=-0.78, p = 0.004 and r=-0.63, p = 0.03) and number of leads with Q waves (r=-0.72, p = 0.01 and r=-0.57, p = 0.06) respectively
Conclusions: Good CCC was related to myocardial viability and LVEF in late presenter MI patients. These patients could benefit from revascularization even late in the course of a MI. A randomized trial should be encouraged to confirm these findings.

P1883

Intraoperative inflammatory response and heart metabolism in patients with severe ischemic heart failure

N Maroz-Vadalazhskaya[1]; I Russkikh[2]
[1]Belarusian State Medical University, Minsk, Belarus; *[2]Scientific and Practical Center of Cardiology , Minsk, Belarus*

Funding Acknowledgements: Grant of Belarusian Republican Foundation for Fundamental Research

Surgical treatment of severe ischemic heart failure (IHF) remains under discussions due to multiple impact factors and relatively low rate of survival.
Aim the study was to test the hypothesis of the inflammatory impact on the heart metabolism during open heart surgery in patients with severe IFH as well as to identify the blood biomarkers as a risk factors of adverse cardiac events.
Cohort: 32 male patients with a mean age of 55,2 years, LVEF <35% and SIHF were included. Patients of gr.1 with stable IHF (n 24 pts, mean age 54.8 ± 11.6 yrs, LVEF 31.7 ± 3.3) underwent CABG along, while 8 patients of gr.2 with IHF and ambulatory NYHA class IV (mean age 56.9 ± 7.6 yrs, LVEF 25.3 ± 2.1, PAPrsyst 56.2 ± 7.4 mm Hg) had CABG+LVAD. All patients were operated in similar conditions. H-FABP, IL-6, IL-6 receptors, glucose, lactate and free fatty acids (FFA) were assessed before surgery, during ischemia and after coronary reperfusion in simultaneously taken arterial and coronary sinus blood.
Results: Patients of both groups basally had significantly increased levels of FFA (p = 0,0001) and lactate (p = 0,0004), and patients of group 2 had lower utilization of FFA after surgery than preoperatively (p <0,0001). Before surgery a 6-fold increased IL-6 level was found in group 2 (p = 0.03 vs normal range), but normal level in gr.1 (between groups p = 0,01). During operation at the end of total ischemia period the increasing of IL-6 was found in both groups, but more significant in coronary sinus in gr.2 (p = 0.03). Simultaneously the increasing of IL-6 receptors level was revealed in coronary sinus blood in gr.2 (OR 1,2-5.1, p = 0.004). Patients of gr.1 had the falling of IL-6 receptors in both arterial and coronary sinus samples (p = 0.06 and p = 0.029 resp.) before repefusion. After reperfusion a 7-fold rocketing of H-FABP (p <0.000), glucose and FFA coronary sinus levels (p <0,001 for both; FFA between arterial and coronary sinus p = NS) was found in patients of gr.2. Preoperatively IL-6 strongly correlated with PAPr sys (r = 0,62 p = 0,001), during ischemia IL-6 as well as IL-6 receptors correlated negatively with postoperative LVEF (p = 0,01), ESVI (p = 0,01). Coronary sinus blood H-FABP level after reperfusion correlated with preoperative right ventricle systolic function (FAC r=-0.54, p = 0.003), systolic pulmonary pressure (r = 0.38, p = 0.037), and early postoperative cardiac death (r = 0.47, p = 0.01) in whole cohort. In patients of gr.2 the level of IL-6 receptors, coronary sinus H-FABP and FFA correlated with the duration of inotrope and artificial circulation support (p = 0,0001), early cardiac death (p = 0,001).
Conclusion: the rocketing of IL-6 receptors is linked to the myocardial washing out of glucose and FFA in IHF patients. The inflammative response could be a cause of myocardial death as well as metabolic depletion in patients with severe IHF, especially in group with end-stage HF. IL-6 receptors and H-FABP could be taken as markers of adverse cardiac events after open-heart surgery.

P1884

Promising 12-months clinical results for anaortic multivessel all-arterial minimally invasive direct coronary bypass surgery via distal mini-sternotomy

I Martinovic[1]; S Lindemann[2]; M Irqsusi[1]; J Mirat[3]; A Vcev[3]; T Wittlinger[4]; M Noutsias[5]
[1]University Hospital Giessen and Marburg, Cardiovascular Surgery, Marburg, Germany; *[2]Helios Hospital Warburg, Cardiology, Warburg, Germany*; *[3]University J.J. Strossmayer, Internal Medicine, Osijek, Croatia*; *[4]Asklepios Clinic Goslar, Cardiology, Goslar, Germany*; *[5]University Clinic Halle (Saale), Mid-German Heart Center, Department of Internal Medicine III (KIM-III), Division of Cardiology, Halle, Germany*

Background: Minimally-invasive direct coronary artery bypass grafting (MIDCAB) was developed to decrease perioperative morbidity, some of which may be related to the use of cardiopulmonary bypass and to cross-clamping of the aorta. We report our initial experience with multivessel MIDCAB through the distal mini-sternotomy (DIMS). DIMS is performed to achieve access to the left and right internal thoracic arteries and to reach the left anterior descending coronary artery, diagonal branches and right coronary artery.
Methods: Between January 2016 and January 2017, n = 12 patients with significant coronary artery disease of the LAD and the RCA underwent multivessel, all-arterial MIDCAB through a distal midline skin incision from the fourth intercostal space to the xyphoid process, with L-or T-shaped division of the sternum. The mean-age was 61.5 +/- 5.2 years (range: 52-71 years).
Results: Patients underwent all-arterial revascularization: LIMA in 12 patients, radial artery (RA) in 10, RIMA in 2 patients. The mean number of grafts per patient was 2.08+/-0.4 (range: 2-3). The mean length of the skin incision was 8.5 +/- 1.3 cm (range: 7 to 11 cm). There was no perioperative ischemia, postoperative bleeding or arrhythmia events. No postoperative cognitive dysfunction occured. The mean hospital stay was 5.6 days. None major adverse cardial event (MACCE) ocured at the 12-month follow-up. All patients were in New York Heart Association class I, and no wound complication occurred during follow-up.
Conclusions: Although MIDCAB-DIMS is technically more demanding than conventional procedures and our experience is limited, we conclude that this technique can be used safely in selected patients promising 12-months follow up results.

P1885

Manual thromboaspiration in patients with myocardial infarction: in-hospital assessment of class of heart failure and systolic function

I A Leonova[1]; S Boldueva[1]; D Maznev[1]; E Shloido[2]; I Kochanov[1]
[1]North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation; *[2]City hospital ? 2, Saint-Petersburg, Russian Federation*

Since the publications on manual thromboaspiration (MT) in ST-elevation myocardial infarction (STEMI) are controversial, it is of interest to assess the severity of heart failure (HF) in such patients during hospitalization.
Materials and Methods: It was performed a retrospective analysis of 146 cases of STEMI treated by percutaneous coronary intervention (PCI). The average age of patients was 60.8 ± 1.3 years, 97 men (66%) and 49 women (34%). In 78% of patients, STEMI was a debut of coronary artery disease. All patients were discharged alive.
Results: Patients were divided into 2 groups: 80 patients treated by PCI only and 66 patients treated by PCI plus MT. Patients of both group were similar by gender, age, localization of MI (anterior MI (55% without MT and 53% with MT p>0.05). The majority of patients in both group (95,9%) had TIMI 3 coronary blood flow. While the degree of myocardial perfusion less than 3 on the MBG scale was 8.2% in the group without MT and 4.1% in patients with MT (p < 0.05). The debris was obtained in 88.4% of cases of thromboaspiration. The majority of patients, both in the group without MT and with MT had a preserved systolic function at the time of discharge (73,3% vs 85,7% p < 0.05). The mild systolic dysfunction of the left ventricle (ejection fraction up to 40%) was observed in 23.3% of patients in the group without MT and 10.9% with MT (p < 0.05); moderate systolic dysfunction (ejection fraction 40-30%) - 3.4% vs. 1.4%, respectively (p < 0.05). Severe systolic dysfunction (ejection fraction less than 30%) was not observed in both group. Mild mitral regurgitation was present

in 39% of patients without MT and 33% after thrombaspiration (p < 0,05); moderate and severe mitral regurgitation - 14.4% and 9.6% (p < 0,05), tricuspid regurgitation of 2-3 degrees-4.8% versus 0.68%, respectively (p < 0,05). 20% of examined patients had pulmonary hypertension. Pulmonary hypertension was observed in 11.6% of patients without thrombospiration and in 2.7% of patients after thromboaspiration (p < 0,05). At discharge 46% patients without MT and 56.32% with MT had no symptoms of HF. The I functional class of HF by NYHA was almost the same in both groups - 21.2% versus 18.5% (p>0.05). However, II and III functional classes HF were more often observed in the group without thromboaspiration - II functional class - 30.1% without MT and 24.5% with MT (p < 0,05); III functional class - 2.7% against 0.68% respectively (p < 0,05).
Conclusions: Performing of manual thromboaspiration could prevent the formation of systolic dysfunction in patients with severe thrombotic lesion of the coronary artery, which provides a lower functional class of heart failure at discharge and improves short-term prognosis in patients with myocardial infarction.

P1886
Mid-range systolic dysfunction outcomes in ST elevated acute coronary syndrome

M Moz[1]; F Cordeiro[1]; J Guimaraes[1]; F Goncalves[1]; R Margato[1]; P Mateus[1]; JI Moreira[1]
[1]*Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal*

Introduction: mid range systolic dysfunction (MidR) represents a new group of patients in whom the prognosis and therapeutic options are not well established post ST elevated acute myocardial infarction (STEMI). These patients were excluded from most randomized trials so there is limited data on their management.
In this study we compare the prognosis of these patients versus patients with normal systolic function (N) and depressed systolic function (Dep)
Methods: Retrospective study of consecutive patients admitted with non-fatal STEMI diagnosis submitted to primary coronary intervention between January 2011 and December 2016. Systolic function was evaluated using ejection (EF) fraction and we compared 3 groups of patients: N with EF = 50%; MidR With EF = 40% and <50% and Dep with EF <40%.
Medical records were used to collect sociodemographic, clinical, previous medical history (heart failure, renal failure, cardiovascular risk factors) and coronary angiography data.
The endpoints studied were heat failure, death and a composite of major adverse events (MACE): revascularization, re-infarction, heart failure and death.
Results: 442 patients were included in the analysis with 65 ± 13.4 years. There were differences in age (N = 63.0; MidR = 65.6 and Dep = 68.4 years p <0.05), prior myocardial infarction (N = 25%; MidR = 25% and Dep = 50% p <0.05) prior coronary intervention (N = 27.6%; MidR = 31.0% and Dep = 41.4% p <0.05) and anterior descending artery as culprit vessel (N = 28.4%; MidR = 33.8% and Dep = 37.8% p <0.05) between groups.
Median follow up was 24 months (14-42 IQR). In multivariate analysis MidR was associated with worse outcome then N patients as they had more heart failure (HR = 4.2 CI:1.6-10.9), heart failure and death (HR = 2.6 IC:1.3-5.45) and MACE (HR = 1.9; CI:1.16-3.13) during follow-up. There were also a trend to higher mortality but did not reach statistical significance (OR = 1.8 p = 0.08).
Conclusion: MidR patients despite the lack of evidence guideline based effective therapies are a group of patients with a clearly worse outcome than patents with N. It is essential to develop new strategies to improve these patients outcomes.

P1887
Effect of intracoronary adenosine administration during primary PCI

A Metwaly[1]; M Altahhan[1]; M Mokarrab[1]; T Bssiony[1]; M Alshorbagy[2]
[1]*Al-Azhar University, cardiovascular department, Cairo, Egypt*; [2]*Al-Azhar University, Clinical Pathology, Cairo, Egypt*

Background: Aim of the present study was to evaluate effect of intracoronary (IC) adenosine versus placebo in STEMI patients undergoing primary PCI (pPCI).
Methods: for eligible STEMI patients this study includes 55 patients divided into two groups, study group who received IC adenosine (30 patients) and control group (25 patients) who received standard therapy , all were subjected to immediate pre and post pPCI 12 leads ECG, pPCI within 90 minutes from first medical contact, TIMI flow grade,TIMI myocardial perfusion grade (TMP), and full study of trans thoracic echocardiography (TTE) within 24 hrs and follow up TTE 40 days post MI. Patients who were randomized to the adenosine group were given 6 mg of adenosine (diluted into 5 ml normal saline) through the guiding catheter into the culprit coronary artery after aspiration of the present thrombi (if applicable) and just prior to stent deployment.
Results: Incidence of ST resolution , TIMI flow grade , TMP grade was significantly higher in the IC adenosine group than in the placebo group ,Furthermore, we found a larger increase in LVEF with a parallel reduction in the incidence of heart failure in the IC adenosine group. Finally, IC adenosine administration was associated with a significantly lower incidence of major adverse cardiac events
(MACE) both at short and long term follow up
Conclusions: This study is demonstrating a clinical benefit for IC adenosine in hard endpoints, such as adverse cardiovascular events and Heart failure in STEMI patients undergoing primary PCI.

P1888
Management of patients diagnosed with tako-tsubo syndrome

C Carmen Collado Moreno[1]; RF Garcia-Gonzalez[1]; I Valiente-Aleman[2]; D Castro-Sanchez[3]; S Blasco-Turrion[1]; I Lobo-Torres[1]; A Gomez-Juanatey[1]; PJ Gonzalez-Perez[1]; FJ Morales-Ponce[1]
[1]*Puerto Real Hospital, Department of Cardiology, Puerto Real, Spain*; [2]*Puerto Real Hospital, Critical Medical Medicine, Puerto Real, Spain*; [3]*University of Cadiz, Cadiz, Spain*

Background and Purpose: Takotsubo syndrome (TTS) was first described in Japan in 1990 by Sato and Mayo Clinic criteria were proposed in 2004 and modified in 2008 facilitating the diagnosis of TTS. The aim of this study is to describe prevalence, clinical features, treatment and short-term prognosis of patients diagnosed with TTS.
Methods: A restrospective observational study of patients admitted to Intensive Care Unit (ICU) of our hospital meeting the criteria for TTS was performed between March 1st 2007 and February 28 th 2017.
Results: A total of 1602 patients with diagnosis of acute MI were registered but only 30 patients fulfilled inclussion criteria for TTS.
The prevalence of TTS was 1.87% with a mean age of 59.73 ± 10.9 years. TTS was more frequent in women (83.3%). Cardiovascular risk factors were hypertension (56.6%), dyslipidemia (30%), diabetes (20%) and smoking (13.3%). Anxiety or depressive disorders were only found in 2 patients (6.6%). Preferred treatments at discharge were aspirin (96%), beta blockers (90%), ACEI/ARBs (83.3%), statins (70%) and DAPT (53.3%). One month follow-up of these patients revealed one death (3.3%) due to cardiovascular disease. This patient suffered a second episode of TTS after an elective major surgical intervention.
Conclusions:
We found a limited number of patients, nevertheless TTS showed an important short-term mortality and prevalence between Acute Coronary Syndromes admitted to our ICU. Clinical features were similar to the International Registry except anxiety or depressive disorders. Beta blockers were preferred to ACEI/ARBs.

P1889
Therapeutic particularities and evolution of acute coronary syndrome in patients with chronic kidney disease

S Antit[1]; B Ben Kaab[2]; C Gharbi[2]; I Slama[1]; S Belakhel[2]; I Boussabeh[1]; M Thameur[1]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*; [2]*Interior Security Forces Hospital, Department of medicine interne, Marsa, Tunisia*

Background: Although the improvement of the diagnostic and therapeutic means, the impact of chronic kidney disease (CKD) on mortality and morbidity in patients acute coronary syndrome (ACS) is still under estimated. The aim of our study is to determine the therapeutic and follow up particularities of ACS in patients with CKD.
Methods: We conducted a retrospective descriptive study on 100 patients hospitalized in interior security forces hospital in Marsa between 2010 and 2016 for an ACS. Our study population was divided into two groups : group 1 patients with creatinine clearance superior or equal to 60ml per minute (50 patients) and group 2 patients with creatinine clearance under 60 ml per minute (50 patients). For every patient included, we assessed demographic, clinic, therapeutic and follow up data.
Results: The mean age of our study population was 61.88 years, 87 males and 13 females. Group 2 patients were older and have more comorbidities than group 1 patients : diabetes p = 0.005, arterial hypertension p = 0.008 and stoke p = 0.001. While diagnosed with ACS, group 2 patients had more acute pulmonary edema (p < 0.001), more left ventricular hypertrophy (p = 0.001) and left ventricular dysfunction (p = 0.001) in echocardiography. Group 2 patients had less thrombolysis (p = 0.001), less low-molecular-weight heparin, beta blockers and angiotensin-converting enzym inhibitors. In percutaneous coronary intervention they had more two and three vessel disease than group 1 patients (p = 0.01). During follow up (48 months), group 2 patients had more major acute cardiovascular and cerebral events (MACCE) than group 2 patients (coronary restenosis p = 0.05, heart failure p < 0.001, death p = 0.001).

Conclusion: ACS represents an event of poor prognosis in patients with CKD. Guidelines require ACS to be managed similarily in patients with CKD as patients with normal renal function.

P1890

Radial artery accesses is associated with lower mortality in patients undergoing primary PCI : a report from scaar

E Elmir Omerovic[1]
[1]*Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: The purpose of this observational study was to evaluate effects of radial artery access (RA) versus femoral artery access (FA) on risk of 30-days mortality (primary endpoint), in-hospital bleeding, stroke and cardiogenic shock (secondary endpoints) in patients with STEMI undergoing primary PCI.
Methods: We used data from SCAAR registry (Swedish Coronary Angiography and Angioplasty Registry) for procedures performed in Sweden between 2005-2016. We evaluated the primary and secondary endpoints in 44,125 patients with STEMI, n = 24,119 in RA and n = 20,006 in FA. The two groups were compared using multilevel logistic regression to account for hierarchical database. Adjustments for differences in baseline characteristics were made with propensity score. The following variables were included in the calculation of the propensity score: age, gender, smoking habits, hypertension, diabetes, hyperlipidaemia, severity of coronary artery disease, previous infarction, previous PCI, previous CABG, anticoagulation therapy with glycoprotein IIb/IIIa receptor antagonists (GP IIb/IIIa), bivalirudin, P2Y12 antagonist, unfractionated heparin/low-molecular weight heparins (UH/LMWH), DES, completeness of revascularization, number of stents, type of lesion, reperfusion time, pretreatment with P2Y12 antagonist, regular vs. off-hours, calendar year, hospital and pharmacological treatment after discharge. We used instrumental variable (IV) method (for adjustment of hidden bias) for sensitivity analysis with calendar year as the treatment-preference instrument. Regression modelling was performed before and after exclusion of patients with cardiogenic shock.
Results: The two groups were different in baseline characteristics with RA patients having generally less traditional risk factors. There were 2,308 (5.2%) deaths, 889 (3.7%) in RA and 1,419 (7.1%) in FA. After adjustment, RA was associated with lower risk of death (OR 0.50, 95% CI 0.45 - 0.57, P <0.001), lower risk of in hospital bleeding (OR 0.46, 95% CI 0.39 - 0.54, P <0.001) and lower risk of cardiogenic shock after PCI (OR 0.50, 95% CI 0.42 - 0.59, P <0.001). We found no interaction between access site and age, gender and cardiogenic shock regarding 30-days mortality and bleeding. Access site did not modify risk of stroke. IV analysis have shown similar risk estimates for death at 30-days and cardiogenic shock. Exclusion of patients with cardiogenic shock did not substantially change the estimated risk of death at 30 days.
Conclusions: In patients with STEMI, primary PCI through radial artery access is associated with reduced risk of 30-days mortality, in-hospital bleeding and cardiogenic shock. Our study supports current ESC guidelines which recommend RA as the first choice for primary PCI.

Introduction: Anemia from prosthetic valve endocarditis (PVE) has a multifactorial origin and represents a disease marker. Nevertheless, current work does not analyzed anemia as prognostic element in patients with an initial antibiotic only intention to treat in a potentially "surgical" disorder.
Purpose: The objective of our study is to evaluate how the hemoglobin (Hb) levels would affect the clinical course, short and long-term prognosis in prosthetic valve endocarditis patients with initial medical intention to treat.
Methods: We analyzed retrospectively 126 cases of infective endocarditis admitted over 5 years (2000-2004) in two centers with reciprocal and surgical backup. From those cases we selected 56 patients with PVE (n = 29 early, n = 27 late) with prior heart failure syndrome. Initial follow up was done at the end of full course of antibiotic (AB) therapy. Long-term follow-up was done after 12.87 ± 0.97 years with the help of national insurance database. Analyzed variable: clinical; hemoglobin at admission: HbA, at the end hospitalization in the medical depatament: HbFin. Patients lost to follow up were excluded from our analysis.
Results: Short term outcome with initial antibiotics only intention to treat and irrespective of antibiotics type with overall AB cure duration 33.55 ± 12.8 day was: 90.4% survival rate, 2% in-hospital death, 71% responders to antibiotics, 21.4% of patients referred for early valve surgery with 66.6% surgical survival rate. Deceased patients presents with a significant (p = 0.07) lower initial hemoglobin (8.58 ± 1.38 g/dl) than survivors (9.76 ± 1.40 g/dl) while final hemoglobin remains persistent low 8.46 ± 0.87 g/dl in first category compared with 10.64 ± 1.4 g/dl in the latest (p = 0.001). Long-term follow up survival rate was 44%, very low compared with other contemporary analysis. After exclusion of those lost to follow up at final follow up (12.87 ± 0.97 years), the same findings were observed regarding hemoglobin levels: HbIn in survivors was10.01 ± 1.55 g/dl versus 9.21 ± 1.22 g/dl in those deceased (p = 0.06), HbFin being 10.81 ± 1.53 g/dl in survivors versus 9.98 ± 1.54 g/dl in deceased ones (p = 0.08). Anemia was not statistically related to hemodynamic instability irrespective of baseline ejection fraction or NYHA class.
Conclusions: Hemoglobin levels were significantly lower in deceased patients than in survivors and this fact correlates significantly with short-term and long-term mortality making it an important independent risk factor of death. In this old series of patients with prosthetic valve endocarditis the initial conservative intention to treat fail at long-term follow. Whether early surgery approaches in this category provide a relevant benefit could not be established due to small sample size.
